Methods: We recently completed a phase 2 clinical trial evaluating ICB administered in the neoadjuvant setting in patients with resectable undifferentiated pleomorphic sarcoma (UPS) of the extremity/trunk or dedifferentiated liposarcoma (DDLPS) of the retroperitoneum (Roland et al. *Nature Cancer* 2024). Leveraging a unique biospecimen resource from this trial, we reconstructed intratumoral BCR heavy and light chain (V_H and V_L) repertoires using pre-treatment baseline tumor biopsies (n = 27), RNA-sequencing, and an in-house pipeline including TRUST4. We then performed single intratumoral B cell immunoglobulin sequencing using cell suspensions from 4 TLS-positive tumors to reconstruct and express 105 recombinant BCR antibodies (rBCR Abs) as IgG1. Flow cytometry (FC) was performed to characterize the binding features of a subset of 20 rBCR Abs with human DDLPS (LPS224, LPS246) and UPS cell lines (UPS186, RIS819.1). Binding was quantified as the ratio of the mean fluorescent intensity (MFI) of the antibody to the MFI of the isotype control for each cell line. Abs with an MFI ratio ≥ 1.2 were classified as binders and tumor surface binding was further assessed by live cell microscopy. Antibody-dependent cellular cytotoxicity (ADCC) assays were performed to assess the functional capacity of this cohort of rBCR Abs to mediate NK-cell dependent tumor killing. The anti-tumor efficacy of 1 lead rBCR Ab was assessed using an MCA205 immunocompetent murine STS model.
Results: Of 105 rBCR Abs screened, 23 (22%) exhibited reproducible surface binding to at least one sarcoma cell line by FC. Among these, 13 (12%) bound LPS lines and 18 (17%) bound UPS lines. To date, 20 rBCR Abs have been confirmed to bind the surface of sarcoma cell lines by live cell staining of which 5 mediated tumor cell killing in vitro. One candidate rBCR Ab has been evaluated in vivo, localizing to tumor and synergized with PD-1/PD-L1 blockade to suppress tumor growth when administered intraperitoneally.
Conclusion: These findings highlight the potential of rBCR Abs to serve as a novel therapeutic strategy and as tools to elucidate the roles of B cells and the BCR repertoire within the tumor immune microenvironment of patients with STS.

#6459 Development of FL115, a novel IL-15 superagonist, as subcutaneous injection for cancer immunotherapy.

Qinghua Wu, Quanxiao Li, **Dong Wei**

Forlong Biotechnology, Suzhou, China

Background: FL115 is an engineered IL-15/IL15Rα-Fbody fusion protein, in which Fbody is a single-chain Fc designed to eliminate classical Fc effects including ADCC/CDC/ADCP while retaining FcRn engagement. In Phase I clinical studies in patients with advanced solid tumors, FL115 administered as weekly IV infusion (dose range: 3-90 μg/kg) demonstrated favorable safety profile and preliminary clinical efficacy including 2 confirmed PR. Dose-proportional pharmacokinetics was observed, with on-target pharmacodynamic activities including sustained significant expansion of NK and CD8+ T cells. Strong transient induction of IFN-γ in plasma was observed, with peak concentration at over 3000 pg/ml compared to IL-6 at ~1 pg/ml at 3 μg/kg dose. Prior IL-15 therapeutic agents have shown significant profile enhancement when administered as subcutaneous injection compared to IV infusion. Here we present the preclinical data supporting further development of FL115 as subcutaneous injection.

Methods: In an SD rat study, a single dose of FL115 was injected subcutaneously at 0.1,0.3 or 1.0 mg/kg or via IV at 0.3 mg/kg, and pharmacokinetic parameters were assessed. In a Cynomolgus monkey study, a single dose of FL115 was injected via IV at 0.23,0.43 or 1.02 mg/kg or subcutaneously at 0.43 mg/kg, and pharmacokinetic parameters were assessed. In a subcutaneous irritation study in New Zealand white rabbits, FL115 was injected subcutaneously at 0.1 ml/kg (FL115 concentration: 21.1mg/ml) per injection site at Day 1 and Day 7, and local injection site reaction was assessed.

Results: In the Cynomolgus monkey study, FL115 of 0.43 mg/kg via IV injection resulted in serum C_{max} of 9350-9360 ng/ml and T_{max} of 0.08 hours, while 0.43 mg/kg via subcutaneous injection resulted in serum C_{max} of 350-436 ng/ml and T_{max} of 4 hours as well as bioavailability of 54.7-65.8%. In the SD rat study, FL115 of 0.3 mg/kg via IV injection resulted in serum C_{max} of 4370 ng/ml and T_{max} of 0.08 hours, while 0.3 mg/kg via subcutaneous injection resulted in serum C_{max} of 223 ng/ml and T_{max} of 6 hours as well as bioavailability of 67%, . A single dose subcutaneous injection at 0.1,0.3 or 1.0 mg/kg in rat also showed good linearity. In the rabbit study, from Day 1 to 24, skin irritation at gross observation was at Grade 0 (no abnormality). At Day 10, histopathological assessment showed mild inflammatory cell infiltration under the skin and in muscle, which was fully resolved at Day 24.

Conclusion: Compared to IV injection, subcutaneous FL115 in rats and monkeys showed a significant delay (up to 4-6 hours) and drastic lowering of C_{max} (up to 26.7×) with bioavailability at ~60% as well as good linearity in PK file. FL115 at approximately 9 mg per injection site in rabbits showed no significant gross skin irritation. These results support continuing development of FL115 as subcutaneous injection for cancer immunotherapy.

#6460 Immunologic and transcriptional features associated with long-term response and resistance to immune checkpoint inhibitors in non-small cell lung cancer checkpoint inhibitors in non-small cell lung cancer.

Yoshihiro Masui[1], Tatsuya Yoshida[1], Jun Miyakoshi[1], Ryoko Higashiyama[1], Akiko Tateishi[1], Yuki Shinno[1], Tomonori Mizutani[1], Yusuke Okuma[1], Hidehito Horinouchi[1], Kouya Shiraishi[2], Takashi Kohno[2], Yasushi Goto[1]

[1]Thoracic Oncology, National Cancer Center Hospital, Tokyo, Japan,[2]Division of Genome Biology, National Cancer Center Research Institute, Tokyo, Japan

Background: Immune checkpoint inhibitors (ICIs) have markedly improved outcomes in non-small cell lung cancer (NSCLC), yet durable benefit is achieved in only a minority of patients. The biological mechanisms underlying tumor response to ICIs—including primary resistance (PriR), acquired resistance (AcqR), and long-term response (LTR)—remain poorly understood.
Methods: We reviewed patients with advanced or recurrent NSCLC who initiated first-line ICI monotherapy at the National Cancer Center Hospital (Japan) between 2015-2020. Patients were classified as LTR (defined as progression-free survival ≥48 months), AcqR (initial disease control followed by progression <48 months), or PriR (best response PD). Clinical characteristics were characterized across these groups. Pretreatment tumor RNA-seq data were subjected to transcriptomic analyses. Differential pathway activity was evaluated using Hallmark and Reactome GSEA, and immune-cell composition was inferred using CIBERSORT.
Results: A total of 216 patients were included in the clinical cohort. Pretreatment tumor RNA-seq data were available for 46 patients (LTR, n=10; AcqR, n=23; PriR, n=13). Compared with responders (LTR + AcqR), PriR tumors showed marked enrichment of inflammatory and immunosuppressive programs, including IL6-JAK-STAT3, TNFα/NF-κB, complement, glycolysis, and hypoxia pathways, suggesting a metabolically stressed and suppressive microenvironment that hinders initial immune activation. In contrast, responders exhibited higher interferon-γ (IFN-γ) signaling and T-cell activation signatures. In a direct comparison between LTR and AcqR, LTR tumors uniquely preserved strong IFN-γ-driven inflammation, intact MHC class I antigen-presentation machinery, and robust cytotoxic and memory T-cell programs. AcqR tumors showed attenuation of antigen-presentation and effector-immune pathways, suggesting that reduced immunogenicity contributes to progression after an initial response. Among PD-L1-high tumors, LTR cases again maintained intact antigen-presentation machinery and sustained IFN-γ-driven cytotoxic T-cell activity, whereas AcqR tumors demonstrated attenuation of these programs.
Conclusion: Compared with PriR and AcqR tumors, LTR tumors showed higher IFN-γ activity, preserved antigen-presentation activity, and sustained effector T-cell signaling. PriR tumors were characterized by inflammatory and metabolically stressed immunosuppressive programs, whereas AcqR tumors showed loss of antigen-presentation and effector-immune activity after the initial response. These features may help identify patients likely to achieve durable ICI benefit and suggest potential targets to overcome resistance.

#6461 Comprehensive cytokine, chemokine and immune marker evaluation in plasma samples of primary, non-metastatic high grade serous ovarian cancer patients to estimate outcome and platinum resistance.

Sabine Kasimir-Bauer[1], Buesra Eser[1], Yipeng Wang[2], Gordon Vansant[2], Stefanos I. Moukas[1], Rainer Kimmig[1], Fabinshy Thangarajah[1]

[1]Department of Gynecology and Obstetrics, University Hospital Essen, Essen, Germany,[2]LuminoDx, San Diego, CA

Background: Ovarian cancer (OC) still has the highest mortality rate of all gynecological malignancies, diagnosed mostly at advanced stages, resulting in a generally poor outcome. Radical tumor debulking, followed by platinum-based chemotherapy with/without bevacizumab and with/without PARP inhibitors is the standard of care in advanced OC. However, the majority of patients will ultimately relapse due to the development of platinum resistance. Efforts to apply immunotherapy has been less successful, however, immunologic processes play an important role in tumorigenesis and therapy response. Little is known about immune-marker, cytokine and chemokine expression in OC. In view of biomarker research to identify patients at high risk for relapse, we here determined cytokine/chemokine/immune-related marker levels in blood samples of primary, non-metastatic, high grade serous (HGS) OC patients before and after therapy to estimate their value with regard to progression-free survival (PFS), overall survival (OS) and platinum resistance.

Patients and Methods: Plasma samples of 53 HGSOC patients were collected prior (n=53) and following platinum-based chemotherapy (n=27) with/without bevacizumab. Cytokine/chemokine/immune-related marker levels were quantified using the Olink Target 48 Cytokine panel and Immune Surveillance Panel (LuminoDx, San Diego, USA), which includes total 89 immune-related proteins and requires only one µL of sample. Results were correlated between cytokine/chemokine/immune related marker levels and PFS and OS using the Cox proportional hazards model and Log-rank test as well as platinum resistance applying the student`s t-test.

Results: Associations between cytokine/chemokine/immune-related marker levels and patient outcomes were evaluated using Cox proportional hazards models. At baseline, lower IL19 levels and higher FASLG and CEACAM5 levels were significantly associated with an improved PFS ($p<0.01$). Lower IL17A, IL19, VEGFA, IL27 and higher FASLG levels were significantly associated with a longer OS ($p<0.01$). Decreases in FASLG and CEACAM5 levels over the course of treatment correlated with a longer PFS while increasing VEGFA levels were significantly associated with a longer OS. Additionally, high baseline IL19 and IL6 levels and low CXCL12 and IL18 levels were significantly associated with the development of platinum resistance ($p<0.05$). IL19 was the only marker demonstrating statistical significance ($p<0.05$) for both, PFS and platinum resistance.

Conclusion: Here we demonstrate the potential value of cytokine, chemokine and immune-related marker plasma levels to better estimate PFS, OS as well as platinum resistance in HGSOC. These prognostic and predictive markers may be further developed into clinical assays to support patient management.

#6462 Baseline peripheral immune signatures associate with toxicity to immunotherapy in melanoma.

Iluja Gautam[1], Patricia Rayman[1], Nickolas Stabellini[1], Jennifer Powers[1], Adam Moen[1], Brian Race[1], Paul Pavicic[1], Mona Patel[1], Alberto J. Montero[2], C. Marcela Diaz-Montero[1]

[1]Cleveland Clinic Research, Cleveland, OH,[2]University Hospitals, Cleveland, OH

Background: Adjuvant immune checkpoint inhibitors (ICIs) improve recurrence-free survival in high-risk melanoma. Despite this, a subset of patients do not respond to ICIs while other experience immune-related adverse events (irAEs) without therapeutic benefits. Predictive biomarkers remain undefined, and grouping patients without accounting for irAE status may obscure meaningful immune correlates. We hypothesized that comprehensive immune profiling of baseline peripheral blood mononuclear cells (PBMCs) may help identify predictive immune signatures associated with both response and toxicity to adjuvant ICI.

Methods: Blood samples were collected from a total of 22 melanoma patients undergoing adjuvant ICI therapies at baseline and on-treatment. PBMCs were isolated using standard density gradient centrifugation and stained using two comprehensive immunophenotyping panels. Data was acquired on FACS symphony A5. FlowJo's built-in UMAP plugin was used to visualize immune cell clustering and further characterized using Marker Enrichment Modeling. Response to therapy was determined retrospectively. Immune subsets were compared between responders and non-responders at the two time points and was further stratified by occurrence of irAEs.

Results: At baseline, responders demonstrated enrichment of central memory T cells and terminally differentiated effector memory T cells, consistent with a primed yet regulated immune state poised for rapid activation. In contrast, non-responders had elevated CD16+ MDSCs, which further expanded on treatment, indicating a suppressive peripheral milieu. Among responders, those developing irAEs demonstrated increased memory-like T cells and CD14+CD62P+ myeloid populations compared to those with no irAEs. Among non-responders, irAE-positive patients displayed higher CD45RA+CD4+CD62L+ memory and CD8+CD57+ effector T cell populations. Within the myeloid compartment, CD62P+ cells were increased in both responders and non-responders with irAEs highlighting platelet-myeloid activation. Non-responders without irAEs showed globally low activation, consistent with an immune quiescent state. No significant treatment induced changes distinguished response categories, underscoring the importance of baseline immune context.

Conclusions: Baseline peripheral immune composition reflects distinct states of immune readiness in melanoma patients receiving adjuvant ICI. Responders display a primed immune profile whereas non-responders exhibit myeloid driven suppression. These findings highlight peripheral immune features that may predict therapeutic efficacy and toxicity in melanoma patients in the adjuvant ICI setting. Importantly, stratifying patients by irAE status is essential to reveal true immune correlates of efficacy and toxicity, as pooled analyses risk conflating biologically distinct activation and suppression states.

#6463 Longitudinal single-cell atlas of GD2-CAR T cell therapy in H3K27M-mutant diffuse midline glioma identifies humoral and cellular anti-CAR immunity.

Yiyun Chen, Kun-Wei Song, Moksha H. Desai, Ying-Wen Huang, Nadya Iswari, Zachary J. Ehlinger, Hossein Daghagh, Maximilian R. A. Koch, Kevin Reynolds, Kelvin C. Mo, Kristin C. Y. Tsui, Skyler Rietberg, Mark P. Hamilton, Snehit Prabhu, Sonia Partap, Jasia Mahdi, Emily Egeler, Steven A. Feldman, Sabine Heitzeneder, Sean A. Yamada-Hunter, Elena Sotillo, Bita Sahaf, Zinaida Good, Michelle Monje, Sneha Ramakrishna, Crystal L. Mackall

Stanford Cancer Institute, Stanford, CA

GD2-CAR T cell therapy has demonstrated clinical benefit in a high fraction of patients with H3K27M-mutant diffuse midline glioma (DMG), but the durability of response is limited in some patients. To define mechanisms underlying loss of response and immune adaptation during repeated CAR T infusions, we performed longitudinal single-cell RNA and TCR sequencing of over 1.4 million cells from apheresis, CAR T products, and serial cerebrospinal fluid (CSF) samples collected from 13 DMG patients enrolled in the Arm A of Phase I trial of GD2-CAR T cell therapy (NCT04196413). Our analysis showed that GD2-CAR T cells exhibited poor persistence in vivo, with minimal detection after six infusion cycles. Endogenous lymphocytes, rather than CAR T cells, dominated the CSF immune compartment over time. Regulatory T cells were significantly enriched in non-responders, suggesting a suppressive immune milieu that limits CAR T activity. Among four patients who initially achieved sustained responses for over 12 months, three eventually relapsed after repeated infusions. Flow cytometry detected presence of anti-CAR antibodies in plasma and CSF these three patients, accompanied by an increase in CSF B cells at the time of relapse, indicating a humoral anti-CAR immune response. Complementing this, single-cell TCR-seq revealed that endogenous T cell repertoires stabilized toward the end of treatment in these relapsed responders, with hyper-expanded clonotypes exhibiting activated, cytotoxic, and exhausted transcriptional programs. In contrast, two durable responders maintained a dominant tissue-resident memory-like T cell program, which is associated with sustained disease control. Altogether, we generated a comprehensive longitudinal collection of single-cell sequencing and other omics data, and identified co-existing humoral and cellular mechanisms of anti-CAR immunity that emerge during prolonged GD2-CAR T cell therapy. These findings illuminate correlates of response and resistance and underscore the immunogenic potential of CAR constructs. Future approaches to reduce host immunoreactivity could improve CAR T cell efficacy and durability in solid tumors.

#6464 Surgery-induced expansion of myeloid-derived suppressor cells and loss of cytotoxic lymphocyte function predict poor survival in pancreatic cancer.

Olivia Johnsson[1], Malin S. Nilsson[1], Roberta Kiffin[1], Johan Bourghardt Fagman[2], Caroline Vilhav[2], Svein Olav Bratlie[2], Peter L J Naredi[2], Kristoffer Hellstrand[3], Anna Martner[1]

[1]TIMM Laboratory, Sahlgrenska Center for Cancer Research, Department of Microbiology and Immunology, Institute of Biomedicine, University of Gothenburg, Gothenburg, Sweden, [2]Department of Surgery, Institute of Clinical Sciences, University of Gothenburg, Gothenburg, Sweden,[3]TIMM Laboratory, Sahlgrenska Center for Cancer Research, Department of Infectious Diseases, Institute of Biomedicine, University of Gothenburg, Gothenburg, Sweden

Pancreatic cancer remains a highly lethal malignancy, with high recurrence rates even after curative-intent resection. Evidence suggests that surgical stress triggers inflammation and immunosuppression, potentially facilitating tumor recurrence. Myeloid-derived suppressor cells (MDSCs) and dysfunctional natural killer (NK) cells are mediators of this process. We hypothesized that surgery-induced immune dysregulation, driven by NOX2-derived reactive oxygen species, impairs immunity and worsens outcomes.

Peripheral blood mononuclear cells from 33 pancreatic cancer patients enrolled in the IPEP trial (ethical no. 057-18) were collected pre- and postoperatively (days 1 and 3-5). Single-cell multiomic profiling (BD Rhapsody) was used to characterize immune populations and activation. Frequencies of immune cells and surface receptor expression were analyzed longitudinally and correlated with patient outcome.

Analysis of 445,152 cells revealed major postoperative shifts in circulating leukocytes (Table 1). $NOX2^+$ monocytic MDSCs (M-MDSCs) expanded markedly on postoperative day 1 and remained elevated through day 3-5. Conversely, cytotoxic T and NK cells significantly declined after surgery, and postoperative NK cells showed reduced expression of the activating receptor NKp30. High postoperative M-MDSC frequencies were associated with poorer overall survival (P = 0.017, n=29, log-rank test).

Pancreatic cancer surgery induces profound immune remodeling characterized by M-MDSC expansion and cytotoxic lymphocyte suppression. These changes associate with adverse outcomes, suggesting that postoperative immune dysfunction may promote recurrence. Targeting NOX2-dependent immunosuppressive pathways may help preserve antitumor immunity and improve postoperative survival.

[1]Mean ± SD[2]Median CLR-normalized protein expression[3]Mixed-effects model with Šídák correction. P values compared with pre-op.

Table 1. Perioperative immune cell subsets in healthy donors and pancreatic cancer patients.

	Healthy donor (n=13)	**Pre-op. (n=33)**	**Post-op. day 1 (n=29)[3]**	**Post-op. day 3-5 (n=29)[3]**
M-MDSC (% of all cells)[1]	0.3 ± 0.6	2.7 ± 3.3	23.3 ± 12.6 (P < 0.0001)	20.2 ± 12.2 (P < 0.0001)

#6465 Validating tumor-infiltrating lymphocyte classification in primary cutaneous melanoma using cytokine immune scores: Addressing biomarker disparities in underserved populations.

Meshack Bida[1], Rodney Hull[2], Thabiso Miya[2], Tebogo Marutha[2], **Zodwa Dlamini**[2]

[1]Department of Anatomical Pathology, University of Pretoria, Pretoria, South Africa,[2]Pan African Cancer Research Institute (PACRI), University of Pretoria, Pretoria, South Africa

Background: Immunotherapy has transformed melanoma treatment, but its promise is not equitably distributed. Biomarker disparities-particularly in tumor-infiltrating lymphocyte (TIL) classification may limit access to precision treatment among patients from low-resource settings. Visual histopathologic scoring of TILs into brisk, non-brisk, or absent categories remains standard practice, but this subjective method is prone to interobserver variability and lacks standardization. This is especially problematic in underrepresented African populations, where diagnostic tools and molecular profiling resources are limited. We aimed to validate conventional TIL classification using cytokine-based immune scoring and explore its implications for biomarker equity in melanoma care.
Methods: A total of 205 formalin-fixed, paraffin-embedded (FFPE) primary cutaneous melanoma samples from South African patients were categorized histologically based on AACR-defined TIL criteria. Immunohistochemical (IHC) staining for tumor necrosis factor-alpha (TNF-α) and interferon-gamma (IFN-γ) was performed using an automated platform. Cytokine expression was quantified using a modified Allred scoring system, which combines staining intensity and proportion of positive cells. Concordance between histologic TIL classification and cytokine-based immune scores was assessed through positive predictive value (PPV) and negative predictive value (NPV) analysis.
Results: In the brisk TIL group, TNF-α and IFN-γ immune scores showed PPVs of 0.68 and 0.79, respectively, suggesting moderate to strong correlation between histologic appearance and cytokine activation. In the absent TIL group, NPVs were 0.84 (TNF-α) and 0.91 (IFN-γ), indicating reliable association with immunologically quiescent tumors. However, a subset of histologically “TIL-absent” tumors demonstrated strong cytokine expression, highlighting biologic heterogeneity and potential misclassification. These discordances have real-world implications, especially where visual interpretation is the only method available to guide treatment.
Conclusion: Our findings underscore the value of cytokine-based immune scoring in validating and standardizing TIL classification. In underserved settings, where access to advanced genomic assays is limited, incorporating affordable and accessible IHC-based immune profiling may improve diagnostic accuracy and expand equitable access to immunotherapy. As immunotherapy eligibility increasingly depends on biomarker evidence, such approaches are essential to closing gaps in precision oncology and addressing global cancer care disparities.

#6466 Preliminary results of a phase 2 study of leronlimab in combination with TAS-102 and bevacizumab in previously treated metastatic colorectal cancer.

Pashtoon M. Kasi[1], Ari Baron[2], Arvind Chaudhry[3], Laura Tenner[4], Daniel L. Adams[5], Alexis B. Duffy[6], Hallgeir Rui[7], Patrick Vittner[8], Joseph Meidling[8], Jacob P. Lalezari[8]

[1]City of Hope Comprehensive Cancer Ctr., Duarte, CA,[2]Division of Hematology Oncology, Sutter/California Pacific Medical Center, San Francisco, CA,[3]Summit Cancer Centers, Spokane, WA,[4]University of Nebraska Medical Center, Fred and Pamela Buffett Cancer Center, Omaha, NE,[5]Creatv MicroTech, Monmouth Junction, NJ,[6]Creatv MicroTech, Inc., Rockville, MD,[7]Thomas Jefferson University, Philadelphia, PA,[8]CytoDyn Inc., Vancouver, WA

Background: CCR5 promotes recruitment of immunosuppressive myeloid populations and contributes to immune evasion in metastatic colorectal cancer (mCRC). Leronlimab is a humanized monoclonal antibody targeting CCR5 with immune-activating effects. TAS-102 plus bevacizumab is a standard regimen in refractory mCRC. This study evaluates the safety of leronlimab in combination with TAS-102/bevacizumab and if this combination enhances objective response rates via immune activation.
Methods: This ongoing multicenter Phase 2 trial will enroll up to 60 previously treated mCRC patients. Leronlimab will be initially dosed 350 mg SC QW with TAS-102/bevacizumab at standard doses. CCR5 expression and PD-L1 CPS is assessed by immunohistochemistry on tumor samples at baseline. PD-L1 and CCR5 is assessed in circulating tumor cells (CTCs) and cancer associated macrophage-like cells (CAMLs) from blood samples.
Results: Among all pre-screened patients with evaluable archival samples, 33/33 (100%) demonstrated CCR5 expression. As of 11/17/ 2025, 10 patients have been enrolled across 6 sites, with preliminary baseline and biomarker data in Table 1. At the City of Hope site, 4/4 patients (with data) had clinical and/or biomarker responses, i.e. declines in CEA, CA19-9, and/or ctDNA, despite refractory liver-metastatic disease. Serial kinetics showed an increase in PD-L1 on CTCs and CAMLs after 1 week on treatment, while the number of CAMLs and CTCs lowered in responders. Leronlimab has been well tolerated, with no unexpected safety signals. This preliminary trial report, which is enrolling ahead of pace, reflects a high unmet need in mCRC disease.
Conclusions: Leronlimab combined with TAS-102 and bevacizumab is feasible, showing promising early biomarker and clinical activity in heavily pretreated mCRC. Universal CCR5 positivity supports CCR5 as a potential therapeutic target. Updated outcomes and correlative data will be presented.

#6467 Myeloma cells with therapy-induced senescence-like phenotype are associated with resistance to CAR-T therapy.

Sofia Arbelaez[1], Andre De Menezes Silva Corraes,[1], Gabriel Alvares Borges[1], Chen Wu[2], Christoph Schaefers[3], Malvika Gupta[1], Zuoyi Shao[1], Kevin Regan[3], Rayaan Kamal[3], Angelo Jose Guilatco[1], Neal I. Sannuli[3], Ying Li[3], Taxiarchis Kourelis[1], Wilson Gonsalves[1], Moritz Binder[1], Melinda Tan[4], Nadine Abdallah[1], Megan Weivoda[1], Yi Lin[1]

[1]Mayo Clinic, Rochester, MN,[2]Mayo Clinic College of Medicine and Science, Rochester, MN,[3]Mayo Clinic Cancer Center, Rochester, MN,[4]Mayo Clinic Cancer Center Minnesota, Rochester, MN

Background: Patients (pts) with myeloma (MM) receiving CAR-T therapy have usually been exposed to many prior therapies. Melphalan (HDM) and other chemotherapies can induce cellular senescence. It has recently been shown that MM cells can also exhibit features of therapy-induced senescence (TIS). TIS tumor cells are associated with resistance to therapy and relapse. To investigate the presence of TIS MM cells prior to CAR-T and association with response, we examined the transcriptome and phenotype of MM prior to CAR-T.
Method: We used scRNA-seq data from bone marrow (BM) MM cells: Boiarsky, et al. (GSE193531, dbGaP: phs001323.v3.p1) newly diagnosed MM (NDMM) pts; Dhodapkar, et al. (GSE210079), pre- and post CAR-T; pts who received CAR-T at Mayo Clinic, pre- (N=10) and post- (N=2). To evaluate TIS, single-cell gene set enrichment analysis (scGSEA) for several gene sets (PMID: 40164720): SenUp (Senescence Upregulated), SenGA (Senescence Growth Arrest), and SCAPs (Senescent Cell Anti-apoptosis Pathways); and a Plasma Cell Senescence (PCSen) gene set (GSE5900, GSE47552). To assess TIS and myeloid phenotype, BM MM cells (CD138+) were stained for CD14, CD16, KLRG1 and GPNMB and analyzed by CytoFlex and Kaluza.
Results: In the integrated dataset, scGSEA showed significantly higher enrichment of PCSen, SenUp, SenGA, and SCAPs in late-stage MM cells (both pre- and post-CAR-T) compared to NDMM and healthy donors ($p<0.05$, Kruskal-Wallis with Dunn's posttest). Conversely, the Normal gene set was significantly enriched in healthy plasma cells relative to MM ($p<0.05$). Expression of CDKN2A, which encodes the senescence marker p16, was also increased in late-stage MM relative to NDMM or healthy plasma cells. Notably, in our newly generated scRNA-seq samples collected within 6 months before CAR-T, a significant inverse correlation between senescence marker expression and progression free survival (PFS) post-CAR-T was seen, suggesting that MM cells exhibiting TIS may be more resistant to T cell mediated cytotoxicity. We found that 62.5% (25/40) of pts had >1% MM cells that were CD14+. Among them, the median CD14+ MM cells were 5.5% (1-71%); and median CD14+CD16+ MM cells were 2.14% (0.4-67%). Among 7 pts with available samples for KLRG1 and GPNMB assessment, 100% (7/7) had KLRG+ MM cells (median: 59% (24-99%)) and 57% (4/7) had GPNMB+ MM cells (median: 15% (3.9-30%)), and KLRG1+GPNMB+ MM cells (median: 9.6% (3.8-17%)).
Conclusion: Our study shows that late-line MM cells exhibit transcriptional and phenotype profiles consistent with TIS. This senescent phenotype may contribute to resistance to immunotherapies, including CAR-T. Additional phenotype data is collected and will be presented. A phase II clinical trial is ongoing (NCT06940297) to assess for the combined treatment with senolytic drugs dasatinib and quercetin peri-CART to deepen clinical response.

#6468 Biopsy site-specific variation in immune signatures identified by RNA profiling in breast cancer.

Smruthy Sivakumar[1], Ericka Ebot[1], Douglas I. Lin[1], Meagan Montesion[1], Jeffrey S. Ross[1], Lee A. Albacker[1], Garrett M. Frampton[1], Michelle Marie Williams[2], Ethan S. Sokol[1]

[1]Foundation Medicine, Inc., Boston, MA,[2]University of Pittsburgh School of Medicine, Pittsburgh, PA

Background: Breast cancer is generally considered to be immune cold; however, emerging data indicate heterogeneity in its immune landscape. Triple negative and HER2-positive tumors typically show higher immune cell infiltration than hormone receptor-positive (HR+) tumors. Additionally, the local microenvironment at the biopsy site may influence the immune profile of the tumor, contributing to distinct immunophenotypes. In this study, we used gene expression profiling to evaluate biopsy site-specific patterns of immune activity in breast cancer.

Methods: Tumor tissue from 1,009 patients with breast cancer (all-comers) underwent targeted RNA profiling using a laboratory-developed test, FoundationOne®RNA, as part of routine clinical care. Scores for immune and stromal gene sets were generated using a single-sample gene set enrichment analysis (ssGSEA) using a research use algorithm. K-means clustering of Z-normalized scores identified two immunophenotypes: immune-high and immune-low. Samples with a negative silhouette width were classified as unknown phenotype.

Results: The most common sample sites were breast (n=363), liver (n=142), lymph node (n=120), bone (n=81), and lung (n=55). Immune ssGSEA scores varied significantly by sample site. Brain biopsies (n=23) exhibited the lowest immune scores, with only 5% (1/23) classified as immune-high, whereas lymph node and lung biopsies showed higher immune scores, with 42% (51/120) and 47% (26/55) classified as immune-high, respectively ($p<0.05$). Among local breast samples, 26% (96/363) were immune-high. Although liver metastases are typically considered to be immune cold, 12% (17/142) in this cohort were immune-high. Consistent with reports of lower immune activity in HR+ tumors, ESR1 expression was significantly higher in immune-low tumors compared to immune-high tumors (median expression 4,872 vs. 986 transcripts per million; $p < 10^{-4}$). Furthermore, distinct immune cell populations and gene signatures also showed site-specific patterns. IFN-γ scores were above median in 60% of breast biopsies, compared with 17% of brain, 39% of liver, and 62% of lung metastases. T-cell and CD8+ T-cell scores were typically higher in lung (65%, 62% above median) and lymph node metastases (66%, 62%), intermediate in breast biopsies (53%, 56%), and lowest in liver (32%, 37%) and brain metastases (17%, 22%). In contrast, dendritic cell scores were highest in liver metastases (83% above median), compared with breast samples (48%).

Conclusion: Immunophenotypes in breast cancer vary substantially by sample site, reflecting-heterogeneity of the local microenvironment. These site-specific immune signatures may have important implications for immunotherapy selection, prognostic assessment, and vaccine development strategies.

#6469 Longitudinal loss of microbiome stability is associated with poor response to immune checkpoint inhibitors in lung cancer and melanoma.

Yujie Zhao[1], Jarushka Naidoo[1], Michael Conroy[2], Jacqueline T. Ferri[1], Joell J. Gills[1], Krista Y. Chen[1], James R. White[3], Sara Glass[1], Willaim O. Assan[1], Kimberly Peloza[1], Megan D. Schollenberger[1], William H. Sharfman[4], Kristen Marrone[5], Patrick M. Forde[6], Julie R. Brahmer[7], Valsamo (Elsa) Anagnostou[6], Drew M. Pardoll[8], Joseph Murray[1], Evan J. Lipson[9], Cynthia L. Sears[1], **Fyza Y. Shaikh**[1]

[1]Johns Hopkins University School of Medicine, Baltimore, MD,[2]Johns Hopkins School of Medicine, Baltimore, MD,[3]Resphera Biosciences, Baltimore, MD,[4]Medical Director, Dept. of Med. Oncology, Johns Hopkins Sidney Kimmel Comp. Cancer Center, Lutherville, MD,[5]Johns Hopkins Hospital, Baltimore, MD,[6]Johns Hopkins University, Baltimore, MD,[7]Sidney Kimmel Comprehensive Cancer Ctr., Baltimore, MD,[8]Johns Hopkins Bloomberg-Kimmel Inst. for Cancer Immunotherapy, Baltimore, MD,[9]Johns Hopkins University School of Medicine, Baltmore, MD

While immune checkpoint inhibitors (ICI)-based regimens and chemo-immunotherapy combinations (chemo-ICI) are now first-line therapy for patients with metastatic non-small cell lung cancer (NSCLC), the number of patients who experience a sustained response to treatment remains limited. The majority of patients will eventually develop progressive disease. Microbiome-based biomarkers offer an opportunity to identify patients who may have a poor response to ICI-based regimens using non-invasive methods, and potentially, the microbiota may be amenable to therapy-enhancing alteration. However, a deep understanding of the longitudinal dynamics of gut microbial features in patients treated with ICIs in NSCLC, a feature of likely importance for microbiome-based therapeutics, remains limited. In this study, we show that patients with NSCLC who experience a poor response to an ICI-based regimen show a loss of intra-individual microbiome stability in the first 4 months during treatment with an ICI-based regimen, independent of antibiotic exposure. Longitudinal loss of microbiome stability was also associated with poor response in patients with melanoma. To identify key microbial species associated with progression, recursive feature elimination with random forest classifiers was used to identify temporally-associated microbial species associated with disease progression. An index of these progression-associated species was able to predict clinical outcomes based on pre-treatment fecal samples, with validation on an independent lung cancer cohort. Together, our data show that microbial instability may be an early indicator of ICI-resistance in patients with NSCLC and melanoma, with the potential to be developed into biomarkers of primary resistance to ICI-based regimens.

#6470 Spatial remodeling of the tumor microenvironment by IL-18-armored CD19 CAR T cells is associated with durable remission in relapsed or refractory lymphoma.

Nakial C. W. Cross[1], Yael A. Day[1], Sonia Ndeupen[1], Vanessa E. Gonzalez[1], Zhen Miao[1], Sam I. Kim[1], Rachel M. Leskowitz[1], Amy Marshall[1], Julie K. Jadlowsky[1], Gabriela Plesa[1], Donald L. Siegel[1], Elizabeth O. Hexner[1], Jakub Svoboda[1], Stephen J. Schuster[1], Nancy R. Zhang[2], Joseph A. Fraietta[1], Andrew J. Rech[1], Carl H. June[1]

[1]Perelman School of Medicine Univ. of Pennsylvania, Philadelphia, PA,[2]Statistics & Data Analysis, Wharton School Univ. of Pennsylvania, Philadelphia, PA

Patients with relapsed or refractory B-cell lymphoma who experience disease progression after CD19-directed CAR T-cell therapy have poor outcomes and few effective treatment options. Subsequent therapies provide only modest benefit, with complete remission (CR) rates near 20% and limited durability. huCART19-IL18, an IL-18-secreting CD19 CAR T-cell product, produced an overall response rate of 81% and a CR rate of 52% after prior anti-CD19 CAR T failure in a phase I trial, but the spatial determinants of durable response within the tumor microenvironment (TME) remain incompletely defined.

We performed multimodal spatial profiling of paired pre- and post-huCART19-IL18 lymph node biopsies from 11 patients (6 with CR, 5 without CR) enrolled in the phase I study. GeoMx whole-transcriptome atlas and protein profiling were integrated with CosMx 6000-plex single-cell spatial imaging to map transcriptional and cellular remodeling across tumor, myeloid, and lymphoid compartments. CoPro, a computational framework for detecting coordinated progression of cell states in space, was applied to identify spatially coordinated gene expression programs within and between myeloid and T-cell compartments.

Post-infusion samples from responders showed increased T-cell and NK-cell infiltration, frequent tertiary lymphoid structures, and induction of interferon (IFN)- and tumor necrosis factor-responsive chemokine and immune effector programs, including enhanced antigen presentation, together with coordinated loss of B-cell identity and signaling. These changes localized to regions enriched for CAR T cells, effector memory $CD4^+$ and $CD8^+$ T cells, and IFN-polarized macrophages, consistent with IL-18-driven recruitment and reprogramming of myeloid and T-cell compartments. Pre-infusion TMEs in responders showed baseline myeloid chemokine signatures associated with clinical response. CoPro revealed that myeloid functional heterogeneity is organized along spatial gradients that are independent of lineage identity and coordinated with T-cell effector programs in CAR T-infiltrated regions.

These findings support a model in which IL-18 armoring promotes spatially organized remodeling of the TME through coordinated myeloid and T-cell activation associated with durable remission after CD19 CAR T failure, nominating myeloid recruitment, antigen presentation, and T-cell exhaustion programs as critical biomarkers and rational engineering targets for next-generation armored CAR T strategies in lymphoma.

#6471 Immune correlates post MMF omission lead to accelerated immune reconstitution without increased graft versus host disease risk signatures for allogenic stem cell transplant (OmitMMF trial).

Vanshika Chauhan, Joseph Lownik, Larry Milshteyn, Haein Kim, Ronald Paquette, Akil Merchant

Cedars-Sinai Medical Center, Los Angeles, CA

Mycophenolate mofetil (MMF) has been a standard practice of care used in combination with post-transplant cyclophosphamide (PTCy) in graft-versus-host-disease (GvHD) prophylaxis regimen. This study evaluated the safety and potential benefits of eliminating MMF in patients receiving reduced-intensity (RI) and myeloablative (MA) conditioning with fludarabine and total body irradiation (FluTBI) prior to peripheral blood stem cell transplants (PBSCT) from matched or haploidentical related, or match unrelated, donors. The outcomes of 60 study subjects were compared to time-matched historical control patients. As we have previously presented, relapse-free survival at 1 year and viral reactivation by day +100 was not different in OmitMMF patients and control patients. While there were no significant clinical differences between treatment arms, we explored whether omitting MMF had significant effects on immune reconstitution. We used a 42-color spectral flow cytometry to characterize T-cells, NK-cells, B-cells, and monocytes. High dimensional clustering was performed using Phenograph to identify T-cell activation state clusters and other granular cell populations. OmitMMF patients had a higher number of T-cells at days +15 and +30, but lower by day +60. This increase was due to increased CD4+ T-cells in the OmitMMF patients and not CD8+ T-cells. Effector CD4+ T-cells were significantly higher while naïve CD4+ T-cells were not different. NK-cells were not significantly different between the two groups, contrasting the published effects of MMF on NK-cell function suggesting an anti-proliferative effect. While NK-cells were higher in the control arm at day 60, this was after MMF was removed and may represent a rebound affect. B-cells were not significantly different between the two groups. Omitting MMF led to faster CD4+ recovery as MMF suppresses CD4+ T-cell proliferation without adding greater risk of developing GvHD. Within the OmitMMF cohort, immune recovery was compared between patients who developed GvHD and those who did not. No distinct early immune correlates, such as a higher CD4+ T-Cells or different NK-cell count, were observed in the patients who developed GvHD, suggesting that omitting MMF reduces immunosuppression without leading to the T-cell signatures that are associated with a higher GvHD risk. Interestingly, the rate of grade II-IV aGVHD was significantly higher in the OmitMMF patients who received MA conditioning than the control group; this is dependent on preconditioning and is being further evaluated with the flow cytometry data. In conclusion, MMF can be safely eliminated in patients receiving RI and MA FluTBI conditioning regimens with the PTCy+tacro prophylaxis, and allows for quicker early T-cell recovery without causing harmful immune overactivity.

#6472 Tumor-cell NY-ESO-1 expression predicts poor response to PD-1/PD-L1 blockade in NSCLC.

Adele Lerue[1], Jean-Philippe Guegan[2], Christophe REY[2], Sophie Cousin[3], Benjamin Besse[2], Fabrice Barlesi[4], Christophe Massard[5], David Planchard[6], Alban Bessede[7], **Antoine Italiano**[8]

[1]Gustave Roussy, Villejuif, France,[23]Cousin (Individual), Bordeaux, France,[4]INSERM U1030 - Gustave Roussy Institute (Molecular Radiotherapy), France,[5]Institute Gustave Roussy, Villejuif, France,[6]Medical Oncology, Gustave Roussy, Villejuif, France,[7]ImmuSmol, Pessac, France,[8]Institute Bergonie, Bordeaux cedex, France

Background: NY-ESO-1 is an immunogenic cancer-testis antigen and a therapeutic target for TCR-based strategies. Its significance as a baseline biomarker in non-small cell lung cancer (NSCLC) treated with PD-1/PD-L1 inhibitors is not well established. Because NY-ESO-1 has biological relevance only when expressed by tumor epithelial cells, we focused our analysis specifically on NY-ESO-1 expression within $CK7^+$ tumor cells and evaluated its association with clinical outcomes in patients receiving immune checkpoint blockade.
Methods: Baseline FFPE tumor samples from 195 patients with advanced NSCLC treated with PD-1/PD-L1 inhibitors were profiled using a validated multiplex immunofluorescence panel including CD8, CD68, CD103, CK7, HLA-ABC, cMAF, NY-ESO-1, and pSMAD3. Digital image analysis was performed using Vectra Polaris imaging, QuPath segmentation, and FlowJo-based phenotyping after signal normalization. Tumor-specific NY-ESO-1 expression was defined by $CK7^+$/$NYESO1^+$ co-localization. Associations with RECIST response, durable clinical benefit (DCB), progression-free survival (PFS), and overall survival (OS) were assessed using Wilcoxon tests, chi-square tests, and cutpoint-based survival modeling. CK7→CD8 and CK7→CD68 intercellular distances were also computed.
Results: Higher $CK7^+$/$NY\text{-}ESO\text{-}1^+$ tumor cell levels were significantly associated with non-response to PD-1/PD-L1 blockade ($p=0.011$), and increased NY-ESO-1 expression intensity also associated with non-response ($p=0.044$). Tumor-restricted NY-ESO-1 was strongly predictive of shorter survival. Patients with high $CK7^+$/$NY\text{-}ESO\text{-}1^+$ tumor expression had a median PFS of 1.8 months, compared with 8.1 months in the low-expression group ($p=7.2\times10^{-5}$). Median OS was similarly reduced, with 11.0 months in the high-expression group versus 33.5 months in the low-expression group ($p=3.9\times10^{-3}$). High tumor NY-ESO-1 also correlated with substantially reduced durable clinical benefit (χ^2 $p=0.013$). Independently of NY-ESO-1, greater CK7→CD8 and CK7→CD68 distances predicted inferior PFS and OS, although no direct association between NY-ESO-1 levels and spatial distances was assessed.
Conclusions: Tumor-cell NY-ESO-1 expression is a robust adverse biomarker in NSCLC treated with PD-1/PD-L1 inhibitors. High $CK7^+$/$NY\text{-}ESO\text{-}1^+$ tumor burden identifies patients with dramatically reduced PFS and OS, lower response rates, and poor likelihood of achieving durable clinical benefit. These findings support the role of tumor-restricted NY-ESO-1 as a clinically meaningful negative baseline predictor of immunotherapy outcome and may help refine patient selection for NY-ESO-1-targeted therapies.

#6473 Clonal consolidation and transcriptional re-programming define non-small cell lung cancers resistant to immune checkpoint inhibitors.

Natalie Vokes[1], Arvind Ravi[2], Mark M. Awad[3], Patrick M. Forde[4], Marta Luksza[5], Benjamin Dylan Greenbaum[6], Adam Jacob Schoenfeld[6], John V. Heymach[7], Alice T. Shaw[8], Pasi A. Janne[9], Jedd D. Wolchok[10], Matt Hellman[11], Gad Getz[12], JUSTIN GAINOR[13]

[1]MD Anderson Cancer Center, Houston, TX,[2]DFCI/Harvard Medical School, Boston, MA,[3]Memorial Sloan Kettering, New York City, NY,[4]Johns Hopkins University, Baltimore, MD,[5]Icahn School of Medicine at Mount Sinai, New York, NY,[6]Memorial Sloan Kettering Cancer Center, New York, NY,[7]UT MD Anderson Cancer Center, Houston, TX,[8]Dana-Farber Cancer Institute, Cambridge, MA,[9]Dana-Farber Cancer Institute, Boston, MA,[10]Weill Cornell, New York City, NY,[11]AstraZeneca, Cambridge, United Kingdom,[12]Massachusetts General Hospital, Charlestown, MA,[13]Massachussetts General Hospital, Boston, MA

Analysis of pre-treatment non-small cell lung cancers (NSCLCs) has helped identify predictors of response to immune checkpoint inhibitors (ICI), including low PD-L1 expression, targetable drivers alterations (*EGFR*, *ALK*), and *STK11*/*KEAP1* mutations. To-date, however, few samples at treatment resistance have been studied, and consequently less is known about the mechanisms contributing to ICI resistance.Methods: Building on our previous analysis Stand Up 2 Cancer-Mark Foundation (SU2C-MARK) Cohort, we identified patients with on or post-treatment samples and performed whole exome (WES) and/or RNA-sequencing, based on tissue availability and quality. Genomic and transcriptomic features in post vs pre-treatment samples were compared. Subclonal evolution in paired samples was assessed using PhylogicNDT, and immune phenotypes were inferred using published gene signatures and deconvolution methods (CIBERSORTx).Results: Building on the original n=393 cohort, 41 patients with on and/or post-treatment samples were identified, with n=45 WES and n=35 RNA-seq on-treatment/post-treatment samples passing QC, for a total of n=445 samples included in the updated cohort, SU2C-MARKv2. N=28 patients had paired samples across treatment time, ranging from 2-5 time points. Only 3 samples had acquired mutations in *B2M* or *JAK2*; more commonly, post-treatment tumors showed persistence of clones containing *STK11*, *KEAP1*, and/or *ARID1A*/*SMARCA4* alterations. The proportion of subclonal alterations decreased at resistance, suggesting elimination of passenger-rich antigenic subclones (median 7.9% vs1.9%, p<0.001). Acquired copy number loss in antigen presentation genes in 6p21 (*STAT1/HLA/TAP1/TAP2*) were observed in 5 treatment pairs, and amplification in 9p24.1 (JAK2/PD-L1/PD-L2) in 4 pairs. In the transcriptional space, resistant tumors demonstrated increased expression of gene sets associated with tumor-intrinsic biology, including MYC, oxidative phosphorylation, and EMT, and decrease in DNA repair genes (ATM). Alterations in immune gene sets were most prominent in on- rather than post-treatment specimens, with increase in T, B and myeloid cell signatures in both responding and non-responding tumors, though numbers were low (n=5). Immune clustering into hot, intermediate, and cold phenotypes confirmed an increase in hot tumors in on-treatment specimens, while post-treatment tumors had predominantly 'intermediate' immune phenotype.Conclusions: Integrated genomic/transcriptomic analysis of the expanded SU2C-MARKv2 cohort suggests that ICI resistance emerges through elimination of immunogenic subclones and selection for resistant subclones that maintain immune-suppressive transcriptomic phenotypes. Further integration of spatial and single-cell data will define the tumor-immune architecture and identify potential treatment targets.

#6474 Robust and precise rare event analysis for immunotherapy clinical trials.

Chengsen Xue[1], Thomas W. Mc Closkey[1], Andew Roche[2]

[1]Biomarker & Diagnostic Assay Development, ICON Laboratory Services, Farmingdale, NY,[2]Scientific Affairs, ICON Laboratory Services, Dublin, Ireland

Modulating the human immune system has become a lifesaving option for selected malignancies. Biomedical approaches with both engineered cytotoxic T cells and cancer vaccines that boost antigen-specific cytotoxic T cells (CTLs) continue to advance the field. Both rely on rare event analysis, detecting and quantifying interactions between uncommon biomarkers and common leukocyte antigens. Flow cytometry is essential for today's clinical research and is the gold standard for identifying and phenotyping very low-frequency events in large mixed cell populations. Careful assay design is required for success, taking into consideration background, brightness, resolution, frequency, and donor to donor variation. We established a practical framework for robust, precise rare event analysis. First, define the rare events of interest—such as CAR T cells in peripheral whole blood, antigen-specific CTLs, circulating tumor cells (CTC), minimal residual disease (MRD), or T lymphocyte stem cells. Sample volume to be tested is critical in order to achieve an appropriate level of precision. For example, achieving about 20% CV (coefficient of variation) at a target frequency of 1 in 100,000 typically requires roughly 2.5 million leukocytes. Inadequate sample volume may yield false negative results and often be a cause of a failed assay. Key performance limits—Lower Limit of Quantitation (LLOQ), Limit of Detection (LOD), and Limit of Blank (LOB)—must be part of the performance characterization of the method. In CAR T immunophenotyping, we assess LLOQ to find a linear, reliable range, then spike CAR T cells across serial dilutions in triplicate. The lowest dose with $\leq$ 35% CV across donors defines the LLOQ. Because rare event work can be computationally heavy, concentrating the target population helps, for example, removing 80% of neutrophils during export of raw flow cytometry fcs data and using a dump channel containing with CD19, CD4, and CD56 focuses the analysis on antigen-specific CTLs within the CD8 subpopulation cells. In summary, our approach improves precision of rare event analysis by addressing data imbalance, statistical bias, and sample inefficiency.

#6475 Myeloma cells with therapy-induced senescence-like phenotype have increased resistance to killing by T cell directed therapies.

Christoph Schaefers[1], Angelo Jose Guilatco[2], Sofia Arbelaez[2], Gabriel Alvares Borges[2], Chen Wu[3], Andre de Menezes Silva Corraes[2], Malvika Gupta[2], Zuoyi Shao[2], Kevin Regan[2], Rayaan Kamal[2], Neal I. Sannuli[2], Ying Li[4], Taxiarchis Kourelis[2], Wilson Gonsalves[2], Melinda Tan[5], Nadine Abdallah[2], Yi Lin[2], Megan Weivoda[2]

[1]Hematology, Mayo Clinic Rochester, Rochester, MN,[2]Mayo Clinic, Rochester, MN,[3]Mayo Clinic College of Medicine and Science, Rochester, MN,[4]Mayo Clinic, Jacksonville, FL,[5]Mayo Clinic Cancer Center Minnesota, Rochester, MN

Background: Therapy-induced senescence (TIS), a tumor cell state associated with distinct gene expression patterns and implicated in therapy resistance, may be activated in Multiple Myeloma (MM) patients (pt) by genotoxic chemotherapies, such as high-dose melphalan (HDM). We investigated whether TIS is activated in MM cells following chemotherapy and linked to resistance to T-cell directed therapies.

Method: We integrated scRNA-seq data from healthy donors (CNTRL) and MM pts (newly-diagnosed (NDMM), pre/post-CAR-T) bone marrow plasma cells (PCs) using two public datasets (Boiarsky, et al.; Dhodapkar, et al.) and a newly generated pt dataset. Senescence was evaluated using scGSEA with published gene sets (SenUp, SenGA, and SCAPs). For in vitro MM cytotoxicity assay, human H929 MM cells were treated with vehicle (Veh) or HDM (3μM, IC90) for 6h and examined for TIS features. H929VEH or H929HDM were co-cultured with CNTRL T cells with or without teclistamab (Tec, 10 nM) or with day 14 PBMCs from MM pts post-CAR-T (E:T 5:1). CAR+ T cells were high among the day 14 PBMC (median±SD: 93.4±7.2% of CD3+ cells, n=6).

Results: scGSEA revealed significantly higher enrichment of SenUp, SenGA, and SCAPs in late-stage MM cells compared to NDMM and CNTRL ($p<0.05$). Expression of CDKN2A, encoding the senescence marker p16, was also increased in late-stage MM relative to NDMM/CNTRL PCs. Of interest, cells enriched for senescence also exhibited enrichment for myeloid markers (TET2, CEBP family). Notably, in pre-CAR-T, increased baseline senescence or myeloid marker expression showed an inverse association with CAR-T progression-free survival (PFS), suggesting TIS confers resistance to T cell mediated cytotoxicity. This may be due to myeloid plasticity. TIS MM cells generated in vitro, H929HDM, exhibited a distinct morphology characterized by increased cell size and enhanced cytoplasmic granularity. Increased CD14 expression was seen in 4 of the 6 experiments (median, range % increase: 11.2%, 2.5%-21%), consistent with myeloid plasticity; Increased KLRG1 expression was seen in 5 of the 7 experiments (median MFI ratio, range: 3.7, 1.3-471). No significant change was seen in GPNMB expression. Compared to H929VEH, H929HDM had a reduction in killing by CAR-T cells (median±SD: 22.8±32.94% n=6, p=0.016, Wilcoxon paired test). Similarly, H929HDM had a 10.69% decrease in Tec-mediated T-cell killing compared to H929VEH (n=8, p=0.02, Wilcoxon paired test).

Conclusions: Late-stage MM cells exhibit transcriptional signatures consistent with TIS, which can be associated with decreased PFS to CAR-T. We report an in vitro model of TIS MM cells for testing of resistance to T cell killing. Based on these findings, a phase II trial (NCT06940297) is underway to test the hypothesis that peri-CAR-T senolytic therapy with dasatinib and quercetin will deepen responses by targeting this resistant TIS MM population.

#6476 Microbiome modulation via CBM588 dampens T cell exhaustion in patients with metastatic renal cell carcinoma on dual immune checkpoint blockade.

Colt A. Egelston[1], Miguel Zugman[1], Hedyeh Ebrahimi[1], Regina Barragan Carrillo[2], Nazli Dizman[1], Salvador Jaime-Casas[1], Xiaochen Li[1], Daniela V. Castro[1], Benjamin Mercier[1], Marice Alcantara[1], Motomichi Takahashi[3], Atsushi Hayashi[3], Tom Parks[4], Sumanta Kumar Pal[1], Peter P. Lee[1], Alexander Chehrazi-Raffle[1]

[1]City of Hope National Medical Center, Duarte, CA,[2]Salvador Zubiran National Institute of Health Science & Nutrition, Mexico City, Mexico,[3]Miyarisan Pharmaceuticals, Tokyo, Japan,[4]Osel Inc, Mountain View, CA

Background: Immune checkpoint inhibitors (ICIs) are well-described to augment T cell responses and boost anti-tumor immune responses, with increased survival benefits of patients with a number of different indications treated with a variety of PD-1, PD-L1, or CTLA-4 targeting monoclonal antibodies. While the combination of nivolumab (nivo) and ipilimumab (ipi) is currently one of the standard-of-care treatments for patients with metastatic renal cell carcinoma (mRCC), the majority of patients still suffer disease progression. CBM588 is a live biotherapeutic product that has previously demonstrated ability to enhance clinical responses to nivo+ipi treatment in patients with mRCC. In our current study, we sought to explore immune correlatives of patients treated with nivo+ipi alone as compared to those treated with CBM588+nivo+ipi.

Methods: Peripheral blood was collected from patients with mRCC treated across two clinical trials: the initial CBM588+nivo+ipi study (NCT0382911) and an ongoing CBM588 dose finding study of patients with (NCT06399419). Both trials enrolled treatment-naïve patient with mRCC with clear cell and/or sarcomatoid histology. The initial trial enrolled patients with or without CBM588 co-treatment at a 2:1 ratio. The initial trial enrolled patients treated with or without CBM588 at 4×10^8 CFU/dose, while the dose escalation study followed a 3+3 design with three dose levels of CBM588 (4×10^8 CFU, 1.2×10^9 CFU, and 4×10^9 CFU). Cryopreserved blood was thawed and analyzed by high parameter spectral flow cytometry for overall immune composition and detailed T cell phenotyping.

Results: No significant differences were observed in myeloid cell or innate lymphocyte changes between patients treated with or without CBM588. Increased frequencies of proliferating CD8+ T cells (Ki-67+) were observed across all patients from baseline to Cycle 3 Day 1. The expansion of proliferating CD8+ T cells was significantly less accelerated in patients treated with CBM588+nivo+ipi as compared to those treated with nivo+ipi alone. Notably, the expanding Ki-67+ CD8+ T cell population identified demonstrated features of T cell exhaustion with less expression of CD127 (IL-7R) and higher expression of CD38, KLRG1, TIM-3 relative to other circulating CD8+ T cell populations.

Conclusions: Our results suggest that CBM588 may improve patient responses to ICIs by restraining CD8+ T cell amplification and attenuating features of T cell exhaustion. The CBM588+nivo+ipi dose escalation study is still ongoing with further immune correlative analyses pending.

#6477 Peptide-based tumor-associated antigen vaccine in glioblastoma: Correlative results of the ETAPA Phase I clinical trial.

Elizabeth Owens, Kelly M. Hotchkiss, Pamela Norberg, Evan Buckley, Katayoun Ayasoufi, Stevie Threatt, Justin T. Low, Madison L. Shoaf, Melody Goldston, Kristen Batich, Margaret O. Johnson, James E. Herndon, Smita K. Nair, Kent Weinhold, Henry S. Friedman, David M. Ashley, Annick Desjardins, John H. Sampson, Mustafa Khasraw

Duke University School of Medicine, Durham, NC

Introduction/Rationale: Immunotherapy has yet to yield benefit in glioblastoma (GBM), in part due to inadequate T-cell priming and insufficient $CD4^+$ helper support. To enhance coordinated $CD4^+$ and $CD8^+$ activation, the ETAPA phase 1 trial (NCT05283109) evaluated P30-EPS, a peptide vaccine linking three class I tumor-associated antigens (CMV pp65, Survivin, EphA2) to the universal class II tetanus toxoid epitope P30 (TVSFWLRVPKVSASHLE). This design aims to broadly recruit $CD4^+$ T-cell help and augment cytotoxic responses.
Methods: Adults with newly diagnosed, MGMT-unmethylated GBM (n = 18) received seven post-radiation intramuscular vaccinations with Hiltonol (20 μg/kg) and either 300 μg (n = 6) or 400 μg (n = 12) of P30-EPS. Peripheral blood mononuclear cells (PBMCs) were analyzed longitudinally by IFN-γ ELISpot, high-parameter spectral flow cytometry, and 5′ scRNA TCR sequencing to quantify antigen-specific cytokine production, helper and cytotoxic phenotypes, lineage distribution, clonal expansion, and repertoire diversity. Paired single-cell V(D)J TCR sequencing of PBMCs was used to resolve $CD4^+$ and $CD8^+$ subsets, define activation and memory-associated transcriptional programs, and map clonotype-specific trajectories. Baseline and on-treatment tumors are being profiled using spatial transcriptomics (ST) and spatial proteomics (SP) to localize vaccine-responsive T-cell populations within the tumor microenvironment.
Results: The vaccine was well tolerated in all 18 patients, with all adverse events ≤ grade 2. P30-EPS induced antigen-specific IFN-γ responses in 11 patients, with stronger recall responses at the 400-μg dose. Patients with longer progression-free survival exhibited higher baseline frequencies of naïve $CD4^+$ T cells and fewer terminally differentiated effector-memory ($CD45RA^+CCR7^-$) cells, indicating a more plastic helper pool capable of sustaining $CD8^+$ priming. Longitudinal TCR sequencing demonstrated expansion of vaccine-associated clonotypes after boosting, including emergence of new low-frequency clones and persistence of dominant clones, consistent with durable memory formation. Early single-cell transcriptomic and paired TCR analyses revealed coordinated activation signatures in helper and cytotoxic compartments that paralleled peripheral clonotype expansion. Pre- and post-vaccination tumor ST and SP analyses will be presented.
Conclusion: ETAPA achieved its primary objectives, demonstrating safety and correlative findings indicating that a universal $CD4^+$ helper epitope can enhance cytotoxic and memory responses in GBM. Integration of PBMC scRNA/TCRseq with tumor ST and SP profiling will define intratumoral correlates of systemic vaccine-induced immunity. These insights now support development of our next epitope-linked personalized vaccine for patients with glioblastoma.

#6478 Temporal dynamics of T cell reprogramming associate with clinical response to ICI-based combination therapy in metastatic renal cell carcinoma.

KyuTae Hwang[1], Seowoo Kim[2], Mi Zhou[3], William Y. Kim[2], Minyong Kang[4]

[1]Department of Health Sciences and Technology, Samsung Advanced Institute of Health Sciences and Technology (SAIHST), Seoul, Korea, Republic of,[2]UNC Lineberger Comprehensive Cancer Center, Chapel Hill, NC,[3]UNC Chapel Hill, Cary, NC,[4]Department of Health Sciences and Technology, Samsung Advanced Institute of Health Sciences and Technology (SAIHST)Samsung Medical Center, Seoul, Korea, Republic of

Immune checkpoint inhibitor (ICI) based therapy, including dual ICI (anti-PD-1 + anti-CTLA4) and anti-PD-1 plus tyrosine kinase inhibition (TKI), has improved outcomes for metastatic renal cell carcinoma (mRCC). While tumor-based immunologic determinants of response have been explored, predictive biomarkers/early changes in peripheral blood mononuclear cells (PBMCs), have not. To understand mechanisms of response and resistance to first line ICI-based therapy, we prospectively collected longitudinal PBMCs at baseline (T0, n = 20) and multiple post-treatment time points (T1-T3: T1 = 1-2 wks post treatment initiation, n = 17; T2 = time of surgery for patients undergoing cytoreductive nephrectomy, n = 11; T3 = at progressive disease (PD), n = 7), as well as paired tumor samples at T0 (n = 20) and T2 (n = 9). scRNAseq and scTCRseq of PBMCs and tumors were used together with single-cell spatial transcriptomics (Xenium 5K, T0, n = 31; T2, n = 26) to define dynamic PBMC and intratumoral immune changes. Few differences at baseline were found in the intratumoral immune contexture or PBMCs of R (responders) and NR (non-responders). Only baseline intratumoral CD56-high NK cells were significantly higher in R and no PBMC immune cell subsets were different. Differential gene expression analysis of CD8+ exhausted T cells showed upregulation of stress response genes (e.g. *HSPA1A*) and the *DUSP1* phosphatase in R. In contrast, there were dynamic temporal changes seen with ICI at T1. In particular a significant increase in the proportion of circulating proliferative T and NK cells in R, which had upregulation of cytotoxicity (*GZMB*, *PRF1*) and effector markers (*CX3CR1*, *FGFBP2*). Furthermore, analysis of multiple $CD8^+$ T cell subsets associated with ICI response demonstrated activation of NF-κB and MAPK module scores in R at T1. Intratumoral scRNAseq profiling at T2 revealed that $CD8^+$ T cells from R had lower exhaustion related genes (*TOX*, *LAG3*, *CD38*) and higher AP1 transcription factor (TF) activation including JUN/FOS, whereas NR accumulated terminally exhausted $CD8^+$ T cells with high level of *BATF* activity. These findings indicate that *JUN/FOS* signaling associates with T cell activation in R, while *BATF* drives terminal exhaustion and NR. Finally, tumor spatial transcriptomics demonstrated significant enrichment of C1QC tumor-associated macrophages (TAM) in the cellular neighborhoods of exhausted CD8+ T cells at T2 of R (but not T0 or in NR). The role of C1QC macrophages in ICI response remains debated. In total, these data demonstrate there is limited discrimination between R and NR at baseline (PBMCs or tumor) but identify early (1-2-week post-treatment) PBMC changes in R (increased proliferative T cells) as well as differences in spatially organized immune trajectories post-treatment tumors of R. The increase in proliferative T cells in PBMCs could serve as a very early biomarker of R.

#6479 Immunotherapy and microbiota interventions as potential treatment options for anaplastic thyroid cancer.

Jocelynn G. Colunga Minutti[1], Naimah Turner[2], Synat Keam[2], Roza Nurieva[1]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]Immunology, UT MD Anderson Cancer Center, Houston, TX

Anaplastic thyroid cancer (ATC) is a rare and aggressive malignancy that accounts for approximately 50% of all thyroid cancer-related deaths despite its low incidence. While it is known that thyroid cancer has a higher incidence in women and a worse prognosis in men, age itself is an independent negative prognostic factor. Despite the median patient age for ATC being 65 years, no animal studies have accounted for age in this type of cancer, which represents a vital gap that must be addressed. Therefore, this research aims to investigate the impact of age and sex on ATC outcomes and treatment response. A Kaplan-Meier survival analysis demonstrated that younger female ATC patients had better survival odds than young males. However, aged patients had poorer overall survival, regardless of sex, suggesting that aging changes the biological mechanisms that confer better survival in younger females. Like ATC patients, our murine ATC model shows that young males display accelerated ATC growth compared to females, while older mice have similarly high growth rates regardless of sex. We correlated worse ATC outcomes in young male mice and aged mice with similar immunosuppressive tumor microenvironments (TMEs) that highly express immune co-inhibitory checkpoint molecules such as PD-1, PD-L1, TIM-3, LAG-3, and CTLA-4. In fact, ATC mice positively respond to combinatorial immune checkpoint inhibitors (anti-PD-1/anti-CTLA-4) regardless of sex or age, when given early in tumor development. In addition, we found that young mice of opposite sexes have very distinct gut microbial communities at baseline compared to aged mice, and this difference is associated with tumor growth outcomes. Moreover, targeting the microbiota through fecal microbial transplant (FMT) resulted in an antitumor benefit for aged groups disregard of sex. Together, these results reveal sex- and age-related immune mechanisms driving ATC progression and highlight the potential for immunotherapy and microbiota interventions.

Osteosarcoma (OS) in pediatric, adolescent, and young adult (AYA) patients is an aggressive malignancy with limited therapeutic progress. About 40% of OS patients develop metastases over time with 15-20% of OS patients already exhibiting metastases at initial diagnosis. Thus, there is a critical need to develop better therapeutics. Genomic analyses from our institution and others highlight recurrent alterations in CDKN2A and CDK4/6, suggesting that CDK4/6 inhibition (CDK4/6i) is a rational therapeutic vulnerability. Although RB1 proficiency (RB1+) is considered essential for CDK4/6i response, over 70% of OS tumors are RB1-deficient (RB1–), raising questions about the utility of CDK4/6i in these patients. Emerging evidence in other solid tumors and in our preliminary OS studies, suggests that CDK4/6i may retain antitumor activity in RB1– contexts. Compounding this complexity, pharmacologic CDK4/6 blockade induces compensatory PI3K/mTOR signaling, which can restore cyclin D–CDK4/6 activity and drive resistance.
We hypothesized that co-targeting PI3K/mTOR would enhance CDK4/6i efficacy irrespective of RB1 status by suppressing adaptive signaling. We evaluated palbociclib, voxtalisib, and the combination across RB1+ and RB1- OS models, using cell lines, patient derived xenografts (PDXs), and an experimental metastasis model. In vitro drug interactions (Chou–Talalay, Bliss) and mechanistic assays (cell cycle, senescence, autophagy) were complemented by in vivo tumor growth kinetics and pharmacodynamic profiling through histopathology, kinome, and proteomic analyses.
In RB1+ OS cells in vitro, palbociclib induced G1 arrest and senescence, accompanied by increased PI3K/AKT phosphorylation consistent with adaptive feedback. Voxtalisib suppressed this response, reinforced autophagic signaling, and maintained pathway inhibition. In vivo, combination therapy was well tolerated and produced significant tumor growth suppression in treatment-naïve and metastatic PDXs. In the RB1+ lung-colonization model, CDK4/6i alone reduced metastatic burden, with combination therapy achieving comparable control.
To interrogate RB1 as a biomarker, CRISPR-engineered human and mouse RB1– OS clones (MG63.3, K7M2) were generated and characterized. As expected, voxtalisib response was RB1-independent, and palbociclib sensitivity was reduced in RB1- cells. However, RB1- cells still exhibited growth inhibition at higher palbociclib concentrations. Notably, combination therapy of palbociclib+voxtalisib produced additive-to-synergistic growth inhibition regardless of RB1 status. In vivo validation studies are ongoing. These findings identify convergent CDK4/6–PI3K/mTOR hyperactivation as a targetable axis in OS and support further evaluation of CDK4/6i-based strategies, including in RB1-deficient disease.

#6484 Divergent roles of SPOP and CHD1 in ACSL4 regulation reveal context-dependent vulnerabilities for targeting ferroptosis in prostate cancer.

Feiyu Chen, Qidong Li, Qianlin Gu, Javier Leo, Xin Liang, Naayaa Mehta, Yin Wang, Francisco R. Saenz, Maya M. Phillips, Wei Shi, Chenling Meng, Jie Zhang, Boyi Gan, Di Zhao

The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Genetic heterogeneity fundamentally shapes therapeutic responses in prostate cancer (PCa). Among the most recurrent alterations, SPOP mutations and CHD1 loss define molecularly distinct PCa subtypes that respond differently to androgen signaling-directed therapies. Ferroptosis, an iron-dependent form of cell death driven by unchecked lipid peroxidation, has recently emerged as a promising therapeutic vulnerability; however, the genetic determinants that govern ferroptosis responsiveness in PCa remain poorly defined.
Methods: We integrated engineered human cell lines, 3D organoid systems, genetically engineered mouse models (GEMMs) and isogenic xenografts to dissect how SPOP mutation and CHD1 deletion modulate ferroptotic sensitivity. Ferroptosis induction and GPX4 dependence were assessed using pharmacologic GPX4 inhibitors (RSL3, ML162, and JKE1674), lipid peroxidation assays, and ferroptosis rescue controls. Transcriptomic, lipidomic, and biochemical analyses, together with ChIP-seq, ChIP-qPCR, and ACSL4 promoter-luciferase reporter assays, were used to delineate how SPOP mutations and CHD1 deletion modulate the MYC-ACSL4 transcriptional axis.
Results: We uncover opposing roles for SPOP and CHD1 in regulating ferroptosis. SPOP mutations markedly sensitize PCa cells and tumors to GPX4 inhibition, whereas CHD1 loss abrogates this vulnerability and confers ferroptosis resistance. Mechanistically, SPOP mutation enhances, while CHD1 deletion suppresses, activation of the MYC-ACSL4 axis. SPOP mutation promotes, and CHD1 loss diminishes, MYC occupancy and transcriptional activation of ACSL4, a key enzyme governing polyunsaturated fatty acid metabolism and ferroptotic lipid peroxidation. Given our prior discovery that CHD1 loss upregulates cholesterol biosynthesis, we asked whether inhibiting this pathway could reverse ferroptosis resistance. Notably, pharmacologic blockade of cholesterol biosynthesis reinstates ACSL4 expression and restores ferroptosis sensitivity in SPOP-mutant/CHD1-deficient tumors in vivo, identifying a targetable metabolic checkpoint underlying ferroptosis resistance.
Conclusions: These findings define SPOP mutation and CHD1 loss as antagonistic genetic determinants of ferroptosis and uncover a MYC-ACSL4-dependent mechanism that governs GPX4 reliance. Pharmacologic inhibition of cholesterol biosynthesis overcomes CHD1-driven ferroptosis resistance, enabling a biomarker-guided combination strategy that couples ferroptosis induction with cholesterol-pathway blockade. This work establishes a precision strategy for exploiting ferroptosis-based combination therapies in genetically stratified PCa.

#6485 Combination of the GCN2 activator HC-7366 with VEGFR-TKI results in greater efficacy than VEGFR-TKI alone or VEGFR-TKI/HIF-2i combinations in ccRCC.

Weiyu Zhang, Kathryn Bieging-Rolett, Ashley LaCayo, Ben Harrison, Jeremy Drees, **Crissy Dudgeon**, Nandita Bose, Eric S. Lightcap

HiberCell, Roseville, MN

Current standards of care for metastatic clear cell renal cell carcinoma (ccRCC) include immune checkpoint inhibitors (ICIs), VEGFR-tyrosine kinase inhibitors (VEGFR-TKIs), or the combination of both. Recently, the HIF-2α inhibitor belzutifan was approved for 2L+ metastatic ccRCC patients and its combination with ICIs or VEGFR-TKIs is being studied in clinical trials. Despite the initial efficacy of these SOCs, most patients eventually relapse. Relapse after VEGFR-TKIs can be due to diverse mechanisms such as activation of non-VEGF angiogenic pathways, stromal remodeling, apoptosis evasion, and HIF upregulation. Therefore, novel therapeutic approaches are needed. HiberCell has developed HC-7366, a GCN2 activator that initiates the integrated stress response, leading to translation inhibition, cell-cycle arrest, HIF-1α suppression, and apoptosis in cancer cells. Based on these effects, we explored the potential of HC-7366 to overcome resistance to VEGFR-TKIs in RCC models. In the 786-O ccRCC xenograft model, HC-7366 treatment at multiple doses corresponding to exposures below the MTD in humans yielded robust combination efficacy with either cabozantinib or lenvatinib. HC-7366 alone achieved 63% tumor growth inhibition (TGI), whereas cabozantinib alone induced 30% regression (1/8 PR) and lenvatinib alone produced 95% TGI. When combined, HC-7366 significantly enhanced responses, achieving 71% regression with cabozantinib and 44% regression with lenvatinib (7/8 and 2/8 PRs, respectively). The combination of belzutifan and VEGFR-TKI was inferior to the HC-7366/VEGFR-TKI doublet, with only 36% regression (1 PR) for lenvatinib/belzutifan and 53% regression (5/8 PRs) for cabozantinib/belzutifan. The triplet combination using HC-7366/belzutifan/VEGFR-TKI was more beneficial than any doublet, further improving TGI and responses. Furthermore, in a single mouse trial of 10 RCC PDX models, addition of HC-7366 to axitinib improved outcomes in 8/10 PDX models and was superior to the belzutifan/axitinib doublet in multiple models. Analysis of xenografts showed the combination of HC-7366 and lenvatinib reduced HIF signaling and broadly suppressed cell cycle, growth factor, and angiogenic signaling while simultaneously inducing pro-apoptotic pathways. Our data reveal that combination of HC-7366 with any VEGFR-TKI may be an effective treatment strategy for RCC patients and has the potential to be superior to a VEGFR-TKI/HIF-2 inhibitor combination. A phase 1b clinical trial is now ongoing to evaluate the safety, tolerability, and efficacy of both HC-7366/belzutifan and HC-7366/cabozantinib doublets in metastatic ccRCC (NCT06234605). These results will form a foundation for future evaluation of triplet combinations that integrate HC-7366, VEGFR-TKIs, and HIF-2 inhibitors.

#6487 Exploratory study of camrelizumab combined with chemotherapy as second-line treatment for advanced esophageal squamous cell carcinoma.

Linlin Wang, Bingjie Fan, Bing Zou, Aiqin Gao, Shijiang Wang, Chunni Wang, Qian Shao, Yishan Yu, Hong Zhao, Jinzhi Wang, Yan Yi, Qingxi Yu

Shandong Cancer Hospital and Institute, Shandong First Medical University and Shandong Academy of Medical Sciences, Jinan, Shandong, China

Background: Patients with advanced esophageal squamous cell carcinoma (ESCC) face a poor prognosis and limited options after first-line therapy failure. This study aims to evaluate the efficacy and safety of camrelizumab combined with chemotherapy as a second-line treatment in patients who with or without prior immunotherapy exposure.
Method:This single-center, multi-cohorts, phase II exploratory clinical trial enrolled patients with locally recurrent or metastatic ESCC who had either failed or were intolerant to first-line treatment. Patients were stratified into two cohorts: those who had previously received immunotherapy (Cohort 1) and those who had not (Cohort 2). All patients received camrelizumab (Q3W, up to 2 years) combined with nab-paclitaxel or fluorouracil based chemotherapy (Q3W, 4-6 cycles).The primary endpoint was progression-free survival (PFS).
Results: Between May 2021 and September 2025, 40 patients were enrolled, with 20 patients in each cohort. The median age was 67 years in Cohort 1 and 66 years in Cohort 2.The median age was 67 years in Cohort 1 and 66 years in Cohort 2. The cohorts comprised 18 (90%) and 15(75%) males;15(75%) and 15(75%) with an ECOG performance status of 1; 10% and 15% with pulmonary metastases; and 55% and 45% with lymph node metastases, respectively. According to RECIST 1.1, among the 15 and 18 evaluable patients in Cohorts 1 and 2, the objective response rate (ORR) was 33.3% and 50.0%, and the disease control rate (DCR) was 93.3% and 88.9%, respectively. The median progression-free survival (mPFS) was 4.5 months(95%CI 2.13-6.8) in Cohort 1 and 9.5 months(95%CI 2.7-16.4) in Cohort 2. The median overall survival(mOS) was not reached.The most common adverse events (AEs) were lymphocyte count decreased (90% and 75%), anemia (85% and 70%), and decreased neutrophils (50% and 40%), which were grade 1-3. No grade 4 or 5 AEs occurred.The most common immune-related AEs (irAEs) was reactive cutaneous capillary endothelial proliferation(64.% and 57.1%), which was grade 1-2 in all cases.
Conclusion: Camrelizumab combined with chemotherapy showed good antitumor efficacy and safety in advanced ESCC as second-line treatment, regardless of whether the patients have previously received immunotherapy.

#6488 Dual targeting of PARP and RAS enhances antitumor activity in pancreatic cancer.

Chani Stossel, Gali Altman, Dikla Atias, Yulia Glick Gorman, Hanita Ovadia, Liora Chouchan, Elina Haimov-Talmoud, Maria Raitses-Gurevich, Tamar Beller, Talia Golan

Sheba Medical Center, Tel Hashomer, Israel

KRAS is the most frequent oncogenic mutation in PDAC. KRAS drives tumorigenesis and enhances mechanisms of DNA-damage repair (DDR). Specifically, KRAS upregulates HR and non-homologous end joining (NHEJ), which are critical pathways for DNA repair. Dual inhibition of these two driver pathways in BRCAmut PDAC, the MAPK/KRAS and the DDR, may have a promising therapeutic effect. However, this effect may be also exploited in the general PDAC population. PARP and RAS combined inhibition may extend and deepen therapeutic effect and delay emergence of therapeutic resistance.Our main goal was to examine the therapeutic effect of PARP and RAS(ON) combined inhibition on tumor growth in BRCAmut and BRCA-WT preclinical models. We established pre-clinical patient derived xenografts (PDX) models (n=160), PDX derived cells (n=37) and 3D organoids (n=11). Models were analyzed by WGS and RNAseq. We tested the effect of PARPi (olaparib) in combination with two RAS inhibitors: A tool RAS(ON) -multi-selective inhibitor RMC-7977 and a tool RAS(ON) G12D-selective inhibitor RMC-9945 (RM-044) in-vitro and in-vivo, utilizing specific models' systems based on BRCA and KRAS status (n=12).In vitro, PDCs were treated with olaparib, RMC-7977, RMC-9945 and combinations for 5 days. A dose response curve was observed for each cell line, with a variability of response between cell lines. Combination of RAS(ON)i and olaparib exhibited significant additive effect. In 3D organoids, combinational treatment of olaparib and RMC-7977 demonstrated a profound effect on viability. This effect was noted on BRCAmut and BRCA-WT cell lines. In-vivo experiment in a platinum sensitive BRCA2 mutated PDX model both RMC-7977 and RMC-9945 significantly attenuated tumor growth rate compared to control ($p<0.05$). The combination demonstrated a comparable effect to PARPi monotherapy. Yet, a tendency towards an enhanced response was observed by ex-vivo tumor volume and tumor weight. We hypothesize that a longer duration of experiment (currently being performed) will enhance response and delay the emergence of therapeutic resistance. In parallel mechanistic functional assays are being performed. Overall, we demonstrate a superior effect of the combination of PARPi and RAS(ON)i on PDAC using patient-derived models in-vitro (BRCAmut and BRCA WT) and in-vivo (BRCAmut). Notably, most models were generated from tumors obtained from patients at clinical resistance to standard of care treatment reflecting models with aggressive biology. Thus, these findings support further evaluation of combinational treatment of both RAS(ON) and PARP inhibition in this population.

#6489 Metabolic molecular subtyping of ovarian cancer reveals the role of oleic acid-CD36 in facilitating cisplatin resistance.

Jiagui Song

Peking University Third Hospital, Beijing, China

Current histopathological classification systems for ovarian cancer cannot adequately predict platinum chemotherapy response, hindering personalized therapeutic strategies. Here, through integrative analysis of multiple datasets from TCGA, ICGC and GEO databases, we stratify patients into metabolic associated chemotherapy-refractory and chemotherapy-sensitive types (MCRT, MCST for short) with distinct prognosis by 20 genes. Lipidomic profiling of ascites from patients with ovarian cancer further identifies oleic acid as a hallmark metabolite in MCRT cases. Oleic acid treatment facilitates the resistance to cisplatin in ovarian cancer cells and patient-derived organoids. Mechanistically, oleic acid activates and promotes nuclear translocation of YAP through CD36. Inhibition of SCD1—genetically or pharmacologically—synergizes with cisplatin in 26 patient-derived organoids and suppresses tumor growth in xenograft models. Our study proposes a new metabolic classification of ovarian cancer that can predict chemotherapy sensitivity. Moreover, it discovers the role of the oleic acid-CD36-YAP signaling axis in promoting cisplatin resistance. These findings shed light on how oleic acid facilitates the resistance to cisplatin in ovarian cancer and provide a potential therapeutic strategy for treating patients with ovarian cancer.

#6490 MEK inhibition overcomes stromal-mediated resistance to a MERTK targeted therapy in AML co-cultures and vascularized mesenchymal organoids.

Chloe Hope[1], Katherine Minson[1], Eleana Vasileiadi[2], Madeline G. Higgins[3], Alejandro De Janon[4], Shuichi Takayama[4], Xiaodong Wang[5], Steven Frye[5], H. Shelton Earp[5], Douglas K. Graham[1], Deborah DeRykere[1]

[1]Aflac Cancer & Blood Disorders Center, Children's Healthcare of Atlanta, & Department of Pediatrics, Emory University, Atlanta, GA,[2]Division of Pediatric Infectious Diseases, University of Pittsburgh Medical Center, Pittsburgh, PA,[3]Department of Surgery, University of Colorado Anschutz Medical Campus, Aurora, CO,[4]Georgia Institute of Technology & Emory University, Atlanta, GA,[5]University of North Carolina Chapel Hill, Chapel Hill, NC

MERTK receptor tyrosine kinase mediates pro-survival signaling and therapeutic resistance and is a potential therapeutic target in acute myeloid leukemia (AML); however, like many therapies, AML interactions with the bone marrow stroma confer resistance to MERTK inhibition, limiting therapeutic efficacy. Rational combination strategies that suppress compensatory signaling in physiologically relevant model systems are needed to overcome microenvironment-driven drug resistance in AML. Here, we demonstrate stromal-mediated ERK activation as a mechanism of resistance to the MERTK inhibitor, MRX-2843. Co-culture with stromal cell lines (Hs27 or Hs5 fibroblasts) or mesenchymal stem cells (MSCs) protected AML cell lines (NOMO-1, OCI-AML5, KASUMI-1) from induction of cell death in response to treatment with MRX-2843 (e.g. no co-culture vs. co-culture: Kasumi-1 + Hs27: 67.6% vs. 31.6% dead, OCI-AML5 + Hs5: 79.4% vs. 36.6%, NOMO-1 + MSC: 77.2% vs. 34.5%). Induction of γH2AX, an indicator of cell death, was also decreased in stromal co-cultures treated with MRX-2843 compared to AML mono-cultures. Mechanistically, MERTK expression was increased in AML cells cultured with stromal cells. ERK phosphorylation was also induced in stromal cell co-cultures and was refractory to inhibition by MRX-2843. Moreover, treatment with the MEK inhibitors PD0329501 or pimasertib in combination with MRX-2843 abrogated ERK phosphorylation and restored induction of γH2AX and anti-leukemia activity in the presence of stromal cells, confirming dependence on MEK/ERK signaling in AML cells for stromal-mediated survival. To better model the impact of the bone marrow microenvironment on anti-leukemia activity, we utilized a novel three-dimensional vascular mesenchymal organoid system that has greater stromal cell complexity and recapitulates many features of the bone marrow observed in human AML (e.g. architecture, cell-cell interactions, cytokine/chemokine production). Combined treatment with MRX-2843 and pimasertib significantly enhanced therapeutic efficacy in organoids established from NOMO-1 and KASUMI-1 AML cell lines, as evidenced by increased γH2AX expression compared to MRX-2843 or pimasertib monotherapies. Notably, these findings were recapitulated in organoids established from a MERTK-expressing patient-derived AML xenograft, reinforcing the translational relevance of the combination therapy. In preliminary dose-finding studies, concurrent treatment with MRX-2843 and pimasertib was well-tolerated in mice. Collectively, these data identify MEK/ERK signaling as a mechanism of stromal-mediated resistance to MERTK inhibition and establish combined treatment with MRX-2843 and a MEK inhibitor as a promising strategy for effective treatment of AML.

#6491 Co-treatment with FAK and PARP inhibitors for the treatment of homologous recombination-proficient high grade serious ovarian cancer.

Caree Carson, Breana Hill, Aarya Ghosalkar, Marjaana Ojalill, Antonia Boyer, Xiao Lei Chen, David Schlaepfer, Dwayne Stupack

UCSD Moores Cancer Center, La Jolla, CA

High grade serous ovarian cancer (HGSOC) - the most common subtype - accounts for the greatest number of patient deaths due to late detection and frequent recurrence. Treatment for HGSOC patients begins with cytoreductive surgery followed by platinum/taxane chemotherapy and adjuvant/maintenance therapy, the latter being specific to whether tumors are homologous recombination-proficient (HRP) or homologous recombination-deficient (HRD). HRD cancers are treated with PARP inhibitors (e.g. Niraparib) while HRP cancers are treated with bevacizumab, an anti-angiogenesis agent. Either regimen can be extended into maintenance therapy. Over 70% of HGSOC tumors present with amplifications or gains in the *PTK2* gene that codes for the focal adhesion kinase (FAK) protein, a key regulator of tumor cell migration, adhesion, and chemotherapy resistance that also regulates the endothelial cell response to VEGF. FAK-targeting drugs have been approved for use in the clinic for the treatment of low grade serious ovarian cancer, but their role in HGSOC is less clear. We have previously shown that FAK inhibition compromises several cell survival pathways, among them, a suite of key DNA repair enzymes. Unexpectedly, we find that FAK inhibition imbues PARP sensitivity on HRP cells. *In vivo*, an enhanced anti-tumor effect was observed with suboptimal doses combinations of FAK and PARP inhibitors. Notably, an even greater effect was observed when combining FAK and PARP inhibitors in a maintenance therapy model for chemoresistant HGSOC. FAK inhibition through treatment with narmafotinib impacts PARP1 protein expression, cleavage, and overall PARylation levels, implicating functional interaction between FAK and PARP pathways within the cell. These results provide an unexpected avenue to evaluate PARP inhibition as a viable therapy for HRP tumors.

#6492 Targeting phospholipase D1 overcomes platinum resistance and enhances cisplatin efficacy in ovarian cancer.

Shin-Wha Lee[1], Sung Wan Kang[1], Dong Woo Kang[1], Yu-na Noh[1], Young-Jae Lee[1], Min-Seo Lee[1], Yong-Man Kim[2]

[1]Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic of,[2]CHA Bundang Medical Center, CHA University School of Medicine, Seongnam, Korea, Republic of

Background: Platinum-based chemotherapy is the standard treatment for high-grade serous ovarian cancer (HGSOC), yet the development of platinum resistance remains a major barrier to effective therapy. Phospholipase D1 (PLD1) has been implicated in tumor progression and stress response pathways, but its potential as a therapeutic target in platinum-resistant ovarian cancer (OC) has not been clearly defined. This study investigated whether targeting PLD1 can restore platinum sensitivity and improve therapeutic efficacy in resistant disease.
Methods: The impact of PLD1 inhibition was evaluated using OC cell lines, patient-derived primary tumor cells, and both cell line-derived and patient-derived xenograft models. Functional assays measured clonogenic survival, proliferation, invasion, sphere formation, apoptosis, and DNA damage. Cisplatin responsiveness was assessed following genetic PLD1 knockdown or treatment with a PLD1 inhibitor.
Results: PLD1 suppression significantly reduced survival, proliferation, and invasiveness in platinum-resistant OC cells, while inducing apoptosis and accumulation of DNA damage. Importantly, PLD1 inhibition restored cisplatin sensitivity across multiple resistant models, leading to a marked reduction in clonogenic survival. In vivo, combined PLD1 inhibition and cisplatin treatment markedly suppressed tumor growth, prolonged survival, and reduced metastatic burden in xenograft and PDX models, with greater therapeutic benefit observed in platinum-resistant tumors.
Conclusions: PLD1 is a key survival determinant in platinum-resistant OC and contributes directly to treatment failure. Targeting PLD1 enhances the antitumor efficacy of cisplatin and provides strong preclinical rationale for PLD1-directed combination therapy in refractory HGSOC.

#6493 Azvudine combined with Doxitinib, a potential therapy for EGFRm⁺ NSCLC.

Jianmei Zhang, Shufang Zhang, Yujie Wang, Limin Jia, Ying Li, Pan Li, Feng Luo, Jinfa Du

Genuine Biotech Co., Ltd., Beijing, China

Osimertinib, a third-generation EGFR tyrosine kinase inhibitor (EGFR-TKI), is the current standard first-line therapy for patients with EGFR-mutant non-small cell lung cancer (NSCLC). Although Osimertinib significantly improves progression-free survival (PFS), some patients exhibit intrinsic resistance, and nearly all eventually develop acquired resistance.

Doxitinib, a deuterated analog of Osimertinib, retains potent EGFR inhibitory activity while significantly reducing the formation of toxic metabolites by up to 80% in preclinical models, suggesting an improved safety profile and the potential for enhanced therapeutic efficacy through higher tolerated dosing. In a phase 1/2 clinical study (ChiCTR2000039281), Doxitinib demonstrated a favorable safety profile without dose-limiting toxicities (DLTs) across doses ranging from 20 to 240 mg daily in patients previously treated with EGFR TKIs. Encouraging clinical activity was observed, including antitumor responses in brain metastases. The ongoing expansion phase is further evaluating Doxitinib in EGFRm⁺ NSCLC patients naïve to EGFR-TKI therapy.

To overcome resistance and enhance antitumor efficacy, we combined Doxitinib with Azvudine (FNC), a fluorinated nucleoside analog with dual antitumor mechanisms. FNC inhibits tumor cell proliferation via its active triphosphate metabolite, which incorporates into DNA or RNA to disrupt nucleic acid synthesis, induce replication stress, and arrest tumor growth. Moreover, FNC modulates the tumor immune microenvironment (TIME) by suppressing myeloid-derived suppressor cell (MDSC) differentiation and infiltration while enhancing $CD8^+$ T cell and NK cell activation, thus shifting the TIME from immunosuppressive to immunoreactive—an essential factor in overcoming EGFR-TKI resistance. In vitro, the combination of FNC and Doxitinib additively inhibited the proliferation of NCI-H1975 (EGFR L858R/T790M/C797S) triple-mutant NSCLC cells. In vivo, the combination achieved superior tumor growth inhibition compared to either monotherapy in the NCI-H1975 (EGFR L858R/T790M) xenograft model.

Collectively, these findings suggest that the combination of FNC and Doxitinib represents a promising therapeutic strategy to enhance efficacy and overcome acquired resistance in EGFRm⁺ NSCLC. Based on these preclinical and clinical findings, a phase 1/2 clinical trial will be initiated to evaluate the safety and efficacy of this combination therapy in EGFR-mutant NSCLC patients.

#6494 The selective YAP/TEAD inhibitor TY-1054 enhances the efficacy of KRAS inhibitors or Trop2-ADC in multiple solid tumors.

Shengli Dong, Zhengfei Guo, Zhiyong He, Apeng Liang, Meihua Li, Guangbin Liu, Chao Zhou, Yu Yu, Xinlong Yang, Hongqiang Li, Chengshan Niu, Shaoqing Chen, Jun Li, Yusheng Wu

TYK Medicines, Inc., Changxing, Zhejiang, China

Introduction: KRAS is one of the most common somatic mutations associated with human cancers. YAP/TEAD activation is a major cause of resistance to various targeted therapies. Recently, YAP/TEAD signaling has been identified as a synthetic lethal target that can enhance the efficacy of KRAS G12C inhibitors. TY-1054 is a potent YAP/TEAD inhibitor developed by TYK Medicines Inc. Results: 1. TY-1054 not only enhanced the efficacy of FDA-approved KRAS G12C inhibitors, Adagrasib and Sotorasib, in Non-Small Cell Lung Cancer (NSCLC) H1373 and H2122 cells, but also enhanced the efficacy of Divarasib (GDC-6036) and pan-KRASi Daroxonrasib (RMC-6236) in NSCLC H1972 and H2122 cells. 2. TY-1054 not only enhanced the efficacy of KRAS G12Di RMC-9805 in SU.86.86 (PDAC, KRAS G12D) in vitro and in vivo, but also enhanced the efficacy of pan-KRASi Daraxonrasib in SU.86.86 in vitro and in vivo. 3. TY-1054 enhances cetuximab efficacy in head and neck squamous cell carcinoma (HNSCC) Cal33 cells. 4. TY-1054 enhances the efficacy of Trop2-ADC (SKB264/Sac-TMT) in triple-negative breast cancer (TNBC) (MDA-MB 231 and HCC1806), NSCLC (H1975 and HCC827), and trastuzumab-resistant breast cancer (JIMT-1) cells. In summary, TY-1054 has a potentially wide therapeutic window and is currently being evaluated in patients in China. IND clearance from the US FDA was received in 2024. This study provides a strong rationale for testing the combination therapy of TY-1054 and KRAS inhibitors or Trop2-ADC in human clinical trials. The successful execution of the TY-1054 clinical trial will provide a powerful solution for precision oncology.

#6495 NXP900, a Phase 1b, first-in-class YES1/SRC inhibitor demonstrates potent synergy with KRAS inhibitors in KRASi sensitive and resistant NSCLC models.

Boback Kaghazchi[1], Enrique Podarosu[2], Asier Unciti-Broceta[1], **Neil O. Carragher**[1]

[1]Institute of Genetics and Cancer, University of Edinburgh, Edinburgh, United Kingdom,[2]Nuvectis Pharma Inc., Fort Lee, NJ

Background: NXP900 (eCF506) is a novel potent and selective SRC family kinase (SFK) inhibitor, (IC_{50} of 0.47 nM against YES1). NXP900 first-in-class mode-of-action locks its target into its native "closed" conformation, thereby inhibiting both kinase activity and scaffolding function with protein signaling partners (Temps et al. Cancer Res 2021). In contrast, other clinically available inhibitors, lock SRC in the active "open" conformation promoting the association of SFK and signaling partners via allosteric facilitation (Higuchi et al. Cell Rep 2021). G12C mutant-selective KRAS inhibitors (KRASi) have been FDA-approved and several mutant-selective, pan-mutant-KRAS, and pan-RAS inhibitors are in development. However, KRASi monotherapy results in limited clinical benefit and face the rapid development of acquired resistance. YAP1 activation is associated with drug resistance to KRASi and promotes the survival of drug-tolerant persister cells after therapy. Induction of YAP1 nuclear localization by SRC/YES1 mediated tyrosine phosphorylation of YAP1 and LATS1 is inhibited by NXP900 in NSCLC cell lines at a low nM concentration. A FIH, dose escalation study, demonstrated that NXP900 potently inhibits the activity of SRC kinase at well tolerated doses (Falchook et al. Cancer Res 2025). Moreover, no CYP3A induction was observed in a drug-drug interaction study in humans indicating the potential of NXP900 to be combined with KRASi to overcome primary and acquired resistance and improve clinical benefit to patients with KRAS mutated cancers.
Materials and methods: Resistant cell lines to the KRASi sotorasib were generated from NCI-H23 cells.
Cell proliferation assay - Cells were diluted in the corresponding ATCC recommended medium and dispensed in a 384-well plate, depending on the cell line used, at a density of 100 - 6400 cells per well. Cells were treated with KRASi and or NXP900 for 120 h and underwent ATPlite viability assay. Drug combination effects were studied using the Bliss independence principle.
Results: NXP900 potently inhibited the activating SRC autophosphorylation, YAP1 nuclear localization and demonstrated synergy in combination with sotorasib in sotorasib-sensitive and resistant cell lines.
Conclusions: Development of effective and tolerable combination therapies are needed to overcome resistance and maximize the clinical impact of RAS-targeted therapy. NXP900 can potently inhibit cell proliferation of KRAS mutated cell lines in combination with a KRASi in NSCLC models. The combination was synergistic both in KRAS sensitive and resistant models. The data suggests that NXP900, currently in a Phase1b expansion in patients with *FAT1, YES1* and other genomic alterations in solid tumors (NCT05873686), is an attractive and translatable combination partner that could synergize with KRASi.

#6496 Methylseleninic acid enhances anti-FN14 CAR-T cell effector function and redirects cytotoxicity against TGF-β-rich kidney, prostate, and brain tumors.

Gloria B. Kim[1], Obed B. Amissah[1], Casey R. Ager[2], Yousef Zakharia[3], Youcef M. Rustum[4]

[1]Mayo Clinic Arizona, Scottsdale, AZ,[2]Mayo Clinic Arizona, Phoenix, AZ,[3]Mayo Clinic Arizona, Pheonix, AZ,[4]Chair, Dept. of Cancer Biology, Roswell Park Cancer Institute, Buffalo, NY

Background: Clear cell renal cell carcinoma (ccRCC), metastatic castration-resistant prostate cancer (mCRPC), and glioblastoma (GBM) are treatment-refractory tumors marked by high TGF-β1, a master suppressor of antitumor immunity and antigen presentation. Pharmacologic methylseleninic acid (MSA) potently inhibits TGF-β1, PD-L1, and VEGF without significant off-target toxicity. FN14, the TWEAK receptor and a metastasis driver, is selectively overexpressed in these malignancies, making it a high-specificity CAR-T target.
Methods: We developed second-generation anti-FN14 CARs with CD28 or 4-1BB costimulation and CD3ζ signaling and lentivirally transduced them into human $CD4^+$/$CD8^+$ T cells. Cytotoxicity against $FN14^+$ ccRCC, mCRPC, GBM lines and patient-derived tumors was measured using LDH release and xCELLigence assays. Effector function was assessed by intracellular cytokines, phenotyping, and multiplex analysis. MSA was tested at physiologic concentrations to evaluate effects on CAR-T viability, metabolism, function, and tumor susceptibility.
Results: Anti-FN14 CAR-T cells mediated rapid, antigen-specific lysis across all tumor types, achieving >50% specific lysis at an E:T ratio of 1:1. MSA (2.5-5 μM) reduced tumor PD-L1 and TGF-β by >40% and improved CAR-T metabolic activity, enhancing IL-2 and IFN-γ secretion. Manufacturing CAR-T cells with MSA (2.5 μM) increased cytotoxicity and persistence versus controls ($p < 0.01$). MSA's effects were dose- and schedule-dependent at clinically compatible concentrations without detectable off-target toxicity.
Conclusion: MSA augments anti-FN14 CAR-T cytotoxicity, metabolic fitness, and sustained effector function by suppressing tumor-derived TGF-β1 and PD-L1 and directly enhancing CAR-T activity. As a clinically relevant TGF-β1 inhibitor and active seleno-L-methionine metabolite, MSA represents a readily translatable strategy to reduce CAR-T exhaustion and improve efficacy in TGF-β-rich solid tumors.

#6497 Synergistic disruption of KRAS and FAK pathways: A preclinical pipeline for PDAC therapy optimization.

Jaeger Moore[1], Taylor Bargenquast[1], Tithi Ghosh Halder[1], Serina Ng[1], Erkut Borazanci[1], Sara A. Byron[2], Cherie Wesley[2], Raffaella Soldi[1], Sunil Sharma[1]

[1]HonorHealth Research Institute, Phoenix, AZ,[2]TGen (The Translational Genomics Research Institute), Phoenix, AZ

Background: KRAS mutations are among the most prevalent oncogenic drivers across solid tumors, with particularly high incidence in Pancreatic Ductal Adenocarcinoma (PDAC). Despite their clinical relevance, direct targeting of KRAS has historically been difficult. The advent of KRAS G12C-specific inhibitors has marked a breakthrough in targeted therapy, yet acquired resistance remains a major challenge. RMC-6236 (daraxonrasib), a noncovalent RAS(ON) inhibitor, targets the active GTP-bound form of both mutant and wild-type RAS isoforms and has shown potent antitumor activity, especially in codon 12 KRAS-mutant cancers. In a Phase 1 trial for metastatic PDAC, RMC-6236 extended progression-free survival to approximately eight months. Recent studies suggest that KRAS inhibition may sustain focal adhesion kinase (FAK) activation, implicating the FAK-YAP axis and tumor-associated fibrosis in resistance. FAK, a key regulator of survival and DNA damage repair, has emerged as a promising co-target, with evidence of synergy between FAK inhibition and KRAS blockade, as well as enhanced sensitivity to PD-1 checkpoint inhibitors and radiation. We hypothesize that dual targeting of KRAS and FAK pathways will yield synergistic therapeutic effects in PDAC by disrupting oncogenic signaling and promoting cell death. To test this, we employ patient-derived organoid (PDO) cultures that preserve tumor architecture, heterogeneity, and stromal structure, enabling physiologically relevant evaluation of drug combinations.
Methods: Patient-derived cells were treated with RMC-6236, defactinib, and ifebemtinib, alone and in combination, in 2D and 3D viability assays. Organoids were generated by co-culturing tumor cells and fibroblasts (1:1) for 72 hours, then treated with an 8-point, 2-fold serial dilution of drugs for another 72 hours. Synergy was assessed using Bliss analysis via Combenefit, and 2D dose responses were analyzed in GraphPad Prism using Student's t-test. Western blotting was performed to evaluate RAS-MAPK pathway inhibition and apoptosis markers.
Results: Preliminary data from four KRAS-mutant PDOs (G12D, G12V, G12R) revealed robust synergy between RMC-6236 and either FAK inhibitor, with up to 10-fold and 100-fold increases in efficacy for defactinib or ifebemtinib and RMC-6236, respectively. Western blot analysis confirmed suppression of RAS-MAPK signaling, downregulation of c-MYC, and increased apoptotic markers including cleaved PARP and activated Caspase-3. These findings support the potential of KRAS-FAK co-targeting strategies in PDAC and lay the groundwork for future clinical development. These findings underscore a mechanistic interplay between KRAS and FAK signaling pathways, suggesting that dual targeting may overcome resistance and enhance cell death in KRAS-mutant PDAC, to improve outcomes in KRAS-driven pancreatic cancers.

#6498 Combination of MDM2 inhibitor and lipophilic gemcitabine: Strong synergism in lung cancer, while antagonism in brain cancer.

Bhoomi Mukeshbhai Dholariya, Akanksha S. Patel, Ketankumar Patel

St. John's University, Queens, NY

Cancer remains the leading cause of mortality worldwide, even in the post-COVID-19 era. Lung and brain cancers account for a substantial proportion of these deaths. Although multiple anticancer agents are available, single-agent therapies often fail to achieve durable responses due to limited efficacy or the development of drug resistance. Combination therapy is therefore recognized as a powerful strategy to enhance therapeutic efficacy and delay resistance.In this study, we investigated the synergistic potential of Idasanutlin (Ida), a second-generation MDM2 inhibitor, and Gemcitabine Elaidate (Gem Eli), a lipophilic prodrug of Gemcitabine, for the treatment of non-small cell lung cancer (NSCLC) and glioblastoma (GBM). Both molecules exhibit hydrophobic characteristics, prompting their incorporation into the lipid bilayer of liposomal carriers. Using a modified hydration method, we developed a liposomal nanoformulation co-loaded with Ida and Gem Eli (IG). A major challenge was the rapid insoluble precipitation of Ida, a brick-dust molecule. To address this, we introduced the cationic ionizable lipid DLin-DMA to enable the formation of a charge-tunable complex between anionic Ida and cationic DLin-DMA. Ionizable lipids remain neutral at physiological pH but acquire a positive charge in acidic conditions (e.g., the tumor microenvironment, pH ~5.5), which facilitates tumor-targeted delivery while minimizing systemic toxicity. The IG formulation was evaluated in NSCLC cell lines (A549 and H460) and a GBM cell line (U-87), all harboring wild-type p53. Strong synergism was observed in NSCLC, with combination index values of 0.07 (A549) and 0.3 (H460). In contrast, U-87 cells demonstrated no synergism; instead, Gem Eli displayed antagonistic behavior, with a ~7-10-fold increase in IC_{50} when combined with Ida across ratios ranging from 1:1 to 1:20. A 3D spheroid assay further confirmed antagonism in GBM, after 10 days of alternate-day treatment, IG, Gem Eli, and Ida reduced spheroid area by 81%, 61.9%, and 81%, respectively, compared to controls. Synergism in NSCLC was further validated using Combenefit analysis, which demonstrated robust synergy in 3D synergy maps. The optimized IG liposomes exhibited a particle size of 131.1 ± 0.68 nm, a PDI of 0.172 ± 0.13, and pH-responsive zeta potentials of -2.06 ± 0.06 (pH 7.4) and +8.88 ± 0.31 (pH 5.5), supporting their suitability for tumor-targeted delivery. Hemocompatibility testing in mouse red blood cells showed <1% hemolysis at concentrations up to 100 µM. Cryo-electron microscopy confirmed uniform particle morphology with no evidence of aggregation. Ongoing studies are focused on elucidating the cellular mechanisms underlying the observed antagonism in GBM.

#6499 Targeting BCR-ABL1-independent mechanisms of resistance in chronic myeloid leukemia.

Mark Pusung[1], Christopher A. Eide[1], Jessica Gibbs[1], Daniel Bottomly[2], Haijiao Zhang[1], Brian J. Druker[3]

[1]Hematologic Malignancies, OHSU Knight Cancer Institute, Portland, OR,[2]Division of Bioinformatics and Computational Biology, OHSU Knight Cancer Institute, Portland, OR,[3]Director, JELD-WEN; Chair of Leukemia Research and Investigator, OHSU Knight Cancer Institute, Portland, OR

Tyrosine kinase inhibitors (TKIs) targeting the BCR-ABL1 fusion gene in chronic myeloid leukemia (CML) have improved patient prognosis. While newer drugs have made inroads against BCR-ABL1-dependent TKI resistance, patients who develop resistance through pathways independent of BCR-ABL1 feature heterogeneous, poorly characterized molecular mechanisms and present a challenge for application of combination targeted therapy. To identify genes contributing to BCR-ABL1-independent resistance, we performed CRISPR/Cas9 genome-wide screens using Ba/F3 BCR-ABL1 cells cultured in the presence of DMSO, imatinib, and asciminib. After 10 days, cells were harvested and analyzed for gene-level enrichment/depletion of sgRNAs. Among candidate resistance genes (whose knockdown was enriched following TKI treatment), independent sgRNA guides for five genes were induced by lentiviral CRISPR/Cas9 knockout in Ba/F3 BCR-ABL1 cell line models for validation studies. Cell lines were evaluated for in vitro sensitivity to a panel of approved ABL1 TKIs and profiled against an expanded inhibitor panel spanning a range of drug targets. Expression levels of candidate resistance genes were compared by RNAseq in primary specimens from CML patients. CRISPR screening revealed varying subsets of genes enriched in TKI-treated cultures. Five candidate genes were selected for validation studies: *Chic2, Stub1* and *Pten* from the imatinib-treated cells and *Fbxo3* and *Ptar1* from the asciminib-treated cells. In Ba/F3 BCR-ABL1 cell line models, knockout of each of these genes resulted in varying degrees of reduced sensitivity to a panel of ABL1 TKIs (2-45-fold increase in IC_{50} compared to wild-type cells). For example, knockout of *Pten* and *Chic2* demonstrated increased IC_{50} values for imatinib of 12,714 and 914 nM, respectively, compared to 277 nM for wild-type cells. Profiling of cell lines using an expanded drug panel revealed differential sensitivities to inhibitors targeting multiple pathways. For example, *Chic2, Stub1* and *Fbxo3* knockout showed greater sensitivity (relative to wild-type cells) to inhibitors of WNT, proteasome, histone deacetylase, bromodomain, and/or nucleoside analog pathways. Lastly, analysis of RNASeq data highlighted differences in expression levels in patient samples. For example, expression levels of both *Ptar1* and *Pten* were reduced in patients with BCR-ABL1-independent resistance to imatinib relative to newly diagnosed patients, and expression of *Fbxo3* and *Chic2* were decreased with disease progression (blast vs chronic phase). Taken together, our results identify genes implicated in tumor suppression (*Pten*), ubiquitination (*Stub1, Fbxo3, Chic2*), and post-translational modification (*Ptar1)* with contributing roles for BCR-ABL1-independent TKI resistance and map these to potential actionable pathways amenable to novel combination targeted therapy approaches.

#6501 Preclinical evidence for synergistic activity of alectinib and everolimus in ALK-positive non-small cell lung cancer.

Hamadi Madhi[1], Habib Serhan[1], Rachel Mercer[1], Benjamin Levy[1], Anna Rottinghaus[1], Liwei Bao[1], Xu Cheng[1], Sharon R. Pine[2], Ross Camidge[2], Angel Qin[1], Nathan M. Merrill[1], Sofia D. Merajver[1], Matthew B. Soellner[3]

[1]Internal medicine, University of Michigan, Ann Arbor, MI,[2]University of Colorado, Aurora, CO,[3]Chemistry, University of Michigan, Ann Arbor, MI

Introductory Sentence: This study investigates the therapeutic potential of dual alectinib and everolimus inhibition to prolong the clinical benefit of alectinib in ALK-positive non-small cell lung cancer.
Pertinent experimental procedures: ALK-rearranged NSCLC cell lines (CUTO8, CUTO9, CUTO29.1, CUTO39, CUTO41, CUTO43, CUTO46) obtained from the University of Colorado; DFCI032 from Dana-Farber; NCI-H2228 and NCI-H3122 from ATCC; and SNU2292 and SNU2535 from Seoul National University were screened using a high-throughput drug-combination platform to identify synergistic interactions between alectinib and a curated library of 1,600 approved and experimental compounds. Functional validation in NCI-H3122 included colony-formation and Glo-Caspase 3/7 apoptosis assays with therapeutically relevant concentrations of everolimus (Cmax and Caverage) plus 100 nM alectinib, ~ten-fold lower than reported Cmax/Caverage. Apoptotic activation was further confirmed by Western blot for cleaved PARP, cleaved caspase-3, and the pro-survival protein MCL-1. In parallel, ex vivo screening was conducted on ALK167-T-01, an ALK-positive PDX model harboring the p.Leu1196Met ALK mutation.
Summary of new unpublished data: High-throughput screening identified a consistent synergistic response to alectinib combined with multiple mTOR inhibitors across all the ALK-rearranged models tested. Synergy was assessed by the Chou-Talalay method, with CI <1 in most ALK-positive cell lines tested. In NCI-H3122, the combination significantly reduced clonogenic potential (alectinib alone VS combo Caverage; $p<0.01$ and alectinib alone VS combo Cmax; $p<0.001$) and induced apoptosis, evidenced by increased Caspase 3/7 activity (alectinib alone VS combo Caverage; $p<0.01$ and alectinib alone VS combo Cmax; $p<0.001$) and significant PARP and caspase-3 cleavage. Ex vivo PDX screening using ALK167-T-01 with Glo-Caspase 3/7 assays at therapeutically relevant everolimus concentrations plus 100 nM alectinib showed higher apoptosis vs single agents (alectinib alone VS combo Caverage; $p<0.001$ and alectinib alone VS combo Cmax; $p<0.0001$), confirming synergy is not exclusive to sensitive lines.
Statement of the conclusions: Dual ALK and mTOR targeting with alectinib and everolimus produces synergistic antitumor activity in vitro and ex vivo, reflected by significantly increased apoptosis vs single agents. These findings support further investigation in in vivo models, including alectinib-sensitive and -resistant tumors.

#6503 Investigating synergistic effects with CK2 and C-KIT inhibition in B-ALL.

Daniel Bogush, **Stephanie Buczkowski**, Rabab Husain, Sameer Ahmed Bhat, Yen Teng Tai, Avinash Kundadka Kudva, Sinisa Dovat

Penn State College of Medicine, Hershey, PA

Survival for pediatric pre-B cell acute lymphoblastic leukemia (B-ALL) has improved substantially, yet high-risk (HR) subgroups continue to experience significant morbidity and mortality. One molecular feature common in HR ALL is deletion of IKZF1, which reduces the tumor-suppressive activity of the transcription factor IKAROS. Casein kinase 2 (CK2), frequently upregulated in ALL, phosphorylates IKAROS and diminishes its DNA-binding capacity, impairing transcriptional regulation. Prior studies show that pharmacologic CK2 inhibition with CX-4945 can restore IKAROS function. Among IKAROS-regulated targets is the receptor tyrosine kinase c-KIT, which is often overexpressed in cancer. These observations suggest that restoring IKAROS-mediated repression of c-KIT may enhance the activity of c-KIT-targeted therapies such as imatinib. This study evaluated whether CX-4945 synergizes with imatinib in B-ALL cells. Nalm6 cells were treated with imatinib for 72 hours to establish the half-maximal inhibitory concentration (IC50), which was then used to guide concentration ranges for combination testing with CX-4945 in a 72-hour cytotoxicity synergy analysis. Cell viability was assessed using a WST-1 assay, and synergy was defined as a combination index <0.85 using Calcusyn. Experiments were repeated with multiple drug concentrations to refine the synergy window. The IC50 of imatinib as a single agent was 25 μM, while CX-4945 showed an IC50 of 4 μM. When CX-4945 was fixed at 4 μM and imatinib was applied across varying doses, multiple combinations demonstrated synergistic cytotoxicity. These results indicate that CK2 inhibition with CX-4945 enhances the therapeutic efficacy of the c-KIT inhibitor imatinib in B-ALL cells, supporting a cooperative mechanism involving restoration of IKAROS function. Given that imatinib is clinically used for Philadelphia chromosome-positive (Ph+) ALL, future work will assess CX-4945/imatinib synergy in Ph+ B-ALL, where an even more potent effect is anticipated. This combination approach may offer a promising therapeutic avenue for HR ALL subtypes characterized by IKZF1 alteration and chemotherapy resistance.

#6505 Combination therapy with selective SMARCA2 (BRM) inhibitor HD-11273 for treatment of SMARCA4 (BRG1)-deficient cancers.

Hyuntae Kim, MinOu Choi, Jongwoo Park, Goeun Yang, Min-Ah Park, Hyo Sun Choi, Yukyung Kim, Doo-Young Kim, Daehoon Kim, Seong Heon Kim, Suk Ho Lee

Hyundai pharmaceutics, Suwon, Korea, Republic of

SMARCA2 (BRM) and SMARCA4 (BRG1) are the catalytic subunits of SWI/SNF chromatin remodeling complexes, functioning in a mutually exclusive manner to regulate nucleosome composition via their ATPase domains. Pan-cancer analysis indicates that SMARCA4 mutations occur at all cancers, in particular, SMARCA4 mutations are found in 8-10% of non-small cell lung cancer (NSCLC) cases, suggesting SMARCA2 as a potential synthetic lethal target. Several studies reported that the co-mutation frequency of KRAS and SMARCA4 in NSCLC is approximately 7.7-10%, with about 39-47% of these SMARCA4-mutant patients harboring KRAS mutations. And patients with SMARCA4-mutant NSCLC generally demonstrate poor responses to conventional chemotherapy. We selected HD-11273 as a preclinical candidate, which showed improved physicochemical properties through the preparation of a specific salt of HD-10991, a selective SMARCA2 inhibitor. Here, we report a combination study of HD-11273 with standard chemotherapy and KRAS inhibitors currently in development. HD-11273 monotherapy significantly inhibited growth of SMARCA4-del A549 CDX model as well as patient derived cancer organoid (PDO) models. Combination therapies targeting multiple pathways are considered essential for overcoming monotherapy limitations, including resistance arising from prolonged treatment. To evaluate the therapeutic benefit, we tested our selective SMARCA2 inhibitor in combination with KRASG12C (storasib, adagrasib), KRASG12D (RMC9805), and pan-KRAS (Draxonrasib) inhibitors in cancers harboring KRAS and SMARCA4 co-mutations. Each combination exhibited robust synergy, suggesting that dual targeting of SMARCA2 and KRAS could be a promising therapeutic strategy. Additionally, we investigated the combinatory effect of a SMARCA2 inhibitor with standard chemotherapy agents for NSCLC; combination with oxaliplatin, docetaxel, or pemetrexed showed partial synergy, indicating that SMARCA2 inhibitors may serve as promising candidates for combination chemotherapy. In conclusion, the combination of HD-11273 with KRAS targeted therapy showed synergistic anti-tumor effect in preclinical models of SMARCA4 and KRAS co-mutated NSCLC. Also, the combination of HD-11273 with standard care for NSCLC chemotherapy significantly enhances anti-tumor activity in preclinical models of SMARCA4-mutated NSCLC.

#6506 Antitumor synergy of AOH1996 and next-generation caPCNA Inhibitors in combination with targeted and chemotherapeutic agents.

Robert G. Lingeman[1], Long Gu[1], Caroline Li[1], Pouya Haratipour[2], Robert J. Hickey[3], Linda H. Malkas[4], Maryam Zangi[3]

[1]Beckman Research Institute of The City of Hope, Duarte, CA,[2]City of Hope Comprehensive Cancer Ctr., Duarte, CA,[3]City of Hope National Medical Center, Duarte, CA,[4]City of Hope National Medical Center, Sylmar, CA

Background: AOH1996 is a small molecule that selectively targets the cancer-associated isoform of proliferating cell nuclear antigen (caPCNA), disrupting DNA replication and repair, and promoting DNA strand breaks through inhibition of effective resolution of transcription-replication conflicts. Building on its promising preclinical efficacy, we are also developing and testing next-generation caPCNA inhibitors with improved potency and druglikeness. We have developed two new inhibitors that exhibit up to 10-fold higher cellular potency relative to the parent compound, and an inhibitor with similar potency as the parent compound but 2.4-fold more soluble. Given PCNA's diverse role in processes that cancer cells depend upon for survival, e.g., coordinating DNA synthesis, damage tolerance, cell cycle control, chromatin assembly, and stress response signaling, it is hard to predict what other anticancer drugs would combine productively with AOH1996 and next-generation inhibitors. To that end, we screened a panel of 179 anticancer drugs with AOH1996 and three next-generation inhibitors to identify potential combinations that exhibit synergy.
Methods: A systematic combination drug screen was performed using AOH1996 and next-generation inhibitors and a drug panel of 179 different anticancer drugs.

- Synergy evaluation: We performed initial screens using the human neuroblastoma cell line SK-N-AS. We assessed the synergy of the combinations using the Chou-Talalay method for drug combination analysis. For favorable drug combinations, we tested additional cell lines including cancer cell types where the drug identified would be used clinically in a treatment regimen.
- Mechanistic studies: We analyzed cell cycle effects and apoptosis by flow cytometry. We also assessed DNA damage and checkpoint activation by using immunoblotting and immunofluorescence to measure γH2AX, cleaved PARP, and phospho-Chk1.

Results: Both AOH1996 and its next-generation analogs demonstrated synergy with some DNA-damaging and repair inhibiting agents such as cisplatin. Tyrosine kinase inhibitors (TKIs) in particular EGFR TKIs synergized well with AOH1996 and next-generation inhibitors. Inhibitors of the mitochondrial apoptosis pathway (e.g., venetoclax) also synergized as well.
Conclusions: AOH1996 and its next-generation analogs exhibit potent synergistic activity with targeted therapies and DNA repair inhibitors, supporting PCNA inhibition as a promising strategy to enhance therapeutic efficacy and overcome resistance. These findings provide a preclinical rationale for clinical development of AOH1996 combination regimens, as well as continued optimization of caPCNA-targeting analogs with superior potency and tolerability.

#6507 Genomic characterization of lung cancer: ERRFI1 and NKX2-1 mutations and CLU expression.

Metamia Ciampricotti[1], Yingying Yu[1], Stamatina Fragkogianni[1], Jyoti Patel[1], **Christine M. Lovly**[2]

[1]Tempus, Chicago, IL,[2]City of Hope Comprehensive Cancer Ctr., Duarte, CA

Introduction: Altered expression of *ERRFI1* (Epidermal Growth Factor Receptor Feedback Inhibitor 1), *NKX2-1* (also known as TTF1), and *CLU,* play a role in the response to targeted therapies and immune checkpoint inhibitors (ICI) in lung cancer. Here, we evaluate the prevalence of *ERRFI1* and *NKX2-1* mutations, changes in their RNA levels, and CLU RNA levels prior to therapy (PT) and upon disease progression (UP), focusing on *EGFR* and *ALK* tyrosine kinase inhibitors (TKIs).

Methods: De-identified records of 34,362 patients (pts) with a primary diagnosis of lung cancer and subjected to Tempus xT/xR NGS were identified. Gene expression levels of *ERRFI1, NKX2-1*, and *CLU* were compared between NSCLC vs. SCLC, squamous vs non-squamous histology, and sample collection time (PT vs UP). The somatic landscape was assessed for *ERRFI1* and/or *NKX2-1* pathogenic/likely pathogenic (P/LP) or variants of unknown significance (VUS) somatic mutations. Somatic differences were compared using Pearson's Chi-squared test or Fisher's exact test, as appropriate. The median log2 (TPM+1) gene expression was compared between groups using the Wilcoxon rank sum exact test.

Results: Among the total cohort, NSCLC had significantly higher expression levels of *ERRFI1* (7.8 vs 6.5, p<0.001) and CLU (7.3 vs 6.3, p<0.001) compared to SCLC, while *NKX2-1* levels were higher in SCLC (6.7 vs 5.5, p<0.001). *ERRFI1, NKX2-1*, and *CLU* expression were higher in non-squamous NSCLC compared to squamous NSCLC (p<0.001). *CLU* expression was significantly higher in UP samples with EGFR TKI (p=0.024), ALK TKI (p=0.033), and ICI treatments (p=0.048) compared to PT samples. *NKX2-1* expression was significantly lower in UP samples for EGFR TKI (p<0.001), ALK TKI (p=0.002), and ICI treatments (p<0.001) compared to PT samples. *ERRFI1* expression was also lower in UP samples with ALK TKI (p=0.013) but not EGFR TKI or ICI treatments. Of those samples, 1% (403/34,362) had somatic mutations in *ERRFI1* only, 6% (1,980/34,362) in *NKX2-1* only and 0.01% (39/34,362) in both. The top co-mutated genes in *ERRFI1* and/or *NKX2-1* mutated tumors included *TP53* (64%), *KRAS* (36%), *FOXA1* (25%), *CDKN2A* (24%), *NFKBIA* (24%) and *EGFR* (21%). *EGFR* co-mutated tumors from pts with a history of TKI had a significantly higher number of *NKX2-1* amplifications compared to those without (p<0.001), while *NKX2-1* deletions were more prevalent in the TKI naive cohort (p=0.002).

Conclusions: Lung cancers with *ERRFI1* and/or *NKX2-1* mutations exhibit distinct genomic profiles, with significant variations in *ERRFI1*, *NKX2-1*, and *CLU* expression across different subtypes. *CLU* expression was higher UP after EGFR TKI, ALK TKI, and ICI, while *NKX2-1* and *ERRFI1* expression were lower UP. Understanding the dynamic expression across disease states may inform knowledge of resistance mechanisms and putative treatment strategies. This could be particularly informative as clusterin inhibitors are undergoing evaluation in clinical trials.

#6512 Exploring clinical actionability of expanded liquid biopsy in advanced breast and colorectal cancers.

Keelia Clemens, Leslie Bucheit, Shaun Forbes, Hashem Alshurafa, Amar Das, Helmy Eltoukhy

Guardant Health, Palo Alto, CA

Background: Liquid biopsy via plasma circulating tumor DNA (ctDNA) analysis is used to aid in targeted therapy selection. While advanced lung cancer has a number of biomarkers with FDA-approved targeted therapies, advanced breast (mBC) and colorectal (mCRC) cancers have fewer targets. As biomarkers expand and technology evolves, it is important to balance broad ctDNA analysis with clinical actionability (CA). This study explored the potential CA of an integrated liquid biopsy leveraging genomic and epigenomic elements.
Methods: Results of mBC (n=2149) and mCRC (n=1345) patients who had genomic and epigenomic ctDNA testing (Guardant360 Liquid) as part of routine clinical care from June 1 - July 16, 2025, were retrospectively queried; only one test per patient was analyzed. Result components were categorized by CA: immediate (guides current therapy selection); expanded (may inform further work-up or future line decision); other (novel biomarkers that may influence care over time). Each patient was classified into one group. Availability of pharmacogenomic (PGx) results was assessed independently.
Results: >85% of mBC and mCRC patients had CA results with >50% classified as immediate (Table 1). For mBC, 99.9% of patients had PGx results, dramatically higher than published testing rates (<10%). Nearly 1 in 2 mBC patients had a blood-based molecular breast subtype (MBS) which may inform additional workup for hormone receptor and HER2 status. 270 mCRC patients had biomarker negative (BN) results with ≥95% confidence in the absence of FDA-approved targets, enabling rapid therapy selection. For mCRC, 99.9% had PGx results, doubling published testing rates (30-50%). Novel features such as MBS and >95% BN increased CA by 6.3% in mBC and 43.7% in mCRC.
Conclusions: A liquid biopsy with both genomic and epigenomic features broadens potential CA in tumors with few targeted therapy options. This data supports use of a multifaceted assay to guide first- and later-line decisions.

Table 1. Result actionability and availability in mBC and mCRC

	mBC (n=2149)	**mCRC (n=1354)**
RESULT ACTIONABILTY		
Total Actionable Findings	1841 (85.7%)	1215 (89.7%)
Immediate: *On-label or resistance alteration, Germline or HRD/GIS (mBC only), ≥90% Confident biomarker negative (mCRC only)*	1080 (50.3%)	939 (69.4%)
Expanded: *Clinical trial or off-label option, Molecular breast subtyping only (mBC only)*	611 (28.4%)	203 (15.0%)
Other: *Tumor fraction >0.05%*	150 (7.0%)	73 (5.4%)
RESULT AVAILABILITY		
Pharmacogenomics	2146 (99.9%)	1352 (99.9%)
Molecular Breast Subtyping	1013 (47.1%)	N/A
≥90% Confident Biomarker Negative	N/A	321 (23.7%)

#6513 Detection of bladder cancer in patients with gross hematuria using Oncuria-Detect, a urine-based multiplex immunoassay.

Sunao Tanaka[1], Yair Lotan[2], Makito Miyake[3], Edward M. Messing[4], Arnold I. Chin[5], Menghan Liu[6], Ian Pagano[7], Toru Sakatani[1], Yingye Zheng[8], Zhen Zhang[9], Charles Joel Rosser[1], Hideki Furuya[1]

[1]Cedars-Sinai Medical Center, Los Angeles, CA,[2]Associate Professor of Urology, UT Southwestern Medical Ctr., Dallas, TX,[3]Nara Medical University, Nara, Japan,[4]Chairman & Professor, Dept. of Urology, University of Rochester Cancer Center, Rochester, NY,[5]Assistant Professor, Dept. of Urology, University of California (UCLA), Los Angeles, CA,[6]Fred Hutchinson Cancer Center, Seattle, WA,[7]UHCC, Honolulu, HI,[8]Fred Hutchinson Cancer Research Ctr., Seattle, WA,[9]Associate Professor, Dept. of Pathology & Oncology, Johns Hopkins University School of Medicine, Baltimore, MD

Background - Cystoscopy is standard of care in evaluating patients with gross hematuria for bladder cancer with hematuria being the primary sign of bladder cancer. Oncuria-Detect, a liquid biopsy to detect *de novo* bladder cancer from a single voided urine sample demonstrated favorable performance.

Methods - To investigate whether Oncuria-Detect, a multiplex immunoassay that detects a urothelial cancer associated diagnostic signature composed of 10 proteins in voided urine could improve detection of urothelial cancer while evaluating participants with gross hematuria. From September 2016 through July 2025, 9 academic, private practice, and hospital facilities in the US and Japan prospectively enrolled 450 participants with gross hematuria into this urothelial cancer evaluation study. Diagnosis of urothelial cancer was based on cystoscopy (or ureteroscopy) with biopsy, which is accepted as the reference standard. Prior to the cystoscopic/ureteroscopic evaluation, participants provided a urine sample for analysis of Oncuria-Detect and BladderChek (analyzed in a blinded manner) as well as urine cytology. The performance of Oncuria-Detect was compared with BladderChek and urine cytology as an aid to detect de novo urothelial cancer with cystoscopy/ureteroscopy and histological evaluation.

Results - Urothelial cancer was diagnosed in 97 participants (4 of whom had upper tract urothelial carcinoma and 93 with urothelial carcinoma of the bladder). The Oncuria-Detect assay was positive in 80 of 97 participants with cancer resulting in a sensitivity of 82.6% (95% CI, 74.9%-89.6%) with a specificity of 33.3% (95% CI, 28.7%-38.7%) and 88.4% adjusted negative predictive value (NPV) (95% CI, 83.8%-93.0%). BladderChek results were positive in 16 of 97 participants resulting in a sensitivity, 16.4% (95% CI, 10.0%-23.5%) with a specificity of 99.2% (95% CI, 98.0%-100.0%) and 82.6% adjusted NPV (95% CI, 81.5%-83.7%), whereas cytology test results were positive in 35 of 97 participants with a noted sensitivity of 35.7% (95% CI, 26.5%-46.1%) at a specificity of 99.7% (95% CI, 99.1%-100.0%) and 86.1% adjusted NPV (95% CI 84.4-88.1). Oncuria-Detect sensitivity remained high for low-grade 81.7% (95% CI, 67.2%-94.7%) *vs.* high grade 82.7% (95% CI, 74.2%-90.9%) and NMIBC 82.9% (95% CI, 74.4%-90.8%) *vs.* MIBC 79.8% (95% CI, 61.3%-94.7%).

Conclusions - In this large prospective trial, Oncuria-Detect, had a substantially superior sensitivity compared to both BladderChek and urinary cytology in detecting *de novo* urothelial cancers, allowing it to effectively rule out approximately 30% of individuals presenting for gross hematuria evaluation.

#6514 Detection of bladder cancer in patients with microscopic hematuria using Oncuria-Detect, interim analysis of an international prospective study.

Sunao Tanaka[1], Yair Lotan[2], Makito Miyake[3], Edward M. Messing[4], Arnold I. Chin[5], Menghan Liu[6], Ian Pagano[7], Yingye Zheng[8], Charles Joel Rosser[1], Zhen Zhang[9], Hideki Furuya[1]

[1]Cedars-Sinai Medical Center, Los Angeles, CA,[2]Associate Professor of Urology, UT Southwestern Medical Ctr., Dallas, TX,[3]Nara Medical University, Nara, Japan,[4]Chairman & Professor, Dept. of Urology, University of Rochester Cancer Center, Rochester, NY,[5]Assistant Professor, Dept. of Urology, University of California (UCLA), Los Angeles, CA,[6]Fred Hutchinson Cancer Center, Seattle, WA,[7]UHCC, Honolulu, HI,[8]Fred Hutchinson Cancer Research Ctr., Seattle, WA,[9]Associate Professor, Dept. of Pathology & Oncology, Johns Hopkins University School of Medicine, Baltimore, MD

Background - Microscopic hematuria occurs in up to 10% of the general population and initiates costly evaluation to ensure no bladder cancer exists. Oncuria-Detect is a 10-plex immunoassay that detects *de novo* bladder cancer by generating a protein biomarker signature from a single voided urine sample. This report details the interim analysis of our prospective study that compares the diagnostic performance of the multiplex Oncuria-Detect assay to that of the single-analyte (*i.e.*, NMP22) BladderChek urine assay and urine cytology for identifying bladder cancer in patients with microscopic hematuria.

Methods - From September 2018 through July 2025, 9 medical facilities in the US and Japan prospectively enrolled 292 eligible patients (~30%) of the proposed 900 patients with microscopic hematuria into this study. The bladder cancer diagnostic reference standard was cystoscopy with biopsy. Pre-cystoscopy, patients provided a urine sample for analysis by Oncuria-Detect and BladderChek (analyzed in a blinded manner) as well as urine cytology.

Results - Bladder cancer was diagnosed in 22 patients (7.5%). The Oncuria-Detect assay had the following performance characteristics 82.0% sensitivity, 37.8% specificity, 97.5% adjusted negative predictive value (NPV) compared to BladderChek (9.3% sensitivity, 99.6% specificity, 95.4% adjusted NPV) and cytology (44.8% sensitivity, 99.3% specificity, 97.2% adjusted NPV). Oncuria-Detect displayed better sensitivity than BladderChek and cytology for identifying early- and late-stage cancer.

Conclusions - In this interim analysis of an international prospective trial, Oncuria-Detect performed favorably in the non-invasive evaluation of bladder cancer presence in patients presenting with microscopic hematuria.

#6515 High-throughput, 96-well plate-based single-cell TCR sequencing for scalable chain-pairing and immunophenotyping of cancer-associated T cells.

Alex Chenchik, Tianbing Liu, Dongfang Hu, Kitt Paraiso, Lester Kobzik, Khadija Ghias, Paul Diehl

Cellecta, Inc., Mountain View, CA

We present a streamlined, plate-based single-cell adaptive immune receptor (AIR) profiling technology that enables the discovery and detailed characterization of disease-relevant TCR clonotypes in cancer-associated T cells. Using a scalable 96-well plate workflow, flow-sorted single cells are individually isolated for multiplex RT-PCR of TCR α β chains together with 36 immunophenotyping genes, followed by Illumina NextSeq sequencing. The approach leverages MiXCR and RCEM software pipelines to deliver full-length paired TCR sequences, high-resolution clonotype frequency data, and a profile of key gene expression markers. Applied to longitudinal samples from T-cell large granular lymphocytic leukemia (T-LGL) patients, this method identified both dominant and rare clonotypes--with functional annotation--across multiple timepoints, including a case with a single expanded cytotoxic effector-memory T-cell clone (n=35 wells, with elevated NKG7 and CCL5 levels). High-throughput, “mini-bulk” configurations (approx. 100 cells/well) allow broader repertoire screening of ~10,000 cells/plate, detecting thousands of unique β chains and α β pairs, and facilitating the identification of rare, disease-associated clonotypes missed by bulk or lower-throughput methods.This rapid, cost-effective (<$0.10/cell), single-day workflow supports large-scale translational studies, providing direct access to paired receptor and phenotypic signatures from a variety of samples without reliance on microfluidics platforms or complex barcoding techniques. The technology significantly expands capacity for immunogenomic discovery and functional immunophenotyping, making it suited for biomarker validation, immunotherapy development, and real-time immune monitoring in cancer research.

#6516 Novel liquid biopsy epigenomic molecular tumor typing in carcinoma of unknown primary (CUP).

Axel Grothey[1], **Daniel Hintz**[2], Jayati Saha[2], Sheila R. Solomon[2], Nicole Zhang[2], Jack Tung[2]

[1]The West Clinic, Memphis, TN,[2]Guardant Health, Palo Alto, CA

Introduction: CUP is diagnostically complex commonly with treatment delays and poor outcomes. Diagnosis integrates clinical, radiologic, and pathologic data, but limited or exhausted tissue can restrict accuracy. Interrogation of cancer-derived epigenomic signatures provides insights that may support CUP adjudication. The Guardant360 Liquid (Guardant Health, Palo Alto, CA) Molecular Tumor Typing predictor (MTT) applies methylation signatures to predict cancer signal of origin with graded confidence across 14 solid tumors. This study describes MTT predictions and genomic landscapes in CUP vs non-CUP (NCUP) patients (pts) and examines real-world (RW) outcomes in CUP pts predicted to have lung cancer. Using InfinityAI Data Library, a database of claims data, treatment outcomes were examined in selected pts with MTT high confidence predictions.

Methods: CUP and NCUP pts with Guardant360 Liquid (LB) testing were identified from InfinityAI Data Library. Pts with high confidence MTT prediction (≥80% confidence) were included (n= 28,712). LB assessed alterations of >700 genes and thousands of differentially methylated regions. RW time to treatment discontinuation (RWTTD) and time to next treatment (RWTTNT) were evaluated as surrogate markers for RWOS and RWPFS, respectively, for CUP pts with MTT-predicted lung cancer vs NCUP pts with lung cancer on test requisition form (TRF). Pts were stratified by first line therapy post LB. Log rank test was used for time-to-event analyses.

Results: Of eligible pts, 1,145 had CUP and 27,641 had NCUP recorded on TRF. MTT with high confidence was generated for 74.7% of CUP and 71.7% of NCUP patients. MTT most often predicted lung (29.4%), biliary (15.5%), and gastroesophageal (10.5%) primaries in CUP, whereas lung (22.4%), breast (17.2%), and colon (18.7%) predominated in NCUP. In CUP pts with MTT predicted lung cancer, common alterations included *TP53* (69.1%), *KRAS* (31.7%), *EGFR* (28.4%), *KEAP1* (28.0%), and *STK11* (25.1%), while NCUP predicted as lung showed *TP53* (77.8%), *EGFR* (28.7%), *KRAS* (28.1%), *ATM* (26.4%), and *PIK3CA* (12.3%). In addition, there was no statistical difference in *KRAS* G12C ($p<0.1813$) and *EGFR* exdel19 ($p=0.273$) between the 2 cohorts. Treatment outcomes were available for 146 CUP-lung and 9,489 NCUP-lung pts. In the first 4 months (mo) RWTTNT was not statistically significant different, though favored targeted therapy. RWTTD was significantly longer in CUP-lung vs NCUP-lung ($p<0.0001$): median 3.7 vs 4.2 mo for non-targeted therapy, and 3.0 vs 8.0 mo for targeted therapy.

Conclusions: This study demonstrated RW pt outcomes after applying a plasma-based epigenomic MTT high confidence predictor. CUP-lung pts with targeted therapy had better survival outcomes vs pts with non-targeted treatment and have unique genomic profiles. This data is encouraging for MTT concordance with patient therapy selection and outcomes.

#6517 A decade-ahead signal of lung cancer from circulating exosomal sncRNAs.

Zhuokun Feng[1], Masaki Nasu[2], Lauren Higa[2], Isam M. Ibrahim[2], Loic L. Marchand[3], Youping Deng[1]

[1]Department of Quantitative Health Sciences, John A. Burns School of Medicine, University of Hawaii at Manoa, Honolulu, HI,[2]John A. Burns School of Medicine, University of Hawaii at Manoa, Honolulu, HI,[3]University of Hawaii Cancer Center, University of Hawaii at Manoa, Honolulu, HI

Lung cancer remains the leading cause of cancer-related mortality worldwide, yet current screening criteria focusing on heavy smoking overlook a significant portion of at-risk individuals. To develop a robust predictive biomarker, we profiled circulating exosomal small non-coding RNAs (sncRNAs, including miRNAs, piRNAs, tiRNAs, and tRFs) in a prospective discovery cohort (UHCC; n = 202 smokers, with up to 16-year follow-up) and an independent validation cohort (CHTN; n = 186) including healthy individuals or patients with either malignant or benign tumor of the lung. A rigorous 5×5 nested cross-validation pipeline integrating differential expression, correlation pruning, and eight classifier comparisons identified a 31-sncRNA panel. Random forest was selected as the optimal model and yielded excellent discrimination in UHCC (AUC=0.97), with sensitivity 0.93 and specificity 1.00 at the Youden-optimized threshold. In the independent validation cohort, the signature demonstrated moderate performance, particularly in discriminating diagnosed cancer patients from healthy controls (AUC=0.73; AUPRC=0.85). Furthermore, the resulting risk score was strongly associated with incident lung cancer in the UHCC cohort, independent of demographic and smoking factors (multivariable OR=13.19, 95% CI 6.83-25.45), and predicted a shorter time-to-diagnosis in a Fine-Gray competing risks model (sHR=4.73, 95% CI 3.61-6.21) with a significant non-linear dose-response. Landmark and time-dependent analyses confirmed robust discrimination up to a decade pre-diagnosis, although precision was attenuated at longer intervals. At last, pathway analysis of the signature's targets implicated key oncogenic pathways, including the PI3K-Akt, p53, MAPK, ErbB, and mTOR signaling pathways. This work establishes a panel of novel exosomal sncRNA signatures as a powerful risk prediction biomarker for lung cancer, enabling early risk stratification and creating a critical window for timely clinical intervention.

#6518 Integrating machine learning to optimize FFPE variant calling in a comprehensive genomic profiling assay for hematologic malignancies.

Grant Hogg[1], Tong Liu[1], Helen Cao[1], Adib Shafi[1], Amanda Williamson[2], Ashraf Shabaneh[1], Kimberly A. Holden[1], John Howitt[2], Xiaojun Guan[1], Michael Mooney[3], Li Cai[2], Eric A. Severson[2], Maria-Fernanda Senosain[4], Erik Vanroey[4], Shakti Ramkissoon[2], Anjen Chenn[2], Robert Daber[5], Marcia Eisenberg[6], Brian Caveney[6], Eyad Almasri[1], Taylor Jensen[2], Jon Williams[1]

[1]Oncology, Labcorp, San Diego, CA,[2]Oncology, Labcorp, Durham, NC,[3]Women's Health and Genetics, Labcorp, Durham, CA,[4]Oncology, Labcorp, Buffalo, NY,[5]Oncology, Labcorp, Metropark, NJ,[6]Labcorp, Burlington, NC

Optimal clinical management of lymphoma and other hematological malignancies require assessment of somatic mutations across a subset of clinically relevant genes. However, most lymphoma specimens are received after being formalin fixed and paraffin-embedded (FFPE), a process that can induce DNA damage leading to reduced specificity when assayed with next generation sequencing (NGS). Here we present the analytical validation results of a targeted NGS panel of 141 clinically relevant genes for pan-heme indications using FFPE samples. We also describe an analysis pipeline that performs additional filtering steps for FFPE specimens. The analysis pipeline is designed to analyze FFPE and non-FFPE samples (blood/bone marrow samples from myeloid or lymphoid malignancies) sequenced on the same flow cell with specific analysis performed for each specimen type automatically. FFPE has distinct variant calling parameters compared to blood/bone marrow and an additional random forest machine learning (ML) model to filter variants associated with FFPE artifacts. The FFPE NGS panel interrogates all coding exons of the 141 genes to detect single nucleotide variants (SNVs) and insertions/deletions (indels) up to 50bp at variant allele frequency ≥ 5%. The custom hybrid capture-based assay utilizes genomic libraries created from 50-182.5 ng gDNA extracted from FFPE tissue, followed by sequencing on Illumina® instruments. Concordance studies were performed on clinical samples previously assessed using orthogonal NGS-based assays for SNVs/indels. In total, 198 FFPE samples including 72 unique clinical FFPE samples were assessed. Analysis of concordance demonstrated a positive percent agreement (PPA) of 93.9% for SNV/indels (388/413) and false discovery rate (FDR) of 4.9% (20/408). Assay precision was determined using three replicates of 5 clinical FFPE samples at minimal DNA input for both intra and inter-assay precision. Overall precision was 95.9% (394/411). Minimal DNA input was established to be >50ng of input material based on results obtained from 6 clinical FFPE samples. Analytical specificity was >99.99% for SNVs/indels based on 5 replicates of FFPE NA12878. Analytical sensitivity was 3.7% VAF for SNV/indels based on a hit rate dilution series. The ML model removed 10 putative FPs throughout the study. Performance on an independent test set of 44 clinical FFPE analysis showed concordance of 95.5% (445/466) compared to 89.5% (445/497) without the ML model. These data describe the FFPE performance of an assay that enables a comprehensive evaluation of genomic alterations in hematologic malignancies from all major specimen types and indications using one laboratory workflow. The workflow includes a flexible pipeline with an optional ML model to successfully filter artefacts associated with FFPE DNA damage.

#6519 *In silico* discovery of fusion-specific RNA biomarkers in pediatric leukemias.

Elizabeth Tsuying Chang, Sean Lee

Tulane University School of Medicine, New Orleans, LA

Purpose: Pediatric leukemia remains a leading cause of cancer-related mortality in children, with fusion-driven subtypes such as KMT2A-rearranged and ETV6-RUNX1 leukemias accounting for a significant proportion of high-risk cases. Despite improvements in overall survival, fusion-positive leukemias are associated with poorer outcomes, suboptimal therapeutic response, and elevated relapse risk. A persistent challenge in pediatric oncology is delayed relapse diagnosis. Although minimal residual disease testing and bone marrow aspiration remain standard for diagnosis and monitoring, these approaches are invasive, costly, and often fail to capture dynamic oncogenic changes. Oncogenic chimeric transcription factors (OCTFs), formed by abnormal gene fusions, are key molecular drivers in many pediatric leukemias. Emerging transcriptomic data suggest that OCTF-driven tumors produce unique noncanonical RNA transcripts termed neogenes which may be highly cancer-specific and represent a promising new class of RNA biomarkers. The purpose of this study is to identify and characterize neogene transcripts in fusion-driven pediatric leukemias with the goal of evaluating their potential as subtype-specific RNA biomarkers for early detection and disease monitoring.
Methods: We assembled a modular transcriptome pipeline to identify neogene candidates in fusion-driven pediatric leukemias. Publicly available RNA-seq datasets were aligned to the human reference genome using STAR (Spliced Transcripts Alignment to a Reference), followed by transcript assembly with Scallop. Unannotated transcripts were identified via Gffcompare and quantified post-normalization. Candidate neogenes were filtered based on novelty, cross-sample recurrence, and biological plausibility. Parallel quantification of non-leukemic fusion-positive and fusion-negative cancers and normal tissues were performed to assess for neogene specificity.
Results: Seven pediatric leukemia subtypes were profiled: AML, AMoL, APL, CML, T-ALL, and preB/proB-cell leukemia. Preliminary analyses reveal that each subtype exhibits a distinct neogene signature not observed in non-leukemic fusion-positive cancers (Ewing sarcoma, rhabdomyosarcoma, and Desmoplastic Small Round Cell Tumor) or in common fusion-negative pediatric malignancies (neuroblastoma, nephroblastoma, and hepatoblastoma). Chromatin accessibility and histone modification markers at neogene loci provide evidence for active transcription and supports biological relevance of transcripts.
Conclusion: In silico findings support the existence of subtype-specific neogene signatures in fusion-driven pediatric leukemias. These transcripts may serve as novel biomarkers for early detection, subtype classification, and treatment monitoring. Further validation is underway to assess clinical utility and translational potential.

#6520 Development and first clinical experiences of a phage display derived bicyclic peptide for EphA2-specific PET imaging.

Ann-Christin Eder[1], Mohamed A. Omrane[1], Christoph-Ferdinand Wielenberg[1], Mohamed El Fakiri[1], Aikaterini Klotsotyra[1], Katia Bruggemann[1], Heiko Becker[1], Michael Quante[1], Michael Mix[1], Anusha Regupathy[2], Ben Blakeman[2], Francesca Wood[2], Gemma E. Mudd[2], Matthias Eder[1], Philipp T. Meyer[1], Martin T. Freitag[1]

[1]University Medical Center Freiburg, Freiburg, Germany,[2]Bicycle Therapeutics, Cambridge, United Kingdom

Background: Erythropoietin-producing hepatocellular receptor A2 (EphA2) is a tyrosine kinase receptor overexpressed in multiple solid tumors including pancreatic, bladder, head and neck, breast, colon, prostate, and lung cancers. EphA2 is associated with increased severity, metastatic disease and poor clinical prognosis. Following successful preclinical optimization of a phage display-derived EphA2-specific bicyclic peptide[1], this study outlines the first in-human application of EphA2-targeting [^{68}Ga]Ga-BCY18469 in PET/CT imaging.

Methods: Preclinical characterization of the EphA2-targeting bicyclic peptide BCY18469 was conducted by assessing stability, binding affinity, internalization, biodistribution and µPET/MR imaging in EphA2^{+} HT1080 and EphA2^{-} MCF-7 xenograft tumor-bearing nude mice. For clinical translation, seven patients with histologically confirmed pancreatic cancer (5 metastatic, 2 newly diagnosed) underwent [^{68}Ga]Ga-BCY18469-PET/CT (compassionate use). Four patients were examined at 15, 30, 45, 60, and 180 min p.i. for biodistribution and dosimetry assessment, three additional patients at 45 min p.i. (172±42 MBq). Time-activity curves were fitted monoexponentially, and dosimetry calculations were done using IDAC-Dose-Software.

Results: [^{68}Ga]Ga-BCY18469 demonstrated EphA2-specific binding and internalization, proteolytic stability up to 72 hours, and rapid background clearance with high tumor uptake, thereby enhancing imaging contrast within 30 minutes in mice. In clinical cases, [^{68}Ga]Ga-BCY18469 demonstrated rapid tumor uptake and was predominantly excreted via the kidneys. Notably, hepatic uptake remained favorably low (SUVmean 0.9±0.3 at 45 min p.i). Mean absorbed doses were 0.49 ± 0.24 mGy/MBq (kidneys), 0.14 ± 0.08 mGy/MBq (salivary glands), and 0.016 ± 0.003 mGy/MBq (liver). EphA2-targeted PET imaging successfully detected 13 liver metastases (SUVmax 6.9±3.4), 2 bone lesions (SUVmax 6.1±0.5), 13 lymph node metastases (SUVmax 5.0±1.1), and 2 peritoneal lesions (SUVmax 5.1±0.8). Primary tumor uptake was observed in 6 of 7 patients, albeit with lower intensity compared to liver metastases (SUVmax 4.8±1.6). Two pulmonary foci and 7 liver lesions identified on CT as morphologically consistent with metastases showed no uptake on EphA2-PET.

Conclusion: This first-in-human application of EphA2-targeting [^{68}Ga]Ga-BCY18469 demonstrates the feasibility for visualization of EphA2-expressing primary tumors and metastases, which is in line with the preclinical findings. These initial clinical results support further investigation of [^{68}Ga]Ga-BCY18469 as a diagnostic tool with potential to improve tumor characterization and patient management strategies in EphA2-positive cancers.

#6521 Actionable fusions and rearrangements can be efficiently identified by Hi-C whole genome sequencing in lung tumors.

Alex R. Hastie[1], Kristin Sikkink[1], Matija Snuderl[2], Darren S. Sigal[3], Sid Selvaraj[1], Anthony Schmitt[1]

[1]Arima Genomics, San Diego, CA,[2]NYU Langone Health, New York, NY,[3]Scripps Clinic and Scripps Cancer Center, La Jolla, CA

Introduction: Molecular testing in lung and other solid tumors has led to the identification of driver mutations that can be effectively targeted by new therapeutics. In addition to single point mutations that activate signaling proteins such as EGFR and KRAS, the presence of various gene fusions that lead to activation of key oncogenic drivers have become prominent drug targets. Detection of these fusions by RNA sequencing is the current gold standard but evidence suggests that fusions are still missed for various reasons. This study aims to improve detection rate of targetable fusions and rearrangements in solid tumors using a new method called Hi-C sequencing.

Methods: Hi-C sequencing is a novel whole genome DNA-sequencing assay for detection of structural variation based on unique Hi-C chemistry which leverages sequencing of linked pairs of reads which occur nearby one another in 3-dimensional and linear space, from FFPE samples. Linking reads amplifies the rearrangement signal by providing many more read pairs spanning the breakpoint and also overcoming masked fusions resulting from breakpoints in non-unique sequences.

Results: In a set of 139 NSCLC samples, Hi-C sequencing demonstrated 100% concordance with FISH and/or RNA sequencing results in cases with known fusions (19/19, including 11 *ALK*, 2 *MET*, 2 *ROS*, 2 *MET*, 1 *NTRK*, 1 *NRG1* and 1 *RET* fusions). The next cohort of 97 samples were previously determined by standard DNA and RNA sequencing to be negative for drivers such as *EGFR* and *KRAS* mutations and fusions of *ALK, MET, NTRK, RET,* and *ROS*. In this cohort, we have detected biomarkers related to drug sensitivity in 16 cases. These include targetable fusions such as *NTRK2* (1), *NRG1* (1), *PRKCA* (1), and *ERBB2* (*1*). Furthermore, we detected loss of function variants indicating sensitivity to checkpoint inhibitors (2 cases), or PARP inhibitors (6). In addition, noncanonical fusions were detected in *NRG1* (1), and *ALK* (1), both retaining their functional domains and potentially indicating sensitivity to inhibitors.

Conclusions: Encouraging results from this study suggest that Hi-C sequencing may be a valuable tool in the molecular classification of NSCLC and other solid tumors and could lead to improvement in patient care. Hi-C can detect gene fusions and rearrangements that are known to drive cancer and may be used for therapy selection, including in cases which were negative by standard genetic testing.

#6522 Novel serum biomarkers that detect ovarian cancer recurrence earlier than CA125.

Cuipeng Qiu[1], Hailing Yang[1], Zhen Lu[1], Joseph Celestino[1], Ridge T. Rogers[1], Karen H. Lu[2], Eleftherios P. Diamandis[3], Ioannis Prassas[4], Robert C. Bast[1]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]Moffitt Cancer Center, Tampa, FL,[3]Lunenfeld-Tanenbaum Research Institute (LTRI) Sinai Health System, Toronto, ON, Canada,[4]University of Toronto, Toronto, ON, Canada

Despite a complete clinical response to primary surgery and chemotherapy, 80% of patients with advanced stage (III-IV) ovarian cancer recur. The serum biomarker CA125 is widely used to monitor patients for recurrence. Doubling of CA125 outside the normal range detects recurrent ovarian cancer in 70% of cases with a lead time of 3 - 4.8 months. Here we report novel biomarkers that detect recurrence missed by CA125 and that detect recurrence at an earlier interval than elevation of CA125. Novel biomarkers for recurrent OC were measured with the Olink multiplexed proximity extension assay. In a previous study, >1,196 Olink biomarkers were screened to identify 21 that detected disease recurrence including MUC16 (CA125), HE4 and 19 novel candidates (Ren et al., *Cancer Research* 80.16_Supplement (2020): 5144-5144). The 21 biomarkers were measured in 309 serial serum samples from 51 OC patients with advanced stage ovarian cancer who had been placed in complete clinical remission with primary surgery and chemotherapy and then monitored for recurrence with CA125 for an average of 4 years (range 1 - 8).Among the 51 OC cases, recurrence was observed in 31 cases with 17 exhibiting elevated CA125 (>35 U/mL) at the time of recurrence and 14 experiencing recurrence without CA125 elevation. Overall, 20 cases remained in remission during the observation period. We identified four biomarkers (DEFB4A, SULT1A1, TBCB, and TCL1A) that detected OC recurrence more than three months prior to clinical confirmation. In cases where biomarkers increased, TCL1A was elevated 131 days, TBCB 104 days, SULT1A1 242 days and DEFB4A 265 days prior to clinical recurrence. A combination of the four markers detected 14 of 31 (45%) recurrent cases at least three months earlier than standard clinical diagnosis. The four-biomarker combination identified 6 of 14 (43%) CA125-negative recurrent cases more than three months in advance. In summary, this study identifies a four-biomarker serum panel that improves early detection of OC recurrence compared to CA125 alone. The panel offers a more than three months lead time for detection of recurrence and detected patients with normal CA125 levels.

#6523 High-purity isolation of tumor-derived extracellular vesicles via SEC-immunoaffinity integration improves diagnostic sensitivity in breast cancer.

Young Kim, Min Woo Kim, Sol Moon, Su Ji Lee, Joon Ye Kim, Seung Il Kim, Jee Ye Kim

Yonsei University College of Medicine, Seoul, Korea, Republic of

Background: Extracellular vesicles (EVs) provide a non-invasive approach for liquid biopsy due to their enriched molecular cargo and structural stability. However, EV heterogeneity and contamination of current EV isolation methods by non-vesicular extracellular particles (NVEPs), particularly lipoproteins, remain substantial obstacles to reliable biomarker analysis. Reports showing that several proposed EV biomarkers are enriched in NVEP fractions underscore the need for high-purity EV isolation.
Methods: To improve plasma-derived small EV (sEV) purification, we systematically evaluated size-exclusion chromatography (SEC) resins using purified control materials representing sEVs, large EVs, lipoproteins (HDL, LDL, VLDL) and albumin. Fraction distribution patterns were mapped to predict NVEP co-elution during plasma processing. Based on these observations, SEC was combined with apoB100-based immunoaffinity depletion to reduce lipoprotein contamination. Tumor-derived EVs (tdEVs) were then enriched using immunocapture targeting breast cancer-associated surface epitopes, enabling downstream multi-omics analysis.
Results: CL-6B generated sharp peaks for individual control materials but showed convergence of VLDL and a portion of LDL in fraction 6, indicating a high likelihood of overlap with sEV-associated fractions when applied to plasma. In contrast, CL-4B produced broader elution patterns, with LDL largely absent from sEV-associated fractions and VLDL distributed across fractions 5-15, reducing the degree of overlap with sEVs. These findings indicate that CL-4B provides more favorable separation characteristics for plasma sEV purification. ApoB100-mediated immunoaffinity depletion further reduced VLDL and HDL signals while maintaining sEV recovery. The resulting fractions showed improved particle-to-protein ratios, decreased ApoA1/ApoB signatures, and retention of canonical sEV markers. Breast cancer-specific immunocapture enriched tdEVs carrying elevated levels of an oncogenic miRNA signature previously reported in our cohorts. Notably, this tdEV-focused miRNA panel demonstrated improved diagnostic sensitivity compared with our earlier total-EV-based approach, suggesting that high-purity tdEV enrichment more accurately reflects tumor-derived molecular profiles.
Conclusion: We developed an analytically stable EV purification workflow that combines optimized SEC with sequential immunoaffinity strategies to minimize NVEP interference while preserving sEV integrity. This high-purity, tumor-focused platform enables reliable multi-omics profiling of circulating tdEVs and supports the development of clinically applicable biomarkers for early breast cancer detection and disease monitoring.

#6524 Identification of diagnostic and prognostic extracellular vesicle biomarker signatures in inflammatory breast cancer.

Serena Lucotti[1], Mara Serena Serafini[2], Eleonora Nicolo[2], Letizia Pontolillo[2], Charles Warren[3], Brenno Pasto[2], Caterina Gianni[2], Nadia Bayou[2], Jacob B. Geri[4], Carolina Reduzzi[2], Massimo Cristofanilli[2], David Lyden[1]

[1]Departments of Pediatrics and Meyer Cancer Center, Weill Cornell Medicine, New York, NY,[2]Department of Medicine, Division of Hematology-Oncology, Weill Cornell Medicine, New York, NY,[3]Tri-Institutional PhD Program in Chemical Biology (TPCB), New York, NY,[4]Department of Pharmacology, Weill Cornell Medicine, New York, NY

Background: Inflammatory breast cancer (IBC) is a rare and aggressive type of BC with a very poor prognosis and accounts for 10% of BC-related deaths. Diagnosis of IBC is particularly challenging, as its symptoms resemble mammary infection and the tumor often presents with metastases at the time of diagnosis. Despite growing body of work, tools for identification and risk stratification of patients with IBC are lacking. Small extracellular vesicles (sEVs) mediate cell-to-cell communication and are released in the blood circulation, thus potentially serving as predictive and prognostic biomarkers. We have previously shown that sEVs are functional determinants of BC progression, but their role in IBC outcomes is not known.
Methods: sEVs were isolated from longitudinal plasma samples collected from patients with IBC (n=20), matched non-IBC patients (n=11), and healthy controls (HC, n=15) by ultracentrifugation and liquid chromatography mass spectrometry. Statistical analyses were conducted in R: (a) Kruskal-Wallis tests, followed by pairwise Wilcoxon rank-sum tests with Benjamini-Hochberg false-discovery rate (FDR) correction (IBC vs. non-IBC and HC); (b) Spearman's correlation with FDR correction for multiple testing (association with clinical parameters); (c) receiver operating characteristic (ROC) curve analysis (diagnostic performance); (d) Kaplan-Meier survival analysis with log-rank testing and Cox proportional hazards regression (association with overall survival [OS]).
Results: Out of the 2540 sEV proteins detected, we have identified a signature of 20+ proteins enriched more than 2-fold in plasma sEVs from IBC patients compared to non-IBC or HC and associated with immune response pathways. In univariate analysis, a total of 10 sEV biomarkers achieved an area under the curve (AUC) > 0.88, including MARCKSL1, which demonstrated the highest discriminatory power for IBC vs. non-IBC (AUC = 0.955, confidence interval [CI]: 0.878-1.000, sensitivity 100%, specificity 81.8%). When sEV proteins were compared with clinicopathological features, 998 significant associations were identified (FDR < 0.05 and p-value < 0.05), with the strongest associations observed for Ki67 proliferation index, tumor grading, and OS. Exploratory survival analyses identified a set of 20+ overrepresented sEV proteins in patients with IBC and worse OS. High composite scores of the top three sEV biomarkers (correlation > 0.81, $p < 0.0001$) showed a trend toward increased mortality with good prognostic discrimination (C-index = 0.705).
Conclusions: Our comprehensive proteomic analysis revealed extensive and robust associations between circulating sEV protein biomarkers, IBC detection, and clinical parameters, suggesting potential clinical utility as “liquid biopsy” biomarkers for IBC diagnosis and prognosis. Further validation in larger independent cohorts is warranted.

#6525 Real-time clinical validation of the Geneverify blood mRNA test for breast cancer screening and diagnosis.

Sudhir Rawal[1], Smreti Vasudevan[1], Samson Mani[1], Vishvak Chanthar[1], Dharam P. Chauhan[2], **Rajvir Dahiya**[3]

[1]Rajiv Gandhi Cancer Institute & Research Centre, New Delhi, India,[2]Geneverify Inc, Hayward, CA,[3]UCSF School of Medicine, San Francisco, CA

Background: Early detection remains the cornerstone of successful breast cancer management. We conducted a real-time clinical validation of the plasma cell-free mRNA-based Geneverify test for early screening and detection of breast cancer. This next-generation approach offers rapid, precise, and non-invasive results, potentially transforming the current diagnostic landscape by reducing dependence on surgical biopsies and enhancing early diagnosis.

Methods: We evaluated the real-time expression of 30 different breast cancer associated genes in plasma samples collected from 51 subjects (41 cases and 10 Controls). Eligible participants were selected based on the availability of paired blood and surgical tissue specimens from cases suspected of breast cancer. We assessed the diagnostic and prognostic potential of a multi-gene expression panel developed by Geneverify Inc. using blood samples. The $\log_2$-fold change in gene expression was calculated and used to generate a risk score for each subject. To determine the test's diagnostic performance and discriminatory power, we constructed receiver operating characteristic (ROC) and calibration curves. The Geneverify scores were compared against biopsy-confirmed results to calculate sensitivity and specificity. Geneverify scores were evaluated with respect to the patient's stage, grade, and metastasis.

Results: A total of 51 subjects were evaluated, including 41 suspected breast cancer cases and 10 healthy controls. The Geneverify Dx genetic risk score effectively distinguished breast cancer patients from benign controls. The area under the ROC curve (AUC), indicating acceptable discriminatory performance. Using a risk score cutoff of 17 yielded 100% sensitivity. Calibration analysis demonstrated that the probability of breast cancer increased progressively with higher Geneverify Dx scores, reaching 100% positivity at scores 35. Spearman's rank correlation revealed a significant positive association between the risk score and clinical stage, as well as pathological grade. Furthermore, metastatic cases exhibited significantly higher scores compared to non-metastatic cases. Benign subjects showed markedly reduced gene expression levels and substantially lower risk scores.

Conclusions: This prospective clinical study represents the first real-time validation of a blood-based, cell-free mRNA Geneverify test for screening and early detection of breast cancer. The test demonstrated exceptional diagnostic precision, reduce reliance on invasive biopsies, and ultimately improve patient management.

#6526 Integrated disc-fluidic platform for high-throughput extracellular vesicle processing in liquid biopsy.

Hakho Lee[1], Hyun-Kyung Woo[1], Cesar M. Castro[1], Jun Seok Park[2], Yoon-Jeong Choi[1]

[1]Harvard Medical School/Massachusetts General Hospital, Boston, MA,[2]Kyungpook National University Medical Center, Daegue, Korea, Republic of

Extracellular vesicles (EVs) represent a promising class of cancer biomarkers, enabling repeated and minimally invasive access to tumor-derived molecular information. A major challenge, however, is that EVs are embedded in complex and variable biological matrices, making the purification and standardized processing of these particles essential for reliable clinical analysis. Existing EV isolation methods are slow, labor-intensive, and prone to variability; limitations that hinder widespread adoption in translational cancer research. Here, we present an integrated centrifugal disc-fluidics platform designed for automated, high-throughput EV processing. The system incorporates key innovative features, including plasma separation, chromatographic EV purification, centripetal liquid transfer, and bead-based EV capture and immunolabeling. These modules operate seamlessly to execute a complete EV workflow on a single disposable disc. Using whole blood inputs, the developed system enriched plasma EVs within 8 minutes while removing >96% of lipoprotein contaminants. It further enabled multiplexed immunolabeling for 16 EV protein targets, completing the entire workflow in <75 minutes. In a pilot clinical study (n = 221 plasma samples), we applied the prototype device for multi-panel (30-marker) EV protein profiling. The resulting signatures robustly distinguished cancer from non-cancer samples and further stratified tumor types. By combining automation, standardization, and throughput, this disc-fluidic platform provides a scalable route toward reproducible EV analytics and has strong potential for advancing EV biomarkers into clinical oncology applications.

#6527 High-sensitivity whole-transcriptome sequencing of FFPE tumors enables immune profiling and predictive biomarker discovery.

Hang Dong[1], **Haoran Tang**[1], Feng Xie[1], Yue Zhang[1], Juanbai Shang[2]

[1]Huidu (Shanghai) Medicine Ltd., Shanghai, China,[2]Shanghai Medical College, Fudan University, Shanghai, China

Background: Immune-based biomarkers are essential for predicting therapeutic response in cancer patients, yet transcriptomic profiling of formalin-fixed paraffin-embedded (FFPE) tissues remains limited by RNA degradation and low input availability. PredicineWTS is a high-sensitivity whole-transcriptome sequencing (WTS) assay optimized for FFPE specimens, designed to support immuno-oncology research and precision therapy development.

Methods: PredicineWTS underwent analytical validation for FFPE inputs, assessing accuracy, precision, linearity, and reproducibility at low RNA quantities. The assay maintains high accuracy and precision at a 30 ng RNA input, enabling reliable transcriptome-wide profiling of challenging FFPE samples. A comprehensive bioinformatics analysis framework was established to perform quality control and characterize gene expression. Differential expression analysis, immune cell infiltration estimation, and HLA typing were performed to profile the tumor immune microenvironment and patient-specific immunogenomic features.

Results: The assay was applied to a clinical cohort of 24 urothelial carcinoma patients with paired pre- and post-treatment FFPE samples to identify transcriptional changes associated with therapeutic response. With 44 out of 48 samples achieving a unique alignment rate >80% and an average exonic rate of 86.9%, the assay demonstrates robust capture of high-quality RNA molecules for expression estimation. Comparative expression analysis revealed five immune-related genes—CD80, OASL, IDO1, HAVCR2 (TIM-3), and GZMB—that were significantly downregulated in responders ($p < 0.01$). These genes have been reported to be immune-associated regulators that reduce immune activation and shift immune contexture during effective therapy. We observed a significant 10% decrease in tumor purity following treatment in responders ($p = 0.03$), while no significant changes were observed in non-responders. These findings implicate a role for the tumor microenvironment in treatment efficacy. The patient-specific HLA typing analysis demonstrated substantial inter-individual variability in antigen presentation capacity, underscoring its relevance for guiding personalized immunotherapy strategies.

Conclusions: PredicineWTS enables highly sensitive, low-input whole-transcriptome profiling of FFPE tumor tissues, supporting robust immunogenomic characterization in clinical research settings. In this clinical cohort, decreased expression of five key immune genes and differential immune infiltration patterns were associated with treatment response. Integration of transcriptomic profiling, immune landscape assessment, and HLA typing provides a comprehensive framework for immunotherapy biomarker discovery and personalized treatment planning.

#6528 Evaluating molecular tumor type predictions for identifying new primary malignancies - A real-world clinical genomics analysis.

Elmira Forouzmand, Jack Tung, Nicole Zhang, William W. Young Greenwald, **Yupeng He**

Guardant Health, Palo Alto, CA

Background: Accurately distinguishing secondary malignancies from metastatic progression is critical in cancer surveillance, as each carries distinct prognostic and therapeutic implications. However, this distinction is often limited by overlapping radiologic features and the need for tissue biopsy. Methylation-based molecular tumor typing (MTT) of circulating tumor DNA (ctDNA) enables inference of tumor origin from blood and could support non-invasive and early identification of secondary malignancies.
Method: The MTT algorithm was developed to differentiate methylation signals across 14 cancer types. For each evaluable sample, MTT reports top predictions and associated confidence scores. We evaluated concordance between MTT predictions and clinical evidence of secondary malignancies in samples tested with the Guardant Reveal (Guardant Health, Palo Alto, CA) assay for MRD detection.
Insurance claims data from GuardantINFORM identified patients with evidence of multiple primary malignancies. Eligible patients had distinct primary cancers supported by sufficient ICD-10 codes and at least one evaluable Reveal sample within ±180 days of the second primary diagnosis. When multiple samples were available, the one closest to the second diagnosis was analyzed. To evaluate the effect of disease timeline on MTT performance, samples were stratified by interval since initial diagnosis: early (<=3 years) and late (>5 years). Second primary diagnoses in the early group were considered more likely to represent diagnostic refinement or recurrence, whereas those in the late group were presumed to reflect biologically independent new primaries.
Results: Of the 101 eligible patients, 82 had a high confidence MTT prediction (81%). Among these 82, 88% (72/82) of top MTT predictions matched either the initial diagnosis or the second diagnosis. MTT results tended to reflect the new primary with longer intervals between initial and secondary diagnoses: For samples collected >5 years after the original diagnosis (late category), MTT matched the second primary in 68% (19/28) and the first in 14.3% (4/28) of cases. In comparison, among samples in the early category, MTT matched the second and first primary in 45% (19/42) and 47.6% (20/42) of cases, respectively. Among the 9 late cases whose MTT prediction did not match the second diagnosis, 4 had MTT aligned with the original primary, and the MTT predictions of another 3 were biologically related to the second diagnosis (e.g., uterine predicted as ovarian; colorectal predicted as gastroesophageal).
Conclusions: This analysis demonstrates the potential of noninvasive epigenomic-based molecular tumor typing to identify evidence of new primary cancers during MRD assessment. This blood-based approach for MTT prediction could enable seamless integration of recurrence monitoring with the detection of new primaries.

#6529 Vaginal microbiome dynamics and clinical outcomes in cervical cancer patients undergoing radiotherapy.

Yogita Mehra[1], Julia Chalif[2], Elizabeth LaPlante[3], Laura Flora[3], Caroline Dravillas[1], January Kim[3], Jessica Aduwo[3], Naa Korley[3], Nyelia Williams[3], Rebecca Hoyd[1], David O'Malley[2], Elizabeth K. Arthur[3], Allison M. Quick[2], Daniel Spakowicz[1], Laura Chambers[2]

[1]The Ohio State University Comprehensive Cancer Center, Columbus, OH,[2]The Ohio State University Wexner Medical Center, Columbus, OH,[3]The Ohio State University, Columbus, OH

Advanced and recurrent cervical cancer (CC) is one of the major causes of death worldwide. Despite the advent of novel therapies and increasing utilization of immune checkpoint inhibitors, patients with advanced or recurrent CC have a poor prognosis, limited treatment options, and significant treatment-related toxicities. Limited evidence suggests that the vaginal microbiome (VM) may predict treatment outcomes and toxicity. Studies of the VM following radiotherapy (RT) using 16S amplicon sequencing observed a reduction in *Lactobacillus* and an increase in *Prevotella*. However, significant gaps remain in our understanding of the functional activities of these communities and their interactions with the host. To fill this gap, we initiated the “vaGinal hEalth in women ReceivinG pelvic radiation” (GEORGIA) trial to assess VM dynamics in CC patients undergoing RT and to investigate whether baseline microbiome composition predicts post-treatment outcomes. The GEORGIA trial (NCT04713618) enrolled 31 patients with CC who received pelvic RT. Vaginal swabs were collected at baseline and up to 24 months post-treatment. We assessed the metatranscriptome (metaT) using 2×150 bp sequencing libraries (>50 million reads per sample) to evaluate microbial abundance, activity, and human gene transcription. Longitudinal mixed-effects models (lme4 in R) and differential abundance analysis (ANCOM-BC2) were used to correlate microbial data with clinical variables, including recurrence status. A total of 27 patients had complete demographic information and longitudinal sequencing data. Over one-third were current smokers (35.5%), while 38.7% had never smoked, and 45.2% were post-menopausal at the time of treatment. Vaginal swab RNAseq reads aligned to human and microbe reference genomes in approximately equal numbers. Pelvic RT significantly altered the VM, driving a shift toward higher alpha diversity, as evidenced by increases in the Shannon ($p = 0.001$) and Simpson ($p = 0.002$) indices over time. When stratified by recurrence status, no significant differences in alpha diversity trajectories were observed. Differential abundance analysis revealed significant enrichment of taxa previously associated with HPV persistence and CC recurrence in VM studies, including *Fusobacterium hominis* ($p = 0.02$) and *Fusobacterium gonidiaformans* ($p = 0.03$), suggesting a potential role in disease progression. These findings underscore the possible influence of the VM on clinical outcomes and highlight its emerging role as a predictive factor in CC recurrence. Ongoing analysis will explore functional profiling and advanced longitudinal modeling to identify early microbial shifts preceding recurrence. We will use predictive modeling, integrating microbial and clinical features, to construct a recovery model and generate hypotheses for underlying biological mechanisms that can be tested experimentally.

#6530 Molecular biological differences between breast and cutaneous apocrine carcinomas.

Kei Kawashima[1], Eleanor A. Fallon[1], Kohei Chida[1], Mahato Sasamoto[2], Masanori Oshi[2], Akimitsu Yamada[2], Itaru Endo[2], Kazuaki Takabe[1]

[1]Roswell Park Comprehensive Cancer Center, Buffalo, NY,[2]Yokohama City University, Yokohama, Japan

Background: Breast apocrine carcinoma (BAC) and cutaneous apocrine carcinoma (CAC) are both adenocarcinomas with apocrine morphology. BAC is a mammary epithelial adenocarcinoma with apocrine metaplasia, whereas CAC arises from cutaneous apocrine glands. The axilla is not only rich in apocrine glands but can also contain ectopic breast tissue, allowing both tumors to arise. Despite different treatments and prognoses, they share highly similar histologic features, and no reliable diagnostic markers exist. We hypothesized that transcriptomic analyses could clarify the biological differences between BAC and CAC and provide molecular insights for distinguishing them.
Methods: We utilized clinical and transcriptomic data from the ORIEN cohort (breast carcinoma, n = 1,797 including 4 BACs; skin cancers, n = 331 including 2 CACs) and YCU (BAC, n = 5; CAC, n = 2). We compared BAC and CAC in terms of clinicopathologic features, gene expression profiles, and pathway analyses. In addition, we developed a diagnostic score based on differentially expressed genes (DEGs) between the two tumor types.
Results: In both the ORIEN and YCU cohorts, CAC showed worse recurrence and survival outcomes than BAC. In transcriptomic analyses, CAC demonstrated significant upregulation of Hallmark pathways related to cell proliferation such as E2F targets, G2M checkpoint and MYC targets v1/v2, and the expression level of Ki67, a proliferation marker gene, was also higher in CAC, although this was not statistically significant. Pathways related to immune responses were also upregulated in CAC; however, infiltration levels of individual immune cell types showed no clear differences between the two groups. We compared the expression of genes corresponding to ten immunohistochemical markers previously reported to distinguish BAC from CAC (positive in BAC: adipophilin, GATA3, mammaglobin, calretinin; positive in CAC: CK5/6, podoplanin, p63, CD14, CK17, and PAX5). CK5/6 and podoplanin showed higher expression in CAC in both cohorts, which was consistent with previous reports, although the differences did not reach statistical significance . The remaining markers showed either no consistent differences between cohorts or exhibited patterns inconsistent with previous reports. We then developed a score to distinguish BAC from CAC using the ORIEN cohort. To create this score, we first built a LASSO regression model using DEGs that separated all breast cancers from all skin cancers, then added a second component based on DEGs between BAC and CAC. By combining these two DEG-based components, we generated the distinguishing score. Validation using the YCU cohort demonstrated 100% sensitivity and specificity, accurately distinguishing BAC from CAC.
Conclusions: CAC exhibited higher cell proliferative activity and poorer prognosis compared with BAC. The transcriptomic score accurately distinguished BAC from CAC.

#6531 Immunoaffinity-enriched extracellular vesicles reveal tumor-derived DNA mutations for breast cancer detection.

Jee Ye Kim, Young Kim, Min Woo Kim, Sol Moon, Su Ji Lee, Joon Ye Kim, Seung Il Kim

Yonsei University College of Medicine, Seoul, Korea, Republic of

Background: Extracellular vesicle-derived tumor DNA (etDNA) has recently gained attention as a potential analyte for liquid biopsy; however, the biological origin and stability of EV-associated DNA remain controversial. These uncertainties highlight the need for size-independent, molecularly specific EV isolation approaches to rigorously evaluate tumor-derived DNA signals. To address this challenge, we isolated breast cancer-derived EVs (BEVs) using EPCAM-targeted immunoaffinity capture and assessed whether etDNA mutations accurately reflect tumor genotypes in both experimental models and clinical samples.
Methods: Mutational targets frequently observed in breast cancer were identified using the TCGA dataset, and four high-prevalence substitutions (PIK3CA p.H1047R, PIK3CA p.E545K, TP53 p.R175H, TP53 p.R273H) were selected. BEVs were isolated from plasma using magnetic beads conjugated with anti-EPCAM antibodies. EV identity was confirmed via nanoparticle tracking analysis and immunoblotting. etDNA was extracted from the isolated BEVs and analyzed by digital droplet PCR (ddPCR). Analytical validation included mutation profiling of breast cancer cell lines, 1D/2D droplet cluster analysis, and limit of detection (LOD) assays. Clinical concordance was assessed using matched tumor tissue sequencing results from breast cancer patients.
Results: In vitro studies demonstrated that etDNA mutations corresponded precisely to the genomic alterations of parental breast cancer cell lines. ddPCR yielded clear separation of mutant and wild-type droplets, and the assay showed high analytical sensitivity with an LOD of 0.08 copies/μL. Among 98 breast cancer patients, tumor tissue sequencing identified target mutations in 27 cases (28%). Of these, 19 had available plasma samples, and 11 patients (58%) harbored a concordant etDNA mutation in BEVs. PIK3CA p.H1047R was the most prevalent mutation in both tissue and etDNA. These findings indicate that EPCAM-enriched BEVs retain tumor-specific genetic alterations and that etDNA detection is feasible even at low DNA input, supporting potential applicability to early-stage or low-shedding disease.
Conclusion: This study demonstrates that etDNA extracted from immunoaffinity-isolated BEVs reliably reflects the mutational landscape of breast cancer. The combination of EPCAM-based BEV capture and ddPCR provides a sensitive and specific workflow for mutation detection, independent of size-based EV purification. These results support the utility of etDNA as a clinically informative biomarker and highlight its potential to enhance the diagnostic performance of liquid biopsy, particularly in early-stage breast cancer or settings with low variant allele frequency.

: Immune Checkpoint Blockade

#6535 Enhancing NSCLC susceptibility to anti-PD-1 - PD-L1 therapy trough PD-L1 ligand-Ir(III) complex conjugates.

Valentina Pagliara[1], Giulia Assoni[2], Giovanna Polcaro[1], Luigi Liguori[1], Pierfausto Seneci[3], Francesco Saverio Di Leva[4], Vincenzo Maria D'Amore[4], Cristina R. Ferrone[5], Stefano Pepe[1], Luciana Marinelli[4], Daniela Arosio[6], Francesco Sabbatino[1]

[1]University of Salerno, Baronissi, Italy,[2]University of Trento, Trento, Italy,[3]University of Milan, Milan, Italy,[4]University of Naples, Naples, Italy,[5]Cedars-Sinai Medical Center, Los Angeles, CA,[6]Consiglio Nazionale delle Ricerche (CNR), Milan, Italy

Immune checkpoint inhibitors (ICIs) targeting the PD-1-PD-L1 axis have revolutionized cancer therapy. However, their limited clinical success and the emergence of resistance mechanisms highlight the need for novel strategies to enhance anti-PD-1-PD-L1 immunotherapy. In this context, Iridium (III) complexes (Ir(III) complexes), have gained increasing attention for their potent anticancer activity and favorable safety profile. They are shown to induce immunogenic cell death (ICD) in non-small cell lung cancer (NSCLC), boosting tumor immunogenicity and improving response to conventional therapy. Here, we investigate whether Ir(III) complexes can synergize with anti-PD-L1 therapy and consequently synthetize a small array of triazine-based PD-L1 ligand-Ir(III) complexes by conjugating our previously reported anti-PD-L1 ligand (compound 10) with a bis-phenyl-pyridine-Ir(III) complex 2. The antitumor and immunomodulatory activity of Ir(III) complex 2 and PD-L1 inhibitor compound 10, as well as of four other PD-L1 ligand-Ir(III) complex conjugates 3-6, was tested in NSCLC cell lines expressing different levels of PD-L1, as well as in co-culture assays with peripheral blood mononuclear cells (PBMCs). Ir(III) complex conjugate 3 significantly enhanced anti-PD-L1-mediated PBMC tumor cell recognition and elimination, by increasing ER stress-mediated calreticulin (CRT) exposure, mitochondrial ROS production, and immunogenic signal release (ATP, HMGB1). More importantly, these effects were abrogated in PD-L1 knockout NSCLC cells incubated with the PD-L1 ligand-Ir(III) complex conjugate 3, validating a PD-L1-mediated selective delivery and dependent mechanism. These findings provide strong evidence that Ir(III) complexes potentiate anti-PD-L1 therapy in NSCLC, supporting the clinical implementation of PD-L1 ligand-Ir(III) conjugates as a novel combinatorial immunotherapeutic strategy for enhancing anti-PD-L1 therapy.

#6536 A novel multi-modal PD-L1xVEGF-ADC, HX116, could be a new potent candidate treatment for pan-solid tumors.

Hang Ke[1], Tao Yang[1], Feiyu Peng[1], Jialin Li[1], Cen Chen[2], Lei Zhang[1], Faming Zhang[1], **Henry Li**[2]

[1]Hanx Biopharmaceuticals, Ltd, Wuhan, China,[2]Hanx Bio, Wuhan, China

PD-L1 is an immune-checkpoint frequently over-expressed in many tumor cells as compared to normal tissues, while VEGF is an angiogenesis growth factor widely present within solid tumor microenvironment (TME). Therefore, both are also considered “tumor-associated antigen (TAA)” targetable by ADC modality, in addition to being druggable by mAbs against PD-L1-mAb (ICI) or VEGF that both are standard cancer treatments. Furthermore, multi-modal bispecific antibody (BsAb) simultaneously against PD-L1xVEGF has recently demonstrated impressive therapeutic benefit against different cancers in clinics, superior to single modal treatments or their combo treatments. It is therefore reasonable to hypothesize that a PD-L1xVEGF BsAb-ADC, HX116, with additional modalities of TOPO-I inhibitor, could become an even more powerful next-generation treatment of cancers than the naked BsAb. We thus tested HX116 for its anti-tumor activity in preclinical settings, in parallel to naked antibodies of HX116-and those against VEGF and PD-L1, respectively, so enabling assessing the roles of each modality of HX116. First, although the naked HX116 BsAb specifically binds to several PD-L1$^+$ tumor cells with high affinity, it exhibited poor internalization in PD-L1$^+$ cells. As a result, HX116 showed poor cytotoxicity in these cells as compared to SGN-PDL1V, a PD-L1-MMAE-ADC that is internalized efficiently. In contrast, HX116 demonstrated as robust cytotoxicity as much as, if not more, as SGN-PDL1V in these two PD-L1$^+$ 3D-tumor organoids *in vitro*, contrasting to the very poor cytotoxicity induction seen in the 2D-cell culture. It also showed robust anti-tumor activity in multiple PD-L1$^+$ human tumor xenograft models *in vivo*, including the ones with poor in vitro cytoxicity induction, and also superior to the naked BsAb, confirming the contributions of the additive ADC modality. Secondly, the parallel VEGF-mAb and naked HX116 BsAb in the same xenografts also demonstrated equal and robust tumor responses, suggesting the contribution of anti-angiogenesis modality. Thirdly, the pharmacology evaluation in human PBMC humanized xenograft model is currently ongoing, its superior activity over naked HX116 BsAb and PD-L1mAb would confirm its ICI contribution to the anti-tumor activity. Considering that the clinical dose for the similar PD-L1xVEGF BsAb needs to be high as 20~30 mg/kg to fully deploy their immune-checkpoint and anti-angiogenesis modalities in human, we have specifically selected a payload with moderate-potency as well as an optimal DAR value that will be tolerated in such high clinical doses. The high safety and tolerability of HX116 will also be confirmed in NHP model. If all are confirmed, HX116 would become a powerful new candidate for future cancer treatment.

#6537 Tumor IDO1 drives resistance to adoptive cell transfer by suppressing T cell recruitment and effector function.

Mamadou Alpha Bah[1], Rachana Maniyar[2], Jonathan F. Khan[2], Anais Assouvie[2], Sadna Budhu[2], Parwiz Abrahimi[2], Inna Serganova[2], Gabrielle A. Rizzuto[3], Taha Merghoub[4], Jedd D. Wolchok[1]

[1]Immunology and Microbial Pathogenesis, Weill Cornell Medicine, New York, NY,[2]Weill Cornell Medicine, New York, NY,[3]Memorial Sloan Kettering, New York, NY,[4]Weill Cornell Medical College, New York, NY

Adoptive cell transfer (ACT) has demonstrated potent anti-tumor efficacy in melanoma, yet therapeutic resistance frequently emerges within immunosuppressive tumor microenvironments. Indoleamine 2,3 dioxygenase 1 (IDO1) is a tryptophan catabolizing enzyme that generates kynurenine (Kyn), an immunomodulatory metabolite known to suppress effector T cell function. Here, we show that tumor overexpression of IDO1 undermines ACT efficacy through dual mechanisms of T cell exclusion and cytotoxic impairment. Using murine B16 melanoma cells engineered to overexpress IDO1 (B16IDO1), we observed elevated Kyn levels, reduced CXCL9/10 and CCL5 chemokine expression, and decreased intratumoral T cell infiltration. In vitro, IDO1 expressing tumor cells exhibited resistance to killing by activated CD8 PMEL T cells, a phenotype dependent on soluble factors in conditioned media and reversible with pharmacologic IDO1 inhibition. In vivo, adoptive transfer of either PMEL or TRP1 T cells, CD4 T cells specific for tyrosinase-related protein 1, failed to control B16IDO1 tumors, correlating with decreased infiltration, function, and survival. Pharmacologic blockade of IDO1 enhanced T cell infiltration and improved ACT mediated tumor control. Together, these findings identify IDO1 as a regulator of ACT resistance by suppressing T cell trafficking and effector activity. Complementary analyses of patient TIL, tumor, and serum samples are underway to assess correlations between IDO1/Kyn levels and immune cell burden, underscoring clinical relevance. Further studies extend this framework to human models, including IDO1^{+} melanoma xenografts and CAR T cells, to explore the translational potential of targeting the IDO1-Kyn-AHR axis to enhance cellular immunotherapy efficacy.

#6538 A phase-separation mechanism underlying PD-1-mediated T-cell inhibition via Shp2 condensation.

Takeya Masubuchi[1], George Wen[1], Xiaoxian Song[1], Haian Shao[2], **Enfu Hui**[2]

[1]UCSD, La Jolla, CA,[2]UCSD, San Diego, CA

Microcluster formation is a hallmark of PD1 engagement, but its physical basis and functional impact have remained unclear. We show that ligand-bound PD1 triggers Shp2 self-association and liquid liquid phase separation, generating dynamic condensates whose liquidity depends on Shp2 catalytic activity. Mutations that disrupt Shp2 self-association weaken PD1 microclusters and reduce inhibitory signaling. These findings identify Shp2 phase separation as a fundamental organizing mechanism of the PD1 pathway, linking enzymatic activation, substrate selectivity, and higher-order assembly to suppress T cell responses. This work reveals a biophysical mechanism of PD1-mediated immune regulation with implications for improving checkpoint blockade therapies.

#6539 Characteristics and predictors of multi-system immune-related adverse events in a large pan-cancer cohort: A retrospective analysis.

Julia G. Contini[1], Min Jung Koh[2], Charmi Trivedi[2], Mackenzie Adams[2], Jacqueline J. Chu[2], Sapana R. Gupta[2], Curtis Petruzzelli[2], Kanika Malani[2], Rebecca Steuer[2], Sandeep Jain[2], William Park[2], May Min[2], Matthew J. Hadfield[2]

[1]The Warren Alpert Medical School of Brown University, Providence, RI,[2]Brown University Health, Providence, RI

Background: Immune checkpoint inhibitors (ICI) can cause complex, multi-system immune-related adverse events (irAEs) that remain poorly described. This study characterizes their frequency and clinical features in a large institutional cohort.

Methods: Retrospective cohort of 2,134 metastatic cancer patients treated with ≥1 ICI at Brown University Health (2015-2025). IrAEs were identified and categorized by affected organ system. Multi-system irAEs were defined as ≥2 affected organ systems. Frequency was stratified by sex, cancer type, and treatment regimen. Fisher's exact tests assessed subgroup differences, and multivariable logistic regression identified independent predictors, reported as odds ratios (OR) with p-values.

Results: Of 2,134 patients, 24.8% (n=530) developed an irAE; 22.4% (n=119) had multi-system involvement, most commonly with two organs (16.8%, n=89) and less commonly three or more (5.7%, n=30). Common pairings included dermatitis + endocrine (10%, n=12), colitis + dermatitis (9.2%, n=11), and colitis + pneumonitis (5.9%, n=7), with clustering across dermatologic, gastrointestinal, pulmonary, and endocrine systems. Multi-system irAEs differed significantly by treatment regimen (5.1% in monotherapy vs. 4.7% in "ICI + chemo/targeted" vs. 13.9% in dual-ICI; p<0.001), but not by sex (p=0.6). They were more frequent in melanoma/skin cancers (p=0.004) and genitourinary cancers (p=0.03). On multivariable logistic regression adjusting for treatment regimen, melanoma/skin cancers remained significantly associated with higher odds of multi-system irAEs (OR: 1.92, p=0.03), while the association with genitourinary cancers was attenuated (OR: 1.37, p=0.2).

Conclusions: Multi-system irAEs comprised nearly one-quarter of all irAEs and were more frequent in melanoma/skin and genitourinary cancers, and among patients who received dual-ICI therapy, supporting the need for closer monitoring in these groups.

#6540 Dissecting mechanisms of tumor immune checkpoint blockade resistance due to host genetic variation within Adam17.

James P. Heiserman[1], Darren Li[1], Ons Mamai[2], Tanuja Desai[1], Rosemary J. Akhurst[3], Szu-Ying Chen[1]

[1]UCSF Medical Ctr., San Francisco, CA,[2]UCSF, San Francisco, CA,[3]Professor in Residence, UCSF Helen Diller Family Comp. Cancer Center, San Francisco, CA

Clinical application of anti-PD-1 or anti-PDL-1 antibodies, also known as immune checkpoint blockade (ICB) therapy, has shown potential as an anti-cancer treatment. However, currently only 10 to 30 percent of cancer patients respond to ICB. Successful ICB treatment depends on a variety of factors including tumor mutation burden, cancer subtype, and patient germline genetics. Therefore, there is a clear need to understand how host genetics influences ICB clinical success to improve patient outcomes. Our laboratory primarily focuses on the study of transforming growth factor-beta (TGF-β) signaling across a variety of disease contexts. We have generated two paired congenic NIH/Ola mouse strains that harbor either NIH/Ola or C57Bl/6J across the *Tgfbm3b* locus on proximal chromosome mouse 12. *Tgfbm3b* is known to modulate TGFβ signaling and encompasses genetic variants of tumor necrosis-alpha converting enzyme (TACE, also known as ADAM17). Utilizing these congenic mice implanted with syngeneic cancer cells, we generated preliminary data suggesting that the C57 “hypoactive” allele of *Adam17*, with amino acid variation at D113N, I613V, correlates with better response to ICB compared to congenic mice that harbor the active NIH allele, which are resistant to ICB treatment. Considering that inheritance of hypoactive *Adam17* enhances ICB response, we employed a highly specific small molecule inhibitor of TACE (TMI-2) finding that it sensitizes ICB-resistant tumors to immunotherapy across two in vivo syngeneic squamous cell carcinoma (SCC) models, suggesting that ADAM17 activity may suppress ICB efficacy. We have detailed the immune cell infiltrate on ICB sensitive and resistant mouse models, with and without ICB, using both flow cytometry and RNA sequencing techniques, and have found differences in myeloid and T cell infiltrate into the tumor microenvironment, suggesting that ADAM17 may regulate the tumor microenvironment landscape. We also have in vitro data suggesting that hypoactive variants of ADAM17 may reduce immune cell secretion of Tumor Necrosis Factor Alpha (TNFα) and TNFα induced cell death in specific immune cell types. TMI-2 is safe in humans, and this study provides support for targeting ADAM17 as a therapeutic target for patients who harbor ICB resistant cancers. The study also provides invaluable insights into the cell-type specific consequences of ADAM17 activity in tumor biology and highlights the need to consider patient genetics when applying ICB therapy.

#6541 Time-of-day of first checkpoint inhibitor dose influences clinical outcomes and immune responses in hepatocellular carcinoma.

Howard L. Li[1], Soren Charmsaz[2], Benjamin J. Reisman[1], Franshisca Hayek[1], Madelena Brancati[1], James M. Leatherman[1], Carlotta Pazzi[1], Royce P. Lee[1], Xiyu Zhao[3], Eric Christenson[3], Waqar Arif[1], Jeric P. Hernandez[1], Caroline Ellis[1], Nicole E. Gross[1], Christopher Thoburn[1], G Scott Chandler[4], Rajat Mohindra[4], Sanjay Bansal[5], Laura Tang[5], Aditi Guha[5], Chi V. Dang[1], Neeha Zaidi[3], Elizabeth M. Jaffee[1], Daniel A. Laheru[2], Daniel J. Zabransky[1], Marina Baretti[1], Won Jin Ho[1], Mark Yarchoan[1], Mari Nakazawa[1]

[1]Sidney Kimmel Comprehensive Cancer Center, Baltimore, MD,[2]Johns Hopkins University School of Medicine, Baltimore, MD,[3]The Johns Hopkins Hospital, Baltimore, MD,[4]Roche, Basel, Switzerland,[5]Genentech, South San Francisco, CA

Background Although immune checkpoint inhibitors (ICIs) have long half-lives, preclinical and early clinical studies across multiple tumor types suggest that the time-of-day of ICI infusion may influence therapeutic efficacy by aligning initial drug exposure with circadian peaks in T-cell responsiveness. However, the impact of initial drug infusion timing on outcomes has not been established. The immunologic basis of improved outcomes in early-day infusions and its clinical relevance in hepatocellular carcinoma (HCC) also remain unknown. **Methods** We prospectively followed patients with advanced/metastatic HCC receiving ICI therapy at Johns Hopkins from 2021-2025, classifying them into the morning group (first infusion before 12:00) or the afternoon group (first infusion after 12:00). We assessed clinical outcomes and compared immunologic responses from baseline to early-on-treatment (month 1 or month 2) by profiling 28 immune cell clusters in peripheral blood mononuclear cells using Cytometry by Time-of-Flight (CyTOF) and 39 plasma cytokines using a Luminex multiplex assay. **Results** Our cohort included 85 patients, 40 of whom received their first infusion in the morning. There were no statistically significant differences in baseline demographic or clinical characteristics between patients initiating therapy in the morning versus afternoon. The morning group had superior progression-free survival (multivariable HR 0.49, 95% CI 0.29-0.82, adjusted $p<0.01$) and higher odds of objective treatment response (multivariable OR 3.26, 95% CI 1.08-10.90, adjusted $p<0.05$), with no significant increase in immune-related adverse events. The timing of subsequent infusions after the first dose had no impact on survival outcomes. Immunologic responses diverged after the initial dose, with morning-treated patients showing reduced IL-6 levels (Wilcoxon rank-sum, $p<0.01$) and greater expansion of cytotoxic central memory CD8+ T-cells (Wilcoxon rank-sum, $p=0.01$) and cytotoxic effector CD8+ T-cells (Wilcoxon rank-sum, $p<0.05$) compared to afternoon-treated patients. **Conclusions** Morning first-dose infusion of ICIs in HCC was associated with improved clinical outcomes and distinct immune responses, including reduced IL-6 signaling and expansion of cytotoxic central memory and effector CD8+ T cells. These findings suggest that the timing of the initial infusion can imprint an immunologic program that shapes subsequent anti-tumor immunity, providing a mechanistic rationale for strategically scheduling ICI administration.

#6542 Targeting ITGB3 reverses terminal T cell exhaustion to enhance therapeutic efficacy in esophageal squamous cell carcinoma.

Beilei Liu[1], Xin-Yuan Guan[2], **Bowen Yao**[2], Hongyu Zhou[3], Licheng Tan[2], Jiayi Huang[2], Shuang Zhang[2]

[1]City University of Hong Kong, Hong Kong, Hong Kong,[2]The University of Hong Kong, Hong Kong, Hong Kong,[3]Shanghai Cancer Center, Shanghai, China

Terminal T cell exhaustion represents a critical barrier limiting the efficacy of immune checkpoint blockade therapies in solid tumors, yet the underlying mechanisms remain to be fully elucidated. Based on the esophageal squamous cell carcinoma (ESCC) mouse cell line mEC25 established in our previous work, we successfully constructed an immunocompetent ESCC mouse CDX (cell-derived xenograft) model that effectively reflects the immune dynamics of ESCC. Single-cell sequencing analysis of this dynamic subcutaneous ESCC model delineated 17 T cell subpopulations, revealing the transition of T cells from activated and effector states to exhaustion and terminal exhaustion. Among these subsets, ITGB3+ T cells exhibited moderate cytotoxicity and moderate exhaustion levels. Pseudotime analysis confirmed that ITGB3+ T cells reside at a critical node in the transition of T cells toward terminal exhaustion, potentially bridging effector and exhausted states through integrin signaling modulation. To address this, we utilized ITGB3-neutralizing antibodies. In vitro tumor-T cell co-culture assays showed that treatment with these antibodies restored T cell proliferation, upregulated the secretion of IFN-γ and granzyme A, and enhanced tumor-killing capacity. In vivo studies demonstrated that neutralizing ITGB3, when administered during early tumor formation, effectively reduces ESCC tumor growth, promotes T cell infiltration into the tumor microenvironment, and diminishes the exhausted T cell pool. Additionally, combination therapy with PD-1 inhibitors further amplified these effects: in vivo experiments showed synergistic tumor suppression, with enhanced T cell cytotoxicity and prolonged survival in treated mice. Further multiplex immunohistochemistry staining on tissue microarrays confirmed that elevated ITGB3 expression in PD-1+ IFN-γ+ double-positive T cells correlates with tumor progression and poor patient prognosis in ESCC, highlighting ITGB3 as a biomarker of T cell dysfunction. These findings uncover a molecular basis for T cell therapy resistance in ESCC and provide a novel strategy to improve the efficacy of immunotherapy for solid tumors.

#6543 NTX1088 demonstrates the first-ever clinical restoration of DNAM1, defining a novel immune-oncology axis.

Anas Atieh[1], Alon Vitenshtein[1], Akram Obiedat[1], Simona Chechik[1], Rivki Cashman[1], Guy Cinamon[1], Keren Paz[1], Paola Kučan Brlić[2], Tihana Lenac Rovis[2], Lea Hirsl[2], marija mazor[2], ema bellulovich[2], Stipan Jonjic[2], Ofer Mandelboim[3], **Pini Tsukerman**[1]

[1]Nectin Therapeutics, Jerusalem, Israel,[2]Center for proteomics, MEDRI, Rijeka, Croatia,[3]HUJI, Jerusalem, Israel

NTX1088, a first-in-class anti-PVR (CD155) monoclonal antibody, is currently being evaluated in a Phase 1, open-label, multi-center study (NCT05378425) as monotherapy and in combination with pembrolizumab in patients with advanced solid malignancies. Preliminary clinical data, for the first time, demonstrate restoration of DNAM1 (CD226) expression and function on peripheral T and NK cells following PVR blockade by NTX1088. This mechanistic breakthrough is robustly observed across multiple dose levels and distinguishes NTX1088 as a unique immunotherapeutic agent, unlike all anti-TIGIT strategies, which have not achieved DNAM1 restoration in clinical settings. Clinical biomarker analyses confirm significant upregulation of DNAM1 across NK cells, CD4+, and CD8+ T cells, effectively reversing PVR-mediated DNAM1 downmodulation, a recognized mechanism of immune escape and resistance to checkpoint inhibition. In contrast to TIGIT blockade, which fails to restore DNAM1, NTX1088 drives a favorable shift in the TIGIT/DNAM1 ratio and expands potent effector subsets, directly enhancing antitumor immune activity. To further dissect the translational impact and molecular mechanisms, extensive in vitro work was performed, using PBMCs from healthy volunteers and Jurkat cell line. In these in-vitro assays, simultaneous engagement of DNAM1 with CD3 signaling resulted in increased induction of activation markers, unique changes in exhaustion profiles, and robust cytokine secretion, functional signatures which showed DNAM1 co-signaling is distinct from conventional CD28-mediated costimulation. Concordant findings in humanized mouse models reveal that much of NTX1088's tumor growth inhibition and immune effector activation are DNAM1-dependent, and DNAM1 positive cells are significantly more activated and primed for anti-tumor activity compared to cells that did not upregulate DNAM1. Collectively, these data establish NTX1088 as the first immunotherapy to achieve clinical restoration of DNAM1, validating both DNAM1 induction and TIGIT/DNAM1 ratio remodeling as actionable biomarkers for drug effect, patient selection, and future immune-oncology combinations. The concurrent restoration of DNAM1, alongside blockade of other PVR inhibitory receptors like TIGIT, CD96, and KIR2DL5A, positions NTX1088 as an attractive therapeutic agent for synergistic IO/IO combinations, charting a transformative course for next-generation anticancer immunity

#6544 Immune checkpoint inhibitor therapy in kidney transplant recipients: Real-world outcomes of antitumor activity and graft rejection risk.

Ali Rezazadeh Roudkoli[1], Elena Barbir[2], Shahin Kavousi[1], Mohamed A. Aboelatta[1], Claudia-Denise Haivas[1], Byron H. Smith[1], Aleksandra Kukla[1], Arkadiusz Z. Dudek[1]

[1]Mayo Clinic, Rochester, MN,[2]University of Alberta, Edmonton, AB, Canada

Background: Kidney transplant recipients (KTRs) have a markedly elevated risk of aggressive malignancies, yet the use of immune checkpoint inhibitors (ICIs) in this population remains limited by concerns for allograft rejection and the absence of prospective evidence. We evaluated real-world antitumor activity, graft safety, and immunosuppression-related outcomes of ICI therapy in KTRs with advanced cancers.

