In vitro studies were conducted across tumor cell lines with high, intermediate, and low EGFR expression, including A431, HCC827, Huh7, NCI-N87, and MIA-PaCa-2. Cetuximab-I21-2 exhibited minimal dark toxicity at concentrations up to several micrograms per milliliter, confirming that the payload remains inactive without illumination. Upon irradiation, the ADC produced potent, energy-dependent cytotoxicity consistent with singlet-oxygen-driven membrane injury and mitochondrial dysfunction. IC50 values were 0.05 μg/mL in A431 and 0.14 μg/mL in HCC827 at 5 J/cm², with substantially reduced potency in EGFR-low cells, demonstrating both antigen-dependent delivery and illumination-triggered activation. Fluorescent ROS probes showed an immediate burst of intracellular singlet oxygen and secondary reactive oxygen species within minutes of irradiation, accompanied by rapid loss of mitochondrial membrane potential and plasma membrane integrity, confirming the dual targeting-activation mechanism.

In vivo antitumor activity was evaluated in A431 xenograft-bearing B-NDG mice treated with a single 35.3 mg/kg intravenous dose followed by localized irradiation at 100 or 200 J. Cetuximab-I21-2 produced distinct, energy-dependent tumor suppression, achieving 22.2% inhibition at 200 J. Histopathology revealed focal necrosis and photodynamic vascular disruption, consistent with ROS-mediated tissue injury. Treated animals maintained stable clinical condition, and transient (<10%) weight loss resolved spontaneously without supportive care, with no evidence of systemic toxicity.

Collectively, these findings demonstrate that Cetuximab-I21-2 provides potent, selective tumor ablation through the integration of EGFR-targeted delivery, payload stability, and externally controlled photochemical activation. This first-in-class photo-responsive ADC platform offers a programmable therapeutic strategy that may improve therapeutic index, enable dose-sparing treatment, and expand precision oncology approaches for EGFR-expressing solid tumors.

#5639 HDP-103, a PSMA targeting amanitin-based ADC, is efficacious even in difficult to treat patient derived xenograft models with heterogenous PSMA expression.

Kristin Decker[1], Christian Orlik[2], Irina Dranova[2], Aniko Palfi[2], Torsten Hechler[2], Andreas Pahl[1], Michael Kulke[1]

[1]Heidelberg Pharma AG, Ladenburg, Germany,[2]Heidelberg Pharma Research GmbH, Ladenburg, Germany

Background
Antibody drug conjugates (ADCs) are increasingly used in the treatment of solid tumors. HDP 103 is an anti PSMA ATAC (amatoxin based ADC) targeting metastatic castration resistant prostate cancer (mCRPC). ATACs offer distinct advantages over conventional ADCs: i) inhibition of RNA polymerase II confers activity in both proliferating and quiescent cells; ii) there are no known resistance mechanisms; iii) ATACs are potent against target low cancer cells; and iv) ATACs show particular good efficacy in patients with 17p/TP53 deletion who have poor prognosis. This study presents preclinical data demonstrating HDP 103 efficacy and a favorable therapeutic window in difficult to treat mCRPC patient derived xenograft models with heterogeneous PSMA expression.
Materials and Methods
HDP 103: anti-PSMA ADC with site specific, cysteine conjugated amatoxin linker.
Immunofluorescence: IF on PDX tumors using HDP 103 antibody.
Efficacy: subcutaneous prostate cancer PDX models treated intravenously with HDP 103 q14d × 3.
Tolerability: cynomolgus monkeys dosed intravenously on days 1 and 22; PK sampling, necropsy, and histopathology performed.
PK/PD: two compartment model with parallel linear and Michaelis-Menten elimination.
Results
HDP 103 produced potent, durable tumor remissions and significantly extended survival in PDX models at doses ≤5 mg/kg, including models with del(17p) and heterogeneous PSMA expression. In cynomolgus monkeys, HDP 103 was well tolerated, causing only transient changes in serum chemistry and hematology, and exhibited a half life of approximately 5-10 days. No salivary gland toxicity was observed; microscopic adverse findings were limited to the kidney. Integrated PK/PD modeling of efficacy and tolerability predicted serum exposures and patient dose ranges consistent with a convenient therapeutic window.
Conclusion
HDP 103, an anti PSMA ATAC for the treatment of mCRPC, demonstrates robust and durable antitumor activity in PDX models representative of the target population, including tumors with heterogeneous PSMA expression and those harboring a del(17p). Combined with a favorable half life and a manageable safety profile in nonhuman primates, HDP 103 warrants further clinical development as a novel treatment option for mCRPC, particularly for patients with del(17p) with a high unmet medical need.

#5640 ZW439, a novel CLDN18.2-targeting pan-RAS inhibitor antibody drug conjugate for the treatment of RAS mutated pancreatic cancer.

Sam Lawn, Andrea Hernandez Rojas, Vidhi Khanna, Jodi Wong, Ambroise Wu, Matthew Bonderud, Victoria Harman-McKenna, Taixiang Wang, Allysha Bissessur, Kaylee Wu, Manuel Lasalle, Vincent Fung, Chayne L. Piscitelli, Dunja Urosev, Luying Yang, Graham A. E. Garnett, Raffaele Colombo, Jamie R. Rich, Stuart D. Barnscher

Zymeworks Inc., Vancouver, BC, Canada

Pancreatic cancer remains one of the most difficult to treat cancers, with 5-year survival rates of just 13%, and there is an urgent unmet need for novel, differentiated, and effective therapeutics. Recently, encouraging progress has been made through inhibition of RAS, a key oncogenic driver mutated in over 90% of pancreatic ductal adenocarcinoma (PDAC). Antibody drug conjugates (ADCs) have demonstrated clinical success at improving the effectiveness of multiple respective classes of small molecules. The full therapeutic potential of pan-RAS inhibitors (pan-RASi) has been limited by toxicities likely arising from on-target inhibition of wild-type RAS in normal tissues, as well as by the emergence of resistance. These challenges may be improved upon by enhancing delivery of a RASi via an antibody drug conjugate mechanism. Here, we seek to leverage the ability of ADCs to enhance the delivery of a novel pan-RASi payload to tumors for improved response, and to provide a differentiated safety profile that mitigates the toxicity limitations of current small molecule pan-RASi. To this end, the novel pan-RASi ADC ZW439 is directed to CLDN18.2, a clinically validated oncology target that is highly expressed in PDAC.

A novel potent pan-RAS inhibitor ADC platform was developed through synthesis, screening, and iterative optimisation of payloads and drug-linkers for favorable ADC biophysical properties, antitumor activity, tolerability and pharmacokinetics (PK). A novel CLDN18.2 targeted antibody was selected for optimal ADC properties including its binding and internalization to CLDN18.2 expressing cells. Tumor cell spheroids were utilized to determine the cytotoxicity of the pan-RASi ADC, and its bystander activity was determined in CLDN18.2 positive and negative tumor cell co-cultures. The antitumor activity and PK of ZW439 were evaluated in multiple mouse xenograft models.

The novel humanized IgG1 antibody of ZW439 features strong and exclusive binding to CLDN18.2 and demonstrates superior internalization to CLDN18.2 expressing tumor cells compared to a clinical benchmark CLDN18.2 targeted antibody. ZW439 demonstrates potent target-specific cytotoxicity to RAS-mutated tumor cells expressing a range of CLDN18.2 levels and drives effective bystander activity to antigen negative cells. In vivo, ZW439 demonstrates highly efficacious anti-tumor activity in multiple CLDN18.2 expressing xenografts and has a favourable PK profile. ZW439's pan-RASi ADC drug-linker platform demonstrates encouraging tolerability, with no significant toxicity observed following dosing up to 200 mg/kg in mice.

The encouraging preclinical profile of ZW439 supports its potential as a differentiated therapeutic for the treatment of Pancreatic cancer.

#5641 BCG037, a first-in-class anti-human ALPP/ALPG therapeutic ADC that inhibits tumor growth in pancreatic cancer and gastric cancer PDX models.

Yong Xie, Peiran Li, Ying Zhu, Yanan Guo

Biocytogen, Waltham, MA, MA

Placental (ALPP) and germ cell (ALPG) alkaline phosphatases, sharing 98% sequence homology, are tumor-associated antigens with a highly restricted expression profile. While largely absent in normal adult tissues, they are frequently overexpressed across a wide spectrum of malignancies, including pancreatic, gastric, ovarian, and lung cancers. Elevated ALPP/ALPG levels correlate with poor prognosis in gastric and ovarian cancers, making them compelling targets for antibody-based therapies. Here, we report the development of BCG037, a first-in-class, fully human IgG1 antibody-drug conjugate (ADC) targeting ALPP/ALPG. The antibody was generated from RenMab™ humanized mice and conjugated with the potent topoisomerase I (Top1) inhibitor payload, achieving a high drug-to-antibody ratio (DAR) of ~8. BCG037 exhibits high affinity (nanomolar range) and cross-reactivity to both human and cynomolgus monkey ALPP/ALPG, with no cross-reactivity to other ALP family members (ALPL, ALPI). Notably, the antibody component of BCG037 demonstrates superior binding affinity to tumor cells compared to the analog used in SGN-ALPV. *In vivo*, BCG037 treatment led to significant and superior tumor growth inhibition in both pancreatic and gastric cancer patient-derived xenograft (PDX) models, outperforming the benchmark ADC, SGN-ALPV-MMAE, and no treatment-related toxicity or weight loss was observed in mice. Collectively, these data validate ALPP/ALPG as promising therapeutic targets and position BCG037 as a highly novel and potent clinical candidate for treating ALPP/ALPG-positive malignancies, including refractory cancers with limited treatment options.

#5642 BCG040, a novel B7-H4-targeting biparatopic ADC, demonstrates superior preclinical efficacy in heterogeneous tumors.

Guan Wang, Peiran Li, Ying Zhu, Yanan Guo

Biocytogen, Waltham, MA, MA

B7-H4 (VTCN1) is overexpressed in many epithelial malignancies, particularly in ovarian, breast, biliary tract, and pancreatic cancers. These tumors are often resistant to both chemotherapy and immunotherapy, due to their aggressive nature and poor prognosis. Here, we present BCG040, a novel first-in-class, fully human IgG1κ biparatopic B7-H4 ADC. BCG040 binds to two non-overlapping B7-H4 epitopes and is conjugated to the potent topoisomerase I (TOP1) inhibitor BCPT02 (DAR≈8) via a hydrophilic protease-cleavable linker. *In vitro*, BCG040 showed nanomolar affinity for B7-H4, superior to Hu2F7 and SGN-B7H4V benchmark analogs, with fully human/cynomolgus cross-reactivity and no off-target binding to other B7 family members. BCG040 exhibited stronger binding and more rapid internalization than the two analogs in breast and ovarian cancer cells. *In vivo*, a single low dose of BCG040 showed durable tumor regressions (~40 days) in breast cancer PDX models and significant efficacy in pancreatic cancer PDX models, outperforming other ADCs such as Hu2F7, SGN-B7H4V, or FPA150 (conjugated with MMAE or BCPT02). This potent efficacy was achieved without observable toxicity and was supported by a favorable pharmacokinetic (PK) profile. Furthermore, this drug demonstrates excellent developability. The enhanced therapeutic activity of BCG040 is attributed to its unique biparatopic design, which promotes receptor clustering and accelerated intracellular trafficking, leading to enhanced delivery of payload. Notably, BCPT02-containing ADCs exhibited potent antitumor activity in heterogeneous PDX tumors, whereas MMAE-based conjugates were ineffective. These findings underscore the potential of BCG040 as a promising therapeutic candidate for the treatment of pancreatic, biliary tract, ovarian, and breast cancers.

#5643 Preclinical characterization of RC118 ADC and identification of its differential binding pattern relative to other anti-CLDN18.2 antibodies.

Lili Wang[1], Xiaoping Zhang[1], Mingyang Li[1], Xiao Wang[1], Yidan Xu[1], Xiaoli He[1], Shengle Ji[1], Shuya Ji[1], Shifu Wang[1], Yinghao Xin[1], Fanxue Bu[1], Yuelei Shen[2], Jianmin Fang[1], **Yuanhao Li**[1]

[1]RemeGen Co., Ltd., Yantai, China,[2]Biocytogen Pharmaceuticals (Beijing) Co., Ltd., Beijing, China

CLDN18.2 is a tight junction transmembrane protein normally buried in the gastric epithelium, rendering it largely inaccessible under physiological conditions. However, it is frequently overexpressed in malignancies such as gastric, gastroesophageal junction (GEJ), and pancreatic adenocarcinomas, where it becomes exposed and functions as a tumor-associated antigen suitable for targeted therapy. Structurally, CLDN18.2 has four transmembrane domains anchoring two extracellular loops (ECL1 and ECL2) that extend into the extracellular space. These loops form β-sheet-rich structures with conserved charged and polar residues critical for paracellular ion selectivity and tight junction integrity. Many therapeutic antibodies and ADCs exploit these extracellular regions to selectively target CLDN18.2-positive cancer cells through diverse mechanisms.

RC118 is an anti-CLDN18.2 antibody-drug conjugate (ADC) developed by RemeGen. It consists of a humanized anti-CLDN18.2 monoclonal antibody conjugated to the monomethyl auristatin E (MMAE) via a cleavable linker. RC118 exhibits strong and selective binding to CLDN18.2-positive cells, inducing rapid internalization and potent cytotoxicity in vitro. In multiple in vivo models, including patient-derived xenograft (PDX) models of gastric and pancreatic cancers, RC118 showed robust antitumor efficacy. Collectively, these findings support RC118 as a promising ADC candidate for gastric cancer therapy.

Structural modeling indicated that RC118 and zolbetuximab, a FDA-approved CLDN18.2 antibody drug, recognize a similar epitope within ECL1 around a loop structure at the end of the β-sheet, whereas a few other comparator antibodies target the side face of the β-sheet region. To further delineate epitope specificity among CLDN18.2-targeting antibodies, we engineered chimeric CLDN18.2/CLDN3-expressing cell lines exposing different extracellular loop configurations for comparative binding analysis. Targeted mutations of the Cys52-Cys62 disulfide motif within ECL1 were introduced to evaluate its contribution to antibody recognition. These studies revealed that RC118 shares a similar binding pattern with zolbetuximab, while differing from other investigational CLDN18.2 antibodies. Structural analyses further suggest that variations in ECL1 engagement may underlie differences in therapeutic activity among these antibodies.

RC118 is currently under evaluation in multiple clinical trials. At the 2025 ESMO meeting, combination data with immunotherapy showed encouraging results, supporting its potential in personalized treatment strategies for CLDN18.2-positive cancers. The emerging clinical outcomes, together with the structural insights into RC118-CLDN18.2 interactions, indicate that RC118 remains a strong and competitive candidate for continued clinical development.

#5644 DA-3501 (AT-211): Evaluation of immune-mediated antitumor activity and combination immunotherapy potential of a site-specific CLDN18.2-targeting antibody-drug conjugate (ADC).

Kyoung-Ho Pyo[1], Seong-Hyun Park[1], Dongsop Lee[2], Haneol Kim[2], Younggyu Kong[2], Younggeun Lee[1], Hojin Yeom[1], Sowon Aum[1], Sun Hee Park[1], Huijo Oh[1], Cheyeon Kim[1], Hyeonseok Jin[2], Hyeonseok Jin[2], Aera Lee[2], Hojeong Hong[2], Ju Hwan Kim[1], Hyungseok Choi[2], Mi-Kyung Kim[2], Taedong Han[1]

[1]AbTis Co., Ltd, Yongin, Korea, Republic of,[2]Dong-A ST Research Headquarter, Yongin, Korea, Republic of

Background: Claudin 18.2 (CLDN18.2) is a clinically validated therapeutic target in gastric and pancreatic cancers. However, acquired resistance to CLDN18.2-directed antibodies such as zolbetuximab and trastuzumab highlights the need for next-generation therapeutics with distinct mechanisms of action. DA-3501 (AT-211) is a CLDN18.2-targeting antibody-drug conjugate (ADC) developed using the AbClick® site-selective conjugation platform. The antibody component exhibits enhanced binding affinity, internalization efficiency, and molecular stability. This study aimed to evaluate the immune-mediated antitumor activity of DA-3501 and explore its potential for combination immunotherapy.
Methods: To assess efficacy in resistant disease contexts, immune organoids derived from gastric cancer patients with acquired resistance to trastuzumab and zolbetuximab were used to evaluate DA-3501 activity. Antitumor effects were analyzed in immune cell co-culture systems to assess cytotoxicity, CLDN18.2-dependent responses, and immune activation markers. Furthermore, in vivo efficacy studies incorporating immune checkpoint inhibitor (ICI) combination groups were conducted under immunocompetent conditions to investigate immune-mediated mechanisms and the combinatorial potential of DA-3501.
Results: DA-3501 demonstrated potent and selective cytotoxicity toward CLDN18.2-positive tumor cells and induced immune cell activation consistent with IgG1-mediated antibody-dependent cellular cytotoxicity (ADCC). In vivo, DA-3501 exhibited robust immune-mediated antitumor activity both as a monotherapy and in combination with ICIs, indicating complementary interactions between the ADC's direct cytotoxic payload and immune-modulatory mechanisms.
Conclusions: DA-3501 (AT-211) is a site-selectively conjugated CLDN18.2-targeting ADC that exerts strong immune-mediated antitumor effects, even in models derived from patients resistant to existing antibody therapies. These results highlight the dual mechanism of action of DA-3501—combining direct cytotoxicity and Fc-driven immune activation—and support the development of rational ADC-immunotherapy combinations as a promising strategy in the evolving landscape of ADC-based cancer treatment.

#5645 NW006-296, a novel ROR1 targeting ADC, demonstrates compelling anti-tumor efficacy in preclinical studies.

Zhaoyu Gou[1], Liqian Zhou[1], Li Liu[1], Zikuo Zhang[1], Gang Liu[1], Yiran Wu[1], Dan Mi[1], Jiabao Liu[1], Yaolan Dai[1], **Zhijian Li**[2], Wenting Luo[1], Bin Liu[1], Desi Pan[1], Zhigang Guo[1]

[1]Chengdu Chipscreen NewWay Biosciences Co., Ltd., Chengdu, China,[2]Chipscreen Biosciences (United States) Ltd, Somerset, NJ

Background: Receptor tyrosine kinase-like orphan receptor 1 (ROR1) was found broadly expressed in both hematological malignancies and solid tumors whereas its expression was largely absent from normal blood lymphocytes and adult tissues, making it an attractive tumor target being explored clinically via mAb, bi-specific abs, CAR-T and ADC. While several ROR1-targeting ADCs with different MoA payloads are in development, we engineered NW006-296, a novel ADC comprising a humanized anti-ROR1 antibody site-specifically conjugated to monomethyl auristatin E (MMAE), aiming to achieve a homogeneous and stable therapeutic agent. NW006-296 was assessed in vitro and in vivo to evaluate its therapeutic potential.

Methods: A library of ROR1-binding clones was screened for affinity, cell binding and internalization. Then the selected antibody is conjugated via cleavable linker to MMAE with drug-to-antibody ratio (DAR) of 4. The binding ability of the conjugates to human ROR1 is tested by enzyme-linked immunosorbent assay (ELISA). Finally, the anti-tumor efficacy of ROR1-targeting ADC is assessed in vitro through cell cytotoxicity assays and in vivo in multiple cell-line-derived xenograft (CDX) models. In detail, mice were treated with single (3 mg/kg, MDA-MB-231 and 5 mg/kg, U2932) and multiple (1 mg/kg or 3 mg/kg in HT-29; 3 mg/kg or 5 mg/kg in NAMALWA) doses of the ROR1-targeting ADC.

Results: The lead antibody showed low nanomolar affinity to human ROR1 (KD=3.9 nM), strong binding to ROR1-expressing cells (EC50=0.4 nM, 0.3 nM, 0.5 nM for MDA-MB-231, HT-29 and NAMALWA, separately) and robust internalization in ROR1-expressing cells. Conjugation to the payload did not compromise binding of the antibody to human ROR1. NW006-296 showed potent cytotoxicity against the previous ROR1-expressing cells in vitro cell cytotoxicity assays. Furthermore, NW006-296 demonstrated significant dose-dependent anti-tumor activity, with tumor regression observed in both in vivo models used. When compared to the benchmark ADC (MK-2140), NW006-296 demonstrated superior anti-tumor activity in all CDX models investigated. Intriguingly, NW006-296 remained potent anti-tumor efficacy more than 40 days after the drug withdrawal in the U2932 CDX model, while the tumor re-growth in the benchmark ADC treating group regressed during therapy. Additionally, NW006-296 was well tolerated in mice as indicated preliminarily by no body weight loss occurring.

Conclusions: NW006-296 has compelling anti-tumor efficacy and supports clinical development for ROR1-targeting ADCs across a broad spectrum of cancers. Further preclinical safety assessment, pharmacokinetics and IND-enabling studies are on-going with the goal to develop NW006-296 as a transformative therapeutic candidate for the treatment of colorectal cancer, breast cancer and hematological malignancies.

#5647 GS24-B057, a potential best-in-class Nectin-4- and Trop-2-directed bispecific ADC, for the treatment of urothelial carcinoma and other solid tumors.

Meihan Li[1], Fu Li[2], Qiuru Che[1], Xiaojing Huang[2], Dongxia Chu[1], Qiyang Zhang[1], Nan Li[2], Qingjuan Ma[2], Weiming He[2], Wenqiang Zhai[2], Yihui Lin[2], Xiaozhen Wang[2], Fanglong Yang[2], Siqing Wang[2], Lei Jin[2], John L. Xu[2]

[1]Changchun GeneScience Pharmaceutical Co., Ltd., Changchun, China,[2]Changchun GeneScience Pharmaceutical Co., Ltd., Shanghai, China

Background: Nectin-4 and Trop-2 are transmembrane proteins commonly co-overexpressed in various solid tumors and associated with tumor progression. ADCs targeting Nectin-4 or Trop-2 have shown promising therapeutic potential in urothelial carcinoma (UC), non-small cell lung cancer (NSCLC), and triple-negative breast cancer (TNBC). Notably, the combination of Padcev™ (a Nectin-4-directed ADC; also referred to as EV) and Trodelvy™ (a Trop-2-directed ADC; also referred to as SG) as second-line therapy for metastatic UC has demonstrated significantly improved efficacy, with the overall response rate (ORR) reaching 70%. However, the safety profile of this combination remains to be a concern, with ≥Grade 3 treatment-emergent adverse events (TEAEs) occurring in 78% of patients. To maintain clinical efficacy while minimizing toxicity, we developed GS24-B057, a dual Nectin-4- and Trop-2-targeting ADC with a drug-to-antibody ratio (DAR) of 6, integrating an optimally engineered bispecific antibody, a tailored topoisomerase I inhibitor payload, and site-specific conjugation.

Materials and Methods: The *in vitro* tumor cell binding activity of GS24-B057 was assessed by flow cytometry. For internalization analysis, Nectin-4- and Trop-2-expressing cells were incubated with pHrodo-conjugated ADC, followed by fluorescence intensity quantification. Cytotoxicity and bystander killing effect were assessed in a Cell Titer-Glo assay and in a luciferase assay, respectively. The *in vivo* anti-tumor efficacy of GS24-B057 was systematically examined in mouse models bearing human cancer cell line-derived xenografts (CDX) and patient-derived xenografts (PDX). Pharmacokinetics was studied in cynomolgus monkeys.

Results: In preclinical studies, GS24-B057 exhibited significantly stronger *in vitro* cell binding and internalization than the EV and SG combination, as well as robust direct cytotoxicity and bystander killing effect in tumor cell lines. GS24-B057 demonstrated potent anti-tumor activity across multiple CDX and PDX models of human cancer, including UC, TNBC, and NSCLC, with superior efficacy *versus* EV, SG, and SKB264 as single agent, and comparable efficacy to the EV and SG combination but at a lower dose level and administration frequency. Furthermore, GS24-B057 featured a favorable pharmacokinetic profile in cynomolgus monkeys.

Conclusion: These data suggest the potential of GS24-B057 as an effective therapeutic option for patients with UC and other solid tumors and support its further evaluation in IND-enabling studies.

#5648 Preclinical efficacy and safety of KIVU-305, a novel CEACAM5-targeting antibody-drug conjugate (ADC) for colorectal cancer (CRC).

Ann MacLaren, Natasja N. Viller, Tessie Ng, Liangyi Zhang, Xiaoyue Jiang, Mohit Trikha

Kivu Bioscience, San Mateo, CA

CEACAM5 (carcinoembryonic antigen-related cell adhesion molecule 5) is a cell-surface glycoprotein highly expressed in CRC, pancreatic ductal adenocarcinoma (PDAC), gastric cancer and non-small cell lung cancer (NSCLC), with minimal expression in normal adult tissues. Elevated CEACAM5 correlates with tumor burden and poor prognosis, making it an attractive ADC target. The first-generation CEACAM5 ADC labetuzumab govitecan demonstrated clinical feasibility but with limited efficacy at tolerable doses, highlighting the opportunity for an improved ADC with more stable linker payload to provide superior clinical benefit.KIVU-305 is a CEACAM5-targeting ADC composed of a humanized monoclonal antibody conjugated to SYNtecan E™ via the GlycoConnect®/ Hydraspace® (GC/HS) site-specific conjugation technology, delivering an exatecan-based topoisomerase I inhibitor payload at an average drug-to-antibody ratio (DAR) of 4. GlycoConnect® leverages the native Fc glycan for site-specific conjugation, while HydraSpace® introduces a hydrophilic spacer to reduce aggregation and systemic payload release, resulting in an ADC with improved manufacturability, plasma stability and pharmacokinetic profile to provide a superior therapeutic index. Upon binding CEACAM5, KIVU-305 undergoes efficient internalization and exatecan release to inhibit DNA topoisomerase I, causing DNA damage, cell cycle arrest and apoptosis. Notably, exatecan is more potent than deruxtecan and is a poor substrate for P-glycoprotein (P-gp), which may help overcome common drug resistance mechanisms in patients.In vitro, KIVU-305 demonstrated potent, target-specific cytotoxicity in vitro at low nanomolar concentrations and robust bystander activity resulting in killing of adjacent CEACAM5-negative cells. In vivo, KIVU-305 induced sustained tumor regressions in multiple CEACAM5-positive CRC and PDAC xenograft models, including models resistant to irinotecan. KIVU-305 exhibited high stability in human and cynomolgus plasma with no measurable DAR loss and minimal free payload release over 21 days. Pharmacokinetic studies in cynomolgus monkeys confirmed linker stability with high intact ADC and minimal systemic payload exposure. Tolerability studies in cynomolgus monkeys demonstrated that KIVU-305 was well tolerated with only mild reversible toxicities consistent with the expected profile of a topoisomerase I inhibitor payload. No on-target toxicities were identified, consistent with historical CEACAM5 ADC experience.Collectively, these data support KIVU-305 as a promising CEACAM5-directed ADC with a favorable safety profile that may provide an improved therapeutic index. A Phase I clinical trial in patients with advanced solid tumors is planned for 2026.

#5649 KIVU-107: A clinical-stage, best-in-class PTK7 antibody-drug conjugate (ADC) with favorable PK and an improved tolerability profile.

Natasja N. Viller, Liangyi Zhang, Xiaoyue Jiang, Ann MacLaren, Mohit Trikha

Kivu Bioscience, San Mateo, CA

PTK7 (protein tyrosine kinase 7) is a catalytically inactive receptor tyrosine kinase associated with tumor-initiating cells and overexpressed in multiple solid tumors, including ovarian, endometrial, lung, breast and gastric cancers. Overexpression of PTK7 is associated with poor prognosis, further exemplifying its pivotal role in carcinogenesis. PTK7 has previously been validated as an ADC target but development of first-generation PTK7 ADCs was limited by payload mediated toxicity, suggesting that an ADC with improved linker payload could improve clinical benefit. KIVU-107 is an antibody-drug conjugate (ADC) composed of a humanized IgG1 monoclonal antibody targeting protein tyrosine kinase 7 (PTK7), conjugated to the SYNtecan E™ linker-payload via the GlycoConnect®/ Hydraspace® (GC/HS) site-specific conjugation technology with a drug-to-antibody ratio (DAR) of 4. The GC/HS platform abolishes Fcγ receptor-mediated effector activity and utilizes a highly polar spacer to reduce hydrophobicity and aggregation, resulting in an exatecan ADC with improved stability to provide a superior pharmacokinetic and safety profile to expand the therapeutic index.KIVU-107 demonstrated rapid internalization and robust target-specific cytotoxicity across high and low-expressing tumor cell lines. The cleavable linker and cell permeable hydrophilic payload conferred potent bystander killing in PTK7-negative cells co-cultured with PTK7-positive cells, addressing tumor heterogeneity. In vivo, a single dose induced complete regression in multiple xenograft models, including patient-derived xenografts (PDXs) resistant to platinum-based chemotherapy and ADCs such as mirvetuximab soravtansine and datopotamab deruxtecan. KIVU-107 also exhibited enhanced efficacy and improved survival when combined with PARP inhibition, standard-of-care in ovarian, breast and prostate cancers, supporting combination strategies. KIVU-107 was highly stable in vitro, with no measurable DAR loss and minimal free payload release over 21 days in human or cynomolgus plasma. Nonclinical pharmacokinetic and safety evaluations in cynomolgus monkeys confirmed the stability of KIVU-107 with high exposure of intact ADC and minimal unconjugated payload levels and demonstrated favorable tolerability, with a highest non-severely toxic dose (HNSTD) of 60 mg/kg. Hematologic effects were mild, transient and reversible, consistent with the expected profile of a topoisomerase I inhibitor payload.Collectively, these data highlight KIVU-107 as a highly stable, next generation DAR4 exatecan ADC with potent anti-tumor activity, bystander effect and broad therapeutic potential. A Phase I clinical trial in patients with advanced solid tumors is ongoing (NCT07229313).

#5650 Preclinical development of LUA006: A bispecific EGFR/B7-H3 ADC with dual payloads to address tumor heterogeneity and resistance.

Shaojuan Zhao[1], **Ling Zhang**[1], Ying Huang[1], Qian Dong[1], Xiaofan Gu[1], Guoshun Tian[1], Xiaoman Li[1], Fanrui Meng[1], Wei Zheng[1], Xiaoshuang Yan[1], Xinmei Wang[2], Yazhi Yuan[2], Shuyong Zhao[2], Ken Qin[1], Yang Yang[1], Hua Ying[1], Weikang Tao[1]

[1]Shanghai QiLu Pharmaceutical Research and Development Center LTD., Shanghai, China,[2]QiLu Pharmaceutical Co., Jinan, China

Background: While antibody-drug conjugates (ADCs) have emerged as a transformative therapeutic class, their clinical utility is largely limited by either on-target, off-tumor toxicities or acquired drug resistance. EGFR and B7-H3 are clinically validated targets that are frequently co-expressed in a range of solid tumors including non-small cell lung cancer (NSCLC), especially lung squamous cell carcinoma (LUSC), esophageal squamous cell carcinoma (ESCC), and Head and neck squamous cell carcinoma (HNSCC), while exhibit rare co-expression in normal tissues. It has been revealed that both heterogeneous expression of a single target and acquired resistance to a single payload often compromise the efficacy of monospecific ADCs containing a single payload. To address these challenges, we generated LUA006, a bispecific ADC targeting both EGFR and B7-H3 with attenuated EGFR binding to reduce on-target, off-tumor toxicity and enhanced B7-H3 binding and internalization dynamics to improve anti-tumor efficacy, particularly in tumors with heterogeneous expression of a single target. Additionally, LUA006 incorporates two distinct payload classes, to achieve deep response and overcome payload-associated resistance.
Methods: A bispecific anti-EGFR/B7-H3 IgG was site-specifically conjugated to two payloads with complimentary mechanism of actions and well optimized DAR values. Meanwhile, the linkers for each payload were screened to enable sequential payload release. LUA006 demonstrated high DAR homogeneity and stability *in vitro*.
Results: LUA006 demonstrated superior internalization efficiency versus parental antibodies, indicating synergistic targeting. It achieved nanomolar-level cytotoxicity against diverse cancer cell lines with variable EGFR/B7-H3 expression, while showing minimal toxicity to normal human epidermal keratinocytes, resulting in a broader therapeutic window than clinical stage EGFR monospecific ADCs *in vitro*. *In vivo*, a single dose of LUA006 induced profound, durable tumor regression in cell-derived xenograft (CDX) models, surpassing combinations of mono-payload ADCs and monospecific ADCs. Critically, LUA006 maintained efficacy in CDX models with intrinsic low sensitivity to each payload used by LUA006 and in models overexpressing drug efflux pumps, demonstrating robust activity against diverse resistance mechanisms.
Conclusion: LUA006 is a novel bispecific ADC with dual payloads that may enhance efficacy in tumors with heterogeneous expression of a single target or with resistance toward either of dual payloads. Its potent efficacy, reduced toxicity profile and activity in resistant models support further development as a promising therapy for EGFR/B7-H3-expressing solid tumors.

#5651 Preclinical development of LUA005: A differentiated bivalent EGFR/cMET bispecific ADC displays strong anti-cancer efficacy and a wider therapeutic window.

Lei Han[1], Ken Qin[1], Ying huang[1], Xi Xiao[1], Zhebin Zhang[1], Wei Wang[1], Wei Zheng[1], Hai Wu[1], Xiaoshuang Yan[1], Dongdong Wu[1], Shuyong Zhao[2], **Ling Zhang**[1], Yang Yang[1], Hua Ying[1], Weikang Tao[1]

[1]Shanghai Qilu Pharmaceutical Research and Development Center LTD., Shanghai, China,[2]Qilu Pharmaceutical Co., Ltd., Jinan, China

Background Compensatory functions between EGFR- and cMET-mediated signaling contribute to resistance to either EGFR- or cMet-targeting agents such as osimertinib. The frequent co-expression of these two targets in solid tumors supports dual targeting strategy, evidenced by the approved bispecific antibody amivantamab. Several EGFR-cMET antibody-drug conjugates (ADCs) have entered clinical trials. While most bispecific ADCs targeting EGFR and cMET use a 1+1 format, we designed and generated LUA005 with bivalent arms for each target. It exhibits low affinity but high avidity to EGFR, coupled with high-affinity to cMET. This design aims to minimize on-target off-tumor toxicity while ensuring robust efficacy across heterogeneous tumors, including those with low EGFR expression. Here, we report the preclinical characterizations of LUA005 as an EGFR/c-Met bispecific ADC with differentiated properties. **Methods** LUA005 was built on the QILU's proprietary novel topoisomerase-1 inhibitor platform, conjugated via a hydrophilic cleavable linker to yield a uniform DAR 8 product. The payload displayed nanomolar activity across various cancer cell lines and much faster systematic clearance than Dxd *in vitro*, to reduce systematic toxicity. Benchmark ADCs were included for comparison. **Results** *In vitro*, LUA005 exhibited strong cytotoxicity against tumor cell lines but minimal killing of normal keratinocytes, indicating a wider therapeutic window than benchmarks. Meanwhile, LUA005 demonstrated superior antitumor activity compared to benchmarks across a spectrum of CDX models with different EGFR and cMET expression levels, highlighting its potential to address tumor heterogeneity. LUA005 also demonstrated remarkable efficacy in a series of patient-derived xenograft (PDX) models, including those resistant to osimertinib, cetuximab, or immunotherapy. Meanwhile, LUA005 was well tolerated in Cyno monkeys, with HNSTD up to 60 mpk Q3W for three times repeated dosing in NHP toxicity study, without obvious on-target toxicity or ILD, consistent with our molecule design. LUA005 demonstrated favorable PK profile in cyno monkeys, with high stability and limited free drug release in circulation. **Conclusions** LUA005, an EGFR/cMET bispecific ADC with differentiated molecular design, demonstrated superior antitumor efficacy with enhanced therapeutic index. Preclinical studies warranted its further development into clinical trials, which are anticipated to start in early 2026.

#5652 Preclinical development of LUA011, a novel CDH17/cMET bispecific ADC with enhanced antitumor efficacy and mitigated gastrointestinal toxicity.

Guoyin Huang[1], Ken Qin[1], Man Wu[1], Lei Han[1], Ying Huang[1], Wei Zheng[1], Xiaoshuang Yan[1], luchan deng[1], Hai Wu[1], Wenshu Huang[2], Shuyong Zhao[2], **Ling Zhang**[1], Yang Yang[1], Hua Ying[1], Weikang Tao[1]

[1]Shanghai Qilu Pharmaceutical Research and Development Center LTD.,, shanghai, China,[2]Qilu Pharmaceutical Co., Ltd.,, Jinan, China

Background: CDH17 is an emerging ADC target in gastrointestinal (GI) cancers due to its overexpression in colorectal, gastric and pancreatic tumors. However, CDH17-directed ADCs suffer on-target GI toxicities. cMET is a clinically validated target in GI malignancies with limited expression in some normal tissues. Expression profiling shows that CDH17 and cMET are frequently co-expressed in GI tumors, while seldomly co-expressed in normal tissues. Therefore, targeting both CDH17 and c-Met might improve therapeutic index and maintain or even enhance efficacy. Here we report the preclinical development of LUA011, a bispecific ADC targeting both CDH17 and cMET, with a proprietary TOPO1i payload conjugated to the antibody via a glycan-based platform.
Results: LUA011 was selected from a panel of bispecific ADC formats based on a comprehensive evaluation of pharmacokinetic properties, *in vivo* efficacy, and overall developability. Both LUA011 and its unconjugated bispecific antibody moiety exhibited strong binding to CDH17-positive and cMET-positive GI cancer cell lines, with EC50 values in the nanomolar range. Rapid internalization of the antibody component was observed in multiple GI cancer cell lines expressing CDH17 and/or cMET. *In vitro*, LUA011 demonstrated potent and specific cytotoxicity against cell lines positive for CDH17, cMET, or both targets, with enhanced activity compared to CDH17 mono-specific ADCs in CDH17 and cMet dual-positive cell lines. LUA011 demonstrated significantly superior antitumor efficacy over CDH17- and cMET-targeting monospecific ADCs across multiple gastrointestinal CDX and PDX models with varying target expression levels. This enhanced activity was consistently observed even when compared to its own CDH17-parental ADC and a benchmark CDH17-specific ADC conjugated with the same linker-payload, underscoring that the therapeutic advantage stems from the bispecific format and the synergistic effect of dual targeting CDH17 and cMET. LUA011 exhibited high stability in human and cynomolgus monkey plasma, with minimal payload release and maintained DAR. In cynomolgus monkeys, LUA011 displayed favorable pharmacokinetics and a promising safety profile, with a maximum tolerated dose exceeding 30 mg/kg.
Conclusions: LUA011 is a novel bispecific ADC targeting both CDH17 and c-Met with favorable physicochemical properties, strong target binding, cellular internalization and potent antitumor activity in preclinical GI cancer models. Its dual targeting activity, along with its optimized payload, conjugation method, and DAR value, contribute to its strong anti-tumor efficacy, improved therapeutic index, and reduced GI toxicities. Further investigation is warranted to advance this promising ADC into clinical development.

#5653 Preclinical characterization of LUA004, a novel 5T4-targeting ADC with improved therapeutic window.

Jinpeng Pei[1], Shaojuan Zhao[1], Ying Huang[1], Junfei Wang[1], Wei Zheng[1], Hai Wu[1], Jie Chen[1], Ke Li[2], Xinmei Wang[2], Shuyong Zhao[2], **Ling Zhang**[1], Yang Yang[1], Daqing Sun[1], Hua Ying[1], Weikang Tao[1]

[1]Shanghai Qilu Pharmaceutical Research and Development Center LTD, Shanghai, China, [2]Qilu Pharmaceutical Co., Ltd., Jinan, China

Background: Trophoblast glycoprotein (5T4), an oncofetal protein, is a member of the leucine-rich repeat family of proteins that is associated with intercellular connectivity, cell morphology and movement, and altering cell adhesion in embryonic development and cell differentiation. 5T4 is upregulated in several cancers, including esophageal, head-and-neck, and lung cancers, especially the squamous subtype, with low or absent expression in adult normal tissues. The high expression of 5T4 was notably correlated with poor survival in different cancer types, which makes it an attractive ADC target. The therapeutic potential of 5T4 as ADC modality was recently unraveled by several ADCs with preliminary clinical efficacy reported. In this study, we present the development of a novel 5T4-targeting ADC with Qilu's proprietary microtubule inhibitor as payload, LUA004, which exhibited excellent efficacy and expanded therapeutic window than vedotin ADC.

Method: LUA004 utilizes a novel microtubule inhibitor payload QLS8152 with a proprietary cleavable linker to achieve a homogeneous product with a drug-to-antibody ratio (DAR) of 8 through site-specific conjugation. The payload QLS8152 showed sub-nanomolar activity across a wide range of cancer cell lines *in vitro* and rapid systematic clearance in rodent models. Our next generation microtubule inhibitor platform QLS8153 demonstrated significantly improved therapeutic window than vedotin technology.

Result: LUA004 showed sub-nanomolar binding affinity and dose-dependent internalization in multiple tumor cell lines with different 5T4 expression levels. LUA004 showed strong (nM range IC_{50}) and comparable *in vitro* cytotoxicity to vedotin-ADC against a variety of 5T4-positive cancer cell lines. Meanwhile, LUA004 showed robust and dose-dependent tumor inhibition in different cell-derived xenograft (CDX) as well as patient-derived xenograft (PDX) models with various 5T4 expression, with comparable tumor inhibition as vedotin-ADC. Moreover, compared to vedotin-ADC, LUA004 exhibits more favorable plasma stability, preclinical pharmacokinetic, and toxicity profiles. LUA004 was well tolerated in cyno monkeys, with HNSTD up to 20 mpk Q3W x 4 in non-GLP toxicity study, indicating a tremendous increase in the therapeutic index compared to vedotin-ADC.

Conclusion: LUA004 represents a novel 5T4-targeting ADC with favorable anti-tumor activity and superior tolerability, which can address the high unmet needs in patients with cancers expressing variable levels of 5T4. The promising preclinical profiles of LUA004 warrant its further development into clinical trials.

#5654 Novel ALDC and ADC with TMEAlinker and eribulin payload demonstrate excellent safety and efficacy in preclinical evaluation.

Tao Chen, Cheng Liu, **Yuan Liu**

Affinity Biopharmaceutical Co., Ltd., Shanghai, China

Overexpression of extracellular legumain in the tumor microenvironment (TME) plays a critical role in tumor invasion and metastasis. TMEAlinkers (TME-activated linkers) are legumain-activated linkers with clinical proof-of-concept (POC) from the phase 3 study of legubicin (an albumin drug conjugate, ALDC). Leveraging this TMEAlinker platform, eribulin can be conjugated to albumin or antibodies via TMEAlinker to generate novel ALDCs and ADCs.

QHL-1848 is a TMEAlinker-based ALDC carrying eribulin as payload. In both in vitro and in vivo studies, QHL-1848 exhibited markedly improved safety data compared with the free payload. In human plasma at 37 °C, only ~0.5% of free eribulin was released after 7 days of incubation, indicating high plasma stability. The maximum tolerated dose (MTD) of QHL-1848 was 0.491 μmol/kg (QWx4) in dogs, displaying a significantly superior safety profile relative to eribulin (MTD = 0.054 μmol/kg, QWx3 in dogs). In murine HT1080 xenograft models, QHL-1848 achieved complete tumor regression of large (750 mm^3) tumors with a dosing regimen of 1 μmol/kg given 3 times.

IMD2128, a bispecific ADC targeting EGFR/c-Met, is conjugated with eribulin via TMEAlinker at a drug-to-antibody ratio (DAR) of 2. IMD2128 demonstrated potent curative antitumor activities across multiple xenograft models, including lung and pancreatic carcinomas, achieving complete tumor elimination with a single dose of 3.75 mg/kg. Remarkably, IMD2128 retained efficacy in models resistant to DXd-based ADCs. In cynomolgus monkeys, IMD2128 was well tolerated with a highest nonseverely toxic dose (HNSTD) over 16 mg/kg, showing a superior safety profile compared to VC linker-eribulin based ADCs (e.g., MORAb-202, HNSTD = 1.95 mg/kg). Pharmacokinetic studies in monkeys revealed a Cmax of 291.07 μmol/mL for IMD2128 ADC versus a Cmax of 0.0000823 μmol/mL for free eribulin (Cmax ratio ≈ 3.54×10^6 : 1), confirming strong linker stability in circulation. Together, these findings highlight the versatility of the TMEAlinker platform for developing both ALDCs and ADCs with eribulin payloads, demonstrating excellent safety and efficacy in preclinical evaluations.

#5655 YL252: A dual-functional PD-L1/VEGF-targeting ADC integrating immunotherapy, anti-angiogenesis, and cytotoxicity.

Wei Lian, Xinzhen Shi, Qing Zong, Hanwen Deng, Chun Deng, Tao Wang, Fang Xu, Shuaikun Wang, Tongtong Xue, Jiaqiang Cai

MediLink Therapeutics (Suzhou) Co., Ltd., Suzhou, China

The clinical success of combining immune checkpoint inhibitors with antibody-drug conjugates (ADCs), as well as the well-established synergy among immunotherapy, anti-angiogenic therapy, and chemotherapy, supports the development of multi-mechanistic therapeutic strategies. Based on this rationale, we developed YL252, a dual-functional ADC designed to simultaneously target PD-L1 and VEGF while enabling controlled payload release within the tumor microenvironment. YL252 is derived from Tumor Microenvironment-Activable Linker platform, incorporating a proprietary protease-cleavable tripeptide linker and a novel DNA topoisomerase I inhibitor payload. YL252 binds PD-L1 to modulate immune suppression, while also sequestering soluble VEGF, thereby exerting anti-angiogenic effects. The engineered drug-to-antibody ratio (DAR) is optimized to align with clinically relevant exposures of anti-PD-L1 and anti-VEGF monoclonal antibodies. We conducted a comprehensive nonclinical evaluation of YL252, including assessments of physicochemical properties, antitumor efficacy, pharmacokinetics, and safety. YL252 showed efficient internalization, potent cytotoxicity, and strong bystander effects in PD-L1-expressing tumor cells. In xenograft models, YL252 produced dose-dependent tumor growth inhibition, including complete regressions, without detectable toxicity. Mechanistic studies confirmed that YL252 effectively blocked PD-L1 signaling, consistent with immune activation alongside cytotoxic and antiangiogenic activity. Pharmacokinetic studies in cynomolgus monkeys demonstrated high systemic stability, as shown by overlapping total antibody and conjugated ADC profiles. Repeat-dose toxicology studies established a favorable safety profile, with a therapeutic index of approximately 100 and no drug-related adverse findings in major organs, including lung, liver, and kidney. In summary, YL252 is the first reported ADC that concurrently blocks PD-L1, inhibits VEGF-driven angiogenesis, and releases a cytotoxic payload in the tumor microenvironment, representing a single-agent approach that integrates immunotherapy, anti-angiogenic therapy, and chemotherapy mechanisms.

#5656 Characterization and translational development of novel pre|CISION® technology compounds delivering complementary dual payloads to the tumor microenvironment following FAP cleavage.

Victoria Juskaite[1], Tom Clough[1], Ellen Watts[1], Iva Zlatareva[1], Folake Orafidiya[1], Hanna Buist[1], Alexa Kennedy[1], Jannah Jeon[1], Greg Billenness[1], Douglas Sammon[1], Sophie Brown[1], Curtis Rink[1], Ruairidh Edwards[2], Vidicha Chunilal[1], Manuel Pinto[1], Dave Liebowitz[2], Francis Wilson[1], Michelle Morrow[1], **David Jones**[1]

[1]Discovery, Avacta Therapeutics, London, United Kingdom,[2]Clinical Development, Avacta Therapeutics, London, United Kingdom

The proprietary pre|CISION® technology incorporates a peptidic substrate that is specifically cleaved by Fibroblast Activation Protein α (FAP). FAP is a post-proline protease that is overexpressed on the surface of cancer associated fibroblasts (CAFs) in many solid tumors, and facilitates delivery of pre|CISION® medicines specifically to the tumor microenvironment (TME). AVA6103 is a pre|CISION®-enabled exatecan candidate in clinical development. AVA6103 consists of exatecan, a potent Topoisomerase I (TOP1) inhibitor, covalently linked to a dipeptide containing a cleaving sequence (D-Ala-L-Pro), which is susceptible to hydrolysis by FAP but is resistant to hydrolysis by other mammalian proteases. The exquisite selectivity of the pre|CISION® substrate for FAP results in release of exatecan payload in the TME, greatly increasing the therapeutic window and hence reducing systemic exposure and associated toxicities. Drug combinations are commonly used in cancer therapy to improve outcomes and overcome resistance, therefore we engineered two complimentary payloads into a single pre|CISION® molecule. This may offer similar benefits whilst minimizing systemic toxicity. To create dual payload pre|CISION® Peptide-Drug Conjugates (PDCs), a series of compounds have been engineered with modifications in the capping-group and linker portions. Using structure-based drug design, clear structure-activity relationships have been established for affinity to, and susceptibility of linker cleavage by FAP and subsequent payload release. We now demonstrate how the use of the pre|CISION® technology platform has been widened to selectively control the release of multiple payloads from a single molecule via a FAP cleavable linker. This includes TOP1 inhibitors and DNA damage response inhibitors as the dual payloads. Selective payload release has been demonstrated in kinetic studies showing the ability to tune the rate of payload release and in cellular studies showing potent cytotoxicity and bystander activity in cell-based assays including tumor cell-fibroblast 3D co-culture models. Synergistic activity of two potentiating payloads and downstream pharmacodynamic markers for each payload have also been evaluated in cancer cell-lines with specific gene expression profiles. This has provided translational evidence for potential biomarkers and clinical indications. Delivery of payloads to mouse tumors in vivo has also been confirmed. We show the potential of the technology to deliver a therapeutically relevant combination of payloads specifically to the TME while reducing systemic dose-limiting toxicities. This broadens the utility of the pre|CISION® platform in the delivery of novel medicines.

#5657 A novel bispecific ADC to treat solid tumors by removing immunosuppression in the tumor microenvironment.

Shiva Bhowmik[1], William Brady[2]

[1]Purdue University, West Lafayette, CA,[2]University of Washington, Seattle, WA

TNBC remains one of the most aggressive breast cancers, with limited success from current antibody and immuno-oncology regimens, largely due to the persistence of myeloid-derived suppressor cells (MDSCs) in the tumor microenvironment. We developed a novel dual-action bispecific antibody drug conjugate (ADC), TRIO-525, a first-in-class Tumor Immunogenicity Enhancing Antibody Conjugate (TIE-ADC) designed for tumor-selective, dual-targeted elimination of both cancer cells (via TROP2) and MDSCs (via CD33).Mechanistically, TRIO-525 utilizes a unique antibody format engineered for higher affinity to TROP2 and, tumor-selective engagement of CD33, enabling selective depletion of immunosuppressive MDSCs within the tumor while sparing hematopoietic and other immune cells. Preclinical studies confirmed TRIO-525's receptor-mediated cytotoxicity. It demonstrated superior potency and specificity compared to existing therapies, with effective and selective killing of both TNBC cells and MDSCs at nanomolar concentrations, restoration of T cell proliferation, and full preservation of healthy immune cells. TRIO-525 induces robust, dose-dependent tumor regression in xenograft models without any toxicity or off-target effects. TRIO-525 also displays exceptional plasma stability with no degradation species.These findings establish TRIO-525 as a ground-breaking solution to generate immunogenic tumors, directly overcoming TME-driven immunosuppression—an unmet need in TNBC and solid tumor therapy. The development of TIE-ADC drugs, as exemplified by TRIO-525, signals a paradigm shift in cancer immunotherapy through simultaneous, tumor-selective eradication of malignant and immunosuppressive cells, with broad implications for overcoming therapeutic resistance and improving patient outcomes.

#5659 Unveiling the PanCancer potential of dual-targeting uPAR-directed ADCs across cancers.

Virginia Metrangolo[1], Lars Henning Engelholm[1], Henrik Jessen Jurgensen[1], Sine Rosendal Syversen[1], Michaela Hansen Blomquist[2]

[1]PanTarg ApS, Copenhagen, Denmark,[2]The Finsen Laboratory/Biotech Research & Innovation Centre (BRIC), Copenhagen, Denmark

Antibody-drug conjugates (ADCs) are revolutionizing cancer therapy; yet, their impact in solid tumors remains limited, partly because most approved ADCs primarily target tumor-associated antigens on malignant cells. This tumor-centric approach is often insufficient in highly desmoplastic cancers such as pancreatic ductal adenocarcinoma (PDAC), where the dense, immunosuppressive stroma promotes tumor progression, restricts drug penetration, and contributes to therapeutic resistance. Targeting both malignant and stromal compartments is therefore a critical unmet need to enhance ADCs' efficacy in these refractory tumors. To address this gap, PanTarg is advancing a novel ADC that targets both the cancer and the surrounding stromal compartment. The ADC specifically targets the urokinase plasminogen activator receptor (uPAR), which is broadly overexpressed across tumor and stromal populations in aggressive cancers, particularly PDAC, while minimally expressed in normal tissues. This dual-targeting strategy aims to overcome stromal barriers and support a broader, potentially Pan-Cancer therapeutic approach. PanTarg's ADC leverages a proprietary uPAR antibody with optimal biophysical and ADC properties. In preclinical models of PDAC and other uPAR-positive tumors, PanTarg ADCs demonstrated potent anti-tumor activity across multiple payload classes. Mechanistic studies revealed stromal targeting, bystander killing of uPAR-negative cancer cells, and immune-modulatory effects promoting a more permissive tumor microenvironment. Moreover, the ADCs showed favorable tolerability consistent with uPAR's restricted expression profile. Overall, these findings validate uPAR as a clinically relevant dual-compartment ADC target and position PanTarg as a promising next-generation therapeutic candidate for PDAC and, more broadly, aggressive uPAR-positive cancers.

#5663 Chemotherapy-induced galectin-1 derives drug-tolerant persister state associated EMT in triple negative breast cancer with targetable vulnerability to ferroptosis inducers.

Shagufa A. Ehtesham Shaikh[1], Kedar Sharma[1], Dipti Bhattacharya[2], Vaibhav Kothari[2], Samruddhi Jadhav[2], Nandini Verma[1]

[1]Tata Memorial Centre-Advanced Centre for Treatment, Research and Education in Cancer (TMC-ACTREC) and HBNI, Mumbai, India,[2]Tata Memorial Centre-Advanced Centre for Treatment, Research and Education in Cancer (TMC-ACTREC), Mumbai, India

Triple-Negative Breast Cancer (TNBC) is the most aggressive and difficult-to-treat disease with high mortality rates. Therapeutic challenges are largely due to limited treatment options, disease heterogeneity, drug resistance, and metastasis to vital organs. Clinical studies established that non-genetic alterations derive chemoresistance and metastasis in TNBC. however, experimental studies investigating residual disease and metastatic recurrence in TNBC are limited. We derived subtype-specific TNBC Drug-Tolerant Persister (DTP) cellular models using taxol and platinum drugs and longitudinally characterized parental, mitotically quiescent and proliferating DTP cellular states to study the molecular basis of post-treatment aggressiveness. We observed that therapeutic agents induced autophagy and dysregulation of ferroptosis regulators including GPX4 and FSP1, irrespective of subtype and EMT largely in basal and luminal androgen receptor-positive TNBC cells. Since these phenotypes are known to be regulated by both intra- and extra-cellular signaling factors we profiled for differentially expressed soluble intracellular and secretome proteome in TNBC DTP cells using label-free quantitative mass spectrometry. Interestingly, we found that soluble factors IGFBP6, SERPINE1 and LGALS1 were among the most upregulated proteins in extracellular protein fractions of DTP cells, LGALS1 was also found significantly high in the cellular fraction. Integrative in-silico analysis of survival and expression data of TNBC patients under treatment accentuated that LGALS1 (Galectin-1) has strong clinical association with adverse prognosis and co-expression with EMT and ferroptosis-related genes. Further, conditioned medium experiment revealed that secretome from proliferating TNBC DTPs was capable of conferring multiple aggressive phenotypes including EMT, migration, invasion, proliferation, antioxidant pathway deregulation, autophagy in parental TNBC cells. These changes were collaborated with an increased activation of pSTAT3, pSrc and MAP kinase signaling pathways. Moreover, genetic and pharmacological targeting of Galectin-1 in TNBC DTP cells significantly attenuation proliferation, EMT, migration and invasion properties, with an increased susceptibility to ferroptosis inducers. Further, Galectin-1 knockdown resulted in downregulation of GPX-4 and FSP-1 in a NRF2-dependent manner, highlighting the therapeutic potential of targeting Galectin-1 in controlling EMT and inducing ferroptotic cell death. Most importantly, considering that tumor-secreted Galectin-1 can be detected in the blood it may serve as a theranostic biomarker for therapy resistance and poor prognosis as well as potential therapeutic target for overcoming chemo-tolerance and metastasis in TNBC patients.

#5664 Targeting cholangiocarcinoma with ferroptosis-inducing siRNA-based nanotherapeutics.

Peyton Classon[1], Danielle Marie Carlson[2], Jayla Millender[1], Irene Yan[3], Sumera Ilyas[1], Rory L. Smoot[4], TUSHAR PATEL[3], Gregory J. Gores[5], Davide Povero[1]

[1]Mayo Clinic, Rochester, MN,[2]Mayo Clinic Hospital-Rochester, Rochester, MN,[3]Mayo Clinic, Jacksonville, FL,[4]Surgery, Mayo Clinic, Rochester, MN,[5]Professor of Medicine, Mayo Clinic, Rochester, MN

Background: Cholangiocarcinoma (CCA) is a highly lethal epithelial cell malignancy of the hepatic biliary tract. Efficacy of current standard-of-care therapy is limited. Ferroptosis, an iron-catalyzed, caspase-independent cell death driven by phospholipid peroxidation, has emerged as a novel therapeutic target. Our goal is to develop a tumor-selective therapeutic approach targeting ferroptosis in CCA using siRNA-based nanotherapeutics.

Materials & Methods: Milk-derived nanovesicles (lactosomes) coated with EpCAM aptamer and packaged with siRNA against Glutathione Peroxidase 4 (siGPX4-lactosomes) and Ferroptosis Suppressor Protein 1 (siFSP1-lactosomes), were used to induce ferroptosis in murine CCA cells (FAC) and in syngeneic liver orthotopic CCA-bearing mice. *In vitro*, lactosome uptake and efficacy were assessed by fluorescence-based, cell-viability and molecular biology assays. *In vivo*, target engagement, tissue distribution, safety and efficacy were assessed.

Results: EpCAM (epithelial cell adhesion molecule expressed on CCA cells)-coated lactosomes showed robust uptake by FAC cells in a EpCAM-dependent manner. EpCAM knockdown via siRNA reduced lactosome uptake, confirming aptamer selectivity. Dose-dependent siGPX4/siFSP1-lactosome treatment led to GPX4/FSP1 knockdown and induced ferroptotic cell death in up to 60% of FAC cells after 72 hours ($p<0.001$ vs. siNC). In CCA-bearing mice, intravenous administration of siRNA lactosomes was well-tolerated with no liver or systemic toxicity observed and demonstrated robust tumor distribution compared to non-tumorous tissues. Efficacy studies demonstrated that siGPX4/siFSP1-lactosomes significantly reduced intratumor *Gpx4* and *FSP1* mRNA expression by 40-60% and induced significant upregulation of ferroptosis markers *Ptgs2* and *Acsl4* ($p<0.01$ vs. siNC). Ferroptosis in siRNA-lactosome treated tumors was confirmed by immunohistochemistry for phospholipid peroxidation markers oxPAPC and 4-HNE. Additionally, proliferation marker Ki67 was significantly downregulated in siGPX4/siFSP1-lactosome treated tumors ($p<0.05$ vs. siNC), indicating ferroptosis-mediated tumor suppression. Importantly, siGPX4/siFSP1-lactosomes reduced tumor burden and expression of CCA markers CK19/7 in treated mice, as compared to control mice.

Conclusions: siRNA-based nanotherapeutics targeting CCA can effectively and safely induce ferroptosis *in vitro* and *in vivo*, representing a potential therapeutic strategy for CCA treatment.

#5665 Levistolide A inhibits bladder cancer progression by suppressing GPX4 expression and activating ferroptosis.

Yixi Gong, Jihye Kim, Ingyu Lee, Xiaoyu Guo, Bomi Han, Eui Man Jeong

Jeju National University, Jeju Special Self-Governing Province, Korea, Republic of

Bladder cancer is the second most common malignant tumor of the urinary system worldwide, with high incidence and mortality rates. However, existing drugs for treating bladder cancer often cause many adverse reactions. Levistolide A (LA), a natural compound isolated from the traditional Chinese herb *Ligusticum chuanxiong Hort*, has been identified as an anti-cancer agent. However, its role in bladder cancer and underlying mechanisms remain largely unknown. In this study, we used the MTT assay and Annexin V/PI staining to detect the co-induced death of bladder cancer cell lines 5637 and T24 by LA and different cell death inhibitors. The rescue experiment show that ferrostatin-1 (Fer-1, ferroptosis inhibitor) could rescue the proliferation of bladder cancer cells prevented by LA or not other inhibitors of cell death. At the same time, through in vivo verification using a xenograft model, LA can effectively inhibit the proliferation of bladder cancer cell line 5637. Subsequent RNA-seq analysis, nude mouse tumor model, MDA detection, and Western blotting, demonstrated that LA-enhanced lipid peroxidation by up-regulating PTGS2 and down-regulating GPX4, accompanied by dysregulation of intracellular iron homeostasis. Furthermore, we also found that in in vivo experiments, co-treatment with LA and RSL3 (ferroptosis inducer) increased the inhibitory effect on bladder cancer cells 5637, highlighting its potential for clinical application. This provides a novel therapeutic strategy for eliminating bladder cancer cells.

#5666 Tambiciclib (SLS009), a CDK9 inhibitor, promotes apoptosis and suppresses MCL-1 levels in AML cell lines.

Elizabeth C. Trull, Philip C. Amrein

Cancer Center, Massachusetts General Hospital, Boston, MA

Background: Tambiciclib (SLS009) is a potent, selective CDK9 inhibitor that has shown promising results in Phase I clinical trials in hematological malignancies (NCT04588922). CDK9 is a critical regulator of transcription elongation through RNA polymerase II. Its inhibition results in downregulation of protein synthesis, thus decreasing the expression of short half-life molecules, such as MCL-1, MYC, E2F, and survivin, which leukemia cells, especially acute myeloid leukemia (AML) cells, depend on for survival. Here, we demonstrate the mechanistic effects of tambiciclib exposure correlated with apoptosis and cell death in AML cell lines.

Methods: We exposed the following cell lines to various concentrations of tambiciclib for 6 to 8 hours followed by washout: THP1 (p53 mutant, MLL-AF9 rearranged, NRAS mutant), NOMO1 (p53 mutant, MLL-AF9 rearranged, ASXL1 mutant), MOLM-13 WT (MLL-AF9 rearranged, NRAS mutant, FLT3 mutant), and MOLM-13 TP53 KO (MLL-AF9 rearranged, NRAS mutant, FLT3 mutant, p53 knockout). We performed viability assays on these cell lines using CellTiterGlo and examined protein expression using western immunoblotting and intracellular flow cytometry. Additionally, we stained cells with Annexin-V and a fixable viability dye before intracellular staining to correlate how protein expression levels change as cells undergo apoptosis and cell death.

Results: Treatment of AML cell lines with tambiciclib demonstrated cytotoxicity in the low nanomolar range and a dose-dependent decrease in cell viability after an 8-hour exposure. Repeated 8-hour exposures of tambiciclib consistently decreased IC50s, warranting further investigation into the mechanism through which this occurs. Our results show that when cells are exposed to 50 nM or 100 nM SLS009 for 6 hours, active caspase-3 levels increase and MCL-1 and survivin levels decrease. These changes in caspase-3 and MCL-1 expression are observed as early as 6 hours and are even more pronounced 24 hours after the completion of treatment. We observed that lower levels of MCL-1 and survivin correlate with increased apoptosis, suggesting that tambiciclib may lower the threshold for AML cell death and therefore may be useful in combination with existing therapeutic agents for leukemia treatment.

Conclusions: These results suggest that AML cell lines undergo cell death and apoptosis at low nanomolar concentrations of tambiciclib. Preliminary analysis of apoptotic molecules and pathways suggests a mechanism involving MCL-1 and survivin. With ongoing investigations into the dose and schedule of tambiciclib, our future directions include optimizing the use of tambiciclib in combination therapy to leverage the mechanistic effects of CDK9 inhibition and provide a novel therapeutic approach to treating patients with high-risk AML.

#5667 Ferroptosis necessitates caspase 5 dependent GSDME cleavage in ovarian cancer.

Mahmuda Akter, Lei Sun, Cheng Chi, Shuang Huang

University of Florida, Gainesville, FL

Ferroptosis, an intracellular iron-catalyzed form of programmed cell death (PCD) driven by lethal lipid reactive oxygen species (ROS)–induced membrane damage, is mechanistically uncharacterized in its execution process as a newly discovered PCD pathway. This study aimed to elucidate the molecular execution cascade of ferroptosis in ovarian cancer and to determine whether it uses common effector proteins shared with other PCD mechanisms. Mesenchymal-like ovarian cancer cells (OCC1, OVCAR8, ES2) were exposed to Erastin and ML162 with pathway-specific inhibitors, providing evidence that only the pyroptosis inhibitor YVAD reduced ferroptosis-induced death, supporting the association of pyroptotic executors. Lactate dehydrogenase (LDH) release and IL-1β secretion indicated that ferroptosis activates a pore-forming execution process, while both YVAD and gasdermin inhibitor disulfiram protected membrane damage. Ferroptotic cells exhibited cleavage of Gasdermin E (GSDME), whereas Gasdermin D was not processed. GSDME knockdown protected ovarian cancer cells from ferroptotic death, confirming its essential role in the execution phase. Our study further illustrated that ferroptosis does not follow the canonical inflammasome pathway by showing that caspase-1 remained inactive, and both NLRP3 inhibition (MCC950) and ASC knockdown did not affect ferroptotic sensitivity. Noncanonical pyroptotic PCD executors, specifically caspase-5 was activated during ferroptosis, but not caspase-4. Additionally, the siRNA Knockdown and CRISPR-Cas9 knockout of caspase-5 significantly suppressed ferroptotic death. The cell-free biochemical assay demonstrated that active caspase-5 directly cleaves full-length GSDME, confirming the interaction between caspase-5 activation and pore formation. Oxidized lipidomic profiling identified the accumulation of oxidized phosphatidylethanolamine (PE) species in ferroptotic cells, suggesting a potential upstream trigger for caspase-5/GSDME activation. Our data define a novel ferroptosis execution pathway mediated by caspase-5 activation and GSDME cleavage, revealing a mechanism with potential therapeutic relevance in ovarian cancer.

#5668 USP7 and ITCH/UBE4B ubiquitin ligase regulate the switch between apoptosis and necroptosis via Ku70 and c-FLIPL polyubiquitination in neuroblastoma.

Christophe Le Clorennec[1], Carla Sampaio[2], Peter E. Zage[2]

[1]UCSD Moores Cancer Center, La Jolla, CA,[2]Pediatrics, UCSD Moores Cancer Center, La Jolla, CA

Dysregulation of the Ubiquitin Proteasome System has been linked to many human diseases, including cancer. Expression of UBE4B ubiquitin ligase is associated with neuroblastoma patient outcomes and its functional roles in neuroblastoma pathogenesis are not known. We have recently identified an ubiquitin ligase complex ITCH/UBE4B which mediates ubiquitination of Ku70 and c-FLIPL proteins for proteasomal degradation allowing HDAC inhibitor-mediated caspase-8 dependent apoptosis. We also confirmed that the deubiquitinase USP7, critical player in tumor suppression and DNA repair, can be a potential therapeutic target for neuroblastoma. Highly selective USP7 inhibitors have demonstrated significant antitumor activity in preclinical models of adult cancer, and we reported that these inhibitors alone can be more effective against neuroblastoma tumor growth. Our hypothesis is that USP7 inhibition will be more effective against neuroblastoma tumors through destabilization of ITCH/UBE4B complex protein targets allowing a stronger induction of cell death in response to treatment for the children. To evaluate efficacy of USP7 inhibitors in combination with HDAC inhibitors or chemotherapy against neuroblastoma tumor growth, neuroblastoma cell lines depleted for UBE4B or USP7 were treated with increasing concentrations of USP7 inhibitors alone or in combination with chemotherapy or with HDAC inhibitors. Cell proliferation was measured using continuous live cell imaging and apoptosis by caspase cleavage and PARP cleavage detection by western blot. We have evaluated also, whether ubiquitination/deubiquitination and degradation rates of p53, Ku70 and c-FLIPL proteins could modulate induction of apoptosis and necroptosis. USP7 inhibition resulted in decreases in cell viability in p53 wild-type neuroblastoma cell lines via the induction of apoptosis and necroptosis by increasing phosphorylation of MLKL, RIPK3 and RIPK1. In UBE4B or USP7 depleted cells, a huge induction of necroptosis and a small rate of apoptosis were observed. We also identified USP7 as a deubiquitinase of Ku70 and c-FLIPL, stabilizing the Ku70/c-FLIPL/Bax “FLIPosome” complex. USP7 inhibition destabilizes ku70 and c-FLIPL for protein degradation leading to induction of apoptosis as well as necroptosis. UBE4B depletion in neuroblastoma inhibits HDAC inhibitors mediated caspase-8 mediated apoptosis but enhances necroptosis, notably because the stabilization of the FLIPosome can allow the blockade of caspase-8 activation and can trigger the activation of the necroptosome. Our data suggests that USP7 and ITCH/UBE4B can control the switch between apoptosis and necroptosis in response to USP7 and HDAC inhibitors. USP7 inhibition and ITCH/UBE4B activation by HDAC inhibitors could be a promising therapeutic strategy for children with high-risk and relapsed neuroblastoma.

#5669 Investigating the role of TRPM4 in the cancer cell death induced by ErSO and derivatives.

Brooke A. Bouwens[1], Michael P. Mulligan[2], Rowan Glover[2], Paul J. Hergenrother[2]

[1]Department of Biochemistry, University of Illinois at Urbana-Champaign, Champaign, IL,[2]Department of Chemistry, University of Illinois at Urbana-Champaign, Champaign, IL

The majority of breast cancers (BC) are hormone receptor positive (HR+/HER2-), and there remains a significant unmet need for alternative therapeutics for patients who become resistant to or no longer respond to endocrine therapy. Endocrine therapies primarily target estrogen receptor alpha (ERα) to inhibit tumor growth; however, acquired resistance and ERα mutations often limit the long-term efficacy of these treatments. Alternative therapeutic strategies that do not rely on endocrine pathways are critical for managing unresponsive breast cancers. Transient receptor potential cation channel subfamily M member 4 (TRPM4) is a calcium-activated monovalent ion channel that has emerged as a promising non-endocrine target in oncology. We have discovered a compound, called ErSO-TFPy, with potent cytotoxicity against TRPM4-positive (TRPM4+) cancer cells via a novel non-apoptotic mechanism. Notably, elevated TRPM4 expression correlates with increased sensitivity to ErSO-TFPy. To investigate the role of TRPM4 in the cell death induced by ErSO-TFPy, we performed studies including cellular thermal shift assays (CETSA) and cellular probe colocalizations. To assess the possibility of leveraging TRPM4 activation as a selective anticancer strategy, we looked at TRPM4 mutations, subcellular localization, temperature sensitivity, and cell viability in response to ErSO-TFPy and related compounds. Our data suggests TRPM4 plays a key role in the cell death induced by ErSO-TFPy.

#5670 Oxidative stress-mediated non-apoptotic, non-autophagic cell death: A mechanistically distinct strategy to overcome resistance in colorectal cancer cells.

Mati Ur Rehman[1], Almuayyad Gajani[1], Mahwish Fatima[1], Paras Jawaid[2], Arooj Shafiq[2], Azhar Hussain Rajabali[2]

[1]Biological and Biomedical Sciences, Aga Khan University - Karachi, Pakistan, Karachi, Pakistan,[2]Aga Khan University Hospital - Karachi, Pakistan, Karachi, Pakistan

Cancer remains a leading cause of mortality worldwide, with therapeutic failure often driven by apoptosis resistance a major hurdle that limits the efficacy of conventional anticancer therapies. Targeting alternative, caspase-independent cell death pathways has emerged as a promising strategy to overcome this resistance. In this study, we evaluated the effects of two mechanistically distinct small molecules a BCL-XL inhibitor and an NRF2 activator on colorectal cancer cell lines to investigate their ability to induce non-apoptotic cell death. Both agents reduced cell viability in a dose- and time-dependent manner. The NRF2 activator triggered cytoplasmic vacuolation at lower concentrations, characteristic of paraptosis, accompanied by endoplasmic reticulum (ER) dilation, oxidative stress, and downregulation of Alix, a key inhibitor of paraptosis. This mode of cell death required de novo protein synthesis and was independent of caspase activation, PARP cleavage, and DNA fragmentation. In contrast, the BCL-XL inhibitor displayed a dose-dependent switch between vacuolation-induced cell death and classical apoptosis, marked by phosphatidylserine externalization and DNA fragmentation. These findings underscore oxidative stress-mediated, vacuolation-associated non-apoptotic cell death as a mechanistically distinct and therapeutically relevant modality for targeting apoptosis-resistant cancer cells. This approach may pave the way for innovative cancer therapies that exploit tumor redox vulnerabilities while bypassing traditional cell death pathways.

#5671 Mitotic entry with DSB induces pyroptosis through 53BP1-mediated NLRP3 inflammasome activation.

Mengshi Luo[1], Yuewen Zhang[1], Wenjian Gong[1], Zhiqi Liao[1], Linghui Wang[1], Qiuyang Xu[1], Xingzhe Liu[1], Yijie Wu[1], Xuejiao Zhao[2], Gorden B. Mills[3], Ding Ma[2], Guangnian Zhao[2], Qinglei Gao[2], Yong Fang[2]

[1]Department of Gynecological Oncology, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China,[2]National Clinical Research Center for Obstetrics and Gynecology,Department of Gynecological Oncology, National Clinical Research Center for Obstetrics and Gynecology, Department of Gynecological Oncology,Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China,[3]Department of Cell, Development and Cancer Biology, Oregon Health and Sciences University, Portland, OR

Background: Accumulated DNA double-strand breaks (DSBs), a key hallmark of cancer, are efficiently repaired during interphase to preserve proper mitotic progression, a process crucial for preventing genomic collapse. This protective strategy also represents a potential vulnerability for selectively eliminating tumor cells. However, when unrepaired DSBs persist into mitosis, the subsequent cellular fate and underlying mechanisms remain poorly understood. Using a cell model harboring under-repaired mitotic DSBs, we found that these mitotic DSBs robustly trigger NLRP3 mediated pyroptosis, an inflammatory form of cell death characterized by the release of inflammatory molecules, which has the potential to stimulate antitumor immunity within the tumor microenvironment. Mechanically, we identify 53BP1, an DNA repair associated protein, as a new regulator that drives mitotic pyroptosis.
Methods and Results: Using flow cytometry, western blot and immunofluorescence co-localization, a cell model in which DSBs prematurely enter into mitosis was established. Leveraging live-cell imaging and the H2B-mCherry system, we observed that DSBs in mitosis induces pyroptosis mediated by NLRP3 inflammation activation, as evidenced by characteristic pyroptotic morphologies, ASC foci formation and GSDMD cleavage. To elucidate the underlying mechanism of NLRP3 activation during mitosis, we employed liquid chromatography-mass spectrometry (LC-MS) combined with a DNA damage response (DDR) gene library analysis. This approach identified p53-binding protein 1 (TP53BP1) as the most abundant and intriguing candidate for NLRP3 interaction and activation in mitosis, which was further validated by molecular cloning, co-immunoprecipitation assays, and immunofluorescence co-localization. Furthermore, validation experiments across multiple cell models demonstrated that the phosphorylated 53BP1 during mitosis promoted NLRP3 inflammation activation and induced pyroptosis. This effect was consistent with the pyroptotic phenotype observed in a mouse model harboring a phosphorylated 53BP1 knock-in mutation.
Conclusion: Our work identifies 53BP1 as a novel NLRP3 regulator that activates NLRP3 inflammation during mitosis and induces pyroptosis, thereby revealing a new mechanism that compensates for the loss of NEK7-dependent NLRP3 activation during mitosis. This study provides an unprecedented insight into the crosstalk between the DNA damage response and the NLRP3 mediated pyroptosis, and offers a conceptual framework for the development of new therapeutic strategies.

#5672 PRMT5 inhibition enhances therapeutic vulnerability to Bcl-xL/Bcl-2 inhibitors in glioblastoma.

Shumpei Onishi[1], Ashis Chowdhury[1], Jean-Paul Bryant[1], Dragan Maric[2], Qi Li[3], Jing Wu[3], Yeshavanth Kumar Banasavadi-Siddegowda[1]

[1]Surgical Neurology Branch, NIH National Institute of Neurological Disorders & Stroke (NINDS), Bethesda, MD,[2]Flow and Imaging Cytometry Core Facility, NIH National Institute of Neurological Disorders & Stroke (NINDS), Bethesda, MD,[3]Neuro-Oncology Branch, NIH National Cancer Institute (NCI), Bethesda, MD

Glioblastomas are aggressive brain tumors characterized by heterogeneity and resistance to standard multimodal therapies. To address this challenge, we investigated potential vulnerabilities arising from the inhibition of protein arginine methyltransferase 5 (PRMT5), an epigenetic regulator critical for glioblastoma cell proliferation and survival. Although previous studies have demonstrate that PRMT5 inhibition induces a senescence-like state, the precise biological and therapeutic implications of this response in glioblastoma remain poorly understood.

Using patient-derived glioblastoma stem-like cells (GSCs), we performed a comprehensive screen of senolytic compounds in PRMT5-depleted GSCs. Among these compounds, the BCL-2/xL inhibitor navitoclax showed the most substantial reduction in cell viability, supporting its selection for subsequent combination studies. We then evaluated the therapeutic potential of combining PRMT5 inhibition, using the CNS-penetrant PRMT5 inhibitor LLY-283, with navitoclax. Treatment with LLY-283 induced G1 cell cycle arrest consistent with senescence induction. Western blot analysis showed that PRMT5 inhibition increased expression of the anti-apoptotic proteins BCL-2 and BCL-xL while reducing MCL-1 levels, indicating a shift in cellular dependency towards the BCL-2/xL axis. Quantitative drug-interaction analysis based on cell viability assay confirmed a synergistic effect between LLY-283 and navitoclax. The combination treatment enhanced the G1 cell cycle and led to a significant increase in cleaved PARP and γH2AX, indicative of enhanced apoptosis as evidenced by Annexin V assay. Mitochondrial functional assays demonstrated a substantial decrease in ATP production along with elevated mitochondrial reactive oxygen species (ROS), implicating mitochondrial dysfunction in the enhanced apoptotic and DNA-damage responses observed under dual inhibition.

In summary, our findings elucidate that PRMT5 inhibition creates a senescence-associated vulnerability in patient-derived glioblastoma cells, which can be effectively exploited through BCL-2/xL blockade. This combinatorial strategy offers a promising therapeutic avenue for overcoming the intrinsic resistance of glioblastoma.

#5673 Ferroptosis induction synergizes with KRAS inhibitors in *KRAS*-mutant lung adenocarcinoma.

Amirali Karimi[1], Yu Qian[1], David Molkentine[1], Alvaro Guimaraes Paula[1], Busra Ernhofer[2], David Hwa Peng[3], Monique B. Nilsson[1], John V. Heymach[1]

[1]Department of Thoracic, Head and Neck Medical Oncology, UT MD Anderson Cancer Center, Houston, TX,[2]Medical University of Vienna, Vienna, Austria,[3]Therapeutics Discovery Division, TRACTION Platform, UT MD Anderson Cancer Center, Houston, TX

Background: KRAS inhibitors hold substantial potential for the treatment of numerous malignancies harboring activating *KRAS* mutations, including non-small cell lung cancer (NSCLC). *KRAS* mutations are present in 25-30% of patients with non-squamous NSCLC, most commonly in the form of G12C mutations. Unfortunately, patients with inactivating mutations in *KEAP1*, which is frequently co-mutated with *KRAS* and *STK11*/LKB1, respond poorly to KRAS G12C inhibitors. *KEAP1* inactivation impairs NRF2 protein degradation, leading to enhanced antioxidant and ferroptosis response in the tumor cells. Whether ferroptosis resistance mediates resistance to KRAS G12C and G12D inhibitors in lung adenocarcinoma cells harboring these mutations is unknown.
Methods: DepMap was used to retrieve the drug sensitivity data for RSL3, erastin, ML162, ML210, sotorasib, and MRTX1133 as well as CRISPR and RNAi screen data in NSCLC human cell lines. A NSCLC ferroptosis resistance gene signature was constructed using genes that positively correlated (Pearson correlation z-score > 3) with resistance to both RSL3 and erastin in human NSCLC cell lines accessed from the Cancer Therapeutics Response Portal. We knocked-out *Keap1* and *Stk11* from murine LKR13 KRAS G12D and KRAS G12C cells using CRISPR-Cas9, to create isogenic models of $Kras^{MUT}$ (K), $Kras^{MUT}/Keap1^{KO}$ (KK), $Kras^{MUT}/Lkb1^{KO}$ (KL), and $Kras^{MUT}/Lkb1^{KO}/Keap1^{KO}$ (KLK) tumor cells. Lipid peroxidation was quantified by flow cytometry using BODIPY™ 581/591 C11.
Results: We determined that *KEAP1*-mutant, but not LKB1-mutant, NSCLC cell lines were resistant to ferroptosis inducers RSL3, ML162, ML210, and erastin. *KEAP1* deficiency also correlated with poor response to KRAS G12C inhibitors (sotorasib and adagrasib) and the KRAS G12D inhibitor MRTX1133 in human and murine cell lines, suggesting that ferroptosis resistance may contribute to KRAS inhibitor resistance. Treatment of KRAS mutant tumor cells with adagrasib or MRTX1133 induced lipid peroxidation- the biochemical defining feature of ferroptosis. In KRAS G12D mutant LKR13 cells, MRTX1133-induced cell death could be partially reversed by the ferroptosis inhibitor ferrostatin-1, but not by apoptosis or necroptosis inhibitors. Moreover, a higher NSCLC ferroptosis resistance gene expression signature correlated with reduced sensitivity to *KRAS* gene disruption in CRISPR and RNAi screens in *KRAS*-mutant NSCLC cell lines. Finally, ferroptosis inducers erastin and RSL3 synergized with adagrasib and MRTX1133 in LKR13 K cell lines.
Conclusions: KRAS inhibition induces ferroptosis in *KRAS*-mutant lung adenocarcinoma cell lines and ferroptosis resistance correlates with resistance to KRAS inhibitors. Combining ferroptosis induction strategies could potentially enhance the effectiveness of KRAS targeting treatments.

#5674 CD47 blockade induces necroptosis and complements the effects of BCL-2 inhibition in hematologic malignancies.

Stephen Jun Fei Chong[1], Rebecca Valentin[2], Jing Wang[2], Fen Zhu[2], Filip Garbicz[2], Kartini Iskandar[3], Brienne C. Y. Toh[4], Marisa Peluso[5], Jeremy Zhang[2], Liam Hackett[2], Benjamin H. Lee[5], Li Ren Kong[6], Catherine J. Wu[2], Wee Joo Chng[4], Shazib Pervaiz[3], Carsten U. Niemann[7], Ruben D. Carrasco[2], Matthew S. Davids[2]

[1]Physiology, Cancer Science Institute, NUS Centre for Cancer Research, National University of Singapore, Singapore, Singapore,[2]Dana-Farber Cancer Institute, Boston, MA,[3]Physiology, NUS Centre for Cancer Research, National University of Singapore, Singapore, Singapore,[4]Medicine, Cancer Science Institute, NUS Centre for Cancer Research, National University of Singapore, Singapore, Singapore,[5]Surface Oncology, Cambridge, MA,[6]Nanyang Technological University, Singapore, Singapore,[7]Institute of Clinical Medicine, University of Copenhagen, Copenhagen, Denmark

Introduction: CD47 is a macrophage checkpoint protein that acts as a "*don't-eat-me*" signal to prevent cell phagocytosis. Its blockade has shown promising results in clinical trials of lymphomas. Interestingly, CD47 blockade-induced cell death beyond phagocytosis, has also been reported, potentially contributing to the overall anti-tumor activity. This cell death mechanism has yet been well-characterized, thus warranting investigation to comprehensively unravel the mechanism of CD47 blockade and to facilitate the identification of optimal drug partners for combination therapy.
Method: Anti-CD47 monoclonal antibodies (mAb), SRF231, magrolimab, B6H12, were evaluated for cell death mechanisms such as apoptosis, autophagy or necroptosis. Techniques used include BH3 profiling, Annexin V, siRNA/CrisprCas9, Western blot and immunohistochemistry. Diffused large B-cell lymphoma (DLBCL) and acute myeloid leukemia (AML) cell lines were used. In vitro results were used to select for appropriate drug to combine with CD47 blockade. Results were validated ex vivo in leukemia patient samples and in vivo in cell line and patient-derived mouse models.
Result: Anti-CD47 mAbs consistently killed tumor cells from 10 cell lines, 24 patients, 3 mouse models by activating necroptosis, while sparing healthy immune cells. Necroptosis was confirmed via increased phospho(p)-RIPK and p-MLKL, which were rescued by necroptosis inhibitors or CD47/MLKL silencing. We further ascertained that PLCγ activation is upstream of necroptosis, as inhibiting PLCγ prevented p-MLKL and necroptosis. Moreover, apoptosis or autophagy was not involved, as inhibiting these pathways did not rescue SRF231-induced cell death. Given that necroptosis is the primary mechanism, we proceeded to leverage on apoptosis as an additional pathway to enhance cell death. Using BH3 profiling, a technique that informs cellular sensitivity to apoptotic inducers - BH3 mimetics, we identified the BCL-2 inhibitor venetoclax as an effective partner for SRF231 against hematologic malignant cells that depend highly on BCL-2 for survival (*i.e.* Cell survival: DMSO - 100%, (50nM) VEN - 71.39%, SRF231 - 57.01%, Combo - 19.53%, $P < 0.0001$). SRF231 and venetoclax combination completely eliminated tumor burden and prolonged progression free survival in BCL-2 dependent DLBCL and AML mouse models (*i.e.* Mice survival at day 70: Control - 0%, VEN - 0%, SRF231 - 58.3%, Combo - 100%; $P < 0.0001$). Importantly, SRF231 was equally effective against non-BCL-2 dependent, venetoclax-resistant DLBCL mouse models (*i.e.* Mice survival at day 200: Control - 0%, SRF231 - 62.5%, $P < 0.0001$).
Conclusion: Our study unravels a novel cell death mechanism of CD47 blockade through necroptosis, thereby permitting the inclusion of venetoclax-induced apoptosis, a complementary combination worthy of further study against BCL-2 dependent hematologic malignancies in the clinic.

#5675 MUC1-C-directed exatecan ADC induces genotoxic stress and transcriptional suppression of UPR-inflammatory pathways in metastatic colorectal cancer.

Surender Kharbanda[1], Deepak Raina[1], Rehan Ahmad[1], Changchuin Mao[1], Sourav Choudhary[2], Brian Lawney[1], Nandita Sreenivasalu[1], Govind Panchamoorthy[1], Ravi Jasuja[1]

[1]Research & Development, Xyone Therapeutics Inc, Canton, MA,[2]Research & Development, Birla Institute of Technology and Science, Hyderabad, India

Background:Metastatic colorectal cancer (mCRC) remains a major cause of cancer mortality and MUC1 is overexpressed in most tumors. However, no approved therapies target the tumor-anchored MUC1 antigen. The MUC1 oncoprotein consists of MUC1-N and MUC1-C, which form a heteromeric complex on the cell surface. The MUC1-N is shed into circulation and is highly heterogeneous in its glycosylation patterns across tumor types, creating both an antigen sink and unpredictable epitope presentation. This glycosylation variability can sequester MUC1-N-directed antibodies and significantly reduce consistent target engagement. In contrast, the membrane-anchored MUC1-C remains structurally accessible and uniform, representing a more reliable target for ADC development and addressing a critical unmet need in mCRC therapy.
Methods: We generated a first-in-class exatecan-based antibody-drug-conjugate (XYA02-8) recognizing the α4 helix within the extracellular domain of MUC1-C through a cleavable linker *. In vitro, cellular and patient-derived xenograft studies were perfomed to evaluate anti-tumor potency and safety of XYA02-8.
Results: The anti-MUC1-C monoclonal antibody displayed high-affinity binding to the MUC1-C extracellular domain and robust, ligand-driven internalization across multiple mCRC cell lines. Conjugation to exatecan via a cleavable linker yielded XYA02-8, an optimized ADC with >98% monomeric purity and a DAR of 8. XYA02-8 induced potent cytotoxicity in vitro, achieving low-nanomolar IC_{50} values across a panel of MUC1-expressing mCRC models. In SW620 xenografts, QW dosing x 3 at 7.5 mg/kg generated pronounced tumor growth inhibition without measurable body-weight loss or overt systemic toxicity. Transcriptomic profiling revealed a dominant exatecan-associated DNA-damage and replication-stress signature, repression of UPR regulators (DDIT4, STC2), and attenuation of pro-inflammatory signaling, concordant with increased γH2AX induction and PARP cleavage. In a MUC1-positive mCRC PDX, XYA02-8 produced substantial tumor regression with minimal toxicity, and efficacy was recapitulated in NCG mice treated at 5 mg/kg QW ×3. High-dose escalation (10× therapeutic level) resulted in negligible changes in hematologic or serum chemistry parameters, supporting a strong preclinical safety margin.
Conclusion: XYA02-8, a first-in-class MUC1-C-directed exatecan ADC, demonstrates potent and selective antitumor activity driven by efficient internalization, high DAR stability, and targeted induction of DNA-damage and replication-stress programs. Its robust efficacy across CDX and PDX models, coupled with minimal systemic toxicity at supra-therapeutic doses, positions XYA02-8 as a strong candidate for clinical translation in MUC1-positive mCRC.

#5676 Bites that kill: Understanding cancer cell fate after macrophage mediated trogocytosis.

Ishwaree Datta[1], Meghan Morrissey[2], Annie Rogers[1]

[1]Molecular, Cellular and Developmental Biology, University of California, at Santa Barbara, Santa Barbara, CA,[2]University of California, Santa Barbara, Santa Barbara, CA

Macrophage therapies are an exciting avenue for targeted cancer cell killing in tumors. Macrophages phagocytose (that is, whole cell engulfment) of dying, dead, and abnormal cells. However, it's been observed that in solid tumors, macrophages primarily perform trogocytosis or nibbling, where they tear away portions of solid tumor cells. Trogocytosis in tumors is observed to be paradoxical: while it allows immune cells to strip away antigen from the cancer cell surface and thus allowing cancer progression. Conversely, it can cause cancer cell death, aiding immunotherapy. This dichotomous result raises the question of how to leverage trogocytosis in immunotherapy to be consistently lethal. We observe higher rates of trogocytosis compared to phagocytosis with Chimeric Antigen Receptor macrophages (CAR-M) when interacting with solid tumor cells. Our 3D tumor spheroid model constructed with SKOV3 cells shows a significant reduction in size with Her2CAR macrophages, with higher trogocytosis. I observe trogocytosed cancer cells to undergo apoptotic cell death via specific targeting by Her2CAR macrophages in 2D cell cultures. However, interestingly, death is not immediate in the co-cultures; instead, it happens following sustained trogocytic attack. In the first 2 hours of co-culture, when trogocytosis is significantly higher than phagocytosis, there's no cancer cell death. Our 3D tumor spheroid model also shows a reduction in spheroid diameter with Her2CAR macrophages after 5 days of co-culture. The cancer cell death can be blocked with a pan-caspase inhibitor Q-VD-Oph. The delayed cancer death suggests that trogocytosed cancer cells overcome initial, non-lethal loss of cell membrane; however, continual trogocytic attack renders cancer cells susceptible to apoptosis at later timepoints. Continuous loss of the cell membrane, followed by continual repair while maintaining homeostasis, is an energy-expensive process for the cancer cells. Thus accumulation of sustained stress in the trogocytosed cancer cells can ultimately push them to undergo apoptosis. I am currently investigating oxidative stress accumulation for activation of apoptosis in trogocytosed cells. Further, a change in transcriptomic profile for certain genes following 3-day co-culture with Her2CAR macrophages is also observed, suggesting the trogocytosed cells can alter their transcriptomic response to trogocytosis. Under current investigation is whether accumulated stress in trogocytosed cells causes this change in transcriptomic profile. CAR-M presents a promising avenue for targeting tumors. However, their efficacy in solid tumors needs to be improved. We observe continual trogocytosis pushes cancer cells to apoptosis at later timepoints. Thus, to make trogocytosis lethal in immunotherapy, understanding the trogocytosed cell response and investigating the fate of trogocytosed cells is essential.

#5677 GPX4-FTH1-ARNT signaling regulates iron efflux to suppress ferroptotic cell death and promote immune remodeling in osteosarcoma.

Md Abdullah[1], Donghee Lee[2], Jong Hyuk Kim[1]

[1]University of Florida, Gainesville, FL,[2]Small Animal Clinical Sciences,, University of Florida, Gainesville, FL

Osteosarcoma is the leading primary malignant bone tumor in children and young adults. Despite multimodal therapy involving surgery and multi-agent chemotherapy, patient survival rates have remained stagnant over the past four decades, necessitating the development of novel, effective therapeutic strategies. Ferroptosis, an iron-dependent programmed cell death, is a promising therapeutic target in osteosarcoma. Our recent findings indicate that osteosarcoma cells may circumvent GPX4-mediated ferroptosis by promoting iron detoxification through the ferroportin (FPN) exporter. This study was designed to define the molecular mechanisms by which osteosarcoma cells withstand redox stress associated with excess intracellular iron and to assess the potential impact of this regulation on the tumor immune microenvironment. First, we found that the TFRC gene, encoding the transferrin receptor responsible for cellular iron uptake, was associated with poor survival time in cervical cancer, glioblastoma, and liver cancer, and renal cancer in TCGA datasets. In contrast, SLC40A1 encoding FPN showed favorable clinical associations in liver cancer, pancreatic adenocarcinoma, and renal cancer. In human osteosarcomas (n = 88) from the Target Osteosarcoma database, SLC40A1 expression was positively correlated with overall immune gene scores ($r = 0.241$, $p = 0.024$) and M1 macrophage transcripts ($r = 0.340$, $p = 0.001$). Comparative transcriptomic analysis in canine osteosarcomas (n = 43) revealed that iron-related genes, including FTH1 ($r = 0.659$, $p < 0.0001$), SLC39A8 ($r = 0.665$, $p < 0.0001$), and ALAS1 ($r = 0.573$, $p < 0.0001$), were associated with immune scores. In DOUG canine osteosarcoma cells, treatment with the GPX4 inhibitor RSL3 significantly altered the expression signature of genes involved in tissue damage and remodeling, including those in in the ECM-receptor interaction, PI3K-AKT, and AGE-RAGE signaling pathway. Specifically, RSL3 treatment resulted in the marked upregulation of ARNT (encoding HIF-1β) and ALDH3A1, both critical components of detoxification and oxidative stress response pathways. Furthermore, Erastin, another ferroptosis inducer, substantially increased HMOX1, a key antioxidant defense gene, in both canine DOUG and COS31 and DOUG canine osteosarcoma cells. These data collectively suggest that osteosarcoma cells employ robust regulatory mechanisms governing iron detoxification and antioxidant defense, potentially influencing tumor immunity. Furthermore, our ongoing studies are investigating the mechanistic role of the GPX4-ARNT-FTH1 axis in immunomodulatory processes in osteosarcomas. This work will also seek to identify a conserved cross-species mechanism that regulates the interplay between iron metabolism and tumor immunity, enabling translational models using naturally occurring canine osteosarcoma.

#5678 Cuproptosis induction in TP53-mutated acute myeloid leukemia.

Yuju An, Xinghan Zeng, Brandy Perkins, Nour S. Naji, Yanyan Wang, Booseong Seo, Yashvi Hemani, Frederick Bunz, Theodoros Karantanos

Johns Hopkins University, Baltimore, MD

Patients with acute myeloid leukemia (AML) carrying *TP53* loss-of-function mutations exhibit extremely poor outcomes, partly due to intrinsic resistance to current treatments such as intensive chemotherapy and venetoclax-based regimens that depend on p53-mediated apoptosis. Developing therapeutic strategies capable of bypassing defective apoptotic pathways and eliminating *TP53*-deficient AML remains a critical need. Copper ionophores, including elesclomol—a compound previously evaluated in clinical trials—and its next-generation analog UM4118, trigger a mitochondria-dependent, nonapoptotic mode of copper-regulated cell death known as cuproptosis. Here, we demonstrate that inducing cuproptosis through these agents effectively targets AML cells in a p53-independent manner.Analysis of the BEAT AML 2.0 dataset revealed that the copper ionophore elesclomol exhibits the strongest anti-leukemic activity in *TP53*-mutated AML cells compared with *TP53* wild-type counterparts. Based on this observation, we hypothesized that cuproptosis induction could suppress AML cell growth and survival independent of p53 status. To test this, *TP53* was disrupted via CRISPR-Cas9 gene editing in 3 *TP53* wild-type human AML cell lines (MOLM13, MV4-11, and UKE-1) to generate isogenic *TP53* knockout derivatives, along with UKE-1 clones harboring heterozygous and homozygous *TP53* R273H mutations. Short-term viability and growth assays demonstrated a marked, dose-dependent reduction in viability 72 hours after treatment with copper ionophores, with comparable sensitivity across *TP53* wild-type, *TP53*-KO, and *TP53*-deficient (TF-1 and F36P) AML cells. In contrast, cytarabine, idarubicin, and venetoclax activity was substantially diminished in *TP53*-deficient cells, consistent with the known resistance of *TP53*-mutated AML to these standard therapies. Notably, combining low-dose elesclomol with the hypomethylating agent decitabine, which has established clinical efficacy in TP53-mutated AML, produced a synergistic increase in apoptosis in *TP53*-deficient AML cells.Together, these findings demonstrate that copper ionophores can bypass *TP53*-associated resistance to AML cell death by activating cuproptosis rather than relying on p53-dependent apoptotic pathways. The robust activity of copper ionophores across diverse *TP53*-deficient AML models, coupled with the enhanced efficacy observed in combination with decitabine, underscores cuproptosis induction as a promising therapeutic approach for *TP53*-deficient AML.

#5679 LIFR inhibition with EC359 triggers ferroptosis to overcome chemoresistance in endometrial cancer.

Emily Jean Aller[1], Baskaran Subramani[1], Xue Yang[1], Paulina Ramirez[1], Bindu Santhamma[2], Hareesh B. Nair[3], Edward Kost[1], Ratna K. Vadlamudi[1], **Suryavathi Viswanadhapalli**[1]

[1]UTHSA, San Antonio, TX,[2]Evestra, San Antonio, TX,[3]Texas Tech University Health Science Center, El Paso, TX

Background: Endometrial cancer (ECa), the most common malignancy of the female reproductive tract, has rising incidence and mortality, highlighting the need for better treatments. Targeting leukemia inhibitory factor receptor (LIFR) with EC359 shows promise by reducing viability and invasion in both Type I and II ECa. Since LIFR signaling is linked to ferroptosis, an iron-dependent cell death, this study explores whether EC359 induces ferroptosis and enhances chemotherapy, offering a novel therapeutic strategy for advanced ECa.
Methods: Chemotherapy-resistant ECa cell lines were established through prolonged exposure to chemotherapeutic agents and validated by RNA sequencing to confirm resistance-associated transcriptional profiles. The antitumor effects of EC359 were assessed in multiple established and patient-derived primary ECa cell models through colony formation assays, MTT-based cell viability assays, and apoptosis analysis. Mechanistic studies were conducted using Western blotting, RT-qPCR, transmission electron microscopy (TEM), and flow cytometry to evaluate ferroptosis-related markers and cellular changes. For preclinical validation, patient-derived organoids (PDO) and xenograft (PDX) models of ECa were employed to determine the therapeutic efficacy of EC359 in combination *in vivo*.
Results: RNA-seq analysis of taxol-resistant ECa cells revealed upregulation of pathways associated with cell proliferation, stemness, and LIFR signaling, along with downregulation of apoptotic pathways. EC359 significantly reduced cell viability in taxol-resistant advanced ECa models. Notably, the cytotoxic effect of EC359 was markedly attenuated when ferroptosis was pharmacologically inhibited using Ferrostatin-1, indicating that ferroptosis is a key mechanism of EC359-induced cell death. Mechanistic studies demonstrated that EC359 suppresses the glutathione antioxidant defense system, thereby promoting ferroptosis. Consistent with this, supplementation with extracellular cystine restored cell viability following EC359 treatment. Moreover, EC359 markedly reduced the expression of key anti-ferroptosis proteins. Flow cytometry confirmed increased lipid peroxidation in EC359-treated cells, while TEM studies revealed characteristic mitochondrial damage associated with ferroptosis. Importantly, EC359 combined with chemotherapy significantly decreased the viability of PDOs and robustly inhibited tumor progression in PDX models of advanced ECa.
Conclusion: Our studies suggest that EC359 induces ferroptosis by disrupting antioxidant defenses and synergizes with chemotherapy and that EC359 serve as a promising strategy to overcome chemoresistance in advanced ECa.

#5680 Hinokitiol targets metal and redox vulnerabilities in liver cancer.

Daniela Delgado[1], Anyssa Rodriguez[2], Subhash C. Chauhan[3], Nirakar Sahoo[1]

[1]School of Integrative Biological and Chemical Sciences, University of Texas Rio Grande Valley, Edinburg, TX,[2]University of Texas Rio Grande Valley, Edinburg, TX,[3]South Texas Center of Excellence in Cancer Research, University of Texas Rio Grande Valley, Edinburg, TX

Hepatocellular carcinoma (HCC) represents one of the most fatal forms of liver cancer, which accounts for most liver cancer deaths worldwide. The current medical treatments offer limited efficacy, especially in advanced stages, so there is a clear need for alternative therapeutic strategies. In recent years, natural compounds have gained attention as options for difficult-to-treat cancers. Hinokitiol (β-thujaplicin) is one such compound. Studies have shown that Hinokitiol possesses anti-cancer properties; interestingly, this compound is also known to bind and mobilize iron. However, the link between iron-mobilizing ability and the type of stress response or cell death pathway it activates in HCC cells remains unclear. Since HCC cells inherently carry more iron, how hinokitol interacts with iron-rich environments and what specific pathway it activates in HCC cells still needs to be elucidated. We used the liver cancer cell SK-HEP1 to characterize the effect of hinokitol. We assessed the cell responses through Western blotting, RT PCR, immunocytochemistry, and live-cell imaging to measure cell viability, lysosome activity, mitochondrial integrity, autophagy, and oxidative stress. Our results showed that the Hinokitiol markedly suppressed liver cancer growth in a time and dose-dependent manner with an IC_{50} ~5 μM at 96 hours; and concentrations at or above this level almost abolished clonogenic growth. At doses near IC_{50}, Hinokitiol enhanced autophagy and stress-related gene expression by roughly 2-4 fold. Western blot analysis also confirmed an increase in LC3 lipidation and lysosome markers, suggesting that Hinokitiol engages the autophagy-lysosome system rather than simple growth arrest. At the same concentrations, Hinokitiol induced the stress-response gene CHAC1 and decreased ferritin protein levels. The live-cell imaging results demonstrated that Hinokitiol treatment caused an increase in lipid peroxidation and expanded labile Fe^{2+} pool sizes in cells compared to control cells. The combined induction of CHAC1, loss of ferritin, and increased lipid damage suggest that Hinokitiol produces iron mediated oxidative stress. Taken together, these findings suggest that Hinokitiol causes cell death through an iron and lipid oxidation-driven mechanism that is independent of apoptosis and necroptosis, and is compatible with a ferroptosis-like form of cell death. By mobilizing excess intracellular iron, Hinokitiol activates ferroptosis-related pathways and takes advantage of iron and redox weaknesses in HCC cells, supporting its potential as a therapeutic agent.

#5681 Mechanism of mitochondria-independent cuproptosis.

Martin Mistrik[1], Martin Loffelmann[1], Petr Dzubak[1], Marian Hajduch[1], Josef Srovnal[1], Zdenek Skrott[1], Lucie Beresova[1], Tomas Pluhacek[2], Petr Tarkowski[2]

[1]Lekarska fakulta UP Olomouc, Olomouc, Czech Republic,[2]Univerzita Palackeho v Olomouci, Olomouc, Czech Republic

Copper is an essential trace element that functions as a cofactor for numerous metabolic and detoxification enzymes. In excess, however, copper exerts marked cytotoxicity in cancer cells and can induce a recently characterized form of regulated cell death termed *cuproptosis*. Currently, cuproptosis is believed to depend on mitochondrial activity, involving the reduction of bivalent copper ions to monovalent, leading to subsequent toxic effects via the oligomerization of lipoylated DLAT (dihydrolipoyl transacetylase) and the loss of iron-sulfur cluster proteins. Here, we evaluated several copper ionophores in their copper-complexed forms, including bis(diethyldithiocarbamate) (CuET), pyrithione, NSC319726, and 8-hydroxyquinoline, to assess their ability to induce cuproptosis. Surprisingly, their cytotoxic effects were comparable in oxidative-phosphorylation-dependent cancer cells and in glycolysis-driven counterparts. Consistently, neither chemical inhibition of individual mitochondrial complexes nor the use of mitochondrial DNA-deficient Rho0 cells revealed differential sensitivity. Instead, all tested ionophores induced aggregation and immobilization of the essential p97 cofactor NPL4, mirroring the mechanism previously reported for CuET. NPL4 dysfunction disrupts the p97/proteasome axis, and its aggregation strongly correlates with cytotoxic outcomes. Ionophore treatment also triggered canonical proteotoxic stress pathways, including the unfolded protein response, the heat-shock response, and accumulation of polyubiquitinated proteins. Importantly, additional treatment with the non-toxic, more potent divalent copper chelator, dibenzyldithiocarbamate, reversed NPL4 aggregation and ionophore-induced cytotoxicity. Together, these findings refine the mechanistic framework of copper-dependent cell killing by revealing a prominent proteotoxic component of bivalent copper associated with targeting the NPL4. This insight strengthens the rationale for targeting copper-regulated proteostasis pathways as a potential anticancer strategy.

#5682 Elucidating and overcoming therapeutic resistance in esophageal adenocarcinoma.

Naren Li[1], Jessica Ji[2], Jaylon C. Aggison[1], Siqi Wu[1], Francisco A. Molina-Pelayo[1], Cristian G. Medina[1], Ritika Raj[1], Yuan Xu[1], Robert T. Ripley[1]

[1]Baylor College of Medicine, Houston, TX,[2]Rice University, Houston, TX

Background: Esophageal adenocarcinoma (EAC) accounts for over 80% of esophageal cancers in the United States and remains a highly lethal malignancy with poor prognosis and rising incidence. Despite advances in therapy, recurrence occurs in most EAC patients, largely due to the emergence of therapeutic resistance. Resistance can be intrinsic or acquired from a rare subpopulation known as Drug Tolerant Persister (DTP) cells, which survive cytotoxic therapy through non-genetic adaptive mechanisms. Unlike genetic resistance, the drug-tolerant state is reversible upon drug withdrawal. This study aims to establish cisplatin-derived DTP(CDDP-DTP) and drug-resistant (CDDP-DR) EAC cell models to elucidate resistance mechanisms, identify therapeutic vulnerabilities, and develop strategies to overcome resistance and prevent recurrence in EAC.

Methods: CDDP-DTP cells were generated by exposing EAC cells to the IC_{80} of CDDP for four days, while CDDP-DR cells were developed via stepwise dose escalation based on the IC_{50}. Cytotoxic effects of compounds targeting ferroptosis, pyroptosis, and epigenetic regulation (RSL3, DMB, BIX-01294, and GSK3326595) were evaluated by MTS assays in four EAC cells (FLO-1, OE19, OE33, SK-GT-4). Drug synergy was analyzed using the Combenefit tool. BH3 profiling was performed to assess mitochondrial apoptotic priming and anti-apoptotic dependency. Seahorse assay was used to evaluate cellular metabolism. Cell cycle distribution and cell death were analyzed by propidium iodide (PI) and annexin V/PI staining. Gene and protein expression were measured by quantitative real-time polymerase chain reaction (RT-qPCR) and western blot.

Results: CDDP-DTP EAC cells exhibited reduced proliferation and upregulation of canonical DTP markers, while CDDP-DR cells displayed >2-fold increased resistance to CDDP, elevated ATF4 expression, an epithelial-to-mesenchymal transition (EMT) phenotype, and resistance to apoptosis accompanied by metabolic reprogramming. Among compounds targeting non-apoptotic, non-genetic adaptive mechanisms, RSL3, DMB and BIX-01294 effectively suppressed EAC cell growth compared with GSK3326595. Notably, BIX-01294 combined with CDDP and DMB combined with a Bcl-xL inhibitor exhibited synergistic cytotoxicity in EAC cells. The target proteins of these compounds—GPX4, GSDMD, and G9A—were upregulated in both TCGA datasets and EAC cells, further highlighting their potential roles as mediators of therapeutic resistance and as promising therapeutic targets.

Conclusions: This study successfully established CDDP-DTP and CDDP-DR models of EAC and revealed that targeting non-apoptotic, adaptive mechanisms can enhance therapeutic response. These findings lay the foundation for multi-omic characterization of resistant EAC populations and support exploration of non-apoptotic vulnerabilities to undermine recurrence and improve long-term outcomes in EAC.

: Mechanisms of Anticancer Drug Action
Poster Session

#5685 Mitotic error-tolerant survival following WRN inhibition is overcome by sustained spindle checkpoint activation.

Sungmin Cho[1], Joong-Bae Ahn[2], Sang Joon Shin[2]

[1]Yonsei University College of Medicine, Seoul, Korea, Republic of,[2]Division of Medical Oncology, Department of Internal Medicine, Yonsei Cancer Center, Seoul, Korea, Republic of

Background: Microsatellite instability-high (MSI-H) cancers are known to depend on the Werner (WRN) helicase, which resolves repetitive TA sequences. Recently, a selective WRN inhibitor, HRO-761, has shown to be highly effective in MSI-H cells, validating WRN as a promising therapeutic target. However, the cellular mechanisms by which WRN inhibition fails to completely eliminate tumor cells remain unclear. In this study, we uncovered a mitotic survival pathway activated upon WRN inhibition and propose a drug combination strategy with Vinblastine to suppress it.
Method: To examine the cellular state following WRN inhibition, we performed confocal microscopy after durg treatment and confirmed spindle assembly checkpoint (SAC) activation by Western blot. Drug sensitivity profiles were analyzed using GDSC2, and OmicsExpression and CRISPRGeneEffect from DepMap (25Q2) were analyzed. Combination effects were assessed using CCK-8 and colony formation assays in MSI-H colorectal cancer cell lines (HCT-116, LOVO, SNU-C2B).
Results: WRN inhibition in MSI-H colorectal cancer cells induced robust cell-cycle arrest and activated SAC, as evidenced by increased MAD2 re-localization (IF) and accumulation of Cyclin B1 and Securin (WB). Despite the initial SAC activation, we also observed subsequent SAC deactivation accompanied by abnormal morphological changes characteristic of mitotic error. These cells continued to survive while bearing persistent mitotic errors, representing an error-tolerant survival phenotype following WRN inhibition.
Transcriptomic analyses revealed that genes involved in kinetochore-microtubule attachment were significantly downregulated after WRN inhibition (NES < -2, adjusted $P < 0.05$). Using whole cell line expression and CRISPR Gene Effect data, we found that cells with reduced kinetochore gene expression exhibited increased dependency on α-tubulin and β-tubulin ($P < 0.05$), suggesting a complementary and potentially synthetic-lethal relationship between WRN loss and microtubule function.
We combined WRN inhibition with Vinblastine, a microtubule-targeting agent(MTA) known to prolong SAC activation, and observed reduced cell viability in CCK-8 and colony-formation assays. In HCT-116 cells, co-treatment with HRO-761 and Vinblastine (0.1 nM) decreased the IC_{50} from 1.058μM to 0.382 μM, demonstrating a clear synergistic effect of the combination.
Conclusion: Based on our findings, we identified a previously unrecognized mitotic error-tolerant survival pathway induced by WRN inhibition. We further demonstrated that Vinblastine, by sustaining spindle checkpoint activation, synergized with WRN inhibition to reduce cell viability and suppress escape mechanism. These results suggest that combining MTA with WRN inhibitors represents a promising therapeutic strategy in MSI-H cancers.

#5686 SF3B1 inhibition suppresses prostate cancer by disrupting ATRX splicing and inducing cell cycle arrest.

Linyue Li[1], Weijian Ding[1], Zhihao Nie[1], Congrong Jiang[2], Ruining Zhao[2], Siyuan Xia[1], **Baotong Zhang**[1]

[1]Southern University of Science and Technology, Shenzhen, China,[2]Department of urology, People's Hospital of Ningxia Hui Autonomous Region, The Third Clinical Medical College of Ningxia Medical University, Yinchuan, China

Prostate cancer is the most common malignancy in men in the United States, and dysregulated RNA splicing has emerged as a critical driver of prostate cancer progression. Although alternative splicing pathway genes are mutated in approximately 4% of prostate cancers, mutations in the core splicing factor SF3B1 represent a disproportionately high fraction (27.5%). However, whether and how SF3B1 inhibition suppresses prostate cancer progression remains unclear. Here, we demonstrate that the SF3B1 inhibitor Pladienolide B exerts robust antitumor activity in prostate cancer cell lines, cell-derived xenografts, and patient-derived xenografts. RNA-seq analysis revealed widespread splicing alterations enriched in pathways regulating cell-cycle arrest, which we validated using flow cytometry and live-cell imaging. Following double-thymidine synchronization, Pladienolide B-treated DU145 cells exhibited a markedly prolonged S phase, indicating that SF3B1 inhibition suppresses tumor growth primarily by inducing cell-cycle arrest. To elucidate the molecular basis of this arrest, we examined individual splicing changes and identified a key event in ATRX, which retained a 74-bp cryptic exon before exon 25 upon Pladienolide B treatment. This aberrant splicing disrupted the ATRX-MeCP2 interaction required for maintaining genome stability through repression of R-loop accumulation in heterochromatin. Interestingly, we further identified CDK12 as a previously unrecognized upstream kinase of SF3B1. CDK12 physically interacted with SF3B1, and its inhibition by THZ531 reduced SF3B1 phosphorylation at T313, induced cell-cycle arrest, and suppressed tumor growth. Given the therapeutic potential of SF3B1 inhibition, we evaluated combinatorial strategies with current prostate cancer treatments. Inhibition of SF3B1 activity by THZ531 or Pladienolide B conferred resistance to docetaxel, a first-line therapy for metastatic disease. Notably, Pladienolide B exhibited synergistic antitumor effects when combined with the PARP inhibitor olaparib. Collectively, our findings reveal how SF3B1 inhibition impairs prostate cancer progression through RNA splicing dysregulation, and they provide a rationale for integrating SF3B1-targeted therapies into prostate cancer treatment.

#5687 Targeting KIFC1 induces anaphase catastrophe in small cell lung cancer.

Minemichi Toda[1], Natsuki Nakagawa[1], Masakatsu Tokunaga[1], Mirei Ka[2], Takahiro Iida[3], Hiroaki Ikushima[1], Takahiro Ando[1], Akiko Kunita[4], Kousuke Watanabe[4], Xi Liu[5], Ethan Dmitrovsky[5], Hidenori Kage[1], Masanori Kawakami[1]

[1]Departments of Respiratory Medicine, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan,[2]Division of Integrative Genomics, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan,[3]Thoracic Surgery, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan,[4]Next-Generation Precision Medicine Development Laboratory, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan,[5]Frederick National Laboratory for Cancer Research, Frederick, MD

Cancer cells often possess more than two centrosomes, which is one of the hallmarks of cancer. By clustering these supernumerary centrosomes during mitosis, cancer cells can achieve bipolar division. We previously reported that in non-small cell lung cancer, CDK2 inhibition suppresses centrosome clustering, leading to multipolar cell division and apoptotic cell death—a phenomenon termed anaphase catastrophe. Because normal cells have only two centrosomes, anaphase catastrophe does not appreciably affect them, making it a promising therapeutic strategy for selectively eliminating cancer cells. However, as CDK2 inhibition also interferes with normal cell cycle progression, identifying therapeutic targets that can induce anaphase catastrophe preferentially is desirable. Motor protein KIFC1 has been implicated in centrosome clustering. Here, we investigated its potential as a novel therapeutic target to induce anaphase catastrophe in small cell lung cancer (SCLC). Owing to p53 inactivation, SCLC is expected to frequently harbor supernumerary centrosomes and be vulnerable to mitotic abnormalities, including anaphase catastrophe. First, in vitro experiments using multiple SCLC cell lines were conducted. Immunofluorescence staining for pericentrin confirmed that centrosome amplification occurs more frequently in SCLC cells than in normal human bronchial epithelial (NHBE) cells. Western blotting revealed that KIFC1 was overexpressed in SCLC cells as compared with NHBE cells. Functional analyses, both pharmacologic (using a specific inhibitor) and genetic (using siRNAs and the CRISPR-Cas9 system), demonstrated that inhibition of KIFC1 induced apoptosis and suppressed proliferation in SCLC cell lines, whereas these effects were largely absent in NHBE cells. Furthermore, immunostaining for α-tubulin, pericentrin, and DAPI showed a statistically significant increase in multipolar mitotic cells and a decrease in cells with clustered supernumerary centrosomes among dividing cells, implicating KIFC1 inhibition in conferring anaphase catastrophe in SCLC. These findings were validated and extended in the in vivo setting. In human SCLC cell-derived xenograft models, administration of KIFC1 inhibitor statistically significantly suppressed tumor growth. Staining of excised tumors for pericentrin revealed reduced numbers of cells with clustered supernumerary centrosomes and increased numbers undergoing multipolar mitosis, consistent with in vitro findings and indicative of anaphase catastrophe induction. Finally, potential combination therapies with other pharmacologic targets were explored and will be presented. In conclusion, inhibition of KIFC1 disrupts the clustering of supernumerary centrosomes and caused anaphase catastrophe, indicating its promise as a novel therapeutic target for SCLC.

#5688 Synthetic lethal targeting of TRIP13 and Aurora A induces mitotic DNA damage and concurrent pyroptotic-apoptotic cell death in Rb-deficient cancer cells.

Lacin Yapindi[1], Soma Ghosh[1], Li Shen[2], Lixia Diao[2], Jing Wang[2], Faye M. Johnson[1]

[1]Department of Thoracic/Head & Neck Medical Oncology, UT MD Anderson Cancer Center, Houston, TX,[2]Department of Bioinformatics and Computational Biology, UT MD Anderson Cancer Center, Houston, TX

There are currently no effective, biomarker-guided therapies specifically targeting cancers with functional loss of the Rb pathway, underscoring the urgent need to exploit their unique vulnerabilities. We previously demonstrated that combined inhibition of TRIP13 and Aurora A elicits a synthetic lethal effect specifically in Rb-deficient cancer cells. To dissect the underlying mechanism of this synthetic lethality, we employed live-cell imaging to monitor single-cell dynamics and found that the combination induces mitotic cell death by inducing prolonged mitotic arrest. These findings were validated using the orthogonal *in vitro* assays assessing apoptosis and cell cycle, which further revealed that the combination leads to DNA damage and concurrent apoptotic and GSDME-mediated pyroptotic cell death in mitotically arrested Rb-deficient cancer cells. The inhibition of mitotic entry using CDK1 inhibitor, RO-3306 abrogated these combination-induced lethal effects, further confirming the essential role of mitotic catastrophe in mediating this synthetic lethality. These *in vitro* findings were strengthened *in vivo*, as the combination of TRIP13 depletion and Aurora A inhibition achieved marked antitumor efficacy and provided a measurable survival benefit in Rb-deficient cell line xenograft model. TCGA analyses of head and neck and lung squamous cell carcinoma cohorts showed that Rb-deficient tumors have significantly higher *CASP3* expression but lower *GSDME* expression than Rb-proficient tumors. This suggests that Rb-deficient tumors may possess an inherent tendency toward stress-induced caspase-3 activation due to elevated baseline *CASP3* levels. The concurrent reduction of *GSDME* expression may therefore reflect an adaptive strategy to mitigate this potential vulnerability by limiting downstream caspase-3-mediated pyroptotic cell death. Here we report for the first time a detailed mechanism behind the synthetic lethal vulnerability of Rb-deficient cancer cells to dual inhibition of TRIP13 and Aurora A. This combination therapy offers new therapeutic avenues for Rb-deficient cancers and provides a rationale for exploiting mitotic vulnerabilities of Rb-deficient cancers.

#5689 Flow-cytometric analysis of cell-cycle arrest and apoptosis induced by a novel benzopyran derivative (SK6) in MCF-7 breast cancer cells.

Mariappan Gurusamy[1], Razia Shaika[2], Brijesh Sharma[2]

[1]Dept of Pharm Chemistry, St Mary's College of Pharmacy, Secunderabad, Telangana, India,[2]Dept of Pharm Chemistry, School of Pharmacy, Institute of Biomedical Education and Research, Mangalayatan University, (U.P.), India, Aligarh, India

Introduction: Breast cancer remains a major global health challenge, accounting for 2.3 million new cases and nearly 670,000 deaths in 2022. The limitations of current therapies, including drug resistance, toxicity, and reduced efficacy, highlight the urgent need for novel anticancer agents.

Purpose of the Study: The aim of this study was to evaluate the anticancer potential of a novel benzopyran derivative (SK6) using flow-cytometric analysis. After identifying SK6 as the most potent compound through MTT assay, its mechanism of action was investigated in MCF-7 cells. Flow cytometry was employed to assess SK6-induced apoptosis using Annexin-V/PI staining. Additionally, PI-based DNA content analysis was performed to determine the compound's effect on cell-cycle progression.

Experimental Methods: In continuation our research on synthesis of benzopyran derivatives, 5 molecules were synthesized and characterized using UV, IR, ^{1}HNMR, and mass spectrometry. Their cytotoxicity was evaluated against MCF-7 cells using the MTT assay. Consequently, SK6 was selected for mechanistic investigation. Flow cytometry (Beckman Coulter Gallios analyser, USA) was employed to assess its effects on the cell cycle and apoptosis in treated MCF-7 cells.

Results: All five benzopyran derivatives were successfully synthesized and structurally confirmed using spectral analyses. Among them, SK6 showed the lowest IC_{50} value i.e. 20.99µg/ml in the MTT assay, demonstrating the strongest antiproliferative activity against MCF-7 cells. Flow-cytometric Annexin-V FITC/PI analysis revealed that SK6 treatment induced a measurable apoptotic response in MCF-7 cells. Annexin-V FITC/PI staining revealed that SK6 induced a measurable apoptotic response. Quadrant analysis showed 78.44% viable cells, 8.40% in early apoptosis, 8.15% in late apoptosis, and 5.01% necrotic. Overall, SK6 induced 16.55% total apoptosis, confirming its ability to activate programmed cell death in MCF-7 cells. The SK6 compound caused a marked alteration in the cell-cycle profile, producing a dominant S-phase arrest. Treated cells showed a substantial increase in the S-phase population (54.33% vs. 13.05% in control) with a drastic reduction in G0/G1 cells (1.02% vs. 62.91%). A moderate rise in G2/M cells and minimal sub-G1 events indicate primarily cytostatic rather than DNA-fragmenting effects. These findings suggest that SK6 disrupts DNA replication and halts progression at the S-phase checkpoint.

Conclusion: SK6 demonstrated potent cytotoxic activity against MCF-7 cells and caused a pronounced S-phase arrest, indicating disruption of DNA replication. This was accompanied by a moderate induction of apoptosis, supporting its antiproliferative effect. Finally, these results highlight SK6 as a promising lead candidate for further development as a selective and effective therapeutic agent against breast cancer

#5690 Mechanisms of efficacy of endonuclease FEN1 inhibition in neuroblastoma.

Carla S. Sampaio[1], Eric Wu[2], Madison Cinelli[1], Erica Steen[1], Andrew Shiau[3], Richard Kolodner[4], Jean Wang[4], **Peter E. Zage**[5]

[1]Pediatrics, UCSD/Moores Cancer Center, San Diego, CA,[2]Cellular and Molecular Medicine, UCSD, San Diego, CA,[3]Cell and Developmental Biology, UCSD, San Diego, CA,[4]Cellular and Molecular Medecine, UCSD, San Diego, CA,[5]UCSD, San Diego, CA

Background: Children with high-risk and relapsed neuroblastoma (NB) need improved therapies, and recurrent cytogenetic abnormalities, such as MYCN oncogene amplification, represent candidate therapeutic targets. MYCN amplification and increased MYCN expression drive deregulated hyper-transcription that leads to development and growth of NB tumors, and MYCN amplifications, which can be found both within the linear genome (HSR) and on circular extrachromosomal DNA (ecDNA), are associated with significantly worse survival rates for children with NB. MYCN overexpression has been linked to an increase in replication stress (RS), and RS and subsequent genome instability are important drivers of tumor initiation and progression. Flap Endonuclease 1 (FEN1), a non-essential DNA replication enzyme, was identified as a synthetic lethal target in BRCA1/2-deficient cancers via induction of RS. Recent success of targeting RS-elevated cancers with replication enzyme inhibitors opens a new avenue to target MYCN-amplified NB.
Methods: The efficacy of FEN1 inhibition was assessed using live cell imaging and cell viability assays, comparing results in MYCN-amplified to -nonamplified NB cells and in NB cells with inducible MYCN expression and repression. Mechanisms of cell death and impacts on replication stress in cells treated with FEN1 inhibitors were evaluated by Western blots.
Results: FEN1 inhibition was effective against NB cells and was significantly more effective in MYCN-amplified NB cells causing reduced cell growth and viability. Increased MYCN expression also led to increased sensitivity to FEN1 inhibition, and reduced MYCN expression reduced sensitivity. FEN1 inhibition led to the induction of apoptosis and responses to FEN1 inhibition were associated with markers of replication stress.
Conclusions: We have discovered that MYCN-amplified NB cells are hypersensitive to FEN1 inhibition, suggesting that FEN1 inhibition may be a promising therapeutic strategy for children with high-risk and relapsed neuroblastoma.

#5691 Per and polyfluoroalkyl substances (PFAS) promote proliferation and migration in genetically distinct kidney cancer cell lines.

Rakesh Kumar Arya[1], Mia Sand[2], Sahab Ram Dewala[1], Can Aydogdu[3], Gabriela M. Diaz[3], Christopher Weight[3], Riccardo Autorino[3], Abhishek Chakraborty[4], Jacob M. Knorr[3], Joseph M. K. Irudayaraj[2], Laura Bukavina[3]

[1]Center for Immunotherapy and Precision Immuno-oncology, Cleveland Clinic Lerner Research Institute, Cleveland, OH,[2]Department of Bioengineering,, University of Illinois Urbana-Champaign, Champaign, IL,[3]Glickman Urological and Kidney Institute, Cleveland Clinic, Cleveland, OH,[4]Department of Cancer Biology, Cleveland Clinic Research, Cleveland, OH

Introduction and Objectives: Per- and polyfluoroalkyl substances (PFAS) such as GenX, PFOA, and PFOS are persistent environmental pollutants increasingly associated with renal carcinogenesis. Their direct effects on kidney cancer progression remain unclear. This study investigated whether PFAS exposure enhances proliferation and migration in two genetically distinct kidney cancer models-human RCC-ER (VHL-mutant) and murine Renca (VHL-wild type).

Methods: RCC-ER and Renca cells were treated with GenX, PFOA, or PFOS at physiologically relevant concentrations (0.5-40 nM). Proliferation was monitored over 72 h using the IncuCyte S3 system. Migration was assessed in ImageLock plates, where wounds were created after 24 h and imaged every 1.5 h for 72 h. Wound closure was quantified by percentage wound closure (WC) and relative wound density (RWD) using IncuCyte software. All experiments were performed in triplicate to assess dose dependency and statistical significance.

Results: PFAS exposure significantly enhanced both proliferation and migration in kidney cancer cells, with compound- and cell line-specific variations. RenCa cells exhibited strong proliferative responses to GenX and PFOS from 0.5-20 nM, peaking at 5 nM respectively, while PFOA showed cytotoxic effects at these doses. In contrast, RCC-ER cells demonstrated increased proliferation in response to PFOA (max at 40 nM) and PFOS (max at 5 nM), whereas GenX had minimal effect on proliferation at low doses. All three PFAS markedly accelerated wound closure and relative wound density in both cell lines, indicating enhanced migratory potential. Collectively, these data reveal that PFAS compounds augment pro-oncogenic behaviors across human and murine kidney cancer models.

Conclusion: PFAS compounds promote proliferative and migratory phenotypes in both murine and human kidney cancer models through distinct but convergent metabolic mechanisms. The conserved effects across VHL-wild-type and VHL-mutant systems underscore PFAS as a potential environmental accelerator of renal tumor progression and justify further mechanistic and translational studies.

#5692 Mechanism of antiproliferative activity of tolfenamic acid.

Fatima Rehman[1], Hesham Syed[2], Umesh T. Sankpal[1]

[1]University of North Texas Health Science Center, Fort Worth, TX,[2]University of Texas at Austin, Austin, TX

Non-steroidal anti-inflammatory drugs have been shown to exhibit anti-tumor activities primarily through the inhibition of cyclooxygenases (COX-2). Among them, tolfenamic acid (TA) has also demonstrated potent anti-cancer effects across multiple cancer cell lines but acts through COX independent pathways. The proposed mechanism of action of TA involves its ability to target specificity protein transcription factors (Sp1, Sp3, and Sp4) which in turn downregulate potential oncogenic proteins such as survivin, VEGF, and c-MET. Recent work from our laboratory demonstrated, in medulloblastoma cells, the ability of TA to induce DNA double-strand breaks (DSBs). In this study we investigated the DNA damaging effects of TA across multiple cancer cell lines (including neuroblastoma, ovarian, breast, pancreatic, and prostate) and examined the activation of the DNA damage response pathways. Cell lines representing various cancers were treated with increasing concentration of TA for 48h and DNA damage assessed by monitoring phosphorylation of histone variant H2AX (γH2AX) by Western blot analysis. Activation of the DSB response following TA treatment, in a medulloblastoma cell line was investigated by examining the activation of ATM / ATR and Chk1 / Chk2 by Western blotting. Apoptosis was detected by cleavage of PARP-1 protein. Consistent with our findings in medulloblastoma, we observed a dose dependent increase in γH2AX, following TA treatment for 48h, in all cancer cell lines tested. Levels of cleaved PARP also increased with TA treatment in all cell lines. Furthermore, in medulloblastoma cells, γH2AX was detected as early as 24h post-treatment. We also demonstrated a dose dependent increase in phosphorylation of ATM and Chk2 proteins. Taken together, these results suggest that TA treatment induces DNA DSBs in cancer cells resulting in the activation of ATM and Chk2, a major DNA damage response pathway, ultimately leading to cell death via activation of apoptosis. The results highlight TA's multi-targeted effects and the potential to develop effective combination strategies with other small molecules or drugs to achieve synergistic therapeutic outcomes.

#5693 Synergy of a CDK4/6 inhibitor and an HDAC inhibitor in pancreatic cancer overcomes autophagy.

Vikas Dukhande[1], Shraddha Bhutkar[2], Anjali Yadav[2]

[1]Pharmaceutical Sciences, St. John's University, Queens, NY,[2]St. John's University, Queens, NY

Pancreatic Ductal Adenocarcinoma (PDAC) is a malignant aggressive tumor with a poor prognosis and survival rate. Therapy resistance in PDAC is common and is attributed to metabolic plasticity, dense desmoplastic stroma, tumor heterogeneity, and immune evasion. Our previous study demonstrated synergy and efficacy of Panobinostat (Pan), a pan-HDAC inhibitor, and Abemaciclib (Abe), a CDK4/6 inhibitor, in PDAC cells. We aimed to identify the mechanism of these synergy effects as they can help in therapy efficacy and in overcoming resistance. Our mechanistic studies to understand the combination effects of Pan-Abe utilized transcriptomics and metabolomics experiments followed by Seahorse analysis. Abe treatment resulted in mitochondrial dysfunction whereas Pan treatment induced autophagy and lysosomal processes. We followed these studies using cell biological experiments assessing autophagy profile using fluorescence microscopy and western blotting. The Pan-Abe combination demonstrated metabolic dysfunction but did not induce robust autophagy response. Interestingly, the synergy of Pan-Abe from PDAC cells was confirmed in MIA PaCa-2 tumor xenograft model. Further studies are needed to understand the role of autophagic processes in the efficacy of Pan-Abe in PDAC.

#5694 SQLE inhibitor triggers ovarian cancer apoptosis by causing ER stress.

Cheng Chi[1], Lei Sun[2], Mahmuda Akter[1], Shuang Huang[1]

[1]University of Florida, Gainesville, FL,[2]University of Florida College of Medicine, Gainesville, FL

High-grade serous ovarian cancer (HGSOC) remains highly lethal due to late diagnosis and the high frequency of chemoresistance, underscoring the need to identify new metabolic vulnerabilities that can be therapeutically targeted. This study investigates the mechanism through which inhibition of squalene epoxidase (SQLE), a rate-limiting enzyme that converts squalene to 2,3-epoxysqualene in the cholesterol biosynthesis pathway, suppresses ovarian cancer cell growth, and evaluates the therapeutic potential of the SQLE inhibitor NB-598. Using ovarian cancer cell lines cultured under cholesterol-replete and cholesterol-depleted conditions, we performed cell growth assays, western blot analysis of ER-stress signaling pathways, and apoptosis assays. NB-598 selectively inhibited ovarian cancer cell growth under cholesterol-depleted conditions, and this effect was fully reversed by cholesterol supplementation. Notably, inhibition of upstream HMG-CoA reductase with atorvastatin abolished NB-598-induced growth suppression, suggesting that NB-598 cytotoxicity does not stem from cholesterol deprivation but instead from the accumulation of squalene. Consistently, activation of ER-stress markers and rescue by JNK and p38 inhibitors implicate ER-stress signaling in NB-598-induced toxicity. Apoptosis was confirmed by cell-cycle analysis, Annexin V/PI staining, and western blotting, demonstrating increased sub-G1 populations, elevated early and late apoptotic cells, and cleavage of PARP and caspase-3 in NB-598-treated cells. Together, these findings identify squalene accumulation, rather than cholesterol depletion, as the primary driver of NB-598-induced cytotoxicity in ovarian cancer cells. This work establishes SQLE as a mechanistically defined metabolic target in ovarian cancer and provides a strong rationale for developing SQLE inhibitors as a novel therapeutic strategy.

#5695 CyTOF analysis of targeted therapy in addition to standard of care against Ewing sarcoma tumor subpopulations.

Kaitlyn H. Smith, Lucy Endean, Kimberly Q. McKinney, Poornima Gourabathini, Kenzie Wells, Jeffrey Huo, Erin M. Trovillion, Javier Oesterheld

Atrium Health Wake Forest Baptist Comprehensive Cancer Center, Charlotte, NC

Introduction: The overall survival for Ewing sarcoma (ES) is ~70% after current standard of care (SOC) chemotherapy but outcomes remain dismal for relapsed or metastatic disease. SOC involves chemotherapy using alternating cycles of Vincristine, Doxorubicin, Cyclophosphamide (VDC) with Ifosfamide and Etoposide (IE). ES tumors are increasingly being studied in the context of the EWS:FLI1 fusion. Recent work has shown that the EWS:FLI1^{high} cells are more proliferative and sensitive to chemotherapy and the EWS:FLI1^{low} cells are more invasive and less sensitive to chemotherapy. Cancer stem cells are another population known to be chemoresistant. The invasiveness and decreased sensitivity of these various populations suggest they may contribute to chemoresistance, relapse, and metastasis, representing a major clinical problem. Previous work has shown that HDAC inhibition synergizes with SOC agents due to an accumulation of DNA damage, though the effect on specific subpopulations within tumors remains unknown. The purpose of this study was to identify effects of romidepsin combined with SOC treatment on specific subpopulations of ES cells.

Methods: For *in vitro* experiments, A673 ES cells were treated with vehicle, romidepsin, IE, or romidepsin+IE for 24 hours and then stained for CyTOF analysis. For *in vivo* experiments, A673 cells were injected subcutaneously into Nude mice. Once tumors were 150-200mm^3, mice were grouped and treatment with vehicle, romidepsin, ifosfamide/etoposide (IE), or romidepsin+IE began. Romidepsin was given on days 1 and 4 and IE was given days 2-4. Tumors were harvested and dissociated on day 5 for CyTOF analysis. The CyTOF panel used was designed to assess tumor subpopulations as well as mechanistic changes.

Results: *In vivo* and *in vitro,* the combination treatment led to a significant increase in pH2AX in the bulk tumor cells, indicative of DNA damage. *In vivo,* UMAP display of phenograph clustering, and associated heatmap of expression, revealed distinct changes in expression patterns among treatment groups. In the EWS:FLI1^{high} population both IE alone and IE in combination with romidepsin led to a significant increase in pH2AX. In the EWS:FLI1^{low} population, only the combination led to a significant increase in pH2AX. Furthermore, only the combination treatment led to a significant increase in pH2AX in the cancer stem cell population.

Conclusions: We have identified that the combination of romidepsin with IE, but not IE alone, leads to an increase in DNA damage in the EWS:FLI1^{low} and cancer stem cell populations. This suggests that the addition of romidepsin to SOC may improve treatment efficacy against subpopulations of tumor cells that are known to be chemoresistant. Further, this study highlights the use of CyTOF to assess treatment effects within ES tumor subpopulations to identify therapies that may be more effective against chemoresistant populations.

#5696 RAS(ON) multi-selective inhibitors stimulate the hydrolysis of RAS-GTP to RAS-GDP and drive synergistic combination benefit with KRAS(OFF) inhibitors in G12 mutant tumors.

Hiroyuki Matsubara[1], Alec Millner[2], Yu C. Yang[2], Jun Sun[2], Stephanie Change[2], Shelby L. Steele[2], Marini Thian[2], Miguel Sandoval[2], Zhican Wang[2], Mike Flagella[2], Mallika Singh[2], Jingjing Jiang[2], Jacqueline A. M. Smith[2], Ryan B. Corcoran[1], **Kyle J. Seamon**[2]

[1]Massachusetts General Hospital, Boston, MA,[2]Revolution Medicines, Redwood City, CA

KRAS mutations are among the most common oncogenic drivers across human cancers. Although RAS was long considered undruggable, recent advances have led to multiple classes of direct RAS inhibitors. KRAS(OFF) inhibitors preferentially target the inactive GDP-bound state whereas RAS(ON) tri-complex inhibitors selectively engage the active, GTP-bound form. In addition to suppressing RAS signaling by disrupting interactions with downstream effectors via steric occlusion, the RAS(ON) multi-selective inhibitor daraxonrasib (RMC-6236) and the preclinical tool compound RMC-7977 also activate RAS(ON) GTPase activity and promote the conversion of RAS(ON) to RAS(OFF). By stimulating formation of the inactive, GDP-bound state the RAS(ON) inhibitor enables potent target engagement by a KRAS(OFF) inhibitor and synergistic inhibition of oncogenic KRAS G12 mutant signaling. The inhibitory activity of the combination of daraxonrasib or RMC-7977 with representative mutant-selective KRAS(OFF) and pan-KRAS(OFF) inhibitors was evaluated in a series of KRAS G12 mutant cancer cell lines. In addition, real-time RAS-RAF complex disruption assays were used to monitor the kinetics of target engagement. As predicted, the RAS(ON) multi-selective inhibitors accelerated the rate of RAS-RAF disruption for KRAS(OFF) inhibitors. Consistent with this, a synergistic increase in potency of inhibition of KRAS signaling and cell viability was observed with the combinations. Synergy was dependent on the ability of the RAS(ON) inhibitors to convert RAS(ON) to RAS(OFF) and was abolished with the use of RAS(ON) inhibitors that do not stimulate GTP hydrolysis or the introduction of mutations in RAS that block GTP hydrolysis. *In vivo*, the combination of daraxonrasib and KRAS(OFF) inhibitors at well-tolerated doses drove deep and durable RAS pathway suppression and tumor regressions in various KRAS G12 mutant xenograft models, including models with reduced sensitivity to either single agent, e.g., those with mutant KRAS amplification. Overall, these preclinical findings provide a mechanistic rationale for, and experimental evidence in support of, the clinical evaluation of the combination of a RAS(ON) multi-selective inhibitor that stimulates the GTPase activity of oncogenic KRAS mutants with a KRAS(OFF) inhibitor as a potential therapeutic strategy to maximize RAS inhibition and enhance antitumor activity in RAS-addicted cancers.

#5697 EZH2 inhibition upregulates GD2 to enhance anti-GD2 immunotherapy in Ewing sarcoma.

Kenzie Wells, Kimberly Q. McKinney, Kaitlyn H. Smith, Poornima Gourabathini, Jeffrey Huo, Erin M. Trovillion, Javier Oesterheld

Atrium Health Wake Forest Baptist Comprehensive Cancer Center, Charlotte, NC

Introduction: Ewing sarcoma (ES) is a rare and aggressive malignancy of the bones and soft tissue for which substantial improvements in treatment options are desperately needed. ES cells heterogeneously express GD2, a surface marker for which there are targeted immunotherapies that are effective in other pediatric malignancies. The use of EZH2 inhibitors has been reported to increase expression of GD2 on the surface of sarcoma tumor cells. This study investigated the *in vitro* efficacy of an EZH2 inhibitor at increasing GD2 expression on ES cells with the aim of sensitizing them to anti-GD2 antibody treatment.

Methods: Both commercial and patient derived ES cell lines were treated with low dose tazemetostat for an extended period, up to 28 days, followed by a withdrawal from treatment for 7 days. GD2 expression, cell cycle, and markers of apoptosis were evaluated at regular timepoints using a novel mass cytometry panel (CyTOF). OMIQ was used for data analysis and visualization. Efficacy of naxitamab was examined using immune cell killing assays on an Incucyte S3.

Results: Tazemetostat treatment was found to increase GD2 expression on ES cells without significant impact on cell cycle or apoptosis. Elevation of GD2 expression was reversed upon withdrawal of drug. The addition of naxitamab displayed increased NK cell-mediated cell death in ES cells in response to increased GD2 expression. When pretreated with tazemetostat, GD2-low cell lines exhibit higher levels of apoptosis after treatment with naxitamab compared to untreated cells.

Conclusions: This data supports the use of the EZH2 inhibitor tazemetostat for ES tumors that express low or heterogeneous levels of GD2 to enhance the effectiveness of GD2-targeting immunotherapeutic approaches. This study demonstrates the capability of CyTOF to look at multiple markers simultaneously to achieve a comprehensive characterization of various samples.

#5698 Exploiting MYC Oncogenic Stress for Therapeutic Benefit in Lymphoma.

Smriti Kanangat, James D. Phelan, Louis Staudt

National Institutes of Health, Bethesda, MD

Diffuse Large B-cell Lymphoma (DLBCL) is the most frequently occurring form of Non-Hodgkin's Lymphoma. Gene expression profiling identified two types of DLBCL based on germinal center reaction cell-of-origin: germinal center B cell-like (GCB) or activated B cell-like (ABC) DLBCL. Though GCB patients respond better than ABC to the standard immunochemotherapy regimen, one subtype of GCB patients paradoxically exhibit the lowest response rates. These represent a clinically and genetically distinct subset of DLBCL with both MYC and BCL2 translocations and overexpression, known as 'double-hit' (DHIT)-GCB.

Recently, the ViPOR phase I/II clinical trial in relapsed/refractory DLBCL, designed to target survival pathways in ABC, demonstrated unexpectedly that DHIT-GCB had a 50% complete response (CR) rate. In vitro drug sensitivity studies revealed that venetoclax, a BCL2 inhibitor in ViPOR, is significantly more toxic in DHIT-GCB cell lines than in other BCL2 translocated GCB lines lacking MYC translocations. Thus, we hypothesized that inhibition of BCL2 renders DHIT-GCB malignant cells vulnerable to MYC-induced toxicity, explaining the selective sensitivity of DHIT-GCB lymphomas to venetoclax.

To test this, we employed the degradation tag (dTAG) system to controllably degrade MYC protein in malignant lymphoma cells. We used a knock-in approach to engineer GCB cell lines stably expressing a MYC-GFP-dTAG fusion protein from the endogenous MYC locus. BCL2 inhibition induced rapid apoptosis in these lines, but notably, concomitant degradation of MYC increased the proportion of live, non-apoptotic cells.

To investigate how MYC modulates response to BCL2 inhibition in DHIT-GCB, we performed unbiased transcriptomic and genomic profiling studies in the MYC-dTAG lines. RNA-seq of MYC degradation in a time-course in DHIT-GCB cells validated that MYC gene expression signatures were the most strongly downregulated but, interestingly, showed upregulation of signatures for B-cell differentiation and proliferation. Genome-wide CRISPR screens sorted on viable, non-apoptotic cells treated with venetoclax +/- MYC degradation demonstrated that the strongest genetic regulators of differential response to venetoclax were DNA replication and damage and cell cycle genes. These results indicated that disruption of these pathways could synergize with high MYC to promote sensitivity of DHIT-GCB cells to venetoclax.

Finally, functional assays with clinically available targeted therapies perturbing DNA damage and cell cycle highlighted how MYC levels relate to these processes in malignant B-cells and thus modulate response to BCL2 inhibition.

These studies may suggest drug combinations strategies that would harness the synergism between MYC and BCL2 in DHIT-GCB, and hopefully improve therapeutic outcomes for these DLBCL patients.

#5699 Tegavivint directly targets TBL1 to inhibit b-catenin nuclear oncogenic activity.

Aundrietta Duncan, Prashi Jain, Elena Ramirez, Julissa Simmons, Mahtab Youseffi, **Stephen Horrigan**

Iterion Therapeutics, Houston, TX

Tegavivint (BC2059) is a first-in-class small molecule that has demonstrated clinical activity in multiple cancer types including HCC and NSCLC. Tegavivint binds to TBL1 resulting in inhibition of Wnt/β-catenin oncogenic activity. To further define tegavivint's mechanism of action, we performed a series of biochemical, cell-based, and structural studies to characterize its interaction with TBL1 family members and β-catenin. TBL1, the human homologue of EBI, is a cancer driver gene and core component of the nuclear coactivator complex that regulates protooncogenic transcription factor activity. The TBL1 gene family consists of three highly conserved family members (TBL1x,TBL1xR1,TBL1Y) which are overexpressed and mutated in aggressive and invasive cancers. TBL1 deletion or silencing suppresses tumor cell growth, whereas overexpression induces invasion and EMT. Notably, TBL1 binds directly to nuclear β-catenin to form a regulatory complex on β-catenin target-gene promoters, positioning it as a critical node in Wnt/β-catenin signaling. To characterize the tegavivint-TBL1 interaction we have performed structural and functional studies using recombinant purified TBL1 proteins. TBL1 was observed to self-assemble into a functional dimer, creating the β-catenin binding site, and also spontaneously forming a larger multimeric complex of three dimers. Tegavivint binds directly to both TBL1x and TBLxR1 with nanomolar affinity. Binding of TBL1 to β-catenin was characterized, and a low nanomolar affinity binding region in β-catenin mapped within an armadillo domain. Cell-based studies across multiple cancer types confirmed tegavivint disrupts the TBL1/β-catenin transcriptional complex, selectively promotes degradation of nuclear b-catenin , and impairs β-catenin nuclear transcriptional activity. These studies also characterized the role of active WNT signaling in modulation of TBL1 function and tegavivint activity. An X-ray crystal structure of TBL1xR1 protein was resolved, enabling precise modeling of tegavivint's binding mode within the β-catenin-binding pocket of TBL1. Further structure-guided computational screens identified multiple new structurally diverse chemical series. Similar to tegavivint, these series bind directly to TBL1, disrupt the β-catenin/TBL1 interaction, inhibit β-catenin dependent transcription, and promote nuclear β-catenin degradation. These findings establish the oncogenic driver gene TBL1 as a novel, druggable target in the WNT/ β- catenin signaling pathway and highlight tegavivint as a differentiated therapeutic strategy for Wnt-driven cancers.

#5702 An image-based approach to visualize ADC internalization and cytotoxicity in patient-derived organoids.

Daniele Mori, Javier Frias Aldeguer, Rene Overmeer, Sylvia F. Boj

HUB Organoids B.V., Utrecht, Netherlands

Antibody-drug conjugates (ADCs) represent an emerging class of cancer therapies designed to address the limitations of traditional chemotherapy, particularly the toxicity that arises from healthy cells being exposed to cytotoxic agents. ADCs combine a target-specific monoclonal antibody with a cytotoxic payload, enabling selective delivery to cancer cells and significantly reducing adverse effects. HUB Patient-Derived Organoids (PDOs) are advanced 3D in vitro models derived from adult stem cells that faithfully replicate the architecture, genetics, and physiology of original patient tissues. By preserving patient-specific genetic and phenotypic traits, including surface marker expression, HUB has established a comprehensive and well-characterized biobank of tumor-derived PDOs. This biobank provides a powerful platform for translational research, drug discovery, and the development of targeted therapies. In this study, we present an organoid-based, image-based internalization assay that complements standard Cell Titer-Glo viability assays by enabling direct visualization of ADC internalization. This assay facilitates a deeper exploration of the mechanisms of action of ADCs. We pre-selected tumor-derived organoids based on HER2 expression, which was assessed using flow cytometry. After treating the organoids with FDA-approved HER2-targeting ADCs, we utilized the internalization assay to support the viability data and to define key parameters such as the timing of action, the effect of the payload, and whether cell death resulted from ADC internalization. Overall, these results reinforce the value of patient-derived organoids as a physiologically relevant preclinical platform for ADC development. They also highlight the suitability of the described image-based assay for investigating critical stages of ADC mechanisms, including internalization and payload activity.

#5703 Profiling osteosarcoma convergent evolution and molecular adaptations through patient-derived organoid drug-screening.

Kailee A. Rutherford, Jonathan N. Levi, Summer Norris, Alice Soragni

Department of Orthopaedic Surgery, David Geffen School of Medicine, University of California Los Angeles, CA, USA, Los Angeles, CA

Osteosarcoma is the most common primary bone malignancy in children and young adults, yet accounts for only 2% of cancers in this age group. Its rarity and extensive molecular heterogeneity have hindered biomarker discovery and therapeutic development for more than three decades. Chromosome instability (CIN) is a defining feature of osteosarcoma and contributes to both intratumoral and intertumoral genetic heterogeneity. Emerging evidence suggests that chromosome instability can promote convergent evolution, where distinct genetic alterations arise within shared pathways across subpopulations and may have common druggable vulnerabilities. Drug treatments impose selective pressures that may further influence convergence, although the resulting adaptations remain poorly understood. To investigate how therapeutics shape molecular evolution, we utilize our established high throughput patient-derived tumor organoid (PDO) drug screening platform. This system leverages unpassaged sarcoma organoids that retain all characteristics of the original tumor and shows promising concordance with clinical drug responses (Al Shihabi et al, Cell Stem Cell 2024). Our expanding osteosarcoma biobank comprises multi-sampled osteosarcomas from the same individuals across distinct clinical sites and timepoints, creating a rare resource to study evolutionary trajectories under drug exposure. To improve drug screen interpretability, we developed a quantitative PDO Response Integrated Scoring Model (PRISM) that integrates multiple viability metrics to classify sensitive and resistant phenotypes and allows reproducible comparisons across hundreds of compounds. Drugs are grouped by shared molecular targets and analyzed through pathway enrichment approaches to identify convergent patterns associated with resistance and vulnerability. We further perform single-cell RNA sequencing of organoids persisting post-treatment to directly characterize molecular profiles of resistant cells. Together, this work will establish a scalable map of adaptive molecular states and convergent vulnerabilities in osteosarcoma. Our goal is to define the pathways repeatedly selected under treatment pressure, identify resistant cell states that emerge and uncover molecular dependencies that can be targeted through rational drug combinations. This framework is intended to guide future precision medicine strategies for patients with osteosarcoma.

#5704 Preclinical studies reveal that protease-mediated payload release and immuno-oncology/immunomodulatory effects contribute to the antitumor activity of HLX43.

Lixin Feng, Jijun Yuan, Wan-Jen Yang, Chenqiang Jia, Ge Song, Qingyu Wang, Jun Zhu

Shanghai Henlius Biotech, Inc, Shanghai, China

HLX43 is an innovative PD-L1-targeted antibody-drug conjugate (ADC) designed for cancer treatment. It consists of HLX20, an engineered anti-PD-L1 humanized IgG1 antibody, conjugated via a protease-cleavable tripeptide linker to a potent camptothecin-derived topoisomerase I inhibitor (C24) at a drug-to-antibody ratio (DAR) of 8. Previously reported preclinical studies have demonstrated that HLX43 retains the binding affinity and internalization kinetics of the parental HLX20 antibody and exhibits favorable stability and potent antitumor activity.

The mechanism of action (MoA) of HLX43 is multifaceted, integrating immune checkpoint blockade with payload-induced cytotoxicity. The preclinical studies reported here show that, as an anti-PD-L1 agent, HLX43 effectively blocks PD-1/PD-L1 interaction and reactivates T-cell activity, evidenced by increased IL-2 and IFNγ secretion in mixed lymphocyte reaction assays. The direct cytotoxicity of HLX43 arises from inhibition of DNA repairing and induction of cell apoptosis as evidenced by cleaved PARP and increased γH2AX. In addition, HLX43 induces immunogenic cell death (ICD) marked by increased cell-surface calreticulin, contributing to its immunomodulatory effects. In parallel, protease-mediated cleavage of the linker within the tumor microenvironment (TME)—by enzymes such as matrix metalloproteinases (MMPs) and cysteine proteases—enables payload release independent of the PD-L1 binding. The extracellularly released payload exerts a bystander effect by diffusing into neighbor tissues and killing adjacent PD-L1-negative cancer cells, a feature that underlies HLX43's robust efficacy in patient-derived xenograft (PDX) models with heterogeneous PD-L1 expression. Beyond direct cytotoxicity, HLX43 also remodels the TME, with *in vivo* studies showing increased infiltration of cytotoxic $CD8^+$ T cells and reduced regulatory T cells (Tregs). These $CD8^+$ T cells display enhanced effector function, including elevated IFNγ and Granzyme B expression.

In summary, HLX43's convergent mechanisms—combining immune checkpoint inhibition, targeted cytotoxicity, and TME modulation—support its potential as both a monotherapy and in combination with other immuno-oncology agents, positioning HLX43 as a promising therapeutic candidate across diverse tumor types

#5705 Identifying androgen deprivation-induced responses in prostate cancer with single cell multiomic analysis.

Anni Peramaki[1], Iina Koivisto[1], Alfonso Urbanucci[1], Frank Claessens[2], Mikael Marttinen[1], Matti Nykter[1]

[1]Tampere University, Faculty of Medicine and Health Technology, Tampere, Finland,[2]KU Leuven, Leuven, Belgium

Understanding how cancer cells adapt to therapy and develop treatment resistance remains a major challenge. The main treatment for advanced primary prostate cancer is chemical castration, or androgen deprivation therapy (ADT), which reduces the activity of androgen receptor (AR) in cancer cells. Castration resistance is characterized by AR reactivation which is the main driver of disease progression. While currently available AR signaling inhibitors (ARSI) are effective, in long term treatment, resistance emerges. It has been proposed and tested in neoadjuvant settings to utilize ARSI in early-stage tumors with curative intent. While these trials have shown effectiveness in reducing tumor volume, some cancer cells manage to survive, thus reducing the benefit for patients. It is expected that mechanisms of resistance are patient specific.

To gain insight into how cells adapt in response to ARSI (here, apalutamide), we generated a single-cell multiomic dataset using the single-cell ultra-high-throughput multiomic sequencing assay (SUM-seq), from selected prostate cancer cell lines: 22Rv1, R1AD1, LNCaP, LNCaP-ResA, LAPC4, and VCaP, to observe cell states and aberrant regulatory interactions in detail. These cell lines exhibit distinct androgen responsiveness and resistance mechanisms, including genetic alterations such as AR mutations and amplifications as well as non-genetic mechanisms like AR splice variants. We focused on the direct response to ARSI and thus characterized the cells at 48 hours after treatment.

Multiplexing resulted in a total of 18,477 cells characterized, each with RNA and chromatin profiles. In all cell lines, the treated and control cells formed separate clusters, indicating that the data recapitulates the expected apalutamide response dynamics. More detailed analysis highlighted distinct treatment-associated molecular differences between the cell lines. ADT-responsive cell lines showed decreasing accessibility in sites enriched for AR, SOX, WNT, and MYC family motifs. Paired single-cell RNA and chromatin profiles are ideal for understanding the gene regulatory programs associated with treatment responses. We inferred the gene regulatory network for each cell line using single-cell Deep multi-Omic Regulatory Inference (scDoRI), highlighting distinct regulatory programs (topics) in response to treatment.

Our data underlines diverse responses to apalutamide treatment by prostate cancer cell lines. Integration with treatment response data from patient samples will help to address the role of these cell states and regulators in context of treatment resistance and provide a foundation for selecting appropriate model systems to validate mechanisms observed from the clinical cohorts.

#5706 Modeling the influence of Tumor Treating Fields (TTFields) treatment usage time and break patterns on therapeutic outcomes.

Rotem Engelman[1], Daria Gerasimova[1], Talya Borkum[1], Eyal Dor-On[1], Itai Tzchori[1], **Hila Fishman**[1], Adi Haber[1], Moshe Giladi[1], Uri Weinberg[2], Yoram Palti[1], Na Tosha N. Gatson[3]

[1]Novocure Ltd, Haifa, Israel,[2]Novocure GmbH, Baar, Switzerland,[3]Department of Neurology and Neurosurgery, Indiana University Health Medical Center, Indianapolis, IN and Department of Neurology, University of Arizona College of Medicine, Phoenix, TX

Introduction: Tumor Treating Fields (TTFields) therapy delivers low-intensity, alternating electric fields that disrupt cancer cell division and tumor growth. Clinical evidence indicates that device usage is directly correlated with patient outcomes. While the clinical recommendation for patients is to aim for maximal average monthly usage, there are no clear guidelines on how to manage treatment interruptions within the month. The aim of the current study was to examine the impact of treatment breaks, including their timing and duration, on TTFields efficacy in vitro.
Methods: Human NSCLC (A549) and GBM (U87 MG) cell lines were exposed to TTFields (150 and 200 kHz, respectively; 1 V/cm RMS) under varying treatment schedules incorporating intentional interruptions. Initially, continuous TTFields exposure for 48 or 72 hours was compared to a 48-hour cumulative exposure delivered within a 72-hour experimental window, including either a single 24-hour interruption at mid-treatment or three distributed 8-hour daily breaks. The effect of break timing was then evaluated by positioning a 24-hour interruption at the beginning, middle, or end of the 72-hour treatment period. Subsequently, the duration of the mid-treatment break was extended to 24, 48, or 72 hours (total experimental duration of 72, 96, and 120 hours, respectively), followed by an assessment of fractionating the 72-hour break across the 120-hour period. Treatment efficacy across all conditions was determined by measuring cell counts at experiment completion, expressed as a percentage relative to untreated time-matched controls.
Results: Implementing treatment breaks totaling up to 24 hours within a 72-hour experimental window yielded similar efficacy to uninterrupted TTFields exposure with the same cumulative treatment duration of 48 hours. Comparable results were observed whether the 24-hour interruption was delivered as a single continuous break or fractionated into three 8-hour intervals. Varying the timing of the 24-hour break - at the beginning, middle, or end - did not significantly influence efficacy. Extending the mid-treatment break from 24 (of 72) to 48 (of 96) to 72 (of 120) hours had little effect on TTFields response in U87 MG cells but markedly reduced efficacy in A549 cells when the interruption lasted 72 hours. Fractionating the 72-hour break for the A549 cells across the 120-hour total experimental duration partially restored efficacy.
Conclusions: These results indicate that TTFields efficacy is preserved under short or fractionated 24-hour interruptions but declines with extended continuous treatment breaks. Optimizing treatment adherence and defining tolerable interruption patterns may help sustain clinical efficacy while reducing device burden and improving patient quality-of-life.

#5707 Mechanism of action of GEM144, a POLA1-HDAC11 dual inhibitor, in colorectal cancer models.

Rana Abdel-Samad[1], Avery Lazaro[1], Maura Mack[1], Berthe Hayar[2], Claudio Pisano[3], Nadine Darwiche[2]

[1]Biology, Saint Mary's College, Notre Dame, IN,[2]American University of Beirut, Beirut, Lebanon,[3]Biogem, Centro Ricerche, Ariano Irpino (AV), Italy

Background and objectives: Colorectal cancer (CRC) initiation and progression are governed by complex molecular networks that regulate cell survival and the epithelial-to-mesenchymal transition (EMT). This malignancy remains one of the leading causes of cancer-related mortality worldwide, underscoring the need for novel therapeutic strategies. One promising approach involves the investigation of new molecular entities with enhanced anticancer properties. In this study, we investigated the mechanism of action of a novel hybrid therapeutic candidate, GEM144, which integrates a DNA polymerase-α (POLA1) inhibitor and a histone deacetylase 11 (HDAC11) inhibitor moieties, both reported to play crucial roles in CRC.

Methods: Using human CRC cell lines HCT116 and HT29, and “normal-like” human colon cells CCD-841-CoN, proliferation assays were performed to analyze the effect of GEM144 on cell survival *in vitro*. In addition, CRC xenograft mouse models were used to demonstrate the effect of GEM144 on tumor growth *in vivo*. Finally, SDS-polyacrylamide gel electrophoresis allowed the identification of molecular pathways that are targeted by GEM144.

Results: Our results revealed that GEM144 decreased CRC cell viability *in vitro*, sparing “normal-like” colon cells. This growth inhibition seemed to be partly relying on apoptosis induction, detected by an increase in the expression of the pro-apoptotic protein Bax when cells were treated with GEM144, at concentrations as low as 1 µM starting 24 hours post-treatment. In addition, GEM144 suppressed the EMT, as evidenced by the upregulation of E-cadherin expression, a key epithelial marker that maintains cell-cell adhesion and epithelial integrity. This was accompanied by a tumor burden reduction in HCT116 xenograft mouse models treated with GEM144.

Conclusion: Collectively, these findings provide new insights into the molecular mechanisms underlying the anticancer activity of GEM144 and support its potential as a promising therapeutic candidate for CRC treatment.

#5708 Dual targeting of PDPK1 and mutated BRAFV600E is synthetically lethal.

Tejinder Pal Khaket, Chandrayee Gosh, Zhongyue Yang, Electron Kebebew

General Surgery, Stanford University School of Medicine, Stanford, CA

Anaplastic thyroid cancer (ATC) exhibits near-uniform activation of the MAPK and PI3K/AKT/mTOR pathways, driving resistance to BRAF-targeted therapies. PDPK1, a key AGC-kinase activator downstream of PI3K, integrates multiple oncogenic and stress-response pathways and represents a critical resistance node. We investigated PDPK1 inhibition using BX795 alone and with BRAF inhibition (dabrafenib) in *BRAF*V600E mutant *in vitro* (8505C, SW1736), *ex vivo* (patient-derived ATC spheroids ATC-01, ATC-02), and orthotopic xenograft models. BX795 monotherapy reduced cellular proliferation and invasion, and in combination with dabrafenib produced strong synergistic anticancer activity (Combination Index <1), and led to ~55% tumor volume reduction *in vivo* without toxicity. Mechanistically, dual blockade of PDPK1Ser241 and MEK/ERK phosphorylation, prevented the compensatory upregulation of PI3K/AKT and MAPK pathways seen with monotherapy. The synthetic lethality of dual targeting of PDPK1 and *BRAF*V600E was due to induction of extensive DNA damage (γ-H2AX↑, ATM/CHK2↑), G_2/M cell-cycle arrest through suppression of CDC25C, CDK1, and cyclin A2, and triggering of mitochondrial hyperpolarization with impaired oxidative phosphorylation and increased ROS generation. Elevated mitochondrial ROS amplified DNA-damage signaling, culminating in BAD dephosphorylation, caspase-3 activation, and PARP cleavage. ROS scavengers (N-acetylcysteine, MitoQ) and CHK2 inhibition partially reversed apoptosis and cell cycle arrest, confirming a ROS-CHK2-dependent cell death mechanism. Together, these findings reveal that combined PDPK1 and BRAF inhibition is synthetically lethal in *BRAF*V600E-mutant cancer. PDPK1 represents a targetable vulnerability for enhancing *BRAF*V600E-targeted cancer therapy and in other MAPK/PI3K-coactivated cancers.

[1]Oncology, Wayne State University School of Medicine, Barbara Ann Karmanos Cancer Institute, Detroit, MI,[2]Medicine, Atrium Health Wake Forest Baptist Hospital, Winston-Salem, NC,[3]TheraBionic GmbH, Ettlingen, Germany

Background: Amplitude-modulated 27.12 MHz radiofrequency electromagnetic fields (AM RF EMF) delivered via a spoon-shaped antenna placed on the patient's tongue result in shrinkage of the primary and metastatic tumors in patients with advanced hepatocellular carcinoma (HCC). Treatment is FDA-approved for patients with advanced HCC who fail 1stline and 2ndline therapy (H220001). The mechanism by which AM RF EMF has a direct antiproliferative effect depends on the influx of extracellular Ca^{2+} into the cancer cell via $Ca_V3.2$ (*CACNA1H*) T-type voltage-gated calcium channel (VGCC). Here we show that HCC-specific AM RF EMF's (HCCMF) therapeutic action is inhibited by drugs with the same binding profile as ethosuximide.
Methods: Computational docking study, using AlphaFold Protein Structure Database (AFDB accession: AF-O95180-F1-v4) showed that ethosuximide binds to an intracellular, hydrophobic pocket formed by amino acids (AAs) Val79 and Phe80 of the free N-terminal segment and Leu160 and Phe161 of S2-S3 linker of CACNA1H Domain 1. To confirm the ethosuximide binding-pocket (EBP) AAs [Val79, Phe80, Leu160, and Phe161] are important for the inhibition of HCCMF, we virtually screened (VS) the FDA library for drugs that would bind similarly to ethosuximide. Drugs predicted / identified via VS where then tested (colony formation, qPCR, and Fluo-4 Ca^{2+} dye) HCCMF-mediated cell proliferation in HCC cell lines.
Results: Tadalafil and abiraterone acetate are the first two drugs found, via VS and tested, to inhibit HCCMF. In the Huh7 cell line, tadalafil blocked HCCMF-mediated cell proliferation with respect to colony formation and Ki-67/Cyclin D1 expression. Tadalafil also blocked Ca^{2+}influx assessed by Fluo-4 in Huh7 and HepG2 cell lines. Interestingly, we found that sildenafil, while belonging to the same class of phosphodiesterase inhibitors as tadalafil, did not block HCCMF-mediated Ca^{2+}influx. This was shown via Fluo-4 Ca^{2+} staining in both Huh7 and HepG2. Specifically, mean fluorescent intensity (MFI) was higher in the HCCMF treated group even when sildenafil was present. HCCMF-MFI increased by 33.07% (*p*-value: 0.0162, n=5) in Huh7 and by 31.86% (*p*-value: 0.0012, n=5) in HepG2 compared to SHAM (no treatment control).
Conclusions: The availability of the EBP AAs is necessary for HCCMF-mediated inhibition of HCC cell proliferation. Theoretical modelling confirmed by laboratory experiments demonstrate that binding of drugs to this pocket interferes with Ca^{2+} influx and block the anti-cancer effects of HCCMF. These results support the use of computational modeling to predict and identify all FDA drugs which could be used during cancer therapy and should thereby be avoided in patients receiving HCCMF treatment.

#5713 Comparative performance of amplicon-based DNA and RNA NGS co-detection versus hybrid-capture DNA-NGS for SNV/INDEL profiling in Chinese NSCLC driver genes.

Zefeng Xie[1], Yuze Zhao[1], Haitao Li[1], Yu Li[1], Yulan Chen[2], Meilian Liu[3], Xuyuan Li[4]

[1]Department of Thoracic Surgery, First Affiliated Hospital of Shantou University Medical College, Shantou City, China,[2]Department of Oncology, The First People's Hospital of Zhaoqing, Zhaoqing City, China,[3]Department of Pulmonary Oncology, The Affiliated Hospital of Guangdong Medical University, Zhanjiang City, China,[4]Department of Oncology, Shantou Central Hospital, Shantou City, China

Background: Although amplicon-based DNA+RNA NGS co-detection has demonstrated clear advantages over hybrid-capture DNA-NGS for identifying gene fusions in non-small cell lung cancer (NSCLC), the clinical relevance of single-nucleotide variants (SNVs) and small insertions/deletions (INDELs) in NSCLC remains equally critical for precision oncology. However, whether amplicon-based DNA+RNA NGS co-detection provides comparable or improved performance for detecting NSCLC driver-gene SNVs/INDELs relative to hybrid-capture DNA-NGS has not been systematically evaluated.

Methods: We performed a comparative analysis of SNV and INDEL detection across 19 clinically relevant NSCLC driver genes, including AKT1, ALK, ARAF, BRAF, EGFR, ERBB2, FGFR1/2, HRAS, IDH1/2, KIT, KRAS, MAP2K1, MET, MTOR, NRAS, NTRK, PDGFRA, PIK3CA, and RET. Detection rates generated by a 35-gene amplicon-based DNA+RNA NGS co-detection assay (n = 2,242) were compared with those obtained using hybrid-capture DNA-NGS (n = 2,504).

Results: Amplicon-based DNA+RNA NGS co-detection demonstrated significantly higher detection rates for EGFR (50.68% vs 45.73%, $P < 0.05$), KRAS (12.25% vs 10.78%, $P < 0.05$), and KIT (0.40% vs 0.08%, $P < 0.05$) compared with hybrid-capture DNA-NGS. The increase in EGFR detection was primarily driven by improved identification of EGFR L858R (23.39% vs 20.01%, $P < 0.05$). For KRAS, differences were mainly contributed by KRAS G12C (4.12% vs 3.75%) and G12D (2.43% vs 1.80%), though these did not reach statistical significance. In contrast, hybrid-capture DNA-NGS showed a significantly higher detection rate for PIK3CA (6.11% vs 4.51%, $P < 0.05$). For all remaining genes, including AKT1(0.32% vs 0.28%), ALK(0.11% vs 0.12%), ARAF(0.12% vs 0.12%), BRAF(2.89% vs 2.6%), ERBB2(2.98% vs 3%), FGFR2(0.08% vs 0.08%), FGFR3(0.21% vs 0.16%), HRAS(0.08% vs 0.16%), IDH1(0.28% vs 0.28%), IDH2(0.12% vs 0.12%), MAP2K1(0.31% vs 0.48%), MET(0.52% vs 0.52%), MTOR(0.26% vs 0.32%), NRAS(0.41% vs 0.52%), NTRK(0.01% vs 0.04%), PDGFRA(0.12% vs 0.16%), RET(0.1% vs 0.12%), the mutation detection rates showed no significant difference between the two platforms.

Conclusion: This large-cohort comparison demonstrates that amplicon-based DNA+RNA NGS co-detection performs comparably to hybrid-capture DNA-NGS for most NSCLC driver-gene SNV/INDEL alterations, while offering significantly higher sensitivity for critical mutations in EGFR, KRAS, and KIT. These findings indicate that co-detection workflows integrating both DNA and RNA may improve mutation detection efficiency for key actionable NSCLC biomarkers, supporting their broader adoption in routine clinical genomic profiling.

#5714 Amplicon-based DNA and RNA co-detection improves ROS1 fusion identification across Chinese solid tumors compared with hybrid capture DNA-NGS.

Meiyi Li

Guangzhou Medical University Affiliated Qingyuan Hospital (Qingyuan People's Hospital), Qingyuan City, China

Background: ROS1 fusions are actionable drivers across many solid tumors, with multiple targeted therapies approved, yet conventional DNA assays show limited sensitivity. Although RNA-NGS improves fusion detection, the relative performance of amplicon-based DNA+RNA NGS co-detection versus hybrid-capture DNA-NGS for ROS1 fusion identification across diverse tumors remains unclear.

Methods: We analyzed a total of 16,424 solid tumor samples using a 35-gene amplicon-based DNA+RNA NGS co-detection assay, including BTC (n=310), COAD (n=3,839), ESCA (n=83), LIHC (n=123), NSCLC (n=11,242), SARC (n=61), and STAD (n=766). In parallel, 4,624 tumors were assessed using a hybrid-capture DNA-NGS assay, including BTC (n=398), COAD (n=857), ESCA (n=83), LIHC (n=269), NSCLC (n=2,504), SARC (n=67), and STAD (n=446). ROS1-positive cases were identified for each tumor type, and fusion orientation and partner genes were characterized to evaluate differences in fusion detection performance between the two sequencing strategies.

Results: Amplicon-based DNA+RNA NGS co-detection identified 217 ROS1-positive tumors, yielding detection rates of 0.32% in BTC (1/310), 0.10% in COAD (4/3,839), 2.41% in ESCA (2/83), 0.81% in LIHC (1/123), 1.82% in NSCLC (205/11,242), 3.28% in SARC (2/61), and 0.26% in STAD (2/766). All detected ROS1 fusions were canonical 5′-3′ events. Across all fusion-positive tumors, the predominant partner genes were CD74-ROS1 (46.08%), EZR-ROS1 (21.66%), SDC4-ROS1 (16.13%), SLC34A2-ROS1 (3.23%), CCDC6-ROS1 (3.23%), GOPC-ROS1 (2.30%), TPR-ROS1 (0.92%), EML4-ROS1 (0.46%), LRIG3-ROS1 (0.46%), PPFIBP1-ROS1 (0.46%), and ZCCHC8-ROS1 (0.46%). In contrast, hybrid-capture DNA-NGS identified only 43 ROS1-positive tumors, with detection rates of 0.75% in BTC (3/398), 0% in COAD (0/857), 0% in ESCA (0/83), 0.37% in LIHC (1/269), 1.56% in NSCLC (39/2,504), 0% in SARC (0/67), and 0% in STAD (0/446). All fusions detected by DNA-NGS were classical 5′-3′ rearrangements, and the dominant partner genes were CD74-ROS1 (53.49%), SDC4-ROS1 (18.60%), EZR-ROS1 (11.63%), GOPC-ROS1 (6.98%), TPM3-ROS1 (2.33%), ROS1-NT5DC1 (2.33%), ROS1-SLC34A2 (2.33%), and ROS1-TBC1D32 (2.33%). Overall, the co-detection strategy demonstrated substantially higher fusion detection rates and broader partner diversity, particularly in ESCA, NSCLC, and SARC.

Conclusion: Amplicon-based DNA+RNA NGS showed higher sensitivity and broader fusion-partner detection than hybrid-capture DNA-NGS for ROS1 rearrangements, underscoring the value of integrating RNA-based methods into routine testing to improve ROS1 fusion identification and support precision oncology.

#5715 Histone-modifying enzymes in androgen-deprived prostate cancer: EZH1 as a synergistic therapeutic target.

Tanaya Purohit[1], **Emily Schmitt**[1], Zachary Schultz[1], Marcelo Bigarella[1], Kayla Bahr[1], Mohammad Rizvi[1], Diana Garcia[1], Sean Sardeson[1], Erika Heninger[2], Shannon Reese[2], Jacob Popp[2], Joshua M. Lang[3], Karla Esbona[4], Wei Huang[4], Peter W. Lewis[5], John M. Denu[5], Bing Yang[1], David F. Jarrard[1]

[1]Department of Urology, University of Wisconsin-Madison, Madison, WI,[2]Department of Medicine, Division of Hematology-Oncology, University of Wisconsin-Madison, Madison, WI,[3]University of Wisconsin Carbone Cancer Center, Madison, WI,[4]Department of Pathology and Laboratory Medicine, University of Wisconsin-Madison, Madison, WI,[5]Department of Biomolecular Chemistry, University of Wisconsin-Madison, Madison, WI

Background: Androgen deprivation therapy (ADT) is the cornerstone of treatment for advanced prostate cancer (PC). While ADT induces apoptosis and senescence, residual tumor cells frequently persist and drive castration resistance. The initiation of ADT may create vulnerabilities that can be therapeutically exploited. We investigated the role of histone-modifying enzymes (HMEs) in supporting tumor cell survival after ADT, hypothesizing that their upregulation contributes to persistence and represents a target for synergistic therapy.
Methods: High-risk prostatectomy samples treated with 3 months of ADT were compared to untreated controls using bulk RNA sequencing (n=10 vs. 26). Publicly available datasets (Wyatt GSE550162; Sowalsky GSE1831003) were interrogated for validation. The expression of EZH1/2 and H3K27me3 was assessed in hormone-sensitive PC (HSPC) cell lines LNCaP, LAPC4 and VCaP treated with ADT (CSS: charcoal-stripped serum) at different timepoints by Western blotting. A tissue microarray was constructed to evaluate the protein expression of EZH1 in 30 ADT-treated and 29 untreated post-prostatectomy HSPC tumors using immunohistochemistry and automated VECTRA imaging and quantification. HSPC cell lines and patient-derived organoids were treated with bicalutamide or darolutamide in combination with dox-inducible EZH1 shRNAs or FDA-approved EZH1/2 inhibitor valemetostat to examine synergistic inhibition of cell growth.

Results: High-risk prostatectomy samples identified four consistently upregulated HMEs: EZH1, MECOM, SIRT1, and GCN5, KDM6B, PRDM5/6/16 after ADT. Among these, EZH1 and MECOM showed increased protein expression with ADT in a validation tissue microarray of 59 patients with EZH1 correlated with adverse clinical features including and PSA recurrence in the ADT-treated cohort. In LNCaP and VCaP cell lines EZH1 expression rose or persisted after early ADT, while EZH2 declined with increased H3K27 methylation levels. Total H3K27me3 levels increased. EZH1 expression positively associates with a subset of EMT and stem cell markers. EZH1 knockdown reduced survival of ADT-treated cells, and patient-derived organoid models showed synergistic cell death with combined either bicalutamide or darolutamide and EZH1/2 inhibition (valemetostat).
Conclusions: ADT induces EZH1 upregulation, which promotes prostate cancer cell persistence potentially through regulation of cancer stemness and epithelial-to-mesenchymal transition. These findings establish EZH1 as a mediator of survival after ADT and a promising target for synergistic therapeutic inhibition.

#5716 Establishing a drug-target relationship between doxycycline/methacycline and acetylated KLF5 in bone-metastatic prostate cancer.

Duo Zhang, Xinyuan Jiang, Yutian Ren, Yujing Qin, Shiqi Deng, Qifan Zhou, Yuanguang Chen, Zhiqian Zhang, Xumu Zhang, **Jin-Tang Dong**

Southern University of Science and Technology, Shenzhen, China

Advanced prostate cancers (PCa) often metastasize to the bone, where they eventually develop resistance to virtually all available therapies. We previously reported that TGF-β induces acetylation of the transcription factor KLF5 at K369, and acetylated KLF5 (Ac-KLF5) is essential for TGF-β to maintain EMT, promote osteoclast differentiation, and cause bone metastasis in prostate cancer. On the other hand, tetracycline derivatives doxycycline (D) and methacycline (M) can inhibit tumor growth and even metastasis, but their molecular targets remain undetermined. In this study, we screened 1987 FDA-approved drugs to identify those that selectively bind to the $KLF5^{K369Q}$ mutant, which mimics Ac-KLF5, using surface plasmon resonance assays. We identified D and M, but not their parent compound, tetracycline (T), as potential inhibitors of Ac-KLF5. Functionally, D and M but not T inhibited $KLF5^{K369Q}$-induced cell invasion, osteoclast differentiation, and osteolytic bone metastasis. RNA-seq and ChIP-seq analyses identified 22 genes transcriptionally regulated by KLF5K369Q via direct promoter binding, with transcription modulated by D and M but not T. One gene, PGK1, was shown to be responsible for D- and M-suppressed cell invasion, osteolytic differentiation, and bone metastasis. These findings suggest a drug-target relationship between doxycycline/methacycline and Ac-KLF5, providing a therapeutic strategy for treating prostate cancer bone metastases resistant to antiandrogen therapy and chemotherapy.

#5717 Identifying the regions responsible for isoaspartylation and aggregation of SCLC antigen ELAVL4.

Shiori Fukutome[1], Diego Alejandro Velarde[1], Chunli Yan[1], Whitaker Cohn[2], Nazarius Lamango[3], Ite A. Offringa[1]

[1]USC Norris Comprehensive Cancer Center, Los Angeles, CA,[2]USC Mann School of Pharmacy, Los Angeles, CA,[3]Professor, Florida A&M Univ. College of Pharmacy, Tallahassee, FL

Small cell lung cancer (SCLC) is the most aggressive type of lung cancer, with a 5-year survival of 9%. Despite the aggressive nature, therapy options are still limited, and there is a need for the development of new treatments. Pulmonary neuroendocrine cells (PNEs), the predominant cells of origin for SCLC, uniquely express embryonic lethal abnormal vision Drosophila-like 4 (ELAVL4) and are presented on surface of SCLC cells. Clinical research has identified that 15% of SCLC patients with naturally-occurring low titer antibodies against ELAVL4 show significantly better survival. Patients with high-titer antibodies can see complete regression but suffer from a paraneoplastic autoimmune syndrome. The characteristic expression of ELAVL4 in SCLC and the observed improved survival of patients with an immune response against ELAVL4 suggest this protein may be used as a new therapeutic target. Our previous work indicates that the anti-ELAVL4 immune response is triggered by isoaspartylation in the unstructured N-terminal region of ELAVL4 adjacent to the first RNA-recognition motif domain (RRM1). Isoaspartylation occurs when asparagine or aspartic acid side chains spontaneously form a cyclic intermediate with the peptide backbone, followed by hydrolysis, resulting in an isoaspartyl kink that can be antigenic. The N-terminal region contains 6 asparagine residues and 2 aspartic acid residues. Some are followed either by a glycine, serine, or histidine, which increases the likelihood of isoaspartylation. One characteristic of isoaspartylation-prone proteins is the formation of protein aggregates, a process that may play a role in triggering immunogenicity. Here, we aim to identify which residues undergo isoaspartylation and trigger aggregation. We have generated four deletion constructs of the amino acid 1-117 ELAVL4 region (comprising residues 1-13, 8-18, 16-29, and 28-38, fused to RRM1), each including isoaspartylation-prone sites. These constructs are incubated under isoaspartyl-inducing conditions (pH 7.4, 37ºC, 7 d, in K-HEPES). We will use Western blots and mass spectrometry to determine which constructs undergo isoaspartylation and aggregation. Understanding the sites of isoaspartylation and aggregation in ELAVL4 will help identify the optimal target for the development of anti-isoaspartylated ELAVL4 monoclonal antibodies, which may provide a novel, targeted immunotherapy for SCLC patients.

#5718 Cbx5 as a potential target to enhance immunotherapy in small cell lung cancer.

Hong Cao[1], Yiting Li[1], Jiajia Gu[1], Yuan Hao[2], Ziyang Wang[1], Benjamin A. Nacev[1], Kwok-Kin Wong[2], **Hua Zhang**[1]

[1]Hillman Cancer Center, University of Pittsburgh Medical Center (UPMC), Pittsburgh, PA,[2]Laura and Isaac Perlmutter Cancer Center, New York University Langone Medical Center, New York, NY

Small cell lung cancer (SCLC) is a highly aggressive neuroendocrine carcinoma with a very poor prognosis and accounts for approximately 15% of all lung cancers. Although immunotherapy is now a key component of standard care for SCLC, the clinical benefits remain modest. Growing evidence indicates that epigenetic regulators play important roles in antitumor immunity and in controlling responses to immunotherapy response. In this study, we report Cbx5 as a potential epigenetic regulator of antitumor immunity in SCLC. Our preliminary data suggests that Cbx5 loss may enhance the responses of SCLC tumors to anti-PD-1 therapy in immunocompetent mice. Our preliminary analysis suggests that Cbx5 loss may activate immune response related genes/pathways, while its depletion may derepress endogenous retroviruses in SCLC. Cbx5 deficiency may potentially remodel the tumor microenvironment by converting SCLC from an immune-cold to an immune-hot state. In summary, our findings indicate that Cbx5 may function as a central epigenetic regulator of immune response and immune evasion in SCLC, revealing a potential epigenetic target to enhance responsiveness to immunotherapy. Additional studies are ongoing to validate these findings and further characterize the immunoregulatory mechanisms governed by Cbx5.

#5719 Contrasting roles of MSH2 and MLH1 in basal-like breast cancer.

Department of Pathology, Immunology and Laboratory Medicine, University of Florida, Gainesville, FL,[7]University of Florida, Gainesville, FL,[8]University of Florida College of Medicine, Gainesville, FL,[9]University of Iowa, Iowa City, IA,[10]University of Iowa, Iowa, IA,[11]University of Baghdad College of Pharmacy, Baghdad, Iraq,[12]Vanderbilt University Medical Center, Nashville, TN,[13]University of Iowa, Iowa city, IA

Basal-like breast cancer (BLBC) is the most aggressive molecular subtype of breast cancer, characterized by high genomic instability. Because of higher mutational load and genetic heterogeneity in BLBC, cancer cells tend to upregulate DNA repair pathways. Therefore, DNA repair-based therapies are considered to have significant potential for BLBC patients. PARP (Poly (ADP-ribose) polymerase) inhibitors are approved by FDA to treat a subset of BLBC patients with *BRCA1/2* mutations. However, most BLBC patients have wildtype *BRCA1/2* and lack good therapeutic targets. We analyzed all available DNA repair genes and proteins using TCGA RNA-sequencing and RPPA (Reverse Protein Phase Array) data. Our investigation identified that mismatch repair (MMR) proteins MSH2 and MSH6 (referred to as MutSα) are highly elevated in BLBC and their higher expressions are correlated to poor survivals of BLBC patients. Conversely, MLH1 and PMS2 (referred to as MutLα), the second major component of the MMR machinery, are downregulated at the mRNA level and cannot predict patient survival in BLBC. In contrast to the known tumor suppressor functions of MMR proteins, our data indicates that MSH2 promotes BLBC metastasis; MLH1, on the other hand, is associated with decreased tumor progression and metastasis. The contrasting functions of MSH2 and MLH1 have never been reported. At the mechanistic level, our data strongly indicate that MSH2, in contrast to MLH1, regulates the expression of chemokines and tumor infiltrating immune cells. Further investigation at the genomic level suggests that MSH2 regulates the expression of interferon alpha/beta receptor 1 (*IFNAR1)*, which plays various roles in the tumor microenvironment (TME) for potential antitumor effects. Deletion of MSH2 initiates a chain of immune reactions via the upregulation of *IFNAR1* expression which explains a highly immune active TME in tumors with MSH2-deficiency. Our study supports the contrasting functions of MSH2 and MLH1 in BLBC progression are due to their distinct transcriptional regulation of immune related genes, not related to their canonical mismatch repair activity. These findings challenge the universal paradigm that all MMR proteins have similar effects on tumor progression or suppression.

#5720 High TROP2 expression is frequent and linked to nodal metastasis in head and neck cancer.

David Dum[1], Juliana Knief[2], Christoph Thorns[2], Morton Freytag[1], Florian Lutz[1], Waldemar Wilczak[1], Katharina Moller[1], Florian Viehweger[1], Fiete Gehrisch[1], Nina Schraps[1], Claudia Hube-Magg[1], Martina Kluth[1], Maria Christina Tsourlakis[1], Ronald Simon[1], Guido Sauter[1], Natalia Gorbokon[1], Munir Hamad[3], Nikolaus Mockelmann[3], Till Clauditz[1], Adrian Munscher[3], **Viktoria Chirico**[1]

[1]University Medical Center Hamburg-Eppendorf, Hamburg, Germany,[2]Pathologie-Hamburg, Medizinisches Labor Nord, Hamburg, Germany,[3]Marienhospital Hamburg, Department of Ear, Nose, and Throat Medicine, Head and Neck Tumor Center, Hamburg, Germany

Head and neck cancers constitute a highly heterogeneous group of malignancies exhibiting variable clinical outcomes. Despite advances in surgery, radiotherapy, and systemic treatments, more than 300,000 patients worldwide die annually from these cancers. The identification of novel molecular markers to improve patient stratification and to guide personalized treatment approaches is therefore urgently needed. The membrane glycoprotein Trophoblast cell surface antigen 2 (TROP2) is the molecular target of sacituzumab govitecan (SG), an antibody-drug conjugate that has been approved for the treatment of metastatic triple-negative breast cancer and advanced urothelial carcinomas. Additionally, it has shown promising clinical activity in other tumor types, such as non-small cell lung cancer, and gastrointestinal cancers. To evaluate the prevalence and potential clinical significance of TROP2 expression in head and neck cancer, we analyzed a total of 583 head and neck cancers by immunohistochemistry (IHC) in a tissue microarray format. H score analysis was used to define cancers as strongly positive (h-score 300), moderately positive (200-299), weakly positive (1-199), or negative (0). TROP2 expression was found to be strong in 53.7%, moderate in 18.8%, weak in 22.8%, and negative in 4.7% of 531 evaluable head and neck carcinomas. There was a marked variability of TROP2 expression between tumors of different localization. TROP2 expression was found to be strong in 61.2% of 336 carcinomas of the oropharynx, 48.0% of 25 cancers of the hypopharynx, 40.1% of 143 cancers of the larynx, 37.5% of 8 carcinomas of the oral cavity, and in 21.4% of 14 carcinomas of the nasopharynx (p=0.0028). Among 347 patients with data on the pN-stage, high TROP2 expression was associated with nodal metastasis (p=0.0002). However, the level of TROP2 expression was statistically unrelated to pT-stage (p=0.3206), histologic grade of malignancy (p=0.7732), presence of distant metastasis (M1, p=0.4024), L-status (p=0.2895), and V-status (p=0.6822). It is concluded from our data, that high level TROP2 expression is very common in head and neck cancers. Accordingly, many patients with these tumors could potentially benefit from SG treatment. Site specific differences in TROP2 expression levels are likely to be driven by location-specific risk factors for subtypes of head and neck cancers.

#5721 Aldehyde dehydrogenase inhibition as a strategy to overcome drug-refractory multiple myeloma.

Michael J. Ingling[1], Robert Chitren[1], Krishne Gowda[2], Shantu Amin[3], Subash C. Jonnalagadda[4], Tulin Budak-Alpdogan[5], Manoj Pandey[6]

[1]Department of Biomedical Sciences, Cooper Medical School of Rowan University (CMSRU), Camden, NJ,[2]Penn State College of Medicine, Hershey, PA,[3]Penn State University College of Medicine, Hershey, PA,[4]Department of Chemistry and Biochemistry, Rowan University, Glassboro, NJ,[5]MD Anderson Cancer Center at Cooper, Cooper University Health Care, Camden, NJ,[6]Rowan University, Glassboro, NJ

Multiple myeloma (MM) remains an incurable hematologic malignancy characterized by inevitable relapse and progressively therapy-resistant disease, despite the widespread use of combination regimens and autologous stem cell transplantation (ASCT). While only ~30% of patients achieve a complete response following initial therapy and ~40-50% with ASCT, the durability of these responses is limited, underscoring the persistence of highly drug-refractory cellular subpopulations. Increasing evidence implicates multiple myeloma stem-like cells (MMSLCs), a $CD138^{-}/ALDH^{+}$ phenotype enriched for self-renewal, metabolic plasticity, and intrinsic chemoresistance, as key drivers of relapse. Aldehyde dehydrogenases (ALDHs) promote MM survival by detoxifying cytotoxic aldehydes and sustaining retinoic acid-dependent stemness pathways, making them attractive therapeutic targets. We report the development and characterization of KS100, a novel pan-ALDH inhibitor, which potently eliminates both bulk MM cells and MMSLC populations in treatment-naïve and treatment-resistant models in vitro and in vivo. KS100 significantly reduces clonogenic growth, exhausts the ALDH-high compartment, and synergizes with standard MM therapies, including proteasome inhibitors and IMiDs, even in models with established resistance. These findings demonstrate that ALDH inhibition disrupts a universal resistance mechanism and position KS100 as a promising therapeutic strategy to eradicate stem-like reservoirs and improve long-term disease control in MM.

#5722 Protein regulator of cytokinesis 1 (PRC1) promotes Wilms tumor progression by orchestrating tumor-stromal crosstalk.

Qiushi Wang, Tianshun Zhang

The Hormel Institute, University of Minnesota, Austin, MN

Wilms tumor (WT) is the most common pediatric renal malignancy and a major cause of cancer-related morbidity in children. Despite advances in multimodal therapy, patients with high-risk histology, relapsed disease, or bilateral WT continue to experience poor survival and long-term treatment-related toxicity. The absence of effective targeted therapies highlights the urgent need to identify new oncogenic drivers and therapeutic vulnerabilities in WT. Using integrative systems biology approaches, including Weighted Gene Co-expression Network Analysis (WGCNA) and survival analysis across TARGET and GEO datasets, we identified Protein Regulator of Cytokinesis 1 (PRC1) as a gene significantly associated with unfavorable prognosis. PRC1, a critical mediator of spindle organization and cytokinesis, has been implicated in multiple adult cancers, yet its role in Wilms tumor remains undefined. We hypothesize that PRC1 drives Wilms tumor progression by dual mechanisms: (1) intrinsically promoting tumor cell proliferation via the β-catenin/WT1 axis, and (2) extrinsically reprogramming the tumor stroma through paracrine signaling between WT cells and cancer-associated fibroblasts (CAFs). These findings will provide new mechanistic insights into the role of PRC1 in pediatric kidney cancer and may inform future targeted therapeutic strategies to improve outcomes for children with aggressive or refractory Wilms tumors.

#5723 TMEM165-CLOCK fusion protein drives metastasis through enhanced lysosomal exocytosis.

Youngkeun Lee, Ji-yoon Choi, Min-jeong Kim, **Sung Wook Seo**

Samsung Medical Center, Seoul, Korea, Republic of

TMEM165-CLOCK is a chimeric protein identified in osteosarcoma, where its expression correlates with poor prognosis. The fusion incorporates CLOCK in reverse orientation without clear functional contribution but truncates the C-terminal transmembrane domain of TMEM165, potentially altering its subcellular localization and function. We investigated its clinical impact and underlying mechanisms. TMEM165-CLOCK expression was quantified by RT-qPCR in UPS and NSCLC cohorts and correlated with clinical outcomes. Subcellular localization was assessed by colocalization imaging. Calcium flux, lysosomal exocytosis, and cathepsin S secretion were compared between parental KHOS/NP cells and TMEM165-CLOCK-overexpressing KHOS/NP cells. Tumor aggressiveness was evaluated by migration, invasion, and a rat metastasis model. RT-qPCR analysis in the UPS cohort showed that higher TMEM165-CLOCK expression correlated with worse progression-free survival (HR: 2.71, p=0.040). In the lung cancer cohort, TMEM165-CLOCK expression significantly correlated with advanced tumor stage (p= 0.038) and nodal stage (p=0.014) at presentation, suggesting cross-cancer relevance. Colocalization imaging revealed a marked shift from Golgi localization to increased presence at lysosomes and the plasma membrane. His-tag imaging confirmed C-terminal exposure on the cell surface, rendering the fusion protein as a druggable target. Despite this redistribution, TMEM165-CLOCK did not alter Golgi glycosylation, as glycosylated LAMP2 levels remained unchanged. In contrast, TMEM165-CLOCK-overexpressing KHOS/NP cells displayed impaired ATP-induced calcium dynamics, with reduced peak amplitude and delayed recovery to baseline, consistent with disrupted calcium homeostasis. These cells showed enhanced lysosomal exocytosis, evidenced by increased surface LAMP1 exposure, and significantly elevated cathepsin S secretion. Functionally, TMEM165-CLOCK overexpression increased cell migration and invasion. siRNA-mediated knockdown of the fusion protein rescued the invasive phenotype, establishing causality. In vivo, rats injected with TMEM165-CLOCK-expressing UPS cells developed markedly greater metastatic burden compared to controls, confirming the fusion's pro-metastatic activity. TMEM165-CLOCK promotes tumor progression through mechanism involving subcellular relocalization, disrupted calcium homeostasis, and enhanced lysosomal exocytosis with cathepsin S release. Its association with aggressive disease across sarcoma and lung cancer identifies TMEM165-CLOCK as a driver of metastasis and potential therapeutic target.

#5724 HMGB1 overexpression is a strong and independent prognostic feature in ERG negative prostate cancer.

Neele Heckmann[1], Nicolas Hertzsprung[2], Christian Bernreuther[3], Eike Burandt[3], Florian Lutz[3], Clara Luhr[3], Clara von Bargen[3], Martina Kluth[3], Maria Tsourlakis[3], Nina Schraps[4], Fiete Gehrisch[4], Ronald Simon[3], Hans Heinzer[1], Alexander Haese[1], Henning Plage[2], Sarah Minner[3], Guido Sauter[3], Thorsten Schlomm[2], Markus Graefen[1], **Cosima Volkl**[3]

[1]Martini-Clinic, Prostate Cancer Center,University Medical Center Hamburg-Eppendorf, Hamburg, Germany,[2]Department of Urology, Charite - Universitatsmedizin Berlin, Berlin, Germany,[3]University Medical Center Hamburg-Eppendorf, Hamburg, Germany,[4]General, Visceral and Thoracic Surgery Department and Clinic, University Medical Center Hamburg-Eppendorf, Hamburg, Germany

High-mobility group box 1 (HMGB1) is a chromatin-associated protein with a key role in DNA damage repair and genome stability, involved in DNA replication, transcription, and chromatin remodeling. By impacting the activity of multiple signaling pathways HMGB1 contributes to critical characteristics of cancer cells including proliferation, migration and invasion, angiogenesis, and cellular energy metabolism. Depending on the tumor type, both increased and reduced expression of HMGB1 have been found to be linked to unfavorable tumor features and poor patient prognosis. To better understand the prevalence and clinical relevance of HMGB1 expression in prostate cancer, a tissue microarray containing 17,747 prostate cancer samples from patients with follow-up data was analyzed by immunohistochemistry (IHC). In normal prostate epithelium, HMGB1 expression was strong in basal cells but only weak in acinar cells which are considered the precursor cells of prostatic adenocarcinoma. HMGB1 IHC was interpretable in 13,642 cancers and was rated negative in 19.9%, weak in 56.1%, moderate in 22.4%, and strong in 1.6% of tumors. HMGB1 staining was significantly more frequent and more intense in cancers harboring the *TMPRSS2:ERG* fusion (91.6% positive) than in ERG fusion negative tumors (70.4% positive; $p<0.0001$). A comparison with clinico-pathological features revealed significant associations between high HMGB1 expression and advanced pT stage, high Gleason grade, high quantitative Gleason grade ($p\leq0.0001$ each), nodal metastases ($p=0.0038$), and early PSA recurrence ($p<0.0001$). A subgroup analysis of 3,854 ERG positive and 4,751 ERG negative cancers revealed that the prognostic impact of HMGB1 expression was entirely driven by the ERG negative group ($p<0.0001$) while the level of HMGB1 expression did not impact PSA recurrence in ERG positive cancers. Several different multivariate analyses considering either preoperatively available (cT, PSA, Gleason grade obtained on biopsies) or postoperatively available (pT, pN, Gleason grade obtained on the entire prostate, R status) parameters unanimously revealed an independent prognostic impact of HMGB1 expression in ERG negative cancers ($p<0.0001$) if compared to established prognostic parameters. It is concluded that HMGB1 overexpression is a potentially clinically useful prognostic feature of ERG negative prostate cancer which can be assessed by IHC. The striking impact of the ERG status on the prognostic role of HMGB1 expression could be identified due to high dimension of our patient cohort. It may be possible that other molecular key alterations also critically affect the impact of established prognostic markers in other cancer types.

#5725 Targeting Rac1 as a therapeutic vulnerability in T-cell lymphomas.

Lucero Alvarado[1], Maria M. Debernardi[1], Gonzalo Gonzalez[1], Helena Andrea Sterle[1], Valeria G. Sanchez[1], Silvina Palmer[2], Sofia Rivarola[2], Jorgelia Real[3], Barrozo Julio[3], Goergina A. Cardama[4], **Florencia Cayrol**[1]

[1]UCA Instituto de Investigaciones Biomedicas, Buenos Aires, Argentina,[2]Servicio de Hematologia, Hospital Britanico, Buenos Aires, Argentina,[3]Servicio de Patologia, Hospital Britanico, Buenos Aires, Argentina,[4]Centro de Oncologia Molecular y Traslacional (COMTra), Universidad Nacional de Quilmes-CONICET, Bernal, Argentina

T-cell lymphomas (TCL) are aggressive and heterogeneous neoplasms with limited therapeutic options and poor prognosis, underscoring the need for novel molecular targets. Here, we investigated Rac1, a Rho GTPase that regulates cytoskeletal dynamics, migration, and survival pathways, as a potential therapeutic vulnerability in TCL. Its central role in these tumor-promoting processes suggests that Rac1 inhibition could represent an innovative strategy to limit lymphoma growth and dissemination. We first evaluated the anti-lymphoma activity of the pharmacological Rac1 inhibitor 1A-116 in a panel of TCL cell lines (EL4, CUTLL1, OCI-Ly12, OCI-Ly13.2, HuT78, MJ, Karpas299). Cell viability was assessed by luminescence assay, and apoptosis by caspase-3/7 activity after 48 h of treatment. We found that 1A-116 markedly reduced cell viability in all models ($p<0.01$), with IC_{50} values ranging from 20 to 250 µM, and induced a 60-200% increase in caspase activity ($p<0.05$). Basal Rac1 expression was elevated compared with healthy murine lymph node controls, showing a 30-60% increase across cell lines ($p<0.05$). Consistently, basal phosphorylated PAK 1-3 levels, an indicator of Rac1 pathway activation, were significantly higher in most lines, except for HuT78 and Karpas299, the most resistant cells to Rac1 inhibition. To further validate the therapeutic potential of Rac1 targeting, we used a syngeneic mouse model bearing subcutaneous EL4 tumors. Daily intraperitoneal injections of 1A-116 (20 mg/kg) for nine consecutive days significantly reduced tumor growth, showing an average 80% reduction in tumor area under the curve ($p=0.0071$) and a 79% decrease in final tumor volume ($p=0.0175$), with no overt signs of toxicity. Finally, analysis of three independent TCL RNA-seq datasets (GSE113113, GSE168508, GSE58445) showed that increased expression of Rac1 activators such as VAV1 and TIAM2, and downstream effectors such as PAK2 and GSK3 correlates with advanced disease and poorer survival ($p<0.05$). In line with these findings, Rac1 immunostaining in 14 TCL biopsies revealed positive expression in all cases, underscoring the clinical relevance of Rac1 signaling in TCL. Together, these results identify Rac1 as a key molecular driver in TCL and establish its pharmacological inhibition as a promising and translationally relevant therapeutic strategy. Our study provides a strong rationale for further evaluation of Rac1 inhibitors, either alone or in combination regimens, to improve treatment outcomes in patients with T-cell lymphomas. Overall, these data identify Rac1 signaling as a promising target that may expand the currently limited treatment landscape for these aggressive malignancies.

#5726 Targeting canine bladder cancer with Nimbolide, a Neem (*Azadirachta indica*) limonoid.

Conner Suen[1], Eashan Sharma[2], Gabriel Gilchrist[2], Neelu Batra[3], Christopher A. Lucchesi[3], Kenneth A. Iczkowski[4], Robert B. Rebhun[5], **Paramita M. Ghosh**[3]

[1]Urological Surgery, University of California Davis, Sacramento, CA,[2]Research Service, VA Northern California Health Care System, Sacramento, CA,[3]Urological Surgery, University of California Davis School of Medicine, Sacramento, CA,[4]Pathology and Laboratory Medicine, University of California Davis School of Medicine, Sacramento, CA,[5]Surgical and Radiological Sciences, University of California Davis School of Veterinary Medicine, Davis, CA

Background: The 5-year relative survival rate for Bladder Cancer (BlCa) patients with distant metastases is about 9%. Hence, novel and innovative therapies for metastatic BlCa are required. Dogs were found to develop muscle-invasive BlCa (MIBC) spontaneously and 10% progress to distant metastases at the time of diagnoses. Currently most dogs with MIBC are treated with non-steroidal anti-inflammatory drugs (NSAIDs); however, <25% respond to them. Our quest was to identify low-cost natural compounds of low toxicity that can be used in dogs. Nimbolide, a limonoid extracted from *Neem* leaves, was found to have anti-tumor effects in human BlCa cell lines. Hence, we tested whether this natural product will be effective in canine BlCa cell lines.
Methods: We obtained two canine BlCa cell lines - K9TCC-PU-AXC (AXC), that formed tumors in nude mice and K9TCC-PU-Pu (PuPu), which did not, from Dr. Deborah Knapp, Purdue University. Cell viability was estimated by MTT assay and by live/dead cell staining on 3D-printed spheroids. Flow cytometry was used to estimate the rate of apoptosis. Autophagy was estimated by the expression of LC3B and p62 whereas EMT was estimated by the expression of vimentin, Snail-1, Snail-2, and cell migration was estimated by scratch assay using a Cytation 5 platform.
Results: Nimbolide was more effective in suppressing proliferation in PuPu cells (IC_{50} = 0.656 µM) compared to AXC cells (IC_{50} = 1.2 µM). Flow cytometric analysis showed that AXC did not undergo apoptosis in response to nimbolide whereas PuPu did; however, nimbolide caused autophagy in both cells. On the other hand, nimbolide prevented epithelial mesenchymal transition (EMT) and migration in AXC, but not in PuPu cells. These effects of nimbolide were not seen in human dermal fibroblasts, underlining the specificity and selectivity of nimbolide.
Conclusions: Based on these results, we intend to develop nimbolide as a therapeutic tool in the treatment of canine BlCa in future studies.

#5727 MTAP deficiency is common in head and neck tumors but dependent on the site of tumor origin.

Juliana Knief[1], Christoph Thorns[1], Morton Freytag[2], Florian Lutz[2], Viktoria Chirico[2], David Dum[2], Waldemar Wilczak[2], Katharina Moller[2], Florian Viehweger[2], Fiete Gehrisch[2], Nina Schraps[2], Claudia Hube-Magg[2], Martina Kluth[2], Maria C. Tsourlakis[2], **Ronald Simon**[2], Guido Sauter[2], Natalia Gorbokon[2], Munir Hamad[3], Nikolaus Mockelmann[3], Till Clauditz[2], Adrian Munscher[3]

[1]Pathology-Hamburg, Medizinisches Labor Nord, Hamburg, Germany,[2]Institute of Pathology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany,[3]Department of Ear, Nose, and Throat Medicine, Head and Neck Tumor Center, Marienhospital Hamburg, Hamburg, Germany

Head and neck cancers (HNCs) represent a heterogeneous group of malignancies with highly variable clinical outcomes. Despite advances in surgery, radiotherapy, and systemic treatments, more than 300,000 patients still die from HNC every year worldwide. S-methyl-5′-thioadenosine phosphorylase (MTAP) is encoded by the *MTAP* gene located at 9p21 and is often homozygously co-deleted in cancer together with cyclin dependent kinase 2A (*CDKN2A*). MTAP deficiency results in a critical vulnerability of cancer cells towards drugs targeting multiple pathways. Since MTAP is ubiquitously expressed and homozygous *MTAP* deletions result in a complete expression loss, MTAP immunohistochemistry (IHC) can be used for its detection. To evaluate the prevalence and clinical significance of MTAP expression loss in head and neck cancer, a total of 583 carcinomas were analyzed by immunohistochemistry (IHC) in a tissue microarray format. MTAP expression was lost (0+; MTAP deficiency) in 15.2%, weak (1+) in 31.2%, moderate (2+) in 29.7%, and strong (3+) in 23.9% of 508 interpretable head and neck carcinomas. The prevalence of MTAP deficiency varied markedly between tumors of different sites of origin. MTAP deficiency occurred in 36.0% of 25 cancers of the hypopharynx, 27.0% of 126 cancers of the larynx, 33.3% of 6 carcinomas of the oral cavity, 21.4% of 14 carcinomas of the nasopharynx, but only 8.6% in 336 carcinomas of the oropharynx ($p<0.0001$). MTAP deficiency tended to be more prevalent in tumors of high pT-stage ($p=0.0923$) and in patients with concomitant metastases (M1; $p=0.0625$) but these differences did not reach a level of statistical significance. MTAP deficiency was unrelated to histologic grade of malignancy, nodal metastasis, L-status, and V-status. Among 432 head and neck cancers lacking MTAP deficiency, the level of MTAP expression (1+ vs 2+ vs. 3+) was unrelated to parameters of cancer aggressiveness. It is concluded from our data, that MTAP deficiency occurs in a relevant fraction of head and neck cancers. Once anti-MTAP treatments should become safe and efficient and approved for patient treatment, many patients with these tumors could benefit. Moreover, IHC analysis for MTAP deficiency appears to have diagnostic utility in assessing dysplasia, given its high prevalence in grade 1 carcinomas.

#5728 Amplicon-based DNA and RNA NGS co-detection enhances ROS1 fusion detection and partner diversity compared with hybrid-capture DNA-NGS in Chinese NSCLC.

Yang Zebo

Cardiothoracic Surgery Department, Yichang Central People's Hospital, Yichang City, China

Background: ROS1 rearrangements are important actionable drivers in non-small cell lung cancer (NSCLC), yet traditional DNA-based assays show limited sensitivity for detecting these fusions. RNA-NGS has been demonstrated to outperform DNA-NGS in fusion detection; however, the relative performance of amplicon-based DNA+RNA NGS co-detection versus hybrid-capture DNA-NGS for identifying ROS1 fusions in large real-world NSCLC populations remains insufficiently characterized.
Methods: We retrospectively analyzed ROS1 fusion detection in NSCLC samples using two next-generation sequencing strategies: a 35-gene amplicon-based DNA+RNA NGS co-detection assay (n = 11,242) and a hybrid-capture DNA-NGS assay (n = 2,504). For both approaches, ROS1 fusion-positive cases were identified, and all confirmed rearrangements were annotated for fusion partners. Detection rates and partner diversity were compared to evaluate differences in analytical performance between the two platforms.
Results: Amplicon-based DNA+RNA NGS co-detection demonstrated a higher ROS1 fusion detection rate (1.82%, 205/11,242) than hybrid-capture DNA-NGS (1.56%, 39/2,504). Amplicon-based DNA+RNA NGS co-detection identified a wide variety of classical 5′-3′ ROS1 fusion partners, with CD74-ROS1 (46.34%), EZR-ROS1 (22.93%), and SDC4-ROS1 (16.10%) being the most prevalent, followed by less frequent partners such as TPM3-ROS1(10/205, 4.88%), SLC34A2-ROS1(7/205,3.41%), CCDC6-ROS1(5/205,2.44%), GOPC-ROS1(2/205,0.98%), TPR-ROS1(2/205,0.98%), and several rare events including EML4-ROS1(1/205,0.49%), LRIG3-ROS1(1/205,0.49%), PPFIBPI-ROS1(1/205,0.49%), and ZCCHC8-ROS1(1/205,0.49%). In contrast, hybrid-capture DNA-NGS detected a narrower spectrum of partners, dominated by CD74-ROS1 (58.97%), SDC4-ROS1 (20.51%), and EZR-ROS1 (12.82%), with only isolated occurrences of GOPC-ROS1, TPM3-ROS1, and a single ROS1-SLC34A2 event. All rearrangements detected by either method were classical 5′-3′ fusions.
Conclusion: In this large real-world cohort, amplicon-based DNA+RNA NGS co-detection outperformed hybrid-capture DNA-NGS by yielding a higher ROS1 fusion detection rate and uncovering a more diverse spectrum of ROS1 fusion partners. These findings highlight the importance of integrating RNA-based analysis into routine NGS workflows to enhance the detection accuracy of actionable gene fusions and support more precise therapeutic decision-making for patients with NSCLC.

#5729 Discovery of tumor-specific antigens in melanoma tissue biopsies via integrated proteogenomic analysis.

Arthur Viode[1], Daniel Gautheret[2], Anamarija Pfeiffer[1], Hughes Hermann[3], Sharane Muralli[3], Severine Roy[4], Antoine Meant[3], Amaury Lachaud[1], **Yuehan Feng**[1], Caroline Robert[3]

[1]Biognosys AG, Schlieren, Switzerland,[2]Institute of Integrative Biology of the Cell (I2BC), Universite Paris-Saclay, CEA, CNRS, Gif-sur-Yvette, France,[3]Biomarqueurs predicteurs et nouvelles strategies moleculaires en therapeutique anticancereuse, Universite Paris-Saclay, Gustave Roussy, Inserm, Villejuif, France,[4]Biomarqueurs predicteurs et nouvelles strategies moleculaires en therapeutique anticancereuse, Gustave Roussy, Inserm, Villejuif, France

Background
Despite significant progress in therapeutic outcomes, melanoma remains frequently resistant to immunotherapy. Efforts to improve response rates include the development of vaccines targeting tumor neoantigens; however, the optimal tumor-associated antigens (TAAs) to target remain uncertain. Recent evidence suggests that the most relevant TAAs may originate from non-mutated protein sequences, including those derived from the so-called dark proteome (1). In this study, we conducted an immunopeptidomic analysis of tumor samples obtained from patients with metastatic melanoma before initiation of systemic therapy
Methods
A total of 35 tumor biopsy samples from melanoma patients were subjected to native tissue lysis, followed by immunoaffinity purification of HLA class I complexes using a pan HLA class I antibody (W6/32) and subsequent elution of the bound immunopeptides. The isolated immunopeptides were analyzed using data-independent acquisition (DIA) mass spectrometry on an Exploris 480 mass spectrometer (Thermo Scientific) equipped with FAIMS Pro. Data analysis was performed using Spectronaut 20 (Biognosys) using directDIA.
For peptide identification, a customized human proteome database was constructed to enable the detection of tumor-associated antigens (TAs). This database included the canonical and isoforms human proteome, a previously reported TA reference dataset (1), and an in-house generated “dark genome” database derived from tumor RNA-sequencing data.
Results
Analysis of these 35 melanoma tissue samples yielded in total over 120,000 unique immunopeptides with an average of ~15,000 per sample, with notable inter-sample variability (ranging from ~6,000 to >28,000 identifications). All samples displayed the expected HLA class I length distribution, with a predominant population of 9-mer peptides. Across the cohort, approx. 70 previously reported tumor-associated antigens (TAs) were identified, spanning multiple categories including tumor-associated antigens (TAA), lineage-specific antigens (LSA), and aberrantly expressed tumor-specific antigens (aeTSA). These TAs originated from both annotated open reading frames (ORFs) and noncanonical translation events such as frameshifts, noncoding RNA (ncRNA), and 5′UTR-derived peptides.
From the RNA-seq-derived database, approximately 22 immunopeptides were mapped to sequences originating from both annotated genes (18 peptides) and previously uncharacterized genomic regions (4 peptides; dark genome).
Together, these results demonstrate that the applied proteogenomic immunopeptidomics workflow enables the detection of tumor-specific and neoantigenic peptides directly from clinical melanoma biopsy samples, underscoring its potential utility in translational immuno-oncology research.

#5730 CDX1 binding to the *PVT1* exon 9-associated promoter drives oncogenic *PVT1* exon 9 overexpression in aggressive prostate cancer.

Chinedum C. Udekwu[1], Siti K. Nuraziza[1], Seidu Adams[1], Rachel E. Bonnaci[1], E. Oluwabunmi Olapade-Olaopa[2], Olorunseun O. Ogunwobi[1]

[1]Biochemistry and Molecular Biology, Michigan State University, East Lansing, MI,[2]Department of Surgery, University of Ibadan, Ibadan, Nigeria

This study elucidates a previously uncharacterized epigenetic-transcriptional regulatory axis involving the transcription factor CDX1 and the *PVT1* exon 9-associated promoter (PEAP) that governs *PVT1* exon 9 overexpression in aggressive prostate cancer. The long noncoding RNA (*lncRNA*) *PVT1*, located at the 8q24 oncogenic locus, has been implicated in prostate tumorigenesis and progression; however, the molecular mechanisms underlying its exon-specific transcriptional activation remains obscure. Through in silico motif discovery using FIMO analysis, we identified a high-affinity CDX1 consensus binding site within the PEAP sequence, suggesting a potential transcriptional regulatory role. DNA methylation profiling of matched prostate tumor and adjacent normal tissues from prostate cancer patients demonstrated promoter hypomethylation at PEAP, concomitant with a significant upregulation of *PVT1* exon 9. While siRNA-mediated CDX1 silencing in *PVT1* exon 9 overexpressing cells (MDA-PCa-2b and C22OH) attenuated *PVT1* exon 9 expression, CDX1 overexpression in RWPE-1 cells enhanced *PVT1* exon 9 transcription. Immunohistochemical and immunofluorescence analysis corroborated the nuclear localization and elevated expression of CDX1 in high-Gleason-grade tumors, underscoring its role as a transcriptional activator. Using digital PCR, CRISPR-mediated base editing of the CDX1 binding sequence on PEAP in MDA-PCa-2b and C22OH revealed drastic reduction in *PVT1* exon 9 copy number compared to scramble. Collectively, these findings delineate a CDX1-PEAP-PVT1 signaling axis that is dependent on CDX1 binding to PEAP, thereby driving oncogenic *PVT1* exon 9 overexpression. This mechanistic insight provides a novel framework for understanding *PVT1* exon-specific regulation and positions the CDX1-PEAP interaction as a promising molecular target for therapeutic interventions in *PVT1* exon 9 overexpressing prostate cancers.

#5731 ID4 maintains undifferentiated and immune-evasive states in aggressive triple-negative breast cancer and represents a novel druggable vulnerability.

Lautaro Rivera[1], Carla Toro[1], Juan Manuel Fernandez[2], Jochen Maurer[3], **Maria Teresita Branham**[1]

[1]IHEM-CONICET, Mendoza, Argentina,[2]FCM-UNCuyo, Mendoza, Argentina,[3]RWTH Aachen University Hospital, Aachen, Germany

Background: Inhibitor of Differentiation 4 (ID4) is overexpressed in triple-negative breast cancer (TNBC) and is essential for proliferation, anchorage-independent growth, and tumorigenicity of MDA-MB-231 cells. These findings position ID4 as a candidate driver of undifferentiated, aggressive TNBC phenotypes. However, its expression pattern across molecularly heterogeneous TNBC subtypes and its therapeutic potential remain undefined.

Methods: We integrated *in silico* analyses of clinically annotated TNBC cohorts with functional studies in ID4-high TNBC models. ID4 expression and co-expression patterns across TNBC subtypes were evaluated using bc-GenExMiner v5.2. ID4 was silenced by CRISPR-Cas9 or shRNA in three representative TNBC cell lines: MDA-MB-231 (mesenchymal stem-like, MSL), MDA-MB-468 (basal-like 1), and BT-549 (mesenchymal-like). Pharmacologic ID4 degradation was achieved using AGX51, a first-in-class pan-ID degrader. Proliferation was monitored by MTT assay and IncuCyte live-cell imaging. Drug response was further assessed in five patient-derived basal-like breast cancer stem cell (BCSC) cultures, with proliferation evaluated in all five and mammosphere formation in two.

Results: *In silico* analysis revealed that ID4 expression is significantly enriched in the two most aggressive, immune-suppressed TNBC subtypes: basal-like immune-suppressed (BLIS) and mesenchymal-like immune-altered/immunomodulatory (MLIA; formerly mesenchymal stem-like/MSL). In MLIA tumors, ID4 strongly co-expresses with mesenchymal, myoepithelial, and stemness programs (YAP/TAZ-Hippo, FOXC1, SOX10, ACTA2, and basal cytokeratins). Both genetic silencing and pharmacologic degradation of ID4 markedly impaired proliferation across all tested cell lines and BCSC cultures. Notably, AGX51 completely disrupted mammosphere formation and 3D structural integrity in the two BCSC models examined. Stable ID4-knockout and knockdown TNBC cell lines were successfully generated for ongoing RNA-seq and DNA-methylation profiling.

Conclusions: These data establish ID4 as a subtype-enriched, druggable vulnerability in the most aggressive and immune-suppressed TNBC subsets. Ongoing transcriptomic and epigenomic studies will elucidate the molecular circuits governed by ID4 and identify rational combination strategies for BLIS, MLIA, and mesenchymal stem-like TNBC. This abstract incorporates text revised with the assistance of artificial intelligence for language clarity and conciseness

#5732 Identification and functional analysis of chloride intracellular channel protein 1-binding peptide and its uses for ProTac-based cancer therapy.

Aryeong Lee, Byungheon Lee

Kyungpook National University, Daegu, Korea, Republic of

Targeted therapy using antibodies that treat only certain cancer cells is currently being studied because it causes less side effects on normal cells. Compared to antibodies, peptides are relatively smaller and have higher tissue penetration ability and lower immunogenicity. Chloride intracellular channel protein1 (CLIC1) is a metamorphic protein as it can exist in two forms: soluble globular protein in the cytoplasm or transmembrane protein. CLIC1 is related to cancer angiogenesis, cell migration and metastasis and is upregulated in various types of cancer, including hepatocellular carcinoma and lung cancer, presenting it as a promising therapeutic cancer target. In this study, we identified a peptide candidate (CLIC1pep) that binds to CLIC1 using phage display. The affinity and specific binding of CLIC1pep to CLIC1 was validated by SPR, ELISA, and pull-down assays. CLIC1pep linked to a cell-penetrating peptide (R7) (R7-CLIC1pep) showed an increased cell penetration and binding to CLIC1 in the cytoplasm, whereas it did not induce tumor cell death. However, R7-linked CLIC1pep inhibited the membrane insertion of CLIC1 and reduced the migration and invasion of cancer cells through reducing the p-ERK levels. Moreover, R7-CLIC1pep-linked E3 ligase peptide was synthesized for a ProTAC against CLIC1 and degraded CLIC1 in tumor cells. These results suggest that R7-CLIC1pep and R7-CLIC1pep-linked E3 ligase peptide hold a potential for a ProTac-based cancer therapy of CLIC1-high tumors.

#5733 Decoding ELAVL4 isoaspartylation in SCLC using engineered PCMT1: A strategy for uncovering immune triggers.

Davin Pan[1], Shiori Fukutome[1], Xuhan Zhou[1], Diego De Luna Moran[1], Chunli Yan[1], Diego Alejandro Velarde[1], Whitaker Cohn[2], Ite A. Offringa[1]

[1]USC Norris Comprehensive Cancer Center, Los Angeles, CA,[2]Department of Clinical Pharmacy, USC Mann School of Pharmacy, Los Angeles, CA

The 5-year survival rate for SCLC patients is only 9%-new therapies are urgently needed. Approximately 15% of SCLC patients develop a low-titer immune response against the neuronal protein embryonic lethal abnormal vision-like 4 (ELAVL4), exhibiting significantly improved survival. In the lung, ELAVL4 is uniquely expressed in pulmonary neuroendocrine cells, the primary cell of origin of SCLC. Prior research in our lab suggests that the anti-ELAVL4 immune response originates from an immunogenic type of post-translational damage called isoaspartylation. We previously mapped the isoaspartylation of ELAVL4 to the 38-amino acid N-terminal unstructured region, upstream of the RNA recognition motif domain (RRM1). Isoaspartylation can occur at asparagine and aspartic acid residues, most commonly when they are located in a flexible protein region and followed by a small amino acid (glycine, serine, or histidine). The asparagine or aspartate side chain reacts with the main chain, forming a cyclic succinimide intermediate that, in 70% of cases, resolves to an isoaspartate (isoAsp), thereby kinking the peptide backbone. Isoaspartylation is repaired by the enzyme protein-L-isoaspartate (D-aspartate) O-methyltransferase (PCMT1) in vivo. PCMT1 deficiency is invariably fatal in mice, illustrating the essential nature of this repair enzyme. PCMT1 utilizes the methyl donor S-adenosylmethionine (SAM) to initiate repair, producing S-adenosylhomocysteine (SAH), which can be quantified via ELISA and bioluminescent assays. Mapping the isoaspartylation site(s) in ELAVL4 is essential, as this will help identify the antigenic epitope used to design future targeted immunotherapies for SCLC patients. However, mapping of isoaspartylation sites is challenging due to minimal molecular weight differences between asparagine, aspartate, and isoaspartate residues. In the past, tritiated SAM has been used in conjunction with PCMT1 to label proteins and detect isoaspartylation. Here, we investigate whether PCMT1 can be utilized in conjunction with mass spectrometry to methylate and detect isoaspartylation in ELAV4. This method is site-specific and avoids the use of radioactivity. We will also assess substrate binding kinetics using a Bruker heliX biosensor. Improved detection and mapping of isoaspartylation sites in ELAVL4 can help identify therapeutic targets that leverage the anti-isoaspartylated ELAVL4 response for new SCLC treatments. Supported by the Robert E. and May R. Wright Foundation Transformative Cancer Research Grant, USC's Undergraduate Research Associates Program, and the Norris Comprehensive Cancer Center core grant, NIH/NCI P30CA014089. DAV and IAO are members of CaRE2 the Cancer Research Education and Engagement Health Center, supported by NIH/NCI grants U54CA233396, U54CA233444, and U54233465.

#5734 Targeting exportin 1 reduces cutaneous squamous cell carcinoma growth alone and in combination with 5-fluorouracil.

Moynul Islam, Justin Rudd, Louise Monga, James Grunkemeyer, Laura Hansen

Biomedical Sciences, Creighton University, Omaha, NE

Background: Cutaneous squamous cell carcinoma (cSCC) affects approximately 1.8 million people annually in the US with an increasing number of cases. Nuclear-cytoplasmic transport of proteins and RNA is vital for cellular homeostasis and becomes dysregulated in skin cancer. Exportins like Exportin 1 (XPO1) transport cargo from the nucleus to the cytoplasm and are upregulated in multiple cancer types. We found increased expression of XPO1 in premalignant actinic keratosis and cSCC. The Exportin 1 inhibitor Selinexor is FDA approved for the treatment of relapsed multiple myeloma and refractory large diffuse B cell lymphoma. This project aimed to determine whether XPO1 targeting could be a useful strategy for the treatment of cSCC, as well as to identify additional targets for combination therapy with XPO1 inhibition. Thymidylate synthase (TYMS) inhibitor 5-Fluorouracil (5-FU), used clinically for the treatment of actinic keratosis and superficial basal cell carcinoma was identified as a potential agent in combination with Selinexor.
Methods: XPO1-targeted or control shRNA was introduced into human cSCC cell line SCC-13 and validated. cSCC cells or subcutaneous tumors were treated with Selinexor or the vehicle. IC_{50}s were established for Selinexor in HaCaT, KerCt, SCC-13, SCC-12B.2, COLO-16, and SRB1 cells, and for other inhibitors in SCC-13 cells. Flow cytometry and Caspase-Glo assays were used for cell cycle and apoptosis analyses. Genome-wide CRISPRi screen was performed in SCC-13 dCas9-KRAB cells and analyzed by MAGeCK followed by GSEA. *In vitro* synergy between 5-FU and Selinexor was evaluated using SynergyFinder 3.0. In addition, we assessed the effects of XPO1 inhibition and of 5-FU-Selinexor combination treatment on TYMS and key DNA damage repair proteins (MLH1, MSH2, CHEK1) using immunoblotting.
Results: XPO1 knockdown or inhibition using Selinexor caused cell cycle arrest and apoptosis of SCC-13 cells. Selinexor was effective at killing cSCC cells with submicromolar IC_{50}s and significantly reduced tumor growth in SCC-13 xenografts. The genome-wide CRISPRi screen identified 293 genes that increased cSCC cell sensitivity and 70 genes that increased resistance to Selinexor. The sensitizers were enriched in DNA damage repair pathways. XPO1 inhibition decreased TYMS and key DNA damage repair proteins (MLH1, MSH2, and CHEK1). 5-FU and Selinexor together decreased the expression of these DNA damage repair proteins compared to Selinexor alone and caused synergistic cell death of SCC-13 cells.
Conclusions: Inhibition of XPO1 was effective at killing cSCC cells in culture and in xenografts. Our genome-wide CRISPRi screen, identified 293 potential sensitizers of Selinexor, one of which was TYMS, the target of 5-FU. 5-FU-Selinexor combination were more effective than either agent alone, suggesting this combination may have potential for the treatment of nonmelanoma skin cancer.

#5735 Imiquimod targets tankyrase 2 to suppress wnt-active colorectal cancer.

Philemon Ubanako[1], Ramesh Pandian[2], Adedapo Adeyinka[3], Bernice Monchusi[1], Clement Penny[1]

[1]Internal Medicine, University of the Witwatersrand, Johannesburg, South Africa,[2]Protein Structure and Function Unit, University of the Witwatersrand, Johannesburg, South Africa,[3]Chemical Sciences, University of Johannesburg, Johannesburg, South Africa

The Wnt/β-catenin signaling pathway is frequently upregulated in colorectal cancer (CRC), driving tumor progression and therapeutic resistance. Tankyrase (TNKS), a key regulator of this pathway, has emerged as a promising therapeutic target. XAV939, a small-molecule inhibitor of TNKS, has been widely used to study Wnt pathway inhibition. TNKS inhibitors suppress Wnt signaling by stabilizing Axin, a key component of the β-catenin destruction complex, which leads to enhanced degradation and thus a reduction in the cellular and nuclear levels of β-catenin. We investigated the anticancer potential of Imiquimod (IMQ), a Toll-like receptor 7 (TLR7) agonist, through its interaction with TNKS2. Molecular docking and dynamics simulations revealed that IMQ binds stably to the PARP catalytic domain of TNKS2, with a higher docking score than the co-crystallized ligand. Notably, IMQ formed critical interactions with residues Tyr1060 and Glu1138, located within the catalytic core of TNKS2, suggesting its ability to modulate Wnt/β-catenin signaling. Cytotoxicity and cell cycle analysis demonstrated differential sensitivity to IMQ and XAV939, across colorectal cancer and normal cell lines. Interestingly, confocal microscopy revealed that IMQ significantly reduced β-catenin expression in DLD1 CRC cells harboring wild-type β-catenin, while no significant decrease was observed in HCT116 CRC cells with mutant β-catenin. This study reveals a novel potential route for repurposing a clinically approved agent to suppress Wnt-driven oncogenesis. This is the first study to propose a mechanism by which IMQ may inhibit Wnt/β-catenin signaling.

#5736 BMAL2 maintains DNA integrity via regulating homologous recombination to promote ovarian clear cell carcinoma tumorigenesis.

Grace Yin Tze Tan, Pei-Yi Lin, Li-Tzu Cheng, Wendy Wenhua Hwang-Verslues

Genomics Research Center, Academia Sinica, Taipei, Taiwan

Ovarian cancer is the most lethal gynecologic malignancy worldwide. Among its subtypes, ovarian clear cell carcinoma (OCCC) is characterized by its intrinsic chemoresistance, poor prognosis, and lack of effective therapies. To date, only ARID1A mutant OCCC has shown modest sensitivity to PARP inhibitors, highlighting the urgent need for novel therapeutic targets. Here, we identified BMAL2, a circadian transcription as a critical DNA integrity regulator in OCCC cells. BMAL2 depletion downregulated RAD51, impaired homologous recombination-mediated DNA repair thereby inhibited cell survival and tumor growth. To pharmacologically target BMAL2, we performed structure-based virtual screening and identified GW-833972A as a small-molecule inhibitor that effectively bound and degraded BMAL2 protein. Mechanistically, GW-833972A mediated BMAL2 degradation impaired DNA repair and suppressed tumor growth *in vivo*. Collectively, these findings reveal the critical oncogenic role of BMAL2 in OCCC and demonstrate that BMAL2 inhibition offers a promising therapeutic strategy for this chemoresistant cancer.