Methods: We retrospectively analyzed 57 KTRs with locally advanced unresectable or metastatic malignancies treated between 2018-2025 at a single tertiary center. Thirty-three received ICIs and 24 received non-ICI systemic therapy. Outcomes included objective response rate (ORR), clinical benefit rate (CBR), progression-free survival (PFS), overall survival from diagnosis (OSd), overall survival from treatment initiation (OSt), acute allograft rejection, and immune-related adverse events (irAEs). Tumor response was assessed by RECIST v1.1.

Results: ICI-treated patients achieved higher ORR (40.0% vs 26.1%) and CBR (60.0% vs 33.3%) compared with non-ICI therapy. Median OSd was 35.8 vs 23.3 months, and median PFS was 4.3 vs 3.5 months (both not statistically significant). Median OSt was significantly longer with ICIs (15.1 vs 7.9 months; p=0.012). Acute rejection occurred in 12.1% of ICI-treated patients (3% irreversible) versus 4.2% with systemic therapy; rejection events were heterogeneous in timing (3 weeks-14 months) and largely responsive to pulse-dose corticosteroids. IrAEs occurred in 27.3% of ICI patients, with grade ≥2 events in 12.1%, and no treatment-related deaths. In the cutaneous squamous cell carcinoma (cSCC) subgroup (n=33), ICI therapy produced an ORR of 47.4% and CBR of 63.2%, with trends toward improved survival relative to controls.

Conclusions: ICIs produced clinically meaningful antitumor activity in KTRs, particularly in cSCC, with a manageable rate of allograft rejection under carefully tailored immunosuppression. Despite higher historical concerns, irreversible graft loss was uncommon. These findings support the feasibility of ICI therapy in selected transplant recipients and highlight the importance of immunosuppression strategy in balancing antitumor efficacy and graft safety. Prospective, biomarker-integrated studies are needed to define optimal immunosuppression during PD-1 blockade in this high-risk population.

#6545 Characterizing ATF6 activation-driven mechanisms improving ICB efficacy.

Sanjay Adhikary[1], Jacob Edmondson[1], Daniel Fil[2], Duah H. Alkam[3], Megan R. Reed[1], Billie Heflin[1], Katherine Bronson[1], Sydnye Shuttlewoth[1], Katherine F. Wallis[1], Nathan Avaritt[1], Sean Taverna[1], Brian S. Koss[1], Alan Tackett[1]

[1]University of Arkansas for Medical Sciences, Little Rock, AR,[2]Biochemistry and Molecular Biology, University of Arkansas for Medical Sciences, Little Rock, AR,[3]UAMS Winthrop P. Rockefeller Cancer Institute, Little Rock, AR

Melanoma is the most fatal skin cancer and incidence continues to rise, particularly among young people. Among the current clinical standards of care for advanced melanoma, immune checkpoint blockade (ICB) therapy has been the most successful for improving the survival of melanoma patients. However, the benefits of ICB therapy are limited to a subset of melanoma patients, with only 50% of melanoma patients responding ICB due to primary resistance. Using a genetic model of activating transcription factor 6 (ATF6), our laboratory has found that constitutively active ATF6 improved ICB efficacy in multiple preclinical, ICB resistant mouse melanoma models and increased T cell mediated-killing (TCK) of melanoma tumor cells *in vitro*. As a translational strategy we used a previously reported small molecule ATF6 activator, AA147, and found an AA147-mediated increase in TCK *in vitro* and an improvement of ICB efficacy in preclinical ICB resistant subcutaneous and metastatic mouse melanoma models. To identify ATF6-dependent mechanisms improving anti-tumor immune response, we performed FactorPath (Active Motif) chromatin immunoprecipitation coupled with sequencing (ChIP-seq) to map the binding of FLAG-ATF6 at a genome-wide scale. We found that the constitutively active form of ATF6 binds to the promoter region of anti-tumor immune regulatory genes. In parallel with ChIP-seq findings, we found constitutively active ATF6 significantly upregulates the protein expressions of anti-tumor immune regulatory genes as determined through quantitative mass spectrometry. These findings indicate that ATF6 is a transcriptional regulator of anti-tumor immune regulatory genes in melanoma tumor cells and upregulation of these pathways leads to enhanced anti-tumor immune response and improved ICB efficacy.

#6546 Beyond density: Topography-aware spatial metrics predict immunotherapy outcomes.

Artur Mezheyeuski[1], Neda Hekmati[2], Ina Hrynchyk[3], Amanda Lindberg[2], Jakob Friedrich[2], Johanna Mattsson[2], Miklos Gulyas[2], Klas Karre[4], Johan Isaksson[2], Carina Strell[5], Patrick Micke[2]

[1]Vall d'Hebron Institute of Research (VHIR), Barcelona, Spain,[2]Uppsala University, Uppsala, Sweden,[3]City Clinical Pathologoanatomic Bureau, Minsk, Belarus,[4]Karolinska Institutet, Stockholm, Sweden,[5]Uppsala University, Dept of Immunology, Genetics and Pathology, Uppsala, Sweden

Background: Accumulating evidence suggests that the spatial organization of tumor-immune ecosystems determines the benefit of checkpoint inhibitors. Therefore, topography-aware metrics that adjust for baseline cell abundance are better suited to quantify spatial immune patterns, such as attraction, repulsion, and clustering, across scales. We hypothesized that such multiscale spatial metrics would outperform immune cell density alone for explaining therapy benefit and survival in advanced non-small cell lung cancer (NSCLC) patients.

Methods: We applied a multiplex immunofluorescence pipeline on diagnostic tissue of 54 NSCLC patients treated with checkpoint inhibitors. Annotated cell classes included cancer cells, $CD8^+$, $CD8^+FoxP3^+$, M1 and M2 macrophages (-/+PDL1), $CD68^-CD163^+$ cells and stromal non-immune cells. To spatially resolve the immune patterns, we computed neighborhood enrichment (ENR) and radial local enrichment (RLE). ENR was computed over k-nearest neighborhoods (k=5-100) and provided information about the attraction tendency between two cell classes, independent from cell density. RLE was evaluated over 10-50 µm radii and reflected the spatial cell clustering tendency. The spatial metrics were associated with therapy response and overall survival.

Results:

$CD8^+FoxP3^+$ cells stratify risk. Responders demonstrate neighboring of $CD8^+$ or $CD8^+PD1^+$ cells to $CD8^+FoxP3^+$ at different scales (ENR k=5-100, p=0.04-0.007), strongest at shorter distances. In the survival analysis, $CD8^+FoxP3^+$ cells were associated with shorter survival when they were closer to PDL1+ cancer cells (ENR: HR 3.7-7.5, p=0.01-0.04).

CD8 geometry in stroma tracks response but not survival. Increased clustering of $CD8^+PD1^+$ associated with higher response to therapy (ENR k=10-100, p=0.05- 0.002). Notably, $CD8^+PD1^-$ cells did not show such associations. This positive impact on therapy response did not translate into a longer overall survival in this cohort.

Tumor purity and compactness is associated with shorter survival. Local enrichment of cancer cells within 10-50 µm was associated with poor response and shorter OS, (RLE: HR 2.2-2.5, p=0.03-0.007), pointing to denser, homogeneous tumor nests as a risk factor.

Conclusion: Topography-aware spatial metrics capture clinically meaningful organization beyond simple density. These findings supported the cellular context-dependent evaluation of biomarkers. Furthermore our findings also provide in situ evidence for a focused evaluation of a rare, hitherto poorly described subtype of $CD8^+FoxP3^+$ immune cells.

#6547 Phase II single arm study of tremelimumab and durvalumab (MEDI4736) (T300+D) in advanced hepatocellular carcinomas with Child-Pugh-B cirrhosis (STRIDE in CP-B).

Sukeshi Patel Arora[1], Lorena Fuentes[1], James Denno[1], Jennifer Moseley[1], Brittany M. Altermatt[1], Elizabeth Diaz[1], Joshua Ray Smith[1], Joel Michalek[2], Lei Zheng[3]

[1]University of Texas Health San Antonio, Mays Cancer Center, San Antonio, TX,[2]UT Health San Antonio, San Antonio, TX,[3]Mays Cancer Center, UT Health Science Center at San Antonio, San Antonio, TX

Background: In registration phase 3 studies, most patients enrolled had Child-Pugh (CP)-A cirrhosis, with CP-B cirrhosis are often excluded from clinical trials, yet in clinical practices, patients are often treated with new agents without efficacy or safety data. Therefore, there is an unmet need to evaluate the efficacy and safety of therapeutics in patients with HCC and CP-B cirrhosis. Based on results from the HIMALAYA trial, tremelimumab and durvalumab (T300+D) is FDA-approved for HCC. In this trial, grade 3/4 treatment-related adverse events (TRAEs) occurred in 25.8% (T300+D), 12.9% (durvalumab), and 36.9% (sorafenib) of patients. Therefore, we hypothesize that T300+D will be safe and tolerated in CP-B patients with HCC, and the safety of efficacy of T300+D in patients with CP-B cirrhosis should be investigated. **Purpose:** Results from this study may establish T300+D as a first-line therapy for CP-B patients with HCC, and therefore, could be practice-changing and set precedence for future studies dedicated to investigating newer agents for CP-B with HCC. **Methods:** Single-arm, phase II study of patients with advanced HCC who are eligible for first-line treatment with T300+D [NCT06526104]. Priming dose of tremelimumab 300 mg intravenously (IV) once (Cycle 1, Day 1 only) with durvalumab 1500 mg IV on Day 1 of each 4-week cycle. Primary Objective: compare the percentage of grade 3 or higher TRTE-AEs with T300+D in patients with CP-B cirrhosis with historical controls of VEGF-targeting therapies. Secondary Objective(s): objective response rate (ORR), overall survival (OS), progression-free survival (PFS), associations of baseline albumin-bilirubin (ALBI) grade with PFS/OS and grade 3/4 AEs with T300+D. Exploratory endpoint: evaluate QOL at baseline and during treatment with T300+D, EORTC-QLQ-C30 and QLQ-HCC18 questionnaires. Inclusion criteria: Patients diagnosed with HCC based on pathologic diagnosis from biopsy or radiographic diagnosis on CT liver or MRI liver (i.e., Barcelona Clinic Liver Cancer (BCLC) stage B and not candidate for locoregional therapies or BCLC stage C), no prior systemic therapies, Child-Pugh-B7 or -B8 liver cirrhosis, and ECOG 0-1. . This study will achieve 80% power for testing H_o: $p_{D300+T}=p_{Historical}$ versus H_1: $p_{D300+T}\neq p_{Historical}$ at $\alpha=0.05$ with n=30 subjects. **Progress:** The study began enrollment in 12/2024, with 13 patients enrolled to the date of abstract submission. Three sites are opening soon with planned completion of enrollment at the end of 2026. **Conclusion:** After 15 patients are enrolled, enrollment will be held pending further review if there is sufficient evidence to suggest that the true probability of (possibly, probably, or definitely) treatment-related, grade 3-5 adverse events exceeds 60%. Results will be presented soon after.

#6548 A human multiorgan microphysiological system for modeling immunotherapies tumor clearance and normal tissue immune injury.

John Collins, Henry C. Wong, Alyssa J. Villegas, Johar Kohana, Harpreet S. Saluja

Biopico Systems Inc, Irvine, CA

Despite the clinical success of CTLA-4 blockade, immune checkpoint inhibitors can trigger immune-related adverse events (irAEs) that remain difficult to predict preclinically, in part because conventional in vitro and animal models lack the capacity to simultaneously evaluate ECM-dependent T-cell infiltration, tumor cytotoxicity, and normal tissue immune tolerance. We developed a multiorgan system to quantify how fibrin matrix density, T-cell donor identity, HLA compatibility, and ipilimumab dose collectively shape immune cytotoxic responses across tumor and normal tissues. Imaging experiments compared fibrin concentrations from 2.5-10 mg/mL to assess physical barrier effects on immune infiltration. Brain (SK-N-SH/HMC3), gut (T84) tumor spheroids, or human primary hepatocyte spheroids with or without Kupffer cells were embedded in a defined fibrin hydrogel (6 mg/mL fibrinogen, 4 U/mL thrombin). Tumor models used two T-cell donors, while the liver model was perfused with either matched or mismatched $CD8^+$ T-cell donors. Ipilimumab was applied from 0-10 µg/mL. Spheroid density, derived from fluorescence-based viability measurements, was plotted against antibody concentration.T-cell penetration into spheroids was strongly dependent on fibrin density with low-to-moderate matrix (2.5-6 mg/mL) supported deep infiltration, whereas high-density fibrin (8-10 mg/mL) restricted immune access and created an immune-excluded phenotype. CTLA-4 blockade overcame this barrier in part, enabling infiltration even through dense matrices. Dose-response analysis demonstrated robust tumor killing in both brain and gut spheroids, exhibiting a steep viability decline beginning at 1 µg/mL and reached near-complete loss at 10 µg/mL.Response magnitude varied between donors, reproducing clinically observed heterogeneity in immune potency. In contrast, normal hepatocyte spheroids remained intact under matched donor conditions across all doses. However, mismatched T cells produced clear dose-dependent injury that was significantly amplified in the presence of Kupffer cells, revealing a macrophage-dependent mechanism of immune-mediated hepatotoxicity.This multiorgan platform recapitulates fibrin-driven immune exclusion, checkpoint-enhanced infiltration, effective tumor cytotoxicity, and HLA mismatch-dependent normal tissue injury, mirroring key therapeutic and toxic outcomes observed in patients. We evaluated antigen-specific T cells, bispecific antibodies, and antibody-drug conjugates to assess on-target efficacy, off-target toxicity, and bystander effects. These findings support the use of human microphysiological systems as predictive tools for immunotherapy, enabling mechanistic dissection of efficacy-toxicity trade-offs prior to clinical testing and supporting FDA-aligned strategies to reduce non-human primate use in monoclonal antibody safety testing.

#6549 Integrating functional biosignatures and same-cell spatial multiomics to predict synergistic benefit of combination checkpoint therapy in head and neck cancer.

Yi Cui[1], Moumita Nath[2], Michael Emilio Patrick[1], Claire Williams[1], Daniel McGuire[1], Jobin K. Paul[2], Kowshik Jaganathan[2], Biswajit Das[2], Mohit Malhotra[2], Shanshan He[1], Joseph M. Beechem[1], Satish Sankaran[2]

[1]Bruker Spatial Biology, Seattle, WA,[2]Farcast Biosciences India, Bengaluru, India

Effective immune checkpoint blockade (ICB) requires coordinated activation, spatial organization, and functional cross-talk among immune populations within the tumor microenvironment (TME). Farcast TruTumor™ platform preserves viable tumor, stromal, and immune compartments in their near-native architecture, aligning with the FDA's New Approach Methodologies (NAM) framework for human-relevant cancer models. The model has shown that in head and neck squamous cell carcinoma (HNSCC) anti-PD-1 response is associated with cytotoxic T-cell (CTL) infiltration into tumor nests, and that moderate responders may be rescued by adding anti-CTLA-4, accompanied by increased spatial separation between CTLs and T regulatory (Treg) cells. Here, we integrate TruTumor's functional characterization with the CosMx® Spatial Molecular Imager (SMI) using same-cell spatial multiomics (64-plex IO protein panel plus whole-transcriptome RNA) to elucidate the dynamics of improved efficacy with nivolumab (N) plus ipilimumab (I) leading to predictors of ICB responses with greater accuracy. Patient-derived HNSCC explants were cultured on the TruTumor histoculture platform and treated for 72 hours with N or N+I. Treatment effects were assessed using histopathology, cleaved caspase-3 IHC, multiparameter flow cytometry, and NanoString nCounter bulk transcriptomics. Spatial profiling was performed using the CosMx SMI same-cell multiomic assay, enabling subcellular quantification of immune checkpoints, activation and exhaustion markers, costimulatory molecules, and whole-transcriptome signatures within intact tissue architecture. Analyses included spatial clustering, cell-cell neighborhood modeling, immune-tumor interface mapping, and ligand-receptor interaction inference. CosMx multiomics revealed treatment-dependent remodeling of immune states and spatial niches not captured by bulk assays. N+I responders exhibited: (i) expansion potential of cytotoxic and proliferative CTLs; (ii) depletion or spatial exclusion of suppressive Tregs from tumor nests; (iii) enhanced antigen-presentation and IFN-γ-response programs in tumor and myeloid cells; and (iv) rewired immune checkpoint and costimulatory ligand-receptor networks at tumor-immune borders. Same-cell integration of protein and RNA markers defined discrete CTL activation and exhaustion trajectories and uncovered microenvironments uniquely sensitized to combination therapy. Combining functional response metrics with spatial features yielded a mechanism-driven biosignature predictive of treatment outcome. Integrating the TruTumor histoculture models with CosMx SMI same-cell spatial multiomics establishes a scalable, NAM-aligned translational platform that enables discovery of predictive biomarkers for next-generation immuno-oncology therapies.

#6550 *In vitro* characterization of fully human antagonistic anti-BTLA monoclonal antibodies.

Bruce L. Daugherty[1], Hsunhui Yang[2], Subhra Mahapatra[2], Yadong Yu[2], Christine L. Hsieh[2], Brian A. Zabel[2], Seth Lederman[1]

[1]Tonix Pharmaceuticals, Inc., Chatham, NJ,[2]Curia Global, Inc., Hayward, CA

Introduction: B and T lymphocyte attenuator (BTLA) is an immune checkpoint receptor essential for immune homeostasis and tolerance. Unlike PD-1 or CTLA-4, BTLA is broadly expressed on lymphoid and some myeloid cells, including T cells, B cells, dendritic cells, and macrophages. Engagement with its ligand HVEM (herpesvirus entry mediator) transmits inhibitory signals that suppress immune activation. Within tumors, BTLA contributes to immune evasion by dampening anti-tumor responses. Given its unique expression profile and regulatory function, we developed monoclonal antibodies (mAbs) targeting BTLA as an immunotherapeutic strategy to enhance anti-tumor immunity.

Methods: Fully human anti-BTLA mAbs identified by hybridoma screening were reformatted as huIgG4 (S228P/L235A) and transiently expressed using Curia's TunaCHO® platform. The S228P mutation prevents Fab-arm exchange, stabilizing mAb structure, while L235A minimizes FcγR binding and effector functions. Binding potency was determined by ELISA; kinetics by Octet® biolayer interferometry (BLI) against human and cynomolgus BTLA. BLI also assessed FcγR, FcRn (at pH 6.0 vs 7.2), and C1q binding to evaluate recycling potential and complement activation. Neutralization of HVEM binding to BTLA was quantified by modified ELISA and cell-based reporter assays.

Results: Six fully human anti-BTLA mAbs and a clinical candidate comparator JS004 displayed similar ~1 nM binding potencies (IC_{50}) values to human and cyno BTLA by ELISA. Clone 13-F7-A exhibited the highest affinity (K_d < 1 nM) for both human and cyno BTLA among all 7 mAbs tested. Four mAbs and the comparator JS004 were high affinity binders to human and cyno BTLA (K_d 1-32 nM). All six fully human mAbs exhibited reduced FcγR binding relative to JS004. Each bound FcRn at pH 6.0 but not at 7.2, consistent with normal endosomal recycling. None bound C1q, whereas a positive-control IgG1 did bind to C1q as expected. In an ELISA-based biofunctional assay, all mAbs blocked HVEM binding to BTLA with similar IC_{50} values (~1 nM).

Conclusions: We generated potent, high affinity, human/cyno cross-reactive, fully human antagonistic anti-BTLA mAbs. Targeting BTLA offers promising opportunities for cancer immunotherapy and may demonstrate strong synergy when combined with other checkpoint antagonists, potentially overcoming resistance mechanisms and improving clinical outcomes.

#6551 Mifepristone-mediated induction of PD-L1 expression in hormone receptor positive breast tumors.

Mariana Salatino, Magali Berton, Joaquin Merlo, Andres M. Elia, Tomas Dalotto Moreno, Claudia Lanari, Gabriel Rabinovich

IBYME-CONICET (Institute of Biology and Experimental Medicine), Buenos Aires, Argentina

Luminal breast cancer has been associated with a poor response to immunotherapy with immune checkpoint blockade (ICB). The selection of patients with high chances of response and the combination of ICB with other therapies, with the ability to turn a 'cold' into a 'hot' tumour, may have a broad impact on the management of this highly frequent type of breast cancer.We previously demonstrated that an endocrine therapy with Mifepristone (MIFE), an antagonist of the classical progesterone receptor, can foster a complete remodeling of the immune landscape in hormone receptor-positive tumours, promoting immune cell infiltration, immunogenicity and activating transcriptional programs associated with response to ICB both in mouse models and patients.Here, we aim to evaluate the effect of MIFE on the expression of the ICB response predictor biomarker PD-L1 in luminal breast human tumour samples derived from the MIPRA clinical trial (NCT02651844). The MIPRA trial enrolled 20 breast cancer patients harbouring HR+ tumours that were treated with MIFE for 14 days before surgery (orally administration of 200mg/day of MIFE). Response to MIFE (reduction in percentage of Ki67 proliferation marker > 30%) was documented in 14 of the 20 patients; however, all patients presented remodeling in the tumour microenvironment. We observed that treatment with MIFE in HR+ luminal breast tumours reorganizes the ECM and the stroma, including the enrichment in lymphocyte infiltration. Immunohistochemistry (IHC) assessment of PD-L1 expression in tumour slides from patients was analyzed in the Ventana BenchMark ULTRA using the anti-PD-L1 (SP263 VENTANA).Twenty untreated luminal tumours with similar clinical characteristics were included as controls. IHC analysis of tumour slides from 20 patients enrolled in the MIPRA trial showed that after MIFE treatment, 47% presented any staining for PD-L1, as compared to newly diagnosed untreated luminal tumours, where only 20% showed PD-L1 staining. Notably, the PD-L1 staining observed was primarily located in the stroma and surrounding the infiltration area (images taken with an Aperio SC2 scanner). We scored the staining on a scale of 0-5, with 5 being the highest area stained and 0 indicating no staining detected. MIPRA trial-participating patients exhibit a significant increase in the score of PD-L1 detection after MIFE treatment ($p<0.05$).These results suggest that endocrine therapy with MIFE can reprogram the immune landscape of luminal breast tumours in patients, promoting a "hot" TME, increasing TILs and PD-L1 expression. This MIFE-mediated immune fitness may sensitize luminal tumours to ICI therapy and open new therapeutic avenues for this prevalent breast cancer subtype.

#6552 Nonresponders to PD-1 therapy share a combined OXPHOS and neuronal-like resistance program in melanoma.

Otilia Menyhart, Janos Tibor Fekete, **Balazs Gyorffy**

Semmelweis University, Budapest, Hungary

BACKGROUND: Immune checkpoint inhibitors (ICIs) targeting PD-1 have transformed melanoma therapy, yet only a subset of patients derive durable benefit. The molecular programs underlying responsiveness remain incompletely defined. We aimed to identify gene-expression patterns that distinguish responders from nonresponders by focusing on alterations specifically related to transformed cancer hallmarks.

METHODS: We compiled pretreatment transcriptional profiles from 17 independent studies, pooling data for 551 melanoma patients, including 233 responders to anti-PD-1 therapy. ROC analyses evaluated the discriminative potential of individual genes. Genes with high AUC and expression values in both responders and nonresponders were identified. Hallmark enrichment was assessed using cancerhallmarks.com, and gene ontology analyses were conducted to characterize the underlying biological programs. Significant differences were based on a fold change ≥ 1.4 and a $p<0.05$.

RESULTS: In responders, 467 overexpressed genes revealed a highly coordinated immune-inflamed state, with enriched Fc-gamma receptor signaling ($p = 3.97\times10^{-82}$), classical complement activation ($p = 1.42\times10^{-81}$), and T- and B-cell receptor signaling ($p = 3.47\times10^{-4}$, 3.06×10^{-4}). GO terms highlighted T-cell activation, lymphocyte-mediated immunity, and a strong IFN-gamma response. Cancer hallmark enrichment analysis identified “Evasion of Immune Destruction” as the only significant hallmark ($p < 0.0001$), emphasizing that clinical benefit arises from a pre-existing immune-activated microenvironment rather than tumor-intrinsic programs, such as proliferation, metabolic rewiring, or differentiation state. The 685 overexpressed genes in nonresponders converged on a metabolically amplified and lineage-rewired tumor state. Reactome analysis revealed a strong upregulation of mitochondrial programs, including mitochondrial RNA processing ($p = 1.47 \times 10^{-12}$) and respiratory electron transport ($p = 2.92 \times 10^{-2}$), defining a high-OXPHOS phenotype that can suppress antitumor immunity. Complementary GO terms related to myelination, oligodendrocyte differentiation, and trans-synaptic signaling highlighted a neuronal-like dedifferentiation program linked to reduced antigen presentation and T-cell exclusion, creating a multilayered barrier to immune recognition.

CONCLUSION: ICI nonresponders consistently exhibit high-OXPHOS metabolism and neuronal-like dedifferentiation, resulting in immune silence. The co-occurrence of these two resistance programs across multiple independent cohorts reveals a combined transcriptional barrier to PD-1 response.

#6553 A comprehensive analysis of HMGB1 as a biomarker for predicting immunotherapy efficacy in small cell lung cancer.

Bohui Zhao, Chaoqi Zhang, Peng Wu, Dongyu Li, Xuanyu Gu, Hengjia Tu, Nan Sun, Jie He

Cancer Hospital, Chinese Academy of Medical Sciences, Beijing, China

Background: High mobility group box 1 protein (HMGB1) is known to be associated with progression and poor prognosis of several solid tumors. However, its role in small cell lung cancer (SCLC) remains unclear. Therefore, we intend to provide the first systematically analysis of HMGB1 as a prognostic and immunotherapy predictive biomarker in SCLC.
Methods: Public datasets and self-tested transcriptomic/proteomic data from SCLC surgical samples were integrated to screen target molecules through differential analysis. HMGB1 expression was validated in multicenter cohorts using qPCR and tissue microarray immunohistochemistry (IHC). Public data and in-house data were utilized to investigate the association between HMGB1 and SCLC transcriptional subtypes as well as clinicopathological features. The impact of HMGB1 on the tumor immune microenvironment was evaluated through transcriptomic enrichment analysis, single-cell sequencing and IHC. In the NCC cohort of over 180 SCLC patients treated with immune checkpoint inhibitors (ICIs), the relationships between HMGB1 and ORR, PFS, and OS were analyzed, with a prediction model constructed. Finally, serum HMGB1 levels were measured by ELISA to assess its value as a secreted protein biomarker.
Results: Multi-omics screening and clinical validation confirmed that HMGB1 was significantly overexpressed in SCLC tumor tissues, and high expression was associated with shorter OS and DFS. HMGB1 expression showed no significant association with the four SCLC subtypes but correlated with high-risk factors such as advanced tumor stage. Transcriptomic enrichment and single-cell analyses revealed that high HMGB1 expression correlated with an immunosuppressive "cold tumor" microenvironment. In the ICIs-treated cohort, patients with high HMGB1 expression exhibited significantly shortened PFS and OS. ROC analysis demonstrated that HMGB1 outperformed traditional markers in predicting treatment response. Multivariate Cox regression confirmed HMGB1 as an independent predictor of immunotherapy efficacy in SCLC. Serum HMGB1 levels were consistent with tumor tissue expression, validating its liquid biopsy potential.
Conclusions: HMGB1 is an independent risk factor for SCLC prognosis. Its high expression shapes an immunosuppressive microenvironment and mediates resistance to immunotherapy. HMGB1 shows a good potential to serves as a novel biomarker for predicting immunotherapy efficacy in SCLC, with clinical applicability for both tissue-based and blood-based detection.

#6554 A bispecific TROP2/PDL1 antibody-drug conjugate demonstrates enhanced antitumor activity and favorable safety profile.

Chuan Chen, Yue Wu, Chenpeng Su, Dandan Liu, Jiyuan Tian, Yujuan Li, Yongxin Shang, Xiaoqian Chen, Rongmei Yan, Liang Tian, Jian Peng, Zhenping Zhu

Earendil Labs, Wilmington, DE

Purpose
This study aimed to develop and characterize a bispecific antibody-drug conjugate (ADC) targeting both TROP2 and PDL1, to address the limitations of current single-target therapies in advanced cancers.
Methods
We engineered a humanized bispecific antibody (bsAb) against TROP2 and PDL1 (α TROP2/PDL1), and subsequently produced the bispecific ADC using an optimized hydrophilic linker and TOP1 inhibitor payload. Comprehensive *in vitro* characterization encompassed binding affinity, internalization efficiency, and PDL1 degradation assays. *In vivo* efficacy was assessed across multiple xenograft models, while safety assessment was conducted in transgenic mice and non-human primates.
Results
α TROP2/PDL1 demonstrated potent bispecific activity, featuring efficient cellular binding and rapid internalization. The bsAb induced significant PDL1 internalization and degradation, and showed marked tumor growth inhibition in MC-38-huTrop2/PDL1 model. The bsAb TOP1i conjugated ADC (α TROP2/PDL1-TOP1i) exhibited enhanced potency, characterized by robust cytotoxicity against multiple Trop2/PDL1-expressing cell lines, potent bystander killing effects, and tumor regression in multiple CDX models. Notably, the ADC showed excellent stability and tolerability in cynomolgus monkeys, with no significant adverse effects observed in safety studies.
Conclusion
α TROP2/PDL1-TOP1i represents a promising therapeutic strategy for treatment-resistant cancers, effectively combining PD1/PDL1 immune checkpoint blockade with TROP2-targeted cytotoxic payload delivery while maintaining a favorable safety profile, supporting its advancement to clinical development.

#6555 BTN1A1 blockade with Nelmastobart potentiates cisplatin-induced tumor suppression in NSCLC.

Seung-Hoon Lee, Jong-Su Park, Young-Seung Kim, Chunai Wu, Bong-Ki Hong, Andrew H. Park, **Stephen S. Yoo**

STCube Pharmaceuticals Inc., Rockville, MD

Background: Butyrophilin 1A1 (BTN1A1) is a novel immune-regulatory checkpoint protein expressed in various solid tumors, including non-small cell lung cancer (NSCLC), where it modulates T-cell activation. We previously demonstrated that BTN1A1 inhibition by Nelmastobart enhances immune-mediated tumor suppression. In this study, we evaluated whether combining Nelmastobart with cisplatin could further potentiate anti-tumor immune responses in NSCLC.
Methods: A549 NSCLC cells, stably expressing RFP, were cultured as 3D spheroids and co-incubated with human peripheral blood mononuclear cells (PBMCs), Nelmastobart, cisplatin, or their combinations. Anti-tumor immune activity was assessed by monitoring spheroid size reduction and RFP intensity loss. To evaluate translational safety, zebrafish embryos were exposed to Nelmastobart alone, cisplatin alone, or both agents at clinically relevant concentrations. Developmental endpoints, including embryo survival, hatching success, axial and craniofacial morphology, pericardial edema, spinal curvature, cardiac rhythm, and early organogenesis of the eye, heart, and somite structures, were systematically evaluated according to established zebrafish developmental toxicity guidelines.
Results: Combination treatment with Nelmastobart and cisplatin induced the strongest PBMC-mediated cytotoxic effect, resulting in substantial reductions in spheroid volume and marked disruption of RFP signals compared to the monotherapies. These findings suggest that BTN1A1 blockade enhances immune recognition, increasing tumor susceptibility to chemotherapy. Zebrafish developmental toxicity testing revealed no significant abnormalities with either Nelmastobart alone or cisplatin alone at clinically relevant exposure ranges. Importantly, no additive or synergistic developmental toxicity was observed in the combination group.
Conclusion: BTN1A1 inhibition by Nelmastobart significantly enhances cisplatin-driven immune-mediated cytotoxicity in A549 3D spheroid models while maintaining a strong safety margin in vivo. These data support the continued clinical advancement of Nelmastobart, both as a monotherapy and in combination with standard chemotherapeutic agents.

#6556 The role of VISTA in the lung tumor microenvironment of metastatic melanoma.

Carly M. Fielder[1], Qianni Hu[2], Hyundong Yoon[1], Raymond Zhang[1], Anjali Raman[3], Megan L. Tigue[1], Chi Yan[2], Vivian L. Weiss[4], Douglas B. Johnson[5], Jin Chen[6], Tae Kon Kim[3]

[1]Cancer Biology, Vanderbilt University, Nashville, TN,[2]Immunology, University of Manitoba, Winnipeg, MB, Canada,[3]Medicine, Vanderbilt University Medical Center, Nashville, TN,[4]Pathology, Microbiology, and Immunology, Vanderbilt University Medical Center, Nashville, TN,[5]Vanderbilt Ingram Cancer Center, Nashville, TN,[6]Cell and Developmental Biology, Vanderbilt University Medical Center, Nashville, TN

Metastatic melanoma remains a significant clinical challenge despite recent advances with immune checkpoint inhibitors (ICIs) like anti-programmed cell death-1 (PD-1), which show variable efficacy across metastatic organ sites. The lung is a frequent site of metastasis, and while complete responses to ICIs occur more often in pulmonary lesions than in other organs, up to 60% of patients with lung metastases fail to respond. Pulmonary metastases are also a leading cause of death in patients with metastatic melanoma. This suggests that we will need to comprehensively understand the tumor immune microenvironments of pulmonary metastatic melanoma including the expression of alternative immune checkpoint targets. V-domain immunoglobulin suppressor of T cell activation (VISTA) is an emerging checkpoint molecule predominantly expressed in myeloid cells that suppresses immune activation. We found that VISTA was highly expressed in human pulmonary metastatic melanoma while PD-L1 expression was not significantly elevated. To investigate the role of VISTA in pulmonary metastatic melanoma, we utilized a variety of mouse models with B16-F10 murine melanoma. VISTA knock-out (KO) mice develop significantly fewer lung metastases than wild-type (WT) controls (lung-to-body weight ratio: VISTA WT = 0.05 ± 0.018, VISTA KO = 0.02 ± 0.011; p = 0.0012), with no difference in subcutaneous tumor growth (p = 0.1625). We assessed the immune cell infiltration in these mice. VISTA KO mice had significantly more proinflammatory monocytes (2.78% ± 1.50 vs. 0.52% ± 0.54; p = 0.0003) and macrophages (14.27% ± 6.18 vs. 6.75% ± 4.27; p = 0.006) in the metastatic lung tissue compared to WT mice. These data suggest that myeloid cell VISTA promotes lung metastasis of melanoma. We also demonstrated that $Rag1^{-/-}$ mice, which lack T and B lymphocytes, showed increased melanoma lung metastases compared to $Rag1^{-/-}$ $VISTA^{-/-}$ mice, suggesting that the metastatic phenotype is independent of T and B lymphocytes ($Rag1^{-/-}$ = 0.03 ± 0.008, $Rag1^{-/-}$ $VISTA^{-/-}$ = 0.01 ± 0.002; p = 0.0008). Mechanistically, VISTA-deficient bone marrow-derived macrophages (BMDMs) produce more TNFα and nitric oxide compared to WT BMDMs, indicating that VISTA suppresses macrophage activation as a mechanism of immune suppression (TNFα: 1.2-fold-change, 1166 vs. 946.3 pg/ml; p = 0.0001; nitric oxide: 3.2-fold-change, 29.42 vs. 9.089 µmol/L). Our findings establish VISTA as a critical regulator of immune suppression in pulmonary melanoma metastases. Ongoing mechanistic studies will clarify its potential as a therapeutic target, leading to improved treatment strategies and patient outcomes.

#6557 Combined PARP inhibition and immune checkpoint blockade elicit differentially improved survival in BRCA1, BRCA2 vs CHEK2, ATM deficient breast cancer by promoting an anti-tumor immune response through tertiary lymphoid structure formation.

Sibapriya Chaudhuri[1], Alberto Emata[1], Scott Thomas[2], Pamela N. Munster[1]

[1]UCSF - University of California San Francisco, San Francisco, CA,[2]Postdoctoral Fellow, Dept. of Hem./Onc., UCSF, San Francisco, CA

Introduction: Breast cancer affects over 2 million women globally every year despite advances in knowledge of disease biology, genomic assessment of disease profile and development of novel therapies. Preclinical and clinical studies suggest a benefit of combining PARP inhibitors (PARPi) and immune checkpoint inhibitors (ICi) in patients with homologous recombination proficient as well as deficient triple negative breast cancers. However, similar to the varied benefits of either drug class as single agent, the benefits of the combination therapy are strongly dependent on tumor mutation landscape. In this study, we identify which homologous recombination deficiency mutation respond best to PARPi and ICi combination therapy and explore the underlying mechanisms driving this sensitivity.

Methods: We used CRISPR engineering to individually repress BRCA1, BRCA2, ATM, CHEK2 in both murine and human breast cancer cell lines (EMT6, 4T1, MDA-MB231). The engineered murine cells were implanted in the mammary fat pad of Balb/cJ mice and subsequently treated with PARPi, ICi and drug combination. We evaluated how single agent and combined treatment affected tumor growth and overall survival. Using different biochemical techniques including spectral flow-cytometry, immunohistochemistry and spatial transcriptomics, we analyzed different immune cell populations in the tumor microenvironment.

Results: In EMT6 tumor models, the repression of BRCA1 or BRCA2 led to both reduced tumor growth and increased survival with either single agent or combination treatment. However, with ATM or CHEK2 repression, single agent ICi both reduced tumor growth and improved survival compared to untreated tumors, but no benefit was observed with PARPi addition. Spatial transcriptomics analysis suggested the formation of tertiary lymphoid structures (TLS) in combination therapy-responsive EMT6 tumors with repressed BRCA1. TLS formation was marked by higher CXCL13 expression, increased regions of B cells expressing CD19 and CD20, which were surrounded with $CD3^+$ T cells. We also observed inward migration of $CD45^+$ and $CD3^+$ cells from the tumor periphery. PDL1 expression was also higher in these tumors. Furthermore, in vitro olaparib treatment resulted in a substantial increase in surface PDL1 expression in EMT6 BRCA1-repressed cells, which was more moderate in EMT6 BRCA2-repressed cells. In 4T1 cells, repression of the HRD genes led to a modest change in PDL1 upregulation upon olaparib treatment.

Conclusion: Our findings mimic findings in the clinic and suggest that TLS formation may correlate with better response to the combination therapy of PARPi and ICi. TLS formation in the therapy responsive tumors might be maintaining the microenvironment necessary for anti-tumor immune response.

#6558 Selenium dependent regulation of immune checkpoint control in acute myeloid leukemia.

Deborpita Sarkar, Fenghua Qian, Robert F. Paulson, K.Sandeep Prabhu

Penn State University, State College, PA

Acute myeloid leukemia (AML) is a hematologic malignancy with a 5-year survival rate of ~27 % among individuals aged 20 years and older. Despite advances in immune checkpoint inhibitor (ICI) therapies such as PD-1/PD-L1 blockade, leukemic cells still evade immunity, leading to relapse. PD-L1 on AML cells binds PD-1 on cytotoxic (CD8+) T cells, driving immune exhaustion and suppression. Given the link between low serum selenium (Se) and poor outcomes in hematologic malignancies, we investigated the mechanisms underlying the anti-leukemic effects of Se in a murine model of human AML. Supplementation with graded levels of dietary Se (as selenite at 0.08 ppm and 0.4 ppm of Se) led to a dose-dependent decrease in PDL1 and PD-1 expression in leukemic stem cells (LSCs) and CD8+ T-cells, respectively, mitigating T-cell exhaustion, resulting in better prognosis when compared to the AML mice on a Se-deficient diet. The effect of Se was mediated, in part, through the activation of GPR44, a GPCR, by prostaglandin J2, an endogenous ligand produced via Se-dependent eicosanoid class-switching mechanisms. Our studies highlight a novel dietary intervention strategy with Se supplementation that could potentially complement existing ICI therapy in AML.

#6559 Investigating the transcriptomic signature of B7-H7-mediated activation of NK cell activity.

Michael Gomez[1], Deepthi Chowbene[2], Nahuel Perrot[2], Nikolaos Kalavros[2], Shuoshuo Wang[2], Antonella Arruda de amaral[2], David F. McDermott[3], Gordon J. Freeman[1], Ioannis S. Vlachos[2], Kathleen M. Mahoney[2]

[1]Dana-Farber Cancer Institute, Boston, MA,[2]Beth Israel Deaconess Medical Center, Boston, MA,[3]Beth Israel Deaconess Medical Center, Milton, MA

Determining how antibodies that target immune checkpoints alter lymphocyte functions can improve our understanding of immune checkpoint inhibitors responses in patients. HERV-H LTR-associating 2 (HHLA2, B7-H7) is an immune checkpoint expressed by many tumors. Our group previously found that B7-H7 has an inhibitory receptor, KIR3DL3, in addition to having an activating receptor, TMIGD2. Both B7-H7 receptors are expressed by subsets of T cells and NK cells. However, little is known about how different subsets of lymphocytes are affected by B7-H7 engagement of these receptors, and multiple B7-H7:KIR3DL3 blocking antibodies are currently enrolling cancer patients in Phase I clinical trials (NCT05824663, NCT06240728).In this study, we explored the effect of tumors expressing B7-H7 on NK cells *in vitro* by single cell RNA sequencing (scRNAseq). NK cells were isolated from peripheral blood and co-cultured with K562 cells or K562 cells overexpressing B7-H7 for 2hr. Co-cultures were performed in the presence of different B7-H7 blocking antibodies or isotype controls. 133,017 cells passed quality control, with 9 distinct NK cell populations being identified. Primary NK cells not co-cultured with tumor cells were mainly composed of two TXNIP+ CD96 hi NK cell clusters that had low expression of cytotoxic and inflammatory genes. Additionally, these two clusters had the highest expression of TMIGD2, suggesting that these populations represent resting NK cells. Co-culture with K562 or K562-B7-H7 cells increased the proportion of highly cytotoxic and inflammatory NK cell clusters. However, XCL2, CSF2, IFNγ and IL3 were higher in NK cells co-cultured with K562-B7-H7 than with K562, suggesting B7-H7 on K562 cells is proinflammatory in this early activation model. Notably, only a small subset of peripheral blood NK cells expressed the inhibitory receptor KIR3DL3, as expected in early NK activation. Furthermore, all antibody treatments regardless of the Fc isotype were associated with increased proportions of CRTAM+ IL2RA+ TNFRSF9+ NK cell clusters, compared to NK cells cultured without antibody. Differential gene expression analysis between B7-H7 antibody clones 6F10 and 2C4 by respective Fc (IgG1 or IgG4) suggested blocking TMIGD2 with the dual receptor blocking B7-H7 antibody (6F10) reduces the extent of activation of the NK cells compared to the B7-H7 antibody (2C4) that blocks KIR3DL3 but not TMIGD2.Our work suggests the importance of selecting B7-H7 therapeutics that spare the interaction of B7-H7:TMIDG2 to maintain any NK-dependent antitumor benefit of B7-H7 expression.

#6560 Targeting fitness surveillance restores T-cell immunity and sensitizes solid tumors to immune checkpoint inhibitors.

Amit Kumar[1], Antonio Palma[2], Praveen Bhoopathi[3], Esha Madan[3], Rajan Gogna[2]

[1]VCU Massey Comprehensive Cancer Center, Richmond, VA,[2]Cellular Molecular and Genetic Medicine, Virginia Commonwealth University, Richmond, VA,[3]Surgery, Virginia Commonwealth University, Richmond, VA

Immune checkpoint inhibitors (ICIs) fail in most solid tumors despite their transformative success in a minority of patients. Here, using integrated human tumor profiling and humanized patient-derived xenograft (PDX) models, we identify Flower-mediated fitness elimination as a dominant, conserved mechanism of T-cell attrition that limits ICI efficacy across epithelial cancers. Stromal compartments in high-grade serous ovarian cancer, non-small-cell lung cancer, colorectal cancer, hepatocellular carcinoma, and pancreatic ductal adenocarcinoma exhibit high Flower-Lose expressioncoupled to severe $CD8^+$ T-cell exclusion. Tumor-infiltrating T-cells themselves acquire a “loser” state marked by elevated Flower-Lose, rendering them vulnerable to competitive elimination by the stromal niche.

Across five orthotopic humanized PDX tumor types and three independent cohorts, ICIs alone produced minimal T-cell restoration, persistent metastatic dissemination, and negligible survival benefit (e.g., median ≈42 days). In contrast, pharmacologic blockade of Flower signaling increased intratumoral T-cell density by 5-7-fold (MixedLM $P < 10^{-15}$), reduced metastatic burden by 54-75%, suppressed tumor growth by >90%, and produced durable survival benefit across all models, with median survival not reached and strong meta-analytic significance ($Z = 10.56$, $P < 10^{-25}$).

Together, these findings reveal Flower-mediated fitness surveillance as a pan-cancer, tissue-level barrier to immunotherapy and establish Flower blockade as a universally effective strategy to restore T-cell persistence and unlock durable ICI responses across historically immune-cold solid tumors.

#6561 Rational design of a B7-H3/PD-L1 bsADC combining checkpoint blockade with targeted cytotoxicity for improved antitumor efficacy.

Zhangyi Song[1], Jie Chen[2], Huifang Zong[2], Zhen Li[2], Shusheng Wang[1], Jianwei Zhu[1], Xiaodong Xiao[1]

[1]Jecho Laboratories, Frederick, MD,[2]Jecho Institute, Shanghai, China

B7-H3 (CD276) is a transmembrane glycoprotein of the B7 family aberrantly overexpressed across diverse solid tumors with limited expression in normal tissues, making it an appealing therapeutic target. In addition to potential immunosuppressive effects on T cells, B7-H3 possesses non-immune regulatory functions in enhancing tumor proliferation, angiogenesis, and therapy resistance, which contribute to aggressive disease progression and poor prognosis. PD-L1, another member of the B7 family with clinically validated immune checkpoint function, is frequently co-expressed with B7-H3 in multiple tumor types. Although B7-H3-targeted antibody-drug conjugates (ADCs) and PD-1/PD-L1 checkpoint inhibitors have shown clinical benefit, therapeutic resistance and limited efficacy in “cold” tumors remain challenges. Co-expression of B7-H3 and PD-L1 creates an opportunity to pair targeted cytotoxic delivery with checkpoint blockade. Moreover, the ability of ADCs to induce immunogenic cell death provides additional rationale for integrating ADCs with immune-oncology therapy to enhance antitumor immunity.

Guided by this rationale, we developed a bispecific ADC (bsADC), JLC062, that engages both B7-H3 and PD-L1. Several anti-B7-H3 antibodies were identified from our fully human naïve phage library, recognizing different epitopes with varying affinities and internalization rates. Fast-internalizing anti-B7-H3 antibodies were formatted as IgGs to enable efficient intracellular delivery, which results in potent *in vitro* cytotoxicity across cancer cell lines with varying B7-H3 expression. A high-affinity PD-L1 binder, also isolated from our library, was fused to the C-terminus of the anti-B7-H3 IgG Fc as an scFv. It exhibited robust PD-1/PD-L1 blocking activity and induced IL-2 and IFN-γ secretion levels comparable to the clinical benchmark avelumab in a mixed lymphocyte reaction assay. Importantly, this anti-PD-L1 arm was intentionally selected as an antibody with minimal internalization to limit toxicity toward immune cells. In a syngeneic mouse model, JLC062 demonstrated significantly greater antitumor efficacy than either parental monotherapy, anti-PD-L1 antibody or anti-B7-H3 ADC, with no observed body weight loss. These findings highlight JLC062 as a promising therapeutic modality that integrates immune checkpoint inhibition with targeted cytotoxic delivery to yield deep and durable antitumor responses.

#6562 Identifying vulnerabilities to immune checkpoint inhibitors of oncogene-addicted non-small cell lung cancer subgroups..

Ines Diaz-Cano[1], Jose Gracia[2], Patricia Cozar[2], Belen Revuelta[2], Nuria Carrizo[2], Laura Garcia-Redondo[2], Joan Russo[2], Rita Manzano[2], Jose Garrido-Mesa[2], Daniel Meraviglia-Crivelli[1], Juan Dubrot[3], Luis Paz-Ares[4], Itziar Otano[1]

[1]H12O-CNIO Lung Cancer Clinical Research Unit, Spanish National Cancer Research Center (CNIO)/Biomedical Research Foundation Hospital 12 de Octubre (FIBH12O)/Spanish Center for Biomedical Research Network in Oncology (CIBERONC), Madrid, Spain,[2]H12O-CNIO Lung Cancer Clinical Research Unit, Spanish National Cancer Research Center (CNIO)/Biomedical Research Foundation Hospital 12 de Octubre (FIBH12O), Madrid, Spain,[3]Solid Tumors Program, Division of Oncology, Center for Applied Medical Research (CIMA), University of Navarra, Pamplona, Spain,[4]H12O-CNIO Lung Cancer Clinical Research Unit, Spanish National Cancer Research Center (CNIO)/Biomedical Research Foundation Hospital 12 de Octubre (FIBH12O)/Spanish Center for Biomedical Research Network in Oncology (CIBERONC)/Complutense University, Madrid, Spain

Purpose: Even though the treatment with PD-(L)1 axis blockers induces tumor response in approximately 20% of unselected lung cancer patients with advanced Non-Small Cell Lung Cancer (NSCLC), patients harbouring *EGFR* alterations or *ALK*-rearrangements have a poor response to immunotherapy. Tyrosine Kinase Inhibitors (TKIs) is the standard of care for these patients. However, resistance to TKIs is almost inevitable. The different clinical response to Immune Checkpoint Inhibitors (ICIs) in the different oncogene-addicted NSCLC subgroups may be explained by the composition and quality of the TME. Thus, we propose to investigate potential vulnerabilities and opportunities to overcome primary resistance to ICIs conferred by oncogene addiction.
Methods: To identify mechanisms involved in the restricted immune response of these subgroups, we performed a sub-genome-scale *in vivo* CRISPR/Cas9 screening, using a lentiviral vector system that allowed selective CRISPR antigen removal (SCAR) from tumor cells after genome editing. Genetically engineered mouse models were used to isolate cell lines bearing *Egfr* exon 19 deletion, *Egfr* L860R missense mutation or the *Eml4-Alk* oncogene fusion. Modified cell lines with the CRISPR/Cas9 sgRNA library were implanted subcutaneously into the flank of immunodeficient NOD-scid IL2Rg^{null} and immunocompetent wild-type (WT) mice. A group of WT mice received ICI treatment at different days post-tumor challenge and sgRNA abundances between the different groups were compared.
Results: As expected, both *Egfr* murine cell lines were sensitive to an EGFR-specific TKI, showing a decrease in phospho-Y1068-EGFR, demonstrating the oncogenic dependence on *EGFR* signaling for growth. However, when these cell lines were injected subcutaneously into immunocompetent mice, these tumors were resistant to PD1 blocking, mirroring the lack of response to human EGFR-mutant NSCLC to immunotherapy. To ensure an optimal coverage of the sgRNA library for *in vivo* studies, we estimated that around 55 mice for each experimental condition were necessary. Based on this estimation, an *in vivo* screen was performed and sgRNAs abundance are being analyzed to determine mechanisms of immune evasion in an *Egfr* oncogenic specific context. Cell lines bearing *Eml4-Alk* gene fusion were positive for TTF1 and SpC and negative for p63, confirming a lung adenocarcinoma phenotype. Phosphorylation of Stat3, Erk1/2 and Akt were also observed. The next steps include genetic modification of *Eml4-Alk* fusion cell lines with the CRISPR/Cas9 sgRNA library, followed by *in vivo* screening.
Conclusion: We expect to identify new resistance mechanisms that could result in novel treatment strategies for these NSCLC subgroups. The identification of these targets will provide the opportunity to reprogram the TME and to improve the efficacy of immunotherapy in a subset of patients with lung adenocarcinoma.

#6563 Immune and clinical determinants of response to immune checkpoint blockade (ICB) rechallenge after perioperative chemoImmunotherapy in gastroesophageal cancer.

Jeremy M. Tchack, Samuel L. Cytryn, Steven B. Maron, Patrick Evans, Jessica Posada, Geoffrey Y. Ku, Jessica Yang, Ryan B. Sugarman, Ping Gu, Laura H. Tang, Amitabh Srivastava, Vivian E. Strong, Daniela Molena, Yelena Yuriy Janjigian

Memorial Sloan Kettering Cancer Center, New York, NY

Background: The addition of perioperative ICB to chemotherapy improves survival in localized gastroesophageal adenocarcinoma (GEA), but optimal treatment at recurrence remains undefined. A key question is whether prior perioperative ICB influences clinical response or immune sensitivity to subsequent ICB in the metastatic setting. We evaluated clinical outcomes and immune correlatives in patients who recurred after perioperative chemo-immunotherapy and underwent ICB rechallenge.
Methods: We retrospectively analyzed patients with localized MSS GEA treated at Memorial Sloan Kettering (2020-2025) with curative intent perioperative chemo-immunotherapy (anti-PD-1 or anti-PD-L1). Patients treated on clinical trials were excluded. Clinical endpoints included RECIST response to ICB rechallenge at recurrence and progression-free survival (PFS) on rechallenge. Correlative studies (ongoing) include immune profiling and TCR clone-tracking from paired baseline and recurrence tumor biopsies and serial PBMCs in a subset of patients.
Results: Among 66 patients with localized gastric (n=26) and esophagus/GEJ (n=40) cancer, 33 received neoadjuvant ICB (anti-PD-1 + FLOT, n=17; anti-PD-1 + FOLFOX/CAPEOX followed by surgery and adjuvant chemo/ICB, n=28; or non-operative management, n=5), and 33 received chemotherapy alone followed by surgery and adjuvant ICB only. Eighteen of 66 patients (27%) experienced disease recurrence or progression; of these, 55% (10/18) were rechallenged with ICB plus chemotherapy at recurrence (4 with prior neoadjuvant ICB; 6 with adjuvant-only ICB). Rechallenged patients had a longer interval from completion of perioperative therapy to recurrence compared with those not rechallenged (6.30 vs 1.27 months; p=0.315). Among rechallenged neoadjuvant-exposed patients, all four experienced tumor regression or disease stabilization with chemo-ICB (1 CR, 2 PRs, 1 SD). Among rechallenged patients who received adjuvant-only ICB, disease progression occurred in 50% (3/6), and two had short-lived responses; all ultimately progressed, including two deaths. Overall, median PFS from time of ICB rechallenge was 6 months (95% CI 4.27-NR): NR (0 events) in the neoadjuvant-exposed group versus 5 months (95% CI 4.14-NR) in the adjuvant-only group (log-rank p=0.056).
Conclusions: In this perioperative chemo-immunotherapy cohort, prior neoadjuvant ICB exposure did not preclude - and may be associated with improved - response to ICB rechallenge at recurrence. Neoadjuvant-exposed patients showed numerically higher response rates and longer PFS on rechallenge compared with those who received adjuvant-only ICB. Ongoing correlative analyses of tumor and PBMC specimens aim to define immune determinants and TCR-based signatures associated with benefit from ICB rechallenge in MSS GEA.

#6564 Spatially resolved immunologic hallmarks of response to neoadjuvant immune checkpoint blockade in metastatic melanoma.

Zichao Liu[1], Xiaofei (Sophia) Song[2], Jodi A. Balasi[2], Wei-Shen Chen[3], Jiang He[4], Justin He[4], Jonathan Nguyen[2], Carlos M. Moran-Segura[2], Joseph O. Johnson[2], Chaomei Zhang[2], Jane L. Messina[2], Zena Sayegh[2], Douglas C. Marchion[5], Sean J. Yoder[2], Vernon K. Sondak[2], Jeffrey H. Chuang[1], Pei-Ling Chen[2]

[1]The Jackson Laboratory, Farmington, CT,[2]Moffitt Cancer Center, Tampa, FL,[3]University of South Florida, Tampa, FL,[4]Vizgen, Cambridge, MA,[5]Research Scientist, Moffitt Cancer Center, Tampa, FL

Background: The recent groundbreaking neoadjuvant immune checkpoint blockade (NICB) clinical trials in melanoma have demonstrated decisively that the administration of ICB prior to intent-to-cure surgeries will become the new standard-of-care for metastatic melanoma and beyond. The paradigm shifts from radiographic to pathologic response assessment also presents an unparalleled “window of opportunity” for the acquisition of abundant “on-treatment” tissues to elucidate the mechanisms and biomarkers of response and for guiding post-surgery personalized therapy decisions. To date, single-cell/bulk RNA studies have demonstrated that TCF7+ stem-like CD8+ T cells and tertiary lymphoid structures (TLS) are positive predictors of ICB response. However, how these immune cells organize and communicate within the spatial context of the neoadjuvant tumor microenvironment remains poorly understood.

Methods: We investigated a unique cohort of 91 FFPE biospecimens from 87 patients with stage III metastatic melanoma, including 60 treated with NICB (31 complete response, 7 partial response, 22 non-response) and 27 treatment-naïve. We deployed state-of-the-art technologies, including multiplexed error-robust fluorescent *in situ* hybridization (MERFISH), single cell sequencing of FFPE blocks, and multiplexed IF for this rich digital resource. Importantly, to analyze these challenging high dimensional spatial datasets, we developed 3 novel computational algorithms, including SCIRA, a scalable quantification method for spatial receptor-ligand (R-L) interactions; GC-SCAN, a graph-based clustering method to detect Germinal Center (GC)/TLS structures in single cell spatial data; and PathNet, an end-to-end AI algorithm for automated GC/TLS detection on H&E slides.

Results: Here, we interrogated ~5.6 million cells and showed that increased GC/mature TLSs, TCF7+ stem-like CD8 and CD4 T-cells, exhausted CD8 T-cells, plasma cells and myeloids in spatially distinct cellular neighborhoods are significantly associated with positive response. Our spatial (R-L) analyses further identified preferential chemokine R-L interactions between GC-B cells and follicular helper T-cell, and TCF7+ stem-like T-cells with CCL19+/CCL21+ fibroblasts in organizing these immune hubs. Lastly, Our PathNet GC/TLS detection algorithm outperforms recent state-of-the-art methods in both specificity and sensitivity, proven potential utility in facilitating clinical response assessment.

Conclusions: We leveraged cutting-edge spatial-omics technologies and novel computational methods to resolve the immunologic hallmarks of NICB response in metastatic melanoma. We believe our approach provides a model for how to precisely identify spatially intricate immune interactions that underline treatment response in the rapidly advancing era of standard of care neoadjuvant immunotherapy.

#6569 Single-cell transcriptomics reveal functional interaction between CD4+ T cells and B cells driving the activated peripheral immune phenotype in healthy women living with germline pathogenic *BRCA1* variants.

Vince Kornel Grolmusz[1], Klaudia Horti-Oravecz[1], Istvan Kelemen[1], Istvan Liko[1], Aniko Bozsik[1], Timea Pocza[1], Janos Papp[1], Szonja Polett Posa[1], Lorinc S. Pongor[2], Henriett Butz[1], Attila Patocs[1]

[1]National Institute of Oncology Hungary, Budapest, Hungary,[2]Hungarian Center of Excellence for Molecular Medicine, Szeged, Hungary

Our previous, mass cytometry-based results signalled an enrichment of peripheral activated CD4+ T and B cells in healthy women living with germline pathogenic *BRCA1* variants (gpath(*BRCA1*)) and in triple-negative breast cancer (TNBC) patients. Our aim was to assess the transcriptional background of this activation and investigate the interrelation between these two cell populations. Peripheral blood mononuclear cells were isolated from five healthy women living with gpath(*BRCA1*), seven women with treatment-naive TNBC living with gpath(*BRCA1*) and seven, age-matched healthy women living without hereditary cancer predisposition (control group). Viable single-cell suspensions were subjected to single-cell transcriptomic library preparation using the Chromium Controller. Libraries were sequenced on a Novaseq 6000 instrument. Bioinformatic analyses were performed using the CellRanger, Seurat, AUCell, CellChat and Monocle3 packages. Following quality control, 100 132 cells were analyzed. CD4+ T cells, CD8+ T cells, NK cells, B cells and monocytes were annotated and subclustered to subpopulations. B cell frequencies in gpath(*BRCA1*) study groups were decreased compared to controls. A pro-inflammatory B cell subpopulation was more frequent in healthy gpath(*BRCA1*) carriers while an activated Th17-polarized CD4+ T cell subpopulation was elevated in both healthy and TNBC-bearing gpath(*BRCA1*) study groups. Ligand-receptor interaction network analysis between these two subpopulations revealed a striking increase in interaction strength in gpath(*BRCA1*) carriers and identified multiple inflammatory cytokines which mediate the observed activated peripheral immune phenotype. Our results confirm the activated peripheral immune profile of healthy women living with gpath(*BRCA1*). This activated peripheral immune phenotype and the functional interactions between CD4+ T cells and B cells might serve as targets during precision prevention approaches in women living with gpath(*BRCA1*).

#6570 Assessment of multiplexed human and mouse cytokines in humanized mouse samples.

Andrew McDermott[1], Amanda Hrabovsky[1], Olivia Williams[1], Eric Bruder[1], Daniel Shoufler[1], Tina Raeber[2], Brooke Gilliam[3], Sineej Madathil[3], Kathryn MacPherson[4]

[1]Immunology and Immunotoxicology, Labcorp, Madison, WI,[2]Millipore Sigma, St. Louis, MO,[3]MilliporeSigma, St. Louis, MO,[4]Immunology and Immunotoxicology, Labcorp, Greenfield, IN

Humanized mice represent a critical model for the evaluation of advanced therapeutics targeting cancer, including chimeric antigen receptor T cell (CAR-T) therapies. Myriad humanized mouse models exist, each with varying levels of immunodeficiency present in the murine immune system and varying levels of immunocompetence engendered by the human graft cells. Furthermore, CAR-T cells themselves can produce human cytokines once transferred into a mouse, and murine stromal cells can release cytokines in response to cancerous cells and therapies . As such, a significant challenge to evaluating immunological responses in humanized mice is detecting and differentiating human and murine cytokines within relatively small sample volumes.

We evaluated the ability of the MILLIPLEX® Humanized Mouse Magnetic Bead Panel to detect 17 human or mouse cytokines in murine serum and plasma. Briefly, human or murine PBMCs were isolated from whole blood and stimulated overnight in the presence of lipopolysaccharide, eBioscience™ cell stimulation cocktail, and Rapid-Act T Cell Activation Kit (mouse or human). Resulting cell culture supernatants were diluted into murine serum and plasma individually and in combination to generate murine serum and plasma samples rich in human, murine, or human and murine cytokines *ex vivo*. These samples were then evaluated for murine IL-2, IL-5, IL-6, GM-CSF, IFNγ, IL-1β, IL-17A, TNFα and human IL-2, IL-5, IL-6, GM-CSF, IFNγ, IL-1β, IL-17A, TNFα, and IL-10 using the MILLIPLEX® Humanized Mouse Magnetic Bead Panel on the Bio-Plex 200 platform.

The MILLIPLEX® Humanized Mouse Magnetic Bead Panel was able to detect human and murine cytokines in samples spiked with human and/or murine PBMC supernatant. Additionally, the kit was able to distinguish between human and murine cytokines within spiked samples. On average, the level of human cytokines detected in serum spiked with human supernatant was 694-fold higher than human cytokine levels detected in serum spiked with murine supernatant alone, while the level of murine cytokine detected in serum spiked with murine supernatant alone was 261-fold higher than serum samples spiked with human supernatant alone. Similar results were seen in plasma samples.

These data demonstrate the utility of the MILLIPLEX® Humanized Mouse Magnetic Bead Panel to evaluate human and murine cytokines within humanized mouse samples. These data demonstrate this kit can detect and distinguish key mediators of inflammation between human and mouse, including IL-2, IFNγ, and TNFα, within small sample volumes. Collectively, this work suggests that this platform is suitable for evaluating human and murine cytokine responses within murine samples, allowing for reliable cytokine analysis across a variety of humanized mouse formats and experimental designs.

#6571 Proliferative T cell infiltration is associated with colorectal cancer molecular subtypes and cancer specific survival.

Yasutoshi Takashima[1], Claire Elizabeth Thomas[2], Andressa Dias Costa[1], Sushma Thomas[3], Evertine Wesselink[4], Conghui Qu[3], Steven Gallinger[5], Robert C. Grant[6], Li Hsu[3], Marios Giannakis[7], Jeroen Huyghe[8], Daniel D. Buchanan[9], Shuji Ogino[10], Riki (Ulrike) Peters[2], Amanda I. Phipps[3], Jonathan A. Nowak[11]

[1]Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, MA,[2]Fred Hutchinson Cancer Center, Seattle, WA,[3]Public Health Sciences Division, Fred Hutchinson Cancer Center, Seattle, WA,[4]Department of Molecular Pathology, The Netherlands Cancer Institute. Antonie van Leeuwenhoek hospital, Amsterdam, Netherlands,[5]Lunenfeld Tanenbaum Research Institute, Mount Sinai Hospital, University of Toronto, Toronto, ON, Canada,[6]Division of Medical Oncology and Hematology, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada,[7]Dana-Farber Cancer Institute, Boston, MA,[8]Public Health Sciences Division, Fred Hutchinson Cancer Research Center, Seattle, WA,[9]University of Melbourne, Kallangur, Australia,[10]Brigham and Women's Hospital, Boston, MA,[11]Department of Pathology, Brigham and Women's Hospital and Harvard Medical School, Boston, MA

The immune microenvironment is a critical regulator of colorectal cancer (CRC) biology and represents a clinically targetable tumor feature in a subset of patients. T cells are one of the most common cell types in the CRC immune microenvironment and exist in a broad variety of subtypes and activation states. Proliferation status represents a general measure of T cell activity that is applicable to many subtypes. Evidence from other tumor types suggests that proliferating cytotoxic T cells may mediate adaptive immunity in cancer. However, T cell proliferation in CRC is incompletely characterized. To investigate the role of proliferating T cells in CRC, we developed a multiplexed immunofluorescence assay assessing CD3, CD4, CD8, FOXP3, PTPRC (CD45RA and CD45RO), MKI67 (Ki67), and KRT (cytokeratin) expression, and assessed 1,610 primary resected CRC specimens from four US/Canadian cohort studies. Digital imaging and pathologist-supervised machine learning were used to decompose image data into single-cell level information. The Kaplan-Meier method was used to describe CRC-specific survival (CSS) and multivariable Cox proportional hazards models were used to examine associations of proliferating and non-proliferating T cell densities with CSS. Multivariable ordinal logistic regression was used to adjust for confounding factors (age, cancer site, sex, and study batch) in analyses of T cell densities and tumor features. Across one million T cells, 4.5 % were classified as proliferating, as defined by positive MKI67 expression. While higher densities of both proliferating and non-proliferating T cells were positively associated with microsatellite instability (MSI), a CpG island methylator high phenotype, *BRAF* mutant status and *KRAS* wildtype status, these associations were stronger for proliferating T cells (e.g., adjusted odds ratio (OR) 2.09, CI 1.62-2.70, p<0.0001 for MSI and higher proliferative T cell density versus adjusted OR 1.40, CI 1.08-1.81, p=0.01 for MSI and higher non-proliferative T cell density). Higher proliferative and non-proliferative T cell densities were both positively associated with CSS (adjusted hazard ratio (HR) 0.75, CI 0.55-1.03, comparing highest versus lowest quartile of proliferative T cell densities (Ptrend=0.018) and adjusted HR 0.42, CI 0.31-0.57, comparing highest versus lowest quartile of non-proliferative T cell densities (Ptrend<0.001). Despite comprising a minor subset of total T cell infiltration in the CRC microenvironment, proliferative T cells are more strongly associated with specific molecular subtypes and are also associated with CSS. These results, across a large series of primary human tumors, suggest that proliferation marks a subset of functionally distinct subset of T cells in the CRC microenvironment.

#6572 Obesity shapes a reversible immune microenvironment that fosters breast cancer growth.

Tao Zhang[1], Shimeng Liu[1], Yi Zhang[2], Alva Yijia Jiang[1], Zachary Sandusky[1], Na Zhang[1], Tara Akhshi[1], Nicole Traphagen[1], Jack Yueyang Wang[1], Lucas Tian[1], Esme Wheeler[1], Yingtian Xie[1], Rong Li[1], Buraq Ahmed[1], Genevra Kuziel[1], Capucine Heraud[1], Mohammed Mutaher[1], Henry Long[1], Kornelia Polyak[1], Myles A. Brown[1]

[1]Dana-Farber Cancer Institute, Boston, MA,[2]Duke University, Durham, NC

Obesity is linked to breast cancer risk and severity, yet the underlying mechanisms remain unclear. Using single-cell RNA sequencing, we identified a role for C1q+ macrophages in mammary tumors and adipose tissues in mouse obesity and breast cancer models. Macrophage-derived C1q promotes the clearance of obesity-associated apoptotic adipocytes, enhancing lipid metabolism and leading to an immunosuppressive tumor microenvironment via the production of prostaglandin E2 (PGE2). Moreover, the tumor-associated macrophages (TAMs) engage tumor cells in a feedforward loop by inducing the production of monocyte-recruiting cytokines further suppressing the anti-tumor immune response. Blockade of C1q, TNF-α, and PGE2 synthesis reduced tumor growth in obese mice. Importantly, weight loss via dietary changes or glucagon-like peptide-1 receptor (GLP-1R) agonism decreased C1q expression and suppressed obesity-driven tumor growth. Interference with the immunosuppressive environment and the feedforward loop may be viable strategies for improving the outcomes of breast cancer patients with obesity.

#6573 Assessment of the T cell receptor repertoire in racially diverse prostate cancer patients.

Paula O. Cooper, Laila N. Scroggins, Sally Elsamanoudi, Amina Ali, Picabo Binette, Beatriz German Falcon, Leigh Ellis, Gregory T. Chesnut, Shyh-Han Tan, Cara C. Schafer

Surgery, Center for Prostate Disease Research, Bethesda, MD

Background: Prostate cancer (PCa), the second leading cause of cancer-related death for US men, gains limited benefits from immune therapies. Interestingly, African American (AA) men respond far better to Sipuleucel-T and undergo different T cell responses than Caucasian American (CA) PCa patients. Growing evidence suggests that variations in TCR diversity may serve as a biomarker for cancer progression and response to immune therapy; however, the extent of the TCR repertoire's contribution to PCa progression and disparate racial responses to treatment remains unclear, highlighting the need for further study.
Purpose: The rapid development of Next Generation Sequencing and single-cell transcriptomics provides a unique opportunity to examine the TCR repertoires of PCa patients in greater depth than previously possible. By examining TCR sequences in a racially diverse cohort from an equal-access Military Health System, we aim to identify how differences in AA and CA repertoires may contribute to variations in PCa initiation, progression, and response to therapy.
Methods: Bulk TCR-seq was performed on 25 AA and 30 CA treatment-naïve tumor biopsies to compare the percent of dominant and unique TCRs (D50) from each sample. Next, peripheral blood lymphocytes (PBLs) were isolated from 4 AA and 4 CA men undergoing radical prostatectomy for diagnosed PCa with no prior treatment, matched for age, Gleason score, and PSA. 10X Genomics V(D)J and GEX technologies were used to produce libraries of individual cell TCRs and transcriptomes. These were compared using previously described bioinformatics pipelines and may be assessed for co-expression of activation, exhaustion, and anergy markers.
Results: TCR-seq revealed significantly higher D50 scores in CA than AA tumors. We also found that men that developed biochemical recurrence and metastasis had significantly higher D50s than those that did not. Single cell V(D)J and RNA seq identified key differences in the TCR sequences of PBLs isolated from AA and CA PCa patients.
Conclusions/future directions: These data may be used to help guide therapeutic options based on predicted responsiveness of an individual. The V(D)J data will be used as a reference set to generate a panel for 10X Genomics Xenium. This will provide spatial data to examine the distribution of identified TCR clones in PCa tumor biopsies.

#6574 NK cell therapy enhances the efficacy of CDK4/6i in breast cancer.

Yinchong Wang, Evdokiya Reshetnikova, Nar Bahadur Katuwal, Anna Vilgelm

Ohio State University, Columbus, OH

Cyclin-dependent kinase 4/6 inhibitors (CDK4/6i) are routinely used for patients with estrogen receptor-positive metastatic breast cancer. Abemaciclib is a CDK4/6 inhibitor that blocks cancer cell proliferation by preventing progression through the cell cycle. However, these drugs primarily inhibit cancer cell growth and do not typically induce complete tumor elimination. Combining CDK4/6i with a synergistic therapeutic modality could enable regression of metastatic breast cancer tumors and dramatically improve patients' outcomes. Adoptive cell therapy is a type of cancer therapy where effector immune cells, such as T and NK cells, are transferred into the patient's body to eliminate malignant cells. We found that CDK4/6i-treated tumor cells secrete NK cell-attracting chemokines and express stress ligands on their surface, which are known to trigger NK cell cytotoxic activity. This indicates that pre-CDK4/6i treatment increases tumor vulnerability to NK cells. Therefore, we hypothesized that CDK4/6i efficacy could be improved by combining it with NK cell therapy, resulting in the elimination of tumor cells.

Methods: We used human MCF7 and mouse PYMT-B6 cell line to evaluate the effect of CDK4/6 inhibition on chemokine production in tumors and NK cell migration toward the tumor. We used spectral cytometry to test the surface expression of NK cell-activating stress ligands on breast cancer cells and patient-derived organoids (PDO). PDOs were co-cultured with NK cells to investigate patient-to-patient differences in CDK4/6 inhibitor-mediated NK cell recruitment and tumor recognition. We performed patient-derived xenograft (PDX) implantation in huIL-15 mouse to test Abema and NK combination treatment *in vivo*.

Results and conclusions: We found that abemaciclib induced the expression of NK cell-attracting chemokines, including CCL5 and CXCL10, by tumor cells. We also found that therapeutic NK cells expressed the corresponding chemokine receptors, suggesting enhanced chemotactic potential. Pre-treatment of tumor cells with abemaciclib significantly increased the expression of stress ligands on the surface of breast cancer cells and PDOs. This stress ligands are recognized by NKG2D receptors on the NK cells that trigger their cytotoxicity. In NK&PDO co-culture assay, pre-treatment with CDK4/6i promoted the killing and infiltration of human NK cells to PDOs. Additionally, NK cells co-cultured with pre-treated tumor cells displaced activated functional phenotype with increased cytotoxicity and cytokine secretion. We conducted patient-derived xenograft (PDX) implantation in mice and observed slower tumor growth and improved survival following treatment with CDK4/6 inhibitors and NK cell infusion.

Significance: This research can provide a pre-clinical basis for the further development of CDK4/6i and immunotherapy combinations that could improve the outcomes of metastatic breast cancer treatment.

#6575 Investigating the role of glucocorticoid-induced leucine zipper (GILZ) in triple-negative breast cancer.

Devyn Aniya Hill[1], Jennifer B. Jacob[2]

[1]Michigan State University, East Lansing, MI,[2]Wayne State University School of Medicine, East Lansing, MI

Breast cancer is one of the leading causes of death for American women, with 1 in 8 expected to develop the disease in their lifetime. Breast cancers that lack the expression of hormone receptors (estrogen/progesterone) and the HER2 receptor are known as triple negative breast cancer (TNBC). TNBC accounts for about 15-20% of all breast cancer cases in American women, and is commonly characterized by a complex tumor microenvironment that often exhibits increased inflammation and immune suppression. This makes TNBC resistant to many treatments, resulting in an overall lower five-year survival rate than other breast cancer subtypes.Evidence found in our lab demonstrates that the gene TSC22D3 is correlated with longer survival in patients with TNBC. TSC22D3 encodes the immunomodulatory protein Glucocorticoid-Induced Leucine Zipper (GILZ). GILZ expression is induced by glucocorticoid binding to hormone response elements in the nucleus and is thought to be one of the first transcripts synthesized after GR activation. GILZ is known to directly inhibit inflammation and cell proliferation by preventing downstream phosphorylation or activation events of enzymes such as mitogen-activated protein kinases (MAPKs), and proteins like rat sarcoma protein (Ras) and hypoxia inducible factor 1 alpha (HIF1a) to suppress inflammatory signaling.While the function and effects of the GILZ protein have been previously studied in many systems including the renal system, central nervous system and digestive system, its expression and effects have not been explicitly observed in breast cancer studies. Furthermore, the mechanism by which GILZ inhibits inflammation is variable with oxygen availability and the biological reason for this also remains unknown. The goal of this project is to 1) identify a potential chemical compound to modulate GILZ expression to better observe the activity in vitro and, 2) investigate key protein-protein interactions that influence GILZ action in variable oxygen availability states in TNBC cells. This work seeks to explore and clarify the specific immunomodulatory effects of GILZ in adaptable tumor microenvironments by investigating existing compounds that can reduce or overexpress GILZ protein levels and examining potential biased protein binding across different environments. All told, characterizing the activity and role of GILZ in varying conditions will potentially lead to the development of targeted therapeutic treatment for inflammation-driven diseases such as triple negative breast cancer.

#6576 Integrative spatial transcriptomics reveals EMT-driven immune regulatory programs underlying metastasis in HNSCC.

Chih-Hung Chung, Han-Hsun Yu, Muh-Hwa Yang

National Yang Ming Chiao Tung University, Taipei, Taiwan

Head and neck squamous cell carcinoma (HNSCC) is a globally prevalent malignancy. Standard treatment typically involves surgical resection, radiotherapy, and chemotherapy. However, for patients with recurrent or distantly metastatic disease for whom surgery or radiation is no longer feasible, systemic therapy consisting of targeted agents combined with chemotherapy or immune checkpoint inhibitors (ICI) becomes the mainstay of management. Despite these advances, clinical outcomes remain suboptimal, underscoring the urgent need to elucidate how immune cell composition and functional states are altered within the tumor microenvironment (TME) of aggressive or metastatic tumors. Such insights are essential for improving the therapeutic effectiveness of ICIs in HNSCC. The objective of this study was to characterize TME compositional changes across diverse HNSCC specimens. We employed the GeoMx Digital Spatial Profiler (DSP) to perform high-resolution, imaging-guided spatial transcriptomic profiling. By comparing EMT-related gene signatures enriched at the invasive tumor front, we identified significant upregulation of canonical EMT markers—including FN1, CD44, and ITGB1. To further dissect the regulatory programs associated with ITGB1-high tumor cells, we applied Single-Cell Regulatory Network Inference and Clustering (SCENIC), which revealed distinct regulon activities. Notably, IRF-associated signaling emerged as a major downstream regulatory pathway in ITGB1-high EMT tumor populations. Subsequently, we analyzed HNSCC tissues using integrative spatial-omics (10x Visium and 10x Xenium) approaches and identified a clear transcriptional trajectory of tumor EMT states. To directly assess how EMT-high tumor cells modulate surrounding immune cells, we performed NicheNet ligand-receptor analysis, which revealed pronounced alterations in ligand-receptor interactions shaping the immune landscape of malignant HNSCC. Collectively, these findings provide mechanistic insights into EMT-driven immune suppression and highlight actionable TME features that could guide personalized therapeutic strategies for patients with head and neck cancer.

#6577 A potential role of NRF-2, MDR-1, and TET-2 in inflammatory bowel disease and colorectal carcinoma: An *in vitro* study.

Jessica Saliba[1], Ali Amhaz[2], Batoul Moussa[3], Souraya Ismail[3], Abdullah Shaito[4], Marwan El-Sabban[5]

[1]Department of Public Health, Faculty of Health Sciences, University of Balamand, Beirut, Lebanon,[2]Department of Medical Laboratory Sciences, Faculty of Health Sciences, University of Balamand, Beirut, Lebanon,[3]Department of Biology, Faculty of Sciences, Lebanese University, Beirut, Lebanon,[4]Biomedical Research Center and Biomedical Sciences, Qatar University, Doha, Qatar,[5]Department of Anatomy, Cell Biology and Physiological Sciences, Faculty of Medicine, American University of Beirut, Beirut, Lebanon

Study purpose: Inflammatory Bowel Disease (IBD) is partly attributed to cytokine storm and infiltrating immune cells. As part of the cell defensive mechanisms, a transcription factor called nuclear factor erythroid 2-related factor 2 (NRF-2) activates genes encoding antioxidant enzymes. Additionally, NRF-2 has recently emerged as an important contributor to chemo-resistance in colon neoplasms, by upregulating multi-drug resistant protein 1 (MDR-1). In addition, epigenetic factors have been shown to influence the onset of IBD and of colorectal cancer. One of these epigenetic factors is the interplay between DNA methylation status. A DNA demethylating enzyme, coded by the ten-to-eleven translocation 2 [tet2], yields the methylcytosine dioxygenase TET-2. Recent studies have demonstrated a potential association between TET-2 and NRF-2 in IBD-associated colon cancer. This study aims to understand the alteration in the expression and activity of these markers under inflammatory conditions.
Experimental procedures: NRF-2, MDR-1, and TET-2 expression level was evaluated in parental HT-29 cells and in HT-29 cells downregulated for TET-2 (HT-29shTET-2) and exposed to an inflammatory milieu; at the transcriptional level by quantitative real-time polymerase chain reaction (qPCR). Markers of the epithelial-to-mesenchymal transition (EMT, E-cadherin and N-cadherin) were also evaluated by qPCR and Western blotting.
Summary of results: Under inflammatory conditions, NRF-2, MDR-1, and TET-2 expression levels increased. However, NRF-2 and MDR-1 expression levels were downregulated in HT-29shTET-2 cells. Interestingly, N-cadherin levels were higher in HT-29shTET-2 exposed to inflammatory media compared to parental HT-29.
Conclusions: NRF-2 and MDR-1 expression levels increase upon exposure of HT-29 cells to inflammation. On the other hand, their expression is downregulated when TET-2 is downregulated, suggesting a potential demethylating role of TET-2 in activating NRF-2 and MDR-1 gene expression.

#6578 Heat shock protein inhibitors suppress cytokine-induced DUOX2 mRNA and protein expression in human pancreatic cancer cells in a JAK, STAT dependent manner.

Yongzhong Wu[1], David J. Mallick[2], Allan Di[2], Smitha Antony[2], Jennifer Meitzler[1], Mariam M. Konate[2], Becky Diebold[1], Krishnendu Roy[2], James H. Doroshow[1]

[1]DTB, National Cancer Institute, Bethesda, MD,[2]Department of Cancer Treatment and Diagnosis, National Cancer Institute, Bethesda, MD

Dual oxidase 2 (DUOX2), one of the seven NADPH oxidases family members, plays a critical role in both host defense and chronic inflammation-associated cancer in the gastrointestinal system. In vitro, pro-inflammatory cytokines, such as IFN- y, IFNα/β, IL-4 and IL-17A, enhance DUOX2/DUOXA2 expression through activation of STATs and NF-kB signaling pathway proteins; in vivo, DUOX protein and mRNA levels are substantially upregulated in chronic pancreatitis, pre-malignant pancreatic intraepithelial neoplasms and the early stages of pancreatic cancer patients compared to histologically normal pancreatic tissues. In pancreatic adenocarcinoma, increased DUOX2 expression is adversely correlated with overall patient survival. Heat-Shock Protein 90 (Hsp90), an important molecular chaperone involved in tumorigenesis, invasion and metastasis of cancer cells, is critical in folding, maturation and stability of many oncogenic client proteins, including kinases such as AKT and JAK1/2, and transcription factors, such as STAT3 and HIF-1α. Several STAT family members, along with Hsp90, are overexpressed in human pancreatic carcinomas. Using a panel of human pancreatic cancer cell lines (BxPC-3, AsPC-1 and CFPAC-1), we found that two different Hsp90 inhibitors, Tanespimycin (17-AAG) and Ganetespib (STA-9090), inhibit JAK1 and JAK2 kinases, blocking cytokine-induced, JAK-regulated STAT phosphorylation. Additionally, these Hsp90 inhibitors suppress cytokine-induced DUOX2, VEGF-A, MMP-7 and PD-L1 expression in human pancreatic cancer cell lines with varying sensitivity. Furthermore, the JAK1/2 inhibitor Ruxolitinib inhibits IL-4 induced and JAK-mediated STAT6 phosphorylation, and DUOX2 mRNA and protein expression in BxPC-3 cells. Similar results were observed with JAK1, STAT1, 2 and STAT6 specific siRNA knockdown. However, simultaneous knockdown of both isoforms of Hsp90, Hsp90α and Hsp90β, with specific siRNA did not inhibit JAK1 activity, cytokine-induced DUOX2 mRNA or protein expression. Either remaining Hsp90 protein or other isoforms of Hsp90 in cells may compensate decreased Hsp90 function after siRNA knockdown. Our data suggests that Hsp90 inhibitors, through blocking the cytokine-activated JAK-STATs oncogenic signaling pathway and their downstream genes such as DUOX2, VEGF-A, MMP-7 and PD-L1expression, may be a valuable therapeutic approach for inflammation-associated pancreatic cancer.

#6579 Investigating the role of signal peptide peptidase in tumor immune evasion via Qa-1-mediated peptide presentation.

Roya Solhi[1], Clara Wolfe[2], Hu Chen[1], Achintya Perumal[1], Kyle Ockerman[2], Grant Brennan[1], Jiayao Ye[1], Adrienne H. Long[2], Marc Schwartz[2], Susan Klaeger[2], Steven A. Carr[2], Thorbald van Hall[3], Jon A. Weidanz[4], Soroush Ghaffari[4], Kathleen B. Yates[2], Robert T. Manguso[2], Qin Ma[1], **Hakimeh Ebrahimi-Nik**[1]

[1]The Ohio State University, Columbus, OH,[2]Broad Institute of MIT and Harvard, Cambridge, MA,[3]Leiden University Medical Center, Leiden, Netherlands,[4]The University of Texas at Arlington, Arlington, TX

Canonical leader peptides, derived from the signal sequences of classical MHC class I molecules, are presented by HLA-E in humans and Qa1 in mice. These peptides serve as ligands for the NKG2A/CD94 receptor complex on NK cells and $CD8^+$ T cells, promoting immune homeostasis. Disruptions of this inhibitory axis—such as during viral infection—can lead to the display of novel peptides that override this inhibition and activate immune responses. However, the mechanisms controlling canonical peptide presentation remain unclear. To better understand how Qa1-restricted inhibitory peptide presentation is regulated, we targeted Signal Peptide Peptidase (SPP), an ER-resident protease that cleaves signal peptides. SPP was knocked out in two tumor models: YUMMER melanoma and KPC pancreatic adenocarcinoma. Changes in Qa1-bound peptides were evaluated using mass spectrometry, and tumor growth was assessed in vivo. Loss of SPP markedly reduced canonical peptide loading in both tumor models. SPP-deficient melanoma tumors were strongly rejected in vivo, while pancreatic tumors lacking SPP showed no such reduction, despite similar decreases in canonical inhibitory peptide levels. Interestingly, the dominant Qa1-bound peptide in both models remained the canonical peptide, indicating that alternative, SPP-independent mechanisms can liberate and generate this peptide for presentation. In the KPC model, novel peptides with potential inhibitory properties were identified. Ongoing studies aim to determine whether these peptides can sustain immune suppression in the absence of the canonical peptide. Our findings demonstrated that even in the absence of SPP, alternative mechanisms maintain inhibitory peptide presentation in tumor cells. Ongoing studies targeting other SPP family members and newly identified candidate inhibitory peptides aim to elucidate these compensatory pathways. A clearer definition of the Qa1/HLA-E inhibitory pathway will help determine whether this axis can be more effectively disrupted to improve anti-tumor immune responses.

#6580 A novel regulator of T-cell motility: Fhl2 controls CD8⁺ T-cell migration and infiltration.

Achintya Perumal[1], Grant Brennan[1], Jiayao Ye[1], Hu Chen[1], Roya Solhi[1], Omar I. Avila[2], Kathleen B. Yates[2], Robert T. Manguso[2], Stanley C. Huang[1], Haoxin Zhao[1], Giovanni Nigita[1], Zihai Li[1], No-Joon Song[1], Hazem E. Ghoneim[1], Ava Lowin[1], Kelley Ptak[1], Qin Ma[1], **Hakimeh Ebrahimi-Nik**[1]

[1]The Ohio State University, Columbus, OH,[2]Broad Institute of MIT and Harvard, Cambridge, MA

For tumor immunotherapy to succeed, CD8⁺ T cells must efficiently migrate into tumor sites, yet the molecular pathways controlling this critical step of T-cell trafficking remain only partially understood. Using a novel reverse-engineered strategy—starting from antigen-experienced CD8⁺ T cells that either robustly rejected tumors in vivo or completely failed to do so despite comparable functional profiles—we identified Fhl2 (Four-and-a-half LIM domains 2) as a novel positive regulator of T-cell migration and infiltration, consistent with its role as a LIM-domain adaptor protein that integrates cytoskeletal and signaling inputs. Fhl2-deficient CD8⁺ T cells exhibited reduced migratory capacity, accompanied by impaired cytoskeletal remodeling and CXCR3-mediated chemotaxis. High-resolution confocal microscopy revealed that Fhl2-wild-type CD8⁺ T cells formed significantly more dendrite protrusions than knockout counterparts, consistent with enhanced motility. These findings were further supported by RNA-seq and Functional Proteomics Reverse Phase Protein Array (RPPA) analyses: RNA-seq revealed higher expression of several chemokine receptors in Fhl2-wild-type cells, including CXCR3 and CXCR6, while RPPA showed positive enrichment of multiple cell-migration-associated pathways in wild-type cells compared to the knockout. Importantly, transwell chemotaxis assays demonstrated that Fhl2-wild-type CD8⁺ T cells exhibit superior chemokine-driven migration compared with Fhl2-deficient cells—both in polyclonally activated populations and in SIINFEKL-stimulated OT-I cells. This enhanced migratory capacity of Fhl2-wild-type CD8⁺ T cells was also reflected in vivo. Collectively, these results establish Fhl2 as a key orchestrator of CD8⁺ T-cell motility and reveal a previously unappreciated molecular pathway that could be harnessed to improve tumor immune surveillance and T-cell-based therapies.

#6581 Reprogramming microglial and GAMs phenotype and function, with HDAC inhibitors to overcome immune suppression in glioblastoma.

Sonia Sebaoui

Georgetown Lombardi Comprehensive Cancer Ctr., Washington DC, DC

Glioblastoma multiforme (GBM) stands as the most aggressive form of primary tumor in the central nervous system, primarily affecting older male individuals. The immune landscape in GBM is significantly influenced by Glioma-associated microglia and infiltrating macrophages (GAMs), which together account for up to 45% of the tumor mass. These cells are highly plastic and can shift their phenotype between tumor-fighting, pro-inflammatory (M1-like) and tumor-supportive, anti-inflammatory (M2-like) states in response to different environmental cues. Epigenetic regulation of this plasticity has emerged as a promising therapeutic strategy to reprogram innate immunity within the TME. Here, we demonstrated that selective class IIb HDAC inhibitor treatment reprograms primarily macrophages and microglia toward a pro-inflammatory, phagocytic, and tumor-killing state. Using the BV2 microglial cell line and bone marrow-derived macrophages, we found that HDAC class IIb inhibitors increased M1 markers, decreased M2 phenotype, and enhanced phagocytosis. Interestingly, they enhanced microglial migration in both M1-like and M2-like cells, potentially reflecting the innate migratory capacity of these resident immune cells in the brain, which are constantly surveilling and rapidly responding to environmental cues. In contrast, these class IIb inhibitors reduced macrophage migration, underscoring the functional divergence between these cell types. To further validate our findings in a physiologically relevant system, we optimized a robust high-purity primary microglia isolation protocol from murine brains. Future work includes transcriptomic profiling and in vivo studies to assess therapeutic efficacy and immune remodeling. Our results support HDAC class IIb inhibition as a promising strategy to modulate immune responses in GBM and suggest that targeting myeloid cell plasticity may enhance the efficacy of immunotherapeutic responses in GBM.

#6582 Cell surface plectin as a master regulator of tumor-immune interactions in pancreatic cancer.

Cody L. Wolf[1], Roxanne K. Ruiz[2], Sokchea Khou[3], Robert Cornelison[4], Edward Stelow[4], Karl M. Kowalewski[5], Matthew J. Lazzara[1], Amanda Poissonnier[6], Timothy N. J. Bullock[4], Lisa M. Coussens[6], Kimberly A. Kelly[1]

[1]Department of Biomedical Engineering, University of Virginia, Charlottesville, VA,[2]Department of Molecular Physiology and Biological Physics, University of Virginia, Charlottesville, VA,[3]OHSU Knight Cancer Institute, Portland, OR,[4]Department of Experimental Pathology, University of Virginia, Charlottesville, VA,[5]Department of Chemical Engineering, University of Virginia, Charlottesville, VA,[6]Department of Cell, Developmental, & Cancer Biology, OHSU Knight Cancer Institute, Lake Oswego, OR

Pancreatic ductal adenocarcinoma (PDAC) is the third deadliest cancer in the United States, with a five-year survival rate of only 13%, and is projected to become the second leading cause of cancer-related mortality by 2030. Despite advances in personalized medicine, therapeutic options for PDAC remain extremely limited, underscoring the need for new, clinically actionable targets. In 2008, *Kelly et al.* utilized a phage-display-based functional proteomics platform that identified plectin, a cytolinker protein normally restricted to the cytoplasm, as aberrantly mislocalized to the plasma membrane of PDAC cells. This cell-surface form of plectin (CSP) has since been detected across multiple malignancies, including PDAC, ovarian carcinoma, and cholangiocarcinoma, while remaining cytoplasmic in normal tissues. Functional studies using an anti-CSP monoclonal antibody (mAb) revealed that CSP supports pro-tumorigenic behaviors such as proliferation, migration, and invasion. A recent early-phase clinical trial (NCT05074472) evaluating an anti-CSP mAb in CSP-positive cancers demonstrated that CSP-targeted therapy is both safe and clinically feasible. To further resolve the molecular and immunologic roles of CSP, we analyzed transcriptomic data from human PDAC bulk and single-cell RNA-sequencing datasets. CSP-high tumors exhibited suppression of pro-inflammatory immune pathways and reduced infiltration of cytotoxic immune populations—hallmarks of the immune-cold PDAC microenvironment. Anti-CSP mAb treatment in vivo promoted infiltration of $CD4^+$ and $CD8^+$ T cells, reduced tumor burden, and generated a durable effector-memory response capable of preventing tumor re-challenge. Collectively, these findings provide the first direct evidence that CSP functions as an immune suppressor in PDAC. Moreover, therapeutic blockade of CSP can restore anti-tumor immunity in this notoriously immunoresistant cancer, offering a promising avenue for personalized treatment strategies for patients with historically few effective options.

#6583 Genetic characterization of KLRC2 deletion in racially diverse prostate cancer patients.

Laila Scroggins, Paula O. Cooper, Stefan DiFazio, Kun-Lin Ho, Sally Elsamanoudi, Jiji Jiang, Shyh-Han Tan, Ayesha A. Shafi, Cara C. Schafer

Surgery, Center for Prostate Disease Research, Bethesda, MD

Natural Killer (NK) cells are key mediators of anti-tumor immunity through direct tumor cell lysis. Emerging evidence suggests significant immune microenvironment differences in prostate tumors between African American (AA) and Caucasian American (CA) men; however, the contribution of NK cell-associated genes to these disparities remains incompletely understood. The NK cell receptor gene *KLRC2* is of particular interest because prior research within our patient cohort demonstrated significantly lower *KLRC2* expression in AA prostate tumors compared to CA tumors. Given that germline *KLRC2* deletion polymorphisms differ across global populations, including those with East and West African ancestry, investigating its deletion status may provide insight into downstream expression differences and associated immune variation. This study aims to gain a deeper understanding of immunobiological differences between AA and CA men with prostate cancer (PCa) by evaluating an NK cell-relevant gene, *KLRC2*, in racially diverse genomic datasets. We hypothesized that germline deletion may contribute to its variability in downstream expression in tumor tissues and ultimately contribute to observed racial disparities in PCa. Understanding germline deletion variations may provide insight into mechanisms driving tumor immune microenvironment differences and strategies to reduce these disparities in PCa outcomes. We analyzed germline, whole genome sequencing data from a large Center for Prostate Disease Research (CPDR) cohort including African American (AA, n=259) and Caucasian American (CA, n=272) men. Bioinformatics workflows were applied to accurately infer *KLRC2* deletion status, including copy-number calling and quality control filtering. We identified a significant difference in the heterozygous deletion status of *KLRC2* between AA and CA men in this robust CPDR cohort. These findings suggest population-level variation in *KLRC2* copy number that may account for reduced KLRC2 expression previously observed in AA prostate tumors. Germline *KLRC2* deletions may influence NK cell-mediated activity within the prostate tumor microenvironment, particularly among African America men. Our findings provide foundational evidence that *KLRC2* status may play a role in racial immune disparities. These findings place *KLRC2* as a promising biomarker and potential candidate for NK cell-based immunotherapeutic strategies.

#6584 Spatial mapping and significance of IL12 signaling in non-small cell lung cancer.

Juan Guiza[1], Lucy Zheng[1], Barani Kumar Rajendran[1], Luciene Borges[2], Sandra Martinez-Morilla[2], Jillian M. Prendergast[2], Reniqua House[2], Kurt A. Schalper[1]

[1]Yale University, New Haven, CT,[2]Boehringer Ingelheim, Ridgefield, CT

Background: Immunostimulatory therapies targeting T-cell co-inhibitory receptors have transformed the management of patients with non-small cell lung cancer (NSCLC) and revealed the potential of harnessing adaptive immunity to treat aggressive malignancy. However, only ~20-30% of patients with advanced NSCLC show clinical benefit to such therapies, highlighting the need for additional developments. Activation of IL-12 signaling in the tumor microenvironment (TME) induces prominent immunostimulatory responses and anti-tumor effect in pre-clinical models and early clinical trials. Understanding the expression, biological role and clinical significance of the IL-12 pathway in human NSCLC could be used to support optimal therapeutic developments.
Strategy: We established multiplexed quantitative immunofluorescence (mQIF) panels to measure and spatially map the IL-12 pathway (DAPI/CK/IL12Rβ1/pSTAT4/CD8), major tumor associated macrophage subpopulations (TAMs; DAPI/CK/CD14/CD68/CD206), dendritic cells (DCs; DAPI/CK/CD11c/XCR1/HLADR) and tumor-infiltrating lymphocytes (TILs; DAPI/CK/CD8/CD4/CD20) in consecutive sections from >600 primary NSCLCs from 4 independent cohorts represented in tissue microarrays. Western blot analysis and flow cytometry from cultured cell preparations of PC-9 human lung adenocarcinoma cell line stimulated for 48 hours with human recombinant IL-12 or IL-23 were used to assess functional responses and support analytical assay validations.
Results: Membranous IL12Rβ1 expression was seen in >95% of primary NSCLCs (mean 1519 ± 83.22 cell/mm^2), with continuous distribution across cases, predominant location in the (intratumoral) stromal compartment and association with pSTAT4 expression and adenocarcinoma histology. No consistent association was seen with other clinicopathologic variables, major oncogenic driver mutations and 5-year overall survival. Elevated abundance of IL12Rβ1/pSTAT4 expressing cells was consistently associated with higher density of M2/3-like polarized TAMs, DCs and CD4+, CD8+ and CD20+ TILs. Notably, 13.2-29.2% of NSCLCs across the cohorts showed IL12Rβ1 expression in cancer cells associated with increased pSTAT4 and reduced expression of pancytokeratin. Treatment of IL12Rβ1+ lung adenocarcinoma cells with human recombinant IL-12 or IL-23 reduced the levels of the epithelial marker EpCAM and increased Ki-67. Supporting enhanced proliferation.
Conclusions: IL-12 pathway expression and activation occurs in most primary NSCLCs with variable levels and is associated with adenocarcinoma histology and a favorable immune TME composition. IL12Rβ1 is expressed in cancer cells from ~23% of tumors and associated with enhanced oncogenic properties, supporting a dual role in immune evasion and malignant progression. These results can support optimal development of IL-12 directed therapies and patient selection strategies.

#6585 DUOX2 is finely tuned by synergism between cytokines IL-6, IL-22, IL-17A, and TNFα in colon cancer.

Becky A. Diebold[1], Agnes Juhasz[1], Mariam M. Konate[2], Jiamo Lu[1], Guojian Jiang[1], Jennifer L. Meitzler[1], Yongzhong Wu[1], Smitha Antony[2], David J. Mallick[2], Krishnendu K. Roy[2], James H. Doroshow[2]

[1]NCI Developmental Therapeutics Branch, Bethesda, MD,[2]NCI Division of Cancer Treatment and Diagnosis, Bethesda, MD

Gastrointestinal inflammation is associated with an increased risk for colorectal cancer (CRC) and is associated with elevated expression of NADPH oxidase (NOX) isoforms, NOX1 and DUOX2, which catalyze the synthesis of superoxide anion radical ($O_2^{\cdot-}$) and hydrogen peroxide (H_2O_2), respectively. To explore the mechanisms that regulate DUOX2, we investigated the effects of a combination of IL-6 and IL-17A on DUOX2 expression in CRC patient-derived cells (PDC) (T-280R, F725, F1126) vs. normal colon cell lines (CCD-112, CCD-841, CCD-18). DUOX2 mRNA levels were generally higher across CRC PDCs relative to the normal colon cell lines. Treatment of PDCs with IL-6 plus IL-17A for 4-6 days resulted in significant upregulation of DUOX2 mRNA and protein. This agrees with data demonstrating elevated DUOX2 levels in CRC tumors relative to corresponding non-malignant tissues. Treatment of HT-29 and Ls513 colon cancer cell lines with IL-6 plus IL-17A for 8-15 days yielded greater-than-additive increases in DUOX2 mRNA, protein, and DUOX2-dependent H_2O_2 production as measured by Amplex Red assays. RNA-Seq analysis of cytokine-treated HT-29 cells indicated that STAT3 and NFkB signaling pathways mediated the IL-6/IL-17A-induced DUOX2 expression. We also investigated the regulation of DUOX2 using a triple-cytokine cocktail of IL-6, IL-17A, and TNFα. The inclusion of TNFα increased the expression of DUOX2 50-fold more than treatment with IL-6 plus IL-17A in HT29 cells, and even more in LS513 cells. There were also substantial increases in DUOX2 activity. In addition, the triple-cytokine treatment shortened the time course of mRNA and protein expression from several days to 24-48 h. When IL-22 was substituted for IL-6 in the triple-cytokine treatment, the fold-increase was even greater. The STAT3 pathway was activated by IL-6 or IL-22, and the NFkB pathway was activated by IL-17A and TNFα in these cell lines. Silencing of STAT3 or RELA by siRNA nearly abolished DUOX2 expression. The triple-cytokine treatments could also induce cell death within 48-72 h, as well as DNA damage as evidenced by phosphorylation of γ-H2AX. In summary, DUOX2 expression and DUOX2-dependent H_2O_2 production in HT-29 and LS513 cells and PDCs could be finely tuned by synergism amongst several pro-inflammatory cytokines known to be overexpressed in CRC.

#6586 CCL3+ tumor cells orchestrate immune equilibrium and stemness maintenance in ESCC via IDE+ M2 macrophages and CCR3+ CAFs.

Beilei Liu[1], Licheng Tan[2], Jiayi Huang[2], Bowen Yao[2], Shuang Zhang[3], Mengsu Yang[4], Xin-Yuan Guan[5]

[1]City University of Hong Kong, Hong Kong, China,[2]the university of hong kong, the department of clinical oncology, China,[3]University of Hong Kong, Shenzhen Hospital, Shenzhen Shi, China,[4]city university of hong kong, BMS, China,[5]The University of Hong Kong, Hong Kong

Immune regulation plays a crucial role in tumor occurrence and development, yet the underlying mechanisms remain largely unclear. By constructing a mouse model to track tumor immune status and utilizing single-cell sequencing technology to dissect the interactions between tumor cells and the tumor microenvironment at different stages, we found that ESCC tumor progression undergoes four key phases: ① immune recognition phase (enhanced CXCL10/H2-K1 antigen presentation signaling); ② immune equilibrium phase (enrichment of PD-1 T cells/CD44 dormant tumor cells); ③ immune escape phase (proliferation of PD-L1+ EMT tumor cells); ④ immune suppression phase (dominated by M2 TAMs/Tregs). Cell communication analysis revealed that intercellular interactions in the tumor primarily occur among tumor cells, macrophages, fibroblasts, and T cells, with tumor cells serving as the core regulatory factor. Further GO analysis of tumor cell subtypes showed enrichment in keratin-reinforced type (Cnfn+), enhanced autophagy type (Plk5+), immunosuppressive type (Ccl3+), and metastasis-enhanced type (Krt8+). Among them, Ccl3+ tumor cells are highly enriched in the immune equilibrium phase and interact with Ide M2 macrophages and Ccr3+ CAFs. In vitro co-culture studies confirmed that tumor cells overexpressing Ccl3 can regulate macrophage polarization toward M2 and promote T cell exhaustion; however, these functions no longer change after knocking down the Ide gene in macrophages. On the other hand, when tumor cells overexpressing Ccl3 are co-cultured with Ccr3-knockout CAFs and control CAFs, the control group significantly enhances the stemness of Ccl3+ tumor cells. These studies confirm that Ccl3+ tumor cells remodel the tumor microenvironment through Ide M2 macrophages and Ccr3+ fibroblasts, thereby regulating stemness and surviving in the immune equilibrium phase. In vivo, neutralizing antibodies targeting Ccl3 effectively inhibit subcutaneous tumor formation and enhance immune effects. This study reveals the key regulatory role of Ccl3 in the immune evolution of ESCC tumors, providing an important molecular basis and potential clinical strategies for overcoming immunotherapy resistance and developing novel targeted therapies.

#6587 Characterizing the autoreactome in thymoma-associated myasthenia gravis.

Rohan Maniar[1], Taylor Bauman[2], Patricia Sikorski[2], Karli Gilbert[3], Patrick J. Loehrer[1], Henry Kaminski[2], Linda Kusner[2]

[1]Indiana University Simon Comprehensive Cancer Center, Indianapolis, IN,[2]George Washington University, Washington DC, DC,[3]George Washington Universtiy, Washington DC, DC

Thymic epithelial tumors (TETs), including thymomas (TMMs), are rare anterior mediastinal malignancies arising from the thymus, an organ essential for early-life T-cell maturation. Paraneoplastic autoimmune disorders (ADs) frequently accompany TMMs, likely due to the tumor's retained, but dysregulated capacity for T-cell processing, leading to defective negative selection and emergence of autoreactive T cells. Myasthenia gravis (MG) occurs in approximately 30-50% of patients with TMM, and nearly all individuals with TMM-associated MG (TAMG) harbor acetylcholine receptor (AChR) antibodies, often accompanied by reactivity against additional skeletal muscle proteins such as titin and ryanodine receptors. Although TAMG is characterized by a complex network of autoreactive immune elements, the breadth and functional relevance of associated autoantibodies remain poorly understood. We hypothesized that TAMG patients exhibit greater diversity of circulating autoantibodies compared with non-autoimmune controls.

Using biospecimens from the Indiana University Simon Comprehensive Cancer Center and the George Washington University Myasthenia Gravis Research Laboratory, we performed autoreactome profiling of sera from TAMG patients and age-matched healthy controls. Samples were interrogated using Molecular Indexing of Proteins by Self-Assembly (MIPSA; Infinity Bio), a high-throughput DNA-barcoded antigen display platform. The screening encompassed >16,000 full-length proteins and ~400,000 peptide sequences.

Autoreactome analysis was completed for 40 TAMG patients and 14 controls. The TAMG cohort had a mean age of 58.7 years; 22 (55%) were female. Twenty-six (65%) patients were AChR-antibody positive, none had MuSK antibodies, one (2.5%) was seronegative, and 13 (32.5%) had unknown serologic status. WHO TET subtypes included A (2.5%), AB (15%), B1 (12.5%), B2 (40%), B3 (20%), metaplastic (2.5%), and unknown (7.5%). Overall, 4,724 proteins and 6,553 peptides were identified as autoantibody targets, with 2,688 proteins and 4,890 peptides uniquely enriched in TAMG. Although TAMG patients demonstrated a higher number of unique autoantibodies than controls, this difference did not reach statistical significance. Notably, interferon-alpha (IFN-α) autoreactivity was observed in 23 (57.5%) TAMG subjects, including 14 with corresponding IFN-α peptide reactivity. Among 20 patients with IFN-α antibodies, we identified novel reactivity against P2X4 receptor and TRIM46, proteins implicated in immune regulation and neuromuscular signaling. These findings suggest a broader and previously unrecognized autoantibody landscape in TAMG. Ongoing studies will evaluate the specificity of these signatures, incorporate TMM patients without MG, and correlate autoreactive patterns with MG-related clinical features.

#6588 Exploring biomarker profiles in canine oncology using multiplex immunoassays.

Joseph B. Hwang, Tina Raeber, Brooke Gilliam, Anthony Saporita

R&D, MilliporeSigma, St. Louis, MO

Canine oncology has garnered significant attention due to the unique role of dogs as companion animals that often develop naturally occurring cancers, mirroring human disease processes. Common types of cancer in dogs include lymphoma, osteosarcoma, mast cell tumors, and hemangiosarcoma, with each presenting distinct clinical challenges. This predisposition to cancer highlights the importance of studying canine oncology not only for the purposes of veterinary medicine but also for advancing human cancer therapies. Dogs present an invaluable opportunity as test subjects for new therapeutic strategies, providing insights into tumor biology and treatment responses that may be applicable to human oncology. We have previously developed a multiplex immunoassay for the measurement of cytokines, chemokines, and growth factors in canine serum and plasma. These immune proteins play a crucial role in the pathophysiology of canine cancers, influencing tumor growth, metastasis, and the host immune response. Additional protein biomarkers, including immuno-oncology targets such as PD-1, PD-L1, and CTLA4 can potentially extend our understanding of tumor progression and the immune response in canine patients. Here we detail the development of a novel multiplex immunoassay which we then use to measure proteins in cell culture supernatant and tissue lysate, as well as serum and plasma samples from healthy and diseased dogs. Multiplex immunoassays offer a powerful platform for the simultaneous measurement of multiple canine cancer biomarkers in plasma and serum, enabling more comprehensive monitoring of disease progression and treatment efficacy. By utilizing this technology, researchers can evaluate the complex interplay of cytokines and other biomarkers, providing a deeper understanding of canine oncology and reinforcing the significance of dogs in comparative oncology research.

#6589 Nrf2 as a therapeutic target to improve T cell function in muscle invasive bladder cancer (MIBC).

Aprajita Tripathi, Nadine Santana-Magal, Jared Rack, Debolina Dasgupta, Benjamin L. Woolbright, Kalyani Pyaram

Cancer Biology, University of Kansas Medical Center, Kansas City, KS

Introduction: Bladder cancer is the seventh most common malignancy in the United States, with an estimated 16,840 deaths in 2024. Despite advances in surgical management and chemotherapy, muscle invasive bladder cancer (MIBC) remains associated with poor survival outcomes. Only ~20% of MIBC patients show durable responses to immune checkpoint inhibitors. Thus, there remains a critical unmet need to understand the mechanisms of immune resistance within MIBC tumor microenvironment and to develop therapies that can enhance T cell functions to improve patient outcomes. Nuclear factor erythroid 2-related factor 2 (Nrf2) is a transcription factor, regulated by Kelch-like ECH-associated protein 1 (Keap1), which protects against oxidative stress. However, its role in modulating the immune microenvironment, particularly the T cells in MIBC, remains poorly understood. Recently, it was reported that Nrf2-mediated oxidative stress response pathway is upregulated in tumor-infiltrating T cells compared to circulating T cells in bladder cancer patients. We and others have reported that loss of Nrf2 in T cells elevates IFN-γ and Granzyme B expression, supporting a cytotoxic phenotype, while Nrf2 activation exerts the opposite effect by repressing these key effector molecules. Based on these observations, we *hypothesized* Nrf2 inhibition will suppress MIBC progression by enhancing T cell-mediated anti-tumor immunity.
Methods: We used mice with T cell-specific deletion of Nrf2 (Nrf2-KO) or constitutive activation of Nrf2 by deleting its negative regulator Keap1 (Keap1-KO) to evaluate the T cell-intrinsic role of Nrf2 in MIBC. *In vivo*, we assessed tumor growth of BBN963 cells in a syngeneic bladder cancer model. *In vitro*, we performed tumor-killing assays by coculturing $CD8^+$ T cells, treated with the Nrf2 inhibitor ML385 and with BBN963 cells.
Results: BBN963 tumors implanted in Nrf2-KO mice (with Nrf2-depleted T cells) exhibited remarkably reduced tumor growth compared to wildtype mice while Keap1-KO mice (elevated Nrf2 in T cells) displayed significantly larger tumors. Pharmacological inhibition of Nrf2 using ML385 improved the tumor-killing ability of $CD8^+$ T cells against BBN963 bladder cancer cells *in vitro*.
Conclusions: Together, these findings identify a previously unrecognized T cell intrinsic role of Nrf2 in suppressing antitumor immunity and promoting bladder cancer progression. Our work highlights Nrf2 as an immune checkpoint for T cells and indicates its targeting as a promising therapeutic strategy, especially in synergy with current immunotherapies, to improve MIBC patient outcomes.

#6590 Investigation of carcinogenic effects of polystyrene microplastic on human bladder cancer cells.

Sahab Ram

Cleveland Clinic Lerner Research Institute, Cleveland, OH

Plastic pollution has become a global environmental problem. Humans are increasingly exposed to microplastics (MPs) and nano-plastics (NPs) through ingestion, inhalation, and skin contact. These particles may affect organs such as the brain, liver, kidneys, and bladder by triggering inflammation, altering immune responses, and disrupting the urothelial barrier-an established risk factor for bladder cancer and interstitial cystitis. We investigated the uptake of micro (0.5 µm) and nano-plastic (0.03 µm) polystyrene microplastics by human bladder cancer cell lines (SW-78 and UMUC-3). Both cell lines showed altered proliferation compared with controls. SW-78 cells responded significantly to 8,000, 16,000, and 32,000 p/mL, while 64,000 p/mL was toxic to cell proliferation. In UMUC-3 cells, proliferation increased at all concentrations in a time-dependent manner. Moreover, cell migration in UMUC-3 cells was not significantly influenced by 0.03 µm PS particles compared with controls, whereas 0.5 µm PS particles affected migration. In SW-78 cells, migration was significantly induced by lower concentrations of 0.03 µm particle but was significantly reduced at 64,000 p/mL. We also confirmed that higher doses of plastic particles caused significant DNA damage and ROS production in a concentration-dependent manner. PS particles showed strong attachment of MPs to the cell surface in live-cell imaging, while confocal imaging confirmed uptake, cytoplasmic accumulation, and nuclear translocation of the PS particles. Our findings suggest that PS microplastics influence bladder cancer cell proliferation and migration in a dose- and size-dependent manner, consistent with mechanisms involved in cancer progression. The presence of microplastics in the cytoplasm is likely to disrupt cellular metabolic processes, warranting further investigation. Given the rise in plastic pollution, microplastics may represent emerging risk factors for bladder cancer, underscoring the need for thorough toxicological and epidemiological studies.

#6591 Cross platform same slide multi-omics reveals Treg heterogeneity and links to spatial niche variability in pre-cancerous colonic inflammation.

Daniel Jimenez-Sanchez[1], Matthew H. Ingalls[1], Sanghamithra korukonda[2], Brian J. Lane[1], Isabella Marie Peshek[3], Patrick Danaher[2], Prajan Divakar[2], Oliver Braubach[1]

[1]Bruker Spatial Biology, St. Louis, MO,[2]Bruker Spatial Biology, Seattle, WA,[3]Division of Gastroenterology, Northwestern University, Chicago, IL

Introduction: FOXP3+ regulatory T cells (Tregs) maintain immune tolerance, and their dysfunction contributes to autoimmunity, chronic inflammation, and cancer. Treg heterogeneity is well documented in ulcerative colitis, where dysregulated Tregs can promote colon cancer. Treg heterogeneity is often defined by transcriptional profiles, which can include technical artifacts due to inherent biological differences between transcript and protein levels. Using cross-platform same-slide multi-omics with CellScape™ proteomics and CosMx™ transcriptomics, we aimed to assess whether quantitative FOXP3 protein improves definition of Treg transcriptional heterogeneity within the colonic microenvironment.
Methods: Eight FFPE intestinal biopsies from a pre-cancerous condition (ulcerative colitis) were profiled with CellScape™ (34-plex VistaPlex), followed by CosMx™ Human Universal Cell Characterization Panel (1K-plex) on the same slide. Whole-slide multimodal alignment used shared morphology markers and WsiReg to generate affine registrations. Segmentation masks were harmonized for pixel-level correspondence, enabling direct integration of protein and RNA per cell. CD4+ T cells were classified into $FOXP3_{neg}$, $FOXP3_{low}$, $FOXP3_{high}$ groups via quantitative automatic cell typing. Spatial neighborhoods (k=15) yielded 25 FOXP3-defined niches, and both protein and RNA features were included in neighborhood and state enrichment analyses.
Results: Quantitative spatial proteomics revealed reproducible $FOXP3_{low}$ and $FOXP3_{high}$ populations with corresponding transcriptomic variation. Neighborhood analysis showed two recurring contexts: (1) $FOXP3_{low}$ cells in innate- and vascular-associated neighborhoods, and (2) $FOXP3_{high}$ cells in adaptive immune-rich and proliferative niches. Integration with CosMx™ enabled transcriptional characterization of $FOXP3^+$ cells and neighbors.
Conclusion: Immune regulation relies on balanced Treg activity and their response to local microenvironmental changes. In ulcerative colitis rectal tissue, $FOXP3_{low}$ and $FOXP3_{high}$ T cells occupy distinct recurrenting spatial niches, indicating multiple $FOXP3^+$ regulatory states within inflamed tissue. Integrating same-slide CellScape™ proteomics with CosMx™ transcriptomics revealed microenvironment-linked patterns that were not evident from either modality alone. These findings underscore the power of spatial neighborhood analysis to expose context-dependent T-cell states in immune-mediated disease and the value of cross-platform multi-omics.

#6592 *In vitro* neutrophil assays to support immuno-oncology drug development.

Christoph Schifflers, Martijn Vlaming, Sofie Pattyn

IQVIA Laboratories, Gosselies, Belgium

Neutrophils play important roles in cancer progression. The presence of tumor-associated neutrophils can promote tumor growth, invasion, angiogenesis, and the formation of metastasis. On the other hand, neutrophils have also been associated with multiple anti-cancer functions, such as killing of antibody-opsonized cancer cells, trogocytosis, or indirectly through the release of cytotoxic mediators. Thereby, Neutrophils represent a target of interest for the development of novel cancer immunotherapy approaches. Here, we report a variety of *in vitro* assays allowing to evaluate the putative impact of drug candidates on neutrophil functions such as antibody-dependent cell-mediated cytotoxicity (ADCC), Neutrophil Extracellular Traps (NET) formation and the release of Reactive Oxygen Species (ROS) by flow cytometry and live-cell imaging. Furthermore, multiplex cytokine and peroxidase release analysis after activation and stimulation of neutrophils can be evaluated using ELISA or Luminex technology. Co-cultures of freshly isolated human neutrophils and fluorescent-labeled tumor cells can be used to screen the potency of candidate therapeutics to enhance anti-cancer neutrophil functions. Lastly, the toxicity of drug candidates on Neutrophils can be evaluated. Key factors to obtain reliable and reproducible results are the access to fresh blood as well as optimized protocols for purifying and culturing untouched neutrophils. Taken together, functional *in vitro* assay using fresh primary human Neutrophils provide cost-effective tools for the characterization and lead selection of drug candidates targeting Neutrophils.

#6593 B-cell guided inflammatory cascade perpetuates ICI-mediated colitis.

Roza Nurieva, Naimah Turner, Synat Keam, Jocelynn Colunga

UT MD Anderson Cancer Center, Houston, TX

Immune checkpoint inhibitor (ICI) therapy is often accompanied by inflammatory toxicities including ICI-colitis. Therapeutic options are limited because the mechanisms that predict its onset are unclear. We uncover a role for B cells in triggering the intestinal inflammatory cascade following ICIs. An increase in circulating B cells, particularly those with gut-homing markers, antigen-presenting capacity, and proinflammatory cytokine production, are found in both asymptomatic patients and mice which are susceptible to ICI-colitis. Furthermore, lack of B cells at the asymptomatic stage abrogates ICI-colitis by reducing the number of pathogenic intestinal T cells in mice. We find that latent microbial dysbiosis may underlie the B cell dysfunction in the asymptomatic stage that predisposes mice to the development of colitis following ICI therapy. Thus, our study examines the immunologic evolution underlying ICI-colitis and proposes B cell dysregulation as a critical initiating factor in this process and a potential biomarker for toxicity risk.

#6594 Establishing *ex vivo* models for targeting leukemic stem cells to investigate relapse and refractory pediatric leukemias.

Sashi Kandel, Jacqelyn M. Nemechek, Tykeem Manor, John N. Maina, John M. Perry

Children's Mercy Hospital, Kansas City, MO

Despite advancements in therapies for leukemia, relapses and refractory cases remain a significant clinical challenge largely due to persisted dormant leukemic stem cells (LSCs) and evade treatment. LSCs represent a rare cell population, making their isolation, culture, and expansion difficult and limiting our ability to study their functional properties. Developing an *ex vivo* model to culture and expand LSCs would enable detailed analysis of their role in drug resistance and relapses. Traditional 2D cultures fail to replicate the complexity of the bone marrow (BM) microenvironment, and animal models are limited by interspecies differences. To overcome these limitations, we are developing BM organoids derived from iPSCs, which are expected to better mimic the native BM architecture and function.In this study, we are establishing an *ex vivo* system for LSC culture and expansion. In previous studies, we demonstrated that mice with hematopoietic stem cell-specific (HSC-SCL-Cre-ER^T) loss of the tumor suppressor Pten and activation of the oncogene beta-catenin develop leukemia by expansion of normal stem cells with transformation to LSCs. BM cells from HSC-SCL-Cre-ER^T+ $Pten^{fl/fl}$ $dBC^{fl/wt}$ mice were harvested and cultured in media supplemented with mTPO and mSCF and treated with 1 μM 4-OHT during serial passaging to induce recombination. Cultures were analyzed at multiple time points (3, 6, 13, and 18 days) using flow cytometry to quantify hematopoietic stem cells (HSCs: Lin^- $CD3^-$ $cKit^+$ $Sca1^+$), LSCs (Lin^- $CD3^+$ $cKit^+$), and blast cells (Lin^- $CD3^+$ $cKit^-$). Preliminary results indicate that HSCs and blast cells increased by day 18 (62.1% and 0.65%, respectively) compared to day 13 (19.3% and 0.22%), whereas LSC frequency declined (0.14% vs. 0.25%). These findings suggest that LSC enrichment peaks around day 13, making this time point optimal for LSC culture. Ongoing work focuses long-term transformation of pre-leukemic HSCs to LSCs with subsequent expansion and maintenance of LSC phenotype and function. Concurrently, we are developing BM organoids. iPSCs were cultured to form embryoid bodies EBs), after which mesodermal induction and subsequent promotion of hemogenic endothelium Sprouting in hydrogel matrix was stimulated by supplementing different cytokines at different stages of culture. Finally, sprouted EBs were harvested and individually seeded into low-attachment 96-well plates. Mature BM organoids were analyzed using flowcytometry, immunofluorescence and PCR. Following organoid formation, LSCs will be engrafted to enable chemoresistance screening. Together, these approaches aim to establish a robust platform for LSC expansion to support immunocompetent functional assays, including co-culture studies, and develop new treatments targeting therapy-resistant leukemia.

#6595 Memory B cell Responses Ignite Anti-Tumor Immunity by Activating CD8+ T cell Cytotoxicity.

Kendrick Nguyen[1], Monika Quackenbush[1], Georgia Lattanzi[1], Daniel Hollern[1], Sara Basbous[1], Haley Rodriguez[1], Daniela Boassa[1], Jingting Yu[1], Asona Lui[2], April Wehner[2], Aatish Thennavan[3], Peter H. Watson[4]

[1]Salk Institute, La Jolla, CA,[2]UC San Diego, La Jolla, CA,[3]UT MD Anderson Cancer Center, Houston, TX,[4]Chief Physician, BC Cancer Agency Vancouver Island Ctr., Victoria, BC, Canada

Immunotherapies aimed at leveraging T cell responses have revolutionized cancer care with demonstrated effectiveness in a myriad of cancers. Yet, challenges remain in patients with solid tumors such as triple negative breast cancer (TNBC) that fail to generate and sustain a durable anti-tumor T cell mediated immune response. Numerous reports demonstrate opportunities to improve upon these treatments by leveraging B cells. Tumor infiltrating B cells have been shown to predict responses to chemo and immunotherapies across cancers. B cells within the tumor have also been experimentally shown to be intimately involved in controlling anti-tumor immune responses and markers for their interactions with T cells have immense prognostic value. However, experimental demonstration of how B cell responses to tumors are regulated and function remains a key gap in research, which limits leveraging B cells in future immunotherapies. Thus, we sought to understand the role of tumor antigen and activation signals of B cell-driven anti-tumor immunity. Our study has revealed that activating the CD40 pathway of B cells in the presence of neo-antigen can directly incite a robust non-germinal center (GC) memory B cell response that is able to facilitate powerful anti-tumor immune responses in mouse models of TNBC. Leveraging single cell sequencing in combination with microscopy approaches we have found that these memory B cells can participate in an anti-tumor response by promoting CD8+ T cell infiltration, organization, and stimulation of CD8+ T cells to promote tumor cell killing. These findings advance the canonical models of B cell and CD8+ T cell regulation along with function. Furthermore, these results showcases novel routes to leverage B cells to promote anti-tumor immunity.

#6596 Understanding DAP12-independent antitumor activation in KIR-based CAR T cells.

Qian Zhang, Kevin Zhou, Zhongze Sun, Chen Zhang, Marta Chebotar, Michael C. Milone

University of Pennsylvania, Philadelphia, PA

We previously described a chimeric killer immunoglobulin (KIR)-like receptor (cKIR) approach to modifying T cell antigenic specificity that mimics the multichain design of natural KIR immunoreceptors (Wang E et al. Cancer Immunol Res 2014). T cells modified to express a cKIR with the natural ITAM-containing adaptor, DAP12 that associates with activating KIRs, show significantly enhanced anti-tumor activity acrossmultiple solid tumor models when compared to traditional CD3z-based chimeric antigen receptors (CARs). However, unlike TCR, where assembly with ITAM-containing CD3 family members is required for plasma membrane expression, natural and chimeric KIR exhibit membrane expression in the absence of DAP12. We show that cKIR engineeredT cells also produce IFN-g and retain cytotoxic activity in the absence of DAP12, revealing previously unrecognized DAP12-independent signaling pathways. This is associated with phosphorylation of ERK, JNK and STAT3 at early time points (30-60 mins) following cKIR engagement with target antigen. Although the cytoplasmic domain of KIR2DS2 used in cKIR is short and lacks canonical signaling motifs, we hypothesized that this domain plays a functional role in T cells by recruiting alternative adaptors to promote noncanonical signaling in the absence of DAP12. Immunoprecipitation of cKIR in T cells lacking DAP12 identified GRB2 as an associated adaptor protein. CRISPR- mediated GRB2 knockout selectively abolished ERK activation, establishing GRB2 as a crucial link to the Ras/MAPK pathway in cKIR-activated T cells. Structure-functionanalysis of the KIR2DS2 cytoplasmic tail, containing one tyrosine, one threonine, and four serine residues, revealed that progressive truncation of these residues had minimal effect on membrane expression, but increasingly impaired cytotoxicity, cytokine production, proliferation, and downstream signaling with a > 25-fold loss of IFN-g andcytotoxicity observed with the truncation of C-terminal to serine residue 3. Collectively, these results suggest that DAP12-independent signaling by cKIR, mediated through GRB2 and likely other yet-to-be-identified adaptors, contribute to diverse signaling in T cells and may contribute to the enhanced anti-tumor function observed with KIR-based CAR T cells compared with conventional CAR designs.

#6600 Triad-SL: A new synthetic lethality paradigm combining two distinct DNA damage response pathway inhibitors and particle radiotherapy.

Neele Haxel, Ivana Dokic, Mahmoud Moustafa, Carmen Klein, Juergen Debus, Amir Abdollahi

Translational Radiation Oncology, National Center for Tumor Diseases (NCT), Heidelberg University Hospital (UKHD) and German Cancer Research Center (DKFZ), Heidelberg, Germany

Current synthetic lethality (SL) strategies in cancer therapy utilize tumor-specific deficiencies in the DNA damage response (DDR)—such as homologous recombination deficiency (HRD) from BRCA1/2 mutations—to selectively eradicate malignant cells by inhibiting backup repair pathways, most notably using PARP inhibitors. However, these vulnerabilities occur in only a small subset of patients, as many tumors exhibit complex or mosaic mutational profiles that only partially resemble classical BRCAness. To overcome this limitation, we propose that engineered synthetic lethality can be achieved by inducing spatially and temporally controlled DNA damage with high-precision particle radiotherapy (RT), combined with dual targeting of distinct DDR pathways. To this end, we systematically evaluated the effect of RT with a combinatorial matrix of potent small-molecule inhibitors targeting ATM, ATR, DNA-PK, and PARP, establishing the Triad-SL paradigm as a framework for next-generation cancer treatment. Single and dual drug concentrations causing minimal or no toxicity when used alone were established by titration experiments to ensure effective cell killing occurs only in the presence of RT and synergistic dual DDR inhibition. Interestingly, we found that conventional viability assays underestimated DDR-dependent effects, especially when combined with RT. When assessed using clonogenic survival assays, the same Triad-SL combinations exhibited up to 1000-fold greater sensitivity. Within their respective pathway classes, DDR inhibitors demonstrated comparable efficacy and synergized effectively with photon- or carbon ion irradiation, respectively. Of note, combined treatment with PARP- and ATM inhibitors produced strong, cell line-specific cytotoxicity, substantially reducing survival fractions even in the absence of irradiation, indicating combined cytotoxic potential. Among all combinations tested, ATM, DNA-PK, and PARP inhibitors yielded the most promising outcomes, producing strong radiosensitizing effects across multiple DDR inhibitor pairings. By leveraging DDR inhibitors with differing biodistribution, pharmacokinetics, and target selectivity, potent synergistic effects may be achieved at reduced doses—particularly when combined with focused irradiation. In conclusion, the multimodal Triad-SL strategy, integrating selective DDR inhibition with tailored radiation quality, represents a promising approach to enhance therapeutic efficacy and broaden the applicability of synthetic lethality in cancer treatment.

#6601 Activation of STING in response to partial-tumor radiation exposure.

Mickael Mathieu[1], Sadna Budhu[2], Prerna R. Nepali[3], James Russell[4], Simon N. Powell[5], John L. Humm[4], Joseph O. Deasy[4], **Adriana NA Haimovitz-Friedman**[1]

[1]Memorial Sloan Kettering Cancer Center, New york, NY,[2]Immunology, Memorial Sloan Kettering Cancer Center, New York, NY,[3]Memorial Sloan Kettering Cancer Center, Fort Lee, NJ,[45]Memorial Sloan Kettering Cancer Center, New York, NY

Purpose: To determine the mechanisms involved in partial volume radiation therapy (RT)-induced tumor response.
Methods and Materials: We investigated 67NR murine orthotopic breast tumors in Balb/c mice and Lewis lung carcinoma (LLC cells; WT, Crispr/Cas9 Sting KO and Atm KO) injected in the flank of C57Bl/6, cGAS or STING KO mice. RT was delivered to 50% or 100% of the tumor volume using a 2X2 cm collimator on a microirradiator allowing precise irradiation. Tumors and blood were collected at different time points post-RT and assessed for cytokine measurements.
Results: There is a significant activation of the cGAS/STING pathway in the hemi-irradiated tumors as compared to control and to 100% exposed 67NR tumors. In the LLC model, we determined that an ATM-mediated non-canonical activation of STING is involved. We demonstrated that the partial exposure RT-mediated immune response is dependent on ATM activation in the tumor cells and on the STING activation in the host, while cGAS is dispensable. Our results also indicate that partial volume RT stimulates a different cytokine expression as compared to 100% tumor volume exposure.
Conclusion: Partial volume RT induces an anti-tumor response by activating STING which stimulates a specific cytokine signature as part of the immune response. However, the mechanism of this STING activation, *via* the canonical cGAS/STING pathway or a non-canonical ATM-driven pathway, depends on the tumor type. Identifying the upstream pathways responsible for STING activation in the partial RT-mediated immune response in different tumor types would improve this therapy and its potential combination with immune checkpoint blockade and other anti-tumor therapies.

#6602 Venetoclax enhances radiation-induced anticancer immunity in breast cancer.

Emma Guilbaud, Ai Sato, Lorenzo Galluzzi

Fox Chase Cancer Center, Philadelphia, PA

Estrogen receptor-positive (ER+) breast cancer (BC) lesions are poorly infiltrated by lymphocytes (immunologically "cold") and are therefore insensitive to immune checkpoint inhibitors (ICIs). Radiation therapy (RT) represents a clinically promising partner for ICIs, as RT converts immunologically "cold" ER+ BC into "hot" lesions, reflecting the ability of RT to elicit BAX/BAK-initiated mitochondrial permeabilization (MOMP) in cancer cells, culminating with cytosolic mtDNA accumulation, CGAS/STING signaling and type I IFN secretion, which supports anticancer immunity. We hypothesized type I IFN signaling could be further enhanced by exacerbating mitochondrial damages with Venetoclax, the FDA-approved BCL2 inhibitor. *In vitro*, Venetoclax treatment in mouse models of ER+ BC amplified RT-induced mtDNA release, increased RT-driven type I IFN production, and upregulated interferon-stimulated gene (ISG) expression. Type I IFN signaling was abrogated by the pharmacologic inhibition of CGAS or STING, as well as in STING-deficient cells or in mtDNA-depleted (Rho0) cells, confirming that Venetoclax enhances RT-driven type I IFN production via the CGAS/STING pathway. *In vivo*, Venetoclax significantly improved RT-mediated tumor control, an effect that was further enhanced by CTLA4 blockage. However, RT also triggered the removal of damaged mitochondria in a dose- and time-dependent manner. This process was suppressed by genetic deletion of the essential autophagy genes *Atg5* or *Atg7*. Moreover, RT-induced mitophagy depended on BAX/BAK-mediated MOMP, as Venetoclax further enhanced RT-induced mitophagy, whereas BAX/BAK-deficient cells failed to activate mitophagy in response to RT and were unresponsive to Venetoclax. By investigating the mechanistic link between mitophagy (which degrades permeabilized, mtDNA-releasing mitochondria) and mtDNA-dependent type I IFN production, we observed that 1) blocking mitophagy with *Atg5*-/- cells increased cytosolic mtDNA accumulation and type I IFN production whereas 2) activating mitophagy with Urolithin A reduced cytosolic mtDNA accumulation and type I IFN production. These findings strongly suggest that mitophagy modulates type I IFN signaling. In summary, RT-driven BAX/BAK-dependent MOMP mediates both mtDNA release, which activates type I IFN signaling and enhances anticancer immunity, but also mitophagy, which limits type I IFN signaling and may therefore constrain anticancer immunity. To maximize MOMP-dependent type I IFN production, it is crucial to uncouple these mechanisms. Collectively, our findings identify both BCL2 and mitophagy as immune checkpoints that suppress RT-induced immune responses. **These pathways represent actionable targets for novel therapeutic strategies to overcome immunotherapy resistance not only in ER+ breast cancer, but also in other "cold" tumor types.**

#6603 MCT4-driven lactate shuttle in the irradiated tumor microenvironment upregulates neutrophils PD-L1 expression for immunosuppression in lung cancer.

Wenqian Yuan[1], Yijun Wang[1], Lingyi Kong[1], Minqi Zhou[1], Yuhan Sheng[2], Yajie Sun[1], Kunyu Yang[1]

[1]Cancer Center, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China,[2]OHSU Knight Cancer Institute, Portland, OR

Purposes: Although tumor metabolic heterogeneity is known to shape tumor microenvironments (TME), the metabolic consequences of radiotherapy remain poorly defined. Thus, this study aims to elucidate the radiation-induced metabolic alterations in the TME, delineate their functional roles in radioresistance, and identify targetable metabolic vulnerabilities.
Methods: Metabolic perturbations were investigated through metabolomic profiling of lung cancer patients serum 5 days after radiotherapy and tumor interstitial fluid collected at 48h post-irradiation. Glycolytic flux was assessed via $^{13}C_6$-glucose-based metabolic flux analysis. Lactate dynamics were assessed through extracellular acidocation rate (ECAR) measurements. Spatial scRNA sequencing was conducted on tumors from Lewis models. All the histone modification antibodies available were used to identify the lactylation site of neutrophils. Cut&Tag assay was performed to elucidate the downstream genes.
Results: Metabolomic profiling of patients serums and irradiated tumors revealed a significantly elevation of lactate. Subsequent functional analyses demonstrated that radiation induces metabolic reprogramming in NSCLC cells, characterized by amplified glycolytic flux, elevated ECAR, and enhanced lactate secretion. Proteomic screening identified MCT4 as the most prominently upregulated glycolytic regulators post-irradiation. MCT4 blockade attenuated radiation-induced glycolytic potentiation and suppressed lactate efflux. Further investigation into the regulatory mechanism revealed that radiation triggers RAB3B expression, which competes with HSC70 for binding to MCT4, inhibiting the HSC70-mediated autophagy of MCT4. In vivo, Gene depletion of Mct4 reversed radiation-induced lactate-enriched TME. Spatial scRNA sequencing further revealed that irradiation induced an immunosuppressive neutrophil phenotype, which was effectively reversed by MCT4 inhibition. Mechanistically, tumor-derived lactate was internalized by neutrophils via MCT1, driving histone H4 lysine 5 lactylation, which subsequently promoted PD-L1 transcription and impaired $CD8^+$ T cells functions. Blocking lactate efflux from tumor reversed histone lactylation and PD-L1 expression in neutrophils, thereby potentiating radiotherapy efficacy.
Conclusion: Our study demonstrates that radiation reprograms tumor metabolism by enhancing glycolytic capacity and lactate efflux. This lactate surge drives PD-L1 expression of neutrophils and suppress the activity of $CD8^+$ T cells. Our findings propose that targeting MCT4 exerts dual therapeutic effects: reversing radiation-induced metabolic adaptation and disrupting immunosuppressive neutrophil remodeling, thereby providing a strategy to amplify radiotherapy efficacy.

#6604 Aurora kinase B inhibition enhances radiation response and activates type 1 interferon signaling in triple-negative breast cancer.

Meirola Amgad Endraws[1], Kassidy M. Jungles[2], Caroline Bishop[2], Cydnee Wilson[2], Priyanka S. Rana[1], Benjamin Hauk[3], Camila Diedrich[1], Vesna Markovic[1], Ethan Hochmuth[4], Breanna Nicole McBean[2], Meilan Liu[2], Lori Pierce[2], James M. Rae[5], Corey W. Speers[1]

[1]Radiation Oncology, University of Alabama at Birmingham, Birmingham, AL,[2]University of Michigan, Ann Arbor, MI,[3]Case Western Reserve University School of Medicine, Cleveland, OH,[4]Radiation Oncology, Case Western Reserve University, Cleveland, OH,[5]University of Michigan Medical School, Ann Arbor, MI

Purpose: Triple-negative breast cancer (TNBC) is an aggressive subtype with limited targeted therapies and poor response to radiotherapy[1]. Aurora kinase B (AURKB), a key regulator of chromosomal segregation during mitosis, is overexpressed in TNBC and correlates with poor recurrence-free survival following radiation[2]. Because radiation-induced DNA damage can promote innate immune activation through type I interferon (T1IFN) signaling[3], we hypothesized that AURKB inhibition would enhance radiosensitivity while amplifying T1IFN-mediated antitumor immune responses in TNBC.

Methods: AURKB expression was analyzed across breast cancer datasets and correlated with clinical outcomes. Pharmacologic inhibition of AURKB using ATP-competitive (barasertib-HQPA) and noncompetitive (SP-96) compounds was evaluated in multiple human and murine TNBC cell lines. Clonogenic survival assays quantified radiosensitization, and DNA damage was assessed by γH2AX and micronuclei formation. Type I interferon (T1IFN) activation was measured using IFN-β reporter assays, quantitative PCR for CXCL10 and PD-L1, and flow cytometry for surface MHC-I and PD-L1 expression. In vivo efficacy of AURKB inhibition combined with radiotherapy was evaluated in syngeneic TNBC models.

Results: AURKB expression was significantly elevated in TNBC and associated with poor outcomes in radiotherapy-treated patients. AURKB inhibition enhanced radiosensitivity in TNBC cell lines in vitro and reduced tumor growth in vivo. Combined AURKB inhibition and radiation increased micronuclei formation, consistent with genomic instability and cytosolic DNA accumulation. This combination also induced a robust T1IFN response, evidenced by increased reporter activity, upregulation of CXCL10 and PD-L1 transcripts, and elevated MHC-I and PD-L1 expression. These effects were observed following both single-dose and fractionated radiation regimens.

Conclusions: AURKB inhibition potentiates the efficacy of radiotherapy in TNBC by augmenting DNA damage and activating antitumoral T1IFN signaling. These findings identify AURKB as a dual radiosensitizing and immune-stimulatory target in TNBC, providing a strong rationale for clinical evaluation of AURKB inhibitors in combination with radiotherapy.

#6605 USP3 stabilizes STING to enhance radiosensitivity and antitumor immunity of NSCLC.

Zeyuan Cheng, Zhengkun Cai, Yihan Xu, jiazhuo yan, Zhiqiang Wu, Zhiyong Yuan

Tianjin Medical University Cancer Institute & Hospital, National Clinical Research Center for Cancer, Tianjin, China

Purpose: Although radiotherapy (RT) is a predominant treatment for non-small cell lung cancer (NSCLC), radioresistance remains a major challenge and is strongly linked to dysregulated tumor immune microenvironments (TIME). Immunoradiotherapy has shown improved therapeutic activity by promoting antitumor immune responses and modifying the TIME. Recent studies positions STING activation as a potent catalyst of this immune reprogramming. Therefore, identifying upstream regulators capable of enhancing STING-mediated immune activation is critical for developing strategies to overcome radioresistance in NSCLC.
Methods: Ubiquitin-specific protease3 (USP3) expression patterns, immune infiltration profiles, and pathway enrichment analyses were performed using public datasets and institutional sequencing data. Prognostic value was evaluated via TCGA datasets and validated in a clinical cohort of 105 NSCLC patients (Tianjin Medical University Cancer Institute & Hospital, 2013-2015). Subsequently, we investigated the interaction between USP3 and STING and the effects of USP3 on RT-induced STING/type I interferon (IFN-Is) signaling through co-immunoprecipitation and immunofluorescence. Finally, we evaluated the effects of USP3 on RT-induced T cell infiltration in tumor and sensitivity to RT and radioimmunotherapy.
Results: USP3 expression was significantly downregulated in NSCLC specimens compared to normal tissues. High USP3 expression correlated with prolonged overall survival in public datasets and our independent clinical cohort. Functionally, USP3 overexpression enhanced the radiosensitivity of NSCLC cells and induced a pro-inflammatory phenotype. Mechanistically, USP3 physically interacted with STING, removed K48-linked polyubiquitin chains, and thereby prevented proteasomal degradation of STING. This stabilization amplified cGAS-STING signaling and downstream IFN-Is production. In vivo, USP3 overexpression remodeled the post-irradiation tumor immune microenvironment, as evidenced by increased infiltration of effector $CD8^+$ T cells and enhanced systemic antitumor immunity.
Conclusion: USP3 deubiquitinates STING and blocks its proteasomal degradation, thereby stabilizing the STING protein, potentiating the cGAS-STING axis and type I interferon signaling. These results highlight USP3 as a promising prognostic biomarker and a potential therapeutic target for overcoming radioresistance and improving radiotherapy-based treatment strategies.

#6606 Overcoming reduced efficacy of fractionated radiotherapy in obese mice.

[1]Radiation Oncology, UC Davis Comprehensive Cancer Center, Sacramento, CA,[2]Radiation Oncology, UC Davis School of Medicine, Sacramento, CA,[3]Surgery, UC Davis Comprehensive Cancer Center, Sacramento, CA,[4]Dermatology, UC Davis School of Medicine, Sacramento, CA

Purpose/Objective(s): Obesity is a medical condition of excess adiposity characterized by chronic inflammation and connected to comorbidities including metabolic disorders and cancer. Identifying how to best treat the growing number of obese cancer patients is paramount particularly as clinical data has implicated poorer outcomes following radiotherapy (RT) in obese patients. We observed using preclinical diet induced obesity (DIO) models that obesity promotes resistance to local fractionated RT; the aims of the current study were to identify the drivers mediating this resistance and if through altered dosing strategies it may be overcome.

Materials/Methods: In vivo obesity models consisted of C57BL/6 diet induced obese (DIO) alongside age matched controls. A syngeneic tumor model(3LL) was utilized for these studies in combination with local RT administered to anesthetized mice (per IACUC guidelines). RT was performed on a 5cm water block with tumors centered in a 2 cm electron light field cutout using a 5mm bolus and treated using 6MeV electron at the desired dose (3x 4Gy fractions or 1x12Gy). In collection studies tumor tissues were harvested either immediately after irradiation or at least a week following treatment regimen for additional analysis including immunofluorescence, RNA, and protein analysis.

Results: We observed that DIO mice demonstrated resistance to a fractionated local RT regimen (4Gy x 3) with no significant change in tumor burden while lean mice had significantly decreased compared to untreated controls. To evaluate if obesity associated resistance could be overcome in DIO mice, we administered a single ablative dose of 12Gy. We observed that a single dose of 12Gy was effective in both DIO and lean mice with a comparable significant decrease in tumor burden. Notably, DIO mice only responded to ablative RT doses while lean mice responded to both fractionated and ablative RT doses. Analysis of yH2AX immunofluorescence staining of treated and untreated tumors demonstrated that DIO mice had increased DNA damage and repair at baseline and following treatment. RNA sequencing of tumors confirmed increases in oxidative stress and DNA repair mechanisms

Conclusion: We identified that DIO mice are resistant to fractionated RT demonstrating reduced treatment efficacy when compared to lean counterparts. However, using a single ablative dose DIO mice demonstrated significant reductions in tumor burden. The observation that tumors from DIO mice had greater baseline levels of yH2AX illustrates increased DNA repair mechanisms, likely secondary to increased baseline oxidative stress in the obese setting, which we hypothesize is diminishing lower dose fractionated RT efficacy. These data have direct implications for patient care as understanding how obesity impacts RT response may assist in developing strategies to overcome RT resistance and improve outcomes in patients with obesity.

#6607 HDAC6 inhibition modulates macrophage function in the post-radiation therapy tumor microenvironment.

Xintang Li[1], Satish K. Noonepalle[1], Sonia Sebaoui[2], Manasa Suresh[2], Marie Durr[1], Bryan Weselman[2], Vidhi Sharma[1], Danae K. Boikos[1], Zazing Mawi[1], Gabriella Rigoli[1], Armijo Marisol. E[1], Scott Grindrod[3], Anatoly Dritschilo[3], Alejandro Villagra[1]

[1]Tumor Biology, Georgetown University, Washington, DC,[2]Georgetown Lombardi Comprehensive Cancer Ctr., Washington,[3]Shuttle Pharmaceuticals, Gaithersburg, MD

Historically, radiation therapy (RT) is the mainstay of cancer therapy, with more than half of the cancer patients receiving RT during the course of their treatment. Besides killing cancer cells by DNA damage, RT also induces immunogenic tumor cell death and reshapes the local antitumor immune response. Often, tumor-associated macrophages (TAMs) play a key role in regulating the innate antitumor immune response within the tumor microenvironment (TME). Post-RT, due to their phenotypic plasticity, TAMs often shift between a pro-inflammatory M1-like phenotype and immunosuppressive tumor-promoting M2-like state. Furthermore, these M2-polarized TAMs recruit circulating monocytes and tissue-resident macrophages into the tumor. This results in negating the therapeutic benefit of RT by promoting tumor growth and metastasis. Therefore, strategies to reprogram TAMs are critical to the success of RT. Our lab has reported that targeting Histone Deacetylase 6 (HDAC6) with isoform-specific inhibitors in macrophages can suppress the M2-like phenotype within the TME. We explored one of several molecular mechanisms underlying the interplay among tumor cells, macrophages, and tumor-infiltrating immune cells.First, we demonstrated that M2-like macrophages migrate toward irradiated tumor cells at a significantly higher rate than M1-like macrophages, a migration that was suppressed by the HDAC6 inhibitor SP-2-225. To unravel the factors involved in the macrophage migration, we analyzed a panel of 38 cytokines and chemokines from the co-culture assay. The data revealed that macrophages irradiated with a single dose of 6Gy significantly increased the expression of CCL5 chemokine. Also, co-culture with irradiated macrophages promoted the proliferation of 4T1 breast cancer tumor cells. In addition, qPCR and flow cytometry analyses showed that SP-2-225 suppressed the expression of CCL5 receptor, CCR5, on macrophages, providing a potential mechanism for the reduced migration. Furthermore, the in vivo combination of SP-2-225 and 6Gy of RT on the syngeneic murine 4T1 triple-negative breast cancer model demonstrated that mice receiving the combination therapy exhibited improved tumor control and delayed post-RT relapse. Overall, these findings suggest that targeting the CCL5-CCR5 axis with an HDAC6 inhibitor in TAMs post-irradiation may enhance the therapeutic efficacy of radiation therapy.

#6608 WNC0901 is a novel DNA-PK inhibitor and potent radiosensitizer of otherwise radioresistant solid tumors.

Jessica L. Abraham[1], Ann C. Mladek[1], Sonia Jain[1], Shiv K. Gupta[1], Paul A. Decker[2], Matthew L. Kosel[2], Katrina K. Bakken[1], Brett L. Carlson[1], Lauren L. Ott[1], Danielle M. Burgenske[1], Jeanette E. Eckel-Passow[2], Wei Zhong[3], Jann N. Sarkaria[1]

[1]Radiation Oncology, Mayo Clinic Hospital-Rochester, Rochester, MN,[2]Quantitative Health Sciences, Mayo Clinic Hospital-Rochester, Rochester, MN,[3]Wayshine Biopharm Inc., Corona, CA

Therapeutic resistance limits the efficacy of radiation therapy in many tumors and provides a compelling rationale to develop novel treatments to enhance radiation sensitivity. DNA-dependent protein kinase (DNA-PK) is a major mediator of DNA repair following radiation, and DNA-PK inhibitors are effective radiosensitizers. WNC0901 is a potent DNA-PK inhibitor in both a cell-free kinase assay (IC50 = 0.073 nM) and a cell-based assay (IC50 = 76 nM). WNC0901 has a 30-fold specificity for DNA-PK relative to other PI3K-related kinases. In a broader kinome screen (363 kinases), 1 μM WNC0901 resulted in >25% inhibition of only five other kinases. There is robust inhibition of radiation-induced DNA-PK autophosphorylation (Ser-2056), as analyzed by Western blotting, with maximal effect at 300 nM WNC0901 in A549 (lung carcinoma), U2OS (osteosarcoma), and HT29 (colorectal) cells. The efficacy of WNC0901 as a radiosensitizer was evaluated in clonogenic assays across these same three radioresistant tumor models. Following treatment with graded concentrations of WNC0901 (0-1000 nM) combined with 2.5 Gy radiation, maximal effects were observed at a 300 nM concentration in A549 (88-fold reduction in relative clonogenic survival compared to RT alone, $p<0.001$), U2OS (5.8-fold decrease, $p=0.002$), and HT29 (59-fold decrease, $p=0.008$) In a full radiation clonogenic, the sensitizer enhancement ratio at 10% survival (SER10) was 3.8 (A549), 2.3 (U2OS), and 1.8 (HT29). In vitro metabolism studies have identified demethylated WNC0901 (WNC0901-M) as a major metabolite. Similar to the parent drug, WNC0901-M is a potent DNA-PK inhibitor with maximal radiosensitizing effects of the metabolite observed at 300nM with SER10 of 2.4 (A549), 1.9 (U2OS), and 1.8 (HT29). The in vivo efficacy of 50 mg/kg WNC0901 combined with 8 Gy was evaluated and compared to another DNA-PK inhibitor, 50 mg/kg peposertib, in A549 tumor heterotopic xenografts. Compared to placebo (median time to endpoint 63 days) or RT alone (median 72 days), the combination of WNC0901 and RT significantly delayed tumor regrowth (median 169 days; $p=0.002$ compared to RT). Interestingly, peposertib + RT was ineffective (median 83 days; $p=0.332$ compared to RT). In a second study, similarly robust sensitizing effects of WNC0901 was observed in HT29 xenografts (placebo - median 45 days; RT - median 75 days; RT + WNC0901 - median >110 days; $p=.03$ relative to RT). Together, these findings demonstrate the robust radiosensitizing effects of WNC0901 in radioresistant tumors and provide a rationale for continued development of this drug.

#6609 Targeting pancreatic cancer with combination RAS inhibition and radiation therapy.

Candise L. Tat[1], Kimal Rajapakshe[2], Emma Rodriguez[2], Vincent Bernard-Pagan[2]

[1]The University of Texas MD Anderson Cancer Center UTHealth Houston Graduate School of Biomedical Sciences, Houston, TX,[2]The University of Texas MD Anderson Cancer Center, Houston, TX

Background
Radiation therapy (RT) is a key treatment modality for locally advanced PDAC, yet PDAC is characterized by intrinsic and acquired radioresistance. Our preliminary data suggest that PDAC radioresistance is driven in part by defenses against cuproptosis, a copper-dependent, oxidative phosphorylation- (OXPHOS) linked cell death pathway. KRAS-mutant PDAC is strongly dependent on mitochondrial OXPHOS and becomes even more cuproptosis-prone with KRAS inhibition. We find that this vulnerability can be exploited therapeutically, with KRAS inhibitors synergizing with RT to amplify copper driven cell death and mitigate radioresistance.
Methods
KPC cancer cells were orthotopically injected into the pancreas of mice and subjected to RT at clinically relevant doses (40 Gy in 5 fractions). Tumors were harvested either immediately post-radiation (day 6 post-stereotactic body radiation therapy, or SBRT) or at the time of recurrence and euthanasia (~day 40), and gene expression changes were identified through single-cell RNA sequencing.
MIA PaCa-2 and PANC-1 cells were treated with a pan-RAS inhibitor (iRAS) to evaluate effects on viability and protein expression, and cuproptosis defense genes were genetically modified to delineate pathways mediating RAS inhibition-induced cell death.
Results
In the recurrent KPC tumors, we found that therapy refractory PDAC tumors consistently overexpress metallothioneins (Mt1 and Mt2). Notably, the expression of Mt1 and Mt2 progressively increases from treatment-naïve status to post-SBRT, and further to the time of recurrence. These metallothioneins play a key role in sequestering intracellular copper, resulting in lower free copper pools in the radioresistant lesions. This sequestration preserves lipoylated enzymes, contributing to tumor cell resistance to RT. Treatment of PDAC cells with iRAS resulted in an increase in lipoylated protein levels at 24 hours. Overexpression of CTR1, a copper importer, in PDAC cells increased susceptibility to RT in the presence of copper and iRAS.
Conclusions
Targeting cuproptosis may be a viable option for therapy-resistant cancers such as PDAC. We have identified that cells upregulate genes related to copper defense upon development of radioresistance, and that iRAS therapy could serve as a primer to sensitize PDAC cells to cuproptosis.

#6610 Gut microbiome modulation shapes tumor responses to radiation in oral cavity carcinoma.

Seyedamirabbas Parizadeh, Elvin Canseco, Angelina Park, Andrew Ortega, Kit Cheung, Stephen L. Shiao, Julie K. Jang

Cedars-Sinai Medical Center, Los Angeles, CA

Tumor associated macrophages (TAMs) are key regulators in the tumor microenvironment (TME) and play an important role in the response to radiation therapy (RT). Therefore, there is a need to better understand the different factors that influence the response to RT. To this end, we used broad-spectrum antibiotics (Abx) to target the microbiome of the gut and oral cavity. We hypothesize that the gut and oral cavity microbiome are key in reshaping the TME after RT. We injected the syngeneic MOC1 cell line orthotopically into the buccal mucosa of C57BL/6 mice. Tumor-bearing mice were treated with an Abx cocktail of ampicillin, imipenem, cilastatin, and vancomycin once tumors reached a volume of 100 mm3. Tumor-bearing mice were focally irradiated (8Gy x 1) using the X-RAD SmART irradiator. At a week post RT, we magnetically isolated CD45+ leukocytes from tumors and performed high-dimensional profiling of the TME using flow cytometry and single-cell RNA sequencing (scRNA-seq). Macrophage polarization can provide insight into targetable pathways of myeloid inflammation to improve prognosis. By scRNA-seq and flow-cytometry, we found that treatment with Abx prior to RT reprograms the TME, leading to an increase in SPP1+ TAMs ($P<0.05$). By multiparametric flow-cytometry, we found that treatment with Abx prior to RT leads to an increase in anti-inflammatory ARG1+F4/80+ macrophages ($P<0.05$). The microbiome regulates the response to RT in OCSCC tumors. Strategies targeting the microbiome can have implications for better understanding the interplay between the TME and the microbiome.

#6611 Ferroptotic vulnerability in M1 and M2 macrophages is associated with adaptive radiation resistance in esophageal adenocarcinoma.

Sadhna Aggarwal[1], Rui Ye[2], Jared K. Burks[3], Steven H. Lin[1]

[1]Radiation Oncology, UT MD Anderson Cancer Center, Houston, TX,[2]Systems Biology, UT MD Anderson Cancer Center, Houston, TX,[3]Hematopoietic Biology & Malignancy, UT MD Anderson Cancer Center, Houston, TX

Background: Radiation resistance remains a critical barrier to enhancing cures after chemoradiation therapy (CRT) in esophageal adenocarcinoma (EAC). Ferroptosis, a lipid peroxidation-driven cell death pathway, is increasingly recognized as a regulator of tumor-immune interactions. We investigated how ferroptotic susceptibility of macrophages might differ in radiation responders (GR) and non-responders (NR) in EAC patients using both single cell sequencing and spatial proteomic analysis.
Methods: scRNA-seq and sequential multiplex-IF using Lunaphore COMET were performed on patient biopsies before, during and after CRT to characterize cellular subsets and ferroptosis markers at single-cell resolution. In vitro ferroptosis assays were performed in THP-1, and human PBMC-derived M1/M2 macrophages following 0-12 Gy radiation ± RSL3 or ferrostatin. Ferroptotic activity was assessed by CellTiter-Glo, BODIPY-C11 oxidation, and GPX4 staining (Confocal, flowcytometry).
Results: scRNA-seq confirmed robust myeloid cell expansion in both GR and NR and revealed that pro-ferroptosis gene programs (BH4 biosynthesis, iron utilization and glycolysis pathway) were upregulated in NR both at baseline and during CRT, particularly in the myeloid population, which greatly expands during CRT. Conversely, anti-ferroptosis pathways (GPX4) were enriched in GR and suppressed in NR. COMET profiling revealed that non-responders (NR) displayed higher baseline M2 macrophage density and significantly elevated ferroptosis marker 4-HNE in both M1 and M2 subsets. During CRT, NRs exhibited a further increase in M2 macrophage infiltration, reinforcing an immunosuppressive TME, whereas good responders (GR) maintained higher M1 representation. In vitro, radiation significantly potentiated RSL3-induced ferroptosis in both human and murine macrophage-like cells; ferrostatin rescued viability, confirming ferroptotic cell death. Human macrophages displayed polarization-dependent susceptibility: M2 macrophages were sensitive to radiation-induced ferroptosis, while M1 macrophages were resistant
Conclusion: CRT response appears to relate to macrophage polarization and ferroptosis susceptibility. Non-responders are characterized by (i) M2-dominant macrophage landscapes, (ii) elevated lipid peroxidation, (iii) expansion of ferroptosis-primed myeloid subsets, and (iv) persistent activation of pro-ferroptosis pathways. Collectively this data ascribes macrophage ferroptosis as a potential targetable axis for radio-sensitization in EAC.

#6612 Targeting CPT-1-mediated fatty acid oxidation causes radiation sensitization in glioblastoma.

Kenneth M. Austin[1], Tingting Huang[2], Todd Miller[3], Kelli B. Pointer[4]

[1]Hampton University, Hampton, VA,[2]Radiation Oncology and Applied Sciences, Tingting Huang, Lebanon, NH,[3]Pharmacology & Toxicology and Pathology, Medical College of Wisconsin, Milwaukee, WI,[4]Radiation Oncology and Applied Sciences, Dartmouth Cancer Center, Lebanon, NH

Background: Glioblastoma (GBM) is the most common primary brain tumor in adults and has a median survival of less than two years despite surgery, chemotherapy, and radiotherapy. A subpopulation of glioma stem-like cells (GSCs) survives radiation and repopulates the tumor. Recent studies have shown that GSCs rely heavily on mitochondrial fatty-acid oxidation (FAO) for ATP production, NAD^+ regeneration, and redox balance. Carnitine-palmitoyl-transferase-1 (CPT-1) catalyzes the rate limiting step of FAO by shuttling long-chain fatty acids into the mitochondrial matrix. We therefore hypothesized that pharmacologic inhibition of CPT-1 will limit GSC metabolism and sensitize GSCs to radiation.

Methods: Human GBM cell line U-118 and a patient-derived GSC line (GNS144) were treated for 72 h with perhexiline (5 μM), etomoxir (10 μM), or vehicle control.Cells then received a single fraction of 0, 2, 4, 6, or 8 Gy. Cell viability was measured 48 h later. Sphere formation assays were performed 7-14 days after radiation; sphere number and mean diameter were recorded. Immunoblotting was performed to evaluate for stem cell markers CD44, Nestin, and Vimentin. All experiments were performed in triplicate; statistical significance was assessed by two-way ANOVA with Tukey post-hoc test ($p < 0.05$).

Results: Perhexiline + radiation and etomoxir + radiation produced a dose dependent decline in cell viability compared with radiation alone ($p < 0.001$). Combination treatment reduced sphere number by 55-70 % across the 4-8 Gy range ($p \leq 0.005$) and lowered mean sphere diameter by 30 % ($p \leq 0.005$). Immunoblotting analysis showed a 2-fold reductions in CD44, Nestin, and Vimentin expression in the drug + radiation arms versus radiation alone ($p < 0.01$).

Conclusions: These results suggest that inhibition of CPT-1-mediated FAO with perhexiline or etomoxir enhances radiation induced cell death, suppresses sphere forming capacity, and downregulates key GSC markers in both standard and patient-derived GBM models. These findings should be investigated further and suggest that CPT-1 blockade could be integrated with current standard of care regimens to overcome stem cell driven radiation resistance.

#6614 Targeting the G2/M checkpoint as a radiosensitizing strategy in BRAF wild-type anaplastic thyroid cancer.

Linlin Yang[1], Eric Perez[1], Andrew Hu[2], Rebecca Packard[2], Terence M. Williams[1]

[1]Radiation Oncology, City of Hope, Duarte, CA,[2]The Ohio State Univeristy, Columbus, OH

Background/Purpose: Genomic profiling of aggressive thyroid cancer, particularly anaplastic thyroid cancer (ATC) revealed high frequency of mutations in RAS-RAF pathway. A phase II trial showed that dual inhibition of BRAF and MEK in BRAF mutant ATC leads to high response rates and improved clinical outcomes. However, non-BRAF mutant ATC accounts for ~ 60-70% of cases, underscoring the necessity for targeted strategies to enhance radiosensitivity in BRAF wild-type ($BRAF^{WT}$) ATC. Aside from RAS-RAF variants, ATC exhibits mutations in DNA damage response and cell cycle checkpoints, including inactivating mutation of TP53 (~60-70%). Tumor cells with dysfunctional TP53 have aberrant genome surveillance at the G1/S checkpoint, causing cells to depend on the intact G2/M checkpoint for DNA damage repair after genotoxic therapies. Therefore, we hypothesize that treating TP53 mutant ATC cells with inhibitors of G2/M checkpoint related proteins, such as ATR and WEE1, will enhance the efficacy of radiation therapy (RT).

Materials/Methods: VX970 and AZD1775, which are highly potent and selective inhibitors of ATR and WEE1 respectively, were investigated individually as radiosensitizers in $BRAF^{WT}$ ATC cell lines. IC50s of VX970 and AZD1775 were assessed by AlamarBlue cytotoxicity assay, and the radiosensitizing effects of these drugs were evaluated by radiation clonogenic assays. The biological outcomes of a combination treatment of ATR or WEE1 inhibition and RT were determined by immunoblotting, propidium iodide flow cytometry, and mitotic catastrophe assay. Additionally, mouse heterotopic and orthotopic thyroid tumor models with CT-guided radiation were generated to evaluate the *in vivo* radiosensitizing effects of VX970 and AZD1775.

Results: In TCGA thyroid cancer data, CHEK1/WEE1/CDK1 gene expressions were significantly upregulated in thyroid cancer compared to normal tissues. The IC50 values of VX970 and AZD1775 in the tested ATC cell lines were ~400nM and ~3000nM, respectively. Both VX970 and AZD1775 significantly enhanced the radiosensitivity of 5 $BRAF^{WT}$ ATC cells lines, 4 of which harbor the TP53 mutations. However, no synergy was found with concurrent ATR and WEE1 inhibition compared to single kinase inhibition. Mechanistically, both drugs suppressed p-$CDK1^{Tyr15}$ expression, attenuated radiation-induced G2/M cell cycle arrest, increased DNA damage and enhanced mitotic catastrophe following RT. *In vivo* studies further validated the role of VX970 and AZD1775 as potent radiosensitizers in ATC tumors by heterotopic and orthotopic tumor models.

Conclusion: Targeted inhibition of G2/M checkpoint by ATR/WEE1 inhibitors markedly sensitizes $BRAF^{WT}$ ATC to radiotherapy in both *in vitro* and *in vivo*. Our findings support that ATR/WEE1 inhibition is a promising new strategy to improve the radiotherapy efficacy for BRAF wild-type ATC patients and warrants further clinical exploration.

#6616 Limiting O-GlcNAcylation support prostate cancer radiation sensitivity through metabolic and epigenetic reprogramming.

Manish Thiruvalluvan, Sandrine Billet, Saravana Kumar Kailasam Mani, Joshua Watson, Neil A. Bhowmick

Cedars-Sinai Medical Center, Los Angeles, CA

Background: Prostate cancer (PCa) frequently develops resistance to radiation therapy (RT), driven in part by DNA repair mechanisms. We previously found that glutamine (L-Gln) enables protein O-GlcNAcylation post-translational modifications linked to DNA repair and therapy resistance. This is highly relevant to irradiation of PCa metastatic sites like the bone and liver microenvironments that have markedly high concentrations of L-Gln and accordingly poor response to irradiation. Here, we investigated whether pharmacologic glutamine depletion using sodium phenylbutyrate (SPB) disrupts this axis and enhances radiosensitivity.

Methods: Radio-resistant 22Rv1 and ARCaP$_M$ lines were generated by iterative chronic irradiation. Subcutaneous and liver xenografts were treated with vehicle, SPB, RT, or SPB+RT. Tumors analyzed by bulk RNA-seq, proteomics, and immunoblotting revealed the importance of NDRG1 and PRDX1 o-glycosylation. CRISPR/Cas9 mutagenesis was used to generate O-GlcNAc-deficient NDRG1 and PRDX1 variants. DNA-damage repair, cell-cycle dynamics, and mitochondrial function were assessed by γH2AX staining, flow cytometry, and Seahorse assays.

Results: SPB+RT produced the greatest tumor reduction and significantly reduced circulating and intratumoral glutamine, compared to either RT or SBP alone. Transcriptomic and proteomic analyses showed downregulation of amino-acid transport, fatty-acid metabolism, and histone demethylase activity, indicating broad metabolic and epigenetic reprogramming. Mass spectrometry identified NDRG1 and PRDX1 as radiation-induced O-GlcNAc targets suppressed by SPB. CRISPR-engineered O-GlcNAc-deficient NDRG1 and PRDX1 variants exhibited greater RT sensitivity as a result of persistent γH2AX foci, prolonged G2/M arrest, reduced nuclear localization, and decreased protein stability. RNA-seq of these variants showed enrichment of p53 signaling, endoplasmic reticular (ER) stress with metabolic compensation through increased c-Myc activity, and oxidative phosphorylation. Nucleoside supplementation did not reverse SPB-mediated radio-sensitization, indicating that SPB's effects extended beyond nucleotide depletion. Instead, the data suggested the role of L-Gln addiction in irradiated PCa tumors was due to NDRG1 and PRDX1 in ER stress-response proteins and activating the unfolded protein response.

Conclusions: O-GlcNAcylation of NDRG1 and PRDX1 stabilizes stress-response proteins to support DNA-repair and metabolic fitness after irradiation. SPB disrupts this L-Gln-driven O-GlcNAcylation axis, to impair protein translation supporting significant radio-sensitization. As SPB is used for chronic management of urea cycle disorders, repurposing to overcome radiation resistance provides a near-term therapeutic translation opportunity for PCa patients.

#6617 Targeting the PLK1-PRMT5 axis enhances radiosensitivity in prostate cancer.

Jia Peng, Xinyi Wang, Daheng He, Jianlin Wang, Qianjin Li, Fatemeh Seilani, Xiongjian Rao, Meng Wu, Jinghui Liu, Ruixin Wang, Pingli Mo, Min Zhang, Sai Wu, Yanquan Zhang, Zhiguo Li, Izumi Tadahide, Xiaoqi Liu

Univ. of Kentucky College of Medicine, Lexington, KY

Prostate cancer remains the most frequently diagnosed cancer and the second leading cause of cancer-related death among men in the United States. We previously demonstrated that Polo-like kinase 1 (PLK1) phosphorylates PRMT5 at the S470 site, a modification required to maintain PRMT5 enzymatic activity and to promote DDR in prostate cancer cells. Here, we further uncover the functional consequences of this phosphorylation on cell cycle regulation and radiosensitivity. RNA-seq analysis revealed that PLK1-associated phosphorylation at S470 influences cell cycle-related pathways. Flow cytometry showed that the phospho-deficient PRMT5 mutant (S470A) accumulates in S and G2 phases compared to wild-type cells. Consistently, ChIP-qPCR analysis demonstrated increased binding of H4R3Me2s to genes inducing cell cycle arrest and decreased association with genes driving cell cycle progression in S470A cells. Importantly, both PLK1 inhibition (Onvansertib) and PRMT5 inhibition (Onametostat) synergized with ionizing radiation (IR) to suppress tumor growth in vitro and in vivo. These findings highlight a previously unrecognized role of PLK1-mediated PRMT5 phosphorylation in cell cycle control and radiosensitivity, suggesting that targeting the PLK1-PRMT5 axis may serve as a promising therapeutic strategy to enhance radiotherapy efficacy in prostate cancer.

#6618 Investigation of 8-O-acetylharpagide induced G2/M arrest and radiosensitization effects on hypopharyngeal cancer.

Wan-Yu Yang, Yi-Jang Lee

National Yang Ming Chiao Tung University, Taipei, Taiwan

[Purpose] AT-1 (8-O-acetylharpagide) is a natural compound purified from the endemic Taiwanese plant *Ajuga taiwanensis* and has been reported to possess anti-aging, anti-inflammatory, and anti-cancer properties, such as skin, liver and breast, but its potential role in Hypopharyngeal squamous cell carcinoma (HPSCC) remains unclear. This study aimed to systematically characterize the cellular responses to AT-1 in human hypopharyngeal carcinoma cells (FaDu) versus normal human periodontal ligament fibroblasts (PDL) and to evaluate its selective cytotoxic and radiosensitizing potential.

[Methods] Cell viability was assessed using the MTT assay. Flow cytometry was performed to analyze cell-cycle distribution and apoptosis. DNA damage was evaluated by immunofluorescence staining and comet assay. Western blotting was used to detect changes in cell cycle- and apoptosis-related proteins. Radiation sensitivity was examined following AT-1 pretreatment and subsequent X-ray exposure.

[Results] AT-1 selectively reduced the viability of FaDu cells while exerting minimal cytotoxicity in PDL cells and induced pronounced G2/M phase arrest in FaDu, accompanied by abnormal upregulation of Cyclin B1 and modulation of cell cycle regulators. Apoptosis analysis revealed that AT-1 triggered cell death through downregulation of pro-survival proteins including AKT, p-AKT, and Bcl-2. Intracellular reactive oxygen species levels did not significantly increase, suggesting that oxidative stress was not directly responsible for AT-1-induced cytotoxicity. Immunofluorescence and comet assays confirmed the presence of DNA double-strand breaks in AT-1-treated FaDu cells, which may underlie the observed G2/M arrest and apoptosis. Furthermore, AT-1 pretreatment enhanced the radiosensitivity of FaDu cells, whereas PDL cells remained relatively resistant to AT-1 alone and to the combination treatment. AT-1 inhibits the growth of hypopharyngeal carcinoma cells by perturbing the cell cycle, inducing DNA damage, and promoting apoptosis, and it acts as a selective radiosensitizer in this model.

[Conclusions] These data demonstrate that AT-1 (8-O-acetylharpagide) induces G2/M arrest and selectively radiosensitizes hypopharyngeal cancer cells while sparing normal cells. AT-1 may represent a promising low-toxicity radiosensitizer candidate for head and neck cancer, and further in vivo and mechanistic studies are warranted to define its impact on DNA damage response.

#6619 Inhibition of PLK4 overcomes radioresistance in locally advanced rectal cancer through genomic instability and apoptotic cell death.

Sung Uk Bae[1], Jeong-Woo Hwang[1], Hyewon Lee[2], Hyowon Hong[2], Sang Jun Byun[2]

[1]Surgery, Keimyung University Dongsan Hospital, Daegu, Korea, Republic of,[2]Keimyung University Dongsan Medical Center, Daegu, Korea, Republic of

Background: Polo-like kinase 4 (PLK4), a key regulator of centrosome duplication, has been implicated in cancer progression and therapeutic resistance. Although PLK4 overexpression is frequently observed in various malignancies, its functional contribution to radiotherapy (RT) response in colorectal cancer (CRC) remains poorly understood.
Methods: To investigate whether PLK4 inhibition enhances radiosensitivity, CRC cell lines HCT116 (p53 wild-type) and HT29 (p53 mutant) were treated with the selective PLK4 inhibitor CFI-400945, RT or their combination. Cell viability and clonogenic assays were performed to evaluate cytotoxicity. DNA damage responses were assessed by γH2AX immunofluorescence and Western blot analysis of p-ATM, p-CHK2, and DNA-PKcs. Cell-cycle profiles and centrosomal abnormalities were examined by flow cytometry and γ-tubulin staining, respectively. Apoptosis was determined through cleaved PARP-1 and caspase-3 expression levels.
Results: CFI-400945 treatment reduced cell viability in a dose- and time-dependent manner and significantly enhanced the cytotoxic effects of RT in both CRC cell lines. Combined treatment markedly increased γH2AX foci formation and upregulated DNA damage response proteins, including p-ATM, p-CHK2, and DNA-PKcs. PLK4 inhibition also induced centrosome amplification, micronuclei formation, and multinucleation, indicating mitotic defects leading to genomic instability. Furthermore, the combination therapy enhanced G2/M arrest and apoptosis, as evidenced by elevated levels of cleaved PARP-1 and caspase-3.
Conclusions: PLK4 inhibition sensitizes colorectal cancer cells to radiation by promoting DNA damage accumulation, mitotic catastrophe, and apoptotic cell death. These findings suggest that targeting PLK4 may serve as a potential therapeutic strategy to overcome radioresistance in CRC.

#6620 CYLD induces ferroptosis through ALOX12B to enhance radiosensitivity in non-small cell lung cancer.

Yihan Xu, Jiazhuo Yan, Huiwen Yu, Lu Zhang, Jinpu Yu, Zhiyong Yuan

Tianjin Medical Univ. Cancer Inst. & Hospital, Tianjin, China

Background: Radiotherapy is is a pivotal treatment for locally advanced or inoperable non-small cell lung cancer (NSCLC), however its efficacy is limited by radioresistance. Approximately 44%-46% of patients develop recurrence or metastasis after chemoradiotherapy, with stage III patients showing a 30%-40% local recurrence rate within five years. Identification of effective therapeutic targets to enhance radiosensitivity remains a critical challenge in NSCLC management. This study aims to elucidate the molecular basis of radioresistance and develop novel approaches to enhance tumor radiosensitivity.
Methods: Through RNA transcriptome sequencing of treatment-naive NSCLC patients (n=87) stratified by RECIST into radiotherapy-sensitive (n=55) and -resistant (n=32) cohorts, and based on histopathological and clinical diagnostic data from Tianjin Medical University Cancer Hospital (2015-2020), we analyzed the association between CYLD expression and radiotherapy outcomes through RNA sequencing and tissue microarrays. The impact of CYLD on radiosensitivity was assessed through flow cytometry and colony formation assays, and further verified in nude mouse xenograft models. To investigate CYLD-related pathways, we performed next-generation sequencing and examined its role in ferroptosis through Western blotting, qPCR, glutathione assays, malondialdehyde measurements, lipid peroxidation assessment, and transmission electron microscopy. Potential CYLD-interacting proteins were identified via mass spectrometry, immunofluorescence, and co-immunoprecipitation assays, while CYLD-mediated deubiquitination of ALOX12B was characterized using ubiquitination immunoprecipitation.Furthermore, we combined database predictions with Western blot, qPCR, chromatin immunoprecipitation, and luciferase reporter assays to establish EGR1 as a transcriptional regulator CYLD expression.
Result: Our findings identify CYLD as a positive regulator of radiosensitivity in NSCLC, We demonstrate that CYLD enhances radiation sensitivity in NSCLC by stabilizing ALOX12B. Mechanistically, CYLD enhances ALOX12B protein stability by deubiquitinating K63- and K48-linked ubiquitin chains, thereby suppressing its proteasomal degradation. This stabilization potentiates cellular ferroptosis and consequently increases radiosensitivity. Furthermore, we identified EGR1 as an upstream transcriptional activator of CYLD that promotes ferroptosis in a CYLD-dependent manner.
Conclusion: Our study demonstrates that CYLD, driven by its transcriptional activator EGR1, promotes ferroptosis and enhances radiosensitivity in NSCLC by mediating the deubiquitination and stabilization of ALOX12B. This study identifies CYLD as both a valuable prognostic biomarker and a potential molecular target for radiosensitization in NSCLC.

#6621 Riluzole as a dual targeted radiosensitizer for osteosarcoma: Targeting tumor cells and angiogenic vasculature to enhance single high dose radiotherapy efficacy.

Pooja P. Rao[1], Adriana Haimovitz-Friedman[2], Charis Herbert[3], Syeda Maryam Azeem[4], Raisa Munira[5], Elena Garay[3], Hadi Askarifirouzjaei[2], Shahana Mahajan[1]

[1]Biochemistry, The Graduate Center, CUNY, New York, NY,[2]Radiation Oncology, Memorial Sloan Kettering Cancer Center, New York, NY,[3]Medical Laboratory Sciences, Hunter college, CUNY, New York, NY,[4]Biology, The Graduate Center, CUNY, New York, NY,[5]Biology, Hunter College CUNY, New York, NY

Osteosarcoma (OS), a highly aggressive bone cancer prevalent among young adults, poses significant challenges in treatment, particularly due to its intrinsic resistance to conventional radiation therapy. This necessitates the development of efficacious radiosensitizers to enhance treatment outcomes. Single high-dose radiation therapy (SDRT) has emerged as a promising strategy for combatting radioresistant sarcomas, particularly those characterized by extensive vascularity. However, its use in OS is constrained by potential toxicity to surrounding normal tissues. Radiosensitizers facilitate effective tumor eradication at reduced radiation doses, limiting normal tissue toxicity and optimizing the therapeutic window. Tumor microvasculature and intrinsic tumor cell mechanisms combinedly drive OS radioresistance. Anti-angiogenic therapies have largely failed as radiosensitizers due to compensatory signaling and cross-talk between surviving endothelial and tumor cells, which reinforces radioresistance. These observations highlight the urgent need for strategies that concurrently target both tumor cells and angiogenic vasculature to enhance the efficacy of SDRT. Riluzole, an FDA-approved drug for Amyotrophic Lateral Sclerosis, is currently under investigation for repurposing in OS treatment. By inhibiting glutamate release and downregulating xCT/SLC7A11, Riluzole increases reactive oxygen species production, promotes DNA damage and induces apoptosis in tumor cells. In parallel, it has shown to inhibit vascular endothelial growth factor A (VEGFA) induced endothelial cell proliferation and abnormal vessel formation. These combined mechanisms positions Riluzole as a promising dual-target radiosensitizer capable of overcoming key limitations of current therapies. In this study, we hypothesize that Riluzole increases the radiosensitivity of OS tumors to SDRT by targeting radioresistance mechanisms in both tumor cells and angiogenic vasculature. Our preliminary results demonstrate that Riluzole significantly reduced the survival fraction of irradiated OS cells compared to cells only exposed to SDRT, signifying potent radiosensitization. Combination treatment markedly increased apoptosis relative to either treatment alone. Mechanistically, Riluzole significantly inhibited the activity of DNA repair enzyme PARP1, and increased radiation induced ROS levels, resulting in enhanced radiation induced DNA damage. Additionally, pre-treatment with Riluzole reduced VEGFA levels in OS cells, suggesting its potential anti-angiogenic activity. In the long term, our objective is to translate these laboratory discoveries into pre-clinical and clinical studies, potentially offering a novel therapeutic approach of radiation therapy for OS patients.

#6622 Novel selective binders for gastrointestinal DCLK1 isoforms.

Uzma Uzmi[1], Shahid Umar[2], Prashanthi Karyala[3], **Rao VL Papineni**[4]

[1]Surgery, PACT and Health, Branford, CT,[2]University of Kansas Medical Center, Kansas City, KS,[3]Applied Sciences, MS Ramaiah, Bengaluru, India,[4]Surgery, University of Kansas Medical Center, Kansas City, KS

Doublecortin-like kinase 1 (DCLK1) is a microtubule-associated protein kinase that plays a critical role in the maintenance of gastrointestinal (GI) epithelial integrity and regeneration. Emerging evidence highlights the functional divergence of its isoforms—particularly the long and short forms—which are differentially expressed during homeostasis and disease. In healthy GI tissue, DCLK1-long primarily maintains stem cell quiescence and epithelial repair. Conversely, DCLK1-short is markedly elevated in several GI malignancies and is associated with oncogenic transformation, invasion, and poor prognosis. We are investigating compounds that modulate DCLK1 isoforms to mitigate irradiation-induced gastrointestinal acute radiation syndrome (GI-ARS). Our research demonstrates that 2-deoxyglucose (2DG) and its non-metabolizable analogue differentially regulate crypt and colonoid growth in ex vivo systems. Treatment with 2DG results in selective suppression of the DCLK1-short isoform while sparing or modestly enhancing the DCLK1-long variant, suggesting a potential therapeutic window for targeting tumor-specific isoform expression. To further identify molecular binders capable of modulating DCLK1 activity, we employed a structure-based virtual screening approach using a focused library of 100,000 small molecules. High-throughput in silico docking enabled the identification of several high-affinity lead compounds with potential isoform-selective binding. The strategy of small-molecule screening offers a promising approach for selective intervention in DCLK1-driven pathologies in GI tissue repair.

#6623 Stem cell transdetermination is a targetable driver of therapeutic response to neoadjuvant chemoradiotherapy in rectal cancer.

Nick Li[1], Petra Vlckova[1], Alistair Wilkinson[1], Ewa Basiarz[1], Aurelie Dobric[1], Corinne Molyneux[1], Rhianna O'Sullivan[1], Shauna Crampsie[1], Benoit Bilanges[1], Bart Vanhaesebroeck[2], Maria A. Hawkins[3], Chris Tape[1]

[1]University College London (UCL) Cancer Institute, London, United Kingdom,[2]Centre Lead, Centre for Cell Signalling, University College London Cancer Institute, London, United Kingdom,[3]Department of Physics and Biomedical Engineering, University College London (UCL), London, United Kingdom

Neoadjuvant chemoradiotherapy (nCRT) is used in about one third of rectal cancer cases in the UK, but treatment response is heterogeneous, leading to difficulties in response prediction and sensitization. Phenotypic plasticity, driven by both cell-intrinsic mutations and cell-extrinsic signals from the tumour microenvironment (TME) has been shown to influence therapy resistance in colorectal cancer. This study explores the role of proliferative cancer stem cells (proCSCs) and revival cancer stem cells (revCSCs) in CRT response, and how phenotypic plasticity can be targeted to improve CRT sensitivity.

Patient-derived organoids (PDOs) from a cohort of 10 patients with microsatellite-stable rectal cancer were subject to combinatorial perturbations of radiation, chemotherapy, exploratory radiosensitizers, and co-culture with cancer associated fibroblasts (CAFs). PDOs were analysed 3 hours and 48 hours after radiation in triplicate, totalling 2,400 experimental conditions. PDOs were analysed using single-cell thiol-organoid barcoding *in situ* mass cytometry (TOB*is* MC), enabling high-dimensional characterisation of CSC states, DNA damage responses, canonical signalling pathways, cell cycle, and apoptosis.

PDOs displayed heterogeneous, patient-specific responses to CRT, and could be classified in the following manner: 1) high signalling response, high apoptosis; 2) high signalling response, low apoptosis; and 3) low signalling response, low apoptosis. Therapy-induced apoptosis did not correlate with on-target DNA damage, but instead strongly aligned with baseline stem cell index (SCI), a metric that describes the relative proCSC-revCSC ratio of each PDO. Higher rates of apoptosis were seen in PDOs that were proCSC-dominant at baseline (high-SCI), whereas revCSC-dominant PDOs (low-SCI) were more resistant apoptosis after treatment. In certain low-SCI PDOs, the proCSC population could be enriched using a PI3Ka activator before radiation, resulting in increased apoptosis after radiation with little toxicity. After CRT, a significant reduction in SCI was seen across the cohort. Blockade of revCSC transdetermination with a YAP/TEAD1 inhibitor also resulted in increased radiation-induced apoptosis. Highly plastic PDOs exhibiting large differences SCI following CRT were identified by high DACH1 expression.

This study suggests that the initial level of on-target DNA-damage following CRT does not dictate cell death, rather, it is due to what state the cancer cell is in when the damage occurs. We find that rectal cancer cells in a proCSC state typically enter apoptosis in response to DNA damage, whereas cancer cells in the revCSC state survive therapy. We also find that pharmacologically enriching proCSCs and blocking access to the revCSC state can sensitize PDOs to CRT, and may have therapeutic importance in treating rectal cancer.

#6624 Exploiting radiation-induced tumor vulnerabilities via targeted antibody-drug conjugates.

P.M. Quan Mai[1], Prapannajeet Biswal[1], Prudhvi Chand Mallepaddi[1], Ngoc Tuyet Tra[1], Sai Kumar Samala[1], Shafqat Ehsan[2], Bhoomika Muruvekere Lakshmisha[1], Khadijeh Koushki[1], Muhammad A. Shohayeb[1], Lydia WT Cheung[1], Geraldine Vijay[1], Sunil Krishnan[1]

[1]Vivian L. Smith Department of Neurosurgery, University of Texas Health Science Center at Houston, Houston, TX,[2]University of Texas MD Anderson UTHealth Houston Graduate School of Biomedical Sciences, Houston, TX

Background: Antibody-drug conjugates (ADCs) demonstrate potent anti-cancer activity but may cause on-target off-tumor toxicity in normal tissues if the target antigen is not strictly tumor-specific. To address this, we leverage on radiation therapy (RT), a main pillar in gastric (GC) and colorectal cancer (CRC) treatment, to kill cancer cells while simultaneously triggering a cancer-specific response that relocates Heat Shock Protein A5 (HSPA5). HSPA5 is intrinsically localized to the endoplasmic reticulum (ER). The ability of RT to promote HSPA5 translocation from ER to the cell surface (cs) opens an opportunity to target cancer cells with anti-HSPA5 ADC. We seek to understand RT-induced csHSPA5 biology and target it via ADC.
Methods: We mined the TCGA data for HSPA5 expression in normal and GC or CRC tissues and for its correlation with patient prognosis. Irradiated human (AGS and MKN45) and murine (YTN16) GC, human (HCT116 and HT29) CRC cells were subjected to flow cytometry (FC) and immunofluorescence (IF) for csHSPA5 levels. csHSPA5+ cells' tumorigenicity was examined by co-staining the cells with HSPA5 and Ki67 (proliferation), CD44 (stemness), N-cadherin (EMT) via FC. To examine the involvement of O-glycosylation in HSPA5 cell-surface presentation, we performed co-immunoprecipitation to detect potential O-glycosylation regulators and inhibited O-glycosylation in AGS (+/-RT). To assess HSPA5 antibody biodistribution, we injected GC/CRC nude mice with anti-HSPA5 antibody-Alexa Fluor 647 dye prior to imaging, with the tumors and organs harvested for FC and IF. Lastly, Annexin V/PI staining was performed with AGS and HUVEC cells treated with RT+anti-HSPA5 ADC.
Results: Expression levels of HSPA5 are higher in GC and CRC against their normal counterparts and are correlated with worse patient prognosis. We detected RT-induced elevation of csHSPA5 in all GC/CRC cells, notably not in normal HUVEC or GES1. csHSPA5+ population is enriched for Ki67+, CD44+, and N-cadherin+ cells compared to csHSPA5- population, indicating the tumorigenic phenotypes of csHSPA5+ cells. Interestingly, our data revealed the cancer-specific csHSPA5 translocation mechanism, in which HSPA5 binds to N-acetylgalactosaminyltransferase 2 (GALNT2) and N-acetylgalactosamine (O-GalNAC) only in cancer cells but not normal cells. Inhibiting O-glycosylation blocks RT-induced HSPA5 cell-surface translocation. The *in vivo* models showed a significant accumulation of HSPA5 antibody in radiated tumors compared to non-irradiated tumors or healthy organs. Moreover, RT+ADC significantly decreased %live cells compared to RT or ADC alone. RT+ADC caused no decreased viability of the normal HUVEC cells, reflecting the low toxicity in healthy cells.
Conclusion: The overexpression of HSPA5 in cancer, coupled with radiation-induced cell-surface expression, renders it a promising ADC target for achieving high anti-tumor specificity.

#6625 Photodynamic activation of CX-5461 enhances its anti-tumor efficacy.

Jakub Trojnar[1], Marta Dudek[1], Kai-Wei Hsueh[2], Ping-Yen Huang[2], **Marco Deiana**[1]

[1]Wrocław University of Science and Technology, Institute of Advanced Materials, Wrocław, Poland,[2]Senhwa Biosciences Inc., New Taipei City, Taiwan

Introduction: CX-5461 (Pidnarulex) is the first selective inhibitor of RNA Polymerase I (Pol I) and a potent stabilizer of DNA G-quadruplexes (G4s), with additional activity as a TOP2 poison. Beyond its transcriptional inhibition, CX-5461 induces cell-cycle arrest, apoptosis, and DNA double-strand breaks, exhibiting broad anti-proliferative effects across diverse cancer models. Clinically, CX-5461 shows promising efficacy in advanced hematologic and solid tumors, such as breast, pancreatic, and ovarian cancers, with phototoxicity as the main adverse effect, manageable through sun protection. G4 structures are guanine-rich and inherently prone to oxidative modification, which has recently positioned them as promising targets for light-activated therapeutics. CX-5461 is known to be light-sensitive and capable of inducing phototoxic reactions; however, in this study we leverage this property as a functional advantage rather than a limitation. We show that CX-5461 acts as an efficient photosensitizer: upon UV irradiation, it generates reactive oxygen species (ROS), leading to enhanced oxidative DNA damage and an approximately ten-fold increase in cytotoxicity relative to its dark state, at concentrations that are otherwise minimally toxic. These findings reveal a photo-responsive mechanism of action for CX-5461, in which G4 binding and light-induced ROS generation converge to potentiate its anti-tumor activity.

Materials and Methods: CT26 and B16F10 cells were treated with a serial dilution of CX-5461, with or without UV exposure. DNA damage, ROS levels, and cell viability were analyzed. In the CT26 syngeneic model, CX-5461 was administered at 25 mg/kg, iv, weekly, alongside UV exposure (10 J/cm^2) for the first three days. B16F10 models received CX-5461 at 25 or 50 mg/kg, iv, weekly, with UV exposure (5 J/cm^2) on Day 1. Tumor size and survival were measured.

Results: CX-5461 exhibits strong absorbance in the UV region and generates both type I and type II reactive oxygen species (ROS), including superoxide anion, hydroxyl radicals, and singlet oxygen, upon UV irradiation. This exposure increased oxidative damage to 8-oxoG, raised ROS levels, and enhanced cytotoxicity in CT26 and B16F10 cells. In vivo studies confirmed that the combination of CX-5461 and UV light significantly inhibited tumor growth in the B16F10 model, with a tumor growth inhibition (TGI) of approximately 100% on Day 12, and in the CT26 model, with a TGI of around 74% on Day 14.

Conclusion: CX-5461 is a photosensitizer that produces both type I and type II ROS, which increases its cytotoxic effects in vitro when exposed to UV light. The efficacy of CX-5461 in combination with UV treatment has been demonstrated in syngeneic models like CT26 and B16F10. These findings suggest that the phototoxic properties of CX-5461 could represent a novel therapeutic strategy for treating of cancers that are amenable to UV light exposure.

#6626 Atomically precise NHC-stabilized gold nanoclusters for enhanced photodynamic and X ray activated cancer therapy.

Hetvi Shah[1], Angus Isaac Sullivan[2], Juan Chen[2], Gang Zheng[2]

[1]Pharmaceutical Sciences, University of Toronto, Toronto, ON, Canada,[2]Princess Margaret Cancer Centre, Toronto, ON, Canada

Gold nanoclusters (AuNCs) are atomically precise, ultrasmall (<2 nm) nanoparticles that exhibit favorable biocompatibility and renal clearance properties[1-2]. N-heterocyclic carbene (NHC) functionalized gold nanoclusters (NHC-AuNCs) are a new class of nanomaterials with high chemical stability, structural tunability, and strong potential to amplify radiation-induced cytotoxicity [3-4]. We have synthesized bis-N-heterocyclic carbene (NHC)-protected Au_{13} nanoclusters that display intrinsic photoluminescence quantum yields, making them attractive candidates for cancer theranostics. Our objective is to improve their therapeutic performance by enhancing their distribution, increasing their tumor-targeting capability, and employing them as sensitizers for photodynamic therapy and/or radiotherapy (RT). In this work, we developed novel NHC-AuNCs with ~20-30% reactive oxygen species (ROS) production efficiency, a key property for inducing ROS-mediated DNA damage in cancer cells. We performed *in vitro* studies, including cytotoxicity, cellular uptake, and PDT potency evaluation, to assess their effectiveness as PDT agents. ICP-MS analyses verified efficient cellular uptake across multiple pancreatic cancer cell lines. Upon PDT irradiation at 10 and 20 J/cm^2, treatment with 5 µM NHC-AuNCs induced over 90% cell death, whereas negligible cytotoxicity was observed in both non-AuNC-treated and no-light-treated control groups. These NHC-AuNCs show high PDT efficacy at half the concentration compared to previously tested AuNCs, making them a potent PDT agent. Ongoing work focuses on refining the nanocluster framework to enhance tumor specificity. The incorporation of surface azide groups enables click-chemistry conjugation of targeting peptides to improve tumour targeting. In parallel, *in vivo* studies assessing biodistribution, PDT efficacy, and survival outcomes in tumor-bearing models are underway to establish the therapeutic potential of these NHC-stabilized AuNCs.The ability of these nanoclusters to act as potent PDT agents provides a powerful nanoplatform for advancing cancer targeted therapy. The ability of various NHC-AuNCs with different photophysical and chemical properties to act as PDT agents will be discussed.

#6627 Integrating padeliporfin vascular-targeted photodynamic therapy with enfortumab vedotin and immune checkpoint blockade in urothelial cancer models.

Abraham R. Meyerson[1], Daniel V. Rodriguez[1], Fengshen Kuo[2], Sanaz Firouzi[1], Sadna Budhu[3], Kwanghee Kim[1], Jonathan Coleman[1]

[1]Urology, Memorial Sloan Kettering Cancer Center, New York, NY,[2]Memorial Sloan Kettering Cancer Center, New York, NY,[3]Weill Cornell Medical College, New York, NY

Vascular-targeted photodynamic therapy (VTP) has demonstrated efficacy in the ongoing phase III trial for low-grade upper tract urothelial carcinoma (UTUC), achieving a 78% complete response rate (NCT0420239). VTP is a local ablation therapy where light activated padeliporfin occludes tumor blood vessels, causing tumor necrosis while sparing healthy urothelium. VTP induces systemic antitumor immunity and was reported to potentiate PD-1/PD-L1 immune checkpoint blockade (ICB) while preventing lung metastases in kidney and bladder cancer models. Enfortumab vedotin (EV), an antibody-drug conjugate targeting Nectin-4, with pembrolizumab (Pembro), improved overall and progression-free survival versus chemotherapy in locally advanced or metastatic urothelial carcinoma, with a 30.4% complete response rate (Phase III EV-302/KEYNOTE-A39, NCT04223856). Given the local ablation and immune activities of VTP, its combination with EV+Pembro may improve UTUC responses.

To better understand how patients with UTUC might benefit from such combination strategies, we investigated antibody drug conjugate (ADC) and ICB target expression using bulk RNA-seq from a UTUC patient cohort at MSKCC (n=100). A correlative study of patient PBMC samples from the VTP Phase-1 trial (NCT03617003) was performed to assess immune-modulatory activities. The effects of VTP on ADC and ICB expression were assessed using preclinical and patient tissue. Therapeutic activities of VTP in combination with ICB or EV in urothelial cancer were evaluated using both syngeneic and patient-derived xenograft (PDX) models.

ADC targets (Nectin-4, Trop2, and ERBB2) were expressed higher in patients with luminal papillary compared to variant histology such as basal and squamous subtypes. ICB targets (PD1, PDL-1, CTLA-4) were higher in aggressive UTUC cases. A PDX model (UCC14) with luminal papillary characteristics and high Nectin-4 demonstrated tumor regression with 3 doses of EV. Flow cytometric analyses of patient PBMCs and preclinical data using the MB49 bladder cancer model demonstrated $CD8^+$ T cell-driven immune modulation, leading us to hypothesize that VTP may complement EV and anti-PD1 by converting immune-desert tumors into more inflamed, treatment-responsive phenotypes. UCC14 and an MB49 high-Nectin-4 model are currently being evaluated to determine whether combining VTP with EV and/or Pembro enhances immune infiltration and response durability, providing translational rationale for integrating VTP with EV+Pembro in UTUC.

#6628 Cancer photodynamic therapy: Silicon quantum dots as therapeutic nanomaterials.

Dorra Gargouri, Artjima Ounkaew, David Antoniuk, Jonathan Veinot, Xuyang Liu

Applied Quantum Materials, Inc., Edmonton, AB, Canada

Cancer photodynamic therapy (PDT) is a minimally invasive cancer treatment that uses photosensitizers to generate reactive oxygen species (ROS) and induce selective tumor cell death. Conventional PDT agents, including organic dyes and metal-based nanoparticles, face significant limitations such as photobleaching, poor tissue penetration, toxicity, and limited photostability which restrict their clinical effectiveness. Silicon quantum dots (SiQDs) offer a new alternative of photosensitizers that can overcome these limitations. The nanomaterials have already shown strong potential in cancer detection and diagnostics. In addition, SiQDs are also ideal PDT agents because they are heavy-metal-free, non-toxic, biocompatible, photostable, and exhibit tunable optical properties with customizable surfaces for targeted delivery, enhanced precision and therapeutics. Applied Quantum Materials Inc. (AQM) synthesizes SiQDs that are highly-pure, have a narrow-size-distribution and showcase exquisite control over surface modifications (including biomolecule conjugation of 8-150 kDa). These nanomaterials display bright, size-dependent luminescence across the visible-NIR spectrum. Biocompatibility studies show >90% cell viability at concentrations up to 500 µg/mL after 24 h incubation, indicating SiQDs have great potential for clinical translation. AQM's recent advances have shown enhanced material uptake into cancer cells along with improved light-triggered therapeutic activity. Under low-level NIR laser irradiation, findings exhibited significantly reduced cancer cell viability, correlating with increased intracellular ROS generation. Initial results indicate cancer cells destruction in 10 minutes. These outcomes offer great potential for SiQDs as effective photosensitizers for PDT.

Poster Session

#6632 Trends in treatment and survival among patients with glioblastoma in the United States, 2000 to 2020: A population-based SEER analysis.

Jianan Chen, Qiong Wu, Catherine Boldig, Rob J B Macaulay, Arnold Etame

Moffitt Cancer Center, Tampa, FL

Background: Population-level patterns in the real-world use of initial treatment combinations for glioblastoma remain poorly characterized. We evaluated national trends in treatment uptake over two decades and examined their associations with survival outcomes.
Methods: We assessed temporal trends (2000-2020) in treatment and survival among 46,186 patients with glioblastoma in the SEER registry. Logistic regression modeled treatment utilization, and Cox regression estimated survival.
Results: Among 46,186 patients (50.0% aged 40-65; 43.0% aged ≥65; 58.0% male), 43.5% underwent gross total resection (GTR), 32.0% subtotal resection, and 24.5% no surgery; 71.8% received radiotherapy and 61.3% received chemotherapy. From 2000 to 2020, utilization increased for any surgery (OR/year 1.03, 95% CI 1.028-1.036), radiotherapy (1.01, 1.010-1.017), and chemotherapy (1.08, 1.081-1.088), whereas the likelihood of GTR vs subtotal resection declined (0.92, 0.915-0.922). Triple therapy increased modestly (1.01, 1.005-1.012) but plateaued at 30%. Older age, non-lobar tumors, unmarried status, and lower income predicted lower odds of triple therapy; after adjustment, calendar year showed a marginal decline (aOR/year 0.99, 0.99-1.00). Median overall survival improved from 6.0 to 10.0 months, with gains in fixed-time survival.
Conclusion: Standard triple therapy conferred the greatest survival benefit; however, GTR rates did not rise in recent years, and substantial disparities in receipt of standard care persisted. Efforts to expand equitable access and prioritize maximal safe resection are essential to achieve greater population-level survival gains.

#6633 PD-L1 expression-dependent efficacy of first-line immune checkpoint inhibitor plus chemotherapy in advanced gastric and gastroesophageal junction adenocarcinoma: A systematic review and meta-analysis of phase III trials.

Jialun Lyu[1], Zhenzhen Zhang[1], Krishnapriya Thangaretnam[1], Md Obaidul Islam[1], Jason Tang[2], Sabine Denize[3], Nadeem Bhat[1], Shoumin Zhu[4], Heng Lu[5], Dunfa Peng[1], Wael El Rifai[1], Zheng Chen[1]

[1]University of Miami Miller School of Medicine, Miami, FL,[2]American Heritage Schools, Plantation, FL,[3]Doctors Charter School of Miami Shores, Miami Shores, FL,[4]University of Miami - Sylvester Comprehensive Cancer Center, Miami, FL,[5]University of Miami, Miami, FL

Background: Immune checkpoint inhibitors (ICIs) have transformed the first-line management of advanced gastric and gastroesophageal junction adenocarcinoma. Several phase III trials have evaluated adding an ICI to chemotherapy, yet results have been heterogeneous. This study aimed to determine the efficacy and safety of first-line ICI plus chemotherapy versus chemotherapy alone and to define a clinically meaningful PD-L1 expression threshold through a systematic review and meta-analysis of randomized phase III trials.
Methods: PubMed, Embase, and the Cochrane Registry of Clinical Controlled Trials were systematically searched up to September 2025. The studies included in this analysis were Phase III randomized controlled trials that compared immune checkpoint inhibitors (ICI) combined with chemotherapy to chemotherapy alone in the treatment of patients with advanced or metastatic gastric cancer or GEJ adenocarcinoma. The combined hazard ratios (HRs) and 95% confidence intervals (CIs) for overall survival (OS) and progression-free survival (PFS) were calculated using a random-effects model. Subgroup analyses were conducted based on the PD-L1 combined positive score (CPS), age, gender, ECOG performance status score (ECOG), geographical region, liver metastasis and tumor location. Safety was assessed through the combined hazard ratio (RR) of grade ≥3 adverse events (AEs) and serious adverse events (SAEs).
Results: Eight phase III trials involving 7,127 patients with previously untreated, HER2-negative, advanced or metastatic gastric or GEJ adenocarcinoma were included. The pooled analysis showed significant improvement in OS (HR = 0.79, 95% CI 0.75-0.83) and PFS (HR = 0.71, 95% CI 0.65-0.79) with ICI plus chemotherapy versus chemotherapy alone. Treatment benefit increased with higher PD-L1 CPS: OS HRs were 0.90 (CPS < 1), 0.76 (CPS ≥ 1), 0.75 (CPS ≥ 5), and 0.65 (CPS ≥ 10); similar trends were seen for PFS (0.87, 0.73, 0.65, 0.63, respectively). Efficacy was consistent across major subgroups (all interaction $p > 0.05$). Combination therapy modestly increased grade ≥3 AEs (RR = 1.16, 95% CI 1.09-1.23) and SAEs (RR = 1.54, 95% CI 1.35-1.77) compared with chemotherapy alone.
Conclusions: First-line ICI plus chemotherapy significantly prolongs OS and PFS in advanced gastric and GEJ adenocarcinoma, with manageable toxicity. The magnitude of benefit is mainly driven by PD-L1 expression, supporting CPS as a clinically meaningful biomarker for treatment selection. ICI-based combinations should be considered a new standard of care across clinically relevant subgroups.

#6634 Real-world comparative outcomes of nivolumab + ipilimumab vs. atezolizumab + bevacizumab in advanced hepatocellular carcinoma: A TRINETX study.

Sameh Gomaa[1], **Abdelrahman Omara**[1], Hatem Ahmed[1], Imad Alabdul Razzak[1], Potdar Rashmika[1], Kuang-Yi Wen[2]

[1]Towerhealth Phoenixville Hospital, Phoenixville, PA,[2]Jefferson Health Sidney Kimmel Comprehensive Cancer Center, Philadelphia, PA

Hepatocellular carcinoma (HCC) is the second leading cause of cancer-related death. Atezolizumab plus Bevacizumab (ATZ+BEV) has transformed the treatment landscape for advanced HCC and is now a first-line option following the IMbrave150 trial. The Checkmate 040 randomized controlled trial has shown that Nivolumab plus Ipilimumab (NIVO+IPI) has improved long-term survival benefit. This study aims to compare outcomes of both treatment modalities for advanced HCC. Methods This is a retrospective cohort study utilizing the TriNetX database. Criteria included adult patients >18 years of age with Advanced HCC recently initiating (ATZ+BEV) or (NIVO+IPI). Outcomes are overall survival, the most recent AFP, AST, ALT, Bilirubin, INR, and Platelet count levels. Time to AFP to reach 0-40 ng/ml. Risk of developing hepatic encephalopathy or coma, hospitalization, and adverse events. Propensity score matching (PSM) was performed for demographics, lab results, MELD and ECOG scores, and confounding comorbidities. Results were expressed in the form of risk difference (RD) with 95% CI. Time to event endpoints using Kaplan-Meier curves and Cox proportional hazards models are reported as hazard ratios (HR) and log-rank P values. Results After matching, the cohort included 1979 patients in the (ATZ+BEV) group and 1973 patients in the (NIVO+IPI) group. (ATZ+BEV) showed significantly increased median survival 997 vs 504 days (HR 0.67, 95 % CI 0.61-0.74 log-rank $p < 0.0001$). However, mean AFP differed statistically (ATZ+BEV) 7,746 vs (NIVO+IPI) 17,495 $p = 0.006$. The time to normalization of AFP to below 40 was not significant ($p = 0.196$). (ATZ+BEV) Recipients experienced a high risk of inpatient visits (RD 2.08%, 95% CI -3.089, 7.257, $P = 0.43$). The risk of developing predefined adverse events was similar between regimens with nonsignificant RD. In conclusion, this real-world matched cohort (ATZ+BEV) conferred superior overall survival but was associated and greater healthcare utilization, while adverse event rates were comparable between treatments.

#6635 Evaluation of stage IV PTCL, NOS of the liver and gastrointestinal tract using a large national cancer database.

Olivia Davis[1], Taha Al-Juhaishi[2], Ryan Wilcox[3]

[1]Department of Internal Medicine, University of Michigan, Ann Arbor, MI,[2]Department of Internal Medicine, Division of Hematology/Oncology, University of Oklahoma, OU Health, Oklahoma City, OK,[3]Department of Internal Medicine, Division of Hematology/Oncology, University of Michigan, Ann Arbor, MI

Introduction: Peripheral T-cell lymphoma, not otherwise specified (PTCL, NOS) is a heterogeneous group of PTCL for which extranodal involvement is common and outcomes are poor. Previous research has suggested that primary disease site may impact overall survival (OS) for early-stage PTCL, NOS with worse outcomes for patients with gastrointestinal/genitourinary involvement. Little is known about the role of primary disease site in advanced stage disease and the impact of discrete gastrointestinal organ involvement. The purpose of this study was to investigate outcomes for stage IV PTCL, NOS with extranodal involvement using a national cancer database.
Methods: Patient and disease characteristics for individuals diagnosed with PTCL, NOS between 2000 and 2015 were extracted from the Surveillance, Epidemiology, and End Results (SEER) database. Patients with extranodal stage IV PTCL, NOS were isolated and included in the final analysis to reflect cases of extensive extranodal involvement. Primary disease sites were grouped into 11 distinct categories based on the most common primary sites identified. Our main primary disease sites of interest were liver and luminal GI tract, but other primary disease sites were analyzed as well with spleen serving as the comparison group. Patient and disease characteristics were analyzed using summary statistics. Survival analyses were performed using the Kaplan-Meier method and Cox proportional hazards models. Treatment status was identified for each case, and survival was compared between chemotherapy and non-chemotherapy groups for each primary disease site.
Results: A total of 464 patients were included in the final analysis. Median age was 63.0 years. Most patients were non-Hispanic white (60.8%) or male (62.3%). Thirteen cases (2.8%) involved primary disease of the liver while 70 cases (15.1%) involved the GI tract. Median OS for stage IV PTCL, NOS involving the liver was 1 month (95% CI (0-4)]. Median OS for stage IV PTCL, NOS of the GI tract was 4 months [95% CI (3-5)]. Primary disease of the liver was associated with worse lymphoma-specific survival [HR=2.400, 95% CI (1.081-5.328); p-value=0.0314]. Primary disease of the GI tract was associated with worse lymphoma-specific survival [HR=2.090, 95% CI (1.220-3.579); p-value=0.0073] and overall survival [HR=1.797, 95% CI (1.121-2.881); p-value=0.0149]. No statistically significant difference in overall survival or disease-specific survival was detected between treatment groups for PTCL, NOS of the liver [HR=0.780, 95% CI (0.185-3.287); p-value=0.7354].
Conclusions: Stage IV PTCL, NOS of the luminal GI tract was associated with worse OS and disease-specific survival. Stage IV PTCL, NOS of the liver was associated with worse disease-specific survival and may be considered a chemotherapy-resistant compartment.

#6636 Clinical outcomes of stage IV mucinous adenocarcinoma based on primary sites.

Wongi Woo[1], Seoin Kim[2], Jongwoo Kim[2], Vincent Lopez[1], Yeena Lee[1], Kirun Chohan[1], Young Kwang Chae[3]

[1]St.Joseph's Medical Center Stockton, Stockton, CA,[2]Metrowest Medical Center, Framingham, MA,[3]Northwestern Univ. Feinberg School of Medicine, Chicago, IL

Background: Mucinous adenocarcinoma (MAC) is an uncommon adenocarcinoma subtype that arises in multiple organs. Its biology and prognosis vary by site, and evidence supporting treatment benefit in stage IV MAC is limited. This study compared clinical features and survival outcomes of stage IV MAC across primary sites with emphasis on pulmonary MAC.
Methods: Clinical data were extracted from the Surveillance, Epidemiology, and End Results (SEER) 17 registries from 2000 to 2021. Patients initially diagnosed with stage IV MAC using the seventh or eighth TNM classification were included. Four major primary sites were analyzed: colorectal, lung, pancreas, and stomach. Exclusions were adenocarcinoma in situ, minimally invasive adenocarcinoma, stage I to III, and missing survival information. Demographic and clinicopathologic variables including age, sex, tumor stage, and socioeconomic factors were assessed with Cox proportional hazard regression to evaluate risk factors for overall survival. Survival differences by treatment were compared across sites by Kaplan Meier lwith log-rank test.
Results: A total of 1,036 patients were included: colorectal (n = 489), pulmonary (n = 160), pancreas (n = 331), and stomach (n = 56). Median age differed across sites ($p < 0.001$), with pulmonary MAC presenting at the oldest age and showing the highest proportion of advanced nodal disease ($p < 0.001$). Survival varied by primary site: Compared with colorectal MAC, pulmonary MAC (hazard ratio [HR] 1.66; 95% confidence interval [CI] 1.31-2.11; $p < 0.0001$) and stomach MAC (HR 1.64; 95% CI 1.13-2.37; $p = 0.009$) had worse outcomes, while pancreatic MAC had the poorest prognosis (HR 2.78; 95% CI 2.36-3.29; $p < 0.0001$). Surgery plus chemotherapy improved survival compared with chemotherapy alone in most sites (colorectal, HR 0.38, $p < 0.001$; lung, HR 0.49, $p = 0.024$; pancreas, HR 0.66, $p = 0.003$). Additionally, Higher income level was associated with better survival (HR 0.61; 95% CI 0.44-0.85; $p = 0.003$).
Conclusions: Stage IV MAC shows marked site specific survival differences. Pulmonary MAC has more favorable outcomes than pancreatic MAC, particularly with multimodal therapy. Tumor related macro/microenvironmental features and molecular profiles may contribute to these differences. The benefit of surgery plus chemotherapy was observed in most MAC. Prospective studies that integrate genomic and treatment related data are needed to guide personalized management.

#6637 Real world outcomes for patients with *KRAS G12D*-mutated non-small cell lung cancer: A University of California Health Data Warehouse retrospective analysis.

Jingtong Liang[1], Tali Azenkot[2], Sandip Patel[2]

[1]Department of Microbiology, Immunology, and Molecular Genetics, University of California Los Angeles - UCLA, Los Angeles, CA,[2]University of California San Diego - Moores Cancer Center, San Diego, CA

Background: KRAS is the most common driver mutation in non-small cell lung cancer (NSCLC), with *G12C* and *G12D* among its most frequent point mutations. Patients with *KRAS G12D* mutations are more likely to be never-smokers with worse response to immune checkpoint inhibitors (ICI) compared to those with *KRAS G12C*. As *KRAS G12D*-targeted therapies are under development, a greater understanding of real-world outcomes associated with current standard-of-care treatments is warranted.

Methods: We retrospectively analyzed NSCLC patients with and without *KRAS* mutations in the University of California Health Data Warehouse. Time on treatment (ToT) of first-line ICIs was estimated, and ICI-related overall survival (OS) was defined as the time from the first ICI infusion until death or loss to follow up. Kaplan-Meier analysis, Cox proportional hazards model, and student's t-test were applied.

Results: We identified 3,391 NSCLC patients, including 158 patients (5%) with *KRAS G12D*, and 735 (22%) with other *KRAS* mutations. Patients had a median (range) age of 64 (20-89) upon diagnosis and 57% were female (Table). Among 842 patient (25%) who received ICIs, 58% were treated with pembrolizumab, 20% with nivolumab (including 5% with ipilimumab), and 8% with either atezolizumab or durvalumab. Compared to patients with other *KRAS* mutations, there were more Hispanic patients with *KRAS G12D* (20 versus 36 patients, $p < 0.01$). When adjusting for age, race, and ethnicity in a Cox model, patients with *KRAS G12D* had similar ToT of ICIs (4.3 versus 4.8 months; $p = 0.25$; HR, 95%CI: 1.30, 0.83-2.04) and ICI-related OS (9.4 versus 14.0 months; $p = 0.36$; HR, 95%CI: 1.23, 0.79 - 1.92) as those with other *KRAS* mutations.

Conclusion: Harnessing the power of a structured, multicenter data collective, we describe real-world outcomes from patients with *KRAS G12D*-mutated NSCLC.

Table. Patient Characteristics.

		KRAS G12D NSCLC patients (n=158)	*KRAS NON-G12D* NSCLC patients (n=735)	P value	All NSCLC patients (n=3391)
Sex	Female	95 (60%)	431 (59%)	0.798	1932 (57%)
	Male	63 (40%)	304 (41%)		1458 (43%)
Age at diagnosis	Median (range)	67 (24-86)	61 (24-89)		64 (20-89)
Ethnicity	Hispanic	20 (13%)	36 (5%)	<0.001	259 (8%)
	Non-Hispanic	136 (86%)	665 (90%)		2994 (88%)
	Unknown	2 (1%)	34 (5%)		138 (4%)
Race	Asian	100 (63%)	512 (70%)	<0.01	1934 (57%)
	Black/African American	4 (3%)	44 (6%)		144 (4%)
	White	25 (16%)	95 (13%)		896 (26%)
	Others	26 (16%)	56 (4%)		325 (10%)
	Unknown	3 (2%)	28 (7%)		92 (3%)
Smoking	Never smoker	10 (6%)	36 (5%)	0.2337	342 (10%)
	Former smoker	8 (5%)	56 (8%)		189 (6%)
	Regular smoker	1 (1%)	20 (2%)		40 (1%)
	Unknown	139 (88%)	623 (85%)		2820 (83%)
ICI ToT (months)	Median	4.3	4.8	0.25	
ICI-related OS (months)	Median	9.4	14.0	0.36	

#6638 Real-World evidence of eflapegrastim (efla) usage in patients with gastrointestinal (GI) malignancies.

Howard Franklin[1], Jeffrey Crawford[2], John H. Baird[3], Kenneth Crist[1], Vincent Marino[4], Neil Shah[4], Lee S. Schwartzberg[5]

[1]Assertio Holdings, Inc., Lake Forest, IL,[2]Duke University Medical Center, Durham, NC,[3]City of Hope National Medical Center, Duarte, CA,[4]Atropos Health, Palo Alto, CA,[5]Renown Health-Pennington Cancer Institute, Reno, NV

Background: Long-acting granulocyte colony-stimulating factors (GCSFs) such as efla and pegfilgrastim (peg) are routinely used to prevent neutropenia in patients (pts) with cancer undergoing neutropenia-inducing chemotherapy. Registration studies compared efla to peg in pts with breast cancer; efla use in GI cancers is not as well characterized. We used real-world data to assess demographics, comorbidities, and clinical outcomes in pts receiving efla or peg and undergoing chemotherapy for various GI malignancies.
Methods: We conducted a retrospective, cross-sectional cohort analysis of pts with GI cancers (ie, malignant neoplasm of the anus, biliary tract, colon, rectum, esophagus, gall bladder, stomach, liver/intrahepatic ducts, pancreas, or small intestine) who received ≥1 dose of efla or peg with chemotherapy. Information was extracted from electronic health records of >60 million US pts in the Atropos Health Apollo data source (v1.1.0) between 2023 and 2025. Clinical outcomes measured through 15 (D15) and 30 (D30) days post-GCSF included febrile neutropenia (FN), absolute neutrophil count (ANC), platelet count, and adverse events (AEs; thrombocytopenia, back and bone pain, myalgia, GI and nontraumatic head bleeding, acute respiratory distress syndrome, and localized skin reaction).
Results: Pts (N=3353) receiving chemotherapy were identified (efla, n=106; peg, n=3247). Cancer types (>5%) in the efla and peg groups included pancreatic (36% each), colon (27% each), esophagus (10% vs 7%), rectum/rectosigmoid (9% vs 18%), gastric (8% vs 9%), and liver/intrahepatic ducts (7% vs 9%). Chemotherapy regimens included FOLFIRI (35% vs 21%) and FOLFOX (48% vs 34%). Pts receiving efla were older and had a higher burden of comorbidities than those receiving peg: mean (SD) age was 70.5 (8.3) vs 64.9 (12.3) y, respectively, and mean (SD) Charlson Comorbidity Index score was 12.0 (4.0) vs 10.5 (4.3), respectively. FN incidence was similar between pts receiving efla or peg through D15 (0.9% vs 1.3%) and D30 (0.9% vs 1.8%), with higher mean ANC observed with efla vs peg: 10.6 vs 6.4 x 10^9/L, respectively, through both D15 and D30. Thrombocytopenia occurred more frequently with efla than with peg (9.4% vs 7.8% through D15, 16.0% vs 11.0% through D30), with lower mean platelet counts through D15 (173 vs 216 x 10^3/μL) and D30 (188 vs 219 x 10^3/μL). Similar, low rates of AEs were reported through D30 with efla and peg.
Conclusions: Pts receiving chemotherapy for GI malignancies who were treated with efla were older and had a higher burden of comorbidities than those treated with peg. The incidence of FN was similar and low between treatments. Other AEs were also comparable between the two groups. These real-world findings suggest the safety and efficacy of efla in adult pts with GI malignancies receiving diverse chemotherapy regimens.

#6639 Impact of preexisting heart disease on survival and postoperative outcomes in pancreatic cancer: A TriNetX analysis.

Charlotte Burch[1], Jacob Lambdin[1], William Royster[1], Adam Khader[2], Leopoldo Fernandez[1], Raphael Louie[1], Ricardo Bello[1], Jose G. Trevino[3]

[1]VCU Massey Comprehensive Cancer Center, Richmond, VA,[2]U.S. Department of Veterans Affairs, Richmond, VA,[3]Div. of Surgical Oncology, VCU Massey Cancer Center, Richmond, VA

Background: Cardiovascular comorbidity is common among patients with pancreatic ductal adenocarcinoma (PDAC) and may influence both long-term survival and perioperative risk, yet its impact in contemporary practice is not well defined. We performed a retrospective database study using TriNetx, a multinational deidentified dataset, to identify patients with PDAC and to examine associations between heart disease, survival, and complications of pancreaticoduodenectomy (PD).
Methods: Using the TriNetx database, we identified patients with PDAC and stratified the cohort by presence or absence of heart disease (ischemic, structural, heart failure). Subgroup analysis was performed of patients who underwent PD. The primary outcome is overall survival, and secondary outcome is rate of post-PD complications. Propensity score matching was performed for age, sex, stage, and comorbidities. Kaplan-Meier curves and log-rank testing were used to determine survival between the groups and multivariable logistic regression was used to evaluate associations between heart disease and postoperative complications. Among patients undergoing PD, secondary outcomes include postoperative pancreatic leak, myocardial infarction (MI), acute kidney injury (AKI), surgical site infection (SSI), and venous thromboembolism (VTE), rates were evaluated using multivariable logistic regression.
Results: We identified 226,966 patients with PDAC, of whom 45,936 (20%) had preexisting heart disease and 181,030 (80%) did not; 12,840 underwent PD. Propensity matched median overall 5-year survival was 703 days for patients without heart disease versus 611 days for those without (HR = 0.90, $p < 0.0001$). In the matched surgical cohort, preexisting heart disease was associated with increased risk of post-operative myocardial infarction (RR = 3.34, $p < 0.0001$) and acute kidney injury (RR = 1.34, $p < 0.0001$) but not associated with post-operative pancreatic leak (RR = 1.11, $p = 0.18$), abscess (RR = 1.15, $p = 0.16$), or surgical site infection (RR = 1.13, $p = 0.16$). Among propensity matched cohorts of patients with PDAC and heart disease who did and did not undergo PD, those who underwent PD had significant improvement in 1-year overall survival (82% vs 63%, $p < 0.0001$).
Conclusions: In this large, real-world cohort of patients with PDAC, preexisting heart disease was an important determinant of overall survival and perioperative morbidity, with clinically meaningful differences in median survival and postoperative complication profiles. The benefit of PD does not seem to be lost to patients with cardiac risk factors, with significant improvement in overall survival seen in the group who underwent PD. These findings may inform risk stratification, treatment selection, and perioperative optimization strategies for this high-risk population.

#6640 Geriatric nutritional risk index at diagnosis predicts survival in pancreatic cancer.

Christina Grinstead, Saunjoo Yoon

University of Florida, Gainesville, FL

Introduction: Pancreatic cancer (PC) is one of the deadliest cancers with decreased overall survival due to cachexia and malnutrition. Early detection of nutritional risk is essential to improve treatment outcomes. Reliable and valid tools that are easily applicable in clinical settings will benefit to resolve this issue. The Geriatric Nutritional Risk Index (GNRI) utilizes commonly available clinical measures to assess nutritional risk, which may be useful in detecting risk as early as at diagnosis. Despite support for the GNRI in oncology, more research is needed to validate its use in PC. The purpose of this study was to examine the predictive value of the GNRI at diagnosis on survival in PC, controlling for demographics and cancer stage.
Methods: 924 adult patients with primary PC, visited between January 1, 2012, and July 31, 2020 were included in the retrospective study using de-identified data from the UF Health electronic health record. GNRI calculated using the Lorenz formula for ideal weight (Wlo). Weight and serum albumin closest to diagnosis within 120 days used. GNRI = [1.489 x albumin (g/L)] + [41.7 x (weight/Wlo)]. Scores categorized into 3 groups: high (<92), low (92-98), no risk (>98). Survival: days between diagnosis and death with censoring. Covariates: age, race, sex, stage. Multiple imputation used for GNRI missing data (290 patients, 31.4%). Statistical analysis: descriptive statistics, survival analysis using accelerated failure time (AFT) models.
Results: Results (Table 1) show GNRI at diagnosis, age, and stage predict survival, but not race or sex.
Conclusion: Higher GNRI scores at diagnosis predicted longer survival in PC, after controlling for other influential variables. With patients at low and no risk having over twice the survival compared to those at high risk, the GNRI is effective in early detection for need of proactive nutritional interventions. Further research is needed to investigate the long-term effects of changes in GNRI score on survival.

Table 1. Descriptive statistics and Survival analysis results

Variables		Total Sample(n=924)	GNRI groups			Univariate Results		Multivariate Results	
			High Risk (n=202)	Low Risk (n=129)	No Risk (n=303)	p-value	AF (95%CI)	p-value	AF (95%CI)
GNRI groups	High risk					Ref.	Ref.	Ref.	Ref.
	Low Risk					**0.0019**	2.26 (1.4-3.8)	**0.0046**	2.04 (1.25-3.34)
	No Risk					**<0.0001**	3.24 (2.1-4.9)	**<0.0001**	2.66 (1.77-4.00)
Survival (days)	Mean	1047	833	1091	1248

#6642 Metabolic predictors of chemotherapy response in pancreatic cancer.

Parnian Naji, Jordan Winter

Surgery, Cleveland University Hospitals, Cleveland, OH

INTRODUCTION: Chemotherapy response in pancreatic cancer (PC) varies and is monitored by CA 19-9. Since PC is linked to metabolic dysregulation, this study evaluates how patient baseline metabolic status (glucose, HbA1c, and BMI) relates to the longitudinal trend of CA 19-9 over six months in non-surgical PC patients.
METHODS: A TriNetX-based study design was employed to analyze longitudinal CA 19-9 trends over six months (representing the optimal chemotherapy response window) in PC patients who did not undergo surgical intervention. Patients were categorized into distinct strata based on (1) glucose levels: <150 mg/dL, 150-250 mg/dL, 251-350 mg/dL; (2) HbA1c levels: <7%, 7-10%, 10%-13.5%; and (3) BMI ranges: 20-25, 25-30, 30-35, 35-40.
RESULTS: For Glucose: Baseline CA 19-9 levels correlated positively with increasing glucose strata. Only the highest glucose group (251-350 mg/dL) showed a statistically significant CA 19-9 reduction during chemotherapy ($p<0.05$). Significant differences emerged when comparing this group to both lower groups ($p<0.05$). Across disease stages, higher glucose levels were consistently associated with greater CA 19-9 declines, indicating enhanced chemotherapy response. This association was most pronounced in locally advanced stages (2,3). For HbA1c: Baseline CA 19-9 values were lower in the high HbA1c group (10%-13.5%). Although within-group declines were not significant, between-group comparisons at six months indicated a significantly greater CA 19-9 reduction in the highest HbA1c group compared with both the <7% and 7-10% groups ($p<0.05$). For BMI: Baseline CA 19-9 levels did not differ across groups. During treatment, only the highest BMI group (35-40) demonstrated a significant decline in CA 19-9 ($p<0.05$), while lower BMI groups (20-35) did not. Patients with BMI 35-40 responded more favorably compared with lower BMI categories ($p<0.05$).
CONCLUSION: This study demonstrates that baseline metabolic factors modulate chemotherapy response in non-surgical PC patients. Higher glucose and BMI, as well as elevated HbA1c, were associated with greater CA 19-9 declines during chemotherapy, suggesting that metabolic status may influence treatment efficacy. These findings highlight the need for further studies and supportive metabolic interventions to optimize chemotherapy outcomes in pancreatic cancer.

#6643 Incidence and outcomes of brain metastasis in ER-low breast cancer: Insights from a National Cancer Database (NCDB).

Aanika B. Warner[1], Sarah Darmon[2], Jeremy Perkins[3], Matt Nealeigh[4], Craig D. Shriver[5], Stan Lipkowitz[6], Kangmin Zhu[7], Takeo Fujii[1]

[1]Women's Malignancies Branch, National Institutes of Health, Bethesda, MD,[2]The Henry M. Jackson Foundation for the Advancement of Military Medicine Inc.,[3]Walter Reed Medical Center, Bethesda, MD,[4]Memorial Sloan Kettering, New York City, NY,[5]Uniformed Services University, Bethesda, MD,[6]National Cancer Institute, Bethesda, MD,[7]Professor, Walter Reed National Military Medical Center, Rockville, MD

Background: Brain metastases (BrM) are aggressive and life-limiting complications that occur more frequently in triple-negative and HER2-positive breast cancers. The optimal cut-off value of estrogen receptor (ER) positivity has been under discussion for over a decade. Emerging data suggest that ER-low (1-10% ER staining) breast cancers exhibit clinical and biological features closer to ER-negative tumors, underscoring the need to investigate the incidence of brain metastasis among ER-low tumors to better identify high-risk populations and optimize patient selection for future clinical trials.

Methods: A retrospective cohort study was performed using the 2022 NCDB Participant User File. We collected patients with de novo stage IV breast cancer from 2018-2022, as 2018 was the first year that ER was defined as a continuous variable allowing categorization of ER. ER status was categorized as ER <1% (negative), 1-10% (low), and >10% (positive). Demographic, clinicopathologic, and treatment variables were compared across ER groups using chi-square or Fisher's exact tests for categorical variables and t-test or Kruskal-Wallis tests for continuous variables. Associations between ER status and brain metastases (BrM) at diagnosis (yes vs no) were evaluated using univariate logistic regression. Overall survival (OS) was assessed using cox proportional hazards model for patients who had BrM.

Results: A total of 18,783 patients were included in the analysis. Most were aged 60-69 years (30.5%), 77.0% were White, 85.0% had infiltrating ductal carcinoma, and 51.7% had grade 3 histology. ER status was negative in 23.0%, low in 3.1%, and positive in 73.9%. HER2 status was negative in 70.2%, low in 10.7%, positive in 14.5%, and unknown in 4.6%. Overall, 7.3% of patients had BrM at baseline. BrM were higher in ER-negative (12.0%) and ER-low (10.0%) tumors vs ER-positive disease (5.7%) [Odds ratio: ER-negative; 2.24 (95% CI: 2-2.52), ER-low; 1.82 (95%CI: 1.38-2.41) compared to ER-positive] in univariate logistic regression. OS among patients with BrM was similar between groups (ER-negative; HR 0.93 [0.71-1.22], ER-low; HR 0.91 [0.43-1.93] compared to ER-positive).

Conclusions: The proportion of BrM at diagnosis in ER-low breast cancer was more similar to ER-negative than ER-positive disease. However, the OS in patients with brain metastasis was similarly poor across all ER subtypes, suggesting that once brain involvement occurs, underlying histology has limited prognostic impact. These findings highlight the similar clinical features of ER-low and ER-negative disease, reinforce prompt evaluation of neurologic symptoms, and encourage greater inclusion of this subgroup in BrM-specific clinical trials.

#6644 Adjuvant dose-dense chemotherapy is not associated with improved recurrence-free survival in early-stage, node-negative, HER2-negative breast cancer.

Jonathan Shpigelman[1], Tasnem Alsebai[1], Kathy Robinson[2], Aum Nimavat[3], Ricardo Cossyleon[2], Krishna Rao[2]

[1]Department of Internal Medicine, SIU School of Medicine, Springfield, IL,[2]Department of Hematology/Oncology, Simmons Cancer Institute at SIU School of Medicine, Springfield, IL,[3]University of Illinois Urbana-Champaign, Urbana, IL

Introduction: Adjuvant dose-dense (DD) chemotherapy improves outcomes in early-stage, node-positive breast cancer and is often extrapolated to node-negative disease despite limited evidence and increased toxicity. Whether DD chemotherapy confers benefit in this low-risk population remains unclear.

Methods: Females aged ≥ 18 years with T1-T2, node-negative, HER2-negative breast cancer who received adjuvant DD or non-DD chemotherapy were retrospectively identified. Recurrence-free survival (RFS) was defined as the time from definitive surgery to first documented recurrence; patients without recurrence were right-censored at their last disease-free clinical or imaging assessment. Median follow-up duration was estimated using the reverse Kaplan-Meier method. RFS was compared using log-rank tests, and adjusted hazard ratios (HRs) were estimated using multivariable Cox proportional hazards regression.

Results: A total of 139 patients were included, 50 (36%) of whom received DD chemotherapy. Patients treated with DD chemotherapy were younger (50 vs. 56 years, $P < 0.001$) and had higher rates of T2 tumors (48% vs. 27%, $P = 0.012$), with no significant differences in hormone receptor status, tumor focality, or lymphovascular invasion. Over a median follow-up duration of 9.9 years (95% CI: 9.0-11.2), 17 patients (12%) developed recurrence (7/50 [14%] in the DD group and 10/89 [11%] in the non-DD group). There was no difference in RFS between DD and non-DD groups ($P_{\text{log-rank}} = 0.509$). After adjustment for age, hormone receptor status, T stage, tumor focality, and lymphovascular invasion, DD chemotherapy was not associated with reduced recurrence risk (HR: 0.97 [95% CI: 0.26-3.26], $P = 0.961$). These findings were consistent across T stages, with no difference in RFS in either T1 ($P_{\text{log-rank}} = 0.947$) or T2 ($P_{\text{log-rank}} = 0.755$) subgroups, and no significant interaction between treatment regimen and T stage ($P_{\text{interaction}} = 0.512$).

Conclusions: DD chemotherapy was not associated with a reduction in recurrence risk among patients with early-stage, node-negative, HER2-negative breast cancer, even after adjustment for clinical and pathological characteristics. Although limited by a low number of recurrence events, these findings suggest that routine use of DD chemotherapy in this low-risk population may not be justified. Larger prospective studies are needed to identify whether any subset of patients derives meaningful benefit.

#6645 Practice patterns impacting relative dose intensity of adjuvant capecitabine among triple negative breast cancer patients with residual disease following neoadjuvant chemotherapy.

Andrea House, Pratik Thakur, Blair Hoeting, Ruth Johnson, Brittany Sandoval, Julie Stephens, Daniel G. Stover, Sagar Sardesai, Tanun Jitwatcharakomol, Sasha Beyer, Arya M. Roy, Nerea Lopetegui-Lia, Dionisia M. Quiroga, Ashley P. Davenport, Gilbert Bader, Nicole O. Williams, Robert Wesolowski, Margaret E. Gatti-Mays, **Kai C. C. Johnson**

The Ohio State University - James Comprehensive Cancer Center, Columbus, OH

Background: This study aims to identify real-world practice pattern factors in capecitabine prescribing and assess which factors lead to higher relative dose intensity (RDI) to help address the variability in dosing strategies that limits the ability to assess the real-world effectiveness of adjuvant capecitabine.
Methods: This institutional retrospective study involved patients diagnosed with triple negative breast cancer from 1/1/2016 to 12/31/2023 who had residual disease following neoadjuvant chemotherapy and received ≥1 dose of adjuvant capecitabine. Our objective was to examine factors that influence the achievement of an RDI >66%, with standard dosing based on a total of 8 cycles of capecitabine over 21-day cycles. Factors included radiation therapy, dose reductions, prescribing schedule, age, race, tumor grade, nodal status, tumor size, residual cancer burden, lymphovascular invasion, and neoadjuvant pembrolizumab & carboplatin. We also examined whether RDI impacts invasive disease-free survival (iDFS) and overall survival (OS) using pre-defined percentiles (0-66%, 67-92%, & 93-100%).
Results: Of the 83 total patients, 45 were RDI≤66, 29 were RDI>67-92, & 9 were RDI≥92-100. Among all clinicopathologic factors listed above, only the use of a 7-day prescribing schedule for capecitabine (28-day cycle) had a meaningful reduction on one's ability to reach an RDI of >66% (p=0.0234). When examining univariate iDFS, no statistically significant difference was noted between RDI percentiles (p=0.667) but a trend towards improved iDFS was noted among higher RDI groups. The 5-year iDFS was 78.4% for RDI≤66, 77.9% for RDI>67-92, & 88.9% for RDI>93-100. Similarly for OS, no statistically significant difference was noted between RDI percentiles (p=0.395), but a trend towards improved OS was noted when RDI exceeded 66%. The 5-year OS was 82.1% for RDI≤66, 92.7% for RDI>67-92, & 88.9% for RDI>92-100.
Conclusion: Real world practice patterns can differ, but the implementation of weekly capecitabine dosing frequency has been shown in this study to significantly influence the ability to achieve higher RDI values. While no statistical difference in iDFS or OS was noted, a trend towards worsening outcomes was recorded for those with an RDI≤66%.

#6646 Impact of histology subtypes (ductal, lobular, and mixed ductal/lobular) on pathological complete response (pCR) following neoadjuvant chemotherapy (NAC) and chemoimmunotherapy (NACI) for estrogen receptor low (ER-low) HER2-negative breast cancer.

Kai C. C. Johnson, Brandon Slover, Yengeniya Gokun, Dionisia M. Quiroga, Sagar Sardesai, Sachin Jhawar, Nerea Lopetegui-Lia, Arya M. Roy, Gilbert Bader, Ashley P. Davenport, Nicole O. Williams, Robert Wesolowski, Margaret E. Gatti-Mays, Daniel G. Stover

The Ohio State University - James Comprehensive Cancer Center, Columbus, OH

Background: Little is known regarding mixed ductal/lobular histology subtypes of breast cancer in terms of how they influence the likelihood of pathologic complete response (pCR) following neoadjuvant chemotherapy (NAC) & chemoimmunotherapy (NACI). Similarly, there is no literature on how estrogen receptor (ER) expression percentiles influence the likelihood of pCR after NACI among this mixed histology subgroup.

Methods: We examined data within the National Cancer Database on those diagnosed with HER2-negative breast cancer between 2018-2022. We categorized patients based on histology subtype (ductal, lobular, & mixed) and ER percentiles, including ER-low (1-10%). Binary logistic regression was used to examine the relationship between pCR & histology type among patients with ER-low disease, adjusting for age, race, ethnicity, tumor grade, tumor size, nodal status, progesterone receptor percentiles, immunotherapy use, endocrine therapy use, & lymphovascular invasion (LVI). Additionally, adjusted Cox proportional hazards regression was fitted between overall survival (OS) and histology subtype.

Results: A total of 58072 ductal, 1330 mixed, & 3500 lobular cases with available residual disease data following neoadjuvant therapy were examined. Among those with ER-low expression (ductal: 3319, mixed: 35, lobular: 80), it was shown that 46.7% (n=1549), 31.4% (n=11), & 12.5% (n=10) of patients, respectively, achieved pCR, which was a significant difference on univariate analysis ($p<0.001$). On adjusted analysis, the difference in pCR between patients with mixed & ductal ER-low disease was non-significant (aOR 0.69, 95%CI 0.27-1.77, reference: ductal). However, lobular patients were associated with 79% lower odds of achieving pCR compared to ductal patients (aOR 0.21, 95%CI 0.08-0.54). On multivariate analysis, variables that significantly improved the odds of achieving pCR were histology type ($p=0.004$), younger age ($p=0.010$), smaller tumor size ($p<0.001$), use of immunotherapy ($p<0.001$), and absence of LVI ($p<0.001$). For OS, larger tumor size ($p<0.001$), positive nodal status ($p<0.001$), & presence of LVI ($p<0.001$) were associated with worsened OS whereas the receipt of endocrine therapy ($p=0.003$) significantly improved OS. Histology subtype was not significantly associated with differences in OS ($p=0.238$).

Conclusion: Tumors of mixed ductal/lobular histology behave more similarly to ductal disease in terms of NACI response, including ER-low subgroups. Additional factors, such as tumor size, LVI, and receipt of immunotherapy play a stronger role in predicting pCR, but the histology subtype remains an important variable to consider when deciding how best to sequence treatment for those with HER2-negative ER-expressing disease.

#6647 MCM2 and the origin licensing complex: A putative node of ER+/HER2- breast cancer therapy resistance.

Alekya Raghavan[1], Rosemary N. Plagens[2], Cynthia X. Ma[3], Stephanie Graff[4], Maryam Lustberg[5], Andrew Elliott[2], George W. Sledge[2], C. Kent Osborne[1], Mothaffar F. Rimawi[1], Ahmed Elkhanany[1], Rachel Schiff[1]

[1]Lester & Sue Smith Breast Center; Dan L Duncan Comprehensive Cancer Center; Department of Medicine, Baylor College of Medicine, Houston, TX,[2]Caris Life Sciences, Irving, TX,[3]Siteman Cancer Center, Washington University at St. Louis, St. Louis, MO,[4]Brown University Health Cancer Institute, Providence, RI,[5]Yale Cancer Center, New Haven, CT

Background: The use of CDK4/6 inhibitors (CDK4/6i) in combination with endocrine therapy (ET) has revolutionized treatment practices for advanced and high-risk ER+/HER2- breast cancer (BC) via effective inhibition of cell cycle activation. However, the vast majority of patients eventually progress on these therapies, underscoring the need for new treatment strategies to select patients, monitor response, and target novel therapeutic vulnerabilities. We previously reported that high expression of *MCM2* and its origin licensing complex (LC) is enriched in primary tumors refractory to CDK4/6i (SABCS22-P2-03-10). LC factors are transcriptionally regulated by E2F/MYC-driven programs, which are activated by diverse drivers of resistance. We propose that *MCM2*/LC expression may be a biomarker reflecting multiple ET and CDK4/6i resistance mechanisms, due to its role in cell cycle activation.

Methods: A retrospective review was conducted on a real-world, treatment-naive ER+/HER2- BC cohort of 1,960 largely metastatic patients with biopsies from breast or other sites (~50% each) that underwent NGS profiling (DNA: 592-gene panel/whole-exome; RNA: whole-transcriptome) at Caris Life Sciences. Tumors were stratified by *MCM2* or LC gene set mRNA into Q4 (high) versus Q1 (low; n=490 each), balanced for ET/CDK4/6i exposure, MSI-H, and TMB-H. Histology, PAM50, mutations (^{mut}), gene amplifications(^{amp}) and deletions(^{del}), and differential gene expression were analyzed. Chi-square, Fisher's Exact, or Mann-Whitney U tests were performed with Benjamini-Hochberg FDR for molecular variables (q<0.05).

Results: *MCM2*-high vs -low tumors were LumB-dominant (LumB 85.5% vs 39.8%; LumA 5.3% vs 56.3%, p<1e-63) with less lobular histology (6.1% vs 17.1%, p=0.0001). Transcriptomically, PI3K/AKT/mTOR, E2F/MYC targets, G2M checkpoint, and DNA repair hallmark pathways were enriched in *MCM2*-high (all FDR q<0.05). Genomically, *MCM2*-high harbored a higher frequency of *TP53*^{mut} (32.6% vs 16.6%, q=4e-6), *RB1*^{mut} (5.8% vs 1.2%, q=0.052), *CCND1*^{amp} (26% vs 6%, q=4.5e-11), *FGF3*/*4*/*19*^{amp} (~25% vs ~6%, q≤2.2e-10), *MYC*^{amp} (5.4% vs 0.8%, q=0.0136), and *CDKN2A*/*B*^{del} (*CDKN2A* 29.3% vs 15.5%, q=6.9e-4; *CDKN2B* 17.5% vs 7.3%, q=1.38e-3). Notably, *MCM2* and *MKI67* gene expression were highly correlated (Spearman's ρ=0.77, p<0.05). Very similar results were found for LC-high vs -low tumors.

Conclusions: In ER+/HER2- BC, high *MCM2*/LC is associated with LumB subtype, E2F/MYC and cell cycle activation, selection of *TP53* and *RB1* mutations, and *CCND1*/*MYC*/*FGF* amplifications. Our findings suggest that *MCM2* or LC mRNA may act as a surrogate marker for a network of oncogenic pathways previously identified to drive endocrine and CDK4/6i resistance. Future studies will evaluate *MCM2*/LC beyond proliferation, as a predictive biomarker for CDK4/6i-based regimens, as we have previously shown in the primary ET-treated setting (SABCS24-P1-03-20).

#6648 Association between area deprivation index (ADI) and treatment persistence (TP) with CDK4/6 inhibitors (CDK4/6i)in HR+/HER2- breast cancer.

Michelle L. Caetano[1], Jessica Liu[2], Britny R. Brown[1], Guannan Gong[3], Sameer Pandya[2], Salma Taghzout[1], Mariah Ramos[1], Edward Tupper[4], Annette Hood[5], Michael Zummo[5], Robert Legare[3], Jing Du[3], Maryam Lustberg[3]

[1]Pharmacy Practice and Clinical Research, University of Rhode Island College of Pharmacy, Kingston, RI,[2]Yale University, New Haven, CT,[3]Yale Cancer Center, New Haven, CT,[4]School of Pharmacy and Physician Assistant Studies, University of Saint Joseph, West Hartford, CT,[5]Department of Pharmacy, Yale New Haven Health, New Haven, CT

Background: CDK4/6i improve invasive disease-free and progression-free survival in HR-positive/HER2-negative breast cancer, yet real-world treatment persistence is suboptimal. ADI is a validated composite of neighborhood socioeconomic disadvantage that has been linked to worse medication adherence and health outcomes. Evaluating the association between ADI and persistence with CDK4/6i may identify equity-sensitive targets for intervention. The primary objective was to assess the association between ADI and TP in early (EBC) and metastatic (MBC) breast cancer.
Methods: We conducted a retrospective cohort study of patients prescribed CDK4/6i at Yale New Haven Health from February 2018 through December 2024. Artificial intelligence and natural language processing were used to extract structured electronic health record data. TP was defined using Epic Beacon treatment plan start and end dates and analyzed separately for EBC and MBC cohorts. Analyses used Python and R. Residential addresses at initiation were batch processed in R (ezADI), geocoded to 12-digit census block group GEOIDs via the U.S. Census Geocoder, and linked to 2020 Neighborhood Atlas ADI percentiles. Records with suppressed or missing ADI were excluded. ADI was dichotomized at the cohort median (above-median = more deprived; below-median = less deprived). Cox proportional hazards models, adjusting for medication, age, and gender were used to estimate hazard ratios (HR) for therapy discontinuation. Kaplan-Meier analyses summarized TP by ADI and CDK4/6i.
Results: A total of 1,363 patients were included in the MBC cohort and 298 in the EBC cohort. The median ADI across both cohorts was 30, which was used as the deprivation cutoff. In MBC, median ADI values were 19 (IQR 11-25) for the less-deprived groups and 47 (IQR 39-62) for the more-deprived groups across agents (abemaciclib, palbociclib, ribociclib). In multivariable Cox models adjusting for medication, age, and gender, higher deprivation was not significantly associated with earlier therapy discontinuation (HR = 0.97; 95 % CI, 0.86-1.08; p = 0.56). Older age was associated with shorter TP (HR = 1.01 per year; 95% CI, 1.00-1.01; $p < 0.001$).
In EBC, median ADI values were 19 (IQR 14-25) versus 47 (IQR 39-63) among abemaciclib-treated patients, and median ADI was 16 (IQR 10-22) versus 50 (IQR 41-59) among ribociclib-treated patients. ADI was not associated with increased discontinuation (HR = 0.98; 95 % CI, 0.78-1.22; p = 0.83).
Conclusions: In this large, real-world cohort, TP with CDK4/6i did not differ by neighborhood socioeconomic deprivation. Further work incorporating individual-level social determinants of health may better elucidate drivers of adherence and persistence disparities.

#6649 Comparative risk of secondary central nervous system metastases in metastatic non-small cell lung cancer: A real-world propensity-matched analysis of pembrolizumab vs atezolizumab monotherapy conducted on TriNetX.

Umer Rizwan[1], Athar Nawab[2], Syed Najafi[2], Karandeep Bawa[3], Fnu Muhibullah[2], Christian Kaftanic[2], Sunanda Tah[2], Sabir Hussain[4]

[1]Jefferson Einstein Philadelphia Hospital, Philadelphia, WV,[2]Internal Medicine Residency, West Virginia University Camden Clark Medical Center, Parkersburg, WV,[3]West Virginia School of Osteopathic Medicine, Lewisburg, WV,[4]Hematology and Oncology, West Virginia University Camden Clark Medical Center, Parkersburg, WV

Background: Bone and bone-marrow metastases significantly worsen morbidity in metastatic non-small cell lung cancer (mNSCLC). Comparative real-world data assessing skeletal metastatic progression between pembrolizumab and atezolizumab monotherapy remain limited.
Methods: We performed a retrospective cohort analysis using the TriNetX US Collaborative Network (69 HCOs). Stage IV mNSCLC patients treated with first-line pembrolizumab or atezolizumab monotherapy were identified. Propensity score matching (1:1) produced balanced cohorts (n=7,768 each). Outcomes were assessed over 365 days following treatment initiation. The primary endpoint was new-onset secondary bone/bone-marrow metastases (ICD-10 C79.51, C79.52, C79.5). Patients with prior skeletal metastases were excluded from outcome analyses.
Results: Following exclusions, 5,277 atezolizumab and 5,780 pembrolizumab patients were analyzed. Atezolizumab was associated with a significantly higher incidence of bone/bone-marrow metastases compared with pembrolizumab (16.5% vs 10.8%; RR 1.53; 95% CI 1.39-1.68; p<0.001). Kaplan-Meier analysis demonstrated reduced metastasis-free survival with atezolizumab (79.5% vs 86.8%, Log-Rank p<0.001). Hazard of metastatic progression was significantly higher with atezolizumab (HR 1.62; 95% CI 1.46-1.80). Atezolizumab also demonstrated a greater mean number of metastatic instances (0.93 vs 0.55; p<0.001).
Conclusions: In this large real-world matched cohort, atezolizumab monotherapy was associated with a significantly greater 1-year risk of secondary bone or bone-marrow metastases compared with pembrolizumab. These findings suggest clinically meaningful differences in skeletal metastatic progression between ICIs and warrant further prospective and mechanistic investigation.

#6650 Safety and efficacy of belzutifan for Von Hippel-Lindau disease-associated tumors.

Peixi Ge[1], Mohamed Atta[2], Nityasree Srialluri[2]

[1]Zanvyl Krieger School of Arts and Sciences, Johns Hopkins University, Baltimore, MD,[2]Johns Hopkins Medicine, Baltimore, MD

Background: Von Hippel-Lindau (VHL) disease is a rare autosomal dominant hereditary syndrome. Patients with VHL disease have a lifelong risk of developing clear-cell renal cell carcinoma (RCC), pancreatic neuroendocrine tumors (pNET), and hemangioblastomas of the central nervous system (CNS). Belzutifan, a hypoxia-inducible factor-2α inhibitor, received FDA approval in 2021 for adults with VHL-associated RCC, pNET, or CNS hemangioblastomas. Phase 2 data demonstrated objective response rates of 49%, 91%, and 30% by RECIST v1.1, respectively. However, real-world clinical outcomes remain limited. We evaluated the safety and efficacy of belzutifan in a real-world cohort.

Methods: We performed a retrospective review of adult patients (≥18 years) at Johns Hopkins Hospital between January 2016 and December 2024 who were genetically or clinically confirmed to have VHL and received belzutifan treatment. Eligible participants had at least one VHL-associated lesion and an available imaging following therapy. Patient demographics and clinical data were collected from EMR. Tumor and cyst characteristics at baseline and during follow-up were evaluated using CT or MRI. The sum of the longest diameters of evaluable lesions—including lesions < 1 cm—was used to assess tumor response. Secondary outcomes included duration of therapy, adverse events (AEs), and reasons for treatment discontinuation.

Results: Fourteen patients were included (mean ± SD age, 36 ± 14 years; 71% female). Among 10 patients with kidney lesions, 4/10 (40%) had ≥30% decrease over a median treatment duration of 18.5 months (range 12 - 27). All 3 (100%) patients with pNET had a ≥30% decrease, with a median follow-up of 24.7 months (range 12-32). Among 9 patients with CNS hemangioblastomas, 7/9 (78%) had ≥30% decrease over a median treatment duration of 18.1 months (range 7-28). The most common AEs were anemia (35%), dizziness (21%), and headache (21%). One patient discontinued treatment due to anemia, and another due to pregnancy planning.

Conclusion: In this real-world cohort of patients with VHL-associated lesions, belzutifan demonstrated clinical activity and a favorable safety profile across various VHL-associated neoplasms. Compared to phase II data, kidney lesions had lower response rates, while pNET and CNS hemangioblastomas showed higher responses. These differences may reflect variations in baseline imaging timing, small patient numbers, or occasional treatment interruptions due to insurance issues or missed doses. These findings support the continued use of belzutifan in VHL disease and highlight the need for larger studies to guide long-term management of VHL-associated tumors.

#6651 Characterizing the risk of infections with T-cell engagers in multiple myeloma.

Lindsay Fogel[1], Harsh Parmar[2], Shucen Wan[3], Adolfo Aleman[2], Pooja Phull[2], David Vesole[2], David S. Siegel[2], Rena Feinman[4], Claire L. Carter[1], Noa Biran[2]

[1]Hackensack Meridian School of Medicine, Nutley, NJ,[2]John Theurer Cancer Center, Hackensack Meridian Health, Hackensack, NJ,[3]Penn State Health Hershey Medical Center, Hershey, PA,[4]Center for Discovery and Innovation (Hackensack Meridian Health), Nutley, NJ

Background: T-cell engagers (TCE) have demonstrated remarkable efficacy in pts with heavily pretreated multiple myeloma; however, they are associated with a higher risk of infections which can contribute to increased morbidity and mortality. Here, we report our experience with infectious complications in relapsed/refractory MM pts receiving TCEs, characterizing their incidence, severity and risk factors.

Methods: This is a single-center retrospective study of 79 consecutive MM pts who received teclistamab (Tec), elranatamab (Elra) or talquetemab (Talq) between 1/2023-9/2025. Demographics, baseline disease characteristics, prior therapies, and toxicities were collected from electronic records. Infections were graded according to CTCAE version 5.0. Overall survival (OS) and progression-free survival (PFS) were estimated using Kaplan-Meier curves. Pts were separated into those with any grade infection versus those without. Univariate Cox proportional hazards regression was performed to identify variables associated with OS or PFS, with significant predictors ($p<0.05$) included in multivariable analysis.

Results: Seventy-nine pts received at least one dose of tec (n=29, 37%), talq (n=40, 51%), or elra (n=10, 13%). Median age was 68 yrs (range 39-86), 56% were female, and pts had a median of 5 prior lines of therapy (range 2-18). 44 pts (56%) had received prior BCMA-directed therapy. High risk cytogenetics were present in 36 pts (46%). A total of 109 infectious events were reported, with pts experiencing a median of 1 infectious event (range 0-12). Grade 1-2 CRS occurred in 58 pts (73%). 48 pts (61%) developed infections with rates varying by TCE: tec 19/29 (66%), talq 19/40 (48%), elra 8/10 (80%). Grade 3-4 infections occurred in 28 pts (35%). 10pts (13%) required intensive care, primarily due to bacterial pneumonia or sepsis. Four pts (5%) discontinued TCE due to infectious complications. 11 pts (14%) experienced infection related mortality while receiving or shortly after discontinuing TCE. At median follow-up of 11.9 mos (95% CI 10.1-14.0), mPFS was 5.5 mos (95% CI 3.7-11.3) and mOS was 16.3 mos (95% CI 7.9-21.6) for the entire cohort. Pts with infections had inferior outcomes compared to those without: PFS 4.2 vs 7.1 mos ($p=0.3$); OS 6.4 vs 17.4 mos ($p=0.027$). IVIG use was associated with improved PFS (14.6 vs 5.7 mos, $p=0.0002$) and OS (21.6 vs 7.9 mos, $p=0.0003$). On MVA, infection (HR 2.14, $p=0.030$) and IVIG (HR 0.28, $p=0.009$) were independent predictors of OS, while only IVIG significantly impacted PFS (HR 0.27, $p=0.0002$).

Conclusion: In this single-center analysis of heavily pretreated MM pts receiving TCEs, infectious complications were frequent, occurring in 61% pts. Infections were independently associated with inferior OS, while use of IVIG was associated with a 72% reduction in risk of death. Prospective studies are required to establish optimal timing and use of IVIG to demonstrate its efficacy in pts receiving TCEs.

#6652 Viral hepatitis paradox: Better outcomes in geriatric HCC transplant patients.

Ewan Kim[1], **Sungsu Park**[2], Amy Choi[3]

[1]Herricks High School, New Hyde Park, PA,[2]Daegu Catholic University School of Medicine, Daegu, Korea, Republic of,[3]Penn State College of Medicine, Hershey, PA

Hepatocellular carcinoma (HCC) causes significant mortality among elderly patients requiring liver transplantation. Traditional assumptions suggest viral hepatitis worsens transplant outcomes. We hypothesized that viral status would significantly influence survival outcomes, with potential interactions between HBV/HCV co-infection and metabolic comorbidities. We analyzed 7,890 geriatric patients (≥65 years) from the United Network for Organ Sharing database who received liver transplants for HCC, stratifying them by hepatitis B virus (HBV) and hepatitis C virus (HCV) status. Contrary to expectations, HCV-positive patients demonstrated significantly superior 5-year survival rates, with HBV+/HCV+ patients achieving 33.9% survival versus 27.3% for HBV-/HCV- patients. Mean survival time was 182 days longer for HBV+/HCV+ patients compared to HBV-/HCV- patients (1,361 vs. 1,179 days, $p<0.001$). Diabetes mellitus showed complex associations with outcomes, with particularly poor survival in coinfected diabetic patients (6.2% vs. 45.0% for non-diabetics). Age showed negative correlations with survival in all groups, relatively high in co-infected patients ($r=-0.160$). These findings challenge current transplant evaluation paradigms, suggesting viral status complexity requires reassessment in geriatric populations. Our results indicate that HCV should not automatically exclude elderly patients from transplant consideration, while diabetes requires careful management, especially in co-infected patients.

#6653 Hepatosplenic T-cell lymphoma gamma-delta versus alpha-beta: A comparative study of clinicopathologic features and outcomes.

Philip A. Haddad[1], Sireesha Vutukuri[2], Ankita Gupta[2]

[1]LSUHSC-S/ Overton Brooks VAMC, Shreveport, LA,[2]Overton Brooks VAMC, Shreveport, LA

Introduction: Hepatosplenic T-cell lymphoma (HSTCL) is an aggressive rare extranodal T-cell lymphoma. It is most commonly derived from γδ T cells, though an αβ variant has been increasingly recognized. While γδ HSTCL is considered the prototypic form and accounts for the majority of cases, the clinical significance, biological behavior, and prognostic impact of αβ versus γδ T-cell receptor (TCR) expression remain poorly defined due to the scarcity of comparative data. We conducted this study to compare the clinicopathological characteristics of both subtypes.
Methods: To study the clinicopathologic characteristics, prognostic factors, and overall survival (OS), we compiled a pooled database of HSTCL cases. Patients were stratified into two groups based on TCR expression: γδ-HSTCL and αβ-HSTCL. Descriptive statistics were used to summarize baseline characteristics. Continuous variables were compared using t-test, and categorical variables by χ^2 test. Survival outcomes were analyzed using Kaplan-Meier methodology.
Results: A total of 226 patients with HSTCL were identified, 52 αβ and 174 γδ. The median age at diagnosis was similar between subgroups (30 vs 34 years), with a slight male predominance in both, more pronounced in the γδ cohort (59% vs 72%). A history of immune suppression was frequent in both groups (76% αβ vs 71% γδ), with comparable durations of exposure (median 4.7 vs 5 years) and latency to lymphoma onset (4 vs 5 years). Both cohorts had high rates of hepatosplenomegaly (100% αβ vs 99% γδ) and marrow infiltration (100% in both). Cytopenias were common and showed no significant differences: anemia (90% vs 95%), leukopenia (66% vs 61%), and thrombocytopenia (86% vs 88%). Median LDH levels were elevated in both subtypes (797.5 vs 968 U/L). Median overall survival was similarly poor—10 months in αβ and 11 months in γδ HSTCL. Immunophenotypically, the two subtypes shared high expression of CD2, CD3, CD7, CD16, CD38, and CD56. However, CD5 was more frequently expressed in αβ cases (39% vs 14%, $P = 0.001$) as well as CD8 positivity (57% vs 31%, $P = 0.005$) and CD57 (41% vs 5%, $P = 0.01$). Trisomy 8 (33% vs 36%) and i/r 7 (72% vs 75%) were prevalent and comparable between groups.
Conclusion: In this large comparative cohort, αβ and γδ HSTCL demonstrated strikingly similar clinical features, patterns of immune suppression, cytopenias, organ involvement, cytogenetic abnormalities, and dismal overall survival. However, significant immunophenotypic differences—most notably higher expression of CD5, CD8, and CD57 in αβ HSTCL—suggest underlying biologic divergence between the two TCR-defined subtypes. These findings highlight that while both forms remain clinically indistinguishable at presentation and equally lethal, their distinct immunoprofiles may have diagnostic relevance and could inform future exploration of targeted therapeutic strategies.

#6654 Assessing skin cancer risk in systemic sclerosis patients with organ transplantation: A cohort study.

Ruhi Kanwar[1], Ellen Anshelevich[2], Goranit Sakunchotpanit[3], Kevin Fettel[4], Vinod E. Nambudiri[1]

[1]Cutaneous Oncology Program, Dana-Farber Cancer Institute, Boston, Massachusetts, Harvard Medical School, Boston, MA,[2]Hackensack Meridian School of Medicine, Nutley, NJ,[3]Tufts University School of Medicine, Boston, MA,[4]Harvard Medical School, Boston, MA

Systemic sclerosis (SSc) is an autoimmune condition characterized by fibrosis of the skin and organs. Cancer is a well-known association of SSc, with a higher incidence in men, and with particular evidence of elevated lung, breast, and melanoma incidence. In addition, non-melanoma skin cancer (NMSC) has been reported to have increased incidence, with one study showing higher incidence in women compared to men. The impact of solid organ or hematopoietic transplantations - known to confer increased risk of NMSC - on skin cancer risk have not been specifically characterized in the SSc population. We sought to explore skin cancer incidence in SSc patients with a history of kidney, bone marrow (BM), or lung transplantation.

The Research Patient Data Registry of Mass General Brigham was queried from 1979 to 2024 for SSc and lung, kidney, or BM transplantation in clinical documentation. For the unexposed cohort, patients with SSc and no transplantation (2:1 controls per case) were matched by age, sex, and race. For each exposed patient, up to one matched unexposed patient was included in the analysis. Among 178 exposed and 374 unexposed extracted, 48 SSc patients with transplant and 45 SSc patients without transplant were included after chart review. NMSC risk was calculated with either basal cell carcinoma (BCC) or squamous cell carcinoma (SCC).

We observed an increased association of skin cancer with transplantation (relative risk (RR) 5.31, 95% p=0.0047), specifically with NMSC (RR 4.69, p=0.0097), compared to non-transplantation. In addition, when examining only skin cancers that emerged after transplantation, there was an increased risk compared to controls (RR 3.75, p=0.0306), specifically with SCC (RR=4.69, p=0.0384). Subsequent subgroup analysis of transplanted patients by sex showed that females had an increased risk of skin cancer (RR 3.7, p=0.0298) and NMSC (RR 3.33, p=0.0468), while males did not.

Cutaneous malignancy amongst SSc patients remains understudied, and characterizing the contribution of transplantation to observed increased risks is necessary. Our results suggest that patients with SSc undergoing transplantation -- specifically females -- may have an increased risk of developing both NMSC and skin cancers compared to those without transplantation. Limitations include our study's retrospective nature and limited generalizability due use of one health system.

#6655 Characterization of adverse cutaneous effects in the setting of ponatinib, bosutinib, andasciminib for chronic myeloid leukemia patients.

Ruhi Kanwar[1], Juna Khang[2], Goranit Sakunchotpanit[3], Ruhi Nayak[2], Nicole R. LeBoeuf[1], Vinod E. Nambudiri[1]

[1]Cutaneous Oncology Program, Dana-Farber Cancer Institute, Boston, Massachusetts, Harvard Medical School, Boston, MA,[2]Harvard Medical School, Boston, MA,[3]Tufts University School of Medicine, Boston, MA

BCR-ABL tyrosine kinase inhibitors (TKIs) are used in the treatment of chronic myeloid leukemia (CML) and include second- and third-generation agents: ponatinib, bosutinib, and asciminib. While cutaneous adverse events (cAEs) of first-generation TKIs such as imatinib are well-documented, real-world reports involving newer agents remain limited and poorly described. We therefore aimed to characterize the range of cAEs in patients with CML receiving ponatinib, bosutinib, or asciminib.

We conducted a retrospective chart review queried from the Research Patient Data Registry of Mass General Brigham from 1979 to 2024. We excluded patients without CML or medication use. 291 patients met inclusion criteria, with 92 (32.3%) receiving ponatinib, 182 (62.5%) receiving bosutinib, and 111 (38.1%) receiving asciminib. 37 (12.7%) patients developed a documented cAE, with 1 patient developing 2 different cAEs. There were 38 total discrete cAEs, including rashes (cAEs=38), pruritus (cAEs=20), xerosis (cAEs=5), hyperpigmentation (cAEs=2) and squamous cell carcinoma (SCC) (cAEs=1). All drugs resulted in acneiform eruptions and maculopapular or papular eruptions. Ponatinib also induced pityriasis rubra pilaris-like, keratosis pilaris-like, petechial, and ichthyosiform eruptions. Photosensitive rashes occurred on ponatinib and bosutinib, while pustular eruptions, plaques, and eczematous eruptions occurred on bosutinib and ascimnib. cAEs were treated with topical steroids (cAEs=14), emollients (cAEs=10), and antihistamines (cAEs=9); TKI dose was held or discontinued for 17 events.

The median duration of cAE ranged from 35 days with asciminib to 91.5 days with bosutinib. 60.5% of events presented within 90 days of medication initiation. No patients required hospitalization for the cAEs; the majority were grade 1 severity (57.2%). There was a significant association between female sex and cAE development (OR 3.30, p=0.003), but no association for age, race, ethnicity, prior CML treatments, and initial dosage.

We present a detailed characterization of real-world presentations of cAEs developing on ponatinib, bosutinib, and asciminib, with observed incidence rates of 16.3%, 8.8%, and 6.3%, respectively. The significantly increased risk in females aligns with prior literature, possibly due to differences in body type, medication adherence, or reporting. Our limitations include retrospective design and single institution use.

#6659 Spatial proteo-transcriptomic profiling of pancreatic adenocarcinoma unveils distinct malignant subtype-associated immune and stromal functional states.

Beatrice Wendler Awasthi[1], Nicole A. Lester[1], Deniz Guney Olgun[2], Yi Cui[3], Gabriel Francisco Pozo Mattos Pereira[1], Nicholas Caldwell[1], Mari Mino-Kenudson[1], Maria Ganci[1], Manisha Madhavan[1], Sierra Mckinzie[4], Jung Woo Bae[1], Xunqin Yin[1], Shanshan He[4], PRAJAN DIVAKAR[3], Martin Hemberg[5], Joe Beechem[3], William L. Hwang[1]

[1]Massachusetts General Hospital, Boston, MA,[2]University of Virginia, Charlottesville, VA,[3]Bruker Spatial Biology, Seattle, WA,[4]Bruker Spatial Biology, Seattle, MA,[5]Brigham and Women's Hospital, Boston, MA

Pancreatic adenocarcinoma (PDAC) remains one of the leading causes of cancer mortality. It has become increasingly clear that the spatial architecture of tumors can drastically influence treatment response and prognosis. Advances in large-scale spatial profiling have enabled detailed in situ mapping of cell types and states, which has unveiled multicellular neighborhoods and interactions associated with distinct clinicopathologic features. For example, we previously applied whole-transcriptome spatial molecular imaging (WT-SMI; ~19,000 protein-coding genes) to a prospective cohort of matched pre- and post-chemoradiation PDAC specimens (DF/HCC 18-469) and identified consistent treatment-induced transcriptional shifts in the tumor microenvironment (TME) that were linked to specific ligand-receptor interactions within distinct multicellular neighborhoods. However, many immune cell populations are poorly characterized at the transcriptional level and are better captured using proteomics. To address this gap, we leveraged a recently commercialized multi-omic SMI platform developed by Bruker Spatial/NanoString Technologies that enables concurrent WT and 64-plex protein analysis of a single tissue section to profile a human PDAC tissue microarray (TMA). Transcriptome-level data was used to assign broad cell type labels, and protein stains guided nested subtyping of immune cells by applying HieraType. This approach enabled the annotation of >450,000 cells at a coverage of >1000 transcripts and >750 unique genes per cell, in addition to quantitative staining of 64 protein targets per cell. Using spatial non-negative matrix factorization, we established cellular signatures for distinct neighborhoods composed of malignant cells, stromal cells and immune cells. Preliminary analyses suggest that different transcriptional neighborhoods correlate with distinct survival outcomes. We then used spatial proteomics data to guide functional annotation of immune cells within cellular neighborhoods. This enabled detailed differentiation of immune subtype populations and their interactions with other cells in the TME, which may uncover new mechanisms of immune evasion and therapeutic resistance. This study highlights a novel spatial multi-omics approach that enables more accurate characterization of key multicellular neighborhoods associated with treatment response and clinical prognosis.

#6660 CellScape Quality Control (CSQC): A tissue- and protein-agnostic platform for spatial proteomics quality assessment.

Daniel Jimenez-Sanchez[1], Brian J. Lane[1], Matthew H. Ingalls[1], Charles Eldon Jackson[1], Steven T. Lott[1], Adam Northcutt[1], Arne Christians[2], Anke Brix[2], Jennifer Brooks[2], Oliver Braubach[1]

[1]Bruker Spatial Biology, St. Louis, MO,[2]Bruker Spatial Biology, Hanover, Germany

Introduction: Spatial proteomics is an emerging diagnostic tool for precision oncology, yet data reproducibility across tissue sections and batches remains a major obstacle towards achieving robust biomarker discovery and clinically actionable results. Variability in tissue quality, tissue preparation, antibody performance, and imaging conditions all introduce artifacts that compromise quantitative accuracy. Manual quality control of imaging data is thus essential, but it is very time consuming and subjective. A standardized, automated, and quantitative quality control framework is therefore essential to support realistic adoption of spatial proteomic workflows in precision oncology.
Methods: We developed CellScape Quality Control (CSQC), a machine learning-based framework for automated stain quality assessment and tissue vetting. CSQC was trained on >100 samples from >20 tissue types from ten CellScape™ precise spatial phenotyping instruments across laboratories. The dataset included more than 50 biomarkers representing nuclear, membrane, and cytoplasmic targets across multiple antibody clones, stain protocols, and imaging magnifications (10x and 20x). Expert annotations were used as ground truth for model training and validation.
Results: CSQC achieved a mean IoU >0.7 for background, artifact, and usable tissue detection, showing strong concordance with expert annotations. The system automatically flagged suboptimal staining and batch-level artifacts, thereby enabling harmonization across instruments and sites. The deployment of CSQC reduced manual review time from several hours to minutes per sample, and thereby allowed rapid scaling of downstream analyses to dozens of slides and proteins analyzed by a single operator in a given time frame. In addition, we observed a noticeable improvement in downstream marker quantification and reproducibility following CSQC vetting.
Conclusion: CSQC provides a standardized, quantitative, and scalable approach to stain and tissue quality control, supporting robust multisite spatial proteomics workflows on the CellScape precise spatial phenotyping platform. This framework facilitates assay harmonization, benchmarked reproducibility, and reliable spatial biomarker discovery for clinical translation.

#6661 High quality whole transcriptome RNA-sequencing from challenging clinical samples.

Pieter Mestdagh, Lisa Van Den Bossche, Thomas Van Wunsel, Hilke Spooren, Emmanuel Riviere, Jan Van de Velde, Ana Carolina Elisa Fierro Gutierrez, Nathalie Bernard, Lien Heyrman, Dirk Goossens, Jurgen Del Favero

CellCarta, Antwerp, Belgium

RNA sequencing (RNA-seq) of clinical specimens poses several challenges due to limited sample material, RNA fragmentation, and high fractions of ribosomal RNA (rRNA) and globin RNA. These factors often result in elevated PCR duplication rates and reduced library complexity, compromising transcriptome data quality and downstream analyses. We evaluated the Watchmaker Genomics RNA library prep with Polaris Depletion workflow and compared its performance to a standard RNA-seq and exome capture workflow. Performance was assessed across a range of sample types, including reference materials, whole blood, and tumor FFPE samples with varying RNA integrity.The Polaris Depletion workflow achieved efficient depletion of both rRNA (< 5%) and globin RNA (< 1% in whole blood), compared to > 5% rRNA and > 50% globin RNA observed with the standard exome capture workflow. PCR duplication rates were approximately twofold lower with the Polaris Depletion workflow (30.2%) versus the standard exome capture approach (62.5%). Notably, the Polaris Depletion workflow demonstrated robust performance across samples of differing RNA quality, provided sufficient RNA input was used for library preparation. Overall performance of the Polaris Depletion workflow was highly reproducible, as confirmed through inter-operator and inter-laboratory experiments.In summary, the Watchmaker Genomics RNA library prep with Polaris Depletion workflow enables the generation of high-quality RNA-seq libraries with efficient rRNA and globin depletion, reduced PCR duplication, and reliable quantification of both coding and non-coding transcripts. These results demonstrate that RNA sequencing of challenging clinical samples can be effectively performed without the need for costly and time-intensive exome capture, thereby improving both sensitivity and workflow efficiency.

#6662 Spatial genomics reveals microenvironmental programs associated with organ-specific metastatic propensity in prostate cancer.

Maryam Ranjpour, Mohamed Omar

Cedars-Sinai Medical Center, Los Angeles, CA

Metastatic prostate cancer (PCa) exhibits pronounced organotropism, particularly to bone, yet the spatially resolved molecular features within primary tumors that correlate with organ-specific dissemination patterns remain poorly characterized. Although bulk and single-cell transcriptomic studies have highlighted microenvironmental heterogeneity in PCa, no validated spatial genomic signatures currently exist that link intratumoral ecosystems to metastatic risk and organotropism. To address this gap, we apply high-resolution spatial genomic profiling with Xenium (10x Genomics) across human tissues and genetically engineered mouse models (GEMMs) that recapitulate PCa initiation, progression, and metastatic competence. GEMMs were used to characterize spatially resolved transcriptional programs and tumor microenvironment (TME) interactions across defined biological stages, enabling controlled dissection of the stromal, epithelial, immune, and neurovascular states associated with metastatic readiness. In parallel, we profile paired primary tumors and anatomically distinct metastatic lesions from PCa patients enrolled in the Cedars-Sinai Molecular Twin Project, including metastases to lymph nodes, bone, liver, and soft tissues. Integrative analyses demonstrate organ-associated spatial gene expression programs and multicellular niches within the primary tumor that mirror the molecular landscapes of their eventual metastatic destinations. These include bone-associated niches enriched for osteomimicry programs, ECM-remodeling fibroblasts, and osteotropic ligand-receptor signaling; nodal-associated niches defined by immune-evasive epithelial states, lymphoid-interacting stromal programs, and chemokine circuits guiding lymphatic dissemination; and visceral-associated niches characterized by metabolic rewiring, hepatotropic signaling modules, and endothelial states predisposing to vascular invasion. These spatially resolved niches highlight shared biological modules that mediate, or are associated with, organ-specific metastatic behavior. Notably, several site-specific programs are detectable within the primary tumor prior to clinical metastasis, suggesting that metastatic organotropism is encoded early through stable TME-tumor interactions. Collectively, this work establishes a cross-species framework for mapping microenvironmentally encoded metastatic trajectories and identifies spatial genomic biomarkers with potential clinical utility for predicting organ-specific metastatic risk. These findings has the potential for identifying new therapeutic strategies aimed at disrupting early metastatic niches before dissemination occurs.

#6663 Integrated spatial transcriptomic and proteomic profiling reveals tumor-immune niches driving heterogeneity and resistance in clear cell renal cell carcinoma.

Qanber Raza, **Nick Zabinyakov**, Lauren Tracey, Liang Lim, Christina Loh

Standard BioTools, Markham, ON, Canada

Clear cell renal cell carcinoma (ccRCC) is a biologically heterogeneous malignancy shaped by complex tumor immune microenvironment interactions. Single-modality profiling often fails to capture this complexity. Spatial transcriptomics enables high-resolution mapping of gene expression, but proteins mediate functional states, signaling and therapeutic targets. Sequential integration of Imaging Mass Cytometry™ (IMC™) technology after spatial transcriptomics on the same tissue section adds a critical layer by quantifying protein expression and post-translational markers while preserving spatial context. Unlike fluorescence-based multiplexing, IMC technology avoids spectral overlap and autofluorescence, making it ideal for post-transcriptomic analysis. This multi-omic approach enables direct correlation of transcriptomic signatures with protein-level functional states, uncovering mechanisms of immune evasion and therapeutic resistance that remain hidden using transcriptomics alone. FFPE tumor sections from Stage 3 ccRCC patient were analyzed using spatial transcriptomics (Xenium 5K assay) followed by hematoxylin and eosin (H&E) staining and IMC with a 43-marker immuno-oncology panel. Data was coregistered for single-cell resolution integration of RNA, H&E and protein expression. Integrated analysis provided unprecedented resolution of the ccRCC microenvironment: Functional subtyping identified metabolically active tumor cells (high LDHA, GLUT-1), TIM-3+ tumor populations with angiogenic potential, and spatially organized immune niches such as tertiary lymphoid structures (TLS) containing B cells, activated T cells and macrophages. Combined profiling revealed spatial proximity and interaction of immune cells (CD4, CD8, CD20, CD38, TCF1, CD11c), stromal components (αSMA, vimentin, fibronectin), and vascular features (CD34, PLVAP) associated with tissue remodeling and dysfunctionality. Unsupervised clustering of RNA and protein data revealed robust immune activation in TLS and differentiated tumor cell states with metastatic potential. IMC analysis after spatial transcriptomics enables pathologist-in-the-loop evaluation, advancing diagnosis from morphology-based to molecularly informed and spatially precise interpretation of tumor heterogeneity and disease progression. Spatial multi-omic profiling delivers unprecedented resolution of tumor and immune landscapes in ccRCC, supporting development of spatially informed biomarkers and targeted therapies. Clinically, this approach could potentially refine patient stratification, identify resistance-associated niches, and guide combination strategies targeting both tumor and immune compartments. *For Research Use Only. Not for use in diagnostic procedures.*

#6664 Single-cell spatial proteomics of 1200+ protein targets in tumor microenvironments from diverse cancers using GeoMx Discovery Proteome Atlas.

Terence C. Theisen, Alexa E. Lasley, Giang Ong, Megan Vandenberg, Brian Filanoski, Lori Hamanishi, Erin Piazza, Sayani Bhattacharjee, Courtney Anderson, Mirko Corselli, Prajan Divakar, Margaret L. Hoang, Joseph M. Beechem

Research and Development, Bruker Spatial Biology, Seattle, WA

The tumor microenvironment (TME) is a heterogeneous landscape where immune cells interact with malignant cells to influence cancer progression and therapeutic response, but to date, dissecting the spatial proteomic signature of the TME has been limited by plex and resolution. Here we introduce the GeoMx® Discovery Proteome Atlas (DPA), a high-plex antibody-based spatial proteomic assay, and use it to characterize, for the first time, the 1200+ plex spatial proteomes of hundreds of individually selected cells from more than 8 FFPE cancer samples. GeoMx DPA includes 130+ Post-Translational Modification-targeting antibodies, allowing for the interrogation of phosphorylation, glycosylation, and ubiquitination modifications missed by transcriptomics or other proteomic methods. We developed and optimized a protocol to collect Regions of Interest (ROIs) at single-cell resolution with segmentation strategies on the GeoMx® Digital Spatial Profiler (DSP) platform (e.g., CD45+ leukocyte and CD3+ T cell markers). We mapped immune infiltration patterns and activation states within distinct tumor niches by comparing ROIs encompassing single cells and ROIs with hundreds of cells. Our analyses revealed tissue- and cancer-specific proteomic signatures, including differential expression of checkpoint molecules (PD-1, CTLA-4, LAG3), kinases, and inflammatory mediators. We examine the expression profiles of tumor infiltrating lymphocytes (T cells, B cells, and neutrophils) in different cancers and the dependency upon tumor spatial proximity. We also compare the single-cell proteomes from cancer tissues to single cell DPA data from more than 30 cell lines to identify protein targets differentially expressed based on cancer or cell line lineage. By integrating high-plex protein data with spatial segmentation strategies, we are providing the field with a critical tool to find more predictive biomarkers to drug response (e.g., PD-L1). The ability to resolve the spatial proteomic patterns of more than 1200 targets within tumor microenvironments, right down to the level of single cells, will enable deeper insights into cellular interactions and inform new approaches for patient treatment.

#6665 Validation of two melanoma biomarkers and two novel ready-to-use multiplex immunofluorescence panels for spatial profiling of the stromal and vascular compartments in the tumor microenviroment.

Paula Juricic, Francois Rivest, Clara Sinthon, Jade Nguyen, Isabelle Blanc, Bastian Nicolai, Alexandre Kehren, **Saska Brajkovic**

Lunaphore, a Bio-Techne brand, Tolochenaz, Switzerland

The use of multiplex immunofluorescence (mIF) to study the tumor microenvironment (TME) has significantly advanced our understanding of spatial dynamics within tumors. This technique has emerged as a valuable tool for identifying biomarkers and therapeutic targets. Despite its growing adoption, mIF protocols remain complex and technically demanding. Their manual execution and reliance on dedicated reagents make them time-consuming and expensive. Additionally, concerns persist regarding their reproducibility and transferability across different tissue types. Ready-to-use, validated antibody panels, such as the SPYRE™ Core Panels, help address these challenges.

In this study, we demonstrate the development and validation of two new antibody panels covering relevant stromal and vessel biomarkers to enable spatial analysis of the TME on the COMET™ platform across various tissue types as well as two additional antibodies against SOX10 and S100B optimized for melanoma studies. The stroma panel enables simultaneous detection of Vimentin, E-Cadherin, Collagen I, and FAP, while the vessel panel contains CD31, CD34, Podoplanin, and LYVE-1. Formalin-fixed paraffin-embedded human tissue sections from a 24-cores multi-organ tissue microarray and whole-section melanoma samples were stained on COMET™ by fully automated sequential immunofluorescence (seqIF™, PMID: 37813886). Staining and detection are done via indirect immunofluorescence using unlabeled primary antibodies and fluorophore conjugated secondary antibodies. Both panels were developed and validated on several tumoral and non-tumoral tissues at the same time. The sections retrieved from COMET™ after seqIF™, were stained by a histology facility with standard immunohistochemistry (IHC) established for pathological diagnosis to compare seqIF™ and IHC staining patterns and verify antibody specificity. All markers demonstrate accurate detection with specific seqIF™ staining, comparable to gold-standard IHC counterparts, as well as robust performance across multiple tissues. Protocols were optimized to achieve high staining quality for all ten markers in terms of sensitivity and signal-to-background ratio. The repeatability and reproducibility of the automated stainings on the COMET™ platform was verified by day-to-day tests on one instrument and tests among multiple ones.

Our validated SPYRE™ Stroma and Vessel Focus panels, along with melanoma-specific antibodies, deliver highly specific and reproducible results across diverse tissues. Ready-to-use on the COMET™ platform and designed as modular extensions of the SPYRE™ Core Panels, they enable quantitative marker detection, combination with custom antibodies, and empower researchers with robust and scalable workflows for advanced spatial biology studies.

#6666 Deriving high-fidelity, low-plex clinical signatures from ultra-high-plex spatial data for immunotherapy response prediction.

Raymond Yan[1], Brian Falkenstein[1], A. Burak Tosun[1], Filippo Pullara[1], **S. Chakra Chennubhotla**[2]

[1]PredxBio, Inc., Pittsburgh, PA,[2]PredxBio, Inc. / University of Pittsburgh, Pittsburgh, PA

Background: Ultra-high-plex multiplex immunofluorescence (mIF) imaging enables detailed characterization of the tumor microenvironment (TME), yet translating these rich datasets into clinically deployable, low-plex biomarkers remains a major barrier for precision immuno-oncology. Existing predictive models rely heavily on high-dimensional features or broad phenotypic panels, limiting scalability, interpretability, and routine pathology integration. A systematic framework is needed to compress spatially resolved molecular information into minimal, clinical-plex, yet highly informative signatures capable of predicting immunotherapy response.
Methods: Our SpaceIQ™ platform is a multi-omic analysis tool that integrates spatial proteomics data with optimized feature selection algorithms to distill molecular signatures. We employ unbiased cell typing and microdomain discovery to identify a differentially expressed network of spatial interactions between these unbiased cell types, utilizing pointwise mutual information (PMI) analysis. Each interaction (either pairwise or higher-order cliques) within this network represents a potential spatial prognostic model capable of predicting patient response. A key component of our approach is the identification of a subset threshold cell population that is enriched for a given unbiased cell type using a low-plex panel. The final prognostic model for a differential clique combines a spatial proximity score with these low-plex marker intensities.
Results: Analysis of ultra-high-plex (=51 markers) spatial data from trial specimens of checkpoint-treated cutaneous T-cell lymphoma patients demonstrated that tumor-immune and immune-immune interactions emerge as microdomains with minimal signatures of 6-8 markers and high prediction accuracies (AUC = 0.87, 95% CI (0.865-0.881)).
Conclusions: The SpaceIQ platform enables the extraction of compact, clinically practical biomarker panels from ultra-high-plex mIF datasets without sacrificing predictive power. By linking spatial microdomain biology to sparse signature derivation, this framework supports scalable deployment of precision immunotherapy biomarkers and enhances patient-selection strategies in clinical practice.

#6667 Integrated spatial transcriptomics and proteomics workflows for high-resolution multiomics analysis.

Cindy Pamela Ulloa Guerrero[1], Michele Bortolomeazzi[1], Pooja Sant[1], Laura Schutze[1], Laura Giese[1], Denise Keitel[1], Julia Boehl[2], Robin Reschke[2], **Jan-Philipp Mallm**[1]

[1]Single-cell Open Lab, DKFZ German Cancer Research Center, Heidelberg, Germany,[2]Max-Eder Research Group Reschke, University Hospital Heidelberg, Heidelberg, Germany

High-resolution tissue profiling increasingly relies on integrated spatial multiomic approaches that unify spatial transcriptomics and antibody-based proteomics to reveal coordinated molecular patterns within complex tissues. This enables a detailed exploration of spatial niches, cell-cell interactions, and tissue microenvironments. However, these modalities are often performed on consecutive sections, limiting precise correlation between molecular and spatial features. Here, we present optimized workflows that combine high-plex imaging and sequencing-based spatial transcriptomic assays with antibody-based proteomics from the same tissue section in a coordinated and customizable manner.

We developed and evaluated experimental adaptations to ensure high data quality and optimal tissue handling across multiple platforms, including Xenium, Visium, and COMET. Quality control procedures were implemented to assess antigen retrieval compatibility, as these conditions can be antibody dependent. We examined the balance between epitope exposure, tissue integrity, and background signal, providing specific recommendations tailored to different research objectives.

We further compared the sensitivity of these technologies and offer guidance on selecting and combining commercially available transcriptomic and proteomic workflows in a controlled, flexible setup. As in all multiomic approaches, signal loss can occur, particularly in the second readout of consecutive analyses. For proteomics, photobleaching and antigen retrieval are key considerations, especially for low-abundance or difficult-to-detect targets. Transcriptomic data can be enhanced by using HiPlex RNAscope Pro on COMET to detect lowly expressed transcripts. For data integration, we employed a straightforward pipeline that includes cell segmentation based on protein data, image registration using nuclear staining and/or segmentation masks, and extraction of single-cell transcript counts and pixel intensity data for downstream analyses within the SpatialData framework.

We applied these workflows to tonsil, skin, and colon tissues using immuno-oncology-focused panels. The combined approach improved molecular resolution and reduced data sparsity, enabling more precise definition of cell states, spatial neighborhoods, and functional niches. These spatial multiomics workflows expand the analytical capabilities and facilitate deeper biological interpretation across diverse tissue contexts.

#6668 Spatial and transcriptomic remodeling of the tumor microenvironment following neoadjuvant atezolizumab in urothelial carcinoma: Insights from the ABACUS Study.

Robbin Nameki[1], Jennifer Kinong[1], Chao-Hui Huang[1], Michelle Saul[1], Aakash Sur[1], Mehmet Tekman[1], Alexander Trageser[1], Wenjing Yang[1], Daniel Chawla[1], Greg Szeto[1], Arne Schmidt[2], Alberto Megina Gonzalo[2], Srishti Munjal Mehta[2], Nina Kozar-Gillan[2], Rosemarie Krupar[2], Sophie Laturnus[2], Cornelius Bohm[2], Marija Pezer[2], Gloria H.Y. Lin[1], Diane Fernandez[1], Keith Ching[1], Jadwiga R. Bienkowska[1], Thomas Powles[3], Craig B. Davis[1]

[1]Pfizer, Inc., San Diego, CA,[2]Aignostics, Berlin, Germany,[3]Experimental Cancer Medicine Centre, Barts Cancer Institute, London, United Kingdom

The ABACUS study was a single-arm, phase II trial evaluating neoadjuvant atezolizumab in operable urothelial carcinoma. Paired baseline and post-treatment tumor specimens were analyzed to identify biomarkers associated with treatment response. Initial bulk transcriptomic and immunohistochemistry analyses suggested links between immune activation, tissue remodeling and resistance pathways were associated with clinical outcome. To further characterize spatial and phenotypic changes at high resolution, artificial intelligence-assisted digital image analysis of hematoxylin & eosin sections and Visium spatial transcriptomics were performed on paired samples. Post-treatment specimens showed extensive remodeling of the tumor microenvironment with marked immune infiltration, stromal expansion, and altered endothelial-tumor proximity. Such alterations were associated with distinct clinical outcomes between stable disease and relapse. These findings indicate that atezolizumab reshapes the tumor microenvironment by enabling immune infiltration and remodeling stromal architecture; however, robust tumor and endothelial activity may sustain immune exclusion and drive resistance despite immune expansion. Spatial and phenotypic biomarkers identified here may inform rational combination strategies for immune checkpoint inhibitor-refractory urothelial carcinoma.

#6669 Spatially resolved multiplex immunofluorescence profiling of antibody-drug conjugate targets in bladder cancer using an AI-powered end-to-end workflow.

Christoph Kuppe[1], Markus Eckstein[2], Samaneh Samiei[1], Katharina Dornblut[3], Niklas Klumper[4], Fabian Schneider[5], Moritz Widmaier[3], Florian Leiss[3]

[1]RWTH Aachen, Aachen, Germany,[2]FAU Erlangen-Nurnberg, Nurnberg, Germany,[3]ZEISS Microscopy GmbH, Jena, Germany,[4]University of Bonn,[5]Mindpeak GmbH, Hamburg, Germany

Background: Bladder cancer is one of the most common malignancies, with significant morbidity and mortality rates. Emerging antibody-drug conjugates (ADC) are promising treatment options for this challenging disease. However, insight about the location and presence of different ADC target molecules is needed to guide treatment decisions. Multiplex immunofluorescent (mIF) offers the opportunity to investigate multiple biomarkers and their spatial distribution at the same time, enabling detailed spatial analysis of ADC targets within a tissue section.
Methods: We utilized a novel mIF reagent system to analyze formalin-fixed, paraffin-embedded (FFPE) bladder cancer samples from a patient cohort by staining clinically relevant ADC target molecules. Slides were imaged using the ZEISS Axioscan 7 spatial biology system and SlideStream automation for high-throughput, standardized acquisition. Image analysis was performed using Mindpeak PhenoScout integrated to the automated workflow, which employs pre-trained AI models for tissue region segmentation, single cell detection, biomarker positivity, and phenotype classification based on multichannel signal integration.
Results: We established an mIF assay to investigate different ADC targets in bladder cancer samples. This information, in combination with AI-based analysis, was used to generate an ADC sensitivity profile for each patient.
Conclusions: Spatially resolved mIF analysis of bladder cancer revealed clinically relevant biomarker signatures, highlighting its potential for patient stratification. The integration of automated imaging and AI-driven analysis ensures robust, reproducible spatial profiling, accelerating the translation of multiplex tissue imaging into precision oncology and personalized treatment approaches.

#6670 Automated co-detection of small RNAs, RNAs and proteins in tumor tissues with Roche DISCOVERY™ULTRA.

Renzo S. Adilardi, Rose Delvillar, Manvir Sambhi, Emerald Doolittle, Sonali Deshpande, Anushka Dikshit, Debia Wakhloo, Henry Lamparski

Advanced Cell Diagnostics, a Bio-Techne brand, Newark, CA

Advances in precision medicine utilizing antisense oligonucleotides (ASOs) and small interfering RNAs (siRNAs) as therapeutic platforms have brought promising solutions for various neurodegenerative/neuromuscular disorders and rare diseases. Currently, 20 oligonucleotide drug products have been commercially approved by the FDA and EMA, and many more are in clinical phase I-III trials. The FDA has issued recommendations to generate nonclinical biodistribution (BD) data for gene therapy products to evaluate and interpret nonclinical pharmacology and toxicology findings before initiating human clinical trials. *In situ* hybridization (ISH) and immunohistochemistry (IHC) are increasingly used to spatially visualize the delivered therapeutic, target gene, transgene, and/or cell markers and complement information gathered from molecular technologies such as quantitative polymerase chain reaction (qPCR) and digital PCR. Direct visualization of oligonucleotides can also monitor the risk of off-target events by studying BD of potential therapies in various organs. A new RNAscope™ ISH assay enabling the detection of ASOs, siRNAs, microRNAs (miRNAs), and other small RNAs was developed on the Roche DISCOVERY™ ULTRA System. This fully automated assay allows the co-detection of small RNAs, RNAs and proteins within the same formalin-fixed paraffin-embedded sections of tissues. This workflow includes protease-free RNA detection to prevent disruption of protease-sensitive epitopes. Multiple RNA species and protein targets can be visualized either chromogenically or fluorescently at the single-cell level, leveraging translucent chromogens or TSA-fluorophores. We investigated the expression profile of miR-21, a microRNA implicated in cancer proliferation and progression, in the human cancer TMA tissue. MicroRNA detection was combined with *PTEN* RNA to assess the impact of miR21 on the expression of *PTEN*, a tumor suppressor that regulates cell growth, proliferation, and survival. Ki67, and CD31 proteins were co-detected in the same sample to correlate with tumor cell proliferation, and neo-angiogenesis, respectively. This new automated ISH assay showed high sensitivity and specificity for the detection of small RNAs with different expression profiles, and subcellular resolution in intact tissue context. This novel assay will be particularly valuable for the study of ASO/siRNAs delivery, biodistribution, stability, and expression profile of their associated RNA targets for the development of new oligonucleotide therapeutics.

#6671 Actionable resistance mechanisms in osteosarcoma uncovered by the elucidate spatial biomarker platform.

Gulpreet Kaur[1], Jason Weirather[1], James Perna[1], Sizun Jiang[2], Will Singleterry[1]

[1]Elucidate Bio, Medford, MA,[2]Harvard Medical School, Cambridge, MA

Same-slide spatial multiomics enables comprehensive characterization of the tumor microenvironment (TME) by integrating high-plex spatial proteomics and whole-transcriptome on the same slide. For patients whose tumors have progressed or metastasized despite standard-of-care therapies, understanding the specific mechanisms active within their tumor becomes essential for guiding next-line treatment decisions. This requires resolving cell identity, state, morphology, and the organization of immune-tumor interactions within spatial neighborhoods. A systematic, multimodal approach is therefore necessary to reveal clinically actionable mechanisms of resistance directly within intact tissue architecture.

Methods

We developed the Elucidate Biomarker Platform using a same-slide spatial multiomics workflow combining 50-plex spatial proteomics and whole-transcriptome spatial transcriptomics. Model-guided annotation was applied for high-fidelity cell detection, quality control, and neighborhood-level analysis. Proteomic data identified phenotypic and spatial features associated with therapeutic response, while transcriptomic profiling on the same slide elucidated molecular pathways underlying these tissue-level patterns.

Results

Application of this platform to an osteosarcoma patient sample uncovered two actionable mechanisms of therapeutic resistance:

1.FAP-mediated T-cell exclusion: Excess fibroblast activation protein (FAP) expression on tumor-associated stromal cells formed a physical and immunoregulatory barrier preventing T-cell infiltration. Clinical treatment of the patient with a FAP-targeted radioligand inhibitor resulted in a positive therapeutic outcome.

2.$CD163^+$ macrophage survival pathway: Same-slide multiomic analysis identified a survival mechanism specific to $CD163^+$ tumor-associated macrophages via PAQR6, which was targetable using mifepristone, suggesting a second actionable therapeutic avenue.

These findings demonstrate that same-slide spatial multiomics, combined with model-guided annotation, delivers a systematic approach for revealing clinically actionable biomarkers and therapeutic targets to guide precision therapy and drug development.

#6672 Expanding the boundaries of spatial proteomics with a universal antibody labeling strategy and EpicIF™ multiplexing chemistry.

Thore Boettke, Jannik Boog, Charles Eldon Jackson, Matthew H. Ingalls, Arne Christians, **Oliver Braubach**

Bruker Spatial Biology, St. Louis, MO

Highly multiplexed immunofluorescence (mIF) has transformed cancer research by enabling the simultaneous visualization of dozens of biomarkers and cell types within the spatial context of the tumor microenvironment (TME). However, mIF assays often require custom antibody content, which is difficult to attain with inflexible or proprietary chemistries. Alternative detection systems provide partial workarounds but frequently rely on harsh conditions that can compromise tissue integrity and reduce assay reproducibility. To overcome these barriers, we developed a universal antibody-labeling strategy compatible with the CellScape™ Precise Spatial Proteomics platform and EpicIF™ multiplexing chemistry. This workflow enables low-volume fluorophore labeling of virtually any IgG antibody, independent of antibody buffer formulations, using standard organic fluorophores in minutes and without specialized instrumentation. The resulting labeled antibodies integrate seamlessly into CellScape workflows for custom, high-quality mIF imaging. In this study, we demonstrate how our universal labeling approach enables the seamless transfer of IHC-validated antibodies to the CellScape Platform without compromising staining quality or specificity. We first compared standard IHC-P DAB and immunofluorescence stains using several well-characterized and routinely applied antibodies. The results show that our universal labeling strategy allows a straightforward transition of these antibodies to multiplexed immunofluorescence staining. Next, we expanded our commercially available VistaPlex Kits with antibodies designed to provide deeper insights into the TME. Our final modified panel includes additional markers for immune infiltration, stromal activation, cellular metabolism, and checkpoint regulation. Applying this panel to whole-section tumor biopsies and tissue microarrays generated unprecedented single-cell-level data describing not only the composition of the TME but also the proteomic states of individual cells. Linking these data with patient treatment regimens and outcomes further revealed quantifiable spatial phenotyping signatures. This study details how a universal labeling strategy can easily expand mIF studies to better understand the TME. Presented here in its sum, our study marks a significant step toward fully user-driven, high-plex mIF assay development, which will accelerate discovery, expand biological insights, and redefine how complex cancer ecosystems are studied *in situ*.

#6673 MERFISH 2.0 enables high-sensitivity, customizable spatial transcriptomics for resolving immune and tumor programs in human cancers.

Renchao Chen, Bin Wang, Bing Yang, **Manisha Ray**, Justin He, Timothy Wiggin, Lizi Maziashvili, Alexander Genshaft, Peter Reinhold, Angela Vasaturo, Jiang He

Vizgen, Cambridge, MA

High-plex, imaging-based spatial transcriptomics with single-cell resolution has substantially advanced our understanding of how heterogeneous tumor ecosystems shape immune architecture and function, target expression, and cell-cell interface dynamics within the human tumor microenvironment (TME). By measuring gene expression directly in intact human tissues, spatial transcriptomics provides detailed insights into immune-cell identity, spatial organization, and molecular programs that govern antitumor activity or immune suppression. Resolving transcripts in situ enables precise delineation of immune-cell states, spatial interactions, and regulatory circuits underlying antitumor responses and context-dependent cellular phenotypes. A key limitation of current spatial transcriptomics approaches is the ability to sensitively detect transcripts across complex and heterogeneous human tumors, particularly when studies require focused interrogation of specific pathways or cellular programs. MERFISH 2.0 overcomes these constraints with an enhanced chemistry and streamlined sample-processing workflow that delivers substantially higher transcript detection efficiency in both frozen and FFPE tissue, enabling robust profiling of panels up to 1,000 genes. Building on these improvements in sensitivity and workflow performance, MERFISH 2.0 also provides the flexibility to add up to 100 custom genes to Pre-designed Panels (PdP), enabling researchers to tailor experiments to specific hypotheses, tumor-intrinsic biology, or emerging clinical signatures. In this study, MERFISH 2.0 was applied to human tumor specimens using an 815-gene PdP with an immune-oncology focus, supplemented with custom gene content selected to capture key biological processes across diverse tumor types and disease stages. Implementation on MERSCOPE® Ultra™ slides generated high-resolution spatial maps that resolved the distribution of specific cell populations, the localization of surface and intracellular markers of interest, and the complex organization of immune infiltrates, stromal architecture, and tumor-intrinsic transcriptional programs within intact tissue environments. The ability to augment MERFISH 2.0 panels with tailored gene sets further expands its utility for dissecting molecular features and spatial patterns of the TME that influence pathway engagement and functional activity. By integrating enhanced sensitivity with customizable panel design, MERFISH 2.0 provides a powerful platform for resolving spatial determinants of immune function and tumor behavior, supporting mechanistic discovery and informing the development of next-generation precision medicine strategies.

#6674 Metabolic reprogramming in advanced renal tumors contributes to a dysfunctional immune response and immune exhaustion within the tumor microenvironment.

Lakshmi Chandramohan, Kirsteen Maclean, Sergio Hernandez, Brigitte Lovell, Courtney Todorov, Harry Nunns, Jiong Fei, Judy Kuo, Erinn A. Parnell, Qingyan Au

NeoGenomics, Fort Myers, FL

Background: Renal cell carcinoma (RCC), a malignancy arising from renal tubular epithelial cells, represents 2-3% of global cancer diagnoses and 85% of all kidney neoplasms with the most common histological subtype being clear cell renal cell carcinoma (ccRCC), an immunologically and histologically diverse tumor associated with poor clinical outcomes. While significant progress has been made in the development of immunotherapy for ccRCC, there are still many unanswered questions regarding mechanisms of immune evasion and resistance, and the development of predictive biomarkers for optimal treatment strategies for individual patients. Emerging evidence suggests that metabolic reprogramming marked by dynamic shifts in nutrient utilization that extend beyond canonical Warburg physiology to include lipid anabolism, nutrient scavenging, catabolic pathways and microenvironment-driven metabolic plasticity, is central to overall ccRCC pathogenesis. This orchestrated rewiring of cellular dynamics has been suggested to sustain tumor proliferation under hypoxia while fostering immunosuppression through metabolite-mediated T cell exhaustion. We therefore investigated the phenotype, functional states, and metabolic competencies of RCC immune cell populations, evaluating their potential associations with tumor clinicopathological features and stage-specific metabolic conditions.

Methods: To investigate the complex interplay between the immunogenic nature of ccRCC tumors and metabolic reprogramming, we performed an integrative multi-omic analysis, combining transcriptomic and spatial proteomic data. We profiled 16 ccRCC patient samples representative across all clinical TNM stages (Stages I-IV) to define the potential changes in metabolic processes and infiltrating immune cells that correlated with advancing disease. Specifically, we incorporated the *new* Paletrra™ end to end spatial proteomic multiplexed immunofluorescence (mIF) workflow (NeoGenomics Laboratories, Inc.) and qualified a panel that includes: CD3, CD4, CD8, FoxP3, CD68, CD80, CD163, CD206, CA9, CD31, LAG3, PD1, PanCK. NanoString nCounter® Metabolic Pathways Panel testing was performed on these samples to investigate metabolic reprogramming, cellular stress, and their relationship to TME composition in advancing disease progression in ccRCC.

Results and Conclusions: We identified substantial TME-driven changes, notably the presence of immunosuppressive immune cells in advanced ccRCC disease, coupled with identification of several metabolism-related genes showing strong correlations with immune infiltration in ccRCC. Identifying and understanding these metabolic alterations within the different staging of RCC will help in designing new targeted therapies and improving diagnostic tools to improve care for patients with this disease.

#6675 An end-to-end quality control pipeline for spatially resolved molecular imaging data in the multi-omic SpaceIQ™ platform.

Brian Falkenstein[1], A. Burak Tosun[1], Raymond Yan[1], S. Chakra Chennubhotla[2], Filippo Pullara[1]

[1]PredxBio, Inc., Pittsburgh, PA,[2]PredxBio, Inc. / University of Pittsburgh, Pittsburgh, PA

Background: The rapid expansion of mIF imaging has increased the need for rigorous, standardized quality control. Variability introduced during sample prep, staining, and image acquisition can obscure biological signals and compromise downstream analysis. Common issues include batch effects that distort foreground-background contrast, acquisition errors causing over/underexposure or low contrast, and physical artifacts such as bubbles, debris, or deparaffinization defects. More difficult to detect is non-specific antibody binding, which can appear in unexpected structures or cell types. These challenges require a human-in-the-loop QC system capable of detecting, correcting, and documenting quality deviations across diverse tissues and platforms.
Methods: Using a pan-tissue real-world mIF dataset, we evaluated the SpaceIQ™ QC pipeline across the most frequent image quality failure modes. QC begins with raw pixel data: a nuclear-derived tissue mask defines foreground/background regions for estimating and correcting batch effects. Channel-level parametric models detect blurring, saturation, bubbles, and other acquisition-related artifacts. Spatial modeling quantifies uneven illumination across tissue areas. A library of expected staining patterns is used to identify non-specific binding. Segmentation outputs are used to flag biologically impossible co-expression events (e.g., PanCK/CD45) as indicators of staining or acquisition issues. Each QC module generates a 0-3 score, from low quality/not-usable to no-artifacts, enabling a simple, interpretable quantitative assessment. All QC outputs are visualized in the SpaceIQ™ interface, which highlights artifact-containing ROIs and enables user confirmation or override.
Results: The pipeline reliably detected and excluded regions affected by blurring, saturation, and uneven illumination. Applying standardized QC steps significantly altered cell counts and subtype distributions by correcting batch effects and removing regions affected by non-specific staining, demonstrating the importance of systematic QC before quantitative analysis.
Conclusions: The SpaceIQ™ QC pipeline provides a platform- and tissue-agnostic framework for automated yet interpretable quality assessment of mIF imaging. By integrating artifact detection, batch correction, and biological validity checks, it improves accuracy, reproducibility, and user confidence, ensuring results reflect true biological signal rather than technical variability.

#6676 Spatial proteomics and AI-driven analysis uncover therapeutic landscapes within the glioblastoma microenvironment.

Nadine Nelson[1], Hoyin Lai[2], Sophie Struble[2], Richard A. Heil-Chapdelaine[2], Natasha F. Diaz Granados[2], **Arindam Bose**[2]

[1]Abcam, Cambridge, United Kingdom,[2]Leica Microsystems, Waltham, MA

Glioblastoma (GBM) is a highly aggressive and spatially heterogeneous brain tumor with limited treatment options and poor prognosis. Effective therapeutic targeting requires a deeper understanding of the tumor microenvironment (TME), particularly the spatial relationships between malignant, immune, and stromal compartments. To address this, we employed the Cell DIVE™ multiplex immunofluorescence platform to perform high-plex spatial proteomic profiling of FFPE glioblastoma tissue section. A customized panel of directly conjugated recombinant antibodies from Abcam was optimized to interrogate markers relevant to tumor biology, immune modulation, and stromal architecture. Following iterative staining and imaging cycles, multi-channel, high-resolution images were analyzed using Aivia, an AI-powered image analysis platform. The workflow enabled accurate segmentation of tissue regions and quantification of spatial protein expression patterns across distinct anatomical zones within GBM. Spatial relationships among protein expression patterns revealed region-specific immune infiltration and phenotypic transitions at tumor-stromal interfaces. Co-localization and proximity analysis further identified potential immune evasion signatures and microenvironmental structures associated with resistance phenotypes. This integrative approach provides a scalable and clinically compatible method for spatially resolved proteomic analysis of complex tumor tissues. The combination of Cell DIVE™ multiplex imaging, Abcam direct-conjugate antibodies, and Aivia-based analysis offers a powerful platform for dissecting the spatial biology of glioblastoma. The translational relevance of this study lies in its potential to inform biomarker development, guide spatially targeted therapies, and support precision medicine strategies in GBM. This methodology is well positioned for integration into clinical research workflows and large-scale translational studies, with potential to inform personalized treatment strategies across neuro-oncology and other solid tumors.

#6677 Multiplexed imaging and AI-guided analysis reveal immune landscape diversity across multiple cancer types.

Lynne Turnbull, Michael J. Smith, Sophie Struble, Vasundhara Agrawal, Debayon Paul, Richard A. Heil-Chapdelaine, Natasha F. Diaz Granados, **Arindam Bose**

Leica Microsystems, Waltham, MA

Understanding the interplay between tumor and host tissues within the tumor microenvironment (TME) is critical for guiding drug development. Immuno-oncology features of the TME can determine whether cancers progress or respond to immunotherapies. Mapping the TME by characterizing the phenotype, functional state, and proliferative status of immune and cancer cells can advance drug discovery. Because of the considerable number of cell types and biomarkers present in cancer samples multiplexed imaging approaches are often required to capture this complexity, while AI-guided analysis platforms can extract meaningful insights from these data-rich experiments. Owing to intra-tumor heterogeneity and expression differences across cancer types, a multi-tumor workflow that examines biomarker panels in diverse tissue sections provides additional value, by enabling differential biomarker profiling, co-expression analysis, and cancer signature discovery. To this end, we utilized the Cell DIVE multiplexed imaging platform to perform multiplex imaging across several cancer types using a novel dye-conjugation strategy with validated antibody panels and specialized dyes. Biomarker expression profiles and phenotypic classifications across the tumor samples were subsequently analyzed using Aivia. In addition, both supervised and unsupervised clustering analysis revealed distinct cancer signatures across tumor types. By combining the high-throughput capabilities of the Cell DIVE platform with newly developed specialized panels and staining reagents, the immune-oncology researcher can gain a comprehensive understating of the biological processes occurring within cancer samples and identify key molecular targets. This integrated workflow provides deeper insight into tumor-immune dynamics, bridging basic research and clinical applications to accelerate the discovery of actionable biomarkers and therapeutic targets.

#6678 Ultra-high-plex immunofluorescence analysis of the tumor-immune microenvironment with EpicIF technology on the CellScape platform.

Arne Christians[1], Thore Boettke[1], Jannik Boog[1], Charles Eldon Jackson[1], Matt Ingalls[1], Brian J. Lane[1], Daniel Jimenez Sanchez[1], Christoph Rocken[2], Niclas Christian Blessin[2], Oliver Braubach[1]

[1]Bruker Spatial Biology, St. Louis, MO,[2]Dept. of Pathology, University Medical Center Schleswig-Holstein, Kiel, Germany

Spatial biology continues to transform cancer research by revealing the intricate molecular and cellular architecture of tissues. Yet, our understanding of the complex processes in the tumor microenvironment is still incomplete, partly because single-cell *in situ* proteomic data remain challenging to achieve. Most high-plex imaging approaches rely on complex and indirect detection schemes that restrict accessibility and decouple detection from direct visualization. To overcome these limitations, we developed EpicIF™ technology for the CellScape platform for precise spatial phenotyping. EpicIF™ technology is a novel multiplex immunofluorescence (mIF) method that employs a proprietary signal-removal chemistry to efficiently eliminate fluorophores between imaging cycles while preserving tissue morphology and antigenicity. This allows repeated rounds of staining and imaging with fluorophore-labeled primary antibodies, thereby eliminating the need for barcoding, oligo labeling, or sequencing-based decoding. Using this chemistry, we first determined biomarker and tissue integrity after 50 EpicIF-based signal removal cycles to ensure feasibility of an ultra-high plex assay. Of 30 representative markers tested, only 2 showed reduction in signal intensities, while the majority of biomarkers showed little or no significant reduction at all. We then performed direct cyclic immunofluorescence imaging of more than 200 protein targets within a single FFPE tissue section. Our antibody panel was entirely sourced from commercially available fluorophore-conjugated antibodies, and it targets a broad spectrum of biomarkers to profile tumor cells, immune cell subsets, the tissue architecture, and key signaling pathways. This broad immune-oncology focused antibody panel was used to stain more than 200 tumor tissues, including breast cancer, lung cancer, melanoma, glioma, colorectal cancer, and other cancer types. The practical realization of this 200-plex immunofluorescence assay was made possible through key enhancements to the CellScape platform, enabling higher imaging throughput, and sustained stability across extended acquisition runs. This platform establishes a new benchmark for spatial proteomics by combining assay innovation with high-throughput instrumentation to deliver rapid, reliable, and ultra-high-plex imaging at single-cell resolution. This approach provides a powerful framework for dissecting the complex cellular and molecular landscape of the TME and opens new avenues for biomarker discovery, therapeutic stratification, and mechanistic insights into tumor-immune dynamics.

#6679 Decoding immune and tumor niches through high-plex spatial multi-omics in human cancer tissues.

Bin Wang, Kevin Hwang, Yijia Sun, Cassandra Kysilovsky, Angela Vasaturo, Jiang He

Vizgen, Cambridge, MA

The tumor microenvironment (TME) is defined by extensive spatial and molecular heterogeneity, and single-biomarker assays fail to capture the complexity of cellular interactions that drive tumor progression and therapeutic response. To overcome these limitations, we present a spatial multi-omics strategy that integrates Vizgen's spatial transcriptomics and proteomics technologies to enable deeper characterization of the TME. The MERSCOPE® Ultra™ Platform, powered by MERFISH 2.0, currently supports high-resolution spatial profiling of up to 1,000 genes and 6 proteins in a single assay. Here, we introduce an expanded multi-omics workflow that increases protein detection capacity up to 30 targets while maintaining simultaneous spatial detection of up to 1,000 RNA transcripts. The workflow is initiated by staining with conjugated antibodies linked to optimized oligonucleotide tags, engineered to ensure high sensitivity and minimal background noise, followed by MERFISH 2.0 RNA imaging. The integrated spatial multi-omics approach seamlessly couples high-plex protein detection with MERFISH 2.0 transcriptomics. The robustness and utility of these integrated methodologies were extensively validated across a broad range of indications and antibody panels. We applied this multi-omics assay to cancer specimens, achieving simultaneous quantification of an up to 30-plex immuno-oncology (IO) protein signature and a comprehensive, pre-designed 815 IO transcript inventory which supports its powerful application in translational oncology. Our results demonstrated robust performance, characterized by high detection sensitivity and minimal background interference for both molecular modalities. A key advantage of the presented assay is the full user customization of both the protein biomarker panels and RNA transcripts, enabling researchers to optimally tailor panel design to specific mechanistic inquiries. Leveraging the subcellular resolution of the MERSCOPE Ultra Platform, we executed granular single-cell spatial profiling, successfully delineating cellular neighborhoods and characterizing cell-to-cell communication within the tumor microenvironment. The resulting multi-omic datasets allowed us to characterize the specific gene signatures and immune cell subsets enriched within distinct tumor regions, illuminating the spatial determinants governing tumor-immune interactions. Therefore, this integrated, expanded spatial multi-omics solution represents a powerful framework to enable comprehensive co-profiling of immune and tumor biomarkers within a single tissue section. By simultaneously capturing protein and RNA expression at single-cell resolution, it provides an unparalleled framework for dissecting cellular interactions, identifying spatially organized biomarkers, and accelerating translational studies aimed at predicting therapeutic response.

#6680 Decoding the tumor microenvironment with triple-omics: Automated spatial analysis of protein-protein interactions, RNA, and protein markers on the same section.

Alice Comberlato[1], Arec Manoukian[1], Pino Bordignon[1], Ge-Ah Kim[2], Sonali Deshpande[2], Florent Jeanpetit[1], **Alix Failletaz**[1], Li-chong Wang[2], Alexandre Kehren[1], Saska Brajkovic[1]

[1]Lunaphore, a Bio-Techne brand, Tolochenaz, Switzerland,[2]Adavanced Cell Diagnostics, a Bio-Techne brand, Newark, CA

Understanding the complexity of the tumor microenvironment (TME) requires simultaneous insight into multiple biological domains. Studying the molecular interactions that govern intercellular and intracellular signaling in combination with the analysis of cell phenotypes and transcriptional states, can guarantee an improved comprehension of key pathways driving tumor growth or the response of anti-cancer therapies. Protein-protein interactions (PPIs), such as PD-1/PD-L1, are central to immune evasion and targets of important immunotherapies. Despite the success of PD-1/PD-L1 and other checkpoint inhibitors, patient stratification for these therapies has been challenging, and marker expression alone has shown to not fully capture functional engagement or predict an efficient drug response. Here, we present a fully automated workflow that combines three omics layers on the same tissue section: protein-protein proximity, RNA, and protein expression, enabling a more comprehensive view of cellular interplay in cancer and modeling of treatment outcomes. The multiomics assay runs on the COMET™ platform. It allows the co-detection of: (i) RNA profiling via RNAscope™ HiPlex Pro, (ii) Protein expression through sequential immunofluorescence (seqIF™, PMID: 37813886), (iii) Protein-protein proximity detection using oligonucleotide-conjugated secondary antibody pairs and RNAscope™ amplification chemistry. Proximity signals are interpreted as probabilistic indicators of molecular interactions and supported by multiple controls to ensure their specificity: from the colocalization of seqIF™ signals to negative controls run on the same section. In this study, we demonstrated that it is possible to combine the detection of proximity signals for the analysis of intercellular interactions controlling anti-tumoral immune responses, alongside protein markers for cell phenotyping and RNA targets for functional markers and cell activation status. In detail, across multiple human FFPE tumor samples, PD-1/PD-L1 interaction was detected in combination with multiple proteins, for immune and stromal phenotyping, and RNA transcripts responsible for the expression of key secreted molecules like cytokines and chemokines. Furthermore, we showed that multiple iterative cycles allow the detection of more than one PPI on the same FFPE section. Tumor progression, immune evasion, and therapy resistance are not driven by single molecules but by complex interaction networks among proteins, signaling pathways, and cellular types. This automated spatial multiomics workflow incorporating protein-protein proximity as a third dimension, can help reveal how these processes are regulated. By combining RNA, protein, and proximity data, the assay offers a powerful approach to support biomarker discovery and improved patient stratification.

#6681 Innovative 10x Genomics technologies enable clinical-scale cancer research and AI-driven biomarker discovery.

Hiroshi M. Sasaki[1], Seayar H. Mohabbet[2], Ian T. Fiddes[3], Francesca Meschi[1], 10x Genomics Development Team

[1]Spatial Biology, 10x Genomics, Inc., Pleasanton, CA,[2]Histopathology Core, 10x Genomics, Inc., Pleasanton, CA,[3]Computational Biology, 10x Genomics, Inc., Pleasanton, CA

Background:
Spatial and single-cell omics are transforming cancer research, offering unprecedented resolution into tumor heterogeneity and microenvironment dynamics. However, the adoption of these powerful tools for large-scale clinical studies and subsequent integration into AI-driven diagnostic pipelines remains hampered by persistent challenges, including high cost, complex workflows, low sensitivity and specificity, and limited scalability and throughput. Addressing these bottlenecks is critical for accelerating the identification and validation of robust cancer biomarkers, especially for early detection.
Methods:
We introduce technology innovations that address the historic compromises inherent in existing spatial and single-cell technologies. These approaches are designed to deliver superior specificity, sensitivity and plex at significantly reduced cost and with streamlined, high-throughput workflow capabilities. Leveraging a novel integration of advanced chemistry and computational analysis, these technologies enable simultaneous, single-cell resolution profiling of both tissue morphology and gene expression signatures across clinically relevant sample scales.
Results:
Application of the technology innovations to clinically archived tumor specimens demonstrates their potential for clinical-scale studies. We achieved robust, high-plex molecular profiling with unprecedented efficiency. Critically, the data generated is inherently low-noise, high-resolution, and scalable, making it immediately amenable to machine learning and AI algorithms. Preliminary analysis highlights its utility in identifying novel biomarkers predictive of therapeutic response and supporting early detection. The simplified workflow dramatically reduces time-to-result, positioning this solution as a key enabler for population-scale cancer research.
Conclusion:
These technology innovations overcome major workflow, cost, and sensitivity limitations, paving the way for the clinical-scale deployment of spatial and single-cell omics. By generating high-quality, AI-ready data across large cohorts, this solution will accelerate biomarker discovery, drive the next generation of early cancer detection strategies, and fully support the ongoing AI revolution in cancer research.

#6682 Chimeric antibodies in oncology research: Properties and application in low-multiplexing assays.

Tom Bright, Nadine Nelson, Antonella Galli, Will Howat, Silvia Sbacchi

Abcam Limited (UK), Cambridge, United Kingdom

Chimeric antibodies, engineered by fusing the variable (antigen-binding) domains of one species (e.g. rabbit) with the constant domains of a different species (e.g. human, chicken), represent a significant advancement in antibody technology. This approach preserves the original antibody's specificity and affinity while introducing desirable features from the second species. Beyond therapeutics, the distinctive characteristics of chimeric antibodies offer notable benefits in *in vitro* diagnostic and research applications, for example in low-multiplexing assays. In particular, chimeric antibodies offer significant advantages in multiplexed assays, where their species-specific constant regions allow for the simultaneous use of multiple primary antibodies with minimal cross-reactivity. The use of chimeric antibodies is compatible with diverse experimental setups allowing researchers to leverage existing secondary antibodies systems. Here we demonstrate the advantage of using chimeric antibodies for building immunohistochemistry (IHC) panels for the co-detection of cancer protein markers and the study of tissue micro environment (TME) in formalin-fixed paraffin-embedded (FFPE) human tumor tissues. By leveraging antibodies derived from multiple host species, including mouse, rabbit, and chicken, we achieved robust and specific staining in both normal and tumor samples. Our results highlight the potential of chimeric antibodies to streamline complex IHC workflows and improve the resolution of multiplexed tissue analyses in cancer research.

#6683 Streamlined high-plex imaging with InSituPlex®and ZEISS Axioscan 7 for spatial phenotyping.

Kevin Hwang[1], Mike Woerdemann[2], Lars Loetgering[2], Moritz Widmaier[2], Cassandra Kysilovsky[1], Sherry Derakhshani[2], Jiang He[1], Angela Vasaturo[1]

[1]Vizgen, Cambridge, MA,[2]Zeiss, Jena, Germany

Multiplex immunofluorescence (mIF) provides a powerful means to visualize complex biomarker signatures with spatial context. Yet, most high-plex mIF approaches depend on repeated cycles of staining and imaging, which introduce workflow complexity and necessitate either labor-intensive manual handling or sophisticated instrumentation capable of automating these multistep procedures. Vizgen's InSituPlex assay supports rapid, multiplexed detection of up to 12 protein biomarkers in a single staining step, leveraging signal amplification to achieve robust detection of both abundant and lowly expressed targets using standard fluorescence filter configurations. When combined with the Axioscan 7 spatial biology platform, engineered for fully automated, high-throughput slide scanning with additional fluorescent channels, this workflow enables higher-plex, single-round imaging without the need for spectral unmixing. Here, we demonstrate the power of this integrated approach to streamline assay development, expand biomarker panel design flexibility, and deliver efficient, scalable multiplexed protein imaging. A next generation InSituPlex® assay was developed to increase the simultaneous detection of markers using the Axioscan 7 spatial biology system. A panel of fluorophores was carefully selected to minimize spectral overlap and maximize detection specificity, ensuring clear distinction of all fluorescent channels without requiring spectral unmixing to deconvolute signals. Signal quality was analyzed using the STARVUE image analysis pipeline which precisely determined positive cell signal intensity and density. The increased number of fluorophores showed excellent signal to noise ratio and no crosstalk between fluorescent channels. The expanded channel capacity of InSituPlex assay allows for a simplified workflow while increasing the number of biomarkers that can simultaneously be detected in tumor samples. This capability further enhances flexibility for InSituPlex panel design and streamlines the assay development process. The integration of the novel InSituPlex fluorescent dye panel and the Axioscan 7 spatial biology platform delivers a superior, high throughput mIF workflow. This combination enables higher-plex imaging while significantly reducing manual steps, leveraging the established reproducibility and throughput of both technologies. We anticipate this integrated platform will empower researchers to unlock deeper, high resolution spatial insights into cancers and their complex environments.

#6684 Spatial multi-omics profiling of clear cell renal cell carcinoma (ccRCC) pre-and post-immunotherapy identifies new druggable targets.

Navneet Kaur[1], Wadih Issa[1], Ze Yu[2], Hua Zhong[3], Aleksandra Weronika Nielsen[4], Jay Jasti[4], Shahed Abdullah[1], Libin Yan[1], Damla Gunenc[1], Qinhan Zhou[1], Andrew DeVilbiss[1], Satwik Rajaram[4], Payal Kapur[3], Chao Xing[5], Liwei Jia[3], Andrew Z. Wang[6], Tian Zhang[1]

[1]Department of Internal Medicine (Division of Hematology-Oncology), Harold C. Simmons Comprehensive Cancer Center, UT Southwestern Medical Center, Dallas, TX,[2]Eugene McDermott Center for Human Growth and Development, UT Southwestern Medical Center, Dallas, TX,[3]Department of Pathology, UT Southwestern Medical Center, Dallas, TX,[4]Lyda Hill Department of Bioinformatics, UT Southwestern Medical Center, Dallas, TX,[5]Lyda Hill Department of Bioinformatics; O'Donnell School of Public Health, Eugene McDermott Center for Human Growth and Development, UT Southwestern Medical Center, Dallas, TX,[6]Department of Radiation Oncology, Harold C. Simmons Comprehensive Cancer Center, University of Texas Southwestern Medical Center, Dallas, TX

Introduction: Immunotherapy (IO) and VEGF targeting TKIs have transformed outcomes of patients with advanced ccRCC. However, much less is known about treatment resistance mechanisms after IO therapy.

Methods: 15 patients (pts) with advanced ccRCC who had tumor samples pre- and post-treatment (Tx, IO-IO or IO-TKI) were included in this study. Tumors were profiled using the Nanostring GeoMx spatial profiling platform. 4 to 12 regions of interest (ROIs) were selected for each patient, and the ROIs were further segmented into tumor (PanCK+), immune (CD45+), and stroma (PanCk-, CD45-) compartments. Differentially expressed genes and proteins were assessed with Gene Set Enrichment Analysis (GSEA). Bulk gene expression was further deconvoluted to profile immune cell subsets using CIBERSORT. Deep learning algorithms analyzed H&E slides for angiogenic, immune gene signatures, and non-negative matrix factorization (NMF) clustering.

Results: In the tumor compartment (PanCK+), several clinically druggable targets such as Axl, HER2, TROP-2, GITR, HIF-1α, and FGFR2 were significantly upregulated after IO. Interestingly, Trop-2 expression was upregulated in IO-IO (Log2FC 0.038, $p<0.01$) post-Tx but not after IO-TKI (Log2FC -0.070, $p<0.01$). Some patients who received IO/TKIs had decreased tumor angiogenic expression post-Tx. NMF clustering classified post-Tx as NMF4 in 6/15 patients (4 of 10 in IO-TKI cohort and 2 of 5 in IO-IO cohort). NMF cluster 3 remained post-IO in most patients.While most pre-IO samples had moderate to high immune infiltration, post-IO samples had even higher levels. Notably, CIBERSORT profiling revealed post-IO proportion of immune suppressive regulatory T cells were decreased (IO-TKI, $p <0.01$), while cytotoxic CD8+ T cells were increased (IO-TKI, $p <0.01$) with both Tx cohorts. However, resting NK cells were increased ($p=0.29$), while activated NK cells were decreased ($p <0.01$) significantly only in IO-IO treated subsets.

Conclusion: Molecular gene expression changes in RCC after IO-based therapy identified clinical targets in residual tumors. NMF cluster 4 persistence, CD8+ infiltration, and reduction in Treg proportion suggests an expansion or persistence of immune cells post-IO. NMF cluster 3 and increased proportion of resting NK cells may explain the resistance of residual tumor post-IO. Given the heterogeneity in RCC, it is imperative to profile individual tumors to improve IO therapy outcomes. Ongoing analyses include IHC target validation.

#6685 Integrated high-throughput multimodal spatial profiling of RNA, protein, and morphology in FFPE sections with the G4X™ Spatial Sequencer.

Michael Lawson[1], Kenneth Gouin[1], Sabrina Shore[2], Yuji Ishitsuka[2], Richard Que[2], Eli Glezer[2], Daan Witters[2]

[1]Singular Genomics, San Diego, CA,[2]Singular Genomics, LA JOLLA, CA

Comprehensive characterization of the tumor microenvironment (TME) benefits from simultaneous measurement of transcripts, proteins, and morphology at single-cell resolution in clinically relevant samples. The G4X Spatial Sequencer is a high-throughput in-situ platform that delivers co-registered RNA, protein, and morphological readouts from the same FFPE section, supporting up to 40 cm^2 of tissue per run and flexible panel customization.We designed four targeted ~300-gene RNA panels for kidney, lung, colon, and breast tissues. Each includes 150 shared immuno-oncology genes, 50 stromal genes, and ~100 tissue-specific targets. A paired 16-plex immuno-oncology protein panel provides spatially resolved multiplexed proteomics measurements. All analytes were acquired from single 5 µm sections and directly aligned with fH&E™, a fluorescent analog of standard H&E.

Sections were processed via the TissuStamp™ transfer workflow in large (ten 10 × 10 mm^2/flow cell) or small (thirty two 4.5 × 4.5 mm^2/flow cell) arrays through antibody staining, padlock probe hybridization, amplification, and sequencing-by-synthesis (SBS). Per-cell detection ranged from 50-200 transcripts and 20-50 unique genes, with dynamic ranges exceeding 500 transcripts in high-expressing cells. RNA false discovery rates were ≤0.5% (typically <0.1%), and genomic DNA FDRs were 0.5-5%, with transcript detection unaffected by concurrent protein imaging.

Protein data quality matched single-plex immunofluorescence, and integration of protein abundance with gene-expression programs improved cross-modal specificity beyond single-gene comparisons.

In addition to curated panels for transcripts and proteins, G4X enables the inclusion of custom targets. The sequencing-based readout preserves probe-level resolution, enabling efficient optimization of custom RNA panels without loss of information, demonstrated across mouse, bone marrow, and pancreas datasets. Two additional custom protein targets were successfully incorporated into the curated 16-plex panel.

To highlight scalability, G4X is deployed in ongoing atlas-scale lung and colorectal cancer studies with academic partners and has been used for 3D reconstruction across serial sections.

Together, these results position G4X as a unified, scalable workflow for multiplexed spatial transcriptomic, proteomic, and morphological profiling of FFPE tissues, enabling large-cohort, integrative analyses of the TME.

#6686 Direct-Seq™ enables spatially resolved *in situ* sequencing of IgH and TCRβ transcripts in FFPE tissue at subcellular resolution.

Michael Lawson[1], Tung T. Le[2], Ryan Shultzaberger[2], Ashley Tsue[1], Zane Hiatt[2], Nathan Ing[1], Kenneth Gouin[2], Eli Glezer[2], Daan Witters[2]

[1]Singular Genomics, San Diego, CA,[2]Singular Genomics, LA JOLLA, CA

Spatial multi-omics is transforming our understanding of the tumor microenvironment, immune responses, and disease mechanisms. A critical gap remains in the ability to sequence highly variable transcript regions in situ at single-cell and subcellular resolution, essential for mapping B- and T-cell clonotypes in their native tissue context.

Here, we present Direct-Seq™, a novel in situ sequencing approach built on the G4X™ in situ multiomic platform, enabling high-resolution profiling of RNA variable regions. Direct-Seq employs probes targeting the V and J regions flanking the diverse CDR3 domain of IgH and TCRβ transcripts, allowing sequencing of both the J and CDR3 regions. The workflow integrates in situ reverse transcription, amplification, and sequencing-by-synthesis chemistry.

We applied Direct-Seq to 5-µm FFPE tonsil and renal cell carcinoma (RCC) sections and 10-µm fresh frozen tonsil sections. Up to 9% of B cells were profiled in FFPE tonsil, and ~20% of B and T cells in fresh frozen tissue. Extensive CDR3 diversity was detected, with clonally expanded B cells carrying highly similar CDR3 sequences localized within germinal centers, demonstrating the high-resolution clonotyping capacity of Direct-Seq.

In Renal Cell Carcinoma (RCC), nine serial FFPE kidney sections revealed clonally expanded B-cell populations enriched around tumor regions and T-cell clones with persistent expansion. One dominant T-cell clone was consistently detected across serial sections, highlighting the method's robustness and ability to track clonal populations spatially.

Direct-Seq was combined with multiplexed protein detection on the same sections, confirming spatial concordance between transcript identity and protein phenotype.

Together, these results establish Direct-Seq as a high-resolution, scalable approach for spatial immune repertoire mapping in both FFPE and fresh frozen tissue, enabling detailed studies of clonality, immune architecture, and translational immunology.

#6690 Unfavorable early progression-free survival of immunotherapy compared to chemotherapy in bladder cancer: A meta-analysis of randomized trials.

Donghwi Choi, Hangyul Lee, Jinha Kim, Young Kwang Chae

Northwestern Univ. Feinberg School of Medicine, Chicago, IL

Introduction: Platinum-based chemotherapy has long served as the first-line standard for advanced urothelial carcinoma. However, the advent of immune checkpoint inhibitors (ICIs) has spurred efforts to evaluate their suitability as initial therapy, especially in patients with strong PD-L1 expression or those who cannot tolerate cisplatin. Early results from randomized controlled trials (RCTs) suggest that ICI-only regimens may produce inferior short-term progression-free survival (PFS) compared with chemotherapy, potentially due to delayed immune activation, lack of rapid tumor shrinkage, or hyperprogressive disease in select cases. To characterize this time-dependent efficacy pattern, we performed a meta-analysis comparing ICI-only regimen with chemotherapy in advanced bladder cancer.
Methods: A comprehensive search of PubMed, Embase, and the Cochrane Library identified phase II-III RCTs comparing first-line ICI-only regimen(Durvalumab, Durvalumab+Tremelimumab, Pembrolizumab) and platinum-based chemotherapy for advanced bladder cancer. Studies conducted exclusively in first-line treatment settings were selected for inclusion. Kaplan-Meier PFS curves from eligible trials were extracted and digitized, and reconstructed patient-level survival data were generated using the Guyot algorithm. Combined Kaplan-Meier estimates were produced from pooled data, and hazard ratio (HR) values comparing immunotherapy with chemotherapy were calculated at 3, 6, 9, and 12 months to evaluate temporal changes in treatment effect. HRs were obtained through two-stage meta-analysis, incorporating study-specific weights to account for differences in sample size and variance across trials.
Results: Three immunotherapy regimens in two RCTs met the inclusion criteria. ICI-only regimens demonstrated worse early PFS outcomes compared to chemotherapy, with HRs of 4.08(95% CI, 2.85-5.82) at 3 months, 2.87(2.23-3.70) at 6 months, 2.05(1.80-2.33) at 9 months and 1.92(1.63-2.25) at 12 months. HRs gradually decreased throughout the 12-month period, indicating slow convergence of survival trajectories. Pooled KM curves showed that immunotherapy exhibited reduced short-term benefit compared to chemotherapy that gradually improved with longer follow-up and ultimately crossed over at 10 months.
Conclusion: In advanced bladder cancer, first-line ICI-only regimen underperforms relative to chemotherapy in the early phase. Survivability slowly improves with follow-up and benefits are apparent around 10 months as the KM curves cross over. These findings underscore the need for vigilant early assessment and support combination or sequential treatment strategies to offset early progression while preserving long-term immunologic benefit.

#6691 Pattern of inferior early progression-free survival with immunotherapy versus chemotherapy in head and neck cancer: A meta-analysis of randomized trials.

Donghwi Choi, Hangyul Lee, Jinha Kim, Young Kwang Chae

Northwestern Univ. Feinberg School of Medicine, Chicago, IL

Introduction: Platinum-based chemotherapy combined with immunotherapy has long been the standard first-line treatment for advanced head and neck squamous cell carcinoma (HNSCC). Recently, pembrolizumab-based regimens guided by PD-L1 expression have introduced immunotherapy-only approaches as viable options for selected patients. However, early data from randomized trials suggest that immunotherapy may result in inferior short-term progression-free survival (PFS) compared with chemotherapy, likely due to delayed immune activation or possible hyperprogression of the disease. To clarify these time-dependent effects, we performed a meta-analysis comparing the early efficacy of immunotherapy versus chemotherapy in advanced HNSCC.
Methods: We systematically searched PubMed, Embase, and the Cochrane Library for phase II-III RCTs evaluating first-line immunotherapy(Pembrolizumab, Nivoluab+Ipilimumab, Durvalumab, Durvalumab+Tremelimumab) with platinum-based chemotherapy in advanced HNSCC. Eligible trials were required to have Kaplan-Meier PFS curves for immunotherapy and chemotherapy arms. Trials including post-first-line settings were excluded. Kaplan-Meier PFS curves were digitized, and reconstructed individual patient data were derived via the Guyot method. Pooled Kaplan-Meier survival curves were then generated, and hazard ratio (HR) values comparing immunotherapy and chemotherapy arms were calculated at 3, 6, 9, and 12 months to assess changes in treatment effect over time. Hazard ratios (HRs) were estimated through a two-stage meta-analytic method, with each study weighted according to its sample size and variance to accommodate inter-trial differences.
Results: Three eligible RCTs were identified. Immunotherapy exhibited a pronounced early disadvantage in PFS compared with chemotherapy, with HRs of 3.77 (95% CI, 3.17-4.48) at 3 months and 2.20 (95% CI, 1.80-2.68) at 6 months. This gap narrowed over time but was still statistically significant by the 9th (HR 1.86; 95% CI, 1.62-2,13) and the 12th month (HR 1.73; 95% CI, 1.49-2.01). Pooled Kaplan-Meier PFS curves mirrored these findings, showing inferior short-term performance of immunotherapy followed by gradual convergence of both arms, with the immunotherapy arm ultimately crossing over the chemotherapy arm around the 12th month.
Conclusion: Among patients with metastatic HNSCC, first-line ICI monotherapy initially shows inferior outcomes compared to chemotherapy, but the survival benefit becomes evident around the 12th month as the delayed effects of immunotherapy emerge. These results highlight the importance of close early monitoring and lend support to combination or sequential regimens to counteract early disease progression while maintaining long-term benefit.

#6692 Self-adjuvanting α-helical polypeptide simultaneously delivers neoantigen mRNAs and activates dendritic cells to eradicate tumors.

Jiadiao Zhou

University of Illinois at Urbana-Champaign, Champaign, IL

mRNA-based vaccines have demonstrated tremendous success during the era of COVID-19, but their therapeutic potential for treating cancer, especially poorly immunogenic solid tumors, remains under-achieved. Herein we report a class of self-adjuvanting α-helical polypeptides that can markedly improve the antitumor efficacy of tumor neoantigen-encoding mRNAs. Ideal carriers for antigen-encoding mRNAs should not only facilitate antigen expression in DCs but also activate DCs and induce effective processing and presentation of expressed antigens. Herein we report the development of cationic α-helical polypeptides as a self-adjuvanting delivery vehicle for antigen-encoding mRNAs.

The α-helical polypeptides facilitate intracellular delivery of mRNAs into dendritic cells (DCs) via temporary membrane disruption, simultaneously activate DCs by regulating NF-κB and IRF pathways, and improve the ability of DCs to process and present mRNA-encoded neoantigens. The cationic polypeptide condenses and stabilizes mRNAs, promotes internalization via its cell-penetrating property, and increases the expression of activation markers (CD86, MHCII, CD40, and CCR7) on DCs by upregulating NF-κB, IRF, and STING pathways. Molecular docking and simulation confirm the stable complexation between mRNA and α-helical polypeptides.

Upon subcutaneous administration, the polyplex migrates to draining lymph nodes, where it transfects and activates DCs, eliciting a strong neoantigen-specific cytotoxic T lymphocyte (CTL) response in vivo. Compared to mRNA-SM102 lipid nanoparticles or Lipofectamine 3000 lipoplexes, the polyplex enhances antigen expression and presentation by DCs, leading to significantly improved priming of antigen-specific $CD8^+$ T cells in vitro and in vivo. The polyplex achieves 83.3% and 33.3% tumor-free survival in E.G7-OVA lymphoma and 4T1 triple-negative breast cancer (TNBC), respectively. This is far exceeding the 0% tumor-free survival of conventional formulations. Polyplexes composed of α-helical L-PPOB50-G and mRNAs encoding 4T1 TNBC neoantigens elicit potent neoantigen-specific $CD8^+$ T cell responses while showing no detectable toxicity in major organs.

The polyplex also reprograms the immunosuppressive tumor microenvironment by enriching DCs, M1-phenotype $CD86^+$ macrophages, and $CD8^+$ T cells in tumors. We also observed increased PD-1 expression on intratumoral $CD8^+$ T cells and PD-L1 on 4T1 tumor cells after polyplex treatment and demonstrated synergistic effects between the polyplex vaccine and anti-PD-1 therapy. Our polyplex system provides a facile and generalizable approach to developing robust mRNA-based cancer vaccines.

#6693 KLRG1^{+}PD-1^{+} CD8^{+} T cells drive potent antitumor immunity induced by a systemic STING nanovaccine.

Shuang Chen[1], Shuyue Ye[1], Qiang Feng[1], Gang Huang[1], Animesha Krishnamurthy[1], Baran Devrim Sumer[2], Jinming Gao[3]

[1]UTSW, Dallas, TX,[2]UT Southwestern Medical Center, Dallas, TX,[3]UT Southwestern, Dallas, TX

Activation of the stimulator of interferon genes (STING) pathway enhances dendritic-cell priming and cytotoxic T-cell immunity, yet systemic STING agonists are limited by off-target toxicity. We recently developed a dual-stimuli-responsive STING nanovaccine that co-delivers HPV E7 antigen and a polymer-conjugated STING agonist, enabling safe systemic activation of antitumor T cells.[1, 2] Despite the strong induction of E7-specific CD8^{+} T cells, the phenotypic and functional heterogeneity of vaccine-elicited T cells remains incompletely understood. Identifying the dominant effector population responsible for tumor clearance is critical for rational vaccine optimization and for developing combination strategies with adoptive or checkpoint-based immunotherapies.[3] To address this, we analyze the splenic immune cells in C57BL/6 tumor-bearing mice after intravenous administration of the dual-stimuli-responsive STING nanovaccine. A distinct KLRG1^{+}PD-1^{+} CD8^{+} T-cell population emerged and was isolated by fluorescence-activated cell sorting for adoptive transfer into naïve, tumor-bearing recipients. Vaccination induced robust activation of dendritic cells (CD86^{+}MHC-II^{+}) in the spleen and lymph nodes, accompanied by expansion of E7-specific CD8^{+} T cells. Within this compartment, the KLRG1^{+}PD-1^{+} subset exhibited high expression of granzyme B and IFN-γ, consistent with a cytotoxic-effector phenotype. Adoptive transfer of these double-positive cells significantly delayed tumor growth and prolonged survival relative to unsorted or untreated controls, confirming their potent antitumor activity. Expansion of this subset correlated with spleen-targeted biodistribution and STING-dependent activation of myeloid cells.These data identify a functionally dominant KLRG1^{+}PD-1^{+} CD8^{+} T-cell subset as a key mediator of systemic STING nanovaccine efficacy. The findings support a mechanistic link between STING-driven myeloid activation and effector-T-cell differentiation. Ongoing single-cell and spatial transcriptomic analyses will define the lineage trajectories and molecular circuitry underlying their generation and persistence, informing future combinations of STING nanovaccines with adoptive-cell or checkpoint immunotherapies for durable systemic tumor control.

Keywords: STING nanovaccine, CD8^{+} T cells, KLRG1, PD-1, adoptive transfer, single-cell RNA-seq, spleen, immunotherapy

#6694 Monocyte-derived dendritic cells for antigen-specific T cell activation.

Kaitlin Hsu, Jessica Voce, Amy Zhao, Jessie Ni

BioLegend, San Diego, CA

This study describes an efficient workflow to generate functional dendritic cells (DCs) from human peripheral blood monocytes and their application in antigen-specific T cell activation assays. Monocytes were differentiated into mature DCs expressing high levels of co-stimulatory molecules and MHC molecules. When pulsed with specific antigens and co-cultured with autologous T cells, these DCs effectively activated CD4+, CD8+, and regulatory T cell populations, as demonstrated by proliferation assays and cytokine profiling. The differential activation kinetics between T cell subsets provided insights into the temporal dynamics of antigen-specific immune responses. Our workflow demonstrates a standardized approach that offers a reliable research platform to investigate DC-T cell interactions, evaluate vaccine candidates, and assess antigen-specific T cell responses. Furthermore, our reproducible workflow may serve as a valuable tool for applications in immunology research, including vaccine development, cancer immunotherapy, and autoimmune condition studies.

#6695 Early progression disadvantage of immunotherapy-only treatment versus chemotherapy in NSCLC: A meta-analysis of randomized controlled trials.

Jinha Kim, Hangyul Lee, Donghwi Choi, Young Kwang Chae

Northwestern Univ. Feinberg School of Medicine, Chicago, IL

Introduction : Immune checkpoint inhibitors (ICIs) have become a cornerstone in the treatment of advanced non-small cell lung cancer (NSCLC). However, across several randomized controlled trials (RCTs), immunotherapy-only arms have demonstrated an early disadvantage in progression-free survival (PFS) and overall survival when compared with chemotherapy or chemo-immunotherapy combinations. This early decline may reflect multiple factors, including lack of cytoreduction, delayed onset of immunotherapy efficacy relative to chemotherapy, or the phenomenon of hyperprogression. To better define this pattern, we conducted a meta-analysis of RCTs comparing immunotherapy-only regimens with chemotherapy in first-line NSCLC to determine whether this early disadvantage is consistent and generalizable.

Methods: We systematically searched three databases (PubMed, Cochrane Library, and Embase) for phase II and III RCTs evaluating an immunotherapy-only regimen (Nivolumab plus Ipilimumab, Pembrolizumab, Atezolizumab, Avelumab, Nivolumab, Durvalumab, Durvalumab plus Tremelimumab, Cemiplimab) in the first-line treatment of advanced NSCLC. Trials limited to later-line therapy were excluded. Eligible studies required Kaplan-Meier curves for PFS. Twelve RCTs met inclusion criteria. Survival curves were digitized, and individual patient data were reconstructed using the Guyot algorithm. Combined Kaplan-Meier estimates were generated from pooled data, and hazard ratios (HRs) comparing immunotherapy-only vs platinum-based chemotherapy were obtained through two-stage meta-analysis with study-specific weights. Area under the curve (AUC) values were calculated to evaluate temporal changes in treatment effect.

Results : Across 12 RCTs, immunotherapy-only regimens showed a clear early disadvantage in PFS. At three months, the hazard ratio for PFS was 2.03 (95% CI 1.77-2.32), indicating a significantly higher risk of progression in the immunotherapy arms. This persisted at six months (HR 1.36, 95% CI 1.18-1.57), but diminished by nine months (HR 1.13) and 12 months (HR 1.08). Over the full follow-up, immunotherapy ultimately outperformed chemotherapy (HR = 0.86, 95% CI 0.74-0.99, p = 0.048), showing a delayed benefit. AUC analysis confirmed an inferior cumulative PFS benefit during the first 6 months, followed by a gradual catch-up.

Conclusion : First-line immunotherapy-only treatment in NSCLC shows an early PFS disadvantage relative to chemotherapy, followed by superior long-term outcomes. This pattern underscores the need for early monitoring and optimized combination strategies to prevent early progression while maintaining immunotherapy's durable benefits.

#6696 A senescent whole-cell vaccine platform derived from conditionally reprogrammed primary tumor cells primes potent T-cell immunity and overcomes ICI resistance in murine breast cancer models.

Sara Rasouli[1], Chongwen Cao[2], Weiyi Gong[1], Haichang Li[3], Bei Liu[4], Anna Vilgelm[2], Jenny Li[2], Xuefeng Liu[2]

[1]Comprehensive Cancer Center, Biomedical Sciences Graduate Program, The Ohio State University, Columbus, OH,[2]Comprehensive Cancer Center, Department of Pathology, The Ohio State University, Columbus, OH,[3]The Ohio State University College of Veterinary Medicine, Columbus, OH,[4]Molecular, Cellular and Developmental Biology Program, Comprehensive Cancer Center, Ohio State University, Columbus, OH

Background: Aggressive cancers, including breast cancer, face challenges of therapeutic resistance and recurrence. Autologous cancer vaccines are limited by difficulties in obtaining sufficient primary tumor material. Our lab uses the Conditional Reprogramming Cell (CRC) method to enable long-term in vitro expansion of primary tumor cells. We are developing a novel vaccine strategy based on cellular senescence, a highly immunogenic state. We hypothesize that irradiated, senescent whole-tumor cells (SWCs) generated via CRC will function as potent, poly-antigenic vaccines to prime robust anti-tumor T-cell responses, synergize with immune checkpoint inhibitors (ICIs), and establish long-term immune memory.
Experimental method: Senescence was induced in murine breast cancer lines by γ-irradiation. Immune priming was assessed by injecting SWCs into naïve syngeneic mice, quantifying systemic T-cell activation ($CD4^+$, $CD8^+$, $CD69^+$, PD-1^+) in spleens and lymph nodes via flow cytometry. Therapeutic efficacy will be evaluated in orthotopic, tumor-bearing mice treated with SWC vaccine + CpG adjuvant, +/- dual ICI blockade (anti-PD-L1/anti-CTLA-4). Endpoints include tumor regression and survival. Vaccine efficacy will also be tested in prophylactic and post-surgical anti-recurrence models (simulating R1/R2 residual disease).
Summary of new data: In vivo immune-priming experiments (four weekly injections) demonstrated that senescent tumor cells elicited a robust, systemic adaptive immune response. Compared to controls, SWC-treated mice showed a marked expansion of both $CD8\alpha^+$ and $CD4^+$ T-cell populations in spleens and lymph nodes. Flow cytometry revealed an activated effector phenotype with elevated CD69 and cytotoxic markers in $CD8^+$ T cells. These findings confirm SWCs are highly immunogenic and induce systemic T-cell activation.
Conclusion: Senescent whole-tumor cells derived via the CRC method are a feasible and potent poly-antigenic vaccine platform. Our preliminary data demonstrate that this strategy breaks immune tolerance, inducing robust T-cell activation. This provides a strong rationale for advancing this personalized, autologous vaccine to overcome immune resistance and prevent recurrence in aggressive solid tumors.

#6697 Pelareorep combined with atezolizumab and chemotherapy shows immune conversion activity in advanced pancreatic cancer: Biomarker results of cohort 1 of the GOBLET trial.

Hendrik Schurmann[1], Sven-Thorsten Liffers[2], Richard Trauger[3], Thomas Heineman[3], Dirk Arnold[4], Jens T. Siveke[2]

[1]Department of Medical Oncology, University Hospital Essen, Essen, Germany,[2]Bridge Institute of Experimental Tumor Therapy, University Hospital Essen, Essen, Germany,[3]Oncolytics Biotech, San Diego, CA,[4]Asklepios Tumorzentrum Hamburg, AK Altona, Hamburg, Germany

Introduction: Pancreatic cancer features a profoundly immunosuppressive microenvironment and no approved immunotherapy to date. Pelareorep (REOLYSIN®) is a wildtype oncolytic reovirus that preferentially replicates in RAS upregulated tumor cells. In cohort 1 of the phase 1/2 GOBLET trial, patients with advanced pancreatic cancer were enrolled to receive first line (1L) pelareorep combined with atezolizumab and gemcitabine/nab-paclitaxel yielding a previously reported confirmed objective response rate (ORR) of 54% (7/13) and disease control rate (DCR) of 85% (11/13).
Methods: In an exploratory biomarker analysis, routine serum markers (CA19-9, CEA, CRP) and 172 circulating proteins quantified via proximity extension assay (PEA; Olink®) were integrated with selected T cell receptor (TCR) sequencing and clinical outcomes. Linear mixed effects models and semi supervised clustering were applied to identify protein patterns reflecting immune and inflammatory activity.
Results: Early on-treatment effects included increased abundance of adaptive immune (e.g. IFN-gamma, CXCL11, TNF) or cytotoxicity associated proteins (e.g. GZMB/H/A) and reduced tumor/stroma-associated proteins (MUC-16, MMP12). A 14-protein signature linked to oncolytic activity (IFN γ signaling, CD8+ and NK cytotoxic functions) stratified patients at week 4 into “hot” versus “cold” immune phenotypes relative to baseline. Despite small numbers, the ‘hot’ phenotype was associated with significantly longer median progression free survival (n=6; mPFS; 7.5 mo, 95% CI: 7.1-14.3) compared with “cold” (n=6; mPFS 5.6 mo, 95% CI: 1.7-6.0; log rank p<0.005).
Conclusion: Pelareorep combined with atezolizumab and gemcitabine/nab-paclitaxel demonstrated promising activity in 1L pancreatic cancer. A hot/cold immune signature detectable after 4 weeks may serve as an early stratification biomarker, supporting identification of patients likely to achieve durable benefit

#6698 EpitopeMiner: Scalable knowledge mining for evidence-driven personalized cancer vaccine design.

Agamjyot Singh Chadha[1], Isaac Jiasheng Cheong[2], Marcia Zhang[2], Wei Kit Tan[2], Wei Lin Tang[1], Jing Quan Lim[3], Solomonraj Wilson[1], Choon Kiat Ong[3], Bernett Lee[4], Chwee Ming Lim[5], Olaf Rotzschke[1], Mai Chan Lau[1]

[1]Singapore Immunology Network Lab, A*STAR - Agency for Science, Technology and Research, Singapore, Singapore,[2]Bioinformatics Institue, A*STAR - Agency for Science, Technology and Research, Singapore, Singapore,[3]Lymphoma Translational Research Laboratory, Division of Cellular and Molecular Research, National Cancer Centre Singapore, Singapore, Singapore,[4]Lee Kong Chian School of Medicine (LKCMedicine), Nanyang Technological University Singapore, Singapore, Singapore,[5]Surgery Academic Clinical Programme (Surgery ACP), Duke-NUS Medical School, Singapore, Singapore

Background: Personalized cancer vaccines hold great promise by eliciting tumor-specific immune responses [1-3]. A key challenge is identifying the right targets — immunogenic protein sequences, or epitopes, presented on tumor cells. While computational pipelines can predict epitope candidates from tumor sequencing, experimental validation is costly and slow. Leveraging literature and database knowledge could bridge this gap by enabling evidence-driven selection of high-confidence targets, but is constrained by fragmented information across journals and immunology databases [4-5]. We introduce EpitopeMiner, which integrates sequence-based candidate screening with evidence-driven knowledge retrieval for epitope prioritization.

Methods: A total of 25,966 tumor-specific epitopes were predicted from whole-genome sequencing of tumor-PBMC pairs from nine patients (including lung, sarcoma, NKTL, DLBCL) using a standard workflow: HLA typing (OptiType), variant calling (Strelka with wANNOVAR), MHC binding prediction (NetMHCpan) and RNA-supported protein-altering filtering. EpitopeMiner combines OpenAI's Large Language Model (LLM) with an in-house Retrieval Augmented Generation (RAG) database comprising (a) 78,461 full-text research articles from PMC, PLOS One, and Europe PMC and, (b) ~2.6 million unique epitopes from IEDB, dbPepNeo, SystemMHC, TANTIGEN, and caAtlas database. EpitopeMiner includes: (i) a screening module that processes an epitope list, detecting exact or ≥ 7 amino acid partial matches from the in-house database, and (ii) a reporting module that analyses each top-ranked hits, defined by highest sequence similarity and evidence density, to generate an LLM response covering 28 immunology keywords with citations.

Results: Among the 25,966 epitopes predicted from the nine patients, EpitopeMiner found 7 exact matches, and 17.6% had ≥ 6 partial matches; mean processing time per epitope was 0.97 seconds. In benchmarking with 3 lung cancer driver-gene epitopes (KITDFGRAK, ITDFGRAKL, TDFGRAKLL), EpitopeMiner outperformed ChatGPT and Gemini, returning the highest amount of relevant immunological information — summarized as (total responses, % with evidence) — (18, 100%), (8, 100%), and (2, 100%) respectively, compared to ChatGPT's (10, 70%), (4, 50%), (6, 33%) and Gemini's (7, 0%), (1, 0%), (1, 0%). In addition, EpitopeMiner retrieved ≥10 partial matches for each epitope, whereas ChatGPT retrieved total of 3 and Gemini none.

Conclusion: We built EpitopeMiner, a computational framework for sustainable literature and database curation. In a 9-patient dataset, EpitopeMiner retrieved experimentally and clinically validated epitope evidence at a scale and speed infeasible with manual analysis. EpitopeMiner outperformed general-purpose LLMs with cited responses, achieving 100% evidence coverage on benchmarks, reducing hallucinations and improving reliability.

#6699 Novel preclinical immunocompetent mouse model for assessment of immunotherapies targeting cGAS-STING axis.

Angela Pappalardo, Philippe De La Rochere, Patricia Isnard-Petit, Gaelle H. Martin, **Fabiane Sonego**, Kader Thiam

genOway, Lyon, France

The cyclic GMP-AMP synthase-stimulator of interferon genes (cGAS-STING) signaling axis represents a pivotal immunostimulatory pathway and an attractive pharmacological target in oncology. Its activation within the tumor microenvironment promotes cross-priming of tumor-associated antigens and enhances infiltration of effector T lymphocytes. Owing to its potent antitumor activity, the cGAS-STING pathway offers significant promise for the development of cancer vaccines, immunotherapeutic strategies such as antibody-drug conjugates, and interventions against virus-driven malignancies. However, translating preclinical findings to clinical applications has been challenging due to species-specific differences between human and mouse cGAS and STING. A model expressing human STING only has been previously reported and showed to be a valuable tool to investigate the activity of STING agonist in different tumor types. Herein, we report an immunocompetent mouse model expressing both human cGAS and human STING (genO-hcGAS-hSTING). Humanization of cGAS and STING did not alter immune cell composition in the spleen, blood and bone marrow when compared to WT mice. Expression of human cGAS has been confirmed in brain and lung by Western Blot, while hSTING expression was confirmed in immune cells in the spleen and blood by flow cytometry. Functionality of cGAS was investigated through activation of splenocytes with the non-human-specific cGAS agonist G3-YSD, which induced IFN-α, IFN-γ, and TNF-α secretion. Similarly, functionality of STING has also been investigated by activating splenocytes with diABZi and DMXAA. While diABZi activates both human and mouse STING, DMXAA activates specifically mouse STING. Indeed, diABZi induces the secretion of IFN-β, CXCL10, and IL-6 in cells from both WT genO-hcGAS-hSTING mice, wherein DMXAA induced cytokine secretion in WT only. These data indicate that human STING expressed in genO-hcGAS-hSTING mice is functional and mouse STING is no longer expressed in these mice. These humanized models provide valuable tools for assessing the efficacy and specificity of compounds targeting human cGAS and STING pathways, potentially streamlining drug discovery and enhancing our understanding of innate immune responses in human health and disease.

#6700 A fully integrated set of *in vitro* and *in vivo* tools for utilization of micro-organisms as new therapeutic weapons against cancer.

Guillaume Serin, Lucie Demontoux, Elizabeth Bertrand, Marie Leblanc, Sylvie Maubant, Ismahene Benzaid, **Marc Hillairet De Boisferon**

Oncodesign Services, Dijon, France

In the dynamic landscape of oncology, innovative approaches are constantly emerging to tackle complex challenges. One such promising avenue gaining attention is the development of micro-organisms like viruses or bacteria to destroy cancer cells and leverage the host immune system to enhance the effect. The combination of loss of intracellular viral and bacterial resistance to increase survival and proliferation pathways, profound changes of tumor microenvironment leading to inactivation of immune response and favored tumor accumulation of small particles by EPR enables microorganisms to massively and selectively colonize and attack the cancer cells. Genetic engineering is added to reduce their natural virulence and tropism and enhancing their therapeutic potential, often by expression of chemokine or antigens to (re)activate the immune response or expression of antibodies or proteins that can trigger T cell engagement or other physiological modification. Alone or combined with specific adjuvants and other therapeutic agents, oncolytic viruses or bacteria have shown significant reduction to even full remission of primary and metastatic tumors.At Oncodesign Services, we have hundreds orthotopic and subcutaneous rodent or human CDX and PDX tumor models readily available to study the activity and mechanism of action of micro-organisms in syngeneic, xenogeneic or humanized immune reconstituted models. Viruses and bacteria can be manipulated in BSL2 and BSL3 status. With 30 years of experience and thousands of studies performed, Oncodesign Services has also the know-how to provide support for testing combinations with other chemo, immuno-onco (ICI, ADC, BiTEs, CAR-T cells) or irradiation therapy to further increase the activity of micro-organisms.In addition to continuum of assays allowing us to evaluate the impact of microorganisms on tumor and/or immune cells (e.g. phenotyping of immune infiltrate, cytokine/chemokine profiling, tumor burden), we have developed assays to detect, quantify, identify and localize live microorganisms (e.g. qPCR, mass spectrometry, bioluminescence) in simple or complex samples.In this poster, we will highlight some results obtained in a cancer context such as the immunostimulatory properties of modified micro-organisms, the selective infection of tumor tissue or the benefits in delivery of therapeutic proteins or antigens.

#6701 Re-engineering cancer vaccines: Bria-OTS+ integrates innate and adaptive immunity for broad and persistent anti-tumor responses.

Miguel A. Lopez-Lago, Pravin Kesarwani, Vikas Bhardwaj, Xiaoyi Zheng, Ying Liu, Sagarika Pachhal, Patience cournoo, Renee Cortez, George Woodfield, Charles Wiseman, William V. Williams

BriaCell Therapeutics Corp., Philadelphia, PA

Background: Despite major advances in immuno-oncology, achieving durable tumor control remains difficult because of tumor heterogeneity, immune evasion, and limited coordination between innate and adaptive immune responses. Whole-cell cancer vaccines offer broad antigenic coverage but have historically lacked potency and persistence. Bria-OTS+ is a next-generation, genetically engineered whole-cell cancer vaccine platform designed to overcome these limitations by integrating innate and adaptive immunity. Bria-OTS+ is composed of genetically reprogrammed tumor cells that naturally display a broad antigen repertoire, while being engineered to express immune-stimulatory cytokines (GM-CSF, IFN-α, IL-12, IL-7), co-stimulatory molecules (CD80, CD86, CD40, 4-1BBL), and diverse HLA-A and HLA-DR alleles, supporting potent immune activation and broad semi-allogeneic compatibility (>99 % population coverage).
Methods: Irradiated Bria-OTS+ cells representing breast, prostate, lung, and melanoma lineages were co-cultured with human PBMCs in a four-phase in vitro vaccination assay (priming, resting, boosting, effector) designed to model sequential immune activation, memory formation, and recall response. Immune activation, proliferation, and cytotoxicity were quantified by flow cytometry and ELISA. Mechanistic dissection employed blocking antibodies to CD86, IL-12, NKp46, and HLA-I/II molecules to define signaling dependencies.
Results: Bria-OTS+ induced coordinated activation of $CD4^+/CD8^+$ T, NK, NKT, dendritic, and B cells, with strong IFN-γ/TNF-α release and up-regulation of CD69/CD25. CD80/CD86 increased on dendritic and B cells, indicating enhanced antigen-presenting potential. NK-cell cytotoxicity dominated early responses and was amplified by IL-12 and CD86 signaling. Upon recall, T and NK cells exhibited amplified cytokine release, proliferation, and tumor-cell killing together with a memory phenotype and controlled checkpoint profile (low PD-1/TIM-3, moderate LAG-3), indicating persistent effector competence without exhaustion. Bria-OTS+ activated PBMCs killed both homologous and heterologous tumor targets, supporting shared antigen recognition and/or NK activity and reduced Immuno-evasion risk.
Conclusions: Bria-OTS+ functions as a modular, immune-educating platform that integrates trained innate and adaptive immunity within a scalable, semi-personalized framework. By coupling multi-cytokine signaling and co-stimulation with HLA-guided antigen presentation, Bria-OTS+ achieves persistent immune activation, broad tumor recognition, and is readily manufacturable for off-the-shelf clinical deployment.

#6702 A *Cxcl10* mRNA-LNP adjuvant enhances immune checkpoint inhibitor responses in melanoma models.

Kaitlyn M. Landreth[1], Katherine Lee[1], Emel Sen Kilic[2], Joshua Chapman[1], Mary Garland-Kledzik[3], F. Heath Damron[1], Tracy W. Liu[1]

[1]MICB, West Virginia Univ. School of Medicine, Morgantown, WV,[2]Embry-Riddle Aeronautical University, Daytona Beach, FL,[3]Department of Surgery, West Virginia Univ. School of Medicine, Morgantown, WV

Immunotherapies have become standard of care in the treatment of melanoma; however, about 50% of patients are immunotherapy resistant. This can be caused by an immunosuppressive tumor microenvironment that has a low infiltration of immune cells, especially T cells. Tumors with high T cell infiltration demonstrate better responses to immune checkpoint therapy, making modulation of the tumor microenvironment to enhance T cell recruitment and activation a critical unmet need. In this study, we hypothesize that using an mRNA encoded “genetic adjuvant” can increase the infiltration of T cells into the tumor microenvironment and improve immunotherapy response. The chemokine CXCL10 plays a key role in T cell recruitment and activation, signaling via the CXCR3 receptor expressed by activated T cells. Consistent with this mechanism, analysis of melanoma patient serum samples showed significantly higher Cxcl10 levels in immunotherapy responders compared to non-responders. To directly enhance CXCL10, we developed a Cxcl10-encoded mRNA lipid nanoparticle (Cxcl10 LNP). A significant increase in CXCL10 levels in the sera and inguinal lymph nodes of C57BL/6J wild-type mice was observed post intramuscular administration of Cxcl10 LNP. Our data shows that intramuscular injection of Cxcl10 LNP significantly reduced the volume of established subcutaneous B16F10 murine melanoma tumors. Cxcl10 LNP treatment lead to a significant increase of CD8+ T cells within the tumor microenvironment at 48 hours assessed by flow cytometry and intravital imaging. Phenotypic profiling further revealed significant increases of TRP-2 tumor specific CD8+ T cells and CD107a+ cytotoxic effector CD8+ T cells 48hrs post intramuscular administration of Cxcl10 LNP. When combined with dual anti-PD-1 and anti-CTLA-4 immune checkpoint inhibitor antibodies, Cxcl10 LNP improved long-term survival and significantly decreased subcutaneous tumor growth, with 20% of mice tumor-free at day 100. Moreover, in our spontaneous metastatic melanoma model, mice received Cxcl10 LNP 24h post primary tumor resection followed by dual anti-PD-1 and anti-CTLA-4 immune checkpoint inhibitors for a total of 3 doses. Adjuvating immune checkpoint inhibitors with Cxcl10 LNP significant reduced lung and lymph node metastasis, with 80% of mice showing no detectable metastases. These findings demonstrate that using Cxcl10 LNP is an effective genetic adjuvant that enhances CD8+ T cell infiltration and cytotoxic function, resulting in improved efficacy of immune checkpoint inhibitors and reducing tumor burden and metastases.

#6703 Rg002: An mRNA-LNP-based immunotherapy targeting HPV-16/18-related malignancies.

Shan Cen[1], Lan Zhu[2], Fei Chen[2], Wei Wang[3], Lihua Qiu[4], Hua Yang[2], Yijie Dong[5], Weiguo Zhang[5], Huizhen Zhang[5], Jing Wang[5]

[1]Institute of Medicina Biotechnology, Chinese Academy of Medical Sciences, Beijing, China,[2]Peking Union Medical College Hospital, Beijing, China,[3]The Second Hospital of Shanxi Medical University, Taiyuan, China,[4]Renji Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China,[5]RinuaGene Biotechnology Co., Ltd., Suzhou, China

Prophylactic vaccines against oncogenic human papillomaviruses (HPVs) are effective in preventing HPV infection but not in treating existing HPV infection and cervical intraepithelial neoplasia (CIN). Current treatments for CIN are often ablative and may lead to long-term reproductive morbidity. Thus, there is a tremendous need for therapies that can treat the millions living with persistent oncogenic HPV infection and CIN and the risk of HPV-related cancers. RG002 is a mRNA-based therapeutic treatment targeting the E2, E6, and E7 proteins of HPV-16/18 with a targeted LNP for selective delivery to spleen and dendritic cells, which demonstrated excellent efficacy and safety in preclinical studies. In the phase I and expanded clinical studies, we evaluated the safety, efficacy, and immunogenicity of RG002 in 12 women with HPV 16/18 associated CIN2/3. Patients receive intramuscular administrations of 25, 75, 150, or 300 μg of RG002 at weeks 0, 2, and 4. RG002 does not cause any serious vaccine-related adverse events at any of the administered doses. Notably, all patients have exhibited complete regression of lesions and viral clearance within 17 weeks after the first dose, along with unprecedented E2/E6/E7 specific IFN-γ-producing T-cell response with clear dose-responses relationships. These initial data demonstrate the strong potential of RG002 as a first-in-class, non-surgical treatment for HPV-16/18-associated CIN2/3 to prevent progression to invasive carcinoma.
Note on Study Status: *The initial cohort (n=12; 3 per dose) is nearing completion. Based on promising early results, the protocol has been amended to enroll an additional 15-30 patients by January 2026. Updated results from over 40 patients, including Week 17 efficacy data for at least 20 patients, are expected in mid-April 2026.*

#6704 Exercise attenuates anti-PD-1-induced adventitial macrophage inflammation in the aorta of aged melanoma-bearing mice.

Jonghae Lee, Sumedha Pareek, Truong Lam, Fei Wang, Guanshu Liu, Jared K Burks, Jun-ichi Abe, Keri Schadler

University of Texas MD Anderson Cancer Center, Houston, TX

Immune checkpoint inhibitors (ICI) improve cancer outcomes but can induce vascular toxicity, potentially threatening long-term survivorship. In our pilot data using young male mice with tumors, anti-PD-1 increased vimentin, an endothelial-to-mesenchymal transition (EndMT) marker linked to early atherosclerosis, in laminar-flow regions of the aorta, and exercise attenuated this response. Given the rapid growth of our melanoma model and the greater vulnerability of aged mice to ICI-associated vascular injury, we used aged mice to capture early vascular responses and determine whether exercise modifies anti-PD-1-induced vascular inflammation. One-year-old female C57BL/6J mice were injected subcutaneously with BP melanoma cells. Once tumors became measurable, mice were assigned to three treatment groups: control IgG (N=12), anti-PD-1 (aPD-1, 150 μg × 5 doses = 750 μg total; N=9), or anti-PD-1 plus moderate treadmill exercise (aPD1+Ex, N=8) for two weeks. Tumor growth was monitored every other day. Thoracic aortas were collected, embedded as FFPE tissue microarrays, and scanned by multiplex immunofluorescence, and analyzed in Visiopharm for tissue segmentation (intima, media, adventitia), cell identification, and immune/vascular phenotyping. Exercise plus aPD-1 suppressed tumor growth significantly better than aPD-1 alone (~60% reduction vs. IgG; $p = 0.04$). Across cross-sectioned aortic rings containing ~706 total cells on average (19,069 cells across 29 vessels), whole-vessel counts of $CD4^+$, $CD8^+$, and $B220^+$ cells were uniformly low across groups. $B220^+$ cells showed a polarized pattern in the aPD-1 group, with elevated counts in only a subset of mice. In contrast, aPD-1 increased adventitial $F4/80^+$ macrophages more than 2.5-fold relative to IgG (N.S.), consistent with early adventitial-driven vascular inflammation. Importantly, exercise significantly reduced adventitial infiltration accumulation ($p=0.03$). Additional spatial analyses of vascular inflammation and immune-vascular interactions are ongoing. In aged tumor-bearing mice, anti-PD-1 induces early aortic vascular toxicity characterized by adventitial macrophage inflammation, paralleling early inflammatory patterns reported in early human large-vessel vasculitis associated with ICI therapy. Exercise markedly attenuates this adventitial macrophage-driven vascular response without compromising antitumor efficacy, suggesting its potential as a non-pharmacologic strategy to mitigate early ICI-associated vascular injury.

#6705 A versatile coacervate based delivery system to overcome engineering barriers in immune cells.

Renxia Zhang[1], **Peipei Zhu**[1], Manman Lu[2], Qing Zhang[1], Lihong Jiang[2], Xiaowen Fei[2], Xiaofei Gao[1]

[1]Westlake University, Hangzhou, China,[2]Nanoportal Biotech, Hangzhou, China

The clinical translation of immune cell engineering (e.g., CAR-T, TCR-T) and functional genomics research in hematologic malignancies are significantly hampered by the limitations of existing gene delivery systems. Viral vectors raise safety and cost concerns, while conventional non-viral methods often suffer from low efficiency and high cytotoxicity, particularly in primary immune cells and refractory hematopoietic cell lines. To overcome these barriers, we developed ProteanFect, the first endogenous protein-based coacervate delivery system. This platform is designed for high-efficiency delivery of diverse genetic payloads, including mRNA, DNA, siRNA, and CRISPR/Cas9 components (mRNA or RNP), enabling robust gene expression and precise gene editing. In primary human immune cells, ProteanFect achieved >90% mRNA transfection efficiency (e.g., GFP mRNA in T cells) with sustained transgene expression and maintained over 90% cell viability. It enabled the generation of functional anti-CD19 CAR-T cells that effectively suppressed tumor growth in vivo. Furthermore, ProteanFect demonstrated high-precision gene editing, achieving 88% knockout efficiency at the TRAC locus in primary T cells via Cas9 mRNA/sgRNA delivery. The platform also showed broad applicability, attaining >70% and >65% transfection efficiencies in natural killer (NK) cells and B cells, respectively, and robust performance in mouse primary immune cells. Simultaneously, ProteanFect effectively addressed transfection challenges in hard-to-transfect hematopoietic cell lines (e.g., Jurkat, K562, THP1, HL-60, Raji, Kasumi-1). It achieved 70-90% RNA and 40-70% DNA transfection efficiency, supported large plasmid (~15.7 kb) delivery with >50% efficiency, and enabled ~70% siRNA-mediated knockdown and ~80% CRISPR/Cas9-mediated knockout in Jurkat cells. Even in more refractory lines, RNA transfection efficiency reached ~80%. The system also facilitated co-transfection and multiplexed gene editing, highlighting its versatility. In summary, ProteanFect represents a transformative non-viral platform that uniquely synergizes high-efficiency nucleic acid delivery with precise gene editing capabilities, all while maintaining minimal cytotoxicity and demonstrating broad applicability across primary human and mouse immune cells as well as challenging hematologic cell lines. Its versatile support for diverse payloads—from mRNA and large plasmids to CRISPR RNP complexes—positions this technology as a pivotal tool that not only accelerates the production of engineered cell therapies but also expands the frontiers of basic research, functional genomics, and therapeutic development in immunology and hematology.

#6707 Developing oncolytic measles virus expressing MG53 for the treatment of lung cancer.

Zhongguang Li[1], Cheng Chih Hsu[1], Fei Jiang[1], Matthew Bu[1], Ellica Leong[1], Umme Lubaba[1], Xuefeng Liu[2], Jianrong Li[1], **Haichang Li**[1]

[1]Ohio State Univ. College of Veterinary Med., Columbus, OH,[2]The Ohio State University, Columbus, OH

Background: Despite advances in lung cancer therapy, effective strategies that simultaneously eradicate tumors and stimulate antitumor immunity remain limited. Oncolytic virotherapy (OV) has emerged as a viable clinical approach for cancer immunotherapy option. Engineered attenuated measles virus strains offer several advantages: excellent safety profiles, tumor selectivity, lack of genotoxicity, and ease of genetic manipulation. MeV replicates preferentially in malignant cells and mediates anti-tumor effects not only on the cellular level by lytic infection of tumor cells, but also on the systemic level by priming anti-tumor immune responses. TRIM72, also known as Mitsugumin 53 (MG53), is a TRIM family protein secreted by muscle tissue and plays an anti-tumor role. In this study, we developed a recombinant measles virus expressing MG53 (rMeV-MG53) and investigated its dual ability to induce tumor cell death and activate antitumor immunity, as well as its potential synergy with immune checkpoint blockade in lung cancer models.

Methods: An attenuated measles virus (MeV) Edmonston vaccine strain was engineered to express MG53, generating rMeV-MG53. A measles virus encoding the mCherry reporter gene served as control. Human lung cancer cell lines were used for *in vitro* studies to evaluate viral infectivity, oncolytic activity, pyroptosis induction, and inflammatory signaling, with Western blotting performed to assess caspase-3/GSDME activation. For *in vivo* studies, mouse lung cancer cells were engineered to express human CD46, rendering them susceptible to rMeV-MG53. hCD46-overexpressing cells were implanted into immunocompetent mice, followed by intratumoral administration of rMeV-MG53 alone or combined with anti-PD-L1 antibody.

Results: *In vitro*, rMeV-MG53 efficiently infected human lung cancer cells and exhibited potent oncolytic activity. Western blot analysis demonstrated enhanced caspase-3/GSDME-mediated pyroptosis compared with rMeV alone. rMeV-MG53 also activated inflammatory signaling pathways, suggesting a role in promoting antitumor immunity. *In vivo*, CD46-overexpressing mouse lung cancer cells were highly sensitive to rMeV-MG53-mediated oncolysis. Intratumoral administration of rMeV-MG53 significantly suppressed tumor growth, with a more pronounced effect than rMeV alone. Combination therapy with rMeV-MG53 and anti-PD-L1 antibody further augmented antitumor efficacy.

Conclusion: These findings demonstrate that rMeV-MG53 exerts robust antitumor effects through direct induction of pyroptosis and activation of inflammatory signaling while synergizing with immune checkpoint blockade. rMeV-MG53 represents a promising oncolytic platform that integrates tumor cell killing with immune activation, offering translational potential as a novel therapeutic strategy for lung cancer.

#6708 Neoadjuvant pembrolizumab with therapeutic DNA vaccine reshape intratumoral immunity in a phase 2 trial of HPV-positive HNSCC.

Hye Ryun Kim[1], June-Young Koh[2], Chang Gon Kim[1], Min Hee Hong[1], Hyun Jun Hong[1], Dahee Kim[1], Nam Suk Sim[1], Sun Och Yoon[1], Gamin Kim[1], Wonrak Son[1], Yeju Kim[2], Chang Geol Lee[1], Kyung Hwan Kim[1], Jeong Seok Lee[2], Chan-Young Ock[3], Yoon Woo Koh[1]

[1]Yonsei University College of Medicine, Seoul, Korea, Republic of,[2]Inocras Inc., San Diego, CA,[3]Lunit Inc., Seoul, Korea, Republic of

Therapeutic cancer vaccines are a promising strategy for inducing antigen-specific T-cell immunity, but their efficacy in solid tumors remains limited by inadequate magnitude, persistence, and functional quality of vaccine-elicited responses. These challenges have intensified efforts to identify adjuvants that can strengthen durable antitumor immunity. Interleukin-7 (IL-7), a cytokine essential for T-cell survival and memory formation, provides a mechanistically grounded strategy for enhancing vaccine responses. To evaluate this in a defined viral antigen setting, HPV-associated head and neck squamous cell carcinoma offers an ideal tumor model for dissecting vaccine immunity and adjuvant mechanisms. We first tested long-acting IL-7 in an HPV16 E6/E7-expressing TC-1 model. IL-7 improved the efficacy of HPV DNA vaccination with PD-1 blockade, producing superior tumor control and enhancing stem-like and memory-associated transcriptional programs within intratumoral $CD8^+$ T cells—features consistent with strengthened long-term responsiveness. Guided by these results, we conducted a phase 2 neoadjuvant trial combining pembrolizumab, HPV DNA vaccine (GX-188E), and long-acting IL-7 (GX-I7) in patients with resectable HPV-positive HNSCC. Major pathologic responses occurred in 63.6% of patients, including 36.4% complete responses. Paired single-cell RNA/TCR sequencing and spatial AI analysis revealed coordinated reshaping of the intratumoral immune landscape. A $GZMK^+$ effector-memory $CD8^+$ population expanded prominently, displaying early memory priming, lymph node-to-tumor recirculation potential, and enrichment of tumor-reactive programs. Increased tertiary lymphoid structures correlated with reduced exhaustion among tumor-reactive $CD8^+$ T cells and appeared to facilitate entry and renewal of $GZMK^+$ $CD8^+$ T cells within tumors. Higher $GZMK^+$ $CD8^+$ abundance corresponded with greater TCR diversity among tumor-reactive clones, indicating sustained replenishment of antitumor specificities. To reconfirm upstream regulatory pathways, foundation-model-based in silico perturbations showed that knockout of IL7R or STAT5 markedly diminished GZMK-directed differentiation, supporting an IL-7-dependent mechanism underlying this effector-memory programming. Analyses of independent HPV-positive HNSCC cohorts aligned with these observations, showing that tumors enriched for GZMK-programmed $CD8^+$ states exhibit stronger antitumor immunity and improved long-term outcomes. Taken together, these comprehensive preclinical, clinical, and exploratory analyses reveal that IL-7 amplifies a $GZMK^+$ effector-memory $CD8^+$ T-cell program driving sustained recirculation, diversification, and renewal of tumor-reactive $CD8^+$ T cells, highlighting a mechanistic axis with potential to enhance the durability of cancer vaccine responses.

#6709 Temporal trends in biomarker utilization across 24,000+ immuno-oncology trials.

Fahad Benthani, Samik Upadhaya, Cynthia L. Neben, Kellie R. McDonald, Alicia Y. Zhou

Cancer Research Institute (CRI), New York, NY

As immuno-oncology (IO) matures beyond the checkpoint inhibitor era, understanding how biomarker-informed trial design is evolving along with therapeutic diversification is important for optimizing future development decisions. The Cancer Research Institute (CRI) has built a comprehensive IO clinical trial database, capturing global activity across cancer types and therapeutic modalities [1]. Here, we leveraged this resource to analyze temporal trends in IO therapeutic development and biomarker adoption to reveal how the field is evolving over time.

We curated over 24,000 interventional IO clinical trials (data cut-off: June 2025), extracting therapeutic modality, molecular targets, cancer indication, trial phase, sponsor type, and biomarker data. We analyzed temporal trends in trial initiation, modality, and biomarker usage. Biomarkers (n=9,849) were classified by molecular type, functional role, and indication-specific usage patterns.

The IO landscape shows clear maturation with over 10,000 currently active trials dominated by phase II studies. While checkpoint inhibitors remain dominant, IO drug target diversity has significantly increased, driven primarily by multi-target combinations designed to overcome resistance. Furthermore, biomarker strategies show striking differences across cancer types. Hematologic malignancies lead in biomarker usage, with about 65% adoption and 31% dual selection/monitoring use, compared to solid tumors (58% and 23% respectively). Among solid tumors, respiratory cancers show the highest adoption at around 66%, driven by established markers like PD-L1 and driver mutations, while gastrointestinal cancers lag at about 50% despite representing the largest trial volume. Protein biomarkers dominate at over 80% of total, with tumor mutational burden and microsatellite instability markers emerging as pan-cancer standards. Notably, biomarker usage dropped below 50% in 2024 for the first time since 2012. This may reflect how the field's strategy is shifting: pursuing broader patient populations while also developing smarter multi-marker approaches for specific indications, representing an important turning point in IO development.

The updated CRI IO landscape database, which integrates global IO clinical trial activity and biomarker utilization, gives the research community a unique look into how immunotherapy is evolving, helping investigators and sponsors see where their work fits in the bigger picture, spot emerging trends, and identify areas where biomarker development hasn't kept pace with new therapies. These landscape insights are important for making better decisions about where to invest resources and effort to have the greatest patient impact.

#6710 Development of T cell activating nucleic acid fusion vaccine to prevent metastatic uveal melanoma establishment.

Vitali Alexeev[1], Mizue Terai[1], Sergei Koshkin[1], Takami Sato[2]

[1]Medical Oncology, Thomas Jefferson University, Philadelphia, PA,[2]Thomas Jefferson University, Philadelphia, PA

Uveal melanoma (UM) is the most common intraocular malignancy in adults. Primary tumor treatment with brachytherapy achieves approximately 80% five-year survival rate, however, later in life nearly half of patients develop predominant liver metastases, resulting in a five-year survival rate of 16% and a median overall survival (OS) of only 3.9 months. Systemic therapy with a new T cell engager Tebentafusp (Kimmtrak) increases median OS to 21.7 months, an objective response rate remains low at about 9%. Given that UM may metastasize to the liver early and remain dormant, we hypothesize that vaccine-based activation of T cell immunity in primary UM patients could prevent the establishment of metastatic disease. Our initial data showed that GNAQ/GNA11 epitopes harboring Q209L tumor driver mutation with mutated leucine in a P9 and anchoring modification at P2 positions of the nonamer activates epitope-specific T cells response. To develop a nucleic acid vaccine, we engineered a plasmid backbone containing 5′ and 3′ untranslated regions, VP22, PADRE, *Tetanus toxoid* P2 epitopes, and an MHC class I trafficking domain. DNA encoding either a single anchor-modified mutant GNAQ epitope or a fusion with MART-1, Tyrosinase, and MC1R epitopes generated two vaccine constructs that activated mtGNAQ-specific T cells *ex vivo*. Activation was confirmed by IFN-γ secretion and cytotoxicity assays using mtGNAQ peptides and UM cells as targets. Solid-phase enrichment of UM-reactive T cells on mtGNAQ peptides further enhanced cytolytic activity. To improve vaccine efficacy, we identified additional immunogenic UM-associated epitopes. Comparative analysis of UM-specific gene expression revealed approximately 50 differentially expressed genes, with four—PMEL17, TYRP1, PRAME, and SLC45A2—showing markedly higher expression in UM compared to cutaneous melanoma or melanocytes. Regions within these antigens enriched for HLA-A*01, -A*02, and -A*03 putative binders were incorporated into the established construct to produce a multiepitope vaccine. cDNA coding for CCL21 chemokine was transcriptionally linked to the open reading frame via a P2A ribosomal skipping peptide to enhance vaccine immunogenicity. T cells activated by the vaccine *ex vivo* exhibited a fourfold increase in UM cell targeting compared to two other constructs. *In vivo* testing in HLA-A2/Kb transgenic mice confirmed that vaccinated animals generated T cells capable of recognizing UM-derived peptides and exerting cytolytic activity against melanocytic cells mimicking human UM.

Overall, these findings indicate that the engineered multiepitope vaccine effectively activates UM-specific T cells. Future work will focus on identifying the most immunogenic epitopes and evaluating whether vaccination can prevent metastatic UM development and progression in relevant animal models of MUM micrometastases.

#6711 Investigating MyD88 and NLRP3 pathway modulation in a TLR4 and TLR9 driven immunotherapy in a murine model of ovarian cancer.

Ania V. Klas, Rita E. Serda

Internal Medicine, University of New Mexico Health Sciences Center, Albuquerque, NM

Ovarian cancer remains one of the most devastating gynecologic malignancies, partly due to an immunosuppressive tumor microenvironment (TME) that limits immunotherapy efficacy. Our previous work showed that syngeneic cancer cell-based immune therapy containing monophosphoryl lipid A (TLR4 agonist) and CpG (TLR9 agonist) stimulates cancer-specific immune responses. Both receptors signal through MyD88 to activate NF-κB and pro-inflammatory cytokine production. These pathways also intersect with the NLRP3 inflammasome, which amplifies inflammation through IL-1β and IL-18. Controlled activation may enhance antitumor immunity, whereas dysregulated inflammasome signaling can promote chronic inflammation and immune suppression. Understanding how MyD88 and NLRP3 shape vaccine efficacy is therefore essential.This study evaluates how inhibition of MyD88 and NLRP3 affects the therapeutic efficacy of our ovarian cancer immune therapy. FVB mice bearing ovarian tumors received TLR-agonist silicified cancer cell immunotherapy with or without the NLRP3 inhibitor MCC950 (10 mg/kg) or the MyD88 inhibitor TJM-2010 (50 mg/kg). Inhibitors were administered around each immune-therapy dose. Ascitic immune cells were analyzed by spectral flow cytometry to assess immune subsets and activation markers.Blockade of the NLRP3 pathway accelerated ovarian cancer growth, while TLR-agonist immune therapy blocked tumor progression and cleared existing tumors. NLRP3 inhibition reduced therapeutic efficacy, tumor size decreased but complete clearance was not achieved. On Day 12, the immune-therapy group showed a significant reduction in tumor burden compared to PBS ($p = 0.0034$). The immune-therapy + NLRP3-inhibited group also differed from PBS but with diminished benefit ($p = 0.0091$). By Day 16, both BR5 immune-therapy and BR5 + inhibitor groups showed highly significant reductions in tumor burden compared to PBS ($p < 0.0001$).These findings demonstrate that NLRP3 signaling contributes critically to TLR4/TLR9-mediated antitumor responses. Ongoing studies will clarify how MyD88 and NLRP3 coordinate innate immune activation and guide future combination strategies to enhance immunity and overcome suppression within the ovarian TME.

#6712 Promoting improved agnostic cross presentation of tumor antigens with an oncolytic adenovirus expressing bispecific macrophage engagers.

Ahmet Hazini[1], Margarida Rei[2], Natanya Cartwright[1], Ricardo A. Fernandes[3], Kerry Fisher[1], Len Seymour[1]

[1]Department of Oncology, University of Oxford, Oxford, United Kingdom,[2]Ludwig Institute, University of Oxford, Oxford, United Kingdom,[3]Nuffield Department of Medicine, University of Oxford, Oxford, United Kingdom

Background: Non-specific ('agnostic') cross-presentation of tumor antigens (TAA) is essential for generating adaptive immune responses against cancer. APCs uptake TAA by phagocytozing proteins from cancer cells and present them on HLA molecules to activate T cells.To induce cancer cell uptake by the APCs, we aimed develop a bispecific macrophage engager (BiME) that can bring cancer cells and APCs into close proximity, and we hypothesized that oncolytic viruses could be used to express BiMEs in the tumor microenvironment.
Methods: We generated an oncolytic adenovirus expressing a BiME (Ad-BiME) designed to bind a tumor-associated antigen on cancer cells and an activating receptor on APCs, thereby promoting interaction and triggering APC activation. The expressed bispecific protein efficiently bound ligands on both APCs and cancer cells. Co-culture assays evaluated phagocytosis, macrophage activation, and antigen cross-presentation. To analyse cross-presentation, we engineered NY-ESO-1-expressing HLA-A2-negative cancer cells and co-cultured them with HLA-mismatched HLA-A2-positive APCs. NY-ESO-1(157-165) peptide-loaded HLA-A2-specific 1G4 TCR primary T cells detected cross-presentation. Finally, freshly dissected colorectal tumor and normal colon biopsies were used to assess cancer-specific virus replication, BiME generation, and macrophage activation.
Results: The BiME significantly enhanced phagocytosis of cancer cells by macrophages, surpassing the clinically tested anti-CD47 antibody. It further activated macrophages, upregulating CD86 and CD80 expression. Notably, Ad-BiME induced the strongest macrophage activation. Tumor antigen cross-presentation by macrophages was markedly increased following BiME treatment. Ex vivo experiments showed that oncolytic viruses replicated and produced BiME exclusively in colorectal tumor biopsies, where they induced endogenous macrophage activation, unlike in normal tissues. Elevated IL-1β, TNF, IL-6, CXCL10, and IFN-γ were detected only in tumor samples, indicating targeted BiME expression. Interestingly, free BiME treatment markedly increased CCL17, a chemokine attracting regulatory T cells (Tregs). In contrast, Ad-BiME did not elevate CCL17, likely due to gradual in situ BiME generation. Bulk RNA analysis further revealed that Ad-BiME uniquely upregulated macrophage pathways linked to antigen cross-presentation and T-cell chemotaxis.
Conclusion: We generated the first oncolytic virus expressing a BiME and demonstrated its potential as a promising mechanism for antigen-agnostic cross-presentation in developing cancer vaccines for solid tumors.

#6713 Engineering a hydrogel-based vaccine to prevent recurrence in pancreatic ductal adenocarcinoma.

Peter Yuxin Xie[1], James P. Agolia[2], Rosyli F. Reveron-Thornton[2], Chuner Guo[2], Maria Moozhiyil Korah[2], Andrea Delitto[2], Deshka Foster[2], Ovijit Chaudhuri[1], Daniel Delitto[2]

[1]Mechanical Engineering, Stanford University, Stanford, CA,[2]School of Medicine, Stanford University, Stanford, CA

Purpose: Surgical resection remains the only curative treatment for pancreatic ductal adenocarcinoma (PDAC), yet only 15% of patients are resectable at diagnosis and up to 40% of patients present with locally advanced tumors involving vital vasculature. Even among those who undergo resection, recurrence rates exceed 60%. To address this, we conceived the idea of a locally implantable hydrogel (PancVax) capable of sustained release of an adjuvant therapeutic over a week post-operative to induce a sustained immune response in a murine model pancreatic cancer involving incomplete resection.

Materials and Methods: We engineered a mechanically tough interpenetrating network consisting of carboxyethyl chitosan with dynamic covalent crosslinks and ionically crosslinked alginate. Hydrogel biocompatibility was assessed incubating hydrogel components with RAW264.7 macrophage cell line and assessing markers for apoptosis and maturation. Release assays were conducted by assessment of the hydrogel supernatant following incubation. Compression failure testing was performed to assess the compression toughness. Our murine model for incomplete resection of pancreatic cancer involved orthotopically implanting a KPC-embedded collagen hydrogel at D0 and performing an incomplete tumor resection and implantation of PancVax at D12. Treatment response to adjuvant therapeutics embedded in the PancVax was monitored through tumor volume, collagen staining, and immune profiling.

Results: Individual hydrogel components were incubated for 24 hours with RAW264.7 macrophages, demonstrating >97% cell viability and <1% MHC-II+ demonstrating cytocompatibility and minimal macrophage activation. The hydrogel released albumin-FITC as a model of cytokines and peptides over a week with a sustained release profile. Hydrogels were microporous, showed a compression toughness of 60.8 kJ/m^3, and maintained structural integrity during suture fixation. Implantation of PancVax with encapsulated adjuvants after tumor resection resulted in a significant reduction in tumor volume compared to resection alone ($p<0.01$).

Conclusion: We successfully developed a hydrogel-based vaccine vehicle with properties of sustained release, high mechanical toughness suitable for suture fixation, and sufficient microporous structure permissive for cell trafficking. This work presents a novel perioperative hydrogel-based immunotherapy platform with the potential to shift the treatment paradigm for PDAC by improving post-surgical tumor control and expanding the pool of patients eligible for curative-intent surgery.

#6714 Humanized SLE mouse model for evaluating B-cell CAR-T therapy efficacy and safety.

Ruowen Zhang, Thi Minh Thi Ho, Bo Peng, Hongjing Qu, Qi Jiang, Benjamin Wei, Qingcong Lin

Medicilon, Lexington, MA

Systemic lupus erythematosus (SLE) is a complex autoimmune disease marked by dysregulated B-cell activation, autoantibody production, and systemic inflammation. Therapy development is limited by species-specific immune differences, poor modeling of human pathology in conventional mice, and low clinical predictive value. Similarly, immune-related adverse events (IRAEs), such as cytokine release syndrome (CRS), remain a major challenge in cell-based cancer immunotherapies like CAR-T. To address these issues, we developed a humanized preclinical SLE mouse model that mirrors human immune responses and serves as a platform to evaluate B-cell-targeted CAR-T therapies and immune toxicity.The SLE phenotype was induced by imiquimod (IMQ), a Toll-like receptor 7 agonist that activates plasmacytoid dendritic cells and B cells. In $CD34^+$ humanized mice, IMQ induced a humanized SLE-like phenotype, allowing human immune cells to respond to TLR7 stimulation and closely modeling human disease.CAR-T cells were delivered in vivo using lipid nanoparticles (LNPs) conjugated with anti-CD5 antibodies to target $CD5^+$ T cells. LNP internalization delivers DNA encoding a CD19-specific CAR, and transfected T cells were characterized by flow cytometry and digital droplet PCR. LNP pharmacokinetics were analyzed via LC-MS/MS, and tissue distribution was assessed by CAR gene detection.T-cell activation and CRS were monitored via multiplex assays for cytokines (IFN-γ, TNF-α, IL-2, IL-4, IL-6, IL-10) and chemokines (MCP-1, CCL5). Anti-drug antibody responses were evaluated by anti-PEG ELISA and anti-CAR MSD assays. CAR-T efficacy was assessed using serum anti-dsDNA antibodies and urinary lipocalin-2, key biomarkers of SLE activity.In summary, this humanized SLE model with integrated analytical panels provides a physiologically relevant platform for evaluating therapeutic efficacy and immune toxicity, accelerating preclinical development of human-targeted therapies for autoimmune disease and cancer immunotherapy.

#6715 Safety, tolerability, and early immune responses in the safety run-in of an HER2 multi-epitope vaccine combined with T-DM1 in residual HER2-positive breast cancer.

Saranya Chumsri[1], Sharmila Giri[2], Andy J. Ness[2], David W. Hillman[2], Nadine Norton[3], Davitte Cogen[3], Brian M. Necela[3], Aziza Nassar[3], Donald W. Northfelt[4], Pooja Advani[1], Rohit Rao[1], Alvaro Mareno-Aspitia[1], Brenda Ernst[4], Kathryn J. Ruddy[5], Matthew P. Goetz[5], Keith L. Knutson[3]

[1]Mayo Clinic Florida, Jacksonville, FL,[2]Department of Quantitative Health Sciences, Mayo Clinic, Rochester, MN,[3]Mayo Clinic, Jacksonville, FL,[4]Mayo Clinic, Phoenix, AZ,[5]Mayo Clinic Cancer Center, Rochester, MN

Background: Patients with residual invasive disease after neoadjuvant chemotherapy (NAC) for HER2-positive breast cancer remain at high risk for recurrence even with standard adjuvant trastuzumab emtansine (T-DM1). H2NVAC, a multi-epitope HER2 peptide vaccine, has previously demonstrated the ability to elicit robust and durable immune responses. Here, we assessed the safety and early immunogenicity of H2NVAC in combination with T-DM1 in this high-risk population.

Methods: Patients with stage II-III HER2-positive breast cancer and residual invasive disease following NAC and HER2-directed therapy received standard adjuvant T-DM1 alongside six priming doses of H2NVAC administered every 3 weeks. The primary endpoint was the occurrence of dose-limiting toxicity (DLT) within 21 days of the first vaccination, with adverse events graded per CTCAE v5.0. Immunogenicity assessments included HER2-specific T-cell responses measured by IFNγ ELISpot and HER-specific serum antibodies measured by ELISA at baseline and 30 days after the sixth priming dose.

Results: 20 patients were enrolled. H2NVAC plus T-DM1 was well tolerated with no DLTs observed. All treatment-emergent AEs were grade 1-2, with fatigue (grade 1 60%, grade 2 5%), peripheral sensory neuropathy (grade 1 35%, grade 2 10%), elevated alkaline phosphatase (grade 1 40%), nausea (grade 1 35%, grade 2 5%), arthralgia (grade 1 30%), and injection-site reactions (grade 1 50%) being most common. Robust vaccine-specific T-cell responses by ELISpot were observed in 94% of evaluable patients, who mounted HER2-specific T-cell responses at 30 days after the sixth priming dose, with a mean 197-fold increase over baseline. Further CYTOF analysis showed a significant decrease in exhausted T-cell phenotypes, with reduced LAG3 and TIM3 expression on both $CD4^+$ and $CD8^+$ T cells. For antibody responses by ELISA, 26% of patients developed HER2 protein-specific antibody responses at this time point. There was no significant increase in antibodies to H2NVAC peptides or to unrelated tumor antigens (p53, IGFBP2, TERT, myoglobin) at 30 days after the sixth vaccine. Ongoing correlative analyses will assess the evolution of immune responses at later time points following completion of T-DM1 therapy.

Conclusions: Concurrent administration of H2NVAC with T-DM1 was safe and did not increase toxicity beyond single-agent T-DM1. To our knowledge, this is the first study to demonstrate that a cancer vaccine can be delivered concurrently with an antibody-drug conjugate without increasing adverse effects while still eliciting robust T-cell responses. Ongoing analyses will further define the kinetics and durability of vaccine-induced antibody and T-cell responses at later time points, as well as evaluate the efficacy of H2NVAC in reducing recurrence risk in the randomized phase 2 trial.

#6716 ALK-mRNA vaccine as a new Immunotherapy for ALK+ cancers.

Gabriele Saccu[1], Alessandro Gasparetto[1], Carmen Mecca[1], Elisa Bergaggio[1], Simone Piane[1], Taek-Chin Cheong[2], Nirmala Tilija Pun[1], Roberto Chiarle[1]

[1]Boston Children's Hospital, Boston, MA,[2]Harvard Medical School, Boston, MA

Anaplastic lymphoma kinase (ALK)-driven cancers, including ALK$^+$ lymphoma and non-small cell lung cancer (NSCLC), are treated with ALK tyrosine kinase inhibitors (TKIs), yet resistance and relapse remain major challenges. Vaccine-based immunotherapy has emerged as a promising approach. Our group previously developed DNA- and peptide-based vaccines that extended survival in NSCLC mouse model. However, their clinical translation is limited. The success of SARS-CoV-2 lipid nanoparticle (LNP)-mRNA vaccines has generated interest in this platform, demonstrating effective antigen delivery and strong T-cell activation. These findings support the evaluation of a new ALK-mRNA vaccination and the direct comparison with the peptide-based strategy. We designed a codon-optimized ALK cytoplasmic domain (exons 20-29) mRNA and formulated it with LNPs using Moderna technology as standard (F#1). Two additional ionizable lipids (F#2 and F#3) were tested to assess delivery efficiency. *In vitro,* ALK protein expression and immunogenic peptide presentation was evaluated in 293T cells (1 µg single dose) in 293T HLA-B*07:02 cells using ALK.TCR-T cell killing assay. *In vivo*, 1 or 10 µg ALK-mRNA or peptide vaccine was administered intramuscularly or subcutis, respectively, in three biweekly doses in BALB/c mice. ALK-specific CD8$^+$ and CD4$^+$ response, T cell immunophenotypes, and anti-tumor activity were evaluated. Moreover, we tested ALK peptide presentation upon ALK-mRNA vaccination in HLA-B*07:02 transgenic model. We demonstrate that the ALK-mRNA vaccine enables the delivery of the expected ALK protein (~65 kDa) without detectable phosphorylation, and antigen presentation was confirmed using an ALK.TCR-T cell killing assay in HLA-B*07:02 cells *in vitro. In vivo*, 1 or 10 µg ALK-mRNA vaccinations induced robust anti-ALK-specific CD8$^+$ T cell responses (40-60%) against immunogenic ALK portion PGPGRVAKI in BALB/c mice, markedly surpassing peptide-based vaccines, particularly with the F#1. The 10-µg dose further elicited a CD4$^+$ ALK-specific response by ELISPOT and promoted CD4$^+$ and CD8$^+$ T cell expansion with increased effector CD44$^+$CD62$^-$ expression. Notably, both ALK-mRNA doses slowed tumor growth and extended survival in a preventive low MHC-I ALK$^+$ lung syngeneic tumor model. Additionally, ALK-mRNA vaccine elicited superior anti-ALK^{RPRPSQPSSL}-CD8$^+$ responses in HLA-B*07:02 mice compared to the peptide vaccine. No adverse effects were observed. Here, we identified F#1 as the best formulation and demonstrated that ALK-mRNA vaccine induces ALK-specific CD8$^+$ and CD4$^+$ strong, non-toxic immune response with an effector immunophenotype *in vivo*. In a preventive setting, ALK vaccination delayed tumor growth in a lung MHC-I-low ALK$^+$ model. Overall, these results outperformed the peptide vaccine and supported further investigation of the ALK-mRNA vaccine in therapeutic settings within ALK$^+$ malignancies for a future Phase I/II clinical trial.

#6717 Preclinical study of armored claudin 18.2 nanobody CAR NK cells targeting gastric cancer.

Byeong-Hyeok Choi[1], Ga-Ram Hwang[1], Morgan Flaherty[1], Vincent M. DeStefano[1], Masayuki Wada[1], Kevin Pinz[2], Jennifer E. Chow[2], Nabil Hagag[2], Yu Ma[3], Jing Luo[3], Yupo Ma[1]

[1]iCell Gene Therapeutics Inc., Stony Brook, NY,[2]iCell Gene Therapeutics, Inc, Stony Brook, NY,[3]iCAR Bio Therapeutics Ltd, Zhongshan, China

Introduction:
Claudin 18.2 (CLDN18.2) is highly expressed in gastric cancer with minimal expression in normal tissues, making it an attractive target for engineered cell therapies. CAR NK cells offer a potentially lower risk of inciting inflammatory cytokines and may be easily sourced for allogeneic or “off-the-shelf” use. However, conventional CAR NK approaches often show limited persistence and reduced activity when engaging with solid tumors. To enhance antitumor activity and persistence, we developed CLDN18.2 nanobody-based CAR NK cells incorporating IL-15/IL15sushi armoring. This study evaluated the antitumor efficacy and persistence in vitro and in vivo of the armored CLDN18.2 CAR NK cell construct generated via a feeder-independent NK expansion platform.
Methods:
Alpacas were immunized with recombinant human CLDN18.2 extracellular domain protein. Peripheral blood mononuclear cell (PBMC) mRNA was extracted and converted into a VHH (nanobody) to generate a library. The library was panned against CLDN18.2 antigen to enrich for high-affinity binders, which were identified through ELISA screening and cellular binding analysis by flow cytometry. VHH clone sequencing were used to generate our cCAR.A CLDN18.2-specific nanobody was identified through screening and used to generate an armored CLDN18.2 CAR NK cell construct. NK cells were isolated from cryopreserved cord blood and expanded using a feeder-independent NK expansion platform. CAR expression was measured by flow cytometry. Cytotoxicity was assessed using SNU-601 and REH-C18.2xp target cells. NSG mice received CAR NK cells.
Results:
The armored CLDN18.2 CAR NK cells displayed strong CAR expression following NK cell transduction. CLDN18.2 CAR NK cells demonstrated remarkable in vitro cytotoxicity across multiple effector-to-target ratios, eliminating CLDN18.2-positive targets rapidly and completely. In vivo, the armored CLDN18.2 CAR NK cells were observed to impart strong anti-tumor activity resulting in regression in SNU-601 xenografts. In NSG mice, armored CLDN18.2 CAR NK cells resulted in rapid tumor reduction and measurable NK persistence in mouse peripheral blood.
Conclusions:
Armored CLDN18.2 nanobody CAR NK cells generated via a feeder-independent NK expansion platform showed strong antitumor activity and improved in-vivo performance in CLDN18.2-positive tumor models. CAR NK cells also demonstrated sustained persistence following infusion. Together, these findings support future clinical investigation of our platform in patients with CLDN18.2-positive gastric cancer.