#5737 Developing agents to target IL-8 signaling and intercept progression to esophageal adenocarcinoma.

Yun Zhang[1], Andrew Alt[2], Nick Santoro[2], Shari Barnett[1], Kiran Lagisetty[1], Jules Lin[1], Rishindra M. Reddy[1], Chigozrim Ekeke[1], Andrew Chang[1], David Odell[1], Laura A. Kresty[1]

[1]University of Michigan, Ann Arbor, MI,[2]Center for Chemical Genomics Members, Life Science Institute, Ann Arbor, MI

The goal of this research was to investigate whether agents targeting Interleukin (IL)-8 and its chemokine receptors (CXCR) 1 and 2 can be identified and exploited to intercept the progression of Barrett's esophagus (BE) to esophageal adenocarcinoma (EAC). Experimental approaches investigated circulating and transcript level changes in IL-8 and CXCR1/2 in EAC progressors and patients with BE, the only known precursor lesion, compared to non-cancer controls or normal tissue, respectively. Gene set enrichment analysis (GSEA) investigated the IL-8 signaling axis in esophageal tissues with progressive pathology changes from BE with low-grade dysplasia (BE.LGD) to BE with high-grade dysplasia (BE.HGD) and EAC. Deconvolution analysis further assessed immune cell alterations in this cohort. Finally, EAC and BE cell lines were employed to investigate various IL-8 assays and determine whether select agents targeting IL-8 signaling induced cell death in BE.HGD or EAC cells. Results showed that plasma IL-8 levels were 3.6-fold (p=0.039) higher in EAC patients compared to non-cancer controls. Moreover, significantly elevated tissue levels of IL-8, CXCR1 and CXCR2 were detected in BE.HGD or EAC compared to BE.LGD. GSEA further implicated the IL-8-CXCR-signaling axis by revealing that 60% of the up-regulated pathway maps during EAC progression contained IL-8 or its receptors (i.e., IL-8-dependent cell migration and adhesion, neutrophil chemotaxis and release of pro-inflammatory factors). Deconvolution analysis identified alterations in multiple immune cell populations with BE progression (BE.LGD to BE.HGD), including up-regulation of neutrophils, which secrete IL-8 and are an abundant cell type at sites of inflammation. Conversely, NK cells, which respond to cellular stress and mediate tumor killing, were downregulated. Proof-of-concept studies conducted in BE.HGD and EAC cell lines showed that a natural product, cranberry proanthocyanidins, as well as the drug lanraplenib, both significantly inhibited IL-8 secretion, followed by potent cell death induction. However, a recent clinical trial with lanraplenib resulted in unacceptable toxic side effects. Ultimately, these results support that IL-8 signaling is induced early during the transition from BE.LGD to BE.HGD and that elevated levels are sustained through EAC development. Thus, we plan to screen the NCI's natural product library for agents that inhibit the IL-8-CXCR-immune signaling axis and that, in turn, may offer efficacious options to intercept BE progression to EAC. This research was supported in part by NCI 1UG3CA299397-01, along with other funding sources.

#5738 Beyond bulk: Resolving RNASeq/mass spectrometry/IHC discrepancies with multiplexed spatial profiling and 3D cluster analysis to refine HER3 (bs)Ab and (bs)ADC therapeutic strategies.

Jeannette Fuchs, Christophe Mas, Eric Durandau, Diana Rocha Gomes, Min Ma, Antoine Attinger, Anna Pokorska-Bocci

Translational Medicine, Debiopharm International S.A., Lausanne, Switzerland

Assessment of target expression for mono- and bispecific antibodies (Ab/bsAb) and antibody-drug conjugates (ADCs/bsADCs) can be challenging due to poor correlation between bulk RNASeq, proteomics and immunohistochemistry (IHC) data. While IHC is sufficient to address single target expression levels at single cell level, multiplexing is required to assess spatial distribution and expression thresholds of multiple targets for bsAb and bsADC use.
To address these challenges, we performed a full characterization of (bs)ADC targets in patient-derived xenografts (PDX) across different omics platforms. Based on these outputs, we created a 3D biologics-tailored analysis tool which allows multifactorial target assessment to guide PDX model selection for evaluation of (bs)Ab/ADC sensitivity.
HER3 and other selected tumor-associated antigens (TAA) were investigated, showing different levels of mRNA/protein correlations and different levels of mass spec-derived proteomics versus IHC. Based on these results, PDX models with a pre-defined TAA expression spectrum were selected for multiplexed spatial proteomics to determine single cell expression intensities and co-localization of those TAAs. Our 3D biologics analysis tool facilitates a multifactorial, granular assessment of the selected targets.
The target-specific variability of correlation between the different analytes highlights once again the importance of proper omics/IHC platform selection depending on each individual target. Once the appropriate expression values are identified, the 3D analysis tool allows dynamic adjustment of expression thresholds of multiple targets with the potential to inform on the sample-specific most promising (bs)Ab/ADC treatment options.

#5739 Defining sodium channel isoforms in oral squamous cell carcinoma *in vitro.*

Kelly Jean Sherman[1], Alexis Gray[2], Dennis Paul[3]

[1]Pharmacology and Experimental Therapeutics, LSU Health New Orleans, New Orleans, LA,[2]Mount Carmel Academy, New Orleans, LA,[3]LSU Health New Orleans, New Orleans, LA

Overview: Sodium channels overexpression contributes to invasion and metastatic behavior and plays a functional role in cancer progression. Many knowledge gaps remain in voltage-gated sodium channels (VGSC's) subtype's role in metastasis, as well as distinguishing the difference of cancer progression of Oral Squamous Cell Carcinoma (OSCC) HPV(-) and HPV(+). Defining isoform-specific regulatory roles in OSCC may serve as potential targets for novel therapeutic treatments. The purpose of the study was to define VGSC isoforms regulating the cell growth, motility, and invasiveness in OSCC.
Methods: To access sodium channel expression patterns and comparisons of components of metastasis, we used two OSCC cell lines, Cal-27 HPV(-) and SCC-090 HPV(+). We measured motility in wound healing, area progression of invasiveness, cell proliferation over time treated with TNF-α, and compared VGSC isoforms and organelle expression patterns using microscopy.
Results: Motility rate for Cal-27 was significantly higher than SCC-090. When treated with TNF-α there was no significant difference relative to controls for either cell line. Invasiveness of Cal-27 exhibited significantly greater migration compared to SCC-090. Under low-glucose conditions, Cal-27 demonstrated a significant decrease in migration, whereas SCC-090 had no significant change. At 24 hours, there was no significant difference in cell growth of either cell line; however, by 48 hours, Cal-27 had a significantly higher growth. Both cell lines treated with TNF-α, demonstrated a concentration-dependent response, with SCC-090 showing a significant reduction in proliferation at higher concentrations. Immunofluorescence was performed for all VGCS isoforms (NaV1.1 - 1.9) and centrosome marker, anti-PCM-1. NaV1.6 and NaV1.7 display distinct expression patterns as punctate signals in both cell lines. In SCC-090 cells, PCM-1 expression closely resembled the NaV1.6/NaV1.7 localization.
Conclusion: Cal-27 cells exhibited greater migratory and proliferative capacity than SCC-090, particularly evident through higher motility at 24 hours, increased migration, and proliferation by 48 hours. While TNF-α did not alter migration in either cell line, it produced a concentration-dependent decrease in proliferation, most notably in SCC-090. Metabolic stress further differentiated between the two lines: low glucose significantly impaired migration in Cal-27 but had no effect on SCC-090. Immunofluorescence revealed that NaV1.6 and NaV1.7 exhibited distinct punctate localization patterns in both cell lines. In SCC-090, this pattern closely aligned with PCM-1 staining. Together, these findings highlight functional and phenotypic differences between Cal-27 and SCC-090.

: Multi-Axis Antineoplastic Agents

#5743 Discovery of a novel orally available microtubule-destabilization agent that targets the colchicine binding site and exhibits antitumor activity in *KRAS*-mutant models.

Yeni K. Romero, Joshua W. Large, Kylie Luther, Molly M. Hood, Ranjan Preet, Chase K. Crawley, Salim Javed, Yu Mi Ahn, Forrest A. Stanley, Bertrand Le Bourdonnec, Bryan D. Smith, Daniel L. Flynn, Jeffery D. Zwicker, Stacie L. Bulfer

Deciphera Pharmaceuticals, LLC, Waltham, MA

Background: Microtubules are essential for regulating cell growth, cell division, protein trafficking, and key cell signaling events. Alterations to the microtubule network affect cell survival, thus making microtubule-targeting agents desirable as cancer therapeutic agents. Currently, several tubulin modulators are approved for cancer treatment. However, development of additional microtubule-targeting agents is still needed to improve treatment outcomes, mitigate side effects, and overcome resistance mechanisms. Here, we describe compound A, a novel, orally available microtubule-destabilizing agent that targets the colchicine binding site and exhibits single-agent antitumor activity in *KRAS*-mutant models.

Methods: Inhibition of tubulin polymerization was measured using a recombinant polymerization assay and a cell-based microtubule sedimentation assay. Binding to the colchicine site of tubulin was determined by a binding competition assay using a BODIPY-colchicine probe. Disruption of tubulin formation was determined by immunofluorescence of microtubules in A549 cells. Compound binding to the tubulin complex was determined via X-ray crystallography. Cellular proliferation of *KRAS*-mutant and isogenic cell lines was measured using resazurin. *KRAS*-mutant mouse xenograft models were used to assess pharmacokinetics (PK), pharmacodynamics, and antitumor activity.

Results: Compound A binds to the colchicine site and destabilizes tubulin polymerization. Treatment resulted in single-agent inhibition of proliferation of *KRAS*-mutant cancer cell lines. Immunofluorescence of microtubules in A549 cells revealed disruption of the microtubule network and dysregulated spindle formation. Compound A exhibited a favorable ADME and PK profile. Oral treatment of compound A as a single agent resulted in 56% tumor growth inhibition in a subcutaneously implanted *KRAS*-mutant lung xenograft model.

Conclusions: Compound A is an orally bioavailable tubulin modulator that binds to the colchicine site and inhibits tumor growth in a *KRAS*-mutant model as a single agent. Our preclinical data provide proof of concept for the development of an orally available microtubule-destabilizing agent.

#5744 Robust anti-tumor activity of the novel KIF18A inhibitor, ATX-295, in preclinical models of chromosomally instable tumors.

Laura Ghisolfi[1], Maureen M. Lynes[1], April Greene-Colozzi[1], David Sutton[1], Jie Wu[1], Livia Shehaj[1], Brian A. Sparling[1], Inbal Gazy[2], Stuart J. Ince[1], Jason A. Sager[1], Serena J. Silver[1]

[1]Accent Therapeutics, Lexington, MA,[2]Imagene AI, Tel Aviv, Israel

KIF18A is a plus-end directed kinesin known to play a role in mitosis by facilitating chromosome alignment and spindle microtubule dynamics. TP53 mutant cells with ongoing chromosomal instability (CIN), such as a subset of aneuploid or whole genome doubled cells, are particularly vulnerable to disrupted mitosis upon KIF18A knockdown or knockout. These findings indicate that KIF18A is a compelling oncology target in the setting of tumors with high levels of chromosomal instability. Analysis of the Cancer Genome Atlas (TCGA) demonstrates that high grade serous ovarian cancer (HGSOC), triple negative breast cancer (TNBC), and squamous non-small cell lung cancer (sqNSCLC) have a high prevalence of CIN, and as such have the potential for therapeutic benefit from KIF18A inhibition. Accent Therapeutics has identified ATX-295, a highly potent and selective inhibitor of KIF18A. ATX-295 has robust *in vitro* anti-proliferative activity in HGSOC, TNBC, and sqNSCLC cell lines. Consistent with the role of KIF18A in orchestrating mitosis in CIN cells, ATX-295 treatment induces phospho-histone H3 (p-HH3) in sensitive cell lines. This corresponds to a dose-dependent increase in G2M arrest and apoptosis selective to CIN cell lines. To further validate the opportunity for ATX-295 in CIN tumor types, it was tested *in vivo* in patient-derived xenograft (PDX) studies in models derived from HGSOC and TNBC patients. Whole genome doubling (WGD) is a known correlate of CIN; robust and durable efficacy was achieved by ATX-295 treatment in WGD+ (positive) HGSOC and TNBC PDX models. These findings support CIN and WGD as predictive biomarkers for ATX-295 response. To assess clinical feasibility, an H&E-based WGD detection model was developed using Imagene AI's OI Suite and TCGA-labeled samples. The model achieved >0.8 AUC on a held-out test set within minutes, demonstrating proof-of-concept for AI-based WGD detection in clinical samples. ATX-295 is currently being evaluated in a first-in-human, Phase 1/2 open-label study assessing safety, pharmacokinetics, pharmacodynamics, and preliminary antitumor activity in patients with advanced solid tumors and ovarian cancer (NCT06799065).

#5745 Discovery of AZD4956, a potent and selective inhibitor of DNA polymerase theta, a clinical candidate for treatment of HRR-deficient tumors in combination with saruparib.

Bernard Barlaam[1], Josep V. Forment[2], Lee Mulderrig[2], de Renty Christelle[2], Harriet Southgate[2], Adina Hughes[2], Derek Barratt[3], Nina Akrap[4], Marcello Maresca[4], Oliver Turner[1], Dougles Ferguson[5], Andy Pike[6], Ross Hill[7], Lenka Oplustil O'Connor[7], Kainat Khan[8], Sonja Gill[8], Stefan Kavanagh[8], Susan Critchlow[2], Sabina Cosulich[9], David Wilson[10]

[1]Oncology Targeted Discovery Chemistry, AstraZeneca, Cambridge, United Kingdom,[2]Oncology Targeted Discovery Bioscience, AstraZeneca, Cambridge, United Kingdom,[3]Discovery Sciences, AstraZeneca, Cambridge, United Kingdom,[4]Discovery Sciences, AstraZeneca, Gothenburg, Sweden,[5]Oncology Targeted Discovery DMPK, AstraZeneca, Waltham, MA,[6]Oncology Targeted Discovery DMPK, AstraZeneca, Cambridge, United Kingdom,[7]Oncology Translational Medicine, AstraZeneca, Cambridge, United Kingdom,[8]Clinical Pharmacology and Safety Sciences, AstraZeneca, Cambridge, United Kingdom,[9]Early Oncology Programs Group, AstraZeneca, Cambridge, United Kingdom,[10]Oncology Targeted Discovery Chemistry and DMPK, AstraZeneca, Cambridge, United Kingdom

Deficiency in the homologous recombination repair (HRR) pathway, which is key for high-fidelity DNA double-strand break (DSB) repair, is prevalent across various cancers (including ovarian, breast, pancreatic, and prostate). It frequently arises from loss-of-function mutations in *BRCA1*, *BRCA2*, or other HRR-associated genes. PARP inhibitors (PARPi) have transformed the treatment landscape and survival outcomes in patients with HRR-deficient tumors. However, despite the remarkable efficacy of PARPi, clinical benefit is variable, and a significant number of patients develop resistance. Combinations of PARPi with targeted agents blocking the cellular DNA damage response have been pursued to improve efficacy of PARPi treatments, but enhanced myelosuppression has limited dosing and, consequently, efficacy of these approaches. DNA polymerase theta (Polθ; POLQ) is a key component of microhomology-mediated end joining (MMEJ) DSB repair pathway. Under HRR-deficient conditions, cellular DSB repair becomes increasingly dependent on POLQ-driven MMEJ. We report the identification and optimization of a novel chemotype of POLQ inhibitors, culminating in the discovery of the clinical candidate AZD4956. AZD4956 is a potent and selective inhibitor of the polymerase domain of POLQ (IC_{50} <10 nM) in biochemical assays. AZD4956 suppresses cellular MMEJ activity with single digit nanomolar potency (IC_{50} 3.95 nM) and shows potent antiproliferative activities (IC_{50} values between 3-10 nM) and induction of genomic instability (assessed by micronuclei quantification) in a wide range of HRR defective cell lines, with no measurable activity in HRR proficient genetic backgrounds. AZD4956 further enhances genomic instability and antiproliferative activity induced by the PARP1-selective inhibitor, saruparib, in multiple HRR defective cell lines, with no activity of the combination in HRR proficient settings. Additionally, combination of AZD4956 and saruparib does not exacerbate hematotoxicity of saruparib treatment in a 3D-bone marrow microphysiological system. Oral daily treatment of AZD4956 combined with saruparib drives sustained regression of the HRR deficient *BRCA2*$^{-/-}$ DLD-1 xenograft model, superior to the respective activities of the two agents as monotherapies. Increased efficacy of the combination can be pharmacodynamically tracked by increased accumulation of micronuclei in circulating red blood cells. The preclinical profile, spanning efficacy, safety, DMPK and physicochemical properties, supports clinical development of AZD4956 as a combination partner with saruparib in patients with HRR deficient cancers. Clinical evaluation of AZD4956 is ongoing in a first-in-human, open-label, multicenter, phase 1/2a study in patients with HRR deficient solid tumors (PARTHENON study) in combination with saruparib.

#5746 The risk of high-grade hyperglycemia with PI3K inhibitors-a meta-analysis.

Zhan Rong[1], Shenhong Wu[2]

[1]Department of Medicine, Stony Brook University Hospital, Stony Brook, NY,[2]Division of Medical Oncology, Department of Medicine, Stony Brook University Hospital, Stony Brook, NY

Background: Phosphoinositide 3-kinase (PI3K) inhibitors are a promising therapeutic class in cancer treatment and their clinical utility has been limited by toxicity, particularly high-grade hyperglycemia. Currently the overall risk of hyperglycemia in patients treated with PI3K inhibitors has not been well understood. We performed a meta-analysis on the risk of high-grade hyperglycemia in patients treated with PI3K inhibitors based on currently available published randomized control trial (RCT) data.
Methods: A systematic meta-analysis was conducted including phase II-III RCTs evaluating PI3K inhibitors in cancer patients. The primary endpoints were the incidence and relative risk of grade ≥3 hyperglycemia. Pooled effect sizes were calculated using random- or fixed-effects models based on the heterogeneity of included studies.
Results: A total of 4977 patients across 16 eligible RCTs were included for analysis. The overall incidence of high-grade hyperglycemia was 12.7% (637/4977). Compared to controls, PI3K inhibition was associated with a significantly increased risk of high-grade hyperglycemia (RR: 2.27; 95% CI, 1.74-2.80; $p < 0.001$), with moderate heterogeneity ($I^2 = 38.9\%$). Subgroup analyses revealed that control type significantly moderated toxicity risk ($p < 0.001$), with the greatest risk observed in trials with placebo controls (RR: 2.60; 95% CI, 2.05-3.15) and active controls (RR:1.50; 95% CI, 0.49-2.52). PI3K inhibitor subtype also moderated risk ($p < 0.001$). PI3K-α selective inhibitors were associated with the highest risk (RR: 3.80; 95% CI, 2.50-5.11), followed by pan-PI3K (RR: 2.15; 95% CI, 1.79-2.52) and PI3K/mTOR dual inhibitors (RR:1.46; 95% CI, 0.61-2.31). Class I α/β/δ inhibitors showed no significant elevation.
Conclusions: PI3K inhibitors substantially increased the risk of grade ≥3 hyperglycemia, with heterogeneity driven by control type and inhibitor subtype. The markedly elevated risk with PI3K-α selective agents highlights the need for vigilant metabolic monitoring and tailored management strategies in clinical use.

#5747 GenSci145: A mutant selective PI3Kα inhibitor overcoming brain metastasis treatment barriers.

Xing Fan, Sheng Zhao, Xiaojing Huang, Yihui Lin, Xiaozhen Wang, **Biao Lu**, Yuanfeng Xia, Fanglong Yang

Changchun GeneScience, Shanghai, China

Background: PIK3CA gene mutations are important targets in cancer treatment and are widely present in various solid tumors. Existing PI3Kα inhibitors lack sufficient selectivity for mutant subtypes, which can lead to dose-limiting toxicities such as abnormal glucose metabolism and skin toxicity, affecting patient tolerance and long-term efficacy. Moreover, PIK3CA mutations may increase the risk of central nervous system (CNS) metastasis in patients. Existing inhibitors have extremely poor permeability across the blood-brain barrier, making it difficult to effectively suppress brain metastases and allowing the CNS to become a “sanctuary” for tumor recurrence. Therefore, the development of highly selective PI3Kα mutation inhibitors with brain-penetrating capabilities has become a key research direction to improve the prognosis of such patients.

Methods: The activity of GenSci145 against PI3Kα mutant/wild-type cells was evaluated through in vitro experiments (CTG proliferation inhibition, HTRF detection of pAKT, kinase selectivity panel). In vivo experiments used CDX (T47D, CAL-33, GP2D), PDX (BR9466, etc.), and brain metastasis models (intracranial + subcutaneous transplantation) to analyze the anti-tumor effects of monotherapy or in combination with fulvestrant (TGI, CFB (change from baseline)).

Results: In *in-vitro* experiments, GenSci145 exhibited nanomolar-level inhibitory activity against PI3Kα mutants (H1047R, E545K, E542K) (IC_{50}: 20-162 nM). It significantly inhibited proliferation (T47D IC_{50}: 120.6 nM, selectivity 28.6-fold) and pAKT signaling (IC_{50}: 67.5 nM, selectivity 11.3-fold) in mutant cells, with no significant effects on other PI3K subtypes or off-target kinases.In *in-vivo* experiments, GenSci145 showed dose-dependent anti-tumor effects in HR-positive, HER2-negative breast cancer CDX/PDX models, with significant synergy when combined with fulvestrant. In the xxT47D-Luc brain metastasis + subcutaneous model, GenSci145 dose-dependently inhibited both subcutaneous and intracranial tumors. For intracranial tumors, the CFB was 4.78 at 25 mg/kg and 1.71 at 100 mg/kg, which was superior to STX-478 (100 mg/kg, CFB=9.56). The results indicated that GenSci145 has the potential to treat patients with brain metastases.

Conclusion: GenSci145 is a highly selective PI3Kα mutant inhibitor that mechanistically avoids the metabolic side effects of traditional inhibitors. Preclinical studies have shown significant anti-tumor effects in various PIK3CA mutant tumor models, with excellent blood-brain barrier penetration and effective inhibition of brain metastases. Overall, GenSci145 is expected to overcome the clinical limitations of existing PI3Kα inhibitors and provide a new treatment option for patients with PIK3CA mutations. It is currently being advanced to the IND application stage.

#5748 PM534, a novel tubulin inhibitor, has antitumor activity in patient-derived xenograft models of soft tissue sarcoma.

Agathe Bouju[1], Daniel Gorgels[1], Chao-Chi (Ally) Wang[1], Kimberly Verbeeck[1], Ulla Vanleeuw[1], Maria J. Guillen[2], Carmen Cuevas[2], Pablo M. Aviles[2], Agnieszka Wozniak[1], Patrick Schoffski[3]

[1]Department of Oncology, KU Leuven, Leuven, Belgium,[2]PharmaMar, S.A., Madrid, Spain,[3]Department of General Medical Oncology, University Hospitals Leuven, Leuven, Belgium

Objective: Soft tissue sarcoma (STS) is an heterogenous group of rare, malignant, mesenchymal tumors. Doxorubicin (DOX)-based chemotherapy is standard of care for advanced/metastatic disease, despite significant toxicity, low response rates and poor disease control. Trabectedin (TRA) is a second-line treatment for liposarcoma (LPS) and leiomyosarcoma (LMS), with clinical activity seen also in other subtypes. We explored the antitumor activity of PM534 (PharmaMar, Spain), a novel tubulin inhibitor, in patient-derived xenograft (PDX) models of STS.

Methods: Female NMRI *nu/nu* mice (n=92) were transplanted bilaterally with UZLX-STS149^{LMS}, UZLX-STS22^{LMS} (LMS) and UZLX-STS112^{DDLPS} (dedifferentiated liposarcoma - DDLPS). Mice were randomized to 4 treatment groups, receiving treatment once weekly *via* tail vein injection 1) vehicle (VEH) 5 mL/kg; 2) DOX 5 mg/kg; 3) trabectedin (TRA) 0.15 mg/kg; 4) PM534 4.75mg/kg. Treatment lasted 16 days and antitumor activity was assessed by tumor volume (TV) analysis, histopathology (markers for proliferation and apoptosis), validated by western blot. The Mann-Whitney U test was used to compare groups on the last day of experiment, the Wilcoxon test to compare the TV evolution during the experiment per group (day 1 *vs* day 16). Statistical significance was defined as $p < 0.05$.

Results: In UZLX-STS22^{LMS} and -112^{DDLPS} treatment with PM534 led to TV stabilization (growth to 156% and 133% on day 16 as compared to baseline). In UZLX-STS149^{LMS} the compound led to tumor growth delay (289% *vs* 644% in untreated controls; p=0.0039). The antitumor effect in all models was significantly better than in vehicle-treated mice, while in UZLX-STS22^{LMS} and -STS112^{DDLPS} PM534 outperformed DOX. Histopathology showed a high degree of necrosis in PM534-treated tumors, and the drug had strong anti-proliferative and pro-apoptotic activity, as assessed with hematoxylin and eosin staining. Both DOX and TRA led to a moderate inhibition of mitosis as compared to untreated controls. PM534 was well tolerated throughout the experiment at the dose administered, while TRA showed some degree of local toxicity at the site of administration. The completed histopathological analysis and western blotting will be reported at the meeting and the efficacy of PM534 will now be explored in additional models.

Conclusion: PM534 has strong antitumor effects in PDX models of LMS and DDLPS, outperforms the *in vivo* efficacy of treatment with standard agents and should be further evaluated in the preclinical and clinical setting.

#5749 DNA damage, apoptosis and cell cycle disruption: Antitumor effects of a novel tin(IV) complexes.

Shubham Sharma[1], Margret H. Ogmundsdottir[2], Helga M. Ogmundsdottir[3], Krishna Kumar Damodaran[1]

[1]University of Iceland, Reykjavik, Iceland,[2]BioMedical Center, University of Iceland, Reykjavik, Iceland,[3]University of Iceland Faculty of Medicine, Reykjavik, Iceland

Introduction: Platinum-based chemotherapeutics like cisplatin are widely used against cancer but are limited by toxicity and drug resistance. Organotin(IV) complexes offer a promising alternative with enhanced efficacy and distinct mechanisms. Here, we evaluated the anticancer activity of dibutyl and diphenyl organotin(IV) complexes and investigated their mechanisms of action across multiple cancer cell lines.

Material and Method: Synthesis of Organotin(IV) Complexes: Dibutyl and diphenyl organotin(IV) (Bu-Sn and Ph-Sn) complexes were synthesized following established protocols. The purity and structural confirmation of the complexes were verified using spectroscopic techniques. Anti-cancer activities: The following human cell lines were used in this study: T-47D (breast carcinoma), HCT116 (colorectal carcinoma), AsPC-1 (pancreatic adenocarcinoma), and MCF-10A (non-tumorigenic mammary epithelial). Following manufactures protocol MTT assay is utilized for the determination of half maximum inhibitory concentration (IC_{50}). The mode of cell death (apoptosis and necrosis) investigated in cell lines via flow cytometry using the Annexin V and propidium iodide (PI) staining method. Analysis of cell cycle with flow cytometry performed to determine the changes in the cell cycle for each cell lines utilizing cisplatin as a reference drug. Subcellular distribution of the organotin(IV) complexes was evaluated by ICP-MS. Treated cells were fractionated into major cellular compartments to determine the predominant localization of the complexes. DNA damage induced by the organotin(IV) complexes was assessed using the Comet assay, allowing quantification of treatment-related DNA strand breaks.

Results and Discussion: Bu-Sn exhibited strong cytotoxic activity across all tested cancer cell lines (IC_{50} < 3.00 μM), with particularly high potency against T-47D human breast cancer cells (IC_{50} = 0.53 μM). Importantly, it showed minimal toxicity toward non-cancerous MCF-10 cells, demonstrating a favorable level of selectivity. In contrast, Ph-Sn displayed only limited cytotoxic activity. Mechanistically, Bu-Sn induced G1 phase arrest and triggered dose-dependent apoptosis in T-47D cells. Subcellular analysis revealed predominant nuclear accumulation (32% for Bu-Sn, 24% for Ph-Sn), correlating with pronounced DNA damage observed in Comet assays, suggesting that nuclear targeting and genotoxic stress underlie its anticancer activity.

Conclusion: Two organotin(IV) complexes containing dibutyl and diphenyl groups were synthesized and fully characterized. The dibutyl complex exhibited strong cytotoxic activity across multiple cancer cell lines while sparing non-malignant cells. Mechanistic studies indicated that these tin complexes primarily target DNA, inducing cell cycle arrest and apoptosis, ultimately leading to cancer cell death.

#5750 Solid tumor cell-intrinsic function of PI3Kδ.

Sarah E. Conduit[1], Elena Lopez-Guadamillas[1], Daniele Morelli[1], Harriet Howard[1], Wayne Pearce[1], Cheryl Scudamore[2], Bart Vanhaesebroeck[3]

[1]University College London (UCL), London, United Kingdom,[2]Exepathology, Devon, United Kingdom,[3]Centre Lead, Centre for Cell Signalling, University College London Cancer Institute, London

PI3Kδ is a predominantly leukocyte-enriched class I PI3K consisting of the p110δ catalytic subunit (encoded by *PIK3CD*) and most commonly the p85α regulatory subunit (encoded by *PIK3R1*). PI3Kδ is an important regulator of B-cell function and has been the target of extensive drug development efforts for B-cell malignancies, with multiple inhibitors approved for this indication. Based on our pre-clinical studies, PI3Kδ inhibition is now also emerging as an immunotherapy approach for solid tumours. Regulatory T-cells (Treg) are exquisitely sensitive to PI3Kδ inhibition, therefore pharmacological PI3Kδ inhibitors preferentially target the Tregs, rebalancing the immune system in favour of an effector T cell-mediated anti-tumour immune response. This concept is currently under investigation in clinical trials in uveal melanoma and non-small cell lung cancer. Notably, we and others have also observed multiple solid tumour types including glioblastoma, melanoma, breast cancer, prostate cancer, neuroblastoma and hepatocellular carcinoma also express wild-type *PIK3CD*, often at much higher levels than their non-transformed cell types of origin. Some studies suggest PI3Kδ promotes proliferation in these tumour cells, but this remains unclear with the potential that inhibitors were used at non-PI3Kδ-specific concentrations, and these findings are not consistently confirmed with genetic approaches. This raises the questions of what function PI3Kδ plays in solid tumours and how the use of PI3Kδ inhibitors for immunotherapy will affect the tumour cells themselves via inhibition of cell-intrinsic PI3Kδ. Using highly-selective PI3Kδ inhibitors and CRISPR-Cas9-mediated *PIK3CD* deletion in solid tumour cell lines, we demonstrate that PI3Kδ inhibition does not affect cell proliferation in these models. However, through both *in vitro* and xenograft studies, we have identified cancer-relevant roles for PI3Kδ in solid tumours, the implications of which will be presented. Our data suggest the solid tumour cell-intrinsic PI3Kδ expression should be considered to inform PI3Kδ-targeting immunotherapy studies.

#5751 (E,E)-bisantrene silences *c-MYC* expression by stabilizing its promotor region G-quadruplex.

Sumit Sahni[1], Emily Ryan[1], Peter Cuthbertson[1], Feroz Ahmad[1], Kirsten Curnow[1], Nehad Elsalamouny[2], Qiang Zhu[2], Haibo Yu[2], Jinho Jang[3], Jonathan Dickerhoff[3], Danzhou Yang[3], Emma-Jayne Proctor[2], Martina Sanderson-Smith[2], Daniel Tillett[1], Michael Kelso[1]

[1]Race Oncology, Sydney, Australia,[2]University of Wollongong, Wollongong, Australia,[3]Purdue University, West Lafayette, IN

Background: G-quadruplex (G4) DNA and RNA are important non-canonical nucleic acid secondary structures that play key roles in many cellular processes. They regulate the expression and translation of several oncogenes, including the master cell growth regulator, MYC. Bisantrene is a small-molecule anticancer agent that has been shown to be safe and effective in >1500 clinical trial patients. This study characterized the binding and stabilization of a G4 region in the *c-MYC* promoter by the (E,E)-bisantrene isomer and silencing of *c-MYC* expression in cancer cells.
Methods: Circular dichroism spectroscopy established if (E,E)-bisantrene stabilizes the *c-MYC* promotor G4 structure, with surface plasmon resonance used to measure the binding affinity. Nuclear magnetic resonance spectroscopy provided structural insights into the binding interactions within the complex. Molecular dynamics simulations modelled the 3-dimensional structure of the complex. Changes in *c-MYC* gene expression were assessed across a range of cancer cell lines after treatment with (E,E)-bisantrene and RNA-seq with pathway analysis was performed.
Results: (E,E)-bisantrene was found to stabilize the *c-MYC* promoter G4 region, producing similar increases in melting temperature to other G4 ligands (i.e., pidnarulex and pyridostatin). NMR spectroscopy and molecular modelling suggests (E,E)-bisantrene binds with a 2:1 stoichiometry to the planar surfaces of the top and bottom G-tetrads. (E,E)-bisantrene potently inhibited *c-MYC* expression in multiple cancer cell lines. RNA-seq analysis showed (E,E)-bisantrene also decreased expression of other oncogenes containing G4 regions in their promoters, including *MET, TERT, VEGFA, ATF4* and *MDM2*. Pathway analysis of the RNA-Seq data demonstrated a transcriptomic profile similar to pidnarulex, a known G4-binding drug in early-stage clinical development.
Conclusion: (E,E)-bisantrene binds to and stabilizes the G4 structure contained within the *c-MYC* promotor region, leading to silencing of *c-MYC* gene expression. These studies support clinical evaluation of (E,E)-bisantrene as a new G4-targeting drug in MYC-driven tumors.

#5752 Bi-functional thiopurine-based oligonucleotides for AML cell-targeted telomere damage and immunostimulation.

Chunsong Yu[1], Elaine Y. Kang[1], Piotr Swiderski[1], Haiqing Li[1], Ya-Huei Kuo[2], Guido Marcucci[2], **Marcin Kortylewski**[1]

[1]Beckman Research Institute of The City of Hope, Duarte, CA,[2]City of Hope, Duarte, CA

Telomerase (TERT) is an enzyme commonly activated in human cancers and critical for maintaining cell survival. TERT expression and activation correlates with more aggressive, treatment-resistant disease, with the highest telomerase activity in relapsed acute myeloid leukemia (AML) patients. Telomerase inhibitors showed promise in preclinical studies on AML leading to leukemic stem cells (LSC) eradication. However, TERT inhibition in cancer cells faced challenges, such as the delayed clinical responses and on-target/off-tumor toxicities to hematopoietic stem cells (HSCs) or to activated T cells that result in cytopenias or immunosuppression, respectively. We previously developed clinically-relevant strategy for targeted delivery of therapeutic molecules into TLR9^{+} positive myeloid cells, such as AML cells including LSCs, using synthetic CpG oligodeoxynucleotides (CpG-ODNs) as a targeting domain. Here, we report generation of new CpG-conjugates for the delivery of a synthetic TERT substrate, 6-thio-2'-deoxy-guanosine (6tdG) into AML cells. CpG-6tdG oligonucleotides (CpG-6tdGOs) comprise multiple (5-10) 6tdG nucleosides in the 3' end of CpG-ODN. The CpG-6tdGOs retain serum stability, while allowing for slow release of the 6tdG nucleotides after uptake into target leukemic cells. *In vitro*, CpG-6tdG-oligonucleotides (CpG-6tdGOs) were selectively cytotoxic to human TLR9^{+}/TERT^{+} AML cells without affecting activated TLR9$^{—}$/TERT^{+} T-cells, HSCs or non-malignant TERT$^{—}$ cells. The liquid chromatography-tandem mass spectrometry (LC-MS/MS) analysis confirmed that 6tdG was effectively incorporated into chromatin of target cancer cells after *in vitro* and *in vivo* treatment using CpG-6tdGO. Repeated intravenous injections of CpG-6tdGO, but not 6tdG nucleoside, within days induced cytotoxic effects against xenotransplanted models of primary human AML with diverse genomic background in immunodeficient NSG mice and inhibited leukemia progression. CpG-6tdGO showed enhanced antitumor activity when tested *in vivo* against syngeneic *Cbfb/MYH11/Mpl* (CMM) and C1498 mouse AML models. In immunocompetent mice, treatment with CpG-6tdGO induced systemic, cancer cell-selective and CD8 T-cell-mediated antitumor immune responses that were at least partly dependent on TLR9- and STING-mediated signaling in response to CpG-6tdGO-induced cancer cell death. Importantly, the repeated treatments were well-tolerated in humanized hCD34/NOG mice. Except for the reduced percentage of human B-cells, CpG-6tdGO did not decrease the numbers of HSCs, myeloid cells, or T-cells. Overall, CpG-6tdGO offers an effective and safer strategy against aggressive TERT^{+} hematologic malignancies and potentially certain solid tumors.

#5753 Clinical-stage anticancer agent BOLD-100 demonstrates protective effects against chemotherapy-induced peripheral neuropathy.

Mark Bazett, Ashish Kumar, Josie C. Setiawan, E. Russell McAllister, Jim Pankovich

Bold Therapeutics Inc, Vancouver, BC, Canada

BOLD-100 is a first-in-class, ruthenium-based anticancer agent in Phase 2 clinical development for advanced gastrointestinal (GI) cancers in combination with the chemotherapy regimen FOLFOX (NCT04421820). BOLD-100 plus FOLFOX improves overall survival and progression-free survival in patients with advanced colon (mCRC), gastric (GC), and bile duct cancers (BTC). While FOLFOX is a standard-of-care therapy for GI cancers, its clinical utility is limited by acute and chronic peripheral neuropathies. However, a significantly lower incidence of oxaliplatin-induced peripheral neuropathy (OIPN) was observed in patients treated with BOLD-100 plus FOLFOX, including those who had been treated with FOLFOX in previous lines of therapy. Any-grade neuropathy was reduced compared to benchmark FOLFOX-alone patients; mCRC (14% vs 53%), BTC (36% vs 68%), and GC (19% vs 63%). To assess BOLD-100's neuroprotective effects *in vivo*, Sprague-Dawley rats received vehicle (10 mL/kg), oxaliplatin (1.5 mg/kg), paclitaxel (1.0 mg/kg), or BOLD-100 (40 mg/kg) alone, plus BOLD-100 in combination with oxaliplatin and paclitaxel. Cold allodynia was measured using the acetone spray test. Rats treated with oxaliplatin alone induced significant cold allodynia by Day 7, while co-treatment with BOLD-100 ameliorated OIPN development. Importantly, BOLD-100 administration starting on day 15 reversed developed OIPN, opening the possibility of BOLD-100 as a treatment option. BOLD-100 also mitigated the development of paclitaxel-induced cold allodynia, highlighting a broader application of BOLD-100. To elucidate the underlying mechanisms, *in vitro* models using primary dorsal root ganglion (DRG) neurons and differentiated PC12 neuronal cells were used to assess neurite outgrowth. In both models, oxaliplatin treatment reduced average neurite length and number, whereas co-treatment with BOLD-100 protected against oxaliplatin-induced neurotoxicity. Oxaliplatin activates stress pathways leading to neuronal damage, including the unfolded protein response (UPR) - pathways BOLD-100 is known to impact. Oxaliplatin treatment induced upregulation of UPR proteins ATF6 and GRP78, whereas BOLD-100 co-treatment attenuated this upregulation. Furthermore, phosphorylated γH2AX, a marker of DNA damage, was markedly elevated following oxaliplatin exposure, while BOLD-100 ameliorated this response. Chemotherapy-induced peripheral neuropathies have limited therapeutic options; these results demonstrate BOLD-100's potential for both neuroprotection and treatment via impacting important stress pathways. Ongoing clinical study BOLD-100-001 is assessing BOLD-100's neuroprotective effects and its ability to enhance patient outcomes and reduce neurotoxicity.

#5754 PM54 suppresses WNT/β-catenin signaling and synergizes with chemotherapy in gastric cancer models.

Francisco Javier Gutierrez Alvarez, Gema Santamaria, Marta Martinez Diez, Maria Jose Guillen, Pablo Aviles, **Marcelo L. Ribeiro**, Carmen Cuevas

Pharma Mar, S.A., Madrid, Spain

Background: PM54 is a lurbinectedin analog that binds CG-rich promoter regions, inducing transcriptional blockade, DNA double-strand breaks, and S-phase arrest culminating in apoptosis. In gastric cancer models, it drives early transcriptional reprogramming with repression of cell-cycle and DNA repair pathways and demonstrates potent single-agent antitumor efficacy in vivo. We aimed to evaluate the antitumor efficacy of PM54 in gastric cancer and to assess its potential synergy with standard chemotherapeutic agents

Methods: WNT/β-catenin activity was assessed in gastric cancer cell lines using TCF/LEF reporter assays and pathway biomarker analysis. Drug interactions with 5-fluorouracil (5-FU) and cisplatin were quantified by combination index analysis. In vivo efficacy was tested in gastric cancer xenografts treated with PM54, chemotherapy, or combinations, with tumor growth monitored over time.

Results: As a single agent, PM54 markedly inhibited the WNT/β-catenin pathway, reducing TCF/β-catenin-driven transcription by about 40% at 6 hours and over 70% at 18 hours post-treatment. In vitro, PM54 showed strong synergy with 5-fluorouracil (5-FU) in diffuse-type gastric cancer cell lines (HGC-27 and Hs746T) and with cisplatin in HGC-27 cells. In vivo, treatment with PM54 (0.9 mg/kg; days 0 and 7) of mice bearing HGC-27 xenograft tumors resulted in strong antitumor activity. On day 10 (last day of survival in the placebo-treated group), the median tumor volume in placebo-treated mice was 1612 mm^3, compared with mice treated with 5-FU (1375 mm^3), cisplatin (1423 mm^3), and PM54 (616 mm^3; $p = 0.019$). The combination of PM54 with 5-FU or cisplatin resulted in clearly superior performance to the corresponding therapies, with a median $\Delta T/\Delta C$ (%) of 29.4 (PM54), 84.2 (5-FU), and 15.0 (combination); a similar pattern was observed with cisplatin, with $\Delta T/\Delta C$ (%) 29.4 (PM54), 85.7 (cisplatin), and 21.5 (combination).

Conclusions: PM54 represses WNT/β-catenin signaling and enhances the efficacy of chemotherapy in gastric cancer models. These findings support its development in rational combination regimens to improve patient outcomes.

#5755 MTORC1/2 inhibition enhances STX-478, a *PIK3CA*^{H1047R} mutant inhibitor, in *PIK3CA*^{H1047R} mutant colorectal cancer.

Alexa E. Schmitz[1], Addison Zick[1], Cheri A. Pasch[1], Dustin A. Deming[2]

[1]Univ. of Wisconsin Madison Sch. of Med. & Public Health, Madison, WI,[2]University of Wisconsin Carbone Cancer Center, Madison, WI

Background: STX-478, a *PIK3CA* mutant selective inhibitor, that we have previously shown to have promise in treating *PIK3CA*^{H1047R} mutant colorectal cancer (CRC) models. A high throughput drug screen was performed and identified AZD2014, an MTORC1/2 inhibitor, to have enhanced response with STX-478. Here, we examine the combination of PI3K inhibition with MTORC1/2 inhibition in *PIK3CA*^{H1047R} mutant colorectal cancer (CRC).

Methods: CRC cell lines SW48 and SW48PK (Horizon Discovery; SW48 with a *PIK3CA*^{H1047R} mutation) were treated with varying concentrations of STX-478 (250-750 nM) and AZD2014 (20-250 nM) and viability measured by WST was performed. *PIK3CA*^{H1047R} mutant PDCOs were treated, imaged, and response was determined by measuring the change in longest diameter of the organoids over time. Glass's Delta was used as a statistical test to measure the effect size of the different treatment groups. Mouse derived cancer organoids (MDCOs) were derived from Fc[1] Apc$^{fl/+}$ Pik3ca^{H1047R} murine colon tumors. MDCOs/PDCOs and CRC cell lines were treated with 750 nM or 500 nM STX-478 and 100 nM AZD2014, respectively, and collected for immunoblotting for apoptosis and PI3K proteins.

Results: Both SW48 and SW48PK had a significant reduction in cell viability with treatment of single agent AZD2014 at 100 nM (SW48 $p<0.001$, SW48PK $p=0.005$). When treated with combination of STX-478 and AZD2014, both cell lines had a significant reduction in cell viability (500 nM STX-478 with 100 nM AZD2014; SW48 $p=0.002$, SW48PK $p<0.001$). For SW48PK, a significant reduction of phosphorylation of ribosomal protein S6 (RPS6; $p<0.001$), AKT ($p<0.001$), and 4EBP1 ($p=0.002$) were observed after treatment with the combination, while no significant difference was seen in SW48. MDCOs had a significant decrease in RPS6 compared to control and single agent STX-478 ($p<0.001$). In *PIK3CA*^{H1047R} mutant PDCOs, a significant reduction in relative change in diameter was observed in the combination treatment compared to control (relative change in diameter control versus combination: 30.2% vs -0.96%; Glass's Delta = 1.67). *PIK3CA*^{H1047R} mutant PDCOs also had a significant decrease in phosphorylation of 4EBP1 ($p<0.001$) and RPS6 ($p<0.001$).

Conclusions: The combination of STX-478 and AZD2014 enhanced response in both 2D and 3D *PIK3CA*^{H1047R} mutant CRC models and shows promise for combining MTORC1/2 with *PIK3CA* inhibition for *PIK3CA* mutant CRC. Future work should investigate STX-478 and MTORC1/2 inhibition in *PIK3CA* mutant CRC *in vivo*.

#5756 Preclinical evaluation of BH4601, a novel tetravalent PD-L1 and B7H3 bispecific antibody-drug conjugate (ADC) with Topo1 inhibitor for the treatment of solid tumors.

Jun Wang[1], Pengfei Rong[2], Jing Wang[1], Yang Liu[1], Mengrui Zhao[2], Jie Feng[1], Lijuan Li[1], Yue Wang[1], Aihong Zhang[1], Dongyang Li[1], Hongjuan Zhang[1], Jingmei Cai[1], Xiaochun Li[1], **Jiangcheng Xu**[1], Jiawang Liu[1], Hui Ding[2], Fangxing Ouyang[2], Kyoungwoo Lee[1]

[1]Beijing Hanmi Pharm. Co. Ltd., Beijing, China,[2]FDC Biotech Kunshan China, Kunshan, China

PD-L1 and B7-H3, members of the B7 superfamily, are frequently overexpressed across various tumor types. While antibody-drug conjugates (ADCs) targeting either PD-L1 or B7-H3 individually have demonstrated modest clinical efficacy, their co-expression in multiple malignancies presents a compelling rationale for dual-targeting strategies. This bispecific approach broadens the scope of tumor targeting and simultaneously alleviates T-cell suppression, potentially leading to enhanced therapeutic efficacy. The dual-targeting strategy addresses the compensatory upregulation observed between these targets—where suppression of B7-H3 leads to PD-L1 upregulation, and vice versa.

A novel bispecific antibody concurrently targeting PD-L1 and B7-H3 was conjugated with a topoisomerase I inhibitor (XYD-295) and BH4601 was generated. In vitro evaluations revealed that BH4601 exhibits excellent target binding and internalization activities, as well as potent PD-1/PD-L1 blockade. Effective tumor control was demonstrated in multiple in vivo models, accompanied by significant T-cell activation. All animals remained well-tolerated at efficacious dose levels.

By simultaneously engaging both PD-L1 and B7H3 pathways, BH4601 achieves enhanced tumor-specific distribution and efficient tumor cell internalization, potentially improving both efficacy and safety profiles compared to its parental ADCs.

#5757 Exatecan payload-based antibody-drug conjugates with a short hydrophilic beta-glucuronidase cleavable linker.

Vasu Jammalamadaka, **Jiang Liu**, Sunil Bhakta, Vidya S. Jonnalagadda, Jagath R. Junutula

Aarvik Therapeutics, Hayward, CA

Antibody-drug conjugates (ADCs) enable the specific targeting of a potent cytotoxic drug to cancer cells expressing a select antigen via the release of the cytotoxin covalently linked to a target-specific antibody. A classic ADC comprises three elements: (a) a target-specific antibody that enables the binding of the ADC to cells expressing the target antigen, (b) a potent cytotoxic drug (payload) that kills cells when released from the ADC, and (c) a linker that covalently links the payload to the antibody until pre-defined conditions cause release of the payload. One of the factors limiting the *in vivo* biological activity of an ADC is high hydrophobicity, which stems partly from the linker or spacer and partly from the payload. In the body, high hydrophobicity often leads to aggregation of the ADC molecules; these aggregates are then rapidly cleared from circulation by the liver. Several approaches investigated in the past to reduce the overall hydrophobicity of ADCs include (a) reducing the hydrophobicity of the payload itself, (b) positioning the (hydrophobic) payload in a shielded pocket of the antibody, and (c) modifying the linker structure by introduction of hydrophilic spacers such as polyethylene glycol (PEG), polysarcosine (PSAR), hydrophilic macrocycles or long hydrophilic XTEN peptides. However, all these linker modifications involve bulky spacers, which can impact permeability into tumor tissue. Our goal was to develop short, streamlined hydrophilic linkers that boost ADC solubility without adding significant bulk. We successfully synthesized and screened several linker-payloads, and validated a novel hydrophilic, lysosomal β-glucuronidase cleavable linker combined with a short sugar-based spacer (AV-L03). We synthesized an ADC comprising trastuzumab conjugated to an exatecan payload via this novel, short, stable, hydrophilic linker AV-L03 at a drug-to-antibody ratio (DAR) of 8 and compared it to Enhertu®, which comprises trastuzumab conjugated to a DXd payload via a (hydrophobic) tetrapeptide linker. The ADC with the novel AV-L03 linker showed superior hydrophilicity, *in vitro* cytotoxicity, improved plasma stability, and *in vivo* efficacy in a mouse xenograft model compared to Enhertu®. The AV-L03 linker makes possible the use of exatecan as a payload for ADCs, which is promising given that exatecan is a more potent inhibitor of TOP1 isomerase compared to DXd, with higher permeability and bystander activity, and is a poorer substrate for some MDR pumps. Moreover, the AV-L03 linker, the shortest hydrophilic linker reported to date, is compatible with diverse payloads, and thus opens up several avenues for the design of superior ADCs.

#5758 Single protein encapsulated SN38: Extremely effective anticancer drug with low toxicity.

C. J. Yu[1], leslie Wang[1], Kinsley Wang[1], Mengmeng Liu[1], Faqing Huang[2], Warren A. Chow[3], Xiaojiang Cui[4]

[1]Sunstate Biosciences, LLC, Pasadena, CA,[2]The University of Southern Mississippi, Hattiesburg, MS,[3]University of California at Irvine, Irvine,, CA,[4]Cedars-Sinai Medical Center, Los Angeles, CA

Purpose: SN38 is a potent antineoplastic agent, however, the poor water solubility prohibited its direct clinical applications. At present, only prodrug approach on SN38 has resulted in 2 types of therapeutics approved by the FDA, irinotecan/ONIVYDE and Trodelvy. Furthermore, the poor enzymatic conversion (2-8%) of irinotecan into the active metabolite SN38 severely limits its efficacy. Numerous attempts of drug delivery systems failed to achieve effective SN38 delivery. Therefore, novel approaches are urgently needed for effectively delivering SN38.
Methods: Our patented single protein encapsulation (SPE) platform, allowing encapsulation of small-molecule drugs by a single protein (albumins or globulins) without artificial nanoparticles and chemical modifications to drugs and proteins, has made the first drug product, SPEDOX-6 into human phase IB/IIA clinical trial (NCT0764018). The great success of SPEDOX-6 has prompted us to utilize the same SPE technology for encapsulation of SN38 by HSA to create SPESN38-5/8 complexes, which were characterized by membrane dialysis, HPLC, UV and dynamic light scattering. We conducted pharmacological evaluations with respect to MTD, PK, *in vitro* and *in vivo* efficacy against various cancers.
Results: Lyophilized SPESN38-5/8 complexes can be dissolved in water to form clear and stable solutions. PK of SPESN38-5 by IV at 55 mg/ kg yielded much higher mouse plasma AUC for SN38 and SN38G, producing a molar ratio of SN38G:SN38 = 1.5:1. We tested *in vitro* growth-inhibitory effect of SPESN38-8 against SK-ES-1 (Ewing Sarcoma), SK-LMS-1 (soft tissue sarcoma), A204 (rhabdomyosarcoma) and HT1080 (soft tissue sarcoma) with IC50 at 0.1079, 0.1526, 1.023, 1.087 uM, respectively, which is 7 to 60-fold lower than irinotecan. *In vivo* antitumor efficacy against 5 cancer models was evaluated: (1) SK-ES-1 model, SPESN38-8 at 35 mg/kg vs DOX at 3.0 mg/kg and Doxil at 4.0 mg/kg; led to 8/8 mice tumor free on Day 21, which were monitored for total 230 days, tumor relapse wasn't found for > 209 days, indicative of cancer eradication; (II) A204, SPESN38-8 at 35 mg/kg vs Doxil at 4.0 mg/kg, led to all 4 females free of tumor & 4 males almost tumor free, (III) SK-LMS-1, SPESN38-8 at 35 mg/kg vs DOX at 5.0 mg/kg, led to 6/7 mice free of tumor, indicative of SPESN38-8's superior anticancer efficacy; (IV) HCT-116 (colorectal cancer) model, SPESN38-5 at 55 mg/kg vs irinotecan at 50 mg/kg, SPESN38-5 was much effective to suppress HCT-116 than irinotecan; (V) A549 (non-small cell lung cancer) model, SPESN38-8 at 35 mg/kg vs irinotecan at 50 mg/kg, SPESN38-8 was extremely effective to inhibit A549 than irinotecan.
Conclusion: SPESN38 complexes provide a novel water soluble SN38 formulation. SPESN38-5 and SPESN38-8 demonstrate better PK values, lower toxicity and superior antitumor efficacy in mouse models, compared with irinotecan, DOX and Doxil. FDA has green-lighted SPESN38-8 (IND #: 164346) for clinical development.

#5759 Genome-wide CRISPR screen identifies GPX4 as a potential vulnerability in cells treated with PI3Kα-mutant selective inhibitor RLY-2608.

Fabiana Napolitano[1], Yuan Wang[1], Dan Ye[2], Jingxuan Lu[1], JINGXUAN CHEN[3], Khushi Ahuja[4], Pamela Luna[2], Yuki Matsunaga[5], Dylan Calhoon[1], Maria Rosario Chica-Parrado[1], Yasuaki Uemoto[1], Javier Garcia Bermudez[1], Jeon Lee[6], Chang-Ching A. Lin[5], Ariella B. Hanker[7], Carlos L. Arteaga[8]

[1]Harold C. Simmons Comprehensive Cancer Center, Dallas, TX,[2]Harold C. Simmons Comprehensive Cancer Center, Dallas, TX, United States, Dallas, TX,[3]Lyda Hill Department of Bioinformatics, Dallas, TX,[4]Medical College of Wisconsin, Milwaukee, WI,[5]UT Southwestern Medical Center, Dallas, TX,[6]Lyda Hill-Dept of Bioinformatics, Dallas, TX,[7]UT Southwestern Harold C. Simmons Comprehensive Cancer Center, Dallas, TX,[8]Director, Breast Cancer Program and Center for Cancer Targeted Therapies, UT Southwestern Simmons Comprehensive Cancer Center, Dallas, TX

Background/Objectives: Approximately 40% of HR+ breast cancers harbor PIK3CA mutations. The clinical efficacy of PI3Kα inhibitors has been limited by toxicity and a narrow therapeutic window. Recently, mutant-selective PI3Kα inhibitors, such as RLY-2608 (zovegalisib), have shown improved efficacy and tolerability. Here, we aimed to identify genetic modulators of response to RLY-2608 in *PIK3CA*-mutant breast cancer cells.

Methods: A genome-wide CRISPR-knockout (KO) screen (80,000 sgRNAs targeting ~20,000 genes) was performed in T47D cells to identify genes whose loss sensitizes to PI3Kα inhibition. Key candidates were validated with CRISPR-Cas9, and RNA-seq was used to assess transcriptomic changes upon treatment.

Results: Among enriched sgRNAs in vehicle-treated controls, *PTEN*, *NF2*, *TSC2,* and *TSC1* showed the highest differential scores, consistent with known resistance mechanisms to PI3K inhibitors, therefore validating the screening's robustness. Among the top depleted genes in RLY-2608-treated cells - potentially associated with increased sensitivity to PI3Kα inhibition - was *GPX4,* encoding the antioxidant enzyme glutathione peroxidase 4. GPX4 protects cells from lipid peroxidation and ferroptosis (iron-dependent cell death). Stable *GPX4*-KO MCF7 and T47D cells, established via CRISPR-Cas9, displayed a 2.5-3-fold increased sensitivity to RLY-2608, respectively. Bliss independence analysis revealed strong synergy between RLY-2608 and the GPX4 inhibitor RSL3. In T47D cells treated with RLY-2608, transcriptome profiling revealed broad upregulation of lipid-associated genes, including enzymes involved in fatty acid β-oxidation, lipid mobilization and membrane lipid metabolism. These data suggest a shift toward enhanced lipid turnover and oxidation. Ongoing BODIPY-C11 and lipidomic analyses aim to quantify resulting lipid peroxidation. Compared to cancer cells without PI3K pathway mutations, *PIK3CA*-mutant cells exhibit suppressed xCT-mediated cystine uptake to preserve NADPH for lipid synthesis. PI3Kα inhibition relieves this suppression, increasing cystine availability; however, the accompanying induction of lipid metabolic and oxidative pathways increases lipid peroxide burden. Thus, we speculated that treatment with a PIK3CA-mutant inhibitor increases dependence on the GPX4-mediated antioxidant system, creating a therapeutically exploitable vulnerability via combination with GPX4 inhibitors.

Conclusions: Genome-wide CRISPR KO screen identified GPX4 inhibition as a vulnerability in HR+/*PIK3CA*-mutant breast cancer cells treated with the PI3Kα-mutant selective inhibitor RLY-2608. These data support a mechanistic link between PI3Kα inhibition, lipid peroxidation, and ferroptosis, providing a rationale for clinical trials with the combination of PI3K pathway and GPX4 inhibitors.

#5760 Metabolic rewiring renders *KEAP1*-mutant lung cancers sensitive to AKR1C3-activated prodrugs.

Michela Ranieri[1], Matthew Cattle[1], Doyeon Jang[1], Kwok-Kin Wong[2], Charles M. Rudin[3], John Thomas Poirier[4]

[1]NYU Langone Health Perlmutter Cancer Ctr., New York, NY,[2]NYU Langone Health, New York, NY,[3]Memorial Sloan Kettering Cancer Center, New York, NY,[4]NYU Langone Health Perlmutter Cancer Ctr., Brooklyn, NY

The AKR1C1-3 family (aldo-keto reductase family 1, members C1-C3) comprises cytosolic NADPH-dependent oxidoreductases that catalyze the reduction of carbonyl groups on steroids, prostaglandins, and xenobiotics. Upregulation of AKR1C enzymes in certain cancers can contribute to resistance to chemotherapeutic agents and oxidative stress, making them key effectors in redox homeostasis and drug resistance. AKR1C3 expression has been exploited to convert inert prodrugs to their active form with tumor selectivity. ACHM-025 is a second-generation AKR1C3-activated prodrug that is reduced in a single enzymatic step to ACHM-025H, a nitrogen mustard that bis-alkylates DNA to form intra- and interstrand cross-links (ICLs) leading to stalled DNA replication fork progression and cell death. ACHM-025 was shown to have potent activity in preclinical models of T-ALL, a cancer that can express high levels of AKR1C3. Loss-of-function alterations in *KEAP1* occur frequently in lung cancer, often co-occurring with alterations in *KRAS*, *STK11*, and *TP53*, forming distinct molecular subgroups that influence therapeutic response. *KEAP1*-mutant tumors are typically resistant to immune checkpoint blockade and platinum doublet chemotherapy, leading to significantly worse clinical outcomes. Previously, we showed that *AKR1C1/2/3* are among the most significantly up-regulated genes in *KEAP1*-mutant lung cancers, which supports preclinical testing ACHM-025 as novel therapeutic agent in this subset of tumors.Using a series of isogenic lung adenocarcinoma cell lines, we found that lines deficient in KEAP1 express high levels of AKR1C3 and are sensitive to ACHM-025. Colony formation and cell viability assays demonstrated dose-dependent sensitivity to ACHM-025, which was positively correlated with the amount of AKR1C3 protein expressed. The *KEAP1*-mutant isogenic clones of H292 and H358 cell lines exhibited IC_{50} values of 171 nM (95% CI: 124-240 nM) and 466 nM (95% CI: 329-689 nM), respectively. Among the tested cell lines, H460 cells showed the greatest sensitivity to ACHM-025, with an IC_{50} of 4 nM (95% CI: 2-10 nM). Co-treatment with SN34037, a potent and selective AKR1C3 inhibitor, abolished ACHM-025 activity, which demonstrated selective activation. Clonal competition assays admixing KEAP1-mutant and wild-type human adenocarcinoma cell lines demonstrated rapid depletion of *KEAP1*-mutant cells with minimal bystander effect. Finally, we confirmed that the cytotoxic effect of ACHM-025 led to increased phosphorylated H2AX (γH2AX) which is consistent with a mechanism of action involving DNA damage.Taken together, our data support the rationale that metabolic rewiring in KEAP1-mutant tumors leads to enhanced sensitivity to ACHM-025 and, therefore, supports AKR1C3 mediated prodrug activation as a potential therapeutic strategy for this subset of lung cancer patients.

#5762 FMC-242, a highly potent and selective covalent inhibitor of the PI3Kα -RAS interaction, demonstrates robust anti-tumor activity as monotherapy and in combination with targeted therapies.

Kevin R. Webster, Ryan McFadden, Abdul Awol, Koli Basu, Barun Bhhatarai, Yu-Hsin Chao, John Conway, Jay Duffner, Dan Erlanson, Robert Everley, Susan Fong, Sarah Gilfillan, Johannes Hermann, Alessandra Ianari, Lata Jayaraman, Svetlana Kholodar, Nathan Lavey, Tiep Le, Laura Marholz, Bethany Parker, Snahel Patel, Emily Sabbey, Shefali Sabhlok, Shayna Simonstein, Luke Utley, John Vassiliadis, Weiru Wang, Yan Wang

Frontier Medicines, South San Francisco, CA

Activation of RAS and PI3Kα are the most frequent oncogenic events in cancer, playing a key role in many aspects of tumor cell physiology, including growth, survival, differentiation, and migration. While treatment options have recently emerged for a subset of KRAS mutant patients and inhibitors of PI3Kα catalytic activity have been approved, both approaches have been limited by drug resistance and in the case of PI3Kα, hampered by poor tolerability (e.g., hyperglycemia). An alternative therapeutic strategy that addresses drug resistance with improved tolerability is needed. Application of the FrontierTM platform, which integrates chemoproteomics, AI, and covalent fragment-based drug discovery, enabled the discovery of FMC-242, a potent, selective, and orally bioavailable covalent inhibitor of the PI3Kα -RAS family interactions disrupting oncogenic RAS and RTK signaling without impacting the insulin homeostasis. FMC-242 rapidly and selectively forms a covalent bond with cysteine 242 in the RAS Binding Domain (RBD) of PI3Kα resulting in allosteric inhibition of PI3Kα -RAS complex formation. This leads to inhibition of AKT activation in tumors with mutations in KRAS or PI3Kα, and where receptor tyrosine kinases, e.g., HER2, are activated. FMC-242 treatment of CDX and PDX models carrying HER2 amplification and/or KRAS mutation results in potent anti-tumor activity including regressions. FMC-242 is well tolerated in vivo, and inhibition of PI3Kα -RAS interaction does not impact insulin signaling or blood glucose level. Combination of FMC-242 with targeted therapies including EGFR inhibitors, KRASG12C inhibitors such as FMC-376, divarasib, olomorasib, or pan-RAS/KRAS agents results in enhanced efficacy and tumor regressions in vivo. Together, these data demonstrate the potential of FMC-242, a selective covalent inhibitor of PI3Kα -RAS interaction, to deliver improved outcomes for patients as monotherapy and in combination with targeted therapies in the clinic.

#5763 Roginolisib stabilizes inactive PI3Kdelta to deliver specific target blockade with reduced immune toxicity.

Giusy Di Conza[1], Oscar Vadas[2], Simon Tiede[3], Elise Solli[4], Maria Chaouki[5], Laura Tesmer[3], Shanlin Rao[3], Remy Visentin[2], Mathias Wenes[6], Denis Migliorini[6], Sigrid S. Skanland[4], Anne Quillet-Mary[5], Loic Ysebaert[5], Julie Guillermet-Guibert[5], Alessio Bevilacqua[1], Lars van der Veen[7], Michael Lahn[1], Kjetil Tasken[4], Gerhard Hummer[3]

[1]iOnctura SA, Geneva, Switzerland,[2]University of Geneva, Geneve, Switzerland,[3]Max Planck Institute for Biophysics, Frankfurt am Main, Germany,[4]Institute for Cancer Research, Oslo University Hospital, Oslo, Finland,[5]Centre de Recherches en Cancerologie de Toulouse, Toulouse, France,[6]Faculty of Medicine, University of Geneva, Geneve, Switzerland,[7]iOnctura BV, Amsterdam, Netherlands

Phosphoinositide 3-kinase (PI3K) is a key target in cancer therapy, but first-generation PI3K inhibitors were associated with toxicities limiting their clinical use. Roginolisib, a next-generation PI3Kdelta inhibitor, is currently being investigated across multiple cancer types. In contrast to previous PI3K inhibitors, roginolisib has shown a well-tolerated profile. We hypothesize that this improved safety is in part due to high selectivity, driven by its structural properties. Structural and biophysical analyses—including X-ray crystallography, molecular dynamics simulations, and hydrogen-deuterium exchange mass spectrometry—demonstrate that roginolisib, unlike the first-generation inhibitor idelalisib, stabilizes the catalytic C-terminal helix (k-alpha12) of PI3Kdelta. This stabilization is specific for PI3Kdelta and locks the enzyme in an inactive conformation, resulting in potent and sustained inhibition of PI3Kdelta activity. This inhibition profile is observed in tumor samples from patients with chronic lymphocytic leukemia (CLL) and in lymphoma cell lines. Although roginolisib and idelalisib exhibit similar potency in CLL cells, their effects on immune cells differ. Notably, high concentrations of idelalisib impair the cytotoxic activity of $CD8^+$ T cells and promote the differentiation of $CD4^+$ T cells towards Th17 and Th2 subsets. By contrast, roginolisib preserves $CD8^+$ T-cell function and does not alter CD4+ T-cell differentiation. This mechanism of inhibition, likely based on conformational stabilization of the inactive kinase, is novel for PI3K small-molecule inhibitors. Hence, our findings may enable the development of more effective and better-tolerated PI3K inhibitors.

#5764 Evaluating the molecular mechanism of axitinib response in head and neck squamous cell carcinoma.

Behirda Karaj, Jiayu Wang, Paul L. Swiecicki, An-Yun Teng, J. Chad Brenner

University of Michigan, Ann Arbor, MI

Head and Neck Squamous Cell Carcinoma (HNSCC), the 6th most common cancer with 800,000 new cases each year, is an extremely aggressive disease with poor overall survival that has remained unchanged for several decades. For patients that develop recurrent and metastatic (R/M) disease, treatment options are extremely limited, and despite the recent success of immune checkpoint inhibitor (ICI) therapies, overall response rates remain low. To overcome this gap in knowledge and improve survival, our team completed a Phase 2 clinical trial of the pan-VEGF inhibitor, axitinib, in R/M patients. Genetic analysis of tumors from this study revealed that 75% of patients with genomic aberrations in either *PIK3CA* or *PTEN* had a longer progression-free survival compared to 17% in those without a PI3K pathway alteration. Importantly, PI3K pathway aberrations are highly prevalent in HNSCC, accounting for 45-55% of all HNSCCs, suggesting the potential for a substantial clinical impact. In our genetically engineered mouse model (GEMM), axitinib significantly extended the overall survival of mice with K14:Pik3ca-H1047R, but not K14:control, tumors. Additionally, the use of in vitro cell proliferation and survival assays in HNSCC cell lines has shown that axitinib reduces cell numbers by 50%, increases γH2AX (DNA damage marker) protein levels as measured by western blots, and is more effective in *PIK3CA* mutant cell lines. Further, when testing the mechanism, we observed that axitinib, but not Lenvatinib (known VEGFR inhibitor), induced apoptosis in HNSCC cell lines. Deeper investigation showed that the HNSCC cell lines did not express any known axitinib targets, suggesting that axitinib may have an additional, unknown mechanism of action (MoA). To test for additional MoA, we used RNA sequencing of axitinib-treated HNSCC cell lines to compare the signal transduction pathways differentially regulated by axitinib compared to other VEGFR and PI3K inhibitors. Future studies will allow us to continue investigating axitinib's mechanism of action and its therapeutic potential in PI3K aberrant HNSCC. Our findings support clinical advancement of axitinib and use of PI3K genetic status as a predictive marker for therapeutic response for a large subset of HNSCC patients with limited therapeutic options.

#5765 Discovery of QLS1522, a mutant-selective allosteric PI3Kα inhibitor for the treatment of PIK3CA-mutant solid tumors.

Yuxing Zhang, Hua Qin, Jiasheng Fu, Naijie Fu, Difei Dong, Changliang He, Lan Zhang, Yu Zhang, Ling Li, Jun Mao, Jianping Chen, Weibo Zhu, Dong Yang, Xinghua Cheng, Guqin Shi, Jinxiao Bao, Ying Wang, Ping Chen, Su Qian, **Liang Xie**, Daqing Sun, Weikang Tao

Shanghai Qilu Pharmaceutical Research and Development Center LTD., Shanghai, China

Background: PIK3CA is a predominant oncogene in human cancers. While approved PI3Kα inhibitors like Alpelisib validate that PI3Kα blockade can suppress tumors and improve outcomes in PIK3CA-mutant ER+HER2- breast cancer, their major on-target toxicity against wild-type PI3Kα interferes with regulation of glucose metabolism which reduces their therapeutic index and limits clinical efficacy. Development of PIK3CA mutant selective inhibitors can significantly improve therapeutic window and anti-tumor efficacy by substantially reducing side effects.
Experimental procedures: The enzymatic activity was evaluated in biochemical and biophysical assays. Viability of cell lines was measured using CellTiterGlo®. Antitumor activity was evaluated in ER+ breast cancer cell line-derived xenograft (CDX) models with either kinase domain or helical domain mutations. The impact on glucose metabolism was analyzed using an oral glucose tolerance test (OGTT).
Results: QLS1522 is a potent, selective allosteric PI3Kα inhibitor designed to spare wild-type PI3Kα. It exhibited nanomolar potency against the PIK3CA H1047R mutation with high selectivity over wild-type PI3Kα and other isoforms (β, γ, δ). In a 447-kinase selectivity panel, QLS1522 showed outstanding specificity, with only Aurora-B kinase exhibiting >50% inhibition at 10 μM (IC_{50} of 7.8 μM for QLS1522 vs. 1.4 μM for STX-478). Cell panel studies revealed that QLS1522 exerted broad inhibitory effects across cancer cell lines carrying either kinase domain or helical domain mutations. In comparative analyses with other clinical-stage candidates such as STX-478 and RLY-2608, QLS1522 showed enhanced inhibition of pAKT in the T47D breast cancer cell line harboring the PIK3CA H1047R mutation. Notably, it maintained selectivity comparable to STX-478 and better than RLY-2608 in wild-type SKBR3 cells. *In vivo*, QLS1522 was well tolerated and exhibited potent antitumor efficacy in multiple ER+ breast cancer CDX models, without inducing significant glucose metabolism abnormalities. The combination of QLS1522 with standard-of-care (SoC) agents resulted in enhanced efficacy compared to monotherapy or SoC alone. QLS1522 demonstrated a favorable drug-like profile, characterized by superior solubility, permeability, and excellent pharmacokinetic properties across species, with a wide therapeutic window.
Conclusions: QLS1522 is a mutant-selective allosteric PI3Ka inhibitor and represents a promising therapeutic candidate for treating PIK3CA-mutant solid tumors. IND-enabling studies are currently in progress.

#5766 Network-level kinase activity associate with differential drug sensitivity in B-Cell lymphoma cell lines.

Simar Pal Singh, Laken Woods, Robin Keijzers, Gitanjali Dharmadhikari, Dora Schuller, Rik de Wijn

PamGene International B.V., 's-Hertogenbosch, Netherlands

Background: B-cell lymphomas display heterogeneous responses to kinase inhibitors, reflecting underlying variability in kinase activity and signaling network states. Understanding how baseline kinase activity and broader signaling network patterns relate to drug sensitivity could improve therapeutic stratification and uncover mechanisms of drug response.
Methods: Drug sensitivity data (IC_{50} values) for B-cell lymphoma cell lines were retrieved from the CancerRxGene database (Genomics of Drug Sensitivity in Cancer) and response variability for small-molecule inhibitors targeting serine/threonine kinase (STK) families was quantified using the standard deviation of its LN(IC_{50}) values across cell lines. For 11 B-cell lymphoma cell lines, kinase activity profiling was performed using KinomePro platform (PamGene International B.V.) and Upstream Kinase Analysis was used to predict kinases from the phosphorylation signatures. We conducted Multi-Omics Factor Analysis (MOFA) to integrate phosphorylation signatures and drug sensitivity data, identifying latent factors that capture correlations between kinases and drug responses.
Results: Drug responses showed substantial heterogeneity across cell lines: 7% of drugs were homogeneous (LN(IC_{50}) SD < 0.5), 41% moderately heterogeneous (SD 0.5-1), and 52% heterogeneous (SD > 1). In cell lines where drug sensitivity was observed, only 10-30% showed elevated activity of the drug target kinase, and this correlation was not statistically significant. Correlation analysis (MOFA) identified latent factors that mapped kinase activity to drug sensitivity and revealed two distinct sensitivity clusters: one comprising PI3K/AKT/mTOR, central to cell growth, survival, metabolism, and proliferation; and a second cluster including CDK, ATM/ATR, Wee1, AURKA, and MAPK, central to DNA damage response, cell cycle regulation and checkpoint signaling. Upstream Kinase Analysis validated that cell lines sensitive to AKT/PI3K/mTOR inhibitors exhibited relatively high AKT and RSK signaling activity, whereas cell lines sensitive to inhibitors targeting cell cycle pathway showed higher baseline CDK and MAPK family kinases.
Conclusions: Our integrative analysis of drug sensitivity and kinase-activity data demonstrates that B-cell lymphoma response is shaped not only by individual kinase activities but also by the architecture of signaling networks. The strong concordance between baseline kinase activity signatures and drug sensitivity highlights network-level determinants of response. Signal-network signatures associated with sensitivity may serve as biomarkers for stratification and provide mechanistic insight into heterogeneous drug responses. These findings lay a foundation for functional validation and the development of combination therapies guided by network-level dependencies.

#5767 Combining SUMO inhibition and irinotecan increases pancreatic cancer cytotoxicity.

Asimina Courelli, Leonie Ren, Herve Tiriac, Yuan Chen, Andrew Lowy

University of California, San Diego, La Jolla, CA

Introduction: Pancreatic cancer (PDAC) has a transient response to chemotherapy, motivating the need for improved treatment options. Irinotecan (IRI) is a standard of care agent for both 1st and 2nd line PDAC therapy. SUMOylation is a post translational modification on topoisomerase 1 (Top-1) that modulates its DNA binding. We hypothesized that combining IRI with Subasumstat (SST—a SUMOi agent) would synergize in reducing Top-1 efficacy, leading to augmented apoptosis.

Methods: *Human single cell RNA sequencing (scRNASeq)*: using the Human Pancreatic Cancer Single-Cell Atlas to identify SUMO2/3 expressing cancer cells after FOLFIRNINOX. *In Vitro Synergy*: KPC46, FC1245, FC1245-Gem Resistant murine PDAC cells treated with IRI and/or SST (1nM-500nM, 24hrs); viability assessed with cell titer glo; synergy plots generated using Combenefit.

Western Blots (WB): KPC46 and FC1245 cells treated with SST and/or IRI (100nM) for 24 hours; probed for Top-1 (chromatin protein fraction), γ-H2AX, and cleaved caspase-3 to validate apoptosis.

Survival Experiments: NSG mice underwent orthotopic KPC46 cell injections—IP injections with SST (15mg/kg q48h) and/or IRI (12.5mg/kg qwkly); tumor volume (TV) assessed with ultrasound.

Human PDAC Cultures: patient tumor slices incubated in 200nM SST and/or IRI for 5 days; flow Cytometry (FC) conducted for EPCAM and PanCK PDAC cell markers.

Results: scRNASeq showed SUMO2/3 is highly expressed PDAC primary tumor cells as compared to adjacent normal tissue and that SUMO2/3 expressing cancer cells persist after FOLFIRINOX treatment. Significant in vitro synergy between SST+IRI occurred as low as 50nM. WB showed the greatest increase in chromatin bound Top-1, total cell Y- H2AX, and cleaved caspase 3 (Band Intensity: IRI: 0.1, SST:0.15, SST+IRI: 0.52; p=0.009) occurred for SST+IRI. Synergistic cytotoxicity of SST+IRI treatment in vivo resulted in significantly improved survival (IRI:16, SST:17, SST+IRI=24 days; p=0.008) and reduced TV (after 2 wk-treatment; AvgTV: IRI=358mm3, SST [all mice dead], SST+IRI=132mm3; p=0.001). In human PDAC slices, SST+IRI treatment yielded the greatest decrease in PANCK+ and EPCAM+ cells (IRI:24.4%, SST:15.5%, SST+IRI:9.5%).

Conclusion: SST+IRI constitutes a promising combination treatment for PDAC with synergistic PDAC cytotoxicity observed in both murine and human models. Clinically, SST could serve as an adjunct to FOLFIRINOX or SST+IRI could be an alternative 2nd line treatment with potential to include a RAS inhibitor.

#5768 Repurposing veratridine, a previously used antihypertensive supplement, for effective treatment of metastatic colorectal cancer.

Morgan Eikanger, Khosrow S. Rezvani

University of South Dakota, Vermillion, SD

Despite significant advances in improving colorectal cancer (CRC) survival over the past decade, therapeutic challenges persist due to the rapid spread of primary tumors. The rising incidence of early-onset colorectal cancer (patients under age 50) across all ethnicities has created another major health concern, as these patients are often diagnosed with advanced, metastatic disease, leading to higher mortality rates. This highlights the urgent need to develop more effective targeted therapies to fight metastatic CRC. The mTORC2 signaling pathway plays a key tumorigenic role in CRC by driving processes such as metastasis and drug resistance. The objective of this study is to develop a selective mTORC2 inhibitor that prevents tumor growth and metastasis without harming normal cells. This project aims to advance Veratridine (VTD), a small plant-derived molecule that transcriptionally upregulates UBXN2A, a colon-specific tumor-suppressor protein. UBXN2A's E3 ubiquitin ligase partners enable it to specifically target and degrade mitochondrial HSP70 (mortalin) oncoprotein and Rictor protein in the mTORC2 pathway. This study demonstrates the dual-action mechanisms of the VTD-UBXN2A axis in patient-derived xenograft (PDX) cell lines. Acute and sub-chronic VTD treatment using both two-dimensional (2D) and three-dimensional (3D) PDX cells, assessed using real-time cell analysis via xCELLigence and Cytation visualizing technologies, revealed that VTD effectively suppresses cell migration and metastatic features of human CRC cells. Our genetic and pharmacological tools have established a platform for repurposing Veratridine, a previously used anti-hypertensive supplement, into a new generation of anti-metastatic drugs that function mechanistically through a ubiquitin-like protein, while simultaneously providing greater safety and therapeutic efficacy in patients with metastatic CRC.

#5769 A potent TOP2 poison with robust preclinical efficacy and a favorable therapeutic window supporting clinical evaluation in pancreatic cancer.

Krzysztof Grela, Stanislaw Skora, Izabela Fokt, Edd Felix, Zofia Zielinska, Mihai G. Iurascu, Mateusz Kwasnik, Rafal Zielinski, **Waldemar Priebe**

UT MD Anderson Cancer Center, Houston, TX

Background. Topoisomerase 2 alpha (TOP2A) is overexpressed in pancreatic ductal adenocarcinoma (PDAC) and its expression strongly correlates with poor prognosis and increased metastatic potential. Several TOP2A targeting drugs, including doxorubicin (DOX) are available, but none represent effective PDAC treatment modalities. Annamycin (ANN), a potent, non-cardiotoxic analog of DOX, but in contrast to DOX exhibits high accumulation in the pancreas and displays robust antitumor activity in orthotopic human PDAC models. It is currently being evaluated as a liposome formulation (L-ANN) in Phase 3 clinical trials in AML patients.

Objective. Our objective was to assess the preclinical anticancer efficacy of L-ANN using the syngeneic KPC cell line model for PDAC, and the potential impact of L-ANN on the tumor microenvironment.

Methods. In vivo efficacy of L-ANN was assessed in a KPC syngeneic model of PDAC in fully immunocompetent mice (C57BL/6). Tumor progression was measured using bioluminescence imaging (BLI) and ultrasound imaging (USI). ANN levels in plasma and tumors were assessed using LC/MS/MS. Immunohistochemistry analysis of residual tumor tissue were quantified using Aperio Image Scope.

Results. The KPC model is derived from genetically engineered mice, in general characterized by profoundly immunosuppressive tumor microenvironment. All mice were injected orthotopically with established KPC cells and showed consistent tumor growth with an average weight of 654.6± 83.8 mg at day 20. However, mice that received 3 weekly L-ANN injections at 4 mg/kg (IV, starting day 7) had significantly reduced tumors (103.5±34.1 mg), with 3 mice exhibiting complete regression. Tumor weight correlated with BLI and USI data and confirmed the dramatic inhibition of tumor growth in the L-ANN cohort. High levels of ANN were measured in residual tumor tissue 1h post injection (5.8±0.5 µg/kg) and were roughly 7-fold higher than the average plasma levels (0.83±0.1 µg/ml). Ex vivo analysis revealed increased levels of DNA damage in residual tumors when compared to vehicle-treated mice (pH2A gamma 35.3±5.4% vs. 5.8±0.3%, respectively). Immune profiling of the tumors revealed significant infiltration of CD8+ and CD4+ cells only in L-ANN treated mice, suggesting their contribution to the antitumor activity of ANN. T cell ablation experiments warrant verification of the role played by CD8+ T cells in the antitumor response.

Conclusion. Our preclinical studies demonstrate robust antitumor activity of L-ANN in different PDAC models, including prior human PDAC models and now an implantable syngeneic immunocompetent KPC model, that correlates with high tumor uptake of L-ANN. Along with low toxicity prolife of L-ANN (e.g. lack of cardiotoxicity) established in ongoing clinical trials, these data substantiate the clinical evaluation of L-ANN in PDAC patients.

#5770 Design, synthesis, and biological investigation of a new class of duocarmycin payloads for ADC development.

Goreti R. Morais, David Pajtas, Enric A. Picher, Sneha Smarakan, Robert A. Falconer, **Klaus Pors**

Institute of Cancer Therapeutics, University of Bradford, Bradford, United Kingdom

Introduction: The duocarmycins belong to a class of agent that has been in the interest of chemist and drug developers for over four decades. Their pico-molar cellular potency, unique mechanism of action, and efficacy against drug-resistant cancer cells makes them attractive as payloads for inclusion in antibody-drug conjugate (ADC) discovery approaches. However, despite great advances in fine-tuning biological activity through structure-activity relationship (SAR) studies, no duocarmycin-based therapeutic has reached clinical approval. Recent duocarmycin-based ADCs under clinical evaluation have been hampered by a narrow therapeutic index, which have inspired us to modulate the duocarmycin scaffold designed by nature. Here we present our design approach, synthesis and biological investigation of new duocarmycin chemotypes.
Methodology: Seco-duocarmycins derived from common scaffolds such as CBI and CPI are precursor molecules where the phenolic OH group essential for spirocyclisation was converted into a triflate. The latter was subjected to (i) Suzuki chemistry to generate novel aryl C-C linked compounds or (ii) or Buchwald-Hartwig reaction to generate aniline-linked duocarmycin target molecules. Subsequently, modulated compounds were studied for their ability to spirocyclise (LCMS), cause DNA damage using γ-H2AX as marker and produce antiproliferative effects in a panel of breast, colon, ovarian, prostate cancer and rhabdomyosarcoma cell lines (MTT assay).
Results: Biochemical assays revealed that these analogues exhibit a slower spirocyclization rate (2-48 hours) compared to the control compounds CPI-MI and CBI-MI (< 90 min). The library of duocarmycin payloads exhibited a wide range of cellular potencies in our panel of cancer cell lines (0.1 - 1000 nM), retaining antiproliferative activity in doxorubicin (MCF7adr) and docetaxel-resistant (PC3-D8) cancer cell lines whilst also be unaffected by the p53 status (HCT116 p53+/+ and p53-/-).
Conclusion: New duocarmycin chemotype design offers an opportunity to reduce spirocyclisation rate and DNA reactivity to fine-tune cellular potency. We hypothesise incorporation of these promising payloads into ADC therapeutics will improve tumour biodistribution, bystander effect and reduce normal tissue toxicity.

: Proximity-Induced Drug Discovery 2
Poster Session

#5774 Discovery of potent CDK8/CDK19 PROTAC degraders with superior anti-leukemia efficacy.

Li Zhang, **Jia Zheng**, Rebekah Martin, Jing Li, Zachary T. Mack, Hao Ji, Eugenia V. Broude, Igor B. Roninson, Campbell McInnes, Mengqian Chen

Drug Discovery and Biomedical Sciences, University of South Carolina, College of Pharmacy, Columbia, SC

Aggressive leukemias, including acute myeloid leukemia (AML), remain highly challenging diseases due to the lack of curative therapies. AML rapidly develops resistance to both conventional and targeted treatments, underscoring the urgent need for more effective therapeutic strategies. Recently, the transcription-regulating Mediator kinases CDK8 and CDK19 have emerged as promising targets, with CDK8/19 kinase inhibitors (CDK8/19i) now in clinical trials for leukemia. However, preliminary data from our laboratory demonstrate that leukemia cell lines exhibit heterogeneous and often incomplete responses to CDK8/19i, with many developing resistance after initial sensitivity. To test the hypothesis that direct depletion of CDK8/19 proteins in contrast to inhibiting kinase activity alone, may elicit more potent and durable anti-leukemia activity, we developed three series of PROteolysis TArgeting Chimeras (PROTACs) based on selective CDK8/19 inhibitors conjugated through diverse linkers to cereblon (CRBN)-recruiting ligands. After extensive optimization of both the kinase targeted warhead and composition of the linker, the most potent degrader obtained, SNX7886, induced efficient and simultaneous degradation of CDK8 and CDK19 across multiple cell types with a DC_{50} of 10 nM. When evaluated side-by-side with its cognate CDK8/19i (BI1347), SNX7886 consistently produced superior and sustained growth inhibition without the adaptive resistance observed with CDK8/19 kinase inhibitors in multiple leukemia lines. Notably, in an aggressive refractory AML cell line NOMO1, prolonged treatment with CDK8/19-PROTACs resulted in complete growth arrest, with no surviving cells detectable over extended exposure. Transcriptomic and proteomic analyses further revealed that CDK8/19-PROTACs engage both shared and distinct molecular pathways compared to CDK8/19i, indicating deeper disruption of transcriptional reprogramming circuits associated with AML survival and adaptation. These findings highlight targeted CDK8/19 degradation as a promising therapeutic strategy capable of overcoming key limitations of CDK8/19 kinase inhibitors in AML.

#5775 When CDK meets CIP: Linking target engagement to functional outcomes in CDK2 molecular glue and CDK-TCIP.

Qing Xue, Zhu Meng, Xue Yang, Qian Wang, Lili Chai, Wei Liu, **Tj (Tiejun) Bing**

ICE Bioscience, Beijing, China

Background: Cyclin-dependent kinases (CDKs) orchestrate cell cycle progression and transcriptional control, and their dysregulation is a hallmark of cancer. While conventional CDK inhibitors have shown utility, emerging modalities such as molecular glues (MGs) and transcriptional/epigenetic chemical inducers of proximity (TCIPs) offer novel mechanisms to modulate or utilize CDK activity. CDK2 MG promote selective degradation of CDK2 complexes, whereas CDK9 TCIP induce proximity-driven transcriptional rewiring. The purpose of this study was to demonstrate linkage of target engagement to cellular outcomes across these two modalities, thereby establishing mechanistic insights for next-generation CDK therapeutics.
Methods: We developed an integrated platform combining biophysical binder screening (Spectrum Shift, SPR, HTRF), cellular assays of CDK2 degradation and cell cycle control (proliferation, phospho-RB, flow cytometry), mechanism-of-action studies in CCNE-amplified and resistant models with drug combinations, CDK-TCIP engagement and transcriptional assays (NanoBRET, BCL6 reporter, qPCR), downstream functional profiling (viability, apoptosis, cancer cell panels, primary cell lines), and off-target evaluation by Western blotting, proteomics, and ICESTP safety panels.
Results: CDK2 MG induced robust CDK2/CRBN ternary complex formation and degradation of CDK2, leading to reduced proliferation, decreased phospho-RB, and G1 arrest. CCNE amplification conferred heightened sensitivity, while palbociclib resistant cell lines revealed CDK2 MG as a potential strategy to overcome drug resistance. In contrast, CDK-TCIP stabilized ternary complexes that drove nuclear translocation and transcriptional activation, evidenced by BCL6 reporter activation and target qPCR upregulation. Functional assays demonstrate broad vulnerability across cancer cell panels, with apoptosis induction in select primary cell lines. Off-target profiling confirmed high selectivity, with minimal liabilities detected across proteomic and ICESTP safety screens.
Conclusions: This study provides comprehensive profiling showing that CDK2 MGs and CDK-TCIPs achieve distinct biological outcomes through degradation versus transcriptional rewiring. By integrating biophysical, biochemical, and cellular analyses, we establish quantitative links between target engagement and phenotypic consequences. These findings define mechanistic frameworks for optimizing CDK-targeting modalities and inform rational design of selective, context-dependent interventions in oncology.

#5776 Discovery of an orally bioavailable AKT degrader with sustained *in vivo* efficacy and translational potential.

Seung Jae Jeong[1], Hyunsun Jo[2], Juyoung Jung[2], Hyunah Yoon[2], Aerim Hwang[2], So-Eun Son[2], Iljin Shin[1], Eun Seo Bae[1], Narkhyun Bae[1], Hyounmie Doh[1]

[1]Daewoong Pharmaceutical, Seoul, Korea, Republic of,[2]Pin Therapeutics Inc., Seongnam-si, Korea, Republic of

The PI3K-AKT signaling pathway is frequently dysregulated across solid tumors, including PIK3CA-mutant cancers. While several PI3K and AKT inhibitors have been approved for clinical use, therapeutic benefit remains limited by feedback reactivation and incomplete pathway suppression. We developed a novel, orally active small-molecule degrader designed to achieve sustained AKT removal and pathway inhibition.

Our AKT degrader lead molecule DWP221/PIN002 induced rapid and sustained degradation of AKT in tumor cells and demonstrated a strong correlation between systemic exposure and pharmacologic response after oral dosing in tumor-bearing mice. In vivo, the degrader achieved dose-dependent tumor growth inhibition and showed preferential distribution to tumor tissue. Exploratory combination with fulvestrant further improved tumor growth control, supporting potential therapeutic complementarity in hormone receptor-positive tumors. DWP221/PIN002 was well tolerated throughout the study period, without notable body-weight loss or overt signs of systemic toxicity, and maintained a favorable exposure-response relationship consistent with its drug-like properties.

This study demonstrates that an orally bioavailable AKT degrader can achieve durable target suppression and in vivo efficacy through sustained exposure and efficient target engagement. These findings support that targeted protein degradation may overcome key limitations of conventional kinase inhibition and provide a differentiated approach toward next-generation targeted therapies for PI3K-AKT-driven cancers.

#5777 Functional role of PLK1 in colorectal cancer progression and its potential to chemoresistance.

Kong Hyejeong[1], Baek MooJun[1], HyoWook Gil[1], Eunjung Yang[1], Kwangseock Kim[1], Taewan Kim[1], jaesung Ryu[1], Beamjun Park[1], Jeong Kyu Bang[2], **Seob Jeon**[1]

[1]Soonchunhyang University Cheonan Hospital, Cheonan, Korea, Republic of,[2]Division of Magnetic Resonance, Korea Basic Science Institute(KBSI), Ochang, Korea, Republic of

OBJECTIVE
Colorectal cancer is a cancer with high prevalence and mortality rates worldwide, treated with surgery, chemotherapy, and radiation therapy depending on the stage. Advanced colorectal cancer is mostly curable by surgical excision combined with chemotherapy remains the primary treatment for most patients with advanced colorectal cancer. Drug resistance is one of the major obstacles in colorectal cancer treatment, highlighting the need for new therapeutic targets. Polo-like kinase 1(PLK1), a key regulator of the cell cycle, is frequently overexpressed in colorectal cancer as well as various malignancies and associated with poor prognosis. To explore the mechanisms of chemoresistance in colorectal cancer and identify potential strategies to overcome it, we investigated the functional role of PLK1 and its impact on drug sensitivity.
METHODS
PLK1 was silenced using siRNA, and functional studies assessing proliferation, migration, invasion, and wound healing were conducted to investigate its role in colorectal cancer. To evaluate chemoresistance, colorectal cancer cells were treated with oxaliplatin. Additionally, we assessed the drug sensitivity of the oxaliplatin versus PLK1-PROTAC+oxaliplatin to evaluate its impact on cell survival. Subcutaneous implantation of CRC cell line-derived tumors was performed in BALB/c nude mice to assess tumor growth after drug treatment.
RESULTS
Suppression of PLK1 expression significantly impaired function of colorectal cancer. Colorectal cancer cells with low PLK1 expression exhibited significantly increased sensitivity to oxaliplatin. Compared to oxaliplatin alone, treatment with a PLK1-targeting PROTAC in combination with oxaliplatin significantly reduced colorectal cancer cell viability. In the in vivo study, PLK1-PROTAC exerted significantly enhanced suppression of tumor growth compared with Oxaliplatin.
CONCLUSION
Suppression of PLK1 expression led to a significant decrease in colorectal cancer cell function highlighting its essential role in sustaining tumor growth and metastatic functions. These findings suggest that PLK1 may serve as a potential therapeutic target for inhibiting colorectal cancer progression and overcoming chemoresistance.

#5778 RCZY-690: A tri-complex molecular glue pan-RAS (ON) inhibitor exhibiting best-in-class potential for RAS-addicted solid tumors.

Xiaojing (Celia) Chen[1], Lin Wang[1], Xiaohong Liu[1], Qiaoni You[1], Shenjun Li[2], Ling Wang[2], Shanshan Bi[2], Jing Jiang[2], Jianming Bao[1]

[1]Rongchang Pharmaceuticals, Ltd., Yantai, China,[2]RemeGen Co., Ltd., Yantai, China

The RAS family, including HRAS, KRAS, and NRAS, acts as a master molecular switch that regulates essential cellular processes, including cell growth, proliferation, survival, and differentiation, and is strongly implicated in cancer. As members of the small GTPase superfamily, RAS proteins cycle between an active (GTP-bound) state and an inactive (GDP-bound) state to control key signaling pathways such as the MAPK/ERK and PI3K/AKT. Oncogenic RAS mutations— mostly occur at codons 12, 13, and 61—impair intrinsic or GAP-stimulated GTP hydrolysis, and shifting the equilibrium toward the active, GTP-bound form of RAS. This persistent activation leads to constitutive downstream signaling, driving uncontrolled cell proliferation, enhanced survival, and tumorigenesis. RCZY-690 is a highly potent, orally bioavailable tri-complex molecular glue pan-RAS (ON) inhibitor with Best-in-Class potential. It specifically targets both mutant and wild-type RAS proteins in their active GTP-bound (ON) state, thereby blocking RAS engagement with downstream effectors and disrupting oncogenic signal transduction. In multiple RAS-mutant cell lines, RCZY-690 exhibited significantly greater inhibition of cell proliferation and more profound suppression of downstream p-ERK levels compared with RMC-6236. RCZY-690 has favorable ADME and PK properties, achieving higher exposure, an extended half-life ($T_{1/2}$), and a flat Cmax/Ctrough concentration-time profile consistent with an improved therapeutic index (TI). Compared to RMC-6236 and ERAS-0015, it shows higher degree of preferential tumor distribution in mouse models. These advantages enable RCZY-690 to achieve comparable tumor growth inhibition (TGI) at doses as low as 1/25th to 1/250th those of RMC-6236 and 1/3rd to 1/10th those of ERAS-0015 across KRAS-mutant CDX and syngeneic tumor mouse models. RCZY-690 demonstrates favorable PK/PD profiles, including more durable DUSP6 suppression than RMC-6236, alongside excellent in vivo tolerability and promising safety margins in preclinical toxicity studies. Taken together, these attributes position RCZY-690 as a promising pan-RAS(ON) inhibitor and support its advancement toward an Investigational New Drug (IND) filing planned for Q2 2026.

#5779 RCZY-869: A highly potent, selective, and orally bioavailable covalent KRAS^{G12D} (ON-state) inhibitor with robust antitumor activity in preclinical models of KRAS^{G12D}-driven solid tumors.

Xiaojing (Celia) Chen, Lin Wang, Xiaohong Liu, Dan Wang, Jianming Bao

Rongchang Pharmaceuticals, Ltd., Yantai, China

KRAS^{G12D} is the most prevalent oncogenic mutation in the RAS family. Among common solid tumors, it drives approximately 40% of pancreatic ductal adenocarcinoma (PDAC), 15% of colorectal cancer (CRC), and 5% of non-small cell lung cancer (NSCLC) cases, underscoring a significant unmet clinical need for targeted therapies. To date, no direct KRAS^{G12D} inhibitors have received global regulatory approval, highlighting the pressing demand for effective agents. In KRAS^{G12D}, the G12D substitution reduces RAS-bound GTP hydrolysis rate by ~2-fold compared to wild-type KRAS (and even more relative to KRAS^{G12C}), resulting in a higher proportion of KRAS^{G12D} existing in the GTP-bound conformation within cancer cells. This makes the “ON” state the dominant, therapeutically relevant form driving oncogenesis. Inhibiting this active, GTP-bound pool directly disrupts the core signaling activity, potentially yielding greater efficacy than targeting the transient “OFF” state. This mechanism supports targeting the GTP-bound conformation as a strategy with high clinical benefit potential. Emerging KRAS^{G12D} inhibitors target OFF, ON, or both states. Phase 1/1b data show ON-state inhibitor RMC-9805 and ON/OFF inhibitor VS-7375 (GFH375) have comparable objective response rates (ORR) and disease control rates (DCR) in NSCLC at their respective recommended Phase 2 doses (RP2D). In PDAC, VS-7375 had marginally higher ORR/DCR (52%/100% vs. 30%/80% for RMC-9805), but RMC-9805 had superior safety: low dose modification rates, no grade 4/5 TRAEs (predominantly grade 1 toxicities), and no DLTs. VS-7375 had a ~4-fold higher discontinuation rate, with 27.5% of patients experiencing grade 3/4 TRAEs. To address these challenges, Rongchang Pharmaceuticals has developed RCZY-869, a highly potent, selective, and orally bioavailable covalent tri-complex inhibitor that specifically targets the GTP-bound (ON) state of KRAS^{G12D}. It engages cyclophilin A (CypA) to form a stable ternary complex with KRAS^{G12D}(ON), blocking downstream effectors and suppressing MAPK signaling. RCZY-869 exhibits significantly greater in vitro antiproliferative activity than RMC-9805 across KRAS^{G12D}-mutant cell lines, favorable ADME properties, and superior oral PK in preclinical species. In KRAS^{G12D} xenograft models, it delivers dose-dependent antitumor effects at well-tolerated doses, achieving tumor growth inhibition (TGI) comparable to RMC-9805 but at substantially lower exposures. These findings position RCZY-869 as a novel ON-state-selective KRAS^{G12D} inhibitor with compelling preclinical potency and efficacy. Ongoing characterization advances its candidate package to support clinical development.

#5780 Discovery of ATH-007, a novel, potent and highly selective CCNE1 molecule glue shows robust anti-tumor activities and better safety profile.

Zhiyong Yu, Wenming Li, Yuyao Zhang, Wenwen Zhao, Youxi Chen, **Feng Zhou**

Atheron Therapeutics, Ltd., Shanghai, China

Cyclin E1 (CCNE1) is a key cell cycle regulatory protein and binds to cyclin-dependent kinase 2 (CDK2), forming a CCNE1-CDK2 complex, which is essential for driving the cell cycle progression to S-phase for subsequent DNA replication. Amplification of the *CCNE1* locus on chromosome 19q12 is prevalent in multiple tumor types, particularly in breast cancer, high-grade serous ovarian cancer, uterine tumors, and gastro-esophageal cancers. In breast cancer, amplification of CCNE1 is a potential cause of resistance to CDK4/6 inhibitor. CCNE1 amplification may also confer resistance to chemotherapy and is associated with poor overall survival. Therefore, there is a significant unmet medical need for tumors with CCNE1 amplification. Compared with CDK2 inhibitors, CCNE1 molecular glues exhibit better selectivity, thereby reducing the adverse effects caused by CDK2 inhibitors in clinical trials. Here, we report that ATH-007 is a highly selective CCNE1 degrader that demonstrates superior degradation selectivity and anti-tumor activity against CCNE1-amplified cells. ATH-007 strongly degrades CCNE1 with DC_{50} of <10 nM and achieves complete protein degradation (Dmax of >95%) and also shows 1000-fold degradation selectivity over other CRBN substrates, including GSPT1, CK1α, and IKZF1, etc. ATH-007 can effectively inhibit the proliferation of MKN1 cells with CCNE1 amplification, however, after the deletion of RB1 (a downstream substrate of CCNE1), the inhibitory effect of ATH-007 on MKN1-RB1-KO cells is abrogated. Across a panel of CCNE1-amplified tumor cell lines, ATH-007 potently inhibits proliferation with GI_{50} values ranging from 1 to 100 nM, similar to the potency of CDK2 inhibitors. In CCNE1-non-amplified cells, ATH-007 exhibits significantly superior selectivity compared to CDK2 inhibitors, rendering it the greater therapeutic window. In terms of *in vitro* hematotoxicity assay, ATH-007 shows no inhibitory effect on the differentiation of all lineages, while CDK2 inhibitors exhibits a strong inhibitory effect. Compared with existing CCNE1 molecular glues, ATH-007 exhibits weaker inhibition of hERG, indicating that it has potentially better safety. ATH-007 exhibits favorable PK properties, which enable us to advance this molecule to *in vivo* experiments. In tumor model with CCNE1 amplification, ATH-007 shows tumor suppression activity even at low doses and inhibit tumor growth in a dose-dependent manner. Furthermore, the inhibitory activity against tumors is correlated with the degradation of CCNE1.

#5781 CXB-7138, A novel GSPT1/ZFP91 dual molecular glue degrader, for targeted treatment of pancreatic ductal adenocarcinoma.

Jin-Hee Park, Jae-Seon Lee, Shin-Hae Lee, NamKyoung Kim, Sumin Kim, Chaeseon Kim, Yong Chan Kim, Eunbin Park, Jiah Kim, **Heung Sik Hahm**, Jung Beom Son, Nam Doo Kim, Hwan Geun Choi

CoBX Bio Co., Ltd, Seoul, Korea, Republic of

Background: Pancreatic ductal adenocarcinoma (PDAC) remains one of the most lethal malignancies, driven by profound intertumoral heterogeneity and a dense tumor microenvironment that limits the effectiveness of current therapies. GSPT1 (eRF3a), a translation termination GTPase historically considered “undruggable,” has recently become targetable through cereblon (CRBN)-mediated protein degradation. ZFP91, an atypical E3 ligase and transcriptional regulator, is also highly expressed in PDAC and correlates with poor clinical outcomes. Here, we present CXB-7138, a CRBN-recruiting molecular glue degrader built on a novel, nontraditional chemical scaffold, designed to induce selective degradation of both GSPT1 and ZFP91. To our knowledge, CXB-7138 represents the first dual-target GSPT1/ZFP91 degrader leveraging CRBN for therapeutic intervention in PDAC.
Methods: A panel of PDAC and non-PDAC cancer cell lines was treated with CXB-7138, and viability was assessed across genetically diverse models. Degradation of GSPT1 and ZFP91 was quantified by proteomics, Western blotting, and HiBiT-based assays. Antitumor activity was evaluated in a subcutaneous PDAC xenograft model following oral administration, with tumor volume and body weight monitored longitudinally.
Results: CXB-7138 exhibited potent antiproliferative activity across a broad spectrum of cancer cell lines—including but not limited to PDAC—with IC_{50} values in the sub-nanomolar to double-digit nanomolar range. Within PDAC models, a trend toward increased sensitivity was observed in cell lines harboring SMAD4 alterations, suggesting a potential genomic determinant of CXB-7138 responsiveness. Comparative proteomic profiling confirmed that the compound’s pharmacologic effects arise from selective and sustained CRBN-mediated degradation of both GSPT1 and ZFP91. In vivo, oral single-agent CXB-7138 inhibited tumor growth in a PDAC xenograft model, demonstrating potent antitumor efficacy with favorable tolerability.
Conclusions: CXB-7138 is a first-in-class CRBN-recruiting dual molecular glue degrader targeting GSPT1 and ZFP91 through a nontraditional scaffold. Its broad antiproliferative activity, molecularly defined sensitivity patterns, and strong in vivo efficacy position CXB-7138 as a highly promising therapeutic strategy for PDAC, a malignancy in urgent need of new treatment options.

#5782 Machine learning and structure-guided discovery of EP300-selective, orally bioavailable degraders for cancer therapy.

Ho Yeon Nam, Sun Young Jang, SeokJong Kang, Yongtaek Lee, Seongil Kang, Taegun Kim, Jooyun Byun, Gunwoo Lee, Wonjong Lee, Hobin Im, Haemin Chon, Yu-Yon Kim, Seunghwan Jung, Young Gil Ahn

Hanmi Pharmaceutical Co., Ltd., Hwaseong, Korea, Republic of

EP300 and CBP are closely related transcriptional co-activators with histone acetyltransferase (HAT) activity that regulate gene expression, cell proliferation, and differentiation. In normal tissues, EP300 and CBP compensate for each other; however, CBP-deficient tumor cells become selectively dependent on overexpressed EP300, creating a synthetic-lethal therapeutic window. Despite this opportunity, designing EP300-selective inhibitors has been challenging because the EP300 and CBP HAT domains share ~90% sequence identity. In this regard, targeted protein degradation (TPD) platform provides potential opportunity to achieve selective degradation. Recent findings indicate that even subtle structural variations, such as a single surface residue near the binding interface or the positioning of a lysine, amplify into significant differences in ternary complex stability and ubiquitination efficiency for proteolysis. Accordingly, we designed and synthesized heterobifunctional degraders that selectively degrade EP300 over CBP. Here, we report the discovery of orally bioavailable EP300 degraders and their evaluation *in vitro*, *in silico*, and *in vivo*. We identified early leads that selectively degrade EP300 over CBP, as confirmed by western blotting, thereby establishing proof-of-concept that TPD can confer EP300 selectivity. To further improve cellular potency, we optimized the initial lead using structure-guided design informed by molecular dynamics (MD) simulations; this analysis highlighted functionally important EP300 residues and guided modifications that increased the stability of the EP300-CRBN ternary complex relative to the starting scaffold. We applied a bioinformatics framework to identify solid tumor indications responsive to EP300 degradation. Using DepMap EP300 CRISPR scores integrated with RNA expression profiles, we developed and optimized a machine-learning model that accurately distinguished sensitive from resistant cell lines. Model-based prioritization identified several indications with the highest predicted sensitivity. Experimental validation confirmed that the optimized EP300 degrader induced robust EP300 degradation and potent growth inhibition across these tumor cell lines. In mouse xenograft models, it achieved high antitumor efficacy with lower toxicity than an EP300/CBP dual inhibitor, consistent with synthetic lethality. In conclusion, this study demonstrates that selective EP300 degradation can be achieved by applying TPD modality, enabling synthetic-lethal strategy and oral bioavailability. Structure-guided design and bioinformatics-driven indication selection provided an efficient path to preclinical candidates, underscoring the therapeutic potential of Hanmi's EP300 degraders for solid cancers.

#5783 HY809382, a PRC2 degrader with best-in-class properties, demonstrates efficacy across multiple tumors and overcomes EZH2 inhibitor clinical resistance caused by EZH2 genetic mutations.

Xin Li[1], Weixing Zhu[1], Ruwei Wang[1], Zengrong Li[1], Liming Zhang[1], Lei Chen[1], Sai Yang[1], Feng Xu[1], Qian Ma[1], Huangtao Jin[1], Xiaotian Huang[1], Ting Zhang[1], Xing Yu[1], Ming Weng[1], Xiaoxiao Wang[1], Xiaohong Hou[1], Manli Hu[1], Tingting Dai[1], **Ruowen Zhang**[2], Juan Du[1]

[1]Yangtze River Pharmaceutical (Group) Co., Ltd., Taizhou, China,[2]Medicilon USA Corp, Lexington, MA

The dysregulation of Polycomb repressive complex 2 (PRC2) is implicated in tumorigenesis across a spectrum of cancers, such as prostate cancer, non-small cell lung cancer, endometrial carcinoma, ovarian cancer, clear cell renal cell carcinoma and hematological malignancies. Furthermore, aberrant PRC2 activity is closely associated with tumor immune evasion and the development of therapy resistance, thereby influencing clinical outcomes. Given its critical role in tumor initiation and progression, the core PRC2 subunits EZH2 and EED have emerged as promising therapeutic targets. Among various EZH2 inhibitors under development, Tazemetostat (Tazverik) was the first to received FDA approval for the treatment of follicular lymphoma (FL) and epithelioid sarcoma (ES). Despite this progress, new challenges have emerged, including acquired resistance through EZH2 mutations and limited efficacy in tumors due to EZH1 compensatory mechanisms. Degradation of EED disrupts the assembly, stability, and activity of PRC2 complex, offering potential advantages over merely inhibiting EZH2 catalytic function. HY809382 is a potent and selective PRC2 degrader that targeted the EED subunit, designed with superior drug-like properties compared to existing EZH2 and EED inhibitors. HY809382 potently inhibited the proliferation of multiple tumor cell lines *in vitro*, including prostate cancer, endometrial carcinoma and gastric adenocarcinoma. Under identical experimental conditions, HY809382 exhibited greater potency than both PF-06821497 (an EZH2 inhibitor) and APG-5918 (an EED inhibitor). Once-daily oral administration of HY809382 demonstrated significant and dose-dependent tumor growth inhibition in xenograft models of prostate cancer, endometrial carcinoma, and gastric adenocarcinoma. Furthermore, HY809382 combined with enzalutamide synergistically suppressed tumor growth in a castration-resistant prostate cancer xenograft model. Clinically identified EZH2 mutations confer resistance to FDA-approved EZH2 inhibitors, whereas HY809382 remained effective in both cellular and *in vivo* xenograft models. Collectively, these data support HY809382 as a promising best-in-class PRC2 degrader candidate, warranting further development for the treatment of tumors exhibiting clinical resistance to EZH2 inhibitors.

#5784 Discovery of FX-111, a first-in-class heterobifunctional degrader of transcriptionally active androgen receptor (AR_{ON}), to treat patients with AR-driven prostate cancer.

Jennifer A. Mertz, Thomas H. Graham, Brian J. Golbourn, Yong Li, Alex P. Rossi, Marco Chiumiento, Phuong A. Nguyen, Jeremy W. Setser, Gregg Chenail, Rainer Wilcken, Jonathan T. Goldstein, Hannah Nguyen, Christina S. Henderson, Kaylyn E. Williamson, Byron DeLaBarre, Christopher M. Bailey, Miljan Kuljanin, Matthew C. Koehler, James E. Audia, Jonathan E. Wilson, Jacob I. Stuckey, Robert J. Sims

Flare Therapeutics, Cambridge, MA

Significant unmet need exists in metastatic castration resistant prostate cancer (mCRPC). As the disease progresses, mutations, amplification and overexpression of the androgen receptor (AR), often accompanied by elevated intratumoral androgen levels, become increasingly prevalent, with 85% of mCRPC cases remaining AR-dependent. Current therapies target the cytoplasmic, hormone-unbound AR (AR_{OFF}); however, rising AR levels as prostate cancer (PC) advances represent a primary mechanism of resistance to these therapies. Nuclear, hormone-bound, transcriptionally active AR (AR_{ON}) is the main driver of androgen signaling and tumor progression in AR-dependent PC. Here we report the discovery of a selective AR_{ON} degrader that utilizes a novel allosteric binding site revealed upon hormone binding. We identified multiple x-ray validated ligands that bind to this novel AR_{ON} pocket. Conversion and optimization of these ligands into Cereblon-based heterobifunctional degraders resulted in the identification of FX-111. FX-111 achieves rapid and sustained degradation of AR (DC_{50} = 10 nM) and displays exquisite selectivity, with no observed degradation of other steroid hormone receptors or other proteins using proteome-wide analysis in multiple cell lines. FX-111 degrades AR and silences AR target genes effectively irrespective of increasing hormone as it is non-competitive with androgen binding, in contrast to the loss of potency seen with orthosteric degraders with increasing hormone levels. FX-111 degrades AR_{ON} when alternative agonists are used to stimulate its activity and can effectively degrade clinically relevant mutant forms of AR. RNA-seq analysis in LNCaP and VCaP cells treated with FX-111 reveals complete inhibition of androgen-driven transcriptional changes, with minimal gene expression impact in hormone-depleted conditions, underscoring FX-111's specificity for AR degradation. In vivo, FX-111 induces robust AR degradation, prostate specific antigen suppression and significant tumor growth inhibition in VCaP xenograft models, with oral administration at 10 mg/kg BID. Addition of exogenous androgen in intact or castrated mice, mimicking intratumoral hormone, did not affect the pharmacodynamic profile or efficacy of FX-111, whereas orthosteric degraders lost both potency and the ability to suppress AR transcriptional activity. Potent suppression of AR function in prostate and testes tissues, with accompanying organ weight loss, was observed in mice. Targeting AR_{ON} in PC could potentially treat all forms of PC that are driven by AR signaling without the need for androgen deprivation. FX-111 is currently in IND-enabling studies with plans to initiate clinical studies in 2026.

#5785 RBM39 degrader anticancer activity against neuroblastoma: CDKN2A/B deletion as a biomarker.

James Finn[1], Imad salhab[2], Haihong Jin[3], Fei Liu[1], Dong Liu[1], Yunkai Zhang[1], Xing Liu[4], James Tonra[1], Lan Huang[1], **Dan Lu**[1]

[1]Seed Therapeutics, King of Prussia, PA,[2]Seed Therapeutics, New York, NY,[3]Vitsgen Therapeutics, Portland, OR,[4]Independent Consultor, King of Prussia, PA

Robust anticancer effects of molecular glue RBM39 degraders have been reported in human neuroblastoma models (DOI: 10.1126/sciadv.abj5405 and 10.1038/s41467-022-28907-3). In the present study we further explored the MOA underlying the potent activity of RBM39 degraders in neuroblastoma, utilizing SEED Therapeutics' optimized RBM39 degrader ST-00937, and its deuterium derivative ST-01156 that was recently cleared by the FDA for clinical testing (NCT07197554**)**. Method In vitro anticancer activity was profiled in 3D clonogenic assays utilizing tissue derived from 4 neuroblastoma patients and 6 human neuroblastoma tumor cell lines. In vivo anticancer efficacy was evaluated in nude mice bearing subcutaneous tumors established with SH-SY5Y human neuroblastoma cells. Cell lysates generated from 2D culture of neuroblastoma cell lines treated with ST-01156 were evaluated by TMT labeling mass spectrometry and Western Blot. Result ST-00937 treatment showed differential anticancer activity in 6 neuroblastoma cell lines and 4 patient-derived models. For the 6 neuroblastoma cell lines, the IC_{50} values ranged from 0.04 to 0.3μM among 5 sensitive cell lines, while SH-EP cells did not respond. The IC_{50} for colony formation ranged from 0.03 to 2.3μm in 4 patient-derived models. Notably, the most insensitive patient-derived model NB0277 has a homozygous CDKN2A/B deletion. In vitro activity was extended to in vivo activity utilizing SH-SY5Y cells. In vivo, complete tumor regressions were observed with 5-Days On/2-Days Off, twice daily oral treatment with ST-01156, without body weight loss. Proteomic analysis in vitro showed that ST-01156 decreased proteins involved in DNA damage and cell cycle control, and increased p53 signaling after 16h treatment. The divergent anticancer responses of SH-SY5Y and SH-EP subclones (both derived from SK-N-SH) warranted further investigation. Although both lines expressed similar levels of RBM39 and exhibited complete RBM39 degradation after treatment, distinct downstream effects were observed. In SH-SY5Y cells (adrenergic CDKN2A wild-type, cMYC amplified), cMYC expression was downregulated and the p21/p53 pathway was upregulated by ST-01156. In contrast, these changes were not detected in SH-EP cells (mesenchymal, CDKN2A/B deletion). This differential regulation may explain why cleaved caspase-3 (apoptosis) was not observed in ST-01156 treated SH-EP CDKN2A/B deleted cells, although DNA damage indicated by γH2AX was increased in both cell lines. Conclusion RBM39 degraders demonstrate differential potency in 6 neuroblastoma cell lines and 4 patient-derived models in vitro, and total tumor regression in SH-SY5Y in vivo. DNA damage and increased p53-mediated apoptosis are confirmed in the sensitive neuroblastoma model SH-SY5Y, while resistance in CDKN2A/B-deleted lines suggests CDKN2A loss may serve as a predictive biomarker of resistance to RBM39-targed therapy.

#5786 Novel non-CRBN based molecular glue identification and corresponding E3 ligase target deconvolution through multi-omics analysis.

Tongrui Hao, Yi Chen, Yan Gao, Jing Wen, Wenzhang Chen, **Zhongyao Ma**, Letian Kuai, Wenji Su

WuXi AppTec, Shanghai, China

Targeted Protein Degradation (TPD) is considered one of the new drug discovery strategies that could address previously “undruggable” disease targets through the ubiquitin-proteasome system (UPS). Although the current Target Protein Centric approach has proven successful in many cases, especially with well-validated E3 ligases such as CRBN and VHL, there is still a strong need to identify potential target protein degraders (PROTACs, molecular glues, etc.) through both target-centric and target-agnostic approaches. This would not only explore and identify potential tissue-specific novel E3 ligases but also greatly expand the range of potential degradable disease targets. In this study, we first developed a molecular glue-focused library consisting of approximately 5,000 compounds through various medicinal chemistry evaluations. A GSPT1-HiBit cell line and a GSPT1-CRBN-KO counter cell line were developed for primary hit screening purposes. More than 100 potential hits were identified through the initial screening, which included both CRBN-dependent and CRBN-independent hits. A GSPT1-based proximity labeling cell line was then constructed for further target deconvolution purposes via proteomics. Potential candidate E3 ligases were subsequently validated using an array-based expression manipulation strategy. Additionally, we tested novel synthetic lethal target discovery through both in vitro and in vivo screens, followed by omics-based target validation. Using a CRBN-focused glue library, we combined both transcriptomics and proteomics assays to evaluate potential “degradable” targets. To sum up, our study demonstrates that integrated target discovery and target deconvolution strategies could be useful for TPD drug discovery as well as other disease scenarios.

#5787 TRI-611, a development stage molecular glue degrader of ALK, promotes the degradation of TKI-resistant ALK fusion proteins and leads to regression of ALK TKI-refractory tumors.

Andrew R. Conery[1], Daniel S. La[1], Artyom A. Alekseyenko[1], David Marcoux[1], Aaron G. Bart[1], **Matt L. Harlow**[1], Patrick R. Arsenault[1], Nico R. Cantone[1], Rebecca L. Casaubon[1], Hari B. Kamadurai[1], Aravind Prasad Medikonda[1], Duncan E. Nunes[1], Tim J. Wigle[1], Maolin Yu[1], Aleksandra Zagulyaeva[1], Christine Zarate[1], Lauren Highfield[2], Nobuyuki Kondo[3], Aaron N. Hata[3], Kenneth Ngo[4], Jisu Lee[4], Prafulla C. Gokhale[4], Kathleen I. Seyb[1], Patrick Trojer[1], Vito J. Palombella[1]

[1]Triana Biomedicines, Lexington, MA,[2]Massachusetts General Hospital, Boston, MA,[3]Massachusetts General Hospital and Harvard Medical School, Boston, MA,[4]Dana-Farber Cancer Institute, Boston, MA

TRI-611 is a potent, brain-penetrant molecular glue degrader (MGD) of anaplastic lymphoma kinase (ALK) that represents the first development stage MGD of an oncogenic fusion protein. By engaging ALK via a novel degron that is distal from the orthosteric tyrosine kinase inhibitor (TKI) binding site, TRI-611 has the potential to promote the degradation of ALK proteins that are either wild-type or mutant in the kinase domain, the latter of which are an important mechanism of disease progression in patients treated with ALK TKIs. Here we show through in vitro biochemical and biophysical studies that TRI-611 is equally effective at promoting the interaction of CRBN with wild-type ALK and the ALK$^{L1196M/G1202R}$ compound mutant protein, as well as subsequent poly-ubiquitination. Through the use of Ba/F3 cells engineered to express 30 distinct alleles of EML4-ALK, we show that TRI-611 effectively targets all tested EML4-ALK mutant proteins in cells, including those that are refractory to ALK TKIs. The broad phenotypic activity of TRI-611 is further highlighted by potent anti-proliferation of cell line and patient-derived ALK+ NSCLC models with multiple ALK TKI resistance alleles. In mouse efficacy studies, TRI-611 leads to the regression of subcutaneous xenografts of CRISPR engineered EML4-ALK-mutant NCI-H3122 cells that do not respond to ALK TKIs. Finally, we show that TRI-611 leads to the regression of an EML4-ALK mutant primary patient-derived xenograft isolated from a patient that had progressed on prior alectinib and lorlatinib. These data demonstrate the potential of TRI-611 to address a key liability of ALK TKIs that all target the same site on ALK and support the development of TRI-611 in all ALK+ NSCLC patients, including patients with wild-type ALK kinase domain and those with acquired TKI resistance mutations.

#5788 Rational discovery of novel molecular glues.

Simon Woehrle[1], Andreas Blum[1], Beatrix Blume[1], Jorg Bomke[1], Hans-Peter Buchstaller[1], Vincenza Dragone[1], Isabella Ferrara[1], Alessia Gambardella[1], Jakub Gunera[1], Ulrich Gradler[1], Ingo Kober[1], Johannes Krieger[1], Birgitta Leuthner[1], Andrea Unzue Lopez[1], Oliver Schadt[1], Christina Schindler[1], Fiona J. Sorrell[1], Ana M. Esteves[2], Sandra P. Santos[2], Raquel L. Sousa[2], Margarida M. S. Silva[2], Ana R. Lemos[2], Pedro M. F. Sousa[2], Tiago M. Bandeiras[2], Maria Emanuela Cuomo[1]

[1]EMD Serono, Inc., The healthcare business of Merck KGaA, Darmstadt, Germany, Darmstadt, Germany,[2]Instituto de Biologia Experimental e Tecnologica (iBET), Oeira, Portugal

Purpose: We developed and applied a streamlined workflow to discover and optimize cereblon (CRBN)-mediated molecular glues.
Methods: We combine computational and structural approaches to define the CRBN target space with both CRBN-focused small molecule and DNA-encoded (DEL) libraries for high-throughput screening of novel molecular glues. Proximity based protein-protein interaction assays are applied to screen for induced CRBN proximity of novel glue degrader targets. Cell-based degradation methods can then drive lead optimization, with advanced biophysical and structural methodologies for structural and functional aided design.
Results and Conclusions: We have identified multiple leads from rational screening approaches inducing concentration-dependent target-CRBN proximity in TR-FRET and NanoBRET assays. Hits were orthogonally confirmed to induce ternary complex formation by biophysical methods including surface plasmon resonance (SPR) and size exclusion chromatography (SEC). Cellular readouts demonstrated degradation activity using HiBiT and immunofluorescence-based methods dependent on CRBN E3 ligase expression or activity and proteasomal degradation. This integrated workflow together with proteomics technologies for on-target and off-target selectivity, is a rapid, mechanism-centric discovery platform for CRBN molecular glues across diverse target classes taking advantage of advanced but readily available methodologies.

#5789 Discovery of a selective molecular glue degrader of CCNE1 for the treatment of CCNE1-amplified solid tumors and CDK4/6i-resistant HR+/HER2- breast cancers.

Benjamin M. Vincent, David Marcoux, Claudia Caligioni, Aaron G. Bart, Matt L. Harlow, Rosaline Y. C. Hsu, Prashant Singh, Rachel Badger, Andrew J. Ingersoll, Thomas B. Jordan, Hari B. Kamadurai, Christine Zarate, Nico R. Cantone, Aravind Prasad Medikonda, Artyom A. Alekseyenko, Duncan E. Nunes, Taras Dauzhenka, Anushka Bhagwat, David Y. Rhee, Patrick R. Arsenault, Andrew R. Conery, Alex Constan, Louis Plamondon, Tim J. Wigle, Daniel S. La, Kathleen I. Seyb, Patrick Trojer, Vito J. Palombella

Triana Biomedicines, Lexington, MA

Cyclin E1 (CCNE1) is a central regulator of the G1 to S-phase transition of the cell cycle and a key dependency in multiple solid tumor types, including ovarian and endometrial cancers, and promotes resistance to CDK4/6 inhibitors in HR+/HER2- breast cancer. CCNE1 lacks a druggable pocket or enzymatic activity, which has precluded attempts to develop drugs that inhibit its function. Efforts to inhibit CCNE1 activity indirectly with CDK2 kinase inhibitors have been hindered by poor selectivity and dose-limiting toxicities that prevent full pathway suppression. Here we report the discovery of a molecular glue degrader (MGD) that co-opts the $CRL4^{CRBN}$ E3 ubiquitin ligase to eliminate the CCNE1 protein. Single-particle cryo-electron microscopy identifies a novel non-G-loop degron on CCNE1 that drives direct recognition of CCNE1 by the MGD:CRBN:DDB1 complex without preventing CDK2 binding to CCNE1. In cell lines analyzed, MGD treatment triggers rapid, CRBN-dependent depletion of CCNE1 with complete selectivity over the rest of the proteome. MGD-induced CCNE1 degradation exerts potent and selective anti-proliferative effects, with over 500-fold greater potency in CCNE1 amplified lines compared to non-amplified lines, a substantial improvement relative to CDK2 inhibitors (~15-fold potency window). In HR+/HER2- breast cancer cell lines with evolved resistance to the combination of a CDK4/6 inhibitor and fulvestrant, co-treatment with the MGD restores sensitivity. Oral administration of the MGD drives robust CCNE1 reduction and antitumor activity in a CCNE1-amplified xenograft model. These data suggest that directly and selectively degrading CCNE1 could provide an effective targeted therapy for CCNE1-amplified solid tumors and overcome resistance to CDK4/6 inhibitors in HR+/HER2- breast cancer.

#5790 Next-generation PRMT5 activity modulation through directed degradation.

Jose C. Clemente, Xuqing Zhang, Brian Vidal, Aaron Stonberger, Sudeep Banjade, Cory T. Rice, Nathan M. Kendsersky, Curran A. Rhodes, Matthew Tudor, Qiaolin Deng, Bomie Han, Clemente Aguilar-Bonavides, Elham Behshad, Steven D. Knight, Corey Strickland, Larry J. Jolivette, Ryan G. Kruger

SK Life Science Labs, King of Prussia, PA

PRMT5 is a key epigenetic regulator that is responsible for symmetric demethylation (SDMA) of arginine residues on histones and non-histone proteins, leading to regulation of transcription, RNA splicing, and genome stability. PRMT5 activity is linked to a range of malignancies, making it an attractive therapeutic target. The therapeutic potential of SAM and protein substrate competitive PRMT5 inhibitors have been hampered by dose-limiting cytopenia leading to incomplete target coverage. In contrast, MTA-cooperative inhibitors exploit the accumulation of MTA, a SAM-competitive inhibitor of PRMT5, in MTAP-deleted tumors to achieve enhanced tumor selectivity. MTA-cooperative degraders offer the potential to eliminate both catalytic and non-catalytic functions of PRMT5 with improved depth and durability of target modulation. Here, we describe PRMT5-directed degraders that rapidly, potently, and selectively eliminate PRMT5. Our degraders exhibit potent and robust PRMT5 degradation within 6 hours of treatment, leading to marked suppression of SDMA. Mechanistic studies demonstrate that PRMT5 loss is strictly dependent on UPS, as pharmacological blockade of ubiquitination or proteasomal activity effectively abrogates degrader-induced PRMT5 turnover. Our data highlights the potential for PRMT5 targeted degradation, driving a rapid and selective silencing of PRMT5 activity that can overcome limitations of first-generation inhibitors and provide a differentiated therapeutic approach for PRMT5-driven cancers.

#5791 Preclinical characterization of NEO-811, a novel molecular glue degrader of ARNT for the treatment of clear cell renal cell carcinoma.

J. Scott Lee, Michelle S. Cruz, Isabella Tran, Kevin Chiu, Jennifer Griffin, Andres H de la Pena, Kurt Januszyk, Xiaoxi Liu, Bryan Lee, Anthony Burt, John Tellew, Mengyu Wu, Leslie Watson, Ana Dominguez-Andres, Ling Huang, Randy Soriano, Devin Knece, Molly FitzGibbon, Jake Fathman, Celin Sanchez, Nathalia Cruz, Zac Neiman, Ana Grant, Mary Matyskiela, Rohan Beckwith, Ben Wen, Klaus Wagner, Philip Chamberlain

Neomorph, Inc, San Diego, CA

A hallmark of clear cell renal cell carcinoma (ccRCC) is inactivation of the von Hippel-Lindau tumor suppressor gene (VHL). Deficiency in VHL results in aberrant stabilization and activation of hypoxia-inducible factors 1α and 2α (HIF-1α/2α) promoting cancer cell survival, metastasis, and angiogenesis. The therapeutic value of targeting hypoxia signaling in ccRCC has been clinically validated by the development of small molecule inhibitors of HIF-2α. However, subsequent studies have also uncovered susceptibility to the onset of resistance conferred by mutations in the small molecule binding pocket. As class I basic helix-loop-helix PER/ARNT/SIM (bHLH-PAS) proteins, HIF-1α/2α require heterodimerization with aryl hydrocarbon nuclear translocator (ARNT, also known as HIF-1β, a class II bHLH-PAS protein) to exert their transcriptional activity. Consequently, ARNT represents a viable alternative target for disrupting oncogenic HIF activity. While traditionally regarded as undruggable, here we highlight the preclinical characterization of NEO-811, a potent, selective, and orally bioavailable molecular glue degrader of ARNT. Consistent with its mechanism of action, NEO-811 induced rapid, cereblon (CRBN)-dependent ARNT depletion in multiple ccRCC cell lines in vitro and in vivo. Global proteomics analysis confirmed that NEO-811 was highly selective and did not degrade well-known neosubstrates. Transcriptomic profiling of NEO-811 activity across several VHL-deficient ccRCC cell lines confirmed suppression of HIF-2α target genes, including cyclin D and vascular endothelial growth factor (VEGF). NEO-811 also uniquely suppressed expression of target genes regulated by other Class I bHLH-PAS transcription factors, including HIF-1α and aryl hydrocarbon receptor (AHR). Critically, NEO-811 retained activity in HIF-2α inhibitor-resistant cells that harbored previously described mutations. In conclusion, our findings highlight the potential of ARNT degradation as a promising therapeutic modality for the treatment of VHL-deficient ccRCC.

#5792 Identification of first in class selective ARID1B degraders.

Madeleine Henley, Benjamin Adams, Richard Caldwell, Jozlyn Clasman, Silvia Escudero, Imran Hossain, Kana Ichikawa, Jamie Im, Alexia Kalogeropulou, Dipti Sadalge, Gabriel Sandoval, Cody Schwarzer, Laura Von der Porten, Nick Yang, Marina Nelen, Gromek Smolen, Kevin Wilson, Steven Bellon

Foghorn Therapeutics, Watertown, MA

ARID1B, a core component of the SWI/SNF chromatin remodeling complex, has long been considered undruggable due to the absence of known binders and lack of ligandable pockets. Striking dependency on ARID1B is observed across multiple cancer indications harboring ARID1A mutations, including endometrial, ovarian, and gastric cancers. This highlights the synthetic lethal relationship between the two paralogs and establishes ARID1B as a high value target for precision oncology. We report the discovery and optimization of first in class selective ARID1B degraders for the treatment of ARID1A mutant cancers. Using our platform and structure based design, we first identified several selective ARID1B binder series, which were then used to develop VHL and CRBN based molecules that induce robust ARID1B degradation via the ubiquitin-proteasome system. These compounds exhibit on mechanism activity, high selectivity, and downstream transcriptional modulation. This work establishes ARID1B degradation as a promising therapeutic strategy and provides a blueprint for targeting previously intractable chromatin remodelers.

#5793 First-in-class potent and selective oral KAT6A degrader development candidate, PRT13722, drives complete tumor regressions as a monotherapy with an improved pre-clinical hematological safety profile.

Monisha Sivakumar, Sarah Pawley, Corey Basch, Jimin Park, Justin Kurian, Anthony Reichelderfer, Yue Zou, Kirsten Gallagher, Miles Cowart, Joy Cote, Alexander Grego, Jessica Burtell, Amy Crossan, Michael Hulse, Anjana Agarwal, Arpita Mondal, Chun Chen, Vijay Devannah, Sina Rezazadeh, Quincy Lewis, Patrick Wen, Ken Ray, Raul Leal, Daniel Porreca, Ganfeng Cao, Neha Bhagwat, Shanthi Ganesan, Stefan Ruepp, Min Wang, Joseph Rager, Koichi Ito, Sandy Geeganage, Andrew Combs, Peggy Scherle, Andrew Buesking, **Jack Carter**

Prelude Therapeutics, Wilmington, DE

KAT6A is a member of the MYST family of histone acetyltransferases and is recurrently amplified in multiple cancer types, driving cancer cell growth. Targeting KAT6 has recently been clinically validated in ER+/HER2- breast cancer (BC) and is being evaluated in Phase 3 trials in combination with fulvestrant (FUL). Notably, MYST proteins (e.g. KAT6A/B, KAT7) co-regulate normal hematopoiesis and current clinical inhibitors co-target these proteins in addition to KAT6A, resulting in dose-limiting neutropenia. Further, KAT6A protein degradation has been shown to drive differential biology compared to inhibition and deeper efficacy than KAT6A/B inhibitors. With the goals of addressing the clinical incidence of neutropenia and improving efficacy, we sought to identify KAT6B-sparing KAT6A heterobifunctional degraders. Utilizing structure-based drug design, we engineered the first known bivalent TPDs to potently and selectively degrade KAT6A over KAT6B. Further optimization of the ADME and physicochemical properties provided our orally bioavailable KAT6A selective degrader development candidate, PRT13722. PRT13722(±) is a picomolar KAT6A degrader with exquisite selectivity over KAT6B (<5% D_{MAX}) and high oral bioavailability across species. Global proteomic and neosubstrate profiling confirmed the selectivity of PRT13722(±), including against other MYST proteins. Despite a lack of KAT6B degradation, we observed PRT13722(±) demonstrated superior (95% E_{MAX}) anti-proliferative activity in T47D ER+ BC cells compared to a KAT6A/Bi (43% E_{MAX}) and good breadth of efficacy. Unlike inhibitors, PRT13722 disrupted the KAT6A complex, driving deeper suppression of global oncogenic gene expression (e.g. *ESR1*, *PGR*, *MYC*). In numerous ER+ BC xenografts, PRT13722(±) safely drove deep and complete tumor regressions as a monotherapy (e.g. T47D TGI = 101%), unlike a clinical KAT6A/Bi plus FUL (T47D TGI = 71%), at low oral daily doses (<5 mg/kg). Repeat dose *in vivo* PD studies demonstrated robust KAT6A (>84%) and no KAT6B degradation at efficacious doses. Mice treated with PRT13722(±) had higher neutrophil counts than those treated with clinical exposures of a KAT6A/Bi. These findings potentially address a clinical limitation of KAT6A/Bi by reducing an overlapping toxicity with other therapeutic agents such as CDK4/6i. Indeed, PRT13722 demonstrated combinability *in vitro* and *in vivo* with CDK4/6i, PI3Ki, and endocrine therapies (ET), while maintaining activity in CDK4/6i- and ET-resistant, and *ESR1*/*PIK3CA* mutant models. In summary, our first-in-class potent and selective oral KAT6A degrader, PRT13722, demonstrates improved efficacy and the potential for reduced off-target neutropenia compared to certain clinically validated KAT6A/B dual inhibitors. IND filing for PRT13722 is on track for mid-2026.

#5794 Leveraging E2 ligases for induced proximity and modulation of novel cancer-relevant targets and neosubstrates.

Xiangrong Chen[1], Vittorio Katis[1], Qilong Wu[1], Lukas Scheibelberger[1], Jesper Hansen[1], Brian D. Dill[2], Oksana Zavidji[2], Maria-Dorothea Nastke[2], Tiffany V. Saunders[2], Clifford G. Phaneuf[2], Andrea Pierangelini[1], Darragh O'Brien[1], Alejandro Gonzalez Orta[1], Niven R. Narain[2], Stephane Gesta[2], Alex N. Bullock[1], Dinesh Chimmanamada[3], Paul Brennan[1], Kilian Huber[1], **Vivek K. Vishnudas**[2]

[1]University of Oxford, Oxford, United Kingdom,[2]BPGbio, Waltham, MA,[3]Coorg Biosciences, Arlington, MA

Ubiquitin-conjugating enzymes (E2s) govern ubiquitin chain topology and flux through the ubiquitin-proteasome system, thereby shaping proteostasis, DNA-damage responses, and oncogenic signaling. Although targeted protein degradation (TPD) has largely focused on E3 ligases, convergent evidence from recent chemical biology and oncology studies indicates that E2s are druggable nodes with dual therapeutic potential for reprogramming using bifunctional and molecular glue degraders. Here, we demonstrate that E2s can act as a recruitment engine for proximity-induced degradation when E3 access or cooperativity is limiting for a distinct set of targets. We introduce a first-in-class, selective, small-molecule-based bifunctional degrader platform that exploits E2 recruitment to degrade oncology-relevant targets, including nuclear receptors and kinases. In biochemical and cellular systems, the ligand engages its E2 target with high selectivity, induces proximity through ternary complex formation and degrades the protein of interest in a proteasome- and Cullen-dependent manner. We validated our approach by designing bifunctional degraders of ERα, coupling ERα and E2 ligands with short linkers, and demonstrating target degradation in MCF7, T47D, SH-SY5Y, and K562 cell lines. We demonstrate early degradation by 6 hours and maximal degradation at 24 hours with a D_{max} of 85% and DC_{50} of 83nM. Further, by conjugating 4 kinase inhibitor scaffolds with 2-6 linker designs, we screened the proteome to cover almost 500 potential kinase targets in K562 and MCF7. We demonstrated dose-dependent degradation of dozens of kinases, including kinases of potential therapeutic interest such as SYK, FYN, and MAPK2. We observed dramatically different sensitivity to degradation across the cell lines tested, and degradation activity was more robust at the 24h timepoint compared to 5h. Collectively, these findings validate E2 ligases as functional recruiters for TPD, expanding the degrader toolbox beyond canonical E3 ligases and establishing a complementary, generalizable framework for therapeutic development.

#5795 The discovery of BLU-020: A potent and selective degrader of CDK2 for the treatment of *CCNE1* aberrant cancers.

Phil Ramsden, Dean Zhang, Maria Iliou, Suhasini Parimi, Jeff Keats, Maxine Chen, Lakshmi Muthuswamy, Guangyan Du, Fereidoon Daryaee, Ben Barlock, James Baker, **Sue Spong**, Ken Kearney, Gramoz Kondakci, Deborah G. Conrady, Stella Li, Xavier Fradera, Yinghui Dai, Tina Tran, Tom Dineen, Chiara Conti

Blueprint Medicines Corporation, Cambridge, MA

Background: Cyclin E1 is the catalytic binding partner of CDK2, which becomes aberrantly activated when *CCNE1* is amplified and overexpressed, driving tumorigenesis. Tumors with aberrant cyclin E1 expression are highly dependent on Cyclin E1/CDK2 activity, presenting a distinct therapeutic opportunity. Selective degradation of CDK2 may limit off-target CDK family-driven toxicities commonly associated with pan-CDK inhibitors. We highlight the discovery of BLU-020, a potent, CDK2-selective, and kinome-sparing investigational degrader of CDK2.
Our efforts began with the design of CDK2-targeted heterobifunctional degraders leveraging Blueprint's proprietary inhibitor library, resulting in the identification of several potent compounds with moderate selectivity. Subsequent modifications led to improvement on both CDK family selectivity and improvement on ADME properties of the lead series. With additional efforts to optimize the degraders for projected human dose, a development candidate, BLU-020, was identified.
Results: BLU-020 is an orally bioavailable, kinome-sparing, CDK2-selective small molecule degrader that leads to potent and sustained pRb inhibition, significant and sustained G1 cell cycle arrest, strong and selective suppression of E2F targeted genes and inhibition of cell proliferation in CCNE1-aberrant CDK2-dependent tumor cell lines. In a screen against a panel of ~100 tumor cell lines, BLU-020's potency and selectivity was demonstrated by showing strong inhibition of CCNE1-aberrant tumor cells bearing the triple biomarker CCNE1 high/RB positive/p16 high, while completely sparing non-CDK2 dependent triple biomarker negative cell lines, with a selectivity ratio of over 500 fold. BLU-020 was able to sensitize tumor cell lines lacking p16 in combination with the CDK4/6i ribociclib. Finally, BLU-020 demonstrated robust and durable in vivo anti-tumor activity in preclinical models of *CCNE1*-amplified cancers such as OVCAR3 CDX model following once-daily oral administration.
Conclusion: With its potency on CDK2 and improved selectivity over other CDK family members and the kinome compared to previous reported CDK2 agents, BLU-020 has best-in-class potential for CCNE1-aberrant ovarian cancers.

#5796 Rpn13Pru targeting small molecules induce mitotic arrest in breast cancer..

Santwana K C[1], Xiuxiu Lu[2], Snehal M. Gaikwad[3], Venkata R. Sabbasani[4], Rolf Swenson[4], Beverly A. Mock[3], Kylie J. Walters[2], Deborah E. Citrin[1]

[1]Radiology Oncology Branch, National Cancer Institute, Bethesda, MD,[2]National Cancer Institute, Frederick, MD,[3]Cancer Biology and Genetics, National Cancer Institute, Bethesda, MD,[4]Chemistry and Synthesis Center, National Heart, Lung, and Blood Institute, Bethesda, MD

Proteolysis-targeting chimeras are heterobifunctional molecules that link a protein of interest (POI) to an E3 ubiquitin ligase, promoting ubiquitylation and degradation of the POI via the ubiquitin-proteasome system (UPS). XL44 is a structurally modified small molecule previously identified as a potent hRpn13^{Pru} degrader, that induces ubiquitin-dependent apoptosis in myeloma cells. and ubiquitin-independent cell cycle defects. Recently, we evaluated two more potent derivatives; XL69 and XL80 with a similar cell cycle arrest mechanism. Here, we evaluated that the anticancer activity of XL69 and XL80 mediated disruption of UPS function in the MCF-7 cell line. MCF-7 cells were treated with XL69 and XL80 for 24 h and the IC_{50} values were determined by MTT assay. For cell cycle analysis, cells were treated with 10 µM of each compound for 24 h and analyzed via flow cytometry. The spindle assembly checkpoint (SAC), and anaphase promoting complex/ cyclosome (APC/C) activity were assessed through western blotting and immunofluorescence microscopy. The MTT assay for XL69 and XL80 showed increased cytotoxicity at concentrations above 30 µM upon treatment but cells exhibited rapid detachment at lower concentrations. Detached, floating cells remained viable for the next 48-72 h post-treatment before cell death and exhibited marked variation in nuclear morphology and cytoskeleton organization. XL69 and XL80 treated MCF-7 cells accumulated in G2/M (65.7% and 54.1%, respectively vs DMSO- (25.2%; $p < 0.001$). In addition, elevated levels of phospho-histone 3 were detected 24 h post-treatment (31.5%, 32.5%, vs DMSO 10.7%, p-value <0.01) indicating robust mitotic arrest. Immunofluorescent detection of aurora B with DAPI nuclear staining confirmed prometaphase-metaphase arrest in treated cells. Western blot analysis showed upregulation of Bub1 and BubR1, confirming SAC activation post mitotic arrest. Activation of the SAC led to formation of the mitotic checkpoint complex, subsequently inhibiting the APC/C, as evidenced by the accumulation of cyclin B and securin. Furthermore, the inhibition of APC/C also prevented degradation of aurora B kinase, resulting in impaired tubulin assembly. Immunofluorescent images showed disordered organization of tubulin with XL69 and XL80 treatment, similar to Nocodazole, a microtubule polymerization inhibitor. These findings suggest that XL69 and XL80 induce mitotic arrest by targeting the APC/C pathway and disrupt microtubule dynamics. These studies demonstrate that the small molecules XL69 and XL80 effectively induce mitotic arrest, impair microtubule dynamics, disrupt cellular attachment leading to cell death in adherent MCF-7 cells. The treatment led to sustained cell cycle arrest, SAC activation, APC/C pathway inhibition and impaired microtubule organization. As such, the study highlights XL69 and XL80 as promising anti-cancer agents that target mitotic progression.

#5797 PK/PD and preclinical ADME characterization of TB-008, a first-in-class CDK9 degrader in xenograft models.

Narayana Narasimhan, Mahesh Koirala, Isabelle Dussault, Lindy Yan, Oscar Kashala, Zoser Mohamed, **Mario DiPaola**

Therabene, Inc., Norwood, MA

Targeted protein degradation (TPD) offers a promising therapeutic strategy by removing, rather than inhibiting, disease-driving proteins. Cyclin-dependent kinase 9 (CDK9) is a key oncogenic regulator implicated in multiple hematologic and solid tumors. TB008 is a rationally designed CDK9-targeting PROTAC developed using an AI-driven degrader platform to achieve high affinity, selectivity, and favorable pharmacologic properties. Preclinical studies have demonstrated potent, selective CDK9 degradation with downstream suppression of oncogenic targets such as c-MYC and MCL-1. TB008 has shown robust antiproliferative and pro-apoptotic activity across cancer cell lines and strong tumor growth inhibition >95% in triple negative breast cancer xenograft model which support further development of TB008 as a CDK9-directed therapeutic candidate. Pharmacokinetics in Balb/c-nude mice (efficacy study species) has shown that TB-008 is rapidly absorbed following an intraperitoneal dose with ~90% bioavailability and a half-life of 1 hr. Interestingly, *in-silico* PK and bioavailability analysis does predict that there is a 90% decrease in drug concentration in mouse plasma within the first hour after administration. Furthermore, also based on *in-silico* evaluation, it is also predicted that higher drug concentration will be in the GI tract, lungs, plasma, spleen and portal vein. Even with the relatively short half-life, the high tumor growth inhibition observed in xenograft studies confirms the potency and fast kinetics of TB-008 in effecting the degradation of the tumor CDK9. We have initiated studies in mouse xenograft models to better understand the PK/PD and design optimal dosing regimens. Also, we will report the efficacy of TB-008 in additional xenograft models. Additional preclinical ADME data and PK in higher nonclinical species will be reported.

#5798 Targeted protein degradation of cell surface proteins through peptide-induced clearance.

Hadir Marei, Sanjana Sen, Patrick Aouad, Victoria Pham, Christopher Rose, Wen-Ting Tsai, Sheil Kee, Eva Lin, Matthew Grimmer, Tim Sterne-Weiler, Xiaosai Yao, Mark Wang, Diana Wu, Russell Xie, Nicholas Agard, Stephen Miller, Robert Yauch

Genentech, Inc., South San Francisco, CA

In recent years, several modalities have emerged that enable the clearance of cell surface proteins. Contributing to the current toolbox, we previously reported the development of an antibody-based degrader platform that enables the repurposing of the Wnt-responsive cell surface E3 ubiquitin ligases, RNF43 and ZNRF3, for the degradation of plasma membrane proteins. In particular, through the design of recombinant bispecific antibodies that we termed Proteolysis Targeting Antibodies (PROTABs), we facilitate the tethering of RNF43 or ZNRF3 to the extracellular domains of different receptors, including IGF1R, HER2 and PD-L1. Consequently, this drives efficient “on demand” target degradation both *in vitro* and *in vivo*. We also demonstrate the broad applicability of this platform through the identification of additional E3 ubiquitin ligases that can be repurposed as cell surface protein degraders. Stemming from this work, we profiled the cell surface proteome in a panel of isogenic ‘Wnt-low’ and ‘Wnt-high’ Colorectal Cancer (CRC) cell lines. Focusing on differentially regulated proteins, we demonstrate that the Transferrin Receptor (TfR1) has increased cell surface expression under ‘Wnt-high’ conditions, a known hallmark of CRC. Consistently, several studies show that TfR1 is commonly upregulated in cancer, which is often attributed to its role in mediating iron uptake. Indeed, the Cancer Dependency Map (DepMap) Project reveals that the viability of a large number of cancer cell lines is dependent on TfR1, highlighting its therapeutic potential. To explore this, we generated anti-TfR1 PROTABs. In an exogenous ligase expression setting, anti-TfR1 PROTABs, induce target degradation, dependent on RNF43/ZNRF3 levels, concomitant with cell viability defects. Intriguingly, while non-targeting bivalent TfR1 bispecific antibodies drive minimal target clearance, treatment induces viability aberrations comparable to that seen with anti-TfR1 PROTABs. We, therefore postulated that TfR1 cell surface clustering might be sufficient to affect cell fitness. To investigate this, we explored alternative target clustering approaches. Excitingly, this led to the development of a multimeric peptide-based modality that mediates efficient target cell surface clearance and protein degradation. Importantly, through testing a large panel of cancer cell lines, we show a dose-dependent effect on cell viability that spans multiple indications beyond CRC. Together, this highlights the therapeutic potential of leveraging anti-TfR1 multivalent peptides as an alternative targeted protein degradation approach.

#5799 Lumit-based profiling of degrader dynamics reveals signaling-dependent, cell context-specific sensitivity to degraders.

Matthew Swiatnicki, Laurie Engel, Hicham Zegzouti

Promega, Madison, WI

While targeted protein degradation (TPD) offers a transformative approach for refractory disease, testing degraders in disease relevant models remains challenging. Determining degrader kinetics and potency often involves engineered cell systems, which despite their merits, are resource intensive and low throughput. To alleviate these issues, we used the Lumit® Immunoassay Cellular Systems (ICS) platform to develop quantitative, high-throughput luminescent immunoassays for TPD targets. These assays measure degrader potency, selectivity, and cell-line variability. Multiple target-degrader pairs have been validated, including BRD4-ARV-771, IKZF1-Iberdomide, and STAT3-SD-36. These validated assays demonstrate the platforms versatility and robustness in capturing diverse degradation mechanisms. Using Lumit to profile the STAT3 degrader, SD-36, across numerous cells lines, we uncovered an unexpected potency shift in A431 cells. This was evidenced by DC_{50} values in the µM range, compared to nM range for other cell lines tested. Multiple avenues were explored to uncover the cause of this shift, including discrepancies in degrader mechanism or the target protein. When looking across multiple cell lines including A431, no discrepancies in degrader membrane permeability, target ubiquitination, cereblon expression, STAT3 expression, or STAT3 turnover were found. However, we uncovered that higher expression of epidermal growth factor receptor (EGFR) correlated with reduced degrader efficacy. Furthermore, we found that degrading EGFR or inhibiting EGFR phosphorylation in A431 cells restored the potency of SD-36. Combined, these data establish EGFR signaling as a key modulator of STAT3 degradation response. This phenomenon was specific to STAT3 degradation, as degraders for other targets maintained comparable nanomolar DC_{50} values across cell lines, including A431. Further exploration also indicated that the PARylation and PERK pathways appear to contribute to the protection of STAT3, with the effect being more pronounced in A431 cells. The PARylation and PERK pathways have previously been shown to affect degradation of certain targets, while our findings point to an additional signaling pathway that seems to specifically regulate STAT3 degradation. While it has been traditionally thought that resistance to TPD therapies can occur due to changes in degrader mechanics or the target protein within the cell, we have demonstrated that intrinsic cellular pathways can impact degrader potency. This discovery may redefine TPD limitations to include signaling-regulated phenotypes.

#5800 Discovery of pan-KRAS molecular glue degraders via protein-first coevolution-guided E3 ligase recruitment.

Roman Timakhov, Haishan Li, Nikolay Savchuk, Alexander Khvat

Eilean Therapeutics, LLC, Dover, DE

Background: KRAS is one of the most frequently mutated oncogenes in human cancer; however, the absence of deep hydrophobic pockets renders it challenging to drug by conventional inhibitors. Molecular glue degraders (MGDs) that induce proximity between KRAS and an E3 ubiquitin ligase represent a promising modality to achieve loss of KRAS function through proteasomal degradation.
Methods: We employed proprietary MGD platform, which initiates with a protein-first, coevolution-driven selection of E3 ligases. Multiple sequence alignments of KRAS and human E3 ligases were analyzed to identify co-mutating amino acid pairs that preserve physiologically relevant protein-protein interaction (PPI) interfaces. Predicted KRAS-E3 complexes were modeled using state-of-the-art protein folding algorithms and molecular dynamics simulations. Ternary complex-compatible sites were then screened *in-silic*o against the commercially available chemical space using flexible, structure-based docking. Hit compounds were evaluated in HEK293T cells stably expressing HiBiT-tagged KRASWT, KRASG12D, KRASG12V, or KRASG13D. Target degradation was quantified by HiBiT luminescence, confirmed by automated capillary electrophoresis (Jess/WES) western blotting of both HiBiT-tagged and endogenous KRAS, and validated for proteasome dependence using MG132. Cytotoxicity was assessed in KRAS-dependent (AsPC-1) and KRAS-independent (RKO BRAFV600E) cell lines over 7 days.
Results: The platform delivered multiple chemically tractable series of small-molecule (<500 Da) MGDs capable of potent, proteasome-dependent degradation of KRAS. Lead compounds induced >70% degradation of HiBiT-tagged KRASWT, G12D, G12V, and G13D at 10 µM after 24 h, with DC50 values in the high-nanomolar to low-micromolar range. Degradation of endogenous untagged KRAS in wild-type HEK293T cells reached 30-40% at 10 µM after 18 h treatment. Rescue experiments with proteasome inhibitors fully reversed degradation, confirming a ubiquitin-proteasome mechanism. Selected degraders exhibited favorable selectivity profiles, with CC50 values >5 µM in long-term proliferation assays and minimal cytotoxicity in KRAS-independent lines.
Conclusions: Our coevolution-guided, protein-first MGD platform enables rapid discovery of small molecules that induce pan-KRAS degradation across major oncogenic mutants. These compounds achieve degradation of KRAS protein through a proteasome-dependent mechanism, distinguishing them from covalent KRASG12C inhibitors and RAS(ON) tri-complex inhibitors. The identified pan-KRAS molecular glue degraders represent a novel therapeutic modality with potential to address the majority of KRAS-driven cancers previously considered undruggable.

#5801 NRX-0305 is an orally bioavailable, pan-mutant BRAF degrader that exhibits single-agent and combination efficacy with MEKi or anti-EGFR across Class 1/2/3 BRAF-mutant cancers.

Ya-Wen Lu, Alexandra Borodovsky, Ge Peng, Karthik Arumugam, Paul L. Auger, Delia Bradford, Lilly G. Carlson, Scott K. Kimura, Daniel Medina-Cleghorn, Mariah J. Mesner, Davorka Messmer, Madeleine P. Nemchek, Ryan B. Rountree, Rusha M. Sardhara, Sangita Sridharan, Jennifer M. Stokes, Leslie Tong, Alexandra M. S. Trotier, Jennifer S. Tung, Ge Wei, Jeffrey Wu, Jordan Ye, Gwenn M. Hansen

Nurix Therapeutics, Inc., Brisbane, CA

Activating mutations in BRAF, a central kinase within the MAPK pathway, promote sustained pathway signaling and drive oncogenic transformation across multiple tumor types including melanoma, non-small cell lung cancer (NSCLC), and colorectal cancer (CRC). BRAF mutations are categorized into three functional classes: Class 1 (e.g., V600X), which are RAS-independent and targetable with approved BRAF inhibitors; Class 2, which signal as constitutive dimers; and Class 3, which are kinase-impaired and depend on upstream RAS activation. While approved BRAF inhibitors provide significant survival benefit to patients with Class 1 mutations, they are ineffective against tumors harboring Class 2 or 3 mutations, which remain refractory to current BRAF-targeted therapies. Motivated by the lack of therapeutic options for patients with Class 2 and 3 BRAF mutations, we developed NRX-0305, a potent and orally bioavailable pan-mutant BRAF degrader that selectively eliminates mutant BRAF while sparing the wild-type protein. In vitro, NRX-0305 potently degraded Class 1/2/3 mutant BRAF and suppressed downstream pERK1/2 signaling, resulting in strong antiproliferative effects across a diverse panel of Class 1/2/3 BRAF-mutant cell lines, including those expressing BRAF fusion proteins. In vivo, daily oral administration of NRX-0305 induced robust, dose-dependent BRAF degradation and pathway inhibition, producing marked single-agent efficacy in multiple Class 1/2/3 cell lines-derived xenograft and patient-derived xenograft models. Furthermore, combination studies of NRX-0305 with MEK inhibitor or anti-EGFR demonstrated enhanced antitumor activity, supporting its potential use in clinically relevant combination regimens. Collectively, these studies demonstrate NRX-0305 is a potent, mutant-selective BRAF degrader that can overcome the limitations of approved BRAF inhibitors, offering broad therapeutic potential both as a single agent and in combination with MEKi or anti-EGFR antibodies across Class 1/2/3 BRAF-mutant cancers.

#5802 Long acting injectable of pan-RAF-MEK molecular-glue: Metronomic exposure for the treatment of pancreatic ductal adenocarcinoma.

Drishti Rathod, Ketankumar Patel

St. John's University, Queens, NY

Pancreatic ductal adenocarcinoma (PDAC) remains one of the most lethal malignancies, with 5-year survival rates below 12%. KRAS mutations (95% of cases) driving aberrant MAPK signaling—yet MEK inhibitors have failed due to rapid resistance, off target inhibition, and poor pharmacokinetics. There is an urgent need of paradigm-shifting approach that blocks MAPK pathway beyond conventional inhibitors. NST-628 (NST) is a potent pan-RAF-MEK molecular glue that provide dual blockade by preventing the activation of MEK and by blocking the RAF proteins, thus enabling prolonged inhibition of MAPK oncogenic signaling pathway. NST's physicochemical properties make oral delivery suboptimal, limiting clinical translation, prompting for a sustained-release injectable formulation of NST to ensure therapeutic efficacy. We developed a self-injectable, biodegradable, sustained-release depot formulation of NST (DepNeST). This represents the first extended-release formulation of a molecular glue for cancer therapy. We aim to a) To evaluate anticancer efficacy in 2D and 3D PDAC models; b) To optimize and characterize DepNeST for sustained NST release kinetics. NST demonstrated potent *in-vitro* cytotoxicity with an IC_{50} of 183.8 nM in MIA PaCa-2 and showed concentration dependent increase in cell size. NST treatment induced concentration-dependent cytoskeletal disruption in MIA PaCa-2, characterized by actin filament accumulation and aberrant lamellipodia/filopodia formation. Acridine orange and Giemsa staining confirmed chromatin condensation and marked morphological remodeling, reflecting NST-driven antitumoral activity. NST triggered 2-fold G0/G1 arrest in MIA PaCa-2 and inducing 1.8- to 2.2-fold increases in apoptosis (acute vs. chronic), effectively blocking proliferation and driving cell death. Multicellular 3D spheroid models demonstrate superior cytotoxicity with ~50% reduction in spheroid area with NST compared to control. Live/Dead assays revealed extensive apoptosis in both regimens, with marked red fluorescence confirming cell death and validating NST's potency in clinically relevant 3D models. DepNeST was fabricated by dissolving biodegradable polymers in different concentrations in a biocompatible solvent, N-methyl pyrrolidone (NMP). Subsequently, NST was dissolved into a polymer-NMP solution. DepNeST formulation with constant PLGA and increasing Poloxamer 338 concentrations enhanced depot dissolution profile. The *in-vitro* release study demonstrated an initial burst release followed by a sustained release of NST from DepNeST over a period of 6 days. This first-ever investigation of NST-628 molecular glue in pancreatic cancer establishes DepNeST as a paradigm-shifting depot platform that delivers sustained MAPK suppression at reduced doses—potentially transforming therapeutic landscape for RAS/RAF-driven malignancies.

#5803 Discovery of a paralog selective p300 protein degrader with potent anti-cancer activity in hematological malignancies.

Marwa Asem, Yan Zhai, Xiaohong Song, Milad Rouhimoghadam, Sreenivas Punna, Fritz G Buchanan, Daniel T Cohen, Ryan McClure, Stephanie Sandoval, Anlu Chen, Shaun McLoughlin, Colin Woodford, Peter Kovar, Vlasios Manaves, Alla V Korepanova, Justin M Reitsma, Andrea Shergalis, Judith A Ronau, Yifei Kong, Yu Shen, Jurgen Dinges

AbbVie Inc., North Chicago, IL

The E1A-associated protein p300 (EP300) functions as a key regulator of oncogenic transcriptional programs, positioning it as an attractive therapeutic target in cancer. However, the high sequence homology between p300 and its paralog CREB-binding protein (CBP) has limited the development of selective inhibitors, often resulting in dose-limiting toxicities. In this study, we report the discovery of a highly potent and selective degrader of p300. Distinct from dual p300/CBP degraders, this compound exhibits enhanced formation and stability of the ternary complex with p300, drives stronger ubiquitination and proteasomal recruitment, and targets a unique lysine residue on p300 for degradation. Hematological malignancies including multiple myeloma, non-Hodgkin's lymphoma, and acute myeloid leukemia were particularly sensitive to p300-selective degradation, which elicited a cytotoxic response in cancer cells and demonstrated robust antitumor activity in xenograft models. Together, these findings establish selective p300 degradation as a promising therapeutic approach for hematologic cancers and a novel strategy to disrupt oncogenic transcriptional dependencies.

#5807 Synergistic integration of nanobodies and a specialized linker library: A novel radionuclide drug conjugate (RDC) platform paving the way for next-generation radiotherapeutics with optimal druggability and therapeutic index.

Chong Liu, Zengyan Mu, Sipeng Li, Qingsong Wu, Yajun Sun, Paul H. Song, Gang Qin

GeneQuantum Healthcare (Suzhou) Co., Ltd., Suzhou, China

Background: Radionuclide drug conjugates (RDCs) represent a promising approach in oncology, yet their development is hindered by the scarcity of targeting moieties possessing both high affinity and favorable pharmacokinetics, leading to intense competition for validated targets. To address this, we have developed a novel and differentiated RDC platform utilizing readily available nanobodies as targeting vectors. This platform incorporates our intelligent Ligase-Dependent Conjugation (iLDC) technology and a proprietary linker, which collectively enhance pharmacokinetic profiles and biodistribution. The platform's efficacy is validated by GR9001, a $^{64}Cu/^{177}Lu$-labeled anti-PSMA nanobody-based RDC, which has demonstrated superior tumor targeting and biodistribution, potent therapeutic efficacy, and a promising safety profile in both preclinical and first-in-human studies.
Results: In preclinical studies, ^{64}Cu-GQ9001 exhibits an enhanced pharmacokinetic profile, along with excellent biodistribution characterized by significantly higher tumor accumulation and retention and minimized kidney uptake. Meanwhile, ^{177}Lu-GQ9001 also demonstrates superior antitumor activity and shows great potential to overcome resistance to Pluvicto®. In mCRPC patients, ^{177}Lu-GQ9001 was well tolerated, and no severe adverse events were observed. SPECT images revealed an optimal circulation half-life of ^{177}Lu-GQ9001 in the blood, with high, increasing tumor uptake and low, rapidly clearing normal tissue uptake. Compared with published data for other PSMA-targeted radioligands (e.g., PSMA-617), ^{177}Lu-GQ9001 exhibited significantly higher normalized absorbed doses in tumor lesions and similar absorbed doses in normal organs. Consequently, this profile resulted in substantially superior tumor-to-background (T/B) ratios. Furthermore, ^{177}Lu-GQ9001 showed superior efficacy at lower doses, with a significant reduction in PSA levels.
Conclusion: By leveraging GQ's nanobody-based RDC platform, a potential best-in-class anti-PSMA RDC has been developed that demonstrates a comprehensively superior profile to Pluvicto®—including optimized half-life, enhanced tumor uptake, excellent safety, and potent efficacy in CDX models and mCRPC patients—thereby establishing a transformative paradigm that expands the promise of nanobody-based therapeutics beyond existing modalities to novel tumor targets.

#5810 [^{212}Pb]Pb-AG1206, A novel fibroblast activation protein-targeted radioligand therapy demonstrated excellent efficacy and safety profile.

Xin Gan[1], Tao Robert Wu[1], Miaomiao Song[2], Shaohua Xu[1], Guiyu Liu[1], Vivi Yang[1], Jinpeng Liu[1], Xuefei Li[1], Hu Li[3], Zhen Cheng[2], Maijing Liao[1]

[1]AlphaGen Therapeutics, Shanghai, China,[2]Shanghai Institute of Materia Medica, Chinese Academy of Sciences, Shanghai, China,[3]Eight Roads Ventures China, Shanghai, China

Fibroblast activation protein (FAP) is highly expressed in a wide range of solid tumors, making it an attractive target for agents designed to accumulate within the tumor microenvironment. Lead-212 (^{212}Pb) is highly effective for targeted alpha therapy causing localized tumor cell killing induced by double strand DNA breaks while sparing surrounding healthy tissue. [^{212}Pb]Pb-AG1206 is a novel macrocyclic peptide radioligand that is designed to bind to FAP selectively, and to have rapid and high tumor uptake and fast renal clearance. When conjugated with the radioisotopes ^{203}Pb (for imaging) or ^{212}Pb (for therapy), AG1206 enables theranostic applications. Preclinical studies demonstrated excellent in vitro and in vivo properties of [^{212}Pb]Pb-AG1206 supporting its clinical development.

Methods: Binding affinity and selectivity were assessed using surface plasmon resonance (SPR). Cell binding and internalization were evaluated in FAP-expressing cell lines. In vivo biodistribution, antitumor efficacy, and dosimetry were performed in subcutaneous mouse cell-derived xenograft (CDX) models that express FAP.

Results: [^{212}Pb]Pb-AG1206 exhibited FAP-specific cellular uptake and high binding affinity in the picomolar (pM) range. It showed rapid tumor accumulation and fast clearance, and robust tumor growth inhibition with an excellent safety profile. Dosimetry studies in preclinical models demonstrated low radiation absorption in normal organs, indicating a favorable safety margin that is translatable to humans. These findings underscore FAP-targeted radioligand therapy (RLT) as a promising strategy for treating a broad spectrum of solid tumors characterized by desmoplastic microenvironments.

Conclusions: In conclusion the data support clinical development of [^{212}Pb]Pb-AG1206 as a novel therapeutic for patients with FAP-expressing solid tumors.

#5811 Preclinical evaluation of [^{212}Pb]Pb-AG1002, a next generation SSTR2-targeting, non-agonist radiopharmaceutical.

Xuexiang Zhang, Xuefei Li, Shaohua Xu, Xiao Tang, Xiang Gu, Vivi Yang, Guiyu Liu, Maijing Liao, Tao Robert Wu, **Xin Gan**

AlphaGen Therapeutics, Shanghai, China

Somatostatin receptor 2 (SSTR2), overexpressed in neuroendocrine tumors and other solid malignancies, is a validated target for radioligand therapies (RLTs). Here, we present the preclinical evaluation of [^{212}Pb]Pb-AG1002, a next generation SSTR2 non-agonist theragnostic agent,with the alpha-emitter ^{212}Pb for therapeutic purposes.

Methods: In-vivo PET/CT imaging, biodistribution and efficacy studies were conducted in athymic nude mice bearing AR42J (SSTR2+) xenografts. The biodistribution of [^{212}Pb]Pb-AG1002 was analyzed by harvesting the organs of interest and measuring the radioactivity with gamma counter. In efficacy studies, [^{212}Pb]Pb-AG1002 was administrated comparing to [^{212}Pb]Pb-DOTAM-TATE. The tumor growth inhibition and median survival time were measured and analyzed at time intervals post dosing.

Results: [^{212}Pb]Pb-AG1002 achieved high radiochemical purities following radiolabeling. In biodistribution studies, it demonstrated a superior pharmacokinetic profile compared to [^{212}Pb]Pb-DOTAM-TATE and [^{212}Pb]Pb-TCMC-JR11, exhibiting higher tumor uptake and prolonged retention, and reduced kidney accumulation, giving rise to excellent tumor-to-kidney ratios. Efficacy studies in SSTR2-expressing models showed that mice treated with [^{212}Pb]Pb-AG1002 had robust tumor growth inhibition and a more durable response than those treated with [^{212}Pb]Pb-DOTAM-TATE. Preclinical dosimetry studies further revealed low radiation absorption in normal organs, indicating a favorable safety profile with strong translational potential to humans.

Conclusion: [^{212}Pb]Pb-AG1002 exhibits excellent radiolabeling efficiency, desirable pharmacokinetics, anti-tumor efficacy and favorable safety profile. Its robust preclinical pharmacological profiles support clinical development as a next generation α-therapeutic agent for SSTR2-positive tumors.

#5812 Preclinical evaluation of [177Lu]Lu-PSMA-617 and [225Ac]Ac-PSMA-617 in mice bearing castration-resistant prostate adenocarcinoma patient-derived xenografts.

Denis Beckford-Vera, Jaeho Lee, Kyle Monger, Erin Kosmowski, Kayla Cotton, Sebastian Brabetz, Markus Hippich, Sarah Maenhout, Paul Heverly, Maria Mancini

Champions Oncology (Rockville, MD), Rockville, MD

Background: Patient-derived xenograft (PDX) models are essential for radiopharmaceutical evaluation because they preserve the genetic and microenvironmental complexity of human tumors, offering a more clinically relevant platform than traditional cell lines. This enables more accurate prediction of drug distribution, target engagement, and therapeutic efficacy, reducing translational gaps in radiopharmaceutical development. This study presents a comprehensive preclinical evaluation of two PSMA-targeted radiopharmaceuticals, [177Lu]Lu-PSMA-617 and [225Ac]Ac-PSMA-617, in murine models bearing PDXs of metastatic, castration-resistant prostate adenocarcinoma. These models are deeply characterized across multiple layers, including in-depth molecular data such as phosphoproteomics.
Methods: PSMA-617 was successfully radiolabeled with lutetium-177 and actinium-225 using optimized protocols that ensured high radiochemical purity. Preclinical evaluation of [177Lu]Lu-PSMA-617 and [225Ac]Ac-PSMA-617 was conducted in mice bearing CTG-2428 (PSMA+) PDX tumors derived from a 67-year-old Caucasian male with metastatic, castration-resistant prostate adenocarcinoma, and CTG-3537 (PSMA-) PDX tumors derived from a 63-year-old African American male with metastatic, castration-resistant prostate adenocarcinoma. Biodistribution studies of [177Lu]Lu-PSMA-617 were performed in mice bearing PSMA+ and PSMA- PDX tumors. Mice received 0.3 mCi (11 MBq) [177Lu]Lu-PSMA-617, and tumors and major organs were collected, weighed, and measured for radioactivity 24 hours post-injection. Therapeutic efficacy of [177Lu]Lu-PSMA-617 and [225Ac]Ac-PSMA-617 was assessed in mice bearing CTG-2428 (PSMA+) PDX tumors. Mice received 1 mCi (37 MBq) of [177Lu]Lu-PSMA-617 or 1 µCi (37 kBq) of [225Ac]Ac-PSMA-617, and tumor size and body weight were measured twice weekly throughout the study.
Results: [177Lu]Lu-PSMA-617 and [225Ac]Ac-PSMA-617 were obtained with radiochemical purity greater than 98%, as determined by radio-TLC and radio-HPLC. The radiotracers demonstrated selective uptake in PSMA-positive tumors, with minimal accumulation in PSMA-negative PDX, confirming target specificity. Importantly, the radiotracers showed excellent tumor-to-tissues ratios. Both agents significantly inhibited tumor growth compared to controls in mice bearing PSMA-positive PDX tumors. Treatment was well tolerated, with no significant weight loss or acute toxicity observed.
Conclusions: Further studies are warranted to optimize dosing strategies and evaluate long-term safety. Importantly, this work underscores the critical role of PDX models in capturing real receptor expression and tumor heterogeneity, thereby enhancing the translational relevance of radiopharmaceuticals in preclinical development.

#5813 Mass dose effects of the immunotheranostic [^{89}Zr]Zr-LNTH-2403 by PET/CT and dosimetry in non-human primates.

Hansel Comas Rojas[1], Marcus Lindsey[1], David Ulmert[2], Abigail Hasson[3], Aseem U. Anand[4], Daniel L. Thorek[3], Reinier Hernandez[1]

[1]Medical Physics, University of Wisconsin-Madison, Madison, WI,[2]Molecular and Medical Pharmacology, UCLA, Los Angeles, CA,[3]Dept. of Radiology, Washington University in St. Louis, St. Louis, MO,[4]Lantheus, North Billerica, MA

Leucine-rich repeat-containing protein 15 (LRRC15) is a TGFB-driven cell surface protein overexpressed selectively on highly aggressive mesenchymal stem cell-derived cancers and on cancer-associated fibroblasts of several solid tumors. Herein, we characterized the in vivo biodistribution, dosimetry, pharmacokinetic (PK) profile, and preliminary safety [^{89}Zr]Zr-LNTH-2403 targeting LRRC15 in healthy non-human primates (NHPs) under different administered mass regimens. The humanized monoclonal antibody (mAb) LNTH-2403 (also known as DUNP-19) targeting and internalizing LRRC15 was conjugated to p-SCN-Bn-DFO at a 5 chelator-to-mAb molar ratio for radiolabeling with ^{89}Zr ($t_{1/2}$=3.3 d). [^{89}Zr]Zr-LNTH-2403 was synthesized with a 174 MBq/mg molar activity and 99% radiochemical purity, as confirmed by iTLC. Three cohorts of two adult male Rhesus Macaques received a single 13 MBq/kg [^{89}Zr]Zr-LNTH-2403 IV bolus at total mAb mass doses of 2, 4, or 8 mg. Serial PET/CT imaging was acquired at 4 time points up to 168 hours post-injection (p.i.). Blood samples were collected at baseline and at each imaging session for PK analysis and CBC and CMP assessments. Volume of interest analyses were performed using the Imalytics Preclinical 3.1. Image-based human dosimetry extrapolations were performed using OLINDA/EXM 1.1 VOI analysis of PET/CT images in the 2 mg cohort demonstrated that [89Zr]Zr-LNTH-2403 exhibited rapid blood-pool distribution, with increasingly prominent adrenal gland uptake, peaking at 27.24 SUV_{mean} at 168 h p.i. Other organs of uptake included the liver, spleen, kidneys, and bone marrow, with peak SUV_{mean} of 7.71, 8.56, 3.98, and 6.56, respectively. Notably, increasing the antibody mass dose to 4 or 8 mg had a significant effect on blood PK and tissue biodistribution, reducing [^{89}Zr]Zr-LNTH-2403 uptake by 3- to 4-fold in the adrenal glands and in the bone marrow, albeit to a lesser extent. The PK profile exhibited a biphasic pattern, with an initial fast distribution half-life of 8.59 hours and a terminal slow half-life of 20.54 hours in the 2 mg cohort. Notably, the slow elimination half-life progressively increased to 33.68 hours at an 8 mg mass dose, evidencing longer antibody circulation. Estimated human-equivalent organ-absorbed doses confirmed that the adrenals received the highest equivalent dose, 2.82 mSv/MBq, followed by the liver, with 1.63 mSv/MBq. The effective whole-body dose was 0.471 mSv/MBq, indicative of acceptable radiation exposure. Blood parameters remained within normal limits. These findings demonstrate a favorable safety and dosimetry profile for [^{89}Zr] Zr-LNTH-2403 in NHPs, supporting its advancement toward first-in-human imaging studies. Importantly, the administered mass of mAb significantly affected the radiotracer's blood and normal organ biodistribution, highlighting the value of preclinical mass-dose optimization in humans.

#5814 Towards treating prostate cancer with $^{188}ReO_4^-$ using an engineered human sodium/iodide symporter (NIS) protein.

Haswitha Sabbineni, Alejandro Llorente-Esteban, Alejandra Paola Torres-Manzo, Dila Karakas, David Lopez-Gonzalez, Vengatesh Kumar Raja, Mohammed Noor Tantawy, Todd Giorgio, Nancy Carrasco

Vanderbilt University, Nashville, TN

The sodium/iodide symporter (NIS) is the plasma membrane protein that mediates the active transport of iodide (I^-) and various clinically approved radiotracers used for imaging [such as pertechnetate ($^{99m}TcO_4^-$), radioiodide ($^{123}I^-$), and tetrafluoroborate ([^{18}F] BF_4^-)] and for therapeutic purposes [e.g., $^{131}I^-$ and preclinically approved perrhenate ($^{186/188}ReO_4^-$)]. For over 80 years, targeted internal radiation therapy (TIRT) has been used successfully to treat thyroid cancer: administered radioactive iodide ($^{131}I^-$) is selectively accumulated in the thyroid cancer cells by NIS. NIS-mediated TIRT is a promising approach to treating prostate cancer, the second deadliest cancer in men in the United States and Europe. About 1 in 8 men will be diagnosed with prostate cancer at some point in their life. Localized prostate cancer is typically treated with prostatectomy or definitive radiotherapy (RT), but these treatments *fail* to cure up to 20-40% of patients. For metastatic castration-resistant prostate cancer (mCRPC), there are only a very limited number of effective agents available with unique mechanisms: androgen receptor antagonists, inhibitors of androgen synthesis, cytotoxic chemotherapy, immune-cell transfer therapy, and bone-directed and prostate-specific membrane antigen (PSMA)-targeted radiopharmaceuticals, all of which improve survival *only modestly*, by ~4 months, in randomized trials for patients with mCRPC. In order for NIS-based TIRT to be successful, three challenges must be overcome: (i) thyroid protection from β-radiation, (ii) immune response mitigation, and (iii) tissue specificity. To overcome these limitations, we engineered a NIS molecule with 2 amino acid substitutions L253P and V254F: PF-NIS. PF-NIS selectively transport oxyanions but does *not* transport I^-. *In vitro* studies demonstrated that PF-NIS-expressing cells were selectively susceptible to $^{186}ReO_4^-$ + 100 μM I^- in contrast to WT-NIS cells, which survived in the presence of 100 μM I^-. To minimize immunogenicity, PF-NIS cDNA was delivered via polyplexes (*in vivo* jetPEI), and tissue specificity was ensured by the prostate-specific antigen (PSA) promoter. Building on these data, athymic nude mice with PF-NIS-bearing tumors were imaged by SPECT-CT, which revealed PF-NIS-mediated tracer accumulation in tumors after intratumoral or intravenous delivery of PF-NIS polyplexes, as well as an ~80% decrease in thyroidal signal following administration of 100 μM I^-. Treatment with $^{188}ReO_4^-$ markedly reduced tumor volume while the thyroids of the mice were protected, leveraging the higher energy and shorter half-life of ^{188}Re vis-à-vis those of ^{186}Re or ^{177}Lu (the radionuclide currently used in most PSMA targeted radiopharmaceuticals). This approach constitutes a novel strategy for NIS-based TIRT, selectively targeting prostate cancer cells while protecting the thyroid.

#5815 pH-targeted gadolinium-based nanoparticles for enhanced radiotherapy.

Jessica Wen, Yuwei Xue, Wu Liu, Guillem Pratx

Radiation Oncology, Stanford University, Palo Alto, CA

Gadolinium-based nanoparticles (GdNP) are sub-5 nm particles designed for radiosensitization and MRI contrast enhancement. The high atomic number of Gd (Z = 64) enables efficient X-ray absorption and dose deposition within tumors, with tumor accumulation facilitated by the enhanced permeability and retention effect. Previous clinical trials have provided preliminary evidence for the safety and potential therapeutic benefit of intravenous GdNP in patients with cervical cancer and brain metastases. To improve tumor specificity, we conjugated GdNP with pH-low insertion peptide (pHLIP), which targets the acidic tumor microenvironment through pH-dependent membrane insertion. Previous work demonstrated that pHLIP conjugated to GdNP enhanced gadolinium uptake and radiosensitization in vitro. In vitro experiments were performed with cultured A549 human lung adenocarcinoma cells at pH 6.2 (tumor-like) and pH 7.4 (physiologic) conditions. Clonogenic assays and ICP-MS analysis revealed that while pHLIP-GdNP (0.17 mM dose) did not significantly alter cell survival, it increased intracellular gadolinium levels by approximately 18-fold under acidic conditions compared to unconjugated GdNP. In vivo, mice bearing subcutaneously implanted A549 tumors received 10 Gy X-ray irradiation with or without unconjugated GdNP or pHLIP-GdNP pretreatment (300 mg/kg; n = 7 mice/group). All irradiated groups exhibited significant tumor growth delay compared to controls ($P < 0.013$), but no additional radiosensitization was observed in the nanoparticle-treated cohorts, despite Gd accumulation in the tumor. MRI T1 mapping demonstrated shortened T1 relaxation times following GdNP administration, with greater reduction following pHLIP-GdNP injection, indicating enhanced contrast agent delivery. These findings suggest that pHLIP conjugation improves gadolinium uptake and MRI visibility but does not enhance radiotherapeutic efficacy under current conditions. Departing from previous work, this study used a simpler covalent bond to conjugate pHLIP to GdNP rather than a disulfide bridge, which may explain the decreased efficacy. Reintroducing the disulfide linkage might be critical, as it allows the conjugate to remain stable in circulation while releasing nanoparticle cargo upon insertion into acidic tumor cells, potentially increasing therapeutic efficacy.

#5816 A novel NTSR1-targeting diagnostic radioligand SKL35502 for noninvasive solid tumor imaging.

Jungtae Na, Taeyun Lee, Seona Jeon, Hyunseok Lee, Sunghak Lee, Sungwan Hwang, Jungshin Park

SK Biopharmaceuticals Co., Ltd., Seongnam-si, Korea, Republic of

Background: Neurotensin receptor 1 (NTSR1) is highly expressed in several aggressive malignancies, including pancreatic ductal adenocarcinoma, colorectal cancer, esophageal cancer, gastric cancer, biliary tract cancer, and head and neck squamous cell carcinoma. Given its role in tumor progression, NTSR1 represents a compelling target for molecular imaging and for selecting patients for NTSR1-directed radionuclide therapy. SKL35502, an ^{111}In-labeled small-molecule NTSR1 ligand, was developed to enable sensitive and selective visualization of NTSR1-positive tumors. This study evaluates the preclinical pharmacology, biodistribution, and imaging performance of SKL35502.
Methods: The binding affinity of SKL35502 was determined using a cell-based saturation binding assay. Time-dependent uptake and internalization were assessed in HCT116 human colorectal carcinoma cells. In vivo biodistribution was evaluated in female mice bearing HCT116 or AsPC-1 xenografts by SPECT/CT imaging up to 168 hours post-injection, and ex vivo biodistribution and excretion were confirmed in HCT116 xenograft models up to 48 hours. Urine and feces were collected at 8, 24, 48, 72 and 96 hours post-dose.
Results: SKL35502 exhibited high binding affinity to HCT116 cells (KD = 0.37 nM). Cellular uptake was time-dependent and NTSR1-specific, reaching 31.5% at 90 minutes and remaining at 30.5% at 240 minutes. Internalization accounted for approximately 56% of total uptake at both time points.
In vivo SPECT/CT imaging revealed an initial widespread distribution followed by rapid clearance from non-target organs (heart, liver, kidney). Tumor uptake peaked at 4 hours post-injection and persisted through 168 hours. *Ex vivo* biodistribution confirmed strong tumor enrichment (44 %ID/g at 8 hours), with tumor exposure (AUC) approximately 22-fold higher than blood. By 96 hours (4 days) post-dose, the total excreted radioactivity was 84.12% of the administered dose
Conclusions: SKL35502 demonstrates high affinity and specific uptake in NTSR1-expressing tumor cells, together with rapid systemic clearance that minimizes nonspecific radiation exposure to healthy tissues. These properties support its potential as a highly sensitive and selective imaging agent for detecting NTSR1-positive tumors and guiding patient selection in NTSR1-targeted theranostic approaches.

#5817 A novel NTSR1-targeting alpha radiotherapeutic SKL35501 demonstrating potent anti-tumor efficacy in HCT116 colorectal tumor model.

Jungtae Na, Taeyun Lee, Seona Jeon, Hyunseok Lee, Sunghak Lee, Sungwan Hwang, Jungshin Park

SK Biopharmaceuticals Co., Ltd., Seongnam-si, Korea, Republic of

Background: Radiopharmaceutical Therapy (RPT) using the alpha-emitter Actinium-225 (^{225}Ac) is emerging as a promising therapeutic approach for advanced solid tumors. Neurotensin Receptor 1 (NTSR1), highly expressed in aggressive cancers such as pancreatic ductal adenocarcinoma, colorectal cancer, esophageal cancer, gastric cancer, biliary tract cancer, and head and neck squamous cell carcinoma, represents an attractive target for RPT. SKL35501, the ^{225}Ac-labeled NTSR1 ligand, was developed as the therapeutic agent. This study evaluated the preclinical characteristics of SKL35501 using the HCT116 cell line. Here, we demonstrate favorable *in vitro* pharmacology, *in vivo* biodistribution, and *in vivo* antitumor activity in a colorectal tumor model.

Methods: *In vitro* cellular uptake/internalization and cytotoxicity of SKL35501 were assessed in NTSR1-expressing HCT116 human colorectal carcinoma cells using uptake and colony formation assays. *In vivo* biodistribution and antitumor efficacy following a single intravenous administration were evaluated in HCT116 xenograft models across multiple dose levels (0, 7.5, 15, and 30 kBq). Safety was assessed by body weight and hematological parameters.

Results: SKL35501 demonstrated rapid and time-dependent, NTSR1-mediated uptake in HCT116 cells, with >90% of cell-associated activity internalized, and showed a dose-dependent colony formation inhibition in the colony-formation assay. *In vivo*, SKL35501 exhibited robust and sustained tumor accumulation (31 %ID/g at 24h, with retention through 168 hours) alongside rapid clearance from non-target organs. A single administration produced dose-dependent tumor growth inhibition, with partial tumor regression at doses ≥15 kBq by Day 75. All SKL35501 dose levels resulted in significantly prolonged survival compared with vehicle ($p=0.0005$).

Toxicity was transient and reversible, characterized by mild hematological suppression and <10% body weight loss, both of which recovered within several weeks.

Conclusions: SKL35501 is a highly effective, first-in-class, ^{225}Ac-labeled NTSR1-targeting alpha radiotherapeutic demonstrating excellent tumor selectivity, durable tumor retention, potent antitumor activity, and a favorable safety profile. These preclinical findings strongly support advancement to the FIH trial for patients with NTSR1-positive advanced solid tumors using the SKL35501.

#5818 *De novo* protein design of calreticulin binders for theranostic applications.

Luke Rathbun[1], Yuvasri Golivi[2], **Rachael Guenter**[2], J. Bart Rose[2], Benjamin Larimer[1]

[1]Radiology, University of Alabama at Birmingham, Birmingham, AL,[2]Surgery, University of Alabama at Birmingham, Birmingham, AL

Background: Calreticulin (CALR) is an endoplasmic reticulum (ER) protein that can translocate to tumor cell surfaces during partial ER stress. Surface CALR is largely absent on normal cells yet upregulated on many types of tumor cells undergoing stress, making it a tumor-specific target with potential ubiquity and application as a tumor-agnostic biomarker. Targeting surface CALR with theranostic agents could offer a novel strategy to visualize tumors and monitor treatment response. We hypothesized that *de novo* protein design could generate a novel CALR-specific theranostic agent.

Methods: We employed the *de novo* protein design platform BindCraft to generate small (<10kDa) high-affinity binders against CALR. A streamlined *in silico* to *in vitro* screening pipeline enabled isolation of CALR binders within two weeks. Binding affinity and specificity were validated by biolayer interferometry (BLI) and flow cytometry. For flow cytometry, human pancreatic cancer cells were treated with doxorubicin, a known surface CALR inducer. Cells were incubated with two CALR binders for 30 minutes, followed by staining with fluorescent antibody. In a Matrigel plug model, mice bearing CALR and control plugs were injected with 100 µCi of [^{64}Cu]Cu-NOTA-binder and imaged by dynamic PET for 1 hour followed by CT.

Results: BLI against CALR identified two high affinity binders, d4 and d6, with calculated dissociation constants of 83.2 nM (k_{on} = 512790 $M^{-1}s^{-1}$, k_{off} = 0.04265 s^{-1}) and 31.2 nM (k_{on} = 551797 $M^{-1}s^{-1}$, k_{off} = 0.01723 s^{-1}), respectively. Flow cytometry showed both CALR binders, d4 and d6, detected increases in surface CALR of 1.6-fold and 2.1-fold, respectively, on doxorubicin-treated cancer cells compared to vehicle. PET imaging revealed significantly higher uptake of [^{64}Cu]Cu-NOTA-d6 in CALR plugs compared to controls as early as 20 minutes post-injection, with sustained retention throughout the imaging period. At 1 hr post-injection, SUV_{mean} of the CALR plug was (0.882±0.270) compared to (0.344± 0.048) for the control plug (p = 0.0272). [^{64}Cu]Cu-NOTA-d6 was cleared renally with insignificant uptake in non-target organs compared to blood pool and an average blood ½-life of 4.2 minutes.

Conclusions: This study demonstrates the feasibility of *de novo* protein design to rapidly generate high-affinity CALR-targeted binders suitable for theranostic applications. Further *in vivo* studies will evaluate tumor-specific uptake and long-term retention of d6 in preclinical cancer models to support its translational development as a theranostic agent.

#5819 PD-L1 targeted radiotherapy can reduce tumor burden and delay tumor growth in a mouse model of triple-negative breast cancer.

Jonathan Moye, Hailey Houson, Sharmila Sridhar, Sherin James, Jason M. Warram, Suzanne E. Lapi, Anna G. Sorace

The University of Alabama at Birmingham, Birmingham, AL

Introduction: Due to lack of targeted therapies, triple-negative breast cancer (TNBC) accounts for 40% of breast cancer mortalities despite only comprising 10-15% of diagnoses. Combination of PD-1/PD-L1 inhibitors with radiation therapy have been shown to have synergistic effects in TNBC. Targeted radiotherapy (TRT), in which a targeting probe is attached to a cytotoxic radioisotope, has emerged as a promising technique to deliver a therapeutic radiation payload to cells expressing the protein of interest. This is advantageous when targeting proteins such as PD-L1, which is highly expressed in TNBC and strongly upregulated after radiation-induced cytotoxicity. The purpose of this study was to assess the efficacy and safety of a novel PD-L1 targeted radiotherapy to improve immunotherapy outcomes in TNBC.

Methods: The PD-L1-targeted antibody atezolizumab was radiolabeled with lutetium-177, a cytotoxic radioisotope, to selectively deplete PD-L1$^+$ cells. Athymic nude mice bearing high PD-L1-expressing MDA-MB-231 tumors were treated with saline (n=6), 250μCi (n=3) or 500μCi (n=5) of [^{177}Lu]Lu-atezolizumab. Mice were imaged with Single Photon Emission Computed Tomography (SPECT) on days 1, 3, and 7 post-treatment, informing on distribution of the tracer in the tissue. Mice were monitored for 60 days for changes in tumor volume and body weight. Upon reaching endpoints, mice were euthanized and relevant organs (tumor, spleen, liver, kidney) were collected. Clearance organs were stained with hematoxylin and eosin to assess gross pathological changes. One- and two-way ANOVAs were utilized to assess differences between tumor volumes and SPECT imaging metrics across time, and log-rank tests were used to assess differences in survival between treatment groups.

Results: Mice treated with 500μCi or 250μCi of [^{177}Lu]Lu-atezolizumab demonstrated a significant reduction in tumor volume compared to control by day 20 ($p < 0.05$) or day 24 ($p < 0.05$) post-treatment, respectively. Increased median survival was observed in both treated groups (35 days in control versus 52 and 60 days in 250μCi and 500μCi treated mice, respectively, $p < 0.01$). No weight loss was observed in any treated groups, and histology revealed minimal splenic and renal toxicity, with mild to moderate hepatotoxicity consistent with reversible changes. SPECT imaging revealed high uptake of [^{177}Lu]Lu-atezolizumab in the tumor by day 1 post treatment and high tumor to background ratios across all three imaging timepoints.

Conclusions: Utilizing TRT to selectively deplete PD-L1$^+$ cells resulted in decreased tumor volumes and increased survival in a mouse model of TNBC. Further, SPECT imaging validated high uptake of the PD-L1-targeted TRT within tumor tissue. These results validate [^{177}Lu]Lu-atezolizumab as a novel PD-L1-targeted radiotherapy which has the potential to improve outcomes of immunotherapy in TNBC patients.

#5820 Biodistribution analysis of Leutetium-177 radiopharmaceuticals in mammary, prostate, and glioblastoma models using Alpha-SPECT Mini and gamma counts.

Kathryn R. Meshaw, William F. Durham, Karsten E. Fynboe, Tyler Rowe, Jacob C. Hauser, Joseph P. Kolb, Kenneth A. Meshaw, Stephanie M. Fogerson, Beth A. Hollister

Powered Research, LLC, Durham, NC

Background: Radiopharmaceuticals play a pivotal role in both diagnostic imaging and targeted radionuclide therapy for cancer. With the increase in clinical use and expansion of oncology indications, accurate characterization of their biodistribution is essential to optimize tumor targeting and reduce systemic toxicity. This study utilizes two approaches, the Alpha-SPECT Mini imaging system and gamma counts, to evaluate the in vivo distribution of radiopharmaceutical agents across three clinically relevant tumor types: human mammary gland adenocarcinoma, prostate carcinoma, and glioblastoma. By utilizing these two methods we aimed to improve profiling of radioligand uptake and clearance patterns across various tumor types and radiopharmaceuticals.
Methods: Subcutaneous xenografts of MDA-MB-231 human mammary gland adenocarcinoma, 22Rv1 and LNCaP human prostate carcinoma, and orthotopic xenografts of U-87 MG-Luc2 human glioblastoma in athymic nude mice were treated with lutetium-177 (^{177}Lu) conjugated Anti-human CD44 (10 µCi), ^{177}Lu-Anti-human PSMA (20-22 µCi or 10 µCi), or ^{177}Lu-Anti-human EGFRvIII (10 µCi), respectively, at a mean start size of 300 mm^3 (subcutaneous) or 3 weeks post cell implant (orthotopic). Alpha-SPECT Mini imaging was performed at 24, 72 and 168 hours post-dose and tissues for gamma counts were collected at 4, 24, 48, 72, and 168 hours post-dose.
Results: Preferential uptake of the radioligand in the tumor was apparent by 24 hours post-dose in the LNCaP, 22Rv1 and U87 MG-Luc2 xenografts, while the MDA-MB-231 xenograft had lower concentrations in comparison to the liver, serum, spleen and whole blood. By 48 hours, only the liver and spleen had higher concentrations than the MDA-MB-231 tumor. Radioligand clearance was observed as early as 48 hours in the MDA-MB-231 tumors. Alpha-SPECT Mini showed similar biodistribution and dynamics of the radioligands to the gamma counts.
Conclusions: Alpha-SPECT Mini imaging and gamma counting provided complementary profiling of radiopharmaceutical biodistribution across tumor types. Tumor-specific uptake patterns were evident, differences in radioligand retention, clearance, and off-target accumulation were observed. These findings underscore the importance of tumor biology in radiopharmaceutical pharmacokinetics and highlight the value of multimodal approaches for accurate profiling and therapeutic optimization.

#5821 Utilize a soluble T-cell receptor TCR targeting tumor intracellular antigen PRAME to develop therapeutic and radioactive diagnostic agents for PRAME-positive tumors.

Yujun Huang[1], Xiao Liang[2], Yajuan Xue[2]

[1]Suzhou Hepius Therapeutics, Suzhou, China,[2]Suzhou Hepius Therapeutics Co, Suzhou, China

T-cell receptor (TCR)-based therapeutics and diagnostics hold great promise for targeting intracellular tumor antigens presented by HLA molecules. The preferentially expressed antigen in melanoma (PRAME) is expressed in many cancers, but is highly restricted in normal tissues, making it a good target for TCR-based therapy. We have established a proprietary high-efficiency TCR discovery platform, enabling rapid identification of antigen-specific TCRs from healthy donors and cancer patients. TCRs specifically targeting PRAME425-433 peptide/ HLA-A*02:01 complex were cloned from healthy donors. T cells transduced with lentivirus encoding PRAME-specific TCR exhibited robust IFN-γ secretion and cytolytic function in an antigen-specific manner. By engineering the constant regions of both TCR α and β chains, the soluble expression of monovalent and bivalent native TCRs was achieved. We developed an exclusive cell based TCR binding assay to screen and identify the soluble forms of native PRAME-specific TCRs with various affinities. Surface plasmon resonance (SPR) analysis demonstrated that the bivalent native TCR protein HP-002 binds PRAME425-433/HLA-A*02:01 with a KD of 1.08×10^{-7} M. The Bivalent native TCR was used to develop TCR-CD3 T cell engager and radioactive diagnostic agent for imaging. Iodine-125 (125I)-labeled bivalent native TCR protein HP-002 exhibited in vivo antigen-dependent tumor accumulation in xenograft tumor models by SPECT/CT imaging. These data highlight the capability of our discovery and molecular engineering platform to develop the soluble TCRs for therapeutics and radioactive diagnostics in cancer. Our ongoing work focuses on TCR affinity maturation and molecular optimization of HP-002 to improve its affinity and selectivity, aiming to achieve enhanced tumor accumulation for future diagnostic and therapeutic applications.

#5822 Efficacy of targeted radionuclide therapy Using ^{131}I-FAPi dimers labeled via tetrazine ligation in a human glioblastoma xenograft model.

Umberto Maria Battisti[1], Marcel Martin[2], Vladimir Shalgunov[2], Filipe Elvas[3], Alan Miranda[3], Andreas Jensen[2], Matthias Herth[1]

[1]University of Copenhagen, Copenhagen, Denmark,[2]Tetrakit Technologies ApS, Copenhagen, Denmark,[3]University of Antwerp, Antwerp, Belgium

The successful use of diagnostic radiotracers targeting the pan-tumor marker fibroblast activation protein (FAP) across numerous cancer types is well established; however, translating these agents into effective therapeutics remains challenging. Compared with monomeric FAP inhibitors (FAPi), FAPi dimers—containing two FAP-targeting vectors—exhibit enhanced tumor retention, resulting in higher tumor doses and encouraging preliminary clinical outcomes. Current therapeutic agents targeting FAP rely largely on chelator-based constructs, restricting their labeling to radiometals. To overcome this limitation, we previously developed FAPi dimers equipped for tetrazine ligation using the novel trans-cyclooctene T4CO, enabling selective formation of a single isomer. Our lead compound, (^{131}I)I-FAPi 5, was synthesized with high yield and purity and evaluated in tumor-bearing animals, where it demonstrated therapeutic effects comparable to the established agent (^{177}Lu)Lu-DOTAGA-Glu(FAPi)$_2$. These findings suggest that (^{131}I)I-FAPi 5 may offer a cost-effective and scalable radioligand therapy (RLT) option to meet the expanding demand for FAP-directed treatments.
(^{131}I)I-DUAL FAPi-5 was prepared by a two-step radiolabeling process using tetrazine ligation. First, a tetrazine-trimethylgermyl precursor was radioiodinated with ^{131}I. The resulting synthon was purified by HPLC and subsequently clicked with the T4CO-FAPi derivative, achieving complete ligation within 10 minutes without requiring further purification. The therapeutic effect was investigated in U87-MG tumor-bearing mice. When the tumors reached 64±4mm^3, the mice received a single intravenous injection of (^{131}I)I-FAPi 5 (30 or 60 MBq), (^{177}Lu)Lu-DOTAGA-Glu(FAPi)2 (30 MBq) or vehicle control (n=6/group). Tumor response was monitored every other day via caliper measurement and survival was assessed up to 70 days after the start of treatment. The mice were euthanized on reaching one of the predefined endpoint criteria.(^{131}I)I-FAPi 5 was obtained in two steps with a final radiochemical yield of 60 ± 5% (n=4), radiochemical purity ≥98% (n=4). In U87-MG xenograft models, the tracer exhibited high and sustained tumor uptake. Treatment with (^{131}I)I-FAPi 5 at both dose levels (30 MBq and 60 MBq) resulted in rapid tumor regression, with therapeutic performance comparable to that of (^{177}Lu)Lu-DOTAGA-Glu(FAPi)$_2$. Our dual-targeting FAPi compound labeled with ^{131}I demonstrated robust tumor uptake and retention, with renal clearance as the primary excretion pathway. These findings confirm the therapeutic efficacy of this agent in preclinical tumor models, showing marked tumor regression and improved survival. Collectively, the results support the potential of this compound as an effective and accessible FAP-RLT candidate.

#5824 First target disclosure for the preclinical development of ATNM-400, a first-in-class actinium-225 radioconjugate with pan-tumor efficacy in solid tumors.

Amanda S. Chin, **Sumit Mukherjee**, Jason Li, Karina Peregrina, Debbie Lewis, Le-Cun Xu, Dhiren Patel, Madhuri Vusirikala, Monideepa Roy, Adeela Kamal

Actinium Pharmaceuticals, Inc., New York, NY

Background: Therapeutic resistance is a major barrier to durable cancer control across solid tumors. We report the first disclosure of a novel membrane target and the preclinical development of ATNM-400, a first-in-class Actinium-225 (225Ac) antibody radioconjugate designed to selectively eradicate therapy-refractory cancer cells. This target is overexpressed and functionally linked to resistance mechanisms in prostate, lung, and breast tumors. We evaluated the pan-tumor efficacy, mechanism of action, and translational potential of ATNM-400 in preclinical models representing advanced and therapy-resistant disease.
Methods: A full-length antibody specific to the novel target was conjugated to p-SCN-Bn-DOTA and radiolabeled with the alpha-emitter 225Ac (>98% purity). Target expression, binding affinity, and cellular internalization kinetics were tested across therapy-resistant tumor models, including enzalutamide- and 177Lu-PSMA-617-resistant prostate cancer, osimertinib-resistant EGFR-mutant lung cancer, hormone positive (HR+) breast cancer, triple-negative breast cancer (TNBC) and tamoxifen- or trastuzumab-resistant breast cancer. In vivo biodistribution, tumor retention, and efficacy were evaluated as monotherapy or in combination with standard-of-care agents.
Results: ATNM-400 selectively bound and rapidly internalized into target-positive tumor cells, inducing robust alpha-particle mediated DNA double-strand breaks. Notably, tumors resistant to other standard of care therapies showed increased target expression, thereby sensitizing the resistant tumors to ATNM-400. In vivo, ATNM-400 demonstrated sustained tumor uptake with off-target exposure in normal tissues, driving potent anti-tumor activity in:
• Prostate cancer: ATNM-400 outperformed androgen receptor (AR) pathway inhibitor enzalutamide, 177Lu-PSMA-617, and 225Ac-PSMA-617, producing durable regressions and complete responses in enzalutamide- and 225Ac-PSMA-617-resistant models.
• EGFR-mutant lung cancer: ATNM-400 synergized with EGFR inhibitor osimertinib, achieving complete cures in animals, correlating with increased target expression in osimertinib-resistant models.
• Breast cancer: ATNM-400 exhibited tumor regressions in HR+ breast cancer, TNBC and combination activity in estrogen receptor (ER) inhibitor tamoxifen- and HER2 antibody trastuzumab-resistant tumors, correlating with increased target expression. No significant toxicity or weight loss was observed at therapeutic doses.
Conclusions: ATNM-400 exhibits robust pan-tumor activity, overcomes resistance to AR, EGFR, and HER2/ER-targeted therapies, and demonstrates a favorable safety profile. These findings support ATNM-400 as a next-generation 225Ac radiotherapeutic platform with broad potential across many refractory solid tumors.

#5825 Discovery of FL-261 as a theranostic RDC vector for the treatment of c-MET overexpression cancers.

Junyu Yang, Guangcheng Jiang, Jiajia Xia, Juan Zhang, Fa Liu

Full-Life Technologies Limited, Shanghai, China

Mesenchymal-epithelial transition factor (c-MET) is an important member in the receptor tyrosine kinase family that is overexpressed and abnormally activated in most malignant tumors, making it an attractive target for radionuclide drug conjugate (RDC) based therapy. Despite the clinical validation of the target by small molecule kinase inhibitors, EGFR/c-MET bispecific antibodies and antibody drug conjugates (ADCs), their efficacy is mostly observed in non-small cell lung cancer (NSCLC). With the aim of developing a novel c-MET targeting RDC vector for the diagnosis and treatment of broader c-MET overexpressing indications, we have applied our UniRDC^{TM} platform technologies and discovered the development candidate FL-261. The binding affinity and selectivity of FL-261 against c-MET was tested by surface plasmon resonance (SPR) protein binding assay. FL-261 was then labelled with ^{111}In and ^{225}Ac, and their radiochemical purity (RCP) was determined by radio high-performance liquid chromatography (radio-HPLC). Their *in vivo* performance, assessed via imaging, *ex vivo* biodistribution and efficacy studies, was evaluated in xenograft mouse models with varying levels of c-MET overexpression. FL-261 showed potent binding affinity against c-MET with a K_D value of 7.5 nM and demonstrated over 450-fold selectivity over structurally similar receptor tyrosine kinases. FL-261 was successfully labeled with ^{111}In and ^{225}Ac, with each achieving an RCP of over 95%. After administration of [^{111}In]In-FL-261 in mice implanted with EBC-1 non-small cell lung cancer (NSCLC) xenografts, SPECT/CT images revealed intense and sustained tumor uptake which was significantly higher than that of normal organs. In addition, the tumor uptake was nearly completely blocked when extra mass of unlabeled FL-261 was co-administrated in the imaging study, suggesting *in vivo* cMET-specificity of FL-261. Separately, *ex vivo* cut-and-count biodistribution studies were performed after administration of [^{225}Ac]Ac-FL-261 in c-MET overexpressing EBC-1 xenograft model, demonstrating persistent and high tumor uptake from 1-hour to 120-hour post-dosing and rapid clearance from normal organs. Furthermore, in multiple xenograft models with varying levels of c-MET expression and one PDX model derived from a patient who became refractory to c-MET ADC therapy, [^{225}Ac]Ac-FL-261 consistently exhibited significant anti-tumor activity resulting in marked tumor regression. In these studies, there were no notable changes in body weight observed, suggesting a favorable safety profile of [^{225}Ac]Ac-FL-261. In summary, FL-261 demonstrates high theranostic potential, with favorable imaging profile of [^{111}In]In-FL-261 and potent antitumor activity of [^{225}Ac]Ac-FL-261 across a diverse set of tumor models. This compelling data set supports the further development of FL-261 as a theranostic agent for c-MET overexpressing cancers.

#5826 RT01: A novel anti-TF, radionuclide drug conjugate (RDC) for theranostic precision oncology.

Yi Zhao, Huahua Hao, Xin Yang, Weiwei Pan, XinxinLiang, Quanai Zhang, Xiaoxia Liu, Jingting Cui, Elizabeth Wu, **Zhican Qu**

Nanolattix, Taiyuan, China

Tissue Factor (TF) is an attractive therapeutic target for various tumors. We developed RT01, a first-in-class, targeted radio-theranostic agent consisting of a humanized anti-TF antibody conjugated to the diagnostic 89Zr or therapeutic 177Lu radionuclide. In a xenograft tumor model, SPECT/CT imaging demonstrated rapid and specific tumor accumulation of RT01-177Lu (single 200μCi i.v. dose), with retention over 6 days and rapid non-target clearance (background decreased by 4 hours post-injection). The tumor-to-kidney ratio of radiation intensity uptake (%ID/cc) exceeded 9.2. This single 200μCi dose injection of RT01-177Lu demonstrated potent anti-tumor efficacy and excellent tolerability. Histopathology analysis of ten major organs (kidney, intestine, brain, lung, liver, femur, spleen, stomach, heart, and pancreas) revealed no observable abnormalities or serious toxicity. In conclusion, the RT01 theranostic pair provides superior tumor targeting, rapid non-target clearance, and a favorable toxicity profile, supporting its continued clinical development for TF-positive cancers.

#5827 Actimab-A, a CD33-targeted actinium-225 radioconjugate, drives mutation-agnostic anti-leukemic activity and synergizes with standard therapies in AML through transcriptional reprogramming.

Amanda S. Chin[1], Merve Sahin[2], Jason Li[1], Le-Cun Xu[1], Monideepa Roy[1], Madhuri Vusirikala[1], Kaitlyn H. Ko[2], Wenbin Xiao[2], Adeela Kamal[1], Sheng F. Cai[2]

[1]Actinium Pharmaceuticals, Inc., New York, NY,[2]Memorial Sloan Kettering Cancer Center, New York, NY

Introduction: Acute myeloid leukemia (AML) is a genetically heterogeneous and aggressive malignancy with limited durable treatment options. Actimab-A (lintuzumab-Ac225), a CD33-targeted antibody radioconjugate, delivers the alpha emitter actinium-225 (Ac-225) to AML cells, inducing potent, localized DNA damage. Clinical studies have shown encouraging responses when combined with CLAG-M chemotherapy in relapsed/refractory AML, including in patients with *TP53* mutations or venetoclax resistance. Previously, we have shown the anti-leukemic activity of lintuzumab-Ac225 in AML cells regardless of mutations (*FLT3*, *TP53*, *NPM1*, and *KMT2A*) in both *in vitro* and *in vivo* AML models. Here, we demonstrated in primary AML patient samples that lintuzumab-Ac225 has strong translational therapeutic potential both as monotherapy and in combination with other therapies. We also defined the transcriptional profiles of AML cells treated with lintuzumab-Ac225 combination therapies to understand the underlying molecular mechanisms of anti-leukemic activity of these combination treatments.

Methods: Lintuzumab was conjugated to p-SCN-Bn-DOTA and radiolabeled with Ac-225. To explore mechanisms of synergy, AML cell lines harboring common mutations (*FLT3*, *KMT2Ar*: MV-4-11, MOLM-13 cells, *NPM1c*: OCI-AML3, and mutant *TP53*: Kasumi-1, HL-60 cells) were treated for 24 hours with standard-of-care (SOC) therapies: FLT3 inhibitors (gilteritinib, quizartinib), menin inhibitors (revumenib, ziftomenib) or azacitidine alone or in combination with lintuzumab-Ac225. We performed RNA sequencing (RNA-seq), followed by comprehensive gene set enrichment analysis. The cytotoxic potency of SOC was evaluated as monotherapies and in combination with Lintuzumab-Ac225 in primary AML patient samples.

Results: Lintuzumab-Ac225 showed a robust, dose-dependent cytotoxicity in primary AML patient samples, irrespective of FLT3, KMT2A, NPM1, or TP53 status. Notably, combining SOC therapies with lintuzumab-Ac225 *in vitro* enhanced their growth inhibitory effects. Lintuzumab-Ac225 combination versus SOC alone produced significant downregulation of MYC, G2M checkpoint, E2F targets and MTORC1 signaling while activating p53-mediated apoptosis, underscoring the mechanistic rationale for clinical development

Conclusions: Lintuzumab-Ac225 shows broad mutation-independent anti-leukemic activity in AML cell lines and primary AML patient samples. When combined with standard therapies, it drives complementary transcriptional programs that enhance depth and durability of response. Together, these findings support the clinical evaluation of lintuzumab-Ac225-based combinations as a strategy to overcome resistance and enhance therapeutic efficacy in AML.

: Tumor Microenvironment, Multispecifics, and Immunomodulation
Poster Session

#5832 Development and utility of precision FISH/IF multiomic panel to elucidate T cell functionality in the tumor microenvironment.
Anushka Dikshit[1], **Chandler Callaway**[2], Sukhbir Lulla[1], Will Paces[2], Alan Busar[2], Sara Wells[3], Mandy Bell[2], Lauren Matelski[4], Sharel Figueredo[1], Lenka Sinik[4]

[1]ACD, a Bio-Techne Brand, Newark, CA,[2]Flagship Biosciences, Broomfield, CO,[3]Flagship biosciences, Bloomfield, CO,[4]Flagship Biosciences, Bloomfield, CO

Immunohistochemistry (IHC) is a widely utilized tool for visualizing biomarker expression in tissues of interest. However, not all biomarkers are amenable to investigation by IHC, including secreted factors, such as cytokines. In these cases, *in situ* hybridization (ISH) may be a suitable alternative. The combination of IHC and ISH approaches allows for investigation of protein and RNA targets in the same multiomic assay, offering greater utility and flexibility than traditional assays. Furthermore, image and spatial analyses can be applied to elucidate the colocalization, proximity, and spatial relationship of RNA and protein biomarkers in the same sample. Flagship Biosciences, in collaboration with Advanced Cell Diagnostics (ACD), is developing a multiplex IHC/ISH fluorescent, which aims to identify and characterize subsets of T lymphocytes in the context of cancer. Using the RNAscope™ Multiomic LS assay we detected CD8, CD3, and Ki67 proteins alongside *IL4*, *IFNG*, and *GZMB* RNA expression to assess the activation and functional state of different T cell subsets based on biomarker expression profiles. Here, we demonstrate the capacity of this analysis on a set of FFPE lung samples from healthy and non-small cell lung cancer subjects. Our approach and analysis highlights the potential of spatial multiomics assays to bridge immunobiology with cancer research. Data generated could prove useful for phenotyping tumors, monitoring therapy response, or better understanding immune cell dynamics within the tumor microenvironment.

#5833 Therapeutic targeting of adhesion receptor GPR56 for the treatment of triple-negative breast cancer.

Yueh-Ming Shyu[1], Joan Jacob[2], Carla Godoy[1], Treena Chatterjee[1], Zhengdong Liang[1], Kendra S. Carmon[1]

[1]UTHealth Houston, Houston, TX,[2]Baylor College of Medicine, Houston, TX

Triple-negative breast cancer (TNBC) is an aggressive subtype lacking durable targeted therapies, and resistance continues to drive poor clinical outcomes. The clinical success of antibody-drug conjugates (ADCs), which combine antibody specificity with potent cytotoxic payloads, highlights their growing clinical impact. Although the approved anti-TROP2 ADC, sacituzumab govitecan, provides clinical benefit, it causes toxicity in normal tissues, underscoring the need for more selective therapeutic strategies. Adhesion-mediated signaling through the FAK-SRC axis is a major survival pathway under therapeutic stress. Our previous study showed that GPR56, an adhesion G protein-coupled receptor (GPCR), activates the FAK-SRC pathway and that targeting GPR56 with an ADC elicited potent antitumor efficacy in colorectal cancer models. Given these results, we examined GPR56 as a potential therapeutic target in TNBC. While TROP2 is a validated ADC target in TNBC, its expression in normal tissues limits tumor selectivity. GPR56, by contrast, is highly expressed in TNBC and associated with poor prognosis, yet shows limited normal tissue expression, potentially conferring a superior therapeutic index for GPR56-targeted ADCs. Our first-generation anti-GPR56 ADC (10C7-Duo), incorporating the DNA-damaging payload duocarmycin, exhibited target-dependent cytotoxicity in GPR56-positive TNBC cell lines, confirming that GPR56 is a viable therapeutic target. However, the monoclonal antibody (mAb) 10C7 exhibited agonistic activity, which could limit its therapeutic potential. Thus, we developed 9E3, a non-agonist anti-GPR56 mAb that internalizes efficiently and traffics to lysosomes for payload delivery. 9E3 was conjugated to a more potent pyrrolobenzodiazepine (PBD) payload using site-specific chemistry, and analyses confirmed successful conjugation, stability, and preserved antigen binding. Functional studies in breast cancer models showed that GPR56 knockdown suppressed, while overexpression enhanced, FAK-SRC phosphorylation, tumor cell growth, and invasion. Currently, we are evaluating 9E3-PBD for in vitro cytotoxic potency and selectivity, as well as in vivo safety and antitumor efficacy in TNBC cell line xenografts and patient-derived models. These findings help establish GPR56 as a clinically relevant adhesion GPCR and introduce a novel ADC approach to target therapeutic resistance in TNBC. By integrating receptor biology with targeted payload delivery, this work lays the foundation for potentially safer and more selective therapeutic options for TNBC patients.

#5834 Dual targeting GLI1 and EZH2 for treatment of invasive breast cancer.

Jer-Yen Yang, Chun Ju Chang, Yu-Wa Lai

China Medical University, Taichung City, Taiwan

About 12% of breast cancers are invasive breast cancers, including triple-negative breast cancer (TNBC), which manifests early metastasis and recurrence with limited treatment options. Therefore, there is an urgent need to better understand key mechanisms governing invasive breast cancers to develop effective treatment strategies. Our clinical database analysis indicates that overexpression of EZH2 is often correlated with metastatic breast cancer, and high expression of the oncogenic GLI1-Hedgehog signaling is positively correlated with poor survival of invasive breast cancers. Our pilot findings indicate that deletion of the EZH2 gene results in reduced expression levels of GLI1 and its downstream target gene, cyclin D1. Previous literature also suggests that cMYC can activate GLI1, and the EZH2-cMYC complex can induce target gene expression in an atypical manner, promoting cancer. However, it is reported that the clinical use of either an EZH2 inhibitor alone or a GLI1 inhibitor alone cannot hinder tumor growth or metastasis. Our data suggest that EZH2 may regulate GLI1 expression, but its synergistic functionality has not been fully elucidated. We expect that EZH2 forms a complex with cMYC and GLI1 to synergistically activate the target genes involved in breast cancer progression (for example, GLI1 and Cyclin D1). As a result, a combination of EZH2 inhibitors and GLI1 inhibitors can synergistically suppress cancer cell growth and metastasis, serving as a new and effective therapeutic option for invasive breast cancers. Using a cell viability assay, the combination therapy was shown to be more effective in inhibiting TNBC cell viability compared to the single-drug treatment and the vehicle groups. The wound healing assay showed that combination therapy was more effective in suppressing TNBC cell migration. The CompuSyn for drug synergy analysis, both the Combination Index (CI) and Dose Reduction Index (DRI) indicated that the combination therapy exhibited significant synergistic effects, where Vismodegib could reduce the dose by ~52-fold, while GSK126 could reduce the dose by ~22-fold. Form the findings, we believe that dual targeting GLI1-EZH2 has potential to become a novel and effective combination treatment for invasive breast cancer in the clinical setting.

#5835 Treatment of pancreatic cancer cells with Tumor Treating Fields (TTFields) and KRAS inhibitors.

Hila Fishman[1], Lena Lifshitz[1], Helena Mumblat[1], Zeina Drawshy[1], Anat Klein-Goldberg[1], Yara Eid Mutlak[1], Hila Ene[1], Efrat Zemer-Tov[1], Tali Voloshin[1], Itai Tzchori[1], Adi Haber[1], Moshe Giladi[1], Uri Weinberg[2], Yoram Palti[1]

[1]Novocure Ltd, Haifa, Israel,[2]Novocure GmbH, Baar, Switzerland

Background: Pancreatic ductal adenocarcinoma (PDAC) remains a major cause of cancer-related mortality, with limited survival despite intensive chemotherapy regimens such as FOLFIRINOX or gemcitabine/nab-paclitaxel. KRAS mutations, present in approximately 90% of PDAC cases, are a central driver of tumor aggressiveness and therapeutic resistance, in part by activating and stabilizing (and often overexpressing) c-MYC—a key regulator of cell growth and metabolism. Tumor Treating Fields (TTFields), electric fields that disrupt cellular processes crucial for cancer cell viability, have recently been shown to suppress c-Myc at the transcript and protein levels in various cell lines. TTFields therapy was shown to improve survival in pancreatic cancer patients when used together with gemcitabine/nab-paclitaxel. The current study aims to examine the benefit of adding TTFields to KRAS inhibitors (KRASi) in PDAC preclinical models.
Methods: KPC pancreatic cancer cells harboring the KRAS G12D mutation were treated for 72 hours with TTFields (150 kHz, 1 V/cm RMS) using the inovitro system. The pan-KRAS inhibitor daraxonrasib (RMC-6236) was applied at varying concentrations, either alone or in combination with TTFields. Following treatment, cell count, colony formation, and apoptosis were quantified, and an overall effect score was derived from changes in cell count and colony formation. Expression of c-Myc was assessed by real-time PCR and Western blot analysis.
Results: Treatment of KPC cells with either TTFields or the KRAS inhibitor resulted in a dose-dependent reduction in cell viability and colony formation, along with increased apoptosis. The co-application of TTFields with RMC-6236 amplified these outcomes, demonstrating a synergistic interaction between the two modalities. Both TTFields and RMC-6236 independently reduced c-Myc expression, with a more pronounced downregulation observed upon co-treatment.
Conclusions: Concomitant application of TTFields and the pan-KRAS inhibitor in KRAS G12D pancreatic cancer cells produced a synergistic antitumor effect, potentially mediated by modulation of the master regulator c-Myc. Ongoing studies are exploring KRAS mutation-specific inhibitors, expanding the analysis to additional pancreatic cancer cell lines harboring diverse KRAS variants, and testing the in vivo efficacy of TTFields with KRAS inhibition.

#5836 Augmented antitumor activity of Tumor Treating Fields (TTFields) with anti-VEGFR and docetaxel treatment in a lung cancer mouse model.

Helena Mumblat[1], Yara Eid Mutlak[1], Yuval Shmueli[1], Ruslana Militsin[1], Catherine Tempel-Brami[1], Shay Cahal[1], Alexandra Volodin[1], Sara Jacobovitch[1], **Martin Gabay**[1], Itai Tzchori[1], Adi Haber[1], Moshe Giladi[1], Uri Weinberg[2], Yoram Palti[1]

[1]Novocure Ltd, Haifa, Israel,[2]Novocure GmbH, Baar, Switzerland

Introduction: Angiogenesis drives disease progression and poor outcomes in non-small cell lung cancer (NSCLC). Ramucirumab, an antibody targeting the vascular endothelial growth factor receptor (VEGFR), is approved as a second-line therapy in combination with docetaxel for metastatic NSCLC. By normalizing tumor vasculature, angiogenesis inhibitors enhance drug delivery and facilitate immune cell infiltration Tumor Treating Fields (TTFields) are electric fields that disrupt cellular processes critical for cancer cell survival. TTFields therapy is approved for metastatic NSCLC concomitant with immune checkpoint inhibitors or docetaxel following progression on/after platinum-based therapy. Here, we investigated the therapeutic impact of TTFields applied together with docetaxel and anti-VEGFR treatment in an orthotopic mouse model of NSCLC.

Methods: C57Bl/6 mice were orthotopically implanted with LL/2 lung carcinoma cells and allowed seven days for tumor establishment. Mice were then exposed continuously to TTFields (150 kHz) or sham (heat) treatment for eight days. The murine anti-VEGFR antibody DC101 (10 mg/kg) or vehicle was administered intraperitoneally on days 1, 4, and 7 of treatment. Docetaxel (3 mg/kg) or vehicle was administered intraperitoneally on days 2 and 6. The study included six treatment groups: control, docetaxel alone, docetaxel + DC101, TTFields alone, TTFields + docetaxel, and TTFields + docetaxel + DC101. At treatment completion, tumors were excised, weighed, and analyzed by immunohistochemistry using anti-CD31 for vessel staining, alongside additional functional markers.

Results: Treatment with TTFields together with docetaxel and DC101 led to a marked reduction in tumor volume compared with all other treatment groups. Tumor weights and MRI analysis consistently showed the strongest inhibition of tumor growth under this regimen. Histological analysis revealed elevated cell death in tumors from the TTFields + docetaxel + DC101 group, as indicated by TUNEL staining. CD31 and αSMA co-staining indicated that TTFields, when applied together with anti-VEGFR therapy, promoted vascular normalization characterized by pericyte coverage and a more organized vasculature. This remodeling of the tumor microenvironment was accompanied by enhanced infiltration of $CD8^+$ cytotoxic T cells, pointing to improved immune accessibility to the tumor core.

Conclusions: Collectively, these findings suggest that TTFields amplify the therapeutic activity of antiangiogenic and chemotherapeutic agents by stabilizing tumor vasculature, facilitating immune cell penetration, and potentiating treatment-induced cell death.

#5837 Tolvaptan as a potential anticancer and immunomodulatory treatment for triple-negative breast cancer.

Laura Naldi[1], Zhi Huang[1], Brionna King[1], Kimberly McCarter[1], Kelsey Gardiner[1], Alessandro Peri[2], Lucio Miele[1], Giulia Monticone[1]

[1]LSU Health New Orleans, New Orleans, LA,[2]University of Florence, Florence, Italy

Background: Triple-negative breast cancer (TNBC) is an aggressive breast cancer (BC) subtype characterized by rapid progression, high risk of recurrence and metastasis. Although immunotherapy has improved outcomes for some patients, treatment resistance remains a major challenge, highlighting the need for novel therapeutic targets and drug repurposing strategies. Hyponatraemia, defined by a serum sodium concentration <135 mEq/L, is the most common electrolyte disorder in cancer, affecting over one-third of BC patients. Tolvaptan, a G protein-coupled (GPC) vasopressin type 2 receptor (AVPR2) antagonist, is clinically used to treat hyponatremia in various settings, including cancer. Beyond its clinical use, *in vitro* and *in vivo* studies indicate that tolvaptan inhibits cancer cell proliferation, reduces invasiveness, and promotes apoptosis in several tumor types. Interestingly, database analysis revealed that TNBC has the highest expression of AVPR2 among all BC subtypes. Further, there is evidence of tolvaptan modulating T cells, and it is known that other GPC receptors can regulate T cell antitumor activity, although the underlying mechanism of tolvaptan immunoregulation remains unclear. This study aimed to investigate the potential anticancer and immunomodulatory effects of tolvaptan in TNBC models.
Experimental Procedures and Results: Tolvaptan treatment significantly reduced TNBC cell viability in MTT assays in murine (C0321) and human (MDA-MB-231, MDA-MB-436) TNBC cell lines from the lowest concentration of 1 nM, while non-tumorigenic MCF10A cells remained unaffected up to 10 µM. In contrast, treatment with the AVPR2 agonist desmopressin had no effect on the viability at any concentration used. In agreement, tumor-derived TNBC organoids treated with tolvaptan showed a significant increase in cell death and a higher number of infiltrating $CD8^+$ T cells compared to those treated with DMSO. Consistently, primary cultures of splenic murine $CD8^+$ T cells treated with tolvaptan exhibited increased expression of the activation marker CD69, as determined by flow cytometry. In an orthotopic syngeneic TNBC mouse model (C0321, FVB mice), tolvaptan treatment (10 mg/kg for 27 days) resulted in smaller tumors, whereas desmopressin (2 µg/kg) promoted tumor growth. Immunohistochemical analysis demonstrated increased cleaved caspase-3 expression and $CD8^+$ T cell infiltration in tolvaptan-treated tumors. Flow cytometry analysis confirmed a higher number of tumor-infiltrating $CD8^+$ T cells and an upregulation of Notch-1 and IFN-γ, markers of an effective antitumor immune response.
Conclusions: Overall, these findings indicate that tolvaptan exerts both direct cytotoxic and immune antitumor effects in TNBC models. The cytotoxicity toward TNBC cells, together with enhanced $CD8^+$ T cell responses, supports the potential use of tolvaptan as a novel therapeutic approach for TNBC.

#5838 QLS2401: A novel PSMA/STEAP1/CD3 tri-specific T-cell engager for the treatment of mCRPC.

Chenjun Tang[1], **Langyong Mao**[1], Jiaxin Yue[1], Moyan Hu[1], Shuyong Zhao[2], Hua Ying[1], Weikang Tao[1]

[1]Shanghai Qilu Pharmaceutical Research and Development Center LTD., Shanghai, China,[2]Qilu Pharmaceutical Co., Ltd., Jinan, China

Prostate cancer (PCa) is one of the most common malignancies in men worldwide. Approximately 10%-20% of PCa patients develop castration-resistant PCa (CRPC) within 5 years and subsequently progress to metastatic CRPC (mCRPC). Current approved therapies for mCRPC patients offer limited survival benefits with unsatisfied long-term remission, underscoring an urgent need for novel therapeutic options. Both STEAP1 (Six Transmembrane Epithelial Antigens of the Prostate 1) and PSMA (Prostate-Specific Membrane Antigen) are frequently co-expressed at high levels in mCRPC, presenting dual targeting opportunity to enhance efficacy. Here, we report the generation and preclinical development of QLS2401, a novel PSMA/STEAP1/CD3 tri-specific TCE engineered to have optimized CD3 affinity and tumor associated antigen (TAA)-binding valency to enhance T cell-mediated cytotoxicity and mitigate the resistance resulting from single antigen-loss. QLS2401 causes potent target-dependent and T cell-mediated cytotoxicity against prostate cancer cell lines and induces tumor regression in prostate cancer xenograft models, demonstrating superior or comparable efficacy to the xaluritamig analog. The avidity-driven activity of QLS2401 enables selectivity for tumor cells with higher STEAP1- and PSMA- expression than normal cells. QLS2401 was well-tolerated in a toxicity study in cynomolgus monkeys, with an HNSTD (Highest Non-Severely Toxic Dose) significantly higher than that of the xaluritamig analog. In conclusion, preclinical studies have demonstrated that QLS2401 exhibits an expanded therapeutic window, superior efficacy and improved tolerability compared to the xaluritamig analog.

#5839 Tumor-selective treatment of metastatic pancreatic cancer with an engineered, probiotic living drug.