#6718 Identifying new cell surface markers of T-cell reactivity through single cell transcriptomic analysis.

Abraham A. Hakim[1], Lisa Kenney[2], Nivedita Mohan Ratnam[3], Jared J. Gartner[4], Ian S. Goldlust[5], Aarushi Bhasin[6], Brian Bui[6], Nicholas D. Klemen[6], Steven A. Rosenberg[3], Frank J. Lowery[3]

[1]NIH-NCI, Bethesda, MD,[2]Laboratory of Integrative Cancer Immunology (LICI), Center for Cancer Research, Bethesda, MD,[3]National Cancer Institute, Bethesda, MD,[4]National Institutes for Health, Bethesda, MD,[5]Surgery Branch, NIH-NCI, Bethesda, MD,[6]Surgery Branch, National Cancer Institute, Bethesda, MD

Background: Adoptive transfer of selected tumor infiltrating lymphocytes (SEL-TIL)+ pembrolizumab has yielded clinical responses of 23.5% in a phases 2 trial.[1] Following expansion in IL-2, TIL cultures are selected for treatment based on in vitro reactivity assays in which TIL are co-cultured with candidate autologous tumor targets, (peptides, tandem minigenes (TMGs), and autologous tumor organoid). Detection of neoantigen reactivity currently relies on 4-1BB, OX40, and interferon-γ (IFN-γ) upregulation.[2] Clinical administration of more neoantigen reactive CD4+ TIL is associated with improved responses.[1] However, there may be additional reactivity markers that would allow for detection of neoantigen relevant fragments and more diverse final treatment products in both CD4+ and CD8+ T-cells.

Methods: Initial screening and selection of neoantigen reactive TIL completed using standard screening via upregulation of 4-1BB, and OX40 by flowcytometry and IFN-γ by ELISpot. These samples with known reactivity were then selected for transcriptomics. scRNA sequencing was performed using 10x Genomics Chromium platform on known tumor-reactive fragments to organoid and negative controls. Conditions were tracked with barcode hashing of TCRs. CITE-Seq, and TCR-seq were also used. Clustering and analysis completed using Seurat.

Results: Upregulation of *TNFRSF9* (4-1BB) and *IFNG* (IFN-γ) were found in a single cluster. An additional larger cluster was found expressing additional genes including *TNFRSF18* (GITR). This activation of GITR, and other markers was not seen in negative control conditions. In additional validation samples, GITR was successfully observed by flow cytometry equal to or greater than 4-1BB when tested as a cell surface marker of activation for CD8 T-cells against autologous organoid.

Conclusions: The methodology of using scRNA transcriptomic analysis is a successful and viable method for identifying new markers of upregulation. GITR is a potential marker of CD8+ T-cell tumor reactivity, however, it requires further validation in additional samples and evaluation of antitumor effects.

#6820 Age-related clonal hematopoiesis drives immune remodeling that promotes lung cancer and alters neoadjuvant chemo-immunotherapy outcomes.

K. Park[1], E. Kim[1], M. Sierra-Rodero[2], Y. Byun[1], T. McPherson[1], S. Kapadia[1], D. Bayer[1], J. Yoo[1], S. Ramalingam[1], W.-Y. Park[3], B. Bosch[4], N. Reguart[5], B. massuti_[6], A. Cruz-Vermudez[2], M. Provencio[2], **J. Woo**[1];

[1]Winship Cancer Institute of Emory University, Atlanta, GA, [2]Hospital Univ. Puerta de Hierro Majadahonda, Madrid, Spain, [3]Translational Genomics Center, Samsung Medical Center, Seoul, Korea, Republic of, [4]Medical Oncology, Institut Catala d'Oncologia, Hospital Universitari Dr. Josep Trueta and Precision Oncology Group (OncoGIR-Pro), Institut d'Investigacions Biomediques de Girona (IDIBGI-CERCA), Girona, Spain, [5]Hospital Clinic i Provincial de Barcelona, Barcelona, Spain, [6]Hospital General Dr. Balmis, Alicante, Spain

More than 20% of individuals ≥70 harbor clonal hematopoiesis (CH) mutations without overt malignancy. CH has been linked to elevated risk of non-hematologic cancers, particularly lung cancer, although causality remains unresolved. The TRACERx study showed that CH in blood and tumor predicts higher recurrence and mortality in NSCLC, and recent reports suggest that TET2-mutant CH may enhance immunotherapy responsiveness. However, how CH shapes lung tumorigenesis and modulates neoadjuvant immunotherapy outcomes in early-stage lung cancer remains unclear. We performed integrated analyses in murine models and NSCLC patients, identifying a CH-driven immunosuppressive program. To test whether age-associated Tet2-mutant hematopoiesis accelerates lung cancer, KP (KrasG12D;Trp53-/-) lung cancer cells were orthotopically implanted into young (8-week) and aged (30-week) Tet2-null (Tet2fl/fl;VavCre), Tet2-heterozygous (Tet2fl/+;VavCre), and WT mice. Aged Tet2-deficient mice developed tumors earlier and with greater burden compared to young counterparts. Spleen and tumor profiling showed expansion of CD11b+ myeloid cells, Tregs, and PD-1+ T cells, with profound NK-cell depletion in older Tet2-deficient mice, indicating enhanced immune suppression in aged Tet2-deficient hosts. We next profiled PBMCs from 59 NSCLC patients using scRNA-seq. Individuals with TET2-mutant CH (n=5) exhibited enrichment of MDSCs, Tregs, effector and exhausted T cells, along with significant reductions in naïve T cells and activated NK cells compared with CH-negative patients (n=45). Long-read variant calling from scRNA-seq further revealed that within CH-positive individuals, both wild-type and CH-mutant immune cells adopted similarly aberrant immune states, unlike those from CH-negative individuals. Ligand-receptor modeling indicated that myeloid cells predominantly drove CD4 T-cell alterations, whereas CD8 T-cell remodeling arose from B- and T-cell interactions—highlighting global immune rewiring triggered by limited CH-derived clones through repeated immune synaptic interactions. Finally, in the real-NADIM cohort treated with neoadjuvant immunotherapy (n=161), patients with CH mutations showed comparable response rates but improved cancer-specific and overall survival compared with CH-negative patients, with this preliminary evidence supporting the idea that CH-induced immune alterations can be therapeutically reprogrammed. Conclusion: age-associated TET2-mutant CH remodels systemic immunity to create tumor-promoting microenvironments. These effects appear reversible with immunotherapy. Ongoing work is evaluating combination strategies targeting both myeloid and T-cell pathways to intercept CH-mediated immune escape in age-associated Tet2-deficient CH and includes spatial transcriptomic analysis of early-stage NSCLCs.

#6821 The temporal dynamics and molecular impact of clonal hematopoiesis in non-small cell lung cancer.

A.-M. Leppa[1], O. Pich[1], J. R. M. Black[1], M. Zagorulya[1], E. Bernard[2], S. Ward[1], A. Rowan[1], H. Slawinski[1], L. Y. Liu[1], C. Grieco[1], R. Slama[3], C. Martinez Ruiz[1], A. Huebner[1], T. Karasaki[1], C. Naceur-Lombardelli[4], S. Veeriah[4], TRACERx Consortium, M. Jamal-Hanjani[4], A. M. Frankell[5], A. Mead[3], C. Swanton[1];

[1]The Francis Crick Institute, London, United Kingdom, [2]Gustave Roussy, Villejuif, France, [3]Medical Research Council Weatherall Institute of Molecular Medicine, University of Oxford, Oxford, United Kingdom, [4]University College London Cancer Institute, London, United Kingdom, [5]Early Cancer Institute, University of Cambridge, Cambridge, United Kingdom

Clonal hematopoiesis (CH) is a common age-associated phenomenon whereby blood cells derived from a somatically mutated hematopoietic stem cell expand, in the absence of hematological disorders. CH is linked to an increased risk of hematological and non-hematological malignancies, including lung cancer. We recently identified tumor-infiltrating CH (TI-CH) as a promoter of non-small cell lung cancer (NSCLC) progression, but its temporal dynamics and effects on the tumor microenvironment remain undefined. To address this gap, we integrated whole exome sequencing and longitudinal cell-free DNA sequencing with single-cell multimodal analyses to characterize CH dynamics in NSCLC patients. Using pre-surgical blood samples from over 800 patients in the TRACERx cohort, we detected CH-associated mutations in 32% of patients through whole exome sequencing, most frequently in DNMT3A and TET2. Of these patients, 46% had TI-CH. Patients with TI-CH exhibited reduced disease-free survival compared to patients without CH (HR = 1.53, 95% CI = 1.20-1.95, p = 0.0006) and to patients with blood-only CH (HR = 1.41, 95% CI = 1.04-1.90, p = 0.03). In 424 patients with longitudinal cell-free DNA from blood plasma samples, we tracked single-nucleotide variants (SNV) across a median of six timepoints per patient using patient-specific liquid biopsy panels. 38 SNV-CH mutations in 35 patients were covered through variant calling. Mixed-effects modeling revealed a modest but significant global expansion of CH clones (Estimate = 0.00022, p = 0.027), with ASXL1 and TET2 mutations showing the strongest positive trends. Adjuvant therapy modestly attenuated clone growth. To extend our analysis to molecular mechanisms, we used two single-cell multimodal frameworks to gain a detailed view of lung tumor microenvironments in the presence and absence of TI-CH. We examined lung tumor immune infiltrates from two early-stage NSCLC patients with mutations in TET2 using TARGET-seq, integrating gene expression and high sensitivity genotyping at single-cell resolution. Additionally, in six patients (3 with TI-CH and 3 without CH) we employed DOGMA-seq to profile gene regulation in single cells across three distinct modalities, including chromatin accessibility, mRNA levels and cell surface proteins. While differences between mutated and non-mutated cells were nuanced, genes involved in inflammasome activation and regulation were upregulated in $TET2^{Mut}$ mononucleated phagocytes compared to those that were $TET2^{WT}$. Collectively, these data show that CH clones expand over time in NSCLC and reshape the tumor immune microenvironment toward an inflammatory state that may potentiate disease progression.

#6822 TFF2 deficiency amplifies IL-1β-driven inflammation and promotes aging-associated gastric tumor progression.

Shuang Li[1], Hualong Zheng[1], Jin Qian[1], Puran Zhang[1], Feijing Wu[1], Yi Zeng[1], Biyun Zheng[1], Juli Lin[1], Hiroki Kobayashi[1], Yosuke Ochiai[1], Mashahiro Hata[1], Arai Junya[1], Leah B. Zamechek[1], Bruce Daugherty[2], Seth Lederman[2], Timothy C. Wang[1]

[1]Columbia University Irving Medical Center, New York, NY,[2]Tonix Pharmaceuticals, Inc, Chatham, NJ

Background: Aging is associated with a chronic low-grade inflammatory state that profoundly influences tumor development and progression, known as inflammaging. While this is due to increased myelopoiesis, the exact mechanisms leading to increased myeloid production and the effects on the gastric tumor microenvironment remain poorly understood.
Methods: We conducted comprehensive analyses of young (3 months) and aged (18 months) Hdc-GFP mice, evaluating expression of the peptide trefoil factor family 2 (TFF2) and abundance of GFP+ MDSCs in the stomach, circulation and other sites. The ACKP orthotopic model and Mist1^{CreERT}; RhoA^{Y42C}CDH1^{ff}; Hdc-GFP mouse (GEM) model were used to test whether aging promotes gastric cancer progression and to explore the underlying mechanisms. TFF2-MSA was given by i.p. injection twice weekly for 2 weeks before ACKP tumor inoculation, to test whether pretreatment could reverse the aging-related pro-tumor effects.
Results: Aging led to a significant reduction in TFF2 levels in both the stomach and circulation, as confirmed by IHC, ELISA, and qPCR. The decline in circulating TFF2 was accompanied by elevated IL-1β expression in bone marrow, peripheral blood, and gastric neutrophils, together with increased circulating IL-1β levels. Enhanced IL-1β signaling contributed to a myeloid-biased hematopoietic phenotype, leading to the increased GFP$^+$ MDSCs in the stomach, spleen, and peripheral blood. Elevated IL-1β in the aged stomach induced fibroblast activation with a senescence-associated secretory phenotype (SASP)-like profile, including increased IL-6, CXCL1 and CXCL2 expression. In the ACKP orthotopic and model and GEM model, with tumorigenesis initiated at 3mo or 18mo, aging significantly accelerated tumor growth and shortened survival. Immunofluorescence analyses of aged ACKP tumor identified an increased subset of IL-1R1$^+$ cancer-associated fibroblasts (CAFs) and CGRP+ sensory nerves. Functionally, pretreatment with TFF2-MSA prior to ACKP tumor implantation decreased IL-1R1$^+$ CAF and sensory nerves, reduced MDSC accumulation and IL-1β expression, and suppressed gastric tumor growth in aged mice.
Conclusion: Our findings uncover a systemic aging axis linking reduced gastric TFF2 production to myelopoiesis and thus to gastric cancer susceptibility. Aging-associated IL-1β signaling from expanded myeloid cells reprograms gastric fibroblasts toward a pro-inflammatory SASP phenotype, fostering immune suppression and tumor growth. Restoring youthful TFF2 levels may provide effective strategies to mitigate the aging-related tumor risk and other associated inflammaging syndromes.

#6823 The role of aging in immune mediated reactivation from metastatic dormancy.

Mitchell Fane, **Kelly Coutant**, Jhon Pasamonte, Pulkit Datt, Anastasia Burtseva

Fox Chase Cancer Center, Philadelphia, PA

Age is the strongest prognostic risk factor for melanoma-related death, and metastasis remains the primary driver of mortality. Yet despite this clear link, the mechanistic basis for why melanoma progression and metastatic outgrowth disproportionately worsen in older adults (>65 years) remains poorly understood. A key gap lies in the field's reliance on young (~8-week-old, equivalent to 20 human years) mouse models, which fail to capture the age-related dynamics such as immune dysfunction that shape metastatic behavior. Moreover, most studies have focused exclusively on lung metastasis, despite melanoma commonly metastasizing to sites such as the liver, which are more resistant to immune checkpoint inhibitors. To address these limitations, we developed novel syngeneic models of melanoma metastasis and colonization in young (8 weeks), middle-aged (12-16 months), and geriatric (22-26 months) mice, targeting metastases specifically to the lung or liver. Strikingly, both lung and liver metastases were increased in middle-aged mice, whereas young and geriatric mice showed limited outgrowth, recapitulating human data where melanoma incidence is low in young adults (<50 years), peaks between ages 65-79, and decreases thereafter (79+). These aging mouse models allow us, for the first time, to systematically assess immune surveillance pathways associated with age-induced melanoma reactivation (middle-aged) and dormancy (young and geriatric). Of the various immune subsets profiled, we found that γδ T-cells are decreased in the lungs and livers of middle-aged mice with metastatic disease but are elevated in young and (surprisingly) geriatric mice. Depletion of γδ T-cells in both young and geriatric mice reawakened dormant melanoma cells and promoted aggressive metastasis. We next assessed cytokine-specific changes in the pre-metastatic lung and liver that might explain this altered γδ T-cell phenotype. We found the cytokine ARG1 was markedly increased by $CD11b^+$ myeloid cells in the middle-aged lung and liver only. r-ARG1 treatment in young mice was sufficient to induce metastatic reactivation, reduce γδ T-cell abundance, promote γδ T-cell exhaustion, and also reduced human Vγ9Vδ2 T-cell killing of human melanoma cells ex-vivo. Finally, in vivo treatment with the ARG1 inhibitor CB-1158 reduced metastatic outgrowth in both the lung and liver of middle-aged mice, with no effect in young or geriatric hosts. Treatment was associated with increased γδ T-cell abundance, enhanced activation, and reduced exhaustion within the metastatic TME of middle-aged mice. These findings uncover a previously unrecognized age-specific ARG1-γδ T-cell immunoregulatory axis that drives melanoma reactivation and metastatic progression selectively in middle-aged hosts. This work underscores the critical need for age-appropriate modeling and identifies ARG1 and γδ T-cells as a promising therapeutic target in elderly melanoma patients.

#6824 Old age uncovers FGFR-dependent metabolic dependencies in TNBC lung metastasis with therapeutic potential.

S. Drapela, R. Chimeh Rad, S. Chang, V. Rubio, N. Sarigul, D. Ilter, P. Rodriguez, A. P. Da Silva Gomes;
Moffitt Cancer Center, Tampa, FL

The clinical manifestation of metastasis in a vital organ is the final stage of breast cancer progression, and the main culprit of breast cancer related mortality. This remain especially problematic in the case of triple negative breast cancer (TNBC), the most aggressive type of breast cancer, often diagnosed in its metastatic form and for which chemotherapies are still the major therapeutic option. Typically, TNBC is seen as a disease of younger women, however, 20% of TNBCs occur in patients aged 65 and older, whose prognosis is equally staggering. Unfortunately, due to co-morbidities, tolerability of chemotherapies, as well as severe reduction in quality of life, majority of women above age 65 can't or decide not to receive chemotherapy ultimately cutting their lives short. Metastatic outgrowth is largely dictated by the ability of TNBC disseminated cancer cells (DCCs) to thrive distal organs and is largely dependent on the physiology of the specific organs. However, how the aging process, a major driver of changes in organismal physiology, affects the interaction between the host organ and TNBC DCCs remains unknown. Here, we adapted several traditional syngeneic models of TNBC metastasis to old mice of different strains and coupled with RNA-seq to unveil molecular adaptations of TNBC DCCs to the aging lung. We show that the changes that occur in the lung with aging drives an increase in mitochondrial fitness in TNBC DCCs, an adaptation that is necessary for metastasis to thrive in the old lung environment. Mechanistically, our data show that the expression of FGF19, a gut hormone not normally expressed in TNBC DCCs, drives this increase in mitochondrial fitness in the old lung through an autocrine signaling axis impinging on activation of FGF-19 cognate receptor family, FGFRs. Inhibition of FGF19-FGFR signaling using an FDA-approved FGFR inhibitor not only blocks the age-induced increase in mitochondrial fitness but also effectively abolishes lung metastasis in old, but not in young, immune competent and immune compromised mice. We traced this to age-specific metastatic adaptation of TNBC lung metastasis to the increase in bile acids, the canonical regulators of FGF19 expression, in the old lung environment. Together, our work demonstrates an important contribution of age-driven metabolic reprogramming of the host to the traits that enable metastasis to thrive in the lung and provides rationale for the use of FDA-approved FGFR inhibitors for the treatment of breast cancer lung metastasis in the most vulnerable of stage IV metastatic TNBC patients, the elderly.

#6825 Age-stratified therapeutic strategies targeting tumor cell subclones that drive chemoresistance and immunosuppression in triple-negative breast cancer.

M. Spasic[1], M. Dolan[1], A. M. Parsons[2], B. Koca[2], D. Lineker[1], J. Hawk[1], H. Starobinets[3], R. A. Freedman[2], E. Mittendorf[2], P. van Galen[1], S. S. McAllister[4];
[1]Harvard Medical School/Brigham and Women's Hospital, Boston, MA, [2]Dana-Farber Cancer Institute, Boston, MA, [3]Mass General Brigham, Boston, MA, [4]Harvard Medical School, Boston, MA

Age is the biggest risk factor for developing most forms of cancer, including breast cancer. While over 50% of cancer cases occur in patients over 65, fewer than 25% of patients enrolled in clinical trials are in this age group. Furthermore, most preclinical models use young mice, together indicating that preclinical research and clinical trials may not appropriately reflect the age of patients most affected by cancer. Triple negative breast cancer (TNBC) is an aggressive subtype of breast cancer that has high rates of recurrent, chemoresistant disease and poor outcomes. Moreover, older patients do not tolerate chemotherapy well, so alternatives are needed.

We used a preclinical mouse model that reflects clinical progression with age, whereby young (~8 week old) and aged (12-16 month old) FVB/NJ mice were orthotopically injected with syngeneic Met1 TNBC cells. Mice were treated with standard therapy consisting of chemotherapy (paclitaxel, PTX) and immunotherapy (anti-PD-L1). Relative to young mice, aged mice did not benefit from combination therapy over monotherapy, which was at least partially due to signs of immune dysregulation and CD8+ T cell exhaustion. RNA sequencing revealed that in response to PTX or combination therapy, tumors from young mice became enriched for immune and inflammatory response hallmark programs, making the young mice look transcriptionally old. Aged mice, however, did not exhibit any response to chemotherapy, - underscoring the lack of response to treatment with age and need for chemotherapy alternatives.

The Met1 TNBC cells used here contain heritable, non-immunogenic, DNA barcodes through which we identified a unique subclone of tumor cells that is resistant to PTX, both in vitro and in vivo. Among minor clones comprising <15% of the tumor cells, this clone expands with age and PTX, drives an EMT-like phenotype, and displays features of immunosuppression. A drug screen using a library of FDA-approved compounds identified histone deacetylase inhibitors (HDACi) as a potent class of drugs that kill this chemo-resistant clone. Finally, we treated young and aged mice with Panobinostat, a pan-HDACi that was the top hit in the screen, in combination with anti-PDL1. This combination led to a more significant therapeutic benefit in aged mice by reducing tumor burden and significantly extending survival compared to young.

We have identified age-tailored therapies that improve TNBC outcomes in both young and aged mice, without the need for chemotherapy in aged mice. Further, specific subclones of tumor cells can drive transcriptional programs impacting age-associated differences in tumor progression, but they can be therapeutically targeted. This work sets the stage for the development of age-stratified therapeutic strategies that do not rely on toxic chemotherapy to improve outcomes for TNBC patients of all ages.

#6826 Age-dependent neuro-immune changes in glioblastoma shape therapeutic response and reveal senescent microglia as a targetable vulnerability.

M. Penco-Campillo[1], O. de Dios[2], M. Callender[3], K. L. Lauing[1], O. Odum[1], T. Koch[1], L. Zhai[1], V. C. Prabhu[1], D. E. Anderson[1], A. V. Germanwala[1], J. P. Thakkar[1], P. Bommi[1], P. Sanchez-Gomez[2], F. Varn[3], D. Wainwright[1];

[1]Loyola University Chicago Stritch School of Medicine, Maywood, IL, [2]Institute de Salud Carlos III (ISCIII-UFIEC), Madrid, Spain, [3]The Jackson Laboratory, Bar Harbor, ME

Background: Glioblastoma (GBM) is the most common aggressive primary brain tumor, with a median overall survival (OS) of ≈15-18 months despite standard of care (SOC). Aging is a major negative prognostic factor, with older adults showing worse OS. Senescent cells accumulate with age and contribute to poorer outcomes. Senolytics clear senescent cells and may improve responses in older hosts. While tumor-intrinsic molecular features appear age-independent, the aging brain microenvironment impact on GBM progression and immunity remains unclear.
Objective: To define age-associated senescence patterns in tumor core and peritumoral (PT) brain in GBM patients and mouse models and assess whether senolytic enhance treatment responses in aged syngeneic and humanized GBM models.
Methods: MRI-guided tumor core and PT biopsies from GBM patients (<65 vs. ≥65) underwent transcriptomic and single-cell analyses to assess age-related neuro-immune and senescence changes. Senescence across tumor regions was examined in young (7-9 weeks) and aged (97-104 weeks) C57BL/6 and INK-ATTAC mice with intracranial SB28 tumors (n=5/group). Flow cytometry quantified β-gal+ senescent populations among neurons, astrocytes, oligodendrocytes, microglia, and immune infiltrates from tumor core and extratumoral brain. Mice received brain radiation, anti-PD-1, and IDO enzyme inhibition, alone ± senolytics (dasatinib+quercetin) or AP compound-induced clearance *p16INK4A+* senescent cells. A human GBM aging model was developed by depleting CD4+, CD8+, CD19+, and NK1.1+ cells in young and aged C57BL/6 mice, prior to patient-derived GBM43 (PDX) intracranial engraftment, followed by SOC radiotherapy + temozolomide ± senolytics.
Results: Transcriptomic profiling showed minimal age-related changes in tumor core but marked alterations in older PT tissues. Aged PT microglia exhibited a senescent phenotype with an upregulation of senescence-associated secretory phenotype (SASP) genes. Senolytics or AP compound significantly reduced extratumoral β-gal+ microglia and synergized with radio-immunotherapy to extend OS in aged mice ($p<0.05$). In the humanized immunodepleted GBM43 PDX model, young and aged mice developed tumors, with faster mortality in older hosts. Therapeutic responses to SOC ± senolytics are ongoing.
Conclusions: The PT brain is a key site of age-dependent immune dysfunction in GBM. Senescent microglia may create an immunosuppressive niche that limits the immunotherapy efficacy in older adults. Senolytics may restore treatment efficacy and improve outcomes in older GBM hosts. We developed a novel immunodepleted GBM PDX model to mechanistically evaluate the role of aging in human tumor progression and therapy resistance. **Keywords:** glioblastoma, peritumoral brain, aging, immunotherapy, senescence, microglia

Management of multiple primary tumours is an increasing clinical burden as the population of cancer survivors rises globally. Despite standard-of-care histological, radiological and panel sequencing diagnostics, identifying multiple primary cancers remains clinically challenging. We characterize multiple primary tumours in the TRACERx study. We integrate baseline and follow up clinical data, centrally-reviewed histopathological assessments with whole-exome sequencing (WES) to identify patients with multiple primary tumours from lung and other sites. Where multi-region sample collection was available, we assessed the genomic relatedness of multiple lesions from the same patient through shared clonal mutations.
205 (24% of 844) TRACERx patients had clinically-diagnosed or genomically-discovered multiple primary cancers. Of these, 82 patients had a prior cancer diagnosis, 56 patients had synchronous primaries at study enrollment, and 95 developed new primaries during follow up. Lung was the most common organ site for additional primaries, with 98 patients having two or more lung primary tumours, including the lung tumour profiled for the TRACERx study.
High resolution tumour WES revealed clinical misclassification in 21 of 138 patients (15.2%) with multiple sequenced lesions. At baseline, clinical classification favoured relatedness between lesions: two patients diagnosed with intrapulmonary metastases actually had independent primary lung cancers. In addition, eight patients with lesions staged histopathologically as single tumours, some with microscopic evidence of histological heterogeneity, were confirmed through WES to be collision tumours composed of 2 to 3 independent lineages. One patient was discovered to have had synchronous lung primaries, undetectable clinically, through WES sequencing of lymph node metastases. During follow up, clinical classification tended to favour independent primary designation, with 6 of 10 discrepancies due to clinically-diagnosed metachronous primary tumours found through WES to be metastases.
Together, the TRACERx multiple primary cohort represents one of the largest multi-region cohorts of multiple primary lung cancers analyzed to date. These data demonstrate the clinical utility of WES in diagnosing independent primary cancers. Ongoing analysis will investigate the association between history of multiple primary cancers and germline cancer susceptibility and patient outcome. Deep, multi-region molecular characterization, available for 58 patients with multiple primary lung cancers, will also allow detailed exploration of the molecular mechanisms driving the evolution of multiple primary cancers, informing potential biomarkers to highlight patients with elevated risk of secondary primary tumours and improve subsequent clinical management.

#6794 The mouse cancer cell line atlas reveals core principles of tissue-specific cancer evolution.

Oncogenes like *KRAS* display striking tissue specificity in their oncogenic potential, genetic interactions and phenotypic effects, but the underlying determinants remain largely unresolved.
To address such fundamental questions, we developed the Mouse Cancer Cell line Atlas (MCCA), a broad utility resource encompassing 590 comprehensively characterized models from a wide spectrum of entities. Comparative and functional studies using the MCCA resource, human cohorts and mouse models uncovered general principles guiding *KRAS*-initiated cancer evolution. We describe how tissue context affects diverse aspects of evolution, including the role of mutant *KRAS* gene dosage variation, the relevance of collaborating cancer pathways, or the sequential order of genetic alterations.
Mechanisms governing tissue-specific evolution transpired at different levels: First, we show that mutant *KRAS* dosage increase through allelic imbalance exerts cell type-specific effects, such as reactivation of developmental programs in the pancreas. Selection of such dosage-sensitive processes defines the timing of *KRAS* imbalance and its phenotypic outcomes in individual entities. Second, we highlight how tissue- and stage-specific evolutionary requirements, such as block of differentiation in the intestine, select for *KRAS*-collaborating alterations. Third, we uncovered tissue-specific epistatic interactions between *KRAS* imbalance and tumor suppression - as demonstrated for *CDKN2A*, which displays distinct levels of chromatin repression in different cell types. We show that resulting reciprocal dosage sensitivities dictate the entity-specific patterns of tumor suppressor alterations in human cancers, explaining their frequency, extent/zygosity and acquisition chronology.
These findings thus highlight how the interplay of pre-existing and acquired determinants instructs cancer evolution along deterministic trajectories in different tissues - with predictable quantitative molecular patterns, temporal dynamics and phenotypic outcomes. Our study provides major advances towards a mechanistic understanding of cancer genomes.

#6795 The Genomics England 100,000 genome programme: Allele-specific KRAS mutational signatures define distinct subtypes in lung adenocarcinoma.

L. C. Woodhouse[1], A. Hawari[1], A. Tapinos[1], A. Gruber[2], A. J. Cornish[3], Genomics England Research Consortium, D. C. Wedge[1], **C. R. Lindsay**[1];
[1]Division of Cancer Sciences, The University of Manchester, United Kingdom, [2]Department of Biology, University of Konstanz, Germany, [3]The Institute of Cancer Research, London, United Kingdom

Background: Lung cancer is the leading cause of cancer mortality worldwide. Somatic RAS mutations are the most common oncogenes in human cancer, and KRAS mutations are the largest molecular subset of lung adenocarcinoma (LUAD). Each cancer genome accumulates a unique combination of somatic mutations, and these mutational signatures provide a genetic imprint of mutational processes that have occurred during tumorigenesis. Mutational signatures provide information on tumor aetiology/maintenance and could inform potential therapeutic targets or early detection strategies.
Methods: Paired tumor and germline WGS data were obtained through the 100 000 Genomes Project (Genomics England). KRAS mutations were annotated using Ensembl Variant Effect Predictor (VEP) v109.0. Single base substitution (SBS), doublet base substitution (DBS), small insertion and deletions (ID), structural variant (SV) and copy number (CN) mutational signature extraction was performed using SigProfiler (COSMIC version 3.4). Survival analysis was performed using multivariate cox-proportional hazard models, adjusting for clinical stage and patient age at diagnosis. Statistical analyses and plotting were performed in R (version 4.2.1), with two-tailed p-values <0.05 considered statistically significant.
Results: 680 LUAD patients were included; 301 KRAS mutant (44%) and 379 KRAS wild type (56%). 64 mutational signatures were extracted from the LUAD cohort, comprising 23 SBS, 10 DBS, 12 Indel, 9 CN and 10 SV signatures. Unsupervised clustering revealed three distinct mutational signature subsets, reflecting different mutagenic origins and biological pathways: a smoking-associated cluster (cluster 2), an APOBEC non-smoking-associated cluster (cluster 3) and a clock-like non-smoking-associated cluster (cluster 1). As anticipated, cluster 2 was strongly associated with KRAS mutation. However, KRAS allele-specific profiling revealed striking variation of smoking impact: G12C and G13C variants displayed strong tobacco-derived mutational signatures, including direct probabilistic associations inferred at the individual KRAS somatic variant level. G12D was more commonly associated with clock-like related mutational processes and RBM10 mutation. G12A was enriched for normal diploid segments (CN1). Finally, CN6, SV2 and SV9 signatures were independently associated with inferior overall survival in a KRAS-dependent context.
Discussion: This is the largest study to date to profile KRAS mutant LUAD mutational signatures using whole genome sequencing (WGS) data. KRAS allele-specific profiling reveals distinct mutational and co-mutation contexts that define biologically and clinically meaningful subtype heterogeneity. Many KRAS-mutant subtypes in LUAD are not a direct consequence of smoking.

#6796 AI enabled imaging and single cell multiomics reveal how gene amplification architecture shapes gene expression.

Cancer cells often carry large gene amplifications that can arise through very different structural mechanisms. In some tumors, amplified oncogenes reside on circular extrachromosomal DNA, or ecDNA. In others, the same oncogenes reside within chromosomes in homogeneously staining regions, or HSRs. While HSRs propagate through conventional chromosomal segregation, ecDNA replicates and divides unevenly, creating extreme variation in oncogene dosage from cell to cell. These architectural differences are increasingly linked to aggressive tumor behavior, therapeutic resistance, and rapid evolution, yet their functional and molecular consequences remain poorly understood. Traditional bulk sequencing cannot distinguish ecDNA from HSRs, and imaging based detection has relied on manual, low throughput workflows, limiting our ability to assess amplification architecture across cell populations. To address this challenge, we developed AI based imaging tools that automatically identify ecDNA and HSRs in fluorescence microscopy images and classify amplification architecture across hundreds of nuclei per experiment. In parallel, we created computational approaches that infer amplification architecture directly from single cell sequencing data, using the characteristic copy number patterns generated by ecDNA versus HSR based amplification. These automated tools provide scalable, reproducible structural profiling of cancer cells. We integrated these structural assignments with 10x Genomics single cell multiome data and BioSkryb ResolveOME, which provides whole genome and whole transcriptome profiles from the same individual cells. We applied this framework to six human cancer cell lines, three dominated by ecDNA and three dominated by HSR amplifications. Across these models, the frequently amplified oncogenic locus PVT1 offered a shared point of comparison. The data revealed striking differences between the two amplification types: Genes amplified on ecDNA showed broad spreads of expression and distinct isoform usage, including a consistent PVT1 isoform whereas HSR amplifications produced tighter, more predictable transcriptional profiles. These findings suggest that ecDNA enables tumors to access a wider range of transcriptional states that may support bet hedging and drug resistant phenotypes. HSRs may stabilize expression programs, emerging through ecDNA reintegration under selective pressure. Together, these results demonstrate how AI enabled imaging and computational inference, combined with single cell multiomics, can uncover the hidden architecture of oncogene amplification in cancer and link it directly to transcriptional output. This framework provides a scalable path for understanding how genome organization drives tumor evolution, therapeutic resistance, and cancer aggressiveness.

#6797 Basal-state origins and genotype-specific trajectories of neuroendocrine plasticity in lung cancer.

M. Wang[1], A. Sabet[1], S. Rakhade[2], E. Spanos[1], L. Morrill Gavarro[1], R. Giri[1], P. Manoj[1], H. A. Yu[1], A. Quintanal-Villalonga[1], J. T. Poirier[3], E. Redin[1], D. Pe'er[1], C. M. Rudin[1], **J. M. Chan**[1]; [1]Memorial Sloan Kettering Cancer Center, New York, NY, [2]Herbert Irving Comprehensive Cancer Ctr., New York, NY, [3]NYU Langone Health Perlmutter Cancer Ctr., Brooklyn, NY

Neuroendocrine (NE) lineage plasticity is a unifying mechanism of therapeutic resistance across lung cancers, enabling adenocarcinomas (LUAD) to evade targeted therapies (e.g. EGFR, KRAS) and adopt high-grade NE histologies, including small cell lung cancer (SCLC) and large cell neuroendocrine carcinoma (LCNEC). The conserved early states and genotype-specific trajectories driving NE plasticity remain unclear.We integrated targeted DNA sequencing, 10X single-cell transcriptomics (75 samples, 52 patients), and Xenium spatial imaging (22 samples, 16 patients) across NE-transformed lung cancers. Both *EGFR*-mutant (mut) and -wildtype (wt) transformed SCLC showed recurrent chromosomal instability and PI3K/AKT activating mutations. *EGFR*-mut cases were enriched for *RB1* loss, whereas *EGFR*-wt had more *CDKN2A* loss as well as *KRAS*, *STK11*, and *KEAP1* mutations. Single-cell data showed greater NE subtype diversity in transformed versus *de novo* NE cancers as well as dynamic transitions between NE and non-NE states. Our computational approaches (scDeBussy pseudotime alignment, factor analysis) converged on a conserved basal-like precursor enriched for JAK/STAT and NF-κB signaling that seeds multiple terminal outcomes, including NE, squamous, and mesenchymal fates. To identify regulators of the basal-to-SCLC transition, we compared transformed and *de novo* SCLC and found *PHOX2B*as the transcription factor most correlated with NE state. *PHOX2B* overexpression in *EGFR*-mut LUAD cells with *TP53/RB1* co-mutations induced NE markers, amplified by *MYC* activation and *REST* suppression. Although insufficient for full SCLC morphology, *PHOX2B* suppressed MAPK signaling (ERK/pERK), consistent with plasticity promoting EGFR independence. Recognizing *STK11/KEAP1* co-mutations as an alternate route to NE plasticity, we analyzed NE tumors with these mutations. LCNEC showed highest frequency of *STK11* and *KEAP1* loss (28-31%) exceeding LUAD or SCLC (10-11%, 1-4%). Regulatory network analysis in LCNEC found a *FOXA2-HNF1/4A* axis reactivating a hepatic developmental program alongside NRF2-aldoketoreductase (AKR)-driven redox adaptation. Spatial imaging uncovered intratumoral zonation of immune-hot and -cold NE states, shaped by immunosuppressive cell-cell interactions (*FGL1-LAG3*, *VEGFA-VEGFR*).Together, these studies delineate a shared basal precursor to NE plasticity with later divergence shaped by genotype. *PHOX2B* represents a late molecular event inducing early NE induction and MAPK bypass in *EGFR*-mut tumors, while *STK11/KEAP1*-mut LCNEC coopts a distinct hepatic-NE program linked to metabolic and immune remodeling. This framework reveals biomarkers and vulnerabilities across early and late stages of LUAD-to-NE transformation, including inflammatory precursors, signaling bypass, metabolic rewiring, and immune evasion, offering multiple points for intervention across NE lung cancers.

#6798 Mechanistic dissection of regulators of cancer plasticity using high-content optical pooled screens at clonal resolution.

M. Godzik[1], R. Walton[1], M. Bogaev[2], L. Bi[3], J. Dilly[1], M. Jankowiak[3], E. Donnard[3], D. T. Ting[4], N. Hacohen[5], E. S. Lander[3], P. Blainey[1], A. Mehta[6];
[1]Massachusetts Institute of Technology, Cambridge, MA, [2]Harvard University, Cambridge, MA, [3]Broad Institute of MIT and Harvard, Cambridge, MA, [4]Massachusetts General Hospital, Charlestown, MA, [5]Harvard Medical School, Cambridge, MA, [6]Column Group, San Francisco, CA

Cancer treatment failure is often attributed to two processes: selection for pre-existing resistant cells and cellular plasticity that allows drug-sensitive cells to become resistant. Plasticity is a hallmark of cancer, but we still lack a clear definition and a mechanistic understanding of how it is controlled in tumors. These gaps are especially problematic in pancreatic ductal adenocarcinoma (PDAC), where epithelial-to-mesenchymal plasticity (EMP) is thought to drive metastasis, tumor initiation, and resistance to therapy. Causally dissecting plasticity requires large-scale perturbation studies that systematically target many genes and measure how they reshape cell-state dynamics at single-cell resolution over weeks to months. Such studies must follow enough cells to observe rare state transitions and clonal heterogeneity, yet current methods force a tradeoff between (i) sufficient molecular phenotyping, (ii) temporal duration, and (iii) cellular throughput, limiting our ability to map regulators of plasticity at scale.

We set out to address both issues by (1) developing a screening platform that overcomes major limitations in existing paradigms to (2) enable discovery of the mechanistic underpinnings of cellular plasticity in pancreatic cancer. Using an engineered patient-derived PDAC model, we performed a paired single-cell CRISPRi transcriptomic screen (Perturb-seq) and high-throughput imaging-based optical pooled screen (OPS) of EMP across a panel of chromatin and transcriptional regulators. We identified factors responsible for distinct plastic behaviors by quantifying state transitions from a FACS-defined initial state linked to high-content imaging phenotypes for 150,000 clones, across 1000 genetic perturbations and 22 million cells after two weeks of sustained perturbation in culture. Crucially, this framework sorted regulators into distinct functional classes of plasticity control, including “maintenance” genes stabilizing the starting state, “transition” genes that biased state switching in one direction, and “catalytic” genes that regulated switching bidirectionally. Our methodology recapitulated many genes previously implicated in EMP and uncovered novel candidate “catalytic” targets that converge on H3K9me3-associated epigenetic reprogramming. This work clarifies how cell state is regulated at clonal resolution, identifies potential vulnerabilities in plastic tumor cells, and establishes a platform that can be extended to studies of cellular plasticity in other biological contexts.

#6799 Dissecting the epigenetic inter- and intra-tumor heterogeneity of glioma at single-cell resolution.

Y. Wu[1], J. Zhou[2], Z. Deng[1], K. Komandur[1], K. L. Hung[3], Q. Zheng[4], A. bartlett[4], J. Nery[4], R. G. Castanon[4], T. Beaumont[5], J. Dixon[4], J. R. Ecker[6];
[1]Salk Institute for Biological Studies, La Jolla, CA, [2]Arc Institute, Palo Alto, CA, [3]Scripps Research, La Jolla, CA, [4]Salk Institute, La Jolla, CA, [5]UC San Diego Health, San Diego, CA, [6]Salk Institue for Biological Studies, La Jolla, CA

Adult diffuse gliomas include IDH-mutant astrocytomas and oligodendrogliomas, as well as IDH-wildtype glioblastomas (GBM), the latter marked by extreme cellular plasticity. Bulk genomic studies from TCGA defined molecular subtypes, but how epigenetic programs coordinate state transitions within tumors remains unresolved. In this study, we applied single-nucleus methylome and 3D genome profiling (snm3C-seq) to 40 human gliomas and interrogated the heterogeneity of DNA methylation and chromatin structure within tumor and across donors. We assigned DNA methylation and chromatin conformation (Hi-C) cell states to individual cells. We reported the following results: 1) Cross-modal state mapping: Most tumors contain large fractions of OPC-like or Astro-like cells with strong concordance between methylation (mC) and Hi-C states. However, certain clusters of cells have discordant mC and Hi-C states, indicating transitional phenotypes. 2) Temporal discrepancy: We observe asynchronous remodeling, where chromatin architecture often shifts towards more differentiated states before DNA methylation during lineage transitions. For example, many cells are OPC-like in methylation and AC-like in chromatin conformation, suggesting 3D genome reorganization as an early indicator of fate change. 3) Copy number alterations in tumor associated normal cells: we detected CNV mosaicism in a large proportion of non-malignant cells, yet their methylation profiles are more similar to normal cells than cancer cells. 4) Clonal evolution and structural variants (SV): Clonal analysis by copy number reveals that some new malignant clones arise with global methylation loss. In contrast to the heterogenous copy number changes in cancer cells, structural variants are often shared by the majority of cancer cell proportions. However, the occurrence of new SV drives cell state transition more strongly than copy number changes. Lastly, we observed that extrachromosomal DNA (ecDNA) are frequently found in WT GBM and they are associated with local epigenetic rewiring at amplified loci. These insights nominate epigenetic states as a biomarker of plasticity and a potential guide for patient-specific interventions.

Leal[13], C. Oswalt[14], B. Izar[15], A. Marangoz-Stager[16], V. Danh[16], G. Lunardi[16], K. Bach[16], N. A. Rizvi[16], A. Azrilevich[16], A. Mehta-Damani[16], M. Oft[16];
[1]NYU, New York, NY, [2]Memorial Sloan Kettering Cancer Center, New York, NY, [3]University of California (UCLA), Santa Monica, CA, [4]Yale, New Haven, CT, [5]The Ohio State University Wexner Medical Ctr., Columbus, OH, [6]DFCI, Boston, MA, [7]Columbia University, New York, NY, [8]Georgetown University, Washington, DC, [9]Northwell Health, Great Neck, NY, [10]Virginia Cancer Specialists, Fairfax, VA, [11]Mass General Hospital, Boston, MA, [12]HealthPartners, Minneapolis, MN, [13]Emory University, Atlanta, GA, [14]Duke University, Durham, NC, [15]Columbia University Irving Medical Center, New York, NY, [16]Synthekine, Menlo Park, CA

Background: STK-012 is a first-in-class α/β-IL-2R biased partial agonist that drives antitumor activity by selectively stimulating CD25+ antigen-activated T-cells and avoids hallmark IL-2 toxicities by sparing pleiotropic activation of lymphocytes including NK cells. In this phase 1a/b study, STK-012 is combined with standard of care pembrolizumab + chemotherapy (PCT) in 1L PD-L1 negative NSQ NSCLC where PCT alone has poor outcomes (ORR 32% and median PFS 6.2 months).
Methods: 1L NSQ NSCLC subjects received STK-012 SC Q3W + PCT. Serial blood samples were analyzed for changes in cytokines in chemoluminescence assays, T cell proliferation and activation markers were analyzed in spectral flow cytometry, and T cell clonality was analyzed by TCR sequencing. Data are shown for a cohort of 22 efficacy-evaluable 1L NSCLC subjects (N=18 PD-L1<1%, N=4 PD-L1=1%) which was enriched for loss-of-function tumor suppressor gene (LoF TSG) mutations (n=11; STK11, KEAP1, SMARCA4) or mucinous histology (n=5) associated with a “cold” TME and primary immune resistance.
Results: STK-012 + PCT demonstrated an ORR of 55% in all efficacy evaluable patients; 50% in patients with PD-L1<1% tumors; 55% in LoF TSG mutations; and 80% in mucinous histology. STK-012 + PCT induced sustained proliferation of CD8+ and CD4+ T cells (13X and 5x increase from baseline, respectively), proliferation of antigen activated T cells including PD-1+ CD8+ (14X) and 4-1BB+ CD8+ (14X) and re-invigoration and proliferation of previously exhausted CD39+ (11x) and TIM3+ (18x) CD8+ T cells. After the first cycle, 3.35% of the total T cell repertoire were T cell clones which were newly detected or expanded ≥10x (n=12). STK-012 + PCT induced key cytokines IFNγ and IL-18 characterizing an activated CD8+ T cell response and increased IP-10 which is associated with enhanced T cell trafficking into tumor tissues (13x,14x and 23x mean increase from baseline, respectively). Sustained elevation of cytokines across treatment cycles (IFNγ median peak of 71, 95, 96 pg/mL in C1, C2 and C6) was observed, supportive of the emerging durability of the combination. Induction of cytokines TNFα and IL-6 was limited (median peak 4, 6 pg/mL), consistent with limited activation of naïve T cells and NK cells and the lack of capillary leak syndrome with STK-012.
Conclusions: STK-012 + PCT led to robust cytokine induction, proliferation and expansion of antigen activated T cells, proliferation of previously exhausted T cells, and remodeling of the T cell repertoire. The addition of STK-012 to PCT has the potential to overcome resistance in immune excluded populations including PD-L1<1% tumors, LoF TSG mutations and mucinous histology. A global, randomized Phase 2 study, SYNERGY-101, of STK-012 + PCT vs. PCT in 1L PD-L1<1% NSQ NSCLC is ongoing (NCT05098132).

#6741 Tertiary lymphoid structure (TLS)-associated immune circuits define response to durvalumab, trastuzumab, and pertuzumab (DTP) in HER2-enriched early breast cancer.

Background: Chemotherapy-free regimens combining HER2-targeted therapy with immune checkpoint blockade are emerging as promising strategies in HER2-Enriched breast cancer. In our Phase II trial of durvalumab, trastuzumab, and pertuzumab (DTP), ER-negative, PR-negative, HER2-Enriched tumors (BluePrint®) achieved a 49% Pathologic Complete Response (pCR) rate, suggesting an immunologically responsive subset. To define the cellular mechanisms underlying response and resistance to this chemotherapy-free approach, we performed single-nucleus RNA sequencing and spatial transcriptomic profiling on paired tumor samples.

Methods: Paired pre-treatment and surgical biopsies (n=37) underwent snRNA-seq to profile immune composition, functional states, and lineage dynamics. Patients were stratified by Residual Cancer Burden (RCB), with RCB-0 considered Responders (n=18) and RCB-2/3 as Nonresponders (n=6). Cell identities were label-transferred to Xenium 5K spatial transcriptomic data to assess cellular localization and interactions within the tumor microenvironment.

Results: We recovered 470, 997 high quality nuclei, including 168,516 immune cells. Pre-treatment Responder samples were enriched for CD4+ T follicular helper cells ($CD4^+CXCL13^+PD\text{-}1^+$ Tfh), CD8+ tissue-resident memory T cells (CD8+ Hobit+ Trm), and CD8+ exhausted T cells (CD8+Tim3+PD-1+ Tex), along with higher frequencies of LAMP3+ mature dendritic cells (mDCs), and naïve B-cells. Spatial mapping revealed co-localization of Tfh, mDCs, and B-cell subsets within tertiary lymphoid structures (TLS) spanning multiple maturation stages. CellChat analyses demonstrated Responders exhibiting a coordinated Tfh-mDC-B-cell communication network enriched in CXCL13-mediated B-cell recruitment, CD40 and CD28 costimulation, and cytokine programs supporting TLS maturation. In contrast, Nonresponders engaged predominantly inhibitory signaling pathways, marked by CD22-mediated suppression, BTLA-HVEM immune dampening, and reduced chemokine guidance, consistent with abortive B-cell activation.

Conclusions: Integrated single-nucleus and spatial transcriptomic profiling identifies coordinated Tfh-B-cell and dendritic-B-cell interactions, spatially organized within TLS, as dominant determinants of response to DTP therapy in HER2-Enriched early breast cancer.

Clinical trial information: NCT03820141.

Research Sponsors: Houston Methodist Hospital and AstraZeneca.

#6742 Nonsense-mediated mRNA decay inhibition augments *in vitro*, *in vivo*, and *ex vivo* anti-tumor immunity.

Introduction: Neoantigens from somatic tumor mutations are essential for effective anti-tumor immune responses. Frameshift insertions and deletions (fs-indels) represent a rare but highly immunogenic mutation subtype, as they create novel open reading frames (neoORFs) that generate peptides that are significantly distinct from self-antigens. Nevertheless, fs-indels often introduce premature termination codons, leading to transcript degradation via the nonsense-mediated mRNA decay (NMD) pathway, leading to loss of immunogenic neoantigen.
Approach: For the first time, we pharmacologically inhibited SMG1, a core component of the NMD pathway, across a range of preclinical models, including human and mouse cancer cell lines, patient-derived tumor organoids (PDTOs), patient-derived tumor fragments (PDTFs), and syngeneic mouse xenografts. We analyzed the changes in transcriptome, proteome, and immunopeptidome following SMG1 inhibition (SMG1i) and peptide reactivity in *in vitro* priming experiments. We then combined tumor-T cell co-cultures and PDTFs to assess the anti-tumor immunogenicity induced by SMG1i. *Ex vivo* and *in vivo* immunological responses were assessed by high-dimensional flow cytometry, cytometric bead array, and single-cell RNA- and TCR-sequencing.
Results: Using multi-omic and checkpoint inhibitor (CPI) response data from over 1,000 patients, we show that decreased expression of the key NMD mediator, SMG1, correlates with improved CPI response. Inhibiting SMG1 *ex vivo* and *in vivo* activates and expands tumor-reactive T cells and sensitizes CPI efficacy. Mechanistically, SMG1 inhibition stabilizes frameshift-derived transcripts, increasing the abundance and surface presentation of immunogenic neoantigens. This results in an increase in neoepitope burden in tumors, similar to that seen in tumors with high tumor mutational burden (TMB), without inducing DNA damage. Co-culturing tumor cells and PDTOs with $CD8^+$ T cells after SMG1i results in strong MHC class I antigen-dependent T cell activation and tumor cell killing.
Conclusion: Our findings highlight SMG1 inhibition as a promising strategy to exploit an untapped source of highly immunogenic peptides. It enhances anti-tumor immunogenicity without introducing DNA mutations, regardless of tumor type or TMB status, providing translational evidence for sensitizing ICB responses.

#6743 Peripheral immune profiling from the DIET trial - A randomized double blinded dietary intervention study in melanoma patients receiving immunotherapy.

Yufan Qiu, Yan Jiang, Nazli Dizman, Courtney Nicholas, Yuwei Zhang, Sreyashi Basu, Elizabeth Burton, Michael A. Davies, Nadim J. Ajami, Padmanee Sharma, Jennifer A. Wargo, Jennifer L. McQuade, **Carrie R. Daniel**

UT MD Anderson Cancer Center, Houston, TX

Background: Dietary fiber intake is associated with improved response to immune checkpoint blockade (ICB) in melanoma. The phase II Diet and Immune Effects Trial (DIET, NCT04645680) was conducted in melanoma patients receiving ICB testing the effects of a high fiber diet intervention vs. healthy control diet. Our early results revealed that the high fiber diet intervention is feasible with promising improvements in treatment outcomes. Herein we report the secondary objective of the effects of dietary intervention on systemic immunity by arm.
Methods: Patients were randomized (2:1) to either a high fiber diet (30-50 g/d ramped-up fiber) or healthy control diet (20 g/d fiber). Cryopreserved paired (pre vs post dietary interventions) peripheral blood mononuclear cells (PBMC) were collected longitudinally and used for NanoString gene expression profiling and CyTOF mass cytometry analyses. For translational human-to-mouse fecal microbiota transplant (FMT) studies, mice received patient stool collected either pre or post high fiber intervention, followed by melanoma inoculation and anti-PDL1 treatment. Endpoint peripheral leukocytes and spleen specimens were collected for CyTOF mass cytometry.
Results: Using NanoString, we were able to identify decreased abundance scores of circulating macrophages (p=.018) and neutrophils (p=.035) (by cell type deconvolution) as well as classical monocytes (p=.06) and dendritic cells (p=.06) (Signature from Lam et al. Cell 2021) within week 5-8 of dietary intervention in high fiber (n=11) vs control arm (n=4). Pathway analysis showed higher transcriptional levels of T cell activation gene signature and T cell receptor signaling in the high fiber arm versus a higher level of Toll-like receptor signaling and type-1 interferon signaling in the control arm. These findings were validated at the protein level by CyTOF, which demonstrated reduced circulating classical monocytes (p=.0059) and increased frequency of effector-memory T cells (p=.01 in CD8+, p=.032 in CD4+) in the high fiber vs control arm within week 5-8 of dietary intervention. Within the high fiber arm, these findings were more prominent in those receiving combination nivolumab + ipilimumab (n=3) compared to those receiving pembrolizumab or nivolumab monotherapy (n=7). Human-to-mouse FMT studies also revealed an improved ICB response with lower frequency of monocytes and dendritic cells in post-high fiber diet stool recipients in the circulation and spleens.
Conclusion: Our analyses suggested microbiome-dependent benefits of a high fiber diet in reducing circulating monocytes and potentially enhancing T cell activation in the peripheral blood. Circulating monocyte levels are known to negatively correlate with ICB response, warranting further mechanistic study on dietary fiber mediated regulation of peripheral immunity during immunotherapy.

#6744 Persistent neuro-antigen-reactive Th17 cells drive IL-17-dependent neurotoxicity in CNS immune-related adverse events.

Yifei Ma[1], **Jingyao Zhang**[2], Fadian Ding[1], Ao Zhang[3], Jun Lv[4], Xinjia Wang[5], Weidong Wang[5], Guangmin Jian[4], Pengfei Zhu[4], Yue Ma[6], Jiacai Lin[7], Denghan Zhang[1], Guanqing Zhong[3], Rui Li[8], Haizhou Liu[1], Shangeng Weng[1]

[1]Fujian Medical University, Fuzhou, China,[2]Danbury Hospital, Danbury, CT,[3]Sun Yat-sen University Cancer Center, Guangzhou, China,[4]the First Affiliated Hospital of Zhengzhou University, Zhengzhou, China,[5]Cancer Hospital of Shantou University Medical College, Shantou, China,[6]Taiyuan Central Hospital of Shanxi Medical University, Taiyuan, China,[7]Hainan Hospital of Chinese PLA General Hospital, Sanya, China,[8]Institute of Neuroscience, Fujian Medical University, Fuzhou, China

Background: Immune checkpoint inhibitors (ICIs) have transformed cancer outcomes but can induce immune-related adverse events (irAEs) that limit therapy. Central nervous system irAEs (irAE-CNS) are rare, often corticosteroid-refractory, and lead to disabling neurological sequelae. Their immunopathogenesis remains poorly understood, hindering effective interventions. We aimed to define the immune mechanisms underlying irAE-CNS and identify therapeutic targets using multi-omics profiling and longitudinal clinical correlation.
Methods: We analyzed cerebrospinal fluid (CSF) from three independent irAE-CNS cohorts and controls (autoimmune encephalitis, CNS infection). Multi-omics profiling integrated OLINK proteomics, single-cell secretome and transcriptome analysis, and paired VDJ-TCR repertoire sequencing with FDG-PET/CT imaging, neurofunctional testing, and 15-month follow-up. Unsupervised clustering (Seurat) and clonotype mapping (CellRanger/IGBLAST) were used to define cell phenotypes and track longitudinal persistence. Neuroantigen reactivity was validated via MHC-multimer sorting and peptide libraries derived from neuronal surface proteins, including NMDAR1. Functional assays assessed T-cell-mediated neuronal cytotoxicity and the effects of IL-17 blockade.
Results: We identified a distinct population of $CD4^+CD137^+PD\text{-}1^+$ effector-memory T-helper cells ($Poly6^+$ Th cells) enriched in irAE-CNS, co-secreting IL-17A, TNFRSF9, CCL11, MCP-1, MCP-4, and Granzyme B, defining a polyfunctional Th17-like signature. $Poly6^+$ Th-cell frequency correlated with intracranial FDG-PET hypermetabolism especially within limbic regions, and with cognitive decline. Single-cell RNA-seq revealed stable $RORC^+IL23R^+GZMB^+$ transcriptional profiles, and VDJ analysis showed persistent, antigen-driven clonal expansion. Dominant clonotypes targeted NMDAR1 epitopes (notably EERITGINDPRLRNP), confirming neuroantigen-specific persistence. In co-culture assays, $Poly6^+$ Th cells induced neuronal apoptosis via IL-17-dependent mechanisms. In patients treated with IL-17 blockade, neurological symptoms and intracranial inflammation improved significantly without reducing ICI antitumor efficacy.
Conclusions: irAE-CNS is driven by persistent, NMDAR1-reactive Th17-like effector-memory cells that mediate IL-17-dependent neurotoxicity. These findings reveal a mechanistic basis for selective cytokine blockade to alleviate CNS autoimmunity while maintaining checkpoint efficacy, providing a framework for biomarker-guided management of ICI-associated toxicities.

#6745 NAT10-MYC loop induces MHC-I loss through autophagy to promote immune evasion and immunotherapy resistance in colorectal cancer.

J. Weng[1], T. Xiong[2], Z. Ye[3], Z. Shan[3], R. Su[4], J. Yu[5], M. A. Caligiuri[2], X. Li[3], A. Goel[6];

[1]Beckman Research Institute of The City of Hope, Duarte, CA, [2]City of Hope National Medical Center, Duarte, CA, [3]Fudan University Shanghai Cancer Center, Shanghai, China, [4]Beckman Research Institute of City of Hope, Monrovia, CA, [5]UC Irvine, Irvine, CA, [6]City of Hope, Duarte, CA

Background: Immune checkpoint inhibitors (ICIs) have significantly improved therapeutic outcomes in colorectal cancer (CRC), particularly for metastatic tumors with microsatellite instability-high (MSI-H) or deficient mismatch repair (dMMR). While patients with metastatic CRC have a median overall survival of only 21 months, MSI-H/dMMR patients treated with ICIs can achieve durable responses and even long-term survival. However, the vast majority are microsatellite-stable (MSS) and remain profoundly resistant to immunotherapy, underscoring a critical unmet clinical need. Therefore, elucidating and overcoming the mechanisms that drive immune resistance is essential to broaden the therapeutic benefit of immunotherapy.

Methods: We investigated the role of the RNA acetyltransferase NAT10, responsible for N4-acetylcytidine (ac^4C) modification, in mediating immune escape in CRC. MYC-mediated transcriptional regulation and NAT10-dependent mRNA stabilization were analyzed. The stability of autophagy-related transcripts and MHC class I expression was assessed. The effects of NAT10 inhibition, achieved through genetic knockdown or pharmacological Remodelin treatment, on immune cell infiltration and response to immune checkpoint blockade were evaluated.

Results: *NAT10* was found to be significantly upregulated in CRC across multiple cohorts, with higher expression in MSS tumors compared to MSI-H tumors (p<0.01-0.001). Elevated *NAT10* expression correlated with immune-cold phenotypes, poorer predicted immunotherapy response, and was negatively associated with T-cell activation genes (p<0.01). NAT10 positively regulated autophagy-lysosome genes, including *BECN1*, *ATG3*, and *ATG5*, through direct ac^4C modification, enhancing their mRNA stability (p<0.05). NAT10 knockout reduced autophagic flux (p<0.001), increased MHC-I expression (p<0.01), and promoted infiltration and activation of $CD8^+$ and $CD4^+$ T cells, leading to enhanced tumor cytotoxicity and suppressed tumor growth, effects that were abrogated by CD8 depletion. A combination of NAT10 knockout with anti-PD-1 therapy resulted in 80% complete tumor regression. MYC was identified as an upstream activator of NAT10, with *MYC* mRNA itself modified by ac^4C. MYC deletion reduced NAT10 expression, global ac^4C levels, and autophagy. Remodelin synergized with anti-PD-1 treatment, underscoring NAT10 as a druggable epitranscriptomic-autophagy checkpoint.

Conclusion: Our findings reveal a novel NAT10-MYC-autophagy axis that drives MHC-I degradation and orchestrates tumor immune evasion and resistance to immunotherapy in CRC. Targeting NAT10 represents a promising therapeutic strategy to overcome immune resistance and enhance the efficacy of immunotherapy in CRC.

#6746 Biomarker-driven restoration of tumor provisional matrix signaling network reverses resistance to checkpoint inhibition immunotherapy.

D. J. Lagal[1], D. Hong[1], A. Papadas[2], E. Geatches[1], G. Yacu[1], S. Naik[1], A. Gibbons[3], A. Cicala[4], K. Pestonjamasp[3], P. Toth[5], K. Matkowskyj[6], D. A. Deming[7], F. Asimakopoulos[1];
[1]Rush University Medical Center, Chicago, IL, [2]Ohio State University, Columbus, OH, [3]University of California, San Diego, La Jolla, CA, [4]Cold Spring Harbor Laboratory, Cold Spring Harbor, NY, [5]University of Illinois at Chicago, Chicago, IL, [6]Mayo Clinic, Rochester, MN, [7]University of Wisconsin Carbone Cancer Center, Madison, WI

Specialized immune niches located in the stroma-tumor junction promote interactions between tumor-resident antigen-presenting cells and effector lymphocytes that are required for immunotherapy efficacy. We have hypothesized that this stromal-based immune crosstalk may be regulated by provisional extracellular matrix signals, analogous to the early-stages of wound healing where provisional matrix hosts robust immune activity. A cardinal provisional matrix remodeling event, the regulated proteolysis of the large proteoglycan versican (VCAN) generates an immunomodulatory fragment (matrikine), versikine, that engages adaptive immunity. We have previously shown that VCAN proteolysis correlates with T-cell infiltration across multiple solid and liquid cancers with the most immune-evasive cancers showing low to negligible rates of VCAN proteolysis (e.g., 0% in pancreatic adenocarcinoma). A recent clinical trial generated informative prospective data linking VCAN proteolysis with immunotherapy outcomes: patients whose metastatic colorectal tumors categorized as VCAN proteolysis-weak (VPW, 60% of cases) demonstrated inferior responses to checkpoint inhibition (CPI, pembrolizumab) and worse outcomes compared to VCAN proteolysis-predominant (VPP, 40%) cases. Leveraging these prospective trial data, we hypothesized that versikine therapy may rationally reverse the immunosuppression associated with the prevalent VPW phenotype. To tailor versikine therapy to specific human biomarker-stratified tumor phenotypes, we studied experimental models replicating partially T-permissive VPW-VCAN^{lo} human cancers and poor-prognosis, immune-exclusionary VPW-VCAN^{hi} cancers. Across VPW-like tumors, versikine promoted the stromal accumulation of CD40lg^{hi}Icos^{hi}Foxp3^{neg} Tfh-like CD4+ T cells that engaged dendritic cells (DC) and CD8+ T cells in “immune triads” even at baseline (prior to CPI), concurrently with the intratumoral expansion of activated CD8+ T cells expressing cytolytic molecules (granzymes, perforin). In VPW-VCAN^{lo} tumors, versikine delivered as LNP-mRNA or recombinant protein demonstrated monotherapy activity, dependent on Batf3-lineage DC and CD8+ T cells. When combined with single-agent CPI, versikine cured most VPW-VCAN^{lo} tumors with memory to tumor re-challenge. In VPW-VCAN^{hi} tumors, versikine synergized with combination immunotherapy modulating “mature DCs enriched in immunoregulatory molecules” (mregDC). Our data provide mechanistic rationale for the biomarker-stratified, therapeutic restoration of a provisional matrix-regulated immune signaling network to reverse resistance to CPI. Moreover, the data highlight the need to reevaluate prior approaches to globally disrupt tumor stroma in favor of biomarker-driven, pathway-focused harnessing of stromal signals that modulate anti-tumor immunity.

Minisymposium

#6785 Evasion of hepatic ILC1 immunosurveillance drives breast cancer liver metastasis.
P. Li, J. Li, A. Cornish, J. Zhang, X. Zhang, M. Li;
Memorial Sloan Kettering Cancer Center, New York, NY

Metastasis is a complex biological process and the principal cause of cancer-related mortality. With dual blood supply and fenestrated sinusoids, the liver's haematogenous route uniquely favors seeding by circulating tumor cells (CTCs). Nonetheless, while portal drainage promotes frequent liver metastases from proximal gastrointestinal cancers such as colorectal carcinoma, hepatic colonization by systemically disseminated CTCs, including those originating from breast cancer, is highly inefficient. The cellular barriers and evasion mechanisms that govern this selective vulnerability remain poorly understood. Here we show that hepatic type 1 innate lymphoid cells (ILC1s) are selectively required for the immunosurveillance of breast cancer liver metastasis, the evasion of which is driven by both cancer cell-intrinsic and microenvironment-associated immune mechanisms. In a large patient cohort, liver metastasis occurred at a relatively later stage and was associated with poorer survival, with body mass index (BMI) above the WHO optimal range associated with higher risk. This metabolic vulnerability was recapitulated in a murine preclinical model, in which breast cancer CTC colonization of the liver—but not the lung—was promoted by a high-fat diet that induced hepatic steatosis. Mechanistically, NK cells expanded and activated in response to CTC challenge and employed both lytic granule and death receptor 5 (DR5, encoded by *Tnfrsf10b*) pathways for cancer cell clearance, hepatic ILC1s preferentially utilized DR5-mediated mechanisms and required high DR5 expression in cancer cells. Notably, loss of heterozygosity of *TNFRSF10B* in breast tumours was associated with a predisposition to liver metastasis, and poorer patient prognosis. Conversely, metabolic dysfunction-associated steatotic liver disease (MASLD), a pathological risk factor for breast cancer liver metastasis, correlated with depletion of hepatic group 1 innate lymphoid cells—a phenomenon recapitulated in high-fat diet-fed mice. Importantly, the high-fat diet-induced reduction in hepatic ILC1s and enhancement of breast cancer liver metastasis were reversed by treatment with glucagon-like peptide-1 (GLP-1) receptor agonists. Collectively, these findings reveal that breast cancer liver metastasis is primarily restrained by liver-resident ILC1s rather than circulating NK cells. Evasion of this immunosurveillance can arise from cancer cell-intrinsic genomic alterations that compromise DR5 sensitivity or from microenvironmental metabolic perturbations that diminish ILC1 function. Restoration of hepatic ILC1 activity by GLP-1 receptor agonists highlights a potential translational opportunity to extend these agents beyond metabolic disease into oncology, with innate lymphocyte-mediated cancer immunosurveillance as a distinct mechanism of action

#6786 Neutrophil extracellular trap inhibition mitigates tumor necrosis and metastasis in colorectal cancer.

E. Gazzara[1], A. Jose[2], S. Dziadowicz[1], S. Han[1], A. Liu[1], Z. Aminzada[1], N. Bhandari[1], V. Shirue[3], B. Shergill[3], M. Curtis[3], S. C. George[3], A. Cicala[1], A. Rishi[4], C. Devoe[4], H. Huang[5], M. Weiss[4], E. Lou[6], D. A. Tuveson[1], S. Beyaz[1], P. M. Westcott[1], M. Egeblad[7], **S. Gholami**[8];

[1]Cold Spring Harbor Laboratory, Cold Spring Harbor, NY, [2]The Francis Crick Institute, London, United Kingdom, [3]University of California Davis, Sacramento, CA, [4]Northwell Health, New Hyde Park, NY, [5]The Feinstein Institutes for Medical Research, Manhasset, NY, [6]University of Minnesota Medical School, Minneapolis, MN, [7]Johns Hopkins University School of Medicine, Lutherville-Timonium, MD, [8]Cold Spring Harbor Labortory, Cold Spring Harbor, NY

Neutrophils (polymorphonuclear cells, PMNs) have been shown to directly induce necrosis through the formation of neutrophil extracellular traps (NETs) in murine models of breast and lung cancer. Although necrosis is a well-recognized predictor of poor outcomes in cancer, it is typically regarded as a passive and non-targetable process. To determine whether NETs actively drive necrosis in colorectal cancer (CRC), we evaluated the pathogenic impact of NET formation in human CRC specimens and complementary preclinical models.In blood samples from patients with CRC, we identified elevated populations of neutrophils primed for NET formation, including an expanded $CD177^{Low}$ subset that retained strong NET-forming capacity with reduced extravasation ability. Histologic and immunofluorescent analyses of human CRC and colorectal liver metastases demonstrated abundant NET accumulation within necrotic regions, forming intravascular deposits. The extent of necrosis correlated with metastatic disease, independent of tumor size. Single-cell RNA sequencing and spatial transcriptomic profiling of human primary CRC and liver metastases showed that NET-rich necrotic tumors activate transcriptional programs associated with myelopoiesis (CSF1, CXCL2, CXCL12), hypoxia signaling, migration, and epithelial-to-mesenchymal transition—features linked to increased metastatic potential. In a mismatch-repair-proficient orthotopic CRC model using AKPS (APC^{KO} $KRAS^{G12D}$ $P53^{KO}$ $SMAD4^{KO}$) organoids implanted via colonoscopic injection, tumor progression was marked by rising circulating PMNs, bone marrow skewing toward myelopoiesis, and increasing NET deposition within necrotic tumor regions. Genetic and pharmacologic inhibition of NET formation reduced intratumoral necrosis and significantly decreased metastatic burden. Collectively, these findings demonstrate that NETs are active drivers of necrosis and metastatic evolution in CRC, reframing necrosis as an immunopathologic process rather than an unavoidable consequence of tumor growth. Targeting NET formation represents a promising translational strategy to improve disease control and oncologic outcomes for patients with CRC.

#6787 Metabolic reuse of tumor-derived signals coordinates dendritic cell function.

[1]Icahn school of medicine at Mount Sinai, New York, NY, [2]Institut Curie, Paris, France, [3]Yale University School of Medicine, New Haven, CT, [4]The Tisch Cancer Institute, New York, NY

Dendritic cells (DCs) are central initiators of antitumor immunity, requiring not only the efficient acquisition of tumor antigens but also the activation of maturation programs that license them to prime T cells. Beyond capturing cellular debris, DCs can repurpose tumor-derived metabolites to support these immunogenic functions, yet how this metabolic reuse shapes DC behavior within the tumor microenvironment remains unclear. We show that DCs mobilize cholesterol recovered from tumor cells (together with newly synthesized pools) to reorganize their plasma membrane and assemble lipid nanodomains that potentiate signaling pathways essential for full maturation. In parallel, polyamines enriched in the tumors act as complementary metabolic cues that facilitate the capacity of DCs to internalize antigens through a Rac-dependent mechanism. Together, these findings reveal that DCs integrate multiple tumor-derived metabolites to tightly couple antigen acquisition with the structural and signaling transitions that drive their maturation. This metabolic cross-talk between tumors and DCs emerges as a key determinant of effective immune priming and highlights cholesterol flux and polyamine pathways as potential targets to enhance DC-mediated antitumor immunity.

#6788 Spatial single-cell analysis reveals stage-dependent mechanisms of anti-IL-1β therapy in lung adenocarcinoma.

B. Zhu[1], M. Aminu[2], Y. Tian[1], S.-W. Lu[1], O. Shi[1], W. Lu[1], H. Chen[2], H. Li[1], Z. Wei[1], M. B. Nilsson[1], L. Solis Soto[1], F. P. Andrew[1], D. L. Gibbons[1], J. V. Heymach[1], C. Cheng[3], J. Wu[1], J. Zhang[1]; [1]UT MD Anderson Cancer Center, Houston, TX, [2]The University of Texas MD Anderson Cancer Center, [3]Baylor College of Medicine, Houston, TX

Introduction: Lung adenocarcinoma (LUAD) is a leading cause of cancer mortality, with IL-1β-driven inflammation playing a central role in tumor progression. Although IL-1β blockade shows promising antitumor effects, its efficacy varies across tumor stages, and the mechanisms behind this stage-dependent response remain unclear. Here, we investigate how tumor-immune interactions and microenvironmental remodeling shape differential responses to anti-IL-1β therapy during LUAD progression.
Methods: We performed spatial single-cell analysis of the immune microenvironment using Visium HD on human (10 adjacent normal, 17 AAH, 12 IAC) and mouse samples (21 adjacent normal, 57 hyperplasia, 13 IAC). Integrating these data with stage-matched scRNA-seq, we mapped IL-1β-IL1R1-mediated cell-cell interactions across LUAD stages. Long-term anti-IL-1β treatment was evaluated in two mouse models—C57BL/6 Kras^G12D (early: 4-14 weeks; late: 20-30 weeks) and 129S4 urethane-induced (early: 4-14 weeks; late: 30-40 weeks)—with efficacy and mechanisms assessed via scRNA-seq and Xenium 5K. Short-term treatments (0, 6, 30 weeks) in C57BL/6 Kras^G12D were performed to further explore mechanisms.
Results: In human tissues, IL-1β-IL1R1 interactions (“IL-1βnets”) occurred primarily between myeloid cells and fibroblasts, epithelial, and endothelial cells, a pattern conserved in mouse tissues. Long-term anti-IL-1β treatment was effective only at the early stage. Early-stage scRNA-seq showed enhanced antitumor immunity and a marked reduction in interactions between IL1R1+ fibroblasts and IL-1β+ myeloid cells (monocytes, macrophages, cDCs, neutrophils), whereas late-stage tissues showed minimal changes. Spatial analysis with Xenium 5K confirmed reduced IL1R1+ cell fractions within IL-1βnets at the early stage, with IL-1βnet number and size largely unchanged. Short-term treatment at the early stage reduced interactions between IL1R1+ epithelial cells and neutrophils and attenuated NF-κB signatures in fibroblasts and epithelial cells; late-stage treatment had no significant effects.
Conclusion: Spatial single-cell profiling revealed the IL-1β-IL1R1 interaction landscape across LUAD progression in humans and mice. Anti-IL-1β therapy was effective in early-stage LUAD, disrupting key interactions between myeloid and fibroblast/epithelial cells, but was largely ineffective at later stages. These findings suggest that fibroblast and epithelial remodeling are critical determinants of stage-dependent anti-IL-1β efficacy.

#6789 Gut commensal dysbiosis modulates the lung microenvironment to promote breast tumor metastasis in a mast cell dependent axis.

M. Poblete, A. Putelo, S. Bajgai, C. Hatzinger, A. Mirani, M. Perusina Lanfranca, A. Feng, U. Miagkov, M. Rutkowski;
University of Virginia School of Medicine, Charlottesville, VA

This study aims to investigate the impact of the gut microbiome as a host-intrinsic factor in breast cancer metastasis to the lungs. The 5-year survival rate of metastatic breast cancer is 31%, however little is known as to what places patients at risk for metastatic disease. Here, we provide evidence that gut commensal dysbiosis, an inflamed and unbalanced microbiome, modifies the lung tissue microenvironment to promote the growth of hormone receptor-positive (HR+) breast tumor cells in a mast cell-dependent mechanism. This work uses a published model of dysbiosis, where we treat mice with oral broad-spectrum antibiotics for 2 weeks, before allowing 4 days of rest to promote optimal growth of antibiotic-resistant species. Non-dysbiotic controls were given vehicle treatment. The HR+ breast tumor cells PyMT were then administered intravenously (IV) to female C57BL/6 mice, mimicking circulating tumor cells to evaluate metastatic growth within the lungs. Mice with pre-established dysbiosis had significantly enhanced lung tumor burden and reduced survival. Pathology score of the lungs of mice challenged with IV tumors showed that at the same time-point dysbiotic mice display elevated tumor grade and inflammation. Furthermore, Luminex screen showed that the lungs of non-tumor-bearing mice displayed significantly elevated IL-6, a pleiotropic cytokine that has been shown to enhance tumor growth in the lungs. Single-cell RNA sequencing identified that mast cells are the main contributor of IL-6 to the lung environment of dysbiotic mice. Finally, to investigate the role of mast cells in promoting the vulnerability of dysbiotic mice to metastatic growth in the lungs, we treated dysbiotic mice with ketotifen, a mast cell stabilizer, before challenging them with PyMT cells as before. Kaplan-Meier analysis showed that dysbiotic mice treated with ketotifen had significantly improved survival compared to vehicle-treated controls. These findings highlight the significant and under-explored connection between the gut microbiome, the immune system, and tumor metastasis, and provoke future questions to investigate the impact of gut microbiome health as a host-intrinsic factor in breast cancer outcomes.

#6790 Myeloid IFN-γsignaling regulates immunosuppressive and fibrotic tumor microenvironment in PDAC liver metastasis.

T. Tanaka, E. Ivleva, A. Savas, K. Chojnacka, S. Grivennikov;
Cedars-Sinai Medical Center, Los Angeles, CA

Background; Pancreatic ductal adenocarcinoma (PDAC) remains one of the most lethal malignancies, and liver metastasis is the leading cause of mortality. Within the tumor microenvironment (TME), macrophages play central roles regulating inflammation and antitumor immunity. However, the specific contribution of macrophage-intrinsic IFN-γ signaling to metastatic progression remains poorly understood.

Methods; To investigate the role of IFN-γ signaling in macrophages, we established a portal vein injection model of PDAC liver metastasis using *Ifngr2*$^{flox/flox}$ LysM-Cre mice. Tumor burden was quantified by gross morphology and histology. Flow cytometry was used to assess macrophage and other immune cell abundance and phenotypes/activation states. Bulk RNA sequencing (Bulk RNA-seq) on whole liver metastases and single-cell RNA sequencing (scRNA-seq) on immune cell types were performed to examine the effect of myeloid-specific IFN-γ signaling on metastatic TME.

Results; We found that IFNgr2 myeloid specific deletion led to a marked increase in metastasis number and overall tumor load compared with WT controls. Flow cytometric analysis demonstrated that tumor associated macrophages (TAMs) in IFNgr2$^{\Delta Mye}$ mice showed increased Arg1 and CD206 expression and reduced MHC-II, CD80, and CD86, indicating a shift toward an immunosuppressive phenotype. Bulk RNA-seq revealed down-regulation of IFN-γ response, antigen presentation, and inflammatory pathways in metastases from IFNgr2$^{\Delta Mye}$ mice. ScRNA-seq analysis further uncovered profound remodeling of macrophage compartment with elevation in TREM2 high lipid-associated macrophages and angiogenic TAMs, accompanied by enhanced TGF-β signaling and fibrotic matrix gene expression.

Conclusions; Loss of macrophage-intrinsic IFN-γ receptor signaling drives the expansion of TREM2 high and angiogenic TAM subsets, promoting an immunosuppressive and fibrosis-prone TME that facilitates PDAC liver metastasis. These findings highlight the IFN-γ-macrophage axis as a critical regulator of metastatic progression and a potential therapeutic target in PDAC.

#6791 Target chronic inflammation in cancer and fibrosis with engineered immune cells.

Z. Zhang[1], Y.-J. Ho[1], X. Fang[2], M. Li[1], M. Kim[1], C. Hinterleitner[1], S. Haubner[1], F. Kogel[1], E. Pratt[1], A. FILLIOL[1], M. Sadelain[3], S. W. Lowe[1];
[1]Memorial Sloan Kettering Cancer Center, New York, NY, [2]Mount Sinai School of Medicine, New York, NY, [3]Columbia University Irving Medical Center (CUIMC), New York, NY

Background: Chronic inflammatory disorders contribute to over 30% of global mortality and underlie major diseases such as cancer, fibrosis, and autoimmunity. Fibrosis is a hallmark of chronic inflammation following tissue injury that drives progressive organ dysfunction and cancer progression. Existing anti-fibrotic therapies are limited by modest efficacy and systemic toxicity. We hypothesize that the selective elimination of fibrogenic and inflammatory effector cells can disrupt self-perpetuating cycles of injury and inflammation, providing a targeted therapeutic avenue for chronic disease. **Methods:** Using proximity-based surface proteomics, we identified the urokinase plasminogen activator receptor (uPAR) as broadly upregulated in senescent and chronically injured tissues across cancer and fibrotic contexts. This was corroborated by a meta-analysis of eight senescence-focused and sixteen cancer transcriptomic datasets, as well as immunohistochemical validation on patient tissue microarrays. uPAR, a GPI-anchored membrane protein central to wound healing and tissue remodeling, is consistently elevated during chronic inflammation in cancer and fibrosis. In a somatic tissue-engineered syngeneic mouse model of ovarian cancer, we demonstrated the anti-tumor efficacy of murine uPAR-targeted CAR T cells. We then generated clinical-grade human uPAR-targeting single-chain variable fragments (scFvs) through phage display and hybridoma screening, and validated their ability to eradicate both orthotopic and metastatic xenograft tumors. **Results:** uPAR-targeted CAR T cells selectively eliminated senescent cells and attenuated fibrosis in preclinical models of liver and lung injury. In cancer, uPAR expression marks aggressive tumor cells undergoing epithelial-to-mesenchymal transition (EMT) and senescent stromal cells embedded in immunosuppressive niches. In multiple solid tumor models, including immune-excluded settings, human uPAR CAR T cells exhibited potent and durable anti-tumor activity. In an ovarian cancer model, adjuvant administration of uPAR CAR T cells post-surgical debulking effectively prevented metastatic recurrence. Therapeutic efficacy was tracked via noninvasive biomarkers, including circulating soluble uPAR and uPAR-targeted PET imaging. Despite detectable expression in subsets of myeloid cells, treatment with uPAR CAR T cells did not induce sustained myelodepletion in mice with a humanized immune system. **Conclusions:** These findings establish uPAR-targeted CAR T cells as a promising therapeutic strategy across cancer, fibrosis, and degenerative diseases by eliminating shared pathological cell states that sustain chronic inflammation and tissue dysfunction.

: KRAS-Targeted Therapies: Overcoming Resistance and Novel Combinations
Minisymposium

#6767 Defining a molecular signature for KEAP1-NRF2 mediated resistance to KRAS inhibition in KRAS-mutant pancreatic and lung cancer.

W.-H. Chang[1], A. J. Vaughan[2], M. Mancini[3], A. G. Stamey[1], M. Hayashi[2], R. Yang[1], R. Robb[1], J. A. Klomp[1], A. M. Waters[1], A. Schaefer[1], D. Andrussier[4], K. L. Bryant[1], A. D. Cox[1], F. M. Simabuco[3], A. J. Aguirre[5], K.-K. Wong[4], C. A. Stalnecker[1], T. Papagiannakopoulos[2], C. J. Der[1];
[1]University of North Carolina at Chapel Hill, Chapel Hill, NC, [2]NYU Langone Health, New York, NY, [3]Federal University of Sao Paulo, Sao Paulo, Brazil, [4]New York University, New York, NY, [5]Dana-Farber Cancer Institute, Boston, MA

Mutational activation of KRAS is critical for driving the tumorigenic growth of pancreatic ductal adenocarcinoma (PDAC) and lung adenocarcinoma (LUAD). Recent approval of inhibitors of one KRAS mutation (G12C) supports the therapeutic value of targeting mutant KRAS in PDAC and LUAD. However, clinical efficacy is hindered by both primary and treatment-associated acquired resistance. With resistance mechanisms still incompletely established, we performed a CRISPR loss-of-function screen to identify genes that modulate the sensitivity of PDAC cells to KRAS inhibition. We determined that loss of *KEAP1* and activation of the transcription factor NRF2 drove resistance to the $KRAS^{G12D}$-selective inhibitor MRTX1133 and the RAS(ON) multi-selective inhibitor RMC-7977. RNA-sequencing analyses revealed that *KEAP1* loss protected cancer cells from oxidative stress and cell cycle arrest induced by KRAS inhibition. Building upon our transcriptomic analyses, we established a PDAC KEAP1-deficient (PKD) gene signature. The PKD signature was prevalent in preclinical models and patients insensitive to KRAS inhibitor treatment. This signature was also distinct from transcriptional changes associated with other mechanisms driving KRAS inhibitor resistance (ERK, MYC, and YAP/TAZ-TEAD). Finally, we observed that *KEAP1*-deficient cells exhibited elevated glutamine metabolism, and combination treatment with the clinical candidate glutamine antagonist DRP-104 (sirpiglenastat) strongly enhanced KRAS inhibitor-mediated growth suppression in KRAS-mutant PDAC and NSCLC tumors in vivo. In summary, our studies established a gene signature for *KEAP1* loss-driven resistance and validated a therapeutic strategy to overcome KEAP1-NRF2-driven RAS inhibitor resistance.

#6768 Selective ULK1/2 inhibitors enhance KRAS pathway blockade and uncover stress-adaptive programs.

S. Bayle, S. Chin Chan, M. Lamptey, M. Teng, A. Monastyrskyi, D. Duckett;
Moffitt Cancer Center, Tampa, FL

KRAS is the most frequently mutated member of the RAS family in lung adenocarcinomas such as NSCLC. Although KRAS pathway inhibition can reduce tumor growth, resistance arises and thwarts its clinical potential. Prior work has suggested that the autophagy pathway is an exploitable vulnerability for mutant RAS-driven tumors. ULK1 is a central upstream regulator of the autophagy pathway, and its inhibition is a promising strategy to abrogate autophagy and improve RAS-driven tumor sensitivity to approved therapeutics. Through structure-based drug design, we generated a 7-azaindole-derived series of ULK1/2 inhibitors and characterized their structure-activity relationships. Biochemical potency was measured via ULK1/2 enzymatic assays, and intracellular target engagement was evaluated using a ULK1 NanoBRET assay. Cellular analyses were performed in KRAS mutant models using viability assays, autophagy flux measurements under starvation or treatment with MEK inhibitor. Combination studies with RAF-MEK-ERK pathway inhibitors were assessed in subcutaneous xenograft models. In order to assess the type of resistance arising from KRAS treatment, we used a combination of DNA barcode technology and transcriptomic studies to distinguish between resistance arising from clonal expansion vs adaptive, reversible survival programs consistent with drug-tolerant persister (DTP) biology. We identified potent, selective ULK1/2 inhibitors, favorable physicochemical profiles, and strong cellular target engagement. The lead analog, MR-2088, inhibited stimuli-induced autophagic flux and displayed pharmacokinetics appropriate for in vivo studies. In cells, MR-2088 enhanced the activity of MEK/ERK inhibitors and produced synergistic reductions in viability. The synergistic effect was observed in vivo. DNA barcode analysis revealed that resistance emerging after KRAS pathway inhibition was not associated with expansion of distinct clonal populations, suggesting a non-genetic adaptive mechanism. Transcriptomic profiling showed enrichment of stress-adaptive pathways, including cell-cycle remodeling, metabolic rewiring, oxidative phosphorylation, and MYC-regulated targets; patterns consistent with previously described drug-tolerant persister-like programs. This study describes a new chemotype of selective, ULK1/2 inhibitors that robustly engage the target, inhibit autophagic flux, and enhance the effectiveness of RAS pathway inhibitors. By disrupting autophagy-supported adaptive programs that arise following KRAS pathway inhibition, ULK1 blockade may enhance therapeutic responses and limit stress-induced survival states relevant to treatment tolerance. These findings support further investigation of ULK1 inhibition as a strategy to augment targeted therapy in KRAS-driven malignancies.

#6769 Modeling of acquired resistance to the multi-RAS inhibitor RMC6236 in KRAS mutant pancreatic ductal adenocarcinoma.

Di Zhan, Jiajia Mei, Jing Yang, Ya Xu, Qikuan Chen, Yuzhou Xu, Yun Zhang, Yinfei Yin

Shanghai ChemPartner Co., Ltd., Shanghai, China

Mutations in the Kirsten rat sarcoma viral oncogene homologue (KRAS) are among the most prevalent oncogenic events in human cancers, with KRAS G12D being the dominant driver in pancreatic ductal adenocarcinoma (PDAC). While covalent KRAS G12C inhibitors have demonstrated clinical efficacy, the absence of effective therapies for non-G12C variants underscores the need for broader KRAS-directed approaches. The recent development of RMC6236, a RAS-MULTI(ON) inhibitor, has shown promising activity in KRAS G12D-driven PDAC, emphasizing the importance of understanding mechanisms underlying acquired resistance to this class of agents. To enable investigation of KRAS resistance pathways, we have established a panel of KRAS G12D PDAC cell models with acquired resistance to RMC6236 using a combination of CRISPR-Cas9-mediated genome editing and advanced engineering techniques. In addition, KRAS-mutant tumor models with engineered inhibitor resistance have been established to support pharmacology and efficacy evaluations. Genomic and functional characterization of these models reveal diverse mechanisms contributing to resistance, including secondary KRAS mutations (Y64C/D/H), BRAF alterations, and MAP2K1 variants, each associated with reactivation of the RAF-MEK-ERK signaling cascade. Beyond genetic adaptations, transcriptional profiling and phenotypic assays indicate the involvement of non-genetic mechanisms such as pathway rewiring and adaptive signaling plasticity. These resistance models provide a controlled experimental framework for dissecting the molecular determinants of multi-RAS inhibitor resistance, and enable comparative evaluation of resistance mechanisms across KRAS alleles, supporting rational development of combination strategies to sustain KRAS pathway inhibition. Collectively, these studies advance our understanding of adaptive resistance to next-generation KRAS inhibitors and inform translational strategies for KRAS G12D-mutant pancreatic cancer.

#6770 Combining RAS inhibitors with the clinical RNR inhibitor BBI-825 to prevent the emergence of extrachromosomal DNA (ecDNA)-driven resistance to RAS-targeted therapies in colorectal cancer.

S. Palladino[1], J. Lange[2], N. Catalano[1], S. Garcia[2], R. Hansen[2], H. Zhao[1], P. Kokate[1], E. De Stanchina[1], C. Hassig[2], R. Yaeger[1];
[1]Memorial Sloan Kettering Cancer Center, New York, NY, [2]Boundless Bio, San Diego, CA

Introduction: The advent of new RAS inhibitors provides an exciting chance to extend targeted therapy to the half of colorectal cancers (CRC) with *KRAS* mutations. However, the rapid development of resistance limits the clinical benefit of this approach. Focal and ecDNA-driven amplifications are a common mechanism of resistance; in the phase 1 trial of daraxonrasib (RAS multi ON), acquired mutant *KRAS* amplifications occurred in 30% of patients. *In silico*, ecDNA$^+$ tumor cells show a strong survival dependence on ribonucleotide reductase (RNR), the rate-limiting enzyme in the *de novo* synthesis of deoxyribonucleotide triphosphates (dNTPs). BBI-825, an oral and selective small molecule inhibitor of RNR, has entered clinical trials. We investigated whether BBI-825, in combination with different RAS inhibitors, can delay or overcome the development of acquired resistance in CRC. Based on the vulnerability of ecDNA$^+$ cells to BBI-825, we anticipated response may vary by tumor microsatellite status and evaluated microsatellite stable (MSS) and instable (MSI) CRC models.
Methods: Human cancer models were treated with combined RAS and epidermal growth factor receptor (EGFR) antibodies. We used parental and resistant models generated from murine and human cancer cell lines, cell derived xenografts (CDX) and patient derived xenografts (PDX) to compare the effect of RAS inhibition alone and in combination with BBI-825 on tumor growth, signaling and acquired resistance. RAS inhibitors used were MRTX1133 and zoldonrasib (*KRAS*^{G12D}), sotorasib and adagrasib (*KRAS*^{G12C}) and daraxonrasib. Metaphase fluorescence in-situ hybridization (FISH) was used to evaluate ecDNA presence.
Results: The addition of BBI-825 to RAS inhibitor (plus anti-EGFR antibody in human cells) delayed or prevented the emergence of resistance in the MSS parental cell lines, CDX and PDX. This combination suppressed the emergence of ecDNA-driven *KRAS*, *RAF1* and *MYC* amplifications. In MSS CRC models that had already acquired resistance to RAS inhibitors, the addition of BBI-825 to RAS plus EGFR inhibition slowed tumor growth and reduced the copies of putative resistance gene amplifications. In contrast, in the MSI model, acquired resistance was likely mediated by new mutations in *KRAS*, and addition of BBI-825 did not significantly impact acquired resistance or tumor growth.
Conclusions: We show in multiple models of MSS CRC that the selective RNR inhibitor BBI-825 combined with RAS inhibitors delayed or prevented RAS targeted therapy-acquired resistance in a novel approach that subverts the emergence of resistance. The selective sensitivity of MSS CRC models, particularly those that harbor ecDNA, further supports the distinct mechanism of action of BBI-825 and this potential new and important strategy to improve RAS inhibitor efficacy.

#6771 Targeting the JAK-STAT pathway sensitizes KRAS-mutant cancer to KRAS inhibitors.

Y. Zhao, Y. Cao, Y. Bao, B. Shen;
Ruijin Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai, China., Shanghai, China

Targeting KRAS is promising in KRAS-mutant cancers. However, primary and acquired resistance to KRAS inhibitors impedes their clinical use. We conducted a Phase IIa clinical trial enrolling 7 patients with resectable PDAC bearing KRAS^G12D mutations, who received standard neoadjuvant chemotherapy plus KRAS inhibitors. Genomic analyses revealed acquired mutations in KRAS and other cancer-related. Single-cell transcriptomic profiling showed significant differences in cancer-associated fibroblast (CAF) populations between responders and non-responders. Kinome CRISPR library screening and FDA-approved compound library screening nominated the JAK-STAT pathway as critical for response to KRAS inhibition. Cell lines resistant to KRAS inhibitors have activated JAK-STAT pathway. In vitro and in vivo, STAT3 inhibition synergized with KRAS inhibition, altered cytokine secretion by cancer cells, and modulated CAF status. These findings demonstrate that activation of the JAK-STAT pathway is a common mechanism of resistance to KRAS inhibitors in diverse KRAS-mutant cancers and suggest that dual targeting of KRAS and STAT3 may enhance therapeutic efficacy.

#6772 VEGFR2 blockade overcomes acquired KRAS G12D inhibitor resistance driven by PI3Kγ activation.

S.-H. Hwang[1], M. Bae[2], J.-W. Kim[3], S. Hyun[4], K.-J. Kim[5], J. Choe[6], M. Kim[7], J. Park[8], S. Jeong[7], S. Choi[1], W. Park[1], J. Seo[1], H. Chae[1], M. Kang[9], E. Jung[3], K. Suh[3], S. Kim[10], J. Kim[10], Y. Kim[3], J. Kim[10], H. Park[11], A. J. Aguirre[12], E. Lee[6], J.-L. Ku[13], K.-W. Lee[3];

[1]Seoul National University Bundang Hospital, Seongnam-si, Korea, Republic of, [2]Boston Children's Hospital, Harvard Medical School, Boston, MA, [3]Department of Internal Medicine, Seoul National University Bundang Hospital, Seoul National University College of Medicine, Seongnam-si, Korea, Republic of, [4]Seoul National University, Seoul, Korea, Republic of, [5]Seoul National University Bundang Hospital, Seongnam-si, [6]Broad Institute of MIT and Harvard, Cambridge, MA, [7]Department of Surgery, Seoul National University Hospital, Seoul National University College of Medicine, Seoul, Korea, Republic of, [8]Seoul National University Hospital, Seoul, Korea, Republic of, [9]Seoul National University Bundang Hospital, Seoul, [10]Seoul National University Bundang Hospital, Seongnam, Korea, Republic of, [11]DFCI/Harvard Medical School, BOSTON, MA, [12]Dana-Farber Cancer Institute, Boston, MA, [13]Seoul National University Cancer Research Institute, Seoul, Korea, Republic of

KRAS G12D mutation is a prevalent oncogenic driver in gastrointestinal (GI) cancer. Recently, novel KRAS inhibitors have shown promise in KRAS-mutant cancers. However, acquired resistance inevitably emerges, limiting clinical efficacy. Nevertheless, their resistance mechanisms and overcoming strategies remain largely undefined. We established nine human GI cancer models of acquired resistance to MRTX1133, a KRAS G12D selective inhibitor: two gastric (AGS and SNU-601), two pancreatic (AsPC-1 and PANC-1), and two colorectal cancer cell lines (SNU-C2A and SNU-C2B), and three colorectal cancer patient-derived organoids (SNU-4646S1-TO, SNU-6325-TO, and SNU-6330-TO). Single-cell RNA sequencing analysis of resistant and parental SNU-4646S1-TO (GSE290526) revealed enrichment of angiogenesis, hypoxia, and epithelial-mesenchymal transition (EMT) signatures in resistant models compared to parental cells. In line with this, all nine resistant models showed markedly elevated VEGFA expression and VEGFR2 activation, which we traced to AKT-mediated nuclear translocation of the transcription factor SP1. Mechanistic investigation revealed that oncogenic KRAS in the resistant state formed a complex with p110γ and p101, subunits of PI3Kγ, leading to hyperactivation of PI3Kγ. This, in turn, established the autocrine VEGFA-VEGFR2 signaling loop via AKT and SP1 activation that reinforced EMT and sustained the resistant phenotype. In the resistant models, disrupting VEGFA-VEGFR2 signaling using KDR knock-out and ramucirumab treatment restored MRTX1133 sensitivity and reversed EMT in resistant cells. Inhibition of hyperactivated PI3Kγ using eganelisib, a selective p110γ inhibitor, also replicated the same results. Indirect co-culture experiments of cancer cells and human large vessel endothelial cells (HUVECs) identified that cancer-endothelial paracrine crosstalk in resistant models further amplified angiogenesis, hypoxia, and EMT signatures (GSE290487) in cancer cells and concurrently promoted endothelial cell proliferation, suggesting a microenvironment-mediated feedback loop. In a mouse xenograft model of MRTX1133-resistant PANC-1 cells, anti-VEGFR2 antibody (DC101) treatment combined with MRTX1133 rechallenge more effectively reduced tumor growth and angiogenesis than either agent alone, without significant changes in body weight. Our study revealed a novel mechanism of acquired resistance to KRAS G12D inhibition in GI cancers: a KRAS-PI3Kγ interaction-driven autocrine and paracrine VEGFA-VEGFR2 signaling axis that fosters EMT and therapeutic escape. Importantly, co-targeting this axis with VEGFR2 or PI3Kγ inhibitor restored sensitivity to KRAS inhibition. These findings provide a rationale for further biomarker-guided clinical trials of combined VEGFA-VEGFR2 and KRAS inhibition in patients experiencing acquired resistance after KRAS inhibitor treatment.

#6773 Targeted therapy-induced chromosomal instability dictates mitotic dependency on Aurora kinase A.

C. Li[1], V. Nangia[2], M. Vieira[1], A. Nimbalkar[1], C. Graser[3], J. Chang[4], M. Syed[1], Y. Shen[1], R. Koranne[1], L. Zou[5], F. Michor[6], S. L. Spencer[7], A. N. Hata[8];
[1]Mass General Cancer Center, Harvard Medical School, Boston, MA, [2]University of Colorado Boulder, Boulder, CO, [3]Dana-Farber Cancer Institute, Cambridge, MA, [4]University of California San Francisco, San Francisco, CA, [5]Duke University School of Medicine, Durham, NC, [6]Dana-Farber Cancer Institute, Boston, MA, [7]Univ. of Colorado Denver School of Medicine, Aurora, CO, [8]Massachusetts General Hospital, Charlestown, MA

Targeted therapies are designed to eliminate cancer cells by directly inhibiting oncogenic driver proteins. In addition to their primary inhibitory effects on oncogenic signaling, these agents frequently impose collateral cellular stresses, such as DNA damage. KRAS-targeted therapies, particularly KRAS G12C inhibitors (G12Ci), represent a major therapeutic advance but remain limited in efficacy. Previous reports of targeted therapy-induced DNA damage, including studies of TKIs and MAPK inhibitors, have primarily been based on cytotoxic dosing conditions. Far less is known about whether DNA damage can also be induced by targeted therapies in less sensitive cancer models, particularly under sublethal doses that better mimic clinical responses. Failure to repair DNA damage can lead to chromosomal instability (CIN) and chromosomal aberrations. CIN is widely recognized to promote tumor evolution by enhancing cellular plasticity and adaptability, thereby contributing to therapeutic resistance and metastatic progression. However, it remains unknown how KRAS G12C inhibition influences CIN and whether G12Ci-induced CIN might generate unique, exploitable vulnerabilities.

In this study, we profiled 15 KRAS G12C-mutant NSCLC cell lines representing diverse mutational backgrounds. We treated these models with the KRAS G12Ci LY3499446 and comprehensively assessed their DNA damage responses, CIN phenotypes, and sensitivity screening to combination therapies with agents that perturb chromosomal stability. We observed heterogeneous induction of DNA damage and CIN across these cell lines. Notably, we identified the strongest correlation between G12Ci-induced CIN and synergistic interaction with the Aurora kinase A inhibitor (AURKAi) LSN3321213. Machine learning-based single-cell image tracking and DNA barcoding analyses revealed that AURKA inhibition alone causes mitotic arrest followed by mitotic slippage, allowing cells to evade death, whereas combined G12Ci and AURKAi treatment triggers catastrophic mitotic cell death. Mechanistically, we found that G12Ci stabilizes Cyclin B1 through mitotic activation of ATR/ATM DNA repair signaling, thereby prolonging mitotic arrest. Under conditions of combined inhibition of KRAS G12C and AURKA, in which Cyclin B1 degradation is impaired, cells fail to exit mitosis and undergo catastrophic cell death. Together, our findings identify CIN as a predictive marker of response to combined KRAS G12C and AURKA inhibition, providing mechanistic rationale to enhance the therapeutic window of AURKA inhibitors when used with targeted therapies.

: Machine Learning Approaches for Cancer Diagnosis and Treatment Prediction

#6722 CUPAI-2: A collaborative multi-agent large language model framework for diagnosis of cancer of unknown primary.
Junhan Zhao[1], Juejie Zhang[2], Lingjie Fan[3], Anzhi Chen[4], Zheyi Ji[5], Zanmei Xu[6], Yannan Zhu[6], **Kai Wang**[7]

[1]The University of Chicago, Chicago, MI,[2]University of Science and Technology of China, Hefei, China,[3]Sichuan University, Chengdu, China,[4]Columbia University, New York, NY,[5]Chongqing University, Chongqing, China,[6]OrigiMed, Shanghai, China,[7]OrigiMed, Boston, MA

Background: Cancers of unknown primary (CUP) accounts for 2-5% of cancers but remains a leading cause of death, as failure to identify the primary site blocks targeted therapy and trial access. We developed CUPAI-2, a multi-agent LLM framework with a website that integrates genomic data to predict CUP primary site.
Methods: CUPAI-2 implements a Molecular Tumor Board (MTB)-inspired architecture comprising (i) domain specialist models and (ii) a meta-decision layer for consensus integration. The specialist tier comprises three LLMs (Qwen-2.5-0.5B, Qwen-3-0.6B, Llama-3.2-1B), each fine-tuned on modality specific corpora including single nucleotide variants, copy number alterations , and chromosomal translocations to produce independent primary site likelihoods and rationales. Their outputs (class probabilities, uncertainty scores, and rationale embeddings) feed a statistical coordinator that performs stacked generalization, employing an XGBoost model as a non-linear meta-learner to arbitrate and integrate predictions. A final oversight agent (DeepSeek) functions as the MTB manager, auditing discordant cases against structured genomic contexts and literature-derived priors, and issuing an adjudicated prediction. We analyzed 20,483 next generation sequencing (NGS) profiled tumors spanning 19 cancer types, and benchmarked CUPAI-2 against experienced oncologists on test sets.
Results: CUPAI-2 achieved robust diagnostic performance with Top1 accuracy of 76.93% and Top3 of 92.82%. Performance exceeded that of oncologists on 190 uniformly distributed cancer cases (Top1: 71.05% vs. 68.42%; Top3: 83.15% vs. 80%), and inter-model reliability within the CUPAI-2 was high as reflected by Jaccard similarity coefficients. Compared with traditional machine learning (Top1/Top3: 60.38%/79.77%), CUPAI-2 achieved substantial improvements of 17.83 and 12.33 percentage points (pp) , respectively. It also delivered additional gains of ~3-5 pp compared with non-collaborative, individually fine-tuned LLMs (75.27%/87.55%). CUPAI-2 further surpassed the current best published voting-based model, establishing a new state-of-the-art for CUP origin prediction while maintaining clinically acceptable computational efficiency. A prototype (https://cupai.origimed.com) enables uploading of NGS reports for CUP prediction and is not intended for clinical decision making.
Conclusions: CUPAI-2, a coordinated MTB-inspired multi-agent LLM architecture, synthesizes heterogeneous genomic features to predict CUP primary sites with greater accuracy, calibration, and interpretability than individual LLMs, conventional models, or human experts. These findings highlight the feasibility and value of multi-agent LLM systems for high dimensional genomic reasoning and suggest a promising clinical decision making direction for improving cancer primary site inference.

#6723 Multisite analysis of a deep learning model for prediction of palbociclib response in patients with ER+ HER2- advanced breast cancer.

A. Singhal[1], X. Zhang[2], K. T. Yeung[2], T. Ideker[3];

[1]University of California, San Diego, La Jolla, CA, [2]Moores Cancer Center, La Jolla, CA, [3]UC San Diego, La Jolla, CA

Deep learning is a powerful methodology that is beginning to impact many aspects of cancer care, including the prediction of therapeutic response. These models, consistent with advances in machine learning, are showing increasingly improved performance on preclinical datasets. For successful clinical deployment of these models, a key step (and frequent barrier) is rigorous evaluation on real-world patient populations. We address this translational gap through several advances. First, we collect two distinct, real-world cohorts of ER+ HER2- advanced breast cancer treated with palbociclib to enable gold-standard evaluation of precision oncology models. These include a novel cohort of 139 patients treated at the University of California, San Diego (UCSD), for which we track demographics, treatment duration, progression-free survival (PFS), and overall survival (OS). We supplement this dataset with a larger independent real-world cohort of 459 patients treated at the Memorial Sloan Kettering Cancer Center (MSK). Second, we the use of these cohorts to provide a full retrospective evaluation of a recently published interpretable deep learning model of palbociclib response. Model analysis results in accurate stratification of PFS (UCSD: HR = 0.38, $P = 0.01$; MSK: HR = 0.60, $P = 2 \times 10^{-3}$) and OS (UCSD: HR = 0.38, $P = 0.05$; MSK: HR = 0.74, $P = 0.05$). Third, model interpretation identifies a collection of rare and common genetic alterations underlying drug resistance in 18 molecular pathways, including RTK signaling, DNA damage response, and cell cycle regulation. Finally, we showcase a visualization schema to augment personalized diagnostic reports for individual patients. Together, these results build evidence to motivate future prospective studies exploring the predictive efficacy of precision oncology models.

#6724 OncoTwin: A multimodal digital twin framework for predicting treatment response and guiding trial design in ALK-rearranged non-small-cell lung cancer.

H. Xu, Y. Y. Elamin, L. Hong, K. Concannon, M. Saad, X. Xu, M. Amgad, H. Li, K. Qin, X. Han, S. Ismail, Y. Kitsel, S. Gandhi, M. B. Antonoff, C. C. Wu, B. W. Carter, G. Shroff, S. Heeke, X. Le, T. Cascone, N. Vokes, M. Altan, D. L. Gibbons, D. Jaffray, J. Chang, Z. Liao, D. Rice, A. Vaporciyan, S. G. Swisher, J. Lee, J. Zhang, J. V. Heymach, J. Wu;
University of Texas MD Anderson Cancer Center, Houston, TX

Introduction: Despite advances with next-generation tyrosine kinase inhibitors (TKIs), response and progression patterns in ALK-rearranged NSCLC vary widely, and currently no reliable biomarkers can predict individualized outcomes under alternative therapies. Digital-twin models offer a solution by integrating real-world evidence to reconstruct patient-specific counterfactual disease trajectories for single-arm trials and evaluation of escalation strategies.

Methods: We integrated real-world and clinical-trial datasets of ALK-rearranged NSCLC treated with TKIs, including MDACC cohort (n = 103, GEMINI database) for model development, Phase III randomized ALTA-1L (n = 207) for external validation, and Phase II BrightStar (n = 32) for clinical application. Tumor burden was quantified at whole-body and organ levels using CT-derived 3D volumetrics, combined with longitudinal routine blood test and demographic variables. Two digital twin models were developed through machine learning: OncoTwin-2D, a parsimonious model based on serial sum of longest diameters (SLD) and demographics, and OncoTwin-3D, an advanced model integrating longitudinal 3D volumetric, blood, and demographic features. Models were evaluated on MDACC and ALTA-1L cohorts by hazard ratio (HR) and log-rank test. The calibrated OncoTwin-3D was further applied to the single-arm BrightStar trial to simulate a counterfactual brigatinib-only control arm and evaluate the added benefit of local consolidation therapy (LCT).

Results: Early tumor response patterns and long-term outcomes differed by TKI generation, with second-generation TKIs showing greater overall and organ-level responses and longer median PFS (29 vs 10 months; HR = 0.45; $p < 0.001$) than first-generation TKI. For our digital twin framework, OncoTwin-2D achieved robust risk stratification (HR = 1.8, $p = 0.034$ in MDACC cohort; HR = 2.1, $p < 0.001$ for external ALTA-1L cohort). Furthermore, model predicted survival outcomes aligned consistently with observed outcomes in ALTA-1L for first- and second-generation TKI. The advanced OncoTwin-3D further improved prognostic accuracy with significant risk stratification in MDACC cohort (HR = 3.9, $p < 0.0001$) and separately for individual TKI subgroups ($p = 0.006$ and $p < 0.001$ for first- and second-generation TKI). In the prospective BrightStar phase II trial, OncoTwin-3D was applied to simulate a counterfactual brigatinib-only control arm, which revealed a significant benefit from adding LCT (median PFS 66 vs. 22 months; HR = 2.8, $p = 0.002$).

Conclusion: We introduced OncoTwin, an AI-driven multimodal digital twin for individualized response prediction and novel escalation evaluation. This scalable framework extends beyond thoracic disease, offering a generalizable paradigm that bridges real-world data and clinical trials to accelerate precision oncology.

#6725 AI-derived H&E biomarkers predict differential survival under immunotherapy vs chemotherapy in phase-3 metastatic NSCLC study NEPTUNE.

C. Parmar[1], V. Roudko[1], V. Muckerson[1], J. Blando[2], J. Daniel[2], J. Diez[3], S. Gunda[4], A. Mendoza Alcala[3], A. Franco[5], I. Stambolic[6], C. Benchea[3], R. Stewart[5], Z. Lai[1], J. S. Reis-Filho[7], M. Scaltriti[8], D. Palmer[9];

[1]AstraZeneca, Waltham, MA, [2]AstraZeneca, Gaithersburg, MD, [3]AstraZeneca, Barcelona, Spain, [4]Astrazeneca, Chennai, India, [5]AstraZeneca, Cambridge, United Kingdom, [6]AstraZeneca, Munich, Germany, [7]AstraZeneca US, Gaithersburg, MD, [8]AstraZeneca - MedImmune, LLC, Gaitherburg, MD, [9]AstraZeneca Oncology, Gaithersburg, MD

Background: Immunotherapy outcomes in metastatic NSCLC are variable, and existing biomarkers (PD-L1, TMB) incompletely predict benefit. Routine H&E slides are widely available and capture spatial tumor microenvironment (TME) context. We applied AI-Pathology to convert H&Es into quantitative, interpretable TME features and assessed whether they predict survival benefit with immunotherapy (IO) versus chemotherapy.

Methods: We conducted a retrospective analysis of H&E slides from NEPTUNE (a phase 3, study in metastatic NSCLC comparing durvalumab+tremelimumab (D+T) vs chemotherapy (CTX)). Slides from 426 patients (D+T n=154; CTX n=272) were processed using models trained independently on external, non-NEPTUNE datasets (>6,000 pathologist-annotated H&Es). Fifteen features (immune, cancer, fibroblast densities/ratios) were extracted in cancer-associated stroma and cancer regions. Overall survival (OS) was analyzed by fitting univariate Coxph regression models with Benjamini-Hochberg FDR control. Treatment × marker interaction terms evaluated predictiveness. Routinely used markers followed cutoffs (PD-L1 ≤25%; bTMB ≤20 mut/Mb) as described in the NEPTUNE study (de Castro Jr G et al., J Thorac Oncol, 2023;18:106-119).

Results: Higher stromal fibroblast density was associated with inferior OS in both arms (D+T HR=1.60 [1.14-2.25]; CTX HR=1.36 [1.05-1.76]) with no treatment interaction (nominal p_interaction=0.82), indicating a prognostic effect. Higher stromal immune density was associated with improved benefit for D+T (HR=0.64 [0.45-0.90]; median OS difference +5.8 months; FDR p=0.04) but not CTX (HR=0.84 [0.65-1.08], FDR p=0.38), with a significant treatment interaction (nominal p_interaction=0.03), supporting a predictive effect. Overall, AI-H&E features showed comparable or stronger stratification of D+T outcomes than established routine markers in this dataset, including PD-L1 (HR=0.67 [0.46-0.96], FDR p=0.08), bTMB (HR=0.78 [0.48-1.26], FDR p=0.45), and ECOG (HR=0.74 [0.52-1.07], FDR p=0.19).

Conclusions: NEPTUNE did not meet its primary endpoint. The observed prognostic fibroblast signal and predictive immune signal from AI-derived H&E features suggest the potential for enriched selection or stratification to improve detection of checkpoint blockade benefit. These assay-free, interpretable biomarkers warrant prospective validation for clinical application.

#6726 A translational deep learning platform predicts metabolic pathway activity from routine H&E slides to enable patient stratification.

Salim Arslan[1], Julian Schmidt[1], Cher Bass[1], Foivos Ntelemis[1], Oscar Maiques[2], Vishali Sharma[1], Jakob Nikolas Kather[3], **Pahini Pandya**[1]

[1]Panakeia Technologies, Cambridge, United Kingdom,[2]Queen Mary University of London, Barts Cancer Institute, London, United Kingdom,[3]Technische Universitat Dresden, Dresden, Germany

Background: Metabolic reprogramming is a hallmark of cancer and a potential therapeutic target, yet clinical assessment remains challenging. We hypothesized that functional metabolic states could be inferred from routinely collected H&E-stained whole-slide images (WSIs), offering a scalable approach to biomarker discovery and patient stratification. We developed a multi-omics platform integrating histomorphology with transcriptomic and metabolic modelling data, applying it across 21 cancer types to identify digital biomarkers predictive of pathway-specific metabolic activity.
Methods: We derived binary biomarkers for 32 pathways using personalized genome-scale metabolic models and transcriptomic data from The Cancer Genome Atlas (TCGA). Pathway activity was inferred by comparing sample-specific gene expression profiles to a generalized metabolic network, with statistical significance determined by t-tests and Benjamini-Hochberg correction (FDR < 0.05). Deep learning models were trained to learn the morphological features predictive of these metabolic states, with cohort sizes ranging from 41 to 887 WSIs per biomarker. Model performance was validated using three-fold cross-validation and evaluated by the area under the curve (AUC), with ± showing standard deviation across folds.
Results: The approach identified robust morphological patterns predictive of key metabolic pathways across diverse tumor types. High predictability was achieved for nucleotide metabolism in testicular germ cell tumors (AUC = 0.85 ±0.13) and pancreatic adenocarcinoma (AUC = 0.79 ±0.08). Strong morphological signals of nuclear transport were observed in colon adenocarcinoma (AUC = 0.79 ±0.05), skin cutaneous melanoma (AUC = 0.75 ±0.06), and lung squamous cell carcinoma (AUC = 0.71 ±0.07). Pathways related to fatty acid beta-oxidation showed consistent predictability (AUC > 0.65) across thyroid carcinoma (AUC = 0.73 ±0.07), liver hepatocellular carcinoma (AUC = 0.70 ±0.05), pancreatic adenocarcinoma (AUC = 0.69 ±0.02), stomach adenocarcinoma (AUC = 0.68 ±0.04), and ovarian serous cystadenocarcinoma (AUC = 0.67 ±0.05).
Conclusions: This study demonstrates the potential of a multi-omics platform for decoding functional metabolic states from routine pathology slides. The platform can identify patient populations with specific metabolic dependencies (e.g., nucleotide metabolism) or pathway dysregulations (e.g., nuclear transport), thereby enabling targeted patient stratification for clinical trials. By translating complex histomorphology from standard H&E slides into actionable molecular insights, this technology offers a scalable and cost-effective solution to accelerate biomarker-driven drug discovery in precision oncology.

#6727 Enhancing lung cancer risk prediction with longitudinal fusion of LDCT data.

H. Ajami[1], A. W. Waqas[1], J. Templeton[2], M. B. Schabath[1], G. Rasool[1];
[1]Moffitt Cancer Center, Tampa, FL, [2]University of South Florida, Tampa, FL

Background: Lung cancer is the leading cause of cancer death, and better early detection is critical to lowering its burden. Sybil, a deep learning model, predicts 6-year lung cancer risk from a single low-dose CT (LDCT). Yet screening patients typically receive annual LDCTs that capture temporal changes in nodules and disease. We hypothesized that fusing longitudinal imaging features across scans would improve long-term risk prediction and generalizability over single-timepoint models.
Methods: We re-implemented Sybil's backbone and feature embedding layers to enable the extraction of intermediate feature representations while preserving the original inference behavior by loading the publicly released pretrained checkpoints unchanged. We developed six longitudinal deep learning architectures trained on the National Lung Screening Trial (NLST; n = 3,977participants, n = 991 cancers over 6 years): (1) Bi-Fusion (MLP and Transformer), integrating baseline + year-1 LDCTs; (2) Tri-Fusion (MLP and Transformer), integrating baseline, year-1, and year-2 LDCTs; (3) Hybrid (Temporal Hybrid and Masked Hybrid), combining CNN backbone, vision transformer, and temporal transformer modules and supporting up to three timepoints with missing scan handling. All models estimated time-to-lung-cancer using a hazard layer and were evaluated using time-dependent AUCs at yearly prediction horizons and Harrell's C-index. External evaluation used Moffitt Lung Screening data (n = 1876 participants, n = 469 cancers). For Hybrid models, only the hazard head was fine-tuned on a Moffitt adaptation subset, followed by evaluation on a held-out external test set.
Results: Hybrid longitudinal models demonstrated the highest performance and stability across follow-up horizons. During internal testing of the NLST, the Masked and Temporal Hybrid models achieved near-perfect discrimination at Year 1 (time-dependent AUC ≈ 0.99), gradually decreasing to 0.91 and 0.90 by Year 6, with a C-index of 0.75 (95% CI: 0.73-0.78). After external fine-tuning and evaluation, Hybrid models generalized robustly to Moffitt, with an AUC of 0.89 at Year 1, declining to 0.81 at Year 6, and a C-index of 0.81 (0.74-0.87). Tri-Fusion architectures peaked at an AUC of ~0.92 at Year 3 and declined to 0.86 by Year 6 in NLST, but demonstrated limited generalizability (0.63 to 0.57, C-index 0.60 [0.53-0.67]). Bi-Fusion performance was intermediate (AUC 0.83 to 0.77 in NLST; ~0.70-0.62 on Moffitt).
Conclusion: Longitudinal fusion of LDCT scans improves risk prediction vs single-timepoint models. Hybrid models using up to three scans show superior accuracy, robust external performance, and may enable more precise risk-based care while reducing unnecessary imaging and invasive procedures; clinical utility will be tested via decision-curve and implementation analyses.

#6728 Predicting gastric cancer response to anti-PD-1 first-line treatment based on multi-modal data: A multi-center study.

J. Wang[1], P. Kuang[2], Y. Lin[3], Y. Liu[1], K. Zheng[2], Y. Jiang[4], G. Yu[4], Y. Ding[1], Y. Hou[1], T. Liu[5];

[1]Zhongshan Hospital Fudan University, Shanghai, China, [2]The First Affiliated Hospital of Nanchang University, Nanchang, China, [3]Zhongshan Hospital (Xiamen), Fudan University, Shanghai, China, [4]Yangtze River Delta Guozhi (Shanghai) Intelligent Medical Technology Co., Ltd., Shanghai, China, [5]Zhongshan Hospital, Fudan University, Shanghai, China

Objectives: Excepted for PD-L1 expression, no predictive maker for immunotherapy has been identified in gastric cancer. Our study aimed to develop a multimodal deep learning model by integrating clinical features, CT-derived radiomics, and H&E-based pathomics to accurately predict the efficacy of first-line immunotherapy in gastric cancer.

Methods: This multicenter diagnostic study retrospectively enrolled 477 gastric cancer patients from 5 centers. Whole-slide images (WSIs) underwent a weakly supervised computational pathology pipeline: CLAM extracted patch-level representations, which were organized into spatially coherent structures for histological pattern aggregation; handcrafted pathomics features (morphological, textural, color) were also extracted to complement deep learning pathology embeddings. Contrast-enhanced CT images were segmented via a nnU-Net cascade. The nnU-Net encoder generated deep radiological embeddings, while handcrafted radiomics features (first-order statistics, texture matrices, shape descriptors) were computed from segmented regions to quantify tumor heterogeneity. A Transformer-based architecture integrated the above pathology/imaging features and patient metastatic information via cross-modal self-attention, enabling synergistic multimodal learning.

Results: The dataset was allocated into training (n = 322, Center 1) and validation cohort (n = 115, Center 2-5). The integrated clinical-radio-pathomic (CRP) model demonstrated strong performance (Validation AUC = 0.857, Test set AUC=0.917, C-index = 0.746 for PFS prediction and C-index = 0.864 for OS prediction) and emerged as an independent prognostic biomarker for PFS (hazard ratio [HR] = 4.29, 95% confidence interval [CI],1.20-15.35, p = 0.025) and OS (HR = 8.39, 95% CI, 1.47-47.75, p = 0.017) controlling for other clinical variables (i.e., age, sex and PD-L1 CPS). Importantly, the CRP model outperformed unimodal models derived from radiology (Test AUC = 0.7583,Validation AUC = 0.759) or pathology (Test AUC = 0.83;Validation AUC = 0.796) alone, as well as PD-L1 CPS.

Conclusion: Our findings highlight the promise of multimodal deep learning in precisely identifying patients who are most likely to benefit from first-line immunotherapy.

#6802 Metabolite signaling drives oncogenic neuron-glioma crosstalk.

K. G. Abdullah[1], K. Miki[1], C. Edgar[2], S. Wu[2], Y. Xiao[2], M. R. Savani[2], M. T. Ghoche[1], J. I. Traylor[3], H. Yuan-Tai[4], D. D. Shi[5], M. Tang[2], S. Oken[1], N. Manoj[1], V. T. Puliyappadamba[2], P. Kaphle[2], T. Shipman[2], R. E. West III[6], S. Ma[2], T. Nolin[6], P. O. Zinn[1], L. G. Zacharias[2], T. P. Mathews[2], J. Gibson[4], K. Huber[4], S. Chamberland[7], R. J. DeBerardinis[2], S. K. McBrayer[2];
[1]Department of Neurosurgery, University of Pittsburgh School of Medicine, Pittsburgh, PA, [2]UT Southwestern Children's Medical Center Research Institute, Dallas, TX, [3]Department of Neurological Surgery, University of Texas Southwestern Medical Center, Dallas, TX, [4]Department of Neuroscience, University of Texas Southwestern Medical Center, Dallas, TX, [5]Department of Radiation Oncology, Dana-Farber/Brigham and Women's Cancer Center, Harvard Medical School, Boston, MA, [6]Department of Pharmacy and Therapeutics, University of Pittsburgh, Pittsburgh, PA, [7]Department of Neuroscience, University of Pittsburgh, Pittsburgh, PA

Our knowledge of the metabolic alterations that modulate glioma-neuron interactions is limited. Therefore, we performed unbiased metabolite profiling on 91 high grade gliomas, lower grade gliomas, brain metastases, and non-malignant brain tissues. Accumulation of guanidinoacetate (GAA), an intermediate in the creatine synthesis pathway, was a hallmark of high grade gliomas, displaying a nearly 100-fold increase in these tumors versus non-malignant brain tissues. However, creatine and related metabolites were not enriched, suggesting that GAA may play a non-canonical role. We found that glioma stem-like cell (GSC) lines robustly synthesize GAA but secrete this metabolite rather than using it to produce creatine.
This finding has a correlate in GAMT deficiency, an inborn error of metabolism in which GAA accumulates and causes neuronal hyperexcitability, neurological deficits, and seizures. These effects are also observed in glioma patients, but the mechanisms underlying neuronal hyperactivity in this context are not fully understood. We hypothesized that high grade gliomas reprogram the creatine synthesis pathway to generate and release GAA, which signals to surrounding neurons, drives local electrochemical activity and promotes glioma aggressiveness.
We found that GAA accumulation excites local, but not distal, neurons in xenografted brain slices. In patch-clamp recording studies, GAA decreased neuronal input resistance by acting as a $GABA_A$ receptor agonist. Although GABA signaling is inhibitory in the adult brain, we found that chloride dysregulation in the glioma microenvironment triggers excitatory GABAergic neurotransmission in response to GAA stimulation. Treating glioma-infiltrated brain tissue with a KCC2 chloride transporter agonist abolished GAA-induced hyperexcitability. Although genetic ablation of GAA synthesis had no effect on GSCs grown in vitro or in subcutaneous xenografts, inhibiting GAA production in orthotopic xenografts reduced local neuronal activity and extended survival of tumor-bearing mice. Collectively, our work nominates GAA as a targetable signaling metabolite that drives oncogenic crosstalk between glioma cells and neurons.

#6803 Targeting mitochondrial complex I overcomes adaptive response to chemotherapy in advanced pancreatic cancer.

S. Attanasio[1], F. Citron[1], R. Shah[1], F. Saj[1], Z. Liu[1], I.-L. Ho[1], E.-Y. Yen[1], C. Dyke[1], H. Kwon[1], L. Cecchetto[1], Z. Chen[1], E. Granato[1], S. S. Sainani[1], S. Loponte[1], Y. [1]UT MD Anderson Cancer Center, Houston, TX, [2]University of Michigan, Ann Arbor, MI, [3]Perlmutter Cancer Center, New York, NY

Chemotherapy remains the mainstay for treatment in patients with advanced pancreatic ductal adenocarcinoma (PDAC), but acquired therapeutic resistance remains a major challenge to sustaining responses. Here, we leveraged a high complexity barcoding technology to identify and isolate clonal lineages showing different sensitivity to chemotherapy *in vivo* in PDAC. Using transcriptomic profiling of chemotherapy sensitive and non-sensitive clonal lineages, we developed a prognostic gene signature named as chemo-type that enables the stratification of patients survival and predicts their response to chemotherapy in two independent datasets including n=301 human PDAC patients. We applied the chemo-type signature to stratify n=36 patient-derived xenograft models of PDAC based on their sensitivity to chemotherapy and to investigate vulnerabilities. We found that Oxidative Phosphorylation (OxPhos) is an adaptive stress response to chemotherapy in a subset of PDAC xenograft models which can potentially benefit from OxPhos inhibition and can be predicted by the chemo-type signature. We demonstrated that a combinatorial approach targeting OxPhos in addition with chemotherapy in PDAC xenograft models eradicates chemotherapy-resistant clones, thereby suppressing tumor relapse and prolonging survival, using a new inhibitor of the mitochondrial complex I named as IM156, which is currently under evaluation in a phase Ib clinical trial for patients with advanced pancreatic cancer.

#6804 Estrogen therapy alleviates cancer-associated cachexia in mouse models of both sexes.

V. T. Pham, V. Sanchez, S. Fu, Y. Nie, K. Liu, Y. Luan, L. Jin, G. Huang;
UT Health San Antonio, San Antonio, TX

Cancer-associated cachexia (CAC) is a multifactorial wasting syndrome marked by progressive loss of skeletal muscle and adipose tissue, affecting up to 80% of patients with advanced cancers and directly contributing to 20-30% of cancer-related deaths. It not only reduces quality of life but also impairs tolerance to therapy and worsens prognosis. Despite its prevalence and impact, CAC remains under-investigated, and although several agents are under clinical evaluation, no FDA-approved treatments exist. The lack of effective therapies represents a critical unmet medical need, as current supportive measures offer little benefit once tissue wasting begins. Clinically, male patients experience more severe and frequent CAC than female patients, suggesting a protective role for female-specific factor(s). To explore this, C57BL/6 mice were inoculated subcutaneously with B16F10 melanoma or KPL ($Kras^{G12D/+}$; $p53^{-/-}$; $Lkb1^{-/-}$) lung cancer cells, our two established models that recapitulate CAC features including severe anemia, muscle wasting, and adipose atrophy. Consistent with patients' data, male mice inoculated with cancer cells also developed significantly more severe CAC features than female mice. To determine whether gonadal hormones influenced this difference, mice of both sexes underwent gonadectomy before tumor implantation. Interestingly, ovariectomy in females markedly worsened CAC symptoms and abrogated female protection, while castration in males produced no effect on severity of CAC, indicating that ovarian factors likely help protect against tissue wasting. Among these factors, 17β-estradiol (E2) was identified as a key candidate due to its known metabolic and tissue-preserving effects. Importantly, when male and ovariectomized female mice were treated with controlled-release E2 pellets before tumor challenge, E2 supplementation preserved skeletal muscle and subcutaneous white adipose tissue, though it had minimal impact on visceral fat and failed to reverse CAC-associated anemia. Thus, these new findings suggest that E2 signaling plays a protective role in CAC progression and could represent a novel therapeutic target. Given the availability of FDA-approved agents that modulate E2 pathways, further studies combining E2 with treatments such as erythropoietin (EPO) may offer new opportunities to address the urgent need for effective CAC therapies and improve outcomes for patients suffering from this devastating condition.

#6805 A ketogenic diet sensitizes pancreatic cancer to metabolic therapies.

O. Hajihassani[1], A. Roichman[2], J. A. Boyer[1], M. MacArthur[2], R. Cordova[2], P. Sunita[1], G. Dey[1], P. Rezvani[1], A. Loftus[3], C. Boutros[1], J. Hue[1], P. Naji[1], N. Manzoor[1], A. Buch[1], H. J Graor[1], J. D. Rabinowitz[2], J. M. Winter[3];

[1]Case Comprehensive Cancer Center, Case Western Reserve University, Cleveland, OH, [2]Ludwig Institute for Cancer Research, Princeton University, Princeton, NJ, [3]UH Cleveland Medical Center, University Heights, OH

Background: Pancreatic cancer is the third leading cause of cancer-related death in the United States, and current chemotherapy options provide limited benefit. Recent studies have shown that a ketogenic diet (KD) can exert anti-tumor effects by reprogramming tumor metabolism and exposing new therapeutic vulnerabilities[1]. Efforts to target glutamine metabolism—an essential pathway in many cancers—have shown promise in preclinical models but have not translated into significant clinical success.

Methods: A ketogenic diet was administered to mice, along with a normal diet in control mice. Pancreatic cancer xenografts were monitored for growth and harvested for biochemical analyses. Tumors were analyzed for metabolites and histone modification by LC/GC-MS and for oxidative stress by measuring the levels.

Result: Here, we show that a KD increases tricarboxylic acid (TCA) cycle activity and elevates reliance on glutamine-related metabolites in murine pancreatic cancer models and in vitro under KD-mimicking conditions. This metabolic adaptation is in response to increased tumor dependence on glutamine-mediated anaplerosis to compensate for reduced glucose availability. Additionally, we examined the impact of a ketogenic diet on redox homeostasis and found that tumors from ketogenic-diet-fed mice exhibited a marked increase in ROS levels. This redox imbalance provides further rationale for combining TCA-cycle inhibition with ROS-inducing agents to amplify metabolic and oxidative stress in PDAC tumors. We demonstrate that combining glutamine metabolism inhibitors, such as CB839 or 6-diazo-5-oxo-L-norleucine (DON), with a KD leads to robust anti-tumor effects in preclinical models of pancreatic cancer. Moreover, the combination of ivosidenib and a ketogenic diet caused a synergistic rise in intratumoral ROS and yielded a 50% survival benefit in treated mice.

Conclusion: Together, these findings demonstrate that a ketogenic diet exposes a metabolic and redox vulnerability in PDAC by increasing reliance on glutamine-driven anaplerosis and elevating intratumoral ROS. Exploiting this state with targeted metabolic inhibitors—alone or in combination with ROS-inducing agents—produces potent anti-tumor responses and highlights a promising therapeutic strategy for pancreatic cancer.

#6806 Metabolic changes associated with senescence in CAFs regulate fibrosis in pancreatic cancer.

D. Sen[1], J. I. Belle[1], B. L. Knolhoff[1], G. Qian[2], P. P. Provenzano[2], D. G. DeNardo[1];
[1]Washington University School of Medicine in St. Louis, Saint Louis, MO, [2]University of Minnesota, Minneapolis, MN

Pancreatic Ductal Adenocarcinoma (PDAC) remains one of the deadliest solid malignancies, with only 13% of patients surviving beyond five years. This dismal prognosis is largely attributed to the metastatic nature of the disease and its resistance to both cytotoxic and immune-based therapies. The treatment-refractory nature of PDAC has been linked to its tumor microenvironment, characterized by a dense fibrotic stroma and impaired immune surveillance. Cancer-associated fibroblasts (CAFs) and the extracellular matrix (ECM) are prominent components of the PDAC stroma. However, CAFs are functionally and phenotypically heterogeneous and thus can harbor both pro- and anti-tumorigenic effects. PDAC contains several subpopulations of CAFs, including *1)* antigen-presenting fibroblasts (apCAFs), *2)*inflammatory fibroblasts (iCAFs), and *3)* myofibroblasts (myCAFs). Although heterogeneity in CAF phenotypes has been investigated, it remains unclear whether CAF subtypes differ in their metabolic profiles and how this metabolic diversity impacts the fibroinflammatory microenvironment of PDAC. Recently, we identified a subset of myofibroblasts in PDAC that have undergone senescence, which we termed “senescent CAFs” (senCAFs). Using a genetic mouse model of spontaneous PDAC with inducible senescent cell depletion {*LSL-KRAS^{G12D}; p53^{flox}; p48-CRE; INK-ATTAC* (KPPC-IA)}, we demonstrated that senCAFs support tumor growth by inducing fibrosis and compromising anti-tumor immunity. In this study, we aimed to determine whether senescence in CAFs is accompanied by metabolic reprogramming and if these metabolic changes are required for the profibrotic property of senCAFs. To address this, we first assessed the architecture of the ECM deposited by senescent fibroblasts using immunofluorescence imaging and found that the collagen fibers deposited by senescent fibroblasts are thicker compared to those from non-senescent fibroblasts. Moreover, transcriptomic and metabolomic analysis on senescent and non-senescent fibroblasts showed an increase in glycolysis and impaired tricarboxylic acid (TCA) cycle flux and mitochondrial function in the senescent fibroblasts. Interestingly, these metabolic changes associated with senescence in fibroblasts led to the accumulation of cellular α-ketoglutarate, a key metabolite required for prolyl 4-hydroxylase and lysyl hydroxylase-dependent collagen hydroxylation and subsequent triple-helix formation. Transcriptomic analysis also revealed high gene expression of collagen prolyl 4-hydroxylase (*P4ha2*, *P4ha3* & *P4hb*) and lysyl hydroxylase (*Plod1*) in senCAFs compared to myofibroblasts. Together, our current data demonstrate differences in the metabolism and architecture of the ECM deposited by senescent CAFs and myofibroblasts. Future experiments will test whether these metabolic alterations in senCAFs impact fibrosis and the progression of PDAC.

#6807 Mitochondrial genome alterations as early drivers of lung adenocarcinoma evolution.

Alvaro Gutierrez[1], Ido Sloma[2], Adrian Daniel Schubert[3], Karthik Suresh[4], Mohammad Obaidul Hoque[3], Carmen Gloria Ili[1], Evgeny Izumchenko[5], Santanu Dasgupta[6], David Sidransky[7]

[1]Center of Excellence in Translational Medicine (CEMT- BIOREN), Universidad de la Frontera, Temuco, Chile,[2]Champions Oncology, Rockville, MD,[3]The Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins University School of Medicine, Baltimore, MD,[4]Division of Pulmonary Critical Care Medicine, Johns Hopkins University, Baltimore, MD,[5]Department of Medicine, Hematology & Oncology, University of Chicago, Chicago, IL,[6]Department of Pathology, University of South Alabama, Mobile, AL,[7]Department of Otolaryngology-Head and Neck Surgery, Johns Hopkins University School of Medicine, Baltimore, MD

Lung adenocarcinoma (LUAD) is thought to arise gradually, beginning as atypical adenomatous hyperplasia (AAH) and advancing through adenocarcinoma in situ (AIS) toward minimally invasive adenocarcinoma (MIA). Although this progression is well-described, the biological events that trigger and sustain these early transitions remain unclear Mitochondrial DNA (mtDNA) is present in many copies, lacks histone protection, and is continually exposed to oxidative stress, making it more prone to mutation than nuclear DNA. Consequently, alterations in the mitochondrial genome may provide an opportunity to identify and classify potentially aggressive preneoplastic lesions long before they reach an invasive stage. We analyzed 109 lesions from 37 non-small-cell lung cancer (NSCLC) patients, encompassing the continuum of AAH, AIS, MIA, and ACA. Whole mitochondrial genome (16.5kb) was sequenced from formalin fixed paraffin embedded (FFPE) tumor and matched normal samples using an amplicon-based Illumina NextSeq approach. Variant detection was performed with a custom pipeline (BWA, SAMtools, GATK Mutect2). We observed that somatic mtDNA alterations arise very early in the neoplastic sequence, with AAH lesions carrying numerous changes across the non-coding tRNA, rRNA, and D-loop regions, as well as repeated nonsynonymous variants in OXPHOS coding genes such as MT-ND5, MT-ATP8, and MT-CYB. Several of these mutations appeared in lesions located in different areas of the same lung, pointing to an early clonal expansion rather than isolated, random events. As lesions advanced into AIS and then MIA, the number of mitochondrial alterations increased steadily. MIA, in particular, showed the greatest accumulation of non-coding changes, and coding variants such as A8860G (ATP6) were frequent across most cases, suggesting that these alterations are not simply incidental. The expression data followed a similar trend. Specifically, in AAH and AIS, numerous mtDNA encoded OXPHOS genes showed higher expression, reflecting an early compensatory response to emerging dysfunction. By the time lesions reached the MIA stage, this pattern became less consistent, with greater variability among patient samples. Once the disease progressed to fully invasive adenocarcinoma, mitochondrial transcripts dropped broadly, fitting with at least partial metabolic shift toward glycolysis known to accompany invasion. Taken together, these patterns point toward early mtDNA instability and evolving mitochondrial transcription as features that accompany and possibly shape the stepwise development of LUAD. Acknowledgements: We extend our special thanks to patients and clinical teams at Johns Hopkins, supported by NCI EDRN grant U01CA271896 . We also acknowledge ANID for providing scholarship funding (21222011, 242230375, 752230204) and Swiss Cancer League grant (BIL KLS-3649-02-2015).

#6808 Targeting metabolism in BRCA-deficient tumors.

M. Di Tano[1], M. Ahmed[2], L. Shiri[2], M. Lyashenko[2], N. Ruthen[3], E. Tse[3], D. Pradella[3], C. Echeverria-Andrade[1], I. Nathoo[1], J. Sanford[1], E. Dantas[1], J. Kim[1], A. Saleh[2], R. Kyu[2], E. Reznik[3], L. C. Cantley[4], M. D. Goncalves[1];

[1]NYU Langone Health, New York, NY, [2]Weill Cornell Medical Center, New York, NY, [3]Memorial Sloan Kettering Cancer Center, New York, NY, [4]Dana-Farber Cancer Institute, Boston, MA

Up to 10% of all cancers are attributed to genetic predisposition, with inherited mutations in *BRCA1* and *BRCA2* being the most significant risk factors for developing breast and ovarian cancers. These mutations also increase susceptibility to other malignancies, including prostate, pancreatic, and colorectal cancers. The BRCA1 and BRCA2 proteins play essential roles in homologous recombination (HR), an error-free DNA repair process. When cells lack functional BRCA1 or BRCA2, they become reliant on alternative, error-prone DNA repair mechanisms, which drive genomic instability and tumorigenesis. Although Poly (ADP-ribose) polymerase (PARP) inhibitors have revolutionized targeted therapy for tumors with *BRCA1/2* mutations, the emergence of resistance limits their long-term efficacy, highlighting the urgent need for novel therapeutic strategies. Cancer metabolism of BRCA1/2-deficient tumors remains largely uncharacterized and poorly understood.To address this gap, we analyzed 10,619 tumors representing 33 cancer types using data from The Cancer Genome Atlas (TCGA). Our findings revealed that tumors with HR deficiency signatures exhibit distinct metabolic profiles compared to HR-proficient tumors. Further validation in BRCA2-/- cancer cell models confirmed that BRCA2-deficient tumor cells rely heavily on the activity of pyruvate kinase (PK), an enzyme that catalyzes the final step of glycolysis. Pyruvate kinase exists as two splice isoforms: PKM1, which is constitutively active, and PKM2, which is allosterically regulated. Most cancer cells predominantly express PKM2, as its low activity state enables metabolic flexibility by redirecting glucose-derived carbons from energy production to biosynthesis for growth and survival. Remarkably, we showed for the first time that BRCA1/2-deficient tumor cells and mouse-derived tumors, not only express PKM2, but also the constitutively active PKM1. Therefore, we targeted PKM, and we found that PKM activators selectively kill BRCA2-deficient cancer cells, but not BRCA2-proficient ones, by inducing DNA damage, reducing lactate production, and decreasing glucose oxidation. Notably, PKM1 overexpression in BRCA2-proficient cells phenocopies the sensitivity of BRCA2-deficient cells to PKM activators, suggesting that PKM1 mediates, at least in part, this effect. Our results also reveal that the toxic impact of PKM activators in BRCA2-deficient cancer cells involves impaired mitophagy and mitochondrial dysfunction.
Together, these findings provide a strong rationale for targeting pyruvate kinase in BRCA1/2 deficient and potentially other HR-deficient tumor subtypes.

#6811 Plasma proteomic signature for persistent smoking effects and its association with risk of smoking-related cancers among former smokers.
D. Le, Q. Cai, J. Long, S. M. Nguyen, W. Zheng, X.-O. Shu;
Vanderbilt University School of Medicine, Nashville, TN

Background: Previous studies have identified circulating protein signatures associated with smoking, which were associated with cancer risk and reduced with years of smoking cessation. A protein signature for persistent smoking effects after quitting smoking is not available. Our study aims to fill this research gap.
Methods: Included in the study are 47,166 UK Biobank participants, aged from 39 to 70 years at baseline without any cancer history, with proteomics and complete smoking history. A total of 2,911 plasma proteins with less than 20% missing values were analyzed. Linear regression analyses were conducted to identify smoking-related proteins among current (N=4,036) and never smokers (N=32,664), adjusting for age, sex, race, alcohol consumption, body mass index, and Townsend deprivation index. To identify protein biomarkers capturing persistent smoking effects, we analyzed smoking-related proteins among former (N=10,466) and never smokers (N=32,664) using similar linear regression analyses. Proteins with significant associations with former smoking status at FDR-corrected p-value < 0.05 were retained for further analysis. We then applied elastic net regression to the regression residuals of proteins to develop a protein signature for persistent smoking effect (PSPSE), using a 70% training and 30% testing sets, which were randomly split between former and never smokers. The PSPSE was derived by a weighted sum of the selected proteins using their coefficients from the elastic net analysis. We used Cox proportional hazard regressions to examine associations between the PSPSE and risk of 12 smoking-related cancers (SRC), including lung cancer (LC) and upper aerodigestive tract cancer (UATC).
Results: Of 2,911 proteins tested, 2081 proteins were associated with current smoking status at FDR p<0.05. Among them, 1,039 proteins were associated with former smoking status at FDR p<0.05. Of them, 242 proteins were selected to develop the PSPSE among 10,466 former smokers. The PSPSE achieved an area under the curve (AUC) of 0.73 in the training set and 0.70 in the testing set. The PSPSE was significantly associated with the elevated risk of SRC (Hazard ratio (HR)=1.33, 95%CI: 1.17-1.51), LC (HR=1.94, 95%CI: 1.52-2.48), and UATC (HR=1.48, 95%CI: 1.06-2.07) independently of smoking pack-year and quitting duration among former smokers. The PSPSE was not related to an increased risk of non-smoking-related cancers.
Conclusions: We developed a proteomics signature capturing the persistent smoking effect among former smokers, which was associated with elevated risks of SRC, particularly LC. If validated, the PSPSE can be used to identify former smokers at high risk of developing cancer for close surveillance and primary prevention. Updated results will be presented at the meeting.

#6812 Adult height and prostate cancer in the Health Professionals Follow-Up Study: Integrating epidemiologic, genetic, and transcriptomic evidence.

A. Wang[1], M. J. Ro[2], M. R. Shanahan[3], D. Fu[3], H. E. Guard[3], J. B. Vaselkiv[3], S. A. Smith-Warner[3], K. H. Stopsack[4], D. Baynes[5], M. Loda[6], A. Pettersson[7], E. L. Giovannucci[3], S. Sutcliffe[8], S. Tyekucheva[9], B. F. Darst[10], L. A. Mucci[3];

[1]University of Southern California, Los Angeles, CA, [2]Harvard College, Boston, MA, [3]Harvard T.H. Chan School of Public Health, Boston, MA, [4]Leibniz Institute for Prevention Research and Epidemiology, Bremen, Germany, [5]Massachusetts Institute of Technology, Boston, MA, [6]Weill Cornell Medicine, New York, NY, [7]Karolinska Institute, Stockholme, Sweden, [8]Washington University in St. Louis, St. Louis, MO, [9]Dana-Farber Cancer Institute, Boston, MA, [10]Fred Hutchinson Cancer Center, Seattle, WA

Taller height has been associated with increased risk of incident and fatal prostate cancer, potentially through hormonal and growth factor activity during early life. We investigated this association by integrating early-life diet, germline genetics, and tumor biology. We included 49,370 men in the Health Professionals Follow-up Study who were cancer-free at study enrollment in 1986 and were followed through 2020. Cox models with age as the time scale estimated hazard ratios (HRs) and 95% confidence intervals (CIs) for height and total and fatal prostate cancer, adjusting for demographics, BMI, smoking, and PSA screening. To decompose height into its determinants, we derived two residual height measures: genetic residual height from regressing observed height on the height polygenic risk score, and dietary residual height from regressing height on teenage dairy intake to isolate early-life dietary influences. To assess prostate tissue-specific effects of height, transcriptomic profiling was performed on prostate tumor (n = 418) and adjacent normal tissue (n = 209) using Affymetrix GeneChip arrays, and on stromal tissue (n = 272 tumor-adjacent, n = 120 tumor-distant) using RNA sequencing. Differential gene expression was analyzed with *limma*, and pathway enrichment with *CAMERA* using Gene Ontology Biological Process annotations. At enrollment, median age was 54 years (IQR 46-62) and median height was 70 inches (IQR 68-72). Over a median of 28 years of follow-up, 8326 prostate cancer cases were diagnosed, including 1189 fatal cases. Taller height was associated with increased risk of fatal (HR per 5 cm: 1.06, 95% CI 1.01-1.11) but not total prostate cancer (HR 1.00, 95% CI 0.98-1.01). The association for genetic residual height with fatal disease was null (HR ≈ 1), suggesting germline genetics largely explains the observed association. Associations using dietary residual height were similar to those for observed height, indicating minimal contribution from early-life diet. Transcriptomic analysis identified 82 height-associated pathways in tumor and 77 in adjacent normal tissue (FDR < 0.05), with top pathways enriched for mRNA splicing regulation and fatty acid metabolism. In stromal tissue, 63 and 15 pathways were identified in tumor-adjacent and tumor-distant stroma, enriched for cytoplasmic translation and sensory perception/stimuli detection. Taller height was associated with increased risk of fatal prostate cancer during up to 34 years of follow-up. The attenuated association after accounting for genetic determinants of height suggests shared genetics between height and prostate cancer, while early-life dairy intake showed minimal impact. Transcriptomic evidence revealed differentially enriched pathways in the tumor and stroma, suggesting potential height-associated downstream biological processes in prostate cancer development.

#6813 Characterization of high-grade serous ovarian cancer copy number alterations in Black and White Women.

I. M. Vlasac[1], B. M. Reid[2], C. Johnson[3], A. R. Richards[2], C. M. Colin Leitzinger[2], S. J. Yoder[2], D. Roeber[4], T. Mesa[2], A. Berchuck[5], B. Fridley[6], J.-Y. Chern[4], J. A. Doherty[7], K. Haller[3], S. Tworoger[8], J. R. Marks[9], J. M. Schildkrau[3], B. C. Christensen[1], L. C. Peres[2], L. A. Salas Diaz[1], on behalf of the African American Cancer Epidemiology Study;
[1]Dartmouth Geisel School of Medicine, Hanover, NH, [2]Moffitt Cancer Center, Tampa, FL, [3]Emory University, Atlanta, GA, [4]Moffit Cancer Center, Tampa, FL, [5]Duke University School of Medicine, Durham, NC, [6]Children's Mercy Hospital, Kansas City, MO, [7]The University of Utah, Salt Lake City, UT, [8]Oregon Health & Science University, Portland, OH, [9]Duke University, Durham, NC

Background: High-grade serous ovarian cancer (HGSC) is a deadly gynecologic cancer and is characterized by widespread copy number alterations (CNA). However, knowledge of racial differences in HGSC CNA is limited. Using methylation-inferred CNA, we defined and characterized CNA-based tumor clusters to assess patterns by self-reported race.
Methods: Tumor CNA were calculated using Illumina EPIC v1/v2 methylation data for 678 cohort participants (African American Cancer Epidemiology Study, North Carolina Ovarian Cancer Study, Nurses' Health Study) compared to 296 blood samples. Probes were binned (≥10; ≥100 kb), segmented using circular binary methods, autocorrected, and filtered (|mean log R ratio|≥0.3; >4 markers), to define cytoband-level copy number states (-1-loss /0-neutral /+1-gain). CNA were clustered with Ward's method. For each cluster, we computed length-weighted cytoband burden (% genome in gain, loss, or neutral states) and region-level ORs to identify CNA-enriched regions. Models clustered by race were then fit to assess differences.
Results: Combined analysis of HGSC samples from 403 White (59%) and 275 Black women (41%), identified three CNA clusters: C1 (27%), C2 (57%), and C3 (15%). Clusters showed distinct genomic burdens (Kruskal-Wallis $p<10^{-55}$). C1 showed widespread losses, notably in 4q (~75% vs 14% in C2/C3, q<10-45), which has been reported in HGSOC, and 17p (71% vs 13% in C2/C3, q<10-46), which includes TP53. C3 exhibited extensive chromosomal gains, including 20p/q (~82%/72%, q <10-38), 1q/1p (~64%/39%, q<10-32), and 2p/2q (~56%/42%, q <10-31). Gains on 2p/q have been linked to advanced stage and poor prognosis, potentially via overexpression of AURKA, GNAS, and TPD52L2. Amplified 1q may enhance DHX9 expression, a regulator of genomic stability, while BARD1 (2q) interacts with BRCA1 in DNA repair; aberrant BARD1 expression correlates with poor outcomes. Cluster membership was similar between Black and White women (C1: 30% vs 26%, C2: 53% vs 59%, C3: 17% vs 15%). However, arm-level copy number racial differences were observed. Overall, 21q loss was more frequent in tumors from Black women (28%) than White women (16%; OR=0.5, 95% CI=0.34-0.73, q=0.02). This difference was most pronounced in C2, where 21q loss occurred in 27% of Black women compared to 10% in White women (OR = 0.31, 95% CI=0.17-0.56, qcluster=0.002).
Conclusion: Broad arm-level CNAs define molecularly distinct HGSC subgroups with characteristic gain/loss patterns. Race-associated genomic alterations, including 21q loss among Black women, appear to be cluster-dependent genomic events suggesting underlying biological heterogeneity related to focal genomic instability or selective pressures rather than the result of wide-spread changes in overall copy number burden.

#6814 Tumor-stroma spatial context of T cell infiltration and exhaustion as determinants of ovarian cancer survival in Black women.

B. M. Reid[1], A. C. Soupir[1], A. J. Alberg[2], E. V. Bandera[3], M. L. Bondy[4], M. L. Cote[5], K. Haller[6], T. Hastert[7], C. Moran Segura[1], J. V. Nguyen[1], E. S. Peters[8], P. D. Terry[9], A. B. Lawson[10], J. R. Marks[11], B. L. Fridley[12], J. M. Schildkraut[6], L. C. Peres[13];

[1]Moffitt Cancer Center, Tampa, FL, [2]University of South Carolina, Columbia, SC, [3]Rutgers, New Brunswick, NJ, [4]Stanford Cancer Institute, Stanford, CA, [5]IUPUI Fairbanks School of Public Health, Indianapolis, IN, [6]Emory University, Atlanta, GA, [7]Wayne State University, Detroit, MI, [8]University of Nebraska Medical Center, Omaha, NE, [9]University of Tennessee, Memphis, TN, [10]The Medical University of South Carolina, Charleston, SC, [11]Duke University, Durham, NC, [12]Children's Mercy Kansas City, Kansas City, [13]H. Lee Moffitt Cancer Center, Tampa, FL

Background: Tumor-infiltrating lymphocytes are associated with improved ovarian cancer (OC) survival in White women but not Black women despite similar T cell abundance. We evaluated whether exhaustion or localization of T cell infiltration may attenuate the survival advantage among Black women using a spatially informed compartment-specific approach to account for heterogeneity of whole tissue sections (WTS).

Methods: Among 221 Black OC cases in the African American Cancer Epidemiology Study, multiplex immunofluorescence and HALO image analysis quantified total (CD3+) and cytotoxic (CD3+CD8+) T cells, along with exhausted (TIM3+) and terminally exhausted (TIM3+PD1+) subsets in FFPE WTS. PANCK-defined tumor and stroma were refined by excluding mixed interface regions detected using point-pattern intensities. Logit-transformed proportions were compared with paired t-tests. Cox proportional hazards estimated associations of compartment features with overall survival, adjusting for clinical factors.

Results: Black OC cases were primarily advanced stage (58%) and high-grade serous carcinoma (HGSC; 69%); mean follow-up was 6.4 years. In tumor, 60% were T cell infiltrated (≥2% of tumor cells), and the median proportion of cytotoxic cells was 30%. Stroma contained 50% more T cells ($p=9.1x10^{-12}$) but lower cytotoxic fractions (ΔT-S = -8%; $p=3.9x10^{-19}$). Immune-excluded tumors (<2% tumor T cells) displayed strong stromal enrichment of total and cytotoxic T cells. Exhausted T cells were rare (1%) with tumors showing higher exhaustion (ΔT-S=1%, $p=1.6x10^{-3}$) and terminal fractions (ΔT-S=15%, $p=8.8x10^{-18}$) than stroma. Neither tumor nor stroma T cell abundance was associated with survival in univariate models. However, in compartment-adjusted models, tumoral cytotoxic T cells were associated with improved survival (hazard ratio [HR]=0.72, 95% confidence interval [CI]=0.53, 0.97), whereas stromal cytotoxic T cells were associated with worse survival (HR=1.65, CI=1.14, 2.37). A larger tumor-stroma gradient in cytotoxic T cells (> tumor) was similarly protective (HR=0.65, CI=0.48, 0.89). In HGSC, that had higher infiltration and exhaustion, infiltrated tumors had improved survival with higher exhaustion (HR=0.83, CI=0.70, 0.98) and terminal exhaustion (HR=0.88, CI=0.79, 0.99), while immune-excluded tumors did not.

Conclusion: Distinct compartment-specific T cell and exhaustion patterns with divergent survival implications were observed in Black women with OC. Cytotoxic T cells confer a survival benefit only when tumor-dominant rather than stroma-dominant, highlighting the importance of characterizing an immune-exclusion phenotype. Improved survival with tumor T cell exhaustion likely indicates active antitumor immunity. WTS-based spatial profiling is essential for accurate interpretation of immune-survival relationships in Black women with OC.

#6815 Biologic processes enriched in the primary tumors of invasive breast cancer patients with disseminated tumor cells.

K. A. Lawson-Michod[1], T. Ahsan[1], K. Malone[1], B. Harmon[1], M. Stackouse[1], P. Seth[1], M. C. Haffner[1], M. Fitzgibbon[1], A. Zevin[1], A. P. Wiita[2], J. Debnath[3], K. E. Varley[4], A. L. Welm[4], S. Riddell[1], C. M. Ghajar[5], C. I. Li[1];

[1]Fred Hutchinson Cancer Center, Seattle, WA, [2]UCSF, San Francisco, CA, [3]UCSF - University of California San Francisco, San Francisco, CA, [4]University of Utah Huntsman Cancer Institute, Salt Lake City, UT, [5]Fred Hutchinson Cancer Research Center, Seattle, WA

Background: Disseminated tumor cells (DTCs) can persist despite systemic therapy and drive distant recurrence, a major cause of breast cancer-related mortality.
Objective: To identify biologic processes enriched in the primary tumors of invasive breast cancer patients with DTCs detected at the time of their breast cancer diagnosis.
Methods: We performed tumor-normal whole-genome sequencing and bulk RNA sequencing on matched tumor and blood specimens from 65 patients with newly diagnosed invasive breast cancer who underwent bone marrow biopsy at diagnosis to assess DTC status. Mutational signatures were identified using *SigProfilerExtractor*. Differential expression and gene set enrichment analyses were conducted with *DESeq2*. Pathways were defined using MSigDB hallmark gene sets. Genes with Bonferroni-adjusted $p < 0.05$ and $|\log_2 \text{fold change}| > 1$ were considered significantly differentially expressed. Analyses were adjusted for tumor purity, tissue source, stage, age, and neoadjuvant therapy.
Results: Among 41 DTC-positive and 24 DTC-negative patients, DTC-positive tumors were more likely to harbor intronic somatic mutations in *MARCHF1* (78.7% vs 56%, $p = 0.001$) and *MARCHF4* (31.9% vs 4%, $p = 0.007$). Mutations in genes within the WNT and RTK-RAS signaling pathways were more frequent in DTC-positive tumors (WNT: 43.5% vs 27.1%, $p = 0.037$; RTK-RAS: 43.5% vs 27.1%, $p = 0.011$). Gene set enrichment revealed upregulation of E2F targets and G2M checkpoint pathways in DTC-positive tumors (normalized enrichment score = 2.12, $p = 0.01$; 2.04, $p = 0.01$, respectively). Individual genes enriched in DTC-positive patients included HAVCR1, TRIM55, MUC13, and KCNJ12. Recurrent somatic mutations in canonical breast cancer genes (*PIK3CA*, *TP53*, *GATA3*, *CHD1*, *MAP3K1*) and mutational signatures associated with APOBEC activity and homologous recombination deficiency occurred similarly across DTC-positive and DTC-negative patients.
Conclusion: Primary tumors of patients with bone marrow DTCs at diagnosis exhibit upregulation of proliferative programs and increased mutation burden in WNT and RTK-RAS signaling genes. These findings highlight candidate biological pathways in the primary tumor that may facilitate early dissemination and persistence of DTCs.

#6816 Germline genetic impact on risk of colorectal cancer according to birth cohorts.

X. Wang[1], C. Turman[1], Y. Chen[1], C. Qu[2], L. Hsu[2], W. J. Gauderman[3], J. D. Potter[2], U. Peters[2], M. Song[1];
[1]Harvard T.H. Chan School of Public Health, Boston, MA, [2]Fred Hutchinson Cancer Research Center, Seattle, WA, [3]University of Southern California, Los Angeles, CA

Background: The incidence of colorectal cancer (CRC) has been rising globally among adults aged under 50 years, particularly those born after the 1950s. We hypothesized that the polygenic risk score (PRS) may show stronger associations with CRC risk in more recent birth cohorts, reflecting interactions between genetic susceptibility and increasingly prevalent life-time environmental exposures such as obesity and sedentary behaviors.
Methods: Among 37,313 CRC cases and 35,891 controls with available birth year information and genetically defined European ancestry from the Genetics and Epidemiology of Colorectal Cancer Consortium, we calculated the PRS as the weighted sum of risk alleles across 205 CRC-associated genetic variants identified so far. We used multivariable logistic models to estimate odds ratios (ORs) and 95% confidence intervals (CIs) of CRC risk associated with PRS across different birth cohorts. We assessed the interaction between PRS and birth cohorts using Wald test and performed subgroup analysis according to age at diagnosis, family history, endoscopic screening, and CRC molecular subtypes.
Results: PRS showed a generally stronger association with risk of CRC across successive birth cohorts (p for interaction = 0.005). The OR for CRC per 1-standard deviation increase in PRS was 1.62 (95% CI: 1.48, 1.78) among individuals born before 1920, 1.55 (1.49, 1.60) for 1920-1929, 1.60 (1.55, 1.65) for 1930-1939, 1.67 (1.61, 1.74) for 1940-1949, 1.64 (1.55, 1.73) for 1950-1959, and 1.79 (1.65, 1.95) for those born in 1960 or later. The birth cohort effect was primarily observed among participants without a first-degree family history of CRC, with ORs of 1.62 (1.45, 1.80) for those born before 1920 and 1.91 (1.73, 2.12) for 1960 or later (p for interaction <0.001). The birth cohort effect did not differ by age at diagnosis or history of screening. Across CRC subsites, the birth cohort effect was observed for distal (p for interaction = 0.003) and rectal CRC (p = 0.002) but not proximal CRC (p = 0.82). For tumor molecular subtypes, we observed no interactions between PRS and birth cohorts for subtypes classified by microsatellite instability, *BRAF* and *KRAS* mutations, or CpG island methylator phenotype, although only 9.7-12.3% CRC cases had molecular data, limiting statistical power.
Conclusions: PRS is more strongly associated with CRC risk in more recent birth cohorts, suggesting the role of gene-environment interaction in the rise in early-onset CRC and highlighting the increasing utility of genetic risk stratification in contemporary populations.

#6817 *STARD13-LATS2* Axis as a potential genetic modifier of BRCA2 in breast cancer.

Shiv Prakash Verma, Mitul Waghmare, Sanchari Bhattacharyya, Catherine Fanjoy, Shao Hong, Xu Zhang, Jonathan Amsalem, Yelena Kemel, Minna Lee, Matthew Buas, Zsofia Stadler, Pedram Razavi, Mark Robson, Sarat Chandarlapaty, Kenneth Offit*, Vijai Joseph*

Memorial Sloan Kettering Cancer Center, New York, NY

Background: Germline *BRCA2* mutations substantially increase breast cancer risk, but penetrance varies, indicating a role for genetic modifiers. These modifiers can influence tumor initiation and progression even among individuals with the same *BRCA2* variant, and their discovery and characterization can improve risk prediction and therapeutic stratification. For many GWAS-identified *BRCA2* modifiers, the biological mechanisms are still unclear. We examined *STARD13*, a cytoskeletal regulator and putative tumor suppressor identified in prior *BRCA2* GWAS signals, may intersect functionally with the Hippo pathway through effects on RhoA-actin dynamics that influence *LATS2* activity, which in turn regulates *YAP/TAZ*-mediated proliferation and genomic stability. Because *LATS2* supports genomic integrity and suppresses oncogenic signaling, we hypothesized that disruption of the *STARD13* and *LATS2* axis may modify *BRCA2*-associated phenotypes in breast epithelial cells.

Methods: *BRCA2* mutants were generated in breast epithelial cell lines using CRISPR/Cas9 genome editing. Allele-specific regulatory effects of the SNPs were assessed by luciferase reporter assays. To investigate *STARD13* as a genetic modifier, siRNA- and shRNA-mediated knockdown was performed in wild-type and *BRCA2* mutant cells. *LATS2* expression was quantified by qRT-PCR. Functional assays measuring proliferation, apoptosis, and DNA damage sensitivity evaluated the impact of *STARD13* knockdown in different *BRCA2* contexts.

Results: In wild-type *BRCA2* cells, *STARD13* knockdown upregulated *LATS2* expression, indicating activation of a compensatory tumor suppressor pathway. In contrast, In BRCA2-mutant cells, loss of STARD13 fails to induce the compensatory increase in LATS2 seen in BRCA2-wild-type cells, identifying STARD13 as a modifier of the BRCA2-deficient state. These data implicate *LATS2* as a modifier of *BRCA2* via *STARD13*-dependent mechanisms. Ongoing experiments in *BRCA2* mutant cell lines and organoids are examining effects on DNA damage, repair, colony formation, gene expression, and responses to PARP inhibitors using shRNA and CRISPR knockouts.

Conclusions: Our findings support *STARD13* as a potential genetic modifier of *BRCA2*, influencing the activity of *LATS2* tumor suppressor and linking cytoskeletal signaling with DNA repair pathways. The differential regulation of *LATS2* in wild-type versus *BRCA2* mutant backgrounds suggests a novel axis that may underlie variation in *BRCA2* penetrance and cancer risk. These studies aim to elucidate the *STARD13-LATS2-BRCA2* interaction network as a determinant of *BRCA2* penetrance, as a potential biomarker to allow targeting to decrease penetrance of hereditary breast cancer in affected kindreds.

#6749 Spatial transcriptomics profiling of colorectal cancer tumors in Alaska Native peoples: Discovery of prognostic biomarkers.

G. Chang[1], D. Redwood[2], A. L. Koehne[1], M. Fitzgibbon[3], C. Qu[1], H. Yin[4], E. Donato[1], M. Lin[1], C. Yeung[1], J. J. Tiesinga[2], S. Thomas[1], L. Hsu[1], C. I. Li[1], T. K. Thomas[2], R. Peters[1], J. Huyghe[1]; [1]Public Health Sciences Division, Fred Hutchinson Cancer Center, Seattle, WA, [2]Alaska Native Tribal Health Consortium, Anchorage, AK, [3]Genomics and Bioinformatics, Fred Hutchinson Cancer Center, Seattle, WA, [4]Department of Medicine, Massachusetts General Hospital, Boston, MA

Colorectal cancer (CRC) is the third most commonly diagnosed cancer and has the second-highest mortality rate overall in the United States (US). Appreciable population differences in incidence and mortality rates persist in the US. These differences are particularly pronounced among Alaska Native peoples who, for over 40 years, have experienced the highest incidence and mortality rates, despite dedicated screening efforts. The reasons underlying these high rates are not understood. A key knowledge gap is the lack of studies characterizing the molecular features of colorectal tumors in Alaska Native patients. This study aims to identify tumor and tumor microenvironment (TME) features present at time of diagnosis that are associated with CRC mortality, and that may contribute to the elevated mortality rate.We analyzed treatment-naïve tumor tissue samples from 217 Alaska Native participants with stage I-III CRC diagnosed at the Alaska Native Medical Center from 2000 to 2017. Participants who died from CRC (n=60) were matched 1:2 to participants who did not die from CRC and who lived at least as long after diagnosis as the participant they were matched to (n=157). Matching was based on age at diagnosis, sex, year of diagnosis, and tumor site and stage. The present study included 139 females (64.1%) and 78 males (35.9%). The median age at diagnosis was 68 years (range: 36-85). At diagnosis, 33 participants (15.2%) had stage I, 93 (42.9%) had stage II, and 91 (41.9%) had stage III CRC. We constructed tissue microarrays (TMAs) from formalin-fixed paraffin-embedded (FFPE) tumor tissue blocks (2 tumor center cores and 1 invasive margin core per tissue) and performed spatial transcriptomics profiling using the GeoMx DSP platform and the Whole Transcriptome Atlas panel. We measured gene expression separately in epithelial and stromal tissue compartments. After quality control, adjustment for batch effects, and normalization, we used DESeq2 to find genes associated with CRC mortality. Analysis was stratified by tissue compartment and tumor location. We performed gene set enrichment analyses using the fgsea R package. Differential gene expression results showed significant downregulation of SPINK4 (3.2-fold decrease, false discovery rate [FDR]-adjusted p=4.72e-3) and MUC2 (2.6-fold decrease, FDR-adjusted p=1.37e-3) genes in the tumor center epithelial compartment in participants who died from CRC. Gene set enrichment analyses showed that upregulation of interferon gamma response hallmark genes was associated with favorable prognosis across tissue compartments and tumor locations, while upregulation of epithelial-mesenchymal transition hallmark genes in the tumor margin was associated with worse prognosis (all FDR-adjusted p<0.05). Additional ongoing work includes cell type deconvolution analyses and expansion of the study size to over 400 Alaska Native participants with CRC.

#6750 Highly multiplexed immunoassays enable discovery of multimarker EV surface signatures as novel biomarkers.

L. Hebert[1], M. Al-Ameen[1], E. A. Gizzie[1], C. Nelson[1], J. H. Butler[1], J. C. Brady[2], J. L. Franklin[3], R. J. Cote[4], R. J. Coffey[3], A. B. Nixon[2], **D. A. Routenberg**[1];
[1]Meso Scale Diagnostics, LLC, Rockville, MD, [2]Duke Univ. Medical Ctr., Durham, NC, [3]Vanderbilt University Medical Center, Nashville, TN, [4]Washington University in St. Louis School of Medicine, St. Louis, MO

Extracellular vesicles (EVs) are lipid bilayer particles that mediate cell communication by carrying molecules that reflect their cell of origin. Their enrichment in disease states and accessibility via minimally invasive sampling make them promising biomarkers. EV heterogeneity remains a challenge as single surface markers are often insufficient to define disease-related EV subpopulations, underscoring the need for technologies enabling single-vesicle resolution and multiplexed detection of composite marker signatures. We developed a highly multiplexed immunoassay technique to count combinations of three surface markers on individual, intact EVs. EVs are captured on magnetic beads using antibodies against tetraspanin proteins broadly expressed on EV surfaces, enabling selective EV enrichment and automation. Plasma is pre-processed using a mixed-mode resin that removes >99.5% of proteins while recovering >60% of EVs, followed by immune-depletion of platelet-derived EVs to improve sensitivity for non-platelet EVs. A panel of barcoded antibodies for different cell-surface proteins is used to bind EV surface antigens. When three antibodies co-localize on an EV, barcodes associated with the antibodies are linked to form a DNA product encoding the three target antigens. A library of probes targeting 63 EV surface markers, selected to distinguish circulating EVs from major cell lineages, enables broad phenotyping. DNA products are PCR-amplified and sequenced, quantifying thousands of 3-marker combinations on individual EVs. We applied our technique to 366 plasma samples provided by collaborators from those with colorectal (CRC), breast, and gastric cancer, alongside 47 healthy controls and cell-line-derived EV samples. Technical precision assessed using replicate controls yielded average inter-plate and intra-plate CVs of 19% and 16%, respectively. Spiking defined EV populations into plasma established a detection limit of 1 part in 10^7. Across all cancer types, differential expression analysis identified elevated 3-marker combinations involving cancer-associated markers (e.g., CEA, CD10, CD13 and N-cadherin) relative to controls. Selected EV populations were validated using ultrasensitive electrochemiluminescence (ECL) assays, showing strong correlation with sequencing results (Pearson's $r > 0.8$). In two longitudinal CRC groups, elevated levels of several 3-marker EV signatures were significantly associated with shorter overall and progression-free survival. This multiplexed single-EV assay offers a powerful, sensitive platform for high-throughput profiling of disease-associated EV populations. Its modular design enables flexible selection of marker panels tailored to specific biological questions. Additionally, it can be integrated with ultrasensitive ECL immunoassays for cost-effective, large-scale validation of selected EV signatures.

#6751 Differences in survival outcomes among metastatic colorectal cancer patients across fibroblast growth factor receptor 2 and 3 expression levels.

S. Soto Trujillo[1], Y. Yang[1], M. Bartolini[1], S. Soni[1], P. Mittal[1], F.-S. Ou[2], L. Torres-Gonzalez[1], U. Shah[1], J. H. Lo[1], Y. Goretsky[1], W. Zhang[1], A. Venook[3], S. Algaze[1], J. Millstein[1], H.-J. Lenz[1]; [1]Norris Comprehensive Cancer Center, Keck School of Medicine, Los Angeles, CA, [2]Mayo Clinic, Rochester, MN, [3]University of California, San Francisco, San Francisco, CA

Introduction: Fibroblast growth factor receptor 2 and 3 (FGFR2 and FGFR3) are metabolic genes overexpressed in malignant epithelia. In colorectal cancer (CRC), intimate crosstalk between FGFR2/3 and epidermal growth factor receptor (EGFR) pathways has been suggested but is not fully elucidated. As a result, this study investigated associations between FGFR2/3 expression levels and clinical outcomes in patients with metastatic CRC (mCRC) enrolled in the phase III clinical trial CALGB /SWOG 80405.

Methods: Data from 433 patients with mCRC enrolled in the CALGB/SWOG 80405 trial were analyzed. Patients received either bevacizumab (bev, n = 226) or cetuximab (cet, n = 207) plus chemotherapy as first-line treatment. Tumor RNA was extracted from FFPE samples and processed through the HiSeq 2500 (Ilumina) platform. Median overall survival (OS) and progression-free survival (PFS) curves were evaluated in all treatment subgroups and stratified according to high (H), medium (M), and low (L) FGFR 2 and 3 gene expression levels. Likelihood ratio tests, hazard ratios (HRs), and 95% confidence intervals (CIs) were calculated using Cox proportional hazards multivariate models, adjusting for age, sex, ECOG performance status, tumor location, number of metastatic sites, *KRAS* status, consensus molecular subtypes, and treatment arm.

Results: Both FGFR2 and FGFR3 expression levels were associated with outcomes in patients treated with cetuximab. FGFR2-L tumors showed significantly longer OS compared to the M (HR = 1.04; 95%CI 0.71-1.51) and H (HR = 1.56; 95%CI 1.06-2.28) expression groups (35.7 vs. 31.2 vs. 23.7 months, p = 0.017). In contrast, FGFR3-L tumors were associated with shorter OS compared to the M (HR = 0.63; 95%CI 0.44-0.92) and H (HR = 0.59; 95%CI 0.41-0.85) expression groups (24.7 vs 32.4 vs 37.1 months, p = 0.0009). Significant differences in PFS were not observed. A nominally significant interaction was found between treatment and FGFR3 expression for both PFS (p = 0.02) and OS (p = 0.0003), but no interaction with FGFR2 expression. No significant associations were detected in patients treated with bev. Neither FGFR2 nor FGFR3 suggested to be prognostic markers after multivariate adjustment analyses.

Conclusions: Our findings suggest a predictive role of FGFR3 in patients with mCRC undergoing anti-EGFR treatment. Differences in survival within the cet subgroup suggest that EGFR inhibitor efficacy may be modulated by FGFR2/3 signaling activity. Interestingly, FGFR2 and FGFR3 expressions were inversely and positively correlated with improved OS. The findings suggest that FGFR2 signaling minimizes the specific effects of cetuximab, while FGFR3 signaling amplifies its therapeutic effects. Further studies should determine whether these associations are seen in other anti-EGFR inhibitors and detail the mechanistic interaction between FGFR and EGFR pathways.

#6752 Mapping the spatial organisation of B cells and immune signalling in TNBC to characterise response to immunotherapy.

L. Ahmad[1], X. Wang[1], N. Masque-Soler[1], E. Schrader[1], C.-S. Huang[2], D. Egle[3], M. Callari[4], M. Dugo[5], B. Bermejo[6], C. Zamagni[7], M. Thill[8], A. Anton[9], S. Russo[10], E. In recent years, B cells and tertiary lymphoid structures (TLS) have emerged as key predictors of immunotherapy response across multiple cancers. B cells exist in various states of spatial organisation within the tumour microenvironment (TME), likely supporting many of their functional roles. However, the landscape of B cell spatial organisation in cancer, and specifically in triple-negative breast cancer (TNBC), is poorly characterised. Organisation and function are processes that are likely orchestrated by a diverse set of immune signalling, but the interplay between organisation and its underlying signalling remains largely uncharacterised in cancer, underscoring the need for a comprehensive and systematic investigation. To characterise the spatial landscape of B cells and immune signalling, we implemented a novel approach for the simultaneous detection of protein and RNA in situ using imaging mass cytometry. We applied this assay to a randomised immunotherapy clinical trial, NeoTRIP, where patients with TNBC were treated with neoadjuvant chemotherapy with or without atezolizumab. Samples were collected from 268 patients at three timepoints: baseline, on-treatment and post-treatment. This study identified that germinal centre B, B and plasma cell densities were significantly associated with response to immunotherapy on-treatment. We identified distinct B and plasma cell niches in TNBC, and showed that B activated niche cell densities were also strong predictors of response to immunotherapy. Additionally, we found that many B and plasma to TME interactions were enriched among immunotherapy responders. These findings were complemented by strong treatment-induced cellular dynamics. Strikingly, the most marked increase in TME cell phenotype abundance in immunotherapy responders was observed in B cells - particularly naïve B cells and broader B cell populations, suggesting that effective immunotherapy induces their expansion following treatment. We subsequently showed that cytokines likely behave in a spatially coordinated manner in the TME, being significantly enriched in the vicinity of the observed B and plasma cell niches. Cytokine expression mirrored the observed immune expansion on-treatment and was also associated with immunotherapy response. Specifically, cytokine-enriched niches appeared to be a feature of immunotherapy responders, suggesting that together organisation and signalling play a central role in treatment responses. Together, these findings highlight a previously unexplored diversity of B cell spatial organisation and its associated immune signalling in TNBC, suggesting that B cell features may serve as on-treatment predictors of immunotherapy response.

#6753 AI-powered Deep Visual Proteomics (DVP) links pancreatic precursor biology to PDAC survival phenotypes.

J. Min[1], L. Schweizer[2], G. Zonderland[2], B. C. Selvanesan[3], J. H. Thomsen[2], L. Oldenburg[2], E. Chelebian[2], B. J. Swanson[4], M. A. Hollingsworth[5], P. M. Grandgenett[6], I. Ummat[2], M. Strauss[2], **A. Mund**[2], A. Maitra[1];

[1]Perlmutter Cancer Center, New York, NY, [2]OmicVision Biosciences, Copenhagen, Denmark, [3]MD Anderson Cancer Center, Houston, TX, [4]University of Nebraska Medical Center, Omaha, NE, [5]UNMC Eppley Institute, F&P Buffett Cancer Center, Omaha, NE, [6]UNMC Eppley Institute for Cancer Research, Omaha, NE

Pancreatic ductal adenocarcinoma (PDAC) exhibits 70-80% post-resection recurrence, yet how the earliest molecular events in PanIN precursors connect to divergent survival outcomes remains unclear. We previously established a spatially resolved proteomic atlas of PanINs that revealed molecular reprogramming preceding histological transformation, using Deep Visual Proteomics (DVP). This work mapped acinar-to-ductal metaplasia, incidental ("iPanIN") and cancer-associated ("cPanIN") lesions, and normal ducts into a continuous trajectory to invasive carcinoma and identified four core programs (stress adaptation, immune engagement, metabolic reprogramming, and mitochondrial dysfunction) evident in morphologically normal ducts and low-grade PanINs, alongside cancer-associated field effects. Our MS-based peptide profiling identified KRAS polyclonality at the protein level, independent of genetic sequencing[1] .We now extend this approach using tile-level Deep Visual Proteomics (TileDVP[2]) to analyze a first-of-its-kind, multi-institutional FFPE biobank of matched primary-metastatic tumor pairs from short- and long-term PDAC survivors. Using laser microdissection of ~15 phenotype-matched cells per sample, TileDVP quantifies 3,500-5,000 proteins, enabling high-resolution molecular profiling of tumor cell populations and metastatic niches at the proteomic level. This workflow represents a 300-fold throughput improvement over DVP, while increasing spatial proteomic resolution. We compare proteomic signatures of survival groups across primary tumors, regional and distant metastases, and metastatic niches, and link precursor biology to recurrence patterns, to define how these programs evolve across metastatic sites within and between organs.By unifying precursors, recurrent tumors, and survival phenotypes in a single spatial proteomics framework, this study identifies potential biomarkers for risk stratification and therapeutic targets for earlier intervention in PDAC.

#6754 Spatial-immune multiomics refines prognostication in early-stage, estrogen receptor-positive breast cancer.

Z. Kinsella[1], A. Chowdhury Jahangir[2], H. N. Nyarko[1], D. Kalinska-Lysiak[3], C. A. Gonzalez[2], V. Murphy[4], A. O'Grady[5], J. Fay[6], K. Sheehan[6], A. Rahman[7], J. Crown[8], C. Kelly[4], S. S. McDade[9], J. Prehn[3], W. M. Gallagher[2], D. P. O'Connor[3];

[1]Royal College of Surgeons in Ireland (RCSI), Dublin, Ireland, [2]University College Dublin, Dublin, Ireland, [3]Royal College of Surgeons in Ireland, Dublin, Ireland, [4]Mater Hospital, Dublin, Ireland, [5]Royal College of Surgeons in 4190, Dublin, Ireland, [6]Beaumont Hospital, Dublin, Ireland, [7]UCD Conway Institute of Biomolec. & Biomed. Res., Dublin, Ireland, [8]St Vincent's Hospital, Dublin, Ireland, [9]Queen's University Belfast, Belfast

Introduction: Despite a strong 5-10 year prognosis, in $ER^{+}HER2^{-}$ breast cancer relapses are common beyond 10 years. Genomic assays employed to determine recurrence risk at diagnosis, and subsequently the required adjuvant treatment, are still ambiguous for a significant proportion of patients with Intermediate risk (i.e. Oncotype Dx Recurrence Score (RS) 16-25). Contemporary management relies on menopausal status as a risk stratifier, which is a source of inaccuracy for the assessment and prescription of personalised treatment regimens.

Methods: We sought to refine risk stratification by incorporating features of the tumour-immune microenvironment. We employed a spatial multiomics workflow to a tissue microarray of Irish patients previously enrolled on the TAILORx trial (whole-transcriptome, ROI-based spatial transcriptomics n=410, 7-plex spatial proteomics n=442). We subsequently validated CD8 IHC in whole-resection specimens of the same patient cohort (n=453). Our primary endpoint was invasive disease-free survival.

Results: Modelling immune infiltration agnostic of underlying genomic risk produced data congruous with the consensus view of ER+HER2- breast cancer immunogenicity. No tumour-infiltrating lymphocyte (TIL) was independently prognostic across the entire cohort, and the distribution of TILs mirrored the categorical 'hot or not' definition of an immunologically "cold" disease (< 10% TILs). However, modelling by underlying genomic risk revealed monotonic trends of increasing TILs and increased risk. We further demonstrated that macrophage and T-helper cells facilitate and impede cytotoxic T-cells, are associated with extracellular matrix remodelling, M2-like macrophage (SPP1) genes, and cytotoxicity (GZMA, GZMB, PRF1), checkpoints (LAG3, PD-1, PD-L2), and exhaustion (TOX) genes respectively, consistent with restrained T-cell activation. Survival analyses underscored how high cytotoxic T-cell infiltrates were associated with poorer 15-year iDFS in patients receiving additional chemoendocrine therapy (CD8 density: High RS $p = 0.017$, FDR < 0.1. CD8%: Intermediate RS $p=0.027$, FDR>0.1). Critically, in randomised treatment arms of the Intermediate RS, a treatment-biomarker interaction indicated chemotherapy inferiority at higher stromal CD8 density (ΔLR-χ^2: 7.36, $p = 0.007$), which was validated orthogonally on whole-resection specimens from the same cohort (ΔLR-χ^2: 7.48, $p = 0.006$).

Conclusions: To our knowledge for the first time, we have outlined a predictive biomarker of chemotherapy inferiority in the Intermediate RS, suggesting a potential treatment change for up to 50% of patients. This discovery requires validation in the larger TAILORx trial before clinical adoption.

#6755 Unbiased phenotyping of CRISPR-edited tumors with Perturb-map and subcellular imaging of the mouse whole transcriptome (22,000-plex).

M. Dhainaut[1], L. Zhang[2], M. Meister[1], A. Mavropoulos[1], A. Benz[1], I. Lee[2], S. McKinzie[2], D. Millman[1], D. Tran[1], D. Ovando[1], L. Cavalcante[1], K. Mitchell[1], E. Margalit[1], D. Antonio[1], A. Mahajan[1], A. Salm[1], E. Siefkas[1], F. Fernandez[1], H. Kaplan[1], H. Winters[1], J. Schmidt[1], J. Tea[1], J. Decalf[1], L. Ryan[1], M. Zolanvari[1], N. Snell[1], R. Schiemann[1], R. Collins[1], R. Huang[1], Y. Xie[1], Y. Falanga[1], S. Virani[1], L. Padron[1], E. Corse[1], S. He[2], D. Bear[1], J. M. Beechem[2], R. W. Alfa[1];

The heterogeneity of tumor phenotypes in patients, and the lack of a holistic definition of tumor subtypes, are major barriers to achieving clinical success. Many clinical programs have been halted for failing to refine the patient population that would benefit from treatment. Our OCTO suite of machine learning models, trained on multi-modal data generated from 1000s of patient samples, provides a unified and unbiased classification of patient subtypes that does not solely rely on genotypes or expression of specific biomarkers. Though OCTO enables us to identify target populations for active clinical programs, predicting response for preclinical assets is still an unmet need.In contrast to patient tumors, traditional preclinical models are by design homogeneous, and often do not represent an actual patient populations. Using a scaled in vivo CRISPR perturbation platform, Perturb-map, we have generated 600+ mouse model variants of NSCLC. Each tissue section from Perturb-map contains hundreds of individual tumors, each carrying a specific genetic perturbation, spatially resolved with a molecular barcode. We built a multi-modal (H&E, mIF, transcriptomics) dataset profiling 100,000s of individual tumors. A subset of samples was profiled using the mouse Whole Transcriptome (WTx) panel (22,000-plex) using the Cosmx Spatial Molecular Imager, providing the first data set coupling high-throughput CRISPR perturbations in vivo with unbiased phenotyping at subcellular resolution.Leveraging the unique combination of throughput from Perturb-map and depth of phenotyping from the WTx panel, we mapped genetic perturbations to their impact on tumor development at an unprecedented scale. Comprehensive phenotyping of hundreds of CRISPR-edited tumors revealed the impact of each gene perturbation on relevant signaling pathways within tumor cells and on the composition of the tumor microenvironment, including deep characterization of the immune compartment. Specifically, we found significant overlap among the molecular footprints of known tumor drivers in NSCLC (including EGFR, KRAS and STK11 mutations) in preclinical models and in patients. We also linked tumor phenotypes with their sensitivity to specific treatments, including to immune checkpoint blockade.Altogether, we present a unique dataset generated by profiling hundreds of NSCLC preclinical model variants, each carrying a specific genetic perturbation, using a comprehensive Whole Transcriptome (WTx) panel. A subset of mouse tumor archetypes presented characteristics of specific patient tumor subtypes, and could be used to evaluate population-specific drug responses.

Dhe-Paganon[1], F. Dequiedt[3], J. Twizere[3], M. Vidal[1]; [1]Dana-Farber Cancer Institute, Boston, MA, [2]Rega Institute for Medical Research, KU Leuven, Leuven, Belgium, [3]University of Liege, Liege, Belgium, [4]Broad Institute of Harvard and MIT, Cambridge, MA, USA, Cambridge, MA, [5]University of Bologna, Bologna, Italy, [6]KU Leuven, Leuven, Belgium

Purpose: Enzymatic pockets, such as those found in histone deacetylases (HDACs), have long served as attractive targets for drug discovery. However, conventional HDAC inhibitors often lack selectivity and cause systemic toxicity due to paralog redundancy and their incorporation into multi-subunit transcriptional regulatory complexes. To identify more selective modulators, we performed an unbiased yeast genetic screen of ~52,000 compounds by interrogating the activity of the conserved HDAC/Rpd3L complex. Follow-up mechanistic studies uncovered hits that do not directly inhibit HDAC catalytic activity but instead modulate repression through alternative mechanisms. We subsequently evaluated the lead compound, E6R, in human neuroblastoma cells and mouse xenografts, benchmarking against the enzymatic inhibitor TSA in vitro and Vorinostat (SAHA) in vivo. These studies demonstrate that E6R, a first-in-class non-enzymatic SIN3-HDAC modulator, achieves comparable anti-tumor efficacy with far greater selectivity and minimal global transcriptional disruption.
Methods: E6R was evaluated in yeast and SK-N-BE(2)-C neuroblastoma cells using bulk and single-cell RNA-seq (Seq-Well S3), SIN3A ChIP-seq, viability and invasion assays, and mouse xenografts.
Results: In yeast, E6R disrupts Sin3/Rpd3L-dependent transcriptional repression without inhibiting HDAC catalytic activity. In human neuroblastoma cells, E6R produced anti-tumor activity comparable to TSA. Transcriptomically, E6R modulated ~14-fold fewer genes than TSA and caused minimal global perturbation. Interestingly, E6R selectively activated stress- and senescence-associated programs governed by the ATF4-driven integrated stress response (ISR), including *GDF15*, *DDIT3*, *ATF3*, and *FGF21*, while inducing minimal off-target effects. SIN3A ChIP-seq revealed promoter-proximal loss of SIN3A binding at several ISR loci, most notably *GDF15* (~55 bp upstream of the TSS), consistent with direct de-repression through dissociation of the SIN3-HDAC complex. Although both compounds shared repression of *E2F*, *MYC*, and glycolytic targets and activation of p53, TNFα/NF-κB, and apoptotic signaling, E6R induced a distinct stress-adaptive state through an HDAC-independent mechanism. Functionally, E6R significantly reduced neuroblastoma cell invasion and tumor growth with limited cytotoxicity. In vivo, E6R inhibited neuroblastoma xenograft growth comparably to Vorinostat, supporting non-enzymatic HDAC modulation as a therapeutic alternative.
Conclusions: Together, these data strongly suggest that E6R is a selective, non-enzymatic SIN3-HDAC modulator that reprograms chromatin from a repressive to a stress-adaptive, anti-proliferative state, offering a mechanistically distinct and potentially safer framework for HDAC-targeted cancer therapy.

#6777 Targeting HIF-2a pathway with a novel and potent ARNT molecular glue degrader for the treatment of renal cell carcinoma.

J. Fathman, C. Sanchez, N. Cruz, Z. Naiman, J. Lee, M. Cruz, I. Tran, K. Chiu, J. Griffin, A. Hernandez, K. Januszyk, X. Liu, B. Lee, A. Burt, J. Tellew, M. Wu, L. Watson, A. Dominguez-Andres, L. Huang, R. Soriano, D. Knece, M. FitzGibbon, A. Grant, M. Matyskiela, R. Beckwith, K. Wagner, B. Wen, P. Chamberlain;
Neomorph, Inc., San Diego, CA

Clear-cell renal cell carcinoma (ccRCC) is often characterized by the inactivation of the von Hippel-Lindau (VHL) gene, leading to the stabilization of hypoxia-inducible factor-2α (HIF-2α) and HIF-1α. HIF-2/1α drive expression of key oncogenic pathway genes involved in angiogenesis, proliferation, metastasis, and tumor immunity; vascular endothelial growth factor (VEGF) being one of these genes. Aryl hydrocarbon receptor nuclear translocator (ARNT), also known as hypoxia-inducible factor-1β (HIF-1β), forms heterodimers with HIF-1/2α and plays an integral role in driving HIF mediated target gene expression. Current therapies targeting HIF-2α in ccRCC and VHL diseases have shown good anti-cancer activity in the clinic. Here we describe NEO-811, an orally bioavailable, potent, selective, cereblon (CRBN)-dependent molecular glue degrader of ARNT as a novel way to target this key pathway in disease progression. NEO-811 showed dose proportional plasma exposure and good bioavailability in mice. Utilizing 786-O xenografts, a human VHL-deficient ccRCC cell line, we show NEO-811 demonstrated deep and sustained degradation of ARNT and modulation of HIF-2α target genes, VEGF and NDRG1. We observed robust efficacy after daily oral dosing of mice bearing 786-O xenografts and showed that NEO-811 was well tolerated and displayed dose dependent tumor regression. Tumor growth inhibition of 786-O xenografts with our ARNT degrader was comparable to treatment with a HIF-2α inhibitor. Importantly, NEO-811 still retained activity in 786-O xenografts that expressed a HIF-2α mutant (i.e., G323E) that conferred resistance to inhibitors. These data provide preclinical evidence and scientific rationale to further investigate NEO-811, a potent and selective ARNT molecular glue degrader, clinically in patients with ccRCC VHL deficient tumors.

#6778 Selective targeting of CCNE1 using molecular glue degraders for the treatment of *CCNE1* amplified cancers.

W. Tahaney[1], Y. Liu[1], A. Abdullah[1], V. Massafra[2], V. Lang[2], M. Baumann[2], A. Dubois[2], A. Osmont[2], X. Lucas[2], C. Quan[1], A. Kostikova[2], A. Diesslin[2], F. Harvey[2], C. Bianda[2], K. Larpenteur[1], K. Jones[1], A.-C. D'Alessandro[2], C. Perdomo Ortiz[2], H. Farine[2], M. Cabanski[2], M. Korpal[1], B. Demarco[1], D. Bonenfant[2], M. Warmuth[1], F. Janku[1], M. Walter[2], S. Townson[1], B. Fasching[1], S. Totoioli[2], C. King[1], L. McAllister[2], B. Ranieri[2], S. Gkountela[2], **R. Tiedt**[2], N. Ilic Widlund[1];

[1]Monte Rosa Therapeutics, Inc., Boston, MA, [2]Monte Rosa Therapeutics AG, Basel, Switzerland

Cyclin E1 (CCNE1) is a critical driver of cell cycle progression and cell proliferation. It acts as the regulatory subunit for the CCNE1-CDK2 holoenzyme, which coordinates cell cycle progression through the G1/S phases and effectively drives cell proliferation via RB phosphorylation and repression. *CCNE1* is frequently amplified or overexpressed across multiple cancer types, including ovarian, endometrial, gastric, breast, and others, and thus pharmacological targeting of CCNE1 is expected to benefit patients whose cancers bear these alterations. Despite the clear therapeutic promise of directly targeting CCNE1 in these patients, CCNE1 has been considered undruggable by conventional means as it is a regulatory non-enzymatic protein. Hence, we sought to identify molecular glue degraders (MGDs) that selectively target CCNE1 for proteasomal degradation. Using our MGD discovery engine QuEEN^{TM} encompassing biochemical and cellular assays as well as *in silico* modelling, we identified and optimized molecules that potently degrade CCNE1. Leveraging a cryptic pocket, our CCNE1 MGDs selectively degrade the cyclin E1/CDK2 holoenzyme complex, while sparing other proteins such as closely related cyclins or CDKs. In *CCNE1* amplified cancer cell lines CCNE1 MGDs selectively inhibit cellular proliferation, while sparing cell lines without amplification, in line with the “oncogenic addiction” paradigm. These anti-proliferative effects were determined to be governed by downmodulation of RB phosphorylation and E2F-driven gene expression, attesting to the on-target function of our CCNE1 MGDs. When assessed *in vivo*, orally dosed CCNE1 MGDs induced robust tumor growth suppression and regression as a monotherapy in *CCNE1* amplified ovarian, breast, and gastric models. We further established that clinical stage CDK2 inhibitors exhibit significant off-target activity through kinome profiling and genetic modeling, demonstrating the superior selectivity of CCNE1 MGDs. Owing to their exquisite selectivity, we expect that CCNE1 MGDs will avoid dose-limiting toxicities associated with less selective CDK2 inhibitors. CCNE1 MGDs represent a first in class opportunity and a paradigm shift due to their ability to directly target a frequently amplified non-enzymatic driver oncogene in distinct populations of cancer patients with high unmet medical need. With their distinctive ability to spare other proteins whose inhibition is associated with dose-limiting toxicities, CCNE1 MGDs offer a unique precision medicine angle for populations in desperate need of treatment options.

#6779 Molecular glue degraders of the RNA binding protein HuR to treat BRAF-mutant colorectal cancer.

Z. Yang[1], X. Lu[2], X. Wang[2], X. Wang[2], L. Wang[1], C. Xu[1], C. Geng[1], L. Wang[2], Y. Pu[2], Z. Zhu[2], L. Ye[2], J. Huang[2], X. Wei[2], F. Bai[2], Y. Zhu[3], X. Qian[4], H. Dou[1], H. Su[1], Y. Cang[1];
[1]Degron Therapeutics Co., Ltd, Shanghai, China, [2]ShanghaiTech University, Shanghai, China, [3]Zhejiang University, Hangzhou, China, [4]Degron Therapeutics, San Diego, CA

BRAF gain-of-function mutations, particularly BRAF(V600E), occur in approximately 10% of colorectal cancer (CRC) patients and are associated with poor prognosis and limited therapeutic options. While combined BRAF and EGFR inhibition is a standard of care, its efficacy is transient, often leading to rapid resistance and relapse. HuR is a key driver of tumor growth, invasion, and therapy resistance but was thought to be “undruggable” in the past. Here we identify novel molecular glue degraders. dHuR, as a representative, exhibited strong CRBN binding affinity and HuR degradation potency by recruiting the CRL4-CRBN ubiquitin ligase to target the RNA-binding protein HuR for degradation. Cryo-EM structural analysis revealed that dHuR created a unique benzofuran-tethered interface on CRBN, engaging a β-hairpin G-loop degron on HuR and recruiting it as a neo-substrate. Functionally, degradation of HuR by dHuR induced skipping of exon 18 in the *BRAF* transcript, leading to reduction in BRAF protein levels. This mechanism resulted in more effective suppression of BRAF-mutant CRC tumor growth *in vitro* and *in vivo*, including in models resistant to BRAF inhibitors. In vitro studies showed dHuR potently reduced viability in all 6 BRAF-mutant lines, while BRAF-WT cell lines remained unaffected. Mice bearing Colo205 tumors were treated with dHuR via oral gavage for 28 days. The treatment resulted in dose-dependent tumor growth inhibition. No significant changes in body weight or adverse clinical observations were reported. Furthermore, a comprehensive kinome-wide CRISPR screen identified EGFR and MEK inactivation as potent enhancers of dHuR cytotoxicity, establishing a strong rationale for combination therapy in refractory disease. Based on this compelling preclinical profile, we have advanced a clinical candidate, DEG6498. We are pleased to report the successful clearance of Investigational New Drug (IND) applications from both the U.S. FDA (IND 174949) and China's NMPA (CXHL2500454). A Phase I clinical trial has been initiated to evaluate the safety, tolerability, pharmacokinetics, and preliminary efficacy of DEG6498 in patients with advanced solid tumors, including BRAF-mutant CRC as an expansion cohort. This trial marks a significant milestone as the first-in-human study of a HuR-targeted molecular glue degrader, offering a novel therapeutic strategy with a distinct mechanism of action to overcome the limitations of current targeted therapies for this aggressive cancer subset.

#6780 The RAS: PI3Kα breaker BBO-10203 inhibits PI3Kα/AKT activity in HER2+ models through non-canonical RAS signaling blockade.

S. Feng[1], C. Feng[1], M. Cabanski-Dunning[2], C. Zhang[1], M. Chen[1], E. Riegler[1], D. J. Czyzyk[3], Y. Yang[1], R. Xu[1], E. M. Wallace[1], D. K. Simanshu[3], D. V. Nissley[3], F. McCormick[2], K. W. Sinkevicius[1], **J. P. Stice**[1], P. J. Beltran[1];

[1]BBOT, South San Francisco, CA, [2]UCSF, San Francisco, CA, [3]Frederick National Laboratory for Cancer Research, Frederick, MD

BBO-10203 is a first-in-class clinical stage small molecule that disrupts the interaction between RAS and PI3Kα resulting in blockade of RAS-driven PI3Kα pathway activation. Unlike PI3Kα kinase inhibitors, BBO-10203 inhibits PI3Kα signaling without directly targeting the kinase domain, thereby preventing hyperglycemia, as insulin receptor signaling does not rely on RAS proteins. BBO-10203 suppresses PI3Kα activation in preclinical models harboring oncogenic KRAS and/or PIK3CA mutations and exhibits complete suppression of AKT phosphorylation (pAKT) in most HER2 amplified or overexpressing cell lines (HER2+). Importantly, this potent inhibitory effect on pAKT drives robust efficacy in HER2+ xenograft models *in vivo*. Although much is known about HER2 and RAS signaling in tumor cells, it is not clear how inhibiting the interaction of RAS and PI3Kα results in pAKT inhibition in HER2+ cells. Using the HER2+ KYSE-410 esophageal cancer cell line we demonstrate that BBO-10203 inhibits PI3Kα /AKT signaling in HER2+ cells via a mechanism that is mainly driven through non-canonical RAS proteins. CRISPR-mediated knock-in of the PIK3CA RAS-binding domain (RBD) mutations (T208D/K227A), which disrupt the interaction of RAS with PI3Kα, significantly reduced pAKT in the KYSE-410 model, strongly supporting the role of RAS proteins in driving pAKT signaling. Treatment with the panRAS inhibitor RMC-6236 showed little effect on pAKT, suggesting that canonical RAS (K-, H- and N-RAS) may not be important players in pAKT signaling. Among individual RAS isoforms screened via siRNA knockdown, only RRAS/RRAS2 knockdown significantly reduced pAKT, whereas knockdown of other RAS members either elevated pAKT (consistent with compensatory expression) or had no effect. Through co-immunoprecipitation experiments, we identified that RRAS2 is present in the same protein complex as HER2 and HER3, providing mechanistic evidence that this association may contribute to pAKT activation in HER2+ cells. Current efforts are focused on elucidating how BBO-10203 affects the interaction of HER2/3, p85/110α and RRAS2 in HER2+ and other RTK-overexpressing cell line models. Given its orthogonal method of pAKT inhibition and potent activity in HER2+ models, we hypothesized that BBO-10203 would show combination activity with standard-of-care HER2-targeted therapies in HER2+ xenograft models. Indeed, BBO-10203 enhanced the anti-tumor activity of HER2-targeted therapies (tucatinib, trastuzumab, or Enhertu) *in vivo*, leading to tumor regression, even in the trastuzumab-resistant JIMT-1 model. BBO-10203 has entered phase 1 clinical trials (NCT06625775) and is being evaluated in HER2+ breast cancers, both as a monotherapy and in combination with trastuzumab.

#6781 First in class catalytic inhibitor of KAT2A/B demonstrates anti-tumor activity in multiple myeloma.

K. Jensen-Pergakes, S. O'Connell, S. Ninkovic, N. Miller, C. Restaino, A. Ranjan, S. Linker, D. J. Ramms, H. Lam, A. Rohner, P. Alan, R. Visswanathan, E. C. Greenwald, P. Shelton, D. Sandoval, J. Hoffman, J. Donaldson, G. Rescourio, K. Abayasiriwardana, A. Udyavar, T. A. Paul;
Pfizer, Inc., San Diego, CA

KAT2A/B are lysine acetyltransferases that function as catalytic members of the SAGA and ATAC protein complexes, which are lineage dependencies in several tumor types including multiple myeloma (MM). Here we describe a first-in-class, small molecule catalytic inhibitor targeting the lysine acetyltransferases KAT2A and KAT2B. KAT2 inhibition disrupts oncogenic transcriptional programs, including MYC and E2F pathways, leading to growth arrest in multiple myeloma. KAT2 catalytic inhibition reduces chromatin accessibility through the loss of H3K9ac and shows single-agent activity across a panel of MM cell lines. KAT2 inhibition demonstrates tumor growth inhibition as a monotherapy in both immune modulatory drug (IMiD) sensitive and resistant multiple myeloma tumor models with good correlation with reduction of H3K9ac in vivo. KAT2 inhibition has synergistic effects with IMiDs in vitro and demonstrates increased tumor growth inhibition in combination with pomalidomide and dexamethasone in vivo. Additionally, KAT2 inhibition enhances tumor immunogenicity by activating interferon regulatory factors (IRFs) and upregulating interferon-stimulated genes (ISGs). Using a syngeneic mouse model of MM, KAT2 inhibition alters the tumor microenvironment through increased infiltration of pro-inflammatory immune cells, resulting in tumor growth inhibition and enhanced survival in combination with a mBCMA-CD3 bispecific antibody. KAT2 catalytic inhibition represents a novel therapeutic approach targeting epigenetic regulation of tumor intrinsic and immune pathways in hematologic malignancies.