Amanda R. Decker-Farrell[1], Stephen A. Sastra[2], Tetsuhiro Harimoto[3], Marie C. Hasselluhn[2], Carmine F. Palermo[2], Tanner C. Dalton[2], Llewelyn Levett[1], Edward R. Ballister[3], Michael A. Badgley[2], Tobias Janowitz[1], Tal Danino[3], Kenneth P. Olive[2]

[1]Cancer Center, Cold Spring Harbor Laboratory, Cold Spring Harbor, NY,[2]Herbert Irving Comprehensive Cancer Center, Columbia University Irving Medical Center, New York, NY,[3]Biomedical Engineering, Columbia University, New York, NY

Treating pancreatic ductal adenocarcinoma (PDAC) with intravenous chemotherapy has remained a challenge, due in part to the hypovascularized and poorly perfused nature of PDAC tumors, thus limiting drug accumulation. However, the features that impede systemic therapy in PDAC may favor bacterial therapies, as bacteria can actively migrate through tissues, thrive in hypoxic microenvironments, and exploit local immune suppression. Once colonized within the tumor niche, live bacteria can provide a stable source of anticancer compounds, rather than relying on repeated systemic doses. Here, we addressed the current drug delivery challenges of PDAC by developing a probiotic-based bacterial therapy. Through 2D monolayer and PDAC tissue-slice screens, we identified the pore-forming Theta toxin (from *C. perfringens*) as a potent candidate and expressed it in a probiotic strain of *E. coli*, Nissle 1917 (Nis). Intratumoral injections of live Nis-Theta bacteria into subcutaneous and genetically engineered mouse models of PDAC (KPC - Kras LSL.G12D/+; Tp53 LSL.R172H/+; PdxCre tg/+) resulted in significantly higher rates of complete tumor regression, reduced tumor growth kinetics, and extended median survival to 35.5 days, compared to 12 days for Vehicle or Gemcitabine controls and 16.5 days for non-toxic bacteria, Nis-GFP. We also thoroughly monitored systemic body response to bacterial treatment for safety. Bacterially treated mice did not exhibit any weight loss, body composition changes, or other infection-like symptoms compared to non-bacterial treatment (Gemcitabine) arms. Bacterial spread to healthy tissues (lung, liver, intestine, and diaphragm) was minimal with no increase in cellular damage in non-tumor tissues. Furthermore, mice systemically cleared the bacteria within several weeks of full tumor regression. Strikingly, while there was minimal spread of bacteria to non-tumor tissues, bacteria translocated to distant secondary tumor sites following injection of the primary pancreatic tumor. Histology showed bacterial co-localization with apoptotic tumor cells in both primary and metastatic lesions, suggesting a mechanism for targeting both known and unknown metastases following local administration. Histological and flow cytometry analyses demonstrated modest recruitment of anti-tumor immune populations in Nis-Theta treated tumors, suggesting potential synergy with immunotherapies. Together these data demonstrate potent preclinical activity of cytotoxic bacterial therapy as a novel drug delivery method to circumvent the challenges of systemic treatment of PDAC. These bacteria demonstrated preferred tumor colonization over healthy tissue with no systemic illness, targeted metastatic lesions, and significantly extended survival in a clinically relevant model of PDAC with only a single dose.

#5840 The development of minocycline-loaded microparticles and injectable alginate scaffolds composites to prolong release for the treatment of glioblastoma.

Florestella Rivera, Dorina A. Madrid, Samantha C. Davila, Serenade Trevino, Jorge L. De Leon, Sebastian Flores, Sue Anne Chew

Health and Biomedical Sciences, The University of Texas Rio Grande Valley, Brownsville, TX

Glioblastoma multiforme (GBM) is a Grade IV malignant brain cancer characterized by rapid progression and high recurrence. Minocycline (MINO), an antibiotic know to have antiangiogenic properties, has potential for GBM treatment ; however to address the limitations of current therapies, this project integrates two biomaterial-based delivery systems: 1) electrosprayed minocycline-loaded PLGA microparticles, which exhibited a 67-80% burst release within the first hour, and 2) injectable alginate scaffolds, which exhibited a 36-43% burst release within the first day. MINO-loaded MPs alone exhibit a significant burst release that limits sustained therapeutic exposure. The alginate (i.e. a biocompatible polysaccharide) injectable hydrogels are capable of decreasing the burst release compared to MPs and possibly increase the control release of drug. Combining both systems may therefore reduce burst release and extend overall delivery.Thus, the objective of this study was to investigate the drug release kinetics from MINO-loaded MPs, MINO loaded alginate scaffolds and MINO-loaded MPs in alginate scaffolds. MINO-loaded MPs were fabricated via vertical electrospraying using a 0.9 mL/ flow rate, 14kV voltage, and 20 cm distance. Polyethylene glycol (PEG) was incorporated to enhance MINO solubility, and the MPs were collected on copper /glass plates. Sodium alginate scaffolds (2.0 wt/vol%) were prepared by dissolving sodium alginate and calcium carbonate, homogenizing with glucono-delta lactone and with MINO or drug loaded MPs and injecting into 24-well plates to mold them uniformly. Release kinetics for MPs, MINO-loaded scaffolds (scaffold + MINO), and MINO-loaded MP scaffolds (scaffold + MINO-loaded MPs) were assessed in 1x DPBS by measuring MINO absorbance at 350 nm with a microplate reader. The drug release kinetics studied showed high burst release on Day 1 for the Mino-loaded MPs alone (45%), and a substantially reduced initial burst release for the other groups (16% for both scaffold + MINO and and scaffold + MINO-loaded MPs). On Day 2, 3 and 6, MINO-loaded scaffold released significantly more drug compared to MINO-loaded MPs and MINO-loaded MP scaffolds had a trend of having a lower percentage of cumulative release of drug compared to MINO-loaded scaffolds. In conclusion, the combination of MINO and PLGA MINO-loaded MPs with the injectable alginate scaffolds will prolong the release of the therapeutic agents and allow better control of the release kinetics compared to using MPs alone with the MINO-loaded MPs and scaffold combination having a trend of being a more promising for sustained released for localized GBM treatment. Future studies will focus on evaluating U87 cell viability following treatment with the different groups to determine whether the prolonged and controlled release results enhance the cytotoxic effect.

#5841 Targeting type XI collagen to facilitate elimination of cancer-associated fibroblasts?.

Annika Hettich, Cecilie Bager, Morten Karsdal, Nicholas Willumsen

Nordic Bioscience, Herlev, Denmark

Background: Fibrotic tumors pose a major therapeutic challenge due to the dense stromal barriers formed by myofibroblastic cancer-associated fibroblasts (myCAFs), which increase tissue stiffness and impede drug delivery. These myCAFs are characterized by elevated expression of type XI collagen, a key component of the fibrous cap. Antibody-drug conjugates (ADCs) offer a targeted approach by linking monoclonal antibodies to cytotoxic payloads, enabling selective delivery within the tumor microenvironment. Here, we present a novel ADC-based strategy that targets tumor-associated type XI collagen to selectively eliminate myCAFs. This approach combines CT11a1, an antibody recognizing a tumor-specific type XI collagen epitope, as the delivery vehicle, with PRO-C11, a circulating biomarker of type XI collagen for potential patient selection and treatment monitoring.
Methods: ELISAs were used to quantify CT11a1 and PRO-C11 collagen epitopes in serum from patients with various cancer types and healthy controls. Pancreatic cancer-associated fibroblasts (CAFs), normal fibroblasts (NFs), and co-cultures of CAFs with pancreatic cancer cells (BxPC3) were cultured in the SiaJ model for 12 days. On day 12, cultures were immunostained with CT11a1 or PRO-C11 antibodies. A CT11a1-ADC was developed and its effect on cell viability was quantified using the Alamar Blue assay.
Results: Among several tested collagen-based biomarkers, PRO-C11 demonstrated the highest diagnostic accuracy (AUC: 0.99) across all cancer types. In contrast CT11a1 was barely detectable in serum. Immunostaining with the CT11a1 antibody on day 12 of the SiaJ model revealed prominent type XI collagen deposition in wells containing CAFs while minimal to no signal was detected in wells with NFs. In contrast, staining CAFs with the PRO-C11 antibody did not result in any detectable signal, indicating limited accessibility or absence of the PRO-C11 epitope in the extracellular matrix (ECM). Staining of co-cultures with the CT11a1 antibody revealed that type XI collagen is localized in the fibrous cap-like structure positioned between the cancer cells and the fibroblasts. Initial treatments with CT11a1-ADC induced a dose-dependent decrease in CAF viability.
Conclusion: Type XI collagen is specific to myCAFs. The CT11a1 epitope is detectable in the CAF-derived ECM, but not in circulation, whereas the opposite is true for PRO-C11. The developed CT11a1-ADC demonstrates potential as an ADC specifically targeting type XI collagen produced by myCAFs. PRO-C11 may serve as a biomarker to identify patients with high type XI collagen production. Further exploration and validation are ongoing.

#5842 Combined KRAS pathway inhibition and liposomal irinotecan treatment enhances tumor regression, attenuates desmoplasia, and augments T cell infiltration in pancreatic ductal adenocarcinoma.

Hari Krishnareddy Rachamala[1], Fang Wei[1], Debabrata Mukhopadhyay[2], Hani M. Babiker[3]

[1]Department of Biochemistry and Molecular Biology, Mayo Clinic, Jacksonville, FL,[2]Mayo Clinic College of Medicine, Jacksonville, FL,[3]Mayo Clinic, Jacksonville, FL

Background: Pancreatic ductal adenocarcinoma (PDAC) is driven predominantly by oncogenic KRAS signaling and characterized by an immunosuppressive, fibrotic tumor microenvironment that limits therapeutic responses. RMC-6236, a pan-KRAS inhibitor, and liposomal irinotecan, an investigational anti-tumor agent, each demonstrate partial activity in KRAS-mutant cancers. However, their combined therapeutic potential in PDAC remains unexplored. Here, we evaluated the anti-tumor efficacy, survival benefit, and immunomodulatory effects of RMC-6236, liposomal irinotecan and irinotecan alone and dual combinations multiple in vitro and in vivo PDAC models.

Methods: In vitro cytotoxicity assays were performed using KPC, PANC-1, AsPC-1, and PANC-02 cell lines. In vivo therapeutic studies were conducted in orthotopic KPC and PANC-1 tumor models. RMC-6236 was administered orally at 10 mg/kg; liposomal irinotecan and irinotecan was administered intravenously at 5 mg/kg. Tumor growth inhibition, survival, collagen deposition, and immune cell infiltration were analyzed. Tumor microenvironment remodeling was quantified via immunohistochemistry for CD8, CD4, collagen I, and fibronectin.

Results: The combination of RMC-6236 and liposomal irinotecan elicited potent anti-tumor effects across all evaluated PDAC cell lines, achieving greater than 90% growth inhibition in vitro. In vivo, co-treatment resulted in more than 90% tumor regression in both KPC and PANC-1 xenograft models, markedly surpassing the efficacy of individual monotherapies and other dual-agent controls. Combination therapy significantly extended overall survival and produced sustained suppression of tumor progression. Mechanistic analyses revealed a substantial reduction in collagen and fibronectin deposition within the tumor microenvironment, consistent with attenuation of desmoplasia. Immune profiling demonstrated a robust enhancement of intratumoral $CD8^+$ and $CD4^+$ T-cell infiltration, along with a pronounced decrease in survivin expression. Importantly, no observable systemic toxicity was detected in treated animals.

Conclusions: RMC-6236 combined with liposomal irinotecan yields synergistic anti-tumor effects, remodels the fibrotic PDAC microenvironment, enhances T-cell infiltration, and significantly improves survival in aggressive pancreatic tumor models. These findings provide strong rationale for clinical evaluation of RMC-6236-based combination therapies for KRAS driven PDAC.

#5843 Beyond viability: Post treatment single cell and spatial transcriptomic profiling in mixtures of PRISM barcoded cancer cell lines.

Laura Doherty[1], Ashish B. George[1], Mustafa Kocak[1], Paul Lund[2], Andrew Kohlway[2], Andrew Boddicker[3], Ben Song[3], Carlos Ruiz Perez[3], Bryan Lajoie[3], Catarina D. Campbell[1], Matthew G. Rees[1], Jennifer A. Roth[1]

[1]Broad Institute of MIT and Harvard, Cambridge, MA,[2]10x Genomics, Pleasanton, CA,[3]Element Biosciences, San Diego, CA

PRISM is a highly multiplexed, genomic barcode-based cell line viability technology of nearly 1000 solid tumor and hematopoietic cell lines. The unique cell line barcodes enable the cell lines to be multiplexed into pools of dozens to hundreds of different cell lines per well or dish, which greatly reduces the time and costs required to profile the viability effects of compounds or biologics across 900+ cell lines. Leveraging underlying genomic characterization of these cell lines enables the discovery of biomarkers of sensitivity and resistance. In addition to enabling viability screening in 900+ cell lines at scale, the PRISM barcoding technology also enables us to profile post-perturbation RNA transcript and protein changes in mixtures of cell lines by adapting commercially available single cell sequencing (10x Genomics Flex v2) and spatial transcriptomic assays (Element Biosciences AVITI24). Expanding the phenotypic readout capabilities of the PRISM technology beyond viability to include gene and protein changes will provide deeper insight into drug mechanisms of action, resistance, off-target effects, and heterogeneity of response. Here we present our work developing multiomic phenotypic profiling assays in barcoded PRISM cell line pools. We leverage 10x Genomics Flex v2 (for genomewide RNA single cell sequencing and PRISM barcode identification) in conjunction with the Flex-compatible Proteintech Human Discovery antibody panel (to measure abundances of 300+ proteins) in response to perturbations. In a pilot of 100 cell lines spanning 20+ lineages, we reliably detect 99 cell lines, recovering on average ~7000 unique genes per cell. In parallel, we are exploring the potential of Element Biosciences AVITI24 for spatial transcriptomic readouts in pools of PRISM cell lines. In a pilot of 25 cell lines spanning 15 lineages, we detect each of the 25 cell lines and although we recover fewer counts per cell, we recover morphology features from 6 cell paint stains (membrane, nucleus, actin, mitochondria, golgi, and ER). In both assays, we treated with a pan-RAS inhibitor and observed a concordant gene signature in differentially expressed genes. The 10x Flex v2 assay has the benefit of depth (detecting more transcripts per cell), while the Element imaging workflow enables culturing cells directly on the flowcell and provides spatial and morphological features. Thus, the two assays are highly complementary. We identify commonalities as well as distinct insights obtained by the two technological approaches and identify cell line specific responses.

#5844 Novel inhibition of transcriptional cyclin-dependent kinases, CDK12/13, using CT7439 as a treatment for colorectal cancer with CDK12 upregulation.

Jason A. Somarelli[1], Wylie Katherine Watlington[1], Divya Dayanidhi[1], Mohammad Zokaasadi[1], John B. Mantyh[1], Pelumi D. Olawuni[1], Gabrielle Rupprecht[1], Jeremy Force[2], Shannon McCall[1], Ashwani K. Bahl[3], David S. Hsu[1]

[1]Duke University, Durham, NC,[2]Daiichi Sankyo, Inc., Bernards Township, NJ,[3]Carrick Therapeutics, Inc., Dublin, Ireland

Introduction: Cell proliferation is a hallmark of cancer growth, and regulation of transcription and translation is key to controlling proliferative capacity. A crucial connection between transcriptional regulation and the cell cycle occurs via transcriptional cyclin-dependent kinases (CDKs), CDK12 and its paralog, CDK13, which regulate transcription by phosphorylating the c-terminal domain of RNA polymerase II. Both CDK12 and CDK13 are often upregulated in solid tumors, rendering them compelling targets for therapeutic intervention.
Methods: A total of eight CDK12 or CDK12/13 inhibitors with different mechanisms of action (covalent, non-covalent, proteolysis-targeting chimera, and molecular glue) were screened against a panel of cancer cell lines spanning five solid tumor types (breast, colorectal, lung, ovarian, and prostate). Colorectal cancer patient-derived organoids (PDO) were used to validate the most efficacious agents, covalent binders (THZ531 and CDK12-IN-E9). In order to determine whether CDK13 plays a compensatory role for loss of CDK12 function, knockdown of CDK13 by siRNAs was employed, followed by CDK12-specific inhibition using a proteolysis-targeting chimera (BSJ-4-116). Finally, synergy was conducted to determine whether CDK12/13 inhibition increases sensitivity to poly-ADP ribose polymerase (PARP) inhibition. qPCR quantified the presence of short and long isoforms of BRCA1 following CDK12/13 inhibition to confirm whether transcription elongation in DNA damage repair genes was prevented.
Results: Covalent inhibition of CDK12/13 was the most efficacious across pan-cancer cell lines. Validation in colorectal cancer PDO showed greater inhibition by covalent inhibitors than standard of care chemotherapies for colorectal cancer (oxaliplatin, SN38, and 5-FU). CDK13 siRNA-mediated knockdown sensitized colorectal cell lines to the CDK12-specific inhibitor, BSJ-4-116, suggesting CDK13 may compensate for CDK12 loss of function. CDK12/13 inhibition led to downregulation of long isoforms of BRCA1, rendering cells susceptible to dual CDK12 and PARP inhibitors. These compelling data prompted evaluation of CT7439, a CDK12/13 inhibitor and cyclin K glue-degrader, which showed efficacy in the low nanomolar range for a panel of colorectal PDO.
Conclusions: Here we highlight CDK12/13 inhibition as a compelling target for colorectal cancers and other solid tumors and show the importance of CDK13 compensation during CDK12 inhibition. These findings support further evaluation of the novel CDK12/13 inhibitor, CT7439, for the treatment of solid tumors with CDK12/13 upregulation.

#5845 BCG010, a potentially best-in-class NKG2A blocker for cancer treatment.

Yong Xie[1], Peiran Li[1], Huichao Liang[1], Tao Wang[2], Yanan Guo[1], Rongjing Zhang[2], Zhe Shao[2]

[1]Biocytogen, Waltham, MA, MA,[2]Dragon Boat Biopharmaceutical, Shanghai, China

BCG010, a fully human IgG1κ monoclonal antibody, has been engineered with an Fc LALA (L234A/L235A) substitution to block the CD94-NKG2A inhibitory checkpoint engaged by HLA-E. This development addresses the limitations of first-generation NKG2A inhibitors, which have shown variable activity, particularly as monotherapy, highlighting the need for molecules with enhanced affinity, selectivity, pharmacokinetics (PK), and developability, as well as cynomolgus cross-reactivity to support clinical translation and combination therapies. BCG010 fulfills these requirements, exhibiting higher affinity for human NKG2A compared to a Monalizumab analog at the nanomolar level, full cross-reactivity with cynomolgus NKG2A, and no binding to human NKG2C or NKG2E. Mechanistically, BCG010 alleviates NKG2A-mediated inhibitory signaling and promotes NK-cell cytotoxicity against K562 targets *in vitro*, akin to the Monalizumab analog, while demonstrating favorable biophysical and developability properties under defined conditions. *In vivo*, BCG010 inhibited tumor growth in B-hNKG2A/hCD94 humanized mice bearing MC38-HLA-E cells, in the K562-bearing B-NDG mouse model when combined with adoptive NK-cell therapy, and in RMA-bearing B-hCD94/hNKG2A mice when combined with an Atezolizumab analog, without inducing weight loss across studies. Notably, BCG010 also exhibits a longer half-life than the Monalizumab analog in B-hNKG2A/hCD94 humanized mice. These data collectively support BCG010 as a promising, potentially best-in-class NKG2A blocker with high affinity, strict selectivity, encouraging efficacy and tolerability, and favorable PK and developability profiles, warranting clinical advancement and the exploration of combination strategies for cancer treatment. The development of the CMC cell line for BCG010 is ongoing.

#5846 AVA6103 is a FAP-enabled pre|CISION®peptide-drug conjugate delivering sustained release of exatecan in the tumor microenvironment with potent antitumor activity.

Curtis Rink[1], Tom Clough[1], Ellen Watts[1], Folake Orafidiya[1], Marine Houee[1], Sophie Brown[1], Victoria Juskaite[1], Gezim Lahu[2], Ruairidh Edwards[3], Karen Campbell[3], Dave Liebowitz[3], David Jones[1], **Francis Wilson**[1], Michelle Morrow[1]

[1]Discovery, Avacta Therapeutics, London, United Kingdom,[2]thinkQ2, Baar, Switzerland,[3]Clinical Development, Avacta Therapeutics, London, United Kingdom

AVA6103 is a novel peptide drug conjugate (PDC) based on proprietary pre|CISION® technology which incorporates a dipeptide that is specifically cleaved by Fibroblast Activation Protein α (FAP).

FAP is a post-proline protease that is overexpressed on the surface of cancer associated fibroblasts (CAFs) in many solid tumors, and facilitates delivery of pre|CISION® medicines specifically to the tumor microenvironment (TME). AVA6103 consists of exatecan, a potent Topoisomerase I payload, covalently linked to a dipeptide containing a cleaving sequence (D-Ala-L-Pro), which is susceptible to hydrolysis by FAP but is resistant to hydrolysis by other mammalian proteases.

Exatecan has been investigated in the clinic, however, its utility is limited by dose-limiting toxicities. The exquisite selectivity of the pre|CISION® substrate for FAP results in release of exatecan payload selectively in the TME, greatly increasing the therapeutic window and hence reducing systemic exposure and associated toxicities.

AVA6103 is a pre|CISION-enabled PDC that demonstrates FAP-dependent release of exatecan and kills cancer cells via a bystander mechanism. In multiple *in vivo* efficacy studies utilizing diverse cell and patient-derived models, AVA6103 achieved complete regressions and sustained, durable responses which remained until study termination. Biomarker assessment indicated on-target activity of the exatecan payload.

The PK profile of AVA6103 and released-exatecan were assessed in tumor-bearing mice, showing that released-exatecan levels in the plasma were undetectable after 4 hours, whereas in the tumor, released-exatecan persisted throughout the 5-day observation period of the study, indicating the potential for AVA6103 to deliver sustained exatecan to the tumor whilst minimizing systemic exposure of exatecan below clinically toxic levels.

To gain a greater understanding of patient populations that may be sensitive to AVA6103, co-expression of FAP and SLFN11, a gene linked to sensitivity to topoisomerase inhibitors, were evaluated using Tempus AI's LENS database. A positive correlation was observed between FAP and SLFN11 across multiple tumor types, further supporting the rationale for clinical development. Additional mechanistic studies demonstrated on-target activity and supported utility of AVA6103 in specific cancer indications to exploit genetic vulnerabilities.

This preclinical data package highlights the potential for AVA6103 to selectively target exatecan to the tumor microenvironment in a wide range of cancers. A Phase 1 dose escalation study designed to evaluate the safety, pharmacokinetics, and preliminary anti-tumor activity of AVA6103 in gastric, pancreatic, cervical and small cell lung cancers is anticipated to start in 1H 2026.

#5847 Development of a selective haem oxygenase-1 inhibitor for the immunotherapy treatment of cancer.

Emre Demirel[1], Alessia Marrocu[1], Meriem Bahri[2], Mark Laws[2], James N. Arnold[1], Khondaker Miraz Rahman[1]

[1]King's College London, London, United Kingdom,[2]University College London, London, United Kingdom

Immunotherapy has been hailed as a breakthrough for cancer therapy, however, only a fraction of patients respond in the clinic. The tumour microenvironment (TME) represents a major obstacle to the success of these treatments in solid tumours, of which, tumour-associated macrophages (TAMs) play a major role. A sub-population of perivascular TAMs express an enzyme called haem oxygenase-1 (HO-1), through which they have been demonstrated to subvert the anti-tumour response by immune suppression and exclusion of $CD8^+$ T cells. $HO\text{-}1^+$ TAM-containing tumours can therefore negate the immune-stimulating effects of chemotherapy to become treatment-resistant. Inhibiting HO-1 has been demonstrated to reverse this effect and re-sensitise tumours to immune-dependent cell death. However, there are no clinically available HO-1 inhibitors, and the current landscape of candidates suffer from undesirable pharmacokinetics and exhibit isoform promiscuity; blocking the activity of both HO-1 and the HO-2 isoform which maintains redox homeostasis in healthy tissues.This study has developed several novel, selective HO-1 inhibitors using a synthetic chemistry approach and validated activity with an *in vitro* microsomal system. We identified two lead compounds based on selectivity and potency for HO-1. A preliminary safety screen took place *in vitro* using non-malignant cells and confirmed a lack of general toxicity. Anti-tumour efficacy was evaluated *in vivo* using a murine model of fibrosarcoma, where administration of either lead HO-1 inhibitor synergised with standard-of-care chemotherapy to deliver durable tumour control and was associated with a re-invigorated lymphoid compartment. We utilised *in silico* modelling to predict lead compound pharmacokinetics, which are expected to be orally bioavailable. Unexpectedly, one of these candidates effectively penetrates the blood brain barrier, which is now under investigation for therapeutic utility in glioblastoma.

#5848 Targeting phosphodiesterase 10A by ADT-030 normalizes the tumor immune microenvironment by inhibiting RAS-MAPK signaling in both cancer cells and myeloid-derived suppressor cells.

Gazi Md Yeashin[1], Ogacheko David Okoko[1], Yan Ye[1], Xin Wang[1], Khalda Fadlalla[2], Adam Keeton[2], Yulia Maxuitenko[2], Xi Chen[2], Lynn Hedrick[1], Huidong Shi[1], **Gary A. Piazza**[2], Gang Zhou[1]

[1]Augusta University Medical Center, Augusta, GA,[2]Auburn University, Auburn, AL

Phosphodiesterase 10A (PDE10A), a cyclic nucleotide-degrading enzyme, is overexpressed in various human cancers. While PDE10A inhibition using small-molecule inhibitors or gene silencing suppresses tumor growth in xenograft models, its precise mechanism of action and immunological impact remain unclear. Here, we report that ADT-030, a novel PDE10A inhibitor, exhibits potent cytotoxicity against a broad range of murine tumor cell lines through suppression of RAS/MAPK signaling in both cancer cells and myeloid-derived suppressor cells (MDSCs). ADT-030 is orally bioavailable and effectively suppresses tumor growth in multiple syngeneic mouse models. Notably, its efficacy is significantly diminished in immunodeficient mice or upon CD8+ T cell depletion, highlighting a critical dependence on host immunity. The immunopotentiating effects of ADT-030 are further evidenced by its synergy with anti-PD-1 therapy, its ability to induce immunogenic tumor cell death and promote dendritic cell (DC) maturation in vitro, and its reliance on cDC1 to elicit antitumor effects in vivo. Comprehensive immune profiling in the 4T1 triple-negative breast cancer model, both in orthotopic and metastatic settings, revealed that ADT-030 selectively reduces tumor-associated neutrophils while restoring the presence and function of CD8+ T cells. These findings highlight PDE10A inhibition as a multi-faceted strategy that not only disrupts tumor-intrinsic oncogenic signaling but also reshapes the tumor immune microenvironment to unleash antitumor immunity.

#5849 Leveraging expression of tumor microenvironment GAGs to enhance platinum-based therapy in pancreatic adenocarcinoma.

Vashti L. Bandy[1], Erica Peterson[2], Nicholas P. Farrell[3], Jose G. Trevino[4], Praveen Bhoopathi[2], Vignesh Vudatha[2], Arunima Punjala[5], Dongyu Zhang[2], Jennifer Koblinski[2], Ada Beaudin[1], Thomas M. Clausen[2], Chunqing Guo[1], Larisa Litovchick[1], Nicholas Woods[6]

[1]VCU Massey Cancer Center, Richmond, VA,[2]Virginia Commonwealth University, Richmond, VA,[3]Professor, Dept. of Chemistry, Virginia Commonwealth University, Richmond, VA,[4]Div. of Surgical Oncology, VCU Massey Cancer Center, Richmond, VA,[5]Virginia Commonwealth University - VCU, Richmond, VA,[6]UNMC Eppley Institute, F&P Buffett Cancer Center, Omaha, NE

Pancreatic ductal adenocarcinoma (PDAC) is often diagnosed at an advanced stage, with most patients experiencing disease progression within 6-12 months following frontline FOLFIRINOX (5-fluorouracil, oxaliplatin, irinotecan, leucovorin), underscoring the need for more effective treatment strategies. Recent evidence suggests that overexpression of glycosaminoglycans (GAGs)—particularly chondroitin-4-sulfate (C4S)—contribute to the dense, fibrotic stroma characteristic of PDAC and tumor resistance to chemotherapy. C4S, a tumor-associated GAG linked to proteoglycans such as CD44, glypicans, and syndecans, is prominently expressed on the cell surface within the tumor stroma. Our studies demonstrate that C4S expression predicts PDAC tumor sensitivity to the Phase II polynuclear platinum agent, Triplatin (BBR3464). The highly cationic structure of Triplatin enhances its binding affinity for negatively charged GAGs, promoting drug accumulation and increased formation of platinum-DNA adducts. These findings provide a strong mechanistic rationale for re-evaluating Triplatin in tumors with high GAG expression, particularly C4S.

Our preliminary data shows that modulating GAG levels in PDAC cell lines alters both the cytotoxicity and cellular uptake of Triplatin. First, Triplatin exhibits greater cytotoxicity than oxaliplatin in the CHX1990 mouse cell line, an established model of PDAC derived from the Kras(G12D)/Trp53 null/Pdx1-cre (KPC) model. Second, a GAG-deficient CHX1990 cell line, B4GalT7 (CRISPR KO of β-1,4-galactosyltransferase 7), verified by reduced binding of the CS-binding peptide rVAR2-V5, shows a correlative loss in cytotoxicity. Finally, Triplatin significantly suppresses CHX1990 tumor growth *in vivo* with minimal changes in body weight relative to untreated controls. Collectively, these findings suggest that GAGs serve as a viable biomarker for Triplatin response in PDAC and may confer significant therapeutic advantage over oxaliplatin in this context.

To further support our studies, we are investigating Triplatin's mechanism of action through proteomic analyses that assess intracellular drug accumulation impacts on DNA repair proteins and apoptosis pathways. To complement this work, spatial transcriptomics will be used to map gene expression within the tumor microenvironment, providing insight into how Triplatin distribution corresponds with tumor cell responses. Additionally, synergy studies examining Triplatin in combination with standard-of-care therapies will help determine its therapeutic effectiveness. Together, these integrated approaches aim to advance Triplatin as a promising therapy for treatment of PDAC.

#5850 Novel platinum nanotherapeutics reprogram the tumor microenvironment to potentiate cancer immunotherapy.

Yongbin Liu[1], Xueying Ge[2], Busra Akay Hacan[1], Dongfang Yu[1], Junjun Zheng[3], Roderic I. Pettigrew[4], Ping-Ying Pan[3], Shu-Hsia Chen[3], Junhua Mai[5]

[1]Nanomedicine, Houston Methodist Academic Institute, Houston, TX,[2]School of Engineering Medicine/ENMED, Texas A&M University, Houston, TX,[3]Center for Immunotherapy Research, Houston Methodist Research Institute, Houston, TX,[4]School of Engineering Medicine, Texas A&M University, Houston, TX,[5]Houston Methodist Research Institute, Houston, TX

Background: Immune checkpoint inhibitors (ICIs)-based immunotherapy has transformed cancer treatment, but its efficacy is often limited by immune suppressive cells in the tumor microenvironment (TME), such as tumor-associated macrophages (TAMs). We recently developed a novel platinum therapeutic (carrier-Pt) that can induce cancer cell death through triggering rapid and robust intracellular reactive oxygen species (ROS) storm. Interestingly, ROS production was found to enhance anti-cancer immunity by inducing immunogenic cell death (ICD) and reprograming immunosuppressive TAMs. Thus, we aim to investigate its underlying mechanisms and potential synergy with immunotherapy.
Methods: CT26 and PyMT-N cells were inoculated into immunocompetent and immunodeficient nude mice, and tumor growth was compared. Immune cell populations were analyzed by imaging mass cytometry (IMC). CT26 cells were treated with carrier-Pt to assess ICD markers (CRT by flow cytometry, ATP by luminescence), while bone marrow-derived macrophages were evaluated for CD80/CD206 (flow cytometry) and TNF-α (ELISA). CT26 tumor-bearing mice received carrier-Pt alone or in combination with anti-PD-1 therapy, and tumor growth was monitored to evaluate therapeutic efficacy.
Results: Carrier-Pt at 4 mg(Pt)/kg significantly inhibited CT26 and PyMT-N tumor growth compared with the untreated group in both immunocompetent and immunodeficient nude mice ($P < 0.0001$). Notably, in immunocompetent mice, 3 out of 10 animals became tumor-free, whereas in immunodeficient nude mice, all tumors continued to grow, although at a slower rate, after carrier-Pt treatment. Carrier-Pt administration significantly increased the infiltration of $CD8^+$ T cells and macrophages in CT26 tumors ($P < 0.05$), with Pt signals predominantly enriched in macrophage and fibroblast populations within TME ($P<0.05$). Notably, carrier-Pt treatment also showed a trend toward increasing the frequency of $CD8^+PD\text{-}1^+$ T cells. M2 macrophages treated with carrier-Pt exhibited a marked upregulation of TNF-α and CD80 ($P < 0.0001$), indicating a shift toward the M1 phenotype. Additionally, CT26 cells exposed to carrier-Pt displayed elevated surface exposure of calreticulin and ATP release ($P < 0.0001$), indicative of ICD. Finally, the combination of carrier-Pt with anti-PD-1 therapy synergistically suppressed CT26 tumor growth compared with either treatment alone.
Conclusion: Carrier-Pt can reprogram the TME by repolarizing immunosuppressive TAMs toward an M1 phenotype and inducing ICD of tumor cells, thereby increasing $CD8^+$ T cell infiltration and enhancing the efficacy of anti-PD-1 immunotherapy. These findings position carrier-Pt as a promising nanotherapeutic to potentiate cancer immunotherapy.

#5851 (Common-light-chain-antibody+nano-body) × multi-matrix-immunization platform facilitates the development of antitumor multispecific antibody drugs.

Yi Gu, Xinde Liu, Peng Li, Feng He, **Feng Hao**, JInying Ning

Kyinno Biotechnology Co., LTD, Beijing, China

Multispecific antibodies represent one of the most advanced and promising therapeutic modalities in contemporary biopharmaceutical development. Among the various design strategies for multispecific antibody assembly, common light-chain(CLC) antibodies and nanobodies offer substantial advantages. They inherently avoid light-chain mispairing, thereby markedly reducing the complexity of subsequent process development. Kyinno's CLC mouse system is protected by global patent rights. Distinct from conventional approaches that introduce only partial heavy-chain germline elements into mice, Kyinno preserves the entire heavy-chain germline repertoire and pairs it with a fixed light-chain germline, which exhibits the highest compatibility with diverse heavy chains. This design minimizes the impact of genetic engineering on sequence diversity within the CLC system. For nanobody discovery, Kyinno operates a parallel system consisting of non-immunized alpaca and a heavy-chain-only mouse, ensuring both low off-target reactivity and high molecular diversity. In addition, Kyinno provides proprietary antigen optimization and immunization strategies that are particularly effective for challenging targets and the development of bispecific monoclonal antibodies. Thus, Kyinno's antibody library and antibody development services offer innovative solutions that overcome the limitations of traditional technologies, thereby accelerating the development of next-generation antibody therapeutics.

#5852 A novel CD33 and TRAIL-R2 targeting bispecific antibody to treat relapsed/refractory acute myeloid leukemia.

Shiva Bhowmik[1], William Brady[2], Kaitlyn Ko[1], Sheng Cai[3], William Grossman[3], Naval Daver[4], Jonathan Gerber[5], Herbert Kim Lyerly[6]

[1]Purdue University, West Lafayette, IN,[2]University of Washington, Seattle, WA,[3]Washington University, St. Louis, MO,[4]Leukemia, UT MD Anderson Cancer Center, Houston, TX,[5]John Hopkins University, Baltimore, MD,[6]Professor, Duke University (Columbus, OH), Durham, NC

Acute myeloid leukemia (AML) remains a challenging disease due to poor survival and high relapse rates as current therapies lack selectivity: cannot eradicate leukemic blasts without causing immune and hematopoietic toxicity, resulting in severe toxicities and low efficacy. Furthermore, current therapies such as hypomethylating agents (HMA) and venetoclax (Ven) fail in patients with TP53 mutations. There is a critical need for therapies that can selectively eliminate leukemic cells while sparing normal hematopoiesis.TRIO-863 is a first-in-class CD33 and TRAIL-R2 targeting bispecific antibody designed to trigger apoptosis selectively in AML blasts through dual engagement of CD33 and TRAIL-R2. By binding CD33 with high affinity and restricting TRAIL-R2 activation to CD33+ cells, TRIO-863 confines apoptotic signaling to leukemic cells minimizing off-target effects. Potency, selectivity, and mechanism of action were evaluated in AML cell lines, including high-risk TP53-mutant and HMA/Ven-refractory patient samples. Safety was assessed ex vivo using human liver microtissue and immune cells.TRIO-863 showed potent CD33-dependent killing of AML cells including high risk TP53-mutant and drug-resistant models, with over 3700-fold greater potency than Mylotarg. It synergized with HMA/Ven and eliminated blasts ex vivo from AML patients who are relapsed/refractory, heavily pre-treated, with unfavorable genetic mutations – including high risk biallelic TP53 mutations. TRIO-863 also exhibited statistically significant and dose-dependent inhibition of TP53-mutant leukemic cell growth in a xenograft model. Anti- leukemic activity of TRIO-863 *in vivo* requires dual engagement of CD33 and TRAIL-R2 suggesting TRIO-863 remains intact *in vivo* as a stable drug. CFU assays with non-leukemic CD34+ progenitors from healthy donors demonstrated TRIO-863 spared normal hematopoietic stem and progenitor cells. In contrast, Mylotarg, a CD33-targeting ADC currently approved for use in fit AML patients, killed non-leukemic hematopoietic progenitor cells. Ex vivo safety studies using primary human liver microtissues showed no liver toxicity by TRIO-863 in contrast to monospecific anti-TRAIL-R2 antibodies that showed high toxicity in the assay. Mechanistic studies confirmed apoptosis depends on dual engagement, overcoming resistance from TP53 inactivation and MCL1 upregulation. CD33 and TRAIL-R2 expression will serve as biomarkers for patient selection; analysis of blasts of AML patients exposed to Ven/HMA and 7+3 confirmed expression of the receptors.TRIO-863 represents a mechanistic breakthrough in AML therapy, selectively inducing apoptosis in malignant myeloid cells while preserving normal hematopoiesis. This approach addresses major limitations of current treatments. Clinical trials are planned for relapsed/refractory AML, including TP53-mutant and drug-resistant cases.

#5853 Bispecific and biparatopic antibodies targeting tumor-specific Tn-glycoepitopes on MUC1 and MUC4 enable broad, selective tumor coverage in epithelial cancers.

Nisha Shrestha, Boris Klebanov, Aaron C. Groen, Constantine Theodoropulos, Hans H. Wandall

GO Therapeutics, Natick, MA

Altered O-glycosylation in epithelial cancers generates tumor-specific Tn-glycoepitopes that are largely absent from normal tissues. Using advanced O-glycoproteomics, we have leveraged these neoepitopes to create a large suite of highly cancer-specific, humanized monoclonal antibodies targeting Tn-glycoepitopes in tumor-associated proteins. Here, we combine select Tn-targeting mAbs to develop two next-generation antibody-drug conjugates (ADCs): Tn-MUC1 biparatopic (M100A×M100B) and MUC1/MUC4 bispecific (M400×M100B) that broaden tumor coverage, increase avidity, while still maintaining the clean target profile with no reactivity to healthy tissue. Both designs were engineered as site-specific ADCs using an mc-vc-PAB-MMAE linker to generate homogeneous DAR2 conjugates. Biophysical analyses confirmed dual-epitope engagement and enhanced binding avidity: M100A×M100B bound two distinct Tn-MUC1 epitopes with sub-nanomolar affinity, mitigating epitope heterogeneity within MUC1, while M400 × M100B simultaneously recognized MUC1-Tn and MUC4-Tn, improving cross-mucin coverage in heterogeneous tumors. Immunohistochemistry demonstrated broad reactivity across breast, lung, ovarian, pancreatic, and gastrointestinal cancers with negligible binding to normal tissue. In vitro, both ADCs exhibited potent cytotoxicity against dual-positive tumor cell lines and sustained activity in mixed A+/B+ heterogeneity models. In vivo, M400 × M100B-vedotin and M100A × M100B-vedotin achieved tumor regressions comparable or superior to combinations of parental ADCs, while maintaining favorable tolerability in preclinical models. These data establish MUC1 and MUC4-targeted bispecific and biparatopic designs as powerful next-generation therapeutics for overcoming tumor heterogeneity and improving selectivity in solid tumors.

#5855 NECTIN4×PD-L1 bispecific antibody-drug conjugate integrating checkpoint blockade and targeted cytotoxicity for urothelial carcinoma and lung squamous cell carcinoma.

Kyoung-Ho Pyo[1], Seong-Hyun Park[1], Dongsop Lee[2], Haneol Kim[2], Younggyu Kong[2], Younggeun Lee[1], Hojin Yeom[1], Sowon Aum[1], Sun Hee Park[1], Huijo Oh[1], Cheyeon Kim[1], Hyeonseok Jin[2], Aera Lee[2], Hojeong Hong[2], Ju Hwan Kim[1], Hyungseok Choi[2], Mi-Kyung Kim[2], Taedong Han[1]

[1]AbTis Co., Ltd, Yongin, Korea, Republic of,[2]Dong-A ST Research Headquarter, Yongin, Korea, Republic of

Background: The first-line approval of enfortumab vedotin plus pembrolizumab validates the clinical rationale for combining ADCs with ICIs. However, administering two separate agents poses challenges in cost, compliance, toxicity management, and in achieving comprehensive coverage of target and immune heterogeneity. To address these limitations, we engineered a NECTIN4×PD-L1 bispecific ADC using Dong-A ST BsAb platform with an enhanced knob-into-hole (eKiH) interface that integrates NECTIN4-directed cytotoxic delivery with PD-L1 axis blockade in a single molecule. The molecule was designed to overcome resistance and spatial heterogeneity in locally advanced/metastatic urothelial carcinoma (la/mUC) and LUSC.
Methods: High-affinity NECTIN4 and PD-L1 antibody leads were identified and assembled into Dong-A ST BsAb platform. Site-selective conjugation was applied to generate ADCs bearing MMAE, exatecan, or dual-payload configurations. Functional characterization included: (i) binding affinity and competition to both targets, (ii) internalization and payload release in NECTIN4-positive cells, and (iii) PD-1/PD-L1 reporter assays and T-cell co-culture cytotoxicity. To support clinical translation, scRNA-seq and tissue microarray-based mIHC were performed on bladder cancer and LUSC cohorts to evaluate NECTIN4/PD-L1 co-expression, spatial heterogeneity, and correlations with immune infiltration and checkpoint pathways.
Results: scRNA-seq revealed intra-patient coexistence of NECTIN4-only, PD-L1-only, and co-expressing tumor subpopulations, with notable inter-patient variability. Multiplex IHC confirmed mosaic and cluster-type spatial heterogeneity. The bispecific ADC maintained high-affinity binding to both targets, exhibited efficient internalization and payload release in NECTIN4-positive cells, and preserved potent PD-1/PD-L1 blockade activity in reporter assays. ADCs carrying MMAE, exatecan, or dual payloads demonstrated consistent in vitro cytotoxicity across NECTIN4-high, PD-L1-high, and co-expressing tumor models, along with enhanced T cell-mediated tumor killing in co-culture. Preliminary in vivo studies showed dose-dependent tumor growth inhibition in bladder cancer and LUSC xenograft models with acceptable tolerability (detailed results pending final analysis).
Conclusions: This NECTIN4×PD-L1 bispecific ADC integrates targeted cytotoxicity (NECTIN4) and checkpoint blockade (PD-L1) into a single therapeutic agent, rationally designed to provide catch-all activity against target and immune microenvironment heterogeneity in la/mUC and LUSC. The preclinical data support evaluation as an early-line therapeutic strategy that could complement or substitute separate ADC+ICI combinations.

#5856 Hanjugator camptothecin platform: Effective, low-toxicity design maximizing antibody functionality and delivering potential best-in-class EGFR/cMet bispecific antibody-drug conjugate.

Rui Liu, Ge Song, Yushi Chi, Lingli Zhang, Fan Yang, Junjie Zhang, Boqi Gu, Chencheng Han, Xiayan Zhang, Wan-jen Yang, Xiaomu Cheng, Xiaoling Yuan, Yi Zhang, Zhiliang Lv, Qian Zou, Huixin Yan, Chen Hu, Jijun Yuan

Shanghai Henlius Biotech, Inc., Shanghai, China

Introduction: High toxin potency in antibody-drug conjugates (ADCs) limits clinical doses to those below optimal antibody levels, diminishing signal blockade potential and emphasizing chemotherapeutic effects. To address this limitation, we developed Hanjugator, a customizable, modular camptothecin-based linker-payload platform with tunable potency—from threefold lower than deruxtecan to comparable with exatecan—enabling a broader therapeutic window and preserving antibody functionality. We applied medium-potency payload to an EGFR/cMet bispecific ADC, a target combination known to require higher clinical doses for optimal receptor occupancy and efficacy.

Methods: Cytotoxicity of toxin candidates and ADCs was assessed via CellTiter-Glo (CTG) assay in immortalized cell lines. ADC binding and internalization were evaluated by flow cytometry on cells with varying antigen expression levels. Pharmacokinetics (PK) of LPA003-based ADC were determined in rats following single intravenous 5 mg/kg dosing. Bystander killing was quantified by co-incubating antigen-positive and -negative (Jurkat) cells, with Jurkat viability measured via CTG assay. *In vivo* efficacy of EGFR/cMet-LPA003 was tested in multiple xenograft models (LU387, SW48, HT29, NCI-H1975). For preliminary toxicology, cynomolgus monkeys were treated with three doses of 30 or 60 mg/kg of the test article, administered every three weeks (Q3W).

Results: The Hanjugator platform delivers a series of highly hydrophilic linker-payloads with excellent compatibility for non-standard, hydrophobic antibodies and superior thermal, plasma, and freeze-thaw stability. These conjugates exhibit bystander killing over 10-fold stronger compared with deruxtecan and outperform multiple clinical-stage linker-payload systems in efficacy studies, despite some competitors' higher intrinsic payload potency. The platform's wide toxin potency range broadens its applications. Medium-potency LPA003, conjugated to EGFR/cMet bispecific antibody, induced significant tumor regression at single 3 mg/kg doses in various xenograft models, outperforming AZD9592 in the HT29 CDX model. Preliminary toxicology shows EGFR/cMet-LPA003 is well tolerated in cynomolgus monkeys after 3 doses at 60 mg/kg Q3W.

Conclusion: We have developed Hanjugator, a versatile camptothecin-based linker-payload platform with tunable toxin potency. This modular design accommodates diverse targets and ADC programs, optimizing dosing regimens and broadening clinical applications. The LPA003-conjugated EGFR/cMet bispecific ADC exhibits a superior therapeutic index, maximizing antibody-mediated signaling blockade, and positions as best-in-class molecule with Investigational New Drug submission anticipated in Q1 2026.

#5857 LBL-054 TDC: A first-in-class CDH17 targeted T cell engager drug conjugate for the treatment of CDH17-positive gastrointestinal cancer.

Yang Ye, Yurong Qin, Xingxing Fang, Xiaoya Liu, Tingting Li, Chengze Ni, Peng Zhang, Chao Chu, Mi Ye, Huan Lin, Wanting Wang, Guojin Wu, Jianming Sun, Hui Yuwen, Yuanzhi Lv, Jing Guan, Min Chen, Yue Zhao, Jordan Zhu, Charles Cai, **Xiao Huang**, Xiaoqiang Kang, Hong Ling

Leads Biolabs Co., Ltd., Nanjing, China

Background: CDH17 is a member of the cadherin superfamily. In normal tissues, CDH17 is highly restricted to the lateral membrane and concealed within intestinal tight junctions, making it inaccessible to immune cell infiltration. In contrast, it is overexpressed and redistributed in 50% to 90% of gastrointestinal cancers, leading to its exposure on the cancer cell surface, therefore becoming more accessible. This unique feature makes CDH17 a promising target for T cell engagers or antibody-drug conjugates for GI cancer. Here, we have developed a novel T cell engager drug conjugate, LBL-054 TDC, targeting CDH17 and CD3 conjugated via our proprietary TOPiKinectics^{TM} linker-payload platform.

Methods: The binding and internalization activity of LBL-054 TDC to CDH17-expressing tumor cell lines and CD3+ T cells were assessed by flow cytometry. Cytotoxicity of LBL-054 TDC against tumor cells and T cells were assessed using Cell Counting-Lite Luminescent Cell Viability Assay kit. Cytotoxicity of LBL-054 TDC against tumor cell lines with varying endogenous expression levels of CDH17 were both evaluated in absence of T cells and in T cell dependent cellular cytotoxicity (TDCC) assay system. Bystander killing of LBL-054 TDC was performed in TDCC system by flow cytometry. The anti-tumor activity of LBL-054 TDC was evaluated in human CD3 transgenic mice bearing MC38/hCDH17 syngeneic model. The safety profile of LBL-054 TDC was evaluated in a cynomolgus monkey dose-range finding (DRF) study.

Results: LBL-054 TDC showed potent binding and internalization on tumor cells, but weak binding and no internalization on T cells. It demonstrated potent cytotoxicity against tumor cells, while has no cytotoxicity to naïve T cells. In TDCC assays, LBL-054 TDC induced potent cytotoxicity under various E:T ratios and CDH17 expression levels, along with lower cytokine release compared to conventional TCE. LBL-054 TDC also mediated potent bystander killing of CDH17^{neg} tumor cells while sparing T cells. In the MC38/hCDH17 syngeneic mouse model, LBL-054 TDC showed stronger anti-tumor effect than TCE and ADC. In a 4-week cynomolgus DRF study, LBL-054 TDC was well tolerated following repeated intravenous infusion.

Conclusions: Our results demonstrate that LBL-054 TDC combines the potent, direct killing of an ADC with the T-cell redirecting activity of a TCE both *in vitro* and *in vivo* while posing a lower cytokine release than a conventional TCE. It also exhibited good safety profiles in cynomolgus monkeys. Overall, LBL-054 TDC holds promise for treating gastrointestinal cancers with varying T-cell infiltration and CDH17 expression, potentially benefiting a broad patient population.

#5858 SCR-M030, an innovative and potential first-in-class trispecific T cell engager targeting PSMA and STEAP1 for mCRPC.

Changyan Chen, Yayuan Fu, Shumei You, Meijuan Gao, Kun Wang, Yi kuang, Chuanchuan Lu, Renhong Tang

State Key Laboratory of Neurology and Oncology Drug Development. Simcere Zaiming Pharmaceutical Co, Ltd., Shanghai, China

Metastatic castration-resistant prostate cancer (mCRPC) represents a highly aggressive and incurable disease, with limited therapeutic options and a dismal prognosis. Among the most promising molecular targets, prostate-specific membrane antigen (PSMA) and six-transmembrane epithelial antigen of the prostate 1 (STEAP1) are both markedly overexpressed in mCRPC, and their expression levels correlate positively with tumor aggressiveness and resistance to androgen-deprivation therapy. Notably, PSMA exhibits significant inter- and intratumoral heterogeneity, a factor that may underlie the heterogeneous clinical responses observed with PSMA-directed agents. In contrast, STEAP1 demonstrates a more uniform distribution across malignant cells, and its expression pattern partially complements that of PSMA in a subset of patients. Leveraging the complementary expression of STEAP1 and PSMA, we generated a first-in-class trispecific T-cell engager (TCE), SCR-M030, that concomitantly binds STEAP1 with high affinity, PSMA with moderate affinity, and CD3 with deliberately attenuated affinity. This avidity-optimized architecture drives preferential docking to double-positive tumor cells, conferring a marked binding advantage over single-target engagement. Functionally, SCR-M030 outperformed PSMA-CD3 and STEAP1-CD3 bispecific controls in vitro, eliciting superior lysis of medium-to-low antigen-expressing tumor cells while releasing minimal cytokines in target-negative conditions, forecasting a reduced risk of CRS. In PBMC-reconstituted prostate cancer xenograft mouse models, SCR-M030 demonstrated specific, dose-dependent antitumor activity. Notably, in the 22RV1 model, SCR-M030 exhibited more potent tumor suppression than the AMG509 analog. Finally, rat pharmacokinetic profiling revealed a long plasma half-life and full compatibility with both intravenous and subcutaneous dosing routes, supporting flexible clinical administration. In conclusion, the novel trispecific TCE SCR-M030 is a strategically designed therapy that demonstrates potent efficacy against challenging low-expression tumors by simultaneously targeting PSMA and STEAP1 with differential affinity. Its robust in vivo performance, favorable pharmacokinetics, and superiority over a relevant comparator underscore its strong potential as a next-generation therapeutic for prostate cancer.

#5859 Novel T cell engager targeting CD3 and CDH17 for the treatment of solid tumors.

Mingkun Zhang[1], Yuqiang Xu[1], Jun Wang[2], Jing Zhao[1]

[1]NeoMab Biotechnology Co,. Ltd, Suzhou, China,[2]GemPharmatech LLC., San Diego, CA

Background: Despite the success of T-cell engagers (TCEs) in hematologic cancers, their translation to solid tumors has been limited by key obstacles such as the immunosuppressive tumor microenvironment, inefficient T-cell trafficking, and antigen heterogeneity. The pursuit of suitable target antigens is therefore critical. Cadherin-17 (CDH17), which is highly expressed in many gastrointestinal malignancies but shows limited normal tissue expression, offers a compelling opportunity for next-generation TCE therapy.
Methods: A novel, bispecific T-cell engager (TCE) was engineered for concurrent binding to CD3 and cadherin-17 (CDH17). Its cytotoxic potency was quantified against a panel of CDH17-positive human cancer cell lines in co-culture assays with healthy donor peripheral blood mononuclear cells (PBMCs). T-cell activation (CD69+/CD25+ upregulation) and cytokine secretion were profiled by flow cytometry and immunoassay, respectively. In vivo antitumor efficacy was evaluated in immunodeficient mice bearing CDH17-positive gastric cancer cell-derived xenografts (CDX).
Results: The CDH17xCD3 T cell engager exhibited high-affinity binding to CDH17, coupled with a modulated affinity for CD3. *In vitro*, the molecule induced potent and specific lysis of CDH17-positive tumor cells in a dose-dependent manner, while sparing CDH17-negative controls. This targeted cytotoxicity was accompanied by a reduced cytokine release profile compared to a conventional CD3-engaging benchmark, *In vivo*, our TCE treatment led to enhanced tumor growth inhibition and marked regression in CDH17-high CDX models, with no significant systemic toxicity observed at efficacious doses.
Conclusion: The novel CDH17xCD3 bispecific T-cell engager exhibits potent and targeted anti-tumor activity, supporting its translational potential as an immunotherapeutic agent for CDH17-positive solid tumors. The favorable efficacy and safety profile observed warrants further clinical investigation.

: Tyrosine Kinase, Phosphatase, and Other Inhibitors
Poster Session

#5863 Enhanced antitumor activity of zipalertinib and amivantamab combination in EGFR mutant NSCLC models.

Kohei Hayashi, Yoshimi Aoyagi, Akihiro Hashimoto, Tomoaki Hitotsumachi, Shuichi Ohkubo

Taiho Pharmaceutical Co., Ltd., Tsukuba, Japan

Zipalertinib is a selective epidermal growth factor receptor (EGFR) tyrosine kinase inhibitor (TKI) that targets mutations in exon 20 insertions (ex20ins) and has demonstrated clinical efficacy in patients with EGFR ex20ins-positive non-small cell lung cancer (NSCLC), including those previously treated with amivantamab and chemotherapy. Currently, amivantamab plus platinum-based chemotherapy is the standard first-line treatment for NSCLC harboring EGFR ex20ins. However, efficacy of EGFR-TKIs combined with amivantamab in EGFR ex20ins positive patient remains unclear. In this preclinical study, we aimed to investigate the therapeutic potential of zipalertinib and amivantamab combination therapy.
EGFR mutant cell lines NCI-H1975, H1975insSVD (EGFR D770_N771insSVD), II-18 (EGFR L858R), and HCC827OR8 (EGFR del19 with MET amplification) were used for in vitro and in vivo experiments. The binding of amivantamab to the cell surface was quantified in the presence or absence of zipalertinib. An antibody-dependent cellular cytotoxicity (ADCC) assay was conducted using H1975insSVD cells cocultured with peripheral blood mononuclear cells (PBMCs) to assess amivantamab-mediated cytotoxicity with or without zipalertinib treatment. In vivo antitumor efficacy was evaluated using human cell-derived xenograft (CDX) mouse models, and tumor volumes were analyzed for statistical significance using the Aspin-Welch's t-test.
Zipalertinib treatment increased EGFR protein expression and enhanced amivantamab binding to the cell surface. Amivantamab induced ADCC in H1975insSVD cells cocultured with PBMCs, and zipalertinib co-treatment further potentiated this cytotoxicity. Additionally, compared to zipalertinib monotherapy, the combination of zipalertinib and amivantamab exhibited significant antitumor efficacy ($p < 0.05$) across all three CDX models, without notable changes in body weight. Complete tumor regression was observed in the H1975insSVD CDX model.
Zipalertinib upregulates EGFR protein expression and enhances amivantamab binding to the cell surface. These results provide mechanistic insights into the observed combinatorial efficacy of zipalertinib and amivantamab, both in vitro and in vivo. Further, our findings support the therapeutic potential of zipalertinib and amivantamab in EGFR-mutant NSCLC and further clinical investigations.

#5864 Taletrectinib, a next generation selective ROS1 inhibitor, demonstrates a differentiated profile in ROS1 fusion models.

Hitisha Patel, Laura Heller, Kevin Bowman, Zheyi Hu, Irma M. Grossi, Max Pan, Gary Hattersley

Nuvation Bio Inc., New York, NY

ROS1 fusions, present in approximately 2% of non-small cell lung cancer (NSCLC) patients, drive cancer cell growth and survival. FDA-approved tyrosine kinase inhibitors (TKI) for ROS1 fusion positive NSCLC include crizotinib, entrectinib, repotrectinib, and more recently, taletrectinib. However, resistance mechanisms such as secondary kinase-domain mutations (e.g., ROS1-G2032R) limit the efficacy of crizotinib and entrectinib, while repotrectinib can cause central nervous system (CNS) adverse reactions including dizziness, ataxia and cognitive impairment, attributed to the inhibition of tropomyosin receptor kinase B, TRKB. Taletrectinib is a potent, CNS-active, selective, next-generation ROS1 inhibitor for the treatment of patients with locally advanced or metastatic ROS1-positive NSCLC. Taletrectinib is currently approved by the US FDA and is also approved in China and Japan. As of Jun 7, 2024, pooled results from the TRUST-I and TRUST-II studies of taletrectinib demonstrated a confirmed objective response rate (cORR) of 88.8%, an intracranial cORR of 76.5%, a median duration of response (mDOR) of 44.2 months and a median progression free survival (mPFS) of 45.6 months in patients with advanced ROS1-positive NSCLC that have not previously received a ROS1 TKI. Durable responses were also reported in patients who had previously been treated with a TKI (Pérol M, et al. *J Clin Oncol*. 2025). Herein, we describe taletrectinib and its differentiated profile in comparison to other approved ROS1 inhibitors. At clinically relevant concentrations, taletrectinib demonstrated complete inhibition of ROS1 wild type and ROS1 G2032R in vitro and inhibited the growth of cell lines harboring single and double mutations in ROS1. Mechanistic studies revealed that taletrectinib inhibited the expression of key markers associated with the epithelial to mesenchymal transition (EMT) pathway and inhibited the migration of lung cancer cells indicating that taletrectinib could potentially inhibit the invasive capacity of lung cancer cells. Taletrectinib treatment also induced tumor regressions in several *in vivo* ROS1 fusion models, regardless of the fusion partner. In summary, our nonclinical data demonstrate that, at clinically relevant concentrations, taletrectinib exhibits activity in ROS1 wild-type and mutant-driven cancers and has a distinct profile that addresses the unmet needs of ROS1-positive NSCLC patients.

#5865 Developing COUPLrs, dual-warhead cysteine-reactive compounds, to target oncoproteins through interaction modulation and degradation.

Diane Yang[1], Stefan Andrew Harry[2], Harrison Byron Chong[2], Edwin Zhang[1], Natalie Shannon Nordenfelt[1], Stefan Kaluziak[1], Elizabeth Codd[1], Nicholas Chen[2], Samay Trivedi[2], Wenxin Yang[1], Abigail Elizabeth Smith[2], Alexander Daniel Carlin[2], Dawn R. Mitchell[1], Neha Khandelwal[2], Brian B. Liau[3], Liron Bar-Peled[2], A. John Iafrate[1]

[1]Department of Pathology, Massachusetts General Hospital, Boston, MA,[2]Krantz Family Center for Cancer Research, Massachusetts General Hospital,, Boston, MA,[3]Harvard University, Cambridge, MA

COUPLrs (COvalent Protein Ligators) are cysteine-reactive small molecules designed to dimerize or disrupt protein complexes, thereby modulating protein function. In our previous work, we identified COUPLrs that bind to the oncogenic fusion protein EML4-ALK in non-small cell lung cancer (NSCLC) cells. These compounds engaged the EML4 rather than the ALK kinase domain targeted by clinical inhibitors. This unconventional binding disrupted ALK signaling and induced proteasome-dependent degradation of the fusion protein, establishing proof of concept that COUPLrs can engage two protein partners simultaneously, altering their interactions and stability. These findings define COUPLrs as a new mechanistic class of molecules capable of bridging or disrupting protein complexes and driving selective degradation, offering opportunities to target proteins lacking conventional binding pockets.To systematically characterize COUPLrs' targets and interaction networks, we employed a two-pronged workflow combining Cysteine Druggability Mapping to identify reactive and accessible cysteine residues across oncogenic proteins, while SDS-PAGE and fractionation assays monitored changes in molecular weight, revealing COUPLr-involved protein complex formation. We synthesized a 32-member library of cysteine-reactive compounds with diverse scaffolds, warheads, and reactivities. Library characterization revealed proteome-wide COUPLr targets, including inter- and intramolecular protein coupling.To expand this analysis, we conducted a proteomic screen across 13 cancer cell lines representing diverse tissue origins, generating a comprehensive atlas of COUPLrs-targetable proteins. This screen revealed both shared and lineage-specific targets, including several proteins previously considered undruggable, such as transcription factors. Notably, some protein showed mutation-specific engagement by COUPLrs, suggesting potential to selectively target oncogenic variants resistant to existing therapies.Collectively, our work establishes COUPLrs as powerful tools for modulating protein-protein interactions. By integrating covalent chemistry with proteomic profiling, we delineated protein interactions stabilized or disrupted by COUPLrs. These findings open new avenues for therapeutic development against previously inaccessible targets in cancer biology.

#5866 Preclinical combination approaches with the pan-KRAS inhibitor AMG 410 in *KRAS*-mutant cancers.

Ying-Chu Chen[1], Tao Osgood[1], Kevin Gaida[1], Gilbert Diaz[1], Chun Su[2], Elissa Swearingen[2], Daniel Lu[2], Deanna Mohn[1], Anne Y. Saiki[1], Monica Leavitt[1], Upendra P. Dahal[2], Ryan P. Wurz[1], Brian A. Lanman[1], Jason DeVoss[2], Karen Rex[1], Paul E. Hughes[1], Rati Verma[1]

[1]Amgen, Thousand Oaks, CA,[2]Amgen, South San Francisco, CA

KRAS is the most frequently mutated oncogene in solid tumors. Covalent KRAS G12C-selective inhibitors have been approved for G12C-mutant non-small cell lung cancer (NSCLC). Despite their clinical success, the durability of response and emergence of resistance have tempered the efficacy of KRAS-targeted therapies, leading to the exploration of combination strategies to enhance clinical outcomes. AMG 410, currently in Phase 1, is a reversible pan-KRAS inhibitor capable of targeting KRAS mutants (e.g., G12D, G12V, and G12C) and wild-type amplification. These altered *KRAS* alleles are prevalent in multiple solid tumor indications, particularly colorectal cancer (CRC), pancreatic ductal adenocarcinoma (PDAC), and NSCLC. Preclinically, AMG 410 demonstrated significant tumor growth inhibition as a single agent in multiple cell line-derived xenograft (CDX) and patient-derived xenograft (PDX) models. Guided by reverse translation findings from the G12C-selective inhibitor sotorasib, we evaluated AMG 410 combination approaches in preclinical models to proactively mitigate potential primary and acquired resistance mechanisms. A large panel of diverse *KRAS*-mutant cancer cell lines representing three indications (NSCLC, CRC, and PDAC) was screened in combination with inhibitors of the RAS signaling pathway, DNA damage repair pathways, cell cycle regulators, and select chemotherapy agents. Robust synergistic effects on cell viability were observed with pan-HER kinase and PI3K/mTOR inhibitors. To further explore resistance mechanisms, an AMG 410-anchored genome-wide CRISPR screen was performed. The Hippo pathway and *YAP1* were identified as key modifiers of response to KRAS inhibition. Co-treatment with YAP/TEAD inhibitors demonstrated strong synergy in multiple *KRAS*-mutant cell lines. To assess whether these observations translated to improved efficacy in vivo, rational combinations were evaluated in tumor xenograft models. Consistent with the in vitro synergy observed with pan-HER inhibition, the combination of AMG 410 with panitumumab resulted in tumor regression in a CRC PDX model. Additionally, enhanced anti-tumor activity was observed when AMG 410 was combined with chemotherapy agents in CRC and PDAC xenografts. Building on the potential benefit of clinical KRAS G12C immune-oncology combinations, treatment with AMG 410 and PD-1 blockade in a *KRAS* G12D syngeneic CRC model led to tumor regression and significantly enhanced survival. Finally, co-treatment with a TEAD inhibitor enhanced durability of response to AMG 410 in vivo. Taken together, these findings support the clinical investigation of AMG 410 combination strategies to extend the therapeutic benefit of KRAS inhibition across diverse *KRAS*-mutant cancers.

#5867 IN10028, a next-generation FAK inhibitor discovered for the treatment of solid tumors.

Baoyuan Zhang[1], Hao Wang[2], Jiaming Gao[1], Fengmin Xi[1], Liyuan Liu[1], Leo Liu[1], Zaiqi Wang[1]

[1]Inxmed (Shanghai) Co., Ltd, Shanghai, China,[2]Pharmablock Sciences (Nanjing), Inc, Nanjing, China

The development of small-molecule inhibitors targeting Focal Adhesion Kinase (FAK) has been ongoing for several decades. In May 2025, the FDA approved a combination therapy involving FAK and MEK/RAF inhibitors for the treatment of low-grade serous ovarian cancer, marking a significant advancement in FAK-targeted therapies. In this study, we present IN10028, a second-generation FAK inhibitor that demonstrates enhanced efficacy in combination therapies and favorable safety profiles. IN10028 effectively targets both FAK1 and FAK2, exhibiting IC50 values of 0.2 nM and 60.1 nM, respectively, and significantly inhibits FAK-related signaling pathways. Compared to IN10018, a first-generation FAK inhibitor, IN10028 shows superior cancer cell cytotoxicity. Notably, IN10028 also demonstrates stronger target engagement than several first-generation FAK inhibitors. Through experiments conducted in animal models, IN10028 was evaluated in both monotherapy and combination therapy settings, consistently outperforming multiple first-generation FAK inhibitors in terms of tumor growth inhibition. Additionally, pharmacokinetic and toxicity studies necessary for Investigational New Drug (IND) filing have been completed, with the IND application anticipated in December 2025.

#5868 Proteomic analysis and efficacy evaluation reveal strong synergistic anti-leukemic activity of lasmotinib combined with menin inhibitors for AML.

An-Na Moon, Hee-sun Hwang, **Ky-Youb Nam**, KyungMin Cha, Sang Beom Lee, ChongChul Chai, Jinsun Kwon, Kyu-Tae Kim, June H. Han, Jeong Hyeok Yoon

Pharos iBio Co., Ltd., Anyang, Korea, Republic of

Acute myeloid leukemia (AML) is a genetically heterogeneous hematologic malignancy. The interaction between menin (*MEN1*) and mixed lineage leukemia 1 (*MLL1*, also known as *KMT2A*) is a critical dependency for KMT2A-rearranged (*KMT2A*-r*)* or nucleophosmin 1 (*NPM1*)-mutant AML, providing a strong rationale for therapeutic targeting. Here, we evaluated a novel combination strategy using lasmotinib (PHI-101), a clinical-stage FLT3 inhibitor, together with menin inhibitors that disrupt the menin-MLL interaction. To investigate synergy in leukemic cells harboring *FLT3*-Internal Tandem Duplication (ITD) mutation and *KMT2A*-r, MV4-11 and MOLM-13 cells were co-treated with lasmotinib and multiple clinical-stage menin inhibitors. Cell viability was assessed using the CellTiter-Glo assay, and the drug interaction profiles were quantified with SynergyFinder. Mechanistic studies of the lasmotinib-bleximenib combination in MV4-11 cells were conducted by Astral-based global proteomics, immunoblotting, and flow cytometry. *In vivo* efficacy of the combination was assessed using a mouse xenograft model of AML. The single-agent treatment with lasmotinib potently suppressed the growth of three AML cells (MV4-11, MOLM-13, and MOLM-14) bearing *FLT3*-ITD mutations, with IC_{50} values from 0.5 nM to 3 nM. Among five menin inhibitors, bleximenib induced strong cytotoxicity against three *KMT2A*-r AML cells, including MV4-11, MOLM-13, and MOLM-14, with IC_{50} values from 3 nM to 23 nM. After the drug combination, lasmotinib enhanced and accelerated the anti-leukemic effects of menin inhibitor bleximenib in both MV4-11 and MOLM-13 cells. SynergyFinder analysis demonstrated strong synergism across multiple menin inhibitors, with high synergy scores (>20) even at low drug concentrations. Global proteomics revealed that the lasmotinib-bleximenib combination substantially reduced expression of key AML oncogenic proteins including MEIS1, FLT3 and c-Myc. Immunoblotting confirmed complete suppression of downstream signaling pathways including p-FLT3, p-STAT5, p-AKT, and p-ERK, while Annexin V/PI flow cytometry analysis showed profoundly increased apoptosis. *In vivo*, combined lasmotinib and bleximenib treatment resulted in markedly synergistic anti-tumor effects. In conclusion, lasmotinib is identified as a highly promising combination partner for menin inhibitors in AML. The strong synergism observed, both in vitro and in vivo, supports further development of lasmotinib plus bleximenib as a compelling therapeutic strategy for *KMT2A-r* and FLT3 mutant leukemia.

#5869 Preclinical characterization of CGT4255, an EGFR sparing, pan-mutant HER2 clinical development candidate with potential best-in-class brain penetration.

Paul Larsen, Tanna Bettendorf, Abiezer Blandon, Karyn Bouhana, Richard K. Brizendine, Eric Brown, LouAnn Cable, Mark J. Chicarelli, Michelle Crow, Brad Fell, John Fischer, Jennifer Fulton, Anna Guarnieri, Jackie Harrison, Leyla Haygood, Ravi Jalluri, Vijay Kumar, Cori A. Malinky, Maralee McVean, Rob Rieger, John Robinson, Lee Stunkard, Francis Sullivan, John I. Trujillo, Logan E. Vine, Shannon Winski, Yeyun Zhou

Cogent Biosciences, Inc, Boulder, CO

HER2 alterations including amplification, overexpression, insertions, and point mutations are established oncogenic drivers across various solid tumor types. HER2 is amplified or overexpressed in 15-20% of breast cancer patients. In contrast, activating mutations are found in approximately 4% of cases with the L755S mutation commonly associated with drug resistance. Up to 50% of patients with HER2+ metastatic breast cancer may develop brain metastasis over the course of the disease, highlighting a critical need for brain penetrant HER2-directed therapies. In lung cancer, activating HER2 mutations occur in 2-4% of advanced cases and are linked to increased incidence of brain metastasis. The risk is especially high in patients whose tumors harbor an exon 20 YVMA insertion. Treating brain metastasis in this group of patients remains a clinical challenge, as most therapeutic options have limited CNS penetration. Herein, we describe the advanced preclinical profiling of CGT4255, an investigational drug targeting mutant and wild type HER2, which spares EGFR and demonstrates potential best-in-class brain penetrance. CGT4255 shows potent activity against commonly occurring point mutations such as L755S and exon 20 YVMA insertions. In vitro assays confirmed that CGT4255 is not a substrate of the P-gp or BCRP efflux transporters at the blood-brain barrier. In vivo pharmacokinetic studies with CGT4255 in mice and monkeys showed high drug levels in the CNS, predicting high human brain exposure. CGT4255 demonstrated robust efficacy in HER2 overexpressed and HER2 YVMA intracranial models. The CGT4255 and T-DXd combination demonstrated enhancement of ADC internalization, thus highlighting a biological rationale for combination therapy. In HER2-overexpressed, L755S, YVMA, and T-DXd resistant subcutaneous xenografts, CGT4255 demonstrated dose dependent TGI with tumor regressions observed at dose levels as low as 30 mg/kg.

#5870 Momelotinib: Unique polypharmacology and novel combination strategies for myelofibrosis and beyond.

Shane O'Brien[1], Shannon McKearnan[1], Ashley Lento[1], Jeffrey Guss[1], Anna Waszkiewicz[1], Bin Wu[1], Allison Hartman[1], Matthew Powell[1], Gabriella Cifelli[1], Maggie Connelly[1], Hoang Tran[1], Bryan Strouse[1], Dwaipayan Patnaik[2], Mary Antonysamy[1], Anthony Mazurek[1], Michael T. McCabe[1]

[1]GSK, Collegeville, PA,[2]GSK, Baar Onyx, Switzerland

Momelotinib (Ojjaara / Omjjara) is a clinically differentiated JAK inhibitor that improves key manifestations of myelofibrosis (MF), including anemia, splenomegaly, and constitutional symptoms. Its efficacy stems from dual inhibition of JAK1/JAK2, addressing pro-inflammatory signaling, and targeting Activin A Receptor Type I (ACVR1/ALK2), which alleviates anemia by suppressing hepcidin expression, increasing iron bioavailability, and improving red blood cell production. Herein, we report comprehensive profiling of momelotinib's kinome selectivity revealing a distinctive polypharmacology beyond ACVR1 that includes inhibition of rho-associated kinases (ROCK1/ROCK2), inhibitor of NF-κB kinases (IKKs), and interleukin-1 receptor-associated kinase 1 (IRAK1). Cellular reporter assays demonstrated that this unique profile enables momelotinib to inhibit NF-kB activity stimulated by either canonical or non-canonical pro-inflammatory cytokines. These findings establish a strong rationale for momelotinib's therapeutic potential beyond MF in pro-inflammatory conditions, such as Vacuoles E1 X-chromosome Autoinflammatory Somatic (VEXAS) syndrome, low-risk myelodysplastic syndrome (LR-MDS), and graft-versus-host disease (GvHD), where these pathways are significantly dysregulated and medical need remains high. Additionally, recognizing momelotinib's differentiated clinical benefit and well-characterized safety profile, drug combination screening was performed to identify combination partners that cooperate with momelotinib to further improve MF patient outcomes. Specifically, two high-throughput drug screens targeting malignant cell viability in $JAK2^{V617F}$ or MPL^{W515L} MF models and hepcidin suppression in a BMP6-stimulated liver cell line were conducted with over 650 small molecules in late-stage clinical development. The viability screen identified inhibitors of signaling pathways that function in parallel to JAK-STAT as promising combination partners to reduce the viability of malignant MF cells. The hepcidin screen identified inhibitors that cooperated with momelotinib to additively suppress hepcidin expression. Notably, the XPO1 inhibitor selinexor emerged as a combination partner that both inhibited malignant cell growth and deepened hepcidin suppression. These discoveries highlight momelotinib's unique activity, both as a monotherapy for expanded indications and as an ideal combination partner to more effectively control anemia and halt disease progression in MF patients.

#5871 Discovery and characterization of firmonertinib, a novel EGFR inhibitor with broad activity against both EGFR classical and exon 20 insertion mutations.

Huibing Luo[1], Qing Li[1], Qiufeng Liu[1], Huayong Zhou[1], Yuting Sun[1], Jerry Y. Hsu[2], Luna Musib[2], Marcin Kowanetz[2], Stuart Lutzker[2], **Zineb Mounir**[2]

[1]Allist Pharmaceuticals, Shanghai, China,[2]ArriVent Biopharma, Burlingame, CA

Background: Lung cancers harboring classical *EGFR* mutations are sensitive to approved EGFR tyrosine kinase inhibitors (TKIs) while those harboring *EGFR* exon 20 insertion mutations (ex20ins) show minimal sensitivity to approved EGFR TKIs and have limited treatment options. Firmonertinib is an investigational novel orally bioavailable and highly brain-penetrant irreversible EGFR TKI targeting classical and uncommon *EGFR* mutations including ex20ins. Firmonertinib received FDA Breakthrough Therapy Designation for first-line treatment of patients with advanced NSCLC with *EGFR* ex20ins mutations, and has now completed enrollment in a global phase 3 trial in these patients (NCT05607550). Here, we describe the structural and preclinical findings supporting the binding potency and anti-tumor activity of firmonertinib in *EGFR* ex20ins mutations.

Methods & Results: Using high resolution crystal structures, we uncover a unique structural attribute that differentiates firmonertinib from other EGFR TKIs and that provides firmonertinib with superior binding to mutant EGFR proteins including those harboring ex20ins. Our biochemical and cellular assay findings are in line with the structural observations and demonstrate that firmonertinib is a potent and mutant selective EGFR inhibitor. In a large cell line panel evaluating *EGFR* ex20ins mutations within different regions of exon 20 (far and near loop, helical domain), all ex20ins mutations evaluated demonstrated a high sensitivity profile to firmonertinib compared to other EGFR TKIs. In addition, firmonertinib was equally highly potent against far and near loop insertion mutations which is a differentiating characteristic from some EGFR TKIs previously tested in the clinic (Elamin et al. 2022). In animal models, our findings demonstrate that firmonertinib is a highly potent inhibitor of cell proliferation in tumors harboring both near and far loop *EGFR* ex20ins mutations.

Conclusions: Findings from this study support the structural mechanism of EGFR binding and inhibition by firmonertinib, eliciting strong anti-tumor activity in multiple *in vitro* and *in vivo* models harboring *EGFR* ex20ins mutations. These findings provide scientific support for the ongoing global Phase 3 study for first-line NSCLC patients with *EGFR* ex20ins mutations (NCT05607550).

#5872 CLK inhibitor BH-30236 synergizes with venetoclax in anti-leukemia activity via splicing modulation in preclinical AML and CLL models.

Wei Deng, Ping Jiang, Zhenping Wang, Yue Hu, Nancy Ling, Danan Li, Joshua Choi, Eugene Y. Rui, Zachary Zimmerman, Geoffrey Oxnard, J. Jean Cui

BlossomHill Therapeutics, Inc., San Diego, CA

Alterations of splicing patterns are increasingly recognized as a hallmark of cancer by promoting proliferation, evading apoptosis, changing cell signaling, and driving drug resistance through aberrantly spliced isoforms. In hematologic malignancies of both myeloid and lymphoid lineages, including myelodysplastic syndromes (MDS), acute myeloid leukemia (AML), and chronic lymphocytic leukemia (CLL), frequent mutations or overexpression of RNA splicing factors are associated with aberrant alternative splicing. CDC-like kinases (CLKs) regulate alternative splicing by phosphorylating serine/arginine-rich splicing factors (SRSFs) which are essential for splice site recognition and spliceosome assembly. Thus, targeting CLKs represents a promising therapeutic strategy, especially in hematologic malignancies with splicing dysregulation. BH-30236 is a novel, potent, orally bioavailable, ATP-competitive, small molecule kinase inhibitor of CLK1/2/4. BH-30236 inhibited the phosphorylation of SRSFs in cancer cells, leading to modulation of splicing patterns and RNA/protein expression of genes related to apoptosis and DNA damage response pathways, thereby promoting apoptosis. In addition, the expression of stem cell markers was downregulated by BH-30236 in AML cell lines. BH-30236 effectively inhibited the proliferation of hematologic cancer cell lines or leukemia cells from AML or CLL patients. In addition, effective anti-tumor activity of BH-30236 was observed in tumor models derived from AML cell lines or leukemia patients. A synergistic anti-cell proliferation effect between BH-30236 and venetoclax, a BCL2 inhibitor, was consistently observed across multiple hematologic cancer cell lines of diverse lineages. The synergy is likely driven by BH-30236 mediated suppression of anti-apoptotic and pro-survival proteins including MCL1, a pro-survival factor whose upregulation is associated with resistance to venetoclax. Moreover, the combination of BH-30236 and venetoclax synergistically induced complete tumor regression in the highly resistant MOLM13 cell-derived xenograft tumor model. This in vivo synergistic effect was observed even when BH-30236 or venetoclax was administered at low dose levels. Notably, modification of combinatory treatment regimen after achieving complete tumor regression to single agent BH-30236 treatment sustained tumor-free survival in mice and maintained tumor free for more than 80 days, even after treatment discontinuation. This finding is consistent with BH-30236 modulation of leukemia stem cells via regulation of alternative splicing. BH-30236 is currently under clinical investigation, either as a single agent or in combination with venetoclax, in adults with relapsed or refractory AML or higher risk MDS in a Phase 1/1b clinical trial (NCT06501196).

#5873 OB-001 boost the brain penetration of multiple TKIs.

Hitesh Mistry, **Jim Millen**, Josh Fleet, Mark Brimble

OncoBayesAlpha Ltd., London, United Kingdom

Background: Osimertinib, Adagrasib, Tucatinib, Mobocertinib and Lorlatinib all demonstrate clinically meaningful CNS activity across numerous cancer types. However, all four agents show incomplete and variable CNS penetration, with reported CSF:plasma or Kp,uu values typically well below unity, largely due to ABCB1/ABCG2 efflux at the blood-brain barrier. OB-001 is a novel KinetiSol amorphous solid dispersion first-in-class efflux transporter inhibitor. We evaluated whether OB-001 can selectively enhance the brain distribution of kinase inhibitors.
Methods: Male CD-1 mice received one of oral Osimertinib, Adagrasib, Tucatinib, Mobocertinib and Lorlatinib following 2-h pretreatment with vehicle or OB-001 (10 mg/kg). Plasma and perfused-brain concentrations were quantified to 24 h by LC-MS/MS. Pharmacokinetic parameters were derived by noncompartmental analysis, and fold-changes in area under the curve (AUC) between brain and plasma were compared.
Results: OB-001 led to a 4, 33, 5, 11 and 4 -fold increase in Brain AUC for Osimertinib, Adagrasib, Tucatinib, Mobocertinib and Lorlatinib respectively. No change in plasma AUC was observed for Osimertinib and Adagrasib with less than 2-fold increase obserevd for Tucatinib, Mobocertinib and Lorlatinb.
Conclusions: OB-001 selectively boosts brain exposure without substantially increasing systemic exposure. These data demonstrate that theoretically a pharmacokinetic window can be achevied with OB-001 whereby enhanced brain metatsases efficacy could be acheived for numerous kinase inhibitors without effecting systemic toxicity. These findings support OB-001 as a first-in-class CNS-targeted efflux modulating adjunct capable of elevating brain drug exposure beyond what is achievable by existing kinase inhibitors alone. OB-001 has strong translational rationale for combination development with Osimertinib, Adagrasib, Tucatinib, Mobocertinib and Lorlatinib—to further extend CNS disease control in numerous cancer types.

#5875 Multikinase inhibitor olverembatinib (HQP1351) is efficacious and synergizes with BTK inhibitor acalabrutinib in mantle cell lymphoma (MCL) preclinical models.

Bo Peng[1], Zhiyan Liang[2], Yan Xiong[1], Bingxing Wu[1], Shujie He[1], Zhou Yu[1], Guoqin Zhai[1], Dajun Yang[1], Yifan Zhai[2]

[1]Ascentage Pharma (Suzhou) Co., Ltd., Suzhou, China,[2]Ascentage Pharma Group Inc., Rockville, MD

Background: MCL is a rare, aggressive type of non-Hodgkin lymphoma. Although Bruton tyrosine kinase (BTK) inhibitors have transformed MCL treatment, response to monotherapy is limited, and efforts are underway to develop combination therapies. Olverembatinib, an investigational multikinase inhibitor (approved in China for chronic myeloid leukemia), inhibits Src-family kinase Lyn, which is essential for B-cell receptor (BCR) signaling and B-cell proliferation, differentiation, and activation. Hypothesizing that dual inhibition of Lyn and BTK pathways enhances antitumor effects, we evaluated olverembatinib combined with acalabrutinib in preclinical MCL models and explored potential mechanisms of action (MOAs).

Methods: MCL cell lines Mino and Rec-1 were selected for *in vitro* growth inhibition assessments. CellTiter-Glo® assays were conducted to evaluate antiproliferative activity. Apoptosis and cell cycle arrest were assayed by flow cytometry. MOAs were examined by tyrosine phosphoproteomic analysis and confirmed by western blotting. *In vivo* activity was evaluated in a subcutaneous cell-derived xenograft (CDX) mouse model.

Results: Olverembatinib potently inhibited MCL cell proliferation, with respective IC_{50} values of 15 and 25 nM in Mino and Rec-1 cells. When combined with acalabrutinib, olverembatinib showed synergistic antiproliferative effects in both cell lines (respective Loewe scores = 10.04 and 10.92). The combination also significantly increased percentages of apoptotic cells (Mino, $p < 0.001$; Rec-1, $p < 0.01$), and significantly induced G0/G1 cell cycle arrest versus either agent alone (Mino, $p < 0.01$; Rec-1, $p < 0.0001$). On tyrosine phosphoproteomic analysis, olverembatinib inhibited kinase activities of Lyn, Fyn, Lck, Syk, and BTK, leading to potent inhibition of BCR signaling. Acalabrutinib inhibited BTK and other Tec-family kinases (e.g., Tec, Itk). Combining both agents potentiated inhibition of BCR and NFkB pathways. These results were further confirmed by western blot analysis. Olverembatinib inhibited phosphorylation of Lyn and its downstream BTK, while the combination further downregulated NF-kB activity. The combination also significantly suppressed cell cycle-promoting protein CDK6 and increased apoptotic markers PARP and caspase-3. In the Mino CDX model, olverembatinib dose-dependently inhibited tumor growth, with a treatment-to-control (T/C) value of 35.35% at 15 mg/kg, while acalabrutinib (10 mg/kg) exhibited a T/C value of 73.37%. When coadministered, both agents further enhanced antitumor activity (T/C = 18.64%), achieving a synergistic index of 1.39.

Conclusions: Olverembatinib is efficacious and synergizes with acalabrutinib in preclinical MCL models. These data provide a rationale for further clinical evaluation of this novel combination therapy in patients with MCL.

#5876 Soluble TNF blockade as a strategy to enhance tyrosine-kinase inhibitor response and control metastatic burden in HER2-positive breast cancer.

Sofia Bruni[1], Marla Ladera[2], Camila Jencquel[2], Federico Waisberg[3], Martin A. Rivas[1], Roxana Schillaci[2], Maria Florencia Mercogliano[2]

[1]University of Miami Miller School of Medicine and Silvester Comprehensive Cancer Center, Miami, FL,[2]Instituto de Biologia y Medicina Experimental, Buenos Aires, Argentina,[3]Instituto Alexander Fleming

Tyrosine kinase inhibitors (TKIs), such as lapatinib and tucatinib, are used to treat metastatic HER2-positive breast cancer, especially those located in the brain, as they can cross the blood-brain barrier. Although both TKIs improve survival, there is still an urge to boost their efficacy and overcome resistance. We have demonstrated that soluble TNF (sTNF) blockade overcomes resistance to trastuzumab-based therapies targeting HER2 by downregulating mucin 4 (MUC4), which shields its epitope on the HER2 molecule. Now, we asked whether sTNF neutralization might overcome TKI-based therapy resistance or enhance its antitumor activity.We used the HER2+/MUC4+ JIMT-1 and its brain-tropic subline JIMT-1BR3-luc cell lines, resistant to lapatinib. For proliferation and cell migration assays, cells were treated with 1 µM lapatinib or 10 µM tucatinib, either alone or combined with 10 µg/ml of a dominant negative (DN) protein that neutralizes sTNF. For preclinical studies, female nude mice bearing JIMT-1 tumors received vehicle, 100 mg/kg lapatinib via oral gavage daily, 10 mg/kg DN i.p. twice a week, or the combination (n=5/group). For JIMT-1BR3-luc tumors, mice were treated with vehicle, 100 mg/kg tucatinib via oral gavage daily, DN twice weekly, or both (n=9/group). Tumor volume was measured biweekly for 21 days; metastases were detected *ex vivo* by IVIS luminescence.Neither lapatinib nor DN alone impacted JIMT-1 cell proliferation, but their combination reduced cell proliferation by 60%. For JIMT-1Br-luc cells, DN and tucatinib decreased cell proliferation by 35 % and 55%, respectively, and the combination enhanced the effect to 80%. Cell migration was significantly inhibited in both cell lines by their respective combo treatment, compared to the monotherapies.In preclinical studies, treatment with DN, lapatinib, or tucatinib did not affect the primary tumor growth, compared to the vehicle. However, the combination of DN and lapatinib reduced JIMT-1 tumor growth by 77% and, in the case of JIMT-Br-luc tumors, treatment with DN and tucatinib inhibited tumor growth by 68%, compared to the monotherapies. The percentage of JIMT-Br-luc tumor-bearing mice with lung metastases was 100% in the vehicle group, 75% in the DN group, 37.5% in the tucatinib group, and 12.5% in the combined group. Animals with brain and liver metastases accounted for 50% and 75% respectively, in the vehicle group, and were 90-100% reversed upon treatment with either tucatinib or DN, or the combination.These findings highlight that sTNF blockade can overcome lapatinib resistance and improve tucatinib inhibitory effect on cell proliferation, both *in vitro* and in *vivo*. In addition, DN was able to curb brain and liver metastasis and lung metastases in combination with tucatinib, underscoring the potential benefit of its use in combination with TKIs in advanced HER2-positive breast cancer patients.

#5877 BH-30643, a novel macrocyclic non-covalent, mutant-selective EGFR inhibitor, addresses the resistance and potency limitations of contemporary EGFR TKIs.

Ping Jiang, Wei Deng, Nancy Ling, Danan Li, Zhenping Wang, Yue Hu, Joshua Choi, Eugene Rui, Geoffrey Oxnard, Jean Cui

BlossomHill Therapeutics, Inc., San Diego, CA

Historical design of EGFR tyrosine kinase inhibitors (TKIs) left them vulnerable to recurrent resistance liabilities which curtail the durability of their clinical effect. These TKIs gain potency either by binding the EGFR kinase back pocket or by forming covalent bond with C797, rendering them susceptible to T790M or C797S resistance mutations. Limited potency or PK exposure of some TKIs also permits regrowth of residual tumor cells and thereby shortening their duration of clinical benefit. BH-30643 was designed as a macrocyclic, non-covalent, mutant selective OMNI-EGFR inhibitor targeting the disease-driven active conformation of mutant EGFRs, allowing super-potency against diverse EGFR oncogenic drivers and resistance mutations while sparing wildtype EGFR. Aiming to characterize how this novel, super-potent OMNI-EGFR inhibitor could address the resistance liabilities of contemporary EGFR TKIs, BH-30643 was studied alongside 10 contemporary EGFR TKIs, approved or in clinical studies with a panel of primary cancer or engineered Ba/F3 cell lines expressing classical *EGFR* mutation (ex19del or L858R) or compound resistance mutations (T790M, C797S, or both). *EGFR* C797S conferred resistance to 6 covalent EGFR TKIs, T790M rendered resistance to 4 EGFR TKIs with a structure motif in EGFR back pocket, while the triple compound mutations with C797S and T790M were resistant to all 10 contemporary EGFR TKIs, leaving BH-30643 as the only TKI capable of overcoming both C797S and T790M resistance mutations while maintaining super potency against classical *EGFR* mutations. Furthermore, BH-30643 and osimertinib were investigated in a long-term colony formation assay in cancer cells with *EGFR* classical mutations. BH-30643 demonstrated markedly prolonged suppression of cell proliferation compared to osimertinib at the same clinically relevant concentration not only under standard growth conditions, but also in the presence of EGF, which mimicked accelerated resistance. These data support the potential of BH-30643, as a super-potent OMNI-EGFR TKI for longer duration of treatment than osimertinib. Upregulation of growth factors are well recognized as a common resistance mechanism for receptor TKIs. Targeting the active EGFR kinase conformation is hypothesized to reduce vulnerability to growth factor-mediated EGFR TKI resistance (eg, EGF). In the presence of EGFR ligands, BH-30643 maintained cell potency in all cell lines, while potency of osimertinib steeply fell, particularly in cells with *EGFR* L858R mutation. The first-in-human trial of BH-30643 (SOLARA) is now enrolling globally, with a focus on advanced *EGFR*-mutant NSCLC either with TKI resistance or prior to targeted therapy exposure (NCT06706076).

#5878 Tumor Treating Fields remain effective in therapy-resistant glioblastoma with kinome shifts revealing novel therapeutic opportunities.

Taylor Lynn Schanel[1], Amber Jones[2], Rhea Pandit[1], Johsua C. Anderson[3], Patricia H. Hicks[1], Corinne Griguer[4], Braden C. Mcfarland[5], Christopher D. Willey[6], **Anita B. Hjelmeland**[1]

[1]University of Alabama at Birmingham, Birmingham, AL,[2]St Judes Children's Hospital, Memphis, TN,[3]Radiation Oncology, University of Alabama at Birmingham, Birmingham, AL,[4]University of Iowa, Iowa City, IA,[5]Postdoctoral Fellow, Dept. of Cell, Developmental and Integrative Biology, University of Alabama at Birmingham, Birmingham, AL,[6]O'Neal Comprehensive Cancer Center at UAB, Birmingham, AL

Glioblastoma (GBM) is the most common primary brain tumor in adults with a median survival of less than 15 months with maximal safe surgical resection, radiation, and the chemotherapy temozolomide. Addition of Tumor Treating Fields (TTFields), or alternating electromagnet fields therapy, to temozolomide was shown to extend the survival of GBM patients by approximately 4.9 months. TTFields disrupt mitosis to inhibit cell growth, but we also determined that TTFields alter the cellular kinome. Using a PamStation, we identified kinases that are predicted to be activated and repressed by TTFields treatment in newly diagnosed and recurrent GBM models that are sensitive or resistant to temozolomide or irradiation, respectively. While the growth of all GBM cells tested was significantly decreased by TTFields, there was a relatively limited set of kinases that were commonly altered in newly diagnosed and temozolomide-resistant GBM cells with little similarly across irradiation resistant GBMs. These kinase data are reminiscent of published data demonstrating kinome variability in radioresistant GBM xenografts. We did find that TTFields were predicted to activate PDGFRα in both newly diagnosed and temozolomide-resistant GBM cells: when combined with TTFields, a blood brain barrier penetrant PDGFR inhibitor, crenolanib, significantly decreased GBM cell growth. Subsequent studies have identified additional kinases to be evaluated in combination with TTFields in radioresistant GBM cells. Using the Novocure inovivo system, we plan to test these novel kinase inhibitor combinations with TTFields in mouse models bearing intracranial GBMs. We hope to identify a kinase inhibitor based treatment strategy that can be translated to the clinic to further improve TTFields mediated increases in patient survival.

#5879 Spleen tyrosine kinase as a novel target in medulloblastoma.

Veena Salvi[1], **Ganesh Naik**[2], Ajay Sharma[3], Nagendra K. Chaturvedi[4]

[1]Chemistry, College of Saint Mary, Omaha, NE,[2]Chemistry, University of Nebraska at Omaha, Omaha, NE,[3]Cancer research readuate program, University of Nebraska Medical Center, Omaha, NE,[4]University of Nebraska Medical Center, Omaha, NE

Background: Group 3 medulloblastoma (MB) is the most aggressive pediatric brain tumor, characterized by MYC oncogene amplification, poor prognosis, and resistance to standard chemoradiation, necessitating novel therapeutic targets. Spleen Tyrosine Kinase (SYK) is known as an important oncogene and signaling mediator in various hematologic and solid malignancies, contributing to proliferation and survival pathways. Because MYC proteins remain largely undruggable, we investigated SYK as a potential therapeutic target based on its reported cooperation with MYC-driven transcriptional programs in other malignancies.
Methods: Since MYC is undruggable, we explored targeting the Spleen Tyrosine Kinase (SYK), a component of MYC-dependent pathways. We used pharmacological inhibition (R406, Bay61, Fostamatinib) in MYC-amplified MB cell lines (HD-MB03 and D425) to assess cell viability and MYC protein levels via MTT assays and Western blotting. We also evaluated the therapeutic potential of SYK inhibition combined with cisplatin in D425 cells. Future work will elucidate the molecular mechanism (transcription/translation) in vitro (via shRNA knockdown, ChIP, RNA sequencing) and evaluate therapeutic efficacy in patient-derived xenograft (PDX) mouse models.
Data: SYK inhibition significantly reduced HD-MB03 cell viability in a dose-dependent manner (R406 reduced viability to ~18% at $5 μM) and caused distinct downregulation of MYC protein in both HD-MB03 and D425 cells. Crucially, the combination of SYK inhibitors with the standard chemotherapeutic agent cisplatin showed a synergistic effect in D425 cells, suggesting a potential chemo sensitization mechanism. These preliminary data strongly support the critical role of SYK in MYC-driven MB oncogenesis.
Conclusions: The preliminary findings support the hypothesis that SYK acts as a key regulator of MYC-driven tumorigenesis in aggressive medulloblastoma. The observed synergistic toxicity when combining SYK inhibitors with cisplatin in D425 cells highlights a prospective chemo-sensitization mechanism. Targeting the SYK-MYC axis using SYK inhibitors, especially in combination with existing chemotherapies, offers a powerful, clinically translatable strategy to overcome treatment resistance and significantly improve outcomes for patients with high-risk, MYC-driven medulloblastoma

#5880 A comprehensive approach to targeting PI3K and Hippo pathways in sarcomas.

Samuel Y. Yu, Keith Garcia, Ali Khan, Souradip Sinha, Colleen Fullenkamp, Munir R. Tanas

University of Iowa, Iowa City, IA

Sarcomas are heterogeneous cancers of mesenchymal origin with limited effective targeted therapies. One frequently dysregulated pathway in sarcomas is PI3K signaling, due to PTEN loss in 30–60% of patient samples. PI3K activation promotes tumor growth via the canonical Akt-mTORC1 axis and a parallel PI3K-TAZ/YAP-TEAD axis. TAZ/YAP are transcriptional co-activators that drive oncogenic gene expression and are regulated by the Hippo pathway consisting of the core kinases MST1/2 and LATS1/2. TAZ/YAP lack DNA binding domains and complex with TEAD transcription factors in the nucleus. The TAZ/YAP-TEAD axis is regulated by PI3K in a LATS1/2 dependent manner. In sarcomas, loss of Hippo kinases is seen in 30-50% of samples, leading to aberrant TAZ/YAP activation. Epigenetic silencing of MST1/2 and MAP4Ks via histone deacetylation may account for a significant subset of these cases. Preliminary data shows HDAC inhibition with Romidepsin restores MST1 expression and reduces TAZ/YAP transcriptional activity, suggesting a therapeutic opportunity. We propose dual inhibition of PI3K-Akt-mTORC1 signaling and TAZ/YAP transcriptional activity to reduce sarcoma proliferation and survival. We hypothesize that combination therapy will be more effective due to the convergence of these pathways on tumor growth.We used three cell lines: RD (embryonal rhabdomyosarcoma), A204 (malignant extrarenal rhabdoid tumor) and RH30 (alveolar rhabdomyosarcoma). Cells were treated with MK2206 (Akt inhibitor), Everolimus (mTORC1 inhibitor), Romidepsin (HDAC inhibitor) and VT-107 (TEAD inhibitor) alone or in combination. Proliferation was assessed via cell viability assays and clonogenic outgrowth was measured to evaluate cell survival. Western blotting was used to assess signal transduction.MK2206 reduced proliferation in A204/RH30 cells at concentrations greater than 1 μM, with corresponding decreases in phosphorylation of Akt-mTORC1 substrates. Clonogenic assays showed reduced colony formation in both lines. Combination treatment with MK2206, VT-107 and Everolimus further suppressed proliferation/clonogenic outgrowth, suggesting additive or synergistic effects. In RD cells, Romidepsin at 5nM significantly reduced proliferation/clonogenic outgrowth, consistent with increased MST1 protein levels and reduced TAZ/YAP activity.PI3K and Hippo pathways are frequently dysregulated in sarcomas and combination therapy targeting both can more effectively inhibit tumor growth. TEAD inhibition disrupts TAZ/YAP transcriptional activity downstream, while HDAC inhibition restores Hippo signaling and suppresses TAZ/YAP transcription, and PI3K pathway inhibitors reduce survival signaling. These findings provide rationale for further investigation into dual-pathway inhibition as a therapeutic strategy, including mechanistic studies and *in vivo* validation to define therapeutic windows and potential clinical applications.

#5881 Fragment-recombination design of a dual VEGFR2/TIE2 inhibitor with sarcoma-selective cytotoxicity.

Youngkeun Lee, Bo Kyoung Kim, Ji-yoon Choi, Min-jeong Kim, **Sung Wook Seo**

Samsung Medical Center, Seoul, Korea, Republic of

Sarcomas have limited systemic options beyond cytotoxic chemotherapy. VEGFR-directed multi-kinase inhibitors such as regorafenib provide modest benefit, but their broad RTK inhibition constrains the therapeutic margin. Because VEGFR2 and TIE2 are central regulators of tumor angiogenesis and vascular stability, we hypothesized that selective dual VEGFR2/TIE2 inhibition would improve potency while reducing off-target toxicity. We applied fragment recombination of validated RTK inhibitor scaffolds, combined with dual VEGFR2/TIE2 docking and phenotypic screening, to design candidate inhibitors with an improved potency-selectivity balance for sarcoma therapy. We computationally designed ~300 dual VEGFR2/TIE2 candidates via fragment recombination and synthesized 15 prioritized by docking and binding-site analyses. Antiproliferative activity was evaluated by MTS assay at 24 and 48 h (2.5-10 μM) in human osteosarcoma lines (143B, MG63, KHOS/NP, U-2 OS) and murine macrophages (RAW264.7) to assess myeloid cell toxicity. Lead compounds were compared with pazopanib, regorafenib, and sorafenib. At 2.5 μM (48 h), pazopanib, regorafenib, and sorafenib maintained ≥100% viability across all sarcoma lines. At 10 μM, pazopanib and regorafenib showed ≥80% viability, while sorafenib reduced 143B viability to 55% but spared other lines (≥80%). Among synthesized candidates, SMC-101-008 and SMC-101-011 showed early activity at 2.5 μM, reducing 143B and MG63 viability to 57-65% (24 h) and 47-84% (48 h). However, at 10 μM (48 h), both compounds also ablated RAW264.7 (1% viability), indicating loss of selectivity at higher doses. In contrast, SMC-101-017 exhibited time- and dose-dependent sarcoma-selective activity. At 2.5 μM, minimal activity was observed at 24 h (≥88% viability), but by 48 h, KHOS/NP and 143B viability dropped to 39% and 19%, respectively, while RAW264.7 remained unaffected (>100%). At 10 μM, SMC-101-017 showed moderate early suppression (66-72% viability across all lines at 24 h) but selectively eliminated KHOS/NP and 143B by 48 h (25% and 7%, respectively) while preserving RAW264.7 viability (>100%) SMC-101-017 demonstrated potent, time-dependent cytotoxicity against osteosarcoma while sparing myeloid cells across a 4-fold dose range, distinguishing it from approved multi-kinase TKIs. These findings nominate SMC-101-017 for target validation and in vivo evaluation, and support fragment-based design for developing kinase inhibitors with improved therapeutic windows.

#5882 Structure- and bioinformatics-driven development of a selective, orally bioavailable HER2 small molecule inhibitor (HM100714) for cancer therapy.

Ho Yeon Nam, Sun Young Jang, Jiyoung Jeon, HyungSeok Yoo, Jooyun Byun, Soonki Park, Soye Jeon, Haemin Chon, Yu-Yon Kim, Boram Kim, Young Gil Ahn

Hanmi Pharmaceutical Co., Ltd., Hwaseong-si, Korea, Republic of

HER2 alterations, encompassing overexpression, amplification, and activating or other mutations, occur across multiple solid tumors and can drive cancer cell growth and metastatic progression. To address these alterations, HER2-targeted therapeutics are under development and clinical evaluation for breast, gastric, cholangiocarcinoma, colorectal, bladder, and non-small-cell lung cancers. However, several existing HER2 inhibitors also inhibit wild-type EGFR, leading to EGFR-related toxicities such as skin rash and diarrhea. Collectively, these considerations support the development of HER2-selective inhibitors that spare wild-type EGFR. Herein, HM100714 covalently targeted HER2 Cys805 and selectively inhibited HER2 while minimizing EGFR-mediated toxicities. To elucidate the improved tolerability, we performed molecular dynamics (MD) simulations of the inhibitor-protein complex. Beyond the covalent linkage to Cys805, MD revealed interactions with HER2-specific residues that are absent in wild-type EGFR, providing a structural rationale for HER2 selectivity and reduced EGFR liability. We further explored potential clinical indications using a bioinformatics framework. We trained a machine-learning model using published *in vitro* datasets of HER2 inhibitors and transcriptomic information from the Cancer Cell Line Encyclopedia to predict sensitivity to the drug. Further *in vitro* validation was done using an in-house panel of 75 cell lines. Extrapolation of the model to patient-derived datasets allowed prioritization of cancer indications predicted to be effective. These results will inform the IND-enabling studies and documentation. HM100714 inhibited HER2-altered enzymes and cell lines and showed a DMPK profile compatible with oral dosing. Guided by bioinformatics-driven indication selection, we evaluated the antitumor activity as a single agent across multiple HER2-altered xenograft models. Oral administration of HM100714 resulted in statistically significant antitumor efficacy in the NCI-N87 xenograft model, which exhibits HER2 overexpression, and in the Ba/F3 xenograft model harboring the $HER2^{A775\_G776insYVMA}$ mutation. We further assessed efficacy in leptomeningeal metastasis and brain metastasis models and characterized the toxicity profile to define a safety margin in support of the IND-enabling studies. In conclusion, HM100714, an orally bioavailable small-molecule inhibitor, demonstrated robust efficacy against HER2-altered tumors with minimal EGFR-related toxicities. Moreover, structure-based analyses and bioinformatics provided key data that streamline clinical readiness. These preclinical results support HM100714 as a promising therapeutic candidate for HER2-altered cancers.

#5883 FAK inhibitor APG-2449 triggers immunogenic ferroptosis in gastric cancer via the AKT-FOXO1-ACSL4 axis.

Lin Zhang[1], Jing Xiao[1], Liqun Chen[1], Siyi Mao[2], Peiyao Song[3], Liqiong Yang[4], Runduan Lin[1], Miaozhen Qiu[5], Dajun Yang[4]

[1]Clinical laboratory, State Key Laboratory of Oncology in South China, Sun Yat-Sen University Cancer Center, Guangzhou, China,[2]Department of Breast Surgery, The First Affiliated Hospital of Guangzhou Medical University, Guangzhou, China,[3]Clinical Laboratory Science, Qingyuan Hospital of Traditional Chinese Medicine Affiliated to Guangzhou University of Traditional Chinese Medicine, Qingyuan, China,[4]Department of Experimental Research, State Key Laboratory of Oncology in South China, Sun Yat-Sen University Cancer Center, Guangzhou, China,[5]State Key Laboratory of Oncology in South China, Sun Yat-Sen University Cancer Center, Guangzhou, China

Gastric cancer remains a major clinical challenge worldwide with limited effective treatment options for advanced stages. APG-2449, an innovative multi-kinase inhibitor targeting FAK, ALK and ROS1, has demonstrated promising clinical potential in various malignancies, though its precise mechanism of action in gastric cancer requires further elucidation. This study aims to investigate the novel hypothesis that APG-2449 exerts its anti-tumor effects through inducing ferroptosis and subsequently activating anti-tumor immunity.Through comprehensive experimental approaches combining in vitro cell culture models and in vivo syngeneic mouse systems, we employed advanced techniques including Western blotting, chromatin immunoprecipitation, lipid peroxidation measurement, and multidimensional immune profiling.Our results demonstrate that APG-2449 effectively suppresses the FAK-AKT signaling pathway, resulting in FOXO1 dephosphorylation and nuclear translocation. Crucially, we provide direct evidence that FOXO1 binds to the ACSL4 promoter region, upregulating its transcription and subsequently driving lipid peroxidation that culminates in ferroptosis execution. Moreover, we establish that APG-2449-induced ferroptosis exhibits distinct immunogenic characteristics, triggering damage-associated molecular pattern release that promotes dendritic cell maturation and enhances CD8+ T cell infiltration and cytotoxic function within the tumor microenvironment. The therapeutic combination of APG-2449 with anti-PD-1 antibody generates significantly superior anti-tumor efficacy compared to either treatment alone.These findings illuminate a previously unrecognized dual mechanism of APG-2449 action: direct induction of ferroptosis via the FAK-AKT-FOXO1-ACSL4 axis coupled with potent activation of anti-tumor immunity, thereby providing a compelling rationale for clinical development of FAK inhibitor and immunotherapy combinations in gastric cancer management.

#5884 Targeting multivalent receptor tyrosine kinases to enhance the efficacy of anti-PD-1 immunotherapy in gastric cancer.

Melanie Genoula[1], SHOUMIN ZHU[2], Mohammed Soutto[2], Nadeem Sidiq Bhat[2], Marwah M. Al-Mathkour[2], Wael El-Rifai[2]

[1]Surgery, Miller School of Medicine, University of Miami, Miami, FL,[2]Surgery, Miller School of Medicine, University of Miami, Miami, FL

Background: Gastric cancer (GC) is the fifth most common cancer and the fifth leading cause of cancer-related deaths globally. The response to immune checkpoint blockade (ICB) therapy in GC is relatively poor with almost two thirds of the patients not responding due to the tumor's ability to maintain an immunosuppressive microenvironment and develop resistance to immunotherapy. Previously, we demonstrated that dovitinib, a multi-target receptor tyrosine kinases (RTKs) inhibitor, suppresses tumor growth and remodels the tumor microenvironment (TME) by facilitating the recruitment of CD8+ T cells into immune-suppressive types of mouse gastric cancer. This study aimed to assess whether dovitinib enhances the therapeutic effectiveness of PD-1 blockade.
Methods: ATP-GLO to measure cell viability in vitro. A syngeneic murine gastric tumor model with two distinct mouse GC cell lines was utilized to assess the synergistic effects of dovitinib and anti-PD-1 treatment. IF and flow cytometry to immunophenotyping.
Results: The combination of dovitinib and PD-1 blockade was significantly more effective than either treatment alone, leading to reduced tumor growth and increased animal survival in both models ($p<0.01$). IF analysis revealed that while dovitinib alone increased CD8+ T cell infiltration in the tumor core, the combination treatment further enhanced the infiltration of cytotoxic T cells (Perforin+ CD8+) compared to the other groups ($p<0.01$). Furthermore, multiparametric flow cytometry combined with FlowSOM clustering analysis showed an increase in CD4+ and CD8+ T cell clusters with higher activation (CD69+) and lower or absent expression of exhaustion markers (PD-1, CTLA-4). In contrast, dovitinib alone was associated with a more exhausted T cell phenotype. Notably, only the combination treatment increased the tumor killing capacity of the cytotoxic T cells.
Conclusion: Our findings demonstrate that the combination of dovitinib and PD-1 blockade is significantly more effective than either treatment alone, as the two therapies synergistically remodel the TME beyond their direct cytotoxic effects. This synergy is achieved by increasing the infiltration of activated tumor-infiltrating lymphocytes (TILs) and reducing the exhaustion phenotype typically seen with monotherapy. This study supports the rationale for combining multi-target RTKs inhibitors with immunotherapies as an effective therapeutic strategy for gastric cancer.

#5885 Targeting myeloid-derived suppressor cells (MDSCs) to restore antitumor immunity in non-small cell lung cancer (NSCLC) via SRC family kinase Inhibition with NXP900.

Bobby Kaghazchi[1], In Hwa Um[2], Amber Ortiz[3], Enrique Podarosu[4], David J. Harrison[2], Neil Carragher[1], Asier Unciti-Broceta[1]

[1]Cancer Research UK Scotland Centre, Institute of Genetics and Cancer, University of Edinburgh, Edinburgh, United Kingdom,[2]School of Medicine, University of St Andrews, St Andrews, United Kingdom,[3]Indica Lab, Albuquerque, NM,[4]Nuvectis Pharma Inc., Fort Lee, NJ

Background: Despite therapeutic advances, non-small cell lung cancer (NSCLC) demonstrates poor survival outcomes, with global 5-year rates of only ~ 16 - 19%. The tumor microenvironment (TME) critically influences NSCLC prognosis and treatment response through immune contexture (cell type, density, and spatial location). Elevated $CD4^+$ and $CD8^+$ T-cell tumor infiltration correlates with improved survival. Contrastingly, increased myeloid-derived suppressor cells (MDSCs) promote immune evasion, angiogenesis, and metastasis. NXP900 (eCF506) is a highly potent and selective SRC family kinase (SFK) inhibitor (IC_{50} of 0.47 nM against YES1) that locks SFKs in their inactive “closed” conformation (type 1.5), inhibiting both enzymatic and scaffolding activities of SFKs. Cancer models exhibiting hippo pathway modulators such as FAT1 or NF2 mutation or loss are associated with increased sensitivity to NXP900 *in vitro* and tumor growth inhibition and regression *in vivo*. Given MDSC dependence on SFKs and YAP/TAZ signaling required for immunosuppressive function, we hypothesized that NXP900 may suppress MDSCs, thereby reversing immune suppression, and enhance antitumor immunity in NSCLC.

Methods: Tumor and immune cell morphology were analyzed in 162 chemotherapy-naïve, early-stage NSCLC adenocarcinomas. Multiplex immunofluorescence (mIF) was performed on a subcohort (n=60) using lymphocyte (CD4, CD8 and CD20) and MDSC panels (CD11b, CD14 and CD15), with population and spatial analysis performed using HALO® software. Induced MDSCs (iMDSCs) were validated *in vitro* via flow cytometry and RT-PCR, treated with NXP900 for 48 hours, and immunostained for YAP1, YES1, phalloidin, and Hoechst and analyzed. Viability was assessed using Presto Blue assay.

Results: $Immune^{high}$ NSCLC patients showed longer overall survival compared with $immune^{low}$ patients (HR = 1.763; 95% CI, 1.098-2.830; *p = 0.03). Elevated MDSC populations negatively correlated with survival (HR, 0.5456; 95% CI, 0.2355-1.265; * p = 0.04) and exhibited contact-dependent suppression of effector T cells. NXP900 treatment depleted iMDSCs, reduced YAP1 phosphorylation and nuclear localization in a dose-dependent manner, and demonstrated pro-immune effects consistent with inhibition of hippo pathway modulation.

Conclusions: These findings identify MDSCs as a key immunosuppressive driver of prognostic significance in NSCLC. NXP900 currently in a Phase 1b study (NCT05873686) including in NSCLC patients with YES1 and FAT1 genomic alterations, effectively suppresses MDSC viability and YAP1 signaling in vitro, supporting its potential as a novel therapy in NSCLC.

#5886 *In vitro* profiling of IDRX-42 and NB003 against secondary and tertiary (AP/AL) mutations found in TKI-resistant GIST.

Michael C. Heinrich[1], Ajia Town[1], Marcelina Roberti[1], Sebastian Bauer[2]

[1]Medical Oncology, Portland VA HCS and OHSU Knight Cancer Institute, Portland, OR,[2]Sarcoma/Medical Oncology, West German Cancer Center, Essen, Germany

Approximately 70-75% of Gastrointestinal stromal tumor (GIST) harbor a KIT mutation and patients with KIT-mutant GIST have durable responses to front-line imatinib (IM). Over time, clinical resistance emerges due to secondary IM-resistance mutations. These secondary mutations are restricted to two regions of the KIT protein: the drug/ATP binding pocket (AP, exons 13 and 14) and the activation loop (AL, exons 17 and 18). Although additional TKI drugs are now approved for 2L-4L+ treatment these agents lack activity against the entire spectrum of known resistance mutations. For example, sunitinib (SU) is potent against AP mutations (V654A, T670I), but has minimal activity against AL mutations. Conversely, ripretinib (RIP) has minimal activity against AP mutations. Neither SU nor RIP has activity against KIT-mutant GIST with both AP and AL mutation paired with the original primary KIT mutation (AP/AL). Recently, two new agents, IDRX-42 and NB-003 have been tested in phase 1 studies of patients with TKI-resistant GIST and are initiating randomized phase 3 studies in the second- and third-line, respectively. However, the cellular potency of IDRX-42 and NB-003 against different primary, secondary, and AP/AL KIT mutations has not been comprehensively described. We assessed the biochemical potency of IDX-42 and NB-003 against cell lines with relevant primary, secondary, and AP/AL KIT mutations. To assess relative potency, we also profiled IM in the same cell line model. IM was potent against primary K11 mutations (K11 exon 11 deletion and K11 V560D) but was much less potent against K11 + secondary mutations, KIT exon 9 (K9) primary mutations, and K9 + secondary mutations. IDRX-42 was active against K11, K11 + V654A, K11 + AL, K9 primary, K9 + AP, K9 +AL mutations. IDRX-42 lacked potency against K9 or K11 with T670I mutations. NB003 was active against K11, K11 + AP, K11 + AL, and K11 + V654A + A829 P (AP/AL), K9 primary, K9 + AP, K9 +AL mutations. Notably, none of these drugs had activity against K11 + AP/AL or K9 + AP/AL mutant kinases. IDRX-42 and NB003 have superior biochemical potency against a panel of primary and secondary KIT mutations compared with IM. NB003 may lack potency against certain K9 + secondary mutations. Neither IDRX-42 or NB003 have activity against K9 + AP/AL or K11 + AP/AL mutations. Ideally, future development of these newer agents should focus on earlier lines of therapy, prior to the development of AP+ AL mutations. The pan-resistance of AP/AL mutations to existing TKIs indicates the need to develop new drugs to target these resistance mutations.

#5887 Profiling of reversible and covalent HER2 kinase inhibitors for anti-tumor activity and broader biological effects to evaluate selectivity and functional activity.

Luciano Galdieri[1], Steven Garner[1], Brogan Epkins[1], Emily Schultz[1], Daria Clucas[1], Pony (Yu-Ling) Lee[2], Chao-Di Chang[2], Chien-Chang Shen[2], Alastair J. King[1]

[1]Eurofins Discovery Services North America, LLC, Saint Charles, MO,[2]Pharmacology Discovery Services Taiwan, Ltd., New Taipei City, Taiwan

Hurman epidermal growth factor receptor 2 (HER2) is a member of the human epidermal growth factor receptor tyrosine kinase family that regulates cell proliferation, survival, and differentiation. Amplification or activating mutations of HER2 result in constitutive signaling through pathways such as PI3K/AKT and MAPK, driving oncogenic transformation and tumor progression in various cancers. This is particularly notable in breast and gastric cancers, making it an important therapeutic target for the treatment of tumors in these tissues. HER2-directed therapies, including monoclonal antibodies, antibody–drug conjugates, and small molecule tyrosine kinase inhibitors (TKIs), have markedly improved outcomes for HER2-positive malignancies. Among TKIs, lapatinib was the first dual HER2/EGFR inhibitor to be approved for clinical use. Its reversible inhibition of both kinases leads to broad pathway inhibition but also to off-target effects, limiting its use. Tucatinib, a third-generation reversible HER2 TKI, was designed for enhanced selectivity towards HER2 with minimal EGFR inhibition, reducing toxicity while preserving efficacy in HER2-driven tumors. Furthermore, tucatinib demonstrates clinical benefit in combination treatments, particularly for HER2-positive breast cancer with brain metastases, due to favorable CNS penetration. Zongertinib is a newly approved next-generation, highly selective covalent HER2 inhibitor with optimized pharmacologic and safety profiles. As such, it retains potent activity against HER2-amplified and HER2-mutant tumors while minimizing off-target kinase effects, which translates into improved tolerability and the potential for broader therapeutic use. We evaluated the activity and selectivity of lapatinib, tucatinib, and zongertinib *in vitro* across a panel of about 300 human tumor cell lines using the OncoPanel® cellular phenotypic platform. Potencies were determined from ten-point dose–response curves to calculate IC_{50} and EC_{50} values, thus allowing the identification of similarities and differences in potency, efficacy, and genomic biomarkers of sensitivity and resistance relating to each drug. Activities are also being assessed in a human tumor xenograft model of the HER2-positive NCI-N87 human gastric cancer cell line, to further enable the comparison and contrasting of these drugs *in vivo*. To complement these *in vitro* and *in vivo* analyses, these HER2 inhibitors were further characterized in the BioMAP® Diversity PLUS® panel of primary human cell systems to assess functional activities across a diverse range of tissue and immune biology contexts. Together, these studies define distinct biological and mechanistic profiles among HER2-targeted TKIs and highlight the evolution of this drug class with increasing selectivity, tolerability, and efficacy.

#5888 Quantitative phospho-proteomics uncovers CX-4945 effects on translational control and differentiation in neuroblastoma.

Marudhu Pandiyan Shanmugam, Muhammed Danial, Upendarrao Golla, Rifat Tasnim Juthi, Yasin Uzun, Hannah Valensi, Giselle Saulnier Sholler, Chandrika Gowda Behura

Pennsylvania State University College of Medicine, Hershey, PA

Introduction: Neuroblastoma is a third most prevalent pediatric cancer of the sympathetic nervous system, which is often diagnosed at a clinically advanced stage with primary or acquired resistance to conventional chemotherapy. Protein Kinase CSNK2A1 (CK2) is an intrinsically active, ubiquitously present serine-threonine kinase overactive in various pediatric solid cancers, including neuroblastoma (NBL) and Ewing sarcoma (EWS). Recurrent genetic alterations in CK2 were not observed in NBL, indicating that its oncogenic role is driven by dysregulated activity rather than mutation. CX-4945 (Silmitasertib) is a potent, ATP-competitive CK2 inhibitor with low-nanomolar Ki values and high selectivity, targeting 49 of 250 tested kinases. CX-4945 has demonstrated potent in vivo antitumor activity in solid tumors and leukemia, with favorable pharmacokinetics and good tolerability in human studies. It is currently under Phase I clinical evaluation for pediatric solid tumors. Here, we report the quantitative phospho-proteomic profiling of CX-4945 treated NBL cells

Methods: The susceptibility of NBL cell lines with and without MYCN amplification was tested against CX-4945. We performed label-free quantitative Phosphoproteomic profiling of 2 NBL cell lines (SMS-KCNR and SHSY5Y) following *in vitro* treatment with CX-4945 for 24 h. Trypsin digested peptides were enriched for phospho-peptides by using Titanium Ion-Metal Affinity Chromatography. Differentially expressed phospho-peptides and their corresponding phosphoproteins were identified using high-resolution LC-MS/MS, and functional enrichment analysis was conducted to map the affected signaling networks. We also performed transcriptomic analysis for comparing the commonly regulated proteins at mRNA and Protein level. For validation studies, WB and IHC-based quantification of selected phosphoproteins, and their associated pathways, was tested in pre-clinical model-derived tissue treated with CX-4945.

Results: Quantitative phospho-proteomics analysis revealed 4064 and 3131 downregulated phospho-proteins in CX-4945-treated NBL cell lines, SMS-KCNR and SHSY5Y, respectively. GPCR5C/IRS4-PI3K-AKT/MYC axis and EIF4A1/MYC axis are found to be downregulated in multi-omics approach. Network analysis highlighted the disruption of translation initiation, proliferation, and neuronal differentiation signaling, suggesting a mechanistic link between CK2 inhibition and altered signaling pathways. CK2 mediated cMYC signaling inhibition was validated using WB and IHC studies.

Conclusion: Protein kinase CK2 is intrinsically active and negatively impacts survival in HR-NBL patients. Phospho-proteomic analysis reveals, changes in multiple pathways which leads to reduced proliferation and increased neuronal differentiation.

#5889 Preclinical evaluation of EO1001 in EGFR-ECD mutant solid tumor models: Toward biomarker-directed therapy.

Jeffrey Bacha[1], Sophia Frentzas[2], Malaka Ameratunga[3], Sarath Kanekal[4], Ian Nisbet[5], Neil Sankar[1], Denni M. Brown[1], Jasmine Borroel[6], Rowan Prendergast[6]

[1]Edison Oncology Holding Corp., Menlo Park, CA,[2]Monash Health, Melbourne, Australia,[3]The Alfred Hospital - Monash Univ., Melbourne, Australia,[4]President, Regulatory Strategy Consulting, San Diego, CA,[5]Senz Oncology Ptd. Ltd., Melbourne, Australia,[6]Certis Oncology, San Diego, CA

Background: EGFR extracellular domain (ECD) mutations—including EGFRvIII, A289 substitutions, R108 variants, and related structural alterations—drive ligand-independent EGFR activation and highly aggressive tumor biology. These mutations are enriched in glioblastoma (GBM) and also occur in head and neck, lung, and gastrointestinal cancers, where they are associated with therapeutic resistance and poorer patient outcomes. EGFR-ECD mutations are intrinsically resistant to approved EGFR TKIs, including osimertinib, erlotinib, gefitinib, and afatinib, because the structural alterations lie outside the ATP-binding pocket and preserve receptor signaling despite drug engagement. EO1001 is an orally bioavailable, irreversible pan-ErbB inhibitor designed to target both wild-type and structurally altered ErbB receptors. Early signals of clinical benefit in EGFR-ECD mutant GBM patients have been observed in an ongoing Phase 1-2a study (ANZCTR: ACTRN12620000583943), underscoring the need for mechanistic validation. To address this, we initiated a focused preclinical program assessing EO1001 activity in patient derived (PDX) cell culture models harboring clinically relevant EGFR-ECD variants.
Methods: PDX GBM cell culture models were selected to evaluate EO1001 across representative EGFR mutation states. EO1001 is tested using a 9-point dose-response curve, run in triplicate at two timepoints. Cell viability and proliferation are quantified using CellTiter-Glo assays. Each plate includes a vehicle control, a DMSO cytotoxicity control, and an FDA-approved EGFR TKI as a positive control to benchmark EO1001 against a clinically used inhibitor known to be ineffective in ECD mutations. Primary endpoints include IC50 values and maximal inhibitory activity to determine whether EO1001 demonstrates direct antiproliferative effects in EGFR-ECD mutant GBM models.
Results: Study is ongoing, data will be presented at the AACR annual meeting. Planned analyses will define whether EO1001 demonstrates meaningful activity against EGFR-ECD variants, which represent a therapeutically intractable subgroup characterized by resistance to existing EGFR inhibitors and poor clinical outcomes.
Conclusions: This preclinical program will further explore mechanisms of EO1001's activity in EGFR-ECD mutant cancers, providing support for biomarker-guided clinical development.

: Functional Roles of Noncoding RNAs in Cancer Progression, Metabolism, and Therapy Response
Poster Session

#5894 Long non-coding RNA LINC01614 overexpression defines a ferroptosis-associated molecular signature in papillary thyroid cancer.
Danielle Quaranto[1], Michelle Carnazza[2], Nicole R. DeSouza[1], Sina Dadafarin[3], Augustine Moscatello[4], Humayun K. Islam[1], Codrin Iacob[5], Raj K. Tiwari[1], Jan Geliebter[1]

[1]Pathology, Microbiology, and Immunology, New York Medical College, Valhalla, NY,[2]General Nutraceutical Technology, LLC, Elmsford, NY,[3]Otolaryngology-Head and Neck Surgery, University of Washington, Seattle, WA,[4]Otolaryngology/Head and Neck Surgery, Westchester Medical Center, Valhalla, NY,[5]New York Eye and Ear Infirmary, Mount Sinai, New York, NY

Papillary thyroid cancer (PTC) is the most common endocrine malignancy, with incidence rising by approximately 3% each year. PTC disproportionately affects females of reproductive age, while male patients often exhibit more aggressive disease. Although overall survival is high, recurrence and metastasis remain significant clinical challenges that can persist for decades after initial diagnosis. Identifying reliable prognostic biomarkers and actionable therapeutic targets is therefore essential. Long non-coding RNAs (lncRNAs), a class of regulatory molecules with diverse roles in gene expression, display tissue- and cancer-specific expression patterns, making them promising candidates for biomarker discovery. Bioinformatic analysis of our PTC vs. normal thyroid genomic repository identified the lncRNA LINC01614 transcript as significantly 12-fold upregulated in PTC. Thus, we are studying LINC01614 as a potential PTC biomarker and/or therapeutic target. LINC01614 expression was found to be upregulated in multiple thyroid cancer cell lines. The PTC cell line K1 (~2 fold upregulated; BRAFV600E; male), was selected for in vitro study. CRISPR interference (CRISPRi) was used to transcriptionally repress LINC01614 in K1 cells. LINC01614 knockdown in K1 resulted in decreased migration (~20%), clonogenicity (~34%) and proliferation (~45%), indicating a role of this lncRNA in supporting malignant phenotypes. RNA sequencing analysis of a CRISPRi knockdown cell line vs. a CRISPRi control demonstrated reduced expression of key ferroptosis-related genes- SLC7A11 and SLC3A2. Both genes encode for the xCT system (cystine/glutamate reverse transporter) that regulates the uptake of cystine - a key precursor for glutathione (GSH) synthesis. GSH is a critical antioxidant defense against lipid peroxidation, further preventing ferroptosis. Thus, these findings suggested LINC01614 involvement in a ferroptosis-related mechanism. Consistent with this, total cell iron levels were quantified and found to be significantly higher in our LINC01614 knockdowns, signifying increased ferroptosis induction. Western blot analyses also showed decreased levels of ferroptosis-associated proteins such as GPX4, an important antioxidant enzyme that reduces lipid peroxidation to prevent ferroptosis. Current studies are ongoing to identify a LINC01614 mechanism of action within the ferroptosis pathway. These findings suggest that LINC01614 contributes to PTC pathogenesis through modulation of ferroptosis-related processes, highlighting its potential utility as a biomarker and/or therapeutic target.

#5895 The role of noncoding transcripts in glucose-dependent gene regulation in estrogen receptor-positive breast cancer.

Barbara Yang[1], Shreya Kolli[2], Melina J. Sedano[3], Enrique I. Ramos[1], Shrikanth S. Gadad[3]

[1]Biological Sciences, The University of Texas at El Paso, El Paso, TX,[2]TTUHSC El Paso, El Paso, TX,[3]Medicine and Oncology, UTRGV School of Medicine, McAllen, TX

Around seventy percent of breast cancers are of the estrogen receptor-positive (ER+) molecular subtype. Conventional treatments include endocrine therapy that antagonizes ER signaling with tamoxifen or aromatase inhibitors. However, over 50% of patients later develop resistance and relapse. Understanding the underlying molecular mechanisms by which ER drives breast cancer will provide new opportunities to diagnose and therapeutically target it. In this regard, we focused on the part of the genome that is pervasively transcribed to produce noncoding transcripts that are overexpressed in the presence of estrogen. These transcripts are advantageous for tracking disease progression due to their specific expression patterns. We resorted to understanding the function of an intergenic noncoding transcript, "long noncoding RNA 16 (*LNC16*)" that we previously characterized. Since ER can also be activated by specific signaling pathways in the absence of its ligand, investigating the role of *LNC16* in an estrogen-independent context could provide insights into the mechanisms underlying the development of resistance and/or the progression toward relapse. Metabolic reprogramming, especially the preference for undergoing glycolysis, is one of the hallmarks of cancer, and affects various signaling pathways, which could also have integral implications in the ligand-independent activation of ER. To study *LNC16*'s role in glucose-dependent gene expression in ER+ breast cancer in the luminal breast cancer cell line, using CRISPR, *LNC16* knockout MCF7 cells (KOs) were created and treated with glucose. We also introduced *LNC16* into MCF7 cells using a doxycycline-inducible overexpression system and treated them with glucose. Then we performed genome-wide transcriptomic analyses to identify the genes and pathways regulated. Gene ontology analysis of unique differentially expressed genes (DEGs) under normal glucose conditions showed plausible roles of *LNC16* in nucleosome assembly, in regulating cell-cell communication, adhesion, and junction, as well as in signaling pathways. Similarly, unique DEGs in higher glucose conditions predominantly have functions in adhesion, signaling, and chromatin remodeling. We also examined the expression of condition-specific DEGs in breast cancer tumors and identified the association with specific clinical outcomes. Currently, we are elucidating *LNC16*'s molecular mechanism by which it regulates gene expression to drive ER+ breast cancer biology using cell- and mouse-based experiments. Collectively, these results suggest that estrogen-regulated transcripts can regulate glucose-dependent gene expression to control ER+ breast cancer phenotypic outcomes.

#5896 Identification of lncRNAs associated with breast cancer prognosis from Latina America patients.

Xinhui Wang[1], Marcio L. Acencio[1], Flavia Rotea Mangone[2], Roger Chammas[3], Dirce Maria Carraro[4], Andrea S. Llera[5], Eliana Abdelhay[6], Nora Artagaveytia[7], Adrian Daneri-Navarro[8], Bettina Muller[8], Osvaldo L. Podhajcer[9], Carlos Velazquez[10], **Maria A. Nagai**[3]

Breast cancer (BC) is the most common cause of female cancer-related death worldwide and is considered a public health problem. Many functional studies have shown that long noncoding RNAs (lncRNAs) play different roles in gene expression regulation, acting as epigenetic factors. Accumulating evidence indicates that lncRNAs modulate diverse biological processes, and their altered expression is associated with the development and progression of cancer, including BC. Here, aiming to identify lncRNAs associated with breast cancer, we performed a re-analysis of the expression data from 1,071 tumors of eligible patients in the project LACRN MPBCS (Latin American Cancer Research-Network - Molecular Profile of Breast Cancer Study). Using normalized data, we compared the expression profiles of triple-negative breast cancer (TNBC; 170 cases) and non-TNBC tumors (782 cases). A total of 59 differentially expressed lncRNAs (DElncRNAs) could be identified based on the criteria of $|\log2FC| > 1$ and FDR < 0.05, using the DESeq2 R package. In the Kaplan-Meier survival analysis, we identified DElncRNAs that affect disease-free survival and/or overall survival, with 8 in TNBC and 26 in non-TNBC patients. Further, we used multivariate Cox proportional-hazards models to evaluate independent predictors of survival. Two of those DElncRNAs, VLDLR-AS1 and PART1, were independent prognostic markers for TNBC patients, and seven, LINC00239, FAM30A, LINC00842, LINC01315, EGOT, LY6E-DT, and SLC25A21-AS1, were independent prognostic markers for non-TNBC patients. Our study identifies several lncRNAs that might participate in tumor progression and may serve as candidate biomarkers for BC.

#5897 piRNA-5939 drives lung cancer progression via PIWIL3-mediated post-transcriptional regulation.

Sudhir Kumar Rai[1], Yuanyuan Fu[2], Masaki Nasu[2], Zhuokun Feng[3], Li Ma[2], Asmita Pandey[4], Lauren Higa[2], Hua Yang[2], **Youping Deng**[2]

[1]Quantitative Health Sciences, John A. Burns Sch. of Med. Univ. of Hawaii at Manoa, Honolulu, HI,[2]University of Hawaii at Manoa, Honolulu, HI,[3]University of Hawaii, Honolulu, HI,[4]John A. Burns Sch. of Med. Univ. of Hawaii at Manoa, Honolulu, HI

Introduction: PIWI-interacting RNAs (piRNAs) constitute a distinct class of small non-coding RNAs initially described for their roles in germline transposon silencing. Recent evidence implicates somatic piRNAs in cancer-associated gene regulation; however, their mechanistic contribution to lung tumor progression remains poorly defined. In this study, we identify piRNA-5939 as a novel oncogenic regulator that enhances lung cancer cell proliferation and migration via PIWIL3-mediated post-transcriptional modulation of gene expression.
Methods: Human lung adenocarcinoma cell lines (A549, ABC1, and H522) were transfected with antisense oligonucleotides targeting piRNA-5939. Proliferation was assessed by MTT, Click-iT™ EdU incorporation, and colony formation assays; migration and invasion were analyzed by wound-healing and transwell assays; and apoptosis was quantified using Annexin V Alexa Fluor™ 488/Propidium Iodide flow cytometry. Global transcriptomic changes following piRNA-5939 knockdown were examined by RNA sequencing, and key targets were validated using qRT-PCR and Western blotting. Cytoplasmic and nuclear RNA fractionation determined piRNA-5939 subcellular localization and its impact on PIWIL family (PIWIL1-4) expression profiles.
Results: Subcellular fractionation revealed heterogeneous cytoplasmic and nuclear distribution of piRNA-5939 across lung cancer cell lines. Baseline profiling demonstrated that PIWIL3 transcripts are preferentially localized to the cytoplasm, and piRNA-5939 silencing led to a significant downregulation of PIWIL3 mRNA and protein expression. Functionally, loss of piRNA-5939 markedly reduced cell proliferation (~40%) and migration (~55%) relative to controls ($p < 0.01$). Transcriptomic analyses highlighted suppression of oncogenic signaling pathways, including those governing cell cycle progression, cytoskeletal remodeling, and RNA stability—all consistent with attenuated PIWIL3 activity.
Conclusions: These findings identify piRNA-5939 as a functional oncogenic piRNA that promotes lung cancer progression through PIWIL3-dependent post-transcriptional regulation of key growth and migration pathways. The piRNA-5939/PIWIL3 axis represents a previously unrecognized regulatory mechanism and a potential therapeutic vulnerability in lung cancer.

#5898 A novel role of snoRNAs in proteasome inhibitor induced apoptosis.

Alexei F. Kisselev, Olasubomi A. Akintola, Chandler R. Earley, Addison M. Wilson, Amit Kumar Mitra

Auburn University, Auburn, AL

Small nucleolar RNAs (snoRNA) are 60-300 nucleotide long RNAs that guide modification of rRNAs during ribosome biogenesis. Many of them have non-canonical functions, such as regulation of splicing, pseudouridylation, and 2'-O-methylation of specific mRNAs. We have made a serendipitous discovery that treatment of cells with proteasome inhibitors (PIs) induces expression of several snoRNAs, including SNORD3 and SNORA71 families. Two other agents that induce production of misfolded proteins, tunicamycin and thapsigargin, also induced these snoRNAs, but DNA-damaging agent doxorubicin did not. Knocking SNORA71D down reduced PI-induced apoptosis. These findings indicate a novel and unexpected role of snoRNAs in proteasome inhibitor induced apoptosis.

#5899 Characterization of prostate-derived glycoRNA in the context of cancer progression.

Esther Jones, Samantha McGuire, Spencer Moen, Julius Nyalwidhe, **Aurora Esquela Kerscher**

Virginia Health Sciences at Old Dominion University, Norfolk, VA

Noncoding RNA harbors a range of post-transcriptional modifications (m6A, pseudouridine, uridine tailing) important for RNA folding, stability, transport, and localization. Dysregulation of these RNA modifications is associated with human diseases, ex., cancer, inflammation, fibrosis, and viral infection. Noncoding RNA carrying a new class of glycosylation modifications was recently noted in cultured human cells metabolically labeled using bioorthogonal chemistry methods normally employed for glycosylated protein enrichment. Nothing is known about the clinical significance of glycoRNA in prostate cancer (PCa). As high-grade forms of PCa often lead to poor prognoses, it is imperative to improve patient stratification screening tools and treatment options to increase patient survivorship. We hypothesize that RNA requires carbohydrate modifications to maintain organ homeostasis and proper immune surveillance, and we predicted that the glycosylated state of RNA could serve as a biomarker correlating with prostate disease progression and patient prognosis. A clearer understanding of how PCa-associated glycoRNA is regulated during disease progression will provide valuable insight into its function in the prostate. We confirmed that prostate glycoRNA exists using a panel of human prostate cell lines that differed in androgen response and metastatic status. We employed a stringent RNA isolation workflow and validated the existence of carbohydrate-modified RNA using two independent approaches: metabolic labeling using azide click chemistry for biotin-tag detection & lectin northern blot analysis. Small (<200 nucleotide) noncoding RNA were found to carry both N-linked and O-linked sugars, with sensitivity to RNase, endoglycosidases (PNGase F, O-glycosidase) and glycosylation inhibitors. As predicted, glycoRNA expression correlated with PCa progression. GlycoRNA was preferentially enriched in human prostate cell lines and syngeneic panels with no/low malignancy compared to metastatic PCa lines. Subcellular fractionation studies showed glycoRNA localization at the plasma membrane of prostate cells, indicating a signaling role. LC-MS/MS analysis showed glycans containing core-fucosylation and α2-3/α2-6 sialylation. Several glycans displayed LacNAc and GalNAc extensions, suggesting lectin binding and biological function. We have profiled a large panel of glycosylation-associated enzymes in prostate cell lines to gain insight into glycoRNA regulation. This work will provide novel insight into how RNA modifications impact PCa progression and identify first-in-class clinical tools to improve patient outcomes.

#5900 LncRNA UCA1 regulates LDHA expression to drive Warburg metabolism and colorectal cancer progression.

Salique H. Shaham, Ricardo Pequeno Bracho, Kaylee Renteria, Manish Tripathi

Oncology and Medicine ISU, South Texas Center of Excellence in Cancer Research, The University of Texas Rio Grande Valley, McAllen, TX

Background: Colorectal cancer (CRC) is the third most common malignancy worldwide and the second leading cause of death in the US. In 2025, an estimated 154,270 new cases of colon cancer will be diagnosed. In the US, colorectal cancer ranks as the second most common cause of cancer-related deaths, with an expected 52,900 deaths in 2025. Urothelial cancer-associated 1 (UCA1), a long noncoding RNA (lncRNA), has been found to be dysregulated in CRC and to promote tumor growth. Unlike carcinogenic colon cells, we have observed that the lncRNA UCA1 is significantly expressed in metastatic CRC cells. Its expression is also linked to glucose metabolism factors, including glucose transporter 1 (Glut1) and lactate dehydrogenase (LDHA). LDHA is essential for the rapid production of ATP in cancer cells, thereby supporting their progression.
Methods: Cell migration, invasion, and proliferation assays were conducted on isogenic CRC cells (SW480 and SW620), as well as on cells overexpressing UCA1 (SW480+UCA1; OE) and those with UCA1 knockdown (SW620+shUCA1; KD). Anoikis induction was examined using the isogenic, OE, and KD cell lines. RT-PCR, Western blot, and immunofluorescence techniques were employed for RNA and protein analysis of YAP1, Glut1, and LDHA. Glucose and lactose levels in CRC cells were also assessed.
Results: LncRNA UCA1 showed significantly higher expression in metastatic CRC (SW620) cells compared to carcinogenic CRC (SW480) cells. After 36 hours under anoikis conditions, UCA1 expression became exponentially higher. UCA1 levels, along with Glut1 and YAP1, are also elevated in metastasis (SW620 cells) compared to carcinogenic (SW480 cells). In UCA1-overexpressing SW480 cells, the gene expression levels of Glut1 and YAP1 increased significantly, indicating that UCA1 plays a role in regulating glucose metabolism. In the Warburg effect, cancer cells convert Pyruvate into lactate even in the presence of oxygen, rather than using it for the TCA cycle. We found that the gene expression of LDHA, the enzyme converting pyruvate to lactate, was significantly higher in metastatic CRC cells compared to carcinogenic CRC cells. UCA1-overexpressing cells also showed significantly increased LDHA expression, suggesting that UCA1 influences LDHA enzyme activity. LDHA correlated with GLUT1 and YAP1, highlighting the crucial role of LDHA during Warburg glucose metabolism and CRC cell progression. Inhibiting LDHA reduces Glut1 levels within the cell and limits tumor cell growth.

#5901 Using chimeric eCLIP to uncover ancestry-related noncoding RNAs in head and neck cancer.

Chayil C. Lattimore, Lu Li, Lauren Gay, Rolf Renne, Mingyi Xie, Kristianna M. Fredenburg

University of Florida, Gainesville, FL

Introduction: Chimeric enhanced cross-linking and immunoprecipitation (eCLIP) is a high-throughput method that enables direct mapping of Argonaute (Ago)-mediated RNA interactions. To our knowledge, this method has never been used to investigate ancestral differences in cancer outcomes. We performed chimeric eCLIP in African and European-ancestry head and neck cancer cell lines, with the goal of identifying canonical and non-canonical RNA interactions that may underscore differences in tumor behavior and therapeutic response related to ancestry.
Methods: We abstracted gene expression data from patients in the Cancer Genome Atlas (TCGA) head and neck cancer cohort with different ancestral backgrounds. Differential expression analysis (edgeR) was used to identify differentially expressed genes (FDR < 0.05, -1 < log((FC)) > 1) and KEGG pathway analysis was performed to identify pathway enrichment (p adj. < 0.05). miRNA-target predictions were generated using miRnet. Admixture analysis was used to validate ancestry from head and neck cancer cell lines. Chimeric eCLIP protocol was performed on these cell lines. Briefly, Ago proteins were covalently cross-linked to their native RNA interaction partners. Ago immunoprecipitation was performed. RNA fragments were phosphorylated and ligated to generate RNA-RNA chimeras. Libraries were reverse transcribed, PCR amplified, and size selected to limit adapter dimer contamination. Paired-end sequencing (150 bp reads) was performed via Illumina NovaSeq.
Results: Higher expressed genes in patients with self-reported African ancestry were enriched for drug metabolic pathways ($p= 8.31E^{-10}$), while lower expressed were enriched for actin cytoskeletal function ($p= 3.22E^{-52}$). miRnet predicted genes associated with drug metabolism and actin cytoskeletal function to be regulated by miR-200, miR-99, and miR-143/145 family members, which play a role in cell growth and survival, epithelial-mesenchymal transition, and cytoskeletal integrity. Preliminary eCLIP data supports this prediction, highlighting miRNA-mRNA pairings such as miR-100-5p/ABCF2, miR-200c-3p/CDK6, and miR-141-3p/ITGB8.
Conclusion: We present evidence of ancestry-related noncoding RNA regulation associated with head and neck cancer. Future analyses will involve differential binding analysis, pathway enrichment analysis, and genetic overlay with SNPs to determine associations with ancestry. Overall, this methodology may be used to uncover pathways in other cancers with differing outcomes. ChatGPT was used for language editing and text refinement of this abstract.

#5902 Long non-coding RNA RFX5-AS1 exhibits upregulated expression in early stages of ovarian cancer.

Alya Juma Al Handhali[1], Shika Malgundkar[2], Ikram Burney[3], Aikou Okamoto[4], Yahya Tamimi[5]

[1]SQU, Al Khodh, Oman,[2]Sultan Qaboos University, Muscat, Oman,[3]Sultan Qaboos Comprehensive Cancer Care and Research Center (University Medical City), Muscat, Oman,[4]Associate Professor, Dept. of Ob/Gyn, Jikei Univ. School of Medicine, Tokyo, Japan,[5]Biochemistry, Sultan Qaboos University, Muscat, Oman

Ovarian cancer (OC) is a significant global health challenge to women's health worldwide, leading to high rates of morbidity and mortality. Early detection of OC remains a serious challenge since it is asymptomatic, and the conventional biomarkers (CA125 and HE4) often lack sufficient sensitivity and specificity in the initial stages. Long non-coding RNAs (lncRNAs) have emerged as promising molecular indicators due to their regulatory roles in tumorigenesis. Previously, bioinformatics analysis using the GEPIA database identified the upregulation of *RFX5-AS1* in OC compared to healthy individuals, suggesting its potential as a biomarker and highlighting its role in OC pathophysiology and tumor progression. The current study investigated the possibility of early detection potential of *RFX5-AS1* as a marker for OC, emphasizing the need for further investigation of this lncRNA to improve diagnosis, prognosis, and therapies. The expression levels of *RFX5-AS1* were analyzed by quantitative real-time PCR (qRT-PCR) in well-characterized ovarian tissue samples obtained from OriGene Technology, USA, encompassing a spectrum of disease stages. Rigorous normalization to housekeeping (β-actin) was performed to ensure reproducibility and accuracy. Statistical analyses were conducted to evaluate differential expression across stages. *RFX5-AS1* was significantly upregulated in early-stage ovarian cancer tissues, with elevated expression observed in stage IIA ($p = 0.0490$) and stage IIB ($p = 0.0113$). Importantly, *RFX5-AS1* expression remained consistently high in advanced disease, with significant increases detected in stage IIIB ($p = 0.0156$) and stage IV ($p = 0.0286$). These findings suggest that *RFX5-AS1* is not only detectable at early stages but also maintains relevance in later progression, underscoring its potential utility as a robust biomarker across the disease continuum. The consistent overexpression of *RFX5-AS1* in both early and late stages of ovarian cancer highlights its promise as a reliable biomarker for early detection and disease monitoring. Incorporation of *RFX5-AS1* into diagnostic workflows may improve sensitivity in identifying OC at stages where current markers are limited, thereby contributing to earlier intervention and improved patient outcomes.

#5903 TUG1-mediated replication stress regulation as a potential vulnerability in bladder cancer.

Akinobu Ishiyama[1], Miho Suzuki[1], Keiko Shinjo[1], Shusuke Akamatsu[2], Yutaka Kondo[1]

[1]Graduate School of Medicine, Department of Cancer Biology, Nagoya University, Nagoya, Japan,[2]Graduate School of Medicine, Department of Urology, Nagoya University, Nagoya, Japan

Bladder cancer (BCa) displays marked genomic instability driven by APOBEC mutational processes, recurrent alterations in TP53, RB1, ERCC2, and ATM, and chronic replication stress (RS). Such RS-rich genomes require mechanisms that buffer R-loop accumulation and replication-associated DNA damage to sustain proliferation. We have previously demonstrated that the long non-coding RNA (lncRNA) Taurine upregulated gene 1 (TUG1) is a RS-responsive lncRNA induced by ATR-CHK1 signaling and essential for maintaining genome stability across multiple cancer types. Our prior work revealed that TUG1 promotes R-loop resolution and supports tumor cell survival under genotoxic conditions. Given that BCa is intrinsically defined by APOBEC-driven mutagenesis, DNA repair defects, and persistent RS, we hypothesized that BCa cells may rely on TUG1-mediated R-loop regulation. To evaluate this possibility, we analyzed TCGA-BLCA and found significantly elevated TUG1 expression in tumor tissues compared with adjacent normal urothelium. RNA-FISH of clinical BCa specimens further confirmed higher expression of TUG1 within malignant epithelial compartments. Functional assays using a TUG1-targeting antisense oligonucleotide (TUG1-ASO) demonstrated efficient depletion of endogenous TUG1, reduced cell viability, and downregulation of cell-cycle-related transcripts. Loss of TUG1 also induced replication stress and DNA damage markers, including pRPA32 and γH2AX, and sensitized BCa cells to RS-inducing conditions.Taken together, these findings indicate that BCa cells depend on TUG1 to maintain proliferation under high RS pressure. Therapeutic depletion of TUG1 disrupts this adaptive mechanism and impairs tumor cell growth, supporting TUG1 as a potential therapeutic target in BCa.

#5904 Long noncoding RNA, *RAMS11,* promotes DNA damage response in colorectal cancer.

Yesol Kim, Shilpa Hebbar, Nicole White, Amy Ly, Christopher A. Maher

Washington University School of Medicine in St. Louis, Saint Louis, MO

Colorectal cancer remains a leading cause of cancer-related mortality worldwide, with approximately 30% of patients developing resistance to standard chemotherapy. Tumors that exhibit defects in DNA damage response (DDR) and DNA repair pathways exhibit increased genomic instability, which can manifest as resistance, underscoring the clinical significance of therapeutic targeting of DDR. While protein-coding drivers in colorectal cancer have been extensively characterized, persistent therapeutic challenges emphasize the necessity of elucidating novel mechanisms driving cancer development. Here, we found that the long noncoding RNA (lncRNA) *RAMS11* is significantly upregulated in metastatic colorectal cancer, particularly in tumors harboring p53 mutations, as revealed by analyses of The Cancer Genome Atlas (TCGA) datasets. p53-mutant metastatic CRC, a population normally reliant on the ATR/Chk1 checkpoint for survival. However, from small-molecule drug screening, we discovered that high *RAMS11* cells showed resistance to ATR and CHK1 inhibitors. While *RAMS11* drives a state of high replication stress, as evidenced by increased RAD51 foci in RAMS11-overexpressing cells, it simultaneously confers profound resistance to ATR and CHK1 inhibitors. Mechanistically, we resolve this paradox by demonstrating that *RAMS11* attenuates the checkpoint response, leading to a blunted pChk1 activation even under replication stress. We find these cells are now critically dependent on an alternative repair pathway, Homologous Recombination (HR), to resolve the DNA damage. Indeed, our functional studies confirm that knockdown of *RAMS11* significantly impairs HR repair capacity. This work identifies that *RAMS11* reroutes DDR dependencies in cells, revealing a new mechanism of intrinsic chemoresistance and suggesting a synthetic lethal strategy targeting the HR pathway. Collectively, these findings suggest that aberrant overexpression of *RAMS11* disrupts the DDR and promotes DNA replication stress, thereby leading to chemoresistance. Elucidating the mechanism of *RAMS11* will provide critical insights into chemoresistance in colorectal cancer.

#5905 Comparative analysis of lncRNA detection using qPCR and ddPCR technologies in breast cancer research.

Srikanth Perike, Nish Kumar, Cynthia Shu, Andrew Prantner, Angelica P. Olcott, Elizabeth Jordan Dreskin

Bio-Rad Laboratories, Pleasanton, CA

Long noncoding RNAs (lncRNAs) are a diverse class of RNA molecules (>200 nucleotides) with limited protein-coding potential. Thousands of lncRNAs have been identified, however, most remain functionally uncharacterized. These molecules play critical roles in gene regulation, chromatin remodeling, and epigenetic control. When dysregulated, they are linked to cancer and other diseases. Their tissue-specific expression makes them promising biomarkers. But their low abundance compared to mRNAs creates significant challenges for detection. Sensitivity is a major obstacle, since lncRNAs are typically expressed at levels much lower than mRNAs, making accurate quantification difficult.

Conventional quantitative PCR (qPCR) has been widely used for gene expression analysis; however, its sensitivity and precision can be limiting when detecting low-abundance targets such as lncRNAs. Droplet digital PCR™ (ddPCR™), by contrast, offers absolute quantification without reliance on standard curves and demonstrates superior sensitivity and reproducibility, particularly for rare transcripts.

In this study, we compared qPCR and ddPCR platforms for profiling breast cancer associated lncRNAs using an assay panel of up to seven targets in the MCF7 estrogen receptor-positive (ER$^+$) cell line and its Tamoxifen-resistant derivative (MCF7-TAMR), including reference genes (HPRT1, RPL13a) from validated panels. We evaluated sensitivity, multiplexing, and workflow efficiency. Droplet Digital PCR consistently outperformed qPCR, providing more accurate measurements of gene expression for low-abundance lncRNAs. The ddPCR platform reliably achieved absolute quantification at levels as low as 0.5 copies per µL. It also detected subtle changes in expression, even those below two-fold differences.

Superior sensitivity and multiplexing capabilities make ddPCR technology especially well-suited for the early detection and monitoring of breast cancer. These results demonstrate Droplet Digital PCR as a highly reliable tool for biomarker validation and translational research. Its advanced capabilities make it valuable for detecting rare transcripts such as lncRNAs. Selecting the right method is crucial for accurately measuring new RNA targets and Droplet Digital PCR offers the reliability needed for absolute quantification.

#5906 Analysis of metabolic dysfunction-associated transcripts in hepatocellular carcinoma.

Karla Perez[1], Frida Mariana Delgadillo[2], Subramanian Dhandayuthapani[1], Murali M. Yallapu[1], Subhash Chauhan[1], Enrique Ramos[2], SHRIKANTH GADAD[1]

[1]The University of Texas Rio Grande Valley, McAllen, TX,[2]The University of Texas at El Paso, El Paso, TX

Hepatocellular carcinoma (HCC) is the primary form of liver cancer, because early symptoms may be absent, it is often detected late, resulting in a median survival of less than a year. Metabolically-dysfunction-associated steatotic liver disease (MASLD), previously known as non-alcoholic fatty liver disease (NAFLD), has been identified as the fastest-growing cause of HCC globally, including in the United States. Vitellius et al. reported that MASLD may account for 35% of HCC cases. Furthermore, Younossi et al. mentioned it is estimated that by 2040, MASLD will be present in 55% of the population. Therefore, understanding the molecular mechanisms by which MASLD progresses to HCC is critical.

In this study, we leveraged the existing whole-transcriptomic data from over 200 patients with MASLD or Metabolic Dysfunction-Associated Steatohepatitis (MASH) to identify all differentially expressed transcripts, compared to normal liver tissue. We examined the expression of unique noncoding transcripts that are associated with metabolism in HCC. To explore their potential functions, we used the Genomic Regions Enrichment of Annotations Tool (GREAT). Currently, we are employing various molecular and phenotypic based assays to identify their function in HCC. We will link their functions to HCC patient outcomes using RNA in situ hybridization in human tissues.

The analysis identified differentially expressed transcripts in MASLD and MASH. We observed overlapping gene expression patterns across both conditions, along with distinct transcriptomic profiles unique to each stage. In MASLD, 4,403 genes were significantly upregulated and 4,411 downregulated compared to controls. Similarly, in MASH, 4,702 genes were upregulated and 4,433 downregulated. Comparative analyses revealed substantial overlap between the two cohorts, while also highlighting transcripts unique to each condition. These findings suggest that as metabolic liver disease progresses from fatty liver to steatohepatitis, many transcriptional alterations are conserved and become increasingly dysregulated. GREAT analyses indicate that these may be linked to various cellular processes known to play critical role in HCC, such as long-chain fatty-acyl-CoA and fatty-acyl-CoA metabolism, cellular catabolism, apoptosis, and kidney development, including mesonephros. Notably, many of these transcripts exhibit distinct expression patterns in HCC, suggesting their potential as diagnostic and therapeutic markers. We have begun elucidating their mechanism of action using loss- and gain-of approaches in HCC and how their expression is regulated in patient tissue samples.

#5907 Splicing of 3'UTR contributes to colon cancer progression.

Jiunn Fung Cheong[1], Xiaonan Fan[2], Xiao Hong Chew[2], Yvonne Tay[1]

[1]National University of Singapore, Singapore, Singapore,[2]Cancer Science Institute Singapore, Singapore, Singapore

The 3′ untranslated regions (3′UTRs) of messenger RNAs (mRNAs) play crucial roles in regulating gene expression. These regions have been found to be involved in important processes, including mRNA stability, localization, and translation. It is shown that 3'UTR splicing is widespread in many cancers and dysregulated 3′UTR splicing leads to cytoplasmic localization of the spliced 3'UTR (3'SP) transcript variant, resulting in increased protein expression, thus contributing to tumor progression. Currently, little is known about the functional mechanism of 3'UTR splicing in the progression of colon cancer and its implications for treatment outcomes. To address this, we integrated short-read RNA sequencing (RNA-seq) data from The Cancer Genome Atlas (TCGA) colorectal cancer cohort, in-house patient samples, single-cell PacBio long-read sequencing, short-read fractionation RNA-seq data of colon cancer cell lines, and in-house patient sample mass spectrometry data. We shortlisted four candidates that have upregulated 3'SP transcript expression in the tumor samples for further validation. Additionally, our fractionation RNA sequencing in colon cancer cell lines showed that the 3'SP isoforms were significantly more enriched in the cytoplasm compared to the nucleus. Further mechanistic studies are ongoing to identify the corresponding splicing and transport factors, which will determine the mechanism controlling the localization of spliced 3'UTR transcripts and how they are linked to dysregulated 3'UTR splicing.

#5908 PCGEM1 overload: Triggering lethal stress responses in castration-resistant prostate cancer.

Sabrina Ledesma-Bazan[1], Pablo Sanchis[1], Rocio Seniuk[2], Gaston Pascual[2], Maria Jimena Rada[2], Manuel Agulleiro[2], Camila Russo[2], Pia Valacco[3], Elba Vazquez[2], Geraldine Gueron[2], Javier Cotignola[2]

[1]1 Laboratorio de Inflamacion y Cancer, IQUIBICEN-CONICET, Buenos Aires, Argentina. 2 Universidad Argentina de la Empresa (UADE), Instituto de Tecnologia (INTEC), Buenos Aires, Argentina,[2]Laboratorio de Inflamacion y Cancer, IQUIBICEN-CONICET, Buenos Aires, Argentina,[3]CONICET-Universidad de Buenos Aires, Instituto de Quimica Biologica de la Facultad de Ciencias Exactas y Naturales (IQUIBICEN), Buenos Aires, Argentina

Metastatic castration-resistant prostate cancer (mCRPC) represents the most advanced stage of the disease, with no curative treatments. lncRNAs are emerging regulators of prostate cancer (PCa) biology and the lncRNA *PCGEM1* has been linked to tumorigenesis and c-Myc activity in AR positive cells, but its role in an androgen independent context is less characterized. PCGEM1 expression across ISUP grades was assessed by linear trend testing, and its association with progression-free survival was evaluated by Kaplan-Meier analysis in the TCGA-PRAD cohort. PC3 cells were transfected with a PCGEM1 expression plasmid or empty vector and validation by qPCR and MTS assays were performed at 24, 48 and 72 h. Clonogenic, hanging drop, and wound healing assays were conducted at 72h. To assess cell morphology, DAPI/phalloidin staining and fluorescence microscopy were performed. ER-stress and EMT programs were examined by RT-qPCR. Proteomic profiling of PC3 transfected cells was performed by LC-ESI-MS/MS followed by GSEA analysis, and pathway enrichment patterns were further evaluated in the MD Anderson PDX and SU2C cohorts. PCGEM1 expression declined with increasing ISUP grade, and higher levels correlated with longer progression-free survival in the TCGA-PRAD cohort. In PC3 cells, PCGEM1 overexpression reduced cell viability at 72 h, markedly impaired clonogenic growth, and decreased spheroid size. Transfected cells displayed an elongated morphology with increased cell area and reduced circularity, but both *CDH1* and *CDH2* expression were reduced whereas *FN1* and *TWIST1* had no changes. Furthermore, PC3-overexpressing cells had migration impaired at all times assessed (3, 6 and 24 h). ER-stress markers (HSPA5, XBP1, DDIT3) were upregulated, indicating activation of stress-response pathways. Proteomic analysis of PC3 transfected cells with PCGEM1 revealed repression of translational and ribosomal-biogenesis programs and downregulation of MYC-target pathways. Finally, the evaluation of MYC-core proteins in PDX models segregated AR-positive adenocarcinomas from poorly differentiated or AR-low tumors, whereas clustering in the SU2C cohort was more heterogeneous. *PCGEM1* is reviewed in literature as an oncogenic lncRNA and its overexpression in AR-positive PCa cells is associated with a more aggressive phenotype. Nevertheless, its overexpression in an androgen-independent context induced ER-stress programs, suppressed protein biosynthetic and MYC-related pathways, and impaired key malignant traits. This response suggests that excessive *PCGEM1* activation becomes incompatible with cellular homeostasis, inducing a hyperactivation-induced lethality mechanism. These findings highlight a previously unrecognized regulatory role for *PCGEM1* and suggest that exploiting lncRNA hyperactivation may uncover a therapeutic vulnerability in advanced, therapy-refractory PCa.

#5909 Functional characterization of specific non-coding transcripts involved in chemo-resistant triple negative breast cancer.

Melina J. Sedano[1], Barbara Yang[2], Subramanian Dhandayuthapani[1], Murali Yallappu[1], Subhash Chauhan[1], Shrikanth Gadad[1]

[1]Division of Cancer Immunology and Microbiology, Medicine and Oncology Integrated Service Unit, The University of Texas Rio Grande Valley School of Medicine, McAllen, TX,[2]Department of Biological Sciences, The University of Texas at El Paso, El Paso, TX

Triple-negative breast cancer (TNBC) accounts for many new breast cancer cases, with poorer outcomes than other molecular subtypes. Compared to other subtypes of breast cancer, TNBC is typically associated with larger, higher-grade tumors and decreased overall and recurrence-free survival rates. Treatment for this type of cancer is often aggressive and includes chemotherapeutic agents like anthracyclines, such as doxorubicin. However, it is not always effective due to dose-limiting toxicity and the development of resistance to doxorubicin over time. There are many theories behind the mechanism of resistance, possibly due to changes at the genetic level, transcriptome, cellular pathways, or epigenetic modifications, warranting further investigation. To study the mechanism of resistance, we developed doxorubicin-resistant MDAMB231 and HCC1143 TNBC cell lines that were engineered using physiological or low-dose doxorubicin concentrations with gradual increments of doxorubicin. We performed integrated genomic analyses to identify transcripts that are potentially contributing to the resistance mechanisms and also drive cancer progression. These transcripts range from coding RNAs, microRNAs, pseudogenes, divergent transcripts, and long noncoding RNAs. We focused on the intergenic long noncoding RNAs that are differentially expressed compared to non-resistant TNBC cells. We analyzed these RNAs by interrogating their neighborhood based on their chromosomal location, revealing that they could be involved in cellular plasticity, which allows cancer cells to adjust to the presence of doxorubicin, possibly through transcriptional reprogramming. A subset of them are localized to chromatin and the nucleus, which have the potential to reprogram the epigenetic landscape and drive resistance-specific genes and cellular pathways, and currently we are studying them for their role in chromatin organization. Additionally, we are also assessing their clinical utility using in vivo xenograft mouse models with genetically engineered chemo-sensitive and chemo-resistant cells, linking outcomes to changes observed in patient samples and associated with clinical prognosis. Collectively, our studies provide insights into mechanisms driving doxorubicin resistance in TNBC, which may offer new avenues for the development of diagnostic markers and targeted therapies.

#5913 Integrative transcriptomic profiling reveals stromal activation patterns in gastric cancer beyond HER2 status.

Woo Sun Kwon[1], Chan Hee Park[1], Sejung Park[1], Choong-Kun Lee[2], Poh Zhong Wee[3], Jia Hui Liew[3], Jingming Chew[3], Sun Young Rha[1]

[1]Yonsei University College of Medicine, Seoul, Korea, Republic of,[2]Yonsei University Health System, Seoul, Korea, Republic of,[3]Auristone Pte. Ltd, Singapore, Singapore

Advanced gastric cancer (AGC) continues to show suboptimal outcomes despite therapeutic progress. Among TCGA-defined subtypes, the genomically stable (GS) subtype remains particularly challenging due to the absence of actionable drivers and its limited responsiveness to immune checkpoint inhibitors. GS tumors frequently exhibit stromal activation—characterized by cancer-associated fibroblasts, desmoplastic fibrosis, and angiogenic remodeling—which contributes to immune exclusion and therapeutic resistance. Although recent clinical activity of trastuzumab deruxtecan has refined HER2 classification, biological determinants of treatment response in non-HER2-driven subtypes, especially GS-like disease, remain poorly understood. Fibrosis- and angiogenesis-related transcriptional scores may capture key tumor-microenvironment programs relevant to AGC biology. We analyzed bulk RNA sequencing data generated from pre-treatment FFPE tumor samples of 120 patients diagnosed with stage IV AGC at Yonsei Cancer Center between 2015 and 2024 (IRB no. 4-2014-0349), categorized into HER2 positive (n=62) and negative (n=58). Differential expression analysis (DEG) and GSVA-based pathway enrichment were used to characterize transcriptomic differences across HER2 groups. Fibrosis and angiogenesis scores were computed and compared among the subgroups, and key findings were validated in the TCGA GC cohort. Across the entire AGC cohort, fibrosis scores (median 29.72, range 0-100) and angiogenesis scores (median 17.92, range 0-98.06) exhibited broad interpatient variability and showed a strong positive correlation ($R^2 = 0.501$, $p < 0.0001$). When samples were mapped to TCGA molecular subtypes, fibrosis scores were highest in GS-likely and were significantly elevated compared with CIN-likely ($p = 0.04$), a trend reproduced in the TCGA cohort. Low PD-L1 expression was associated with lower angiogenesis scores ($p = 0.0059$), indicating a relationship between angiogenic activation and immune phenotype. No significant differences in stromal scores were observed across HER2 subgroups, suggesting that stromal activation is largely independent of HER2 status. Within HER2-defined subgroups, HER2-low showed distinct transcriptomic programs characterized by KRAS pathway activation, loss of SNF-related tumor-suppressor activity, enrichment of proliferation-related signaling, and a marked reduction in inflammatory and interferon-related pathways compared with the other two groups. Stromal remodeling, represented by fibrosis and angiogenesis scores, is a major biological feature of AGC and is particularly enriched in GS-like tumors, independent of HER2 status. These findings suggest that fibrosis- and angiogenesis-based stromal programs may improve biological stratification and identify tumor-microenvironment-driven vulnerabilities in advanced gastric cancer.

#5915 Utility of long-read RNA-sequencing for isoform and fusion discovery in lung cancer.

Kevin Levine[1], Colette Felton[2], Tanvi Damle[1], Christina Baik[1], Angela Norie Brooks[2], **Alice H. Berger**[1]

[1]Fred Hutchinson Cancer Center, Seattle, WA,[2]UC Santa Cruz, Santa Cruz, CA

Isoform expression is frequently dysregulated in lung cancer via cis-acting splice site mutations or trans-acting mutations in splicing factors such as U2AF1, RBM10, and SF3B1. While prior studies have sought to characterize the isoform landscape in cancers, the short reads of next-generation sequencing platforms, ranging in length from 50-150 bp, preclude the accurate phasing of alternative splicing events across the full transcript length (typically exceeding 1 kb). To provide a more comprehensive and accurate view of expressed isoforms in lung cancer, we performed long-read RNA-sequencing on 32 matched tumor/normal pairs of early stage resected lung adenocarcinoma, four biopsies from tumors that had progressed on targeted therapy treatment, and 14 non-small cell lung cancer cell lines. RNA was isolated from fresh frozen tissue specimens and cDNA prepared using the PacBio Kinnex full-length isoform method. PacBio HiFi data were generated per manufacturer's recommendations at the University of Washington Long Reads Sequencing Center or UC Davis DNA Technologies core. Libraries were sequenced on the PacBio Revio system to a read depth of >10M HiFi reads per sample, providing >80% saturation of known isoforms. FLAIR3 was used to identify and quantify isoforms, including novel isoforms, and phase isoform expression with somatic mutations including SNVs and insertion/deletion mutations. Analysis of alternative splicing patterns in RAS-pathway genes identified increased expression of the minor *KRAS* isoform, *KRAS4A*, in tumors compared to normal samples. Phasing of somatic variants enabled integration of *KRAS* mutation with *KRAS* isoform expression and validated the previously identified role of KRAS Q61 variants on aberrant *KRAS* splicing. In addition, we identified deletions predicted to inactivate tumor suppressor genes and identified novel rearrangements in clinically actionable oncogenes including *EGFR*. Together these data demonstrate the utility of long-read RNA sequencing for accurate and complete isoform characterization in cancer.

#5917 Single-cell profiling of NK cells in chronic myeloid leukemia identifies distinct cell states with gene regulatory signatures associated with differential outcomes after imatinib discontinuation.

Santoshi Borra[1], Da Yan[2], Robert S. Welner[3], **Zongliang Yue**[4]

[1]Department of Bioinformatics, Indiana University, Bloomington, IN,[2]Department of Computer Sciences, Indiana University, Bloomington, IN,[3]Department of Medicine, University of Alabama at Birmingham, Birmingham, AL,[4]Department of Health Outcomes Research and Policy, Auburn University, Auburn, AL

Background: Treatment-free remission (TFR) is an emerging therapeutic goal in chronic myeloid leukemia (CML), achieved by ~40% of patients who discontinue tyrosine kinase inhibitor (TKI) therapy after maintaining a deep molecular response. However, the immunogenomic mechanisms that distinguish sustained remission from molecular relapse remain incompletely defined. Previous single-cell RNA (scRNA-seq) and TCR sequencing studies revealed that CML is characterized by an expanded population of activated CD56dim natural killer (NK) cells and anti-PR1 T cells that mediate anti-leukemic immunity.
Methods: Building on these findings, we reanalyzed NK cell transcriptomes from six CML patients, two with early relapse, two with late relapse, and two maintaining durable TFR, using an integrated computational framework combining unsupervised clustering, pseudotime trajectory inference, gene regulatory network (GRN) reconstruction, and artificial intelligence-assisted gene panel discovery. Longitudinal samples collected at TKI discontinuation and at 6- and 12-month post-therapy were analyzed to delineate transcriptional dynamics and regulatory drivers of immune outcomes.
Results: Comparative GRN modeling revealed distinct transcription factor modules governing NK cell activation, differentiation, and exhaustion. Patients maintaining TFR exhibited higher activity in RUNX3, EOMES, ELK4, and REL regulons, whereas relapse cases showed modules enriched for FOSL2 and MAF with inflammatory/translational targets. Pseudotime analysis revealed altered state-transition kinetics between functional NK subtypes, with accelerated exhaustion trajectories in relapsing patients. An AI-guided gene prioritization model further identified a gene NK cell regulatory panel, including previously uncharacterized transcriptional mediators that robustly separated TFR, late relapse, and early relapse groups. Pathway enrichment linked these genes to IFN-γ signaling, metabolic reprogramming, and immunoregulatory feedback networks.
Conclusions: This integrative reanalysis highlights transcriptional control and regulatory network rewiring as key determinants of immune persistence versus exhaustion following TKI cessation. The AI-derived gene panel provides a scalable framework for exploratory biomarker discovery and mechanistic stratification of CML remission outcomes. Together, these findings advance our understanding of the immune architecture underlying successful TFR and identify candidate transcriptional targets to improve remission durability in CML.

#5918 Single cell functional characterization of cancer mutations and their cellular phenotype.

Huiyun Sun, Dongin Lee, HoJoon Lee, Susan M. Grimes, Raegan Wood, Hanlee P. Ji

Stanford University, Stanford, CA

Many cancer driver mutations lead to proteins with amino acid substitutions which dramatically affect their function. This class of cancer mutations play a critical biological role in cancer progression and maintenance of nearly all malignancies. However, the effect of substitution mutations is mostly inferred computationally rather than functionally tested. As a result, there is practically no biological information about their functional consequences for these substitutions except for a small number.We developed a high-throughput single cell approach to systematically investigate the functional effects of reported cancers substitutions. This system provides parallel, highly scalable testing of many cancer mutations across multiple genes in a single experiment. It uses CRISPR base editors to introduce specific cancer mutations into the genome, identifies the newly introduced mutation genotype among individual cells and determines each mutation's transcriptional phenotype per a given cell. Specifically, long-read targeted sequencing is applied to single cell cDNAs. Single cell long read sequencing identifies the presence of an engineered mutation in each cDNA assigned to an individual cell. To determine phenotype of the mutation, we integrate the short-read transcriptome profile from the same single cells. This integrative approach enables single-cell direct genotyping of the introduced genetic variant and matching phenotype from the same cell.We chose a set of mutations that occur with high frequency as reported in the TCGA's pan-cancer atlas. All the possible gRNAs were designed based on the location of the C/A bases in the oncogenic mutations' sequence context. We detected the engineered mutations by linking actual mutation genotype determined by long-read sequencing with corresponding transcriptome change detected by short-read sequencing in one single experiment.These results demonstrate how combining single cell genomics and direct genome engineering method increase the scale for characterizing diverse cancer-associated mutations. In the future, we will evaluate in parallel large sets of different cancer mutations, how they alter gene expression and changes in the cellular states. Importantly, characterizing the function of novel oncogene mutations may lead to the discovery of new targeted therapeutics for cancers.

#5919 Dissecting gene regulation of cellular states in glioblastoma using single-cell multi-omics.

Min Yang[1], Nicolas L. Gonzalez Castro[2], Alexander Jucht[1], Sophia Kovatsis[1], Channing Pooley[1], Sydney Dumont[1], Kevin Johnson[3], Julie Laffy[4], Bo Xia[1], Roel Verhaak[3], Itay Tirosh[5], Mario Suva[1]

[1]Department of Pathology and Krantz Family Center for Cancer Research, Massachusetts General Hospital and Harvard Medical School, Boston, MA,[2]Center for Neuro-Oncology, Dana-Farber Cancer Institute, Boston, MA,[3]Yale School of Medicine, Department of Neurosurgery, New Haven, CT,[4]Broad Institute, Boston, MA,[5]Department of Molecular Cell Biology, Weizmann Institute of Science, Rehovot, Israel

Glioblastoma (GBM) is an incurable and aggressive brain cancer characterized by profound intra- and intertumoral heterogeneity and remarkable cellular plasticity. Single-cell transcriptomic analyses have revealed several major cell states, including NPC-like, OPC-like, GPC-like, AC-like and MES/Hypoxia-like. However, the cis-regulatory networks that govern GBM cell state transitions remain poorly understood. In this study, we performed single-cell chromatin accessibility profiling and multi-omics analysis on 35 GBM IDHwt samples. Firstly, we developed a new scATAC-seq data analysis framework and reconstructed six malignant consensus cis-regulatory element (CRE) modules. Four of these modules were specifically associated with malignant cell states corresponding to the MES/Hypoxia-like, AC-like, OPC-like, and NPC-like identities. Interestingly, cycling cells exhibited broadly open chromatin across all four CRE modules, while GPC-like cells showed accessibility in both the AC-like and OPC-like states, suggesting a role as an intermediate or hybrid regulatory state. Further epigenetic information quantification revealed that NPC-like malignant cells harbor higher regulatory information content compared with other cell states. Master regulator enrichment analysis identified AP-1 transcription factors as key regulators of differentiated (MES/AC-like) malignant state-associated CRE modules, whereas neuronal-development transcription factors were enriched in stem-like (NPC/OPC-like) state-associated modules. Through in vitro gain- and loss-of-function experiments, we screened and validated several transcription factors that modulate malignant cell-state transitions. Additionally, our scATAC-seq-based copy number alteration (CNA) analysis captured hallmark GBM genomic events at high resolution, including EGFR focal amplification, CDKN2A/B deletion, and CDK4 and MDM2 amplifications. Leveraging these CNA profiles, we successfully constructed a high-resolution phylogenetic tree, capturing the clonal architecture and evolutionary trajectory of GBM. By integrating transcriptomic, chromatin accessibility, and genetic CNA data, we elucidated the evolutionary landscape of GBM progression and cellular plasticity. Our findings provide significant insights into the regulatory architecture of GBM and establish a foundational framework for precision therapies targeting distinct cell states.

#5921 Cell type-specific mapping of endometrial cancer risk genes using single-nucleus multi-omics.

Preety Bajwa, Carly Chapman, Dylan Glubb, Tracy O'Mara

QIMR Berghofer Medical Research Institute, Brisbane, Australia

Endometrial cancer is a common gynecological malignancy with more than 410,000 new cases diagnosed worldwide in 2020. Endometrial cancer genome-wide association study (GWAS) have identified 21 robust susceptibility regions, most of which lie in non-coding regions and are presumed to act through cell type-specific regulatory elements. However, bulk tissue and cell-line models cannot fully resolve these regulatory programs. This project uses single-nucleus multi-omic (RNA+ATAC) profiling, enabling simultaneous measurement of chromatin accessibility and gene expression within the same nucleus, to generate cell type-specific enhancer-gene maps in endometrial tumors. By integrating these maps with GWAS data, we aim to identify a comprehensive set of candidate endometrial cancer risk genes. We used the 10X Multimodal GEX+ATAC single nucleus sequencing kit to map open chromatin and gene expression profiles in archival endometrial tumors available through the Australian National Endometrial Cancer Study (ANECS), a population-based case-control study of endometrial cancer with extensive clinical data. Libraries were sequenced on the NextSeq2000 platform before data processing using Cell Ranger, Seurat and Signac for cell-type-resolved enhancer-gene mapping. Exploratory enhancer-gene mapping was performed using co-accessibility and gene expression correlation analysis in Signac. Credible risk variants from 21 endometrial cancer GWAS loci were intersected with enhancers to identify candidate causal risk variants and corresponding target genes. Approximately 25,000 nuclei were successfully profiled and clustered into major endometrial cell types, including epithelial (ciliated and unciliated), fibroblast and immune cells. Initial enhancer-gene mapping using Signac co-accessibility analysis identified endometrial cancer risk variants at the 13q22.1 locus residing within epithelial cell enhancers that correlate with *KLF5* expression. We have generated the first single-nucleus multimodal map of endometrial cancer, enabling direct linkage of endometrial cancer risk variants to cell type-specific regulatory elements and target genes, including *KLF5*, a transcription factor that regulates uterine epithelial remodeling and promotes endometrial cancer cell proliferation in experimental models. This work represents an ongoing pilot study, with further tumors and loci being analyzed to reveal cell type-specific endometrial cancer risk genes.

#5922 Single-cell mapping of the colon epithelium reveals a pre-malignant stem cell that defines early transformation risk.

Yujin Lee[1], Moray J. Campbell[2], James C. Fleet[1]

[1]Dept. of Nutritional Sciences, The University of Texas at Austin, Austin, TX,[2]Karmanos Cancer Institute, Wayne State University, Detroit, MI

Intestinal stem cells (ISC) are viewed as the origin of colorectal cancer (CRC), but the early stages of carcinogenesis are unclear. We hypothesize that early, non-transforming mutations reprogram ISCs into a preneoplastic state that increases the risk of transformation. We performed single-cell RNA sequencing (scRNA-seq) on colon epithelial cells from Car1-Cre (CAC) mice, which express Cre specifically in colon epithelial cells. CAC mice were crossed to those with floxed oncogene alleles to generate mice with one ($Apc^{+/-}$, AC) or two ($Apc^{+/-}$; $Kras^{G12D/wt}$, AKC) non-transforming mutations. AC mice had normal crypt morphology and low adenoma incidence, while AKC mice exhibited crypt elongation by 4 weeks and multiple adenomas by 8-10 weeks. Cells from distal colonic crypts (n=7) and from tumors (n=3) representing phenotypes ranging from normal to malignant were profiled using the 10X Genomics Chromium. Processing and clustering with Cell Ranger and Seurat yielded 58,906 cells from crypts and 36,327 from tumors. Initial clustering identified epithelial, immune, endothelial, and cancer groups. The epithelial group was subclustered and visualized by UMAP. Cells from CAC crypts followed the classic differentiation path: Stem, Progenitor, Transit-amplifying, Absorptive epithelial cell, Goblet, Tuft, and Enteroendocrine. Stem cell clusters were classified as Normal (CAC), Abnormal 1 (young AKC), or Abnormal 2 (older AKC). The abnormal ISC states in the crypt structures are distinct from the cancer stem cells found in the cancer group. Trajectory analysis revealed that each stem cell population follows a distinct differentiation sequela, with abnormal ISC giving rise to transcriptionally divergent epithelial lineages. This was validated by integrating scRNA-seq data with spatial transcriptomics data from the same lines, showing that abnormal epithelial populations progressively overtake the normal crypt epithelium while retaining crypt structure. Differential gene expression analysis and Gene Set Enrichment Analysis showed that normal ISC was enriched for classic stemness markers (e.g., Lgr5, Lrig1, Smoc2). Abnormal 1 ISC began to lose these features and instead exhibited increased expression of cell-cycle regulators (e.g., Ccna2, Aurkb) and markers of oxidative stress (e.g., Prdx4, Gsta3, Gpx2). Gene expression profiles in Abnormal 2 ISC showed enrichment of pathways controlling p53 (e.g., Cdkn1a, Smad7), RAS/MAPK (e.g., Map2k1, Epha2), and PI3K/Akt/mTOR signaling (e.g., Akt3, Pik3r3, Mtor), as well as for an inflammatory response (e.g., Fos/Jun, Nfkbiz, Il18). Collectively, these findings show that early, non-transforming mutations push ISC into preneoplastic states marked by increased proliferation and stress response signaling favorable for malignant progression.

#5923 Optical pooled CRISPR screening coupling multiplexed guide RNA detection and single-cell spatial multi-omics.

Yi Cui[1], Marena I. Trinidad[2], Nurel Arriaran[2], Isabel Lee[1], Chia-Ying Lee[1], Shanshan He[1], Timothy Riordan[1], Joseph Beechem[1], Alexander E. Ehrenberg[2], Hanqin Li[2]

[1]Bruker Spatial Biology, Seattle, WA,[2]Innovative Genomics Institute, Berkeley, CA

Optical pooled screening (OPS) enables high-throughput measurement of cellular responses to genetic perturbations directly in situ. However, most sequencing-by-synthesis (SBS)-based OPS approaches remain limited to single-gene perturbation readouts or narrow phenotypic panels, restricting their ability to resolve the full complexity of perturbation-driven cellular states. In contrast, multiplexed in situ hybridization-based platforms offer an orthogonal detection strategy capable of simultaneously measuring multiple gRNAs and rich multiomic phenotypes within the same cell. We establish a framework for large-scale pooled CRISPR screening using the CosMx® Spatial Molecular Imager (SMI), enabling spatially resolved, single-cell whole-transcriptome profiling integrated with multiplexed gRNA detection. We evaluated diverse vector architectures expressing barcoded gRNAs to minimize guide-barcode decoupling, a major obstacle in pooled optical screens. Using a reporter-based functional assay, we identified an optimized vector design that preserves Cas9 activity while enabling sensitive, accurate, high-fidelity detection of barcoded gRNAs in situ. We further demonstrate seamless coupling of gRNA detection with high-dimensional RNA and protein profiling at subcellular resolution within the standard CosMx workflow. This provides a practical and scalable path to pooled optical combinatorial CRISPR screening with omics-level phenotypes. By leveraging whole-transcriptome spatial readouts, this approach captures global gene expression changes, emergent cell states, microenvironment-dependent phenotypes, and spatially coordinated transcriptional responses not detected using targeted phenotyping or dissociated single-cell methods. Importantly, spatially resolved whole-transcriptome OPS enables knockouts to be interpreted in their native architectural context, revealing how genetic perturbations influence cell-cell communication, signaling cascades, neighborhood formation, and ligand-receptor interactions. These capabilities position CosMx-enabled pooled CRISPR OPS as a transformative platform for cancer research. It allows investigators to map causal genetic mechanisms within complex in vitro and ex vivo models, uncover cryptic phenotypes that manifest only in spatially organized environments, and identify therapeutic targets invisible to conventional pooled screens. Together, these results establish a strong foundation for next-generation multimodal spatial CRISPR screening. The ability to perform pooled perturbations with unbiased, spatially resolved whole-transcriptome readouts will accelerate discovery of cancer-relevant pathways, support mechanism-of-action and resistance studies, and enable development of spatially aware functional genomics atlases and AI-driven predictive models of tumor biology.

#5924 Single-cell full-length transcriptome of lung cells reveals genetic effects on isoform regulation beyond eQTL.

Bolun Li[1], Thong Luong[2], Elelta Sisay[3], Jinhu Yin[4], Zixuan Zhang[5], Ju Hye Shin[6], Jinyoung Byun[7], Yoon Soo Chang[6], Maria Teresa Landi[8], Nat Rothman[9], Erping Long[10], Qing Lan[11], Christopher I. Amos[7], Tongwu Zhang[12], Jianxin Shi[13], Nicholas Mancuso[14], Haoyu Zhang[15], Jin Gu Lee[16], Eon Young Kim[6], Jiyeon Choi[17]

[1]NIH-NCI, Bethesda, MD,[2]National Cancer Institute, Rockville, MD,[3]NCI, Rockville, MD,[4]DCEG, National Cancer Institute, Rockville, MD,[5]Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA,[6]Yonsei University College of Medicine, Seoul, Korea, Republic of,[7]University of New Mexico Comprehensive Cancer Center, Albuquerque, NM,[8]Senior Investigator, Dceg, NCI-DCEG (Division of Cancer Epidemiology and Genetics), Bethesda, MD,[9]NCI-DCEG, BETHESDA, MD,[10]Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China,[11]NCI Div. of Cancer Epidemiology & Genetics, Bethesda, MD,[12]DCEG, National Cancer Insititute, Rockville, MD,[13]National Cancer Insititute, Potomac, MD,[14]Keck School of Medicine, University of Southern California, Los Angeles, CA,[15]National Cancer Inst. Div. of Cancer Epidemiology & Genetics, Bethesda, MD,[16]Department of Thoracic and Cardiovascular Surgery, Yonsei University College of Medicine, Seoul, Korea, Republic of,[17]NCI, Bethesda, MD

Background: Lung cancer is one of the most prevalent and life-threatening cancers worldwide. Genetic factors contribute to lung cancer risk in smokers and non-smokers, and genome-wide association studies (GWAS) identified > 50 genomic loci from diverse populations. Expression quantitative trait loci (eQTL) and splicing QTL (sQTL) analyses can reveal distinct genetic effects on gene- or transcript isoform-level regulation contributing to GWAS signals to identify target genes and elucidate etiology. However, current sQTL studies using short-read sequencing of bulk tissues fail to capture full-length and novel isoforms or cell-type-specific splicing events contributing to tumorigenesis.**Methods**: We present an isoform-level lung cell atlas from 129 never-smoking Korean women using single-cell long-read RNA-sequencing. Epithelial cells, where lung cancer originate, were enriched by FACS sorting. Isoform signatures of each lung cell type were identified by differential analysis. We mapped isoform-level QTLs (isoQTLs) using jaxQTL negative binomial model of pseudo-bulk counts. Colocalization and transcriptome-wide association study (TWAS) with GWAS were performed to prioritize susceptibility isoforms.**Results:** We identified 325,865 full-length isoforms from 360,133 lung cells, where 83% are novel isoforms not annotated in GENCODE v32. We identified isoform-level signatures of 37 lung cell types, where 67.2% of differential isoforms display larger differences than in gene levels. Isoform-QTLs (isoQTLs) identified unreported genes in bulk tissue-based sQTL studies attributed to cell-type-specific and unannotated isoforms. Compared to the barcode-matched short-read expression data, 46% of isoQTLs did not colocalize with eQTLs in the same cell type. Consistently, isoQTLs were distinctly enriched in the functional elements of splicing and post-transcriptional regulation. Colocalization of isoQTLs with lung cancer and trait GWAS signals nominated candidate isoforms, where 69% were previously unreported at the gene level. Moreover, 71% of GWAS-colocalized isoforms were independent from eQTLs, including *PPIL6-207* for lung cancer. TWAS of ancestry-matched lung adenocarcinoma identified 12 isoforms from the sub-threshold GWAS regions, which include lineage or cell-type-specific genes.**Conclusions:** We established an isoform-level lung cell atlas using single-cell long-read sequencing and detected isoQTLs that are cell-type-specific and independent from eQTLs. This isoform-level resource advances our understanding of cell-type-specific isoform regulation and its contribution to lung cancer and diseases.

#5925 Diagnostic concordance of WHO 2021 standards, WGS, and DNA methylation classification in diffuse gliomas: A single-center cohort study.

Jungyu Kim[1], Yongjae Lee[1], Jeong Seok Lee[1], Tae Hoon Roh[2], YOUNG SEOK JU[1]

[1]Korea Advanced Institute of Science and Technology, Daejeon, Korea, Republic of,[2]Neurosurgery, Ajou University School of Medicine, Daejeon, Korea, Republic of

Background: Diffuse gliomas exhibit significant clinical and molecular heterogeneity. However, the real-world concordance among WHO 2021 clinical diagnoses, whole-genome sequencing (WGS), and DNA methylation-based classification remains to be fully characterized.

Methods: We retrospectively analyzed 111 glioma patients treated at Ajou University Hospital (2013-2022). Following strict quality control (excluding low tumor fraction <20%, sample swaps, and recurrent-only cases), 93 patients (104 tumors) underwent WGS, enzymatic methyl-seq (EM-seq), and bulk RNA sequencing. Clinical diagnoses were updated to WHO 2021 standards using routine immunohistochemistry and targeted panel sequencing (astrocytoma, n=14; glioblastoma, n=76; oligodendroglioma, n=14). WGS was utilized to refine classifications based on *IDH* mutation, *TERT* promoter mutation, *EGFR* amplification, and chromosome 7 gain/10 loss. Methylation classes (e.g., GBM RTK I/II, Mesenchymal, MID, HGNET-BCOR) were assigned using an AI-driven classifier trained on Illumina array data (~20,000 CpGs). We evaluated the diagnostic concordance across these three layers.

Results: Diagnostic concordance was 100% for *IDH*-mutant astrocytomas and oligodendrogliomas across clinical, WGS, and methylation layers. In contrast, discrepancies emerged in cases clinically diagnosed as glioblastoma. One case was reclassified as *pediatric-type diffuse hemispheric glioma, H3 G34-mutant*. Another tumor in a 13-year-old patient, harboring complex alterations (*ATRX, PTEN, TP53, PIK3R1, PTPRD, CDKN2A*), was assigned non-GBM methylation labels (CONTR/INFLAM), precluding definitive subclassification. Among tumors classified as GBM RTK I (9/10), GBM RTK II (18/18), or Mesenchymal (15/16) by methylation, nearly all fulfilled molecular glioblastoma criteria (*IDH*-wildtype, TERTp mutation, *EGFR* amp, chr7+/10-). Conversely, tumors in the MID and non-GBM methylation classes frequently lacked these canonical features (17/21). Notably, WGS identified a *BCOR::EP300* translocation in a sample with an HGNET-BCOR methylation profile—a fusion undetected by routine clinical testing—expanding the spectrum of *BCOR*-altered CNS tumors beyond canonical internal tandem duplications.

Conclusions: Integrated WGS and methylation profiling in this single-center cohort demonstrate that DNA methylation-based classification refines WHO 2021 diagnoses, particularly for tumors routinely diagnosed as glioblastoma. This approach uncovers rare entities, such as pediatric-type gliomas and *BCOR*-altered tumors, that may be missed by targeted panels alone. Our findings support the implementation of a multi-omics framework to capture biological heterogeneity obscured by limited molecular markers.

#5926 Overcoming low SEPTIN14 expression to detect EGFR-SEPTIN14 fusion in RNA sequencing.

Suhyun Hwangbo, Sungyoung Lee

Department of Genomic Medicine, Seoul National University Hospital, Seoul, Korea, Republic of

EGFR-SEPTIN14 fusion is a rare but clinically significant oncogenic event, occurring in approximately 3-4% of glioblastoma (GBM) cases. This fusion retains the tyrosine kinase domain of EGFR fused to the coiled-coil domain of SEPTIN14 but is often undetected by RNA sequencing (RNA-seq) due to minimal SEPTIN14 expression outside the testis. To overcome this limitation, we developed a novel detection approach that leverages soft-clipped reads mapped to EGFR with perfect matches to SEPTIN14 sequences, enabling detection even in the absence of SEPTIN14 transcript reads. Using this method, we identified EGFR-SEPTIN14 fusion in positive controls, samples with DNA-based evidence, and additional previously undetected cases in the SNUH cohort. These GBM samples exhibited characteristic oncogenic mutation profiles, including TERT promoter mutation, EGFR amplification, and CDKN2A/B deletions, which may as markers indirectly indicating fusion presence. Notably, one fusion-positive patient treated with erlotinib showed a partial response, suggesting potential sensitivity to EGFR tyrosine kinase inhibitors. Application of our approach to the TCGA-GBM dataset also identified novel positive samples with similar mutation profiles, demonstrating scalability to whole transcriptome data. Overall, our strategy increased detection sensitivity 66.7%, addressing a key limitation of current RNA-seq fusion detection tools and supporting recognition of EGFR-SEPTIN14 fusion as an additional actionable oncogenic driver in solid tumors.

#5927 Integrative analysis of EMT and hippo pathway activity in gastric cancer peritoneal metastasis.

Juin Park[1], Woo Sun Kwon[2], Chan Hee Park[2], Tae Soo Kim[2], Jingmin Che[2], Sun Young Rha[3]

[1]Department of Medicine, Yonsei University College of Medicine, Seoul, Korea, Republic of,[2]Song-Dang Institute for Cancer Research, Yonsei University College of Medicine, Seoul, Korea, Republic of,[3]Yonsei University College of Medicine, Seoul, Korea, Republic of

Gastric cancer (GC) is one of the most aggressive malignancies, with poor patient outcomes often due to frequent peritoneal metastasis. Epithelial-mesenchymal transition (EMT) plays a pivotal role in this metastatic process. Recent studies highlight the involvement of the Hippo signaling pathway in regulating EMT and tumor progression. However, the molecular interplay between Hippo signaling components and *ARID1A*, a key chromatin remodeling factor frequently mutated or lost in GC, remains poorly understood. This study investigates the relationship between Hippo pathway dysregulation and *ARID1A* alteration in gastric cancer peritoneal metastasis (GCPM). Genomic and molecular profiling were performed on 47 GCPM cell lines of CIN and GS-like subtypes. Hierarchical clustering classified the cell lines into EMT and non-EMT groups, as well as into Hippo and non-Hippo groups. EMT and Hippo pathway activity scores were calculated using single-sample gene set enrichment analysis (ssGSEA). Expression of genes related to EMT, Hippo pathways, and *ARID1A* was analyzed at mRNA and protein levels. Invasiveness was evaluated by transwell invasion assays, and sensitivity to the YAP inhibitor CA3 (CIL56) was assessed using cell viability assays. Hierarchical clustering divided the cell lines into EMT (n=34) and non-EMT (n=13) groups. The EMT group was enriched in gene sets related to EMT, YAP, and TGF-β pathways and exhibited significantly higher EMT and Hippo pathway scores ($p < 0.05$). These molecular features were accompanied by markedly higher invasive capacity. CA3 sensitivity varied widely across PMGC cell lines, with a mean IC_{50} of 0.65 μM (range, 0.07-1.98 μM). No significant differences in CA3 sensitivity were observed across TCGA molecular subtypes, EMT, or Hippo subgroups. Notably, *ARID1A*-altered cell lines demonstrated significantly enhanced sensitivity to the YAP inhibitor CA3 compared with *ARID1A*-wild-type lines, suggesting a dependency on YAP activity in *ARID1A*-deficient tumors. Together, these findings indicate that *ARID1A* alterations enhance Hippo-YAP pathway dependence and confer increased sensitivity to YAP inhibition in GCPM. *ARID1A*-deficient tumors may therefore benefit from therapeutic strategies targeting the Hippo-YAP axis.

#5929 Global mRNA 3'UTR lengthening in small-cell neuroendocrine carcinoma.

Yi Zhang[1], Xiaofan Zhao[1], Ya-Mei Hu[1], Xiao-Xin Sun[2], Faming Zhao[3], Nicole Andeen[2], Rosalie C. Sears[2], Jonathan R. Brody[3], Joshi J. Alumkal[4], Gordon B. Mills[3], Mushui Dai[2], Zheng Xia[2]

[1]Biomedical Engineering, Oregon Health & Science University, Portland, OR,[2]Oregon Health & Science University, Portland, OR,[3]OHSU Knight Cancer Institute, Portland, OR,[4]Rogel Cancer Center, Ann Arbor, MI

Small-cell neuroendocrine carcinoma (SCNC) is a rare but highly malignant tumor subtype, primarily arising in the lung and prostate. The convergence of SCNCs across diverse tissues enables their identification through conserved SCNC-specific molecular markers, facilitating tumor subtype classification. As a critical post-transcriptional regulatory mechanism, alternative polyadenylation (APA) is involved in various biological processes, especially in tumor progression. However, its role across tumor subtypes remains unclear. Here, we revealed a global 3'UTR lengthening pattern due to APA in the SCNCs. We identified a set of conserved lengthening 3'UTR events across SCNCs originating from different tissues, showing a high association with neural development and related signaling pathways. More broadly, we developed a prediction model using a neural network framework to identify SCNCs based on the SCNC-specific APA signatures as additional molecular markers. Our work provides new insights into the post-transcriptional landscape of SCNCs and establishes APA as a potential biomarker for SCNC identification.

#5930 Spatial transcriptomics of colonic neoplasia presenting mucinous adenocarcinoma with genetically-engineered mouse model.

Haruki Sada[1], Hiroaki Niitsu[2], Hikaru Nakahara[2], Masashi Miguchi[3], Hirotaka Tashiro[1], Hideki Ohdan[4], Takao Hinoi[2]

[1]Surgery, NHO Kure medical center, Kure, Japan,[2]Clinical and Molecular Genetics, Hiroshima University Hospital, Hiroshima, Japan,[3]Department of Gastroenterological Surgery, Hiroshima Prefectural Hospital, Hiroshima, Japan,[4]Gastroenterological and Transplant Surgery, Hiroshima University,, Hiroshima, Japan

Background: We previously established a genetically engineered mouse model in which Apc and Tgfbr2 are specifically knocked out in the colonic epithelium (CDX2P-G19Cre; $Apc^{flox/+}$; $Tgfbr2^{flox/flox}$). In this model, 40% of mice developed mucinous adenocarcinoma (MAC) in the colon, while 25% exhibited non-mucinous high-grade dysplasia with the same genotype. The mucinous tumors invaded beyond the muscularis mucosae, and nuclear localization of β-catenin was observed in the deep invasive lesion. To elucidate the mechanisms underlying the development of mucinous colorectal carcinoma, we previously performed transcriptomic analysis comparing MAC and non-mucinous dysplasia. In the present study, we conducted spatial transcriptomic analysis to characterize the spatial distribution of gene expression, cellular composition, and cell-cell interactions within MAC tissues.**Methods:** Tumors diagnosed as MAC by H&E staining were obtained from CDX2P-G19Cre; $Apc^{flox/+}$; $Tgfbr2^{flox/flox}$ mice. FFPE tissue blocks were sectioned to prepare libraries and sequencing was performed using the NovaSeq platform. Data were analyzed using Space Ranger software and visualized in Loupe Browser (10x Genomics).**Results:** Spatial transcriptomic profiling revealed heterogeneous tumor microenvironments within the same MAC lesion. In the deepest invasive lesion, increased infiltration of SPP1 (secreted phosphoprotein 1)-positive macrophages was identified, suggesting the presence of a localized immunomodulatory niche associated with invasion.**Conclusions:** Spatial transcriptomic analysis demonstrated distinct intratumoral regions characterized by unique cellular compositions and gene expression profiles. These findings provide novel insights into the spatial heterogeneity and progression mechanisms of mucinous colorectal carcinoma, potentially informing future therapeutic strategies.

#5931 Modeling of bladder cancer evolution from field effects by multi-platform spatial mapping on the whole-organ scale.

Bogdan A. Czerniak[1], Sangkyou Lee[1], Khanh Ngoc Dinh[2], Huiqin Chen[3], Yishan Wang[3], Jiansong Chen[3], June Goo Lee[1], Sung Yun Jung[4], Nagireddy Putluri[5], Neema Navai[6], David McConkey[7], Charles Chuanhai Guo[1], Peng Wei[3], Marek Kimmel[8]

[1]Department of Pathology, UT MD Anderson Cancer Center, Houston, TX,[2]Irving Institute for Cancer Dynamics & Department of Statistics, Columbia University, New York, NY,[3]Department of Biostatistics, UT MD Anderson Cancer Center, Houston, TX,[4]Molecular & Cellular Biology, Baylor College of Medicine, Houston, TX,[5]Metabolomic Core, Baylor College of Medicine, Houston, TX,[6]Department of Urology, UT MD Anderson Cancer Center, Houston, TX,[7]Department of Urology, University of Rochester, Rochester, NY,[8]Department of Statistics, Rice University, Houston, TX

Introduction: Understanding the mechanisms driving evolution of the mucosal field effects to invasive cancer is not possible unless they are analyzed in the context of their geographic distribution in the entire organ. Bladder cancer is an ideal model disease for such studies as it effects an anatomically simple organ permitting the multi-platform analysis of the affected mucosa on the scale of whole organ.

Methods: We performed comprehensive multi-platform analyses on nine cystectomies with invasive bladder cancer comprising of 433 mucosal tissue samples analyzed by bulk whole-exome and mRNA sequencing, genome-wide copy number variation and methylation profiling complemented with proteomics, metabolomic and single cell sequencing spatial mapping. The data from multi-platform profiling were geographically annotated to microscopically normal urothelium (NU) and low-grade intraurothelial neoplasia (LGIN; n=243), high-grade intraurothelial neoplasia (HGIN; n=90), and invasive urothelial carcinoma (UC; n=100).

Results: We identified ~16000 non-silent mutations per cystectomy. In two maps the hypermutator phenotypes with ~48000 and ~57000 mutations were detected. The mutational analysis identified three types of mutations based on the variant allele frequency and geographic distribution referred to as α, β, and Ƴ. Time modeling by a parsimonious time-continuous Markov model incorporating cell migration (immigration) and growth (branching) revealed that bladder carcinogenesis takes approximately three decades and can be divided into dormant and progressive phases. Low selection α mutations were private and most frequent. They continuously developed over 30 years primarily in the dormant phase of carcinogenesis. β mutations clonally expanded regionally and signified the advent of progressive phase of carcinogenesis which lasted five years. Ƴ mutations were the ultimate drivers of the progressive phase and emerged 2-3 years before the final progression to invasive bladder cancer. The mutational landscape developed on the background of severely dysregulated urothelial differentiation and increased immune infiltration with T-cell exhaustion. The proteomic and metabolomic changes involved a wide-spread disorganization of glycolipid energy metabolism with downregulation of mitochondrial oxidative phosphorylation.

Conclusion: Dysregulated mitochondrial energy metabolism converging on anerobic glycolysis and oxidative phosphorylation with Warburg phenotype emerged as the leading mechanism driving the progression of mucosal field effects to invasive cancer.

#5932 Cell free DNA based genomic analysis revealed the distinct whole genome landscape and chronology of intravascular large B cell lymphoma.

Takuto Mori[1], Kazuyuki Shimada[2], Kaito Mimura[1], Suguru Fukuhara[3], Koji Izutsu[3], Daisuke Kawauchi[4], Yoshitaka Narita[4], Akiko Miyagi Maeshima[5], Ryosuke Koyamada[6], Nobuhiro Hiramoto[7], Hirona Maeda[8], Nobuyuki Kakiuchi[8], Ai Okada[9], Kenichi Chiba[9], Yuichi Shiraishi[9], Akifumi Takaori–Kondo[10], Seishi Ogawa[8], Akihiro Tomita[11], Kenichi Yoshida[1]

[1]Division of Cancer Evolution, National Cancer Center Research Institute, Tokyo, Japan,[2]Department of Hematology and Oncology, Nagoya University Graduate School of Medicine, Nagoya, Japan,[3]Department of Hematology, National Cancer Center Research Institute, Tokyo, Japan,[4]Department of Neurosurgery and Neuro-Oncology, National Cancer Center Research Institute, Tokyo, Japan,[5]Diagnostic Pathology, National Cancer Center Research Institute, Tokyo, Japan,[6]Department of Hematology, St. Luke International Hospital, Tokyo, Japan,[7]Department of Hematology, Kobe city medical center general hospital, Kobe, Japan,[8]Department of Pathology and Tumor Biology, Kyoto University, Kyoto, Japan,[9]Division of Genome Analysis Platform Development, National Cancer Center Research Institute, Tokyo, Japan,[10]Department of Hematology, Kyoto University, Kyoto, Japan,[11]Department of Hematology, Fujita Health University School of Medicine, Tokyo, Japan

The scarcity of tumor cells in biopsies has hampered genomic analysis of intravascular large B-cell lymphoma (IVLBCL), an aggressive lymphoma characterized by selective tumor growth within vessels. The utility of cell-free DNA (cfDNA) for genomic studies, demonstrated in our previous work, may help reveal the genetic alterations of IVLBCL, which might differ from those of related subtypes of lymphoma subtypes, such as immune-privileged large B-cell lymphoma (IP-LBCL).To comprehensively characterize the mutational landscape of IVLBCL, we performed whole-genome and whole-exome sequencing of 36 IVLBCL samples, which are derived from cfDNA (n = 32) and patient-derived xenografts (n = 4), as well as 25 biopsy or surgical samples from IP-LBCL, including 12 central nervous system and 13 testicular lymphomas, and compared their genomic profiles.The majority of cfDNA from IVLBCL was derived from tumor cells (median, 88.8%; range, 55-98%). Most frequently mutated genes were *PIM1*, *MYD88, CD79B, TBL1XR1, MPEG1*, and *ETV6*. Mutational signature analysis showed that clustered mutations, such as kataegis, were caused by activation-induced cytidine deaminase (AID). However, in general, driver mutations such as *MYD88* mutations were not affected by AID activity. Copy number (CN) analysis showed recurrent arm-level changes such as loss-of-heterozygosity (LOH) of 9p and 3p, gain of 1q, and deletion of 6q. As for focal CN changes and/or structural variants (SVs), deletions involving *CDKN2A, TOX, PRDM1*, and *CD58*, as well as focal amplification or multiple types of SVs involving *CD274/PDCD1LG2*, were frequently observed in IVLBCL. Timing analysis indicated that *MYD88* mutations and 9p LOH targeting *CDKN2A* were acquired at early stages of tumor evolution.Comparing IVLBCL and IP-LBCL, most genetic abnormalities, including early *MYD88* mutations and 9p changes, were shared, but several lesions differed significantly between the two. *RAC2* coding mutations were enriched in IVLBCL (33% vs 0%). As for immune pathway, one of the notable differences was the frequency of *CD274/PDCD1LG2* abnormalities, which were observed in about 40% of IVLBCL but were rarely detected in 4% of IP-LBCL. In contrast, *B2M* abnormalities were more frequent in IP-LBCL than IVLBCL. Although the earliest driver mutations and CN abnormalities in IVLBCL are similar to those in IP-LBCL, our findings suggest that the immune-evasion-related genetic alterations uniquely observed in IVLBCL may reflect its distinct interactions with the tumor microenvironment and could help distinguish IVLBCL from IP-LBCL.

#5933 Whole-genome sequencing of lung neuroendocrine neoplasms reveals a *TP53*^{WT} / *RB1*^{WT} subtype with *CCND* amplification.

Minjun Ha[1], Kwon Joong Na[2], Soyeon Kim[3], Miso Kim[4], Bhumsuk Keam[5], Tae Min Kim[5], Dong-Wan Kim[5], Jeonghwan Youk[4], Young Tae Kim[2]

[1]Cancer Research Institute, Integrated Major in Innovative Medical Science, Seoul National University College of Medicine, Seoul, Korea, Republic of,[2]Cancer Research Institute, Department of Thoracic and Cardiovascular Surgery, Seoul National University Hospital, Seoul National University College of Medicine, Seoul, Korea, Republic of,[3]Cancer Research Institute, Biomedical Research Institute, Seoul National University Hospital, Seoul National University College of Medicine, Seoul, Korea, Republic of,[4]Cancer Research Institute, Department of Internal Medicine, Seoul National University Hospital, Seoul National University College of Medicine, Seoul, Korea, Republic of,[5]Cancer Research Institute, Integrated Major in Innovative Medical Science, Department of Internal Medicine, Seoul National University Hospital, Seoul National University College of Medicine, Seoul, Korea, Republic of

Background: Lung neuroendocrine neoplasms (LNENs) comprise a spectrum of entities, including typical/atypical carcinoid, large cell neuroendocrine carcinoma (LCNEC), and small cell lung cancer (SCLC). Data from both whole-genome sequencing (WGS) and targeted panel sequencing show that SCLC is typically associated with biallelic inactivation of *TP53* and *RB1* in 91% of cases. While SCLC has been extensively profiled using WGS, other LNEN subtypes have largely been investigated using targeted panels or whole-exome sequencing, limiting comprehensive genomic characterization. To advance the understanding of early-stage LNEN biology, we performed WGS on a surgically resected cohort spanning the full spectrum of LNENs.

Methods: We analyzed ~30× WGS data from 58 surgically resected LNENs at Seoul National University Hospital (carcinoid n=11; LCNEC n=22; SCLC n=25). Somatic single-nucleotide variants (SNVs), structural variants (SVs), copy-number profiles, and mutational signatures were evaluated.

Results: Across the cohort, median SV/SNV burdens were 0.015 [28/1,929] for carcinoids, 0.006 [186/28,954] for LCNECs, and 0.002 [62/36,181] for SCLCs. Three SCLC samples exhibited markedly elevated SV/SNV ratios compared with other SCLCs (patient #135: 0.092 [345/3,750]; patient #144: 0.158 [331/2,098]; patient #147: 0.031 [94/3,053]; other SCLCs: 0.000-0.005). This pattern was absent in LCNECs but was detected in one carcinoid sample (patient #126: 0.024 [50/2,128]). These four cases (three SCLCs, one carcinoid) uniformly lacked tobacco-associated mutational signatures and were *TP53*^{WT}/*RB1*^{WT}. Two samples from patients #126 and #135 demonstrated chromothripsis involving chromosomes 3 and 11, whereas the remaining two from patients #144 and #147 showed dense rearrangements between chromosomes 12 and 20 with prominent copy-number oscillations. These alterations converged on amplification of *CCND1* (chr11) or *CCND2* and *CDK4* (chr12), with shared losses involving *FHIT*, *TGFBR2*, and additional copy-number alterations on partner chromosomes. Pathologic review further revealed coexisting atypical carcinoid and SCLC components in one SCLC case (patient #135).

Conclusions: All four cases displayed convergent *CCND*-*CDK4* pathway activation and characteristic complex SV-driven genome remodeling. Together with the histological coexistence of atypical carcinoid and SCLC in patient #135, these data raise the possibility that *CCND*-dependent SCLC may evolve from a carcinoid precursor. The observation of one carcinoid in patient #126 provides independent evidence of *CCND*-dependent tumorigenesis. Although limited by sample size, our findings highlight a distinct, early-stage LNEN subset defined by catastrophic SV events and G1-S checkpoint dysregulation, suggesting potential therapeutic vulnerability to cell-cycle-targeted strategies.

#5934 Genomic signatures of chromosomal instability from a pan-cancer landscape of haplotype-specific copy-number alterations.

Chunyang Bao[1], Matthew Leventhal[2], Hansol Park[1], Gang-Hee Lee[1], Ryul Kim[1], Won-Chul Lee[1], Jonghoon Lee[1], Yoonsuh Lee[1], Beomki Lee[3], David Lehotzky[4], Ron Solan[4], Antonia Kowalewski[4], Xavi Loinaz[4], Vasuki Narasimha Swamy[4], David I. Heiman[4], Samantha Van Seters[4], Saveliy Belkin[4], Sam Wiseman[4], Andrew D. Cherniack[4], Luis Antonio Corchete Sanchez[4], Brian P. [1]Inocras Inc., San Diego, CA,[2]Department of Data Science, Dana-Farber Cancer Institute, Boston, MA,[3]Graduate School of Medical Science and Engineering, Korea Advanced Institute of Science and Technology, Dajeon, Korea, Republic of,[4]Cancer Program, Broad Institute of MIT and Harvard, Cambridge, MA

Whole-chromosome and segmental copy-number changes are nearly ubiquitous in human cancers. Here, we present the first pan-cancer landscape of haplotype-specific somatic copy number alterations (SCNAs) in nearly 9,000 cancers across 30 cancer types from The Cancer Genome Atlas (TCGA) whole-genome sequencing (WGS) data. This analysis was primarily carried out with CancerVision, a proprietary bioinformatic workflow for detecting both somatic and germline variants in cancer samples developed by Inocras. The haplotype-specific copy-number analysis provides three pieces of information not available from previous analysis. First, the haplotype-specific SCNAs enables a more accurate assessment of aneuploidy, i.e., the fraction of the cancer genome with copy number alterations. Second, the haplotype resolution directly resolves interactions between germline variant genotypes and SCNAs. Finally, haplotype-specific SCNAs directly inform the instigating mechanisms of chromosomal instability. In this study, we provide examples demonstrating each scenario. Notably, we observed a diverse range of haplotype-specific SCNA patterns, each reflecting a distinct mechanism of chromosomal instability, including arm-level alterations related to WGD, segmental changes indicative of breakage-fusion-bridge (BFB), complex rearrangements displaying signatures of successive BFB cycles and chromothripsis, as well as focal amplifications consistent with extrachromosomal DNA (ecDNA) formation. Our analysis of haplotype-specific SCNAs in TCGA suggests a mechanism-based classification of copy-number patterns linked to chromosomal instability. Extending this framework to treatment-exposed samples could provide new insights into synthetic lethality dependencies, with potential diagnostic and therapeutic implications for cancer precision medicine.

#5935 Accurate detection of DNA variants and ecDNA from prostate FFPE biopsies using LinkPrep.

Shiting Li[1], Alexander Fortuna[2], Rahul Mannan[1], John Zachary Sanborn[3], Yuping Zhang[1], Xuhong Cao[1], Natalie Fredriksson[2], Lisa Munding[2], Saravana M. Dhanasekaran[1], Marcin Cieslik Cieslik[1], Arul M. Chinnaiyan[1]

[1]University of Michigan, Ann Arbor, MI,[2]Cantata Bio, LLC, Scotts Valley, CA,[3]Dovetail Genomics, Scotts Valley, CA

Detecting genomic variants and structural rearrangements in formalin-fixed paraffin-embedded (FFPE) tumor biopsies simultaneously remains challenging and lacks comprehensive clinical utility assessments. Here we performed the novel Dovetail®-FFPE (LinkPrep), an *in vitro* transposition Hi-C assay free from restriction enzyme bias to 20 prostate cancer samples. These included 5 normal adjacent to tumor (benign), 10 primary localized, and 10 metastatic castration-resistant prostate cancer (mCRPC) patient samples. By leveraging patient and site-specific in-house matched fresh-frozen (FF) whole-genome sequencing (WGS), exome capture sequencing, transcriptomics sequencing, and a publicly available cohort of 80 mCRPC FF Hi-C samples data, we performed a comprehensive evaluation on FFPE LinkPrep library preparation and sequencing performance. Our evaluation covered multiple aspects including 3D genome contact detection, single nucleotide variant (SNV)/indel calling, copy number variation analysis, structural variant (SV) detection, ecDNA detection and compartments definition.Our analysis shows that FFPE sample achieves good contact capture efficiency that is slightly lower but comparable performance (Wilcoxon test p=0.33) to the FF Hi-C data for mCRPC tumors. For SNV/INDEL calling, using FF WGS or exome capture sequencing as the gold standard, the assay reached a mean recall rate of 97% across five samples based on two different variant- calling algorithms. By comparing with 2 FF WGS, 4 transcriptomic and 80 external Hi-C data, we further demonstrated that FFPE samples can accurately identifies whole-genome copy number variations and chromatin compartments. Additionally, we developed a robust SV-calling pipeline with carefully designed denoising steps suitable for FFPE samples that accurately detected common structural variants in prostate cancer, such as TMPRSS2-ERG fusions (6/7) and FOXA1mutations (2/2). Lastly, by applying the new developed Hi-C specific pipeline for extrachromosomal DNA (ecDNA) detection, we identified AR ecDNA in one sample, which was supported by matched FF WGS AmpliconSuite result. Overall, the comprehensive analysis and performance evaluation demonstrates that FFPE LinkPrep accurately captures DNA-level variants and holds strong potential for application in FFPE clinical samples.

#5936 Massively parallel installation and evaluation of cancer coding mutations.

Xiaoyu Zhao[1], Isabella Panagiotou[1], Rachel Collier[1], Catalina Fogg[1], Katherine Licon[1], John J. Y. Lee[1], Dylan Fong[1], Jing Chen[1], Paulina Rios[2], Ondine Atwa[2], Samuel I. Gould[2], Ingoo Lee[1], Jiahao Gao[1], Francisco J. Sanchez-Rivera[2], **MARCUS R. KELLY**[1], Trey Ideker[1]

[1]Medicine, University of California San Diego School of Medicine, La Jolla, CA,[2]Koch Inst. for Integrative Cancer Research at MIT, Cambridge, MA

Most cancer coding mutations are of unknown function, limiting their biological and therapeutic interpretation. While prime editing enables precise genomic alterations, mutations often reside in sequence contexts unfavorable to current prime-editing guide RNA (pegRNA) designs. Here we develop CodonPrime, a prime-editing framework that exploits codon degeneracy surrounding a mutation site to substantially expand its targeting set of pegRNAs. We use this approach to screen ~2500 coding mutations spanning 298 cancer genes, yielding a 9.2-fold increase in amino-acid editing efficiency over conventional prime editing. Approximately 10% of coding mutations enhance cell growth, recovering known oncogenic hotspots and revealing oncogenic potential for previously uncharacterized mutations (e.g. $HNF1A^{R272C}$). Our analysis uncovers dominant effects in paralogous genes (e.g. RHOBTB1/2) and organization of mutant phenotypes in pathways (e.g. PI3K-MTOR signaling). We formulate a general-purpose transformer for design of CodonPrime pegRNAs, enabling scalable interrogation of human coding variants.

#5937 Panorama of chromosomal instability in 1209 lung cancer genomes.

YANG YANG[1], Tongwu Zhang[2], **Lixing Yang**[1], Maria Teresa Landi[2]

[1]University of Chicago, Chicago, IL,[2]National Cancer Institute, Bethesda, MD

Lung cancer is the leading cause of cancer death worldwide in both men and women. It is a highly heterogeneous disease primarily driven by tobacco smoking. About 20% of lung cancers occur among never smokers. There are major differences between lung cancers in patients who have never smoked (LCINS) and who have smoked in patient ancestry, sex, tumor histology and clinical features. LCINS occur more frequently in Asians and females and are predominantly adenocarcinomas. *EGFR* mutations are enriched in LCINS, whereas *KRAS* and *TP53* mutations are more common in tumors from patients who have smoked. Our understanding of the etiology of LCINS is still limited. Here, we perform a comprehensive study in 1,209 whole-genome sequenced lung cancers collected from 30 different locations across four continents through Sherlock-Lung Project as well as published studies. Among these tumors, 1024 of them are adenocarcinomas and 864 are LCINS. This cohort represents the largest genomics cohort in lung cancer to date. Our study focuses on somatic structural variations (SVs) which are large-scale chromosomal rearrangements. In total, we detect 182,429 somatic SVs in 1209 tumor samples with an average of 151 SVs per sample. Complex SVs, such as chromothripsis, are studied separately from simple SVs because they arise through one-time catastrophic chromosome shattering and rejoining. About two-thirds of the SVs in our cohort are part of complex events. We deconvolute a total of 8 complex SV signatures based on event topology and 8 simple SV signatures using non-negative matrix factorization. They likely represent divergent molecular mechanisms. Among these, chromatin bridge signature, driven by dicentric chromosomes, is the most abundant complex SVs; and median size deletion is the most common simple SVs. SVs are more abundant in tumors from patients who have smoked; however, they are more complex and play more important roles in tumorigenesis in LCINS. The SV breakpoints have distinct distributions across the genome depending on the signatures due to combined effects of mutagenesis and positive selection. Many established cancer-driving genes are recurrently rearranged by multiple SV signatures suggesting functional convergence of these genome instability mechanisms. *EGFR* mutations and *KRAS* mutations profoundly and independently shape the SV landscape. *EGFR* mutant tumors have higher SV burden and more cancer-driving SVs. In contrast, *KRAS* mutations are associated with lower SV burden and fewer driver SVs. Our study has deepened our understanding of genomic landscape and etiology of lung cancer.

#5938 High-resolution multi-omic dissection of bone marrow in TP53-mutant acute myeloid leukemia.

[1]Informatics and Predictive Sciences, Bristol Myers Squibb, Cambridge, MA,[2]Weatherall Institute for Molecular Medicine, Headington,[3]Informatics and Predictive Sciences, Bristol Myers Squibb, San Diego, CA,[4]Translational Development, Bristol Myers Squibb, Brisbane, CA,[5]Informatics and Predictive Sciences, Bristol Myers Squibb, Summit, NJ,[6]Informatics and Predictive Sciences, Bristol Myers Squibb, Seattle, WA,[7]University of Oxford, Oxford, United Kingdom,[8]Translational Development, Bristol Myers Squibb, Summit, NJ,[9]Informatics and Predictive Sciences, Bristol Myers Squibb, Sevilla, Spain,[10]Translational Development, Bristol Myers Squibb, Cambridge, MA,[11]University of Oxford, Department of Biochemistry, Oxford, United Kingdom

TP53-mutated (*TP53*m) AML is a distinct biological entity with adverse prognosis, characterized by prominent clonal heterogeneity; cells within a patient may exhibit wild type, monoallelic, or biallelic *TP53* status, alongside co-occurring genomic alterations and transcriptomic heterogeneity. This complexity poses challenges in accurately aligning genotypes with transcriptomic and epigenomic profiles at single-cell resolution.

To address this, we integrated single-cell RNA-seq (10x and long-read Oxford Nanopore, ONT) with open chromatin profiles (scATAC-seq) and whole-genome sequencing (WGS) to capture structural variants (SV), copy number alterations (CNV), and single nucleotide variants (SNV) from bone marrow samples taken from a cohort of 47 *TP53*m, 7 *TP53* wild-type (wt) AML patients, and 4 healthy donors.Cell type annotation for scRNA-seq (335K cells) utilized a bone marrow reference dataset, while scATAC-seq (130K cells) was annotated using the ArchR label-transfer method. Cell type proportions were concordant across modalities (median correlation, $\rho = 0.76$).

SV and CNV profiles showed that *TP53*m samples displayed frequent loss of Chr5q (72.5%), Chr17p (52.5%), and Chr7q (40%); chromothripsis was present in 16 (40%) samples. All these events were reported to occur in under 3% of *TP53*wt AMLs. In contrast, *TP53*m samples showed relative paucity of SNV co-mutations.We leveraged CNV profiles to map genetic gain/loss effect in scRNA and scATAC-seq compared to healthy donors, providing a clear separation of cells with abnormal CNV profiles. In TP53m AML, apart from mature lymphoid populations, >80% of cells including lymphoid progenitors (LMPP), displayed abnormal CNV status. Abnormal CNV cell fractions by sample strongly correlated with orthogonal tumor purity estimations from WGS for scRNA ($\rho = 0.81$) and ATAC-seq ($\rho = 0.84$).Single-cell SNV mapping was attempted with the standard 10x pipeline, where we detected driver hotspot mutations in only ~3% of non-lymphoid cells. To improve mutation calling, we developed a new SNV pipeline using long-read ONT chemistry on full-length cDNA. SNV calling rates rose to 15% in non-lymphoid cells. Mature lymphoid cells showed low alteration rates: SNVs (1-2%), CNVs (5%), while expressing lineage-specific markers, confirming cell-type assignment.

Long-read *TP53* transcript sequencing also enabled phased variant genotyping. Combined with WGS SV and CNV profiles, we observed that *TP53* loss-of-function dosage distinctly associates with the genomic architecture: biallelic loss of *TP53* was associated with extensive intrachromosomal breaks and chromothripsis, whereas monoallelic loss primarily induced numerical chromosomal changes.

This multi-omic framework enables high-resolution characterization of somatic genomic alterations at the single-cell level in *TP53*m AML, providing a powerful platform for mechanistic interrogation of disease biology.

#5939 A large-scale sequencing study identifies a novel non-coding structural variant as a high-penetrance susceptibility variant for melanoma.

Approximately 10% of cutaneous malignant melanoma cases are familial. Variants in *CDKN2A* account for ~40% of melanoma-prone families, with 10% more explained by other established genes. Strikingly, many unexplained families nonetheless show genetic linkage to chromosomal band 9p21, which harbors *CDKN2A*, suggesting that high-penetrance non-coding variants in the region may contribute to familial risk.As a part of a large-scale study of high-risk melanoma families from the Mediterranean region, we conducted germline whole-genome sequencing (WGS) on a melanoma case from a four-case family from Genoa, Italy, that is negative for variation in known susceptibility genes. We identified a novel 100kb deletion mapping to 9p21 205kb from *CDKN2A* and verified cosegregation in the two other available cases. The deletion is not protein-coding but contains annotated melanocyte enhancer elements and open chromatin that we find to interact with the promoters of the p16 and p14 transcripts of *CDKN2A* in melanocytes using H3K27Ac Hi-ChIP.To identify additional deletion carriers in whole-exome sequencing (WES) data, we searched for nearby exonic variants that cosegregate in the discovery family to serve as a proxy of the deletion, identifying a rare cosegregating missense variant in *MTAP* (rs755147810; chr9: 21,802,755:T:G; p.Ser3Ala; gnomADv4.1 Non-Finish European MAF: $3.4x10^{-6}$). We assessed this variant in WES data from 3,574 high-risk Mediterranean melanoma patients and 2,673 controls, identifying 17 additional Italian melanoma cases (mostly from Genoa) and a single control, and subsequently confirmed all carriers of rs755147810 harbored the deletion. We verified cosegregation of the deletion in all available cases from four additional families (3/3, 2/2, 2/2 and 2/2 cases). The association of the *MTAP* variant with melanoma risk was highly significant when considering unrelated individuals from Italy, Spain, and Greece (3,219 cases and 2,266 controls; $P = 4.34 \times 10^{-4}$; OR = 13.88) as well as Italian samples alone (2,170 cases, 1,888 controls; $P = 4.14 \times 10^{-4}$; OR = 14.01). Analysis of a shared haplotype among carriers suggests a founder haplotype with the most recent common ancestor (MRCA) dating approximately 26 generations, *i.e.* the 17th century, when Italy was repeatedly struck by devastating outbreaks of plague that profoundly affected major urban and commercial centers. The coincidence of the estimated MRCA timeframe with this major population collapse suggests that the demographic effects of the plague epidemic may have contributed to the persistence of this genetic variant in modern populations.In conclusion, our study provides evidence of a distant high-penetrance non-coding variant conferring melanoma susceptibility, with potential translational impact on facilitating screening and early-detection efforts in high-risk individuals.

#5940 Chromosome-level phasing to resolve haplotypes using multiomic data in multiple myeloma reveals complex distal interactions between chromosomes that impacts epigenetic states and gene expression.

Nathan J. Becker[1], Enze Liu[1], J. Zachary Sanborn[2], Attaya Suvannasankha[3], Kelvin Lee[3], Dickran Kazandjian[1], Benjamin Diamond[1], Abhishek Pandey[1], Rafat Abonour[1], Ola Landgren[1], Elizabeth M. Munding[2], Aneta Mikulasova[4], Brian A. Walker[1]

[1]University of Miami, Miami, FL,[2]Dovetail Genomics, Scotts Valley, CA,[3]Indiana University, Indianapolis, IN,[4]University of Edinburgh, Edinburgh, United Kingdom

Introduction: Linking markers together into large phase-blocks, and examining the interaction of different sequencing modalities, allows complex genomic and epigenomic states to be integrated to generate true multiomic haplotypes at the chromosomal level.
Methods: Fourteen multiple myeloma patient-derived xenografts were used to generate multiomic data including short- (Illumina) and long-read (PacBio) whole genome sequencing (WGS) to identify single nucleotide variations (SNVs), copy number (CN) abnormalities, structural variation (SV), and DNA methylation, as well as expression, chromatin states (Cut&Tag-IT), and Micro-C/LinkPrep (Dovetail Genomics) to identify 3D chromatin architecture. Chromosome-scale haplotypes of SNVs, SVs, CNVs, DNA methylation, expression, and chromatin marks were generated.
Results: For the first time, complete haplotype-resolved assemblies at the chromosomal level have been generated in multiple myeloma. A 100x coverage genome Micro-C/LinkPrep libraries we were able to phase the long and short arms of each chromosome, resulting in an average 94.3% haplotype phasing per autosome - thereby generating chromosome length haplotypes up to 241.9 Mb. Haplotype-specific heatmaps were generated allowing us to examine the interaction of complex SVs across chromosomes. In one sample, we identified a primary t(11;14) and additional SV events linked to the t(11;14) including a t(3;14), t(11;17), and t(3;17) which created a cyclical pattern. We found that 70-83.5% of reads support specific combinations of haplotype interactions, and that all four SV events were linked and involved the same haplotypes on each chromosome. The pattern of interactions combined with breakpoint analysis in this case indicated a four-way complex reciprocal translocation between chromosomes 3,11,14 and 17. Integration of epigenetic data in this complex SV showed DNA hyper-methylation 17 kb upstream of *CCND1* next to the t(11;14) breakpoint as well as increased H3K27ac marks on the same haplotype, indicating spreading of the activating broad domain from the *IGH* super-enhancer on chromosome 14. Equally, the hypomethylated DNA marks at the *IGH* promoter are spread to chromosome 3, via the t(3;14), resulting in over-expression of the proto-oncogene *SKIL*. The same is true for the t(3;17), which shows hypomethylation on both sides of the breakpoint, compared to the non-translocated allele.
Conclusion: We have generated the first chromosome scale haplotype-resolved genomes in multiple myeloma and integrated them with epigenetic states to identify interactions across chromosomes and resolve complex SVs as well as their epigenomic consequences to understand the intricate nature of how the genome is organized.

#5941 Large-scale analysis reveals distinct molecular subtypes in real-world gastric cancer data.

Akul Singhania[1], Swati Kaushik[1], Brandon L. Mapes[1], Lee F. Langer[1], Kayla R. Bastian[1], Samantha Cowher[1], Yaakov E. Stern[1], Bo Hu[2], Gonzalo Lopez[2], Ruslan Novosiadly[2], Maria Ortiz-Estevez[2], Kai Wang[2], Nick Callamaras[1], Richard A. Klinghoffer[1], Justin Guinney[1], Radia M. Johnson[1]

[1]Tempus AI, Inc., Chicago, IL,[2]Bristol Myers Squibb, Princeton, NJ

Introduction

Gastric cancer (GC) remains a global health concern, with limited outcome improvement despite targeted therapy. Here, a large real-world dataset of diverse disease stages and tumor sites was used to profile the molecular and clinical landscape of GC.

Methods

De-identified clinico-genomic records from GC patients profiled with Tempus xT (DNA) and xR (RNA)-seq assays were analyzed. Molecular subtyping used non-negative matrix factorization on xR data from primary tumors of the stomach and esophagus (n=1,385; 89.9% Stage III/IV). A classifier trained on tumor-intrinsic features was applied to metastatic sites (n=640; 99% Stage III/IV) and samples with low subtype probability were excluded (n=159). Real-world overall survival (rwOS), from first-line therapy to death was evaluated in patients with available data (31.5%). Sensitivity analysis for delayed entry included prospective-like patients with samples received/sequenced before treatment. Only subtypes with ≥20 patients contributing rwOS data were reported.

Results

To enhance interpretability and biological relevance, nine clusters were identified and merged into seven molecular subtypes with prognostic differences (p=0.01) based on centroid distance. The G1 subtype (25.6%; median OS 12.2 months, 95% CI 6.4-16.1) was associated with chromosomal instability (CIN) (78% CIN-High), Stage IV (91%), liver site samples (26%), microsatellite stability (MSS; 97%), and low tumor mutation burden (TMB<10; 97%). G1 exhibited *TP53* mutations (81.9%), *CCNE1* amplifications (16.7%), and *CDKN2A*/*B-MTAP* deletions (~15%). The G2 subtype (21.8%; median OS 20.6 months, 95% CI 14-22.2) had the highest TMB (TMB≥10; 21%), microsatellite instability (MSI; 20%), frequent *ERBB2* (14.3%) and *FGFR2* (5.9%) amplifications, and lower *TP53* mutations (62.6%). The G3 subtype (21.8%; median OS 18.1 months, 95% CI 11.6-27.4) had diffuse histology (58%), *CDH1* mutations (21.2%), low TMB (94%), and stomach site enrichment (54%). The G4 subtype (5.6%) was enriched for *KRAS* mutations (11.4%) and amplifications (9.6%), *TP53* mutations (75.4%), and CIN (62%, trending significance). The G5 subtype (6.4%) had the highest PD-L1 (CPS≥10; 40%), EBV positivity (16%), high TMB (17%), and low CIN (55%). G5 exhibited *ARID1A*/*B* (41.9%/9.3%), *PIK3CA* (21.7%), and *KRAS* mutations (18.6%), and had the lowest *TP53* mutation proportion (46.5%). The G6 subtype (4.9%) was enriched for Stage III (22%) and *CDKN2A*/*B-MTAP* deletions (~13%). The G7 subtype (17.1%; median OS 20.6 months, 95% CI 7.6-15.5%) was associated with diffuse histology (67%), *CDH1* mutations (23.9%), MSS (97%), low TMB (97%), and low CIN (53%).

Conclusions

This study shows that real-world data integration enables identification of clinically relevant, biologically distinct GC subtypes with prognostic differences. These findings provide a foundation for tailoring therapeutic strategies and improving patient outcomes.

#5942 Longitudinal liquid biopsy profiling in breast cancer patient: Clinical utility and guidelines.

Aurelia Robert[1], Alexandre Xu-Vuillard[1], Thomas Grinda[1], Antoine Italiano[2], Christophe Massard[2], Elie El-Rassy[1], Adrien Mouren[2], Alessandro Viansone[1], Barbara Pistilli[1], Joana Mourato-Ribeiro[2], Cyril Roussel-Simonin[2]

[1]Departement de Medecine Oncologique, Gustave Roussy, Villejuif, France,[2]Departement des Innovations Therapeutique et des Essais Precoces (DITEP), Gustave Roussy, Villejuif, France

Background:The clinical impact of repeated liquid biopsies in metastatic breast cancer have not been fully established. While circulating tumor DNA (ctDNA) profiling provides actionable insights, its value after an initially positive test is uncertain. We evaluated the clinical relevance of serial ctDNA analyses according to the initial biopsy result.
Methods:Patients from the prospective STING trial (NCT04932525) who underwent ≥2 plasma-derived ctDNA next-generation sequencing assays were analyzed. Somatic variants were classified according to the ESMO Scale for Clinical Actionability of Molecular Targets (ESCAT). Mutational burden, clonal evolution, and emergent actionable alterations were compared between the first (BL1) and subsequent (≥BL2) biopsies. Clinical trial and off-label therapy access were recorded.
Results:Among 152 patients, 77% had hormone receptor-positive and 19% triple-negative disease. The number of liquid biopsies ranged from 2 to 6 (median = 2). Fifty-nine patients (38.8%) had a non-contributive first biopsy; 38 became contributive at BL2 and 3 at BL3, while 14 remained non-contributive. The total number of mutations did not differ significantly between BL1 and later biopsies ($p = 0.274$) but showed a strong correlation (Spearman $\rho = 0.65$). Newly emergent variants mostly involved clonal hematopoiesis-related (*TP53, DNMT3A, TET2*) or resistance-associated genes (*RB1, BR*CA). Eighty-six patients accessed a clinical trial or off-label targeted therapy; 68 (79%) were guided by alterations already detected at BL1 and 14 (9%) by emerging mutations. Only 10 patients developed new ESCAT I-III alterations, including 7 with ESR1 mutations; others involved ERBB2, PTEN, and somatic BRCA2. Four patients acquired ESCAT IV alterations.
Conclusions:Serial liquid biopsies are most relevant in patients with an initially non-contributive assay, with a conversion rate of 64%, as repetition frequently yields actionable findings. In contrast, repeating full-panel sequencing after a contributive biopsy provides limited added value, except for ESR1 mutation monitoring after aromatase inhibitor exposure, which could be performed using lower-cost targeted assays. These results underline that the choice of re-biopsy should balance potential clinical impact and cost-effectiveness.

Poster Session

#5946 Proteomics at the guanylin gene locus reveals Wnt/β-catenin regulatory factors underlying GUCY2C hormone silencing in colorectal cancer.

Adi Caspi[1], Ariana A. Entezari[1], Jasmine R. Alvarez[1], Annie K. Londregan[1], Thomas J. M. Kuret[1], Jeffrey A. Rappaport[2], Adam E. Snook[1], Scott A. Waldman[1]

[1]Pharmacology, Physiology, and Cancer Biology, Thomas Jefferson University, Philadelphia, PA,[2]Department of Medicine, Johns Hopkins University, Baltimore, MD

Guanylin (GUCA2A) is a paracrine hormone expressed in the colonic epithelium that activates the transmembrane receptor guanylyl cyclase C (GUCY2C). Activated GUCY2C promotes fluid secretion, genome stability, barrier integrity, and homeostasis through cGMP signaling. In early colorectal cancer (CRC), guanylin expression is universally suppressed, silencing the GUCY2C signaling cascade and contributing to tumorigenesis. Repression of guanylin is mediated transcriptionally by aberrant Wnt/β-catenin/TCF4 signaling at a Wnt-sensitive enhancer upstream of the *GUCA2A* gene. Using unbiased proteomics in Wnt-inducible CRC cell lines, we sought to directly identify regulators that mediate Wnt sensitivity to guanylin expression and control its transcriptional silencing in the context of tumorigenesis. sgRNAs targeting the *GUCA2A* regulatory element, consisting of the promoter and enhancer, were coupled to a dCas9-APEX2 fusion protein to capture the desired DNA locus. ChIP-qPCR and ChIP-seq confirmed sgRNA effectiveness and specificity in targeting *GUCA2A*. APEX2-mediated proximity biotinylation was performed to label proteins associated with the targeted site. Streptavidin affinity pulldown followed by LC-MS/MS-based proteomics revealed candidate regulatory proteins differentially enriched at the *GUCA2A* promoter under Wnt-on and Wnt-off conditions, including the previously identified Wnt-modulated guanylin activator p38α (MAPK14). Additionally, other candidates were enriched at the promoter irrespective of Wnt status, suggesting regulation of guanylin that is either Wnt-independent or requires post-translational control downstream of Wnt signaling. Potential regulators of guanylin expression identified in this analysis are undergoing validation using a knockdown screen in combination with a *GUCA2A* luciferase reporter with the goal of identifying the regulatory machinery underlying guanylin loss in CRC. As GUCY2C functions as a tumor suppressor, new insights into the mechanism of guanylin transcriptional silencing will provide an opportunity to inform prevention and treatment strategies to repair the signaling pathway and oppose disease.

#5947 LSD1 performs demethylase-independent and context-specific functions in Ewing sarcoma.

Rachel D. Dreher, Cenny C. Taslim, Ira Miller, John W. Sherman, Ariunaa Bayanjargal, Emily R. Theisen

Nationwide Children's Hospital, Columbus, OH

Ewing sarcoma (EwS) is an aggressive malignancy afflicting adolescents and young adults. A chromosomal translocation fusing the *EWSR1* gene to the *FLI1* gene (EWSR1::FLI1) causes 85% of cases. Due to the inability to target EWSR1::FLI1, the field has attempted to target critical co-regulators to disrupt oncogenesis. One candidate is Lysine specific demethylase 1 (LSD1), which is overexpressed in EwS, colocalizes with the fusion, and inversely correlates with patient prognosis. LSD1 inhibitors have shown mixed activity in EwS. Noncompetitive LSD1 inhibitors have potent cytotoxic activity, but these effects are not seen with irreversible inhibitors. Recent work from our group suggests the activity of noncompetitive inhibitors is likely LSD1-indpendent. This has left the precise function of LSD1 in EwS unclear. We hypothesize that LSD1 has important nonenzymatic functions in EwS. We have developed a suite of genetic and pharmacological tools to deplete LSD1 and define its nonenzymatic functions. Genetically, we knocked out LSD1 via CRISPR genome editing. Pharmacologically, we degraded full-length LSD1 protein with UM171. We assessed proliferation and transformation capacity and identified differentially expressed genes with RNA sequencing. To distinguish between enzymatic and nonenzymatic functions, we also used genetic and pharmacological approaches. We engineered a full length, wild type LSD1 (LSD1wt) and a K661Q/A539E mutant enzymatically dead LSD1 (LSD1ed). Pharmacologically, we treated parental cells with irreversible inhibitor OG-L002. RNA-sequencing was used to define genes regulated by enzymatic and nonenzymatic functions. Surprisingly, LSD1 KO does not impair proliferation or anchorage independent growth. In contrast, degradation of LSD1 protein caused a pronounced, cell line-dependent reduction in colony formation. This cell line-specific reduction in colony formation was recapitulated with OG-L002 treatment. Overlap and pathway analysis found that LSD1 has both shared and cell line-specific targets. Across all cell lines, LSD1 consistently represses genes involved in neurotransmitter functioning and e-cadherin targets. In A673 cells, LSD1wt and LSD1ed demonstrated highly overlapping expression profiles. In addition, OG-L002 treatment showed no phenotype, suggesting that LSD1's enzymatic activity is dispensable for core functions in A673. When we define nonenzymatic functions pharmacologically, we see that LSD1 performs core functions through both enzymatic and nonenzymatic means. Interestingly, repression of e-cadherin target genes is consistently a nonenzymatic function. Our results demonstrate that LSD1 has a core set of functions that it regulates via cell line dependent mechanisms. In addition, the changes seen in 3D assays with LSD1 inhibition and depletion suggest LSD1 plays a more important role in 3D growth and that future studies should prioritize 3D assays.

#5948 EGR1 Expression and Perineural Invasion in Salivary Duct Carcinoma: A comparison of SDCDN and SDCXPA.

Airi Sakyo[1], Eijitsu Ryo[2], Seiichi Yoshimoto[3], Go Omura[3], Chihiro Fushimi[3], Toshihiko Sakai[3], Yoshifumi Matsumoto[1], Azusa Sakai[3], Kohtaro Eguchi[3], Yo Suzuki[1], Kazuki Yokoyama[4], Yoshitaka Honma[4], Yasushi Yatabe[5], Fumihiko Matsumoto[1], Taisuke Mori[5]

[1]Otorhinolaryngology, Juntendo University Faculty of Medicine, Tokyo, Japan,[2]Division of Molecular Pathology, National Cancer Center Research Institute, Tokyo, Japan,[3]Head and Neck Surgery, National Cancer Center Hospital, Tokyo, Japan,[4]Department of Head and Neck, Esophageal Medical Oncology, National Cancer Center Hospital, Tokyo, Japan,[5]Diagnostic Pathology, National Cancer Center Hospital, Tokyo, Japan

Salivary duct carcinoma (SDC) is primarily categorized as de novo (SDCDN) or ex pleomorphic adenoma (SDCXPA). Previous reports indicate a higher frequency of HMGA2 and PLAG1 fusion events in SDCXPA. Surgical resection remains the main intervention due to limited guidance on new treatment strategies. However, frequent recurrence and challenging management of metastasis highlight the necessity for innovative treatments. This study aimed to investigate SDC characteristics, including perineural invasion (PNI), and elucidate its carcinogenic mechanisms and adverse prognostic factors. We analyzed 52 patients with SDC diagnosed in the National Cancer Center Hospital from 2014 to 2023. To compare gene expression profiles, we performed immunohistochemical staining, including Her2, androgen receptor (AR), PLAG1, and HMGA2, followed by human epidermal growth factor receptor 2 (HER2) in situ hybridization and RNA sequencing of 30 cases. Differential analysis identified genes subjected to immunohistochemical staining and statistical analysis. Based on histologic classification using PLAG1 and HMGA2, 52 cases were classified as 26 cases (50%) SDCDN and 26 cases (50%) SDCXPA. Compared with SDCXPA, SDCDN showed higher perineural, venous, and lymphatic invasion rates ($P = .0005$, .0294, and .0044, respectively). Genetic expression profiling revealed clustering tendencies between these subtypes. Focusing on PNI, gene expression was decreased in early growth response 1 in tumor portions infiltrating perineural tissues, indicating a negative correlation ($P < .0001$). Similarly, ARID1A expression was elevated in tumor regions of cases with perineural invasion; however, immunohistochemical analysis showed no difference between perineural and non-perineural areas. Furthermore, RNA sequencing identified three novel fusion genes in SDC. In conclusion, clinical disparities between SDCDN and SDCXPA based on molecular and pathological features were observed. We found early growth response 1-brain-derived neurotrophic factor-linking crosstalk between cancer cells and nerves for PNI in SDC, offering insights into future treatment and prognostic factors.

#5949 Targeting SLC25A13 sensitizes melanoma to treatment and reduces tumor aggressiveness via metabolic rewiring.

Beatriz Cristina Biz Tonin[1], Ana Luisa P. Auyb[1], Jeremie Nsengimana[2], Hatylas Azevedo[1], Beatriz Kopel[3], Nadja C. Souza-Pinto[3], Frank John Slack[4], Miriam G. Jasiulionis[1]

[1]Federal University of Sao Paulo (UNIFESP), Sao Paulo, Brazil,[2]Newcastle University and NIHR Newcastle Biomedical Research Centre, Newcastle, United Kingdom,[3]Universidade de Sao Paulo (USP), Sao Paulo, Brazil,[4]Professor, Harvard Medical School, Boston, MA

Therapy resistance is one of the main challenges for melanoma treatment, prompting the investigation of new therapeutic targets to elucidate novel therapeutic approaches and molecular insights. In this melanoma study, we have investigated the role of SLC25A13 which in humans encodes citrin, a mitochondrial carrier protein with a well-characterized function in metabolic diseases. We demonstrated that SLC25A13 upregulation in tumors is associated with poor survival in two large melanoma cohorts with long follow-up. Functional assays revealed that overexpression of SLC25A13 alters the level of key metabolites, leading to a metabolic syndrome-like state that is essential for the survival of metastatic melanoma cells. We propose that SLC25A13 functions as a key metabolic node promoting melanoma aggressiveness by enhancing proliferation, invasion, and tumor progression. Notably, we show that silencing *Slc25a13* in aggressive mouse melanoma cells sensitizes them to both dacarbazine and MEK inhibition, highlighting its potential as a therapeutic target. Thus SLC25A13 is a key biomarker and a promising target for overcoming therapy resistance in metastatic melanoma.

#5950 Dynamic low-complexity domain interactions of PAX3::FOXO1 mediate endogenous pathological transcriptional hub formation in alveolar rhabdomyosarcoma.

Yanghao Zhong, Michael Di Martino, Shasha Chong

Division of Chemistry and Chemical Engineering, California Institute of Technology, Pasadena, CA

Rhabdomyosarcoma (RMS), a cancer of skeletal muscle tissue, is the most common pediatric soft tissue sarcoma with 5-year survival rate less than 30% in high-risk RMS, despite advances in prognosis and treatment over the past few decades. PAX3::FOXO1 (P3F1) is a fusion oncoprotein found in 60% cases of alveolar RMS (aRMS), the most aggressive subtype of RMS, and has been thought to drive oncogenic transcription in aRMS. However, the molecular mechanisms by which P3F1 regulates transcription remain poorly understood, and the extent to which these transcriptional changes contribute to tumorigenesis is unclear. In the current study, we first demonstrated exogenously expressed P3F1 exhibited neomorphic hub formation propensity which is not observed for its parental proteins. Using CRISPR/Cas9-based gene editing method, we endogenously labeled P3F1 with a fluorogenic HaloTag in patient-derived aRMS cells, allowing us, for the first time, to visualize P3F1 at its native pathological environment. We discovered that endogenous P3F1 forms transcriptional hubs at its target genes, and the average hub size is ~117 nm characterized by photoactivatable localization microscopy. Single particle tracking experiment showed that P3F1 molecules have longer chromatin bound residence time in the hubs compared to those outside the hubs, suggesting an important role of P3F1 hubs in target gene transcription. We found disrupting the intrinsically disordered low complexity domains (LCDs) of P3F1 impaired its hub formation propensity, target gene transcription and its ability to recruit coactivator p300. Using a phase-separation-induced interactome detection (PhaseID) method, we mapped unique interacting proteins that P3F1 hubs recruit and utilize to influence oncogenic transcription. In summary, our results uncover a neomorphic hub formation behavior of pathological P3F1 and provide a strong rationale of targeting P3F1 hub formation as new therapeutics for aRMS.

#5951 Hypertrophic chromatin condensates govern oncogene control in cancer.

Bjorn Stolte, David Pease, Max Slotnik, Anna Pertl, Nancy Hannett, Tong Ihn Lee, Richard Young

Whitehead Institute For Biomedical Research, Cambridge, MA

Summary: This study shows that hypertrophic transcriptional condensates are the defining regulatory architecture for oncogenes in diverse cancers, describes mechanisms that lead to their assembly and regulation, and suggests therapeutic concepts that may be broadly applicable to cancers with dysregulated transcription.
Pertinent experimental procedures: We investigate oncogenic transcriptional condensates using an integrated cell-biological, genomic, and biochemical framework. Alterations of protein, DNA, and RNA constituents of transcriptional condensates and dependencies on these components are analyzed in public and experimentally generated datasets. Condensate dynamics are quantified using microscopy approaches, such as fluorescence recovery after photobleaching (FRAP) and single particle tracking (SPT) with acute genetic and pharmacologic perturbations of condensate constituents. Interactions between oncogenic transcription factors (TFs) and cis-regulatory elements are assessed by chromatin immunoprecipitation and complementary methods and combined with chromatin-accessibility mapping. Key molecular interactions are identified by approaches including co-immunoprecipitation, proximity labeling, and mass spectrometry.
Description of the new, unpublished data: Hypertrophic transcriptional condensates, defined as exceptionally large pathogenic assemblies of transcription apparatus with specialized physicochemical properties, are assembled at driver oncogenes in a broad spectrum of cancers. These transcriptional condensates differ from those in most normal cells in their exceptional size, the genetic and biochemical mechanisms involved in their assembly, and their components' dynamics. Some hypertrophic transcriptional condensates incorporate a disproportionately large portion of the transcription apparatus, encompass nearly a megabase of DNA, remain assembled longer than typical transcriptional condensates, and arrest the properties that produce condensate dissolution in normal cells. Some of the properties of the hypertrophic condensates are amenable to new approaches that concentrate drugs within the pathological assembly.
Conclusions: Driver oncogenes in cancers share a unifying theme: their transcription is controlled by hypertrophic transcriptional condensates, which differ from normal transcriptional condensates in terms of their exceptional size, the genetic and biochemical mechanisms involved in their assembly, and their components' dynamics. We present common features to this condensate architecture and describe mechanisms that lead to their assembly and unusual regulatory behaviors. The concept that hypertrophic transcriptional condensates evolve to serve oncogenic drivers, and evidence of their specialized physicochemical environments, offers new opportunities for antineoplastic drug discovery.

#5952 A unifying mechanism for shared splicing aberrations in splicing factor mutant cancers.

Rahul Roy, Prajwal C. Boddu, Manoj M. Pillai

Yale School of Medicine, New Haven, CT

Cancer-associated mutations in splicing factors (SFs) such as SF3B1, U2AF1, and SRSF2 generate well-recognized cis-acting alterations in splice site choice, specific to each mutational subtype. However, there is substantial overlap in alternative splicing (AS) defects across these genetically distinct mutation groups which has remained unexplained. We hypothesized that this convergence reflects a shared trans-regulatory mechanism. To answer this, we profiled global transcriptomes to delineate AS programs across SF-mutant states using a cohort of 395 patients with SF-mutant clonal myeloid disorders and 64 healthy donors. While the majority of AS alterations were mutation-specific, we identified a robust subset of shared events, strongly enriched for retained intron (RI) signatures. These RI defects were bidirectional (both increase and decrease in RI) yet strikingly concordant across SF3B1, U2AF1, and SRSF2 mutants. Given that RNA binding proteins (RBPs) are the primary regulators of AS, we compared these SF-mutant RI to those in cells with loss of 356 individual RBPs (ENCODE). SF-mutant RI closely mirrored RI in resulting from SRSF1 loss of function. Phosphoproteomics revealed that SF-mutant cells have hypophosphorylation of RS domains in SRSF1, impairing its splicing activity. This reduction stemmed from a shift in the AMPKα-AKT signaling balance, which suppressed the AKT-SRPK1-SRSF1 phosphorylation axis. We next traced this signaling imbalance to an upstream trigger: R-loop-associated transcriptional stress, which activates a DNA damage response (DDR). DDR activation enhanced AMPKα signaling while diminishing AKT activity, thereby reducing SRPK1-mediated phosphorylation of SRSF1. Pharmacologic DDR activation recapitulated SRSF1 hypophosphorylation, decreased AKT/SRPK1 activity, and induced RI defects resembling those in SF-mutant cells. Conversely, relief of DDR signaling restored AKT/SRPK1 activity, normalized SRSF1 phosphorylation, and corrected RI abnormalities. These results were confirmed in SF-mutant clonal myeloid cells from patients using RNAseH over-expression to reverse R-loops and quantifying effect on colony formation by CFU assays. Together, our findings demonstrate that, beyond distinct cis-acting splice site changes, SF-mutant cancers share a stress-driven, trans-acting splicing program coordinated through DDR-mediated rewiring of SRSF1 activity. This unified mechanism links replication stress, kinase signaling, and RNA processing across diverse clonal states, and highlights novel actionable nodes (DDR, AMPK/AKT balance, and SRPK1-SRSF1 coupling) with therapeutic potential.

#5953 Unlocking new frontiers in mouse research by exploring the whole-transcriptome in space and time with mouse embryo stages E11 - E14.

Michael Patrick, Liang Zhang, Isabel Lee, Shanshan He, Martin Shelton, John Lyssand, Joseph M. Beechem

Bruker Spatial Biology, Seattle, WA

Bruker Spatial Biology introduces the CosMx® Mouse Whole Transcriptome Assay: a 21,242 gene panel that covers the entirety of the protein-coding mouse transcriptome. CosMx Spatial Molecular Imager (SMI) is a first-in-class instrument that offers spatially resolved, single-cell transcriptomic analysis at a scale an order of magnitude greater than any other commercially available system. This study profiles four FFPE mouse embryo sections - E11, E12, E13, and E14 - using a development lot of CosMx Mouse Whole Transcriptome (WTX) Assay. Each slide was stained with a 5-channel segmentation cocktail of PanCK, CD3, CD45, CD298/B2M, and DAPI prior to RNA profiling. Cells are segmented according to presence of DAPI and a combined overlay of all four segmentation markers using a machine learning algorithm based on the open-source platform CellPose, trained on staining information collected on over a dozen human and mouse tissue types on CosMx SMI. RNA transcripts are decoded using a multiplexed barcoding strategy where individual ISH probes are assigned unique barcode across 39 reporter sequences, a strategy that is key to allowing over twenty-thousand targets to be detected simultaneously in space. The CosMx Mouse WTX Assay unveils an unprecedented depth of information on each mouse sample. Cell typing was performed on each embryo to identify each developing organ, and niche analysis was used to identify spatial neighborhoods unique to each timepoint. The development of specific organs during these timepoints, such as the retina, liver, gonads, and heart, are interrogated in detail by comparing localized gene expression across the whole transcriptome throughout timepoints, offering a unique four-dimensional window (three spatial dimensions, one time dimension) into embryonic development with the unparalleled resolution of spatial transcriptomics. Capitalizing on the high number of genes available per cell, single cell pathway scores were assigned to each slide, and differential expression was used to quantify which pathways are upregulated at each timepoint. Unbiased spatial algorithms such as Insitucor were used to identify localized gene module expression based on normalized expression across nearby cells, and disease/control perturbation algorithms such as Insitudiff revealed spatial domains defined by gene perturbations of later timepoints relative to E11. CosMx Mouse WTX Assay delivers a first-of-its-kind opportunity to examine the development of mouse embryos in four dimensions using >20,000 spatially resolved genes. This study on mouse embryo development provides a first look at the limitless applications that a whole-transcriptome mouse panel can unlock for researchers including cancer research.

#5954 Enabling single-cell transcriptomics from samples with degraded and low-input RNA using TempO-LINC.

Kevin White[1], Albus Kilili[2], Hanna Ha[2], Dennis Eastburn[1], Nathan Jayne[1], Salvatore Camiolo[2], Zhoutao Chen[1], Bruce Seligmann[1]

[1]BioSpyder Technologies, Inc., Carlsbad, CA,[2]BioClavis, LTD, Glasgow, United Kingdom

Background: Single-cell RNA sequencing (scRNA-seq) technologies enable characterization of cellular heterogeneity and rare cell types, and mapping of cell states in complex tissues. However, scRNA-seq performance in clinical samples is limited by RNA degradation, fragmentation, or inherently low RNA abundance. Peripheral blood mononuclear cells (PBMCs) are a common low RNA, heterogeneous sample, while formalin-fixed paraffin-embedded (FFPE) tissues, an invaluable archive of human samples, often contain degraded RNA of poor quality/quantity, due to tissue processing. Thus, TempO-LINC, a targeted, instrument-free single-cell transcriptomics assay, was designed for high-throughput gene expression profiling with strong tolerance to low RNA integrity. Here, we report that TempO-LINC enables robust gene expression profiling and rare cell subtype detection in human PBMCs and dissociated FFPE tissues from human and mouse.
Methods: The TempO-LINC assay is a scalable, combinatorial split-pool barcoding approach to uniquely index RNA molecules in fixed cells/nuclei. Cryopreserved PBMCs from three donors were fixed using the TempO-LINC Fixation Kit and profiled with the TempO-Seq human whole transcriptome v2.1 probe set. FFPE blocks from human lung and mouse brain were sectioned, two 30µm thick sections per block, deparaffinized, enzymatically dissociated, filtered, and then processed with the TempO-LINC Fixation Kit. TempO-LINC scRNA-seq was performed on FFPE lung and brain using the human whole transcriptome v2.1 and mouse whole transcriptome v1.1 probe sets, respectively. Data processing and visualization were performed using the open-source Python Scanpy and R Bioconductor packages.
Results: Analysis of 12,027 PBMCs revealed 16 transcriptionally distinct cell populations, including major classes of blood/immune cell subsets, and rarer cell populations of hematopoietic stem/progenitor cells and proliferating CD4+ T cells, demonstrating high sensitivity in low-RNA contexts. TempO-LINC successfully generated FFPE single-cell expression profiles with mean mapping rates from 71-93% and ~1,000 genes detected per cell. UMAP data shows clearly defined cell subtypes from dissociated FFPE lung and brain tissues.
Conclusion: The TempO-LINC scRNA-seq assay enables high-resolution gene expression profiling across heterogenous, low-RNA PBMCs and FFPE samples. These results highlight the assay's high sensitivity in determining rare cell types from samples with degraded RNA. Applying TempO-LINC scRNA-seq on FFPE specimens unlocks new opportunities in precision medicine, biomarker discovery, and mechanistic toxicology.

#5955 Dissecting the enhancer logic in breast cancer metastasis through transcriptional, chromatin accessibility profiling and footprint-inferred transcription factor activity.

Frances Heredia Negron[1], Homer W. Fogle[1], Michael R. Kelly[2], Kamila Wisniewska[2], Lisa A. Carey[2], Hector L. Franco[1]

[1]Comprehensive Cancer Center of the University of Puerto Rico, San Juan, PR,[2]Lineberger Comprehensive Cancer Center, University of North Carolina at Chapel Hill, Chapel Hill, NC

Breast cancer metastasis remains a major clinical challenge, highlighting the need to dissect the molecular mechanisms involved. In this project, we generated a multi-omic resource consisting of RNA-seq and ATAC-seq profiles from ER-positive primary breast tumors and matched liver and lung metastases. We collected samples from four patients collected at diagnosis and eight patients collected at autopsy following cancer-related death, enabling a comprehensive assessment of metastatic regulatory programs. We hypothesized that breast cancer metastasis is driven by tissue-specific enhancer networks, in which differential transcription factor (TF) motif activity coordinates distinct gene regulatory programs across metastatic sites. Towards this end, RNA-seq reads were aligned using STAR, quantified with HTSeq, and analyzed with DESeq2 to identify differential gene expression between primary and metastatic tissues. ATAC-seq reads were processed with the PEPATAC pipeline, and differentially accessible chromatin regions were identified using DiffBind. Peak-to-gene correlation analyses integrating ATAC-seq and RNA-seq data revealed putative metastasis-driver genes including 99 liver specific genes and 9 lung specific genes. Notably, there were 23 shared genes across both metastatic sites, including CCNF, SPINT1, and SLC2A1. The majority of these genes were associated with three or more enhancers in metastases but not in primary tumors, suggesting enhancer rewiring as a key mechanism of metastatic progression. To identify TFs that may drive these regulatory changes, we applied TOBIAS footprinting to infer TF occupancy by integrating motif information with chromatin accessibility. By combining footprint scores with gene expression correlations, we uncovered tissue-specific TF activity: KLF5, KLF12, SP3, and KLF10 predominated in lung metastases, whereas SP5, SP1, SP4, KLF14, and KLF15 dominated liver metastases. Most chromatin accessibility peaks exhibited differential TF motif usage between tissues, further supporting distinct enhancer regulatory programs in liver versus lung metastases. Only a minority of peaks shared the same top motifs across tissues, and some peaks contained motifs in one tissue but not the other, underscoring both shared and tissue-selective regulatory mechanisms that likely shape metastatic adaptation. By analyzing TF motif activity utilizing patient-specific depth of coverage across peaks allowed us to refine transcription factor binding predictions in ways that reflect individual tumor biology. Prioritizing TFs based on activity within these regulatory landscapes may ultimately improve the development of targeted therapeutic strategies to combat metastatic breast cancer.

#5956 Effect of the evolutionary selected Andean Aymara *NFKB1* polymorphisms on inflammatory and HIF-dependent gene expression in endometrial and ovarian cancer.

Jihyun Song[1], Soo Jin Kim[1], Anthony Panarelli[2], Linus Chuang[3], David Doo[3], Leslie Andriani[3], Shatovisha Dey[2], Syeda Rashid[2], Steven Sieber[4], **Sabina I. Swierczek**[2]

[1]Division of Hematology and Hematological Malignancies, School of Medicine University of Utah/Huntsman Cancer Institute, Salt Lake City, UT,[2]Rudy Ruggles Research Institute, Nuvance Health, Danbury, CT,[3]Gynecologic Oncology, Nuvance Health, Danbury, CT,[4]Pathology, Nuvance Health, Danbury, CT

JS,SS-corresponding authors; SJK, AP-equal contributionGynecological cancers cause ~132/1 million deaths in women /year worldwide (PMID: 39148469). Endometrial cancer (EC) is the most common gynecological cancer, while ovarian cancer (OC) is the most lethal, with a 5-year US mortality ~51% overall and less than 30% in advanced stage of disease. NF-κB signaling contributes to progression, chemoresistance, and relapse in both EC and OC. The evolutionary selected Aymara *NFKB1* variant (rs230511; CC, CT, TT genotype), existing in ~30% Europeans, Asians, and Hispanics, correlates with expression of inflammatory and hypoxia-inducible factor (HIF)-regulated genes (PMID:39971917). Because inflammation and hypoxia promote tumor growth, invasion, metastasis, and resistance to treatment, this variant may influence EC/OC biology and clinical outcomes. We investigated role rs230511 genotypes in inflammatory and HIF-dependent gene expression in EC and OC.Genomic DNA from blood mononuclear cells from EC (n=103), OC (n=108) and benign controls (n=86) was genotyped for rs230511. Tumors samples from treatment naïve patients (25 OC, and 20 EC) and normal tissues from (ovary n=6; endometrium n=9) were collected. RNA was extracted and gene expression analysis of HIF-targeted genes (*VEGFA, SLC2A1, LDHA)* and inflammatory genes *(IL6, P2RY2, CCR7, CXCL8, IL1B, NFKB1*, *TNF*), with *GAPDH* as the housekeeping gene evaluated. No differences in allele frequencies or genotype distributions of rs230511 were observed among EC, OC, and benign groups, indicating that this *NFKB1* variant does not predispose to OC/EC. In EC tumors, *NFKB1* mRNA were significantly lower than in normal endometrium (p=0.004) *NFKB1* expression in EC positively correlated with the expression of HIF-targeted genes (*VEGFA*, *SLC2A1*) and inflammatory genes (*IL6, P2RY2, TNF*). Patients carrying the *CT* genotype had lower expression of *IL6* and *P2RY2* than the *CC*, suggesting less aggressive tumors.; the expression of other inflammatory genes (*CCR7, CXCL8, IL1B, TNF)* also trended lower but were not significant. The *CT* genotype was associated with lower white blood cell counts than *CC*, consistent with reduced inflammation. In OC, *NFKB1* mRNA was lower than in normal ovary. OC patients with the *CT* and *TT* genotype had lower *NFKB1* mRNA than *CC* carriers. In OC inflammatory genes (*CCR7, CXCL8, IL1B*, *TNF*) were highly expressed but did not correlate with *NFKB1* mRNA levels and genotypes. HIF-target genes positively correlated with inflammatory gene levels, suggesting HIF, not NFKB1, drives inflammation in OC. *NFKB1* genotype-dependent variation and its downstream pathways appear to influence EC but not OC, potentially contributing to differences in tumor aggressiveness and prognosis. The effect of the *NFKB1* genotype is undergoing analysis of overall survival, tumor aggressiveness and treatment response.

#5957 Transcriptional alterations in neoplastic transformation.

Usman Hyder, Nova Fong, Benjamin Erickson, David Bentley

University of Colorado Anschutz Medical Campus, Aurora, CO

Genetic alterations aberrantly turn on oncogenic transcription programs, thereby driving cellular transformation and tumor progression. Transcription comprises multiple steps, including initiation, promoter-proximal pausing, pause release, elongation, and termination. Because these steps are essential in both normal and cancer cells, targeting transcription has historically lacked therapeutic specificity. To address this problem, a key unmet need for the field is to identify differential features of transcription between normal and transformed cells to then exploit factors that regulate those distinctions. In line with this goal, we have identified two distinct changes in global transcription dynamics in normal breast cells undergoing oncogenic transformation. First, oncogenic transformation is associated with global increases in transcription elongation rate, or the speed by which RNA Polymerase II (Pol II) travels in gene bodies. This heightened rate is not just observed at genes inducible upon transformation, suggesting that oncogenic signaling may exploit elongation control to globally alter the transcriptome to advance cellular transformation. Second, oncogenic transformation is associated with decreases in promoter proximal pausing, implying that one of two potential mechanisms is elicited once cells undergo this cell state change: (i) increased premature termination to evict Pol II off promoters, and/or (ii) decreased Pol II recruitment. Given these findings, I hypothesize that oncogenic transformation requires global alterations to multiple transcription steps, and that perturbation of factors that selectively regulate these steps may obstruct the transformation process without killing normal cells, enabling the identification of targetable therapeutic approaches.

#5958 APOBEC4, a novel regulator of p53-dependent tumor suppression.

Dipesh Thapa[1], Atul Ranjan[2], Alejandro Parrales Briones[2], Elizabeth Thoenen[3], Shigeto Nishikawa[4], Jay Vivian[2], Tomoo Iwakuma[2]

[1]The University of Kansas Medical Center, Kansas City, KS,[2]Children's Mercy Research Institute, Kansas City, MO,[3]Washington University in St. Louis , St. Louis, MO,[4]Kyoto University, Kyoto, Japan

Introduction: The tumor suppressor protein p53 (p53) functions as a transcription factor that activates downstream target genes such as *p21*, *PUMA, NOXA, BAX,* and *GADD45α* to induce cell cycle arrest, senescence, apoptosis, and other biological processes. However, p53 activity is frequently compromised during tumorigenesis, with approximately half of human cancers harboring TP53 mutations. Even in tumors retaining wild-type p53 (wtp53), it gets degraded or inhibited through various mechanisms, including the overexpression of its E3 ubiquitin ligase MDM2. MDM2 antagonists such as Nutlin-3a are promising strategies to restore p53 function and inhibit tumor growth. Yet, factors/biomarkers regulating the efficacy of MDM2 antagonists and p53-mediated tumor suppression remain poorly understood. Identifying such factors and understanding their functions are essential for optimizing p53-targeted therapies.
Experimental Procedures: Using a human whole-genome shRNA library screen, we sought to identify factors regulating p53-dependent tumor suppression in osteosarcoma U2OS cells treated with Nutlin-3a. This screening and subsequent validation revealed APOBEC4 as a critical factor for p53-mediated colony suppression following Nutlin-3a treatment. Deletion of *APOBEC4* attenuated Nutlin-3a-induced p53 transcriptional activation and reduced p53-dependent cell cycle arrest and apoptosis across multiple p53-proficient cancer cell lines. To investigate the underlying mechanism, we performed co-immunoprecipitation (Co-IP) and proximity ligation assays (PLA), which revealed APOBEC4 binds to p53. Furthermore, cellular senescence induced by H_2O_2 and oncogenic $HRAS^{G12V}$, was also reduced upon *APOBEC4* knockdown. Importantly, APOBEC4 deletion significantly attenuated Idasanutlin-mediated tumor suppression *in vivo*.
Conclusion: Our findings identify APOBEC4 as a novel regulator of p53-dependent cell cycle arrest, senescence, apoptosis, and tumor suppression, highlighting its potential as a biomarker for p53-targeted therapies.

#5959 Therapeutic targeting of HuR using a specific small-molecule inhibitor in triple negative breast cancer.

Arundhathi Dev J R[1], Ajay Gogia[1], Sandeep R. Mathur[2], Ashutosh Mishra[3], Chandra Prakash Prasad[1]

[1]Medical Oncology, All India Institute of Medical Sciences New Delhi, New Delhi, India,[2]Pathology, All India Institute of Medical Sciences New Delhi, New Delhi, India,[3]Surgical Oncology, All India Institute of Medical Sciences New Delhi, New Delhi, India

Human Antigen R (HuR/ELAVL1) is an RNA-binding protein that interacts with U/AU-rich elements in target mRNAs, and its aberrant cytoplasmic accumulation have been observed in multiple cancers. HuR modulates the expression of key oncogenic and survival-related transcripts, thereby driving tumor progression, metastasis, and therapeutic resistance. Given this central role, HuR represents a compelling molecular target for cancer therapy. The present study specifically evaluates the potential of CMLD2, a highly selective small-molecule inhibitor of HuR, in the context of Triple-Negative Breast Cancer (TNBC). Comparative assessments were conducted using CMLD2 and DHTS across *in silico* and *in vitro* models. Immunohistochemical analysis of 71 TNBC samples revealed HuR overexpression in 66% of cases, along with elevated expression of HuR downstream target MMP9 (56%). Furthermore, in silico analysis established significant association between HuR overexpression and poor patient survival ($p = 0.028$). Functional assays in TNBC cell lines MDA-MB-231 and MDA-MB-468 demonstrated that both inhibitors suppressed proliferation, invasion, and clonogenicity; however, CMLD2 exhibited markedly higher specificity and consistency in inhibiting HuR function. Mechanistically, CMLD2 treatment downregulated HuR and its downstream effectors MMP9 and β-catenin, while reversing epithelial-mesenchymal transition (EMT) marker expression (E-cadherin, N-cadherin and Vimentin). Immunofluorescence and cell fractionation confirmed effective cytoplasmic HuR inhibition. Moreover, CMLD2 distinctly suppressed aerobic glycolysis, evidenced by reduced extracellular acidification and downregulation of key glycolytic mediators—PFKP, LDHA, and MCT4—validated at both transcript and protein levels. HuR silencing by siRNA supported the role of HuR in glycolytic regulation and TNBC progression. *In vivo*, CMLD2 significantly impaired tumor-forming ability in female BALB/c mice. Together, these findings underscore the therapeutic promise of CMLD2 as a specific and potent HuR inhibitor, providing strong experimental rationale for its further development as a targeted intervention in Triple-Negative Breast Cancer.

#5960 CRISPR-Cas engineering of allogeneic regulatory T cells reveals an essential role for steroid receptor coactivator 3 (SRC-3) in maintaining FOXP3 expression and suppressive function.

Subhashree Pradhan, Bryan Nikolai, Aiden Lynn Moser, Davis Alexander Graham, Lanz Rainer, Bert W O'Malley, David Lonard

Baylor College of Medicine, Houston, TX

Genetically engineered allogeneic regulatory T cells (Tregs) represent a promising off-the-shelf therapy to prevent graft-versus-host disease and transplant rejection, but their clinical utility is constrained by immune rejection and alloreactivity. Using CRISPR-Cas editing, we generated hypoimmunogenic human Tregs through multiplex knockout of B2M (reducing HLA class I), TCRα/β (eliminating receptor-mediated alloreactivity), and SRC-3 (a transcriptional coactivator linked to Treg stability). In prior murine studies, SRC-3 disruption enhanced tumor clearance, but in human Tregs, its deletion impaired suppressive function, underscoring SRC-3's role in maintaining lineage identity. Functionally, SRC-3 knockout Tregs failed to suppress effector T cell proliferation, a defect mirrored in triple knockout (TCR+B2M+SRC-3) cells. Co-culture with unedited Tregs restored suppression, suggesting functional compensation. FOXP3 protein levels were markedly reduced in SRC-3 and triple knockout Tregs, consistent with destabilized lineage commitment. These findings highlight SRC-3, TCR, and B2M as central regulators of transcriptional and antigen-presentation pathways shaping Treg identity. RNA sequencing revealed that triple knockout Tregs exhibited increased transcript diversity compared to controls. SRC-1/NCOA1 and SRC-2/NCOA2 were upregulated in SRC-3 and triple knockout samples, while B2M and TRAC were strongly downregulated in triple knockouts. Chemokine transcripts were elevated in SRC-3 and triple knockout Tregs, with triple knockouts also showing diverse cytokine upregulation. Collectively, these results demonstrate that while genome editing can enhance allogeneic compatibility, SRC-3 is indispensable for human Treg stability and suppressive function. Effective engineering of universal Tregs must therefore balance hypoimmunogenic design with preservation of functional integrity for adoptive cell therapy.

#5961 The roles of METTL3 in colorectal cancer.

Hung Mai, Sidi Zhao, DEBANJAN SAHA, Jace Webster, Li Lin, Emily Rozycki, Ashna Agarwal, Muheng Liao, Christopher Maher

Department of Medicine, Washington University, St. Louis, MO

Colorectal cancer (CRC) is a leading cause of cancer-related mortality worldwide, accounting for 10% of all cancer deaths. Metastatic disease occurs in half of all CRC cases, with a 5-year survival rate of 14%. Thus, understanding molecular mechanisms of CRC progression is important for improving diagnostics and therapies. Recent studies identified the m6A (N6-methyladenosine) RNA methyltransferase-METTL3 as a key oncogene in CRC, suggesting the important role of epitranscriptomic regulation in cancer. M6A modification affects multiple aspects of RNA metabolism, including degradation, export, and translation. However, the precise mechanisms of METTL3 in CRC remain undefined. We identified YTHDF1, an m6A reader, as the most upregulated reader in CRC patients. Yet, the METTL3-YTHDF1 interplay in CRC progression is unclear. This study aims to define how METTL3 and YTHDF1 act together to promote CRC progression via m6A modifications, and to identify novel, clinically relevant m6A targets. To achieve this, we performed Nanopore direct RNA-seq in METTL3-knockdown cells to map METTL3-dependent m6A sites across the CRC transcripts. To identify genes whose m6As are read by YTHDF1, we conducted short-read RNA-seq in METTL3- and YTHDF1-knockdown cells to determine shared transcriptional changes associated with RNA methylation. Integrating these datasets with patient data revealed clinically relevant transcripts regulated by METTL3 and YTHDF1. m6A enrichment on selected candidates were validated by MeRIP-qPCR. Comparison with two existing m6A databases confirmed overlapping sites and uncovered previously unannotated sites. Among these, *TRIB3*, a known oncogene in CRC, consistently emerged as a top m6A target across datasets, with expression significantly reduced upon METTL3 or YTHDF1 knockdown. Thus, TRIB3 was selected as a conceptual target for further studies. Using RNA immunoprecipitation, we found YTHDF1 interacts with *TRIB3*, and this interaction is reduced upon METTL3 depletion. Knockdown of METTL3 or YTHDF1 reduces *TRIB3* RNA stability and polysome occupancy causing decreased transcript and protein levels. To directly remove m6As on *TRIB3*, we used dCasRX conjugated to ALKBH5, an m6A demethylase, and coupled with sgRNAs targeting *TRIB3*. Dual sgRNAs effectively removed m6As on *TRIB3* and reduced its expression, confirming functional roles of m6As in regulating TRIB3 level. TRIB3 overexpression rescued migration and invasion defects in METTL3 knockdown cells, while m6A removal on *TRIB3* by dCasRX-ALKBH5 suppressed these phenotypes, indicating METTL3 and YTHDF1 promote CRC invasion and migration through TRIB3 regulation. Our study highlights the role of the YTHDF1-TRIB3 axis in cooperating with METTL3 to promote CRC. Additionally, our unbiased analyses reveal several other potential m6A targets in CRC. These findings provide new insights into CRC progression and highlight potential therapeutic paths targeting the m6A regulatory network.

#5962 METTL1-mediated m7G modification of valine tRNAs drives pancreatic ductal adenocarcinoma progression.

jiabei zhu[1], Qi Zhang[2], Rui Su[3], Qiuhui Pan[2], Ajay Goel[1]

[1]Department of Molecular Diagnostics and Experimental Therapeutics, Beckman Research Institute of City of Hope, Monrovia, CA,[2]Department of Clinical Laboratory, Shanghai Children's Medical Center, Shanghai, China,[3]Department of Systems Biology, Beckman Research Institute of City of Hope, monrovia, CA

Background: Transfer RNA (tRNA) modifications play a critical role in regulating codon-specific mRNA translation and supporting tumor cell adaptation. The RNA methyltransferase METTL1 installs N7-methylguanosine (m7G) modifications on tRNAs, shaping their codon usage landscape and influencing protein synthesis. However, the function and mechanism of the METTL1/tRNA axis in pancreatic ductal adenocarcinoma (PDAC) remain poorly understood. This study examines the role of METTL1-mediated m7G tRNA modification in the progression of PDAC and its associated metabolic reprogramming.

Methods: METTL1 expression was analyzed using transcriptomic data from The Cancer Genome Atlas (TCGA) and validated in an independent PDAC tissue cohort by qRT-PCR. METTL1-knockout PDAC cell lines were generated via CRISPR/Cas9. Cellular proliferation and migration were assessed through MTT, colony formation, and wound-healing assays, while tumor growth was evaluated in xenograft models. Global tRNA m7G levels were measured using dot blot, and qRT-PCR was used to quantify specific tRNA abundances. Polysome profiling identified METTL1-dependent translational targets, and mitochondrial function was assessed by Seahorse Mito Stress testing.

Results: METTL1 was significantly upregulated in PDAC ($p < 0.001$) and correlated with poor patient survival ($p < 0.05$). METTL1 knockout suppressed PDAC cell proliferation, migration, and tumor growth ($p < 0.001$) in vitro and in vivo. Mechanistically, METTL1 loss decreased the abundance of m7G-modified valine tRNAs, particularly Val-AAC, Val-CAC, and Val-TAC (all $p < 0.001$), leading to reduced translation of valine codon-enriched oxidative phosphorylation genes. Consequently, METTL1 deficiency impaired mitochondrial respiration and energy production. Consistently, valine tRNA expression was elevated in PDAC tissues ($p < 0.01$), and selective knockdown of these tRNAs inhibited proliferation and migration ($p < 0.001$) by disrupting mitochondrial function. Reintroduction of Val-AAC, Val-CAC, and Val-TAC restored growth ($p < 0.001$) and migratory capacity ($p < 0.01$) in METTL1-deficient cells.

Conclusions: METTL1-mediated m7G modification of valine tRNAs promotes PDAC progression by reprogramming the translational landscape to support mitochondrial metabolism. This METTL1-tRNA-mitochondrial axis represents a novel metabolic vulnerability and a promising therapeutic target in pancreatic cancer.

#5963 mTORC1-eIF4A1 dependent translational regulation of oncogenic fatty acid desaturases.

Yujin Chun[1], Joohwan Kim[1], Izabelle Le[2], Cuauhtemoc B. Ramirez[1], Won-Suk Song[2], Cholsoon Jang[2], Gina Lee[1]

[1]Department of Microbiology & Molecular Genetics, University of California, Irvine, School of Medicine, Irvine, CA,[2]Department of Biological Chemistry, University of California, Irvine, School of Medicine, Irvine, CA

Cells actively remodel their lipid composition to support membrane integrity, organelle function, and signaling as environmental and nutrient condition changes. While transcriptional control of lipogenesis has been extensively studied, how these pathways are controlled at the translational level remains incompletely defined. Our prior works identified transcriptional and post-transcriptional regulation of de novo lipogenesis. Here, we found that the mTORC1-eIF4A1 axis selectively enhances the translation of the oncogenic fatty acid desaturases stearoyl-CoA-desaturase 1 (SCD1) and fatty acid desaturase 2 (FADS2), which together supply monounsaturated fatty acids (MUFA). Across multiple mTORC1-hyperactive cancer cell lines, eIF4A1 inhibition by siRNA or small molecules (silvestrol and zotatifin) reduced the desaturase protein abundance while other lipogenic enzymes were unchanged. Using polysome assay and 5'UTR luciferase assays, we confirmed that the translational regulation is via their unique 5'UTR structures. In addition, to investigate how eIF4A1 perturbation affects cellular lipidome, we applied ^{13}C-isotope tracing to examine newly synthesized fatty acids and related lipids. eIF4A1 inhibition lowered cellular MUFA content, shifted phospholipids toward more saturated fatty acids and induced ER stress and lipid peroxidation. This impaired fatty acid balance and lipid composition led to decreased cell proliferation upon eIF4A1 inhibition and was partially rescued by MUFA supplementation. Extending these findings in vivo, zotatifin treatment in a Tsc2$^{+/-}$ kidney tumor mouse model, where loss of Tsc2 hyperactivates mTORC1, reduced tumor burden, decreased desaturase expression, and increased lipid peroxidation. Together, these data establish a direct link between translational control and fatty acid desaturation in cancer cells, and support eIF4A1-targeted strategies to simultaneously suppress two oncogenic fatty acid desaturases in mTORC1-hyperactive tumors.

#5964 Single-cell multi-omics profiling unveils the regulatory mechanisms of small cell lung cancer.

Charny Park[1], Namhee Yu[1], Jung-Hyun Kim[1], Sehwa Hong[1], Mihwa Hwang[1], Bo Ram Song[1], Sunshin Kim[1], Soo Young Cho[2], Beung-Chul Ahn[1], Ji-Youn Han[3]

[1]National Cancer Center - Korea, Goyang-si, Korea, Republic of,[2]Hanyang University, Seoul, Korea, Republic of,[3]National Cancer Center - Korea, Goyang-Si, Korea, Republic of

Small cell lung cancer (SCLC) is a highly aggressive lung cancer with an extremely poor prognosis. The mechanisms underlying its tumor progression and therapeutic strategies remain poorly understood. To address this clinical challenge, we utilized single-cell ATAC-RNA multiomic profiling to investigate clonal progression and its regulatory mechanisms. Patient-derived cells (n=73,546) were collected from pleural effusions (n=22) and categorized into tumor, stromal, lymphoid, and myeloid populations. Tumor cells exhibited progression along two clonal trajectories, characterized by *ASCL1*+ and *NEUROD1*+ subtypes. *ASCL1*+ cells, derived from *KEAP1*-mutated patients, activated the NRF2-KEAP1 pathway and ferroptosis. Notably, patients with *KEAP1* mutations were diagnosed with both large-cell neuroendocrine carcinoma and SCLC. In contrast, *NEUROD1*+ cell evolution was associated with upregulation of G protein signaling and Rho GTPase pathways, along with neuronal development. Tumor progression regulators were identified in both *ASCL1*+ (*FOXA1*, *KLF2*, *NR2C1*, *NRF1*) and *NEUROD1*+ (*PITX1*, *RORB*) subtypes. The mechanisms of these transcription factors identified target genes, which consistently reflected tumor cell progression along distinct trajectories. Among TME cells, exhausted T cells and *TREM2*+ macrophages were more prevalent in longer-survival and post-treatment patients. Cell-cycle-associated cancer fibrosis was abundant in progression and shorter-survival patients. When investigating cell-cell interactions, *ASCL1*+ tumor clusters predominantly interacted with myeloid and stromal cells through the GAS6 and SPP1 signaling networks, while NCAM and NEGF pathways enhanced the function of *NEUROD1*+ tumor cells by promoting communication within neuroendocrine tumor cells. This study delineates distinct clonal trajectories in SCLC, with *ASCL1*+ and *NEUROD1*+ subtypes driving tumor progression through specific regulatory pathways. Key transcription factors were identified as pivotal drivers of tumor evolution. Immune and stromal profiles suggest that immune exhaustion and fibrosis significantly impact patient survival, underscoring potential targets for therapeutic strategies and post-treatment interventions.

#5965 Plk1-BRN2 signaling axis drives lineage plasticity in castration-resistant prostate cancer.

Fatemeh Seilani[1], Meng Wu[1], Jia Peng[2], Mohammad Esfini Farahani[1], Xinyi Wang[1], Jinghui Liu[1], Yanquan Zhang[1], Ruixin Wang[1], Xiaoqi Liu[1]

[1]University of Kentucky, Lexington, KY,[2]Univ. of Kentucky College of Medicine, Lexington, KY

Prostate cancer frequently acquires resistance to androgen receptor (AR)-targeted therapies through lineage plasticity, leading to neuroendocrine prostate cancer (NEPC), an aggressive and therapy-resistant subtype. BRN2 (POU3F2) is a key transcription factor that drives this transition and is normally repressed by AR signaling; however, the upstream mechanisms that activate BRN2 during therapy resistance remain poorly defined. We identify Polo-like kinase 1 (Plk1), a mitotic kinase upregulated in advanced disease, as a previously unrecognized upstream regulator of BRN2. Plk1 directly phosphorylates BRN2 at a conserved motif, enhancing its transcriptional activity and promoting downstream neuroendocrine reprogramming. Disruption of this phosphorylation markedly diminishes neuroendocrine marker expression and inhibits cellular plasticity. RNA-seq analysis further revealed suppression of EMT-associated transcriptional programs as a major downstream consequence of impaired BRN2 phosphorylation. In vivo, using a robust NEPC mouse model, inhibition of Plk1-dependent BRN2 activation reprograms tumor histology and molecular phenotype toward an AR-positive prostate adenocarcinoma (ARPC) state, indicating inhibition of lineage plasticity. These findings identify Plk1-mediated BRN2 phosphorylation as a critical driver of neuroendocrine transdifferentiation and highlight the Plk1-BRN2 axis as a promising therapeutic target to prevent NEPC progression in castration-resistant prostate cancer.

#5966 Barcoded cell state specific transcription factors screen identifies SIX1 as a critical regulator of neuroblastoma plasticity and drug resistance.

Xingyu Liu[1], Ying Wu[2], Haiyan Lei[1], Wendy Fang[1], John Shern[1], Zhihui Liu[1], Carol Thiele[1]

[1]Cell and Molecular Biology Section,, Pediatric Oncology Branch, Center for Cancer Research, National Cancer Institute, National Institutes of Health, Bethesda, MD,[2]Advanced Biomedical Computational Science, Frederick National Laboratory for Cancer Research, Frederick, MD

Neuroblastoma (NB) is characterized by intratumoral heterogeneity, consisting of at least two distinct cell types: adrenergic (ADRN) and mesenchymal (MES). These cell states can spontaneously interconvert, potentially driven by changes in super-enhancer landscapes and transcription factor (TF) networks. This interconversion presents a significant therapeutic challenge, as MES NB cells are less differentiated, more migratory, and drug-resistant, emerging during treatment and contributing to relapse. Therapeutic strategies targeting one state (like ADRN) may leave behind or select for more chemoresistant MES cells, complicating treatment efforts. Understanding the mechanisms behind the plasticity between the ADRN and MES states is critical for developing more effective treatments that prevent therapy resistance, tumor relapse, and improve patient outcomes. This MES cell state exhibits resistance to standard cytotoxic treatments and is associated with a more aggressive, migratory phenotype, contributing to poor therapeutic outcomes in NB. Additionally, NOTCH3 signaling drives the transition from ADRN to MES, with PRRX1 acting as a key reprogramming driver that reshapes the super-enhancer and mRNA landscapes of ADRN cells toward a MES state. However, what are the other TFs are involved with the transdifferentiation between ADRN and MES? What are the other TFs are responsible for the resistance of the cytotoxic therapies remain unclear. Furthermore, the most effective strategies to therapeutically target these pathways to prevent MES transition and overcome therapy resistance remain unknown.

#5967 Overexpression of the transcription factor gene TGIF1 inhibits proliferation in NRAS-driven acute myeloid leukemia cells.

Michael Roberts[1], Herryung Choi[2], Chase Mitchell Weizer[3], Helena Holley[4], Mishra Pranav[5], Ellsa Hritz[6], Jeffrey Forrester[1]

[1]Dickinson College, Carlisle, PA,[2]Biology, Dickinson College, Carlisle, PA,[3]Dana-Farber Cancer Institute, Boston, MA,[4]Molecular Medicine, University of Maryland, Baltimore, MD,[5]Yale University, New Haven, CT,[6]Data Analytics, Dickinson College, Carlisle, PA

The relatively few oncogenic driver mutations in most acute myeloid leukemia (AML) cells signifies that the numerous phenotypic hallmarks of cancer are established through the dysregulated expression of normal genes, by creating a leukemic transcriptome. We have sought to identify key transcriptional regulators that have the capacity to reprogram the AML transcriptome in ways that promote more normal cell behavior. The AML cell line HL-60 is responsive to treatment with phorbol esters, such as phorbol 12-myristate 13-acetate (PMA), that activate Protein Kinase C (PKC) and result in cell cycle arrest, myeloid differentiation, and eventual apoptosis. Through DNA microarray and RNA sequencing gene expression assays, we have identified approximately 100 genes encoding transcriptional regulators that significantly change in expression level during the PMA response. Among them, the TALE homeobox protein TGIF1 is up-regulated and serves as an expression prognostic marker demonstrating greater overall survival for patients expressing high levels compared to low expression samples by Kaplan-Meier survival plot analyses. Here we show that overexpression through transfection of TGIF1 in AML cell lines inhibits proliferation, as measured by Ki67 and DNA content levels using flow cytometric assays. These findings confirm a tumor suppressor role for TGIF1 in certain AML subtypes as has been previously described in pancreatic cancer. We also provide evidence that the mechanism for TGIF1 proliferation inhibition includes transcriptional repression of MYC and CCND1 expression. A more complete understanding of how TGIF1 directs the AML cell transcriptome is currently in progress using RNA sequencing to identify differentially expressed genes defining TGIF1 targets.

#5968 *FOXM1* as a key regulator of metastatic outgrowth in brain metastasis of breast cancer.

Shannon Cartay Kalsi[1], Lara Luzietti[1], Aoibheann Dowd[1], Aoibhin M. Powell[1], Gabriela Gomez[1], Jason McGrath[2], Nicola S. Cosgrove[3], Hian Hui Young[2], Arnold D. K. Hill[3], Stefan Prekovic[4], Leonie S. Young[2], Damir Vareslija[1]

[1]School of Pharmacy and Biomolecular Sciences, Royal College of Surgeons in Ireland (RCSI), Dublin, Ireland,[2]Department of Surgery, Royal College of Surgeons in Ireland (RCSI), Dublin, Ireland,[3]Department of Surgery, Beaumont RCSI Cancer Centre, Dublin, Ireland,[4]Center for Molecular Medicine, University Medical Center Utrecht, Utrecht, Netherlands

INTRODUCTION: Brain metastases occur in approximately 20% of breast cancer patients. These secondary lesions exhibit distinct phenotypic and genomic alterations compared to primary breast tumours, often driven by specific transcription factors. Identifying such factors may reveal novel therapeutic targets for treating brain metastases. We investigate FOXM1 as a key regulator in breast cancer brain metastasis, highlighting it as a potential prognostic and therapeutic marker.

MATERIALS AND METHODS: We performed RNA sequencing on 45 paired patient samples of primary breast tumours and corresponding brain metastases. Gene co-expression network analysis was conducted to identify preserved modules, focusing on the FOXM1-driven module. FOXM1 expression levels were assessed across patient cohorts to evaluate their correlation with survival outcomes and enrichment in tumours that progressed to brain metastasis. The impact of FOXM1 silencing on tumorigenicity and metastatic potential was investigated using breast-to-brain metastatic cell lines and *in vivo* models, with subsequent analysis of metastatic cluster formation and cellular proliferation.

RESULTS: The FOXM1-driven gene module was conserved in brain metastases and associated with poor clinical outcomes, including reduced overall survival. High FOXM1 expression was notably enriched in tumours that relapsed in the brain and correlated with diminished recurrence-free survival. Genetic and pharmacological inhibition of FOXM1 significantly impacted proliferation across multiple models of breast cancer brain metastasis representing all major subtypes. Transcriptomic analysis following FOXM1 silencing revealed the regulation of key pathways, including mTOR, TGF-β, EGFR, and epithelial-mesenchymal transition (EMT). Genetic silencing of FOXM1 *in vivo* models significantly inhibited the formation and size of brain metastasis clusters, reducing both proliferation and metastatic capacity.

CONCLUSION: FOXM1 is a critical regulator of breast cancer brain metastasis. Inhibition of FOXM1 hinders metastatic growth in the brain and improves survival-related outcomes. Targeting FOXM1 may signify a promising therapeutic strategy for patients with breast cancer brain metastasis. These findings underscore the importance of FOXM1 in brain metastases progression and suggest that targeting it could offer a novel therapeutic avenue.

#5969 Splicing variability and oncogenic isoforms: Transforming our understanding of HNSCC biology.

Daria Gaykalova[1], Madeleine Ndahayo[2], Ishita Gupta[3]

[1]Otorhinolaryngology, University of Maryland, Baltimore, Baltimore, MD,[2]University of Maryland, Baltimore, Baltimore, MD,[3]University of Maryland School of Medicine, Baltimore, MD

Head and neck squamous cell carcinoma (HNSCC) remains a cancer type with limited effective targeted therapies, currently restricted to anti-EGFR (Cetuximab) and anti-PD1 agents (Nivolumab and Pembrolizumab), and only one clinically established biomarker (HPV or its surrogate p16, applicable to ~30% of patients). Despite extensive genomic sequencing efforts, no new targeted therapy or biomarker has been approved for HNSCC in the past two decades. Our research addresses this critical gap by focusing on alternative splicing events (ASEs), which can profoundly alter gene function independently of mutations and represent an underexplored mechanism of oncogenesis. We hypothesize that ASEs in HNSCC contribute to tumor progression and can serve as biomarkers and therapeutic targets. To test this, we analyzed RNA-Seq data from The Cancer Genome Atlas (TCGA) and institutional cohorts, identifying 110 recurrent ASEs, including those in AKT3, PIK3R1, and HOXC6. These isoforms frequently originate from alternative transcription start sites (TSS) and display a strong inverse correlation between promoter DNA methylation and ASE expression, coupled with a positive correlation between H3K27ac enrichment and ASE expression. Together, these findings implicate chromatin architecture as a critical regulator of cancer-specific splicing programs. Functional validation revealed that these isoforms are frequently upregulated in tumors and drive oncogenic phenotypes such as increased proliferation and migration through activation of PI3K/AKT and other signaling pathways. To systematically characterize splicing variability and its immunogenic potential, we developed Splice Expression Variability Analysis (SEVA), enabling detection of differential isoform usage across tumor subtypes, and SpliceMutr, a computational pipeline for predicting splicing-derived neoantigens. These tools have uncovered splicing-driven vulnerabilities that may inform immunotherapy strategies and precision oncology. In conclusion, our findings created a map of ASE in HNSCC and established ASEs as a major contributor to HNSCC oncogenesis, independent of coding mutations, and highlighted the interplay between epigenetic regulation and RNA processing. Detection of oncogenic isoforms offers a path toward novel biomarkers, while targeting isoform-specific mechanisms could lead to innovative therapeutic strategies. This work introduces a paradigm shift in understanding HNSCC biology and opens new avenues for biomarker discovery and treatment development.

#5970 Rescuing VHLD missense mutations to prevent or treat renal cell carcinoma.

Shabnam Pirestani

Drexel University College of Medicine, Philadelphia, PA

Von Hippel-Lindau disease (VHLD) is an autosomal dominant cancer syndrome caused by germline mutations that occur throughout the *VHL* gene, affecting approximately 1 in 36,000 individuals. VHLD most commonly results in clear cell renal cell carcinoma (ccRCC) but can cause pancreatic neuroendocrine tumors and central nervous system hemangioblastomas, depending on the site of mutation. Somatic mutations in VHL are also common features of spontaneous ccRCC. The VHL protein (pVHL) serves as the substrate recognition component of the VCB E3 ubiquitin ligase complex (Elongin B/C, Cullin-2, and Rbx1), which targets hydroxylated HIF-α for proteasomal degradation under normoxic conditions. When *VHL* is mutated or oxygen is limited, HIF-α accumulates, activating genes such as *VEGFA* and *TGFα* that promote angiogenesis and proliferation. pVHL also has HIF-independent functions that are less understood but may contribute to VHLD pathogenesis. Belzutifan, which inhibits HIF-2α activity, has emerged as a valuable treatment for VHLD and spontaneous ccRCC, but not all patients respond, possibly due to cancer-promoting, HIF-independent consequences of VHL loss. This suggests the potential value of targeting pVHL directly.To evaluate how distinct missense mutations affect the canonical HIF-degradation role versus non-canonical functions, we analyzed public databases to identify common *VHLD* mutations associated with ccRCC versus other VHLD syndromes. We selected mutations distributed across the protein surface, including those disrupting interactions with VCB or HIF. We then generated lentiviruses encoding wild-type, null, and 10 VHLD-associated mutations, and used these to establish a series of isogenic models in *VHL*-null 786-O cell line. Cell models were characterized for pVHL and HIF-2a expression, as well as a series of non-canonical VHL-regulated phenotypes including control of mitotic integrity and spindle checkpoint activity. We then compared the ability of belzutifan and three pVHL-targeting drugs (VH298, CP4, CP4.29) to reverse phenotypes associated with VHLD mutations or loss. Whereas VH298 disrupts the VHL:HIF interaction interface, the recently described CP4 and its derivative CP4.2 bind a cryptic pocket near Asp197 in pVHL, stabilizing the structure and potentially restoring multiple protein functions. We will discuss activity of these compounds in rescuing essential VHL activities across diverse VHLD mutations, for canonical and non-canonical pathways. The goal of this work is to develop a new therapeutic approach for VHLD patients.

#5971 MYC cooperatives with KDM7A to repress SIDT2 and dampens dsRNA-mediated anti-tumor immunity.

Tae-Won Lee[1], Kyung-min Lee[1], Carlos L. Arteaga[2], Ariella B. Hanker[3], Seung Han Son[1]

[1]Life Science, Hanyang University College of Natural Sciences, Seoul, Korea, Republic of,[2]Director, Breast Cancer Program and Center for Cancer Targeted Therapies, UT Southwestern Simmons Comprehensive Cancer Center, Dallas, TX,[3]UT Southwestern Harold C. Simmons Comprehensive Cancer Center, Dallas, TX

MYC is a proto-oncogene frequently amplified in various cancers and is well known for its transcriptional activation functions, yet the mechanisms by which MYC mediates transcriptional repression remain poorly understood. Through integrative multi-omics analysis, we identified *SIDT2* as a novel direct target repressed by MYC. Analysis of public single-cell RNA sequencing datasets revealed mutually exclusive expression patterns between MYC and *SIDT2*, and their expression levels were inversely correlated across tumor transcriptome datasets. Loss of *SIDT2* reduced cytoplasmic double-stranded RNA (dsRNA) levels, leading to decreased expression of inflammatory chemokines including *CXCL9*, *CXCL10*, *CXCL11* and *CCL5*, resulting in impaired T cell recruitment. Inhibition of *DDX58* and *IFIH1*, two dsRNA sensors essential for innate immune signaling, abrogated the cytokine reduction caused by *SIDT2* loss, demonstrating that *SIDT2*-dependent cytokine expression is mediated through the dsRNA pathway. Consistent with its functional role, *SIDT2* expression correlated positively with cytotoxic T lymphocyte infiltration and was associated with favorable outcomes in patients receiving immune checkpoint blockade therapy. To identify factors that facilitate MYC-mediated transcriptional repression, we examined genes directly bound and suppressed by MYC and found substantial overlaps with gene targets regulated by KDM7A, a histone demethylase. Mechanistically, KDM7A functions as a transcriptional cofactor that enables MYC to repress *SIDT2* transcription. MYC and KDM7A co-occupied the regulatory region of *SIDT2*, forming a cooperative repressive complex, and loss of KDM7A abolishes MYC-dependent downregulation of *SIDT2*. ATAC-seq analysis further supported this mechanism by showing that MYC knockdown markedly increases chromatin accessibility at the *SIDT2* locus, whereas this chromatin remodeling does not occur when KDM7A is inhibited or depleted, indicating that KDM7A is essential for maintaining the repressive chromatin state imposed by MYC. Together, these findings reveal a previously unrecognized MYC-KDM7A cooperative mechanism that silences *SIDT2*, providing a mechanistic basis for MYC-mediated transcriptional repression and clarifying how oncogenic MYC suppresses dsRNA-driven anti-tumor immune responses.

#5972 Transcriptional dysregulation of pediatric B-ALL derived from Hispanic/Latino patients with and without high-risk genetic structural variants.

Joseph Schramm, **Brindangnanam Pownraj**, Bing He, Yali Ding, Daniel Bogush, Singh Chingakham, Katarina Dovat, Diwakar Bastihalli Tukaramrao, Sinisa Dovat

Penn State College of Medicine, Hershey, PA

Childhood Acute Lymphoblastic Leukemia (ALL) is the most common cancer diagnosis in children and teens. Relapsed ALL still contributes to leading cancer mortality in children and teens with ALL given it is highly prevalent. Hispanic/Latino (H/L) patients are a vulnerable population due to higher incidence of diagnosis and mortality compared to NHW despite correction for socioeconomic risk factors. H/L children have a higher incidence of high-risk genetic structural variants such as BCR-ABL1 translocations. IKZF1-del occurs more frequently and is frequently accompanied by other high-risk translocations or deletions such as CRLF2. CRLF2 translocations along with JAK2 alterations result in high-risk Ph-like B-ALL. We analyzed H/L leukemia samples from 42 H/L children and 18 NHW children using transcriptomics derived from RNAseq to uncover dysregulated regulatory pathways for childhood H/L ALL. We compared these two patient groups based on wildtype IKZF1 status or IKZF1 deleted status. Using ranked gene set enrichment analysis we found increased representation of dysregulated pathways for multiple genome maintenance pathways that affect replication, repair, and histone modification in H/L B-ALL with IKZF1 deletion. When comparing samples from H/L and NHW with wildtype IKZF1, gene set enrichment analysis showed downregulated showed increased dysregulated expression of DNA repair, cell cycle regulation, as well as amino acid metabolism pathways. Reduced representation bisulfide sequencing analysis of equal H/L and NWH B ALL samples (n = 16) showed altered methylation signatures for H/L patients in comparison to NHW for genes represented in cytoskeletal structure, vesicle trafficking, cancer cell signaling, amino acid response pathways, and long noncoding RNAs associated with cancer. The data show that there are some fundamental differences in the transcriptomics and transcriptomic regulation of B-ALL derived H/L patients compared to that of NWH. This was observed even in the absence of high-risk genetic structural variants. The H/L B-ALL results suggest that further research into the mechanisms of this transcriptional dysregulation will result in new approaches for risk adapted therapy to address this vulnerable population.

: RAS/MAPK Signaling, KRAS Targeting, and Adaptive Resistance
Poster Session

#5976 Spatiotemporal control of RAS-RAF signaling at the single-molecule level.

Rodrigo E. Caceres-Gutierrez[1], Rebika Shreshta[1], Jean Castillo-Badillo[1], Vanessa Wall[1], Scott Eury[1], Katie Powell[1], William Burgan[1], Min Hong[1], Peter Frank[1], Dwight V. Nissley[1], Frank McCormick[2], Thomas Turbyville[1]

[1]Frederick National Laboratory for Cancer Research, Frederick, MD,[2]UCSF Helen Diller Family Comprehensive Cancer Center, San Francisco, CA

RAS GTPases are central drivers of proliferation, differentiation, morphology, and apoptosis, yet oncogenic RAS remains largely untreatable: only two KRAS G12C–specific therapies are approved, benefit a minority of patients, and face clinical resistance. A key unresolved problem is how RAS activates its main effector, RAF, inside cells. Bulk affinity measurements show strong RAS–RAF binding but obscure the lifetimes of individual encounters and their spatial context. Here we integrate single-molecule with both *in vitro* and live-cell approaches to quantify the spatiotemporal dynamics of RAS–RAF binding. To directly visualize one-to-one RAS–RAF and RAF–RAF interactions in a TIRF microscope, we conducted dynamic single-molecule pulldowns: we built artificial 2- or 8-lipid membranes on coverslips (supported lipid biolayers) with tethered recombinant human RAS proteins. Then, BRAF or CRAF proteins from crude human cell lysates were captured by the membrane-bound RAS. This system allowed us to quantitate the biophysical parameters of RAS-RAF complexes diffusing on a lipid bilayer in real time. Strikingly, most individual RAS-RAF encounters only lasted a few tens of milliseconds. These short-lived interactions are consistent with constant interaction turnover detected in conventional co-immunoprecipitation assays. In live cells, we built upon a human HEK cell line devoid of endogenous H/N/KRAS and A/B/CRAF genes (6 KOs), to stably express halo-KRAS4b and snap-CRAF at stoichiometric, low levels. Then, we imaged single-molecule halo-KRAS4b and snap-CRAF using simultaneous two-color TIRF video acquisition, and analyzed the dynamics of the RAS/RAF interaction. Similar to our *in vitro* results, we observed that CRAF exhibits very short membrane dwell times in live cells, which increased upon MAPK pathway activation with soluble EGF. By bridging millisecond-scale binding kinetics with MAP kinase pathway activation, our work outlines how transient RAS–RAF contacts are regulated in space and time. This could reveal potential vulnerabilities for therapeutic intervention beyond current RAS inhibitors.

#5977 mTOR inhibition activates the EGFR-MAPK network by a novel AKT-initiated feedback loop promoting adaptive resistance.

Keiichi Koshizuka[1], Hiroki Izumi[2], Tomohiko Ishikawa[3], Kuniaki Sato[3], Jean-Philippe Coppe[4], J. Silvio Gutkind[3]

[1]Moores Cancer Center, University of California, San Diego, San Diego, CA,[2]National Cancer Center Hospital East, Kashiwa-shi, Japan,[3]University of California, San Diego, San Diego, CA,[4]UCSF - University of California San Francisco, San Francisco, CA

Head and neck squamous cell carcinoma (HNSCC) is the sixth most common cancer globally, resulting in more than 300,000 deaths each year worldwide. Treatment options for HNSCC patients include surgery, radiation, chemotherapy, and molecularly targeted therapies, and although immunotherapies have recently revolutionized the treatment landscape, <20% of HNSCC patients respond to immune checkpoint blockade (ICB) therapies. The survival rate of HNSCC patients has changed only modestly over the past decades, and therefore, HNSCC is a significant global health problem with high mortality and morbidity. Genomic alterations converging on persistent activation of the PI3K/mTOR pathway (>80% of cases) represent one of the most frequently altered signaling circuits in HNSCC. This overreliance on PI3K/mTOR signaling for tumor growth may expose a cancer vulnerability that can be therapeutically exploited, as revealed by recent clinical trials of mTOR inhibitors (mTORi) in HNSCC in the adjuvant and neoadjuvant settings. However, mTORi are ineffective in patients with advanced HNSCC, highlighting the urgency of elucidating the mechanisms underlying mTORi resistance. By combining the power of systems biology and computational approaches, including a high-throughput kinase activity mapping strategy, CRISPR/Cas9 synthetic lethal screening, CRISPR-guided GFP-tagging of endogenous EGFR, and the analysis of the spatiotemporal activation of intracellular ERK pools, we have now identified the activation of EGFR-MAPK signaling induced by mTORi in HNSCC as a major adaptive compensatory resistance pathway. Mechanistically, we found that mTOR inhibition activates the EGFR-MAPK pathway by disrupting a novel AKT-regulated feedback loop that inactivates EGFR. Ultimately, our findings suggest that the adaptive activation of EGFR represents a new mechanism of mTORi resistance, and that EGFR co-targeting may be a potent therapeutic option for HNSCC. These findings may be relevant to a large number of cancer types that depend on PI3K/mTOR signaling but fail to respond to mTORi therapies as single agents.

#5978 SPR2015, a highly potent and selective KRAS G12D (on) inhibitor, exhibits favorable pharmacokinetic behavior and significant anti-tumor efficacy against colorectal cancer as monotherapy in preclinical models.

Yi Qian, Zirong Zhang, Zhifei Fu, Kai Zhou, Meibi Dai, Shuqin Liu, Yang Zhang, Tao Hu

SciBrunch Therapeutics Co., Ltd, Shanghai, China

Colorectal cancer (CRC) is the third most common malignancy and the second leading cause of cancer-related deaths worldwide. To date, effective treatments for CRC remain limited. About 40% of colorectal patients harbor KRAS mutations, with KRAS G12D mutation accounting for the largest population. Although many KRAS G12D (off or on) selective inhibitors are currently in clinical development, with several reported promising clinical results in pancreatic ductal adenocarcinoma (PDAC) and non-small cell lung cancer (NSCLC) patients, none have demonstrated clinically meaningful efficacy in CRC patients as monotherapy. SPR2015 is a highly potent and selective KRAS G12D (on) inhibitor with nanomolar proliferation inhibitory activities in various KRAS G12D cell lines while with good selectivity over KRAS wild type. Co-crystal structure showed that SPR2015 formed tri-complexes via binding tightly with cyclophilin A (CypA) and forming a covalent bond with G12D. SPR2015 exhibited longer CypA residence time and improved target engagement kinetics in both human and mouse CypA binding assays. Oral administration of SPR2015 in mice—alone or together with another G12D (on) inhibitor (cassette PK) — clearly confirmed target-mediated drug disposition (TMDD) PK behaviors of this type inhibitors. SPR2015 outperformed the other G12D (on) inhibitor achieving rapid and sustain target engagement via enhanced CypA competitive binding. In mouse PDAC/NSCLC xenograft models, SPR2015 effectively inhibited tumor growth at 10 mg/kg (oral, q.d.) and achieved tumor regression at 30 mg/kg (oral, q.d.). Accompanying PK/PD studies in these models established the correlation between tumor growth inhibition efficacy, downstream PD inhibition on DUSP6 mRNA, and drug exposures in blood, tumor, and other tissues. Furthermore, a mouse head-to-head clinical trial was evaluated between SPR2015 and another G12D (on) inhibitor in over 15 CRC cell-derived xenograft (CDX) or patient-derived xenograft (PDX) models, using a single dose at 100 mg/kg (oral, q.d.). SPR2015 showed significantly superior efficacy in these in vivo CRC xenograft models, achieving a 64.7% objective response rate (ORR) and 94.1% disease control rate (DCR) as monotherapy. On the safety part, SPR2015 demonstrated favorable in vitro safety profiles and was well-tolerated in a 28-day rodent repeat dosing tox studies. SPR2015 is currently under IND-enabling and is expected to advance to human Phase 1 study by the end of 2026.

#5979 RASurgence: ARF6 boosts RAS oncoprotein synthesis and accelerates tumor progression..

Gwen Kramer[1], Deja M. Brooks[2], Joshua Tay[3], Prachi Gupta[2], Sheri L. Holmen[3], Thomas Jacob[2], **Allie H. Grossmann**[2]

[1]Providence Portland Medical Center, Portland, OR,[2]Providence Cancer Institute, Providence Portland Medical Center, Portland, OR,[3]University of Utah Huntsman Cancer Institute, Salt Lake City, UT

Oncogenic mutations in *RAS* genes occur in approximately twenty percent of all cancers and drive lethal malignancies such as lung, pancreatic, colorectal carcinoma and melanoma. Despite decades of research, *RAS*-mutant cancers remain difficult to treat and resistance to emerging RAS targeted therapies is a major clinical challenge. The small GTPase ADP-Ribosylation Factor 6 (ARF6), a member of the RAS superfamily, is critical for endomembrane trafficking, cytoskeletal remodeling, and production of phosphatidylinositol 4,5-bisphosphate (PIP_2), a substrate for PI3K and PLC lipid signaling. We have previously shown that ARF6 mediates invasion, metastasis and adaptive immune suppression in BRAF-mutant melanoma. Here we present preliminary data suggesting that ARF6 supports survival of *RAS*-mutant cancer cells and accelerates RAS-driven tumor progression by augmenting oncoprotein expression. In human *NRAS*-mutant melanoma and *KRAS*-mutant carcinoma cells, inhibition or knockdown of *ARF6* significantly reduces viability. In genetically engineered, immunocompetent mice bearing $NRAS^{Q61R}$ melanomas, tumor-specific deletion of *Arf6* delays tumor onset, slows tumor growth and prolongs overall survival. Mechanistically, activation of ARF6 stimulates PI3K-AKT-mTOR signaling and increases expression of RAS, BRAF and PI3K oncoproteins, at least partly through mTOR-mediated protein translation. Together these data suggest that oncogenic RAS signaling relies on ARF6 to fortify expression of key oncoproteins in the RAS pathway and enhance tumor progression.

#5980 AUBE00: A novel cyclic peptide pan-KRAS inhibitor targeting KRAS-activated cancers including KRAS-mutant cancers and wild-type colorectal cancer.

Kana Takei[1], Mayuki Ueda[1], Toshiaki Tsunenari[1], Ai Shinoda[1], Munehiro Yuki[1], Hitoshi Sase[2], Saki Michisaka[1], Yukako Tachibana[1], Masami Hasegawa[1], Toshihiko Fujii[1], Shino Kuramoto[1], Miho Nagayasu[1], Mengxuan Gao[1], Kazuhiro Ohara[1], Keisuke Oki[1], Mikito Owa[1], Seiya Hirai[1], Haon Futamata[1], Takuya Torizawa[1], Hatsuo Kawada[1], Mirai Kage[1], Mikimasa Tanada[1], Takuya Shiraishi[1], Hitoshi Iikura[2], Takehisa Kitazawa[1], Hiroshi Tanaka[1]

[1]Chugai Pharmaceutical Co., Ltd., Yokohama, Japan,[2]Chugai Pharmaceutical Co., Ltd., Tokyo, Japan

KRAS represents the most frequently mutated oncogene in human cancers, with mutations occurring in approximately 30% of all malignancies. Significant progress has been made in RAS-targeted therapies over recent years. These include the FDA approval of G12C inhibitors such as sotorasib and adagrasib that target the OFF state of RAS, as well as the ongoing development of various non-G12C inhibitors and ON-state RAS inhibitor.

Here we present AUBE00, a novel cyclic peptide that selectively binds to the OFF state of KRAS. AUBE00 demonstrates equivalent binding affinity across a broad spectrum of KRAS mutations. In vitro studies revealed potent antiproliferative activity against cancer cell lines harboring various KRAS alterations.Pharmacokinetic evaluation across multiple species demonstrated favorable oral bioavailability of AUBE00. Oral administration resulted in robust in vivo antitumor efficacy in preclinical models.

The intracellular equilibrium between ON and OFF states of the KRAS protein is thought to vary depending on mutation types. Wild-type RAS predominantly exists in the OFF state under physiological conditions. The G13D mutant retains higher susceptibility to NF1-dependent hydrolysis compared to G12X mutants, suggesting a relatively higher proportion of OFF-state conformation. Based on this biological insight, we compared efficacy of AUBE00 with RMC-6236, a pan-RAS(ON) inhibitor among models with various KRAS alterations. Our findings demonstrate that AUBE00 exhibits superior antitumor activity against cancers with KRAS wild-type amplification or KRAS G13D mutations compared to RMC-6236.

Notably, RAS wild-type colorectal cancers typically show high dependency on EGFR signaling, with anti-EGFR antibodies established as standard therapy. This clinical observation suggests that downstream activation of wild-type RAS signaling significantly contributes to cancer proliferation and progression. Our investigations revealed that AUBE00 demonstrates significant antitumor activity in RAS wild-type colorectal cancer models. Furthermore, combination treatment with cetuximab and AUBE00 exhibited synergistic antiproliferative effects in vitro.

In conclusion, our preclinical data establish AUBE00 as a promising therapeutic option for cancers harboring KRAS mutations as well as RAS wild-type colorectal cancer. AUBE00 is currently being evaluated in a Phase 1 dose escalation study to assess its safety, tolerability, and preliminary efficacy in patients with advanced solid tumors.

#5981 Metabolic stress conditions dictate MAPKAPK2-dependent efficiency of MEK1/2 inhibition in colorectal carcinoma.

Niti Kumari[1], Xu Chen[2], Amber M. Baldwin[1], Kristin I. Clemons[1], Mohammad Alharakeh[1], Lilian Calisto[1], Balawant Kumar[3], Qiaoqiao Zhang[4], Jiang Min[5], Bin Xiao[6], Amar B. Singh[3], Bin Wang[2], **Brian J. North**[1]

[1]Biomedical Sciences, Creighton University School of Medicine, Omaha, NE,[2]Daping Hospital, Chongqing, China, Chongqing, China,[3]Department of Medicine, Division of Gastroenterology, Hepatology and Motility, Kansas University Medical Center, Kansas City, KS,[4]Jinfeng Laboratory, Chongquing, China,[5]Gastrointestinal Surgery Department, The First Affiliated Hospital of Chongqing Medical University, Chongqing, China,[6]Chongqing Medical University, Chongqing, China

The kinase MAPKAPK2 regulates cell survival, proliferation, and death, and is upregulated in colorectal carcinoma (CRC) where it is associated with tumor growth and progression. However, how it regulates tumor progression in conjunction with other signaling pathways, such as MEK/ERK, remains elusive. Solid tumors are often subjected to metabolic stress, notably glucose deprivation. Here we demonstrate that MAPKAPK2 protein levels in CRC regulate cell fate decision during stress conditions, such as glucose deprivation and therapeutic treatment. While MAPKAPK2 expression is a limiting factor for CRC growth *in vitro*, depleting MAPKAPK2 or inhibiting its activity pharmacologically provides a survival advantage to CRC cells under glucose limiting conditions. Subjecting CRC cells to low glucose resulted in an ERK1/2-mediated decline in MAPKAPK2 to promote survival. Additionally, cells with reduced MAPKAPK2 activity were less sensitive to trametinib under glucose limiting conditions. Utilizing transcriptomic profiling, we found that glucose deprivation and MAPKAPK2 depletion activate pathways associated with survival during metabolic stress. This relationship was also observed in CRC patients (TCGA), where tumors with low MAPKAPK2 expression had higher ERK1/2 activation and upregulated stress-induced pathways, leading to poor survival. Finally, MAPKAPK2 modulated growth of CRC organoids, subcutaneous tumors, and patient-derived xenografts (PDX), and reduced MAPKAPK2 levels decreased efficacy of trametinib, *in vitro* and *in vivo*. Overall, this study identifies an interrelationship between MEK/ERK and p38/MAPKAPK2 signaling pathways during glucose deprivation to support cell survival and features MAPKAPK2 loss as a possible mechanism leading to reduced efficacy of trametinib-based anticancer therapy and poor patient outcomes in CRC.

#5982 Eradicating metastatic cancers by targeting a major tumor vulnerability of the K-RAS pathway: Seven in absentia homolog (SIAH).

Jonathan M. Baker[1], Emanuel Frank Petricoin[2], Julia Wulfkhule[2], Andrew Howell[3], Ashleigh Hannah[3], Amy H. Tang[4]

[1]Biomedical and Translational Sciences, Macon & Joan Brock Virginia Health Sciences Eastern Virginia Medical School at Old Dominion University, Norfolk, VA,[2]George Mason University, Manassas, VA,[3]Eastern Virginia Medical School, Norfolk, VA,[4]Old Dominion University, Norfolk, VA

Background: Persistent activation of the K-RAS pathway is multipotent: its downstream signaling networks promote tumorigenesis, drug resistance, relapse, and metastasis. Despite newly developed state-of-the-art therapies, none have yet to achieve durable antitumor efficacy. Seven in absentia homologues (SIAHs) are a conserved family of RING-domain E3 ubiquitin ligases that function as the most downstream signaling gatekeepers in the K-RAS pathway. Our preclinical studies demonstrated that SIAH inhibition leads to a tumor eradication phenotype of multiple stage IV human cancer cell lines both in vitro and in vivo.

Aims: We propose SIAH is a major tumor vulnerability and actionable drug target for inhibiting K-RAS pathway activation. In this study, we aim to elucidate the molecular mechanisms underpinning the antitumor efficacy of our potent SIAH inhibitor, $SIAH_2^{PD}$, as a new targeted therapy to achieve tumor eradication.

Methods: Reverse phase protein arrays (RPPAs) and principal component analysis (PCA) were used to quantify statistically significant fold-changes of 294 signaling proteins and phospho-proteins in response to SIAH blockade in five stage IV cell lines. RPPAs were performed in triplicate on MiaPaCa, MDA-MB-231, MDA-MB-468, HeLa, and A459 cell lines in which $SIAH_2^{PD}$ expression was controlled by a doxycycline (DOX)-inducible Tet-ON/OFF system. Four experimental conditions were used: Tet-ON vector control cells without DOX (**group A**) and with DOX induction (**group B**); Tet-ON-$SIAH_2^{PD}$ experimental cells without DOX (**group C**) and with DOX induction (**group D**). The ratios of each group were calculated in a pairwise comparison after normalization to GAPDH as an internal control. To validate putative targets of interest, immunofluorescence (IF), flow cytometry (FC), and Western blots (WB) were performed on cells for **group C** and **D** at 3-, 5-, and 7-days post-DOX-induction. Adherent and single cell suspensions were used respectively for cell-based assays in biological triplicates and normalized to α-Tubulin. Target protein expression was quantified and validated, and statistical analyses were performed by one-way ANOVA and T-tests using GraphPad Prism software.

Results: The altered expression of NFκB, Caspase-3, Caspase-7, Cofilin, and PARP in response to SIAH blockade were independently validated by RPPA, WB, FC, and IF, demonstrating the roles of heightened cellular stress, apoptosis, and dysfunctional DNA damage and repair pathways induced by $SIAH^{\text{loss of function}}$ as mechanistic, synergistic to kill cancer cells and prevent tumor growth.

Conclusions: RPPA cancer pathway mapping provides invaluable molecular insights into cancer network rewiring in response to SIAH blockade, revealing a major tumor vulnerability. This study supports the design of anti-SIAH-based, anti-EGFR/K-RAS targeted therapies to control and eradicate incurable human cancers.

#5983 Functional characterization of the RAS processing enzyme Rce1.

David Van Dongen

Memorial Sloan Kettering Cancer Center, New York, NY

Proteins containing a C-terminal CaaX motif undergo post-translational modifications required for their localization to membrane surfaces and biologic functions. These post-translational modifications consist of: lipidation by a protein prenyltranferase, endoproteolytic cleavage by RAS-converting enzyme 1 (Rce1), and carboxyesterification by isoprenylcysteine carboxymethyltransferase (ICMT). These enzymatic processes are possible targets for cancer therapeutics, as they are necessary for the signaling function of RAS GTPases and other oncoproteins. However, difficulties associated with the biochemical purification and characterization of membrane embedded proteins have limited our understanding of the enzymatic mechanism of Rce1, which resides within the ER membrane. To address this, we identified a biochemically tractable ortholog of Rce1 from *Drosophila melanogaster* and developed a strategy to purify the enzyme in its catalytically active form. Purified Rce1 recapitulates known enzymatic properties, including a requirement for its substrates to contain an attached prenyl lipid. Characterization of the enzyme's kinetic properties reveal slow enzymatic turnover (~ 20 hr^{-1}), which is consistent with other integral membrane proteases. We find that Zn^{2+} and the lipid PA inhibit Rce1, raising the possibility these factors may regulate its catalytic activity *in vivo*. Mass spectrometry analysis of the purified protein indicates that the enzymatic mechanism does not utilize metal ions. We hypothesize that conserved histidine and glutamate amino acids have catalytic roles, which differentiates Rce1 from most other proteases. This study provides insights into the catalytic mechanism of the enzyme, which could be useful for developing mechanism-based inhibitors.

#5984 Small molecule induced KRAS activation triggers ferroptosis in mutant KRAS expressing PDAC.

Haiyuxin Zhu[1], Kartini Iskandar[1], Nur Syafiqah B. Suleiman[1], Benedict J. Leong[1], Hanqing Pang[1], Alessandro Carrer[2], Anne-Sophie ARMAND[3], Franck Oury[4], **Shazib Pervaiz**[1]

[1]National University of Singapore, Singapore, Singapore,[2]University of Padua, Padua, Italy,[3]University of Paris Cite, Paris, France,[4]Institut Necker, Paris, France

Pancreatic ductal adenocarcinoma (PDAC) is the most prevalent histological subtype of pancreatic cancer with limited treatment options and poor prognosis. More than 90% of PDAC harbor mutations in the oncogene *KRAS* and are dependent on downstream pro-survival and/or proliferative factors such as AKT, MEK and MAPK. As such, targeting these downstream pathways has been employed as a therapeutic strategy, however, recent success in developing KRAS-specific inhibitors has added an important dimension in the management of PDAC. The clinical efficacy of the direct KRAS inhibitors has been less than optimal, which circumvents the need for identifying new therapeutic strategies. To that end, we recently described a novel approach using a small molecule that induced KRAS activation-dependent, ROS-mediated, execution of mutant *KRAS* driven cancer cells (*Iskandar, K. et al. Autophagy 2024*). Here we investigated the effect of this small molecule (merodantoin; C1) on mutant *KRAS* expressing PDAC. Results show that C1 selectively targets PDAC cells (cytotoxicity, colony formation and spheroid formation) harboring *G12 KRAS* mutation compared to wild-type *KRAS* expressing cells. Mechanistically, C1 treatment led to significant increase in both intracellular and mitochondrial reactive oxygen species (ROS), increase in labile iron levels due to increased transferrin receptor 1 (TfR1) and decreased ferritin heavy chain (FTH1), and disruption of the glutathione-based antioxidant system by reducing cystine uptake and decreasing Glutathione peroxidase 4 (GPX4) expression. These changes together triggered lipid peroxidation, a key sign of ferroptosis. Experiments using ferroptosis inhibitors, iron chelators, and ROS scavengers restored cell viability, confirming that C1 triggered cell death in PDAC cells by ferroptosis. Importantly, genetic and pharmacological modulation of *KRAS* provide evidence that mutant *KRAS* is upstream of ferroptotic cascade. Moreover, *KRAS* mutations were shown to make PDAC cells more sensitive to ferroptosis by naturally lowering their antioxidant defences and iron storage capacity. This was evident in the reduced baseline expression of GPX4 and SLC7A11, along with decreased cystine uptake in mutant *KRAS* expressing cell lines compared to wild-type controls. Beyond *in vitro* validation, C1 demonstrated strong effectiveness in patient-derived PDAC organoids and significantly limited tumor growth in a orthotopic PDAC mouse model. Evidence presented here strongly argue in support of targeting ferroptosis vulnerability of KRAS-mutant PDAC as a novel treatment strategy.

#5985 *GNAS*^{R201C} enhances peritoneal carcinomatosis in K*RAS*^{G12D}-driven gastrointestinal cancer models.

Ichiaki Ito, Saikat Chowdhury, John Paul Shen

UT MD Anderson Cancer Center, Houston, TX

Background*KRAS*^{G12D} and *GNAS*^{R201C} co-mutations are common in low-grade appendiceal mucinous neoplasms and promote peritoneal metastasis. We examined the role of *GNAS*^{R201C} in tumor progression using syngeneic mouse models.

Methods We generated *cdx2-Cre;LSL-Kras*^{G12D}*;Rosa26R-LSL-rtTA;TetO-Gnas*^{R201C} (cdx2-Kras/Gnas) mice, where *KRAS*^{G12D} is constitutively active and *GNAS*^{R201C} is doxycycline (dox)-inducible in the intestine. Protein levels were compared in RPPA between dox- and dox+ appendiceal organoids (cdx2-Kras/Gnas) generated from cdx2-Kras/Gnas mice. Pancreatic IPMN cells (p48-Kras/Gnas) were tested in a syngeneic peritoneal carcinomatosis model. Tumor burden, signaling, and survival were assessed.

Results In cdx2-Kras/Gnas mice, phospho-p44/42 MAPK Erk1/2 was robustly increased in cecum and colon without histologic abnormalities after 3-9 months of dox administration. In cdx2- Kras/Gnas organoids, dox induced *GNAS*^{R201C} expression (>3000-fold) and increased phosphorylated PKA substrates, accelerating organoid growth (doubling time: 78.5 h in dox+ vs. 121 h in dox−). In RPPA, proteins related to 1) survival and anabolic signaling (AKT2 pS474), 2) ER stress response and amino acid biosynthesis (PERK, Calnexin, and ASNS), and 3) glycolytic and lipid metabolism (Hexokinase II, ACSL, and UGT1A) were increased in dox+ vs. dox− organoids. To test the role of *Gnas*^{R201C} in peritoneal carcinomatosis, cdx2-Kras/Gnas and p48-Kras/Gnas cells were IP implanted in C57BL/6 mice. No peritoneal tumor formation was detected in mice after cdx2-Kras/Gnas cell IP implantation, whereas p48-Kras/Gnas cells formed pancreatic tumor, and extensive peritoneal and visceral metastases including liver and mesenteric lymph nodes in dox+ mice, reducing median survival to 11.5 days (log-rank p = 0.0368). Dox− mice implanted with p48-Kras/Gnas cells showed minimal disease. $CD3^+$ immune cells were locally enriched in dox+ pancreatic tumors, whereas minimal infiltration was observed in dox− tumors.

Conclusion *GNAS*^{R201C} cooperates with *KRAS*^{G12D} to promote peritoneal metastasis and alter the tumor microenvironment, suggesting GNAS signaling as a therapeutic target.

#5986 Deletion of AKT1 inhibits PTEN-loss induced intrahepatic cholangiocarcinoma but not hepatocellular carcinoma development in mice.

Ielyzaveta Slarve[1], Yining Ding[1], Yushan Wang[1], Zifei Xu[1], Lina He[1], Bangyan L. Stiles[2]

[1]USC - University of Southern California, Los Angeles, CA,[2]Assistant Professor, USC School of Pharmacy, Los Angeles, CA

Liver cancer is the third most common cause of cancer-related mortality worldwide, with hepatocellular carcinoma (HCC) and intrahepatic cholangiocarcinoma (ICC) representing the two most common subtypes. Mice lacking the tumor suppressor PTEN in the liver (*Pten*$^{loxP/loxP}$; albumin [*Alb*]-*Cre*$^{-/+}$; LiPten) display gradual, age-dependent development of hepatosteatosis and combined HCC-ICC. *Pten* loss results in activation of the serine/threonine kinase AKT. Of the three AKT isoforms identified to date, AKT1 isoform is implicated in regulation of cell growth, proliferation, and survival. In the present study, we investigated the role of AKT1 in mediating PTEN-loss induced liver cancer development by generating a novel double knockout mouse model (*Pten*$^{loxP/loxP}$; *Akt1*$^{loxP/loxP}$; *Alb-Cre*$^{-/+}$; LiPtenA1). Compared to 6-month-old control animals (*Alb-Cre*$^{-/-}$), LiPten mice fed normal chow developed marked hepatomegaly and diffuse steatosis. Loss of AKT1 in LiPten animals was unable to reverse steatosis, and LiPtenA1 animals did not exhibit any differences in body or liver weights. At 12 months old, LiPten mice developed tumor nodules on their livers, with microscopic features of steatosis, ductal proliferation and ectasia, HCC, and ICC. Like LiPten mice, all LiPtenA1 animals developed tumor nodules by 12 months of age. Microscopically, livers of LiPtenA1 mice displayed features of fatty nodules and HCC. Our preliminary analysis of expression of ICC-related genes and immunohistochemical staining of livers for ICC markers revealed significant reduction of ICC phenotype in LiPtenA1 mice. The induced phenotypic switch from combined HCC-ICC in LiPten mice to predominantly HCC in LiPtenA1 mice suggests a role for AKT1 in ICC development and contributes to the understanding of the role of AKT isoforms in regulating liver tumorigenesis.

#5987 Dual targeting of Pyk2/FAK and MEK/ERK pathways enhances growth suppression in glioblastoma.

Emely Morales-Colon[1], Kevin A. Rosa- Gonzalez[1], Lilia Kucheryavykh[2]

[1]Biochemistry, Universidad Central del Caribe, Bayamon, PR,[2]Universidad Central del Caribe, Bayamon, PR

Glioblastoma (GBM) is a highly aggressive brain tumor characterized by strong resistance to both chemotherapeutic and targeted therapeutic interventions. Our previous studies demonstrated that pharmacological inhibition of Focal Adhesion Kinase (FAK) and Proline-rich Tyrosine Kinase 2 (Pyk2) signaling in mouse glioma models significantly reduces tumor growth but results in only a modest increase in overall survival, suggesting the development of compensatory resistance mechanisms. Additionally, compensatory activation of the MEK/ERK signaling pathway was observed following the inhibition of FAK/Pyk2. We therefore hypothesized that concurrent targeting of FAK/Pyk2 and MEK/ERK signaling pathways could overcome MEK/ERK activation and enhance the therapeutic efficacy of FAK/Pyk2 inhibition in GBM.

Western blot analysis of primary human GBM cell lines and the GL261 glioma model in C57BL/6 mice revealed increased phosphorylation of MEK and ERK following treatment with the dual Pyk2/FAK inhibitor defactinib (5 μM in vitro; 50 mg/kg in vivo) for 72 hours. Combinatorial treatment with the MEK/ERK inhibitor avutometinib (1 μM in vitro; 0.3 mg/kg in vivo) abolished this compensatory activation, resulting in a 10-fold reduction in ERK phosphorylation in vitro and a 3-fold reduction in vivo. Cell cycle analysis demonstrated an accumulation of cells in the G2/M phase and induction of apoptosis following 72-hour treatment with defactinib, indicating cell cycle arrest. In contrast, avutometinib treatment for 72 hours resulted in cell accumulation in the G0 phase, accompanied by a decrease in cyclin D1 expression, as confirmed by Western blot analysis, consistent with a cytostatic effect. Combined treatment induced cell cycle arrest at both the mitotic (G2/M) and G0 phases, reflecting the additive effects of both inhibitors. Cell viability assays supported these findings, showing that defactinib and avutometinib monotherapies induced approximately 50% and 20% cell death, respectively, together with 60% and 25% reductions in live cell populations compared to untreated controls.

In conclusion, combined inhibition of Pyk2/FAK and MEK/ERK signaling produced an additive anti-tumor effect in glioma cells, suppressing compensatory MEK/ERK activation and enhancing growth inhibition.

#5988 MEK1/2 degraders uncover kinase-independent role of MEK1/2 in CRAF stabilization and maturation.

Jason S. Wasserman[1], Alison M. Kurimchak[1], Carlos Herrera-Montavez[1], Glenn A. Doyle[1], Brandon D. Fox[1], Ishadi K. M. Kodikara[1], Jian Jin[2], **James S. Duncan**[1]

[1]Fox Chase Cancer Center, Philadelphia, PA,[2]Icahn School of Medicine at Mount Sinai

The mitogen-activated protein kinase (MAPK) cascade is an evolutionarily conserved signaling pathway comprised of RAS GTPases, and downstream effector kinases (RAF, MEK, and ERK) that promote cell growth and survival. MEK1 and MEK2 (MEK1/2) are ubiquitous members of the dual-specificity MAP2K kinase family that phosphorylate and activate ERK1/2, controlling cellular proliferation. MEK1/2 paralogs share highly similar kinase domains, including their activation loops, which are phosphorylated by the upstream RAF family of kinases ARAF, BRAF, and CRAF. The activation of MEK1/2 by RAF is thoroughly described; RAF directly interacts with and phosphorylates MEK1/2, resulting in MEK1/2 kinase activation and subsequent phosphorylation of ERK1/2. In contrast, how the upstream RAF kinase, particularly CRAF, is activated is highly complex, involving an orchestration of chaperones, phosphorylation, and RAF dimerization, ultimately resulting in the phosphorylation of MEK1/2. The recognized CRAF signaling cascade has MEK1/2 functioning solely as a substrate of CRAF, binding to CRAF after RAS binding and RAF dimerization. However, there is evidence that MEK1 can directly regulate CRAF activity independent of RAS, suggesting that MEK1 has additional functions in the CRAF cycle. Here, using MEK1/2 proteolysis targeting chimeras (PROTACs), we discovered that MEK1/2 have kinase-independent functions in the regulation of CRAF protein stabilization, maturation, and kinase activation. Our findings reshape the current view of the CRAF activation cycle, establishing MEK1/2 binding to CRAF as an early required stabilizing event preceding CRAF-RAS engagement. Thus, MEK1/2 functions as both an activator and substrate of CRAF.

#5989 Targeting SHOC2 and GAB2 in acral melanomas driven by RAS-GTP.

Rony Andre Francois[1], Nick Lertwiriyapiti[2], Lucy C. Young[1], Matthew J. Sale[1], Frank McCormick[1]

[1]UCSF Helen Diller Family Comprehensive Cancer Ctr., San Francisco, CA,[2]University of California San Francisco, San Francisco, CA

Acral and cutaneous melanomas both rely on sustained mitogen-activated protein (MAP) kinase pathway activation for growth, however, unlike cutaneous melanoma, acral melanomas harbor distinct genomic drivers. These include frequent amplifications of *GAB2*, loss of function mutations in *NF1*, activating mutations in the KIT receptor tyrosine kinase (RTK), and mutations in canonical RAS (often codons 12 or 13 of NRAS). These mutations may occur separately or co-occur, and converge to increase RAS-GTP, resulting in oncogenic MAPK signaling.RAS-driven cutaneous melanomas have recently been found to be particularly dependent on SHOC2 for sustained MAPK signaling, however the extent to which RAS-driven acral melanomas rely on SHOC2 and/or GAB2 for sustained MAPK signaling has not extensively studied to date. To determine the extent to which SHOC2, GAB, and RAS-GTP contribute to MAPK signaling in acral melanoma, we used targeted si-RNA to SHOC2, GAB1, GAB2, or a combination of these, to determine the necessary RAS/MAPK pathway components critical for pathway activation. In parallel, we also utilized the RAS-ON inhibitor RMC-6236 (Daraxonrasib), the MEK inhibitor Trametinib, or a combination of both agents in RAS-driven acral melanoma cell lines. We found that the *NRAS* G12-mutant acral melanoma cell lines HS852T and Ma-Mel-27 were markedly sensitive to SHOC2 knockdown, with concurrent SHOC2/GAB1/GAB2 knockdown conferring the greatest inhibition of MAPK activity. Similarly, both cell lines were sensitive to RAS-GTP inhibition with RMC-6236, with the addition of Trametinib resulting in the greatest decrease in MAPK activity.These results demonstrate that RAS-driven acral melanomas rely on components upstream of RAS that activate MAPK signaling, such as GAB, as well as components downstream of RAS such as SHOC2 for maximal MAPK pathway activation. In keeping with this, pharmacologic inhibition of RAS-GTP with RMC-6236 combined with the MEK kinase inhibitor Trametinib resulted in maximal pathway inhibition. Therefore, targeting RAS/MAPK signaling using a vertical inhibition approach warrants further exploration in RAS-driven acral melanomas.

#5990 UBE3A and SV2A modulate GBM progression through MAPK pathway regulation..

Lee Eunju[1], MIN-JEE KIM[2], Peter CW Lee[2]

[1]Department of Biochemistry & Molecular Biology, Brain Korea 21 Project, University of Ulsan College of Medicine, Asan Medical Center, Seoul, Korea, Republic of,[2]Department of Biomedical Sciences, University of Ulsan College of Medicine, Seoul, Korea, Republic of

Glioblastoma (GBM) is the most aggressive and common primary brain tumor in adults, yet effective therapeutic strategies remain limited. In this study, we integrated transcriptomic and clinical data from the Chinese Glioma Genome Atlas (CGGA) and found that high UBE3A expression is significantly associated with poor prognosis in GBM. As an E3 ubiquitin ligase within the ubiquitin-proteasome system (UPS), UBE3A plays a crucial role in maintaining protein homeostasis and cellular processes. Functional assays in GBM cell lines demonstrated that UBE3A knockdown markedly reduced cell proliferation, colony formation, migration, and invasion. Mechanistically, UBE3A physically interacted with SV2A and promoted its ubiquitination, indicating that SV2A is one of its potential substrates. Either UBE3A depletion or SV2A overexpression reduced ERK and p38 phosphorylation, indicating suppression of MAPK signaling, and was accompanied by increased apoptotic signaling (enhanced PARP cleavage and caspase-3 activation). These findings indicate that UBE3A and SV2A drive GBM progression mainly via MAPK pathway regulation. Although additional studies of the UBE3A-SV2A axis and downstream MAPK signaling are needed, this axis may represent a promising therapeutic target in glioblastoma.

#5991 p53-induced FBXL20 suppresses the PP2A regulatory subunit PR55α.

Alison L. Camero[1], Michel Ouellette[2], Keith Johnson[3], Ying Yan[4]

[1]Genetics, Cell Biology, & Anatomy, University of Nebraska Medical Center, Omaha, NE,[2]Internal Medicine, University of Nebraska Medical Center, Omaha, NE,[3]Oral Biology, University of Nebraska Medical Center, Omaha, NE,[4]Radiation Oncology, University of Nebraska Medical Center, Omaha, NE

Background:Protein phosphatase 2A (PP2A) is a major serine/threonine phosphatase that regulates cell survival and proliferation. Each PP2A holoenzyme consists of a scaffolding subunit, a catalytic subunit, and a regulatory subunit, with the regulatory subunit determining substrate specificity and cellular localization. Work from our group and others has shown that the PR55α regulatory subunit promotes oncogenic signaling through YAP, c-Myc, β-catenin, and ERK pathways. Despite its established role in supporting tumorigenesis and progression, the upstream mechanisms controlling PR55α expression and activity remain poorly understood. Pancreatic cancer (PC), one of the most lethal human cancers, is characterized by frequent loss of p53 function, with mutations occurring in more than 75% of cases. We recently discovered that p53 induces the F-box protein FBXL20, which in turn reduces PR55α stability and expression. This finding reveals a previously unrecognized mechanism whereby p53 restrains PR55α through SCF-mediated ubiquitination and proteasomal degradation. Defining this regulatory interaction is essential for understanding how p53 loss enhances PR55α-driven oncogenic signaling in PC.
Methods:To identify the FBXL20 interaction site on PR55α, we generated Myc-tagged PR55α truncation constructs and performed co-immunoprecipitation assays. Additional immunoprecipitations are underway to determine whether FBXL20 engages PR55α within an assembled SCF complex by assessing SKP1 and CUL1-4 association. To evaluate functional consequences, we are generating PR55α point mutations that disrupt FBXL20 binding and will examine their biological effects on PR55α stability and downstream signaling pathways.
Results:Mapping studies indicate that FBXL20 binds to a region between WD40 domains 5-6 of PR55α, potentially involving an α-helical linker. FBXL20 also associates with the heterotrimeric PR55α-PP2A complex, suggesting that PR55α engagement with PP2A does not block its recognition by the SCF ligase. Ongoing experiments are testing whether core SCF components co-precipitate with PR55α, which will determine whether a functional ubiquitin ligase complex forms. Parallel studies using PR55α point-mutation constructs are examining how loss of p53/FBXL20 interaction alters PR55α stability and downstream signaling.
Conclusions:Our findings establish a novel mechanism by which p53 constrains PR55α abundance through FBXL20-mediated ubiquitination and proteasomal degradation. Identifying the FBXL20 recognition site on PR55α provides a foundation for defining the phosphodegron required for its turnover and significance on PR55α stability and oncogenic activity. Understanding this regulatory pathway offers insight into how p53 loss through mutations enables unchecked PR55α/PP2A-driven oncogenic signaling in PC and other malignancies and may uncover new PR55α-based therapeutic strategies.

#5992 A hotspot phosphorylation site on SHP2 drives oncoprotein activation and drug resistance.

Prashath Karunaraj[1], Remkes Scheele[2], Malcolm L. Wells[2], Ipek S. Gokulu[1], Lila Taylor[1], Ruchita Rathod[2], Sophia Abrahamson[2], Lamia Chowdhury[2], Abiha Kazmi[2], Weixiao Song[3], Anum Glasgow[2], Neil Vasan[1]

[1]NYU Langone Health Perlmutter Cancer Ctr., New York, NY,[2]Columbia University Irving Medical Center, New York, NY,[3]WuXi AppTec, Suzhou, China

SHP2, a protein phosphatase encoded by *PTPN11*, is a critical mediator of receptor tyrosine kinase (RTK)-driven RAS/mitogen-activated protein kinase (MAPK) signaling and is targeted by allosteric inhibitors that stabilize its autoinhibited conformation. Despite promising preclinical data, SHP2 inhibitors have shown minimal clinical efficacy (monotherapy response rate ~0%), with no defined mechanisms of primary resistance in patients. Here, we elucidate phosphorylation of SHP2 at tyrosine 62 (pY62) as a hotspot phosphorylation site enriched across normal cells and tissues, cancer cells, and varied RTK-driven tumor types in patients. We demonstrate that SRC family kinases (SFKs) directly phosphorylate SHP2 at Y62, downstream but not directly phosphorylated by RTKs. Using biochemical and biophysical analyses, we show that SHP2 pY62 enforces an open, active conformation, resulting in constitutive phosphatase activation that is sufficient to activate MAPK signaling and confer resistance to allosteric SHP2 inhibitors. These findings establish SHP2 pY62 as a phosphorylation hotspot phenocopying mutational activation, as a mechanism of primary resistance to SHP2 inhibitors, and as a cancer drug target distinct from wildtype SHP2.

#5993 The Rho-GEF ECT2 links Rho GTPases to MEK/ERK pathway activation in pancreatic ductal adenocarcinoma.

Dania Al-Qasrawi[1], Nayya N. Murray[1], Ryan A. Argo[1], Alicia K. Fleming Martinez[1], Prita Pandya[1], Anaya Y. Clarke[1], Kayla C. Winter[1], Murli Krishna[2], Peter Storz[1], Nicole R. Murray[1], **Verline Justilien**[1]

[1]Cancer Biology, Mayo Clinic Florida, Jacksonville, FL,[2]Pathology/Lab Medicine, Mayo Clinic Florida, Jacksonville, FL

Pancreatic ductal adenocarcinoma (PDAC) remains one of the most lethal human malignancies due to its silent clinical onset, rapid progression, and limited responsiveness to current treatment options. These features underscore the urgent need for early detection strategies and for new molecular targets that can be exploited therapeutically. Epithelial Cell Transforming Sequence 2 (ECT2) is a Rho family guanine nucleotide exchange factor that was originally identified as an oncoprotein and later shown to regulate cytokinesis. In this study, we examined the clinical relevance of ECT2 expression in PDAC and determined its functional contribution to transformed growth and tumorigenicity. Our analyses revealed that ECT2 expression increases at the earliest stages of PDAC development, remains persistently elevated during disease progression, and associates with reduced overall patient survival. Furthermore, a substantial fraction of ECT2 is aberrantly localized to the cytoplasm of PDAC cells. Functional studies demonstrated that depletion of ECT2 suppresses three-dimensional growth, invasive behavior, and tumor formation in vivo, while having little impact on PDAC cell cytokinesis. Mechanistically, we found that ECT2 is required for activation of Rac1 and RhoA and downstream MEK/ERK and ROCK signaling, respectively. Consistent with these results, analyses of PDAC patient datasets revealed a strong positive association between ECT2 expression and Rho GTPase as well as MEK/ERK and ROCK pathway signatures. Together, our data identify ECT2 as an early driver of PDAC transformation and highlight it as a promising therapeutic target.

#5994 Mechanism of oncogenicity induced by overexpression of the PRL phosphatases.

Jingmei Yu[1], Frederick Nguele Meke[1], Yunpeng Bai[1], Meaghan Maureen Broman[2], Haoran Zhang[1], Abhinanda Kar[1], Zhong-Yin Zhang[1]

[1]Borch Department of Medicinal Chemistry and Molecular Pharmacology, Purdue University, West Lafayette, IN,[2]Department of Comparative Pathobiology, Purdue University, West Lafayette, IN

The phosphatases of regenerating liver (PRL) phosphatases are frequently overexpressed in a wide variety of human cancers and are correlated with cancer progression, metastasis, and poor patient outcomes. Although PRLs appear to be linked to oncogenesis, it is not yet fully understood whether PRL overexpression is sufficient to drive spontaneous tumorigenesis *in vivo* or the mechanisms by which PRLs contribute to cancer. To address this gap, we developed a novel genetically modified mouse model that conditionally overexpresses PRL2 in the prostate epithelium, mimicking the onset of human cancers. Our findings indicate that transgenic overexpression of PRL2 leads to a multifocal low-grade prostatic intraepithelial neoplasia (LGPIN) phenotype, with a rare occurrence of malignancy in older mice. Furthermore, elevated PRL2 promotes significant acceleration and progression from high-grade prostatic intraepithelial neoplasia (HGPIN) to prostatic adenocarcinoma mediated by PTEN heterozygosity, whereas PRL2 overexpression is dispensable for PTEN-loss-mediated transformation. The initiation and progression of prostate cancer following PRL2 overexpression correlate with decreased PTEN levels and upregulation of AKT/mTOR pathways. Taken together, these findings elucidate the pivotal role of proto-oncogenic PRL2 in promoting tumorigenesis through the downregulation of PTEN. Therefore, PRLs are compelling therapeutic targets for cancer drug discovery, and PRL2 inhibition may be a novel approach for cancer treatment through PTEN augmentation in both PTEN-deficient and wild-type backgrounds.

#5995 Pterostilbene enhances dabrafenib activity in BRAF mutant melanoma through synergistic MAPK suppression and apoptotic induction.

Joshua Steven Fraser[1], Jordan Bury[1], Colt Summers[1], Jennifer Meyer[2], Gennie Lynne Parkman[3]

[1]Chemistry, Utah Tech University, St George, UT,[2]Utah Tech University, St George, UT,[3]Weber State University, Ogden, UT

Resistance to BRAF inhibitors limits durable responses in melanoma. Pterostilbene (PTB), a dietary polyphenol, has anti-proliferative and pro-apoptotic properties and may augment targeted therapy. We evaluated whether PTB enhances the activity of the BRAF inhibitor dabrafenib (DAB) in BRAF-mutant melanoma cells. IC_{50} values for PTB and DAB were determined in A375 and HT144 melanoma cells following 48 h treatment. Synergy studies were conducted in HT144 cells using 5×5 fixed-ratio matrices based on experimentally determined IC_{50} values, and synergy was quantified using Loewe additivity, Bliss independence, ZIP synergy, and Combination Index models. Mechanistic effects were assessed by Western blot analysis of key markers of MAPK signaling and apoptosis. In A375 cells, IC_{50} values were ~12 nM for DAB and ~60 μM for PTB. In HT144 cells, IC_{50} values were ~3 nM for DAB and ~45 μM for PTB. Multiple PTB+DAB combinations in HT144 produced strong synergy, with the most synergistic doses (e.g., PTB ~12 μM + DAB ~0.8-3 nM) showing Loewe CI < 0.7 and corresponding Bliss/ZIP synergy. Synergistic treatment decreased MAPK pathway activation and increased apoptotic markers relative to single agents, consistent with enhanced signaling suppression and apoptosis induction. PTB enhances DAB efficacy in BRAF-mutant HT144 melanoma cells, producing robust synergy and mechanistic evidence of MAPK pathway inhibition and apoptosis. These findings support further evaluation of PTB as a low-toxicity adjuvant to improve responses to BRAF-targeted therapy in melanoma.

#5997 Network based mapping reveals mechanistic drivers and targetable hubs contributing to Sotorasib resistance in KRAS G12C lung cancer.

Atish Ranjan Mohanty[1], Baiyi Quan[2], Dana Do[1], Ting-Yu Wang[2], Tsui-Fen Chou[2], Prakash Kulkarni[1], Ravi Salgia[1]

[1]City of Hope National Medical Center, Duarte, CA,[2]California Institute of Technology, Pasadena, CA

KRAS mutations are among the most common oncogenic drivers in lung adenocarcinoma, present in 30% of NSCLC cases. Most occur at codon 12, impairing KRAS's intrinsic GTPase activity and locking it in a constitutively active state. Although KRAS was long considered "undruggable," the development of covalent inhibitors, such as sotorasib, which bind to the KRAS G12C GDP-bound form, marked a significant therapeutic advance. However, the clinical responses remain limited, as many patients exhibit intrinsic resistance or eventually develop acquired resistance. These limitations highlight that cancer cells expressing KRAS G12C were not solely dependent on KRAS signaling for survival. Instead, they adapt to therapeutic pressure by rewiring their underlying gene regulatory and protein-protein interaction networks. These networks are highly complex, coordinated, and dynamic in nature rather than fixed. Environmental cues, drug exposure, and intrinsic signaling programs can reshape network topology, generating new regulatory states that sustain tumor survival and drive resistance. Therefore, a systems-level examination of these topological transitions is essential for identifying the mechanistic basis of KRAS inhibitor resistance and identifying the upstream nodes that may serve as therapeutic vulnerabilities. Methods: Mass-spectrometry-based proteomic and phosphoproteomic profiling was performed on parental and isogenic resistant NCI-H23 cells, with and without sotorasib treatment. Network-based analyses were conducted to identify signaling alterations associated with the development of resistance. Results and Conclusion: The integrated analysis suggests that tolerance to KRAS G12C inhibition is not mediated by a single pathway, but rather by a coordinated network of mitotic, replication stress, RNA processing, and chromatin remodeling mechanisms. Upregulation of mitotic regulators (FOXM1, MELK, PLK4, NEK2), replication-stress proteins (RRM2, RFC3, MCM5/6, RPA2/3), and splicing/chromatin factors (CLK1, SRPK1, SRSF1&3, SUZ12, EED) creates a robust stress-adaptation network that enables survival under KRAS-G12C inhibition. This coordinated pathway maintains cell proliferation, stabilizes stalled forks, supports chromatin plasticity, and promotes the emergence of drug-tolerant persisters. Together, these data support a model in which sotorasib-exposed cells adapt by coupling mitotic and replication-stress programs with RNA and chromatin remodeling, thereby maintaining viability in a chromosomally unstable state that can give rise to drug-tolerant persisters and, ultimately, fully resistant clones. In addition, these findings also highlight a set of actionable vulnerabilities within the mitotic and replication-stress machinery that may be targeted to prevent or delay resistance to KRAS G12C inhibitors.

Poster Session

#6000 Transglutaminase 2 mediates the p53-dependent senescence-associated secretory phenotype.
Xiaoyu Guo[1], Jihye Kim[1], Yi-Xi Gong[1], Ingyu Lee[1], Bomi Han[1], Ki Baek Lee[2], In-Gyu Kim[2], Eui Man Jeong[1]

[1]Jeju National University, Jeju, Korea, Republic of,[2]Seoul National University, Seoul, Korea, Republic of

Senescent cells secrete a variety of NF-κB-dependent proteins, collectively known as the senescence-associated secretory phenotype (SASP), which promotes paracrine senescence, resistance to apoptosis, and chronic sterile inflammation. To clarify the role of SASP in both tumorigenesis and age-related diseases, we investigated the mechanism underlying NF-κB activation in senescent cells. Here, we demonstrate that transglutaminase 2 (TG2) functions as an effector enzyme that activates NF-κB in response to DNA damage-induced stress. In normal cells, senescence inducers upregulated TG2 expression in a p53-dependent manner, thereby enhancing SASP. In contrast, in p53-inactivated cells, senescence inducers further elevated TG2 expression through a positive feedback loop, accounting for the paradoxical increase in SASP. Both TG2 knockdown and pharmacological inhibition reduced SASP. Moreover, TG2 promoted apoptotic resistance in senescent cells by inhibiting caspase-3 activity. Consistently, TG2-deficient mice exhibited reduced Ras-induced cytokine production and inflammation, while tissue-specific TG2 expression increased with age. Collectively, these findings identify TG2 as a key regulator of SASP and suggest its contribution to age-related pathologies.

#6001 Senescence-inhibitory Δ133p53α mitigates accelerated ageing in mice.

Leo Yamada, Huaitian Liu, Natalia Von Muhlinen, Curtis C. Harris, Izumi Horikawa

National Cancer Institute, National Institutes of Health, Bethesda, MD

Hutchinson-Gilford progeria syndrome (HGPS), a premature aging disorder caused by a de novo LMNA G608G mutation, is characterized by the accumulation of DNA damage and persistent inflammation, which drive accelerated aging and lead to severe clinical manifestations, including skin atrophy, alopecia, and progressive deterioration of the aortic wall due to loss of vascular smooth muscle cells, resulting in severely shortened lifespan. Mouse models of HGPS recapitulate these pathological aging phenotypes, including cardiovascular defects, increased cellular senescence, DNA damage accumulation, systemic inflammation, and shortened lifespan.The human p53 isoform Δ133p53α, which lacks the N-terminal 133 amino acids, is a naturally occurring truncated variant with distinct biological functions. In HGPS patient-derived fibroblasts, Δ133p53α suppresses cellular senescence, reduces pro-inflammatory IL-6 production, limits DNA-damage accumulation, and extends replicative lifespan. These findings suggest that Δ133p53α selectively attenuates p53-mediated cell-cycle arrest and senescence while preserving DNA-repair functions.Here, in a heterozygous HGPS mouse model, we show that transgenic expression of Δ133p53α reproduces these in vitro-observed effects across multiple organs in vivo and extends median lifespan by approximately 10% (387 vs. 358 days, P = 0.0235). In the aorta and skin, Δ133p53α mitigates progeria-associated pathological changes and preserves tissue integrity. Δ133p53α also mitigates spinal kyphosis characteristic of the HGPS mouse phenotype. RNA-sequencing analysis suggests that Δ133p53α promotes mitochondrial function and metabolic fitness. The effects of Δ133p53α in naturally aging mice are under investigation. Our human expression database analysis shows an age-associated downregulation of Δ133p53α in multiple human tissues, including aorta and skin.This study suggests not only a Δ133p53α-based therapeutic approach for HGPS but also broader interventions for preventing or delaying aging.

#6002 The lncRNA TUG1 enhances helicase-mediated R-loop resolution through RNA-protein interaction.

Shuya Mimura[1], Jingqi Xie[1], Miho M. Suzuki[2], Yutaka Kondo[3]

[1]Nagoya University, Nagoya, Japan,[2]Nagoya Univ. Graduate School of Medicine,[3]Nagoya City University Medical School, Nagoya, Japan

Long non-coding RNAs (lncRNAs) are emerging regulators of genome stability. Taurine upregulated gene 1 (TUG1) is highly expressed in cancer cells and rapidly induced by ATR-CHK1 signaling under replication stress. We previously showed that TUG1 interacts with replication protein A and the DEAE/DEAD-box helicase DHX9, enabling the resolution of pathogenic R-loops and supporting cancer cell proliferation. To expand our understanding of TUG1 function, we comprehensively profiled its interacting proteins using a CRISPR-based RNA-protein detection approach coupled with proteomic analysis. A conserved set of R-loop-associated factors, including RNA helicases, was enriched under replication stress, suggesting dynamic remodeling of TUG1-protein interactions in response to R-loop accumulation. Structural and biochemical analyses further suggested that TUG1 promotes helicase-mediated R-loop resolution through direct RNA-protein association. Collectively, our findings uncover a replication stress-responsive TUG1-helicase axis that maintains genome integrity by promoting R-loop resolution. Given that TUG1-targeting antisense oligonucleotides are already advancing into clinical trials, this study provides a mechanistic foundation supporting TUG1 as a promising therapeutic target for cancer treatment.

#6003 Modulation of cytokine-induced senescence in melanoma cells by JAK inhibitor: A possible way to improve therapeutic efficacy of immune checkpoint inhibitor.

Min You[1], Niramol Savaraj[1], Ying-Ying Li[2], Chunjing Wu[2], Mano Nagarajan[1], Medhi Wangpaichitr[1], Lynn G. Feun[1]

[1]University of Miami Miller School of Medicine, Miami, FL,[2]Miami VAMC, Miami, FL

Apart from the direct blocking of immunosuppressive checkpoint signaling, a prominent feature of immune checkpoint inhibitors (ICIs) is the enhancement of cytokine production by immune cells to facilitate anti-cancer immunity in the tumor microenvironment. Prolonged cytokine stimulation may also lead to immune suppression. On the other hand, it is known these cytokines can act on cancer cells to induce cellular senescence (cytokine-induced senescence, CIS). It has also been recognized that cellular senescence is intertwined with stemness or cell plasticity, and these phenotypic changes can be adopted by cancer cells to evade the anticancer effect of therapeutics agents including ICIs, resulting in resistance to treatment and or relapse post treatment. In this study, we attempt to investigate whether senomorphics such as JAK inhibitors can ameliorate CIS in melanoma cells and whether this reduction is accompanied by changes in the stemness and senescence-associated secretory phenotype (SASP). Melanoma cell line SK-MEL-28 was treated with INF-γ and TNF-α to establish CIS as indicated by SA-β-gal staining and detected with flow cytometry. Ruxolitinib (Ruxo) as a JAK1/2 inhibitor was then used to treat the cells, and at the end of the treatment the expression of stemness markers, SASP components, and immune checkpoint ligands was measured with qPCR. We observed that Ruxo was able to partially reduce the SA-beta-gal fluorescence in SK-MEL-28 (express PD-L1) at 10 nM and to the levels comparable of non-senescent control with non-senescent cell morphology at 10 μM. Furthermore, the expression of SASP component IL-1β and stemness markers CD271 was upregulated (about 4-fold) in the CIS state. Subsequent Ruxo treatment (10 μM) could partially attenuate the upregulation of IL-1β (by about 23%) and CD271 (by about 40%). However, Ruxo was unable to downregulate the increased expression of the stemness marker CD133 (1.77-fold from control); on the contrary, further upregulation (by about 31%) was noted. In addition, the expression of immune checkpoint ligands PD-L1 and PD-L2 showed moderate increase (by about 37% and 61%, respectively) in CIS and was not largely altered by Ruxo (increased by about 3% and 13%, respectively) while the increase of TIGIT ligand CD155 in CIS (by about 43%) could virtually be reverted by Ruxo. In summary, Ruxo could revert the senescent morphology and elevated SA-β-gal activity in the CIS of SK-MEL-28. Moreover, it could attenuate the expression of some stemness markers and SASP component elevated during CIS in melanoma cells. Further expansion of this study such as inclusion of more molecular markers and mechanism(s) is underway. Clinical study to include JAK inhibitor with ICI will also be initiated. This work is supported by the fund from Woman Cancer Association. Sylvester Comprehensive Cancer Ctr, U. of Miami and Miami VA Med. Ctr.

#6004 A link between the nuclear envelope protein LEM2 and an endoplasmic reticulum stress signaling pathway provides new insight into features of tumor development.

Natasha O. Saik[1], Maho Niwa[2], Katharine S. Ullman[1]

[1]Oncological Sciences, Univ. of Utah Huntsman Cancer Inst., Salt Lake City, UT,[2]Molecular Biology, University of California San Diego, School of Biological Studies, San Diego, CA

Cancer is often associated with reduced levels of certain nuclear envelope (NE) proteins, which contributes to irregularly shaped nuclei or nuclear dysmorphia. Nuclear dysmorphia can reflect compromised nuclear integrity and impaired DNA repair, which together can drive genomic instability and tumor development. Accordingly, expression levels of NE proteins—including LEM-domain proteins—are emerging as informative biomarkers for tumor detection, classification, and patient prognosis. Given that LEM2, an NE-associated LEM-domain protein, is altered in multiple cancers, we explored the effects of LEM2 depletion on phenotypic outcomes associated with cancer progression. Traditionally, the role of NE proteins in cancer phenotypes has been studied within the context of their canonical nuclear roles. However, hints from the literature suggest LEM2 contributes to the regulation of a physically connected organelle, the endoplasmic reticulum (ER). Despite the functional coupling and the physical continuity between the membranes that enclose the nucleus –the NE– and the ER, how changes originating in the nucleus influence ER organization and homeostasis remains poorly understood. Therefore, we examined whether disrupting LEM2 affects ER homeostasis—an important regulator of cancer progression. When ER homeostasis is disrupted, the unfolded protein response (UPR) pathway relays ER stress signals to the nucleus via transcriptional programs to alleviate ER stress and promote cell survival. Cancer cells often exploit the adaptive features of the UPR, and UPR components have emerged as promising biomarkers for predicting treatment response and prognosis. Here, we identify a novel mechanism of nucleus-to-ER communication in which loss of LEM2 triggers non-canonical activation of a specific branch of the UPR. Rather than responding to classic proteotoxic stress, the UPR activated by LEM2 depletion appears to arise from alterations in specific lipids. Our findings define a novel nucleus-to-ER signaling axis through which the NE modulates lipid-mediated UPR activity in the ER. Ongoing work aims to determine how this nucleus-to-ER pathway affects additional cancer phenotypes and to dissect how NE perturbations alter ER lipid homeostasis to activate the UPR. More broadly, uncovering the inter-organelle regulatory mechanisms of NE-ER communication provides a novel framework for gaining insight into tumor development.

#6005 Human DEAH-box RNA helicase 8 regulates HSF1-mediated stress response and cancer-associated pre-mRNA splicing.

Jennifer R. Tall, Robert Te Poele, Alexandra Vasile, Pradeep Ramagiri, Caitlin Davies, Marissa Powers, Toby Roe, Deivendran Sankaran, Konstantinos Mitsopoulos, Bissan Al-Lazikani, Robert L. Van Montfort, Emmanuel de Billy, Paul Workman, **Paul A. Clarke**

Centre for Cancer Drug Discovery, The Institute of Cancer Research, Sutton, London, United Kingdom

Background: Heat Shock Factor 1 (HSF1) drives stress tolerance, oncogenic transformation, and survival in diverse human cancers. Although pharmacologic inhibition of HSF1 remains challenging, identifying druggable upstream regulators of HSF1 offers a promising alternative strategy to disrupt stress adaptation in tumours.
Methods: A focused siRNA screen targeting 7,598 druggable genes was performed in human osteosarcoma cells to identify modulators of HSF1-activation. Transcriptomic, RNA immunoprecipitation (RIP), and enhanced CLIP (eCLIP) analyses were used to define the function and RNA-binding sites of the DEAH-box RNA helicase 8 (DHX8). Genetic rescue with wild-type versus ATPase- and RNA-binding-defective DHX8 mutants validated the mechanistic requirements for HSF1 mRNA processing. Functional assays (viability, cell cycle, apoptosis) assessed the effects of DHX8 depletion across tumorigenic and non-tumorigenic cell lines.
Results: DHX8 was identified and validated as a potent regulator of the HSF1 stress response. DHX8 silencing led to the accumulation of intron-retained HSF1 transcripts, decreased HSF1 protein levels, and suppression of HSF1 target genes. Genome-wide RNA-seq revealed broad DHX8-dependent splicing changes, dominated by intron retention, affecting>1,300 mRNAs. eCLIP profiling identified DHX8 binding between the lariat branch site and 3′ splice junction, consistent with its role in late-stage mRNA splicing. Rescue experiments demonstrated that both ATPase and RNA-binding activities are essential for HSF1 mRNA maturation. Acute degradation of DHX8 using a dTAG system phenocopied siRNA knockdown, confirming on-target effects. Functionally, DHX8 depletion in tissue culture experiments was generally tolerated by non-tumorigenic lines, but induced G_2/M arrest, apoptosis, and loss of viability in cancer cells.
Conclusions: DHX8 is a key regulator of HSF1 mRNA processing and cancer-associated splicing programs. Loss of DHX8 disrupts the oncogenic stress response, suppresses heat shock gene induction, and preferentially kills tumour cells. These findings establish DHX8 as a potentially druggable node linking RNA splicing to HSF1-driven cancer-survival pathways, offering a new therapeutic entry point for targeting stress resilience in malignancy.

#6006 Discovery of nuclear p62-PI4,5P$_2$ colocalization suggests a new regulatory layer in cancer proteostasis.

Alexandra Gebbia, Oisun Jung, Suyong Choi

Eppley Institute for Research in Cancer and Allied Diseases, University of Nebraska Medical Center, Omaha, NE

Aggrephagy, the selective autophagic clearance of protein aggregates, is essential for maintaining cellular homeostasis, particularly in cancer cells undergoing metabolic or proteotoxic stress. This process is mediated by the cargo receptor p62 (sequestosome-1, SQSTM1), which canonically recognizes ubiquitinated protein aggregates in the cytoplasm and delivers them to autophagosomes for lysosomal degradation. Intriguingly, p62 is also detected within nuclear condensates, a phenomenon that remains poorly understood given that autophagy has traditionally been regarded as a strictly cytoplasmic pathway.

Within the Phox and Bem1 (PB1) domain of p62, we identified a putative polybasic motif (PBM) capable of binding nuclear phosphoinositides, as well as a ZZ domain previously implicated in DNA binding. Because nuclear phosphoinositides and the kinases that generate them, such as phosphatidylinositol 4-phosphate 5-kinase type 1 alpha (PIP5K1A), regulate transcription, DNA repair, and other spatially organized nuclear processes, we hypothesized that p62 may engage lipid-defined microenvironments within the nucleus.

To test this hypothesis, we examined the nuclear interplay of p62 with the signaling lipid phosphatidylinositol 4,5-bisphosphate (PI4,5P$_2$) generated by PIP5K1A. We identified a previously unrecognized nuclear colocalization of p62 and PI4,5P$_2$ in breast cancer cell lines, a pattern not observed in pancreatic ductal adenocarcinoma (PDAC) models, suggesting that nuclear lipid-p62 regulation is highly cell-type specific. Nutrient deprivation reduced both p62 puncta and total p62 protein abundance, indicating that p62 levels are tightly coupled to metabolic status. Notably, genetic loss of PIP5K1A decreased total p62 levels independent of nutrient conditions, revealing that phosphoinositide signaling and metabolic cues converge to control p62 expression.

Together, these findings uncover a novel nuclear interaction between p62 and PI4,5P$_2$ and point to a regulatory axis involving PIP5K1A that may influence nuclear condensate formation and p62-dependent stress responses. Ongoing studies using proximity ligation assays, lysosomal activity measurements, and pharmacologic perturbation aim to define the functional significance of this pathway, which may represent an unrecognized therapeutic vulnerability in cancers dependent on p62-mediated proteostasis.

#6007 Fibroblast-driven IGF1 signaling suppresses CD44 and promotes tumor cell senescence at the invasive front of colorectal cancer.

Tae Jun Park[1], Hee Young Kang[1], Jang Hee Kim[1], Seok Yun Kang[1], Hyun Woo Lee[1], Sang Wun Kim[2], Hong Seok Kim[3], Soon Sang Park[1]

[1]Ajou University School of Medicine, Suwon, Korea, Republic of,[2]Yonsei University College of Medicine, Seoul, Korea, Republic of,[3]Inha University School of Medicine, Incheon, Korea, Republic of

Senescent tumor cells are cancer cells that undergo cell-cycle arrest in response to diverse intrinsic and extrinsic stresses. In our previous study, we observed that senescent tumor cells are preferentially enriched at the invasive front of colorectal cancer, where they display a marked global reduction in CD44 expression—including both standard and variant isoforms—an important hyaluronic-acid receptor associated with stress tolerance and redox resistance. Single-cell RNA-seq-based ligand-receptor interaction analysis revealed that senescent tumor cells are highly active in both sending and receiving intercellular signals. Among these, IGF1-IGF1R signaling between fibroblasts and senescent tumor cells was prominently upregulated.Mechanistically, activation of IGF1R triggered downstream AKT signaling, which suppressed CD44 transcription in tumor cells. Loss of CD44, a major regulator of cellular oxidative stress buffering, led to increased intracellular ROS levels. Elevated ROS subsequently downregulated DNMT1 expression, resulting in reduced methylation of the $p16^{INK4a}$ promoter and robust induction of $p16^{INK4a}$, thereby driving tumor cells into a senescent state. Consistent with this mechanism, in vitro treatment with recombinant human IGF1 or co-culture with fibroblasts induced AKT activation, decreased CD44 levels, increased ROS, and ultimately promoted p16 expression.Together, these findings identify a previously unrecognized tumor-stromal crosstalk in which fibroblast-derived IGF1 activates the IGF1R-AKT-CD44-ROS-DNMT1-$p16^{INK4a}$ axis to promote tumor cell senescence at the invasive front. This stromal-driven process suggests that the invasive front is not merely a region of physical invasion but an active signaling niche where fibroblasts dictate tumor cell fate. Our study highlights this signaling cascade as a key regulatory mechanism shaping senescence, redox biology, and phenotypic plasticity in colorectal cancer progression.

#6008 Defining PON2 as a metabolic immune checkpoint of iron redox balance and ferroptotic defense in lung adenocarcinoma.

Yonatan Amzaleg[1], Angel Perez-Hunt[1], Chi Li[2], **Aaron M. Neely**[1]

[1]Integrative Translational Sciences, Beckman Research Institute of The City of Hope, Duarte, CA,[2]Brown Cancer Center-University of Louisville, Louisville, KY

Lung adenocarcinoma (LUAD), the predominant subtype of non-small cell lung cancer, survives persistent oxidative stress through adaptive remodeling of mitochondrial and metabolic networks. Redox equilibrium therefore dictates whether LUAD cells withstand oxidative pressure or succumb to ferroptosis; a lipid peroxidation driven form of regulated cell death[1]. The mitochondrial enzyme paraoxonase 2 (PON2) functions as an intrinsic antioxidant that detoxifies lipid peroxides and sustains respiratory integrity[2]. In LUAD, chronic activation of NRF2 (NFE2L2); frequently through loss of KEAP1, drives constitutive antioxidant programs involving glutathione synthesis and GPX4, FSP1, and PON2 dependent ferroptosis defenses[3-4]. These redox insulated states promote metabolic resilience, suppress immunogenic cell death (ICD), and reinforce immune excluded tumor architectures[4-5].We identify PON2 as a metabolic immune checkpoint that integrates NRF2/KEAP1 driven redox adaptation with ferroptosis resistance and immune escape. Integrative genomic, spatial, and functional analyses reveal that PON2 expression stratifies LUAD by ferroptotic vulnerability; aligns with antioxidant and iron handling networks (TFRC, FTH1, FTL); and that PON2 loss increases lipid peroxide burden, disrupts mitochondrial flux, and heightens ICD signaling in patient derived LUAD models.These findings delineate how PON2 enforces ferroptosis resistance and immune invisibility, revealing targetable redox metabolic bottlenecks that could be leveraged to restore tumor immunogenicity[6].

#6009 Mitochondrial glutathione reductase as a redox vulnerability in KEAP1/NRF2-mutant non-small cell lung cancer.

Yun Huang[1], Chao Ting[1], Jing-Chun Lin[2], Ryan Martin[1], Duy T. Nguyen[1], Jose Serrano-Velez[1], Yun Pyo Kang[3], Nathan P. Ward[4], Ana P. Da Silva Gomes[1], Mingxiang Teng[1], **Chang Jiang**[1]

[1]H. Lee Moffitt Cancer Center, Tampa, FL,[2]H Lee Moffitt Cancer Center and Research Institute, Tampa, FL,[3]Seoul National University, Seoul, Korea, Republic of,[4]H. Lee Moffitt Cancer Center, Wesley Chapel, FL

Non-small cell lung cancer (NSCLC) accounts for 85-90% of lung cancers. NRF2 is a master transcription factor that orchestrates antioxidant defense. Under basal conditions, KEAP1 binds NRF2, promoting its ubiquitination and degradation. Oxidative stress alters KEAP1 conformation, preventing NRF2 binding and enabling NRF2 nuclear accumulation and activation of cytoprotective genes. NSCLC frequently harbors KEAP1 or NRF2 mutations—often within the KEAP1 Kelch domain or the NRF2 Neh2 domain—that impair KEAP1-mediated turnover and drive constitutive NRF2 activation. Such tumors are resistant to chemo-, radio-, and immunotherapy, yet direct NRF2 inhibitors remain elusive due to the absence of catalytic pockets and concerns about systemic toxicity. To identify synthetic-lethal targets that heighten ROS-induced death in NRF2-active NSCLC, we performed negative-selection CRISPR/Cas9 screens using a focused antioxidant-enzyme sgRNA library. Cells were treated with a sublethal dose of the NQO1-bioactivatable ROS-generating prodrug β-lapachone. As expected, NQO1 was the top sensitizing hit, and TXNRD1/TXN were enriched among resistant hits, consistent with the protective thioredoxin pathway. Unexpectedly, genes required for de novo glutathione synthesis (GCLM, GCLC, GSS) showed minimal dropout, indicating limited contribution of GSH biosynthesis to β-Lap sensitivity. Instead, the NRF2 target gene GSR—responsible for reducing GSSG to GSH—emerged prominently, suggesting that GSR loss uniquely impairs survival under oxidative stress. Across multiple ROS-inducing agents, GSR knockout strongly sensitized KEAP1/NRF2-mutant cells but not KEAP1/NRF2-intact cells. Importantly, toxicity was not driven by global GSH depletion. Rather, we found that mitochondrial GSR is essential: cytosolic-only GSR could not rescue GSR-deficient cells, whereas forced mitochondrial localization fully restored viability. Mechanistically, GSR loss caused severe mitochondrial fragmentation, compromised electron transport chain (ETC) integrity, and reduced ETC activities. GSR-deficient cells accumulated mitochondrial ROS and showed decreased expression of iron-sulfur cluster-containing proteins, collectively driving mitochondrial dysfunction and cell death. In vivo, GSR deletion triggered redox collapse and dramatically sensitized KEAP1-mutant tumors to chemotherapy. Together, these findings reveal an unrecognized mitochondrial redox dependency in KEAP1/NRF2-mutant NSCLC and identify GSR as a promising therapeutic vulnerability for overcoming NRF2-mediated ROS resistance.

#6010 Cellular senescence in the cancer microenvironment.

Subhiksha Meenakshisundaram, Robyn Laura Kosinsky, Dominik Saul

Robert Bosch Centre for Tumor Diseases, Stuttgart, Germany

Cellular senescence is a stress-induced state of stable cell cycle arrest accompanied by sustained metabolic activity. In the context of cancer, senescence acts as a double-edged sword, halting cell growth while simultaneously creating conditions that favor tumor advancement. To understand the pro-tumorigenic effects of senescence, we analyzed publicly available single-cell RNA-seq datasets of six major cancers, with a refined and robust definition of cellular senescence based on cell-cycle arrest and senescence-associated secretory phenotype (SASP) gene signatures. We quantified senescent cell burden in six cancers and observed a significant enrichment in colorectal and pancreatic tumors compared to healthy controls. Comparative genomic and transcriptomic analyses revealed that senescent tumor cells exhibit distinct molecular features, reflecting a reprogrammed senescence biology within tumors. Trajectory inference analysis demonstrated that senescence represents a terminal cellular state, indicating that tumor-associated senescence constitutes a reprogrammed, terminal fate. Having characterized senescence at the single-cell level, we next examined the spatial impact of its SASP. Spatial transcriptomic analysis revealed that SASP signaling acts as a key mediator of local inflammation and promotes bystanding cells across the tumor microenvironment. By inducing cellular senescence in colorectal and pancreatic cancer cell lines *in vitro*, we confirmed the senescence induction using telomere associated foci (TAF) staining and profiled their molecular signatures. Given the pro-tumorigenic effects of senescent cells, we subsequently evaluated the impact of senolytic drugs and treated these senescent cells with senolytics, namely Dasatinib and Quercetin (D+Q) as well as fisetin. Both senolytic treatments effectively reduced the expression of senescent markers, confirming selective clearance of senescent cells. The treatment also significantly reduced tumor proliferation. Collectively, our findings refine the molecular and spatial characterization of tumor-associated senescence and highlight senolytics as a promising therapeutic strategy to mitigate its tumor-promoting effects and controlling tumor growth in distinct tumor entities.

#6011 Treatment-induced senescence in metastatic colorectal adenocarcinomas: implications for single-cell biology and therapeutic intervention.

Antoine Hollebecque[1], Marine Aglave[2], Mohamed-Amine Bani[3], Trang Nguyen[1], Ludovic Bigot[4], Thierry Mathieu[5], Florence Lhospice[5], Benjamin Le Calve[5], Eric Angevin[6]

[1]Drug Development Department (DITEP), Gustave Roussy, Villejuif, France,[2]Bioinformatics facility, Gustave Roussy, Villejuif, France,[3]Biopathology Department, Gustave Roussy, Villejuif, France,[4]Research Division, Gustave Roussy, Villejuif, France,[5]Starkage Therapeutics, Lille, France,[6]Clinical Research Division, Gustave Roussy, Villejuif, France

In cancers, the harmful effect of senescence is now well recognized and mediated by the local production of pro-inflammatory cytokines, soluble immunosuppressive factors and metalloproteinases, called 'SASP' phenotype. Many chemotherapy and radiation regimens can induce senescence of tumor cells and a deleterious microenvironment that promote tumor growth, invasion and neoangiogenesis leading to treatment resistance, relapse and poor prognosis, especially at advanced stages. Senescence biomarkers, such as dipeptidyl-peptidase 4 (DPP4/CD26), a membrane glycoprotein involved in chemotactic and inflammatory responses, is frequently constitutively expressed and/or overexpressed on primary tumors and metastases, including in colorectal adenocarcinoma (mCRC). A study aimed at dissecting the pathophysiology of senescence induced by standard of care (SoC) treatments is currently underway on a large series of mCRC, as well as other digestive cancers and hepatic carcinomas. The pre- and post-SOC scoring of DPP4 expression is assessed by immunohistochemistry and will be correlated to clinical annotations and other senescence features on primary tumors and liver metastases (n=100 samples). A comprehensive bioinformatic study is conducted on a large pan-tumor bulk RNA sequencing database (n=1155 samples) assessing the expression of a broad panel of candidate genes and signatures relevant to senescence pathways, including DPP4, and signaling signatures of interest from MSigD, CellMarker2.0, panglaoDB and SenNet. The same evaluations are conducted on a large set of single cell RNA sequencing (scRNASeq) data from different mCRC cohorts (n=105 patients) in which pre- and post-SoC treatment samples were collected on treatment-naïve primary tumor or liver metastatic samples (n=72) and post-SoC biopsies (n=54), including MSI-high tumors (n=16). Bioinformatics pipelines were designed to address correlations of candidate genes and molecular signatures to cellular heterogenicity, context, biology and clinical outcomes. To our knowledge, this study will be the first to highlight at the protein and scRNASeq levels the deleterious impact of senescence in a large series of patients with mCRC during the progression and treatments of cancer. This could have important implications for the development of innovative therapies targeting senescence biomarkers and related signaling pathways for cancer cell elimination in refractory tumors.

#6013 TUSC2 drives NK cell maturation and aging-associated functional decline.

Salvador Gonzalez Ochoa[1], Metin Aksu[2], Karan Lagisetty[3], Edward J. Hughes[2], Thanigaivelan Kanagasabai[1], Muna A. Mohammed[4], Alla Ivanova[1], Anil Shanker[5]

[1]Department of Biochemistry, Cancer Biology, Neuroscience and Pharmacology, Meharry Medical College, Nashville, TN,[2]Department of Clinical Sciences, Meharry Medical College School of Medicine, Meharry Medical College, Nashville, TN,[3]Undergraduate Summer Intern Program, Meharry Medical College, Nashville, TN,[4]Department of Biomedical Sciences, Meharry Medical College School of Graduate Studies, Meharry Medical College, Nashville, TN,[5]The Office for Research and Innovation, Meharry Medical College, Nashville, TN

Background: Aging is a biological process that drives metabolic and functional decline across physiological systems, including immune system. Natural killer (NK) cells, key mediators of tumor and viral surveillance, have emerged as a promising immunotherapeutic tool; however, the molecular and metabolic pathways that shape NK-cell function during aging remain poorly defined. We show that expression of Tumor Suppressor Candidate 2 (TUSC2), a mitochondrial protein with structural features consistent with a calcium sensor, steadily declines across multiple human tissues with age. We investigated further how the loss of TUSC2 impacts NK-cell development and the differentiation of distinct functional NK-cell subsets.
Methods: Phase 1: Human single-cell RNA-seq data from harmonized datasets of healthy blood NK cells and tissue-resident or tumor-associated NK cells were analyzed. Core functional programs including interleukin signaling, metabolic pathways, and developmental signatures were examined. Differential expressions between TUSC2high and TUSC2low NK cells were assessed and integrated with these programs. Phase 2: Splenocytes were collected from young (1-3 months) and aged (18-21 months) Tusc2 wild-type (WT) and knockout (KO) mice. Single-cell immune suspensions were stained with NK lineage and maturation markers: CD122, CD49b, CD11b, and NKp46 to delineate developmental stages I-IV. Following surface staining, cells were labeled intracellularly to identify transcription factors and functional mediators.
Results: TUSC-2 expression strongly correlated with the maturation of NK1C (effector-terminal) population, as well as with cytotoxic and metabolic programs in these functional subsets. NK cells at early developmental stages (I-III) showed comparable frequencies between WT and KO mice, indicating preserved early progenitor commitment. However, absence of Tusc2 generates an inappropriate downregulation of Tcf7/Tcf1 and Gata3 with age, suggesting their persistent stem-like state that impaired maturation. Aged Tusc2-KO NK cells also exhibited elevated expression of IL15Rα, FasL, and CX3CR1 at early stages, reflecting heightened activation potential and migratory responsiveness, yet failed to acquire effector markers such as CD16, indicating uncoupling between activation, licensing, and effector differentiation. Consistent with this impaired progression, the frequency of Stage IV (mature NK) populations markedly declined with age in KO mice, whereas WT mice maintained Stage IV NK-cell frequency.
Conclusion: These findings indicate that TUSC2 is required for proper coordination of developmental transcriptional programs and for the acquisition of effector and metabolic competence during NK-cell aging, particularly within terminal effector subsets.

#6014 From metal to malignancy: How ROS and inflammatory cytokines accelerate cadmium-induced prostate carcinogenesis.

Kunj Bihari Gupta[1], Truett Taylor[1], Siva S. Panda[2], Vinata B. Lokeshwar[3], Bal L. Lokeshwar[1]

[1]Georgia Cancer Center, Augusta University, Augusta, GA,[2]Department of Chemistry and Biochemistry, Augusta University, Augusta, GA,[3]Department of Biochemistry and Molecular Biology, Augusta University, Augusta, GA

Cadmium (Cd) is a toxic metal ubiquitous in nature and an industrial pollutant. Exposure to elemental Cd or its salts lead to their high accumulation in tissues and clears very slowly, biological half-life; >30 years. Abnormally high levels of Cd are reported in human prostate tissues. The studies on rodents have shown that their exposure causes prostate cancer. The mechanism of carcinogenesis caused by Cd remains unclear. This study tested the hypothesis that continuous low-dose exposure to Cd induces chronic inflammation driven by high levels of Reactive Oxygen Species (ROS) which promote sustained up-regulation of proinflammatory cytokines and accelerating the transformation of healthy prostate epithelial cells to tumorigenic cells. We used two non-transformed prostate epithelial cell lines (RWPE-1 and NHPrE-1) and exposed to 10μM of Cadmium Chloride ($CdCl_2$) continuously up to one year. The $CdCl_2$ exposed cells and culture media were regularly analyzed for changes in oxidative stress, inflammatory cytokines, elevated carcinogenesis markers. Cd exposure significantly increased the cellular ROS levels beginning in the first week of exposure and remained elevated. Analysis of a repertoire of cytokines, pro-tumorigenic growth factors and several transcription factors using ELISA, qPCR, cytokine array and transcriptomic RNA-seq analysis showed a strong correlation with exposure time and an increase in the levels of key cytokines and transcription factors. We found IL-8 was the first cytokine to increase when exposed to $CdCl_2$, followed by activation of NF-κB (p65-rel), VEGF-A, & B and other factors. Further, IL-1β, IL-6, IFN-γ, and TGF-β and IL-8 receptors CXCR1, and CXCR-2 were also elevated with prolonged exposure to Cd. In addition, when compared to unexposed cells, we observed activation of Nuclear Factor-kB (NF-κB), and pro-tumorigenic growth factors involved in angiogenesis vascular endothelial growth factors VEGF-A and B); all at RNA and protein levels. The inflammatory cytokine array analysis also supported the occurrence of a “cytokine storm” in the $CdCl_2$-exposed RWPE-1 and NHPrE-1 cells. Neutralizing oxidative stress with ROS scavenger [e.g. N-Acetyl cysteine (NAC)], significantly reduced the mRNA levels of cytokines and pro-inflammatory chemokines. RWPE-1 and NHPrE-1 cells exposed to $CdCl_2$ for a year were fully transformed into tumorigenic cells and formed subcutaneous tumors in less than 30 days in male NOD/SCID mice. In summary, IL-8 and NF-κB mediated signaling axis is critical for Cd-induced carcinogenesis and controlling this axis is a potential strategy to prevent metal-induced toxicity and carcinogenesis.

#6015 Senescence-associated secretory phenotype drives PGCC's lifecycles and blastomere-like reprogramming to promote therapeutic resistance.

Zhiqian Zhang[1], Xiaoran Li[2], Xinxin Tian[1], Limin Deng[1], Jin-Tang Dong[1], **Jinsong Liu**[2]

[1]Southern University of Science and Technology (SUSTech Shenzhen), Shenzhen, China,[2]UT MD Anderson Cancer Center, Houston, TX

Background: Polyploid giant cancer cells (PGCCs) are stress-responsive tumor subpopulations linked to treatment resistance and poor prognosis. While prior studies have characterized their senescent-like phenotypes and capacity for developmental reprogramming, two core questions remain poorly understood, including the temporal dynamics governing PGCC's lifecycle progression and the precise mechanistic role of senescence in shaping their biology.
Methods: We induced PGCC formation using vincristine (VCR), a mitotic destabilizer, and tracked their lifecycle via live-cell fluorescence imaging. We assessed proliferative activity, EMT, blastomere-like features, and differentiation potential *in vitro*, alongside tumorigenicity *in vivo*. Mechanistically, we interrogated SASP cytokines using genetic silencing and pharmacologic inhibition.
Results: VCR activated an endoreplication-based lifecycle in PGCCs, replacing canonical mitosis. PGCCs progressively exhibited reduced proliferation but enhanced EMT, progressive blastomere-like stemness, and multilineage differentiation. Both PGCC populations and their progeny acquired time/dose-dependent malignant traits and tumorigenic capacity. PGCCs partially adopted senescence, marked by elevated SASP cytokines. Silencing IL1β/IL6/IL8 or inhibiting their receptors suppressed PGCC formation, budding, EMT, and stemness, thus identifying SASP as critical for PGCC homeostasis and fate.
Conclusion: Our work delineates PGCCs' lifecycle evolution and establishes SASP as a key driver of their lifecycle and the emergence of aggressive, therapy-resistant progeny, bridging senescence, developmental reprogramming, and cancer progression.

#6016 Identification of a novel non-flavonoid senolytic agent from natural resources targeting oncogene- and DNA damage-induced senescence.

Jihye Kim, Xiaoyu Guo, Yi-Xi Gong, Ingyu Lee, Bomi Han, Eui Man Jeong

Jeju National University, Jeju, Korea, Republic of

Senolytics represent a promising therapeutic strategy for age-related diseases by selectively eliminating senescent cells. In this study, we screened a library of 101 extracts derived from natural resources indigenous to Jeju Island to identify potential senotherapeutics. We evaluated their senolytic activity using two distinct models of cellular senescence: Oncogene-Induced Senescence (OIS) in human diploid fibroblasts and DNA Damage-Induced Senescence (DIS) in A549 lung cancer cells. Through this screening, we identified a specific extract that exhibited significant selective cytotoxicity against senescent cells while sparing proliferating cells. Following bioassay-guided fractionation, we isolated an active compound, designated as ACE. Interestingly, ACE-induced cell death was significantly attenuated by pretreatment with Z-VAD (a pan-caspase inhibitor) and Necrostatin-1, suggesting that ACE exerts its senolytic effect via regulated cell death pathways, primarily apoptosis. Flow cytometry and Western blot analyses confirmed that ACE treatment significantly reduced Senescence-Associated β-galactosidase (SA-β-gal) activity and downregulated key senescence markers, including p16, p21, and p53, in a dose- and time-dependent manner. Mechanistically, ACE activated the p38 MAPK signaling pathway, leading to the accumulation of reactive oxygen species (ROS). Notably, chemical analysis revealed that ACE is a non-flavonoid compound. Collectively, these findings suggest that ACE is a novel senolytic candidate derived from Jeju natural resources with potential clinical applications.

#6017 BET inhibition potentiates salvage chemotherapy response through TXNIP upregulation in osteosarcoma.

Keiko E. Kreklau[1], Niknam Riyahi[2], Ryli E. Justice[1], M. Reza Saadatzadeh[3], Erika A. Dobrota[1], Harlan E. Shannon[1], Rada Malko[4], Christopher Davis[1], Khadijeh Bijangi-Vishehsaraei[3], Sara Covin[1], Melissa A. Trowbridge[5], Kathy Coy[5], Felicia M. Kennedy[5], Anthony L. Sinn[5], Christopher D. Collier[6], Steven P. Angus[3], Karen E. Pollok[3], Pankita H. Pandya[3]

[1]Herman B Wells Center for Pediatric Research, Indiana University School of Medicine, Indianapolis, IN,[2]Department of Biochemistry & Molecular Biology, and Pharmacology, Indiana University School of Medicine, Indianapolis, IN,[3]Department of Pediatrics, Division of Pediatric Hematology/Oncology, Indiana University School of Medicine, Indianapolis, IN,[4]Department of Medical and Molecular Genetics, Indiana University School of Medicine, Indianapolis, IN,[5]Preclinical Modeling and Therapeutics Core, Indiana University Melvin and Bren Simon Comprehensive Cancer Center, Indianapolis, IN,[6]Department of Orthopaedic Surgery, Indiana University School of Medicine, Indianapolis, IN

Osteosarcoma (OS) is an aggressive bone cancer in pediatric adolescent and young adult patients. Survival rate for metastatic and relapsed OS patients remains dismal at <30%. Additionally, no effective standardized salvage therapy currently exists for these patients, in part due to genomic complexities arising from moderate levels of replication stress (RS). Bromodomain and extra-terminal domain protein inhibitors (BETi) are an underexplored option to target RS, as BET inhibition creates an imbalance between transcription-replication kinetics thereby exacerbating oncogenic RS and cell death. BETs (BRD2,3,4) are epigenetic readers that play a role in regulating gene expression networks as well as DNA replication and repair. We hypothesized that BET inhibition with AZD5153 would suppress OS growth by inducing tumor suppressive mechanisms that exacerbate DNA damage and sensitize tumors to DNA-damaging chemotherapeutic agents. AZD5153 monotherapy significantly suppressed OS tumor growth compared to vehicle ($p<0.05$) in female and male patient-derived xenografts (PDXs) established from both treatment-naïve (PDX96, PDX115, PDX112) and metastatic OS (PDX77-TT2). Mechanistic evaluation showed increased γ-H2AX and p-RPA2 S8 following AZD5153 exposure in PDX96, indicative of enhanced RS. RNA-seq and protein analyses revealed dysregulation of DNA damage response genes, including upregulation of TXNIP, a tumor suppressor that promotes DNA damage and apoptosis, and downregulation of PDGFRA. Similar TXNIP upregulation and PDGFRA suppression were observed in AZD5153-treated PDX115. Increased TXNIP expression was also evident in vitro when BET/BRD4 activity was inhibited in OS cell lines by siRNA, PROTAC-mediated degradation, or disruption of BRD4-histone interactions via AZD5153. These effects were accompanied by elevated c-PARP levels, a marker of cell death. Ongoing studies suggest BRD4 inhibition elevates TXNIP via AKT pathway suppression, as indicated by reduced phospho-AKT in AZD5153-treated tumors. In vitro combination studies showed additive-to-synergistic effects between AZD5153 and a variety of salvage agents (etoposide, SN38, and topotecan). In particular, AZD5153 in combination with topotecan resulted in enhanced apoptosis, increased TXNIP, decreased AKT, and elevated RS markers (γ-H2AX, comet assays). In vivo, dose finding studies indicated that PDX77-TT2 was resistant to salvage agents ifosfamide and SN38 but moderately sensitive to topotecan. Furthermore, AZD5153 alone or in combination with topotecan improved survival compared to single agents ($p<0.05$) and was well tolerated. Collectively, these data support BET inhibition alone or with salvage therapy as a promising therapeutic approach for aggressive OS, potentially mediated through TXNIP upregulation and AKT pathway suppression.

#6018 Reactive oxygen species (ROS)-sensitive SOX4 signaling mediates ferroptosis in esophageal adenocarcinoma.

Heng Lu[1], Farah Ballout[2], Dunfa Peng,[2], Lei Chen[3], Zheng Chen[2], Wael El-Rifai[2]

[1]Surgery, University of Miami, Miami, FL,[2]University of Miami Miller School of Medicine, Miami, FL,[3]University of Miami, Miami, FL

Introduction: Esophageal adenocarcinoma (EAC), a malignancy largely driven by gastroesophageal reflux disease (GERD), remains highly resistant to chemotherapy, resulting in poor clinical outcomes. Ferroptosis is an iron-dependent, non-apoptotic form of regulated cell death characterized by lipid peroxidation and oxidative membrane injury. SOX4, a critical transcription factor, has been broadly implicated in tumorigenesis and the maintenance of cancer stemness. This study investigates SOX4-mediated anti-ferroptosis as a mechanism of chemoresistance in EAC, focusing on the reactive oxygen species (ROS)-sensitive APE1-redox-STAT3-SOX4 signaling axis, with the goal of identifying novel therapeutic strategies.

Methods: Public datasets and multiple experimental models were employed, including 3D organotypic cultures, patient-derived organoids, and tumor spheres. *In vivo* validation was performed using a patient-derived xenograft (PDX) model.

Results: Analysis of EAC public datasets revealed significant enrichment of the SOX4 transcriptional signature in tumor tissues. SOX4 activation was induced by elevated ROS and APE1 protein under reflux-mimicking conditions (acidic bile salt exposure, ABS), while treatment with a ROS scavenger, N-acetyl-l-cysteine (NAC), blocked ABS-induced SOX4 upregulation. Chromatin immunoprecipitation (ChIP) assay identified a STAT3 binding site within the SOX4 promoter, indicating that STAT3, an APE1 redox-sensitive transcription factor, directly regulates SOX4 expression. Silencing of APE1 or pharmacological inhibition of STAT3 suppressed SOX4 expression under both reflux conditions and oxaliplatin treatment. Single-sample gene set enrichment analysis (ssGSEA) demonstrated a strong correlation between ferroptosis-related signaling and the SOX4 signature in the TCGA EAC cohort. Notably, SOX4 knockdown reduced GPX4 expression and sensitized both intrinsically resistant SK-GT-4 cells and acquired oxaliplatin-resistant FLO-1 cells to oxaliplatin. These findings were validated in PDX tumors treated with the APE1 redox-specific inhibitor APX2009 in combination with oxaliplatin.

Conclusion: ROS/APE1-dependent activation of SOX4 plays a crucial role in anti-ferroptosis and chemoresistance in EAC. Targeting the redox function of APE1 represents a promising therapeutic approach to overcome SOX4-mediated ferroptosis resistance and enhance chemotherapy efficacy in EAC.

#6019 Fatty acid exposure promotes age-related mammary tissue alterations with pro-tumorigenic potential.

Mariana Bustamante Eduardo[1], Abul B.M.M.K. Islam[2], Curtis W. McCloskey[3], Maria Paula Zappia[2], Ashok Z. Samuel[4], Maxim V. Frolov[2], Rama Khokha[5], Rohit Bhargava[4], Elizaveta V. Benevolenskaya[2], Seema A. Khan[1], Susan E. Clare[1]

[1]Northwestern University, Chicago, IL,[2]University of Illinois at Chicago, Chicago, IL,[3]University of Pittsburgh, Pittsburgh, PA,[4]University of Illinois at Urbana-Champaign, Urbana, IL,[5]Princess Margaret Cancer Centre, Toronto, ON, Canada

Introduction. Exposure of non-transformed breast cells and breast microstructures to the medium-chain (MC) fatty acid (FA) octanoic acid (OA) induces a metabolic shift toward the serine, one-carbon, glycine and methionine pathways (SOG/methionine), enhancing epigenetic plasticity, increasing reactive oxygen species (ROS), promoting cell survival and disrupting cell-cell communication. Similarly, the aged mammary gland is characterized by disrupted cell-cell communication, epigenetic plasticity and increased ROS. We hypothesize that FA-induced metabolic reprogramming leads to biological aging of the mammary gland, contributing to pro-tumorigenic alterations observed during chronologic aging.

Methods. MCF-10A cells were exposed to OA for proteomics. Breast microstructures exposed to ± OA were analyzed by scRNAseq. Breast microstructures and 3D mammary spheres derived from primary cells were embedded in Matrigel, exposed to ± OA for 7 days, stained for luminal and basal markers, F-actin, and nuclei, and imaged by confocal microscopy to assess migration/invasion. Migratory cell populations enriched in OA-containing media were identified with scRNAseq. Raman spectroscopy (RS) was used to characterize the lipid content in normal breast tissue.

Results. OA treatment induced changes previously reported in aging and tumorigenic contexts, including: (1) upregulation ($p < 0.01$) of aging-related genes (*GDF15, MDK, PLIN2*), and downregulation ($p < 0.01$) of lineage markers and *MMP7*, a gene whose downregulation promotes mammary epithelial aging; (2) upregulation ($p < 0.01$) of Senescence-Associated Secretory Phenotype (SASP) genes, including *AREG* (reprogramming) and *ANGPTL4* (migration); (3) increased secreted signaling via *AREG*, *GDF15*, and *MDK;* and (4) reduced extracelular matrix (ECM)-receptor and cell-cell interactions. *Ex vivo*, OA altered tissue architecture disrupting the basal barrier and promoting cellular migration. BMYO1, LASP1, and LHS1 epithelial subtypes were among the migratory cells in OA media and expressed SASP, cancer (*MYC*, *EGFR*, *SREBF1*), migration (*S100A4*, *NCAM1*), aging and SOG/methionine genes. FB1 fibroblasts dominated in vehicle media, but OA favored ECM-disassembling FB2 cells. RS analysis demonstrates the presence of both saturated and unsaturated FAs and revealed the presence of MCFAs, such as OA, with higher intensities observed in the postmenopausal tissue supporting the *in vivo* plausibility of our *in vitro/ex vivo* findings.

Conclusions. Our data supports a model suggesting that chronological and biological aging processes increase the release of free FAs, due to elevated GDF15-induced lipolysis. The rise in FAs drives mammary gland remodeling and accelerates aging of the gland. Chronological and biological aging increase vulnerability to breast cancer. This model suggests potential preventive strategies such as targeting GDF15 and SOG/methionine.

#6020 Cargo profiling of extracellular vesicles from senescent glioblastoma identifies small nucleolar RNAs as candidate liquid biomarkers for therapy-induced senescence.

Valerie DeLuca[1], Nathaniel Hansen[1], Priya Digumarti[1], Nanyun Tang[1], Karen Fink[2], George J. Snipes[2], Patrick Pirrotte[1], Michael E. Berens[1]

[1]TGen (The Translational Genomics Research Institute), Phoenix, AZ,[2]Baylor Scott & White Medical Center, Dallas, TX

Therapy-induced senescence (TIS) in glioblastoma (GBM) is an undesirable cell fate that contributes to GBM treatment resistance and tumor outgrowth. While emerging senescence-targeting drugs called senotherapies may be beneficial for patients who undergo TIS following standard of care, identifying candidate patients with an appreciable TIS burden is difficult. Current methods to measure TIS are tissue based and require repeated, sequential biopsies for robust analysis. The impracticality of such an effort for GBM patients therefore necessitates the development of novel, less-invasive approaches that can detect TIS clinically over time. To this end, we aimed to identify candidate extracellular vesicle (EV) liquid biomarkers for TIS by profiling senescence-associated cargo changes within GBM EVs. Using a panel of GBM patient derived cell lines, we show that radiation induces TIS across GBM models and that this is associated with a reprogramming of the cargo in the corresponding senescent-derived EVs (senEVs). In particular, senEV transcriptomes have an increased abundance of senescence-associated RNA species and enrichment of senescence-associated gene sets. Most striking, however, was the observed enrichment of small nucleolar RNAs (snoRNAs), which represented over 50% of the top 20 most upregulated species in senEVs. This signature was conserved in 4/5 GBM models of TIS and was validated by qRT-PCR. Interestingly, the increased snoRNA abundance in EVs is not a simple function of increased cellular content, as whole cells did not show consistent upregulation upon TIS. We further found that snoRNAs are likely packaged with their partner proteins, as mass spectrometry of senEVs revealed an increased abundance of snoRNA-associating proteins. Notably, a GBM model of temozolomide-induced stress that does not result in prominent senescence failed to promote increased snoRNA cargo, supporting snoRNA enrichment as a TIS-selective finding. Ongoing work is focused on identifying whether this senEV profile is conserved across tumor types and senescence-inducing stimuli, and whether nucleolar stress during TIS plays a mechanistic role in snoRNA EV packaging. Finally, to determine the feasibility of detecting these candidate biomarkers in patient biofluids, we employed a small patient cohort of matched pre-operation and post-standard of care plasma samples. Promisingly, we identified increased senescence-associated RNA such as *CDKN2B* and *GLB1* and the snoRNA *SNORA49* in post-standard of care EVs. This data suggests that senEV RNA species, specifically snoRNAs, are strong candidates for TIS biomarker development.

#6024 Decoding new mechanisms of stromal-driven inflammation in breast cancer.

Fernanda G. Kugeratski[1], Lisa Neilson[2], Adrian Kacperczyk-Perdyan[3], Juan R. Hernandez-Fernaud[2], Sergio Lilla[2], Jakub Mieczkowski[3], Sara Zanivan[1]

[1]Department of Experimental Therapeutics, The University of Texas MD Anderson Cancer Center, Houston, TX,[2]CRUK Scotland Institute, Glasgow, United Kingdom,[3]Medical University of Gdańsk, Gdańsk, Poland

Cancer-associated fibroblasts (CAFs) are an abundant cell population of the breast tumor microenvironment (TME). Several CAF phenotypes exist in tumors, being the inflammatory type (iCAF) characterized by the high expression of interleukin 6 (IL-6). Hypoxia promotes the iCAF phenotype and is linked to poor prognosis of breast cancer patients. However, the molecular mechanism driving the iCAF program upon hypoxia exposure remains elusive. We analyzed the changes in the proteome and secretome of patient-derived CAFs exposed to hypoxia and identified a Leucine Rich Repeat Containing Protein (LRRC) as one of the most up-regulated proteins. Further analyses revealed that LRRC in induced by hypoxia at transcriptional level in a HIF1α-dependent manner. Histological analyses show that LRRC is uniquely expressed in CAFs across species, in both human and murine breast tumors. Stromal specificity of LRRC was further confirmed by single-cell RNA sequencing of breast cancer patients. Through loss-of-function approaches in CAFs we uncovered that LRRC is an upstream regulator of IL-6, a key driver of pathological angiogenesis and inflammation in cancer. Notably, LRRC$^+$ CAFs activate STAT signaling in cancer and TME cells. Supporting similar roles in tumors, increased STAT phosphorylation was also observed in tumors of breast cancer patients with high expression of LRRC, in proteomics data from TCGA. Thus, by regulating IL-6, LRRC may function as a driver of pathological angiogenesis and inflammation in breast cancer. Indeed, we observed that LRRC promotes endothelial sprouting angiogenesis and an inflammatory transcriptional program in CAFs and TME cells. Suggesting tumor-promoting roles of LRRC, high levels of LRRC correlate with worsened survival of breast cancer patients in TCGA datasets. To determine the influence of LRRC$^+$ CAFs on the surrounding TME, we are utilizing spatial proteomic analysis of breast cancer patient tissues. Together, our findings position LRRC as a central regulator of inflammatory signaling in breast cancer. By functioning upstream of IL-6 and driving activation of STAT, LRRC emerges as a key molecular nexus linking hypoxia to the iCAF phenotype and its tumor-promoting functions. The discovery of microenvironmental factors that fuel breast cancer inflammation is a sought-after milestone in the field since it may lead to the development of novel therapeutic interventions aimed at disrupting stromal-driven inflammation and tumor progression.

#6025 Transgelin-positive cancer-associated fibroblasts promote pancreatic cancer progression.

Keiko Shinjo[1], Xingxing Wang[1], Kohei Kumegawa[2], Reo Maruyama[2], Shinji Mii[3], Yukihiro Shiraki[1], TATSUNORI NISHIMURA[1], Yoshiteru Murofushi[1], Miho Suzuki[1], Atsushi Enomoto[1], Yutaka Kondo[1]

[1]Nagoya University, Nagoya, Japan,[2]Japanese Foundation for Cancer Research, Tokyo, Japan,[3]Department of Pathology, Hiroshima University, Hiroshima, Japan

Pancreatic ductal adenocarcinoma (PDAC) is characterized by a pronounced desmoplastic reaction, predominantly composed of cancer-associated fibroblasts (CAFs), including a major population of myofibroblastic CAFs (myCAFs). This study was designed to elucidate the biological significances of CAFs in PDAC tumorigenesis. We performed a single-cell assay for transposase-accessible chromatin with high-throughput sequencing (scATAC-seq) on pancreas tissues from KPC mice (*LSL-Kras*$^{G12D/+}$; *LSL-Trp53*$^{R172H/+}$; *Pdx-1-Cre*). Epigenetic profiling uncovered substantial heterogeneity within the myCAF population, revealing distinct subclusters characterized by specific transcription factor (TF) motifs, such as those associated with Srf, Cebpb, Prrx1, and Smad4. Parallel single-cell RNA sequencing (scRNA-seq) further identified three transcriptionally distinct myCAF subtypes, each enriched for unique TF-associated signaling pathways, validating the TF motifs identified in the scATAC-seq analysis. Among the identified myCAF subtypes, Transgelin (Tagln), an actin-binding protein highly expressed in activated fibroblasts, emerged as a potential functional driver. In an orthotopic PDAC mouse model, *Tagln* knockout mice exhibited significantly reduced PDAC tumor burden compared to wild-type controls. Analysis of TCGA data revealed that high *TAGLN* expression in PDAC samples was significantly associated with poor overall survival. These findings highlight the functional heterogeneity of myCAFs and identify TAGLN-expressing myCAFs as critical mediators of tumor progression, providing the evidence that targeting stromal TAGLN may represent a promising therapeutic strategy for PDAC.

#6026 Iron metabolism underlies the activation of cancer associated fibroblasts.

Kedi Huang, Minh Duc Pham, Chang-il Hwang

Microbiology and Molecular Genetics, UC Davis, Davis, CA

Pancreatic ductal adenocarcinoma (PDAC) has one of the highest mortality rates among major cancers with a 5-year survival rate of 13%. This malignant disease is characterized by a dense, fibrotic stroma primarily driven by cancer-associated fibroblasts (CAFs). However, little is known about the molecular mechanism underlying the activation of CAFs. Our analysis of ATAC-seq conducted on in vitro myofibroblasts/inflammatory CAF (myCAFs/iCAFs) models suggest that a distinct landscape of chromatin accessibility underlies the activation of pancreatic stellate cells into both myCAFs and iCAFs. Here, we show that pharmacologic inhibition of the p300/CBP histone acetyltransferase complex with A485 suppresses activated CAF morphology, CAF transcriptional signatures, as well as the growth of tumor organoids in co-culture systems. Interestingly, RNA-seq analysis revealed an upregulation of heme metabolism that coincides with A485 treatment for both myCAFs and iCAFs, suggesting the potential dependency of CAF activation on iron metabolism. Both iCAFs and myCAFs also showed significantly reduced viability and CAF marker expression upon iron chelation compared with quiescent PSCs, and iron supplementation rescued this phenotype. Together, these findings suggest a link between epigenetics and iron metabolism in the context of CAF activation. Targeting the iron metabolic pathway for CAFs in PDAC may therefore serve as a promising strategy to reduce stromal remodeling and improve therapeutic interventions.

#6027 Cancer associated fibroblasts-derived PDE3A promotes lipid raft-regulated IGF-1R translocation and immunotherapy resistance in triple negative breast cancer.

Na Hao

The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China

Objective: Immunotherapy resistance remains a significant clinical challenge in the treatment of triple-negative breast cancer (TNBC). Cancer-associated fibroblasts (CAFs)-mediated induction of an immunosuppressive tumor microenvironment (TME) is a key contributing mechanism, but the underlying molecular regulatory networks are inadequately understood. This study aims to systematically elucidate the specific role and molecular mechanisms of PDE3A-expressing CAFs (PDE3A+CAFs) in TNBC immunotherapy resistance, and to assess the safety and therapeutic efficacy of a PDE3A-targeted degrader combined with immunotherapy.
Methods: Single-cell sequencing analysis was performed on tumor tissues from TNBC patients undergoing immunotherapy to identify CAF subpopulations associated with immunotherapy resistance. Functional experiments were conducted to evaluate the effects of PDE3A+CAFs on the infiltration of myeloid-derived suppressor cells (MDSCs) and the function of T cells. Mechanistic investigations included assessments of the interaction between PDE3A and Cbl-b, the lipid raft translocation of insulin-like growth factor 1 receptor (IGF-1R), and the activation of signal transducer and activator of transcription 3 (STAT3) signaling axis. Additionally, experiments such as chromatin immunoprecipitation (ChIP) were used to verify the regulatory relationship between STAT3 and PDE3A transcription.
Results: A specific subpopulation of PDE3A+CAFs was identified as a pivotal mediator of TNBC immunotherapy resistance. Functional experiments confirmed that PDE3A+CAFs significantly promoted MDSC infiltration into TNBC tumors while suppressing T cell function and activity. Mechanistically, PDE3A in CAFs inhibited the negative regulator Cbl-b in a phosphodiesterase-independent manner, thereby facilitating IGF-1R lipid raft translocation and activating the STAT3 signaling axis. Activated STAT3 further recruited MDSCs via upregulating C-X-C motif chemokine ligand 12 (CXCL12) secretion, fostering an immunosuppressive TME. Moreover, STAT3 directly regulated PDE3A transcription, forming a positive feedback loop that sustained pathway activation.
Conclusion: PDE3A+CAFs play a critical role in driving TNBC immunotherapy resistance through the PDE3A-Cbl-b-IGF-1R-STAT3-CXCL12 axis and the STAT3-PDE3A positive feedback loop. Targeting PDE3A combined with immunotherapy holds promising potential as a novel therapeutic strategy to overcome immunotherapy resistance and improve TNBC treatment outcomes, providing a solid theoretical foundation for clinical translation.

#6028 The impact of CAF-derived ANKRD1 on the lung cancer tumor microenvironment.

Kazuhiro Okada, Ken Suzawa, Shunsuke Mori, Kenta Manabe, Ryunosuke Fujii, Kousei Ishimura, Ryota Fujiwara, Kazuya Hisamatsu, Ryo Yoshichika, Atsushi Matsuoka, Yuma Fukumoto, Hidejiro Torigoe, Kazuhiko Shien, Shinichi Toyooka

Okayama Univ. Graduate School of Med., Dentistry & Pharm. Sci., Okayama, Japan

Background: Cancer-associated fibroblasts (CAFs) constitute a major component of the tumor microenvironment (TME) and are key drivers of cancer progression, therapeutic resistance, and malignancy. To improve treatment outcomes in lung cancer, it is essential to identify stromal factors that contribute to tumor aggressiveness.
Methods: RNA sequencing was performed to compare gene expression profiles between normal fibroblasts (NFs) and CAFs. Clinical databases were analyzed to determine the prognostic significance of ANKRD1 expression in lung cancer. We investigated whether cancer-derived stimuli activate ANKRD1 in NFs by exposing them to cancer cell-derived growth factors. NFs with overexpressed ANKRD1 were established and used to evaluate the effects of ANKRD1 on migration ability and treatment resistance through migration assays and colony formation assays. The effects on angiogenesis were assessed by measuring VEGF secretion and performing HUVEC (Human Umbilical Vein Endothelial Cells) tube formation assays.
Results: ANKRD1 was significantly overexpressed in CAFs compared to NFs and was associated with poor prognosis, particularly in lung adenocarcinoma. TGF-β stimulation induced ANKRD1 expression in NFs. ANKRD1-overexpressing NFs exhibited enhanced migratory ability and increased therapeutic resistance. Conditioned medium from ANKRD1-overexpressing NFs promoted VEGF secretion by cancer cells and enhanced angiogenic activity in HUVECs, suggesting that ANKRD1 activation contributes to angiogenesis both indirectly and directly.
Conclusions: ANKRD1 activation in fibroblasts within the lung cancer TME promotes tumor progression, angiogenesis, and treatment resistance through fibroblast-cancer cell crosstalk. These findings highlight ANKRD1 as a promising therapeutic target for modulating the TME and improving lung cancer outcomes.

#6029 SFRP4+ cancer-associated fibroblasts drive IL-6/STAT3-mediated EMT and immunosuppressive tumor microenvironment in hepatocellular carcinoma.

Hyo Jung Cho[1], Sujin Kim[1], Hye Ri Ahn[1], Minsu Kwon[2], Myungchan Park[3], Tae Jun Park[1]

[1]Ajou University School of Medicine, Suwon, Korea, Republic of,[2]Ulsan University School of Medicine, Seoul, Korea, Republic of,[3]Inje University College of Medicine, Busan, Korea, Republic of

Background: Secreted frizzled-related protein 4 (SFRP4) is a Wnt modulator, and SFRP4$^+$ fibroblast subsets have recently been identified across various cancer types. However, evidence that SFRP4$^+$ cancer-associated fibroblasts (CAFs) directly mediate immunosuppression and therapeutic resistance in hepatocellular carcinoma (HCC) remains limited. This study aimed to elucidate how SFRP4$^+$ CAFs reprogram the tumor microenvironment (TME) to drive immune suppression and treatment resistance in HCC.

Methods: Whole-transcriptome sequencing (WTS) was performed on eight matched CAF and paracancer fibroblast (PAF) pairs from HCC patients, and five publicly available HCC datasets were integrated to identify candidate genes. Cell-cell interactions in the TME were analyzed using CellChat analysis in the GepLiver database. Functional validation was conducted through *in vitro* coculture assays using primary CAFs and HCC cell lines, as well as *in vivo* xenograft and humanized mouse models. Transcriptomic profiling of tumors from atezolizumab-bevacizumab (Atezo/Beva) responder and non-responder groups was further performed to assess clinical relevance.

Results: SFRP4$^+$ CAFs exhibited an inflammatory phenotype characterized by marked induction of *IL6* and *NECTIN2* expression. Coculture of HCC cells with SFRP4$^+$ CAFs increased phosphorylated STAT3 and CD44 expression, enhancing proliferation, invasion, and stemness, while these effects were abrogated by SFRP4 knockdown. In the immune compartment, SFRP4$^+$ CAFs promoted regulatory T-cell (Treg) infiltration via NECTIN-TIGIT interactions and induced M2 macrophage polarization, establishing an immunosuppressive milieu.
In the humanized mouse model, tumors co-implanted with SFRP4$^+$ CAFs showed increased Treg infiltration and M2 polarization based on enrichment score analysis. Clinically, Atezo/Beva non-responder tumors exhibited upregulation of SFRP4, IL6-STAT3/CD44, and NECTIN-TIGIT pathways, accompanied by reduced *CD8A* and *GZMA* expression.

Conclusions: SFRP4$^+$ CAFs orchestrate a multifaceted pro-tumor program through IL6-STAT3/CD44 signaling, NECTIN-TIGIT-mediated Treg recruitment, and M2 macrophage polarization. High SFRP4 expression correlates with impaired cytotoxic immunity and poor response to Atezo/Beva therapy in HCC. Targeting SFRP4$^+$ CAFs may represent a promising therapeutic strategy to overcome stromal-mediated immune resistance in liver cancer.

#6030 Gli2 increases Osteopontin expression to alter cancer associated fibroblast behavior.

Zenaida Fuentes, Rachel Mangano, Jade Miller, Erik Beadle, Julie Rhoades

Cancer Biology, VANDERBILT UNIVERSITY - NASHVILLE - TN, Nashville, TN

Breast cancer is known to often metastasize into the bone. Among the subtypes, triple negative is the most aggressive. Once the cancer spreads to the bone it activates a positive feedback loop known as the vicious cycle of bone metastasis. In this cycle, Parathyroid hormone-Related protein (PTHrP) is released from tumor cells which activate osteoblasts inducing their expression of Receptor Activator of Nuclear factor Kappa-B Ligand (RANKL). RANKL binds to Receptor Activator of Nuclear factor Kappa-B Ligand (RANK) expressed on osteoclasts, thereby activating the osteoclasts to induce bone resorption subsequently releasing growth factors that fuel the tumor. This can lead to increased risk in bone fractures from the tumor indirectly activating osteoclasts. Chemotherapy is commonly given to patients with breast cancer such as paclitaxel, however, drug resistance often occurs, and treatment becomes less effective, particularly in metastatic disease. Fibroblasts are cells that are responsible for wound healing in normal circumstances. However, in cancer they can transform into Cancer Associated Fibroblasts (CAFs) capable of producing extracellular matrix proteins that surround the tumor which prevents drugs and immunotherapies from reaching the tumor. Our recent studies indicate that a transcription factor from hedgehog signaling known as GLI2 binds is upregulated in response to the chemotherapeutic, paclitaxel. RNA-sequencing analyses showed that increased expression of Gli2 increases genes associated with CAFs including osteopontin (OPN), a secreted glycoprotein. Furthermore, using the JASPAR transcription binding software, we found that Gli2 is predicted to bind to the SPP1 promoter (gene name for OPN) on chromosome 4 at a potential Gli2 binding element. Therefore, we hypothesize that osteopontin secretion is directly regulated by GLI2 in the tumor cells through direct binding of the SPP1 promoter. To test this, we knocked out GLI2 expression in bone metastatic breast cancer cell lines and showed a reduction in OPN secretion. Additional studies with a Gli2 small molecule inhibitor Hedgehog Pathway Inhibitor 1 (HPI-1) showed a 75% reduction in SPP1 by QPCR and a significant reduction of OPN secretion by ELISA. Furthermore, we showed direct changes in the production of collagens and other matrix proteins both by QPCR and immunohistochemistry. In the future, we will directly examine changes in the surrounding fibroblast phenotypes and investigate the impact on drug resistance that CAFs may play in bone metastatic tumors. Taken together, this suggests that Gli2 expressing tumors can increase OPN secretion and this may alter the production of extracellular matrix proteins by the surrounding CAFs.

#6031 The Treg-fibroblast axis shapes the immunosuppressive tumor microenvironment in colorectal cancer.

Liqian Ma[1], Mingying Bi[2], Bonnie Huang[2], Lilian Ho[2], Hin Ching Lo[1], Min Liao[2], Gaurav Mehta[2], Nicole Belmar[2], Michelle Chen[2], Tifani Anton[1], Areej Ammar[1], Haiyan Li[2], Kyle Halliwill[1], Kate MacDonald[2]

[1]Quantitative Medicine & Genomics, Genomic Research Center, AbbVie Bay Area, South San Francisco, CA,[2]Oncology Discovery Research, AbbVie Bay Area, South San Francisco, CA

The tumor microenvironment (TME) is a critical regulator of cancer progression and therapeutic response. Cancer-associated fibroblasts (CAFs) are a heterogeneous and significant component of the TME. Among CAFs, the subset marked by leucine-rich repeat containing 15 (LRRC15) is enriched in tumors and has been implicated in immune suppression and resistance to immunotherapy. However, the functional interactions of LRRC15+ CAFs within the TME, particularly with regulatory T cells (Tregs), remain incompletely understood. While it has been reported that LRRC15+ CAFs are induced by TGFβ signaling, we show in murine models that blockade of TGFβ pathways does not reverse LRRC15 expression, indicating that maintenance of LRRC15+ CAFs in the tumor microenvironment is not solely dependent on TGFβ. Using multi-omics and spatial analysis of human tumor samples, we define the specific molecular profile of LRRC15+ CAFs, which strongly correlates with Treg abundance and shows frequent proximity to Tregs within the TME. Finally, functional studies in mouse models demonstrate that Treg depletion leads to pronounced remodeling and reduction of the LRRC15+ CAF compartment. Together, these findings reveal a Treg-LRRC15+ fibroblast axis that actively shapes the immunosuppressive landscape of colorectal cancer via Treg maintenance of CAF phenotype and suggest that targeting this interaction may disrupt stromal-mediated immune evasion in immuno-oncology.

#6032 Subtypes of cancer-associated fibroblasts, myCAF, iCAF, and apCAF, might be associated with adverse prognostic signature of patients with gastric cancer.

DONGHENG MA, Hinano Nishikubo, Tomoya Sano, Daiki Imanishi, Takashi Sakuma, Canfeng Fan, Yurie Yamamoto, Masakazu Yashiro

Osaka Metropolitan University, Osaka, Japan

Background: It has been reported that the tumor microenvironment (TME) may play an important role for the progression of various carcinomas, including gastric cancer (GC). The cancer-associated fibroblast (CAF) is one of major stromal components of TME. CAF includes 3 subtypes such as myofibroblastic CAF (myCAF), inflammatory CAF (iCAF), and antigen-presenting CAF (apCAF). In this study, we investigated the clinicopathologic significance of 3 CAF subtypes in GC.
Methods: A total of 1330 GC specimens was collected in this study. Immunohistochemical study was performed using 3 antibodies against myCAF, iCAF, and apCAF. Staining level of fibroblasts was scored using a semi-quantitative combined score (from 0 to 6) which was obtained by the addiction of intensity score (0 to 3) and the proportion score (0-3).
Results: myCAFs were found significantly ($p<0.05$) frequent in GC patients with advanced T stage, high lymphatic invasion, and high venous invasion. apCAFs were found significantly ($p<0.05$) frequent in GC patients with advanced T stage, lymphatic metastasis, distant metastasis, and postoperative recurrence. In contrast, iCAF showed significantly ($p<0.05$) lower in GC patients with tumor infiltration and few postoperative recurrence. Univariable Cox indicated that myCAF+ showed significantly shorter overall survival (OS; HR 1.97, 95%CI 1.34-2.90, $p<0.001$), iCAF+ showed significantly shorter OS (HR 1.29, 1.04-1.61, $p=0.022$), and apCAF+ showed significantly shorter OS (HR 1.26, 1.03-1.54, $p=0.027$). After adjustment for age, sex, T/N/M stage, histology, cytology, and lymphatic invasion, only myCAF+ remained to be independent prognostic factor for OS (HR 1.56, 1.04-2.34, $p=0.032$), whereas iCAF+ and apCAF+ were not ($p>0.05$). The triple-positive signature of myCAF, iCAF, and apCAF+) conferred significantly ($p<0.001$) high risk for OS (univariable Cox HR 2.98, 95%CI 1.83-4.83; multivariate Cox HR 2.48, 95%CI 1.51-4.06).
Conclusions: In this GC cohort, myCAF, iCAF, and apCAF are individually associated with lower survival, and myCAF, iCAF, and apCAF defined an independent adverse prognostic signature. Cooperative stromal programs might provide rationale for CAF subtype status as a prognostic factor. CAF subtypes might be associated with adverse prognostic signature of GC patients.

#6033 Different roles of cancer-associated fibroblasts in pancreatic cancer and biliary tract cancers cancer-associated fibroblasts as a tumor suppressor in biliary tract cancers.

Ryota Tanaka, Kenjiro Kimura, Naoki Tani, Shimpei Eguchi, Daisuke Inoue, Takuto Yasuda, Changgi Ahn, Koichi Nakanishi, Kosuke Hatta, Shigeaki Kurihara, Jun Tauchi, Sadaaki Nishimura, Masahiko Kinoshita, Kohei Nishio, Hiroji Shinkawa, Takeaki Ishizawa

Department of Hepato-Biliary-Pancreatic Surgery, Osaka Metropolitan University Graduate School of Medicine, Osaka, Japan

Background and aims: Cancer-associated fibroblasts (CAFs) are a major component of the tumor microenvironment and can exhibit cancer-promoting functions; however, recent studies indicate that CAFs can also inhibit cancer growth and progression. In this study, we identified CAFs that act in an inhibitory manner in biliary tract cancer and elucidated their mechanisms.
Materials and Methods: We retrospectively evaluated alpha-smooth muscle actin (αSMA) expression in CAFs from 114 cases of pancreatic ductal carcinoma (PDAC) and 154 cases of biliary tract cancers (BTCs) who underwent surgical treatment at our institution from 1996 to 2017. The BTC cell lines, PDAC cell lines, and CAFs were isolated from resected specimens of BTC and PDAC were used to evaluate the proliferative potential of cancer cells. Conditioned media (CM) were prepared from CAFs (CM-CAF). Protein array analysis of CM-CAFs was conducted to identify candidate factors responsible for growth suppression.
Results: PDAC patients with positive αSMA expression showed significantly shorter overall survival and recurrence-free survival than αSMA-negative patients ($p = 0.003$, $p = 0.009$, respectively). On the other hands, BTC patients with positive αSMA expression showed better recurrence-free survival than αSMA-negative patients ($p = 0.03$). CM-CAF suppressed the proliferation of cancer cells only in BTC cancer cell lines, not in PDAC cell lines. Protein arrays of CM-CAFs revealed that IL-6 and IL-8 were key suppressive factors on BTC cancer cell proliferation. The inhibitory effects on BTC cell proliferation were abolished upon neutralization of IL-6 and IL-8.
Conclusions: CAFs serve as a favorable prognostic factor in BTC but not in PDAC. We demonstrated the presence of tumor-suppressive CAFs in BTC, which exert their anti-proliferative effects through the secretion of IL-6 and IL-8. These findings suggest a novel, context-dependent role for CAFs in the tumor microenvironment of biliary tract cancers.

#6035 Non-immune stromal reprogramming shapes breast cancer immunotherapy resistance: insights from mouse models.

Yujia Yue, Stephanie Mittman, Rohit Reja, Julia Lau, Minyi Shi, Ana Xavier-Magalhaes, Jonathan Paw, Carolina De Amat Herbozo, Marco De Simone, Yan Qu

Genentech, Inc., South San Francisco, CA

Background: PD-1/PD-L1 blockade benefits only a subset of breast cancer patients.While tumor and immune cells have been extensively studied, the role of non-immunestroma such as endothelial cells (ECs) and cancer-associated fibroblasts (CAFs) intherapeutic resistance is less understood.
Methods: We performed single-cell RNA sequencing of $CD45^-$ cells from threesyngeneic breast cancer models with divergent ICB responses (4T1: resistant, EMT6:partial responder, EO771: responder). Stromal composition, functional programs (GOBiological Process), and tumor-stroma paracrine communication (CellChat) wereanalyzed. Findings were compared with published human breast and lung cancerdatasets (Cell Res 30, 745-762 (2020)).
Results: Distinct stromal states were linked to ICB outcomes. 4T1 were enriched forfibroblast- and extracellular matrix-dominant stroma with immune-silent endothelium,while EMT6 tumors showed endothelial expansion and interferon-active CAFs. EO771tumors displayed pericyte-stabilized, quiescent vasculature and immune-stimulatoryfibroblast programs. Pathway-level analysis highlighted conserved modes of stromalcommunication and identified fibroblast-associated signatures that correlated withdisease stage in human cohorts. Pathway-level analysis highlighted conserved modesof stromal communication and identified fibroblast-associated signatures that correlatedwith disease stage in human cohorts.
Conclusions: Stromal reprogramming contributes to ICB resistance. Cross-speciesanalysis highlights endothelial and fibroblast states as potential biomarkers andtherapeutic entry points to enhance immunotherapy efficacy.

#6036 Antigen-presenting cancer-associated fibroblasts in murine pancreatic tumors differentially control regulatory T cell phenotype and function via CCL22.

Saumya Maru[1], Meredith Wetzel[2], Jacob Mitchell[2], Nicole Gross[2], Lalitya Andaloori[3], Kathryn Howe[3], Emma Kartalia[4], Guanglan Mo[3], James Leatherman[4], Won Jin Ho[2], Elana Judith Fertig[5], Luciane Tsukamoto Kagohara[6], Edward J. Pearce[4], Elizabeth M. Jaffee[4]

[1]Fox Chase Cancer Center, Philadelphia, PA,[2]Convergence Institute, Johns Hopkins University School of Medicine, Baltimore, MD,[3]Department of Oncology, Johns Hopkins University School of Medicine, Baltimore, MD,[4]Johns Hopkins University School of Medicine, Baltimore, MD,[5]University of Maryland School of Medicine, Baltimore, MD,[6]Johns Hopkins University, Baltimore, MD

Pancreatic ductal adenocarcinoma (PDAC) is characterized by an immunosuppressive tumor microenvironment (TME), where cancer-associated fibroblasts (CAFs) play pivotal roles in shaping therapeutic responses. Among these, MHC-II-expressing antigen-presenting CAFs (apCAFs) modulate CD4 T cell activity, yet their contribution to the antitumor immune response remains unclear. Using tumor clones of the KPC murine PDAC model differing in sensitivity to immune checkpoint blockade (ICB), we show that immunosensitive (sKPC) tumors exhibit greater apCAF infiltration than resistant (rKPC) tumors. Depletion of apCAFs in sKPC tumors impaired responsiveness to ICB, highlighting their role in mediating effective antitumor immunity. Ex vivo assays revealed that apCAFs from both models activate CD4 T cells and induce regulatory T cell (Treg) differentiation. However, single-cell transcriptomics revealed that rKPC apCAFs promote Tregs with heightened immunosuppressive signatures, driven by distinct chemokine signaling. Notably, we identified elevated CCL22 expression and signaling in rKPC-derived apCAFs as a contributor to enhanced Treg-mediated suppression. Functional blockade of CCL22 reduced TGFβ secretion by rKPC apCAF-induced Tregs, supporting a mechanistic role for this pathway in fostering an immunosuppressive TME. These findings position apCAFs as regulators of CD4 T cell antitumor immunity in PDAC, and suggest that modulating apCAF-T cell interactions could offer strategies to enhance immunotherapy efficacy.

#6037 An immune-activating and tumor-suppressive subtype of cancer-associated fibroblasts identified in gastric cancer.

HUAITAO WANG, Takashi Semba, Atsuko Yonemura, Takatsugu Ishimoto

Japanese Foundation for Cancer Research, Tokyo, Japan

The tumor microenvironment (TME) is a critical determinant of progression and therapy resistance in advanced gastric cancer (GC), with cancer-associated fibroblasts (CAFs) being a key component. While protumorigenic CAFs have been extensively characterized, the identity and regulatory mechanisms of tumor-suppressive CAF subsets remain elusive. To address this, we analyzed single-cell RNA sequencing (scRNA-seq) datasets derived from gastric cancer (GC) samples and identified fibroblast subclusters characterized by high expression of antitumor-associated genes such as CXCL10 and ASPN. Further analysis revealed that RARRES2, encoding Chemerin, was one of the signature genes defining this CAF subpopulation. Chemerin is a multifunctional protein exhibiting chemotactic and metabolic functions. Accumulating evidence indicates that Chemerin mediates the recruitment of multiple immune cell types, thereby influencing immune surveillance and inflammatory processes. However, its precise roles within the tumor microenvironment have yet to be fully elucidated. Functionally, recombinant Chemerin potently induced CD8+ T cell migration in vitro. Through co-culture models and mechanistic dissection, we demonstrated that tumor cells actively suppress RARRES2/Chemerin expression in CAFs by activating the Jag1-Notch2-HDAC5 signaling axis, leading to epigenetic silencing. Crucially, CAF-specific overexpression of RARRES2 in vivo was sufficient to attenuate tumor growth and profoundly augment the recruitment of CD8+ T cells into tumors. Our findings definitively identify Chemerin+ CAFs as a pivotal stromal subset that orchestrates antitumor immunity by recruiting cytotoxic T cells. Furthermore, we unveil a dynamic and therapeutically targetable crosstalk wherein tumor cells subvert this stromal defense mechanism via Jag1-Notch2-HDAC5 signaling, thereby identifying a novel immune-evasion pathway in GC.

#6038 Cancer associated fibroblast subtype heterogeneity in colorectal cancer influences primary tumor invasion.

Bethany Haliday[1], Carly Strelez[2], Eileen Fung[2], Shannon M. Mumenthaler[2]

[1]University of Southern California, Los Angeles, CA,[2]Ellison Medical Institute, Los Angeles, CA

The influence of the tumor microenvironment (TME) on cancer progression has become a major area of study, driven in part by the continual advances in single-cell and spatial technologies that reveal the TME to be highly heterogeneous. Cancer associated fibroblasts (CAFs), a major component of the tumor stroma, have been classified into several subtypes, each with distinct functionality and influences on the tumor progression. Among these, inflammatory CAFs (iCAFs) and myofibroblastic CAFs (myCAFs) are typically defined by characteristic biomarker profiles and have been shown to have distinct spatial distributions within the tumor. However, the specific functions of these subtypes in contributing to cancer progression, particularly metastasis, is largely unknown. With metastatic disease having poor prognoses, it is vital to elucidate the roles these CAF subtypes play within the metastatic cascade. To address this gap, we have built a diverse biobank of CRC patient-derived tissue samples and matched CAF lines. Single cell RNA-sequencing of patient tissues identified distinct CAF subpopulations. These transcriptional signatures were then applied to bulk RNA-sequencing of the patient-derived CAF lines, which revealed expression patterns consistent with iCAF and myCAF profiles. Flow cytometry and secretome analysis further confirmed expression of subtype-specific markers, suggesting that each CAF line retains features of the originating subtypes.To investigate how these different CAFs influence tumor cell invasion, we developed a CRC organ-on-chip co-culture model. Specifically, this microfluidic device simulates gut-relevant biomechanical cues, including fluid flow and peristalsis-like motion, and is composed of two extracellular matrix-coated overlapping channels separated by a porous membrane, allowing biochemical and cellular exchanges between compartments. Patient-derived CAFs and GFP-labelled CRC tumor cells are cultured together in the top “epithelial” channel, while the endothelial cells line the bottom “vascular” channel. Using time-lapse confocal microscopy, GFP+ tumor cells intravasating into the vascular channel are tracked and quantified, providing real time invasion rates. We observed patient-specific differences in CAF-induced CRC invasion when exposing human CRC cells on-chip to CAF-conditioned media and in physical co-cultures. Interestingly, a myCAF-enriched line promoted invasion in only physical co-culture conditions, suggesting contact-dependent signaling. Additionally, each CAF line displayed distinct morphology and invasion patterns on-chip with the myCAF-enriched line invading before the CRC cells. Collectively, these results suggest that there may be specific CAF phenotypes that induce tumor invasion which could give insight into determining the invasive potential of a primary CRC tumor at diagnosis.

#6039 Cancer cell-driven HIF-1α activation enhances the motility of cancer-associated fibroblasts in the lung tumor microenvironment.

Jihye Park[1], Sieun Lee[1], Jonathan M. Kurie[2], Young-Ho Ahn[1]

[1]Ewha Womans University College of Medicine, Seoul, Korea, Republic of,[2]Professor, Dept. of Thoracic & H&N Onc., UT MD Anderson Cancer Center, Houston, TX

Cancer-associated fibroblasts (CAFs) display significant phenotypic heterogeneity driven by dynamic interactions within the tumor microenvironment. To investigate motility-driven CAF heterogeneity, we utilized a 3D culture system and the photoconvertible fluorescent protein Dendra2, to isolate ‘motile’ and ‘static’ CAF subpopulations. Transcriptomic analyses revealed that motile CAFs upregulated hypoxia- and glycolysis-related genes, which are downstream targets of HIF-1α. In line with these findings, HIF-1α activation enhanced CAF motility, while the knockdown of its downstream targets, ALDOA and LDHA, significantly reduced CAF motility. Notably, mesenchymal-like lung cancer cells enhanced both HIF-1α activity and motility in CAFs through secretory factors. Using mass spectrometry, we identified ceruloplasmin (CP) as a key secretory protein from these lung cancer cells, whose transcription was regulated by the EMT-inducing transcription factor ZEB1. Functionally, CP knockdown abolished the ability of lung cancer cells to promote CAF motility in vitro and to metastasize in vivo. Collectively, these findings demonstrate a novel mechanism where lung cancer cell-secreted CP facilitates HIF-1α signaling in CAFs, thereby driving their motility and promoting metastasis.

#6040 Targeting EP3$^+$FAP$^+$ stromal reprogramming uncovers a therapeutic vulnerability in early recurrent hepatocellular carcinoma.

guiqi zhu[1], guan zhiqi[1], yinghong shi[1], weiren liu[1], zheng tang[1], Kang Wang[2], jia fan[1]

[1]Zhongshan Hospital Fudan University, Shanghai, China,[2]Karolinska Inst. Cancer Ctr., Stockholm, Sweden

Early recurrence after curative therapy remains a major obstacle in hepatocellular carcinoma (HCC), yet the stromal determinants of early relapse are poorly defined. Across integrated mouse and human datasets, this stromal program was consistently associated with early relapse. Integrating bulk, single-cell and spatial transcriptomics with functional assays from primary and relapse HCC, we identify a recurrence-enriched cancer-associated fibroblast (CAF) population marked by FAP and EP3. A CAF- and neutrophil-derived high-risk gene signature predicted early relapse and was accompanied by expansion of FAP$^+$EP3$^+$ CAFs, immunosuppressive neutrophils and stem-like tumor epithelial cells in relapsed lesions. Lineage and perturbation studies indicate that CD36$^+$ lipid-associated CAFs are reprogrammed by tumor-derived PGE_2 into FAP$^+$EP3$^+$ matrix CAFs, linking stromal plasticity to recurrence. Mechanistically, FAP physically associates with EP3 on CAFs to potentiate PGE_2-induced EP3 signaling, thereby amplifying downstream cAMP-PKA activation. This FAP-EP3 complex drives a proline-metabolic, senescent and inflammatory CAF phenotype characterized by PYCR1-dependent proline production and SASP factors including IL-6 and TIMP1. PGE_2-FAP-EP3-cAMP/PKA signaling engages the chromatin reader BRD9 and pioneer factor FOXA1 to establish super-enhancer landscapes at IL6, FAP, PYCR1 and TIMP1, locking EP3$^+$FAP$^+$CAFs into a relapse-permissive state and sustaining SASP output. Imaging mass cytometry and spatial analyses revealed that EP3$^+$FAP$^+$ CAFs organize relapse-associated niches enriched for neutrophils, CD44$^+$/CD133$^+$ stem-like tumor cells, FOXP3$^+$ Tregs and CD163$^+$ macrophages, in close apposition to invasive tumor fronts. In autochthonous HCC models, genetic deletion of EP3 in fibroblasts or pharmacologic blockade of EP3 or BRD9 reduced tumor burden, decreased pro-tumoral neutrophils and exhausted CD8$^+$ T cells, and enhanced effector CD8$^+$ differentiation. Combined EP3 inhibition and anti-PD-1 therapy produced superior tumor control, indicating that stromal targeting can sensitize HCC to immune checkpoint blockade. In human HCC cohorts, EP3$^+$FAP$^+$ CAF signatures correlated with T cell exhaustion, high PTGES expression and poor survival, validating the clinical relevance of this stromal program. Together, our data uncover a PGE_2-FAP-EP3-cAMP/PKA-BRD9-FOXA1 axis that epigenetically locks CAFs into a relapse-permissive, metabolically active SASP state and remodels the immune microenvironment. Targeting EP3$^+$FAP$^+$ CAFs or their epigenetic circuitry represents a promising strategy to limit HCC recurrence and improve responsiveness to immunotherapy.

#6041 Fidaxomicin targets PDGFR$^+$ cancer-associated fibroblast to restrain colorectal cancer progression.

Haoxiang Zhang, Xudong Zhu, Chang Li, Yinping Jiang, Yuning Zhou, **B. Mark Evers**, Qingding Wang

UK Markey Cancer Center, Lexington, KY

Background: Colorectal cancer (CRC) features a stroma-rich, immunosuppressive tumor microenvironment (TME) where activated fibroblasts drive tumor progression and correlate with poor prognosis. PDGFR$^+$ cancer-associated fibroblasts (CAFs)—including PDGFRα$^+$ inflammatory CAFs (iCAFs) and PDGFRβ$^+$ myofibroblastic CAFs (myCAFs)—are proportionally increased and serve as key hubs of intercellular communication in CRC. High PDGFR$^+$ CAF signatures are associated with unfavorable outcomes. Fidaxomicin, an FDA-approved oral antibiotic which selectively eliminates pathogenic *Clostridioides difficile*, inhibits ileal fibrosis and suppresses PDGFR expression in intestinal fibroblasts. The purpose of this study was to define the mechanisms by which PDGFR$^+$ CAFs promote CRC progression and to evaluate the anti-tumor effects of fidaxomicin targeting PDGFR.
Methods: We performed R-based analyses of datasets from human CRC and matched normal tissues to compare cellular subpopulation proportions, functional enrichment, cell-cell communication, and virtual cell states. Effects of fidaxomicin on the proliferation of CRC cells and CAFs were assessed *in vitro* using 2D and 3D cultures and *in vivo* using an orthotopic colon cancer model (MC38 co-implanted with mCAF cells). CAF-neutrophil interactions were examined through 3D co-culture, multicolor immunofluorescence, and flow cytometry.
Results: Analysis of datasets from single-cell transcriptomics revealed markedly activated fibroblasts and increased monocyte-macrophage and neutrophil populations within the TME of CRCs. Tumor-enriched CAF subsets, including PDGFRα$^+$ iCAFs and PDGFRβ$^+$ myCAFs, expressed high levels of PDGFR and neutrophil-attracting chemokines such as CXCL1 and CXCL14. ssGSVA scores of CAF signature genes strongly correlated with poor prognosis. Treatment of CAFs with fidaxomicin significantly reduced PDGFR expression at both mRNA and protein levels, inhibited STAT3 phosphorylation, and downregulated CXCL1 and CXCL14 transcription. Moreover, oral fidaxomicin administration suppressed MC38 tumor growth. Mechanistically, fidaxomicin inhibited the transcriptional activity of the NOTCH-RBPJ-HDAC1/HDAC3 complex, leading to PDGFR downregulation and blocking PDGFR-mediated STAT3 activation and nuclear translocation that drives CXCL14 transcription and immune evasion.
Conclusions: Our results demonstrate that PDGFR$^+$ CAF subsets play a critical role in CRC progression. Fidaxomicin disrupts PDGFR$^+$ CAF-neutrophil interactions, remodels the TME, and inhibits tumor growth. Importantly, our findings suggest a potential usage of fidaxomicin, which maintains a favorable safety profile with minimal systemic toxicity, for CRC treatment.

#6042 Targeting GABA signaling in cancer associated fibroblasts to reduce immunosuppression in pancreatic cancer.

Ariana Musa de Aquino[1], Myree Graves[2], Kyra Langley[3], Peter Sajjakulnukit[4], Ian Loveless[5], Nina Steele[6], Julie Clark[1], Alexander Muir[7], Costas Andreas Lyssiotis[4], Ralph Francescone[8], Debora B. Vendramini-Costa[3], Guilaume Cognet G[7], David Kwon[9]

[1]Pancreatic Cancer Center, Henry Ford Health, Detroit, MI,[2]Department of Surgery- Pancreatic Cancer Center, Henry Ford Health, Detroit, MI,[3]Department of Surgery - Pancreatic Cancer Center, Henry Ford Health, Detroit, MI,[4]University of Michigan, Ann Arbor, MI,[5]Henry Ford Health System, Bexley, OH,[6]University of Cincinnati, Cincinnati, OH,[7]University of Chicago, Chicago, IL,[8]Department of Surgery-Pancreatic Cancer Center, Henry Ford Health, Detroit, MI,[9]Department of Surgery, Pancreatic Cancer Center, Henry Ford Health, Detroit, MI

Pancreatic ductal adenocarcinoma (PDAC) is a devasting disease with few therapeuticoptions. This is due, in large part, to the expansion of the non-tumor cellular compartmentknown as the stroma. Cancer-associated fibroblasts (CAFs) are one of the major celltypes that populate the stroma of PDAC tumors and are extremely immunosuppressivebecause they produce large amounts of cytokines, growth factors and metabolites. Thus,understanding how CAFs impart severe immunosuppression in the tumormicroenvironment is critical to make PDAC amenable to immunotherapies. Using a novel3D culturing method, our data support the notion that PDAC CAFs produce the glutamatemetabolite and inhibitory neurotransmitter gamma aminobutyric acid (GABA), *de novo*,and we detected GABA (~27μM) in tumor interstitial fluid (TIF) isolated from patient tissue(10 patients). Surprisingly, CAFs lacked expression of glutamate decarboxylase, thecanonical enzyme responsible for converting glutamate into GABA, which led us toexplore alternative, non-canonical pathways for GABA synthesis. We found that CAFsderived from patient PDAC tumors expressed the enzymes of the non-canonicalsynthesis pathway (ODC1, DAO, ALDH1A1 and ALDH9A1), and to a greater degreewhen compared to normal fibroblasts. In parallel, we demonstrated that, by exploringparacrine signaling, GABA treatment of CAFs resulted in changes in expression of p-p70,p-JNK, p-MTOR and p-AKT proteins, key signaling hubs involved in overcomingmetabolic stress in PDAC. In addition, GABA treatment increased the production of pro-tumor cytokines, such as TGFβ, IL8, and IL6, by CAFs. In preclinical orthotopic murinetumor models of PDAC, inhibition of GABA synthesis through ALDH1A1, and GABAsignaling through GABAB receptor inhibitors, reduced tumor burden, increased influx ofanti-tumor T and NK cells, and blocked production of pro-tumor cytokines in tumorexplants. Translationally, we have acquired patient matched plasma, TIF, and tissue from10 patients, and will compare their metabolic, immune, and spatial transcriptomic profileswith well annotated clinical parameters, in order to develop improved diagnostic tests.Overall, we have uncovered a novel signaling circuit driven by GABA that plays a role incontrolling the extremely immunosuppressive PDAC microenvironment.

#6043 Deactivating liver metastatic colorectal cancer-associated fibroblasts with all-trans retinoic acid.

Brandon Choi[1], Ken Huang[2], Yuyuan Zhou[2], Seungil Kim[2], Eileen Fung[2], Shannon M. Mumenthaler[2]

[1]Keck School of Medicine, University of Southern California, Los Angeles, CA,[2]Ellison Institute, LLC, Los Angeles, CA

Cancer-associated fibroblasts (CAFs) are a prominent component of the tumor microenvironment (TME) and are known to support tumor growth and disease progression. Reprogramming the stroma, particularly targeting the pro-tumorigenic functions of CAFs, has emerged as a promising therapeutic intervention to disrupt the supportive environment tumors rely upon. An in-house drug screen of FDA-approved oncology therapies was conducted on patient-derived colorectal cancer CAFs and tumor organoids (PDTOs) to identify compounds that may be repurposed as stroma targeting agents. This preliminary screen identified all-trans retinoic acid (ATRA) as a potential candidate that selectively inhibited CAF proliferation without affecting PDTO viability. ATRA is an active metabolite of vitamin A and can inhibit canonical transforming growth factor beta (TGF-β) signaling, a primary means of CAF activation and maintenance of the pro-tumorigenic TME. To investigate the mechanism underlying ATRA-mediated CAF deactivation, patient-derived liver metastatic CAFs were treated with ATRA for 5 days and analyzed at the transcriptional, protein, and metabolic level. qPCR was performed to assess the expression of glycolytic enzymes, CAF activation markers, and ATRA signaling genes. Western blots quantified expression of SMAD 2/3 and α smooth muscle actin (αSMA), a biomarker of CAF activation. ATRA-mediated alterations to CAF secretomes were validated with ELISAs probing for the following CAF activating cytokines: TGF-β, stromal derived factor 1 (SDF-1), and IL-6. Finally, alterations to the metabolic activity in response to ATRA was measured using Fluorescence Lifetime Imaging Microscopy (FLIM), providing a functional readout of TME normalization. All three patient-derived CAF lines treated with ATRA showed increased expression of retinoic acid receptor β (RARβ), a documented indicator of active ATRA signaling. Similarly, αSMA and TGF-β signaling were reduced across all lines in response to treatment. Secretome profiling was also consistent across patient lines, with ATRA lowering the quantities of TGF-β, SDF-1 and IL-6 released from CAFs. However, qPCR analysis revealed heterogeneity in transcriptional response: two CAF lines showed broad downregulation of CAF activation and glycolytic markers, but one line showed variable results. Finally, at a single-cell resolution, FLIM analysis revealed an ATRA-driven shift in metabolism away from aerobic glycolysis, a metabolic state associated with activated CAFs. Overall, these results suggest that ATRA effectively reprograms CAFs toward a deactivated phenotype but also highlights the inherent heterogeneity of CAFs and the impact this may have on drug response.

#6044 Immunosuppressive role of DKK1 and cancer-associated fibroblasts across molecular subtypes of endometrial cancer.

Alessandro Canella[1], Danielle Glassman[1], Keith Brownewell[1], Caprice Eisele[2], Aharon Gideon Freud[2], **Casey Cosgrove**[1]

[1]Division of Gynecologic Oncology, Department of Obstetrics and Gynecology, The Ohio State University Wexner Medical Center, James Cancer Hospital and Solove Research Institute, Columbus, OH,[2]Department of Pathology, The James Cancer Hospital and Solove Research Institute, The Ohio State University, Columbus, OH

BACKGROUND. Endometrial Cancer (EC) is the most diffuse and leading cause of gynecologic cancer-related mortality in the United States. Unlike many other cancers, EC mortality has continued to rise over the past two decades. Although recent advances in immunotherapy, particularly immune checkpoint inhibitors, most EC patients have limited or modest responses to current immunotherapies. The TCGA classification stratifies EC into four molecular subtypes: POLE-mutated, mismatch repair-deficient (MMRd), no specific molecular profile (NSMP), and p53-abnormal (p53abn). Each subgroup differs in tumor biology, immune cell infiltration, and prognosis. A deeper understanding of immune evasion across these subtypes and tumor grades is critical for improving targeted immunotherapies. Dickkopf-1 (DKK1), a secreted inhibitor of the canonical WNT pathway, has emerged as a key immunosuppressive regulator in several solid tumors. High DKK1 levels correlate with increased infiltration of myeloid-derived suppressor cells (MDSCs) and suppression of CD8+ T and NK cell cytotoxicity in breast and colorectal cancer. A recent study in breast cancer identified stromal fibroblasts as major contributors to extracellular DKK1, leading to suppression of NK cell cytotoxicity.
METHODS. We analyzed fresh and FFPE tumor samples across molecular subtypes from newly diagnosed, ICI-naïve EC patients who underwent surgical staging at The Ohio State University. Total RNA was extracted and analyzed using bulk RNAseq, single-cell RNAseq (scRNAseq), GSEA, and immune deconvolution. The tumor immune and stromal microenvironment was investigated by immunofluorescence (IF), multiplex IF, and DSP.
RESULTS. High-grade EC tumors showed significant upregulation of genes and pathways associated with tumor proliferation, invasion, WNT signaling, immunosuppression, and stromal fibroblasts proliferation. DKK1 expression was significantly higher in the tumor microenvironment (TME) of high-grade EC tumors, with spatial colocalization of DKK1 and perivascular CAF polarization. No DKK1 expression was detected in EC cells. scRNAseq confirmed exclusive upregulation of DKK1 in CAFs. Analysis of the TCGA-UCEC dataset confirmed significant upregulation of DKK1, and a positive correlation between DKK1+CAFs, immunosuppressive myeloid cells, and exhausted NK cells.
CONCLUSIONS. Our findings highlight CAF-derived DKK1 as a key immunosuppressive factor in high-grade and aggressive EC, suggesting that targeting DKK1 may enhance cytotoxic immune cell activation and improve immunotherapeutic outcomes.

#6045 Exploring surface interactors promoting viability of CLL cells in contact with stromal fibroblasts.

Uday Aditya Sarkar[1], Domenico Maisano[1], Stacey M. Fernandes[1], Kiyomi Mashima[1], Colin Mcnulty[1], Nikhil C. Munshi[1], Jennifer R. Brown[1], Fabiana Perna[2], Eugenio Morelli[3], Paolo P. Ghia[1]

[1]Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, MA,[2]Department of Blood and Marrow Transplant and Cellular Immunotherapy, Moffitt Cancer Center, Tampa, FL,[3]Candiolo Cancer Institute, Candiolo (TO), Italy

INTRODUCTION

Survival and expansion of chronic lymphocytic leukemia (CLL) B cells are strongly shaped by interaction with the tissue microenvironment. This pro-survival activity is sustained by indirect and direct interactions, through soluble and surface factors, respectively. In this study, we aimed at exploring the lesser-known direct cell-to-cell surface interactions between CLL cells and their microenvironmental stroma that support the increased viability in CLL cells.

METHODS

Primary CD19+/CD5+ cells from 20 untreated patients with CLL (16 with unmutated IGHV) were cultured in the presence or absence of HS-5, a human bone marrow derived fibroblast cell line, that was also grown alone, as control. After 72 hours, viability of the primary CLL cells was assessed and HS-5 cells were harvested from the 2 culture conditions, with and without CLL cells, respectively, to be processed for RNA sequencing. Cell surface protein annotation method was used to identify the most prominent proteins expressed on the cell surface. These genes were used to design the CRISPR/Cas9 screening library encapsulated in lentiviral particles to infect HS-5 cells.

RESULTS

As expected, direct cellular contact with stroma increased the viability of CLL B cells by ~30% at day 3 ($p < 0.0001$) compared to CLL cells cultured alone. Using the method of surface protein annotation, we analyzed the RNA-Seq data obtained from HS-5 cells grown in co-culture and identified a list of 120 genes, likely coding for surface proteins, that were differentially expressed as compared to HS-5 cells cultured alone. Pathway enrichment analysis of these genes, particularly including notable names like *ALCAM*, *DDR2*, *TM4SF1*, *ITGB8* & *GJA1* etc., identified few vital cellular activities such as cell-adhesion, extracellular matrix protein binding, integrin binding and kinase binding. We have created a CRISPR/Cas9 library to enable functional testing directly in HS-5 cells to selectively remove each gene of interest. These modified HS-5 cells will be used for co-culture with primary CLL B cells to identify specific genes whose removal may show a significant impact on leukemic viability in our *in vitro* model.

CONCLUSIONS

In our work, we focused on the surface interactions, occurring between CLL and stromal cells, supporting the contact-dependent survival of the leukemic clone. By combining RNA-seq-based surface protein annotation with a targeted CRISPR screen, we establish a functional approach to identify a number of surface molecules on stromal cells that are potentially involved in direct surface interactions. This strategy may expose microenvironmental vulnerabilities that can be targeted to disrupt CLL-stroma interactions. Therapeutically, this study may pave the way to define the stromal interface as a tractable target to exploit novel treatment strategies for CLL in future.

#6046 Spatial transcriptomic profiling of cancer-associated fibroblast niches in extrahepatic cholangiocarcinoma.

Giulia Petroni[1], Simone Romagnoli[2], Daniele Lavacchi[3], Giulia Massaro[3], Francesca Rizzo[4], Elena Alexandrova[4], Costanza Winchler[3], Alfonso Carleo[4], Gian Luca Grazi[1], Daniele Rossini[1], Luca Messerini[5], Matteo Benelli[2], Serena Pillozzi[2], Lorenzo Antonuzzo[1]

[1]Department of Experimental and Clinical Medicine, Universita degli Studi di Firenze - UniFI (University of Florence), Firenze, Italy,[2]Department of Experimental and Clinical Biomedical Sciences 'Mario Serio', Universita degli Studi di Firenze - UniFI (University of Florence), Firenze, Italy,[3]Clinical Oncology Unit, Careggi University Hospital, Firenze, Italy,[4]Department of Medicine, Surgery and Dentistry "Scuola Medica, Salernitana", University of Salerno, Salerno, Italy,[5]Department of Experimental and Clinical Medicine, Pathology Unit, Universita degli Studi di Firenze - UniFI (University of Florence), Firenze, Italy

Background. Cholangiocarcinoma (CCA) is a rare and highly lethal malignancy characterized by a dense desmoplastic stroma containing cancer-associated fibroblasts (CAF). While CAF have been extensively studied in intrahepatic CCA, their impact on TME remodeling and chemo-immunotherapy (CIT) efficacy in extrahepatic (e) CCA remains largely unexplored. A comprehensive characterization of CAF in eCCA is needed to identify therapeutic strategies able to improve the CIT efficacy, that, so far, is limited in these patients.