#6782 Discovery of a new class of mutant-targeted catalytic RAS(ON) inhibitors with retained antitumor activity in setting of emergent resistance due to elevated RAS flux.

K. Seamon[1], J. Yin[1], O. Onguka[1], O. Lai[1], C. Blaj[1], L. Jiang[1], J. Liu[1], Y. Huang[1], A. Marquez[1], J. Knox[1], J. Cregg[1], Y. Zhuang[1], Y. Yang[1], U. N. Wasko[1], Q. Liu[1], J. A. Roth[2], M. G. Rees[2], M. Ronan[3], B. J. Maldonato[1], M. Al-Radhawi[1], K. Jayashankar[1], Z. Wang[1], M. Flagella[1], E. Quintana[1], E. S. Koltun[1], M. Singh[1], Z. Wang[1], A. L. Gill[1], D. [1]Revolution Medicines, Inc., Redwood City, CA, [2]Broad Institute, Cambridge, MA, [3]Broad Institute of MIT and Harvard, Cambridge, MA

RAS family proteins regulate cell growth by transitioning between GTP-bound (ON) and GDP-bound (OFF) conformations. Transition to the OFF state is facilitated by endogenous GTPase activating proteins (GAPs). Oncogenic mutations in RAS - among the most prevalent genetic events in human cancer - perturb this regulatory cycle by disrupting GAP-mediated stimulation of GTP hydrolysis, leading to sustained RAS activation. The investigational RAS(ON) multi-selective inhibitor daraxonrasib has a dual mechanism of RAS(ON) inhibition: disrupting RAS(ON) effector binding and activating RAS(ON) GTPase activity. Daraxonrasib has demonstrated encouraging response rates and durable antitumor activity with acceptable tolerability in patients with RAS-addicted cancers. Additional strategies are needed to counter emergent drug resistance and further extend clinical benefit. The majority of acquired genomic resistance mechanisms to daraxonrasib converge on reactivation of RAS(ON) and, in particular, RAS gene amplification, highlighting a potential opportunity for RAS(ON) inhibitors less sensitive to such resistance mechanisms. We have leveraged our understanding of tri-complex RAS(ON) inhibitors to design a new class of inhibitors that mimic the catalytic activity of natural GAPs. These compounds bind non-covalently to cyclophilin A to form a binary complex that selectively engages RAS(ON) proteins, including mutant and wild-type variants. The primary mechanism of action of these catalytic RAS(ON) inhibitors is to markedly accelerate the GTPase activity of oncogenic RAS mutants and promote conversion of RAS(ON) to RAS(OFF). Importantly, a single CYPA:catalytic RAS(ON) binary complex can inactivate multiple RAS(ON) proteins. In G12-mutant cell lines the catalytic RAS(ON) inhibitors more efficiently reduced RAS-GTP levels and exhibited more potent inhibition of RAS(ON) signaling and cell proliferation compared to daraxonrasib. In vivo oral administration of the catalytic RAS(ON) inhibitor RM-055 preferentially suppressed RAS pathway activation in G12-mutant tumors relative to normal tissues. At well-tolerated doses RM-055 demonstrated robust antitumor activity represented by deep and particularly durable responses across a panel of G12-mutant xenograft and syngeneic models of PDAC, NSCLC, and CRC, including models refractory to daraxonrasib monotherapy. Furthermore, RM-055 overcame acquired resistance to RAS(ON) inhibition, driving deep and durable regressions in models with elevated oncogenic RAS signaling, such as those with RAS amplification. Collectively, these preclinical data support evaluation of the potential of this new class of mutant-targeted catalytic RAS(ON) inhibitors to sustain clinical antitumor activity in the setting of emergent resistance mechanisms that rely on enhanced RAS pathway flux.

#6731 CQ-0736, a new polysaccharide-based therapeutic modality, targets pan-KRAS tumors with robust antitumor activity via macropinocytosis.

Jinghua Hu, Si Wang, Yikang Shi, Xiaohai Li, Weiping Jia, Maoxu Ge, Tingchao Liu, Li Yang, Meng Huo, Anny Wang, Ling Zhao

Santolecan Pharmaceuticals LLC, Jupiter, FL

Oncogenic RAS mutations are among the most prevalent and intractable drivers of human cancer, present in nearly 20% of cases. These mutations not only fuel uncontrolled tumor growth but also reprogram cellular metabolism by dramatically increasing macropinocytosis. This unique “nutrient scavenging” pathway is critical for RAS-driven cancer cells yet largely dispensable in normal tissues and presents a powerful and underexploited therapeutic opportunity.

To address this unmet need, we developed CQ-0736, a first-in-class “Trojan horse” therapeutic that exploits macropinocytosis to selectively co-deliver two synergistic drugs into the pan-KRAS tumors. CQ-0736 is a polysaccharide-based dual-drug conjugate consisting of a 100 kDa dextran backbone covalently grafted with docetaxel (DTX) and gamma-linolenic acid (GLA). This drug construct converts the RAS-driven tumor cell membrane from a “natural barrier” into an “active transport interface”, enabling unprecedented levels of intracellular drug accumulation specifically at tumor sites.Preclinical studies demonstrate the highly transformative potential of CQ-0736. *In vitro*, it exhibited markedly greater cytotoxicity than parent DTX across multiple pan-KRAS cancer cell lines harboring $KRAS^{G12D,}$ $KRAS^{G12C}$, and $KRAS^{WT}$ mutations. Several *in vivo* xenograft models showed that CQ-0736 achieved more than 95% tumor growth inhibition without weight loss or observed toxicity, regardless of KRAS mutation status. Remarkably, the direct head to head *in vivo* comparisons revealed that CQ-0736 significantly outperformed the world-class pan-RAS inhibitor RMC-6236 and the marketed KRAS targeted drug Krazati, displaying superior efficacy, longer durability, and much less drug resistance.Mechanistic analyses confirmed that CQ-0736 robustly suppresses proliferation (decreasing PCNA and Ki-67) while driving apoptosis (elevating cleaved PARP), producing superior effects to parent DTX. These findings underscore the conjugate’s dual impact on tumor biology and highlight its potential to overcome key limitations of both conventional chemotherapy and next-generation targeted RAS inhibitors, including systemic toxicity and acquired resistance.

Conclusion: CQ-0736 represents a highly innovative and clinically promising therapeutic strategy for RAS-driven cancers, a disease with devastating prognosis and few effective options. By turning a fundamental vulnerability of RAS-driven tumors into a drug delivery advantage, CQ-0736 opens a new therapeutic paradigm with the potential to significantly improve outcomes for patients with some of the most aggressive and treatment-resistant malignancies.

#6732 Potent, orally bioavailable small molecules that inhibit c-Myc translation and suppress tumor growth *in vivo*.

M. Kriner, C. Hwang, F. Koyanagi, B. Israels, T. Phan-Everson, W. Kratzman, I. Gupta, J. Fontana, D. Sparkman-Yager;
Wayfinder Biosciences, Seattle, WA

Dysregulation of c-Myc is implicated in over half of all cancers, making it the most important undrugged oncogene. As a transcription factor, the c-Myc protein is not amenable to traditional small molecule inhibition. Recent attempts to reduce c-Myc activity with novel modalities have had limited success in the clinic, highlighting the need for Myc-targeted therapeutics with improved potency and cell permeability. We previously reported discovery of small molecules that bind to structured elements in the 5' UTR of the c-Myc mRNA and repress translation of the c-Myc protein. Here, we describe our hit-to-lead campaign, in which we dramatically improved the potency (>70x), selectivity (>5x) and oral bioavailability (>13x) of our c-Myc RNA-targeting small molecules, yielding a lead series that suppresses tumor growth in an in vivo cell line-derived xenograft (CDX) model of small cell lung cancer (SCLC).

Using a ligand-based approach, we designed and synthesized over 150 analogs of our top hit series and characterized their ability to repress c-Myc protein levels and reduce viability of the highly MYC-amplified SCLC cell line NCI-H82. Notably, we observe excellent correlation between c-Myc protein repression and compound potency, supporting an on-target mechanism. Our compounds demonstrate rapid (~30 min half-life), selective and reversible protein knockdown, consistent with inhibition of c-Myc translation initiation followed by normal protein turnover. We have now achieved single-digit nanomolar potency and continue to make improvements thanks to the establishment of a strong structure-activity relationship for our lead series.

In parallel, we dramatically improved the ADME/PK properties of our series by identifying and correcting a structural liability for liver metabolism. The resulting tool molecule achieved >60% oral bioavailability and exposure above the in vitro IC50 for extended periods, enabling twice-daily oral dosing. This compound achieved significant tumor growth inhibition in a SCLC CDX model and, importantly, dosing was well tolerated by all animals. Beyond SCLC, we observe in vitro efficacy against cell lines from a range of solid and heme cancers, opening the door for xenograft studies in additional indications.

Together, our results validate an RNA-targeted small molecule approach to repress c-Myc. Our promising in vivo data, coupled with sustained oral exposure and favorable tolerability, highlight the potential of this modality to overcome long-standing barriers in MYC drug discovery. Ongoing xenograft and mechanistic studies are expected to further expand the clinical opportunities for treating MYC-driven solid and hematologic cancers.

#6733 Discovery and characterization of CBL-B intramolecular glue inhibitors that increase T cell activation and suppress tumor growth.

S. Gajewski, A. Taherbhoy, B. Bravo, K. Dhamnaskar, J. Sheung, D. Haria, A. Tenn-McClellan, J. Gosling, M. C. Clifton, M. Cardozo, P. A. Barsanti, J. R. Perkins, K. Boyle, T. Cummins, M. Lawrenz, M. Gallotta, J. T. Mihalic, N. O'Connell, S. Prakash, A. Saha, R. Rountree, C. Wang, D. R. Weiss, C. W. Zapf, **F. Cohen**;
Nurix Therapeutics, Brisbane, CA

Background. CBL-B, a RING-type E3 ubiquitin ligase, is a master regulator of peripheral T-cell activation and a promising immuno-oncology (IO) target. Genetic ablation of CBL-B in mice leads to enhanced T-cell activation and spontaneous tumor rejection, suggesting that pharmacological inhibition of CBL-B could reverse immunosuppression in the tumor microenvironment and potentiate anti-tumor immunity. This work describes the rational discovery of intramolecular glue inhibitors targeting the auto-inhibited conformation of CBL-B.
Methods. We designed and executed a high-throughput screening (HTS) campaign using a homogeneous time-resolved fluorescence (HTRF) assay to identify small-molecule inhibitors that stabilize the autoinhibited, closed conformation of CBL-B. Hits were validated through orthogonal HTRF and surface plasmon resonance (SPR) assays. The binding mode was elucidated by X-ray co-crystal structure. The series was optimized for affinity and properties through iterative cycles of medicinal chemistry. Lead compounds were evaluated for their ability to enhance T-cell activation and cytokine secretion in primary human T cells and for anti-tumor efficacy in a syngeneic mouse model.
Results. HTS of >250,000 compounds yielded a singleton hit that inhibited CBL-B activation with K_D = 24.12 ± 8.90 μM. Structure-guided optimization resulted in NRX-8766, with a K_D of 0.033 ± 0.001 μM for CBL-B. Treatment of human peripheral blood mononuclear cells (hPBMCs), with NRX-8766 results in 3- to 4-fold increases in T-cell activation markers (CD25, CD69) and 2- to 25-fold increases in cytokine secretion (IL-2, IFN-γ, TNF-α) when stimulated with α-CD3 or α-CD33/α-CD28. In vivo, oral administration of NRX-8766 to mice bearing syngeneic CT26 tumors significantly increased T-cell activation and suppressed tumor growth.
Conclusions. These studies demonstrate that pharmacological inhibition of CBL-B reproduces the reported mouse knockout phenotype. NX-1607, a first-in-class CBL-B inhibitor, is now in clinical development as a potential cancer immunotherapy.
Keywords: Immuno-oncology, CBL-B, molecular glue, T-cell activation, small-molecule inhibitor, high-throughput screening, tumor immunity

#6734 Discovery and optimization of NEO-811, a first-in-class molecular glue degrader of ARNT, utilizing structure-based drug design.

J. Griffin, A. Hernandez, X. Liu, K. Januszyk, B. Lee, A. Burt, J. Tellew, J. Lee, M. Cruz, I. Tran, K. Chiu, M. Wu, L. Bateman, A. Dominguez-Andres, L. Huang, J. Fathman, C. Sanchez, N. Cruz, R. Soriano, D. Knece, M. Fitzgibbon, A. Grant, M. Matyskiela, R. Beckwith, P. Chamberlain;
Neomorph, Inc., San Diego, CA

ARNT (HIF-1β), a member of the HIF family of transcription factors, heterodimerizes with HIF-2α to regulate the transcription of the hypoxic-response pathway. pVHL mutation leads to constitutive overactivation of HIF transcription, driving cancers such as clear cell renal cell carcinoma (ccRCC). Targeted degradation of ARNT represents a novel therapeutic approach to targeting this oncogenic pathway. Herein we disclose a structure-based drug design approach which afforded NEO-811, a first-in-class ARNT molecular glue degrader. Biochemical and cellular mechanism of action studies revealed ARNT degradation mediated by the CRL4-CRBN E3 ligase. A cryo-EM structure confirmed direct ARNT recruitment to CRBN and revealed opportunities to enhance the depth of degradation and selectivity against neosubstrates. A medicinal chemistry campaign incorporating structure-based drug design enabled the development of NEO-811, a potent and selective degrader of ARNT entering clinical trials for treatment of ccRCC.

#6735 DNA-templated, spatially controlled proteolysis targeting chimeras enable coordinated degradation of the Cyclin D1-CDK4/6 complex.

R. Zheng, A. Prasad, D. Satyabola, Y. Xu, S. Roy, Y. Yan, P. Sulc, H. Yan;
Arizona State University, Tempe, AZ

Background: Hyperactivation of the Cyclin D-CDK4/6 complex drives tumor proliferation across cancers. Although CDK4/6 inhibitors provide clinical benefit, durability is limited by resistance and by Cyclin D1's CDK-independent oncogenic functions that are not addressed by kinase blockade. A strategy that removes the entire Cyclin D1-CDK4/6 complex could suppress both kinase-dependent and independent signaling; however, Cyclin D1 lacks a druggable active site, and prior PROTACs have degraded CDK4/6 individually rather than the intact complex. These gaps motivated the development of DNA templated degraders to program geometry and enable synchronous complex degradation.
Methods: This study engineered DNA-templated proteolysis-targeting chimeras (DTACs) by positioning a CDK4/6 binder and an E3 ligase recruiter on complementary oligonucleotides, enabling systematic variation of intermolecular distance and orientation. A panel of DTACs was profiled for target engagement and degradation (Cyclin D1, CDK4, CDK6), cell-cycle distribution, and antiproliferative activity across cancer cell models. Lead constructs were evaluated for in vivo target degradation and antitumor activity in xenograft models.
Results: Spatial programming dictated degrader performance: DTAC variants exhibited distance- and orientation-dependent degradation of the Cyclin D1-CDK4/6 complex. The optimized construct induced synchronous loss of Cyclin D1 together with CDK4 and CDK6, yielding pronounced G1 arrest and suppression of cellular proliferation. In a xenograft mouse model, lead product exhibited potent therapeutic efficacy by effectively degrading Cyclin D1–CDK4/6 and suppressing tumor growth.
Conclusions: DNA templating provides a modular strategy to control degrader geometry and achieve synchronized degradation of multi-protein complexes. DTACs enable coordinated Cyclin D1-CDK4/6 degradation with functional pathway blockade and antitumor activity. Overall, these findings demonstrate the feasibility of DTAC as a rapid, scalable, and modular platform for the spatial control of functional inhibitors for optimal effectiveness, making it a promising method for proximity-based therapeutics.

#6736 Discovery and characterization of BH-501284: A non-covalent, pan-KRAS inhibitor for treatment of diverse *KRAS*-mutant tumors.

Nancy Ling, Evan Rogers, Eugene Rui, Wei Deng, Ping Jiang, Zhenping Wang, Yue Hu, Joshua Choi, Danan Li, Anindya Sarkar, Levan Darjania, Geoffrey Oxnard, **Jean Cui**

BlossomHill Therapeutics, Inc., San Diego, CA

KRAS mutations are among the most prevalent oncogenic drivers, representing 25% of human cancers. While recently approved covalent KRAS G12C inhibitors have demonstrated meaningful clinical benefit, no targeted therapies are currently approved for other KRAS variants. Consequently, a large portion of the KRAS-driven patient population, including those with pancreatic carcinoma (PDAC), colorectal cancer (CRC), and non-small cell lung cancer (NSCLC), remain underserved. Furthermore, available G12C inhibitors have modest potency and limited durability of effect in clinic. Research attributed these modest outcomes to adaptive resistance mechanisms associated with secondary KRAS mutations or activation of bypass pathways. This resistance, along with unmet medical needs, has driven the development of new KRAS-directed therapies capable of targeting multiple KRAS mutants. Here, we describe BH-501284, a potent, selective, orally available, non-covalent, pan-KRAS inhibitor, targeting the allosteric switch-II pocket of KRAS. BH-501284 inhibited cell viability and suppressed ERK phosphorylation in KRAS-mutant cells (G12D/C/V/S, G13D) and KRAS WT amplified cells with low to sub-nanomolar activity. BH-501284 also demonstrated greater than 300-fold selectivity against both HRAS and NRAS and showed no anti-proliferative activity in non-RAS driven cells. Raf1 effector binding assay data showed BH-501284 to bind KRAS mutants in the inactive (OFF) state, with binding affinity in the picomolar range as measured by SPR. Cellular wash off studies confirmed that BH-501284 tightly engaged KRAS, similar to covalent inhibitors. This unique target engagement allows BH-501284 to more comprehensively reduce active KRAS proteins than other reversible KRAS (ON) inhibitors. Importantly, the anti-proliferation activity of BH-501284 was only minimally affected by growth factors (e.g. EGF) that drive KRAS into the active state and lead to resistance. Durable and potent activity of BH-501284 was also observed in cell-derived xenograft (CDX) tumor models with KRAS G12D, G12V, and G12C mutations, covering NSCLC, CRC, and PDAC. PK profiling revealed good oral bioavailability of BH-501284 in multiple species and dose dependent plasma exposures in mouse xenograft tumor models. Lastly, BH-501284 showed synergistic effects with inhibitors of EGFR, FAK/SRC, and others in combination studies. Altogether, these findings position BH-501284 as a strong candidate for further development.

#6737 Selective degradation of pathologic multimers via a novel TRIM21-engaging molecular glue and PROTAC platform.

N. Huang[1], **A. Yu**[2], Y. Liu[2], N. Zheng[2], T. Han[1];
[1]Tsinghua University, Beijing, China, [2]DeepKinase Biotechnologies Ltd., Beijing, China

Background: Targeted protein degradation (TPD) holds great promise for cancer therapy, but its application is often constrained by the limited repertoire of E3 ligases and the challenge of selectively eliminating pathologic protein assemblies, such as those driving oncogenesis, while sparing monomeric forms. The E3 ligase TRIM21 is a compelling yet underexplored effector, as its activation is hypothesized to require substrate multimerization, potentially conferring intrinsic selectivity for diseased-associated protein complexes.
Methods and Results: We report a novel TPD strategy centered on the activation of TRIM21. Initially, we discovered that (S)-ACE-OH, a metabolite of acepromazine, functions as a molecular glue by inducing a productive interaction between TRIM21 and the multimeric Nuclear Pore Complex (NPC) component NUP98. To systematically map the specificity and scope of this degradation event, we employed quantitative and TurboID proteomics. This analysis confirmed the potent and selective degradation of multiple NPC proteins, consistent with the disruption of a large multiprotein complex. Crucially, monomeric proteins remained unaffected, validating the hypothesized multimer-selectivity of TRIM21-based degradation. This selectivity was further demonstrated by engineering acepromazine-based PROTACs, which effectively degraded diverse multimeric client proteins, including components of biomolecular condensates.
Conclusion: Our work establishes TRIM21 as a promising new E3 ligase for TPD, capable of selectively targeting multimeric proteins and pathologic assemblies. The proteomic analyses were pivotal in unequivocally defining this unique selectivity profile, providing a robust experimental foundation for this platform. This TRIM21-based degradation strategy opens a new therapeutic avenue for directly targeting undruggable, multimeric oncoproteins, with broad implications for cancer treatment.

#6758 MUlti-epitope Targeting Tetravalent Antibody (MUTTA™) platform for developing NexGen ADCs with an improved therapeutic window.

Sunil Bhakta, Jiang Liu, Levi Blazer, Jarrett Adams, Vasu Jammalamadaka, Anbalagan Jaganathan, Shane Miersch, Viswanatham Katta, Anay Limaye, Ying-Ping Jiang, Vidya S. Jonnalagadda, Reva Raghupathi, Pradeep Fernandes, Sean Givens, Paul Polakis, Sachdev S. Sidhu, **Jagath R. Junutula**

Aarvik Therapeutics, Inc., Hayward, CA

Antibody-drug conjugates (ADCs) are a class of targeted chemotherapeutic precision medicines that became available to oncology clinical practice in 2000. In the 25 years since, >450 ADCs have progressed into the clinic, of which only 15 ADCs have been approved by the FDA, while >130 have been discontinued or are inactive. The high failure rate (~90%) of ADCs in the clinic is often associated with factors such as low tumor antigen copy number, heterogenous expression of tumor targets in solid tumor cancers, target antigen escape, poor internalization, efficacy-limiting off-target toxicity, and developability risks. Aarvik Therapeutics has developed a novel MUlti-epitope Targeting Tetravalent Antibody (MUTTA™) platform to engineer NextGen ADCs with multifunctional properties to tackle difficult-to-treat solid tumor cancers. The MUTTA™ ADC platform is designed to overcome many of the limitations described above and to broaden the therapeutic window of ADCs. MUTTA™ ADCs apply an OR-gate approach and can address therapeutic limitations such as antigen escape seen with monospecific ADCs in the treatment of solid tumors. We focused initially on developing tetravalent antibody formats with optimal manufacturing properties by screening several tetravalent antibody formats using few hundred constructs and successfully identified MUTTA™ formats specifically suitable for the ADC drug development. To develop and validate the MUTTA™ platform and to test its utility to generate multifunctional therapeutic antibodies, we initially applied this technology to well-validated tumor targets such as Her2 and EGFR for which clinically proven function-blocking antibodies (e.g., trastuzumab, pertuzumab, cetuximab) are available. We successfully engineered a MUTTA™ antibody with 4 different antibody functionalities (4-in-1) and demonstrated functional synergy in blocking-ERK phosphorylation in a trastuzumab-resistant cancer cell line. We demonstrated that multi-target MUTTA™ antibodies display superior internalization over single-target antibodies. In addition, MUTTA™ ADCs exhibited superior cellular potency compared to single-target ADCs and exhibited normal IgG-like pharmacokinetic properties. We further applied the MUTTA™ platform to several solid tumors such as Breast, Colon, Lung, Ovarian, Prostate and Pancreas by first identifying complementary tumor antigens based on co-expression profiles in these solid tumor cancers and then engineering optimally-designed multi-target MUTTA™ ADCs based on this analysis. We will present data that demonstrate *in vitro* and *in vivo* validation of multi-target MUTTA™ ADCs and their improved therapeutic window compared to single-target ADCs, as well as the broad applicability of the MUTTA™ platform across several tumor antigens.

#6759 High-throughput drug screening and single-cell network analysis identify rational combination therapies in IDH-mutant glioma.

Patrick Kerwin, Luca Zanella, Andrea Califano

Columbia University, New York, NY

IDH-mutant gliomas are lethal brain tumors marked by multiple coexisting malignant cell states, likely to elicit heterogeneous drug sensitivities thus limiting the effectiveness of monotherapy. To address this challenge, we integrated multimodal single-cell analysis and functional high-throughput drug screening to identify and pharmacologically target state-specific vulnerabilities, thus supporting rational combination therapy development. Single-nucleus RNA sequencing (snRNA-seq) of 20 treatment-naïve, low-grade IDH-mutant gliomas, followed by Master Regulator (MR) analysis, identified key proteins representing mechanistic determinants of three established malignant states: astrocyte-like (AC), oligodendrocyte-like (OC), and neural progenitor cell-like (NPC). The analysis revealed that the AC state is transcriptionally orthogonal to OC, whereas the OC and NPC share substantial regulatory architecture. OncoMatch analysis identified patient-derived models (SF10417, SU-A03) that optimally recapitulate the MRs of these malignant subpopulations, supporting screening of a 374 oncology-focused compounds (FDA-approved and investigational) followed by transcriptional profile analysis at 24h, using the PLATE-seq technology, resulting in a comprehensive drug perturbational compendium for IDH-mutant gliomas. OncoTreat analysis prioritized compounds based on their ability to invert the aberrant MR activity signatures of each malignant state, revealing highly cell-state-specific drug sensitivities, supporting the design of rational combination strategies targeting tumor plasticity. For example, we found that AC-like cells may first be primed with the mTOR inhibitor temsirolimus to reprogram them toward a more drug-sensitive OC-like state, thereby converting a resistant lineage into one that is more vulnerable, including to the new class of IDH1 inhibitors. A second-line agent such as the HDAC inhibitor romidepsin or the topoisomerase inhibitor irinotecan can then be used, possibly in combination with IDH1 inhibitors, to target the resulting OC-like and pre-existing OC/NPC cells, thus implementing a two-step, sequential treatment strategy. In parallel, barcode-based lineage tracing in SF10417 and SU-A03 is being used to monitor cell-state stability and plasticity under drug treatment, while top candidate agents and combinations are being validated in patient-derived *ex vivo* glioma slice cultures that preserve the native microenvironment. Single-cell and spatial transcriptomic profiling (10x Genomics Xenium) of treated slices will map the reprogramming and elimination of malignant subpopulations in situ. Together, this framework provides a blueprint for discovering state-specific dependencies in IDH-mutant glioma and for guiding rational, combination-based strategies to overcome intratumoral heterogeneity.

#6760 Age-dependent lung vulnerability identifies serum hyaluronic acid as a predictive biomarker of ADC-induced interstitial lung disease.

Liming Jin[1], Ye Lu[2], Qing Wei[3], Peng Guo[2], Liu Yang[4], Dawei He[5]

[1]Hangzhou Institute of Medicine, Hangzhou, China,[2]Hangzhou Institute of Medicine, Chinese Academy of Sciences, Hangzhou, China,[3]Zhejiang Cancer Hospital, Hangzhou, China,[4]Zhejiang Provincial People's Hospital, Hangzhou, China,[5]Children's Hospital of Chongqing Medical University, Chongqing, China

Background: Interstitial lung disease (ILD) is a serious and unpredictable toxicity associated with antibody-drug conjugates (ADCs) such as trastuzumab deruxtecan (T-DXd). However, the cellular origins, age-specific susceptibility, and actionable biomarkers of ADC-induced ILD remain undefined. Here, we combined animal modeling, single-cell transcriptomics, functional assays, and clinical validation to elucidate the mechanistic basis of ILD susceptibility and identify circulating biomarkers predictive of ADC-induced ILD.
Methods: Age-stratified mouse models (postnatal, adolescent, adult) were treated with T-DXd, followed by lung pathology evaluation and pulmonary function analysis. Single-cell RNA sequencing profiled the lung microenvironment across age groups. Functional assays assessed the maturity and phagocytic capacity of alveolar macrophages. Endothelial injury was evaluated by immunohistochemistry, TEM, and analysis of hyaluronidase expression. Plasma hyaluronic acid (HA) levels were quantified, correlated with ILD severity, and tested in a clinical validation cohort consisting of 20 ADC-induced ILD patients and non-ILD controls.
Results: ILD susceptibility was strongly age-dependent, with only adult mice developing interstitial thickening, inflammatory infiltration, and impaired lung function, whereas postnatal and adolescent mice remained protected. Single-cell profiling revealed an adult-specific inflammatory ecosystem with expansion of ILD-associated immune populations absent in immature lungs. Postnatal mice were protected by immature alveolar macrophages with low phagocytic activity and reduced inflammatory signaling, contrasting with the mature, pro-inflammatory macrophages in adults that facilitated ILD onset. Endothelial cells emerged as the earliest and most vulnerable targets of T-DXd, showing the greatest transcriptional perturbation and induction of HYAL2/TMEM2, supported by protein-level and ultrastructural evidence of injury. HYAL2/TMEM2 activation drove excessive HA release into circulation, and plasma HA correlated with ILD severity across mouse models. Importantly, clinical validation in 10 ILD patients showed significantly elevated HA levels compared with 10 ADC-treated controls, with ROC analysis confirming HA as a predictive biomarker consistent with preclinical findings.
Conclusions: Using age-stratified models and single-cell resolution, we identify endothelial injury and hyaluronidase upregulation as early, age-dependent drivers of ADC-induced ILD. We further show that circulating HA is a clinically validated biomarker capable of predicting ILD risk. This integrated preclinical-clinical study provides a new understanding of ILD susceptibility and establishes serum HA as a promising biomarker for early ILD detection and risk stratification in ADC therapy.

#6761 Antitumor activity of datopotamab deruxtecan in a co-clinical trial with patient derived xenografts.

Dhruv Chachad[1], Kurt W. Evans[1], Ming Zhao[1], Erkan Yuca[1], Ran Zhang[1], Yasmeen Rizvi[1], Gabriela Raso[2], Argun Akcakanat[1], Stephen Scott[1], Justin M. Roberts[1], Ming Sun[1], Nakul Shah[3], Hong Zebger-Gong[4], Gunnar Klauss[4], Yui Tanaka[4], Daisuke Okajima[4], Funda Meric-Bernstam[1]

[1]Investigational Cancer Therapeutics, UT MD Anderson Cancer Center, Houston, TX,[2]Translational Molecular Pathology, UT MD Anderson Cancer Center, Houston, TX,[3]Division of Cancer Medicine, UT MD Anderson Cancer Center, Houston, TX,[4]Daiichi Sankyo, Inc., Berlin, Germany

Trophoblast cell-surface antigen-2 (TROP2) is expressed in multiple cancers. Datopotamab deruxtecan (Dato-DXd) is an antibody drug conjugate (ADC) consisting of a humanized anti-TROP2 IgG1 monoclonal antibody covalently linked to a highly potent topoisomerase I inhibitor payload. Dato-DXd is FDA approved for hormone receptor-positive, HER2-negative breast cancer and *EGFR*-mutated non-small cell lung cancer following EGFR-directed therapy and platinum based chemotherapy. However, determinants of response and optimal combinations need further study. We performed a co-clinical trial, to determine the concordance of anti-tumor activity of Dato-DXd in patient derived xenografts (PDX) and matched patients treated with Dato-DXd (TP01) and to assess potential of combinations.We generated 23 PDX models of different cancer types: breast invasive ductal carcinoma, lung adenocarcinoma, urothelial carcinoma, esophageal adenocarcinoma, head and neck carcinoma and pancreatic adenocarcinoma (PDAC). Nineteen models were created from biopsies performed just before Dato-DXd treatment of patients and 4 models were generated after the patients acquired resistance to Dato-DXd. The antitumor efficacy of Dato-DXd and the isotype control-DXd (IgG-DXd) were tested. Antitumor activity was assessed by objective response and event-free survival (time to tumor doubling) per PDXNET metrics. Based on our results from a previous synergy screen *in vitro*, four PDAC cell lines were also treated with a combination of Dato-DXd and gemcitabine. A total of 49 models were implanted, and 23 PDX models generated across 6 tumor types (PDX take rate of 47%). Of 13 pretreatment PDXs tested for Dato-DXd efficacy: 5 (38.5%) had a partial response, 3 (23%) had stable disease, and 5 (38.5%) had progressive disease. Antitumor activity in PDXs was concordant with matched patients treated with Dato-DXd and assessed by RECIST V1.1. in 10 out of 13 (77%) models. Ten of 13 (77%) PDXs had significant prolongation of event-free survival (EFS). Among 4 PDAC PDXs tested 2 (50%) had prolongation of EFS. We sought to identify chemotherapy combinations that enhance activity of Dato-DXd in PDAC cell lines *in vitro*, and determined that the combination of Dato-DXd and gemcitabine was synergistic. A pretreatment PDX model was generated from a patient with PDAC who had received topoisomerase inhibitor treatment (FOLFIRINOX) as well as gemcitabine/abraxane, and had PD as best response to Dato-DXd. The PDX model progressed on both Dato-DXd and gemcitabine monotherapy, but the combination therapy showed tumor regression, and significantly prolonged event-free survival compared to monotherapy ($p = 0.0067$ for both comparisons). Dato-DXd has antitumor activity in several tumor types. Combinations may further enhance antitumor activity. Further studies are needed to explore the mechanisms of resistance and potential combinations.

#6762 A novel therapeutic approach for targeting p53-mutant cancers by leveraging DNA damage response vulnerabilities.

Mohammed M. Alruwaili[1], Yanqi Guo[2], Justin Zonneville[2], Thomas Melendy[3], Robert M. Straubinger[4], Barbara A. Foster[5], Priyanka Rajan[2], Henry G. Withers[6], Sarah Chatley[7], Renuka V. Iyer[7], Christos Fountzilas[7], **Andrei V. Bakin**[2]

[1]Medical Laboratory Technology, Northern Border University, Arar, Saudi Arabia,[2]Department of Cancer Genetics and Genomics, Roswell Park Comprehensive Cancer Center, Buffalo, NY,[3]Department of Microbiology and Immunology, University at Buffalo, Buffalo, NY,[4]Department of Pharmaceutical Sciences,, University at Buffalo, Buffalo, NY,[5]Department of Pharmacology and Therapeutics, Roswell Park Comprehensive Cancer Center, Bufflo, NY,[6]Department of Biostatistics and Bioinformatics, Roswell Park Comprehensive Cancer Center, Buffalo, NY,[7]Department of Medicine, Roswell Park Comprehensive Cancer Center, Buffalo, NY

The tumor suppressor gene TP53 is frequently mutated in most solid malignancies, including colorectal and pancreatic cancers, driving tumor progression and metastasis. However, existing treatments often lack selectivity for p53-mutant (p53mut) cancers and are associated with high toxicity. To address this clinical challenge, we developed a two drug therapeutic approach that selectively targets p53-mutant cancers by combining TAS102, with a PARP inhibitor (PARPi). Mechanistically, incorporation of TFT into DNA triggers post-replicative repair, generating single-strand break intermediates. While PARP facilitates their repair, inhibition of PARP converts these intermediates into lethal double-strand breaks. In p53 wild-type (WT) cells, TAS102 and PARPi activate a p53-dependent G1/S checkpoint, enabling DNA repair and preventing excessive damage. In contrast, p53mut cells, lacking this checkpoint, experience uncontrolled DNA damage accumulation, leading to cell death. This combination demonstrated superior anti-tumor efficacy in p53-mutant cell lines and patient-derived xenograft (PDX) models compared to either agent alone, and was well tolerated in preclinical studies. This two-drug strategy is now being tested in Phase I clinical trial (NCT04511039) in advanced CRC patients showed no significant toxicity and improved PFS relative to historical TAS102 monotherapy. To further elucidate its mechanism, we investigated the DNA damage response (DDR) and checkpoint signaling in p53mut cancer cells. Our findings show that TAS102-PARPi induces a p53-independent G2/M checkpoint mediated by ATR kinase, which activates downstream kinases CHK1 and WEE1 to inhibit CDK1, thereby halting entry into mitosis. Our transcriptomic profiling revealed a marked induction of homologous recombination (HR)-associated double-strand break repair genes, including BRCA1, BRCA2 and RAD51, in p53-deficient cells following TAS102-PARPi treatment. This pronounced upregulation likely reflects enhanced DNA repair activity at the G2 checkpoint, orchestrated by ATR kinase. Based on this mechanistic, we tested whether the TAS102-PARPi regimen could be potentiated by targeting G2-checkpoint kinases. We developed a triple-drug therapeutic strategy that combines our two-drug regimen with a G2-checkpoint kinase inhibitor. Subsequent inhibition of checkpoint kinases such as WEE1 or ATR releases the G2-arrested cells into mitosis, resulting in mitotic catastrophe and cell death. Importantly, sequential administration, delaying the G2-kinase inhibitor after TAS102-PARPi, allows p53WT cells time to repair DNA, thereby minimizing toxicity to normal tissues. This sequential triple-drug strategy acts through a synthetic lethality mechanism, producing massive cell death in p53mut cancer models. In PDXs models, this regimen achieved robust tumor suppression without detectable toxicity.

#6763 KBD111 is a highly selective, long-acting and brain-penetrant PARP1 inhibitor.

Jing Zhang, Yang Chen, Yonggang Wei, Fei Ye, Zhiyong Li, **Xiaoke Liu**, Jiannan Cui

Kangbaida (Sichuan) Biopharmaceutical Technology Co., Ltd, Chengdu, China

Background: Currently, several pan-PARP inhibitors such as olaparib, niraparib, and rucaparib are approved for the treatment of cancers with homologous recombination deficiency (HRD). While these inhibitors have demonstrated significant clinical efficacy, their use is frequently limited by severe toxicities, especially hematological side effects associated with PARP2 inhibition. These adverse effects constrain the potential for combining PARP inhibitors with other anticancer therapies, underscoring the need for selective PARP1 inhibitors.

Methods: An enzymatic evaluation was performed to assess the activity and selectivity profile of KBD111 against major PARP family members. Cell proliferation was evaluated in the DLD-1 $^{BRCA2-/-}$ cell line. Pharmacokinetic studies were conducted in mice, rats, and dogs. The antitumor efficacy of KBD111 was investigated in DLD-1 $^{BRCA2-/-}$ and MDA-MB-436-luc mouse xenograft models. Mechanistic analysis revealed that PARP1 activity was reduced in DLD-1 $^{BRCA2-/-}$ tumor-bearing tissues. In addition, hematological toxicity was evaluated in vitro in $CD34^+$ hematopoietic stem cells and in vivo in rats.

Results: KBD111 exhibited over 5,000-fold selectivity for PARP2 by DNA-trapping assays, demonstrated potent anti-proliferative activity against BRCA-mutant cancer cell lines, while showing markedly reduced cytotoxicity toward normal $CD34^+$ hematopoietic stem cells (IC_{50} >10,000 nM) compared to talazoparib (IC_{50} = 27 nM). In addition, KBD111 exhibited excellent pharmacokinetic properties in different preclinical species and high blood-brain barrier (BBB) permeability. Furthermore, KBD111 achieved superior tumor growth inhibition compared to AZD5305 in DLD-1 $^{BRCA2^{-/-}}$ xenograft models following once every two weeks oral dosing. In an intracranial MDA-MB-436-luc model, KBD111 also demonstrated enhanced efficacy relative to AZD9574 under QW oral dosing. Notably, in vivo studies demonstrated that weekly (QW) treatment exhibited a better safety profile than QD dosing. Moreover, KBD111 was well tolerated in the 14-day toxicity studies in SD rats with 60-fold therapeutic window.

Conclusions: KBD111 is a highly potent, long-acting and brain-penetrant PARP1 inhibitor with superior PK properties in different species, supporting its development as a promising candidate for once every two weeks (Q2W) dosing. KBD111 demonstrated much less hematotoxicity than Olaparib and was well-tolerated in 14-day toxicity studies. A Phase 1 trial is planned for 2026.

#6764 Comparative profiling of TEAD palmitoylation and YAP-TEAD protein-protein interaction inhibitors as combination agents with KRAS inhibitors.

Danielle J. Sanchez[1], Jacob A. Gordon[1], Cynthia Xu[1], Alex Koers[2], Sarah Ross[2], James E. Brownell[1], Simon T. Barry[2], Carla P. Martins[2]

[1]Early Oncology R&D, AstraZeneca, Waltham, MA,[2]Early Oncology R&D, AstraZeneca, Cambridge, United Kingdom

TEAD proteins are the transcriptional effectors of the Hippo pathway that bind coactivators YAP/TAZ to activate genes involved in cell survival, proliferation, and drug resistance. Deregulation of the Hippo pathway leading to increased TEAD activity occurs in multiple cancers, including as an adaptive resistance mechanism to targeted therapies. TEAD transcriptional signatures are elevated in KRAS inhibitor-resistant cell lines, and genome wide CRISPR screens have identified multiple hits in the Hippo pathway which sensitize or confer resistance to KRAS inhibitors. Therefore, targeting the YAP/TAZ-TEAD axis has the potential to inhibit tumor growth as a monotherapy or combination strategy across diverse indications. TEAD inhibitor modalities being investigated clinically include TEAD “central pocket” palmitoylation inhibitors (CPIs) and YAP-TEAD protein-protein interaction inhibitors (PPIs). However, limited data exist on how targeting TEAD with these different classes of inhibitors compare in combination studies. We profiled the activity of a TEAD CPI and PPI alone and as combination agents with $KRAS^{G12C}$ and $KRAS^{G12D}$ inhibitors, assessing effects on TEAD-dependent transcription, proliferation, and tumor growth inhibition. In long-term *in vitro* outgrowth studies in six $KRAS^{G12C}$ and $KRAS^{G12D}$ cell lines, the TEAD PPI demonstrated increased growth inhibition compared to the CPI when combined with KRAS inhibitors. Additionally, the PPI re-sensitized $KRAS^{G12C}$-mutant NCI-H2122 cells resistant to AZD4625, a $KRAS^{G12C}$-selective inhibitor. Combination efficacy was observed across KRAS-mutant but not WT lines, confirming on-target activity of dual TEAD and MAPK pathway suppression. Mechanistically, the PPI suppressed TEAD-dependent transcription to a greater extent than the CPI *in vitro*, while reduced MAPK signaling was driven by KRAS inhibitors and not further enhanced by TEAD inhibition. Given the differences between CPI and PPI activity *in vitro*, combination efficacy was evaluated *in vivo* in three KRAS-mutant tumor models. In contrast to the *in vitro* results, CPI and PPIs drove equivalent regression of NCI-H2122 NSCLC xenografts when combined with the $KRAS^{G12C}$ inhibitor sotorasib, followed by similar outgrowth once dosing was stopped. However, the robust combination efficacy observed *in vitro* did not translate to significant tumor growth inhibition with either TEAD modality in two $KRAS^{G12D}$-mutant pancreatic models, Panc04.03 and Panc10.05. Collectively, these findings suggest that while differential activity was observed between TEAD CPI and PPIs *in vitro*, the two modalities drove similar therapeutic benefit *in vivo* when combined with KRAS inhibitors. Careful exploration of the long-term benefit of TEAD and KRAS inhibitor combinations is warranted due to the disconnect between *in vitro* and *in vivo* data.

CML is defined by evolution from chronic phase (CP) to increased disease burden during blastic phase, but the cellular mechanisms that create these disease states and produce the transition between states is not understood. We previously used state-transition models to show that CML evolution is not encoded in single-cell transcriptional microstates but instead emerges only when gene expression is aggregated into population-level macrostates where distinct phenotypic disease states emerge. Here, we extend this framework to ask how antagonistic teams of genes and their regulatory network defined steady states give rise to these macrostates. Using weekly time-series single-cell RNA sequencing from both CP and blast crisis (BC) inducible CML mouse models, we assessed the origin of phenotypic disease macrostates in each cell type by identifying antagonistic teams of genes. We identified these teams for each cell type lineage by selecting the genes where their eigenvalue in the state-space construction and their observed expression change combine to indicate that the gene either strongly promoted (pro-CML) or strongly opposed (anti-CML) leukemia. To coarse grain the large number of resulting of genes per lineage, we applied weighted gene coexpression network analysis (WGCNA) to define gene modules and module eigengenes that define coordinated transcriptional programs. Each module produced by this process were strongly enriched for either pro- or anti-CML which suggests that they define functional units in leukemia development. We then inferred gene regulatory networks for these modules using Bayesian network inference constrained by prior knowledge from curated interaction and regulatory databases. This produced module-level networks that were unique for each of the B, T, myeloid, and stem cell compartments. For each inferred network, we computed steady states (attractors) and projected the stable transcriptional configurations into the state-space to determine whether the gene derived attractors align with lineage-specific macrostates in the state-space. Preliminary analyses reveal that module networks can reproduce the early, transitional, and late CML macrostates observed from our previous study. Further, we performed in silico perturbations of the networks to predict shifts in attractor occupancy and recapitulate our previous findings that the dominant contributions of B and myeloid compartments to disease progression observed previously. These results support a mechanistic view of leukemia where CML macrostates arise from cell type-specific teams of genes organized into low-dimensional regulatory networks. These network level attractor states could provide a new approach to identify therapeutic targets that are directly related to disease phenotypes and, therefore, new approaches for preventing CML disease evolution.

#6831 Virtual clinical trials of BMP4 differentiation therapy.

Nicholas Harbour[1], Lee Curtin[2], Loizos Michaelides[3], Matthew E. Hubbard[4], Pamela Jackson[2], Vinitha Rani[3], Rajappa Kenchappa[3], Virginea Farias[3], Anna Carrano[3], Markus Owen[1], Alfredo Quinones-Hinojosa[3], Kristin Swanson[2]

[1]Centre for Mathematical Medicine and Biology, The University of Nottingham, Nottingham, United Kingdom,[2]Mathematical Oncology Systems Analysis of Imaging Center (MOSAIC), Cedars-Sinai, LA, CA,[3]Department of Neurosurgery, Mayo Clinic Florida, Jacksonville, FL,[4]School of Mathematical Sciences, The University of Nottingham, Nottingham, United Kingdom

Glioma stem cells (GSCs) are considered a major driver of glioblastoma (GBM) progression and are highly resistant to standard cytotoxic treatments. BMP4 has been shown to promote GSC differentiation, enhance radiosensitivity, slow tumor growth, and extend survival in animal models. Despite this promise, BMP4 has yet to achieve clinical impact, owing largely to heterogeneous and nonlinear responses across preclinical experimental systems. To elucidate how BMP4 could function as an effective targeted differentiation therapy in GBM, we develop a mathematical model that describes the growth of a GBM tumor via a hierarchy of GSCs, progenitor and terminally differentiated cells. We parameterize our model using new radiotherapy and proliferation assay data (with and without BMP4 exposure) from twelve patient-derived GSC lines. This integration of model and data allows us, for the first time, to quantitatively capture patient-specific heterogeneity in BMP4 sensitivity. We perform global sensitivity analysis on the model, identifying proliferation rate and GSC self-renewal sensitivity as key determinants of BMP4 efficacy. These parameters act as model-derived biomarkers that distinguish BMP4-responsive tumors from non-responsive ones. In an in silico analysis across a broad cohort of virtual patients, we find that continuous BMP4 delivery from surgical resection through radiotherapy consistently outperforms a single-dose strategy. Virtual clinical trials further show that, without stratification using these model-derived biomarkers, BMP4 yields little observable therapeutic benefit. In contrast, selecting patients with more proliferative, BMP4-responsive GSCs markedly increases the likelihood of observing a significant treatment effect.

#6832 Toward personalized rotational multi-agent therapies to overcome treatment resistance in pancreatic cancer: A virtual trial framework in mice.

Krithik Vishwanath[1], Hoon Choi[2], Mamta Gupta[2], Rong Zhou[3], Anna G. Sorace[4], Thomas E. Yankeelov[5], Ernesto A.B.F. Lima[6]

[1]Oden Institute for Computational Engineering and Sciences, The University of Texas at Austin, Austin, TX,[2]Department of Radiology, The University of Pennsylvania, Philadelphia, PA,[3]Department of Radiology, Abramson Cancer Center, The University of Pennsylvania, Philadelphia, PA,[4]Department of Radiology, Department of Biomedical Engineering, The University of Alabama, Birmingham, Birmingham, AL,[5]Oden Institute for Computational Engineering and Sciences, Department of Biomedical Engineering, The University of Texas at Austin, Austin, TX,[6]Oden Institute for Computational Engineering and Sciences, Texas Advanced Computing Center, The University of Texas at Austin, Austin, TX

Introduction. Pancreatic ductal adenocarcinoma (PDAC) is highly lethal in part because tumors rapidly evolve resistance to potent regimens. Rotational, multi-agent schedules have emerged as a promising approach to outpace this adaptive escape. To attack this problem, we propose a mechanistic “virtual-trial” framework that couples an ordinary differential equation model with patient-specific data to quantify responses to three first-line chemotherapies (cisplatin, paclitaxel, gemcitabine), stromal-modulating agents (calcipotriol, losartan), and an immune-checkpoint inhibitor (anti-PD-L1). Using an estimated dynamic resistance, our model provides an in-silico testbed for generating and ranking rotational-therapy hypotheses before clinical translation, supporting more adaptive treatment design for pancreatic cancer.

Methods. Longitudinal tumor volume measurements for five distinct combinations of therapy agents were acquired in 49 mice over 14 days. Our mathematical model captures key physiological features such as tumor proliferation, drug efficacy, and temporal treatment resistance to emulate the progression and regression of pancreatic tumors to predict variation in tumor growth. Bayesian calibration of model parameters is derived on data from *in vivo* experiments conducted on mice with a genetically engineered model (GEM) of pancreatic cancer (KPC). We use adaptive optimization to develop personalized rotational therapy regimes across a 2-week simulation of 1000 patients.

Results. The model successfully mimics tumor growth in both control and treatment cases, with an average concordance correlation coefficient (CCC) of 0.99 ± 0.01 when comparing observed and predicted changes in tumor volumes. We extend our analysis by conducting leave-one-out predictions (average CCC = 0.7 ± 0.06), mouse-specific predictions (average CCC = 0.75 ± 0.02), and group-informed, mouse-specific predictions (CCC = 0.85 ± 0.04). Group-informed, mouse-specific predictions show an 82.17 ± 15.07% accuracy in discerning responders from non-responders. Our optimization predicts that switching to a personalized, adaptive schedule would cut median tumor burden by 30.5% and shrink final tumor volume by a median 65.9% relative to any fixed protocol in simulated mice.

Conclusion. Our modeling framework reproduces the experimental tumor-growth data and demonstrates strong predictive power for how pancreatic tumors respond to varied therapeutic combinations. By correctly classifying most responders versus non-responders and by forecasting sizable reductions in tumor burden with individually optimized rotational schedules, the approach offers a practical in-silico tool for designing adaptive treatment regimens. Our framework lays the groundwork for adaptive clinical trials poised to finally outmaneuver PDAC resistance and improve outcomes.

#6834 Modeling the role of homeostatic T-cell reconstitution in durable response to CAR T-cell therapy.

Philipp Martin Altrock[1], Alvaro Martinez-Rubio[2], Maria Rosa[3], Arne Traulsen[4], Michael D. Jain[5], Frederick L. Locke[6]

[1]Hematology & Oncology, Universitatsklinikum Schleswig-Holstein, Kiel, Germany,[2]Computational Oncology Unit, Institut Curie, Paris, France,[3]Biomedical Research and Innovation Institute of Cadiz, Puerta del Mar University Hospital, Cadiz, Spain,[4]Department of Theoretical Biology, Max Planck Institute for Evolutionary Biology, Ploen, Germany,[5]H. Lee Moffitt Cancer Center & Research Institute, Tampa,, FL,[6]H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL

Anti-CD19 Chimeric Antigen Receptor (CAR) T-cell therapy is a promising option for relapsed or refractory lymphoma patients, yet our mechanistic understanding of response heterogeneity remains incomplete. Using retrospective longitudinal data from 21 patients treated with axicabtagene ciloleucel (including CAR T counts, absolute lymphocyte counts, tumor burden, and survival), we developed a computational modeling approach to distinguish between two expansion mechanisms: homeostasis- and antigen-driven. For each patient, we trained and compared three-compartment models to describe the dynamics of normal T-, CAR T-, and tumor cells. Comparisons revealed two distinct patient groups: patients who can be exclusively characterized by homeostatic proliferation as the CAR T expansion mechanism (homeostatic expanders, 10/21) and those of mixed type (mixed homeostatic/antigen-driven expanders, 11/21). These groups were distinguished by differences in the relationship between baseline metabolic tumor volume (taken one to two weeks before CAR T) and the inferred tumor burden at dosing. Notably, homeostatic expanders demonstrated significantly better overall survival (60% vs. 10% beyond day 180, $p = 0.011$), with 6 of 7 patients in this group achieving long-term responses. Our findings highlight how the ability of CAR T-cells to function in a homeostatic reconstitution context and the ability to quantify tumor burden at CAR T dosing influence the predictability of long-term responses. Our personalized mathematical modeling approach provides novel insights into optimizing CAR T-cell therapy and understanding the dynamics of cellular immunotherapy. Importantly, the absence of antigen-driven expansion increases the negative impact of high tumor burden at the time of infusion.

#6835 Multiomic state-transition framework reveals chemotherapy-induced metabolic reprogramming in acute myeloid leukemia.

Jennifer Rangel Ambriz[1], Ziang Chen[1], Yu-Hsuan Fu[1], David Eugene Frankhouser[1], Denis O'Meally[1], Lianjun Zhang[1], Ying-Chieh Chen[1], Sergio Branciamore[1], Jihyun Irizarry[1], Bin Zhang[1], Guido Marcucci[2], Russell Rockne[1], Ya-Huei Kuo[1]

[1]Beckman Research Institute of The City of Hope, Duarte, CA,[2]City of Hope National Medical Center, Duarte, CA

Acute myeloid leukemia (AML) is a highly lethal hematological malignancy with a long-term survival below 32%, largely due to disease relapse driven by treatment-resistant leukemia stem cells and metabolic reprograming. This poor prognosis underscores the need for frameworks that can predict disease dynamics and treatment effects. We previously applied state-transition theory to model AML disease evolution as trajectories of the mRNA and microRNA (miRNA) transcriptomes in their respective AML state-space, characterized by a leukemogenic potential with three critical points representing health, transition, and leukemia states. Here, we apply state-transition theory to characterize chemotherapy-induced transcriptomic and metabolic changes and test the hypothesis that chemotherapy alters the leukemogenic potential landscape by promoting transitions towards health while inducing metabolic shifts. Using a CBFB::MYH11 knock-in murine model of AML, we collected weekly peripheral blood samples before and after a “5+3” chemotherapy regimen consisting of cytarabine and daunorubicin, modeling the standard-of-care “7+3” regimen. All blood samples were subjected to bulk RNA-seq and miRNA-seq and we used PCA to construct mRNA- and miRNA-based state-spaces. Analyzing the mRNA and miRNA transcriptome trajectories over time, we observed that both transcriptome trajectories transitioned towards a health state post-chemotherapy but ultimately relapsed. Notably, the miRNA trajectories exhibited a delayed response of 2 or more weeks after treatment, revealing desynchronized mRNA-miRNA dynamics. To assess metabolic implications, we performed a Gene Set Variation Analysis (GSVA). This analysis revealed that oxidative phosphorylation, glycolysis and fatty acid metabolism pathways were downregulated during remission, indicating a low metabolic state, but were upregulated during relapse, consistent with metabolic reprogramming as a hallmark of AML recurrence. Finally, we extended the state-transition framework to two-dimensions (2D) to characterize how chemotherapy affects the mRNA-miRNA interplay and multiomic potential landscape. The multiomic state-space revealed a strong mRNA-miRNA correlation during AML progression, which is altered after chemotherapy. Further, the 2D state-transition model enables us to capture the effects of chemotherapy on multiomic potential and simulate how the mRNA-miRNA interplay changes over time. Importantly, model simulations capture response followed by relapse similar to the mRNA and miRNA time-series data trajectories. Together, our findings demonstrate that a mathematically grounded, multiomic state-transition framework captures chemotherapy-induced transcriptomic and metabolic dynamics, offering a systematic approach to predict response and identify metabolic vulnerabilities in AML.

#6836 Mechanistic modeling platform predicts patient response to guide antibody-drug conjugate clinical development.

NING Wang, Nathan Siemers

Decode Origin, Palo Alto, CA

To address the critical translational gap in predicting patient responses to novel antibody-drug conjugates in preclinical or early clinical stages, we developed a mechanistic modeling platform integrating drug mechanism and patient genomic profiles to predict response rates before mature clinical data becomes available.

Methods: We developed PatientMatrix, a systems pharmacology modeling-machine learning hybrid platform, and built a specialized platform for antibody-drug conjugates (PatientMatrix-ADC). The platform comprises three components: a mechanistic ADC model employing systems pharmacology to convert drug properties into patient response predictions, a machine learning model, and a combination model integrating both outputs. This platform enables prediction of ADC monotherapy or combination with PD(L)1 inhibitor. We applied this framework to sacituzumab govitecan, a TROP2-targeted ADC. The mechanistic model captures three critical properties: antigen target, payload sensitivity, and resistance mechanisms. The platform was trained on harmonized patient genomic data and clinical trials including ASCENT, then applied to TCGA reference cohorts to predict patient responses.

Results: PatientMatrix-ADC accurately predicted sacituzumab govitecan plus pembrolizumab responses in the EVOKE-02 trial (metastatic NSCLC), achieving accuracy across PD-L1 subgroups: 77.6% predicted vs 75.0% observed (PD-L1 ≥50%), 50.6% predicted vs 44.0% observed (PD-L1 <50%), and 58.1% predicted vs 54.0% observed (ITT population). The model demonstrated qualitative concordance beyond fitted indications, with first-line predictions of 29.0% (endometrial) and 54.3% (urothelial) appropriately trending higher than second-line reports (22.2% and 27.4%, respectively), as expected for treatment-naive patients. Indication prioritization across TCGA identified several candidate tumor indications missed by TROP2 target expression-based approaches. Esophageal cancer emerged as a potential opportunity despite low TROP2 expression, driven by favorable SN38 sensitivity scores. Critically, PatientMatrix-ADC predicted target expression-stratified responses (TROP2 high, medium, and low) learned from ASCENT clinical trials. This enabled the model to estimate TROP2-stratified patient responses in ASCENT-03.

Conclusions: The PatientMatrix modeling platform uses genomic, clinical, and mechanistic data to predict patient response rates to novel therapeutics in preclinical and early clinical stage, and guide indication selection and patient stratification for agents in clinical development. Case studies with sacituzumab govitecan clinical trials demonstrated the utility of the approach as well as broader ability to predict response in adjacent clinical settings or indications.

#6837 Scalable cell type and spatial domain modeling using spatially informed topic inference of cancer niches.

Jeongbin Park, Tingrui Zhang, Cong Ma

University of Michigan, Ann Arbor, MI

Spatially resolved transcriptomics (SRT) has revealed the heterogeneity of cancer samples. Yet, the capability of computationally identifying the full hierarchy of spatial organization in modern large-scale SRT data remains limited. Although many computational methods have been developed to identify spatial domains and cell types, most of them do not consider the entire hierarchy of spatial organization or explicitly model the relationships among adjacent hierarchical layers. Only a few models (BASS, CytoCommunity, and SpaTopic) model the relationship between spatial domains and their cell type composition. However, BASS is not scalable to the latest SRT data, and both CytoCommunity and SpaTopic require user-provided cell-type annotations and assume that these annotations are accurate. Our goal is to infer the hierarchical spatial organization of tissues from large-scale high-dimensional SRT data, which requires uncovering hidden multi-scale structure in the measurements. To achieve this, we use a variational autoencoder (VAE) framework to learn low-dimensional latent variables that explain the observed gene expression, and we place biologically motivated prior distributions on these variables so that the inferred hierarchy remains close to reality. Concretely, our model consists of three coupled artificial neural networks: (1) multiple graph convolutional networks (GCNs) for modeling spatial domains with Gaussian Markov Random Field (GMRF) and Dirichlet prior, (2) a VAE for reconstructing gene expression and revealing cell types and cell-type-wise gene expression profiles, and (3) a feed-forward multi-layer perceptron for modeling cell types from spatial domains. Our model required 4 minutes for inference when applied to a Xenium data of 17K cells. We found that the domain annotations in breast cancer tissue separated the SRT data into three clear structural groups: invasive regions, DCIS type 1, and DCIS type 2. Furthermore, when we compared our predictions with the ground truth, the inferred cell types revealed malignant subpopulations that were not captured by the original labels, highlighting additional layers of tumor heterogeneity. Importantly, we also identified niches where immune cells and cancer cells were co-localized; these niches differed in their proportions of T cells, plasma B cells, pDCs, and monocytes/macrophages. Our method explicitly models the relationship between adjacent layers in the hierarchy, thus revealing the co-varying relationships among cell types and the cell type compositions within spatial domains, which cannot be directly identified by many previous methods that model cell types and spatial domains separately. We expect that this study can be used to identify distinct pathophysiological features in cancer tissues, which will help uncover biological heterogeneity closely associated with cancer progression.

#6838 Most severe adverse events in approved combination therapies occur at rates consistent with independent action.

Kunhee Kim[1], Rishi Bollapalli[2], Adam C. Palmer[2]

[1]Univ. of Connecticut School of Medicine, Farmington, CT,[2]University of North Carolina at Chapel Hill, Chapel Hill, NC

Introduction: Cancer combination therapies are widely used, but tolerability may limit their application. Although ~95% of approved combination therapies show additive or less-than-additive effects on Progression-Free Survival (Hwangbo et al. (2023)), it remains unclear whether severe AEs follow similar patterns. Since grade 3-4 AEs are consistently reported in clinical trials and critical determinants of clinical trial outcomes, we assessed whether grade 3-4 combination AE incidence follows independent action of individual drugs or by a model of maximum-monotherapy-incidence (MMI), in which the expected combination incidence equals the greater monotherapy value.

Methods: We systematically identified 29 phase III trials of combination therapy that included matching monotherapy arms and extracted all grade 3-4 AEs reported (A vs. B vs. A+B). Combination AE incidences were calculated under the null hypothesis of independent action: P(A+B) = 1 - (1-P(A))(1-P(B)) (Palmer et al. (2017)). Deviations from independent action were quantified using Wald z-scores with Benjamini-Hochberg adjustment. We also compared the number of AEs better explained by independent action versus MMI model, and whether monotherapy AE incidence affected the results, and performed subgroup analyses by cancer type, drug class, and AE category.

Results: Across all grade 3-4 AEs, 6% (12/198) largely exceeded expected incidence, 23% (45/198) fell below it, and 71% (141/198) remained within a 0.5-2.0 fold range of expectation. Deviation from the null, measured as mean squared error (MSE), varied markedly by drug class: immunotherapy combinations showed the least MSE (0.0003), solid cancers without immunotherapy were intermediate (0.0028), and hematologic cancers deviated most (0.0121). Independent action explained more AEs (130) than the MMI model (68), and accuracy did not depend on monotherapy AE incidence. Many hematologic AEs were below independence, consistent with shared mechanisms such as bone marrow suppression, whereas immunotherapy AEs aligned with independence, suggesting distinct pathways to toxicity.

Conclusions: The incidences of serious adverse events from combination therapies are predominantly explained by independent action, similar to prior findings on efficacy of combination therapies. The proportion of AEs with ‘more than expected’ (6%) or ‘less than expected’ (22%) incidence are interestingly similar to rates of ‘more than expected’ efficacy (5%) and ‘less than expected’ efficacy (27%) (Hwangbo et al. (2017)). These results indicate that toxicity, like efficacy, is driven mainly by independent drug action and inter-patient heterogeneity, with synergistic or antagonistic toxicities being uncommon. The predictability of combination AEs supports integrating toxicity modeling into trial design to improve combination selection and escalation or de-escalation strategies.

#6839 Structural vulnerabilities of the breast tumor-draining lymph node to radiotherapy-induced fibrosis and lymphedema risk.

Laia Vancells, Leopold Green, Nan Kong

Purdue University, West Lafayette, IN

Lymphedema is a significant survivorship burden in breast cancer, associated with chronic morbidity, diminished quality of life, and increased susceptibility to locoregional recurrence. Radiotherapy to the axillary lymph node, the principal drainage and immune-surveillance hub for the breast, is the dominant late driver of this condition, producing lymphocyte loss, stromal injury, and progressive fibrosis that restricts normal lymphatic flow. Yet the specific intranodal structures that fail first under radiotherapy stress, and how their collapse contributes to impaired antitumor immunity, remain unclear. To date, direct experimental resolution is limited, as lymph nodes cannot be repeatedly imaged after radiotherapy, and existing animal studies lack the spatial resolution and sex-specific depth needed to map structural collapse. This challenge is further compounded by the lymph node's highly nonlinear stromal-sinus architecture, where even small disruptions can propagate unpredictably across the transport network, making computational modeling essential. To address this gap, we developed an agent-based model of the breast tumor-draining lymph node that integrates established fibroblastic reticular cell microanatomy with the broader sinus architecture. To our knowledge, this is the first structural model capable of identifying radiotherapy-induced failure modes within the draining lymph node. Radiotherapy injury was modeled as progressive fibrosis, introducing targeted removal of stromal-sinus connections, local increases in flow resistance, and reduced HEV-paracortex communication based on published radiotherapy injury profiles. Across injury scenarios, radiotherapy consistently produced early nonuniform disruption at stromal-sinus junctions that serve as conduits for lymph inflow and immune-cell entry. Loss of these regions impaired drainage, prolonged antigen transit, and reduced T-cell delivery to antigen-rich compartments, revealing a selective degradation of the LN's core transport axis. Together, these failures define a reproducible intranodal "collapse axis" whose breakdown forecasts diminished antitumor surveillance and generates a radiotherapy immune-risk map that pinpoints the pathways most vulnerable to fibrotic injury. These insights represent a paradigm shift toward structure-guided radiotherapy planning, enabling lymph-node-sparing treatment strategies, more precise recurrence-risk stratification, and targeted interventions to prevent chronic morbidity in breast cancer survivors.

#6840 Developing a data assimilation framework to forecast patient-specific tumor burden in low-grade glioma.

Sophia Ty[1], Devika Shankar[2], Bikash Panthi[2], Mohamad El-Jammal[2], Victoria White[2], Holly Langshaw[2], Eleni Konstantinopoulou[2], Hannah Green[2], Ashi Jain Chakresh[2], Vishantan Kumar[2], Thomas E. Yankeelov[3], Caroline Chung[2], David A. Hormuth[3]

[1]Oden Institute for Computational Engineering and Sciences, The University of Texas at Austin, Austin, TX,[2]The University of Texas, M.D. Anderson Cancer Center, Houston, TX,[3]The University of Texas at Austin, Austin, TX

Low-grade gliomas (LGG) typically grow gradually for years with limited clinical symptoms but may later exhibit erratic growth patterns and undergo transformation to high-grade glioma. This presents challenges to disease management creating a need for novel methods to simulate and predict LGG behavior. Towards this goal, we implemented a data assimilation framework utilizing a previously developed biophysical model capable of spatiotemporally forecasting patient-specific tumor dynamics. The study cohort includes nine LGG patients treated with radiation therapy at the MD Anderson Cancer Center. All patients were longitudinally monitored using magnetic resonance imaging (MRI) to assess tumor cellularity (diffusion-weighted MRI) and extent of disease (T_1-weighted MRI with & without gadolinium-based contrast, T_2-fluid attenuated inversion recovery). MRI was acquired before treatment and approximately at the 4, 5, 6, and 12-month post-treatment visits. Brain and tumor regions were segmented using a semi-automated algorithm. Our biophysical model is a reaction-diffusion equation that explicitly accounts for tumor cell proliferation, invasion, and treatment response. The model focuses on changes in non-enhancing tumor regions, a hallmark of LGG. Total tumor cell count (TTC) derived from spatiotemporal tumor response forecasts was used to quantify tumor burden. The data assimilation framework incorporates MRI data acquired with each subsequent visit then updates its forecast. Predictive accuracy was quantified via the concordance correlation coefficient (CCC) between the observed and predicted TTC for both short (e.g., 1 - 3 months) and longer-term predictions (e.g., 6, 12-months). A Mann-Whitney U test compared short and longer-term prediction performance. The median and interquartile range (IQR) of the model parameters describing tumor cell proliferation and invasion are reported for each follow up visit. The tumors experienced a median volumetric change of -36.4% over 12 months. The model accurately forecasts TTCs at short (CCC: 0.71) and longer interval times (CCC: 0.96) with no statistically significant difference (p-value: 0.34) in performance between groups. The model estimated tumor cell proliferation rate had a median and IQR of 0.10 (0.06) at the 4-month visit, 0.07 (0.04) for the 5-month visit, 0.04 (0.05) at the 6-month visit, and 0.04 (0.04) $days^{-1}$ at the 12-month visit. Similarly, the model estimated tumor diffusion coefficient had a median and IQR of 0.15 (0.10), 0.16 (0.10), 0.18 (0.06), and 0.16 (0.09) mm^2/days for the 4, 5, 6, and 12-month visit. Our preliminary findings demonstrate the model's ability to predict patient-specific LGG behavior and offers a step towards the development of a personalized decision support tool for managing LGG care.

#6842 ctDNA precedes imaging: A predictive model for real-time treatment adaptation in HPV-associated anal squamous cell carcinoma.

Phebe M.A Havor[1], Brandon M Huffman[2], James Cleary[2], Renee Brady-Nicholls[1]

[1]Integrated Mathematical Oncology, H. Lee Moffitt Cancer Center, Tampa, FL,[2]Dana-Farber Cancer Institute, Boston, MA

Background: Real-time assessment of treatment response in HPV-associated anal squamous cell carcinoma (ASCC) remains challenging. Traditional tumor volume measurements require serial imaging that is costly, time-intensive, and delays clinical decision-making. Consequently, patients may receive prolonged suboptimal therapy or unnecessary toxicity from over-treatment. Circulating tumor DNA (ctDNA) offers a more accessible, real-time alternative biomarker—yet its predictive value and clinical utility for guiding treatment adaptation remain undefined.

Methods: We developed a mechanistic mathematical model of tumor volume-ctDNA dynamics which we parameterized and calibrated to longitudinal data from 32 HPV-associated ASCC patients who received immunotherapy (pembrolizumab, once every 3 weeks, up to 2 years). The model was fit across three clinical scenarios: simultaneous measurements (8 patients), volume preceding ctDNA (14 patients), and ctDNA preceding volume (2 patients). We quantified ctDNA's predictive capacity for early treatment response assessment.

Results: ctDNA demonstrated strong positive correlation with tumor burden (SLD) and predicted clinical response status within 4 weeks of treatment initiation. Critically, ctDNA kinetics *preceded* volume changes in multiple patients, providing early signal for response assessment before imaging confirmation. The mathematical model robustly captured heterogeneous patient dynamics across all measurement scenarios, validating its predictive framework.

Conclusions: ctDNA functions as a leading indicator biomarker enabling early identification of treatment response in HPV-associated ASCC. Our quantitative framework translates this biomarker into actionable clinical predictions, allowing clinicians to make real-time decisions on treatment escalation, maintenance, or de-escalation. This approach enhances precision oncology by replacing burdensome imaging with accessible blood-based monitoring—particularly impactful for underserved populations with limited imaging access. Future studies will prospectively validate this model to inform personalized, adaptive treatment strategies.

#6843 A joint model for integrating serial methylation-based tumor fraction and *ESR1* assessment to forecast overall survival in patients with ER+/HER2- metastatic breast cancer.

Christopher Pretz[1], Matthew Ellis[2], Mitchell J. Elliott[3], Caroline Weiport[2], Amar Das[2], Carin Espenschied[4], David Cescon[3]

[1]Guardant Health, Redwood City, CA,[2]Guardant Health, Palo Alto, CA,[3]Princess Margaret Cancer Centre, Toronto, ON, Canada,[4]Guardant Health, Spokane, WA

Background: Methylation-based tumor fraction (TF) dynamics are highly associated with outcomes in metastatic ER+/HER2- breast cancer. Gain-of-function *ESR1* mutations frequently arise under therapeutic pressure and serve as actionable biomarkers. Because TF reflects tumor burden and *ESR1* mutations reflect clonal evolution, jointly modeling their trajectories may improve understanding of biomarker co-evolution and strengthen outcome prediction. We developed a statistical framework that simultaneously characterizes serial *ESR1* mutation burden and TF, capturing both genetic adaptation and epigenetic quantification of tumor fraction.

Methods: A joint model (JM) was applied to serial liquid biopsy data from ER+/HER2- mBC patients enrolled in a prospective plasma-collection study while receiving endocrine therapy (ET) and CDK4/6 inhibitors (CDK4/6i). Patients contributed baseline and ≥ 2 on-treatment samples. TF was measured using Guardant Reveal and *ESR1* alterations were assessed using Guardant360 Liquid. TF and *ESR1* variant allele frequency (VAF) using the *ESR1* alteration with the highest VAF were logit-transformed for modeling and back-transformed for interpretation. A hierarchical cubic spline mixed-effects sub-model captured longitudinal TF and *ESR1* patterns, paired with a Cox regression sub-model for overall survival (OS). Baseline covariates, incorporated in both sub-modules, included age, CDK4/6i agent, line of therapy, and prior treatment.

Results: Forty-nine patients (279 ctDNA timepoints) met inclusion criteria. After covariate adjustment, current TF and *ESR1* values were significantly associated with OS ($p < 0.05$). Rising TF or *ESR1* trajectories corresponded to poorer survival, whereas decreasing trajectories delineate improved outcomes. The model also captures interactions between TF and *ESR1*, showing how molecular signals evolve together and impact outcome. Individualized survival predictions, informed by the dynamic biomarker trends, are visualized through patient-level dynamic prediction plots.

Conclusions: Joint modeling of TF and *ESR1* mutation dynamics provides an integrated view of tumor evolution, capturing both clonal adaptation and tumor burden over time. This approach yields continuously updated, patient-specific survival predictions that may support real-time clinical decision-making. Integrating genomic and epigenomic biomarkers within a unified dynamic model represents a meaningful advance in disease monitoring. Future work should validate this framework in larger, more diverse cohorts and assess feasibility in routine clinical use.

#6844 Functional data analysis of spatial protein imaging data using spatial trajectories with application to ovarian cancer.

Brooke L. Fridley[1], Alex C. Soupir[2], Daisy Liao[3], Chase Sakitis[1], Joellen Schildkraut[3], Andrew B. Lawson[4], Mary K. Townsend[5], Shelley Tworoger[5], Kathryn L. Terry[6], Julia Wrobel[3], Lauren Cole Peres[7]

[1]Children's Mercy Kansas City, Kansas City, MO,[2]Moffitt Cancer Center, Tampa, FL,[3]Emory University, Atlanta, GA,[4]Medical University of South Carolina, Charleston, SC,[5]Oregon Health Sciences University, Portland, OR,[6]Asst. Professor, Dept. of OB/GYN, Brigham and Women's Hospital, Boston, MA,[7]H. Lee Moffitt Cancer Center, Tampa, FL

Background: Researchers can study both the abundance and spatial architecture of cell types within the tumor microenvironment (TME) using spatial technologies. Often, Ripley's K or nearest-neighbor G are used to measure spatial clustering of cells. These measures can be computed at various radii to assess clustering at different spatial ranges. We propose the use of functional principal component analysis (FPCAs) to model the association of the spatial clustering of T cell populations in the TME with survival from high grade serous ovarian cancer (HGSOC).

Methods: We applied FPCA to study the clustering of CD3+ and CD3+CD8+ cells in the ovarian TME with survival. Five ovarian cancer studies were included in the analysis: Nurses' Health Study (N=239), Nurses' Health Study II (N=68), New England Case Control Study of Ovarian Cancer (N=175), African American Cancer Epidemiology Study (N=155), and the North Carolina Ovarian Cancer Study (N=136). Protein imaging data was collected using AKOYA Biosciences OPAL™ IHC Kit with image analysis completed using Vectra®3 Automated Quantitative Pathology Imaging System. Spatial trajectories using G statistic were computed for samples with at least 8 positive cells for a cell type. FPCA was applied to the spatial curves with the top two components (FPC1, FPC2) associated with survival, adjusting for stage, age of diagnosis, and abundance of the cell population (high vs low using 1% threshold). A second model was fit to assess interaction between the abundance and spatial clustering. Analyses were completed for each study with results combined using a random-effect meta-analysis.

Results: From the model without spatial information, we observed that high abundance of CD3+ (hazard ratio (HR): 0.81, 95% confidence interval (0.66, 0.98)) and CD3+CD8+ cells (HR: 0.64 (0.52, 0.79)) were associated with improved survival. The model with both abundance and spatial clustering detected a significant effect for CD3+CD8+ clustering (FPC1 HR: 1.17 (1.04, 1.33)) and a borderline association for CD3+ cells (FPC1 HR: 1.06 (0.99, 1.14)). When fitting a model with interactions for abundance and spatial clustering, a significant interaction for CD3+ cells (HR: 1.23 (1.07, 1.42)) and a borderline interaction for CD3+CD8+ cells (HR: 1.19 (0.98, 1.43)) was observed. Hence, we estimated the HRs for 4 tumor types (high/low abundance and high/low spatial clustering). We observed that patients with high abundance but low spatial clustering of CD3+ and CD3+CD8+ cells had the improved survival, with HRs for the high abundance / low spatial clustering group being 0.74 and 0.41, respectively.

Discussion: In studying the HGSOC TME using spatial proteomics and FPCA, we found that not only is the abundance of T cell populations related to survival, but also the spatial clustering of these cell populations, with improved survival for women with tumors with diffuse T cell infiltration.

#6845 Using cell-type-specific nucleosome patterns to improve cell-free DNA fragmentation models in lung cancer.

Brian Sun Liu, Mengran Zhang, Mohammad Shahrokh Esfahani

Department of Radiation Oncology, Stanford University School of Medicine, Stanford, CA

Background: Cell-free DNA (cfDNA) profiling has emerged as a promising tool in cancer detection. Methods include the identification of circulating tumor DNA (ctDNA), the profiling of cfDNA methylation, and the analysis of cfDNA fragments, including fragment size and position. We previously showed that fragment size diversity is strongly correlated with gene expression (Esfahani et al, 2022). We subsequently developed a mechanistic model for the cfDNA fragmentation process to enhance gene expression inference from cfDNA (Liu et al, 2025).
However, analysis of cfDNA fragment size distribution alone leaves out useful information about fragment position. Since fragment position arises from nucleosome position, we incorporate prior knowledge about nucleosome positioning to improve our cfDNA fragmentation models. We hypothesize that incorporating cell-type-specific nucleosome patterns can progress cfDNA models towards cell-type deconvolution.
Methods: In order to incorporate prior knowledge about cell-type-specific nucleosome organization into our cfDNA fragmentation model, we use Micrococcal Nuclease sequencing (MNase-seq) data from (Valouev et al, 2011) and MNase-Transcription Start Site Sequence Capture method (mTSS-seq) data from (Druliner et al, 2016). For each transcription start site (TSS), we leverage this prior knowledge about nucleosome organization to simulate well-positioned nucleosomes. Then, we generate additional nucleosomes given the gene's strand information and cell type. Next, we generate cuts, and generate a mixture of simulated fragments from various cell types.
Results: In order to evaluate the efficacy of our updated cfDNA fragmentation model, we calculate the coverage over 10 bp intervals within a window of the TSS, and compare it with the coverage for cfDNA control samples. We also calculate the coverage for simulated cfDNA fragments using our previous model, and compare it with the coverage for cfDNA control samples. Our updated model incorporating prior knowledge about nucleosome organization outperformed our previous model in simulating cfDNA fragmentation.
Conclusions: We show that integrating cell-type-specific nucleosome patterns improves cfDNA fragmentation models. Further improvements can be made given nucleosome organization information from additional cell types. We envision that this model-based approach will enhance tissue-of-origin classification and cancer detection.

#6846 Using physiologically-based pharmacokinetics-quantitative systems pharmacology model to optimize peptide-drug conjugates design.

Yuezhe Li, Cole Zmurchok, Daniel C. Kirouac

Metrum Research Group, Boston, MA

Introduction: Peptide-drug conjugates (PDCs) are being developed as new cancer treatments. Compared to larger antibody-drug conjugates (ADCs), they retain the advantage of a targeted therapy, binding to tumor-associated antigens (TAA) to deliver payload, while having better tumor penetration than ADCs. PDCs typically exhibit faster plasma clearance than ADCs, and therefore potentially have less tumor exposure to the drug. The pharmacokinetics is influenced by the molecular weight (MW) of the peptide used in the PDC. A physiologically-based pharmacokinetics (PBPK)-quantitative systems pharmacology (QSP) model would be useful to understand the interplay of pharmacokinetics (PK), tissue disposition, and tumor drug exposure of PDCs.
Methods: A platform PBPK-QSP model was developed based on a published PBPK model (Li et al., 2019) and a genetic tumor QSP model (Scheuher et al., 2024) by coupling these two models with a MW-based tumor penetration relationship. Through calibrated model simulations and sensitivity analysis, we interrogate how parameters of the peptide (e.g., molecular weight, binding affinity towards TAA) impact the PK, tissue disposition, and tumor drug exposure.
Results: The model predicted higher tumoral PDC concentration when the peptide was small, corresponding to the knowledge that smaller peptides resulted in better tumor penetration. However, a bell-shaped relationship was predicted between peptide size and PDC or payload exposure. The model predicts that a peptide with MW of approximately 86 kDa results in maximum tumor PDC or payload exposure despite exhibiting more rapid PK clearance than a 150 kDa ADC. This is in contrast with tissue disposition, as larger peptides led to higher non-tumoral tissue exposure. Further sensitivity analysis indicated this relationship is insensitive to tumor characteristics, such as TAA expression, or PDC binding affinity towards the TAA, but is sensitive to the peptide size.
Conclusions: This work demonstrated that this platform PBPK-QSP model can be a useful tool to guide PDC design and lead selection by optimizing peptide size for PDCs.

#6848 HPlot: A novel quantitative framework for spatial profiling of Immune heterogeneity in tumor microenvironments.

Chao Hui Huang[1], Jadwiga Renata Bienkowska[2], Diane Fernandez[1], Sara Beth Linker[1], Xinmeng Jasmine Mu[2], Robbin Nameki[2], Jennifer Kinong[1], Michelle Saul[1], Aakash Sur[3], Mehmet Tekman[1], Alexander Trageser[1], Wenjing Yang[1], Daniel Chawla[1], Greg Szeto[3], Arne Schmidt[4], Alberto M. Gonzalo[5], Srishti Munjal Mehta[5], Rosemarie Krupar[4], Nina Kozar-Gillan[4], Sophie Laturnus[6], Cornelius Bohm[4], Marija Pezer[4], Gloria H.Y. Lin[1], Darlan Conterno Minussi[1], Keith Ching[1], Thomas Powles[7], Craig Davis[8]

[1]Pfizer Inc., San Diego, CA,[2]Pfizer, Inc., San Diego, CA,[3]Pfizer Inc., Bothell, CA,[4]Aignostics, Berlin, Germany,[5]Aignoistics, Berlin, Germany,[6]AIgnoistics, Berlin, Germany,[7]Barts Cancer Centre, London, United Kingdom,[8]Sage Healthcare Insights, Albany, NY

Spatial organization of immune and tumor cells plays a critical role in disease progression and therapeutic response. Existing spatial analysis methods often treat tissue regions as uniform compartments and fail to quantify how immune composition and functional states change across tumor boundaries. This limits the ability to detect spatial biomarkers associated with treatment outcomes.

We developed H-Plot, a quantitative framework for profiling spatial immune heterogeneity with high resolution. The method is compatible with whole-slide imaging and modern single-cell spatial biology platforms. H-Plot integrates three components:

(1) Cell prediction and classification using machine-learning-based single-cell image analysis or spatial transcriptomics-derived cell subtyping to generate a high-fidelity cellular map;

(2) Cell-function enrichment analysis to identify biologically meaningful structures such as tumor regions, lymphoid aggregates, and tertiary lymphoid structures (TLS) through localized functional program detection; and

(3) Cell spatial profiling, which measures spatial relationships and computes layer-wise distances from biological structure boundaries (e.g., tumor margins) to capture spatial gradients across the tumor-immune interface.

Applying H-Plot to the ABACUS bladder cancer dataset revealed that treatment responders exhibited higher lymphocyte enrichment adjacent to tumor borders and smoother immune-layer transitions, whereas non-responders showed shallow or fragmented infiltration. In the TEMPUS mCRPC cohort, reduced pre-treatment lymphocyte proximity and weaker enrichment layers were associated with poorer clinical outcomes and aligned with RNA-based immune signatures and histological assessments.H-Plot provides a reproducible, interpretable, and visualization-ready framework for quantifying tumor-immune spatial heterogeneity. By converting complex spatial arrangements into layer-wise quantitative profiles and intuitive visualizations, H-Plot enables systematic comparison across patients, treatments, and tumor types. This framework supports spatial biomarker discovery and offers a scalable tool for translational oncology research.

#6849 Tumor microenvironment gene expression dynamics: Keystone cell types and non-cancer cell driver genes.

Yongzhong Zhao, Yixiao Cui, Ji Zheng, Cody Stevens, Jenny Bundy, Eranga Wettewa, Christopher Edwards, Victoria Thilker, Donald Carpenter, Zhongqiang Qiu, Zhijiu Zhong, Eric Zhao, Lili Liao, Qiang Xu, Nan Zhang, John Lin

Frontage Laboratories, Exton, PA

Cancer is not a disease, rather, of multi-scale heterogeneity, i.e., each victim of cancer is of unique evolutionary dynamics at distinct levels. Indeed, cancer therapeutics has been evolving from non-specific chemo and radiation therapy, mutation-specific targeted therapy, immunotherapy, as well as combination therapies, to ongoing tumor microenvironment (TME) specific interventions, in a broader sense, targeting tumor ecosystems. However, the critical schemata of TME with cell-type specific gene expression dynamics underpinning mechanistic druggable key driver genes remains largely obscure. Here, we present an integrated approach of AI-powered modeling TME gene expression dynamics via borrowing ecology models, namely, treating cell types as the counterpart of species in ecological settings. We represent each TME as a tensor with public non-small cell lung cancer (NSCLC) data settings, mainly focusing on lung adenocarcinoma (LUAD) and lung squamous cell carcinoma (LUSC) with scRNA-seq, snRNA-seq, and spatial transcriptomics data. Given that up to 72 distinct cell types/states were found in LUSC and 57 in LUAD, we validated these distinct cell types/states with the uniLung database via wavelet-transformed cell cluster analysis. Furthermore, we treated these cell types as species via incorporating a network ecology model (40 spatial transcriptomics data for NSCLC study, E-MTAB-13530, among other data settings). We found distinct keystone cell types in driving cancer progression in addition to key driver gene sets. These patient specific keystone cell types are not limited to cancer cells, rather many immune and stromal cell types are indeed ecology drivers, such as certain subtypes of cancer associated fibroblast (CAF). Distinct to LUAD, LUSC is of more loss of function of tumor suppressors, such as chromatin remodeling genes *SMARCA4* and *PBRM1*. Of note, *DNMT3A*, *TET2* and *ASXL1* are of immune cell driver genes, much individualized. Thus, tumor driver genes are not limited to cancer cells, yet to discover more non-cancer cell tumor driver gene sets. We propose validation and qualification strategies with our available bioassay platforms, spanning from genomics, cell-based assays and biomarkers. We continue to cross-validate this ecology network model with expanded distinct data setting. Of particular interest, we have been examining these complex interactions via cancer organoid models. Taken together, targeting tumor ecosystems with individualized biologics alongside geography ecology modeling of TME, we advocate integrated AI-powered single-cell level temporospatial analytics infrastructure as we have been building central laboratory logistics for fresh and frozen cancer samples, clinical pathology, automation, high throughput biomarker assays, scRNA-seq and snRNA-seq, spatial transcriptomics, flow cytometry, Elispot assay, cell potency, as well as organoid platforms.

#6850 Dynamic modeling of invisible tumor growth with simulated residual disease and PDX data.

Bryan A. Hawickhorst, Daniel J. McWilliams, Jonathan M. Baker, Amy H. Tang

Old Dominion University, Norfolk, VA

Tumor dormancy, early relapse, and treatment resistance remain poorly understood. After neoadjuvant or adjuvant therapy, the locally advanced and systemically disseminated invisible tumor cells may persist undetected for months or years despite clean MRI or CT scans. Reported detection thresholds and residual tumor sizes vary in the literature, further complicating prognostic accuracy in patient risk stratification. To address this unmet clinical need, we developed mathematical models and generated a computational algorithm to predict the time course of invisible tumor relapse, improve predictive accuracy, and model the invisible-to-visible tumor transition within the detection limits of the MRI/CT tumor imaging tools. We simulated remission-to-relapse trajectories for invisible residual tumors beginning with 1, 10, 10^2, 10^3, and 10^4 cells, and calculated the time for each to progress into a 3 cm^3 visible tumor. Exponential growth models with unrestricted doubling times from 2 to 30 days were used to capture rapid, unimpeded tumor growth. A modified logistic model was then used to model the time course of invisible tumor growth *in vivo*, with doubling times of 5 to 30 days to reflect varying aggressiveness, tumor and tumor microenvironment interactions, and tempo-spatial-context-treatment dependence in response to varied tumor remission and extended tumor latency. To improve mathematical modeling, we refined, verified, and authenticated several variable factors/clinicopathological parameters in experimental biology by fitting our hypothetical tumor growth models to the real-time TNBC tumor growth curves from six patient-derived xenograft (PDX) TNBC models in NSG mice. By varying the clinically invisible residual tumor sizes from 10^{-6} mm^3 to 10^{-2} mm^3, we found that tumors relapsed rapidly once tumor growth resumed, often exceeding the clinical detection thresholds before the regularly scheduled follow-up appointments and allowable MRI/CT-imaging intervals could capture them. Our results highlight the hidden risk of residual diseases, the major challenge of invisible tumor modeling, and the lack of accuracy in relapse prediction in the clinic. Exponential and logistic model fits to the PDX tumor implantation data were complete; the model authentication, relapse prediction augmentation, and correct interpretation of these fitted models will be augmented with the new chemo-resistant PDX models in NSG mice. This work underscores the unmet need and critical importance of modeling invisible tumor growth to improve the accuracy of tumor relapse prediction and patient risk stratification. Future work will focus on transforming this mathematical model into a companion prognostic tool in combination with our selected biomarker panel to predict tumor relapse risk, quantify therapeutic efficacy, and assist and support oncologists' decision-making in real time in the future.

#6851 Multi-cell type model for analyzing spatial single-cell protein imaging data with application to ovarian cancer.

Professor, Dept. of OB/GYN, Brigham and Women's Hospital, Boston, MA

Background: Understanding the tumor immune microenvironment (TIME) is essential for advancing cancer research and improving treatment strategies. Multiplex immunofluorescence (mIF) is a spatial proteomics imaging technique enabling simultaneous analysis of multiple markers in preserved tissues. However, mIF-derived cell abundance data pose statistical challenges, such as zero-inflation, over-dispersion, hierarchical cell relationships, and repeated measures, that must be addressed to extract meaningful insights and enhance translational impact.
Methods: We developed a novel Bayesian multi-cell type analysis model that simultaneously models the relationship of immune cell abundances with clinical and epidemiological factors, while incorporating the biological relationships between immune cell populations. We applied this model to three large studies assessing the TIME of high-grade serous ovarian cancer: Nurses' Health Study I/II (NHSI/II) (N=321), African American Cancer Epidemiology Study (AACES) (N=92), and University of Colorado Ovarian Cancer Study (UCOCS) (N=103). The mIF staining for these studies was performed using the AKOYA Biosciences OPAL™ 7-Color Automation IHC Kit with the Vectra®3 Automated Quantitative Pathology Imaging System (0.499µm/pixel) utilized for image collection. InForm and HALO were utilized for spectral unmixing and cell phenotyping, respectively. Our analysis examined associations between immune cell infiltration (T-cells, B-cells, macrophages) and clinical variables (cancer stage, age at diagnosis, debulking status) with comparisons to the single-cell type model.
Results: In the NHSI/II analysis, our multi-cell type model detected a positive association between age at diagnosis and abundance levels of 6 of the 7 cell types in the analysis while the single-cell type model only detected 2 of the 7. This indicates improved association detection, with our multi-cell type model. We also observed that our multi-cell type model had narrower credible intervals (CIs) for all 7 cell types demonstrating higher accuracy in the association estimation. With cancer stage as the predictor in the NHSI/II analysis, neither model detected an association although our multi-cell type model had narrower CIs for 3 of the 7 cell types compared to the single-cell type model. Despite not capturing any associations between the predictors (age, stage, debulking status) and immune cell populations in the AACES or UCOCS, our Bayesian multi-cell type model had narrower CIs for every cell type in both studies for each predictor.
Discussion: Our Bayesian multi-cell type model offers a flexible framework for incorporating immune cell relationships and is well-suited for cancer studies of the TIME utilizing TMAs, regions of interest, or whole-slide imaging data.

#6852 Measure of three cell population co-localization for spatial protein imaging data analysis.

Kirill Sabitov[1], Alex Soupir[2], Lauren C. Peres[2], Brooke L. Fridley[1]

[1]Children's Mercy Research Institute, Kansas City, MO,[2]Moffitt Cancer Center, Tampa, FL

Background: Spatial protein imaging technologies enable detailed study of the tumor microenvironment (TME) to characterize cell abundance and spatial architecture. Pairwise colocalization metrics (e.g., Ripley's K) miss higher-order patterns, while enumerating all triangles for three cell populations is computationally infeasible on whole-slide images. Metrics using a triangle's longest edge poorly distinguish compact triples from elongated or dispersed arrangements. Thus, we propose a new trivariate colocalization measure using triangle area.

Methods: We developed a Horvitz-Thompson Monte Carlo estimator and benchmarked the unweighted and isoperimetrically weighted area variants against a longest-edge analogue on simulated data. These metrics were applied to a study of primary high-grade serous carcinoma (n=101) to quantify colocalization among T cells (CD3+), cytotoxic T cells (CD3+CD8+), B cells (CD19+), and macrophages (CD68+). Cox PH models evaluated associations between normalized clustering metrics and overall survival at radii of 15 and 25 µm - adjusted for diagnosis age, stage, and debulking.

Results: Simulations showed unbiased, consistent colocalization estimates with lower small-radius variance for area-based measures. Monte Carlo sampling achieved a $>10^5$-fold runtime reduction versus full enumeration. In the ovarian study, lower three-cell colocalization levels of lymphocytes with macrophages corresponded to small improvements in overall survival, though not significant (Table 1). Narrower confidence intervals were also observed for area-based estimators, with weighted and unweighted area variants performing similarly.

Discussion: Our framework enables scalable quantification of higher-order spatial organization in the TME. Despite comparable associations across estimators in the ovarian study, the greater stability of area-based measures supports their use as surrogates of complex cellular architecture in future spatial studies.

Table 1: Cox model hazard ratios and 95% confidence intervals for study cell triples at chosen radii

Cell Triple	Radius	Longest-Edge	Unweighted Area	Weighted Area
T Cell B Cell Macrophage	15	0.83 (0.61, 1.14)	0.93 (0.66, 1.31)	0.89 (0.65, 1.21)
	25	0.90 (0.65, 1.23)	0.91 (0.67, 1.23)	0.93 (0.68, 1.27)
Cytotoxic T Cell B Cell Macrophage	15	0.95 (0.73, 1.23)	0.90 (0.68, 1.17)	0.93 (0.73, 1.20)
	25	0.85 (0.65, 1.12)	0.86 (0.66, 1.11)	0.84 (0.64, 1.09)

#6853 A segmentation-free method for modeling high-resolution spatial transcriptomics at the molecule level.

Xiao Wang[1], Nan Zhang[2], Chi Zhang[3], **Sha Cao**[4]

[1]Indiana University, Bloomington, IN,[2]Fudan University, Shanghai, China,[3]Knight Cancer Institute, Oregon Health & Science University, Portland, OR,[4]Biomedical Engineering, Oregon Health and Science University, Portland, OR

Modern platforms such as Xenium and Visium HD measure the spatial coordinates and identities of millions of individual RNA molecules per tissue section, providing unprecedented resolution to study tumor heterogeneity and the spatial organization of cellular compartments. However, most current analyses rely on cell segmentation, which can be error-prone in densely packed or morphologically complex tumors. Here, we introduce a segmentation-free statistical framework for modeling RNA molecules in high-resolution spatial transcriptomics data using Log-Gaussian Cox Processes (LGCPs). Building on our recently developed efficient variational method for fitting LGCPs, we treat each RNA molecule as a point in continuous space and model gene-specific log-intensity surfaces with a latent Gaussian random field prior. This framework enables us to (i) infer smooth intensity fields for selected genes, (ii) estimate spatial cross-covariance between these fields as a direct measure of gene-gene co-localization, and (iii) perform direct association analyses quantifying how the local abundance of one gene varies as a function of genes or spatial features, all without requiring cell boundaries. These quantities define molecule-level association scores that capture local enrichment or exclusion of RNA species, facilitating the discovery of ligand-receptor hotspots, metabolic niches, and immune-tumor interaction zones at subcellular resolution. By aggregating molecule-level association patterns over marker gene sets, our approach further supports inference of cell type and subtype-level spatial organization and interactions. Simulation studies demonstrate that our segmentation-free LGCP approach accurately recovers underlying intensity surfaces and spatial associations with favorable runtimes. Overall, this work provides a scalable, model-based tool for leveraging the full richness of high-resolution spatial transcriptomics to map RNA molecule associations in cancer tissues without relying on cell segmentation.

#6857 Sex differences in the gene regulatory mechanisms of lung aging and their implications in lung cancer risk.

Enakshi Saha

University of South Carolina, Columbia, SC

Lung cancer is the leading cause of cancer-related deaths worldwide. While disease risk increases with age in both sexes, there is significant difference in prevalence between males and females, even after adjusting for smoking history. We use novel computational models to infer individual-specific gene regulatory networks integrating transcriptomic and epigenomic data. These networks represent gene regulatory interactions between transcription factors, DNA methylation levels and target gene expression at individual-level resolution. We use sex-specific transcription factor motif and protein-protein interaction data as prior information in our network estimation to further highlight sex-specific regulatory interactions. Comparing gene regulatory networks from healthy normal lung tissue from the Genotype Tissue Expression Project across varying ages, we observe that genes involved in immune response , cell proliferation, and cancer-related pathways are differentially regulated with age in a sex-differential manner. Aging-related gene regulatory changes are influenced by estrogen receptor and androgen receptor transcription factors in females, with significant inflection points between ages 40 and 60. Examining individual-specific networks from lung adenocarcinoma samples from The Cancer Genome Atlas, we observe that aging-related gene regulatory changes converge with cancer-associated regulatory patterns. Critically, at any given age, regulatory patterns of immune and cell proliferation pathways in females without a history of smoking resemble disease-related patterns significantly more than their male counterparts. This finding highlights the role of aging-related gene regulatory changes in elevating cancer risk with age, and disproportionately so in females. Individuals with a history of smoking have regulatory signatures more akin to accelerated aging, resembling patterns observed in older never-smokers, and show greater similarity with disease states. These findings underscore age- and sex-specific mechanisms of lung cancer susceptibility, independent of smoking exposure, and highlight the need for tailored prevention strategies, informed by individual age and sex.

#6858 Single-cell elucidation of molecularly distinct states and therapeutic vulnerabilities in IDH-mutant glioma.

Luca Zanella[1], Patrick M. Kerwin[1], Mikko Turunen[1], Peter A. Sims[2], Peter D. Canoll[3], Andrea Califano[4]

[1]Department of Systems Biology, Columbia University Irving Medical Center, New York, NY, New York, NY,[2]Department of Systems Biology and Department of Biochemistry and Molecular Biophysics, Columbia University Irving Medical Center, New York, NY,[3]Department of Pathology and Cell Biology and Department of Neurological Surgery, Columbia University Irving Medical Center, New York, NY,[4]Dept. of Systems Biology and Dept. of Medicine and Dept. of Biomedical Informatics and Dept. of Biochemistry & Molecular Biophysics, and HICCC, Columbia University Irving Medical Center; Chan Zuckerberg Biohub, New York, NY

IDH-mutant gliomas, including oligodendrogliomas (IDH-O) and astrocytomas (IDH-A), are a molecularly defined class of fatal primary brain tumors characterized by mutations in the IDH1 and IDH2 genes. Despite advances in standard-of-care approaches, prognosis remains poor with median survival rates of 5-15 years. Substantial inter- and intra-tumor heterogeneity limits the efficacy of current monotherapies and necessitates *ad hoc* combination strategies targeting distinct tumor subpopulations. To comprehensively characterize the cellular landscape of IDH-mutant gliomas, we generated >250k high-quality single-nucleus transcriptomic profiles from 20 IDH-mutant glioma tumors (grade II and grade III; 10 IDH-O; 10 IDH-A) obtained from the Molecular Pathology Shared Resource (MPSR) Tumor Bank at Columbia University. Gene expression analysis revealed glioma cells, microglia, neurons and mature oligodendrocytes as the predominant cell types in both IDH-O and IDH-A, with a striking depletion of microglia in IDH-O. Network-based VIPER analysis of single-nucleus profiles identified Master Regulator (MR) proteins representing molecular dependencies of three previously described glioma states: astrocyte-like (AC), oligodendrocyte-like (OC) and neural-progenitor-like (NPC). Notably, the AC state was transcriptionally orthogonal to OC, whereas OC and NPC largely shared their regulatory architecture. To predict rational combination therapy candidates, we employed NYS CLIA-certified OncoTarget and OncoTreat algorithms. OncoTarget identifies small molecule inhibitors targeting individual state-specific MRs, while OncoTreat predicts candidate drugs by assessing their ability to invert the activity of glioma-specific MRs, leveraging large-scale drug perturbation assays generated by PLATE-seq. Specifically, we generated a library of genome-wide RNA-seq profiles from patient-matched *in vitro* models, one adherent cell line (SF10417) and one neurosphere (SUA03), 24 hours after treatment with 374 compounds from a library of FDA approved and investigational compounds. OncoTarget uncovered distinct pathway dependencies across glioma states, including STAT3/PI3K/AKT in AC cells, PDGFRA in OC, and RTK/EGFR/MET signaling in NPC cells. OncoTreat identified CNS-permeable agents predicted to invert glioma-specific MR programs. Future work will include validation of candidate compounds in patient-derived acute slice cultures to assess single-cell responses within an intact microenvironment. Complementary Xenium spatial profiling will map the microenvironmental context and cell-cell communication of molecularly distinct subpopulations, informing rational therapeutic strategies. Overall, our study establishes a generalizable framework for precision oncology in transcriptionally complex tumors and provides actionable targets for clinical translation.

#6859 Targeting master regulators to reprogram neutrophils and enhance PD-1 blockade efficacy in castration-resistant prostate cancer.

Melania Franchini[1], Florencia Picech[2], Cory Abate-Shen[3], Andrea Califano[4]

[1]Department of Systems Biology, Columbia University, New York, NY,[2]Department of Molecular Pharmacology and Therapeutics, Columbia University Irving Medical Center, New York, NY,[3]Department of Molecular Pharmacology and Therapeutics, Department of Urology, Columbia University Irving Medical Center, New York, NY,[4]Dept. of Systems Biology and Dept. of Medicine and Dept. of Biomedical Informatics and Dept. of Biochemistry & Molecular Biophysics, and HICCC, Columbia University Irving Medical Center; Chan Zuckerberg Biohub, New York, NY

Introduction: Neutrophil-mediated immunosuppression limits immunotherapy in Castration-Resistant Prostate Cancer (CRPC), but its mechanisms are unclear. This study aims to identify the drivers of this immunosuppression and evaluate whether targeting Master Regulator (MR) proteins can reprogram neutrophils, remodel the tumor microenvironment (TME), and enhance PD-1 blockade efficacy.
Methods: We used orthotopic CRPC models treated with MR inhibitors and anti-PD-1 therapy to assess neutrophil depletion and immune remodeling. Spatial profiling with the 5,000-plex Xenium panel along with cell types annotation via a curated scRNA-seq atlas, revealed a detailed map of tissue organization. Treatment effects on immune populations and spatial reorganization, particularly neutrophils, were quantified. VIPER-based analysis defined MR-driven neutrophil functional states, and spatial mapping was conducted using Xenium data. Finally, ligand-receptor interactions between neutrophils and tumor cells were explored through cell-cell communication network analysis.
Summary of unpublished data: We conducted a pilot Xenium study across four treatment arms (vehicle, Trametinib, anti-PD1, and combination) to assess MR inhibition's effect on immune responses through cell abundance and spatial reorganization. Anti-PD1 induced broad immune recruitment, especially neutrophils, while Trametinib had minimal effect. Combination therapy reduced neutrophil abundance below baseline, attenuating checkpoint blockade-induced neutrophil accumulation. NK/T cells, monocytes, and dendritic cells increased, while macrophages remained stable. Spatial analysis showed that anti-PD1 caused tumor cells to marginalize, while combination therapy partially restored integration. Neutrophils transitioned from marginalization to forming an immunological barrier around tumor cells, and NK/T cells interacted mainly with stromal/myeloid cells, indicating immune exclusion. Despite upregulating PD-L1 in all treatments, combination therapy induced PD-L1 expression without barrier formation, suggesting that spatial organization, not just ligand expression, drives neutrophil-mediated immune exclusion.
Conclusion: Treatments reshape tumor-immune architecture without disrupting tissue organization, relying on both immune cell abundance and their spatial distribution within the TME. Anti-PD1 induces broad immune infiltration, but neutrophils form a barrier limiting tumor penetration, which is relieved by the MR-inhibitor Trametinib. Neutrophils upregulate PD-L1 across all treatments, peaking after anti-PD1, while Trametinib and combination therapy drive PD-L1 expression without barrier formation.

#6860 Ensemble somatic variant calling and transcript reconstruction for high-fidelity neoantigen discovery in mRNA cancer vaccine design.

Po-Yuan Chen[1], Mi-Hua Tao[2], **Tai-Ming Ko**[3]

[1]Academia Sinica, Taipei, Taiwan,[2]Research Fellow, Academia Sinica, Taipei, Taiwan,[3]National Yang Ming Chiao Tung University, Hsinchu, Taiwan

Personalized neoantigen vaccines require accurate identification of tumor-specific epitopes with clinical-grade confidence. However, pipelines that rely on single-caller somatic variant detection and reference-based transcript reconstruction often inflate false-positive neoantigens and mishandle complex mutations such as frameshifts and stop-codon disruptions, limiting the fidelity of candidates for mRNA cancer vaccines. We developed a GPU-accelerated workflow integrating whole-exome sequencing (WES) and RNA-seq, implemented on NVIDIA Parabricks to achieve more than a tenfold reduction in preprocessing time compared with conventional CPU-based pipelines. Somatic variants are identified using an ensemble consensus (≥2 of DeepSomatic, Strelka2 and VarScan), reducing inter-caller discordance while preserving biologically plausible events; germline variants are called with GATK HaplotypeCaller. To support neoepitope generation, we implemented a transcript reconstruction module that integrates all germline and somatic variants into patient-specific, strand-aware open reading frames, applies context-dependent peptide trimming (for example, ±20 amino acids for SNVs and dynamic windows for indels), and validates candidate coding changes against sequencing evidence, resolving multi-isoform usage and early terminations. Benchmarked on clinical solid tumor samples, the ensemble strategy improved reproducibility across technical replicates and showed high concordance with orthogonal variant validation. The reconstruction module robustly recovered mutant transcripts in diverse genomic contexts and enabled precise neoepitope extraction and HLA-binding prediction. Integrated with HLA genotyping and MHC binding models, this reproducible pipeline mitigates upstream sources of epitope inflation and provides a scalable bioinformatics framework for high-fidelity neoantigen discovery in personalized mRNA cancer vaccine design.

#6861 NeonDisco: A Nextflow orchestration framework for in silico discovery and prioritization of recurrent neoantigen candidates.

Mohd Suffian Azizan, Min Hui Tan, Jia Wern Pan, Sok Ching Cheong

Cancer Research Malaysia, Subang Jaya, Malaysia

Neoantigen-based cancer immunotherapy necessitates discovery of tumor-specific antigens that elicit clinically observable response in patients. Advances in bioinformatics have allowed in silico predictions of neoantigens, yet cancer vaccine development have been limited by low discovery rate of immunogenic neoantigens. This is primarily due to the restricted search space from which neoantigens are predicted, namely single-nucleotide variations (SNVs) or insertion-deletion mutations (indels), the prevalence of which also varies across different cancer types. Therefore, expanding the neoantigen landscape beyond SNVs/indels is imperative, both to improve novel neoantigen detection and to make universal, off-the-shelf cancer vaccine development possible. We have implemented NeonDisco, a multimodal bioinformatics pipeline in Nextflow to facilitate discovery of recurrent, immunogenic neoantigens from RNA-seq data. The pipeline incorporates state-of-the-art bioinformatics tools, with a focus on modularity to enable predictions from expanded neoantigen sources. We have prototyped a gene fusion neoantigen discovery module in NeonDisco and analyzed RNA-seq libraries of 990 patient samples from the Malaysian breast cancer cohort, MyBrCa. We identified 96 recurrent fusion breakpoints found across 208 unique samples out of 886 fusion-positive samples, translating to a cohort coverage of 23%. Neopeptide prediction part of the pipeline identified 2,827 unique neoepitope sequences predicted to have IC50 <500 nM to 5% top common MHC-I alleles in the MyBrCa cohort. Future works would focus on extending the discovery modules into alternative-splicing-derived and RNA-editing-derived neoantigen search space, as well as validating gene fusion prediction shortlist in vitro. NeonDisco attempts to consolidate innovative neoantigen discovery algorithms into one streamlined, automated pipeline, and this effort constitute our first step in an optimized strategy to develop off-the-shelf cancer vaccines.

#6862 A scalable workflow for *in silico* TMA construction and groupwise comparison of spatial transcriptomic data for analyzing tumor microenvironment.

Dongjoo Lee, Sungwoo Bae, Yeonjae Jung, Kwon Joong Na, Hongyoon Choi

Portrai, Inc., Seoul, Korea, Republic of

Background:
Spatial transcriptomics provides high-resolution characterization of the tumor microenvironment (TME), offering insights into cellular architecture, spatial interactions, and molecular heterogeneity. However, integrating data across multiple tissue sections or multiple samples from tissue microarrays (TMAs) remains a substantial challenge, particularly for bioinformatics workflows requiring scalability and flexible cohort design. The difficulty is amplified in high-density platforms such as Visium HD, where datasets contain large numbers of cells and preserving spatial relationships during multi-slide integration is critical. Consequently, there is a growing need for a scalable computational framework that enables efficient in silico TMA construction and supports groupwise comparisons for robust TME analysis.
Methods:
We developed a flexible and modular computational workflow enabling in silico TMA construction and groupwise comparison of gastric cancer Visium HD data. From a total of 48 samples (2 mm core), yielding over 3.1 million 8-μm bins of spatially resolved expression data, was used for the integration and scalable group-wise comparison. Selected cores from different slides were digitally reassembled into new TMA-like layouts with automatically re-registered H&E images reflecting updated spatial coordinates. For batch correction and large-scale integration, the workflow employs stratified subsampling and the scArches model, allowing efficient harmonization of datasets containing millions of spatial bins. Interactive visualization modules support region-level comparison and cross-core analysis of cellular composition.
Results:
Preliminary groupwise analyses of the reconstructed TMA revealed reproducible spatial patterns across tumor regions. Areas with dense stromal activation exhibited enrichment of fibroblast and endothelial-related signatures, whereas immune hotspots showed localized $CD8^+$ T-cell and macrophage co-accumulation near the tumor invasive front. Gene expression-based metabolic pathway analysis revealed subtle gradients (glycolytic vs oxidative) between core groups with distinct histopathologic features. The entire integration pipeline processed 3.1 million spatial bins in under 2hours on a single NVIDIA A6000 GPU(48GB VRAM), demonstrating the framework's potential to detect spatially resolved tumor-stroma interactions and immune heterogeneity at scale.
Conclusions:
This workflow provides a scalable approach for constructing virtual TMAs and comparing spatial transcriptomic data. By integrating >3 million Visium HD bins from gastric cancer slides, it enables systematic TME profiling and identification of spatially resolved biomarkers relevant to tumor progression and therapeutic response.

#6863 Integrating computational and experimental approaches to optimize RNA fusion identification in BRCA associated breast cancer.

Janvi Sandhu[1], Anjana Bhardwaj[1], Chathurani Ranathunge[2], Dilshan C. Adhikari[2], Shiyanth Thevasagayampillai[2], Jamal Hill[3], Abhijit Mazumdar[3], Preethi H. Gunaratne[2], Isabelle Bedrosian[1]

[1]Department of Breast Surgical Oncology, UT MD Anderson Cancer Center, Houston, TX,[2]Department of Biology and Biochemistry, University of Houston, Houston, TX,[3]Department of Clinical Cancer Prevention, UT MD Anderson Cancer Center, Houston, TX

Background: Germline testing has improved detection of high-risk breast cancer patients but risk reduction in germline BRCA carriers is limited to surgical intervention with no chemoprevention options. RNA fusions, somatic events from chimeric transcripts, generate neoantigens that can serve as targets for preventative vaccines but its presence in BRCA associated breast cancer is unknown. While these fusions can be predicted from RNA sequencing by tools like *Arriba*, the prediction pipelines need in-vitro validation to optimize target identification. We hypothesize RNA fusions can be identified *in silico* in BRCA associated cancers and validated at high frequency.

Methodology: For identification of fusions in BRCA tumors, public repertoire of RNA sequencing of 34 BRCA associated breast cancers was utilized. Mammary tissue from 21 cancer free subjects were used as controls. For validation of in silico predictions, RNA sequencing was performed on mammary tissues or tumors from 7 normal-like BRCA $c^{o/co}$ Cre $^{+\backslash+}$ p53 $^{+\backslash+}$ controls and 23 BRCA $c^{o/co}$ Cre $^{+\backslash+}$ p53 $^{+\backslash-}$ mice. RNA fusions in both human and mouse samples were detected using Arriba pipeline, followed by post-Arriba filters excluding fusions in normal controls, intra-genic, non-coding RNA and fusion without coding or splice-site breakpoints. Mouse fusion candidates were validated using PCR and Sanger Sequencing.

Results: In human BRCA tumors 338 fusions were detected by *Arriba*; with post- *Arriba* filters, 33 noncanonical, 251 noncoding genes & 3 fusions in CDS/CDS splice sites were removed with 51 patients specific fusions remaining. Fusions were detected in 50% of patient tumors. In 23 BRCA mouse samples, *Arriba* initially detected 352 fusions ; 157 noncanonical, 107 noncoding genes and 22 fusions present in normal control samples were excluded, yielding 69 fusions. Five recurrent mouse fusions- *Thoc1-Usp14* (2 breakpoints), *Tmcc-Raf1*, *Usp14-Thoc1*, *Krt5a-Krt6* (5 breakpoints), *Runx2-Tmem191c* with read counts of 4-21, 31-49, 2-4, 1-3 and 1 respectively were selected for validation. Four of these (except *Runx2-Tmem191c)* were validated by PCR followed by Sanger sequencing. In *Krt5a-Krt6a* fusions, three of five fusion junctions with >1 read count were confirmed. Notably, *Usp14-Thoc1* showed fusions in 8 more samples, suggesting isoforms in common gene partners missed due to low sequencing depth. Overall validation rate of integrated *Arriba*-post *Arriba* pipeline was 80% reaching 100% with >1 supporting reads.

Conclusion: RNA Fusions were successfully detected in both human and mouse samples using *Arriba*. Computational predictions using *Arriba* plus stringent post-filtering, reliably predicts RNA fusions when supported by >1 read count underscoring the importance of integrating computational prediction with *in vitro* validation to accurately characterize fusion landscapes in BRCA-associated breast cancer models.

#6865 A knowledge graph screen of innovative versus incremental lung cancer trials for need-aligned designs.

Mahitha Simhambhatla[1], Maya Ylagan[1], Praneeth Sajja[1], Daruka Mahadevan[2], Erik S. Ferlanti[1], James Carson[1], Boone Goodgame[3], Ehsan Irajizad[4], Samir M. Hanash[4], Jeanne Kowalski[1]

[1]The University of Texas at Austin, Austin, TX,[2]UT Health Science Center at San Antonio, San Antonio, TX,[3]The university of Texas at Austin, Austin, TX,[4]UT MD Anderson Cancer Center, Houston, TX

Background. ClinicalTrials.gov lists >500,000 studies, raising the question of how often “new” trials are truly novel versus incremental design variants. Lung cancer remains a leading cause of cancer-related death worldwide, underscoring the need for innovative over incremental trials. Prior work has used clinical trial knowledge graphs (KGs) to support design recommendations. Here, we apply a small cell lung cancer (SCLC) patient-anchored KG to classify lung cancer targeted therapy trials as “novel additions” versus “aggregate similarity” and to identify gaps where new, need-aligned trial designs are warranted.
Methods. We curated 286 adult lung cancer targeted therapy trials from ClinicalTrials.gov that were retrieved as matches to a SCLC case. We built a trial-to-trial KG by linking each trial to key entities (e.g., tumor type, genomic alterations, targets/pathways, drug classes) and learned graph-based embeddings to obtain trial-level representations. Cosine similarity was used to quantify trial similarity between embeddings; community detection was used to define trial clusters. Clusters with ≥5 trials and median within-cluster similarity ≥0.80 were labeled “aggregate similar.” A novelty score (1 – maximum similarity to any other trial) and betweenness centrality were combined to label “novel additions”. A predefined set of SCLC molecular report-matched trials was cross-referenced to characterize their distribution across identified clusters.
Results. Altogether, we defined 4 trial clusters (median size 67), three of which met our criteria for aggregate similarity, comprising 74% (n=212) of large community trials of highly similar designs. Across all 286 trials, median pairwise (0.74) and nearest-neighbor similarity (0.98) were consistent with dense replication of existing biomarker- and line-of-therapy-defined templates. Only 38 trials (13%) were classified as novel additions based on combined novelty (median=0.070) and betweenness centrality (median 0.004) thresholds, and showed significantly ($p < 0.01$) higher median scores in both as compared to non-novel trials. Novel additions were enriched in a single aggregate similarity cluster (24/74 trials) that contained most case molecular report-matched trials (65/68). The remaining trial clusters had 1-10% novel additions, indicating that case-level matching occurs within dense targeted therapy communities, whereas a KG analysis can surface structurally distinctive, novel addition trials.
Conclusions. KG analysis of lung cancer trials provides a principled way to operationalize “novel addition” versus “aggregate similarity” at the portfolio level. This patient-anchored framework can support sponsors, investigators, and regulators in prioritizing innovative trials, reducing redundancy in an already crowded lung cancer trial landscape, and ultimately aligning trial development with unmet patient needs.

#6866 Mapping cancer-relevant genetic interactions with functional module prediction and in4mer enCas12a platform.

Chenchu Lin[1], Veronica Gheorghe[1], Juihsuan Rosalind Chou[1], Sabriyeh Alibai[1], Subin Kim[1], Nazanin Esmaeili Anvar[1], Yixin Xu[1], Xingdi Ma[1], Lori L. Wilson[1], Russell Moser[2], Junjie Chen[1], Christopher J. Kemp[2], Scott Kopetz[1], Glen Traver Hart[1]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]Fred Hutchinson Cancer Center, Seattle, WA

Genetic interaction (GI), particularly synthetic lethality, is essential to functional genomics and cancer therapy. In yeast, systematic GI mapping has produced a near-complete network covering ~90% of genes, establishing core principles of GI network architecture and defining major functional modules. However, translating this success to human cells has been far more challenging due to the larger genome, greater complexity, and extensive cellular heterogeneity. Even the million-scale CRISPR Cas9 combinatorial screens sample only ~0.1% of the possible search space, highlighting the need for predictive models and more efficient multiplex perturbation technologies. To address this challenge, we leveraged insights from the yeast GI network to prioritize human gene modules predicted to be enriched for genetic interactions. Through this strategy, we identified five densely gene modules, including receptor tyrosine kinase (RTK) signaling and the DNA damage response (DDR) pathway, providing a tractable search space for systematic GI mapping. Using our optimized CRISPR enCas12a-based in4mer platform, which enables compact, high-fidelity multiplex perturbations, we performed all-by-all GI screens within these modules. With a single 88k construct library, we performed all pairwise combinations of 206 RTK genes, 167 DDR genes, and 4,435 curated paralog pairs, along with positive and negative controls, across 12 cancer cell lines. Consistently, paralogs remained the dominant source of strong genetic interactions across screens, while integrated multi-line analysis revealed weaker but consistent synthetic lethal and suppressor interactions. Notably, we identified a dense GI network within the ER-localized protein glycosylation pathway and validated key interactions in 3D organoid and patient-derived xenograft, demonstrating that 2D GI screens are robust predictors of GI dependencies in more physiologically relevant systems. In conclusion, combining functional-module prioritization with enCas12a multiplex screening provides an efficient strategy for uncovering meaningful subsets of the human GI landscape and supports discovery of therapeutically relevant vulnerabilities at scale.

#6867 Uncovering the systems-level mutational landscape of intrinsically disordered regions in cancer.

Kivilcim Ozturk[1], Hannah K. Carter[2]

[1]UC San Diego School of Medicine, La Jolla, CA,[2]UC San Diego, La Jolla, CA

Biological functions and cellular behaviors arise from interactions among proteins and other molecules within cells, and cancers often act to perturb these interactions, resulting in disease phenotypes. Many proteins contain intrinsically disordered regions (IDR) that perform biological functions without relying on a single well-defined conformation. While IDRs of several cancer drivers have emerged as central mediators of oncogenic signaling and post-translational modifications, their role in protein-protein interactions (PPI) is less clear. Here, we set out to characterize the mutational landscape of IDRs in how they contribute to perturbation of underlying protein interaction networks in cancer. A comprehensive analysis of our structurally resolved PPI network showed that IDRs mediating protein interactions are significantly targeted by cancer missense mutations. Furthermore, proteins containing IDRs are more centrally located in the PPI network, especially cancer drivers, where disordered drivers are significantly more central than ordered ones, suggesting that the inherent conformational heterogeneity of IDRs might enable them to interact with a wider range of molecular partners, allowing them to easily propagate signals through the cell and the mutations targeting them to generate a larger impact on cellular activity and phenotypes. Overall, our work demonstrates the importance of uncovering the systems-level mutational landscape of IDRs to identify mechanisms driving cancer development and progression, enabling more effective selection and development of cancer therapeutics.

#6868 Understanding molecular mechanisms of prostate cancer via transcriptome-wide causal gene regulatory networks.

Min Zhang, Zhongli Jiang, Xiaolin Zi, Danni Liu, Yan Li, Dabao Zhang

UC Irvine, Irvine, CA

Background: Prostate cancer remains the most common malignancy among men and a leading cause of cancer-related death worldwide, with an estimated 313,780 new cases expected in 2025. Despite recent advances in screening and treatment, the molecular mechanisms driving prostate cancer are not fully understood. The growing availability of multi-omics data from the same patients provides an unprecedented opportunity to reveal disease pathways and identify novel therapeutic targets. However, integrating these large-scale, multi-modal, and heterogeneous omics profiles poses substantial statistical and computational challenges.

Methods: Transcriptomic and genomic data were obtained from prostate tumor samples in GEO (GSE70768). After pre-processing and quality control, the dataset included 17,426 genes and 272,564 single nucleotide polymorphisms (SNPs) from 90 patients. We applied SIGNET to identify instrumental variables (IVs), yielding 7,806 gene-IV pairs for 3,309 genes. Using these IVs, we then applied SIGNET to conduct causal inference and construct transcriptome-wide gene regulatory networks for prostate cancer based on the integrated genomic and transcriptomic data, supported by 100 bootstrap datasets.

Results: We identified 1,840 gene regulations that were repeatedly recovered in ≥80% of the bootstrap datasets, of which 369 appeared in ≥95% of the constructions. Within these robust subnetworks, we detected hub genes including DDX51, PNPT1, FARSLB, and IFI6. Using data from the Cancer Genome Atlas (TCGA) project, we validated that IFI6 is highly correlated with its predicted targets (correlation coefficient 0.52 ~ 0.90, $p < 0.01$). IFI6 is a negative regulator of innate immunity and has been reported to be overexpressed in multiple cancers, with emerging evidence supporting its role in tumorigenesis and drug resistance. Our findings nominate IFI6 as a candidate regulator in prostate cancer, warranting further functional studies to define its role in tumor proliferation, metastasis, therapy responses, and the immune tumor microenvironment. Finally, Ingenuity Pathway Analysis (IPA) of top subnetworks with high bootstrap frequency highlighted several significant pathways, including primary immunodeficiency signaling and communication between innate and adaptive immune cells.

Conclusion: Using multi-omics data from prostate cancer tissues coupled with transcriptome-wide causal inference, our data-driven detection of regulator-target pairs provides new insights into the molecular mechanisms of prostate cancer and may ultimately facilitate the development of personalized treatment strategies.

#6869 Multi-omic profiling identified three molecular clusters in urothelial carcinoma: A path towards clinical precision.

Nils Cornelis Hendricus van Creij[1], Piotr Tymoszuk[2], Florian Handle[3], Andreas Seeber[4], Teresa Sellemond[1], Agnieszka Martowicz[4], Eva Comperat[5], Hamed Wafa[1], Steffen Ormanns[6], Michael Gunther[6], Walther Parson[7], Maxim Noeparast[8], Frederic Romain Santer[9], Jose Daniel Subiela[10], Petros Grivas[11], Roger Li[12], Zoran Culig[1], Renate Pichler[13]

[1]Experimental Urology, Medical University of Innsbruck, Innsbruck, Austria,[2]Data Analytics As a Service Tirol, Worgl, Austria,[3]XPseq Analytics GmbH, Innsbruck, Austria,[4]Internal Medicine V (Hematology and Oncology), Medical University of Innsbruck, Innsbruck, Austria,[5]Pathology, Medical University of Vienna, Vienna, Austria,[6]General Pathology, Medical University of Innsbruck, Innsbruck, Austria,[7]Legal Medicine, Medical University of Innsbruck, Innsbruck, Austria,[8]Translational Oncology, II. Med Clinics Hematology and Oncology, University of Augsburg, Augsburg, Germany,[9]Gynecology and Obstetrics, Medical University of Innsbruck, Innsbruck, Austria,[10]Urology, Instituto Ramon y Cajal de Investigacion Sanitaria, Hospital Universitario Ramon y Cajal, Madrid, Spain,[11]Fred Hutchinson Cancer Center, University of Washington, Seattle, WA,[12]GU Oncology, Moffitt Cancer Center, Tampa, FL,[13]Urology, Medical University of Innsbruck, Innsbruck, Austria

Introduction: Urothelial carcinoma (UC) is a molecularly heterogeneous disease, and transcriptome-based classification systems have given important insights into its biology. The current consensus classifications for UC represent a major step toward biological stratification; however, its prognostic and predictive relevance remains uncertain, limiting use in clinical guidelines. Furthermore, most molecular schemes have been developed either for non-muscle invasive (NMIBC) or muscle-invasive disease (MIBC), relying only on bulk transcriptomic data. This fragmentation hinders comparability across studies and integration with proteomic or single-cell datasets. A simplified molecular framework is therefore needed to capture UC heterogeneity more comprehensively and to support personalized therapeutic approaches.

Materials & Methods: Using the TCGA bulk bladder cancer transcriptome dataset, we developed three distinct molecular UC clusters, which were validated using 18 transcriptome, 3 proteome and 33 UC cell line datasets. Making use of *in silico* predictions, we selected promising treatment strategies, which were further screened *in vitro* using the IncucyteS3 live-cell imaging system and RNA-sequencing on representative cell lines.

Results: Our transcriptomic and proteomic analyses revealed three UC clusters with distinct molecular, biological and clinical features. Each cluster showed specific mRNA and protein expression patterns, metabolic profiles, and driver gene alterations, translating into divergent prognoses and predicted therapeutic sensitivities. Novel approaches, like liquid biopsy-based stratification using ECM-derived urinary peptides or IHC-based profiling of the proposed distinct markers, are currently being investigated. The stroma-rich, high-risk cluster #1 was associated with responsiveness to ferroptosis inducers and PARP inhibition. Cluster #2, which is highly proliferative and immune-infiltrated with basal/squamous traits, showed predicted benefit from cytotoxic agents and inhibition of EGFR or MEK signaling pathways. Cluster #3, dominated by luminal papillary, low-risk tumors with minimal stromal and immune components, appeared susceptible to epigenetic therapies and EGFR/FGFR inhibition.

Conclusion: Our new integrative molecular classification scheme provides a practical framework for patient stratification, personalized transcriptome- and proteome-based risk assessment, preclinical research and clinical trial design, including both NMIBC and MIBC.

#6870 Quartet: A database of robust somatic mutations in tumor cell lines.

Daniel Halmos[1], Trey Ideker[2]

[1]UCSD Medical Ctr., San Diego, CA,[2]UC San Diego, La Jolla, CA

Introduction: Current collections of tumor cell lines, and their genomic, proteomic, and phenotypic reference data, have been vastly important to cancer research. Given the centrality of these datasets, it is paramount that they be of the highest quality. Here we show that up to 20% of mutations identified within these collections are erroneous, owing to sequencing artifacts, misaligned reads, in addition to other sources of error. To achieve a high-quality set of mutation profiles for all 329 tumor cell lines sequenced by the Cancer Cell Line Encyclopedia (CCLE), we processed all genomes using the consensus of four complementary mutation identification tools, yielding an online resource we call Quartet. We demonstrate considerable benefit from its use compared to currently used mutation profiles across a variety of tasks.
Methods: We retrieved raw sequence data previously generated by the Cancer Cell Line Encyclopedia. We filter for short sequences that disproportionately contribute to noise in mutation profiles, identify candidate mutations using 4 mutation identification tools, and then filter those candidate mutations to the subset with agreement from at least 3 tools. Using a HCC1395 cancer cell-line sequenced at ultra-high depths as a positive control, we attribute roughly 1/5 of mutations originally generated by CCLE to technical artifacts and demonstrate enrichment of True-Positive mutations from Quartet. These artifactual mutations persist at the gene-level, where we observe divergence between predicted variant effects from our ground truth and those expressed in CCLE, a divergence which is significantly recovered through Quartet. When aggregated across all cell lines and viewed with respect to Variant Allele Fraction (VAF) in original CCLE mutations, we observe a bimodal distribution of variants whose lesser mode is enriched for technical artifacts which Quartet effectively filters. We demonstrate these artifactual mutations cannot be removed post-hoc through either VAF thresholds or Variant Effect Prediction, nor through use of alternate databases such as DepMap. We then leverage this recalled CCLE dataset to train pharmacogenomics models and show significant improvement to predictive performance across 10 anti-cancer drugs.
Conclusion: Quartet presents a public resource of cancer cell lines which use consensus support of mutation callers. Quartet demonstrates depletion of artifactual mutations and their deleterious effects in a variety of downstream tasks. These results highlight the potential to enhance cancer biological discovery through Quartet, and we expect these benefits to compound as additional cell lines are incorporated. Quartet data are made publicly available through zenodo and source code is made available at https://github.com/digitaltumors/quartet.

#6871 Real-world analytical concordance of four next-generation sequencing assays: Impact of assay methodology and bioinformatics on clinical decision-making.

Liudmila Zhukova, **Sergei Smolin**, Svetlana Smolina, Nikolai Karnaukhov

Moscow Clinical Scientific Center, Moscow, Russian Federation

Background: Broad tumor genomic profiling is increasingly required for selecting targeted therapies, yet analytical concordance across next-generation sequencing (NGS) assays used in routine practice remains uncertain. We conducted a real-world comparison of four NGS platforms to evaluate variability in key clinically relevant metrics, including tumor mutational burden (TMB), driver SNVs, and driver CNVs.
Methods: Ten patients provided four matched FFPE eppendorfs each. Each aliquot contained at least 10 FFPE sections of 5-7 µm thickness, and all blocks met a ≥20% tumor cell requirement, ensuring uniform pre-analytic quality across all submitted material. All aliquots were analyzed in parallel across four laboratories: FMI (reference CGP), Private Lab 1, Private Lab 2, and Private Lab 3. For the primary comparison, assays were evaluated for patient-level reporting success (≥1 analyzable aliquot per patient), tumor mutational burden (TMB), driver SNVs, and driver CNVs.
Results: FMI and Private Lab 1 successfully generated complete reports for 10/10 patients, Private Lab 3 reported 9/10. Private Lab 2 produced reports for 2/10 patients, an analyzability rate insufficient for inclusion in comparative metrics. TMB was reported for 10/10 patients by FMI and Private Lab 1 and 9/9 evaluable patients by Private Lab 3. For clinically actionable SNVs, FMI identified 6 variants; concordance was Private Lab 3 100% (6/6) and Private Lab 1 67% (4/6). For driver SNVs, FMI detected 31 variants; Private Lab 3 showed strong concordance across analyzable patients (83-100%), whereas Private Lab 1 showed markedly lower concordance (0-33%). For driver CNVs, FMI detected 14 alterations; Private Lab 3 identified 6/14, while Private Lab 1 detected none. Even within the two patients analyzed by Private Lab 2, concordance with FMI was inconsistent. Driver SNVs showed partial overlap, and several FMI-confirmed alterations were not detected. Driver CNVs were not identified in either patient, despite their presence in the reference assay.
Conclusions: Concordance across NGS assays was suboptimal even among aliquots that were successfully processed, indicating substantial assay-to-assay variability. The markedly limited analyzability of the fourth platform further demonstrates that test performance in real-world settings is driven not only by the biological material but also by pre-analytic workflow, laboratory methodology, and the robustness of bioinformatic pipelines. Our findings show that results from different assays can diverge significantly, which may directly affect therapeutic decisions for patients. These observations underscore the need for independent analytical validation of every NGS assay before its results are used to guide clinical management.

#6872 Assessing the Impact of Variant Calling Pipelines on *De Novo* SBS Mutational Signature Extraction.

Zichen Jiang[1], Jessica Nghi Au[1], Mariya Kazachkova[2], Marcos Diaz-Gay[3], Raviteja Vangara[1], Ludmil B. Alexandrov[1]

[1]Department of Cellular and Molecular Medicine, Department of Bioengineering, Moores Cancer Center, University of California San Diego, La Jolla, CA,[2]Department of Cellular and Molecular Medicine, Moores Cancer Center, Biomedical Sciences Graduate Pr, University of California San Diego, La Jolla, CA,[3]Digital Genomics Group, Cancer Genomics Program, Spanish National Cancer Research Center, Madrid, Spain

Deconstructing the mutational processes in a tumor's genome, known as mutational signatures, provides critical insights into cancer etiology and evolution. However, how the upstream variant-calling strategies propagate to affect the accuracy of *de novo* signature extraction remains underexplored. Here, we systematically evaluate how mutation-calling algorithms influence single-base substitution (SBS) signature analysis using over 8,900 whole-exome sequences from The Cancer Genome Atlas and 1,800 whole genomes from the Pan-Cancer Analysis of Whole Genomes study. We demonstrate that consensus variant-calling strategies produce remarkably stable mutational signatures across different reference genomes and pipeline versions. In contrast, individual variant callers introduce systematic false-positive mutations that manifest as stable, artifactual signatures, detectable by three signature extraction tools. A minimal consensus approach, requiring agreement between just two variant callers, successfully eliminates technical signatures while preserving genuine biological signals and is especially important for high SBS mutational context analysis. Our findings establish consensus variant calling as essential for robust mutational signature analysis and provide a clear framework for distinguishing biological processes from technical artifacts.

#6873 Knowledge graph driven insights and drug repurposing opportunities for neuroendocrine prostate cancer.

Pawan Verma, Prasanna Kumar Sekar Sekar, Dharani Dadi, Manimala Sen, Nobal Dhruw, Abhishek Jha

Elucidata Corporation, San Francisco, CA

Biomedical Knowledge Graphs (BKGs) have emerged as powerful tools for integrating, managing, and exploring this complex information landscape. Elucidata has built a knowledge graph that integrates 20+ high-quality, well-curated knowledge sources. Additionally, we have developed a GUI-based application that enables users to derive insights in a no-code manner. This facilitates the discovery of drugs that modulate a target's activity through upstream or downstream network effects.Neuroendocrine prostate cancer (NEPC) represents a highly aggressive histologic subtype of prostate cancer. Literature review shows that the “true biological problem” for drug repurposing in NEPC is not the disease state itself, but the underlying causal process of treatment-induced lineage plasticity. This transition is initiated by RB1 and TP53 loss and sustained by a mutually reinforcing MYCN-AURKA-EZH2 regulatory axis. The outcome of this shift is the loss of conventional therapeutic targets (such as AR and PSMA) and the emergence of new, actionable vulnerabilities—including AURKA, EZH2, BCL2, and DLL3.Its poor clinical outcomes stem from a combination of delayed detection, rapid disease progression, and the absence of effective therapeutic options. Additionally, the number of publicly available NEPC datasets is very low, hampering early-stage R&D. We demonstrate how knowledge graphs can be queried to identify genes with dependency profiles similar to MYCN’s essentiality. Genes with similar essentiality profiles are almost always functionally related (e.g., belonging to the same complex or pathway). We further provide evidence for drugs approved for other diseases that share molecular underpinnings with NEPC and may be advanced into clinical trials to treat NEPC.

#6874 A transcriptome-based AI meta-model for immunotherapy response classification in hepatocellular carcinoma.

Jimin Seo[1], Na Young Kwon[2], Ki Wook Lee[1], Han-En Lo[1], Young-Jun Jeon[1]

[1]Department of Integrative Biotechnology, Sungkyunkwan University, Suwon, Korea, Republic of,[2]Department of MetaBioHealth, Sungkyunkwan University, Suwon, Korea, Republic of

Immune checkpoint inhibitor (ICI) is frequently selected as first-line therapy in advanced hepatocellular carcinoma (HCC), yet current biomarkers that predict therapeutic response show limited accuracy. Robust and clinically applicable predictors of ICI response in HCC need to be established. We performed tissue RNA-seq on ICI-treated HCC patients (Atezolizumab plus Bevacizumab, Nivolumab, or Ipilimumab plus Nivolumab) and developed an AI stacking-based meta-model to classify responders (R, n=32) and non-responders (NR, n=57). To address class imbalance, 80% of samples were distributed into three balanced training sets, and the remaining 20% were used as an internal test set. Gene-feature selection performed with six tree-based algorithms (AB, ERT, GB, LGB, RF, and XGB) improved mean AUC from 0.58 to 0.73 and mean MCC from 0.25 to 0.43. The stacking meta-model, incorporating 14 algorithms (AB, CB, ERT, GB, LGB, RF, XGB, four SVM kernels, LR, NB, and MLP), further increased mean AUC to 0.95 and MCC to 0.79. The meta-model achieved an AUC of 0.92 and MCC of 0.62 in the internal test set, and an AUC of 0.84 and MCC of 0.82 in an external ICI-treated HCC cohort (Table 1). Meta-scores derived from the model clearly stratified clinical outcomes. Patients with high scores showed improved PFS (HR 0.27, 95% CI 0.17-0.45; p<0.0001) and OS (HR 0.37, 95% CI 0.22-0.62; p<0.0001). Feature selection identified 11 AI-important gene (AIG) sets (10-173 genes each), and each set overlapped with at least two others through shared AIGs, reflecting convergent biological signals. Analysis of AIG sets in immune-cell populations from an external single-cell RNA-seq cohort revealed enrichment patterns consistent with known mechanisms of immune activation and resistance. These findings demonstrate that the AI meta-model can help to classify immunotherapy response in HCC and stratify survival outcomes, while revealing biologically relevant AIG signatures.

Table 1. Performance of the final AI meta-model for immunotherapy response classification in HCC

	MCC	**ACC**	**AUC**	**Sensitivity**	**Specificity**
Training	0.88	0.94	0.96	0.96	0.93
Internal Test	0.62	0.76	0.92	1.00	0.64
External Validation	0.82	0.90	0.84	1.00	0.80

#6875 Mapping convergent neurodegenerative and oncogenic pathways in ALS using a multi-scale knowledge-graph framework.

Vasileios Alevizos[1], Sabrina Edralin[2], Clark Xu[3], George A. Papakostas[4], **Zongliang Yue**[5]

[1]Department of Learning, Informatics, Management and Ethics, Karolinska Institutet, Solna, Sweden,[2]Department of Crop Sciences, University of Illinois Urbana-Champaign, Urbana, IL,[3]Mayo Clinic Artificial Intelligence & Discovery, Rochester, MN,[4]Department of Informatics, Democritus University of Thrace, Kavala, Greece,[5]Health Outcomes Research and Policy, Auburn University, Auburn, AL

Amyotrophic lateral sclerosis (ALS) affects approximately 1.5 per 100,000 person-years in the United States, with a point prevalence of 3.8-5.6 per 100,000. ALS arises from the intersection of diverse pathogenic mechanisms spanning genetic mutations (C9orf72, SOD1, FUS, TARDBP), protein misfolding, RNA-metabolism defects, nucleocytoplasmic transport failure, prion-like propagation, mitochondrial dysfunction, and neuroinflammation. Increasing evidence from plasma proteomics and machine-learning studies indicates that these perturbations emerge years prior to clinical onset, highlighting an urgent need for mechanistically grounded patient stratification. At the same time, epidemiologic and molecular studies suggest unexpected parallels between ALS and cancer—including dysregulated DNA-damage responses, cell-cycle control, metabolic rewiring, and aberrant immune signaling—yet these cross-disease links remain fragmented and poorly mapped. We developed a multi-scale ALS-cancer knowledge graph integrating genetic, transcriptomic, proteomic, neuropathological, and longitudinal clinical datasets. Knowledge-graph completion approaches, including link prediction, graph embeddings, and embedding-based reasoning, were applied to infer missing edges and reveal latent modules connecting ALS-associated genetic lesions to oncogenic pathways implicated in genome instability, altered proliferation, metabolic remodeling, and immune dysregulation. This approach enables systematic interrogation of shared molecular programs across ALS and cancer, exposing under-characterized immune, metabolic, and axonal-transport circuits whose dual roles have been suggested but never comprehensively mapped. Predicted associations were evaluated using enrichment for established ALS genes, overlap with curated oncogenic and neurodegenerative pathways, and their ability to stratify patients by site of onset, progression rate, and biomarker signatures. These analyses generated patient-specific pathway fingerprints that (i) resolve dominant biological mechanisms across clinical subgroups, (ii) illuminate mechanistic intersections between neurodegeneration and malignancy, and (iii) prioritize repurposed oncology targets with potential relevance to ALS. This knowledge-graph framework provides a scalable and mechanistically informed strategy for classifying ALS patients, uncovering ALS-cancer pathway convergence, and supporting targeted therapeutic discovery across traditionally siloed disease domains.

#6877 Chromatin networks inform the development of prognostic gene expression signatures in human cancers.

Lucio R. Queiroz[1], Shreyas Rajaram[1], Karnika Singh[1], Angelo Corso Faini[1], Erika Minonne[1], Nicola Barbaro[2], Scarfo Federico[3], Pushpita Roy[1], Wikum Dinalankara[1], **Luigi Marchionni**[1]

[1]Pathology and Laboratory Medicine, Weill Cornell Medicine, New York, NY,[2]Universita di Torino, Torino, Italy,[3]Universita San Raffaele, Milano, Italy

Chromatin architecture is a fundamental determinant of transcriptional regulation across cancer types, yet its integration into biomarker development has been limited. Here, we leverage DNA methylation as a surrogate for large-scale 3D genome structure to reconstruct A/B chromatin compartments and derive chromatin interaction networks that capture spatially coordinated gene organization. Using these methylation-informed networks, we define gene communities that reflect shared regulatory environments and potential co-functional behavior. We apply this framework to two prototypical epithelial malignancies—prostate cancer (PCa) and breast cancer (BCa)—using publicly available DNA methylation and transcriptomic datasets to identify chromatin-constrained modules whose coordinated dysregulation marks aggressive disease biology.

Across both cancer types, chromatin-driven gene communities show stronger coherence with known biological pathways than modules derived solely from expression data, underscoring the value of incorporating 3D genome context into molecular profiling. Using machine-learning approaches, we develop chromatin-informed prognostic signatures that integrate network topology with transcriptional alterations to predict metastasis and lethal outcome.

These signatures demonstrate robust performance across independent datasets and consistently outperform baseline expression-only predictors, highlighting the generalizability of chromatin context as a key source of prognostic information.

Functional analyses reveal that signature genes in both PCa and BCa are enriched for processes implicated in tumor progression, including lineage plasticity, hormone receptor signaling adaptation, disruption of chromatin insulation, and loss of compartmental integrity. Although the specific pathways differ in lineage-specific ways—such as androgen receptor signaling in PCa and estrogen receptor circuitry in BCa—the unifying mechanism lies in perturbations of higher-order genome organization that facilitate oncogenic rewiring.

Together, these findings demonstrate that methylation-derived A/B compartment structure provides a powerful and generalizable framework for reconstructing chromatin networks and identifying biologically coherent regulatory modules. By embedding transcriptomic alterations within their 3D genome context, we advance chromatin-informed gene expression signatures with strong prognostic utility across multiple cancer types, illustrated here through prostate and breast cancer.

Disclosures: AI was used to assist the preparation of this abstract.

#6878 AI-driven structural variant annotation expands therapeutic stratification in breast cancer.

Kriti Shukla[1], Yue Wang[2], Philip M. Spanheimer[3], Elizabeth Brunk[2]

[1]Department of Chemistry, University of North Carolina at Chapel Hill, Chapel Hill, NC,[2]Department of Pharmacology, University of North Carolina at Chapel Hill, Chapel Hill, NC,[3]Department of Surgery, University of North Carolina at Chapel Hill, Chapel Hill, NC

Interpreting variants of unknown significance (VUS) remains a critical barrier to precision oncology, particularly in breast cancer, where the majority of somatic mutations are rare and lack functional annotation. We developed VAMOS (Variant Annotation through Multi-Omics and Structural Biology), a machine learning framework that integrates genomic, transcriptomic, and protein structural data to predict the regulatory impact of coding variants on cancer-driving pathways.

Applied to >14,000 mutations across 1,000+ breast tumors, VAMOS identified 395 variant clusters in 346 proteins associated with dysregulated ESR1 and EZH2 activity, which are two key regulators of endocrine response and epigenetic reprogramming. Spatially resolved clustering revealed that 36% of rare variants co-localize with known oncogenic hotspots, enabling functional reclassification of clinically ambiguous mutations. These predictions were validated using CRISPR dependency and drug response datasets, revealing subtype-specific vulnerabilities. For example, distinct PIK3CA and TP53 clusters were differentially associated with response to mTOR, AKT, and DNA repair inhibitors.

This structure-informed approach expands the set of potentially actionable variants by over 30%, offering new biomarkers for patient stratification and rational therapeutic targeting. By linking variant positions in 3D protein space to transcriptional phenotypes and drug sensitivity, VAMOS provides a scalable framework to bridge molecular profiling and clinical decision-making. These findings support the integration of AI-driven structural genomics into translational oncology pipelines to improve precision treatment strategies.

#6879 Integrating omics-driven digital avatars with patient-derived experimental models to accelerate precision oncology.

Bulak Arpat[1], Amel Bekkar[1], Michelle Barnard[2], Mark Eccleston[3], Ioannis Xenarios[1], Kevin Buyens[1], Michael Prosser[1]

[1]TwinEdge Bioscience SA, Epalinges, Switzerland,[2]ValiRx plc, Nottingham, United Kingdom,[3]Inaphaea Biolabs Ltd., Nottingham, United Kingdom

Precision oncology increasingly depends on linking patient-specific molecular profiles to experimentally validated therapeutic response models. ValiRx and Inaphaea BioLabs are developing advanced patient-derived functional cancer models, while TwinEdge Bioscience is building large-scale Digital Avatar collections that mechanistically represent individual tumours across genomics, transcriptomics, proteomics, regulatory-network dynamics, and drug-response modules. By combining these complementary capabilities, we established a closed-loop translational framework for predicting, testing, and refining precision-treatment strategies, integrating (i) omics profiling of ValiRx's patient-derived cancer models, and (ii) construction of mechanistic Digital Avatars using TwinEdge's modelling engine.

Methods: Avatars are formed by integrating gene expression patterns, pathway activity states, inferred regulatory network, and compound-response modules. We generated digital avatars by integrating matched multi-omics datasets - transcriptomic, genomic, proteomic, and phenotypic layers - into large-scale, mechanistic network models that capture cell-state dynamics. Each individual avatar was then embedded within a population of thousands, allowing systematic comparison to identify subgroups that respond to a given intervention through shared mechanistic signatures. These mechanistically aligned avatars were then analysed to uncover repurposing opportunities and novel biomarker candidates.

Results: Across breast, ovarian, and colorectal cancer models, the Digital Avatars were shown to faithfully recapitulated tumour-specific regulatory features, including pathway activation, metabolic rewiring, and stress-response signatures. Avatar-based predictions revealed compound-specific vulnerabilities across multiple patient-derived models and uncovered previously uncharacterised mechanisms underlying differential responses to both targeted and broad spectrum agents. For certain models, observations pointed to the loss of regulation around VEGF-A, network rewiring around DNA/damage and some loss of c-Myc regulatory feedback. Together, these findings highlight the likelihood of a partial or full response, and allow suggestion of potential therapeutic intervention that would convert partial responders into full responders.

Conclusion: The TwinEdge-ValiRx translational program demonstrates the power of integrating computational Digital Avatars with patient-derived functional models. This combined framework enhances mechanistic interpretability, improves drug response prediction, and accelerates preclinical decision making. These early results form a concrete proof-of-concept that Avatar based loop dynamics capture treatment specific regulatory rewiring and can guide downstream therapeutic evaluation.

#6880 Optimization of a urine based NGS assay for detecting minimal residual disease in bladder cancer.

Yujia Zheng[1], Philip H. Abbosh[1], Muhammed Murtaza[2], Rhea Arya[3]

[1]Fox Chase Cancer Center, Philadelphia, PA,[2]University of Wisconsin Carbone Cancer Center, Madison, WI,[3]University of Florida, Gainesville, FL

Background: Current clinical tools struggle to accurately distinguish minimal residual tumor from benign bladder tissue following neoadjuvant chemotherapy in radicl cystectomy patients. Identification of complete responders might permit avoidance of radical cystectomy. To address this need, we developed an NGS-based urine assay to support non-invasive detection of chemotherapy response. This study focuses on optimizing key pre-analytical factors, including preservative selection and DNA extraction methods.
Methods: To overcome the logistical constraints of immediate -80 °C freezing, multiple urine preservatives were evaluated for their ability to maintain DNA integrity. Two DNA extraction strategies were compared: Sepharose-based extraction and a popular commercial kit. DNA from each condition was subjected quality control testing and to shallow pass whole-genome sequencing, followed by fragmentomics analysis, fragment end-motif profiling, and copy-number alteration (CNA) estimation.
Results: Sepharose extraction combined with a specially designed salt buffer yielded the highest DNA recovery. Commercial products did not promote fragment stability. Fragmentomics analyses showed that cancer patients exhibited higher fraction of aberrant fragments (FAF) than healthy controls when processed with Sepharose extraction. Distinct fragment end-motif patterns were also observed between the two groups. CNA analysis demonstrated that buffer-preserved samples produced higher estimated tumor fractions than samples processed with immediate freezing, indicating improved tumor signal retention. Unexpectedly, Sepharose extraction yielded improved signal-to-noise ratio as well.
Conclusions: The assay shows strong potential for detecting minimal residual bladder cancer and supporting non-invasive evaluation of complete response after chemotherapy. Salt buffer effectively enhances urinary DNA preservation and improves tumor-derived signal detection compared with immediate freezing. We are continuing to collect more urine samples to further refine and clinically validate the assay for clinical use.

#6881 Fast and cost-effective cloud-based pipelines to analyze cancer sequencing data.

Sam Wiseman[1], Samantha Van Seters[1], Saveliy Belkin[1], David I. Heiman[1], Vasuki Narasimha Swamy[1], Antonia Kowalewski[1], Scott Ritterbush[1], Zachary Everton[1], Ron Solan[1], Chip Stewart[1], David Lehotzky[1], Luis Antonio Corchete Sanchez[1], Xavi Loinaz[1], Haruna Tomono[1], Andrew D. Cherniack[1], Gengchao Wang[1], Brian P. Danysh[1], Young Seok Ju[2], Esther Rheinbay[1], Gad Getz[1]

[1]Broad Institute, Cambridge, MA,[2]Inocras Inc., San Diego, CA

With the release of high-quality resequencing of the TCGA cohorts, the scientific community has gained an opportunity to deepen its understanding of cancer's underlying causes and create paths forward for its treatment. Well-experienced with these cohorts, we have developed (i) state-of-the-art computational pipelines that accurately characterize variants in sequenced cancer data, as well as (ii) the infrastructure to run these pipelines quickly and cost-effectively in the cloud. Using a combination of established tools and specialized filters that reduce the likelihood of false calls, our pipelines have been honed over years of use and run extensively in numerous cancer studies. The TCGA cohort presented a unique challenge of >8,000 deep coverage, PCR-free whole-genome-sequenced (WGS) tumor-normal pairs, requiring a massive upscaling of our pipeline infrastructure. Enhancements to individual tools and refinements of our cloud-based workflow engine have reduced the time and cost of our pipeline execution by more than 50% since the start of 2025, allowing us to characterize more than 8,000 of the pairs in less than 1 month. This undertaking detected more than 262 million mutations and 1.17 million structural variants that we believe will provide deep insight into cancer biology and potential therapeutic targets.

#6882 Mechanism-concordant cell-line selection: Bridging real-world tumor drivers and *in vitro* models for target validation.

Aviva G. Beckmann, Phillip Comella, Qi Pan, Jonathan Tyler, Enrique Podaza, Veronica Calvo-Vidal, Mark Fereshteh, Iker Huerga, Eric E. Schadt

Pathos AI, New York, NY

Cancer cell lines remain workhorses for mechanistic studies and preclinical drug prioritization, but their transcriptional programs can shift as they move from in vivo to in vitro conditions and drift under prolonged culture. Selection for growth advantage and stress tolerance can alter lineage and resistance programs, yet these models are still used to infer mechanisms of action and project efficacy to patients, often without a rigorous link to patient-level disease biology.

We leveraged multimodal real-world data comprising longitudinal clinical records, tumor DNA and RNA sequencing, to infer in vivo driver mechanisms that impact outcomes under standard of care. We then developed an integrative framework that connects these patient-level mechanisms to in vitro systems where they can be perturbed and pharmacologically modulated. For each disease context, we construct predictive network models of cancer progression and identify cell type-localized “mechanism programs” whose activity associates with survival and progression. In parallel, we build matched network models for cancer cell lines using multiomic and perturbation data, deriving corresponding mechanism programs in vitro.

The key step is establishing mechanistic and phenotypic concordance between patients and models. For each patient-inferred driver mechanism, we search the in vitro network space for subnetworks with similar structure and activity, defining mechanism-concordant lines and tissue cultures. In phenotypically concordant systems, perturbing the mechanism program shifts molecular state and cell viability in a manner consistent with the direction of the patient-level outcome association; in discordant systems, the same program either fails to respond or drives phenotypes inconsistent with clinical benefit, revealing culture-induced artifacts.

We illustrate this framework in ovarian cancer. Multimodal real-world data reveal distinct driver mechanisms across the disease course, including hormone signaling, lineage plasticity, and platinum resistance networks. A restricted subset of ovarian cell lines and ex vivo cultures are mechanistically and phenotypically concordant for these programs; in these models, genetic or drug perturbation of implicated subnetworks reduces viability, whereas non-concordant models show limited effects. Future work aims to prospectively test modulators nominated by the integrated system in patient-derived ex vivo cultures and assess whether agents targeting concordant mechanisms shift molecular programs and viability as predicted, while agents predicted to be inactive do not. This patient-to-model mechanism bridge enables systematic selection of appropriate in vitro systems, prioritization of targets with both outcome-level and perturbation support, and calibration of preclinical effect sizes against clinically meaningful benefit.

#6883 An RNA-based survival model predicting real-world response to trastuzumab deruxtecan.

Klemen Ziberna, Anze Lovse, Zan Kuralt, Janez Kokosar, Marcel Levstek, Luka Ausec, Miha Stajdohar, Rafael Rosengarten, Mark Uhlik, **Joshua Wheeler**

Genialis, Inc., Boston, MA

Antibody-drug conjugates (ADCs) such as trastuzumab deruxtecan (T-DXd, Enhertu) have redefined therapy for HER2-expressing breast cancer, yet clinical benefit remains unpredictable across HER2-positive, -low, and -ultralow disease. Current IHC/FISH diagnostics quantify receptor abundance but fail to capture the molecular state that governs ADC sensitivity.To address this gap, we developed an RNA-based survival model for Enhertu using the Genialis Supermodel, a large molecular foundation model. The Supermodel maps gene expression into hundreds of biomodules, algorithmic representations of biology that capture diverse oncologic hallmarks including signaling pathways, stress responses, and drug-target mechanisms. We used biomodules specific to ADC mechanisms-of-action as input features in predictive models that learn biological patterns associated with T-DXd response.In a real-world clinical cohort (n≈90 T-DXd-treated patients) from the Tempus real-world multimodal database, we performed survival modeling of time-to-next-treatment (rwTTNT). Stratified nested cross-validation was used to assess model robustness and predictive performance. Prognostic specificity was assessed in prior-line rwTTNT and in an independent clinically matched cohort. The model showed statistically significant discrimination (C-index 0.632, HR 2.22 [95% CI 1.14-4.35], p = 0.017). Predicted-benefit patients had longer rwTTNT (345 vs 245 days), and no prognostic signal appeared in control cohorts (C-index ≈ 0.5), suggesting predictive specificity. Top predictive features aligned with ADC biology, including TOP3B and TOP2A (topoisomerase payload), ATM and TP53 (DNA damage response), HIF1A (hypoxia), ESR1 (hormone signaling), and XBP1/NFATC1 (stress and immune regulation).This Enhertu survival model applies biologically structured AI to real-world RNA-seq data to reveal treatment-specific patterns of response. Integrating large-scale embeddings, mechanistic biomodules, and survival modeling, we identified biological programs related to DNA repair and stress response associated with T-DXd benefit.

#6884 Quantum mechanics-based multi-tensor AI/ML correctly predicts — glioblastoma patients' overall survival, gene targets to sensitize the tumors, and the tumors' response to their targeting — from their whole genomes.

Orly Alter[1], Sri Priya Ponnapalli[2], Marissa Coppola[3], Angela C. Gushue[3], Tessa O. House[3], Penelope L. Miron[4], Kristy L. S. Miskimen[4], Kristin A. Kiernan[9], Huanming Yang[10], Jay Bowen[8], Ghunwa A. Nakouzi[7], Doron Lipson[6], Jill S. Barnholtz-Sloan[5], Andrew E. Sloan[11], Tiffany R. Hodges[4], Asaf Zviran[12], Jessica W. Tsai[3]

[1]University of Utah and Prism AI Therapeutics, Inc., Salt Lake City, UT,[2]Scale AI, Inc., San Francisco, CA,[3]Children's Hospital of Los Angeles and University of Southern California, Los Angeles, CA,[4]Case Western Reserve University School of Medicine, Cleveland, OH,[5]Winship Cancer Institute of Emory University, Atlanta, GA,[6]Ultima Genomics, Inc., Fremont, CA,[7]HudsonAlpha Clinical Services Lab LLC, Huntsville, AL,[8]The Abigail Wexner Research Institute at Nationwide Children's Hospital, Columbus, OH,[9]Illumina, Inc., San Diego, CA,[10]Complete Genomics, Inc., San Jose, CA,[11]Wright State University, Dayton, OH,[12]Prism AI Therapeutics, Inc., Salt Lake City, UT

Despite the growth in targeted therapy development, the drug failure rate has increased to ~95%. As clinical trials demonstrated, the targeted gene alone does not predict whether patients would have longer life expectancy in response to a drug. As studies with model organisms showed, the effect of the drug, and the mechanisms underlying it, depend on the entire multi-ome. But multi-omic data are small-cohort, noisy, and high-dimensional, i.e., extremely difficult to model.

We have developed our quantum mechanics-based artificial intelligence and machine learning (AI/ML) to overcome these challenges [doi: 10.1158/1538-7445.AM2025-CT227].

We demonstrated our algorithms in the unsupervised modeling of, e.g., whole genomes of 85 astrocytoma patients. Mechanistic interpretation showed that the model blindly removed batch effects, separated normal demographic variations, and discovered a disease-specific genome-wide pattern of DNA copy-number alterations. This pattern was used to derive an actionable predictor of patients' overall survival (OS) and gene targets to sensitize their tumors.

We computationally validated both the predictor and the modeling in federated studies of mutually-exclusive sets of ~50-250 patients. The modeling repeatedly discovered a representation of the predictor in every study, in astrocytoma grades II, III, and IV, i.e., glioblastoma (GBM), patients.

We experimentally validated the predictor in a clinical trial in 79 GBM patients, initially retrospectively, and, in a four-year follow up, also prospectively [doi: 10.1063/1.5142559, 10.1145/3624062.3624078]. In all the cohorts, the predictor, with 75-95% concordance with survival, was more accurate than all standard-of-care indicators. With 100% reproducibility among Complete Genomics, Illumina, and Ultima whole-genome sequencing, and >99% when including Affymetrix and Agilent DNA microarrays, the predictor was also the most precise.

Here, we describe functional genomics experimental validation of both a gene target predicted to sensitize the tumors, as well as the predicted tumors' response level. Guide RNAs were designed and a lentiviral CRISPR-Cas9 all-in-one vector was utilized to knock out the candidate target. Knockout validation at the protein level was performed using Western blot. Knockout in patient-derived GBM cell lines resulted in significantly attenuated cell viability and proliferation. The level of attenuation was significantly different between the cell lines, in agreement with their whole genome-based predicted response.

We conclude that our quantum mechanics-based multi-tensor AI/ML solved the 75-year-old problem of correctly predicting — GBM patients' OS, gene targets to sensitize the tumors, and the tumors' response to their targeting — from their whole genomes.

#6888 scDeBussy: Cohort-level pseudotime alignment reveals recurrent dynamic gene programs in histological transformation.

Meng Wang[1], Jose Meza-Llamosas[2], Xinjun Wang[3], Joseph Chan[1]

[1]Human Oncology & Pathogenesis Program, Memorial Sloan Kettering Cancer Center, New York, NY,[2]Tri-Institutional PhD Program in Computational Biology & Medicine, New York, NY,[3]Department of Epidemiology & Biostatistics, Memorial Sloan Kettering Cancer Center, New York, NY

Introduction: Lineage plasticity and histological transformation are key drivers of therapeutic resistance in cancer. However, recurrent dynamic transcriptional programs are hard to model across patients due to intertumoral heterogeneity and uneven cell-state representation. Existing trajectory alignment methods rely on pairwise comparisons, predefined topologies, or batch correction, limiting detection of shared cohort-level transitions. To address this, we developed scDeBussy, a cohort-level trajectory alignment method that identifies shared dynamic gene programs across samples.
Methods: scDeBussy uses dynamic time-warping barycenter averaging to derive a unified reference trajectory from patient-specific probabilistic pseudotime, enabling cross-sample comparison of gene trends. We modeled aligned pseudotime with generalized additive models, clustered gene trends into early, intermediate, and late transcriptional modules, and quantified recurrence across patients while controlling for clinical covariates. Latent-Factor Multi-Output Gaussian Process simulations show scDeBussy recovers the global latent pseudotime and aligns cells derived from patients sampled at disparate stages of the underlying trajectory. We applied scDeBussy to new and published single-cell RNA-seq datasets of histological transformation, including lung adenocarcinoma (LUAD) to small cell lung cancer (SCLC) and lung adenosquamous cancer, to identify recurrent transcriptional dynamics of lineage plasticity.
Results: scDeBussy aligned patient-specific trajectories despite heterogeneous sampling. In LUAD-to-SCLC neuroendocrine (NE) transformation, it revealed a reproducible continuum from alveolar/secretory states through basal/mesenchymal intermediates to terminal NE states. Early module was enriched for JAK/STAT inflammatory signaling, intermediate module for basal and squamous programs marking a stem-like bottleneck, and late module for NE commitment. In lung adenosquamous cancer, scDeBussy inferred a continuous adeno-to-squamous transition, with early module enriched for LUAD-associated transcription factors (FOS, FOXA1/2) and late module dominated by LUSC drivers (TP63, E2F). Projecting matched scATAC-seq profiles onto pseudotime uncovered epigenetic priming events along the transition, including signatures of epigenetic reprogramming (EZH2), stemness (KLF4, JUN/FOS), and EMT (ZEB1, SMAD2-4).
Conclusion: scDeBussy enables cohort-level pseudotime alignment to detect recurrent dynamic gene programs underlying state transitions. Applied to LUAD-to-SCLC and adeno-to-squamous transformation, it reveals key transitional modules toward distinct terminal fates. By resolving these conserved dynamics, it offers a generalizable approach to dissecting disease processes marked by plasticity and divergent lineage outcomes.

#6889 AI-empowered virtual immunopeptidomics uncovers novel regulators of neoantigen immunogenicity.

Yuhao Tan, Ziqi Yang, Julia Fleming, Hailong Hu, Bo Li

University of Pennsylvania, Philadelphia, PA

Adaptive immunity is governed by both qualitative and quantitative features of antigen presentation. In anti-cancer T cell responses, 'quality' reflects peptide-MHC binding, whereas 'quantity' reflects how abundantly each epitope is displayed. Although binding has been studied extensively, the contribution of peptide abundance to neoantigen immunogenicity remains poorly understood, mainly because of limited immunopeptidome datasets. To bridge this gap, we developed epiVIP, a novel virtual immunopeptidomics method that predicts HLA-I peptide abundance. We first established that mass spectrometry (MS) intensity provides a robust and scalable approximation of absolute epitope abundance. Leveraging this, we curated and uniformly quantified 1.7 million HLA-I peptides from 254 tumors with paired transcriptomes, creating the largest quantitatively standardized immunopeptidome resource to date. We then developed epiVIP, a deep neural network that integrates peptide and HLA sequences with the expression of the peptide's source gene and 472 putative regulators of antigen presentation. To minimize batch effects, we used a pairwise ranking loss strategy. epiVIP achieved high prediction accuracy and generalizability for within-sample abundance, with AUC>0.8 for 20 held-out samples and 24 independent samples.

Applying epiVIP to 33,782 neoantigens from four studies, we observed that higher predicted abundance was strongly associated with increased immunogenicity. Importantly, the effect was conditional on self-discrimination, defined as the sequence similarity between the neoantigen and its wild-type counterpart. Neoantigens with low self-discrimination required high abundance to elicit T cell responses, whereas those with high self-discrimination were immunogenic regardless of abundance. In three immune-checkpoint blockade cohorts, the summed abundance of low self-discrimination neoantigens outperformed tumor mutational burden in predicting response and survival ($p = 4.7*10^{-4}$ vs $1.3*10^{-3}$ in one cohort).

To identify regulators of epitope abundance, we first validated that the predicted abundance changes accurately recapitulated antigen-repertoire remodeling after PSME4 knockdown in A549 cells. We then extended predictions to 409 regulatory gene knockdowns in HCT116 and HEK293T using pseudobulked perturb-seq profiles. We observed that perturbation effects clustered by C-terminus amino acid properties and identified 32 regulators with C-terminal-specific effects, including PSME4 and PSMF1.

In summary, epiVIP establishes epitope abundance as a key quantitative determinant of neoantigen immunogenicity, provides a model to predict abundance when immunopeptidomics is unavailable, and offers a framework to identify gene perturbations that enhance presentation of desired epitopes for TCR-T and cancer vaccine development.

#6890 Subcellular 3D multi-omic models of CDH1-mutant diffuse gastric cancer improve recapitulation of tumor microenvironment structure and reveal precancer signature niches.

Jean R. Clemenceau[1], Yunhe Liu[2], Idania Carolina Lubo Julio[3], Soyoung Im[4], Seock-Jin Chung[1], Sam C. Wang[5], Paul F. Mansfield[6], Luisa Maren Solis Soto[3], Linghua Wang[2], Tae Hyun Hwang[1]

[1]Section of Surgical Research, Vanderbilt University Medical Center, Nashville, TN,[2]UT MD Anderson Cancer Center, Houston, TX,[3]Department of Translational Molecular Pathology, UT MD Anderson Cancer Center, Houston, TX,[4]Department of Pathology, The Catholic University of Korea St. Vincent's Hospital, Suwon, Korea, Republic of,[5]Department of Surgery, UT Southwestern Medical Center, Dallas, TX,[6]Department of Surgical Oncology, UT MD Anderson Cancer Center, Houston, TX

Diffuse-type gastric adenocarcinoma (DGC) presents as the more invasive and aggressive gastric cancer subtype with poorer prognosis. Hereditary germline CDH1 mutations are known to drive DGC in 1-3% of cases in what is known as hereditary diffuse gastric cancer (HDGC). Despite the genomic characterization of HDGC, the mechanisms of onset are still poorly understood, given that evidence suggests it can bypass the classic cascade of gastric intestinal metaplasia (IM) to dysplasia to cancer. Additionally, HDGC presents a complex tumor microenvironment (TME) given by its highly infiltrative distribution with increased immune and stromal interactions, as well as IM and dysplastic marker gene expression. These factors present an opportunity to better understand the complex cellular dynamics to elucidate the etiology of this disease. New advances in spatial transcriptomics and fluorescence imaging have reduced per-sample costs of spatial biology assays, allowing the scale necessary for studying serial sections.

HDGC samples were collected as formalin-fixed, paraffin embedded blocks. Samples were serially sectioned at 5µm thickness into G4x gel pads. Regions of interest (10mm x 10mm) were isolated from the gels pads and transferred to a G4x X2 spatial flow cell. Samples were processed using Singular Genomics G4x spatial multi-omic assay with a custom pre-gastric cancer panel consisting of 16 proteins, 341 transcripts, and fluorescent-based H&E images for every section of tissue. Data was processed following quality control, implementing cell type annotation, followed by registration of cell coordinates, incorporation of histopathological tissue annotations by a board-certified pathologist, and cell neighborhood analysis.

Two models were produced with 7 and 9 serial sections (16 total) representing a tissue depth of 35 µm and 45 µm and populations of 1.6M and 3.4M cells, respectively. The models recapitulate 3D morphology of known tissue structures, such as non-neoplastic epithelial glands, vasculature, and tertiary lymphoid structures. We observed TFF2, a SPEM cell IM marker, expression in the tumor-adjacent gastric mucosa. We also found small clusters of TFF2+ cells within the superficial tumor-invasive area, only present in a few of the total tissue layers.

We successfully built two 3D spatial multi-omic, subcellular resolution models for CDH1-mutant HDGC representing 35-45µm of tissue thickness that recapitulate the samples' histological structures. We show the spatial distribution of metaplastic markers expressed in tumor-adjacent epithelium. Our 3D models allowed for the identification of rare-cell events, such as small TFF2+ cell clusters within tumor-infiltrated tissue regions. These results show the promise that high-resolution 3D models present for improving our understanding of complex TMEs, such as HDGC.

#6891 Context dependent functional aneuploidy in cancer.

Polly L. S. Hung, Stephanie S. Liu, Tina N. Wei, Lesley S. K. Lau, Kui Liu, Karen K. L. Chan, Haonan Lu

Department of Obstetrics & Gynaecology, The University of Hong Kong, Hong Kong SAR, China

Background: Aneuploidy shows strong cancer-type specificity, yet its mechanistic basis remains unclear. Classic events like 8q gain in ovarian cancer or 17p loss in breast cancer highlight recurrent patterns, but the standard 98% arm-coverage rule obscures meaningful CNV boundaries. We hypothesised that recurrent breakpoints across tumours provide a more functional definition of aneuploidy. To address this, we developed BAGEL, which quantifies copy-number alterations by defining CNV segments using BISCUT breakpoints rather than fixed chromosome-arm thresholds.
Methods: We mapped recurrent CNV breakpoints across 38 cancer types using BISCUT and validated them across nine datasets spanning multiple sequencing platforms and segmentation algorithms (APOLLO, CPTAC3, CGCI, TARGET, DepMap, PCAWG, TCGA and two in-house cohorts). BAGEL-derived aneuploidy scores were tested for prognostic value using Cox and Kaplan-Meier analyses in TCGA high-grade ovarian cancer, with validation in PCAWG. Functional effects were assessed by integrating DepMap CRISPR screens and modelling essentiality differences using mixed-effects models. Chromatin constraints were quantified using TAD penetration scores from colorectal tumours and breast and lung cancer cell lines.
Results: BAGEL replaced the arbitrary 98% arm rule by defining CNV segments directly from shared breakpoints. Breakpoints were highly reproducible (mean deviation = 0.089), including 34 nearly identical sites across eight HGSOC cohorts. Prognostic modelling by multivariate cox showed that Breakpoint-defined aneuploidy strongly predicted survival in both HGSOC and breast invasive carcinoma, with TCGA dataset-built model $p<0.0001$ for both and showed consistent trend in PCAWG dataset (5 year OS $p = 0.085$ for HGSOC and $p = 0.026$ for breast invasive carcinoma). Mixed-effects modelling between 584 cancer-pairs showed significant interaction between cancer type and presence of breakpoint event in 123 arms (FDR < 0.05), indicating that the CRISPR essentiality difference between aneuploid and non-aneuploid samples varies substantially across cancer types. Hi-C-derived TAD penetration scores demonstrated consistent structural constraints across tumour and cell-line datasets. Breakpoints showed a subtle but reproducible bias toward TAD boundaries, particularly for negatively selected events, indicating that 3D genome architecture shapes permissible CNA breakpoint positions.
Conclusions: Breakpoint-defined aneuploidy captures recurrent, biologically constrained CNV segments, reveals cancer-type-specific selective pressures, identifies aneuploidy-linked gene-essentiality shifts, and exposes a reproducible positional bias toward TAD boundaries. These findings demonstrate that aneuploidy evolution is shaped jointly by selective fitness pressures and 3D chromatin architecture.

#6892 A pan-cancer atlas of telomere length in tissues and plasma cell-free DNA.

Junming Shi, Leslie Espinoza, Mengran Zhang, Mohammad Shahrokh Esfahani

Stanford University School of Medicine, Stanford, CA

Background:
Telomeres shorten with age because of incomplete replication and limited telomerase activity, and their dysfunction promotes genomic instability in cancer. Existing estimators rely on strict repeat counts and often miss error-affected or biologically shortened fragments. This is problematic in plasma cfDNA where most fragments are ~170 bp and ctDNA is even shorter (Cristiano et al., 2019; Chabon et al., 2020). Nanopore-based assays provide precise measurement (Sanchez et al., 2024; Karimian et al., 2024), but an accurate, error-tolerant short-read approach remains unmet.
Methods:
We developed VERACITY, a machine-learning method that estimates telomere length (TL) from short-read WGS by modeling telomeric-repeat patterns and sequencing-error profiles. VERACITY also computes a Telomere Ambiguity Index (TAI) that quantifies heterogeneity in telomere maintenance. We applied VERACITY to 10,363 TCGA WGS samples (4,847 tumors; 5,089 matched normals; ages 14-85) across 27 cancer types, 3 deep (~200×) cfDNA genomes with systematic down-sampling, and 462 low-pass (2-3×) cfDNA genomes from the DELFI cohort (233 cancers; 229 healthy; ages 14-86), generating an atlas of telomere biology in tissues and plasma.
Results:
Down-sampling showed reliable TL estimation down to ~2.5× coverage, supporting low-pass cfDNA application. Tissue and cfDNA trends were highly concordant. Across cancers, TL declined with age in tumors and matched normals, with tumors showing far steeper erosion (tissue tumor: β_{age} = -62.5*, β_{age^2} = 0.5* vs. normal: -10.8, 0.02; cfDNA cancer: -13 vs. healthy: 0 bp). Male tumors showed greater loss (TCGA: -90.0*, 0.66*; cfDNA: -99.1*, 0.8) than female tumors (TCGA: -15.5, 0.16; cfDNA: -0.9, -0.1).
Age-associated trajectories varied widely: GBM, TGCT, and STAD showed steep nonlinear declines, whereas CESC, KICH, and LGG showed minimal or positive slopes, consistent with adjusted TL residuals. Although stomach tissues show the weakest TL-age correlation (Demanelis et al., 2020), gastric cancers exhibited one of the strongest declines in both tissue (β_{age} = -135.2 bp) and cfDNA (-63.5 bp) and among the lowest Gini and ATR values. Several cancers, including PRAD and TGCT, displayed elevated TAI, suggesting diverse or unstable maintenance strategies.
Conclusions:
VERACITY provides an accurate and scalable framework for TL estimation from standard and low-pass sequencing, enabling the most comprehensive atlas to date of telomere dynamics across cancers in tissues and plasma. The analysis reveals accelerated, sex-stratified, and cancer-type-specific telomere erosion, substantial inter-tumor heterogeneity, and distinct maintenance mechanisms. cfDNA TL patterns closely mirror tissue-derived trends and highlight the potential of telomere metrics as minimally invasive biomarkers of telomere dysfunction, tumor biology, and treatment-relevant telomere states.

#6893 MambaSV: Accurate germline and somatic structural variant calling from long-reads with deep sequence model.

Zhihan Zhou, Tong Zhu, Pankaj Vats

Nvidia Corporation, Santa Clara, CA

Somatic structural variants (SVs) are difficult to detect from long-read sequencing due to the inherent complexity of tumor genomes characterized by low variant allele fractions (VAFs), variable tumor ploidy/purity, and highly complex rearrangement patterns. Deep learning models are underexplored in this problem due to the lack of labeled data. To leverage it, we introduce a novel data simulator that generates paired normal-tumor BAM files with accurate haplotype-aware SV labels to facilitate model training and benchmarking. Built on this, we present MambaSV, a GPU-native deep sequence model for haplotype-resolved somatic SV calling. The scalable, end-to-end, and haplotype-aware data simulator for long read sequencing (PacBio and ONT) is designed to capture real-world somatic SV complexities. It simulates SVs across five SV classes (INS, DEL, DUP, INV, BND) following empirically derived length distributions, partition them by haplotype and sample, and inject them together with SNPs and INDELs into CHM13 to create synthetic genomes. Longreads are simulated from the synthetic genomes with real statistics (e.g., length, error rate, etc.). For Fusions we generate artificial sequence constructs in FASTA format by concatenating relevant sequence fragments to reproduce true breakpoint signatures. To model tumor heterogeneity, we mix reads from SV and SNP-only genomes to achieve per-event VAFs from 0-100%, simulate copy-neutral loss of heterozygosity (cnLOH) in tumor, and haplotag both BAMs with third-party tools to mirror practical workflows. MambaSV is trained to discover SVs from matched tumor and normal alignments. MambaSV formulates SV discovery as a per-base multi-class classification task. At each base, a 30-feature vector (mapping qualities, supplementary evidence, etc.) is computed across three channels (hap1, hap2, unphased) and both samples. Haplotype-specific inputs combine each haplotype with the unphased channel. Leveraging a Siamese network with shared weights, MambaSV jointly processes tumor and normal samples with a bi-directional Mamba-2 backbone that preserves megabase-scale context without loss of single-base resolution. A lightweight decoder outputs haplotype-resolved somatic predictions, which are post-processed to merge contiguous signals and emit VCFs. Trained solely on HiFi BAMs and tested on held-out samples (~23 k SVs), MambaSV achieves F1 = 92.27 (HiFi) and 89.32 (ONT), outperforming Severus (69.18/70.31), Svision-pro (53.92/54.24), SAVANA (56.37/53.93), and Nanomonsv (42.42/42.20). To conclude, our comprehensive simulation framework fuels MambaSV's development by enabling rigorous training and broad generalizability in challenging real-world scenarios, while MambaSV unifies base-level features, haplotype structure, and long-range genomic context in a single deep model to set a new standard for somatic SV calling from long-read data.

#6894 Predict, perturb, and process: A systems biology pipeline for identifying synthetic lethality.

Juihsuan Chou[1], Chenchu Lin[1], Iulia Veronica Gheorghe[1], Sabriyeh Alibai[1], Subin Kim[1], Lori Wilson[1], Xingdi Ma[2], Junjie Chen[3], Glen Traver Hart[3]

[1]Systems Biology, The University of Texas MD Anderson Cancer Center, Houston, TX,[2]Genitourinary Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX,[3]UT MD Anderson Cancer Center, Houston, TX

The synthetic lethality principle holds great promise for cancer therapy, but identifying synthetic lethals presents enormous challenges. Synthetic lethality, where loss of two genes causes cell death, but loss of either gene alone does not, is difficult to assay because combinatorial perturbation technologies are inefficient and because the search space is well beyond the capacity of current experimental systems: 19,000 protein coding genes offer more than 180 million candidate gene pairs. To address this, we combine network-driven predictive models with the In4mer CRISPR/Cas12a combinatorial knockout platform to conduct tractable pairwise knockout screens with high probability of identifying synthetic lethals.Even with these advances, effective methods for quantifying GIs in these screens remain limited. To address this gap, we developed GRAPE (Genetic interaction Regression Analysis of Pairwise Effects), a novel regression-based method for analyzing GIs in all-by-all gene knockout (KO) library designs. GRAPE infers single-gene KO fitness from multiplex CRISPR arrays, predicts combinatorial gene KO fitness, and identifies synthetic lethals that deviate from this expectation. Since no gold-standard exists for benchmarking, we built a simulation framework to systematically evaluate GRAPE, demonstrating improved computational efficiency, adaptability, and precision-recall performance over existing methods.Using the network-driven experimental design, In4mer screening, and GRAPE analysis, we screened all pairwise combinations of 206 genes involved in receptor tyrosine kinase (RTK) signaling, all pairs of 167 genes in DNA damage response (DDR) pathways, and over 4,000 paralog pairs across 12 diverse cancer cell lines. Our DDR results closely align with findings reported by other studies, while our RTK network provides novel insight into ER-mediated protein modification and oncogenic signaling dependencies. Overall, our efforts confirm that we can predict and detect both global and background-specific genetic interactions, advancing the state of the art in functional genomics and cancer target finding.

#6895 DISSECT integrates cytological images and spatial transcriptomics for cell segmentation.

Yufeng He[1], Yanping Zhao[2], Rui Zhang[1], Heli Yang[3], Zhaode Bu[3], Yuan Luo[4], Deng Pan[5], Zexian Zeng[1]

[1]Peking-Tsinghua Center for Life Sciences, Academy for Advanced Interdisciplinary Studies, Peking University, Beijing, China,[2]Tsinghua-Peking Center for Life Sciences, School of Life Sciences, Tsinghua University, Beijing, China,[3]Center of Gastrointestinal Cancer, Peking University Cancer Hospital & Institute, Peking University, Beijing, China,[4]Department of Preventive Medicine, Feinberg School of Medicine, Northwestern University, Chicago, IL,[5]Tsinghua-Peking Center for Life Sciences, Department of Basic Medical Sciences, Tsinghua University, Beijing, China

Advances in both imaging- and sequencing-based spatial transcriptomics technologies have significantly increased panel size and resolution, enabling the measurement and analysis of spatially resolved single-cell transcriptomics. However, challenges remain in accurately segmenting cells due to variability in cell morphology, tissue processing, and staining methods, leading to reduced accuracy and poor generalization of existing cell segmentation algorithms. To address this, we propose DISSECT, a novel cell segmentation model that combines cytological image segmentation with transcriptome-guided fine-tuning. DISSECT leverages a pre-trained deep generative model to identify cell nuclei or membrane boundaries, unifies the gradient fields of both images and transcriptomics to refine cell boundaries, and reconstructs spatial single-cell transcriptomes. We benchmarked DISSECT using the ground-truth dataset profiled by the Visium HD, Stereo-seq, Xenium 5k, and CosMx 6k platforms, demonstrating higher mean average precision than other tools. Furthermore, evaluations on independent 10x Xenium 1k, Nanostring CosMx 1k, and Stereo-seq datasets further validate that DISSECT achieves superior segmentation accuracy, especially in densely packed cell regions. Additionally, DISSECT was applied to three paired gastric adenocarcinoma samples, which we collected before and after PD-1 treatment and sequenced using Stereo-seq, a transcriptome-wide NGS-based sequencing technology, showcasing its potential for driving in-depth biological discoveries.

#6896 ELEVATE: Axis-coupled mapping of co-varying gene programs in single-cell transcriptomic data.

Kourosh Kouhmareh[1], Richard L. Klemke[2]

[1]UC San Diego School of Medicine, La Jolla, CA,[2]UCSD Moores Cancer Center, La Jolla, CA

Differential expression analysis has long been the standard for identifying genes that distinguish one condition from another. However, it is inherently binary and static (comparing X vs Y, high vs low), offering only a snapshot of differences rather than revealing how expression programs develop. Pseudotime algorithms address this by reconstructing *inferred* trajectories that model temporal progression, yet these paths are manifold driven rather than anchored to a defined biological axis, which can allow for dominant sources of variation to mask processes of interest. To directly interrogate how a gene or gene set is upregulated and which associated processes rise alongside it, we developed *ELEVATE (Expression LEVEL-based Variational Analysis of Transcriptional Evolution)*, a trajectory-agnostic framework that orders cells by an anchor gene or signature, partitions them into equal, ascending single-cell Variational Inference (scVI) expression-based percentile bins, and performs sequential adjacent-rising comparisons to identify genes that rise or decline monotonically with the anchor. We additionally define an inflection bin, the percentile interval where anchor gene induction triggers the largest aggregate transcriptomic shift. Applying this framework to single-cell RNA-sequencing data from primary human tumors, we show that *ELEVATE*-based profiling provides finer resolution than discrete clustering, disentangling genes that rise continuously with the anchor from those that don't fully contribute to the end-state expression profile. *ELEVATE* provides actionable, pathway-level insights clarifying how expression programs evolve, and prioritizes candidate drivers and targets for experimental validation.

#6897 A bi-partition function algorithm to evaluate inferred subclonal structures in single-cell sequencing data.

Farid Rashidi Mehrabadi[1], Erfan Sadeqi Azer[2], **John D. Bridgers**[3], Teresa M. Przytycka[3], Salem Malikic[1], Funda Ergun[4], Cenk Sahinalp[1]

[1]National Cancer Institute, National Institutes of Health, Bethesda, MD,[2]Google LLC, Sunnyvale, CA,[3]National Library of Medicine, National Institutes of Health, Bethesda, MD,[4]Computer Science Department, Indiana University, Bloomington, IN

Clonal evolution of cancer results in intratumor heterogeneity, making treatment and cure challenging. Single-cell sequencing has advanced our understanding of intratumor heterogeneity, but tracing subclonal evolution using mutational profiles of cells is limited by scale and noise. Moreover, available tumor progression tree inference methods usually offer a single tree to explain the progression of a tumor, and do not inform about alternative evolutionary scenarios.

We introduce the bi-partition function for a tumor progression tree, to assess the reliability of any proposed subclonal structure in a single-cell sequenced tumor. By using the bi-partition function, we calculate the probability that any given subset R of mutation-profiled single cells from a tumor forms a clade rooted by a specified mutation ρ across all possible tumor progression trees. This provides the means to evaluate whether R forms a subclone with ρ as a possible subclonal driver, which is especially useful if the cells of R are biologically or clinically significant, e.g., have aggressive growth, therapy resistance, or metastatic potential.

We also introduce an algorithm to estimate the bi-partition function, which treats the ground truth as a probability distribution derived from mutational profiles of single cells and samples a tumor progression tree from this distribution independently in each iteration. We prove that our algorithm's estimate of the bi-partition function asymptotically approaches the ground truth and demonstrate its accuracy on simulated data.

Applying our algorithm to the tumor progression tree inferred from single-cell-derived melanoma sublines revealed that, while major clades and their root mutations are robust, (i) the placement of one clade in the tree is unreliable, which we later observed to be a result of Loss of Heterozygosity, and (ii) some of the mutations identified as false positives in the tree are unreliable, which later turned out to be the result of a doublet - a subline which has contamination from another subline. Interestingly, bootstrapping, a technique commonly employed for species trees, failed to point out any of these issues. After correcting the input data for these issues, the reliability of the progression tree improved substantially, demonstrating how our bi-partition function algorithm can aid studies on tumor evolution and intratumor heterogeneity.

#6898 Identifying robust subclonal structures through tumor progression tree alignment.

Jacob Gilbert[1], **Chih Hao Wu**[2], Marina Knittel[3], Alejandro Schaffer[4], Salem Malikić[2], S. Cenk Sahinalp[2]

[1]Department of Computer Science, University of Maryland, College Park, MD,[2]Cancer Data Science Laboratory, NIH-NCI, Bethesda, MD,[3]Department of Computer Science and Engineering, University of California, San Diego, CA,[4]National Cancer Institute, Bethesda

Understanding and comparing tumor evolutionary histories is fundamental to cancer genomics, with direct implications for tracking subclonal population dynamics, treatment resistance, and tumor heterogeneity. Clonal trees, widely used to model tumor progression, are rooted, unordered trees in which each node represents a subclone labeled by a set of distinct mutations. Various principled and efficient methods have been developed for inferring clonal trees from either bulk or single-cell sequencing data. However, no existing computational approach offers a method that is both efficient and principled to fully align clonal trees and to compare their subclonal architectures, which limits the robustness of any downstream analysis based on inferred clonal trees. We introduce omlta, the optimal multi-label tree alignment of two clonal trees, which removes the minimum number of mutation labels, so that the remaining trees are isomorphic. Computing omlta is NP-hard. Here, we present a fixed-parameter tractable algorithm to compute the omlta, with a running time of O(L^3 log L 2^k) where L is the number of mutation labels shared between the input trees and k is the minimum possible number of mutation labels that need to be removed for the alignment - which we call omltd, the optimal multi-label tree edit distance. Our approach provides an exponentially better (in k) asymptotic runtime than the state-of-the-art algorithm by Akutsu et al. for computing the classic tree alignment and edit distance, concepts similar to what omlta/omltd optimizes on clonal trees. We applied omlta to 126 multi-sample bulk-sequencing data from the TRACERx study on non-small cell lung cancers by comparing clonal trees inferred by CONIPHER and PairTree. Despite the theoretically exponential runtime, we could compute the tree alignment for each tumor quickly, often within seconds. The omltd between CONIPHER and PairTree clonal trees on the same tumor varies substantially across tumors and the distances are negatively associated with the mean cancer cell fraction among mutations. For the tumors characterized by mutations with low cancer cell fractions, it is thus advisable not to use a single tree, but rather the alignment of multiple alternative trees, so that downstream inferences are informed only by robustly placed mutations.
We further evaluated our algorithm on an in-house melanoma sample with clonal trees inferred by PhISCS and ScisTree, highlighting the utility of omlta on trees inferred from single-cell sequencing data. On these datasets, our algorithm completed all analyses in practical wall-clock times and showed that it can identify common evolutionary trajectories among clonal trees representing (i) distinct tumors, (ii) distinct samples from the same tumor, (iii) distinct sequencing data from the same sample. Additional supplementary results demonstrate the robustness of our approach in comparison to alternatives on simulated data.

#6900 Wakhan: Reconstruction of chromosome-scale copy number profiles of tumor genomes with long-read sequencing.

Tanveer Ahmad[1], Ayse Keskus[2], Mikhail Kolmogorov[2], Sergey Aganezov[3], Michael C. Dean[4], Midhat S. Farooqi[5], S. Cenk Sahinalp[2], Benedict Paten[6], Karen H. Miga[7], Salem Malikić[2], Yuelin Liu[2], Byunggil Yoo[8], Ataberk Ataberk Donmez[9], Anton Goretsky[9]

[1]National University of Science and Technology (NUST), Islamabad, Pakistan,[2]NIH-NCI, Bethesda, MD,[3]Oxford Nanopore Technologies, Cambridge, MA,[4]National Cancer Institute - Cancer Genomics Research Laboratory (CGR), Rockville, MD,[5]Children's Mercy Research Institute, Kansas City, MO,[6]University of California, Santa Cruz, Santa Cruz, CA,[7]Biomolecular Engineering Department, University of California, Santa Cruz, Santa Cruz, CA,[8]Children's Mercy Kansas City, Kansas City, MO,[9]University of Maryland, College Park, MD

Introduction. Copy number alterations (CNA) is a phenomenon during cancer evolution where some regions of the genome may be amplified or deleted. This results in heterogeneous collections of cancer cells. Profiling and classification of CNA profiles play a vital role in understanding the cancer heterogeneity and evolution to better inform diagnosis and treatment. There are several short-reads haplotype-specific CNA profiling tools but short reads provide a limited phasing range. Long-reads facilitate the direct phasing of genomic variants into megabase-scale haplotypes, which supports the reconstruction of longer, up to chromosome-scale, CNA profiles. Here we present Wakhan, a tool to analyze haplotype-specific chromosome-scale somatic copy number aberrations using long reads. Leveraging high-quality genome assembly coverage profiles, we show that Wakhan significantly outperforms other common short- and long-read CNA callers in achieving chromosome-level CNA consistency.

Methods. Wakhan uses tumor-normal long-read BAMs and phased germline SNP calls as input. It first extends the input phasing to be chromosome-scale by exploiting haplotype coverage imbalance. Wakhan detects those phase switch regions and corrects them by taking into consideration the changes in haplotype-specific coverage. Next, Severus utilizes this enhanced phasing to generate phased structural variant (SV) calls. Finally, Wakhan's integrated CNA algorithm uses the SV calls as boundaries and employs a haplotype coverage model to assign integer copy-number states to the resultant CNA regions.

https://github.com/KolmogorovLab/Wakhan

Results. We sought to compare Wakhan's performance against several state-of-the-art haplotype-specific CNA calling tools. The tools selected for short-read analysis included: Purple, Hatchet, Battenberg and for long-read analysis Purple and Savana are included. As benchmarks for small variants and SV calling are available but no similar benchmarks for somatic CNA calls are available. We designed a CASTLE panel based CNA calling benchmark, consisting of 6 pairs of tumor/normal cell lines sequenced with multiple short- and long-read sequencing technologies. We define *segment error* (SE) as for each CNA segment, we calculate the haplotype-specific mean squared distance between expected and reference coverage at heterozygous SNPs. This is then used to compute a weighted chromosomal average, normalized by the tumor haplotype's mean coverage. Similarly, for *chromosome error* (CE), compare the phase of the whole chromosome against the reference coverage. In the five CASTLE datasets, Wakhan and PURPLE had the lowest SE50 and SE75, indicating high accuracy in reconstructing individual CNA segments. We also evaluated Wakhan on a tumor-only dataset. Both Wakhan and PURPLE handled the absence of normal samples well and accurately reflected the expected tumor/normal profiles.

#6901 Hierarchical Dorfman screening for robust pathway-aware feature selection identifies predictors of MEK-inhibitor response in NSCLC.

Wanru Guo, Juan Xie

University of Maryland, Baltimore, Baltimore, MD

Background: Gene expression predictors of targeted therapy response often exhibit strong within-pathway correlation, heavy-tailed noise, and contamination from batch effects. Such structure severely degrades performance of conventional feature selection methods (LASSO, elastic net, SIS) and existing group-regularized approaches including group LASSO, sparse group LASSO, and group SIS/AR2.
Methods: We introduce Dorfman Screening, a computationally efficient hierarchical feature selection framework for pathway-structured genomic data. The method (1) groups genes into biological pathways using Hallmark annotations and dynamic tree cut clustering, (2) performs global pathway-level testing, (3) conducts within-pathway gene screening, and (4) applies a final regularized selection (Dorfman-LASSO or Dorfman-EN). Robust Dorfman variants additionally incorporate Huber-weighted regression to handle heavy-tailed errors, outliers, leverage points, and batch contamination. All tuning is data-driven through cross-validated RMSE.
Results: In extensive simulations (p=1000, n=200) with varying correlation structures and severe contamination, Dorfman methods consistently outperformed LASSO/EN, SIS, SIS-LASSO, group-LASSO, sparse-group-LASSO, and group-AR2-gpLASSO. Dorfman-EN achieved the highest accuracy under strong correlations (ρ=0.8), while Dorfman-LASSO excelled at lower correlation levels. Robust variants showed marked resilience under nonlinear distortions and heavy-tailed noise, maintaining the lowest false discovery rates. Applied to Genomics of Drug Sensitivity in Cancer (GDSC) RNA-seq data for trametinib response in non-small cell lung cancer (NSCLC), Dorfman methods achieved substantially improved predictive accuracy (RMSE=2.41-2.45) compared to LASSO/EN (RMSE=2.53-2.59) and group-regularized methods (RMSE=2.63-3.66). When genes were stratified into literature-supported biomarker tiers, Dorfman selections were significantly enriched for high-confidence genes and revealed previously unreported candidates not discovered by competing methods.
Conclusions: Dorfman Screening provides a scalable, robust, and biologically interpretable approach for pathway-structured genomic data, yielding improvements in both prediction performance and biomarker discovery for MEK-inhibitor response in NSCLC.

#6902 Remodeling of cancer cell architecture by chemotherapy.

Gege Qian[1], Xiaoyu Zhao[2], Leah V. Schaffer[3], Kyung-Mee Moon[2], Jiahao Gao[2], Emma Lundberg[4], Leonard Foster[2], Trey Ideker[5]

[1]UC San Diego School of Medicine, La Jolla, CA,[23]University of California San Diego - UCSD, San Diego, CA,[4]Schools of Engineering and Medicine, Stanford University, Stanford, CA,[5]UC San Diego, La Jolla, CA

How chemotherapy reshapes tumor cells—and how these changes influence outcomes such as drug resistance—remains largely unclear. Here, we present a multimodal, global characterization of tumor subcellular organization and its reorganization by chemotherapy. We use self-supervised learning to encode protein coordinates across four orthogonal data modalities: proteome-wide size-exclusion chromatography fractionation (before and after treatment with cisplatin or vorinostat), native-state immunofluorescence imaging, affinity purification, and primary sequence information covering 7,579 proteins. This integrated map resolves 174 subcellular components, spanning molecular assemblies from protein complexes to organelles across a size range of ~10-9 to10-5nm. 58 components undergo significant remodeling upon treatment, recapitulating known mechanisms of action and revealing previously unrecognized alterations in pathways such as cytoskeletal organization and metabolic rewiring. We systematically validate these “chemotherapy-response assemblies” using genome-wide CRISPR knockout drug-sensitivity profiling, identifying which assemblies confer drug sensitivity versus resistance. Chemotherapy-remodeled components serve as convergence points for cancer mutations that predict therapeutic response—including those involved in homologous recombination repair, chromatin remodeling, and double-strand break repair.

#6903 A transcript-only framework for pseudocell boundary inference in high-resolution spatial transcriptomics.

Sungwoo Bae, Hongyoon Choi, Dongjoo Lee, Daeseung Lee

Portrai, Inc., Seoul, Korea, Republic of

Background: High-resolution spatial transcriptomics (ST) enables subcellular expression profiling, yet cell-level analysis remains critical for understanding tissue organization. Current cell segmentation methods in ST like bin2cell rely on H&E-based nuclear expansion, making them susceptible to image quality issues, 2D nuclear overlap artifact, bias caused by transcript contamination from neighboring cells, and dependent on histological staining. To address this, we developed HIPSTER (Hotspot-guided Inference of Pseudocell boundaries in Spatial Transcriptomics), a method that delineates cell boundaries solely using transcript density, and validated its accuracy against bin2cell.

Methods: HIPSTER was applied to a human colorectal cancer Visium HD data (2 μm bin). Total UMI counts were normalized using a destripping algorithm to correct for irregularities of ST bin. Transcriptionally dense hotspots were identified by calculating the Getis-Ord Gi* Z-scores to localize maxima (threshold of 0.125). Initial seed regions from local maxima were expanded based on gene-specific transcript distributions to refine cell boundaries. Segmented cells were filtered by size (excluding >144 bins) and total counts (<10). The tissue was divided into 60 segments: 48 (80%) for parameter optimization and 12 (20%) for testing. Performance was assessed via Leiden clustering quality on segmented cells using Average Silhouette Width (ASW), Calinski-Harabasz Index (CHI), and Davies-Bouldin Index (DBI).

Results: Parameter optimization showed that Gaussian smoothing provided no benefit, whereas an 8-bin radius to capture seed regions from local maxima offered the optimal balance between cell clustering performance and cell detection count. In the independent test set (n=12), HIPSTER demonstrated statistically significant and superior clustering performance compared to bin2cell across all three metrics (ASW, CHI, and DBI). Notably, HIPSTER achieved a higher CHI score, reflecting superior cluster separability, in every single paired comparison without exception. Although HIPSTER detected fewer total cells than bin2cell, this reduction reflects a selective focus on transcriptionally meaningful hotspots, resulting in cleaner boundaries and more biologically coherent clustering.

Conclusion: HIPSTER is a robust and effective transcript-only segmentation tool for high-resolution ST data. By defining cells via functional transcriptomic activity rather than H&E-derived nuclear staining, it significantly outperforms the bin2cell method in distinguishing cell clusters by their expression profiles. This improved separation presents a clear trade-off, as HIPSTER's focus on transcriptional hotspots may result in the non-detection of cells characterized by very low local transcript density.

#6904 OTTER: Optimal transport-based transcriptomics and genomics representation fusion for T-ALL subtyping.

Lusheng Li, Jieqiong Wang, **Shibiao Wan**

University of Nebraska Medical Center, Omaha, NE

T-lineage acute lymphoblastic leukemia (T-ALL) is an aggressive pediatric malignancy that hasn't been fully characterized, partly due to the high prevalence of noncoding genomic alterations driving oncogenic deregulation. Identifying T-ALL subtypes is essential for downstream risk stratification and therapeutic strategy selection. Conventional methods for T-ALL characterization, such as immunophenotyping, cytogenetic analysis, fluorescence in situ hybridization (FISH), and targeted molecular assays, are often labor-intensive, time-consuming, and costly. Furthermore, many T-ALL cases harbor alterations in noncoding genomic regions, which are difficult to detect by standard diagnostic workflows. To address these challenges, we present OTTER (Optimal Transport-based Transcriptomics and gEnomics Representation), a novel multi-modal learning framework that integrates transcriptomics data and genomics data for accurate and cost-effective T-ALL subtyping. OTTER first processed single nucleotide variations (SNVs) and gene expression profiles, respectively, through attention modules to capture the most informative features. Then, it leveraged an optimal transport (OT) method to align and fuse heterogeneous omics modalities, capturing complementary biological information across data types. Based on this, the OT-derived cost matrix learned the cross-modal interdependencies by quantifying the cost of aligning one modality to the other. In this way, OTTER generated a shared latent representation that integrated both omics data, enabling a more comprehensive and coherent representation of each patient sample. Experimental results based on >1,300 T-ALL patients demonstrated that multi-omics integration via OTTER significantly outperformed single omics approaches in subtype classification across performance matrices. In addition, OTTER achieved a substantially higher performance than the baseline models (e.g., ensemble learning models and attention-based models). Furthermore, the embeddings derived from OTTER could more clearly separate different T-ALL subtypes in tSNE visualization compared to approaches without OT, highlighting its ability to uncover subtype-specific molecular features for T-ALL. In summary, OTTER is an accurate and cost-effective framework for T-ALL subtyping that could leverage multi-omics data for improved T-ALL characterization performance. Based on this, we believe OTTER will significantly improve downstream T-ALL patient risk assessment and personalized treatment design.

#6905 Reconstruction of Tumor Clonal Trees with Multi-Sample Bulk Sequencing Data by Integrative Combinatorial Optimization.

Salem Malikic[1], Hamza Iseric[2], Chih Hao Wu[1], Erin Molloy[2], S. Cenk Sahinalp[1]

[1]Cancer Data Science Laboratory, Center for Cancer Research, National Cancer Institute, Bethesda, MD,[2]Department of Computer Science, University of Maryland, College Park, MD

Multi-sample bulk DNA sequencing enables reconstruction of a tumor's clonal history, but scalable methods often rely on heuristic search and provide no optimality guarantees. We present CITUP2, an integrative combinatorial optimization framework that reconstructs clonal trees from descendant cell fractions (DCFs) of mutational clusters. CITUP2 formulates tree inference as a mixed-integer quadratic program (MIQP) that jointly determines the tree topology and clone prevalences across samples. It minimizes a weighted discrepancy between observed and inferred DCFs, with options to prioritize trees exhibiting consistency in the presence-absence patterns of parent-child clones. Under this formulation, CITUP2 returns provably optimal solutions (with respect to the model) and avoids the combinatorial explosion of exhaustive topology enumeration used by existing methods with optimality guarantees. In addition, CITUP2 can report a user-specified number of best trees. In simulations and analyses of a large, recently published multi-sample TRACERx cohort, CITUP2 scales to trees with tens of clones (approximately 30) and matches or improves on the fit attained by state-of-the-art approaches, while providing clear optimality certificates.

#6906 Test-time compute for subtype classification in pediatric T-cell acute lymphoblastic leukemia using transcriptomics.

Tarun Karthik Kumar Mamidi, Irina Pushel, Byunggil Yoo, Midhat S. Farooqi, Keith J. August

Clinical Genetics, Children's Mercy Research Institute, Kansas City, MO

Background: T-cell Acute Lymphoblastic Leukemia (T-ALL) represents a highly aggressive hematologic malignancy characterized by profound molecular and clinical heterogeneity. While current T-ALL subtype classifications may not yet be universally integrated into clinical decision-making, the potential for accurate and rapid classification holds significant promise for future prognostic stratification and guiding targeted therapies. Traditional classification methods can be time-consuming and labor-intensive, highlighting the need for efficient, data-driven approaches. Leveraging transcriptomic data alone, we aimed to overcome these limitations by developing a novel approach for precise T-ALL subtype classification.

Methods: We developed a machine learning pipeline for T-ALL subtype classification from RNA-seq data, introducing test-time compute paradigm. Initially, a Random Forest model was trained on a large discovery cohort (Polonen et al., 2024; 1,112 samples, 24,619 genes) to identify top predictive features by selecting the top 100 genes per subtype. At prediction time, the pipeline dynamically executes: (1) filtering preselected features from both training and test datasets (e.g., TARGET cohort, 264 samples, 22,688 genes); (2) batch correction via pycombat; (3) re-training of the Random Forest classifier on the processed training set; and (4) prediction on processed test data. This test-time pipeline is accessible via a Streamlit WebApp and Command Line.

Results: We used F1 score to evaluate the performance of our classifier. Random Forest on initial training with discovery cohort achieved 93% classifying TAL-like, TLX-like, NKX2-1, ETP-like and 'other' subtypes. Selecting the top 100 features from each subtype yielded 478 features. Benchmarking the performance of our model using these selected features resulted in a 96% F1 score. We then applied our test-time pipeline on the independent TARGET cohort with 264 samples. The final model achieved 83% accuracy across 5 subtypes. Performance was highest for clinically relevant subtypes: TAL-like (F1: 0.96), TLX-like (F1: 0.94), and NKX2-1 (F1: 0.89). The “other” category scored moderately (F1: 0.60), while ETP-like was absent in the validation set.

Conclusion: Our RNA-seq-based model delivers robust, scalable T-ALL subtype classification by leveraging test-time compute, integrating dynamic batch correction and real-time model retraining with a curated 478-gene feature set. Strong performance on an independent cohort highlights its clinical utility as a rapid, reliable tool for precision oncology.

#6907 ecSegCls: Deep learning-based method for detecting extrachromosomal DNAs in both interphase and metaphase cancer cells.

Se Young Chun[1], Hoigi Seo[1], Yoonjoo Nam[2], Dong Un Kang[1], Hyewon Bae[1], Ruda Lee[3], Hoon Kim[4]

[1]Department of Electrical and Computer Engineering, Seoul National University, Seoul, Korea, Republic of,[2]Department of Biopharmaceutical Convergence, Sungkyunkwan University, Suwon, Korea, Republic of,[3]Institute of Industrial Nanomaterial (IINa), Kumamoto University, Kumamoto, Japan,[4]Pharmacy, Sungkyunkwan University, Suwon, Korea, Republic of

Extrachromosomal DNA (ecDNA) is an acentric circular DNA element that derives from but exists independently of chromosomes. EcDNAs often carry oncogenes with high copy numbers, contributing to tumor heterogeneity, and poor patient outcomes. Whole genome sequencing provides genome-wide detection of ecDNAs but lacks spatial resolution, while imaging methods such as fluorescence in situ hybridization (FISH) capture spatial context but rely on labor-intensive manual annotation by experts. Existing tools for automated detection of ecDNAs from FISH, such as ecSeg, partially address this limitation but remain restricted to metaphase cells, demonstrating modest classification performance. Here, we present ecSegCls, an automated pipeline for segmenting and classifying ecDNA in FISH and DAPI images with high accuracy. Our proposed method exploits both deep learning-based segmentation model and its extracted features, as well as XGBoost-based classification model, leading to the pipeline of segmenting nuclei, chromosomes, and ecDNA regions, and predicting the presence of ecDNA in both metaphase and interphase cells. Data augmentation and noise simulation were used for improved robustness and segmentation-derived features were used for training an XGBoost classifier. Ablation studies further identified key predictive features, enhancing interpretability. Using a public dataset of 483 FISH images from cancer cell lines as a model training set and a dataset of 776 FISH images internally generated 8 cancer cell lines as a classification set, we assessed and compared the performance of our model with those of previously published architectures, including UNet, UNet++, DeepLabV3+, Swin UNet, FATNet, HiFormer, DAEFormer, and ecSeg. Our proposed ecSegCls has achieved remarkable qualitative and quantitative performance, yielding high performance on diverse regions with diverse metrics in both segmentation and classification benchmarks, thus establishing ecSegCls as a robust and scalable automated framework for accurate ecDNA detection, advancing imaging-based research and clinical applications with ecDNA.

#6908 Large-scale patient cohorts integration via a novel Bayesian transfer learning framework identifies robust drug response signatures in AML.

Dharani Thirumalaisamy[1], Evan F. Lind[2], Elie Traer[3], Jeffrey W. Tyner[4], Mehmet Gonen[5], Olga Nikolova[6]

[1]Biomedical Engineering, Oregon Health & Science University, Portland, OR,[2]Molecular Microbiology and Immunology, Oregon Health & Science University, Portland, OR,[3]Division of Hematology/Medical Oncology, Oregon Health & Science University, Portland, OR,[4]Cell and Developmental Biology Program, Oregon Health & Science University, Portland, OR,[5]College of Engineering, Koc University, Istanbul, Turkey,[6]Division of Oncological Sciences, Oregon Health and Science University, Portland, OR

Introduction: Transfer learning considers distinct but related tasks defined over heterogeneous domains like patient or organoid data, and improves generalization and predictive performance through knowledge transfer between tasks. It can be especially advantageous in applications where training data is limited (i.e. small patient cohorts), where joint learning across domains can enable inference in otherwise underpowered datasets.
Methods: We present a novel Bayesian transfer learning framework that supports multi-task and multi-modal learning across scales, from bulk to single-cell resolution. Our approach is generative and learns latent space representation within each domain, simultaneously across multiple domains, using a feature-wise prior (e.g. genes, drugs, cellular programs) to model complex non-linear relationships. Our model can be pre-trained on an unlimited number of patient cohorts or new approach methodology (NAM) datasets from diverse assay bulk or single-cell platforms to make predictions in previously unseen samples.
Results: We apply our method to predict drug response and identify gene signatures for therapy stratification in acute myeloid leukemia (AML). We benchmark our model's performance in a battery of experiments and compare to five existing approaches. By integrating disjoint large-scale patient cohorts, we enable robust statistical inference in an otherwise underpowered dataset (N=29). Our model successfully transferred information even from cohorts with molecularly characterized samples that lacked matched drug response to inform and improve predictions in other cohorts with statistical significance and impactful effect size. Our approach was especially effective in modeling multi-kinase inhibitors, where our feature-wise priors captured multi-target interactions.
Conclusion: Our novel approach enables joint learning across unlimited number of patient cohorts and other multi-omic and functional data domains and scale. In AML we achieve significant improvements in drug response accuracy and gene signature identification and enable robust statistical inference in very small patient cohorts. Our framework is scalable, interpretable, and adaptable across target phenotypes, offering a robust solution for a wide range of heterogeneous problems.

#6909 Dimensionless, null-calibrated spatial indices from Xenium RNA and protein in breast IDC and lung adenocarcinoma.

Jinghao Tian[1], Tommy Tran[2], Elim Cheung[2], Rikita Gakhar[2], Vidyodhaya Sundaram[2]

[1]Johns Hopkins University, Baltimore, MD,[2]BioChain Institute, Inc., Newark, CA

Spatial features of the tumor-immune microenvironment, including immune exclusion at tumor borders, tertiary lymphoid structures, and checkpoint engagement, shape local control and treatment response, yet routine single-marker IHC or bulk assays miss single-cell context and cell-cell interactions. Same-section spatial multi-omics now measure transcriptome (RNA) and proteome (protein) in interacting cells. Compact metrics are designed from these data to compare regions and cases. Two Xenium slides from FFPE tissue were profiled, each including paired primary tumor (PT) and adjacent normal (PN) regions from breast invasive ductal carcinoma and lung adenocarcinoma using a Human Immuno-Oncology panel plus six protein subpanels. Regions of interest (ROIs) were the analysis unit. Cell types were annotated with SingleR against public single-cell references, and spatial morphologies were inspected. Segmentations showed expected differences: PT breast was dominated by luminal epithelium with stromal and immune heterogeneity, whereas PN breast was fibroblast rich. Lung samples contained epithelial, fibroblast, endothelial, and immune populations with shifts between PT and PN, providing diverse microenvironments on which spatial indices were computed. Three dimensionless indices quantified complementary features of the tumor-immune microenvironment. The Exclusion Index (EI) integrates reduced CD8 T-cell penetration into tumor nests with peritumoral macrophage enrichment and diminished antigen-presenting-cell ingress. The TLS Score identifies B/T aggregates consistent with tertiary lymphoid structures, supported by local chemokine signal and simple maturity surrogates. The Checkpoint Contact Index (CCI) quantifies adjacency between PD-1-positive T cells and PD-L1-positive tumor or myeloid neighbors within a small radius compared with ROI label-shuffle spatial nulls. For all indices, values were centered on PN regions within each case, converted to z-scores within tumor type, and scaled 0-1. The pipeline produced coherent cell-typing and index summaries that aligned with visible histology and tumor-normal heterogeneity, providing a quantitative complement to descriptive reads. Grounding the indices in same-section RNA and protein and explicit spatial nulls yields a practical framework for reporting tumor-immune microenvironment on small-N slides and a common language transferable across studies and pathology teams.

#6910 Consistency-guided diffusion reconstruction enhances peri-hepatic tumor visibility in magnetic particle imaging.

Gen Shi[1], Ziwei Chen[1], Yimeng Li[1], Zeyu Zhang[1], Xin Feng[2], Jie Tian[3]

[1]Beihang University, Beijing, China,[2]Institute of Automation，Chinese Academy of Sciences, Beijing, China,[3]Key Lab of Molecular Imaging, Chinese Academy of Sciences, Chinese Academy of Sciences, Beijing, China

Background: Magnetic Particle Imaging (MPI) is radiation-free and highly sensitive, enabling quantitative tracking of superparamagnetic tracers, which makes it attractive for tumor imaging. In abdominal applications, SPIO tracers accumulate in the liver via hepatic metabolism, creating dominant background that obscures nearby lesions and suppresses tumor contrast. To address this from the reconstruction side, we propose a consistency-guided diffusion method that couples a learned prior with the MPI forward model to recover concentration-faithful peri-hepatic images, without altering hardware or tracer formulation.
Methods: We implement a consistency-guided diffusion procedure that alternates two steps: (i) denoising by a generative diffusion prior trained on abdominal slices, and (ii) a lightweight projection that enforces agreement with measured signals under the MPI forward operator u=Sx. A null-space stabilization term moderates trajectories when liver-tumor concentration disparity is large. Training data are synthesized from public abdominal datasets by extracting liver and tumor masks, deriving concentration maps, and forming z-axis slices; simulated signals are generated with additive white Gaussian noise. Evaluation covers (a) peri-hepatic simulation cases and (b) 3D-printed liver-tumor phantoms filled with SPIOs on an in-house MPI system. Baselines include Kaczmarz, conjugate gradient, ADMM, and a deep-equilibrium reconstruction.
Results: The proposed approach improves fidelity and structure preservation versus classical solvers (higher PSNR/SSIM and lower error) and reduces the over-smoothing typical of equilibrium-based methods. In phantom studies with 5 mm and 2 mm tumor-liver separations, reconstructions exhibit suppressed background streaks/rings and clearer lesion edges, yielding consistent visual detectability across separations. Runtime overhead is modest: a single CG update per diffusion step suffices to maintain consistency. We also applied the method to in vivo human stem-cell MPI imaging experiment, yielding encouraging results and suggesting potential utility for stem cell-based cancer therapies.
Conclusions: Consistency-guided diffusion reconstruction improves peri-hepatic lesion visibility in MPI under strong liver background while remaining software-only and system-agnostic. Its low operational cost and compatibility with existing scanners and tracers support translational potential for liver-adjacent oncologic imaging.

#6911 Frequency-domain signal separation network improves dual-tracer detection of aneurysm regions in magnetic particle imaging.

Ziwei Chen[1], Yimeng Li[1], Gen Shi[1], Jian'an Ye[1], Zeyu Zhang[1], Xin Feng[2], Yu An[1], Jie Tian[1]

[1]Beihang University, Beijing, China,[2]Institute of Automation, Chinese Academy of Sciences, Beijing, China

Aneurysms are vascular abnormalities characterized by marked structuralheterogeneity, and their rupture risk is closely associated with regional dilation, focalweakening, and inflammatory activity. Therefore, reliably distinguishing normalvessels from aneurysm-affected regions is essential for aneurysm detection, regionalvisualization, and lesion assessment. Compared with existing medical imagingtechniques such as magnetic resonance imaging (MRI) and computed tomography(CT), Magnetic Particle Imaging (MPI) offers unique advantages including zero tissuebackground, high sensitivity, real-time imaging, and excellent quantitative capability,making it well suited for multi-tracer vascular imaging. Different superparamagneticiron oxide (SPIO) tracers exhibit inherent differences in magnetic properties andmagnetization dynamics, providing the physical basis for multi-tracer MPI; however,noise, cross-talk, and signal imbalance in practical measurements can obscure thesedifferences and hinder accurate dual-tracer separation. To enhance the reliability ofmulti-tracer MPI, we propose a frequency-domain dual-tracer separation framework,the Frequency-Domain Signal Separation Network (FSS-Net).FSS-Net maps raw MPI signals into a two-dimensional harmonic-frequencyrepresentation, predicts tracer-specific masks through a separation module, andreconstructs interference-free dual-channel harmonic signals using afrequency-domain decoder. To validate its performance, we constructed a dual-traceraneurysm phantom in which normal vessel regions and aneurysm lesions were labeledwith different SPIO tracers, simulating heterogeneous nanoparticle distribution indiseased versus healthy vasculature. FSS-Net was compared with two establishedmulti-color MPI methods—System Matrix Concatenation (SM Cat) and MKZ.Quantitative evaluation using PSNR and SSIM showed that FSS-Net significantlyoutperformed both methods in signal fidelity and structural preservation, effectivelyreducing cross-talk and improving visualization of normal vessels andaneurysm-affected regions.Overall, FSS-Net enables high-quality dual-tracer MPI signal separation and offers areliable approach for aneurysm region detection, regional visualization, andnanoparticle distribution analysis, demonstrating strong potential for vascularpathology imaging and nanoparticle-based biomedical research.

#6912 Phasing tumor clones by timing point mutations using bulk long-read sequencing.

Ataberk Donmez, Mikhail Kolmogorov

National Cancer Institute, Bethesda, MD

Cancer cells differ from healthy cells due to somatic aberrations (e.g., somatic mutations or structural variations). Studying these mutations helps us better understand tumor evolution and opens the way to more effective treatment strategies. Cancer cells exhibit heterogeneity across different populations, even within a single tumor, and these populations are defined by their unique somatic mutations. Given a set of somatic mutations -some shared across different clones and some unique- determining which mutations co-occur enables phasing of tumor clones. Ultimately, phasing these mutations from bulk sequencing data is crucial for studying tumor evolution.

SNVs and short indels are the most common somatic mutations in tumor cells and even though these mutations can be effectively detected with short reads, linking nearby mutations remains challenging due to the nature of these reads. On the other hand, long reads have been successfully used in direct phasing of germline variants into megabase-scale phase blocks by enabling linkage of distant SNVs and thus shows promise for phasing somatic variants.Reconstruction of tumor clones is a multi-allelic phasing problem. Obtaining a phylogeny of detected somatic point mutations (PM) is a first step in phasing these mutations into different clones where nodes in the constructed phylogeny correspond to possible clonal haplotypes. For this purpose, we propose timing pairs of PMs against each other based on their co-occurrences in the reads that cover both locations and whether these reads support the reference or alternate allele. Given two point mutations and a set of reads that cover these two positions; it is possible to deduce whether these two mutations occurred one after the other in the same branch, co-occurred together, or occurred in different branches (i.e., divergent). Since timing of PM pairs are transitive, it is possible to obtain longer chains by timing PM pairs that are not connected by reads. We represent these relationships as a graph where PMs are nodes and each type of relationship is represented by a different edge.

We applied our approach to H2009 and H1437 cell lines from the CASTLE collection (https://github.com/CASTLE-Panel/castle) with regular and ultra-long (100kb+) Oxford Nanopore reads. Although these cell lines are less heterogeneous compared to typical real tumor samples, phasing somatic mutations can also distinguish duplicated chromosome copies. For H1437 and H2009 cell lines, we detected a total of 87,999 and 162,334 somatic SNPs. The graphs constructed with these SNPs contained connected components with median spans of 102Kb and 55Kb (maximum: 9.5Mb and 6.4Mb). For both cell lines, connected components had a median of 2 (maximum: 56 and 80) haplotypes. Of these detected haplotypes, median of 1 for both cell lines (maximum: 23 and 46) consists of multiple SNPs. We plan to extend our approach to include timing of structural variations.

#6913 Unbiased cell type identification and biological interpretation of spatial molecular data.

Filippo Pullara[1], Raymond Yan[1], Brian Falkenstein[1], A. Burak Tosun[1], S. Chakra Chennubhotla[2]

[1]PredxBio, Inc., Pittsburgh, PA,[2]PredxBio, Inc. / University of Pittsburgh, Pittsburgh, PA

Background: While pre-defined, or biased, phenotyping algorithms are a popular approach for analyzing spatial molecular data, offering ready biological interpretation (e.g., CD8+ T-cells, CD68+PD-L1+ macrophages) and reproducibility across labs with consistent threshold choices, they suffer from subjectivity, coarseness, and an inability to capture emergent biology. Conversely, unbiased phenotyping algorithms have the potential to address these limitations, but they currently lack straightforward biological interpretability.
Methods: Our SpaceIQ™ multi-omics platform performs recursive cell typing (RCT) instead of standard hierarchical clustering and other graph-based algorithms for unbiased cell identification. RCT leverages the wide dynamic range (variance) in spatial proteomics, transcriptomics, and morphology data, driven by protein abundance and other technical factors, as biologically insightful. Unlike normalized standard methods, RCT allows markers with larger variances to drive early differentiation, with smaller-variance markers defining subsequent subpopulations.
Results: We demonstrate the broad applicability of RCT using the SpaceIQ™ platform across three publicly available spatial datasets, including proteomics, transcriptomics, and brightfield pathology. To facilitate biological interpretation of the resulting unbiased cell populations, RCT approach: (i) identifies discriminatory biomarker signatures for annotating each RCT; (ii) calculates the probability of pre-defined phenotypes within any unbiased cell type; and (iii) generates a minimal marker panel that can approximate any given unbiased cell type with high probability.
Conclusions: Unbiased cell typing, achieved through RCT, is critical in cancer research. This approach ensures the representation of all cell states—rare, abundant, positive, negative, and transitional—regardless of antigen expression. By not relying on extensive cell-type specific training, it is uniquely suited to capture the full spectrum of cellular heterogeneity.

#6914 STCS: Spatial transcriptomics cell segmentation outperforms existing methods on multiple slides.

Xinyu Hu[1], Fengwei Zhan[1], Lixia C. Wu[1], Jose Gonzalez[1], Chuhanwen Sun[1], Rachel Ofer[1], Tyler Tran[2], Michael Verzi[1], Jiekun Yang[1]

[1]Department of Genetics, Rutgers University, New Brunswick, NJ,[2]Quantitative Biomedicine Program, Rutgers University, New Brunswick, NJ

Spatial transcriptomics (ST) has long been recognized as an advanced technique that provides insights on spatial information beyond what can be obtained from single-cell RNA sequencing. However, widely used sequencing-based ST approaches cannot provide cell level data because their results are aggregated into discrete bins rather than assigned to individual cells. With the advent of Visium HD and other subcellular-resolution platforms, accurate cell segmentation has become essential for extracting biologically meaningful, cell-level information.Here, we present STCS (Spatial Transcriptomics Cell Segmentation), a segmentation framework tailored for high-resolution ST data. We benchmarked STCS against several existing methods—including STHD, bin2cell, and Space Ranger—using a slide with both Visium HD and Xenium results. Evaluation using ground-truth Xenium cell boundary annotations demonstrated that STCS delivers the best performance, achieving 40% accuracy in cell-type prediction and showing the lowest spatial chaos score, a metric that quantifies how spatially continuous clusters are. We also applied STCS to another Visium HD slide from mouse intestinal regeneration model which contains tissue from different time points after radiation. Compared to default Visium HD binning, STCSsegmented cells show clear transcriptional differences by timepoints and identify several rare immune cell types. As a result, downstream analyses such as spatial cell-cell interaction inference and regional pattern characterization can be done in cell level which include more cell types and more immune related pathways like JAK-STAT pathway with STCS.
In addition, STCS is versatile and can be applied to other sequencing-based ST methods like Stereo-seq, which offers nanometer-scale resolution. And it's also an open-source tool with adjustable parameters for different tissue types.In summary, STCS is a robust and flexible cell segmentation tool that provides a one-stop solution for deriving biologically meaningful, cell-level information from high-resolution sequencing-based ST datasets.

#6915 Investigating the role of the conserved notch pathway in glioblastoma cells.

Larissa Barroso[1], Megan E. Keniry[2]

[1]University of Texas Rio Grande Valley - UTRGV, Edinburg, TX,[2]University of Texas Rio Grande Valley, Edinburg, TX

Glioblastoma (GBM) remains the most aggressive primary brain cancer, representing nearly 50% of all brain malignancies, with a median survival of less than 15 months. Our lab has identified a role for the FOXO4 transcription factor in maintaining a stem-like phenotype in GBM. To further investigate this novel role, we performed RNA sequencing on *FOXO4* knockout U87MG cells generated in our laboratory using CRISPR Cas9 mutagenesis. We found that loss of *FOXO4* in U87MG cell lines altered the expression of *NOTCH3* and its downstream targets, such as *CCND1*. Furthermore, exogenous *NOTCH3* induced *CCND1* expression in U87MG cells. These preliminary findings suggest that FOXO4 transcriptional activity may influence glioblastoma aggressiveness at least in part by modulation of *NOTCH3* activation. Ongoing studies aim to confirm whether the FOXO4–NOTCH3 axis is essential for maintaining stem-like states in GBM cells. Elucidating this interaction could uncover novel molecular targets for therapeutic intervention and advance our understanding of GBM pathogenesis.

#6920 Preclinical development of a first-in-class CD64-ADC to target leukemic monocytes and tumor-associated macrophages.

Lia Buffa[1], Cintia Garro[1], Constanza Marin[2], Alejandra Garcia[2], Diego Andino[1], Melisa Capitanelli[2], Laura Bertoldi[2], Florencia Villafanez[2], Natalia Monjes[2], Agustina Garcia-Melani[2], Laura Guantay[2], Daniela Arroyo[2], Alejandro Moyano[2], Gimena Ferreira[3], Belkys Marelli[4], Tarek Zaki[1], Gerardo Gatti[2], Candelaria Llorens de los Rios[2], **Gaston Soria**[1]

[1]OncoPrecision, New York, NY,[2]OncoPrecision, Cordoba, Argentina,[3]Sanatorio Allende, Cordoba, Argentina,[4]ICIVET-LITORAL, CONICET-UNL, Esperanza - Santa Fe, Argentina

Cells of the monocytic lineage are involved in the pathophysiology of several human cancers. In myeloid hematologic malignancies such as chronic myelomonocytic leukemia (CMML) and monocytic AML (M4/M5 FAB subtypes), leukemic monocytes display poor response to standard of care treatments and dismal complete remission rates. In solid tumors, tumor-associated macrophages (TAMs) are critical cells of monocytic origin that promote an immunosuppressive tumor microenvironment in malignancies such as TNBC, PDAC, and GBM, thereby driving tumor growth and resistance to PD-1/PD-L1 blockade. Interestingly, both leukemic monocytes and TAMs share a highly differentiated phenotype and a low proliferative capacity, which render them refractory to the mechanism of action (MOA) of established chemotherapeutic regimens. Therefore, identifying druggable targets with broad expression across the monocytic maturation lineage is a promising strategy for designing antibody-drug conjugates (ADCs) aimed at overcoming monocyte-driven resistance.
In this work, we leveraged OncoPrecision's Patient Micro-Avatar (PMA) ex vivo platform to validate novel targets and the optimal payload to develop an ADC to target leukemic monocytes and TAMs. This screening campaign identified CD64 as a target with high expression and druggability in patient-derived monocytic-cells and unveiled PNU-159682 (PNU) as the payload with the optimal MOA to deplete monocytic cells. Intriguingly, payloads with proven clinical success in other malignancies, such as Exatecan and MMAE, displayed poor/null activity against leukemic monocytes and TAMs, thus highlighting a non-obvious vulnerability of monocytic cells to PNU.
ONC001, our first-in-class ADC conjugated to PNU through a non-cleavable linker displays picomolar activity against a panel of monocytic cell lines in vitro and against patient-derived leukemic monocytes and TAMs ex vivo. Multiple in vivo models of leukemia and solid tumors also confirmed a remarkable efficacy and selectivity of ONC001, including a humanized mouse model in which TAMs from the TME of established xenografted tumors were efficiently depleted after a single injection of the ADC. Importantly, we extensively investigated the safety of ONC001 by evaluating its on-target and off-target activity in multiple animal models, and observed remarkable tolerability with no signs of toxicity. Together, these preclinical findings demonstrate a favorable therapeutic index for ONC001, supporting its potential as a powerful agent for depleting pathogenic monocytes in cancer treatment.

#6921 Phosphonate-antibody-drug conjugates, a novel immunostimulatory class of ADCs driving inside-out activation of Vγ9Vδ2 T cells leading to selective tumor cell killing.

Mary J. van Helden, Genny Filliciotto, Wendela A. Kappers, Diels van den Dobbelsteen, Panagiota I. Spantidea, Marga Gunnewijk, Myrthe Rouwette, Anja Scholzen, Seline A. Zwarthoff, Stefanie J. J. J. van Kuppeveld, Benny de Wit, Gijs Verheijden, Ruud Ubink, Benno Ingelse, Miranda M. C. Van der Lee, **Wim H. A. Dokter**

Byondis B.V., Nijmegen, Netherlands

Gamma delta (γδ) T cells are cytotoxic effectors capable of recognizing and eliminating tumor cells independently of major histocompatibility complex (MHC) presentation. Their presence within tumors correlates with improved clinical outcomes across various cancer types. Vγ9Vδ2 T cells, the predominant γδ subset in human blood, recognize intracellular phosphoantigens (pAgs) through inside-out activation of the butyrophilin (BTN)3A/BTN2A complex. Clinical trials have previously been conducted using aminobisphosphonates or synthetic pAgs, either alone or in combination with low-dose interleukin-2 (IL-2); however, these compounds lack tumor specificity and are limited by a very short plasma half-life *in vivo*. To address the lack of tumor targeting and short half-life, we engineered antibody-drug conjugates (ADCs) that selectively deliver phosphonates to tumor cells, enabling inside-out activation of Vγ9Vδ2 T cells. These phosphonate-ADCs consist of a monoclonal antibody directed against a tumor-associated antigen (TAA), conjugated to a phosphonate payload via a linker that is cleavable by lysosomal proteases. We applied this strategy to various TAA-targeting antibodies, including CD123, CD20, TROP2 and HER2 directed IgG1-based monoclonal antibodies. TAA-positive tumor cell lines pretreated with phosphonate-ADCs effectively triggered Vγ9Vδ2 T cell activation through a BTN3A-dependent mechanism. This activation led to robust cytokine secretion, degranulation, and efficient tumor cell lysis. Vγ9Vδ2 T cell activation was successfully replicated with *ex vivo* patient tumoroids (EVPTs) and autologous peripheral blood mononuclear cells (PBMCs), supporting the translational relevance of this approach. In an acute myeloid leukemia (AML) adoptive transfer mouse model, Vγ9Vδ2 T cells significantly reduced the tumor burden in the presence of the tumor-targeting phosphonate-ADC. In cynomolgus monkeys, the lead phosphonate-ADC candidate displayed excellent tolerability at a single dose of up to 100 mg/kg, with no clinical signs of cytokine release syndrome (CRS). Immunostimulatory phosphonate-ADCs represent a novel strategy for targeted, physiologically relevant activation of Vγ9Vδ2 T cells by delivering phosphonates directly to tumor cells. This modular platform can be combined with virtually any tumor-targeting monoclonal antibody with the possibility to preserve Fcγ receptor-mediated effector functions. The resulting dual mechanism, integrating the antibody's direct anti-tumor activity with the immune-stimulatory properties of the phosphonate payload, offers a versatile and powerful therapeutic modality. Overall, this platform holds significant promise not only for targeted cancer immunotherapy but also for potential applications in other disease areas.

#6922 BHB810: A novel site-specific CDH17-directed VHH-Fc ADC for gastric cancer.

Ryan Henrici, Timothy Park, Melanie Montgomery, Barbara Steurer, Danielle Barreras, Natalie Alba, Srujan Vadlamudi, Hunter Elliott, Jon Wojciak, John Corbin, Peyton Greenside

BigHat Biosciences, Inc., San Mateo, CA

Background: Gastric cancer remains a significant and growing cause of morbidity and mortality globally, with nearly 1 million newly diagnosed patients each year. Treatment paradigms are limited to checkpoint inhibitors, angiogenic blockade, and conventional chemotherapy, with few patients achieving durable responses. HER2 and CLDN18.2 directed therapies represent breakthroughs but substantial unmet need remains. CDH17 represents one of the most widely expressed tumor-associated antigens, offering the potential to treat 50-60% of patients with gastric cancer, including a substantial population of those without HER2 or CLDN18.2 expression.

Methods: A single domain VHH anti-CDH17 antibody was engineered using BigHat's Milliner platform for optimal internalization, humanized, and subsequently conjugated to MMAE via a site-specific and serum-stable, enzyme-cleavable linker using GlycoConnect SYNstatin E technology. The antibody drug conjugate (ADC) was subsequently interrogated in vitro and in vivo, including in cynomolgus macaques as part of a comprehensive preclinical therapeutic research program.

Results: BHB810 is fully cross-reactive to human, cyno, and rodent orthologues and features robust and maximized internalization within 24 hours. The VHH-Fc fusion was conjugated to achieve a homogeneous DAR 4 with remarkable serum stability, providing a significantly enhanced therapeutic window compared to typical maleimide-vedotin conjugates. Compared to a benchmark clinical-stage CDH17-directed IgG ADC that rapidly loses payload via retro-Michael addition, BHB810 features no detectable deconjugation, payload transfer, or payload loss in human serum. The humanised VHH-Fc fusion backbone of BHB810 is 50% smaller than a typical IgG, resulting in superior tissue penetration. In PDX models, BHB810 leads to complete or near-complete tumor clearance in a panel of 13 different primary gastric cancers, including those with low and heterogeneous antigen densities. Preclinical modeling of pharmacokinetics and safety demonstrate a multi-day half-life, superior tolerability, and no evidence of on-target toxicities in non-malignant organ systems compared to benchmarks. In vivo imaging demonstrates robust target engagement and on-target ADC accumulation with reduced plasma exposure. BHB810 was evaluated in a 1 month GLP primate toxicity study exploring doses up to 5 mg/kg q2w (10 mg/kg of a conventional IgG ADC). No MTD was reached.

Conclusion: BHB810 is a novel, potentially best-in-class CDH17-directed ADC for the treatment of advanced gastric and other GI malignancies. The molecule was engineered on BigHat Biosciences's AI/ML-powered antibody design platform to maximise ADC internalization and potency against cells that express CDH17. First-in-human studies are planned for 2026, prioritizing patients with gastric cancer.

#6923 Targeting tumor-specific Tn-glycoforms of MUC1 and MUC4 with first-in-class antibody-drug conjugates: Preclinical efficacy and translational potential of GO-M100B and GO-M400.

Nisha Shrestha[1], Aaron Christopher Groen[1], Boris Klebanov[1], Constantine Theodoropulos[1], **Hans H. Wandall**[2]

[1]GO Therapeutics, Cambridge, MA,[2]University of Copenhagen, Copenhagen, Denmark

Aberrant O-glycosylation in epithelial cancers generates tumor-specific neoepitopes absent from normal tissues. GO Therapeutics has developed monoclonal antibodies that selectively recognize these Tn-glycoforms on mucins, including GO-M100B, targeting Tn-MUC1, and GO-M400, targeting Tn-MUC4. These antibodies bind aberrantly truncated O-glycans presented on mucin backbones with sub- to low-nanomolar affinity and exceptional site-specificity. These programs exemplify our “clean target” approach that exploits cancer-restricted glycoepitopes to enhance selectivity and therapeutic index. Structural and biochemical characterization revealed that M100B and M400 recognize proprietary glycopeptide neoepitopes unique to malignant epithelial cells, enabling precise tumor targeting. Immunohistochemistry confirmed broad reactivity across epithelial cancers. This includes breast, lung, ovarian, pancreatic, and gastrointestinal tumors. Negligible binding was seen to normal tissues. Both antibodies were engineered as site-specific antibody-drug conjugates (ADCs) using an mc-vc-PAB-MMAE linker to generate homogeneous DAR2 conjugates. These ADCs exhibited potent, selective cytotoxicity against Tn-positive cell lines, achieving sub-nanomolar IC_{50} values, while showing no measurable activity in Tn-negative or primary normal cell models. In vivo, M100B-vedotin and M400-vedotin induced marked tumor regression in both cell-derived (CDX) and patient-derived xenograft (PDX) models, with favorable pharmacokinetics and clean toxicology profiles in cynomolgus monkeys and mice. By targeting cancer-specific glycosylation patterns on mucins, M100B and M400 expand the therapeutic frontier of “clean target” oncology. These next-generation ADCs demonstrate exceptional tumor selectivity, strong preclinical efficacy, and favorable safety, supporting advancement into IND-enabling studies and clinical development for multiple epithelial malignancies.

#6925 Leveraging AI-enhanced multi-omics discovery of novel tumor-selective targets for ADC development.

Daniel Montoro, **Christoph Muus**, Karthik Jagadeesh, Cecile Rouleau, Yueyue Shi, Sho Takahashi, James Meador, Ritika Singh

Research and Development, TenSixty Biosciences, Cambridge, MA

TenSixty Biosciences employs an innovative AI-enhanced multi-omics discovery framework to enable the development of next-generation antibody-drug conjugates (ADCs). This integrated approach identified novel tumor-selective targets with high therapeutic potential by combining:
1. Multi-dimensional omics analysis integrated with advanced AI analytics to uncover therapeutically relevant cancer targets
2. Specialized proteomic profiling focused on unique post-translational modifications (PTMs) that reveal tumor-specific variants of targets, enabling enhanced tumor-selective targeting
3. Proprietary antibody discovery and engineering generates tumor-selective antibodies directed against these variants, yielding highly potent ADC candidates
Applied to small cell lung cancer (SCLC), this framework identified a novel therapeutic target exhibiting tumor-specific hypoglycosylation. Antibodies directed against the epitope exposed by altered glycosylation showed exceptional tumor selectivity and markedly enhanced ADC efficacy. AI-driven integration across discovery and development stages further accelerated target validation and candidate optimization.

#6926 An AI-guided biparatopic DLL3-targeting ADC demonstrates enhanced preclinical efficacy.

Chuan Chen, Yue Wu, Chenpeng Su, Zhaohui Chen, Dandan Liu, Jiyuan Tian, Xiaoqian Chen, Yang He, Yongxin Shang, Rongmei Yan, Liang Tian, Jian Peng, Zhenping Zhu

Earendil Labs, Wilmington, DE

Purpose This study aimed to develop a novel biparatopic antibody-drug conjugate (ADC) targeting delta-like ligand 3 (DLL3) for small cell lung cancer (SCLC) and other neuroendocrine neoplasms, addressing limitations of previous DLL3-targeted therapies.
Methods Leveraging our AI-guided antibody development platform, we engineered a biparatopic anti-DLL3 antibody with optimized binding and internalization properties. The antibody was conjugated with various linker-payload combinations. In vitro cytotoxicity of the ADCs were evaluated using DLL3-expressing cell lines and in vivo efficacy were assessed using CDX mice models. Safety was assessed in transgenic mice and non-human primates.
Results The biparatopic antibody demonstrated higher internalization efficiency compared to the monoclonal antibody counterparts. The ADC showed potent cytotoxicity across multiple DLL3-expressing cell lines and achieved significant tumor suppression in CDX models. Toxicological studies revealed a favorable safety profile in both transgenic mice and non-human primates.
Conclusion This biparatopic ADC represents a promising therapeutic candidate for DLL3-expressing tumors, demonstrating enhanced efficacy and favorable preclinical safety compared to previous approaches.

#6927 ADCE-T02 - A clinical stage antibody drug conjugate targeting tissue factor demonstrates strong efficacy in preclinical models of head and neck squamous cell carcinoma.

Thomas Tuxen Poulsen[1], Olga Ilina[1], Pernille Barkholt[1], Daniela Pontieri[1], Jette Bomholt Lange[1], Jonathan Henry Wardman[1], Christophe Come[1], Christina Hjaresen[1], Shu-Hui Liu[2], Xun Meng[3], Yue Zhang[3], Dominik Mumberg[1]

[1]Adcendo ApS, Frederiksberg, Denmark,[2]Multitude Therapeutics, Redwood City, CA,[3]Multitude Therapeutics, Shanghai, China

Tissue Factor (TF, F3, coagulation factor III, thromboplastin, or CD142), a membrane protein involved in blood coagulation, demonstrates confined expression to the perivascular compartment in healthy tissues but is over-expressed in many solid tumors, making it an attractive target for Antibody Drug Conjugates (ADC). The TF-targeted ADC Tisotumab vedotin is approved for treatment of cervical cancer and has demonstrated efficacy in Head and Neck Squamous Cell Carcinoma (HNSCC)[1], but treatment is limited by substantial side effects including ocular toxicities, peripheral neuropathy, and bleeding warranting development of a more efficacious and better tolerated modality.

ADCE-T02 is a clinical stage TF-targeted ADC composed of a humanized anti-TF antibody specifically designed to limit the impact on blood coagulation, conjugated via a novel T1000 linker moiety to the Topoisomerase-1 inhibitor Exatecan payload at a drug-to-antibody ratio of ~4.

The expression level of TF was evaluated in patients with HNSCC, confirming broad and high TF expression in the majority of tumors, regardless of Human Papilloma Virus (HPV) status. *In vitro,* the efficacy of ADCE-T02 was evaluated and confirmed in a panel of HNSCC tumor cell lines with varying TF expression levels. *In vivo,* ADCE-T02 also demonstrated strong anti-tumor activity in both cell line and patient derived HNSCC xenograft models with varying TF expressions. Intriguingly, strong efficacy of ADCE-T02 (dosed from 1 mg/kg) was observed in HNSCC tumors expressing high levels of Epidermal Growth Factor Receptor (EGFR) but with limited response to anti-EGFR therapy. Furthermore, administration of a single dose of ADCE-T02 to mice bearing large tumors (≥1000mm^3) caused remarkable tumor shrinkage often resulting in complete tumor eradication. In addition, strong antitumor responses of a single dose of ADCE-T02 were observed in large tumors growing out following anti-EGFR therapy.

In summary, ADCE-T02 demonstrates broad efficacy in HNSCC models with varying levels of TF expression including models resistant to EGFR targeted agents. A phase I clinical study of ADCE-T02 in patients with advanced solid tumors is currently ongoing and actively recruiting (Clinical Trial ID NCT06597721).

#6928 Dual-payload antibody drug conjugate targeting TROP2: Multi-Payload Conjugates™ targeting orthogonal mechanisms of cell killing.

Marco Lobba[1], Samantha Brady[1], Devin Trinter[1], Maxwell Nguyen[1], Chanez Symister[1], Andrew Lau[1], Derek Garcia-Almedina[1], Charlotte Choi[1], Saurabh Johri[1], Matthew Francis[2], Richard Kendall[1]

[1]CatenaBio, Berkeley, CA,[2]Chemistry, University of California at Berkeley, Berkeley, CA

Introduction: Antibody-Drug Conjugates (ADCs) have a tremendous impact on patient outcomes in breast and other cancers. Dato-DXd, for example, is a 2nd-line therapy for stage IV, HR+/HER2 negative metastatic breast cancer and EGFR mutant non-small cell lung cancer (NSCLC). Sacituzumab govitecan (SG), is approved as a 3rd line therapy in metastatic HER2 negative breast cancer. Many patients fail to respond or relapse after treatment with these ADCs due to tumor heterogeneity and resistance to the mono payload ADC. Dosing in patients is further limited by off-target toxicity due to instability of the maleimide bond between the antibody and linker. Combination therapies have historically outperformed monotherapies across most solid tumors, pointing to a potential for improvement of ADC efficacy. CatenaBio is developing next generation Multi-Payload Conjugates™ (MPCs™) with dual payloads and a more stable C-Y bond, that deliver targeted combination chemotherapies within a single molecule with reduced toxicities to address shortcomings in current ADCs.

Method: CatenaBio has developed highly stable, dual-payload ADC combination therapies, with tunable payload ratios. Our selective conjugation platform allows the attachment of distinct payloads targeting different mechanisms of action at three unique sites on antibody scaffolds replacing the unstable maleimide bond with a more stable C-Y bond.

Results: Catena's lead TROP2 targeting dual payload MPC, CATB-101, features an optimized combination and ratio of tubulin and TOP1 inhibitors. CATB-101 demonstrates superior tumor growth inhibition and excellent tolerability in multiple TROP2 expressing CDX and PDX models of TNBC, gastric, and lung cancers. In head-to-head comparisons, CATB-101 outperforms T-DXd, SG and Dato-DXd with full tumor elimination at low doses. CATB-101 eliminates tumors in models following progression on SG treatment, demonstrating potential in ADC relapsed patients. Non-GLP non-human primate (NHP) toxicology trials with CATB-101 demonstrate a remarkable safety profile, by eliminating or reducing off-target toxicity.

Conclusion: Advances have been made in the design of ADCs to expand to previously unaddressed populations. High patient relapse and the failure of recent mono-payload ADCs in late-stage trials indicate a need for next generation multi-payload conjugates. Catena's MPCs™ offer a next step in ADC design and allow for targeted delivery of multiple mechanisms of action with a single MPC™ while reducing off-target toxicity. CATB-101 is highly efficacious at eliminating tumors across multiple CDX and PDX models of cancer that display a range of target surface expression. Validated in early NHP toxicology studies with a significantly enhanced therapeutic window, these molecules offer the potential to circumvent tumor resistance pathways to deliver more durable patient responses.

#6929 Targeting intracellular KRAS^{G12D}/HLA-A11 pMHC with a novel TCR-mimic antibody-drug conjugate (TCRm-ADC) demonstrates potent antitumor activity in preclinical models.

Chia-Chun Chao[1], Wei-Ze Hong[1], Hsin-Yu Chang[2], Jhen-Yu Chen[3], Yi-Wen Jiang[3], K.S. Clifford Chao[3], Kevin Chih-Yang Huang[3]

[1]NDV Therapeutics Corp., Hsinchu, Taiwan,[2]National Yang Ming Chiao Tung University, Hsinchu, Taiwan,[3]China Medical University, Taichung, Taiwan

Antibody-drug conjugates (ADCs) targeting tumor-associated antigens (TAAs) frequently cause on-target, off-tumor side effects. TCR-mimic antibodies (TCRms) imitate the capacity of T cell receptors (TCRs) to interact with peptide-MHC complexes (pMHCs), offering a solution to target previously undruggable intracellular cancer antigens, such as KRAS mutations. Here, we screened and identified a TCRm with high specificity and affinity for the KRAS^{G12D}/HLA-A*11 pMHC complex using phage display, ELISA, and cell-based assays. We further confirmed the specificity and safety of the TCRm antibody *in vitro* and *in vivo*. Furthermore, the TCRm-ADC, NDV-ADC01-exatecan, which targets the KRAS^{G12D}/HLA-A*11 pMHC complex, mediated specific antitumor activity *in vitro* and *in vivo* without obvious toxicity in xenograft models of lung, pancreatic, and colorectal cancer. Additionally, NDV-ADC01-exatecan significantly elicited antitumor immunity and reshaped the tumor microenvironment when combined with low-dose radiotherapy in a humanized HLA-A*11/hB2M transgenic model. Together, these screening and engineering processes provide a novel therapeutic strategy to target undruggable KRAS^{G12D}-mutated cancers.

#6930 Preclinical efficacy of BCG018, an ADC targeting ITGB6 and incorporating a topoisomerase I inhibitor payload, was demonstrated to be effective in PDX models.

Yi Yang, Mengran Li, Chengzhang Shang

Biocytogen, Waltham, MA

Integrin αvβ6 is a heterodimer composed of αv and β6 subunits that is primarily found on the surfaces of epithelial cells and is known to be upregulated during the epithelial-mesenchymal transition (EMT). Its overexpression in various solid tumors, which correlates with poor patient prognosis, makes it a promising target for ADC therapy. However, the large size and complexity of the integrin family present significant challenges in developing specific antibodies.

In our studies, we identified the anti-ITGB6-B antibody, which selectively binds to ITGB6 over other beta integrins. This specificity was established using fully human common light chain RenLite mice with ITGB6 knockout. The anti-ITGB6-B antibody demonstrated good binding affinity for both ITGB6 and its heterodimer αvβ6, outperforming the benchmark, as confirmed by SPR and ELISA experiments.

Furthermore, anti-ITGB6-B exhibited excellent binding characteristics across multiple tumor cell lines, effectively targeting cells with varying levels of ITGB6 expression. Importantly, its internalization activity was found to be comparable to or greater than that of the benchmark, enhancing its potential for therapeutic applications. Notably, the anti-ITGB6-B did not block the interaction of ITGB6 with its ligand LAP in ELISA assays, indicating its potential as a targeted therapy without disrupting critical signaling pathways. The anti-ITGB6-B also exhibited excellent physicochemical properties and developability, making it a promising candidate for further development in ADC therapy.

The anti-ITGB6-B was then conjugated to vcMMAE. The resulting conjugate demonstrated superior efficacy to that of the benchmark ADC in PDX models, regardless of ITGB6 expression levels. Additionally, the BCG018, which is anti-ITGB6-B conjugated with a novel topoisomerase I inhibitor (BLD1102), showed superior efficacy to benchmark ADC in models of pancreatic, colorectal, and NSCLC PDX or CDX xenografts. Overall, BCG018 conjugates offer a promising strategy for targeting integrin αvβ6 in solid tumors with specific and potent efficacy.

#6931 Preclinical study of BCG044, a novel bispecific ADC targeting EpCAM and HER3 for the treatment of colorectal and other tumors.

Jeremy Lee, Zhuolin Li, Chengzhang Shang, Yi Yang

Biocytogen, Waltham, MA

Colorectal cancer (CRC) is the third most common cancer and the second leading cause of cancer-related deaths. Unfortunately, current therapies have limited effectiveness on long-term survival. Antibody-drug conjugates (ADCs) represent an emerging class of treatments with potential in oncology, but their efficacy in colorectal cancer has been limited thus far. Therefore, identifying new drug targets and developing ADCs are essential for improving treatment outcomes. Epithelial cell adhesion molecule (EpCAM) is a transmembrane glycoprotein widely expressed in various cancers, notably colorectal, gastric, ovarian, and lung cancers. However, its presence in normal tissues has led to adverse effects from previous biologic therapies, including gastrointestinal toxicity and pancreatitis associated with systemic administration.
In this study, we developed an innovative approach to generate a bispecific ADC targeting both EpCAM and HER3, another antigen that is widely overexpressed in various solid tumors, including gastrointestinal cancers, breast cancer, and NSCLC. By employing a "1+1" format, we aimed to mitigate EpCAM-related toxicity while enhancing tumor selectivity. The BCG044 bispecific antibody (bsAb) effectively bound to a diverse range of gastrointestinal tumor cell lines. Notably, the monovalent form of EpCAM and HER3 resulted in decreased internalization within tumor cells. In contrast, simultaneous engagement of both targets by bsAbs maximized internalization. This suggests that bsAb requires targeting of tumor cells with bivalency. When conjugated with BLD1102, a novel TOP1 inhibitor linker-payload, BCG044 exhibited potent efficacy comparable to the EpCAM benchmark ADC and demonstrated stronger effects than the HER3 benchmark ADC in colorectal, breast, and NSCLC PDX models. Subsequently, we utilized humanized EpCAM mice to test a surrogate ADC that contained the same EpCAM arm, along with a HER3 arm that cross-reacted with mouse HER3. The surrogate ADC demonstrated better tolerance compared to both the parent EpCAM ADC. In summary, BCG044 exhibited the potential to enhance tumor selectivity while maintaining potent efficacy against colorectal and other solid tumors.

#6932 BCG045: A first-in-class bispecific ADC targeting TROP2 and MUC1 demonstrates promising tumor efficacy and potentially reduced toxicity in preclinical studies.

Jeremy Lee, Yifu Zhang, Chengzhang Shang, Yi Yang

Biocytogen, Waltham, MA

Although TROP2 ADCs provide clinical benefits, they face challenges with on-target toxicity and resistance. MUC1 is another crucial biomarker in oncology. In cancer cells, MUC1 loses its normal polarity and redistributes across the cell surface and cytoplasm. It consists of two subunits: the transmembrane domain (MUC1-C), which activates key oncogenic signaling pathways, and the extracellular domain (MUC1-N), which can be shed into circulation. Both TROP2 and MUC1 are overexpressed in various epithelial tumors and are linked to poor prognosis. Furthermore, the induction of TROP2 expression can occur through the binding of galectin-3 to MUC1.

In this study, we developed a bispecific ADC that targets both TROP2 and MUC1, aiming to enhance efficacy while reducing target-related toxicity. To minimize the on-target toxicity associated with TROP2, we identified a TROP2 binder designed to reduce its internalization in a monovalent format with low affinity. To prevent the neutralization of antibodies/ADC by circulating shed MUC1, thereby affecting efficacy and pharmacokinetics, we developed a MUC1 binder that specifically recognizes the MUC1-N/C junction of membrane-bound MUC1 on tumor cells. This membrane-bound MUC1 binder demonstrated high specificity for MUC1 and robust affinity for both human and monkey MUC1. In tumor-bearing mouse models, the MUC1 binder exhibited an improved pharmacokinetic profile compared to benchmark antibodies, as well as strong anti-tumor efficacy. Notably, the performance of the MUC1 binder was unaffected by the presence of shed MUC1, suggesting its potential for effective therapeutic use in targeting MUC1-overexpressing tumors.

The TROP2×MUC1 bispecific antibody (bsAb) demonstrated broad binding capabilities across a range of tumor cell lines with varying expressions of TROP2 and MUC1. Notably, the bsAb exhibited efficient internalization in tumor cells, while also showing reduced internalization activity in TROP2 single-positive cells, which is an important feature for minimizing on-target toxicity. When conjugated with a TOP1 inhibitor (TOP1i) linker-payload, designated as BLD1102, to form BCG045, the bispecific ADC displayed potent efficacy in various patient-derived xenograft (PDX) models.

BCG045 outperformed the benchmark ADCs in certain models, indicating its enhanced therapeutic potential. Overall, the data suggest that BCG045 could be a promising new treatment option for multiple tumors, offering improved efficacy and safety.

#6933 GQ1035: First-in-class ADC against novel targets for gastric cancer and ovarian cancer discovered via high-throughput screening.

Shanshan Xie, Meijun Xiong, Lina Wang, Yajun Sun, Chong Liu, Zhongsheng Hu, Xinju Gao, Yanwen Feng, Yu Han, Zengyan Mu, **Paul H. Song**, Gang Qin

GeneQuantum Healthcare (Suzhou) Co., Ltd., Suzhou, China

Background: Antibody-drug conjugates (ADCs) constitute a breakthrough in gastric cancer (GC) and ovarian cancer (OV) therapy; however about over 50% of patients remain ineligible for existing options, underscoring the urgent need for next-generation ADCs against novel targets. Among these, Target A has emerged as a promising candidate due to its high expression in GC and OV, with no significant correlation to CLDN18.2 or FRα—supporting its potential for ADC development. The iScreener™ platform's high-throughput conjugation capability, rooted in iLDC™/iGDC™ technologies, enables a screening-based strategy for the rapid identification of lead ADCs against Target A.

Method/Results: To develop ADCs against Target A, we constructed a diverse library of ~150 candidates on the iScreener™ platform by combining 11 antibodies with varied linker-payloads. The ADC library was screened using gastric cancer patient-derived organoid (PDO) models. In this screen, Topoli-ADC and Exatecan-ADC demonstrated superior anti-tumor activity compared to other payload-based ADCs (e.g., DXd, MMAE, Eribulin). During in vivo screening, Topoli-ADCs and Eribulin-ADCs emerged as the top candidates by demonstrating potent anti-tumor efficacy in a model resistant to a Topo1 inhibitor-based ADC. Through further refinement in PDX models, GQ1035 was selected based on its ability to induce significant tumor regression across models with varying target expression levels, while maintaining a good safety profile with no significant body weight loss. Safety study for lead candidate is currently ongoing in non-human primates (NHPs).

Conclusion:GQ1035 shows a promising efficacy profile against gastric and ovarian cancers in preclinical PDO and PDX models. This positions GQ1035 as a potential breakthrough therapy in an area of high unmet medical need. It stands as a pioneering example of the strategic shift in biomedicine from “by design” to “by screening”.

#6934 Integrated evaluation of payload-, Fc-, and target-mediated mechanisms of ADCs using streamlined complementary platforms.

Alpana Prasad[1], Surekha Bonasu[1], Radhika Venkatnarayanan[1], Jennifer Lin-Jones[1], Jane E. Lamerdin[1], Gaurav Agrawal[1], Nguyen Ly[2], Jesus A. Diaz de Leon[2], Venkatesh Chari[1]

[1]Eurofins DiscoverX, Fremont, CA,[2]Biosensing Instrument, Tempe, AZ

This study demonstrates an integrated approach for comprehensive characterization of antibody-drug conjugates (ADCs) using complementary bioanalytical platforms. The objective was to evaluate target binding, internalization, and both payload- and Fc-mediated cytotoxic mechanisms to generate a holistic understanding of ADC mode of action.ADC binding affinity and kinetic parameters were characterized by surface plasmon resonance microscopy (SPRm) to assess cell-surface receptor engagement. Internalization was measured in engineered tumor cell lines expressing relevant antigens (e.g., BCMA, CD33) using enzyme-fragment complementation (EFC)-based PathHunter® internalization assays. Functional cytotoxicity was quantified using the KILR® Cytotoxicity platform, providing direct readouts of target-cell death. Fc-effector functions, including antibody-dependent cellular cytotoxicity (ADCC) and phagocytosis (ADCP), were evaluated using effector cell models to distinguish immune-mediated from payload-driven mechanisms.Here we show characterization data for 2 different ADCs which demonstrated high-affinity binding by SPRm and efficient internalization by PathHunter assays. In KILR assays, the ADC produced a concentration-dependent cytotoxic response distinct from its unconjugated parental antibody. Comparative analysis revealed that payload-mediated killing dominated overall cytotoxicity, while measurable ADCC and ADCP activities reflected retained Fc function. Integration of biophysical and cell-based results provided mechanistic resolution of ADC function at multiple levels. Combining SPRm, PathHunter internalization assays, and KILR cytotoxicity enables comprehensive ADC characterization encompassing binding, uptake, and multi-mechanistic cytotoxicity. This integrated workflow supports discovery, optimization, and lot-release testing by linking molecular properties to functional outcomes, enhancing mechanistic understanding critical for ADC development.

#6935 BCG029: An ADAM9-Targeting ADC Featuring a Novel Topoisomerase I Inhibitor Payload Demonstrated Potent Efficacy in PDX Models.

Yong Xie, Mengran Li, Chengzhang Shang, Yi Yang

Biocytogen, Waltham, MA

ADAM9 (A disintegrin and metalloprotease 9) is a membrane-anchored protein that is crucial for various physiological functions, mainly through its disintegrin domain for adhesion and metalloprotease domain for ectodomain shedding of cell surface proteins. Its overexpression in various cancers, including pancreatic, esophageal, breast, gastric, lung, and colorectal cancers, is linked to increased tumor aggressiveness and poor prognosis. Although ADAM9 is a promising target for ADC development, its expression in human tissues and immune cells, such as monocytes, macrophages, and neutrophils, poses challenges. This overlapping expression raises the risk of off-target effects and toxicity to normal tissues, which may hinder the efficacy and safety of ADC therapies targeting ADAM9.

Therefore, we have developed an ADAM9 clone, Ab.01, utilizing the fully human RenLite ADAM9 knockout (KO) mice. Ab.01 specifically binds to the membrane-proximal region of ADAM9-L while disregarding the secreted isoform, ADAM9-S. This clone targets ADAM9 without cross-reactivity to other ADAM family members, a specificity confirmed using an ADAM9 KO cell line. Additionally, Ab.01 demonstrated broad binding activity to a panel of cancer cell lines. Ab.01 also showed effective internalization activity. Furthermore, in a PBMC binding assay, Ab.01 demonstrated minimal binding activity to myeloid cells compared to the benchmark antibody. This observation suggests that Ab.01 may reduce off-target interactions, underscoring its potential for improved specificity in therapeutic applications.

Ab.01 conjugated to vcMMAE showed superior efficacy in several PDX models compared to benchmark antibodies conjugated with the same payload. Ab.01 was then conjugated with BLD1102, a novel Top1 inhibitor, resulting in BCG029, which demonstrated potent efficacy in PDX models. Ongoing *in vivo* studies are continuing to evaluate the performance of BCG029.

These findings underscore the therapeutic potential of BCG029 in targeting solid tumors that express ADAM9. By targeting ADAM9 specifically, BCG029 could provide a safer and more effective treatment option for patients with ADAM9-expressing tumors.

#6936 A novel MSLN×CDH3 bispecific antibody-drug conjugate (BsADC) demonstrates promising anti-tumor efficacy.

Haochen Wei, Zihao Wang, Weiqiu Lan, Xi Yang, Kunying Hao, Jinhua Zhao, Yang Chen, Baihong Liu, Chengzhang Shang, Yi Yang

Biocytogen, Waltham, MA

Background Mesothelin (MSLN) and P-cadherin (CDH3) are cell-surface proteins and co-expressed in multiple solid tumor types (e.g., ovarian, pancreatic) with restricted normal-tissue accessibility, supporting their selection for targeted therapeutics. Their co-expression or spatial complementarity of MSLN and CDH3 in solid tumors provides a mechanistic basis to mitigate antigen escape and enhance internalization-driven delivery. Recent advances suggest that bispecific ADCs (bsADCs) can improve internalization and payload delivery in co-expressing tumors.

Method We developed a fully human anti-human MSLN×CDH3 bsAb using our proprietary common light chain RenLite® mouse platform. Our bsADC employs a monovalent “1+1” architecture with two linker-payload options: monomethyl auristatin E (MMAE), a clinically validated microtubule inhibitor, and BLD1102, a newly developed DNA topoisomerase inhibitor.

Results The anti-MSLN×CDH3 bsAb demonstrates good physicochemical and developability. In vitro, bsAb showed higher binding activity to various types of cancer cell lines, as well as enhanced internalization activity compared to parental antibodies. Next, the bsAb was conjugated with MMAE to generate an anti-MSLN×CDH3 bsADC. This bsADC displayed stronger antigen-dependent cytotoxicity than parental ADC controls across different cell lines, consistent with enhanced internalization. In vivo, we also tested the efficacy of the MSLN×CDH3 bsAb conjugated to BLD1102. Both anti-MSLN×CDH3 bsADC (MMAE) and anti-MSLN×CDH3 bsADC (BLD1102) exhibited superior efficacy in patient-derived ovarian and pancreatic ductal adenocarcinoma xenograft models.

Conclusion Together, these results suggest that anti-MSLN×CDH3 bsADC has the potential to be a novel therapeutic alternative for MSLN and CDH3-expressing tumors.

#6937 BCG046, a CDCP1 ADC that targets CTF, has demonstrated potent *in vitro* and *in vivo* efficacy.

Haochen Wei, Na Zhang, Chengzhang Shang, Yi Yang

Biocytogen, Waltham, MA

Background CUB domain-containing protein 1 (CDCP1) is a type I transmembrane glycoprotein that is associated with tumor progression, drug resistance, and a poor prognosis. CDCP1 is highly expressed in various types of cancer, including pancreatic, breast, prostate, ovarian, colorectal, and lung cancers. It is closely tied to patient prognosis. CDCP1 can be cleaved by extracellular proteases, resulting in the shedding of the protein. The presence of these shedding CDCP1 in the serum of cancer patients raises concerns regarding the neutralization of biologic therapeutics.
Results Thus, we developed the antibody clone Ab.168, which specifically targets the C-terminal fragment (CTF) of CDCP1, utilizing our fully human RenMice platform. Ab.168 exhibited cross-reactivity with human, monkey, and mouse CDCP1, demonstrating a strong affinity for and effective binding to a variety of tumor cell lines. This broad reactivity underscores its potential for use in preclinical development and transition. Additionally, it displayed efficient internalization in cell lines with varying levels of CDCP1 expression, with performance comparable to or better than both the CTF and amino-terminal fragment (ATF) benchmarks. Moreover, Ab.168 exhibited robust development potential, as its binding activity remained unaffected by stress conditions, and it showed no nonspecific binding in polyreaction assays. When conjugated to vcMMAE, Ab.168-vcMMAE demonstrated superior or comparable efficacy to benchmark ADCs in NSCLC and colorectal patient-derived xenograft (PDX) models.
Conclusion These findings underscore the therapeutic potential of Ab.168 in developing an ADC as a promising strategy for treating colorectal cancer and other solid tumors characterized by CDCP1 expression. Further preclinical studies are underway.

#6938 BCG026: FAP × GPC1 bispecific ADC - A novel targeting approach for stromal and tumor cells in pancreatic cancer and other solid tumors.

Haochen Wei, Na Zhang, Kunying Hao, Chengzhang Shang, Yi Yang

Biocytogen, Waltham, MA

Background Pancreatic adenocarcinoma (PAAD) is a highly aggressive cancer that urgently needs new therapeutic strategies. Characterized by a dense fibrotic and desmoplastic stroma, PAAD leads to rapid disease progression, treatment resistance, and poor clinical outcomes. The primary components of this stroma are cancer-associated fibroblasts (CAFs), which accumulate within the tumor and increase the expression of collagen and fibronectin, thereby remodeling the extracellular matrix. CAFs also facilitate the desmoplastic response, contributing to early invasion, high recurrence rates, and resistance to treatment in PAAD. As a result, CAFs represent a promising therapeutic target not only in PAAD but also in other solid tumors. Fibroblast activation protein (FAP) is selectively expressed by CAFs in the majority of human epithelial cancers. Glypican 1 (GPC-1) is aberrantly expressed and plays a significant role in various cancers. It is notably increased in PAAD and has also been found at elevated levels in colorectal, prostate, and breast cancers.
We have confirmed that the PAAD tissue microarray (TMA) showed high expression levels of both FAP and GPC1. In response, we developed BCG026, a novel bispecific ADC that targets both stromal and tumor cells. This approach aims to deplete the tumor stroma, thereby improving efficacy against the stroma barrier and tumor heterogeneity, as well as overcoming resistance associated with traditional single-target therapies. A fully human bispecific antibody against FAP and GPC1 was generated using Biocytogen's RenLite® transgenic mice. The bsAb backbone demonstrated high affinity for both FAP and GPC1, effectively binding to a diverse panel of tumor cells.
Results Furthermore, it exhibited robust binding activity in both stromal and tumor cells, regardless of their varying expression levels of FAP and GPC1. Notably, the bsAb also showed efficient internalization in both stromal and tumor cells, indicating its capacity to deliver therapeutic payloads effectively to stroma and tumor cells. We then conjugated the bsAb with TOP1i linker-payload (BLD1102) to create BCG026. This novel bsADC exhibited a CAF-dependent bystander killing effect *in vitro*, suggesting its ability to induce cytotoxicity in FAP-positive stroma and tumor cells that may not express the target antigens, but are present in proximity to CAFs. Furthermore, BCG026 demonstrated potent efficacy in pancreatic and lung cancer PDX models, as well as a superior synergistic effect to that of the parent ADCs in certain models.
Conclusion These findings underscore its significant potential as a powerful therapeutic agent for targeting PAAD and other tumors. Further preclinical studies are currently underway.

#6939 Tri-specific ADC platform offers potential therapeutic advantage over bi-specific ADC.

Yang Wang, Lixia Cao, Cui Feng, Fangdun Jiang, lixia Gu, Chen Li, Yifan Yang, Qi Zhang, Ming Zhou, Cancan Li, Wei Huang, Bonan Yan, Ziping Wei, Yuhong Zhou

Preclinical Research & Development, Bliss Biopharmaceutical Co., Ltd., Hangzhou, China

Co-expression of EGFR and HER3, along with other tumor-associated antigen (TAA such as c-MET, HER2, B7H3, PD-L1, or others), is frequently observed across diverse human tumors. Targeting more than two TAAs simultaneously presents engineering challenges but offers distinct advantages: increased tumor cell avidity for ADCs, circumvention of antigen-loss-driven resistance, synergistic blockade of cross-talk between signaling pathways, mitigation of tumor heterogeneity, and broadened applicability across cancer types. A tri-specific ADC platform has been developed by combining one arm with both HER3 and EGFR affinities and another arm with affinity for a third TAA. Binding and internalization were assessed in cell lines with varying TAA expression levels to evaluate uptake efficiency. *in vitro* cytotoxicity was measured via dose-response assays across multiple lines with modest expression of each TAA. *in vivo* efficacy was tested in murine xenograft models representing diverse target antigen profiles, in comparison with benchmarks Izalonatamab brengitecan (BL-B01D1, EGFR/HER3 bispecific ADC) and an Amivantamab (EGFR/c-MET bispecific mAb)-derived ADC. Our results show that tri-specific ADCs exhibit significantly faster and more efficient internalization than the EGFR/HER3 bispecific ADC, particularly in cells with medium-to-low EGFR and HER3 expression. *in vitro*, tri-specific ADCs achieved lower IC50 values, indicating enhanced cytotoxic potency across a broad panel of tumor lines. In xenograft models, tri-specific ADCs delivered superior tumor growth inhibition relative to the bispecific benchmark, irrespective of heterogeneous target antigen expression. In conclusion, tri-specific ADCs offer a robust advantage *in vitro* and *in vivo* over EGFR/HER3 or c-MET bispecifics by enabling enhanced tumor cell binding, improved internalization, and more effective delivery of cytotoxic agents. This strategy holds promise for broader clinical application in tumors with varied receptor expressions and may address resistance in heterogeneous cancers.

#6940 A first-in-class PD-L1/B7-H3/VEGF tri-specific ADC achieves enhanced preclinical antitumor efficacy through direct cytotoxicity, immune checkpoint blockade and VEGF inhibition.

Jiajia Pan, Pengfei Wang, Hongwang He, Mengfan Peng, Meng Cheng, Jie Zhang, Chengyi Ju, Jun Wang, Li Li, Hui Feng

Allink Biotherapeutics, Shanghai, China

PD-L1 is an established immunotherapy target highly expressed in various solid tumors, while B7-H3 is another extensively investigated target overexpressed on a wide range of tumor cells. ADCs targeting PD-L1 or B7-H3 have entered clinical development and shown promising efficacy. PD-L1-directed ADCs may combine direct cytotoxicity and immunotherapy, demonstrating antitumor activity even in PD-L1-negative patients. However, ADC-related toxicity may limit their clinical dosing and thus restrict the full immune-mediated effects. Meanwhile, VEGF/PD-(L)1 bispecific antibodies are emerging as next-generation immunotherapies, with multiple trials exploring their combination with ADCs. Here, we developed ALK208, a trispecific ADC targeting PD-L1, B7-H3, and VEGF, conjugated to a topoisomerase I inhibitor payload. It is designed to integrate direct tumor cell killing, immune checkpoint blockade, and anti-angiogenic activity for maximal antitumor efficacy. Through optimized linker-payload design and DAR, ALK208 exhibited an improved safety profile, enabling higher dose levels to support robust PD-L1 blockade and VEGF neutralization. In preclinical studies, ALK208 simultaneously bound B7-H3, PD-L1, and VEGF with affinity comparable to monospecific antibodies. It effectively blocked VEGF/VEGFR and PD-1/PD-L1 interactions in reporter assays. Concurrent binding of B7-H3 and PD-L1 enhanced cellular binding and internalization in B7-H3/PD-L1 double-positive tumor cells, leading to more potent cytotoxicity than monospecific ADCs. VEGF-mediated crosslinking further strengthened binding, internalization, and cell-killing activity compared to a PD-L1/B7-H3 bispecific ADC. In the presence of VEGF homodimer, ALK208 also showed enhanced PD-L1 blockade in functional assays. Importantly, it did not kill activated T cells or APCs in vitro, suggesting a favorable immune safety profile. In xenograft models, ALK208 outperformed clinical-stage PD-L1 and PD-L1/B7-H3 ADCs. In summary, ALK208 is a first-in-class PD-L1/B7-H3/VEGF trispecific ADC that integrates multiple complementary mechanisms to maximize antitumor efficacy while maintaining a promising safety profile.

#6941 Bi- and tri-specific ADCs that target two distinct growth factor receptor forms of MUC1* and HER2 or alpha-v-beta-6 inhibit tumor recurrence and overcome acquired resistance.

Cynthia Carol Bamdad, Benoit J. Smagghe, Scott Moe, Mark G. Carter, Kevin R. Yi, Michael J. Nash, Robert McDermott, Trevor J. Grant, Salvatore Marchese, Daniel S. Miller, Natalie K. Miller, Andrew K. Stewart

Minerva Biotechnologies, Woburn, MA

Purpose: Develop more effective cancer therapeutics by simultaneously targeting multiple drivers of growth, metastasis and resistance.
Methods: MUC1 is aberrantly expressed on over 75% of solid tumor cancers. Although cloned 30 years ago, there is still no approved MUC1-targeted drug. Previous attempts, including those targeting trapped glycans, targeted the tandem repeat domain, which is shed after cleavage by cancer-associated enzymes. MUC1* with a 45-amino acid ecd (extracellular domain) is the only form that has been shown to function as a growth factor receptor via dimerization of ecd by embryonic growth factors. We show that where MUC1 is cleaved determines the conformation of the remaining ecd. Even within a truncated 45-amino acid ecd, there are distinct conformations that only exist on cancer cells and others that are only on progenitor cells. All these species have been mistakenly grouped together as “MUC1-C”. We developed monoclonal antibodies that specifically bind to each conformation and mapped their expression on cancer vs normal tissues vs progenitor cells. We then generated bi- and tri-specific ADCs that simultaneously bind to 2 or 3 cancer targets.
Results: Data show there are 2 distinct MUC1* receptors that drive tumor growth and metastasis. Targeting one and not the other led to tumor recurrence. We developed bi- and tri-specific antibodies that simultaneously bind to both MUC1* growth factor receptors, and HER2 or alpha-v-beta-6. In antibody internalization experiments, multi-specific antibodies were internalized faster and more completely than mono-specifics. In ADC format, bi-specific antibodies that hit both MUC1* growth factor receptors inhibited tumor recurrence in animals. ADCs incorporating both a MUC1* antibody and Trastuzumab killed Trastuzumab-resistant cancer cells with an IC50 of 0.05 nM compared to 0.73 nM on Trastuzumab sensitive parent cells. Indeed, in Phase I huMNC2-CAR44 trial, patients who had acquired resistance to Trastuzumab or Fam-Trastuzumab Deruxtecan-nxki were best responders in our trial with 75% DCR, 11-month OS, 11.3 month increased survival in patients with high MUC1* expression. In animals, our novel linker payload out-performed industry gold standard Deruxtecan.
Conclusions: It is critical that MUC1-targeted therapeutics hit the cancer-specific forms of MUC1*. Therapeutics that incorporate antibodies that bind to hematopoietic stem cells, for example, would be disastrous if given to cancer patients. Therapeutics that target full-length MUC1, whether aberrantly glycosylated or not, could give initial positive responses via ADC bystander killing. However, the hypothesis is that by killing cells expressing full-length MUC1, which plays no role in cell growth, the MUC1*-positive cell population would be enriched and would accelerate tumor growth and metastasis.

#6942 Validation of HER2, TROP2, and NECTIN4 IHC prediction algorithms for the ADC MATCH trial.

Kyle A. Beauchamp[1], Elizabeth Mauer[1], Kaveri Nadhamuni[1], Elizabeth morency[1], Alia Zander[1], Xingyu Zheng[1], Katherine Mclean[1], Sayantoni Mukhopadhyay[1], Seung Won Hyun[1], Chithra Sangli[1], Kate Sasser[1], Halla Nimeiri[1], Charles Koyias[1], Michelle Ting-Lin[1], Funda Meric-Bernstam[2]

[1]Tempus AI, Inc., Chicago, IL,[2]UT MD Anderson Cancer Center, Houston, TX

Introduction

Antibody-drug conjugates (ADC) have recently emerged as a leading class of targeted oncology therapies. Their usage remains complex, with approvals ranging from broad, tumor-agnostic immunohistochemistry (IHC) companion diagnostic approvals to narrower indication-specific labels. The ongoing ADC MATCH clinical trial (NCT06311214) examines whether a treatment algorithm defined by reflex RNA/IHC testing of the HER2, TROP2, and NECTIN4 gene/proteins can lead to successful biomarker-directed treatment of advanced solid tumors. This study describes the validation of an RNA-seq algorithm for identifying likely IHC-positive patients as required by the ADC MATCH study.

Methods

Three retrospective, de-identified RNA+IHC datasets were collected to enable accuracy studies of CAP/CLIA lab-developed tests for HER2 IHC prediction, TROP2 IHC prediction, and NECTIN4 IHC prediction. RNA-seq was performed by Tempus AI, Inc (Tempus xR), while IHC was performed by Neogenomics, Inc (HER2; clone 4B5), Tempus AI, Inc. (TROP2; clone SP294), or Histologix (NECTIN4; AB192033). IHC positivity was defined as 2+/3+ score groups (i.e., approximately an H-score > 100). High expressors were defined as binary thresholds using log2 gene tpm values of 7.9 (HER2), 4.9 (TROP2), and 6.8 (NECTIN4).

Results

The sample sizes for the three accuracy studies were 2,018 (HER2), 184 (TROP2), and 478 (NECTIN4), respectively. The performance of IHC prediction was assessed for these three targets using positive percent agreement (PPA) and negative percent agreement (NPA). The PPA of each target was found to be 47% (HER2; n=545), 93% (TROP2; n=146), and 35% (NECTIN4; n=71). The corresponding NPA of each target was found to be 89% (HER2; n=1473), 55% (TROP2; n = 38), 92% (NECTIN4; n=407). PPA and NPA varied among cancer types; for example, the TROP2 PPA in colorectal cancer was substantially lower than other cancers (62% vs 95%; $p < .05$).

Conclusion

IHC prediction using RNA-seq data is a promising approach to identify patients who are likely to test positive for specific protein biomarkers, potentially aiding in clinical trial screening and treatment decisions. Future studies, such as the ADC MATCH clinical trial, will assess the clinical value and outcomes of this approach.

#6943 Bispecific antibody with dual-payload ADC for metastatic castration-resistant prostate cancer.

Wenkai Zhao, Xiaofei Zhou, Ting Wang, Furong Guo, Huijie Zhao, Ning Wang, Teddy Yang, Ying Lei, Li Tong, **Fei Peng**

Hongcheng Biopharma, Shanghai, China

Treatment of metastatic castration-resistant prostate cancer (mCRPC) remains a significant clinical challenge. While monospecific ADCs have shown promise, target heterogeneity often leads to treatment resistance and relapse. To address this, we developed a bispecific ADC (BsADC) targeting both Prostate-Specific Membrane Antigen (PSMA) and Six-Transmembrane Epithelial Antigen of the Prostate 1 (STEAP1). The BsADC is armed with two distinct payloads with different mechanism of action: designed to enhance antitumor efficacy through dual antigen targeting and synergistic payload mechanisms. A humanized bispecific antibody against PSMA and STEAP1 was generated. The antibody was site-specifically conjugated with tubulin inhibitor and a topoisomerase 1 inhibitor. The PSMA/STEAP1 BsADC demonstrated optimal affinity, simultaneous binding to both targets, with no observable cross-reactivity to unrelated antigens. Unlike monospecific ADC, the BsADC was efficacious against cell lines expressing either or both antigens. The combination of MMAE and TOP1i payloads induced synergistic cell killing. In vivo, the dual-targeted, dual-payload BsADC achieved robust and durable tumor regressions in both homogeneous (PSMA+STEAP1+) and critically, in heterogeneous xenograft models. We have successfully developed a novel BsADC that co-targets PSMA and STEAP1 and delivers two mechanistically distinct warheads. This approach mitigates the issue of antigen escape and leverages synergistic payload activity, resulting in superior efficacy against heterogeneous prostate tumors. Our compelling preclinical data warrant further clinical development, and this BsADC represents a promising therapeutic candidate for patients with mCRPC, including those resistant to current ADC therapies.

#6944 Preclinical evaluation of a novel and highly differentiated FGFR2b-targeting ADC with low risk of ocular toxicity.

Zhaojun An[1], Jia Ge[1], Zhiqiang Xu[1], Yuhao Wang[2], **Barry Duplantis**[2], Quan Yu[1], Xiangyu He[1], Yi Li[1]

[1]Shanghai Ailux Biotechnology Co., Ltd., Shanghai, China,[2]Ailux Inc, Somerville, MA

Background: Fibroblast growth factor receptor-2 isoform IIIb (FGFR2b) plays a crucial role in the tumorigenesis and disease progression of several solid tumors, its overexpression is associated with poor prognosis. About 30% of gastric and gastroesophageal junction (G/GEJ) adenocarcinomas express FGFR2b with limited overlap with current biomarkers, this makes FGFR2b an attractive target. Bemarituzumab, an ADCC-enhanced FGFR2b antagonist, has demonstrated efficacy in patients with FGFR2b-overexpressing G/GEJ cancer. However, its therapeutic benefit appears to be limited by corneal adverse events, likely resulting from the strong blockade of FGFR2b ligands FGF7 and FGF10. Here we developed a novel FGFR2b-targeting ADC based on a highly differentiated antibody, ALX007, which completely spares ligand-receptor interaction and showed an encouraging ocular safety profile in preclinical models.
Methods: Hit antibodies were generated by hybridoma, triaged using a proprietary structural modeling algorithm, and humanized. Antibody binding and internalization were evaluated, and blockade of FGF7 and FGF10 binding to FGFR2b-overexpressing cells was analyzed by flow cytometry. The lead antibody was conjugated to a topoisomerase I inhibitor via a stable and enzyme cleavable linker. Anti-tumor efficacy of the resulting ADC was assessed using FGFR2b-positive xenograft mouse models. PK profile and ocular toxicity were evaluated in relevant mouse models.
Results: The naked antibody ALX007 demonstrated selective, high-affinity FGFR2b binding and rapid internalization in cell lines with varying levels of FGFR2b protein expression. Importantly, ALX007 did not inhibit the interaction between FGF7/FGF10 and FGFR2b even at high concentrations, distinguishing it from Bemarituzumab and several other reference antibodies with potent ligand blockade (IC_{50} < 5 nM). Both structural modeling and epitope binning experiments revealed that ALX007 recognizes a novel, non-ligand-blocking epitope. Functional studies further confirmed that ALX007 did not inhibit FGF7/FGF10-induced FGFR2b phosphorylation. In the SNU-16 gastric cancer xenograft model, a single dose of the FGFR2b-targeting ADC showed sustained and superior anti-tumor efficacy compared with repeated doses of Bemarituzumab. Both the ALX007 naked antibody and its ADC exhibited significantly lower corneal dystrophy than Bemarituzumab in mice. In a human FcRn transgenic mouse model, no apparent difference in serum concentrations was observed between conjugated and total antibodies, indicating a stable antibody-linker conjugation.
Conclusion: Together, these data demonstrate preclinical efficacy and low risk of ocular toxicity of a FGFR2-targeting ADC utilizing ALX007 as a highly differentiated antibody backbone. Further development for the treatment of FGFR2b-expressing tumors is warranted.

#6945 HDM2024: A novel EGFR and HER3 bispecific antibody-drug conjugate exhibits superior antitumor activity and favorable toxicological profile.

Qingyu Shu, Yan Xia, Zhaofeng Qin, Shengxing Zhao, Yang Chen, Rongrong He, Hao Pan, Hongwen Li, Dongzhou Jeffrey Liu

Huadong Medicine Co., Ltd., Hangzhou, China

Introduction: The epidermal growth factor receptor (EGFR) and human epidermal growth factor receptor 3 (HER3) are frequently co-expressed in a variety of solid tumors and play crucial roles in driving tumor growth, therapeutic resistance, and metastasis. To overcome the limitations of single-target approaches, we developed a novel bispecific antibody-drug conjugate simultaneously targeting EGFR and HER3.
Methods:HDM2024 was engineered using single-valency design, consists of a clinically validated HER3 antibody paired with an EGFR-targeting VHH antibody. The antibody was conjugated with exatecan via a cleavable linker, drug-antibody ratio (DAR) is 4. The efficacy and safety of HDM2024 were tested in xenograft and patient derived xenograft (PDX) models and monkeys, respectively.
Results:HDM2024 was designed with balanced affinity towards EGFR and HER3 antigen. In vitro, HDM2024 demonstrated high-affinity binding to both EGFR and HER3 expressing tumor cells, efficient internalization, and potent cytotoxicity across a panel of cancer cell lines with varying expression levels of EGFR and HER3. In vivo, HDM2024 exhibited robust antitumor efficacy in multiple xenograft and patient-derived xenograft (PDX) models, achieving complete or durable tumor regressions at well-tolerated doses. In GLP toxicity study, HDM2024 showed favorable safety with the highest non-severely toxic dose (HNSTD) reaching up to 40mg/kg administered every 2weeks (Q2W) for three cycles.
Conclusion: Collectively, these results support HDM2024 as a promising therapeutic candidate for solid cancer treatment. A differentiated ADC drug design endows HDM2024 with enhanced pharmacological efficacy and safety advantages, giving it the potential to become a best-in-class drug candidate. HDM2024 is expected to start the clinical trial in Mar 2026.

#6946 Preclinical evaluation of BCG017, a novel bispecific ADC targeting PTK7 and EGFR.

Zipeng Zeng, Na Zhang, Chengzhang Shang, Yi Yang

Biocytogen, Waltham, MA

Background: The long-term effectiveness of targeting the key oncogenic driver EGFR can be limited by acquired drug resistance, along with concerns related to on-target toxicity. PTK7, a member of the receptor tyrosine kinase (RTK) family, plays a significant role in Wnt signaling and influences cancer progression and metastasis. PTK7 is overexpressed in various types of solid tumors and has been shown to interact with the extracellular region of EGFR. BCG017, a first-in-class bispecific ADC specifically designed to target both EGFR and PTK7, aims to overcome the resistance mechanisms associated with EGFR while enhancing tumor selectivity through its dual targeting approach.The BCG017 backbone (PTK7×EGFR bsAb) was developed using the fully human common light RenLite® mouse platform, and it exhibits a higher affinity for PTK7 than for EGFR. The bsAb showed strong binding activity and effective internalization in various cancer cell lines, while the monovalent EGFR antibody had reduced capabilities. Furthermore, the bsAb exhibited efficacy comparable to that of monovalent antibodies in cell lines expressing either target alone, suggesting that optimal function relies on the simultaneous binding of both arms.

Results: The bsAb was then conjugated to vcMMAE. The MMAE conjugate exhibited enhanced efficacy in PDX models compared to both benchmark treatments and parental ADCs, even when PTK7 expression levels were low. These findings suggest that the PTK7×EGFR bsADC has a synergistic effect by targeting two distinct antigens, which may help to effectively address tumor heterogeneity in comparison to single-target ADCs. Moreover, while the MMAE conjugate displayed optimal activity, its monovalent ADC counterparts showed reduced efficacy in PDX models. These results highlight the importance of engaging both arms of the bsADC to achieve maximal therapeutic effectiveness. Additionally, the findings indicate a high degree of tumor selectivity, which could potentially minimize EGFR-related toxicity in normal tissues.Then, BCG017 was conjugated with BLD1102, a proprietary topoisomerase 1 inhibitor (TOP1i) linker-payload. BCG017 demonstrated potent in vivo efficacy in PDX models representing various tumor types expressing both EGFR and PTK7, including gastric, colorectal, esophageal, breast, and lung cancers. BCG017 consistently showed superior efficacy to MMAE conjugate using the same bsAb backbone in PDX models. BCG017 exhibited favorable pharmacokinetics in mice, effective tumor delivery in a xenograft model, and good plasma stability.

Conclusion: These results highlight the promising efficacy of BCG017 in preclinical models, indicating improved tumor selectivity and suggesting that it could address the limitations of EGFR-targeting therapies while expanding treatment options for PTK7 and EGFR co-expressed settings.

#6947 A novel bispecific antibody-drug conjugate, BCG016, that targets 5T4 and MUC1, demonstrates robust preclinical antitumor activity.

Zipeng Zeng, Yangyang Xu, Chengzhang Shang, Yi Yang

Biocytogen, Waltham, MA

BackgroundTrophoblast glycoprotein (5T4) is significantly overexpressed in a variety of cancers, including breast, lung, ovarian, endometrial, bladder, pancreatic, esophageal, and colorectal cancers, while demonstrating minimal expression in normal tissues. Its presence in cancer stem cells is correlated with poor prognoses, possibly contributing to metastasis, resistance, and recurrence. MUC1, a highly glycosylated member of the transmembrane mucin family, is also overexpressed across a range of solid cancers. Abnormalities in MUC1 expression and glycosylation in cancer activate multiple pathways that drive tumor migration, invasion, and accelerated growth. Importantly, 5T4 and MUC1 are frequently co-expressed in various solid tumors, such as lung, breast, ovarian, colorectal, and pancreatic cancers.
ResultsIn our study, we generated and evaluated antibodies targeting 5T4 and MUC1 using fully human common light chain RenLite mice. The 5T4 parental antibody demonstrated stronger and specific binding and greater efficacy than the benchmark in vivo. We previously generated the MUC1-C parental antibody, which was identified as targeting membrane-bound MUC1 on cancer cells. The anti-5T4×MUC1 bsAb demonstrated good binding to tumor cells with varying levels of 5T4 and MUC1 expression, with enhanced binding observed in cases of high expression of both 5T4 and MUC1. The bsAb demonstrated efficient internalization activity in the 5T4/MUC1 co-expression cell line, performing either as well as or better than benchmark antibodies. Notably, the anti-5T4×MUC1-vcMMAE demonstrated improved efficacy compared to parental ADCs, outperforming benchmark ADCs in patient-derived xenograft (PDX) models. BCG016, in combination with a TOP1 inhibitor linker-payload (BLD1102), exhibited enhanced efficacy in PDX models compared to parental ADCs, significantly outperforming benchmark ADCs targeting 5T4 and MUC1.
ConclusionIn summary, we have developed a novel bispecific ADC that targets both 5T4 and the membrane-bound MUC1-C. BCG016 showed superior anti-tumor efficacy in PDX models, underscoring its potential as a new therapeutic option for tumors that co-express 5T4 and MUC1.

#6948 A novel bispecific antibody-drug conjugate targeting CEACAM5 and CDH17 exhibits potent anti-tumor activity and enhanced tumor-selectivity.

Jinxiu Hou, Tingting Gu, Lisha Dong, Jiyuan Tian, Xiaoqian Chen, Dandan Liu, Yongxin Shang, Rongmei Yan, Kezhen Ye, Liang Tian, Jian Peng, Zhenping Zhu

Earendil Labs., Wilmington, DE

CEACAM5 and CDH17 are preferentially expressed in gastrointestinal tumors, including more than 95% of colorectal cancers, 80% of gastric and pancreatic cancers, and 70% of cholangiocarcinomas. Moreover, these two molecules are frequently co-expressed in gastrointestinal cancers. Recent advancements in CEACAM5 and CDH17 research have unveiled their potential as the promising targets for developing novel cancer therapeutics. Here we engineered a bispecific antibody (bsAb) capable of simultaneously binding to both CEACAM5 and CDH17. The cell binding and internalization activities of the bsAb were compared to a panel of monoclonal antibodies, including M9140 analog (an anti-CEACAM5 monoclonal antibody) and TORL-3-600 analog (an anti-CDH17 monoclonal antibody), using multiple colorectal and pancreatic cancer cell lines, The bsAb was conjugated to various topoisomerase I inhibitor payloads to generate several bispecific ADC molecules (bsADCs). The activity of these bsADC was studied in vitro in tumor cell-killing assay, and in vivo in multiple CDX models of GI malignancies. We further investigated the bsADC stability in human and cynomolgus monkey plasma over a three-week period, its pharmacokinetic profile and tolerability in both SD rats and cynomolgus monkeys. The results demonstrated that the bsAb exhibits excellent developability, and the resulting bsADCs maintained high purity after conjugation with different linker-payloads. The lead bsADC candidate showed superior bystander killing activity. In GI cancer CDX models with varying CEACAM5/CDH17 expression levels, it showed tumor inhibition comparable or superior to M9140a and TORL-3-600a, suggesting a broad application in GI cancer patients. Furthermore, the candidate exhibited favorable stability in human/cynomolgus plasma and good pharmacokinetic profile and tolerability in SD rats and cynomolgus monkeys. Taken together, these data support further development and broad utility of this bsADC for GI cancer treatment.

#6949 A novel multi-modal PD-L1-ADC could be a potential BIC candidate treatment for pan-solid tumors with enhanced tumor-specificity.

Tao Yang, Hang Ke, Feiyu Peng, Jialin Li, Cen Chen, Lei Zhang, Faming Zhang, **Henry Li**

Hanx Bio, Wuhan, China

PD-L1 is an immune-checkpoint frequently over-expressed oon the surface of many tumor cells, as compared to normal tissues, and it may thus be considered a tumor-associated antigen (TAA), although usually not considered a good one due to wide expression among many normal tissues. Immuno-checkpoint inhibitors (ICIs), *e.g.* mAbs against PD-L1 and its binding partner, PD1 on effector T-cells within tumors ($TIL\text{-}T_{eff}$), become powerful modality to treat cancers. However, only 15~30% of patients across different cancers responded to PD-(L)1 ICIs whereas most of them eventually relapse and become resistant. Combination therapies, *e.g.* ICIs plus chemotherapies, have been proven productive with significant clinical benefit in overall survival (OS) and have become standard practice. Chemotherapy usually comes with severe side-effects with narrow therapeutic window (TW). In recent years, ADC, as a new generation of chemo-modality with significantly improved TW due to tumor targeting specificity, witnessed great success in clinics. We hypothesized that an ADC targeting PD-L1, combining specific tumor-targeting and/or ICI, could become a new powerful multi-modality treatment of cancers, superior to existing single-modal chemotherapy or ICI. To test this, we have created a novel ADC, a PD-L1-mAb conjugated with a topoisomerase-I inhibitor as payload, which is being tested for its anti-tumor activity in preclinical settings. Specifically, although specifically binds to several PD-L1-expressing tumor cell lines with high affinity, its naked antibody exhibited poor internalization in PD-$L1^+$ cells. The ADC showed poor cytotoxicity induction in these cells as compared to FIC SGN-PDL1V that internalized efficiently. However, in contrast, the ADC demonstrated robust cytotoxicity in PD-$L1^+$ 3D-tumor organoids *in vitro*, as well as robust antitumor activity in xenograft models *in vivo*, even stronger than SGN-PDL1V and significantly superior to the cytotoxicity seen in 2D-cell culture. This interesting discrepancy seen between 2D cell culture and “tumor” (3D-organoid or xenograft tumor) may imply added tumor-specificity, in addition to the differential PD-L1 expression between tumors and normal tissues. It is believed that this ADC maximized its immunomodulation as well as cancer cell killing, along with the observed “tumor-specificity”, which may implicating a potential “BIC” PD-L1-ADC for treating pan-solid tumors with enhanced TW.

: High-Dimensional Immune Profiling and Preclinical Modeling for Cancer Immunotherapy
Poster Session

#6954 Comprehensive immune profiling using a validated high-parameter flow cytometry assay to advance pharmacodynamic biomarker discovery for solid tumor immuno-oncology clinical trials.

Angelina Bisconte[1], Vaishali Shinde[2], Jackie Benko[1], Jorge Pardo[1], Samantha Splitt[1], Rachel Owen[1], Deborah J. Phippard[1]

[1]Precision for Medicine, Frederick, MD,[2]Corbus Pharmaceuticals, Inc., Norwood, MA

Immuno-oncology (IO) research demands robust tools to characterize immune responses in solid tumors and peripheral blood. High-dimensional flow cytometry enables simultaneous assessment of lineage, activation, exhaustion and functional markers, providing critical insights into mechanisms of response and resistance to immunotherapies. Precision for Medicine developed and validated a 32-parameter flow cytometry assay to advance translational research and biomarker discovery in IO clinical trials.

This high-parameter panel profiles major immune subsets in cryopreserved PBMCs - including T cells, memory T cell subsets, regulatory T cells, B cells, NK cells and myeloid populations - while assessing activation (CD25, CD69, CD86), exhaustion (PD-1, LAG-3, TIM-3), proliferation (Ki67), and functional markers (Granzyme B, TCF-1), alongside cytokine expression (IL-2, IL-4, IFNγ, TNFα). Validation followed CLSI guidelines for precision, accuracy, and sensitivity using cryopreserved PBMCs from healthy donors.

The assay demonstrated reproducibility (CV less than 15% for major immune populations), sensitivity for low-frequency subsets such as TCF-1+ stem-like T cells, and robust functional readouts post-stimulation. Clinical relevance was confirmed through profiling of exhaustion and activation states critical for IO trials and solid tumor studies.

This validated high-parameter flow cytometry assay enables scalable immune monitoring in IO clinical trials, supporting biomarker discovery, mechanism of action studies and pharmacodynamic endpoint assessment longitudinally in patients receiving novel immunotherapies. Its reproducibility and functional depth make it suitable for multi-site implementation and integration with computational pipelines, facilitating patient stratification and advanced biomarker insights for solid tumor research.

#6955 Development of a 32-color spectral flow cytometry panel for comprehensive immunophenotyping of PBMCs from cancer patients receiving immunotherapy and radiotherapy.

Yao-Hui Sun[1], Logan Vick[2], Jonathan E. Van Dyke[3], Andrea L. Gompers[2], Sohan Dhar[1], Emanual M. Maverakis[2], Sean J. Judge[4], Robert J. Canter[4], Megan E. daly[1], William J. Murphy[2], Arta M. Monjazeb[1]

[1]Radiation Oncology, UC Davis Medical Center, Sacramento, CA,[2]Dermatology, UC Davis Medical Center, Sacramento, CA,[3]UC Davis Flow Cytometry Shared Resource, UC Davis Medical Center, Sacramento, CA,[4]Surgical Oncology, UC Davis Medical Center, Sacramento, CA

Background: High-dimensional immune profiling is essential for understanding how radiotherapy (RT) and immunotherapy (IO) reshape systemic immunity. Spectral flow cytometry offers major advantages over traditional flow by enabling >30 markers to be measured simultaneously in a single tube, which is critical when PBMC samples are limited and multiple panels are not feasible. This approach also improves detection of rare or functionally important immune subsets that cannot be reliably captured with smaller conventional panels. Using Sony ID7000, we developed a 32-color spectral flow cytometry panel to profile PBMCs from cancer patients enrolled in an ongoing RT/IO clinical trial.

Methods: A 32-color panel was designed to resolve major immune populations (T cells, B cells, NK cells, monocytes, dendritic cells) and key functional markers of differentiation (CD45RA, CCR7, CD27), activation (CD69, HLA-DR, CD38), proliferation (Ki-67), and exhaustion (PD-1, TIGIT, TIM-3, CTLA-4). Panel development incorporated fluorochrome similarity assessments and spectral signature analyses from the five-laser, 147-detector Sony ID7000. Single-color controls, FMOs, and fully stained references were used for spectral unmixing. Validation included both unstimulated PBMCs and anti-CD3/CD28-stimulated samples to assess activation and exhaustion profiles. Data was analyzed with Sony Spectral Analysis Software and FlowJo.

Results: The panel reliably identified all major PBMC lineages and resolved fine T-cell differentiation states, including naïve, memory, regulatory, and exhausted subsets. Myeloid subsets and dendritic cell populations were consistently distinguished with minimal spectral spreading. Stimulation assays produced expected functional changes—such as increased activation/proliferation marker expression—confirming panel sensitivity and functional applicability. Spectral unmixing, gating strategies, and marker resolution were highly reproducible across acquisition days and sample batches.

Conclusion: We developed and validated a robust 32-color spectral flow cytometry panel capable of comprehensive immunophenotyping of PBMCs from cancer patients. The spectral platform provides substantial advantages for limited clinical samples, enabling deep single-panel profiling and improved detection of rare populations. This panel is now being implemented in an active clinical trial (UCDCC#272) involving combined radiotherapy and immunotherapy, supporting immune monitoring and biomarker discovery in translational RT/IO research.

#6956 A 61-parameter CyTOF panel for comprehensive profiling of human PBMC to characterize immune activation, checkpoint expression and cytokine signatures with applications in cancer immunology.

Michael Cohen, Stephen Li, **Lauren Janette Tracey**, Katrina Thomson, Christina Loh

Standard BioTools, Markham, ON, Canada

Understanding the complexity of immune responses in cancer is critical for developing effective immunotherapies and predicting patient outcomes. High-parameter cytometric analysis enables deep profiling of immune cell phenotypes and functional states, revealing mechanisms of tumor immune evasion and therapeutic resistance. CyTOF™ technology is a single-cell analysis platform that uses metal-tagged antibodies to resolve 50-plus markers in a single tube. Unlike fluorescence-based cytometry, spectral unmixing and single-stain controls are not required. Therefore, it is uniquely possible with CyTOF technology to rapidly design high-parameter panels enabling simultaneous assessment of lineage, activation, exhaustion and intracellular signaling pathways. This study aimed to design a 61-parameter CyTOF panel optimized for functional immune profiling of human PBMC to support cancer immunology research. The panel incorporates lineage markers for major immune subsets and an extensive set of T cell phenotyping targets including activation, differentiation, immune checkpoints (for example, PD-1, CTLA-4, TIGIT) and intracellular cytokines relevant to tumor immunity. Untreated and stimulated PBMC were barcoded, pooled and stained. Samples were cryopreserved and later acquired using a CyTOF XT PRO system to minimize technical variation. High-dimensional analysis of stimulated PBMC demonstrated the panel's ability to resolve extensive immuno-functional diversity at the single-cell level. Co-expression patterns of activation markers, immune checkpoints and intracellular cytokines were detected across effector, memory, cytotoxic, regulatory and exhausted immune cell subsets. These findings highlight the panel's potential to uncover signatures relevant to tumor immunity and immunotherapy response when applied to cancer patient samples or tumor-associated immune cells. CyTOF systems enable the highest number of simultaneous measurements in a single panel, allowing for comprehensive immune profiling alongside high resolution of intracellular targets to interrogate functional potential. Overall, studying functional immunology using CyTOF technology can elucidate the complex nature of immune responses to provide an understanding of how they relate to disease and treatments. For Research Use Only. Not for use in diagnostic procedures.

#6957 GAS-Luc2 reporter cell lines enable sensitive detection of interferon-gamma signaling for immune activation and CAR-T evaluation across 2D and 3D systems.

Hyeyoun Chang[1], John G. Foulke[1], Luping Chen[1], Catherine McManus[2], Meghan Sikes[1], Fang Tian[2]

[1]ATCC, Gaithersburg, MD,[2]ATCC, Manassas, VA

Background: Interferon-gamma (IFN-γ) is a key cytokine regulating cellular immune activation and is widely used as a functional biomarker in immunotherapy development. Standard ELISA method has limited sensitivity for early, low-level IFN-γ detection and does not effectively capture paracrine signaling in three-dimensional (3-D) models. To address these limitations, we developed IFN-γ-responsive luciferase reporter cell lines driven by a gamma-interferon activation site (GAS) promoter.
Methods: Three cancer cell lines with high endogenous expression of checkpoint ligands (PD-L1, CD155, B7-H3) were engineered with a GAS-Luc2 construct. An additional GAS-Luc2 reporter cell line was generated from THP-1 cells for monocyte- and macrophage-related applications. Reporter activity was evaluated after stimulation with recombinant IFN-γ, T cell-conditioned media, and co-culture with primary T or NK cells. Assays were performed in 2-D and 3-D systems and compared with IFN-γ ELISA. CAR-T cells were also evaluated using both methods.
Results: Reporter cells showed strong dose-dependent luciferase expression, with 100- to 250-fold increases after recombinant IFN-γ treatment and 50- to 100-fold induction with T-cell conditioned media. Co-cultures with primary immune cells produced 3- to 12-fold activation. Reporter signals remained robust in 3-D models and detected IFN-γ levels below the ELISA detection limit. In CAR-T assays, reporters identified early and low-level cytokine signaling not measurable by ELISA.
Conclusions: GAS-Luc2 reporter cell lines provide a sensitive, quantitative, and scalable platform for monitoring IFN-γ signaling. Their superior performance over ELISA, especially for early activation and 3-D applications, supports their utility in immunotherapy evaluation, immune checkpoint studies, and CAR-T functional assessment.

#6958 Donor source-dependent B cell receptor repertoire patterns visualized by the pGen-SHM plot reveal differences in adaptive immune reconstitution after hematopoietic stem cell transplantation.

Sakuya Matsumoto[1], Yohei Funakoshi[1], Kimikazu Yakushijin[1], Goh Ohji[2], Takaji Matsutani[1], Hidetomo Takakura[1], Yuri Okazoe-Hirakawa[1], Rina Sakai[1], Yumiko Inui[1], Taiji Koyama[1], Yoshiaki Nagatani[1], Keiji Kurata[1], Shiro Kimbara[1], Shinichiro Kawamoto[1], Naomi Kiyota[1], Hironobu Minami[1]

[1]Division of Medical Oncology/Hematology, Department of Medicine, Kobe University Hospital and Graduate School of Medicine, Kobe, Japan,[2]Division of Infection Disease Therapeutics, Department of Microbiology and Infectious Diseases, Kobe University Hospital and Graduate School of Medicine, Kobe, Japan

Background A reliable method to monitor adaptive immune reconstitution after allogeneic hematopoietic stem cell transplantation (HSCT) has not been established, leaving many aspects of donor-source-dependent differences in immune reconstitution unclear. Here, we developed a new method, "probability of generation (pGen)-somatic hypermutation (SHM) plot (pGen-SHM plot)", to objectively and visually monitor long-term immune reconstitution after HSCT.

Methods We conducted longitudinal B cell receptor (BCR) repertoire analysis on peripheral blood mononuclear cells (PBMCs) from six cord blood transplantation (CBT) (21 samples) and six bone marrow transplantation (BMT) patients (14 samples) from two months to approximately two years post-HSCT. PBMCs from 12 healthy adults were used as controls. pGen value, representing the probability of sequence generation by the recombination process, was calculated using OLGA. SHM rates were determined by nucleotide-level identity to the reference V gene. Maturation of repertoire was visualized by plotting the two-dimensional probability density distribution of pGen and SHM rates using Kernel density estimation, which we termed the pGen-SHM plot.

Results After CBT, the proportions of both high pGen (> 1e-15) and low SHM (< 4%) strongly correlated with post-HSCT days ($r = -0.86$ and $r = -0.91$, respectively) and gradually approached levels observed in healthy adults. Furthermore, the plot analysis revealed a continuous transition from the $pGen^{high}SHM^{low}$ to $pGen^{low}SHM^{high}$ population during the post-CBT period. This finding was validated using publicly available datasets of healthy individuals aged 0 to 15 years, which showed a similar age-related shift. In contrast, the proportions of high pGen (> 1e-15) and low SHM (< 4%) after BMT were already close to healthy adult levels by Day 67 and showed little change over two years. Remarkably, the plot analysis identified two distinct populations in the early post-BMT, $pGen^{high}SHM^{low}$ and $pGen^{low}SHM^{high}$; the latter disappeared at around six months while the former gradually shifted toward $pGen^{low}SHM^{high}$, resembling the pattern observed after CBT. We then performed a detailed analysis of the two populations identified in the pGen-SHM plot after BMT. The $pGen^{low}SHM^{high}$ population showed a lower frequency of IgG1-switched sequences and higher frequency of IgG2-switched sequences compared with the $pGen^{high}SHM^{low}$ population. These findings suggest that $pGen^{low}SHM^{high}$ represents graft-derived mature B cells, whereas $pGen^{high}SHM^{low}$ corresponds to newly generated and maturing B cells derived from hematopoietic stem cells.

Conclusion The pGen-SHM plot objectively and visually captured distinct patterns of adaptive immune reconstitution after HSCT, depending on the donor source.

#6959 Functional evaluation of immuno-oncology drug candidates targeting lymphoid and myeloid cells using *in vitro* assays.

Christoph Schifflers, Martijn Vlaming, Sofie Pattyn

IQVIA Laboratories, Gosselies, Belgium

The growing understanding of the complexity of anti-tumor immunity provides novel targets for the development of cancer immunotherapies. However, lead selection methods can be costly and time-consuming and often rely on animal models associated with ethical considerations and limitations. In addition, new drug designs and modes of action can require the development of new or customized assays for functional screenings. In this context, IQVIA Laboratories developed a variety of *in vitro* assays relying on primary immune cells to enable accelerated cost-effective functional characterization of candidate drugs and lead selection. Leveraging optimized PBMC isolation and cryopreservation protocols, a large biobank of quality-controlled and well-characterized samples was generated, providing a critical component for the reliable and reproducible functional screening of drug candidates. Another critical element consists of well-established functional *in vitro* assays involving cultures of specific lymphoid (e.g. T cells, NK cells) and myeloid cell populations (e.g. Macrophages, Neutrophils) or complex co-cultures (e.g. cancer cells, stem cells). These assays can be used to assess immunogenicity (e.g. Neoepitopes), antigen presentation (e.g. Immunopeptidomics), macrophage phenotypes/function (e.g. M2-Suppression Assay), T cell activation (e.g. Suppressive MLR Assay, Priming Assay), Fc-functions (ADCC, ADCP and CDC), Neutrophil function (e.g. NET Formation, Trogocytosis). Several assays can also be performed with primary immune cells of animal origin (e.g. cyno, mouse, dog) with the aim of reducing animal requirement for *in vivo* studies. The combination of well-characterized high-quality PBMCs and a diverse panel of robust functional *in vitro* assays provides a useful tool for cost-effective accelerated lead selection of immuno-oncology drug candidates.

#6960 Improving immune checkpoint blockade efficacy using combination therapy with bioactive molecules.

Dhanir Tailor[1], Arpit Dheeraj[1], Sushil Kumar[2], Wendy Li[2], Bailey F. Keefe[3], **Annah S. Rolig**[4], Shivaani Kummar[4], Lisa M. Coussens[5], Sanjay V. Malhotra[1]

[1]Knight Cancer Institute, Oregon Health & Science University, Portland, OR,[2]OHSU, Beaverton, OR,[3]OSU, Corvallis, OR,[4]OHSU Knight Cancer Institute, Portland, OR,[5]OHSU Knight Cancer Institute, Lake Oswego, OR

Immune checkpoint blockade (ICB) therapies, such as aPD-1 and aPD-L1, reactivate T cells to fight tumors. While these therapies have transformed cancer treatment, with nearly half of U.S. cancer patients eligible for ICB therapy, their efficacy is limited, with highly variable and generally low response rates. Significant investments aimed at improving ICB response rates have primarily focused on combining therapies with ICB, as demonstrated by the thousands of clinical trials testing anti-PD-1 or anti-PD-L1 with additional agents. However, this significant investment has only resulted in marginal improvements, underscoring a critical unmet need for an innovative, streamlined approach to identify compounds that enhance ICB efficacy. To address this gap, we developed a high-throughput screen (HTS) drug discovery platform that efficiently screens compounds for synergy with ICB. One primary mechanism that limits ICB efficacy is the complex tumor microenvironment (TME), which includes tumor-associated macrophages (TAMs) that take on an immunosuppressive (M2) phenotype and suppress T cell recruitment, proliferation, and function. The abundance of TAMs correlates with poor prognosis in numerous cancers, making TAMs a prime target for compounds that synergize with ICB. To identify potential targets that can reduce TAM immunosuppression, our validated HTS uses an *ex vivo* co-culture system of bone marrow-derived macrophages and spleen-derived $CD4^+$ and $CD8^+$ T cells. After incubation with small molecule libraries, cultures are evaluated for increased T cell activity; thus, this assay aims to identify small molecules that diminish myelomonocytic cell-dependent T cell suppression and enhance T cell activity when combined with ICB. Using this HTS, we screened over 3270 bioactive small molecules, identifying 128 that showed TAM-modulating activity. Of those 128 compounds, seven synergized with anti-PD1 and six with anti-PD-L1. One compound synergized with both anti-PD-1 and anti-PD-L1. These compounds were evaluated *in vivo* in syngeneic murine breast cancer models to assess anti-tumor effects. Indeed, combining these agents with anti-PD-1/anti-PD-L1 significantly slowed tumor growth in triple-negative breast cancer (TNBC) models (EMT6), which are generally resistant to anti-PD-1/anti-PD-L1 monotherapy. By tackling the challenges posed by the TME and immune evasion, in a target- and tumor-agnostic manner, our platform has the potential to uncover novel, transformative ICB combination therapies with broad translational potential across multiple malignancies.

#6961 Patient matched organoid-immune co-culture model as a predictive platform for immunotherapy response in precision oncology.

Maryam Nakhjiri[1], Sraboni Chaudhury[1], Youssel Kriko[1], Mohamad Orabi[1], Liwei Bao[1], Mary Horn[1], Rudnick Avery[1], Albana Grajqevci[1], Andrew Chang[1], David Odell[1], Udit Singhal[1], Rishindra M. Reddy[2], Tudor Borza[1], Tasha Hughes[1], Michael Sabel[1], Lesly Dossett[1], Joshua Piche[1], William Aibinder[1], Sofia Merajver[1], Nathan Merrill[1]

[1]Rogel Cancer Center, Ann Arbor, MI,[2]University of Michigan, Ann Arbor, MI

Background: Immunotherapy (IO) is increasingly integrated into cancer treatment, with checkpoint inhibitors (anti-CTLA-4, anti-PD-1/PD-L1) improving progression-free and overall survival in subsets of patients. However, many across cancer types do not respond, highlighting the need for predictive preclinical models to test and tailor IO-based therapies. Traditional in vivo models and 2D cultures fail to replicate the complexity of the human tumor-immune microenvironment. To bridge this gap, we refined a patient-derived organoid (PDO) and immune cell co-culture platform for rapid drug screening of IO combinations, aligning with the NIH directive to reduce animal use. PDOs can be tested within 10-15 days, providing a personalized system to evaluate treatment response and tumor-immune interactions across solid tumors.
Methods: We established a rapid (<7-day) PDO-peripheral blood mononuclear cell (PBMC) co-culture integrating short-term organoid generation, immune activation, and checkpoint blockade assays. PBMCs were isolated, cryopreserved, and reactivated prior to co-culture using optimized cytokine cocktails (IL-2, IL-7, IL-15, IL-21) and tested in multiple media (AIM-V, X-VIVO, HPLM, RPMI). Cell viability was measured using CellTiter-Glo 3D and apoptosis via Caspase-Glo 3/7 assays. Activated PBMCs were co-cultured with PDOs at 5:1 and 10:1 effector-to-target ratios under IO or combination chemotherapy.
Results: We developed a rapid workflow to generate immune-competent PDOs from breast, bladder, and lung cancers co-cultured with autologous PBMCs. Mono- and combination therapies were tested across tumor types, including various IO agents, platins (cisplatin, carboplatin), taxanes, antibody-drug conjugates, and targeted therapies. Multiple functional parameters were measured, and an apoptotic effectiveness index (AEI) is being developed to rank treatment responses. Across all tumor types, IO combined with platinum or taxane agents produced the highest AEI, reflecting strong synergy in standard-of-care regimens and validating the model's predictive potential. AEI-based ranking identified differential apoptotic responses among tumor types, supporting the model's utility in predicting patient-specific responses.
Conclusions: We established and validated a platform that rapidly assesses whether a patient's immune cells can be activated to kill their tumor organoids in the presence of specific immunotherapy or chemotherapy combinations. We anticipate identifying key biomarkers, including immune phenotypes and cytokine signatures, that distinguish immunotherapy-responsive from non-responsive PDO co-cultures across breast, bladder, and lung cancers. These findings lay the groundwork for predictive tools and future clinical correlations.

#6962 Expanding multiplexing capabilities with TrailBlazer StarBright Dye antibody conjugation kits.

Sharon Sanderson[1], Leon Huang[2], Yoon-Tae Kang[3], Ryan Mendoza[2], Errile Pusod[3], Michael Blundell[1], Tracey Long[1]

[1]Bio-Rad Laboratories, Oxford, United Kingdom,[2]Bio-Rad Laboratories, Hercules, CA,[3]Bio-Rad Laboratories, Ann Arbor, MI

Imaging, western blotting, and flow cytometry multiplexing experiments are often constrained by the availability of suitable fluorophores for some antibodies, hindering panel size and optimal experimental design. Here we address those issues using TrailBlazer™ StarBright™ Dye Antibody Labeling Kits. Custom antibody-dye conjugates can be generated using labeling kits, however options are typically restricted to standard fluorophores, such as FITC, which can be suboptimal and limit panel expansion. The newly introduced TrailBlazer Tag and Label Kits have been launched to enable antibody conjugation to superior StarBright Dyes, with 32 options spanning the five main laser lines. Our data shows that antibodies conjugated with TrailBlazer Kits are stable for up to one year, owing to the novel SpyTag-SpyCatcher technology used. This makes them ideal for long-term storage and eliminates the need for repeated labeling reactions, giving reproducible data particularly in longitudinal studies. We also present new data illustrating the versatility of these conjugates in various applications. This includes immunocytochemical (ICC) staining microscopy data, where they provide additional options when multiplexing by using kit-conjugated primary or secondary antibodies. In addition, flow cytometry data show that panels can be expanded to include antibodies that have limited fluorophore options, without compromising optimal panel design and without the use of secondary antibodies. In summary, TrailBlazer Kits offer a significant advance for researchers, delivering an easy self-conjugation method and enabling the generation of robust, reproducible multiplexing data in complex biological studies in multiple applications.

#6963 Empowering IL-2 therapy development: A novel humanized mouse model with functional IL-2 and IL-15 receptors.

Fengqian Chen, Zhenlan Niu, Zhi Zhang, Linlin Wang, Xiaofei Zhou

Biocytogen, Waltham, MA

The efficacy of immuno-oncology therapies, particularly those involving cytokines like IL-2 and IL-15, is often limited by their species-specificity and complex receptor interactions, which are poorly recapitulated in wild-type mice. To establish a robust preclinical platform for evaluating novel human-specific immunotherapies and their combinations, we developed a comprehensive seven-gene humanized mouse model.

The B-hPD-1 plus/hIL2/hIL2RA/hIL2RB/hIL2RG/hIL15/hIL15RA mouse model was engineered on a C57BL/6 background by co-integrating seven key human genes: PD-1, IL2, IL2RA, IL2RB, IL2RG, IL15, and IL15RA. Humanization and cell surface expression of the encoded proteins were confirmed via flow cytometry. The IL2 and IL15 were detected by ELISA. Comprehensive immune cell profiling was performed. The model's functionality was validated *in vivo* using syngeneic tumor models treated with human IL-2 (hIL-2), an anti-human PD-1 antibody (Ketruda), and their combination.

Flow cytometry and ELISA confirmed successful expression of the membrane proteins and the secreted protein, respectively. Immune phenotyping demonstrated the presence of key lymphocyte populations capable of responding to human cytokines. In therapeutic studies, monotherapy with hIL-2 or Ketruda significantly inhibited tumor growth compared to control groups. Notably, the combination of hIL-2 and Ketruda resulted in superior, synergistic antitumor efficacy, significantly outperforming either agent alone. Ongoing histopathological (H&E) and clinical pathology (hematology and serum biochemistry) analyses to date indicate no overt toxicity, supporting the model's utility for safety and efficacy assessments.

We have successfully developed and validated a novel seven-gene humanized mouse model that robustly expresses human PD-1, IL-2, IL-15, and their complete receptor complexes. This model supports functional *in vivo* evaluation of human-specific mono- and combination therapies, as demonstrated by the enhanced efficacy of hIL-2 plus anti-PD-1. It represents a unique and powerful preclinical tool for the screening and mechanistic study of next-generation immunotherapies, including cytokines, checkpoint inhibitors, and their synergistic combinations.

#6964 A novel NSG-SGM3xIL15xDKO-based PBMC humanized mouse model to evaluate efficacy and cytokine release of immunotherapies.

Xiaoqing (Nancy) Zheng, Guoxiang Yang, Beau Parry, James G. Keck, Li-Chin Yao

The Jackson Laboratory, Sacramento, CA

We have observed better engraftment of human peripheral blood mononuclear cells (PBMCs) in NSG-SGM3xIL15xDKO (SDKO) mice compared to NSG-MHC I/II DKO (DKO) mice without irradiation. Irradiation is a way to stimulate immune responses. We examined how irradiation affects human PBMC engraftment in SDKO mice and compared engraftment in irradiated SDKO and DKO mice with and without cancer cells. Efficacy and toxicity of anti-CD3xCD19 BiTE were also tested in Raji model of irradiated SDKO and DKO. **Methods** SDKO and DKO mice were intravenously injected with PBMCs with/without irradiation. Retro-orbital (RO) bleeding was performed to check engraftment with flow cytometry. SDKO and DKO mice were also injected with cancer cells prior to intravenous injection of PBMCs after irradiation. RO blood and spleen were collected to check engraftment of various cell types. Raji-luc-bearing SKO and DKO mice with irradiation were treated with PBS or anti-CD3xCD19 BiTE. Xenogen was performed to measure tumor burdens, and plasma was collected to measure cytokine levels with Luminex assay. **Results** Irradiation accelerated human CD45 (hCD45) cells engraftment in SDKO mice. On day 10 or 14, SDKO mice after irradiation showed 3 folds of hCD45 engraftment compared to SDKO mice that didn't receive irradiation. CD3+ T cells, CD19+ B cells and CD56+ nature killer (NK) cells were engrafted at 2-6 fold higher in irradiated SDKO mice at early timepoints compared to non-irradiated mice. Irradiation significantly improved B cells and NK cells in SDKO mice compared to no irradiation. PBMCs were engrafted at higher levels in SDKO compared to DKO after irradiation. It included CD4+T cells, CD8+T cells, B cells and NK cells in the blood and spleen. On day 9, T cells, B cells, NK cells, dendritic cells (DC) and macrophages in the spleen were 2-10 fold higher in irradiated SDKO compared to DKO. B cell lymphoma Raji cells stimulated PBMCs to engraft after irradiation, including T cells, NKs and macrophages in the spleen. More importantly, SDKO was engrafted at significantly higher cell counts compared to DKO with Raji cells stimulation, including DCs and macrophages. Lastly, we found SDKO supported Raji growth with higher tumor burden on three days after implantation compared to DKO. At the same time, Raji-bearing SDKO responded to anti-CD3xCD19 BiTE faster than DKO, making SDKO a more sensitive model to test BiTE efficacy than DKO. In addition, cytokines production after anti-CD3xCD19 BiTE was much higher in SDKO than DKO in the Raji model. **Conclusion** Irradiation not only expediates engraftment of human PBMCs in SDKO mice. Various cell types, including B cells, NK cells, DCs and macrophages, plus T cells are engrafted at higher cell counts in SDKO than DKO with/without cancer cells stimulation with irradiation. In addition, SDKO implanted with cancer cells is a more sensitive platform than DKO to test drug efficacy and toxicity.

#6965 Utilizing a humanized CD8 mouse model for non-clinical studies of cancer immunotherapy.

Hannah Horton[1], Zhi Zhang[1], Zhiyuan Shen[2], Zhenlan Niu[1], Xiaofei Zhou[1]

[1]Biocytogen, Waltham, MA,[2]Biocytogen, Beijing, China

Background: The CD8 is a cell surface glycoprotein found on most cytotoxic T lymphocytes that mediates efficient cell-cell interactions within the immune system. The CD8 acts as a coreceptor with the T-cell receptor on the T lymphocyte to recognize antigens displayed by an antigen-presenting cell in the context of class I MHC molecules. The coreceptor functions as either a homodimer composed of two alpha chains or as a heterodimer composed of one alpha and one beta chain. Both alpha and beta chains share significant homology to immunoglobulin variable light chains. Cytotoxic CD8+ T cells of the adaptive immune system are the most powerful effectors in the anticancer immune response and constitute the backbone of cancer immunotherapy.
Methods: To more accurately evaluate the efficacy of drugs targeting the human immune system, Biocytogen generated a CD8 humanized mouse model that expresses the human CD8 protein.
Results: Protein expression analysis of this novel humanized CD8 mouse strain indicates that the model exclusively expresses human CD8 protein without mouse CD8 protein detection. Immunoprofilling analysis demonstrates that the proportions of various immune cell subsets remain unaffected following CD8 humanization. This model possesses normal T cell immunogenic function, as confirmed by OVA-induced immune responses. *In vivo* efficacy studies show that CD8+ T cells in this model can effectively kill tumor cells. These findings indicate that the CD8 mouse model serves as a powerful research tool, which can not only be used to study and validate the *in vivo* efficacy of anti-human CD8 agonistic antibodies, but also to investigate CD8-targeting drugs or their synergistic effects with other therapies (such as checkpoint inhibitors).
Conclusion: We have established a promising preclinical research model using CD8 humanized mice. This model serves as a powerful preclinical tool for assessing the efficacy of CD8+ T cell-based immunotherapies, including immune checkpoint blockers, neoantigen vaccines, CAR-T, and TCR-T cell therapies.

#6966 A novel humanized mouse model for evaluating anti-human IL23R drugs.

Qiurong Wang, Chun Wang, Chong Li, Xiaofei Zhou, Linlin Wang, Jing Guo

Biocytogen, Waltham, MA

Background: Numerous clinical studies have found increased levels of IL-23 in various autoimmune diseases, including psoriasis, inflammatory bowel disease (IBD), rheumatoid arthritis (RA), and multiple sclerosis (MS). Targeted therapy against IL-23 has made significant progress in the field of autoimmune diseases, becoming a research hotspot and a key therapeutic target. However, new research indicates that the role of IL-23 is not limited to autoimmune diseases; its potential in tumor immunotherapy is equally noteworthy. Preclinical studies have shown that IL-23 exhibits tumor-promoting properties in various cancer models and is associated with poor patient prognosis. Therefore, ablation of IL-23 or its receptors could reduce tumor burden. Most currently developed drugs targeting human IL23R do not recognize mouse IL23R, therefore mouse models cannot be used for preclinical efficacy or safety evaluations.

Methods: To conduct preclinical evaluation of anti-human IL23R-based therapies, Biocytogen developed a novel humanized mouse model, B-hIL23R/hIL12RB1 plus/hIL12RB2 ad mice, expressing human IL23R, IL12 receptor β1, and IL12 receptor β2. The function of the humanized IL12 receptor complex was validated by stimulating isolated mouse CD4+ T cells with recombinant mouse IL12 and human IL12 and measuring mouse IFN-γ secretion. The function of the humanized IL23 receptor complex was validated by stimulating isolated mouse CD4+ T cells with recombinant mouse IL23 and human IL23 and measuring mouse IL17A secretion. The effect of the test article TA1 (provided by the client) on the humanized IL23 pathway was validated *in vitro*.

Results:*In vitro* stimulation with mouse IL12 and human IL12 induced the secretion of mIFN-γ by CD4+ T cells of C57BL/6 mice, while human IL12 induced the secretion of mIFN-γ by CD4+ T cells of B-hIL23R/hIL12RB1 plus/hIL12RB2 ad mice, confirming the function of the humanized IL12 receptor complex. *In vitro* stimulation with mouse IL23 and human IL23 induced the secretion of mIL17A by CD4+ T cells of C57BL/6 mice and B-hIL23R/hIL12RB1 plus/hIL12RB2 ad mice, confirming the function of the humanized IL23 receptor complex. *In vitro* use of the test article TA1 (provided by the client) significantly inhibited the secretion of mouse IL17A in the humanized IL23 pathway of B-hIL23R/hIL12RB1 plus/hIL12RB2 ad mice.

ConclusionThe humanized IL12 receptor complex and humanized IL23 receptor complex in B-hIL23R/hIL12RB1 plus/hIL12RB2 ad mice are functional and provide a valuable preclinical evaluation mouse model for assessing therapies targeting human IL23 and human IL12 receptors.

#6967 Humanized HLA-A11.1 mice: A preclinical platform for novel vaccine evaluation.

Qiurong Wang, Zhenlan Niu, Shuaiqiang Zhang, Xiaofei Zhou

Biocytogen, Waltham, MA

The Major Histocompatibility Complex (MHC) plays a critical role in the immune defense by presenting antigenic peptides and initiating T cell-mediated immunity. Due to significant genetic differences between animal MHC and the human leukocyte antigen (HLA) system, HLA-humanized mouse models provide a valuable platform for investigating HLA-A-restricted immune responses and facilitating vaccine development.

In this study, we established a novel B-HLA-A11.1 humanized mouse model and systematically characterized its phenotypic and immunological profiles. Blood routine examination and biochemical analysis revealed that B-HLA-A11.1 mice exhibited parameters comparable to those of wild-type controls, indicating that HLA-A11.1 humanization did not adversely affect erythrocyte composition, hematocrit morphology, or the health of major organs such as the heart, liver, and kidneys. Overall, these results support the normal development of B-HLA-A11.1 mice and the absence of spontaneous pathology attributable to HLA humanization. To assess HLA-restricted immunogenicity, HLA-A11.1 and wild-type mice were immunized with a KRAS*G12V peptide. ELISPOT analysis confirmed the induction of peptide-specific T-cell responses exclusively in HLA-A11.1 mice, underscoring the model's HLA-restricted functionality. Furthermore, immunization of the mice with the candidate peptide, followed by tetramer staining flow cytometry, demonstrated that the peptide activated antigen-specific CD8+ T cells. These activated T cells can be utilized for subsequent T cell receptor (TCR) screening.

We further evaluated the efficacy of an mRNA vaccine targeting KRAS*G12V in B-HLA-A11.1 mice. The vaccine significantly suppressed tumor growth compared to the control group. Furthermore, we investigated the combination of the mRNA vaccine with an anti-PD-1 antibody in this model. The experimental data revealed that the combination therapy induced a significantly greater inhibition of tumor growth than either monotherapy.

In summary, our findings demonstrate that the B-HLA-A11.1 humanized mouse model serves as a robust preclinical platform for the *in vivo* and *ex vivo* assessment of novel peptide- and mRNA-based vaccines.

#6968 Preclinical assessment of cell, gene, and antibody therapies using humanized mice.

Audrey Wetzel, Emilie Bayon, Sebastien Tabruyn, **Dan Georgess**

TransCure bioServices, Archamps, France

The preclinical assessment of cell, gene, and antibody therapies is substantially more predictive when performed in humanized immune system (HIS) mice engrafted with human tumors than in immunodeficient or syngeneic models. Here, we present a series of studies illustrating how HIS mice enable evaluation of efficacy, persistence, biodistribution, and safety for diverse therapeutic modalities in ways not achievable in other mouse systems.In the therapeutic antibody category, we first show that HIS mice reconstituted with hematopoietic stem cells from different donors recapitulate the inter-patient heterogeneity observed in responses to immune checkpoint inhibitors (ICIs), and that combining ICIs with macrophage-targeting antibodies markedly enhances antitumor efficacy. In complementary studies, we used HIS mice to rank three engineered variants of T-cell engagers (TCEs) and, separately, three variants of antibody-drug conjugates (ADCs) on the basis of both efficacy (tumor growth inhibition) and safety (systemic IFN-γ, body-weight loss, and survival), identifying the top-performing lead in each class. We also compared the activity of a TCE as a single agent versus a tumor-targeting antibody (TTA) and their combination. Finally, we conducted dose-response efficacy studies of a natural killer cell engager (NKCE). None of these investigations would be feasible in models lacking sufficient reconstitution of human T lymphocytes, macrophages, and NK cells. In the cell therapy category, we evaluated CAR-T, CAR-NK, and TCR-T cells across multiple tumor types. We show that HIS mice enable de-risking of immunogenicity by revealing rapid clearance of allogeneic CAR-T cells that are insufficiently stealthy, yet would otherwise persist for days-to-weeks in immunodeficient mice. Through adoptive cell-transfer experiments, we further demonstrate that CAR-NK cells can be durably supported in HIS mice and exhibit potent antitumor activity, and that iterative optimization of TCR-T constructs can fully suppress growth of an aggressive tumor model. Across these studies, HIS mice reproduced clinical, cellular, and molecular features of immune-related adverse events (irAEs) and cytokine release syndrome (CRS), while concurrently enabling assessment of biodistribution, target engagement, long-term persistence, and therapeutic efficacy. In conclusion, HIS mice constitute a powerful platform for reducing false-positive and false-negative outcomes in the preclinical evaluation of novel therapeutics, thereby improving predictivity and supporting more informed clinical-trial decision-making.

#6969 Analysis of 1000 secreted proteins in functional genomics and compound screens reveals cytotoxic and immunomodulatory targets.

Nathaniel Robichaud[1], Amy Johnson[1], Alistaire Sherman[1], **Eric Miller**[2], Narges Rashidi[1], Milad Dagher[1]

[1]Nomic Bio Inc, Montreal, QC, Canada,[2]Sales and Marketing, Nomic Bio Inc, Montreal, QC, Canada

The identification of novel cancer immunotherapies and the characterization of their immunomodulatory effects is complicated by the plasticity of immune cells and the wide range of phenotypes they may adopt. However, the high cost of capturing this diversity at scale limits typical drug discovery efforts to simple readouts. The Nomic platform is a novel proteomics tool capable of quantifying thousands of proteins at high-throughput and low cost, leveraged here in functional genomics and compound screens, simultaneously characterizing immunomodulatory and cytotoxic effects.

We collected supernatants for secretome analysis from the CPJUMP1 dataset, in which U2OS osteosarcoma cells were perturbed with matched ORF, CRISPR KO, and compound libraries targeting 161 genes, and quantified 191 cytokines using a Nomic Flex panel. Overexpression of upstream kinases induced an inflammatory phenotype, consistent with established oncogene-induced inflammation. Furthermore, as seen in morphological analyses, CRISPR KO phenotypes were poorly matched with the phenotypes of compounds targeting corresponding genes due to poor specificity of compounds for individual targets.

To further characterize on-target and off-target immunomodulatory effects of compounds, we quantified 1000 proteins in supernatants from hepatocytes treated with 510 compounds at three concentrations for 48h, using the Omni 1000. Cytotoxic compounds such as staurosporine resulted in intracellular proteins leaking out of cells and being detected in the supernatant, whereas resiquimod, a TLR7/8 agonist, induced the expression of a variety of cytokines. Clinically-relevant immunotoxicity was captured: thus, methylprednisolone was generally anti-inflammatory, but with paradoxical increases in SAA and IL-6, consistent with paradoxically inflammed livers seen in patients. Actinomycin D was cytotoxic while inducing IL-1b and TNFa, consistent with the immune contribution to this compound's anti-cancer properties. Finally, we demonstrated the capacity of secretome analysis to probe pathways regulating cytokine expression. For example, comparison of a set of 11 mTOR inhibitors identified on-target immune modulation and off target effects at increasing doses, enabling characterization of compound potency and specificity.

Our results demonstrate the value of high-throughput proteomics to identify new immunomodulatory targets and compounds, evaluate potential toxicities, and characterize potency and specificity.

Poster Session

#6973 B-NDG hIL15, FcγR KO mice: An optimized humanized model for evaluating T cell-modulating antibodies.

Jiyue Chen, Yanhui Nie, Dexuan Huang, Qingqing Xu, Qiang Liu, Xiaofei Zhou

Biocytogen, Waltham, MA

Background:
Immune checkpoint inhibitors targeting PD-1, PD-L1, and CTLA-4 have achieved remarkable clinical success, but preclinical validation using human immune system (HIS)-reconstituted mice remains challenging. Conventional immunodeficient models often fail to reproduce the efficacy observed in target humanized or immunocompetent mice. The poor antibody pharmacokinetics and suboptimal immune function in HIS models contribute to these discrepancies. In particular, murine innate immune cells expressing Fc gamma receptors (FcγRs) can bind therapeutic antibodies, accelerate their clearance, and induce nonspecific antibody-dependent cellular phagocytosis (ADCP), confounding efficacy assessment. Moreover, insufficient reconstitution and activation of human T cells limit the evaluation of the immune response. Human IL-15 is known to enhance T-cell survival and function following human PBMC engraftment in immunodeficient mice.
Methods:
To address these limitations, Biocytogen developed B-NDG hIL15, FcγR KO mice by expressing human *IL15* and knocking out the murine FcγR genes on the B-NDG background lacking mature T, B, and NK cells. Flow cytometry confirmed the absence of all four FcγRs in splenocytes. After injection of human IgG1 antibody, binding of IgG1 to CD45+ cells was detected in B-NDG mice and B-NDG hIL15 mice, but not in B-NDG hIL15, FcγR KO mice, confirming successful gene deletion. Serum human IL-15 concentration was approximately 112 pg/mL. The distribution and frequency of granulocytes, monocytes, macrophages, and dendritic cells were comparable between B-NDG hIL15 mice and B-NDG hIL15, FcγR KO mice.
Results:
Pharmacokinetic analysis after intravenous injection of an anti-human CTLA-4 IgG1 antibody revealed that antibody clearance was fastest in B-NDG mice and slowest in B-NDG hIL15, FcγR KO mice, indicating significantly prolonged serum half-life. To evaluate antibody efficacy, human PBMCs were engrafted into B-NDG hIL15, FcγR KO mice, followed by subcutaneous implantation of three human PD-L1-high tumor cell lines (HCC827, NCI-H1975, and MDA-MB-231). Treatment with a Keytruda analog (anti-human PD-1 antibody, in-house) via intraperitoneal injection resulted in significant tumor growth inhibition across all models, demonstrating improved immunotherapeutic responsiveness.
Conclusion:
The huPBMC-B-NDG hIL15, FcγR KO mice provide a superior platform for evaluating the efficacy of therapeutic antibodies that modulate human T-cell functions, including immune checkpoint inhibitors.

#6974 A CD3/CD19 double-humanized mouse model for preclinical evaluation of CD19-targeted T-cell engagers.

Shuang Li, Lei Ci, Yi Li, Ruilin Sun

GenoBioTX LLC, Sugar Land, TX

Background: Immunotherapy has transformed the treatment landscape for cancer and autoimmune diseases, with T-cell engagers (TCEs) emerging as a highly promising therapeutic modality. Among them, CD19-targeting TCEs have achieved notable clinical success in B-cell malignancies such as leukemia and lymphoma. However, despite these advances, the development of more sophisticated preclinical models remains essential to better recapitulate human immune responses and to deepen our understanding of TCE efficacy and safety. To address this need, we established a novel CD3/CD19 double-humanized mouse model specifically designed to provide a more accurate and comprehensive in vivo platform for evaluating CD19-directed TCE therapies.

Methods: The CD3 humanized mouse model was generated via ES cell-based gene targeting, in which full-length mouse *Cd3e/Cd3d/Cd3g* gene clusters were replaced with the corresponding human *CD3E/CD3D/CD3G* coding sequences. Separately, we developed the CD19 humanized mice using CRISPR/Cas9 engineering and subsequently crossed them with hCD3 strain to obtian the CD3/CD19 dual humanized mouse model. The expression of human CD3 and CD19 protein in hCD3/hCD19 dual knockin mice was confirmed by flow cytometry. We further characterized the model by examining immune cell subsets—including T and B cell populations—as well as basic physiological and biochemical parameters to ensure normal baseline health status. Finally, the hCD3/hCD19 dual knockin mice were treated with Blinatumomab, a first-in-class CD19-targeting BiTE used clinically for B cell malignancies, to evaluate its efficacy in depleting B cells in vivo.

Results: As expected, the expression profiles of human CD3 and CD19 in hCD3/hCD19 dual knockin mice were consistent with those observed in human. Additionally, the CD3/CD19 humanized mice displayed a fully functional immune system with well-developed T and B cell populations, and their physiological parameters were comparable to those of wild-type controls. Following Blinatumomab administration, the hCD3/hCD19 mice exhibited robust B cells depletion, confirming the model's suitability for assessing CD19-directed therapeutic activity. Furthermore, in hCD3/hCD19 mice with induced systemic lupus erythematosus (SLE), Blinatumomab treatment reduced anti-dsDNA antibody levels in parallel with B cell depletion, indicating the utility of this dual humanized model for preclinical evaluation of anti-CD19 therapies for autoimmune disease.

Conclusion: Our CD3/CD19 double-humanized mouse model represents an advanced and reliable tool for preclinical evaluation of CD19-targeted immunotherapies, including TCEs.

#6975 Endogenous retrovirus-derived neoantigens enable a personalized cancer vaccine strategy for glioblastoma.

Megan Campbell Benz[1], Kenan Zhang[2], David M. Ashley[3], Christian Garde[4], Kirit Singh[3], Ohrt Andersen Rasmus[4], Birgitte Rono[4], Daniela Kleine-Kohlbrecher[4], Stine Friis Thorsen[4], Kelly M. Hotchkiss[1], Jose R. Conejo-Garcia[1], Mustafa Khasraw[5]

[1]Duke University School of Medicine, Durham, NC,[2]Duke University, Durham, NC,[3]Duke University Medical Center, Durham, NC,[4]Evaxion Biotech, Horsholm, Denmark,[5]Duke Cancer Institute, Durham, NC

Introduction/Rationale: Glioblastoma is refractory to immunotherapy because of low mutational burden and paucity of canonical neoantigens. Aberrant expression of endogenous retroviral elements (ERVs), reactivated genomic remnants of ancient viral insertions, may provide an alternative, tumor-specific antigen source suitable for personalized vaccines incorporating both mutation- and ERV-derived epitopes.
Methods: Tumor and matched normal tissues from 25 glioblastoma patients, including 18 long-term survivors (>5 years) and 7 short-term survivors (<18 months), underwent whole-genome and RNA sequencing. Candidate antigens were predicted using AI-based pipelines to identify mutation-derived neoantigens and to derive ERV-encoded epitopes. AI-identified tumor-specific vaccine candidates were ranked by expression, predicted MHC class I and II binding affinity, clonality, and immunogenicity. Top candidates informed design of a personalized DNA vaccine encoding ten patient-specific sequences with a CCL19 molecular adjuvant to enhance dendritic-cell recruitment. ERV-derived immunogenicity was assessed by IFN-γ ELISpot using peripheral blood mononuclear cells (PBMCs) from HLA-typed healthy donors stimulated with synthetic peptides.
Results: High-quality mutation-derived neoantigens were rare (median 3 per patient). In contrast, all tumors expressed abundant, patient-specific ERV transcripts independent of mutation load, with several loci showing clonal, tumor-restricted expression. ERV-derived peptides demonstrated strong predicted MHC class I and II binding, and 22 of 25 tumors contained ERV epitopes meeting criteria for vaccine inclusion. These mapped predominantly to HERV-K and HERV-W families and frequently overlapped interferon-stimulated genomic loci, consistent with innate immune or epigenetic activation. Functional validation studies have demonstrated significant ERV-specific IFN-γ responses in certain HLA allele contexts, highlighting the potential for allele-specific immunogenicity. While T-cell responses were observed in selected donor profiles, others exhibited more restricted reactivity despite validated positive controls, underscoring the importance of genetic context in immune response profiles. Additionally, our ongoing analyses are focused on elucidating ERV expression signatures that may correlate with sustained immune control by comparing long-term and short-term survivor cohorts, with the aim of identifying key immunological patterns associated with favorable outcomes.
Conclusion: ERVs are consistently expressed, immunogenic, and largely tumor-restricted in glioblastoma, providing a scalable antigen source that may overcome limitations imposed by low mutational burden. These findings offer a strong proof-of-concept for personalized DNA vaccines incorporating ERV-derived neoantigens.

#6976 B-CDG mice: A novel severe immunodeficient model suitable for radiotherapeutic and radiopharmaceutical evaluation.

Qiurong Wang, Yanhui Nie, Ruili Lv, Chengzhang Shang, Meiqi Zhang, Qingqing Xu

Biocytogen, Waltham, MA

Background:
Radiopharmaceuticals have emerged as an important therapeutic strategy, but their evaluation in preclinical models is limited by the radiosensitivity of commonly used immunodeficient mice. The B-NDG mice (NOD.CB17-*Prkdc*^{scid} *Il2rg*^{tm1Bcgen}/Bcgen), generated via *Prkdc* mutation, lack mature T and B cells but are hypersensitive to DNA damage due to impaired DNA repair, leading to rapid body weight loss and mortality under irradiation.
Methods:
To overcome these limitations, Biocytogen developed the B-CDG mice on a C57BL/6 background by knocking out *Rag2* and *Il2rg*. This strain lacks mature T, B, and NK cells but retains normal DNA repair capability. Comparative analyses of B-CDG mice and B-NDG mice were performed under X-ray irradiation at doses of 1, 2.5, 4, and 7 Gy. Survival, body weight, hematology, and histopathology were assessed. Additionally, multiple human tumor cell lines—LNCap Clone FGC, 22Rv1, BT-474, AsPC-1, and SHP-77—were tested for xenograft formation.
Results:
B-CDG mice demonstrated superior tolerance to radiation. At 1 Gy and 2.5 Gy, all B-CDG mice survived 30 days, while all B-NDG mice exposed to ≥2.5 Gy died within 2 days. At 4 Gy, partial survival was observed in B-CDG mice, with recovery of body weight after initial decline. Hematology revealed dose-dependent decreases in leukocytes, erythrocytes, and platelets, with subsequent recovery at 30 days. Histological analysis showed extramedullary hematopoiesis in the liver and spleen of B-CDG mice, milder cellular injury, and compensatory marrow regeneration compared to B-NDG mice. Moreover, all tested tumor cell lines successfully established xenografts in B-CDG mice.
Conclusion:
B-CDG mice are a novel severe immunodeficient strain that maintains DNA repair competence and radiation tolerance. These characteristics make B-CDG mice an ideal platform for evaluating the efficacy and toxicity of radiopharmaceuticals and other DNA-damaging agents.

#6977 B-NDG MHC I/II DKO mice plus: A refined humanized model for evaluating T cell engager efficacy and toxicity.

Kelvin Yin, Yanhui Nie, Zhi Zhang, Meiqi Zhang, Yanling Wang, Qiang Liu

Biocytogen, Waltham, MA

Background: T cell engagers (TCEs) have demonstrated potent anti-tumor efficacy but can cause severe immune-related toxicities such as cytokine release syndrome (CRS). Accurate preclinical evaluation of TCE efficacy and safety requires an appropriate humanized animal model. Human PBMC-engrafted immunodeficient mice, such as B-NDG mice that lack mature T, B, and NK cells, are commonly used for this purpose. However, in B-NDG mice, human T cells become aberrantly activated due to interspecies MHC incompatibility, leading to severe graft-versus-host disease (GvHD) that confounds TCE efficacy and toxicity assessments.
Methods: To reduce GvHD, B-NDG MHC I/II DKO mice plus were developed by deleting *B2m* and *H2-Ab1* genes encoding MHC class I and II molecules, respectively. Additionally, a fusion of *B2m* and *Fcgrt* genes was introduced to restore expression of heterodimeric FcRn, minimizing the impact of *B2m* deletion on IgG metabolism. Flow cytometric analysis confirmed the absence of MHC I/II expression in splenocytes. After intravenous administration of anti-human CTLA antibody, serum drug concentrations in B-NDG MHC I/II DKO mice plus were comparable to those in parental B-NDG mice, indicating preserved IgG pharmacokinetics.
Results: To assess the effect of MHC deletion on GvHD, B-NDG, B-NDG B2m KO plus, and B-NDG MHC I/II DKO mice plus were irradiated and intravenously injected with human PBMCs from three donors. Most B-NDG and B2m KO mice developed severe GvHD and died within four weeks, whereas B-NDG MHC I/II DKO mice plus exhibited markedly alleviated GvHD with donor-dependent variability. These findings indicate that dual MHC I/II deletion significantly mitigates PBMC-induced GvHD. Furthermore, in PBMC-humanized B-NDG MHC I/II DKO mice plus bearing subcutaneous NCI-N87 gastric tumors, treatment with an anti-human CD3/HER2 bispecific antibody analog (in-house) significantly inhibited tumor growth. Similarly, in SHP-77 small cell lung cancer xenografts, Tarlatamab analog treatment suppressed tumor progression and elevated serum cytokines (IFNγ, TNFα, IL10, IL6, IL4, IL2) following dosing, reflecting robust T cell activation.
Conclusion: B-NDG MHC I/II DKO mice plus effectively alleviate human PBMC-induced GvHD while retaining normal antibody pharmacokinetics and enabling reliable assessment of TCE anti-tumor efficacy and cytokine-mediated toxicity. This model provides a refined and translationally relevant platform for preclinical evaluation of TCE therapeutics.

#6978 HIS models lacking FcγR provide increased predictability and facilitate study design for evaluation of immuno-oncology therapeutics.

Monika Buczek, Philip Dube, Nicholas Smith, Janell Richardson, Louise Baskin, Esther Andino, Debra Freer, Kathleen Bott

Taconic Biosciences, Inc., Rensselaer, NY

Humanized immune system (HIS) mouse platforms that support durable human NK and T cell function are essential for evaluating CAR-NK and CAR-T therapies. Residual murine Fc gamma receptors (FcγRs) can confound interpretation of IgG-based therapeutics and engineered cell products. We compared hIL-15 NOG and FcγR-null FcResolv™ hIL-15 NOG mice engrafted with human NK cells and observed equivalent ≥12-week persistence and stable $CD56^{+}CD16^{+}$ profiles, enabling extended engineered-cell studies. In $CD34^{+}$ HIS tumor models, anti-PD1 efficacy and pharmacodynamics were accurately detected only in FcResolv™ mice. FcγR-null HIS platforms improve predictive assessment of CAR-NK/CAR-T efficacy, trafficking, and off-target responses.

#6979 An immune-competent, durable MB49-Luc orthotopic bladder cancer model demonstrates bladder-specific tumor immunity for translational immunotherapy research.

Melanie He, Mirian Sifuentes, Neo Wang, Zhigang Peng, Minqi Huang

EnquBio Inc., San Diego, CA

Background and Objective: Bladder cancer remains a significant health concern in the United States, with approximately 85,000 new cases and 17,000 deaths annually. Nearly 70% of cases present as non-muscle-invasive bladder cancer (NMIBC), commonly treated with transurethral resection followed by intravesical immunotherapy. However, limited and inconsistent responses to current therapies underscore ongoing clinical challenges. To enable effective therapeutic development, a reliable, immune-competent, and longitudinally trackable preclinical model capable of representing the unique immune and physiological features of bladder cancer is essential. Despite decades of effort to refine syngeneic orthotopic bladder cancer models in mice, low tumor take rates and limited in-life study duration remain major challenges. Here, we present a syngeneic orthotopic bladder cancer model with extended in-life monitoring capacity that recapitulates bladder tumor immunity and enables robust immunotherapy evaluation.

Method and Result: A luciferase-expressing MB49 cell line was generated via lentiviral transduction. Female C57BL/6 mice were implanted intravesically to establish an orthotopic tumor model. In-life bioluminescence imaging (BLI) using IVIS revealed stable and quantifiable bladder-localized tumor signals for more than 21 days, with a 100% tumor take rate. Tumor presence in the bladder lumen was confirmed by H&E histopathology. Tumor-bearing bladders collected on Days 10 and 21 underwent next-generation sequencing (NGS) and subsequent enrichment analysis. Differential gene expression revealed biomarker signatures reflective of early- and late-stage tumor burden, along with dynamic immune-profiling changes. Pathway enrichment analysis linked these gene-level differences to functional networks governing immune regulation, tumor progression, and bladder cancer physiology.

Conclusion: We established an optimized MB49-Luc orthotopic bladder cancer model that preserves immune relevance, provides a prolonged imaging window, and demonstrates distinct molecular transitions during tumor progression. This long-duration, immune-competent platform enables rigorous evaluation of intravesical and immuno-oncology therapeutics and offers meaningful translational insights to support next-generation NMIBC immunotherapy development.

#6980 PDX*ovo*: Avian embryos as hosts for rapid and quantitative modelling of immunotherapy responses in patient-derived xenografts.

Olivia R. Grafinger[1], Kabir A. Khan[1], Esther Matus[2], Ping Xu[1], Sara Mar[2], Yan Li[1], David E. Goertz[1], Wilder Scott[1], Jean Gariepy[1], Katarzyna J. Jerzak[2], Robert S. Kerbel[1], Hon S. Leong[1]

[1]Sunnybrook Research Institute, Toronto, ON, Canada,[2]University of Toronto, Toronto, ON, Canada

The purpose of patient-derived xenograft (PDX) technology as a pre-clinical model for drug sensitivity testing is well established, but this does not include immunotherapies. When mouse hosts are used, the non-cancer cells within the human tumor xenograft are replaced with murine stromal cells. The lack of the patient's tumor-infiltrated lymphocytes (TILs) within these mouse-based xenografts prohibits immunotherapy testing. We show that avian embryos as a host for PDXs are a superior model because of the ability to test a wide range of therapies, including immunotherapies, because TILs from the patient are still present in the xenograft within days of engraftment in the chorioallantoic membrane (CAM) of the avian embryo. To validate this model for immunotherapy drug testing, we engrafted murine tumors sensitive to PD-L1 immunotherapy into CAM of avian embryos and battle-tested this technology in various experimental conditions. By controlling the amount of mouse TILs in these xenografts, we demonstrate the utility of the PDX*ovo* (PDX *ex ovo*) for testing immunotherapies. We then performed feasibility studies on fresh material from kidney, colorectal, and breast cancer human patients, revealing anti-tumor responses concordant with the initial and final number of human TILs. Finally, spatial omics technology was applied to compare the tumour-immune microenvironment of the original murine tumours to their xenograft counterparts grown in the avian embryo. These findings demonstrate compelling evidence supporting the efficacy of the PDX*ovo* system for maintaining the integrity of the original tumour architecture as well as immune cell populations. Additionally, this model offers high tumor take rate of fresh tumor material, all within 10 days of engraftment. The speed of these experiments is also mirrored by their low cost, which points to their potential role for timely drug sensitivity testing and patient eligibility for existing and emerging therapies.

#6981 Involvement of type I interferon signaling in anti-PD-1-induced tumor rejection in a novel humanized NOG-FcγR$^{-/-}$ mouse model.

Tatsuhito Ii[1], Ting-Wei Yu[1], Katsutoshi Sato[1], Hirotaka Inoue[2], Ayumu Tsubosaka[3], Miwako Kakiuchi[3], Daisuke Komura[3], Ikumi Katano[1], Nao Suzuki[1], Iyo Ootsuka[1], Motohito Goto[4], Misa Mochizuki[5], Kenji Kawai[6], Shumpei Ishikawa[3], Masami Suzuki[5], Takeshi Takahashi[1]

[1]Division of Advanced Biomedical Research, Central Institute for Experimental Medicine and Life Science, Kawasaki, Japan,[2]Department of Neurosurgery, Graduate School of Medical Sciences, Kumamoto University, Kumamoto, Japan,[3]Preventive Medicine, Graduate School of Medicine, The University of Tokyo, Bunkyo-ku, Japan,[4]Laboratory Animal Resource Center, Central Institute for Experimental Medicine and Life Science, Kawasaki, Japan,[5]Division of Translational Research, Central Institute for Experimental Medicine and Life Science, Kawasaki, Japan,[6]Central Institute for Experimental Medicine and Life Science, Kawasaki, Japan

Introductory sentence: To investigate the relationship between anti-PD-1 therapy and immune cells, a model that recapitulates the human tumor microenvironment is required. We previously established a humanized NOG-FcγR$^{-/-}$ mouse model, in which anti-tumor effects by anti-human PD-1 anibody can be confirmed in vivo. Among several tested cell lines, the head and neck carcinoma line HSC4 showed the highest sensitivity in this model. In the present study, we grafted HSC4 cells into humanized NOG-FcγR$^{-/-}$ mice and performed single-cell RNA sequencing (scRNA-seq) and spatial transcriptomic analyses to elucidate the molecular and cellular mechanisms of the tumor rejection.

Experimental procedures: Human immune cells were reconstituted in NOG and NOG-FcγR$^{-/-}$ mice by transplantation of human hematopoietic stem cells. One week after grafting HSC4 cells, the mice received intraperitoneal injections of anti-human PD-1 antibody once weekly for two weeks.For scRNA-seq, CD45^{+} cells were isolated from the grafted tumors, whereas FFPE tumor samples were used for spatial transcriptomic analysis following standard protocols.

New, unpublished data: In the scRNA-seq data, human immune cells were clustered into naïve-like CD4^{+} T cells, cytotoxic CD8^{+} T cells, regulatory CD4^{+} T cells, CXCL13^{+} helper T cells, and macrophages. Pseudobulk analysis with GSEA identified the interferon-α (IFN-α) response as a top enriched pathway in nivolumab-treated NOG-FcγR$^{-/-}$ mice. Feature plots showed that IFN-α-related genes were broadly expressed across human immune cell populations. To further explore this response, we analyzed the transcriptional profiles of CXCL13^{+} helper T cells, since their role in tumors remains unclear.In the spatial transcriptomic analysis, after excluding mouse-derived and low-RNA-content spots, five tumor clusters and one immune cluster containing human T cells and macrophages were identified based on marker genes and spatial context. GSEA revealed that tumor cells located near CXCL13^{+} immune cells predominantly exhibited basal-like features, along with upregulation of type I IFN-related pathways. RNAscope analysis confirmed CXCL10, an IFN response marker, in immune cells and tumor cells with basal-like feature but not in tumor cell with squamous differentiation.

Conclusions: Our results suggest that tumor regression in this model is mediated by type I IFNs within the tumor microenvironment. This mechanism parallels the effects of nivolumab in human tumors, suggesting that this model provides a valuable platform for studying immune checkpoint inhibitor therapy.

#6982 Patient-derived uveal melanoma organoids reveal HLA-I-restricted tumor antigens and tumor-reactive T cells.

Alexander Lim, Wei Tian, Zhuoning Li, Mara Monetti, Alexander Noor Shoushtari, James Smithy, Samuel Tischfield, Mark Donoghue, David A. Scheinberg, **Chenyang Zhan**

Memorial Sloan Kettering Cancer Center, New York, NY

Background: Uveal melanoma (UM) is a rare but aggressive melanoma subtype with limited response to immune checkpoint inhibitors. Identifying tumor-specific or associated antigens and tumor-reactive T cells is critical to advancing precision immunotherapy. Patient-derived tumor organoids (PDOs) offer a physiologically relevant *ex vivo* model to study tumor-immune interactions and to uncover novel therapeutic targets.
Methods: PDOs were established from fine-needle aspiration biopsies of five patients with metastatic UM. HLA-I-restricted immunopeptidomes were successfully characterized in three PDOs through immunoprecipitation of HLA-peptide complexes followed by mass spectrometry (MS). Identified peptides were matched against the UniProt human reviewed database. Dissociated tumor cells from one PDOs were treated with IFN-γ to enhance antigen presentation and then co-cultured with autologous peripheral blood mononuclear cells (PBMCs) for sequential stimulations over four weeks. After a third stimulation, $CD8^+$ T cells were analyzed by flow cytometry and subjected to single-cell RNA and paired V(D)J sequencing using the 10x Genomics platform to define phenotypes and clonotypes of activated T cells. Tumor-reactive TCR clonotypes were identified, and their CDR3β sequences were analyzed using the TCRMatch tool in the IEDB database to assess sequence homology and potential antigen specificity.
Results: Immunopeptidomic analysis identified 3,628, 6,735, and 10,407 unique 8-11mer peptides across three PDOs. Shared tumor-associated antigens (TAAs) included CSPG4, TYRP1, SLC45A2, OCA2, PMEL, TYR, MLANA, and SOX10. T-cell activation assays demonstrated that 12.3% of $CD8^+$ T cells exhibited HLA-I-dependent activation upon restimulation with autologous PDOs, which was abrogated by HLA-I blockade. Single-cell RNA sequencing of $CD8^+$ T cells in the co-culture revealed activated cytotoxic clusters unique in the restimulated cells, characterized by high expression of CD137, GZMH, MIR155HG, PKM, and LAG3. TCR clonotype analysis using TCRMatch identified candidate tumor-reactive TCRs possibly recognizing PMEL, MART-1, and MAGEA10.
Conclusions: This study demonstrates the feasibility of using PDOs from metastatic UM to define the HLA-I-restricted immunopeptidome and to identify tumor-reactive T-cell clonotypes through autologous PDO-PBMC co-culture. The integration of immunopeptidomics with single-cell RNA/TCR sequencing provides a robust framework for mapping patient-specific tumor-immune interactions. Identified TAAs and tumor-reactive TCRs represent potential biomarkers and targets for next-generation precision immunotherapies, including personalized tumor vaccines and TCR-based adoptive cell therapies.

#6983 A novel syngeneic model for evaluating the efficacy of MYC-driven liver cancer targeted and immunotherapy.

Lei Ci, Kai Zhou, Jiangyan Liu, Ruilin Sun

GenoBioTX LLC, Suger Land, TX

In liver cancer, MYC and its signaling pathways undergo significant changes, exerting a profound impact on liver cancer progression. These effects include tumor proliferation, metastasis, dedifferentiation, metabolism, immune microenvironment, and resistance to comprehensive therapies. This makes MYC a highly attractive therapeutic target.Our laboratory engineered mice on a C57BL/6 background with hepatocyte-specific expression of mouse c-Myc, resulting in rapid, spontaneous hepatocellular carcinoma (abbr. c-Myc/ALB model). Primary tumors were harvested and cultured to establish a novel spontaneous tumor cell line. In the c-Myc/ALB syngenic tumor model of immunocompetent C57BL/6 mice, the c-Myc inhibitor 10058-F4 significantly inhibited tumor growth in a dose-dependent manner. The PD-1 antibody in combination of 10058-F4 and immune checkpoint inhibitor PD-1 antibody showed better anti-tumor efficiency.

#6984 Modeling late-stage ovarian cancer and validating oncolytic adenoviral tools for transgene expression and tumor monitoring.

Lakshmi Kadkol[1], Eric Gauchat[2], Maria Jose Godoy Calderon[1], Manali Patwardhan[1], VK Gadi[1]

[1]Medicine, University of Illinois at Chicago, Chicago, IL,[2]Cancer Center, University of Illinois at Chicago, Chicago, IL

Purpose: High-grade serous ovarian cancer (HGSOC) is characterized by profound immune exclusion and peritoneal spread, hypothesized to be orchestrated by the TGF-β and GM-CSF cytokines. We established an immunocompetent murine model of advanced HGSOC and evaluated the tumor selectivity and transgene delivery efficiency of hTERT-driven oncolytic adenoviruses encoding GM-CSF and/or a soluble TGF-β receptor Fc fusion (sTGFβR-Fc).

Experimental Procedures: A syngeneic orthotopic model of advanced HGSOC was established by intraperitoneally injecting luciferase-labeled MOE-KRAS/PTEN (MKP) cells into immunocompetent FVB/N mice. Tumor burden was monitored longitudinally by bioluminescence imaging (BLI). Four hTERT-driven oncolytic adenoviruses (Ad.Null, Ad.GM-CSF [Ad.GM], Ad.sTGFβR [Ad.sT], Ad.sTGFβR.GM-CSF [Ad.sT.GM]) were evaluated in vitro for infectivity, cytolytic activity (Incucyte/caspase 3/7), and transgene expression (flow cytometry) in MKP tumor cells, NIH 3T3 fibroblasts, and 3T3-derived cancer-associated fibroblasts (CAFs).

Results: Serial BLI showed consistent peritoneal tumor engraftment and progression by day 26 (n = 14) confirming model fidelity for late-stage disease. In vitro, IncuCyte live-cell imaging revealed strong, selective apoptosis in MKP cells following oncolytic infection, while NIH 3T3 fibroblasts and CAFs (non-tumor controls) showed minimal response. Apoptotic activity in MKP cells rose sharply at 30-35 hours and peaked at 45 hours post-infection (>60-80% fold increase in caspase3/7+ area over untreated but minimal apoptotic activity in 3T3 and CAFs (<8-fold over untreated). Notably, among virus constructs, Ad.GM and Ad. Null induced the most rapid and robust apoptosis, whereas Ad. sT and Ad.sT.GM showed significantly delayed and reduced effects (Ad.GM vs Ad. Null: $p = 0.0042$; Ad. sT vs Ad.GM or Ad. Null: $p < 0.0001$; 2-way ANOVA with Sidak's test). Transgene expression was quantified by flow cytometry following 48-hour infection. Ad.GM and Ad.sT.GM treatments produced GM-CSF positive cells (2.25% and 1.04% gated, mean fluorescence intensity 6217.54 and 5508.2 respectively) while Ad.sT and Ad.sT.GM treatments produced sTGFβR-Fc positive cells (8.04% and 9.75% gated, mean fluorescence intensity 85092.63 and 84097.65 respectively); live cell frequencies decreased in treated groups (61.45-67.83%) compared to untreated (96.32%) controls. These results demonstrate selective transgene expression and cytotoxicity in tumor cells achieved by the engineered oncolytic constructs.

Conclusions: These data confirm the fidelity for advanced-stage HGSOC model and establish oncolytic adenoviral platforms as effective mechanistic tools—functioning both as cytolytic agents and as delivery vehicles for functional transgenes—to mechanistically dissect TGF-β and GM-CSF signaling in ovarian cancer.

#6985 Overcoming pancreatic ductal adenocarcinoma immunoresistance: Microfluidic-primed organoid interacting lymphocytes demonstrate superior infiltration, cytotoxicity, and tumor suppression in patient-derived models.

Eleftherios Makris, Damian Hutchins, Tiefu Liu, Adam Hall, Lance Miller, Shay Soker, Konstantinos Votanopoulos

Wake Forest University School of Medicine, Winston Salem, NC

Background: Pancreatic ductal adenocarcinoma (PDAC) remains refractory to immunotherapy due to its immunosuppressive tumor microenvironment (TME), characterized by dense desmoplasia, immune exclusion, and T cell exhaustion. With 5-year survival <13%, novel strategies are urgently needed. We developed a platform to generate and evaluate tumor-specific cytotoxic lymphocytes using immunocompetent patient-derived organoids (PTOs) that recapitulate the PDAC TME.
Methods: Immunocompetent PTOs (iPTOs) were established by co-culturing resected PDAC tissue with autologous tumor-draining lymph node cells. Autologous PBMCs were primed via microfluidic tumor-on-a-chip circulation, generating Organoid Interacting Lymphocytes (OILs). OILs were expanded for 14 days and co-cultured with patient-matched PTOs at 5× and 10× effector:target ratios. Tumor-immune dynamics were quantified using high-resolution time-lapse microscopy with automated single-cell tracking, flow cytometry (CD45, CK19, viability), and longitudinal tumor area measurements over 96 hours.
Results: Flow cytometry demonstrated robust immune infiltration, with CD45+ cells comprising 26% of OIL-treated cultures versus 0.5% in tumor-only controls. OILs induced 93% tumor cell death compared to 68% with unstimulated PBMCs. Quantitative tracking revealed OILs migrated 6.1 pixels closer to tumor cells versus 0.6 pixels for PBMCs over 24 hours ($P<0.05$). At 27 hours, OIL-treated organoids exhibited consistent tumor area reduction (-2% to -13%), while PBMC-treated wells showed variable responses including tumor expansion (+7%). Longitudinal analysis confirmed sustained suppression with live OILs, whereas heat-killed OILs permitted 15-fold tumor expansion, demonstrating viability-dependent cytotoxicity. Time-lapse microscopy captured direct killing events, immune synapse formation, and tumor clustering consistent with immune evasion. These findings replicate observations in appendiceal and mesothelioma models where OILs outperformed tumor-infiltrating lymphocytes.
Conclusions: OILs represent a potent, patient-specific adaptive cell therapy capable of overcoming PDAC's immunosuppressive TME. This immunocompetent organoid platform enables quantitative real-time assessment of personalized immunotherapies and supports clinical translation of OIL-based therapies for pancreatic cancer.

#6989 RBM10 loss promotes *KRAS*-mutant non-small cell lung cancer immune tolerance and PD-1 inhibitor resistance via a non-canonical STING/ NF-κB axis.

Minh Truong Do[1], Teng Zhou[1], Mhd Yousuf Yassouf[1], Richard Lee[1], Obada E. Ababneh[1], Yanhua Tian[1], Leticia B. Rodriguez[1], Jayanthi Gudikote[1], Haniel A. Araujo[1], Stephanie T. Schmidt[2], Jing Wang[3], Frank R. Rojas Alvarez[4], Luisa M. Solis Soto[4], Marcelo V. Negrao[1], Alexandre Reuben[1], Don L. Gibbons[1], Jianjun Zhang[1], John V. Heymach[1], Ferdinandos Skoulidis[1]

[1]Thoracic and Head and Neck Medical Oncology, UT MD Anderson Cancer Center, Houston, TX,[2]Genomic Medicine and the Institute for Data Science in Oncology, UT MD Anderson Cancer Center, Houston, TX,[3]Bioinformatics and Computational Biology, UT MD Anderson Cancer Center, Houston, TX,[4]Translational Molecular Pathology, UT MD Anderson Cancer Center, Houston, TX

Loss-of-function mutations in *RBM10*, encoding a protein involved in the regulation of alternative splicing, are observed in ~10% of non-squamous NSCLC and are enriched in tumors harboring activating mutations in *KRAS*, yet little is known about how *RBM10* inactivation promotes lung cancer progression or influences response to standard-of-care systemic therapies. Here, we elucidated the cooperative interplay between oncogenic *KRAS* activation and *RBM10* loss in NSCLC pathogenesis using a novel genetically engineered mouse model with conditional *RBM10* deletion, as well as multiple isogenic syngeneic allograft models that faithfully recapitulate *RBM10*-deficient human lung adenocarcinoma. We found that loss of *RBM10* accelerates *KRAS*-mutant NSCLC progression by fostering the establishment of a tolerogenic, myeloid cell-rich tumor immune microenvironment (TIME). Mechanistically, *RBM10* loss promoted R-loop accumulation and chronic DNA damage signaling that engaged the non-canonical TRAF6-STING pathway in a cGAS-independent manner, leading to sustained NF-κB activation. We identified several cytokines and chemokines, canonical targets of NF-κB signaling, such as IL-1β, IL-6, TNFα, and MCP-1, that were upregulated in *RBM10*-deficient cells. This NF-κB-driven secretome promoted the development of an inflamed, TIME characterized by accumulation of suppressive myeloid cell subsets - most notably monocytes and M2-like macrophages, and dysfunctional tumor infiltrating lymphocytes (TILs) thereby fostering immune evasion and cancer progression. Furthermore, we exploited the RNA-seq database of human lung adenocarcinoma from The Cancer Genome Atlas (TCGA) and again found that *RBM10* loss was significantly linked to impaired DNA damage response, upregulation of the HALLMARK_TNFA_SIGNALING_VIA_NF-κB, and enrichment of M2-macrophages. Strikingly, targeting the CSF1/CSF1R axis with an anti-CSF1R antibody significantly curtailed the growth of *RBM10*-deficient tumors in syngeneic immunocompetent models and synergized with anti-PD-1 therapy to promote tumor regression. In conclusion, our findings uncovered a novel critical role of *RBM10* inactivation in driving immune escape and PD-1 inhibitor resistance in *KRAS*-mutant NSCLC and suggest a potential therapeutic strategy by co-targeting suppressive myeloid cells to improve cancer immunotherapy for patients bearing *KRAS;RBM10* co-mutated tumors.

#6990 Identification of a secretory immune regulatory ligand.

Benjamin Nicholson, Sydney Fisher, Matthew Wren, Weijie Guo, Yuxuan Phoenix Miao

University of Chicago, Chicago, IL

Immunotherapies have transformed cancer treatment, but subsets of patients experience differential responses. Patients with squamous cell carcinomas (SCCs) in various tissues exhibit a high rate of relapse after initial responses to immunotherapies. Recent research highlighted the critical role of a group of stem cell-like tumor-initiating cells (TICs) in driving resistance to anti-tumor immunity and promoting relapse of both cutaneous (CSCCs) and head and neck (HNSCCs) SCCs despite intact antigen presentation. Although TICs drive SCC relapse, they compose less than 5% of the total tumor cell population, so their unique immune resistance mechanisms have been largely overlooked. We analyzed single-cell RNA-seq data profiling the gene signatures of various tumor populations in spontaneous GEMM CSCCs and identified that cytotoxic T lymphocyte-associated protein 2a (*Ctla2a*) was specifically activated in TICs. Ctla2a is a cysteine peptidase inhibitor with high homology to the I29 inhibitory domain of mouse and human cathepsins. Silencing *Ctla2a* in SCC cells reduced tumor growth, increased the frequency of granzyme B+ CD8+ T cells infiltrating the tumor, and sensitized SCC tumors to immunotherapy. We have found that the conditioned medium from SCC cells overexpressing *Ctla2a* is sufficient to blunt granzyme B production in CD8+ T cells and reduce CD8+ T cell antigen-specific cytotoxicity *in vitro*. Taken together, these results suggest that SCC TICs can secrete Ctla2a to modulate CD8+ T cell anti-tumor cytotoxicity. This interaction may serve as a target for next-generation immunotherapy that is able to blunt TIC-specific immune resistance.

#6991 Direct adhesion of activated platelets suppresses anti-tumor activity of CTL through CD62p-PSGL1 binding.

Sae Nishiguchi[1], Masaru Yokomura[1], Yuki Gomibuchi[2], Seiji Nagano[3], Takuo Yasunaga[4], Hiroshi Kawamoto[3], Satoshi Takagi[5], Ryohei Katayama[6]

[1]Japanese foundation for Cancer Reserch, Tokyo, Japan,[2]Department of Physics and Information Technology, Faculty of Computer Science and Systems Engineerin, Kyushu Institute of Technology, Fukuoka, Japan,[3]Institute for Life and Medical Sciences, Kyoto, Japan,[4]Department of Physics and Information Technology, Kyushu Institute of Technology, Fukuoka, Japan,[5]Division of Experimental Chemotherapy, Japanese foundation for Cancer Reserch, Tokyo, Japan,[6]Japanese Foundation for Cancer Research, Tokyo, Japan

T cell-based immunotherapies, such as CAR-T and TCR-T cell therapies, have shown remarkable success owing to their high target specificity and durable efficacy. However, their clinical efficacy is known to be limited by the immunosuppressive tumor microenvironment (TME). In this study, we focused on platelets as one of the immunosuppressive components in the TME. Platelets can extravasate from leaky tumor vessels and infiltrate into tumor tissues, where they directly interact with various types of cells in the tumor tissue. In addition to direct cell-cell interactions, platelets can influence tumor progression and modulate the function of immune cells through the released factors such as EGF, PDGF, and TGF-β upon platelet activation. In this study, we sought to assess the effect of platelets to the cytotoxic T lymphocytes (CTL). To assess this effect, we performed co-culture experiments of CTLs and tumor cells with human platelets. For the CTLs, we used cancer antigen WT1-specific T cells (CTL3-3) re-differentiated from iPS cells. Cytotoxicity of CTL3-3 was evaluated by co-incubate with HLA matched cancer cells expressing luciferase. After incubation of CTL3-3 with cancer cells with or without WT1 peptide, antigen-specific cytotoxicity was evaluated with luciferase assay. When platelets derived from healthy donors were added to this co-culture system, antigen-specific cytotoxicity was significantly suppressed with IFN-γ release suppression. This result indicated that platelets inhibited CTL3-3 activity. Interestingly, supernatant from activated platelets by collagen I treatment, partially suppressed the CTL3-3 cytotoxicity, suggesting that intact platelets interaction contribute significantly to the inhibitory effect. We then evaluated the direct interaction of platelets with cancer cells, and CTL3-3. Flow cytometry analysis revealed that platelets, which express the activation marker CD62p, preferentially adhered to CTL3-3. Immunofluorescence and electron microscopy analysis further confirmed this adhesion. Both flow cytometry and quantification using fluorescence images demonstrated that neutralizing antibodies against CD62p or its known binding partner, PSGL-1 significantly reduced platelets-CTL3-3 adhesion, suggesting that activated platelets adhere to CTL3-3 through CD62p and PSGL-1. In conclusion, our findings revealed a mechanism by which platelets inhibit antigen-specific CTL activity through direct adhesion, in addition to the soluble factor-mediated killing activity suppression of CTLs. These results suggest that targeting platelet-CTL interaction might enhance the efficacy of T cell-based immunotherapies and provide a potential strategy to overcome immunosuppressive barriers within the TME.

#6992 Tumor stem cells reprogram neutrophils to establish a protective niche.

Weijie Guo[1], Jingyun Luan[2], Yuxuan Phoenix Miao[2]

[1]Ben May, University of Chicago, Chicago, IL,[2]University of Chicago, Chicago, IL

The heterogeneous nature of tumor-associated neutrophils (TANs) has been recognized, but how different cell states of TANs emerge, evolve, distribute, and impact cancer immunotherapy efficacy remain elusive. Using single-cell RNA sequencing, spatial transcriptomics, and genetic manipulations, we show that anti-PDL1 + CD40 agonist immunotherapy can induce interferon responses in TANs, allowing them to regain antitumor activities in squamous cell carcinomas (SCC). In contrast, TANs residing at the tumor-stroma interface can preserve their immune suppressive state. Importantly, we identify a group of SOX2 High tumor-initiating stem cells (tSCs) at the tumor-stroma interface that upregulate fatty acid desaturase 1 (Fads1) to produce arachidonic acid (AA). This tSC-specific pathway enhances the prostaglandin E_2 (PGE_2) signaling in TANs, which can disrupt the interferon response and prevent the interferon-induced anti-tumor functions in TANs. By fine-tuning the plasticity of neutrophils, tSCs shape neutrophil heterogeneity and sculpt a protective micro-niche to survive from immunotherapy and drive cancer relapse.

#6993 Targeting PDE4A ablates an immune checkpoint and unleashes STING-Driven anti-tumor immunity.

Yuting Bai[1], Kejia Xu[1], Huimin Liu[1], Haojie Chen[1], Yi Shi[1], **Rong Xiang**[2]

[1]Nankai University, Tianjin, China,[2]Nankai University, Tian jin, China

Dysregulation of the cGAS-STING pathway is a common mechanism of immune evasion. Here, we identify phosphodiesterase 4A (PDE4A) as a pivotal suppressor of this pathway in tumor cells. High PDE4A expression dampens cGAS-STING signaling and type I interferon production, resulting in impaired infiltration of cytotoxic CD8+ T cells into the tumor microenvironment and accelerated metastasis. Strikingly, both genetic knockdown of PDE4A and its pharmacological inhibition with roflumilast reversed this immune-suppressive phenotype, potently enhanced CD8+ T cell infiltration, and suppressed metastatic progression. Our findings unveil PDE4A as a novel therapeutic target to reactivate anti-tumor immunity and combat metastasis, nominating PDE4A inhibition, particularly with the clinically available agent roflumilast, as a promising immunotherapeutic strategy.

#6994 Proline metabolic competition drives CD8⁺ T cell ferroptosis in BRAF-mutated thyroid cancer.

Yuanxing Dong[1], Xinyue Liu[2], Xiangqian Zheng[1]

[1]Department of Thyroid and Neck Tumor, Tianjin Medical University Cancer Institute and Hospital, National Clinical Research Center for Cancer, Key Laboratory of Cancer Prevention and Therapy, Tianjin's Clinical Research Center for Cancer, Tianjin, China,[2]Department of Pancreatic Cancer, Tianjin Medical University Cancer Institute and Hospital, National Clinical Research Center for Cancer, State Key Laboratory of Draggability Evaluation and Systematic Translational Medicine, Tianjin Key Laboratory of Dige, Tianjin, China

Proline metabolism intermediate pyrroline-5-carboxylate (P5C) has been implicated in regulating T-cell signaling and effector activity, yet how proline availability shapes tumor-immune interactions remains poorly understood. Here, we demonstrate that tumor-driven proline depletion induces ferroptosis in CD8⁺ T cells and thereby promotes tumor progression. We identify proline dehydrogenase (PRODH) as a key metabolic regulator that is markedly upregulated in BRAFV600E-mutant thyroid cancer and strongly associated with enhanced tumor aggressiveness and poor prognosis. Elevated PRODH accelerates proline catabolism in tumor cells, creating pronounced metabolic competition with CD8⁺ T cells and resulting in nutrient deprivation, ferroptotic death, and impaired antitumor function. Mechanistically, BRAFV600E activates MAPK signaling, which induces ERK- and JUN-dependent transcriptional upregulation of PRODH. Sustained proline consumption disrupts the “proline-glutamate-GSH” metabolic axis, leading to redox imbalance, excessive ROS accumulation, and ferroptosis-mediated T-cell dysfunction. Notably, pharmacological inhibition of the proline transporter SLC6A20 alleviates proline shortage, restores glutathione biosynthesis, and rescues CD8⁺ T-cell fitness. In addition, functional restoration of this metabolic circuit enhances cytokine production, promotes T-cell persistence within the tumor microenvironment, and significantly suppresses tumor growth in vivo. These findings identify the BRAFV600E-ERK-PRODH axis as a central driver of proline metabolic reprogramming that simultaneously enhances tumor malignancy and undermines antitumor immunity. Moreover, we highlight the essential role of the proline-glutamate-GSH axis in protecting CD8⁺ T cells from ferroptosis and demonstrate that proline supplementation or blockade of SLC6A20 can reestablish this protective pathway and reinforce T-cell-mediated antitumor responses, offering a promising therapeutic strategy for BRAFV600E-driven cancers.

#6995 Spatial immune landscape in metastatic colorectal cancer.

Susrutha Puthanmadhom Narayanan[1], Chien-Wei Peng[1], Adrienne Visani[1], Xiangwei Fang[1], Andre Luiz N. Targino da Costa[1], Jingxian Liu[2], Reyka G. Jayasinghe[1], Ambrose Plante[1], John M. Herndon[1], Jacqueline Mudd[1], Preet Lal[1], Wagma Caravan[1], Kapur B. Dhami[2], Jennifer Ponce[1], Robert S. Fulton[1], Michael Heinz[1], Milan G. Chheda[1], Feng Chen[2], Michael Iglesia[1], Ryan C. Fields[1], Li Ding[2]

[1]Washington University in St. Louis, St. Louis, MO,[2]Washington University School of Medicine in St. Louis, St. Louis, MO

Microsatellite stable (MSS) metastatic colorectal cancer (mCRC) does not respond well to immunotherapy, but clinical trials have shown promise with immunotherapy in MSS mCRC without liver metastases, especially lung only metastatic disease. To understand the underlying reasons for this site-specific difference in response, we investigated the spatial immune landscape in liver and lung metastases using spatial transcriptomics (Xenium) and single nuclear RNA-sequencing (snRNA seq) on immunotherapy naive, MSS tumors (9 primary, 9 liver and 6 lung samples for Xenium and 17 primary, 21 liver and 5 lung samples for snRNA seq). We defined three spatial regions in Xenium samples- tumor region (contains tumor cell nests), peritumor region (stromal and immune cells that separate tumor region from adjacent parenchyma) and adjacent parenchyma (adjacent normal-appearing tissue in the same section). Expressed as a proportion of all immune cells, liver tumor regions had higher macrophage infiltration ($p<0.01$), while lung tumor regions had higher CD8 T cell infiltration ($p=0.03$). CD8 T cell proportion was not different between liver and lung metastases in peritumor regions or adjacent parenchyma, or in the sn-RNA seq data, highlighting the spatial gradient of CD8 T cells in different organ sites. CD8 T cell density (per mm2) in liver tumor regions (but not peritumor region or adjacent parenchyma) was lower than paired primary colon ($p=0.03$) and lung metastasis (not significant). Tumor regions had a higher proportion of exhausted CD8 T cells (expressing at least one exhaustion marker-*PDCD1, HAVCR2, TIGIT, CTLA4, LAG3*) than the peritumor region or adjacent parenchyma in all three organs. Among T cells that infiltrated tumor regions, liver had a higher Treg proportion than lung ($p=0.02$), this did not hold true in peritumor region and adjacent parenchyma. Differential gene expression between Tregs of liver and lung tumor regions revealed upregulation of *ENTPD1* (codes for CD39, which suppresses CD8 T cells) in liver Tregs; this finding was also present in our sn-RNA seq data. To investigate the reasons for organ-specific variability in the immune landscape of mCRC, we compared the expression of chemokine genes in non-tumor cells of liver and lung metastases. Liver samples had markedly higher levels of *CXCL12* (highest in the adjacent parenchyma) than lung metastases. Tregs and CD8 T cells in the liver had higher levels of *CXCR4* (CXCL12 receptor) than the lung. Spatial gradients in CXCL12 (highest in adjacent parenchyma), may impair CD8 T cell infiltration in the tumor. In summary, we identified an immunosuppressive immune microenvironment in liver than lung mCRC with unique spatial patterns of CD8 T cell and Treg infiltration, and chemokine expression. This may explain the differential response of immunotherapy between these two sites. Inhibition of the CXCL12-CXCR4 axis and CD39 may be potential strategies to augment immunotherapy in patients with liver mCRC.

#6996 Immune regulatory functions and therapeutic opportunities of MIF signaling in pancreatic cancer.

Blake Schwettmann, Fei Peng, Angad Kumar, Valli Annamali, Jason Toombs, Rolf Brekken, Ravikanth Maddipati

UTSW, Dallas, TX

Background: Pancreatic ductal adenocarcinoma (PDAC) is projected to become the second leading cause of cancer-related death in the US, yet current treatments remain largely ineffective. The immunosuppressive tumor immune microenvironment (TIME), particularly tumor-associated macrophages, represents a critical barrier to therapeutic success. To identify critical targets and interactions in the PDAC TIME, we cross-referenced RNA sequencing from the KPCX autochthonous mouse model that recapitulates tumor heterogeneity with RNA sequencing from a cohort of PDAC patients. Through this analysis we identified macrophage migration inhibitory factor (MIF) as an important tumor-derived secreted factor whose function in PDAC immune evasion remains to be fully elucidated. This study investigates how MIF signaling regulates immune responses and promotes immune evasion in PDAC.

Methods: To dissect MIF signaling and the relative contribution from tumor and stromal compartments, we utilized orthotopic syngeneic PDAC allografts in wild-type and Mif $^{-/-}$ mice. We also investigated MIF's cognate receptor, CD74, through orthotopic allografts in global CD74$^{-/-}$ mice and cell-type-specific deletion models targeting macrophages/monocytes (CD74f/f;Cx3cr-Cre). We also incorporated pharmacologic inhibition of MIF in our orthotopic PDAC models. Tumor growth and immune composition were quantified by flow cytometry and immunohistochemistry. MIF signaling on macrophages was also characterized *in vitro* using co-cultures with Mif$^{-/-}$ murine PDAC cell lines 6419 and 6694. M1 (iNos, CD86) and M2 polarization (Arg1, CD206) markers were characterized using RT-qPCR.

Results: Loss of MIF profoundly reduced tumor burden. Syngeneic PDAC cells implanted into Mif$^{-/-}$ mice demonstrated a 50% reduction in tumor growth compared to wild-type mice. Reciprocally, Mif$^{-/-}$ tumor cells showed a marked growth reduction in wild-type recipients, indicating MIF functions in both tumor and stromal compartments. Surprisingly, CD74 deletion, either globally or specifically in macrophages, had minimal impact on tumor growth, suggesting that MIF signals through alternative receptors or acts on other immune populations. Pharmacologic MIF inhibition reduced tumor burden by 50%, decreased pro-tumor M2-like macrophages by 50%, and increased CD8+ T cells 2-3 fold.

Conclusions: Our findings demonstrate that tumor-derived MIF promotes immune evasion in PDAC through CD74-independent mechanisms and involves multiple immune cell types. MIF inhibition remodels this immunosuppressive TIME and thus represents a promising therapeutic strategy to enhance the efficacy of immunotherapy or other targeted therapies in PDAC.

#6997 Defining mechanisms limiting NK cell function in the multiple myeloma tumor microenvironment.

Sadia Afrin, Michelle Becker-Hapak, Lyra Morina, Wilbur Song, Jennifer A. Foltz, Alice Zhou, Kunal Shetty, Yeeun Paik, Samuel Ameh, Emily Philips, Timothy Schappe, Mark Foster, Lynne Marsala, Sushanth Pureti, Yoo-Jin Ahn, David Russler Germain, Todd A. Fehniger

Washington University in St. Louis, St. Louis, MO

Natural killer (NK) cells are cytotoxic cells that have an intrinsic ability to mediate anti-tumor responses. However, the immunosuppressive tumor microenvironment (TME) can limit their efficacy. Multiple myeloma (MM) is a hematologic malignancy characterized by clonal proliferation of plasma cells within the bone marrow. There is a growing understanding that the tumor microenvironment (TME) is a critical factor influencing the effectiveness of cellular therapies. A hallmark characteristic of rapidly proliferating cancer cells is the production of a high amount of lactic acid. Myeloma cells also produce metabolites, including lactic acid, that suppress the effector function of T cells. How lactic acid affects NK cell function remains poorly understood. In this study, we hypothesize that increased lactic acid in the TME inhibits NK cell functionality and thereby serves as a key TME checkpoint on NK cell anti-tumor responses. To test this, primary conventional (c)NK cells and ML NK cells were exposed to varying concentrations of lactic acid and assessed for cytotoxicity, proliferation, and cytokine production in vitro. We observed that cNK cell IFN_γ production (P=0.0035) significantly decreased with 15mM lactic acid conditions compared to controls (0mM and 3mM). ML-differentiation resulted in a partial rescue of lactic acid-induced reductions in IFN_γ production (p=0.0417) observed in cNK cells. Next, we found that degranulation (measured via sCD107a) was significantly (P=0.0018) reduced in both cNK and ML NK cells under 15mM lactic acid treatment conditions compared to controls (0mM and 3mM). cNK and ML NK cytotoxicity were significantly decreased in 15 mM lactic acid compared to controls, with ML NK cells again exhibiting partial resistance to lactic-acid compromised killing. To investigate the impact of lactic acid on NK cell proliferation, we activated the NK cells with IL-12, IL-15, and IL-18 overnight and labeled them with cell trace violet (CTV) . CTV-labeled cells were incubated in media with lactate conc. By day 7, NK cell proliferation was abrogated with exposure to 15 mM lactic acid, while 40% of NK cells proliferated in control conditions (0mM or 3mM lactic acid). This data suggests that NK cell proliferation are suppressed with high lactic concentration. Our data further revealed that lactic acid (15mM) markedly suppressed IL-15-induced pSTAT5 signaling in cNK cells. In contrast, ML NK cells maintained higher pSTAT5 levels in response to IL-15 under high lactic acid (15mM) conditions, demonstrating greater resilience to this TME stress. Finally, we identified the acidity as the major driver of NK cell dysfunction induced by lactic acid by comparing it to sodium lactate and matched pH control conditions. These data suggest that lactic acid is a metabolic checkpoint on NK cells, and ML differentiation and strategies to insulate NK cells from lactic acid effects may improve NK cell anti-tumor responses.

#6998 Use of non-steroidal anti-inflammatory drugs, acetaminophen and somatic immune profiles in breast tumors.

Clara Bodelon[1], James Hodge[1], Daniel G. Stover[2], Melissa A. Troester[3], Lauren E. McCullough[4], Alpa V. Patel[1], Lauren R. Teras[1]

[1]American Cancer Society, Atlanta, GA,[2]OSUCCC - James, Columbus, OH,[3]Assistant Professor of Epidem., UNC Lineberger Comp. Cancer Center, Chapel Hill, NC,[4]Emory University, Rollins School of Public Health, Atlanta, GA

Background. Tumor-infiltrating lymphocytes (TILs) represent a prognostic biomarker in several cancers, including breast cancer. Enrichment of TILs may help to identify highly immunogenic and immune-vulnerable tumors that may be more responsive to immune-mediated mechanisms and are associated with improved outcomes. Recent data suggest that the use of acetaminophen may have immunosuppressive effects. In this study, we investigated the relationship between the use of common analgesics and immune profiles in breast tumors from patients within a population-based prospective cohort study.
Methods. This analysis was conducted among females with invasive breast cancer enrolled in the Cancer Prevention Study 3 (2006-2013). Use of non-steroidal anti-inflammatory drugs (NSAIDs), and acetaminophen was assessed at enrollment and follow-up surveys (2015 and 2019). Analgesic information came from the survey prior to, but closest in time to, their cancer diagnosis. Eligible patients were required to have formalin-fixed paraffin-embedded breast tumor samples available. Immune profiles were generated from tumor RNA using a previously published method to derive ten immune cell-type-specific scores plus a cytotoxic cell score from breast tumors. Linear regression was used to estimate the associations between each type of analgesic use and the immune scores, adjusting for age at diagnosis, stage, and estrogen receptor (ER) status. Multiple testing was addressed using the false discovery rate (FDR), with FDR<0.05 considered statistically significant.
Results. This analysis included 887 breast cancer patients with a median age at diagnosis of 58 years (interquartile range: 51, 63). At the time of diagnosis, most of the women were post-menopausal (61%), had ER positive tumors (80%) and localized disease (65%). Among the breast cancer survivors included in the analysis, 450 (51%) reported NSAID use and 137 (15%) acetaminophen use. Patients who reported use of NSAID had similar immune profiles to non-users (FDR>0.05). However, acetaminophen users had lower scores for T-cells, T helper cells, Treg cells, natural killer (NK) cells, neutrophils, eosinophils and cytotoxic T cells compared with non-users (FDR<0.05). Results among patients with ER-positive tumors were similar to the overall results with the exception that the CD8+ T cell score was also significantly lower among acetaminophen users (FDR<0.05). Among women with ER-negative tumors, there was no difference in immune profiles between NSAID users and non-users. Only NK cell, neutrophil, and eosinophil scores were significantly lower among acetaminophen users compared with non-users (FDR<0.05).
Conclusions. NSAID use does not appear to influence the breast tumor immune microenvironment. In contrast, we observed that acetaminophen use lowers the scores of multiple immune cell types, including those related to improved prognosis.

#6999 GDF-15 inhibition overcomes treatment resistance to platinum- and taxane-based cytotoxic chemoimmunotherapy.

Neha Vashist[1], Amelie Kohler[1], Daniel Schatzlein[1], Sabrina Gen?ler[1], Katja Rungger[2], Hubert Hackl[2], Matthias Kist[1], Sarah Lutzenberger[1], Julia Weigandt[1], Jose Medina-Echerverz[1], Christine Schuberth-Wagner[1], **Thorsten Ross**[1]

[1]CatalYm GmbH, Planegg, Germany,[2]Institute of Bioinformatics, Medical University of Innsbruck, Innsbruck, Austria

Background: GDF-15 is a stress-induced cytokine that restricts $CD8^+$ T cell infiltration, drives immunotherapy resistance, and mediates chemotherapy-induced nausea, emesis, anorexia, and cancer cachexia. Durable responses to GDF-15 blockade have been reported in PD-1-refractory NSCLC and UC, supporting its role as a clinically relevant mediator of immune escape. Because platinum agents and other DNA-damage-inducing therapies strongly upregulate GDF-15, we investigated whether therapy-induced GDF-15 limits the antitumor activity and tolerability of combined PD-1 blockade and cytotoxic chemotherapy.
Methods: Human tumor cell lines were treated with platinum compounds, docetaxel, and a panel of DNA-damage inducers, DNA-damage-repair inhibitors, and cell-cycle and transcriptional stress-inducing agents, and GDF-15 secretion was quantified. Syngeneic MBT-2 and MC-38 models received cisplatin or docetaxel plus anti-PD-1, with or without a GDF-15-neutralizing antibody. Tumor growth, survival, body weight, serum GDF-15, intratumoral immune populations, and peripheral CD8+ T cell activation were analyzed by ELISA, flow cytometry, bulk RNA sequencing, and single-cell RNA sequencing.
Results: A broad range of DNA-damage-inducing, DNA-damage-repair-inhibitory, and cell-cycle stress-inducing agents robustly induced GDF-15 in vitro. In vivo, cisplatin plus anti-PD-1 markedly increased systemic GDF-15 but yielded limited tumor control. Adding GDF-15 blockade substantially delayed tumor growth, extended survival, and fully prevented cisplatin-associated weight loss. Single-cell RNA sequencing demonstrated increased intratumoral $CD8^+$ T cell infiltration. scRNA-seq and bulk RNA sequencing together showed enrichment of activation, co-stimulation, cytotoxicity, and TCR-signaling programs (Lck, Fyn, Zap70, Lat; Gzmb, Prf1; CCL5). Flow cytometry confirmed increased peripheral $CD8^+$ T cell proliferation ($Ki67^+$) and a higher proportion of activated effector $CD8^+$ T cells, including increased PD-1 expression. Bulk RNA-seq revealed an M2-like macrophage signature (CD163, Chil3, Retnla, Marco, Rnase2a) in chemoimmunotherapy-treated tumors, and flow cytometry showed reduced cDC1 activation; both were reversed by GDF-15 blockade.
Conclusions: These findings suggest that therapy-induced GDF-15 contributes to resistance to platinum- and taxane-based PD-1 combinations and may exacerbate treatment-related toxicity. Neutralizing GDF-15 restores antitumor $CD8^+$ T cell immunity, reprograms suppressive myeloid states, and improves the overall activity and tolerability of combined PD-1 blockade and cytotoxic chemotherapy. GDF-15 inhibition therefore holds potential to enhance responses to first-line chemoimmunotherapy in tumors such as NSCLC and UC.

#7000 Genome-wide CRISPR screening reveals tumor-intrinsic immune evasion mechanism in ovarian cancer.

Junyong Park[1], Jiho Lee[1], Hyun Ju Kang[2], Jin-Ku Lee[1]

[1]Department of Biomedical Sciences, Seoul National University, Seoul, Korea, Republic of,[2]Genomic Medicine Institute, Medical Research Center, Seoul National University, Seoul, Korea, Republic of

Ovarian cancer is the most lethal gynecologic malignancy. Previous studies demonstrated high levels of tumor-infiltrating T cells in ovarian cancer, which predict benefit from immunotherapy. However, clinical trials such as KEYNOTE-100 report only ~10% overall response to pembrolizumab. This discrepancy indicates that ovarian cancers harbor heterogeneous, tumor-intrinsic mechanisms of immune evasion.To distinguish immune-resistant cancer cell lines, we established a reporter-based co-culture platform in which pre-activated human T cells were directly co-cultured with ovarian cancer cell lines. We profiled 24 ovarian cancer cell lines engineered with a real-time cytotoxicity reporter to quantify tumor-cell death. Pre-activated T cells from two healthy donors were co-cultured with each cancer cell line, and reporter readouts stratified the set into 11 immune-sensitive and 6 immune-resistant lines. To uncover genetic determinants of resistance, we selected the two most resistant cell lines for whole-genome CRISPR screening. Following co-culture of CRISPR-edited cancer cells with pre-activated T cells, sgRNA abundances were sequenced and analyzed using the MAGeCK-MLE pipeline. Focusing on concordant depletions, we identified 56 genes ($P < 0.05$; $\beta < -0.5$) whose loss augments T-cell-mediated tumor killing in both cell lines. Among these, we prioritized ITGA8 (integrin α8) as a promising surface target. ITGA8 heterodimerizes with β1 to form α8β1, which engages extracellular-matrix ligands and activates adhesion- and survival-linked signaling axes, including FAK/Src. Given that integrins regulate immune-cell infiltration into tumors and pathways such as TGF-β signaling, we hypothesize that ITGA8 sustains pro-survival signaling that constrains T-cell activity. Accordingly, pharmacologic or biologic blockade of ITGA8 may offer a surface-accessible strategy to convert immune-resistant ovarian tumors into immune-sensitive disease.

#7001 Tumor-intrinsic suppression of phagocytosis by RRP1 (ribosomal RNA processing 1) in glioblastoma.

Eshika Kudaravalli, Amr Elkholy, Mostafa Mohamed, Hasan Alrefai, Saeed Zakakhosravi, Satoru Osuka, Christopher D. Willey, Erin Ahn

University of Alabama at Birmingham, Birmingham, AL

Glioblastoma (GBM) is the most aggressive and common malignant brain tumor in adults, with a median survival of just 14.6 months. Standard treatment, comprising maximal surgical resection followed by radiation and temozolomide, offers limited long-term benefit, highlighting the urgent need for more effective therapies. While other cancers have seen promising advances through T-cell immunotherapy, GBM has remained stubbornly resistant, largely due to its immunosuppressive microenvironment dominated by tumor-associated macrophages (TAMs). These macrophages, instead of engulfing tumor cells, are often hijacked to support tumor growth and evade immune clearance. GBM evades immune clearance in part by expressing “don’t eat me” signals such as CD47; however, clinical trials of anti-CD47 therapy in leukemia faced challenges, including toxicity and limited therapeutic efficacy. This gap in effective TAM-targeted therapies highlights an urgent need to uncover new, safer targets that could restore macrophage function.

To address this, we performed a genome-wide CRISPR knockout screen in GBM cells (MGG18-RR) using human peripheral blood-derived macrophages polarized by GBM-conditioned media to identify tumor-intrinsic genes that inhibit macrophage phagocytosis. Our cytometry imaging results demonstrated that tumor-conditioned macrophages adopted distinct polarization profiles relative to unpolarized macrophages, thus establishing them as a more reliable experimental model. Our screen revealed RRP1 (ribosomal RNA processing 1) as a key regulator suppressing macrophage clearance of GBM cells. Proteomic data from the Clinical Proteomic Tumor Analysis Consortium (CPTAC) and the International Cancer Proteogenome Consortium (ICPC) showed that the RRP1 protein was increased in GBM tumors compared to normal brain tissue, indicating RRP1 upregulation as a feature of the GBM proteome. However, RRP1’s role in GBM phagocytosis remains unknown. Thus, to validate RRP1 as a therapeutic target in-vitro, we engineered RRP1 KO GBM cells (JX14P-RT) labeled with pHrodo dye which emits fluorescence when cells are phagocytosed. We performed this in-vitro phagocytosis assays with human peripheral blood-derived macrophages and RAW 264.7 macrophages, co-culturing a ratio of 200K macrophages per 1 million JX14P-RT cells for 20 hours. Co-cultures of CD47-KO-JX14P-RT tumor cells and macrophages were used as a positive control, and co-cultures of CD47-KO-JX14P-RT tumor cells and macrophages with Cytochalasin D, a known phagocytosis inhibitor, were used as negative control. Phagocytosis was quantified by the total Texas Red fluorescent signals. We found that loss of RRP1 significantly increased tumor cell engulfment ($p < 0.05$).

Together, these findings highlight RRP1 as a promising immunotherapeutic target and support further investigation of RRP1 inhibition in vivo using syngeneic murine GBM models.

#7002 Immune evasive characteristics of the KRAS mutant colorectal cancer tumor microenvironment.

Elizabeth A. Boeree[1], Katherine A. Johnson[1], Cheri A. Pasch[1], Dustin A. Deming[2]

[1]Univ. of Wisconsin Madison Sch. of Med. & Public Health, Madison, WI,[2]University of Wisconsin Carbone Cancer Center, Madison, WI

Background: Recent clinical trials have indicated that KRAS mutant colorectal cancer (CRCs) are more resistant to combination immunotherapy approaches compared to KRAS wild-type (WT) microsatellite stable (MSS) CRCs, potentially related to an immune suppressive tumor microenvironment (TME). Here, we investigate the TME of MSS KRAS mutant CRCs to characterize the immune-related signaling pathways and factors that modulate the immune evasive TME associated with KRAS mutant CRCs.
Methods: A gene-set enrichment analysis (GSEA) on the Colorectal Adenocarcinoma (TCGA, PanCancer Atlas) dataset was performed to identify differential gene expression patterns between patients with MSS CRCs with or without a KRAS mutation. A second GSEA analysis explored RNA expression data from the NCI Patient-Derived Models Repository (PDMR) database of matched patient organoid and whole tumor samples from KRAS mutant and WT CRCs.
Results: A total of 496 MSS CRC subjects were identified in the TCGA dataset. KRAS mutant CRCs (195) were compared to a WT cohort consisting of patients lacking a KRAS, NRAS, or BRAF mutation (255). KRAS enriched gene sets (FDR q-value<0.25) included hallmark mitotic spindle, p53 pathway, glycolysis, oxidative phosphorylation, reactive oxygen species pathway, and estrogen response late. The WT cohort had enrichment of immune-related gene sets, including hallmark allograft rejection, inflammatory response, and IL6 JAK STAT3 signaling. Significantly expressed genes (q-value<0.05) in the KRAS enriched gene sets were involved in TGF-beta signaling (TGFB1 (Log2FC: 0.85), EPHA2 (0.4), KLK11 (1.47), INHBE (0.51)), M2-macrophage recruitment (KLK10 (1.24), CA12 (0.75), KLK8 (0.79), and immune exclusion (CD44(0.35), LAMC2 (0.43), KLK8 (0.79), NT53/CD73 (0.66)). Genes upregulated in the WT cohort were associated with immune cell activation and T-cell regulation (GZMB (0.83), MERTK (0.66), PROCR (0.59), CD40 (0.48)), M1-macrophages (AK4 (0.65)), and immune infiltration (SPAG4 (0.49)). RNA expression data from the PDMR database was analyzed from patients with APC and TP53 mutations with or without a KRAS mutation (three patients/cohort). GSEA revealed that immune-related gene sets were significantly enriched in WT tumors including interferon gamma/alpha response, TNFA signaling via NFKB, complement, allograft rejection, and inflammatory response. When immune TME signaling was isolated by separating gene expression present in the organoid data from the original tumor samples, similar results were observed.
Conclusion: KRAS mutant CRCs are characterized by an immune suppressive TME. Further analysis of the pathways and genes driving this phenotype will help identify actionable therapeutic targets to improve immunotherapy responses for these patients.

#7003 The RKIP-HER2 axis regulates breast cancer immune evasion.