Methods. Spatial transcriptomics was performed on treatment-naive tumor specimens from 8 patients with advanced eCCA treated with durvalumab + cisplatin/gemcitabine. A total of 126 microregions were profiled with the GeoMx Digital Spatial Profiler and classified based on pan-CK and ACTA2/αSMA straining, as follow: tumor ($CK^+\alpha SMA^-$), distant and peritumor CAF-enriched stroma ($CK^-\alpha SMA^+$) or peritumor αSMA-negative stroma ($CK^-\alpha SMA^-$).

Results. αSMA staining revealed marked stromal heterogeneity across all eCCA, with some tumor nests surrounded by a dense CAF-enriched stroma and others by αSMA^- cells within the same sample. Based on CD45 staining all samples were classified as immune-desert or -excluded, with no intratumoral immune infiltration. GSEA showed a positive enrichment of epithelial-mesenchymal transition (EMT) signatures, coupled with the downregulation of immune activation and IFN response pathways, in both CAF-enriched regions and tumor cells surrounded by αSMA^+ cells. Interestingly, genes encoding matrix metalloproteinase 11 (MMP11) and secreted phosphoprotein 1 (SPP1) were found overrepresented in CAF-enriched regions adjacent to tumor nests, as compared to distant CAF regions, suggesting CAF as major source of stromal MMP11 and SPP1. Finally, receptor-ligand interaction modeling performed using the CellChat tool showed that CAF-enriched regions exhibited significant interactions with adjacent tumor cells, throughout the secretion of factors involved in EMT-remodeling, tumor progression and immunosuppression (i.e., POSTN, HGF, WNT5A, TGFB1, INHBA, SPP1).

Conclusions. Our findings suggest that $MMP11^+SPP1^+$ CAF may promote desmoplastic barrier formation in eCCA, thereby hindering intratumoral recruitment of immune cells and limiting CIT efficacy. Ongoing analyses aim to further characterize CAF states and CAF-tumor crosstalk to support the development of strategies to enhance CIT responsiveness in eCCA.

#6047 CTHRC1-TGFb crosstalk between myofibroblasts and tumors drives invasion in early-stage lung adenocarcinoma.

Abhilasha Sinha, SEUNGYEUL YOO, Nanzeeba Faraby, Thinh Nguyen, Hideo Watanabe, Alexander Tsankov, Jun Zhu, Charles A. Powell

Icahn School of Medicine at Mount Sinai, New York, NY

Background Despite significant improvements in lung cancer detection, lung cancer remains leading cause of cancer related deaths in both men and women in United States. This is due to high heterogeneity in tumor microenvironment (TME). Cancer associated Fibroblasts (CAFs) are essential components of TME and are associated with tumor progression. Recently, single-cell RNA profiling of LUAD tumors has identified heterogenous CAF subpopulations. However, their role in early-stage tumor invasion is largely unclear.
Methods We performed unsupervised clustering of 53 esLUAD tumors and examined their association with invasiveness. We investigated enrichment of pro-invasive and indolent signatures and key drivers of the invasive subnetworks (Sinha and Yoo 2022) in different cell populations from 3 LUAD scRNA seq datasets and spatial gene expression dataset from Kras/TP53 (KP) tumors. We co-cultured conditioned media (CM) from human lung fibroblasts (HLF) and LUAD cells (HCC78 and HCC2209) and used techniques such as immunofluorescence, ELISA, co-culture migration/invasion assay, neutralization assays and bulk RNA sequencing to investigate crosstalk between cancer cells and myofibroblasts.
Results Unsupervised clustering of 53 esLUAD tumors identified four groups (G1-G4), capturing a linear progression of invasiveness which correlated with their histology. Key drivers of COL1A2 subnetwork, COL1A1 and CTHRC1, were significantly upregulated in G2 (LPA) vs G1 (AIS/MIA), indicating early ECM activation. Invasiveness programs were localized to tS2 tumor cells and myofibroblast subsets. Within fibroblasts, CTHRC1+ CAFs exhibited higher COL1A2 subnetwork scores than CTHRC1- CAFs and normal fibroblasts in all 3 LUAD scRNA seq datasets. Spatial analysis of KP tumors displayed focal Cthrc1 and high pro-invasion/COL1A2 programs in Tgfbr2-KO. Our in vitro data revealed that exposure to LUAD cells CM transforms fibroblasts into myofibroblasts leading to elevated CTHRC1 secretion. The CM from myofibroblasts induced significant increase in migration and invasion phenotype in LUAD cells, which was attenuated on blocking TGFb signaling. Our RNA seq data revealed that exposure to CM from
myofibroblasts induces EMT signature in LUAD cells. Additionally, exposure to recombinant CTHRC1 to HCC78 LUAD induced increased migration and invasion phenotype and enrichment of Wnt/b-Catenin signaling.
Conclusion Taken together, our data indicates that Tgfb-CTHRC1 crosstalk between LUAD tumors and myofibroblast plays important role in development of invasive features in esLUAD tumors. This data suggests the clinical importance of myofibroblast in LUAD invasiveness and potential value of CTHRC1 as target for combination therapy for invasive esLUAD tumors.

#6048 CAF-secreted periostin promotes tumor aggressiveness in BRAF-mutant papillary thyroid carcinoma by upregulating MMP1.

ZHUORAN LIU, JINYUE LIU, JIE KUANG, WEIHUA QIU

Rujin Hospital, SHANGHAI, China

Papillary thyroid carcinoma (PTC) harboring the *BRAF* V600E mutation sometimes demonstrates higher invasiveness and an increased risk of metastasis; however, the underlying mechanisms are not fully elucidated. Cancer-associated fibroblasts (CAFs) are key components of the tumor microenvironment. This study aims to investigate the role and molecular mechanisms of CAFs in promoting invasiveness in *BRAF*-mutant PTC. Bioinformatic analysis suggested that high expression of the stromal protein periostin (*POSTN*) is associated with poor prognosis in *BRAF* V600E-mutant PTC. We demonstrated that the *BRAF* mutation, via activating the MAPK signaling pathway, promotes the secretion of IL-1β by PTC cells, which stimulates CAFs to express *POSTN*. Functional assays further revealed that CAF-secreted *POSTN* significantly enhances the migration and invasion capabilities of PTC cells by upregulating matrix metalloproteinase-1 (MMP1). Animal experiments further confirmed that the combination of a *BRAF* inhibitor (encorafenib) with knockdown of *POSTN* in CAFs most effectively suppressed lung metastasis of PTC and prolonged mouse survival. This study uncovers a novel signaling axi—*BRAF* mutation/IL-1β/CAFs/*POSTN*/*MMP1*—that plays a critical role in enhancing the aggressiveness of PTC. Thus, a combined therapeutic strategy targeting *BRAF* and inhibiting CAF-secreted *POSTN* represents a promising strategy to improve the prognosis of aggressive *BRAF*-mutant PTC.

#6049 Cartilage oligomeric matrix protein, cancer-associated fibroblast phenotypes, and versican proteolysis modulate CD8+ T cell infiltration in colorectal cancer.

Cadence E. Brown[1], Ruchi Shah[1], Cindy Wuerz[1], Isoline M. Donohue[1], Katherine A. Johnson[1], Cheri Pasch[1], Dustin A. Deming[2]

[1]Univ. of Wisconsin Madison Sch. of Med. & Public Health, Madison, WI,[2]University of Wisconsin Carbone Cancer Center, Madison, WI

Background: Cytotoxic T cell infiltration in colorectal cancers (CRCs) is critical for immunotherapy response and is regulated by various tumor microenvironment (TME) factors. Cartilage oligomeric matrix protein (COMP), a large pentameric glycoprotein involved in extracellular matrix (ECM) organization and stability, has been implicated in elevated fibrosis and immunomodulation in CRC. Likewise, myofibroblastic and inflammatory cancer-associated fibroblasts (myCAFs and iCAFs) regulate ECM remodeling and immunomodulation in the TME. Versican (VCAN) and its proteolysis product, versikine (Vkine) also impact CD8+ T cell infiltration. Here, we evaluate the impact of COMP on CD8+ Tumor-infiltrating lymphocyte (TIL) abundance alone and in combination with CAF phenotypes and VCAN proteolysis status.

Methods: Immunohistochemistry was performed on CRC samples from 243 patients to evaluate COMP, myCAF, αSMA, TAGLN, PDPN, ICAM1, CD8, VCAN, and Vkine. CD8+ TILs were quantified per high-power field (HPF). COMP was scored from 0-3 based on staining abundance and intensity in the cancer epithelium, CAFs, immune cells, ECM, and the total stromal compartment. All other stains were scored from 0-3 based on stromal abundance and intensity. αSMA and TAGLN scores were averaged to calculate a myCAF score, and PDPN and ICAM1 were averaged to calculate an iCAF score. CAF and VCAN status was assigned as per previous.

Results: Abundant COMP was observed in the cancer epithelium (80%), CAFs (77%), immune cells (76%), ECM (36.2%), and stroma overall (64%). High stromal COMP expression is more prevalent in myCAF high cancers (25%) relative to iCAF high (8%) cancers. High stromal COMP expression is more prevalent in VCAN proteolytic weak (VPW, percent of samples 41%) vs VCAN/Vkine low (VVL, 15%) and VCAN proteolytic predominant (VPP, 19%) cancers. CD8+ TIL abundance increased with COMP expression across all compartments. A trend of higher CD8+ TIL abundance in stromal COMP high cancers relative to stromal COMP low cancers for iCAF high was observed (mean CD8+ TILs/HPF in COMP low cancers 8, COMP high cancers 10), while myCAF high cancers were comparable (5, 5). Interestingly, CD8+ TIL abundance was significantly higher in iCAF high cancers with high CAF COMP expression vs low CAF COMP (high CAF COMP mean CD8+ TILs/HPF 12, low CAF COMP 3, p=0.0488), though myCAF high cancers exhibit the opposite trend. CD8+ TIL abundance was also higher in stromal COMP high VPP cancers and VVL cancers vs VPW cancers (mean CD8+ TILs/HPF 19, 8 vs 4, respectively, p=1.398e-05).

Conclusion: COMP is abundant in the CRC TME and can vary with other TME features. The presence of COMP correlates with enhanced CD8+ T cell infiltration in the setting of a pro-inflammatory TME, including VPP and iCAF high cancers. Mechanistic studies are needed to evaluate how COMP may enhance T cell infiltration.

#6051 Pancreatic tumor expressed growth factors activate a neural-like program in human fibroblasts which is associated with poor prognosis.

Myriam Iliana Ibanez Rios, Maelle Batardiere, Alexandre Archambault-Marsan, Elham Dianati Ajibisheh, Vincent Quoc-Huy Trinh, David J.H F. Knapp

Institute for Research in Immunology and Cancer (IRIC), Montreal, QC, Canada

Pancreatic ductal adenocarcinoma (PDAC) is one of the most aggressive cancers, with a 5-year survival of less than 14%. The tumor microenvironment (TME) plays a central role in PDAC progression and is composed primarily of cancer-associated fibroblasts (CAFs), together with smaller populations of tumor, nerve, and immune cells. Recently, a population of stromal cells exhibiting a neural-like program has been identified within the PDAC TME, and its presence correlates with poor outcomes and chemoresistance. However, the origin of these neural-like cells and their role in tumor progression remain unclear. In a related project using Xenium spatial transcriptomics, we found that some CAFs express this neural-like program and often cluster near tumor cells. Based on this, we hypothesized that this program can be activated in CAFs through exposure to growth factors secreted by PDAC cells.To validate our Xenium findings, we performed cyclic immunofluorescence on 32 macrodissected PDAC samples across disease stages, staining for tumor, fibroblast, and neural markers. These analyses showed that a subset of CAFs expresses a neural-like program. Unbiased clustering further demonstrated that higher densities of neural-program-activated CAFs, as well as their closer proximity to tumor cells, are associated with disease progression. Next, we investigated in vitro the relationship between tumor cells and the neural-like program in human cell line fibroblasts. When co-cultured with PDAC cells, fibroblasts promoted tumor growth and activated neural markers even without added growth factors, indicating that tumor cells can drive this reprogramming. After gemcitabine treatment, neural-program-activated fibroblasts survived better than normal fibroblasts, while tumor cells remained sensitive. This suggests that the neural-like program enhances fibroblast survival rather than directly promoting tumor chemoresistance, potentially supporting the proliferation of residual tumor cells, although this requires further validation.Finally, we aimed to identify the mechanisms underlying neural-like program activation. Xenium data highlighted several neural-associated growth factors as candidates. Exposing human fibroblast cell lines to combinations of these factors showed that two of them were sufficient to induce neural markers. Re-analysis of mass cytometry data identified the downstream signaling pathways involved, and the use of inhibitors confirmed these findings.Overall, our work shows that PDAC cells can activate a neural-like program in fibroblasts through growth factor-mediated signaling and implicates this plasticity as a contributor to tumor progression and treatment resistance. Further dissecting this process could reveal new intervention points to limit CAF support for the tumor and enhance chemotherapy effectiveness in PDAC.

#6055 Targeting CEP55 as a universal oncogenic dependency: Integrating spatial multi-omics and targeted therapy across translational preclinical cancer models.

Behnam Rashidieh[1], Pirjo Apaja[2], Quan Nguyen[3], Nigel McMillan[4], Kum Kum Khanna[1]

[1]Mater Research, University of Queensland, Brisbane, Australia,[2]SAHMRI, University of Adelaide, Adelaide, Australia,[3]QIMR Berghofer Medical Research Institute, Brisbane, Australia,[4]Griffith University, Gold Coast, Australia

CEP55 is an emerging oncogenic driver that is overexpressed across diverse cancers. It promotes genomic instability, and hyperactivates PI3K/AKT signaling, contributing to aggressive, metastatic, and therapy-resistant cancers. However, the mechanistic basis of CEP55-driven tumor progression and its potential as a therapeutic target have remained unresolved. To dissect Cep55 function across the evolutionary trajectory of transformation, we developed a hierarchical mouse embryonic fibroblast (MEF) cell lines encompassing primary (non-malignant), SV40-immortalised (early-transformation), and E1A/Ras-transformed (fully oncogenic) states with Cep55 deletion. This unbiased platform enabled stage-specific mapping of CEP55-controlled pathways. In parallel, we generated an inducible Cep55 KO mouse and interrogated CEP55 dependency *in vivo* using PTEN-deficient Cre^{ERT2} system and $KRAS^{LSL\text{-}G12D}$; $TP53^{fl/fl}$ (KP) lung adenocarcinoma GEMMs. We integrated quantitative proteomics, spatial transcriptomics, histopathology, and functional assays, with additional validation using human cancer datasets. Finally, to overcome the “undruggable” nature of CEP55, we deployed a CEP55-targeted antisense oligonucleotide encapsulated in tumor- antigen targeted lipid nanoparticles (ASO-LNP). Inducible Cep55 deletion was well tolerated in adult tissues, indicating Cep55 is non-essential for adult homeostasis but critical for tumorigenesis. Cep55 loss profoundly impaired oncogenic traits most strikingly in E1A/Ras MEFs, reducing proliferation, adhesion, migration, and invasion. In vivo, Cep55 ablation delayed tumor onset and progression, and significantly extended survival in both PTEN-deficient and KP GEMMs. Spatial transcriptomics revealed extensive CEP55-dependent remodeling of the tumor microenvironment, including disrupted extracellular matrix architecture, altered collagen networks, impaired integrin expression and trafficking, and collapse of focal-adhesion-PI3K/AKT-ERK signaling axes. Stress-response and anti-proliferative pathways were concomitantly activated. Proof-of-concept therapeutic studies showed that CEP55-targeting ASO-LNP suppressed tumor growth in vitro, providing a foundation for optimization and evaluation of CEP55 inhibition using precision RNA-based therapies in preclinical models. CEP55 is a fundamental oncogenic dependency that coordinates ECM remodeling, integrin signaling, and multiple oncogenic pathway activation during tumor initiation and progression. Its genetic ablation suppresses transformation, delays tumor growth, and prolongs survival across multiple cancer models. Together, these findings validate CEP55 as a compelling therapeutic target and establish ASO-LNP delivery as a promising strategy for targeting this previously undruggable node.

#6056 The KSHV genome, devoid of the essential immediate early transactivator RTAORF50, induces angiosarcoma in transgenic mice.

Dirk P. Dittmer, Kyle Shifflett, Eason B. Anthony, Su Huanjuan, Zhigang Zhang, Blossom Damania

Lineberger Comprehensive Cancer Center, University of North Carolina at Chapel Hill, Chapel Hill, NC

Kaposi Sarcoma-associated herpesvirus (KSHV) extensively alters host cell signaling to induce a variety of malignant and premalignant phenotypes, including Kaposi sarcoma (KS). The mechanisms by which KSHV initially induces KS remain unclear due to a lack of animal models, as the human pathogen KSHV does not productively infect rodents or non-human primates. Our lab has recently developed a small-animal model of KS by integrating the entire 160-kb KSHV viral genome into the germline of mice, thereby circumventing rodent barriers to viral replication. KSHV transgenic mice develop a murine angiosarcoma indistinguishable from human KS by histology and transcriptional profile; however, deletion of the viral miRNA locus was required for the transgene founder animals to produce offspring. This yielded the FVBNJ-Tg(HHV8)197DtmrMmnc line (Cell Host Microbe. 2024 32(5):755-767). We have now generated another KSHV transgenic mouse line that carries all viral miRNAs but lacks the immediate-early transactivator RTA/ORF50, which is necessary and sufficient to induce lytic gene transcription. Without RTA/ORF50, the viral miRNAs are compatible with embryonic development. The intact transgene is transmitted in Mendelian fashion, and homozygous animals are viable. The Tg(HHV8dRta) mice have significantly higher overall survival but still develop angiosarcoma. The dispensability of RTA for murine KS has significant implications for the role of viral replication in KSHV oncogenesis. Pending further studies, we hypothesize that RTA-dependent genes are not required for tumor formation. Alternatively, transcripts that are classified as strictly lytic in other herpesviruses may have alternative modes of regulation in KSHV. Tumor cell lines derived from HHV8dRta murine KS tumors grow indefinitely in culture, providing a powerful new tool for KSHV research. A detailed comparison of tumor biology in KSHV transgenic mice with or without the essential immediate early transactivator will be presented.

#6057 The IKZF1 N159Y partial tandem duplication mutant drives chromatin remodeling, B-cell developmental defects and leukemia initiation.

Ruth W. Wang'ondu, Devanand Bondage, Qiong Zhang, Yiming Wu, Baranda Hansen, Chun Shik Park, Prady Baviskar, Emily Backhaus-Wagner, Ilaria Iacobucci, Surbhi Sona, Huiyun Wu, Qingsong Gao, Wojciech Rosikiewicz, Beisi Xu, Hongjian Jin, Ti-Cheng Chang, Stanley Pounds, Laura Janke, Trevor Cunningham, Kristine R. Crews, Jun J. Yang, Shondra Pruett-Miller, Charles G. Mullighan

St. Jude Children's Research Hospital, Memphis, TN

IKZF1 N159Y, present as a partial tandem duplication (hereafter N159Y), defines a distinct subtype of B-cell precursor acute lymphoblastic leukemia (B-ALL). The mechanistic basis of leukemogenesis of this mutation, in contrast to diverse IKZF1 alterations present across the spectrum of B-ALL, is unknown. Here we elucidate mechanisms of N159Y. We generated cell lines with heterozygous or hemizygous N159Y expression. Motif enrichment, luciferase assays, and AlphaFold3 modeling were used to evaluate altered DNA interactions. Inducible knock-in mouse models and in vitro colony-forming assays assessed developmental and self-renewal phenotypes. Cell fitness and cytotoxicity assays assessed epigenetic dependency. N159Y leukemia cells displayed a characteristic gene expression signature with activation of non-B lineage pathways and repression of B-cell identity genes. N159Y bound both canonical IKZF1 motifs and neomorphic bHLH motifs. Downregulated genes were associated with super-enhancer-linked B-cell developmental regulators. ChromHMM revealed gain of active and poised enhancers driven by N159Y. In IKZF1-null NALM6 cells, N159Y bound more sites than WT. In 293T cells, N159Y repressed the ETS motif-containing MCL1 promoter. N159Y leukemia cells showed dependency on *EP300* and *CREBBP*, and sensitivity to A-485, JQ1, and vorinostat. In mouse models, N159Y caused a marked reduction of mature B cells with expansion of aberrant B-cell precursors, and was associated with leukemia development, while also conferring abnormal self-renewal capacity in vitro. We show that N159Y is a chromatin-remodeling transcription factor mutant with neomorphic chromatin-binding. It disrupts B cell development and induces B-ALL.

#6058 Tumor suppressor gene inactivation shapes the landscape of EGFR-mutant lung adenocarcinoma progression with therapeutic implications.

Mariana Do Carmo[1], Matthew Martin[2], Michael Rosen[3], Lily Blair[3], Anna Tribe[2], Keita Maemura[1], Giorgia Foggetti[4], Francisco Exposito[1], Zeynep Ugur[1], Lafia Sebastian[3], Vy Tran[3], Ian Lai[3], Alyna Katti[3], Ian Winters[3], Dmitri A. Petrov[5], Nicolas Floc'h[2], Monte M. Winslow[6], Katerina A. Politi[7]

[1]Yale School of Medicine, New Haven, CT,[2]Bioscience, Oncology R&D, AstraZeneca, Cambridge, United Kingdom,[3]D2G Oncology, Mountain View, CA,[4]Comprehensive Cancer Center, IRCCS San Raffaele Scientific Institute, Milan, Italy; Vita-Salute San Raffaele University, Milan, Italy, Milan, Italy,[5]Department of Biology, Stanford University, Stanford, CA,[6]Asst. Professor, Dept. of Genetics, Stanford University School of Medicine, Stanford, CA,[7]Yale Cancer Center, New Haven, CT

Oncogenic alterations in exons encoding the kinase domain of the Epidermal Growth Factor Receptor (e.g. EGFR L858R mutations) occur frequently in lung adenocarcinomas (LUADs) and promote tumor growth. EGFR tyrosine kinase inhibitors (TKIs), like osimertinib, have greatly improved lung cancer outcomes, yet EGFR TKI resistance remains inevitable. In addition to mutations in oncogenes, co-occurring genomic alterations in tumor suppressor genes (TSGs) have emerged as core determinants of LUAD tumor fitness and therapeutic response. Moreover, recent work suggests that the oncogenic driver dictates the effect of putative TSG inactivation on the fitness landscape of tumorigenesis. To study the effects of co-occurring TSG mutations *in vivo*, we leveraged autochthonous, immunocompetent genetically engineered mouse models (GEMMs) of EGFR L858R-driven LUAD, in *Trp53* proficient and deficient settings, carrying a conditional *Cas9* allele for CRISPR-Cas9 genome editing. We investigated the effect of inactivation of 58 putative TSGs on EGFR-driven LUAD tumor growth, tumor initiation, and osimertinib sensitivity. In parallel, we also induced tumors using the same lentiviral pool in models of Kras G12D, Kras G12D;*p53*-deficient, and Kras G12C-driven LUADs. In mutant EGFR-driven tumors, we identified genes that when inactivated: (i) promote tumor growth, (ii) suppress tumor growth, and (iii) reduce sensitivity to osimertinib. Inactivation of *Tsc1* or *Tsc2*, negative regulators of mTOR-complex signaling, and the ubiquitin ligase associated genes *Cul3* and *Rnf43* significantly promoted tumor growth in addition to *Apc*, *Rbm10*, *Rb1* described in a prior screen. Surprisingly, we also identified a set of genes, enriched in chromatin modifiers, that decreased tumor fitness in mutant EGFR-driven LUADs, including *Crebbp* and *Smarca4*. Conversely, loss of these same genes did not affect the growth of Kras G12C and G12D-driven tumors, suggesting that fitness effects of gene inactivation can vary across oncogenic contexts, even within what is conventionally considered a linear signaling axis. Indeed, loss of *Setd2*, *Kmt2d*, *Ep300*, and *Stk11* all had significant detrimental effects on tumor growth in an EGFR context but had significant effects promoting tumor growth in a Kras G12C context. Through this screen we also identified genes that when inactivated contribute to reduced osimertinib sensitivity in mutant EGFR-driven tumors including *Nf1*, *Kmt2d*, and *Pten* in *Trp53* proficient and deficient settings, whereas loss of *Nf2* and *Kdm6a* only reduced sensitivity in a *Trp53* deficient setting. These results inform the biology of tumor growth and reveal new genetic interactions in EGFR-driven LUADs with therapeutic implications.

#6059 Vertical MAPK pathway targeting is required for tumor regression in novel human and mouse models of NF1-inactivated melanoma.

Olvania-Danyca Hilaire[1], Alexis M. Jones[1], Moriah H. Nissan[1], Sebastien Monette[1], Jordan Eichholz[1], Cailian Liu[1], Xia Yang[1], Ayana Sawai-Frantz[1], Elisa de Stanchina[1], Taha Merghoub[2], Neal Rosen[1], David B. Solit[1], Aphrothiti J. Hanrahan[1]

[1]Memorial Sloan Kettering Cancer Center, New York, NY,[2]Weill Cornell Medicine, New York, NY

Inactivating, oncogenic alterations in the tumor suppressor neurofibromin 1 (*NF1*), a RAS-GTPase, have been identified in approximately 4% of all cancers and in a significant subset of melanomas, nerve sheath tumors, and gliomas. While the MEK inhibitor selumetinib has been FDA approved for pediatric patients with Neurofibromatosis type 1 with benign plexiform neurofibromas arising from germline *NF1* mutation, MEK inhibitors and other therapies targeting the MAPK pathway have had limited clinical benefit in patients with tumors driven by *NF1*-inactivation. In melanoma, inactivation of *NF1* is insufficient to induce tumorigenesis. Sequencing data from 1,912 melanoma tumor/normal pairs generated as part of MSK-IMPACT identified oncogenic mutations in *TP53* as the most significant event common to *NF1*-inactivated melanoma, with oncogenic *BRAF* mutations frequently co-occurrent. Given the lack of models for studying NF1 loss, a cohort of genetically engineered mice were generated with melanocyte-restricted conditional loss of $Nf1^{fl/fl}$ and/or $Trp53^{fl/fl}$, and/or conditional gain of oncogenic BRAF V600E ($Braf^{CA}$). Combined *Nf1/Trp53* knockout induced hyperpigmentation and melanoma formation with features common to the human disease including pigmented melanocytic and amelanotic spindle-shaped neoplasms and S100-positive staining in most. Other genetic cohorts developed were $Braf^{CA}/Nf1^{fl/fl}/Trp53^{fl/fl}$ and $Braf^{CA}/Trp53^{fl/fl}$ (faster onset, high penetrance) and $Braf^{CA}/Nf1^{fl/fl}$ (latent onset, lower penetrance) mice. To facilitate preclinical and functional studies, 22 mouse tumor-derived, syngeneic, immunogenic cell lines were generated. As anticipated, loss of *Nf1* conditioned the response to treatment with a BRAF monomer inhibitor (vemurafenib). While *Nf1*-inactivated cells were more sensitive to MEK inhibition (trametinib), or combined BRAF/MEK inhibition, as seen by suppression of ERK phosphorylation (pERK), cyclin D1 and DUSP6 expression, and cell proliferation, levels of pERK quickly rebounded. BRAF V600E/NF1/TP53-mutant cells were also transiently sensitive to combined inhibition of BRAF and the positive RAS adaptor SHP2 (using SHP099); with the rebound of pERK mitigated only by MEK, not upstream BRAF/SHP2, inhibition. In mice with established $Braf^{CA}/Nf1/Trp53$-null tumors as well as in a genetically similar PDX of human melanoma (SK-MEL-1273A), combination strategies such as the triple regimen of RAF/MEK/SHP2 inhibitors induced more durable suppression of pERK and tumor regression. Studies evaluating vertical MAPK targeting strategies that include direct inhibition of RAS or inhibition of parallel survival pathways are ongoing in this molecularly defined cohort.

#6060 Patient-derived models of primary breast cancer for preclinical evaluation of neoadjuvant therapies.

Stefan J. Hutten[1], Xue Chao[1], Madelon Badoux[1], Timo Eijkman[1], Michael Sheinman[2], Roebi de Bruijn[1], Andrea Herencia-Ropero[3], Alba Llop-Guevara[3], Catrin Lutz[1], Jelle Wesseling[1], Violeta Serra[3], Jacco Van Rheenen[1], Colinda LGJ Scheele[4], Jos Jonkers[1]

[1]Netherlands Cancer Institute, Amsterdam, Netherlands,[2]Weizmann Institute of Science, Tel Aviv, Israel,[3]Vall D'Hebron Institute of Oncology, Barcelona, Spain,[4]VIB-KU Leuven Center for Cancer Biology, Leuven, Belgium

Targeted therapies are important for invasive breast cancer (IBC) treatment but are generally not standard-of-care in the neoadjuvant setting. To identify therapies with the potential to improve neoadjuvant treatment response, it is essential to develop patient-derived preclinical models that faithfully reflect the diversity of primary IBC subtypes in patients. Here, we collected data of all breast cancer patients (N=1675) diagnosed in the Antoni van Leeuwenhoek hospital (AVL) for a period of three years, while simultaneously receiving tissue samples of 314 patients to establish a collection of mouse-intraductal patient-derived xenograft (MIND-PDX) models fully recapitulating the heterogeneity of primary IBC. Serial transplantation of lesions resulted in the first large-scale cohort of 60 transplantable IBC-MIND models, comprising 31 luminal (i.e., ER+/HER-), 5 HER2+ and 24 TN models, as well as 7 matching PDX organoid (PDXO) models. We show that our IBC-MIND cohort can serve as a platform for preclinical evaluation of experimental neoadjuvant treatments. For triple-negative IBC, we demonstrate that neoadjuvant treatment does not benefit from addition of a PARP inhibitor, while for estrogen receptor (ER) positive IBC the combination of a CDK4/6 inhibitor and fulvestrant improves neoadjuvant treatment response. Our work provides a valuable resource of primary IBC models to study breast cancer biology and develop novel neoadjuvant treatments.

#6061 Development of pancreatic and colon patient-derived xenograft (PDX) tumor microarrays (TMAs) from the NCI patient derived models repository.

Cindy R. Timme[1], Lindsay Dutko[2], Sayak Ghatak[2], Ting-Chia Chang[2], Alice P. Chen[3], Li Chen[2], Biswajit Das[2], Tara Grinnage-Pulley[3], Shahanawaz Jiwani[2], Kaci Paulus[2], Chris A. Karlovich[2], Sergio Alcoser[3], Yvonne Evrard[1], Melinda G. Hollinghead[3], James H. Doroshow[4]

[1]Frederick National Laboratory for Cancer Research, Advanced Development Research Directorate, Leidos Biomedical Research, Inc., Frederick, MD,[2]Molecular Characterization Laboratory, Frederick National Laboratory for Cancer Research, Leidos Biomedical Research, Inc., Frederick, MD,[3]Biological Testing Branch, Developmental Therapeutics Program, National Cancer Institute at Frederick, Frederick, MD,[4]Division of Cancer Treatment and Diagnosis, National Cancer Institute, NIH, Bethesda, MD

The National Cancer Institute's Patient Derived Models Repository (NCI PDMR; https://pdmr.cancer.gov) has developed a national repository of Patient-Derived Models (PDMs) currently comprised of over 1000 patient-derived xenograft (PDX), 450 organoid (PDOrg), 500 tumor cell culture (PDC), and 425 cancer associated fibroblast (CAF) models. Over 450 PDXs have matched PDOrg and/or PDCs allowing for complimentary/parallel in vivo/in vitro studies. These PDMs are clinically annotated with molecular information available in a public database for the extramural community with additional molecular features including OncoKB annotated mutations, microsatellite instability (MSI), human leukocyte antigen (HLA) typing, and clinically relevant fusions. Researchers can use these clinical and molecular features or perform their own independent analyses using the public data to aid in their selection of preclinical models. Due to the large number of NCI PDMR models within histologies and research community interest, we have developed histology-based PDX TMAs to further facilitate the selection of models for cancer research. Each TMA panel includes up to 60 unique PDX models, with two 1.5mm cores/model plus murine control tissue. Quality control (QC) assessment of the TMA cores is performed by a pathologist. Each core is reviewed with an initial pass/fail threshold set to ≥10% human tumor/core area with ≥500 tumor cells. TMA slides pass QC if they meet these criteria and ≥75% of the models have at least one passing core. TMA blocks are QC'd at regularly set intervals to ensure all distributable slides meet these requirements. The first PDX TMA panel available for distribution this year (PANC I) contains 60 pancreatic cancer PDXs (predominantly pancreatic adenocarcinoma [PAAD]) derived from primary and metastatic lesions from treatment naïve through heavily pretreated patients. *KRAS* mutated models include 28 G12D, 15 G12V, 10 G12R, 3 G12C, 1 Q61H, and 3 *KRAS* wildtype. Other genes frequently mutated in pancreatic cancer are also found in this cohort including *TP53*, *SMAD4*, and *CDKN2A*. Also in development are four colorectal cancer TMAs panels: (1) a general set of colon adenocarcinomas (COAD) with features including early onset, non-European ancestry, and MSI-High; (2) *KRAS* mutated COAD; (3) Treatment naïve COAD and wildtype *APC* COAD; and (4) Rectal adenocarcinoma models. These TMAs can be used to stratify models by therapeutic target, develop predictive markers or classify differential signaling in disease subtypes, integrative analysis of genomic and protein expression, and discover or validate biomarkers of disease in an efficient and cost-effective way. Targeted model selection is of high importance to better understand the biology of these cancers and improve preclinical drug testing and screening design to translate novel therapeutics from bench to clinic.

#6062 The role of sex hormones and sex chromosomes in urethane-induced lung carcinogenesis.

Maksat Babayev[1], Carolyn D. Ekpruke[1], Omar Borges Sosa[1], Shikha Sharma[2], Dustin Rousselle[1], Chukwudike Igwe[1], Patricia Silveyra[1]

[1]Environmental & Occupational Health, Indiana University, Bloomington, IN,[2]Forensic Science, University of New Haven, Bloomington, IN

Lung cancer is the leading cause of cancer-related deaths worldwide and remains among the top ten causes of mortality in the United States. Non-small cell lung cancer (NSCLC) constitutes approximately 85% of all lung cancer cases, with lung adenocarcinoma (LUAD) being the most prevalent subtype. Intriguingly, sex differences in lung cancer incidence and mortality have been observed, particularly among non-smokers, where LUAD is more common in females. Understanding the sex-specific mechanisms underlying LUAD progression is critical for developing targeted therapeutic strategies. In this study, we used the “four core genotypes” (FCG) ArnoJ (C57BL/6J background) mice in which gonadal sex is decoupled from the sex chromosome complement. We applied urethane-induced lung cancer protocol (a well-established mimic of human LUAD), to investigate the roles of gonadal hormones and sex chromosomes in lung tumor progression. Mice of 6-8 weeks of age received urethane (1 g/kg body mass, weekly for 10 weeks) or the same volume of PBS (control) injections and were evaluated after a 20-week tumorigenesis period. We assessed cytological changes in bronchoalveolar lavage fluid (BALF), changes in mice body weights, histological/immunohistochemical (IHC) analysis in fixed lung tissue. All animals experienced increased BALF total counts and weight loss after urethane treatment (vs. control). When comparing animals of different genotypes, we found that the XXM (female chromosomes, male gonads) displayed the most prominent weight reduction between urethane and control groups. When combining mice with the same chromosomes treated with urethane vs. PBS, animals with XX composition displayed a greater difference in weight than those with XY chromosomes. In contrast, when comparing animals with the same gonads, mice with male gonads showed a stronger effect in weight reduction than those with female gonads. Overall, BALF from urethane-treated mice had higher total cell counts than PBS-treated mice. Differences across genotypes were also noted. Our preliminary analysis indicates that mice with female gonads experienced a more prominent increase in cell counts than mice with male gonads. No apparent differences were noted when comparing animals with XX or XY chromosomes. The IHC analysis with anti-Ras (Q61R) antibody (Abcam) revealed that sex hormones have a statistically significant ($p=0.00178$) effect on mutated RAS (Q61R) levels independent of genotype. The IHC analysis on cell proliferation rate (Ki-67, CST) did not reveal significant differences between groups. In conclusion, our preliminary analysis of this pilot experiment revealed a potential contribution of sex hormones and sex chromosomes to urethane-induced weight loss and BALF counts. Further analysis of histological and molecular markers in these mice will reveal additional information that could help us understand sex-specific mechanisms of carcinogenesis.

#6063 MICAL2 promotes oncogenic *Kras*-induced pancreatic cancer initiation by regulating acinar to ductal metaplasia.

Nirakar Rajbhandari, Evangeline Mose, Mojgan Hosseini, Deepa Sheik Pran Babu, Herve Tiriac, Andrew Lowy

UC San Diego, La Jolla, CA

Background: Pancreatic ductal adenocarcinoma (PDAC) is a deadly form of pancreatic cancer with the poorest 5-year survival rate among all solid cancers. Therefore, identifying effective therapeutic strategies is crucial for treating this disease. Using a genome-wide screening approach to find novel and targetable factors in human PDAC, we identified MICAL2 (microtubule-associated monooxygenase, calponin, and LIM domain containing 2) as a gene uniquely enriched in PDAC patients. Our research has shown that MICAL2 is highly expressed in human PDAC and is linked to a worse prognosis for patients. Additionally, tumor growth and distant metastasis are reduced in PDAC tumors silenced for MICAL2. Although these findings establish MICAL2 as a key regulator in PDAC, its role in pancreatic cancer initiation and progression remains poorly understood.

Methods: We utilized a genetically engineered mouse model of early pancreatic tumorigenesis (LSL-Kras$^{G12D/+}$, Pdx1-Cre, i.e. KC), where we conditionally deleted the Mical2 gene (Mical2$^{flox/flox}$) specifically in the pancreas to understand the importance of MICAL2 (M) in the early tumor initiation. We performed comparative histological analysis and in vitro biochemical studies to identify early tumor lesions and understand the underlying differences in the wild-type (KC) and the Mical2-deficient KC (KCM) mice.

Results: Our preliminary studies indicate that deleting MICAL2 in a genetically engineered mouse model (GEMM) of pancreatic cancer functionally delays PDAC initiation and progression. Biochemical and histopathological analysis show that removing MICAL2 impairs oncogenic KRAS-induced acinar to ductal metaplasia (ADM), which involves a significant cytoskeletal rearrangement and is linked to PDAC initiation. Additionally, extensive biochemical studies, gene expression analyses, and immunostaining reveal a significant decrease in RAC1 and ARP2 expression, along with reduced EGFR and PI3K/AKT activity when MICAL2 is inhibited during KRAS-driven pancreatic duct neoplasia.

Conclusions: Our observations indicate that MICAL2 plays a crucial role downstream of oncogenic Kras during the early stages of pancreatic cancer initiation by regulating RAC1 and ARP2, as well as EGFR and PI3K/AKT activity, which are necessary for Kras-induced ADM. This suggests that inhibiting MICAL2 could be a viable target for prevention and therapeutic strategies in PDAC.

#6064 The *in vivo* impact of UBTF tandem duplications on hematopoiesis and leukemia development.

Lisett Contreras, Juan Martin Barajas, Tamara Westover, Melvin Thomas III, Emily Xiong, Catherine Callahan, Chandra Rolle, Masayuki Umeda, Michael Walsh, Jing Ma, Laura Janke, Jeffery Klco

St. Jude Children's Research Hospital, Memphis, TN

This study aims to investigate hematopoietic and leukemic development in a physiological UBTF-tandem duplication (TD) model to better understand the biology underlying this subtype-defining alteration of acute myeloid leukemia (AML). UBTF-TDs are characterized as somatic, heterozygous, in-frame tandem duplications (TDs) within exon 13 of *UBTF* (upstream binding transcription factor). These alterations are associated with an overall inferior outcome. We developed a conditional knock-in mouse in which Ubtf-TD is expressed from the endogenous *Ubtf* locus after recombination by Cre recombinase driven by the hematopoietic *Vav* promoter, recapitulating the somatic mutation observed in patients. We first assessed the self-renewal potential of hematopoietic stem progenitor cells (HSPCs) from 8-10-week mice using colony-forming unit (CFU) assays. To assess leukemic burden, we monitored peripheral blood using flow cytometry and complete blood cell count. The hematopoietic compartments (bone marrow and spleen) from mice that progressed to terminal disease were examined by RNA sequencing (RNA-Seq) to characterize the expression profiles. Tumors that developed were transplanted into sub-lethally irradiated recipient mice to assess their engraftment potential. To investigate hematopoietic development in Ubtf-TD mice, we performed a comprehensive cellular and molecular characterization using multiparameter flow cytometry. We then performed single-cell RNA-seq to examine pre-leukemic progression. Finally, to explore functional dependencies of murine Ubtf-TD tumor cells, we conducted *in vitro* CRISPR knockout (KO) screens of 210 genes prioritized from RNA-seq data, UBTF-TD cord-blood CD34 (cbCD34) functional studies, and key UBTF-TD AML genes. Murine HSPCs expressing Ubtf-TD exhibit increased self-renewal capacity both *in vitro* and *in vivo*. Ubtf-TD expression induces a myeloid leukemia by 45 weeks of age. Clinical features include elevated white blood cell counts, anemia, and splenomegaly. Phenotypically, these leukemias exhibit high levels of CD11b and Gr-1 expression, are serially transplantable, and have dysregulated *Hoxa/Hoxb* gene expression. Flow cytometry further reveals increases in the granulocyte-monocyte progenitor (GMP) and multipotent progenitor (MPP3) populations in Ubtf-TD mice. Dependency screens revealed that Ubtf-TD cells rely on *Xpo1*, *Men1, Kmt2a,* and *Meis1*. Collectively, our work demonstrates that UBTF-TD is sufficient to drive leukemia development *in vivo* and that this model recapitulates key phenotypes observed in UBTF-TD AMLs. This mouse model provides a platform for evaluating leukemia initiation, progression, and therapeutic vulnerabilities, including XPO1 inhibition (eltanexor) and Menin inhibition (revumenib), both of which have demonstrated efficacy in cbCD34 and patient-derived xenograft (PDX) UBTF-TD models.

#6065 Decoding KRAS signaling intensity: A key driver of tumor aggressiveness and response to RAS inhibition in pancreatic cancer.

Mehrnaz Salehi[1], Sara Raji[1], Mohammadreza Ranjouri[1], Fengming Chen[2], Ashley Fletcher[1], Peter J. Allen[3], **Zahra Kabiri**[1]

[1]Surgery, Duke University School of Medicine, Durham, NC,[2]Pathology, Duke University School of Medicine, Durham, NC,[3]Duke University School of Medicine, Durham, NC

Background: Pancreatic ductal adenocarcinoma (PDAC) is a highly aggressive malignancy, with KRAS mutations present in near 90% of cases, most frequently in codons 12 and 61. Increased KRAS copy number, resulting in elevated KRAS signaling intensity, correlates with poor prognosis and limited chemotherapy response. However, the role of KRAS signaling intensity in PDAC initiation, progression, and response to treatment remains unclear due to the lack of suitable *in vivo* models.

Methods: We developed a unique set of pancreatic cancer mouse models ranging from low to high levels of KRAS signaling by crossing the *Pdx1-CreER*$^{(+)}$/*Trp53*$^{(fl/fl)}$ mice with Cre-inducible *Kras*-LSL^{G12D} or *Kras*-LSL^{Q61R} alleles that either express these oncogenic alleles with native codons (low expression) or optimized codons (high expression). Tumor onset, progression, metastasis, and survival were systematically assessed. Additionally, 24 murine PDAC cell lines were established from these models, and eight human PDAC cell lines were classified into low- and high-intensity KRAS signaling groups to evaluate therapeutic response to the pan-RAS inhibitor RMC-6236.

Results: KRAS signaling intensity profoundly influences the timing of PDAC onset, disease progression, and metastatic potential. Mice with high, intermediate, and low KRAS signaling developed PDAC at approximately 4-5, 12-16, and 16-24 weeks of age, respectively. Survival analysis over a 52-week period revealed striking differences in overall survival, with median survival times of 8 weeks (high), 23 weeks (intermediate), and 41 weeks (low). Notably, the high-intensity group exhibited significantly higher rates of distant metastases to the lung and liver compared with the intermediate- and low-intensity groups. In vitro treatment suggested that cells with lower KRAS signaling intensity tended to be more sensitive to RMC-6236, highlighting its potential as a biomarker for patient stratification and therapeutic decision-making.

Conclusions: KRAS signaling intensity is a key determinant of PDAC initiation, progression, metastasis, and overall clinical outcomes. Moreover, it may serve as a predictive biomarker for response to RAS-targeted therapies. Collectively, these findings suggest that quantifying KRAS signaling intensity could enable precision medicine approaches and guide therapeutic decision-making in PDAC.Generative AI tools were used to assist with text editing and improvement of this abstract.

#6066 A model of spontaneous brain metastasis in small cell lung cancer undergoes epithelial-to-neuronal transition.

Shreoshi Pal Choudhuri[1], Thomas Salisbury[1], Mantre Dehnad[1], Bratati Mukherjee[1], Braeden Freitas[1], Kyle May[1], Seth Hamilton[1], Shruti Raghavan[1], Victor Stastny[1], Kimberley Avila[1], Jui Wan Loh[1], Urooba Nadeem[1], Luc Girard[1], Jeon Lee[1], Michael S. Lawrence[2], Genevieve Konopka[1], James Kim[1], Benjamin J. Drapkin[1]

[1]UT Southwestern Medical Center, Dallas, TX,[2]Broad Institute of Harvard and MIT, Cambridge, MA

Brain metastases (BrMs) occur in 40-60% of small cell lung cancer (SCLC) patients, causing significant morbidity and mortality. Although most patients present with extracranial metastases (EMs) at diagnosis, approximately two-thirds of BrMs arise after diagnosis and could be prevented by effective and tolerable therapies. However, SCLC models rarely form BrMs in mice, hindering translational research. We report patient-derived xenograft (PDX) models of SCLC that form recurrent, spontaneous, and symptomatic BrMs. By refining a surgical approach to generate solitary orthotopic primary (OP) tumors within the margins of the left lung parenchyma, six PDX models developed diffuse EMs within 8 weeks of OP detection by MRI. In a model harboring therapy-induced subclonal mutations, we confirmed that these EMs arose spontaneously from the left lung OP tumors, and further validated this finding with a lentiviral DNA barcode library. Model MGH1564-1A, derived from a relapsed SCLC patient shortly after the emergence of small BrMs, produced delayed ataxia and hydrocephalus in 70% of mice (median onset ~100 days). Whole brain sectioning of these mice consistently revealed BrMs up to 2 mm in diameter, whereas in mice without neurologic symptoms, BrMs were not detected. Intriguingly, when compare with the OP tumors, these spontaneous BrMs demonstrated an epithelial-to-neuronal transition (ENT) in global transcription that was confirmed by immunohistochemistry. This transition was absent from EMs within the same animals, suggesting that ENT is a BrM-specific adaptation. Two additional PDX models demonstrated recurrent BrMs, suggesting brain tropism as a property of some PDX models but not others. To our knowledge, these are the first models of human SCLC to reliably develop spontaneous BrMs that limit animal survival, providing a preclinical system for investigating the drivers of brain organotropism in SCLC and for evaluating anti-BrM therapies.

#6067 HPV+ and HPV- head and neck cancer patient-derived models in the NCI Patient-Derived Models Repository.

Yvonne A. [1]Frederick National Laboratory for Cancer Research, Frederick, MD,[2]Molecular Characterization Laboratory, Frederick National Laboratory for Cancer Research, Frederick, MD,[3]Division of Cancer Treatment and Diagnosis, National Cancer Institute, Bethesda, MD,[4]Biological Testing Branch, Developmental Therapeutics Program, National Cancer Institute-Frederick, Frederick, MD

Head and neck (HN) cancers are a rare set of cancers defined by their anatomical point of origin including mouth, sinus, throat, or nose. Human papilloma virus (HPV) infection plays a pathogenic role in HN cancers resulting in distinct clinical and molecular characteristics from those that are HPV-. The National Cancer Institute's Patient-Derived Models Repository (NCI PDMR; https://pdmr.cancer.gov) has developed a national repository of patient-derived models (PDMs) comprised of patient-derived xenografts (PDXs), organoids (PDOrg), tumor cell cultures (PDCs) and cancer associated fibroblasts (CAFs). These models are clinically annotated with molecular information available in a public database for the extramural community. To date, 361 patient HN tumor specimens have been received from 351 unique patients across a range of histologies including lip/oral, pharyngeal, laryngeal, salivary and sinonasal with an overall PDX take rate of 48% (322 assessable specimens). The NCI PDMR currently has 200 public HN PDX, PDOrg, and PDC models from 124 unique patients. Thirty-three models (PDX, PDOrg, PDC) from 20 unique patients are positive for HPV16 or 18 (one double positive) as detected by PCR and one sinonasal PDOrg model is positive for HPV33 identified in NextGenSeq data. As has been reported in the clinical literature, *TP53* and *CDKN2A* mutations are found predominantly in PDX models that are HPV- (84% and 65%, respectively) but not HPV+ (0%; 0%) and *PIK3CA* is more commonly mutated in HPV+ models (47% vs 25%). No significant difference in loss of heterozygosity is observed in the models. However, significant differences in chromosome arm copy number changes (copy gains in 7p, 11p and 12p and copy losses in 3p, 9p and 18q [P-value<0.05; Wilcoxon Rank-Sum test]) are observed in HPV- compared to HPV+ models. Gene set enrichment analysis (GSEA) suggest the E2F_TARGETS, G2M_CHECKPOINT, and DNA_REPAIR gene sets are significantly up-regulated in HPV+ while the APOPTOSIS gene set is significantly down-regulated using MSigDB Hallmark dataset (P-value<0.05). In all analyses, differences are consistent whether examining *in vivo* PDX models or *in vitro* PDC/PDOrg models indicating the fidelity of the models. These preclinical models recapitulate the molecular differences reported in HPV+ versus HPV- clinical cases providing an important tool for the development of novel therapeutics for HN cancers. Funded by NCI Contract No. HHSN261200800001E

#6068 The double-edged role of anti-inflammatory drugs in ovarian carcinosarcoma, in a *Trp53;Brca2;Pten* genetically engineered mouse model.

Einav Bangiev Girsh[1], Roba Gabesh[1], Eden Gal[1], Amir Basis[1], Sharona Tornovsky-Babeay[2], Gwo Yaw Ho[3], Dimitri Goncherovsky[4], Morad Zayoud[5], Paul Zannou[1], Inna Naroditsky[6], Tamar Klienberger[1], Liron Berger[1], Oren Parnas[2], Ruth Perets[1]

[1]Technion-Israel Institute of Technology, Haifa, Israel,[2]The Hebrew University of Jerusalem, Jerusalem, Israel,[3]Monash University, Wantirna South, Australia,[4]Bnei-Zion Medical center, Haifa, Israel,[5]Ziv Medical Center, Safed, Israel,[6]Rambam Health Care Campus, Haifa, Israel

Introduction: Ovarian carcinosarcoma (OCS) is a rare and deadly subtype of ovarian cancer, characterized by an admixture of epithelial and mesenchymal components. The limited understanding of its pathogenesis and the lack of effective therapies highlight the need for pre-clinical OCS models. In particular, the role of inflammation in OCS pathogenesis remains unknown.
Methods: We generated an inducible genetically engineered mouse model of OCS by deleting relevant tumor suppressor genes, namely Trp53, Brca2 and Pten, in the ovarian surface epithelium and fallopian tube epithelium. To assess the role of NSAIDs in OCS, mice were treated with indomethacin starting shortly after tumor induction. We performed single-cell RNA sequencing (scRNA-seq) analysis of tumors and metastases and validated key findings using immunohistochemistry and flow cytometry. Finally, we created murine OCS cell lines and conducted an in vivo omentum migration assay and bulk RNA-seq, to distinguish the effects of NSAIDs on tumor cells versus the tumor microenvironment (TME).
Results: Mice in our model developed ovarian tumors that recapitulated the dual epithelial-mesenchymal morphology of OCS and expressed clinically relevant OCS markers. Deletion of Trp53 and Pten was essential for tumor formation, whereas Brca2 deletion had only a minimal effect on survival. Tumors with combined Trp53, Brca2, and Pten deletion demonstrated high macrophage infiltration within the TME, mirroring human OCS and supporting the model's suitability for investigating the role of inflammation in this disease. Indomethacin-treated mice developed markedly smaller primary tumors and exhibited prolonged survival, yet showed a significant increase in metastatic burden, highlighting the double-edged role of inflammation in OCS. scRNA-seq analysis revealed that indomethacin affected both cancer cells and the TME. Indomethacin-treated cancer cells expressed lower levels of genes associated with angiogenesis and extra cellular matrix turnover. Indomethacin led to a marked reduction in macrophages abundance within primary tumors, accompanied by decreased CD4 and CD8 T cells and an increase in T regulatory cells. An in vivo omentum migration assay demonstrated a metastasis-suppressing effect on the pre-metastatic niche, alongside a direct metastasis-enhancing effect on the tumor cells. Finally, bulk RNA-seq of mOCS cells treated with indomethacin revealed a dramatic upregulation of cholesterol homeostasis pathways, potentially mediating the pro-metastatic effect on cancer cells.
Conclusions: We developed a reproducible OCS model that faithfully mirrors key pathological and molecular features of the human disease. While the tumor-suppressive effects of NSAIDs were discussed in other cancer types, we caution that NSAIDS might have contradictory and complex roles in specific tumor types.

#6069 Mutant BRAF and AKT cooperate to induce melanoma formation.

Camden VanTassell[1], MiKaela N. Field[2], Boyd Griffiths[1], Landen Barnett[1], Madison Hawkins[1], Joshua Knight[1], Katie Culver[2], Allison Stevens[1], Sheri L. Holmen[2], Gennie Lynne Parkman[1]

[1]Weber State University, Ogden, UT,[2]University of Utah Huntsman Cancer Institute, Salt Lake City, UT

Genetic studies have greatly advanced our understanding of the molecular and genetic drivers underlying the steps of melanomagenesis. Although activation of the mitogen-activated protein kinase (MAPK) signaling pathway—specifically in the form of a single driver mutation in the oncogenes BRAF or NRAS—triggers melanocyte proliferation in over 60% of cases, mutations in the RAS pathway alone are not sufficient for melanoma formation. However, the addition of activating tumorigenic mutations or loss of tumor suppressor functions in the phosphoinositide 3-kinase (PI3K) pathway promotes the escape from oncogene-induced senescence, leading to the formation of malignant melanomas. While dysregulation of the PI3K lipid signaling cascade in melanoma is conventionally believed to occur through activation of AKT, it has not been shown whether constitutively active AKT can substitute for mutationally activated PI3K or loss of PTEN in mutant BRAF melanomagenesis in the absence of Cdkn2a loss.In this study, we investigated the potential of aberrant MAPK signaling through mutational activation of BRAF to cooperate with dysregulated AKT signaling to drive melanoma tumor formation and observed that genetic alterations in both BRAF and Akt1 are sufficient to promote melanomagenesis. Using an established autochthonous melanoma mouse model, we evaluated the ability of constitutively active Akt1 to promote tumor initiation and progression and found that Akt1 was sufficient to initiate tumorigenesis with an average tumor onset of 130.5 ± 32.5 days and a median overall survival of 178 ± 2.70 days. We have previously established the potential of myrAkt1 to enhance tumor activity and metastasis with additional genetic events such as loss of the tumor suppressors Pten and Cdkn2a. We now demonstrate that Akt1 not only drives melanoma progression and promotes metastasis but also plays a role in melanoma initiation. Furthermore, proteomic analysis of tumors using reverse-phase protein array (RPPA) revealed an upregulation of total FAK protein in the Pten samples, a finding that we are currently investigating further. Results from this study establish a role for Akt1 in melanoma initiation and highlight the ability of multiple alterations in the PI3K/AKT signaling pathway to influence BRAF mutant melanoma initiation, progression, and metastasis.

#6070 Clinical and genomic determinants of PDX engraftment across solid tumors.

Leva Gorji[1], Kurt W. Evans[2], Xiaofeng Zheng[3], Erkan Yuca[2], Ran Zhang[2], Hung Le[2], Gabriela Raso[4], Argun Akcakanat[2], Ana Galan Cobo[2], Timothy P. DiPeri[1], Milind Javle[5], Burak Uzunparmak[2], Funda Meric-Bernstam[2]

[1]Surgical Oncology, The University of Texas at MD Anderson Cancer Center, Houston, TX,[2]Investigational Cancer Therapeutics, The University of Texas at MD Anderson Cancer Center, Houston, TX,[3]Bioinformatics and Comp Biology, The University of Texas at MD Anderson Cancer Center, Houston, TX,[4]Translational Molecular Pathology, The University of Texas at MD Anderson Cancer Center, Houston, TX,[5]GI Medical Oncology, The University of Texas at MD Anderson Cancer Center, Houston, TX

Introduction: Patient-derived xenograft (PDX) models support investigation of tumor biology and treatment response, yet determinants of successful engraftment and the extent to which PDXs retain patient tumor genomic features remain incompletely defined. This study evaluated clinical and actionable genomic characteristics associated with PDX establishment across solid tumors.
Methods: Tumor specimens from biopsies in 529 patients (555 tumors) were implanted into immunodeficient mice and classified as take or no-take based on successful implantation. Clinical diagnoses and histologic subtypes were recorded. Matched patient tumors and PDXs underwent sequencing to assess mutations, amplifications, deletions, and composite alteration events across actionable genes.
Results: Of the 555 implanted tumors, 266 PDXs were generated (~47% take rate). We generated PDXs from 250 patients across more than 27 tumor types; 14 patients contributed two models, and one contributed three longitudinal models. Pancreatic and esophageal tumors demonstrated higher engraftment frequencies, while peritoneal and appendiceal tumors showed lower frequencies. Among breast cancers, engraftment was higher in triple-negative tumors compared with hormone receptor-positive or HER2-positive subtypes (52% TNBC, 39% HR+, 36% HER2+). Engraftment was more common in tumors bearing *TP53* alterations; however, significance was not retained after adjustment for multiple testing (62.6% vs 50.2%; p=0.007, adjusted p=1). Sequencing of 114 PDXs were compared to clinical sequencing in matched patients. Patients harbored alterations in 159 actionable genes; 157 were also detected in PDXs. All PDXs harbored at least one shared actionable alteration, and 36 PDXs retained all actionable alterations present in their matched patient tumor. Additionally, 88 actionable alterations were detected in at least one PDX but not in patients, and 106 PDXs harbored at least one such alteration. All PDXs acquired additional actionable alterations relative to their matched patient tumors.
Conclusions: PDX engraftment is feasible from biopsies in advanced cancer; engraftment success varies across tumor types. Sequenced PDXs broadly preserved patient tumor actionable alterations but may also have acquired additional events.

#6072 Characterization of the immunological responses in a mouse model expressing humanized FcγR/FcRn.

Angela Pappalardo[1], Julie Donaghey[2], Danielle Huggins[2], Patrick Kirby[2], **Fabiane Sonego**[1], Gaelle H. Martin[1], Kader Thiam[1]

[1]genOway, Lyon, France,[2]Merida Biosciences, Cambridge, MA

Therapeutic antibodies have revolutionized cancer treatment by leveraging immune mechanisms such as Fc-effector functions, which depend on interactions between IgG and Fcγ receptors (FcγRs). However, preclinical evaluation of antibody pharmacokinetics (PK) and pharmacodynamics (PD) remains challenging due to species-specific differences in FcγR and FcRn expression and function. We previously reported a FcγR humanized mouse model that expresses a human-like pattern of FcγRs (including FcγRI, FcγRIIA, FcγRIIB, FcγRIIIA, and FcγRIIIB - genO-hFcγR). These receptors are functional and enable accurate evaluation of Fc-effector functions such as ADCC and B-cell depletion. The model demonstrated Fc-dependent activity of therapeutic IgG, allowing differentiation between antibodies with regular versus enhanced FcγR binding, and supports ranking of Fc-engineered antibodies in preclinical studies. Herein we describe a model expressing human FcRn in addition to humanized FcγRI, FcγRIIA, FcγRIIB, FcγRIIIA, and FcγRIIIB. As the FcRn is involved in IgG recycling and transport, this model was developed to enhance the translatability of PK studies by enabling human FcRn-mediated IgG recycling, while maintaining PD assessment of Fc-engineered therapeutic antibodies**.** We now aim to characterize the immunological competence of the humanized genO-FcγR/FcRn model in the context of inflammation and humoral immunity. Specifically, we investigated whether the immune responses of these mice are comparable to those of wild-type (WT) mice when exposed to defined immunological challenges. We assessed cytokine profiles and cell activation following lipopolysaccharide (LPS) stimulation. Upon LPS challenge, genO-hFcγR/hFcRn mice secreted inflammatory cytokines at levels comparable to WT controls. Additionally, CD25 and CD69 were upregulated on NK and T cells. Similarly, treatment with anti-mouse CD3 antibody triggered a rapid immune response characterized by elevated production of multiple cytokines in both genO-hFcγR/hFcRn and WT mice. Finally, to evaluate humoral responses, we performed a T-cell dependent antibody response assay using Keyhole Limpet Hemocyanin (KLH) as immunogen. genO-hFcγR/hFcRn mice successfully produced antigen-specific IgG and IgM antibodies in response to treatment with KLH, confirming functional cooperation between T and B cells, as observed in WT mice. In summary, these results demonstrate that genO-hFcγR/hFcRn mice are immunologically competent and respond physiologically to immune challenges. This model is a robust and reliable tool for studying Fc-engineered therapeutic antibodies in a context that preserves native immune functionality. The genO-hFcγR/hFcRn model is also being improved to enable tolerability to hIgG1 antibodies, and flexibility of therapeutics testing through expression of human immune checkpoints.

#6073 Establishment and characterization of a panel of EGFR-mutant lung XPDX models representing naïve, chemotherapy, and targeted therapy-resistant patient populations.

Christopher Nelson[1], Mia Lopez[1], Amy Fredrickson[1], Alyssa Simonson[1], Natalia Banos Herraiz[1], Shaquille Johnson[1], Ian Sturgill[1], Guillermo Sanz Martin[1], Jim Lund[1], Jennifer Garcia[1], Kyriakos P. Papadopoulos[2], Victor Moreno Garcia[3], Chris Takimoto[2], Michael J. Wick[2]

[1]The START Center for Cancer Research- XenoSTART, San Antonio, TX,[2]The START Center for Cancer Research, San Antonio, TX,[3]The START Center for Cancer Research- Madrid, Madrid, Spain

Background: Epidermal growth factor receptor (EGFR) mutations represent clinically actionable driver alterations in non-small cell lung cancer (NSCLC), defining a molecular subset with distinct biology, therapeutic vulnerabilities, and patterns of resistance. While common activating mutations including exon 19 deletions (19del) and L858R substitutions have well-characterized responses EGFR tyrosine kinase inhibitors (TKIs), the landscape of EGFR-driven disease is increasingly complex. Uncommon EGFR variants (e.g., D761Y, Y801C, G863C) and acquired compound mutations such as T790M and C797S as well as other resistance mechanisms drive resistance and disease progression. These biologically diverse contexts underscore the need for translational research platforms that accurately represent clinical heterogeneity and enable evaluation of therapeutic strategies across the evolving spectrum of EGFR-mutant disease. To this end, we have established and characterized a panel of EGFR-mutant lung PDX models representing naïve, chemotherapy, and targeted therapy-resistant patient populations. These models were characterized for receptor expression, genomic alterations, and in vivo drug sensitivity to relevant therapies.
Methods: XPDX models representing EGFR 19del and L858R-mutated lung cancer were established from primary or metastatic samples collected from naïve or pretreated patients; additional lung XPDX models harboring uncommon EGFR mutations were also established. Resulting models were passaged and further developed until growth stabilization. Resulting models were characterized using histopathology, WES and RNA_{seq} and in vivo drug sensitivity studies. For in vivo studies, single agent osimertinib or afatinib were evaluated at standard treatment regimens. Study endpoints included tumor volume and time from treatment initiation with %T/C values and tumor regression reported at study completion.
Results: Histopathology confirmed models as similar to patient in most cases. Sequencing identified EGFR co-mutations including T790M, C797S, and several uncommon mutations including D761Y (ST5185B), Y801C (ST6984), G863C (STM225C), and an A767ASVG inframe insertion (ST6963). Several EGFR 19del and L858R-mutated models from naïve patients were sensitive to osimertinib or afatinib while most models from patients treated with one or more EGFR inhibitors were resistant to single agent therapies. ST5185B, ST6963, and STM225C were insensitive to either therapy; however, afatinib but not osimertinib was active towards ST6984.
Conclusion: We have established and characterized a panel of EGFR-mutated lung XPDX models representing naïve, chemotherapy, and targeted therapy-resistant patients. These models can be utilized as a valuable tool in better understanding EGFR-mutated lung cancer.

#6075 Lentiviral vector induced modeling of low grade glioma in the minipig spinal cord.

Kecheng Lei[1], Angeliki Mela[2], Thais Federici[1], Muhibullah S. Tora[1], Marybeth Yonk[1], Yuliya Lakhina[1], Brett Henshey[1], Melissa Danielle Babbitt[1], Roy Raheb Khelo[1], Jeffrey N. Bruce[2], Peter Canoll[2], Nicholas M. Boulis[1]

[1]Emory University, Atlanta, GA,[2]Columbia University, New York, NY

Gliomas represent a diverse spectrum of central nervous system tumors, ranging from aggressive high-grade gliomas (HGG) to less aggressive low-grade gliomas (LGG). Our group previously developed a high-grade glioma model in the minipig spinal cord using PDGFB, HRAS, and TP53. We now report the development of a minipig low-grade glioma model. Lentiviral vectors gene expression of PDGFB, BRAF V600E, and TP53 were used to generate the low-grade glioma model. Disease progression was monitored through behavioral assessment, MRI imaging for lesion detection, and histopathological analysis. Unlike the previously characterized high-grade phenotype, these models demonstrated a distinct, less aggressive low-grade phenotype. Both groups developed spinal cord lesions with divergent histological features: Group 1 (PDGFB + shTP53) displayed diffusely infiltrative gliomas with uniform tumor cells, edema, and minimal necrosis, while Group 2 (PDGFB + BRAF V600E + shTP53) exhibited heterogeneous lesions combining diffuse gliomatous and spindle cell components with increased atypia, apoptosis, and greater axial involvement. These spindle cells appear to originate from myeloid rather than glial lineage. This work establishes the first minipig low-grade glioma model, providing a clinically relevant large animal system for investigating low-grade glioma biology and developing novel therapeutic interventions for spinal cord tumors.

#6076 Preclinical models of cancer cachexia: Bridging the gap to clinical applications.

Hongyan Sun, Dan Zhou, Yunlong Jiang, Yujing Zhang, Jianming Xu, Jing Zhao, Xiang Gao

GemPharmatech Co., Ltd., Nanjing, China

Cancer cachexia (CC) is a multifactorial syndrome affecting up to 80% of advanced cancer patients. Characterized by unintentional weight loss, skeletal muscle wasting, and fat depletion, CC significantly impairs quality of life, treatment tolerance, and patient survival. Despite its prevalence, effective therapeutic options remain limited, underscoring the urgent need for preclinical models that closely mimic clinical symptoms to support drug development. Towards this end, we developed and validated a CC preclinical model with HT-1080 xenograft in NCG mice, which demonstrated hallmark CC features, including body weight loss, fat and muscle loss, as well as impaired physical performance. The tumor-bearing mice also displayed elevated hGDF15 levels (undetectable in non-tumor-bearing (NTB) mice), and significantly reduced cumulative food intake. In this study, we used Ponsegromab (anti-GDF15 monoclonal antibody) as a positive treatment for CC starting when mice had lost ~7% body weight. At the end of the study, mice in hIgG1-treated control group suffered over 15% body weight loss, while the Ponsegromab treatment restored body weight to baseline levels. Although Ponsegromab treated mice remained lighter than NTB PBS controls, our data suggested that Ponsegromab treatment could significantly improve food intake and increase survival rates. Fat and muscle tissue weights, including gonadal, peri-renal, and inguinal subscapular white fat, as well as gastrocnemius and soleus muscles, were significantly reduced in the hIgG1-treated control group compared to baseline controls. Ponsegromab treatment preserved fat and muscle weights to levels similar to the baseline group. Motor function assessed via rotarod performance, and grip strength showed coordination and strength impairments in tumor-bearing mice, while Ponsegromab significantly improved grip strength and physical performance in comparison to the hIgG1-treated control group. In conclusion, our validated preclinical cachexia models closely align with clinical CC manifestations, providing a robust platform for the evaluation of novel therapeutic strategies. These models enable detailed exploration of CC mechanisms and support the development of effective interventions to mitigate cachexia and improve patient outcomes.

#6077 A natural antibody response associated with improved survival of SCLC patients can be actively induced in a SCLC mouse model and leads to significantly improved survival.

Diego Alejandro Velarde[1], Joseph Valdes[2], Chunli Yan[1], Sarah Elmalh[3], Hannah Lee[4], Daniel James Mullen[3], Angie Moreno[1], Matthew A. Gladstone[3], JONATHAN CASTILLO[5], Crystal N. Marconett[6], Nicky Nie[3], Ming Li[3], W. Martin Kast[7], Ite A. Offringa[1]

[1]USC/Norris Comprehensive Cancer Center, Los Angeles, CA,[2]University of California San Diego, San Diego, CA,[3]USC - University of Southern California, Los Angeles, CA,[45]City of Hope Beckman Research Institute, Duarte, CA,[6]Beckman Research Institute of The City of Hope, Glendale, CA,[7]Keck School of Medicine of USC, Los Angeles, CA

BACKGROUND: Small cell lung cancer (SCLC) has a 5-year survival of 8%, killing over 20,000 Americans annually. New therapies are urgently needed. ~15% of SCLC patients exhibit a natural “anti-Hu” antibody response against ELAVL4 and show improved response to therapy with significantly better survival. Rare SCLC patients develop a severe and sometimes lethal autoimmune response to ELAVL4 and can show complete SCLC regression. We determined that the antigenic epitope consists of ELAVL4 that is isoaspartylated in its unstructured N-terminal region (aa 1-38). Isoaspartylation is an immunogenic type of protein damage that is normally repaired but appears to be abnormally present in ELAVL4 in SCLC. IsoAsp-ELAVL4 constitutes a cancer-specific neo-antigen. ELAVL4 has been shown to be expressed on the outside of SCLC cells. In rare cases the anti-ELAVL4 antibody response can lead to autoimmunity through epitope spreading.
METHODS: Here we tested whether actively inducing an immune response against recombinant isoaspartylated Elavl4 (isoAsp-Elavl4) in a mouse SCLC model improves survival. We used a $Trp53^{fl/fl}$; $Rb1^{fl/fl}$ inducible SCLC mouse model to examine: 1) Whether immunization with isoAsp-Elavl4 prior to SCLC induction is protective, and 2) Whether immunization with isoAsp-ELAVL4 following completion of cisplatin+etoposide therapyincreases survival. Mice were immunized with a recombinant N-terminal fragment of Elavl4 (isoAsp-Elavl4, aa 1-117) generated in Clear Coli and incubated under isoaspartyl-inducing conditions (7 days in PBS at 37°C), then emulsified in incomplete Freund’s adjuvant (IFA). The negative control was PBS in IFA; Elavl4 naturally undergoes isoaspartylation even after short periods under physiological conditions, preventing its use as a negative control. The trajectories of mice were closely monitored with a detailed body metric score, and serum was collected from blood draws every 2 weeks to monitor the anti-Elavl4 antibody response. The tumor immune microenvironment of ELAVL4 and control-immunized mice was examined using Visium HD spatial transcriptomics.
RESULTS: ELISA data showed that all isoAsp-Elavl4-immunized animals became immune responsive against isoAsp-Elavl4, and just as in human SCLC patients, a small fraction of control-immunized animals spontaneously developed anti-Elavl4 reactivity. Immunization alone before SCLC induction in the absence of chemotherapy did not improve survival. In contrast, immunization following cisplatin+etoposide therapy significantly increased survival ($p < 0.001$). Visium HD analyses will be presented.
CONCLUSIONS: An immune response against isoAsp-Elavl4 can be actively induced, and when given after chemotherapy can significantly improve SCLC survival in a mouse model. We are leveraging these observations for the development of a new SCLC therapy.

#6078 Integrating patient-derived systems to model metastatic prostate cancer and decode therapy resistance.

Agustina Sabater[1], Pablo Sanchis[2], Jun Yang[3], Jiabin Dong[3], Peter Shepherd[3], Nicolas Anselmino[3], Christopher J. Logothetis[3], Geraldine Gueron[4], Estefania Labanca[3]

[1]Universidad de Buenos Aires (UBA) - IQUIBICEN - CONICET - Universidad Argentina de la Empresa (UADE), CABA, Argentina. UT MD Anderson Cancer Center, Houston, TX, [2]Universidad de Buenos Aires (UBA) - IQUIBICEN - CONICET - Universidad Argentina de la Empresa (UADE), Buenos Aires, Argentina, [3]UT MD Anderson Cancer Center, Houston, TX, [4]Universidad de Buenos Aires (UBA) - IQUIBICEN - CONICET, Buenos Aires, Argentina

Prostate cancer (PCa) lethality is driven by treatment-refractory disease and skeletal metastases, yet progress in understanding these processes has been hindered by the lack of physiologically relevant models. To address this gap, we developed an integrated platform of MD Anderson PCa Patient-Derived Xenografts (MDA PCa PDXs) and PDX-derived organoids, that recapitulate the heterogenous biology of advanced PCa. These models enable genetic manipulation and mechanistic interrogation of metastasis, therapeutic resistance and microenvironment influence. Our PDX series comprises over 150 models with molecular characterization. When engrafted intrafemorally, these models reproduce hallmark osteogenic phenotypes observed clinically, as monitored by multi-modal imaging and bone histomorphometry analyses. Particularly, MDA PCa PDX 118b, a double-negative PDX, generates bone even when injected subcutaneously. Moreover, we performed intracardiac injections of luciferase engineered cell lines and PDXs. This approach allowed us to explore their metastatic potential and tropism using *in vivo* imaging systems (IVIS), providing a model to study therapeutic approaches that could mitigate progression. Through cross-species molecular profiling and spatial analysis, we contrasted subcutaneous and intrabone tumors. This revealed how epithelial-stromal interactions and transcriptional reprogramming at the bone-tumor interface drive niche-specific adaptations. Building on these observations, we investigated molecular drivers of skeletal colonization. We have previously identified Fibroblast Growth Factor Receptor 1 (*FGFR1*) signaling as a key driver of skeletal colonization. Thus, we tested Erdafitinib, a pan-FGFR inhibitor, using intrabone PDX models with different FGFR status. We observed significant changes on both tumor growth and, mainly, in bone compartment architecture, highlighting the importance of the metastatic niche in supporting tumor growth. Beyond skeletal colonization, we also sought to model relapse trajectories. Using relapsed PDXs, we uncovered metabolic rewiring upon castration resistance, including enhanced ketone body utilization. In our *in vitro* and *in vivo* models, targeting the ketogenic enzyme ACAT1 emerged as a promising strategy to counteract therapy-induced metabolic plasticity. Together, these therapeutic insights complement our platform's broader utility. Collectively, these models bridge clinical observations with experimental systems, enabling functional studies of metastatic tropism and therapeutic escape. The combination of PDXs, organoids, different engraftment approaches, and in vitro studies, integrated with ongoing clinical feedback, iteratively refines experimental strategies and enhances model accuracy of disease complexity.

#6080 Multi-omics analysis revealed clonal evolution of sarcoma patient-derived xenografts.

[1]National Cancer Center Research Institute, Tokyo, Japan,[2]Hoshi University, Tokyo, Japan,[3]Kyoto University Graduate School of Medicine, Kyoto, Japan,[4]The University of Tokyo, Tokyo, Japan,[5]National Cancer Center Hospital, Tokyo, Japan

Patient-derived xenografts (PDXs) are used in translational research and are particularly valuable for studying rare cancers such as sarcomas. Although it is critical to understand how accurately they reflect the genetic and phenotypic features of the original tumor, comprehensive analyses that access changes in both single-nucleotide variants (SNVs) and copy number variants (CNVs) during the establishment and passaging of PDXs remain scarce. In addition, as previous studies have focused on those derived from early-stage tumors or major cancer types, it remains unclear how genomic features are preserved in PDXs derived from advanced, treatment-resistant sarcomas.

Here we performed whole-exome sequencing, RNA-seq and DNA methylation analysis of 144 sarcoma PDXs established from 39 patients, along with their matched primary tumors when available. The cohort was enriched for highly recurrent cases (n = 29) and included not only major sarcoma types, such as osteosarcoma (n = 11), but also ultra-rare sarcomas, including alveolar rhabdomyosarcoma (n = 4) and *CIC*-rearranged sarcoma (n = 2). PDXs were successfully established from a wide range of molecular subtypes, including fusion-driven tumors, *TP53*-mutated cases, and hypermutated types associated with microsatellite instability. Targetable genomic alterations, including amplifications of *CCNE1* or *MDM2* and deletions of *MTAP*, were identified in 55% of cases. Several PDXs harbored mutations associated with resistance to molecular targeted agents and immunotherapies.

The vast majority of somatic alterations detected in the primary tumors were retained in the PDXs (97% for SNVs, 99% for CNVs). Moreover, mutational signature analysis suggested that mutations detected exclusively in PDXs likely represent low-frequency mutations already present in the original tumors. Extrachromosomal DNAs involving oncogenes such as *MYC*, *CDK4*, and *MDM2* were also identified in 28% of PDXs and were retained in 83% of cases during serial PDX passaging. Despite overall genomic stability, clonal architecture changed during establishment and passaging, with highly diverse patterns, and clonal shifts were observed in 53%, 65%,71% of cases based on SNVs, CNVs, and both combined, respectively. Interestingly, clonal shifts were observed in all models derived from diagnostic samples (n = 9) and primary tumors (n = 8), which was much more frequent than in models derived from relapsed or metastatic tumors (62%). In addition, gene expression and methylation clustering revealed distinct clusters within each cancer type and individual cases, suggesting that key tumor characteristics were preserved during PDX establishment and passaging.

Our data reveal the genetic and phenotypic stability of sarcoma-derived PDX models during their establishment and passaging, and provide new insights into their clonal evolution, which we believe will contribute to the clinical utility of PDX models.

#6081 Development of a lung cancer orthotopic transplantation model for investigating the TME and evaluating anticancer agents for preclinical studies.

Chiyoko Nishime, Eiko Nishinaka, Hitomi Satou, Toshio Imai, Masayuki Komatsu, Misa Mochizuki, Taichi Yamamoto, Masami Suzuki

Department of Development Research, Central Institute for Experimental Medicine and Life Science, Kawasaki, Japan

Heterotopic subcutaneous (SC) tumor transplantation models are widely used in cancer research owing to their technical simplicity and ease of tumor monitoring. However, these models fail to recapitulate the native tumor microenvironment (TME). To overcome this limitation, we developed a bronchoscopy-based orthotopic (ORT) lung cancer model in mice and compared its TME and drug response with those of the SC model.Three luciferase-expressing lung adenocarcinoma models were used: A549-Luc, RERF-LC-KJ-Luc, and LC-58-Luc (a cell line derived from a patient-derived xenograft, CIEM-established). In the ORT model, 3% lauryl-10 solution was administered via bronchoscopy to the left lung lobule three days prior to transplantation, followed by instillation of 1×10^5 cells in 20 µL medium containing 10% Matrigel. SC tumors were established by subcutaneous injection of the same cells (1×10^5 cells in 100 µL with 50% Matrigel). Tumor growth was monitored via bioluminescence (ORT) or caliper measurements (SC). Mice received carboplatin (CBDCA, 50 mg/kg, i.p., 3 doses at 5-day intervals) and paclitaxel (PTX, 15 mg/kg, i.p., 5 doses at 3-day intervals). VEGF inhibitor combination chemotherapy was also evaluated. RNA sequencing was performed using 150 bp paired-end NovaSeq, with the reads processed using TrimGalore, Xenogsort, STAR, and RSEM. The human–mouse interactome was analyzed using MultiNicheNet. CBDCA and PTX showed significant antitumor effects in both SC and ORT models. In the SC tumors, combination chemotherapy with the VEGF inhibitor significantly reduced the number of mCD31-positive endothelial cells, which is consistent with the anti-angiogenic response. By contrast, no such effect was observed in the ORT tumors, highlighting the TME-dependent differences in vascular responses. RNA sequencing showed ORT-specific upregulation of surfactant genes (*SFTPA1*, *SFTPB,* and *SFTPC*), indicating lung-specific adaptation. MultiNicheNet analysis revealed ORT-enriched ligand–receptor pairs linked to perineural invasion and adhesion, underscoring enhanced host–tumor crosstalk. This ORT model better mimics clinical TME dynamics and enables a more translationally relevant evaluation of anticancer agents.
Bronchoscopy-based ORT lung cancer models recapitulate physiologically relevant tumor–host interactions and TME-dependent drug responses. By incorporating VEGF inhibitor response and transcriptomic profiling, this model provides a better preclinical platform for evaluating antitumor agents and improving translational predictability compared with SC models.

#6082 IFNα polarizes granulocytic MDSCs from neutrophils by inducing protein translation.

Juanita L. Merchant, Lin Ding

Medicine, Univ. of Arizona Health Sciences Ctr., Tucson, AZ

The extensive heterogeneity in the tumor immune microenvironment is a problem plaguing immune-based treatment failures for solid tumors because it prevents defining the specific vulnerabilities of the various cells to develop treatments with greater precision. Myeloid-derived suppressor cells (MDSCs) are a heterogenous collection of immunosuppressive monocytes and granulocytes (neutrophils) whose link to poor cancer survival is not well understood. Most MDSCs exhibit features of immature granulocytes (Gr-MDSCs) and exert their T cell suppression by secreting reactive oxygen and nitrogen species (RONS). Gr-MDSCs can survive for days by recruiting mechanisms to protect protein translation despite generation of RONS. One MDSC subtype of interest is defined by their polarization in response to type 1 interferon (IFNα) that we previously identified in chronic *Helicobacter*-infected mice with gastric metaplasia, suggesting that a *Helicobacter*-infected stomach polarizes neutrophils to acquire an immunosuppressive phenotype. We hypothesize that IFNα initiates neutrophil reprogramming by increasing protein synthesis required to alter their metabolic activities as they acquire the Gr-MDSC phenotype. We performed scRNA-Seq on biopsies from 5 groups of patients referred for endoscopy and showed no gastric abnormalities, were *H. pylori*+ (Hp), had intestinal metaplasia (IM) or gastric adenocarcinoma (GAC) and identified that the IFN-polarized MDSC population initially present in IM increased substantially in GACs but was not detected in normal and *Hp*-infected patients, confirming the polarization of IFN-polarized Gr-MDSCs once IM appears. We showed that the IFN-polarized Gr-MDSCs re-programmed from neutrophils in vitro and required induction of protein translation. To analyze translation, we treated primary cultures of granulocytes from mouse bone marrow or human PBMCs with IFNα and quantified protein translation by flow cytometry after incubating the cultures with 20μM O-propargyl-puromycin (OPP) and proliferation with EdU. In vivo analysis was performed by administering OPP to mice before euthanization. In the in vitro neutrophil cultures, about 28% of the polarized neutrophils were $CD11b^{+}Gr\text{-}1^{+}$ MDSCs, and 85% of these Gr-MDSCs induced their protein synthesis coincident with increased proliferation. scRNA-Seq analysis of both mouse and human gastric tissues demonstrated induction of mediators of the unfolded protein response (UPR), e.g., CHOP. In summary, polarization of Gr-MDSCs by type 1 IFNs from neutrophils requires induction of protein translation, revealing possible metabolic pathways that may be targeted to reprogram the immunosuppressive tumor microenvironment.

#6083 Intracarotid injection-based brain metastasis models without disrupting the blood-brain barrier for preclinical drug evaluation.

Arianna Bandini[1], Gojko Bijelic[2], Melanie Heisler[2], Pia Norz[2], Philipp Metzger[2], Cynthia Obodozie[2], **Holger Weber**[2]

[1]Department of Translational Research and New Technologies in Medicine and Surgery, University of Pisa, Pisa, Italy,[2]Reaction Biology Europe GmbH, Freiburg, Germany

Brain metastases are one of the most common and serious complications of solid tumors, affecting 20-40% of patients. They are common in lung, breast, and melanoma cancers and are associated with a poor prognosis and limited treatment options. Key challenges include the blood-brain barrier (BBB), which restricts penetration of many therapeutic agents, and the brain's historically immune-privileged status, limiting immune responses against tumor cells. Establishing in vivo models that accurately replicate the natural metastatic process to the brain is essential for understanding disease mechanisms and advancing therapeutic research.

Most current preclinical brain metastasis models rely on intracranial implantation of tumor cells directly into the brain or systemic delivery via intracardiac injection. Although intracranial implantation enables rapid local tumor formation, this approach disrupts the BBB integrity and limits physiological relevance for studying natural metastatic progression and evaluating compounds with specific BBB-crossing properties. In contrast, intracardiac injection allows systemic dissemination of tumor cells and can lead to brain metastases in ~50% of cases using MDA-MB-231 cells and 70%-80% using JIMT-1 cells while likely preserving BBB integrity. However, these models are limited by suboptimal brain metastasis rates or early euthanasia due to aggressive extracranial tumor growth, hindering study of brain-specific disease progression over time.

In this study, we present a more physiologically relevant brain metastasis model based on intracarotid injection. This approach enhances the targeted delivery of tumor cells to the brain while preserving BBB integrity, increasing translational relevance. We report take rate and intracranial tumor growth kinetics of human breast cancer cell lines following intracarotid injection and compare these outcomes with those from conventional intracardiac injection. The intracarotid technique yields a high rate of brain metastasis and confines tumor growth to the brain region. To further validate the model, we evaluate efficacy of standard-of-care (SOC) therapies within this system, providing insights into therapeutic responsiveness under conditions closely mimicking clinical scenarios. Additionally, we present data on the growth of 4T1 syngeneic tumor cells in the brain, enabling the study of immune-tumor interactions in an immunocompetent host. This syngeneic model adds another dimension by allowing exploration of immunological mechanisms and testing of immunotherapies in a controlled, biologically relevant setting.

In conclusion, these findings suggest that the intracarotid injection model is a valuable tool for preclinical evaluation of novel therapies targeting brain metastases.

#6087 SOX2-LGR5 signaling mediates ovarian cancer cell survival in response to loss of anchorage..

Shriya Kamlapurkar[1], Amal T. Elhaw[2], Mythreye Karthikeyan[3], Nadine Hempel[1]

[1]University of Pittsburgh School of Medicine, Pittsburgh, PA,[2]Penn State University, Hershey, PA,[3]University of Alabama at Birmingham, Birmingham, AL

Ovarian cancer (OVCA) primarily metastasizes through the transcoelomic route, where tumor cells detach, passively disseminate through the peritoneal cavity and establish metastatic niches in the abdominal cavity. A feature of transcoelomic spread is the development of malignant ascites, which is characterized by tumor cells that adapt to survive anchorage-independence (a-i) by evading detachment-induced cell death, known as anoikis. Malignant ascites are frequently observed in advanced stage and recurrent patients and are associated with tumor aggressiveness and therapy resistance. We previously reported that OVCA cells manipulate their transcriptomic profile to promote the expression of anoikis resistance genes in a-i and identified SOX2 as a key detachment-responsive transcription factor necessary for OVCA cell survival in a-i and metastasis. However, the key factors downstream of SOX2 transcriptional regulation in a-i remain unknown. Here, we identified the leucine-rich G-protein coupled receptor, LGR5, as a novel SOX2 regulated gene that is specifically under the control of SOX2 in a-i conditions. LGR5 is a marker of cancer stemness known to promote cancer cell motility, epithelial-to-mesenchymal transition, and tumor formation by potentiating Wnt signaling upon binding with its ligand, R-spondin1 (RSPO1), which is abundant in OVCA ascites. We demonstrate that LGR5 expression is critical for OVCA cell a-i survival. Interestingly, the effects of LGR5 are not driven via canonical Wnt/beta-catenin signaling but are associated with widespread transcriptional repression. In addition, we find that LGR5 knock-down leads to upregulation Wilms' Tumor-1 (WT1) regulated transcription. These studies show for the first time that SOX2 has context specific functions as a transcription factor in a-i conditions, and that OVCA cells may compensate for inhibition of SOX2 or LGR5 by upregulating WT1 signaling. Current studies are focused on understanding the SOX2-LGR5-WT1 regulatory axis further and its impact on driving ovarian cancer cell survival and metastasis. In addition, using transcriptomics and CUT&RUN sequencing analysis we are exploring the context-specific SOX2 transcriptome and role of SOX2 on the epigenome in a-i. Although SOX2 remains a hard-to-drug target in cancer, identifying novel downstream pathways facilitating a-i survival and potential resistance mechanism to SOX2 inhibition are critical for therapeutic targeting of metastatic disease.

#6088 USP15 promotes ovarian cancer progression by modulating cell cycle checkpoints and DNA damage signaling.

Ayokunnumi Sewanu Ogunsanya, Noel Amadu, Achuth Padmanabhan

Biology, University of Maryland, Baltimore County, Baltimore, MD

Ovarian cancer remains one of the deadliest gynecologic malignancies and the sixth leading cause of cancer-related death among women in the United States. Poor clinical outcomes are largely driven by late diagnosis and limited therapeutic options for metastatic disease. Therefore, there is an urgent need to identify molecular drivers of ovarian cancer progression and develop strategies to target them. Analysis of tumor gene expression datasets revealed that the deubiquitinase USP15 is significantly upregulated in metastatic ovarian tumors compared to normal tissues. Elevated USP15 expression also correlates with decreased progression-free survival in patients. Although USP15 has been shown to promote tumorigenesis in several cancer types, its role and the mechanisms regulating its levels in ovarian cancer remain poorly understood.

We hypothesize that elevated USP15 promotes ovarian cancer progression and metastasis, and that its depletion sensitizes tumors to chemotherapeutic agents. To test this, we generated stable USP15 knockdown ovarian cancer cell lines and assessed metastatic properties using in vitro assays and in vivo xenograft models. Mechanistic studies examined cell-cycle and DNA damage responses via flow cytometry and western blotting.

USP15 knockdown significantly reduced cell proliferation, migration, and invasion of ovarian cancer cells. In xenograft models, USP15 depletion suppressed metastasis, confirming its role in promoting ovarian tumor progression. Cell-cycle analysis revealed a G2/M arrest phenotype in USP15-depleted cells, consistent with impaired cell-cycle progression or checkpoint activation. Western blotting also showed altered expression of key cell-cycle regulators and increased activation of DNA damage markers.

Collectively, these findings indicate that USP15 regulates ovarian cancer cell-cycle progression, checkpoint control, and DNA damage responses. Targeting USP15 may therefore represent a promising strategy to inhibit ovarian tumor progression and metastasis.

#6089 Comprehensive analysis of NR2F2 functions during tumor initiation and progression in a genetically engineered mouse model of high-grade serous ovarian carcinoma.

Miranda Mansolf[1], Danqi Liao[2], Samantha Goncalves Novo[1], Tobias M. Hartwich[1], Jasmine Jathan[1], Kevin Yang[1], Viktoriia Kolesnyk[1], Smita Krishnaswamy[2], Yang Yang-Hartwich[1]

[1]Yale School of Medicine, New Haven, CT,[2]Yale University, New Haven, CT

High-grade serous ovarian carcinoma (HGSOC) is often diagnosed at late stages when tumors have metastasized in the peritoneal cavity. We know HGSOC can originate from fallopian tube secretory epithelial cells, yet the molecular and cellular processes controlling tumor metastasis from the origin are still unclear. Using a genetically engineered mouse model (GEMM) and patient-derived cell lines, we aim to understand the molecular mechanism of tumor progression and metastasis in HGSOC with a focus on the orphan nuclear receptor NR2F2, which was identified as a potential transcriptional regulator in a subpopulation of fallopian tube secretory epithelial cells with tumor forming ability. Inhibition of NR2F2 has shown therapeutic effects in prostate and breast cancer preclinical models. A better understanding of NR2F2 functions in HGSOC is a critical step in developing therapeutic approaches to target oncogenic NR2F2.

Method: Distal oviducts collected from BPRN mice at different timepoints of ovarian tumor formation (2, 4, 6, and 8 months) were analyzed using single cell RNA-sequencing and deep learning AI tools (PHATE and MIOFlow). Bulk RNA sequencing was subsequently used to evaluate gene expression changes in murine and human ovarian cancer cell lines expressing inducible shRNA targeting NR2F2 or scramble shRNA. Co-immunoprecipitation and mass spectrometry (Co-IP/MS) were performed to identify NR2F2-interacting proteins in human ovarian cancer cells overexpressing NR2F2 or treated with a small molecule inhibitor of NR2F2. Chromatin immunoprecipitation sequencing (ChIP-seq) was used to characterize genes and related pathways regulated by NR2F2 and its co-factors.

Result: Trajectory analysis of single cell RNA-sequencing data identified that NR2F2 and its target genes are enriched in a subpopulation of oviduct epithelial cells. The upregulated NR2F2 pathway is associated with tumor development and gene signatures of metastasis. Bulk RNA sequencing of human and mouse cancer cell lines with inducible NR2F2 knockdown demonstrated that NR2F2 regulates signaling pathways involved in cell cycle, cytokine signaling, and extracellular matrix/integrin interactions. Co-IP/MS results show that NR2F2 interacts with several key regulators of tumor progression including PARP1, beta-catenin, and menin 1. ChIP-seq results identified genes directly regulated by NR2F2 and its co-factors.

Conclusion: Through comprehensive analyses of NR2F2 functions in the GEMM, we identified genes and co-transcriptional factors that are regulated by NR2F2. This knowledge will advance our understanding of NR2F2's role in regulating HGSOC initiation and metastasis from the fallopian tubes. Our findings support the rationale of evaluating the therapeutic potential of NR2F2 inhibitors in preventing metastatic recurrence after debulking surgery.

#6090 Characterization of eIF3h as a driver of triple negative breast cancer progression.

Tiffany J. Rios-Fuller

Ponce Health Sciences University, Ponce, PR

Background: Triple-negative breast cancer (TNBC) has a worse prognosis than other breast cancer subtypes, leading to a 5-year relative survival rate of just 15% if metastasized. TNBC is aggressive and challenging to treat, as it lacks estrogen, progesterone, and HER2 receptors. It also exhibits a high rate of proliferation and chromosome instability and is extremely metastatic. Unfortunately, there are limited effective therapy options for TNBC. In breast and other cancers, tumor cells often alter how they translate genetic signals from mRNA into proteins, allowing them to adapt and become more aggressive. This understudied mechanism is crucial for continuous cell proliferation, survival under physiologic stress, and metastasis. Eukaryotic translation initiation factors (eIFs) are among the master players of protein synthesis and are involved in the formation of large pre-initiation complexes (PICs) containing 40S ribosome subunits and mRNA. PICs, including the eIF3 complex, specifically eIF3h, are involved in mRNA translation and regulate the key processes of translation initiation, including recruitment and disassembly of ribosomes. In metastatic breast tumors, eIF3h is up-regulated, and it forms the basis of cell growth and survival; nevertheless, inhibition decreases cell viability and inhibits colony formation. Nonetheless, its specific function in TNBC metastasis remains relatively unexplored, suggesting that inhibiting eIF3h function may be a potential therapeutic target.
Objective/Hypothesis: We hypothesize that increased expression levels of eIF3h are the primary driver of TNBC progression and metastasis, resulting from the activation of oncogenic pathways that promote high-grade TNBC growth, leading to poor overall, relapse-free, and metastasis-free survival.
Results: Unpublished preliminary data support this hypothesis. First, survival analyses performed on several large public datasets (GEO, EGA, TCGA) show that high eIF3h expression correlates with reduced overall survival ($p = 0.0038$), distant metastasis-free survival ($p = 0.018$), and relapse-free survival ($p = 0.0012$). Second, transcriptomic data from normal, tumor, and metastatic breast tissues (GDC, GTEx, GEO) revealed significantly increased eIF3h expression in both tumors and metastases ($p < 0.0001$). Third, genomic profiling conducted using cBioPortal (TCGA) identifies repeated co-alterations in eIF3h-high tumors that modulate the action of anti-apoptotic, autophagic, cell cycle progression, angiogenic, and epithelial-to-mesenchymal transition (EMT) pathways, which mediate tumor progression and metastasis.
Conclusions: These findings collectively demonstrate that eIF3h overexpression is a significant negative prognostic risk factor and a contributor to TNBC progression, therapy resistance, and metastasis through the induction of a potent regulatory mechanism for oncogenic translation.

#6091 Neuronal architect Pax6 orchestrates stemness and brain metastatic progression.

Laiba Anwar[1], Asad Ur Rehman[1], Md Arafat Khan[1], Mohammad Abbas Ali Zaidi[1], Zahraa Wajih Alsafwani[1], Nivedeta Krishna Kumar[1], Mahek Fatima[1], Aatiya Ahmad[1], Parvez Khan[1], Moorthy P. Ponnusamy[1], Metin Uz[2], Juan A. Santamaria-Barria[3], Surinder K. Batra[1], Mohd Wasim Nasser[1]

[1]Biochemistry and Molecular Biology, University of Nebraska Medical Center, Omaha, NE,[2]Chemical and Biomedical Engineering, Cleveland State University, Ohio, OH,[3]Department of Surgery, Division of Surgical Oncology, University of Nebraska Medical Center, Omaha, NE

At the time of breast cancer (BC) diagnosis, many patients have already seeded disseminated tumor cells in the brain, where these cells can persist in a dormant, clinically silent state for years before reactivating to form devastating brain metastasis (BrM). The molecular programs and signals that enable dormant cells to awaken in the neural microenvironment remain an area of limited understanding. Yet this transition is thought to rely heavily on the acquisition of stem cell-like properties. To decipher its mechanism, we performed integrative analyses of publicly available paired primary tumor and brain metastatic transcriptomic patient datasets to identify genes that may be involved in neuronal mimicry. We identified Pax6 as one of the most consistently upregulated genes in metastatic lesions, which was further confirmed through BCBrM tissue microarray. Pax6 is a key neuronal developmental transcription factor that orchestrates CNS specification and sustains neural stem cell identity during embryogenesis. Functional studies using CRISPR/Cas9-mediated Pax6 knockout (KO) in BCBrM cell lines revealed profound reductions in proliferation, migration, and wound closure. Pax6 loss also diminished core stemness programs, including suppression of OCT4, NANOG, and KLF4 expression, diminished CD44+/CD24- tumor initiating cell populations, and impaired mammosphere formation and side populations, a phenotype consistent with a collapse of stem-like potential. Consistently, genes previously linked to BrM were elevated upon Pax6 overexpression (OE) in primary BC cells and were downregulated in Pax6 KO models, further supporting Pax6 as an upstream regulator of BrM - associated transcriptional programs. To critically examine if the observation holds true in preclinical setting, we performed intracardiac injection of Pax6 KO BrM cells in athymic nude mice. We observed that Pax6 KO cells failed to form significant brain macro metastasis, demonstrating the importance of Pax6 in establishing BrM outgrowth. Conversely, Pax6 OE in primary BC cells induced a BrM-like phenotype with increased cell proliferation, migration, and induction of stemness-associated markers, supporting a causal role of Pax6 in promoting metastatic reprogramming. Together, these findings identify Pax6 as a developmental stem cell regulator hijacked by BC cells to escape dormancy and acquire the functional plasticity necessary for growth within the brain microenvironment. By showing that Pax6 plays a key role in driving BCBrM, this work highlights a potential targetable weakness and suggests that therapeutic targeting of Pax6 or its associated pathways may offer a new therapeutic strategy to limit brain metastatic progression and improve clinical outcomes.

#6092 STAT5 modulates STAT3 and the aggressive behaviors of triple negative breast cancer.

Alexandra E. Temple, Emily C. Armlin, **Sarah R. Walker**

University of New Hampshire, Durham, NH

Triple Negative Breast Cancer (TNBC) is an aggressive subtype of breast cancer that accounts for about 15-20% of cases and often has high rates of metastasis. Signal transducer and activator of transcription 3 (STAT3) is constitutively active and highly associated with TNBC. Alternatively, STAT5 expression is often lost or reduced in TNBC and metastasis. STAT5 activation in breast cancer is generally associated with more differentiated tumors and better response to therapies. Interestingly, breast tumors with concurrent activation of STAT3 and STAT5 generally have improved prognostic outlooks compared to tumors with activation of STAT3 alone, suggesting that STAT5 can attenuate some of the aggressive characteristics associated with STAT3 activity. Therefore, understanding how STAT5 can modulate these aggressive phenotypes associated with STAT3 could improve therapies for individuals with TNBC or metastatic breast cancer. STAT3 and STAT5 are latent transcription factors that reside in the cytoplasm. Upon phosphorylation of a specific tyrosine residue, these STATs can enter the nucleus and regulate transcription of target genes. To characterize STAT3 and STAT5 activity in breast tumor subtypes, activity scores were calculated for patients from the Cancer Genome Atlas. STAT3 activity was found to be highest in basal tumors, whereas STAT5 activity was lowest in basal tumors. Furthermore, epithelial to mesenchymal (EMT) scores were calculated for each patient using gene set variation analysis and STAT5 activity was negatively correlated with EMT. Additionally, relapse free survival was improved in patients with high levels of STAT5 and low levels of STAT3 in basal breast tumors. To determine if STAT5 directly modulated EMT and STAT3 in TNBC, a doxycycline-inducible constitutive STAT5 construct was introduced into the TNBC cell line, MDA-MB-231, which contains constitutively active STAT3. It was determined that constitutive STAT5 activation can reduce the viability of these cells. Moreover, preliminary results suggest that STAT5 can affect response to drug treatment and may modulate expression of certain genes involved in EMT. Lastly, in rare cases, breast cancer can metastasize to the peritoneal cavity. Using a mesothelial clearance assay adapted for breast cancer, we found that constitutive STAT5 activation in TNBC cells reduced mesothelial clearance, which is an important step in peritoneal metastasis. Moreover, activation of constitutive STAT5 and concurrent inhibition of STAT3 reduced mesothelial clearance with a greater effect compared to activation of STAT5 or inhibition of STAT3 alone. Therefore, activation of STAT5 can potentially reduce the aggressive behaviors of TNBC. These findings have potential implications in treating patients with TNBC and metastatic breast cancer.

#6093 Investigating the role of stress induced nuclear relocalization of SIPA1 in breast cancer metastasis.

Nirupama S. Kotian[1], Kent W. Hunter[2]

[1]Center for Cancer Research, National Cancer Institute, NIH, Bethesda, MD,[2]National Cancer Institute, Bethesda, MD

Breast cancer is the most commonly diagnosed cancer among women in the U.S., and metastasis is the leading cause of deaths in breast cancer patients. This disease presents with an 87.2% 5-year (2015-2021) survival rate in regional tumors which drops to 32.6 % in metastasized cancers. The goal of Hunter laboratory is therefore to understand the dynamics of cancer progression by identifying mechanisms of metastasis. In this study, we hypothesize that when breast cancer cells are under stress during metastasis, the relocalization of metastasis susceptibility proteins to the nucleus is essential for metastatic progression. Previous work in the laboratory revealed that metastasis susceptibility genes were present in the nucleolus, a central stress sensor. During stress, cytoplasmic proteins are sequestered in the nucleolus and the size of the nucleolus increases. We showed that SIPA1 (Signal Induced Proliferation-associated 1), one of the first metastasis susceptibility genes identified in the laboratory, relocalizes to the nucleus under stresses mimicking metastasis. SIPA1 is a mitogen-induced GTPase activating protein predominantly known to be present in the perinuclear region. However, SIPA1 can relocalize to the nucleus, a phenotype associated with poor prognosis in breast cancer patients. In current experiments, we observed that SIPA1 relocalizes to the nucleus in response to stress conditions like heat shock, nutrient deprivation, hypoxia and low dose chemotherapy drugs. This stress-induced relocalization is primarily in nuclear speckles, a splicing factor storage site, and partially in the nucleolus. Additionally, SIPA1 also binds to higher order repeats near the centromeric regions of multiple chromosomes. Through spectral karyotyping, we observed that knocking down SIPA1 in breast epithelial cells alters chromosomal stability. Future experiments involve assays to determine the mechanism of nuclear relocalization of SIPA1 under stress and proximity assays to identify the interacting proteins in the proximity of SIPA1. Revealing mechanisms that control the relocation of SIPA1 in the nucleus, will further clarify the pathways responsible for stress response in breast cancer cells during metastasis.

#6094 Caveolin-1 modulates stemness and chemosensitivity in triple negative breast cancer.

Shreya Pokharel[1], Naveen Chintala Ramulu[1], Biplov Sapkota[1], Dhirendra Pratap Singh[2], Abhishek Pandit[1], Shilpa Thota[1], Rizwana Begum[1], Shobhit Srivastava[3], Yuxio Yo[1], Shang Su[1], Dayanidhi Raman[3], Joseph Francis[1]

[1]Louisiana State University, Baton Rouge, LA,[2]Radiology and Imaging Science, Indiana University, Indianapolis, IN,[3]University of Toledo, Toledo, OH

Triple-negative breast cancer (TNBC) is the most aggressive subtype of BC, characterized by a therapy-refractory phenotype, higher propensity to early metastases, and worse prognosis. TNBC has a high expression of cancer stem-like cells (CSC), contributing to a poor clinical outcome. Notably, an upregulation of caveolin-1 (CAV-1), a major structural protein of caveolae within the plasma membrane, is associated with TNBC. In agreement, the Kaplan-Meier survival analysis predicted that patients with high CAV-1 expression have a significantly worse survival than those with low expression. Consistently, immunoblot analysis of PDX tumor samples revealed inter-tumor variation with high CAV-1 expression, supporting the role of dysregulated CAV-1 expression in TNBC progression. Previously, we have shown that CAV-1 knockout (Cav-1 KO) mitigated BC metastasis to the lungs via integrin alpha3 in a 4T1 syngeneic 4T1-murine model of TNBC. Upon further investigation, we observed a significant downregulation of pluripotent transcription factors such as SOX2, OCT-4, and NANOG when CAV-1 was depleted in mouse 4T1 and human SUM159PT cells. We hypothesized that CAV-1 regulates TNBC stemness through focal adhesion kinase (FAK)/ c-Myc signaling. Consistently, depletion of CAV-1 altered the levels of pY397FAK and c-Myc, confirming CAV-1-dependent suppression of CSC-like traits to be associated with FAK/c-Myc signaling. Next, we observed that CAV-1 KO cells exhibited enhanced chemosensitivity to paclitaxel (PTX) as compared to the corresponding 4T1 control cells (PTX IC_{50}: 24.51nM in Cav-1 KO vs 30.82nM in 4T1 at 48h). The observed chemosensitivity was due to the downregulation of multidrug resistant protein 1 (MRP1/ABCC1) and P-glycoprotein (ABCB1). Importantly, CAV-1 expression was significantly higher in PTX-resistant human Pac200 cells as compared to the naïve SUM159PT cells. Collectively, these findings indicate that CAV-1 loss impairs major drug efflux pathways and promotes chemosensitivity. Overall, our study proposed a putative role for CAV-1 in TNBC stemness and multidrug resistance through FAK/c-Myc dependent modulation of the stemness pathway and ABC efflux transporters. Therefore, targeting CAV-1 provides a therapeutic strategy to enhance chemotherapy efficacy and overcome drug resistance in TNBC. Since CAV-1 lacks enzymatic activity or ligand-binding pockets, small-molecule targeting may not be a feasible approach. Hence, selective degradation of Cav-1 by (CAV-1)targeting PROTAC offers an innovative first-in-class therapeutic strategy to abrogate cancer stemness and effectively treat metastatic TNBC.

#6095 Breast cancer metastasis to the liver; a new mouse model system.

Jesus Garcia-Lerena, **Eran Andrechek**

Michigan State University, East Lansing, MI

While 30% of breast cancer metastasis occurrs in the liver, the majority of genetically engineered mouse models only metastasize to the lungs. Using a bioinformatic approach and human TCGA data, we predicted genetic pathways that were involved in metastasis to other locations and examined these genes in mouse model systems. We repeatedly observed a role for the E2F5 transcription factor loss in metastasis. We therefore generated a conditional knockout of E2F5 in the mammary epithelium and this alone was sufficient for development of mammary tumors after a long latency that were highly metastatic, including metastases to the lymph, liver and lung among other sites. Using a serial transplantation approach, we enriched for either lymph or liver metastasis and examined these tumors through RNAseq to determine which genetic pathways were involved with liver specific metastasis. Our gene expression analysis revealed a concerted alteration to the primary tumor cells through multiple mechanisms, both metabolomic and genetic, to allow the tumor cells to use the coagulation cascade to drive liver metastasis. We observed that the E2F5 transcription factor normally repressed several genes in the coagulation cascade and with the conditional knockout, these coagulation genes were derepressed. This resulted in a striking ability of these tumor cells to induce a fibrin clot in an *in vitro* clotting assay with human pooled plasma. However, expression of the clotting cascade genes alone is insufficient to induce a fibrin clot and we noted that the tumor cells could clot due to a negative charge on the membrane, were also positive for external phospholipids and had altered lipid uptake and reactive oxygen species. To definitively test whether clotting was essential for breast cancer liver metastasis, we treated mice with low molecular weight heparin as we implanted a metastatic tumor into the fat pad. In several lines, this resulted in a near complete blockage of liver metastasis. To test whether this treatment and pathway might also be functional in human cancer, we turned to the Truveta electronic health record data. This revealed that human pancreatic cancer patients that had been administered heparin for other reasons had a 40% reduction in liver metastasis rates. Thus, our work suggests that inhibition of the clotting cascade on the fibrin side may also be beneficial for prevention of breast cancer liver metastasis.

#6096 Characterization of a novel doxycycline inducible model of EZH2 overexpression in mammary glands.

Ahmad Eido[1], **Maria E. Gonzalez**[1], LiJyun Syu[2], Andrzej A. Dlugosz[3], Celina G. Kleer[4]

[1]University of Michigan, Ann Arbor, MI,[2]MM Dermatology, University of Michigan, Ann Arbor, MI,[3]Professor, Dept. of Dermatology, University of Michigan, Rogel Cancer Center, Ann Arbor, MI,[4]Harold A. Oberman Collegiate Professor, Dept. of Pathology, University of Michigan Medical School, Ann Arbor, MI

Background: Enhancer of Zeste Homolog 2 (EZH2) is a histone methyltransferase and catalytic subunit of the Polycomb Repressive Complex 2 (PRC2), responsible for trimethylating histone H3 at lysine 27 (H3K27me3). In human breast cancer, EZH2 overexpression is an independent prognostic marker and is significantly associated with negative ER and PR expression. However, the timing and functional significance of EZH2 overexpression in breast cancer development is still unclear. Towards this, we generated a conditional model of EZH2 overexpression to the mammary gland in FVB mice.

Methods: We generated a doxycycline-inducible transgenic mouse model MMTV-rtTA;TetO-EZH2 and appropriate controls in an FVB background to enable targeted overexpression of EZH2 within mammary epithelial cells. We administered doxycycline (2 mg/mL) in the drinking water to 10-week-old female mice for 96 hours and in chow for 6 months, to induce EZH2 overexpression. At this age, the mammary glands are mature. At study endpoints, mammary glands were resected and analyzed using whole-mount carmine alum staining to assess ductal architecture. Mammary glands were embedded in paraffin and studied by histopathology and immunostaining using anti-EZH2 antibodies.

Results: Induction of EZH2 expression in adult mice for 96 hours led to increased numbers of ductal branches compared to induced and uninduced controls. Long-term EZH2 induction also resulted in a hyperbranching phenotype and development of mammary epithelial nodules observed in carmine alum stains of whole glands, which were not present in the controls. Additional studies, including histopathological evaluation, immunostaining, and spatial analyses are underway to further characterize the biological and molecular consequences of EZH2 induction.

Conclusions: We present the development and initial characterization of a novel inducible EZH2 overexpression model in the mammary glands of adult mice. Preliminary studies show that EZH2 overexpression results in intraductal epithelial hyperplasia and ductal hyperbranching recapitulating human preneoplastic lesions. Future studies will combine this novel model with other breast cancer mouse models to explore the consequences of EZH2 overexpression on tumor initiation and progression.

#6097 In vivo CRISPR knockout screen reveals ribosome biogenesis as a driver and a potential therapeutic target for melanoma metastasis..

Anna Fakhardo[1], Chethana Gowda[1], Emily Johnson[1], Ricardo Petroni[2], Vivek Tomar[2], Zhenqiu Liu[3], Andres Blanco[2], Jacob Janssen[1], Irina Elcheva[1], Matthew Lanza[1], Serge Fuchs[2], Vladimir Spiegelman[1]

[1]Penn State University, Hershey, PA,[2]University of Pennsylvania, Philadelphia, PA,[3]Radiation Effects Research Foundation, Hiroshima, Japan

Metastatic melanoma is a highly aggressive cancer that spreads rapidly, with a five-year survival rate below 15%. Despite advancements in treatment options, patient outcomes remain poor, highlighting the urgent need for novel therapeutic approaches. Here, we have applied *in vivo* CRISPR KO screening to uncover new genes involved in metastasis and identified Polr1a as one of the drivers of melanoma metastasis. Polr1a is a major subunit of RNA polymerase I (Polr1), which is responsible for the transcription of 47S rDNA, resulting in the generation of 5.8S, 18S, and 28S rRNA needed for ribosome formation. Pharmacological and genetic inhibition of Polr1a impaired migration of melanoma cells, leading to the hypothesis that moderate inhibition of Polr1a preferentially suppresses the translation of genes needed for the metastatic spread. Indeed, genetic inhibition of Polr1a significantly decreased the invasion ability of melanoma cells. Importantly, pharmacological inhibition with CX-5461 (Polr1 inhibitor) significantly slowed down the primary tumor growth and dramatically decreased the number of lung metastases. Also, CX-5461 treatment significantly suppressed metastasis when used in combination with primary tumor resection, demonstrating an impressive metastasis-specific effect independent of primary tumor growth inhibition. To identify the potential mechanism by which Polr1a regulates melanoma metastasis, we have conducted in parallel RNA seq and Ribo seq analysis in Polr1a KD melanoma cells. Inhibition of Polr1a did not affect global translation; however, KEGG enrichment analysis has revealed the non-canonical NF-κB signaling pathway as one of the most strongly impacted on the translational level. Indeed, western blot analysis of the cells with Polr1a KD confirmed that a decrease in Polr1a level is associated with the decrease of p52 and RelB, which are the key proteins responsible for the activation of the non-canonical NF-κB pathway. Re-expression of RelB in the cells with Polr1a KD rescued the migration phenotype, demonstrating that Polr1a regulates melanoma migration ability in an NF-κB-dependent manner.Overall, these results suggest Polr1a as a prospective new target for the treatment of metastatic melanoma and shed light on a potential mechanism responsible for the pro-metastatic effect of this gene.

#6098 Signature surface glycan architecture promotes galectin-8-mediated vascular adhesion and metastatic dissemination of human melanomas.

Jose Souchak[1], Basilio Garcia[2], Norhan B. B. Mohammed[2], Lee Seng Lau[3], Ismaray Govea[2], Brandon Fernandez[2], Charles J. Dimitroff[2]

[1]Herbert Wertheim College of Medicine, Florida International University, Miami, FL,[2]Florida International University, Miami, FL,[3]Herbert Wertheim College of Medicine (FIU), Miami, FL

The molecular mechanisms enabling circulating melanoma cells to adhere to the vascular endothelium and disseminate systemically remain poorly defined. Prior data by our laboratory indicate that, as melanocytes progress to aggressive melanoma cells, they display signature surface glycan features defined by loss of I-branched poly-N-acetyllactosamines (poly-LacNAc) and a gain of galectin (Gal)-8-binding i-linear poly-LacNAcs. Here, we investigated how Gal-8-binding i-linear poly-LacNAcs remodeling influences melanoma metastasis. Flow cytometry and parallel-plate flow chamber assays were used to assess expression of canonical vascular endothelial (E)-selectin-binding glycans, sialyl Lewis$^{X\ or\ A}$, and of E-selectin-mediated adhesion and Gal-8-binding pathways; RT-qPCR was used to evaluate glycosyltransferase expression necessary for canonical E-selectin binding glycans; and experimental metastasis xenograft assays were used to examine metastatic colonization. Data showed that human melanoma cells lacked E-selectin-binding glycans and expression of α1,3 fucosyltransferases essential for sialyl Lewis$^{X\ or\ A}$ biosynthesis, though they possessed an abundance of Gal-8-binding glycans, which supported robust Gal-8-mediated vascular endothelial adhesion under physiological blood flow conditions. Furthermore, in experimental metastasis assays designed to model metastatic colonization potential and our flow-based adhesion assays, exogenous rhGal-8 facilitated significantly more systemic dissemination of human i-linear poly-LacNAc^{high} melanoma cells than control I-branched poly-LacNAc^{high} melanoma cells. These findings support the hypothesis that Gal-8 can bridge vascular endothelial cells to i-linear poly-LacNAc^{high} melanoma cells to support intravascular melanoma cell adhesion, implicating the Gal-8 - Gal-8-binding poly-LacNAc axis as a novel therapeutic target for disrupting systemic dissemination.

#6099 Identification of key pathways regulating colorectal cancer stemness and metastasis through compound screening.

Teruaki Fujishita, Yanqing Niu, **Masahiro Aoki**

Pathophysiology, Aichi Cancer Center Research Institute, Nagoya, Japan

Distant metastasis is the leading cause of mortality in patients with advanced colorectal cancer (CRC), underscoring the need for novel therapeutic targets. Although cancer stem cells are thought to contribute to metastatic progression, the regulatory mechanisms governing CRC stemness remain incompletely understood. Using an autochthonous metastatic mouse model harboring sporadic mutations in *Ctnnb1*, *Kras*, *Trp53*, and *Smad4* genes (CKPS mice), together with CRC cell lines derived from these mice (CKPS cells), we previously demonstrated that the cAMP/PKA/CREB signaling promotes CRC stemness and metastasis partly by inducing the stemness markers ALCAM (CD166) and PROM1 (CD133).To further elucidate pathways sustaining CRC stemness, we performed a compound screen of approximately 500 agents using CKPS spheroid cultures. Among them, QNZ—an inhibitor reported to target NF-κB—significantly downregulated ALCAM and PROM1 and markedly suppressed liver metastasis. Unexpectedly, genetic analysis revealed that these effects were independent of canonical NF-κB signaling. Integrating proteomic and RNA-seq analyses, we identified transcription factors GRHL2 and SOX9 as candidates linking spheroid-induced transcriptional changes to QNZ responsiveness. *Grhl2* knockout reduced ALCAM expression in CKPS spheroid cultures and impaired liver metastasis. On the other hand, *Sox9* knockout or *Ctnnb1* knockdown attenuated PROM1 induction in CKPS spheroids, consistent with SOX9 functioning downstream of Wnt/β-catenin signaling.Collectively, these findings reveal the involvement of multiple pathways—including GRHL2- and Wnt/SOX9-mediated regulation—in maintaining CRC stemness and metastatic potential, providing new insights into therapeutic vulnerabilities of metastatic CRC.

#6100 MYADM drives RhoA-dependent amoeboid plasticity and chromatin remodeling to promote metastasis.

Tai-Lung Cha[1], Yi-Ta Tsai[2], En-Ting Liu[2]

[1]National Institute of Cancer Research, National Health Research Institutes (NHRI), Zhunan, Taiwan,[2]School of Life Science, National Defense Medical University, Taipei, Taiwan

Metastasis relies on the ability of cancer cells to adopt amoeboid migration, yet the upstream regulators of this highly plastic phenotype remain incompletely defined. We identified MYADM, a transmembrane protein normally expressed during myeloid maturation, as a central driver of amoeboid migration and metastatic competency. Cancer cells hijack MYADM to mimic leukocyte-like trafficking, enabling RhoGDI interaction and RhoA activation, which induce leukocyte trafficking-associated genes, membrane blebbing, invasiveness, and anoikis resistance. Multi-omics profiling further revealed that MYADM remodels chromatin accessibility (CA) to control intermediate filament dynamics and establish a pro-metastatic transcriptional state. Loss of MYADM activates CA-driven cell-death pathways and completely suppresses metastasis—an effect selective for cancer cells but not monocytes. These results identify MYADM as a master regulator linking RhoA signaling, cytoskeletal plasticity, and chromatin remodeling, and establish MYADM inhibition as a promising therapeutic strategy to block amoeboid migration and metastatic progression.

#6101 Spectrin SPTAN1 loss triggers genome instability and tumor growth in bladder cancer.

Jim Sheu, Chun-Yu Su

National Sun Yat-sen University, Kaohsiung, Taiwan

Spectrin αII (SPTAN1) is a cytoskeletal protein which plays important roles in actin filament organization and chromosome segregation. Alterations in spectrin network was found to influence cell division and enhance tumor progression. By analyzing cancer genomics data from TCGA databank, silent mutations in spectrin gene *SPTAN1* and its down-regulation were frequently detected in patients with muscle invasive bladder cancer (MIBC), the most aggressive cancer type of bladder cancer. To investigate the possible role of spectrin αII loss in MIBC development, we established stable MB49 cell clones (SPTAN1-KD) which constitutively express SPTAN1-specific shRNAs, leading to down-regulation of SPTAN1 expression. Multinucleated cells with micronuclei were found in SPTAN1-KD cells which were associated with strong staining of γ H 2AX and pCHK2, suggesting DNA damage and genome instability triggered by SPTAN1 loss. Interestingly, these cells can escape the genome crisis-induced cell death by down-regulating the cGAS-STING pathways, a mechanism frequently found in metastatic cancer cells with genome instability. Cell proliferation assay by MTT assay revealed enhanced growth rate in SPTAN1-KD cells as compared to control cells transfected with pLKO empty vector or the parental cells. Xenografted tumor model also confirmed higher tumor growth rate in lesions formed by SPTAN1-KD cells Transcriptome analysis indicated up-regulation of several pathways involved in T cell exhaustion, lipid metabolism and ECM remodeling in SPTAN1-KD cells, which associated with down-regulation of pathways related to immune surveillance. Our study therefore suggests that SPTAN loss functions as a driving force to promote cancer progression by inducing genome instability and cell proliferation. SPTAN loss can also enhance cancer survival by triggering immune editing through transcriptional reprograming.

#6102 *In vivo* CRISPR screening of chromatin regulators reveals p53-dependent drivers of lung metastasis in esophageal cancer.

Raul Navaridas[1], Gizem Efe[1], Ali Iftikhar[2], Karen J. Dunbar[1], Katherine Cunningham[1], Emily Esquea[2], Noriyuki Noriyuki[1], Constanza Tapia Contreras[1], Alice E. Shin[1], Francisco J. Sanchez-Rivera[3], Chao Lu[2], Anil K. Rustgi[1]

[1]Herbert Irving Comprehensive Cancer Center, Vagelos College of Physicians and Surgeons, Columbia University Irving Medical Center, New York, NY,[2]Herbert Irving Comprehensive Cancer Center, Department of Genetics and Development, Columbia University Irving Medical Center, New York, NY,[3]Koch Inst. for Integrative Cancer Research at MIT, Cambridge, MA

Metastatic esophageal cancer exhibits a strong predilection for dissemination to the lungs. Lung metastases are associated with poor survival outcomes, therapeutic resistance, and limited treatment options, underscoring the urgent need to identify targetable mechanisms driving lung colonization. Yet, these molecular mechanisms driving lung-specific tropism remain poorly understood, which serves as the basis for our novel approaches. Herein, we employed state-of-the-art *in vivo* CRISPR-Cas9 knockout screens using a sgRNA library targeting chromatin regulators to identify epigenetic modulators of lung metastasis in esophageal cancer. This screen targeted 600 genes with a pooled sgRNA library enriched for epigenetic regulators and chromatin remodelers. The library, containing 6 sgRNAs per gene and appropriate non-targeting controls, was transduced into isogenic cells with either mutant *Trp53*$^{R172H/-}$ (a frequently detected hotspot *Trp53* mutation in the DNA binding domain) or its depletion at a low multiplicity of infection to ensure single sgRNA integration per cell. The transduced cells were injected orthotopically or via tail-vein into mice, and comparative abundance analysis was performed between the pre-implantation pool and lung metastatic lesions. Our screen uncovered key chromatin regulators that selectively promote lung colonization in the presence of mutant p53, including histone methyltransferases and demethylases (Kmt2d, Kdm1b, Kdm4d), histone deacetylases (Hdac4), and additional DNA and chromatin modifiers (Eya2, Prmt8, Parp14, Tox4, Eny2, and Gata2a). To elucidate the mechanisms by which these epigenetic regulators contribute to metastatic potential, we are performing comprehensive histone methylation and acetylation profiling in the corresponding KO clones, in combination with ATAC-seq and RNA-seq. This integrative approach will enable us to correlate histone modification landscapes with chromatin accessibility and gene expression programs, delineating how mutant p53 cooperates with specific chromatin regulators to reprogram enhancer networks and drive pro-metastatic transcriptional states. Collectively, these studies will define epigenetic mechanisms underlying lung tropism in esophageal cancer and identify actionable vulnerabilities for therapeutic targeting, with broader implications for TP53-mutant cancers.

#6103 Extrachromosomal circular DNA-mediated NOSIP amplification drives OXPHOS-dependent metastasis in hepatocellular carcinoma.

Xiaorong Lin, Yusheng Luo, Yuxi Pan, Guofei Deng, Yuqing Lin, Yuzhi Zhang, Jiancheng Wang, Shuo Fang

The Seventh Affiliated Hospital, Sun Yat-sen University, Shenzhen, China

Background: Distant metastasis is the major cause of cancer-related mortality in hepatocellular carcinoma (HCC), yet the molecular determinants that confer metastatic competence remain poorly defined. Extrachromosomal circular DNA (eccDNA), a non-chromosomal genetic element capable of amplifying oncogenes and promoting tumor evolution, has recently gained attention. However, the functional landscape of eccDNA-carried genes in HCC and their mechanistic roles in metastatic progression remain undefined.
Methods: Paired primary and metastatic HCC tissues were analyzed using Circle-seq to identify metastasis-associated eccDNAs. Candidate drivers were further evaluated through integrated multi-omics analyses and validation using public datasets. Functional studies were performed in HCC cell lines with stable NOSIP overexpression or knockdown, followed by migration and invasion assays. Protein interactors were identified by immunoprecipitation-mass spectrometry. Cellular bioenergetic function was evaluated using Seahorse XF analysis, and the mechanistic relevance of identified interactions was further examined in vitro and in vivo.
Results: NOSIP-containing eccDNA was markedly enriched in metastatic HCC samples, and elevated NOSIP expression correlated with poor overall survival. NOSIP overexpression significantly enhanced cell migration and invasion, while knockdown suppressed these phenotypes. Proteomic profiling identified pyruvate dehydrogenase E1 subunit beta (PDHB) as a major NOSIP-binding partner. NOSIP upregulation increased oxygen consumption rate and activated oxidative phosphorylation (OXPHOS), indicating enhanced mitochondrial metabolic activity. These findings demonstrate that eccDNA-mediated NOSIP amplification promotes metastatic traits by engaging PDHB-dependent mitochondrial metabolic reprogramming.
Conclusion: In conclusion, this study identifies NOSIP-containing eccDNA as a previously unrecognized molecular driver of OXPHOS-dependent metastatic adaptation in HCC. The proposed eccDNA-NOSIP-PDHB axis reveals a mechanistic link between non-chromosomal genetic amplification and mitochondrial metabolic remodeling, offering a potential metabolic vulnerability for therapeutic intervention in advanced HCC.

#6104 STK11 loss enhances stress-adaptive programs supporting shear resilience in circulating tumor cells from KRAS-driven lung adenocarcinoma.

Anna Showalter[1], Princess Rodriguez[1], David Joseph Seward[2], Paula B. Deming[1], **Melissa Nicole Scheiber**[1]

[1]University of Vermont, Burlington, VT,[2]University of Vermont Medical Center, Burlington, VT

Lung adenocarcinoma (LUAD) remains the leading cause of cancer-related mortality, with the KRAS/STK11 (LKB1) co-mutant subtype displaying marked therapeutic resistance and metastatic potential. Metastatic success depends on the ability of circulating tumor cells (CTCs) to withstand the oxidative and mechanical challenges of blood flow, yet the contribution of STK11 loss to fluid shear stress (FSS) tolerance is not fully defined. Using our embryonic zebrafish xenograft model with KRAS-mutant parental and STK11-null LUAD lines, we conducted longitudinal imaging of CTC behavior in physiologic circulation. Under glutamine-deprived conditions that simulate metabolic stress, STK11-null cells exhibited higher micrometastatic burden and increased frequency of extravasation at four days post-injection compared with parental controls. RNA-seq performed under glutamine deprivation and analyzed using Reactome GSEA revealed enrichment of broad stress- and stimulus-response pathways. An FSS-specific gene panel further demonstrated enrichment of shear-adaptive programs, notably NRF2-mediated antioxidant responses, highlighting the need to define these programs directly in vivo. Our data support a model in which STK11 loss facilitates CTC persistence and outgrowth through NRF2-driven survival mechanisms engaged under oxidative and mechanical strain. Ongoing studies leverage high-speed confocal imaging (200–500 fps) and Fiji/ImageJ velocity quantification to map the relationship between shear forces and CTC survival, with planned pharmacologic tuning of cardiac output to modulate intravascular FSS. Future directions include defining molecular programs mediating shear-adaptive survival through candidate panels assessing NRF2 oxidative stress targets, YAP/TEAD outputs, and NF-κB/survival regulators. Collectively, this work identifies NRF2-mediated shear adaptation as a potential mechanism driving metastasis in KRAS/STK11 LUAD and a targetable vulnerability in shear-tolerant tumor cells.

#6105 Cholecystokinin-B receptor epigenetic regulation and targeted therapy in hepatocellular carcinoma.

Martha Gay, Hong Cao, Wenqiang Chen, Jill P. Smith

Medicine, Georgetown University, Washington, DC

Background: Metabolic dysfunction and dietary saturated fat contribute to rising hepatocellular carcinoma (HCC) rates. The cholecystokinin-B receptor (CCK-BR) is upregulated in HCC, yet the upstream mechanisms driving its expression remain undefined. Emerging evidence suggests that microRNA dysregulation and DNA methylation may promote oncogenic receptor signaling. This study investigates whether saturated fat induces CCK-BR expression through epigenetic repression of miR-148a and evaluates whether CCK-BR antagonism suppresses HCC progression in vivo.
Methods:
Epigenetic Regulation: HCC cells were treated with palmitic acid for 8, 24, and 48 hours. qRT-PCR quantified miR-148a and CCK-BR mRNA expression. To validate miRNA-dependent regulation, Hepa1-6 cells were transiently transfected with miR-148a mimics or negative controls using Lipofectamine 2000. To assess diet-induced DNA methylation, genomic DNA from livers of high-fat diet (HFD) and control mice was bisulfite-converted and amplified across CpG-rich regions of the miR-148 promoter. PCR products were cloned into pCR2.1-TOPO vectors and sequenced using PyroMark MD instrument and bisulfite pyrosequencing. To test reversibility, HCC cells are treated with 5-azacytidine, and expression of miR-148a and CCK-BR reassessed.
In Vivo Therapeutic Targeting: Luciferase-expressing RIL-175 HCC cells are orthotopically injected into C57BL/6 mouse livers. After recovery, mice (N=10/group) received either proglumide-treated or untreated water. Tumor growth and metastasis were monitored weekly via IVIS imaging. At week 5, serum α-fetoprotein (AFP) was assessed by ELISA, and livers were analyzed for tumor burden and metastatic spread.
Results: Palmitic acid is expected to suppress miR-148a and increase CCK-BR expression, with miR-148a mimic transfection reversing this effect. HFD livers are predicted to show hypermethylation of the miR-148 promoter correlating with elevated CCK-BR. 5-azacytidine should restore miR-148a and downregulate CCK-BR. In vivo, proglumide therapy is anticipated to reduce tumor flux, AFP levels, tumor size, and metastasis.
Conclusions: These studies define an epigenetic mechanism linking saturated fat exposure to CCK-BR upregulation in HCC and provide preclinical evidence supporting CCK-BR antagonism as a therapeutic strategy for metabolically driven liver cancer.

#6106 Targeting intracellular Galectin-3 disrupts BRAF^{V600E} mutated dormant cell dissemination and restores chemosensitivity in thyroid cancer.

Chiara Modica[1], Vincenzo Davide Pantina[1], Francesco Verona[2], Roberta Drago[1], Giulia Bozzari[1], Matilde Todaro[2], Giorgio Stassi[1]

[1]Department of Precision Medicine in the Medical, Surgical and Critical Care Areas, University of Pa, University of Palermo, Palermo, Italy,[2]Department of Health Promotion, Mother and Child Care, Internal Medicine and Medical Specialties (PR, University of Palermo, Palermo, Italy

Introduction: Papillary Thyroid Carcinoma (PTC) often exhibiting local invasion and the capacity for distant metastasis. While Galectin-3 (Gal-3) is a well-established diagnostic marker, absent in normal thyroid tissue and benign lesions, its intracellular functional role in thyroid cancer remains largely unknown. This study aimed to determine whether cell-autonomous Gal-3 in **BRAF^{V600E}** mutated cells contributes directly to tumor aggressiveness by activating an invasive and metastatic program.

Experimental procedures: We profiled Gal-3 expression in well-differentiated, poorly differentiated, and metastatic TC samples and used genetic modulation in TC cells to test its impact on proliferation, migration, invasion, and cell cycle. Transcriptomic and proteic profile characterization investigated the dormancy pathway and the interaction of Gal-3 with CD44v6 signaling axis to uncover intra and extra-cellular cooperative mechanisms in thyroid carcinoma progression. Synergistic anti-cancer effects of Gal-3 knockdown in combination with chemotherapy were tested both in vitro and in vivo trough ortothopic mouse models, to understand the intracellular Gal-3's impact on primary tumor growth, metastasis and chemosensitivity.

New data: Our data establishes Gal-3 as a pivotal molecular character in PTC pathogenesis. Elevated Gal-3 expression is a hallmark of high-grade disease, showing a striking correlation with poorly differentiated and metastatic tumors compared to their well-differentiated counterparts, underscoring its prognostic significance. Mechanistically, the CD44v6 signaling cascade acts upstream, promoting the intracellular accumulation of Gal-3. This accumulation triggers a transcriptional program that simultaneously dictates cell cycle arrest, fuels enhanced migration and invasion, and crucially, activates a disseminated-dormant phenotype.Remarkably, disrupting Gal-3 via knockdown fundamentally destabilizes this dormant state, forcing dormant TC cells to exit quiescence and undergo outgrowth. This vulnerability translates directly into a therapeutic opportunity: combining Gal-3 silencing with standard chemotherapy profoundly sensitizes these slow-cycling, metastatic cells, achieving a synergistic enhancement of therapeutic efficacy.

Conclusions: These findings unequivocally position Gal-3 as a functional driver of both invasive potential and the elusive dormant phenotype in TC. Furthermore, its modulation represents a highly promising strategy to re-sensitize slow-cycling, treatment-refractory metastatic TC cells, offering a novel avenue for treating patients with advanced disease.

#6107 Activation of NF-κB signaling drives pro-metastatic programs in STK11-deficient lung adenocarcinoma.

Allison R. Racela[1], Shannon M. Prior[1], Sean M. Lenahan[2], Cole M. Royer[1], David Joseph Seward[3], Paula B. Deming[1]

[1]University of Vermont, Burlington, VT,[2]Dana-Farber Cancer Institute, Boston, MA,[3]University of Vermont Medical Center, Burlington, VT

Lung cancer remains the leading cause of cancer-related deaths worldwide and is characterized by marked clinical aggressiveness, including high rates of therapy resistance and metastatic progression. Although recent therapeutic advances have modestly improved 5-year survival in lung cancer, overall response rates remain low (~25%), and effective treatments for metastatic disease are limited. A particularly strong genotype-phenotype correlation predicting broad treatment resistance, early disease dissemination, and poor overall survival in KRAS-driven lung adenocarcinomas (LUADs) is loss of the Serine/Threonine kinase 11 (STK11) tumor suppressor. Patients with STK11-deficient tumors commonly present with advanced-stage disease, exhibit enhanced metastatic potential and experience an especially aggressive clinical course. Despite these well-established clinical associations, the molecular mechanisms driving this aggressive, treatment-refractory phenotype remain largely undefined. We performed whole transcriptome and pathway enrichment studies comparing a KRAS-driven/STK11-competent LUAD (K) cell line with KRAS-driven/STK11-null (KS) cell line and identified STK11-loss-dependent activation of the NF-kappa B (NF-κB) signaling pathway in response to glutamine deprivation. Kmeans clustering of the RNA transcripts highlighted 36 genes induced upon glutamine depletion in KS cells. These genes were subsequently downregulated in the absence of the NF-κB transcription factor (p65) through genetic ablation or pharmacological inhibition (using *PS-1145*), with corresponding decreases in protein expression of candidate oncogenes and anti-apoptotic markers. These findings indicate that NF-κB activation is essential for transcriptional induction of survival, proliferation, and premetastatic genes under glutamine stress. We then showed that p65 consistently accumulates in the nucleus of KS cells following the removal of glutamine, suggesting transcriptional regulation through NF-κB signaling. Following pharmacological inhibition of NF-κB and glutamine depletion, p65 was unable to translocate into the nucleus and was sequestered in the cytoplasm of KS cells. To assess whether glutamine stress and NF-κB signaling promote metastasis we used a 3D spheroid model. Spheroid models more closely mimic the microenvironment of *in vivo* tumors, in which nutrients and oxygen become restricted. Glutamine deprivation enhanced ameboid-like single-cell invasion in KS spheroids, an effect markedly reduced by p65 knockout or PS-1145 treatment. Using a combination of transcriptomic analyses and *in vitro* invasion assays to model metastasis, these results suggest that STK11 loss in KRAS driven lung adenocarcinoma promotes an NF-κB-dependent metastatic phenotypes.

#6110 Systemic inflammation induced by calprotectin (S100A8/S100A9 complex) triggers reactivation of dormant cells in mouse models of breast cancer.

Ahmet B. Caglayan[1], Ying Xin[1], Aysun Caglayan[1], Shruti Nagaraja[1], Deeksha Sharma[1], Cody Hager[1], Fulya Koksalar-Alkan[2], Hilmi K. Alkan[2], Monika Burness[1], Hasan Korkaya[2], Max S. Wicha[1]

[1]Internal Medicine Hematology/Oncology, University of Michigan, Ann Arbor, MI,[2]Department of Oncology, Karmanos Cancer Institute and Wayne State University, Detroit, MI

Breast cancer is the most common cancer in women in the developed countries. Cancer stem cells play key roles in tumorigenesis, dormancy and recurrence in breast cancer, yet they are resistant to many treatments. Despite recent advances in the field in terms of imaging and adjuvant therapies, disseminated dormant tumor cells (DTCs) resistant to these therapies are major cause of late metastatic relapse. However, the mechanisms by which the dormancy maintenance and reactivation, particularly within bone and lung niches remain poorly understood, due in part to limited preclinical models. There is a need for better mouse models to study breast cancer dormancy to mitigate the risk of late metastatic recurrence. Systemic inflammation is increasingly recognized as a trigger of dormancy escape but its mechanistic role in awakening DTCs in vivo is not fully explored. To address this, we evaluated two murine breast cancer syngeneic models in mice to establish a tractable platform for studying tumor dormancy and its awakening. Using orthotopic implantation of EMT6-Luci cells followed by surgical resection in BALB/c mice and intracardiac injection of D2.0R-Luci cells, we examined whether systemic inflammatory cytokines, including IL-1b, G-CSF or Calprotectin (S100A8-S100A9 heterotetramer) promote escape from dormancy. Beginning 30 days post-resection of EMT6-Luci or post-injection of D2.0R-Luci cells, mice received intraperitoneal treatment of indicated cytokines. We monitored the dormancy awakening longitudinally using IVIS bioluminescence imaging as well as the peripheral immune profile assessed by flow cytometry. D2.0R-luci cells demonstrated a robust sensitivity to inflammatory cues. Treatment with Il-1b, G-CSF or calprotectin all markedly increased the frequency of mice exhibiting bioluminescent reactivation of dormant cells compared to the control vehicle mice. Notably, calprotectin induced reawakening in 100% of treated mice versus 33% in control animals highlighting its potent pro-inflammatory and pro-metastatic role. In contrast, disseminated EMT6-luci cells remined below the detection threshold in lung and bone marrow following resection, indicating differences in dormancy biology. Our findings reinforce emerging evidence that systemic inflammation is a critical driver of dormant tumor cell awakening. Our work provides a robust syngeneic dormancy platform for dissecting systemic and microenvironmental regulators of metastatic reactivation and establishes calprotectin as strong candidate mediating dormancy escape. Ultimately, these models will facilitate the development of therapeutic strategies to eliminate dormant cells and prevent late metastatic relapses in breast cancer patients.

#6111 Opposite regulation of brain and lung metastases by endothelial FAK deletion.

Shoko Noda-Narita, Atsu Aiba

The University of Tokyo, Tokyo, Japan

Introduction: In lung metastasis, tumor-derived factors, such as VEGFs and TNF-α, activate focal adhesion kinase (FAK) in vascular endothelial cells (ECs). Activated FAK promotes VE-cadherin phosphorylation and facilitates the extravasation of cancer cells. In contrast, cerebral blood vessels possess much stronger intercellular adhesion, supported by surrounding pericytes and astrocytes. This highly restrictive barrier, known as the blood-brain barrier (BBB), is regulated differently from the endothelial barrier in trunk ECs, and the role of endothelial FAK in brain metastasis remains unclear. In this study, we investigated the function of the cerebral endothelial FAK and compared its contribution to brain metastasis with lung metastasis.

Methods: We generated tamoxifen-inducible, EC-specific FAK knockout (FAK-cKO) mice (*VEcad-Cre^{ERT2}; FAK-flox/flox*) and established brain metastatic (BrM) and lung metastatic (LuM) cell lines from Ex3LL murine lung cancer cell line. BrM cells were intracardially injected into FAK-cKO mice, and brain metastases were analyzed using the CUBIC tissue-clearing system. Lung metastases were also evaluated following tail vein injection of LuM cells.

Results: While endothelial FAK deletion reduced lung metastasis, it conversely increased brain metastasis. The number of brain metastases increased in FAK-cKO mice, whereas the size of individual lesions remained unchanged. These findings suggest that endothelial FAK deletion promotes the initiation of brain metastasis but does not enhance the proliferation of metastatic tumors in the brain. FAK-cKO mice showed no difference in adhesion molecule expression or BBB permeability compared with control mice. However, primary brain ECs from FAK-cKO mice sporadically exhibited internalization of PECAM-1 and VE-cadherin, suggesting endothelial-to-mesenchymal transition (EndoMT). BrM cells co-cultured with these ECs preferentially localized to the dysregulated ECs. This increased susceptibility of FAK-deficient brain ECs to BrM cells suggests that brain endothelial FAK plays a critical role in maintaining BBB integrity and suppressing brain metastasis.

Conclusion: Endothelial FAK deletion exacerbated brain metastasis, while reducing lung metastasis. These findings suggest that endothelial FAK differentially regulates vascular barrier functions in the brain and lung, thereby exerting opposing effects on cancer metastasis. Further investigation is required to elucidate the mechanisms by which endothelial FAK preserves BBB integrity and prevents brain metastasis.

#6112 Inflammatory niche remodeling by metastatic breast cancer stem cells.

Claire Engstrom[1], Jessica Pham[2], Wenxue Ma[2], Emma Klacking[3], Kendale Wirtjes[2], Patrick Chang[1], Inge van der Werf[2], Catriona H. M. Jamieson[4]

[1]UCSD, San Diego, CA,[2]UCSD, La Jolla, CA,[3]UCSD Medical Ctr., San Diego, CA,[4]UCSD Moores Cancer Center, La Jolla, CA

Metastatic breast cancer (MBC) remains one of the leading causes of cancer-related mortality among women in the United States. Cancer stem cells (CSCs), which are characterized by immune evasion, self-renewal, and regenerative potential, are thought to be critical drivers of metastasis and recurrence.Here, we performed single-cell RNA sequencing on eight MBC samples from accessible secondary tumor sites with diverse hormone receptor and HER2 status, including three pleural effusions, one ascites, and five breast to bone metastases. To investigate the relationship of these metastatic cells to their microenvironment, we utilized the package CellChat which uses expression of receptor-ligand pairs to infer communication between populations.Across all samples, we identified a rare population of non-immune ($CD45^-$ $CD24^-$) cells that consistently formed a distinct transcriptional cluster and expressed canonical stemness and cancer markers, including *CD44*, *CD47*, *ALDH1A3*, *MET*, *HER3*, *THY1*, and *PROCR*. Notably, they exhibited elevated expression of the RNA- and DNA-editing enzymes ADAR1 and APOBEC3C which are deaminases previously implicated in mutagenesis, splicing dysregulation, and cancer progression. This population also showed consistent downregulation of retrotransposable elements, a proposed mechanism of immune evasion in leukemia stem cells and consistent with upregulation of base deaminases, which are known repressors of retroelement activation. We uncovered a high degree of autocrine and paracrine signaling from this CSC population, particularly via the IL-6 pathway which is a known inducer of ADAR1 and APOBEC3C, and we performed downstream in vitro and in vivo analysis in patient-derived xenograft mice and nanobioreactor tumor organoid models to investigate the inflammatory and base deaminase activation through cytokine arrays and flow cytometry.Our findings highlight a conserved metastatic niche remodeling CSC-like population across MBC patients that may drive metastasis through base editing, inflammatory signaling, and retroelement repression, and targeting these pathways could offer new avenues for diagnostics and intervention.

#6113 ccRCC lung metastases harbor cancer associated fibroblast lymphocyte exclusion sites that form a confined TME as revealed by single cell and spatial multi-omics.

Yufei Wang[1], Jae-Won Cho[2], Yasmin Nabil Laimon[2], Wenxin Xu[1], Kun Huang[1], Aseman Bagheri Sheshdeh[2], Nithyassree Murugan[1], Hsien-Chi Yuan[1], Jon Wee[2], David Alexander Braun[3], Toni K. Choueiri[1], Catherine J. Wu[1], Sabina Signoretti[2], Gordon J. Freeman[1], Martin Hemberg[2], Wayne A. Marasco[4]

[1]Dana-Farber Cancer Institute, Boston, MA,[2]Brigham and Women's Hospital, Boston, MA,[3]Yale School of Medicine, New Haven, CT,[4]Associate Professor, Dana-Farber Cancer Institute, Boston, MA

Tumor progression and metastasis is driven by interplays between cancer cells and their surrounding tumor microenvironment (TME). Investigating the spatiotemporal transcriptomic and proteomic profile of primary and metastatic tumors sheds light on how differences in spatial architecture shape the TME and promote tumor metastasis. Here, we profiled six primary clear cell renal cell carcinoma (ccRCC) specimens and their lung metastases using three different spatial transcriptomic and proteomic platforms: CosMx, Xenium and CODEX. After cell segmentation and annotation, we incorporated the cellular context and spatial information to identify niches by identifying spatial regions with similar cell type composition. This revealed 12 distinctive niches including cancer, stroma, alveolar, and tertiary lymphoid structure (TLS) niches, formed by 25 different cell types. Furthermore, we analyzed cell-cell communication and architecture were analyzed to understand the intercellular interplay and spatial organization in primary and metastatic ccRCC. The architecture analysis showed that the metastatic lesion has a distinct architecture compared to the primary tumor which we refer to as Cancer Associated fibroblaST Lymphocyte Exclusion Sites (CASTLES). The key characteristic of CASTLES is that malignant cells surrounded by cancer associated fibroblasts (CAFs), endothelial cells as well as tumor associated macrophages (TAMs), constituting a physical barrier. In contrast, primary ccRCC cells were accessible to tumor infiltrating leukocytes (TILs). This difference in spatial organization supports the aggressive characteristics of metastatic cancer cells. Our results show the impact of spatial architecture on primary and metastatic ccRCC, as well as the relation between spatial organization of the cellular context and cell-cell communication. In addition, it suggests that cancer-associated fibroblasts (CAFs) and immune cells are essential components of the ccRCC TME. Their interaction constitutes a major factor not only for tumor progression but also limiting therapy response in metastatic ccRCC.

#6114 Integrated single-cell and spatial atlas of tumor-draining lymph nodes reveals metastasis-associated stromal and immune remodeling.

Enshuo Zhang[1], Lu Zhang[2], Haitang Yang[1], Feng Yao[1]

[1]Department of Thoracic Surgery, Shanghai Chest Hospital of Shanghai Jiao Tong University of Medicine, Shanghai, China,[2]Shanghai Chest Hospital of Shanghai Jiao Tong University of Medicine, Shanghai, China

Introduction: Tumor-draining lymph nodes (TDLNs) are critical sites for anti-tumor immunity and important targets of immunotherapy. However, they are also early sites of tumor dissemination, and lymph node-resident metastatic tumors exhibit reduced responsiveness to immunotherapy compared with their primary counterparts. How metastasis reshapes TDLN stromal-immune ecosystems remains underexplored.
Methods: We built a pan-cancer TDLN atlas, which consists of >1 million cells from healthy lymph nodes (hLN), non-metastatic TDLNs (nLN), and metastatic TDLNs (mLN) across 15 cancers and 70 donors using single-cell RNA sequence (scRNA-seq) and spatial transcriptomics (ST). Key findings were validated in independent patient specimens and mouse models.
Result: Our integrated analysis constructed a public resource named PanTDLN, which identifies myeloid cells, stromal cells, and T cells as the most altered populations after metastasis, with characteristics including hypoxia, activation, and exhaustion. Spatially, four cross-cancer niches that form after metastasis are identified: naïve-enriched, tumor-reactive, peritumoral, and metastatic tumor, each with distinct cellular compositions and ligand-receptor networks. Naïve-enriched zones are filled with naïve T/B cells and PD-1+ CXCL13+ T helper cells with enrichment of immune-recruiting and activating chemokine axes. Peritumoral niches are built by a unique barrier-forming fibroblastic reticular cell (FRC) with the strongest extracellular matrix remodeling program, which spatially segregates the tumor-reactive niche, rich in antigen-presenting cells and cytotoxic lymphocytes, from the tumor mass. Within the tumor niches, hypoxia-associated macrophages and monocytes (HAMs) are specifically enriched, leading to an intratumoral immune desert. Meanwhile, these HAMs promote regulatory T cells (Tregs) within tumor-reactive niches toward terminally differentiated phenotypes via the TNF-TNFR axis, resulting in dysfunction of activated cytotoxic T/NK cells in the tumor-reactive niche. Animal models prove that targeting barrier-forming FRCs and the communication between HAMs and Tregs can disrupt the stromal-immune remodeling and enhance immunotherapy response in mLNs.
Conclusion: PanTDLN decodes the spatiotemporal stromal-immune remodeling during TDLN metastasis and provides potential cross-cancer therapeutic targets, facilitating the treatment of lymph node-positive cancer patients.

#6115 Deciphering tumor microenvironment dynamics in tumorigenesis and lymph node metastasis of esophageal squamous cell carcinoma using single-cell and spatial transcriptomics.

Tae Hee Hong[1], Hansoll Na[1], Chung Lee[2], Young Ho Yang[1], Ha Eun Kim[1], Byung Jo Park[1], Min Hee Hong[3], Hye Ryun Kim[3], Hyun Ki Kim[2], Dae Joon Kim[1]

[1]Department of Thoracic and Cardiovascular Surgery, Yonsei University College of Medicine, Seoul, Korea, Republic of,[2]Department of Pathology, Yonsei University College of Medicine, Seoul, Korea, Republic of,[3]Division of Medical Oncology, Department of Internal Medicine, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, Korea, Republic of

Esophageal squamous cell carcinoma (ESCC) is an aggressive malignancy with late diagnosis and high propensity for lymph node (LN) metastasis. Given the major prognostic and therapeutic impact of LN involvement, defining the cellular and molecular features distinguishing metastatic LNs from primary tumors is imperative. We aimed to delineate tumor microenvironment (TME) dynamics between primary tumors and metastatic LNs integrating single-cell RNA/TCR sequencing (scRNA/TCR-seq) with high-resolution spatial transcriptomic validation.

We performed scRNA-seq on 344,790 cells from 58 upfront surgical specimens of 18 stage T1-2N0-1M0 ESCC patients. Samples included paired tumor mucosa (TM), normal mucosa (NM), tumor-associated LNs (TLN), and normal LNs (NLN). scTCR-seq in 8 patients delineated clonal trajectories and functional T-cell states. Additionally, spatial transcriptomics using the CosMx 6K platform profiled 3,493,957 cells across 34 specimens (NLN, TLN, and TM) from 13 patients, enabling in situ validation of compartment-specific cellular interactions.

Our analysis revealed marked divergence between TM and TLN immune landscapes. TM showed an immunosuppressive milieu dominated by regulatory T cells (T_{REG}s) and sharp loss of cytotoxicity in CD8 exhausted T cells (T_{EXH}s). In contrast, TLN retained partially functional T_{EXH}s following two trajectories: a pre/intermediate-exhausted path with sustained *GZMB* and *PRF1* expression, and a terminally-exhausted path showing steep functional decline—prominent in TM but attenuated in TLN. TCR clonotype analysis supported this, as shared TM-TLN clones preserved cytotoxicity whereas TLN-restricted clones displayed weaker effector programs, suggesting antigen-driven trafficking from primary tumor. Myeloid profiling showed *TREM2*^{high} macrophages (M) enrichment in TLN, while TM featured T_{REG}-dendritic cell (DC) interactions. Spatial transcriptomics validated these compartmentalized suppressive circuits, demonstrating colocalization of *TREM2*^{high} Ms with T_{REG}s or T_{EXH}s in TLN. SPP1-mediated signaling between these populations appeared exclusively in TLN, highlighting niche-specific immunoregulatory interactions within metastatic sites.

This integrated single-cell and spatial transcriptomic study highlights distinct immunoregulatory programs driving ESCC progression and LN metastasis. While TLNs contained T_{EXH}s with preserved cytotoxicity and reinvigoration potential, TMs exhibited abrupt functional collapse. We identified compartment-specific suppressive networks—TREM2^{high} M-mediated axes in TLN and DC-mediated axes in TM—validated by spatial analysis. These findings offer mechanistic insight into LN metastasis and may inform biomarker development, neoadjuvant treatment optimization, and tailored immunotherapy in ESCC.

#6116 Spatial multi-omics dissection of colorectal cancer micrometastasis.

Yang Liu, Akshaya S. Jadhav, Yuwen Pan, Jianlong Liao, Isha Khanduri, Yunhe Liu, Riham Katkhuda, Wei Lu, Kyung Serk Cho, Tieling Zhou, Baohua Sun, Mei Jiang, Sharia D. Hernandez, Idania Carolina Lubo Julio, Patrick Brennan, Guangsheng Pei, Kai Yu, Yibo Dai, Tian Chu, Fuduan Peng, Khaja Khan, Saxon Rodriguez, Ling Xia, Youming Guo, Alicia Mejia, Zhiming Tong, Sean W. Barnes, Ou Shi, Shreeya Indulkar, Alaa Mohamed, Natalie Wall Fowlkes, Timothy Newhook, Yun Shin Chun, Van K. Morris, David G. Menter, Dadi Jiang, Jean-Nicolas Vauthey, Ruoyan Li, Humam Kadara, Luisa M. Solis Soto, Scott Kopetz, Linghua Wang, Dipen M. Maru

The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Colorectal cancer (CRC) metastases frequently recur due to minimal residual disease (MRD) and persisting micrometastases after therapy. However, the spatial and molecular features underlying micrometastatic persistence and CRC recurrence remain poorly defined.
Study design and methods: We performed integrative spatial multi-omics profiling—including Visium spatial transcriptomics (ST), Visium HD ST, laser-capture microdissection with whole-genome sequencing (LCM-WGS), and PhenoCycler-Fusion multiplex imaging—across 49 tumors from 19 patients with paired primary CRC, liver (CLiM), and lung (CLuM) metastases. The analysis encompassed 341,328 Visium spots and approximately 3.8 million Visium HD bins. Non-negative matrix factorization (NMF) was applied to identify conserved and distinct spatial metaprograms across CLiM, CLuM, and primary CRC using Visium ST datasets. For Visium HD ST data, StarDist-SMURF segmentation was used to transform subcellular bins into single-cell-level data. Cross-modality alignment and Jaccard similarity analyses integrated spatially resolved DNA, RNA, and protein profiles across both corresponding and independent tissue blocks, enabling multi-layer characterization of tumor evolution and microenvironmental organization.
Results: Spatial phylogenetic and molecular analyses delineated distinct evolutionary trajectories of primary and metastatic CRC, revealing early clonal divergence and stem-like phenotypes in liver micrometastases (CLiMi) across DNA, RNA, and protein levels. Spatial profiling uncovered stromal interactions in both CLiM and CLuM, with macrophages enriched in CLiM and lymphocytes predominating in CLuM. Micrometastases exhibited pronounced immunosuppression and T cell exhaustion, potentially mediated by PGE2/PTGES2-PTGER4 and NECTIN2/3-TIGIT signaling interactions. A CLiMi-specific six-gene signature predictive of micrometastasis was identified and validated, correlating with disease-free survival (DFS) and MRD-DFS in the MDACC cohort (n = 117), and with DFS and overall survival (OS) in TCGA (n = 610) and GSE17538 (n = 232).
Conclusions: Our integrative spatial multi-omics analysis provides a comprehensive atlas of CRC micrometastases, revealing their evolutionary and immune landscapes. These findings illuminate the molecular and spatial determinants of micrometastatic persistence and identify potential therapeutic vulnerabilities for preventing CRC recurrence.

#6117 Fibroblast-derived extracellular vesicles promote organ-specific tumor growth and chemoresistance in pancreatic cancer liver metastasis via ptch2 downregulation.

Mahsa Pahlavanneshan[1], Weikun Xiao[2], Eileen Fung[2], Chae Young Eun[2], Chang-Il Hwang[3], Shannon Mumenthaler[2], Reginald Hill[2]

[1]Alfred E. Mann Department of Biomedical Engineering, University of Southern California, Los Angeles, CA,[2]Ellison Medical Institute, LLC, Los Angeles, CA,[3]Department of Microbiology and Molecular Genetics, University of California Davis, Davis, CA

Pancreatic ductal adenocarcinoma (PDAC) is the 3rd leading cause of cancer death in USA with a 5-year survival rate of only 13%. Early diagnosis is very difficult and 53% of patients are diagnosed after metastasis has already occurred, with liver being the most frequently affected site. Both primary tumors and metastases have dense desmoplastic stroma, which contributes significantly to chemoresistance. However, the mechanisms by which primary and metastatic fibroblasts influence tumor behavior remain understudied. This study aims to investigate the contributions of fibroblasts-derived extracellular vesicles (EVs) at the primary versus metastatic sites. To achieve this, we developed tunable 3D biomimetic models that replicate aspects of the tumor microenvironment (TME) of primary PDAC and the liver metastatic niche (LMN). We used matched primary PDAC and liver metastatic (LM) organoids derived from the *Kras*$^{+/LSL\text{-}G12D}$*; Trp53*$^{+/LSL\text{-}R172H}$*; Pdx1-Cre* genetically engineered mouse model of PDAC, combined with either primary PDAC or liver fibroblasts. We hypothesized that primary and metastatic site derived fibroblasts possess distinct properties influenced by their different TMEs, that lead to organ-specific effects on tumor growth and chemoresistance. Supporting this hypothesis, fibroblasts enhanced tumor growth and chemoresistance to gemcitabine, only when paired with the organoids from the same site. Fibroblast-derived EVs were identified as critical drivers of this site-specific tumor support. Mechanistically, we found that expression of *Ptch2*, a tumor suppressor in the Sonic Hedgehog (SHH) signaling pathway, is significantly decreased in organoids exposed to site-matched fibroblasts or their EVs, while EV depletion restores *Ptch2* expression. Finally, we pharmacologically modulated the SHH pathway via a small molecule *Ptch2* agonist, Robotnikinin, which appeared to reduce organoid growth and chemoresistance in our models, indicating a potential role for SHH pathway targeting. These findings suggest that site-specific fibroblast-derived EVs may carry distinct *SHH* ligands that differentially interact with *Ptch2* in tumor cells of the corresponding site, which is currently under investigation. Taken together, our findings underscore the importance of developing models to elucidate the pivotal role of the organ-specific microenvironment in driving tumor progression. Our tunable 3D biomimetic model faithfully recapitulates the tumor-stroma interactions and provides a platform to evaluate therapeutic strategies aimed at disrupting fibroblast-tumor crosstalk. Defining how SHH signaling contributes to tumor growth and chemoresistance driven by fibroblast-derived EVs in an organ-specific manner can potentially uncover novel therapeutic strategies for targeting the metastatic niche in pancreatic cancer.

#6118 Spatially resolved SEED (stromal-enriched metastatic decider) niches integrate tumor, stromal, and immune ecosystems to enable lymph node dissemination in LUAD.

Junghan Oh[1], Hoyeon Jeong[1], Yoon La Choi[2], Donggun Lee[1], Misook Lee[1]

[1]Samsung Advanced Institute of Technology, Seoul, Korea, Republic of,[2]Samsung Advanced Institute for Health Sciences and Technology, Seoul, Korea, Republic of

Purpose Lung adenocarcinoma (LUAD) displays substantial intratumoral heterogeneity, but the precise primary-tumor subregions that give rise to lymph-node metastasis remain unclear. We aimed to identify metastasis-competent SEED regions and characterize their microenvironmental context using paired single-cell-resolution spatial transcriptomics.
Methods Formalin-fixed tissues from 17 LUAD patients were profiled using the 10x Genomics Xenium 5K panel, generating paired datasets from primary tumors and matched lymph-node metastases. Spatial and transcriptional integration was performed using Seurat and SpatialData, and metascores and differential expression analyses were computed with Scanpy.
Results Integrated primary-lymph node analysis revealed a recurrent tumor-cell cluster whose transcriptional state aligned most closely with lymph-node profiles, representing a metastasis-competent SEED population. SEED regions showed elevated metascores and enrichment of invasion and hypoxia-associated programs, including robust HIF1A upregulation. The surrounding microenvironment was spatially distinct: fibroblasts immediately adjacent to seed clusters exhibited high POSTN expression, forming a dense stromal shell, while CXCR4-high B-cell aggregates accumulated peritumorally. In contrast, T-cell distribution remained relatively uniform across regions, indicating that SEED-associated remodeling was driven by specific stromal and B-cell interactions rather than general immune infiltration. Together, these spatially coordinated patterns delineate a niche in which HIF1A-high tumor cells interface with POSTN-rich fibroblasts and CXCR4-expressing B cells to support metastatic competence.
Conclusions Paired single-cell spatial mapping identifies discrete metastasis-prone SEED niches within LUAD primary tumors. These niches are defined by HIF1A-high tumor cells embedded in a POSTN-rich stromal compartment and surrounded by CXCR4-high B-cell aggregates. This spatial ecosystem provides a mechanistic framework for how only specific primary-tumor regions acquire the capacity for lymph-node dissemination and suggests niche-level targets for metastasis interception.

#6119 Immune-vascular profiles in primary tumors and paired liver metastases of colorectal cancer.

Alfonso Martin-Bernabe[1], Tove Bekkhus[2], Elisabet Rodriguez-Tomas[2], Reetta Peltonen[3], Pauliina Reijonen[3], Emerik Osterlund[4], Caj Haglund[5], Jaana Hagstrom[3], Helena Isoniemi[3], Bengt Glimelius[1], Tobias Sjoblom[1], Arne Ostman[2], Ari Ristimaki[3], Teijo Pellinen[5], Pia Osterlund[6]

[1]Uppsala University, Uppsala, Sweden,[2]Karolinska Institutet, Stockholm, Sweden,[3]Helsinki University Hospital and University of Helsinki, Helsinki, Finland,[4]The University of Texas MD Anderson Cancer Center, Houston, TX,[5]University of Helsinki, Helsinki, Finland,[6]Tampere University Hospital and Karolinska Institutet, Tampere/Stockholm, Finland

Background: The immune and vascular features of the tumor microenvironment influence outcomes of patients with colorectal cancer liver metastases (CRLMs). However, comparative analyses of these features, and their interactions, between primary colorectal tumors and their matched CRLMs, as well as their treatment-driven remodeling are limited.
Methods: We analyzed 1-3 TMA cores per tumor (1 mm) from 50 matched primary tumors and CRLM (15 untreated, 35 neoadjuvant-treated with cytotoxic ±VEGF-/EGFR-targeted agents before liver resection). We used multiplex immunofluorescence to quantify T-cell densities (CD3, CD4, CD8, PD1, FOXP3, TIM3, Ki67), vessels (claudin-5) and perivascular (PV) subset (αSMA, PDGFRβ) fractions. Statistical analyses included non-parametric tests (Wilcoxon, Mann-Whitney, Spearman) and Intraclass Correlation Coefficient (ICC) for concordance.
Results: Comparisons of untreated paired primary tumors and CRLMs identified significantly lower densities of CD3+CD8+Ki67+, CD3+CD4+Ki67+, CD3+CD4+FOXP3+, and CD3+CD8+PD1+ cells (all p≤0.006) in CRLMs. Regarding vessels, CRLMs showed a lower fraction of αSMA+PDGFRβ+ PV subset (p=0.001), higher fraction of αSMA+PDGFRβ- PV subset (p<0.001), and increased vessel density (p=0.01). Analyses contrasting untreated and treated CRLM showed reduced vessel size (p=0.002) in treated CRLM. Analysis of immune-vascular co-occurrence patterns of potential functional significance was also performed. In untreated primaries, the αSMA-PDGFRβ+ PV subset correlated positively with densities of CD3+CD8+FOXP3+ (r=0.66, p=0.008), CD3+CD8+Ki67+ (r=0.61, p=0.016), and CD3+CD4+PD1+ (r=0.59, p=0.002) cells. In contrast, in untreated CRLMs, the αSMA+PDGFRβ+ PV subset correlated with CD3+CD4+Ki67+ (r=0.56, p=0.03) and CD3+CD4+PD1+ (r=0.62, p=0.013) cell densities. Furthermore, in CRLMs, larger vessel size was uniquely associated with higher CD3+CD4+ cell density (r=0.54, p=0.04). Treatment-exposed CRLMs lacked the associations of untreated CRLMs and instead displayed new associations such as αSMA-PDGFRβ+ PV subset and CD3+CD8+Ki67+ cells (r=0.40, p=0.018). Finally, ICC analyses of inside-case concordance regarding marker status in untreated primary, and CRLM showed that vascular metrics were more stable within patients (αSMA-PDGFRβ+ PV subset ICC=0.60; vessel size ICC=0.36), than T-cell densities (mean ICC=0.02).
Conclusion: These exploratory analyses indicate that CRLM is characterized by lower immune cell densities and a different PV stroma compared to primary tumors. Treatment appears to have a stronger impact on CRLM vessel features than on immune features. Furthermore, immune-vascular co-occurrence patterns are site specific and modulated by treatment. Collectively, these preliminary results identify immune-vascular features for further exploration regarding biomarker and drug target potential.

#6120 Histologic growth pattern dictates immune cell spatial topography in liver metastases.

Artur Mezheyeuski[1], Gemma Garcia-Vicien[2], Nuria Ruiz[2], Jose C. Ruffinelli[3], Kristel Mils[4], Maria Banuls[4], Natalia Molina[5], Miguel A. Pardo[4], Laura Llado[6], Patrick Micke[7], David G. Mollevi[8]

[1]Vall d'Hebron Research Institute (VHIR), Barcelona, Spain,[2]IDIBELL, L'Hospitalet de Llobregat, Barcelona, Spain,[3]Institut Catala d'Oncologia, L?Hospitalet de Llobregat, Spain,[4]Institut Catala d'Oncologia, Barcelona, Spain,[5]IDIBELL, Barcelona, Spain,[6]Hospital Universitari de Bellvitge, Barcelona, Spain,[7]Uppsala University, Uppsala, Sweden,[8]Laboratori de Ricerca Translacional, Institut Catala D'Oncologia, Barcelona, Spain

Background: Hepatic metastases from colorectal cancer represent one of the leading causes of mortality associated with this disease, and their management remains a clinical challenge that requires increasingly precise diagnostic and therapeutic strategies. We have previously reported colorectal liver metastases (CRCLM) with desmoplastic histological growth pattern (dHGP) to have more cytotoxic immune environment, enriched by $CD8^+$ lymphocytes over tumor nests. $FoxP3^+$ cells followed the $CD8^+$, but $CD4^+FoxP3^+$ (Tregs) did not demonstrate difference. Here we focused on rare lymphocyte subset: $CD8^+FoxP3^+$ cells.

Methods: We applied multiplex IHC panel with immune cell markers for tissue samples from 100 patients with CRCLM, characterized by HGP. Cell classes included Cytokeratin (CK)-positive cells, CD8, CD4, $CD4^+FoxP3^+$, $CD8^+FoxP3^+$, $CD20^+$ and HSA (Hepatocyte specific antigen). Cell density defined as number of cells per mm^2. To resolve spatial patterns, we computed neighborhood enrichment (ENR) and the pair correlation function (PCF). ENR, evaluated distance to k-nearest neighbors (k=5-100), and quantified attraction or avoidance between cell classes while controlling for cell density. PCF, computed over radial distances (10-50 µm).

Results: The initial cell density analysis demonstrated that $CD8^+FoxP3^+$ cells were significantly more abundant in dHGP (p=0.003), following similar arrangement of larger CD8+ cell set (p=0.007). Spatial analysis, adjusted to cell density, demonstrated more complex patterns. **First**, $CD8^+FoxP3^+$ showed strong spatial attraction to CD8 cells in non-dHGP, while in dHGP, where both cell types were significantly more abundant, they tended to disperse (confirmed by agreement across five spatial metrics, with k=5-50, r=50, p=0.01-0.004). **Second,** In dHGP, the $CD8^+FoxP3^+$ cells had strong tendency to neighbor to $CD20^+$ (B-cells) (confirmed by agreement across five spatial metrics, with k=5-25, p=0.05-0.005). **Third,** $CD8^+FoxP3^+$ cells demonstrated attraction to cancer cells, in dHGP, detected by ENR at k=5-25 (p=0.01), indicating nearest vicinity or direct contact.

Conclusions: The neighboring tendencies observed between $CD8^+FoxP3^+$ and $CD8^+$ cells in non-dHGP, suggest either a strong biological interaction between these two T-cell subsets or dynamic conversion between states of $CD8^+$ linage. In dHGP, $CD8^+FoxP3^+$ cells were instead redirected toward $CD20^+$ B-cell rich areas and showed nearest-neighbor attraction to CK-positive tumor cells, consistent with positioning in or near tertiary lymphoid structure (TLS)-like niches and at the tumor-stroma interface. Altogether, this provides the first spatially resolved description of $CD8^+FoxP3^+$ cells in CRCLM and highlights their abundance and neighborhood context as potential contributors to the distinct immune architectures and clinical behavior of dHGP versus non-dHGP liver metastases.

#6121 Hippo/YAP1 mediated interplay of tumor-stromal-immune suppressive TME through IL6/gp130/STAT3 axis in advanced gastric cancer.

Junsong Zhao[1], Xiaodan Yao[1], Yibo Fan[2], Dipti Athavale[1], Yanting Zhang[1], Francis Spitz[3], Generosa Grana[3], Shilpa S. Dhar[2], Jaffer A. Ajani[2], Shumei Song[1]

[1]Coriell Institute for Medical Research, Camden, NJ,[2]UT MD Anderson Cancer Center, Houston, TX,[3]Camden Cancer Research Center, Camden, NJ

Abstract

Background: Peritoneal metastases (PMs) occur in ~45% of patients with advanced gastric cancer (GC) and are associated with debilitating symptoms and median survival of less than six months, yet the tumor-stromal–immune mechanisms sustaining the immune suppressive metastatic niche in GC with PM (GCPM) remain poorly defined. Single-cell RNA sequencing of patient-derived PMs revealed that, in addition to tumor epithelial clusters, a subset of activated cancer-associated fibroblasts (CAFs) expresses high levels of the Hippo pathway coactivator YAP1, which associates with CAF activation programs and poor survival. We hypothesized that YAP1^{high} CAFs orchestrate an IL-6-dependent immunosuppressive metastatic niche that can be therapeutically targeted.

Methods: Primary CAFs were established from GCPM implants and malignant ascites. YAP1 was genetically ablated using CRISPR/Cas9, and effects on the CAF secretome were assessed by cytokine arrays, multiplex ELISA, and qPCR. Co-culture assays with GC cell lines and CAFs with YAP1^{hgih} or YAP1^{KO} to determine the effects of YAP1 in CAFs on tumor cell malignant behaviors including tumor invasion, growth and tumor sphere formation; Co-culture of CAFs with YAP1^{hgih} or YAP1^{KO} with PBMC from peripheral blood or malignant ascites-derived CD45^{+} immune cells were used to evaluate the effects of YAP1 in CAFs on T-cell function. In vivo, genetic and pharmacologic YAP1 inhibition were tested in YAP1^{high} patient-derived xenograft (PDX) and patient-derived orthotopic (PDO) models and in the KP-luc2 syngeneic GC model using the TEAD inhibitor VT00278, the STAT3 inhibitor WP1066, and their combinations with anti-PD-1.

Results: YAP1 knockout in CAFs reduced invasion and growth of co-cultured tumor cells in vitro and enhanced T-cell activation in co-culture with PBMC. Secretome profiling by cytokine array identified interleukin-6 (IL-6) as the most strongly YAP1-dependent cytokine, IL-6 was highly expressed in YAP1^{high} CAFs and enriched in malignant ascites, whereas IL6R/gp130 were upregulated in exhausted CD4^{+}/CD8^{+} T cells, fibroblasts, and tumor cells within PM samples. YAP1 depletion decreased IL-6 expression and secretion, and pharmacologic blockade of the IL-6/gp130/STAT3 axis partially phenocopied the effects of YAP1 loss on tumor and T-cell function. Ongoing PDX, PDO, and KP-luc2 studies are evaluating dual YAP1/TEAD and STAT3 inhibition, with or without PD-1 blockade, as a strategy to remodel the PM microenvironment.

Conclusions: These data support a model in which YAP1^{high} CAFs drive an IL-6/gp130/STAT3–dependent immunosuppressive metastatic niche in GCPMs. Dual targeting of YAP1/TEAD and IL-6/STAT3, potentially combined with immune checkpoint blockade, represents a rational novel therapeutic strategy that will be prioritized for clinical translation in GC patients with PM.

#6122 Organ-specific immune and metabolic programs shape spatial microenvironments in MSS colorectal cancer metastases.

Jian Ye[1], Colt A. Egelston[2], Chongkai Wang[3], Marwan Fakih[4]

[1]Department of Medical Oncology and Therapeutics Research, City of Hope National Medical Center, Duarte, CA,[2]Department of Immuno-Oncology, Beckman Research Institute of the City of Hope, Duarte, CA,[3]City of Hope National Medical Center, Department of Medical Oncology and Therapeutics Re, CA,[4]City of Hope National Medical Center, Duarte, CA

Background: Our previous spatial analysis of MSS metastatic colorectal cancer (mCRC) revealed organ-specific differences in immune infiltration across metastatic sites (Ye et al., *Cancer Res Commun*, 2023). Building on that work, we expanded the cohort and applied high-plex spatial transcriptomic and proteomic platforms to characterize region- and organ-dependent microenvironmental programs.

Methods: Spatial transcriptomic profiling using the GeoMx WTA (70 specimens) was performed across malignant, stromal, invasive-margin, distal, and TLS-associated regions. A 56-plex CODEX spatial proteomic panel (120 specimens) was used for whole-tumor multiplex imaging to visualize immune and stromal architecture.

Results: Spatial compartment was the primary driver of transcriptional variation, with malignant epithelial regions from different organs clustering closely together and separating distinctly from normal colon villus epithelium and stroma. Liver outer-margin and distal regions formed a separate transcriptomic cluster from analogous regions in other organs, indicating a strong liver-associated imprint. Within this region-defined structure, GSEA revealed coherent organ-specific archetypes. Primary colon generally showed intermediate immune and metabolic programs. Liver metastases showed broad metabolic activation across regions, including lipid and amino-acid metabolism, mitochondrial and peroxisomal activity, and complement-related signatures, reflecting a metabolically conditioned liver niche. Lung metastases were associated with immune-enriched stromal, margin, and distal regions, marked by strong NK-cell cytotoxicity, T cell differentiation, cytokine signaling, mucosal-like immune networks, and antiviral pathways. Peritoneal metastases showed metabolically and immunologically quiet tumor cores, while outer and distal regions were enriched for lipid and steroid metabolism, and ECM and mesothelial activation, consistent with a lipid-rich, immune-poor peritoneal niche. Preliminary CODEX observations were broadly consistent with these patterns. Lung metastases often showed abundant T-cell infiltration; liver metastases showed lymphocytes accumulating at tumor boundaries with myeloid-enriched tumor centers; and peritoneal metastases displayed dense stromal or fibrotic architecture with limited intratumoral lymphocytes.

Conclusions: High-plex spatial profiling reveals distinct organ-imposed microenvironmental programs in MSS mCRC. Liver metastases adopt a highly metabolic and complement-associated niche, lung metastases display strong peritumoral immune activity, and peritoneal metastases develop within a lipid-rich but immune-low environment. These findings highlight how each organ shapes metastatic ecology and may guide site-adapted therapeutic strategies.

#6123 TNBC-derived lipocalin-2 potentiates metastasis by inducing immunologic reprogramming of premetastatic and metastatic microenvironments.

Gabriela Ortiz-Soto[1], Joshua Gamez[2], Carolyn Rentz[1], Raynah Cheng[1], Francesca Sanchez[3], Abigail Terry[1], Peter Gray[4], Mary Lauren Benton[1], Jonathan Kelber[1]

[1]Baylor University, Waco, TX,[2]Biology, California State University - Northridge, Northridge, CA,[3]California State University - Northridge, Northridge, CA,[4]Independent Research Consultant, Los Angeles, TX

Triple negative breast cancer (TNBC) is distinguished by the absence of estrogen/progesterone receptors and HER2 overexpression. Generally, the median survival for metastatic TNBC is a dire 8-10 months, representing a sharp drop from the five-year survival for metastatic breast cancer of other subtypes (~40%) or non-metastatic TNBC (~75%). Metastatic TNBC is associated with anti-inflammatory tumor immune microenvironments (TIMEs) and little is known about how primary and secondary tumors communicate with one another during disease progression. The Lipocalin-2 gene (LCN2) encodes a cytosolic and secreted protein (Lcn2) that regulates receptor trafficking, inflammation, microbiome dynamics and iron homeostasis. Previous work from our group and others has shown that LCN2/Lcn2 promotes tumorigenesis; however, questions persist regarding the specific contexts in and mechanisms by which it functions to potentiate cancer progression. To define the molecular and cellular factors that govern LCN2-mediated tumor progression, we developed the Py230-C57Bl/6 syngeneic experimental metastasis model for interrogating mechanisms by which tumor cell-secreted factors condition premetastatic lung tissue to potentiate TNBC cell seeding/expansion. Using this model and TCGA data, we identify LCN2/Lcn2 as a molecular candidate that is upregulated in lung-tropic Py230 cells and other human TNBC cells, and that predicts poor TNBC patient outcomes. We demonstrate that TNBC cell-secreted Lcn2 potentiates premetastatic lung reprogramming to increase tumor cell seeding and expansion. Our analyses of global transcriptome and single-cell spatial proteome data in premetastatic lung tissue collected from mice systemically educated by mock media or breast cancer conditioned media from Py8119 (Lcn2-low), Py230-IgG2a (Lcn2-hi) or Py230-αLcn2 (Lcn2-blocked) cells reveal novel gene set enrichments affiliated with oxidative phosphorylation and proliferating B cells. Further single-cell spatial proteome analyses on Lcn2-potentiated lung metastases indicate an increase in proliferating regulatory T cells (FoxP3-pos) indicating that Lcn2-mediated reprogramming of the tumor-naïve lung microenvironment suppresses inflammation to support increased tumor burden. Finally, by using single-cell spatial transcriptomics on matched primary and metastatic TNBC samples, we determine that LCN2 expression localizes to a subpopulation of epithelial and hybrid EMT cells near T cells within primary tumor sites. Notably, within corresponding matched metastatic TNBC samples, we find immune cells that are enriched for genes affiliated with oxidative phosphorylation and anti-inflammatory signaling. Taken together, we report a novel immunologic reprogramming role for LCN2 in TNBC that may be targeted to block or reverse disease progression and improve patient outcomes.

#6124 TIM3⁺tumor associated M2 macrophages impair antitumor T cell immunity and promote gastric cancer progression and peritoneal metastasis.

Xiaodan Yao[1], Junsong Zhao[1], Yibo Fan[2], Yanting Zhang[1], Dipti Athavale[1], Curt Balch[1], Mikel Ghelfi[1], Anthony Pompetti[1], Jiankang Jin[2], Yong Ki Hong[3], Jamin Morrison[3], Madeline Torres[3], Francis Spitz[3], Generosa Grana[3], Shilpa S. Dhar[2], Linghua Wang[2], Jaffer A. Ajani[2], Shumei Song[1]

[1]Coriell Institute for Medical Research, Camden, NJ,[2]UT MD Anderson Cancer Center, Houston, TX,[3]Cooper University Hospital, Camden, NJ

Background: Peritoneal metastases (PM) are the leading cause of cancer-related death in gastric cancer (GC), with typical survival of <9 months and no effective targeted or immune therapies available. T-cell immunoglobulin and mucin domain-3 (TIM3) was initially identified on the surface of T helper 1 (Th1) cells and cytotoxic (CTL) lymphocytes as an immunosuppressive molecule that interacts with its ligands (GAL-9, CEACAM1, HMGB1, and PtdSer), and its expression is associated with advanced cancer stage. However, its functional role in promoting GC-associated PM (GCPM) and its clinical relevance in advanced GC remain unclear.

Methods: multiple profiling and functional assays including scRNA-seq, CyTOF, qRT-PCR, cytokine arrays, kinase arrays, ELISA, and Western blotting were used to evaluate gene expression and secretion. TIM3 was genetically ablated using CRISPR/Cas9 in in macrophages to determine its functional role in tumor cells and T cells by co-culture system. *In vivo*, genetic and pharmacologic inhibition of TIM3 in macrophages co-innovation with tumor cells were tested in $TIM3^{high}$ vs $TIM3^{KO}$ macrophages on tumor growth in patient-derived xenograft (PDX) and patient-derived orthotopic (PDO) models and in the KP-luc2 syngeneic GC model.

Results: We demonstrate that TIM3 and its ligands increased along the GC continuum and are associated with poor survival. Integrated omics analyses, multi-flow and co-immunofluorescent staining revealed that TIM3 is highly enriched in $CD163^{+}$ tumor associated M2 immunosuppressive macrophages, which significantly increased tumor cell invasion *in vitro*, and promoted tumor growth *in vivo*. TIM3 depletion in macrophages reduced tumor cell malignant phenotypes and enhanced T-cell immunity from PBMCs or $CD45^{+}$ immune cells isolated from malignant ascites in co-culture assays. Cytokine and kinase array analyses showed that TIM3 depletion in macrophages reduced production of key cytokines and chemokines from M2 macrophages. We further identified the RSK/CCL20/CCR6 axis as essential for the pro-tumor activity of $TIM3^{+}$ macrophages. Finally, we show that TIM3 blockade or genetic knockout exhibits strong antitumor effects, especially when combined with anti-PD-1/PD-L1 immunotherapy or mitomycin C (MMC) chemotherapy. Together, these findings reveal a critical role for TIM3 in tumor associated macrophages and highlight the potential of TIM3 targeted immune therapy in GC patients with PM.

Conclusion: TIM3 is highly enriched in tumor associated macrophages in GC with PM and plays a pivotal role in promoting GC progression and suppressing T-cell function. Thus, targeting TIM3 especially in combination with anti-PD1/PD-L1 or chemotherapy MMC may provide a novel therapeutic strategy for advanced GC patients with PM.

#6125 Osteosarcoma exploits macrophage VCAM1-VLA4 signaling axis to facilitate pulmonary metastasis.

Daniel Kingsley, Sung Hee Choi, Jay Myers, Alex Y. Huang

Case Western Reserve University, Cleveland, OH

Osteosarcoma (OS) is an aggressive bone cancer primarily found in children and young adults with a five-year survival rate that drops significantly in patients with metastatic disease. At diagnosis, around 20% of patients have lung metastases, reducing survival from 70% to 30%. We believe that an indicator of metastatic potential is the aberrant expression of Vascular Cell Adhesion Molecule 1 (VCAM-1) on the tumor surface as human OS tissues have been shown to overexpress this molecule; however, its precise role remains unclear. We hypothesize that the interaction between VCAM-1 on OS cells and its receptor, the α4β1 integrin (VLA-4) on macrophages, contributes to the ability of OS to metastasize. Our preliminary evidence suggests that tumorigenic effects of VCAM-1 are isoform dependent, and truncated VCAM-1 is critically important to metastasis. Our research model uses bone marrow-derived macrophages exposed to murine OS cell lines K7 and K7M2, the latter being highly metastatic. Early data show that VCAM-1-VLA-4 binding induces a pro-tumoral macrophage phenotype, upregulating Arginase 1, an M2 macrophage marker. Currently, we are investigating whether this effect is specifically driven by the truncated isoform and exploring the role it plays in the PI3K-AKT signaling pathway. We plan to evaluate this hypothesis by looking at expression of the proteins in this signaling axis on bone marrow derived macrophages (BMDMs) that have been influenced by the aforementioned osteosarcoma cell lines. By elucidating how VCAM-1-VLA-4 interactions drive macrophage polarization, we aim to identify novel therapeutic targets that could shift macrophage behavior and improve treatment outcomes in OS.

#6126 Multiomics integration unveils a shifted balance in the sphingosine-1 phosphate/ceramide rheostat fueled by macrophage immunosuppression in metastatic colorectal cancer.

Michelle M. Maurin[1], Siddabasave Gowda B. Gowda[2], Divyavani Gowda[3], Heiman Wang[1], Michael Nebozhyn[4], Ramani Soundararajan[1], Mckayla Carr[1], Punith M Sundaraswamy[5], Ashley Alden[1], Carolina Martinez[1], Robert David Bennett[1], Allen Chudzinski[1], Andreas Karachristos[1], Timothy M. [1]Department of Surgery, University of South Florida, Tampa, FL,[2]Graduate School of Global Food Resources and Faculty of Health Sciences, Hokkaido University, Sapporo, Japan,[3]Faculty of Health Sciences, Hokkaido University, Sapporo, Japan,[4]Director, Informatics&Analysis, Merck & Co., Inc., Boston, MA,[5]Graduate School of Global Food Resources, Hokkaido University, Sapporo, Japan,[6]Vanderbilt University Medical Center, Nashville, TN,[7]Biostatistics and Bioinformatics Department, Moffitt Cancer Center, Tampa, FL,[8]Department of Internal Medicine, University of South Florida, Tampa, FL,[9]Buck Institute for Research on Aging, Center for Phenom Health., Novato, CA,[10]Tampa General Hospital and Department of Molecular Medicine, University of South Florida, Tampa, FL

Background Thirty years ago, a S1P/ceramide “sphingosine rheostat” model was proposed based on ceramide’s pro-apoptotic *vs.* sphingosine-1 phosphate (S1P) pro-survival role, where in cancer, the rheostat tilts towards enhanced synthesis of S1P from ceramides, increasing the ratio. Human tumor data supporting the hypothesis, however, are very limited.
Objective To leverage quantitative multi-omics to explore the balance in the synthesis of lipids within the S1P/Ceramide metabolic pathway in a large set (n = 629) of human colorectal cancers (CRC).
Design Quantitative LC-MS/MS analysis was performed on 525 primary and 104 metastatic CRC (mCRC). An integrative multi-omics analysis combining quantitative lipidomics with whole transcriptomics, quantitative RT-PCR of selected genes and clinical data was completed.
Results We demonstrated that mCRC versus primary specimens are relatively enriched in S1P and sphinganine-1-P (Sa1P), whereas the long chain ceramides (24:1) are relatively decreased. Gene-expression analysis of a large (n = 2200) CRC patient dataset and qRT-PCR of CRC revealed that S1P/Sa1P-synthesizing enzymes and their receptors are enriched in mCRC and are linked to poor prognosis. scRNA-seq analysis showed that their expression prevailed in myeloid cells. Finally, a three-gene S1P macrophage-associated signature correlated with stage and patient survival.
Conclusion Our findings define an imbalance in the synthesis of S1P/Ceramide linked to poor prognosis and cancer progression, and attributable to proinflammatory macrophages in the tumor microenvironment, validating the sphingosine rheostat hypothesis in mCRC.

#6127 Hepatic niche driven metabolic-epigenetic reprogramming mediates metastatic colonization through liver progenitor like plasticity.

Ajit Kumar SHARMA[1], Nobuyuki Takahashi[2], Sophie Zhuang[3], Amira Kazi[3], Michael Nirula[3], Abhinav Joshi[3], Yingying Cao[4], Rajesh Kumar[4], Kanak Parmar[3], Christopher Schultz[5], Parth Anil Desai[6], Samantha Nichols[3], Linda Sciuto[3], Yue Huang[7], Chiori Tabe[3], Yang Zhang[3], Sanghvi Neel[1], Nishanth Ulhas Nair[4], Christopher A Febres Aldana[1], Nir Friedman[8], Simone Difilippantonio[9], Thorkell Andresson[3], Eytan Ruppin[3], Stephen M. Hewitt[3], Anish Thomas[4]

[1]NIH/National Cancer Institute, Bethesda, MD,[2]National Cancer Center Hospital East, Kashiwa, Japan,[3]National Institutes of Health, Bethesda, MD,[4]National Cancer Institute, Bethesda, MD,[5]Department of Medical Oncology, Fox Chase Cancer Center, Philadelphia, PA,[6]Fox Chase Cancer Center, Philadelphia, PA,[7]Developmental Therapeutics Branch, NIH/National Cancer Institute, Bethesda, MD,[8]The Hebrew University of Jerusalem, Rehovot, Israel,[9]Leidos Biomedical Research, Inc., Frederick, MD

Background
Liver metastasis is a major cause of mortality in small cell lung cancer (SCLC), but the organ-specific cues that enable metastatic colonization are poorly understood. We hypothesized that the hepatic microenvironment promotes a stem-like, high-plasticity state required for metastatic outgrowth.
Methods
We analyzed patient-derived SCLC liver metastases using RNA-seq, ATAC-seq, and metabolomics, combined with spatial transcriptomics and orthotopic liver colonization models. Regional hypoxia, HIF1α signaling, and metabolic flux were assessed by protein quantification and 13C-glucose tracing. Functional studies included pharmacological ACLY inhibition (SB204990) and CRISPR-mediated ACLY knockout in vivo.
Results
Across patient specimens and in vivo models, metastatic SCLC cells in the liver adopted a distinct stem-like transcriptional state, marked by activation of regenerative programs and chromatin accessibility at stemness loci (HNF1A, HNF4A, SOX9, ATF3). Spatial profiling revealed that tumor cells adjacent to hepatocytes experienced localized hypoxia, resulting in HIF1α stabilization and the transcriptional induction of ACLY, a key enzyme that generates nuclear acetyl-CoA. ATP-citrate lyase (ACLY)-dependent generation of nuclear acetyl-CoA, driving histone hyperacetylation and chromatin remodeling at liver-lineage transcription factors HNF1A, HNF4A, and SOX9. Liver-metastatic cells undergo glycolytic reprogramming, a metabolic shift that parallels hepatocyte regeneration during liver injury, providing acetyl-CoA and biosynthetic precursors to support epigenetic remodeling and lineage adaptation. Similar progenitor-like hepatic plasticity is observed across other epithelial cancers with liver tropism, including breast, colon, and non-small cell lung cancers, indicating a conserved mode of metastatic adaptation. ALY activity mediated histone hyperacetylation and epigenetic remodeling required for the stem-like state. ACLY was functionally essential. Pharmacologic ACLY inhibition blocked the induction of stem-like programs, reduced histone acetylation, and growth rate of liver metastatic cells. CRISPR-ACLY knockout prevented the acquisition of the reprogrammed phenotype. Similar hepatic niche-induced stemness signatures were observed in liver metastases from breast, colon, and NSCLC, suggesting a conserved mechanism across epithelial cancers.
Conclusions
The liver microenvironment actively promotes metastatic competency by inducing a HIF1α-ACLY-acetyl-CoA-driven stem-like state in disseminated tumor cells. ACLY inhibition disrupts this metabolic-epigenetic reprogramming and markedly suppresses liver metastatic outgrowth, highlighting ACLY as a tractable therapeutic target for liver metastasis.

#6129 Microenvironmentally-driven dynamic deposition of histone H3.3 controls entry and exit from dormancy in disseminated cancer cells.

Stanislav Drapela[1], Cristina Megino-Luque[2], Rojan Chimeh Rad[1], Devesh Raizada[1], Nadir Sarigul[1], Didem Ilter[3], Brian J. Czerniecki[4], Javier J. Bravo-Cordero[2], Ana P. Da Silva Gomes[1]

[1]Department of Tumor Microenvironment and Metastasis, Moffitt Cancer Center, Tampa, FL,[2]Department of Medicine, The Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, NY,[3]Moffitt Cancer Center, Tampa, FL,[4]Department of Breast Oncology, Moffitt Cancer Center, Tampa, FL

Breast cancer metastases can go undetected for long periods of time, are highly resistant to therapy, and are the cause for more than 90% of breast cancer mortality. Dormancy is a critical step in the metastatic cascade, whereby disseminated cancer cells (DCCs) enter a non-proliferative state at distal sites until they reactivate and give rise to overt metastasis, often years after disease remission. As such, dormancy represents a major clinical obstacle in breast cancer patient care. Chromatin remodeling serves as a foundation for the cellular reprogramming required to drive cell fate transitions. However, little is known about the nature of this remodeling in dormancy. Here, we hypothesize that differential deposition of histone H3.3 determines whether DCCs enter and remain dormant in secondary organs or proliferate and form overt metastases. We used a combination of H3.3 deposition sensors and genetic tools to manipulate H3.3 and its cognate chaperone, HIRA, *in vitro* and *in vivo* to track H3.3 deposition through the metastatic cascade and evaluate its importance for dormancy. Our data demonstrates that H3.3 incorporation at secondary sites is heterogenous, revealing a subset of DCCs with low H3.3 in chromatin. Blocking H3.3 deposition onto chromatin leads to a reversible arrest in G0/G1 which tracks with the activation of canonical dormancy signaling. To define mechanism of regulation, we used a combination of whole genome sequencing (ChIP-seq, ATAC-seq and RNA-seq) followed by in-depth analysis and functional validation. Our data supports a model where blocking H3.3 incorporation into chromatin directly represses the expression of SKP2, the main regulator of progression through the restriction point of cell cycle via regulation of p27 degradation. SKP2 suppression in turn leads to the accumulation of p27 thereby causing cell cycle arrest in G0/G1 and dormancy establishment. We traced this H3.3-mediated regulation of dormancy through the dynamic regulation of H3.3 histone chaperone, HIRA, whose levels inversely correlate with dormancy in experimental models as well as in patient samples. Moreover, we found that HIRA levels respond to the metastatic microenvironment where fibrotic conditions induce HIRA expression and trigger metastatic outgrowth in an H3.3-dependent manner. Together, our work unveils for the first time a patient-relevant epigenetic mechanism, impinging on H3.3 deposition and HIRA as its driver, as a major regulatory point of DCCs' cell fate at secondary organs controlling both entry of DCC's into dormant state as well as their reactivation and thriving as overt metastasis.

#6131 BDNF-TrkB.T1 receptor signaling modulate an immunosuppressive tumor microenvironment and epithelial-mesenchymal transition in gliomas.

Leyre Merino-Galan[1], **Jin-Yih Low**[1], Sergio Ortiz-Espinosa[2], Hawa L. Jagana[1], John M. Hemmenway[1], Ashmitha Rajendran[1], Mathew R. Hattaway[1], Taylor S. Jackson[1], Maryam Shabar[1], Noemi Reche-Ley[1], Sonali Arora[2], David Johnson[1], Daniel A. Kuppers[2], Patrick J. Paddision[2], Siobhan S. Pattwell[1]

[1]Ben Towne Center for Childhood Cancer and Blood Disorders Research, Seattle Children's Research Institute, Seattle, WA, [2]Division of Human Biology, Fred Hutchinson Cancer Center, Seattle, WA

Introduction: Gliomas are the most common and aggressive brain tumors in children and adults. The tumor microenvironment (TME), including neurons, glial cells, blood-brain barrier, and immune components, plays a key role in glioma progression and therapy resistance. Brain-derived neurotrophic factor (BDNF) and its receptor, tropomyosin receptor kinase B (TrkB), encoded by NTRK2, are emerging as central players in glioma biology. Among TrkB isoforms, truncated TrkB.T1 is the most abundantly expressed variant in human gliomas and various adult and pediatric tumors. Recent studies show TrkB.T1 is the predominant isoform during embryogenesis and organogenesis, with high expression along mesenchymal trajectories, suggesting a role in glioma epithelial-mesenchymal transition (EMT). Previously, we showed TrkB.T1 overexpression in human neural stem cells downregulated genes in the MHC Class II and interferon-gamma signaling pathways, both essential for antigen presentation and cytotoxic T cell recruitment. This study aims to elucidate BDNF-TrkB.T1 signaling in modulating glioma TME and EMT phenotype.
Approaches: We performed in silico analyses using publicly available single-cell RNA sequencing data (GSE182109), stratified into NTRK2 high, medium, and low clusters, and correlated with PTPRC (CD45) expression. Using the PDGFB RCAS-tva model, we generated in vivo gliomas via intracranial RCAS-PDGFB + RCAS-TrkB.T1 injection in Nestin/tv-a;Ink4a/Arf-/- mice at postnatal day 1-2. Tumors were collected at 3.5-5 weeks post-injection for immunofluorescence and flow cytometry. We also created a TrkB.T1 knockout (KO) mouse model and performed blood immune profiling. For in vitro studies, we used 448T (TrkB.T1 high) and 559T (TrkB.T1 low) glioma stem cells (GSCs) to assess BDNF-TrkB.T1 signaling effects on cytokine profiles and neutrophil chemotaxis. EMT changes were examined via western blot and transwell migration assays.
Results: NTRK2 expression in gliomas was inversely correlated with PTPRC, and higher NTRK2 levels were linked to reduced immune cell infiltration. In vivo, TrkB.T1 expression reduced classical dendritic cells and T cell-activating cytokines, while increasing microglial density and neutrophil infiltration, indicating an immunosuppressive TME. Conversely, TrkB.T1 KO mice showed increased effector CD8+ T cells. In vitro, BDNF-TrkB.T1 signaling promoted chemokine release linked to neutrophil recruitment and T-cell inactivation, and enhanced neutrophil migration in GSC-BDNF chemotaxis assays. BDNF stimulation also increased N-cadherin and GSC migration, indicating an EMT phenotype.
Conclusion: These findings reveal the role of BDNF-NTRK2 splice variant TrkB.T1 in promoting immunosuppressive TME and EMT in gliomas, suggesting a therapeutic opportunity to target TrkB.T1 in future translational and clinical studies.

#6132 Linking metabolic reprogramming to JAK-STAT signaling in triple-negative breast cancer brain metastasis.

Jayshree Mishra[1], Narendra Kumar[2]

[1]Pharmaceutical Sciences, Texas A&M University, KINGSVILLE, TX,[2]Texas A&M University, Kingsville, TX

Introduction: Triple-negative breast cancer (TNBC) is an aggressive breast cancer subtype disproportionately affects younger patients and associated with high recurrence rates and rapid disease progression. TNBC cells that colonize the brain undergo extensive metabolic reprogramming to survive in this specialized microenvironment. Understanding the mechanisms by which TNBC cells adapt their metabolism and signaling networks to thrive in the brain niche is critical to uncovering novel vulnerabilities for therapeutic intervention.
Materials and Methods: To address this knowledge gap, we conducted integrated metabolomic and transcriptomic analyses utilizing a TNBC brain metastasis (BM) xenograft mouse model, with validation in human patient-derived tissues. Metabolite profiling was performed using liquid chromatography-mass spectrometry equipped with an ACQUITY UPLC BEH C18 column. Matched samples from primary tumors, brain metastases, and serum were analyzed. Metabolite deconvolution employed AMDIS software, and compound identification was cross-referenced with NIST and HMDB spectral databases. Unique metabolites enriched in brain metastases and serum were identified and subjected to pathway enrichment analysis using MetaboAnalyst. To integrate metabolic findings with gene expression, pathway-associated genes were cross-referenced against transcriptomic datasets (GEO GSE76714), enabling network analysis of metabolite-gene interactions.
Results: Our integrative analyses revealed that RNF125, an E3 ubiquitin ligase involved in immune regulation and oncogenesis, functions as a central regulatory node connecting metabolic pathways to the JAK-STAT signaling axis. RNF125 upregulation was inversely correlated with JAK3 activity, suggesting a role in modulating cytokine signaling to promote TNBC cell adaptation within the brain microenvironment.
Conclusion: This study identifies RNF125 as a novel biomarker and potential therapeutic target in TNBC brain metastasis.

#6133 Horizontal mitochondria transfer stimulates pro-tumorigenic astrocyte reprogramming in glioblastoma.

Jonathan Mitchell[1], Brandon Leon[1], Oriana Teran Pumar[1], Asmita Pathak[1], Carolina De La Pena Fernandez[1], Pedro Assenza Tavares Coroa[1], Ogechukwu Mbegbu[2], Yi-An Chen[2], Floris P. Barthel[2], Justin Ruiz[1], Irem Karaman[1], Anna Lasorella[1], Antonio Iavarone[1], Defne Bayik[1], Dionysios C. Watson[1]

[1]University of Miami Miller School of Medicine, Miami, FL,[2]The Translational Genomics Research Institute, Phoenix, AZ

Glioblastoma (GBM), the most aggressive primary brain tumor, co-opts astrocytes in the tumor microenvironment (TME) to facilitate growth, immunosuppression, and therapeutic resistance. However, the signaling mechanisms driving these pro-tumorigenic astrocyte states are poorly defined. We previously showed that astrocytes donate mitochondria to GBM cells to augment GBM metabolism and self-renewal, but the role of mitochondria transfer in astrocyte biology and TME signaling remains unclear. To assess mitochondria transfer to astrocytes, we transduced patient-derived GBM cells (PDCs) with mitochondria-localized GFP (mito-GFP) and co-cultured them with human astrocytes, revealing that GBM cells transfer mitochondria to astrocytes in a cell type-dependent manner, with rates approaching 40% in some models. To additionally validate transfer, we performed deep mitochondrial DNA (mtDNA) sequencing of co-cultured astrocytes and detected transfer of unique PDC mtDNA variants to astrocytes. To evaluate transfer in the tumor microenvironment, we intracranially implanted mito-GFP PDCs in an orthotopic mouse model and found that tumor-associated astrocytes contained GBM-derived mitochondria at similar frequencies to in-vitro observations. Initial survival studies demonstrated that co-implantation of astrocytes with PDCs increased tumorigenesis, and we subsequently showed that co-implantation of astrocytes harboring GBM mitochondria further accelerated tumor growth. To characterize the functional consequences of GBM mitochondria transfer, we assessed transfer-positive astrocyte phenotypes and observed increased cell cycling, proliferation, cellular ROS, and altered oxidative metabolism. Critically, we found that astrocytes acquiring GBM mitochondria increased secretion of the chemokine CCL2 and facilitated enhanced recruitment of immunosuppressive myeloid cells. Collectively, these results suggest that GBM mitochondria transfer to astrocytes is both a pro-tumorigenic mechanism and a therapeutic vulnerability in the GBM TME. Ongoing studies will define the astrocyte signaling networks activated by mitochondria acquisition and identify molecular regulators of transfer initiation to enable therapeutic intervention.

#6134 Immunomodulatory *PIGR*$^{+}$*RORC*$^{+}$dendritic cells (PRDCs) are enriched in malignant ascites.

Steven M. Blum[1], Thomas L. Chan[1], Neal P. Smith[1], Courtney Ambrose[1], Katherine H. Xu[1], Alice Tirard[1], Nandini Samanta[1], Sidney Martin[1], Roya Best[1], Elizabeth Tuttle[1], Christopher T. Stueber[1], Vaishnavi R. Yalala[1], Haley Barnes[1], Sean T. Bannon[1], Yuhui Song[1], Benjamin Y. Arnold[1], Mushriq Al-Jazrawe[2], Joseph J. Zhao[3], Kamil Slowikowski[1], Jessica Tantivit[1], Kasidet Manakongtreecheep[1], Lukas M. Altenburger[1], Simon Knott[4], Matthew R. Strickland[1], Michael G. Drage[1], Linda T. Nieman[1], Jesse S. Boehm[2], Raghav Sundar[5], Gary Reynolds[1], Samuel J. Klempner[1], Alexandra-Chloe Villani[1]

[1]Massachusetts General Hospital, Boston, MA,[2]Koch Inst. for Integrative Cancer Research at MIT, Cambridge, MA,[3]Yong Loo Lin School of Medicine, Singapore, Singapore,[4]Cedars-Sinai Medical Center, Los Angeles, CA,[5]Yale University School of Medicine, New Haven, CT

Background: Peritoneal carcinomatosis and malignant ascites are frequently caused by solid tumors, and the presence of ascites is associated with a poor prognosis and resistance to immune checkpoint inhibitors. While some immunosuppressive features of ascites have been described, the role of dendritic cell (DC) subsets in this microenvironment is unknown. Recently, a subset of DCs that express *RORC* have been found in normal mouse and human tissues, and they have been linked to tolerance of gut antigens. However, this DC population has not previously been associated with cancer or well characterized in humans.

Methods: We performed single-cell RNA sequencing (scRNA-seq) with paired surface proteomics (CITE-seq), and secreted proteomics (n = 109 analytes) on ascites (n = 23) and matched peripheral blood (n = 15) from patients with gastric and gastroesophageal adenocarcinoma (GEA; n = 523,322 total cells). Allogeneic mixed lymphocyte reactions (MLRs) were performed using DCs from GEA and pancreas cancer patients with ascites. *In vitro* differentiation experiments leveraged cDCs from healthy donors and cultured them in media supplemented with ascites supernatant or paired plasma from GEA patients.

Results: We identified a DC subset expressing *PIGR* and *RORC* (PRDCs) that were transcriptionally distinct from canonical DC subsets and similar to tolerogenic cell subsets. Analysis of >1x10^{7} cells from public datasets suggest that PRDCs are found in other human tissues but enriched in malignant ascites from both GEA and ovarian cancers. Sorted PRDCs stimulated T-cell proliferation in MLRs. However, scRNAseq of T cells stimulated by PRDCs showed that those T cells were less effectively polarized due to reduced expression of effector cytokine genes (*e.g.*, *IFNG*, *IL5*, *IL13*) compared to T cells stimulated by cDC2s. Spatial transcriptomics confirmed the presence of PRDC-like cells in human lymphoid tissues, and neighboring, proliferating CD4 T cells similarly showed reduced polarization signatures. Features of the PRDC transcriptional program could be induced by culturing blood-derived cDC1s from healthy donors in supernatant from patients with malignant ascites, suggesting that PRDCs are induced in the ascites microenvironment.

Conclusions: PRDCs represent a conserved, immunomodulatory DC subset enriched in malignant ascites. PRDCs are capable of modulating T-cell responses and may represent a tolerogenic state induced by the ascites microenvironment. Targeting PRDCs or their differentiation pathways may offer new strategies to enhance anti-tumor immunity in patients with peritoneal metastases.

#6135 Amyloid-β accumulation in glioblastoma is driven by vascular remodeling and APP-processing pathways.

Felix Y. Narvaez Irizarry, Alondra M. Bermudez Adorno, Lilia Kucheryavykh

Biochemistry, Universidad Central del Caribe, Bayamon, PR

Background: Glioblastoma (GBM) is an aggressive brain tumor with a poor prognosis.Identifying biomarkers for targeted therapies remains a major challenge in GBM treatment.Recently, we demonstrated that amyloid-β (Aβ), a peptide classically associated with neurodegenerative diseases, accumulates in GBM tumors. This study aims to investigate the mechanism underlying Aβ accumulation in GBM tissues.
Methods: Immunohistochemical analysis and confocal imaging were performed to assessAβ localization in human GBM tissue sections. Glial fibrillary acidic protein (GFAP), ionizedcalcium-binding adaptor molecule 1 (Iba1), and CD31 were used as markers of astrocytes, microglia, and blood vessels, respectively. Western blot analysis was performed toevaluate the expression of Aβ and amyloid precursor protein (APP), along with matrixmetalloproteinases 2 and 9 (MMP-2 and MMP-9), presenilin-1, nicastrin proteins involved inAβ production and vascular endothelial growth factor (VEGF). Pearson correlation analysis was conducted to assess relationships among Aβ, VEGF, MMP-2/9, presenilin-1, and nicastrin.
Results: Confocal imaging revealed robust Aβ accumulation in blood vessels and in tumor regions with high vascularization, as well as strong Aβ accumulation in microglia and, to alesser extent, in glioma cells. Western blot analysis showed strong correlations betweenAβ levels and factors such as VEGF, MMP-2, and presenilin-1, indicating complex regulatory interactions driving Aβ accumulation.
Conclusion: These findings demonstrate that Aβ accumulation in GBM is closely linked to tumor vascularization and microglial involvement. The strong correlations with VEGF, MMP-2, and presenilin-1 suggest that both vascular remodeling and proteolytic processing contribute to Aβ buildup.This study was supported by: NIH Grants 1R15CA287203 and 1R16GM153522

#6136 Macrophages support the growth of pediatric posterior fossa ependymoma type A.

Gabrielle L. Persad[1], Kaitlin Kharas[1], Andrea Ribeiro[2], Alexandra Rasnitsyn[1], Michael D. Taylor[3], Lincoln David Stein[2]

[1]University of Toronto, Toronto, ON, Canada,[2]Ontario Institute for Cancer Research, Toronto, ON, Canada,[3]Baylor College of Medicine, Houston, TX

Posterior fossa type A ependymoma (PFA), the most prevalent of the nine ependymoma molecular subtypes, predominantly affects the hindbrain of infants and young children and has a five-year overall survival of only 56%. PFA harbors few genetic mutations, aside from H3K27M (2-4% of cases) and chromosome 1q gain (~20%). Instead, PFA displays hypoxia-dependent metabolic and epigenetic regulation. *In vitro*, even transient exposure of PFA cells to normoxia results in irreversible toxicity and rapid senescence.

To investigate microenvironmental support, we applied single-cell and spatial transcriptomics to primary PFA tumors. Metabolic pathway analysis revealed that macrophages upregulate glycolysis-related programs. Both macrophages and hypoxic tumor cells exhibited elevated inflammation and glycolysis signatures, suggesting a shared metabolic niche. Spatial mapping revealed a regional hypoxic microenvironment consisting of proliferating PFA cells in close apposition to macrophages.

Functional studies using co-culture and conditioned media experiments revealed a high-molecular weight diffusible factor in macrophage-conditioned media that enhances PFA cell growth under hypoxia and, strikingly, enables their growth under normoxic conditions, where PFA cells are otherwise non-viable.

These findings uncover a critical functional interaction between PFA cells and macrophages that supports tumor growth beyond the hypoxic conditions. Exploring and leveraging intercellular crosstalk between PFA and its microenvironment could open up new avenues for novel therapeutic intervention. Additionally, as there are currently no reliable mouse models to study PFA, understanding how the tumor grows could enable the development of the cells and conditions required for successful patient-derived xenograft models.

#6137 Multi-omicsinpostoperative lymphatic exudate in HPV-negative head and neck cancer.

Zachary Costliow[1], Seka Lazare[1], Zhuosheng Gu[1], Adam Harmon[1], Maciej Pacula[1], Megan Rivera[1], Aadel A. Chaudhuri[2], Jose P. Zevallos[3], Jessalyn Marie Ubellacker[4], Wendy Winckler[1]

[1]Droplet Biosciences, Inc., Cambridge, MA,[2]Mayo Clinic, Rochester, MN,[3]University of Pittsburgh Medical Center, Pittsburgh, PA,[4]Harvard T.H. Chan School of Public Health, Boston, MA

Our team has demonstrated that lymphatic exudate collected via surgical drains (“lymph”) is a proximal biofluid rich in ctDNA and prognostic of recurrence in HPV-independent Head and Neck Cancer (HPV- HNSCC). Other analytes such as proteins, metabolites, and cells are also abundant in lymph. To understand the liquid tumor microenvironment (TME) immediately after tumor resection, we characterized lymph at 24 hrs in HNSCC. We performed a multi-omic survey, demonstrating that lymph is distinct from plasma and represents a largely unexplored source of biomarkers relevant to immune modulation and metastasis.Metabolomics and proteomics were run on lymph supernatant and plasma. Proteomic screening was performed via Olink and normalized to internal standards for quantitative analysis. Metabolomic samples were assayed via LC-MS and normalized. 16s libraries were sequenced utilizing Illumina and analyzed in QIIME. 16s sequencing on 6 patients indicated an array of bacterial genera present in post-surgical lymph with consistency across patients. The distribution consisted primarily of microbes native to the oral cavity, suggesting post-surgical lymph may reflect the native microbiome prior to surgery. Pathogenic blooms were observed in a subset of patients. Ongoing analysis will correlate microbiome data with both cancer and surgical outcomes.Metabolite profiling was performed on post-surgical lymph and matched plasma from 4 patients, including 3 who recurred within 1 year of surgery. The metabolite profile in lymph of all 4 patients was more diverse than plasma with higher metabolite abundance per mL. 13% of identified metabolites were >2-fold enriched in lymph. Lymph from recurred patients showed high levels of saturated and monounsaturated fatty acids, reported to be associated with metastasis. Post-surgical lymph has a unique and largely uncharted metabolome to mine for biomarkers associated with recurrence.Proteomes were compared between lymph and plasma from 44 HPV-HNSCC patients. This cohort consists of 25 recurred (REC) and 19 patients with no evidence of disease (NED) with >1 year of follow up. Lymph and plasma displayed highly non-overlapping protein repertoires. The mean absolute volcano score was 25.2, indicating a strong global difference between lymph and plasma. Lymph was significantly enriched in 91 proteins (p range 4.1e-47 to 0.037), many associated with inflammation. REC lymph was also enriched in inflammatory markers compared to NED, including IL-1a, TNF, and TSLP (p = 0.002, 0.015, 0.003, respectively), which have been implicated in cancer metastasis, invasion, and angiogenesis. Lymph hits were largely non-overlapping with plasma, indicating the opportunity for novel biomarker discovery in this fluid.
Analysis of the microbiome, metabolome, and proteome of post-surgical lymph reveals a rich and differentiated tumor-adjacent biofluid to study biomarkers relevant to metastasis and the TME.

#6138 Profiling the unique resident immune cell compartment in acral skin and its implications for acral melanoma tumor immunity.

Joshua K. H. Tay[1], Emilio Cortes-Sanchez[2], Amanda Jiang[3], Anastasia Prokofyeva[3], Robert Judson-Torres[4], Melissa Q. Reeves[1]

[1]Microbiology & Immunology, Huntsman Cancer Institute, Salt Lake City, UT,[2]Surgical Oncology, Huntsman Cancer Institute, Salt Lake City, UT,[3]Oncological Sciences, Huntsman Cancer Institute, Salt Lake City, UT,[4]Dermatology, Huntsman Cancer Institute, Salt Lake City, UT

Acral melanoma is a rare and understudied form of melanoma that arises in either glabrous skin or the nail matrix and bears distinct characteristics from other cutaneous melanoma subtypes. The purpose of our study is to investigate biological underpinnings that may explain why acral melanomas have worse prognosis and worse response to therapy, including immunotherapy, when compared with other cutaneous melanoma subtypes in patients. It has been previously reported that the tumor microenvironment in acral melanoma is less infiltrated by T cells compared with other cutaneous melanomas subtypes. We hypothesized that the resident immune cells in non-tumor bearing skin may differ between skin sites and could help explain the downstream immune response to a tumor. To test this hypothesis, we obtained paired sets of non-tumor bearing glabrous (acral) and non-glabrous skin from a human donor and enzymatically treated them to enable mechanical separation of the epidermis from the dermis. We then profiled the resident immune cells in the epidermis and dermis separately by flow cytometry. We quantified T cells, macrophages, dendritic cells, and Langerhans cells and discovered a distinct cadre of immune cells at each site. We observed a dramatic reduction in the abundance of Langerhans cells in the epidermis at glabrous sites. Langerhans cells are skin-resident antigen presenting cells that play a critical role in immune surveillance, and reside in the epidermis, the same layer of the skin as melanocytes, the cell of origin of melanoma. These findings open new avenues for future investigation into how early immune surveillance by Langerhans cells to nascent melanomas may directly influence long-term tumor immunity in acral melanoma and its response to immunotherapy.

#6139 Development of a flow cytometry panel for microglia and immune cell populations in a brain tumor model.

Helen Ketteringham[1], Cheryl Davis[2], Mollie McArthur[1], Corrine Silvio[3], Shannan Paul[3], Ben Hoerner[3], Victoria Caruso[3], Liz Bailey[4], Chris Holding[5], Aliccia Koznecki[5], Dawn Lusk[3], Shorena Nadaraia-Hoke[3]

[1]Reaction Biology Corp, Malvern, PA,[2]Reaction Biology Europe GmbH, Freiburg im Breisgau, Germany,[3]Reaction Biology Corp, Hummelstown, PA,[4]Reaction Biology Corp, Boston, MA,[5]Reaction Biology Corp, Hershey, PA

Accurate characterization of microglia and infiltrating immune cell populations is essential for understanding the immunological landscape of brain tumors and for evaluating therapeutic responses. Here, we report the development and optimization of a multicolor flow cytometry panel tailored to discriminate resident microglia from peripheral myeloid and lymphoid subsets within an experimental brain tumor model. Marker selection was guided by tissue-specific expression profiles, leveraging differential levels of CD45, CX3CR1, and P2RY12 to resolve microglia, while incorporating canonical markers for infiltrating macrophages, dendritic cells, neutrophils, and T cells. Enzymatic dissociation conditions, viability dye selection, and gating hierarchy were systematically optimized to preserve epitope integrity and maximize signal resolution. Validation using tumor-bearing and control brain tissues demonstrated robust separation of microglial and infiltrating populations with reproducible quantification across biological replicates. This workflow provides a reliable and scalable approach for immune profiling in brain tumor research, enabling deeper insight into neuroimmune interactions and immunotherapy-driven changes within the tumor microenvironment.

#6143 Tumor exosome-initiated neutrophil IRG1/itaconate axis awakens dormant tumor cells and promotes lung metastasis.

Yue Deng, Jialin Lu, Xiao Yang, Lingyi Kong, Chao Wan, Kunyu Yang

Cancer Center, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China

Purpose/Objective(s): Tumor cell dormancy and metabolic reprogramming are critical events in metastatic relapse. However, the mechanisms, particularly how the lung pre-metastatic niche and its associated metabolic alterations awaken dormant disseminated tumor cells (DTCs), remain elusive. This study aims to decipher the cascade from primary tumor-derived exosomes to DTC reactivation in the pre-metastatic lung, specifically identifying the key metabolite-mediated pathway driving this process.

Materials/Methods: We employed multiple mouse models of spontaneous lung metastasis (e.g., B16-F10, Lewis). To comprehensively profile the pre-metastatic niche, we performed untargeted metabolomics on lung tissues to identify differentially enriched metabolites, and single-cell RNA sequencing (scRNA-seq) to delineate the cellular source of *Irg1*. Other key techniques included: *in vivo* imaging and H&E staining for metastasis tracking; generation of $Irg1^{flox/flox}$ mice with Mrp8-Cre for neutrophil-specific *Irg1* deletion; RNA-seq of sorted alveolar macrophages; co-immunoprecipitation and Western blotting for itaconate-mediated LATS2 alkylation validation; chromatin immunoprecipitation (ChIP) for YAP1 nuclear translocation.

Results: We delineated a sequential pathway driving metastatic reactivation in the lung. Initially, primary tumor-derived exosomes educated $SPP1^{+}$ alveolar macrophages to bolster the production of CXCL2 and ensue neutrophil recruitment. Subsequently, these lung-infiltrating neutrophils specifically expressed *Irg1*, resulting in a marked accumulation of the metabolite itaconate within the pre-metastatic niche. Mechanistically, itaconate directly alkylated dormant DTCs at the C910 and C911 site of the key upstream kinase LATS2 in the Hippo pathway. This modification inhibited the LATS2's capacity to phosphorylate YAP1, thereby promoting the nuclear translocation of unphosphorylated YAP1 to activate a pro-proliferative transcriptional program, forcing DTCs to exit dormancy. Crucially, this entire axis was disrupted by either neutrophil-specific genetic ablation of *Irg1* or pharmacological inhibition of CXCR2, both of which significantly reduced tumor lung metastasis.

Conclusions: Our work unveils a novel paradigm in which the tumor exosome-neutrophil axis drives metastatic reactivation via metabolite-mediated protein alkylation. We pinpoint the neutrophil-IRG1-itaconate axis as a pivotal signaling cascade in this process, and our findings demonstrate that therapeutic targeting of this axis, either upstream at CXCR2 or at the metabolite itaconate, represents a viable strategy to prevent tumor lung metastasis.

#6144 A site-specific microenvironmental program in plantar skin confers heightened metastatic capacity to acral melanomas.

Marie Elena Portuallo[1], Tyler Aprati[2], Limin An[1], Steffanus Pranoto Hallis[3], Kuai Yu[1], MiKaela N. Field[4], Sheri L. Holmen[4], David Liu[2], Vito Rebecca[1]

Acral melanoma is an aggressive melanoma subtype with a predilection for metastasis and poor clinical outcomes, yet no FDA-approved therapies are tailored specifically for this population. Progress has been hindered by limited clinico-genomic data and a lack of orthotopic preclinical models. Here, we integrate genomic profiling and longitudinal clinical annotations from 29 patients with metastatic acral melanoma—alongside a comparison cohort of 455 patients with cutaneous melanoma—revealing an enhanced metastatic capacity in acral disease. We further show that the plantar skin microenvironment fosters a human acral melanoma, pro-metastatic cell state through elevated matrix stiffness, and identify a matrix stiffness-induced FAK-SRC-YAP vulnerability as a therapeutically actionable axis to combat distant metastasis. This work establishes the first series of orthotopic models of metastatic acral melanoma and uncovers tractable drivers of distant organ metastasis, offering new avenues for tailored therapeutic strategies.

#6145 Regulation of small extracellular vesicle production by sirtuin 1 as a determinant of breast cancer metastasis.

Yu-Wei Chang[1], Michael Guo[1], Aidan M. Quinn[1], Anthony M. Chen[1], James J. Mullmann[1], Andrew D. Miller[2], Richard A. Cerione[3], Marc A. Antonyak[4], Robert S. Weiss[1]

[1]Department of Biomedical Sciences, Cornell University, Ithaca, NY,[2]Department of Population Medicine and Diagnostic Sciences, Cornell University, Ithaca, NY,[3]Department of Molecular Medicine & Department of Chemistry and Chemical Biology, Cornell University, Ithaca, NY,[4]Department of Molecular Medicine, Cornell University, Ithaca, NY

Metastatic breast cancer remains a major clinical challenge and the primary cause of breast cancer-related mortality. Increasing evidence points to a role for tumor-derived small extracellular vesicles (EVs) secreted by cancer cells in preparing distant sites for metastasis. Sirtuin 1 (SIRT1), a metabolic and epigenetic regulator frequently downregulated in advanced breast cancer, influences key cellular processes, including lipid metabolism and autophagy, both of which are implicated in EV biogenesis. However, the mechanisms by which SIRT1 loss alters small EV production and function to promote breast cancer metastasis remain unclear. In this study, we investigated how SIRT1 expression influences the production and cargo of small EVs released by breast cancer cells, and how these changes affect aggressiveness. First, using triple-negative breast cancer (TNBC) cell lines with genetically altered SIRT1 levels, we observed that SIRT1 loss increased small EV secretion. Second, incubation of recipient breast cancer cells *in vitro* with small EVs derived from SIRT1-deficient cells enhanced their migration and invasiveness to a greater extent than with small EVs from SIRT1-proficient control cells. *In vivo*, inhibition of SIRT1 by genetic or small molecule approaches led to the development of larger tumors in both orthotopic transplantation and MMTV-PyMT mouse mammary tumor models. Moreover, animals preconditioned with small EVs derived from SIRT1-deficient cells, followed by tail vein injection of mammary tumor cells, showed increased lung colonization and metastatic outgrowth compared to those preconditioned with EVs derived from control cells, suggesting that SIRT1 regulation of EV cargo contributes to shaping a pro-metastatic microenvironment. In conclusion, this work identifies a novel link between SIRT1 status in breast cancer cells and their small EV-mediated signaling potential. Our findings position SIRT1 as a key regulator of small EV content and underscore the therapeutic potential of targeting SIRT1-dependent pathways that drive small EV-mediated metastasis in breast cancer.

#6146 Analysis of potential drivers of tungsten-enhanced breast cancer metastasis: A longitudinal study of bone marrow adipocytes.

Charlotte Marie McVeigh[1], Jennifer A. Tjung[1], Jorge L. Moreno[1], Sydnee J. Yazzie[2], Lauren K. Heine[1], Grace A. Picha[1], Guy W. Herbert[1], Sebastian Medina[1], Alicia M. Bolt[1]

[1]Pharmaceutical Sciences, University of New Mexico Health Sciences Center, Albuquerque, NM,[2]Pathology, University of New Mexico Health Sciences Center, Albuquerque, NM

Tungsten (W) is classified as an emerging environmental toxicant due to increased human exposure and lack of knowledge of the health risks. Epidemiological and *in vivo* studies reveal exposure to W contributes to the carcinogenic process, but molecular mechanisms are poorly defined. Due to a cohort of breast cancer patients accidentally exposed to W during intraoperative radiotherapy, our lab is investigating the effects of W on breast cancer progression and metastasis. W is known to store in the bone, causing long-term exposure and toxicity. Previous research in our lab has shown in multiple triple-negative breast cancer orthotopic models, W enhances breast cancer metastasis to the bone niche. Bone marrow adipocytes (BMA) play an important role in metastasis through secretion of adipokines/cytokines that drive tumor cells homing, colonization, and growth by changing the microenvironment. Understanding changes throughout metastasis is crucial to uncover adipokines/cytokines that could drive colonization and proliferation of tumor cells in the bone niche after W exposure. 6-8 week old female BALB/c or C57BL/6 mice were exposed to 15ppm W in drinking water or tap water for 4 weeks. After 4 weeks, mice had orthotopic injections of 4T1 (BALB/c) or E0771-Luc (C57BL/6) cells into the mammary fat pad. Longitudinal time points were taken to track changes with no tumor cell injection (0 week; 0W), 2 week post injection (2 week; 2W), and 3 week post injection (3 week; 3W). At the end, femurs were used for immunohistochemistry staining of Perilipin-1+ (Plin1+) adipocytes in bone marrow. Bone marrow from tibiae was cultured to select for mesenchymal stromal cells (MSC), which were then differentiated into BMA. Cell supernatant and RNA were collected from both MSCs and BMA to profile changes in adipokines/cytokines. Both models had increased metastasis to the bone after W exposure, 4T1 induced greater systemic inflammation compared to E0771-Luc. Adiponectin levels remained unchanged in E0771-Luc, but increased after W exposure at 2W and 3W in 4T1. CXCL2 expression was increased after W exposure at 0W and 2W and trending at 3W in 4T1 and increased at 3W in E0771-Luc. Plin-1+ staining revealed E0771-Luc has more adipocytes compared to 4T1, regardless of exposure. Some analytes did not change with W exposure or weekly, suggesting that those may not be not the main drivers of metastasis. Analytes like Adiponectin showed changes after W exposure, but were dependent upon the model. This suggests that there are differences between models and W might do slightly different things in each one, including systemic inflammation that we observed more in the 4T1 compared to the E0771-Luc. CXCL2 was increased in both models, suggesting a common key player in enhanced metastasis to the bone. This study provides insights into adipokine/cytokines that might be crucial players in W enhanced breast cancer metastasis to the bone.

#6148 GPR35 as a therapeutic target to halt breast cancer progression and osteolytic bone metastasis.

Gunjan Sharma, KM Abdullah, Seema Singh, Ajay Singh, Jawed Siddiqui

Cell and Molecular Biology, UMMC Cancer Center and Research Institute, Jackson, MS

Bone metastasis is a frequent and devastating complication of breast cancer (BC) and causes severe skeletal-related events, reduced quality of life, and poor overall survival. BC cells engage in bidirectional interactions with the bone microenvironment by modulating the expression of various chemokines and their receptors, thereby promoting metastatic colonization and niche formation. Numerous G protein-coupled receptors (GPCRs) are implicated in oncogenic processes. Among them, G protein-coupled receptor 35 (GPR35), the cognate receptor for CXCL17, has recently been identified as a key regulator of tumor progression and metastasis. Nevertheless, its precise role in cancer progression, metastatic spread, and modulation of the bone microenvironment remains poorly understood. GPR35 is overexpressed in BC patients, and its elevated expression is strongly associated with reduced overall survival. Consistently, our study also demonstrates elevated GPR35 expression in breast cancer bone-metastatic (BC-BoneMet) cell lines, further supporting its potential role in driving bone metastatic progression. To functionally validate these observations, we generated GPR35 knockout (KO) BC-BoneMet cell lines using the CRISPR/Cas9 system. GPR35 deletion significantly reduced cell migration, invasion, and colony-forming ability *in vitro*. *In vivo* studies showed that loss of GPR35 in breast tumor cells led to significantly reduced primary tumor growth in syngeneic mice, supporting a critical role for GPR35 in driving tumor progression. To evaluate the therapeutic benefits of targeting the GPR35, we employed a highly selective GPR35 inhibitor (GPR35i). In functional studies, GPR35i markedly reduced the proliferation, migration, and clonogenicity of BC-BoneMet cells even under CXCL17 stimulation. Furthermore, flow cytometry revealed that GPR35i significantly induces apoptosis and cell cycle delay in BC-BoneMet cells. Given that most BC bone metastases are osteolytic (bone-destructive) and osteoblasts regulate osteoclast functions, we also investigated the effects of the tumor secretome on bone cells. The secretome of GPR35-deficient tumor cells failed to promote bone cell differentiation. Similar effects were observed when the secretome of GPR35i-treated BC-BoneMet cells was applied to osteoblast and osteoclast differentiation assays. Conclusively, these findings demonstrate that GPR35 plays a key role in breast cancer bone metastasis by remodeling the bone microenvironment and supporting the formation of a metastatic niche. These findings highlight GPR35 as a promising therapeutic target for preventing osteolytic progression and reducing metastatic burden in bone.

#6149 Oncogenic ASPP2*kappa* exerts a regulatory role within the tumor microenvironment and promotes metastasis in TNBC models.

Cornelia Wincek[1], Alessia Ruiba[1], Wenfeng Liu[2], Sakthi Kembu Chettiar Ravichandran[1], Marcus M. Schittenhelm[1], **Kerstin Maria Kampa-Schittenhelm**[1]

[1]Med. Oncology and Hematology, HOCH Health Ostschweiz, St. Gallen, Switzerland,[2]HOCH Health Ostschweiz, St. Gallen, Switzerland

Breast Cancer is the most common cancer in woman to date. While cure rates in localized stages are relatively good, tumor-associated death rates increase dramatically in the distant metastatic stage. Composition of the tumor microenvironment plays a decisive role therein. Metastasis is a complex, multistep process involving a multitude of intracellular steps of transformation, as well as interactions of tumor cells with the surrounding environment. The mechanisms underlying these processes are only partially understood. We have evidence that ASPP2*κ*, a novel, oncogenic isoform of the p53-related tumor suppressor ASPP2, is involved in this process. ASPP2*κ* is highly expressed in breast cancer and characterized by loss of the p53- as well as BCL-2 and NFκB-binding sites, impairing major pathways controlling cellular fate. We have demonstrated, that ASPP2*κ* promotes a more aggressive tumor biology and shorter patient survival. We now show that ASPP2*k* exerts a pro-tumorigenic role within the tumor microenvironment, facilitating neo-angiogenesis and early metastasis. To study the role of ASPP2*κ* in a tissue context, we established a TNBC *ASPP2κ* knock-down (KD) NOD/SCID as well as an immunocompetent BALB/C orthotopic *ASPP2k* knock-in mouse model, employing the human TNBC MDA-MB-231 and the murine 4T1 cell lines. ASPP2*k* KD and KI primary and metastatic lesions, as well as the respective controls, were explanted and analyzed on the transcriptional and translational level. Proteome arrays and bulk RNA sequencing was performed on TNBC cell models. Results were confirmed by qPCR, WB, FACS and ELISA assays. All conducted analyses confirme a driving role of ASPP2*k* in angiogenesis and early metastasis as well as a tumor promoting role in the microenvironment. Comprehensive analyses of our bulk RNA sequencing data identified significant differential expression patterns of genes clustered within the GO terms “angiogenesis”, “EMT” and “immune response” (149/200 genes within GO:0001525 angiogenesis, 33/43 genes associated with GO:0001837 EMT and 134/194 genes linked to the GO:0006955 Immune Response). Pathways involved in metastasis, angiogenesis and pro-inflammatory signaling were studied in detail in dependency of ASPP2*κ* expression. ELISA readouts confirmed secretion of pro-angiogenic growth factors (eg. VEGF, Angiogenin or PDGF) in dependency of ASPP2*κ* expression (KD cells: VEGF 247.2 ± 97.8 pg/mL vs. 535.9 ± 60.8 pg/mL in controls). TNBC tumoroid models confirme inhibition of invasive growth in ASPP2*κ* attenuated models. Differences in vascularization were confirmed by immunohistochemistry and confocal microscopy.

We here demonstrate, that ASPP2*κ* exerts a regulatory role on key hallmarks of metastasis and the tumor microenvironment, promoting tumor progression and metastasis. Therapeutic inhibition of ASPP2*κ* might provide a completely new approach to combat metastasis in the future.

#6150 Cathepsin G as a central regulator of tumor plasticity and osteolytic metastasis in breast cancer.

Ridhi Bhola[1], Reegan Sturgeon[2], Gabriel Tonucci[1], Rakesh K. Singh[3]

[1]Pathology, Microbiology, and Immunology (PMI), University of Nebraska Medical Center, Omaha, NE,[2]University of Nebraska Medical Center, Omaha, NE,[3]Professor, Dept. of Microbio. & Path., University of Nebraska Medical Center, Omaha, NE

Breast cancer frequently metastasizes to bone, where osteolytic lesions drive substantial morbidity. We identified Cathepsin G (CTSG), a serine protease expressed by both tumor cells and neutrophils, as being highly upregulated at the tumor-bone interface. However, the distinct contributions of tumor- versus neutrophil-derived CTSG remain poorly defined. To examine the role of CTSG in modulating malignant phenotype, we treated breast cancer cells with recombinant CTSG (rCTSG), which reduced proliferation, induced cell cycle arrest, promoted homotypic aggregation and collective migration; and induced a luminal to basal shift. Modeling tumor-derived CTSG through stable overexpression reproduced these effects and, in vivo, suppressed tumor growth yet paradoxically enhanced osteoclast activation and bone destruction. Immunohistochemical analysis indicated that tumor-derived CTSG reduced proliferation, did not significantly affect apoptosis, and altered epithelial characteristics, particularly at the tumor-bone interface. To assess neutrophil-derived CTSG, we co-cultured breast cancer cells with neutrophils, which similarly inhibited proliferation, promoted aggregation and migration, implicating a paracrine role. Together, our findings position CTSG as a central regulator of tumor phenotype and bone-tumor interactions and highlight it as a potential therapeutic target in breast cancer bone metastasis.

#6151 ESR1 mutations rewire TGF-B and hedgehog signaling to drive endocrine resistance and osteolytic bone metastasis in estrogen receptor-positive breast cancer.

Erykah J. Coe[1], Julie Rhoades[2]

[1]Program in Cancer Biology, Vanderbilt University School of Medicine, Nashville, TN,[2]Department of Medicine, Vanderbilt University Medical Center, Nashville, TN

Endocrine therapy-resistant ER+ breast cancer frequently acquired activating *ESR1* mutations (e.g. Y537S) conferring ligand-independent ER activation and aggressive bone metastasis, yet underlying mechanisms remain unclear. We hypothesized that *ESR1* mutations promote bone colonization by simultaneously dysregulating TGF-β/SMAD and Hedgehog/Gli2 pathways. Wild-type and mutant (Y537S) MCF7 and T47D cells with ERE-luciferase reporters showed Y537S cells maintained elevated basal PTHrP transcription independent of estrogen while responding to TGF-β. Intratibial xenografts demonstrated Y537S tumors induced greater osteolytic lesion burden than wild-type, with TGF-β neutralization significantly reducing lesion formation. RNA-seq revealed Y537S cells exhibited dramatic Gli2 and PTHLH upregulation. Critically, ligand-stimulation activated Gli2/PTHLH in mutant but not in wild-type cells. CRISPR-mediated Gli2 knockout reduced PTHrP production while Gli2 overexpression maximized osteolytic potential. These results demonstrate that *ESR1* mutations reprogram ER to activate dual bone-remodeling pathways (TGF-β/SMAD and Hedgehog/Gli2) explaining aggressive bone metastatic phenotypes and identify ER, TGF-β/SMAD, and Gli2 as rational combination therapeutic targets.

#6154 A single-cell atlas reveals a tumor microenvironment-dominated ecosystem in breast cancer brain metastasis.

Chuanbao Zhang[1], Wang Jia[2], Lei Xing[1], Md Tauhidul Islam[1]

[1]Stanford University, Stanford, CA,[2]BEIJING TIANTAN HOSPITAL, CAPITAL MEDICAL UNIVERSITY, Beijing, China

Purpose. Brain metastasis in breast cancer is a major cause of mortality, yet the cellular heterogeneity and dynamic evolution of the tumor microenvironment (TME) during metastatic progression remain poorly defined. The aim of this study was to elucidate the transcriptional and microenvironmental reprogramming that accompanies breast cancer metastasis to the brain.
Experimental Design. We integrated single-cell RNA sequencing data from primary breast tumors, lymph node metastases, and brain metastases (n=65) to construct a comprehensive single-cell transcriptomic atlas. We performed Non-negative Matrix Factorization to identify malignant cell metaprograms and applied multi-layered analyses to assess genomic instability, subtype plasticity, and cell-cell communication within the TME. We further validated the results in bulk RNA sequencing data (N=1184).
Results. Metastatic progression was associated with increased genomic instability and amplification of brain-metastasis-specific genes, including UBE2M, which correlated with poor prognosis. At single-cell resolution, we observed marked transcriptional plasticity of clinical subtypes, with ER$^+$ tumors frequently converting to more aggressive intrinsic subtypes in the brain. Ten malignant metaprograms were defined, with conserved inter-program interactions but sample-type-specific activity; notably, hypoxia and oxidative phosphorylation programs were enriched in brain metastases. The TME underwent profound remodeling, becoming depleted of stromal and immune infiltrates but developing a dense, autonomous intercellular signaling network dominated by myeloid and endothelial cells.
Conclusions. This study delineates the co-evolution of tumor-intrinsic states and the TME during metastatic dissemination, revealing that the brain microenvironment becomes an independent signaling hub that supports colonization. These findings underscore the pivotal role of the TME in shaping metastatic adaptation and suggest new avenues for therapeutic intervention in advanced breast cancer.

#6155 S-Nitrosylated COX-2 is a microenvironment-regulated breast cancer biomarker of mesenchymal phenotypes.

Reuben J. Hoffmann[1], AeSoon Bensen[1], Mark Dane[2], Jane Arterberry[1], Rebecca Smith[2], James Korkola[2], Pepper Schedin[1]

[1]CDCB, OHSU Knight Cancer Institute, Portland, OR,[2]BME, OHSU Knight Cancer Institute, Portland, OR

COX-2 is an inducible enzyme key to the production of inflammatory prostaglandins. COX-2 also has tumor intrinsic oncogenic activity in mouse models of breast cancer. Previously, we reported that increased expression of Cys-526-nitrosylated COX-2 (SNO-COX-2), but not non-nitrosylated COX-2, associated with progression of early-stage human breast cancer to invasive ductal carcinoma. Here, we used a 3D culture model of early-stage human breast cancer (MCF10DCIS cells) to investigate the relationship between SNO-COX-2 expression and mesenchymal/invasive tumor cell morphology. We find that SNO-COX-2, but not non-nitrosylated COX-2, closely associated with mesenchymal phenotypes induced by fibrillar type I collagen. Interestingly, invasive phenotypes did not associate with induction of classic epithelial-to-mesenchymal transition (EMT) markers including *SNAIL*, *CDH2* (N-cadherin), and *VIM* (vimentin). By contrast TGFβ-1 strongly induced EMT-related transcripts, but not SNO-COX-2 protein expression nor mesenchymal phenotypes. These observations suggest that in MCF10DCIS cells, SNO-COX-2 associates with mesenchymal phenotypes more strongly than non-nitrosylated COX-2 protein or expression of classic EMT transcripts. Supporting these observations *in vivo*, a heterogeneous mouse breast tumor model (D2A1 cell injection) demonstrates that invasive mesenchymal tumor regions also have increased SNO-COX-2 expression compared to epithelial tumor regions. Further, using a microenvironment microarray to test MCF10DCIS.com cells 300 distinct tumor microenvironment conditions we find SNO-COX-2 protein expression is driven by inflammation, wound resolution, and cancer-associated factors. Standouts include TNC, SPP1, decorin, fibrillar type I and III collagens, INF-γ, and IL-4/13, with evidence for specific extracellular matrix-ligand interactions driving both high and low SNO-COX-2 expression. In sum, in MCF10DCIS cells, expression of SNO-COX-2 is highly microenvironment-dependent and strongly associated with invasive/mesenchymal growth, indicating potential for SNO-COX-2 as a biomarker to assess risk of early-stage breast cancer progression.

#6156 Omega-6 lipid-gene module linked to colorectal cancer pre-metastatic niche.

Ramani Soundararajan[1], Lance Pflieger[2], Gunjan Upadhyay[3], Michelle M. Maurin[1], Mingli Yang[1], Michael Schell[4], McKayla Carr[1], Ahalya Sekhar[1], Rachel Kenis[1], Heiman Wang[1], Michael Nebozhyn[5], Andrey Loboda[6], Aejaz Nasir[7], W. Jack Pledger[8], Ganesh V. Halade[3], Timothy J. Yeatman[9]

[1]Surgery, University of South Florida, Tampa, FL,[2]Buck Institute for Research on Aging, Novato, CA,[3]Internal Medicine, University of South Florida, Tampa, FL,[4]Biostatistics and Bioinformatics, Moffitt Cancer Center, Tampa, FL,[5]Merck Research laboratories, Boston, MA,[6]Director, Informatics&Analysis, Merck Research laboratories, Boston, MA,[7]BJ's Diagnostic and Precision Oncology, Tampa, FL,[8]Molecular Medicine, University of South Florida; Tampa General Hospital Cancer Institute, Tampa, FL,[9]Surgery, University of South Florida;Tampa General Hospital Cancer Institute, Tampa, FL

Introduction: We recently reported (Soundararajan *et. al.*, GUT, 2024) a strong pro-inflammatory lipid mediator bias in colorectal cancer (CRC), possibly related to the omega-6 rich fatty acid preponderance in western-style diets. The current project expands on those findings, linking omega-6 fatty acids to expression of inflammatory genes in human CRC and mouse models.
Method: We performed an integrative, multi-omics, weighted gene co-expression network analysis (WGCNA) of 25 quantified arachidonic acid-derived lipid mediators with whole transcriptomes from 293 primary and 77 metastatic human CRCs, to identify a lipid-gene module significantly associated with metastasis. In mice fed omega-6:omega-3 (10:1 w/w) *vs.* control (1:1 w/w) diets, we analyzed syngeneic CRC subcutaneous tumors using whole transcriptome RNA-sequencing. THP1-derived gene expression signatures for M0, M1 and M2 macrophages were correlated with the lipid-gene module.
Results: In the human tumors using an *unsupervised* analysis, we identified a pro-inflammatory lipid-gene module, linked to the clinical feature of metastasis (P< 1.1e-42), with prominence of "hallmark" genes linked to coagulation, complement, inflammation and EMT/tumor progression and associated with M1 macrophages. Analysis of murine tumors derived from animals fed a diet enriched with omega-6 fatty acids revealed a significant (p < 3.7329E-06), shared enrichment of 18 coagulation and EMT related genes --orthologous to those identified in the pro-inflammatory human lipid-gene module. Among the 18 genes, *SerpinA1b*, *SerpinA1d*, *SerpinA3k*, *Ambp* and *Plg* with anti-inflammatory and coagulation- *inhibitory* properties were *downregulated* in omega-6 fed mice. Moreover, we observed a dramatic *decrease* in *Serpina1* protein expression in the hepatic sinusoids in omega-6 mice.
Conclusion: A human tumor pro-inflammatory lipid-gene module was identified, and its gene expression was shared with tumors derived from mice fed with an omega-6-rich diet. Hallmark gene analysis found inflammation and deranged coagulation prominent. In omega-6 fed mice, decrease in *Serpina1* protein expression in liver sinusoidal endothelial cells---the first target of metastasizing cells---suggests localized inflammation with enhanced coagulation. Collectively, these data suggest omega-6 enriched murine and human western diets may foster the development of an inflammatory, coagulopathic pre-metastatic liver niche, with M1 macrophages as the main contributors of CRC inflammation.

#6157 Single-cell characterization of tumor niches driving liver metastasis in colorectal cancer.

Jinho Jang[1], Yoojeong Seo[1], Kyung Pil Ko[1], Jie Zhang[1], Sohee Jun[1], Jae-Il Park[2]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]Asst. Professor, Exp. Radiation Oncology, UT MD Anderson Cancer Center, Houston, TX

Metastasis has been linked to the tumor microenvironment, but the cellular interaction networks that organize metastatic niches in microsatellite-stable colorectal cancer are not fully characterized. We performed single-cell RNA sequencing of colon normal tissue, primary colorectal tumors, liver metastases, and matched liver normal tissue to define microenvironmental remodeling with a focus on T-cell and fibroblast compartments. Tumor-associated fibroblasts showed broad upregulation of collagen genes, enrichment of apical junction and surface-related pathways, increased communication among fibroblast subsets, and the emergence of metastasis-associated fibroblast populations. In parallel, liver metastases exhibited depletion of $CD8^+$ T cells and NK cells compared with liver normal tissue, accumulation of regulatory T cells and $CD8^+$ exhausted T cells and strengthened fibroblast-$CD8^+$ T-cell interactions. Ligand-receptor analysis revealed CLEC signaling between fibroblasts and T cells across multiple conditions, with selectively enhanced CLEC-mediated interactions in liver metastases compared with liver normal tissue. Galectin-mediated communication was restricted to tumor settings and, while broadly distributed across fibroblast clusters in primary tumors, became selectively intensified within a specific fibroblast subset in liver metastases. Fibroblasts in liver metastases also preferentially engaged $CD8^+$ exhausted T cells through NRXN signaling. Together, these data delineate fibroblast-centered, site-specific signaling circuits that shape immune composition and function during metastatic progression and nominate fibroblast-T-cell communication hubs as candidate targets for modulating the tumor niche in microsatellite-stable colorectal cancer.

#6158 Senescent tumor-associated macrophages promote peritoneal metastatic niche formation in gastric cancer.

Tadahito Yasuda[1], Mayu Yasuda[1], Atsuko Yonemura[2], Fabio de Mello[1], Feng Guo[1], Boping Jing[1], Hudie Li[1], Takatsugu Ishimoto[2], Yaoqi Alan Wang[1]

[1]Indiana University School of Medicine, Indianapolis, IN,[2]The Cancer Institute, Japanese Foundation for Cancer Research, Tokyo, Japan

Peritoneal metastasis represents a major clinical challenge in gastric cancer (GC), yet the mechanisms underlying metastatic niche formation remain poorly understood. In particular, the specific tumor-associated macrophage (TAM) subsets that drive peritoneal dissemination remain poorly characterized. Here, we identify a subset of senescent macrophages that promote metastatic niche propagation in GC. Using a newly established GC cell line, GAN-KPC (harboring a $Kras^{G12V}$ mutation with Trp53 and Cdh1 knockout), and a syngeneic gastric wall transplantation model in C57BL/6 mice, we investigated the cellular landscape of metastatic niche formation. High-resolution spatial transcriptomics (10x Visium HD) revealed macrophages within metastatic niches exhibiting transcriptional features of cellular senescence. Pharmacologic clearance of senescent cells with the senolytic agent ABT263 markedly reduced peritoneal tumor formation, and macrophage-specific $p16^{INK4a}$ knockout further confirmed the essential role of senescent macrophages in metastatic niche formation. Complementarily, single-cell mass cytometry (CyTOF) of ascitic fluid from GC patients with peritoneal metastasis revealed a macrophage subset expressing p16 and SASP-associated factors. These findings uncover a previously unrecognized role of senescent macrophages in peritoneal metastatic niche formation and suggest that targeting senescent cells may represent a promising therapeutic strategy to limit peritoneal dissemination in GC.

#6159 Co-evolution of cancer cells and their microenvironment of primary and lymph node metastatic prostate cancer under androgen deprivation therapy.

Ping Xu[1], Yuehui Zhao[1], Yun Yan[1], Rui Ye[1], Chenling Tang[1], Emi Sei[1], Shanshan Bai[1], Tuan Tran[1], Cole Ruoff[1], Christine Ly[2], Keyi Zhu[2], Miao Zhang[2], Bila A. Siddiqui[3], Sumit K. Subudhi[3], Paul Corn[3], Christopher J. Logothetis[3], Patricia Troncoso[2], Amado J. Zurita-Saavedra[3], Nicholas Navin[1]

[1]Department of Systems Biology, UT MD Anderson Cancer Center, Houston, TX,[2]Department of Pathology, UT MD Anderson Cancer Center, Houston, TX,[3]Department of Genitourinary Medical Oncology, UT MD Anderson Cancer Center, Houston, TX

Prostate cancer (PC) is the most commonly diagnosed malignancy and the second leading cause of cancer-related death among men in the United States. The presence of lymph node (LN) metastases is a strong prognostic indicator of progression. Although LNs are the second most frequent metastatic site after bone, they are the first site of detectable metastasis in patients. Currently, the molecular and microenvironment transitions from primary tumors to LN metastases remain poorly understood. Prior bulk sequencing studies have provided important insights into metastatic tumors but failed to resolve the cellular heterogeneity and spatial organization in the tumor microenvironment (TME). We hypothesized that both cancer cell-intrinsic transcriptional programs and their interactions with the TME drive LN metastasis and resistance to androgen deprivation therapy (ADT). To test this, we integrated single-nucleus RNA sequencing with multiple spatial transcriptomic platforms (10x Visium, Vizgen MERSCOPE, and Xenium) to profile primary prostate tumors and matched LN metastases. Spatial analyses revealed site-specific remodeling of the TME between cancer and adjacent normal regions in both the prostate and LN. Despite being distinct organs, the prostate and LN also exhibit overlapping enrichment of specific immune and stromal cell populations within tumor regions, reflecting conserved functional roles across these environments. Non-negative matrix factorization identified recurrent cancer cell metaprograms (MPs), including an androgen receptor (AR) associated program enriched in LN metastases. By integrating MP activity with TME composition through ecotype analysis, we defined distinct ecotypes representing combinations of cancer states and their microenvironment cell types. One ecotype characterized by AR signaling and protumorigenic TME components was preferentially enriched in LN metastases. Ecotype-based stratification of primary tumors identified a ‘pre-metastatic’ subgroup, which showed ecotype contributions similar to those of LN metastases, and a ‘non-metastatic’ subgroup, which displayed different ecotype profiles. Primary tumors characterized by pre-metastatic ecotypes were linked to significantly poorer clinical outcomes. Collectively, these findings delineate the co-evolution of prostate cancer cells and their microenvironment during LN metastasis. Our study establishes ecotypes as a framework for linking cancer-intrinsic programs with TME remodeling, providing new biomarkers of progression and resistance and offering opportunities for precision therapeutic intervention.

#6160 TRPV6/CXCR4 signaling complexes as therapeutic targets to prevent osteoblastic bone metastasis in castration-resistant prostate cancer.

Clement Cordier[1], Aurelien Haustrate[1], Adriana Mihalache[2], Erika Duval[2], Emilie Desruelles[1], Corentin Spriet[3], Lofti Slimani[4], Baptiste Casel[4], Laurent Allart[1], Pierre Gosset[2], Natalia Prevarskaya[1], V'yacheslav Lehen'kyi[1]

[1]Inserm U1003, Phycel, Physiology Cellulaire, University of Lille, France, Lille, France,[2]Pathology Department, Saint Vincent de Paul Hospital, Hospital Group of Catholic Institute of Lille (GHICL), Lille, France, Lille, France,[3]University of Lille, CNRS, Inserm, CHU Lille, Institut Pasteur of Lille, US 41 - UAR 2014 - PLBS, Lille, France, Lille, France,[4]University of Paris Cite and Sorbonne Paris Nord, Inserm UMR1333, Oral Health, Montrouge, France, Lille, France

Background: Bone metastasis is a leading cause of morbidity and mortality in advanced prostate cancer, affecting up to 90% of patients with castration-resistant prostate cancer (CRPC). Around 85% of these lesions are osteoblastic. The calcium channel TRPV6 is absent in healthy prostate tissue but produced de novo during malignant transformation, with higher expression in advanced and castration-resistant stages. TRPV6 regulates calcium influx and downstream signalling pathways that promote proliferation, invasion and survival. Previous studies have shown that TRPV6 promotes epithelial-mesenchymal transition (EMT), migration, invasion and metastatic dissemination, particularly to bone, and forms functional complexes with the chemokine receptor CXCR4, a key mediator of tumour cell homing to bone. Here, we investigated how the TRPV6-CXCR4 axis contributes to osteoblastic bone metastases and whether its pharmacological inhibition could be therapeutically beneficial.

Methods: TRPV6 and CXCR4 expression and co-localization were analyzed in human prostate cancer tissues and bone metastases. Functional assays using TRPV6-overexpressing or TRPV6-knockout cells evaluated osteoblast-mediated migration, invasion and activation. In vivo studies assessed the effect of targeting TRPV6 and CXCR4, individually or in combination, with monoclonal antibodies on metastatic burden and bone lesion phenotype.

Results: TRPV6 expression strongly correlated with tumor aggressiveness and metastatic progression in clinical samples. TRPV6 activation triggered CaMK2 phosphorylation, NF-κB nuclear translocation and upregulation of EMT-associated transcription factors (Twist, Snail, Slug), enhancing migratory and invasive phenotypes. Concurrently, TRPV6 promoted stable CXCR4-TRPV6 complex formation, amplifying pro-metastatic signalling. In co-culture assays, TRPV6-expressing cells markedly increased osteoblast activation markers (ALP, RUNX2, OPN) and matrix mineralisation, indicating functional tumour-osteoblast crosstalk driving osteoblastic niche formation. In vivo, TRPV6-positive tumors primarily produced osteoblastic bone lesions, and dual targeting of TRPV6 and CXCR4 reduced the incidence of metastases, attenuated pathological bone remodeling, and prolonged overall survival.

Conclusions: These results highlight the TRPV6-CXCR4 complex as a key regulator of osteoblastic bone metastasis in CRPC. Dual targeting of TRPV6 and CXCR4 provides a proof-of-concept therapeutic strategy to prevent or limit bone metastasis in prostate cancer.

#6161 Ybx1 correlates with an immunosuppressive microenvironment in bone-metastatic lung adenocarcinoma.

Yongsheng Wang[1], Liyun Miao[2]

[1]Respiratory Diseases, Nanjing Drum Tower Hospital, Nanjing, China,[2]Nanjing Drum Tower Hospital, Nanjing, China

Bone metastasis in lung cancer is frequently associated with immunotherapy resistance, yet its underlying mechanisms remain elusive. Here, we demonstrate that the transcription factor YBX1 orchestrates both bone metastasis and immunosuppressive microenvironment formation in non-small cell lung cancer (NSCLC) through IL6 and CCL5 signaling, respectively. Mechanistically, YBX1 protein stability is regulated by glycosylation-dependent mitophagy, wherein O-GlcNAc transferase (OGT)-mediated glycosylation at T271 enhances its mitochondrial membrane localization and subsequent autophagic degradation. Notably, reduced YBX1 glycosylation was observed in highly bone-metastatic NSCLC cells. Through drug screening, we identified Icaritin(iac) as a small molecule that potentiates YBX1 glycosylation, accelerates its degradation, and consequently suppresses bone metastasis while reversing immunosuppression. Our findings unveil YBX1 as a dual-functional therapeutic target for simultaneously inhibiting NSCLC bone metastasis and sensitizing tumors to immunotherapy.

#6165 Matrix density shapes early invasion and EWSR1::FLI1 protein dynamics in Ewing sarcoma.

Manon Watzky, James Amatruda

Children's Hospital Los Angeles, Los Angeles, CA

Ewing sarcoma (EwS) is a pediatric bone and soft tissue cancer driven by chromosomal translocations generating fusion oncogenes, primarily EWSR1::FLI1. Metastasis is the most adverse prognostic factor, associated with persistently low survival rates. The low mutational burden in EwS suggests that tumor progression relies more on how cells adapt to their environment than on genetic selection. Invasion represents the first transition where cells leave the primary tumor and face new environmental constraints that can shape their metastatic potential. This study aims to establish a model that captures early EwS adaptation during invasion and to determine how extracellular matrix (ECM) parameters influence this process. To study EwS adaptation, we use cell lines derived from primary tumors or metastases to generate 3D spheroids embedded in collagen I matrices of defined densities, allowing us to monitor invasion and its associated morphological and molecular changes. We notably focus on EWSR1::FLI1 dynamics and its regulatory mechanisms during invasion onset, as this transcription factor is essential for EwS transformation and proliferation, yet reduced activity has been suggested in metastatic contexts. The ECM-embedded spheroid model shows that active invasion is restricted to metastasis-derived cells. Spheroids from primary tumors expand or sense the matrix but display rare cell detachment, whereas metastasis-derived spheroids show robust invasion with elongated, amoeboid, and collective behaviors captured by high-resolution microscopy. Increasing collagen density gradually reduces invasion, highlighting the strong influence of matrix properties. This prompted us to examine EWSR1::FLI1 dynamics, with immunohistochemistry revealing a spatial decrease at spheroid edges and within invading cells. Low heterogeneity is detectable before spheroid embedding, but the extent of EWSR1::FLI1 downregulation markedly expands during invasion. Time-course analyses show that this downregulation precedes active detachment. Moreover, fewer EWSR1::FLI1-low cells are observed at the edge of spheroids embedded in invasion-restrictive high-density matrices, further linking matrix density with invasive behavior and EWSR1::FLI1 dynamics. RNAscope shows that spheroid-edge and invading cells retain high EWSR1::FLI1 transcript levels, suggesting that the regulation occurs at the protein level. In line with this, proteasome inhibition with MG132 prevents invasion onset without inducing major cell death, supporting proteasome-dependent regulation of early EwS invasion. Taken together, these findings identify an ECM-associated EWSR1::FLI1-low state as an early adaptive feature during invasion onset. Our model enables dissection of this regulation -from matrix sensing to active detachment- and suggests a role for proteasome-mediated mechanisms in shaping early metastatic traits in Ewing sarcoma.

#6166 Next-generation models to advance pediatric solid cancer treatments.

Emon Nasajpour[1], Dena Panovska[2], Ruolun Wei[3], Conrado Soria[4], Calvin J. Kuo[5], **Rachana Agarwal**[4]

[1]Neurology and Stanford Cancer Model Development Center, Stanford University, Stanford, CA,[2]Neurology, Stanford University, Stanford, CA,[3]Neurosurgery, Stanford University, Stanford, CA,[4]Frederick National Laboratory for Cancer Research, Leidos Biomedical Research, Inc., Frederick, MD,[5]Stanford University, Stanford, CA

Drug development is notoriously inefficient, slow, and expensive. In oncology, only 5% of new compounds identified during the drug discovery phase successfully progress to clinical trials. This high attrition rate is attributed to patient intra- and inter-tumor heterogeneity, as well as an over-reliance on 2D cell cultures and animal models, which often fail to accurately replicate patient tumor biology and physiology. The adoption of advanced, clinically relevant preclinical models at earlier stages of drug development is essential for better identifying and prioritizing agents with a higher likelihood of success in clinical trials. The Human Cancer Models Initiative (HCMI) is a global initiative founded by the National Cancer Institute (NCI), in collaboration with the Cancer Research UK, Wellcome Sanger Institute, and the foundation Hubrecht Organoid Technology. The mission is to generate patient-derived next-generation cancer models from diverse tumor types as a community resource. Unlike traditional cancer models, the new models are cultured under optimized, predominantly 3D conditions that better preserve the characteristics of the parental tumors than historical culture conditions. This preservation is validated through phenotypic and molecular analyses of tumor tissue and models, which are shared with the community alongside standard operating procedures, informed consent templates, and associated clinical and molecular data. To contribute towards the goal of the HCMI, several Cancer Model Development Centers (CMDC) have been generating cancer models from a variety of tumor types. This includes the Stanford CDMC which is currently dedicated to models of pediatric solid tumors, emphasizing central nervous system (CNS) tumors, the leading cause of cancer-related death in children. We developed a standardized bioprocessing pipeline which yielded a functional tumor bank, achieving a 60-70% success rate in establishing next-generation cancer models for long-term passaging. We have successfully generated and submitted 85 pediatric cancer models along with case-associated clinical and biospecimen data, as well as internal QC data validating the derived cancer models, for further characterization and distribution via the HCMI pipeline. Our next-generation cancer models partially capture the heterogeneity of pediatric CNS tumors, neuroblastoma, hepatoblastoma, Wilms tumor, and brain metastases from neuroblastoma and rare sarcoma-related cancers. Longitudinal biobanking has identified and characterized novel onco-fusion proteins, rare tumor entities, and recurrences, and therapeutic vulnerabilities through multi-omics. In summary, next-generation cancer modeling overcomes known challenges by benchmarking models and creating standardized protocols and procedures, thereby enhancing their predictive capabilities, therapeutic efficacy and promoting personalized treatment strategies.

#6167 Modeling the impact of chemotherapy and small molecule inhibitors on the 3D microenvironment of pediatric bone sarcomas.

Allison Haley Reno[1], Joshua Kelley[2], Reid Barker[3], Jamie Silverman[3], Jack Hyland[3], Cameron Bumbleburg[4], Elizabeth Maahs[3], Anna Tingler[4], Denis C. Guttridge[4], Melinda A. Engevik[4], Yongren Wu[2], Casey Langdon[4]

[1]Pediatrics, The Medical University of South Carolina, Charleston, SC,[2]Clemson-MUSC Bioengineering, Clemson University, Charleston, SC,[3]Biology, The College Of Charleston, Charleston, SC,[4]Medical University of South Carolina, Charleston, SC

One of the main types of pediatric sarcomas is primary bone sarcoma (PBS) where the sarcoma initially occurs in the bone matrix. PBS includes osteosarcoma and Ewing sarcoma, both of which are primarily seen in pediatric populations. Treatment for osteosarcoma often includes amputation or limb salvaging surgery, along with pre- and post-operative chemotherapy, both of which are significant surgeries for adolescents. These surgeries can significantly limit their long-term mobility, altering their quality of life. These sarcomas produce osteoid and a porous, mineralized matrix like that of native bone tissue. In this work, we have designed pediatric sarcoma 3D cell culture models by creating custom hydrogel materials to match the ECM properties of bone sarcomas such as osteosarcoma and Ewing sarcoma. We refined the composition of this material using nanoscale mechanobiology analysis to assess the nanoscale stress, strain, compression, and Young's modulus to match the mechanical properties of the native bone sarcoma ECM. We have cultured organoids in this material using imaging to track and quantify the ECM remodeling by the 3D culture tumor model. Like what is seen in literature we have found that with tumor proliferation and progression comes increased collagen, collagen remodeling for increased mechanical stiffness, and overall ECM stiffness increased to create a denser, mechanically stiffer tumor. We hypothesize that chemotherapies and small molecule inhibitors may be able to weaken the dense tumor formation and ECM remodeling seen in our 3D cell culture models as the drugs penetrate through the hydrogel induce apoptosis in the cells and lead to a decrease in ECM components and cell-matrix bonding. Both AKT and proteasome inhibitors block the pathways associated with collagen type I, III, and IV driving tumor progression through the pERK and PI3K/AKT pathways. The goal is to test these targeted therapies on our sarcoma 3D cell culture models to see if they would then slow or inhibit the effects of collagen on driving tumor growth and progression in pediatric solid tumors where collagen plays such a vital role. Additionally, in immune "cold" tumors such as Ewing sarcoma collagen functions as an important immunosuppressive signaling molecule so inhibiting collagen in signaling helps to turn Ewing sarcoma and other pediatric sarcomas into more immune "hot" tumors by taking away the role collagen plays in keeping this an immune "cold" tumor. We anticipate our novel 3D culture models can model the complex relationships between tumor, microenvironment, and therapeutic response.

#6168 Investigating the mechanism of oncogenesis of BCOR-CCNB3 fusion positive sarcomas.

Victoria Ann Pete[1], Ryota Shirai[1], Sydney Hakim[1], Joshua Broadman[1], Naoki Oike[2], Andrew E. Goodspeed[3], **Masanori Hayashi**[1]

[1]The University of Colorado School of Medicine, Aurora, CO,[2]Niigata Univ. School of Medicine, Niigata, Japan,[3]University of Colorado Cancer Center, Aurora, CO

BCOR-CCNB3 sarcomas (BCS) are a subtype of small cell sarcomas that represent a recently recognized group of solid tumors identified by rearrangements of BCOR. Gene expression profiles of patient samples demonstrate a very similar profile to other BCOR rearranged solid tumors, such as BCOR-MAML3 fusion sarcomas, and CCSK with BCOR ITD. BCOR is a corepressor of the transcription factor BCL6 and is a critical member of the non-canonical polycomb repressive complex (PRC), PRC1.1, which mediates transcriptional repression through epigenetic modifications. In stem cells, PRC1.1 complexes are recruited to the chromatin through binding of KDM2B to nonmethylated CpG islands, catalyzing the ubiquitination of the histone H2A (at Lys119) via the RING-PCGF1 enzymatic core, leading to the repression of target genes. Through this process, the PCGF1-interacting PUFD region of BCOR is critical for the BCOR-PRC1.1 interaction. Despite this evolving understanding of the diagnostic profile of BCS, preclinical and mechanistic investigations of BCOR rearranged sarcomas have been limited due to the lack of models. Here, using two distinct BCS model systems, we investigated the mechanism of how BCOR-CCNB3 contributes to the oncogenesis of BCS. First, BCOR was knocked down in NBC-1, a patient-derived BCOR-CCNB3 cell line, and confirmed by western blotting and qRTPCR. Next, we created a vector transposon system to create isogenic cell lines expressing FLAG-tagged BCOR-CCNB3 or wild type BCOR. Interestingly, in NBC-1 cells, while the knockdown of the fusion gene did not lead to a statistically significant change in proliferation or survival, RNA-seq analysis identified that BCOR-CCNB3 knockdown led to a significant decrease of the expression of HOX family genes. Furthermore, co-IP identified that the fusion BCOR-CCNB3 was not bound to PRC1.1 components, including KDM2B, RING1, and PCGF1. In the isogenic cell model, we were able to establish an inducible BCOR-CCNB3 expression model, and demonstrate that the exogenous expression of BCOR-CCNB3 leads to increased cell proliferation.These results indicate that the BCOR-CCNB3 oncogenesis occurs through the disruption of the PRC1.1 complex function, and cannot be reversed by fusion gene targeting. Future work is currently ongoing to define the interaction of BCOR-CCNB3 with the various subunits of PRC1.1 through co-immunoprecipitations, IP-mass spectrometry and CUT&Tag analysis.

#6169 Evaluating TCR mimetic CAR T cell preclinical therapeutics in an immunocompetent MYCN-driven murine neuroblastoma allograft model.

Elisabeth Posthill[1], Minu Samanta[1], David Groff[1], Colleen Casey[1], Tina Acholla[1], Anna Maria Giudice[1], Kristopher R. Bosse[1], Ruoning Wang[2], Timothy T. Spear[1], John M. Maris[1]

[1]Center for Childhood Cancer Research, Division of Oncology, Children's Hospital of Philadelphia, Philadelphia, PA,[2]Nationwide Children's Hospital, Columbus, OH

Background: Tractable immunocompetent murine models for adoptive cellular therapies could fill a critical gap in preclinical evaluations. Peptide-centric (PC) chimeric antigen receptor (CAR) T cells targeting pMHC of a 9mer peptide derived from the neuroblastoma intracellular oncoprotein PHOX2B presented by HLA-A*24:02 (A24) is now in Phase 1 clinical trial for relapsed neuroblastoma (NCT07007117). To study therapeutic limitations and enhancement strategies, we developed a syngeneic model of PHOX2B/A24-targeting murine (m)PC-CARs.

Methods: C57BL/6 (BL/6)-penetrant TH-MYCN-derived allografts and cell lines were engineered with a chimeric human/murine MHC HLA-A*24:02/H-2K^{b} to present conserved PHOX2B 9mer peptide. MSCV retroviral vectors encoding second-generation mPC-CARs containing the clinical scFv conjoined to murine CD28 or 4-1BB with CD3ζ were used to create stable GPE86 producer cell lines. Truncated mCD19 or luciferase was included to monitor transduction efficiency and *in vivo* trafficking. BL/6 splenocytes were activated and transduced *ex vivo* with human (h)IL-2, and expanded in hIL-7/15. Multiplex functional assays were performed using flow cytometry, ELISA, real-time cell impedance, and O-link proteomics.

Results: Transduction efficiency reproducibly ranged from 40-60%. mPC-CAR-T cells expanded 15 to 20-fold over 14 days while maintaining balanced memory and effector immunophenotypes with minimal exhaustion markers post-manufacture. Against PHOX2B-A24-H-2K^{b}-expressing cell lines, mPC-CAR-T cells with CD28ζ or 4-1BBζ costimulatory domains exhibited robust IFN-γ, IL-2, and TNFα secretion and potent cytotoxicity down to an effector:target ratio of 0.5:1 up to 14 days post-manufacture and after cryopreservation. CD28ζ mPC-CAR T cells maintained 100% cytotoxicity upon serial tumor rechallenge, whereas cytotoxicity of 4-1BBζ was limited to 50% after 3 challenges. In the absence of exogenous cytokine support, tumor exposure induced CD44^{+}IL7Rα^{-} terminal effector phenotype and upregulation of exhaustion markers CD39, CTLA-4, and Tim-3. *In vivo* studies to assess anti-tumor potency, persistence, and barriers to efficacy are ongoing and will be reported.

Conclusion: We created a tractable MHC hybrid TH-MYCN-derived neuroblastoma allograft model in BL/6 mice. This model is currently being deployed to study various PC-CAR enhancement strategies such as mRNA encoded epitope vaccination and cytokine armoring with accompanying spatial transcriptomics that will inform further clinical development of our PHOX2B-directed PC-CAR T cells.

#6170 Development and characterization of 3D osteosarcoma models recapitulating tumor heterogeneity and bone microenvironment.

Margaux Chantoiseau[1], Pierre Khneisser[2], Birgit Geoerger[3], Nathalie Gaspar[3], Maria Eugenia Marques da Costa[3], Antonin Marchais[1]

[1]Anti-tumor immunology and cancer immunotherapy, Gustave Roussy, Villejuif, France,[2]Department of Medical Biology and Pathology, Gustave Roussy, Villejuif, France,[3]Department of Pediatric and Adolescent Oncology, Gustave Roussy, Villejuif, France

Introduction: Osteosarcoma is the most common primary bone cancer in adolescents and young adults. It is characterized by high heterogeneity and a hostile bone microenvironment shaped by osteoclasts, endothelial cells, and immunosuppressive myeloid populations, underscoring the need for innovative models to evaluate novel therapeutic strategies. Objective: This study aims to develop and characterize novel three-dimensional (3D) culture models that recapitulate the complexity and the microenvironment of osteosarcoma.
Methods: Tumor samples from patient-derived xenografts (PDXs) established from patients with osteosarcoma at relapse or treatment failure were processed to generate 3D tumor cultures. Tumor tissues were mechanically and enzymatically dissociated into single-cell suspensions and seeded into round-bottom plates with very low adhesion to promote spontaneous formation of 3D tumoroids. Culture conditions were optimized using medium supplemented with specific growth factors to support cell viability and proliferation. Morphology and growth of the tumoroids were monitored over time. The resulting 3D models were characterized by histology (H&E and specific immunostaining like SATB2, SPP1, SOX9⋯), and by RNA sequencing and Whole exome sequencing (WES) to assess transcriptional stability relative to the parental primary/PDX tumors. In addition, these 3D tumoroid models were used for drug testing to evaluate therapeutic responses and identify potential treatment sensitivities.
Results: We established five 3D osteosarcoma models from PDX with an establishment rate of 83%. The tumoroids formed spontaneously under low-adhesion conditions within approximately 7 to 30 days, (depending on the derived sample) and remained viable and morphologically stable during this culture period. Histological analysis revealed that the 3D tumoroids recapitulated key features of the parental PDX tumors and the patient tumors, including cellular heterogeneity, hypoxic regions, and osteoid-like matrix deposition. RNA sequencing and drug testing studies to evaluate therapeutic responses are currently ongoing.
Conclusions: Patient-derived 3D osteosarcoma models faithfully preserve tumor heterogeneity and microenvironmental features, providing a robust and scalable system for preclinical drug testing. This approach holds a strong potential to accelerate the development of personalized combination therapies targeting both tumor cells and their supportive bone microenvironment in osteosarcoma.

#6171 Patient-derived pediatric glioblastoma models provide key insights into IDH1-driven drug resistance.

Stephen Friend, Matthew Graziano, Ruby E. Thamert, Heather Branscome, Utsav Sharma, Abhay Andar, **Carolina Lucchesi**

Microphysiological Systems, American Type Culture Collection (ATCC), Manassas, VA

Background: Pediatric glioblastoma (GBM) is a rare, aggressive brain cancer with molecular characteristics distinct from adult GBM. IDH1 mutations, which occur more frequently in pediatric cases, are associated with unique clinical outcomes and resistance mechanisms. Despite its severity, GBM remains incurable, with limited treatment options. Pediatric populations rarely participate in clinical trials, making clinically relevant in vitro models critical for preclinical research and therapeutic development. The Human Cancer Models Initiative (HCMI) has developed patient-derived brain tumor models, including organoids and spheroids, annotated with comprehensive clinical and molecular data. These models offer a platform to study tumor biology and drug response in IDH1-mutant GBM.

Methods: Patient-derived glioblastoma models from the HCMI biobank—representing primary and recurrent tumors—were genomically profiled for key pediatric GBM mutations (IDH1, ATRX, TP53, KRAS, RELA). Histopathology confirmed IDH1 status and supported molecular classification. Genomic data were compared to patient records and The Cancer Genome Atlas (TCGA) to validate model fidelity. A subset of models was exposed to a panel of four compounds, including standard and experimental drugs. Drug sensitivity was assessed via 12-point dose curves, with IC50 values calculated. Cytotoxicity was measured using live/dead staining and ATP-based viability assays. This integrated approach links genomic alterations to drug resistance, supporting the development of targeted therapies for high-risk pediatric GBM.

Results: Patient-derived GBM organoid models were sequenced and confirmed to carry key mutations, including IDH1 p.R132H, ATRX p.C1590Y/p.R1739, TP53 p.R273C, KRAS Q22R/G13R, and RELA rearrangements. Drug screening across a 10-compound panel revealed variable responses based on genotype and dosage. Taxanes and platinum agents showed broad cytotoxicity, while PARP and KRAS inhibitors exhibited limited effects except at high concentrations. Viability was assessed via fluorescent staining and ATP-based assays, demonstrating the utility of these models for genotype-informed therapeutic screening in pediatric GBM.

Conclusion: HCMI-derived pediatric GBM models recapitulate IDH1-driven genomic features and reveal mutation-specific drug responses. These 3-D platforms support high-throughput screening and integrated genomic-pharmacologic profiling to inform targeted therapy development for high-risk pediatric GBM. Importantly, these preclinical models bridge a critical gap by providing insights from patient populations that cannot participate in clinical trials, reinforcing their role in precision oncology.

#6172 The transcription factor DMRTA2 regulates radial glial maintenance and tumorigenicity of pediatric high-grade glioma.

Hitomi N. Royston[1], Autumn B. Hampton[1], Elissa G. Oliver[1], Jayden Jackson[1], Ibukunoluwa Florence Tella[1], Miriam D. Emerson[1], Dhruv Bhagat[1], Daijiro Konno[2], Kosuke Funato[1]

[1]University of Georgia, Athens, GA,[2]Kindai University, Higashiosaka, Japan

Brain tumor is the leading cause of cancer-related death in children. Among them, pediatric-type diffuse high-grade glioma (HGG) accounts for 40% of brain tumor deaths in children. Diffuse hemispheric glioma (DHG), H3 G34-mutant (DHG-H3G34), represents a highly malignant subtype of HGG with a poor prognosis. Although dysregulated developmental programs have been implicated in these tumors, the exact mechanisms that drive subtype-specific tumorigenesis remain unclear. DMRTA2, a member of the Doublesex-mab3-related (DMRT) transcription factor family, has been linked to the proliferation and maintenance of neural progenitor cells. However, its functions in human brain development and pediatric glioma are not yet fully understood.

To address this gap, we first analyzed previously published single-cell RNA-seq datasets from human fetal brains and cerebral organoids. We found robust *DMRTA2* expression in neural progenitor populations, particularly in radial glial (RG) cells. To investigate the functional role of DMRTA2 in human brain development, we knocked out the *DMRTA2* gene using CRISPR-Cas9 genome editing in human embryonic stem cell (hESC) lines and differentiated them into cerebral organoids. *DMRTA2* KO organoids exhibited reduced size, decreased proliferation, and a marked depletion of RG cells, suggesting an important role of DMRTA2 in early cortical development.

We next examined *DMRTA2* expression in DHG-H3G34 patient tumors and observed its high and specific expression compared to other subtypes of pediatric brain tumors. To investigate the role of DMRTA2 in DHG-H3G34, we knocked out *DMRTA2* in hESC-based DHG-H3G34 model cells that we developed. Loss of *DMRTA2* resulted in a significant decrease in RG-like population and a marked increase in differentiated cells. In our mouse xenograft studies using luciferase-labeled *DMRTA2* WT and KO cells, loss of *DMRTA2* significantly reduced tumor growth in vivo. KO tumors also displayed reduced proliferation and fewer RG-like cells.

Together, our findings suggest that DMRTA2 is a key regulator of radial glial cells in human cortical development and promotes tumorigenicity in pediatric DHG-H3G34 tumors.

#6173 Developing zebrafish avatars for pediatric sarcomas to support functional precision oncology.

Karoline Felisbino, Jonathan Tyler Kinder, Colin Williams, Andrew Gaines, Jessica Blackburn

Molecular and Cellular Biochemistry, University of Kentucky, Lexington, KY

Pediatric sarcomas, including rhabdomyosarcoma (RMS) and osteosarcoma, remain associated with poor outcomes in relapsed or high-risk disease, highlighting the need for rapid functional models to guide patient-specific therapeutic decisions. Zebrafish patient-derived xenografts (zPDX “avatars”) provide a low-cost, scalable in vivo platform to test drug responses within days. As a foundation for pediatric sarcoma avatars, we optimized zebrafish xenografts using human RMS cell lines (RD, embryonal; RH30, alveolar) prior to introducing primary patient samples. GFP-labeled RD cells injected into the dorsal perivitelline space (PVS) of 48-hours-post-fertilization larvae produced approximately 60% larval survival, nearly 100% engraftment at 1 day postinjection (dpi), and stable tumors through 4 dpi, enabling reproducible conditions for standardized tumor size and short-term drug testing. CellTiter-Glo assays at 34 °C, the incubation temperature required for zPDX experiments, confirmed that RD cells retain drug sensitivity under these conditions: dactinomycin (DAC) significantly reduced RD viability at low nanomolar concentrations (≥10 nM), whereas vincristine (VIN) was effective at 2-10 nM. Parallel larval toxicity assays indicated that both drugs were generally well tolerated by zebrafish larvae at concentrations ≤200 nM for 72 h, establishing a practical exposure window for in vivo testing. As a proof-of-concept for drug response assessment, GFP+ RD cells were injected into 48 hpf larvae and tumor burden (fluorescence intensity) and dissemination were evaluated following treatment with VIN and DAC at 15 nM. At this concentration, no statistically significant differences were observed versus control, although a trend was noted toward reduced tumor size and dissemination. In contrast, RH30 cells did not persist beyond 1-2 dpi when injected in simple carriers (PBS or HBSS + 1-2% FBS), prompting systematic optimization of the injection medium. Guided by media described for zPDX, we developed an enriched medium containing HEPES, glutamine, MEM-NEAA, B27, nicotinamide, ITS, Y-27632, SB202190, N-acetylcysteine, and EGF/FGF with reduced serum. Using this formulation, we achieved approximately 100% tumor-positive larvae up to 4 dpi, indicating that medium composition, particularly exogenous growth factors, are critical for xenograft retention. Together, these preliminary data define robust survival and engraftment parameters for RMS xenografts in zebrafish, validate the feasibility of this platform for rapid chemotherapy response readouts, and establish an optimized injection medium that enables even challenging sarcoma subtypes to persist in vivo. These advances provide the foundation for extending this platform to primary pediatric sarcomas, including osteosarcoma, to generate zebrafish avatars for functional precision oncology.

#6175 Development of a human neuroblastoma organoid model.

Simon Tusnady[1], Eva Bakos[2], Anna Lovrics[2], Katalin Monostory[2], Jozsef Tovari[3], Andras Furedi[2], Kornelia Szebenyi[2]

[1]Semmelweis University, Budapest, Hungary,[2]Institute of Molecular Life Sciences, HUN-REN Research Centre for Natural Sciences, Budapest, Hungary,[3]KINETOLab Biotechnology, Budapest, Hungary

Neuroblastoma (NB) is the most prevalent solid malignancy in infants, with approximately 20% of cases classified as high-risk due to amplification of the MYCN oncogene - a marker associated with aggressive tumor behavior and poor prognosis. Despite therapeutic advances, relapsed high-risk NB accounts for nearly 15% of pediatric cancer-related mortality. Studies using non-human models may yield misleading results due to species-specific differences in sympathoblast development -the fetal precursors of NB cells - which differ markedly between mice and humans. To address this, we developed and characterized an iPSC-derived human neuroblastoma organoid model that enables the study of early tumorigenesis in a tissue-like context.
First, we developed a differentiation protocol to generate human neural crest (NC) organoids from hiPSCs. Key neural crest markers, detected by fluorescent microscopy and Western Blot, were used to characterize the cell types present in the organoids. We then engineered transgenic iPSCs harboring a removable STOP cassette upstream of the MYCN gene (MYCN-GFP hiPSCs) and control iPSCs lacking MYCN (GFP hiPSCs). We verified the success of genomic integration by PCR and differentiated NC organoids from the transgenic hiPSCs using the previously established protocol. Then NC organoids were transduced with a Cre-expressing adeno-associated virus (AAV) that induced MYCN expression in a sympathoblast-specific manner. Changes in organoid size and GFP expression were observed over time with flow cytometry and fluorescent microscopy. The resulting neuroblastoma-like (NB) organoids were characterized by fluorescent microscopy and bulk RNA-sequencing. NB organoids were also treated with chemotherapeutics and were implanted subcutaneously into mice.
Successful generation of NC organoids from wild type and transgenic iPSC lines was validated by the expression of neural crest markers. The formation of tumor tissue was observed in organoids generated from MYCN-GFP hiPSC lines after AAV-mediated MYCN overexpression in targeted cells. The resulting NB organoids displayed hallmark features of high-risk NB and were sensitive to clinically relevant chemotherapeutics. NB organoids could also engraft and expand in vivo in mice.
We have created a hiPSC-based three-dimensional human neuroblastoma organoid model that includes tumor cells as well as healthy cells of neural crest origin forming the tumor environment. This innovative human organoid model of high-risk neuroblastoma provides a platform to study tumor initiation and investigate resistance mechanisms emerging after repeated chemotherapy cycles. Its application in drug screening may facilitate the discovery of novel, more effective therapies tailored to aggressive NB subtypes.

#6176 Embryonic reprogramming of neural crest cells drives the development of Ewing sarcoma.

Elena Vasileva[1], Claire Arata[2], Yongfeng Luo[1], Gage Crump[2], James Amatruda[1]

[1]Children's Hospital Los Angeles, Los Angeles, CA,[2]Keck School of Medicine, University of Southern California, Los Angeles, CA

Ewing sarcoma (ES) is a pediatric cancer of the bone and soft tissues with poor outcomes for patients with metastatic or relapsed disease. Ewing sarcoma cells are characterized by the presence of a driver fusion oncogene, most commonly EWSR1::FLI1. In the absence of a genetic animal model due to the severe toxicity of the oncofusion, the developmental aspects of ES initiation, including its cellular origin, have remained poorly understood. To address these questions, we developed a stable zebrafish transgenic model enabling tissue-specific expression of the human EWSR1::FLI1 oncofusion in neural crest cells, one of the proposed cell of origin for ES (Vasileva et al., Cell Reports 2025). Using this model, we demonstrated that expression of human EWSR1::FLI1 oncofusion in neural crest cells can lead to their transformation and the development of tumors in vivo. Single-cell analysis of tumor initiation shows that EWSR1::FLI1 reprograms neural crest-derived cells to a mesoderm-like state, strikingly resulting in ectopic fin formation throughout the body. Such hijacking of the limb development program led to abnormal activation of developmental signaling pathways in EWSR1::FLI1-induced outgrowths, resulting in dysregulation of the FGF signaling cascade and HOX gene expression. EWSR1::FLI1 reprograms neural crest cells by hijacking developmental enhancers and upregulating the expression of mesodermal regulators. One such regulator is tbxta (Brachyury or T), a key transcription factor controlling mesodermal specification. Notably, tbxta/TBXT expression was maintained in a subset of zebrafish and human tumors. Our model provides a mechanism by which a neural crest cell lineage can be transformed into Ewing sarcoma, a malignancy with predominant mesenchymal features. Taken together, these findings show how a single mutation can disrupt normal developmental trajectories, driving neural crest cells reprogramming and initiating malignant transformation.

#6177 Targeted posterior fossa A ependymoma therapy using a tumor-selective nanoparticle drug delivery approach.

Jon D. Larson[1], Darren Finlay[1], Yan Yuen Lo[1], Rabi Murad[1], Ming Zhao[1], Antony MichaelRaj[2], Sachin A. Kumar[3], Kristen Vogt[4], Ian Pass[1], Charles Handley[1], Bryan K. Li[5], Robert J. Wechsler-Reya[6], Michael D. Taylor[7], Kristiina Vuori[1], Michael Jackson[1], Daniel A. Heller[4], G. Praveen Raju[8], Lukas Chavez[1]

[1]Sanford Burnham Prebys Medical Discovery Institute, La Jolla, CA,[2]University of Pittsburgh, Pittsburgh, PA,[3]Boston Children's Hospital, Harvard Medical School, Boston, MA,[4]Molecular Pharmacology Program, Memorial Sloan Kettering Cancer Center, New York, NY,[5]Department of Pediatrics, University of California, San Diego, La Jolla, CA,[6]Herbert Irving Comprehensive Cancer Center and Department of Neurology, Columbia University Medical Center, New York, NY,[7]Cancer and Hematology Center, Texas Children's Hospital, Houston, TX,[8]Department of Neurosciences, University of California, San Diego, La Jolla, CA

Ependymoma (EPN) is the third most common malignant pediatric brain tumor. The most frequent and aggressive EPN subgroup, posterior fossa ependymoma group A (PFA-EPN), occurs predominantly in younger children with a 5-year progression-free survival of 33%. In the absence of recurrent mutations, PFA EPN tumors are driven by EZHIP overexpression resulting in global loss of the gene repressive chromatin mark H3K27me3. Despite progress in EPN molecular characterization, the standard treatment remains surgery with adjuvant radiation therapy. As such, identifying novel therapies for PFA-EPN is an important unmet medical need. To define therapeutic sensitivities for PFA-EPN, we performed a drug screen using multiple drug libraries: (i) a 120 drug FDA-Approved Oncology collection (ODL3), (ii) a CTD^2 Informer Set of 320 tool compounds, and (iii) a 336 drug Epigenetics Drug Collection on three patient-derived PFA-EPN cell lines. We found that these PFA-EPN cell lines were sensitive to several clinically relevant drugs, including those targeting epigenetic regulators. Multiple histone methyltransferase, proteasome, BCL2, and BET domain inhibitors were also identified as high-value drug candidates. These results warrant further PFA-EPN functional evaluation *in vivo*, but dose-limiting toxicity and limited blood-brain barrier (BBB) penetration are known limitations for many of the identified compounds. To overcome these limitations, we are applying a novel P-selectin-targeted fucoidan-based nanoparticle (FiNP) technology recently shown as a viable approach for effective BBB drug penetration specifically at brain tumor sites *in vivo*. As proof of principle, we have successfully fucoidan-encapsulated BET domain inhibitor drugs including a BRD2/3/4 PROTAC degrader (dBET6) providing improved pharmacological properties. Our preliminary results show P-selectin expression on treatment-naive human PFA-EPN tumor vasculature with current studies underway to assess effects of low dose ionizing radiation on P-selectin tumor vasculature expression enhancement, FiNP tumor localization throughout the tumor space, as well as therapeutic assessment in PFA-EPN PDX mouse models. Collectively, these findings provide new putative therapeutic approaches in these rare yet aggressive tumors.

#6178 Establishment and analysis of spontaneous metastatic PDX models of Ewing sarcoma.

Ali Mokhtar Mahmoud, Unsun Lee, Arnulfo Mendoza, Christine M. Heske

Pediatric Oncology Branch, Center for Cancer Research (CCR), NCI, NIH, Bethesda, MD

Although improvements in local therapy have increased the 5-year survival rate for localized Ewing sarcoma (EWS) from less than 20% to 70%, little progress has been made in the treatment of metastatic disease, which has a 5-year survival rate of less than 30%. A major challenge in the field is a lack of preclinical models that can recapitulate spontaneous metastatic disease and can be used to better understand the disease and identify new vulnerabilities. In this study, we present and characterize a murine model of spontaneous distant EWS metastasis derived from human patient-derived xenografts (PDX) in two different mouse backgrounds that mimics the clinical progression of the human disease. A panel of seven molecularly diverse patient-derived xenograft (PDX) models (SJ18, SJ17, S049, NCH1, NCH4, PDMR-098, PDMR-077) were injected orthotopically into the gastrocnemius muscle in the left hind leg of athymic nude and NOD SCID gamma (NSG) mice. Once primary tumors reached 1500 mm^3, hind limb amputation survival surgery was performed, and we observed animals for the development of distant spontaneous metastases. EWS PDXs formed spontaneous macrometastases in multiple sites including lymph nodes, lung, liver, and kidney in both NSG and nude mice. Each PDX model exhibited a distinct pattern of macrometastasis formation, based on site, metastasis frequency, and mouse strain. Immunohistochemical analysis for CD99 positivity revealed the presence of micrometastases in some locations where no macrometases were evident. The highest frequency of distant metastases (macro- plus micro-) was seen in PDMR-098 and SJ18 models in NSG mice (75% and 73.3% respectively); SJ18 most frequently metastasized to lung, whereas PDMR-098 most frequently metastasized to liver and mesenteric lymph nodes. Comparing results in NSG versus nude mice, we observed variations in metastasis frequency and site preference, with NSG mice demonstrating a higher rate of metastasis overall. Here we describe a preclinical model of spontaneous distant EWS metastasis that recapitulates the characteristics of human disease. The site and frequency of metastases vary based on the specific PDX model as well as the mouse background, highlighting that modeling metastasis formation is a multifactorial process driven by complex interactions between the tumor and host. Metabolomic profiling conducted to compare primary and macrometastatic tumors between models and metastatic sites revealed differences in multiple metabolic pathways. Future studies will focus on identifying potentially targetable metabolic vulnerabilities that could be used in the development of treatments for metastatic EWS.

#6179 Differential sensitivity of paired FUS-TFCP2+ RMS PDX models developed from tumor specimens obtained prior to and after ALK inhibitor therapy.

Erika Dobrota[1], M. Reza Saadatzadeh[1], Barbara Bailey[1], Keiko Kreklau[1], Gabe Mervis[1], Kathy Coy[2], Felicia Kennedy[2], Melissa Trowbridge[2], Anthony Sinn[2], Christopher Davis[1], Steven Angus[1], Michael Ferguson[3], Pankita Pandya[4], Karen Pollok[4]

[1]Wells Center for Pediatric Research, Indiana University School of Medicine, Indianapolis, IN,[2]Preclinical Modeling and Therapeutics Core, Indiana University Simon Comprehensive Cancer Center, Indianapolis, IN,[3]Department of Pediatrics, Division of Pediatric Hematology/Oncology, University of Louisville, Louisville, KY,[4]Indiana University Simon Comprehensive Cancer Center, Indianapolis, IN

FUS-TFCP2-positive rhabdomyosarcoma (FUS-TFCP2+ RMS) is a rare subtype of spindle cell/sclerosing RMS with a craniofacial predilection. These tumors are highly aggressive, quick to metastasize and evade conventional chemotherapies. FUS-TFCP2 fusion results in a gain of function transcription factor that promotes proliferation and activates survival pathways while blocking myogenic differentiation and inhibiting DNA repair. Currently, there is no effective standard of care, surgery can be difficult due to location and patients typically succumb to the disease within 15 months of diagnosis. Overexpression of downstream target, Anaplastic Lymphoma Kinase (ALK), is characteristic of FUS-TFCP2+ RMS. However, while case reports of targeted treatment with ALK inhibitors (ALKi) have shown modest results, resistance always emerges. In collaboration with the Pediatric Cancer Precision Genomics Program at the Riley Hospital for Children, we developed a paired set of FUS-TFCP2+ RMS patient-derived xenografts (PDXs). ALKi-sensitive PDX174 was derived from a patient tumor sample obtained prior to an 11-month ALKi (lorlatinib) regimen. Subsequently, a second sample was acquired following disease progression from which ALKi-resistant PDX199 was established. RT-PCR validated the fusion site in both models. In vivo studies confirmed PDX174 sensitivity and PDX199 resistance to lorlatinib (0.1mg/kg and 1mg/kg). Concordant with FUS-TFCP2+ characterization, transcriptome analysis showed significantly increased expression of ALK in both PDX174 (14.9-fold) and PDX199 (11.1-fold). Western blot analysis revealed robust overexpression of ALK isoforms in PDX174, whereas ALK expression in the ALKi-resistant PDX199 was only barely detectable. Instead, PDX199 exhibited increased levels of TERT, CDK4/6, and BET proteins. To further compare the models, we utilized two complementary approaches to evaluate the activated kinome of ALKi-resistant PDX199 compared to ALKi-sensitive PDX174. Kinase activity profiling using PamGene peptide microarrays revealed a statistically significant increase in kinase activity of components involved in PI3K/AKT pathway and cell cycle CDKs (CDK1,2,4), with concomitant suppression of kinase activity of JNK/p38 MAPKs, indicating a shift toward PI3K/mTOR-driven pro-survival signaling and potential vulnerability to PI3K/AKT and CDK inhibition. Global kinome analysis using multiplexed inhibitor beads also showed an increase in CDK4/6 activation in ALKi-resistant PDX199 versus ALKi-sensitive PDX174. Pre-clinical models such as these provide a platform to connect molecular signatures with targeted therapy, increase our mechanistic understanding of tumor adaptive responses and design therapies that will mitigate the emergence of therapeutic resistance.

#6180 Gene editing in the mouse reveals functional mechanisms of ASPS-TFE3 induced translocation renal cell carcinoma.

Gopinath Prakasam, Alana Christie, Lisa Kinch, Jeffrey Miyata, Quyen Do, Mylinh Nguyen, Robert Hammer, Payal Kapur, James Brugarolas

UT Southwestern Medical Center, Dallas, TX

Translocation renal cell carcinoma (tRCC) is an aggressive form of kidney cancer that predominantly affects children and young adults. With no specific FDA-approved therapies, it remains an unmet clinical need. Patients often present with metastatic disease and median overall survival is less than two years. tRCC is driven by oncogenic fusion proteins involving transcription factors of the MiTF family, most commonly TFE3, yet the mechanisms by which these fusion proteins promote tumorigenesis remain poorly understood. To investigate tRCC tumorigenesis, we expressed human ASPS-TFE3, the most prevalent oncogenic fusion, in postnatal renal proximal tubule cells generating the first tRCC mouse model faithfully reproducing the human disease. These mice developed aggressive tRCC with complete penetrance and short latency. In addition, they also developed ASPS and PEComas, illustrating a shared pathogenesis that goes beyond MiTF fusion oncoproteins. Through integrated histologic, ultrastructural, transcriptomic, proteomic and functional analyses, we found that ASPS-TFE3 simultaneously activates mTORC1 signaling and lysosomal pathways. To dissect the role of ASPS-TFE3 in tumor initiation, we employed CRISPR-mediated gene editing. Structural modeling, mutagenesis, and localization studies identified a bHLH domain mutant [ASPS-TFE3(2RA)] that retains nuclear localization but fails to bind DNA and lacks transactivation activity. Unlike wild-type fusions, ASPS-TFE3(2RA) failed to induce tRCC, demonstrating that DNA binding is essential for tumorigenesis. Furthermore, its broader expression in renal epithelial cells compared to ASPS-TFE3 (despite the same driver) illustrates oncogene-induced protective mechanisms expanding our ex vivo studies. Interbreeding experiments coupled with phenotypic and functional studies revealed a context-dependent lineage-specific dominant-negative effect modulating tumor spectrum and latency. Together, these findings provide insight into ASPS-TFE3 tRCC pathogenesis and establish a genetically tractable platform to dissect fusion-driven oncogenesis and evaluate therapeutic strategies.

#6181 Development of a clinically relevant *in vitro* model of ETMR and implications for drug efficacy studies.

Evangelos Liapis, Adele Ponzoni, Lea Anne T. Maristela, Claire L. Carter, Derek Hanson

Hackensack Meridian Center for Discovery and Innovation, Nutley, NJ

Background: Patient-derived 3D models of pediatric brain tumors are increasingly used in preclinical drug screening due to their greater clinical relevance. However, no guidelines or widely adopted methods exist, and most drug screening studies still rely on small tumorspheres. The primary ETMR line, BT183, retains key molecular features, including C19MC amplification and LIN28A overexpression, yet its conventional tumorsphere format fails to recapitulate the characteristic multilayered rosettes observed in patients, lacks cellular complexity, and remains size-restricted for functional studies and drug screening. To overcome these limitations, we established a more clinically relevant 3D pseudo-organoid model by optimizing the culture medium, promoting growth from 700-3000 µm in diameter, and co-culturing with non-tumor cell populations, including blood brain barrier (BBB) and immune cells.
Methods: BT183 cells were cultured as tumorspheres in NeuroCult (NC) or as pseudo-organoids in tumor stem cell medium (TSM). Rosette abundance was quantified in H&E sections, while rosette architecture and size were assessed by 3D multiplex immunofluorescence (mIF) of optically cleared whole pseudo-organoids followed by confocal imaging and morphometric analysis. Drug screening was performed across multiple sizes and drug penetration was evaluated by mass spectrometry imaging (MSI). Multicellular BBB pseudo-organoids were generated by staged seeding of tumor, microglia, neuronal, endothelial, and pericyte populations in ratios reflecting ETMR patient samples; Integration and layering were evaluated by mIF. Large (> 2 mm) organoids were produced with or without Matrigel under constant agitation.
Results: Pseudo-organoids grown in TSM contained significantly more rosettes compared to tumorspheres grown in NC. There was a divergence in the size of the spheroids once they reached 500 µm, with the rosette forming model growing to larger sizes faster than the conventional model. Notably, the rosettes forming pseudo-organoid model demonstrated drug-dependent enhanced chemoresistance to clinically relevant agents compared to the standard model. MSI provided quantification of drug penetration and spatial distribution across models to correlate with efficacy. BBB pseudo-organoids showed successful incorporation of cell populations, including endothelial cells and pericytes. Prolonged culture under agitation, coupled with Matrigel dome embedding, further supported the formation of large, structurally complex organoids.
Conclusions: Our ETMR pseudo-organoid model recapitulates the multilayered rosette architecture characteristic of patient tumors. Ongoing work is being carried out to further refine this system into multicellular, large-scale 3D organoids that further advance preclinical modeling and therapeutic testing in embryonal tumors with multilayered rosettes.

#6182 Post-transcriptional silencing of p14ARF drives retinoblastoma malignant conversion in CRISPR-engineered retinal organoids.

Jinlun Bai, David S. Koos, Kevin Stachelek, Bhavana Bhat, Susan Asatrian, Patrick Belen, Sunjum Sanghari, Kayla Stepanian, Scott Fraser, Rex A. Moats, David Cobrinik

Children's Hospital Los Angeles, Los Angeles, CA

Purpose: This study aims to elucidate the molecular mechanisms driving malignant transformation from pre-malignant lesions, leveraging a CRISPR-engineered human retinoblastoma retinal organoid (RBRO) model that recapitulates the cone cell-of-origin and timing of multi-step retinoblastoma genesis.

Background: Most retinoblastomas arise from maturing cone photoreceptor precursors (CPs) following biallelic *RB1* inactivation. The process can be recapitulated in explanted fetal retina, where pRB-depleted CPs proliferate, followed by a 3-5 month indolence phase and emergence of retinoblastoma-like masses at tissue ages mirroring in vivo disease. CRISPR engineered retinal organoids (ROs) provide a promising model with which to define mechanisms that underlie malignant progression.

Methods: We generated *RB1* knockout iPSC lines through CRISPR editing of the GNAT2-EGFP cone reporter (Bai *et al*., PMID 37902188). Chimeric RBROs were produced by mixing *RB1* knockout and unedited parental iPSCs. Proliferation dynamics, cell identities and cell state changes of EGFP+ $RB1^{-/-}$ cones were evaluated by live imaging of hydrogel-embedded RBROs, immunofluorescent (IF) staining, and deep full-length scRNA-seq. Additional CRISPR edits were introduced to test candidate drivers of indolence entry and escape.

Results: In *RB1* WT ROs, EGFP specifically, robustly and innocuously labeled post-mitotic cones. In RBROs, live imaging and IF staining revealed initial EGFP+ $RB1^{-/-}$ cone proliferation followed by a pre-malignant indolence phase starting at ~d120. Most of the initially proliferating cones become Ki67-negative, with some adopting mature cone morphology. Retinoblastoma-like foci composed of cells co-expressing EGFP, cone markers, and Ki67 formed after ~d280, a tissue age that equates to the first post-natal month when retinoblastomas emerge. Single-cell transcriptomic profiling at different tumorigenesis stages revealed distinct $RB1^{-/-}$ cell proliferation, cell differentiation, and cell stress states with high expression of $CDKN2A^{ARF}$ RNA and p14ARF protein. In contrast to initially proliferating pre-indolence CPs, the later proliferating post-indolence retinoblastoma-like cells expressed $CDKN2A^{ARF}$ RNA but not p14ARF protein, consistent with post-transcriptional silencing of p14ARF as a mechanism underlying indolence escape. RBROs lacking p14ARF exhibited sustained initial cone proliferation similar to indolence-escaped p14ARF-WT RBROs.

Conclusion: We established a human retinoblastoma organoid model that recapitulates the cell-of-origin, developmental context, and temporal sequence of multi-step retinoblastoma genesis. This system uncovers stage-specific molecular signatures and highlights p53 pathway regulation – particularly p14ARF post-transcriptional silencing – as a key driver of the indolence-malignancy transition.

#6183 MIAC51 cells induce rapid-onset leukemia across multiple rat strains: A novel and reproducible model of Chloroleukemia.

Joel Costoya[1], Joaquin J. Jimenez[2]

[1]Department of Biochemistry and Molecular Biology, University of Miami Miller School of Medicine, Miami, FL,[2]Dr. Phillip Frost Department of Dermatology and Cutaneous Surgery, University of Miami Miller School of Medicine, Miami, FL

The American Cancer society states leukemia as the most prevalent form of pediatric cancer, nearly 1 in 5 cases of childhood leukemia are acute myeloid leukemia (AML). Advances in risk-group stratification, and chemotherapeutic regimens, have improved clinical outcomes for pediatric patients such that 5-year survival rates are at around 70%. Significant challenges remain in their treatment of leukemia, considering as many as 30% of patients relapse and the expected survival rate is drastically lower. Efforts to understand the mostly unknown etiology of childhood leukemia have been greatly improved by animal modeling which can simulate biological multi-system involvement and a more accurate disease state. We aim to document a new viable animal model in the limited repertoire of AML models using MIAC51 cells, a rat Chloroleukemia cell line. Multiple strains of rat pups, at 7 days old, were injected intraperitoneally with MIAC51 rat cells and compared to respective control groups who received saline solution. All pups had 50 µL of blood drawn at both 7- and 14-days post-injection via tail snip method. Complete blood count (CBC), and differential staining were performed to detect presence of leukemia. At 14 days post-injection, all breeds tested: Wistar, Sprague Dawley, Long Evans, Brown Norway, and Fischer 344, developed leukemia with 100% success rate. Chloroleukemia blasts were found in peripheral blood, indicative of AML as confirmed by Wright stain and CBC. Established here is a novel and reproducible young-rat leukemia model using MIAC51 cells, demonstrating consistent engraftment and leukemic transformation across all tested breeds. Induction of leukemic-state was confirmed by the presence of Chloroleukemia blasts in peripheral blood staining and CBC abnormalities. This model will accelerate translation of hematological science research by providing a platform for studying leukemogenesis, and leukemic pathophysiology in a young-host, with relevance to childhood acute myeloid leukemias. Inquiry into the mechanistic basis for Chloroleukemia induction, and further genetic analysis of the leukemia model will help define its fidelity to human pediatric AML and determine its utility in downstream pre-clinical application.

#6184 Site-specific tumor modeling: DIPG and meningioma in mice.

Melissa Tran[1], Cheryl Davis[2], Ben Hoerner[1], Victoria Caruso[1], Helen Ketteringham[3], Corrine Silvio[4], Shannan Paul[3], Chris Holding[3], Aliccia Koznecki[3], Dawn Lusk[4], Shorena Nadaraia-Hoke[4], Delaney McCormick[1], Jocelyn Saurbaugh[1]

[1]Reaction Biology Corp, Malvern, PA,[2]Reaction Biology Europe GmbH, Freiburg im Breisgau, Germany,[3]Reaction Biology Corp, Hershey, PA,[4]Reaction Biology Corp, Hummelstown, PA

Diffuse intrinsic pontine glioma (DIPG) and meningioma are central nervous system tumors where anatomical location critically influences disease behavior and therapeutic response. To investigate this impact, we have developed and compared preclinical models using SF8628-GFP$^+$/Luc$^+$ (DIPG) and Ben-Men-1-Luc (meningioma) across three inoculation sites: (1) clinically relevant locations (pons for DIPG; skull base for meningioma), (2) general intracranial sites, and (3) subcutaneous sites. Tumor progression was monitored longitudinally using bioluminescence imaging and confirmed by histopathology. This study sought to determine how site-specific microenvironments affect growth kinetics, infiltration patterns, and imaging characteristics. Understanding these differences is essential for drug development, as orthotopic models better replicate blood-brain barrier constraints, tumor vascularization, and local tissue interactions that influence therapeutic delivery and efficacy.

: Spatial Niches and Functional Boundaries within the Tumor Microenvironment 2
Poster Session

#6187 Elevating bulk sequencing with high-resolution spatial transcriptomics: A paired-data analysis of clinically-relevant spatial niches in CRC and NSCLC.

Yajas Shah, Tianyou Luo, Christine M. Hoeman, Luca Lonini, Stanislaw Szydlo, Eduardo Diaz, Rossin Erbe, Matthew B. Maxwell, Michelle M. Stein, Andrew J. Sedgewick, Nicholas Rachell, Zachary Chelsky, Sonal Khare, Ryan D. Jones, Kate Sasser, Richard A. Klinghoffer, Justin Guinney, Chi-Sing Ho

Tempus AI, Chicago, IL

Background. Bulk RNA-next generation sequencing (RNA-NGS) is a standard tool for the molecular characterization of solid tumors and is used in clinical practice to guide therapy selection. However, the spatial organization of the tumor microenvironment (unobservable in bulk RNA-NGS) plays an important role in clinical phenotypes and therapy response. While spatial transcriptomics (ST) overcomes the limitations of bulk sequencing, the relationship amongst ST, bulk NGS, and clinical phenotypes in real-world cancer patients has not been explored. To address this, we generated and analyzed a large multimodal, real-world cohort of colorectal (CRC) and non-small cell lung cancer (NSCLC) tumors profiled with ST, bulk RNA-NGS and targeted DNA-NGS data from the same biospecimen.
Methods. Gene expression data from 3.7 million cells, sourced from 42 NSCLC (16 metastatic) and 19 CRC (6 lung and 6 liver metastases) patients were generated at whole-transcriptome level using 10X Genomics Visium HD platform. Cells were integrated using scVI and annotated using SCimilarity. Spatially-informed clusters were generated using CellCharter. Association testing between spatial, clinical, and biomarker features, including the Tempus Immune Profile Score (IPS) were performed using linear models adjusted for clinical (tumor type, stage, histology, metastasis) and molecular features (TMB) as appropriate.
Results. Visium HD pseudo-bulk showed high correlation with paired bulk RNA, with a median Spearman correlation of 0.79 (IQR: 0.78-0.81). Spatial clustering of gene expression revealed six distinct spatial niches: two enriched for epithelial cells, one for stromal cells, and three for immune cells (myeloid-rich, lymphoid-rich, and tumor-immune mixed regions). Among NSCLC tumors sourced from the lung, we found that the myeloid, lymphoid and stroma-rich niches were enriched for Stage I, II and IV cases respectively ($p < 0.05$). Spatial niches were associated with key oncogenic alterations in NSCLC (lymphoid-, myeloid- and stroma-rich, *CDKN2A*, *KEAP1*, *RBM10*, $p < 0.05$) and CRC (lymphoid- and myeloid-rich, *KRAS*, *TP53*, $p < 0.05$). Patients with higher IPS scores were associated with an enrichment of lymphoid and tumor-immune mixed niches ($p < 0.05$), while cells from tumor-immune mixed regions had higher expression of immune infiltration and exhaustion markers than the lymphocyte-rich regions (*IKZF2*, *TOX2*, *PTPRC*, *CD69*).
Conclusion. Our work profiles the genomic and transcriptional features contributing to spatial heterogeneity, revealing distinct molecular patterns associated with immune cell infiltration. This dataset provides a powerful foundation for understanding tumor microenvironment-driven phenotypes and translating spatial-only insights into scalable biomarkers, empowering future translational discovery in precision oncology.

#6188 Decoding the archetypes and ecotypes of triple-negative breast cancer in responses to chemotherapy.

Yun Yan[1], Yiyun Lin[1], Tapsi Kumar[1], Shanshan Bai[1], Aatish Thennavan[1], Jianzhuo Li[1], Tuan Tran[1], Min Hu[1], Mitchell Rao[1], Anna Casasent[1], Elizabeth Ravenberg[1], Gaiane Margishvili Rauch[1], Alyson Clayborn[1], Debu Tripathy[1], Alastair Thompson[2], Bora Lim[1], Lei Huo[1], Lei Huo[1], Stacy Moulder[1], Clinton Yam[1], Nicholas E. Navin[1]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]Baylor College of Medicine, Dan L. Duncan Cancer Center, Houston, TX

Triple-negative Breast Cancer (TNBC) is an aggressive subtype of breast cancer. The pillar of treatment is chemotherapy, but only half of the patients have a complete response and good survival. To resolve inter- and intra-tumoral heterogeneity and determine their clinical associations, we performed single-cell RNA-sequencing and spatial transcriptomics experiments (including Xenium, Visium HD, and Visium) on treatment-naïve samples of TNBC patients in the ARTEMIS clinical trial. We find that TNBC is classified into 4 major archetypes at patient level: luminal secretory-like, basal-like, interferon responsive, and androgen receptor-enriched. At cell level, cancer cells exhibited intratumoral heterogeneity in 13 gene expression metaprograms. The TNBC tumor microenvironment (TME) consisted of 49 distinct immune and stromal cell states, many of which were reprogrammed relative to normal breast tissues from disease-free women. We further identified 8 ecotypes of cancer cells and TME cell states that co-occurred among patients and were associated with specific archetypes and chemotherapy response groups. Using the Xenium data, we identified 10 distinct spatial niches based on the co-localization of cancer and TME cells, including the tertiary lymphoid structure (TLS) niche, the immune-'hot' niche enriched for interferon signaling, and the EMT-associated niche characterized by the angiogenic and ECM-remodeling macrophages together with the hypoxic, EMT-related cancer cells. In contrast to previous work on T-cells, our data showed the importance of macrophage cell states and cancer cell metaprograms for interferon signaling, HLA expression and cell cycle activity that were associated with chemotherapy response. To facilitate a clinical application, we developed a 13-gene-based model of response prediction, which was validated using public TNBC cohorts. Collectively, this study provides new insights into the natural biology of untreated TNBC tumors and their association with chemotherapy response.

#6189 *ERBB2* expression and the immune landscape shape the tumor microenvironment and influence prognosis in esophageal adenocarcinoma brain metastases.

Nora M. Lawson[1], Ines Martin-Barrio[1], Lingqun Ye[1], Bo Zhao[1], Thomas Mitchell[2], Mesut Unal[1], Chae Yun Cho[1], Andrew Futreal[3], Kadir C. Akdemir[1]

[1]Neurosurgery, UT MD Anderson Cancer Center, Houston, TX,[2]Genetics, UT MD Anderson Cancer Center, Houston, TX,[3]Genomic Medicine, UT MD Anderson Cancer Center, Houston, TX

Esophageal adenocarcinoma (EAC) is a prevalent and fatal malignancy, ranking sixth globally in cancer-related deaths. Brain metastases from EAC are rare, occurring in only 2-6% of cases, and little is known about the molecular drivers or tumor microenvironment (TME) characteristics that underpin this metastatic spread. To investigate drivers of brain metastasis, we analyzed a test cohort of frozen primary and brain metastasis pairs (n = 8) and an expansion cohort of 60 FFPE brain metastases from surgeries performed at MD Anderson Cancer Center (2010-2018).To characterize molecular determinants of EAC brain metastases, we performed multi-omics profiling, integrating whole-genome sequencing, fluorescence in situ hybridization (FISH), and single-cell spatial transcriptomics (10x Genomics Xenium). *ERBB2* amplification emerged as a recurrent and potentially targetable alteration, present in 90% of brain metastases versus 20-25% of primary and extracranial tumors, suggesting an early and frequent driver event. The cohort included 12 long-term survivors (LTS; >3 years), including one patient alive 17 years post-diagnosis, whereas most patients succumbed within one year. Several received HER2-targeted therapy with variable clinical responses, underscoring the need to elucidate factors distinguishing LTS from short-term survivors (STS; <1 year). Single-cell spatial transcriptomics revealed distinct tumor-immune ecosystems associated with *ERBB2* copy number. LTS tumors with high *ERBB2* amplification exhibited immune-active microenvironments enriched in macrophages, T cells, and endothelial cells, with fewer cycling tumor cells, indicative of effective immune surveillance. In contrast, low-*ERBB2* tumors were proliferative and immune-poor. Across all cases, *ERBB2* expression correlated with T cell infiltration and tertiary lymphoid structures (TLS). Differential gene expression confirmed LTS tumors up-regulated immune activation and T cell persistence genes (*IGH1, IGH3, IGH4, IL2RB, TOX*), whereas STS tumors expressed pro-tumor, inflammatory, and angiogenic genes (*MUC5AC, REG4, CXCL1, CXCL3, RGS5, ACE2*). These findings indicate that *ERBB2* amplification and immune contexture jointly shape the tumor microenvironment and prognosis in EAC brain metastases, suggesting that *ERBB2*-directed therapies combined with strategies to enhance immune activity may improve outcomes in this patient population.

#6190 Spatial architecture analysis reveals disrupted lymphotoxin signaling gradients associate with recurrence in high-grade serous ovarian cancer.

Zhewei Zhang, Tat San Lau, Chi Chiu Wang

The Chinese University of Hong Kong, Shatin, Hong Kong

Background: Recurrence drives mortality in ovarian cancer patients, with tumor-stromal signaling interactions playing critical roles in disease progression. Lymphotoxin family signaling, operating through lymphotoxin-LTBR interactions between tumor and stromal compartments, orchestrates chemokine-mediated immune cell recruitment. However, existing studies have focused on expression levels rather than spatial organization of these signaling networks. We aimed to characterize spatial gradient patterns of lymphotoxin signaling in high-grade serous ovarian cancer (HGSC) and determine whether spatial organizational features distinguish recurrent from non-recurrent disease.
Methods: We integrated publicly available subcellular spatial transcriptomics datasets spanning multiple independent cohorts, comprising >100 HGSC patients and >2.5 million spatially resolved cells. Patients were stratified by 2-year progression-free survival into recurred versus non-recurred groups. We quantified spatial expression gradients using neighborhood-based approaches, calculating spatial autocorrelation and tumor boundary-associated expression patterns for lymphotoxin family genes (LTA, LTB, LTBR) and related chemokines.
Results: Recurrent HGSC exhibited disrupted spatial organization of lymphotoxin signaling despite comparable expression levels. LTB displayed reduced spatial autocorrelation in recurrent tumors (-0.254 vs -0.320, $p=0.029$), indicating loss of organized spatial expression patterns. LTBR showed attenuated tumor boundary gradients in recurrent samples (Spearman $\rho=-0.121$ vs -0.178, $p=0.034$), suggesting disrupted spatial signaling architecture at tumor-stromal interfaces. LTB also demonstrated diminished tumor boundary enrichment in recurrent cases ($\rho=-0.010$ vs 0.070, $p=0.055$). Cellular composition and overall gene expression showed no significant differences, confirming that spatial organization rather than abundance drives these findings.
Conclusion: Disrupted LTB/LTBR spatial gradients in recurrent HGSC indicate that immune evasion involves spatial disorganization of tumor-stromal signaling beyond expression-level changes. These findings suggest that interventions restoring spatial chemokine gradients—such as engineered lymphotoxin delivery or spatially-targeted stromal reprogramming—may enhance immune infiltration and warrant investigation as strategies to prevent ovarian cancer recurrence.

#6191 Decoding the interactions between cancer cells and monocyte-derived macrophages in a co-culture model using flow cytometry and bead-based multiplexing immunoassay panels.

Amy Zhao, Anugraha Gandhirajan, Michael Hunegnaw, Anil Kumar Jaiswal, Jessie Ni

BioLegend, San Diego, CA

Macrophages play a pivotal role in the immune response and in the maintenance of tissue homeostasis. It is well known that many tumors recruit monocytes from circulation and transform them into an immunosuppressive subset called Tumor-Associated Macrophages (TAMs). TAMs are highly plastic and can alter their phenotypes between M1 pro-inflammatory and M2 anti-inflammatory according to their location and surrounding cytokine milieu in the tumor microenvironment. M1 macrophages are associated with the recognition and destruction of cancer cells whereas M2 macrophages are thought to promote proliferation, angiogenesis, and metastasis of cancer cells. In this study, monocytes-derived THP1 macrophages were cultured with conditioned medium collected from various cancer cell lines, such as colon cancer cell line HT29, lung cancer cell line A549 and breast cancer cell line MDA-MB-231, to study the influence of cancer cells and their secreted factors on the activation and differentiation of monocyte-derived macrophages. The phenotypes of the macrophages in the culture were characterized by flow cytometric analysis of macrophage surface markers including CD86, CD206, CD163, CD274, CD11b, CD14 and CD40, and the soluble factors produced by them including the M1 and M2 markers were measured using the LEGENDplex ™ Human Macrophage Panel and Human Tumor-Associated Macrophage Panel. In a parallel study, macrophages were activated and polarized into M1 and M2 phenotypes, followed by co-culture with cancer cells. The proliferation and viability of cancer cells were measured at the end of the incubation by flow cytometry to assess the distinct influences of M1 and M2 macrophages on cancer cell cultures. Our data suggests that cancer cells could release soluble factors to actively influence the phenotypes of monocyte-derived macrophages. Moreover, the study demonstrated that M1 and M2 macrophages may have different impact on cultured cancer cell's viability and proliferation. This *in vitro* study enhances our understanding of the interplay between cancer cells and tumor-associated macrophages, underscoring the utility of LEGENDplex^{TM} panels in studying tumor-associated macrophages.

#6192 Multi-omics reveals the diversity of CAF in ESCC lymph node metastasis.

Licheng Tan[1], Beilei Liu[2], Shuang Zhang[3], Jiayi Huang[4], Bowen Yao[4], Xin-Yuan Guan[4]

[1]Department of Clinical Oncology, University of Hong Kong, Hong Kong, Hong Kong,[2]City University of Hong Kong, Hong Kong,[3]University of Hong Kong, Shenzhen Hospital, Shenzhen Shi, Hong Kong,[4]University of Hong Kong, Hong Kong, Hong Kong

1. Introduction Esophageal squamous cell carcinoma (ESCC) is among the most common and lethal malignancies in China, accounting for the fifth-highest rate of cancer-associated mortality. Cancer-associated fibroblast (CAF) plays an important role in tumor microenvironment (TME). Lymph node metastasis is a key risk factor that leads to worse prognosis of ESCC patients. However, the initiation and mechanism of lymph node metastasis is still uncertain. Our previous study has revealed that CAF can promote ESCC lymph node metastasis through secreting MFGE8 to activate AKT/STAT3 signaling. Thus, we decided to further explore the role of CAF in ESCC lymph node metastasis.
2. Materials and methods We collected ESCC tumor samples for spatial transcriptome sequencing. Combined with our single-cell RNA sequencing data and published single-cell sequencing cohort, we performed multi-omics spatiotemporal analysis to reveal the diversity of CAF in ESCC. We also performed multi-plex immunohistochemistry (mIHC) to verify the subtype in ESCC samples. We collected fresh ESCC samples from patients and murine models to isolate CAF from tumor for in vitro and in vivo experiment. Sirius red staining was performed for collagen composition analysis. KYSE30, KYSE180, KYSE410, KYSE520, and mouse mEC25 cell lines were cultured for in vivo and in vitro experiments.
3. Results We integrated our single-cell RNA sequencing data (GSE203067) and another published cohort (GSE160269), which contained 64 ESCC patients. After unsupervised clustering, we got 6 subclusters of fibroblast (including pericyte and smooth muscle cell). Tissue distribution showed that MMP11+ Fib was enriched in primary tumor and metastatic lymph node, while PI16+ Fib was enriched in normal esophagus. Then we analyzed spatial transcriptome sequencing data via deconvolution algorithm, and revealed the spatial distribution of different fibroblast subtypes in ESCC tumor. MMP11+ Fib showed a higher proportion in primary tumor of patients with lymph node metastasis. Gene Set Enrichment Analysis indicated pathways with extracellular matrix and epithelial-mesenchymal transition were upregulated in MMP11+ Fib. Western blot and immunofluorescent staining verified the expression of MMP11 in CAF from ESCC patients and murine ESCC model. Cell-cell interaction analysis, based on spatial localization, indicated the POSTN-(ITGAV/ITGB5) ligand-receptor signaling was significantly activated between MMP11+ Fib and tumor cell.
4. Conclusion CAF in ESCC showed a huge diversity, and the MMP11+ Fib is a pro-tumor and pro-metastasis subtype of CAF, which is a potential target for ESCC treatment.

#6193 Spatial remodeling of immune and stromal microenvironments in sentinel lymph nodes during melanoma progression.

Shankar Suman[1], Wendy K. Nevala[1], Noah A. Stueven[1], Raymond M. Moore[1], Chathu L. Atherton[1], Jeffrey E. Johnson[1], Ray Guo[2], James W. Jakub[2], Svetomir N. Markovic[1]

[1]Mayo Clinic, Rochester, MN,[2]Mayo Clinic, Jacksonville, FL

The sentinel lymph node (SLN) is often the first site of melanoma spread and a critical immune checkpoint that determines local tumor dissemination to systemic metastasis. Although lymph nodes are central to antitumor immunity, the mechanisms that render them permissive to metastasis remain poorly understood. This study used spatial imaging to characterize immune and stromal phenotypic alteration in tumor-negative SLNs (SLN^-) and tumor-positive SLNs (SLN^+) from patients with cutaneous melanoma, compared to non-melanoma-associated normal lymph nodes (NLN). We performed multiplex immunofluorescence (MxIF) analysis of formalin-fixed, paraffin-embedded lymph node tissues from patients with cutaneous melanoma and control subjects, including two subjects per group (NLN, SLN^-, and SLN^+). Furthermore, quantitative single-cell segmentation and classification using QuPath generated median fluorescence intensities for immune, stromal, and tumor markers across LN, SLN^- and SLN^+ regions of interest. In addition to the initial analysis, we employed spatial neighborhood analysis to characterize markers expression profiles surrounding target immune population. This approach quantified local microenvironment based on marker normalized intensity-based co-expression pattern and stromal remodeling signatures. We grouped these markers based on the functional panels representing T-cell activation and exhaustion, myeloid polarization, tumor interaction, stromal remodeling, and apoptosis pathways providing insights into how prometastatic niche evolve within SLN.

Normalized data, via centered log ratio (CLR) transformation and Gaussian Mixture Model (GMM) gating was analyzed using principal component analysis, UMAP/tSNE embedding, and hierarchical clustering in in python. Progressive immune remodeling was observed from normal NLN to SLN^+, including expansion of regulatory T cells, enrichment of exhausted T cells as well as myeloid-derived suppressor cells (MDSC), and transition toward an M2-like macrophage phenotype. The spatial data from SLN^- samples showed an early sign of immune suppression, with reduced cytotoxic capacity. These results show that SLN gets features of peripheral immune tolerance for melanoma early, prior to pathological dissection of metastatic spread supporting the existence of a pre-metastatic niche that facilitates lymphatic colonization of tumor cells. This work provides insights into early immune escape and may inform strategies for immunotherapy and early intervention in melanoma.

#6194 Spatial architecture of immunochemotherapy response in pleural mesothelioma.

Harim Chun[1], Yeoun Eun Sung[2], Sook Hee Hong[3], Sangjeong Ahn[4], Sung Hak Lee[2]

[1]Department of Medical Science, Graduate School, The Catholic University of Korea, Seoul, Korea, Republic of,[2]Department of Hospital Pathology, Seoul St. Mary's Hospital, The Catholic University of Korea, Seoul, Korea, Republic of,[3]Division of Oncology, Department of Internal Medicine, Seoul St. Mary's Hospital, The Catholic University of Korea, Seoul, Korea, Republic of,[4]Department of Pathology, Korea University Anam Hospital, College of Medicine, Korea University, Seoul, Korea, Republic of

Introduction: Pleural mesothelioma (PM) is a rare and aggressive malignancy originating from the mesothelial cells of the pleural lining, with a well-established etiological association with asbestos exposure. Although immunochemotherapy is being applied as a first-line treatment, most patients fail to respond to the therapy. Previous single-cell RNA sequencing studies on PM have revealed cellular heterogeneity but lack spatial resolution and comparative analyses of immune checkpoint inhibitor (ICI) responses, limiting understanding of tumor microenvironment (TME)-mediated resistance mechanisms. This study aims to comprehensively identify the cellular composition and spatial architecture of the TME, as well as mechanisms responsible for ICI resistance in PM.
Methods: Spatial transcriptomics analysis using the Xenium Prime 5K platform was conducted on baseline samples from 21 mesothelioma patients who received neoadjuvant immune checkpoint inhibitors (nivolumab/pembrolizumab), stratified as Responders (CR/PR, n=7) and Non-responders (PD/SD, n=14). Transcript-aware cell segmentation was performed with Proseg, followed by clustering and downstream analysis using Scanpy and Seurat. Copy number variations (CNV) were inferred with insituCNV, and pathway analysis was conducted via PROGENy and KEGG. Conserved spatial niches were identified using the BuildNicheAssay() function in Seurat v5.
Results: Spatial transcriptomics identified distinct 36 cell clusters, including mesothelial, immune, stromal, and normal alveolar cells. Mesothelial cells exhibited chromosome 22 deletions, with CNV scores inversely correlating with treatment response. Mesothelial cells of non-responders displayed “Active & Proliferative” phenotype with the high MAPK/PI3K/VEGF activities, whereas responders demonstrated “Stressed & Adaptive” state with elevated p53/TRAIL pathway activities. Responders demonstrated increased B cells, proliferating T cells, CD8 effector memory T cells, and exhausted T cells (CD8 Tex), whereas non-responders showed elevated tumor-associated macrophages. Among the 12 recurrent spatial niches, two tumor-reactive immunity niches of CD8 Tex and B cell-enriched tertiary lymphoid structure-like regions were prominent in responders. Immunosuppressive niches featuring mesothelial cells and SFRP2+ cancer-associated fibroblasts with active TGFβ pathways predominated in non-responders.
Conclusion: This study defines the TME architecture, mesothelial cell functional states, and cell type proportions associated with therapeutic response in PM. Cell type proportions and spatial niche composition featuring tumor-reactive immunity in responders versus TGFβ-driven immunosuppression in non-responders demonstrate predictive value for treatment outcomes and establish novel therapeutic targets to enhance immunotherapy responses.

#6195 Spatial transcriptomics analysis reveals tumor cell plasticity and diverse tumor microenvironments in Ewing sarcoma.

Heng Luo[1], Clemence Henon[2], Gleb Rukhovich[1], Stefanie Kutschmann[2], Nina Wilhelm[1], Wolfgang Hartmann[3], Uta Dirksen[4], Duncan T. Odom[5], Thomas G. Grunewald[2], Moritz Gerstung[1]

[1]Division of Artificial Intelligence in Oncology, DKFZ German Cancer Research Center, Heidelberg, Germany,[2]Division of Translational Pediatric Sarcoma Research, DKFZ German Cancer Research Center, Heidelberg, Germany,[3]Gerhard-Domagk-Institute of Pathology, Munster University Hospital, Muenster, Germany,[4]Pediatrics III, University Hospital Essen, West German Cancer Center, NCT West, Essen, Germany,[5]Division of Regulatory Genomics and Cancer Evolution, DKFZ German Cancer Research Center, Heidelberg, Germany

Objective

Ewing sarcoma (EwS) is a highly aggressive fusion-driven cancer of childhood and adolescence that can arise in both bone and soft tissue.In EwS, the tumor microenvironment (TME) is composed of cell types from the mesenchymal and hematopoietic lineages. Complex interactions between tumor cells and their TME are believed to shape the TME structure and the tumor cell plasticity in EwS. There have been existing efforts to characterize the fusion related tumor cell heterogeneity in EwS using bulk RNA-seq. In contrast, the TME of Ewing sarcoma remains largely underexplored at both single-cell and spatial level due to limited accessibility to patient samples and the constraints of contemporary staining methods. The aim of this project is to chart the EwS tumor cell heterogeneity and to characterize the interaction between the EwS tumor cells and the cells from the TME.

Methods

We performed single-cell FFPE sequencing (scFFPEseq) on four EwS tissue blocks. By utilizing the scFFPEseq data, we developed a probe panel comprising 480 genes. This refined selection includes cell type markers, differentially expressed genes (DEGs), highly variable genes (HVGs), hallmarks of tumor heterogeneity, pathway signatures, and specific receptor-ligand pairs, enabling precise in situ profiling of gene expression. We then performed spatially-resolved single-cell transcriptomics (10x Xenium) on 1 whole-section EwS sample and 137 EwS core sets from archived tissue microarrays.

Results

We generated a spatially-resolved single-cell dataset of 138 Ewing sarcoma patient samples, comprising 3.14 million cells. Meta program analysis on this dataset revealed 5 transcriptional states shared among EwS tumor cells across samples. These states include cell cycle, protein regulation, hypoxic stress, interferon response and high EWSR1-FLI1 fusion activity. The EwS TME consists of four stromal cell types and eight immune cell types. Spatial analysis showed that the EwS tumor cell states co-localize with distinct TME cells, giving rise to 8 recurrent niches.In the necrotic regions, SPP1+ macrophages and NK cells are found enriched in close proximity to hypoxic tumor cells. In regions with lymphocytic infiltration, co-localization with C1QC+ macrophage is associated with increased interferon response and JAK-STAT pathway activity in the EwS tumor cells.Finally, spatial single-cell interaction analysis suggests that lower EWSR1::FLI1 signature levels in the EwS tumor cells may be attributed to FGFR1 signaling stimulated by proximal fibroblasts.

Conclusion

In this project, we defined 5 shared tumor cell programs and 8 recurrent spatial neighborhoods across 138 EwS patient samples. The interplay between EwS tumor cells and fibroblasts via FGFR1 was found to be associated with lower EWSR1::FLI1 fusion signatures. This finding will lead to a potential therapeutic value of FGFR1 in the EwS treatment.

#6196 Neutrophil extracellular traps is involved in ovarian cancer-associated venous thrombosis.

Gaku Yamamoto[1], Mahiru Kawano[1], Mina Sakata[1], Michiko Bun[2], Aasa Shimizu[1], Erika Nakatsuka[1], Yasuto Kinose[3], Kenjiro Sawada[1], Michiko Kodama[1]

[1]Graduate School of Medicine Osaka University, Osaka, Japan,[2]Osaka Kaisei Hospital, Osaka, Japan,[3]Sakai City Medical Center, Osaka, Japan

Aims: Ovarian cancer patients have increased risk of venous thrombosis. However, the responsible mechanism of ovarian cancer associated venous thrombosis is not fully understood. This study aimed to investigate the formation of neutrophil extracellular traps (NETs) and its pathologic role in ovarian cancer patients. Methods: Human neutrophils were isolated from peripheral blood by density gradient centrifugation. Neutrophils were incubated in various conditions and tested for NETs formation in vitro. NETs formation was quantified by observing neutrophils stained with DNA-binding dye under fluorescent microscope. Several benign tumor sera and ovarian cancer sera were analyzed by cytokine array and ELISA. Serum NETs levels were measured by sandwich ELISA using anti-neutrophil elastase (NE) and anti-double strand DNA antibody. Clinical records of ovarian cancer patients who underwent surgery at our institution were retrospectively reviewed to evaluate the association between serum NETs levels and clinical. Immunohistochemistry with NETs marker, citrullinated histone H3 (CitH3) and myeloperoxidase (MPO), was performed for the samples of intravascular thrombosis in ovarian cancer patient. Results: Neutrophils could be isolated from peripheral blood with high purity. Conditioned media collected from OVCAR8 and OVKATE induced neutrophils to form NETs strongly. Serum from ovarian cancer patient predisposed neutrophils to form NETs more strongly than that from benign tumor patient (Median of index: 0.55 vs. 1.64; $p < 0.05$). Serum granulocyte-colony stimulating factor (G-CSF) levels from ovarian cancer patients were significantly higher than those from benign patients (Mean [pg/mL]: 4.5 vs. 9.9; $p < 0.05$). The stimulation with recombinant G-CSF induces neutrophils to form NETs. By cytokine array, Insulin-like Growth Factor 1 (IGF-1), C-C motif chemokine ligand 5 (CCL5), Angiogenin and Epidermal Growth Factor (EGF) were upregulated in ovarian cancer serum. However, when we verify CCL5 levels using multiple samples, there were no significant differences between benign tumor and ovarian cancer. Neutrophils isolated from ovarian cancer patients form NETs more greatly than neutrophils from benign tumor patients (Mean of index: 1.12 vs. 2.34; $p < 0.05$). Serum NETs level was significantly higher in ovarian cancer patients than in benign tumor patients (Median index: 0.0318 vs. 0.0667; $p < 0.05$). High NETs concentration was related to poor prognosis, increased neutrophil count, high platelet count, elevated CA125 level, advanced stage and venous thrombosis. Among them, thrombosis was significantly related to high NETs concentration in multi-variate analysis. Immunohistochemical analysis revealed NETs foci in thrombosis in ovarian cancer patients. Conclusion; It is suggested that ovarian cancer predisposed neutrophils to form NETs, which might have a causal effect on venous thrombosis.

#6197 Spatial transcriptomics reveal distinct tumor microenvironment associated with clinical response in thymic epithelial tumors after neoadjuvant therapy.

Hyunsu Kim[1], Jinyong Kim[1], Hyun-Ae Jung[1], Jong-Mu Sun[1], Se-Hoon Lee[1], Jin Seok Ahn[1], Myung-Ju Ahn[1], Yeong Jeong Jeon[2], Junghee Lee[2], Jong Ho Cho[2], Hong Kwan Kim[2], Yong Soo Choi[2], Seong Yong Park[2], Woong-Yang Park[3], Yoon-La Choi[4], Sehhoon Park[1]

[1]Division of Hematology-Oncology, Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of,[2]Department of Thoracic and Cardiovascular Surgery, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of,[3]Department of Health Sciences and Technology, Samsung Advanced Institute of Health Sciences and Technology, Sungkyunkwan University, Seoul, Korea, Republic of,[4]Department of Pathology & Translational Genomics, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of

Background: Thymic epithelial tumors (TETs) are rare malignancies, mostly treated with surgical resection as the standard approach. However, recurrence rates remain high and immunotherapy can lead to immune-related adverse events, highlighting the need for improved therapies and predictive biomarkers. In this study, TET patients were administered three cycles of neoadjuvant immunochemotherapy prior to surgery. We aimed to characterize the tumor microenvironment (TME) to identify the association with treatment response.
Methods: We performed 18 single-cell RNA sequencing and 15 spatial transcriptomics on surgical specimens from 19 patients treated with neoadjuvant immunochemotherapy. Major pathological response (MPR) was defined as less than 10% viable tumor cells in resected specimens. Patients were stratified into three pathological response groups — thymic carcinoma (TC) with MPR, TC non-MPR, or thymoma (TM) non-MPR.
Results: Analysis of cell composition and ligand-receptor interaction networks revealed distinct TME differences according to pathological response group. In TC, tumors with MPR were characterized by extensive immune infiltration, tertiary lymphoid structures (TLS) formation, and prominent malignant cell necrosis. This immunologically hot TME featured robust interactions between lymphocytes and dendritic cells (DCs). Conversely, the TC non-MPR TME was dominated by thymic epithelial cells (TECs). Within the tumor core, these TECs orchestrated a localized immunosuppression by promoting the exhaustion of infiltrating CD8+ T cells and driving the polarization of tumor-associated macrophages into an M2-like state. This suppressive niche was further compounded by a scarcity of DC. In the context of TM, the non-MPR tumors was defined by scattered cortical TECs (cTECs) and thymocytes, alongside a sparse infiltration of effector T cells. Notably, cTECs maintained an immature TME by promoting thymocyte survival and retention while concurrently impairing the tumor-killing functionality of CD8+ T cells. Detailed cell-to-cell interaction results that further elucidate these TME dynamics will be presented.
Conclusions: Our findings that responses to neoadjuvant therapy in TETs are closely associated with distinct spatial characterization of the TME. Leveraging integrated single-cell and spatial multi-omics data, this study provides valuable insights into the TME and may inform a rationale for therapeutic strategies to improve clinical outcomes in TETs.

#6198 Single cell spatial multi-omic characterization of the tumor microenvironment in transformed follicular lymphoma.

Shaocheng Wu[1], **Eric Lee**[1], Anne-Sophie Fratzscher[1], Andrew Lytle[1], Spencer D. Martin[2], David G. Huntsman[1], David W. Scott[1], Christian Steidl[1], Andrew Roth[1]

[1]BC Cancer Agency, Vancouver, BC, Canada,[2]University of British Columbia, Vancouver, BC, Canada

Histological examination of follicular lymphoma (FL) biopsies remains the cornerstone for diagnosis and staging of FL. Single cell sequencing approaches, while transcriptomically rich, require tissue dissociation and therefore lose the native spatial context that may underpin FL progression and transformation to a high-grade lymphoma, typically diffuse large B cell lymphoma (DLBCL). By single cell spatial profiling, we aimed to characterize the spatiotemporal heterogeneity and interplay between malignant B cells and the tumor microenvironment (TME) during transformation from FL to DLBCL histology.

Single cell spatial transcriptomics (Nanostring CosMx) and proteomics (Cell DIVE) were performed on FFPE tissue cores of 14 tFL patients with paired FL (tFL-FL) and DLBCL (tFL-DLBCL) timepoints, and 13 FL patients without evidence of progression or transformation (non-tFL; >6y of follow-up). Spatial omics confirmed malignant B cell dominated follicular structures in non-tFL and tFL-FL while absent in tFL-DLBCL, consistent with pathologic classification. Follicles were then delineated (defining intra-follicular, peri-follicular and extra-follicular regions) and enriched proliferation and exhaustion features were observed in intra-follicular regions compared to extra-follicular counterparts. Moreover, differential spatial interaction patterns were observed, amongst which Galectin-9 crosstalk components were identified as being differentially expressed and exhaustion-related pathways were more prevalent in intra-follicular and peri-follicular regions in non-tFL and tFL-FL timepoints. Macrophage phenotypes also markedly shifted across spatial regions with progression: intrafollicular FOLR2$^+$ and IL4I1$^+$ macrophages present in non-tFL progressively diminished, while CD163$^+$, SPP1$^+$, and NLRP3$^+$ macrophages became increasingly enriched in extra-follicular regions in tFL-DLBCL. Cell neighborhood analysis showed differential abundance among non-tFL, tFL-FL, and tFL-DLBCL timepoints. For B-cell-predominant cell neighborhoods (CNs), the germinal center (GC) score was higher in non-tFL than tFL-FL, whereas tFL-FL and tFL-DLBCL shared similar GC score levels. Within CNs of similar cell type compositions, T cells were more exhausted and macrophages were more polarized towards anti-inflammatory phenotypes in the transformed state. Subsequent single cell proteomics validated the differential follicular Galectin-9 signaling and macrophage-related gene expression patterns among spatial regions.

In summary, we delineated the spatial landscape of both indolent and transformed FL. We identified a spatiotemporal shift in TME composition, spatial interactions, and cell neighborhoods. This study provides novel insights into the spatial lymphoma architecture associated with FL transformation, contributing to a refined disease evolution model.

#6199 Spatially revealed malignant and microenvironment ecosystems in PanIN- and IPMN-derived PDAC.

Tengyu Zhang[1], Assya Legrini[1], Mari-Claire McGuigan[1], Stephan B. Dreyer[1], Ghazal Latifi[1], Claire Kennedy Dietrich[1], Hannah Morgan[1], Eva Verkolf[2], Virginia Padoan[2], Yoana Doncheva[1], Joao Da Silva Filho[3], Michail Doukas[4], Bas Groot Koerkamp[2], Joanne Edwards[1], Nigel Jamieson[1]

[1]School of Cancer Science, Univ. of Glasgow, Glasgow, United Kingdom,[2]Department of Surgery, Erasmus Medical Center, Rotterdam, Netherlands,[3]School of Infection and Immunity, Univ. of Glasgow, Glasgow, United Kingdom,[4]Pathology and Clinical Bioinformatics, Erasmus Medical Centre, Rotterdam, Netherlands

Introduction: Pancreatic ductal adenocarcinoma (PDAC) arises from distinct precursor lesions, mainly pancreatic intraepithelial neoplasias (PanINs) and intraductal papillary mucinous neoplasms (IPMNs), which differ in genetics, differentiation ecosystem, and clinical behavior. PanIN-derived PDAC typically demonstrate more molecular and spatial heterogeneity, with pronounced classical-basal divergence. IPMN-derived adenocarcinomas display different histologic types: intestinal-type lesions often develop colloid carcinoma, where adenocarcinomas arising from pancreatobiliary(PB)-type IPMN resemble conventional PanIN-derived PDAC. Defining how precursor origin shapes malignant states, spatial microenvironment ecosystems are essential for PDAC classification.

Method: Single-cell spatial transcriptomics was performed by CosMx SMI (Bruker) in whole transcriptome and 6K-panel. Two different Tissue Microarrays (TMAs) cohorts were used (1.5-mm cores) include PanIN-origin PDAC (15 patients) and IPMN-origin PDAC (10 patients). Cell Segmentation performed by *CellPose* and strict quality control (QC) thresholding yielded 459,195 high-quality cells. Data was log-normalized and integrated with *scVI* using patient-level correction. Hierarchical annotation was performed by combining expert histopathological alignments with Leiden-based refinements. Downstream spatial analysis used Python based methods including Squidpy.

Results: Cross-cohort integration revealed marked origin-dependent divergence in the malignant spatial atlas. Malignant epithelium in PanIN-PDAC exhibited higher heterogeneity with more diverse and dispersed cell states. In contrast, the tumor cells in IPMN-derived PDAC presented obvious differentiation features for each carcinoma type. Intestinal-type IPMN PDAC developed unique malignant program that exhibiting typical goblet-like subtype, which was not observed in either other IPMN-type PDAC or PanIN-derived PDAC. However, the PB-type IPMN-PDAC showed substantial similarity with PanIN-PDAC, sharing multiple malignant programs, primarily including pEMT, progenitor cell-like and ADM-like subtypes. Furthermore, PanIN-PDAC retained specific tumor programs as exocrine-like, squamous, and inflammatory-association basal-like. Notably, although PB-type in IPMN PDAC and PanIN-PDAC share similarities in some tumor states, further analysis revealed significant differences in the spatial patterns and cell communication between tumor and microenvironments (TME). This suggests potentially different evolution of microenvironments.

Conclusion: Precursor origin fundamentally shapes PDAC malignant states and stromal-immune ecosystems. Together, this work establishes a spatial framework for understanding PDAC heterogeneity and highlights the importance of origin-aware stratification in clinic and biology.

#6200 Single-cell spatial CRISPR screen for tumor microenvironment.

Boyoung Jeong, Xuejiao Zhao, David Kilburn, Kang Jin Jeong, Soon Young Park, Hongli Ma, Gordon B. Mills

OHSU Knight Cancer Institute, Portland, OR

The tumor microenvironment (TME) comprises diverse cell types, including mesenchymal, endothelial, adipocyte, stromal, and immune cells. Among them, cancer-associated fibroblasts (CAFs) represent one of the most abundant and functionally active components. CAFs play a crucial role in tumor progression through bidirectional communication with cancer cells. They originate from various sources, such as normal fibroblasts, endothelial cells, and mesenchymal cells, and once activated, promote tumor cell invasion and metastasis. Recent studies have revealed that CAFs consist of multiple subpopulations with distinct phenotypic and functional properties. This heterogeneity of CAFs has provided new insights into tumor biology and has become a key focus in the development of novel targeted therapeutic strategies across different cancer types. CRISPR/Cas9 is a powerful genome-editing tool widely used for knock-out (KO) gene studies to investigate gene function. To overcome the limitations of conventional phenotyping and bulk analysis, a barcoding system known as Perturb-map was developed by the Brown laboratory that allows KO of genes in tumor cells and facilitates identification of effects of the KO on the TME. Perturb-map utilizes triplet combinations of linear epitope protein barcodes (Pro-codes) that enable the identification of cells expressing distinct CRISPR guide RNAs (gRNAs). In this study, we applied the Perturb-map approach to perform parallel CRISPR KO of 34 genes closely associated with CAF function in the TME in a syngeneic mouse breast cancer model. This approach allowed us to simultaneously assess the functional roles of multiple TME-related genes in tumor cells, providing a comprehensive understanding of their contributions to tumor progression. Pro-code-expressing tumors were analyzed using cyclic immunofluorescence (CycIF), a highly multiplexed proteomics imaging platform that enables spatial and single-cell level analysis. We developed, validated, and applied mouse antibody panels targeting approximately 100 proteins, allowing comprehensive profiling of tumor heterogeneity, cellular states, fibroblast, and immune cell activities. Through this approach, we identified potential therapeutic targets in tumor cells that confer growth advantages and contribute to remodeling of the TME. Furthermore, we identified effects of the KOs on CAF subtypes with distinct functional states. CD274 and IL11Rα1 KO tumors exhibited accelerated tumor growth accompanied by an increased abundance of myofibroblastic CAFs (myCAFs). In contrast, Snai2 KO tumors showed a marked enrichment of inflammatory CAFs (iCAFs). Our findings demonstrate the power of integrating functional genomics with high-dimensional proteomics to characterize TME dynamics at single-cell resolution.

#6201 PaintScape™ enables multiomic in-situ direct visualization of spatial 3D genome architecture of single cells in intact fresh frozen Glioblastoma tissue in native tumor microenvironments.

Matija Snuderl[1], Yuxiu Wang[1], Neha Dhasmana[1], Pamela Flatley[2], Stacy Elliott[2], Douglas Werner[2], Jude Dunne[2], **Huy Nguyen**[2], Shyamtanu Chattoraj[2]

[1]NYU Langone Health, New York, NY,[2]Bruker Spatial Genomics, San Jose, CA

The 3D organization of genome structure, which plays a critical role in regulating gene expression and cellular function, is often restructured in many different cancers including Glioblastoma (GBM). Characterized by extreme molecular and phenotypic diversity, GBM is the most aggressive and lethal form of brain cancer and often show clonal and sub-clonal variations across genomic, epigenomic, transcriptomic, and proteomic signaling networks within distinct tumor microenvironments. Structural aberrations such as copy number variations (CNVs), structural variations (SVs), and topological changes rewire the 3D genome allowing aberrant activation of oncogenes, repression of tumor suppressors and dysregulation in gene expression. Current methods such as WGS or Hi-C provide bulk-level understanding of dysregulation but lack single-cell spatial resolution and do not provide insight into spatial distribution and association between molecular subclones and microenvironment in intact tissue. Since tumor heterogeneity drives therapy resistance and hinders successful GBM treatment, understanding the molecular mechanism in a heterogenous spatial context demands state-of-the-art in-situ single cell and spatial technologies that can provide deeper insight into early detection and disease progression.

In this study, we present a novel multiomic jebFISH™ protocol on the PaintScape™ platform that can be used to analyze and directly visualize 3D chromatin architecture of fresh frozen GBM cells in different tissue microenvironments such as perinecrotic, perivascular, infiltrative, at single-cell, sub-population and population level. Using the ChromoPaint™ PanChromo MPX Panel, which visualizes over 400 loci across all chromosomes, we show disruption in 3D folding of individual chromosomes such as re-organization of chromosome territory, differential p-q arm interaction, intra and inter-chromosomal proximity at single cell and sub-population level in intact GBM tissue. By combining jebFISH with multiplexed immunofluorescence proteomic detection of hypoxia and microvasculature, we show how different tissue microenvironment e.g. hypoxic vs normoxic regions within the same GBM tissue section have different 3D genome aberrations and structural organization in the cancer cell sub-populations. We characterize chromosomal instability, CNVs and SVs of different GBM cancer cell and immune cell states at sub-chromosomal level in-situ within the tissue.

The PaintScape system will enhance understanding of glioblastoma disease progression by providing deeper insight into the 3D genomic heterogeneity of single cancer cells and sub-populations with unique spatial context within intact tissue microenvironments, potentially guiding better cancer treatment design in the future.

#6202 Integrated multiomic atlas of pancreatic solid pseudopapillary neoplasms suggests acinar cells as a potential cell-of-origin.

Biren Reddy, Maria Korah, James P. Agolia, Rosyli Reveron-Thornton, Maggie Lam, Deshka Foster, Michael T. Longaker, Daniel Delitto

Stanford University, Stanford, CA

Introduction:
Solid pseudopapillary neoplasms (SPNs) of the pancreas are rare, low-grade tumors that typically affect young women and occasionally recur or metastasize. While the histological features and mutational profile of SPNs are well documented, their cell-of-origin and spatial organization remain incompletely understood. The purpose of this study was to delineate the development and spatial transcriptomic landscape of SPNs.

Methods:
Regions of interest from 10 surgically resected SPN specimens collected between 2020 and 2025 were profiled using the G4X Singular In Situ Multiomic platform. Gene expression data were integrated and analyzed to generate spatial embeddings, followed by unsupervised clustering. Cell types were annotated using canonical markers, and proteomic data were integrated for further resolution.

Results:
Spatial transcriptomic profiling of 30 SPN sections from 10 patients yielded 3.6 million high-quality cells. The cohort was entirely female, with a median age of 31.5 years. Integrated analysis demonstrated a heterogeneous tumor microenvironment composed of exocrine pancreatic cells, immune cells, fibroblasts, endothelial cells, and tumor cells. Tumor cells demonstrated intra- and inter-tumoral heterogeneity, with five distinct subpopulations: (1) CPB1$^+$ tumor cells, (2) MYH11$^+$ tumor cells, (3) FN1$^+$ VIM$^+$ MMP2$^+$ tumor cells, (4) IGHG1$^+$ FCGR1A$^+$ TBX21$^+$ tumor cells, and (5) STAT1$^+$ TAP1$^+$ CD74$^+$ tumor cells. Mapping these tumor transcriptional states back onto the tissue sections revealed distinct microenvironmental niches. IGHG1$^+$ FCGR1A$^+$ TBX21$^+$ tumor cells and MYH11$^+$ tumor cells were the most prevalent tumor cells across samples. STAT1$^+$ TAP1$^+$ CD74$^+$ tumor cells, characterized by elevated antigen-presentation and interferon-signaling programs, were localized in areas with high immune-infiltration, which was further corroborated and delineated proteomically. CPB1$^+$ tumor cells showed relatively increased expression of acinar cell markers and formed spatial gradients at tumor-acinar interfaces, suggesting that SPN tumor cells may arise from an acinar lineage.

Conclusion:
We present the first multiomic analysis of SPNs of the pancreas, establishing a high-resolution atlas of their cellular and spatial architecture. We identify conserved tumor transcriptional and proteomic states that occupy distinct spatial niches. Spatial gradients in CPB1$^+$ tumor cells suggest a potential acinar origin for SPN tumor cells, warranting further lineage-focused investigation. These findings collectively refine our understanding of SPN tumor biology.

#6203 Spatial transcriptome mapping identifies endothelial anergy and CD4⁺ T cell stress as key drivers of immune escape in colorectal cancer liver metastasis.

Peter Kok-Ting Wan[1], Ranchu Cheng[1], Len Seymour[1], Kerry Fisher[1], Alex Gordon-Weeks[2]

[1]Department of Oncology, University of Oxford, Oxford, United Kingdom,[2]Nuffield Department of Surgical Sciences, University of Oxford, Oxford, United Kingdom

Background

Colorectal liver metastasis (CRLM) remains poorly responsive to immunotherapy, yet the mechanisms underlying its immune-resistant microenvironment are not fully understood. To address this, we generated a single-cell spatial transcriptomic atlas from four replacement-only, microsatellite-stable CRLM treated with neoadjuvant FOLFOX chemotherapy, representing the most common clinical scenario. Our dataset spans intratumoral, peritumoral, and adjacent normal liver, comprising 1,930,656 cells. In parallel, we performed thirteen whole-slide multiplexed immunohistochemistry to dissect the spatial cellular and molecular interactions shaping the immune landscape in CRLM.

Results

We identified a progressive shift in endothelial phenotypes across regions: from a non-inflamed state in the normal liver, to a highly inflamed peritumoral endothelium characterized by TNFα, NFκB, STING and inflammasome signature enrichment, and finally to an anergic, angiogenic endothelial population within CRLM. This anergic endothelial state was defined by reduced expression of adhesion molecules required for T cell extravasation, including SELE, SELP, ICAM1 and VCAM1, in contrast to the more immune-permissive peritumoral endothelium. In line with these endothelial differences, the peritumoral region contained a high density of T cells, most of which were TCR-reactive yet displayed features of exhaustion. The intratumoral region contained far fewer T cells (p <0.01), and those present were predominantly CD4⁺ cells adopting a stress-response phenotype, characterized by an upregulation of genes related to integrated stress response, unfolded protein response, and heat-shock protein pathways. These intratumoral CD4⁺ T cells lacked cytokine expression, showed minimal TCR activity, and localized to hypoxic niches. Their transcriptional profile reflected a hypoxia- and PGE2-driven stress programme rather than classical exhaustion, suggesting that CD4⁺ T cell dysfunction in CRLM is driven by stress-induced pathways. Fibroblasts also demonstrated marked regional variation. In CRLM, fibroblasts secreted neutrophil-attracting chemokines CXCL1 and CXCL8, and produced ECM-remodeling factors such as LOXL2 and TNC. This cancer-associated fibroblast population showed strong spatial correlation with ‘glial-like’ cells, which were found almost exclusively within CRLM (p <0.0001). These glial-like cells expressed neural ligands, including NGF and NPY, supporting a glial-fibroblast signaling axis that may reinforce fibroblast activation and matrix deposition.

Conclusions

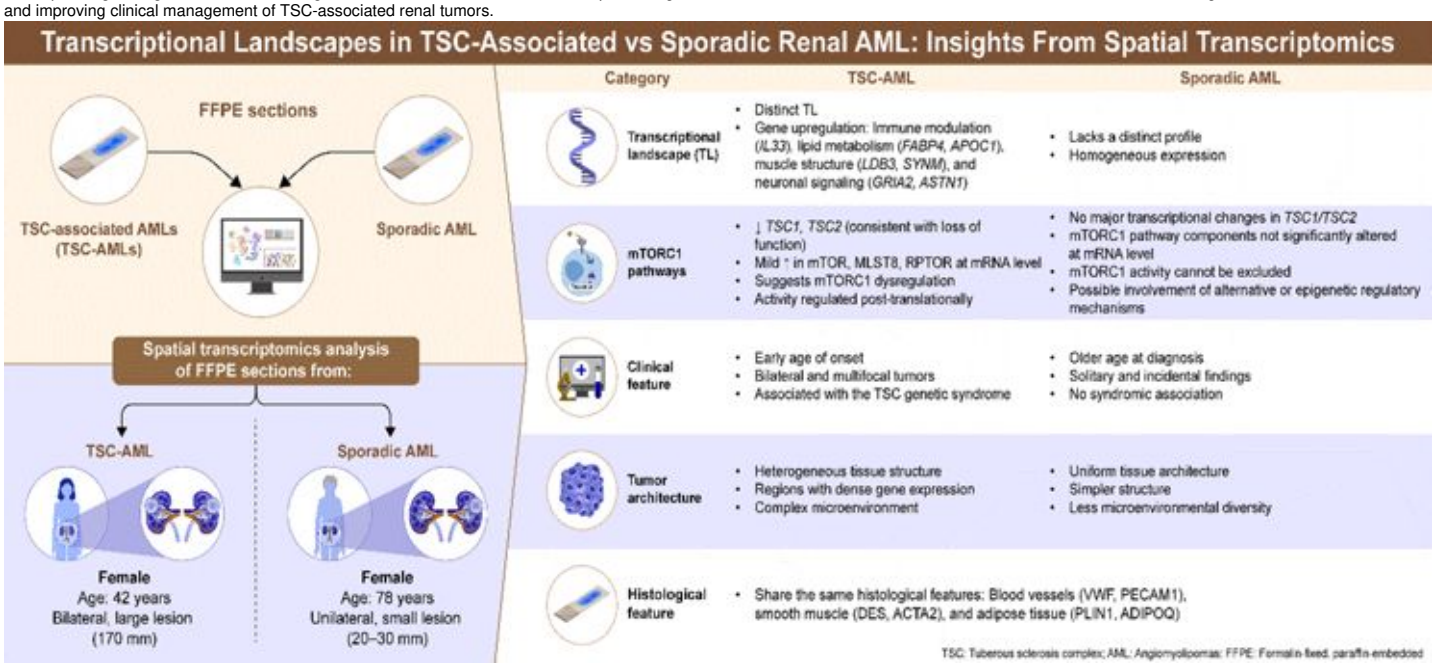
Together, these findings reveal key mechanisms driving immune exclusion in CRLM, highlighting endothelial anergy, intratumoral CD4⁺ T cells in a stress-response state, and a glial-fibroblast axis as central features of its immunosuppressive landscape.

#6204 Spatial transcriptomic dissection of TSC-associated angiomyolipoma reveals microenvironmental programs driven by mTORC1 dysregulation.

Ryuta Watanabe[1], Kensuke Shishido[1], Shota Nobumori[1], Naoya Sugihara[1], Keigo Nishida[1], Haruna Arai[1], Takatora Sawada[1], Shunsuke Haga[1], Osuke Arai[1], Tomoya Onishi[1], Kenichi Nishimura[1], Tstsuya Fukumoto[1], Noriyoshi Miura[1], Mie Kurara[2], Riko Kitazawa[3], Yuki Miyauchi[1], Tadahiko Kikugawa[1], Takashi Saika[1]

[1]Department of Urology, Ehime University Graduate School of Medicine, Toon, Japan,[2]Department of Analytical Pathology, Ehime University Graduate School of Medicine, Toon, Japan,[3]Division of Diagnostic Pathology, Ehime University Hospital, Toon, Japan

Background
Tuberous sclerosis complex-associated angiomyolipoma (TSC-AML) frequently presents in young patients with multifocal and large tumors, leading to clinical complications such as hemorrhage and renal dysfunction. Although mTORC1 activation due to TSC1/TSC2 loss is recognized, the spatially organized transcriptional architecture and differences from sporadic AML remain unclear. This study applied spatial transcriptomics to characterize molecular features underlying TSC-AML structure.
Methods
Formalin-fixed, paraffin-embedded sections from one case each of TSC-AML, sporadic AML, and renal cell carcinoma (RCC) were analyzed using the 10x Genomics CytAssist Visium platform. Clustering, differential expression, and pathway analyses were performed to identify spatial transcriptional patterns and TSC-AML-specific signatures.
Results
Spatial gene expression maps showed that TSC-AML and sporadic AML shared the classic triphasic architecture of vascular, smooth muscle, and adipose components, consistent with a PEC lineage origin, whereas RCC displayed a distinct epithelial profile.TSC-AML demonstrated reduced TSC1/TSC2 expression with mild upregulation of MTOR, MLST8, and RPTOR, indicating mTORC1 pathway dysregulation.Comparative analysis identified 42 genes specifically upregulated in TSC-AML, including neurodevelopment-related (GRIA2, ASTN1), lipid metabolism-associated (FABP4, APOC1), structural (LDB3, SYNM), and immune-regulatory (IL33, ABCC8) genes. These transcriptional differences represent potential molecular features distinguishing TSC-AML from sporadic AML.Spatial mapping further highlighted intratumoral heterogeneity and structural component-dependent variation in gene expression.
Conclusions
Despite the single-case limitation, this study provides a detailed spatial transcriptomic profile of TSC-AML, revealing transcriptional programs linked to TSC1/TSC2 dysfunction and identifying TSC-AML-specific gene signatures. These findings offer candidate biomarkers and therapeutic targets and establish a foundation for future multi-case studies aimed at refining molecular characterization and improving clinical management of TSC-associated renal tumors.



#6205 Establishing reproducibility standards for Xenium spatial transcriptomics through multi-replicate validation and cross-sectional analysis.

Tommy Tran, JingHao Tian, Elim Cheung, Rikita Gakhar, Vidyodhaya Sundaram

BioChain Institute, Inc., Newark, CA

Spatial transcriptomics technologies such as Xenium are rapidly gaining relevance in translational and clinical research, yet there remains a lack of standardized reproducibility benchmarks and quantitative quality-control (QC) metrics. Establishing technical validation frameworks is essential for ensuring cross-run, cross-section, and eventually cross-site comparability as the field moves toward regulated environments.

Methods: We conducted a multi-replicate validation study using eight sections derived from a single FFPE block containing four human carcinoma tissues (lung, breast, colon, and stomach). Each slide included four tissue regions, yielding 32 total spatial transcriptomic datasets generated with the Xenium Human Multi-Tissue and Cancer Gene Expression Panel (10x Genomics). Sections at defined depths (X3-4, X14-15, X16-17, X20-21) enabled evaluation of technical reproducibility across both slide-to-slide and depth-dependent variation. Technical reproducibility metrics—including cross-replicate correlation, coefficient of variation, spatial pattern consistency, cell-type abundance stability, and gene-level variance—were assessed to define preliminary QC thresholds suitable for multi-replicate benchmarking.

Results:Initial analyses demonstrate high reproducibility across replicates, with consistent gene expression profiles, stable spatial organization of major cell populations, and low variance across serial depths. Spatial pattern concordance remained robust across all carcinoma types, and variance decomposition suggests minimal depth-related technical drift. Ongoing analyses include expanded statistical modeling and evaluation of QC thresholds that could serve as standardized criteria for platform validation.

Conclusions: This study establishes a practical framework for defining reproducibility and QC standards for Xenium spatial transcriptomics. By integrating multi-replicate evaluation with cross-sectional comparisons, we outline a foundation for reproducible spatial data generation that supports clinical translation, regulatory readiness, and harmonization across studies and institutions.

#6206 Spatially resolved cell-cell architecture in WHO grade 4 *IDH*-wildtype glioblastoma revealed by CosMx 6K discovery panel.

Dexter Wing Lun Lee[1], Kaiyan Xu[2], Parker Li[3], Joshua Jing Xi Li[4], Wei Dai[1], Karrie Kiang[5], Gilberto Ka-Kit Leung[5], Aya El Helali[1]

[1]Department of Clinical Oncology, School of Clinical Medicine, The University of Hong Kong, Hong Kong, Hong Kong,[2]Centre for Oncology and Immunology, Hong Kong Science Park, Hong Kong, Hong Kong,[3]School of Biomedical Sciences, LKS Faculty of Medicine, The University of Hong Kong, Hong Kong, Hong Kong,[4]Department of Pathology, School of Clinical Medicine,, The University of Hong Kong, Hong Kong, Hong Kong,[5]Department of Surgery, School of Clinical Medicine, The University of Hong Kong, Hong Kong, Hong Kong

Background: *IDH*-wildtype glioblastoma is well-known for its intratumoral heterogeneity, with malignant, immune, and stromal populations coexisting in shared microenvironment that may shape hyper-progression and therapeutic resistance. These could be highly localized while spot-resolution spatial assays probably mask the underlying cellular architecture. Targeted single-cell spatial transcriptomics, like CosMx SMI now provide confident cells segmentation for delicate patient-specific interaction networks across GBM.

Methods: GBM tissues were profiled using the CosMx 6K Human Discovery Panel. Standardized preprocessing, including RNA QC, batch harmonization, and multi-reference cell typing were completed with Seurat v5. Cells underwent stepwise cleanup, which are the removal of AtoMx-flagged cells and those below the first quartile of number of detected genes and total transcript counts and further exclusion of fields of view (FOVs) retaining <50% of cells after cell filter. SCTransform, PCA and UMAP were applied on raw counts using AtoMx-recommended parameters with Giotto v4. Spatial networks and neighborhood were built using radius-based and k-nearest neighbor criteria. Co-localization was evaluated with Ripley's K-function. L-R networks were inferred with CellChat v2. All computation and analysis were with reference to AtoMx manual v2.1 (MAN-10162-10) under R 4.4.1 located at HPCF2, CPOS, HKU.

Results: After the stringent filtering, 297,125 confident cells across 413 FOVs in 23 TMA cores were retained for studying cell-cell communication. Pearson correlation of 0.99 indicated that cell density did not bias per-core analyses. Radius-based spatial network revealed extensive intratumoral heterogeneity between and within patient. Of notes, Patient #025 showed a marked shift, with a stem-like/mesenchymal-like cluster dominating one core and differentiated-like cells predominating in another, given both cores extracted from the same FFPE block resected at primary diagnosis. k-nn modeling showed reproducible tumor-tumor and tumor-vascular adjacency, while myeloid and lymphoid cells remained spatially diffuse across the cores, which was further confirmed significantly with Ripley's K function. Next, highly heterogeneous L-R pairs were inferred across patients, with a mean of 546 highly variable ligand-receptor pairs per core. A set of canonical GBM interaction pathways, like NCAM1-, CD99-, and JAG1-mediated signaling was conserved across cores. Apart from the homotypic network within tumoral and vasculature, there are extensive patient-specific L-R, like CNTN1-NOTCH1 networking in patient # 011.

Conclusions: By resolving cell-cell interaction, CosMx exposed distinct ligand-target dependencies across patients, which is a basis for designing bespoke neoantigen-directed vaccines or ligand-target bispecific antibody approaches.

#6207 Spatial organisation of tumor-infiltrating B cells in Claudin 18.2-expressing advanced gastric cancer predicts response to immune checkpoint inhibition.

Joseph J. Zhao[1], Choong-Kun Lee[2], Allison Si-Yu Chan[3], Wenyi Luo[4], Li Chang[5], Woo Sun Kwon[6], Sejung Park[6], Minkyu Jung[7], Joe P. Yeong[8], Anand Devaprasath Jeyasekharan[1], Maria Rodriguez Martinez[5], Sun Young Rha[6], Raghav Sundar[4]

[1]National University of Singapore (NUS), Singapore, Singapore,[2]Yonsei University Health System, Seoul, Korea, Republic of,[3]Cancer Science Institute of Singapore, Singapore, Singapore,[4]Yale University School of Medicine, New Haven, CT,[5]Biomedical Informatics and Data Science, Yale University School of Medicine, New Haven, CT,[6]Yonsei University College of Medicine, Seoul, Korea, Republic of,[7]Yonsei University Cancer Center, Seoul, Korea, Republic of,[8]Singapore General Hospital, Singapore, Singapore

Background: Claudin 18.2 (CLDN18.2), a tight junction protein aberrantly expressed during malignant transformation of gastric cancer (GC), has emerged as a key therapeutic target. This study seeks to understand the role of CLDN18.2 in shaping the tumor microenvironment (TME).

Methods: This single-center study included 99 patients with advanced gastric cancer treated first-line immune checkpoint inhibition (ICI) agent(s) with chemotherapy. CLDN18.2 expression was determined using immunohistochemistry (VENTANA 43-14A, Roche) on FFPE biopsies, reported as % 2+/3+. To enable a balanced representation of CLDN18.2 status, a median split approach was employed. Samples were also stained with multiplex-IHC (CK, CD4, CD8, FOXP3, CD68 and CD20) to elucidate the corresponding TME. Orthogonal validation was undertaken through independent analyses of whole transcriptome sequencing (WTS) data from 6 cohorts comprising 1,098 GC tumor samples. Cellular neighbourhood (CN) analyses were conducted using a *k*-nearest neighbors' algorithm. Survival analyses were conducted with a Cox-proportional hazards model.

Results: We retrieved CLDN18.2 status through median-split of CLDN18.2 expression (25.1%), yielding 44 CLDN18.2^{high} samples and 45 CLDN18.2^{low} samples. We observed an increase in CD20^{+} B cell density in CLDN18.2^{high} samples (p=0.042), whereas no significant differences in cell density were observed in CD4^{+}/CD8^{+} T cells, CD68^{+} macrophages and FOXP3^{+} Tregs. These findings were orthogonally validated utilizing immune cell deconvolution (xCell, Epic & MCP-counter) across the 6 independent WTS cohorts. CLDN18.2 status alone did not predict for response or survival (overall survival [OS], HR=1.02, p=0.947). GCs with increased CD20^{+} B cell density was found to confer a greater magnitude of benefit from first-line ICI (OS, HR=0.71, p=0.196), but the benefit was largely conserved amongst CLDN18.2^{low} tumors and not in CLDN18.2^{high} tumors (OS interaction p=0.109). We identified 4 B cell related CNs: B-TumorInfiltrating, B-MacrophageNiche, B-LA/TLS (Lymphoid Aggregate/Tertiary Lymphoid Structure) and B-ImmuneNiche. In CLDN18.2^{high} tumors, we observed a relative increase in CD20^{+} B cell abundance within B-TumorInfiltrating and B-MacrophageNiche CNs and a relative decrease in B cell abundance within B-LA/TLS and B-ImmuneNiche CNs in comparison to CLDN18.2^{low} tumors. While B-ImmuneNiche and B-LA/TLS conferred ICI sensitivity, the relative enrichment of B cells within a B-TumorInfiltrating CN compared to a B-ImmuneNiche CN conferred ICI resistance, particularly in CLDN18.2^{high} tumors (OS, HR=2.60, p=0.040).

Conclusions: The CLDN18.2^{high} gastric cancer microenvironment is characterized by an enriched humoral response. Intra-tumoral B cell infiltration confers ICI resistance in a CLDN18.2^{high} microenvironment.

#6208 Subcellular imaging of murine models of metastatic colorectal cancer using a whole transcriptome spatial molecular imaging panel.

Liang Zhang[1], Isabel Lee[1], **Shanshan He**[1], Martin Shelton[1], Owen J. Sansom[2], Joseph M. Beechem[1]

[1]Bruker Spatial Biology, Seattle, WA,[2]Cancer Research UK Scotland Institute, Glasgow, United Kingdom

Spatial transcriptomics enables in situ characterization of molecular and cellular heterogeneity within complex tissues. However, such high-plex subcellular resolution analysis has not previously been available for mouse models, which are central to cancer biology and therapeutic development. To address this gap, we have developed a new mouse Whole Transcriptome (WTX) assay containing over 20,000 targets, enabling comprehensive subcellular imaging with potential for future multiomic integration. Using the CosMx Spatial Molecular Imager (SMI), we profiled formalin-fixed paraffin-embedded (FFPE) primary and metastatic colorectal cancers from advanced murine models of Kras-mutant colorectal cancer. Each slide was processed according to standard CosMx workflow. UMAP and clustering analyses were performed to identify spatially resolved cell populations. Cell type annotation was guided by canonical marker genes. Transcriptional heterogeneity and adaptive plasticity of the tumour epithelium and supporting micro-environment in response to targeted KRAS inhibition was interrogated in both primary colonic cancers and in hepatic metastases. The CosMx mouse WTX assay demonstrated robust detection sensitivity and dynamic range across both liver and colon cancer samples. Distinct cellular niches were identified within tumor and stromal compartments, revealing transcriptionally unique clusters corresponding to hepatocytes, immune cells, and fibroblast subtypes. In the colon tumor, spatially distinct tumor regions exhibited divergent gene expression patterns, suggesting differential microenvironmental influences. Transcriptional adaptation to therapeutic challenge was observed across tumour compartments in both primary and secondary disease, highlighted novel, exploitable avenues to drive improved therapeutic response. We present the first application of a mouse Whole Transcriptome assay on the CosMx platform, enabling subcellular spatial resolution across >20,000 targets. This new capability opens avenues for multiomic integration, allowing comprehensive investigation of tumor-stroma interactions and immune microenvironments in mouse models. Together, these advances bridge preclinical and translational spatial biology, providing a new foundation for spatially resolved discovery in cancer research.

#6209 Gynecologic carcinosarcomas beyond epithelial-mesenchymal transition: Morpho-transcriptomic evidence of an immune gradient in the tumor microenvironment.

Amel Kime[1], Julie Berthet[1], Juliette Renard[1], Antoine Gaudet Chardonnet[2], Pierre Laurent-Puig[1], Jerome Alexandre[3], Bruno Borghese[2], Guillaume Beinse[3]

[1]MEPPOT Team, Cordeliers Research Center, Paris, France,[2]Gynecologic Surgery Unit, APHP - Cochin Port-Royal Hospital, Paris, France,[3]Oncology Unit, APHP - Cochin Port-Royal Hospital, Paris, France

Introduction: Gynecologic carcinosarcomas (GynCS) are rare, aggressive uterine and ovarian cancers with a median survival under two years. Their biology is marked by epithelial-mesenchymal transition (EMT), driving dissemination and a biphasic carcinoma-sarcoma morphology. However, the molecular drivers of intratumoral heterogeneity beyond EMT remain poorly understood. This study seeks to clarify these mechanisms by characterizing the transcriptomic landscape of GynCS.
Methods: Hematoxylin-eosin-saffron (HES) slides from 35 uterine and ovarian carcinosarcomas were reviewed by a gynecologic pathologist. A total of 251 tumoral tissue sectors, including carcinoma, sarcoma and mixed components, were selected for morphological assessment and bulk RNA sequencing (RNA-seq) using the SMARTer library preparation kit.
Results: Among 35 tumors included in cohort, 33 (94%) were TP53-mutated, 2 (4%) had no specific molecular profile, 1 (2%) was mismatch repair-deficient and none was POLE-mutated. EMT expression signature correlated with histological features despite 26% of histologicaly sarcomatous sectors being reclassified as epithelial based on RNAseq (WISP classifier). Gene set enrichment analysis (GSEA) in all carcinoma sectors compared to all sarcoma sectors revealed a depletion in the response to inflammation and immunity as the main mechanism alongside EMT. Both cell-type deconvolution on RNA-seq data and immunohistochemical CD3 staining on FFPE slides suggest an enrichment in T cells, particularly cytotoxic T cells, in the tumor microenvironment of carcinoma sectors compared to sarcoma sectors. Within-tumor immune gene set analysis in a subset of tumors (n=15) revealed heterogeneous microenvironmental switch across patients, with 53% of tumors (n=8) shifting from a hot-to-cold microenvironment while most others (47%; n=7) remained immune-deprived. Gene expression profiles revealed the sustained activation of non-canonical NFκB pathway by cGAS-STING as a potentially leading cause of immune exhaustion and associated with EMT. Spatial RNAseq (Visium2) of 4 representative cases confirmed inflammation response as among most spatially variable features.
Conclusion: This study suggests that chromosomal instability, acting through the cGAS-STING pathway, plays a dual role in driving immune exhaustion and promoting EMT as key biological features, despite notable inter-tumor variability in this process. These findings are consistent with existing literature on the non-canonical NFκB pathway. This work highlights potential therapeutic opportunities, including the emerging STING-targeted treatments and personalized immunotherapeutic strategies tailored to the unique immune landscape of each tumor.

#6210 Spatial compartmentalization of tumor and immune cellular architecture defines opposing prognostic roles in prostate cancer.

Ahmed Elsehemy[1], Xinpei Ci[2], Magnus Lam[3], Matthew Ramotar[2], Alejandro Berlin[4], Theodorus van der Kwast[5], Housheng Hansen He[5]

[1]Radiation Oncology, Medical Biophysics, University of Toronto, Toronto, ON, Canada,[2]Medical Biophysics, University Health Network, Toronto, ON, Canada,[3]Medical Biophysics, University of Toronto, Toronto, ON, Canada,[4]Radiation Oncology, University of Toronto, Toronto, ON, Canada,[5]University Health Network, Toronto, ON, Canada

Background:
Understanding the role of immune cells in prostate cancer (PCa) remains challenging, with conflicting reports on immune infiltration's prognostic value. We hypothesized that spatial localization, rather than immune cells absolute bulk abundance, drives their association with clinical outcomes. To test this, we generated a clinical cohort of PCa patients integrated with multiplex IHC from spatially profiled immune cells in both the tumor and surrounding stroma (n=41).

Methods:
IHC multiplex assay was utilized to assess CD3+, CD8+, CD20+, FoxP3+, and CD68+ cells within cytokeratin-positive (CKpos; epithelial nests) and cytokeratin-negative (CKneg; stroma) compartments. Cell counts, densities, and ratios were correlated with time to metastasis (TTM), biochemical recurrence (BCR), BMI, tumor burden, intratumoral heterogeneity, PSA, and TMPRSS2:ERG/ETV4 fusions. After data collection validation and curation, statistical analysis of correlations between continuous variables was done using Spearman's or Pearson's correlation, while Chi square test was used for categorical variables.

Results:
Our association analysis revealed a pattern where immune infiltration within CKpos tumor nests (cancer cells) showed consistently favorable associations with clinical outcome (r=0.36-0.52, $P < 0.001$), with CD8+ T-cells showing the strongest correlation with prolonged TTM and delayed BCR. In contrast, the same immune populations in CKneg compartment (stroma) demonstrated opposite correlations (r=-0.31 to -0.47, $P < 0.05$), with stromal FoxP3+ T-cells most strongly associated with accelerated metastasis. Interestingly, identical immune subsets displayed opposite prognostic directions within the same patient samples, despite strong cross-compartment correlations (r=0.66-0.79, $P < 0.001$), indicating coordinated recruitment but compartment-specific roles. Higher BMI correlated exclusively with increased stromal (non-protective) lymphocytic infiltration (r=0.39-0.59, $P < 0.05$). Tumor burden inversely correlated with intratumoral T-cell and stromal macrophage ratios. TMPRSS2:ERG and ETV4/TMPRSS2 fusions were significantly associated with elevated stromal CD8+ infiltration, and higher pre-treatment PSA correlated with stromal CD68+ density, linking tumor biology with macrophage recruitment.

Conclusion:
This work demonstrates that the spatial location of immune cell populations determines their association with outcomes in PCa. Notably, our data indicate that high-burden aggressive tumors might be associated with suppression in protective intratumoral immunity. Our current work is aimed at validating these observations in a larger cohort. These findings highlight the need for a shift towards spatially-resolved tumor microenvironment and immune biomarkers for risk stratification and patient selection for immunotherapies.

#6211 AI-guided spatial multi-omics integration reveals immune and stromal heterogeneity underlying population disparities in prostate cancer..

Samuel Mwakisha Mwamburi, Jevon Layne, Niki Talebian, Ezra G. Baraban, Ashley Kiemen, Clayton C. Yates

Pathology, Johns Hopkins University School of Medicine, Baltimore, MD

Prostate cancer disproportionately affects African American (AA) men, who experience higher incidence and mortality rates than European American (EA) men. The purpose of this study was to develop and apply an artificial intelligence (AI)-based framework to investigate biological mechanisms contributing to these disparities through spatial characterization of the tumor microenvironment (TME). We employed CODA, a computational method that reconstructs large tissues at subcellular resolution from serially sectioned hematoxylin and eosin (H&E)-stained slides, for histological segmentation and multi-omics integration.CODA was trained on 600 H&E-stained prostate tumor sections from AA and EA patients using a deep convolutional neural network optimized for pixel-level classification of nine compartments, including tumor, stroma, vasculature, and inflammation. Model performance, evaluated using a confusion matrix, achieved over 90% classification accuracy and generalized robustly across cohorts. CODA segmentation maps were aligned with 10x Genomics Visium HD spatial transcriptomic data to generate biologically annotated domains such as luminal secretory, stromal, inflammatory epithelial, and immune regions.Functional analysis revealed distinct TME niches, including adaptive immune, myeloid-rich, cytotoxic, fibroblast, and luminal-epithelial compartments. AA tumors demonstrated higher immune infiltration and inflammatory activity than EA tumors, characterized by dense lymphoid aggregates and cytokine signaling enrichment. Integration with spatial proteomics data from the AKOYA IO60 panel (60 immune and stromal markers) confirmed immune clusters (CD20+, CD3e+, CD68+, CD8+) and revealed a level of discordance between transcript expression and protein signaling, suggesting context-dependent regulation.Three-dimensional reconstructions from serially sectioned tumors (one AA, one EA) visualized compartment continuity and immune-stromal interfaces. Collectively, these findings provide new evidence of population-specific immune and stromal heterogeneity that may contribute to prostate cancer disparities and demonstrate the utility of AI-guided spatial multi-omics for advancing equitable precision oncology.

#6212 Spatial immune and vascular remodeling defines recurrence in oligodendroglioma.

Julia Louw[1], Kenan Zhang[1], Anna Corcoran[1], Elizabeth Owens[1], Jodie Jepson[1], Jose R. Conejo-Garcia[2], David M. Ashley[3], Kanish Mirchia[4], David R. Raleigh[5], Mustafa Khasraw[6]

[1]Duke University, Durham, NC,[2]Duke University School of Medicine, Durham, NC,[3]Duke University Medical Center, Durham, NC,[4]UCSF, San Francisco, CA,[5]University of California San Francisco, San Francisco, CA,[6]Duke Cancer Institute, Durham, NC

Introduction/Rationale: Oligodendrogliomas recur after therapy but how spatial immune architecture changes during recurrence is poorly understood.
Methods: Visium Spatial Transcriptomics (ST) from primary and matched recurrent tumors (n = 14 patients) were processed with SpaceRanger. Cell-type deconvolution was performed using SpaCET's low-grade glioma model, generating spatial immune and stromal distributions. Cell-type fractions were normalized using Centered Log-Ratio transformation and clustered (k = 5, Euclidean distance) to define niches. Immune subsets were compared to assess niche-specific remodeling. Propensity score matching was used to control for baseline differences between treated and untreated tumors.
Results: Five spatial niches were identified, including immune-enriched perivascular regions and infiltrative tumor-immune interfaces. Recurrent tumors showed contraction of adaptive immunity, with downregulation of $CD4^+$ T-helper subsets, Th1, Th2, Th17, and Tfh ($log_2FC \approx -3$), and depletion of total $CD4^+$ T cells (-2.9). This reduction was greatest in previously treated patients suggesting therapy-associated collapse of adaptive immune niches. Myeloid cells including macrophages and microglia, were preserved or increased, indicating a shift toward myeloid-dominant, immunosuppressive microenvironment. Perivascular immune regions demonstrated reduced T-helper diversity and enhanced myeloid signaling, consistent with immune exclusion and vascular remodeling. These patterns persisted after propensity score matching, with treated recurrences enriched for myeloid-driven immunosuppressive niches ($p < 0.05$). Applying cNMF-derived activity programs, treated recurrent tumors showed upregulation of systemic inflammatory genes (IL1B, OSMR, CXCL8) but downregulation of microglial inflammatory genes (CXCR4, CX3CR1, JUN, EGR1), reflecting partial loss of lymphocyte related pathways. Complement-associated immunosuppressive programs were mildly increased, while scavenger receptor-associated programs were slightly reduced, indicating therapy-related myeloid shifts. Untreated recurrences had upregulation of inflammatory and immunosuppressive programs, reflecting activated and suppressive immune states. Validation with Xenium and CODEX will be presented.
Conclusion: Recurrent tumors undergo remodeling marked by collapse of adaptive immune niches, loss of $CD4^+$ T-helper diversity, and a shift toward myeloid-dominant signaling. Treated recurrences show weaker microglial inflammatory activity and partial transition to a myeloid-driven immunosuppressive state, whereas untreated recurrences display activation of inflammatory and suppressive programs. These findings identify therapy-associated depletion of adaptive immunity and enrichment of suppressive myeloid niches, a features that can be exploited to identify therapeutic targets.

#6213 Single cell imaging uncovers a coordinated tumor-immune-stroma spectrum with genomic associations in pancreatic ductal adenocarcinoma.

Ferris Nowlan[1], Noor Shakfa[1], Sibyl Drissler[1], Tan Tiak Ju[1], Elizabeth Sunnucks[1], Edward LY Chen[1], Cassandra J. Wong[1], Brendon Seale[1], Zhen Yuan Lin[1], Michelle Chan-Seng-Yue[2], Amy Zhang[2], Sabiq Chaudhary[2], Chengxin Yu[1], Golnaz Abazari[1], Michael Geuenich[1], Matthew Watson[1], Jiaxi Peng[1], Somaieh Afiuni-Zadeh[1], Ayelet Borgida[3], Ricardo Gonzalez[1], Sheng-Ben Liang[4], Klaudia Nowak[4], Miralem Mrkonjic[5], Anna Dodd[4], Julie M. [1]Lunenfeld-Tanenbaum Research Institute, Toronto, ON, Canada,[2]Ontario Institute for Cancer Research, Toronto, ON, Canada,[3]Pancreatic Cancer Canada, Toronto, ON, Canada,[4]University Health Network (UHN), Toronto, ON, Canada,[5]Mount Sinai Hospital, Toronto, ON, Canada,[6]West German Cancer Center, Essen, Germany,[7]Princess Margaret Cancer Centre, Toronto, ON, Canada,[8]Postdoctoral Fellow, Princess Margaret Cancer Centre, Toronto, ON, Canada,[9]Professor of Surgery, Div. of General Surgery, University of Toronto University Health Network, Toronto, ON, Canada,[10]St. Vincent's University Hospital, Dublin, Ireland

Pancreatic ductal adenocarcinoma (PDAC) has consistent genomic drivers and established classical and basal transcriptional subtypes, but despite this, there exist many intermediate state tumors, a multiplicity of copy number aberrations and low frequency mutations, and a complex, spatially heterogeneous tumor microenvironment. These elements are not random; they are evidence of coordinated biological programs and evolving signaling networks that underlie tumor progression. Merging data from these varied molecular and spatial layers is essential to clinically define and therapeutically target a) tumors that fall into the ‘grey zone’ of pancreatic cancer subtyping and b) specific collusive epithelial-stromal niches.To identify the in situ interdependencies between distinct tumor cell states, fibroblast phenotypes, deposited extracellular matrix, immune infiltrate, and vasculature, we performed imaging mass cytometry on three serial sections of a PDAC tissue microarray (221 resected tumors, ~4 cores each), generating >800 multiplexed images (40-43 channels) each focused on deeply profiling a different cell lineage. We captured 76 immune and stromal cell types and states, as well as six cancer cell types that recapitulated the classical and basal PDAC signatures, plus four discrete “intermediate” states with distinct associations to RNA subtype (n = 92), tumor ploidy (n = 192), and patient outcome. We clustered our immune and stromal cell populations to define 8 recurrent microenvironments, and found the microenvironment dominated by CD105+ CAFs was significantly spatially associated to classical tumor cells with strong epithelial differentiation transcription factor expression (pairwise Fisher’s exact test, odds ratio = 3.7), ECM-rich microenvironments were proximal to basal tumor cells (odds ratio = 4.3), and pMLC2+ CAFs were enriched near the poor-prognosis, low-ploidy S100A4+ tumor phenotype (odds ratio = 4.2). We additionally denote a specific fibroblast-centric microenvironment associated with neoadjuvant treated tumors (n = 26). Using matched 30X whole-genome sequencing (n = 192), we found specific mutations and copy number changes that were associated changes in tumor and microenvironment composition, and performed Lasso-based machine learning to determine the most important cross-omic features for overall survival prediction. Together, our findings define a phenotypic and molecular framework of PDAC from genome to tumor-microenvironment, provide insight into the connection between tumor phenotype and stromal niches, and offer a refined basis for patient stratification.

#6214 Mapping the tumor landscape: spatial multiomics reveals immune and stromal heterogeneity across early and late-stage NSCLC.

Gaurav N. Joshi, Nicholas Sciascia, Michael Yang, Brenna Fearey, Junya Yoshioka, Fumiki Yanagawa

Nikon Bioimaging Lab, Nikon Instruments Inc, Lexington, MA

Background: Lung cancer accounts for 12% of all cancers and 20% of cancer-related deaths. Rapid advances in spatial biology are uncovering mechanisms of disease, patient-to-patient variability, and immune biomarkers predictive of response to immunotherapy. Using a combination of spatial multiomics approaches and data analysis in the same section, we characterized the spatial distribution, phenotypes, and functional states of tumor, immune, and stromal cells between stage IA (early) and IIIA (late) non-small cell lung cancer (NSCLC).
Method: 5 µm formalin-fixed paraffin-embedded (FFPE) tissue sections were prepared from stages IA and III A human NSCLC with confirmed histology of adenocarcinoma. Same sections were analyzed using two complementary platforms, (1) multiplex immunofluorescence (mIF) with a 30-antibody panel on Lunaphore COMET system and (2) spatial transcriptomics using 10x Genomics Visium CytAssist. Protein-level data were processed using HORIZON, and transcriptomic data were analyzed in Loupe Browser. Unbiased clustering (Leiden) and cellular phenotyping were performed to identify region-specific cell populations and marker co-expression patterns.
Results: In early NSCLC tumor, CD8+, CD4+ T cells were more concentrated within the tumor core. In addition, fewer Tregs, immunosuppressive macrophages, and cells expressing immune checkpoint were observed. There were less stromal remodeling, fibrosis and angiogenesis and more TLSs in stage IA tumor. On the other end, late NSCLC tumor showed an increased expression of markers associated with immunosuppression/evasion and stromal remodeling, including an increase in Treg cells, TAMs, CAFs and immune checkpoint expression. A difference in the gene expression signature between early and late-stage NSCLC support observations from protein expression. Early-stage tumor was enriched for genes associated with immune surveillance and active cytotoxic response, whereas late-stage tumor was enriched for immune suppression and stromal remodeling genes. Spatial analysis also highlighted changes in various chemokines and cytokines between the two tumor types.
Conclusions: The integration of multiomics technologies on the same section helped identify diverse processes and transcriptional changes associated with a varied tumor and immune landscape between early and late-stage NSCLC. Cellular phenotyping triaged cell types based on marker expression in pathologist annotated regions. These findings highlight intra and inter-tumor changes, the biology within and helped with the identification of potential biomarkers for immunotherapy response and intervention.

#6215 Spatial biology tools identify distinct spatially localized fibroblasts in adenomacarcinoma lung cancer predictive of survival.

Calum MacAulay, Paul Gallagher, Martial Daniel Guillaud

BC Cancer Research Institute, Vancouver, BC, Canada

Predicting overall patient survival from excised lung cancer tissue is a challenging task. We applied spatial biology tools to define 10 cell types using unsupervised clustering and using the spatial distributions of these 10 cell types and unsupervised clustering to define 8 cell neighborhoods to over 400 Adenocarcinoma TMA spots.
The unsupervised cell type clustering identified 4 types of tumour/epithelial cells, 4 types of immune like cells and 2 types of potentially CAF cells. The frequencies of the cell types within the TMA spots correlated with a host of clinical variables such as stage, tumor size, differentiation degree, EGFR mutation status, patient sex, etc. As did the frequencies of the cells in the 8 neighborhoods. Collapsing the 8 neighborhood types into 3 neighborhoods (tumor, stroma and cells boarding tumor and stroma) and selecting the 2 types of CAF cells identified we calculated the frequency and density of CAF cells in the three neighborhoods.
We found that the density and frequency of CAFs in the stroma neighborhood was highly predictive of overall survival in early stage (< 1B) Non smokers (p=0.0005 females, p=0.00007 males) but not as strong in early stage smokers. For Late stage lung cancers (>=1b) the frequency of a type of large tumor cell combined with the density (number of stromal cells per mm2) was highly predictive (p=0.000005) of outcomes for late stage current smokers in both males and females.
Key to the success of this analysis was the exact segmentation of the all the DNA specific stained nuclei, even in areas of highly overlapping nuclei, using a novel deep learning enabled segmentation that allow pixels to belong to more than one nucleus.

#6216 Novel whole transcriptome spatial transcriptomics technology reveals CAF/TAM-mediated basement membrane remodeling at the invasive front.

Amanda Janesick, McKenzi Toh, Syrus Mohabbat, Stephanie Kravitz, 10X Genomics Development Team

10x Genomics, Inc., Pleasanton, CA

Introduction:
A precise understanding of the Tumor Microenvironment (TME) requires comprehensive, high-resolution transcriptomic profiling that can classify the functional states of numerous cell types and map their interactions with neighboring cells. In this study, we use novel technologies to investigate TME-mediated basement membrane (BM) remodeling in lung, kidney, breast, and ovarian cancers. We identify key proteases and laminins enriched in the tumor periphery surrounding hypoxia-adapted cancer cells and the invasive front.

Methods:
Formalin-fixed, paraffin-embedded (FFPE) tissues were stained for H&E on Superfrost slides, then analyzed using spatial transcriptomics and subsequent cytoplasmic/cell membrane marker-based segmentation. Data were visualized using a 10x Genomics interactive workspace, which enables the subcellular mapping of transcripts overlaid on morphology images, alongside integrated capabilities for normalization, clustering, and differential gene expression analysis. We employed a spatial neighborhood approach and ROI export to quantify BM and TME marker expression. These molecular findings were subsequently correlated with the local cell type composition of the tumor region.

Results:
Spatial transcriptomic analysis demonstrated significant changes in the expression of laminins and metalloproteases in close proximity to the tumor's invasive front. These remodeling activities were found adjacent to proliferating cancer cells expressing oncogenes known to function in angiogenesis, glycolysis, and invasion. Critically, in breast cancer, we observed alterations to BM markers even where the myoepithelial layer remained histologically intact, suggesting that traditional markers are insufficient to capture early tumor progression. Hypoxia-adapted cancer cells expressing VEGFA and chemokines recruited Cancer-Associated Fibroblasts (CAFs) and Tumor-Associated Macrophages (TAMs), which were identified as the primary source of metalloprotease secretion. Furthermore, T-cells in these regions exhibited an exhausted phenotype, indicating a robust immune-evasive pathway.

Conclusions:
By employing high-resolution spatial transcriptomics, this study provides a comprehensive, spatially-resolved analysis of molecular heterogeneity within the TME, precisely localizing BM-remodeling activity to the invasive front. We successfully demonstrated the capacity of this technology to enable the discovery of novel, spatially-defined biomarkers and provide mechanistic insight into cancer progression.

#6220 Stromal SPARC drives tumor-nerve-stroma crosstalk and perineural invasion in pancreatic ductal adenocarcinoma.

Satoru Furuhashi[1], Ryuta Muraki[2], Yoshifumi Morita[1], Daiki Nishiwaki[1], Akio Matsumoto[1], Yuji Shimizu[1], Tomohiro Murakami[1], Makoto Takeda[1], Hirotoshi Kikuchi[1], Yoshihiro Hiramatsu[1], Hiroya Takeuchi[1]

[1]Hamamatsu University School of Medicine, Hamamatsu, Japan,[2]Shizuoka General Hospital, Shizuoka, Japan

Background: Perineural invasion (PNI) is frequent in pancreatic ductal adenocarcinoma (PDAC) and contributes to poor outcomes. However, the stromal-neural mechanisms that underlie tumor neurotropism remain poorly understood. We hypothesized that soluble factors secreted by stromal fibroblasts, in cooperation with nerves and cancer cells, drive PNI-related tumor aggressiveness.
Methods: A vertical transwell tri-culture system was established using human PDAC cells (MIA PaCa-2) in the upper chamber and neonatal mouse dorsal root ganglia (DRG) with human pancreatic stellate cells (PSCs) in the lower chamber. PDAC cell migration was quantified after 24 h. Conditioned media from each condition (control, DRG, PSC, DRG + PSC) were analyzed by LC-MS/MS with intensity-based quantification; candidate proteins were selected by correlation with migration (Pearson $r \geq 0.95$) and ≥ 2-fold enrichment in DRG + PSC. Clinical significance was assessed using TCGA-PDAC and GTEx datasets. Cell-of-origin was inferred by CIBERSORTx deconvolution and single-cell RNA-seq analysis. Stromal versus epithelial SPARC protein expression and its association with PNI were evaluated by immunohistochemistry and semi-automated QuPath scoring in 81 resected PDACs.
Results: Tri-culture with DRG + PSC significantly enhanced PDAC migration compared with control or either single-cell condition (all $p < 0.001$). Proteomic profiling identified Secreted Protein Acidic and Cysteine-Rich (SPARC) as one of the most enriched proteins in DRG + PSC condition, with abundance strongly correlating with migratory activity. In transcriptomic datasets, SPARC was markedly upregulated in PDAC relative to normal pancreas, and high SPARC expression was associated with shorter overall survival. CIBERSORTx and single-cell analyses localized SPARC expression primarily to fibroblast/cancer-associated fibroblast (CAF) populations. In clinical specimens, SPARC protein was concentrated in the desmoplastic stroma and significantly higher than in tumor epithelium ($p < 0.0001$). Stromal SPARC levels were elevated in PNI-positive versus PNI-negative tumors in our institutional cohort ($p < 0.0001$), with consistent results in TCGA-PDAC ($p = 0.032$).
Conclusions: A nerve-stroma-conditioned microenvironment accelerates PDAC cell migration, with CAF-derived SPARC serving as a pivotal driver of tumor-nerve crosstalk and PNI. Through extracellular matrix remodeling and promotion of neural infiltration, SPARC emerges as a promising biomarker and therapeutic target for stroma-directed, anti-PNI strategies in PDAC.

#6221 Senescent cancer-associated fibroblasts drive perineural invasion and pain in pancreatic ductal adenocarcinoma.

Jinpeng Lu[1], Ziyi Tu[1], Shuncang Zhu[1], Hongyi Lin[1], Yinhao Chen[1], Yiting Chen[2], Zuwei Wang[1], Haoxiang Zhang[1], Shi Chen[1]

[1]Shengli Clinical Medical College of Fujian Medical University, Fuzhou, China,[2]College of Biological Science and Engineering, Fuzhou University, Fuzhou, Fujian 350108, People's Republic of China, Fuzhou, China

Background Pain in pancreatic ductal adenocarcinoma (PDAC) correlates with perineural invasion (PNI), severely impairs quality of life, and predicts poor prognosis. The mechanisms driving this PNI-pain axis, particularly the role of senescent cancer-associated fibroblasts (senCAFs), and effective therapies remain elusive.
Methods We correlated pain scores (NRS) with PNI (IHC/IF) in two PDAC cohorts. Single-cell/spatial transcriptomics and lipidomics were performed and cross-validated with external datasets. Human/murine senCAFs were co-cultured with tumor cells, dorsal root ganglion (DRG) neurons, and patient-derived organoids (PDOs), with neuronal activity assessed via patch-clamp electrophysiology. In vivo studies utilized orthotopic models with fibroblast-specific knockouts, evaluated by behavioral and nociceptive analyses.
Results Higher pain grades strongly correlated with increased PNI, nerve density, and poor prognosis. scRNA-seq and spatial analyses revealed p16+ senCAFs enriched near nerves, confirmed by flow cytometry in painful tumors. Orthotopic co-inoculation with senCAFs induced nociceptive hypersensitivity prior to differences in tumor burden. Mechanistically, senCAFs activated an IL-6-JAK2/STAT3 feedback loop, sensitizing DRG neurons. JAK2 blockade normalized neuronal excitability and reduced pain behaviors. This neural-stromal crosstalk was bidirectional: senCAFs sensitize DRGs via IL-6-JAK2/STAT3, while activated DRGs release ATP, triggering P2RX7-mediated tumor cell depolarization to promote invasion. This loop is stabilized by tumor-derived, SPHK2-dependent S1P signaling via S1PR2 on CAFs, reinforcing the senescent phenotype. In vivo, JAK2 inhibition combined with nab-paclitaxel/gemcitabine significantly improved pain control and overall survival.
Conclusion p16+ senCAFs orchestrate a vicious cycle by activating the IL-6-JAK2/STAT3 pathway, enhancing neuronal firing and pain; this in turn amplifies ATP/P2RX7-driven tumor cell depolarization and progression. This cycle is stabilized by tumor-derived sphingolipid reprogramming of CAFs. Targeting this senCAF-driven neural-stromal axis via JAK2 inhibition, combined with standard chemotherapy, provides a translationally potent therapeutic strategy for PDAC-related pain.

#6222 Microbiotas activate a tuft cell-sensory neuron feedback loop to promote esophagogastric junction (EGJ) tumorigenesis.

Yi Zeng[1], Feijing Wu[1], Puran Zhang[1], Ruhong Tu[1], Xiaofei Zhi[2], Biyun Zheng[1], Jin Qian[1], Hualong Zheng[1], Shuang Li[1], Hiroki Yi Kobayashi[1], Yosuke Ochiai[1], Masahiro Hata[1], Juli Lin[1], Junya Arai[1], Leah B. Zamechek[1], Zaisheng Ye[3], Timothy C. Wang[1]

[1]Columbia University Irving Medical Center, New York, NY,[2]Nantong University, Nantong, China,[3]Fujian Cancer Hospital, Fuzhou, China

Background Esophagogastric junction (EGJ) adenocarcinoma is rising in developed countries. While diet and reflux contribute, microbial-neuronal mechanisms remain poorly defined.

Methods Metabolomic and 16S rRNA sequencing were performed on 40 paired human EGJ tumors and adjacent tissues, and single-cell RNA sequencing on five pairs. Mechanistic studies used the pL2-IL1B mouse model of Barrett's esophagus, Cck2r-CreERT2 mice to label EGJ progenitors, and crosses to $p53^{R172H}$; pL2-IL1B to provide a tumor-prone background. Dclk1-CreERT2 targeted Tuft cells, while Trpv1-Cre, hM3Dq, and Ramp1 flox examined sensory signaling. Additional lines (Cck2r-CreERT2; $Ramp1^{flox/flox}$, Dclk1-CreERT2; $Cox1^{flox/flox}$; $Cox2^{flox/flox}$, Pou2f3-CreERT2; DTA) dissected the Tuft-neuron-epithelial circuit. P. melaninogenica colonization and deoxycholic acid (DCA) supplementation modeled microbial-metabolic effects. Calcium imaging, phospho-ERK staining, and Tuft-neuron co-cultures assessed functional signaling.

Results EGJ tumors were enriched in *Firmicutes/Bacteroidota* and *Prevotella*, while adjacent tissues contained *Proteobacteria* and *Helicobacter*. *Prevotella* abundance correlated positively with arachidonic-acid and negatively with tryptophan metabolites. Single-cell data showed epithelial, immune, and metabolic clusters, with bile- and fatty-acid pathways enriched in proliferative cells. *P. melaninogenica*, linked to bile-acid-rich, cancer-prone environments, was selected for mechanistic study. DCA alone enhanced EGJ dysplasia in pL2-IL1B mice. Oral *P. melaninogenica* colonized the EGJ, further increased by DCA, forming a bile-acid niche. Colonization amplified $CGRP^+$ neuronal signaling, expanded Tuft cells, and aggravated dysplasia. Tumor-prone Cck2r-CreERT2; p53R172H; pL2-IL1B mice showed more Tuft-$CGRP^+$ contacts, and pseudotime analysis indicated enhanced $Cck2r^+$-to-Tuft differentiation. In ex vivo organoids, activation of $Dclk1^+$; $hM3Dq^+$ Tuft cells elevated PGE_2/NGF secretion, strengthened Tuft-nerve contacts, and induced calcium influx in co-cultured $Trpv1^+$; $GCaMP6s^+$ DRG neurons. $Trpv1^+$ neurons co-expressed CGRP and EP4. Combined DCA + CNO treatment in Trpv1-Cre; hM3Dq; pL2-IL1B mice further increased dysplasia. Tuft ablation (Pou2f3-CreERT2; DTA), Tuft-specific Cox1/2 loss, or Ramp1 deletion in $Cck2r^+$ cells suppressed *P. melaninogenica*-induced dysplasia, demonstrating that blocking the Tuft-neuron-progenitor axis halts tumor progression.

Conclusions We define a microbiota-bile-acid-Tuft-neuron feedback loop driving EGJ tumorigenesis. *P. melaninogenica* and DCA activate Tuft cells to release PGE_2/NGF, stimulating EP4-CGRP/Ramp1 signaling and promoting epithelial dysplasia. Disrupting this circuit suppresses tumor growth, highlighting a metabolic-neuronal target for EGJ cancer prevention.

#6223 Characterize the role of cholinergic signalling in pancreatic cancer liver metastasis.

Xiaotong Long[1], Christine Chio[2], Tak W. Mak[3]

[1]Medical Biophysics, Univ. of Toronto Faculty of Medicine, Toronto, ON, Canada,[2]Columbia University, New York, NY,[3]UHN Princess Margaret Cancer Centre, Toronto, ON, Canada

Cholinergic signalling, traditionally attributed to the parasympathetic nervous system, is increasingly recognized as an immunoregulatory pathway in diverse disease contexts. Acetylcholine, the primary neurotransmitter in cholinergic signalling, is reported to be secreted by immune cells and plays an important role in hepatocellular carcinoma, liver regeneration, and metabolic dysfunction-associated steatohepatitis. However, whether immune cell-derived ACh influences cancer metastasis to the liver remains unknown. Pancreatic ductal adenocarcinoma (PDAC) frequently metastasizes to the liver, providing a relevant model to interrogate the neuroimmune mechanisms that shape the metastatic microenvironment. Using a spontaneous liver metastasis model generated by orthotopic or splenic injection of murine pancreatic cancer cells, we observed a marked induction of the ACh-synthesizing enzyme choline acetyltransferase (ChAT) in immune cells during liver metastatic progression, suggesting that immune cells contribute to a local immune-derived cholinergic niche. These findings identify a previously unrecognized cholinergic-immune axis in the pancreatic cancer metastatic niche, where immune-derived ACh increases during liver metastasis. Targeting neuroimmune pathways may offer new strategies to modulate the liver metastatic microenvironment in PDAC.

#6224 Neurotrophic receptor GFRα2 drives pro-metastatic programming of Kupffer cells in liver metastases.

Jintian CHEN, **Jingying Zhou**

School of Biomedical Sciences, Chinese University of Hong Kong, Hong Kong, China

Gastrointestinal cancers such as colorectal, gastric and pancreatic cancers frequently metastasize to the liver, contributing significantly to cancer-related mortality and resistance to immune checkpoint inhibitors (ICIs). Recent multidisciplinary studies have highlighted a functional and mechanistic interplay between the nervous and immune systems in cancers, termed as neuroimmune axis. Given the rich hepatic innervation, we investigated whether neuroimmune signaling contributes to liver metastasis by analyzing the expression profiles of 217 known receptors involved in efferent signal transmission using single-cell omics datasets from colorectal cancer liver metastasis (CRLM) patients, among which glial cell line-derived neurotrophic factor (GDNF) family receptor alpha 2 (GFRα2) was identified due to its reproducibly and exclusively elevated expression on CRLM adjacent livers compared with healthy livers from transplantation donors. Using scRNA-seq, high-dimensional flow cytometry and multiplex-immunofluorescence analysis in mice and patients with CRLM, we further confirmed that GFRα2 was selectively expressed and upregulated on Kupffer cells (KCs). Notably, GFRα2$^+$KCs were found in close proximity to liver-infiltrating nerve fibers in CRLM, whereas chemical liver denervation led to reduced expression of GFRα2, suggesting a possible neural regulation on GFRα2$^+$KCs. Functionally, lentiviral shRNA-mediated *Gfra2* knockdown significantly suppressed liver metastasis without affecting primary colorectal tumor growth, which could be abolished by KCs depletion using liposomal clodronate. Mechanistically, GFRα2$^+$KCs displayed impaired antigen presentation capacity, but enhanced pro-angiogenesis and neutrophil recruitment, suggesting a reprogrammed, metastasis-promoting phenotype. Notably, *Gfra2* knockdown significantly reduced neutrophil accumulation and angiogenesis, but increased MHCII$^+$KCs. Taken together, our findings pinpointed that GFRα2 upregulation reprograms KCs towards a pro-metastatic state, thereby facilitate liver metastasis.

#6225 Spatial biomarker related to PNI and LVI in stage II colon cancers.

Hanqing Hu[1], Hongzhe Sun[2], Lin Zhu[2], Shuo Han[2], Zhifu Zhang[2], Enkai Zhang[3], Na Li[3], **Guiyu Wang**[1]

[1]Department of Colorectal Surgery, the Second Affiliated Hospital of Harbin Medical University, Haerbin, China,[2]Beijing PhenoVision Bio Co., ltd, Beijing, China,[3]Hangzhou PhenoVision Bio Co., ltd, Hongzhou, China

Multiple retrospective studies and meta-analyses have shown that presence of lymphovascular invasion (LVI) and/or perineural invasion (PNI) is associated with significantly worse disease-free and overall survival in stage II colorectal cancer (CRC), and these features are commonly considered when deciding whether to recommend adjuvant chemotherapy for stage II disease. Current study reviewed 32 stage II CRC patient archived FFPE samples to investigate immune cell features among LVI, PNI or no-invasion groups. IHC control, multiplex immunofluorescence (mIF) panel control and the followed mIF staining were conducted using PN 7-Plex Detection Kit (PhenoVision Bio Co., ltd) targeted CD68, CD3, CD20, panCK, PD-1, PD-L1 and CD68, panCK, CD3, CD8, CD163, αSMA, respectively. The QC procedures made sure each marker from mIF results exhibited identical location and density of the same marker from IHC staining. The 64 staining slides were scanned, tumor areas were lined out by pathologist based on H&E staining from the serial section of each sample. Non-tumor region, tumor invasive margin (IM) , which was defined as 360μm within and outside of tumor boundary *i.e.* total 720μm, tumor parenchyma, tumor stromal, 30μm region inside and outside of tumor parenchyma boundary were analyzed using PhenoVision mIF AI analysis system trained from Oncotopix Discovery system (Visiopharm). Positive cell percentage were analyzed for further analysis. Statistical analysis exhibited correlation of CD20 and CD20+/PD-1- cell percentage to PNI condition (p=0.046 and 0.046, respectively) in tumor invasive region and CD68+/CD163- cell percentage to PNI (p=0.048) of 30μm outside tumor parenchyma based on binary logistic regression. There were higher CD20+ positive cell percentage and CD20+/PD-1- cell percentage in PNI group *vs.* non PNI group (p=0.013 and 0.013, respectively) at tumor invasive region. Whereas lower CD68+CD163- cell percentage was observed in PNI group *vs.* non PNI group of 30μm outside of tumor parenchyma region (p=0.01). There was significant more panCK cell percentage in LVI positive group at tumor parenchyma region compared to non LVI group (p=0.000). Current study indicates that spatial biomarkers are correlated to PNI and LVI in tumor invasive margin and tumor parenchyma region of stage II colon cancers which may be related to stage II CRC prognosis. Increased sample number of the spatial marker distribution feature to disease prognosis analysis are scheduled.

#6226 Integrative multi-omic analysis identifies neuronal reprogramming and vascular remodeling as hallmarks of recurrent high-grade serous ovarian carcinoma.

Ilaha Huseynli[1], Gregory Gibson[1], Benedict B. Benigno[2], Stephen N. Housley[1]

[1]School of Biological Sciences, Georgia Institute of Technology, Atlanta, GA,[2]Ovarian Cancer Institute, Atlanta, GA

Background: High-grade serous ovarian carcinoma (HGSOC) is the most common and aggressive subtype of epithelial ovarian cancer, with over 80% of patients experiencing recurrence after initial therapy. Recurrent disease is typically chemoresistant and remains the leading cause of gynecologic cancer mortality, yet the molecular changes driving recurrence, particularly at the cell type-specific level, are poorly understood.
Objective: To define cell type resolved transcriptional programs that distinguish late primary from recurrent disease, to place these programs into a stage aligned cellular context from benign tissue through recurrence, and to nominate robust biomarkers with external replication and genomic concordance.
Methods: Matched late primary and recurrent HGSOC specimens were profiled by snRNAseq with additional benign and early tumors included for stage contextualization. Paired pseudobulk differential expression between late primary and recurrence was performed using DESeq2 and limma voom with patient blocking, low expression filtering, trimmed mean normalization, and false discovery rate control. Replication of 46 significant genes was assessed in four external cohorts. In addition, somatic variant and copy number profiles from late primary tumors generated by whole exome sequencing were compared with transcriptional effects at panel loci. A transcriptional signature was related to time to recurrence using exact rank statistics with bootstrap assessment of robustness.
Results: snRNAseq of matched late primary and recurrent HGSOC revealed a recurrence program that maps to tumor associated endothelium and to a neuronal lineage state in malignant epithelium. *FLT1 STC1* and *CA2* and selective suppression of the endothelial long noncoding RNA *MEF2C AS1; FLT1* and *CA2* together with *MEF2C AS1* constitute novel recurrence associated endothelial markers in this disease. Malignant cells exhibited a novel neuronal reprogramming signature defined by induction of *NTM* and *KCNQ5* with reciprocal downregulation of *PEG3*, and stromal compartments showed reduced *ABCA8* and the novel marker *PLCXD3*. Whole exome copy number profiling of late primary tumors provided directional concordance with the transcriptome, including deep loss at *KCNQ5*, late stage copy number reduction at *FLT1*, *ESM1,* and *NTM* aligned with their induction at recurrence, and late stage gain at *C7* and *PLCXD3* aligned with its suppression at recurrence.
Conclusion: Our integrative multi-omic analysis reveals that recurrent HGSOC is characterized by coordinated vascular remodeling in tumor-associated endothelium and neuronal reprogramming in malignant epithelium, accompanied by stromal reconfiguration. These findings nominate cell-state-specific biomarkers and pathways for prospective validation and therapeutic targeting in recurrent disease.

#6227 Cancer-associated enteric glial cell abundance as a prognostic marker in gastric cancer revealed by single-cell analysis.

Carolyn R. DePinho[1], Jianming Zeng[2], Xiling SHEN[2], Sandra W. Ryeom[1]

[1]Columbia University Irving Medical Center, New York, NY,[2]MD Anderson Cancer Center, Houston, TX

Enteric glial cells (EGCs), essential regulators of gastrointestinal barrier function, immune responses, and neuro-epithelial homeostasis, remain largely unexplored in the context of gastric cancer (GC). EGCs are a specialized population of peripheral neuroglia that, along with enteric neurons, make up the enteric nervous system. While neural innervation in GC has been increasingly recognized, the presence and functional significance of cancer-associated EGCs (CAEGCs) within the gastric tumor microenvironment (TME) remain undefined.

In this study, we utilized integrative single-cell transcriptomic analysis of human GC to identify a rare but distinct population of CAEGCs residing within the stromal compartment. Defined by consistent expression of canonical glial markers, this CAEGC population emerged as a robust and reproducible signature across six independent datasets. To evaluate clinical relevance, we then applied LASSO-Cox regression modeling to The Cancer Genome Atlas Stomach Adenocarcinoma (TCGA-STAD) cohort to establish a GAEGC-derived glial signature that stratified GC patients into high- and low-risk groups with significant survival differences ($p < 0.001$) and distinct molecular features. This GAEGC-derived glial signature also aligned with established molecular subtypes and predicted response to therapy.

Our findings reveal a prognostically relevant and previously underappreciated population of CAEGC-like stromal cells within the GC TME. This GAEGC-derived glial signature offers a way to predict GC relapse risk and survival, and it highlights neuro-glial interactions as a potential site of therapeutic intervention in GC.

#6228 Reactive oligodendrocytes promote glioblastoma progression through CCL5/CCR5-mediated glioma stem cell maintenance.

Nicholas Mikolajewicz[1], Kui Zhai[2], Anish Puri[2], Petar Miletic[2], Nazanin Tatari[2], jiarun Wei[1], Neil Savage[2], Zhi Huang[3], Qian Huang[3], Seon Yong Lee[1], Mahta Jan-Ahmadnejad[4], Roseanne Nguyen[4], David Chen[1], Tiegan Korman[2], Daniel Mobilio[2], Maxwell Topley[2], Jack Qinyu Lu[2], Matthew R. Voisin[2], Zsolt Zador[2], Shawn C. Chafe[2], Chitra Venugopal[2], Kevin R. Brown[1], Gelareh Zadeh[5], Hong Han[2], Julien Muffat[4], Shideng Bao[3], Sheila K. Singh[2], **Jason Moffat**[1]

[1]Genetics and Genome Biology, Sick Children's Hospital, Toronto, ON, Canada,[2]McMaster University, Hamilton, ON, Canada,[3]Cancer Biology, Cleveland Clinic, Cleveland, OH,[4]Neurosciences and Mental Health, Sick Children's Hospital, Toronto, ON, Canada,[5]University Health Network, Toronto, ON, Canada

Glioblastoma (GBM) evolves within a microenvironment abundant in oligodendrocyte-lineage (OL) cells. In this study, we utilized single-cell and spatial transcriptomics from primary and recurrent GBM tumors, immunohistochemistry, cytokine profiling, and migration assays to show that GBM cells recruit OLs to the tumor border via CXC3L1/CXC3R1 signaling. A pan-disease human OL meta-atlas and syngeneic mouse models reveal an interferon-induced reactive OL state, akin to those seen in demyelinating inflammatory and traumatic injury, which is enriched in CNS malignancies. These reactive OLs secrete pro-tumorigenic cytokines, notably CCL5, that promote GBM tumor cell growth through CCR5 signaling. CCR5 is preferentially expressed in glioma stem-like cells (GSCs) and upregulated at recurrence. Targeting CCR5 with genetic knockdown or FDA-approved drug Maraviroc impairs GSC stemness and prolongs survival in GBM models. Our work highlights the functional interplay between OLs and GBM cells and positions the CCL5/CCR5 axis as a druggable target in GBM.

#6229 Neighborhood analyses in nerve fiber-associated tumor regions in hereditary diffuse gastric cancer.

Idania Carolina Lubo Julio[1], Yunhe Liu[1], Sharia Hernandez[1], Alejandra G Serrano[1], Wei Lu[1], Larisa Kostousov[1], Sean Barnes[1], Khaja Khan[1], Karen Colbert[1], Yanshuo Chu[1], Yang Liu[1], Rebecca Waters[1], Jeremy L. Davis[2], Paul F. Mansfield[1], Linghua Wang[1], Luisa Maren Solis Soto[1]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]University of Maryland School of Medicine, Baltimore, MD

Background: In carcinomas**,** perineural invasion and tumor-nerve niches are increasingly recognized as associated with cancer progression. In Hereditary Diffuse Gastric Cancer (HDGC), the molecular programs behind these interactions are not fully understood. In this study, we aim to depict multicellular neighborhoods and spatial transcriptomics programs associated with tumor-nerve interactions in patients with HDGC.

Methods: Six FFPE specimens from five patients with invasive HDGC were sectioned at 5-um thickness. Histological sections from ≥T3 tumors were analyzed using Spatial Gene Expression of a capture area of 11 x 11 mm. Histological spot-level annotations were performed to identify niches enriched for nerve fibers. Granular annotations identifying tumor cells and their microenvironment (TME) were conducted. Tumor cells were categorized by morphology as signet-ring, intermediate-stage, moderately differentiated/tubular and undifferentiated cells. Immune cells, connective tissue, smooth muscle, and vessels were annotated to define the TME. Integration with markers of both nerve tissue and potentially altered genes was conducted. Using identified nerve tissue as epicenter we measured the distance between spots (approximately 900 um). We then conducted comprehensive analysis of these areas for cell type enrichment, gene profile and intercellular crosstalk in the nerve neighboring tumor region.

Results: The spatial mapping of nerve fibers showed that they were distributed in the submucosa and predominantly in myenteric layers; nerve-enriched niches were highly associated with undifferentiated, and moderately differentiated cells/tubular patterns. Non-nerve niches were enriched with signet ring cells or intermediate-stage cells. Connective tissue, smooth muscle, and vessels were not enriched in nerve-niches. Differential gene expression (DGE) analysis of tumor cells in the nerve-niches showed upregulation of genes related to cell integrity (*MYOC, CLDN17*), metabolic programs (*ADIPOQ, PLIN1*), cell cycle regulation (*FAM83D*), and inflammatory response (*CCL3*). Also, transcription factors related to neural survival were upregulated (*NR4A1, NR4A2, NR4A3, EGR2*). Importantly, DGE in the TME annotations showed that nerve-niches had upregulation of immune enriched pathways associated with chemokines, immune cell adhesion and immune cell migration *(CXCL13, CXCL14, ITGB2, ITGB4, ITGB6, ITGBP6, ITGBP7, CD46, CD79B, CD14, XRCC6, CCL5, CD74).*

Conclusions: Spatial transcriptomic profiling in HDGC delineated distinct morphological domains and transcriptomic signatures linked to tumor-associated nerve niches pointing to tumor-nerve-TME interaction programs that may act as critical modulators of cancer aggressiveness, offering novel insights into vulnerabilities that could be leveraged to impede gastric cancer progression.

#6230 Tumor nuclear uPA: A transcriptional modulator of perineural invasion in PDAC.

Yun HE, Zonghua Su, Feng Ding, Zheng Chen, Xinxing Cui, **Liu Yang**, Shuangying Qiao, Yaru Hou, Aiping Lu, Fangfei Li

Hong Kong Baptist University, Hong Kong, Hong Kong

Perineural invasion is highly prevalent in pancreatic ductal adenocarcinoma and correlates with poor outcomes; clinical approaches to inhibit PNI remain limited. Using integrated transcriptomic analyses of PDAC parenchymal cells with escalating nerve-invasive potential, we identified PLAU (uPA) as a key determinant of PNI capacity. Patient single-cell datasets showed that high tumor PLAU expression is associated with enrichment of Schwann cells in the tumor microenvironment and strengthened ductal cell-Schwann cell communication. Functionally, nuclear uPA in PDAC parenchymal cells activates Schwann cells in a coculture perineural invasion model. Mechanistically, chromatin profiling revealed that nuclear uPA occupies a compact set of genomic sites enriched near transcription start sites and linked to genes governing neural development and neuronal signaling. Motif analysis, biolayer interferometry (BLI), and co-immunoprecipitation showed that uPA binds c-Jun; the uPA-c-Jun complex engages DNA and serves as a co-regulator that drives pro-neurogenic transcriptional programs. Together, these findings establish nuclear uPA as a central mediator of tumor-nerve crosstalk in PDAC and highlight targeting its nuclear function as a promising strategy to inhibit perineural invasion.

#6231 Schwann like reprogramming of cancer associated fibroblasts remodels the tumor neural niche in pancreatic ductal adenocarcinoma.

Liu YANG, Xinxing Cui, Shuangying Qiao, Yun HE, Zonghua Su, Zheng CHEN, Feng DING, Aiping LU, Fangfei Li

Hong Kong Baptist University, Hong Kong, China

Pancreatic ductal adenocarcinoma (PDAC) has a significantly higher incidence of peripheral neuropathy compared to other cancers, which is associated with local recurrence and a poor prognosis for PDAC patients. Notably, Schwann cells, the principal glia of peripheral nerves, are critically involved in this process due to their multifaceted roles in tumorigenesis and neural remodeling. Nevertheless, the biological sources of the increased Schwann cell population and overall increased neuronal density in PDAC are still mainly unknown. Here by employing an integrative approach combining single-cell RNA sequencing, immunofluorescence, and functional assays, we revealed a novel neural reprogramming of cancer-associated fibroblasts (CAFs) in PDAC: the Fibroblast-Schwann Transition (FST), through which a subset of CAFs directly transdifferentiates into Schwann-like states. The FST was confirmed by pseudotime trajectory analysis, which showed a cell fate transition from CAFs to Schwann-like cells. Multiplex immunofluorescence of patient tumors identified transitional interface cells co-expressing canonical Schwann and CAF markers, which is consistent with the computational inference. Furthermore, in the co-culture of tumor cells and CAFs, CAFs developed Schwann-like features, with upregulation of Schwann-cell genes, highlighting their profound plasticity. To figure out the regulatory driver of this process, SCENIC analysis identified key fibroblast-specific transcription factors as critical regulators of the FST program. Additionally, a Schwann-like phenotype was induced in vitro by overexpressing the candidate transcription factor in CAFs, as evidenced by decreased CAF-associated gene expression and increased Schwann-cell markers.Overall, our findings suggest that the FST is a biological process associated with the increased neuronal density observed in PDAC. This study identifies a previously unknown cellular plasticity mechanism in the tumor microenvironment and proposes that targeting FST could be a potential therapeutic strategy for treating peripheral neuropathy in PDAC.This work is supported by the Hong Kong RGC Theme-based Research Scheme (No. T12-201/20-R, HongKong, China), Hong Kong General Research Fund (No. 12102722, HongKong, China), and the 2020 Guangdong Provincial Science and Technology Innovation Strategy Special Fund (No. 2020B1212030006, GuangDong, China).

#6233 Proximity-based gene expression profiling identifies multi-pathway activation in perivascular, perineural, and pseudo-capsule adjacent human prostate cancer cells.

Rafael Sainz[1], Kelvin W. Pond[1], Beatrice S. Knudsen[2], Gregory C. Rogers[1], Noel E. Warfel[1], Anne E. Cress[1]

[1]University of Arizona Cancer Center, Tucson, AZ,[2]University of Utah, Salt Lake City, UT

Prostate cancer (PCa) progression is critically driven by the tumor microenvironment (TME), which imposes selective pressures and dictates specialized invasive behaviors, such as perineural and lymphovascular invasion. We hypothesized that heterogeneity within the tumor allows for the selection of functionally specialized cancer cell clones based on their proximity to TME niches. Using Spatial Transcriptomics, we profiled cancer cell populations at three critical invasive fronts: near nerves, vessels, and the prostatic pseudo-capsule from 55 human prostate tissue datasets. Differential expression analysis revealed distinct, niche-specific functional signatures: neurotropic clones near nerves exhibited a loss of prostate identity and a gain of neural adhesion genes (e.g., NCAM1, NTN1) consistent with perineural invasion; perivascular clones showed upregulation of ECM remodeling and an EMT-like state (e.g., ANXA2, CCN1), suggesting priming for intravasation; and pseudo-capsule-adjacent clones displayed a highly proliferative phenotype (e.g., CCND1, CDK4). These results demonstrate that the TME drives the functional specialization of PCa cells, refining our understanding of invasion and nominating several niche-specific pathways as potential therapeutic targets. Studies are currently ongoing to validate these signatures, refine heterogeneity scoring, and cross-link the identified genes with pharmacological databases for future in-vitro inhibition assays.

#6234 Characterizing the competitive interactions between glioblastoma and oligodendrocyte progenitor cells.

Lindsey A. Dudley[1], Sunlan Lu[2], Beatrice O'Brien[2], Carol Watkins[3], Travis Perryman[4], Riki Kawaguchi[1], Steve A. Goldman[5], Kunal S. Patel[4], Harley I. Kornblum[6]

[1]The Intellectual and Developmental Disabilities Research Center, UCLA, Los Angeles, CA,[2]UCLA, Los Angeles, CA,[3]CIRM Bridges Program, California State University, Northridge, Northridge, CA,[4]Department of Neurosurgery, UCLA, Los Angeles, CA,[5]Center for Translational Neuromedicine, University of Rochester Medical Center, Rochester, NY,[6]Professor Psychiatry, Pharmacology and Pediatrics, UCLA David Geffen School of Medicine, Los Angeles, CA

Resection of glioblastoma (GBM) often only includes the contrast-enhancing (CE) solid portion of the tumor and radiation therapy also targets this region. These therapies leave behind infiltrating tumor cells that lay beyond the CE border in the non-enhancing region (NE) with the capacity to propagate the tumor following therapy. Non-transformed cell types in the brain have been shown to promote GBM progression via a variety of mechanisms. We performed single nucleus RNA-sequencing (snRNA-seq) on 17 biopsies from the NE and CE regions of seven different primary IDH WT glioblastoma tumors during maximal resection surgery. While some oligodendrocyte progenitor cells (OPCs) are present in the NE region, they are almost absent in the CE region, a finding corroborated by our prior study of recurrent tumors. OPCs, the most common cycling cells in the brain, share many genes with GBM and the interaction between the two cell types has yet to be described on a single cell level. Prior work has demonstrated that in the developing and adult brain young, more fit OPCs can outcompete older OPCs leading us to hypothesize that brain tumor cells can compete with non-transformed OPCs. To explore possible interactions between GBM and OPCs we utilized predictive cell-cell interaction software, finding that OPCs express transcripts that are predicted to respond to GBM signals to induce proliferation, migration and differentiation. Compared to snRNA-seq of healthy OPCs, the OPCs from our biopsies were more likely to be proliferative, migratory, and differentiated. To assess possible enrichment of pathways associated with a more competitive state, we performed differential expression between OPCs contained in our biopsies and GBM cells. This revealed a significant enrichment of the YAP1 pathway which is associated with a more competitive state. GBM cells were predicted to be activated by OPCs to proliferate, migrate and have increase synaptic activity. To investigate how soluble factors secreted by OPCs and GBM cells influence each other by culturing each cell population in conditioned media (CM) derived from the opposite cell type. OPCs treated with GBM CM have shown increased proliferation and GBM cells treated with OPC CM have shown decreased proliferation, possibly due to younger nature of OPCs that were differentiated from iPSCs. Our findings support the hypothesis that there are complex and possibly competitive interactions between OPCs and GBM cells, extending the concept of “cancer neuroscience”. Further studies are ongoing to establish the nature and mechanisms of these interactions.

#6235 Smoking behavior is associated with increased tumor-associated neurogenesis in prostate cancer.

Kunwar Somesh Vikramdeo[1], Shashi Anand[1], Amod Sharma[1], Muhammad Tahir[2], Varsha Manucha[3], Seema Singh[1], Ajay Pratap Singh[1]

[1]Department of Cell and Molecular Biology, Cancer Center and Research Institute, University of Mississippi Medical Center, Jackson, MS,[2]Department of Pathology, UW Medicine-University of Washington Medical Center, Seattle, WA,[3]Department of Pathology, Cancer Center and Research Institute, The University of Mississippi Medical Center, Jackson, MS

Tumor-associated neurogenesis is being increasingly recognized as a contributor to cancer progression and therapeutic resistance. While tobacco smoking is known to influence inflammation and microvascular remodeling, its relationship with tumor neurobiology remains poorly understood. In this study, we investigated whether smoking behavior is associated with alterations in nerve density within the prostate cancer microenvironment. Prostatectomy specimens from prostate cancer patients with documented smoking history were selected (n=53), and smoking status was categorized as never (n=24), former (n=18), or current (n=11) smoker. The tumor tissues were sectioned and subjected to immunohistochemistry for S100B (Schwann cells) and TUBB3 (neuronal axons). Nerve density was quantified by measuring the number of neural clusters in five random fields, and an average value was calculated for each tumor. The difference in nerve density was compared between current, former, and never smokers using Kruskal-Wallis non-parametric test. Current smokers and former smokers exhibited significantly higher ($p < 0.001$) intratumoral nerve density compared to never-smokers. However, the difference was not significant ($p=0.268$) between current smokers and former smokers. In grade-wise comparisons, a significant difference ($p < 0.001$) between never smokers and current /former smokers was observed in low/medium (Gleason's score ≤7) grade tumors but not in high-grade tumors (Gleason's score >7). Interestingly, nerve mini-bundles at tumor edges were also more frequent in current smokers than in never smokers or former smokers. Altogether, our data demonstrate that the smoking behavior is associated with enhanced neural remodeling in prostate cancer, characterized by increased nerve density and Schwann cell/axon clustering at tumor margins. These findings suggest that host exposure to tobacco smoke promotes a neurotrophic tumor microenvironment, which may be linked to prostate cancer aggressiveness and a higher risk of recurrence.

#6239 Military cancer outcomes research (MilCan): A sub-study of the Millennium Cohort Study.

Erin L. Richard[1], Sheila F. Castaneda[1], Anna Baccetti[1], Anna C. Rivera[1], Rudolph P. Rull[1], Aaron Auerbach[2], Diego A. Vicente[1]

[1]Naval Health Research Center, San Diego, CA,[2]Joint Pathology Center, Silver Spring, MD

Background: Cancer remains a leading cause of death in the US, and US service members and veterans have higher rates of certain cancers than the US general population. Military-specific occupational exposures, such as aviation-related ultraviolet radiation exposure, chemical toxicants, and blasts leading to immune system dysregulation have been hypothesized to have long-term implications for cancer risk.
Methods: The Millennium Cohort Study (MCS) is a large-scale, prospective cohort study designed to examine the long-term health effects of military service. Over 260,000 US service members were enrolled between 2001 and 2021, and follow-up of participants is planned through 2068. As the cohort matures, there is increased focus on age-related diseases such as cancer. The MCS has collected longitudinal survey data on well-established cancer risk and protective factors, such as tobacco and alcohol use, physical activity, and obesity. The Military Cancer Outcomes Research (MilCan) initiative aims to develop a military cancer data warehouse platform that will link data from various military and civilian data sources (eg, electronic health records, military environmental exposures, lifestyle behaviors, and tumor biology, pathology, and imaging).
Results: Preliminary analyses of available survey and medical record data suggest there are at least 11,000 occurrences of cancer in the MCS. The study team is in various stages of linking with the (1) Department of Defense Cancer Registry, a centralized database of patients diagnosed with cancer in the Military Health System; (2) Virtual Pooled Registry Cancer Linkage System, a web-based, streamlined process for researchers to conduct minimal risk linkage studies with the nationwide resource of Central Cancer Registries; (3) Joint Pathology Center, which is part of the Defense Health Agency and maintains the world's largest collection of human pathology specimens; and (4) Individual Longitudinal Exposure Record, which includes historical deployment information and occupational exposures.
Conclusion: The planned data and specimen linkages with MCS survey data will allow MilCan to conduct population-based research on a wide range of military occupational, environmental, and behavioral exposures on the etiology of cancer among post-9/11 service members and veterans and could inform the development of policies and programs to prevent cancer.

#6240 Serum concentrations of per- and polyfluoroalkyl substances and mosaic chromosomal alterations in the Prostate, Lung, Colorectal and Ovarian (PLCO) Cancer Screening Trial.

Jongeun Rhee[1], Cynthia Rebecca Robbins[1], Vicky C. Chang[2], Weiyin Zhou[2], Mitchell J. Machiela[2], Jonathan N. Hofmann[2], Mark P. Purdue[2], Sonja I. Berndt[2]

[1]Center for Prostate Disease Research, Murtha Cancer Center Research Program, Uniformed Services University of the Health Sciences, Bethesda, MD,[2]Division of Cancer Epidemiology and Genetics, National Cancer Institute, Rockville, MD

Per- and polyfluoroalkyl substances (PFAS) are persistent organic pollutants detectable in the serum of most U.S. adults. Some PFAS are established or possible human carcinogens. Mechanistic studies in human cells and animals suggest PFAS may have genotoxic effects through indirect DNA damage caused by oxidative stress or other pathways; however, evidence from human populations remains limited. We investigated the relationship between serum PFAS concentrations and mosaic chromosomal alterations (mCAs), including autosomal mCAs among both men and women and mosaic loss of chromosome Y (mLOY) among men, as biomarkers of genotoxicity and genomic instability. We analyzed blood-derived DNA from 2,377 men and 696 women in three nested case-control studies within the PLCO Cancer Screening Trial. mCAs were detected using high-density genotyping array intensity data for the autosomes in men and women and separately in the male-specific region of the Y chromosome for mLOY. Pre-diagnostic serum concentrations of four PFAS [perfluorooctanoate (PFOA), perfluorooctane sulfonate (PFOS), perfluorohexane sulfonate (PFHxS), perfluorononanoate (PFNA)] were measured. Using study-specific multivariable logistic regression, we estimated odds ratios (ORs) and 95% confidence intervals (CIs) for the associations between serum PFAS concentrations and any detectable autosomal mCA, any mLOY, and mLOY affecting ≥10% of cells (expanded mLOY) among cancer cases and cancer-free controls, separately. Study- and case-control-specific results were summarized using random effects meta-analyses. Overall, autosomal mCAs were detected in 7% of men and 8% of women. Among men, 22% had mLOY, including 8.3% with expanded mLOY. 2% of men had both autosomal mCAs and mLOY. We found a suggestive positive association between serum PFOS concentrations and autosomal mCAs (per doubling in serum concentration, summary $OR_{continuous}$=1.43, 95%CI=0.93-2.21; I-squared=49%, P-heterogeneity=0.08). Among men, serum PFHxS was marginally positively associated with mLOY (any mLOY, summary $OR_{continuous}$=1.14, 95%CI=0.83-1.40; I-squared=59%, P-tenerogeneity=0.03), and the magnitude of the association was stronger for those with a higher proportion of affected cells (expanded mLOY; summary $OR_{continuous}$=1.19, 95% CI=0.89-1.59; I-squared=58%, P-tenerogeneity=0.03). No associations were observed for other PFAS. In conclusion, in this large population-based study, we observed suggestive evidence of a positive association between elevated serum PFOS concentrations and autosomal mCAs among men and women, and between serum PFHxS and mLOY among men. As the first study to evaluate PFAS in relation to mCAs, our findings, if confirmed, may provide new insights into PFAS-related effects on genome maintenance that are relevant to cancer development.

#6241 High-throughput screening for cancer-relevant chemicals in hair relaxer products sold in Kenya.

Elissia T. Franklin[1], Alexis A. Schaefer[2], Sstuti D. Mehra[3], Tabitha C. Hardin-Zollo[2], Karthik Mahakala[4], Jasmine A. McDonald[5], Mary Beth Terry[2], Beatrice N. Irungu[6], Cecilia Kimani[6], Esther Matu[6], Adana A. M. Llanos[2]

[1]Silent Spring Institute, Newton, MA,[2]Epidemiology, Columbia University Mailman School of Public Health, New York, NY,[3]Data Science, Columbia University, New York, NY,[4]Columbia University, New York, NY,[5]Columbia University Irving Medical Center, New York, NY,[6]Kenya Medical Research Institute, Nairobi, Kenya

Introduction: Hair relaxer use is associated with increased risks of several hormone-related cancers, including uterine, ovarian, and breast cancer. Given the high prevalence of relaxer use among Black women and women of African ancestry, unequal exposure to toxicants in these products might contribute to observed disparities in cancer incidence and mortality. Although recent regulatory efforts have targeted specific chemicals such as formaldehyde and formaldehyde releasers, hair relaxers may contain additional unregulated chemicals and chemical mixtures of concern. Comprehensive data on the chemical composition of these products remain limited.

Methods: As part of a larger investigation, we identified commonly used hair relaxers among women in two counties in Kenya (Embu and Nakuru) and purchased 19 products (11 cream relaxers and 8 multi-component relaxer kits) from local retailers and beauty shops between May and July 2024. Non-targeted two-dimensional gas chromatography-high-resolution mass spectrometry (GCxGC-HRMS) was used to identify and semi-quantify semi-volatile compounds in sample extracts. Inductively coupled plasma-mass spectrometry (ICP-MS) and atomic absorption spectroscopy were employed to screen for heavy metals and mercury, respectively. The Highlight™ machine learning system and a search of the National Institute of Standards and Technology library facilitated data processing and suspect screening. Tentatively identified chemicals were cross-referenced with authoritative hazard databases, including the European Union's Cosmetics Regulation (EC) No 1223/2009 lists of prohibited (Annex II) and restricted (Annex III) chemicals, which align with the Kenya Bureau of Standards cosmetic regulations.

Results: We detected 353 individual features across all samples and identified 83 chemicals with medium-to-high identity confidence, including multiple known or suspected carcinogens. Over 50% of samples contained at least one chemical appearing on an established hazard list. Notably, lead and radioactive uranium—both banned in EU cosmetics—were detected in nearly 10% of the samples.

Conclusions: This study provides the first high-throughput chemical characterization of commercially available hair relaxers commonly used by Black women and women of African ancestry in Kenya. The detection of numerous carcinogenic and restricted substances highlights an urgent need for strengthened regulatory oversight, policy action, and evidence-based interventions to reduce exposure to hazardous chemicals in hair and personal care products, emphasizing the importance of evidence-based policies and interventions to eliminate hazardous exposures and advance equitable cancer prevention globally.

#6242 Hair products usage and breast cancer among Latinas living in Puerto Rico: The HERSAFE Study.

Nancy Raquel Cardona-Cordero, Brenda Gonzalez, Ana Patricia Ortiz

University of Puerto Rico Comprehensive Cancer Center, San Juan, PR

Introduction. Hair products are widely used for aesthetic enhancement, yet their prolonged usage raises concerns about potential health risks. Many shampoos, conditioners, mascaras, dyes, among other products, contain ingredients that have been linked to endocrine disruption and possible carcinogenic effects. This study aims to assess the use of hair products across the lifespan of Latina women and breast cancer risk.

Materials and Methods. The ongoing “HERSAFE” case-control study examines the relationship between beauty product use and breast cancer among Hispanic women in Puerto Rico. Participants were recruited from Comprehensive Cancer Hospital and Radiotherapy Center. Data collection included a 45-60-minute survey on socio-demographics, lifestyle, maternal health, and beauty product usage. Data was stored in RedCap. STATA was used for demographics and logistic regression analysis (95%CI).

Results. Participants (n=105) mean age was 55.4 (SD±11.5). Only 28% of participants live below poverty levels (<$20,000) and 87% had at least one child. Around 23% of the participants reported a darker skin tone, compared to the lightest color. Participants reported the use of permanent and semi-permanent products during their lifetime; with 57% and 16% of the participants reporting over 10 years of permanent dye and semi-permanent dye. A non-significant trend of increased risk of breast cancer was observed among users of semi-permanent dye (AOR 1.65 95%CI:0.64-4.21). Similar results were observed for those who used permanent dye.

Conclusion. This research aims to enhance awareness of cosmetic safety, encourage informed consumer choices, and advocate for stricter regulations on harmful ingredients in beauty care products. Further research with larger samples and additional variables is needed to better understand potential influences on breast cancer risk for this population.

#6243 Mapping risk: spatial analysis of 2,4-D herbicide emissions and colorectal cancer.

Danny Baxter[1], Dan Dixon[1], Andrew Morris[1], Tongzhang Zheng[2], **Yong Zhu**[1]

[1]University of Arkansas for Medical Sciences, Little Rock, AR,[2]Brown University, Providence, RI

Colorectal cancer (CRC) incidence remains disproportionately high in rural agricultural regions, including Arkansas, where environmental exposures may contribute to persistent cancer disparities. Yet, ambient community-level herbicide exposures have been minimally studied as potential CRC risk factors, representing an important knowledge gap. To identify candidate environmental contributors, we integrated county-level air pollutant emission estimates from the EPA AirToxScreen dataset with age-adjusted CRC incidence from the National Cancer Institute State Cancer Profiles. Screening 133 pollutants in Arkansas identified 2,4-dichlorophenoxyacetic acid (2,4-D), one of the most widely used herbicides in U.S. agriculture, as the exposure most strongly correlated with CRC incidence (Spearman $\rho = 0.338$, $p = 0.003$). Linear regression indicated that each one-log-unit increase in 2,4-D emissions corresponded to 6.28 additional CRC cases per 100,000 population ($p = 0.001$), with similar associations in rural and urban strata. Extension to 2,555 U.S. counties demonstrated a consistent association nationally ($\beta = 5.94$, $p < 0.001$). Spatial error regression improved model fit and confirmed the association after accounting for geographic autocorrelation ($\beta = 2.55$, $p = 0.001$). Adjustment for county-level poverty modestly strengthened the association ($\beta = 2.81$, $p < 0.001$), suggesting that both socioeconomic conditions and herbicide exposure may jointly contribute to CRC burden in agricultural regions. While ecological and not causal, this study is among the first to evaluate ambient, population-level 2,4-D exposure rather than occupational exposure, and demonstrates a spatial epidemiologic approach for identifying environmental carcinogen candidates relevant to precision public health and rural cancer equity. These findings support the need for follow-up studies integrating individual-level exposure biomarkers, mechanistic data, and targeted CRC screening strategies in high-exposure regions.

#6244 Agricultural glyphosate use and early-onset colorectal cancer mortality in the United States.

Jiayu Lin[1], Malia Cortez[1], Caroline Nondin[1], Seigi Karasaki[2], Sam L. S. Chao[3], Trang VoPham[1]

[1]Epidemiology Program, Public Health Sciences Division, Fred Hutchinson Cancer Center, Seattle, WA,[2]Fred Hutchinson Cancer Center, Seattle, WA,[3]Public Health Sciences Division, Fred Hutchinson Cancer Center, Seattle, WA

PURPOSE Early-onset colorectal cancer (CRC) (diagnosis before age 50 years) incidence has risen dramatically. Individuals born in the 1990s compared to the 1960s have a four-fold higher risk for early-onset CRC. Recent evidence suggests that risk factors experienced in early life and/or emerging in relatively later generations may play an etiologic role in early-onset CRC. One environmental exposure potentially contributing to the surge in early-onset CRC is glyphosate, the most widely utilized herbicide in the world that substantially increased in usage following the introduction of glyphosate-resistant crops in 1996. Glyphosate is hypothesized to promote colorectal carcinogenesis through mechanisms such as gut microbiome dysbiosis. Our objective was to conduct an epidemiologic study examining the association between agricultural glyphosate use and risk for early-onset CRC-specific mortality in the United States.

METHODS We extracted mortality and sociodemographic data from death certificates of all individuals in the United States who died from early-onset CRC (defined as death before age 50) (ICD-9 153.0-153.4, 153.6-154.1; ICD-10 C18.0, C18.2-C18.9, C19, C20) from 1989-2023 from the National Center for Health Statistics. Annual average glyphosate use was estimated by linking nationwide agricultural pesticide application data from the United States Geological Survey with the year and county of residence at death. Quasi-Poisson regression with robust standard errors was used to estimate mortality rate ratios (MRRs) with 95% confidence intervals (CIs) for the association between glyphosate use and early-onset CRC-specific mortality risk adjusted for individual-level age, sex, race, ethnicity, year, marital status, and education level, and county-level socioeconomic status.

RESULTS A total of 108,315 deaths from CRC among those <50 years old were included in this study. We observed a statistically significant dose-response relationship, in which higher annual average glyphosate use was associated with incremental increases in risk for CRC-specific mortality (adjusted MRR highest quintile (>5.74 kg/km2) vs. lowest quintile (<=0.08 kg/km2): 1.10, 95% CI 1.06-1.13; p trend <0.0001).

CONCLUSIONS Higher agricultural glyphosate use was associated with increased risk for early-onset CRC-specific mortality in the United States. Future research should further explore the role of glyphosate in early-onset CRC through examining incidence outcomes and life-course exposures using residential address histories.

#6245 Lead Bioaccumulation Drives Genomic Instability and Apoptotic Resistance in Human Breast Cancer.

Rita Bonfiglio, Anatomical Pathology Tor Vergata, Manuel Scimeca

Experimental Medicine, University of Rome Tor Vergata, Rome, Italy

Introduction: Lead (Pb) is a widespread environmental toxicant classified by IARC as a probable human carcinogen, yet its mechanistic involvement in breast cancer remains poorly defined. Epidemiological studies suggest an association between Pb exposure and breast cancer risk, but tissue-level data linking Pb accumulation to molecular cancer features are limited. Understanding whether Pb bioaccumulates within breast tumors and influences key cancer hallmarks may reveal overlooked environmental determinants of breast cancer progression.
Methods: Formalin-fixed paraffin-embedded breast cancer samples from 26 female patients. Lead concentration was quantified using inductively coupled plasma mass spectrometry (ICP-MS). Whole-genome sequencing and RNA-seq were performed on frozen tumor aliquots (n = 21), enabling assessment of Tumor Mutational Burden (TMB), Microsatellite Instability (MSI), mutational signatures, and PAM50 molecular subtypes. Spearman correlation, bootstrap confidence intervals, and non-parametric tests assessed relationships between Pb concentration and clinicopathological or molecular variables.
Results: Lead was detected in 100% of breast cancer samples, with a mean concentration of 18.2 ± 16.2 mg/kg (range: 0.2-310 mg/kg). Lead levels showed no association with age or classical pathological features, including histologic grade ($p = 0.8$) and lymph-node metastasis ($p = 0.6$). Notably, Pb concentration was independent of PAM50 subtypes, suggesting that Pb accumulation reflects a biological dimension distinct from established intrinsic classifications.A significant relationship emerged between Pb accumulation and genomic instability. Lead concentration strongly correlated with TMB ($\rho = 0.87$; $p < 0.0001$) and MSI ($\rho = 0.79$; $p < 0.0001$). Tumors with the highest Pb levels also harbored TP53 missense mutations and frameshift deletions, underscoring a link between Pb burden and DNA repair pathway dysregulation. These findings support a model in which Pb bioaccumulation promotes mutational processes, potentially via disruption of mismatch repair mechanisms.Pb concentration was also positively associated with expression of BCL2 ($\rho = 0.66$; $p = 0.001$) and p53 ($\rho = 0.65$; $p = 0.002$), pointing toward enhanced resistance to regulated cell death.
Conclusion: Data here reported highlighted the need to incorporate environmental metal burden into breast cancer risk assessment particularly for patients exhibiting elevated TMB/MSI who may benefit from immunotherapy.

#6246 Associations between natural radionuclides in borehole water and cancer risks: A comprehensive population-based study from Finland.

Peng Li[1], Pekka Martikainen[2], Mikko Myrskyla[1]

[1]Max Planck Institute for Demographic Research (MPIDR), Rostock, Germany,[2]University of Helsinki, Helsinki, Finland

Background:
Carcinogenic effects of radioactive elements in environmental background for all cancer types have not been fully investigated.
Methods:
This paper assesses the associations between radioactive elements in borehole water and all cancer types based on total Finnish population. National registries of the general population living continuously in Finland during 1987-2016 were linked to annual municipality-level concentrations of uranium (Ur) and radon (Rn) in borehole water. Average radiation exposures over 30 years were calculated individually based on residential location annually. Newly diagnosed cancers were followed from 2017 until 2021 based on national cancer registry. Associations between exposures and cancer incidences were assessed via Cox proportional hazards models, adjusted for pre-existing health conditions and socio-economic factors. Multiplicity was adjusted using Bonferroni correction.
Results:
Totally 1,013,054 men and 1,101,589 women with non-missing municipality-level exposures were included. During follow-up period, totally 62,085 cancer cases of 70 sub-types were diagnosed in men and 57,627 cancer cases of 73 sub-types were diagnosed in women respectively. Significant associations between environmental radiation exposures and elevated risks of cancer were observed in men (Ur: hazard ratio [HR] 1.05, 95% confidence interval [CI] 1.03-1.07; Rn: 1.04, 1.02-1.05) and women (Ur: 1.07, 1.05-1.09; Rn: 1.05, 1.03-1.07). After correction of multiplicity, significantly elevated risks were observed for cancers of uncertain lymphoid and hematopoietic tissue (1.66, 1.39-1.97), mesothelioma (1.48, 1.18-1.86), myeloma (1.36, 1.18-1.57), melanoma (1.31, 1.22-1.40), leukemia lymphoid (1.28, 1.12-1.48) in men with higher exposure to Ur; and Polycythemia vera (1.79, 1.30-2.45), uncertain lymphoid and hematopoietic tissue (1.61, 1.36-1.91), myeloma (1.52, 1.32-1.75), melanoma (1.22, 1.14-1.31) and bladder (1.20, 1.08-1.32) with higher exposure to Rn. Significantly elevated risks were observed for uncertain lymphoid and hematopoietic tissue (1.78, 1.52-2.08), leukemia lymphoid (1.48, 1.24-1.77), melanoma (1.33, 1.24-1.44), lung (1.26, 1.19-1.34) and breast (1.07, 1.04-1.10) in women with higher exposure to Ur; and uncertain lymphoid and hematopoietic tissue (1.73, 1.48-2.03), Polycythemia vera (1.72, 1.26-2.35), myeloma (1.51, 1.30-1.75), melanoma (1.28, 1.19-1.38) and lung (1.21, 1.14-1.29) with higher exposure to Rn. In sensitivity analysis, similar patterns were observed in samples who only lived in houses during 1987-2016. Dosage-response trends were observed for total cancer risks in men and women respectively.
Interpretation:
High environmental radiation exposures were significantly associated with elevated total cancer risks and several sub-types in the general population.

#6248 Long-term air pollution and lung cancer incidence by histological subtypes.

Sun-Young Kim, Jeongho Park, Miyoun SHIN, Yoon-Jung Choi

National Cancer Center, Goyang, Korea, Republic of

Background: There is mounting evidence of long-term exposure to air pollution and incidence of lung cancer based on large cohort studies worldwide. A few subsequent studies have suggested that the association may vary by histological subtypes, although findings have been inconsistent. This study aimed to investigate whether air pollution affects a specific histological subtype of lung cancer more than the others using a population-representative cohort including 2 million adults.
Methods: Our study population includes 2,346,332 adults who were aged 30 years or over in 2007, participated in health examinations for 2005-2007, and were retrospectively followed-up until 2020 in the National Health Insurance Services database linked with the Korea Central Cancer Registry of South Korea. We identified lung cancer incidence of three histological subtypes, including adenocarcinoma (AD), squamous cell carcinoma (SqCC), and small cell carcinoma (SCC), based on the International Classification Diseases for Oncology. Individual-level long-term exposures to particulate matter ≤ 2.5 $\mu g/m^3$ in diameter ($PM_{2.5}$) and nitrogen dioxide (NO_2) were 5-year average concentrations estimated at district-level home addresses by previously-validated exposure prediction models. Then, we applied time-varying Cox proportional hazard model to estimate hazard ratios of lung cancer incidence for 10 $\mu g/m^3$ and 10 ppb increases in $PM_{2.5}$ and NO_2 respectively.
Results: For 20,811 new lung cancer cases occurred over 13 years, AD, SqCC, and SCC made up 52, 21, and 10 %, respectively. We found no association of total lung cancer incidence for both pollutants ($PM_{2.5}$: HR=1.065, 95% CI=0.957–1.186; NO_2: 0.980, 0.957–1.004). However, $PM_{2.5}$ was associated with SqCC (1.353, 1.054 –1.738), but not associated with AD (0.892, 0.722–1.038) and SCC (1.148,0.818–1.609). In contrast, NO_2 showed the association for AD (1.064, 1.027–1.102) but not for SqCC 0.905 (0.861 – 0.951) and SSC 0.956 (0.888 – 1.029).
Discussion: Our findings of different associations by pollutants and histological subtypes suggest different mechanistic roles in lung cancer development depending on the pollutant.

#6249 PM2.5 and black carbon levels associated with increased mortality in lung cancer patients.

Victoria A. Chu[1], Xianhong Xie[1], Kith Pradhan[1], George S. Downward[2], Thomas E. Rohan[1], Haiying Cheng[3], Brendon Stiles[4], Xiaonan Xue[1], Tamar Nobel[5], Aditi Shastri[6], H. Dean Hosgood[1]

[1]Department of Epidemiology and Population Health, Albert Einstein College of Medicine, Bronx, NY,[2]Department of Population Health Sciences, Utrecht University, Utrecht, Netherlands,[3]Departments of Oncology and Medicine, Albert Einstein College of Medicine, Bronx, NY,[4]Departments of Oncology, Medicine, Cardiothoracic & Vascular Surgery, Albert Einstein College of Medicine, Bronx, NY,[5]Departments of Epidemiology and Population Health, Cardiothoracic & Vascular Surgery, Albert Einstein College of Medicine, Bronx, NY,[6]Departments of Oncology, Medicine, Developmental & Molecular Biology, Albert Einstein College of Medicine, Bronx, NY

Lung cancer is the leading cause of cancer mortality in the United States. Over recent years, lung cancer incidence among never-smokers has been rising. Additionally, heterogeneity in treatment responses among patients with lung cancer have not been fully elucidated. Outdoor air pollution (OAP) is a known lung carcinogen, but little is known about the effects of OAP on lung cancer survival and prognosis. Therefore, this study aimed to assess the association between OAP exposure and lung cancer survival. A retrospective cohort study was conducted by gathering patient and clinical data from a cohort of 8,793 non-small cell lung cancer (NSCLC) patients from the Montefiore Einstein Comprehensive Cancer Center (MECCC) in the Bronx, NY. Environmental exposure to OAP was estimated based on the patients' geo-coded addresses. Pollutants were estimated by combining Aerosol Optical Depth retrievals from different instruments with the GEOS-Chem chemical transport model. The data were calibrated to regional ground-based observations using a geographically weighted regression. Quantitative analyses were performed using Kaplan-Meier curves and Cox proportional hazard models. Stepwise regression model selection for confounding variables, including smoking, sex, age, histology, stage, treatment (transplant, surgery, chemotherapy, radiation), and other pollutants (NH_4, organic matter, SO_4) was used. Exposure to >9ug/m^3 of PM2.5 and >median levels of Black Carbon at the time of diagnosis were associated with an 8% and 6% decrease in overall lung cancer survival, respectively ($p<0.0001$). PM2.5 was associated with decreased lung cancer survival by 5-9% in all sex, smoking, and histology groups ($p<0.0001$). Black Carbon was associated with a 4-9% decrease in lung cancer survival in male ($p=0.01$), female ($p<0.0001$), never ($p=0.05$) or ever ($p<0.0001$) smoker, and Adenocarcinoma ($p<0.0001$) subgroups. Consistent with previous studies, we observed an association between PM2.5 exposure and decreased lung cancer survival. Black Carbon, not tested in previous studies, was also associated with decreased lung cancer survival. Future research is needed to explore the relationship(s) between additional geospatially correlated exposures, OAP, and lung cancer survival.

#6250 Chemical composition of fine particulate matter and mortality of older lung cancer patients.

Jiaowei Gong[1], Edgar Castro[2], Min Zhang[3], Robert O. Wright[3], Christine C. Ekenga[4], Joel D. Schwartz[2], **Yaguang Wei**[3]

[1]Department of Global Health and Population, Harvard T.H. Chan School of Public Health, Boston, MA, [2]Department of Environmental Health, Harvard T.H. Chan School of Public Health, Boston, MA, [3]Department of Environmental Medicine, Icahn School of Medicine at Mount Sinai, New York, NY, [4]Emory University, Rollins School of Public Health, Atlanta, GA

Importance: Lung cancer mortality remains elevated despite advances in treatment. Although ambient fine particulate matter ($PM_{2.5}$) has been identified as Group 1 carcinogen for lung cancer, which increases the incidence, the role of chemical components in mortality of lung cancer patients and the identification of harmful components and susceptible groups remain unclear.
Objective: To evaluate whether long-term exposure to $PM_{2.5}$ chemical components is associated with all-cause mortality among lung cancer patients, and whether the associations differ by histology and stage at diagnosis, demographics, and comorbidity.
Design, Setting, and Participants: This cohort study derived from the SEER-Medicare database that identifed 495,339 adults aged ≥65 years with lung cancer diagnosed between 2000 and 2019. Patients were followed annually from diagnosis until death, loss to follow-up, or the end of 2019 (mean follow-up, 4.1 years). The SEER-Medicare database provided longitudinal residential ZIP code, demographics, cancer-specific characteristics, and comorbidities.
Exposures: Annual exposures to 15 $PM_{2.5}$ chemical components were estimated from 2000 to 2019 using high-resolution spatiotemporal models and linked to each patient based on residential ZIP code in each year.
Main Outcome: The primary outcome was the relative risk of all-cause mortality, measured from the year of lung cancer diagnosis until death or the end of follow-up. We used generalized weighted quantile sum regression to estimate both cumulative effects of annual exposure to all components and individual contributions for each component, adjusted for demographic, cancer-specific characteristics (histology, stage, treatment), comorbidities, and neighborhood-level covariates.
Results: Joint exposure to $PM_{2.5}$ components was associated with increased all-cause mortality, with relative risk [RR] being 1.012 (95% confidence interval [CI], 1.011-1.014) per decile increase in all components. Iron contributed most strongly (8.3% of total effects), followed by organic carbon, vanadium, ammonium, bromine, and silicon. Associations were stronger among patients with non-small cell lung cancer, particularly squamous cell carcinoma, as well as among women and those with regional-stage disease.
Conclusions and Relevance: Long-term exposure to $PM_{2.5}$ components was linked to greater mortality among patients with lung cancer, especially in those diagnosed with non-small cell and squamous cell carcinoma, women, and with advanced stage. Chemical components that contributed most to this effect emitted from traffic, power generation, biomass burning, and heavy fuel oil, highlighting the need for targeted emission reductions to improve outcomes in high-risk populations.