Ania Khachikian, Mai Ho, Benjamin Bonavida

Microbiology, Immunology & Molecula Genetics, UCLA - University of California Los Angeles, Los Angeles, CA

Introduction: Breast cancer (BC) is a prevalent malignancy worldwide among women. HER2 overexpression in a subset of BC (HER2+ BC) serves as a critical oncogenic driver and contributes to immune evasion. The Raf Kinase Inhibitor Protein (RKIP), a metastasis suppressor and an immune enhancer, is under-expressed in HER2+ BC. Treatment of HER2+ BC with anti-HER2 mAbs or chemical inhibitors has resulted in significant clinical responses in a subset of patients. However, acquired and induced resistance in HER2+ BC patients highlights the need for new effective therapies.
Procedure: We have analyzed the signaling pathways mediated by both RKIP and HER2 and have found that RKIP and HER2 inductions and downstream signaling showed inverse cross-talks.
Findings: The inverse cross-talks enabled us to establish a dysregulated RKIP-HER2 axis in HER2+ BC. The role of this dysregulated axis in immune evasion was examined. HER2 expression positively regulates immune evasion as it is involved in the expression of PD-L1, the polarization of TAMs, the infiltration of suppressor cells (Tregs, MDSCs), the inhibition of anti-tumor CD8T cells, and an overall immunosuppressive TME. In contrast, RKIP inhibits critical signaling pathways that regulate HER2 expression, including the Raf-MEK-ERK, NF-κB, and PI3K/Akt pathways, thereby preventing immune evasion. The inverse functional relationship between RKIP and HER2 was further supported by bioinformatic analyses that examined expressions and correlations by proteomics and survival analyses.
Conclusion: Various therapeutic strategies are proposed aimed at targeting the dysregulated RKIP-HER2 axis in HER2+ BC to circumvent resistance and immune evasion.

#7005 Tumor cell CEBPB expression contributes to T cell-mediated immune evasion of microsatellite stable colorectal cancer.

Hye Jeong Yun[1], Chan Ho Park[2], Dahye Yun[1], Hye-Ri Shin[3], Naeun Park[1], Changhee Park[4], Jeong Dong Lee[1], Kiyeon Kim[2], Heejun Shim[2], Hyejin Sim[1], Se Min Kim[1], Min Jung Kim[5], Ji Won Park[5], Seung-Bum Ryoo[5], Yoojoo Lim[6], Seung-Yong Jeong[5], Kyu Joo Park[5], Tae-You Kim[4], Junil Kim[2], Jae-Kyung Won[3], Sae-Won Han[4]

[1]Cancer Research Institute, Seoul National University Hospital, Seoul, Korea, Republic of,[2]Department of Bioinformatics, Soongsil University, Seoul, Korea, Republic of,[3]Department of Pathology, Seoul National University Hospital, Seoul, Korea, Republic of,[4]Department of Internal Medicine, Seoul National University Hospital, Seoul, Korea, Republic of,[5]Department of Surgery, Seoul National University Hospital, Seoul, Korea, Republic of,[6]Lunit, Seoul, Korea, Republic of

Background: Microsatellite stable (MSS) colorectal cancer (CRC), which accounts for approximately 80-85% of all colorectal cancer cases, exhibits a poor response to immune checkpoint inhibitors. Tumor protein 53 (*TP53*) mutations are frequently observed in colorectal cancer and may contribute to tumor-driven immunosuppression. In this study, we aimed to investigate the immunosuppressive mechanisms associated with *TP53* mutations in MSS CRC.

Methods: We performed single-cell RNA sequencing (scRNA-seq) on tumor samples from 30 CRC patients and *Trp53*- knockout (KO) CT26 tumors in syngeneic mice to profile the tumor microenvironment and analyze tumor cell gene expression profiles based on *TP53* mutation status. We identified CCAAT enhancer-binding protein beta (*CEBPB*) as a potential immunosuppressive factor associated with *TP53*-mutant CRC. To demonstrate the role of *CEBPB* in T cell immunosuppression, we analyzed T cell-tumor cell co-cultures and *CEBPB*-overexpressing (oe) tumor-injected syngeneic mouse models by flow cytometry.

Results: scRNA-seq analysis of 30 CRCs revealed increased proportions of $CD4^+$ T cell subsets, including Treg, Th17, and Tcm cells, in *TP53* mutant tumors. Immune activation pathways, such as the immune system and interferon-gamma response, were down-regulated in T cells compared to *TP53* wild-type tumors, suggesting that *TP53* mutations might contribute to immune evasion by negatively affecting T cells. scRNA-seq analysis of *Trp53*-KO CT26 tumors identified *CEBPB* as notably upregulated, and we confirmed that loss of *Trp53* WT led to increased *CEBPB* mRNA expression and protein stability in CRC cell lines. *CEBPB* expression was associated with reduced $CD4^+$ T cell infiltration and positively correlated with cytotoxic T lymphocyte-associated protein 4 (*CTLA4*) expression in regulatory T cells (Treg) and exhausted T cells (Tex). *CEBPB*-oe CT26 tumors in syngeneic mice showed reduced $CD4^+$ T cell infiltration and upregulation of CTLA-4 expression on $CD4^+$ T cells *in vivo*. Consistently, spleen T co-cultured with *CEBPB*-overexpressing CT26 cells showed increased CTLA-4 expression and decreased proliferation of $CD4^+$ T cells.

Conclusion: Tumor cell *CEBPB* expression, upregulated by *TP53* mutation, may mediate T cell-mediated immunosuppression and is considered as potential therapeutic target for regulating immune evasion in MSS CRC.

#7006 Inhibiting intracellular cPLA2α in cervical cancer cells enhances antitumor immunity and facilitates the efficacy of anti-PD1 checkpoint immunotherapy.

Yuchao He, Xiangdong Tian, Liwei Chen, Yi Luo, Yu Wang, Lu Chen, Hua Guo

Tianjin Medical Univ. Cancer Inst. & Hospital, Tianjin, China

Immunotherapy has emerged as a breakthrough in treating cancer. However, only a limited subset of patients responds to the treatment and maintain a long-term response. Hence, there is an urgent need to explore the mechanisms of tumor resistance to immune checkpoint blockade (ICB) to identify effective targets and develop efficient combination therapies. Here, we demonstrate genetic ablation of cPLA2α in tumor cells profoundly inhibits tumor growth and prolongs survival in immunocompetent mice but shows minimal effect in immunodeficient mice, implicating the critical role of the adaptive immune system. Wild-type (WT) and cPLA2α-knockout (KO) tumors are profiled by single-cell RNA sequencing, revealing significant differences in genome-wide transcription and the presence of cancer cells, macrophages, and T cells. To elucidate the multifaceted regulatory functions of cPLA2α, we performed multiple functional perturbations, uncovering that: cPLA2α-high tumor cells drive ferroptosis-associated oxidative lipid metabolism via the SLC7A11/ALOX12 axis, leading to 12-HETE accumulation; these lipids are taken up by macrophages via GPR31 to induce M2-like polarization; concurrently, ferroptosis processes in tumor cells suppress the levels of effector factors GZMB in $CD8^+$ T cells. Both effects exert potent immunosuppressive activity, collectively forming a barrier against T cell attack. In contrast, cPLA2α-KO cancer cells downregulate 12-HETE production, promote the polarization of $MKi67^+$ M1-like macrophages, accompanied by upregulation of CXCL16 expression; meanwhile, cPLA2α-KO facilitates the differentiation of T cells into effector memory $CD8^+$ T cells with elevated CXCR6 level. Cell-cell communication analysis reveals that M1-like macrophages and T cells primarily interact via the CXCL16-CXCR6 axis, which facilitates $CD8^+$ T cell recruitment and activation. Furthermore, cPLA2α-KO increases the infiltration of effector memory $CD8^+$ T cells into tumors, triggers $CD8^+$ T cell-mediated control of tumor growth, enhances their cytotoxic functions (e.g., IFNG, GZMB), and reduces the proportion of naïve $CD8^+$ T cells. Loss of cPLA2α enhances T cell proliferation, activation, and the sensitivity of tumor cells to $CD8^+$ T cell cytotoxicity *in vitro*. Depleting $CD8^+$ T cells *in vivo* largely rescues the tumor growth induced by cPLA2α-KO, confirming that $CD8^+$ T cells are responsible for the antitumor effect. Notably, the cPLA2α cancer signature serves as a prognostic indicator for survival and shows an inverse correlation with T cell infiltration intensity in cervical cancers, consistent with its immunosuppressive effects, and targeting cPLA2α synergistically enhances anti-PD1 immunotherapy efficacy. Therefore, disrupting cancer cell cPLA2α-mediated immune escape may offer potential therapeutic strategies to enhance antitumor immunity.

#7007 Hypoxia-mediated suppression and memory of IFI44L and its interaction with STING in breast cancer metastasis and immune evasion.

Rebecca Marker[1], Aidan Moriarty[2], Remi Klotz[3], Min Yu[4]

[1]University of Maryland, Baltimore, Baltimore, MD,[2]University of Maryland School of Medicine, Baltimore, MD,[3]University of Maryland Baltimore, Baltimore, MD,[4]University of Maryland, Baltimore, MD

Solid tumors often contain patches of hypoxic regions that yield aggressive, pro-metastatic phenotypes. Prevention and understanding of metastases is critical for the future of breast cancer research, as metastatic cancer is extremely difficult to manage and treat. Recent work in our lab has shown that long-term hypoxia suppresses type I interferon (IFN) signaling in breast cancer cells. Even upon reoxygenation, these gene expression changes are maintained, indicative of “hypoxic memory.” Breast cancer cells that have disseminated from the primary tumor as circulating tumor cells with this “post-hypoxic” memory phenotype show enhanced metastatic potential. IFNs typically boost and enhance immune cell activity through interferon-stimulated genes (ISGs); thus, hypoxic suppression of IFN signaling yields an immunosuppressive tumor microenvironment. More research is needed to understand how ISGs are downregulated in hypoxia and how those changes in gene expression contribute to immunosuppressive ability of hypoxic and post-hypoxic cells. Interferon-inducible 44-like (IFI44L) is an ISG that has been associated with tumor-suppressive properties, and correlated with presence of tumor-infiltrating lymphocytes in other cancers, but its role in breast cancer has not been studied. We found that IFI44L is significantly suppressed in breast cancer cells in hypoxia and maintained after reoxygenation as a hypoxic memory. To understand the implications of hypoxic memory and suppression of IFI44L, we generated IFI44L overexpression and knockdown models in MCF7 and NT2.5 breast cell lines, and Brx68s, a circulating tumor cell line. We discovered that in adherent MCF7 cells, IFI44L OE significantly increases STING expression, whereas in suspension circulating tumor cells, IFI44L OE suppresses STING expression. We see that IFI44L does not impact canonical STING signaling molecules, pIRF3 and pTBK1. The consequences and mechanisms of STING regulation by IFI44L are unknown and experiments are ongoing in the lab to address these questions; in vivo studies of IFI44L are ongoing to elucidate the impact this gene has on tumor formation and metastasis. We expect to see that IFI44L OE has a tumor suppressive mechanism, and expect the opposite with IFI44L KO. Additionally, we plan to investigate STING regulation by IFI44L and the possible impact that this has on immune evasion and metastasis.

#7008 Multi-omic analysis nominates SPP1-IL10 axis as a novel immunotherapeutic target in gastric peritoneal carcinomatosis.

Turcios Lilia[1], Neelima Hosamani[1], Ellen Beswick[2], Joseph Kim[1], **Mautin Barry-Hundeyin**[1]

[1]University of Kentucky, Lexington, KY,[2]University of New Mexico, Albuquerque, NM

Gastric cancer is 3rd leading cause of cancer-related mortality worldwide. The peritoneum is the most common site of metastasis, accounting for 60% of recurrences. Peritoneal carcinomatosis results in 65% of gastric cancer-associated deaths, resulting in a median overall survival of 6-9 months. Therefore, identifying novel therapies remains a clinically unmet need. SPP1 (osteopontin) is a glycoprotein involved in diverse biological functions. It is secreted by benign and malignant cells. Its role in gastric carcinomatosis is not well defined. Utilizing publicly available transcriptomic datasets, we show that SPP1 is overexpressed in gastric peritoneal metastasis and malignant ascites. Bulk and single-cell analysis demonstrated that SPP1 expression positively correlated with macrophage infiltration in the tumor microenvironment. SPP1 mutant tumors were enriched for macrophage-excluded phenotype. In conjunction with the human data, cytokine array analysis identified elevated SPP1 secretion by murine gastric tumor cells. Recombinant SPP1 promoted macrophage migration and inhibited the secretion of IL-10 in-vitro. Intercellular signaling networks from single-cell sequencing data sets of human malignant ascites revealed SPP1+ epithelial cells regulate macrophage expression of IL-10. Using syngeneic murine models of gastric peritoneal carcinomatosis, we observed that targeted SPP1 blockade diminished tumor growth as demonstrated by a 50% decrease in tumor weight and number of peritoneal nodules. In addition, in-vivo macrophage trafficking and secretion of IL-10 were inhibited by SPP1 blockade. In summary, we have uncovered a novel mechanism of cancer-macrophage crosstalk, suggesting that targeting SPP1 may be effective for reprogramming of the tumor microenvironment in gastric peritoneal carcinomatosis

#7009 From correlation to causation: SOX11 drives a coordinated immune-suppressive network that represses antigen presentation in triple-negative breast cancer.

Salomat Abdulkhuseynova[1], Ashok Pullikuth[2], Lance D. Miller[2]

[1]Wake Forest Institute for Regenerative Medicine, Wake Forest University School of Medicine, Winston Salem, NC, [2]Wake Forest University School of Medicine, Winston Salem, NC

Background: Triple-negative breast cancer (TNBC) is an aggressive subtype with no targeted therapies and limited response to immunotherapy. TNBC evades immune surveillance by repressing antigen presentation machinery (APM) genes, reducing MHC Class I expression. Using bioinformatics, we identified SOX11 as a potential transcriptional regulator associated with APM suppression and immune evasion in TNBC.
Methods: We analyzed gene expression data from basal breast cancer (BRCA) tumors (n = 189) in TCGA and cancer cell lines (n = 1,189) in DepMap. Spearman correlation coefficients were used to evaluate associations between a T-cell infiltration signature and an APM signature. SOX11 was prioritized as it was strongly negatively correlated with both signatures. To identify downstream effectors, we performed RNA-seq analysis on SOX11 knockdown (KD) CAL-148 cells (high endogenous SOX11) and integrated these results with publicly available SOX11-overexpression and KD datasets. To validate key targets, SOX11 KD and MEX3A KD were performed using siRNA, followed by flow cytometry to measure surface MHC Class I (HLA-ABC) expression.
Results: SOX11 was strongly inversely correlated (rho < -0.4, adjusted $p < 0.01$) with APM and T-cell infiltration signatures in basal BRCA and DepMap datasets. In basal BRCA tumors, SOX11 expression was enriched in T-cell cold tumors ($p < 0.01$). Analysis of our SOX11 KD RNA-seq data, integrated with public SOX11-modulated datasets, revealed a highly reproducible SOX11-driven gene signature. This signature was notably enriched for known suppressors of innate immunity. Among the most consistent SOX11 targets were genes implicated in **destabilizing HLA-A (MEX3B)**, **degrading innate immune sensors (MEX3A)**, activating **immunosuppressive signaling (SBK1)**, and facilitating **epigenetic silencing of interferon pathways and APM (RCOR2, NELL2)**. Consistent with this, SOX11 KD in CAL-148 cells significantly increased surface HLA-ABC expression. Furthermore, targeted knockdown of its effector, **MEX3A**, also resulted in a significant increase in APM gene expression.
Conclusions: SOX11 suppresses HLA-A/B/C expression and contributes to immune evasion in TNBC. Its high expression in T-cell cold tumors and its regulation of multiple APM-suppressive targets highlight its potential as a therapeutic target. We hypothesize that SOX11-mediated APM repression is not driven by a single gene but by the concerted activity of this multi-effector network. Targeting SOX11 or its key effectors could restore antigen presentation, promote immune recognition, and enhance immunotherapy responses in TNBC.

#7010 Trogocytosis-orchestrated CLDN18.2-dressed CD8$^+$ T cells drive pancreatic cancer progression via glucose metabolic reprogramming-induced cytotoxicity debilitation and systematic immune senescence-cascade.

Jingrui Yan[1], Tianxing Zhou[2], Jun Yu[1], Jihui Hao[1]

[1]Tianjin Medical Univ. Cancer Inst. & Hospital, Tianjin, China,[2]Tianjin Medical Univ. Cancer Inst. & Hospital, He Xi Qu, China

Background: CLDN18.2 is an established therapeutic target in gastrointestinal cancers; however, a significant proportion of CLDN18.2-positive tumors do not respond to treatment. While its expression has been extensively studied in epithelial cells, the expression, functional role, and regulatory mechanisms of CLDN18.2 in immune cells remain unexplored.

Results: Challenging the conventional paradigm that CLDN18.2 is exclusively epithelial, we report for the first time the presence of CLDN18.2 protein on CD8$^+$ T cells within tumors. Tumor-derived CLDN18.2 is transferred to T cells via ALCAM-CD6-mediated trogocytosis, a process requiring cell-cell contact. Its acquisition correlates with poor prognosis and resistance to immunotherapy in PDAC. In T cells, trogocytosed CLDN18.2 binds directly to β-catenin, recruits the CK1α/GSK3β complex, and promotes β-catenin phosphorylation, recognition by β-TrCP, and subsequent ubiquitin-proteasome degradation, thereby attenuating Wnt/β-catenin signaling. This suppression induces metabolic reprogramming characterized by reduced glucose uptake and glycolytic activity, resulting in impaired T-cell proliferation, activation, granzyme B and IFN-γ production, and overall cytotoxic function. Furthermore, CLDN18.2$^+$ CD8$^+$ T cells exhibit enhanced homing to the bone marrow via CXCL12/CXCR4 signaling, secrete IL-1α, promote hematopoietic stem cell myeloid skewing (expanding GMP/MDP populations), and contribute to systemic immune senescence, collectively dampening antitumor immunity. Based on the CLDN18.2-β-catenin interaction, we developed a peptide inhibitor, PC18.1, which disrupts this signaling axis, reverses glycolytic suppression, restores effector T-cell function, mitigates immune senescence, and synergizes with anti-PD-1 therapy to inhibit PDAC progression in vivo.

Conclusions: Our findings reveal CLDN18.2 as a metabolic immune checkpoint transmitted via trogocytosis from tumor to T cells: transfer of CLDN18.2 inhibits β-catenin signaling, suppresses glycolysis, compromises T-cell cytotoxicity, and induces systemic immune senescence. Therapeutic targeting of the CLDN18.2-β-catenin interface—for instance, with PC18.1—reinvigorates T-cell function and represents a promising strategy for improving treatment outcomes in CLDN18.2-high solid tumors.

#7011 ROCK2-regulated LIF-STAT3 drives immunosuppression in pancreatic cancer.

Varunkumar Krishnamoorthy[1], Sudhakar Jinka[1], Siddharth Mehra[1], Phuong Hong Ngoc Tao[2], Daysi Daniela Manrique[3], Rimpi Khurana[4], Yuguang Ban[4], Vineet Kumar Gupta[1], Austin Dosch[1], Nagaraj Nagathihalli[1]

[1]Department of Surgery, University of Miami Miller School of Medicine, Sylvester Comprehensive Cancer Center, Miami, FL,[2]Department of Microbiology and Immunology, University of Miami, Miami, FL,[3]Department of Biochemistry and Molecular Biology, University of Miami Miller School of Medicine, Miami, FL,[4]Department of Public Health Sciences, University of Miami Miller School of Medicine, Miami, FL

Background: Immunosuppression is a key characteristic of pancreatic ductal adenocarcinoma (PDAC), contributing to metastasis and poor survival. Our studies have identified tumor cell intrinsic Rho-associated coiled-coil containing protein kinase-2 (ROCK2) as a key regulator of extracellular matrix remodeling. In this study, we investigated how ROCK2 regulates immunosuppression in PDAC by modulating Leukemia inhibitory factor (LIF) and its effects on STAT3.

Methods: TCGA PDAC patient dataset was used to compare the ROCK2 and LIF expression in normal and PDAC tissues. CIBERSORT analysis of the PDAC dataset estimated the proportion of tumor infiltrating immune cell subsets. Genomic editing using the CRISPR/Cas9-system in LSL-$Kras^{G12D/+}$; $Trp53^{R172H/+}$; $Pdx1^{Cre/+}$ (KPC) cells was performed to generate KPC Rock2 knockout ($Rock2^{KO}$) cells. Cytokine array was performed on $Rock2^{EV}$ and $Rock2^{KO}$ conditioned media and ELISA was used to validate the results. Flow cytometry was used to profile LIF receptor (LIFR) expression in different cell types from KPC orthotopic tumors. Bone marrow-derived macrophages from C57BL/6 mice were treated with recombinant LIF (rLIF) and LIFR inhibitor (EC359), then analyzed for polarization by flow cytometry. KPC orthotopic tumors were generated, and Immune cell profiling was performed to evaluate alterations in immune cell subsets following treatment with EC359. Findings from ROCK2 and ROCK2-regulated LIF-STAT3 targeting, both in vitro and in vivo were validated using Immunoblotting and immunohistochemistry.

Results: Analysis of the TCGA dataset revealed that Human PDAC tissues have increased expression and correlation of ROCK2 and LIF. Further analysis showed that macrophages constitute a substantial proportion of the immune cell infiltrate. Cytokine array and ELISA-based studies revealed decreased LIF secretion with ROCK2 knockout, providing evidence for ROCK2 dependent regulation of LIF. KPC orthotopic tumors demonstrated higher LIFR expression in tumor-associated macrophages (TAMs) and EC359 treatment reduced ARG1 and PD-L1 expression on these cells. Additionally, EC359 treatment led to a significant increase in the activated effector and effector memory T cell populations. Furthermore, rLIF treatment increased pSTAT3 levels in macrophages, while EC359 lowered its expression, highlighting the role of ROCK2-regulated LIF-LIFR in STAT3 activation.

Conclusion: These findings demonstrate that tumor cell-intrinsic ROCK2 regulates LIF-STAT3, which mediates immunosuppression and can serve as a potential therapeutic target for PDAC.

#7012 Single-cell multi-omics identifies MRD-associated Tr1-like CD4 cells in B-ALL.

Qianyun Luo, Rebecca LaRue, Enoc Granados Centeno, Kyra Bergerud, Michael Farrar, Sean Tracy

University of Minnesota, Minneapolis, MN

Background: The persistence of measureable residual disease (MRD) after frontline chemotherapy in B-cell acute lymphoblastic leukemia (B-ALL) predicts relapse, yet the mechanisms allowing leukemic persistence remain unclear. Despite endogenous leukemia-specific T-cell response, these effector populations fail to eliminate MRD, suggesting active immune evasion. A major unmet need is to define immune programs that enable MRD survival and relapse after chemotherapy and CD19-directed immunotherapies. We aim to delineate the immune mechanisms underlying leukemic immune escape, leveraging a ~350,000-cell single-cell multiomics dataset generated from early-treatment bone marrow aspirates containing residual leukemia.

Methods: Bone marrow aspirates from 11 patients (collected within 100 days of diagnosis; MRD 0-20%) and 2 healthy controls were profiled using the 10x Chromium Flex platform with TotalSeq-C antibodies. Samples were enriched for $CD19^+$ blasts, $CD3^+$ T cells, and non-B/non-T populations, uniquely barcoded, fixed, probe-hybridized, and multiplexed into four captures, yielding ~350,000 cells with RNA + protein profiles. Data were processed with Cell Ranger and analyzed in Seurat. TCR-driven activation was quantified using the TCAT Antigen-Specific Activation (ASA) score.

Results: Across all samples, we observed that all major immune cell lineages in leukemia samples segregated distinctly from healthy controls. Two subsets of highly activated CD4+ T-cells were observed, and both subsets corresponded to known regulatory/suppressive populations. These included a FOXP3+ T-regulatory (Treg) subset, and a FOXP3- IL10+ Type-1 regulatory (Tr1) like population. While FOXP3+ Tregs were also observed in healthy control samples, Tr1 like cells were found only in samples from patients with leukemia. Among CD8+ T-cells, we predominantly observed transcriptomic signatures of early activation and effector/memory features. Only small frequencies (0.01%) of CD8+ T-cells expressed an exhausted phenotype (PD1+/TIM3+/LAG3+), and cells in this subset continued to express TCF7, consistent with an early-progenitor-exhausted state, rather than terminal exhaustion.

Conclusion: At an early-treatment timepoint, the MRD microenvironment undergoes extensive immune remodeling. Activated CD4+ T-cells are dominated by regulatory/suppressive subsets including transcriptionally distinctive FOXP3+ Treg subsets and a unique population of Tr1 like population that expands with increasing MRD, suggesting a dynamic role in immunosuppression. Conversely, CD8+ T-cell display signatures of suboptimal activation, without evidence of terminal exhaustion. Overall, suppressive $CD4^+$ programs appear to limit effective anti-leukemia immunity and may facilitate relapse.

#7014 SPIN1 drives PD-1 immunotherapy resistance in gastric cancer by inducing M2 macrophage polarization and suppressing CD8⁺ T-cell immunity.

Beibei Lyu[1], Zijun Yidan Xu-Monette[2], Xiaoyan lin[1]

[1]Shandong Provincial Hospital Affliated to Shandong First Medical University, Jinan, China,[2]Duke University Medical Center, Durham, NC

Introduction: Resistance to anti-PD-1 therapy remains a major obstacle to improving outcomes in gastric cancer (GC). Although the chromatin reader SPIN1 has been implicated in tumor progression, its contribution to shaping the tumor immune microenvironment (TIME) and driving immunotherapy resistance is not well understood. This study aimed to elucidate how SPIN1 modulates immune components within the TIME to promote resistance to PD-1 blockade.

Experimental Procedures: SPIN1 expression and immune infiltration patterns—including CD8⁺ T cells, CD163⁺ and CD206⁺ macrophages, and TIM-3⁺ exhausted lymphocytes—were assessed by multiplex immunohistochemistry (mIHC) in GC patients treated with anti-PD-1 therapy. Mechanistic studies were performed using GC cell lines with stable SPIN1 knockdown or overexpression in macrophage co-culture assays, metabolic profiling, and flow cytometric characterization of M1/M2 markers. Antitumor efficacy was evaluated in syngeneic mouse models treated with a SPIN1 small-molecule inhibitor, anti-PD-1 antibody, or the combination.

Data Summary: Clinically, SPIN1 expression was significantly higher in non-responders than in responders to PD-1 blockade. Elevated SPIN1 levels strongly correlated with increased infiltration of immunosuppressive M2 macrophages (CD163⁺/CD206⁺) and reduced CD8⁺ T-cell presence in tumor tissue. In vitro, SPIN1 silencing diminished, whereas SPIN1 overexpression enhanced, M2-associated gene expression and surface markers. Flow cytometry confirmed that SPIN1 drives macrophage polarization toward an M2 phenotype. SPIN1-conditioned macrophages subsequently suppressed CD8⁺ T-cell proliferation and cytotoxic function while inducing T-cell exhaustion, evidenced by increased PD-1, TIM-3, and LAG-3 expression. In vivo, pharmacologic inhibition of SPIN1 reshaped the TIME by reducing M2 macrophage accumulation and restoring CD8⁺ T-cell infiltration and effector activity. Notably, combining a SPIN1 inhibitor with anti-PD-1 therapy produced a synergistic antitumor response and significantly reversed acquired resistance compared with either single agent.

Conclusions: This study identifies SPIN1 as a key regulator of immune suppression and therapeutic resistance in GC. By promoting M2 macrophage polarization and driving CD8⁺ T-cell exhaustion, SPIN1 establishes a TIME that limits the efficacy of PD-1 blockade. These findings highlight SPIN1 as both a predictive biomarker for immunotherapy response and a promising therapeutic target for sensitizing gastric tumors to PD-1-based immunotherapy.

#7015 USP5 suppresses MRE11 endonuclease function to facilitate tumor immune escape.

Chuan-Chun Lee[1], Wan-Rong Wu[2], Liang-Chih Liu[1], Ting-Yi Liao[1], You-Zhe Lin[2], Fang-Ying Lin[2], Yi-Chun Shen[2], Yuan-Liang Wang[1], Chih-Hao Lu[3], Wei-Chung Cheng[2], Wei-Chao Chang[1], Yi-Chuan Li[1], Chih-Tung Lin[1], Chung-Yu Chen[2], Sheng-Wen Chen[2], Hsin-An Shih[4], Steven Lin[4], Chen-Yuan Lin[1], Chang-Fang Chiu[1], **Shao-Chun Wang**[2]

[1]China Medical University Hospital, Taichung City, Taiwan,[2]China Medical University, Taichung City, Taiwan,[3]National Yang Ming Chiao Tung University, Hsinchu, Taiwan,[4]Academia Sinica, Taipei City, Taiwan

Replication stress is a hallmark of cancer that generates abnormal cytosolic DNA, thereby activating intrinsic immune pathways that constrain tumor growth. To survive, malignant cells must counteract these immune surveillance mechanisms, yet the underlying regulatory processes remain incompletely understood. The MRE11 nuclease plays a dual role in maintaining genome stability and processing stalled replication forks, where its endonuclease activity produces single-stranded DNA (ssDNA) capable of activating the cGAS-STING axis to induce anti-tumor immunity. In this study, we uncover a ubiquitin-dependent mechanism that connects DNA replication stress to immune evasion. Loss of tyrosine 211 phosphorylation on PCNA (pY211-PCNA) induces endogenous replication stress and promotes site-specific polyubiquitination of MRE11. This modification enhances MRE11 endonuclease activity, resulting in cytosolic ssDNA accumulation, activation of innate immune signaling, and increased susceptibility to natural killer (NK) cell-mediated cytotoxicity. Conversely, in cells expressing pY211-PCNA, the deubiquitinase USP5 is recruited to replication forks, where it removes ubiquitin from MRE11, thereby attenuating its endonuclease activity and suppressing cytosolic ssDNA formation and immune activation. Clinically, elevated USP5 expression correlates with tumor metastasis and poor prognosis in breast cancer. Genetic ablation or pharmacologic inhibition of USP5 restores MRE11-dependent ssDNA production, promotes NK cell infiltration, and suppresses tumor growth in immune-competent but not immune-deficient mouse models. An unbiased drug screen identified two FDA-approved compounds as potent USP5 inhibitors, which mimic USP5 depletion by enhancing cytosolic ssDNA accumulation, triggering NK- and PBMC-mediated killing of patient-derived tumor organoids (PDTOs), and suppressing tumor growth in syngeneic mouse models. These results identify USP5 as a critical negative regulator of MRE11-driven immunogenic DNA processing and reveal a therapeutic strategy to potentiate anti-tumor immunity through targeted USP5 inhibition.

#7016 Targeting sialylation promotes anti-tumor immunity in small cell lung cancer.

Alex D. Doan[1], Kelly Heard[1], Jackson Fatherree[1], Mallika Yalangi[1], Pritha Chanana[2], Mitchell Kluesner[1], Daniel S. Hippe[3], Cody Jenkins[1], Hannah Kerbyson[1], Shivani Srivastava[1], David MacPherson[1]

[1]Human Biology Division, Fred Hutchinson Cancer Center, Seattle, WA,[2]SR Bioinformatics, Fred Hutchinson Cancer Center, Seattle, WA,[3]Clinical Biostatistics, Fred Hutchinson Cancer Center, Seattle, WA

Small cell lung cancer (SCLC) is a highly lethal subtype of lung cancer with a 5-year relative survival rate of less than 10%, even with the addition of immune checkpoint blockade to standard of care therapy. The tumor immune microenvironment of SCLC has been characterized as highly immunosuppressive, and SCLC suppresses the expression of antigen presentation machinery, likely contributing to the lack of effective prolonged immunotherapy responses. Our project investigates the targeting of sialic acid, a sugar molecule overexpressed in many cancers, to increase anti-tumoral immune responses. Studies in other malignancies have shown that cancer cells can hijack this axis as a mechanism of immune evasion through interactions with the SIGLEC family of inhibitory receptors on infiltrating immune cells. We hypothesize that SCLC also utilizes sialic acids for immune masking, and that tumor desialylation would improve anti-tumor responses and could be a potential novel therapeutic approach for SCLC.

Using SCLC lines that we derived from genetically engineered mouse models harboring *Rb1/Trp53* inactivation, we performed genome wide CRISPR deletion screens and identified *Gne* as a top gene regulating SCLC sialylation. We then deleted *Gne* and confirmed robust decreases in sialylation. Under interferon-γ stimulated conditions, *Gne*-deleted cells exhibited elevated MHC-I expression and IFNγ signaling pathway, suggesting that loss of sialylation leads to increased antigen presentation and intrinsic immunogenicity. These results are relevant as recent clinical data revealed SCLC patients with low MHC-I expression respond poorer to anti-PDL1 therapy. When the *Gne*-deleted cells were propagated into mice as flank tumors or as a disseminated metastatic model, we observed delayed tumor kinetics and prolonged survival in syngeneic immunocompetent hosts, but not in immunocompromised recipients, suggesting that the observed effects are immune dependent. Immunophenotyping of syngeneic tumors by flow cytometry revealed increased tumor MHC-I expression and higher infiltration of tumor antigen specific CD8+ T cells upon *Gne* deletion. Furthermore, co-culturing of *Gne*-deleted cells expressing ovalbumin with ovalbumin antigen (OT-I) specific CD8+ T cells showed increased tumor cell killing and T cell activation. Lastly, analysis of patient SCLC samples in the IMpower133 clinical trial revealed a survival benefit with chemo-immunotherapy for patients expressing lower transcriptional levels of key sialic acid biosynthesis genes, while this effect is absent in the chemotherapy only group. Altogether, our data suggests that desialylation improves immunogenicity and anti-tumor immunity in SCLC.

Ultimately, our work improves the understanding of the mechanisms behind immune responses in SCLC and has potentially uncovered a novel glyco-immunotherapeutic approach to develop new treatments for SCLC in the clinical setting.

#7017 EMP2 is a potential immunotherapeutic target to modulate macrophage-induced phagocytosis in glioblastoma.

Amr Elkholy[1], Eshika Kudaravalli[1], Mostafa Mohamed[1], Hasan Alrefai[2], Saeed Zakakhosravi[1], Satoru Osuka[1], Christopher D. Willey[2], Ahn Erin[1]

[1]University of Alabama at Birmingham, Birmingham, AL,[2]O'Neal Comprehensive Cancer Center at UAB, Birmingham, AL

Glioblastoma (GBM) is the most aggressive primary brain tumor. Despite advances in immunotherapy for other solid tumors, T-cell checkpoint blockades have failed to improve overall survival in GBM patients, largely due to low T-cell infiltration. In contrast, tumor-associated macrophages (TAMs) comprise 82-97% of the immune cell population in newly diagnosed GBM. TAMs, however, often fail to engulf tumor cells, partly due to the phagocytosis inhibitory “do not eat me" signals such as CD47, which interacts with macrophage SIRPα to suppress phagocytosis. Although, CD47 blockade enhances phagocytosis in preclinical models, clinical trials of anti-CD47 therapies such as magrolimab were halted due to increased mortality and limited efficacy in acute myeloid leukemia patients, highlighting the need for alternative phagocytosis-inducing therapies. To identify novel tumor-expressed genes that inhibit macrophage phagocytosis, we performed a genome-wide CRISPR screen using two rounds of coculture of radioresistant GBM tumor cells (MGG18-RR) and tumor-conditioned human peripheral blood (hPBMCs)-derived macrophages. Tumor-conditioned hPBMCs macrophages were considered more reliable, as our cytometry imaging results revealed distinct polarization states compared to unpolarized (M0) macrophages. In the first round, MGG18-RR GBM cells were co-cultured with tumor-conditioned hPBMCs-derived macrophages at a 1:5 ratio for 7 days, with media refreshed every 2 days. Parallel tumor-only cultures served as controls. Tumor cells that survived this first co-culture were pooled and subjected to a second 7-day co-culture with freshly differentiated and polarized macrophages. After the second round, the remaining tumor cells were collected, and genomic DNA was extracted for library prep and sequencing. Among the top 100 hits, several known regulators of phagocytosis, including CD47 and KRAS were enriched, validating the reliability of the screen. We identified Epithelial Membrane Protein 2 (EMP2) as a novel tumor-expressed gene that suppresses macrophage phagocytosis. EMP2 showed high expression in glioma cells in publicly available single-cell sequencing data for GBM patients. EMP2 is highly expressed in GBM and associated with tumor progression and poor survival. Functional validation using the pHrodo in-vitro phagocytosis assay demonstrated a significant increase in the engulfment of EMP2-knockout GBM cells (JX14P-RT) by both hPBMCs-derived macrophages and RAW246.7 macrophages ($p < 0.05$), compared to wild-type tumor cells, suggesting that EMP2 acts as an anti-phagocytic regulator in GBM. Ongoing studies aim to validate that EMP2 knockout enhances macrophage phagocytosis in syngeneic murine GBM model. Collectively, our findings highlight EMP2 as a novel regulator of macrophage-mediated tumor clearance and a promising therapeutic target for macrophage-based immunotherapy in GBM.

#7018 The CBS-CXCL10 signaling axis supports tumor progression by driving immune suppression within the tumor microenvironment.

Fanghui Chen, Fan Yang, Jianqiang Yang, Nabil Saba, **Yong Teng**

Emory University, Atlanta, GA

Cystathionine β-synthase (CBS), a key enzyme in the transsulfuration pathway, is overexpressed in cancer cells and promotes tumor progression in part through hydrogen sulfide-mediated metabolic reprogramming. However, its role in shaping the tumor microenvironment and antitumor immunity is not well defined. Here, we show that CBS is highly expressed in head and neck cancer (HNC) tissues and cell lines, and that CBS knockdown slows tumor growth while enhancing antitumor immune responses in orthotopic syngeneic mouse models. Mechanistically, CBS silencing downregulates PSAT1 transcription, a key enzyme in the serine biosynthesis pathway, leading to intracellular serine depletion, DNA damage, and increased oxidative stress. These stress responses activate the cytosolic DNA-sensing pathway, triggering the cGAS-STING axis with phosphorylation and nuclear translocation of IRF3 and subsequent transcription of the chemokine CXCL10. Elevated CXCL10 functions as a potent chemoattractant for cytotoxic T cells, enriching the tumor microenvironment with effector lymphocytes and enhancing tumor control in vivo. Immunophenotyping and functional assays support a reprogrammed microenvironment consistent with heightened antitumor immunity upon CBS knockdown. Importantly, these effects are observed in an immunocompetent, orthotopic model, suggesting that CBS-driven signaling intersects with innate DNA sensing to modulate adaptive immunity in HNC. Collectively, these findings reveal a previously unrecognized immunomodulatory role for CBS in HNC and identify CBS as a potential metabolic-immune-target to augment tumor-reactive immunity and improve immunotherapy outcomes

Poster Session

#7022 Investigating PRMT5 as a therapeutic target in EGFR TKI resistant NSCLC and assessing the role of mucins in NSCLC as blood biomarkers.

Aditya Krishnan[1], James Jin[2], Usama Altayeh[3], Jessica Hindenburg[1], Neelu Puri[4]

[1]University of Illinois College of Medicine (Rockford), Rockford, IL,[2]College of Medicine, University of Illinois College of Medicine (Rockford), Rockford, IL,[3]Department of Biomedical Sciences, University of Illinois College of Medicine (Rockford), Rockford, IL,[4]University of Illinois at Chicago, Rockford, IL

Lung cancer is on track to cause over 124,000 U.S. deaths in 2025, and about 10-15% of all lung cancers in the United States involve EGFR-resistant NSCLC. Patients with EGFR-mutant NSCLC are initially responsive to TKIs but frequently relapse within 19 months. PRMT5, a type II arginine methyltransferase, drives oncogenic and inflammatory signaling primarily through P13K-Akt signaling, which may be increased by cigarette smoke. We hypothesize that inhibiting PRMT5 by using siRNA will modulate these pathways and restore EGFR-TKI sensitivity. PRMT5 expression was analyzed in EGFR-mutant NSCLC parental cell lines (H3255P, H1975P, PC9) and resistant cell lines (H3255OR, H1975OR, PC9OR) using qPCR and Western blotting following cigarette smoke extract (CSE) exposure and siRNA knockdown using DharmaFECT. Cytokine expression was profiled using qPCR to assess downstream inflammatory effects. Immunohistochemistry (IHC) was performed on normal and tumor tissues from smokers and non-smokers to evaluate PRMT5 levels. The PRMT5 levels were analyzed using a Keyence microscopic software (BZX-800 Analyzer) and statistical analysis was done using Fisher's Exact test. CSE increased PRMT5 mRNA across EGFR-mutant lines by 1.2-11.5 fold at 48 h ($p<0.01–0.001$). Immunoblotting confirmed PRMT5 upregulation at 24–48 h in resistant cells by 1.3-2.5 fold ($p<0.01–0.001$). In H3255-OR and PC9-OR cells, siPRMT5 reduced the 48-h CSE–induced cytokine surge (170-760%) by 10-20%. Compared to Mock plus CSE, siPRMT5 plus CSE reduced IL-8 (60–75%), TNF-α (30–50%), and IL-1β (35–55%). Downregulation of these cytokines was also seen after combinatory treatment with osimertinib and siPRMT5. In PC9-P/OR cells, siPRMT5 lowered PRMT5 transcripts by 35–50% compared to Mock and siPRMT5 plus CSE reduced by 15–45% relative to Mock plus CSE. IHC on 21 smoker and 20 non-smoker lung tissues from lung cancer patients showed PRMT5 expression was higher in smokers versus non-smokers ($p<0.05$). Studies were also conducted on normal lung tissue from 25 smokers and 19 non-smokers and PRMT5 expression was found to be higher in smokers compared to non-smokers using Fisher's exact test ($p<0.001$). In conclusion, PRMT5 is upregulated by CSE in osimertinib-resistant EGFR-mutant cells and is upregulated in smokers. PRMT5 knockdown suppresses inflammatory cytokines and supports the rationale that inhibiting PRMT5 could help restore EGFR-TKI sensitivity.

#7023 ENPP1 inhibits the cGAS-STING pathway to mediate immune evasion in EGFR-TKI resistant NSCLC.

Chao Zhou[1], Yuqing Liu[2], Jun Lu[1], Baohui Han[1]

[1]Shanghai Chest Hospital, Shanghai, China,[2]Shanghai Jiao Tong University School of Medicine, Shanghai, China

Third-generation EGFR tyrosine kinase inhibitors (TKIs), such as osimertinib, have demonstrated promising clinical efficacy in EGFR-mutant non-small cell lung cancer (NSCLC). Despite substantial progress with EGFR-TKIs, the development of acquired resistance remains a major clinical challenge. Notably, the addition of immunotherapy after TKI resistance has not resulted in significant survival benefits compared to chemotherapy. In this study, single-cell RNA sequencing analysis of key immune cell subpopulations and tumor immune features revealed an immunosuppressive shift in the tumor microenvironment of TKI-resistant tumors, characterized by an increased proportion of M2 macrophages, reduced dendritic cells (DCs) and M1 macrophages, and immune function scores indicative of an immunosuppressive state. Comprehensive transcriptomic profiling of established osimertinib-resistant NSCLC cell lines (HCC827OR, H1975OR, PC9OR) demonstrated a significant upregulation of ENPP1 expression compared with their parental, TKI-sensitive counterparts. Given that ENPP1 functions as a cGAMP hydrolase and is implicated in STING pathway suppression and immune evasion, we first assessed cGAMP hydrolysis activity and found that resistant cells exhibited enhanced cGAMP-degrading capacity. Co-culture experiments of tumor cells with antigen-presenting cells (APC) revealed that resistant tumor cells more effectively suppressed cGAS-STING signaling in APCs, thereby attenuating T-cell activation and cytotoxicity. Both genetic silencing of ENPP1 via siRNA and pharmacological inhibition using the ENPP1 inhibitor ENPP-1-IN-1 enhanced STING pathway activation in APCs and restored T-cell activation and cytotoxic functions in co-culture systems. Bioinformatic prediction and dual-luciferase assays identified SP1 as a direct transcriptional regulator of ENPP1. Finally, immune reconstitution mouse models confirmed that ENPP-1-IN-1 potentiated the efficacy of anti-PD-1 therapy in HCC827OR xenografts by increasing immune infiltration and T-cell activity. Collectively, our study highlights a critical role for ENPP1 in mediating immune evasion through suppression of the cGAMP-STING pathway in the EGFR-TKI resistant tumor, supporting ENPP1 as a promising therapeutic target to enhance immunotherapy efficacy in EGFR-TKI resistant NSCLC.

#7024 Simultaneous targeting of CHI3L1 and PD-1/PD-L1 axis to overcome drug resistance and immune tolerance of EGFR non-small cell lung cancer.

Suchitra Kamle[1], Bing Ma[2], Brianna Pham[3], Isabella Fish[3], Marlo Hulnick[3], Taka Sadanaga[2], Hanseok Jeong[2], Mara Hofstetter[4], Hina Khan[5], Christopher Azzoli[5], Katerina A. Politi[6], Roy S. Herbst[6], Chun Geun Lee[2], Jack Elias[1]

[1]Molecular Microbiology & Immunology, Legorreta Cancer Center at Brown University, Providence, RI,[2]Molecular Microbiology & Immunology, Brown University, Providence, RI,[3]Brown University, Providence, RI,[4]University of Zurich, Zurich, Switzerland,[5]Legoretta Cancer Center at Brown University, Providence, RI,[6]Yale Cancer Center, New Haven, CT

Background: Lung cancer is the leading cause of cancer deaths worldwide. Non-small cell lung cancer(NSCLC) accounts for 85% of all lung cancers. The overall prevalence rate of NSCLC with epidermalgrowth factor receptor (EGFR) mutations are significantly increasing in US. Oncogenic EGFR is atransmembrane protein which gets auto-phosphorylated to cause EGFR mutations (L858R, T790M, exon-19-deletion) in exon 18-21. Tyrosine kinase inhibitors (TKIs) are effectively targeted to treat mutated EGFRlung cancer. These TKIs showed favorable responses on patient's treatments for 9-18 months but duringthe treatment, patients acquired EGFR mutations which results into the TKIs drug resistance and at thatpoint TKIs stops its efficacy for further treatment. Thus, there is a high medical unmet need for a newtherapeutic strategy to overcome drug resistance in patients with EGFR mutations. CHI3L1 expressed bymacrophages, neutrophils, epithelial cells, smooth muscle cells, chondrocytes including other immune cells.The levels of circulating CHI3L1 are increased in many malignancies including cancers of the prostate,colon, rectum, ovary, kidney, breast, glioblastomas, malignant melanoma, and lung cancer. CHI3L1contributes to pulmonary metastasis and spread via the regulation of immune-checkpoint (ICP) molecules.Our studies showed that CHI3L1 regulates and is a potent stimulator of PD-1/PD-L1 and PD-L2. CHI3L1stimulates the EGFR physiologic ligands EGF or TGF-a, a well-defined growth factors that stimulate EGFRphosphorylation. EGFR-YAP/TAZ signaling plays a growth-promoting role in cancers harboring EGFRalterations, and that inhibition of YAP/TAZ in combination with EGFR might be beneficial to prevent TKIdrug resistance and cancer recurrence.
Methods: We analyzed EGFR mutant and resistant cells using techniques qPCR, protein accumulation,immuno-pull-down assay, immunofluorescence, FACS and therapeutic effect of YAP inhibitors in-vitroand in-vivo.
Results: We identified that CHI3L1 augments YAP/TAZ nuclear translocation in EGFR mutant and TKIresistant cells. Also, YAP/TAZ inhibitors and agonists (Verteporfin, K-975) able to block YAP/TAZactivation and that suppress PD-1/PD-L1 in EGFR mutant and TKI resistant cells.
Conclusion: These findings led us to understand that CHI3L1 and PD-1/PD-L1 axis mediated throughactivation of Hippo-YAP/TAZ signaling pathways play an essential role in TKIs drug resistance andimmune tolerance that enhances the progression of EGFR NSCLC. Additionally, simultaneous targeting ofCHI3L1 and PD-1/PD-L1 axis employing bispecific antibody (CHI3L1xPD-1) may provide a bettertherapeutic option to overcome TKI resistance and immune tolerance of EGFR NSCLC.

#7025 Mechanisms of zongertinib resistance in HER2-mutant non-small cell lung cancer and potential strategies to overcome resistance.

Yuji Shibata[1], Monique B. Nilsson[2], Ximeng Liu[2], Li (Lily) Cai[2], Hong Jiang[2], Linghzi Hong[2], Alvaro Guimaraes Paula[2], Hibiki Udagawa[2], Jacqulyne Ponville Robichaux[3], Junqin He[2], Xiaoxing Yu[2], John V. Heymach[2]

[1]Thoracic Head & Neck Medical Oncology, UT MD Anderson Cancer Center, Houston, TX,[2]UT MD Anderson Cancer Center, Houston, TX,[3]AstraZeneca Oncology, Houston, TX

Activating mutations in HER2 are found in approximately 2-4% of non-small cell lung cancer (NSCLC). Zongertinib is currently the only FDA-approved tyrosine kinase inhibitor (TKI) for patients with HER2-mutant NSCLC. However, the mechanisms underlying acquired resistance remain unclear, and understanding zongertinib-resistance mechanisms is essential for developing subsequent effective therapeutic strategies in HER2-mutant NSCLC. To identify candidate genomic alterations in HER2 mediating zongertinib resistance, we analyzed HER mutation profiles in clinical samples from NSCLC patients after progression on zongertinib, reviewed previously reported resistance mutations from other HER2 TKIs, and employed the LentiMutate scanning mutagenesis system. Candidate HER2 resistance mutations identified through these approaches were then transduced into Ba/F3 cells and the effect on drug sensitivity was assessed. We detected secondary HER2 mutations including S783C, C805S, and T862A in post-zongertinib clinical samples in combination with the originally observed activating HER2 mutations or NRG1 fusions. Our LentiMutate analysis identified HER2 alterations including C805S, T862A, S783P as well as T798I and L726F as being enriched in zongertinib resistant cells. We next engineered Ba/F3 cells to express HER2 activating mutations (e.g. Y772dupYVMA) alone or in combination with potential secondary HER2 resistance mutations including S783C, T798I, C805S, or T862A, and observed that expression of these mutations rendered cells resistant to zongertinib in vitro. However, S783C and C805S mutations did not impact in vitro sensitivity to the HER2 TKI sevabertinib. Structural analysis revealed that T798I acts as a gatekeeper mutation, whereas S783C and T862A disrupt hydrogen bonds between the drug and HER2, and C805S disrupts a covalent bond, thereby weakening zongertinib-HER2 binding. Next, we implanted mice with tumor cells expressing HER2 activating mutations alone or in combination with S783C or C805S and evaluated the anti-tumor activity of zongertinib and sevabertinib. Consistent with our in vitro findings, tumors bearing C805S or S783C secondary mutations were resistant to zongertinib but sensitive to sevabertinib. Our findings identify novel HER2 mutations that mediate zongertinib resistance and indicate that sevabertinib may be effective against a subset of these genomic alterations.

#7026 IL-1 alpha expression induces drug resistance to all generations of EGFR inhibitors in HNSCC.

Nafis Md Irfan[1], Ishrat Nourin Khan[2], Nurgul Koyuncu[2], Krishna Awasthi[2], Andrean L. Simons-Burnett[1]

[1]Free Radical and Radiation Biology Program, Department of Radiation Oncology, University of Iowa, Iowa City, IA,[2]University of Iowa, Iowa City, IA

Epidermal Growth Factor Receptor (EGFR) expression is upregulated in the majority of head and neck squamous cell carcinomas (HNSCC) and is associated with poor clinical outcomes. Unfortunately, the incorporation of EGFR inhibitors (EGFRIs) into the management of HNSCC has not improved long term survival rates in HNSCC patients despite high EGFR expression. Additionally, EGFR tyrosine kinase inhibitors (TKIs) in particular, have failed to show clinical benefit for HNSCC patients in clinical trials. Therefore, the identification and understanding of strategies that will improve the efficacy of EGFRIs may improve patient treatment and survival. Previous work in our lab has shown that HNSCC cells treated with erlotinib, a first-generation EGFR TKI, increased expression and release of the proinflammatory cytokine interleukin-1 alpha (IL-1α) resulting in inflammation and the development of drug resistance. The goal of this study is to determine if IL-1α-induced drug resistance is maintained across second, third and fourth generation EGFR TKIs.EGFR wildtype-positive HNSCC cells (FaDu, Cal-27 and SQ20B) were treated with the IC_{50} doses of erlotinib (first generation), afatinib (second generation), osimertinib (third generation), and silevertinib (fourth generation) EGFR TKIs for 48 h. Cell viability responses to EGFR TKIs were assessed using MTT assays. IL-1α and IL-6 cytokine expression was detected by ELISA and Western blot. Manipulation of IL-1 expression and signaling was performed using neutralizing antibodies to human IL-1α antibody (nIL-1α) and IL-1β (nIL-1β), and the human IL-1 receptor antagonist - anakinra. Results showed that all four EGFR TKIs triggered the release of IL-1α but not IL-1β from all 3 HNSCC cell lines. Additionally, all four EGFR TKIs increased IL-6 (IL-1α signaling endpoint) release, which was suppressed by nIL-1α and anakinra (but not nIL-1β) implying that IL-1α, rather than IL-1β, acts upstream of IL-6 activation. Overexpression of IL-1α in Cal-27 cells resulted in resistance to all four generations of EGFR TKIs. Lastly, erlotinib-resistant Cal 27 and SQ20B cells also demonstrated resistance to all other generations of EGFR TKIs. Collectively, these findings identify IL-1α expression as a central mediator of poor response and resistance to all EGFR TKIs via an EGFR mutation-independent mechanism. Hence, targeting IL-1α expression/signaling could be a promising strategy to improve long term tumor response to EGFR TKIs in HNSCC.

#7027 Multi-lineage evolution of drug resistance via a novel keratin 17+ drug tolerant persister population in *EGFR*-mutant NSCLC.

Benjamin B. Morris[1], Monique B. Nilsson[1], Ethan Earlie[2], Eric E. Gardner[3], Hong Chen[1], Santiago G. Trevino[1], Alexa J. Halliday[4], Yuanxin Xi[4], Jing Wang[4], Natalie Vokes[1], Don Gibbons[1], Jianjun Zhang[1], Ashley M. Laughney[2], Yasir Y. Elamin[1], Xiuning Le[1], John V. Heymach[1]

[1]Thoracic/Head and Neck Medical Oncology, UT MD Anderson Cancer Center, Houston, TX,[2]Department of Systems and Computational Biomedicine, Weill Cornell Medicine, New York, NY,[3]Weill Cornell Medicine, New York, NY,[4]UT MD Anderson Cancer Center, Houston, TX

Background: EGFR mutant lung cancers initially respond to frontline targeted therapy. However, resistance inevitably develops through diverse mechanisms. Resistant tumors universally emerge from drug tolerant persister cells (DTPCs) that survive initial treatment. Despite this knowledge, the biology of EGFR mutant DTPCs is not well understood. This study was conducted to interrogate DTPC phenotypes that enable evolution of therapy resistance.

Methods: DTPC models were generated by treating EGFR mutant cell lines with >IC90 concentrations of osimertinib for 14 days. After 14 days, cells were profiled with 10X 3' single cell RNA sequencing (scRNAseq). Seurat was used to integrate data, normalize data, cluster cells, and conduct differential expression analyses. UCell was used to score cells for activity of biology pathways. scanpy was used to analyze scRNAseq data from the Gardner et al. ERPMT mouse model. Human patient samples were collected from lung cancer patients treated at MD Anderson Cancer Center using IRB approved protocols. Samples were profiled with 10X 5' scRNAseq. scanpy was used to integrate data, normalize data, and cluster cells. Palantir was used to perform trajectory analyses.

Results: Differential expression (DE) analysis comparing DTPCs and control cells were conducted for cell line pairs. Using DE results, we generated consensus gene signatures capturing genes universally upregulated or downregulated across DTPC models. Review of these genes identified that *KRT17* was highly upregulated in osimertinib DTPCs. We found *KRT17*+ DTPCs upregulate epithelial-to-mesenchymal (EMT), stemness, and aberrant basaloid signatures compared to *KRT17*- DTPCs. Subclustering showed that *KRT17* DTPCs are heterogeneous and label non-overlapping EMT, proliferative, and *MET* expressing populations. To validate our *in vitro* findings, we analyzed scRNAseq datasets from multiple in vivo sources. In GEMM models, *Krt17*+ cells populate minimal residual disease (MRD) following suppression of mutant EGFR. *Krt17*+ cells were a stem-like population that emerged as residual tumor cells lost alveolar epithelial identity prior to neuroendocrine transformation. Lastly, we confirmed the clinical relevance of our findings by investigating human patient clinical specimens. Compared to treatment naïve samples, *KRT17*+ cells were significantly enriched in osimertinib-treated MRD samples. Trajectory analyses demonstrated that *KRT17* expression characterized cell populations that preceded development of resistance through several known mechanisms, including *MET* amplification and histologic transformation (HT).

Conclusions: Our data demonstrate that EGFR-mutant cells surviving initial treatment converge onto a novel *KRT17*+ DTPC state which serves as a multipotent progenitor population capable of leveraging diverse mechanisms to resist therapy, including HT.

#7028 Investigating the role of PLK4 and GDF15 in NSCLC tumorigenicity and EGFR-TKI resistance.

Subaranjana Saravanaguru Vasanthi[1], Georgia Kapetaneas[2], Meet Patel[3], Neelu Puri[1]

[1]Department of Biomedical Sciences, University of Illinois College of Medicine (Rockford), Rockford, IL,[2]College of Medicine, University of Illinois College of Medicine (Rockford), Rockford, IL,[3]Cancer Biology, University of Alabama at Birmingham, Birmingham, AL

Background: Non-small cell lung cancer (NSCLC) accounts for nearly 85% of all lung cancers, and the development of resistance to Epidermal Growth Factor Receptor (EGFR) Tyrosine Kinase Inhibitors (TKIs) remains a major clinical challenge, limiting long-term therapeutic success. Emerging evidence shows that PI3K/Akt and TGF-β-signaling are key drivers of EGFR-TKI resistance. Polo-like kinase 4 (PLK4), a serine/threonine kinase, regulates centriole duplication and maintains genomic stability, while its overexpression can promote oncogenic transformation and tumor progression through PI3K/Akt activation. Notably, PLK4-driven signaling intersects with stress-responsive pathways, creating a cellular environment conducive to survival and therapeutic resistance. Within this context, Growth differentiation factor 15 (GDF15), a stress-responsive cytokine and member of the TGF-β superfamily, is significantly upregulated in NSCLC, particularly in patients with a history of smoking. GDF15 promotes metastasis, epithelial-mesenchymal transition (EMT), and therapy resistance through TGF-β and ErbB crosstalk. Moreover, GDF15 is also emerging as a novel biomarker and potential therapeutic target in NSCLC, playing a key role in EGFR-TKI resistance and enhancing tumorigenicity.
Hypothesis/Aims: We hypothesize that overexpression of PLK4 and GDF15 drives tumorigenesis and EGFR-TKI resistance through PI3K-Akt-mTOR, TGF-β and ErbB signaling in NSCLC, and that modulating these key biomarkers may help reduce tumorigenicity and overcome resistance.
Study Design: We examined PLK4 and GDF15 expressions in drug-resistant - Osimertinib-resistant (OR) and Erlotinib-resistant (ER) and drug-sensitive (parental) NSCLC cell lines after 24- and 48-hour CSE treatment using qPCR, western blotting, and immunofluorescence.
Results: Immunoblot analyses revealed that PLK4 protein expression levels were upregulated by ~2.0- to 4.0-fold in both OR and ER NSCLC cell lines compared with parental controls ($p < 0.05$) also supported by strong immunofluorescence signals. Quantitative PCR further showed significant GDF15 upregulation from 1.4- to 3.4-fold in both Osimertinib and Erlotinib resistant cells particularly after 48 h of cigarette-smoke-extract exposure, suggesting that smoking-related stress may further enhance its expression. These findings indicate that both PLK4 and GDF15 contribute to enhanced proliferative capacity, survival signaling, and the maintenance of resistant phenotypes.
Conclusion: Collectively, our data suggests that overexpression of PLK4 and GDF15 activates PI3K/Akt/mTOR, TGF-β, and ErbB pathways, promoting EGFR-TKI resistance and NSCLC progression. Targeting these key biomarkers may help overcome resistance and limit tumor growth, particularly in smoking-associated NSCLC cases.

#7029 Engineering isogenic models harboring resistance mechanisms to the latest-generation EGFR inhibitor in non-small cell lung cancer.

Hyeyoun Chang[1], Florencia M. Rowdo[2], Kirsty Wienand[2], John G. Foulke[3], Paul Lovell[1], Francisca Vasquez[2], **Fang Tian**[4]

[1]American Type Culture Collection (ATCC), Manassas, VA,[2]Broad Institute of MIT and Harvard, Boston, MA,[3]ATCC, Gaithersburg, MD,[4]ATCC, Manassas, VA

Background: EGFR-mutant lung cancer was among the first epithelial cancer subsets where directly targeting an oncogene yielded significant clinical benefit. While improved inhibitors, such as third-generation EGFR inhibitor Osimertinib, have significantly improved clinical outcomes of non-small lung cancer (NSCLC) patients, acquired resistance to targeted therapies remains a major barrier to durable responses. To address this challenge, we developed three sets of isogenic NSCLC cell models harboring clinically resistant mutations to EGFR targeted therapy through genetic engineering approach.
Method and Results: To systematically investigate resistance mechanisms and associated vulnerabilities, we engineered isogenic NSCLC cell lines to model clinically relevant mechanisms of acquired resistance. Using CRISPR gene editing, three sets of resistant cell lines were generated from three osimertinib-sensitive parental lines (HCC827, HCC4006, and NCI-H292). The engineered alterations included *BRAF V600E*, *KRAS G12D*, *PIK3CA E545K*, *EGFR C797S*, and additional fusion genes such as *TPM3-NTRK1*. Sequence verification and osimertinib sensitivity assays were performed for all models. The engineered cell lines exhibited reduced osimertinib sensitivity consistent with the introduced resistance mechanisms. Initial genomic validation confirmed the intended edits and additional genetic screening will be performed to further characterize the isogenic cell lines. Selected models were further evaluated in 3D culture systems to assess phenotypic impact.
Conclusion: These validated novel models provide a robust platform for the research community and industry to dissect mechanisms of drug resistance, identify therapeutic vulnerabilities and develop combination therapy strategies. This ATCC and Broad institution collaborative effort will also support the establishment of the Resistance Map (ResMap) within DepMap to systematically characterize vulnerabilities in EGFR-driven NSCLC.

#7030 Tumor-macrophage crosstalk promotes resistance to EGFR targeted therapy in lung adenocarcinoma.

Philippe Gui, Victor Olivas, Tiffany Li, Whitney Tamaki, Hannah Bergo, D. Lucas Kerr, Wei Wu, Collin M. Blakely, Trever G. Bivona

UCSF Helen Diller Family Comprehensive Cancer Ctr., San Francisco, CA

Lung cancer remains the leading cause of cancer-related mortality worldwide. Non-small cell lung cancer (NSCLC) is the predominant histologic subtype, with lung adenocarcinoma the most common form of NSCLC. Approximately 15-20% of lung adenocarcinomas harbor activating mutations in the tyrosine kinase domain of the epidermal growth factor receptor (EGFR). Although targeted therapies have substantially improved clinical outcomes for patients with EGFR-mutant NSCLC, most patients do not achieve complete response, underscoring the need to elucidate mechanisms of resistance to EGFR tyrosine kinase inhibitors (TKIs). We hypothesize that, in addition to tumor-cell-intrinsic mechanisms, interactions between cancer cells and the tumor microenvironment could contribute to treatment resistance. Leveraging clinical sequencing data alongside cell co-culture systems, organoid models, and in vivo studies, we show that TKI-treated EGFR-mutant cells upregulate cytokines and chemokines that promote recruitment and maintenance of tumor-infiltrating macrophages, a population associated with poor clinical outcomes. Moreover, interactions between therapy-treated cancer cells and newly recruited macrophages support tumor survival by enhancing cancer cell viability and reducing phagocytic clearance. Genetic and molecular profiling further reveal that soluble pro-inflammatory mediators secreted by macrophages, including TNF-α and IL-1β, engage the NF-κB signaling pathway in EGFR-mutant cells, thereby driving residual disease and resistance. Together, these findings provide a rationale for disrupting microenvironmental crosstalk between EGFR-mutant tumor cells and tumor-infiltrating macrophages as a strategy to limit residual disease. Targeting these interactions may enable a new class of microenvironment-directed therapies to overcome resistance to EGFR TKIs.

#7031 Intra-tumoral *Porphyromonas gingivalis* mediates osimertinib resistance in EGFR-mutant lung adenocarcinoma through gingipain-mediated IGF1R activation.

Wendong Li[1], Mahima Raul[1], Keqiang Zhang[1], Jan Potempa[2], Yuanyuan Gao[1], Dan Raz[1]

[1]City of Hope National Medical Center, Duarte, CA,[2]University of Louisville School of Dentistry, Louisville, KY

Background: Epidermal growth factor receptor tyrosine kinase inhibitors (EGFR-TKIs) are the main therapy for advanced EGFR-mutant lung adenocarcinoma LUAD, but treatment response varies widely and options are limited once resistance develops. Mechanisms of primary EGFR-TKI resistance remain inadequately understood. We found that multiple bacteria of the Bacteroidetes phylum, including the periodontal pathogens *Porphyromonas gingivalis* (Pg), lead to EGFR-TKI resistance in vitro. Pg infection is implicated in the pathogenesis and progression of several malignancies, including lung cancer, likely through secreted virulence factors and immune modulation. This led us to investigate the effect of Pg on EGFR-TKI sensitivity in EGFR mutant lung cancer.

Methods: EGFR-mut LUAD cells were treated with Pg preconditioned medium (PCM) under EGFR-TKI or control conditions, followed by evaluation of drug response, IGF1R signaling activation, and the contribution of Pg gingipains through mutant analyses and treatment with purified gingipains. The presence of Pg in human lung cancer was investigated using Fluorescence In Situ Hybridization (FISH) probes specific to Pg. Human EGFR-mut lung tumor tissue slices were used to assess the Pg effect on osimertinib resistance. Direct interaction between gingipains and IGF1R were analyzed by dot-blot and co-immunofluorescence assays. The equilibrium binding constants (Kd) for IGF1R binding to Kgp and RgpA were determined to quantify the strength of their non-covalent, reversible protein-protein interactions.

Results: Infection with Pg significantly decreased the sensitivity of multiple EGFR-mut LUAD to EGFR-TKIs including osimertinib and lazertinib in both human and mouse EGFR-mutant lung cancer cells through activation of the IGF1R pathway. Pg infection with osimertinib showed higher pIGF1R levels and lower cleaved caspase-3 levels in human lung tumor slice versus osimertinib alone. Mutant gingipain-deficient Pg abolished the activation of IGF1R signaling and restored TKI sensitivity. Clinical isolates of Pg derived from individuals with periodontal disease were also led to dramatic decreases in EGFR-TKI sensitivity. Purified gingipains RgpA and Kgp both activate IGF1R pathway by directly binding to IGF1R protein. The K_d value showed strong binding interaction between IGF1R and RgpA, and moderate binding interaction between IGF1R and Kgp.

Conclusion: Pg, commonly identified within LUAD tissues, induces EGFR-TKI resistance in EGFR-mut LUAD via Pg gingipain-dependent activation of IGF1R. Gingipains directly interact with IGF1R, revealing a new bacterium-tumor crosstalk mechanism that promotes drug resistance and suggesting potential therapeutic benefits of targeting bacterial enzymes or the IGF1R pathway. Additional studies on the effect of Pg on EGFR-TKI response in humans are needed.

#7032 GLAST (SLC1A3), a novel therapeutic target for overcoming osimertinib resistance in lung cancer.

Sara Bernstein[1], Sophie Kim[1], Clara Takanohashi[1], Beatriz P. Peixoto[1], Kathy Nguyen[2], Hiromi Inoue Wettersten[3]

[1]UCSD, La Jolla, CA,[2]Western University of Health Sciences, Pomona, CA,[3]Pathology, UCSD, La Jolla, CA

Lung cancer is the leading cause of cancer-related death in the U.S. with EGFR-mutant non-small cell lung cancer (NSCLC) as the second most common subtype. Although osimertinib, a third-generation EGFR inhibitor, is the preferred first-line treatment and significantly improves outcomes, resistance inevitably develops. The mechanisms driving this resistance are not fully understood, with current research primarily focused on genetic alterations while non-genetic, metabolic factors remain largely unexplored. This knowledge gap limits our ability to design effective therapies to overcome resistance. The objective of this study is to investigate the metabolic pathways that EGFR-mutant NSCLC cells exploit to develop osimertinib resistance. Prior studies with earlier EGFR inhibitors suggest that cancer cells rewire glutamine metabolism to survive EGFR inhibition; therefore we hypothesize that upregulation of glutamine metabolism enables lung cancer cells to acquire osimertinib resistance. To test this hypothesis, osimertinib-resistant and -naive NSCLC cell lines were established from xenograft tumors in mice, and levels of enzymes and transporters in glutamine metabolism were compared. Osimertinib-resistant cells exhibited increased expression of GLAST (SLC1A3), a glutamate transporter, compared to naive cells. Both genetic and pharmacological inhibition of GLAST selectively reduced viability of osimertinib-resistant but not -naive cells. Additionally, patient whole exome sequencing data showed that high GLAST expression correlates with poor prognosis in osimertinib-treated patients.These findings identify GLAST as a novel therapeutic target to overcome osimertinib resistance in EGFR-mutant NSCLC.

#7033 Inhibition of PGC1b/mitochondrial biogenesis as a critical event in mediating therapeutic response of EGFR mutant NSCLC to third generation EGFR inhibitors.

Zhen Chen[1], Dongsheng Wang[2], Songqing Fan[3], Qiming Wang[4], Suresh S. Ramalingam[1], Shi-Yong Sun[5]

[1]Emory Winship Cancer Institute, Atlanta, GA,[2]Research Associate, Dept. of Hem./Onc., Emory University, Atlanta, GA,[3]The Second Xiangya Hospital, Central South University, Changsha, China,[4]The Affiliated Cancer Hospital of Zhengzhou University & Henan Cancer Hospital, Zhengzhou, China,[5]Emory University, Atlanta, GA

Third generation EGFR tyrosine kinase inhibitors (EGFR-TKIs) such as osimertinib are used for the treatment of advanced non-small cell lung cancer (NSCLC) harboring activating EGFR mutations. However, despite robust clinical efficacy of these agents, the inevitable issue of acquired resistance needs to be urgently addressed. Here we reported *PPARGC1B* expression was downregulated, and its regulated mitochondrial biogenesis was inhibited by osimertinib as well other EGFR-TKIs in EGFR mutant (EGFRm) NSCLC cells through a previously unidentified FOSL1/AP-1-mediated transactivation of the *PPARGC1B* gene. Once cells or tumors became resistant to osimertinib, PGC1β encoded by *PPARGC1B* showed rebound elevation and was resistant to downregulation by osimertinib. Enforced overexpression of *PPARGC1B* in osimertinib-sensitive EGFRm NSCLC cell lines conferred resistance to osimertinib, whereas knockdown of *PPARGC1B* in osimertinib-resistant cells restored sensitivity to osimertinib. Moreover, osimertinib combined with a mitochondria-targeting agent such as CPI-613 synergistically decreased cell survival with enhanced suppression of mitochondrial biogenesis and induction of apoptosis in osimertinib-resistant cells and effectively inhibited the growth of osimertinib-resistant tumors. Hence, it is apparent that the modulation of PGC1β/mitochondrial biogenesis critically impacts the therapeutic outcomes of osimertinib in the treatment of EGFRm NSCLC. Our findings not only reveal a novel mechanism underlying osimertinib acquired resistance, but also suggest a potential therapeutic strategy for overcoming acquired resistance to osimertinib via co-targeting PGC1β, particularly mitochondrial biogenesis.

#7034 The potential of dequalinium chloride and osimertinib combination in overcoming osimertinib acquired resistance in EGFR-mutant non-small cell lung cancer.

Jing Sun[1], Dongsheng Wang[2], Suresh S. Ramalingam[3], **Zhen Chen**[4], Shi-Yong Sun[5]

[1]Peking University Cancer Hospital & Institute, Beijing, China,[2]Research Associate, Dept. of Hem./Onc., Emory University School of Medicine, Atlanta, GA,[3]Emory University School of Medicine, Atlanta, GA,[4]Emory Winship Cancer Institute, Atlanta, GA,[5]Emory University, Atlanta, GA

Third-generation EGFR tyrosine kinase inhibitors (TKIs), such as osimertinib, have significantly improved outcomes for patients with EGFR-mutant non-small cell lung cancer (NSCLC). However, nearly all patients eventually develop acquired resistance after an initial response, highlighting the urgent need for novel therapeutic strategies to overcome this challenge. Dequalinium Chloride (DQC) is a clinically used cationic amphiphilic antimicrobial agent with low toxicity that selectively accumulates in mitochondria and induces mitochondrial dysfunction. Leveraging these properties, we investigated the therapeutic potential of combining DQC with osimertinib to overcome resistance in EGFR-mutant NSCLC models. The DQC-osimertinib combination synergistically reduced cell viability, suppressed colony formation, and induced Bim-mediated apoptosis in resistant cell lines. In xenograft models, the combination markedly inhibited tumor growth without increasing systemic toxicity. Mechanistically, in osimertinib-sensitive cells, osimertinib alone increased reactive oxygen species (ROS) levels and decreased mitochondrial membrane potential, whereas these effects were absent in resistant cells, indicating mitochondrial adaptation during acquired resistance. Co-treatment with DQC and osimertinib induced profound mitochondrial dysfunction, characterized by elevated ROS accumulation, loss of mitochondrial membrane potential, and increased γ-H2AX foci formation indicating ROS-dependent DNA damage. The ROS scavenger N-acetylcysteine (NAC) attenuated mitochondrial dysfunction and apoptosis, confirming a ROS-mediated mechanism. Moreover, DQC combined with osimertinib synergistically reduced the survival of EGFR-mutant NSCLC cell lines with primary resistance to osimertinib. In osimertinib-sensitive models, the combination also suppressed proliferation and delayed the onset of acquired resistance. Collectively, these findings demonstrate that targeting mitochondrial homeostasis with DQC enhances osimertinib efficacy and delays resistance, supporting a mitochondria-targeted therapeutic approach for EGFR-mutant NSCLC.

#7035 CD24 as a therapeutic vulnerability in osimertinib-induced drug-tolerant persister cells of EGFR-mutant NSCLC.

Ji Ae Ko[1], Ji Hyung Moon[1], Youwon Lee[2], Minyeop Kim[2], Eun Ji Lee[2], Seung Yeon Oh[2], JI WOO LIM[2], So Young Park[2], Sujin Choi[2], Jii Bum Lee[2], Min Hee Hong[3], Jae-Hwan Kim[4], Sun Min Lim[2], Byoung Chul Cho[2], **Mi Ran Yun**[1]

[1]Severance Biomedical Science Institute, Seoul, Korea, Republic of,[2]Yonsei University College of Medicine, Seoul, Korea, Republic of,[3]Yonsei University College of Medicine SBSI, Seoul, Korea, Republic of,[4]Yonsei University Hospital Cancer Center, Seoul, Korea, Republic of

Drug-tolerant persister (DTP) cells survive therapeutic pressure and drive residual disease, limiting the long-term efficacy of targeted therapies. The third-generation epidermal growth factor receptor (EGFR) tyrosine kinase inhibitor (TKI) osimertinib has markedly improved outcomes for patients with EGFR-mutant non-small cell lung cancer (NSCLC). However, resistance inevitably emerges. This resistance is largely driven by the persistence and adaptive evolution of DTP cells. Nevertheless, the molecular mechanisms underlying the formation and maintenance of osimertinib-induced DTP cells remain poorly understood. To better define these mechanisms, we performed single-cell RNA sequencing (scRNA-seq) on resected tumor specimens from patients with EGFR-mutant NSCLC treated with neoadjuvant osimertinib. Analyses included paired pre-treatment biopsy samples and post-treatment surgical specimens, stratified by pathological response (major pathological response [MPR] vs. non-MPR). Key findings were validated using TCGA/GTEx, public scRNA-seq datasets, IHC of clinical residual tumors, and functional assays in CRISPR/Cas9-edited cell lines and long-term drug-treatment models. Pre-treatment epithelial cells in non-MPR tumors exhibited markedly higher CD24 expression and $CD24^+$ fractions compared with MPR tumors, and these levels remained stable post-treatment, indicating a pre-existing $CD24^+$ state associated with reduced initial response. In contrast, MPR tumors displayed a robust post-treatment increase in CD24 expression and $CD24^+$ epithelial subsets, consistent with public EGFR-TKI DTP datasets. Re-clustering of MPR epithelial cells revealed seven subclusters, among which C1, C3, and C5 were enriched for post-treatment cells and classified as DTP-like. CD24 expression peaked in C1 and C6, with C6 containing balanced pre/post cells. Pseudotime analysis identified three transcriptional trajectories, placing CD24-high clusters C1 and C6 at terminal states enriched for post-treatment cells, with CD24 expression progressively increasing toward this endpoint. Notably, pre-treatment cells within C6 were exclusively CD24-high, suggesting selective preservation of a pre-existing $CD24^+$ subset. CD24-high clusters were enriched for ferroptosis, ROS signaling, and autophagy—canonical DTP programs. *In vitro* DTP models also demonstrated significant upregulation of CD24 following osimertinib treatment, while CD24 depletion reduced basal proliferation, enhanced the antiproliferative effect of osimertinib, and delayed regrowth after drug withdrawal. Together, these results identify CD24 as a marker of both pre-existing and therapy-induced epithelial states that sustain DTP survival and regrowth, highlighting CD24 as a potential therapeutic vulnerability for achieving more durable responses to osimertinib in EGFR-mutant NSCLC.

#7036 EcDNA-mediated oncogene amplification underlies EGFR TKI resistance in NSCLC.

Boyoon Kim[1], Sujin Kim[2], Jeonghee Cho[3], Hoon Kim[4]

[1]Department of Biohealth Regulatory Science, Sungkyunkwan University, Suwon, Korea, Republic of,[2]Department of Biomedical Sciences & Biosystems, Dankook University, Cheonan, Korea, Republic of,[3]Department of Biomedical Sciences & Biosystems, Department of Nanobiomedical Science, Dankook University, Cheonan, Korea, Republic of,[4]Department of Biopharmaceutical Convergence, Department of Pharmacy, Sungkyunkwan University, Suwon, Korea, Republic of

Extrachromosomal DNA (ecDNA) drives oncogene amplification and therapeutic resistance in multiple cancers, but its contribution to acquired resistance to EGFR inhibitors (EGFRi) in EGFR-mutant non-small cell lung cancer (NSCLC) is not well defined. While EGFR TKI resistance frequently arises through acquisition of the EGFR T790M mutation, many cases remain unexplained. We therefore aimed to determine whether ecDNA represents an additional mechanism associated with EGFR TKI resistance. We analyzed whole-genome sequencing datasets from TCGA, PCAWG, and the Hartwig Medical Foundation, encompassing 536 NSCLC tumors, and detected ecDNA structures using AmpliconArchitect. Across these public cohorts, ecDNA prevalence was markedly elevated in EGFR TKI-treated tumors (50%, 10/20) compared with primary tumors (14%, 20/147; OR≈6.35, $p<0.001$) and advanced untreated tumors (25%, 92/369; OR≈3.01, $p=0.02$), indicating a significant association between EGFR TKI exposure and increased ecDNA prevalence. Notably, all ecDNAs detected in the EGFR TKI-treated group harbored oncogenic drivers, underscoring their potential functional relevance. To investigate whether this enrichment reflects resistance-associated events, we established an isogenic PC9 resistance model by generating WGS and RNA-seq data from resistant subclones derived from a single EGFR TKI-sensitive clone following long-term erlotinib exposure. Analysis of 25 resistant PC9 samples revealed ecDNA acquisition in approximately 20% of clones (5/25), all of which contained oncogenes. These ecDNA-positive clones were mutually exclusive with EGFR T790M-positive samples (also 20%, 5/25), suggesting that ecDNA emergence represents an alternative resistance route rather than a secondary event downstream of T790M. Functional analyses demonstrated activation of EGFR downstream signaling pathways in ecDNA-positive resistant cells. For example, in one resistant subclone harboring a newly formed RAF1 ecDNA (copy number ~24), we observed over 100-fold RAF1 overexpression and marked MAPK/ERK pathway activation, as supported by GSEA (NES = 1.39, $p < 0.01$). Functional RAF1-inhibition experiments further confirmed that suppressing RAF1-driven signaling restored erlotinib sensitivity, providing strong evidence that ecDNA-mediated RAF1 amplification leads to EGFR-independent MAPK pathway activation. EcDNA may promote the development of EGFR TKI resistance by enabling alternative signaling pathways that bypass EGFR activity. EcDNA-mediated oncogene amplification represents an important feature of EGFR TKI-resistant NSCLC and a potential therapeutic vulnerability, providing a foundation for strategies aimed at overcoming ecDNA-driven resistance.

#7037 Phospho-reprogramming mitochondrial respiration underlies sunitinib resistance in renal cell carcinoma.

Gianna Lee Mochi[1], Samhitha Adavikolanu[2], Julia K. Burkacki[2], Mark R. Woodford[3]

[1]Urology, Biochemistry & Molecular Biology, SUNY Upstate Medical University, Syracuse, NY,[2]SUNY Upstate Medical University, Syracuse, NY,[3]Urology, SUNY Upstate Medical University, Syracuse, NY

Clear cell renal cell carcinoma (ccRCC) is the most common type of kidney cancer. While surgery is effective for localized ccRCC, advanced disease necessitates the use of additional therapies such as immune checkpoint inhibitors or tyrosine kinase inhibitors (TKIs). Emergent resistance limits TKI efficacy, and prognosis in patients with refractory disease is poor. Recent work indicates that metabolic reprogramming underlies TKI resistance, however the details are poorly understood. Phosphoproteomics study has shown that sunitinib-resistant ccRCC tumors exhibit differential phosphorylation of the electron transport chain Complex II subunit SDHA and the mitochondrial chaperone TRAP1. TRAP1 controls metabolic flux by regulating the activity of the mitochondrial respiratory machinery, indicating a role for TRAP1 phosphorylation in tuning this activity. The objective of our work was to determine the impact of SDHA & TRAP1 phosphorylation on metabolism and TKI resistance.Transient transfection of SDHA phospho-mutants in wild-type 293 or TRAP1 phospho-mutants in TRAP1 knockout 293 cells was used to model phosphorylation changes in SDHA and TRAP1. Immunoblotting and immunoprecipitation were used to evaluate protein expression and interaction. Seahorse Mito stress test analysis was used to measure the respiratory capacity of 293 cells expressing TRAP1 and SDHA phospho-mutants, while MTT assay was used to measure the viability of 293 cells expressing TRAP1 phospho-mutants in response to TKI treatment. MTT assay was additionally used to measure proliferation of naïve and TKI-resistant normal kidney and ccRCC cell lines upon TRAP1 inhibition with Gamitrinib-TPP. We observed that expression of TRAP1 and SDHA phospho-mutants modulated respiration and impacted sensitivity to the TKIs sunitinib and cabozantinib, suggesting a common resistance mechanism. Furthermore, sunitinib-resistant ccRCC cell lines exhibited differing sensitivity to a small molecule TRAP1 inhibitor, suggesting a potential therapeutic intervention. Post-translational modifications regulate the activity of many metabolic proteins, including TRAP1 and SDHA, thereby tuning cellular metabolic flux. Differential phosphorylation of these proteins is correlated with ccRCC sensitivity to sunitinib, and metabolic dysregulation underlies TKI resistance. We found that blocking phosphorylation of SDHA and TRAP1 suppressed respiration, and TRAP1 phospho-null mutation decreased cell sensitivity to TKIs. Furthermore, we observed that sunitinib-resistant ccRCC cell lines demonstrated increased sensitivity to TRAP1 inhibition. Collectively, our work demonstrates the potential for novel combination therapies for targeting TKI-resistant ccRCC.

#7038 SIPA1L3 loss induces TKI resistance via Rap1-MAPK activation in ALK-/RET-fusion positive NSCLC.

Xinzhao Wei[1], Jun Adachi[2], Ryohei Katayama[3]

[1]Division of Experimental Chemotherapy, Cancer Chemotherapy Center, Japanese Foundation for Cancer Research, Tokyo, Japan,[2]Laboratory of Proteomics for Drug Discovery, Center for Drug Design Research, National Institutes of Biomedical Innovation, Health and Nutrition, Osaka, Japan,[3]Japanese Foundation for Cancer Research, Tokyo, Japan

ALK-/RET-fusion-positive non-small cell lung cancer (NSCLC) accounts for 3-5% and 1-2% of total NSCLC cases, respectively. Selective tyrosine kinase inhibitors (TKIs) against ALK or RET have demonstrated remarkable efficacy, and six ALK-TKIs and two RET-TKIs have been approved for the treatment of ALK- or RET-rearranged NSCLC. However, resistance can occur even in patients who initially achieve marked tumor shrinkage. To date, many investigators have reported mechanisms of ALK- or RET-TKI resistance, focusing on secondary mutations, activation of bypass signaling pathways, or EMT transition. Still, in a significant number of cases, the mechanism of resistance remains unknown.To discover additional potential resistance mechanisms, we conducted a genome-wide CRISPR/Cas9 screening under floating culture condition culture conditions in CCDC6-RET fusion positive LC2/ad cells treated with selpercatinib or pralsetinib for nine days. sgRNAs in surviving drug-tolerant cells were then analyzed by NGS. We identified multiple candidate genes, including MED12 and SIPA1L3, that contribute to drug-tolerant persister (DTP) cell survival during RET-TKI treatment. SIPA1L3 encodes a Rap1 GTPase-activating protein (GAP) that promotes the conversion of the active GTP-bound form of Rap1 to its inactive GDP-bound form. Knockout of SIPA1L3 induced significant increase of Rap1-GTP, leading to resistance through activation of the MAPK and PI3K/Akt/mTOR pathways. Phosphoproteomic analysis confirmed upregulation of phospho-Raf, -ERK, and -S6, indicating enhanced MAPK signaling in SIPA1L3-deficient LC2/ad cells after selpercatinib treatment as compared to control cells after the same treatment.These findings highlight the critical regulatory role of SIPA1L3 on Rap1 activation in bypassing RET inhibition through MAPK activation. Notably, combining RET-TKIs with MAPK pathway inhibitors —particularly the Raf-MEK dual inhibitor avutometinib—markedly reduced DTP cell survival *in vitro,* and induced tumor shrinkage in SIPA1L3-knocked-out tumors that relapsed on selpercatinib single treatment *in vivo*, suggesting a promising strategy to overcome such resistance. Furthermore, loss of SIPA1L3 also conferred ALK-TKI resistance in the ALK-fusion H3122 cell line, accompanied by increased Rap1-GTP expression. Co-treatment with alectinib and avutometinib effectively suppressed DTP formation.In conclusion, this study identifies SIPA1L3 as a critical mediator of ALK- or RET-TKI resistance in NSCLC from genome-wide CRISPR screening and underscores the therapeutic potential of avutometinib in combination with ALK-/RET-TKIs to overcome drug-tolerant persistence and improve treatment outcomes in ALK-/RET-rearranged NSCLC.

#7039 FER drives drug-tolerant persister cell survival in EGFR-mutant lung cancer.

Bobak Parang[1], Rabia Khan[2], Ariana Kupai[1], Yuyun Huang[1], Sungyun Cho[2], Michal J. Nagiec[2], Eric E. Gardner[2], Florencia M. Rowdo[2], Benjamin D. Hopkins[2], Qin Fu[3], Sheng Zheng[3], Timothy F. Burns[1], John Blenis[2]

[1]The Ohio State University College of Medicine, Columbus, OH,[2]Weill Cornell Medicine, New York, NY,[3]Cornell University, Ithaca, NY

Approximately 20% of patients with metastatic non-small cell lung cancer (NSCLC) harbor an EGFR-mutation (EGFRm). Osimertinib, a third generation EGFR inhibitor, has dramatically improved patient outcomes, but invariably, residual disease or drug-tolerant “persister” (DTP) cells survive treatment, eventually giving way to resistant or progressive disease. Eradicating DTPs remains a key challenge. Although DTPs have been characterized at the transcriptional level, a major gap in our understanding is how the tyrosine kinome is perturbed. We hypothesized that defining the phospho-tyrosine landscape of DTPs would uncover kinases that could be exploited therapeutically.

We generated DTPs by treating EGFRm cell lines with osimertinib (IC90) for 14 days and performed tyrosine-enriched, phospho-proteomics. Analysis using Kinase Library revealed that FER, a non-receptor tyrosine kinase that has been implicated in regulating a variety of pathways, is highly active in DTPs. To validate our findings, we confirmed that FER is auto-phosphorylated in DTPs. We then demonstrated that FER and its known substrates are phosphorylated within hours of osimertinib treatment, suggesting FER is activated early and throughout treatment. Next, we tested the functional impact of FER. FER knockdown had no effect on baseline phenotypes such as morphology or proliferation, but FER knockdown markedly decreased DTPs after 14 days of osimertinib treatment.

We thus evaluated inhibiting FER as a therapeutic strategy. Alectinib, a well-tolerated FDA approved drug designed to target the ALK kinase, potently inhibits FER. We hypothesized that inhibiting FER using alectinib would eliminate DTPs and prevent osimertinib resistance. We first confirmed that 1) alectinib inhibits FER kinase activity and 2) ALK is not expressed in EGFRm NSCLC, consistent with prior reports. We subsequently treated cells with alectinib at 500nM, the physiologic concentration achievable using low dose alectinib in patients. Combining alectinib with osimertinib dramatically reduced DTPs in four EGFRm cell lines. Phospho-proteomics and RNA-sequencing revealed that alectinib and osimertinib suppressed FER phosphorylation and RHO GTPase signaling, a pathway known to drive DTP survival. Combining alectinib with osimertinib also significantly enhanced osimertinib sensitivity in patient-derived, EGFRm organoids. To test the strategy *in vivo*, we treated EGFRm xenografts with osimertinib or osimertinib and alectinib for only 21 days. After stopping treatment, 100% of the osimertinib-only treated mice had to be euthanized while 33% of mice treated with combination osimertinib and alectinib were disease-free after 150 days of observation. Collectively, our data show that FER is a key tyrosine kinase that is activated in DTPs and that targeting it with alectinib, an FDA approved drug, could be an effective strategy to enable durable remission in patients with EGFRm NSCLC.

#7040 Cancer persister cells are sensitized to copper-mediated death.

Anna Elizabeth Stuhlfire, August (Gus) Finley Williams, Masayoshi Higuchi, Ariel H. Nguyen, David A. Gervasio, Claire Turkal, Janani Nagasubramanya, Michael Nguyen, Suejean Chon, Matthew Hangauer

Dermatology, UC San Diego, La Jolla, CA

Drug-tolerant cancer persister cells survive drug treatments and contribute to acquired resistance. Elimination of persister cells may increase the durability of treatment responses but there are currently no clinically approved therapies targeting persister cells. We previously showed cancer persister cells which survive oncogene-targeted therapy are selectively vulnerable to ferroptosis induced by GPX4 inhibition. While nontoxic bioavailable GPX4 inhibitors have yet to be developed, the recent emergence of bioavailable FSP1 inhibitors allows for induction of ferroptosis in FSP1-dependent tumor cells in vivo. However, we recently found persister cells are more dependent on GPX4 than FSP1 in cell culture and it remains to be determined whether FSP1 inhibition alone is sufficient to kill persister cells in vivo. Here, we considered other clinically available drugs which may selectively kill persister cells. It was previously reported that persister cells are sensitized to disulfiram, an FDA-approved treatment for alcohol use disorder based on disulfiram's aldehyde dehydrogenase (ALDH) inhibition activity. However, we found disulfiram-mediated persister cell killing is independent of ALDH inhibition. Disulfiram also depletes glutathione and we found glutathione replenishment protects persister cells from disulfiram, but glutathione depletion alone is insufficient to kill persister cells because near complete inhibition of glutathione biosynthesis with buthionine sulfoximine is not consistently toxic to persister cells. Furthermore, we found that persister cells are variably rescued from disulfiram treatment by soluble antioxidants or caspase inhibition, and are not rescued by anti-ferroptosis lipophilic antioxidants. However, in all tested persister cell models, disulfiram-induced killing is inhibited by treatment with copper chelator tetrathiomolybdate. Indeed, disulfiram is also a copper ionophore recently demonstrated to induce cuproptosis. We found another clinically tested copper ionophore elesclomol also selectively kills persister cells. Furthermore, other groups have previously shown that co-treatment of EGFR mutant non-small cell lung cancer tumors with disulfiram or elesclomol improves response durability. Therefore, though disulfiram and elesclomol have failed to produce robust clinical benefit when paired with genotoxic chemotherapies or radiation in treatment-refractory tumors, no prior trials have applied either drug to targeted therapy treated tumors or minimal residual disease. Our observations support repurposing copper ionophores to target minimal residual disease in the context of oncogene-targeted therapy treatments.

#7041 Integrated multi-omics and spatial transcriptomics reveal tumor stroma co-evolution driving dabrafenib resistance in BRAF-V600E cholangiocarcinoma.

Nai-Jung Chiang[1], Ya-Chin Hou[2], Chi-Che Hsieh[3], Chao-Chun Cheng[4], Che-Hung Shen[4]

[1]Department of Oncoloy, Taipei Veterans General Hospital, Taipei, Taiwan,[2]Institute of Clinical Medicine, College of Medicine, National Cheng Kung University, Tainan, Taiwan,[3]School of Dentistry, Taipei Medical University, Taipei, Taiwan,[4]National Institute of Cancer Research, National Health Research Institutes, Tainan, Taiwan

Background: BRAF-V600E mutation represents one of the most therapeutically actionable oncogenic alterations in cholangiocarcinoma (CCA). Although BRAF inhibitors such as Dabrafenib have demonstrated clinical benefit, responses in CCA are often transient, with rapid disease recurrence and high invasiveness compared to melanoma or thyroid cancer. The mechanisms underlying such therapy-induced adaptation remain poorly understood.

Methods: We established a Dabrafenib-resistant BRAF-V600E CCA model and its drug-sensitive counterpart, followed by integrated transcriptomic, proteomic, and metabolomic profiling. In parallel, spatial transcriptomics (ST) was performed on paired pre-treatment and post-recurrence CCA patient specimens to spatially dissect malignant cells, cancer-associated fibroblasts (CAFs), and $CD45^+$ immune cells within the tumor microenvironment (TME).

Results: Multi-omics integration identified 3,562 differentially expressed genes, 1,986 proteins, and hundreds of metabolites that collectively revealed a TME-driven resistance phenotype. Resistant malignant cells displayed activation of epithelial-mesenchymal transition (EMT) and xenobiotic detoxification pathways, while CAFs underwent profound PPAR-driven fatty acid metabolic reprogramming and CYP450 enrichment, transforming the stroma into a nutrient-rich and drug-inactivating niche. Concurrently, the $CD45^+$ compartment exhibited transcriptional signatures of KRAS/E2F signaling, chronic inflammation, and metabolic exhaustion. Strikingly, Complement and Coagulation Cascades were spatially co-localized and synchronously activated across all three compartments, suggesting a unified mechanism of immune evasion and stromal barrier formation.

Conclusions: Our findings reveal that acquired Dabrafenib resistance in BRAF-V600E CCA arises from the co-evolution of intrinsic EMT and extrinsic TME remodeling. The CAF metabolic axis and shared TME-Coagulation pathway emerges as actionable vulnerabilities, offering a mechanistic rationale for combination strategies to overcome therapeutic resistance in recurrent CCA.

#7042 Missense mutant p53 regulates DNA replication and damage response to promote resistance to targeted therapies in ALK fusion lung adenocarcinoma.

Esther Redin, Barbara P. Mello, Yingian A. Zhan, Nicholas Socci, Samuel Tischfield, Alexander Lim, Hong Zhong, Mark Donoghue, Richard Koche, Elisa De Stanchina, Alexander Drilon, Alvaro Quintanal-Villalonga, Charles M. Rudin

Memorial Sloan Kettering Cancer Center, New York, NY

ALK gene fusions drive oncogenesis in ~5% of lung adenocarcinomas (LUADs), and ALK tyrosine kinase inhibitors (TKIs) such as lorlatinib have improved outcomes. However, acquired resistance remains a challenge, with >30% of mechanisms unknown. To uncover novel drivers of resistance, we performed multi-omic profiling of clinical samples and PDXs. Genomic analysis of 83 ALK+ LUADs revealed frequent co-occurring alterations, including CDKN2A deletion (34%), TP53 mutation (32%), and MYC amplification (13%). Transcriptomic profiling highlighted enrichment of DNA replication and repair pathways, MYC targets, epithelial-to-mesenchymal transition, and TGF-β signaling in resistant tumors. scRNAseq of matched sensitive and resistant PDXs revealed extensive heterogeneity and diverse resistance pathways, mirroring those in clinical samples. Notably, elevated DNA replication and repair activity strongly correlated with TP53 missense mutations in clinical samples. Analysis of MSK clinical cohort showed that 80% of TP53 mutations in ALK+ LUAD occur in the DNA-binding domain, predominantly missense variants with potential gain-of-function (GOF) properties. The presence of TP53 missense mutations predicted worse prognosis in ALK-fusion LUAD patients treated with TKIs.To assess the role of mutp53 in resistance, we overexpressed R175H and R273H in ALK+ H3122 and H2228 cells. Co-immunoprecipitation and mass spectrometry revealed that mutp53 associates with DNA repair, cell cycle, and chromatin remodeling proteins. Mutp53-expressing cells were refractory to lorlatinib compared to isogenic p53-deficient clones. Overexpression of mutp53 upregulated DNA replication proteins, including ORC and MCM family members, as well as DNA repair proteins such as BRCA1, ATM, CHEK1, and MSH6. Notably, mutp53-expressing cells maintained DNA replication and repair protein levels following lorlatinib-induced DNA damage, unlike p53-deficient counterparts. Immunofluorescence of the DNA damage marker pH2A demonstrated complete repair of lorlatinib-induced lesions in the presence of mutp53, revealing a novel GOF role for these mutants. Furthermore, mutp53 enhanced DNA synthesis by promoting origin firing, thereby facilitating cellular survival under targeted therapy. Similar effects were observed in EGFR-driven LUAD cells, indicating that mutp53 contributes to resistance across oncogene-driven LUADs.To target this axis, we tested the proteasome inhibitor carfilzomib which inhibited mutp53 proteins and promoted the degradation of DNA replication proteins. Carfilzomib synergized with lorlatinib in resistant ALK+ p53 mutant cells and induced robust tumor response in TP53 mutant ALK+ PDX models resistant to lorlatinib, demonstrating therapeutic potential. In summary, missense mutp53 promotes ALK TKI resistance by enhancing DNA replication and repair.

#7044 Resistance to sorafenib leads to epithelial-to-mesenchymal transition and alterations in cell phenotype in HCC.

Paulina Marona[1], Anna Ferenc[1], Isabel Fabregat[2], Ester Gonzales Sanchez[2], Esther Bertran[2], Javier Vaquero[2], Jolanta Jura[1], Katarzyna Miękus[1]

[1]Jagiellonian University, Faculty of Biochemistry, Biophysics and Biotechnology, Krakow, Poland,[2]TGF-β and Cancer Group, Oncobell Program, Bellvitge Biomedical Research Institute IDIBELL, Barcelona, Spain

Introduction: Hepatocellular carcinoma (HCC) remains a highly aggressive malignancy with limited therapeutic options, and the development of resistance to sorafenib—the first-line systemic treatment for advanced disease—significantly compromises clinical outcomes. Understanding the mechanisms underlying the acquisition of sorafenib resistance is crucial, as it not only limits the drug's therapeutic efficacy but also promotes tumor progression and treatment failure in patients with advanced HCC. Previously, we demonstrated that MCPIP1 can partially reverse sorafenib resistance in clear cell renal cell carcinoma. Therefore, the main aim of our research is to investigate the molecular basis of sorafenib resistance in HCC and the potential protective role of MCPIP1 during this process.
Material and Methods: We used two HCC cell lines—HUH7 and SNU449—continuously treated with sorafenib. We analyzed cell proliferation, migration, and invasion. Next, we performed mass spectrometry analysis and validated the obtained results using western blotting and real-time PCR. To determine changes in cell phenotype, we conducted a series of immunohistochemical stainings. To examine the effect of MCPIP1, wild-type and sorafenib-resistant cell lines were transduced to overexpress MCPIP1 along with appropriate controls.
Results and Discussion: Exposure to sorafenib induces notable phenotypic changes in HCC cell lines. In HUH7 cells, which normally display an epithelial phenotype, prolonged treatment is commonly associated with a shift toward a more mesenchymal-like state, characterized by reduced cell-cell adhesion and pronounced morphological alterations, including the formation of membrane protrusions such as filopodia and lamellipodia. SNU449 cells, which already exhibit relatively mesenchymal features, further reinforce this phenotype under sorafenib pressure, displaying increased motility and a more invasive appearance. Consistent with these observations, we detected substantial reorganization of the actin cytoskeleton as well as elevated levels of structural and regulatory proteins such as vimentin, RhoA, RhoB, and Ras. Together, these changes reflect a transition toward epithelial-to-mesenchymal characteristics. Interestingly, all resistant cells exhibited a significantly decreased level of MCPIP1. Following MCPIP1 overexpression, we observed a reduction in EMT-related markers, including vimentin and Snail, suggesting a potential suppressive role of MCPIP1 in the development of sorafenib resistance.
Conclusions: In conclusion, our results indicate that sorafenib resistance in HCC is associated with EMT and cytoskeletal remodeling, and that MCPIP1 may act as a suppressor of this process, representing a potential therapeutic target to overcome resistance.
This study was supported by National Science Center grant no. 2022/47/B/NZ5/02724.

#7045 Multi-omics identifies EMT and PI3K/AKT pathways as mechanisms for Astragalus membranaceus polysaccharide-mediated reversal of osimertinib resistance.

Kenneth K.W. To[1], Longling Wang[1], Zhong Zuo[1], William C. Cho[2]

[1]School of Pharmacy, The Chinese University of Hong Kong, Hong Kong, China,[2]Department of Clinical Oncology, Queen Elizabeth Hospital, Hong Kong, China

Background and Aim: Osimertinib is the only 3rd generation epidermal growth factor receptor (EGFR) tyrosine kinase inhibitor approved for the 1st line therapy of advanced NSCLC patients with EGFR mutations. However, drug resistance severely hinders its efficacy. There is limited therapeutic option after osimertinib failure. *Astragalus membranaceus* (AM) is a medicinal plant long used in traditional Chinese medicine. When combined with chemotherapy, AM has been shown to enhance anticancer efficacy and reduce side effects. The beneficial biological effects of AM are mainly attributed to its polysaccharides (AMP). However, the underlying mechanisms remain elusive. This study employed a multi-omics approach to investigate the mechanism by which AMP overcome osimertinib resistance, focusing on key genetic abnormalities and alterations in critical signaling pathways.

Method: The extraction of AMP from the dry roots of AM has been optimized and standardized. The crude herb and AMP were authenticated based on morphological and chemical properties as per the Chinese Pharmacopoeia. The circumvention of osimertinib resistance by AMP was investigated in NSCLC cell lines *in vitro* and patient-derived tumor xenograft (PDX) in NSG mice. In PDXs that demonstrated promising drug combination effect, RNA sequencing was conducted on total RNA extracted from the tumor tissues to evaluate the dynamic gene expression profile changes. Moreover, mass spectrometry (MS)-based phosphoproteomic analysis was conducted to identify the proteomic signatures and signaling pathway alterations associated with the circumvention of osimertinib resistance by AMP.

Results: Among the tested osimertinib-resistant NSCLC cell lines, AMP was the most effective at potentiating osimertinib in EGFR T790M mutated and *MET* amplified H820 cells. AMP also significantly inhibited tumor migration and invasion. AMP was further shown to remarkably potentiate the antitumor effect of osimertinib in two drug refractory PDX models, without causing notable toxicity. By RNA-seq analysis, GSEA results indicate significant enrichment of EMT-related gene sets in AMP-treated PDX tumors. Using connectivity mapping, AMP was found to share a highly similar transcriptomic signature with PI3K/mTOR inhibitors, suggesting a putative mechanism of action. Global quantitative MS revealed a characteristic proteomic signature of EMT reversal by AMP. MS for phosphorylated proteins further revealed enrichment of ErbB and Rap 1 (KEGG database) and PI3K/AKT signaling pathways (REACTOM database) following AMP treatment. Taken together, our study identified novel mechanisms by which AMP overcome osimertinib resistance at transcriptomic, global proteomic, and phosphoproteomic levels.

Conclusion: The findings support clinical evaluation of AMP for treating osimertinib refractory NSCLC.

#7046 BRAF/EGFR inhibition induces ERBB2 as a targetable tolerance mechanism in *BRAF*-mutant colorectal cancer.

Sara Peltola, Kari J. Kurppa, Klaus Elenius

MediCity Research Laboratories and Institute of Biomedicine, University of Turku, Turku, Finland

Acquired drug resistance remains a major limitation to the long-term efficacy of targeted cancer therapies. The development of acquired resistance can involve the emergence of drug-tolerant persister (DTP) cells, which survive treatment through nongenetic adaptations such as activation of compensatory signaling pathways. Notably, Neuregulin 1 (NRG1) is a growth factor known to promote resistance to targeted therapies across multiple cancer types. This ligand engages the receptor tyrosine kinases ERBB3 and ERBB4, which bind it directly and signal through dimerization with ERBB2. This study aims to define the functional role of NRG1/ERBB signaling in DTPs arising from targeted inhibition of their oncogenic drivers and to evaluate strategies to inhibit this pathway to prevent acquired drug resistance.

NRG1/ERBB pathway activity following targeted therapy was evaluated in a panel of oncogene-addicted cancer cell lines. CRISPR-Cas9-mediated ERBB knockouts were employed to assess the dependency of DTPs on these receptors. The efficacy of NRG1/ERBB axis inhibition with pan-ERBB inhibitors or ERBB-targeting antibody-drug conjugates was evaluated by Incucyte live-cell imaging and colony formation assays.

Upregulation of the NRG1/ERBB signaling axis on transcriptional and protein level was observed in most tested oncogene-addicted cell lines upon therapy against their driver oncogene. Marked upregulation of ERBB2 was detected in drug-tolerant *BRAF*-mutant colorectal cancer (CRC) cell lines treated with dabrafenib and cetuximab. Our flow cytometry data suggest a shift from EGFR to ERBB2/ERBB3 signaling upon treatment in this cancer context. Furthermore, preliminary results using ERBB2 knockout cells demonstrate a dependency of ERBB2 in *BRAF*-mutant CRC DTPs under BRAF/EGFR inhibition. Combination of dabrafenib with a pan-ERBB inhibitor resulted in an improved treatment response *in vitro* compared to dabrafenib with cetuximab.

Taken together, our data imply that drug tolerant *BRAF*-mutant CRC cells upregulate ERBB2/ERBB3 to resist BRAF/EGFR inhibition. Targeting the NRG1/ERBB signaling axis with a pan-ERBB inhibitor in combination with dabrafenib offers a potential strategy to prevent the emergence of resistance.

#7047 Characterization of TKI-induced drug-tolerant persister cells from patient-derived cell lines.

Floriane Braye[1], Inmaculada Alonso Garcia[1], Vincent Boursier[1], Ludovic Bigot[1], Kristi Beshiri[2], FRANCESCO FACCHINETTI[2], Jean-Paul Thiery[2], Benjamin Besse[2], Ken A. Olaussen[3], Luc Friboulet[4]

[1]INSERM U981 (Gustave Roussy), Villejuif, France,[2]Gustave Roussy, Villejuif, France,[3]Inserm U981, Institute Gustave Roussy, Villejuif, France,[4]INSERM U981 (Gustave Roussy), villejuif, France

Introduction: Targeted therapies provide substantial clinical benefit in oncogene-driven cancers, yet relapse remains inevitable. Increasing evidence suggests that a small population of drug-tolerant persister (DTP) cells survives initial therapy and ultimately gives rise to resistance. Understanding the vulnerabilities of these DTP cells is therefore essential for developing strategies that could prevent resistance before it emerges.
Materials and Methods: Patients-derived cell lines (PDC) were established from NSCLC patients included in two prospective clinical trials: MATCH-R study (2015 to 2022) and the ongoing STING trial. The two main models used were MR57, harboring EML4-ALK fusion and ALK C1156Y/G1269A mutation and sensitive to the 3rd generation ALK inhibitor lorlatinib, and ST6566, carrying an EGFR L858R mutation and highly sensitive to osimertinib.
Results and Discussion: DTP cells are characterized by marked phenotypic plasticity. In two PDC models, we observed the co-expression of epithelial and mesenchymal markers, supporting a hybrid EMT state. This plasticity is supported by BRD4, which regulates EMT-associated transcriptional programs, and by FGFR signaling, through pathway rewiring. Phospho-RTK and phosphokinase arrays revealed increased IGF1R and STAT3 phosphorylation level, consistent with adaptative signaling in DTP cells. In parallel, DTP cells displayed elevated γH2AX foci relative to treatment-naive cells, consistent with TKI-induced genomic instability that may induce a dependency on DNA-damage response pathways. *In vitro* models also enable to functionally assess these features, as well as other key DTP cells hallmarks, using long-term survival readouts, including crystal-violet clonogenic assays and IncuCyte live-cell imaging. These experiments revealed that targeting EMT-associated transcriptional control with the BRD4 inhibitor JQ1, inhibiting FGFR-driven signaling with erdafitinib, or blocking DNA-damage repair via the ATM inhibitor AZD-0156 each significantly delayed DTP regrowth. Together, these findings underline multiple actionable weaknesses emerging during the DTP state.
Conclusion: Overall, our results demonstrate that DTP cells regrowth can be delayed *in vitro*, suggesting exploitable vulnerabilities. While further validation is required, they provide a rational for testing these strategies *in vivo*, with an ultimate goal of informing patient therapeutic approach.

#7048 Neuregulin-1(NRG1*)*-directed therapies induce alkaline phosphatase placental (ALPP) expression in *NRG1*-fusion positive cancers: Preclinical data and therapeutic perspective.

Manon Barre[1], Clarisse Thiollier-Schmitt[1], Marie Issenmann[1], Celia Cortay[1], Emeline Cros-Perrial[1], Sandra Ortiz-Cuaran[1], Nicolas Gadot[2], Elodie Voilin[2], Sylvie Lantuejoul[3], Anthony Ferrari[4], Eric Cumunel[4], Charles Dumontet[1], Lars Petter Jordheim[1], Michael Duruisseaux[5]

[1]Cancer Research Center of Lyon (CRCL), Lyon, France,[2]Research pathology platform East, Cancer Research Center of Lyon (CRCL), Lyon, France,[3]UNICANCER Centre Leon Berard, Lyon, France,[4]Gilles Thomas bioinformatics platform, Cancer Research Center of Lyon (CRCL), Lyon, France,[5]Hospices Civils de Lyon, Bron, France

Background: *NRG1*-fusion positive (*NRG1+*) cancers define a new molecular subtype of solid tumors. NRG1 chimeric proteins signal through ERRB3/ERRB2 dimerization, activating PI3K/AKT and MAPK signalling pathways, promoting pro-tumoral properties. *NRG1+* cancers targeting relies on bispecific anti-ERBB2/ERBB3 antibodies such as zenocutuzumab (zeno) or ERBB2 inhibitors such as afatinib (afa). These therapies have limited clinical efficacy, suggesting that the biology of the NRG1/ERBB3 pathway is not totally understood. Our objective is to understand the mechanisms of resistance to NRG1-directed therapies in *NRG1+* cancers.
Material and Methods: We have generated afa-resistant models by continuous exposure to increasing concentrations of afa, using MDA-MB-175 cells. They grew in presence of 256 nM afatinib. Afa-sensitivity was assessed by Prestoblue test. MDA-MB-175 cells exhibit an endogenous *PPP6R3-TENM4-NRG1* fusion and are sensitive to afa, zeno and other NRG1-directed therapy. Bulk RNA sequencing data from afa-naive and afa-resistant MDA-MB-175 were subjected to unsupervised and comparative analysis. Characterization of these models was completed by quantitative RT-PCR and western blotting.
Results: Five afa-resistant MDA-MB-175 models were generated, showing 10-to-100-fold increase in IC50 as compared to sensitive cells. RNA-seq data unsupervised analysis showed that afa-resistant (n=5) and afa-naive (n=5) MDA-MB-175 formed two distinct clusters. *ALPP* was one of the ten most differentially expressed genes in afa-resistant models (log2FoldChange = 8.1, $p = 2.46.10^{-20}$) and the only one with a confirmed lack of expression in afa-naive and expression in afa-resistant MDA-MB-175 at the RNA and protein levels. In afa-resistant models, ALPP expression disappeared after 2-8 weeks when cultured without afa. In afa-naive and afa-resistant MDA-MB-175, an increase of ALPP expression was observed after one or two days of afa exposure. Investigation of NRG1-ERBB3 pathway in afa-resistant models showed a decrease of phospho-ERBB3 and phospho-ERK with no variation of total ERBB3 and ERK.
Conclusion: Afa induced early *ALPP* expression in *NRG1+* MDA-MB-175 cells, and afa-resistance was associated with high ALPP expression and a decrease of ERBB3 and ERK phosphorylation. Validation of ALPP as a relevant target is ongoing using ALPP KO and overexpressing NRG1+ models, including NRG1+ engineered preclinical models and NRG1+ patient-derived models from patients exposed to NRG1-directed therapies. Zeno and zongertinib impact on ALPP expression in preclinical models as well as ALPP expression in a cohort of *NRG1+* non-small cell lung cancer and pancreatic ductal adenocarcinoma is ongoing. Overall, ALPP may represent an attractive target in NRG1+ cancers that may prevent resistance to NRG1-directed therapies.

#7049 Genome-wide CRISPR-Cas9 screen identifies genes conferring lenvatinib resistance in hepatocellular carcinoma.

Ayumu Taguchi[1], Shuang Zhou[1], Hisanori Isomura[1], Haruki Mori[2], Toru Miyake[2], Yuichi Abe[3], Miyako Tanaka[4], Seiji Natsume[3], Masataka Okuno[3], Waki Hosoda[3], Masaji Tani[2], Takayoshi Suganami[4]

[1]Nagoya City Univ. Medical School, Nagoya, Japan,[2]Shiga University of Medical Science, Otsu, Japan,[3]Aichi Cancer Center, Nagoya, Japan,[4]Nagoya University, Nagoya, Japan

Background: Tyrosine kinase inhibitors (TKIs), such as lenvatinib, sorafenib, and regorafenib, form a key component of current systemic therapy for advanced hepatocellular carcinoma (HCC). However, intrinsic and acquired resistance significantly diminish their clinical benefit. Although multiple signaling pathways have been implicated in TKI response, the molecular determinants that sustain broad TKI resistance remain incompletely defined. To uncover these mechanisms, we performed an unbiased genome-wide genetic interrogation in a mouse HCC cell line.
Materials and Methods: We established a murine HCC cell line from melanocortin-4 receptor-deficient mice fed a high-fat diet. These cells exhibited pronounced intrinsic resistance to lenvatinib. To identify genes underlying this resistance, we performed a genome-wide CRISPR-Cas9 knockout screen using a pooled sgRNA library. Top candidates were prioritized by guide depletion scores and validated using siRNAs and shRNAs. Transcriptomic and proteomic analyses were conducted to define downstream pathways. To assess therapeutic relevance, we tested inhibitors targeting enzymes within this network and evaluated their combinatorial effects with lenvatinib and other TKIs across multiple cancer cell lines.
Results: The CRISPR screen identified PCIF1, an mRNA methyltransferase responsible for installing m6Am modification at the 5′ cap, as a leading determinant whose loss markedly sensitized human HCC cells to lenvatinib in both in vitro assays and in vivo tumor models. Integrative multi-omics analysis revealed that PCIF1 regulates a MYBL2-driven transcriptional program that converges on nucleotide metabolic pathways. Within this downstream network, a rate-limiting enzyme in nucleic acid biosynthesis (Molecule A) emerged as a key effector. Pharmacological inhibition of Molecule A exhibited potent synergistic effects not only with lenvatinib but also with additional TKIs, enhancing drug sensitivity and suppressing proliferation across human HCC and other cancer cell lines. Expression of Molecule A was significantly associated with lenvatinib resistance, underscoring its potential relevance as a biomarker and therapeutic target beyond the PCIF1-MYBL2 regulatory axis.
Conclusion: Our findings demonstrate that, even when proliferation appears unchanged, TKI exposure imposes a metabolic stress that drives a rewiring of nucleotide biosynthesis and a pronounced dependency on Molecule A. This adaptive shift is observed across distinct TKIs and cancer types, indicating that altered nucleotide metabolism represents a broadly conserved mechanism of drug resistance. Because clinically approved inhibitors of Molecule A are already available, these results provide a strong rationale for therapeutic repositioning strategies aimed at overcoming TKI resistance in hepatocellular carcinoma.

#7050 A novel 149-amino acid protein encoded by circSOD2 inhibits ferroptosis and promotes cisplatin resistance in bladder cancer.

Shanqi Guo[1], Zhihong Lv[2], Nan Wang[3], **Xingkang Jiang**[2]

[1]First Teaching Hospital of Tianjin University of Traditional Chinese Medicine, Tianjin, China,[2]The Second Hospital of Tianjin Medical University, Tianjin, China,[3]Wake Forest Baptist Comprehensive Cancer Ctr., Winston-Salem, NC

Circular RNAs (circRNAs) play pivotal roles in bladder cancer (BCa) tumorigenesis, metastasis, and chemoresistance, but their functional involvement in cisplatin-induced ferroptosis remains poorly defined. Herein, we identified circSOD2 as a significantly upregulated circRNA in cisplatin-resistant BCa cell lines and clinical specimens via RNA sequencing. Functional assays demonstrated that circSOD2 overexpression enhanced BCa cell proliferation and cisplatin resistance in vitro (CCK-8, colony formation, and ferroptosis detection assays) and in vivo (xenograft mouse models). Mechanistically, ribosome profiling and Western blot analyses confirmed the protein-coding potential of circSOD2, which translates into a novel 149-amino acid peptide (SOD2-149aa). Co-immunoprecipitation (Co-IP) and glutathione S-transferase (GST) pull-down assays verified that SOD2-149aa directly binds to the RING domain of tripartite motif 26 (TRIM26), a ubiquitin E3 ligase. This interaction activates TRIM26-mediated K63-linked polyubiquitination of glutathione peroxidase 4 (GPX4) — a key anti-ferroptotic enzyme — at lysine residue 148, thereby preventing GPX4 proteasomal degradation and enhancing its protein stability. Stabilized GPX4 efficiently scavenges lipid reactive oxygen species (ROS) and reduces iron-dependent lipid peroxidation, ultimately mitigating cisplatin-induced ferroptosis and conferring cisplatin resistance in BCa. Conversely, circSOD2 silencing or SOD2-149aa knockout abrogated TRIM26-GPX4 interaction, diminished GPX4 stability, and restored BCa cell sensitivity to cisplatin. Collectively, our findings uncover a novel circRNA-encoded peptide that regulates ferroptosis and chemoresistance via the TRIM26-GPX4 axis, highlighting circSOD2/SOD2-149aa as a promising prognostic biomarker and therapeutic target for overcoming cisplatin resistance in BCa.

#7054 BET domain functions in IDH1^{R132H}/p53$_{mut}$/ATRX$_{loss}$ astrocytoma malignancy.

Leyi Xie, Qingzhu Gao, Jayden Zhang, Lopez-BertoniHernando, John Laterra, **Yunqing Li**

Hugo W. Moser Research Institute at Kennedy Krieger, Baltimore, MD

Grade II/III astrocytomas are the most common primary brain cancer in young adults and are increasingly recognized as epigenetically driven tumors. Their defining mutational background IDH1^{R132H},p53$_{mut}$, and ATRX$_{loss}$ (triple-mut) establishes a hypermethylated and chromatin-disrupted state that reshapes transcriptional networks and creates unique therapeutic vulnerabilities distinct from primary glioblastoma (GBM). This epigenetically altered landscape suggests that tumor progression and treatment response in triple-mut astrocytoma are strongly influenced by chromatin-based mechanisms that can be targeted pharmacologically. BET proteins as epigenetic readers that regulate gene transcription by binding acetylated histone and recruiting master transcription factors to chromatin, yet the specific roles of individual BET family members and their bromodomains remain poorly understood. Analysis of TCGA datasets revealed that BRD3 and BRD2 expressions are significantly elevated in clinical triple-mut gliomas compared to IDH1 wild-type gliomas. Consistently, the immunoblot analysis showed that BRD3 expression is induced by the triple-mut and further enhanced by ionizing radiation (IR) and temozolomide (TMZ) treatment**.** Functionally, inhibition of BET proteins using either pan-BET inhibitors (JQ1, OTX015) or bromodomain 1 (BD1)-selective inhibitor GSK778—but not bromodomain 2 (BD2)-selective inhibitor GSK620— markedly reduces triple-mut glioma cell growth and impairs neurosphere self-renewal**,** and enhances TMZ-induced cell death**.** Moreover, BD1 inhibition significantly suppresses PD-L1 induction triggered by the triple-mut, IR/TMZ treatment, or IFN-γ stimulation. Mechanistically, we find that BD1 inhibition decreases YAP1 and TAZ expression and disrupts YAP1/TAZ transcriptional signaling, whereas BD2 inhibition does not. These findings identify a BD1-dependent transcriptional network that regulates astrocytoma cell phenotype and contributes to an immunosuppressive microenvironment. Targeting BD1 represents a rational therapeutic strategy by simultaneously suppressing tumor cell-intrinsic oncogenic signaling (e.g.,YAP1/TAZ signaling) and reshaping the immunosuppressive microenvironment.

#7055 Synergistic effects of HM97662 as an EZH1/2 dual inhibitor combined with DNA-damaging agents on malignant lung cancers harboring SMARCA4-deficiency.

Seung Hyun Jung, Jaeyul Choi, Aran Park, Seungheon Baek, Jooyun Byun, Young Gil Ahn

Hanmi R&D Center, Hanmi Pharmaceutical Co., Ltd., Gyeonggi-do, Korea, Republic of

EZH (enhancer of zeste homolog) is a histone methyltransferase that catalyzes the trimethylation of H3K27 and functions as a catalytic subunit of the polycomb repressive complex 2 (PRC2). Through epigenetic regulation, EZH modulates the transcription of tumor suppressor genes, thereby contributing to cancer cell survival, proliferation, metastasis, and drug resistance. In particular, the enzymatic activity of EZH2 is strongly associated with poor clinical outcomes, indicating that EZH2 has high therapeutic potential in cancer treatment. Under normal conditions, EZH1 and EZH2 function complementarily to support PRC2 and maintain epigenomic homeostasis. However, inhibiting EZH2 alone can trigger compensatory activation of EZH1, reducing benefit and enabling resistance. Thus, dual inhibition of EZH1 and EZH2 is a rational strategy to overcome resistance *via* broad PRC2 suppression across the tumor microenvironment. Thoracic SMARCA4-deficient undifferentiated tumor (TSDUT) which has been classified in 2021 by World Health Organization (WHO) at first, is a newly defined, high-grade malignancy with undifferentiated/rhabdoid features, marked aggressiveness, and poor prognosis. It is molecularly characterized by SMARCA4 deficiency or concurrent loss of SMARCA2, which are key subunits of the SWI/SNF complex that are often mutated and show synthetical lethal relationships in various cancers. Owing to its rarity and histological heterogeneity, diagnosis is challenging, and standard treatments are lacking; TSDUT frequently recurs after surgery, shows radio-resistance, and responds poorly to chemotherapy. Notably, EZH1/2 inhibition may enhance SLFN11-mediated sensitivity to DNA-damaging agents, offering a promising therapeutic avenue through combination. Herein, we introduce a novel EZH1/2 dual inhibitor, HM97662, which concurrently suppressed the methyltransferase activity not only wild-type EZH1, but also wild-type and gain-of-function mutant EZH2 at nanomolar concentrations. Furthermore, HM97662 demonstrated robust antitumor efficacy in DMS114 and SBC-5 xenograft mouse models of multiple SMARCA4-deficient cancers, including TSDUT. HM97662 synergized with chemotherapies especially topoisomerase 1 inhibitors and other DNA-damaging agents. Collectively, these findings indicate that combining HM97662 with DNA-damaging agents can drive enhanced *in vivo* tumor regression at well-tolerated doses in malignant lung cancers. In conclusion, this preclinical study demonstrated that HM97662, an EZH1/2 dual inhibitor, has promising therapeutic potential against advanced solid tumors, either alone or in combination with DNA-damaging agents. HM97662 is currently underway in a Phase 1 clinical trial, and these results will further support its clinical development.

#7056 Telomir-1: A novel metal ion modulator targeting aging-related disorders and cancer.

Itzchak Angel, **Erez Aminov**

Telomir Pharmaceuticals, Inc, Miami, FL

Background: Telomir-1 is a first-in-class small-molecule metal modulator engineered to selectively regulate intracellular iron and copper homeostasis. It is being developed as a therapeutic candidate for aging-related diseases and cancer, leveraging a dual mechanism of action involving metal balance and epigenetic regulation.
Rationale: Aggressive tumors—including triple-negative breast cancer and prostate cancer—often display an 'iron addiction' phenotype, characterized by excessive iron uptake, storage, and utilization to sustain rapid proliferation and survival. Telomir-1 targets this metabolic vulnerability by reducing the labile intracellular pools of iron and copper required for malignant cell growth, while sparing normal tissues.
Mechanism of Action: Through coordinated modulation of metal-driven redox biology and chromatin-mediated gene control, Telomir-1 addresses two fundamental hallmarks of cancer: 1. Disrupted metal metabolism (iron/copper overload and oxidative stress) 2. Epigenetic repression of tumor-suppressor pathways This integrated mechanism positions Telomir-1 as a novel therapeutic strategy for malignancies driven by metal-dependent metabolic and epigenetic dysregulation. Molecular Insights: Many epigenetic enzymes—particularly iron- and copper-dependent histone demethylases (KDMs)—are overactive in aggressive cancers and require these metal cofactors for catalytic function. This creates a metabolic-epigenetic dependency, whereby malignant cells rely on elevated iron and copper to maintain an epigenetic state favorable to proliferation and survival. Telomir-1 precisely regulates labile metal pools, disrupting the activity of metal-dependent epigenetic enzymes and reactivating silenced tumor-suppressor programs, while simultaneously reducing oxidative stress and tumor metabolism.
Conclusions: By bridging metal biology and chromatin control, Telomir-1 introduces a new therapeutic paradigm with potential applications in iron-dependent and epigenetically dysregulated cancers, including triple-negative breast cancer and prostate cancer, as well as broader aging-related pathologies.

#7057 Therapeutic potential of PCNA and HDAC inhibitor combinations in cutaneous T-cell lymphoma and other cancers.

Caroline M. Li, Robert G. Lingeman, Long Gu, Robert J. Hickey, Linda H. Malkas

Beckman Research Institute of The City of Hope, Duarte, CA

AOH1996, a small molecule inhibitor designed to target protein binding of proliferating cell nuclear antigen (PCNA) in cancer, was previously shown to inhibit cell growth across the NCI-60 human tumor cell line screen with minimal toxicity to nonmalignant cells. Guided by post-translational modification signature enrichment analysis of phosphorylated proteins after AOH1996 treatment, we tested its combination with histone deacetylase inhibitors (HDACi) belinostat and vorinostat. Treatment with AOH1996 and HDACi showed synergistic growth inhibition in neuroblastoma, breast, colon, and cutaneous T-cell lymphoma (CTCL) cell lines. A CRISPR interference screen and selective HDACi studies suggested that the synergy with AOH1996 involved HDAC3 and HDAC6. Furthermore, AOH1996 combined with vorinostat or romidepsin, both FDA-approved for treatment of CTCL, showed synergistic growth inhibition in four cell lines derived from CTCL. Mechanistic studies revealed enhanced DNA damage response, cell cycle arrest, and apoptosis in CTCL cells treated with AOH1996 and HDACi. These findings support the therapeutic potential of combining AOH1996 with HDACi for the treatment of cancers, including CTCL.

#7058 Highly selective HDAC6 inhibitors: Are they the answer for immunomodulation?.

Silvia Rizzo, Edoardo Cellupica, **Chiara Ripamonti**, Grazia Rovelli, Barbara Vergani, Valeria Spadotto, Michela Bottani, Christian Steinkuhler, Gianluca Fossati

Italfarmaco S.p.A., Milan, Italy

Pan-HDAC inhibitors have been approved for the treatment of hematologic malignancies, but their use in solid tumors remains limited due to poor efficacy and significant side effects although direct and immune mediated antitumor effects can be triggered. To overcome these limitations, attention has been focused on the development of selective HDACi. In particular, the generation of selective HDAC6 inhibitors (HDAC6i) has gained interest, since its involvement in tumor progression and immune regulation. HDAC6 knockout mice are viable and fertile, suggesting that selective inhibition could offer therapeutic benefits with minimal toxicity. Among HDAC6i, hydroxamic acid-based compounds such as ITF3756 and ACY-1083 have shown high potency and selectivity, although off-target effects resulting from the binding to other HDACs or non-HDAC targets cannot be ruled out at high concentrations. More recently, difluoromethyl-1,3,4-oxadiazole (DFMO) -based HDAC6i have emerged, offering unprecedented selectivity, prolonged residence time and lack of hydroxamic acid-related limitations. Our group synthesized various DFMO-based HDAC6i and investigated their immunomodulatory potential by evaluating PD-L1 expression and cytokine production in activated human monocytes and CD3 T cells. However, only ITF3756 significantly reduced PD-L1 expression and modulated cytokine release, including TNF-α, IL-1β, IL-10, IFN-γ, and IL-17. DFMO compounds did not exhibit significant effects on these immune responses. These findings suggest that specific HDAC6 inhibition may fail to reproduce the immunomodulatory effects observed with less selective inhibitors or in HDAC6 knockout models. To further explore this discrepancy, we tested PROTAC-DFMO compounds designed to degrade HDAC6, using either Cereblon (CRBN) or Von Hippel-Lindau (VHL) recruiters. Both PROTACs effectively and selectively degraded HDAC6 and increased α-tubulin acetylation. However, only the CRBN-linked PROTAC reduced cytokine production in monocytes, an effect that we determined being attributable to the pomalidomide recruiter itself. In contrast, VHL-linked PROTACs had limited impact. None of the PROTACs significantly modulated cytokine production in T cells. These results indicate that HDAC6 degradation alone is not sufficient to modulate certain immune cell functions, suggesting that broader HDAC inhibition may be required to achieve effective immunomodulatory activity. Furthermore, our results point-out that the effects of degraders in an immunological context may be influenced by their recruiter moiety, rather than being solely driven by target degradation. Overall, this work highlights the complexity of HDAC6's contribution to immune regulation and suggests that while high selectivity may reduce toxicity, it could limit therapeutic efficacy in immuno-oncology contexts.

#7060 Targeting KMT2C induces paralog synthetic lethality in KMT2D null DLBCL through DREAM targets regulation.

Hsiangyu Hu[1], Neeraj K. Aryal[1], Tim Nieuwenhuis[2], Daniel Barrell[3], Ultan McDermott[3], Laura B. Prickett[4], Ming Tang[2], Derek Oien[1], Laura Pasqualucci[5], Anas Younes[6], Lisa Drew[1], Omid Tavana[1]

[1]Hematology Discovery Research and Early Development, AstraZeneca, Waltham, MA,[2]Oncology Data Science & AI, AstraZeneca, Waltham, MA,[3]Functional Genomics Centre, AstraZeneca UK, Cambridge, United Kingdom,[4]Dynamic Omics, Centre for Genomic Research, Discovery Sciences, BioPharmaceuticals R&D, AstraZeneca, Waltham, MA,[5]Inst. for Cancer Genetics, Dept. of Pathology & Cell Biology, & HICCC, Columbia University, New York, NY,[6]Hematology Discovery Research and Early Development, AstraZeneca, New York, NY

KMT2D is a histone methyltransferase that regulates enhancer activation by catalyzing H3K4 mono/di-methylation, in part through a cooperative interaction with CBP/p300. Epigenetic regulation is commonly perturbed in cancer due to recurrent genetic alterations. In particular, KMT2D inactivating mutations are the most common genetic alterations in germinal center-derived B cell lymphoma, including ~30% of diffuse large B cell lymphoma and up to 80% of follicular lymphoma. To identify novel synthetic lethal targets in KMT2D mutant lymphoma, we performed a genome-wide CRISPR knock-out screen in a panel of KMT2D-wt vs -null DLBCL cell lines and revealed the paralog histone methyltransferase KMT2C as a top hit in KMT2D-null cell lines. Interestingly, KMT2C is rarely mutated in KMT2D mutant lymphoma and its protein expression is well-conserved across DLBCL cell lines, suggesting KMT2C may compensate for the loss of KMT2D methyltransferase activity.To validate KMT2C dependency, we knocked out KMT2C in KMT2D proficient or mutant/deficient DLBCL cell lines as well as in KMT2D isogenic knockout models. KMT2C loss leads to G0/G1 cell cycle arrest and apoptotic induction in the KMT2D deficient but not in KMT2D proficient context. To gain mechanistic insights into the preferential sensitivity of KMT2D-null cell lines, we performed RNA-seq in cell lines with varying phenotypic response to KMT2C knockout. In line with the observed cell cycle arrest phenotype, we identified the DREAM (Dimerization partner, RB-like, E2F, and MuvB) complex targets as significantly downregulated upon KMT2C loss. The DREAM complex is a key regulator of cell cycle progression by repressing multiple genes particularly during cell cycle exit. Epigenetic profiling revealed that KMT2C binds to promoters of specific DREAM targets, suggesting a direct regulatory mechanism. Additionally, the protein DYRK1B is known to promote DREAM complex assembly at target promoters. We noticed KMT2C knockout upregulates DYRK1B protein expression only in KMT2D mutant cell lines. Further, overexpression of DYRK1B in KMT2D mutant lines induced anti-proliferative effects, suggesting dual mechanisms by which KMT2C regulates DREAM targets. These results provide mechanistic rationales into how KMT2C loss induces paralog lethality. Lastly, to identify potential combination partners with KMT2C knockout, we performed a combination screen using different small molecules for DLBCL treatment. We observed that inhibitors targeting CBP/p300 and chemotherapy agents like vincristine and doxorubicin combined with KMT2C loss drive deeper responses in KMT2D mutant models. Taken together, our data demonstrate that B cell lymphoma carrying KMT2D mutations are addicted to the residual KMT2C activity and suggest that targeting KMT2C as a monotherapy or in combination may benefit patients with KMT2D loss.

#7061 Mechanistic understanding of a novel CBP/p300 inhibitor in fusion-positive rhabdomyosarcoma.

Md Imdadul H. Khan, Matthew Chang, Yaw Asante, Maya Al-Haddad, Jordyn Kelly, Bhavatharini Udhayakumar, Carrietta Farma-Hai, Berkley Gryder

Genetics and Genome Sciences, Case Western Reserve University School of Medicine, Cleveland, OH

Fusion-positive rhabdomyosarcoma (FP-RMS) is a pediatric soft tissue carcinoma characterized by poor survival rate and limited therapeutic options. The fusion oncoprotein PAX3-FOXO1 (P3F) is the key driver for FP-RMS, and its transcriptional activity is dependent on histone acetyltransferase CBP/p300. Given the challenge of directly targeting the transcription factor P3F, CBP/p300 represents an attractive therapeutic target in treating FP-RMS. Through a focused screening of different epigenetic-modifying agents against FP-RMS, the inhibition of CBP/p300 emerged as the most effective strategy in selectively suppressing P3F-driven transcriptional activity. To overcome the limitations, such as toxicity and efficacy of the existing CBP/p300 inhibitors, we employed structure-based drug design to develop a potent CBP/p300 dual inhibitor, IHK-44. We used chemical genetic approaches to enable precise and temporal control of its function in investigating the underlying mechanism of CBP/p300 in the context of FP-RMS. In studying the basis of IHK-44's selectivity and potency in FP-RMS compared to other CBP/p300 inhibitors and degraders, we conducted a comprehensive series of studies, including luciferase reporter assays, live-cell imaging, RNA-seq, ChIP-seq, and proteomics. These studies revealed that FP-RMS exhibits unique epigenetic dependencies, particularly at 3D clusters of histone acetylation lacking CpG islands. The predictor of gene responsiveness to CBP/p300 inhibition with IHK-44 is to be found by mapping the 3D enhancer/promoter loops into clusters and quantifying the extent of CpG island involvement in the elements that make up clusters. Genes driven CpG-poor clusters, often very rich in enhancers, are hypersensitive to IHK-44, while CpG-rich clusters, usually promoter-rich, are recalcitrant. This allows us to define clear categorization to distinct types of gene regulation hubs in the cancer epigenome. High-throughput screening across 900 cell lines revealed that FP-RMS is one of the cancer subtypes most sensitive to IHK-44, whereas normal cell lines and fusion-negative RMS were resistant. In summary, our findings suggest a novel therapeutic strategy for FP-RMS by targeting CBP/p300 and highlight the potential of IHK-44 as a promising candidate for further preclinical development.

#7062 EP102: Pharmacological inhibition of METTL3 is effective as a monotherapy and potentiates radiation therapy in pancreatic adenocarcinoma via DNA damage and stemness modulation.

Andrea Casazza, Nicolas Parmentier, Catherine Sorlet, Killian Oukoloff, Guillaume Dutheuil, Graeme L. Fraser

EPICS Therapeutics, Charleroi, Belgium

N^6-methyladenosine (m^6A) is the most abundant internal mRNA modification, regulating RNA stability, splicing, and translation. METTL3, the RNA methyltransferase predominantly responsible for the addition of m^6A, is frequently overexpressed in solid tumors and acts as an oncogenic driver by promoting proliferation, survival, and therapy resistance. In pancreatic ductal adenocarcinoma (PDAC), METTL3 upregulation correlates with aggressive disease and poor prognosis. Mechanistic studies implicate METTL3 in PDAC progression through m^6A-dependent regulation of oncogenic transcripts and pathways such as DNA damage repair, contributing to chemoresistance and tumor stemness. Radiotherapy is an established treatment modality for pancreatic cancer, used in neoadjuvant, adjuvant, and locally advanced settings, often combined with chemotherapy. The aim of this work was to evaluate EP102, a selective METTL3 inhibitor, for its efficacy and synergy with radiation therapy in PDAC xenografts and to explore underlying mechanisms. Two independent studies were conducted in Balb/c nude mice bearing PANC08.13 tumors. EP102 was administered alone (47 mg/kg PO, TIW) or combined with radiation (3 Gy × 3) in Study 1 and EP102 alone at 30 mg/kg (PO, TIW) or combined with radiation (2 Gy x 3) in Study 2. Both studies confirmed significant dose dependent tumor growth inhibition by EP102 and marked tumor shrinkage with the combination, supporting synergy across doses. Blood profiling after 4 days of treatment indicated minimal hematologic impact with EP102 alone, supporting its tolerability. Radiation alone and in combination with EP102 led to a pronounced decrease in lymphocytes; notably, the combination suggested a compensatory shift toward innate immunity, where myeloid cells may transiently expand or activate to maintain host defense under genotoxic stress. Mechanistic analysis by Western blot revealed that METTL3 inhibition impairs the expression of key DNA repair and survival genes leading to accumulation of DNA damage: γH2AX and p-CHK2 were upregulated, indicating double-strand break accumulation and checkpoint activation. Importantly, when combined with radiation, EP102 markedly amplified these effects: γH2AX and p-CHK2 surged, BRCA1 and MCL-1 were strongly downregulated, and the expression of stemness marker OV-6 dropped significantly. This combination triggered robust apoptosis and pronounced HR deficiency, correlating with dramatic tumor regression. Together, these findings support a model where EP102 impairs m^6A-dependent repair and survival pathways, and radiation potentiates this disruption, driving synergistic antitumor activity. These findings validate METTL3 as a therapeutic target and provide a strong rationale for combining EP102 with radiotherapy in pancreatic cancer.

#7063 p300 bromodomain inhibitors impair cell proliferation by inducing senescence in HPV positive head and neck squamous cell carcinoma.

Jessica Catarine Frutuoso do Nascimento[1], Wendi Quinn O'Neill[2], Quintin Pan[2]

[1]Case Western Reserve University School of Medicine, Cleveland, OH,[2]University Hospitals Cleveland Medical Center, Cleveland, OH

The incidence of human papillomavirus (HPV)-associated head and neck squamous cell carcinoma (HNSCC) has risen sharply in recent decades and now accounts for most new oropharyngeal cancers diagnosed in the United States. Standard of care therapies are effective but cause significant toxicities and long-term morbidities, highlighting a critical need for alternative treatment strategies. HPV-associated cancers, including oropharyngeal tumors, present a unique opportunity for targeted therapeutic intervention since their pathogenesis depends on the inactivation of major tumor suppressor pathways by the viral oncoproteins E6 and E7. One key oncogenic mechanism is the ability of HPVE6 to bind the transcriptional co-activator p300/CBP, thereby blocking p53 acetylation and activation. Therefore, we hypothesized that p300/CBP bromodomain inhibitors (BDIs) may disrupt the HPVE6-p300/CBP interaction and restore the p53 tumor suppressor program. We evaluated the effect of two p300/CBP BDIs, CCS1477 and GNE-781, on the HPV16+ HNSCC cell line, UM-SCC-47. Cell proliferation was assessed by Incucyte® live cell imaging, clonogenic survival by colony formation assays, and cell-cycle distribution by flow cytometry with propidium iodide. Senescence was measured by β-galactosidase staining, and protein levels of key p53 targets were analyzed by immunoblot. Both p300/CBP BDIs markedly reduced cell proliferation and colony formation. Proliferation decreased in a dose-dependent manner, with an IC50 of 23.66 nM for CCS1477 and 9.06 nM for GNE-781. At 100 nM, CCS1477 and GNE-781 reduced colony formation by 94% ($p<0.0001$) and 97.9% ($p<0.0001$), respectively. p300/CBP BDIs induced G1 arrest, reflected by a 15% ($p<0.0001$) increase in the proportion of cells in G1 and a 30% ($p<0.0001$) reduction in S phase. Both inhibitors triggered a >8-fold ($p<0.0001$) increase in the number of senescent cells. Immunoblot analysis showed increased levels of p53, acetylated p53 (K382Ac), and p21 with no change in caspase 3, supporting senescence, not apoptosis, as the main mechanism responsible for the anti-proliferative effects. In summary, the p300/CBP BDIs, CCS1477 and GNE-781, show anti-tumor activity in HPV16+ UM-SCC-47 cells, reactivating the p53 program and inducing senescence. These findings support further evaluation of p300/CBP BDIs in other HPV+ cancer model systems.

#7064 Development of a new class of KAT6A/B inhibitors with *in vivo* efficacy.

Antonius ter Laak[1], Roman Hillig[2], Steven Ferrara[3], Daniel Korr[2], **Peter Staller**[2], Naomi Barak[1], Philip Lienau[1], Simon Herbert[1], Amaury Fernandez[1], Roland Neuhaus[2], Matyas Gorjanacz[1], Vera Puetter[2], Volker Badock[2], Wilhelm Bone[2], Craig Strathdee[3], Franziska Siegel[1], Christoph Schatz[1], Nowak-Reppel Katrin[2], Olaf Doehr[1], Stefan Gradl[1], Ingo Hartung[1], Matthew Meyerson[3], Lea Bouche[1]

[1]Bayer Pharma AG, Berlin, Germany,[2]Nuvisan ICB GmbH, Berlin, Germany,[3]Broad Institute of MIT and Harvard, Center for the Development of Therapeutics, Boston, MA

KAT6A and KAT6B encode lysine acetyltransferases that catalyse the transfer of acetyl groups from acetyl-CoA to lysine residues on histone proteins, thereby influencing chromatin structure and gene expression. Amplification of these genes is observed in several cancers, with the 8p11-p12 chromosomal region—containing KAT6A—being increased in copy number in approximately 12-15% of breast cancer cases, leading to higher expression of chromatin-modifying enzymes. In this study, we introduce a novel series of acylsulfonamide-benzofuran compounds that function as selective inhibitors of KAT6A and KAT6B. These inhibitors were first identified via high-throughput screening and subsequently refined through computational modelling and co-crystallization studies. The lead compound from this series, BAY-184, demonstrated efficacy in an in vivo proof-of-concept experiment, confirming its potential as a tool for targeting KAT6A/B activity.

#7065 Targeting MTAP-deleted/KRAS mutant cancers using RAS inhibitors in combination with AMG 193, an MTA-cooperative PRMT5 inhibitor.

Katherine Slemmons[1], Siyuan Liu[1], Chun Su[2], Raul Lazaro[1], Tao Osgood[1], Rati Verma[1], Brian Belmontes[1], Paul E. Hughes[1]

[1]Oncology Research, Amgen, Thousand Oaks, CA,[2]Automation, Research Data Systems, Informatics & AI, Amgen, South San Francisco, CA

AMG 193 is a clinical stage MTA-cooperative PRMT5 inhibitor designed to exploit the metabolic vulnerability created by homozygous *MTAP* deletion in tumors. By binding PRMT5 in the presence of accumulated methylthioadenosine (MTA), AMG 193 selectively inhibits PRMT5 activity in MTAP-deleted cells resulting in alternative RNA splicing, DNA damage, and cell cycle arrest. In patients, AMG 193 has demonstrated single-agent antitumor activity and a favorable tolerability profile, supporting its potential as a precision therapy for MTAP-deleted cancers (Rodon et al, 2024).

To further understand the potential for AMG 193 activity, we evaluated combination strategies using AMG 193. We previously demonstrated that AMG 193 synergizes with standard of care chemotherapy by increasing DNA damage, a strategy currently under clinical investigation (NCT06360354, NCT06333951). Given that *MTAP* deletions frequently co-occur with KRAS mutations in pancreatic ductal adenocarcinomas (PDAC; ~30%) and non-small cell lung cancer (NSCLC; ~4%), we hypothesized that dual inhibition of PRMT5 and RAS signaling could further enhance antitumor activity.

Here, AMG 193 was evaluated in combination with the KRAS G12C inhibitor sotorasib or the pan-RAS inhibitor RMC-6236 (daraxonrasib). In the KRAS G12C mutant PDAC cell line MIAPACA2, all RAS inhibitor combinations exhibited similar levels of synergy (Combination Index < 0.5). Nuclear counts confirmed a greater cell growth inhibition in the combination groups and immunoblots confirmed inhibition of both PRMT5 and RAS signaling. RNA-seq analysis revealed synergistic regulation of the RAS pathway and an inhibition of translation and rRNA processing after sotorasib combination treatment. *In vivo*, combination treatment of AMG 193 with sotorasib in MIAPACA2 PDAC xenografts resulted in 28% tumor regression.

In addition, AMG 193 combined with RMC-6236 produced robust synergy across a variety of KRAS G12X mutant PDAC and NSCLC cell lines *in vitro*. *In vivo* efficacy studies evaluating AMG 193 in combination with RAS inhibitors is ongoing in a variety of MTAP-deleted/KRAS mutant tumor models. We also observed that AMG 193 monotherapy efficacy was independent of KRAS mutational status in a NSCLC PDX mouse clinical trial. Overall, AMG 193 displays synergy with RAS targeted agents *in vitro*, and combination treatment with sotorasib *in vivo* substantially inhibits tumor growth. A clinical study evaluating AMG 193 in combination with RMC-6236 in MTAP-deleted PDAC is ongoing (NCT06360354).

#7066 Comparative *in vivo* evaluation of RG-7388, CM-272, and SGI-1027 to determine epigenetic targeting as an effective strategy for treating high-risk neuroblastoma.

Umamaheswari Natarajan[1], Shyam S. Jaganathan[2], Appu Rathinavelu[2]

[1]Rumbaugh-Goodwin Institute for Cancer Research, Barry and Judy Silverman College of Pharmacy, Nova Southeastern University, Fort Lauderdale, FL,[2]Rumbaugh Goodwin Institute for Cancer Research, Barry and Judy Silverman College of Pharmacy, Nova Southeastern University, Fort Lauderdale, FL

Background: High-risk neuroblastoma remains a therapeutic challenge due to its chemoresistance, epigenetic modification, and TP53 pathway dysregulation. SK-N-AS cells, which harbor *TP53* mutations and exhibit highly aggressive behavior, provide a clinically relevant model for evaluating novel epigenetic and apoptotic pathway-targeting agents. This study investigated the therapeutic efficacy of the MDM2 inhibitor (RG-7388), the dual DNMT1/G9a inhibitor (CM-272), and the DNMT inhibitor (SGI-1027) in an SK-N-AS xenograft mouse model.

Methods: Athymic Nu/Nu mice bearing subcutaneous SK-N-AS tumors were randomized into treatment groups and administered RG-7388, CM-272, SGI-1027, or vehicle control (DMSO) according to an optimized dosing schedule. Tumor volumes, body weight, survival rate, and treatment-related toxicity were monitored over the study period. Excised tumors were analyzed for cell-cycle arrest markers, DNA-methylation regulators, apoptotic mediators, and histone acetylation/methylation levels *via* qRT-PCR and Western blot.

Results: Treatment of Cell Derived Xenograft (CDX) animals with CM-272 significantly reduced tumor growth compared to control. Interestingly, treatment with RG-7388 also induced potent tumor suppression but exhibited a less durable response compared to CM-272. The anti-cancer effects produced by CM-272 was robust by showing significant reduction in tumor volume with minimal toxicity, accompanied by marked up-regulation of cell-cycle arrest markers, apoptotic mediators. In addition, a significant increase in the histone acetylation levels, which often serve as DNA/histone methylation regulators, indicated strong epigenetic reprogramming. Mechanistically, both CM-272 and SGI-1027 exhibited strong apoptotic activation, while RG-7388 primarily removed MDM2-associated stress signaling, despite the mutant/null status of *TP53* in SK-N-AS cells. Survival analysis showed that CM-272 prolonged survival the most, followed by RG-7388 and SGI-1027.

Conclusion: Epigenetic targeting of DNMT and G9a *using* CM-272 produced the strongest anti-tumor and survival benefit in the SK-N-AS CDX model, outperforming both RG-7388 and SGI-1027. CM-272's ability to simultaneously inhibit DNMT1 and G9a, appears to reduce repressive chromatin marks, and activate apoptosis cascade that highlights its translational potential for treating *TP53*-mutant and epigenetically driven neuroblastoma. These initial findings suggest advancing preclinical optimization and combination-therapy strategies involving CM-272 for high-risk neuroblastoma.

Acknowledgements: This work was supported by the National Pediatric Cancer Foundation (NPCF), the Florida Department of Health through a Bankhead-Coley Infrastructure Grant, and the Royal Dames of Cancer Research, Inc., Ft. Lauderdale, Florida.

#7067 Synergistic cytotoxicity through combination of DNA methyltransferase (DNMT) inhibitors in cancer cells.

Angelo B. A. Laranjeira[1], Dat Nguyen[1], Michael Difilippantonio[2], Alice P. Chen[3], **Sherry X. Yang**[1], James H. Doroshow[4]

[1]Division of Cancer Treatment and Diagnosis, National Cancer Institute, Bethesda, MD,[2]NCI/NIH, Bethesda, MD,[3]National Cancer Institute, Bethesda, MD,[4]NCI Division of Cancer Treatment and Diagnosis, Bethesda, MD

A new class of DNA methyltransferase inhibitors (DNMTi) including 4'-thio-5-aza-2'-deoxycytidine (aza-TdC) and 4'-thio-2'-deoxycytidine (TdC) demonstrated anti-tumor activity, with IC_{50s} largely in the nanomolar range in DNMTi-sensitive cancer cells, and single to two-digit micromolar spans in DNMTi-resistant cells. In an aza-TdC phase I clinical trial of patients with solid tumors, a best response of stable disease was achieved in eleven (78.6%) of the 14 patients evaluable for response (J Clin. Oncol. Vol 39, No15_suppl). Adverse effect and low clinical activity against human solid tumors remain the limiting factors for their progress in clinical development and application. To overcome the limitations, we investigated synergistic anti-tumor activity by combining either aza-TdC or TdC with a fixed low dose of another DNMTi and antimetabolite - 5-fluoro-2'-deoxycytidine (FdC) - in colorectal and ovarian cancer cells. IC_{50} by aza-TdC, TdC or FdC alone was >10 μM, >10 μM or ~10 μM in DNMTi-resistant/ *DNMT1* knockout colorectal HCT116 cells. In the presence of 0.5 μM FdC, the cytotoxicity of aza-TdC and TdC was dramatically potentiated, showing IC_{50} of 0.24 μM for aza-TdC and <0.001μM for TdC in the DNMTi-resistant cells. The IC_{50} by aza-TdC, TdC or FdC alone was 0.8 μM, 6.29 μM or 0.67 μM in ovarian cancer OVCAR3 cells. The cytotoxicity of aza-TdC and TdC in the presence of 0.5 μM FdC was similarly enhanced, and IC_{50s} were about 0.001 μM for aza-TdC and < 0.001 μM for TdC. In addition, the synergistic potentiation through the combination of 0.5 μM FdC with either aza-TdC or TdC was also observed in other colorectal and ovarian cancer cell lines such as parental HCT116 and SKOV3 cells. Thus, low dose FdC substantially potentiated the cytotoxic effects of novel DNMT inhibitors in DNMTi-resistant and DNMTi-sensitive cancer cells. It warrants to investigate the underlying mechanism of this type of cytotoxic synergy.

#7069 Co-targeting menin and LSD1 dismantles oncogenic programs and restores differentiation in MLL-rearranged acute myeloid leukemia.

Tulasigeri Totiger[1], Mina Tayari[1], Claudia Cabrera Pastrana[1], Florencio Munoz-Legarre[1], Anna Kingham[1], Helena Gomes Dos Santos[1], Felipe Beckedorff[1], Eduardo Bravo[1], Katarzyna Ciurko[1], Declan Foley[1], Efe Karaca[1], Daniel Bilbao[1], Claude-Henry Claude-Henry Volmar[2], Shaun P. Brothers[2], Ramin Shiekhattar[1], Justin Watts[1], Justin Taylor[1]

[1]Univ. of Miami Sylvester Comprehensive Cancer Ctr., Miami, FL,[2]University of Miami Miller School of Medicine, Center for Therapeutic Innovation and Department of Psychiatry & Behavioral Sciences, Miami, FL

Acute myeloid leukemia (AML) with KMT2A-rearrangement carries a poor prognosis, underscoring the urgent need for new therapeutic approaches. Menin inhibitors demonstrate promising anti-leukemic activity in KMT2A-r AML; however, their efficacy as monotherapy may be limited by partial responses and emerging resistance mutations. Combination strategies using epigenetic modulators may enhance their therapeutic potential. In this study, we performed a combination drug screen using an epigenetic compound library in KMT2A-r AML cells to identify synergistic agents that could potentiate menin inhibitor activity.

MV4-11 cells were treated with DSP-5336 (menin inhibitor) to optimize assay performance ($Z' > 0.5$). Cells were then screened with a 932-compound epigenetic library to assess drug effects alone or with DSP-5336. Follow-up studies used ORY-1001 (LSD1 inhibitor) and SNDX-5613 (menin inhibitor) across dose ranges. Viability, IC_{50}, and synergy were evaluated using SynergyFinder 2.0. Mechanistic analyses included Western blotting, co-IP, ChIP-qPCR, CUT&RUN, and mass spectrometry to examine LSD1 binding, interactions, and genome-wide occupancy with the Menin-MLL complex. Patient-derived xenograft cells were implanted in NSG mice.

The combination screen performed robustly and identified LSD1 inhibition as the strongest synergistic enhancer of menin inhibitor activity. LSD1 blockade substantially increased DSP-5336-mediated killing in KMT2A-rearranged AML cells. Mechanistically, LSD1 depletion disrupted key leukemic transcriptional programs and reduced chromatin occupancy at Menin-MLL target loci. LSD1 immunoprecipitation revealed the known MLL interactor PSIP1(LEDGF) as a novel LSD1 interacting partner via mass spectrometry, suggesting cooperative roles of these epigenetic targets in maintaining leukemic gene expression and stem-like properties. The combination of menin and LSD1 inhibition promoted differentiation, shown by an increased proportion of $CD11b^+$ cells compared with either single agent. In an aggressive MLL-AF6 AML PDX model, co-treatment with SNDX-5613 and ORY-1001 produced superior in vivo efficacy. Mice receiving the combination showed markedly reduced leukemia burden and significantly prolonged survival relative to monotherapies, as evidenced by decreased $hCD45^+$ levels and improved survival.

This study identifies LSD1 inhibition as a top synergistic partner for menin-directed therapy in KMT2A-r AML. These findings suggest that combining menin inhibitors with epigenetic modulators such as LSD1 inhibitors may overcome resistance and strengthen anti-leukemic effects. Ongoing in vivo studies aim to further elucidate the underlying mechanisms and therapeutic potential of this combination. Ultimately, this work may guide the development of innovative combination treatment strategies for KMT2A-r AML patients.

#7070 Butyrate modulates key oncogenic pathways in oral squamous cell carcinoma: Insights from transcriptomic profiling.

Oscar A. Loperena Gonzalez[1], Ariana S. Garcia- Lopez[2], Liah M. Roman-Calderon[1], Gabriel Borges Velez[1], Esther Peterson Peguero[2], Josue Perez Santiago[1]

[1]University of Puerto Rico Comprehensive Cancer Center, San Juan, PR,[2]University of Puerto Rico Rio Piedras, San Juan, PR

Introduction: Oral squamous cell carcinoma (OSCC) is a highly aggressive epithelial malignancy that accounts for 90% of oral cancer. Due to late detection, therapeutic resistance and lacking targeted therapies the survival rate for OSCC is below 60%, therefore there is a need for identifying molecular drivers that can be therapeutically targeted. Short chain fatty acids, particularly butyrate has anti-inflammatory, immunomodulatory, and antineoplastic effects in several cancers. We have observed that butyrate treatment reduces cell viability, inhibits migration, and proliferation on OSCC. Thus, to identify the molecular mechanisms related to butyrate treatment and investigate its therapeutic potential in OSCC, we measured transcriptomic changes after butyrate treatment of OSCC.
Methods: OECM-1 (OSCC cell model) were treated with 5 mM butyrate for 24 hours. RNA was extracted, quantified and sequenced on the Illumina NextSeq 550 (PE 2x75 bp). Following quality control (FastQC and Trimmomatic), high-quality reads were aligned to the human genome (GRCh38) using STAR and quantified with RSEM. Differential gene expression was analyzed using R statistical software (tximport and DESeq2 packages). Genes were considered significant if the adjusted p-value was <0.001 and had a log2 fold change >2 or <-2. Functional annotation and protein interaction analyses of significant differentially expressed genes were conducted using Metascape and STRING.
Results: Butyrate treatment had a distinct transcriptomic profile than untreated cells, characterized by a significant alteration of the expression of 1,975 transcripts in OECM-1. The most upregulated transcript (11-fold increase) was NPPB, involved in cell apoptosis and anti-proliferative signaling. Conversely, CCNA2, controls both G1/S and G2/M transition phases of the cell cycle, showed a 3-fold decrease. Additionally, SYC, a modulator of epithelial cell growth, cell proliferation and differentiation, showed a 3.7-fold decrease. Enrichment analysis showed biological processes involved in oncogenesis, including cell proliferation, differentiation, apoptosis, and survival. Protein-protein interaction network identified clusters associated with cell cycle regulation, protein phosphorylation, cell death and transcription factors, with several gene hubs (≥15 connections) including CCNA2, BIRC5, KIF20A and CDCA8, known prognostic markers for cancer.
Conclusions: Our results demonstrate that butyrate modulates the transcriptome of OECM-1 cells, targeting pathways involved in oncogenic processes such as cell cycle, proliferation signaling, genetic regulators and apoptosis, consistent with our cellular results. NPPB is a novel marker for gastric cancer, showing butyrate's capacity to regulate antiproliferative pathways. These findings support butyrate's potential as a microbiome-derived therapeutic for OSCC.

#7071 CRISPRi screening identifies epigenetic vulnerabilities and an ARID1A-PRC2 synthetic-lethal axis sensitizing cutaneous T-cell lymphoma to combined JAK/STAT and EZH2 inhibition.

Yan-Jin Liu[1], Laura Pincus[2], Yu-Ru Chang[3], Frank McCormick[4], Weiyun Z. Ai[5]

[1]Department of Medicine (Hematology/Oncology), UCSF, San Francisco, CA,[2]Department of Dermatology, UCSF, San Francisco, CA,[3]Human Biology, UC Davis, Davis, CA,[4]UCSF Helen Diller Family Comprehensive Cancer Ctr., San Francisco, CA,[5]Asso. Clinical Professor, Dept. of Medicine, UCSF, San Francisco, CA

Advanced-stage cutaneous T-cell lymphoma (CTCL) is life-threatening and has limited treatment options. Aberrant JAK/STAT activation is a defining molecular feature, and a phase II trial demonstrated that ruxolitinib, a JAK1/2 inhibitor, is efficacious in T-cell lymphomas. However, responses are modest and short-lived, highlighting the need for mechanism-based combination strategies.Polycomb repressive complex 2 (PRC2), driven by its catalytic subunit EZH2, regulates H3K27me3-mediated transcriptional repression and functions as a key oncogenic driver in T-cell lymphomas. ARID1A, a core SWI/SNF subunit, physiologically counteracts PRC2-mediated chromatin silencing. Loss or reduction of ARID1A disrupts this antagonism, increasing cellular reliance on PRC2 and sensitizing cells to EZH2 inhibition.To identify genetic modifiers of ruxolitinib response, we performed a genome-wide CRISPR interference screen in CTCL cell lines (HH and Hut78) exposed to JAK/STAT blockade. Ruxolitinib treatment enriched a coherent epigenetic network directly linked to PRC2 function, suggesting that epigenetic modifiers may act synergistically with ruxolitinib.To assess clinical relevance, we analyzed published transcriptomic data from advanced CTCL skin biopsies (n = 70) and normal skin (n = 29). EZH2 expression was significantly elevated in CTCL (P = 0.0014), suggesting heightened PRC2 dependence in advanced-stage disease. We then evaluated the combined inhibition of JAK and EZH2 in primary CTCL PDX-derived tumor cells using a matrix of drug concentrations, yielding 15 paired combinations. This combination produced strong, dose-dependent synergy in growth inhibition and apoptosis induction across three PDX samples, with Loewe synergy scores of 17.54, 27.27, and 20.597, respectively.Mechanistically, CRISPRi profiling revealed depletion of ARID1A sgRNAs under ruxolitinib selection pressure (Hut78: –27.5%, P = 0.0071; HH: –14%, P = 0.069), indicating that JAK/STAT blockade increases CTCL dependence on EZH2 for survival. This ARID1A–PRC2 synthetic-lethal interaction provides a biological basis for the observed drug synergy.Together, these findings demonstrate that JAK/STAT inhibition drives CTCL cells into a PRC2-dependent, EZH2-high epigenetic state, creating a therapeutically actionable vulnerability. These data provide a strong rationale for combining JAK and EZH2 inhibition, and ongoing CTCL PDX in vivo studies will further define the translational potential of this strategy.

#7073 Targeted inhibition of PRC1 in acute leukemia models induces prominent cell growth and differentiation effects.

Sydney Musser, Yiwu Yao, Se Ra Park, Miranda Simes, Hongzhi Miao, Alyssa Winkler, Trupta Purohit, Jolanta Grembecka, Tomasz Cierpicki

University of Michigan, Ann Arbor, MI

Background: Polycomb repressive complex 1 (PRC1) is an epigenetic regulatory complex that silences genes important for cellular identity, stemness and differentiation. All PRC1 complexes contain a RING1A or RING1B protein core which elicits E3 ligase activity to monoubiquitinate histone H2A lysine 119 (H2Aub). PRC1 complex binding and H2Aub deposition induces chromatin compaction and repression of target genes. Previous studies have emphasized the role of PRC1 activity in the maintenance of a leukemic stem cell phenotype, and implicated RING1A/B ubiquitination activity as an important driver of leukemogenesis. Indeed, knockdown of RING1A/B in acute myeloid leukemia (AML) stem cells impairs proliferation and induces myeloid differentiation. Therefore, the development of small molecule inhibitors of PRC1 presents a valuable therapeutic strategy for acute leukemia treatment.

Results: Here, we report the biological activity and molecular mechanisms of a novel small molecule inhibitor of PRC1, RB-231, in acute myeloid and lymphoblastic leukemia (ALL) models. RB-231 is a lead compound among the first-in-class PRC1 small molecule inhibitors developed in our lab, which bind directly to RING1A/B at the nucleosome interface to prevent PRC1 complex binding and H2Aub deposition. RB-231 has shown potent sub-micromolar activity across panels of both AML and ALL cell lines harboring a variety of chromosomal translocations and mutational drivers. Treatment of acute leukemia cell lines with RB-231 results in significant cell growth inhibition, apoptosis, and differentiation, as demonstrated by increased cell surface and gene expression of lineage-associated maturation markers (CD11b, CD14, CD20 and CD86). Treated cells also exhibit morphological changes resembling mature hematopoietic cells and a reduction of leukemic blast populations. Notably, colony formation assays with RB-231 treated primary AML patient samples display reduced colony number, smaller size, and differentiated morphology, while normal human CD34+ bone marrow cells are unaffected by treatment, suggesting selectivity towards a leukemic stem cell phenotype. RNA-sequencing analyses of RB-231 treated acute leukemia cell lines reveal significant upregulation of PRC1 target gene *CDKN1A*, encoding for the p21 cell cycle inhibitor. This effect is also observed in p53-mutant AML cell lines. Indeed, CUT&RUN analysis shows significant reduction of H2Aub enrichment at *CDKN1A*, demonstrating direct de-repression at this locus and RB-231 on-target activity.

Conclusions: Overall, our studies have shown that acute leukemia models are sensitive to PRC1 inhibition and demonstrate significant mechanistic and developmental changes upon treatment. Based on these findings, PRC1 inhibition may offer a novel therapeutic approach for leukemia treatment.

#7074 PLX-61639, a potent and orally bioavailable SMARCA2-selective monovalent direct degrader, enhances efficacy of standard of care agents in SMARCA4 mutant tumor models.

Greg Parker[1], Geoffray Leriche[2], Aleksandar Jamborcic[1], Taylor Kampert[1], Linette Yang[1], Julia Toth[1], Kenneth Steadman[1], Jay Chung[1], Duc Tran[1], Luis Lopez[2], Farhana Barmare[2], Kyohei Hayashi[2], Gang Liu[2], Jianguo Ma[1], Alex Campos[1], Meg McCarrick[2], Kevin Freeman-Cook[2], Peggy Thompson[1]

[1]Biology, Plexium, San Diego, CA,[2]Chemistry, Plexium, San Diego, CA

SMARCA2 and SMARCA4 are mutually exclusive, essential catalytic subunits of human BAF complexes, which are involved in controlling gene expression through the remodeling of chromatin structure. In a subset of solid tumors, SMARCA4 is frequently mutated, rendering cancer cells with SMARCA4 loss-of-function (LOF) mutations highly dependent on SMARCA2 for proliferation and survival. This synthetic lethal dependency offers an opportunity to develop safe and effective treatment options for patients with SMARCA4^{MUT} tumors through the development of selective SMARCA2 degraders. Here we describe the *in vitro* and *in vivo* properties of PLX-61639, a potent, selective, and orally bioavailable SMARCA2 degrader currently in clinical development. PLX-61639 was developed utilizing a monovalent direct degrader strategy where small molecules are designed to bind the target protein and induce its degradation through the recruitment of an E3 ligase complex. PLX-61639 elicits potent and selective degradation of SMARCA2 by inducing a ternary complex with the E3 ligase DCAF16. An electrophilic moiety of PLX-61639 promotes the formation of a covalent drug-E3 ligase adduct and enables extended degradation kinetics and prolonged pharmacodynamic effects. The selective degradation profile of PLX-61639 leads to robust anti-proliferative activity in SMARCA4^{MUT} tumor models and demonstrates the synthetic lethal dependency. *In vivo*, daily oral administration of PLX-61639 in SMARCA4^{MUT} mouse xenograft models exhibits sustained target degradation and dose-dependent tumor growth inhibition and regression at well-tolerated doses. In addition to single agent activity, rational combination strategies were explored, guided by SMARCA2-dependent transcriptionally regulated gene sets and/or specific co-mutations often observed in SMARCA4^{MUT} tumors. PLX-61639 demonstrates robust combination benefit with multiple standard of care agents utilizing different modalities, suggesting potential effective treatment options for future development. The results disclosed here highlight the development of PLX-61639, a potent and selective SMARCA2 monovalent direct degrader, and demonstrate its utility in the treatment of SMARCA4^{MUT} solid tumors.

#7075 Preclinical characterization of FHT-171, a first-in-class degrader targeting CREB-binding protein (CBP) in CBP-dependent solid tumors.

Darshan Sappal[1], Molly M. Wilson[1], Laura La Bonte[1], Meiyun Lin[1], Breanna Bullock[1], Shawn Schiller[2]

[1]Foghorn Therapeutics, Watertown, MA,[2]Orionis Biosciences, Waltham, MA

The paralog lysine acetyltransferases CREB-binding protein (CBP) and E1A-binding protein P300 (EP300) function as transcriptional coactivators that regulate diverse cellular programs. Functional screens have revealed a bidirectional synthetic relationship between these two paralogs in tumor cell biology. This synthetic lethal relationship offers a therapeutic opportunity in selectively targeting CBP in *EP300*-mutant as well as other CBP-dependent cancers. Herein, we present a comprehensive preclinical evaluation for a first-in-class, selective CBP degrader, FHT-171, designed to target transcriptional co-activator dependencies in solid tumors. Through a series of in vitro and in vivo studies, we characterize the compound's biochemical selectivity, cellular degradation kinetics, transcriptional impacts, antitumor efficacy and tolerability across multiple solid tumor models. These findings provide mechanistic and non-clinical translational insight into the therapeutic potential of CBP degradation and support further development of this novel modality for the treatment of CBP-dependent malignancies.

#7076 Discovery of a highly potent and selective KAT6A degrader ATH-002 that demonstrates robust anti-tumor activity with a low risk of hematotoxicity in preclinical studies.

Hanyu Wang, Lei Jiang, Youxi Chen, Baoying Chen, Yuyao Zhang, Nianfeng Huang, Fan Yang, **Feng Zhou**

Atheron therapeutics, Ltd., Shanghai, China

KAT6A, a member of the MYST family of histone acetyltransferases, regulates gene transcription by acetylating histone H3K23 and thereby participates in multiple cellular processes, such as proliferation and differentiation. Amplification or overexpression of KAT6A have been observed in various cancers, including breast cancer, where it is amplified in approximately 15% of patients, highlighting its potential as a promising target for therapy. PF-07248144, the first KAT6A/6B dual inhibitor to enter the clinic, demonstrates durable anti-tumor activity in ER+HER2− metastatic breast cancer, especially in combination with fulvestrant. However, Phase 1 data also revealed hematologic dose-limiting toxicities of neutropenia and anemia. The on-target toxicities resulting from the simultaneous inhibition of KAT6A/6B, which synergistically promote hematopoietic stem cell development. Furthermore, studies have suggested that KAT6A has non-enzymatic functions by its role in DNA damage repair via interaction with PARP and by the observation that depletion of KAT6A more efficiently suppresses the proliferation of KMT2A-rearranged AML cells than blocking its acetyltransferase activity alone. These evidences provide the rationale to develop a KAT6A-specific degrader with the potential for improved efficacy and reduced hematotoxicity. Here we report a potent and oral KAT6A degrader, ATH-002. It effectively induced KAT6A degradation with DC_{50} <1nM, and the degradation could be abolished when E3 was inactive, suggesting a direct mediation by the ubiquitin-proteasome system via E3-ligase binding. Global proteome analysis demonstrated an excellent selectivity against proteins, including KAT6B and other MYST family members. ATH-002 robustly inhibited proliferation in KAT6A amplified cell lines, but not in cells with low KAT6A expression, indicating the activity was driven by the specific KAT6A degradation. Mechanism studies further showed that ATH-002 dose-dependently blocked the H3K23 acetylation, down-regulated ER expression, and concurrently reduced BRPF-1 level, which might be induced by a bystander degradation effect. In contrast to KAT6A/6B inhibitors, ATH-002 significantly decreased hematotoxicity, especially in the myeloid lineage with EC_{50}>30 μM. In a KAT6A amplified xenograft model, ATH-002 effectively inhibited tumor growth, which correlated with KAT6A degradation. Besides monotherapy, ATH-002 displayed an enhanced anti-proliferation effect in combination with SERDs or CDK4/6 inhibitors without overlapping hematotoxicity, implying a potential application of KAT6A degrader and SOC therapy. Collectively, our findings support ATH-002 as a clinical candidate for the treatment of KAT6A-amplified tumors.

#7077 ISM1745, an MTA-cooperative PRMT5 inhibitor for the treatment of MTAP-deleted cancer.

Yilin Yang[1], Zhongying Cao[1], Meng Zhang[1], Xiaoyu Ding[1], Hongfu Lu[1], Qingchuan Zhao[1], Xiaoxia Lin[1], Jiaojiao Yu[1], David Gennert[2], **Suguna Rachakonda**[2], Xiao Ding[1], Xin Cai[1], Man Zhang[1], Feng Ren[1], Alex Zhavoronkov[2]

[1]Insilico Medicine, Shanghai, China,[2]Insilico Medicine, Cambridge, MA

MTAP deficiency is observed in approximately 15% of human cancers and leads to accumulation of methylthioadenosine (MTA), which competes with the methyl-donor S-adenosylmethionine (SAM) to partially inhibit post-translational methyltransferase activity of PRMT5. This molecular context creates a vulnerability in MTAP-deleted tumors, rendering them particularly susceptible to PRMT5 inhibition. MTA-cooperative PRMT5 inhibitors preferentially bind to PRMT5 when MTA occupies the SAM-binding pocket of PRMT5, thus increasing inhibitory specificity to MTAP-deficient cells. Here, we characterize ISM1745, a novel, orally bioavailable MTA-cooperative inhibitor.

ISM1745 potently inhibits formation of symmetric dimethylarginine (SDMA), the PRMT5-catalyzed methylation product, and impairs cell growth in MTAP-deficient HCT116 cancer cells *in vitro* (IC_{50} = 1.1 nM), with 272-fold selectivity over MTAP wild-type HCT116 cells. In addition, Safety44 and methyltransferase panel screening indicated minimal off-target activity for ISM1745. Mechanistically, ISM1745 induces apoptosis, cell cycle arrest, and DNA damage specifically in MTAP-deleted cells, as indicated by an increased proportion of annexin V-positive cells, accumulation in the G1 phase, and elevated expression of DNA damage markers such as γH2AX. Once-daily oral administration of ISM1745 results in marked and sustained tumor growth inhibition in MTAP-deleted xenograft models. Moreover, when combined with ISM3412, an inhibitor of MAT2A, which catalyzes formation of SAM, ISM1745 exhibits significant synergistic anti-tumor activity, highlighting its promise as part of a combinatorial strategy for targeting MTAP-deficient cancers.

In addition to its robust biological potency and high selectivity, ISM1745 exhibits favorable drug-like properties, including optimal in vitro ADMET profiles, excellent in vivo exposure, low clearance (CL<30% Qh in non-rodent species), and moderate to high oral bioavailability across multiple preclinical species. Taken together, these findings support ISM1745 as a potent and selective MTA-cooperative PRMT5 inhibitor with robust anti-tumor efficacy, providing potential therapy for treatment of MTAP-deleted cancers.

#7081 Enzyme hyperactivation to target isocitrate dehydrogenase mutations.

Erick Gonzalez[1], Shengqi Hou[1], Andrew M. Intlekofer[2]

[1]Human Oncology and Pathogenesis Program, Memorial Sloan Kettering Cancer Center, New York, NY,[2]Human Oncology and Pathogenesis Program and Department of Medicine, Memorial Sloan Kettering Cancer Center, New York, NY

Somatic mutations in isocitrate dehydrogenase (IDH) enzymes are hallmarks of acute myeloid leukemia (AML), glioma, and several other cancers. Mutations in IDH result in the neomorphic ability to convert alpha-ketoglutarate (α-KG) into the oncometabolite 2-hydroxyglutarate (2HG), which competitively inhibits α-KG-dependent enzymes and locks malignant cells in a stem cell-like state. Targeted inhibition of mutant IDH enzymes effectively shuts off production of the oncometabolite 2HG and benefits some patients with IDH-mutant cancers. However, the majority of IDH-mutant tumors are impervious to 2HG inhibition. Even for those cases that respond to mutant IDH inhibition, drug resistance invariably develops. Thus, there is an unmet need for novel therapeutic approaches beyond simple inhibition of mutant IDH. Based on mechanistic studies of an unusual drug resistance mutation identified in patients with acquired resistance to IDH inhibitors, we discovered that genetic hyperactivation of mutant IDH2 converts the activity of mutant IDH2 into a lethal metabolic liability. Using chemical screens, we identified small molecules that hyperactivate mutant IDH2, unleash metabolic toxicity, and selectively eliminate IDH2-mutant cancer cells. Thus, we propose that hyperactivation (rather than inhibition) of mutant IDH offers an unexpected and effective new therapeutic approach for targeting IDH-mutant cancers.

#7082 Pseudoginsenoside F11 enhances YBX1-mediated transcriptional repression of PRPS2 to inhibit the stemness and pulmonary metastasis of triple negative breast cancer.

Kejia Xu[1], Huimin Liu[1], Yuting Bai[1], Haojie Chen[1], Yi Liu[1], Yimeng Liu[2], Xing Wan[2], Rong Xiang[1]

[1]Nankai University, Tianjin, China,[2]Tianjin Medical University Cancer Institute and Hospital, Tianjin, China

Background: Hyperactive de novo nucleotide synthesis is a metabolic hallmark of pulmonary metastatic triple-negative breast cancer (TNBC), largely driven by the upregulation of phosphoribosyl pyrophosphate synthetase 2 (PRPS2). The absence of specific PRPS2 inhibitors represents a significant unmet therapeutic need for preventing TNBC metastasis.**Methods:** We screened a library of 320 traditional Chinese herb-derived compounds using a PRPS2-promoter-driven luciferase reporter assay in TNBC cells. The lead compound was evaluated in vitro for effects on PRPS2 expression and cancer stemness, and in vivo using a murine pulmonary metastasis model. The direct target of PF11 was identified via biotin-conjugated pull-down assays. Mechanistic insights were gained through chromatin immunoprecipitation (ChIP) and reporter assays.**Results:** Pseudoginsenoside F11 (PF11) was identified as a potent inhibitor of PRPS2 transcription. Treatment with PF11 significantly suppressed PRPS2 expression, cancer cell stemness, and pulmonary metastasis in murine models. We identified the transcription factor YBX1 as the direct binding target of PF11. PF11 binding enhanced YBX1's affinity with the PRPS2 promoter, enabling it to compete with and displace the transcriptional activator c-Myc. Subsequently, YBX1 recruited the NuRD corepressor complex to the promoter, leading to transcriptional repression of PRPS2.**Conclusion:** Our findings unveil a novel mechanism by which PF11 activates a YBX1-NuRD corepressor complex to downregulate PRPS2, thereby attenuating TNBC stemness and metastasis. We propose PRPS2 as a druggable target and PF11 as a promising natural compound for the targeted therapy of TNBC.

#7083 ABSK211, a highly potent and orally available pan-KRAS inhibitor, demonstrates robust antitumor efficacy in combination with multiple agents.

Qianqian Chen, Bin Shen, Xiao Chen, Jie Wang, Jie Zhang, Manqi Liu, Hongping Yu, **Nannan Zhang**

Abbisko Therapeutics Co., Ltd., Shanghai, China

Background: KRAS mutations are prevalent oncogenic drivers in pancreatic, lung, and colorectal cancers. Although current KRAS inhibitors have shown promising clinical activity, rational combination strategies may yield greater therapeutic benefit. ABSK211, a highly potent and orally available pan-KRAS inhibitor discovered by Abbisko, represents a promising therapeutic candidate targeting a broad spectrum of KRAS-driven tumors. This study evaluates the preclinical combination potential of ABSK211 with mechanistically diverse agents to enhance anti-tumor efficacy.

Methods: *In vitro* synergistic anti-proliferative effects of ABSK211 were assessed in combination with the MTA-cooperative PRMT5 inhibitors, the EGFR monoclonal antibody (mAb), and chemotherapies across KRAS-mutant pancreatic, lung, and colorectal cancer models. Synergy was quantified using combination index analysis. *In vivo* efficacy of the combination regimens was assessed in various tumor models to determine tumor growth inhibition and response durability.

Results: ABSK211 demonstrated *in vitro* synergy with the evaluated combination partners in anti-proliferation assays. Pronounced synergy was observed with PRMT5 inhibitor across diverse KRAS mutation contexts. Similarly, combinations with cetuximab or chemotherapy agents showed strong synergy in KRAS G12D and G12V colorectal and pancreatic models. *In vivo*, combinations of ABSK211 with ABSK131, cetuximab, immunotherapy, or chemotherapy produced markedly enhanced tumor growth inhibition compared with monotherapies in various tumor models.

Conclusions: These findings provide a strong preclinical rationale for advancing these combinations of ABSK211 into clinical development to improve outcomes for patients with KRAS-mutant cancers.

#7084 β-Caryophyllene induces apoptosis and inhibits angiogenesisin colon cancer models.

Loiy Ahmed Hassan, Saad Sabbar, Yasser Tabana

School of Pharmaceutical Sciences - USM, Penang, Malaysia

Beta-Caryophyllene (BCP), a naturally occurring sesquiterpene abundantly found in cloves, hops, and cannabis, is the active candidate of a relatively new group of vascular-inhibiting compounds that aim to block existing tumor blood vessels. The present study aimed to investigate the effects of BCP on *in-vitro*, *ex vivo*, and *in-vivo* models of anti-angiogenic assays and evaluate its anti-cancer activity in xenograft tumor (both ectopic and orthotopic) mice models of human colorectal cancer. Computational structural analysis and an apoptosis antibody array were also performed to understand the molecular players underlying this effect. BCP exhibited strong anti-angiogenic activity by blocking the migration of endothelial cells, tube like network formation, suppression of vascular endothelial growth factor (VEGF) secretion from human umbilical vein endothelial cells and sprouting of rat aorta microvessels. BCP has a probable binding at Site#0 on the surface of VEGFR2. Moreover, BCP significantly deformed the vascularization architecture compared to the negative control in a chick embryo chorioallantoic membrane assay. BCP showed a remarkable reduction in tumor size and fluorescence molecular tomography signal intensity in all the mice treated with BCP, in a dose-dependent relationship, in ectopic and orthotopic tumor xenograft models, respectively. The histological analysis of the tumor from BCP-treated mice revealed a clear reduction of the density of vascularization. In addition, BCP induced apoptosis through downregulation of HSP60, HTRA, survivin, and XIAP, along with the upregulation of p21 expressions. These results suggest that BCP acts at multiple stages of angiogenesis and could be used as a promising therapeutic candidate to halt the growth of colorectal tumor cells.

#7085 Obscurin-PH as a chemo-sensitizer in triple-negative breast cancer.

Kelly Griffiths, Matthew Eason, Aikaterini Kontrogianni-Konstantopoulos

Biochemistry and Molecular Biology, University of Maryland School of Medicine, Baltimore, MD

Triple-negative breast cancer (TNBC) is the most aggressive subtype of breast cancer due to its proclivity to migrate, invade, and metastasize. Given the lack of targetable cell surface markers, the standard of care for TNBC is systemic chemotherapy and surgery. The anthracycline doxorubicin (dox) is an efficacious mainstay chemotherapy for TNBC despite its toxicity, as it triggers dilated cardiomyopathy in up to 20% of patients. Thus, tolerable targeted therapeutics for TNBC are an urgent priority. Obscurin is a giant cytoskeletal protein richly expressed in normal breast epithelium; its expression is often lost in breast cancer, leading to lower survival and reduced responsiveness to anthracyclines. Intriguingly, administration of sublethal dox in TNBC cells upregulates the oncogenic PI3K/AKT axis, potentially conferring a survival advantage. Obscurin's pleckstrin homology domain (obscurin-PH) tightly binds and sequesters the p85 regulatory subunit of PI3K, suppressing PI3K/AKT activation and preventing migration, invasion, and metastasis. We hypothesized that obscurin-PH may act as a chemo-sensitizer by synergizing with dox, improving its efficacy and allowing for lower, less toxic doses to be used for TNBC treatment. The potency of a cocktail combining obscurin-PH and dox was evaluated across 3 TNBC cell lines with distinct PI3K activation patterns (Table 1). Excitingly, our data shows a strong synergy between obscurin-PH and dox across all cell lines, allowing for the use of sub-cardiotoxic dox doses, with the minimal effective synergistic dose varying based on the PI3K activity in each cell line. Mechanistically, the dox-induced survival advantage is blunted via inhibition of the pro-survival/metastatic PI3K/AKT/NF-κB axis. This data underscores the potential of obscurin-PH as a novel non-chemical PI3K inhibitor exhibiting anti-growth, anti-metastatic, and chemo-sensitizing properties. Moreover, it highlights the importance of precision medicine to avoid overtreatment and toxicity.

Table 1. Obscurin-PH synergizes with dox in TNBC cells with varying modes of PI3K activation.

Cell line	**PI3K pathway mutation(s)**	**Clinical significance**	**$IC50_{DOX}$ (μM)**	**$IC50_{OBSCURIN-PH}$ (MOI)**	**Relative Inhibition $(RI)_{DOX}$**	**Relative Inhibition $(RI)_{OBSCURIN-PH}$**	**Combination Sensitivity Score (CSS)**	**CSS > RI = synergy; CSS < RI = antagonism**
MDA-MB-231	N/A	N/A	3.82	941.48	15.43	-2.47	30.58	Synergy, CSS > RI

SUM159	*PIK3CA* mutant [p.His1047Leu]	Pathogenic, oncogenic	5.0	8549.62	42.43	13.81	49.74	Synergy, CSS > RI

#7086 Preclinical characterization of a potent and selective Werner helicase (WRN) inhibitor with activity in low-TA repeat microsatellite instability-high (MSI-H) cancers.

Pablo E. Hollstein[1], Daniel A. Aiello[1], Anne Y. Saiki[1], Keegan S. Cooke[1], Petia Mitchell[1], Xiang Yi[2], Ishwar N. Kohale[3], Matthew J. Rardin[3], John Rodgers[4], Mauro Poggio[5], Chun Su[6], Sigurgeir Olafsson[7], Doruk Beyter[7], Jennifer A. Roth[8], Nuria A. Tamayo[9], Kevin L. Greenman[9], Andrew J. Holland[1], Paul E. Hughes[1]

[1]Oncology Research, Amgen, Inc., Thousand Oaks, CA,[2]LD&TPD, Amgen, Inc., South San Francisco, CA,[3]Discovery Proteomics, Amgen, Inc., South San Francisco, CA,[4]PKDM-BA, Amgen, Inc., South San Francisco, CA,[5]Precision Medicine, Amgen, Inc., South San Francisco, CA,[6]Automation, Research data systems, Informatics & AI (ARIA), Amgen, Inc., South San Francisco, CA,[7]Amgen deCODE Genetics, Amgen, Inc., Reykjavik, Iceland,[8]Broad Institute, Cambridge, MA,[9]Small Molecule Therapeutic Discovery, Amgen, Inc., Thousand Oaks, CA

Werner syndrome helicase (WRN), a member of the RecQ family of DNA helicases, is a synthetic-lethal dependency in DNA mismatch repair-deficient cancers that exhibit high microsatellite instability (MSI-H). Here, we characterize Compound 1, a potent and selective small molecule WRN inhibitor. Compound 1 binds within an allosteric pocket in the helicase domain of WRN and forms an irreversible covalent interaction with cysteine 727 (C727), a residue not conserved in other RecQ helicases. *In vitro*, Compound 1 potently inhibited WRN's helicase activity and was confirmed to be a highly selective covalent inhibitor of WRN C727 by mass spectrometry-based cysteine profiling in human MSI-H cancer cells. Consequently, Compound 1 potently impacted the viability of a broad panel of MSI-H cell lines, including colorectal SW48 and RKO (IC50 = < 10 nM and < 100 nM, respectively), and ovarian TOV-21G (IC50 < 300 nM) cells. Treatment with Compound 1 elicited robust induction of pharmacodynamic (PD) biomarkers including sensors of DNA damage and the proteasome-dependent degradation of WRN across the panel. Notably, these responses were selective for MSI-H cells and were not observed in microsatellite-stable (MSS) cells nor in cell lines derived from normal tissues up to the highest concentration tested (5 μM).

In vivo, Compound 1 treatment resulted in a dose-dependent modulation of PD biomarkers, which correlated with strong anti-tumor efficacy in SW48, RKO, and TOV-21G MSI-H cell line-derived xenograft (CDX) models. Covalent engagement of WRN by Compound 1 was measurable in tumor tissue and in peripheral blood monocytes. The exposure and target occupancy of Compound 1 required for efficacy strongly correlated with the expansion of repetitive thymine-adenine (TA) nucleotide DNA microsatellites. These repeats form non-canonical secondary structures that interfere with DNA replication in MSI-H cells and require unwinding by WRN. Long-read DNA sequencing confirmed that the extent of TA-repeat expansion was associated with Compound 1 activity in MSI-H CDX models. An analysis of primary MSI-H tumor cohorts revealed that the majority of patient tumor samples exhibited TA-repeat expansions within the range of Compound 1 efficacy observed in cell-based models. Importantly, dosing of Compound 1 was sufficient to elicit tumor regression in low-TA repeat CDX MSI-H models (RKO, TOV-21G), which have proven to be refractory to WRN inhibitors advanced previously. Together, these data demonstrate that covalent inhibition of WRN by Compound 1 is an effective strategy to selectively kill MSI-H tumor cells with expanded TA repeats.

#7087 Optimizing the linker of venetoclax-artemisinin conjugates to improve water solubility and antileukemia effects.

Jingyi Zhang[1], Linghui Hou[1], Zhenwei Zhang[1], Samuel Waxman[2], Linxiang Zhao[1], Yongkui Jing[1]

[1]Shenyang Pharmaceutical University, Shenyang, China,[2]Samuel Waxman Institute for Aging and Cancer, New York, NY

Venetoclax based combination therapy is utilized as the first-line treatment for elderly acute myeloid leukemia (AML) patients with short remission time due to resistance and relapse. Previously, we reported that artesunate enhanced venetoclax-induced apoptosis by promoting NOXA-mediated degradation of Mcl-1. By employing a chemical conjugation approach, we linked dihydroartemisinin (DHA) to venetoclax using a two-carbon methylene spacer, yielding the conjugate A1. A1 maintains Bcl-2 inhibitory activity and overcomes Mcl-1/Bcl-xL-mediated resistance. However, due to its large molecular size, A1 has limited bioavailability and solubility. To address these limitations, we incorporated various polyethylene glycol (PEG) units between venetoclax and DHA, generating conjugates A18-A20. These derivatives exhibited approximately two-fold greater solubility than A1, and more potent activity to inhibit colony formation of U937 cells in soft agar assays. Moreover, A19 and A20 significantly suppressed tumor growth in vivo. The tumor growth inhibition rates for A19 and A20 (75.6% and 65.8%, respectively) were significantly higher than that of venetoclax alone (33.9%). We further modified the PEG backbone of A20 by incorporating nitrogen-containing polar groups, resulting in compounds A21-A23. These modifications led to further increased aqueous solubility and colony-forming inhibitory activity. These novel conjugates represent promising next-generation venetoclax derivatives capable of overcoming resistance.

#7088 NAD(P)H: Quinone oxidoreductase 1 (NQO1): Is it a potential molecular target in colorectal cancer?.

Chaithanya Ganji[1], Raasil R. Basha[2], Karthikeya Ganji[3], Mehmet Akce[4], Bassel F. El-Rayes[5]

[1]Hematology and Oncology, O'Neal Comprehensive Cancer Center at UAB, Birmingham, AL,[2]Missouri Southern State University, Fort Worth, TX,[3]Harrison High School, Kennesaw, GA,[4]University of Alabama at Birmingham, Birmingham, AL,[5]University of California San Diego, La Jolla, CA

Background: Colorectal cancer (CRC) is the third most frequent cancer in the United States, and it is linked to poor outcomes. NAD(P)H: Quinone Oxidoreductase 1 (NQO1) is an enzyme that has been demonstrated to help in chemoprotection in CRC. The purpose of this meta-analysis is to investigate the relationship between NQO1 C609T polymorphisms and the risk of CRC. The study also investigates the binding ability and efficacy of BBI 608 against NQO1 in CRC using molecular docking.

Methods: Google Scholar, PubMed, and Web of Science were utilized for bibliographic searches. The NQO1 C609T analysis included 18 studies. Data was collected and then calculated using the pooled odds ratio (OR) with a 95% confidence interval. Molecular docking, Western Blot, and QRT-PCR were utilized to determine BBI 608 and NQO1's molecular function.

Results: The NQO1 polymorphism was significantly associated with CRC risk (OR = 1.19, 95% CI = 1.06-1.34, $p < 0.001$). A stratified examination by ethnicity found a significant connection between the NQO1 polymorphism and CRC risk (TT + CT vs. CC: OR = 1.17, 95% CI = 1.08-1.27, $p < 0.001$). This study demonstrates that the NQO1 C609T polymorphism increases the risk of CRC in both Asians and Caucasians. Computational techniques were used to explore the molecular characteristics of BBI 608 (an NQO1 inhibitor) and determine the precise mechanism of NQO1 in CRC. This study provides a deep insight into the interplay between NQO1 and BBI 608, as well as its implications for CRC treatment. *In vitro* experiments were conducted to supplement this computational analysis. BBI 608 causes dose-dependent cytotoxicity in CRC cell lines. BBI 608 treatment significantly ($p < 0.001$) decreased NQO1 expression at protein and RNA levels in both CRC cell lines (HCT116 and RKO).

Conclusion: According to a meta-analysis and computational technique, NQO1 is a valid biomarker and possible molecular target in CRC. *In vitro* studies revealed that suppressing NQO1 with BBI 608 reduced cell growth in both CRC cell lines. Knockout, overexpression, and site-directed mutagenesis are necessary for a deeper understanding of BBI 608-targeted NQO1 and its amino acid residues.

#7089 Diphyllin induces autophagy-mediated ferroptosis in liver cancer.

Jinfang Zhang[1], Zhanghao Li[1], Zheng CHEN[1], Chao Wang[2], Aiping Lu*[1]

[1]Hong Kong Baptist University, Hong Kong, Hong Kong,[2]Guangdong Pharmaceutical University, Guangzhou, China

Background: Liver cancer is one of the most prevalent malignancies and a leading cause of cancer-related mortality worldwide, underscoring the urgent need for novel therapeutic strategies. Ferroptosis, a newly discovered form of regulated cell death characterized by iron accumulation and lipid peroxidation, has emerged as a significant mechanism in cancer biology and a potential therapeutic target. Diphyllin, a natural compound and potent V-ATPase inhibitor, displays promising anticancer activity in preliminary liver cancer studies. However, the molecular mechanism underlying the anti-tumor efficacy of diphyllin remains unclear, thus elucidating these mechanisms may not only deepen our understanding of liver cancer pathogenesis but also provide a scientific foundation for developing diphyllin-based therapies.
Methods: The proliferative effect and cell death of diphyllin on liver cancer cells were quantitatively assessed using the EdU assay and Annexin V-FITC/PI staining followed by flow cytometry. To visualize the morphological alterations induced by diphyllin, the ultrastructure of treated cells was examined using transmission electron microscopy (TEM). For mechanistic exploration, transcriptomic analysis was performed to capture global gene expression changes. The western blotting and confocal immunofluorescence staining were used to measure the ferroptosis key proteins and autophagy markers. Furthermore, pharmacological autophagy inhibitors were applied to determine the dependency of ferroptosis on autophagy.
Results: Treatment with diphyllin significantly suppressed the proliferation activity and increased the cell death rate in liver cancer cell lines. Transcriptomic profiling and western blot analysis revealed that diphyllin triggered ferroptosis, as evidenced by a marked downregulation of GPX4 protein expression. Furthermore, TEM analysis and immunofluorescence staining demonstrated that diphyllin induced autophagy, characterized by an elevated LC3B-II/LC3B-I ratio and a reduction in p62. Notably, the suppression of GPX4 expression was partially reversed upon treatment with an autophagy inhibitor, suggesting a functional link between diphyllin-induced autophagy and ferroptosis. Together, these results indicate that diphyllin promotes ferroptosis in liver cancer cells through an autophagy-dependent pathway. These findings provide a mechanistic basis supporting further preclinical investigation of diphyllin as a potential therapeutic agent for liver.
Conclusions: This study demonstrates that diphyllin suppresses liver cancer by inducing both ferroptosis and autophagy. Mechanistic investigations revealed that diphyllin induced ferroptosis is an autophagy-dependent process, evidenced by the restoration of GPX4 upon autophagy inhibition. These findings establish autophagy-mediated ferroptosis as the novel mechanism underlying diphyllin's anti-tumor efficacy.

#7090 Preclinical characterization of ABSK211: A highly potent, orally bioavailable and selective pan-KRAS inhibitor with broad and robust activity in KRAS-driven tumors.

Yongxian Zhang, Fei Yang, Zhigang Feng, Meimei Sun, Xinyan Huang, Haibing Deng, Hongping Yu, **Haiyan Ying**

Abbisko Therapeutics, Shanghai, China

KRAS is frequently mutated in human cancers, including pancreatic (~90%), colorectal (~35%), and lung cancers (~25%). Several selective pan-KRAS inhibitors have advanced into clinic but their potency against KRAS mutations remained to be further improved. Here we describe that ABSK211, discovered by Abbisko, is a highly potent, and orally bioavailable small-molecule inhibitor with broad activities against multiple KRAS mutations. ABSK211 exhibited strong target engagement *in vitro* against a range of KRAS mutations. Treatment with ABSK211 effectively impaired cell viability at sub-nanomolar to nanomolar concentrations across a diverse panel of cancer cell lines with different KRAS alterations, including G12 mutation, G13 mutation, Q61 mutation and WT amplification. Meanwhile ABSK211 displayed marginal inhibition in normal cell proliferation. *In vivo* daily oral dose of ABSK211 induced deep tumor regression in several KRAS G12V CDX models across different human cancer types. Strong target engagement *in vivo* was also observed. Additionally, ABSK211 exhibited robust anti-tumor activity in xenograft models with other KRAS mutations, such as KRAS G12D/S and KRAS G13D. ABSK211 is currently undergoing IND-enabling studies; its superior preclinical profile supports its advancement into clinical studies.

#7091 DWP216, a TEAD1/2 inhibitor, enhances efficacy of diverse KRAS inhibitors by reversing resistance mechanisms in RAS-dependent cancers.

Bora Yoo, Ye Gi Han, Hye-Been Yoo, Ahreum Kwon, Jiyoon Seok, Youngwoo Choi, Ji-Duck Kim, Hyounmie Doh

Innovative Drug Discovery Center, Daewoong Pharmaceutical Co., Ltd., Yongin-si, Gyeonggi-do, Korea, Republic of

YAP-TEAD pathway plays critical in regulating cell proliferation, tissue regeneration, and organ size control, and it promotes tumor progression and metastasis in cancer. Additionally, YAP-TEAD pathway not only reinforces anti-apoptotic signaling but also remodels the tumor microenvironment into an immune-evasive state, representing a key mechanism driving drug resistance.DWP216 is a selective TEAD1/2 inhibitor with high selectivity over TEAD3, a TEAD form associated with renal toxicity, conferring a more favorable safety profile than pan-TEAD inhibitors. DWP216 has demonstrated superior efficacy in NF2-deficient tumor models and is currently in the final stages of GLP toxicology studies.KRAS mutations are a major oncogenic target, occurring in approximately 95% of pancreatic cancers and 40% of lung cancers. KRAS mutations also promote YAP-TEAD activation and, when KRAS signaling is inhibited, YAP-TEAD frequently functions as a key adaptive bypass pathway.In this study, we evaluated the combinatorial potential of DWP216 with various KRAS inhibitors. We observed that Hippo pathway gene set is upregulated in KRAS inhibitor-resistant cancer cells. DWP216 demonstrated in vitro combinatorial efficacy not only with a G12C inhibitor but also with a G12D inhibitor and a pan-RAS inhibitor. Resistance-associated mechanisms to KRAS inhibition such as activation of MAPK signaling and the PI3K/mTOR pathway, were observed in KRAS inhibitor-resistant cancer cells. Treatment with DWP216 reduced Hippo pathway activation and restored sensitivity to KRAS inhibition by reversing these compensatory mechanisms. Combination treatment with DWP216 and KRAS inhibitors also increased pro-apoptotic markers. In vivo CDX models harboring KRAS mutations showed strong combinatorial activity of DWP216 with KRAS inhibitor. In conclusion, DWP216 can be effectively combined with various KRAS inhibitors and may be extendable as a combination strategy against RAS-dependent cancers such as PDAC.

#7092 Highly potent and mutant-selective p53 Y220C reactivators with best-in-class potential.

Chiou-Hong Lin[1], Benjamin C. Milgram[2], Brendon Ladd[2], Weixue Wang[2], John P. Vu[1], Jun Jacob Hu[2], Yemin Lan[2], Keyur Gada[2], Heidi Koldsoe[2], Stephanie M. Reeve[2], Robert Hicklin[2], Mint Sirisawad[1], Brendan J. Hilbert[2], Jack A. Henderson[2], Simon A. Roberts[2], Gregory Kryukov[2], Hsu-Ping Kuo[1], Natasja Brooijmans[2], Angel Guzman-Perez[2], Darrin D. Stuart[2], Erica L. Jackson[1]

[1]Antares Therapeutics, South San Francisco, CA,[2]Antares Therapeutics, Boston, MA

Background: The tumor suppressor p53, encoded by the *TP53* gene, is a transcription factor that regulates genes involved in DNA repair, cell cycle arrest, senescence, and apoptosis. *TP53* is the most frequently altered tumor suppressor gene with mutations occurring in over 50% of human cancers. *TP53* mutations result in a loss of function, rendering cells incapable of responding to a variety of cellular stresses, making them susceptible to tumorigenesis. The Y220C hotspot mutation accounts for 1.8% of all p53 mutations, occurring in ~1% of all solid tumors. p53 Y220C is a structural mutation that causes destabilization of the p53 protein. Small molecules that bind to a pocket formed by the Y220C mutation, but absent in the p53 wild-type protein, can stabilize the protein to restore normal function. Rezatapopt (PC14586) is the first p53 Y220C reactivator to enter clinical trials, where it is showing clinical benefit. However, because this molecule has modest potency, its efficacy may be limited by insufficient p53 reactivation despite a high RP2D (2000 mg QD), particularly in KRAS mutant patients.

Materials and Methods: Antares's p53 Y220C reactivators were evaluated biochemically in SPR binding and thermal shift assays. Cellular activity was assessed in target engagement, target gene expression and cell proliferation assays across a panel of p53 Y220C mutant cell lines. Additionally, chromatin binding and target gene expression conferred by p53 Y220C reactivation were analyzed by ChIP-seq and RNA-seq. Finally, the *in vivo* efficacy was studied in several human CDX and PDX p53 Y220C models.

Results: Antares's orally bioavailable p53 Y220C reactivators demonstrated a ≥10-fold improvement in *in vitro* potency over rezatapopt in target engagement, ChIP-seq and RNA-seq assays, with corresponding potency improvements in cell proliferation assays across a panel of p53 Y220C mutant cell lines. *In vivo*, these compounds were effective in inhibiting tumor growth in multiple p53 Y220C CDX models at a significantly lower dose than rezatapopt. Importantly, these p53 reactivators exhibit a marked improvement in activity in a KRAS mutant model, both *in vitro* and *in vivo*.

Conclusions: The significantly improved potency of the novel p53 reactivators described here offers the opportunity to restore p53 function in less sensitive patient populations and meaningfully improve upon the clinical response profile of rezatapopt.

#7093 Potential use of MYCN and AURKA dual inhibitors for the treatment of pediatric cancers.