#6251 Long-term exposure to wildfire smoke $PM_{2.5}$ and survival of older lung cancer patients.

Min Zhang[1], Juan P. Wisnivesky[2], Minghao Qiu[3], Mahdieh Danesh Yazdi[4], Rosalind J. Wright[5], Joel D. Schwartz[6], Christine C. Ekenga[7], Robert O. Wright[1], **Yaguang Wei**[1]

[1]Environmental Medicine, Icahn School of Medicine at Mount Sinai, New York, NY,[2]Medicine, Icahn School of Medicine at Mount Sinai, New York, NY,[3]School of Marine and Atmospheric Sciences, Stony Brook University, Stony Brook, NY,[4]Family, Population, and Preventive Medicine, Stony Brook University, Stony Brook, NY,[5]Public Health, Icahn School of Medicine at Mount Sinai, New York, NY,[6]Environmental Health, Harvard T.H. Chan School of Public Health, Boston, MA,[7]Emory University, Rollins School of Public Health, Atlanta, GA

Importance Fine particulate matter ($PM_{2.5}$) is a key risk factor of lung cancer incidence and mortality. However, the specific effect of $PM_{2.5}$ originating from wildfire smoke, an increasingly important contributor to total $PM_{2.5}$ in the US driven by climate change, on mortality of patients with lung cancer remain unclear.

Objective To explore the effect of long-term exposure to wildfire smoke versus non-smoke $PM_{2.5}$ on all-cause mortality of older lung cancer patients.

Design, Setting, and Participants This cohort study included patients ≥65 years with primary diagnosis of lung cancer from the SEER-Medicare database from 2006 to 2019 linked with estimates of exposure to wildfire smoke and non-smoke $PM_{2.5}$ based on patients' residential zip codes.

Exposures Three-year moving average exposures to wildfire smoke and non-smoke $PM_{2.5}$.

Main Outcomes and Measures The study outcome was all-cause mortality after primary lung cancer diagnosis. A time-varying Cox proportional hazards model was applied to estimate hazard ratios (HRs) for mortality risk.

Results Among 503,409 patients with 1,542,491 person-years of follow up, each 1-μg/m³ increase in wildfire smoke $PM_{2.5}$ was associated with a 9.3% increased mortality risk (HR: 1.09, 95% CI: 1.08-1.11), substantially greater than that of non-smoke $PM_{2.5}$ (HR: 1.020, 95% CI: 1.018-1.022). The number of smoke days and of smoke waves, reflecting duration and frequency of wildfire smoke $PM_{2.5}$ exposure, were also positively associated with mortality risk. Larger effect of wildfire smoke $PM_{2.5}$ was observed among women, patients with lung cancer other than non-small cell lung cancer, patients with comorbidities, and those not receiving first course treatment after diagnosis.

Conclusions Wildfire smoke posed a substantially larger risk in older lung cancer patients than non-smoke $PM_{2.5}$. Under a changing climate, strengthening wildfire management and reducing wildfire smoke exposure in clinical care could improve survival of older lung cancer patients.

HR for mortality and corresponding annual excess deaths associated with smoke and non-smoke PM2.5

Three-year moving average wildfire smoke $PM_{2.5}$ exposure	Hazard ratio (95% CI)	Annual excess deaths (95% CI)
Concentration, per 1-μg/m^3 increase		
Smoke $PM_{2.5}$	1.0927 (1.0801, 1.1055)	2,908 (2,513, 3,310)
Non-smoke $PM_{2.5}$	1.0202 (1.0182, 1.0222)	634 (571, 696)
Smoke-event duration and frequency, per day/event increase		
Number of smoke days	1.0040 (1.0037, 1.0043)	125 (116, 135)
Number of smoke waves	1.0209 (1.0185, 1.0233)	656 (580, 731)

#6253 Spatial association between thyroid cancer incidence and environmental carcinogen emissions in Korea.

Taehoon Kim, Sangjun Lee, Sue K. Park

Department of Preventive Medicine, Seoul National University, Seoul, Korea, Republic of

Background: Thyroid cancer is the most commonly diagnosed cancer in Korea, with a recent resurgence in incidence since 2016. Environmental and occupational exposures—including air pollutants such as nitrogen dioxide (NO_2), particulate matter (PM2.5), ozone (O_3), and industrial chemicals such as toluene and mercury—have been reported as potential risk factors. This study examined whether regional variation in thyroid cancer incidence across Korea can be explained by differences in community-level carcinogenic emissions.
Methods: An ecological study was conducted across 229 districts in Korea, using thyroid cancer incidence (ICD-10: C73) from 2014-2018 as the outcome. Exposure variables were district-level annual emissions of carcinogenic substances reported in the Pollutant Release and Transfer Register (PRTR), aggregated into three latency-reflective periods (2004-2008; 2009-2013; 2004-2013). Missing emission values were spatially interpolated using Bayesian spatial assumptions. Covariates included demographic (sex ratio, proportion aged 25-44), behavioral (smoking, obesity), and socioeconomic indicators (number of physicians per 1,000 population, basic livelihood recipient rate). Bayesian hierarchical Poisson models with BYM2 spatial structure were fitted using Integrated Nested Laplace Approximation (INLA). Model fit was assessed using WAIC, and relative risks (RRs) were estimated for each exposure period.
Results: Higher district-level carcinogen emissions were associated with increased thyroid cancer incidence. In baseline models, a 1-unit increase in log-transformed emissions corresponded to RRs ranging from 1.037 to 1.051 across exposure periods. Spatially interpolated emission datasets showed similar associations (RR 1.037-1.041). In adjusted models controlling for demographic, behavioral, and socioeconomic factors, associations remained directionally consistent, with RRs between 1.023 and 1.028 for raw emission data and 1.024-1.025 for interpolated data. Spatial clusters of high relative risk were identified in urbanized and industrialized regions.
Conclusions: Districts with higher emissions of carcinogenic substances exhibited increased thyroid cancer incidence after accounting for spatial dependence and community-level covariates. These findings support the hypothesis that environmental pollution from industrial facilities contributes to regional disparities in thyroid cancer and that latency windows of 5-10 years are relevant. Future research should incorporate refined exposure assessments at the individual level, improved temporal matching, and linkage to targeted prevention or screening strategies for high-risk regions.

#6254 Pre-diagnosis green space exposure and survival in women diagnosed with ovarian cancer.

Jaileene Perez-Morales[1], Hari S. Iyer[2], Jaime E. Hart[3], Francine Laden[4], Laura D. Kubzansky[5], Joshua M. Moreau[1], Guillermo Armaiz-Pena[6], Shelley Tworoger[1], **Charlotte Roscoe**[1]

[1]Division of Oncological Sciences, OHSU Knight Cancer Institute, Portland, OR,[2]Rutgers Cancer Institute of New Jersey, New Brunswick, NJ,[3]Channing Division of Network Medicine, Department of Medicine, Brigham and Women's Hospital and Harvard Medical School, Boston, MA,[4]Department of Environmental Health, Harvard T.H. Chan School of Public Health, Boston, MA,[5]Department of Social and Behavioral Sciences, Harvard T.H. Chan School of Public Health, Boston, MA,[6]Cancer Biology and Women's Health Divisions, Ponce Health Sciences University School of Medicine, Ponce, PR

Background: Despite treatment advances, the five-year relative survival is 50% for patients with invasive ovarian cancer. Increasing literature demonstrates that distress, depression, and other psychosocial stressors negatively influence survival. Exposure to green spaces - e.g., parks, gardens, forests and street trees - has been associated with lower stress hormone levels and reduced risk of depression. Thus, our objective was to evaluate if greenness exposure, pre-diagnosis, was associated with improved ovarian cancer survival among cases in the Nurses' Health Study (NHS) and NHSII cohorts.

Methods: Greenness exposure was assessed seasonally within nearby (270m) and walkable (1230m) distance buffers surrounding NHS and NHSII cohort participants' residential addresses (updated biennially from 1988 to 2018) using the Normalized Difference Vegetation Index (NDVI; $30m^2$ resolution)-a satellite-derived indicator of photosynthetic vegetation cover. We used time-varying Cox proportional hazards models to assess cumulative, pre-diagnosis, maximum average NDVI exposure and ovarian cancer specific survival among confirmed cases. Models were adjusted for age and calendar time, US region, population density, and pre-diagnosis factors associated with ovarian cancer survival, including menopause status, family history of breast or ovarian cancer, and parity. Time-varying depression - self-reported antidepressant use or clinician diagnosed depression - was additionally adjusted to evaluate potential mediation of the relationship between greenspace exposure and survival.

Results: Analyses included 1,052 women with confirmed ovarian cancer. We observed a suggestive decrease in ovarian cancer mortality risk for a 0.1 unit (10%) increase in cumulative pre-diagnosis 270m NDVI exposure (aHR 0.92; 95% CI 0.79, 1.07) when adjusting for all factors except depression. Adding depression led to a slightly stronger inverse association (aHR 0.90 95% CI 0.76, 1.07), although it did not reach statistical significance. No association was observed for cumulative pre-diagnosis 1230m NDVI exposure.

Conclusions: Pre-diagnosis near-residence greenness exposure was suggestively associated with improved survival among ovarian cancer cases. Adjusting for depression status slightly strengthened the inverse association, indicating that the association of greenness with survival is unlikely to be fully explained by depression status; other potential mechanistic pathways (e.g., pollution and temperature reduction, improved sleep quality, physical activity, vitamin D levels and immune function) should be explored. On-going analyses will assess associations by histologic subtype. Future studies are needed to assess the type and quality of nature exposure, including but not limited to green spaces, with risk and survival among patients, with stratification by geographic and ecological regions.

#6255 Occupation and breast cancer risk in the Long Island Breast Cancer Study Project cohort.

Hannah M. Thompson[1], Susan L. Teitelbaum[1], Yaguang Wei[1], Zoey Laskaris[2]

[1]Environmental Medicine, Icahn School of Medicine at Mount Sinai, New York, NY,[2]Barry Commoner Center for Health and the Environment, Queens College, New York, NY

Purpose: Work is a modifiable risk factor that may influence breast cancer incidence, yet the role of specific occupations is understudied. We evaluated associations between longest held job and breast cancer incidence in the well-characterized Long Island Breast Cancer Study Project (LIBCSP).
Methods: The LIBCSP, a population-based case-control study, enrolled women with first primary invasive and in situ breast cancer diagnosed between 1996-1997. Frequency matched controls were identified via random digit dialing and Health Care Finance Administration rosters. Socioeconomic (race, ethnicity, and education), reproductive (parity, age at first birth, lactation, age of menarche, family history of breast cancer, and use of oral contraceptives and hormone replacement therapy), and lifestyle (body mass index, alcohol use, and smoking status) factors were collected via interviewer-administered questionnaires. Self-reported occupational histories were coded using the 1980 Standard Occupational Classification (SOC) and 1987 Standard Industrial Classification systems, then crosswalked to the 2018 SOC and 2017 North American Industry Classification System codes. Participants without at least one occupation held for >1 year were excluded. Multivariable logistic regression estimated the odds ratio (OR) for breast cancer using longest held minor occupation group as the exposure and other longest held minor occupation groups as the reference, adjusting for key factors as above. Effect modification by menopausal status was examined.
Results: Analyses included 3001 study participants (1468 cases and 1533 controls). Most participants were non-Hispanic White. Cases were older at first birth ($p=0.03$) and more likely to have a first degree relative with breast cancer ($p <0.001$). The average duration of the longest held job was 13.0 years among cases and 12.2 among controls. Most occupations were not associated with breast cancer risk. However, elevated risks were observed for financial clerks (OR=1.54, 95% confidence interval [CI] 1.10-2.14) and personal appearance workers (OR=2.02, 95%CI 1.07-3.78) compared with all other occupations when controlling for socioeconomic, reproductive, and lifestyle factors. Stratified analyses indicated increased risk among pre-menopausal financial clerks and post-menopausal personal appearance workers.
Conclusions: Specific occupations, financial clerk and personal appearance worker, were independently associated with increased risk of breast cancer. Future work will seek to better understand the relationship between work and breast cancer risk by evaluating industry and occupation types based on exposure, which may further delineate why certain jobs are associated with an increased risk of breast cancer. Incorporating occupational history into population-based cancer research may identify important cancer risk prevention opportunities.

#6256 Leveraging the Healthy Oregon Project (HOP) to evaluate environmental exposures during critical reproductive periods and young-onset breast cancer risk.

Charlotte Roscoe[1], **Sofia I. Chapela Lara**[2], Wesley Stoller[1], Marit Simmons[1], Hailey Brack[1], Jackilen Shannon[1], Pepper J. Schedin[1], Zhenzhen Zhang[1]

[1]Division of Oncological Sciences, OHSU Knight Cancer Institute, Portland, OR,[2]School of Public Health, Oregon Health & Science University, Portland, OR

Background: Young-onset breast cancer (YOBC), diagnosed before age 50, has twice the mortality of cases diagnosed ≥50. In the US, YOBC diagnoses increased by 1.4% annually from 2012-2021, with higher increases in non-metropolitan vs. metropolitan areas in western states. Geographic disparities may be influenced by environmental factors, such as neighborhood socioeconomic context, limited healthcare access, and exposure to environmental hazards (e.g., pesticides, per- and polyfluoroalkyl substances [PFAS]-contaminated water, wildfire smoke), which have been associated with breast tissue inflammation and increased breast cancer risk. Shifts in critical reproductive periods (e.g., menarche, delayed childbirth, menopause) and parity or nulliparity, which may be shaped by these environmental factors, may also affect risk and interact synergistically with environmental stressors. Our objective was to assess environmental exposures during critical reproductive periods to evaluate YOBC risk in a western US state with strong urban-rural environmental exposure contrasts.
Methods: We used the Healthy Oregon Project (HOP) - a statewide prospective cohort of >50,000 Oregonians - to assess rurality of residential addresses of enrolled females, 18-49 years old, diagnosed with YOBC. Cases were identified via self-report on the HOP baseline questionnaire. Baseline residential addresses were linked to the USDA Economic Research Service's Rural Urban Commuting Area (RUCA) codes, and classified as Urban (codes 1-3), Rural (codes 4-9), or Frontier (code 10). A supplementary reproductive lifecourse questionnaire, including residential addresses during critical reproductive windows, is in development to allow us to link spatial datasets (e.g., fine particulate air pollution [$PM_{2.5}$], wildfire smoke, temperature, PFAS in water, land cover, agricultural pesticides) to YOBC cases and matched controls.
Results: HOP has consented 51,978 Oregonians (~1.5% of the state's 3.4 million adult residents). On baseline questionnaires, 37,695 (72.5%) identified as female at birth, and 615 reported a YOBC diagnosis. Overall, participants resided in Urban (72.5%), Rural (13.5%) and Frontier (1.9%) areas, with 12.1% missing. Those diagnosed with YOBC showed a similar distribution (79.8%, 13.5% and 2.3%, respectively; 4.4% missing).
Conclusion: Rurality of HOP participants' residences was similar across those with YOBC and the overall cohort; this distribution is representative of Oregon's urban-rural composition. Future analyses will link historic residential addresses during critical reproductive windows across the lifecourse to spatiotemporally aligned environmental and socioeconomic exposure data to evaluate how cumulative, and potentially synergistic, environmental exposures contribute to YOBC risk.

#6257 Associations of area level deprivation with survival outcomes among patients with newly diagnosed colorectal cancer considered across the lifespan.

Jessica R. Burns[1], Maria F. Gomez[2], Stephanie Hogue[1], Esther Jean-Baptiste[1], Julaxis Love[1], Erin Siegel[2], Adetunji T. Toriola[3], Christopher I. Li[4], Jane C. Figueiredo[5], Nicole C. Lorona[5], Biljana Gigic[6], David Shibata[7], Seth Felder[8], Patricia A. Erickson[9], Mmadili N. Ilozumba[9], Ildiko Strehli[9], Megan Mclaws[9], Victoria Damerell[6], Shaneda Warren Andersen[10], Caroline Himbert[9], Cornelia M. Ulrich[9], Sheetal Hardikar[9], Doratha A. Byrd[2]

[1]Non-Therapeutic Research Office, Moffitt Cancer Center, Tampa, FL,[2]Department of Cancer Epidemiology, Moffitt Cancer Center, Tampa, FL,[3]Siteman Cancer Center, Washington University School of Medicine in St. Louis, St. Louis, MO,[4]Division of Public Health Sciences, Fred Hutchinson Cancer Center, Seattle, WA,[5]Department of Medicine at Samuel Oschin Comprehensive Cancer Institute, Cedars-Sinai Medical Center, Los Angeles, CA,[6]Department of General, Visceral and Transplantation Surgery, Heidelberg University Hospital, Heidelberg, Germany,[7]Department of Surgery, University of Tennessee Health Science Center, Memphis, TN,[8]Department of Gastroenterological Oncology, Moffitt Cancer Center, Tampa, FL,[9]Huntsman Cancer Institute, Salt Lake City, UT,[10]University of Wisconsin, Madison, WI

Background: Colorectal cancer (CRC) is the second overall leading cause of cancer-related deaths in the United States (US). The Area Deprivation Index (ADI), a neighborhood socioeconomic disadvantage measure, reflects multiple CRC survival-related exposures including access to resources, healthcare, quality of life, and other opportunities for economic mobility. These exposures may vary by birth cohort, making it important to examine ADI across age of onset. The purpose of this study is to investigate the associations of ADI with overall (OS) and disease-free survival (DFS) by age of onset (early: <50 years (EO), average: 50-64 years (AO), older: ≥65 years (LO)) in the ColoCare Study.

Methods: We included US data from the ColoCare Study, a prospective multicenter cohort study of newly diagnosed stage I-IV CRC patients. National- and state-level ADI were calculated using residential addresses captured at study entry. We compared ADI across ages of onset and estimated hazard ratios (HRs) and 95% confidence intervals (95% CI) for the associations of ADI with OS and DFS using multivariable Cox proportional hazard models, overall and stratified by age of onset, race, and ethnicity.

Results: There were 2,477 participants from the ColoCare study with ADI data, with a median follow-up time of 3.6 years (SD=2.5) starting at the date of diagnosis and ending at the date of death, last follow-up, or censored at 5 years. On average, individuals in the LO group had higher national ADI (mean=4.08 [2.81]) compared to the AO group (mean=3.93 [2.85]; P<0.001) and early onset group (mean=3.49 [2.72]; P<0.001]). Survival associations of the ADI based on national percentiles tended to be stronger than those based on the state. Considered per 10-percentile increase in national-level ADI, there was an 8% (95% CI=1.01, 1.15; P=0.02) and 10% (95% CI= 1.01, 1.21; P=0.03) higher overall mortality risk among LO and EO groups, respectively. After adjusting national-level ADI for race, there was a 6% and 3% higher overall mortality risk among the LO and AO groups, respectively. Among average onset individuals, the association of the ADI measures with OS was closer to the null and not statistically significant. Associations of ADI with DFS were weaker and not statistically significant among the EO and LO groups, but the ADI was positively associated with DFS among the AO groups (HR_{DFS} =1.09; 1.01-1.16; P=0.02). Though not statistically significant, the associations of ADI with OS and DFS were strongest among Non-Hispanic Black individuals (HR_{OS} = 1.12; 95% CI=0.92, 1.36; P=0.27; and HR_{DFS} =1.14; 0.93-1.40; P=0.20).

Conclusion: We observed that older CRC survivors tended to live in more deprived areas; however, across the lifespan, area level determinants of health were associated with poorer CRC survival outcomes.

#6258 Age at menopause, epigenetic aging, and cancer risk: A secondary analysis of the PLCO Trial.

Tiffany Y. Pei[1], Ting Zhai[2], Jinyoung Byun[1], Vernon S. Pankratz[1], Shuguang Leng[1]

[1]Department of Internal Medicine, University of New Mexico, Albuquerque, NM,[2]Department of Environmental Health, Harvard T.H. Chan School of Public Health, Boston, MA

Background: Our previous studies have linked early menopause (early-M, <45 years) with increased risks of lung-related morbidities and mortalities. However, its relationship with other cancer types and the underlying biological and causal mechanisms remains unclear. **Aim**: To conduct a secondary analysis evaluating the associations between early-M and blood-based epigenetic aging biomarkers, and cancer risks and mortalities using the prospective Prostate, Lung, Colorectal, and Ovarian (PLCO) cancer screening trial.
Methods: Genome-wide DNA methylation (DNAm) profiles were available from baseline blood samples in 1,517 PLCO participants who subsequently developed breast cancer or who remained cancer-free. Epigenetic age acceleration was estimated using four established DNAm clocks, HorvathAge, HannumAge, PhenoAge, and GrimAge, as well as DNAm-based telomere length. An epigenome-wide association study (EWAS) was performed followed by pathway enrichment analysis and exploratory analyses integrating immune marker data. For cancer risk and mortality analyses, we included all postmenopausal women of European ancestry with natural menopause from the full PLCO cohort with genotype and phenotype data available (n = 31,022). A polygenic risk score (PRS) for age at natural menopause was constructed using 154 genetic variants identified from the NHGRI-EBI GWAS Catalog, after quality control based on imputation quality, minor allele frequency, Hardy-Weinberg equilibrium, linkage disequilibrium, and ambiguity filtering. The associations between this PRS and cancer incidences and mortalities were modeled using Cox proportional hazards regression.
Results: Phenotypic early-M was associated with higher GrimAge acceleration (0.57 years, 95%CI=0.04, 1.10) in the 1,517 PLCO participants. EWAS and pathway analyses identified CpG sites enriched in estrogen response and immune regulation pathways, consistent with immune marker profiling that revealed upregulation of immune-related proteins among women with early-M. In the full trial, genetically predicted younger age at natural menopause (per 1 SD change) was associated with lower risks of breast cancer incidence (HR=0.14, 95%CI=0,12, 0.16) and longer survival (HR=0.27, 95%CI=0.19. 0.40), and lower risk for incidence of ovarian (HR=0.07, 95%CI=0.04, 0.11) and lung (HR=0.30, 95%CI=0.17, 0.50) cancers. In contrast, a higher incidence of bladder cancer (HR=3.34, 95%CI=1.05, 10.61) was observed. No significant associations were found for colon, melanoma, or hematologic malignancies.
Conclusion: Early-M is associated with accelerated biological aging and distinct immune and hormonal regulatory patterns, with the potential to contribute to heterogeneous cancer risk profiles across cancer types.

#6259 Circadian disruption from time zone position and risk of colorectal cancer precursors in women.

Bethsaida Cardona[1], Trang VoPham[2], Kyriaki Papantoniou[3], Eva Schernhammer[4], Jaime E. Hart[5], Mingyang Song[6], Andrew T. Chan[1]

[1]Clinical and Translational Epidemiology Unit, Department of Medicine, Massachusetts General Hospital, Boston, MA,[2]Fred Hutchinson Cancer Center, Seattle, WA,[3]Barcelona Institute for Global Health (ISGlobal), Barcelona, Spain,[4]Department of Epidemiology, Center for Public Health, Medical University of Vienna, Vienna, Austria,[5]Department of Environmental Heath, Harvard TH Chan School of Public Health, Boston, MA,[6]Department of Epidemiology, Harvard TH Chan School of Public Health, Boston, MA

Background/Aims: Research on the link between circadian disruption, particularly from night shiftwork, and colorectal cancer (CRC) has been limited and inconsistent. Few studies have investigated whether other sources of circadian disruption may be associated with CRC or its precursors. One source is solar jetlag that leads to residents in the western vs. eastern part of a time zone to receive less light exposure in the morning and greater light exposure at night, likely suppressing melatonin release and reducing sleep propensity and sleep duration. The objective of this study was to examine the association between solar jetlag and CRC precursors in the United States.
Methods: Our study consisted of Nurses' Health Study (NHS) II participants who received one or more lower endoscopies between 1991-2015. Cases self-reported colorectal polyps in biennial questionnaires and were confirmed by medical record review. As a proxy for solar jetlag, we calculated the distance from the time zone meridian (TZM), based on participant's geocoded residential address histories, which was modeled as a per 5-degree increase in longitude moving east to west within a time zone. Time-varying multivariable-adjusted logistic regression models for clustered data estimated odds ratios (OR) and 95% confidence intervals (CI).
Results: Over a 24-year follow-up period, 72,612 NHSII participants received at least one lower endoscopy; 4,450 conventional adenomas and 4,873 serrated polyps were diagnosed. We found no statistically significant association between distance to TZM and conventional adenomas (OR=1.03; 95% CI=0.99,1.07) or serrated polyps (OR=0.98, 95% CI= 0.95,1.02). Results were similarly null in analyses stratified by age at endoscopy (<50 vs. ≥ 50 years), polyp size, anatomical location, malignant potential, or reason for endoscopy. We observed statistically significant effect modification in which positive associations were observed in the Mountain time zone, among those never engaging in rotating night shift work, areas with higher ultraviolet radiation, and lower latitudes.
Conclusions: Although we did not observe an association between distance to TZM and CRC precursors, we found significant effect modification in the association by various covariates determined a priori. These findings require further research into the mechanisms of action and confirmation in other cohorts.

#6260 Proteomic aging clock (PAC) is cross-sectionally associated with frailty in cancer survivors: The Atherosclerosis Risk in Communities (ARIC) study.

Shuo Wang[1], Anne H. Blaes[1], Josef Coresh[2], Corinne E. Joshu[3], James S. Pankow[1], Bharat Thyagarajan[1], Weihua Guan[1], Sanaz Sedaghat[1], Anna Kucharska-Newton[4], Elizabeth A. Platz[3], Anna Prizment[1]

[1]University of Minnesota, Minneapolis, MN,[2]New York University Grossman School of Medicine, New York, NY,[3]Johns Hopkins Bloomberg Sch. of Public Health, Baltimore, MD,[4]University of North Carolina, Chapel Hill, NC

Background: Accelerated aging induced by cancer and its treatment contributes to a higher prevalence of frailty in cancer survivors than individuals without cancer. Frailty in cancer survivors poses significant challenges for healthcare providers, as it increases the risk of adverse health outcomes and leads to high rates of hospitalization. However, current frailty assessments often require in-person evaluations in clinics, which can be time-consuming and difficult to perform, particularly in older cancer survivors. Therefore, a biomarker that could predict frailty is needed to facilitate risk stratification in this population. Our previous study suggested that PACs could capture accelerated aging in cancer survivors; however, no previous studies have tested PACs' associations with frailty in cancer survivors. This study examined the cross-sectional associations of a previously validated PAC (Wang et al. [2025]) with frailty in cancer survivors in the ARIC study.
Methods: ARIC is an ongoing cohort of White and Black men and women initiated in 1987. At Visit 5 (2011-13), 5,000 plasma proteins were measured using SomaScan in 3,699 participants without a history of cancer (cancer-free) and 806 cancer survivors, all aged 66-90. We previously created a PAC in 67% of randomly selected cancer-free participants and validated it internally in ARIC and externally in another large cohort. We calculated age acceleration after regressing PAC on chronological age (PAC-accel). At Visit 5, ARIC assessed frailty using the cumulative frailty index (FI) and the Fried Frailty Phenotype (FFP). We examined the cross-sectional associations of PAC-accel with frailty in cancer survivors (after cancer diagnosis), using linear regression for FI and logistic regression for FFP (Frail & Pre-frail vs. Robust). All associations were adjusted for chronological age, sex, race, education, BMI, smoking status, diabetes, cardiovascular disease, and eGFR.
Results: In our study, cancer survivors had a mean FI (SD) of 0.21 (0.10), and 57.8% of them were either frail or pre-frail. Considering the most common cancers (lung, colorectal, breast, prostate), both mean FI and the proportion of frail & pre-frail cancer survivors were highest among lung cancer survivors (0.28 (0.10) and 80%). In all cancer survivors, PAC-accel (per 5 years) was cross-sectionally associated with both FI (difference = 0.04, 95% CI 0.03-0.05) and FFP (OR = 2.56, 95% CI 1.77-3.70). Limited sample size precluded examining associations with frailty by cancer type.
Conclusion: Our findings suggest a cross-sectional association of PAC with frailty. Our next step is to examine whether PAC is associated with future frailty risk. This research will help determine whether PAC holds promise as a tool for frailty risk stratification among older cancer survivors in clinical settings.

Background: Chronic inflammation is implicated in ovarian carcinogenesis, but how different inflammation-related exposures individually or jointly affect histotype-specific associations remains unclear. Materials and Methods: We pooled data from 16 case-control studies in the Ovarian Cancer Association Consortium to evaluate associations of eight inflammation-related factors (anti-inflammatory: aspirin use, tubal ligation (TL); pro-inflammatory: endometriosis, obesity, lifetime ovulatory cycles (LOC), smoking, pelvic inflammatory disease (PID), polycystic ovary syndrome (PCOS)) with epithelial ovarian cancer (OvC) by histologic subtype. We examined individual associations and clustering of risk factors across histotypes and computed population attributable risk (PAR) for each factor. We assessed additive and multiplicative interactions for exposure combinations. Results: Associations with OvC risk differed by histotype (e.g., high-grade serous: aspirin: OR=0.90; 95%CI 0.82, 0.99; TL: OR=0.80; 95%CI 0.73, 0.88; overall serous: endometriosis: OR=1.17; 95%CI 1.03, 1.31; high LOC: OR=1.42; 95%CI 1.28, 1.58; obesity (low-grade serous): OR=1.50; 95%CI 1.14, 1.98). Clustering analyses showed highly correlated risk profiles in endometrioid and clear cell (r=0.91). High-grade serous and mucinous profiles were moderately correlated with endometrioid and clear cell (r=0.60) tumors. The profile for low-grade serous (r=0.36) tumors was distinct from other histotypes. PAR estimates suggested modifying aspirin use, TL, and LOCs could substantially reduce burdens of endometrioid, clear cell and mucinous tumors. Out of 28 exposure combinations tested in overall OvC and 189 by histotype, we observed 12 interactions. Not using aspirin regularly showed positive additive interactions with obesity and high LOCs, particularly in endometrioid tumors (obesity relative excess risk due to interaction (RERI)=0.74, 95%CI 0.31, 1.18; P_{int}=0.001 for; LOCs RERI=0.80, 95%CI 0.03, 1.56; P_{int}=0.04). Not using aspirin regularly also showed a positive additive interaction with endometriosis in clear cell tumors (RERI=1.77, 95%CI 0.03, 3.52; P_{int}=0.05). Lack of TL showed positive interactions with obesity in endometrioid (RERI=0.86, 95%CI 0.17, 1.53; P_{int}=0.01) and mucinous (RERI=1.10, 95%CI 0.23, 1.97; P_{int}=0.01) tumors, while negative additive interactions were observed for smoking and endometriosis in endometrioid tumors (RERI=-1.12, 95%CI -2.19, -0.05; P_{int}=0.04). A multiplicative interaction was observed between obesity and endometriosis in mucinous tumors (P_{int}=0.01). Conclusion: The findings suggest ovarian tumorigenesis is strongly shaped by pro- and anti-inflammatory pathways that act largely independently. Further examining these pathways may clarify the origins of histotype heterogeneity and guide prevention strategies.

#6262 Intraprostatic inflammation and FoxP3, a marker of Regulatory T cells, increase with age in benign prostate biopsies irrespective of clinical indication: placebo arm of the Prostate Cancer Prevention Trial (PCPT).

[1]Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD,[2]National Cancer Inst. - Bethesda Campus, Rockville, MD,[3]Department of Pathology, Koc University School of Medicine, Istanbul, Turkey,[4]Department of Pathology, Ankara City Hospital, University of Health Sciences, Ankara, Turkey,[5]Fundacion Santa Fe de Bogota University Hospital, Bogota, Colombia,[6]Department of Basic Sciences, Universidad de Cartagena School of Medicine, Cartagena, Colombia,[7]SWOG Statistics and Data Management Center, Fred Hutchinson Cancer Center, Seattle, WA,[8]Department of Pathology, University of Colorado Denver, Aurora, CO,[9]Department of Urology, CHRISTUS Santa Rosa Medical Center Hospital, San Antonio, TX,[10]Columbia University Irving Medical Center, New York, NY,[11]The James Buchanan Brady Urological Institute, Johns Hopkins University School of Medicine, Baltimore, MD,[12]Sidney Kimmel Comprehensive Cancer Center, Baltimore, MD,[13]Department of Medicine, Boston University Chobanian & Avedisian School of Medicine and Boston Medical Center, Boston, MA,[14]Department of Pathology, Oncology, and Urology, The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins and the James Buchanan Brady Urological Research Institute, Baltimore, MD

Background: Intraprostatic inflammation is suspected to contribute to prostate cancer pathogenesis. Prostate cancer has the steepest age-related rise in incidence in solid cancers, and inflammation is thought to increase with age. But prostate tissue is typically obtained only from men with clinical indications, e.g., elevated plasma prostate-specific antigen (PSA). Associations between age and inflammation could be biased, given that PSA concentration increases with age, prompting biopsy. Thus, we used benign prostate tissue collected irrespective of indication to assess the association between age and intraprostatic inflammation and abundance of immune cells.

Methods: We performed a cross-sectional analysis in a subset of men of the PCPT placebo arm. Using slides containing biopsy cores (mean 4) from protocol-prompted end-of-study prostate biopsies at Year 7, we visually assessed the presence and extent of inflammation and quantified immunohistochemistry staining for CD4 (CD4+ T cells), CD8 (CD8+ T cells), CD68 (macrophages), FoxP3 (T regulatory cells), and c-KIT (mast cells) using a score (0: none - 4: extensive). Scores were weighted by total number of cores per man. Associations between age (continuous or quartiles) and inflammation measures (any core inflamed vs none; all or some cores inflamed vs none; mean percent tissue inflamed ≥3% or <3% vs 0%) were estimated using logistic regression. Associations between age and immune cell marker scores (continuous) were estimated using linear regression. Estimates were adjusted for race, BMI, smoking, physical activity, education, diabetes, statin use, and aspirin use.

Results: Participants (N=357) were 62 to 85 years of age at biopsy (median 70, IQR 65-74). Older age was associated with presence of inflammation [Q4 of age vs Q1: OR, 2.3; 95% CI, 1.1-4.9, p-trend across age, 0.003]. Positive associations were also observed with having some [Q4 OR, 2.1; 95% CI, 1.0-4.3] or all cores inflamed [Q4 OR, 7.8; 95% CI, 2.0-30.6]. Age was also associated with having ≥3% mean tissue with inflammation [Q4 OR, 2.6; 95% CI, 1.2-6.0, p-trend, 0.006]. Age was positively associated with FoxP3 score [p-value, 0.01], but not with any other immune cell markers. Associations were slightly attenuated when excluding men with PSA >4 ng/mL, diagnosed with prostate cancer, or who received for-cause biopsy.

Conclusion: Age is associated with increasing presence and extent of intraprostatic inflammation in biopsies taken irrespective of indication. Consistent with findings in circulation, prevalence of T regulatory cells in prostate biopsies increased with age. Findings may inform the etiologic pathway, mediated by inflammation, between increasing age and prostate cancer. Funding: P50 DK082998, U01 CA182883, UG1CA189974, T32 CA09314, R01 CA255349, DOD.

#6263 Association of tumor infiltrating lymphocytes and proinflammatory biomarkers with breast cancer molecular subtypes: Analysis of the MEND study..

Jovita Byemerwa[1], Drew Neish[1], April Deveaux[1], Lukeman Forgah[2], Omolola Salako[3], Adetola Daramola[3], Olusegun Alatise[4], Gabriel Olabiyi Ogun[5], Tomi Akinyemiju[1]

[1]Population Health Sciences, Duke University School of Medicine, Durham, NC,[2]Chicago Medical School, Chicago, IL,[3]Lagos University Teaching Hospital, University of Lagos College of Medicine, Lagos, Nigeria,[4]Obafemi Awolowo University Teaching Hospital, Ile-Ife, Osun State, Nigeria,[5]University College Hospital, University of Ibadan, Ibadan, Nigeria

Background: The tumor microenvironment is characterized by tumor-infiltrating lymphocytes (TILs) and proinflammatory biomarkers/cytokines, factors that inform therapeutic options and predict treatment response and tumor progression. Breast tumors in Nigerian women are relatively more aggressive; however no prior study has characterized the landscape of TILs and proinflammatory biomarkers across molecular subtypes in this population.

Materials and Methods: A total of 436 newly diagnosed, treatment-naïve BC patients from Nigeria were included in the study. BC molecular subtyping was determined by immunohistochemistry (IHC), and TILs were quantified on H&E-stained tumor slides using the International TILs Working Group criteria. Serum levels of proinflammatory biomarkers (IL-6, IL-8, IL-1B, TNF-α, and leptin) were assessed using immunoassays by Meso Scale Discovery. Descriptive statistics were used to evaluate the distribution of study covariates, and Spearman correlation was used to test the association of each proinflammatory biomarker and TILs. Multivariable logistic and multinomial regression models were used to estimate adjusted odds ratios (aOR) and 95% confidence intervals (95% CI) for the association of TILs and proinflammatory biomarkers with molecular subtype.

Results: The median age of study participants was 49, and 52.8% and 28.9% were diagnosed with grade 2 or 3 tumors respectively. The majority of BC tumors were of triple-negative subtype (43%), compared with 31% luminal A, 12% luminal B and 15% HER2-enriched subtype. Overall, BC patients had a median (Q1, Q3) TIL (%) of 10.0 (4.0, 21.0), with 49% categorized as low TIL (<10%), 41% categorized as intermediate TILs (10% ≤ TIL < 40%) and 10% categorized as high TIL (≥ 40%). Among a subset of 109 patients with proinflammatory biomarkers' data, TNF-α significantly correlated with TILs (ρ: 0.21; p = 0.026). Patients in high TIL category (vs low TIL category) were approximately 5-fold (OR: 5.03, 95% CI: 1.01, 24.94) more likely to be diagnosed with TNBC, while each standard deviation increase in TNF-α levels was significantly associated with 3.5-fold higher odds of TNBC (OR: 3.42, 95% CI: 1.32, 8.86) after adjusting for age, BMI, menopausal status, and all proinflammatory biomarkers. Other proinflammatory biomarkers showed no significant associations.

Conclusion: Our study, first to our knowledge to characterize the TME by molecular subtype in Nigerian women, reveal strong associations of high TIL levels and TNF-alpha with TNBC subtype, highlighting opportunities for immunotherapy and the prognostic significance of TNF-α in this population.

#6264 Familial gastric conditions indicating helicobacter pylori infection and risk of childhood leukemia.

Julia E. Heck[1], Yu Chen[2], Johnni Hansen[3]

[1]University of North Texas, Denton, TX,[2]NYU Langone Medical Center, New York, NY,[3]Danish Cancer Institute, Copenhagen, Denmark

Background: *Helicobacter pylori* (*H. pylori*) is a cause of gastric cancer and B-cell MALT lymphoma. Cancer may arise from bone-marrow derived hematopoietic stem cells. *H. pylori* antigens are linked to B-cell proliferation, secondary to T cell response and the release of cytokines. However, *H. pylori* may inhibit T-cell proliferation. *H. pylori* is genotoxic and promotes chronic inflammation and oxidative stress. Infection is typically acquired in childhood, resulting from close personal contact with infected family members. Infections are suspected to play a role in the etiology of childhood leukemia. However, an earlier study found mixed results for any association between maternal *H. pylori* IgG and IgM antibodies. The purpose of this study was to investigate parental and childhood *H. pylori*-related diagnoses of peptic ulcer and gastritis in relation to risk for childhood leukemia. *H. pylori* colonizes the stomach lining and is a major cause of gastritis and peptic ulcer disease. As the study was based on registry data, we used these diagnoses as proxy for *H. pylori* infection.

Methods: The study was based upon Danish national registers (births 1968-2013). We extracted *H. pylori*-related diagnoses of peptic ulcer and gastritis (ICD8 codes: 531-534; ICD-10 codes: K25-K28) and gastritis (ICD-8 code: 535; ICD-10 code: K29) from the National Patient Register for the parents and children. We linked these to childhood leukemia diagnoses from the Cancer Registry. Controls were 20:1 matched and selected at random from the Central Person Register. Conditional logistic regression was used to estimate associations between *H. pylori*-related diagnoses and childhood acute lymphoblastic leukemia (ALL), with adjustment for covariates.

Results: We observed 3.1% of mothers and 4.2% of fathers had ever been diagnosed with gastric conditions. Maternal lifetime diagnosis with gastric conditions was not notably related to offspring ALL (OR=1.21, 95% CI 0.89-1.65). When we examined maternal gastric conditions diagnosed prior to the child's cancer diagnosis, risks increased (OR=1.74, 95% CI 1.11-2.73). There was no association with paternal lifetime history of gastric conditions (OR=1.10, 95% CI 0.83-1.45). Children's lifetime diagnosis of gastric conditions was associated with ALL (OR=1.87, 95% CI 1.08-3.23).

Conclusions: Maternal and childhood *H pylori*-related diagnoses of peptic ulcer and gastritis are related to increased risk of childhood leukemia, perhaps related to aberrant immune responses. The child's increased risk may reflect heightened medical surveillance in cancer survivors and should be taken with caution. The findings warrant replication using serologic data.

#6265 Association of Area Deprivation Index with immune functioning and history of abnormal cervical screening among Appalachian young women.

Chloe M. Hery[1], Yesung Kweon[1], Mohamed I. Elsaid[1], Cecilia DeGraffinreid[1], Mack T. Ruffin[2], Electra D. Paskett[1]

[1]The Ohio State University, Columbus, OH,[2]Pennsylvania State University, Hershey, PA

Introduction: High chronic stress can influence immune response; therefore, we aimed to examine how residing in areas of high deprivation (marker for high stressor) is associated with Epstein-Barr Virus (EBV) reactivation, a proxy measure of immune function, and abnormal Papillomavirus (Pap) smear tests among young women in Appalachia.
Methods: Baseline data were available for 145 women aged 18-26 who were enrolled in the Community Awareness, Resources, and Education (CARE II) initiative, Project 3, which focused on reducing cervical cancer in the Ohio Appalachian. Area Deprivation Index (ADI) was geocoded from U.S. Census Block Group data to identify high- and low-deprivation areas based on the highest deprivation quartile. EBV was grouped into low/negative or medium/high levels, with the latter suggesting poor immune functioning. Participants were also asked if they ever had an abnormal Pap test (yes/no). Generalized Estimating Equations models with robust variance were fitted using a modified Poisson regression for binary outcomes: EBV reactivation and abnormal Pap test. All models were adjusted for age group, race, education, smoking status, marital status, and insurance.
Results: Average age of participants was 22.8 years, most had some college education (53.3%), and were never married (65.4%). The proportion of women with medium/high EBV reactivation was significantly higher among those residing in areas of high deprivation (89.5% vs. 69.1%, P=0.01). Similarly, living in high deprivation areas was associated with an over 2-fold increase in reporting a history of abnormal Pap tests (46.7% vs. 22.7%, P=0.01). Those living in high-deprivation areas had a 31% increased risk of medium/high EBV reactivation compared with those in low-deprivation areas (RR: 1.31, 95% CI: 1.11-1.54). This association remained significant after multivariable adjustment (aRR: 1.29, 95% CI: 1.06-1.56). Additionally, those living in high deprivation areas had 2.08 times the risk of reporting a past abnormal Pap test compared to those living in low deprivation areas (RR: 2.08, 95% CI: 1.22-3.53), and this remained significant after adjustment (aRR: 2.11, 95% CI: 1.12-3.99).
Conclusions: Our study found that residing in areas of high deprivation was associated with an increased risk of EBV reactivation, a proxy measure of poor immune functioning, and history of abnormal Pap tests. Stress caused by where one lives may have a significant impact on immune response and should be further examined to better implement cervical cancer control efforts.

#6266 Functional Class I, Class II, and nonclassical HLA variation drives lymphoma and myeloma risk in the all of us research program.

Lara Sucheston-Campbell[1], Saanika Tambe[1], Lian Zuo[1], Alyssa Clay-Gilmour[2], Vijai Joseph[3], Benjamin Tycko[4], Wendy Cozen[5]

[1]Wayne State University, Barbara Ann Karmanos Cancer Institute, Detroit, MI,[2]Epidemiology and Biostatistics, University of South Carolina, Columbia, SC,[3]Memorial Sloan Kettering Cancer Centre, New York City, NY,[4]Hackensack Meridian School of Medicine, Nutley, NJ,[5]UCI School of Medicine, Irvine, CA

Background: HLA-mediated immune surveillance involves classical, non-classical, and class I-like pathways. Because lymphoma and myeloma rely on different immune mechanisms, we evaluated HLA class I/II, non-classical, and class I-like loci across ancestries using allele-level amino acids(AA), heterozygosity (HET), evolutionary divergence (HED), IEDB-derived peptide-binding breadth (PBW; 9-mer binding entropy), and positional amino-acid heterozygosity (residue mismatch).
Methods: Hodgkin lymphoma (HL), NHL and subtypes, and multiple myeloma (MM) in All of Us Cohort were identified using ICD/SNOMED; controls lacked hematologic malignancy. HIBAG-imputed allele with n>20 cases were analyzed in EUR, AFR, and AMR. Models adjusted for age, sex, PCs, and admixture proportions tested ORs, 95% CIs, and FDR<0.1. We used joint PRS-HLA models to test whether HLA metrics contributed risk information beyond the lymphoma PRS.
Results: We replicated EUR HET and/or HED class I/II associations with NHL (N=1668), DLBCL (N=490), HL (N=393), and FL (N=435), and extended these patterns using PBW and AA-level metrics. In NHL, we confirmed that HET-C reduced risk (p=0.027) and found greater PBW was protective (OR=0.49; p=0.09). Similarly, in CLL, we replicated the HET-A association (p=0.027), identified PBW-A effect (OR=0.25; p=.03), and a positional signal at A-163 (OR=.83, p=0.015) that also appeared in NHL(p=.015). Neither locus showed HED effects.Novel MM associations with HET-B and -C (OR≈0.74; p<0.03), were supported by a positional hit at B-42 (OR=0.77; P=0.033) and a PBW-C effect (OR≈0.24; p=0.01), while HED remained null. In contrast, DLBCL showed protection across all class I metrics as well as at MICB (OR=0.75; p=0.006) and MHC-like HET (OR=0.73; p=0.084). In EUR DLBCL, A*01:01 (OR=1.23; p=0.076) and A26:01 (OR=1.56; p=0.051) showed risk effects consistent with some prior reports reinforced by multiple A-locus positional signals (P<0.02).Novel AFR-specific findings included A*68:02 in: HL (OR=2.88; $p=1.8\times10^{-5}$), mirrored by a positional hit at A-30 (OR≈3.0, p=.0004), NHL at B*07:02 (OR=1.69; p=0.018) and for C1-motif alleles C07:01 (OR=1.51, p=.04) and C*07:02 (OR= 2.02, p=.00017) consistent with a KIR-C1 mechanism.The DLBCL PRS replicated (which includes an HLA-B variant) in EUR (OR=1.25, 95% CI 1.15-1.36; $p=7.3\times10^{-7}$) and joint models showed HED (p=0.0028) and HET (OR=0.86, 95% CI 0.80-0.93, $p=7.0\times10^{-5}$) remained significant when combined with PRS. AIC identified HET + PRS with covariates as the best model. The PRS did not replicate in AFR or AMR.
Conclusion: We replicated classical HLA associations and identified novel non-classical and functional HLA features that shape B-cell malignancy risk across ancestries. Furthermore, adding orthogonal HLA metrics provided substantial, independent information beyond the PRS.

#6267 Advancing cancer prevention through policy: State-level variation in HPV vaccine mandate in the United States.

Grace Kwakyewaa Kyei[1], Esther Nana Kwaning[1], Evans F. Kyei[2]

[1]Umass Boston, Boston, MA,[2]Capstone College of Nursing, The University of Alabama, Tuscaloosa, AL

Purpose: Human papillomavirus (HPV) vaccination remains a cornerstone of cancer prevention, yet adolescent coverage in the United States is inconsistent. According to the National Conference of State Legislatures (NCSL), five jurisdictions - Hawaii, Puerto Rico, Rhode Island, Virginia, and the District of Columbia - require the HPV vaccine for school attendance, although mandate scope and enforcement vary. This study examined policy determinants influencing mandate adoption to inform equitable cancer prevention strategies.
Methods: Guided by Kingdon's Multiple Streams Framework and Policy Diffusion Theory, a comparative qualitative policy analysis was conducted across eight purposively selected states representing variation in HPV vaccine mandate status and coverage. Data sources included state statutes, legislative records, health department documents, and CDC immunization data. A theory-driven coding and state-by-variable matrix identified patterns in mandate design, exemption structures, diffusion mechanisms, and implementation barriers.
Results: Jurisdictions with HPV vaccine mandates achieved higher adolescent vaccination coverage compared with non-mandate states. Effectiveness was influenced by the scope of mandates, enforcement mechanisms, and availability of medical and nonmedical exemptions. Non-mandate states with high vaccination rates demonstrated comparable outcomes through robust public health infrastructure, provider engagement, and school-based education initiatives. Policy diffusion of mandates remains limited due to ideological resistance, politicization of adolescent vaccines, and the absence of coordinated federal or interstate incentives.
Conclusions: HPV vaccine mandates can increase coverage when designed with clear enforcement provisions, limited exemptions, and strong public communication. Comparable progress may also be achieved through mandate-equivalent policies that strengthen provider engagement and community outreach. Findings highlight actionable strategies for policymakers, nursing leaders, and cancer prevention advocates to accelerate HPV vaccination and reduce HPV-related cancer disparities across U.S. states.

#6272 Enhancing variant interpretation through multi-database and systematic variant classification: Reducing uncertainty in clinical genomics.

Bharat Sinha Bhosale[1], Sandhya Iyer[2], Mina Darooei[2], Madhura Basavalingegowda[2], Anay walunjkar[2], Mohan Uttarwar[2], Kanchan Hariramani[2], Aarthi Ramesh[2], **Gowhar Shafi**[3]

[1]BB Precision Oncology, Mumbai, India,[2]OneCell Diagnostics India Private Limited, Pune, India,[3]1Cell.Ai, Pune, India

BackgroundInterpretation of Variants of unknown significance (VUS) is one of the major challenge in the era of comprehensive genomic profiling (CGP) in precision oncology. With several broad genomic panels hitting the oncology market, most struggle with VUS and its clinical utility. Thus, it is critical to understand and interpret VUS in patient context for utmost utility. Utilizing large language models and automated systems for VUS reclassification is on the rise. This will certainly impact several aspects including patient management, treatment surveillance, prophylactic opportunities, and preventing disease inheritance. Here, we describe the utility of our machine model system for effective interpretation and reclassification of VUS in patient context to reduce uncertainty and achieve high clinical utility.
MethodsCGP was performed on patients using next-generation sequencing (NGS) with the OncoIndx® panel. Variant reclassification was performed through our in-house automated precision classification and interpretation system.
ResultsUsing our computational molecular oncology workflow, a precision classification and interpretation system has been developed for the confirmation of variants of uncertain significance (VUS). The system when tested on several VUS intronic based on *in silico* evidence (PP5, PM2, BP4) and low evolutionary conservation scores (-0.423), ended up being reclassified as likely pathogenic. The system also investigates for the presence of conditions like Lynch-syndrome and its associated genomic findings including high microsatellite instability, loss of MSH2 protein on IHC. Functional consequences of the computational predictions such as weakening of the native acceptor site, and functional RNA studies are also utilized to confirm functionality. Finally, the patient and family history act as critical parameters. Using these combined evidence, the precision classification system generates a final verdict of reclassification.
ConclusionWhen complementary lines of evidence pertaining to functional loss of a variant (PS3), its identification in affected individuals (PS4_supporting), segregation-consistent family history (PP1), rarity in population databases (PM2), and supportive *in silico* predictions (PP3/BP4)—are integrated, a coherent and biologically consistent explanation can be generated for disease causation. Our automated machine system in-built with robust and essential criteria for variant classification, thus can be optimally utilized to reclassifiy VUS and improve clinical outcomes.

#6273 Clinicopathological and genetic features of Algerian patients with suspected Li-Fraumeni Syndrome: Implications in genetic screening and testing.

Farid Cherbal[1], Chiraz Mehemmai[1], Djamel-Eddine Seddik[1], Mouchira Saidi[1], Mohammed Oukkal[2], Fatiha Gachi[3]

[1]Molecular Genetics Research Team, LBCM-Tamayouz, Faculty of Biological Sciences, University of Science and Technology Houari Boumediene (USTHB), Algiers, Algeria,[2]Clinic of Medical Oncology Amine Zirout, Issad Hassani University Hospital, Beni-Messous, University of Health Sciences, Algiers, Algeria,[3]Children's Cancer Center, Lamine Debaghine University Hospital, Bab-El-Oued, School of Medicine, University of Health Sciences, Algiers, Algeria

Background: Li-Fraumeni Syndrome (LFS) is a rare hereditary cancer predisposition syndrome. LFS is an autosomal dominant disease caused by heterozygous germline pathogenic variant in *TP53* gene and frequently predisposes to a broad spectrum of cancers including early-onset cancers. Because of the rarity of LFS, data on clinical and genetic features in Algerian patients are limited. Our study aimed to report clinicopathological and genetic features in 25 families with suspected LFS.

Patients and Methods The present study investigated 25 patients and 22 relatives from 25 families with suspected LFS. Patients and relatives were referred through Children's Cancer Center and medical oncology services in two University hospitals. Clinical and pathological information was extracted from medical records of the patients with particular attention to age of diagnosis and updated Chompret clinical criteria such presence of adult rare tumors, childhood rare tumors and early-onset breast cancer. Family history of LFS was obtained from interviews of adult patients and relatives, pedigree and chart review of patients. TP53 exons 2-11 were screened in 25 patients and 22 high risk relatives using PCR-Sanger sequencing, respectively.

Results We identified various primary cancers in our study. The following"Core"cancers were observed in 25 patients, early- onset breast cancer, adult sarcomas and rare childhood tumors including: rhabdomyosarcoma, osteosarcoma and adrenocortical carcinoma, respectively. In addition, we observed early-onset colorectal cancer in relatives from 9 LFS families. Rhabdomysarcoma was most frequently observed (N=12) in children. The median age at diagnosis for early-onset breast cancer, adult sarcomas and childhood cancers was 30.5 years, 38 years and 6.8 years, respectively. The genetic analysis identified 11 individuals (23.4%) with TP53 germline variants. The TP53 common germline variant c.215C>G/p.Arg72Pro has been identified in eight patients. Interestingly, the rare germline TP53 c.314G>T/p.Gly105Val has been identified in 4-year old girl (the index case) who developed rhabdomyosarcoma at age 3 years and secondary cancer in the right lung at age 4 years after radiotherapy. Her mother is also a carrier of this rare variant, she developed an early-onset breast cancer at age 30 years. To date, the TP53 c.314G>T has been initially classified as a Variant of Uncertain Significance in the ClinVar database. Interestingly, our present study reclassifies the variant as"likely Pathogenic" (Class 4) based on ACMG criteria, which directly impacts patient care, risk assessment, and management.

Conclusions Our study highlights the importance of understanding clinical features of LFS and germline genetic variants of TP53 gene in underrepresented populations, such as Algeria, where clinical and genomic features of LFS are largely unknown.

#6275 Multidimensional analyses of pedigree, epidemiologic, and molecular data provide etiologic clues for myalgic encephalomyelitis/chronic fatigue syndrome.

Roxana Moslehi[1], Anil Kumar[1], Amiran Dzutsev[2]

[1]University at Albany, Albany, NY,[2]National Cancer Institute, Bethesda, MD

Background: Myalgic encephalomyelitis (ME)/chronic fatigue syndrome (CFS) is a complex disabling disorder with no known etiology or approved treatment. Estimates of the prevalence suggest that up to 3.4 million Americans may be afflicted and emerging evidence indicates that the COVID-19 pandemic may lead to a significant increase in ME/CFS cases globally. We conducted a molecular epidemiologic study to identify risk factors and biologic mechanisms for ME/CFS.

Methods: Our clinic-based case-control study involved 60 carefully selected ME/CFS patients and 61 appropriately matched healthy controls. We compared cases and controls with respect to the following: 1. prevalence of autoimmune disease (AID) and cancer among their first-degree relatives, 2. prevalence of epidemiologic factors, 3. serum levels of 48 cytokines, and 4. whole-blood RNA-seq gene expression data. We used conventional and machine learning approaches to calculate associative and predictive metrics, and to identify cytokine and gene expression profiles of ME/CFS.

Results: First-degree relatives of ME/CFS cases were more likely than those of the controls to have AID [Relative Risk (RR)=3.52, p=0.0014) and early-onset (diagnosed <60 years of age) cancer (RR=2.24, p=0.034) including blood cancers (p=0.047). Comparison of epidemiologic factors identified several risk factors such as history of allergies requiring medication [Odds Ratio (OR)=6.00, p<0.0001), exposure to contaminants (OR=4.35, p=0.0002), history of illness requiring hospitalization (OR=4.33, p=0.0004), ≥4 episodes of significant illness requiring hospitalization (OR=24.36, p<0.0001), and ≥2 episodes of significant stress (OR=3.07, p=0.03). The most common self-identified perceived *causes* of ME/CFS reported by cases in response to an open-ended question were Infectious Illness (27.3%), Infectious Agents (15.9%), and Stress (15.9%).

We identified a cytokine signature of ME/CFS, which classified patients with AUC>0.75, sensitivity>80%, and specificity>70% at an optimized threshold in all three tested machine learning models: XGBoost, k-nearest neighbors, and Support Vector Machines. Key cytokine predictors included IL-27, IP-10, RANTES, and Fractalkine among others. Whole blood RNA-seq analysis identified 115 differentially expressed genes with FDR<0.25 belonging to biologic pathways relevant to infectious diseases and neurologic disorders.

Conclusions: Our multidimensional analysis identified previously unreported risk factors for ME/CFS, links with AID and early-onset cancer, a dysregulated immune profile, and potential biologic mechanisms—such as neuronal injury—thus providing etiologic clues and druggable targets for treatment.

#6276 Predictors of engagement on a closed social support network for individuals with Hereditary Breast and Ovarian Cancer syndrome and Lynch syndrome.

Patrick Boyd, Yi Xiao, Sandra Davey, Jenna R. Hoopes, Cassiel Suarez, Justin Martinez, Alex Capasso, Kathryn Reyes, Ilana Solomon, Stacy W. Gray

City of Hope National Medical Center, Duarte, CA

Background: Genomic testing is increasingly used in cancer care, but patients often receive results without formal psychosocial support. Many social support platforms for patients exist, but few are embedded within genomic results portals while also focusing on providing support for populations with hereditary cancer risk. To address this, we developed a closed Social Support Network (SSN) at City of Hope integrated in a program (HOPE-Genomics) that delivers patient-friendly genomic results. This SSN was piloted with patients with pathogenic/likely pathogenic (P/LPs) variants associated with Hereditary Breast and Ovarian Cancer syndrome (HBOC) and Lynch syndrome. We examined engagement patterns and predictors of SSN use to inform future implementation of the SSN in broader populations for patients with hereditary risk for cancer.
Methods: 120 patients from City of Hope were invited to use the SSN for 4-6 months. Participants completed baseline and follow-up surveys that included psychosocial indicators (e.g., social isolation and cancer fatalism) and the Feelings About genomiC Testing Results (FACToR) scale. A subset of users participated in qualitative interviews following their participation in the pilot (n=9). SSN activity (logins, posts, likes, page views) was tracked. Patients who logged in at least once were classified as users. Chi-square/Fisher's exact tests and multivariable logistic regression were used to compare users vs. non-users across demographic and psychosocial variables.
Results: 68.3% (n=82) completed the baseline survey, 50.8% (n=61) logged in at least once, and 45.0% (n=54) completed the follow-up survey. Across all participants, there were 1081 page views, 51 posts, and 82 likes. The first discussion thread topic, "Living with a Genomic Change," had the most activity, indicating the importance of discussion thread topic placement over content. Page views peaked approximately halfway through the pilot (i.e., 3 months). Ethnicity was a significant predictor of SSN use whereby having a Hispanic/Latino identity was associated with a lower likelihood of being a user relative to not having a Hispanic/Latino identity (OR=0.40; 95% CI=0.16-0.99; p=.047). In interviews, all participants recommended the use of the platform to others with similar P/LPs, however, most participants described useability issues such as difficulty sub-commenting and navigation obstacles on smartphones (vs. desktops or laptops)
Conclusion: A closed SSN integrated in a genomic results portal achieved moderate uptake and engagement. Thread visibility drove activity. The ethnicity gap in user status indicates a need to understand decreased uptake among Hispanic/Latino participants in future research. Qualitative interviews highlighted needs for smartphone optimization, sub-commenting, and private messaging capabilities.

#6277 Determinants of Cancer Risk in Hereditary Cancer-Prone Individuals: The eGene Study.

Zhengwei Zhang[1], Lou Romanens-Renard[2], Li Zhang[3], Pamela N. Munster[2]

[1]Department of Epidemiology and Biostatistics, University of California San Francisco, San Francisco, CA,[2]Helen Diller Family Comprehensive Cancer Center, University of California San Francisco, San Francisco, CA,[3]Department of Medicine, University of California San Francisco, San Francisco, CA

Background: Individuals with genetic cancer predisposition have higher risks of cancer. However, the role of lifestyle, environmental factors, and health history in modifying cancer risk in these individuals is not well defined. The eGene study was designed to address this gap by utilizing large-scale self-reported data.**Methods**: The 216-item eGene questionnaire was used to assess environmental, behavioral, and medical history factors that may influence cancer risk among individuals with or without hereditary cancer gene variants. Participants were recruited through Eureka and MyChart. To assess the association between each factor and cancer risk, Odds Ratios (OR) with 95% Confidence Intervals (CI) obtained by univariable logistic regression models were reported.**Results**: Among all 1603 participants, the median age was 52, 68% were females, 82% were white, 27% had a personal history of cancer, and 60.5% had a family history of cancer. Among 615 individuals who had genetic testing, 354 tested positive for a pathogenic variant (PV) and 185 tested negative. For PV carriers, 60% never had cancer, 19% had breast cancer history, 5.4% had non-melanoma skin cancer history, and 3.8% had prostate cancer history. For no PV carriers, 62% never had cancer, 14% had breast cancer history and 3.4% had prostate cancer. PV incidence rate was higher in black (58.6%) and mixed populations (58.8%) compared with Asian (42.9%) and American Indian (33.3%). The most common PVs in both cancer cases and controls were in *BRCA1*, *BRCA2* and *ATM* genes. Table 1 summarizes the list of variables statistically significantly associated with cancer incidence within PV carriers and no PV carriers. **Conclusion**: These findings suggest increased environmental susceptibility in PV carriers. Ongoing analyses will further examine associations between medical, lifestyle, and environmental factors and cancer incidence in the general population in a multivariable fashion and explore possible gene-environmental interactions.

Table 1: list of variables statistically significantly associated with cancer incidence

Variable	Level	PV OR (95% CI)	No PV OR (95% CI)
Medication			
Hormone therapy	Yes	16.2 (6.01, 43.7)	28.6 (9.54, 85.80)
Thyroid	Yes	2.61 (1.36, 5.00)	2.44 (1.22, 4.86)
Steroids	Yes	3.21 (1.65, 6.24)	1.82 (0.94, 3.49)
Vitamin D	Yes	2.93 (1.61, 5.37)	2.04 (1.08, 3.86)
Calcium	Yes	2.33 (1.44, 3.79)	2.18 (1.30, 3.65)
Lifestyle			
Strengthening exercise (ref: 0 hour)	0-1 hours	0.56 (0.24, 1.17)	1.19 (0.56, 2.58)
	1-2hours	0.31 (0.11, 0.79)	1.41 (0.57, 3.43)
	2-4 hours	3.23 (0.59, 16.11)	2.28 (0.79, 6.54)
	>4 hours	0.45 (0.12, 1.48)	1.47 (0.41, 5.23)
Lived with a smoker for at least a year	Yes	1.97 (1.18, 3.27)	1.37 (0.83, 2.26)
Age of starting drinking alcohol once a week (ref: < 25)	25-29	2.25 (0.96, 5.34)	1.44 (0.66, 3.08)
	30-39	1.04 (0.31, 3.08)	2.43 (0.94, 6.36)
	40-49	1.66 (0.40, 6.53)	5.15 (1.34, 25.0)
	50-59	12.5 (2.06, 239)	5.51 (1.13, 39.9)
	≥ 60	2.08 (0.08, 53.2)	2.94 (0.62, 15.6)
Still drinking more than once a week	Yes	0.55 (0.31, 0.97)	2.22 (1.12, 4.39)
Medical			
Hepatitis B	Yes	3.09 (1.46, 6.86)	5.81 (2.70, 13.2)
Measles	Yes	3.72 (1.42, 10.9)	3.83 (1.79, 8.51)
Meningococcal	Yes	2.58 (1.33, 5.06)	3.36 (1.67, 6.92)
Mumps	Yes	3.30(1.35, 8.62)	4.10 (2.03, 8.58)
Rubella	Yes	2.48 (0.96, 6.67)	3.62 (1.52, 8.93)
Smallpox	Yes	0.49 (0.24, 0.95)	0.38 (0.14, 0.94)
Colonoscopy (ref: No)	Yes, once	2.55 (1.38, 4.74)	3.07 (1.66, 5.79)
	Yes, > 1	4.67 (2.63, 8.44)	3.55 (1.89, 6.82)
PSA (ref: No)	Yes, once	1.00 (0.04, 10.8)	3.00 (0.53, 17.8)
	Yes, >1	7.20 (1.93, 35.4)	5.19 (1.49, 21.7)
Environmental			
Chemicals, Acids, Solvents	Yes	2.49 (1.22, 5.24)	0.89 (0.42, 1.83)
Diesel Engine Exhaust	Yes	7.70 (1.22, 149)	0.68 (0.14, 2.49)
Gasoline Exhaust	Yes	3.45 (1.32, 10.1)	0.55 (0.17, 1.49)
Pesticides Herbicides	Yes	4.71 (1.37, 21.6)	2.78 (0.67, 13.8)
Wood Dust	Yes	4.71 (1.37, 21.6)	1.63 (0.50, 5.34)

#6278 Unraveling the missing heritability of unexplained familial cancers with germline genome sequencing.

Noah Fields[1], Ryan Collins[1], Seunghun Seunghun Han[1], Erin Shannon[1], Ryan Buehler[1], Deborah Wood Neklason[2], Jihye Park[1], Junne Kamihara[1], Judy Garber[1], Riaz Gillani[1], Saud H. AlDubayan[1], Eliezer Van Allen[1]

[1]Dana-Farber Cancer Institute, Boston, MA,[2]University of Utah Huntsman Cancer Institute, Salt Lake City, UT

While established predisposition genes account for syndromes like Cowden and Lynch syndrome, cancers frequently cluster in families without any identifiable pathogenic variant (PGV). We hypothesized that other germline factors beyond established PGVs might partially explain the large fraction of familial cancer cases with no known PGV. In this study, we systematically assessed potential genetic risk factors in 2,721 germline whole genomes from individuals with no recognized PGV, comparing 1,389 familial cancer cases across 18 cancer types to 1,332 controls with no family history of cancer in the NIH AllofUs Biobank. We performed genome-wide germline variant discovery using GATK-HC and GATK-SV to capture the full spectrum of rare and common SNVs, indels, and structural variants (SVs), notably including a total of 309,848 high-confidence SVs (9,639 SVs per genome). We first examined the rates of rare germline structural variants (SVs) predicted to cause loss-of-function of established predisposition genes, finding elevated rates of these likely pathogenic SVs in most cancer types compared to cancer-free controls, with neuroendocrine, colorectal, and ovarian cancer patients harboring notably high rates of these SVs (ORs: neuroendocrine 2.9; colorectal 3.1; ovarian 2.4). We also observed a small fraction of breast cancer patients carrying structural variants overlapping the BRCA1 promoter. We next tested for enrichment of rare missense variants of uncertain significance in established predisposition genes and found significant enrichment in endometrial, hematologic, prostate, and neuroendocrine cancer patients ($p < 0.05$). To search for potential new predisposition genes, we performed rare variant association tests for all 18,544 autosomal protein-coding genes, which nominated several candidate predisposition genes driven by rare damaging variants, such as BRAT1 in breast cancers (p=3.99e-5) and TSTD2 in thyroid cancers (p=3.26e-5). Finally, we assessed common-variant contributions and found that polygenic risk, long recognized in sporadic cancers, strongly contributed to familial cases in 11 of 15 cancer types with existing polygenic scores. Notably, polygenic risk scores were higher in patients from families with multiple occurrences of the same cancer type compared to patients whose own diagnosis was the only instance of that cancer in their family; conversely, in families with clusterings of a given cancer type, unaffected probands had polygenic risk scores for that cancer type on par with individuals who were both cancer-free and had no family history. Collectively, we estimate that 1-8.8% of unexplained familial cancers can be attributed to germline genetic factors detectable by genome sequencing but missed by routine gene panels, underscoring the potential clinical and diagnostic value of high-resolution germline testing for hereditary cancer patients and their families.

#6279 Socioeconomic and geographic disparities in germline genetic testing for Korean male breast cancer.

Jun-Ha Jang[1], Eun Gyeoung Lee[2], Hyun-Jin Kim[3], Kong Sun-Young[4]

[1]Public Health & AI, National Cancer Center Graduate School of Cancer Science and Policy, Goyangsi, Korea, Republic of,[2]Center for Breast Cancer, National Cancer Center, Goyangsi, Korea, Republic of,[3]National Cancer Control Institute, National Cancer Center, Goyangsi, Korea, Republic of,[4]Laboratory Medicine, National Cancer Center, Goyangsi, Korea, Republic of

Introduction: Male breast cancer (MBC) accounts for <1% of all breast cancers. Germline genetic testing (GT) is recommended for all MBC patients for treatment and family risk assessment. In Korea, reimbursed GT initially focused on BRCA1/2 then expanded to multigene panel testing (MGPT) in 2017. Nationwide data demonstrate a 2.6-fold increase in MGPT utilization from 2019 to 2023; however, 89.7% of tests were performed in tertiary centers raising concerns about equitable access. We aimed to examine time trends in GT utilization and quantify socioeconomic and geographic disparities in access among Korean MBC patients.

Methods: We assessed time trends, determinants and survival outcomes according to GT receipt using the Cancer Public Library Database in K-CURE (Korea-Clinical data Utilization network for Research Excellence), a nationwide registry linking cancer incidence, insurance claims, and mortality data. Total of 774 MBC cases (ICD-10 C50) diagnosed between 2014 and 2019 were identified after applying a 2-year washout period, with follow-up available through 2021. GT was defined as BRCA or MGPT within 12 months of diagnosis. Time trends and associated factors (income level, hospital type, and region) of GT receipt was evaluated. Survival according to GT receipt was explored using Cox proportional hazards models with propensity score matching and inverse probability weighting.

Results: Overall, 360 patients (46.5%) received GT, and the proportion undergoing testing increased significantly from 7.0% in 2014 to 68.9% in 2021 ($p<0.001$). This trend was driven predominantly by BRCA testing, which accounted for 92.3% of the overall increase, whereas MGPT contributed only 7.7%. GT receipt was significantly lower among medical aid recipients than among patients in the highest income quintile (20.0% vs. 51.4%, $p<0.01$), and in small hospitals compared to tertiary centers (25.0% vs. 52.6%, $p<0.01$). Geographic centralization was prominent that 42.8% of GT was performed in Seoul, among them 48.0% were non-Seoul residents. Higher income ($p=0.013$) and residence in Seoul ($p=0.023$) were independently associated with higher GT receipt, while hospital type was not significant ($p=0.087$) in multivariable models. For overall survival (OS), GT receipt was associated with improved OS [adjusted HR 0.55 (95% CI 0.36-0.83); $p<0.01$].

Conclusion: Despite sustained increases in GT utilization, marked socioeconomic and geographic disparities in access indicate that precision oncology for Korean MBC remains inequitable. These findings highlight gaps between national reimbursement policies and the real-world delivery of guideline-concordant care. Further targeted interventions to reduce income- and region-based barriers to GT would be needed. (This study was supported by grants from the National Cancer Center, Korea Grant No. NCC2410821 & NCC2510430)

#6280 Leveraging RNA and long-read DNA to improve genetic etiology identification in individuals with elevated cancer risk: A pilot study in individuals with Li-Fraumeni-like phenotype.

Yewon Kim[1], Anvith Kakkera[1], Asher Bryant[1], Sharon A. Savage[2], Michael C. Dean[3], Payal Khincha[4], Misha Kolmogorov[1], Sheila Rajagopal[1]

[1]Cancer and Data Science Laboratory (CDSL), National Cancer Institute (NCI), Bethesda, MD,[2]NCI Div. of Cancer Epidemiology & Genetics, Rockville, MD,[3]National Cancer Institute - Cancer Genomics Research Laboratory (CGR), Rockville, MD,[4]Clinical Genetics Branch, National Cancer Institute (NCI), Rockville, MD

Individuals with clinical Li-Fraumeni Syndrome (LFS) are at hereditary risk of developing multiple cancers in their lifetime. Among those meeting classic LFS criteria, about 10% do not have a germline mutation identified in *TP53*. Long-read DNA sequencing identifies complex and structural variants (SVs) missed on short-read sequencing. Clinical germline testing labs also recently began using short-read RNA-seq to characterize alternative splicing events. This project aims to explore underlying genetic etiology of those with LFS and no identifiable germline *TP53* variant using long-read DNA-seq and RNA-seq.

We performed germline Oxford Nanopore long-read DNA-seq and Illumina short-read RNA-seq on blood samples from 21 individuals participating in the NCI's Li-Fraumeni Syndrome Study. Selected individuals had a personal history of cancer and/or at least 2 1st degree relatives diagnosed with cancer and no known pathogenic germline *TP53* variant. Insertion-deletion variants (indels) in the long-read DNA-seq were called using Clair, and SVs were called using Severus. Annotation was performed using AutoGVP (indels) and LRGenotate (SVs). Variants were excluded if they were designated as benign/likely benign or if they were common (>1% for indels, >0.1% for SVs) in GnomAD populations. Variants were prioritized if they were designated as "pathogenic" or "likely pathogenic" or if they were predicted to have functional effects. We used RNA-seq to compare relative expression levels of candidate associated genes versus housekeeping genes as compared to control blood samples from the GTEx dataset. We also used rMATS to calculate a Percent Spliced In index (PSI) for splicing variants to parallel commercial labs.

We identified 21 indels in 11 genes classified as pathogenic/likely pathogenic and confirmed by IGV. The genes most affected by these prioritized variants were *ATXN3, ADCY2, KRT10*, *ITPKB, CCDC103, TBP, MUC5B, KRT81, MPO* and *GBE1*. Two related individuals (one diagnosed with cancer, one not) had a *TP53* variant of uncertain significance (c.845G>A) and two unrelated individuals had variants in *ATM*: c.9023G>A and c.8147T>C. We identified 2,453 SVs, with one deletion within *DHX32* and other SVs most often involving *SOS2*, *DICER1*, *NTHL1*, *TSC2*, *RUNX1*, *WAS*, and *GPC3*. We did not observe any significant difference in expression levels of *TP53* compared to housekeeping genes when comparing our samples to GTEx. We did not observe any family-specific PSI patterns.

Long-read DNA-seq and RNA-seq can help characterize the familial cancer syndromes without established genetic etiology. In this pilot study, we are actively evaluating potential causal genes related to clinical presentations of LFS with no identifiable pathogenic germline *TP53* variant.

#6281 Germinal pathogenic variants in Chilean early-onset gastric cancer patients.

Advanced Center for Chronic Diseases, Santiago, Region Metropolitana, Chile

Aim: This study aims to identify and describe the pathogenic/likely pathogenic (P/LP) germline variants found in 159 Chilean patients with early-onset gastric cancer (EOGC).
Introduction: Early-onset gastric cancer (EOGC), diagnosed before the age of 45 or 50, is increasingly recognized as a distinct clinical entity. Familial gastric cancer, which clusters within families often with early onset, is associated with specific genetic syndromes. Hereditary gastric cancer (HGC) accounts for about 10% of all gastric cancer cases, with mutations in the CDH1 gene being the most frequently observed in HGC. A previous report from our group described a Chilean family with hereditary diffuse gastric cancer (HDGC) harboring a pathogenic CDH1 variant, suggesting a lower frequency of pathogenic variants in this population.
Methods: Gene panel analysis was performed on 124 patients, and whole-exome sequencing (WES) was conducted on 35 patients using the Agilent SureSelect Human All Exome V7 kit. Alignment and variant calling were performed using Dragen v3.8, and variants were annotated with Illumina Nirvana and Annovar. Genotyping of index patients and their relatives was done using PCR and Sanger sequencing.
Results: Nine P/LP germline variants were identified across five genes in 11 patients. No P/LP pathogenic variants were found in the **CDH1** gene, consistent with prior findings. A P/LP variant in the **CTNNA1** gene (c.531T>G, p.Tyr177Ter) was found in one patient. Additionally, a high CAAD score variant of uncertain significance (VUS) (c.293G>A, p.Arg98Gln) was found in a large HDGC family. Two **BRCA2** P/LP variants were identified: c.4740_4741dupTG (p.Glu1581fs) in two unrelated patients and c.5439delT (p.Leu1813_Val1814insTer) in one patient, both variants having been previously described in Chilean hereditary breast cancer patients. Three **ATM** P/LP variants were identified, including c.3381_3384del (p.Gln1128fs) in a family with three affected individuals, and c.3894dup (p.Ala1299fs) and c.8122G>A (p.Asp2708Asn) in other unrelated patients. A **RUNX1** variant (c.1270T>G, p.Ser424Ala) was found in three independent cases, and a **POT1** variant (c.1087C>T, p.Arg363Ter) was identified in a family with multiple gastric cancer cases.
Conclusion: These families exhibited incomplete penetrance and multi-organ cancers. This is the first report of P/LP variants in the **RUNX1** and **POT1** genes in hereditary gastric cancer. **RUNX1** is associated with hereditary myeloid malignancies, and **POT1** with hereditary colorectal cancer. This study provides new insights into the genetic basis of early-onset gastric cancer in the Chilean population, highlighting the need for further investigation of these variants in familial gastric cancer syndromes.

#6282 Evidence for pathogenicity of inherited biallelic *MSH3* variants causing early-onset colorectal cancer.

Yuki Aisu, Minoru Koi, John M. Carethers

Medicine, UC San Diego, La Jolla, CA

Background. We previously reported on an individual from a fourth family worldwide with early-onset colorectal adenocarcinoma with germline compound heterozygous *MSH3* variants (c.2436-1G>A / c.3265A>T). Tumor DNA from this individual demonstrated microsatellite instability-low (MSI-L) and elevated microsatellite alterations at selected tetranucleotide repeats (EMAST) suggestive that both alleles were pathogenic. Additionally, tumor cells exhibited MSH3 in the cytoplasm, with some cells showing loss of MSH6 that might be suggestive of at least one MSH3-expressing allele having a dominant-negative effect on MSH2, which binds to both MSH3 and MSH6 for their stability. Here, we aimed to prove that both *MSH3* variants are pathogenic as well as to assess effects on other mismatch repair proteins.

Methods. Both *MSH3* variants, c.2436-1G>A and c.3265A>T, were introduced individually into SW620 cells using CRISPR/Cas9. Presence of each variant was confirmed by Sanger sequencing. Western blotting (WB) and fragment analysis were performed on variant clones and compared with parental SW620 cells.

Results. We successfully established *MSH3* variant clones with homozygous c.2436-1G>A and clones with homozygous c.3265A>T. WB analysis revealed complete loss of MSH3 protein in cells containing homozygous c.2436-1G>A. However, variant MSH3 protein was detected in cells containing homozygous c.3265A>T, although the amount of protein was less than that of wild-type (WT) MSH3 expressed in parental SW620. These results suggest that the transcription rate of variant c.3265A>T may be reduced and/or variant-generated protein may be less stable than WT MSH3. Expression levels of MSH2, MSH6 and MLH1 in these 2 variant cell lines were similar to expression in parental SW620 cells. MSI-L/EMAST was detected in 18.8% (6/32) of subclones isolated from each variant indicating loss of MMR function, whereas no subclones (0/32) from SW620 showed MSI-L/EMAST.

Conclusions. We established cell models of two germline *MSH3* variants (c.2436-1G>A and c.3265A>T) which had been identified in an early-onset colorectal cancer patient. Cells with each variant exhibited MSI-L/EMAST indicating loss of MSH3 function, proving that these two germline variants are pathogenic. As we did not observe any change in cell MSH6 expression, further studies are in progress to generate cells that are compound heterozygous for these two variants and to further elucidate the pathological effects of the combinations of these variants.

#6284 Putative pathogenic germline variants associated with hereditary cancer syndromes identified through clinical tumor-only sequencing.

Sheehyun Kim, Suhyun Hwangbo, Sungyoung Lee, Hongseok Yun

Seoul National University Hospital, Seoul, Korea, Republic of

Background: Clinical tumor sequencing using next-generation sequencing (NGS) is widely applied to identify targetable variants and molecular biomarkers in cancer patients. Due to time and cost constraints, most institutions perform targeted gene panel sequencing only on tumor tissue, rather than on both tumor and matched normal samples. However, tumor-only sequencing cannot reliably distinguish true germline variants carried by the patient, particularly those associated with hereditary cancer syndromes.
Methods: We retrospectively collected clinical tumor-only sequencing data from cancer patients at Seoul National University Hospital (SNUH) between December 2022 and May 2025. All data were generated using targeted NGS with a customized SNUH FiRST Cancer Panel consisting of 336 cancer-related genes. Potential pathogenic germline variants (PPGVs) were classified based on the recommendations of the ESMO Precision Medicine Working Group and the patient's clinical and family history. Finally, we confirmed true pathogenic germline variants using Sanger sequencing or targeted NGS methods with normal genomic DNA from peripheral blood mononuclear cells.
Results: A total of 2,513 tumor samples underwent clinical targeted cancer panel sequencing during the examined period. Of those samples, 239 PPGVs were identified in 221 samples (8.8%) of various cancer types. While most cancers were breast or ovarian, different types of cancer were also associated with PPGVs, including those of the colon, pancreas, bladder, kidneys, prostate, bile ducts, and uterus. Of the 239 PPGVs, 129 (54.0%) were validated through germline confirmation testing. Of those, 88 (68.2%) were confirmed as true pathogenic germline variants, while the remaining 41 (31.8%) were somatic. Most germline variants were found in genes involved in homologous recombination repair (HRR), such as BRCA1, BRCA2, PALB2, BRIP1, RAD51D, CHEK2, and RAD50; or in genes involved in mismatch repair (MMR), such as MLH1, MSH6, MSH2, and PMS2. Among the PPGVs, 85.0% of BRCA1 variants were confirmed as germline, whereas only 12.5% of PTEN variants were verified to be germline. The germline variants showed an average variant allele frequency (VAF) of 58.1%, which is sufficiently high to be considered germline. However, the somatic variants exhibited a mean VAF of 51.5%, making them difficult to distinguish from true germline variants without additional confirmatory testing.
Conclusions: Clinical tumor-only sequencing can not only identify therapeutically actionable mutations but also infer PPGVs associated with hereditary cancers. Therefore, careful attention to PPGVs is essential when interpreting tumor-only sequencing results for the accurate diagnosis and prevention of hereditary cancer syndromes.

#6285 A novel functional cell line model for high throughput assessment of SDHA VUS for pathogenicity.

Michael C. Heinrich, Christine Robbins, Ajia Town

Medical Oncology, Portland VA HCS and OHSU Knight Cancer Institute, Portland, OR

Pathogenic (P), loss-of-function (LOF) SDHA germline mutations are associated with an increased risk of developing GI stromal tumors, paraganglioma/pheochromocytoma, or renal cell carcinoma. Although the penetrance of SDHA germline mutations appears less than for other SDH complex members, international guidelines recommend surveillance of germline pathogenic mutation carriers for early detection of SDH mutant cancers using a combination of laboratory testing, routine medical examinations, and periodic imaging. The number of SDHA VUS far exceeds the number of mutations that are classified as benign (B), likely benign (LB), likely pathogenic (LP), or pathogenic (P). As of November 2025, of the 1531 missense SDHA mutations in ClinVar, 1412 (92%) are VUS. We previously generated a CRISPR KO Hap1 cell line with integration of a single genomic copy of a landing pad cassette. Using targeted recombination of individual SDHA variants and measurement of SDHA enzymatic activity measurements, we determined that 19/20 control P/LP variants met the criteria for PS3strong evidence and 16/20 control benign B/LP variants met the criteria for BS3supporting (6 variants) or BS3moderate (10 variants). Using this model we functionally profiled 21 VUS and combined the weight of evidence with pre-existing population frequency data and computational predictions. Using this functional data, we were able to definitively classify 17/21 VUS as either LB (1) or LP (16) with only 4 remaining as VUS. Despite the utility of this model to functional profile and classify individual VUS, the throughput of this system is too limited to meaningful profile large numbers of VUS. Notably, these cell lines have metabolically adapted to culture conditions, and we cannot select against loss-of-function (LOF) variants. To enable metabolic selection against LOF variants, we developed a novel system where parental HAP1 cells with intact genomic SDHA are stably “pre-rescued” by lentiviral SDHA cDNAs that have mutation of the PAM and sgRNA binding sites for our most efficient SDHA sgRNA. The cDNAs encode for variants of interest (WT, VUS, control B and P variants). Stably expressing cells are then transduced with an SDHA sgRNA that edits the genomic SDHA gene but not the cDNA transgene. Parental or empty vector cells are nearly eliminated after transduction of SDHA sgRNA due to efficient editing of the essential genomic SDHA gene, whereas SDHA WT cDNA transduced cells are minimally depleted at 10-14 days after transduction. To date we have profiled 18 P and 18 B control variants in both systems and had 100% agreement between the assay systems. Overall, we profiled 79 variants in our depletion assay system and compared the results to those from our landing pad system and found excellent agreement with a r^2=0.89. This system is suitable for deep mutational scanning (DMS) as LOF variants are efficiently depleted. Pilot DMS experiments are currently in progress.

#6286 Functional assessment of RECQL4 missense variants identified in *RECQL4*genetic disorder-associated osteosarcomas.

Brian Rodemoyer, Samuel Brito, Thales C. Nepomuceno, Alvaro N. Monteiro

Cancer Epidemiology, Moffitt Cancer Center and Research Institute, Tampa, FL

Pathogenic germline mutations in *hRECQL4*, a member of the highly conserved family of RecQ DNA helicases, are associated with three rare genetic disorders: Rothmund-Thomson Syndrome type II (RTS type II), Baller-Gerold Syndrome (BGS), and RAPADILLINO. All three disorders predispose patients to an array of cancers including osteosarcoma, breast, ovarian, and lymphoma. While most known pathogenic mutations found in *RECQL4*-associated disorders lead to premature protein termination, a subset of patients also display missense variants, making their clinical classification more challenging. Moreover, some missense variants of unknown significance (VUS), are present in the general population, however, their contribution to disease prevalence has remained mostly unexplored. To assess the functional impact of RECQL4 missense VUS, we selected 15 missense variants identified in *RECQL4*-associated disorders from the ClinVar and genomAD databases. Our dataset includes three known benign, three known pathogenic, nine VUS, and the helicase-dead K508M variant. Here, we utilize immunochemical and fluorescence microscopy techniques to assess the functional impact of these 16 RECQL4 missense variants. Using a *pcDNA5-FRT-eGFP-RECQL4* construct, we generated missense variants by site-directed mutagenesis followed by transient transfection into endogenous *RECQL4*-silenced U2OS osteosarcoma cells in triplicate. Missense variants were analyzed by Western blotting for alterations in protein expression compared to the wildtype. While the benign variants p.(E71G) and p.(E267D) displayed expression like the wildtype as expected, pathogenic variants p.(P466L) and p.(S1079I) showed markedly reduced expression levels. Interestingly, VUS p.(L566P), p.(V768A), and p.(R1058G) also displayed reduced protein expression as compared to the wildtype, indicating a possible mechanism of pathogenicity. Furthermore, we performed fluorescence microscopy to assess the effect of the variants on subcellular localization under basal conditions and in the presence of the oxidative DNA damaging agent Streptonigrin. The pathogenic p.(P466L) variant, which is located in the nuclear localization signal (NLS), failed to localize to the nucleus, however, VUS p.(L566P), which is located downstream of the NLS, also impaired nuclear localization. Even under oxidative DNA damage conditions, which targets RECQL4 to the nucleolus, neither pathogenic p.(P466L) nor VUS p.(L566P) were capable of nuclear localization. In summary, we have successfully generated 16 *RECQL4* missense variant constructs and evaluated them for both protein expression and subcellular localization under normal and oxidative DNA damaging conditions, identifying a VUS that behaves similarly to a known pathogenic variant.

#6287 Ancestry-enriched *ACKR1* germline variant and its functional impact on normal and breast cancer biology.

Stephanie Adama[1], Adedeji Adebayo[2], Sedat Kacar[3], Poornima Bhat-Nakshatri[4], Jiang Guanglong[5], Cihat Erdogan[5], Bryan P. Schneider[6], Kathy D. Miller[6], Harikrishna Nakshatri[7]

[1]Translational Cancer Biology, Indiana University Melvin and Bren Simon Comprehensive Cancer Center, Indianapolis, IN,[2]Winship Cancer Institute, Emory University, Atlanta, GA,[3]Center for Computational Biology and Bioinformatics, Indiana University School of Medicine, Indianapolis, IN,[4]Surgery, Indiana University School of Medicine, Indianapolis, IN,[5]Center for Computational biology and Bioinformatics, Indiana University School of Medicine, Indianapolis, IN,[6]Division of Hematology/Oncology, Indiana University School of Medicine, Indianapolis, IN,[7]Surgery, Indiana University School of Medicine/ VA Roudeboush Medical Center, Indianapolis, IN

Atypical chemokine receptor 1 (*ACKR1*) gene, harbors single nucleotide polymorphisms in its regulatory and coding regions. The regulatory region variant rs2814778 is enriched in African and Arab populations and it confers protection against malarial infection. However, it is responsible for the Duffy-Null (CC) /heterozygous (C/T) phenotype, characterized by a significant reduction in *ACKR1* expression in epithelial and non-epithelial cells. *ACKR1* functions as a decoy receptor for several chemokines including the breast cancer metastasis-associated CXCL12, to regulate immune/ inflammatory pathways. There is a growing interest to include Duffy genotyping in clinical trial design to account for normal biological differences underlying aggressive breast cancer outcomes in black women. We seek to investigate the potential influence of *ACKR1* variant on breast cancer outcomes, with a long-term goal of identifying therapeutic vulnerabilities. We established a model system by generating immortalized breast epithelial cell lines with functional *TT* (wild type that express *ACKR1* -African and European ancestry), heterozygous (*C/T*) and homozygous (*CC*), using breast tissues from the institutional resource of Komen Normal Tissue bank. Cell lines with TT expressed higher *ACKR1* mRNA levels relative to *C/T* or *CC* in the regulatory region. We hypothesized that reduced *ACKR1* expression alters chemokine signaling which may influence intrinsic and extrinsic signaling to activate downstream oncogenic pathways. To test this, we investigated WNT/GSK-3β signaling and observed that *ACKR1* variant influences differential phosphorylation of β-catenin, facilitating nuclear translocation. We sought to explore further the effect of cytokines including inflammatory IL-6 secreted as a result of *ACKR1* variant on downstream oncogenic pathways. We observed increased phosphorylation of STAT3, a surrogate of IL-6 activity in breast epithelial cells of *ACKR1 CC* and *C/T* cells compared to *TT*. Our analysis of the UALCAN database further revealed that reduced *ACKR1* expression in breast cancer correlates with progression to brain metastases. Consistent with this, our results demonstrate enrichment of CD271-high populations; indicative of cancer stem-like properties in *ACKR1 CC* and *C/T* cells. These findings suggest that reduced *ACKR1* expression may promote acquisition of stem-like and metastatic properties. In vivo studies are underway to evaluate the effect of *ACKR1* status on distinct tumor characteristics including cancer stem cell properties, increased metastatic potential and response to targeted and conventional chemotherapy. A positive outcome from this study will have a transformative impact, establishing *ACKR1* germline variants as determinants of breast cancer biology and highlight the need to integrate ancestry-informed genotypes into clinical trial design and therapeutic decision-making.

#6288 Rational pairing of tumors with off-patent targeted therapies (TT): Next^3 generation sequencing with global applications for the unprivileged patients!.

Farah Mazahreh, **Liyan Mazahreh**, Ahmad Mazin Safar

University of Arkansas for Medical Sciences, Little Rock, AR

Since the success of imatinib as the inaugural TT, attempts to identify rational targets for similar approaches have gained prime importance. Cancer is defined by genomic alterations producing constantly activated oncogenes (O). Classically, this was inferred by clonal DNA alterations in proto-oncogenes which became the basis for identifying actionable changes in Next Generation Sequencing (NGS) platforms (successful in <25% of cases). Mutations, translocations and amplifications generate 'constant' pathologic state but this can also result from DNA amplification of transcription factors (TF) or ligands (for receptor Os). TTs are priced beyond the reach of uninsured or impoverished populations. Few TTs are off-patent, however, with affordable formulations enabling access to such agents even in underprivileged communities. We hypothesized that a substantial portion of cancers might be rationally paired to off-patent TTs if extended, but scientifically sound, criteria were used to identify therapeutic targets. Methods: We examined The Cancer Genome Atlas for cases that are wild type but over-expressed for an inclusive O list. We report on amplifications of the TF or ligand of receptor Os. We then examined the list for cases that could benefit from unpatented TTs. We also report on cases with increased transcriptional O activity. All histologies/stages were included when >5 cases were available. Results: Table reports the findings per type of tumor examined. Conclusions: Our method provides underprivileged patients with affordable TTs that wouldn't have otherwise been considered with classic NGS in 9-60% of genomically defined Os. Pairing Os with effective TT should extend beyond the classic NGS criteria. Relevant DNA events in TFs and ligands seem to play a variable role in O-wild type cancers depending on histology (0% in pancreas, kidney, thyroid and glioma). In others, the finding is noted in 13-100% of cases.

#6289 Targeted sequencing of common cancer susceptibility genes reveals germline variants in African prostate cancer patients.

Kennedy Memorial Hospital, Monrovia, Liberia,[12]Maseno University, Maseno, Kenya,[13]Jaramogi Oginga Odinga Teaching & Referral Hospital, Kisumu, Kenya,[14]Mayo Clinic Florida, Jacksonville, FL

Background: Prostate cancer (PCa) is the leading cause of cancer-related deaths globally and disproportionately affects men of African ancestry. African men often present at younger ages and with more aggressive disease, and approximately half of the PCa risk has been attributed to genetic factors. Africa is the most genetically diverse region of the world, and even within the continent, populations show important differences in allele frequencies and patterns of pathogenic variation. Despite this diversity, African men remain underrepresented in genomic studies, creating significant gaps in knowledge that limit precision medicine efforts.

Methods: A total of 182 prostate cancer patients were recruited from teaching hospitals in Benin, Côte d'Ivoire, Ghana, Kenya and Nigeria. 50 cancer susceptibility genes using the Aviseq ONCO50 panel and the Illumina MiSeq platform. Variant calling was performed using an in-house Snakemake workflow, followed by additional bioinformatic steps to distinguish true PMS2 variants from PMS2CL-related artifacts. Pathogenicity assessment relied on annotations from ClinVar and LOVD databases.

Results: Pathogenic and likely pathogenic variants were detected in 31.3% of the study group identified in 26 genes. The five most frequently altered genes were RAD50, PTCH1, MSH6, MUTYH, and NF1. Nigerian patients accounted for 52.6 percent of all pathogenic variants, with recurrent alterations observed in MSH6, MUTYH, NF1, and PTCH1. In contrast, pathogenic BRCA1 and BRCA2 variants were observed primarily in patients from Kenya, Benin, and Côte d'Ivoire. Several frameshift, nonsense, and splice-site variants identified in this study have not been previously reported in African populations.[SR1]

Conclusion: This study provides one of the most detailed assessments of inherited cancer susceptibility gene variants in African PCa patients. The findings reveal substantial regional variation in the spectrum of pathogenic variants and highlight population-specific genomic signatures that may contribute to the unequal burden of PCa in men of African ancestry. These data emphasize the importance of expanding genomic research efforts within Africa to strengthen precision oncology and reduce global PCa disparities.

#6290 Next-generation sequencing utilization among U.S. Veterans with metastatic cancer in the VA Healthcare System.

John R. Bihn[1], Aditi Hazra[1], Kaelyn Nannini[1], Cassidy Kenny[2], Rachel E. Ward[1], Jennifer La[1], Nathanael R. Fillmore[1], Gieira S. Jones[2], J. M. Gaziano[1]

[1]VA Boston Healthcare System, Boston, MA,[2]Merck and Co., Inc, Rahway, NJ

Background: Access to molecular and genetic testing enables the delivery of precision oncology and improved cancer outcomes. However, patterns of testing utilization among U.S. Veterans remain understudied. This study evaluated the receipt of FoundationOne next-generation sequencing (NGS) testing for metastatic patients across three common cancers. We assessed demographic, clinical, and social determinants of health (SDOH) correlates of testing within the nationwide Veterans Affairs (VA) healthcare system.

Methods: We conducted a retrospective cohort study of U.S. Veterans recorded in the VA Cancer Registry with metastatic lung, colorectal, or prostate cancer and treated in the VA system from 2019 - 2023. We evaluated the utilization of FoundationOne NGS panels (CDx and Liquid) by year and cancer type as accessed through the National Precision Oncology Program (NPOP) database; for this study period other NGS platforms were beyond the scope of this study. Associations of testing frequency with SDOH, including self-reported race, ethnicity, age, sex, rurality, and socioeconomic status, were examined using descriptive statistics, with standard mean differences (SMD) >0.1 considered significant.

Results: Among 71,569 cancer patients, 17.4% (n = 12,465) had metastatic disease. Of these, 4,743 patients received FoundationOne NGS testing (38.1%) including 514 colorectal cancer patients, 2,519 lung cancer patients across histologies, and 1,710 prostate cancer patients. Tested patients were younger than non-tested patients (median age of 71.5 vs. 72.8, SMD = 0.26). Differences in racial distribution were observed (SMD = 0.14); for example, 27.7% of tested patients were Black or African American compared to 22.4% of non-tested patients. Tested patients were more likely to be non-frail (36.6% vs. 31.8%) and less likely to be severely frail (4.2% vs. 6.0%, SMD = 0.15) than non-tested patients, while no substantial disparities were found across sex (SMD = 0.053) or ethnicity (SMD = 0.04). The proportion of rural patients was lower for tested colorectal (20.2% vs. 24.7%, SMD = 0.11) and lung cancer patients (29.3 % vs. 34.3%, SMD = 0.12) versus non-tested patients; tested patients also resided closer to VA facilities for colorectal (median of 24.6 km vs. 31.9 km, SMD = 0.13) and prostate cancer (25.6 km vs. 32.1 km, SMD = 0.11).

Conclusion: Among Veterans with common metastatic cancers, we identified differences in FoundationOne NGS testing utilization for some demographic and clinical factors, while other factors showed similar testing rates. Future directions include evaluating additional NGS platforms utilized in the VA, as well as NGS testing through community care. Continued investment in interventions such as tele-oncology and targeted outreach may help increase NGS testing and ensure all Veterans benefit from precision cancer care.

#6291 Clonal hematopoiesis and incident hematologic and myeloid malignancy in ARIC.

Elizabeth A. Platz[1], Hidetaka Uryu[2], Vernon A. Burk[1], Meng Ru[1], Sergiu Pasca[3], Lukasz P. Gondek[3], Katherine Y. King[4], Anna E. Prizment[5], Corinne E. Joshu[1], Pradeep Natarajan[6], Margaret A. Goodell[4], Christie M. Ballantyne[4], Koichi Takahashi[2]

[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD,[2]UT MD Anderson Cancer Center, Houston, TX,[3]Johns Hopkins University School of Medicine, Baltimore, MD,[4]Baylor College of Medicine, Houston, TX,[5]University of Minnesota, Minneapolis, MN,[6]Massachusetts General Hospital, Harvard Medical School, Boston, MA

Background: Clonal hematopoiesis (CH), defined using mutations in myeloid-lineage driver genes (N=74 [classic], Bick et al. *Nature* 2020), is a risk factor for hematologic malignancy (HM). Bernstein et al. (*Nature Genetics* 2024) identified 17 additional genes with mutations that are positively selected in the population, and documented a positive association with HM. Continuing to refine CH mutations that convey risk is critical for clinical use and research on modifiable drivers of CH to HM. Thus, we developed a CH-calling pipeline that detects CH from population-based sequencing data using an expanded gene list as well as a variant pathogenicity score based on Google AlphaFold 3. We investigated associations between CH called by the new pipeline and HM risk in a community-based cohort with long follow up.

Methods: We conducted a prospective analysis of 9,365 participants in the Atherosclerosis Risk in Communities study aged 44-80 years, without a cancer history, and with whole exome sequencing data. 410 HMs (147 myeloid) were ascertained mainly by cancer registry linkage in a median follow up of 21 years. Follow up is longer than in the original well-known CH studies. With a mean depth of 100x, mutations with a variant allele frequency (VAF)>3.8% were considered for CH. We classified definitive CH as mutations in classic CH genes and truncating mutations in genes additionally identified by Bernstein et al. For missense mutations in the additional genes, we applied AlphaFold 3 to predict pathogenicity and called probable if score≥0.9. We estimated hazard ratios (HR) and 95% confidence intervals (CI) for the association of small (3.8<vaf<10%) and="" large="" (vaf≥10%)="" ch="" (both="" vs="" no="" ch)="" with="" incident="" hm="" myeloid="" malignancy="" adjusting="" for="" age,="" sex,="" race.="" comparison,="" we="" ran="" the="" same="" analyses="" using="" classic="" (bick="" et="" al.="" defined="" vaf≥2%).</vaf<10%)>

#6292 Comprehensive whole-Genome profiling reveals Cooperative PI3K-TP53-RB1-ATRX pathway alterations and immune-modulatory drivers in myxoid liposarcoma.

Jonathan Gonzalez[1], Hayde Caro-Sanchez[1], Dorian Y. Garcia-Ortega[1], Andrea Ramirez[1], Rodrigo Cruz-Nieto[1], Claudia Garcia-Cuellar[1], Diddier Prada[2]

[1]Innstituto Nacional de Cancerologia, Mexico City, Mexico,[2]Icahn School of Medicine at Mount Sinai, New York, NY

Background: Myxoid liposarcoma (MLS), a genetically stable soft-tissue sarcoma driven by FUS-DDIT3 fusions, harbors additional somatic alterations contributing to progression and microenvironmental adaptation. These remain underexplored in non-European populations.
Methods: We conducted whole-genome sequencing (WGS) on tumors from 56 Mexican MLS patients using a standardized pipeline (BWA-MEM2 alignment, GATK Mutect2 variant calling, VEP annotation). We analyzed somatic SNVs/indels, mutational signatures, gene-specific clustering (OncodriveCLUST), and co-occurrence patterns via cohort-level MAF files. Results were visualized with oncoplots and positional analyses.
Results: Tumors exhibited moderate mutational burden (median 6.4 × 104 variants/sample), dominated by missense substitutions and C>T transitions (SBS1 and SBS5 signatures). Recurrent alterations enriched in structural genes (e.g., *MUC3A*, *MUC4*, *MUC5AC*, *MUC16*, *AHNAK2*, *FLG*, *TTN*, *ZNF*) suggested extracellular and cytoskeletal remodeling. Key oncogenic hits included *PIK3CA* (89%; activating p110α variants), *TP53* (98%; DNA-binding loss-of-function), *RB1* (87%; RB_A/RB_B disruptions), and *ATRX* (98%; helicase/ADD domain mutations), implicating PI3K-TP53-RB1-ATRX pathway cooperation and telomere instability. Co-occurrence clustered in adhesion/matrix genes without exclusivity, while OncodriveCLUST hotspots (*DEFB4A*, *DEFB107A*, *USP17L17*, *FOXD4L4*) pointed to immune and epigenetic modulation.
Conclusions: Beyond FUS-DDIT3 fusions, MLS features coordinated PI3K-TP53-RB1-ATRX alterations, structural remodeling, and immune hotspots. This first WGS study in Mexican (and one of few in Latin American) MLS patients establishes a genomic atlas for diverse populations, informing targeted therapies like PI3K inhibitors.

#6293 Distinguishing radiation-induced from sporadic thyroid cancers after the Chornobyl nuclear power plant accident.

Danielle M. Karyadi[1], Tetiana I. Bogdanova[2], Stephen W. Hartley[1], Vladimir Drozdovitch[1], Sergii Masiuk[3], Belynda Hicks[4], Kristine Jones[4], Amy Hutchinson[4], Petra Lenz[4], Maria Brown[4], Aaron M. Rozeboom[4], Elizabeth K. Cahoon[1], Mykola Chepurny[3], Liudmyla Yu Zurnadzhy[2], Vibha Vij[1], Cari M. Kitahara[1], Michael Dean[1], Gayle E. Woloschak[5], Dale A. Ramsden[6], Mykola D. Tronko[7], Stephen J. Chanock[8], **Lindsay M. Morton**[1]

[1]National Cancer Inst. Div. of Cancer Epidemiology & Genetics, Bethesda, MD,[2]2 Laboratory of Morphology of the Endocrine System, V.P. Komisarenko Institute of Endocrinology and Metabolism of the National Academy of Medical Sciences of Ukraine, Kyiv, Ukraine,[8]Sect. Head & Director, CGF/ATC, National Cancer Institute, Rockville, MD

Radioactive fallout from the 1986 Chornobyl accident increased papillary thyroid carcinoma (PTC) risk after childhood exposure. Radiation-induced versus sporadic tumors cannot be distinguished by clinical characteristics, histologic features, or known COSMIC signatures. A recent analysis examined the pattern of DNA damage that generated PTC oncogenic drivers from Chornobyl-exposed and unexposed individuals because such patterns reflect DNA repair mechanisms, e.g., healthy cells engage efficient DNA double-strand break (DSB) repair without substantial DNA loss. PTC with fusion/structural variant (SV) drivers generated from two breakpoints and <20 basepairs (bp) breakpoint gain/loss (Fusion$^{2B<20bp}$) were consistent with having been caused by radiation (higher frequency with increasing radiation dose, even distribution by sex), whereas fusion/SV-driven PTC with ≥3 breakpoints and ≥1000 bp breakpoint loss (Fusion$^{3B\geq1000bp}$) and *BRAF*^{V600E}-driven PTC exhibited no radiation dose association and strong female predominance. To investigate radiation dose and sex distributions for additional fusion/SV driver categories and replicate the previous report, we reconstructed thyroid radiation doses and sequenced 244 histologically-confirmed PTCs (Table). Radiation doses were significantly higher for all fusion/SV-driven PTC with <1000 bp breakpoint loss (P=0.0084 to 7.1×1^{-10}), regardless of the number of fusion/SV driver breakpoints, compared with *BRAF*^{V600E}-PTC, while doses were comparably low for fusion/SV-driven PTC with ≥1000 bp breakpoint loss, albeit based on small numbers. Only the Fusion$^{2B<20bp}$-PTC replication group had a lower female predominance compared with *BRAF*^{V600E}-PTC (67.1% vs. 79.0%, P=0.068). These results provide evidence that the amount of gain/loss at the fusion/SV driver breakpoint is a more informative feature than the number of DNA DSBs for distinguishing radiation-induced from sporadic tumors in this dose range.

Distribution of sex and radiation dose by PTC oncogenic driver category

		Sex			Thyroid radiation dose (mGy)								
		Female	Male		Unexposed	1-99	100-199	200-499	500-999	≥1000

#6294 Rare germline variants in key pathways contribute to hepatocellular carcinoma risk in Hispanics.

Xiangnan Li, Spiridon Tsavachidis, Priya B. Shetty, Yanhong Liu, Aaron P. Thrift

Baylor College of Medicine, Houston, TX

Background: Hepatocellular carcinoma (HCC) is the sixth most common cancer and the third leading cause of cancer-related death. The primary cause of HCC is shifting from viral hepatitis infections to metabolic dysfunction-associated steatotic liver disease (MASLD). In the U.S., Hispanics have the highest incidence of HCC. Furthermore, MASLD-related HCC occurs more frequently in Hispanics compared to non-Hispanic Whites and Blacks. These disparities suggest population-specific genetic mechanisms underlying HCC development. While genome-wide association studies have uncovered genetic risk factors for HCC, most studies have focused on East Asian and European ancestry populations and common variants, which often confer small effect sizes. Rare variants can exert larger effects than common variants and may provide novel biological insights, particularly in underrepresented Hispanics.
Methods: We performed whole-exome sequencing on blood samples from 719 Hispanic individuals, including 455 HCC cases and 264 controls. Analyses focused on 576 genes previously implicated in HCC and MASLD. We prioritized rare, protein-altering variants with minor allele frequency ≤ 0.01 in both our controls and the Admixed American (AMR, primarily Hispanic/Latino ancestry) population from the Genome Aggregation Database (gnomAD). Only variants present in ≥ 3 HCC cases and predicted to be deleterious (with a scaled Combined Annotation Dependent Depletion (CADD) score ≥ 15) were considered. Associations were evaluated using single-variant allelic analysis and gene-based burden tests. Allele counts from gnomAD AMR population controls (n = 30,019) were integrated into the analysis to improve the estimation of odds rations (ORs) and 95% confidence intervals (CIs).
Results: Among 576 genes examined, we identified 27 rare deleterious variant candidates across 24 genes significantly enriched in HCC cases. Top candidate variants included those in immune response genes such as HLA-DRB1 (W38X; OR 15.13, 95% CI 4.91-39.90) and in cell growth genes such as SIK3 (A1272V; OR 7.19, 95% CI 1.85-20.11). Several lipid metabolism genes also showed enrichment, including *PLB1* V417L (OR 21.95, 95% CI 3.81-88.18), *ADAMTS9* S1638L (OR 3.09, 95% CI 0.98-7.47), *TM6SF2* R138W (OR 2.66, 95% CI 1.55-4.28). These genes also showed significant aggregation of rare variants in the burden test. Notably, *TM6SF2* R138W significantly enriched in HCC cases born in the US and in HCC cases with alcohol liver disease and MASLD etiologies (OR = 3.30, 95% CI: 0.98-14.27, P = 0.040).
Conclusion: These results highlight that rare, deleterious variants across immune, cell-regulatory, and lipid-metabolic pathways contribute to elevated HCC risk in Hispanics. These findings further suggest potential gene-environment interactions that may underlie HCC disparities and provide a genetic basis for future targeted prevention strategies in high-risk populations.

#6295 Mutational processes in esophageal and gastroesophageal junction adenocarcinomas across geographical regions.

Laura Torrens[1], Sarah Moody[2], Jiali Pang[2], Behnoush Abedi-Ardekani[1], Ayesha Noorani[2], Haoran Zhang[3], Pilar Gallego-Garcia[4], Valerie Gaborieau[1], Thomas Cattiaux[1], Priscilia Chopard[1], Stephen Fitzgerald[2], Calli Latimer[2], Christine Carreira[5], Marcos Diaz-Gay[4], Laura Humphreys[2], Ludmil B. Alexandrov[3], Michael R. Stratton[2], Sandra Perdomo[1], Paul Brennan[1], on behalf of the MUTOGRAPHS project

[1]Genomic Epidemiology Branch, International Agency for Research on Cancer (IARC/WHO), Lyon, France,[2]Cancer, Ageing and Somatic Mutation, Wellcome Sanger Institute, Cambridge, United Kingdom,[3]Moores Cancer Centre, University of California San Diego, San Diego, CA,[4]Digital Genomics Group, Cancer Genomics Program, Spanish National Cancer Research Center (CNIO), Madrid, Spain,[5]Evidence Synthesis and Classification Branch, International Agency for Research on Cancer (IARC/WHO), Lyon, France

Esophageal adenocarcinomas (EAC) and gastroesophageal junction cancers (GEJ) share multiple risk factors such as reflux disease, obesity, and tobacco smoking. Despite their anatomical proximity and overlapping etiology, they are often considered as esophageal and gastric tumors, respectively. This study aims to decipher the mutational processes that have been operative in EAC and GEJ cancer development and determine whether these are shared across tumor sites and geographical regions.

Whole-genome sequencing data were generated from 520 EAC/GEJ cases (159 EAC and 361 GEJ) from eight countries (China, Iran, United Kingdom, Canada, Kenya, Malawi, Brazil, and Colombia), with available demographic, lifestyle, and environmental exposure data. Mutational signatures were extracted using SigProfilerExtractor and decomposed into reference signatures. Associations between the mutational signatures and epidemiological or molecular features were assessed using multivariate regression models.

Our analysis revealed 17 reference signatures from the COSMIC catalogue, and three signatures described in previous cancer datasets. EAC/GEJ tumors exhibited high burdens of SBS17a and SBS17b, linked to acid reflux, accounting for 26.8% of the median signature burdens. Signature SBS-D, which has been speculated to be caused by DNA repair infidelity, was the second most abundant signature (12% median relative burden), suggesting a relevant role in EAC/GEJ carcinogenesis. EAC and GEJ cancers shared a highly similar mutation, driver, and copy number profile, pointing to shared mutagenic processes, with the exception of SBS-D, which showed enrichment in cancers from the lower and distal esophagus. Signatures SBS17a/b were positively associated with obesity (p-value<0.0005), particularly in EAC cases, supporting the epidemiological notion that obesity may exacerbate reflux disease. We observed no differences in signature burdens with other risk factors, such as tobacco, suggesting its carcinogenic effect in this cancer type could be promotional rather than mutagenic. Finally, we found an association between age-standardized incidence and the signatures SBS5, SBS8, and SBS-D, suggesting a potential dysregulation of endogenous cellular functions in high-risk populations.

This study delineates the mutational forces driving GEJ/EAC cancers. Our results show an overall shared mutational profile across tissues and suggest that obesity enhances the presence of reflux-related mutagenesis. The observed differences across countries could provide relevant information to aid in the development of global prevention strategies.

#6296 Deciphering the promotional determinants of esophageal cancer in countries with varying incidence.

Esophageal squamous cell carcinoma (ESCC) incidence varies widely across the world, correlating with exposure to known risk factors like alcohol, smoking, and hot liquids. It has traditionally been assumed that such exposures lead to malignant cell transformation by directly or indirectly causing DNA mutations. However, recent evidence revealed that most ESCC risk factors do not elicit distinct mutation profiles, suggesting that these carcinogens may act as non-mutagenic tumor-promoting agents. This study aims to investigate the role of exogenous exposures in promoting the clonal expansion of pre-initiated cells in normal esophageal tissue, leading to ESCC.

To address this, we are examining the clonal structure of 200 esophageal epithelium samples from ESCC patients and non-cancer donors across nine geographical regions in China, Iran, Malawi, South Africa, Russia, Brazil, and Canada, with age-standardized ESCC incidence rates ranging from 1 to 84 per 100,000. Detailed demographic, lifestyle, and exposure information, including tobacco, alcohol, and hot liquids, is available. Esophageal epithelial tissues are dissected and analyzed by NanoSeq for mutational signature and mutation burden evaluation, and by 500x whole-exome sequencing to identify mutant genes under positive selection. Spatial proteomics and transcriptomics are ongoing to profile the phenotype of premalignant cells and their microenvironment niches.

Preliminary analyses of 97 cases from high- and intermediate-risk regions revealed a strong mutagenic effect of alcohol and tobacco on normal esophageal tissue. Alcohol-related mutational signatures SBS16 and ID11 were detected in 73% of drinkers (22/30), and were enriched in cases exposed to both alcohol and tobacco. In contrast, hot liquid consumption was not related to distinct mutation profiles. dN/dS analysis in 47 cases with available WES data identified 11 genes under positive selection, including *NOTCH1*, *TP53*, *FAT1*, and *PPM1D*. Cases exposed to tobacco presented higher fractions of mutated epithelia in several of these cancer genes. Notably, the fraction of *NOTCH1*-mutant epithelia was inversely associated with ESCC incidence, suggesting a reduction of clones harboring this protective mutation in high-risk populations.

These findings shed light on the complex interplay between mutagenic and promotional processes in ESCC development and provide insights into the role of known and suspected risk factors in clonal selection. This work may ultimately guide preventive strategies targeting the earliest stages of esophageal carcinogenesis.

#6300 How do healthcare providers approach breast cancer diagnoses in young women? Findings from the BRAVE Study.

Alice W. Lee[1], Mojgan Sami[1], Peyton Fisher[2], Diana Aguilar-Cruz[1], Thien-Y Do[1], Melissa Vargas[1], Aleah La Flair[2], Nicole Wells[2]

[1]California State University, Fullerton, Fullerton, CA,[2]The Young Breast Cancer Project, Chula Vista, CA

Background: Young women face unique challenges when it comes to breast cancer. Not only are they more likely to be diagnosed with late stage tumors and have poorer prognoses relative to older women, but they are also more likely to experience diagnostic delays. Given the complexity of delays and how they can stem from both the patients themselves as well as the healthcare system, we sought to better understand the barriers and facilitators to a timely diagnosis of breast cancer in young women from the perspectives of primary care and obstetrics/gynecology (OB/GYN) providers who often serve as the first point-of-contact for health issues for female patients.
Methods: As part of the Breast Cancer in Young Women: Awareness, Views, Experiences (BRAVE) Study, we conducted one-on-one interviews with four primary care and three OB/GYN physicians, who routinely see young female patients in their California-based practice, to understand their perceptions, approaches, and procedures to diagnosing a young woman with breast cancer. Each interview was recorded, transcribed, coded, and analyzed using NVivo 15, and emergent themes were identified. A survey that included demographic, medical training, and practice-related questions was also administered.
Results: The average age of the providers was 47 years with most identifying as Asian American (57%). Four key themes emerged from the interviews. First, there appeared to be a distinction between provider autonomy versus healthcare system constraints with providers in private practice having greater flexibility to deliver more personalized care. Second, we noted how provider-led education could facilitate early detection of breast cancer by reducing stigma surrounding feminine bodily self-awareness. Third, providers acknowledged how there were insurance and financial barriers, which often prevented coverage for diagnostic tests or problem-based visits and left women unable to access needed care. Fourth, it seemed like the diagnostic process was often impacted by providers having to balance screening guidelines with patient anxiety.
Conclusions: When it comes to the diagnosis of breast cancer in young women, structural, institutional, and provider-specific factors play critical roles. Providers working in institutions that allow them more clinical autonomy often have the flexibility and time to deviate from standardized guidelines and deliver more personalized care. Clinical autonomy may facilitate timely diagnosis particularly in young women under age 40 whose case may not conform to standardized screening and diagnostic recommendations. Given that a timely diagnosis can be attributed to factors related to patients as well as providers, our study is currently exploring this topic from both perspectives. Focus groups with young breast cancer survivors have already been conducted, and additional interviews with providers are planned.

#6301 Coronary atherosclerosis as an incidental finding within the lung cancer screening program.

Edoardo Sostero[1], Kathrin Chiffi[1], Lisa Jungblut[2], Vanessa Englmaier[2], Thomas Frauenfelder[2], Isabelle Opitz[3], **Sven Hillinger**[1]

[1]Thoracic Surgery, University Hospital, Zurich, Switzerland,[2]Radiology, University Hospital, Zurich, Switzerland,[3]Thoracic Surgery, University Hospital Zurich, Zurich, Switzerland

Purpose: Smoking is a leading cause of preventable morbidity and mortality worldwide, contributing to lung cancer, COPD, stroke, and coronary heart disease. Lung cancer remains the deadliest malignancy, with smoking as its main etiologic factor. Early detection via low-dose computed tomography (LDCT) reduces mortality. Since 2019, a national feasibility study on LDCT-based lung cancer screening (LCS) has been conducted at University Hospital Zurich. Because smoking also increases coronary atherosclerosis risk, this study aimed to determine the prevalence, severity, and clinical significance of coronary artery calcification (CAC) as an incidental finding in LCS participants and assess its relationship with age and smoking exposure.
Methods: 201 participants from the Swiss LCS cohort were retrospectively analyzed. All were current or former heavy smokers meeting national screening criteria. LDCT scans were assessed by two thoracic radiologists using the SHEMESH score, grading calcification in LM, LAD, LCx, and RCA from 0 (absent) to 3 (severe), with total CAC scores 0-12. Relationships between CAC, age, and smoking exposure (pack-years) were analyzed using a generalized linear mixed model. Participants with CAC > 4 were advised to undergo stress testing and followed for four years for cardiologic evaluation or cardiovascular events.
Results: CAC was detected in 55.7% (112/201): 30.8% mild (1-3), 15.9% moderate (4-6), and 8.9% severe (7-12). CAC correlated significantly with age ($p = 0.032$) and pack-years ($p = 0.011$). Among 50 participants with CAC > 4, one was lost to follow-up; two did not undergo evaluation due to palliative care or non-cardiac death; 18 are under assessment. Eight (19.5%) had prior cardiac events; 18 had negative stress tests. Three (6.3%) had positive tests or symptoms, leading to angiography and stent placement; in two cases, the treated vessel matched the highest CAC score. Most calcifications were in LAD and RCA. Nine of 49 reported exertional dyspnea or atypical chest discomfort, prompting further evaluation.
Conclusions: Incidental CAC was highly prevalent in smokers undergoing LDCT screening, with severity linked to age and cumulative tobacco exposure. CAC detection during LCS offers an opportunity for cardiovascular risk assessment without added radiation or scan time. Integrating CAC evaluation into LDCT protocols could enhance early identification of at-risk individuals, support preventive cardiology, and improve outcomes. This study supports LDCT screening as a dual-purpose tool against lung cancer and coronary atherosclerosis, aligning with precision preventive medicine strategies.

#6302 Impact of biological aging due to chemotherapy on breast cancer survivorship.

Swarnavo Sarkar[1], Mina S. Sedrak[2], Judith E. Carroll[2], Clyde Schechter[3], Hyman B. Muss[4], Jeanne S. Mandelblatt[1]

[1]Georgetown University, Washington, DC,[2]UCLA - University of California Los Angeles, Los Angeles, CA,[3]Albert Einstein College of Medicine, Bronx, NY,[4]University of North Carolina, Chapel Hill, Chapel Hill, NC

Background: Chemotherapy improves breast cancer survival, but also increases the accumulation of senescent cells in breast cancer survivors. Excess accumulation of senescent cells increases inflammation and tissue damage, which leads to premature onset of age-related diseases (biological age acceleration) in breast cancer survivors.

Objective: We integrate a systems biology model of accumulation of senescent cells with chronological age and a well-established Cancer Intervention and Surveillance Modeling Network (CISNET) breast cancer simulation model to estimate the impact of biological age acceleration on survivorship outcomes.

Methods: We used published data on senescence biomarker expression level ($p16^{INK4a}$ mRNA expression) in chemotherapy recipient breast cancer survivors to simulate the elevated senescence expression level in the remaining lifetime of breast cancer survivors. The difference in the senescence expression level in the chemotherapy group was evaluated against the expression level in the general female population to quantify the biological age acceleration after chemotherapy. The biological age, instead of chronological age, was used to determine the hazard of non-breast cancer mortality in chemotherapy recipient breast cancer survivors. We used CISNET breast cancer simulation model to simulate multi-birth cohorts of US females diagnosed with breast cancer to estimate survivorship outcomes after chemotherapy. Outcomes included remaining life years after breast cancer diagnosis, absolute number of non-breast cancer deaths, and time-point of transition to dominant risk of non-breast cancer mortality.

Results: Biological age acceleration after anthracycline-based regimens caused a greater loss of life years than anthracycline-free regimens for women diagnosed at ages 30-39 years (median of 17.7 years vs. 2.8 years lost). Within the anthracycline group, life years lost varies from 10.4 years to 23.3 years, depending on the level of biological age acceleration. The loss in life years diminished with increasing age at diagnosis (median of 7.5 years vs. 2.2 years lost for 70-79 year old women). The risk of non-breast cancer mortality exceeded breast cancer mortality up to 10-15 years earlier than expected based on chronological age, especially after anthracycline-based regimens.

Conclusions: Including biological age acceleration as a factor in breast cancer life history simulation models can help to identify subgroups of breast cancer survivors who need targeted survivorship care for non-breast cancer mortality. Biological age acceleration is a crucial factor especially for the long-term care of younger chemotherapy recipient breast cancer survivors.

#6303 Designing an integrative theoretical framework for predicting endocrine toxicity in a large prospective cohort of cancer patients treated with immune checkpoint inhibitor therapy.

Hala Awad[1], Mostafa Mohamed[2], Michelle C. Janelsins[3], Jeremy Jonathan McGuire[4], Lisa Danish[1], Song Yao[5], Charles Kamen[4]

[1]Department of Surgery, Univ. of Rochester School of Medicine & Dentistry, Rochester, NY,[2]Department of Public Health Sciences, Univ. of Rochester School of Medicine & Dentistry, Rochester, NY,[3]Postdoctoral Fellow, Dept. of Radiation Onc., Univ. of Rochester Cancer Ctr., Rochester, NY,[4]University of Rochester, Rochester, NY,[5]Postdoctoral Res. Associate, Dept. of Cancer Prev. & Control, Roswell Park Cancer Institute, Buffalo, NY

Immune checkpoint inhibitors (ICI) are associated with immune-related adverse events (irAEs) involving the endocrine system. The rate of endocrine irAEs can vary significantly depending on the agent used, with an average all-grade occurrence of 23% and a severe-grade occurrence of 19%. Unlike other irAEs, endocrinopathies frequently persist after ICI treatment discontinuation, highlighting the need for risk stratification and predictive monitoring. The current understanding of endocrine irAEs is limited, and there are no reliable methods to identify individuals who are most at risk of developing these complications prospectively or to stratify risk at the initiation of treatment. The current study presents an theoretical framework for systematically investigating underlying mechanisms and risk factors for endocrine irAEs. The primary objective is to generate hypotheses and advance methodological approaches for subsequent predictive modeling and clinical trials, thereby supporting the development of tailored strategies for the early detection and management of these irAEs. Within this framework, we propose that endocrine irAEs are complex and result from multidimensional interactions among various clinical, biological, and lifestyle determinants. We examine endocrine irAE risk through a multifaceted approach encompassing: (1) clinical and treatment factors (ICI agent selection, dosing schedules, treatment sequencing), (2) biomarkers of immune dysregulation (CBC-derived indices and lymphocyte/neutrophil counts), (3) inflammatory mediators (IL-6, IFN-γ, TNF-α, IL-8, TGF-β), (4) genetic predisposition, and (5) behavioral and environmental exposures (nutrition, physical activity, tobacco use, comorbid diseases). Sex is also hypothesized to be a critical effect modifier, specifically influencing the predictive utility of specific CBC indices for immune dysregulation parameters for susceptibility to irAEs. Using a systems biology framework informed by mechanistic data and current empirical evidence, we develop an integrative approach that combines quantitative biomarkers with patient-reported assessments of behavioral and environmental exposures. Robust predictive models, we propose, require integration of clinical, biological, modifiable risk, and environmental factors, stratified by sex. This approach seeks to move toward a systems-based approach rather than biomarker assessment, providing a structured foundation for subsequent empirical validation and integration into clinical trial methodology. By integrating clinical, biological, and lifestyle factors, this framework supports the development of predictive models and tailored surveillance protocols that can be implemented in future clinical trials and oncology practice.

#6304 Predictors of engagement and healthcare resource utilization in chemotherapy patients using a text message response system.

Suma Sri Chennapragada, Yang Wang, Jay Carlson, Aswanth Reddy

Mercy Hospital, Fort Smith, AR

Background: Patients receiving chemotherapy face a high risk of treatment-related complications, often leading to increased healthcare resource utilization (HCRU). Mercy Hospital, St. Louis, implemented a text message response system (TRS) to proactively capture patient-reported symptoms and facilitate timely nursing interventions. We evaluated demographic and clinical factors associated with TRS engagement and their relationship to HCRU.

Methods: We analyzed data from 3,899 patients across hospitals in three states (January-July 2025), including 2,750 TRS responders and 1,149 non-responders. Variables assessed included age, sex, ethnicity, comorbidities (cerebrovascular disease [CVD], chronic obstructive pulmonary disease [COPD], renal disease), cancer type, and HCRU (emergency department [ED] visits, inpatient [IP] admissions). Statistical analyses employed Welch t-tests, Pearson χ^2 tests, odds ratios (OR) with 95% confidence intervals (CI), and Holm correction for multiple comparisons.

Results: Responders were slightly younger than non-responders (mean age 67.22 vs. 67.91 years, p=0.111). Female patients were more likely to respond (73.2% vs. 67.5%; OR=1.31, 95% CI 1.15-1.51, p=0.00010). Response rates did not differ significantly by ethnicity or comorbidities. Cancer type showed modest variation (χ^2=19.77, p=0.011, Cramér's V=0.065), though no pairwise differences remained after correction. ED utilization was higher among responders (14.33% vs. 10.71%; OR=1.39, 95% CI 1.12-1.73, p=0.0014), while IP admission rates were similar (15.96% vs. 16.10%, p=0.915). Leading IP diagnoses included sepsis (41.94%) and anemia (38.4%), while pain (48.41%) and nausea (14.96%) dominated ED visits.

Conclusions: TRS engagement was higher among female and younger patients, while older adults were less likely to respond, suggesting the need for alternative outreach strategies such as direct telephone calls. Responders demonstrated greater ED utilization, primarily for pain and nausea, but comparable IP admission rates. These findings underscore the importance of targeted interventions—such as infusion center support and palliative care integration—to proactively manage chemotherapy-related symptoms and reduce HCRU in the outpatient setting.

#6305 Prostate cancer chronotherapy: Influence of treatment timing on radiation efficacy and quality of life.

Andrea A. Almeida, Jiji Jiang, Sally Elsamanoudi, Carrie Cheung, Ayaan Hussein, Tracy Pletcher, Faisal Del, Fouad Mumayiz, Arwa Fallatah, Gregory T. Chesnut, Ayesha A. Shafi

Center for Prostate Disease Research, Bethesda, MD

Circadian-controlled genes influence numerous physiologic processes, including hormone regulation. Emerging evidence across cancer types suggests that aligning therapy delivery with circadian cycle (chronotherapy) may optimize efficacy and reduce toxicity. Given the hormone-sensitive nature of prostate cancer (PCa) and frequent use of androgen deprivation therapy (ADT) combined with external beam radiation therapy (EBRT), the timing of EBRT relative to circadian phase may modulate treatment response. Thus, we investigated whether time-of-day (TOD) of EBRT delivery is associated with PCa outcomes overall and by ADT status. Patients with localized PCa enrolled in the Center for Prostate Disease Research Multicenter National Database Study (2007-2023) were eligible for inclusion if treated with EBRT. TOD of EBRT was categorized as morning (≥80% of sessions before 10AM), afternoon (≥80% of sessions after 10AM), or mixed. Clinical endpoints included biochemical recurrence (BCR), metastasis, and death. Quality of life was longitudinally evaluated over 36 months via the Expanded Prostate Cancer Index Composite (EPIC). Cox proportion hazards regression models estimated hazard ratios (HR) and 95% confidence intervals (CI) for associations between TOD of EBRT and PCa outcomes. Kaplan-Meier analyses were used to examine survival. Among 339 included patients, 156 received morning EBRT, 137 afternoon EBRT, and 46 mixed TOD EBRT. On average, patients were 69.9 years old, had clinical stage T1 disease (78.8%), and had a PSA of 9.0 ng/mL at EBRT initiation. ADT was more often administered to afternoon (55.5%) and mixed TOD patients (58.7%) than morning patients (38.5%). Afternoon EBRT was not associated with death (HR=1.24, 95% CI 0.66-2.33) or BCR/metastasis (HR=1.37, 95% CI 0.66-2.85) relative to morning EBRT. Results were similar when stratified by ADT status. There were no differences in BCR-free, metastasis-free, or overall survival by TOD or ADT status. Overall, morning and afternoon patients reported similar EPIC scores; sexual function and bother scores were notably lower than other scores. Among those who received ADT, afternoon patients reported worse urinary bother (UB) and sexual bother (SB) scores (*p-values*: UB month 36=0.04; SB month 18=0.01; SB month 30=0.04) than morning patients. Scores were similar among morning and afternoon patients who did not receive ADT. Within an equal-access healthcare setting, TOD of EBRT was not associated with oncologic outcomes for localized PCa. However, the combination of ADT and afternoon EBRT was associated with worse urinary and sexual quality of life, suggesting potential interaction between circadian regulated hormone signaling, ADT, and treatment timing. This study provides evidence that ADT may interact with TOD of PCa therapy and that further research in circadian biology, ADT timing, and chronotherapeutic optimization in PCa is warranted.

#6306 Novel application of the iCCaRE consortium virtual reality assistant (ViRA) to support Black men at the point of prostate cancer diagnosis.

Folakemi T. Odedina[1], Che Ngufor[2], Christopher Williams[3], Mary Ellen Young[4], Floyd Willis[5], Adam M. Kase[1], Arnold Merriweather[6], Emelina Asto-Flores[1], Dee M. Glaser-Boivin[5], Jada Melton[1], Monica L. Albertie[7], Michelle Fudge[1], Quincy Wimberly[1], Inclusive Cancer Care Research Equity (iCCaRE) Consortium, Prostate Cancer Transatlantic Consortium (CaPTC)

[1]Mayo Clinic Florida, Jacksonville, FL,[2]Mayo Clinic, Rochester, MN,[3]Urological Assoc Inc, Jacksonville, FL,[4]University of Florida College of Public Health & Health Professions, Gainesville, FL,[5]Mayo Clinic, Jacksonville, FL,[6]Black Male Prostate Coalition of Florida, Jacksonville, FL,[7]Cancer Services, Mayo Clinic, Jacksonville, FL

Background: Black men carry a disproportionate prostate cancer (CaP) burden and often experience significant psychosocial distress at the point of prostate cancer diagnosis (PPCD). Many report emotional shock, uncertainty, and limited access to culturally competent guidance, which can negatively affect treatment decisions and long-term survivorship. To address these needs, we developed the PPCD Virtual Reality Assistant (ViRA), an immersive, AI-enabled intervention co-designed with Black CaP survivors. ViRA delivers tailored psycho-oncology support, emotional guidance, and navigation of social determinants of health (SDOH) within virtual reality environments. This study evaluated the feasibility, acceptability, and usability of the PPCD ViRA (NCT06535802).
Methods: ViRA was developed through a structured, seven-step co-design process with survivors, integrating mobile immersive technologies, SDOH navigation, and culturally grounded psycho-oncology content. Personalization was enabled through AI-driven predictive analytics and a recommendation engine. Alpha testing assessed initial usability and acceptability among 10 participants (seven team members and three Black CaP survivors). Beta testing with 24 Black men in Florida examined feasibility and preliminary efficacy.
Results: A demonstration of ViRA is available (https://www.youtube.com/watch?v=1mI-HS5R6sk). Alpha testing indicated strong usability, positive emotional engagement, and clear promise for enhancing support at the PPCD. In Beta testing, participants varied in age; most were married (58.3%), held a bachelor's degree (45.8%), were retired (45.8%), and had a family history of cancer (83.3%). ViRA use was associated with increased engagement and reduced distress across participants. Overall, 74% rated ViRA as “excellent,” while the remainder rated it as “good” or “very good.” More than 90% reported being “very satisfied,” with the rest indicating satisfaction.
Conclusions: Findings demonstrate high feasibility, acceptability, and cultural relevance of the PPCD ViRA for supporting Black men at diagnosis. Lessons learned highlight the need for culturally embedded design, emotional timing, community co-creation, flexible delivery formats, and strong community partnerships to advance digital health equity. The refinement and larger-scale validation to establish clinical utility and readiness for implementation is ongoing (NCT07126548).

#6307 Feasibility of a survivorship app for black prostate cancer survivors: Results from a 12-week mHealth pilot study.

Gaurav Kumar[1], Parisa Ghasemi[1], Yan D. Zhao[1], Zsolt Nagykaldi[1], Kathleen A. Dwyer[1], Andrew G. McIntosh[1], Ernie Kaninjing[2], Mary E. Young[3], Dickey Sabrina[4], Daniel Morton[1], Opeyemi Bolajoko[5], Darla E. Kendzor[1], Motolani Ogunsanya[1]

[1]The University of Oklahoma Health Campus, Oklahoma City, OK,[2]Georgia College & State University, Milledgeville, GA,[3]Mayo Foundation for Medical Education and Research, Jacksonville, FL,[4]Florida State University, Tallahassee, FL,[5]Mayo Clinic Florida, Jacksonville, FL

Introduction: Black prostate cancer (CaP) survivors experience unique quality-of-life (QoL) and recovery challenges after treatment compared with their White counterparts. Smartphone-delivered mobile health interventions offer promising avenues for symptom tracking and lifestyle changes; but their feasibility, user engagement, and acceptability in this population remain unclear. This study assessed the feasibility, engagement, and preliminary impact of the Survivorship App for Ethnically Diverse Black Prostate Cancer Survivors (SAFE-CaPS), designed to improve self-monitoring behaviors and health outcomes.

Methods: Nine Black CaP survivors (seven U.S.-born, one African-born, and one Caribbean-born) participated in a 12-week pilot study of SAFE-CaPS. The app provided daily prompts for symptoms (pain, sleep, fatigue, sexual function, anxiety, depression) and behavior tracking (physical activity, diet), brief self-management support, and physician alerts for severe symptom reports. Mental health (GAD-7 and PHQ-9) and QoL (FACT-P) were assessed at baseline and after 12 weeks. Feasibility was evaluated based on adherence rates (i.e., ≥70% of daily diary entries). Engagement and acceptability were assessed via app analytics and qualitative interviews on usability and cultural relevance. Participants were compensated up to $125 via Greenphire ClinCard. Surveys were analyzed with SPSS v29, and interviews with Atlas.ti v23.

Results: Participants' median age at diagnosis was 56 years; six had a positive family history of CaP, and four had undergone radical prostatectomy. Four participants met the feasibility threshold, and eight completed the study. Most daily entries reflected mild pain, fatigue, bowel and urinary issues, and generally good sleep. Several participants frequently reported severe sexual dysfunction, and most diary responses indicated <20 minutes of physical activity per day. Fruit/vegetable intake was low, with about half of daily responses showing 1-2 servings. At baseline, eight participants had minimal anxiety, while five had moderate depression. Overall, QoL improved from week 1 to week 12 in physical, emotional, and functional well-being, while social well-being declined over time. Interviews emphasized the app's user-friendly design, ease of navigation, and acceptability as key strengths, with several participants highlighting its simplicity and ease of use, with recommendations to reduce repetitive items and address minor technical issues.

Conclusions: SAFE-CaPS was feasible and well accepted. Sexual dysfunction, low physical activity, and moderate depression emerged as key concerns, heightening the need for integrated mental health, activity support, and stronger engagement strategies in future mHealth interventions.

#6308 Adhesive capsulitis vs. metastasis: Comparative frequency in oncology patients with hip pain.

Laasya Madana[1], Avneesh Chhabra[2], Alireza Eajazi[2]

[1]UT Southwestern Medical Center, Dallas, TX,[2]Musculoskeletal Radiology, UT Southwestern Medical Center, Dallas, TX

Background: Adhesive capsulitis (AC) is defined as the gradual, progressive loss of range of joint motion due to inflammation, adhesions, and capsular thickening. Shoulder AC is well established with a prevalence of 2-5% in the general population, but the prevalence of hip AC remains unknown, likely due to underdiagnosis. Existing literature suggests shared risk factors between shoulder and hip AC—including diabetes, thyroid disease, trauma, and surgery. In addition, while AC has been studied in the general population, its prevalence has not been extensively evaluated in the oncologic population. Oncologic patients with hip pain frequently undergo contrast-enhanced MRI to exclude metastasis, yet the relative frequency of tumor infiltration versus adhesive capsulitis remains unclear. Prior (few) studies have only used non-contrast, fat-suppressed T2W MRIs, making it challenging to differentiate the capsule from the iliofemoral ligament clearly. CEMR incorporates non-contrast sequences, allowing assessment of key AC features—including capsular and iliofemoral ligament thickening or enhancement, as well as preferential fluid pooling in the posterior recess or iliopsoas bursa.
Purpose: To determine the frequency of AC in patients with known primary malignancy undergoing CEMR of hip joint at a tertiary care academic center.
Methods: In this cross-sectional retrospective analysis, from 01/2021 to 01/2025, CEMR studies of hip joints were identified, yielding 57 eligible examinations. Adult patients (>18) with a known primary malignancy were included. Exclusions comprised non-contrast MRIs, absence of confirmed malignancy, significant artifacts, recent trauma, or known inflammatory or infectious conditions. Prospectively, reports were generated by fellowship-trained MSK radiologists in our center. Studies were subsequently re-reviewed by an additional radiologist to evaluate for features of AC, including capsular thickening, capsular enhancement, fluid pooling in synovial recesses, and/or presence of tumor lesions in the imaged hips.
Results: Preliminary analysis yields AC in 9/57(16%) cases. 48/57 (84%) MRIs demonstrated a malignant lesion, non-AC condition. Further analyses will assess how often hip adhesive capsulitis occurs across age groups, genders, and malignancy types. Quantitative measures of capsular thickening, enhancement, and joint recess distention will help refine characterization of these imaging findings.
Conclusion: Though occurring at a smaller frequency, AC can present as hip pain in patients with known primary malignancy. Recognizing this pattern can help clinicians direct appropriate management and prevent unnecessary concern for metastatic disease.

#6309 Perturbations in gut liver axis functions are associated with chemotherapy induced nausea and fatigue in patients with breast cancer.

Komal Preet Singh[1], Brenda J. Ernst[1], Jun Chen[2], Surendra Dasari[2], Felipe Batalini[1], Cindy Tofthagen[3], Kathryn J. Ruddy[4], Keenan Pituch[5], Linda Chlan[6]

[1]Mayo Clinic Cancer Center Arizona, Phoenix, AZ,[2]Health Science Research, Mayo Clinic, Rochester, MN,[3]Mayo Clinic Cancer Center, Jacksonville, FL,[4]Mayo Clinic Cancer Center, Rochester, MN,[5]Arizona State University, Phoenix, AZ,[6]Mayo Clinic Rochester, Rochester, MN

Background: Up to 50% of patients with breast cancer experience chemotherapy-inducednausea (CIN) and 95% experience fatigue. A comprehensive understanding of biological mechanisms remains elusive. Herein, we evaluated the association of CIN and fatigue with clinical and multi-omics features, including serum and stool metabolites before (T1) to after chemotherapy (T2).
Methods: Patients with breast cancer (n=36) who were to receive chemotherapy, provided symptom assessment using the Memorial Symptom Assessment Scale, stool and blood samples at T1 and T2. Patients provided dietary intake data using a Dietary Screener Questionnaire at T1. Descriptive and univariate analyses evaluated associations of co-occurringsymptoms and diet with CIN and fatigue at T2. Gut microbiome was sequenced using shotgun metagenomics. Targeted metabolomics was performed on stool and serum. Shift in the abundance of taxonomic groups and metabolite levels from T1 to T2 were evaluated in association with CIN and fatigue.
Results: Approximately 64% of the patients experienced CIN and 94% experienced fatigue atT2. Three gastrointestinal symptoms co-occurred with CIN and fatigue. Higher daily average intake of calcium ($p=0.013$) and dairy ($p=0.035$) were associated with CIN. Levels of hexosylceramides, ceramide, phosphatidylcholine and sphingomyelins were significantly perturbed in association with CIN and fatigue ($p<0.05$).
Conclusion: CIN and fatigue are associated with perturbation in the sphingolipid turnover pathway, which negatively impacts functions in the gut-liver axis that include apoptosis activity and change in bile acid levels. Confirmatory studies are warranted to support the development of interventions to alleviate CIN and fatigue in patients with breast cancer receiving chemotherapy.Keywords: breast cancer; chemotherapy-induced nausea; fatigue; metabolites; sphingolipids

#6310 Reduction of infections with intravenous immunoglobulin in chronic lymphocytic leukemia: A single-center retrospective analysis.

Nirja Shah, Tulsi Patel, Thomas J. Kipps, Michael Y. Choi

UCSD Medical Ctr., San Diego, CA

Hypogammaglobulinemia is common in chronic lymphocytic leukemia (CLL). Guidelines recommend Intravenous Immunoglobulin (IVIG) prophylaxis for patients with recurrent, serious infections (e.g., those requiring IV antibiotics or hospitalization) and IgG < 500 mg/dL. Prior trials showed reduced infections with IVIG without survival benefit, but predate modern CLL therapy. This study evaluates infectious outcomes in CLL patients who received IVIG between 2005 - 2022.

This was a single-institution retrospective cohort study of CLL patients. Patients were identified by IVIG receipt and excluded if IVIG was given for other indications (e.g., autoimmune hemolytic anemia). Infection frequency and severity were assessed during the year prior to and the year following IVIG initiation. Treatment history, concurrent therapy, and baseline immunoglobulin levels were also collected.

Of 79 patients identified with IVIG treatment, 48 met inclusion criteria of IVIG use for hypogammaglobulinemia and infections, based on charts available for close review. The median age at IVIG initiation was 58 years; mean time from CLL diagnosis to IVIG initiation was 10.5 years. At initiation, 52% had Rai stage 0-II disease and 48% had Rai stage III - IV disease. Baseline mean IgG prior to IVIG was 411 mg/dL (range 93 - 894 mg/dL) and baseline mean IgA was 42 mg/dL (range 4 - 177 mg/dL).

Pre-IVIG: 73% of patients experienced at least one grade 2 or 3 infection in the year prior to initiation of IVIG. Most patients had recurrent infections; the average number of grade 2 or higher infections was 1.6 (range 0 - 4). Only two patients had a grade 3 infection in the year prior to IVIG initiation, though notably 15 others had prior grade 3 infections since they were diagnosed with CLL. In total, 17 patients (35%) had a grade 3 infection at any time prior to IVIG.

Post-IVIG: Only 12 patients (25%) experienced a grade 2 or higher infection in the year following IVIG initiation, with a mean of 0.375 infections (range 0 - 4). Two of these patients (4%) had grade 3 infections, which were multifocal pneumonia and cellulitis. This represents a 66% relative risk reduction, and a Number Needed to Treat (NNT) of 2.1 to prevent grade 2 or higher infections in the year following IVIG initiation (RR 0.34, P = 0.0001, 95% CI: 0.20 - 0.58). No significant differences were observed between patients with and without post-IVIG infections in prior CLL treatment (75% vs. 83%, p = 0.57), baseline IgG (p = 0.91) or IgA levels (p = 0.93).

To conclude, IVIG prophylaxis significantly reduced both moderate (grade 2 or higher) infections, consistent with prior data. While IVIG is recommended primarily for patients with severe infections (2025 NCCN guidelines), our findings suggest IVIG may also meaningfully reduce grade 2 infections and improve quality of life. Future IVIG studies should incorporate quality of life metrics to define the role of IVIG in modern CLL care.

#6315 High prevalence of clonal hematopoiesis in biopsy-proven MASH and implications for cancer care.

Sourat Darabi[1], Brian T. Lee[2], Tse-Ling Fong[2], Benjamin H. Goldenson[1], Carlos E. Zuazo[1], John S. Cupp[3], Michael J. Demeure[1], Patrick Lee[2], David R. Braxton[1]

[1]Hoag Family Cancer Institute, Newport Beach, CA,[2]Liver Program, Hoag Digestive Health Institute, Newport Beach, CA,[3]Pathology, Hoag Memorial Hospital Presbyterian, Newport Beach, CA

Background: Metabolic dysfunction-associated steatohepatitis (MASH) is a systemic disease increasingly recognized for its oncologic relevance. Patients with MASH face elevated risks of visceral malignancies, including hepatocellular, colorectal, and endometrial cancers. Age-related clonal hematopoiesis (CH)—defined by somatic mutations in peripheral blood cells—is associated with inflammation, cardiovascular disease, malignancy, and therapy-related myeloid neoplasms. Recent studies suggest CH contributes to MASH pathogenesis, yet its prevalence and clinical impact remain unclear. We evaluated the prevalence of CH in biopsy-proven MASH patients within a community hepatology cohort.
Methods: We conducted a cross-sectional study of 20 patients with biopsy-confirmed MASH who underwent next-generation sequencing using a commercial hematologic malignancy panel. CH was defined as the presence of somatic mutations with variant allele frequency (VAF) ≥2.5%. Demographic, metabolic, and hepatic (including transient elastography with FibroScan® and histologic characteristics) parameters were analyzed for association with CH.
Results: Among 20 patients (13 female, 7 male; mean BMI 29; mean age 57.0 ± 15.5 years, range 25-84), CH was detected in 5 (25%; mean age 59.4 ± 12.4 years, range 45-75). Compared with the expected population prevalence of 10% at age 70, the relative risk of CH was 2.5, with an indirect age-adjusted relative risk of 3.07. Detected driver mutations (VAF%) included *ASXL1* (8.2), *ATRX* (3.6), *CBL* (2.7), *DNMT3A* (3.7), and *KMT2C* (4.1). All CH-positive patients were low risk by clonal hematopoiesis risk score (CHRS) and none reported tobacco use. ALT was significantly lower in CH-positive vs CH-negative patients (median 36.5 vs 70 U/L; p = 0.048). No significant differences were observed in age, BMI, AST, NAFLD activity score, fibrosis stage, liver stiffness measurement, or peripheral blood counts.
Conclusions: CH is enriched in biopsy-proven MASH, independent of fibrosis or disease severity. Given its oncologic implications, CH testing may help identify MASH patients at increased risk for cancer and therapy-related complications. Integration of CH screening into hepatology-oncology workflows could enhance risk stratification and inform treatment planning for this high-risk population.

#6316 Accumulation of p21+ cells and enrichment of growth arrest signature in persistent high-grade premalignant lesions.

Alexis Assante[1], Khosbayar Lkhagvadorj[1], Hyunmin Kim[2], Kimberly R. Jordan[3], Daniel T. Merrick[4], Robert L. Keith[1], York E. Miller[5], Moumita Ghosh[1]

[1]Pulmonary, Allergy and Critical Care Medicine, University of Colorado, Aurora, CO,[2]Genetic and Genome Sciences, Case Western University, Cleveland, OH,[3]Department of Immunology and Microbiology, University of Colorado, Aurora, CO,[4]Department of Pathology, University of Colorado, Aurora, CO,[5]Rocky Mountain Regional Veteran Affairs Medical Center, Aurora, CO

Introduction: Lung squamous cell carcinoma is preceded by premalignant lesions (PML) or dysplasia that may persist, progress, or regress. Individuals with persistent PMLs have a significantly higher risk of incident cancer compared to those whose lesions regress. Mechanisms that control dysplasia fate, therefore, could be important for early detection and prevention. Epithelial basal progenitors are critical for maintaining a healthy airway, but their role in determining PML fate has not been studied before.
Methods: Basal progenitors grown from endobronchial biopsies collected from high-risk individuals were assayed for their cardinal features of self-renewal and multipotent differentiation. A combination of cellular, functional, and molecular analyses, including mutations and single-cell (sc) RNAseq, was used to investigate progenitor function and their roles in determining PML fate.
Results: Progenitor function decreased with worsening dysplasia grade, and poor progenitor self-renewal predicted dysplasia persistence and progression to cancer. Mutational analysis of high- and low-self-renewing progenitors did not detect any meaningful difference in overall mutational burden, including oncogenic mutations. Interestingly, there were increased numbers of cells expressing cyclin-dependent kinase inhibitor (CDKN1A) or p21 in the progenitors with low self-renewal compared to those with high self-renewal. Single-cell (sc) RNA-seq of biopsies revealed enrichment of p21-expressing basal cells in lesions with low progenitor self-renewal. VECTRA multiplexed immunofluorescence staining of PMLs confirmed significantly greater numbers of p21+ cells in persistent lesions, and the abundance of p21+ cells increased over time. Integration of the multiplexed immunostaining images with the VISIUM spatial transcriptomic profiles generated from serial sections of the same biopsies allowed for direct alignment of p21 protein expression and the corresponding transcriptomic features. A spot-level differential analysis between six $p21^{high}$ and $p21^{low}$ regions from four PMLs revealed the enrichment of specific pathways (primary cilium, cell-cycle arrest, DNA damage responses, metabolic rewiring, and immune engagement) in $p21^{high}$ spots.
Conclusions: p21 is a key determinant of cell cycle progression, and increased expression of this molecule indicates growth arrest by induction of a transient G0 state. The discovery of p21+ cells in PMLs containing low self-renewing progenitors and spatial analyses confirming the presence of a cell-cycle arrest signature in the $p21^{high}$ areas in multiple high-grade PMLs indicated a role of these pathways in determining PML fate. Future studies will focus on analyzing these signatures in independent PMLs with a known natural history of persistence, progression, and regression.

#6317 A reference-free PCR assay for absolute quantification of cancer methylation biomarkers.

Ziming Li, **Huichuan Yu**

The Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China

Background:DNA m5C methylation is a valuable resource for disease biomarkers widely applied in diagnosis. However, current qPCR methods rely on reference assays of genes or repetitive elements (e.g., ACTB, ALU-C4) for data normalization, which may bring inaccuracy and false negatives. To overcome these limitations, we developed a reference-free qPCR technology, MeRFPCR, that enabled accurate and absolute quantification of m5C methylation without external normalization.
Methods: MeRFPCR utilized uncomplementary sense and antisense DNA strands yielded from C-to-T conversion in bisulfite treatment, allowing the design of two sets of primers and fluorescent probes targeting the methylated CpGs in the sense strand and the adjacent CpG-free region in the antisense strand. An absolute methylation level was quantified as the ratio of the methylated signal to the CpG-free signal following PCR amplification, eliminating the need for external reference normalization. We evaluated specificity, sensitivity, and reproducibility across multiple loci, and benchmarked MeRFPCR against quantitative methylation-specific PCR (qMSP) with external reference normalization and bisulfite pyrosequencing. The assay was further applied to detect cancer methylation biomarkers in both tissue and liquid biopsy samples.
Results: MeRFPCR preserved robustness under challenging conditions, yielding reproducible methylation percentages across technical replicates (CV <5%) with inputs as low as 2 ng and fragment sizes ranging from 80 to 200 bp. In 20 matched tumor and adjacent normal tissues from colorectal cancer patients, *SEPT9* methylation measured by MeRFPCR showed excellent concordance with pyrosequencing (R^2 = 0.97) and distinguished all tumors from normal tissues. In contrast, qMSP showed lower concordance (R^2 = 0.73) and failed to resolve tumor-normal differences in several cases (sensitivity 90%). Of note, the workflow of MeRFPCR is faster, easily accessible and more cost-effective compared with pyrosequencing. In addition, MeRFPCR accurately detected methylated *SEPT9* in circulating cell-free DNA from as little as 300 µL of plasma in metastatic CRC patients. These findings support the technical accuracy and advantages of MeRFPCR resulting from the reference-free methods, highlighting its specific diagnostic potential in compromised samples and across laboratory settings where reference-based assays are limited.
Conclusion: The MeRFPCR technique is a fast, accurate, cost-effective, and reference-free method for absolute quantification of DNA methylation. It holds promise for reducing batch effects across platforms and improving detection in challenging clinical samples, including liquid biopsy and stool DNA. These findings highlight the potential of MeRFPCR as a basic and valuable tool for facilitating noninvasive detection of cancer methylation biomarkers and broader epigenetic applications.

#6318 Distinct molecular signatures in dense breast tissue as potential drivers of breast cancer development.

Jay William Fox[1], Natalia Dworak[2], Patcharin Pramoonjago[3], Christopher A. Moskaluk[4], **Ana Karina de Oliveira**[3]

[1]Assoc. Director, University of Virginia Cancer Center, Charlottesville, VA,[2]Spatial Biology Core, University of Virginia School of Medicine, Charlottesville, VA,[3]Department of Pathology, University of Virginia School of Medicine, Charlottesville, VA,[4]Assoc. Professor, Dept. of Pathology, University of Virginia Health System, Charlottesville, VA

Breast density is a significant independent risk factor for breast cancer; women with dense breasts have a 4-6-fold increased risk of the disease compared to women with non-dense breasts. It has been suggested that 30% of all breast cancer cases occur in women with > 50% dense areas. Breast density reflects variations in breast tissue composition. It is characterized by high proportions of stroma, containing collagen and other ECM proteins, fibroblasts, endothelial cells, and immune cells, suggesting a pro-tumor inflammatory microenvironment. To investigate molecular differences between dense and nondense breast tissue and their association with triple-negative breast cancer (TNBC), we used the PanCancer IO 360 panel to explore RNA expression and signaling pathway regulation across the samples. We observed differences in RNA expression among subjects, thereby identifying distinct molecular groups in dense breasts. The subjects were clustered into 3 subtypes with distinct molecular signatures and biological pathways. We identified a group (G1) with increased expression of genes involved in inflammatory processes, but still maintains a closer association with the phenotype of non-dense breasts. We also identified two other groups (G2 and G3) that are more distinct regarding the non-dense group and different from each other. These groups are related to reorganization and cellular architecture in the microenvironment (G2) and to proliferative regulation, cancer pathways, and increased gene expression in tumor development (G3). These groups do not seem to correlate with age or menopause stage in this first screen; instead, they resemble more subtypes of density or stages of density development. Additionally, analyzing RNA expression in TNBC samples, we identify an association with dense G3 samples that express more RNAs related to DNA repair, with upregulation of pathways in DNA damage, epigenetic regulation, apoptosis, and metabolic stress. At the same time, the pathways such as interferon signaling, immune cell adhesion and migration, and NF-kappa-beta are downregulated. These results suggest that specific density subtypes with distinct molecular signatures may promote tumor development more than others. To better understand this association and determine whether there are similarities in the resident cells of dense breast and TNBC samples, we are conducting spatial biology analyses to explore their microenvironments. The accurate classification of these subtypes has the potential to impact breast cancer prevention strategies and early diagnosis. Further investigations with a larger cohort are underway to understand better how molecular alterations in dense groups contribute to tumor development.

#6319 Using paired germline genome to predict the age of onset in pediatric cancer.

Kai Ren Chen[1], Safa Majeed Grant[1], Brianne Laverty[1], Ashby Kissoondoyal[1], Adam Shlien[2], David Malkin[3]

[1]Genetics and Genome Biology Program, The Hospital for Sick Children, Toronto, ON, Canada,[2]Pediatric Laboratory Medicine, The Hospital for Sick Children, Toronto, ON, Canada,[3]Division of Hematology/Oncology, The Hospital for Sick Children, Toronto, ON, Canada

Background: Germline events play a role in influencing the age of onset of pediatric cancers, but their specific contribution remains incompletely understood. Approximately 18% of children with cancer harbor a germline gene mutation associated with a Cancer Predisposition Syndrome (CPS). However, this fraction is believed to be an underestimation, given that a substantially larger proportion of childhood cancers is thought to have a genetic basis due to the limited environmental exposure in children compared with adults. Carriers of cancer predisposition gene mutations typically undergo clinical surveillance for early tumor detection. However, many children carry germline risk that would not be recognized by their cancer or family cancer phenotypes and are therefore not identified for surveillance, reflecting a major gap in leveraging whole genomic data for individual prediction. One notable example of a monogenic CPS is Li-Fraumeni Syndrome (LFS), caused by germline mutations in the *TP53* tumor suppressor gene. Our lab has demonstrated that additional (epi)genetic events that modify the LFS phenotype and enable more precise prediction of tumor onset, underscoring the need for a better understanding of the contribution of germline events to age of onset across pediatric cancers. In this study we analyze a broad range of pediatric cancer types, using their paired germline genomes to develop machine learning (ML) models that predict age of onset, uncover genomic predispositions, and support earlier tumour detection.
Methods: Whole genome sequencing data from the SickKids Cancer Sequencing (KiCS) program's initial cohort of poor-prognosis childhood cancer patients (n=333), ~18% of whom meet CPS criteria, were analyzed. After grouping germline variants by gene and pathogenicity according to ACMG guidelines, these variants were used as input features for UMAP and random forest models to classify the age of onset. Generative AI was used solely to modify code, refine written content, and identify relevant journal articles. All AI-assisted content was verified.
Results and Conclusion: Preliminary models achieved an average AUROC of ~0.63 in classifying onset before versus after various selected ages (1-17). These findings suggest that genomic profiles are dependent on developmental stages. The UMAP performed on the same variants led to the observation that one cluster contained a higher proportion of pediatric-enriched cancer subtypes (75%) compared to the other clusters (58%). Preliminary findings suggest that genomic profiles that are more consistent with hereditary cancer can be separated from genomic profiles that are more consistent with sporadic cancer. Integrating genomic data with predictive modelling may improve our understanding of how germline events collectively influence age of onset across pediatric cancer types, which could inform risk stratification in clinical surveillance protocols.

#6320 Plasma proteomics of cancer risk in patients with chronic kidney disease.

Lucas A. Mavromatis[1], Aditya Surapaneni[1], Carina Flaherty[1], Peter Ganz[2], Lawrence J. Appel[3], Morgan E. Grams[1]

[1]Department of Medicine, NYU Grossman School of Medicine, New York, NY,[2]Department of Medicine, University of California, San Francisco, San Francisco, CA,[3]Welch Center for Prevention, Epidemiology and Clinical Research, Johns Hopkins University, Baltimore, MD

Background Patients with chronic kidney disease (CKD) have higher cancer risk and worse cancer outcomes than the general population. Although circulating proteins are important biomarkers of incident and recurrent cancer, CKD profoundly remodels the proteome. High-throughput proteomic assays enable systematic interrogation of protein-phenotype associations and can disentangle CKD-specific proteomic biomarkers and pathways of cancer risk.

Methods We analyzed 4,091 plasma proteins measured by SomaScan (v4) at the year 1 visit of the Chronic Renal Insufficiency Cohort study (CRIC). The cohort included participants without prior cancer and with complete baseline covariates. For each protein, we fit Cox models for time-to-event (breast, colon, head & neck, leukemia, lung, lymphoma, prostate, and overall cancer). Fully adjusted models included age, sex, race, eGFR, smoking history, alcohol use, urine albumin-to-creatinine ratio, body mass index, diabetes, prior cardiovascular disease, and socioeconomic indicators. We reported Benjamini-Hochberg FDR-significant proteins and flagged “nominal” associations ($P < 0.001$ and HR per SD ≥ 1.5 or ≤ 0.67). Downstream analyses assessed overlap between proteomic signatures across cancer types. Hallmark and KEGG enrichment analyses highlighted biological pathways associated with oncologic endpoints.

Results Among the 2,975 participants who met study inclusion criteria (median age 59.5 years, 45.2% female), 395 developed cancers over a median of 12.5 years. Across cancer types, 78 proteins were FDR significant in demographics-adjusted models. In fully adjusted models, 37 met the nominal significance threshold and 12 remained FDR-significant, spanning colon, leukemia, lung, and prostate cancers. Many identified proteins were biologically plausible: higher soluble CD163—a marker of tumor-associated macrophages—was associated with colon cancer; Gremlin-2, a DAN-family BMP antagonist implicated in hematopoietic dysregulation, was associated with leukemia; RAN-binding protein 3, a regulator of nuclear export and TGF-β signaling, was associated with lung cancer; and cystatin C, a kidney filtration marker, was inversely associated with prostate cancer risk. Cancer types displayed distinct protein signatures, but pathway enrichment overlapped across outcomes, highlighting shared biological processes including epithelial-to-mesenchymal transition, KRAS signaling, inflammatory signaling, and cell adhesion.

Conclusions Plasma proteomics revealed early circulating biomarkers associated with future cancer in CKD. Many identified proteins have established or mechanistically plausible roles in cancer biology. Protein-cancer associations were cancer type-specific; however, the proteomic signatures of different cancers converged on known oncogenic pathways. Identified proteins, if replicated, might facilitate earlier detection of cancer in CKD.

#6321 Characterizing plasma protein LEG1 homolog, a novel potential risk factor for post-menopausal breast cancer.

Vernon A. Burk, **Elizabeth A. Platz**

Johns Hopkins Bloomberg School of Public Health, Baltimore, MD

Background: We previously identified and confirmed a positive association between plasma protein LEG1 homolog and post-menopausal breast cancer risk in 2 cohort studies in models adjusted for breast cancer risk factors. This evolutionarily conserved protein is understudied. We now aim to characterize the protein's within-person variation over time, its correlates and residual association after accounting for correlates.

Methods: We analyzed data from the Atherosclerosis Risk in Communities study, in which we first identified the protein (Syleouni M et al. *JNCI* 2025). We included 4,403 post-menopausal women (74% not taking hormone replacement therapy [HRT]) without cancer. Plasma proteins were previously measured by SomaScan® 5K at Visits 2, 3 and 5 (3, 18 years apart). We used demographic, anthropometric, lifestyle, and reproductive data collected by interview or measured by trained staff. Previously, plasma estradiol and testosterone were measured. We assessed within-person variation over time (ICC) and identified correlates of LEG1 after $\log_2$ transformation (linear regression). We re-analyzed the LEG1-breast cancer association stratifying by or adjusting for the correlates using multivariable-adjusted Cox regression. For highly correlated factors, we first regressed LEG1 on each correlate and then modeled LEG1 residuals.

Results: The ICC for LEG1 was 0.52 across the 3 time points. LEG1 was highly correlated with prolactin-inducible protein (r=0.95) and extracellular glycoprotein lacritin (r=0.86); these correlations were almost identical by age, race, HRT use, BMI, and diabetes. The remaining 4,709 proteins had $r< |0.35|$, including weak correlations for kidney function (albumin, ALT, AST) and inflammation (CRP) markers. LEG1 was only weakly correlated with estradiol (measured 3 years apart, N=316, r=0.13, p=0.02) and testosterone (measured 3 years apart, N=3,134, r=0.05, p=0.02). LEG1 declined modestly with age (p<0.0001). Adjusting for age, level was notably higher in Black than White women (p<0.0001). Adjusting for both age and race, LEG1 level was lower in women with higher BMI and diabetes. Direction of the association appeared to differ by race for HRT use (level was higher in users in White women only) and reproductive factors. The residuals of LEG1 after regression on prolactin-inducible protein (p=0.0001) or extracellular glycoprotein lacritin (p=0.015) were statistically significantly positively associated with breast cancer. Associations for LEG1 were stronger in women not using HRT, ≥median BMI, and with diabetes; we previously reported no difference in the association by race.

Conclusions: This study provides continued support for plasma protein LEG1 homolog as a risk factor for post-menopausal breast cancer. This protein should be considered for its utility in current risk stratification tools. Mechanistic studies are needed. Support: NHLBI, NCI, NPCR

#6322 Uncovering causal protein markers in prostate tissue for prostate cancer: A proteome-wide association study and functional validation.

Jingjing Zhu[1], Pramod KC[1], Sweaty Koul[1], Yijun Tian[2], Hua Zhong[1], Thomas G. Beach[3], Hyeyoon Kim[1], Athena A. Schepmoes[4], Karl K. Weitz[4], Tyler Sagendorf[4], Tao Liu[4], Maarit I. Tiirikainen[5], Lucio Miele[1], Nicholas Mancuso[6], Timothy R. Rebbeck[7], David V. Conti[6], Christopher A. Haiman[8], the PRACTICAL/ELLIPSE consortium, Chong Wu[9], Liang Wang[2], Hari K. Koul[1], Lang Wu[1]

[1]Louisiana State University Health Sciences Center, New Orleans, LA,[2]Moffitt Cancer Center, Tampa, FL,[3]Banner Sun Health Research Institute, Sun City, AZ,[4]Pacific Northwest National Laboratory, Richland, WA,[5]Associate Specialist/Genomics Shared Resource, University of Hawaii Cancer Center, Honolulu, HI,[6]University of Southern California, Los Angeles, CA,[7]Dana-Farber Cancer Institute, Boston, MA,[8]Co-Director, USC Genomics Ctr., USC Norris Comprehensive Cancer Center, Los Angeles, CA,[9]UT MD Anderson Cancer Center, Houston, TX

Background: Prostate cancer (PCa) is the second most frequently diagnosed malignancy among men. While multiple protein markers have been implicated in PCa, findings from conventional studies are often inconsistent due to methodological limitations such as selection bias and uncontrolled confounding. The proteome-wide association study (PWAS) design leverages genetic instruments to identify protein biomarkers with potential causal roles in diseases. Although candidate causal proteins in blood have been identified for PCa in our previous work, few studies have focused on prostate tissue.

Methods: We conducted the first prostate tissue-based PWAS using data from the PRACTICAL/ELLIPSE consortia, comprising 122,188 PCa cases and 604,640 controls. Proteomic and genomic data were generated from 201 frozen prostate tissue samples without PCa, quantifying 11,575 proteins. We used data of 195 unrelated subjects for model building. Prediction models for protein abundance were built using nearby unambiguous SNPs of potentially associated variants, applying BLUP, LASSO, elastic net, and top1 methods. Association testing was performed for genetically predicted protein levels with PCa risk and aggressiveness. For one of the identified proteins eIF4G1, we performed knockdown of its gene expression in androgen-sensitive (LNCaP), enzalutamide-resistant LNCaP (NO-LNCaP-ENZR), and castration-resistant (22RV1) PCa cell lines, and investigated the effects on multiple phenotypes. Survival analysis was also performed using TCGA primary PCa RNA-seq data.

Results: A total of 1,034 protein models achieved cross-validated $R^2 > 0.01$ and were retained for association testing. Fifty-six proteins showed significant associations with PCa risk, including 18 associated with advanced disease and seven distinguishing advanced from non-advanced cases. One of the top novel proteins, EIF4G1, is required for the initial steps of translation. Disrupting eIF4F complex activity via *EIF4G1* knockdown reduced cell proliferation, colony formation, and spheroid culture growth, and decreased cell migration and invasion. *EIF4G1* knockdown also sensitized LNCaP cells to enzalutamide treatment and inhibited clonogenic potential of enzalutamide-resistant cells. Pharmacological inhibition of eIF4F with SBI-756 reproduced these effects and induced G1 phase cell cycle arrest. Polysome profiling revealed decreased mRNA loading onto polysomes, indicating that knockdown of *EIF4G1* impaired cap-dependent translation. Elevated expression of *EIF4G1* in tumors was also associated with shorter disease-specific survival.

Conclusions: Our study reveals novel prostate tissue proteins putatively causally linked to PCa risk and aggressiveness. Our functional work suggests that a novel protein, eIF4G1, presents a new target for limiting PCa progression and overcoming therapy resistance.

#6323 Plasma proteomic profiling reveals shared biomarkers for MASLD-related hepatocellular carcinoma and gastrointestinal cancers in the UK Biobank.

Qing Wang, Yacong Zhang, **Ke-Xin Chen**

Tianjin Medical Univ. Cancer Inst. & Hospital, Tianjin, China

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is a major global health challenge and markedly elevates the risk of hepatocellular carcinoma (HCC) and extrahepatic gastrointestinal (GI) cancers. Reliable biomarkers for early detection in MASLD populations remain lacking. We leveraged large-scale plasma proteomic profiling from the UK Biobank to identify circulating protein markers for MASLD-related HCC and GI cancers.
Methods: We performed a nested case-control study within the UK Biobank. Differentially expressed plasma proteins were identified and evaluated using Gene Ontology, Kyoto Encyclopedia of Genes and Genomes (KEGG) pathway enrichment, and protein-protein interaction (PPI) network analyses. Overlapping dysregulated proteins between cancer types were mapped to determine shared pathways.
Results: The UK Biobank cohort included 19,341 MASLD patients with proteomics data (mean age 61.1 ± 6.3 years), comprising 40 MASLD-HCC cases and 589 MASLD-GI cases. After excluding samples with protein data missing rates exceeding 30%, the study included 33 MASLD-HCC cases and 516 MASLD-GI cancer cases, matched 1:3 by age and sex to 99 and 1,548 MASLD controls, respectively.Quantitative proteomics identified 45 significantly dysregulated (44 upregulated and 1 downregulated) proteins in MASLD-HCC compared to MASLD, including established HCC-related keratins (e.g., KRT8, KRT18) and novel candidates (e.g., SPINT3, ADGRG1). Enriched pathways highlighted lipid metabolic dysfunction and xenobiotic metabolism. IL-6 and AGXT emerged as central hub genes in the PPI network. In MASLD-GI cancers, 24 proteins were significantly altered. Notably, 14 proteins were consistently dysregulated across both MASLD-HCC and MASLD-GI cancers, including CDHR2, INSL3, GPRC5C, FGF21, MME, CES1, KRT18, ADGRG1, HAO1, KLK3, GAST, and FOLR3.
Conclusion: This large prospective proteomic study delineates distinct and overlapping plasma protein signatures of MASLD-related cancers. The shared biomarkers map to a unified "metabolism-damage-inflammation" axis, suggesting common mechanisms underlying carcinogenesis in MASLD. These findings provide a promising biomarker panel with potential utility for multi-cancer early detection and risk stratification in MASLD populations.

#6324 A proteomics-based model improves the accuracy of upper gastrointestinal cancer prediction.

Xinyu Liu, Zhangyan Lyu, **Kexin Chen**

Tianjin Medical University Cancer Institutet and Hospital, Tianjin, China

Background: Upper gastrointestinal cancers (UGI), including esophageal cancer (EC), gastroesophageal junction cancer (GEJ), and gastric cancer (GC), pose a major global health burden, with prognosis heavily dependent on early diagnosis. Current screening strategies inadequately identify high-risk individuals. While advances in proteomics offer promise for risk assessment and early detection, their application in UGI cancer screening remains underexplored.
Methods: We conducted a prospective analysis within the UK Biobank. Participants were randomly divided into training and testing sets at a 7:3 ratio. Among proteins measured using the Olink Explore 3072 panel, those with >30% missing values were excluded, resulting in a final analysis set of 2,920 proteins. The associations of proteins with UGI cancer were identified by Cox proportional hazards models (FDR < 0.05). L1-penalized LASSO-Cox regression with ten-fold cross-validation was then applied to select candidate proteomic biomarkers. Then, two risk prediction models (a simple model based on epidemiological factors and an integrated model that further incorporated proteins) were developed and internally validated. The discrimination of the models was assessed using the area under the curve (AUC) and compared via DeLong's test.
Results: After excluding participants with baseline cancer or missing data, 48,366 individuals were included (median follow-up: 14.7 years; 261 UGI cancer cases). We identified 912 proteins significantly associated with UGI cancer (830 risk-related, 82 protective). LASSO-Cox regression refined this set to 46 proteins (31 risk, 15 protective), including five novel risk-related proteins—TEX101, MYBPC1, KIR2DL3, CLSTN2, and ADAMTS4—while the remaining 41 have been previously reported in the literature. Compared to the traditional model, which incorporated a novel high-risk status variable (defined as age ≥45 years plus at least one of: smoking history, heavy alcohol consumption, precancerous lesions, *Helicobacter pylori* infection, or an unhealthy diet), the integrated model demonstrated superior diagnostic performance, with significantly higher AUCs in both the training set (0.83 [95% CI: 0.80-0.86] vs. 0.70 [0.67-0.73]) and the testing set (0.81 [95% CI: 0.77-0.85] vs. 0.69 [0.65-0.74]; DeLong's test, $p < 0.05$).
Conclusion: We developed an integrated model that combines 46 plasma protein biomarkers with traditional epidemiological factors. This approach demonstrated superior performance over the traditional model in identifying UGI cancer. Further prospective studies in diverse regions and populations are needed to validate the generalizability of this promising early screening strategy.

#6325 Smoking and sex specific proteomic markers of lung cancer: A prospective cohort study.

Zhangyan Lyu, Xinyu Liu, Kexin Chen

Tianjin Medical University Cancer Institute and Hospital, Tianjin, China

Background While circulating proteins hold promise for elucidating lung cancer (LC) etiology, large-scale studies comprehensively assessing their associations with LC risk are limited. Crucially, the roles of these proteins across different sexes and smoking statuses, particularly in females and non-smokers who constitute a significant proportion of LC cases with distinct etiology, remain poorly characterized.

Methods We integrated observational analyses from the UK Biobank (UKB) cohort (N=49,370 cancer-free at baseline; 444 incident LC cases; median follow-up 11 years) with two-sample Mendelian randomization (MR). Plasma levels of 2,920 proteins were measured at baseline. Cox regression identified proteins associated with incident LC, with stratified analyses by sex and smoking status. MR used cis-pQTLs from UKB-PPP and deCODE studies as instruments for proteins and LC GWAS data from FinnGen, TRICL, and Pan-UKBB. Robust causal evidence was defined by a significant MR result (IVW $P<0.05$) combined with either a colocalization posterior probability (PPH4) > 0.75 or a significant SMR result (HEIDI $P>0.01$).

Results Sex-stratified analysis revealed 532 significant proteins in males and 375 in females. Among these, 271 were male-specific (e.g., C1R, HR=5.48, 95%CI: 2.23-13.50) and 114 were female-specific (e.g., SMAD5, HR=4.53, 95%CI: 2.39-8.58). Only 261 proteins were shared between sexes. Smoking-stratified analysis identified 683 significant proteins in smokers and 39 in non-smokers. A vast majority (657 proteins) were smoker-specific, including top risk protein SERPINA1 (HR=24.62, 95%CI: 5.65-107.39) and top protective protein GSN (HR=0.15, 95%CI: 0.09-0.27). In contrast, only 13 proteins were non-smoker-specific, such as risk protein CYTL1 (HR=3.46, 95%CI: 1.11-10.82) and protective protein CNTN4 (HR=0.17, 95%CI: 0.07-0.45). MR analysis provided genetic support for IL19 for LC among smokers (OR=1.18, 95%CI: 1.03-1.35 from cis-MR; OR=1.12, 95%CI: 1.01-1.23 from SMR).

Conclusion This study unveils strikingly distinct proteomic signatures of LC risk by sex and smoking status, predominantly in males and smokers, with genetic validation for key candidates like IL19. These findings underscore etiological heterogeneity and support stratified approaches to LC risk prediction and prevention, pending external validation in diverse populations.

#6326 Pregnancy, lactation, and involution-induced remodeling and cell state changes in breast tissues of healthy women.

Poornima Bhat-Nakshatri[1], Cihat Erdogan[1], Hongyu Gao[1], Yunlong Liu[1], Rana German[1], Michele L. Cote[2], **Harikrishna Nakshatri**[1]

[1]Indiana University School of Medicine, Indianapolis, IN,[2]IUPUI Fairbanks School of Public Health, Indianapolis, IN

Pregnancy, lactation, and involution have opposing effects on breast cancer incidence and tumor aggressiveness. While breast feeding and subsequent involution protects against breast cancers, pregnancy-associated breast cancers (breast cancers diagnosed during pregnancy and within 2 years postpartum) are associated with poor outcome. Clear understanding of these opposing effects of reproductive cycle needs single cell resolution of breasts during pregnancy, lactation and involution. We recently reported a reference single nucleus chromatin accessibility and transcriptome atlas of breast tissues of women of diverse genetic ancestry and reported 10 major cell types in the breasts. These include three epithelial cell types [luminal hormone sensing (LHS), luminal adaptive secretory precursors (LASP), and basal-myoepithelial cells (BM)], two adipocyte subtypes, two endothelial cell subtypes, T cells, macrophages, and fibroblasts. In this study, we generated single nucleus atlas of breast tissues of healthy women collected during pregnancy, lactation, and involution. Pregnancy, lactation, and involution are associated with dramatic changes in cell type proportions and cell state shifts within a cell type. LASP cell numbers increased from 24% in the normal reference breasts to 71% during pregnancy, 63% during lactation but returned to 25% during involution. There is also a dramatic shift in LASP cell states during pregnancy, lactation and involution. While the LASP cells in the normal reference breasts and breasts during pregnancy were in both LASP-basal-luminal (LASP-BL) and LASP-alveolar (LASP-AP) states, LASP-AP cells were dominant in lactating and involuting breasts. Increase in LASP cells during pregnancy and lactation is at the expense of BM cells, which reduced from 27% in the normal reference breasts to 7-9% during pregnancy and lactation. While T cell proportion was similar between normal reference and pregnant breasts (2-3%), it increased to 7-8% during lactation and involution, which a recent study has suggested to be responsible for breast feeding-associated protection against breast cancer. Increase in T cells during lactation and involution is likely due to expansion of tissue resident T (T_{RM}) cells as T cells of lactating and involuting breasts expressed higher levels of T_{RM} cell markers CD69 and CXCR6. We present pregnancy, lactation and involution-associated chromatin accessibility and transcriptome changes at individual gene and cell type levels. Several biomarkers associated with these changes have been identified, which will be a useful resource to mechanistically evaluate evolution of breasts during reproductive history and breast cancer development.

#6327 Translation of lung cancer biomarkers from nanoparticle-based LCMS to enzyme-linked immunosorbent assay.

Nga Ho, Jinlyung Choi, Guanhua Shu, Alicia Furlan, Ghristine Bundalian, Arcel Cunanan, Janelle Dela Vega, Jacob Waiss, Zachary Yanagihara, Joon-Yong Lee, Robert Zawada, Chinmay Belthangady, Brian Koh, Manway M. Liu, Bruce Wilcox

PrognomiQ Inc, San Mateo, CA

Lung cancer is the leading cause of cancer-related mortality in the United States. Newly diagnosed lung cancer patients generally have poor prognoses, in large part due to being diagnosed at later stages of disease. Earlier diagnoses, enabled by more effective screening, are expected to reduce morbidity and mortality. In pursuit of this, we previously reported on an unbiased, multi-omics discovery study to identify blood-based biomarkers for lung cancer that may be developed into a more effective screening test. A machine-learned model trained on nanoparticle-based LCMS measurements could achieve a specificity of 74% at a sensitivity of 85% across all lung cancer stages and sensitivity of 74% on stage-1 lung cancer alone. These results illustrate the power of unbiased LCMS plasma proteomics to identify proteins with high disease discrimination; however, there is limited demonstration of translating findings from nanoparticle-based unbiased LCMS proteomics to immunoassays. Here, we report on the translation of 8 of the most cancer discriminative, plasma proteins identified from our discovery study to enzyme-linked immunosorbent assay (ELISA). On a set of 404 subjects (110 cancer and 294 non-cancer) from the discovery study, a machine-learned model trained on nanoparticle-based LCMS measurements of these 8 proteins achieved an AUROC of 0.93 (95% CI 0.90-0.96) and $\geq$ 80% specificity at 87.5% sensitivity. The corresponding model trained on ELISA measurements of the same 8 proteins achieved an AUROC of 0.90 (95% CI 0.86-0.94) and $\geq$ 70% specificity at 87.5% sensitivity. The directionality and magnitude of the fold-changes between cancer and non-cancer subjects were preserved for each of the 8 proteins between the two assays. Statistically significant (adjusted p-value $\leq$ 0.05) and positive Spearman correlations were also observed between measurements of each of the 8 proteins on these two assays across the 404 subjects. These results demonstrate the feasibility of translating from nanoparticle-based LCMS to immunoassays while preserving lung cancer discriminative signals and set the foundation for the development of an immunoassay-based Lab Developed Test (LDT) for lung cancer detection.

#6328 Expression of hypoxia-inducible factor 1-alpha in diverse histological types of uterine cervical carcinoma and correlation with the aggressiveness of tumor type: An immunohistochemical study.

Conwell Ngobeni[1], Meshack Bida[1], Benny Mosoane[1], Rahaba Marima[2], Tebogo Marutha[2], **Zodwa Dlamini**[2], Tebogo Medupe[1]

[1]Department of Anatomical Pathology, University of Pretoria, Pretoria, South Africa,[2]Pan African Cancer Research Institute (PACRI), University of Pretoria, Pretoria, South Africa

Background:
Cervical cancer is the fourth leading cause of cancer-related deaths in women worldwide, with high prevalence in South Africa. High-risk human papillomavirus (HPV), along with genetic and epigenetic alterations, drives cervical carcinogenesis. Hypoxia-inducible factor 1-alpha (HIF-1α) is frequently expressed in cervical carcinoma and other solid tumors. Under normoxia, HIF-1α is degraded via the Von Hippel-Lindau pathway, while hypoxia stabilizes it, inducing angiogenic factors. HIF-1α immunohistochemistry has been proposed as a prognostic and therapeutic marker; however, previous studies are limited by small cohorts, single-center designs, and variable histology. This study assessed HIF-1α expression across cervical carcinoma subtypes and its association with tumor aggressiveness.
Methods:
We conducted a retrospective study of cervical carcinoma cases diagnosed at the University of Pretoria (2017-2022). Archived formalin-fixed paraffin-embedded tissues were retrieved, yielding 63 cases. HIF-1α immunohistochemistry was performed, and three pathologists independently scored staining using a modified quick Allred system, classifying cases as positive if the combined score exceeded zero.
Results:
HIF-1α expression was positive in 19/63 cases (30%) and negative in 44/63 (70%). Basaloid squamous cell carcinoma accounted for 26% of positive cases, CIN III-like and papillary squamous-urothelial carcinomas each 21%, adenoid basal, papillary squamous, and clear cell carcinomas 10% each, and adenosquamous carcinoma 5%. No adenoid cystic, small cell, or villoglandular carcinomas were positive. Positivity within subtypes was highest in papillary squamous-urothelial (57%) and clear cell (50%) carcinomas, followed by basaloid squamous cell (38%), adenoid basal (33%), CIN III-like and papillary squamous cell (28.5%), and adenosquamous (25%).
Conclusion:
HIF-1α is expressed in a subset of cervical carcinomas, predominantly in histological variants associated with aggressive behavior, suggesting a potential link with poorer prognosis. Limited sample size and single-center design warrant caution. Larger multicenter studies with clinical follow-up are needed to clarify whether HIF-1α can guide prognostic assessment or targeted therapy in cervical carcinoma.

#6329 Improved sensitivity in high-risk HPV genotype detection via processor-mediated PCR.

Niloufar Mertz, Eric K. Pomaranski, Adam McCoy, Vladimir Makarov

Signal Bioscience, Ann Arbor, MI

High-risk human papillomavirus (hrHPV) genotypes, particularly HPV16 and HPV18, drive the majority of cervical and several anogenital and oropharyngeal cancers. Although molecular screening assays have grown more sensitive, major limitations remain. Current NGS-based methods offer genotype resolution but are costly, slow, and difficult to implement in routine screening. Digital PCR (dPCR) provides absolute quantification, but most assays target only one or two conserved regions, making it difficult to distinguish transforming infections from transient or non-oncogenic HPV. Additionally, HPV DNA in patient samples is often fragmented, integrated, or present at low abundance, complicating amplification and reducing both sensitivity and specificity. We developed a Processor-Mediated PCR that decouples amplification from fluorescent readout using a universal processor oligo and tunable universal probes. This enables high multiplexing regardless of instrument channel count. To improve specificity, we created iProbes, multi-domain probes that trigger fluorescent response only when their full target sequence is present, allowing discrimination between oncogenic and non-oncogenic HPV even within highly conserved regions. Using HPV16 as a model, we built a multi-fragment assay that detects 10 genomic regions (<90 bp each), including E6/E7 oncogenic segments, in a single dPCR or qPCR reaction. Processor-Mediated PCR is tunable to multiple applications and supports either multichannel or single-channel fluorescent readouts, ensuring compatibility with instruments with limited channel capacity. This broad molecular coverage enhances detection of fragmented or partially degraded viral genomes. Together, Processor-Mediated PCR and iProbe-based multiplexing provide sensitive, high-specificity detection of cancer-associated HPV fragments in one assay, addressing key limitations of current NGS and PCR methods and improving HPV screening and triage.

#6330 Evaluating targeted versus universal BRCA testing in Asian women with ovarian cancer.

Boon Hong Ang[1], Sook-Yee Yoon[2], Joanna Lim[3], Nur Tiara Hassan[2], Mei-Chee Tai[1], Zhi Lei Wong[1], Jo Yi Chow[1], Xin Wen Lee[1], Meow-Keong Thong[4], Gaik-Siew Ch'ng[5], Jamil Omar[6], Chee-Meng Yong[7], Ismail Aliyas[8], Rozita Abdul Malik[9], Suguna Subramaniam[10], Wee-Wee Sim[11], Chun-Sen Lim[12], Saw-Joo Lee[13], Keng-Joo Lim[14], Mohamad Nasir Shafiee[15], Fuad Ismail[16], Mohd Pazudin Ismail[17], Mohamad Faiz Mohamed Jamli[18], Suresh Kumarasamy[19], John Seng Hooi Low[20], Ahmad Muzamir Ahmad Mustafa[21], Mary Jenifer Makanjang[22], Shahila Tayib[23], Nellie Lay Chin Cheah[24], Chee-Kin Fong[25], Kean-Fatt Ho[26], Azura Deniel[27], Soo-Fan Ang[28], Ahmad Radzi Ahmad Badruddin[29], Lye-Mun Tho[30], Boon-Kiong Lim[9], Yin Ling Woo[9], Weang-Kee Ho[31], Soo-Hwang Teo[1]

Radzi's Integrated Oncology Clinic & Daycare Centre, Johor Bahru, Malaysia,[30]Beacon Hospital Sdn Bhd, Petaling Jaya, Malaysia,[31]Univ. of Nottingham Malaysia, Semenyih, Malaysia

Background: Germline genetic testing for BRCA1 and BRCA2 pathogenic variants (PVs) is recommended for all ovarian cancer patients, as identifying PVs informs treatment planning and facilitates family cascade testing. However, in resource-limited settings, high testing costs often limit feasibility and uptake. An alternative approach is to use predictive models to prioritize patients with a higher likelihood of carrying PVs, optimizing resource allocation. Existing models are largely Western-derived and underperform in Asians; while we have a validated model for breast cancer, no equivalent model currently exists for ovarian cancer.
Methods: Using data from a multi-center study of 1,126 Asian ovarian cancer patients (including 147 BRCA PV carriers), we developed predictive models incorporating routinely collected information such as cancer history and clinicopathological features to estimate likelihood of carrying BRCA PVs. We evaluated model performance in terms of discrimination, calibration, overall accuracy, sensitivity, and specificity, and compared the associated genetic testing volumes and costs to those of universal testing.
Results: Our final model demonstrated good calibration and strong discriminatory power, with an area under the curve of 0.80 (95% confidence interval: 0.74-0.87). Factors included in the model were age at diagnosis, ethnicity, personal and family cancer history, and clinicopathological features. At the optimal threshold, the model achieved 77% accuracy (73% sensitivity and 73% specificity), compared with 13% accuracy for universal testing (100% sensitivity but 0% specificity). In practice, this translates to identifying one carrier for every three patients tested, versus one in eight under universal testing, reducing the genetic testing cost per carrier identified from USD 4,000 to USD 2,000. From a budget perspective, even when we need to detect every carrier, as in universal testing, the model reduces testing volume by 15%, yielding potential savings of USD 70,000 for every 800 patients screened annually.
Conclusions: Targeted testing using a mutation prediction model offers a more efficient alternative when universal testing is not feasible, with adjustable risk thresholds that can be tailored to local resources to optimize impact in resource-limited settings.

#6331 A translational framework for high-plex spatial profiling and complexity reduction toward diagnostic assay development in colorectal polyps.

Ettai Markovits[1], Joanne Edwards[2], Gerard Patrick Lynch[3], Ofir Rimer-Cohen[1], Aidan Lynch[4], Aula Ammar[2], Luke McNickle[2], Claire Kennedy-Dietrich[2], Amna Matly[2], Meir Azulay[1], Lina Sakhneny[1], Noori Maka[5], Lewis Irvine[2], Pamela McCall[6], Ken Bloom[1], Grainger Greene[1], Stephen McSorley[2], Nigel Jamieson[2]

[1]Nucleai, Tel Aviv, Israel,[2]University of Glasgow, Glasgow, United Kingdom,[3]Institute of Cancer Sciences, University of Glasgow, Glasgow, United Kingdom,[4]School of Cancer Sciences, University of Glasgow, Glasgow, United Kingdom,[5]NHS Scotland, Edinburgh, United Kingdom,[6]College of MVLS, Univ. of Glasgow Inst. of Cancer Sciences, Glasgow, United Kingdom

Background:
Accurate risk stratification of colorectal polyps is essential for reducing unnecessary surveillance while ensuring that high-risk patients receive timely intervention. Pathology workflows rely on morphology from H&E slides, while emerging immune-profiling techniques such as multiplex immunofluorescence (mIF) offer deeper biological resolution but are often too complex and costly for routine clinical deployment. To address this, we propose a diagnostic-assay development framework that integrates high-plex spatial profiling with computational complexity-reduction strategies to derive a clinically practical biomarker panel.
Methods:
We designed a 20-plex mIF panel to characterize immune cell populations and spatial interactions within colorectal polyp microenvironments. Corresponding H&E whole-slide images were analyzed to extract epithelial, stromal, and architectural features using area-based models and computational morphology descriptors. These multimodal data were integrated into a unified predictive modeling pipeline for stratifying patients into low- and elevated-risk groups. To support translation into a deployable assay, we implemented a complexity-reduction framework incorporating iterative feature selection, redundancy elimination, model pruning, and simulation of assay-ready marker subsets.
Results:
An initial dataset of 200 mIF and H&E slides was used for model fine-tuning, biomarker feature extraction, and preliminary integration of immune and morphological signatures. Early-stage mIF-based models captured >10 immune cell populations, distinguished epithelial subtypes, and localized key microenvironmental interactions. H&E-based models identified colorectal compartments, stromal-epithelial organization, inflammatory patterns, and dysplasia-related features. This groundwork enabled refinement of feature sets, assessment of model stability, and establishment of the multimodal fusion strategy guiding downstream predictive modeling and assay simplification later to be verified on a larger ~1000 sample cohort.
Conclusions:
We present a scalable framework that unifies high-plex mIF discovery with H&E-based computational morphology to support biomarker identification, feature reduction, and diagnostic assay development for colorectal polyp risk stratification. This platform provides the foundation for forthcoming clinical validation and deployment within colorectal surveillance programs.

#6332 nELISA high-throughput protein profiling applied to the RADIOHEAD cohort: Insights from the largest plasma proteomics study of patients receiving checkpoint inhibitor therapy.

Amy R. Johnson[1], Nathaniel Robichaud[2], Samantha I. Liang[3], **Jens Eberlein**[1], Grant Ongo[1], Enjun Yang[3], John CONNOLLY[3], Milad Dagher[1]

[1]Nomic Bio, Montreal, QC, Canada,[2]Nomic Bio, Montreal, QC, Canada,[3]Parker Institute for Cancer Immunotherapy, San Francisco, CA

Background Proteomics holds great promise for cancer immunotherapy, with intensive efforts being exerted for early disease identification, patients selection, and adverse event prediction. Despite this potential, the high cost and low throughput of existing tools to profile circulating proteins render such studies prohibitively slow and costly, limiting their wide-spread application. As a result, proteomics studies in the field have been constrained to sample sizes in the 10s and 100s, restricting the power to discover key biomarkers.

Methods The Nomic platform is a highly multiplexed immunoassay technology that enables the profiling of hundreds of proteins across 1536 samples per instrument daily, at significantly reduced costs. The method miniaturizes sandwich immunoassays by placing antibody pairs on the surface of color-coded microparticles, which can then be analyzed via high-throughput flow cytometry. RADIOHEAD is a prospective study of 1070 immunotherapy naive pan-tumor patients on standard of care immune checkpoint inhibitor (ICI) therapy regimens from community oncology clinics. Longitudinal samples were collected pre- and post-ICI, as well as following irAEs.

Results We previously reported leveraging the nELISA protein profiling platform to quantify 600 circulating proteins across 3000 samples from the RADIOHEAD cohort, resulting in the identification of greater than 200 proteins associated with response to ICI and greater than150 proteins associated with the development of irAEs. Here, we further dissect the dataset to capture treatment-specific biomarkers. Specifically, analysis of clinical data identified factors impacting response to ICI, including age, smoking, chemotherapy, radiotherapy, systemic corticosteroids, opioids, etc. We will present biomarkers associated with each of these factors, and their impact on response to ICI.

Conclusions Pairing nELISA protein profiling of these longitudinal samples with associated demographic metadata and clinical outcomes provides an opportunity to identify clinically actionable mechanisms to guide ICI therapeutic approaches. Here, we highlight biomarkers and protein signatures related to patient outcomes, to reveal additional insights and further accelerate research in the field of cancer immunotherapy.

#6333 Serum protein signatures specific to breast cancer in treatment-naive African American women identified using integrated proteomics and multivariate pattern analysis.

Padma P. Tadi Uppala[1], Hyun J. Kwon[2], Elmer C. Rivera[2], Sharon S. Lum[3]

[1]School of Population Health, Nutrition & Wellness, Andrews University, Berrien Springs, MI,[2]Department of Engineering, Andrews University, Berrien Springs, MI,[3]Department of Surgery, Loma Linda University Health, Loma Linda, CA

Background: Breast cancer is the leading cause of morbidity and mortality among African American women. Identifying population-specific serum biomarkers is essential for early detection and risk stratification. To address limitations of traditional univariate analyses, we developed an integrated platform combining classical proteomics (2D-DIGE, MALDI-TOF/TOF, LC-MS/MS) with Random Forest (RF) and cumulative distribution function (CDF)-based analyses to robustly discover and validate serum biomarkers.
Population: Two cohorts of treatment-naïve African American women were examined following depletion of high-abundance proteins. The primary cohort included eleven breast cancer patients median age 50 years, range 29-74, and 11 age-matched healthy controls analyzed by 2D-DIGE and MALDI-TOF/TOF. An independent cohort of 6 patients and 6 controls was assessed by LC-MS/MS (MudPIT). Patients represented both pre- and postmenopausal status and diverse tumor subtypes and receptor profiles. Controls were healthy women without a cancer history.
Methods: Proteomic analysis using 2D-DIGE gels combined with MALDI-TOF/TOF allowed the detection and identification of differentially expressed serum proteins. LC-MS/MS data were analyzed with RF (1,000 bootstrap iterations) using Gini importance to rank peptide relevance, and the CDF evaluated distribution differences using an S statistic derived from 1,000 permutations (S threshold greater than or equal to 3). The combination of RF and CDF enabled the detection of relevant signals under conditions of high dimensionality, collinearity, and potentially non-Gaussian distributions.
Results: The integrated approach revealed multiple differentially expressed serum proteins in breast cancer. Representative biomarkers included Ceruloplasmin, Complement C3; Alpha-1B-glycoprotein, angiotensinogen precursor, Insulin-like growth factor-binding protein complex acid labile subunit, Hemopexin precursor, and vitamin D binding protein. Complementary 2D-DIGE and MALDI-TOF/TOF analyses allowed direct determination of these differential protein patterns, while LC-MS/MS combined with RF and CDF prioritized peptides with high discriminatory power and independently confirmed their statistical significance.
Conclusion: The integration of classical proteomics techniques (2D-DIGE and MALDI-TOF/TOF) with LC-MS/MS combined with RF and CDF analysis enables reliable detection and prioritization of serum biomarkers. This approach combines the sensitivity of multivariate proteomics with non-parametric statistical rigor, making it suitable for small, high-dimensional cohorts, and demonstrates potential for identifying biomarkers specific to underrepresented populations, supporting precision oncology applications in breast cancer.

#6334 *CervicalMethDx:*A precision tool to enable at-home sampling and expand access to cervical cancer prevention while reducing unnecessary biopsies in the United States and Puerto Rico..

Ashley Ramos Lopez[1], Yanira Gonzalez Rodriguez[1], Amanda Garcia Negron[1], Paola Quinonez Mendez[1], Guie Beeu Guerrero Hunt[2], Adhi Guerrero Thillet[1], Mariana Brait[2], Teresa Diaz-Montes[3], Josefina Romaguera[4], Lourdes Fernadez[5], David Sidransky[2], Rafael E. Guerrero-Preston[1]

[1]LifeGene-Biomarks, Inc, Toa Baja, PR,[2]Oncology, Johns Hopkins Medical Insts., Baltimore, MD,[3]Gynecologic Oncology Center, Mercy Medical Center, Baltimore, MD,[4]Obstetrics and Gynecology, University of Puerto Rico School of Medicine, San Juan, PR,[5]Harvard University, Cambridge, MA

CervicalMethDx is a molecular precision tool designed to expand access to cervical cancer prevention through self-collection while reducing unnecessary biopsies. Two cohorts were analyzed: women from Salud Integral en la Montaña (SIM, *n* = 82) and the University of Puerto Rico School of Medicine (UPR, *n* = 105) cervical cancer clinics who participated in an IRB-approved study comparing *CervicalMethDx* and Human Papilloma Virus (AmpFire, Atila BioSystems) test results in physician-collected (PreservCyt, Hologic) and self-collected vaginal swabs (MSwabs, Copan). Participants completed structured questionnaires assessing demographics, reproductive and screening histories, and experiences using the LifeGene BioMarks self-collection kit. Acceptability and preference of sampling methods were evaluated using Likert scales. Cramér's V was used to measure associations between sample collection preference and participant characteristics. Additional acceptability data of self-sampling were collected through 300 structured interviews with women from Puerto Rico, the United States, and Latin America attending Bad Bunny's *Residencia* concerts in Puerto Rico and through an online market study of 2,800 statistically representative women from seven municipalities in rural Puerto Rico served by SIM. Health-economic modeling used biopsy data from UPR clinics (2022-2024, *n* = 422) and BRFSS data (2016-2020) to estimate cost savings from reduced unnecessary biopsies. Self-collection was highly acceptable: 88-94% "would do at home," 87-95% "satisfied," and >95% "recommend to others." SIM participants more often preferred self-collection (52%) than UPR participants (42%), where physician collection remained preferred (48%). Employment and education showed modest influence on preference (Cramér's V = 0.27 and 0.16, respectively). Community market study revealed 86% willingness to self-test if validated, affordable, and endorsed by physicians. In the online sample, 72% expressed intent to use at-home kits. Motivators included convenience (50%), privacy (49%), and time savings (48%), while concerns centered on accuracy (50%) and correct use (45%). Pharmacies were the preferred distribution channel (73%). Health-economic modeling showed that applying *CervicalMethDx* rule-out thresholds could reduce unnecessary biopsies from 81% to 10-25%, translating into potential savings of $16.7-23.2M annually in Puerto Rico and $2.0-2.7B in the U.S. *CervicalMethDx* demonstrates high acceptability across diverse settings and potential to reduce unnecessary procedures and healthcare costs, supporting its integration into cervical cancer screening algorithms.

#6335 Temporal profiling of the EGF-induced transcriptional cascade in PC3 prostate cancer cells reveals biphasic oncogenic reprogramming.

Amit Kumar Tripathi, Jamboor K. Vishwanatha

College of Biomedical and Translational Sciences, UNT Health Science Center, Fort Worth, TX

The Epidermal Growth Factor (EGF) signaling pathway is a potent driver of prostate cancer progression, yet a comprehensive, time-resolved understanding of its transcriptional dynamics remains incomplete. This study employed temporal RNA-sequencing on PC3 prostate cancer cells to profile the transcriptomic landscape at critical intervals (0, 30 min, 1 h, 6 h) following EGF stimulation. Our analysis reveals a **biphasic oncogenic reprogramming**. The initial phase, evident within 30-60 minutes, is characterized by a rapid surge of immediate-early genes (*FOS, JUN, EGR* family) and the coordinated activation of pathways promoting cell migration, inflammation (NF-κB, IL-17), and early signaling (MAPK). This is followed by a distinct secondary phase at 6 hours, where the transcriptome pivots to strongly enrich processes dedicated to sustained growth and survival, including cell cycle progression, DNA replication, and the PI3K-AKT-mTOR signaling axis. Having established this kinetic map, we demonstrate that the previously characterized L-peptide inhibitor, LA3IK, effectively suppresses this program. Co-treatment with EGF and LA3IK for 6 hours resulted in significant inhibition of genes across these critical pathways, including PI3K-AKT, MAPK, and cell cycle. To overcome the proteolytic limitations of the L-peptide, we then employed its D-enantiomer, D-LA3IK, which yielded **superior results**, driving a more profound and comprehensive reversal of the EGF-induced transcriptome and exhibiting enhanced efficacy in functional assays. This work delineates the phased transcriptional cascade orchestrated by EGF and establishes targeted peptide inhibition, particularly with the stable D-isomer, as a potent strategy to disrupt this oncogenic program.

#6336 AmbientcfRNApreservation: standardized extraction reveals superior stability in a multi-analyte tube.

Emily Medina[1], Tony Baker[1], Kamran Syed[2], Jason Saenz[2], Cameron Van Dieren[2], Carlos Hernandez[2], Daniel Cedeno[2], Mayer Saidian[2], Nafiseh Jafari[2]

[1]Truckee Applied Genomics, Reno, NV,[2]nRichDX, Irvine, CA

Introduction: Liquid-biopsy readouts are highly sensitive to pre-analytical variability: cellular lysis and nuclease activity can inflate background, suppress rare signals, and impair reproducibility. Concurrent stabilization of multiple targets at the time of collection, paired with a controlled extraction workflow, is therefore critical. We assessed two blood-collection tubes—a single-tube matrix designed for multi-analyte stability—using the magnetic bead-based chemistry, focusing on cfRNA signal integrity and compatibility with downstream RT-qPCR.
Methods: Whole blood from healthy donors was drawn into Tube-A (TAG FLEX-LB™) and Tube-B (Streck Nucleic Acid BCT) aliquots were spiked with purified total RNA from H441 cells (KRAS G12V) at a fixed concentration per mL. Tubes were stored at ~21-25 °C and processed at T0 and T7. cfRNA was isolated using silica-magnetic bead Revolution cfTNA Max 20 Kit. Endpoints: allele-specific RT-qPCR for KRAS G12V (Ct; ΔCt = T7-T0; amplification efficiency and recovery), hemolysis proxy hsa-miR-16 (ΔCt), and RNA integrity (RIN; 18S/28S).
Statistics: paired tests with 95% Confidence Intervals.
Results: With one extraction workflow across both tubes, KRAS G12V amplified consistently at T0. After 7 days at room temperature, Tube-A showed minimal degradation, preserved efficiency, and maintained high recovery. Tube-B exhibited greater degradation and reduced efficiency in recovery. Hemolysis signal was lower in Tube-A: Day-7 miR-16 abundance was lower than Tube-B. RNA integrity remained stable in Tube-A but declined in Tube-B. Assay QC pass rate were higher for Tube-A.
Conclusions: Under a realistic 7-day ambient hold, cfRNA targets remained quantifiable when stabilization was adequate. In this head-to-head study, the multi-analyte stabilizing tube better preserved KRAS-G12V detectability, showed lower hemolysis, and maintained RIN/18S-28S metrics relative to a different tube, using an identical extraction workflow. These findings support cfRNA workflows and underscore the need for standardized pre-analytics—spanning both preservation and extraction.

#6337 Single-reaction KRAS variant profiling via processor-mediated PCR: Enhanced SNV discrimination using the iProbe.

Eric K. Pomaranski, Adam M. McCoy, Karl Spork, Niloufar Mertz, Vladimir Makarov

Signal Bioscience, Ann Arbor, MI

Accurate discrimination of single-nucleotide variants (SNVs) remains a major limitation of quantitative PCR (qPCR) and digital PCR (dPCR). Even with optimized hydrolysis probes, subtle thermodynamic differences between alleles often lead to cross-reactivity, reduced sensitivity near the limit of detection, and the need for multiple singleplex reactions. These constraints are particularly problematic for oncology applications requiring detection of low-frequency variants across closely spaced mutation sites. KRAS mutations in codons 12 and 13 represent clinically actionable drivers in multiple solid tumors, influencing prognosis and response to targeted therapies. However, the extreme proximity of these variants makes simultaneous, highly specific detection difficult; most current PCR-based assays require separate reactions or exhibit off-target signal among neighboring alleles. We developed processor-mediated PCR, a detection architecture that decouples target amplification from readout using a universal “processor” oligo and universal fluorescent probes. This chemistry supports high multiplexing, reduced assay cost, and tunable specificity independent of fluorophore channel limitations. In parallel, we engineered a modular multi-domain probe structure, iProbe, that generates signal only upon complete hybridization to a target variant, enabling exceptional SNV discrimination. To demonstrate this platform, we created a single-tube KRAS G12/G13 assay combining processor-mediated PCR with domain-engineered iProbes. In dPCR, the assay simultaneously detected all major KRAS codon 12 and 13 mutants with no detectable cross-reactivity. Sensitivity studies confirmed reliable detection at allele frequencies down to 0.01% (1:10,000 mutant:wild-type) with clean digital separation. Processor-mediated PCR with iprobes provides a powerful solution to longstanding specificity and multiplexing barriers, enabling cost-effective, highly selective detection of clinically relevant SNVs in a single reaction.

#6338 Clinical validation of a multi-gene blood test for kidney cancer screening and stratification.

Taigo Kato[1], Koji Hatano[2], Yohei Okuda[3], Dharam P. Chauhan[4], Norio Nonomura[5], Rajvir Dahiya[6]

[1]Urology, The University of Osaka Graduate School of Medicince, Suita, Japan,[2]Urology, Osaka Univ., Suita, Japan,[3]The University of Osaka Graduate School of Medicince, Suita, Japan,[4]Geneverify Inc, Hayward, CA,[5]Professor, Osaka University Graduate School of Medicine, Suita, Japan,[6]UCSF School of Medicine, San Francisco, CA

Background: Kidney cancer remains one of the most aggressive and fatal urological malignancies. To address this issue, we developed and clinically validated the Geneverify blood-based, cell-free mRNA test, a cutting-edge liquid biopsy platform that enables real-time, non-invasive genomic profiling. By quantifying circulating tumor-derived transcripts in plasma, this next-generation assay delivers rapid and precise molecular insights, paving the way for precision screening, early diagnosis, and treatment monitoring.
Methods: In this prospective clinical study, we evaluated real-time expression levels of 30 kidney cancer associated genes in plasma samples from 51 subjects (41 suspected cancer cases and 10 healthy controls). The primary objective was to assess the diagnostic and prognostic performance of a blood-based multi-gene expression panel developed by Geneverify Inc. Log_2 fold-change values were calculated for each gene and integrated to generate a composite Geneverify risk score for each subject. Geneverify scores were compared with biopsy-confirmed diagnoses to determine assay sensitivity and specificity. Additional statistical analyses assessed correlations between Geneverify scores and pathological grade as well as clinical stage.
Results: All cancer samples demonstrated Geneverify scores greater than 10. Using an optimized threshold of 10, the assay achieved 100% sensitivity in detecting cancer cases. Specificity could not be determined because the study cohort did not include benign or non-cancer subjects; therefore, AUC relative to non-cancer controls was also not estimable. Baseline Geneverify scores from healthy volunteers served as the reference for comparison. Most patients in the cohort had T1a (early-stage) kidney cancer. Elevated Geneverify scores showed clear correlations with tumor stage, grade, and treatment status. In the majority of late-stage metastatic cases receiving systemic therapy, Geneverify scores decreased significantly, suggesting a favorable treatment response.
Conclusions: This study provides the first real-time clinical validation of a blood-based, cell-free mRNA genomic assay for kidney cancer detection. The Geneverify test demonstrated high diagnostic accuracy, strong concordance with biopsy results, and robust prognostic value, establishing it as a powerful non-invasive alternative for early detection. Its adoption in clinical workflows may reduce surgical biopsies, improve patient stratification, and accelerate personalized oncology care.

#6339 Methylation profiling of a novel donor-derived reference material using methylation-sensitive restriction enzyme digestion and droplet digital PCR.

Daniel Wasik[1], Yves Konigshofer[2], Mona Shahbazian[1], Adam Corner[1], Eddy vanCollenburg[1], Jayanthi Ramprakash[2], Nish Kumar[1], Andrew Anfora[2], Mai Ho[1]

[1]Bio-Rad Laboratories, Hercules, CA,[2]LGC Clinical Diagnostics, Gaithersburg, MD

Aberrant DNA methylation, along with other epigenetic modifications, are important indicators in the development of cancer. Unique tissue-specific patterns of hyper-methylated genes have been linked to certain cancer types and are increasingly leveraged to identify tumor type and monitor disease progression including minimal residual disease (MRD) and ongoing cancer surveillance. Accurate DNA methylation analysis relies on robust reference standards to validate assay performance and ensure clinical relevance. Traditionally, methylation standards are produced by mixing fully methylated DNA and non-methylated DNA at defined ratios. While these mixtures provide a convenient benchmark for quantitative linearity, they fall short of capturing the complex methylation heterogeneity found in patient samples, which can diminish the utility of these standards for translational research and clinical diagnostics. To address this gap, our study evaluates a novel, differentially methylated DNA standard, specifically engineered to mimic physiologically relevant methylation patterns and better reflect the complexity observed in real-world patient samples.

In this study, methylation-sensitive restriction enzymes (MSRE) are utilized in conjunction with droplet digital PCR (ddPCR) to establish a platform characterized by high sensitivity and precision for the quantitative analysis of DNA methylation. Compared to bisulfite conversion, MSRE digestion requires substantially less input material and eliminates the need for depurination, reducing the risk of DNA degradation; and when paired with ddPCR, it enables a streamlined, target-specific methylation detection in a single-tube workflow.

We assessed methylation at seven colorectal cancer gene loci across three reference materials: enzymatically methylated DNA standard, non-methylated DNA standard, and the differentially methylated standard. Consistent with manufacturer's stated performance, the enzymatically methylated standard showed consistently high methylation, while the non-methylated standard exhibited low background methylation. In contrast, the differentially methylated reference material displayed locus-specific methylation heterogeneity, with targets ranging from non-methylated to partially methylated, and none were found to be completely methylated. These results demonstrate that Bio-Rad's ddPCR platform reliably detects methylation heterogeneity, supporting both research and assay development across both contrived and physiologically relevant control materials.

(For Research Use Only)

#6340 Detection of ectopic phosphorylated PDGFRA antibodies in the serum samples of HCC patients.

Jian-Hua Luo, Muhamuda Kader, Yan-Ping Yu

University of Pittsburgh, Pittsburgh, PA

Hepatocellular carcinoma (HCC) is one of the most lethal cancers for humans. Early diagnosis of HCC can significantly enhance the treatment outcomes and reduce disease mortality. MAN2A1-FER is one of the most frequent oncogenic fusion genes in HCC. Our previous studies showed that MAN2A1-FER ectopically phosphorylated the extracellular domain of PDGFRA. The present study aimed to examine the diagnostic utility of antibodies specific for the ectopically phosphorylated PDGFRA generated by MAN2A1-FER in HCC patients' serum samples. In this study, 130 serum samples from HCC (65) patients and non-HCC (65) patients were analyzed. Our results showed that the antibody levels specific for the ectopically phosphorylated PDGFRA were 3.5- to 10-fold elevated in the serum samples from HCC patients in comparison with individuals without liver cancers and negative for MAN2A1-FER gene fusion. The higher titers of anti-ectopic-pPDGFRA-N-terminus in the serum samples correlated with the HCC diagnosis and outperformed the serum alpha-fetal protein for the diagnosis of HCC. The presence of these antibodies was also highly correlated with the levels of MAN2A1-FER mRNA in these serum samples. We concluded that the elevated serum levels of anti-pPDGFRA-N-terminus antibodies are highly predictive of liver cancer and can be utilized as a potential diagnostic marker for HCC.

#6341 High-fidelity detection and classification of ovarian cancer from histopathological images using Artificial Intelligence.

Elangovan Krishnan[1], Jansi R. Sethuraj[2], Sophia Ahmed[3], Gowrishankar Palaniswamy[4], Muhammad Waqas Khan[4], Aravind Raghavan[4], Tayyiba Wasim[3]

[1]AIMDOCTOR, Thiruverkadu, India,[2]Texas Heart Institute at St. Luke's Episcopal Hospital, Houston, TX,[3]Allama Iqbal Medical College, Lahore, Pakistan,[4]The Medical University of South Carolina, Charleston, SC

Introduction: Ovarian cancer is a lethal gynecological malignancy with a substantial economic burden. Accurate histopathological subtype classification is critical for precision therapy and prognostication. Traditional pathological diagnosis relies on subjective interpretation, which is vulnerable to significant interobserver variability. Convolutional neural networks leveraging residual architectures enable automated, objective feature extraction from histopathological images. This study investigates ResNet18-based ovarian cancer subtype classification to accelerate diagnostic accuracy and support evidence-based clinical decision-making.

Methods: Anonymized histopathological images from the University of British Columbia Ovarian Cancer Subtype Classification dataset encompassing five ovarian cancer subtypes (n=513) were procured. The dataset was randomly proportioned into training (60%), validation (20%), and testing (20%) cohorts. Images underwent comprehensive preprocessing and augmentation prior to training using the ResNet18 architecture. The diagnostic performance was assessed using accuracy, precision-recall, F1 and F2-scores, and area under the receiver operating characteristic curve (AUROC) on both validation and test sets. The trained model was deployed in a universally accessible, cross-platform application for expert validation globally.

Results:

ResNet18 demonstrated robust discriminative capability across ovarian cancer subtypes, achieving >98% training accuracy and >82% validation accuracy. Precision-recall analysis showed excellent performance, especially for the endometrioid subtype (0.95). These results indicate ResNet18's potential to augment histopathology workflows, facilitating equitable ovarian cancer subtype stratification.

Conclusion: ResNet18-based analysis provides automated, accurate ovarian cancer diagnosis. High validation accuracy and strong AUROC scores across histological subtypes indicate efficacy in standardizing diagnostic interpretation. Integration into clinical workflows could reduce diagnostic variability and support precision-guided therapy. Further validation in prospective multicenter cohorts will translate this into an effective diagnostic tool.

#6342 Performance of longitudinal cancer screening in Li-Fraumeni syndrome.

Payal P. Khincha[1], Sophia Ty[2], Siddharth Roy[3], Jessica N. Hatton[1], Ashkan Malayeri[4], Megan N. Frone[1], Margarita Aryavand[1], Phuong Mai[5], Paul Albert[3], Sharon A. Savage[6]

[1]Clinical Genetics Branch, Division of Cancer Epidemiology and Genetics, National Cancer Institute, Bethesda, MD,[2]Oden Institute for Computational Engineering and Sciences, The University of Texas at Austin, Austin, TX,[3]Biostatistics Branch, Division of Cancer Epidemiology and Genetics, National Cancer Institute, Bethesda, MD,[4]Department of Radiology and Imagi, Fairfax radiology Centers, Fairfax, VA,[5]Magee-Womens Hospital, University of Pittsburgh Medical Center, Pittsburgh, PA,[6]NCI Div. of Cancer Epidemiology & Genetics, Rockville, MD

Li-Fraumeni syndrome (LFS), a cancer predisposition syndrome caused by germline [likely] pathogenic (P/LP) *TP53* variants, confers elevated multi-organ cancer risks from infancy and high lifetime risk of multiple primary cancers. The heterogeneous cancer spectrum necessitates multi-modal lifelong cancer screening to facilitate early detection. The study included 145 individuals (62% female) with a germline P/LP *TP53* variant who enrolled in the National Cancer Institute's IRB-approved longitudinal LFS study (NCT01443468) and received cancer screening at the NIH Clinical Center including annual whole-body MRI (WBMRI), brain MRI, breast MRI (females>20 years), mammography (females>40 years), bloodwork, triennial colonoscopy (>25 years), and abdominal ultrasound every 4 months (age 3-16 years). Median age was 34 years (range 3-68) at the first screening visit. In all, 772 annual screening visits were completed (median 5 visits per participant, range 1-10) and 3956 screening tests performed at a compliance of 92.8%. Screening tests led to 545 follow-up tests. WBMRI led to at least one follow-up test in 29.1% scans (n=225/772). Invasive biopsies comprised 8.3% (n=45/545) of all follow-ups, 48.9% (n=22/45) of which resulted in a cancer diagnosis. WBMRI led to 62% (n=28/45) of all biopsies, of which 42.8% (n=12/28) resulted in a cancer diagnosis. Of the 72 cancers/pre-cancers diagnosed during the study, 75% (n=54) were screen-detected (32/54, 59% from WBMRI). The 18 (25%) interval cancers were diagnosed at a median of 8 months (range 3-13) after last screening test. Prevalence of asymptomatic cancer was 7% at first visit, varying between 4% and 11% at subsequent visits. The screening protocol had a sensitivity of 71.7%, specificity 89%, false positive rate (FP) 11%, negative predictive value (NPV) 99.1%. Diagnostic properties of each screening test for screen-detectable cancers were analyzed using logistic regression with generalized estimating equations. WBMRI sensitivity was 94%, specificity 94.8% (between 91.6% for thoracic cancers and 97.6% for upper extremity), FP 27%, NPV 99.9%. Brain MRI had sensitivity of 85.7%, specificity 98%, FP 2%, NPV 99.9%. Breast MRI had sensitivity of 88.9%, specificity 83.6%, FP 16.3%, NPV 98.9%. Neither germline *TP53* variant nor age significantly affected specificity. A previous cancer diagnosis in an anatomical region reduced specificity of WBMRI (OR=0.12, 95% CI 0.06-0.25, <0.001). A previous false positive finding in an anatomic region increased the probability of additional false positive findings in that region (p<0.001). This largest longitudinal LFS cancer screening study to date shows that multi-modal screening performs well with most reported cancers being screen-detected. FP rate is high but lower than previously reported. While further research on alternative screening strategies and cancer prevention is needed, screening is clinically crucial to early cancer detection in LFS.

#6343 Integrative analysis of proteomic, transcriptomic, and FACS-based surface marker data for ADC target discovery in cancer cell lines.

Nadine Obier[1], Vincent Vuaroqueqeaux[2], Johannes Krumm[3], Anne-Lise Peille[2], Daniel Feger[1], Sarah Ulrich[1], Johanna Wallner[3], Hannes Hahne[3], **Jan E. Ehlert**[1]

[1]Reaction Biology Europe GmbH, Freiburg im Breisgau, Germany,[2]Apex OncoSience SAS, Mulhouse, France,[3]Omicscouts GmbH, Munich, Germany

In the preclinical space of cancer drug discovery, multi-omics characterization of cancer models is essential for model selection, understanding mechanisms of action, and early biomarker discovery. We launched a panel of 160 cell lines (CL Proliferation Panel) to study drug responses across a large variety of cancer types and validated their molecular characteristics at both the transcriptomic and genomic levels. Recently, we characterized this set of models at the proteomic level using mass spectrometry, identifying a total of more than 15.000 proteins. In the present work, we aim to investigate the relevance of this new dataset in the daily practice of cancer model utilization. First, we demonstrated the robustness of the established proteomic profiles, showing high concordance among duplicate samples. Using a multiomics comparison and dimensionality reduction approaches, we curated the proteomic dataset to remove outlier and irrelevant protein profiles, ensuring high data quality. Next, unsupervised hierarchical clustering of the proteomic profiles revealed accurate classification of models according to their tumor type of origin, confirming the relevance of the data. Given the growing importance of proteomic information in the context of antibody-drug conjugate (ADC) development, we further assessed the relevance of our dataset for evaluating the expression of top 20 ADC targets such as ERBB2 and TACSTD2, among others. We also established a multi-omics strategy integrating transcriptomic and proteomic data to enhance target characterization. Finally, we explored the relationship between protein expression of the targets and drug sensitivity by analyzing ADC targets in the context of responses to clinically approved ADCs, including trastuzumab emtansine (Kadcyla), and sacituzumab govitecan.

#6346 How case based education elevated clinical performance in metastatic breast cancer management: A study for TROP2 directed antibody drug conjugates.

Meghan Coulehan[1], Serena Welch[1], Komal Jhaveri[2], Lavanya Anantharaman[1], Emily Kitterman[1], Aisha Suhail[1]

[1]Answers in CME, New York, NY,[2]Memorial Sloan Kettering Cancer Center, Scarsdale, NY

Background: The treatment landscape of metastatic breast cancer (mBC) has advanced with antibody-drug conjugates (ADCs), notably the TROP2-directed agents sacituzumab govitecan and datopotamab deruxtecan. These options have extended treatment potential for patients with HER2- mBC. However, rapid updates pose challenges for clinicians in adopting evidence-based, personalized strategies.
Objective: To assess whether a digital, case-based, short-format CME activity could address knowledge and competence (K/C) gaps regarding the evidence-based use of TROP2-directed ADCs in HER2- mBC.
Methods: A 15-minute, case-based, accredited online activity ("Opportunities to Personalize Care: Making the Case for TROP2-Directed ADCs in HR+, HER2- mBC") launched March 28, 2025. Global academic and community oncologists completed pre-/post-assessments measuring K/C outcomes. A qualitative follow-up questionnaire, 4 weeks post-launch, evaluated practice changes and implementation behaviors.
Results: As of June 3, 2025, 4,073 learners participated. Post-activity data showed a 20% mean improvement in K/C scores. Participants improved notably in identifying appropriate patients and applying ADCs in alignment with clinical evidence. The lowest baseline knowledge area—patient identification—showed marked gains, though further reinforcement may optimize impact in practice. Notably, 73% reported practice changes attributable to the activity. Post-education assessment revealed increased implementation of personalized and evidence-based treatment decision-making and adverse event management (Table 1).
Conclusion: This case-based CME activity effectively improved clinician K/C regarding TROP2-directed ADCs for HER2- mBC and supported sustained practice change. Personalized, digital education formats may accelerate integration of newly available and emerging therapies into oncology care.

Table 1: Impact of Education on Practice Change

Change in practice	Initial analysis, %; n=33	4 week F/U after participation, %; N=55
Identify appropriate patients with HR+, HER2-negative mBC who are candidates for TROP2-directed ADCs	58	71
Recognize appropriate characteristics to select between ADCs for patients with HR+, HER2-negative mBC	64	85
Proactively implement best practices to manage AEs for patients with mBC on TROP2-directed ADCs	39	69
Apply guideline recommendations to select TROP2 directed ADCs for patients with HR+, HER2-negative metastatic breast cancer	48	56

#6347 Cancer Voices: A community-engaged approach to transform cancer disparities through verbatim theater.

Azlan G. Smith, Craig A. Richard, Zeynep Madak Erdogan

Cancer Center at Illinois, Urbana, IL

Cancer outcome disparities persist among underserved populations in central Illinois, yet traditional research approaches often fail to capture lived experiences or engage affected communities in meaningful partnerships. This project employs verbatim theater, a documentary performance methodology, to address cancer disparities through storytelling, qualitative research, and community engagement, aiming to increase representation of historically excluded groups, identify barriers to patient-centered research, and foster collaboration among patients, caregivers, researchers, and clinicians. Building on 50+ interviews with cancer survivors, family members, healthcare providers, and researchers across central Illinois. Interview transcripts are being transformed into a verbatim theater script that authentically documents cancer treatment experiences and illuminates structural barriers to equitable care. Through partnerships with University of Illinois Cancer Research Advocacy Group, Prairie Dragon Paddlers, Carle-Mills Breast Cancer Institute, Station Theater, and other community organizations, we will present two live performances (April-May 2026) projected to reach 500+ community members, with digital distribution extending impact to broader audiences. Pre- and post-performance surveys coupled with facilitated discussions will assess changes in audience understanding of cancer disparities, research engagement intentions, and perceived barriers to care. Preliminary findings reveal significant therapeutic and educational value. Interview participants consistently report that sharing their narratives through this qualitative process has been healing and supportive. Both survivors and clinicians express enthusiasm for seeing diverse cancer experiences represented collectively in an accessible format they have never previously encountered. Participants identify isolation, fragmented communication, and silence as pervasive challenges during cancer treatment. Many view this verbatim theater intervention as a critical mechanism to bridge divides between stakeholder groups and foster new collaborations in cancer research and care delivery. This approach uniquely combines immediate quality-of-life benefits for participants with long-term structural change potential. By centering community voices and creating accessible science communication, this model offers a replicable framework for other institutions addressing cancer disparities through patient advocacy, community engagement, and implementation science strategies. (The trailer can be found at https://ipmnewsroom.org/u-of-i-funding-to-help-showcase-cancer-research-through-theater/)

#6348 Cover stories: How journal front pages amplify cancer research reach.

Ekaterina Zvorykina, Ella Marushchenko, Aleksandr Tokarev

Ella Maru Studio, Mount Pleasant, SC

Nowadays online communication and social media have become powerful amplifiers of scientific visibility and influence. Increasingly, scientists rely on decentralized networks and social media, such as X (formerly Twitter), YouTube, and other online platforms. They're used to disseminate findings, build collaborations, and engage broader audiences beyond traditional institutional channels. Emerging evidence suggests that scholarly work promoted online attains greater visibility and citation impact, underscoring the growing role of strategic digital engagement in shaping research dissemination and recognition.In this study, we investigated whether visual prominence through cover selection in Nature Cancer predicts enhanced article visibility and impact. We analyzed all publications from the six volumes of Nature Cancer (2020-present), comparing engagement metrics between articles featured on the journal's cover and those that were not. Metrics included article accesses, Altmetric scores, and citation counts. Altmetric data were further used to quantify public engagement through mentions in news outlets, policy documents, and online platforms.Statistical comparisons revealed that cover-featured articles persistently achieved significantly higher engagement across all dimensions: readership ($t = 3.78$, $p = 0.00026$), online attention ($t = 2.49$, $p = 0.014$), and scholarly citations ($t = 3.57$, $p = 0.00055$). Strong positive monotonic correlations were observed among accesses, Altmetric attention, and citations (Spearman $\rho = 0.68$-0.80), indicating that articles attracting online attention tend to be more widely read and cited. Temporal analyses from 2020 to 2024 showed that the "cover advantage" persisted annually and was most pronounced between 2021 and 2023, coinciding with the journal's rapid audience expansion. Even after accounting for citation-time bias, cover-selected papers consistently exhibited approximately twice the citation rate, 1.6× higher Altmetric scores, and 1.7× more accesses compared to non-cover articles.Our findings demonstrate that visual prominence through cover selection predicts measurable scientific impact. The results highlight a robust and sustained "cover advantage," suggesting that visibility-enhancing editorial decisions can substantially amplify both digital and scholarly reach. Future work should examine potential confounders, such as article type and topicality, to further elucidate the mechanisms linking visual presentation to scientific influence.

#6349 Engaging communities in cancer research: Outcomes from the CaRE^2 health center's 2025 community scientist ambassador program.

Carolina Aristizabal[1], Fern Webb[2], Sandra Suther[3], John Luque[3], Eduardo Ibarra[4], Ileana Guzman[5], Brooke Vintilla[6], Janet Rodriguez[7], Rosa Barahona[4], Mariana C. Stern[8], Jennifer Tsui[9], Lourdes Baezconde-Garbanati[9]

[1]USC Norris Comprehensive Cancer Center, Los Angeles, CA,[2]University of Florida College of Medicine - Jacksonville, Jacksonville, FL,[3]Florida A&M University, Tallahassee, FL,[4]University of Southern California, Los Angeles, CA,[5]University of Florida, Orlando, FL,[6]Universtiy of Florida, Gainesville, FL,[7]USC Norris Comprehensive Cancer Center, Ontario, CA,[8]Associate Professor, Dept. of Prev. Medicine, USC Norris Comprehensive Cancer Center, Los Angeles, CA,[9]Keck School of Medicine of USC, Los Angeles, CA

Background: Collaborative relationships between communities and scientists are essential for ensuring inclusivity and relevance in cancer research. The Florida-California Cancer Research, Education, and Engagement (CaRE^2) Health Center established the Community Scientist Research Ambassador (CSRA) Program to train community members to become informed about cancer research. The program, now in its eight years, aims to increase knowledge about cancer and ongoing research, improve confidence in community research engagement, and expand two-way communication between community members and researchers to promote full participation in cancer studies. Recruitment occurs primarily through community organizations, the CaRE^2 registry, and personal networks.

Methods: The CSRA program is implemented over ten weeks using a hybrid learning model that includes 90% virtual sessions and one in-person laboratory experience. The curriculum addresses topics such as cancer health differences, social determinants of health, policy, ethics, genomics, and community-based participatory research. All materials and sessions are available in English and Spanish with human interpreters. Participants complete pre- and post-program surveys to assess their knowledge, self-efficacy, and satisfaction, and complete an individual project. Descriptive and inferential analyses were conducted using Wilcoxon signed-rank tests.

Results: Of the 21 participants in 2025, 85.7% were female, 93.3% identified as Black/African American, and 35.0% identified as Hispanic/Latino. Most participants (66.7%) held a university degree or higher. Cancer knowledge scores significantly increased by program end (mean proportion correct 0.73 ± 0.08 pre-program vs. 0.81 ± 0.09 post-program; p=0.001), indicating higher understanding of cancer research concepts. Self-efficacy scores also improved (mean 4.39 ± 0.69 pre vs. 4.75 ± 0.45 post; p=0.032), reflecting increased confidence to share cancer research information with others and engage in advocacy. Participant satisfaction was uniformly high (mean satisfaction score 4.91 ± 0.20; evaluation score 4.79 ± 0.31), with nearly all respondents affirming that they gained new knowledge, improved their support skills, and intended to share information with others in their communities.

Conclusions: The CaRE^2 Community Scientist Research Ambassador Program effectively enhanced cancer research literacy and self-efficacy among community members completing the program. The CSRA program is responsive to community needs, fosters community capacity, strengthens communication with scientists, and promotes participation in cancer research. Sustaining and scaling this program advance cancer research by bridging gaps between community engaged ambassadors and the scientific enterprise.

#6350 Social media and technology preferences among colorectal cancer patients.

Itzya B. Ulloa[1], Daisy Hernandez[2], Charite N. Ricker[2], **Elena Taylor**[2], Rosa Barahona[3], Blanca Ovalle[2], Bo Y. Wang[2], Caryn Lerman[2], Julie O. Culver[2], Juan P. Lewinger[3], Mariana C. Stern[4], John D. Carpten[5], Heinz Josef Lenz[2], Lourdes Baezconde-Garbanati[2]

[1]USC Norris Comprehensive Cancer Center, Los Angeles, CA,[2]Keck School of Medicine of USC, Los Angeles, CA,[3]USC, Los Angeles, Los Angeles, CA,[4]Associate Professor, Dept. of Prev. Medicine, USC Norris Comprehensive Cancer Center, Los Angeles, CA,[5]City of Hope, Duarte, CA

Background: Knowledge, attitude, and beliefs impact participant engagement in genetics and genomics research. However, there is still room to better understand how information is disseminated within the community. The widespread use of smartphones has made health information more accessible, but understanding the devices and platforms used, as well as usage frequency is essential for effective health education.

Methods: A cross-sectional survey was conducted among 57 colorectal cancer (CRC) patients aged 18+ recruited at two Los Angeles area hospitals. The survey assessed knowledge, attitudes, and beliefs regarding cancer genetics/ genomic testing, as well as social media and technological device usage and preferences. Recruitment and survey administration were based on each participant's preferred language.

Results: The average age of participants was 53.96 years (SD = 10.38). Most, 66.7%, reported using social media at varying frequencies, while 33.3% reported never using social media. Among daily social media users, Facebook was the most popular platform (48.7%), followed by WhatsApp (36.8%), TikTok (35.1%), and Instagram (24.3%). Regarding access to technology, all participants reported owning a smartphone, while only 26% had access to a tablet and 22% had access to a laptop or desktop. Notably, 64% of participants reported needing assistance to access Zoom. The majority (63%) of participants were male, and 64.9% reported an annual household income of less than $25,000.

Conclusion: These findings indicate that smartphones are the primary device utilized by study participants to access online educational materials and videos. Social media platforms could be effective to disseminate health education materials (as 66.7% used it). However, relying solely on this would exclude the one in three participants who reported not using social media at all. While Zoom offers an alternative to overcome transportation and accessibility barriers, 64% of participants require assistance to use it, highlighting the need for dedicated support from research staff. Future research should explore how patients seek information through social media to develop effective health education materials.

#6351 Leveraging artificial intelligence and short educational videos to expand accessible cancer education for diverse communities.

Bianca Rosales[1], Yaneth L. Rodriguez[2], Rosa Barahona[2], Letech Caldera-Huerta[2], Samantha Verganza[2], Lourdes Baezconde-Garbanati[3]

[1]USC Norris Westside Cancer Ctr., Inglewood, CA,[2]USC, Los Angeles, Los Angeles, CA,[3]Keck School of Medicine of USC, Los Angeles, CA

Background: Colorectal cancer (CRC) is the second leading cause of cancer death in the United States, yet many adults lack knowledge about screening, symptoms, and genetic risk. Traditional materials often do not reach diverse socioeconomic and cultural groups because of low health literacy and differences in media use. Many Americans, especially younger and lower income adults, spend several hours each day on screens. This creates an opportunity for mobile friendly and visually engaging education. Artificial intelligence (AI) offers a rapid way to create accessible and adaptable cancer information that fits current media habits.

Methods: We created an early stage framework that uses AI to produce scalable and culturally adaptable cancer education. The approach uses generative video platforms, AI assisted scriptwriting, simplified language, and multilingual narration to create short films on prevention, screening, and genetic testing. The framework aims to increase knowledge and early detection behaviors, reduce production time and cost, support mobile and screen based viewing, and adapt content across languages, cultures, and socioeconomic settings. Initial prototypes include videos on lifestyle risk reduction, family history, genetic testing, and timely screening.

Results: Our team produced AI assisted scripts for a storyboard, a storybook concept, and a film to educate African American (AA) communities about CRC. Four focus groups with a total of 27 AA and African immigrant adults were conducted in person and on Zoom through the AltaMed patient network. Participants reported that the script was clear, easy to understand, and communicated the main ideas. Community specific statistics were motivating and relevant. Participants asked for more information about the screening experience and reassurance to reduce fear. Their feedback informed the development of a script board with key message cards that address barriers and essential CRC information for AA audiences.

Conclusions: AI assisted workflows can support the creation of culturally relevant CRC education materials while maintaining clarity and community alignment. This approach shows strong potential for producing high quality materials for populations underserved by traditional communication. The next phase will assess feasibility, acceptability, comprehension, and intent to seek CRC screening among diverse audiences, with planned use in community outreach, patient navigation, and digital education programs.

#6352 Strengthening guideline compliant care delivery in a safety net hospital through artificial intelligence (AI) enabled technology solutions.

Vishesh Khanna[1], Nagashayana Gampalahalli[2], Naresh Ramarajan[2], Anand Bhagat[3], Ajay Punpale[4], Pramod Kalidas Tike[5], Brijmohan Zawar[6], Ramya B[2], Nikhil Ghadyalpatil[7]

[1]Medical Oncology, Stanford University, California, CA,[2]Navya Care, Bangalore, India,[3]Surgical Oncology, Anand Cancer and Multispeciality Hospital, Nanded, Maharashtra, India,[4]Surgical Oncology, Latur Superspeciality Hospital Pvt Ltd, Latur., Maharashtra, India,[5]Consultant Radiation Oncologist, Vivekanand Cancer Hospital, Latur, Maharashtra, Maharashtra, India,[6]Consultant Surgical Oncologist, Vivekanand Cancer Hospital, Latur, Maharashtra, Maharashtra, India,[7]Medical Oncology, Apollo Cancer Centre, Hyderabad, Hyderabad, India

Background: Concordance with guideline-based cancer care is often low in resource-constrained settings, leading to under- or over-treatment and delays in care. Navya Earthshot is a validated AI-enabled decision support system that matches patient records to standard-of-care cancer treatment guidelines to generate evidence-based recommendations. This study evaluated the implementation of Navya Earthshot at a safety-net hospital in India to assess improvement in concordance with National Cancer Grid (NCG) guidelines and reduction in delays to care.
Methods: A prospective pre-post observational study conducted over six months at a safety net cancer center in the public health system of India. Baseline data prior to Navya Earthshot integration were collected for comparison. Key outcomes included concordance of treatment decisions and average number of hospital visits per treatment decision. Navya Earthshot was integrated into routine workflows. The system matched patient-specific information to NCG guidelines to generate treatment options, which were reviewed by treating oncologists and discussed in daily tumor boards. Diagnostic testing was streamlined by eliminating non-mandatory investigations, reinforced through digital care navigation and structured follow-up by lay cancer navigators.
Results: During the study period, 892 patients presented to the hospital for a first cancer visit. Among 537 patients requiring active treatment decisions (290 pre-implementation; 247 post-implementation), 411 were evaluable (210 pre; 201 post). Guideline concordance improved from 67% (140/210; 95% CI +/-6%) at baseline to 87% (175/201; 95% CI +/-5%) after Navya Earthshot integration—a 20% absolute increase. Integration of Navya Earthshot, combined with digitally enhanced care navigation, reduced the average number of patient visits before treatment initiation of care from an average 3.45 to 2.5 visits (0.95 visits, 27.5% reduction), primarily due to elimination of non-mandatory report-review visits. Care initiation moved forward from 6 weeks at baseline down to 4 weeks after intervention (2 weeks, 33% reduction).
Conclusion: Implementation of Navya Earthshot improved adherence to standard-of-care guidelines and reduced time to treatment in a resource-constrained setting. Integrating validated AI decision support tools into oncology workflows can strengthen cancer care delivery and enable broader adoption of guideline-based treatment in resource-constrained health systems.

#6353 Age-related differences in lung cancer patients' and caregivers' perceptions and challenges: 2025.

Joan Schiller[1], Dhru Deb[2], Alexandre Reuben[3], Peixin Jiang[3], Amy Cipau[4], Hildy Grossman[5], Marc Muskavitch[6], Sara Patton[7], **Mary Lisa Spain**[8]

[1]OUCH - International, Richmond, VA,[2]Lung Cancer Research Foundation, Philadelphia, PA,[3]The University of Texas MD Anderson Cancer Center, Houston, TX,[4]Lung Cancer Initiative, Raleigh, NC,[5]Upstage Lung Cancer, Brookline, MA,[6]ALK Positive, Atlanta, GA,[7]International Association of the Study of Lung Cancer, Denver, CO,[8]Rexanna's Foundation, Prosper, TX

Background Studies have been conducted looking at aspects of patient experiences with lung cancer, but a comprehensive assessment of how challenges may differ by age of US patients is missing. The Research team within the LungCAN organization conducted this project. LungCAN is a collaborative group of lung cancer advocacy organizations that work together to raise public awareness about the realities of lung cancer.

Methods 2055 surveys were sent out with 46% returned (63.39% patients, 45.09% caregivers). The cohort was stratified by age (44 and under vs. 45 and over) to determine if age influenced perspectives in fears or concerns about living with or supporting someone with lung cancer, and challenges faced with medical care or treatment. Chi-square test of independence was used to identify significant differences in fears, concerns, and challenges between age groups.

Results Statistical analysis suggested a significant disparity in fears concerning lung cancer between the two cohorts (p-value = 1.24e-09). Major concerns of the younger cohort (≤44) were psychosocial and emotional impact (19.2%) and social stigma (4.4%). The older cohort (≥45) was preoccupied with clinical and practical issues including disease progression and recurrence (24.3%) and insufficient information and support (11.3%).

Significant age-based divergence was observed in the challenges faced with medical care and treatment (p-value < 2.2e-16). The cost of care was the predominant concern across participants, but prevalence was substantially higher among participants aged 44 and below (67.3%) compared to the older group (46.9%). The younger cohort viewed transportation as a challenge with significantly greater frequency (41.5% vs. 30.5%) while job related issues were more prominent among the elder cohort (16.9% vs. 9.1%).

Conclusions Age reveals differences in how patients and caregivers perceive the challenges associated with lung cancer. Age-sensitive approach to support strategies are warranted.

Fears and Challenges faced with living with or supporting someone with lung cancer.

		Total N (%)	N (%)	N (%)
		Total 842* (%)	44 and under 364 (%)	45 and over 478 (%)
Fears	Disease progression & recurrence	149(17.7%)	33(9.1%)	116(24.3%)
	Death	193(22.9%)	98(26.9%)	95(19.9%)
	Physical Symptoms, Side Effects, and QOL	177(21.0%)	79(21.7%)	98(20.5%)
	Emotional & Psychological Impact	128(15.2%)	70(19.2%)	58(12.1%)
	Financial & Emotional Impact on Family	155(18.4%)	70(19.2%)	85(17.8%)
	Inadequate Information and Lack of Support Systems	69(8.2%)	15(4.1%)	54(11.3%)
	Social Stigma & Isolation	30(3.6%)	16(4.4%)	14(2.9%)
Challenges	Transportation to and from appointments	297(35.3%)	151(41.5%)	146(30.5%)
	Cost of care and payment	469(55.7%)	245(67.3%)	224(46.9%)

	Other	112(13.3%)	6(1.6%)	106(22.2%)

*The participants include patients, their close and extended family members, and staff from health care providers.

#6354 Unpacking clinical trial referral processes: A qualitative study of community and academic oncologists.

Carma Bylund[1], Naomi Parker[1], Kelsey Lunsford[1], Jonathan Thomas[1], Margo Michaels[2], Tithi Amin[1], Stephanie Staras[1]

[1]College of Medicine, University of Florida, Gainesville, FL,[2]Health Care Access & Action, Boston, MA

Purpose: The purpose of this study was to examine how oncology clinicians, particularly those in community settings where the majority of patients receive care, navigate referrals to academic centers, including for clinical trial enrollment, by identifying factors that influence their referral practices, with the ultimate goal of improving partnerships between community and academic centers.
Methods: We conducted semi-structured interviews (N=23) with community oncology clinicians (oncologists, n=8; nurse practitioner, n=1; physician assistant, n=1) and academic oncologists at an NCI-designated cancer center (n=13) to examine their experiences and perspectives across the referral process to academic centers, including connecting patients to appropriate clinical trials. Both groups were included to capture the diverse contexts in which trial referrals occur and to understand how organizational environments shape referral practices. Transcripts were thematically analyzed.
Results: Oncology clinicians described three key considerations shaping the clinical trial referral process: (1) reasons to refer to academic centers, or reasons referrals were received to academic centers; (2) perceived barriers to referrals, such as logistical and financial barriers, and lack of communication; and (3) referral facilitators, including institutional support, scheduling efficiency, and strong communication between oncologists and trial teams. Oncology clinicians concluded by providing suggestions for improvement, such as streamlining referral pathways, reducing logistical or structural barriers, and improving patient education on clinical trials.
Conclusions: Oncology clinicians' engagement in the academic center referral process, including referrals to clinical trials, is shaped by multiple interrelated factors, including motivations, barriers, and facilitators for referrals. The oncology clinicians in our sample outlined several opportunities for improvement in the referral process. Understanding these considerations across both community and academic settings can inform strategies to streamline referrals, enhance trial participation, and improve patient access to novel therapies. Our findings highlight the importance of addressing context-specific barriers to enhance trial accessibility and participation. Strengthening communication channels and providing tailored institutional support may strengthen alignment between community and academic settings, thereby expanding equitable access to oncology clinical trials.

#6355 Building the first comprehensive research ecosystem and preclinical model platform for myoepithelial carcinoma.

Jamie Barber, Naomi Natale, **Michael Casaus**

cureMEC, Albuquerque, NM

Myoepithelial carcinoma (MEC) is an ultra-rare, clinically aggressive malignancy (incidence 0.013/100,000) that affects both children and adults and arises in diverse anatomic sites, most commonly the salivary gland and soft tissues. Despite its severity, MEC remains profoundly understudied, with no established therapeutic standards and historically limited access to biospecimens, molecular data, or disease-relevant models. Although recurrent gene fusions, most frequently involving EWSR1 with partners such as ATF1, KLF15, KLF17, PBX1, and POU5F1, define a subset of pediatric and young adult cases, MEC overall exhibits substantial biological heterogeneity that has yet to be systematically characterized. To address longstanding barriers to progress, cureMEC: The Myoepithelial Carcinoma Project was launched in 2022 as a patient-driven research initiative dedicated to building the foundational infrastructure required to study MEC across molecular subtypes. In partnership with the Rare Cancer Research Foundation (RCRF) and Pattern.org, cureMEC has established the first dedicated MEC biorepository and integrated clinical-molecular data platform, supporting systematic specimen acquisition, multiomic profiling, and open-access research engagement. MEC biospecimens are now incorporated into large-scale programs spanning transcriptomics, proteomics, and high-throughput drug-screening pipelines. Early achievements include creation of the first coordinated MEC biobanking network and establishment of two novel MEC cell lines have been developed and identification of a patient-derived xenograft (PDX) molecularly confirmed to harbor EWSR1-KLF15. These models will support mechanistic studies of EWSR1-driven oncogenesis, surface-protein mapping to identify therapeutic targets, and high-throughput drug-repurposing screens across fusion-defined contexts. Together, these efforts establish the first integrated research ecosystem for MEC, combining patient partnership, biospecimen infrastructure, and proteogenomic discovery. This model demonstrates how patient-driven collaborations can rapidly build foundational scientific resources for ultra-rare cancers, creating the tools necessary to elucidate disease mechanisms and accelerate the development of targeted therapies.

#6356 MATCHMAKERS Cancer Grand Challenge Team: Partnership and purpose to maximize patient research advocate involvement in collaborative preclinical research.

Annie Ellis[1], Luciana Holtz[2], Michele Rakoff[3], Tracy Solak[4], Matheus O. de Souza[5], Michael Birnbaum[5]

[1]Ovarian Cancer Research Alliance / SHARE Cancer Support, New York, NY,[2]Instituto Oncoguia, Sao Paolo, Brazil,[3]Breast Cancer Care and Research Fund, Los Angeles, CA,[4]Advocate, National Breast Cancer Coalition, Washington, DC,[5]Massachusetts Institute of Technology (MIT), Cambridge, MA

Objectives Patient research advocate (PRA) involvement in clinical trials has increased, yet involvement in pre-clinical research remains limited because pathways for incorporating patient perspectives are not always clear. MATCHMAKERS seeks to build models for effective PRA participation in pre-clinical science.
Background Cancer Grand Challenges (CGC), founded by NCI and CRUK, supports global interdisciplinary teams advancing cancer research and requires patient advocate involvement to ensure real-world impact. Launched in 2024, CGC Team MATCHMAKERS includes researchers from 10 institutions across six countries working to crack the code of how T cells recognize cancer cells using structural biology, high-throughput screening, and artificial intelligence to inform predictive immunotherapy tools.
Methods Four PRAs from the USA and Brazil contribute lived cancer experience and advocacy expertise. PRAs attend monthly research meetings, PRA meetings, CGC advocate sessions, and annual CGC and MATCHMAKERS summits. The Lead PI and Program Manager attend PRA meetings and coordinate interactions with trainees and investigators to facilitate bidirectional learning and involvement.
Results PRAs have partnered with five trainees from four labs, co-developing shared language, context, and communication tools. PRA involvement has strengthened understanding of MATCHMAKERS research goals, while trainees report appreciation of patient needs and translational relevance. Key activities and trainee reflections are summarized in the Table.
Conclusions Early experience demonstrates that structured PRA involvement fosters mutual respect, trust, and more patient-centered scientific thinking. Next steps include expanding PRA-trainees partnerships across institutions and contributing to CGC-wide best-practice development for PRA involvement in pre-clinical research.

PRA goals, key outputs, and trainee reflections

Category	
PRA Goals	Bring patient perspective into research; support trainee education; share MATCHMAKERS science with patient communities; develop best practices for pre-clinical advocacy
Outputs	Glossary; lay summaries; lay TCR overview; education module for advocates; lab-visit video series
Trainee Reflections	“I think more about applicability beyond fundamental research.” “Advocacy input keeps me focused on clinical translation.” “Engagement helps me see the broader purpose and communicate better.”

#6357 *Surprising myself of how much more confident I got in being able to share my voice*: A qualitative study exploring patient and public engagement in cancer research.

Piotr Teodorowski[1], Joi Miner[2], Jonathan B. Green[2], Daniel G. Garza[2], Marcus Arana[2], Beth Maclin[3], Edward Duncan[1], Jonine Figueroa[3], Liz Forbat[1], Sarah S. Jackson[3]

[1]University of Stirling, Stirling, United Kingdom,[2]Community Advisory Board, University of Stirling, Stirling, United Kingdom,[3]National Cancer Institute, Bethesda, MD

Background Patient and public engagement is becoming recognised as important to strengthen cancer research. This means that research is conducted with, rather than to, about, or for, members of the public. When done in a non-tokenistic way, engagement has the potential to improve the quality and relevance of research findings. However, there is limited methodological guidance and understanding of how to deliver meaningful engagement at every stage of the research process. This study aims to address these gaps by exploring the experiences of cancer researchers and members of the public engaged in cancer research in the United States.

Methods Qualitative interview design involving semi-structured interviews with cancer researchers (n=15) and members of the public engaged in cancer research (n=15), exploring how engagement is delivered, barriers, facilitators and its impact. Data were analysed using reflexive thematic analysis, supported by NVivo 20. A community advisory board comprising four lived experience experts who were previously involved in cancer research served as co-researchers. They come from diverse communities and have lived experience of cancer. Their contribution was throughout the entire study process, from design (including topic guides development) through data analysis and reporting.

Results The findings capture the experiences of researchers and members of the public around patient and public engagement in cancer research. They identify the enablers (e.g., institutional support) and barriers (e.g., financial) to public engagement in cancer research, capture existing strategies to mitigate these barriers, and examine the impact of engagement activities on the research project, researchers and members of the public. This study offers new insights into establishing and delivering effective engagement activities. First, it highlights the importance of identifying suitable community representatives who can advise researchers on selecting appropriate members for the advisory boards. Second, it describes how the public can contribute to research throughout the engagement process, and how researchers can support them to ensure everyone has confidence to contribute fully. Third, it suggests options for public engagement when financial resources are limited.

Conclusion Genuine patient and public engagement in cancer research is still evolving in the United States, with various approaches currently in use; however, there is a growing consensus that researchers should adapt their work to include public voices. This study will provide further understanding and guidance for cancer researchers on how to involve patients and the public in cancer research in an inclusive and impactful way.

#6358 Project CoMMunity: A local learning network deployed to address multiple myeloma care gaps in two communities.

Cesar Rodriguez[1], John T. Mckay[2], Abdur Rahman Jabir[2], Alex Lieberman-Cribbin[3], Sean Paul Ormond[1], **Kimberly Brunisholz**[4], Kristi Cohn[5], Dianna S. Howard[5]

[1]Mount Sinai Health System, New York, NY,[2]Atrium Health Wake Forest Baptist Comprehensive Cancer Center, Winston-Salem, NC,[3]Tisch Cancer Institute, Mount Sinai Health System, New York, NY,[4]Johnson & Johnson, Salt Lake City, UT,[5]Petauri Kinect, New York, NY

Introduction Treatment advances in multiple myeloma (MM) have resulted in five-year survival improvements. However, gaps remain in access and adoption of standard of care (SOC) and novel therapies. As a result, variation in care persists. Project CoMMunity is a multi-center, local learning network to detect unmet needs, understand barriers impacting SOC treatment access, and address care gaps through innovative oncology partnerships and targeted interventions.

Materials/Methods A multi-method approach was used to implement an integrated local learning network among academic and community oncology practices within New York City, NY and Winston-Salem, NC. A needs assessment and co-creation session to identify barriers and solutions was performed through community roundtables with diverse stakeholders. Electronic medical record data of patients with MM were compared across communities. Clinician-reported barriers and root causes limiting access and adherence to SOC treatments were solicited through 1:1 interviews.

Results Among 12 clinicians and 4 social workers/patient advocates that participated in the roundtables, common barriers were health literacy/socioeconomic factors, limited community/academic clinical relationships, cultural/racial issues and low patient trust, complex patient priorities/medical conditions, and limited clinical trial exposure. Stakeholders indicated opportunities to support education and awareness, improve care continuity transitions among community and academic sites, and development of educational materials. Of 332 patients (NY 237; NC 95), quantitative analysis highlighted clinical variation in time from diagnosis to specialist visit (NY: 34 vs NC: 62 days), frontline therapy (1LOT) count (quadruplet, NY: 62.3% vs NC: 11.6%; triplet, NY: 34.3% vs NC: 79.0%) and stem cell transplantation incidence (NY: 30.8% vs NC: 50.5%). Time from diagnosis to 1LOT and proportion of patients referred to sub-specialists were consistent among sites. Overall, few patients (5.1%) received innovative therapies (eg, CAR-T, bispecific antibodies). Among 10 interviews, clinician-reported barriers and root causes limiting access to SOC treatment included patient characteristics, care barriers, referral/treatment protocols, and community engagement/support resources.

Conclusion Local communities vary in needs, capacity, stakeholders, and existing healthcare infrastructure. Programs striving to improve access and adoption of SOC and novel therapies need to be multi-faceted and designed with local implementation in mind. A local learning network with regional participants provides a robust framework to efficiently transfer insights and clinical best practices while deploying local interventions that are responsive to needs of a diverse community. A one size fits all model will not succeed given unique setting and community needs.

#6359 Lineberger Excellence in Advocacy Program (LEAP): Implementation and evaluation of a comprehensive patient and community engagement program at the University of North Carolina to improve patient centered research.

Patricia A. Spears[1], Jennifer A. Potter[1], Veronica Carlisle[1], Hayley Morris[1], Barbara Alvarez Martin[2], Stephanie B. Wheeler[3], Marjory Charlot[4]

[1]Community Outreach and Engagement, UNC Lineberger Comprehensive Cancer Center, Chapel Hill, NC,[2]Community Outreach and Engagement, Population Science, UNC Lineberger Comprehensive Cancer Center, Chapel Hill, NC,[3]UNC Gillings School of Global Public Health, Community Outreach and Engagement, UNC Lineberger Comprehensive Cancer Center, Chapel Hill, NC,[4]Community Outreach and Engagement, Patient Engaged Research, UNC Lineberger Comprehensive Cancer Center, Chapel Hill, NC

Introduction: Engagement of advocates in cancer research ensures research is patient centered. However, engagement of advocates has been inconsistent in some cases and lacks equitable representation across cancer types. Some researchers find it challenging to identify advocates to engage in research and advocates feel underutilized and underrepresented. Lineberger Comprehensive Cancer Center (LCCC) has established a comprehensive advocate engagement framework called Lineberger Excellence in Advocacy Program (LEAP). By creating a comprehensive program through the office of Community Outreach and Engagement, LCCC can maintain meaningful and sustainable relationships between community members, patients and researchers.
Methods: LEAP began in 2022 and is an umbrella program that centralizes key components necessary to maintain adequate bi-directional involvement between community members, patients, and researchers. LEAP entails recruitment, training, advocate-researcher matching, compensation guidance (pre and post award), and evaluation. A Patient Advocate Learning Portal was developed to support LEAP members. The portal offers on-demand access to training videos (e.g., grant review, plain language), webinars (e.g., ASPIRE program), and supplementary resources, including key articles and websites, to enhance member knowledge and engagement. Advocate-researcher matching is accomplished through a simple process. Researchers submit a LEAP member request form in Qualtrics and a request email is sent to LEAP members. We track requesters, opportunity, time to fill the request, and advocates who volunteer in Excel. We also evaluate meaningful engagement of advocates and researchers through surveys and interviews, respectively. Advocate evaluations are conducted annually using a 31-item survey assessing demographics, activities, perceived value, decision-making, and engagement opportunities. LEAP facilitates recruitment and sustained engagement through an email listserv.
Results: LEAP has over 92 members of which 72 identify as 53% white, 27% Black/African American, 4% other and 20% unknown. There have been 86 requests from researchers since 2023. These have resulted in 257 LEAP engagements in research projects among the 92 members. Advocate-researcher matches were not made in 6% of the requests due in part to the specificity of the request (e.g., rare cancers). LEAP evaluations from 2024 and 2025 demonstrated that over 90% of advocates indicated high satisfaction on a 5-point Likert scale with feeling valued, respected and heard.
Conclusion: LEAP has increased the engagement of patient and community members in LCCC research, enhanced advocate-researcher satisfaction and improved the alignment of advocates with researchers' specific projects.

#6360 Project Cure CRC: A patient-powered ecosystem uniting data, discovery and accelerating cures for colorectal cancer.

Kim Newcomer, Travis Hyams, Tina Zeff, Marc Mason, David Fenstermacher, Michael Sapienza, Erin Siegel

Colorectal Cancer Alliance, Washington, DC

Background: Colorectal cancer (CRC) remains a leading cause of cancer mortality despite significant advances in molecular and immunologic science. Progress is limited by fragmented research infrastructure, underrepresentation of diverse populations, and a lack of coordinated translation between discovery and clinical care. The Colorectal Cancer Alliance launched Project Cure CRC in 2023 to build a national ecosystem that unites patients, investigators, and partners through research acceleration, data integration, patient empowerment, and collaborative partnerships. Project Cure CRC's goal is to improve overall survival from colorectal cancer and advance new therapies.

Methods: Project Cure CRC has several components that have never been combined before for colorectal cancer: 1) K-SPY, an adaptive platform trial evaluating perioperative, neoadjuvant, and minimal residual disease (MRD) interventions in colorectal cancer; 2) BlueLake, a data and real-world evidence platform connecting clinical, genomic, and patient-reported outcomes data to inform research and care delivery; 3) BlueHQ, a digital patient support, navigation, and engagement hub enabling patients to connect with each other and patient navigators, contribute longitudinal data, access tailored educational resources, and participate in research opportunities; and 4) A competitive request for proposals (RFPs) focused on accelerating translational progress towards a cure: Early-Career Investigator Awards, Senior Investigator Awards, Pilot Awards, and Team Science Awards. Each proposal is peer-reviewed and designed to feed forward into ongoing K-SPY and BlueLake efforts, ensuring rapid translation of discovery into clinical utility.

Results: Since its launch, Project Cure CRC has received 525+ proposals and has distributed over $15 million in funding across 33 projects, advanced multicenter biomarker and equity studies, and finalized governance frameworks for K-SPY submission to the FDA. More than 150 academic investigators, 20 industry partners, and patient participants are now engaged, forming the largest philanthropic CRC research network in the United States. In 2025, the Alliance launched a patient advisory council consisting of a diverse group of colorectal cancer patients to provide feedback on the ecosystem.

Conclusions: Project Cure CRC demonstrates a scalable, patient-powered model that connects discovery research, adaptive clinical trials, and real-world data within a single coordinated ecosystem. By aligning research acceleration, data integration, patient empowerment, and collaborative partnerships, the initiative is transforming colorectal cancer research and accelerating cures.

#6361 Patient and patient group engagement in cancer clinical trials in low- and middle-income countries.

Linsey Eldridge[1], Annette Galassi[2], Satish Gopal[1], Ophira Ginsburg[1], Mishka Kohli Cira[1]

[1]National Cancer Institute, Bethesda, MD,[2]Leidos Biomedical Research, Inc, Gaithersburg, MD

We conducted qualitative focus group discussions (FGD) with cancer patients and patient groups in low- and middle-income countries (LMICs) to understand their role in the cancer clinical trial ecosystem and identify strategies to improve engagement. These FGDs are part of a broader mixed-methods effort led by the National Cancer Institute to better characterize the clinical trial landscape in LMICs. Participants from six WHO regions were recruited through partner organizations, which disseminated email invitations including a link to a recruitment form collecting demographic and clinical trial experience information. Individuals in LMICs who have lived experience with cancer were invited to attend. Nine 90-minute semi-structured FGDs were conducted with 45 participants from 25 countries. Interviews were recorded, transcribed, and double-coded in Dedoose using directed content analysis. Most participants reported their primary role as a cancer patient advocate or person with cancer or survivor (33/45). Most participants said that patients and patient groups are not systematically involved in clinical trials, citing limited awareness about value of engagement and perceived researcher resistance as the greatest challenges. Limited availability of trials in LMICs and poor standard of care emerged as major challenges. When involved, engagement activities included educating patients about clinical trials and supporting recruitment. Participants described an ideal role that included serving as a bridge between patients and researchers, with involvement sought by researchers from design through dissemination. Participants noted several facilitators to increase patient engagement, including knowledge about the clinical process, access to information about specific clinical trials, capacity building for both patient groups and researchers, and implementing a formal process and compensation for engagement. Improving cancer care quality and access emerged as an important priority for many. This study provides an initial assessment of patient and patient group involvement in cancer clinical trials in LMICs from the perspective of people with lived experience. Findings reveal a gap between current and ideal levels of patient and patient group engagement, driven by limited awareness, structural barriers in LMICs, and perceived researcher resistance. Strengthening awareness, capacity, and structured mechanisms for involvement may enable patient groups to serve as effective bridges between communities and researchers and help improve patient-centered cancer care globally.

#6362 Optimization of outreach and engagement of patients/survivors and community supporters to reduce the cancer burden.

Lourdes Baezconde-Garbanati[1], Sandra Suther[2], Fern Webb[3], John Luque[2], Jennifer Tsui[1], Carolina Aristizabal[4], Brooke Vintilla[5], Ileana Guzman[6], Eduardo Ibarra[7], Rosa Barahona[7], Janet Rodriguez[8], Pastor Rhonda Holbert[1], Mariana C. Stern[9]

[1]Keck School of Medicine of USC, Los Angeles, CA,[2]Florida A&M University, Tallahassee, FL,[3]University of Florida College of Medicine - Jacksonville, Jacksonville, FL,[4]USC Norris Comprehensive Cancer Center, Los Angeles, CA,[5]University of Florida, Gainesville, FL,[6]University of Florida, Orlando, FL,[7]University of Southern California, Los Angeles, CA,[8]USC Norris Comprehensive Cancer Center, Ontario, CA,[9]Associate Professor, Dept. of Prev. Medicine, USC Norris Comprehensive Cancer Center, Los Angeles, CA

Introduction

Cancer deaths from prostate, lung, and pancreatic cancers remain highest in low-income communities. Survivors and caregivers report that these losses stem not only from disease, but from gaps in communication, trust, access, and culturally relevant information. Their lived experiences are essential for shaping solutions. The CaRE2 Health Center views patients and survivors as partners whose insights ensure scientific progress reaches those most affected.

Procedures

To elevate patient leadership, the CaRE2 Community Outreach Core (CaRE2-COC) uses an engagement model guided by a Florida-California Tri-Institutional Community Advisory Committee (CAC). The 13-member CAC—largely survivors and caregivers—meets quarterly to set priorities and ensure research reflects patient needs. Two training programs, the Community Supporters Academy (CSA) and the 10-week Community Scientists Research Academy (CSRA), build cancer knowledge, research literacy, and advocacy skills so participants can guide research and engage others. They co-create culturally tailored materials distributed at community events and online. A Community Contact Registry tracks willingness to join research, clinical trials, and biospecimen donation; low biospecimen comfort prompted creation of a patient-friendly biorepository video. Partnerships, a podcast, and public events expand opportunities for survivors to share stories and access information.

Results

The CAC ensures patient and survivor perspectives guide CaRE2-COC programs. Since 2019, the CSA has trained 150 ambassadors, and 80 community scientists completed the CSRA with stipends to lead local projects. Pre/post assessments show gains including increased confidence engaging other survivors and improved cancer-screening knowledge. A Cancer Community Conference reached 527 participants, and 5,000 community members received tailored educational materials. Registry data show strong willingness to complete surveys but lower biospecimen comfort, reinforcing education needs. The survivor-story podcast reached 240 listeners, and social media engagement exceeded 28,000 impressions. Events such as an Orlando Magic partnership brought cancer information into trusted community spaces.

Conclusions

CaRE2-COC strengthens patient, survivor, and community leadership by ensuring their experiences guide communication and research priorities. By training trusted influencers and embedding engagement into screening, prevention, and research, CaRE2-COC builds stronger community-academic partnerships, increases research participation, and advances its mission to reduce cancer burdens in California and Florida.

#6363 Supportive community and patient-centered spaces for discussing health concerns throughout the cancer journey.

Elena B. Nieves[1], Rosa Barahona[2], Marya Shegog[3], Dana Dornsife[3], Erin Miller[3], Lourdes Baezconde-Garbanati[4]

[1]USC Norris Comprehensive Cancer Center, Los Angeles, CA,[2]University of Southern California, Alhambra, CA,[3]Lazarex Cancer Foundation, Danville, CA,[4]Keck School of Medicine of USC, Los Angeles, CA

Background: Through purposeful collaboration with USC NCCC, the Lazarex Cancer Foundation established the Lazarex Cancer Wellness HUBs pop-up model to offer a supportive, welcoming space that reflects and responds to the cultural needs and unique cancer challenges of the diverse and vulnerable communities we serve. Advancing cancer health equity means partnering with our communities to create spaces that reflect who they are and provide culturally and language-specific guidance. With this purpose, the HUB ensures equitable access to cancer programs and support that strengthen outcomes across the full cancer-care continuum.

Methods: The Wellness Hubs have maintained a steady presence across Los Angeles County, partnering with various community and faith-based organizations—including the Chinatown Service Center, Black Men's Wellness Day, the Alhambra Lunar New Year Festival, and Macedonia Baptist Church of LA and at local YMCAs. We expanded our offerings with mindfulness workshops that help participants cultivate calm, emotional balance, and resilience throughout the cancer journey. Our speaker series, featuring scientists and expert guests, has continued to bring the community up-to-date information on cancer research, treatment options, and available support services.

Results: Our approach emphasizes active community participation. We have shared critical cancer information with over 11,000 individuals from diverse racial and ethnic backgrounds. Our speaker series has drawn more than 3,000 attendees and explored topics such as brain cancer, current research, access to care, and breast and cervical health. In addition, 86 community members have participated in our mindfulness workshops, using mind-body techniques to enhance emotional and physical well-being.

Conclusion: Our community outreach approach ensures that we remain present and engaged within Los Angeles County's diverse communities, providing culturally and locally tailored information. We offer education and connections to cancer support services, so individuals feel supported before, during, and long after their cancer journey. This includes sharing screening guidelines, emphasizing the need for diversity in cancer clinical trials, promoting self and patient advocacy, and directing community members to trusted sources. Through this work, we are actively helping to reduce cancer disparities.

#6364 A qualitative evaluation of storytelling narratives designed as strategy to increase uptake of lung cancer screening for veterans.

Hannah Brooks[1], Anna Gallion[1], Carolyn Audet[1], Rebecca Selove[2], Sally York[3], Fred Hendler[4], Drew Moghanaki[5], Robert Dittus[1], Christianne Roumie[1], Jennifer Lewis[1], Lucy B. Spalluto[1]

[1]Vanderbilt University Medical Center, Nashville, TN,[2]Tennessee State University, Nashville, TN,[3]VA Tennessee Valley Healthcare System, Nashville, TN,[4]Rex Robley VA Medical Center, Louisville, KY,[5]VA Greater Los Angeles, Los Angeles, CA

INTRODUCTION: Lung cancer screening with low-dose computed tomography (LDCT) reduces lung cancer mortality. However, LDCT utilization remains low, including in the Veterans Health Administration. Personal storytelling narratives are an evidence-based strategy to influence healthy behaviors like lung cancer screening. However, little is known about how Veterans might respond to narratives. We aimed to develop 3 preliminary digital (video) narratives about lung cancer screening and elicit feedback from Veterans about the narratives.
METHODS: In partnership with StoryCenter, we worked with three Veterans (i.e., Storytellers) to develop preliminary personal digital storytelling narratives about their lung cancer screening experiences. To elicit feedback, we recruited Veterans (i.e. interviewees) at a single Veterans Affairs Medical Center between January 14, 2025, and June 13, 2025 to view the narratives and participate in an interview. Guided by the Learner Verification and Revision technique, we conducted semi-structured interviews. We analyzed and organized qualitative data by constructs of the Learner Verification and Revision technique including: i) visual and auditory appeal of the tool (Attraction); ii) whether the tool is socially agreeable (Acceptability); iii) how well the viewer understood the central message of the tool (Comprehension) and whether the message compels the viewer to complete the suggested action (Persuasion); and iv) how confident the viewer is they are able to complete the suggested action (Self-efficacy).
RESULTS: Interviewees (n=30) generally perceived the videos as having compelling visual and auditory elements, noting the importance of subtitles and high-quality images (Attraction). Interviewees found few aspects of the narratives unacceptable, although casual language and discussion topics were noted as potentially off-putting (Acceptability). Narratives that displayed the CT scanner and portrayed Storytellers' screening experiences were most informative, reduced anxiety and built trust. Interviewees connected with narratives that reflected shared experiences such as smoking history, military service, and family responsibilities, viewing these as motivational to pursue screening. Nevertheless, some aspects of the narratives were less well-liked due to personal histories and experiences (Comprehension/Persuasion). Several interviewees stated the videos motivated them for screening, but noted the videos did not adequately describe next steps (Self-efficacy). Interviewees suggested future narratives emphasize the ease and benefits of screening, while integrating relatable and motivating messages.
CONCLUSIONS: Leveraging Veteran feedback to modify preliminary personal digital storytelling narratives can inform and improve future iterations of narratives for broader implementation.

#6365 Prostate cancer awareness and car show: An initiative to increase prostate cancer screening.

Vivian Carter, Doreatha Heard

Psychology and Sociology, Tuskegee University, Tuskegee, AL

Introduction: While data reflect that Prostate Cancer is lower in rural areas this can be misleading as rural communities also have higher death rates and higher rates of Prostate Cancer reoccurrence compared to urban areas. Macon County Alabama has one of the highest Prostate Cancer Mortality rates in the nation. Macon Means a Cancer Support Nonprofit Organization partnered with local health advocacy organizations, Civic organizations and Universities to support a health initiative specifically for men in rural communities.
Summary: The initiative was to sponsor a men's health fair alongside a car show. The combination of the health fair with the car show would bring more men out to the event and provide an opportune time for a one stop informational about their health and the necessary check ups they should have and provide access to the screening service on site. mobilize Macon County communities in the fight to eliminate prostate cancer racial disparity. The Prostate Cancer Awareness Health Fair and Car Show with Free PSA Screening was held on September 28, 2024, in Downtown Tuskegee.
Conclusion: The event united organizations throughout the state to raise awareness about critical health issues, forty-three (43) vendors delivered essential health services to over 275 people in attendance. Forty-seven (47) men received free PSA screenings; fourteen percent (14%) required further follow-up.

: Drug Delivery
Poster Session

#6370 Targeted polymeric nanoconjugates for BBB penetration and time specific delivery of PDL1 blocking small peptides via LRP1 targeting in melanoma brain metastases.

Saurabh Sharma[1], Prabhjeet Singh[2], Jay Chadokiya[3], Amanda R. Kirane[1]

[1]Stanford University School of Medicine, Stanford, CA,[2]Stanford University, Stanford, CA,[3]General Surgery, Stanford University School of Medicine, Stanford, CA

Background: Melanoma brain metastases (MBM) show high CNS tropism with limited benefit from single-agent ICB; a combination regimen with an AXL inhibitor may improve responses but carry substantial toxicity. The brain TiME features scarce T cells, abundant TAMs, and glial PD-L1, promoting immune evasion and poor ICB efficacy. BBB penetrant strategies via peptide-based Immuno-Nano-Conjugates (INCs) are under development, though intrathecal delivery has not improved survival. LRP-1-mediated INCs delivery may enable BBB transport and TAM-TiME reprogramming. Here, we report a targeted nanoplatform that crosses the BBB and delivers PD-L1-blocking peptides to the TiME.
Methods: Immuno-Nano-Conjugates (INCs) were synthesized by conjugating a biocompatible malic acid polymer conjugated with (i) P-12, a PD-L1 blocking peptide, and (ii) Angiopep-2 (AP2), a ligand for LRP-1 mediated transcytosis. Therapeutic efficacy, safety, toxicity, and biodistribution studies were assessed using an *in vitro* static BBB-on-a-chip brain tumor model and *in vivo* in established murine cancer models. Clinical transcriptomic correlation data from metastatic melanoma (TCGA-SKCM, n = 471) were analyzed via the GDC legacy archive to construct Kaplan-Meier survival curves.
Results: The INCs traversed the BBB and demonstrated penetration in a BBB-on-a-chip brain tumor model. Upon delivery, INCs were selectively internalized by the activated TiME environment, thereby promoting antitumor immune cell activation and proliferation. *In vivo* efficacy, safety, toxicity, and biodistribution revealed superior brain accumulation of INCs relative to ICB agents and significant efficacy and a better safety profile. Clinically, high AXL expression correlated with nonresponse to ICB in Stage IV melanoma and aligned with immunosuppressive myeloid signatures, demonstrating an association with reduced survival in patients with brain metastases. In subcutaneous melanoma models, the combination of P-12 (anti-PD-L1)- based peptides with the AXL inhibitor Bemcentinib yielded greater tumor burden reduction than anti-PD-1 monotherapy, suggesting the potential to circumvent ICB resistance in MBM settings.
Conclusion: Our data indicate that BBB transcytosis of INCs via LRP-1 mediates enhanced delivery of PD-L1 blocking peptides to the TiME, supporting improved therapeutic exposure for MBM. AXL emerges as a critical therapeutic target and a rational axis for combination strategies with targeted nanoplatforms to treat resistant MBM. Ongoing studies across additional MBM-relevant models aim to validate these findings and further optimize second-generation bispecific INCs approaches.

#6371 Enhanced therapy for triple-negative breast cancer (TNBC) using combinatorial drug delivery.

Santosh K. Singh[1], Melad Dababneh[2], Brian M. Rivers[1], Rajesh Singh[1]

[1]Morehouse School of Medicine, Atlanta, GA,[2]University of Alabama at Birmingham, Birmingham, AL

Breast cancer (BrCa) is the most common cancer among women. Although there has been progress in early detection and specific therapies, long-term success is still limited, especially for triple-negative breast cancer (TNBC). This challenge arises from issues such as recurrence, drug resistance, and side effects associated with treatments. Chemoprevention, which involves using natural compounds to delay, suppress, or prevent cancer development in individuals at high risk, shows promise, but clinical success is limited by poor bioavailability. Hedgehog (Hh) signaling pathways are being studied for the growth and metastasis of BrCa; thus, targeting Hh represents a promising therapeutic strategy. To address these challenges, we studied the effects of combining two drugs: honokiol (HNK), a natural compound derived from *Magnolia officinalis*, alongside the chemotherapy drug docetaxel (DTX) for treating TNBC. For this purpose, we employed gold nanoparticles (AuNPs). Our results show that dual drug delivery (HNK+DTX), combined with sonic hedgehog (Shh) DNA aptamer (AP32)- conjugated AuNPs, effectively targets the Hh pathway in TNBC cells that express it at high levels. We characterized the formulated AuNPs, including a Zetasizer for charge and size analysis, Transmission Electron Microscope (TEM), Fourier-Transform Infrared Spectroscopy (FTIR), Nuclear Magnetic Resonance (NMR), and Nanoparticle Tracking Analysis (NTA), before applying them to TNBC cells (MDA-MB-468 and MDA-MB-231). A cell viability/ cytotoxicity assay was performed to determine the IC_{50} values and assess drug combination synergy. Additionally, 3D cell models confirmed the internalization of AuNPs and the efficacy of combination AuNPs compared to single-drug or scramble aptamer AuNPs (control). Mechanistic studies using immunofluorescence, flow cytometry, qRT-PCR, and Western blot analysis show that Shh-targeted delivery suppresses the expression of downstream signaling molecules, Gli1 and Ptch1, induces cell cycle arrest at the G_0/G_1 phase, and triggers apoptosis. Furthermore, results from molecular dynamics simulations suggest that HNK influences both NF-κB-driven transcription and Shh-mediated signaling, subsequently affecting tumor cell-environment interactions. These findings highlight the potential of combination AuNPs for pathway-specific intervention in addressing TNBC, providing a foundation for further research in this area.

#6372 Regulating epithelial-to-mesenchymal transcription-driven metastatic capacity with molybdenum disulfide (MoS2) nanoparticles.

Samantha Michelle Foster, Kanwar A. Singh, John Soukar, Olajumoke Ogunlusi, Christian Nguyen, Subiksha Sankar, Anna Keller, Tapasree Roy Sarkar, Irtisha Singh, Akhilesh Gaharwar

Texas A&M University, College Station, TX

Epithelial-to-mesenchymal transition (EMT) is the process by which stationery, tightly connected epithelial cells transform into more mobile, flexible phenotype. This plays a significant role in allowing cancer cells to detach from the original tumor, invade surrounding tissues and spread throughout the body. While EMT plays a role in significant physiological functions such as wound healing, the development of a mesenchymal phenotype within the tumor microenvironment is detrimental, promoting cancer cell escape into circulation and subsequent development of the pre-metastatic niche. EMT is a major contributor to the risk and progression of metastatic cancers and targeting and blocking EMT presents a potential therapeutic intervention for preventing the development of metastases. Here, we introduce molybdenum disulfide (MoS_2) nanoparticles as a potential drug-free inhibitor of EMT, which is advantageous over traditional chemotherapy-type drugs due to lack of adverse off-target effects in distant tissues. This study investigates the impact of MoS_2 nanoparticles on epithelial-to-mesenchymal transition in highly metastatic triple-negative breast cancer both *in vitro* and *in vivo*. Treatment of MoS_2 nanoparticles decreased migratory capacity of *in vitro* and *in vivo* models of ER+ and triple negative breast cancer, demonstrating the anti-metastatic motility property of MoS_2. *In vitro*, MoS_2-treated breast cancer cells observe decrease in focal adhesion proteins and genes associated with cellular motility. Furthermore, cells show decrease in TGFβ signaling and expression of EMT markers after 72h of exposure, indicating that MoS_2 nanoparticles inhibited EMT progression mediated through cellular motility and TGFβ signaling. This effect was further demonstrated with functional 3D mammosphere assays, which indicated reduced mammosphere formation and size. Similarly, clonogenicity was significantly reduced in cells following treatment with MoS_2 nanoparticles. *In vivo*, direct injection of MoS_2 into 4T1 mouse mammary tumors significantly decreased primary tumor growth and burden as well as the number of metastatic foci in the lung. Our work demonstrates that MoS_2 nanoparticles inhibit integrin activity as well as the TGFβ signaling cascade pathway, blocking the transition of cells to a mesenchymal-like phenotype. These findings suggest that MoS_2 nanoparticles hold promise for drug-free cancer therapeutic applications in reducing metastatic potential.

#6373 Development of a lipid nanoparticle formulation of the bifunctional PARP and HDAC inhibitor kt-3283.

Sarah Truong[1], Samar Alsudir[2], Laila Al-Alwan[2], Beibei Zhai[1], Louise Ramos[1], Mona Marzban[1], Fariba Ghaidi[1], Haidar Almubarak[2], Qassem Alalaiwi[2], Aljohara Albabtain[2], Kally Singh[3], John Langlands[3], Dennis Brown[3], Ali H. Alhasan[2], Jeffrey Bacha[3], Mads Daugaard[4]

[1]Vancouver Prostate Centre, Vancouver, BC, Canada,[2]NanoPalm, Riyadh, Saudi Arabia,[3]Rakovina Therapeutics Inc., Vancouver, BC, Canada,[4]University of British Columbia, Vancouver, BC, Canada

Poly(ADP-ribose) polymerase (PARP) plays a major role in DNA repair and PARP inhibitors (PARPi) have shown clinical benefit in a number of tumor indications. Deacetylation of histones, controlled by histone deacetylases (HDACs) is a key regulatory event in DNA repair and inhibition of HDACs has been shown to reduce tumor growth *in vitro* and *in vivo*. PARPi combined with HDAC inhibition has demonstrated enhanced efficacy in pre-clinical studies in various tumor indications, and in patients with metastatic breast cancer. However, combination therapies can be limited in clinical utility due to overlapping toxicities and different pharmacokinetic profiles. kt-3283 embodies synthetic lethality by integrating two synergistic mechanisms—PARP inhibition and HDAC-mediated chromatin remodeling—into a single compound thereby eliminating the need for simultaneous or staggered drug combination regimens and the risk of overlapping toxicities. Previous studies have demonstrated strong inhibition of PARP1/2 and HDAC enzymes *in vitro*, inhibition of cell cycle arrest and DNA damage marker upregulation, significant inhibition of cell viability across multiple tumor types, and inhibition of metastatic seeding in an *ex vivo* pulmonary metastasis assay. While kt-3283 has demonstrated potent anti-tumor activity in vitro, its clinical viability is limited by low bioavailability and poor metabolic stability. Lipid nanoparticles (LNPs) are nanocarriers for oncology drugs, offering superior encapsulation efficiency, with the ability to incorporate hydrophobic and hydrophilic payloads, protecting them from degradation and targeting for tumor selectivity. Patterned LNPs (pLNPs) designed using the EnsaliX AI platform are novel class of LNPs enable superior targeting, stability and safety through highly ordered structures. Kt-3283 is being encapsulated into the EnsaliX-designed pLNPs to produce pLNP/kt-3283. Physicochemical parameters of kt-3283 (solubility, pKa, thermal behavior, and metabolic stability) are being integrated for optimal pLNP/kt-3283 fabrication supporting enhanced encapsulation efficiency, and superior in vitro cell uptake, stability and bioavailability. Development of pLNP/kt-3283 uniquely combines design, formulation, and evaluation of a DDR-targeting compound, overcoming metabolic instability, and off-target limitations, and improving the therapeutic index.

#6374 Sodium chloride nanoparticles as urinary bladder cancer therapeutics.

Xinning Lai

University of Georgia, Athens, GA

In 2025, bladder cancer ranks sixth in incidence and tenth in cancer mortality in the United States, with an estimated 84,870 new cases and 17,420 deaths. Surgical transurethral resection of bladder tumors (TURBT) is the first step in standard bladder cancer treatment, followed by adjuvant intravesical chemotherapy or immunotherapy to eliminate existing or residual tumors. Local-regional therapy is particularly effective for bladder cancer because it targets superficial cases and maximizes therapeutic exposure, resulting in improved anticancer effect. Ion homeostasis is critical for maintaining cellular integrity and ensuring proper cell function. The balance between ion influx and efflux is tightly regulated by ion channels and transporters. While several strategies have been developed to target ion homeostasis as potential anticancer agents, including channel blockers and ionophores, the sodium chloride nanoparticle strategy may offer additional advantages in the context of cancer therapy.Immunogenic cell death (ICD) is a unique form of regulated cell death that promotes an anti-tumor immune response and contributes to the success of several cancer therapies such as cisplatin and mitoxantrone (MTX). ICD is characterized by damage-associated molecular patterns (DAMPs), including calreticulin (CRT), ATP, and HMGB1, which engage pattern-recognition receptors on antigen presenting cells, promoting dendritic-cell maturation and cross-presentation to T cells. Nanoparticle platforms that trigger ICD have shown promise in augmenting conventional therapies. We recently found that sodium chloride nanoparticles (SCNPs) not only kill bladder cancer cells but also induce ICD, positioning them as competitive immunotherapeutics. In this study, we presented a novel approach using phospholipid-coated sodium chloride nanoparticles (PSCNPs) as a potential treatment for bladder cancer. We synthesized and characterized SCNPs of various sizes and coated them with a layer of DSPE-PEG(2000) Amine, resulting in PSCNPs that can be stably dispersed in aqueous solutions. We investigated the degradation, endocytosis, and effects of PSCNPs on cellular ion homeostasis, as well as their effects on cell viability and cell death mechanisms. Furthermore, we evaluated the ability of PSCNPs to induce ICD and their impact on the tumor microenvironment (TME) and major organs. Finally, we evaluated the therapeutic efficacy of PSCNPs in subcutaneous tumor models, both as a single treatment and in combination with αPD1. Our results suggest that PSCNPs hold promise as a novel and effective treatment for bladder cancer, with the potential to boost immunity and transform the tumor microenvironment without causing systemic toxicity.

#6375 Tardigrade Dsup mRNA nanoparticles reduce chemotherapy-induced normal tissue toxicity.

Ian C. Sutton, Pascal Cuhat, Ashley Cooney, James D. Byrne

University of Iowa, Iowa City, IA

Bleomycin is a commonly used chemotherapeutic in the treatment of lymphomas and germ-cell tumors, yet its utility can be restricted by dose-limiting pulmonary toxicity. Bleomycin-induced generation of reactive oxygen species (ROS) causes significant damage to the alveolar epithelium. This leads to alveolar cell death, senescence, and maladaptive crosstalk with stromal cells, ultimately driving irreversible pulmonary fibrosis. Despite the clinical need, no approved strategy directly protects the lung epithelium from bleomycin toxicity. Certain natural organisms, namely tardigrades, can tolerate high levels of ROS-driven cellular damage. This tolerance is partially attributed to the tardigrade-specific Damage suppressor (Dsup) protein which interacts with chromatin and shields DNA from ROS. Our laboratory has recently shown that Dsup expression can protect other types of epithelia from radiation-induced injury. Because bleomycin and radiation share a common cytotoxic mechanism, we believe that Dsup could similarly protect alveolar epithelium. To this end, we developed a KC2/cholesterol/PEG/DOPE lipid nanoparticle (LNP) formulation optimized for Dsup mRNA delivery to human airway epithelium. This formulation was optimized to achieve >95% transfection efficiency in human small airway epithelial cells (HSAECs) and A549 cells with minimal impact on viability or clonogenicity. Transient Dsup expression significantly attenuated bleomycin-induced DNA damage in A549 and HSAECs, reducing γ-H2AX foci by ~50% and decreasing alkaline comet % tail DNA by ~25% relative to controls. Dsup expression also mitigated epithelial cell senescence (detected via β-galactosidase assay) after bleomycin treatment. In A549 and HSAECs, β-gal-positive cells were reduced by ~40% at 16 days post-bleomycin treatment. To support translational feasibility, we evaluated the compatibility of our LNP formulation with nebulization and demonstrated that the LNPs retained particle size, polydispersity, and transfection efficiency after nebulization. We further assessed delivery in physiologically relevant models that typically resist nonviral mRNA transfection. In human and pig airway air-liquid-interface (ALI) cultures, multiple LNP formulations generated robust reporter (luciferase) expression. Additionally, dilution of LNPs in 4.5% NaCl further enhanced reporter expression by ~100-fold in our ALI models compared with isotonic conditions, highlighting an additional strategy to improve airway transfection. Collectively, these data demonstrate that Dsup expression substantially reduces bleomycin-induced DNA damage and senescence in airway epithelial cells and establishes that our LNP formulation can effectively deliver mRNA to human airway epithelium in vitro. This work provides a mechanistic foundation for the development of a novel approach for preventing bleomycin-induced pulmonary fibrosis.

#6376 Magnetoelectric MOFs for ferroptosis-driven and immune-enhanced glioblastoma therapy.

Huiwen Lien[1], Shang-Hsiu Hu[1], Alan Yueh-Luen Lee[2]

[1]National Tsing Hua University, Hsinchu City, Taiwan,[2]National Institute of Cancer Research, National Health Research Institutes, Miaoli County, Taiwan

This study explores the innovative application of magnetoelectric metal-organic frameworks (MOFs) for inducing ferroptosis in glioblastoma (GBM), aiming to transform both therapeutic precision and diagnostic efficacy. MOFs, with their tunable chemical and physical properties, serve as versatile platforms for precision oncology. Here, magnetoelectric MOFs are engineered to harness electromagnetic fields, regulating intracellular iron redox states to elevate reactive oxygen species (ROS) production and drive lipid peroxidation—the hallmark of ferroptosis, a distinct iron-dependent form of programmed cell death.To enhance tumor specificity, these MOFs are conjugated with extracellular vesicles (EVs), enabling selective delivery to GBM cells and minimizing off-target toxicity. This targeted system not only improves therapeutic efficacy but also reduces side effects. Moreover, the magnetoelectric MOFs are MRI-compatible, allowing real-time tumor imaging and precise localization. This dual diagnostic-therapeutic capacity offers a powerful, non-invasive treatment strategy.Beyond direct cytotoxicity, MOF-induced ferroptosis promotes the release of tumor-associated antigens, triggering immune activation and potentially initiating immunogenic cell death (ICD). This immunomodulatory effect broadens therapeutic benefit by reshaping the tumor microenvironment. Collectively, this multifunctional MOF-based platform integrates diagnostics, therapy, and immunogenic modulation, representing a paradigm shift for treating one of the most aggressive and therapy-resistant cancers.

#6377 Intranasal delivery of lipid-based nanoparticle encapsulating CXCR7 agonist improves PD-L1 blockade efficacy in glioblastoma.

Chan-Chuan Liu[1], Yao-Wei Yeh[2], Cheng-Lin Wu[2], Tsung-Lin Tsai[2], **Kwang-Yu Chang**[3]

[1]National Health Research Institutes (NHRI), Zhunan, Taiwan,[2]National Cheng Kung University, Tainan, Taiwan,[3]National Health Research Institutes, Tainan, Taiwan

[Background] Glioblastoma (GBM) is characterized by limited treatment options and poor survival outcomes. Glioblastoma-associated macrophages (GAMs) are crucial factors that tailor the immunosuppressive tumor microenvironment (TME). Our previous study revealed that VUF11207 (VUF), a CXCR7 agonist, effectively recaptured the efficacy of the anti-PD-L1 antibody (αPD-L1) in GBM-bearing mice through inhibited CXCL12 release from tumor to transmit signals to GAMs. However, the efficacy of VUF may be hindered by poor brain delivery due to the blood-brain barrier (BBB).

[Methods] To optimize the drug delivery, we developed lipid-based nanoparticle (LNP) formulations with a non-invasive naso-to-brain delivery manner by spray. We applied an *in vivo* brain-penetration evaluation platform to assess their ability to bypass BBB. The effect of LNP-encapsulated VUF (VUF@LNP) was then assessed by observing its molecular effect and the response to αPD-L1 treatment in the animal model.

[Results] The particle size, surface charge, and shape structure of the lipid nanoparticles was controlled by mixing lipids. Studies of LNP formulations encapsulated with Evans blue (EB) have shown that the highest brain penetration efficiency is achieved with LNPs exhibiting a positive charge when synthesized at a 1,2-Dioleoyl-3-trimethylammonium-propane (DOTAP) to 1,2-Dioleoyl-sn-glycero-3-phosphocholine (DOPC) ratio of 1:4. Next, the *in vivo* bioluminescent and fluorescent imaging confirmed that DiL-labelled VUF@LNP with intranasal delivery was able to accumulate in brain tumor sites. Comparing with systemic and intranasal administration of VUF, intranasal delivery of VUF@LNP significantly improved the survival outcome of GBM-bearing mice. Intranasal delivery of VUF@LNP combined with αPD-L1 treatment markedly prolonged survival in comparison with intranasal delivery of free VUF with αPD-L1 treatment. No significant body weight changes were observed, supporting the biosafety of VUF@LNP. In terms of biological aspects, intranasal-administrating VUF@LNP significantly reduced CXCL12 and pERK1/2 levels in TME, leading to PD-L1 downregulation in GAMs and increased $CD8^+$ T-cell infiltration in comparison with systemic-administrating VUF and intranasal-administrating LNP control.

[Conclusion] Together, these findings indicated that intranasal VUF@LNP provides a BBB-bypassing, non-invasive strategy for delivering CXCR7 agonists to reprogram the immune TME. This approach may be a potential nanotherapeutic platform for combinatorial immunomodulation against GBM.

#6379 Gadolinium-based nanocomposite as a theranostic agent for triple-negative breast cancer: Synergistic radiosensitization, immune modulation, and image-guided therapy.

Yue Wang, Jiazhuo Yan, Yihan Xu, Zhengkun Cai, Zhiyong Yuan

Tianjin Medical Univ. Cancer Inst. & Hospital, Tianjin, China

Purpose: Triple-negative breast cancer (TNBC) is an aggressive malignancy with limited therapeutic options and frequent radiotherapy (RT) resistance. This study developed a novel gadolinium-based nanocomposite (GdB) with dual functions—radiosensitization and immune modulation—to establish a diagnostic-therapeutic integrated approach for precision RT in TNBC.
Methods: GdB nanoparticles were characterized structurally (TEM, XRD, EELS) and functionally (peroxidase-like activity). Cytotoxicity and radiosensitization were assessed in vitro using CCK-8, colony formation assays, apoptosis (flow cytometry, JC-1 staining), ROS generation, and DNA damage (γ-H2AX immunofluorescence and Western blot). Biocompatibility was evaluated in vivo using blood biochemistry, histopathology, and fluorescence imaging. The mechanism of immune activation was verified by measuring immunogenic cell death markers (CRT, ATP, HMGB1 release) and identifying activated pathways through transcriptomic analysis and qPCR. Immune responses were tracked in vitro (co-culture, cytokine secretion) and in vivo. Immune cell infiltration, cytokine levels (ELISA), and the immune landscape of primary and distant tumors were comprehensively analyzed using flow cytometry and single-cell RNA sequencing.
Results: GdB formed uniform spherical crystalline nanoparticles exhibiting excellent peroxidase-like activity. Mechanistically, GdB significantly enhanced radiosensitivity by promoting DNA damage and apoptosis. GdB induces ICD and activates the cGAS-STING pathway, leading to Type I interferon production, providing a robust basis for immune enhancement. GdB demonstrated excellent biocompatibility in vivo at experimental doses. Functionally, GdB served as an MRI contrast agent, enhancing tumor contrast for precise GTV delineation and facilitating real-time monitoring of tumor response to RT. Therapeutically, the combination of GdB with RT markedly inhibited tumor growth by reprogramming the tumor microenvironment from an immunosuppressive "cold" state to an immune-activated "hot" state. This conversion was marked by increased infiltration of key effector immune cells and elevated levels of anti-tumor cytokines. Crucially, the combination treatment generated a systemic anti-tumor immune response, resulting in the inhibition of distant metastases.
Conclusion: GdB is a highly effective theranostic platform for precision radiotherapy in TNBC, as its dual functions of radiosensitization and cGAS-STING pathway-mediated immune modulation substantially enhance RT efficacy and systemic anti-tumor response. Furthermore, its function as an MRI contrast agent integrates precise diagnosis with enhanced therapeutic outcomes, supporting its strong potential for clinical translation in image-guided radiotherapy.

#6380 Targeted delivery of RNA using synthetic bacterial spores.

Federico Machinandiarena, Domenico D'Atri, David J. Fitzgerald, Kumaran S. Ramamurthi

NIH-NCI, Bethesda, MD

Background: RNA therapy holds increasing promise for the treatment of various diseases. Delivering RNA, however, typically requires encapsulation in lipid nanoparticles, and a limitation of this technology is achieving tissue specificity beyond the liver and kidneys. We previously reported synthetic bacterial spore-like particles, termed “SSHELs,” for targeted cargo delivery [1]. SSHELs, composed of defined, biocompatible materials, were shown to specifically bind to HER2-positive cancer cells and accumulate in tumors [2]. This study explores whether SSHELs can deliver RNA to tissue-specific locations, focusing on HER2-positive cells.
Methods: The experimental approach involved protein purification, SSHEL assembly, mRNA and siRNA loading, and assessing RNA delivery specificity via confocal microscopy and flow cytometry. In vitro and in vivo assays were conducted to assess the production of EGFP and luciferase in target cells. Experimental models included cell cultures and mice.
Results: By decorating SSHELs with anti-HER2 affibodies and modulating lipid composition, we achieved specific mRNA and siRNA delivery to HER2-positive cells, resulting in selective protein induction or silencing. Loading SSHELs with RNA was highly efficient (~95%), yielding thousands of transcripts per particle. In further investigations, we observed a distinctive feature of SSHELs made with DOTAP: they did not elicit or suppress inflammatory cytokine production (e.g., TNF-α, IL-6). This characteristic is noteworthy, as it suggests the biocompatibility and immunologically inert nature of SSHELs formulated with DOTAP. Ongoing in vivo experiments are assessing the efficacy of mRNA-loaded SSHELs in delivering cargo to HER2-positive tumors.
Conclusions: SSHELs represent a novel approach in RNA therapeutics due to their unique characteristics. These particles, which mimic the structure of bacterial spores, provide a biocompatible and versatile platform for the targeted delivery of myriad therapeutics, such as small molecules, peptides, and RNAs.

#6381 Extracellular vesicle-mediated co-delivery of FSL-1 and LY2157299 for immunotherapy of small-cell lung cancer liver metastases.

Yue Huang, Amira Kazi, Rajesh Kumar, Kanak Parmar, Chiori Tabe, Ajit Kumar Sharma, Anish Thomas

National Institutes of Health, Bethesda, MD

Small-cell lung cancer (SCLC) frequently metastasizes to the liver, where macrophage-dominated immunosuppression sustains tumor outgrowth. Bioinformatic analyses of SCLC liver metastases implicate macrophage metabolism as a driver of hepatic progression. We engineered extracellular vesicles (EVs) co-delivering FSL-1 (TLR2/6 agonist) and LY2157299/galunisertib (TGF-βRI inhibitor) to reprogram macrophages. In vitro, dual-loaded EVs more efficiently shifted macrophages toward pro-inflammatory, antigen-presenting states. In vivo, EVs efficiently targeted intrahepatic tumor sites, decreased liver tumor growth, and prolonged mouse survival. These data support EV-mediated co-delivery of FSL-1 and LY2157299 as a macrophage-centric strategy for SCLC liver metastasis.

#6382 Temozolomide co-encapsulated radioPDT nanoparticles possess effective cytotoxicity for the treatment of glioblastoma.

Muhammad Rafiq[1], Deepak Dinakaran[2]

[1]Biological Science Platform Sunnybrook Research Institute, Toronto, ON, Canada,[2]Department of Medical Biophysics, Temerty Faculty of Medicine, University of Toronto, Toronto, ON, Canada

Introduction: Radiation-activated photodynamic therapy (radio-PDT) has emerged as a promising approach to overcome the limitations of conventional photodynamic therapy, particularly the poor tissue penetration of external light sources. This study focuses on the synthesis, characterization, and evaluation of the effect of temozolomide co-encapsulated radio-PDT nanoparticles for the treatment of glioblastoma.

Material and Methods: An inorganic nanoscintillator was synthesized, and its comprehensive physicochemical characterization was assessed using electron dispersive x-ray spectroscopy (EDS), Transmission Electron microscopy (TEM), and X-ray diffraction (XRD) to evaluate the evolution of composition, size, and structure. The nanoscintillator was encapsulated with the photosensitizer protoporphyrin IX (PPIX), in combination with Temozolomide (TMZ), in a nanocarrier of PEG-PLGA. The characteristics of nanoparticles was assessed using TEM, Dynamic light scattering (DLS), and zeta potential was recorded. The tumor cytotoxicity of these nanoparticles was evaluated in vitro by using the U251 cell line. Furthermore, the molecular mechanism was elucidated using western blot.

Results:Our results showed the size of 15±5 for nanoscentilator, which was encapsulated with PPIX and temozolomide in the nanocarrier PEG-PLGA. The final nanocomposite was 100±10 with a Zeta potential (ZP) of -21.5. These nanoparticles demonstrated significant cytotoxicity against tumor cells compared to the control condition. Western blot analysis showed, decrease in the expression of AKT, PERK, and BCL2, while an increased expression of cleaved caspase 3 in radioPDT and TMZ Co-encapsulated radioPDT with a low dosage of irradiation.

Conclusion: Our results support the use of TMZ Co-encapsulated radioPDT and radioPDT with radiation can be used as an efficient approach for deep-seated tumors in particularly radio-resistant glioblastoma. These nanoparticles exhibited excellent biocompatibility, effective cytotoxicity towards tumor cells, and potential for translation into an in vivo tumor study.

#6383 Targeted co-delivery of paclitaxel and honokiol using MUC1-aptamer PBM-NP encapsulation for enhanced breast cancer treatment.

Briana Kinnel[1], Amit Kumar Srivastava[2], Santosh K. Singh[1], Rajesh Singh[1]

[1]Morehouse School of Medicine, Atlanta, GA,[2]School of Forensic Sciences, Uttar Pradesh State Institute of Forensic Sciences, Lucknow, India

Despite advancements in breast cancer (BrCa) treatments, dose-limiting toxicities caused by off-target exposure to healthy tissues remain a significant barrier to effective treatment options. This study aimed to enhance the anticancer properties of paclitaxel (PTX) and honokiol (HNK) through encapsulation in planetary-ball milled nanoparticles (PBM-NP) and coating with MUC1-aptamer (S2.2) for targeted delivery. Both *in silico* and *in vitro* methods were used to evaluate the efficacy of the encapsulation of PTX and HNK in aptamer-conjugated PBM-NPs (PTX-S2.2-PBM NP and HNK-S2.2-PBM NP). Pharmacokinetic simulations demonstrated the potential advantage of using PTX and HNK in combination while targeting MUC1 for BrCa treatment. Tissue microarray analysis confirmed the expression of MUC1 in BrCa tissues. It was found that MUC1 tissue expression was stage-dependent, with the highest MUC1 expression observed in Stage IV BrCa tissue (93.9%) compared to Stage III (36.5%), Stage II (11.3%), and Stage I (0.4%), respectively. NHS coupling was utilized to synthesize PTX-S2.2 and HNK-S2.2 PBM-NPs. Dynamic light scattering (DLS), FTIR, and HPLC were utilized to characterize the NPs. Cytotoxicity was assessed using MTT and Live/Dead cell assays. DLS analysis revealed that the NPs have a desirable size and zeta potential that are suitable for systemic circulation and improved therapeutic outcomes. Successful encapsulation and conjugation were confirmed through FTIR and HPLC analysis. Cell viability and proliferation studies demonstrated that PTX-S2.2-PBM NPs and HNK-S2.2-PBM NPs, when used individually, exhibited cytotoxicity comparable to or greater than that of free PTX and HNK, respectively. When combined, a synergistic effect was observed. Utilizing copolymers (PCL/PEG) and aptamer conjugation, PTX has the potential for improved bioavailability and reduced off-target effects compared to its free drug counterparts. Based on these findings, we believe that PTX-S2.2 and HNK-S2.2 PBM NP could represent a promising treatment option for BrCa.

#6384 Nanoparticle mediated disruption of tumor-nerve crosstalk enhances pancreatic cancer treatment and pain mitigation.

Songyu Wu[1], Lei Zhu[2], Weiping Qian[2], Tongrui Liu[2], Lisa Sudmeier[1], Charles A. Staley[2], Lily Yang[3]

[1]Emory Winship Cancer Institute, Atlanta, GA,[2]Emory University, Atlanta, GA,[3]Emory University School of Medicine, Atlanta, GA

Introduction: Pancreatic ductal adenocarcinoma (PDAC) is a highly aggressive malignancy with a dismal prognosis. Dense fibrous tumor stroma creates a drug delivery barrier, cultivates aggressive tumor biology and immunosuppression in PDAC. A well-recognized hallmark of PDAC is nerve infiltration into tumors and cancer cells invading neurons, which correlate with local invasion and poor survival. Neural invasion leads to severe and intractable pain in PDAC patients, due to release neurotransmitters and pro-inflammatory responses. Sympathetic nerves release catecholamines interacting with β-adrenergic receptors (β-AR) to stimulate tumor cell proliferation and invasion, induce immunosuppression and increase pain sensation. Clinical studies revealed treatment with β-AR inhibitors improved survival of PDAC patients. In this study, we have developed tumor cell, stroma, and cancer nerve targeted hyaluronic acid nanoparticles (HANPs) carrying SN-38 and β-AR blocker (Propranolol, Pro) for targeted therapy of PDAC and mitigation of neuropathic pain.
Methods: To enhance targeted delivery, we leveraged the biological properties of upregulation of urokinase plasminogen activator receptor (uPAR) and MMP14 in invasive tumor cells to developed a biomimetic nanoparticle drug delivery platform targeting to uPAR with MMP14 for stroma-penetration and drug delivery. The hydrophobic SN38 (an active metabolite of irinotecan) and Pro, were encapsulated into HANPs by self-assembling, resulting HANP/Pro+SN38 (HANP/PS). A uPAR targeted stroma penetrating recombinant ligand, ATFmmp14 was conjugated to HANP/PS to produce ATFmmp14-HANP/PS (AM-HANP/PS). Targeted delivery and therapeutic response were evaluated in an orthotopic PDAC patient derived xenograft model.
Results: Our results showed that NIR 830 dye labeled-AM-HANP/PS led to a high tumor accumulation (46%) in a PANC XXIV PDX model. AM-HANP/PS treatment by co-delivery of SN38 (4 mpk) and Pro (10 mpk) resulted in significantly stronger inhibition of tumor growth (67%) compared with single drug delivery (40%) or free SN38+Pro (46%). Histological analysis revealed nearly complete elimination of sympathetic and sensory nerves in treated tumors, while other formulations showed a moderate level of nerve reduction. Pain evaluation showed decreased pain in AM-HANP/PS treated mice. The level of pain neurotransmitter, substance P, was significantly reduced in tumors. These findings support AM-HANP/PS as an effective tumor and nerve targeted therapy.
Conclusion: AM-HANP/PS that targets PDAC tumor cells and cancer neurons achieved a high level of tumor accumulation. Co-delivery of SN38 and Pro significantly inhibits tumor growth, reduces density of sympathetic and sensory nerves, and relieves cancer-related pain. This dual-targeted strategy exhibited both antitumor efficacy and neuropathic pain mitigation in PDAC PDX model.

#6385 Targeted delivery of suicide gene to tumor cells using PD-L1-targeted extracellular vesicles for cancer therapy.

Geuna Park[1], SeokMin Lee[1], Eun Jung Park[2], Byungheon Lee[1]

[1]Kyungpook National Univ. School of Med, Daegu, Korea, Republic of,[2]National Cancer Center, Goyang, Korea, Republic of

Herpes simplex virus-thymidine kinase (HSV-TK) gene, a well-known suicide gene, causes cell death in rapidly dividing cells when treated with ganciclovir (GCV). The HSV-TK activates GCV and makes GCV-triphosphate. Insertion of activated GCV-triphosphate in elongating DNA by cellular DNA polymerases interferes DNA duplication and eventually leads to cell death. The suicide gene therapy, however, has been limited by non-specific cytotoxicity in off-target cells such as normal cells. In this study, we explored PD-L1-targeted extracellular vesicles (EVs) carrying the HSV-TK mRNA to deliver the HSV-TK selectively into tumor cells. HEK 293FT cells were transduced using lentivirus with the GFP-tagged, HSV-TK gene containing a sequence that is recognized by EV-trafficking RNA-binding protein. Stable HEK 293FT cells expressing the HSV-TK gene were established. EVs were isolated from the stable cells and labeled with a PD-L1-binding peptide (CVRARTR) using click chemistry to target PD-L1-high tumor cells. Delivery of the HSV-TK mRNA after incubation of cells with the EVs was validated by observing the fluorescence of GFP tag under a microscope. The PD-L1-targeted EVs carrying the HSV-TK mRNA exerted an efficient cytotoxicity in PD-L1-high MDA-MB-231 tumor cells. On the other hand, the EVs showed low levels of cytotoxicity in PD-L1-low tumor cells and normal cells. Systemic administration of the EVs inhibited the growth of MDA-MB-231 tumor xenografts in mice. These results demonstrate that the PD-L1-targeted EVs containing the HSV-TK mRNA provide a new avenue for the targeted delivery of a suicide gene. Keywords: HSV-TK; Peptide; PD-L1; Suicide gene therapy

#6386 Small bowel obstruction and short bowel syndrome may impair the efficacy of Avutometinib and Defactinib in recurrent low grade serous ovarian cancer: A case report.

Sarah Ottum[1], Luca Palmieri[2], Victoria Ettorre[1], Tobias Hartwich[1], Cem Demirkiran[1], Namrata Sethi[1], Stefania Bellone[1], **Alessandro D. Santin**[1]

[1]Department of Obstetrics, Gynecology, and Reproductive Sciences, Yale University, New Haven, CT,[2]Gynecologic Oncology Unit, Department of Woman and Child Health and Public Health, Fondazione Policlinico Universitario A. Gemelli IRCCS, Universita Cattolica del Sacro Cuore, Rome, Italy

The treatment of recurrent low grade serous ovarian cancer (LGSOC) is a challenge, but when complicated by recurrent small bowel obstructions (SBO) and/or major small bowel resections, the decreased absorption/efficacy of oral medications must be considered. We report the case of a patient with recurrent LGSOC previously treated with multiple debulking surgeries, neoadjuvant and adjuvant carboplatin/paclitaxel, and maintenance aromatase inhibitor therapy. A few weeks after initiating treatment within the RAMP-201 trial with the combination of Avutometinib (MEK inhibitor) and Defactinib (FAK inhibitor), two drugs recently approved by the FDA for the treatment of adult patients with KRAS-mutated LGSOC, she developed a small bowel obstruction that ultimately required extensive bowel resections, resulting in short bowel syndrome. Whole-exome sequencing (WES) of the recurrent LGSOC collected at the time of the bowel resection revealed copy number gains in multiple key genes within the RAS/RAF/MEK/ERK and FAK pathways, conferring potential tumor sensitivity to MEK/FAK inhibitors. In agreement with the WES results, the matched patient-derived xenograft (PDX) model established from the recurrent LGSOC demonstrated a remarkable sensitivity to the avutometinib/defactinib combination in vivo. Despite the high sensitivity of the PDX model, the patient progressed on the drug combination and had to be removed from the clinical trial. The experimental PDX results combined with our patient's clinical data strongly suggest that recurrent SBO and/or major bowel resections may represent unrecognized causes of resistance to avutometinib and defactinib significantly impairing the absorption of the oral drugs and decreasing the effectiveness of the regimen in recurrent heavily pretreated LGSOC patients. An earlier use of the novel oral drug combination in recurrent LGSOC is warranted.

#6387 Optimizing GPC3 gene editing in liver cancer: A comparison of Cas9 RNP and mRNA nanoliposome delivery systems.

Joshua Nieves-Reyes, Pablo E. Vivas-Mejia

Biochemistry, University of Puerto Rico - Medical Sciences Campus, San Juan, PR

Primary liver cancer ranks as the third leading cause of cancer-related deaths worldwide and has one of the lowest survival rates among all cancers. Late-stage detection and resistance to first-line therapies underscore the urgent need for novel treatment approaches. Glypican-3 (GPC3), a heparan sulfate membrane proteoglycan that is often overexpressed in hepatocellular carcinoma (HCC), is associated with a worse prognosis. As it is absent from healthy adult liver, it makes an attractive therapeutic target. Clustered Regularly Interspaced Short Palindromic Repeats (CRISPR)-Cas9 gene editing offers a versatile method to disrupt genes overexpressed in cancer, such as GPC3. The purpose of this study was to compare the efficiency of nanoliposomes carrying CRISPR-Cas9 ribonucleoproteins (RNPs) versus nanoliposomes carrying Cas9 mRNA for GPC3 targeting liver cancer cells. Nanoliposomes were designed using various lipid formulations and loaded either with Cas9-GFP RNPs or Cas9-GFP mRNA. We performed liposome-mediated Cas9-GFP RNP and mRNA internalization experiments in liver cancer cells, followed by fluorescence microscopy to compare delivery efficiency, while particle size distribution was determined using Dynamic Light Scattering (DLS). GPC3 knockout efficiency was evaluated using immunoblotting. Preliminary observations indicate that both RNP-loaded and mRNA-loaded nanoliposomes successfully enter liver cancer cells, with notable differences in internalization and intracellular GFP distribution between distinct lipid compositions. Initial comparisons also suggest that further optimization is required to achieve effective GPC3 protein reduction. This study demonstrates that both Cas9 RNP and Cas9 mRNA-loaded nanoliposomes show potential for delivering CRISPR components to liver cancer cells, with each approach offering distinct advantages for gene silencing. These results provide the bases for future therapeutic experiments in liver cancer mouse models.

#6388 Subcutaneous ANtibody-conjugated microGel platform enabling combination immunotherapy for refractory solid tumors.

Jongseong Kim, Yun Jin Chae, Yeobin Kim, Jaehee Lim

R&D center, Oncolab Co., Ltd., Goyang, Korea, Republic of

Background: Drug delivery systems (DDSs) are increasingly utilized to enhance the precision and durability of biologics in oncology. However, current cancer immunotherapies show limited efficacy in solid tumors due to profoundly immunosuppressive tumor microenvironments, underscoring the need for innovative delivery platforms. We developed the ANtibody-conjugated microGel (ANGel), a deformable hydrogel-based submicron particle engineered to deliver combination monoclonal antibodies (mAbs) targeting both the PD-1/PD-L1 axis and co-stimulatory pathways.
Methods: ANGel formulations were generated by surface affinity loading of multiple mAb types. In vitro studies assessed therapeutic synergy between two anti-PD-1/PD-L1 mAbs and two co-stimulatory mAbs when formulated with ANGel. Lead combinations were evaluated in vivo using triple-negative breast cancer (TNBC) mouse models. Subcutaneous administration was performed at peritumoral sites to assess local delivery, antitumor activity, and survival. Dose sensitivity and formulation parameters were fine-tuned to identify optimal therapeutic regimens.
Results: ANGel significantly enhanced in vitro synergy between PD-1/PD-L1-targeting and co-stimulatory mAbs compared with free-antibody mixtures. In TNBC models, subcutaneous peritumoral delivery of combination ANGel (dANGel) formulations produced marked tumor-growth delay relative to free-combination mAbs, including combinations with hyaluronidase. Antitumor efficacy of dANGel formulations demonstrated strong dose-dependent and regimen-dependent sensitivity, enabling optimization for maximal therapeutic output. Notably, dANGel treatment extended progression-free survival to 204 days, compared with 23 days achieved by anti-PD-L1 plus anti-CTLA-4 mAbs formulated with hyaluronidase.
Conclusions: These results demonstrate ANGel as a potent local delivery platform capable of overcoming key barriers to solid-tumor immunotherapy. By enabling subcutaneous peritumoral administration of synergistic mAb combinations, ANGel provides a novel therapeutic strategy with the potential to substantially improve outcomes in refractory solid tumors. Preclinical findings support dANGel as a strong candidate for clinical translation.

#6389 Maximizing systemic LNP-DNA delivery for cancer-activated expression of immunotherapy agents using nanoprimer technology.

Nadege Morisot[1], Blaine McCarthy[1], Sushil Lathwal[1], Jayalakshmi Ramani[1], Ajda Rojc[1], Francis Mpambani[2], Laurence Poul[2], Julie Devalliere[2], Matthieu Germain[3], Dang Dang[1], Robby Chandra[1], Xiaobin Wu[1], Moataz Reda[1], Badriprasad Ananthanarayanan[1], David Suhy[1]

[1]Earli Inc, Redwood City, CA,[23]Nanobiotix, Paris, France

Earli is developing a platform technology that utilizes lipid nanoparticle (LNP)-delivered recombinant DNA constructs containing cancer-activated synthetic promoters that drive the selective expression of therapeutic proteins such as cytokines to treat the tumor. Our approach demonstrated robust therapeutic impact in vivo via tumor-specific secretion of IL-2 and IL-12 which are uniquely produced in cancer cells, but not normal tissues to control syngeneic tumors growth. While LNP-DNA vehicles often offer advantages over viral vectors, their efficacy can be limited by rapid clearance via the mononuclear phagocyte system (MPS). Although modifications to the surface of LNPs, like pegylation, can extend circulation time, the hepatic clearance remains a challenge that reduces LNPs systemic bioavailability, hinders tumor accumulation, and can contribute to toxicity. In addition, LNP-DNA may produce transient acute inflammation primarily via the intracellular activation of the cGAS/STING pathway, a major host defense mechanism. To address this challenge, Nanobiotix's Nanoprimer technology, engineered biocompatible lipid-based nanoparticles that transiently occupy MPS clearance pathways, was utilized to extend blood circulation time of subsequently administered therapeutics. We investigated the impact of Nanoprimer pre-treatment on the pharmacokinetics , biodistribution, and tolerability of two Earli proprietary extrahepatic LNP formulations, longer-circulating FRM177 and fast clearing FRM146, which encapsulate a recombinant DNA comprised of a strong constitutive promoter to drive firefly luciferase expression in tumor naive mice. The pre-treatment improved the blood bioavailability of FRM146-DNA by 8-fold, while having a minor effect on the delivery of FRM177-DNA. Furthermore, a 2-fold decrease in hepatic DNA accumulation at 48h post dose for both LNP-DNA was observed as well as reduced hepatotoxicity as evidenced by normal levels of liver enzymes. Finally, both LNP-DNA produced a transient mouse body weight loss and serum cytokine elevation, effects that were ameliorated by the Nanoprimer, revealing improved tolerability. Our data demonstrates that the Nanobiotix technology can be a successful strategy to significantly improve the extrahepatic biodistribution and tolerability of LNP-DNA, even those already engineered for extrahepatic delivery. These results expand the known potential of the compound in MPS blockade for clinically relevant LNP-DNA constructs for cancer immunotherapy applications and confirms the relevance of further clinical development for systemically administered LNP-nucleic acid therapeutics. Ongoing studies are focused on determining the impact of Nanoprimer on the anti-tumor efficacy of our cancer-activated cytokine-expressing DNA constructs in syngeneic cancer models.

#6390 Nanoprimer technology for enhanced efficacy of intravenously administered vaccines.

Matthieu Germain, Maxime Bergere, Francis Mpambani, Jordan Da Silva, Andromeda Savary, Sebastien Paris, Laurence Poul, Julie Devalliere

Nanobiotix, Paris, France

The efficacy of intravenously (IV) administered therapeutic agents is often limited by hepatic clearance, resulting in reduced accumulation at the target site and in potential hepatotoxicity. Nanobiotix's innovative Nanoprimer technology aims to shift the balance of therapeutics' bioavailability and toxicity. The Nanoprimer is a biocompatible, engineered liposome that transiently occupies cells of the mononuclear phagocyte system, responsible for the clearance of nanoparticles. Administered shortly before the therapeutic agent, the Nanoprimer reduces the early elimination and increases bioavailability during the agent's critical window of activity. proofs of concept were realized with multiple modalities including nucleic acid-based products. Our latest research has expanded the evaluation of the Nanoprimer for enhancing the efficacy of cancer vaccines. The Nanoprimer's effect on antigen-specific CD8⁺ T cell responses was evaluated using 2 vaccine platforms: mRNA-loaded lipoplex encoding an ovalbumin epitope and ovalbumin peptide-loaded liposomes. *De novo* priming of CD8⁺ T cells was assessed 7 days post-immunization. To evaluate the functional activity of generated CD8⁺ T cells, splenocytes were restimulated *ex vivo* with the antigenic peptide for 24 hours, and IFN-γ production was quantified. In a single-dose immunization study, using peptide-loaded liposomes, pre-treatment with the Nanoprimer resulted in a 6-fold increase in antigen-specific CD8⁺ T cells and a marked elevation of IFN-γ production by splenocytes, indicative of a strong effector function. Similar studies using a single dose of mRNA-lipoplex demonstrated that the Nanoprimer dramatically enhanced the generation of antigen-specific CD8⁺ T cells, reaching up to 20% of the total CD8⁺ T cells. The expansion of antigen-specific CD8⁺ T cells was correlated with increased IFN-γ secretion, consistent with functional cytotoxic activity. For the evaluation of the memory immune response, animals received a primary vaccination (three repeated injections of the vaccine at days 0, 7 and 14), and memory response was assessed on day 73 by measuring the frequency of antigen-specific CD8+ T cells, 3 days after the booster immunization. The Nanoprimer increased antigen-specific CD8+ T cell responses, reaching up to 54% of total CD8+ T cells for mRNA-lipoplex (compared to 27% with vaccine alone) and up to 27% for peptide-liposome (with no detectable response observed in the vaccine alone group). These findings demonstrate that the Nanoprimer can enhance acute and memory cellular immune responses across multiple vaccine modalities. Its ability to increase antigen-specific CD8⁺ T cell quantities and functional cytokine responses underscores its potential to improve the therapeutic index of cancer immunotherapies. Overall, Nanoprimer technology represents a promising strategy to unlock the full clinical potential of innovative therapies.

#6391 Development of a stabilized Z-endoxifen topical formulation for breast cancer prevention.

Alison Wissmann, Travis Belknap, Lindsey Lafal, **Quentin Lawrence**, Jonathan White

MRIGlobal, Kansas City, MO

Purpose: The primary objective of this work was to develop a pharmaceutically stable, transdermal delivery strategy for Z-endoxifen, the highly potent and bioactive metabolite of tamoxifen.
Methods: Four distinct topical formulation types were prepared. Each formulation type was evaluated with a control and four different antioxidants, allowing for the assessment of both water-soluble and lipid-soluble antioxidant effects across various bases. Each prepared formulation was stored at both refrigerated conditions and ambient temperature for a period of up to 6 months. Formulations were evaluated for visual appearance and isomeric purity over time. Isomeric purity was determined by high-performance liquid chromatography.
Results: Our study identified specific antioxidant combinations that mitigated Z-endoxifen isomerization. Combined with reduced temperature storage, these strategies led to the successful development of a stable topical formulation of Z-endoxifen.
Conclusion: Instability challenges of Z-endoxifen in a topical formulation were overcome by adding specific antioxidants into varied formulation bases and controlling storage temperature. This advancement enables the development of a more potent and potentially safer localized breast cancer prevention therapy by delivering the highly bioactive Z-isomer and minimizing systemic exposure. Future work will involve in vivo pharmacokinetic/pharmacodynamic studies to confirm localized breast tissue delivery and minimal systemic absorption, paving the way for advanced clinical trials aimed at providing an improved preventative treatment for women at high risk for breast cancer.

#6392 Harnessing facial neuronal pathways via iontophoresis for targeted intradermal delivery of bimodal spherical nucleic acids to the brain for anti-glioma effect.

Akanksha S. Mahajan[1], **Davin Hickman-Chow**[2], Gaelen Clayton[3], Seunghyun Kim[1], Rachel Jarvis[1], Emma Shen[1], Clara Foltz[1], Cao Dai Phung[1], Eric Leuthardt[4], Alexander Stegh[5]

[1]Taylor Family Department of Neurosurgery, The Brain Tumor Center, Washington University in St. Louis, Saint Louis, MO,[2]Department of Biomedical Engineering, Washington University in St. Louis, Saint Louis, MO,[3]Department of Mechanical Engineering,, Washington University in St. Louis, Saint Louis, MO,[4]Department of Neuroscience, Neurosurgery, Mechanical Engineering, Biomedical Engineering, Washington University in St. Louis, Saint Louis, MO,[5]Taylor Family Department of Neurosurgery, The Brain Tumor Center, Department of Neuroscience, Washington University in St. Louis, Saint Louis, MO

Background: Glioblastoma (GBM) remains one of the most aggressive brain tumors due to barriers in drug delivery across the blood-brain barrier (BBB) and its profoundly immunosuppressive tumor microenvironment (TME). These limitations restrict therapeutic penetration into tumor sites. While intranasal strategies exploit trigeminal/olfactory routes, mucociliary clearance and off-target exposure have limited clinical translation. Here, we developed a facial dermal iontophoresis-based system to deliver immune-modulating nanoparticles through the facial neuro-lymphatic network to bypass the BBB and reprogram the TME.

Methods: To overcome delivery barriers affecting immunotherapies intended to modulate tumor-associated and peripheral immunity, we integrated two approaches. First, we established iontophoresis as a minimally invasive method to bypass the BBB and enhance the transport of therapeutics delivered via facial intradermal (i.d.) injection. Second, we engineered a bimodal Spherical Nucleic Acid (bi-SNA) platform that activates cGAS and inhibits STAT3. Bi-SNAs consist of a 15-nm gold core functionalized with a hairpin oligonucleotide with STAT3-decoy sequences, enabling simultaneous cGAS activation and STAT3 sequestration. Bi-SNAs elicit potent antitumor immunity in multiple HGG models and outperform cGAS-agonist monotherapies. A dedicated iontophoresis device was designed for preclinical assessment using murine GBM models, and iontophoretic parameters (current density, waveform, electrode placement) were optimized for controlled transdermal SNA transport. Biodistribution was measured by 3D fluorescence CT-IVIS with ICG-labeled SNAs, gold levels by ICP-MS, and immune modulation by multispectral flow cytometry.

Results: I.d. Bi-SNA delivery with iontophoresis significantly suppressed tumor progression, depleted immunosuppressive myeloid cells, and increased recruitment/activation of effector T cells. IVIS imaging showed a two-fold increase and faster kinetics of SNA trafficking from facial planes to the brain without detectable systemic spread, with preferential accumulation along maxillary-olfactory and temporomandibular conduits. ICP-MS revealed ~20-fold higher gold deposition in the brain and trigeminal nerve within 12 hours compared with passive i.d. delivery.

Conclusions: Iontophoresis-enhanced i.d. delivery provides a powerful non-invasive strategy for brain-targeted immunotherapy, leveraging neuronal pathways to bypass the BBB and reprogram the GBM TME. This establishes a foundation for patient-adaptable, at-home nanotherapeutic delivery for brain tumors.

#6393 Polo-like kinase 4 inhibition enhances radiosensitivity in non-small cell lung cancer via apoptosis and epithelial-mesenchymal transition regulation.

Hye Won Lee[1], Shin Kim[2], Jeong-Woo Hwang[2], Eun-Young Gong[1], Hyowon Hong[3], SangJun Byun[1], Sung Uk Bae[1]

[1]Keimyung University School of Medicine, Daegu, Korea, Republic of,[2]Keimyung University, Daegu, Korea, Republic of,[3]Keimyung University Dongsan Medical Center, Daegu, Korea, Republic of

Non-small cell lung cancer (NSCLC) remains one of the leading causes of cancer-related mortality worldwide. Radiotherapy (RT) is a mainstay of treatment; however, the frequent development of radioresistance limits its therapeutic efficacy. Polo-like kinase 4 (PLK4), a master regulator of centriole duplication and centrosome integrity, has been implicated in chromosomal instability, DNA damage responses (DDR), and epithelial-mesenchymal transition (EMT). Therefore, targeting PLK4 may represent a novel strategy to overcome radioresistance. In this study, we investigated the effects of the selective PLK4 inhibitor CFI-400945 in NSCLC cells exposed to RT. CFI-400945 treatment significantly reduced cell viability and clonogenic survival in combination with RT compared to either treatment alone. Mechanistically, CFI-400945 amplified apoptotic signaling, with marked upregulation of p53 and cleaved PARP1. In addition, PLK4 inhibition promoted G2/M cell cycle arrest by reducing RT-induced p-AKT and cyclin B1 expression level. Furthermore, PLK4 inhibition enhanced RT-induced DNA damage as indicated by increased γH2AX expression. Importantly, RT alone promoted EMT progression, characterized by reduced E-cadherin and increased N-cadherin and vimentin expression, as well as enhanced migratory capacity. These effects were significantly reversed by CFI-400945, indicating that PLK4 inhibition attenuates RT-induced EMT progression. Collectively, these findings demonstrate that PLK4 inhibition with CFI-400945 sensitizes NSCLC cells to RT by augmenting DNA damage and apoptosis while suppressing RT-induced EMT. Our results highlight PLK4 as a critical regulator linking centrosome abnormalities, DDR, and EMT, and suggest that combining PLK4 inhibition with RT may provide a promising therapeutic approach to overcome radioresistance in NSCLC.

#6394 Ferroptosis amplified by a tumor-targeted artesunate nano-derivative for effective colon cancer treatment.

Jianing Li, Dake Song, Qiutong Guan, **Zhenhua Li**

China Medical University,School of Pharmacy, Shenyang, China

Background: Artesunate (ART), a proven antimalarial drug, is promising but has limited antitumor activity because of its poor stability, low potency, and lack of tumor selectivity. While its effect is linked to ferroptosis, an iron-dependent form of cell death driven by lipid peroxidation, clinical translation in oncology requires enhanced drug delivery and targeting. We hypothesized that engineering a tumor-targeted nanoparticle of an ART prodrug could amplify ferroptosis induction and therapeutic efficacy against colorectal cancer (CRC).
Methods: We systematically designed and synthesized six amino acid-modified ART derivatives. The most potent conjugate was further functionalized with 3-aminophenylboronic acid (PBA) to create the final prodrug, AAP. AAP self-assembled into nanoparticles (AAP NPs) via a one-step precipitation method. The size, PDI, and morphology of the NPs were characterized. Efficacy was evaluated in multiple CRC cell lines (CT26, HCT116, SW480, SW620) and a hepatoma cell line (Huh7) via CCK-8 assays. Cellular uptake was visualized via coumarin-6-loaded NPs. The antitumor effect, systemic safety, survival benefit, and mechanism of AAP NPs were comprehensively investigated in a BALB/c mouse model bearing CT26 tumors.
Results: AAP demonstrated superior in vitro cytotoxicity compared with native ART, with IC50 values 1.77- to 2.09-fold lower across CRC and hepatoma cells. The resulting AAP NPs were monodisperse spheres with a uniform size of 174.44 ± 9.97 nm and a low PDI of 0.046. Compared with ART or ART-AA (no PBA), the completed AAP NPs exhibited significantly stronger, dose- and time-dependent cytotoxicity against all cancer cells tested ($P < 0.05$) and were effectively internalized by CT26 cells. In vivo, AAP NPs achieved the most potent tumor growth inhibition, reducing the tumor volume and weight to 531.29 ± 132.20 mm^3 and 483.14 ± 118.91 mg, respectively, significantly outperforming the control, ART, and ART-AA NP groups ($P < 0.05$). Critically, AAP NPs significantly prolonged mouse survival ($P < 0.05$) . Mechanistically, AAP NP treatment led to significant accumulation of ROS in tumor tissues, confirming the induction of ferroptosis.
Conclusion: We developed a dual-targeted ART nanoprodrug that leverages PBA-mediated active targeting and the EPR effect. This strategy potently inhibits CRC growth by triggering ferroptosis and exhibits an excellent safety profile, offering a compelling approach to repurpose ART for targeted cancer therapy.

#6395 Enhanced antitumor efficacy of berbamine dihydrochloride nanomedicine via apoptosis induction in colorectal cancer.

Chan Zhang, Qiutong Guan, **Zhenhua Li**

School of Pharmacy, China Medical University, Shenyang, China

Background: Berbamine dihydrochloride (BBM), a natural bisbenzylisoquinoline alkaloid, exhibits broad antitumor activity. However, its clinical translation is hampered by nonspecific tissue distribution, poor bioavailability, and dose-limiting toxicity. Bovine serum albumin (BSA) nanoparticles represent an ideal drug delivery platform because of their biocompatibility, low immunogenicity, and inherent tumor-targeting capability. This study aimed to develop BBM-loaded BSA nanoparticles (BBM-BSA-NPs) to enhance drug targeting and antitumor efficacy against colorectal cancer (CRC).

Methods: BBM-BSA-NPs were prepared and characterized. In vitro cytotoxicity was assessed against CRC cell lines (CT26, HT29) and other cancer lines (AGS, CAOV3, HepG2) via CCK-8 assays. Selectivity was evaluated by comparing the effects on cancer cells with those on normal 293 cells. Apoptosis induction was measured by flow cytometry. In vivo antitumor efficacy and systemic safety were investigated in a murine CT26 tumor model.

Results: Compared with native BBM, BBM-BSA-NPs significantly increased the cytotoxicity to CT26 and HT29 cells in a concentration- and time-dependent manner ($P < 0.05$). The formulation showed selective toxicity toward cancer cells, with markedly greater inhibition in HepG2 cells ($P < 0.05$) and minimal effects on normal 293 cells at 24 h and 48 h. Notably, BBM-BSA-NPs effectively induced morphological changes and apoptosis in CT26 cells, with apoptosis rates significantly exceeding those of native BBM at all concentrations tested ($P < 0.05$). In vivo, BBM-BSA-NP treatment resulted in a remarkable reduction in tumor volume (279.19 ± 46.75 mm^3) and weight (0.13 ± 0.04 g), significantly outperforming native BBM (456.75 ± 54.64 mm^3; 0.29 ± 0.04 g; $P < 0.05$). No significant changes in body weight or systemic toxicity were observed, confirming the safety of the treatment. The blank BSA-NPs showed no antitumor activity, confirming that the efficacy and safety benefits were attributable to the nanoformulation.

Conclusion: We successfully developed a novel BBM-BSA nanoparticle system that significantly enhances the selective cytotoxicity and apoptotic induction of BBM against colorectal cancer while improving its therapeutic efficacy in vivo. This study provides a compelling rationale for leveraging albumin nanoparticles to repurpose BBM as a potent and safe therapeutic agent for CRC.

#6396 Next-generation sabizabulin nanoformulation for cervical cancer treatment.

Vivek Kumar Kashyap[1], Prashanth KB Nagesh[2], Qinghui Wang[3], Upendra Nayek[1], Tusha Sharma[1], Bilal B. Hafeez[1], Duane D. Miller[4], Wei Li[5], Murali M. Yallapu[1], Subash Chauhan[1]

[1]Division of Cancer Immunology and Microbiology, University of Texas Rio Grande Valley, McAllen, TX,[2]Laboratory of Signal Transduction, Memorial Sloan Kettering Cancer Center, New York, NY,[3]Department of Pharmaceutical Chemistry, University of California, San Francisco, CA,[4]Professor, Chair and Associate Dean, University of Tennessee Health Science Center - College of Medicine, Chattanooga, Memphis, TN,[5]University of Tennessee Health Science Center, Memphis, TN

Background: Cervical cancer (CC) remains a significant global health burden in women, with intrinsic and acquired chemotherapy resistance limiting therapeutic efficacy. Sabizabulin (VERU-111) is an orally bioavailable colchicine-binding site inhibitor that offers a new way to treat cancer by targeting microtubule dynamics and changing the HPV-driven CC phenotype. However, optimization of its pharmaceutical formulation is critical to maximize efficacy while minimizing systemic toxicity and improving tumor-specific drug accumulation. In this study, we engineered and evaluated a next-generation nanoparticle formulation of sabizabulin to enhance its bioavailability, improve tumor-targeted delivery, and overcome chemotherapy resistance in CC models.
Methods: We engineered a multi-layered Pluronic F127 and polyvinyl alcohol stabilized and poly-L-lysine coated Sabizabulin-loaded poly(lactic-co-glycolic acid) nanoparticle formulation (PSab-NPs). PSab-NPs were characterized for physicochemical properties, stability, and drug loading efficiency by TEM, FT-IR, DSC, TGA, and HPLC. Cellular internalization was assessed after 6 hours of incubation with PSab-NPs in CC cells. To determine the therapeutic efficacy of PSab-NPs, we performed various in vitro (MTS, wound healing, Boyden chamber, real-time xCELLigence, and apoptosis assays) and in vivo xenograft mouse models using CC cells. We evaluated the effect of PSab-NPs on various key oncogenic signaling pathways using Western blot, immunohistochemistry (IHC), confocal microscopy, and qRT-PCR.
Results: Our novel PSab-NPs formulation provided an average size of 120-150 nm in dynamic light scattering (DLS) and exhibited -10.46 to -12.73 mV zeta potential with an outstanding loading efficiency. Cellular uptake and internalization studies demonstrate that PSab-NPs efficiently evade lysosomal degradation, facilitating strong endosomal release into the cytosol. PSab-NPs showed remarkable anti-cancer potential in various CC cells (HeLa, SiHa, CaSki, and C33A). Mechanistically, PSab-NPs more effectively modulate the PI3K/AKT/MDM2 signaling pathway and suppress HPV E6 and E7 in vitro and CaSki cell-derived xenografts in athymic nude mice.
Conclusions: Taken together, our findings suggest that PSab-NPs represent a novel, promising nanoparticle platform that has more anti-cancer potential than free sabizabulin. PSab-NPs may reduce the toxicity and improve the bioavailability of free sabizabulin and could be used for the effective management of CC.

#6397 Immunogenic eradication of melanoma via ultrasmall lactoferrin-ICD inducer nanoconjugates integrated with BRAF-inhibitory liposomes.

Ahmad Ziada[1], Mousa El-Sayed[2], Asmaa Reda[2], Leo Ren[3], Cuiyan Xin[4], Ahmed Elzoghby[2]

[1]Amherst College, Amherst, MA,[2]Engineering in Medicine, Brigham and Women's Hospital, Harvard Medical School, Boston, MA,[3]Rice University, Houston, TX,[4]Renal Medicine, Brigham and Women's Hospital, Harvard Medical School, Boston, MA

Approximately 50% of human melanoma is driven by B-Raf protooncogene mutation (BRAF-mutant). Tumors with such mutation are highly immunosuppressive, and often resistant to immune checkpoint inhibitor (ICI) therapies. Blocking the BRAF-MAPK pathway in the BRAF-mutant melanoma cells markedly increases the tumor antigen expression and hence enhances the ability of T cells to recognize autologous BRAFV600 mutant melanoma cells. In parallel, induction of immunogenic cell death (ICD) of melanoma cells can overcome immunosuppression and enhance the antigen presenting capacity of dendritic cells (DCs). Therefore, our goal is to engineer a novel nanomedicine for combined delivery of BRAF inhibitor and ICD inducer drugs for immunogenic eradication of melanoma cells and thus boost the efficacy of ICI therapy. First, we engineered liposomes encapsulating dabrafenib (DFN, BRAF inhibitor) and selumetinib (SLM, MEK inhibitor). To ensure their stability, we coupled DFN and SLM to cholesterol via pH-responsive carbamate and ester bonds, respectively prior to incorporation into liposomes. The liposomes showed uniform size, high drug loading and excellent physical stability as well as high internalization and cytotoxicity against A375 melanoma cells. Moreover, the expression of MHC I & II by A375 cells was enhanced after treatment with liposomes. Second, we synthesized ultrasmall lactoferrin (LF) nanoconjugates with ICD inducer drugs including doxorubicin (DOX), shikonin and bortezomib via a pH-responsive hydrazone bond to induce ICD of melanoma cells. The LF-DOX nanoconjugate showed a small size (38.4 nm) with efficient internalization into A375 cells resulting in high cytotoxicity. The engineered nanoconjugate successfully induced ICD of melanoma cells as evidenced by increased surface exposure of CRT and reduced intracellular expression of HMGB1 in A375 cells. Moreover, the ICD inducing nanoconjugate induced remarkable degree of apoptosis (33%) of A375 melanoma cells compared to control non-treated cells (5.7%). Finally, we encapsulated the ultrasmall ICD inducing LF-drug nanoconjugate into the aqueous core of the pH-responsive DFN/SLM liposomes decorated with αPD-L1 antibody. A mouse syngeneic melanoma model with BRAF mutation was established by subcutaneously implanting YUMM1.7 Melanoma cells (1×10^5) in the flanks of 4-6 weeks old C57BL/6 mice. The intravenously injected nanomedicine markedly increased the antitumor efficacy with significant reduction of tumor volume relative to vehicle treated group and mice treated with αPDL1 alone. In conclusion, the combined delivery of BRAF inhibitory and ICD inducing nanomedicine into one platform could boost the antitumor immune response to αPDL1 therapy and hence overcome the immune resistance of melanoma cells.

#6401 A translational screening platform with AI integration for clinically predictive discovery of safe and effective macropinocytosis-dependent cancer therapeutics.
Qiuming Chu, Antonio Bonanno, **Yanping Kong**

Kongs Pharmaceutical, Lowell, MA

Background: Macropinocytosis-dependent cancers rely on nutrient-scavenging pathways to sustain tumor growth under stress. Current therapies rarely provide durable control, underscoring the need for strategies that stabilize cancer progression as a chronic condition. Although extensive clinical data exist for approved drugs—linking mechanisms of action (MoAs), safety, and efficacy—clinically translatable, macropinocytosis-relevant cell-based screens remain limited. We developed an AI-driven translational discovery platform integrating phenotypic screening with clinical correlation to identify safe, mechanistically meaningful, and clinically predictive therapeutic candidates.
Methods: An automated image-based cytometry assay was optimized to quantify macropinocytosis in cancer cells with minimal human bias. FDA-approved drugs and proprietary compounds were screened with this medium throughput method. AI algorithms correlated *in vitro* phenotypes with retrospective clinical data, integrating MoA, toxicity, and efficacy metrics. Mechanistic clustering identified shared therapeutic pathways among clinically effective agents. AI modeling also predicted clinical performance and generated rational combination hypotheses emphasizing safety and translational potential.
Results: AI validation confirmed strong concordance between phenotypic results and clinical safety/efficacy profiles from 892 FDA-approved cancer and non-cancer drugs, demonstrating high translational fidelity. Mechanistic clustering revealed a convergent signaling axis associated with durable benefit and low toxicity. Several novel in-house compounds exhibited comparable inhibition profiles and AI-predicted clinical potential. AI modeling proposed synergistic combinations between approved and proprietary agents with underexplored mechanisms, prioritizing safe, durable therapeutic responses.
Conclusions: This platform unites bias-free phenotypic assays with AI-guided clinical validation, enabling early identification of therapeutically meaningful and translatable drug candidates. Discovery of a shared mechanistic target and AI-predicted novel compounds demonstrates a clinically grounded, data-driven model for developing safe, effective, and chronic disease-oriented cancer therapies.

#6402 Identification of novel CRBN molecular glue ternary binders from a highly diverse CRBN MG library.

Qingbo Xu, Hailong Yang, Yongqiang Wang, **Zhenyu Wu**, Hongbo Zhang

HitChem, Wilmington, DE

High-throughput screening (HTS) of cereblon (CRBN) molecular glue (MG)-biased libraries remains a key strategy for proof-of-concept studies and hit identification against emerging targets. Because the CRBN binding pocket and its induced interface can adopt multiple conformations, and the substrate binding pocket is often unpredictable at the early stages of discovery, the structural diversity of both CRBN binders and substrate-recognition motifs is crucial to screening efficiency.In this work, we constructed a high-quality, CRBN MG-biased library derived from more than 40 validated CRBN binders. To further enhance chemical diversity, we introduced novel fragments using a tailored AI-based molecular generation model, designed to maximize variations in substrate-binding motifs. HTS case studies demonstrated that this library effectively identified CRBN-substrate ternary binders and degraders with unique scaffolds, representing promising starting points for further optimization.

#6403 High-content morphology profiling identifies autophagy-modulating compounds and their off-target activities.

Petr Dzubak[1], Alzbeta Srovnalova[2], Pavel Polishchuk[3], Anna Siskova[1], Martin Mistrik[4], Matthew Lacey[4], Marian Hajduch[4]

[1]Insititute of Molecular and Translational Medicine, Palacky University and University Hospital in Olomouc, Olomouc, Czech Republic,[2]Institute of Molecular and Translational Medicine, Palacky University and University Hospital in Olomouc, Olomouc, Czech Republic,[3]Faculty of Medicine and Dentistry,, Palacky University and University Hospital in Olomouc, Olomouc, Czech Republic,[4]Institute of Molecular and Translational Medicine, Palacky University and University Hospital in Olomouc, Olomouc, Czech Republic

Background: Autophagy gives many tumors a way to cope with stress, adjust their metabolism, and weather therapy. Compounds that interfere with this process, therefore, attract considerable interest. To efficiently spot such compounds, we rely on screening methods that detect subtle shifts in cell structure. The Cell Painting assay offers this possibility: by capturing rich morphological snapshots, it lets us see how different compounds alter organelles and pathways involved in autophagy.
Methods: We exposed HepG2 cells for 24 hours to several well-characterized autophagy inhibitors—chloroquine, bafilomycin A1, dauricine, daurisoline, and dorsomorphine—as well as two established activators, rapamycin and PP242. MCOPPB and its derivatives MS107 and MS108 were included in the same panels, alongside JUMP-target controls. After staining, we imaged the cells on a Yokogawa CV8000 microscope, recording four channels across nine fields per well. From these images, we extracted and normalized 1,065 single-cell features using pycytominer. Dimensionality reduction (UMAP) and correlation analyses were performed in R, and autophagy markers (LAMP2B, p62/SQSTM1, and LC3) were assessed by immunofluorescence.
Results: The morphological profiles separated inhibitors from activators with a clear margin, each group forming tight clusters. Inhibitors produced the expected signatures: a fragmented Golgi apparatus, swollen mitochondria, and expanded ER structures, all indicative of impaired autophagic flux. Compounds with known mechanisms behaved as anticipated. Strikingly, MCOPPB—usually classified as a NOP receptor agonist—fell directly into the inhibitor cluster. Follow-up staining corroborated this pattern: disrupted autophagosome-lysosome fusion, p62 accumulation, and LC3 changes all pointed toward autophagy inhibition.
Conclusion: Cell Painting proved effective at distinguishing autophagy-modulating compounds through their characteristic organelle-level effects. The unexpected behaviour of MCOPPB highlights a previously overlooked mechanism. Combining morphological profiling with marker-based validation provides a practical framework for identifying new modulators of autophagy with potential oncological relevance.
This work was supported by the Technology Agency of the Czech Republic project PERMED: T2BA (TN02000109). We also acknowledge the contributions from infrastructural projects CZ-OPENSCREEN (LM2023052), EATRIS-CZ (LM2023053), IGA_LF_2025_21, and the SALVAGE project (CZ.02.01.01/00/22_008/0004644) supported by OP JAK, with cofinancing from the EU and the State Budget.

#6404 A robust organoid-based platform for high-throughput screening and drug discovery.

Rene Overmeer, Mariana Martins Costa Silva, Gerben ten Hag, Mayke Doorn, Yasmine Abouleila, Ricardo Korporaal, Francisco Morales Rodriguez, Merel Derksen, Carla Verissimo, Robert G. J. Vries, Sylvia F. Boj

HUB Organoids B.V., Utrecht, Netherlands

Patient-derived organoids (PDOs), or HUB Organoids®, are advanced 3D models generated from adult stem cells of normal and malignant epithelial tissues and stored in high-quality biobanks to ensure reproducibility. HUB Organoids faithfully recapitulate the physiology, molecular heterogeneity, and morphological and functional characteristics of the original tissue, effectively mimicking patient response and bridging the gap between laboratory research and clinical application—bringing the “patient into the lab.” The rapid development of Petosemtamab (MCLA-158) exemplifies the value of organoid technology in drug development, as this target could not have been identified using conventional 2D models. Further supporting this, recent publications highlight the ability of organoids to predict treatment response in metastatic colorectal cancer. Here, we present our capabilities for medium- to high-throughput screening, enabling the evaluation of over 6,000 compounds across multiple organoid models in parallel. Available readouts include plate reader-based viability assays (CellTiter-Glo 3D) and imaging-based assays (CyQuant). Beyond initial large-scale screening, rapid iterations of follow-up structure-activity relationship (SAR) studies or expanded screening across diverse patient models are facilitated by the precision and reproducibility of our platform. In summary, we offer a robust, clinically relevant, and cost-effective platform to support drug development from early-stage compound screening to advanced validation studies.

#6405 Small-molecule screening of HiBiT-tagged PAX3::FOXO1 rhabdomyosarcoma cell lines identifies eltanexor as a potent therapeutic agent against fusion-positive rhabdomyosarcoma.

Soumili Dey[1], Yong Y. Kim[2], Katrina Jia[1], Mehal Churiwal[1], Michele Ceribelli[1], Teresa S. Hawley[1], Raj Chari[1], David Milewski[1], Young K. Song[1], Xinyu Wen[1], Hsien-Chao Chou[1], Vineela Gangalapudi[1], Jun S. Wei[1], Craig Thomas[1], Robert G. Hawley[3], Javed Khan[1]

[1]National Cancer Institute, NIH, Bethesda, MD,[2]Stanford University, Palo Alto, CA,[3]Anatomy & Regenerative Bio., The George Washington University, Washington

Introduction: Rhabdomyosarcoma (RMS) is a highly malignant soft tissue sarcoma. An aggressive subtype, fusion-positive RMS (FP-RMS), which is driven by PAX3/7::FOXO1 translocations, has a dismal 5-year overall survival rate of 13% for patients with metastatic disease. We hypothesized that targeting the oncogenic driver PAX3::FOXO1 with small molecules would be an effective treatment. To test this, we developed cell lines with endogenous PAX3::FOXO1 tagged with HiBiT epitope and performed a drug screen to identify drugs that downregulate PAX3::FOXO1 protein. **Study Design:** Using CRISPR-Cas9, we endogenously tagged PAX3::FOXO1 with HiBiT in two RMS cell lines (RH4 and SCMC), enabling the monitoring of PAX3::FOXO1 protein levels. We performed a drug screen using the Mechanism Interrogation Plate (MIPE) library of 2,480 compounds, of which 53% are FDA-approved or in clinical trials. NanoGlo Luciferase assays monitored levels of HiBiT-tagged PAX3::FOXO1, while CellTiterGlo measured cell viability at 24 hours. We selected hits that showed a difference in area under the curve (AUC) between the two readouts of ≥ 90 for drugs that preferentially reduce the fusion protein level over general cytotoxicity. We investigated whether inhibitors led to nuclear accumulation and reduced total protein levels using Western blot and immunofluorescent imaging. Candidates were validated in the parental cells and *in vivo* studies. **Results and Conclusions:** The screen identified 183 hits, including Eltanexor, an XPO1 inhibitor. XPO1 exports over 200 proteins from the nucleus by recognizing their nuclear export sequences (NESs). Since the fusion gene retains the NES of FOXO1, a known XPO1 target, we tested whether PAX3::FOXO1 is a substrate. We observed that Eltanexor enhanced PAX3::FOXO1 nuclear accumulation at 6 hours in RH4, and at 2 hours in SCMC, followed by protein downregulation at 24 hours by Western blotting. Furthermore, Eltanexor induced p53 nuclear accumulation, detectable at 6 hours in SCMC, suggesting that early accumulation of PAX3::FOXO1 may drive cytotoxicity. At 24 hours, RNA-seq in Eltanexor-treated cell lines demonstrated downregulation of PAX3::FOXO1 and MYCN signatures, components of the core regulatory network in FP-RMS. Preliminary *in vivo* studies also showed Eltanexor induces delays in tumor progression in an RMS xenograft model. Furthermore, Eltanexor in combination with Mivebresib, a validated BRD4 inhibitor, demonstrated significant synergy against FP-RMS cells. We will perform site-directed mutagenesis studies to disrupt PAX3::FOXO1's NES and validate combination with Mivebresib *in vivo*. In conclusion, we identified Eltanexor, an XPO1 inhibitor, as a novel therapeutic agent that suppressed PAX3::FOXO1 activity and levels, induced nuclear accumulation and led to cytotoxicity in incurable FP-RMS.

#6406 Accelerating selective cancer ligand discovery through an accessible phage display analysis suite.

Stephen Lees[1], Monica Shokeen[2], KIMBERLY KELLY[3]

[1]Biomedical Engineering, University of Virginia, Charlottesville, VA,[2]Washington University in St. Louis, St. Louis, MO,[3]University of Virginia, Charlottesville, VA

Identifying novel druggable targets remains a major challenge in cancer research. Of the approximately 5,000 potentially druggable cancer genes found through various sequencing techniques, 94% are well characterized, yet only 14.3% have approved drugs. This gap highlights the limitations of indirect, sequence-driven approaches, which infer targets rather than directly measuring functional binding. Direct discovery platforms like phage display help overcome this barrier by screening ligands in biologically relevant contexts. Phage display is a high-throughput screening technology that presents vast libraries of randomized peptides or proteins on bacteriophage surfaces to identify ligands that selectively bind cancer associated targets. Broader use of this technique is limited by restricted access to high-diversity libraries and the absence of standardized, user-friendly pipelines for analyzing next-generation sequencing (NGS) phage screen data. These barriers make it difficult to distinguish true binders from artifacts caused by non-specific binding, amplification bias, or sequencing noise. These challenges are especially pronounced in whole-cell and tissue-based screens, where identifying true binders is critical for discovering targets in authentic cancer environments. To address these limitations, we developed a high-diversity ($>10^8$), disulfide-constrained, variable-loop-length peptide library optimized for cancer target discovery, along with a unified phage screen NGS analysis pipeline. The library design supports high-affinity binders and enables analysis of sequence and loop-size biases across targets. The software pipeline provides a standardized processing workflow which directly influences downstream analysis. Machine-learning-based denoising and robust motif discovery further improve identification of enriched sequences and true binders. The platform has been validated with established protein-target screens and successfully used to identify ligands selective for known protein targets in multiple myeloma. These results provide a strong foundation for ongoing whole-cell panning on drug-resistant multiple myeloma lines to discover ligands with therapeutic and diagnostic potential. Our long-term aim is to build a community-driven database of phage screens processed with this unified pipeline, analogous to TCGA for RNA-seq, allowing cross-study comparisons and in-silico identification of ligands or binding motifs selective for cancer instead of surrounding healthy tissue. This standardized platform lowers barriers to actionable ligand discovery in cancer research and accelerates the development of selective agents for cancer therapeutics.

#6407 Deep learning-driven image analysis for tracking nucleolar morphology.

Leif E. Lindberg[1], Katelyn R. Alley[1], Sylvia M. Kennerly[1], Ian Reynolds[1], Ryan W. Holly[2], Jongtae Yang[2], Chris L. Vonnegutt[2], John C. Rogers[2], Victoria J. DeRose[1]

[1]Chemistry and Biochemistry, University of Oregon, Eugene, OR,[2]Thermo Fisher Scientific, Eugene, OR

Introduction: The nucleolus, a membraneless nuclear organelle responsible for ribosome production, is highly sensitive to stress. A subset of chemotherapeutic drugs induce nucleolar stress, which could influence their apoptotic mechanisms. However, tracking morphological changes of the nucleolus during treatment remains challenging due to its amorphic state and nanoscale organization. A major bottleneck for drug screening and mechanistic studies is the reliance on time-intensive manual imaging and immunostaining to identify nucleolar stress. To overcome this we have developed a suite of image analysis models to rapidly identify and classify cells.

Methods: The mechanisms that lead to nucleolar stress by small molecules and mechanisms that allow the nucleolus to recover from reversible stress remain unclear. To facilitate time-dependent morphological studies as well as general drug screening for nucleolar defects, we developed deep learning models leveraging Thermo Fisher Scientific's RNA-selective dyes to automatically detect and quantify nucleolar stress from microscopy images. Using osteosarcoma cells, we successfully classified stressed and unstressed populations with SYTO™ RNASelect™ Red, a novel RNA-selective dye developed by Thermo Fisher Scientific. This dye can be implemented into rapid high-throughput imaging methods for cancer detection and drug screening. Using these deep-learning models we can rapidly screen for novel chemotherapeutics and study the efficacy of current nucleolar stress-causing drugs.

Results: Osteosarcoma cells labeled with SYTO™ RNASelect™ Red and treated with chemotherapeutics display distinct nucleolar staining enabling precise segmentation and quantitative analysis. Under chemotherapeutic treatment nucleoli decrease in size and become more rounded. Our deep learning models not only identify which cells are experiencing nucleolar stress but also determine the specific stage of stress for each cell. These results have been validated through current known methods to identify nucleolar stress such as immunocytochemistry and RNA production assays. This platform now allows us to investigate how cells recover from reversible nucleolar stress, providing a high-throughput approach to dissect nucleolar function, resilience, and responses to chemotherapeutic treatment.

Conclusions: SYTO™ RNASelect™ Red is an effective RNA dye because it provides a bright stain for the nucleolus, enabling clear segmentation and quantitative analysis using machine learning. Its compatibility with immunocytochemistry allows for high-resolution, dynamic studies of RNA biology and cellular stress responses, making it a versatile tool for both single cell and population-level investigations. This dye, coupled with our deep-learning methods, opens the door to broad screening protocols, allowing for a spectrum of drug candidates to be tested rapidly.

#6408 Unlocking the unlockable: AS-MS for swift hit identification against challenging targets.

Renaud Renaud

Edelris SAS, Lyon, France

Affinity selection-mass spectrometry (AS-MS) is a label-free, high-throughput platform that can be used to screen small-molecule ligands by incubating them with biomolecular targets, separating bound complexes via size-exclusion or ultrafiltration, and detecting binders using high-resolution mass spectrometry. This approach bypasses the need for chemical modifications, fluorescent tags, or functional assays, thereby preserving native binding interactions and minimizing artifacts. As a label-free method, it allows for the rapid evaluation of large libraries and ranking of binding affinities without requiring functional data. Additionally, the flexibility of AS-MS enables diverse hit identification strategies, including exploration of combinatorial libraries while remaining agnostic to binding sites or mechanisms, thus uncovering novel allosteric and orthosteric ligands.In particular, the versatility of AS-MS enables adaptation of affinity selection methods to target particularities by relying on SEC-based, filter-based, or pull-down techniques. These orthogonal selection modalities can be fine-tuned—by adjusting buffer conditions, SEC polymers and volume, incubation times, wash volumes, or competitive inhibitors—to modulate assay sensitivity and selectivity, thereby maximizing enrichment for ligands with desired on/off rates. In conjunction with chemically diverse libraries, it is a powerful and highly effective approach to identify agents with innovative mechanisms of action.As an illustration of how AS-MS accelerates drug discovery by accessing challenging or “undruggable” targets lacking enzymatic activity or favorable binding pockets, we present here several case studies. In these, we have utilized AS-MS screening technology in the search for novel molecular glues and targeted protein degraders (on the VHL-BRD3 pair and other undisclosed targets), and against a wide range of challenging targets, including transcription factors (such as TEAD), RNAs, and membrane proteins such as GPCRs or ion channels (P2X4 receptor), either as isolated targets or embedded in membrane preparations.In summary, AS-MS accelerates discovery against intractable targets, compressing timelines and delivering validated, mechanism-rich hits for optimization. Its integration with downstream biophysics (e.g., SPR, NMR) and structural biology further validates hits, paving the way for next-generation therapeutics against previously intractable disease drivers.

#6409 AI-accelerated discovery of B7-H3 and DLL3-targeted cyclic peptide radioligands: From library design to preclinical validation.

Tj (Tiejun) Bing

ICE Bioscience, Beijing, China

Background: Radiopharmaceutical drug conjugates (RDCs) represent a transformative paradigm in precision oncology, yet target-specific ligand discovery remains a critical bottleneck. We developed an integrated AI-augmented platform to rapidly identify cyclic peptide binders for two emerging RDC targets: B7-H3 (immune checkpoint) and DLL3 (Notch ligand).
Methods: A structurally diverse phage display library (1.5×10^{11}capacity; 8-17 aa macrocycles) was engineered with NGS-validated complexity. Recombinant 4Ig-B7-H3 (2Ig-B7-H3 as off-target counterscreens), DLL3 (and counterscreens DLL1/DLL4) underwent orthogonal biophysical characterization by SPR and Spectral shift assay (SPS). Hit triangulation employed: (1) Deep sequencing-driven consensus motif analysis, (2) AlphaFold3 multimer modeling of peptide-target complexes, and (3) Parallel SPR/spectral shift assays (10^{-7} M affinity threshold). Top candidates were Cy5-labeled for real-time binding and internalization kinetics in engineered tumor lines.
Results: Discovery: 15/40 phage clones demonstrated target binding - AI optimization: AlphaFold3 predictions revealed a conserved β-turn motif in 7/15 top hits that anchors to a cryptic pocket in targets - Validation: Hit peptide were synthesized and showed: (i) KD 8.2×10^{-7} M (SPR), (ii) >3-fold selectivity over homologous target proteins (iii) showed binding on cells
Conclusions: This platform addresses critical challenges in RDC development by providing a streamlined solution for hit discovery, optimization, and validation. The integration of AI-driven structural prediction with high-throughput experimental validation compresses traditional hit discovery timelines This platform will significantly accelerate the RDC development pipeline—especially for hit binder identification for neo tumor antigens or other validated surface proteins like GPCRs, transporters, to accelerate RDC drug discovery using cyclic peptide as the modality.

#6410 mtKO: A dedicated guide RNA library for mitochondria redox biology research.

Karambir Kaur[1], Fengchao Lang[1], **Chunzhang Yang**[2]

[1]NIH-NOB (Neuro-Oncology Branch), Bethesda, MD,[2]NIH-NOB (Neuro-Oncology Branch), Bethesda, Maryland, MD

Mitochondria are multifunctional organelles essential for both physiological regulation and pathological progression. In malignant cancer cells, mitochondrial reprogramming establishes a metabolic foundation that supports tumor growth, which is essential for cancer cells to overcome intrinsic metabolic abnormalities and stress. To uncover key mitochondrial pathways involved in cancer development, we developed mitochondrial Knockout (mtKO) — a robust, flexible, and unbiased CRISPR/Cas9 guide RNA screening platform designed to systematically identify critical mitochondria-associated functions. The mtKO library target genes involved in diverse mitochondrial-guided processes, including biosynthesis, transmembrane transport, oxidative phosphorylation, and redox regulation. Through a mtKO dropout screen, we identified the mitochondrial antioxidant enzyme superoxide dismutase 2 (SOD2) as indispensable for the fitness and survival of cancer cells harboring oncogenic mutations in isocitrate dehydrogenase 1 (IDH1). Mechanistically, SOD2 mitigates mitochondrial reactive oxygen species (ROS) generated by dysfunctional Krebs cycle activity in IDH1-mutant glioma and chondrosarcoma cells. Functionally, SOD2 maintains redox homeostasis and preserves mitochondrial integrity thereby controlling disease manifestation both *in vitro* and *in vivo*. Overall, our study introduces a powerful functional genomics approach to interrogate mitochondrial biology and uncovers a selective mitochondrial redox vulnerability in Krebs cycle-deficient cancers, highlighting mitochondrial redox imbalance as a potential therapeutic target.

#6411 A high content live cell cancer toolbox uniquely enabled by high throughput imaging.

Matthew Boisvert, Lydia Hernandez

Araceli Biosciences Inc., Portland, OR

Live cell imaging assays are essential for in vitro cancer biology, enabling interrogation of cellular state over time, tracking changes in growth and phenotype. High content imaging (HCI), where resolution and multiparametric quantification is key to extracting insight from cellular features, is stymied by slow imaging times, preventing live cell screens at scale. However, the Araceli Endeavor® newly enables live cell high throughput high content imaging, capturing the majority of cells in a 1536-well plate in <6 minutes in 5 channels with submicron resolution. Here, we apply this speed to cancer biology, scaling up the subcellular detail of HCI to live cell screening over a multi-day time-course. We first examine cell growth and quantify where cells are in the cell cycle based on DNA content and morphology, showing changes over time in response to drug treatment. Using fluorescent dyes, we further assess changes in cell death, mitochondrial function and cellular morphology, as well as evaluate cell proliferation. High resolution brightfield imaging, added to fluorescent imaging here in <30 seconds/run, provides a dynamic, unbiased look into off-target effects and generates the detailed image features needed for machine-learning-based analysis.

Both proliferation and cell cycle measurements are traditionally done with fixed endpoint flow cytometry but these assays have limited insight. Live assays are far more revealing and vital to drug development. For instance, potential therapeutics may appear to suppress cancer in vitro, only for growth to rebound hours later, or this fixed endpoint may miss the window where a treatment is effective altogether. Unlike traditional HCI, Endeavor's speed ensures that the first well is the same state as the last, not hours older. Overall, live cell HCI offers exquisitely detailed insight over time: here correlating cell growth, death, location, morphology, and mitochondrial dynamics in a single assay, at the speed and scale required for modern screening.

#6412 Development of a high-throughput assay platform for the screening of selective integrin inhibitors in cancer.

Ziwei Zhang, Yu Zhou, **Peichuan Zhang**, Zhonghua Yan

WuXi AppTec, Shanghai, China

Integrins are critical mediators of cancer progression, facilitating cancer cell invasion, survival in circulation, and metastatic outgrowth. Integrins result in cancer progression by activating pro-survival signaling pathways and remodeling the cancer microenvironment, and thus represent promising targets for anticancer treatments. To accelerate the discovery of novel integrin-targeted therapeutics, we developed an integrated platform of high-throughput screening assays for the evaluating integrin inhibitors of diverse modalities, including small molecules, peptides, antibodies, and antibody-drug conjugates. In this study, we developed a panel of cell-free fluorescence polarization (FP) assays in 384-well plate format using a Cy3B-RGD probe to screen compounds against multiple RGD-binding integrins (αvβ1, αvβ3, αvβ5, αvβ6, αvβ8 and α8β1). In addition, we generated HEK293 cell lines stably overexpressing integrins such as α8β1, and developed ELISA as well as IncuCyte based α8β1-Mfge8 competition binding assays for compounds screening in cell-based assays. The assay results were further validated using cancer cell lines endogenously expressing high levels of integrins such as α8β1, confirming compound binding and activity in a more physiologically relevant model. In summary, we have created a robust high-throughput screening platform that combines cell-free and cell-based assays. This integrated integrin assay platform enables the efficient evaluation of selective integrin inhibitors, accelerating the development of novel integrin inhibitors for target-based cancer treatment.

#6413 Cellular DNA-Encoded Library (DEL) Screening Coupled with MICRO-TAG Real-Time Cellular Target Engagement Enables Discovery of Novel Therapeutics.

Ivan Babic, **Elmar Nurmemmedov**

CellarisBio, San Diego, CA

Transcription factors are challenging drug targets that require the native cellular environment for interrogation of direct engagement with potential therapeutic candidates. The transcription factor β-catenin is a therapeutically valuable yet challenging drug target, serving as signaling hub of the complex and highly interconnected WNT signaling network. Its central role and extensive pathway crosstalk have complicated efforts to distinguish effectors that bind β-catenin directly from those acting indirectly through upstream WNT components. This mechanistic distinction is critical for guiding rational drug discovery. We applied the MICRO-TAG® Cell Target Engagement technology to interrogate 25 reported β-catenin/WNT effectors. Using a novel direct target engagement system employing real-time temperature series, we quantified ligand-dependent stabilization of β-catenin across multiple doses, profiling their cellular target engagement potencies, under cellular conditions. Parallel functional assays, including TOPFlash reporter activity and WNT-responsive surface markers, integrated direct binding with downstream signaling readouts. This integrated approach distinguished direct β-catenin binders from effectors acting indirectly through upstream pathway components. By coupling cellular target engagement with functional readout, the MICRO-TAG® system enables scalable, mechanism-resolved drug discovery system for complex signaling pathways. This approach establishes a new paradigm for functionally interrogating therapeutic candidates through integrated target engagement and functional readout, within a unified, quantitative, and biologically relevant framework that is readily translatable to other challenging drug targets.

#6414 Ultra-sensitive structural biomarker discovery for TNBC and pancreatic cancer using a deep VHH repertoire (IBMET): A translational platform for tissue-agnostic target identification.

Akihiro Imura[1], Ryota Maeda[1], Hiroyuki Yamazaki[1], Tsuyoshi Inoue[2], Sadako Aakashi-Tanaka[3], Hiroko Tsukada[3]

[1]COGNANO INC., Kyoto, Japan,[2]Pharmaceutical Sciences, Osaka University, Suita, Japan,[3]Breast Surgery, Tokyo Women's Medical University, Tokyo, Japan

Background: In cancers with substantial unmet medical need (UMN), the limited availability of reliable and tumor-selective surface biomarkers continues to hinder therapeutic development. This challenge is particularly evident in triple-negative breast cancer (TNBC) and pancreatic ductal adenocarcinoma (PDAC), where currently available targets often show insufficient specificity or restricted applicability across patient subgroups.
Methods: We established the Inverse Biomarker Exploration Technology (IBMET), a systematic framework designed to detect pathological structural alterations on tumor cells. IBMET utilizes a large alpaca-derived VHH antibody repertoire as highly sensitive structural probes. Alpacas were immunized with multiple tumor cell lines, and the resulting VHH library was analyzed using phage display and next-generation sequencing. Candidate antibodies were selected based on statistical enrichment and evaluated by IHC/IF across an extensive panel of tumor and normal tissues. Antigen identification was performed by cross-linking immunoprecipitation, SDS-PAGE, and LC-MS/MS. Clinical relevance was examined using a breast cancer biopsy cohort (n = 106).
Results: IBMET identified several structural biomarker candidates relevant to TNBC and PDAC. The lead antibody, VHH89, selectively recognized a previously uncharacterized low-molecular-weight isoform of ALCAM (approximately 70 kDa; designated ALCAM70). VHH89 showed lesion-selective staining in tumor tissues with minimal reactivity in normal organs, indicating a high degree of tumor specificity. In clinical breast cancer specimens, VHH89 demonstrated positivity in more than 20% of TNBC cases. In addition, subsets of pancreatic cancer and cholangiocarcinoma specimens also showed VHH89 positivity, suggesting that this isoform may represent a structurally altered antigen present across multiple tumor types.
Conclusion: IBMET offers a reproducible and scalable approach for identifying structurally defined biomarkers that may not be detectable using genomic or transcriptomic analyses alone. By systematically excluding antibodies that react with normal tissues and enriching for tumor-associated conformational epitopes, IBMET broadens the spectrum of actionable targets for aggressive cancers. These findings support the potential integration of IBMET-derived antibodies into the development of next-generation antibody-drug conjugates, radioligand therapies, and companion diagnostics. To facilitate broader validation, COGNANO will make eight PDAC-selective VHH antibodies available for research use at AACR 2026.

#6415 Champions: Scalable chem-seq and functional-seq platforms for profiling chemical and genetic perturbations in patient-derived organoids.

Devin Porter[1], BanuPriya Sridharan[2], Gervaise Henry[1], Kakajan Komurov[1], Yamini Nallana[1], Brandon Walling[1]

[1]Champions Oncology (Rockville, MD), Rockville, MD,[2]Champions Oncology, Inc. (Hackensack, NJ), Hackensack, NJ

Background :
Large-scale functional drug screening has been limited by low throughput reliance on simple 2D systems and a lack of high-resolution mechanistic readouts. To address these challenges, we implemented Chem-Seq and Functional-Seq, scalable transcriptomic profiling platforms that enable high-content screening of both chemical and genetic perturbations in clinically relevant cancer models.
Methods :
Experiments were conducted across six tumor models, including cell lines and four patient-derived xenograft organoids from Champions Oncology's proprietary Patient-Derived Xenograft Organoid (PDXO) bank, which preserves tumor heterogeneity and 3D architecture. We applied Chem-Seq to 44 standard-of-care (SOC) oncology therapeutics spanning diverse pathways, including MAPK, PI3K/AKT/mTOR, CDK, EGFR/HER2, MET, AMPK, proteasome, and topoisomerase inhibition. Compounds were tested at various concentrations to capture dose-dependent transcriptional changes and pathway-specific effects. Functional-Seq was performed in parallel using siRNA-mediated knockdown of selected drug targets to generate loss-of-function signatures that anchor interpretation of Chem-seq profiles. This also serves as a proof-of-concept for using a predefined siRNA signature bank to match unknown compounds in larger screens.
Results :
Chem-Seq produced robust transcriptional signatures with high reproducibility across replicates. SOC compounds targeting the same pathway (e.g., MEK, PI3K, EGFR) clustered cohesively, while structurally distinct inhibitors of related pathways were separable. Functional-Seq knockdowns phenocopied chemical inhibition of select targets, confirming on-target activity. Dose-response profiling revealed concentration-dependent separation of cytotoxic versus pathway-selective signatures, demonstrating sensitivity and dynamic range.
Future Directions and Conclusions:
Following validation, the workflow will scale to ~50,000 perturbations per week. Combined with the PDXO bank, this high-dimensional dataset will be leveraged to support mechanistic insight, compound prioritization, and toxicity prediction. Additionally, machine-learning tools can be applied to predict compound responses and guide de novo compound generation for desired traits. By integrating high-throughput transcriptomics with patient-derived 3D biology and AI-driven analytics, this platform offers a powerful, scalable tool for accelerating preclinical drug discovery and advancing personalized therapeutic strategies.

#6416 DEL-chemomics approach for the discovery of targeted protein degraders for cancer therapy.

Ying Zhang[1], Anthony D. Keefe[2], Matthew A. Clark[1], Marie-Aude Guie[2], John Guilinger[1]

[1]X-Chem Pharmaceuticals, Waltham, MA,[2]X-Chem, Inc., X-Chem, Inc., MA

DNA-encoded chemical library (DEL) technology has become a powerful tool for hit identification, enabling the efficient screening of large collections of encoded compounds with advantages over traditional high-throughput screening in terms of library size, cost, and resource efficiency. The high chemical diversity and encoding fidelity of DELs yields extensive data that can support computational approaches such as machine learning (ML), 3D pharmacophore generation and structure-based discovery. This DEL-chemomics approach has been applied to the discovery of novel E3 ligase receptor ligands, expanding the repertoire of E3 ligands beyond the traditional CRBN and VHL for degradation of drug targets. A case study of the discovery of DCAF1 ligand and its application in PROTACs that targeted WDR5 for degradation will be presented.

#6417 High-throughput peptide screening for radioligands by DNA encoded libraries.

Yihui Xie

BioDuro, Irvine, CA

Targeting ligands play a critical role in radiopharmaceuticals for cancer diagnosis and therapy. Due to their excellent binding affinity and specificity, peptides have been widely used to conjugate with radionuclides for delivery to cancer cells in targeted lesions. Current high-throughput de novo peptide hit finding heavily relies on phage display and mRNA display. While efficient, the generation of those peptide libraries is still limited by the biological translation process. As an emerging peptide screening approach, DNA encoded library technology (DELT) offers a higher degree of chemical flexibility. Unnatural amino acids and a variety of cyclization strategies that are inaccessible to display technologies can be readily incorporated into DEL peptides, leading to improved pharmacokinetic profiles including prolonged retention time and increased in vivo stability. Here we report our efforts in developing billion-member peptide libraries and primary screening for radioligand discovery through DELT, followed by high-throughput solid-phase synthesis that accelerates hit confirmation and affinity maturation.

#6418 Adapting the SAR-MAP chemical biology platform to target tumor immune checkpoints.

Hannah L. Thirman[1], Stephanie Medina[1], Jonathan M. Irish[2]

[1]Vanderbilt University, Nashville, TN,[2]University of Colorado, Aurora, CO

A major challenge in preclinical drug discovery is adapting deep cellular profiling of complex primary human cells to scalable small-molecule screening and subsequent structure-activity relationship (SAR) studies. This is especially the case when the goal is to target an intercellular interaction, such as a tumor immune checkpoint. We previously developed Structure-Activity Relationships by Multiplexed Activity Profiling (SAR-MAP; PMC12313981), a single cell chemical biology platform that quantitatively maps how small structural changes in compounds can drive distinct functional responses within human cells. SAR-MAP integrates phospho-specific flow cytometry with fluorescent cell barcoding to efficiently profile dozens of key intracellular signaling nodes, surface markers, and cell states in parallel. This platform revealed previously unrecognized mechanistic heterogeneity for the rocaglate natural product family, including a structural feature that confers selective anti-leukemia activity. Here we adapted SAR-MAP to primary human macrophages and established a scalable screening assay capable of dissecting IFN-γ responsive pathways, immune checkpoint regulation, and fundamental immune-relevant signaling nodes within a single experiment. Monocytes were isolated from peripheral blood, differentiated, and polarized to an M1-like proinflammatory state using IFN-γ in a fluorescently barcoded 96-well format suited for screening and iterative SAR. Multiplexed activity profiling quantified key functional and surface markers including PD-L1, CD14, CD206, and CD32, confirming that IFN-γ polarization robustly induces PD-L1 relative to baseline macrophages. This adaptation enables simultaneous evaluation of multiple mechanisms regulating immune checkpoint expression, including direct PD-L1 blockade, modulation of IFN-γ, and JAK-STAT1 or mTOR pathway interference. Small molecules that selectively modulate these pathways not only have translational relevance but may also illuminate previously unrecognized targets and mechanisms governing immune regulation. Together, these studies further establish SAR-MAP as a scalable, high-content approach for linking chemical structure to immune regulation in primary human cells.

#6419 Automated culture and AI-enabled image analysis of compound responses in patient-derived colorectal cancer organoids.

Oksana Sirenko[1], Prathyushakrishna Macha[1], Zhisong Tong[1], Nikki Carter[2], Felix Spira[1]

[1]Molecular Devices, LLC, San Jose, CA,[2]Molecular Devices, LLC (Moldev), San Jose, CA

Organoids transformed biomedical research by providing physiologically relevant models for cancer studies, essential for investigating disease mechanisms and drug responses. However, manual organoid culture processes are labor-intensive and prone to variability, limiting widespread adoption. Additionally, extracting information from complex biological systems remains a major challenge in organoid research. Here, we present the development of methods for automated culture, expansion, and end-point assays using patient-derived organoids, combined with machine-learning approaches for image-based analysis of compound responses. Patient-derived colorectal cancer (CRC) organoids were cultured in Matrigel domes using the CellXpress.ai automated cell culture system, which enables automated seeding, media exchanges, imaging, and passaging. Imaging and media exchanges were set periodically, while passaging was either triggered by users or automatically, based on image analysis and phenotypes of organoids. Using this system, we successfully maintained organoid cultures for over a month and expanded them to quantities sufficient for multiple 96-well assay plates. Cultured organoids were treated with a panel of anti-cancer drugs representing diverse mechanisms of action. Dose-dependent effects on organoid morphology and cell viability were evaluated using automated confocal high-content imaging. Following drug treatment, organoids were either stained live with viability dyes or fixed and stained with a panel of markers for nuclei, cytoskeleton, mitochondria, and RNA content. Images were analyzed using a deep learning model in IN Carta analysis software. Machine learning tools offer an unbiased and comprehensive approach to analysis by automatically identifying organoids and scoring them as intact or damaged. The analysis protocol extracted a panel of quantitative features per organoid. These included morphological descriptors, intensity metrics across three fluorescent channels, textural features, and spatial distribution patterns. Features were extracted enabling multidimensional phenotypic profiling of organoid populations. Classification was performed using a combination of unsupervised and supervised machine learning. Unsupervised clustering grouped organoids into phenotypic clusters based on feature similarity, which were then curated into biologically relevant categories using user-defined criteria. The classification allowed evaluation of compound effects in a concentration-dependent manner. Unlike single-parameter readouts, this approach incorporates a broad morphological context. In summary, we demonstrated a fully automated workflow for evaluation of compound effects using 3D human organoids. The described approach enables AI-driven phenotypic profiling for assessing drug-induced effects in organoid models.

#6420 Monitoring S-adenosylmethionine (SAM) and S-Adenosyl homocysteine (SAH) using a homogeneous luminescent assay.

Said Goueli[1], Dareen Mikheil[2], Nathan H. Murray[3], Kevin Hsiao[4], Hui Wang[5], Matt Larsen[5]

[1]Promega, Madison, WI,[2]Research and development, Promega Corp., Madison, WI,[3]Research, Promega Corp., Madison, WI,[4]Research and Development, Promega Corp., Madison, WI,[5]Promega Biosciences, San Louis Obispo, CA

Methylation is the enzymatic process of transferring a methyl group (-CH_3) to a substrate molecule (DNA, RNA, proteins, lipids, small metabolites). The universal substrate and product for these methyltransferases are S-Adenosyl Methionine (SAM) and S-Adenosyl homocysteine (SAH) respectively. SAH is a competitive inhibitor of many methyltransferase reactions. Thus, high SAH leads to reduced methylation capacity. More recently, there's an immunometabolic angle where tumor cells can out-compete CD8+ T cells for SAM/SAH availability, impairing T-cell survival; and supplementing SAM improved T-cell effector function and reduced tumor growth in vivo. Other cancers such as hepatic cancer were reported to have reduced SAM/SAH ratio because SAM production is impaired and/or SAH accumulates, leading to disturbed methylation and potentially contributing to oncogenes. One-carbon metabolism (methionine cycle, folate cycle, trans-sulfuration) is tightly integrated with cellular signaling and metabolic status thus, nutrient supply, amino acid availability, redox state, methyl donor availability all influence signaling pathways. The SAM/SAH ratio is therefore a "metabolic sensor" to some degree. Thus, it is apparent that the "ratio" of SAM to SAH is often used as a surrogate metric for cellular "methylation potential" or "methylation index". Thus, development of an assay that monitors the concentration of SAM and SAH and thus SAM/SAH ration determination is needed to investigate the role of SAM/SAH ratio in normal and abnormal physiological processes. Current methods to monitor these metabolites include LC-MS/MS, or ELISA in some cases in the relevant cellular/tissue context. We have found ELISA not to be reliable assay for SAM since all commercially available assays do not measure SAM and LC-MS/MS requires technical expertise and expensive equipment. Towards this goal we embarked on the development of homogenous assay that is simple and amenable to high throughput formatting. The assay relies on the complementation of nanoluc luciferase fragments that are linked to two interacting molecules. We use an SAM selective aptamer that is biotinylated, and Streptavidin linked to nanoluc large fragments. In the presence of SAM linked to the small nanoluc fragment, the proximity of the two fragments results in complementation of nanoluc luciferase and upon addition of Fumerazine substrate, light is generated. However, in the presence of free SAM, it competes with SAM linked to the small fragment (sensor) and thus no complementation of nanoluc occurs and no light. A decreasing signal indicates high SAM concentration and high signal indicates the absence or low SAM. Similar strategy was followed to develop a SAH sensor. The assays are homogenous, sensitive and easy to use and selective for SAM and SAH and we demonstrate it utility in monitoring SAM/SAH ratio changes in different physiological models.

#6421 Enabling phenotypic high-throughput drug screening with patient-derived organoids.

Abraham Lin[1], Maxim Le Compte[1], Rebecca Stone[2], Tyler Gilcrest[2], Edgar Cardenas De La Hoz[3], Geert Roeyen[4], Jeroen M. H. Hendriks[5], Filip Lardon[1], Christophe Deben[1]

[1]Center for Oncological Research, University of Antwerp, Wilrijk, Belgium,[2]Orbits Oncology, Palo Alto, CA,[3]Industrial Vision Lab, University of Antwerp, Antwerp, Belgium,[4]Department of Hepatobiliary Transplantation & Endocrine Surgery, University Hospital Antwerp, Wilrijk, Belgium,[5]Thoracic and Vascular Surgery, University Hospital Antwerp, Wilrijk, Belgium

Patient-derived organoids (PDOs) can recapitulate patient tumors in the lab, making them more realistic models compared to traditional *in vitro* cell cultures. However, challenges in reproducibility, standardization, and analysis have limited the use of PDOs in drug discovery, especially for high-throughput screening (HTS) applications. To address this, we have developed an efficient workflow, using automation equipment and interoperable computational platforms to facilitate the adoption of PDOs for HTS applications[1]. Our protocol leverages live-cell imaging techniques to capture the dynamic, complex PDO-drug interactions for more comprehensive analysis. Using label-free detection of organoids from brightfield images, we integrated growth-rate-based drug response metrics[2] with drug synergy metrics to significantly improve the identification of synergistic drug interactions[3]. Here, we screened 10 distinct drug combinations on 10 PDOs, sourced from healthy lung, non-small cell lung cancer, and pancreatic ductal adenocarcinoma. In particular, we focused on repurposing the Thioredoxin reductase inhibitor, Auranofin. This screen required a total of 20 384-well plates and resulted in 37,000 images captures. With lab automation, organoid seeding only took 1 hour, and with analysis automation, all 37,000 images were analyzed in under 8 hours. Altogether, we identified drug candidates that can synergistically enhanced the efficacy of Auranofin in a tumor selective manner. Our study highlights the advantage of combining lab automation with computational automation to enable HTS with PDOs. The implementation of our method supports the current push by the FDA to reduce animal experimentation for the discovery of effective therapeutic strategies. We are now further investigating streamlined integration techniques between different lab automation systems.

#6422 A 3D bioprinted vascularized tumor tissue model of non-small cell lung cancer: A model for drug screening.

Fahimeh Shahabipour[1], Yuchi Chen[1], Yen-Ting Tung[2], Min Jae Song[2], Marc Ferrer[3]

[1]NIH-NCATS (National Center for Advancing Translational Sciences), Bethesda, MD,[2]NIH-NCATS (National Center for Advancing Translational Sciences), Rockville, MD,[3]NCAT/NIH, Rockville, MD

Lung cancer remains the leading cause of cancer-related death worldwide, with non-small cell lung cancer (NSCLC) accounting for 80-85% of all cases. There is therefore a need for new, effective treatments for lung cancer. A major challenge in preclinical drug development is the lack of assay platforms that accurately recapitulate the tumor microenvironment (TME), thereby enabling the investigation of cell-cell interactions between the tumor and surrounding stroma cells. To address this gap, we have developed a 3D-bioprinted vascularized lung cancer tissue model in a 96-well format that incorporates human NSCLC cells within a physiologically relevant TME. The TME tissue model includes GFP-expressing lung endothelial cells, pericytes, and fibroblasts that form a vascular network, surrounded by RFP-expressing NSCLC cells (A549, H1975, or H460). Using this platform, we conducted quantitative fluorescence cell imaging to assess vascular morphology, including angiogenesis and tumor growth. Our results revealed distinct tumor morphologies for each of the three NSCLC cell lines used, with H1975 cells showing migration toward the vessels and forming irregular tumor shapes. In contrast, H460 cells formed spheroidal tumors, with no migration to the vessels. We are currently conducting single-cell RNA sequencing on these tissue models and will apply a pharmacogenomics approach to identify novel therapeutic targets based on cancer cell-tumor microenvironment (TME) interactions. This engineered 3D lung cancer model provides a scalable, clinically relevant approach to discovering new treatments for NSCLC patients.

#6423 DNA-encoded chemical library screening for glue discovery for oncology targets.

Anthony D. Keefe, Paolo A. Centrella, Zhen Chen, Matthew A. Clark, Paige Dickson, Marie-Aude Guie, John P. Guilinger, Ying Zhang

X-Chem Inc., Waltham, MA

There is considerable interest in the discovery of novel molecular glues that induce proximity between oncology targets and their modulators. Induced proximity can be used to degrade proteins by a range of mechanisms, including ubiquitination and trafficking to the proteasome. DNA-Encoded Chemical Library screening can readily be adapted to the discovery of glues, and we will describe case studies that exemplify how carefully designed screening campaigns with highly diverse encoded compound libraries can identify small molecules capable of inducing proximity. Case studies will include a small molecule discovered in a DEL screen against ATAD2 that is able to inappropriately dimerize ATAD2 thereby reducing its ability to bind to acetylated histones and an activator of the integrated stress response pathway that only binds to the eIF2b complex, not its isolated components, thereby stabilizing it.

#6424 MICRO-TAG® cell target engagement redefines GPCR drug discovery with functional relevance.

Ivan Babic, Elmar Nurmemmedov

CellarisBio, San Diego, CA

G protein-coupled receptors (GPCRs) form the largest and most pharmacologically important family of membrane proteins, translating extracellular cues into intracellular signaling cascades. As master regulators of cell metabolism, differentiation, growth, neurotransmission, and sensory perception, GPCRs remain among the most valuable yet technically challenging therapeutic targets. Discovery of drugs targeting these receptors is a challenge in early drug discovery. Conventional biophysical methods that rely on recombinant or purified proteins have achieved limited success, as they poorly capture the structural and functional relevance of GPCRs outside of their native cellular context. Here, we present the MICRO-TAG® Cell Target Engagement platform as a cellular and translatable assay system capable of identifying and functionally validating compounds that directly bind GPCRs in their native membrane environment. Using GPR75 — a receptor implicated in obesity, cancer, and metabolic syndrome—as a model, we demonstrate the ability of MICRO-TAG® to: (1) detect direct ligand-receptor binding, (2) monitor downstream GPCR signaling, and (3) provide sensitive reporter-based readouts of agonist or antagonist activity. By integrating direct target engagement with functional pathway interrogation in a cellular environment, MICRO-TAG® enables scalable and physiologically relevant drug discovery for some of the most challenging drug target classes in biology.

#6425 High throughput screening identifies novel drugs for calreticulin surface translocation in pancreatic ductal adenocarcinoma.

Yuvasri Golivi[1], Steven D. Forsythe[1], Rachael Guenter[1], Faris Zaibaq[1], Michele Ceribelli[2], Craig Thomas[2], J. Bart Rose[1]

[1]University of Alabama at Birmingham, Birmingham, AL,[2]Lymphoid Malignancies Branch, National Cancer Institute, NIH, Bethesda, MD

Background: Pancreatic ductal adenocarcinoma (PDAC) is currently the fourth leading cause of cancer-related deaths in the United States and is projected to increase within the next decade due to its poor prognosis and increasing incidence. There is an urgent need to develop more effective therapeutic options and detection strategies to improve survival outcomes for PDAC patients. Calreticulin (CALR), an endoplasmic reticulum protein, is known to translocate to the cell surface following cellular stress. Surface-expressed CALR holds promise for cancer detection or therapeutic delivery. To explore this potential, we performed high-throughput screening to identify compounds which induce surface CALR expression.

Methods: Two human PDAC cell lines (Panc1, MIA Pa Ca-2) were engineered using the Nano-Glo HiBiT Extracellular Detection System to stably integrate HiBiT into the *CALR* gene. A high throughput screen for surface CALR-inducing compounds was performed at the National Center for Advancing Translational Sciences (NCATS). Cell lines expressing HiBiT-CALR were treated with approximately 3,000 drugs from the Mechanism interrogation PlatEs (MIPE) library for 24 or 48 hours and then assessed for cell viability using CellTiter-Glo and surface CALR levels by luminescence. Surface HiBiT-CALR and cell viability signals were quantified using a ViewLux microplate imager and automated processes utilizing the XTS Staubli UniVAL robotic system. The top ten drugs demonstrating high CALR signal (AUC) with minimal toxicity were validated for surface CALR induction by flowcytometry. Cells were also analyzed for viability using MTT assay, with $P < 0.05$ considered significant.

Results: Out of the compounds evaluated, 102 compounds showed increased CALR surface expression and were selected for secondary screening, from which ten were further chosen for in-lab validation. Among these, bisindolylmaleimide IV and AEM1 were identified to reliably increase CALR. Flow cytometry analysis confirmed significant increases in live surface CALR+ cells, with bisindolylmaleimide IV (1.1μM) increasing CALR by 1.7-fold in MIA Pa Ca-2 and 1.32-fold in Panc1, while AEM1 (10μM) increased CALR by 7-fold in MIA PaCa-2 and 3.7-fold in PANC-1. Viability assays confirmed low cytotoxicity for bisindolylmaleimide IV (1.1 μM), with 77% and 84% cell viability observed in MIA PaCa-2 and PANC-1 cells, respectively. Similarly, AEM1 (10 μM) showed 81% viability in MIA PaCa-2 and 76% in PANC-1 cells.

Conclusion: Our results identified the potential of two novel drugs, bisindolylmaleimide IV and AEM1, as promising candidates for enhancing surface CALR expression, offering new avenues for PDAC detection and tumor specific delivery of therapies.

Keywords: Calreticulin, pancreatic ductal adenocarcinoma, drug discovery, therapeutic delivery, HiBiT-CALR.

#6426 Development and validation of HTS assays for discovery of SMARCAL1 ATPase inhibitors.

Matthew Blackburn, **Robert Lowery**

BellBrook Labs, Madison, WI

SWI/SNF-related matrix-associated actin-dependent regulator of chromatin subfamily A-like protein (SMARCAL1) is an ATP-dependent SNF2 motor protein family annealing helicase that maintains genomic stability during DNA replication by catalyzing fork regression and Holliday junction migration. Loss of SMARCAL1 and the attendant DNA damage has been shown to increase tumor immunity via stimulation of the cGAS/STING pathway and suppression of PDL-1 expression, making it an attractive target for cancer immunotherapy. Here we describe development of HTS-compatible assays for screening and profiling SMARCAL1 inhibitors using the Transcreener ADP^2 Assay to measure DNA-dependent ATPase activity. The Transcreener ADP^2 Assay directly detects ADP in a competitive immunoassay with far-red, fluorescence polarization (FP), fluorescence intensity (FI) or time-resolved Förster-resonance-energy-transfer (TR-FRET) readouts. This format is homogenous (mix-and-read), compatible with diverse DNA substrates, and resistant to interference from screening compounds. A human SMARCAL1 construct comprising the core catalytic domain plus the HARP1, HARP2 domains, produced in BaV-infected insect cells, showed robust ATPase activity in initial testing with synthetic forked DNA (fDNA) and sheared salmon sperm DNA (sssDNA); hydrolysis of ATP was completely dependent on the presence of DNA. The K_m for ATP with either substrate was 110 µM, and the K_m values for sssDNA and fDNA were 30 ng/ml and 38 pM, respectively. The enzyme showed remarkable catalytic rates (kcat) of 58.6 s^{-1} and 81.1 s^{-1} with the two respective DNA substrates, enabling the use of less than 100 pM enzyme to produce a robust signal under initial velocity conditions. The kinetic parameters determined using the three different assay readouts (FP, FI and TR-FRET) were in concordance. The FP assay was validated for HTS by screening a collection of 1280 bioactives, yielding a Z' > 0.9 and identification of hits that were confirmed in dose response experiments.

#6427 BRETTSA: A BRET-based assay for ultra-sensitive measurement of target engagement through protein denaturation in live cells.

Cesear Corona[1], James Vasta[2], Matthew B. Robers[3], Michael Beck[4], Inhong Hwang[1], Min Zhou[5], Ani Michaud[6], Wenhui Zhou[7], Mei Cong[6]

[1]Discovery, Promega Corporation, San Luis Obispo, CA,[2]Promega Corporation, Madison, WI,[3]Research and Development, Promega, Fitchburg, WI,[4]R&D, Promega Corporation, Madison, WI,[5]Research Scientist, Research & Development, Promega Corp., San Luis Obispo, CA,[6]Promega, Madison, WI,[7]Promega Corp, San Luis Obispo, CA

Understanding ligand-target interactions within the native cellular environment is a persistent challenge in early drug discovery. Conventional thermal shift assays (TSAs) enable evaluation of target engagement in cells with minimal prior knowledge of the target, but their reliance on protein aggregation limits both sensitivity and scalability for high-throughput screening (HTS). We introduce a novel bioluminescence resonance energy transfer-based thermal shift assay (BRETTSA) that detects ligand-protein interactions in intact cells by monitoring protein denaturation events. In this approach, cell-permeable, denaturation-sensitive dyes report on the unfolded state of a NanoLuc-tagged target protein following a controlled thermal challenge. Ligand binding is quantified as a shift in the protein's thermal stability profile, observed as a dose-dependent decrease in BRET signal within live cells. BRETTSA is broadly applicable and has been successfully deployed to assess ligand binding for more than 100 targets spanning 20 protein families and six subcellular compartments, including transcription factors and integral membrane proteins. The method exhibits a wide dynamic range, enabling detection of ligand interactions across at least five orders of magnitude—surpassing the performance of aggregation-based TSAs. Beyond classical small-molecule binding, BRETTSA can also characterize molecular glues, bifunctional degraders, and cooperative ternary complexes. Together, these results establish BRETTSA as a robust, sensitive, and scalable platform for quantifying ligand engagement directly in living cells, offering a powerful tool for hit discovery and target validation in drug development.

#6428 DiscoveryDirect: Extending direct-to-biology paradigms to accelerate oncology drug discovery.

Allan Michael Jordan[1], Daniel Clare[2], Kam Chohan[1], Rick Davies[2], Jonathan Finlayson[2], Euan Fordyce[2], Clare Hammond[2], Philip MacFaul[2], Christopher Pearce[1], Raquel Faba Rodriguez[2], Alexandra Stowell[2], Denise Swift[3], Megan Thompson[2], Graeme Walker[2], Terence Wu[2]

[1]Sygnature Discovery, Nottingham, United Kingdom,[2]Sygnature Discovery, Macclesfield, United Kingdom,[3]Sygnature Discovery, Nottingham

The average timeline from project initiation to preclinical candidate delivery in oncology drug discovery is approximately four years. To compress these timelines, direct-to-biology strategies are increasingly employed to expedite early decision-making and compound progression. However, conventional approaches often remain limited to biophysical off-rate assessments of crude reaction mixtures (CRMs), restricting their utility. To overcome these constraints, we have expanded this paradigm through integrated methodologies, including Direct-to-Crystallography (D2C), to validate hits and elucidate structure-activity relationships (SAR), enabling pre-candidate delivery in as little as 18 months.

Harnessing our Hit Synergy platform which combines complementary screening technologies, we rapidly generated novel, high quality and structurally diverse hits for a challenging and clinically relevant oncology target. Early deployment of D2C, using existing HTS liquid stocks, delivered ligand-bound structures without delays associated with hit re-synthesis or re-acquisition. These structures confirmed target engagement and revealed novel binding interactions. Orthogonal hit validation employed direct-to-biology approaches such as off-rate screening, alongside tailored biochemical and cellular assays on purified samples.

Integration of structural insights and biological data accelerated hit expansion *via* high-throughput chemistry (HTC) and complementary direct-to-biology assays validated for both pure compounds and CRMs. Robust D2C determinations from CRMs yielding as little as 15% product further streamlined SAR generation and hypothesis testing, influencing medicinal chemistry design and decision making and compressing the design-make-test cycle. Generative AI-driven idea generation and direct-to-physicochemical assays further supported optimization for developability.

Together, this fully integrated, multi-modal workflow enabled rapid, holistic decision-making at critical project stages, delivering pre-candidate quality derivatives in a significantly truncated timeframe. By embedding direct-to-discovery methodologies throughout the pipeline, we successfully accelerated progression from hit identification to candidate selection, advancing novel therapeutics toward the clinic with unprecedented efficiency.

#6429 NMR assessment of ternary complex formation by targeted protein degraders.

Emily M. Grasso, David Fry, Nabin Panth, Zachary Sparta, Madhavi Latha S. Chalasani, Adam Haidi, Steven Murkli, Nareshkumar Jain

NJ Bio, Inc., Princeton, NJ

Targeted protein degradation (TPD) is an increasingly prominent therapeutic strategy for targeting systems previously thought to be undruggable. Unlike typical small molecule inhibitors or agonists, TPDs induce the degradation of specific proteins by forcing them into proximity with the cell's native proteasomal degradation machinery. Many companies are rapidly developing new TPDs, and several degraders have reached clinical trials. From a chemistry standpoint, there are three main aspects of a TPD to study and optimize: 1) a ligand that binds and recruits a target protein, 2) a ligand that binds an E3 ligase, and 3) a linker that orients the two ligands and their associated proteins at the correct geometry for degradation. TPDs present a more complicated case of lead optimization than traditional programs since they bind simultaneously to two proteins forming a non-native protein:protein complex. The formation of these target protein-TPD-E3 ternary complexes is of particular interest in the field. As in any drug development program, knowing structural details of how TPDs bind to their target proteins provides critical information that may offer new and unique insights into future TPD design. Further, ideal TPDs allow for turnover of the degradation machinery, meaning that these molecules act catalytically to degrade more target protein at low concentrations, which complicates the desired kinetics for the formation and dissolution of ternary complexes. Recent work has shown that these complexes may be fundamentally dynamic and involve non-optimal interactions.

Nuclear magnetic resonance (NMR) spectroscopy is uniquely poised to study these TPD complexes since it can be used to study both the structure and dynamics of molecules in solution. We report our use of NMR to characterize ternary complexes consisting of a TPD bound to both its target protein and the E3. Using isotopically labeled proteins, we first study the TPD binary complexes to establish how each end of the TPD binds before assessing additional changes that occur in ternary complexes. With this approach, we have the capacity to discriminate between changes due to ligand binding and those due to novel protein-protein interactions between the target protein and the E3. We find that the presence of the second protein in the ternary complex affects how the TPD binds to each protein, suggesting that these experiments report on the cooperativity of binding and the possible structural basis of this cooperativity. We further explored the use of NMR data acquired across a series of TPDs with different linkers to guide our understanding of the idealized ternary complex structural ensemble when combined with traditional assays for degradation. The study of ternary complex dynamics using NMR offers a new strategy to allow for the design and optimization of the next generation of TPDs. We will be disclosing all the structures related to this study.

#6434 Affective trajectories during adaptive pharmacotherapy for smoking cessation: Insights from EMA data.

Hadeel Al-Sahli[1], Ferdous Qudus[2], George Kypriotakis[3], Paul Cinciripini[3], Yong Cui[3]

[1]UT Health Houston McGovern Medical School, Houston, TX,[2]Philadelphia College of Osteopathic Medicine, Philadelphia, PA,[3]University of Texas MD Anderson Cancer Center, Houston, TX

Background: Medications such as varenicline and combination nicotine replacement therapy (NRT) have demonstrated efficacy in promoting smoking cessation. However, the underlying psychological mechanisms that drive successful abstinence are less well understood. This study used Ecological Momentary Assessment (EMA) to evaluate the impact of cessation medications and adaptive treatment phases on affect among adults undergoing a two-phase smoking cessation trial.

Methods: Adult smokers (N=490) were randomized to receive varenicline (VAR) or nicotine replacement therapy (NRT) in a two-phase study. At the end of *6-week Phase* 1, non-abstinent participants were re-randomized for the 6-week Phase 2 to continue, switch, or augment their pharmacotherapy, while abstinent participants continued with their initial pharmacotherapy. Participants provided daily ecological momentary assessment (EMA) data on positive and negative affect, which were averaged by week and phase. Linear mixed effects models were used to examine the effects of medication group, treatment phase, and weeks since quit date on positive and negative affect, allowing the effect of phase to vary randomly by subject.

Results: Several trends emerged when examining the affect trajectories over time. Visual inspection of the data suggests that participants on augmented medication tended to show greater improvements in affect scores compared to those remaining on standard NRT or varenicline alone. For positive affect, individuals in the augmented varenicline and augmented NRT groups showed an upward trajectory in Phase 2, with mean positive affect increasing steadily in the weeks following adaptation of their medication regimen. In contrast, participants in the standard NRT and varenicline groups demonstrated relatively stable or only modest increases. For negative affect, participants who were augmented in Phase 2 exhibited sharper decreases in negative affect, while those in the non-augmented medication showed more variable or persistent negative affect scores across both phases.

Conclusion: Adaptive pharmacotherapy strategies for smoking cessation show greater improvement in positive affect and reduction in negative affect over time. Importantly, there was substantial heterogeneity in affective response, suggesting that individual characteristics such as age and sex may influence emotional adjustment during smoking cessation. Clinicians should consider evaluating and, when appropriate, adjusting medication regimens to support desirable affective trajectories throughout the quitting process. Future studies should investigate how changes in affect are linked to abstinence outcomes and explore how personalized medication strategies can optimize both affect and quit rates in diverse populations.

#6435 Dose optimization in multi-indication oncology basket trials: Leveraging Bayesian borrowing to identify OBD.

Danny Lu[1], Yutao Liu[1], Yanning Wu[2], Nelson Liu[3], Jayne Marshall[4], Cindy Lu[3]

[1]AstraZeneca, Mississauga, ON, Canada,[2]Case Western Reserve University, Cleveland, OH,[3]AstraZeneca, Waltham, MA,[4]AstraZeneca, Cambridge, United Kingdom

Introduction: Project Optimus encourages early identification of the Optimal Biological Dose (OBD) by balancing efficacy and safety, moving beyond the maximum tolerated dose paradigm. For programs spanning multiple indications, a key challenge is that the OBD may differ by indication. We propose a basket trial strategy that formally borrows information across indications to improve dose selection efficiency, aiming to reduce per_indication sample size and time to decision while maintaining robust inference when OBDs are heterogeneous.
Methods: We assume a basket trial design to address dose optimization up front within a single trial rather than multiple separate cohorts. We apply a utility based, three outcome decision rule (recommend low dose, consider, or high dose) integrating efficacy-toxicity tradeoffs. We compare three strategies: fully exchangeable Bayesian hierarchical modeling (BHM-EX) that borrows across all indications, latent cluster hierarchical modeling (BHM-LC) that borrows within data driven clusters, and no borrowing (NB) analyzing indications independently. We evaluate operating characteristics and sample size efficiency via simulations across varying sample sizes and true OBD heterogeneity.
Results: When indications share the same true OBD, borrowing improves correct dose selection and enables fewer patients per indication to reach decisions; BHM-EX performs best, particularly under uneven enrollment. NB shows higher misselection risk with small samples. When true OBDs differ, BHM-EX underperforms due to full pooling, whereas BHM-LC is more robust, maintaining improved accuracy without overborrowing.
Conclusions: Bayesian borrowing in basket trials can reduce sample size while maintaining the same probability of correct OBD selection and time to decision, especially when indications share OBDs or have imbalanced enrollment. Clinical, preclinical, and clinical pharmacology insights should guide assumptions about similarity across indications and the choice of borrowing strategy, with prespecified sensitivity analyses to support regulatory confidence.

#6436 Carmel Awadallah , MD.

Carmel Awadallah[1], Myer Marc Warshawsky[2]

[1]St. John's Episcopal Hospital, Far Rockaway, NY,[2]Hematology and Oncology, St. John's Episcopal Hospital, Far Rockaway, NY

Background: Pancreatic ductal adenocarcinoma (PDAC) remains one of the most lethal malignancies despite adjuvant chemotherapy. Immunotherapy has transformed adjuvant therapy in other solid tumors, yet its role in PDAC is undefined. We aimed to characterize the landscape of adjuvant systemic trials in resected PDAC, with a focus on immunotherapy, to identify progress and barriers to clinical impact.
Methods: We queried ClinicalTrials.gov for interventional phase 2-3 adjuvant trials in resected PDAC registered between January 2000 and January 2025. Trials were categorized as immunotherapy, targeted therapy, other novel systemic strategies, or traditional chemotherapy. Phase, enrollment, sponsor type, and endpoints were extracted and summarized descriptively.
Results: Thirty-six eligible trials were identified. Most were phase 2 (n=27, 75%), with only two phase 3 studies (6%). Enrollment was modest: 27 trials (75%) included fewer than 50 patients, while only three (8%) enrolled ≥200. Overall survival was the most common endpoint (n=35, 97%), followed by safety/toxicity (n=23, 64%) and disease-free survival (n=10, 28%); surgical endpoints were rare, including R0 resection (n=6, 17%) and pathologic complete response (n=2, 6%). Sponsorship was predominantly academic (n=28, 78%), with limited industry-led (n=3, 8%) or mixed (n=5, 14%) involvement. Immunotherapy approaches were mainly vaccines (GVAX, TG-01, ELI-002) and immune modulators, with only one small trial testing a checkpoint inhibitor (CT-011).
Conclusions: Over two decades, adjuvant immunotherapy in PDAC has not advanced beyond small, exploratory studies. Trials were underpowered, academic-led, and focused largely on vaccine-based strategies, with minimal checkpoint inhibitor evaluation and no definitive phase 3 programs. Adequately powered, industry-supported phase 3 trials are urgently needed to establish effective adjuvant immunotherapy strategies in resected PDAC.

#6437 Comparative efficacy of adjuvant CDK4/6 inhibitors in early breast cancer: A hazard ratio-based network meta-analysis using the NetMetaEasy platform.

Janos Tibor Fekete, **Balazs Gyorffy**

Semmelweis University, Budapest, Hungary

BACKGROUND: Adjuvant CDK4/6 inhibitors have shown variable results across phase III trials in hormone receptor-positive, HER2-negative early breast cancer, and no direct comparisons exist to clarify their relative efficacy. Network meta-analysis (NMA) enables the integration of direct and indirect evidence to compare multiple treatments simultaneously. In this study we applied a hazard ratio-based NMA to evaluate the comparative effectiveness of abemaciclib, ribociclib, and palbociclib using invasive disease-free survival (iDFS) as the primary endpoint. Endocrine therapy (ET) served as the standard-of-care reference across trials.

METHODS: Data from four randomized phase III trials (case n=17,741) were analyzed. Treatment nodes included abemaciclib+endocrine therapy (ET), ribociclib+ET, palbociclib+ET, and ET alone. Analyses were performed using the NetMetaEasy platform (https://www.metaanalysisonline.com/netmetaeasy), an R/Shiny-based implementation supporting binary, continuous, and summary-effect inputs. A frequentist random-effects NMA was conducted using the inverse-variance method with the DerSimonian-Laird estimator for between-study variance (τ^2). Standard NMA outputs were generated, including forest plots, network geometry, treatment ranking (P-scores), inconsistency assessments, and funnel plots.

RESULTS: Ribociclib+ET showed the strongest effect versus ET (HR 0.72; 95% CI 0.62-0.83). Abemaciclib+ET also improved iDFS (HR 0.73; 95% CI 0.66-0.82). Palbociclib+ET did not differ significantly from ET (HR 0.89; 95% CI 0.79-1.00). Indirect comparisons yielded HR 0.82 (95% CI 0.70-0.97) for abemaciclib versus palbociclib, HR 1.25 (95% CI 1.03-1.50) for palbociclib versus ribociclib, and HR 1.03 (95% CI 0.85-1.23) for abemaciclib versus ribociclib. P-scores ranked ribociclib+ET highest (0.86), followed by abemaciclib+ET (0.80) and palbociclib+ET (0.33). Funnel-plot inspection did not indicate small-study effects.

CONCLUSIONS: In this hazard ratio-based NMA, abemaciclib and ribociclib significantly improved iDFS compared with endocrine therapy, whereas palbociclib did not. Our findings illustrate the utility of NMA for comparative evaluation in the absence of head-to-head trials.

#6438 Unfinished stories: Consequences of melanoma clinical trial discontinuation and non-publication.

Hadeer Hafez[1], Abdelrahman Hagag[1], Mohamed Ashraf Mohamed[2], Mohamed Saad Rakab[3], Ismail Zakaria Ismail[4], Aya Jamal Elkenani[5], Nada Elmetwally Ahmed[1], Abdelrahman M. Hafez[6], Doaa Mashaly[1], Ali Tarek Lasheen[2], Mohamed Abdelsalam[1]

[1]October 6 University, Faculty of Medicine, Giza, Egypt,[2]Misr University for Science and Technology, Faculty of Medicine, Giza, Egypt,[3]Faculty of Medicine, Mansoura University, Giza, Egypt,[4]Faculty of medicine, Misr University for Science and Technology, Giza, Egypt,[5]Faculty of Medicine, Mansoura University, Mansoura, Egypt,[6]Faculty of Medecine, Damietta University, Damietta, Egypt, Damietta, Egypt

Background: Melanoma is a major cause of skin cancer-related death, and clinical trials are essential for advancing melanoma treatment options. However, many trials either are terminated prematurely or are never published, eaving critical data unreported. These “unfinished stories”, hinder scientific progress, waste resources, and limit informed clinical decision-making. Therefore, understanding how many and what factors predict unpublished or discontinued melanoma trials is key to improving the transparency of research and advancing best care for patients.
Objective: To identify the extent, characteristics, and variables related to Discontinuation and Non-Publication melanoma clinical investigations.
Methods: We systematically searched ClinicalTrials.gov for Melanoma studies up to March 1, 2025. Studies completed within the past 24 months were excluded to account for potential delays in the peer review process. Publication status was identified using NCT numbers. Data on participant gender, age, study design, funding source, type of intervention, sample size, and trial location were collected and analyzed. Multiple logistic regression was used to identify factors associated with trial discontinuation or non-publication. All statistical analyses were conducted using Jamovi version 2.6.24.
Results: In total, there were 2,144 trials, with 712 (33.2%) published, 1,215 (56.7%) non-published, and 217 (10.1%) unknown. Of the discontinued trials (516, 24.1%), just 59 (11.4%) were published. Non-publication status was noted to be significant among trials of genetic interventions (OR = 0.104, 95% CI: 0.027-0.401, p=0.001), procedural interventions (OR = 0.262, 95% CI: 0.121-0.567, p<0.001), and in a multicenter trial (OR = 0.185, 95% CI: 0.123-0.278, p<0.001). Also, a study was considerably more probable to be discontinuation if smaller-sized (≤500 participants, p<0.001) or earlier (Phase 1/2, p<0.001).
Conclusions: The high frequency of Discontinuation and Non-Publication trials record highlights the importance of efforts toward completing and/or fully publication melanoma clinical investigations, particularly those for genetic and/or procedural treatments and/or smaller trials.

#6439 Growth rate of fastest-growing lesion predicts survival better than growth rate of RECIST 1.1 sum of diameters: A real-world retrospective study of 84 NSCLC patients over multiple treatment lines.

Dean C. Bottino[1], Jayant Narang[2], Michael Hanley[1], Maria Guzman Castillo[3], Heidi Loponen[3], Risto Kesavuori[4], Juha Mehtala[3], Mark Lin[1]

[1]Takeda Development Centers America, Cambridge, MA,[2]Imaging, Takeda Development Centers America, Cambridge, MA,[3]MedEngine Oy, Helsinki, Finland,[4]University of Helsinki, Helsinki, Finland

Background: Sum of Diameters (SoD) of up to 5 target lesions is the continuous metric used for Response Evaluation Criteria In Solid Tumors (RECIST) classifications. As demonstrated in many studies, RECIST based outcomes such as progression free survival and response rate do not always correlate well with overall survival, warranting the need to explore alternative ways of assessing response, particularly in the setting of novel therapies. Many studies have correlated SoD rates of change to overall survival (OS) in solid tumor indications such as non-small cell lung cancer (NSCLC). To test the hypothesis that a patient's survival could be influenced more strongly by their most poorly responding or quickly progressing lesion, we compared the ability of SoD growth rate and the growth rate of the fastest growing target lesion to predict OS.

Methods: CT scans from 84 adult (18+) stage III/IV NSCLC patients with varying baseline mutation status (N=19 non-Exon-20 EGFR mutation, 15 ALK rearrangements, 5 other mutations, 44 No driver mutation), treated in Finland in secondary care setting were analyzed by a radiologist to identify and track the diameters of up to 5 target lesions in each patient. Lesion diameters from the last two CT scans of each treatment line (representing 224 distinct patient-lines of treatment: 78 1st Line, 63 2nd Line, 99 3rd -6th Line, 4 unknown) were analyzed in two ways: EGRmax = max of the (signed) exponential growth rates (EGR) of target lesions; EGRSoD = EGR of SoD of target lesions. EGRmax and EGRSoD values were then clustered into three categories: low (L), medium (M) and high (H). Kaplan-Meier (KM) and Cox Proportional Hazards (CPH) analyses were then performed to determine the correlation of EGRmax or EGRSoD categories to OS.

Results: Clustering analysis (independent of OS) resulted in EGRmax cutoffs of 0.06/month between L and M and 0.25/month between M and H (resulting in N=137/75/12 patient-lines in L/M/H categories), and EGRSoD cutoffs of -0.015/month between L and M and 0.095/month between M and H (resulting in N=46/151/27 patient-lines in L/M/H). Directionally, the KM analysis was as expected, with higher EGRs correlating with lower OS. However, KM analysis revealed consistent separation between L, M, and H categories for EGRmax (median OS of 33, 17.8 and 15.4 months respectively), while the KM curves for EGRSoD were overlapping for L and M and only separated for H (median OS of 19.5, 27.7, and 17 months respectively). Accordingly, CPH analysis indicated a spread of statistically significant hazard ratios (HRs) for EGRmax (HR = 1.97 for M/L and 3.28 for H/L), while only significant differences between H and L for EGRSoD (HR = 0.98 for M/L and 1.99 for H/L).

Conclusions: In this population of NSCLC patients across several treatment lines, EGRmax appears to be a better predictor of OS than RECIST-based EGRSoD.

#6440 Effects of cumulative tobacco exposure on lung cancer genomic profiles in Latin Americans.

Javiera Garrido[1], Evelin Gonzalez[2], Alejandro Blanco[2], Gonzalo Sepulveda-Hermosilla[2], Matias Freire[3], Solange Rivas[2], Katherine Marcelain[4], Gareth I. Owen[5], Carolina Ibañez[6], Alejandro H. C. Camargo Cancer Center, Sao Paulo, Brazil

Motivation: Tobacco exposure is a major determinant of tumor genomic landscapes in non-small cell lung cancer (NSCLC). Two of the most clinically relevant actionable genes in lung cancer, EGFR and KRAS, show opposite patterns, with smokers exhibiting a higher prevalence of alterations in KRAS and never-smokers in EGFR. Yet, the dynamic and evolution of genomic changes as a function of cumulative tobacco exposure has received limited attention. Here, we examine how tumor genomic profiles vary according to smoking intensity, duration, and time since cessation (TSC). Our study focuses on an underrepresented population of Latin American patients, where additional research is needed to better characterize tumor heterogeneity.

Methodology: The population was obtained from the protocol *Characterization and Validation of Molecular Diagnostic Technologies for Lung Cancer Patients from Chile, Brazil, and Peru*. Participant recruitment was between July 2015 and October 2018 across 37 different centers. Primary or metastatic NSCLC specimens were analyzed, and genomic profiles were generated with the Oncomine Focus Assay (OFA). A total of 1,864 participants yielded QC-approved genomic profiles. Covariates of interest were assessed at enrollment. Cumulative tobacco exposure, including smoking intensity (cigarettes per day), duration, and TSC, was quantified using the Comprehensive Smoking Index (CSI). In addition, smoking status (current vs. never) was recoded as a function of TSC in order to identify the time period during which major genomic alterations (GA) are most likely to occur. Descriptive statistics, generalized linear models, and generalized additive models were used to evaluate the association between CSI and the prevalence of GA across genes. All models were adjusted for potential confounders, including country, age, sex, NSCLC subtype, cancer stage and history of cancer.

Results and Conclusions: A total of 1100 patients had complete genomic and tobacco exposure information. Among current smokers, median smoking intensity and duration were 20 cigarettes per day and 48 years, respectively, compared with 30 cigarettes per day and 47 years among former smokers. Ninety percent of former smokers had ceased tobacco use at least 10 years prior to diagnosis, with a median TSC of 1 year. CSI analysis identified 14 genes significantly associated with genomic alteration status, including EGFR, PIK3CA, ALK, MTOR, ERBB3, and RET. Higher CSI values (4th quartile) showed approximately double the frequency of genomic alterations compared with the lowest CSI quartile for ALK (16.2% vs. 8.7%), RET (12.8% vs. 6.9%), and MTOR (15% vs. 6.9%). Mid-range CSI values exhibited the lowest prevalence of alterations in EGFR (12.6% vs. 31%) and PIK3CA (6.9% vs. 14.5%). Overall, these findings support the value of CSI in refining exposure-genotype associations and the need for improves risk stratification efforts in diverse populations.

#6441 Safety profile of post-CDK4/6 treatments in HR+/HER2– metastatic breast cancer (mBC): A network meta-analysis.

Martina Pagliuca[1], Roberto Buonaiuto[1], Michelino De Laurentiis[2], Carmine De Angelis[1]

[1]Scuola Superiore Meridionale, Napoli, Italy,[2]Istituto Nazionale Tumori IRCCS "Fondazione G.Pascale", Napoli, Italy

Several treatments (tx) are available for HR+/HER2- mBC; however, choosing subsequent tx after progression on first-line CDK4/6 inhibitor + endocrine therapy (ET) remains challenging. Assessing the safety profiles of these options is crucial for guiding tx selection. We performed a network meta-analysis (NMA) to compare the safety of systemic tx approved for this setting. Tx strategies were retrieved through a systematic review of randomized phase II-III trials published from January 2014 to October 2025 (PROSPERO CRD420251234039) and only FDA- and/or EMA-approved tx were included. Each tx was compared with standard ET or chemotherapy (CT). A frequentist random-effects NMA was performed using the netmeta package in R. Risk ratios (RRs) for safety outcomes (grade[G] ≥3 adverse events [AEs], any grade AEs, and AEs leading to discontinuation) were calculated from each trial using pairwise comparisons and pooled using a random-effects model estimated by restricted maximum likelihood. Results were shown as forest plots with 95% confidence intervals (CI), and tx ranked based on P-scores. The NMA included 16 trials. Among ET-based strategies, the lowest RRs were observed for: imlunestrant alone (0.98, 95% CI 0.92-1.05) for any G AEs; camizestrant 75 mg (0.81, 0.36-1.83) for G≥3 AEs; elacestrant (1.45, 0.66-3.16) for AEs leading to discontinuation. While among antibody-drug conjugates (ADCs) the lowest RRs were observed for: sacituzumab govitecan (SG) for any G AEs (1.00, 0.99-1.01); datopotamab deruxtecan (Dato-DXd) (0.47, 0.37-0.59) for G≥3 AEs; SG (0.83, 0.26-2.66) for AEs leading to discontinuation. The estimated RRs and P-scores are shown in table. Among ET-based options, novel mono-ETs (oral SERDs and PROTACs) showed the lowest risk of discontinuation and G≥3 AEs. Among ADCs, TROP2-directed agents had fewer discontinuations, while ADCs with DXd as a payload showed higher rates of any G AEs but (except for DESTINY-Breast06) lower G≥3 AEs risk than other tx strategies.

Trial	Treatment strategy	Control arm	RR (95% CI) any grade AEs	P-score any grade AEs	RR (95% CI) G≥3 AEs	P-score G≥3 AEs	RR (95% CI) AEs leading to discontinuation	P-score AEs leading to discontinuation

#6442 Persistent elevation of plasma Neuropilin-1, a tumorigenic protein, during the first month after minimally invasive colorectal cancer resection.

Chandana S. K. Herath Mudiyanselage[1], Yi-Ru Chen[2], Neil Mitra[2], Monica S. Naparst[2], Elizabeth Nilsson Sjolander[2], Vesna Cekic[3], Richard L. Whelan[2]

[1]Surgery, Northwell Health, Lenox Hill Hospital, New York, NY,[2]Department Surgery, Northwell Health, Lenox Hill Hospital, New York, NY,[3]Department Surgery, Northwell Health, Lenox Hill Hospital, Ney York, NY

Introduction: Neuropilin-1 (NRP1), also known as CD304, is a transmembrane glycoprotein that functions as a co-receptor for VEGF, PLGF, TGF-B1 and other ligands. NRP1 is expressed in various tissues and in endothelial cells (EC), tumor and immune cells. NRP1 upregulation is closely associated with enhanced angiogenesis in tumors and can promote EC proliferation, migration, and neovascularization. NRP-1 also plays a role in the tumor microenvironment by stabilizing regulatory T cells, which suppress the immune response. NRP1 is overexpressed in various tumors including colorectal cancer (CRC) and elevated plasma levels are linked to tumor progression, higher tumor grades, and poor clinical outcomes. NRP-1 also plays a role in the tumor microenvironment by stabilizing regulatory T cells,that suppress the immune ability. NRP1 regulates VEGF-driven wound angiogenesis, with peak vascular growth followed by regression that restores normal capillary density. Surgery's impact on blood levels of NRP1 levels is poorly studied. This study's purpose was to measure plasma NRP1 levels before and during the first month after minimally invasive colorectal resection (MICR) for CRC.

Method: This study included CRC patients from an IRB-approved data/plasma bank who underwent MICR for whom sufficient plasma samples were available. Clinical data were reviewed, and blood was collected preoperatively (preop) and at defined postoperative (postop) intervals. Plasma was stored at -80°C and late samples were grouped into 7-day bundles intervals. NRP1 levels were measured in duplicate using ELISA (ng/ml) and reported as mean± SD mean ± SD. The paired t-test was used for statistical analysis (significance $p<0.05$).

Results: Preop and 1 or more late postop plasma sample were available for 92 MICR patients (colon 71%; rectal 29%; 47 male /45 female, mean age 64.3± 14.1years). The mean incision length was 8.3± 3.6 cm and mean length of stay was 6.8 ± 4.2 days. The final cancer stage breakdown was; Stage I, 30%, Stage II, 30%, stage III, 35% and stage IV, 5%. The mean Preop NRP1 level was 296.0± 68.8 ng/m; in comparison, mean postop levels were significantly elevated ($p<0.0001$) on postop day (POD) 3 (384.3±96.6, n=88), POD7-13 (405.4±111.9, n=73), and POD14-20 (380.4±101.7, n=28) , POD 21-27(346.8±87.9, n=16,p-0.01) and on POD 28-41 (342.8± 84.3, n=18; $p<0.001$).

Conclusion: Following MICR for CRC, plasma NRP1 levels were significantly increased from POD3 through POD 28-41. The rise in NRP1 levels may reflect enhanced shedding from EC and circulating tumor cells, potentially driven by angiogenesis related processes associated with wound repair and regeneration. Surgery-induced inflammatory signaling likely contributes to increased NRP1 expression and release. Elevated levels of NRP1 may promote angiogenesis in residual tumor deposits after surgery. Further investigation is warranted.

#6444 Prognostic impact of ctDNA status and multi-site disease burden for patients with peritoneal metastases from appendiceal or colorectal cancer.

Justin M. Bader[1], Kelsey LaBella[1], Nicole Aguirre[1], Kwasi Ofori[1], Princy Gupta[1], Anup Sharma[2], Huxley Smart[1], Alexander Kim[1], Robert Tseng[1], SANGWON YUN[1], Michael Cecchini[2], Raghav Sundar[2], Kiran Turaga[1]

[1]Yale New Haven Hospital, New Haven, CT,[2]Yale School of Medicine, New Haven, CT

Purpose: Circulating tumor DNA (ctDNA) is prognostic for patients with metastatic appendiceal and colorectal cancer (CRC), however, its impact on therapy considerations and surgical candidacy is unclear. Current randomized trials are exploring approaches to locoregional therapy for management of multi-site oligometastatic disease. We investigate the role of ctDNA-guided locoregional therapies in the management of peritoneal metastases (PM) with or without multi-site disease.

Methods: The study cohort included high-grade appendiceal or CRC patients with single site (peritoneum) or multi-site metastases (peritoneum plus liver, lung, or distant lymph node involvement) who had curative intent surgical interventions for PM between 2023-2025. ctDNA testing was performed in the pre- and post-operative setting. Univariate and multivariate analysis of demographics, pathological, and ctDNA dynamics were performed. Overall survival (OS) was analyzed using Kaplan-Meier (KM) curves to evaluate prognostic impact of ctDNA status and presence of multi-site disease.

Results: Of the 61 patients in the study, 67% (n=41) had CRC and 33% (n=20) had high-grade appendiceal cancer. Median postoperative follow up was 18 months with 82% of patients alive at last follow up. Prior to surgery, 33% (n=17) of patients were ctDNA positive with 13% clearing their ctDNA postoperatively initially. However, none of these patients maintained durable negative ctDNA as all converted back to ctDNA positive within 6 months. Of those with negative ctDNA preoperatively, 32% converted to ctDNA positive postoperatively - including 91% converting to positive within 1 year. Patients with ctDNA negative status preoperatively had KM-estimated 2-year OS of 91.2%.

History of multi-site disease was present in 39% (n=24) of patients at time of surgery including 50% (n=12) with active multi-site disease and 50% (n=12) with previously treated disease. KM-estimated 2-year OS was excellent for ctDNA negative patients regardless of multi-site disease involvement (2-year OS = 83.3%) or peritoneal-only metastases (2-year OS = 95.6%).

Conclusion: This study analyzed the prognostic impact of ctDNA status and multi-site disease for patients with PM from CRC or appendiceal cancer who underwent locoregional therapy. ctDNA appears to be prognostic in patients undergoing curative intent surgical resection for peritoneal metastases. Furthermore, patients with multi-site disease who have negative ctDNA and undergo surgery for peritoneal metastases appear to have survival comparable to patients with peritoneal only metastases. With variable approaches and conflicting guidelines for the management of patients with PM and oligometastatic disease, ctDNA could augment treatment selection, surgical eligibility, and clinical trial enrollment.

#6445 Clinical benefits of perioperative chemotherapy for patients with stage I-II large cell lung cancer: A SEER database analysis.

Wongi Woo[1], Seoin Kim[2], Jongwoo Kim[2], Yoonjin Cha[3], Duk Hwan Moon[4], Sungsoo Lee[4], Young Kwang Chae[5]

[1]St Joseph's Medical Center Stockton, Stockton, CA,[2]Metrowest Medical Center, Framingham, MA,[3]Yonsei University College of Medicine, Seoul, Korea, Republic of,[4]Gangnam Severance Hospital, Seoul, Korea, Republic of,[5]Northwestern Univ. Feinberg School of Medicine, Chicago, IL

Background: Large cell lung cancer (LCLC), a neuroendocrine subtype of non-small cell lung cancer, remains an aggressive malignancy with limited therapeutic options. Even early-stage disease shows high recurrence rates and suboptimal survival after resection. Evidence guiding the role of perioperative chemotherapy (CTx) in stage I-II LCLC is limited. This study evaluated the association between perioperative CTx and survival outcomes in surgically resected LCLC using a nationally representative dataset.

Methods: Patients with stage I-II LCLC diagnosed between 2000-2021 were identified from the Surveillance, Epidemiology, and End Results Program (SEER) 17 registries. Inclusion criteria were pathologically confirmed LCLC, surgical resection, and American Joint Committee on Cancer (AJCC) 7th/8th edition staging. Demographic, clinicopathologic, and socioeconomic variables were collected. Overall survival (OS) and cancer-specific survival (CSS) were compared between surgery alone and surgery plus perioperative CTx using Kaplan-Meier analysis. Multivariable Cox regression was performed to identify independent predictors of CSS among stage II LCLC.

Results: A total of 1,894 patients met inclusion criteria, including 489 who received neoadjuvant and/or adjuvant CTx . Patients receiving neoadjuvant and/or adjuvant CTx were younger (median 65 vs. 70 years, $p<0.001$), had more advanced T and N stages, and more frequently had advanced stages ($p<0.001$). Socioeconomic factors were not significantly different between groups. Perioperative CTx was significantly associated with improved CSS (Hazard ratio (HR) 0.71, 95% confidence interval (CI) 0.60-0.85, $p<0.001$) and OS (HR 0.67, 95% CI 0.58-0.78, $p<0.001$) with a more pronounced benefit among patients with nodal involvement. On multivariable analysis among stage II LCLC, perioperative CTx independently predicted better CSS (HR 0.79, 95% CI 0.57-0.86, $p<0.001$); age over 75 (HR 1.76), male sex (HR 1.26), and N1 nodal status (HR 2.10) were also associated with higher mortality.

Conclusions: In this large SEER cohort, neoadjuvant and/or adjuvant chemotherapy was associated with significantly improved cancer-specific survival in patients with resected stage I-II LCLC, with the greatest benefit observed among patients with nodal disease. Although information on surgical extent and mediastinal lymph node dissection was limited, these findings support consideration of perioperative CTx for early-stage LCLC and underscore the need for prospective studies to define optimal treatment strategies.

#6446 Molecular profiling to predict the first site of recurrence in pancreatic cancer patients receiving neoadjuvant therapy followed by surgery.

Luigi Liguori[1], Marco Ventin[1], Liti Zhang[1], Erica Daniels[1], Giulia Cattaneo[1], Chiara Camillo[1], Maoyang Qi[1], Enrica Quattrocchi[1], Eduardo Tejeda-polanco[1], Arsen Osipov[1], Alexandra Gangi[1], Andrew Hendifar[1], Nicholas Nissen[1], Kambiz Kosari[1], Francesco Sabbatino[2], Cristina R. Ferrone[1]

[1]Cedars Sinai Medical Center, Los Angeles, CA,[2]University of Salerno, Baronissi, Italy

Pancreatic ductal adenocarcinoma (PDAC) remains one of the most lethal cancers, with a five-year survival rate of only 13%. Although neoadjuvant chemotherapy and radiotherapy have improved resectability and survival outcomes, most patients ultimately experience disease recurrence. Identifying biomarkers that can stratify recurrence patterns is therefore critical for optimizing patient selection and tailoring postoperative management. We retrospectively analyzed data from PDAC patients who underwent neoadjuvant therapy followed by surgery at Cedars Sinai Medical Center between May 2013 and November 2024. Uni- and multivariable binary logistic regression including clinicopathologic variables and NGS-based molecular features was used to predict the first site of recurrence. Among 244 patients receiving neoadjuvant therapy for PDAC, 138 had complete clinicopathologic and NGS-based molecular data. Most common mutated genes included *TP53* (69.6%), $KRAS^{G12D}$ (43.5%), $KRAS^{G12V}$ (31.2%), *CDKN2A* (24.6%), *SMAD4* (20.3%), $KRAS^{G12R}$ (12.3%), *CDKN2B* (10.1%), $KRAS^{Q61X}$ (7.2%), *ATM* (5.1%), and *BRCA2* (4.3%). First-site recurrence patterns were locoregional (25.5%), liver (32.6%), lung (21.0%), peritoneum (14.5%), and bone (7.2%). Molecular features independently and significantly predicted the first site of recurrence. Specifically, $KRAS^{Q61X}$ mutation was associated with increased risk of locoregional recurrence (OR, 5.6, 95% CI 1.4-22.4, p=0.01), CDKN2B mutations with liver recurrence (OR, 4.4, 95% CI 1.2-16.2, p=0.02), ATM mutations with both lung (OR, 7.7, 95% CI 1.3-44.9, p=0.02) and peritoneal recurrence (OR, 5.0, 95% CI 1.0-24.4, p=0.04), and BRCA2 mutations with bone recurrence (OR, 7.7, 95% CI 1.2-48.9, p=0.03). Our study demonstrates that molecular profiling can predict the first site of recurrence in PDAC patients who have undergone neoadjuvant therapy followed by surgery. While prospective validation in larger cohorts is warranted, this work provides a foundation for developing risk-adapted postoperative surveillance strategies in PDAC.

#6447 FOLFIRINOX plus nivolumab promotes plasma cell production from intra-tumoral lymphoid aggregates in borderline resectable pancreatic adenocarcinoma.

Serena Zheng[1], Jason Link[1], Alykhan Premji[1], Michael Srienc[1], McKensie Hammons[2], Shineui Kim[2], David Dawson[3], Zev Wainberg[4], Timothy Donahue[1]

[1]Surgery, UCLA Medical Center, Los Angeles, CA,[2]UCLA David Geffen School of Medicine, Los Angeles, CA,[3]Pathology, UCLA Medical Center, Los Angeles, CA,[4]Medicine, UCLA Medical Center, Los Angeles, CA

Background: Combination chemotherapy and immune checkpoint inhibitors have shown limited benefit in pancreatic ductal adenocarcinoma (PDAC) despite their success in other solid tumors. However, most studies were conducted in advanced disease. In a phase 1b/2 investigator-initiated clinical trial, we evaluated immunologic effects of neoadjuvant FOLFIRINOX (FFX) plus nivolumab (nivo) in patients with borderline-resectable (BR) PDAC.

Methods: Resected tumor tissue was analyzed by bulk RNA sequencing with CIBERSORT leukocyte deconvolution, immunohistochemical (IHC) quantification of plasma cells and characterization of lymphoid aggregates (LAs), and 10x Xenium spatial transcriptomics (ST) to investigate LA organization. In parallel, tumor draining lymph node (TDLN) cores from untreated, FFX-only, and FFX+nivo cohorts were profiled with Xenium ST.

Results: Across paired pre- and post-treatment samples, intra-tumoral CD8 T cells and plasma cells increased concurrently. Compared with historical FFX controls, nivo-treated tumors had significantly higher plasma cell abundance ($p=0.002$) and a modest CD8 T cell increase ($p=0.037$). IHC revealed that plasma cell abundance correlated with dense intra-tumoral LAs lacking germinal center-like structures ($p<0.001$), consistent with extrafollicular B cell differentiation. ST identified irregular LAs within the tumor bed with high plasma cell to B cell ratios (PBRs) enriched for terminally exhausted CD8 T cells and de-enriched for progenitor exhausted CD8 T cells and central memory CD4 T cells. In TDLN follicles from nivo-treated patients compared to historical FFX controls, plasma cells were again enriched ($p=0.049$), and PBR was significantly higher ($p=0.035$). However, CD8 T cell and memory B cell density decreased within the lymph node follicles ($p<0.001$ and $p=0.005$, respectively). T follicular helper (Tfh) cells provide a critical link between antigen-specific B cells and CD8 T cells; accordingly, IL-21 expression was de-enriched in TDLN Tfh cells from patients treated FFX+nivo compare to FFX alone ($p<0.0001$).

Conclusion: Neoadjuvant FFX plus nivo in BR PDAC is associated with disorganized intra-tumoral LAs, extrafollicular-like plasma cell differentiation, and accumulation of terminally exhausted CD8 T cells within the tumor bed. TDLN follicles in nivo-treated patients also showed plasma cell-skewed, high-PBR architecture, but with reduced CD8 T cell and memory B cell density and selective loss of IL-21 expression in Tfh cells. These features may represent barriers to effective anti-PD-1-based chemoimmunotherapy in PDAC.

#6448 The obesity paradox in pancreatic cancer.

Jacob Lambdin[1], Charlotte Burch[1], William Royster[1], Adam Khader[2], Leopoldo Fernandez[1], Raphael Louie[1], Ricardo Bello[1], Jose G. Trevino[3]

[1]VCU Massey Comprehensive Cancer Center, Richmond, VA,[2]U.S. Department of Veterans Affairs, Richmond, VA,[3]Div. of Surgical Oncology, VCU Massey Cancer Center, Richmond, VA

Introduction: The “obesity paradox,” in which higher body mass index (BMI) appears to confer a survival advantage despite its role in carcinogenesis, has been reported in several solid tumors, but its relevance across racial groups in patients with pancreatic cancer is unclear. We performed a retrospective database study using TriNetx, a multinational deidentified dataset, to identify patients with pancreatic cancer and to examine associations between BMI, race/ethnicity, survival, and post operative complications.

Methods: Using the TriNetx database, we identified patients with pancreatic cancer and stratified the cohort by BMI at time of diagnosis: underweight (UW) (BMI < 18.5 kg/m²), healthy weight (HW) (18.5-24.9 kg/m²), and overweight (OW) (≥25.0 kg/m²). Subgroups were created of Black, Hispanic, and White patients within each BMI cohort to evaluate for racial/ethnic differences in BMI associated outcomes. The primary outcome was overall survival with secondary outcomes of post-operative complications. Propensity score matching was performed for age, sex, stage, comorbidities, and type of surgical resection performed. Kaplan-Meier curves and multivariable Cox models were used to evaluate survival across BMI categories overall and within racial strata. Multivariable logistic regression was used to evaluate associations between BMI category and postoperative complications.

Results: We identified 247,150 patients with pancreatic cancer, including 51,057 (87%) OW, 3241 (6%) HW, and 3815 (7%) UW patients. In propensity matched models, BMI category was found to be associated with overall survival. Compared with HW, OW was associated with a longer 5-year median survival (895 vs 493) and reduced hazard of death (HR = 0.76, 95% CI (0.70-0.82)), while UW was associated with worse survival than HW (HR = 1.24, 95% CI 0.74-0.87)). The magnitude and direction of these associations differed by race/ethnicity with OW Black (HR = 0.69, 95% CI (0.59-0.85)) and OW Hispanic patients (HR = 0.88, 95% CI (0.62-1.25)) deriving more substantial survival benefit over HW when compared to their OW White counterparts (HR = 0.80, 95% CI (0.73-0.86)). Among propensity matched surgical patients, OW was associated with increased risk intraabdominal abscess (10.2% vs 5.1%, RR = 2, p = 0.02), and increased odds of AKI (19.7% vs 12.9%, RR = 1.53, p = 0.026) compared with HW individuals. No significant difference in postoperative pancreatic leak was identified between the OW and HW cohorts. (11.5% vs 11.8%, RR = 0.97, p = 0.89).

Conclusions: In this large, real-world cohort of patients with pancreatic cancer, BMI and race were significant determinants of survival and postoperative morbidity, with patterns consistent with an obesity paradox. These data may refine risk stratification and motivate studies of adiposity and pancreatic cancer biology across diverse populations.

#6449 Adenosine blockade combined with FOLFIRINOX chemotherapy enhances T follicular helper cell function in pancreatic adenocarcinoma draining lymph nodes from mice and humans.

Michael K. Srienc[1], Serena Zheng[1], Jason Link[2], Alykhan Premji[1], McKensie Hammons[3], Shineui Kim[3], Evan Abt[1], Caius G. Radu[3], David W. Dawson[1], Zev A. Wainberg[4], Timothy R. Donahue[5]

[1]UCLA Health, Los Angeles, CA,[2]UCLA Dept of Surgery, Los Angeles, CA,[3]UCLA David Geffen School of Medicine, Los Angeles, CA,[4]UCLA Medical Center Santa Monica, Santa Monica, CA,[5]Assistant Professor, Dept. of General Surg., UCLA David Geffen School of Medicine, Los Angeles, CA

Over 90% of all pancreatic cancer cases are pancreatic ductal adenocarcinoma (PDAC), an aggressive disease with poor prognosis and limited treatment options. Chemotherapy and immunotherapy efficacy are both limited by the immunosuppressive PDAC tumor microenvironment (TME). Treatment-related tumor cell death leads to accumulation of extracellular adenosine, a potent immunosuppressive metabolite in the PDAC TME; accordingly, we investigated the effects of blocking adenosine during chemotherapy treatment. In an orthotopic murine model of PDAC, CD73 - the primary enzyme responsible for extracellular adenosine - inhibition in combination with FOLFIRINOX reduced tumor size by 57% (P=0.04) and significantly increased survival compared to treatment with FOLFIRINOX alone. FOLFIRINOX+CD73i significantly decreased suppressive SPP1+ tumor-associated macrophages, increased Type I and Type II interferon signaling of multiple cell types in the TME, and was CD4+ and CD8+ T cell dependent. To track antigen-specific CD4+ T cells, we engineered expression of an MHC-II restricted epitope in orthotopically implanted tumor cells and found that FOLFIRINOX+CD73i treatment increased follicular helper T (Tfh) cells in tumor-draining lymph nodes but that these cells were not enriched for tetramer-positive, tumor antigen-specific cells. In contrast, Treg cells in the TME were enriched for tetramer-positive cells suggesting that CD73i may drive antigen-reactive T cells toward a suppressor phenotype. Targeting activated T cells by adding anti-CCR8 to FOLFIRINOX+CD73i significantly decreased tumor masses compared to FOLFIRINOX+CD73i alone (P=0.02).
To investigate the effect of CD73i on adaptive immune responses in PDAC patients, we performed Xenium image-based spatial transcriptomics on 53 tumor-draining lymph nodes from patients treated with neoadjuvant FOLFIRINOX+anti-PD-1+CD73i, FOLFIRINOX+anti-PD-1, FOLFIRINOX alone, or untreated. In line with our mouse model, we found a significant CD73i-dependent increase in intra-follicular antigen-experienced B cell density (P=0.037) with a concomitant increase in intra-follicular CD8+ T cell density (P<0.001), which could be explained by enhanced function of Tfh cells. Accordingly, we found enrichment in IL-21 expressing Tfh cells in tumors treated with FOLFIRINOX+anti-PD-1+CD73i compared to FOLFIRINOX+anti-PD-1. These results indicate that CD73i may drive distinct immune remodeling in PDAC, boosting Tfh cell function in draining lymph nodes but favoring antigen-specific Treg enrichment in the tumor microenvironment.

#6453 Serum pharmacodynamic biomarkers of IPI/NIVO/RELA plus sarilumab in Stage III-IV melanoma: Stage 1 results of a Simon Phase II trial (NCT05428007).

Teruyuki Mizutani[1], Amrutesh Puranik[1], Inderjit Mehmi[2], Judith Goldberg[1], Maya Dimitrova[1], Perla Arriola[1], Stanzin Idga[1], Xiaochun Li[1], Benjamin Levinson[1], Justine Cohen[3], Elizabeth I. Buchbinder[3], Donald Lawrence[4], Alissa Kalyan[1], Morgan Simons[1], F. Stephen Hodi[3], Ryan J. Sullivan[4], Omid Hamid[2], Michelle Krogsgaard[1], Janice M. Mehnert[1]

[1]NYU Langone Health Perlmutter Cancer Ctr., New York, NY,[2]The Angeles Clinic and Research Institute, Los Angeles, CA,[3]Dana-Farber Cancer Institute, Boston, MA,[4]Harvard Medical School/Massachusetts General Hospital, Boston, MA

Background: Assessing biomarkers to predict response is crucial for optimizing melanoma treatment with immune checkpoint inhibitors (ICIs). In this context, monitoring cytokine dynamics over time provides a rational strategy to determine whether IL-6R inhibition with sarilumab is biologically active and to identify pharmacodynamic signatures associated with clinical outcomes. Here, we focus on longitudinal serum cytokine profiling using Luminex assays to explore pharmacodynamic biomarkers for response in a phase II trial combining nivolumab (3 mg/kg), ipilimumab (1 mg/kg), the IL-6 receptor inhibitor sarilumab (150 mg), and the LAG-3 antibody relatlimab (160 mg) (INR + S) in patients with unresectable or advanced melanoma.
Methods: We analyzed serum cytokines from 33 melanoma patients treated with INR + S using samples from baseline, week 4, week 6, week 12, week 18, and week 28 (final timepoint after discontinuation of sarilumab), and categorized patients according to response and toxicity. Patients were classified into PR/CR, SD, and PD groups, as well as grade 1-2 versus grade 3 or greater toxicity. Serum cytokines were profiled using Luminex assays, measuring 23 analytes. In total, 152 samples from 33 patients were analyzed. Statistical analyses were conducted using Mann-Whitney U test, paired t-test, and Kruskal-Wallis test, with the significance level set at 0.05.
Results: The best overall response rate was 63.6%. Grade 3-5 irAEs occurred in 12% of patients by week 24. At baseline, no pretreatment predictive factors for either treatment response or > grade 3 irAEs were identified. Across all patients, several significant post-treatment patterns that correlated with clinical benefit were observed compared with baseline at one or more time points for IL-6, IL-6R, OSM, CXCL10, IL-4, IL-10, G-CSF, and M-CSF. Notably, PR/CR patients showed increased IL-6 and decreased IL-6R levels over time, which returned to baseline levels after discontinuation of sarilumab. When comparing baseline with week 4, progressive disease was associated with marked increases in OPN, and IL-8, whereas PR/CR patients showed decreases in IL-6R, IL-4, and G-CSF.
Conclusion: Longitudinal analyses in the present study revealed increased IL-6 and decreased IL-6R levels. These dynamics likely reflect a more active mode of IL-6R blockade and may have contributed to improved clinical outcomes. The next phase of the trial is a randomized comparison of INR +/- S, and biospecimens from this randomized comparison will be analyzed to build on our findings.

#6454 Enhanced monocyte activation and T cell cytotoxicity underlie the benefit of neoadjuvant durvalumab plus gemcitabine-cisplatin (D+GP) in localized biliary tract cancer (BTC): Phase 2 DEBATE study.

Changhoon Yoo[1], Hyung-Don Kim[1], Chang Yeon Kim[2], Joon Oh Park[3], Hyehyun Jeong[1], Kyu-Pyo Kim[1], Jung Yong Hong[4], Sang Hyun Shin[4], Tae Jun Song[1], Dongwook Oh[1], Woohyung Lee[1], Jae Hoon Lee[1], Dae Wook Hwang[1], Jeong Seok Lee[5]

[1]University of Ulsan College of Medicine, Seoul, Korea, Republic of,[2]Seoul National University College of Medicine, Seoul, Korea, Republic of,[3]Associate Professor, Dept. of Hem./Onc., Samsung Medical Center, Seoul, Korea, Republic of,[4]Samsung Medical Center, Seoul, Korea, Republic of,[5]Korea Advanced Institute of Science and Technology, Daejeon, Korea, Republic of

Introduction: The prognosis of localized BTC remains poor despite surgery. The role of neoadjuvant therapy in BTC has not been well established.
Methods: DEBATE is a multicenter, randomized, non-comparative phase 2 trial enrolling treatment-naïve patients (pts) with localized BTC. Pts were randomized (2:1) to receive 4 cycles of neoadjuvant D+GP or GP alone. Those undergoing surgery received 6 cycles of adjuvant durvalumab. The primary endpoint was the R0 resection rate. Biomarker analyses included single-cell RNA sequencing (scRNA-seq) of peripheral blood mononuclear cells (PBMCs), and plasma proteomics (baseline and cycle 1 day 8 [C1D8]).
Results: A total of 45 pts were enrolled (D+GP, n=31; GP, n=14). Surgery was performed in 64.5% vs. 42.9%, and R0 resection rates were 48.4% vs. 42.9% in the D+GP and GP arms, respectively. In the D+GP group, the objective response rate was 38.7%, median PFS 19 months (1-sided 80% CI, 15-21), and OS 28 months (24-43), versus 14.3%, 6 months (3-11), and 30 months (23-44) in the GP group. Biomarker data were available in 98% (n=44). scRNA-seq showed a significant enrichment of classical monocytes with pro-inflammatory signatures in the D+GP group, especially among responders, along with increased CXCL10 expression in both scRNA-seq and plasma proteomics. Responders in the D+GP group also exhibited increased CD8+ T cell cytotoxicity, CD4+ Terminally differentiated effector memory T (TEMRA) cells, and IL12RB2 expression. TIGIT expression in CD4+ TEMRA cells decreased from baseline to C1D8 only in responders treated with D+GP.
Conclusion: Neoadjuvant D+GP was feasible and demonstrated encouraging efficacy in localized BTC. Integrated biomarker analyses suggest that enhanced monocyte activation and T cell responses contribute to the added benefit of durvalumab. Current study provide the rationale of adding anti-TIGIT to D+GP in BTC (NCT04308174).

#6455 Cytotoxic T-cell signatures underlie therapeutic response to 177Lu-DOTATATE plus pembrolizumab in well-differentiated gastroenteric neuroendocrine tumors.

Naoki Mizutani[1], Shloka Shukla[1], Nicholas Fidelman[2], Bridget P. Keenan[2], David Y. Oh[2], Kira Chan[2], Li Zhang[2], Emily K. Bergsland[2], Thomas Hope[2], Lawrence Fong[1]

[1]Translational Science and Therapeutics Division, Fred Hutchinson Cancer Center, Seattle, WA,[2]University of California San Francisco, San Francisco, CA

Background

Peptide receptor radionuclide therapy (PRRT) with 177Lu-DOTATATE is an established treatment for well-differentiated neuroendocrine tumors (WD-NETs). PD-1 blockade with pembrolizumab has been investigated in NETs; however, radiographic responses are limited when used as monotherapy. As such, we investigated the combination of PRRT and pembrolizumab as an investigational approach to enhance antitumor immunity and efficacy in 26 patients with grade 2 or 3 WD-NET (NCT03457948). The overall response rate (ORR) by RECIST 1.1 was 34.6% (9/26), but the systemic immune changes induced by this combination remain incompletely understood. We now report the results of our investigation of peripheral immune remodeling and T-cell clonal dynamics using single-cell (sc) transcriptomic and TCR repertoire profiling of PBMCs.

Methods

A total of 111 PBMC samples were collected longitudinally from 26 patients treated with PRRT plus pembrolizumab. scRNA sequencing and TCR sequencing were performed using the 10x Genomics platform. Major immune populations were annotated, and transcriptional and clonal characteristics were analyzed in relation to treatment response. Patients were stratified into pancreatic NET (pNET, N=14; 5 responders [36%, PR] and 9 non-responders [64%; 7 SD, 2 PD]) and extrapancreatic NET (epNET, N=12; 4 responders [33%, PR] and 8 non-responders [67%; 7 SD, 1 PD]), with the latter including tumors of intestinal, pulmonary, and unknown primary origin. Statistical analysis was performed with Mann-Whitney U test.

Results

In epNET responders, the frequency of $CD8^+$ T cells increased across timepoints compared with epNET non-responders ($p<0.05$). Further subclustering of T cells revealed that both $CD4^+$ and a subset of $CD8^+$ cytotoxic T cells were significantly elevated ($p<0.05$) and exhibited prominent clonal expansion in epNET responders, particularly post treatment. Non-responders showed an enrichment of immunosuppressive subsets, including $CD4^+$ regulatory T cells (Treg) and $CD4^+$

Th2 cells ($p<0.05$). Differential gene expression analysis demonstrated that several cytotoxic genes (*NKG7*, *CCL5*, *GNLY*, and *GZMH*) were upregulated in both $CD4^+$ and $CD8^+$ T cells in the responders compared with non-responders. In contrast to epNET, systemic immune remodeling was generally limited in pNET patients regardless of response status.

Conclusions

Integrated single-cell and TCR analysis revealed distinct systemic T-cell activation profiles between responders and non-responders to PRRT plus PD-1 blockade, but this effect varied by site of origin. Responding patients with epNET exhibited prominent clonal expansion and upregulation of cytotoxic genes. These findings highlight key differences in peripheral immune dynamics associated with treatment response in WD-NETs and may inform strategies to optimize combination therapy.

#6456 Pan-tumor investigation of peripheral biomarkers of excellent response to anti-PD(L)1-based therapy.

Howard L. Li[1], Soren Charmsaz[2], Chester Kao[1], Carlotta Pazzi[1], Madelena Brancati[1], James Leatherman[1], Nicole E. Gross[1], Royce P. Lee[1], Xiyu Zhao[3], Christopher Thoburn[1], Jeannie Hoffman-Censits[1], Evan J. Lipson[1], Yasser Ged[1], Marina Baretti[1], G Scott Chandler[4], Rajat Mohindra[4], Laura Tang[5], Sanjay Bansal[5], Aditi Guha[5], Elizabeth Jaffee[1], Daniel J. Zabransky[1], Won Jin Ho[1], Mark Yarchoan[1], Mari Nakazawa[1]

[1]Sidney Kimmel Comprehensive Cancer Center, Baltimore, MD,[2]Johns Hopkins University School of Medicine, Baltimore, MD,[3]The Johns Hopkins Hospital, Baltimore, MD,[4]Roche, Basel, Switzerland,[5]Genentech, South San Francisco, CA

Background: Immune checkpoint inhibitors (ICIs) have transformed contemporary cancer care, yet few patients experience objective responses. There is a need for novel peripheral biomarkers that can not only identify patients likely to respond but also distinguish those with excellent, durable benefit to enable improved patient selection, therapeutic monitoring, and target discovery.
Methods: We prospectively collected serial blood samples from patients with advanced/metastatic solid tumors treated at Johns Hopkins on anti-PD(L)1-based therapy from 2021-2024. Patients with complete or durable partial response with progression-free survival (PFS) greater than one year were classified as excellent responders (ERs); other patients were classified as non-ERs. Peripheral blood mononuclear cells were analyzed using CyTOF to quantify 28 immune cell clusters with associated functional markers, and plasma samples were analyzed using a Luminex multiplex assay to quantify concentrations of 39 cytokines at baseline and early-on-treatment (month 1 or 2).
Results: Our total cohort included 123 patients, 30 of whom were classified as ERs. The most common tumor types were HCC, head and neck cancer, RCC, and bladder cancer. Our cytokine cohort included 118 patients. At baseline, ERs had significantly elevated Th17-associated cytokines, IL-17F, IL-21, and IL-23 compared to non-ERs (Wilcoxon rank-sum, $p<0.05$). Non-ERs had elevated baseline IL-8 concentrations ($p<0.05$). These results persisted early-on-treatment, with the addition of elevated on-treatment IL-6 being associated with non-ER ($p<0.05$). Patients with greater than median IL-17F concentrations at baseline demonstrated improved PFS ($p=0.075$), while greater than median IL-6 and IL-8 baseline concentrations demonstrated worse OS ($p=0.053$ and $p<0.001$). Our CyTOF cohort included 116 patients. As compared to non-ERs, ERs were associated with greater early-treatment expansion of NK cells and double negative (CD4-CD8-) T-cell as well as multiple Th2-central memory clusters ($p<0.05$). Th17 cells were also increased in ERs as compared to non-ERs, although this result did not reach significance ($p=0.06$). Immune cell functional marker analysis in non-ERs shows that Th17 cells had increased proliferation of exhausted T-cells (Ki67+TIGIT+) from baseline to early-on-treatment (Linear mixed model, $p < 0.01$), which was not present in ERs.
Conclusions: In a prospective, pan-tumor cohort, we find that Th17 cytokines, IL-17F, IL-21, and IL-23, as well as Th2-central memory cells are associated with excellent ICI response, in addition to re-demonstrating the negative prognostic implications of Th17 cytokine, IL-6, as well as IL-8. Our study highlights the Th17 pathway as a polarizing determinant of excellent ICI response and represents a comprehensive exploration of other peripheral cytokines and immune cells in mediating durable ICI benefit.

#6457 Phase I study of STA551 (STA) a tumor-selective CD137 agonist, as monotherapy and in combination with atezolizumab (atezo) using CD8 PET imaging to assess pharmacodynamic effects.

Udai Banerji[1], Diogo Silva[1], Joshua Ting[1], Zoulikha Zair[2], Prakash Manoharan[2], Toshihiko Doi[3], Shigehiro Koganemaru[3], Noboru Yamamoto[4], Takafumi Koyama[4], Seiichi Ikeda[5], Yuki Kanai[5], Michiyasu Inatani[5], Hitomi Takeshita[5], Akiko Hashimoto[6], Yoshitaka Ogita[5], Yuma Takano[5], Kei Higashikawa[5], Fiona Thistlethwaite[2]

[1]The Institute of Cancer Research; The Royal Marsden Hospital, London, United Kingdom,[2]The Christie NHS Foundation Trust, Manchester, United Kingdom,[3]National Cancer Center Hospital East, Chiba, Japan,[4]National Cancer Center Hospital, Tokyo, Japan,[5]Chugai Pharmaceutical Co., Ltd., Tokyo, Japan,[6]Chugai Pharma Europe Ltd., London, United Kingdom

Background: CD137 is a promising costimulatory receptor for cancer immunotherapy. Several CD137 agonist antibody biologics have been developed, but none show clear promising clinical potential due to severe toxicity. STA, an ATP-dependent switch antibody, is designed to selectively activate CD137 within tumors, and minimize systemic toxicity. We conducted a phase I study of STA alone or the combination of STA and atezo to evaluate tolerability, PK and pharmacodynamics using CD8 PET imaging, in patients with advanced solid tumors.

Methods: The Phase 1 study includes dose escalation and CD8 PET cohorts. For the dose escalation cohorts, patients were treated with either STA monotherapy IV q3 weekly or STA in combination with atezo (1200 mg) q3 weekly. For the CD8 PET cohort, patients received STA q3 weekly for two cycles as monotherapy, followed by combination therapy with atezo 1200 mg from cycle 3 onwards. Zr-89 crefmirlimab berdoxam (a minibody targeting CD8, labeled with Zr-89) was used as the tracer of CD8 PET scan. CD8 PET scans were done at baseline, after two STA doses (Cycle 2 Day 9), and after two combination doses (Cycle 4 Day 9).

Results: A total of 94 patients were treated in the dose escalation cohorts (41 patients in monotherapy and 41 patients in the combination) and in the CD8 PET cohort (12 patients). The most common treatment related adverse events (≥10%) were AST increased (17.1%), fatigue (14.6%), and ALT increased (12.2%) in mono cohorts; ALT increased (22.6%), AST increased (18.9%), infusion related reaction (IRR) (15.1%), nausea (13.2%), diarrhoea (11.3%) and fatigue (11.3%) in combination and CD8 PET cohorts. No severe adverse events related to Zr-89 crefmirlimab berdoxam were reported. No dose limiting toxicities were observed up to STA 1200 mg alone. The maximum tolerated dose was 450 mg of STA in combination with 1200 mg of atezo administered q3 weekly. The PK analysis showed STA increased in a dose proportional manner. In the CD8 PET cohort, 10 patients were evaluable for efficacy and CD8 PET analyses. One partial response (PR) was observed in a heavily pretreated patient with triple negative breast cancer. Five patients had stable disease. Increased tracer accumulation in tumor lesions was indicated in a subset of patients. Notably, in the patient who achieved a PR, clear increased accumulation was observed in all evaluable lesions. No clear increase in the tracer accumulation was observed in the spleen which has been reported with other systemic CD137 agonists.

Conclusions: STA demonstrated a manageable safety profile both as monotherapy and in combination with atezo. CD8 PET analysis suggested STA increased intratumoral $CD8^+$ T cell levels in a subset of patients, with limited effects in normal organs. These findings potentially support the tumor-selective mechanism of action of STA as a CD137 agonist.

#6458 Harnessing tumor-informed B cell receptors for discovery and antibody-based immunotherapy in sarcoma.

Background: Soft tissue sarcomas (STS) are rare and heterogenous cancers, with limited effective treatments and poor prognosis. While some patients with STS respond to immune checkpoint blockade (ICB), the majority do not benefit. This highlights an urgent need to elucidate mechanisms of response and resistance to ICB and develop novel immunotherapeutic approaches for patients with STS. We and others have shown that tumor infiltrating B cells (TIL-Bs), particularly those in tertiary lymphoid structures (TLS) are associated with response to ICB and longer survival. However, the antigen specificity, mechanisms of action, and therapeutic potential of these TIL-Bs and their B cell receptors (BCRs) remain unknown.