Nur Awaliyah Mentari Sukma, Wan-Ping Wang, Cheng-Ping Jheng, Chung-Chi Lee, Teng-Kuang Yeh, Jyh-Haur Chern, **Ya-Hui Chi**

National Health Research Institutes (NHRI), Zhunan, Taiwan

Aberrant activation of MYCN through genomic copy gain is a defining feature of high-risk neuroblastoma, which continues to have poor clinical outcomes despite intensive therapy. In MYCN-amplified tumors, AURKA contributes to malignant progression by stabilizing MYCN via a protein-protein interaction. Transcriptomic analysis of the St. Jude Children's Research Hospital database revealed that neuroblastomas co-overexpressing high levels of MYCN and AURKA exhibit significantly worse progression outcomes compared with tumors overexpressing either gene alone. We also identified a subset of pediatric soft-tissue tumors with concurrent MYCN and AURKA overexpression, among which Ewing's sarcoma showed a strong negative correlation between co-overexpression and overall survival. Across neuroblastoma and Ewing's sarcoma cell lines, MYCN expression level positively correlated with sensitivity to dual MYCN/AURKA inhibitors, including alisertib and 6K465. To evaluate translational potential, we compared the antitumor efficacy of alisertib and DBPR728 (the prodrug of 6K465) in the SK-N-BE(2) CDX model. DBPR728 administered at 300 mg/kg once weekly produced more durable tumor suppression than alisertib at 50 mg/kg once daily for three weeks. These findings define MYCN/AURKA coactivation as a therapeutic vulnerability and support the further development of dual MYCN/AURKA-targeting agents for pediatric cancers with elevated MYCN and AURKA expression.

#7094 Discovery of QLS1303, a potent and selective KIF18A inhibitor with robust anti-tumor activity in CIN+ preclinical cancer models.

Fei Chen, Wei Wei, Xiaobing Lv, Xiaoping Zheng, Chen Yang, Lili Fan, Fang Zhang, Junguo Hao, Xinrui Shao, Yan Wu, Ling Li, Ping Chen, Dong Yang, Hua Dong, Guqing Shi, Dongdong Wu, Yanling Xu, Weimei Sun, **Liang Xie**, Wenyuan Qian, Daqing Sun, Weikang Tao

Shanghai Qilu Pharmaceutical Research and Development Center LTD., Shanghai, China

Background: Chromosomal instability (CIN) underlies the aneuploidy present in ~90 % of solid tumors and engenders a persistent requirement for the plus-end kinesin KIF18A to silence mitotic checkpoints and align extra chromosomes. Consequently, KIF18A inhibition triggers catastrophic mis-segregation exclusively in CIN-high cells, inducing mitotic arrest or apoptosis, while sparing normal diploid cells. This synthetic-lethal interaction makes KIF18A as an attractive, cancer-selective therapeutic target, which prompted multiple drug-discovery programs, including AMG 650, a clinical-stage KIF18A inhibitor. Here we report the discovery and preclinical profiling of QLS1303, a novel, potent and orally bioavailable KIF18A inhibitor engineered to against aneuploid cancers with CIN-specific vulnerability.
Experimental Procedures: The inhibitory activity of QLS1303 was assessed through biochemical (KIF18A motor activity) and cellular proliferation assays using CIN+ and near-diploid cancer cell lines. In vivo efficacy and tolerability were evaluated in TP53mut/aneuploidy-high CDX models following once-daily oral administration. Selectivity and safety were profiled against a panel of 46 safety targets.
Results: QLS1303 potently inhibited KIF18A motor activity (IC_{50} = 13 nM) with a good selectivity over known toxic kinesin family members. It selectively suppressed proliferation of CIN+ cell lines (IC_{50} = 4-14 nM) with minimal effects on near-diploid cells. Once-daily oral administration of QLS1303 at 3 and 10 mg/kg was well-tolerated and induced tumor regression in multiple TP53mut/aneuploidy-high CDX models, and achieved tumor stasis at one-tenth of AMG 650 dosage in OVCAR3 xenograft model. A clean selectivity and safety profile were confirmed with no significant inhibition (IC_{50} > 10 μM) across the 46-target panel. In addition, QLS1303 exhibits favorable drug-like properties and a promising predicted therapeutic window.
Conclusion: QLS1303 is a highly potent, selective, and orally bioavailable KIF18A inhibitor, demonstrating robust anti-tumor activity in CIN+ preclinical models and a compelling safety profile. These data strongly support its advancement into clinical studies.

#7095 QLS1403, a novel and potent PARG inhibitor with robust anti-tumor efficacy in homologous recombination deficient cancer models.

Tingting Xia, Wei Wei, Xiaobing Lv, Jianfei Wang, Shengnan Zhang Zhang, Jun Chen, Xianyun Huang, Guozhi Liang, Lan Zhang, Ling Li, Ping Chen, Dong Yang, Fangfang Chen, Guqin Shi, Jiahua Chu, Dongdong Wu, Weimei Sun, **Liang Xie**, Wenyuan Qian, Daqing Sun, Weikang Tao

Shanghai Qilu Pharmaceutical Research and Development Center LTD., Shanghai, China

Background: Cancer cells experience high levels of endogenous replication stress due to persistent proliferative signaling. Poly (ADP-ribose) polymerase (PARP) is a first responder to DNA damage, catalyzing the synthesis of poly (ADP-ribose) (PAR) chains that serve as docking platforms for DNA repair proteins. The hydrolysis of these PAR chains, a critical step for the turnover of repair complexes, is primarily mediated by poly (ADP-ribose) glycohydrolase (PARG). Pharmacological inhibition or genetic loss of PARG prevents PAR chain hydrolysis, which results in persistent stalling of replication fork, nucleolytic degradation of nascent and parental DNA and ultimately cell death. IDE-161, a first-in-class PARG inhibitor has entered clinical trials. This study reports the discovery and characterization of QLS1403, a proprietary PARG inhibitor designed to selectively treat homologous recombination deficient (HRD) cancers, particularly those resistant to PARP inhibitors (PARPi) or T-Dxd.
Experimental Procedures: The activities of QLS1403 were characterized by biochemical PARG inhibition assay, cellular viability assessment in HRD-positive and PARPi-resistant or T-Dxd-resistant cancer cell lines and *in vivo* evaluation of efficacy in ovarian and breast cancer xenograft models. In addition, the pharmacodynamic effect, i.e., the PAR chain accumulation and its pharmacokinetic properties were assessed in both cells and animals.
Results: QLS1403 demonstrated exceptional PARG inhibitory activity (IC_{50} = 0.35 nM) and remarkable cellular activity in HRD-positive cancer cell lines, showing approximately 10-fold greater potency than IDE-161. Notably, QLS1403 showed strong activity in PARPi- or T-Dxd-resistant cell lines. Also, QLS1403 caused tumor regression at lower doses across multiple xenograft models with intrinsic PARPi resistance, accompanied by dose-dependent PAR accumulation in tumors. In addition, QLS1403 exhibited a clean selectivity and safety profile *in vitro*, with no significant off-target activity observed in safety assessment panels.
Conclusion: QLS1403 demonstrates superior potency, sustained efficacy in PARPi-resistant and T-Dxd-resistant cancer cell lines, while displaying favorable safety. These compelling data support its clinical evaluation as a new therapeutics for patients with HRD-positive cancers with acquisition of resistance to PARPi or potentially other existing treatments, such as T-Dxd.

#7096 Design and development of a biparatopic antibody-drug conjugate against CDH17.

Jinxiu Hou, Lisha Dong, Tingting Gu, Jiyuan Tian, Dandan Liu, Yongxin Shang, Rongmei Yan, Lifeng Pan, Liang Tian, Jian Peng, Zhenping Zhu

Earendil Labs., Wilmington, DE

CDH17 is overexpressed in various adenocarcinomas, including colorectal, gastric, and pancreatic cancers. High levels of CDH17 are associated with metastatic disease and poor prognosis in patients with these malignancies, In normal tissues, the expression of CDH17 is limited. Currently, various CDH17-based therapeutics, including bispecific antibodies, ADCs, and CAR-T, are under clinical investigation for treating CRC. Here, we describe the discovery and optimization of a novel biparatopic anti-CDH17 antibody. The biparatopic antibody exhibits efficient CDH17-directed cell binding and promotes rapid internalization at a much higher efficiency than the mono-epitope targeting ADCs. Next, we conjugated the biparatopic antibody to various cytotoxic payloads. The ADCs showed selective cytotoxicity towards multiple tumor cell lines with varying levels of CDH17 expression in vitro, and potently inhibited the growth of CDH17-expressing tumor xenografts in animal models. Together, these findings indicate that our lead biparatopic anti-CDH17 ADC is a promising candidate for the treatment of cancers that overexpress CDH17.

#7097 Non-clinical characterization of GSK5764227, a novel B7-H3-directed antibody-drug conjugate (ADC).

Jeremy Waight[1], Yuanfeng Zhou[2], Danni Sun[2], Lu Zhang[2], Michael Adam[1], Dawson Knoblock[1], Wenjin Zhou[2], Pengchao Qiu[2], Jifa Fan[2], Hannah Chenoweth[3], Johannes Breuning[3], Huifeng Niu[2], Srujana Neelam[1], Juan Liu[1], Shannon McKearnan[4], Natacha Steinckwich-Besancon[1], Takahiro Sato[1], Derek Poore[1], Alexander Cocks[3], Prajna Behera[5], Chris Hopson[1], Kenneth W. Hance[1], Klaas Bakker[3]

[1]GSK, Collegeville, PA,[2]Hansoh Pharmaceutical Group Co., Ltd., Shanghai, China,[3]GSK, London, United Kingdom,[4]GKS, Collegeville, PA,[5]GSK, Waltham, MA

B7-H3 (B7 homolog 3 protein), also known as CD276, is an important immunoregulatory ligand and member of the B7-CD28 family. Despite being widely expressed across tissues at the RNA level, the expression of B7-H3 protein is limited, where it can be found in cell-expressed and soluble forms. Notably, B7-H3 protein is found to be overexpressed in a variety of tumor tissues, including gastric, lung, prostate, kidney, oral, and bladder cancer, as well as osteosarcoma and hematologic malignant diseases - making B7-H3 an attractive target for tumor-selective approaches, such as antibody drug conjugates (ADCs). The expression of B7-H3 in tumor tissues is most prevalent on tumor epithelial and stromal cells (e.g., cancer associated fibroblasts and endothelial cells) but has also been described on tumor infiltrating dendritic cells (DCs), macrophages and monocytes. Consistent with its described immunoregulatory and tumor promoting role, B7-H3 is closely associated with poor prognosis and negative clinicopathological features, including metastasis, disease recurrence, and resistance to certain chemotherapeutics.

GSK5764227 is a novel ADC developed by Shanghai Hansoh Biomedical Technology Co., Ltd that is comprised of a fully human anti-B7-H3 monoclonal antibody (mAb) conjugated to an exatecan-derived topoisomerase I (TOPO1) inhibitor (SHR-9265, GSK5757810A, average DAR of 4).

Here we describe various non-clinical characteristics of GSK5764227, including biophysical, functional, and mechanistic attributes of the ADC. In vitro, GSK5764227 demonstrated binding to and internalization into B7-H3-expressing tumor cells, resulting in concentration-dependent tumor cell cytotoxicity. GSK5764227 also elicited cell cycle arrest (S-phase) and bystander killing capability.

In vivo, GSK5764227 exhibited significant and dose-dependent tumor growth inhibition (TGI) towards multiple CDX models, including the small cell lung cancer (SCLC) tumor cell line NCI-H146. Similar anti-tumor activity was observed in human PDX models of SCLC. Importantly, the strong antitumor activity in SCLC models align with early phase clinical data (ARTEMIS-001), where GSK5764227 demonstrated >60% ORR in extensive stage SCLC patients [Wang, 2025]. Collectively, these non-clinical observations, in tandem with emerging clinical data, support GSK5764227 as a promising cancer therapy and its rapidly progressing global clinical development.

#7099 Novel Ect2-Rac inhibitor CPV-337 in breast and pancreatic cancer.

Jessica Colon Gonzalez[1], Nilmary Grafals-Ruiz[1], Anamaris Torres-Sanchez[1], Cornelis Vlaar[2], Suranganie Dharmawardhane[1]

[1]Department of Biochemistry, School of Medicine, University of Puerto Rico Medical Sciences Campus, San Juan, PR,[2]Department of Pharmaceutical Sciences, School of Pharmacy, University of Puerto Rico Medical Sciences Campus, San Juan, PR

Metastasis is the leading cause of treatment failure and poor prognosis in cancer patients; however, there are few metastasis targeted therapies. The homologous Rho GTPases Rac and Cdc42 are viable targets in metastatic cancer due to their central role in cancer cell proliferation, viability, survival, migration, and invasion. In cancer, Rac and Cdc42 are not generally mutated but activated by oncogenic guanine nucleotide exchange factors (GEFs), which exchange the GDP for a GTP. We developed the clinical-stage compound MBQ-167, a Rac and Cdc42 inhibitor, as a metastasis inhibitor. CPV-337 is an MBQ-167 derivative that is specific for Rac (Rac1,2, 3, Rac1b) with an IC50 of ~50nM (i.e., 2X more effective than MBQ-167) in HER2++ breast cancer and an IC50 of <100nM in pancreatic cancer. CPV-337 has a GI50 of 57nM in metastatic breast cancer cells without affecting mammary epithelial cells. In a mouse model of HER2++ breast cancer experimental metastasis, treatment with 5mg/kg CPV-337 resulted in ~90% reduction in mammary tumor growth and metastasis, to the same extent as 10 mg/kg MBQ-167. The objective herein was to characterize the mechanism by which CPV-337 acts as an anticancer agent. We show that CPV-337 inhibits the phosphorylation of Rac downstream effectors PAK and Cofilin, which regulate actin cytoskeletal structures, such as lamellipodia. A significant reduction of the Rac downstream effector WAVE protein that also regulates the actin cytoskeleton, was also observed following CPV-337 treatment. Accordingly, CPV-337 inhibits lamellipodia formation, invasion, and migration of HER2++ breast cancer cells. To identify the mechanism by which CPV-337 inhibits Rac1, pulldowns were conducted using the Rac1(G15A) nucleotide-free mutant, which has a higher affinity for activated GEFs. Of the GEFs tested, Ect2 (Epithelial Cell Transforming 2) was identified as the major Rac.GEF inhibited by CPV-337. To date there are no known Rac-Ect2 specific inhibitors, despite Ect2 being a critical oncogene that regulates cytokinesis and cell cycle progression. Overexpression of Ect2 in different types of cancer has been associated with poor prognosis and reduced overall survival. Ongoing studies are evaluating the inhibitory mechanism of CPV-337 and its specificity using CRISPR-Cas9 Rac-1 knockout breast cancer cells. In conclusion, CPV-337 is a promising anti breast and pancreatic cancer drug with a unique and specific mechanism of inhibition.

#7100 VS-7375: An oral, selective KRAS G12D dual ON/OFF inhibitor with potent anti-tumor activity as a single agent and in combination with other agents.

Silvia Coma[1], Ian Smith[2], Cristina Caffarra Malvezzi[3], Clint A. Stalnecker[4], Emilia Berardelli[3], Enrico Patrucco[3], Fusheng Zhou[5], Channing Der[4], Chiara Ambrogio[3], David G. DeNardo[2], **Jonathan A. Pachter**[1]

[1]Verastem Oncology, Needham, MA,[2]Department of Medicine, Washington University School of Medicine, st louis, MO,[3]Department of Molecular Biotechnology and Health Sciences, University of Torino, Torino, Italy,[4]University of North Carolina at Chapel Hill, Chapel Hill, NC,[5]Genfleet Therapeutics, Shanghai, China

KRAS G12D is the most prevalent KRAS mutation in human cancers, present in 40%, 15%, and 5% of pancreatic, colorectal and lung cancers, respectively. Currently, there are no FDA-approved RAS inhibitors for patients with KRAS G12D-mutated (mt) cancers. VS-7375 (GFH375) is an oral, selective KRAS G12D dual ON/OFF inhibitor exhibiting extremely high affinity (K_D = 12-18 pM) and long residence time (18-24 hours) for the ON and OFF states of human KRAS G12D. VS-7375 has shown potent single agent anti-tumor efficacy with oral dosing across multiple KRAS G12D mt xenograft models representing pancreatic, colorectal and lung cancers. To assess potential benefits of dual ON/OFF inhibition relative to ON-only RAS inhibitors, we compared efficacy in KRAS G12D mt in vivo models relative to the KRAS G12D ON-only inhibitor zoldonrasib (RMC-9805) and the pan-RAS ON-only inhibitor daraxonrasib (RMC-6236). In the KP4 KRAS G12D pancreatic cancer model, VS-7375 (50 mg/kg twice daily orally) showed similar initial tumor regression (through day 9) relative to zoldonrasib (100 mg/kg once daily orally) and daraxonrasib (25 mg/kg once daily orally). However, by approximately 20 days of dosing, zoldonrasib and daraxonrasib progressively lose their anti-tumor activity with associated tumor outgrowth (mean tumor volume >850 mm^3 by day 30) in contrast to those treated with VS-7375 which showed sustained tumor regression (mean tumor volume ~80 mm^3 by day 30). Accordingly, pharmacodynamic analysis with pathway-specific gene signatures showed that whereas all three KRAS inhibitors inhibited MAPK, MYC and PI3K signaling at day 6, only the G12D ON/OFF inhibitor VS-7375 maintained inhibition of these signaling pathways by day 20. VS-7375 also showed deeper tumor regression compared to these RAS ON-only inhibitors in KRAS G12D mt lung and colorectal xenograft models. Currently, we are assessing the anti-tumor efficacy of VS-7375 in combination with other anti-cancer agents including EGFR, PRMT5 and FAK inhibitors. Briefly, the combination of the anti-EGFR antibody cetuximab with VS-7375 induced strong tumor growth inhibition in KRAS G12D mt cancer models. Furthermore, addition of a PRMT5 inhibitor with VS-7375 increased duration of tumor regression in KRAS G12D mt;MTAP-deleted pancreatic cancer models. Lastly, addition of a FAK inhibitor with VS-7375 increased duration of tumor regression in KRAS G12D mt cancer models, altogether supporting the potential clinical evaluation of novel combination strategies with VS-7375 in patients with KRAS G12D mt cancers for maximal anti-tumor efficacy and durability. VS-7375 is currently in phase 1/2 clinical evaluation in the US (VS-7375-101; NCT07020221) and in advanced clinical evaluation in China (NCT06500676) as monotherapy and in combination with cetuximab or chemotherapy ± pembrolizumab for patients with KRAS G12D mt cancers.

#7101 Discovery of first-in-class YTHDC1 small molecule inhibitors for the treatment of MYC-driven cancers.

Richard C. Centore[1], Mark Charles[2], Mansi Arora[1], Marius Rebmann[2], Michael J. Rawling[2], Jerome Cattin[2], Xuejing Yang[3], Emily Batchelor[3], Matthew Watson[2], Nagakumar Bharatham[2], Alexander Howarth[2], Seema Qamar[2], Laura Andraghetti[2], Andrew Seeber[1], Michael G. Kharas[3], Sam Cohen[2], Martin Kulander[2], Tuomas Knowles[2], **Shilpi Arora**[1]

[1]Transition Bio, Inc., Cambridge, MA,[2]Transition Bio Ltd., Cambridge, United Kingdom,[3]Memorial Sloan Kettering Cancer Center, New York, NY

The m6A reader protein YTHDC1 is essential for cancer cell survival, through its ability to form nuclear biomolecular condensates that stabilize oncogenic transcripts such as *MYC*. Here, we report a new class of potent, selective, orally bioavailable small-molecule inhibitors of YTHDC1. These compounds occupy the RNA binding pocket of YTHDC1 and disrupt its interaction with m^6A-modified RNA at nanomolar potency in both biochemical and cellular assays. They display high selectivity for YTHDC1 over other YTH family members, selectively dissolve m6A-dependent YTHDC1 condensates without affecting unrelated condensate systems, and exhibit clean profiles across broad kinase and safety panels. The optimized leads are drug-like, orally bioavailable and possess favorable ADME and *in vivo* properties. Pharmacological inhibition of YTHDC1 disrupts oncogenic YTHDC1 condensates and robustly suppresses MYC signaling resulting in growth arrest, differentiation, and apoptosis of acute myeloid leukemia (AML) and additional cancer cell types, while sparing normal hematopoietic cells. These optimized inhibitors display strong single-agent anti-tumor activity across heme and solid tumor models including AML, small cell lung cancer and neuroendocrine prostate cancer. Moreover, YTHDC1 inhibition shows pronounced synergy with standard of care agents such as venetoclax in AML. Collectively, these findings establish YTHDC1 as a tractable therapeutic target for MYC-driven malignancies.

#7102 Overcoming cytidine deaminase (CDA) mediated resistance via EO-4426 dual DNA-replication targeting: Implications for CDA-high solid tumors and mesenchymal GBM.

Jeffrey Bacha[1], Denni M. Brown[2], Richard Daniels[1], Sarath Kanekal[3], John Langlands[4]

[1]Edison Oncology Holding Corp., Menlo Park, CA, CA,[2]Edison Oncology Holding Corp., Menlo Park, CA,[3]President, Regulatory Strategy Consulting, San Diego, CA,[4]Valent Technologies LLC, Menlo Park, CA, CA

Background: EO-4426 (tezacitabine) is a brain-penetrant, deamination-resistant cytidine analog that uniquely inhibits both DNA polymerase-α (Polα) and ribonucleotide reductase (RNR), leading to dNTP-pool depletion, replication-fork collapse, and DNA-damage accumulation in rapidly proliferating tumor cells. Unlike gemcitabine and hydroxyurea, EO-4426 resists cytidine deaminase (CDA)-mediated inactivation. Tumors with high CDA expression or APOBEC3G-linked cytidine-metabolism activity—including mesenchymal GBM, TNBC, NSCLC, and ovarian cancer—are predicted to exhibit heightened dependence on Polα/RNR function and may therefore be particularly susceptible to dual-targeting strategies.

Methods: Ongoing invitro studies are assessing EO-4426 across engineered and naturally CDA-high cancer cell models to define mechanistic pharmacology and biomarker-enrichment hypotheses. Experimental approaches include: (i) LCMS quantification of EO-4426-induced dNTP-pool depletion; (ii) evaluation of replication-stress and DNA-damage biomarkers (γH2AX, pRPA32, pCHK1) by immunoblot and high-content imaging; (iii) characterization of APOBEC3G→CDA pathway activity and its impact on drug sensitivity; (iv) flow cytometric analysis of S-phase arrest and replication-fork perturbation; and (v) combinatorial studies with ionizing radiation and DDR-targeting agents, including ATR inhibition.

Preliminary Findings: Prior nonclinical studies demonstrate that EO4426 retains potent activity in CDA-high tumor environments and is not susceptible to rapid deamination, distinguishing it from gemcitabine, which is efficiently converted to inactive dFdU. Published work also reports enhanced antitumor activity in combination with DNA-directed agents and fluoropyrimidines, consistent with strong replication-stress induction and dNTP-depletion biology. Clinically, EO4426 has been evaluated in multiple third-party sponsored Phase I/II trials, showing predictable myelosuppression as the principal toxicity and evidence of antitumor activity, including objective responses and durable disease stabilization, in heavily pretreated solid-tumor populations.

Conclusions: New data are being developed to support further investigation of EO-4426 in cytidine metabolism-driven tumor contexts and biomarker guided clinical development strategies for CDA-high solid tumors and mesenchymal/APOBEC3G-enriched GBM. Comprehensive in vitro mechanistic data, biomarker correlations, and combination treatment findings will be presented at the Meeting.

#7103 Evaluation of anti-parasitic agents as potential therapeutics in ovarian cancer.

Aneth Ochoa Negrete[1], Tiffany Duque[1], Adithi Kankanala[1], Gisel Gutierrez[1], Riyaz Basha[2]

[1]UNT Health, Fort Worth, TX,[2]University of North Texas Health Science Center, Fort Worth, TX

Ovarian cancer is projected to claim approximately 13,000 lives in the United States in 2025. Current treatment options remain limited and often insufficiently effective, underscoring the need for alternative therapeutics that may improve survival outcomes. To explore such possibilities, we screened two anti-parasitic drugs: ivermectin (IV) and fenbendazole (FZ). These drugs have been reported to exhibit anti-cancer properties. Both drugs were tested on the ovarian cancer cell lines SKOV3 and ES-2 using a luminescence-based CellTiter-Glo cell viability assay kit (Promega). Previous studies indicate that these compounds can inhibit proliferation and promote apoptosis in some cancer cell lines and mouse xenograft models. FZ in particular has been reported to alter the expression of *MYC*, a gene involved in cancer cell growth, proliferation, and survival. Using the open-access cancer database, we retrieved data from The Cancer Genomic Atlas and found that high *MYC* expression in ovarian cancer patients significantly correlates with decreased survival ($p = 0.044$). Our cell viability assays revealed cell line-dependent anti-proliferative responses. ES-2 cells displayed a clear dose-dependent decrease in viability following IV or FZ treatment, whereas SKOV3 cells were comparatively less sensitive. For ES-2, IV at 8, 4, 2, and 1 µM doses at 48-hour post-treatment, yielded viabilities of 0.88%, 4.91%, 18.82%, and 78.97%, respectively; for SKOV3, the corresponding viabilities were 8.92%, 56.62%, 76.61%, and 100.0%. FZ produced a similar trend: ES-2 viabilities at 5, 2.5, 1.25, and 0.625 µM were 6.97%, 27.02%, 50.52%, and 69.46%, while SKOV3 viabilities were 17.32%, 19.46%, 20.49%, and 50.54%, respectively. IC_{50} calculations further highlighted these differences. In SKOV3, the IC_{50} for FZ (1.02 µM) was lower than that for IV (3.678 µM). In ES-2, both drugs produced similar IC_{50} values (IV: 2.5345 µM; FZ: 2.3285 µM). These findings suggest the potential anti-cancer activity of these anti-parasitic agents and further testing their efficacy as therapeutic candidates for ovarian cancer. Our laboratory is currently investigating the combination therapies involving these drugs with standard chemotherapeutics and other agents shown to modulate MYC and other emerging anti-cancer compounds to improve treatment efficacy for ovarian cancer patients.

#7104 BBO-11818: An orally bioavailable, highly potent and selective non-covalent pan-KRAS(ON) and (OFF) inhibitor with robust anti-tumor activity in KRAS-mutant preclinical models.

Carlos E. Stahlhut Espinosa[1], Anna E. Maciag[2], Kyle A. Sullivan[1], Kanchan Singh[1], Nadege Gitego[1], Zuhui Zhang[1], Albert H. Chan[2], Alok K. Sharma[2], Patrick Alexander[2], Jin Shu[1], Yue Yang[1], Megan Rigby[2], Roger Ma[2], Molly Grandcolas[1], Saman Setoodeh[1], Brian P. Smith[2], Jun Pei[3], Dana Rabara[2], Erik K. Larsen[2], David Turner[2], Cathy Zhang[1], Cindy Feng[1], Siyu Feng[1], James P. Stice[1], Rui Xu[1], Ken Lin[1], Andrew G. Stephen[2], Felice C. Lightstone[3], Chunmei Ji[1], Keshi Wang[1], Dhirendra K. Simanshu[2], Dwight V. Nissley[2], Eli Wallace[1], Bin Wang[1], Kerstin Sinkevicius[1], Frank McCormick[4], Pedro J. Beltran[1]

[1]BridgeBio Oncology Therapeutics, South San Francisco, CA,[2]NCI RAS Initiative, Frederick National Laboratory for Cancer Research, Frederick, MD,[3]Physical and Life Sciences (PLS) Directorate, Lawrence Livermore National Laboratory, Livermore, CA,[4]UCSF Helen Diller Family Comprehensive Cancer Ctr., San Francisco, CA

KRAS is commonly mutated in human cancer. Inhibitors of $KRAS^{G12C}$ have shown promising clinical efficacy; however, there are currently no approved targeted therapies against other KRAS variants, and a significant underserved patient population across several major cancer types, including pancreatic carcinoma (PDAC), colorectal cancer (CRC), and non-small cell lung cancer (NSCLC), remains. We discovered BBO-11818: a potent, selective, orally bioavailable small molecule KRAS inhibitor with activity against multiple KRAS mutants, including $KRAS^{G12D}$ and $KRAS^{G12V}$, in both their active GTP-bound (ON) and inactive GDP-bound (OFF) states. BBO-11818 binds the switch II pocket with high affinity and selectivity, locking the active form in the signaling-incompetent state 1 to disrupt the association of GTP-bound KRAS with its key effector RAF1, and sequestering the inactive form. BBO-11818 potently inhibits several oncogenic KRAS mutants in cell-based assays, resulting in the suppression of MAPK signaling and inhibition of cell proliferation with single-digit nanomolar EC_{50} values. The selectivity of BBO-11818 for KRAS is demonstrated by its >1000-fold lower potency against NRAS- and BRAF-mutant cell lines. BBO-11818 exhibits favorable pharmacokinetic (PK) and pharmacodynamic (PD) properties in mouse models of cancer. Single dose, oral administration results in strong dose- and time-dependent inhibition of pERK in $KRAS^{G12D}$ and $KRAS^{G12V}$ cell-derived xenograft (CDX) models. BBO-11818 monotherapy induces strong anti-tumor responses, including regression at well-tolerated doses in CDX and patient-derived xenograft (PDX) models of KRAS-mutant PDAC, NSCLC, and CRC. Combination treatment with BBO-10203, a clinical-stage (NCT06625775), selective RAS:PI3Kα breaker that blocks RAS-mediated activation of the PI3Kα-AKT pathway, results in decreased cellular proliferation, increased apoptosis, and enhanced efficacy in CDX and PDX models harboring $KRAS^{G12D}$ or $KRAS^{G12V}$ mutations. Similarly, combination treatment with BBO-11818 and cetuximab, an approved anti-EGFR monoclonal antibody, results in enhanced anti-tumor activity in a $KRAS^{G12D}$ CDX model. Finally, BBO-11818 shows combination benefit with anti-PD-1, resulting in complete tumor regressions in the $KRAS^{G12D}$ CT-26 syngeneic tumor mouse model. BBO-11818 is a potent pan-KRAS inhibitor with activity against both the GTP- and GDP-bound states of KRAS, presenting the opportunity to address a large fraction of KRAS-mutant tumors currently lacking targeted therapeutic options. BBO-11818 has entered Phase 1 clinical trials for patients with various KRAS mutations in colorectal, pancreatic, and lung cancers (NCT06917079).

#7105 Therapeutic targeting of ADAR1 p150 splicing activity impairs CD44$^+$ TNBC cell populations in preclinical studies.

Wenxue Ma[1], Jessica Pham[1], Emma Klacking[1], Kendale Wirtjes[1], Inge van der Werf[1], Peggy Wentworth[1], Sheldon Morris[1], James La Clair[1], Michael Burkart[2], Catriona Jamieson[1]

[1]University of California San Diego, La Jolla, CA,[2]Department of Chemistry and Biochemistry, University of California San Diego, La Jolla, CA

Background: Triple-negative breast cancer (TNBC) remains clinically challenging due to the lack of targeted therapies and the presence of therapy-resistant tumor-propagating cells. CD44 and ADAR1 contribute to TNBC progression and therapeutic resistance. Rebecsinib is a small-molecule inhibitor designed to block splicing-mediated activation of ADAR1 (adenosine deaminase acting on RNA 1). This study evaluates its efficacy in selectively targeting CD44$^+$ and ADAR1$^+$ cells in preclinical humanized TNBC models.

Methods: MDA-MB-231 TNBC cell line-derived xenograft (CDX) models were established in Rag2$^{-/-}\gamma c^{-/-}$ and NSG-SGM3 mice. MDA-MB-231 ADAR-nanoluciferase-GFP expressing cells enable tracking of ADAR1 activity by IVIS imaging. Engrafted mice received vehicle, Rebecsinib IV (10 mg/kg), or Rebecsinib PO (15mg/kg), twice a week for two weeks. Tumor burden was measured by IVIS and single-cell suspensions from peripheral blood, and tissues (lung, liver, spleen, and bone marrow) were analyzed by flow cytometry to quantify CD44$^+$ and ADAR1$^+$ cells.

Results: Rebecsinib significantly reduced CD44$^+$ cells in peripheral blood ($p < 0.05$), lung ($p < 0.01$), liver ($p < 0.01$), and spleen ($p < 0.05$) in Rag2$^{-/-}\gamma c^{-/-}$ models (Student *t* test). Corresponding decreases in ADAR1$^+$ cells was observed in the lung ($p < 0.05$), liver ($p < 0.01$), and spleen ($p < 0.01$) in NSG-SGM3 mouse models (Student *t* test). IVIS imaging demonstrated tumor bioluminescence in Rebecsinib-treated groups ($p = 0.02$, student *t* test). Combination with Fedratinib further suppressed tumor growth, indicating a synergistic effect ($p < 0.05$, student *t* test).

Conclusion: Rebecsinib selectively reduces CD44$^+$ and ADAR1$^+$ TNBC cell populations and inhibits tumor progression in humanized preclinical models. These findings support further evaluation of Rebecsinib alone and in combination, as a targeted therapeutic approach for TNBC.

Keywords: TNBC, ADAR1, CD44, Rebecsinib, targeted therapy, preclinical models.

#7106 Q-2361, a treatment for skin cancer prevention in organ transplant recipients.

Rebecca Pouwer[1], **Kimberley Beaumont**[1], Margaret Veitch[2], Maria Parra Reyes[2], Bhanu Chintala[2], Hui Yi Chew[2], Peter Soyer[3], Scott Campbell[4], James Wells[2], Andrew Harvey[1], Terrie-Anne Cock[1], Brian Dymock[1]

[1]QEDDI, UniQuest, University of Queensland, Brisbane, Australia,[2]Frazer Institute, Faculty of Medicine, University of Queensland, Brisbane, Australia,[3]Frazer Institute, Dermatology Research Centre, University of Queensland, Brisbane, Australia,[4]Faculty of Medicine, University of Queensland, Brisbane, Australia

Solid organ transplant recipients require life-long immunosuppression in order to prevent the immune-mediated rejection of their transplanted organs. Tacrolimus, a mainstay in immunosuppressive therapy, acts systemically to suppress the activity of T cells within and around transplanted organs. Consequently, however, these patients suffer a 65- to 250-fold increased risk of developing cutaneous malignancies including squamous cell carcinoma (SCC) and Kaposi's Sarcoma. SCC is the most prevalent cancer in solid organ transplant recipients, with a more aggressive clinical course compared to the general population and is a significant contributor to morbidity and mortality. We have identified a small molecule drug candidate (Q-2361), to locally inhibit the unwanted effects of tacrolimus on T cells and ketatinocyes in the skin. Q-2361 potently blocked the interaction between tacrolimus and FKBP12 and rescued both mouse and human T cell activation and proliferation in the presence of tacrolimus *in vitro*. Functional studies in multiple 'regressor' mouse models of skin cancer showed that the local administration of Q-2361 induced tumor regression in mice that had been systemically immune-suppressed with tacrolimus. Mechanistically, Q-2361 treatment permitted CD8 T cell activation, proliferation, and effector function, and Q-2361 could not induce tumor regression when CD8 T cells were depleted, demonstrating that Q-2361 induces tumor regression through the reactivation of cytotoxic T cells. In separate studies, Q-2361 blocked multiple effects of tacrolimus on UV-damaged keratinocytes, and prevented the formation of SCC tumours in UV-treated nude mice fed a tacrolimus-diet. A simple solution-based Q-2361 topical formulation achieved high and sustained residence in skin with negligible drug in the blood. Thus, topically applied Q-2361 shows high potential for the reactivation of T cells and the rescue of keratinocyte function locally in the skin but not at other body sites, which paves the way to clinical trials of topical Q-2361 treatments for skin malignancies in immunosuppressed organ transplant recipients.

#7107 Dual FLT3/BRAF inhibitor PHI3 overcomes RAS-driven resistance in FLT3-mutant AML.

Shikhar Sharma[1], Anna Skwarska[1], Evangelia Matenoglou[1], Sovira Chaudhry[1], Selvam Murugan[2], Catherine Smith[3], Pamela Sung[2], Eunice Wang[2], Donald Small[4], **Evripidis Gavathiotis**[1], Marina Konopleva[1]

[1]Albert Einstein College of Medicine, Bronx, NY,[2]Roswell Park Comprehensive Cancer Center, Buffalo, NY,[3]University of California San Francisco, San Frncisco, CA,[4]John Hopkins, Sidney Kimmel Comprehensive Cancer Center, Baltimore, MD

Background: FLT3 mutations define a high-risk subset of AML, and FLT3 inhibitors are routinely used in combination with induction chemotherapy in fit patients, and with a low-intensity HMA/Venetoclax backbone in older patients. However, the majority of relapses arise from activation of bypass signaling, most commonly through the RAS/MAPK pathway. RAS mutations emerge in ~20% of patients who progress on gilteritinib or other FLT3 inhibitors, driving sustained MAPK activation and therapy resistance. We hypothesized that simultaneous inhibition of FLT3 and the downstream RAS effector RAF would suppress MAPK reactivation and overcome this dominant resistance mechanism. Here, we characterize PHI3, a novel dual BRAF/FLT3 kinase inhibitor, and evaluate its preclinical activity in FLT3-mutant and RAS-mutant AML models.
Results: Biochemical assays and nanoBRET target-engagement studies showed that PHI3 potently inhibits wild-type BRAF, BRAFV600E, and FLT3 at nanomolar concentrations. Immunoblot analysis confirmed robust suppression of FLT3, MEK, and ERK phosphorylation by PHI3 in FLT3-ITD+ MOLM13 and MOLM14 cells (IC50 ~35 nM), with activity also observed in OCI-AML2 and OCI-AML3. In contrast to gilteritinib, PHI3 effectively inhibited MAPK signaling in MOLM14 NRASG12C cells (IC50 ~125 nM). FLT3-ITD AML lines were most sensitive to PHI3 (IC50 31-90 nM) and underwent apoptosis within 24 h. RAS-mutant cell lines showed variable but meaningful sensitivity: OCI-AML2/3 (IC50 ~330-340 nM), SKM1 KRASK117N (61 nM), and THP-1 NRASG12D (2.6 µM). MOLM14 isogenic NRAS mutants, resistant to gilteritinib (IC50 1 µM), retained marked sensitivity to PHI3 (IC50 276-690 nM). PHI3 also reduced clonogenic growth, viability (IC50 ~190 nM), and MAPK signaling in primary FLT3/RAS-mutant AML specimens (n=9). PHI3 combined with venetoclax produced additive activity in FLT3-ITD models. In vivo, PHI3 and gilteritinib both reduced tumor burden and prolonged survival in MOLM13 xenografts compared with vehicle control (median of 29 vs 20 days). PHI3 had superior efficacy compared with Gilteritinib in mice engrafted with MOLM14 NRASG12C, with a median survival of 20 days in vehicle-treated mice, 24 days in gilteritinib and 38 days in PHI3-treated mice. Leukemic cells from MOLM14-engrafted mice showed MAPK suppression with both PHI3 and gilteritinib, whereas in MOLM14 NRASG12C mice, MAPK signaling was reduced only with PHI3. No weight loss or other side effects were noted in mice that received PHI3 therapy.
Conclusions: PHI3 is a potent dual BRAF/FLT3 inhibitor that effectively suppresses MAPK pathway reactivation and overcomes RAS-driven resistance to FLT3 inhibitors in AML. Its strong in vivo efficacy and tolerability positions PHI3 as a promising therapeutic candidate. These findings provide a clear mechanistic and translational rationale for advancing dual FLT3/BRAF targeting in patients with FLT3-mutant and FLT3/RAS co-mutant AML.

#7108 Polyamine depletion via ivospemin and doxorubicin combination treatment leads to alterations in the ovarian tumor immune microenvironment.

Cassandra E. Holbert[1], Ashley C. Nwafor[2], Lauren J. Imasa[1], Robert A. Casero[2], Tracy Murray Stewart[2]

[1]Loyola University Maryland, Baltimore, MD,[2]Johns Hopkins Sidney Kimmel Comprehensive Cancer Center, Baltimore, MD

Polyamines are protonated alkylamines that influence many cellular processes including growth, transcription, and survival. Cancer cells are fully reliant on elevated polyamine pools to sustain their continual proliferation and survival. As such, pharmacological modulation of polyamine metabolism is promising as a cancer metabolic therapeutic strategy. Previous work has linked DFMO-mediated polyamine depletion with pro-inflammatory changes in the tumor microenvironment. Our work aims to evaluate ivospemin, a spermine analogue, in ovarian cancer. Considering nearly three-quarters of late-stage ovarian cancer patients develop resistance to platinum-based chemotherapies and these tumors are usually immunotherapy-insensitive, the aim of our study is to determine the combinatorial efficacy and potential immune-priming properties of ivospemin and doxorubicin. We previously demonstrated that ivospemin treatment decreases viability in a variety of cancer cell lines through depletion of intracellular polyamines via downregulation of the polyamine biosynthetic enzyme ornithine decarboxylase (ODC) and induction of the polyamine catabolic enzyme spermidine/spermine-N^1-acetyltransferase (SSAT). Additionally, ivospemin increases the efficacy of gemcitabine and topotecan *in vivo* by delaying tumor onset and reducing overall tumor burden. Here we examine the potential of combining ivospemin with doxorubicin, a common chemotherapeutic used in platinum-resistant ovarian cancer. Ovarian adenocarcinoma lines treated with ivospemin and doxorubicin exhibit an additive decrease in survival that is associated with changes in polyamine metabolic enzyme activity and depleted overall polyamine levels. Using the syngeneic VDID8+ ovarian model, we evaluated the efficacy of combination treatment *in vivo*. Co-treated animals exhibited increased median survival, delayed tumor onset, and decreased tumor burden. Polyamine analysis of ascites fluid confirmed decreased polyamine content and N^1-acetylated spermidine accumulation, consistent with upregulation of SSAT activity. The survival benefit was completely absent in an immunocompromised NSG model indicating significant reliance on the immune system for response. Compared to single agent treatment, ascites from co-treated animals showed an increased presence of CD45+ lymphocytes. While treatment did not influence peritoneal macrophage numbers, the polarization of macrophages was altered with a transition from a predominately M2-like phenotype to an M1-like phenotype following treatment. Additionally, an upregulation of PD-L1 was observed suggesting that treatment may increase sensitivity to immune checkpoint inhibitors (ICIs). Future studies will evaluate ivospemin/doxorubicin in combination with various immunomodulatory drugs such as ICIs, TGFβ blockade, and CD-40 agonists.

: Novel Strategies to Reverse Drug Resistance
Poster Session

#7112 Understanding and overcoming resistance of triple-negative breast cancer brain metastases to RET monotherapy.

Phi-Long Tran[1], Elissa Bloom[1], Angelina Regua[2], Shivani Bindal[2], Mariana Najja[1], Sham Syed[2], Hui-Wen Lo[1]

[1]Department of Cell Biology and Genetics, Naresh K. Vashisht College of Medicine, Texas A&M University Health Science Center, College Station, TX,[2]Vivian L. Smith Department of Neurosurgery, McGovern Medical School, The University of Texas Health Science Center at Houston, Houston, TX

Breast cancer is the most common cancer among American women, with over 315,000 new cases and more than 42,000 deaths projected in 2025. Triple-negative breast cancer (TNBC), the most aggressive subtype, has a high incidence of brain metastasis (BrainMet)—up to 45%. Clinical studies show that TNBC patients with BrainMet have the shortest survival times (4-6 months) compared to those with lung, liver, or bone metastases. This poor prognosis is mainly due to a lack of actionable therapeutic targets and blood-brain barrier (BBB)-permeable drugs. No effective TNBC-BrainMet therapeutics have been identified, underscoring the urgent need for novel treatment modalities. Rearranged during transfection (RET) is implicated in tumorigenesis and metastatic progression in non-small cell lung cancers, thyroid carcinoma, and breast cancers. The orally FDA-approved RET inhibitors, Pralsetinib and Selpercatinib, demonstrated brain penetration, with 70-91% intracranial response rates in lung cancer patients with BrainMet, suggesting their possible utility in treating TNBC-BrainMet. In this study, we investigated the role of RET in TNBC-BrainMet and assessed the therapeutic efficacy of these selective RET inhibitors as a TNBC-BrainMet treatment. Our datamining analyses revealed that RET is hyperactivated in TNBC-BrainMet patients and is associated with worsened survival outcomes. Overexpression of RET in TNBC cells promoted brain metastasis in our intracardiac injection and intracranial inoculation mouse models. Treatment with RET inhibitors reduced tumor burden and brain metastasis in the BrainMet prevention mouse study in *vivo*. However, we observed drug resistance to RET inhibitors in the BrainMet treatment model *in vivo*. We also found lower sensitivity to RET inhibitors in brain-tropic TNBC cells compared to parental TNBC cells. To identify the potential mechanisms of resistance, we further investigated whether RET pathway is co-activated with other oncogenic pathways in breast cancer brain metastasis using the TCGA database analyses. We observed that RET is concurrently activated with multiple signaling pathways, including t-GAS, VEGF, AKT, and ERK. Notably, co-inhibition of RET and these signaling pathways produced synergistic effects in suppressing the proliferation of brain-tropic TNBC cells. Our findings suggested that these co-inhibitions may overcome RET monotherapy resistance in TNBC-BrainMet. In summary, targeting RET is promising for preventive therapy; co-inhibition of RET and its associated pathways may overcome RET monotherapy resistance and advance TNBC-BrainMet treatment, providing preclinical evidence to support future clinical evaluation and development of new effective therapies for TNBC patient with brain metastasis.

#7113 Targeting breast cancer brain metastasis through novel combination of FDA-approved orally active BBB-permeable RET and tGLI1 inhibitors.

Joshua Cha[1], Angelina Regua[2], Mariana Najjar[1], Shivani Bindal[3], Elissa Bloom[1], Hui-Wen Lo[3]

[1]The University of Texas MD Anderson Cancer Center UTHealth Houston Graduate School of Biomedical Sciences, Houston, TX,[2]Vivian L. Smith Department of Neurosurgery, McGovern Medical School, The University of Texas Health Science Center at Houston, Houston, Houston, TX,[3]Department of Cell Biology and Genetics, Naresh K. Vashisht College of Medicine, Texas A&M University Health Science Center, College Station, TX

Breast cancer is the most diagnosed cancer in American women, and breast cancer brain metastasis (BCBM) exhibits the worst prognoses, with a life-expectancy averaging 8 months. The short survival stems largely from the lack of effective treatment. Major challenges remain, including the limited number of actionable targets for targeted therapy and the scarcity of effective blood-brain barrier (BBB)-permeable drugs. Hence, identifying new therapeutic targets and BBB-permeable agents is urgently needed. Our lab identified the Rearranged during Transfection receptor tyrosine kinase (RET) as a potential BCBM target. RET inhibitors Pralsetinib and Selpercatinib, FDA-approved for lung and thyroid cancers, exhibit intracranial activity. We previously reported overexpression of RET in BCBM and found that RET monotherapy significantly suppressed BCBM incidences in mouse models but failed to halt the progression of established BCBM. Thus, we sought to identify potential secondary pathways contributing to the observed resistance to RET monotherapy. Through pathway correlation analysis using publicly available breast cancer datasets, Truncated Glioma-Associated Oncogene Homolog 1 (tGLI1) was identified as positively correlated with RET. tGLI1 is an alternatively spliced, gain-of-function variant of the GLI1 transcription factor that is overexpressed in and promotes BCBM. Consequently, we examined IHC-stained patient samples of matched primary and BCBM tumors and observed concurrent elevation in RET activation and tGLI1 expression in over 80% of BCBM tumor samples. Western blot analysis also revealed increased activated RET and tGLI1 levels in brain-tropic breast cancer cell lines compared to parental counter parts. Datamining analysis with patient-derived datasets indicated significantly higher RET and tGLI1 co-activation in patients with brain metastasis, associated with worse clinical outcomes. Finally, tGLI1-knockdown via antisense oligonucleotides sensitized resistant BCBM subline to Pralsetinib. Thus, we hypothesized that RET and tGLI1 functionally crosstalk to mediate BCBM progression and co-targeting them with FDA-approved orally active BBB-permeable inhibitors overcomes the RET monotherapy resistance and synergistically inhibits BCBM. *In vitro* cell proliferation assays using tGLI1-overexpressing BCBM sublines demonstrated increased Pralsetinib resistance but enhanced sensitivity to tGLI1 inhibitor, Ketoconazole. Pralsetinib+Ketoconazole combination treatment yielded synergistic inhibition of BCBM cell viability and migration *in vitro*. The underlying mechanism is under analysis through RNA-sequencing, and *in vivo* efficacy of the Pralsetinib+Ketoconazole combination therapy on BCBM remains to be validated with mouse models. Together, we report a novel mechanism and combination treatment for BCBM patients.

#7114 Therapeutic potential of BTK targeted degrader in B-cell malignancies harboring ibrutinib-resistant mutation.

Shuai Zhao[1], Xiujuan Wu[1], Ting Ni[2], Jian Xiang[3], Zhixiang Zhang[3]

[1]In Vivo Pharmacology Unit, WuXi AppTec, Suzhou, China,[2]WuXi AppTec, Suzhou, China,[3]WuXi AppTec, Shanghai, China

The long-term efficacy of Ibrutinib is limited by the emergence of resistance mutations (e.g., C481S, L528W). These mutations preclude formation of a covalent bond with BTK, leading to diminished drug efficacy and disease progression. Therefore, novel therapeutic strategy is urgently needed for patients who have acquired resistant mutations of Ibrutinib. Targeted protein degradation represents a potential and powerful means to overcome Ibrutinib resistance. To evaluate BTK degradation as a strategy to overcome ibrutinib resistance, we characterized Bexobrutideg (NX-5948), a novel cereblon E3 ligase-engaging small molecule that induces BTK protein degradation. *In vitro*, NX-5948 exhibited potent antiproliferative effects against ibrutinib-sensitive and -resistant B-cell malignancy models (including BTK-C481S and BTK-L528W mutants). *In vivo*, NX-5948 achieved significant tumor growth inhibition in xenografts harboring these resistance mutations, demonstrating its potential to overcome clinical resistance to Ibrutinib. In summary, we have validated the anti-tumor activity of NX-5948 in Ibrutinib-resistant cell lines, both in vitro and in vivo. These findings support targeting BTK degrader could be as a promising strategy to bypass resistance by eliminating mutant BTK in patients with B-cell malignancies.

#7117 Pharmacological disruption of YAP1/TEAD and NF-kappa B crosstalk suppresses prostate cancer.

Sebnem Unlu[1], Abdulrahman M. Dwead[2], Marwah M. Al-Mathkour[2], **Bekir Cinar**[1]

[1]Center for Cancer Research and Therapeutic Development and Department of Biological Sciences, Clark Atlanta University, Atlanta, GA,[2]Clark Atlanta University, Atlanta, GA

Patients with advanced prostate cancer have poorer prognoses, characterized by persistent morbidity and mortality, primarily due to the development of metastatic castration-resistant disease. Recent studies indicate that crosstalk between the YAP1/TEAD and NF-kappa B pathways is critical for cellular biology and disease pathogenesis, including cancer progression, metastasis, and therapeutic relapse. However, the functional association of these oncogenic pathways in prostate cancer remains insufficiently characterized. This study aims to evaluate the effects of two pharmacological inhibitors: TED-347, a selective YAP1/TEAD inhibitor, and genistein, a phytoestrogen that inhibits NF-kappa B signaling, on prostate cancer growth in both cell culture and animal models. Both TED-347 and genistein result in substantial reductions in prostate tumor cell growth in vitro and in vivo. Mechanistically, TED-347 and genistein decrease the expression and activity of YAP1/TEAD and NF-kappa B/RELA in prostate xenografts. These reductions are accompanied by decreased expression of cancer stem cell markers CD44, CXCR4, and ALDH1A1, as shown by immunohistochemistry, suggesting impaired self-renewal and tumor-initiating capacity. Treatment with these agents also increased CDKN1A expression, reduced Ki-67 staining, and significantly elevated cleaved caspase-3 levels. Notably, our data also reveal that genistein attenuates the interaction between RELA and TEAD, a process mediated by YAP1. These findings provide mechanistic insights into how TED-347 and genistein suppress prostate cancer cell growth and induce cell death, directly linking these agents to reduced tumor progression, metastasis, and therapeutic relapse. The molecular reprogramming induced by TED-347 and genistein leads to increased apoptosis and reduced tumor viability, supporting their potential as therapeutic strategies for treatment-resistant prostate cancer and justifying further investigation in preclinical and clinical settings.

#7118 TNKS inhibition rewires AMOT-YAP signaling to overcome YAP-driven therapy resistance in solid tumors.

Jae Sung Kim, Young-Ju Kwon, Dong Young Kim, Yuna Kim

Korea Institute of Radiological & Medical Sciences (KIRAMS), Seoul, Korea, Republic of

Therapy-resistant tumors frequently rely on hyperactivated YAP signaling, particularly in KRAS-mutant contexts, where YAP serves as a major bypass survival pathway. Because direct pharmacologic inhibition of YAP remains challenging, strategies that modulate its upstream regulatory networks are required. Here, we demonstrate that tankyrase (TNKS) inhibition attenuates YAP oncogenic output by stabilizing angiomotin (AMOT), a core scaffold protein that promotes YAP cytoplasmic sequestration. In YAP-high colorectal cancer (CRC) models, TNKS inhibition increased AMOT abundance, strengthened AMOT-YAP complex formation, and restricted YAP nuclear localization, leading to a global reduction in YAP-dependent transcriptional activity. This reprogramming of YAP signaling sensitized KRAS-mutant CRC cells to MEK inhibition, indicating that the TNKS-AMOT axis directly intersects adaptive resistance mechanisms. In CRC models with established MEK inhibitor resistance driven by YAP reactivation, TNKS inhibition restored therapeutic sensitivity in vitro and in vivo. Similar combinatorial enhancement was observed across additional YAP-activated solid tumors, including pancreatic, lung, and breast cancers, while YAP-inactive tumors showed minimal response, highlighting pathway specificity. Together, these findings support TNKS inhibition as a mechanistically grounded approach to constrain YAP-driven oncogenic signaling through AMOT stabilization, offering a promising therapeutic strategy to overcome YAP-mediated resistance and improve targeted or radiation-based treatment responses in YAP-dependent cancers.

#7119 Large-scale drug screening identifies clinically actionable combinations to overcome BTK/PI3K inhibitor resistance in marginal zone lymphoma.

Alberto J. Arribas[1], Elena Mariotto[2], Eleonora Cannas[1], Giampietro Viola[2], **Francesco Bertoni**[1]

[1]Institute of Oncology Research, Universita della Svizzera italiana, Bellinzona, Switzerland,[2]Dipartimento di Salute della Donna e del Bambino - SDB, Universita degli Studi di Padova, Padova, Italy

Background. BTK inhibitors (i), and, more recently, BTK degraders have become clinically relevant drugs for patients with B-cell malignancies, including marginal zone lymphoma (MZL). PI3Ki are also active drugs, although the first- and second-generation molecules are now less used due to toxicity. Here, we present data from a large pharmacological screen involving over 3,500 compounds in 2 MZL models with secondary resistance to BTK/PI3Ki, developed through prolonged exposure to idelalisib (Arribas 2022) or ibrutinib (Arribas 2025).

Methods. Parental VL51 and resistant derivatives were exposed to DMSO or a library of 3,527 compounds (Mariotto 2023) as single agents (5μM) or in combination with either PI3Ki idelalisib (1μM) or BTKi ibrutinib (500nM) for 72 hours. Spatial and intra- and inter-plate effects were corrected. Robust Z-values were then DMSO-normalized. Highly active compounds across parental and resistant lines, as well as those with improved responses in either idelalisib-resistant or ibrutinib-resistant lines, were selected for further validation by combination with idelalisib or ibrutinib (MTT assay, 72 hours). Synergy of combinations was evaluated according to the Chou-Talalay combination index (CI) and to the MuSyC, HSA and ZIP algorithms.

Results. We identified 127 highly active compounds as single agents in both parental and the 2 resistant ($Z<0.5$), 10 compounds with higher activity in both resistant lines ($Z<0.3$), and 27 and 54 with increased response in BTKi and PI3Ki resistant ($Z<0.3$), compared to the parental counterpart, respectively. The identified molecules targeted apoptosis, cell cycle, PI3K/AKT/mTOR, chromatin/epigenetics, GPCR, DNA damage and repair, and immune signaling. Among these compounds, we selected those more advanced in the clinical setting for further testing in combination with BTKi and PI3Ki. The AChE/cytochrome-P450-i acetylshikonin was synergistic when combined with idelalisib or ibrutinib in six cell lines. The addition of the PAK4/NAMPTi KPT-0247 or the antibiotic diclazuril restored sensitivity to BTKi and improved the potency of BTKi in resistant cells, but not in the parental cells. Adding the alisertib (AURKAi), rigosertib (PLKi), fimepinostat (PI3K/HDACi), lanatoside-C (Na+K+ATPase), astragalin (apoptosis), astragaloside-I (WNT) and oridonin (AKT) was of benefit (additivity or synergism) in both parental and resistant cells.

Conclusions. This large-scale screen identifies multiple actionable vulnerabilities in BTKi- and PI3Ki-resistant MZL. Several clinically advanced agents—particularly PAK4/NAMPT, AURKA, WNT, and Na^+/K^+-ATPase inhibitors—enhanced or restored the activity of BTKi/PI3Ki. These findings highlight new therapeutic strategies for relapsed/refractory MZL and support clinical evaluation of targeted combinations to overcome acquired resistance.

#7120 Rinzimetostat, an allosteric EED inhibitor with best-in-class properties for the treatment of prostate cancer, is effective in PRC2 methyltransferase-resistant settings in preclinical studies.

Xi Chen, Livia Ulicna, Eunice Lopez-Fuentes, Anjana Ramnath, Ashley Pereira, Archana Kumar, Robert Warne, Kyle A. Edgar, Aleksandr Pankov, Jason E. Long, Ajit Narang, Lori S. Friedman, Anneleen Daemen, **Melissa R. Junttila**

ORIC Pharmaceuticals, Inc., South San Francisco, CA

Polycomb repressive complex 2 (PRC2) regulates transcription by trimethylating histone H3 at lysine 27 (H3K27me3) to impact cell growth and differentiation. PRC2 dysregulation is a poor prognostic in prostate cancer and promotes lineage plasticity and therapeutic resistance. The key PRC2 subunits, EED, SUZ12, and EZH1 or EZH2, are required for chromatin recruitment and histone methyltransferase activity. In vivo prostate cancer studies have shown PRC2 inhibitor combinations with AR inhibitors prolong survival and inhibit tumor growth. Rinzimetostat (ORIC-944) is a next-generation allosteric PRC2 inhibitor targeting EED, with best-in-class drug properties in preclinical studies including solubility, ADME/PK, and excellent half-life. In assessing rinzimetostat as a potential best-in-class PRC2 inhibitor, further preclinical studies investigated targeting EED vs EZH2 or EZH1/2 in the context of potential acquired resistance mechanisms.

EZH1 paralog compensation has the potential to be a tumor escape mechanism for EZH2 inhibitors, therefore inhibitors of EED, EZH2, and EZH1/2 were assessed in biochemical assays on PRC2 complexes that contained either EZH1 or EZH2 as the enzymatic subunit. Rinzimetostat had comparable potency on PRC2 with either EZH1 or EZH2 in the complex, while other PRC2 inhibitors had reduced activity on EZH1-containing complexes. In prostate cancer cells engineered to overexpress EZH1, the EZH2 inhibitors tazemetostat and mevrometostat lost potency whereas rinzimetostat, an EED inhibitor, retained activity.

We next investigated the activity of PRC2 inhibitors in the context of an EZH2 inhibitor acquired resistance mutation observed in the clinic. As predicted from drug binding sites, EZH2 Y666N mutant-expressing prostate cancer cells were impervious to H3K27me3 reduction by EZH2 inhibitors mevrometostat or tazemetostat; however, rinzimetostat inhibited H3K27me3 in EZH2 Y666N mutant cells.

Cells engineered with an EZH1/2 inhibitor acquired resistance mutant, EED H213R, demonstrated loss of effectiveness upon treatment with EZH1/2 inhibitor valemetostat, whereas rinzimetostat equally inhibited H3K27me3 in the EED mutant and wildtype settings. Together, these data suggest that rinzimetostat, as an EED inhibitor, has the potential for superiority in EZH2 and EZH1/2 inhibitor-acquired resistance contexts.

In summary, preclinical results demonstrate potential best-in-class drug properties of rinzimetostat, as well as the potential superiority of targeting EED to address paralog compensation and avoid acquired resistance mechanisms that may be liabilities for EZH2 or EZH1/2 inhibitors. Rinzimetostat is under clinical evaluation in combination with AR inhibitors in a global Phase 1b study (NCT05413421).

#7121 CRISPR druggable-genome screen identifies BRD4 as a synergistic vulnerability with the natural product cerberin in pancreatic cancer organoids.

Md Shahadat Hossan[1], Lauryn E. Flannagan[1], Michela Cadarso[1], Molly A. Nellen[2], Ethan S. Lin[1], Austin Stram[3], Dustin Rubinstein[4], Derek Pavelec[4], Mark E. Berres[5], Sean Ronnekleiv-Kelly[3], Jeremy D. Kratz[1]

[1]Department of Medicine, University of Wisconsin-Madison, Madison, WI,[2]OVCR, UWBC Advanced Genome Editing, University of Wisconsin-Madison, Madison, WI,[3]SMPH, Department of Surgery, University of Wisconsin-Madison, Madison, WI,[4]OVCR, UWBC Administration, University of Wisconsin-Madison, Madison, WI,[5]OVCR, UWBC Bioinformatics, University of Wisconsin-Madison, Madison, WI

Background: Pancreatic ductal adenocarcinoma (PDAC) acquires resistance to systemic therapy, requiring novel therapeutic combinations. Our prior work demonstrated that cardiac glycosides including cerberin can inhibit PI3K/AKT/mTOR signaling yielding low nanomolar potency in PDAC viability. We recently optimized pooled CRISPR-Cas9 “druggable-genome” screening in 3D PDAC patient-derived organoids (PDOs). Here, we used this platform to define genetic dependencies under cerberin pressure and to nominate synthetic lethal combinations.

Methods: The $KRAS^{G12D}$-mutant PDO line Pan21 was transduced with a lentiviral CRISPR-Cas9 library targeting 2,312 druggable genes (~10,000 sgRNAs; Millipore-Sigma) using optimized viral particle: cell ratios and 6-day puromycin selection. Baseline samples were collected following. PDOs were expanded using media control and cerberin 10nM for 6 days, followed by 2 days of recovery. Guide representation was assessed by next-generation sequencing, and gene-level dropout was analyzed with MAGeCK robust rank aggregation (RRA). For functional validation, dose-response combination matrices were generated for cerberin or digoxin in combination with the BET inhibitor ZEN-3694 in Pan21 PDOs. Viability was measured at 144h using 3D CellTiter-Glo (CTG, 50% v/v), and synergy was quantified in SynergyFinder 3.0.

Results: Library QC confirmed stable Cas9 expression, recovery of more than 95% of sgRNAs, and similar $\log_2$ read-count profiles across baseline, control, and cerberin-treated samples. Cerberin treatment generated a consistent dropout pattern enriched for signaling and metabolic regulators; among the highest-ranked negative-selection hits were CYGB, ANXA2, NR1I2, PIK3R1, TWF2, ENPP2, FDX1, PRG2, and the epigenetic reader BRD4. Although this pilot was limited to stringent FDR thresholds, these genes showed low RRA scores at nominal p-values < 0.005. BRD4 was selected among the top 10 depleted genes (RRA score ~6×10^{-4}; nominal $p \approx 0.003$) due to availability for synthetic inhibitors from NCI’s Cancer Therapeutics Evaluation Program. In Pan21 PDOs, dose-response combinations of cerberin with ZEN-3694 produced robust synergy (HSA 26.2, Bliss 23.3, ZIP 23.6), with values in a range generally interpreted as strong positive drug-drug interaction and clear synergy “hot spots” at submaximal concentrations of both agents. Similarly, digoxin with ZEN-3694 exhibited a synergistic landscape (HSA 25.3, Bliss 24.7), supporting a cardenolide class effect.

Conclusions: Adopting a CRISPR/Cas9 druggable screen in 3D PDAC PDO models, we provide proof-of-concept for synergy between cardiac glycosides and BRD4/BET inhibitors. This work links a PDO-based CRISPR platform with natural-product pharmacology to provide a framework for mechanistic partners to advance the use of cardiac glycosides for clinical translation.

#7122 Nanoparticle-mediated restoration of pomalidomide sensitivity in multiple myeloma.

Joseph Uche Ogbede[1], Kaiqi Long[2], Michael S. Rogers[1], Jinjun Shi[2], Robert J. D'Amato[1], Bruce R. Zetter[1]

[1]Vascular Biology, Boston Children's Hospital, Harvard Medical School, Boston, MA,[2]Nanomedicine and Anesthesiology, Brigham and Women's Hospital, Harvard Medical School, Boston, MA

Multiple myeloma (MM), a plasma cell malignancy, is the second most common hematologic malignancy in the United States after non-Hodgkin lymphoma. Treatment options include immunomodulatory imide drugs (IMiDs). FDA approved IMiDs (thalidomide, lenalidomide, and pomalidomide) have remained among the primary treatments for MM and have helped extend the lifespan of patients up to several years after diagnosis. IMiDs bind to cereblon (CRBN), a component of E3 ubiquitin ligase, to exert their anti-proliferative effect on myeloma cells. While the majority of newly diagnosed myeloma patients respond to treatment with IMiDs, most eventually develop resistance. Cereblon genetic alterations contribute about one-third of acquired resistance observed in the clinic. We aim to restore sensitivity to pomalidomide-resistant cells through nanoparticle-mediated delivery of wildtype cereblon mRNA to cells. We designed lipid nanoparticles and used it to deliver in vitro transcribed cereblon mRNA to pomalidomide-resistant MM1.S cells. We showed that the lipid nanoparticle efficiently delivered cereblon mRNA to the resistant cells with subsequent restoration of pomalidomide sensitivity. Next, delivery of cereblon mRNA-loaded nanoparticles precisely to malignant plasma cells is important to ensure the desired outcome. Among cell surface proteins, B-cell maturation antigen (BCMA) and CD38 are known to be highly expressed by multiple myeloma cells. We therefore screened for peptides that bind to BCMA and CD38 using phage display libraries. Following DNA sequencing, three clones containing cyclic peptides with affinity for these proteins were identified. These peptides have been synthesized and are being tested; they will be conjugated with the nanoparticle-coated cereblon mRNA for targeted delivery to the malignant plasma cells. Our results show that delivery of cereblon mRNA to pomalidomide-resistant cells using lipid nanoparticles led to substantial restoration of pomalidomide sensitivity.

#7123 QW-5-70 targets the colchicine site to overcome multidrug resistance and shows potent antitumor activities.

Yang Xie[1], Ruida Hou[1], Najah Albadari[1], Hao Chen[1], Darcie J. Miller[2], Judith Quadrozzi Gruntz[2], Michael L. Oldham[2], Mir Shahriar Kamal[1], Jianxiong Jiang[1], Zhongzhi Wu[1], Duane D. Miller[1], Wei Li[1]

[1]University of Tennessee Health Science Center, Memphis, TN,[2]St. Jude Children's Research Hospital, Memphis, TN

Drug resistance driven by efflux transporters and altered tubulin dynamics limits the clinical efficacy of taxanes and vincristine in high-risk neuroblastoma (NB) and castration-resistant prostate cancer (CRPC). We developed QW-5-70, a colchicine-binding-site inhibitor (CBSI), engineered to retain subnanomolar potency in both parental and drug-resistant cancer cells by evading P-glycoprotein (P-gp)-mediated efflux. QW-5-70 binds to the colchicine site, inhibits tubulin polymerization, disrupts microtubule networks, and induces mitotic arrest. Across a panel of NB and prostate cancer lines, QW-5-70 maintained subnanomolar activity and remained effective in vincristine-resistant BE2C/VCR and paclitaxel-resistant PC-3/TxR cells. Unlike vincristine and paclitaxel, its activity was unchanged by co-treatment with verapamil, suggesting its ability to circumvent P-gp-mediated drug resistance. In vitro, QW-5-70 significantly reduced colony formation and impaired migration in both parental and resistant cancer cells, and induced G2/M cell cycle arrest and mitochondrial apoptosis. In vivo, QW-5-70 significantly suppressed tumor growth in drug-resistant PC-3/TxR and BE2C/VCR xenografts, with modest weight loss and no evident histopathology in the major organs. Combination testing revealed strong quantitative synergy with DFMO in viability assays and marked increases in apoptosis with reduced clonogenic survival when paired with DFMO or the Aurora A inhibitor MLN8237. Collectively, QW-5-70 is a potent CBSI that circumvents P-gp-associated resistance, triggers mitotic arrest and apoptosis, and achieves robust antitumor activity in multidrug-resistant tumor models with acceptable tolerability, supporting its further preclinical development alone and in combination with other drugs.

#7124 Resistance to the SFK inhibitor NXP900 in cholangiocarcinoma is characterized by IL13RA2-AKT signaling and can be overcome by combination therapy.

Shelby K. Yee[1], Hendrien Kuipers[1], Danielle M. Carlson[2], Jack W. Sample[1], Enis Ozmert[1], Hidemi Nishi[1], Erik Jessen[3], Dong-Gi Mun[4], Aushinie M. Abeynayake[2], Jennifer L. Tomlinson[1], Amro M. Abdelrahman[1], Nathan W. Werneburg[2], Binbin Li[2], Mitesh J. Borad[5], Mark J. Truty[1], Sumera I. Ilyas[2], Gregory J. Gores[2], Rory L. Smoot[1]

[1]Department of Surgery, Mayo Clinic, Rochester, MN,[2]Department of Gastroenterology and Hepatology, Mayo Clinic, Rochester, MN,[3]Department of Biomedical Statistics and Informatics, Mayo Clinic, Rochester, MN,[4]Department of Laboratory Medicine and Pathology, Mayo Clinic, Rochester, MN,[5]Department of Hematology-Oncology, Mayo Clinic Cancer Center, Phoenix, AZ

Introduction: Src Family Kinases (SFKs) have a crucial role in tumor proliferation, survival, and metastasis. NXP900 is a highly selective SFK inhibitor with a novel mechanism of action that locks SFKs in a closed, inhibited conformation, providing sustained suppression of catalytic and non-catalytic functions, which is distinct from other SFK inhibitors like dasatinib. A phase I clinical trial of NXP900 in patients with advanced solid tumors is ongoing. Our preclinical studies showed therapeutic efficacy of NXP900 in cholangiocarcinoma (CCA) through decreased YAP, RAF-MAP and PI3K-AKT signaling. Multiomic profiling (RNA-seq, proteomics, phosphoproteomics) of CCA patient-derived xenografts implicated AKT pathway activation in primary NXP900 resistance. NXP900-resistant CCA cell lines generated via prolonged sublethal dose escalation showed a strong IL13RA2-AKT signature on multiomic analysis. Thus, we hypothesized that IL13RA2-AKT signaling was a mechanism of NXP900 resistance. We aimed to define this mechanism and demonstrate that the combinatorial targeting of IL13RA2 or AKT resensitizes to NXP900 treatment.

Methods: HuCCT1 or HuCCT1-Resisant (HuCCT1-R) cells were injected bilaterally into the flanks of NOD/SCID mice and were allowed to grow for 3 months prior to tumor collection and analysis. Tumor engraftment and growth between HuCCT1 and HuCCT1-R groups were compared. To delineate the mechanisms for acquired NXP900 resistance, in-vitro treatment studies were performed using siRNAs targeting IL13RA2 as well as combination treatment with capivasertib, a pan-AKT inhibitor.

Results: The HuCCT1-R cell line exhibited a higher rate of tumor engraftment and formed significantly larger tumors compared to the parental HuCCT1 cell line, indicating enhanced tumorigenic potential associated with acquired resistance. Silencing of *IL13RA2* in HuCCT1-R cells resulted in pronounced reduction of cell proliferation and partially restored sensitivity to NXP900 treatment. Immunoblot analysis demonstrated a corresponding reduction in phosphorylated AKT (Thr308), consistent with suppression of downstream PI3K-AKT signaling. Furthermore, combination treatment of HuCCT1-R cells with the AKT inhibitor capivasertib, and NXP900 led to a significant increase in cell death and a greater inhibition in cell proliferation compared to either agent alone, indicating enhanced responsiveness and improved therapeutic efficacy.

Conclusion: These findings confirm the central role of IL13RA2 signaling and the PI3K-AKT pathway in mediating acquired resistance to NXP900, consistent with our previous multiomics analysis. Importantly, this study identifies combination strategies that may be able to overcome NXP900 resistance, supporting the development of combinatorial approaches to restore therapeutic efficacy in resistant tumors.

#7125 Mechanistic basis of resistance to HDAC6 inhibitors reveals proteasome inhibition as a rational combination strategy in breast cancer.

Jose Silva[1], Tizita Zewde Zeleke[2], Qingfei Pan[3], Jiyang Yu[3]

[1]Icahn School of Medicine at Mount Sinai, New York, NY,[2]Pathology, Icahn School of Medicine at Mount Sinai, New York, NY,[3]St. Jude Children's Research Hospital, Memphis, TN

Introduction: Cancer treatment is increasingly driven by personalized medicine approaches, where targeted therapies are favored over traditional chemotherapy due to improved specificity and reduced toxicity. Although pan-histone deacetylase inhibitors show antitumor activity in several cancers, their clinical use is limited by toxicity. In contrast, HDAC6-specific inhibitors such as ricolinostat are well-tolerated and demonstrate clinical activity in subsets of breast cancer (BC) patients. However, intrinsic resistance restricts their broader therapeutic utility. Here, we present new evidence identifying proteasomal function as a critical determinant of resistance to HDAC6 inhibitors and show that combinatorial targeting of HDAC6 and the proteasome can overcome this resistance.
Methods: We performed multi-omics analyses comparing the response to HDAC6 inhibitors of sensitive and resistant BC models. These studies led us to hypothesize that enhanced proteasomal capacity drives therapeutic resistance. To test this, we quantified steady-state proteasomal activity using fluorometric assays that measure chymotrypsin-like, trypsin-like, and caspase-like proteolytic functions in vitro. We also conducted therapeutic studies treating sensitive and resistant BC cells with HDAC6 inhibitors alone or in combination with proteasome inhibitors.
Results: Omics profiling revealed that HDAC6 inhibition in sensitive cells induces the unfolded protein response (UPR), downregulates MYC, and upregulates ER-stress markers (BiP, CHOP) in both BC cell lines and MMTV-Neu tumors, indicating activation of a stress-adaptive transcriptional program. Given HDAC6's role in the aggresome-autophagy pathway and the proteasome's role in protein degradation, we assessed whether resistant cells compensate through elevated proteasomal activity. Our data revealed that resistant BC cells exhibited significantly higher basal activity across all three proteolytic subunits. Consistent with this, ricolinostat combined with the proteasome inhibitor bortezomib induced growth inhibition in resistant cells, reversing the resistance to HDAC6i/s. Conversely, chemically enhancing proteasomal function with oleuropein reduced sensitivity to ricolinostat in previously sensitive lines, supporting a mechanistic dependence on limited proteasomal activity for the responses to HDAC6 inhibition.
Conclusions: These findings identify elevated proteasomal capacity as a key driver of resistance to HDAC6 inhibitors, supporting a therapeutic strategy that combines HDAC6 and proteasome inhibition to overcome resistance in breast cancer.

#7126 Targeting Aurora A kinase together with alternative survival signaling overcomes resistance to endocrine and CDK4/6 therapies in ER+ breast cancer.

Chia-Chia Liu[1], Alekya Raghavan[1], Lanfang Qin[1], Sarmistha Nanda[1], Fu-Tien Liao[1], Georg F. Bischof[2], Mothaffar F. Rimawi[1], C. Kent Osborne[1], Jamunarani Veeraraghavan[1], Rachel Schiff[1]

[1]Lester & Sue Smith Breast Center; Dan L Duncan Comprehensive Cancer Center; Department of Medicine, Baylor College of Medicine, Houston, TX,[2]Puma Biotechnology Inc., Los Angeles, CA

Background: Endocrine therapy (ET) in combination with CDK4/6 inhibitors (i) is the standard-of-care for estrogen receptor (ER)+ metastatic breast cancer (BC). Though effective, resistance is inevitable. Aurora A kinase (AURKA) drives mitotic entry and spindle assembly for proper cell division. Clinically, high AURKA levels have been linked to cancer aggressiveness, poor prognosis, and CDK4/6i resistance. A recent phase II trial (NCT02860000) reported clinically meaningful benefit of the AURKAi, alisertib (ALS), in advanced, endocrine-resistant ER+ BC. Identifying biomarkers and key signaling pathways involved in AURKA inhibition is essential to optimize ALS use and guide effective combination strategies to enhance sensitivity and overcome resistance in ER+ BC.
Methods: ER+ BC cell models naïve or resistant (R) to various ET (EndoR) and/or palbociclib (PalboR, a CDK4/6i) were used. ALS-resistant (ALSR) derivatives were developed via long-term exposure to gradually increasing ALS concentrations (≥150 nM). Molecular changes associated with growth and survival signaling, senescence, and apoptosis were assessed by Western blot upon short-term ALS treatment (72 hr) and at resistance. Signaling profiles guided the choice of specific drug combinations, which were then evaluated by cell growth assays.
Results: Morphological changes, characterized by flattened, enlarged giant cells, slowed growth, senescence, and elevated p21, γH2AX, and c-PARP levels were observed in the ALSR derivatives of EndoR and/or PalboR models. In general, induction of various components of the HER/PI3K/MAPK pathways was seen across all ALSR models, with a specific increase in phosphorylated AKT levels in some models. Indeed, AKTi plus ALS was the most effective combination to overcome resistance in the ET-naïve/PalboR and the estrogen-deprivation (ED)R/PalboR/ALSR models. In the tamoxifenR/PalboR model and its ALSR derivative, in line with the signaling changes, EGFRi, pan-HERi (Neratinib, Nrb), or MEKi together with tamoxifen+Palbo+ALS showed strong efficacy. In the dual fulvestrantR/PalboR model, ALS+Nrb was highly effective, and adding Palbo further enhanced this effect, while in its ALSR derivative, fulvestrant+Palbo+ALS+Nrb regimen was needed to achieve substantial growth inhibition.
Conclusions: Our findings highlight the potential of combining ALS with AKT, MAPK, and HER pathway inhibitors, to enhance efficacy or overcome ALS resistance in ET- and CDK4/6i-resistant ER+ BC, inferred by ALS-induced signaling changes. The presence of flattened and enlarged giant cells may reflect ongoing endoreplication, potentially indicating a dormant or persister cell state that may eventually support relapse and disease progression. Additional studies are underway to determine how these cell states can be targeted to induce cell death and overcome resistance.

#7127 RalBP1 inhibition: A novel therapy for prostate cancer.

Sharad S. Singhal, Madhu Krishna, Prakash Kulkarni, David Horne, Ravi Salgia

Beckman Research Institute of The City of Hope, Duarte, CA

Prostate cancer is a predominant cause of cancer related death in men and in most cases, it is difficult to diagnose and adequately monitor. Cancer cells entail targets for effective therapy; however, non-malignant cells do not because they are not expressed in the same way in a cancer cell as in normal cells. RalBP1 functions as a crucial mercapturic acid transporter, playing an essential role in cancer cell survival and therapy resistance. RalBP1 has been identified as the key to radiation and chemotherapy resistance as it is an overexpressed, multi-specific ATP-dependent transporter. Therefore, we investigated its involvement in modulating critical signaling proteins that influence upstream survival pathways and mechanisms responsible for chemo-radiotherapy resistance in prostate cancer. Evidence from *in vitro* cell cultures and *in vivo* tumor models suggests that cancer cell survival depends on RalBP1, as its inhibition or depletion results in selective toxicity toward malignant cells. By generating glutathione-electrophile conjugates (GS-Es) within cells, RalBP1 induces apoptosis in cancer cells. *In vivo* studies revealed that treatment of DU145 prostate cancer xenograft-bearing mice with RalBP1-directed agents; antibodies, siRNA, or antisense oligonucleotides that led to a marked suppression of tumor growth, even in already established subcutaneous tumors, and did so without signs of systemic toxicity. Interestingly, both RalBP1 antibodies, which block RalBP1-mediated transport function, and gene-silencing approaches such as siRNA and antisense, which diminish RalBP1 expression, demonstrate nearly equivalent tumor-regressive effects. This equivalence suggests that disrupting RalBP1 transport function at the cell membrane is sufficient to elicit an anticancer response. Collectively, these findings uncover a novel therapeutic potential for RalBP1 inhibition or depletion in prostate cancer and underscore its promise as a target for new treatment strategies. (This work was supported in part by the Department of Defense grant HT9425-25-1-0500. Funding from the Beckman Research Institute of City of Hope is also acknowledged).

#7128 The rise of YAP: A new hope in glioblastoma treatment.

Shuhan Cao, Ethan C. L. Wong, Gilberto K. K. Leung, Karrie M. Y. Kiang

Department of Surgery, Li Ka Shing Faculty of Medicine, Hong Kong, Hong Kong

Despite advances in cancer treatment, glioblastoma (GBM) remains the most malignant subtype of adult brain tumours, with an overall prognosis of only approximately 18 months. The first-line treatment and current standard of care for GBM, aside from maximum surgical resection, is temozolomide (TMZ). Yet, despite TMZ's initial promising results in improving survival, drug resistance and tumour relapse remain nearly unavoidable. Yes-associated protein (YAP) is a key downstream effector of the Hippo pathway that can translocate to the nucleus to induce the transcriptional enhanced associated domain (TEAD)-mediated expression of genes related to cell growth and proliferation. This makes the Hippo signalling pathway critical in tumorigenesis. Through both in vitro and in vivo models, we investigated the role of YAP in GBM. We found upregulation of YAP in GBM to be associated with poor clinical outcomes, with TMZ-resistant GBM showing greater YAP upregulation compared to chemotherapy-sensitive strains, suggesting its role in driving chemoresistance. When YAP is knocked down, there is a decrease in GBM malignant phenotype, including decreased cell proliferation and colony formation in vitro, and decreased tumour growth in vivo. Finally, we elucidated that YAP mediates GBM chemoresistance by inducing tumour cell stemness, which can be overcome by using the YAP inhibitor verteporfin, increasing GBM susceptibility to TMZ in both sensitive and resistant cell lines. In conclusion, this highlights the importance of YAP in driving GBM cell stemness and chemoresistance, a significant clinical problem, and underscores the potential YAP inhibitors hold as a promising and novel adjuvant or combination therapy in the treatment of chemoresistant GBM.

#7129 Targeting PARPi drug tolerant persistence and progression on treatment with clinical stage ATM inhibitors in advanced prostate cancer.

Akshaya Karthikeyan[1], Bryan Correa Gonzalez[1], Jose G. Torres-Gonzalez[2], Love A. Moore[3], Anamitra Bhaumik[4], Ethan Sandoval[4], Alan P. Lombard[5]

[1]UC Davis Medical Center, Sacramento, CA,[2]UC Davis Medical School, Sacramento, CA,[3]UC Davis, Davis, CA,[4]UC Davis, Sacramento, CA,[5]Urologic Surgery, UC Davis Medical Center, Sacramento, CA

Background: PARP inhibitors (PARPi) have improved prostate cancer management, but progression is inevitable. Drug tolerant persistence (DTP) is characterized by tumor cells which survive treatment and drive failure through transient acquisition of insensitivity. Cycling DTP cells may adapt and expand, giving rise to drug tolerant expanded persister (DTEP) populations which are thought to model progression on treatment. Emerging evidence supports a critical role for DTP in promoting PARPi progression. Identifying and targeting DTP and DTEP vulnerabilities may provide therapeutic strategies to combat disease progression.
Methods: Viability assays, western blots, and additional assays defined treatment response in PARPi-sensitive C4-2B metastatic castration-resistant prostate cancer cells and C4-2B abiraterone-resistant derivative AbiR cells. DTP and DTEP models were developed through prolonged PARPi exposure. NGS profiled DTP cells. Clinical stage ATM inhibitors were tested for their effects on both DTP and DTEP populations.
Results: Response to PARP inhibition is heterogeneous, characterized by cell death and emergence of a largely cytostatic, persistent population. C4-2B and AbiR cells exposed to clinically relevant PARPi dosing for 9 days followed by drug holiday regain normal, parental cell morphology and become re-sensitized to treatment in line with acquisition of a DTP phenotype. DTP cells display differential sensitivity to other classes of drugs compared to parental cells. DTP cells may be broadly stratified into two classes; 1) a minority which cycle and 2) those which don't. Prolonged PARPi treatment is observed to result in drug tolerant expanded persisters (DTEP) derived from cycling-DTP cells. DTP and DTEP cells display increased phospho-ATM levels suggesting constitutive DNA damage response activation. Utilization of clinical stage ATM inhibitors both prevent DTP progression into DTEPs and resensitize DTEPs to PARP inhibition.
Conclusions: Our data suggest that drug tolerant persistence may mediate survival of tumor cells which drive progression on treatment. ATM inhibition may be used to prolong time to progression or to treat progressive disease. Future studies will focus on translating these strategies.

#7130 GRN-300 restores PARP inhibitor sensitivity through inhibition of the HDAC-MEF2A-RAD51 pathway in BRCA2-revertant ovarian cancer.

Carlos Flores Suarez, Janice M. Santiago-O'Farrill, Weiqun Mao, Hailing Yang, Zhen Lu, Robert C. Bast

UT MD Anderson Cancer Center, Houston, TX

Genomic instability is a hallmark of cancer. Germline mutations in DNA repair genes such as BRCA1 and BRCA2 predispose to tumor development but also confer vulnerabilities exploitable by therapy. Poly ADP-ribose polymerase (PARP) inhibitors selectively target tumors with homologous recombination deficiency (HRD) caused by BRCA1/2 mutations and elicit strong responses in ovarian cancer. However, resistance frequently emerges through secondary BRCA1/2 reversion mutations that partially restore DNA repair function, underscoring the need for strategies to overcome PARP inhibitor resistance. Salt-inducible kinase 2 (SIK2), an AMPK-related kinase, is required for ovarian cancer cell proliferation and metastasis. The selective SIK2 inhibitor GRN-300 induces DNA double-strand breaks (DSBs) in HR-proficient cells and synergizes with PARP inhibitors to produce synthetic lethality. Here, we investigated whether GRN-300 can restore PARP inhibitor sensitivity in BRCA2-revertant ovarian cancer. GRN-300 markedly reduced the IC_{50} of olaparib in both PARP-sensitive PEO1 cells (1.98 to 0.64 μM) and resistant BRCA2-revertant PEO1-C4-2 (6.87 to 0.92 μM) and PEO4 (3.47 to 1.17 μM) ovarian cancer cells, restoring responsiveness. GRN-300 increased ROS production, enhanced caspase-3/7 activation, and promoted olaparib-induced apoptosis while suppressing colony formation. In PEO1-C4-2 xenografts, GRN-300 plus olaparib significantly inhibited tumor growth without affecting body weight. Combination treatment increased γ-H2AX and comet-tail formation, indicating enhanced DNA damage accumulation. Mechanistically, GRN-300 reduced RAD51 expression and RAD51 foci formation. SIK2 inhibition decreased phosphorylation of class IIa HDAC4/5/7, abrogating HDAC class II-MEF2A transcriptional activity. ChIP-qPCR revealed reduced MEF2A binding to regulatory regions of DNA repair genes, including RAD51 and RAD50, thereby suppressing DSB end resection and strand invasion mediated by the MRN complex. In summary, GRN-300 restores PARP inhibitor sensitivity in BRCA2-revertant ovarian cancer through inhibition of the HDAC-MEF2-RAD51 pathway, providing a promising therapeutic strategy to overcome PARP resistance.

#7131 Targeting oxidative phosphorylation with lixumistat overcomes PARP inhibitor resistance in ovarian cancer.

Sa deok Hong[1], Min Sil Kang[1], Nar Katuwal[1], Mithun Ghosh[1], Seong Min Park[1], Kim Ju Hyeon[1], Seul-Gi Kim[2], Yong Wha Moon[2]

[1]CHA University, Seongnam-si, Korea, Republic of,[2]CHA Bundang Medical Center, Seongnam-si, Korea, Republic of

Ovarian cancer remains the leading cause of gynecologic cancer-related mortality worldwide. Although poly(ADP-ribose) polymerase (PARP) inhibitors show remarkable efficacy in BRCA1/2-mutated ovarian cancer, nearly half of patients eventually develop resistance. In this study, we investigated whether lixumistat, a novel oxidative phosphorylation (OXPHOS) inhibitor, could overcome PARP inhibitor resistance in preclinical BRCA1/2-mutated ovarian cancer models. Long-term olaparib exposure generated olaparib-resistant BRCA-mutated ovarian cancer cell lines and patient-derived tumor xenograft (PDTX) models. Lixumistat, alone or combined with olaparib, was evaluated in vitro and in vivo. Olaparib-resistant cells exhibited elevated OXPHOS activity, and combining lixumistat with olaparib produced synergistic antitumor effects in both olaparib-sensitive and -resistant cell lines and PDTX models. Switching from olaparib monotherapy to combination therapy markedly suppressed tumor growth in partially resistant and acquired-resistant PDTX models. These results suggest that early integration of lixumistat could enhance efficacy and delay PARP inhibitor resistance. Mechanistically, lixumistat inhibited the OXPHOS-NAD^+-poly(ADP)-ribosylation (PARylation) axis, thereby reducing NAD^+ availability and PARylation to restore PARP inhibitor sensitivity. Notably, exogenous NAD^+ supplementation reversed these effects. Additionally, lixumistat downregulated the SNAIL-phosphorylated RB pathway, impairing cell-cycle progression and further enhancing PARP inhibitor efficacy. Together, these findings identify a novel OXPHOS-associated mechanism underlying PARP inhibitor resistance and establish lixumistat as a promising combinatorial strategy to potentiate PARP inhibitors in both PARP inhibitor-naïve and -resistant ovarian cancer.

#7132 Rinzimetostat blockade of PRC2 activity, a key mechanism of treatment resistance, improves response of androgen receptor pathway inhibition across a spectrum of prostate cancer models.

Aleksandr Pankov, Amber W. Wang, Natalie Yuen, Livia Ulicna, Jason E. Long, Xi Chen, Gina Andretta, Lori S. Friedman, Melissa R. Junttila, Anneleen Daemen

ORIC Pharmaceuticals, South San Francisco, CA

Prostate adenocarcinoma is driven by the lineage-specific transcription factor androgen receptor (AR), with androgen deprivation and AR pathway inhibitors (ARPIs) being highly effective treatments that are a mainstay in the clinic. However, therapeutic resistance that bypasses ARPIs eventually develops due to emergence of tumor heterogeneity highlighted by the acquisition of AR alterations and diverse phenotypic states, including cells with heightened plasticity and divergent lineage features.

The availability of genomic datasets across the prostate cancer treatment continuum enables unprecedented insight into the molecular alterations underpinning disease progression and treatment resistance. We explored the transcriptomes of >1,000 patients with primary prostate cancer, metastatic castration-resistant prostate cancer (mCRPC) and neuroendocrine prostate cancer (NEPC). Analysis of these data and projection along a pseudotime axis revealed gene expression patterns driving prostate cancer progression.

Pseudotime analysis showcased that AR signaling and luminal marker expression increase during primary tumor formation and remain elevated in the early stages of mCRPC. The eventual reduction in AR expression, AR signaling and luminal identity during mCRPC may facilitate lineage plasticity and cell state reprogramming. Integrated analysis of prostate tumors across treatment lines additionally identified cell cycle-associated genes and epigenetic regulators whose expression increase from primary to mCRPC and NEPC tumors, suggesting that they play a key role in driving molecular heterogeneity necessary to circumvent ARPI treatments. One such epigenetic regulator identified, the polycomb repressive complex 2 (PRC2), is a compelling and tractable target for prostate cancer.

Rinzimetostat (ORIC-944) is a next-generation, potent, highly selective, orally bioavailable small molecule inhibitor of PRC2 that allosterically targets the EED subunit, with potential best-in-class drug properties including reduced drug-drug interaction liabilities and superior half-life as compared to other clinical compounds. Rinzimetostat in combination with the ARPI darolutamide demonstrated antitumor activity across a breadth of in vivo models representing the prostate cancer continuum and capturing a broad spectrum of treatment resistance settings including castration-sensitive and -resistant, ARPI-sensitive and -resistant, and AR-mutant and -wildtype. Thus, rinzimetostat represents a promising therapy to re-sensitize resistant tumors to ARPIs and block prostate tumor adaptation. Rinzimetostat is under clinical evaluation in combination with AR inhibitors in a global Phase 1b study (NCT05413421).

#7133 Combined anti-CSF-1R and anti-TIM-3 overcome macrophage-mediated mechanisms of PARP inhibitor (PARPi) resistance in BRCA1-associated triple negative breast cancer.

Adam Nelson[1], Anita K. Mehta[1], Madeline G. Townsend[1], Daniel E. Michaud[1], Madisson Oliwa[1], Kelly F. Zheng[1], Carlos W. S. Wanderley[1], Alex P. Gottlieb[1], Kenichi Shimada[2], Patrice A. Lee[3], Nicholas A. Saccomano[3], Filipa Lynce[4], Nabihah Tayob[4], Geoffrey I. Shapiro[4], Jennifer L. Guerriero[5]

[1]Department of Surgery, Brigham and Women's Hospital, Boston, MA,[2]Harvard Medical School, Boston, MA,[3]Pfizer-Boulder Research and Development, Boulder, CO,[4]Dana-Farber Cancer Institute, Boston, MA,[5]Brigham and Women's Hospital, Boston, MA

Background: Poly (ADP-Ribose) polymerase inhibitors (PARPi) have improved outcomes for *BRCA*-associated triple negative breast cancer (TNBC); however, resistance develops, resulting in lack of durable responses. Our prior work demonstrated that PARPi activates cGAS/STING signaling, driving CD8+ T-cell recruitment, essential for tumor clearance. These studies led to clinical trials testing PARPi plus immune checkpoint blockade (ICB). However, clinical trials demonstrated no benefit compared to PARPi monotherapy, indicating T-cells in the tumor microenvironment (TME) are inhibited. We previously showed that PARPi induce suppressive tumor-associated macrophages (TAMs) which contribute to PARPi resistance. Removing TAMs with anti-CSF-1R therapy significantly enhanced overall survival (OS) when combined with PARPi and is now being tested in clinical trials (NCT03604692). Here, we test if ICB can enhance the CSF-1R +PARPi combination in both treatment naïve and PARPi-resistant tumors.

Methods: Mice bearing naïve or PARPi-resistant BRCA1-deficient TNBC (*K14-Cre;Brca1*$^{f/f}$*;Trp53*$^{f/f}$) tumors were treated with PARPi ± CSF-1R inhibition (CSF-1Ri) ± ICB and followed for tumor size and OS. Flow cytometry was employed to define immune mechanisms of response.

Results: In PARPi-naïve tumors, PARPi + CSF-1Ri significantly increased OS compared to PARPi monotherapy. The combination of PARPi + CSF-1Ri + anti-PD-1 led to a modest improvement in efficacy compared to PARPi + CSF-1Ri treatment. In contrast, the addition of anti-TIM3 to PARPi + CSF-1Ri resulted in durable therapeutic benefit, with a significant increase in OS compared to PARPi + CSF-1Ri. The combination of PARPi + CSF-1Ri + anti-TIM-3 significantly increased CD8+ T-cell infiltration, granzyme B production, and reduction in Tregs indicating an increased anti-tumor immune response. Additionally, anti-TIM-3 induced a pro-inflammatory phenotype in TAMs. In PARPi-resistant tumors TAMs expressed higher levels of CSF-1R compared to PARPi-naïve tumors. Additionally, PARPi-resistant tumors had increased infiltration of Tregs, and higher expression of PD-1 on T-cells, strongly indicating an increased immunosuppressive TME. In PARPi-resistant tumors, anti-CSF-1R therapy restored PARPi efficacy and significantly increased OS. Furthermore, addition of anti-TIM-3 to the anti-CSF-1R + PARPi combination significantly increased OS in PARPi-resistant tumors, whereas anti-PD-1 did not enhance therapy efficacy.

Conclusion: PARPi-resistant tumors have increased T-cell exhaustion and infiltration of immunosuppressive TAMs. Importantly, our data shows that targeting TAMs through the CSF-1R axes can overcome acquired PARPi resistance, which can be further enhanced with anti-TIM3 therapy, defining a novel strategy addressing a critical unmet medical need.

#7134 Developing drug combinations with AMG 193, a novel MTA-cooperative PRMT5 inhibitor, using patient-derived xenograft models of *MTAP*-deleted non-small cell lung cancer and mesothelioma.

Florence T. H. Wu[1], Nhu-An Pham[1], Yu-Hui Wang[1], Ming Li[1], Nikolina Radulovich[1], Katrina Hueniken[1], Quan Li[1], Siyuan (Claret) Liu[2], Brian Belmontes[2], Paul Hughes[2], Ming-Sound Tsao[3], Adrian Sacher[4]

[1]Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada,[2]Amgen Research, Thousand Oaks, CA,[3]Princess Margaret Cancer Centre, University Health Network; Departments of Laboratory Medicine & Pathobiology and Medical Biophysics, University of Toronto, Toronto, ON, Canada,[4]Princess Margaret Cancer Centre, University Health Network; Departments of Medicine and Immunology, University of Toronto, Toronto, ON, Canada

BACKGROUND: AMG 193 is an MTA-cooperative PRMT5 inhibitor designed for preferential selectivity against *MTAP*-del tumor cells. AMG 193 is currently being investigated in phase I-II clinical trials in *MTAP*-del solid tumors (MTAPESTRY-101,104, 201). *In vivo* testing in patient-derived xenograft (PDX) models has significant potential to inform focused clinical development of AMG 193.

OBJECTIVES: Using *MTAP*-del PDX models from our institutional biobank, we sought to: (i) identify promising drug combination partners for AMG 193 across lung adenocarcinomas (LUAD), lung squamous cell carcinomas (LUSC), and mesotheliomas (MESO); and (ii) investigate mechanisms of primary or acquired resistance to AMG 193.

METHODS: We identified 21 PDX models with *MTAP* deep deletion by SNP array or MTAP loss by immunohistochemistry - including 7 LUAD (including 2 *KRAS* G12C; 1 *EGFR* L858R + *MET* amp), 10 LUSC, and 6 MESO. *In vivo* AMG 193 activity was characterized in 7 models subcutaneously implanted in NOD SCID or NSG mice (n=5-7 per group).

RESULTS: Four models (2 *KRAS* G12C LUAD; 1 LUSC; 1 MESO) showed sustained sensitivity to AMG 193. Two models (1 *KRAS*-wildtype LUAD; 1 MESO) exhibited primary resistance to AMG 193. One LUSC model showed acquired resistance to AMG 193 after initial sensitivity. Interestingly, the two *KRAS* G12C LUAD models demonstrated additive/synergistic activity with AMG 193+sotorasib despite exhibiting resistance to sotorasib monotherapy.

CONCLUSIONS: A spectrum of AMG 193 activity was demonstrated across *MTAP*-del LUAD, LUSC, MESO PDX models, recapitulating the range of response & resistance seen clinically. Combination therapy with AMG 193 overcame sotorasib resistance in *KRAS* G12C LUAD models. Other drug combinations will be evaluated in primary or acquired resistance models. Acute dosing studies are underway to further characterize response to AMG 193 in these models.

Summary of 7 MTAP-deleted PDX models

PDX model	**Drug Activity†**	**Doubling time in weeks, from linear mixed-effects modeling** (N.R. = not reached due to complete response)
***KRAS* G12C LUAD#239**	Sotorasib monotherapy: resistant. AMG 193 monotherapy: sensitive. Sotorasib + AMG 193: sensitive with accelerated deep response	On-treatment (d10-21), Vehicle 2.3 vs. Sotorasib 3.6 P=0.20, AMG 193 N.R. P<0.001 ***, Combo N.R. P<0.001 ***.

#7135 A first-in-class orally bioavailable small molecule to overcome treatment resistance in hormone receptor-positive breast cancer.

Hee-Sung Park, Chakrapani Subramanyam, Kyu-kwang Cho, Se Hee Hyun, Yeonjee Kahm

Promedigen, Daejeon, Korea, Republic of

CDK4/6 inhibitors combined with antiestrogens such as fulvestrant represent frontline therapy for hormone receptor-positive (HR+) breast cancer; however, therapeutic resistance inevitably emerges in a substantial subset of patients through diverse molecular mechanisms. To address this challenge, we developed PMG-A9, a novel, orally bioavailable small molecule designed to restore the function of a key tumor suppressor frequently inactivated across cancers. PMG-A9 potently downregulates major resistance drivers, including Cyclin D1 and c-Myc, in a dose-dependent manner at sub-nanomolar concentrations, while upregulating cell-cycle inhibitors and pro-apoptotic proteins, demonstrating its potential to overcome resistance to CDK4/6 inhibitors and/or fulvestrant. In preclinical HR+ breast cancer xenograft models, PMG-A9 exhibits robust single-agent antitumor activity and pronounced synergy when combined with these agents. These findings highlight tumor-suppressor reactivation as a promising and broadly applicable therapeutic strategy with the potential to address resistance not only in HR+ breast cancer but also across a wide range of tumor types.

#7137 Targeting RRM2 to enhance PARP inhibitor sensitivity in TNBC.

Tamanna Islam[1], Howard L. Elford[2], Jesika S. Faridi[1]

[1]University of the Pacific, Stockton, CA,[2]Molecules for Health, Inc., Richmond, VA

Triple-negative breast cancer (TNBC) remains one of the most aggressive and therapeutically refractory breast cancer subtypes, primarily due to the absence of hormone receptors and HER2 expression. Poly ADP-ribose polymerase (PARP) inhibitors such as olaparib have demonstrated substantial efficacy in BRCA1/2-mutated TNBC by exploiting synthetic lethality in tumors with defective homologous recombination repair. However, the emergence of acquired resistance to olaparib significantly limits its long-term clinical utility. Ribonucleotide reductase (RR), the rate-limiting enzyme responsible for converting ribonucleotides to deoxyribonucleotides, plays a pivotal role in DNA synthesis and cell-cycle progression. Didox (3,4-dihydroxybenzohydroxamic acid) is a ribonucleotide reductase inhibitor with additional iron-chelating and free-radical scavenging activities. Our previous work identified that the RRM2 subunit is upregulated in TNBC cells and contributes to the development of chemoresistance. The present study investigates whether pharmacologic inhibition of RRM2 using Didox can potentiate olaparib activity and mitigate PARP inhibitor resistance in TNBC models. Four TNBC cell lines—MDA-MB-231, MDA-MB-468, MDA-MB-436, and HCC1937—were utilized to encompass both BRCA-wild-type and BRCA-mutant backgrounds. Cytotoxic responses to olaparib and Didox were quantified by MTS-based IC_{50} determination, followed by combination index (CI) analysis using the Chou-Talalay method to assess potential drug synergy. Our data show that MDA-MB-436 (BRCA1-mutant) cells were highly sensitive to olaparib, whereas MDA-MB-231 and MDA-MB-468 (BRCA1-wild-type) exhibited marked resistance. Didox displayed moderate single-agent cytotoxicity, however substantially enhanced olaparib sensitivity in resistant lines. Western blot analyses revealed increased DNA damage signaling under combination treatment, indicating that RRM2 inhibition augments PARP inhibitor-induced genotoxic stress. Collectively, these findings support the therapeutic potential of adding an RR inhibitor to overcome PARP inhibitor resistance in TNBC and warrant further in-depth mechanistic and *in vivo* evaluation.

#7138 Acquired saruparib (AZD5305) resistance in BRCA1-deficient triple negative breast cancer is vulnerable to DNA damage response-targeted therapeutics.

Matthew R. Jordan[1], Pamela S. VanderVere-Carozza[1], Jessica Lynn Kersey[1], Katherine Pawelczak[2], John J. Turchi[1]

[1]Indiana University School of Medicine, Indianapolis, IN,[2]Nerx Biosciences, Inc., Indianapolis, IN

The development of poly (ADP)-ribose polymerase (PARP) inhibitors (PARPi) for the synthetic lethal killing of BRCA1/2-deficient cancers revolutionized BRCA1/2-deficient patient outlook and survival. PARPi are now commonly used to treat BRCA1/2-deficient or homologous recombination (HR)-deficient breast, ovarian, prostate, and pancreatic cancers. Despite this clinical success, 30-40% of BRCA1/2-deficient patients do not respond to PARPi and the vast majority that do initially respond, ultimately develop PARPi resistance. This represents a major challenge limiting the clinical impact of PARPi treatment. Understanding PARPi resistance mechanisms is essential for developing better treatment strategies for intrinsic and acquired PARPi-resistant cancers. Recent efforts to better treat BRCA1/2-deficient cancers and combat PARPi resistance led to the development of saruparib (AZD5305), a PARP1-specific inhibitor with significantly improved safety profiles due to limited off-target inhibition of other PARP family members and hence reduced toxicity. Saruparib is currently undergoing phase 3 clinical trials and is anticipated to be the standard of care PARPi for BRCA1/2- and HR-deficient cancer patients. We have generated 5 saruparib-resistant (SR) cell lines from parental BRCA1-deficient MDA-MB-436 triple negative breast cancer (TNBC) cells that are >1000-fold resistant to saruparib but exhibit differential sensitivity to other nonspecific clinical PARPi. SR cell lines exhibit altered inhibition of cellular PARP activity and PARP trapping in response to saruparib and the nonspecific PARPi talazoparib. Whole genome sequencing identified PARP1 active site mutations in each SR cell line, and *in vitro* reconstitution of these mutants suggests that they are driving resistance to saruparib and altered sensitivity to other nonspecific clinical PARPi. Importantly, despite acquired saruparib resistance, SR cell lines retain sensitivity to other DNA damage response targeted therapeutics. Collectively, this work characterizes what we believe to be the first BRCA1-deficient models of acquired saruparib resistance and uncovers vulnerabilities that may inform rational combination strategies and novel therapeutic approaches for patients who progress on saruparib in the clinic.

#7139 Uncovering PGRMC1-PARP interaction: A novel combination therapeutic strategy in triple-negative breast cancer.

Mahalakshmi Vijayaraghavan[1], Ramadevi Subramani[2], Michel Rojo Amador[1], Kyle Nguyen[1], Kariina Garcia[1], Poornima Devi Narayanan[1], Alfredo Roman[1], Abigail Ramirez[1], Jazmin Lopez[1], Rajkumar Lakshmanaswamy[1]

[1]Texas Tech Univ. Health Sciences Ctr. El Paso, El Paso, TX,[2]Postdoc. Research Assoc., Dept. of Biomed. Sci., Texas Tech University Health Sciences Center (El Paso, TX), El Paso, TX

Background: Triple-negative breast cancer (TNBC) is an aggressive subtype characterized by altered DNA repair pathway with insufficient therapeutic options. Poly (ADP-ribose) polymerase (PARP) is a key enzyme involved in DNA repair, and has emerged as an effective treatment for TNBC and BRCA-associated cancers in clinical trials. Despite these advances, 40-70% of patients ultimately develop resistance to PARPi, highlighting the need to identify additional modulators of therapeutic response. Previous work from our laboratory has shown that Progesterone Receptor Membrane Component 1 (PGRMC1) plays a critical role in regulating cancer cell growth by modulating PI3K/AKT/mTOR and EGFR signaling pathways in both ER-positive and TNBC cells. However, the mechanisms driving PGRMC1 overexpression in TNBC and its potential role in influencing PARP function remains unexplored. To address this challenge, we investigated the unexplored interaction between PARP inhibition and PGRMC1 inhibition in TNBC models.
Methods: TNBC cell lines (BRCA-wild type: MDA-MB-231, MDA-MB-468; BRCA-mutant: HCC1395, MDA-MB-436) were treated with chemical inhibitors targeting PGRMC1 and PARP. Basal expression levels of PARP and PGRMC1 were compared between normal breast cells and TNBC cells by western blotting, and treatment-induced changes were quantified using western blot and qRT-PCR. Cell viability was measured by MTS assay and colony formation assay following inhibitor treatment across TNBC models. DNA damage was evaluated by γ-H2AX and RAD51 immunofluorescence staining. Ferroptosis induction was assessed through intracellular iron quantification and flow cytometry.
Results: We observed markedly elevated PGRMC1 expression in both BRCA-wild-type and BRCA-mutant TNBC cell lines compared with normal controls. Chemical inhibition of PGRMC1 or PARP led to increased DNA damage, evidenced by enhanced γ-H2AX staining and reduced RAD51 levels. Modulating PGRMC1 significantly altered PARP expression, and reciprocal regulation was also observed. These treatments further induced DNA damage markers (γ-H2AX, phospho-RAD51) and altered intracellular heme levels, promoting ferroptosis. The combination strategy effectively reduced cell survival regardless of BRCA mutation status, highlighting a strong dependence on PGRMC1 for survival under PARP inhibitor treatment.
Conclusion: Targeting PGRMC1 may enhance PARPi response in TNBCs. This work identifies PGRMC1 as a promising therapeutic target and supports combination strategies for improving TNBC treatment. Future studies will dissect the mechanistic crosstalk between PGRMC1 and PARP using PGRMC1 knockdown and overexpression models.

#7140 Synthetic lethality of Hsp90beta-selective inhibition with PARPi in homologous recombination repair proficient ovarian cancer.

Sanket Mishra

Grannus Therapeutics, Indianapolis, IN

A significant unmet need exists for cancer patients who are ineligible for PARP inhibitor (PARPi) therapy due to their genetic makeup and/or acquired PARPi resistance. Synthetic lethality occurs when PARP inhibition is combined with an agent that disrupts the DNA double-strand breakage (DSB) repair mechanisms, causing apoptosis and cell death. Inhibition of the Heat Shock Protein 90 (Hsp90) represents an ideal candidate to disrupt DSB repair and induce synthetic lethality with PARP inhibitors, as multiple Hsp90 client proteins are involved in the DSB repair pathways including homologous recombination (HR) repair pathway. Unfortunately, no Hsp90 inhibitor is FDA approved for use due to dose-limiting and on-target toxicities. Hsp90 exists as four isoforms in the cell, Hsp90α, Hsp90β, Grp94 and Trap-1. The cytosolic isoforms Hsp90α and Hsp90β significantly contribute to cancer growth and progression. Interestingly, inhibition of Hsp90α by non-selective (pan-Hsp90) inhibitors can cause cardiac and ocular toxicities. Additionally, inhibitor binding to the inducible isoform, Hsp90α, can also contribute to dosing-challenges associated with previously evaluated pan-Hsp90 inhibitors. Therefore, Hsp90β-selective inhibition has been proposed as safer alternative to pan-Hsp90 inhibition for cancer treatment. This presentation will contain results from mechanistic, efficacy and safety studies of the orally bioavailable and efficacious Hsp90beta-selective inhibitor in combination with a PARP inhibitor.

: Overcoming Microenvironmental and Delivery Barriers in Cancer Therapy
Poster Session

#0485 ML-016: A silicon “plateloid”-based phenotype targeting platform for lung and liver malignancies.

Qingxin Mu, Lorenzo Pradella, Brian Sapp, Mauro Ferrari

BrYet US, Inc, Houston, TX

The treatment of metastatic and drug-resistant tumors in the lungs and liver remains a major challenge for conventional chemotherapeutic agents, including doxorubicin. ML-016 is a novel injectable Phase I drug product developed by BrYet using a proprietary silicon “plateloid” technology designed to exploit distinct vascular and microenvironmental phenotypes. The platelet-shaped silicon microstructures (~2.6 µm in diameter and ~700 nm in thickness) are engineered to optimize hemodynamic behavior and endothelial interaction. The targeting mechanism of ML-016 integrates multiple phenotype-driven nodes acting sequentially across the tumor vasculature and microenvironment: enhanced margination under tumor-associated shear stress; preferential transmigration via polyglutamic acid-doxorubicin (pDox) conjugation; formation of pDox “exosomoids” and efficient internalization into tumor cells; local drug release through pH-mediated cleavage; and intracellular trafficking of released doxorubicin beyond the active range of multidrug-resistance pumps, yielding high perinuclear and nuclear accumulation. This multi-node phenotype targeting approach enhances tumor penetration, reduces systemic toxicity, and overcomes drug resistance. Our preclinical studies have shown strong antitumor efficacy in triple-negative breast cancer models with a 50% long-term functional cure (Nature Biotechnology, 2016, 34(4), 414-418). In a current lung metastasis model of soft-tissue sarcoma, ML-016 has produced durable tumor suppression and markedly prolonged survival, with 50-80% of treated animals surviving beyond five months after tumor inoculation, whereas all vehicle- or free-doxorubicin-treated animals succumbed within the same period. ML-016 has recently received Phase I/II Human Research Ethics Committee (HREC) approval in Australia, marking the initiation of first-in-human evaluation. Overall, ML-016 represents an innovative application of silicon plateloid technology that coordinates vascular, microenvironmental, and intracellular mechanisms to enable efficient phenotype-targeted therapy for resistant tumors in the lung and liver, supporting its continued development toward multi-cancer clinical validation.

#7144 A general method to overcome the binding site barrier in antibody-based therapeutics.

Yuanzheng Li[1], Shili Yao[2], Peng Guo[2]

[1]University of Science and Technology of China, Hefei, China,[2]Hangzhou Institute of Medicine, Chinese Academy of Sciences, Hangzhou, China

Background: Insufficient intratumoral penetration remains a major limitation of antibody-based therapeutics in solid tumors. The binding site barrier (BSB), driven by high-affinity interactions near perivascular regions, restricts deeper tissue distribution of ADCs and bispecific antibodies and thereby limits their therapeutic index. Current strategies such as co-dosing with parental antibodies or engineering lower-affinity variants are constrained by target specificity and require redesign of each therapeutic. A broadly applicable, novel approaches that transiently modulates BSB without altering antibody structure is needed to improve tumor penetration.

Methods: We evaluated DSPE-PEG2000, an FDA-approved amphiphilic phospholipid-polymer conjugate, as a general BSB modulator. Using HER2-, TROP2-, and PD-1/VEGF-targeted therapeutics, we quantified changes in cell-surface engagement, receptor accessibility, and internalization across multiple cancer cell models via flow cytometry, confocal microscopy, and live-cell imaging. In subcutaneous xenograft models, we assessed the intratumoral distribution of Cy3-labeled ADCs and a PD-1/VEGF bispecific antibody using longitudinal IVIS imaging and spatial analysis of tumor sections. Antitumor efficacy was evaluated by tumor growth suppression, treatment durability, and survival. Biosafety assessments included serum chemistry and histopathology of major organs.

Results: DSPE-PEG2000 rapidly incorporated into tumor cell membranes and generated a short-range PEG layer that transiently reduced antibody-antigen interactions by 40-60% across diverse targets (e.g., HER2, TROP2, and PD-1/VEGF). This surface modulation did not impair antibody internalization or downstream trafficking. In vivo, DSPE-PEG2000 substantially broadened the intratumoral distribution of ADCs and bispecific antibodies, enabling deeper penetration beyond perivascular regions. The improved spatial delivery translated into greater tumor growth inhibition and prolonged survival, consistent across multiple ADC payloads and antibody architectures. Co-administration did not increase systemic exposure or off-tumor tissue accumulation, and no treatment-related toxicity was observed.

Conclusions: DSPE-PEG2000 provides a generalizable, target-independent strategy to overcome the binding site barrier and enhance the distribution and functional efficacy of antibody-based therapeutics in solid tumors. By transiently modulating BSB through membrane-anchored PEG grafting without modifying antibody affinity or structure, DSPE-PEG2000 offers a practical and clinically compatible approach to improve tumor penetration of current and next-generation antibody therapeutics.

#7145 A spatial PK/PD framework predicts ADC response in solid tumors by integrating drug delivery, target engagement, and microenvironmental readiness.

Corinne Ramos[1], Martha Baydoun[1], Sandra Delebecq[2], Amandine Gerstenberg[2]

[1]R&D, Aliri, Loos, France,[2]Aliri, Loos, France

Background: Antibody-drug conjugates achieve their effect only when payload delivery, target accessibility, and microenvironmental readiness align within the tumor. Conventional biomarkers capture fragments of this biology, but not the spatial interplay that ultimately determines response. To address this gap, we conducted a translational spatial PK/PD study to determine whether high-resolution tissue mapping could predict early ADC activity in solid tumors.

Methods: Tumor biopsies from patients and PDX models treated with a clinically relevant ADC were analyzed using an integrated spatial PK/PD workflow. Quantitative payload imaging by mass spectrometry imaging was combined with spatial proteomics and transcriptomics to map antigen distribution, stromal architecture, vascular organization, immune niches, and early pharmacodynamic activation. All data modalities were spatially registered and modeled using AI-based neighborhood analysis to generate a continuous delivery-engagement score for each tumor region. Importantly, pharmacodynamic readouts such as cleaved caspase-3 and γH2AX were evaluated in a blinded manner.

Results: Across fourteen matched tumor samples, the analysis revealed a consistent pattern linking spatial drug behavior with early biological response. Regions showing strong spatial convergence between payload localization and antigen-rich tumor pockets exhibited significantly higher apoptotic signaling. Tumors displaying coherent payload influx along perfused vascular corridors were more likely to show downstream pharmacodynamic activation, regardless of their bulk target expression. In addition, microenvironments enriched for dendritic cells, $CD8^+$ T cells, and interferon-responsive stromal states demonstrated enhanced sensitivity to the ADC even before radiographic change. When integrated into a unified spatial competency score, these features correctly classified early responses in eleven of fourteen samples.

Conclusion: This study shows that a spatial PK/PD framework can predict ADC response by capturing the coordinated alignment of delivery, target engagement, and microenvironmental readiness within tissue. These findings provide a mechanistically grounded, clinically relevant approach for improving patient selection and advancing predictive biomarker strategies for next-generation ADCs.

#7146 Targeting tumor macrophage TGF-β signaling overcomes immunotherapy resistance in hepatocellular carcinoma.

Hui Yue, Yan Liu, Han Wang, Yalin Tu, Yaxian Wang, Siyuan Huang, Haoran Wu, Xiaohang Long, Carol Tong, Alfred Sze-Lok Cheng

The Chinese University of Hong Kong, Hong Kong, Hong Kong

Background: Immune checkpoint blockade (ICB) has improved outcomes in hepatocellular carcinoma (HCC), but its response rates remain limited. We aimed to investigate the role of transforming growth factor-beta (TGF-β) signaling in ICB resistance and develop a targeted strategy to enhance therapeutic efficacy.

Methods: We analyzed our in-house clinical single-cell RNA sequencing (scRNA-seq) data (NCT03419481) from HCC patients. An ICB-resistant mouse model was used for therapeutic validation. *In vivo* phage display screening was employed to identify a tumor-associated macrophage (TAM)-homing peptide, which was then conjugated to nanoparticles for targeted delivery of the TGF-β receptor inhibitor (TGFBR1) Vactosertib.

Results: Our scRNA-seq revealed a broad upregulation of TGF-β ligand and pathway activity within the tumor microenvironment (TME) of ICB non-responders compared to responders. Further analysis identified TREM2+ macrophages as the dominant recipients of TGF-β signaling, a finding corroborated by their significant abundance in non-responders, suggesting their central role in a TGF-β-driven resistance pathway. To functionally validate this clinical observation, we employed an ICB-resistant HCC mouse model. Treatment with Vactosertib, in combination with anti-PD-1, markedly restored tumor growth control and significantly prolonged survival, effectively reversing the resistant phenotype. To definitively establish the causal role of macrophage-specific TGF-β signaling in driving resistance, we developed a targeted nanomedicine strategy. Using an *in vivo* phage display screening, we identified a peptide with high specificity and affinity for TAMs. By conjugating this TAM-homing peptide to nanoparticles, we achieved precise delivery of Vactosertib to the TAM population. This targeted intervention not only recapitulated the synergistic anti-tumor effect observed with systemic Vactosertib administration but also more potently reversed the immunosuppressive TME signature, providing direct evidence that TGF-β acts primarily through TAMs to mediate ICB resistance.

Conclusions: Our study establishes TGF-β signaling in TAMs as a key mechanism of ICB resistance in HCC. The TAM-homing nanoparticle platform provides a powerful tool for dissecting macrophage-specific mechanisms and represents a versatile strategy for developing precision immunotherapies that target specific cellular niches within the immunosuppressive TME.

Acknowledgements: This study is supported by RGC GRF14119023, LiKaShing Foundation, and Strategic Seed Funding for Collaborative Research Scheme.

#7147 CAR T-Cell therapy efficacy evaluation inTumorGraft3D tri-culture platform with reconstructed tumor microenvironment.

Stefano Cairo[1], **Fu-Ju Chou**[2], Sumanun Suwunnakorn[2], Annamaria Rapisarda[2], Marianna Zipeto[2], Michael Ritchie[2], Markus Hippich[2], Daniel Ciznadija[3], Veena Jagannathan[2], Brandon Walling[2], Mara Gilardi[2], Haoting Hsu[2], BanuPriya Sridharan[2]

[1]Champions Oncology, Inc. (Hackensack, NJ), Rockville, MD,[2]Champions Oncology (Rockville, MD), Rockville, MD,[3]Champions Oncology, Hackensack, NJ

Chimeric antigen receptor (CAR) T-cell therapy represents one of the most transformative innovations in cancer immunotherapy, offering the ability to redirect a patient's own immune cells toward malignant targets through genetic engineering of tumor-recognizing receptors. While clinical successes in hematologic malignancies such as B-cell acute lymphoblastic leukemia & diffuse large B-cell lymphoma have validated the concept of CAR T-cell-mediated cytotoxicity, extending this efficacy to solid tumors has proven significantly more challenging due to the immunosuppressive nature of the tumor microenvironment (TME), the heterogeneity of antigen expression, &the presence of physical & biochemical barriers that limit CAR T-cell infiltration & persistence. To address these limitations, we developed the TumorGraft3D-Tri-Culture platform, a physiologically relevant ex-vivo system capable of recapitulating the complex interactions that occur among tumor cells, cancer-associated fibroblasts (CAFs), & immune suppressive components such as M2 macrophages. In this study, CD70-directed CAR T-cells were evaluated in a renal cell carcinoma with high CD70 expression. Standard targeted CAR T-cells expressing the CD27 receptor were compared to armored CAR T-cells incorporating a dominant-negative TGFβ receptor II (dnTGFβRII) designed to resist TGFβ-mediated immunosuppression. The tri-culture system consisted of tumor cells, cancer-associated fibroblasts (CAFs), & M2 macrophages, providing a physiologically relevant TME that supported tumor proliferation & cytokine-driven immune suppression. Addition of CAR T-cells enabled a quad-culture system used to assess therapeutic efficacy under suppressive conditions. Tumor cells were seeded at a 1x baseline ratio, with CAFs at 0.5x & M2 macrophages at 0.1-0.5x. Both targeted & armored CAR T-cells reduced tumor viability compared with controls, but armored CAR T-cells showed enhanced cytotoxicity & sustained activation. CD69 expression was markedly elevated in both CAR T-cell types, indicating robust activation, while CD70 surface expression on tumor cells decreased following treatment, reflecting target engagement & selective killing. Brightfield imaging & luminescence analyses confirmed significant tumor lysis, especially in armored CAR T-cell groups. The 3D platform successfully recapitulated stromal & immune-mediated resistance mechanisms absent in conventional two-dimensional systems, validating its translational relevance. These findings demonstrate that TGFβ-resistant armored CAR T-cells maintain effector function within an immunosuppressive TME & highlight CD70 as a viable & selective therapeutic target. Collectively, this work establishes the TumorGraft3D tri-culture platform as a robust preclinical tool for evaluating & advancing next-generation CAR T-cell therapies in solid tumors.

#7148 Stress adaptation defines therapeutic response to CDK4/6 inhibitors in sarcoma.

Jinfen Xiao[1], Emily Ko[1], Ashley Smith[1], Roberta Piras[2], Annaliese Fowler[1], Kristin Ishaya[2], **Jlenia Guarnerio**[1]

[1]Genetics, University of Texas MD Anderson Cancer Center, Houston, TX,[2]Biomedical Science, Cedars-Sinai Medical Center, Los Angeles, CA

CDK4/6 inhibitors are under active clinical evaluation in sarcoma, yet the mechanisms that determine therapeutic sensitivity and resistance remain poorly understood. Here, we show that the CDK4/6 inhibitor abemaciclib not only suppresses tumor cell proliferation but also induces a robust type I interferon (IFN-I) response driven by intracellular double-stranded RNA accumulation—an effect essential for its antitumor activity. Abemaciclib further remodels the sarcoma immune microenvironment by enhancing T cell infiltration and increasing interferon-producing monocytes. Through integrated transcriptomic and proteomic analyses, we identify a stress-adaptive signaling program that is selectively upregulated in tumor cells upon treatment and correlates with poor patient prognosis. Functionally, this pathway mitigates IFN-induced mitochondrial stress, limiting reactive oxygen species accumulation and apoptosis, whereas its suppression exacerbates mitochondrial dysfunction and promotes tumor cell death. In vivo, targeting the adaptive stress-response program synergizes with abemaciclib to inhibit tumor growth and extend survival. These findings define a previously unrecognized mechanism of stress adaptation to CDK4/6 inhibition and highlight a promising strategy to potentiate interferon-driven antitumor responses in sarcoma.

#7150 ICA-1S targets protein kinase C-iota to inhibit the WNT/β-catenin signaling in hepatocellular carcinoma.

Abigail Oluwafisayo Olatunji, Nuzhat Nowshin Oishee, Abiral Hasib Shourav, Grazielly Teodoro, Mildred Acevedo-Duncan

University of South Florida, Tampa, FL

Liver cancer is one of the leading causes of cancer-related mortality in the United States and a significant threat to public health. Despite the projection of the World Health Organization that the global deaths from liver cancer would exceed one million by 2030, liver cancer continues to receive limited attention in oncology drug development. The activation of the WNT/β-catenin signaling pathway is a key molecular event in hepatocellular carcinoma (HCC), and the canonical pathway is activated in approximately one-third of HCC cases. However, therapeutic targeting of this pathway has been limited by challenges in specificity. In this study, we investigated the role of atypical protein kinase C-iota (PKC-ι) and its specific inhibitor, 5-amino-1-((1R,2S,3S,4R)-2,3-dihydroxy-4-methylcyclopentyl)-1H-imidazole-4-carboxamide (ICA-1S), in regulating β-catenin stability and suppressing its signaling in liver cancer cells. We assessed the pathways affected by PKC-ι inhibition by cell proliferation assays, Western blotting, Co-immunoprecipitation, and siRNA knockdowns. HepG2 liver cancer cells were seeded 8×10^4 per well and treated with ICA-1S (10-50 μM) for 72 hours. Untreated wells served as controls. In comparison, we achieved PKC-ι gene knockdown with 80 nM siRNA using polymer-based transfection reagent siTran 2.0. We then assessed protein expression by Western blotting and normalized it to beta-actin. The dose-response curve of ICA-1S showed a 15%, 35%, 53%, 55%, and 63% reduction in proliferation at concentrations of 10 μM, 20 μM, 30 μM, 40 μM, and 50 μM, respectively, after three days of treatment. Moreover, treatment with 20 μM ICA-1S increased cytochrome C (39%), Bcl-2 Interacting Mediator of cell death (BIM) (25%), cleaved Caspase-3 (24%), and cleaved Poly (ADP-ribose) polymerase (PARP) (24%), while reducing total PARP (35%), indicating an intrinsic apoptotic response. ICA-1S reduced β-catenin stability, suggesting that PKC-ι maintains the anti-β-catenin degradation complex. We also observed the downstream effectors of the WNT/β-catenin signaling pathway in response to 20 μM ICA-1S, which resulted in 53% upregulation of Axin-1, 37% downregulation of disheveled segment polarity protein-3 (DVL3), and 55% and 63% downregulation of Low-density lipoprotein receptor-related protein-6 (LRP6) and phospho-LRP6 levels, respectively. Epithelial cadherin and tumor protein p53 were upregulated by 41% and 13%. We have shown in this study that ICA-1S could inhibit proliferation and induce apoptosis in liver cancer cells by destabilizing β-catenin and disrupting the WNT/β-catenin signaling pathway. Our findings identify PKC-ι as a promising therapeutic target, supporting the further development of ICA-1S or related compounds as potential anti-HCC agents that can overcome pathway-specificity challenges in liver cancer therapy.

#7151 Targeted inhibition of atypical PKC isoforms PKC-ι and PKC-ζ by ICA-1S and ζ-Stat suppresses oncogenic signaling and cytokine-mediated bone metastasis in prostate cancer.

Grazielly Teodoro, Wishrawana Sarathi Ratnayake, Luke Lajmi, Sloan Breedy, Aaron Todman, Shreejana Rimal, Mildred Acevedo-Duncan

University of South Florida, Tampa, FL

Bone metastatic prostate cancer (BMPC) remains the leading cause of mortality among prostate cancer patients due to its resistance to current therapeutics and its reliance on the osteogenic microenvironment. The atypical protein kinase C (aPKC) isoforms PKC-ι and PKC-ζ have emerged as pivotal regulators of prostate cancer progression, metastasis, and inflammatory signaling. In this study, we investigated the molecular effects of two selective small-molecule inhibitors, ICA-1S (targeting PKC-ι) and ζ-Stat (targeting PKC-ζ), in DU-145 and PC-3 prostate cancer cells, as well as their interactions with the human osteoblast line hFOB 1.19. Our results demonstrated that both inhibitors effectively suppressed phosphorylation and activity of PKC-ι/ζ and downstream effectors, including Stat3, NFκB, and JNK/c-Jun, leading to marked reductions in cell migration and survival. Cytokine array analysis revealed that ICA-1S and ζ-Stat treatment significantly downregulated pro-metastatic and pro-inflammatory cytokines, including IL-6, IL-8, and CXCL-1, while upregulating IL-18 and ICAM-1, indicating a shift toward apoptotic and pyroptotic signaling. Immunofluorescence confirmed a decreased nuclear localization of Stat3. At the same time, co-immunoprecipitation assays demonstrated a reduced interaction between 14-3-3 and PKC-ι/ζ, supporting the disruption of key scaffold assemblies required for metastatic signaling. Collectively, our findings suggest that dual aPKC inhibition attenuates critical oncogenic cascades and reprograms the osteogenic niche to suppress prostate cancer survival and colonization in bone. These results identify ICA-1S and ζ-Stat as promising lead compounds for precision targeting of aPKC-driven prostate cancer metastasis.

#7152 ICA-1S targets PKC-ι and Cx43 to inhibit glioblastoma multiforme progression.

Grazielly Teodoro, Shreejana Rimal, Wishrawana Sarathi Ratnayake, Gaurab Raj Khanal, mildred acevedo-duncan

University of South Florida, Tampa, FL

Glioblastoma multiforme (GBM) is an aggressive brain cancer, characterized by poor therapeutic outcomes. Atypical protein kinase C iota (PKC-ι) plays a critical role in GBM progression by regulating cell proliferation, motility, and invasion. Connexin 43 (Cx43), a key gap junction protein, mediates intercellular communication between glioma and surrounding astrocytes, promoting tumor growth, invasion, and chemoresistance. Targeting the PKC-ι and Cx43 represents a novel approach to disrupt oncogenic interactions and inhibit GBM progression. This study evaluates the therapeutic potential of ICA-1S ((-Amino-1-[(1R,2S,3R,4R)-2,3-dihydroxy-4-[(phosphonooxy)methyl]cyclopentyl]-1H-imidazole-4-carboxamide), a selective PKC-ι inhibitor, on GBM cell proliferation, signaling, and Cx43 regulation. Treatment of T98G and U87MG cells with ICA-1S resulted in significant reductions in cell proliferation by about 50% in T98G and 40% in U87MG ($p < 0.001$). Co-immunoprecipitation experiments demonstrated that PKC-ι directly interacts with Cx43. Treatment with ICA-1S led to decreased expression of both PKC-ι and Cx43, as shown by Western blot analysis. In addition, ICA-1S promoted autophagy and inhibited critical oncogenic signaling pathways, including PI3K/AKT, while also reducing the expression of proteins involved in epithelial-mesenchymal transition. These results indicate that ICA-1S is a promising candidate for targeted GBM therapy.

#7153 Selective atypical protein kinase C inhibitor reduces proliferation and promotes apoptosis in malignant endometrial cancer cells.

Gaurab Raj Khanal[1], Shreejana Rimal[2], Grazielly Teodoro[2], Mildred Acevedo-Duncan[2]

[1]Chemistry, University of South Florida, Tampa, Florida, US, Tampa, FL,[2]University of South Florida, Tampa, FL

Endometrial cancer is a type of uterine cancer. It starts in the inner lining of the uterus, known as the endometrium. Endometrial cancer is the most commonly diagnosed type of cancer that affects the gynecologic organs in the United States. Globally, endometrial cancer accounts for about 420,000 new cases and nearly 98,000 deaths annually (as of 2022), making it one of the most common gynecologic cancers worldwide. Endometrial cancer primarily affects postmenopausal women, with peak incidence between 60 and 70 years of age. Overall, it remains a disease largely associated with older, postmenopausal women. Among the Protein Kinase C (PKC) family, the atypical PKC (aPKC) subgroup, consisting of Protein Kinase C-iota (PKC-ι) and Protein Kinase C-zeta (PKC-ζ), has been implicated in cancer cell proliferation and survival. PKC-ι, in particular, is frequently overexpressed in various malignancies, including endometrial cancer. 5-amino-1-((1R, 2S, 3S, 4R)-2, 3-dihydroxy-4-methyl cyclopentyl)-1H-imidazole-4-carboxamide (ICA-1S), an inhibitor selective for PKC-ι, has demonstrated anticancer activity in multiple tumor types such as glioblastoma, prostate, ovarian, and lung cancers. In our study, 50,000 Hec1A endometrial cancer cells were seeded in six-well plates and treated with various concentrations of ICA-1S. A concentration-dependent decrease in cell proliferation was observed, with reductions of 17%, 22%, 52%, 38%, and 58% at 1 µM, 5 µM, 10 µM, 20 µM, and 50 µM ICA-1S, respectively. The 10 µM concentration, which produced a significant inhibitory effect, was selected for subsequent experiments. Sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE) followed by Western Blot analysis showed a marked reduction in the expression and phosphorylation of PKC-ι. Similarly, there was a significant reduction in the levels of PKC-ζ and phosphorylated PKC-ζ. Additionally, expression of key apoptotic markers such as survivin, caspase-3, and poly (ADP-ribose) polymerase (PARP) was significantly decreased in ICA-1S-treated cells compared to untreated controls, suggesting induction of apoptosis. Future experiments will focus on identifying the signaling pathways affected by ICA-1S treatment through more Western Blotting, Immunofluorescence, Co-Immunoprecipitation, and Flow Cytometry to elucidate further the molecular mechanisms underlying the reduced proliferation and enhanced apoptosis observed in Hec1A cells following PKC-ι inhibition.

#7154 The role of TNIK and MINK1 in TNBC tumorigenesis and invasion.

Caroline McCauley, Bruce Bunnell

University of North Texas Health Science Center, Fort Worth, TX

Introduction: TRAF2- and NCK-interacting kinase (TNIK) and Misshapen-like kinase 1 (MINK1) are implicated in MAP kinase signaling cascades, including Wnt signaling. These kinases play a role in cancer-associated processes, like migration and epithelial-to-mesenchymal transition (EMT). Migration and EMT are hallmarks associated with poorer cancer outcomes, specifically in breast cancer patients. Triple-negative breast cancer (TNBC) is more aggressive and challenging to treat, making the identification of novel targets of the utmost importance. TNIK and MINK1 are relatively understudied in TNBC; therefore, our group is studying the effect of TNIK and MINK1 knockdown on TNBC tumorigenesis, invasion, and migration.

Methods: To better understand the role of TNIK and MINK1 in TNBC, an shRNA-mediated knockdown of TNIK and MINK1 was performed in a patient-derived xenograft-derived TNBC cell line: TU-BcX-4IC (4IC). Using pre-validated shRNAs that were pre-packaged in lentiviral particles and specifically target TNIK and MINK1, the expression of these genes was diminished. We confirmed knockdown at the transcript level, as well as by monitoring GFP expression via fluorescent microscopy. We then assessed the effects of knockdown on 4IC cell spheroid formation and invasion, as well as EMT marker gene expression, using a collagen-embedded sphere migration assay and quantitative real-time PCR (qRT-PCR), respectively.

Results: TNIK and MINK1 expression were diminished after stable transduction. TNIK expression was reduced by 82% compared to the scrambled shRNA control. MINK1 expression was decreased by 92%. shTNIK and shMINK1 cell lines were unable to form as tightly compact tumor spheroids as their scrambled shRNA control counterparts. Upon characterizing the spheroids, the area and perimeter of the shMINK1 spheroids were significantly larger, while the circularity and solidity were diminished considerably compared to the control. There was no significant difference in these parameters for the shTNIK spheres, but a biological difference appears to exist. There was no significant difference in spheroid migration through collagen in either group, despite the spheres being much larger and less compact.

Conclusions: Overall, MINK1 and TNIK knockdown have an effect on TNBC cells' spheroid-forming capacity, despite no significant difference in migration being observed compared to the scrambled control. This suggests that MINK1 and TNIK may play a role in tumorigenesis, but not in migration, from a central tumor. However, further research is needed. In the future, we plan to repeat these experiments, as well as stain sectioned spheroids for extracellular matrix (ECM) markers to assess if TNIK and MINK1 are associated with changes in the ECM that may be driving the inability to aggregate. We also plan to generate a double knockdown cell line, which could provide clearer insight into the roles of both proteins simultaneously.

#7155 Therapeutic potential of a selective protein kinase Ciota inhibitor, in suppressing PI3K/AKT driven pancreatic ductal adenocarcinoma proliferation.

Shreejana Rimal[1], Grazielly Teodoro[2], Gaurab Raj Khanal[1], Abigail Oluwafisayo Olatunji[3], Abiral Hasib Shourav[2], Mildred Acevedo-Duncan[4]

[1]Chemistry, University of South Florida, Tampa, FL,[2]University of South Florida, Tampa, FL,[3]University of South Florida - Upward Bound, Tampa, FL,[4]University Of South Florida, Tampa, FL

Pancreatic cancer remains one of the most lethal malignancies due to its late-stage diagnosis and pronounced chemoresistance, ranking as the third leading cause of cancer-related deaths in the United States. Atypical Protein Kinase C (aPKC) isoforms, Protein Kinase C-iota (PKC-ι) and Protein Kinase C- zeta (PKC-ζ), are critical regulators of oncogenic signaling pathways that drive cancer cell proliferation, metastasis, and survival. In this study, we investigated the therapeutic potential of ICA-1S [5-amino-1-((1R,2S,3S,4R)-2,3-dihydroxy-4-methylcyclopentyl)-1H-imidazole-4-carboxamide], a selective PKC-ι inhibitor, in pancreatic adenocarcinoma cell lines AsPC1 and PANC1. Dose-response analyses revealed maximal inhibitory effects at 10 μM ICA-1S, reducing cell proliferation by 52% in AsPC1 and 49.8% in PANC1 cells. Western blot analysis performed on AsPC1 cell line confirmed downregulation of PKC-ι and PKC-ζ protein expression following treatment. Mechanistic studies demonstrated that ICA-1S (10 μM) significantly attenuated the Phosphatidylinositol 3-Kinase (PI3K)/Protein Kinase B (AKT) signaling cascade, phosphorylated Phosphatidylinositol 3-Kinase (pPI3K) by 51%, and total PI3K by 18%. This suppression led to a 39% decrease in phosphorylated AKT (pAKT) and an 18% decrease in total AKT, demonstrating inhibition of downstream PI3K pathway signaling. Additionally, ICA-1S treatment induced apoptosis in AsPC1 cells, as evidenced by increased expression of Cleaved Caspase-9 by 10%, increased Cytochrome c release by 17%, and decreased expression of the anti-apoptotic protein Survivin by 42%. Wound-healing assays further demonstrated the anti-metastatic effect of ICA-1S, with treated AsPC1 cells failing to close wounds even after five days, while control cells achieved complete closure.Collectively, these findings indicate that ICA-1S effectively suppresses PKC-ι-mediated PI3K/AKT signaling and promotes apoptosis in pancreatic cancer cells, underscoring its potential as a promising targeted therapeutic agent for pancreatic adenocarcinoma. Ongoing studies will employ Water-Soluble Tetrazolium (WST) assays, immunoprecipitation, immunofluorescence, and extended Western blot analyses to further delineate the downstream molecular effects of ICA-1S.

#7156 Inhibition in the proliferation of pediatric glioblastoma facilitated with atypical protein kinase c inhibitors.

Shreejana Rimal[1], Grazielly Teodoro[2], Gaurab Raj Khanal[3], Mildred Acevedo-Duncan[4]

[1]Chemistry, University of South Florida, Tampa, FL,[2]University of South Florida, Tampa, FL,[3]University of South Florida - Upward Bound, Tampa, FL,[4]University Of South Florida, Tampa, FL

Pediatric glioblastoma (pGBM) is an aggressive brain tumor with a five-year survival rate of approximately 5%. Current therapeutic options are limited, primarily due to poor blood-brain barrier penetration of available drugs. Atypical Protein Kinase C (aPKC) isoforms, Protein Kinase C- iota (PKC-ι) and Protein Kinase C- zeta (PKC-ζ), play crucial roles in tumor cell proliferation and survival. In this study, we investigated the effects of ICA-1S [5-amino-1-((1R,2S,3S,4R)-2,3-dihydroxy-4-methylcyclopentyl)-1H-imidazole-4-carboxamide], a selective PKC-ι inhibitor, and ζ-Stat [8-hydroxy-1,3,6-naphthalenetrisulfonic acid], a PKC-ζ inhibitor, on pediatric glioblastoma SF188 cells. SF188 cells (50,000/well) were seeded in 6-well plates and treated with varying concentrations of ICA-1S and ζ-Stat for three days. On the fourth day, cell viability was determined to generate a dose-response curve. ICA-1S showed maximal inhibition at 75 μM, while ζ-Stat decreased proliferation by approximately 50% at 20 μM. These results suggest that both PKC-ι and PKC-ζ contribute to SF188 cell proliferation. To explore the molecular mechanisms underlying this inhibition, protein lysates from treated and untreated cells were analyzed via Sodium Dodecyl Sulfate-Polyacrylamide Gel Electrophoresis (SDS-PAGE) and Western blotting. Both ICA-1S and ζ-Stat treatments resulted in downregulation of PKC-ι and PKC-ζ protein expression compared to control samples. Furthermore, expression of the apoptotic marker Caspase-3 was found to be decreased in drug-treated cells, suggesting activation of apoptotic signaling following inhibition of aPKCs. These findings indicate that selective inhibition of aPKCs suppresses proliferation and induces apoptosis in pediatric glioblastoma cells. Ongoing and future studies will employ immunoprecipitation, immunofluorescence, and WST assays to elucidate downstream signaling pathways and validate ICA-1S and ζ-Stat as potential therapeutic candidates for pediatric glioblastoma.

#7157 Programmable RNA-triggered cancer cell elimination using CRISPR-Cas12a2.

Jared Thompson[1], Paul Scholz[2], Kadin Crosby[3], Nathan Krah[4], Grant Schlauderaff[1], Alivia Jolley[1], Emily Wilson[5], Xiaoyang Zhang[5], Ryan Jackson[3], Chase Beisel[6], Yang Liu[1]

[1]Department of Biochemistry, University of Utah School of Medicine, Salt Lake City, UT,[2]Akribion Therapeutics GmbH, Zwingenberg, Germany,[3]Department of Chemistry and Biochemistry, Utah State University, Logan, UT,[4]Department of Internal Medicine, University of Utah, Salt Lake City, UT,[5]Department of Oncological Sciences, Huntsman Cancer Institute, Salt Lake City, UT,[6]Helmholtz Institute for RNA-based Infection Research (HIRI), Helmholtz Centre for Infection Research (HZI), Wurzburg, Germany

Selective eradication of cancer without harming healthy tissue is vital to precision oncology. Although traditional interventions such as chemotherapy or ionizing radiation are broadly applicable across many cancer types, they often exhibit off-target cytotoxicity; conversely, targeted small molecules and biologics improve specificity by binding to protein mutations, yet may not be as broadly applicable. Developing a therapeutic approach with both high specificity and broad applicability thus remains a major challenge in modern cancer care. Here, we show that Cas12a2, a recently discovered CRISPR nuclease exhibiting RNA-triggered DNA shredding, enables programmable sequence-specific elimination of mammalian cells expressing a target transcript. Target-expressing cultures electroporated with NLS-tagged Cas12a2 undergo massive cell death within five days. Activating Cas12a2 elicits widespread double-strand DNA breaks in the nucleus, leading to mitotic catastrophe, cellular inflammation, and apoptosis. We demonstrate that Cas12a2 distinguishes different RNA targets within heterogeneous cultures and induces cell death without observable off-target activity. Leveraging this approach, we eliminate NCI-H23 cancer cells harboring the prevalent oncogenic *KRAS*(G12C) point mutation, including cells with resistance to the FDA-approved *KRAS*(G12C) inhibitor Sotorasib. Taken together, these findings present Cas12a2 as a specific and broadly applicable therapeutic platform for personalized cancer treatment. These findings further establish the basis for use of Cas12a2 as a potent cell ablation tool across disciplines of basic and applied research.

#7158 Human sialidase-armed anti-B7-H3 antibody that enhances innate and adaptive antitumor immune responses.

Wayne Gatlin[1], Jen-Kuan Chang[2], Lizhi Cao[1], Hui Xu[1], Hrishikesh Metha[1], Maryann Timins[1], Mark Yang[1], Jim Broderick[1], Yanling Wang[2], Wilbert Tam[2], Grace Chung[2], Chunlei Ge[3], Lixin Feng[2], Li Peng[1]

[1]Palleon Pharmaceuticals, Waltham MA, MA,[2]Henlius USA, Milpitas, CA,[3]Shanghai Henlius Biotech, Shanghai, China

Tumor hypersialylation, overexpression of sialoglycans on cancer cell surfaces, plays a critical role in cancer progression by suppressing both innate and adaptive anti-tumor immunity. Previously, we demonstrated that an untargeted engineered human sialidase enzyme exhibited single agent and T cell-dependent antitumor activity in preclinical tumor models, a favorable safety profile in non-human primates (NHPs) and cancer patients, and proof-of-mechanism of immune modulation and antitumor signals in cancer patients in a clinical trial (NCT05259696). These findings enabled the development of a platform technology in which the engineered human sialidase is fused to tumor-associated antigen (TAA)-targeting antibodies to achieve deeper and longer tumor desialylation, enhancing both antibody-mediated effector cell cytotoxicity (innate immunity) and T-cell-mediated tumor killing (adaptive immunity). Here we report that fusion of the engineered human sialidase to anti-B7-H3 nanobody, designated E-688 (also called HLX316) significantly improves tumor desialylation depth, durability, and efficacy *in vitro* and *in vivo*, while maintaining a favorable safety profile. In assays using hypersialylated, B7-H3-expressing cancer cell lines, E-688 demonstrated markedly increased potency and pharmacodynamic (PD) effects compared with the untargeted sialidase, showing > 1,000-fold improvement in desialylation. *In vivo*, E-688 also exhibited increased durability of desialylation compared with the untargeted sialidase, extending the PD effect in disease models. Furthermore, desialylation of tumor cell surfaces with E-688 was shown to potentiate antibody-dependent cellular cytotoxicity (ADCC) and antibody-dependent cellular phagocytosis (ADCP), enhancing antibody-mediated effector cell-killing of tumor cells. Single-agent *in vivo* efficacy was observed in multiple mouse tumor models. In an A375 humanized mouse model, E-688 was superior to the B7-H3 antibody, untargeted sialidase, and anti-PD-1 antibody. E-688 was also well tolerated with no toxicity findings in a Good Laboratory Practice (GLP) one-month repeat-dose toxicity study in NHPs, with the NOAEL (no observed adverse effect level) determined to be 150 mg/kg. In summary, E-688 represents a first-in-class cancer therapy, a human-sialidase-armed anti-tumor antibody, that desialylates immunosuppressive tumor-surface sialoglycans to enhance innate and adaptive antitumor immunity. By enabling deeper and more sustained tumor desialylation, E-688 enhances antibody-mediated NK- and macrophage- killing of tumor cells and adaptive antitumor immune responses, while maintaining a favorable tolerability profile. Its clinical development is supported by strong *in vitro, in vivo*, and GLP toxicology data. Additional targets are currently in development to support a platform-based approach.

#7159 Antitumor activity of Avaren-Fc, a novel high-mannose-glycan-targeting immunotherapy, in ovarian cancer.

Katarina Mayer[1], Noel Verjan-Garcia[2], Nobuyuki Matoba[3]

[1]Pharmacology and Toxicology, University of Louisville School of Medicine, Louisville, KY,[2]Center for Predictive Medicine, University of Louisville, Louisville, KY,[3]Pharmacology and Toxicology, Center for Predictive Medicine, Brown Cancer Center, University of Louisville, Louisville, KY

Ovarian cancer (OVCA) is the most lethal and eighth most common gynecological cancer worldwide. Current standard-of-care treatments lack tumor specificity and fail to effectively manage chemoresistant disease recurrence, highlighting the need for new therapeutics. Avaren-Fc (AvFc) is a novel lectin-Fc fusion protein designed to target aberrant *N*-linked high-mannose-type glycans, an underutilized OVCA biomarker. After binding to cancer-associated high-mannose glycans, AvFc can activate Fcγ receptors and induce cytotoxic effector functions. Our previous work showed that AvFc binds to and induces antibody-dependent cell-mediated cytotoxicity (ADCC) activity against multiple human OVCA cells lines (A2780, CAOV3, SKOV3, and SW626) in an *in vitro* luciferase-based ADCC reporter assay using a FcγRIIIa-expressing cell line. AvFc also selectively recognized stage I high-grade serous OVCA tumors over adjacent normal tissue by immunohistochemistry. In the present study, we assessed the anti-OVCA activity of AvFc using the murine ID8 cell line in *in vitro* experiments and a syngeneic orthotopic challenge model in C57BL/6 mice. Flow cytometry analysis demonstrated that AvFc binds to ID8 cells in a dose-dependent manner at nanomolar concentrations, with negligible binding to isolated murine reproductive cells. AvFc binding to ID8 cells significantly increased following treatment with kifunensine, a class I α-mannosidase inhibitor, and this enhanced binding was abolished following high-mannose glycan digestion with endoglycosidase H, confirming high-mannose dependence. AvFc also induced surrogate ADCC activity against ID8 cells by activation of FcγRIIIa. AvFc's antitumor efficacy was assessed in the ID8 OVCA model, where mice were intraperitoneally (i.p.) challenged with $2x10^6$ ID8 cells and treated with 15 doses of AvFc (25 mg/kg, i.p., every other day), a non-sugar binding AvFc mutant, or vehicle beginning one-week post-challenge. AvFc treatment significantly prolonged median survival from 46 to 70 days compared with the vehicle control (p adj=0.0216, Log-rank [Mantel-Cox] test with Bonferroni's correction). Cytometry by time-of-flight (CyTOF) analysis performed one day after the final dose revealed that AvFc treatment uniquely led to the expansion of total spleen leukocytes, including Tbet+ Th1 cells, and increased $CD8^+$ T cells expressing the degranulation marker CD107a in the peritoneal fluid, suggesting that AvFc's anticancer efficacy was partially mediated by adaptive immunity. Imaging mass cytometry analysis of ID8 tumors is ongoing. Taken together, these findings highlight AvFc's promising potential as an immunotherapeutic agent for OVCA.

#7160 NEK2 drives pathogenesis, drug resistance, and LMP1 expression in EBV-positive non-Hodgkin lymphoma.

Maria C. White[1], Philip T. Lange[1], Blossom A. Damania[2]

[1]University of North Carolina at Chapel Hill, Chapel Hill, NC,[2]Associate Professor, Lineberger Cancer Ctr., University of North Carolina at Chapel Hill, Chapel Hill, NC

Non-Hodgkin lymphoma (NHL) is one of the most common cancers worldwide, representing 90% of malignant lymphomas. NHL is a diverse group of malignancies, and a subset of these lymphomas are caused by infection with the human gammaherpesvirus, Epstein-Barr virus (EBV). Many EBV-positive lymphomas are highly aggressive and rapidly develop resistance to treatment, leading to poor patient outcomes. Here, we identify the cellular kinase, NEK2, as a therapeutic target for EBV-positive NHL. We demonstrate NEK2 protein expression is increased in primary lymphocytes following EBV infection, NEK2 expression is significantly upregulated in EBV-positive NHL, and that NEK2 is necessary for the growth and survival of EBV-positive NHL. Inhibition of NEK2 resulted in lymphoma-specific cell death characterized by reactive oxygen species accumulation and gasdermin D cleavage. Additionally, protein levels of the major EBV oncoprotein, LMP1, were decreased following NEK2 inhibition. Furthermore, we demonstrate that MRP1 is the major drug resistance transporter protein in EBV-positive NHL. NEK2 inhibition reduced the expression and activity of cellular drug resistance transporter proteins including MRP1, leading to increased lymphoma cell chemosensitivity. Finally, using a humanized mouse model of EBV-driven lymphomagenesis, we demonstrate that NEK2 inhibition significantly decreased tumor burden and tumor incidence while prolonging survival *in vivo*. Taken together, our data suggest NEK2 inhibition as a promising treatment strategy for EBV-positive NHL.

#7161 A novel StarLinker™-based, CLDN18.2/PD-L1 bispecific dual-payload ADC (CAN017) overcomes tumor heterogeneity.

Pengqi Xu[1], Shaoshan Wang[1], Sanlong Wang[1], Ya Luo[1], Yili Yang[1], Wanping Geng[1], Weihao Li[1], Liying Li[1], Qin Pan[2], Xiangdong Qu[2], Henry N. Yu[1]

[1]CanWell Pharma Inc., Woburn, MA,[2]Qure Biotechnology (Shanghai) Co., Ltd., Shanghai, China

Introduction: Antibody-drug conjugates (ADCs) against the tumor-specific antigen Claudin18.2 (CLDN18.2) have now reached the clinic to treat gastrointestinal (GI) cancers (gastric, pancreatic, esophageal). PD-L1 is an immune checkpoint inhibitor and its antibodies have been approved mainly for lung and hepatocellular cancers. However, their utilities are limited by tumor heterogeneity and resistance leading to disease progression. Now we report to employ the StarLinker™ technology to engineer a first-in-class bispecific ADC (CAN017) targeting CLDN18.2 and PD-L1 bearing two different cytotoxic payloads, and assessed its antitumoral effects in vivo compared with mono-payload ADCs or single-target ADCs.

Methods: CanWell's StarLinker™ technology, which ensures stable conjugation, controlled drug-to-antibody ratio (DAR), and efficient on-target release via a cleavable linker, was used to construct an ADC by conjugating a humanized bispecific antibody targeting CLDN18.2 and PD-L1 with two distinct cytotoxic payloads. The binding, cytotoxicity of this ADC against tumor cell lines expressing CLDN18.2 only, PD-L1 only, and both targets were separately tested. The DMPK profiles of CAN017 were measured *in vivo* and *in vitro*. Furthermore, the antitumor efficacy of CAN017 was evaluated in mouse CDX and PDX tumor models, which overexpress only CLDN18.2, PD-L1 or both targets. We also compare CAN017 with single-target ADCs as references and unconjugated bispecific antibody.

Results: *In vitro* studies confirmed the high-affinity binding of CAN017 to both CLDN18.2 and PD-L1 expressing cells, and potent cytotoxic activity across all tested cell lines. CAN017 demonstrated superior cell-killing activity over single-payload or single-target ADC controls. The compound also exhibited excellent plasma stability and a favorable pharmacokinetic (PK) profile. Moreover, CAN017 showed outstanding anti-tumor activities in all tested CDX and PDX models. Notably, it achieved superior tumor growth inhibitions not only in CLDN18.2+/PD-L1+ tumor models with complete tumor regression and significantly prolonging progression-free survival, but also surprisingly in the models in which tumor cells only express single target (CLDN18.2 or PD-L1). CAN017 has demonstrated its potential to overcome tumor heterogeneity and enhance therapeutic efficacy. The results from non-human primate (NHP) toxicology studies will be presented.

Conclusion: The CLDN18.2/PD-L1 bispecific dual-payload ADC (CAN017), enabled by the StarLinker™ technology, shown superior antitumoral effects in various preclinical tumor models. Coupling with its preliminary excellent DMPK and safety profiles, it provides a strong path to become a potent next-generation ADC for the treatments of advanced solid tumors, particularly pancreatic and GI cancers.

#7162 CD180-targeting ADCs with a topoisomerase I inhibitor payload achieve strong efficacy in AML tumors.

Garima Kaushik[1], Marina Bell[1], Bandana Vishwakarama[2], Abdul Mondal[1], Maxwell Hilbert[1], Arnab Mukharjee[3], Michael Ritchie[1], Kakajan Komurov[1]

[1]Corellia AI, Rockville, MD,[2]Champions Oncology, Rockville, MD,[3]Champions Oncology (Rockville, MD), Rockville, MD

CD180 (RP105) is a type I single-pass transmembrane protein that heterodimerizes with MD-1 or MD-2 to enable stable surface expression. Characterized as an orphan Toll-like receptor predominantly expressed on mature B cells, dendritic cells, and macrophages, CD180 is also upregulated in multiple hematologic malignancies, including diffuse large B-cell lymphoma, mantle cell lymphoma, and acute myeloid leukemia (AML). Here, we identify CD180 as a novel and promising therapeutic target for AML and describe the development of a CD180-directed antibody–drug conjugate (ADC) along with its biochemical properties, antitumor activity across AML models, and pharmacokinetic and safety characteristics in non-human primates.Consistent with emerging datasets, we observed high, homogeneous CD180 expression on AML blasts, including leukemic stem and progenitor compartments, across a large cohort of primary AML specimens, with minimal to no expression on healthy hematopoietic stem cells, common myeloid progenitors, or normal tissues. We generated a fully human monoclonal antibody with high-affinity, selective binding to the human and cynomolgus CD180/MD-1 complex and no reactivity to rodent CD180.This antibody was conjugated to a topoisomerase I inhibitor with a drug-to-antibody ratio (DAR) of 8, selected for its potency and favorable stability profile in hematologic malignancies. The ADC demonstrated rapid internalization, high specificity for CD180-expressing cells, and potent cytotoxicity in AML cell lines, primary ex vivo samples, and patient-derived xenograft models, with therapeutic response strongly correlating with CD180 expression levels.In an exploratory toxicity study in cynomolgus monkeys (10, 30, and 60 mg/kg), the ADC was well tolerated, with no target-related toxicities or cytopenias observed at any dose. All clinical and histopathological findings were mild and reversible, establishing a maximum tolerated dose of 60 mg/kg. The ADC also demonstrated excellent physicochemical stability and developability properties.Together, these findings support advancement of CD180-targeted ADC therapy into clinical development for patients with CD180-positive AML.

#7164 Preclinical characterization of TRO-01, a novel CLDN18.2-targeting ADC, with potent anti-tumor efficacy and favorable PK and safety.

Young Hun Lee, Jeongho Kim, Hyun Ju Lee, Sunhwa Lee, Dong Hoon Seo, Myoungki Baek, Sung Ho Woo

TriOar Inc., Daejeon, Korea, Republic of

Claudin 18.2 (CLDN18.2) is a tight junction protein normally restricted to the gastric mucosa. Loss of epithelial polarity during malignant transformation exposes CLDN18.2 on the surface of gastric and gastroesophageal junction (G/GEJ) adenocarcinoma cells. As CLDN18.2 is highly expressed in 30–40% of G/GEJ cancers and is associated with poor prognosis, it has emerged as a promising therapeutic target for gastric cancer, where effective targeted therapies remain limited. We developed TRO-01, an antibody-drug conjugate (ADC) composed of a fully human anti-CLDN18.2 monoclonal antibody conjugated to a topoisomerase I inhibitor via the proprietary TROSIG^{TM} linker. This cleavable, highly stable, and hydrophilic linker enables a high and uniform drug-to-antibody ratio (DAR) of 8. In vitro studies demonstrated that TRO-01 specifically binds to CLDN18.2 but not to CLDN18.1, exhibiting enhanced affinity compared with competitor antibodies, with cell binding affinities in the single nanomolar range across tested cell lines. Additionally, TRO-01 showed efficient internalization and potent cytotoxicity in CLDN18.2-positive cell lines, with IC_{50} values ranging from sub-nanomolar to double-digit nanomolar depending on the cell type. In vivo, TRO-01 treatment resulted in significant tumor growth inhibition (TGI) in both cell line-derived xenograft (CDX) and patient-derived xenograft (PDX) models. In the Patu8988s CDX model, a single dose of 3 or 6 mg/kg resulted in 86% and 101% TGI, respectively. In the SNU-601 CDX model, BIW x 4 dosing at 0.3 or 0.5 mg/kg resulted in 109% and 111% TGI. In two gastric and two pancreatic PDX models, TRO-01 treatment (QW x 2, 2.7 mg/kg) resulted in 89% and 93% TGI in gastric, and 75% and 84% TGI in pancreatic PDXs, with no significant body weight loss. Pharmacokinetic studies in monkeys demonstrated favorable PK properties ($t_{1/2}$ = 7.2 days, AUC = 13,800 hr·μg/mL, CL = 0.364 mL/hr/kg, Vd = 0.082 L/kg at 5 mg/kg). Toxicology studies in cynomolgus monkeys revealed a favorable safety profile, with a highest non-severely toxic dose (HNSTD) of 40 mg/kg after single dosing. Collectively, these findings highlight TRO-01 as a promising therapeutic candidate for the treatment of CLDN18.2-expressing gastrointestinal cancers.

#7165 The role of NEK2 and AURKB on triple-negative breast cancer progression.

Elliott Rodriguez-Lopez, Alexandra Aquino-Acevedo, Joel Orengo-Orengo, Gretchen Albarran-Acosta, Katiushka Berrocales, Harold Saavedra

Basic Sciences, Ponce Health Sciences University, Ponce, PR

Triple-negative breast cancer (TNBC) is the most aggressive subtype of breast cancer, accounting for 10-20% of all cases. TNBC's aggressiveness is mostly attributed to its high rates of chromosomal instability, proliferation, and metastatic potential. Molecular subtyping has revealed that overexpression of mitotic kinases NEK2 and AURKB is implicated in chromosomal instability and epithelial-to-mesenchymal transition (EMT). Recent studies have shown that the mitotic kinases NEK2 and TTK (a kinase regulated by AURKB) are involved in early metastatic signaling by promoting EMT, cell migration, and invasion through distinct transcriptional pathways. Despite their clinical relevance, no co-targeting therapeutic strategy exists to interrupt the distinct mitotic signaling pathways driven by these kinases. Thus, our study aims to investigate the functional convergence of NEK2 and AURKB signaling pathways as drivers of EMT and metastatic progression in TNBC. We hypothesize that NEK2 and AURKB cooperatively regulate mitotic and EMT-associated phosphorylation events that fuel early metastasis. Our approach leverages TNBC cell models representing ancestrally distinct origins (MDA-MB-231 and MDA-MB-157) and utilizes genetic knockdown to dissect how individual and dual suppression of NEK2 and AURKB alters the phosphorylation state and functional behavior of TNBC cells. Preliminary findings using Kaplan-Meier survival analysis confirm that high expression of NEK2 or AURKB is significantly associated with overall survival and relapse-free survival. STRING (Search Tool for the Retrieval of Interacting Genes/Proteins) protein-protein interaction analysis showed that both AURKB and NEK2 may converge on EMT-related processes, while STRING-based GO enrichment suggested that their inhibition may impair metastatic progression by disrupting EMT signaling in TNBC. Western blot analysis confirmed a decrease in EMT biomarkers Vimentin and Slug after individual and dual knockdown of NEK2 and AURKB. Moreover, invasion assays demonstrated a statistically significant reduction after individual and dual knockdown of both kinases. Overall, these results suggest that suppression of the mitotic kinases NEK2 and AURKB could disrupt EMT-associated metastatic potential in TNBC MDA-MB-231 cells. Ongoing experiments will further confirm and expand these findings. This project may advance the development of more effective precision-targeted approaches for TNBC, particularly for African American and Caribbean Hispanic/Latino women who are disproportionately affected.

[1]Department of Pathology, Oslo University Hospital, Oslo, Norway,[2]Department of Immunology, Oslo University Hospital, Oslo, Norway,[3]Department of Medical Genetics, Oslo University Hospital, Oslo, Norway,[4]Department of Breast and Endocrine Surgery, Akershus University Hospital, Oslo, Norway,[5]Department of Oncology, Akershus University Hospital, Oslo, Norway,[6]Department of Radiology, Akershus University Hospital, Oslo, Norway,[7]Department of Pathology, Akershus University Hospital, Oslo, Norway,[8]University of Oslo, Oslo, Norway,[9]KU Leuven, Leuven, Belgium

Background. Aromatase inhibitors like letrozole and exemestane play a pivotal role in the treatment algorithms for estrogen receptor (ER) positive breast cancer in all phases of the disease. However, resistance to such therapies is not fully understood and remains a major clinical challenge.
Methods. To investigate the mechanisms of sensitivity and resistance to aromatase inhibitors in ER-positive HER2-negative breast cancer, we conducted single-cell RNA (scRNA-seq), T cell receptor (scTCR-seq), and B cell receptor (scBCR-seq) sequencing on tumor biopsies obtained before and during neoadjuvant therapy with letrozole and exemestane given in a randomized sequence for 6 months.
Results. We examined 472,737 single cells from 73 biospecimens collected at baseline (n=25), at mid-therapy (n=24) and at the end of neoadjuvant treatment (n=24). We identified transcription start site usage at single cell level to study the role of enhancer activity in the evolution of breast tumors under treatment pressure. Malignant cells that were sensitive to treatment exhibited elevated ER-signaling and increased activity in enhancers containing ER binding sites. Conversely, resistant malignant cells showed upregulated androgen receptor (AR) signaling, cellular de-differentiation, and neuroendocrine-like characteristics. The activity of AR cis-regulome increased under treatment in non-responders, suggesting a role of epigenetic modifications in treatment resistance. Treatment-naïve tumor microenvironment was predictive of response. Non-responders displayed high proportions of naive lymphoid and undifferentiated myeloid cells, indicating an ineffective immune landscape. In contrast, responders were characterized by clonal expansion of T cells.
Conclusions. Taken together our longitudinal single-cell analyses delineate the genetic, epigenetic and cellular mechanisms that drive sensitivity and resistance to aromatase inhibitors in ER positive breast cancer, opening avenues for improved treatment strategies. Footnotes. Ilayda Altinönder and Villads Winton are shared first authors. Jürgen Geisler, Xavier Tekpli have jointly supervised this work.

#7170 AKT inhibition with capivasertib counteracts tumor microenvironment remodeling and enhances AR-targeted therapy in PTEN-deficient prostate cancer.

Marco A. De Velasco[1], Kazuko Sakai[1], Daiki Nakatsu[1], Mamoru Hashimoto[1], Saizo Fujimoto[1], Shingo Toyoda[1], Takafumi Minami[1], Kazuhiro Yoshimura[1], Simon T. Barry[2], Cath Eberlein[2], Claire Rooney[2], Kazuto Nishio[1], Hirotsugu Uemura[1], Kazutoshi Fujita[1]

[1]Kindai University Faculty of Medicine, Sakai City, Japan,[2]AstraZeneca, Cambridge, United Kingdom

Background: PTEN loss in prostate cancer activates PI3K/AKT/mTOR signaling, driving extensive tumor microenvironment (TME) remodeling characterized by stromal desmoplasia, angiogenesis, and immune suppression. Capivasertib (AZD5363), a potent pan-AKT inhibitor, has shown therapeutic benefit in PTEN-deficient tumors when combined with androgen deprivation therapy (ADT) and abiraterone, as demonstrated in preclinical studies and the Phase III CAPItello-281 trial.
Objective: To investigate how AKT inhibition modulates TME dysregulation in PTEN-deficient prostate cancer following AR-targeted therapy.
Methods: Conditional Pten-knockout mouse tumors underwent baseline transcriptomic profiling to characterize AKT-driven changes and ADT effects. TME responses were evaluated in conditional Pten/Trp53 knockout mice after four weeks of ADT and abiraterone (Abi), with or without capivasertib. Analyses included qRT-PCR panels, flow cytometry, and quantitative immunohistochemistry (IHC).
Results: PTEN deletion induced AKT hyperactivation and upregulated MSigDB hallmark pathways associated with TME remodeling, including hypoxia, angiogenesis, inflammatory response, IL6-STAT3, and TGFβ signaling. ADT amplified these changes, while abiraterone further increased extracellular matrix (ECM) remodeling gene expression. Capivasertib co-treatment significantly downregulated ECM and angiogenesis-related genes. Histological evaluation revealed reduced dense, haphazard collagen deposition and fewer inflammatory infiltrates in capivasertib-treated tumors. IHC confirmed decreased stromal p-S6 and p-PRAS40, lower Ki67-positive stromal cell counts, and reduced microvessel density (CD31). Gene signatures for PMN cells, MDSCs, and TAMs—key mediators of ECM remodeling—were diminished, particularly in mice showing strong antitumor responses to capivasertib. Flow cytometry and IHC corroborated the reduction of PMN/MDSC populations in treated tumors.
Conclusion: Capivasertib enhances tumor growth inhibition achieved by ADT plus abiraterone and mitigates TME remodeling associated with PTEN loss and AR-targeted therapy. These findings highlight AKT inhibition as a strategy to counteract TME-driven disease progression and improve therapeutic outcomes.

#7171 Antitumor and antiangiogenic activities of E7386 in combination with lenvatinib in human endometrial carcinoma xenograft models.

Yusuke Adachi, Yudai Narita, Shogo Yamaguchi, Taro Semba

Tsukuba Research Laboratories, Eisai Co., Ltd., Ibaraki, Japan

Background: E7386 is an inhibitor of the protein-protein interaction between CREB-binding protein (CBP) and β-catenin. Currently, a clinical study of E7386 in combination with lenvatinib (LEN), a multiple receptor tyrosine kinase inhibitor mainly targeting VEGFRs and FGFRs, is ongoing for the treatment of advanced solid tumors including endometrial carcinoma (EC) (NCT04008797). We previously reported that E7386 in combination with LEN showed greater antitumor activity and reduction of tumor microvessels than each agent alone in preclinical hepatocellular carcinoma tumor models. In this study, we investigated the antitumor and antiangiogenic activities of E7386 plus LEN in multiple human EC xenograft models.
Methods: Human EC cell lines (HEC151, HEC251, JHUEM2, and HEC50B) were subcutaneously inoculated into female nude mice. Mice with EC xenograft tumors were treated with E7386 at 6.25-50 mg/kg (orally [PO], once daily [QD]) and/or LEN at 10 mg/kg (PO, QD) for 7-14 days. Tumor microvessel analysis of formalin-fixed and paraffin-embedded tumor samples was performed by immunohistochemistry staining using the anti-CD31 antibody.
Results: E7386 in combination with LEN showed enhanced antitumor activity compared with either monotherapy alone without severe body weight loss (>20% body weight loss) in all EC xenograft models tested. Notably, tumor regression was observed by the combination treatment in HEC251 and HEC50B models. The enhancement of antitumor activity was consistently observed across models with E7386 doses at 25 and 50 mg/kg. Tumor microvessel analysis in the HEC151 model revealed that LEN monotherapy decreased the microvessel density, and the combination treatment showed more potent antiangiogenic activity compared with LEN monotherapy.
Conclusion: These results suggest that the combination of E7386 with LEN exerted enhanced antiangiogenic activity against tumor microvessels compared with LEN-alone, and demonstrated potent antitumor activity in preclinical EC xenograft models.

#7172 Combination of B7-H4-TOP1i ADC, PD-1/TIGIT bispecific antibody, and PARP inhibition orchestrates angiogenesis suppression and interferon-program activation in a syngeneic mouse model.

Octavio Morante-Palacios[1], Jon Chesebrough[2], Yoshimi Johnson[3], Raymond Rothstein[3], Varsha Shankarappa[4], Joseph Boland[5], Elizabeth Galery[5], Anna Dominika Staniszewska[6], Mark R. Albertella[6], Alex Cazes[2], Paul Chariou[3], Bilal Omar[3]

[1]Early Oncology Data Science, Oncology Data Science & AI, Oncology R&D, AstraZeneca, Barcelona, Spain,[2]Early Oncology- Oncology Targeted Delivery-Drug Conjugates, Oncology R&D, AstraZeneca, Gaithersburg, MD,[3]Clinical IO Discovery, IO Discovery & Cell Therapy Oncology, Oncology R&D, AstraZeneca, Gaithersburg, MD,[4]Oncology Data Science Platforms, Oncology Data Science & AI, AstraZeneca, Barcelona, Spain,[5]Translational Medicine, Oncology R&D, AstraZeneca, Gaithersburg, MD,[6]Bioscience, Oncology R&D, AstraZeneca, Cambridge, United Kingdom

Purpose: To define the pharmacodynamic mechanisms and synergies of a B7-H4 antibody-drug conjugate (ADC) with a topoisomerase I inhibitor (puxitatug samrotecan; AZD8205), a PD-1/TIGIT bispecific antibody (rilvegostomig; PD-1 arm engineered for murine binding), and a PARP1-selective inhibitor (saruparib), using single-cell RNA sequencing (scRNA-seq) in the MC38 hB7-H4 P1A9 murine syngeneic model.
Methods: C57BL/6J mice bearing MC38 hB7-H4 P1A9 tumors received vehicle, NIP228 (7 mg/kg ADC control), AZD8205 (7 mg/kg), rilvegostomig (10 mg/kg), saruparib (0.1 mg/kg), or doublet combinations. Tumors were collected on day 11 post-treatment and analyzed through scRNA-seq. scRNA-seq data underwent quality control, log normalization, dimensionality reduction, and clustering. After filtering, 356,930 high-quality cells across 38 samples were selected for downstream analyses (n = 4-5 per group). Gene set enrichment analysis (GSEA) using MSigDB Hallmark pathways was performed on pseudobulk differential expression analysis (DEA) profiles for each annotated cell type, comparing treatment groups. Enrichment was considered significant at FDR < 0.01 with |NES| > 1.5, and multiple testing correction was applied across all gene sets per cell type.
Results: All treatment groups showed increased immune infiltration versus vehicle. Pseudobulk DEA showed the most pronounced transcriptional changes occurred with AZD8205 in tumor cells, rilvegostomig in CD8+ T cells, and saruparib in macrophages. Doublet treatments suppressed epithelial-mesenchymal transition, hypoxia, and angiogenesis hallmarks in tumor cells, with decreased *Vegfa* expression, particularly in the AZD8205+ rilvegostomig group. CD8+ T cells from combination groups displayed heightened interferon response programs, and macrophages exhibited concordant interferon-response activation compared to single treatments. Further T cell sub-clustering revealed that rilvegostomig boosts effector T cells and reduces regulatory T cell representation, especially in combination with AZD8205.
Conclusions: scRNA-seq results indicate that the studied drug combinations produce a transcriptomic remodeling characterized by coordinated tumor-cell program suppression and system-wide interferon response amplification in immune cells. AZD8205 doublet treatments deliver the most extensive tumor-intrinsic transcriptional changes, while rilvegostomig or saruparib each add orthogonal immune activation, yielding complementary and potentially synergistic pharmacodynamics that are not observed with individual drugs. The ongoing BLUESTAR clinical trial (NCT05123482) is exploring these combinations in patients. Our preclinical findings suggest potential mechanisms of action and support further investigation.

#7173 Mechanistic studies of fibroblast activation protein activated prodrug AVA6000 in pancreatic and liposarcoma models.

Lisa Pickard[1], Ekta Paranjape[1], Brian Cunningham[2], **Udai Banerji**[2]

[1]The Institute of Cancer Research, London, United Kingdom,[2]The Institute of Cancer Research, London, London, United Kingdom

Background: This study shows single agent and combinatorial activity of AVA6000 (Faridoxorubicin, FAP-Dox), in pancreatic cancer and liposarcoma, cancer associated fibroblast co-culture models. Fibroblast activation protein (FAP) is a transmembrane serine protease and present in cancer associated fibroblasts and some cancer cells. AVA6000 is a FAP cleavable peptide drug conjugate comprised of doxorubicin and a dipeptide that is selectively cleaved by FAP to release active doxorubicin within the tumour microenvironment. We aimed to study a) FAP-specific release of doxorubicin b) combinatorial activity of AVA6000 with DNA damage repair inhibitors, in preclinical models.

Methods: Cancer cells, labelled with GFP, were co-cultured with pancreatic stellate cells (PSCs) showing features of myofibroblastic cancer associated fibroblasts (such as alpha smooth muscle antigen expression) which expressed FAP. Cancer cell growth was quantified by counting the number of GFP labelled cancer cells per well, with cancer cells alone (i.e. no CAFs) used as controls. In addition, we studied the effects of the FAP inhibitor Talabostat (PT100) in reversing the effects of AVA6000 in co-culture conditions. Further, we tested the effects of the combination of an ATR inhibitor BAY1895344 in combination with AVA6000 in the coculture system.

Results: The GI_{50} of AVA6000 in two pancreatic cancer cell lines ASPC-1 and Mia-Paca-2 in the co-culture system with PSCs was 58±21.4nM, (Stdev,n=3) and 66.5±16.3nM (Stdev, n=3). No GI_{50} was obtained in both cell lines at the highest concentration of AVA6000 studied in both cell lines (>100nM n=3) if PSCs were not included in the culture. In addition, we demonstrated that the FAP inhibitor talabostat at 100μM reversed any growth inhibition by AVA6000 (highest concentration of AVA6000 tested 100nM) confirming AVA6000 activation was FAP dependent. We further studied the growth inhibition of AVA6000 in the liposarcoma cell line SW872-GFP in co-culture with FAP expressing fibroblasts GI_{50} 30.6±6.7 nM (StdevD, n=4). The GI_{50} of AVA6000 was not achieved in the absence of fibroblasts at >100nM and the FAP inhibitor talabostat reverses this growth inhibitor effect in the co-culture system. The combination of AVA6000 and BAY1895344 in the co-culture yielded a 2 fold shift in GI_{50}.

Conclusions: AVA6000, is selectively activated by FAP expressing PSCs and is active in pancreatic and liposarcoma co-culture models. It also exhibits synergistic growth inhibition activity with ATR inhibitors in liposarcoma co-culture models. Clinical trials of AVA6000 are ongoing (NCT04969835).

#7174 Restoring antitumor immunity and improving immunotherapy outcomes in KRAS-mutant NSCLC through MYC inhibition by OMO-103.

Inigo Gonzalez-Larreategui[1], Silvia Casacuberta-Serra[2], Magda Arnal[2], Daniel Capitan-Leo[1], Sandra Martinez-Martin[2], Vera Adradas[3], Melina Peressini[3], Laura Vera[4], Lorena Sansegundo-Barbosa[2], Fabio Giuntini[1], Manuel Lillo-Valero[1], Manrique Valdes-Bango Martin[1], Erika Serrano del Pozo[1], Judit Grueso[1], Laia Foradada[2], Sergio Lopez-Estevez[2], Hugo Thabussot[2], Jonathan R. Whitfield[1], Marie-Eve Beaulieu[2], Jon Zugazagoitia[3], Silvestre Vicent[4], Laura Soucek[1]

[1]VHIO Vall D'Hebron Institute of Oncology, Barcelona, Spain,[2]Peptomyc S.L., Barcelona, Spain,[3]H12O-CNIO Lung Cancer Clinical Research Unit, Health Research Institute Hospital 12 de Octubre (imas12)/Spanish National Cancer Research Center (CNIO), Madrid, Spain,[4]Center for Applied Medical Research (CIMA), Pamplona, Spain

Background: MYC is a key oncogenic driver that promotes tumor progression, immune evasion, and therapy resistance. In KRAS-mutant non-small-cell lung cancer (NSCLC), where effective treatments remain limited, MYC functions as a major downstream effector of RAS signaling. High MYC expression in KRAS-mutant NSCLC patient samples is associated with reduced immune engagement and suppression of Tumor Necrosis Factor (TNF) superfamily pathway, suggesting a role for MYC in shaping the tumor immune microenvironment (TIME). We investigated whether MYC inhibition using OMO-103 (Omomyc), the first clinically viable direct MYC inhibitor, could reprogram the TIME and enhance immunotherapy response.

Methods: We performed transcriptomic analysis of KRAS-mutant NSCLC patient samples and generated a $KRAS^{G12D}$-driven transgenic mouse model exhibiting MYC-dependent immunosuppression. Using cell lines derived from this model, we evaluated the effects of MYC inhibition on proliferation and immune-related signaling. *In vivo* studies were conducted in multiple KRAS-driven NSCLC mouse models to assess tumor growth, immune infiltration, and TNF receptor pathway activation. Clinical relevance was examined through analysis of patient samples from the MYCure Phase I trial (NCT04808362).

Results: MYC inhibition impaired cell proliferation and upregulated multiple immune-activating pathways *in vitro. In vivo*, OMO-103 halted tumor progression, increased immune cell infiltration, and enhanced activation of TNF receptor family members—including OX-40 and 4-1BB—on tumor-infiltrating T cells, driving secretion of interferon-γ and TNF-α. Combining OMO-103 with TNFR-targeting immunotherapies resulted in significantly greater tumor regression and overall response rate than monotherapy. Analysis of MYCure patient samples confirmed that OMO-103 induces a more immune-active TIME, with increased interferon response and antigen presentation. Notably, patients with clinical benefit displayed increased expression of TNF superfamily members in tumors and serum, with the KRAS-mutant NSCLC patient showing the highest induction.

Conclusions: MYC inhibition with OMO-103 not only suppresses tumor growth but also reprograms the TIME to promote anti-tumor immunity and enhance response to immunotherapy. These findings support MYC blockade as a promising therapeutic strategy to overcome immunotherapy resistance in KRAS-mutant NSCLC.

#7175 Targeting spatial patterns of CAFs and tumor cells for precision stroma-targeted radionuclide therapy.

Yuning Sun[1], Ye Yang[2], Guanyu Zhu[3], Jiangang Zhang[1], Xiaowei Fan[4], Jian Wang[1], Yang Liu[1], Shaoyan Liu[1], Yansong Lin[5], Xi-Yang Cui[6], Zhibo Liu[7], **Ziren Kong**[1]

[1]Department of Head & Neck Surgery, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China,[2]Department of Pathology, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China,[3]Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China,[4]Changping Laboratory, Beijing, China,[5]Department of Nuclear Medicine, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China,[6]Institute of Radiation Medicine, Chinese Academy of Medical Sciences and Peking Union Medical College, Tianjin, China,[7]Beijing National Laboratory for Molecular Sciences, Radiochemistry and Radiation Chemistry Key Laboratory of Fundamental Science, NMPA Key Laboratory for Research and Evaluation of Radiopharmaceuticals, Key Laboratory of Bioorganic Chemistry and Molecular, Beijing, China

Stroma-targeted imaging, particularly fibroblast activation protein inhibitor (FAPI) PET-CT, has demonstrated remarkable diagnostic success across multiple cancer types. In contrast, stroma-targeted radionuclide therapy using ^{177}Lu-labeled compounds showed limited clinical efficacy (response rate: 10%-20%), despite achieving sufficient macroscopic accumulation within tumor lesions. We therefore hypothesize that the microscopic spatial organization between cancer-associated fibroblasts (CAFs) and tumor cells critically influences intratumoral distribution and radiation dose deposition of ^{177}Lu at the microscale. The primary objective of this study is to investigate how spatial pattern affects ^{177}Lu distribution and dose deposition, and to experimentally validate the differential therapeutic outcomes across different spatial patterns.Using medullary thyroid carcinoma (MTC) as a representative model, we performed quantitative histopathological analysis of 279 tissue sections from 15 patients through co-registration, automated image segmentation, and spatial distribution profiling. This identified two recurrent spatial patterns: a "surrounding" type, where CAFs form a continuous ring around tumor clusters, and an "infiltrative" type characterized by a reticular CAF network with dispersed tumor nests. These patterns were consistently observed across primary tumors, lymph node metastases, and invasive foci.Monte Carlo simulations revealed highly heterogeneous ^{177}Lu dose distributions across spatial patterns. While infiltrative lesions showed effective dose delivery, surrounding lesions exhibited dose deposition primarily confined to CAF-rich peripheries. We established biologically relevant 3D bioprinted models mimicking both patterns using 6% GelMA 30 hydrogel, which matches human thyroid mechanical properties (10-20 kPa). Immunohistochemical and immunofluorescence analyses confirmed biological fidelity. Autoradiography with [^{177}Lu]Lu-FS-86 demonstrated distinct uptake patterns - concentrated in CAF rings (surrounding) versus homogeneous distribution (infiltrative) - validating functional relevance.

These models confirmed that the infiltrative pattern allowed homogeneous dose distribution of ^{177}Lu and significant cell death, whereas the surrounding type exhibited limited penetration and limited response. Importantly, we observed consistent therapeutic outcomes across multiple cancer types including lung, liver, breast, and medullary thyroid carcinomas, indicating that stroma-targeted radionuclide efficacy is spatial pattern-dependent rather than tumor type-dependent. The establishment of this spatial classification system provides a framework for identifying optimal stroma-targeting radionuclides based on distinct spatial patterns, demonstrating significant potential for clinical translation.

#7176 Next-generation human vascularized tumor models reveal HER2-independent efficacy and reduced vascular toxicity of T-DXd.

Francesco Bonollo[1], Soheila Zeinali[1], Sabine Schneider[1], Christian Moser[2], Olivier Thierry Guenat[1]

[1]ARTORG Center, University of Bern, Bern, Switzerland,[2]vitronco AG, Bern, Switzerland

Purpose: Antibody-drug conjugates (ADCs) elicit complex responses that conventional 2D assays fail to capture, especially in HER2-low and HER2-negative tumors. We developed human vascularized 3D tumor models to assess the efficacy of HER2-targeting ADC, their mechanism of action, and vascular toxicity with improved physiological relevance.
Methods: Vascularized 3D breast cancer microtissues (HER2-positive and HER2-negative) were generated using human breast cancer cell lines and microvascular networks. Trastuzumab deruxtecan (T-DXd) or Trastuzumab-emtansine (T-DM1) treatment was performed for four days. Real-time monitoring was performed to assess anti-tumor efficacy and vascular toxicity by quantifying the tumor cell-associated fluorescent signal and vascular area density.
Results: T-DXd showed significant cytotoxicity in both HER2-positive and HER2-negative vascularized tumors, whereas in 2D monocultures, T-DXd cytotoxicity against HER2-negative cells was not detected. T-DM1 was effective only in HER2-positive vascularized tumors. T-DM1, unlike T-DXd, induced a strong vascular toxicity in both HER2-positive and HER2-negative tumor models with vascularization.
Conclusions: Human vascularized tumor models capture key pharmacodynamic features of ADCs, including the HER2-independent mechanism of action, extracellular payload activity, and vascular toxicity, which are not recapitulated in 2D systems. HER2-independent efficacy of T-DXd, but not of T-DM1, has also been reported in in vivo breast cancer xenograft models in agreement with these findings. Furthermore, real-time monitoring enabled quantification of tumor regression and vascular remodelling, underscoring the functional relevance and predictive performance of the platform. This platform offers a rapid, quantitative, and predictive approach for evaluating next-generation ADCs, thereby enhancing translational alignment with in vivo outcomes.

#7178 Targeted modulation of the blood-tumor barrier enhances drug delivery and survival in glioblastoma models.

Philippa C. Vaughn-Beaucaire[1], William Hawkins[2], Jasmine S. Clark[2], Jorge Luis Jimenez Macias[3], Bin Wu[4]

[1]Pathology and Laboratory Medicine, Brown University, Providence, RI,[2]Legorreta Cancer Center at Brown University, Providence, RI,[3]Brown University, Providence, RI,[4]Cytodigm, Natick, MA

Efficient drug delivery in glioblastoma (GBM) remains a major therapeutic challenge due to the restrictive properties of the blood-brain and blood-tumor barriers (BBB/BTB). We previously identified a BTB-associated transcriptional signature highlighting CDH5 (vascular endothelial cadherin) as a critical regulatory molecule highly expressed in GBM vasculature. Using bulk RNA sequencing and spatial transcriptomics, we confirmed that CDH5 and its associated genes are selectively enriched in tumor-associated endothelial cells compared with healthy brain tissue. Mechanistically, we show that the indirubin derivative 6-bromoindirubin acetoxime (BIA) significantly downregulates CDH5 and additional BTB-signature genes, including ACVRL1, ENG, and CD93. This molecular modulation disrupts endothelial barrier integrity, demonstrated by reduced trans-endothelial electrical resistance and increased dextran permeability in vitro, as well as enhanced intratumoral sodium fluorescein and cisplatin accumulation in vivo in murine GBM xenograft models. BIA treatment further augments cisplatin efficacy by increasing DNA damage, resulting in significantly extended survival compared with monotherapy. To investigate underlying mechanisms, we are assessing the effects of BIA on transcription factors involved in BBB regulation (including CREB and ERG) and on cytoskeletal dynamics. Given that BIA is a broad-spectrum kinase inhibitor with limited translational potential, we are actively evaluating FDA-approved kinase inhibitors, such as dasatinib. as clinically viable alternatives for rapid translation. Preliminary data indicate that dasatinib similarly disrupts BTB integrity and enhances chemotherapeutic penetration into GBM tumors. Ongoing studies are testing dasatinib's preclinical efficacy, specifically its impact on drug delivery, safety, and therapeutic effectiveness. Collectively, these findings position targeted BTB modulation as a promising therapeutic strategy. Leveraging both novel agents such as BIA and repurposed FDA-approved drugs like dasatinib may significantly enhance drug delivery, improve therapeutic outcomes, and ultimately benefit patients with GBM.

#7182 Development and evaluation of a novel high affinity PSMA-targeted radioligand ^{177}Lu-PSMA-3D1015 for prostate cancer.

Lu Hou[1], Quanpeng Wang[1], Haitian Fu[1], Chuang Xi[1], Wanggui Yang[2], Fangqiang Tang[2], Qing Gao[2], Lan Qin[2], Wenhua Huang[2], Henry Ho[2], Chunjing Yu[3], **John Gong**[2]

[1]Department of Nuclear Medicine, Affiliated Hospital of Jiangnan University, Wuxi, China,[2]3D Medicines Co., Ltd., Shanghai, China,[3]Department of Nuclear Medicine, Affiliated Hospital of Jiangnan University; Jiangnan University, Wuxi, China

Background: The clinical efficacy of PSMA targeted RLT for metastatic PCa has been well established by Pluvicto®. However, the suboptimal characteristics of existing agents, such as short tumor retention and rapid clearance, may limit the efficiency of radiation energy from ^{177}Lu decay. The small molecular compound, 3D1015, is a newly designed PSMA-targeted ligand with high affinity. Its radiolabeled product, ^{177}Lu-PSMA-3D1015 (hereafter "3D1015"), has been developed to prolong its retention in the tumor tissue, and has shown excellent tumor inhibition effect at low dose, along with great safety profile.
Method: The binding affinity of ligand to PSMA was evaluated using LNCaP cells via FACS-based competition assay, with PSMA-617 as a reference. In vivo biodistribution and efficacy were assessed in LNCaP xenograft B-NDG mice by calculating uptake (%ID/g) and measuring TGI (%) across dose groups. A single-dose toxicity study in SD rats was conducted to determine the dose tolerance and identify target toxic organs. An exploratory study further investigated the dosimetry and safety of 3D1015 in patients with PSMA-positive mCRPC who had failed SOCs. Eligible patients received a single administration of 3D1015 (10 mCi, *i.v.*) then underwent qSPECT/CT at different timepoints.
Results: IC_{50} values were 1.47 nM for 3D1015 ligand and 4.11 nM for PSMA-617. Radiolabeling with ^{177}Lu under mild conditions achieved >97% RCP. Biodistribution studies revealed rapid and sustained tumor uptake of 3D1015, reaching 36.50 %ID/g at 120 h, with renal excretion indicated by high kidney exposure (max: 59.47 %ID/g at 72 h). Efficacy studies demonstrated dose-dependent efficacy (TGI: 80.0%, 98.3%, and 99.8% at 0.1, 0.5, and 1.0 mCi/mouse, respectively). A dose of 0.5 mCi 3D1015 achieved superior TGI versus 1.0 mCi ^{177}Lu-PSMA-617 (TGI: 94.0%). Toxicity study identified the spleen as the primary target organ, with a MTD of 15 mCi/kg; transient toxicities in body weight, food intake, and hematology were fully reversible. Two patients received a single dose of 10 mCi of 3D1015. SPECT/CT imaging indicated that the drug was primarily excreted via the hepatobiliary/intestinal route rather than the renal excretion pathway as shown in the previous animal toxicity research. Uptake of *3D1015* was observed in all pre-identified lesions till 216 h. Mean absorbed dose in kidneys, submandibular and parotid glands, liver, spleen, and bone marrow was 0.80, 1.35, 0.44, 1.12, and 0.12 mGy/MBq, respectively. No > G2 TRAEs occurred. A 14% decline of PSA was observed in 1pts after one dose of 10mCi infusion.
Conclusion: ^{177}Lu-PSMA-3D1015 exhibits high PSMA affinity and prolonged retention in tumor, potentially driving potent efficacy at lower doses. Its distinct hepatobiliary excretion profile differentiates it from existing therapies. These findings address key limitations of current RLTs, and further clinical trials are ongoing.

#7183 SCN-PYTA: A new bifunctional chelator (BFC) for trivalent radiometals to develop target-specific radiopharmaceuticals for imaging and therapy.

Shankar Vallabhajosula[1], Nikki A. Thiele[2], Kyu J. Son[1], Vicente Navarro[1], Md Faizul Islam[2], Alex Brown[1], Neil H. Bander[1], Phillip W. Kantoff[1]

[1]Convergent Therapeutics, Inc., Cambridge, MA,[2]Chemical Sciences Division, Oak Ridge National Laboratory, Oak Ridge, TN

Introduction: The 18-membered macrocycle PYTA is a universal chelator that can complex trivalent radiometals (e.g., ^{225}Ac, ^{177}Lu, ^{111}In and ^{44}Sc) useful for imaging and targeted therapy (Chemical Sci 2024;15:11279-11286). The investigators at ORNL synthesized a BFC, SCN-PYTA, which contains an amine-reactive thiocyanate (SCN) group appended to the pyridine in the PYTA chelator. To establish PYTA as a platform to prepare theranostic radiopharmaceuticals, we investigated the conjugation characteristics of SCN-PYTA to monoclonal antibodies (mAb) and radiometals (^{111}In and ^{225}Ac) to define the chelation properties of PYTA-mAb conjugates. For direct comparison, labeling studies were performed using two other BFCs: SCN-DOTA and SCN-Macropa.

Materials and Methods: Anti-PSMA mAb, rosopatamab and anti-TROP-2 mAb, sacituzumab solutions at 10 mg/mL were prepared in sodium carbonate buffer, pH 9.0±0.2. The BFC solutions (at 5-10 mg/mL) were prepared in metal-free water. Different molar ratios of BFC to mAb were incubated at 37^{o}C for 90 min. The chelate conjugated mAbs were purified by gel chromatography and 0.05 M HEPES buffer, pH 7.5. The chelator:antibody ratios (CAR) were determined using a modified colorimetric arsenazo assay. Chelate-antibody conjugates (0.025-2.0 mg) were incubated (at RT or 37^{o}C) with 0.05-0.5 mCi of ^{225}Ac or ^{111}In chloride in sodium acetate or tetramethylammonium acetate buffer, pH 6±0.3. Radiolabeled mAbs were purified using PD-10 gel permeation chromatography and saline solution containing 1% albumin, and assessed for radiochemical purity (RCP), stability, and immunoreactivity.

Results: PYTA and Macropa conjugated mAbs complex ^{225}Ac or ^{111}In radionuclides very efficiently at RT within 5 min with labeling yields of >97%. The radiochemical purity (RCP) of purified ^{225}Ac-chelator-mAb preparations were >99%. In contrast, DOTA-conjugated mAbs do not label efficiently at RT. Higher labeling yield (80-95%), however, can be obtained at 37^{o}C with longer incubation of 1-2 hours. ^{225}Ac-PYTA-mAbs showed remarkably high in vitro stability at 2-8^{o}C for >10 days (with >99% RCP). Similar stability was observed when challenged with serum or excess chelate (EDTA and DTPA) concentrations. Based *on in vitro* cell binding studies using PSMA+ LNCaP cells and TROP-2+ MCF-7 cells, the immunoreactive fraction (IRF) of ^{225}Ac-PYTA-Rosopatamab and ^{225}Ac-PYTA-Sacituzumab at an infinite antigen concentration (Lindmo assay) was >99%.

Conclusion: SCN-PYTA is an ideal BFC and a suitable platform to develop target specific imaging and therapeutic radiopharmaceuticals based on trivalent radiometals, peptides, proteins, and small molecules. Our preliminary data also suggests that radiolabeled sacituzumab has significant potential as a theranostic radiopharmaceutical for imaging and targeted therapy of TROP-2 positive cancers.

#7184 GT-008: A monoclonal antibody enabling selective radionuclide delivery to a tumor-associated glycosylation form of CD24 - Preclinical proof-of-concept study.

Johanna Gellert, **Andreas Franz**, Manon Weis, Evelyn Hartung, Stephanie Gurka, Lydia Verlaat, Sophie Marinoff, Antje Danielczyk, Patrik Kehler, Dirk Pleimes

Pentixapharm AG, Berlin, Germany

Aberrant O-glycosylation is a hallmark of cancer and many tumor-associated proteins carry truncated O-glycans like Tn or TF antigens. CD24 is a glycoprotein with a fundamental role in tumorigenesis, expressed on solid tumors, but also on selected normal cell types. We developed a humanized IgG1 mAb (GT-008) which binds CD24 only in presence of tumor-associated TF (core-1) glycosylation with limited abundance on normal tissues. This glycoform-selective recognition enables GT-008 to distinguish tumor from normal CD24 and mediate its mode of action in a tumor-selective manner. Unlike protein-specific anti-CD24 antibodies that block the “don’t-eat-me” checkpoint, GT-008 exploits its glycosylation-dependent binding of CD24 for direct cytotoxic activity, including selective radionuclide delivery to tumors. Binding specificity and tumor selectivity of GT-008 was analyzed by ELISA, FACS and immunohistochemistry. After bioconjugation and radiolabeling, *in vitro* validation comprised binding and internalization assays with breast cancer cell lines. The pharmacokinetic profile of GT-008 was analyzed in athymic nude mice. Biodistribution and efficacy studies were performed in a cell-line derived xenograft breast cancer model. GT-008 demonstrated selective recognition of cancerous tissues, including including female cancers of the breast, endometrium and ovaries. It exhibited high-affinity binding in the low nM range and internalization in breast cancer cells, while showing no internalization in healthy CD24+ immune cells. Biodistribution studies showed specific and stable uptake in MCF7 tumors and clearance from other organs resulting in high tumor-to-organ ratios. Therapeutic single doses of GT-008 labeled with alpha or beta radiation emitting isotopes (^{225}Ac-GT-008, 10 + 3 kBq; ^{177}Lu-GT-008, 10 + 3 MBq) resulted in robust control of MCF7 breast tumors. Due to the high linear energy transfer and potent DNA-damaging capacity of α-emitters, ^{225}Ac-GT-008 achieved superior tumor growth inhibition and a higher rate of complete remissions compared with ^{177}Lu-GT-008. All treatments were well tolerated. These findings supports the development of GT-008 as a theranostic radioligand for solid tumors, including female cancers, while supporting its broader potential across CD24-directed modalities such as ADCs, bispecifics, and cellular CAR therapies.

#7185 ^{225}Ac-RAX104: A novel PSMA-targeted radioligand optimized for actinium-225 demonstrates enhanced tumor retention and superior efficacy.

Xupeng Hu, Yang Cao, Min Hong, Shuanglong Liu, **Guangzhou Han**, Gang Chen

RadAlliance Therapeutics Inc, San Diego, CA

Prostate cancer is the second most common malignancy in men and remains a significant cause of cancer-related mortality worldwide. Although the clinical success of ^{177}Lu-PSMA-617 (Pluvicto) has established PSMA-targeted radioligand therapy (RLT) as an effective treatment for metastatic castration-resistant prostate cancer (mCRPC), emerging clinical evidence indicates that ^{225}Ac-based RLT can deliver even greater therapeutic efficacy owing to the high linear energy transfer of α-particles and the radionuclide's 9.92-day physical half-life. To fully exploit these properties, ^{225}Ac-RAX104 was rationally designed to enhance PSMA affinity and tumor retention, thereby kinetically matching the physical and radiobiological characteristics of ^{225}Ac to maximize antitumor potency. RAX104 was successfully synthesized and radiolabeled with ^{225}Ac at a molar activity of up to 3 μCi/nmol, achieving radiochemical purity greater than 95% and maintaining stability for more than 110 hours. Surface plasmon resonance analysis revealed that the RAX104 precursor exhibited approximately 22-fold higher affinity for PSMA than PSMA-617, primarily driven by slower dissociation kinetics. In PSMA-overexpressing PC3 cells, ^{225}Ac-RAX104 showed markedly enhanced cellular uptake and internalization compared with ^{225}Ac-PSMA-617. In PSMA-low 22Rv1 xenografts, ^{225}Ac-RAX104 achieved more than 3-fold higher tumor-absorbed activity ($AUC_{0-\infty}$) and a significantly prolonged biological half-life in tumors relative to ^{225}Ac-PSMA-617, while both radioligands showed comparable blood pharmacokinetics. Consistent with these pharmacokinetic advantages, ^{225}Ac-RAX104 demonstrated superior antitumor efficacy: a single 14.8 kBq dose produced greater tumor growth inhibition and longer survival than 74 kBq (fivefold higher activity) of ^{225}Ac-PSMA-617 in the 22Rv1 model. Toxicity evaluation in normal ICR mice revealed only transient and reversible reductions in white blood cell, neutrophil, and reticulocyte counts, without clinical chemistry abnormalities, indicating a favorable safety profile. An investigator-initiated trial (IIT) of ^{225}Ac-RAX104 has been proposed in mCRPC patients to generate human dosimetry data to inform the design of subsequent clinical studies. Collectively, these results demonstrate that ^{225}Ac-RAX104 achieves optimal kinetic alignment with ^{225}Ac's physical decay and biological action, delivering enhanced tumor exposure and potent therapeutic efficacy at one-fifth the dose of ^{225}Ac-PSMA-617. These findings support ^{225}Ac-RAX104 as a promising next-generation PSMA α-radioligand therapy with the potential to improve outcomes in mCRPC and warrant further clinical development.

#7186 Characterization of LY4257496, a novel GRPR antagonist radiolabeled with lutetium-177.

Shreyas Lingadahalli[1], Gabriela Krivdova[1], Kate Huang[1], David Rodriguez[1], Matt Alteen[1], Chun Ping Yu[2], Chantal Trieu[1], Loredana Puca[3], Robin Hallet[1]

[1]Eli Lilly Canada, Toronto, ON, Canada,[2]Eli Lilly, China R&D Center, Shanghai, China,[3]Eli Lilly and Company, New York, NY

Background: Gastrin-releasing peptide receptor (GRPR) is a G protein-coupled receptor overexpressed in HR+ breast cancer and other solid tumors while having low expression in normal tissues. Although first generation GRPR antagonists have demonstrated utility in diagnostics, their therapeutic potential is limited by poor *in vivo* stability. Here, we present the preclinical profile of LY4257496, a novel GRPR antagonist labeled with lutetium-177, which shows favorable biodistribution, resistance to systemic cleavage, and promising tumor-to-healthy tissue uptake ratio.
Methods: The binding affinity of LY4257496 was evaluated by a competitive binding assay in CHO cells engineered to express human, mouse, and rat specific GRPR isoforms. Biodistribution of LY4257496 (10MBq, 100MBq/nmol) was evaluated in T47D-tumor bearing and non-tumor bearing female mice. Efficacy of LY4257496 was evaluated as mono- and combination therapy in T47D xenografts and clinically relevant HR+ breast cancer PDX models.
Results: A competitive binding assay revealed that LY4257496 specifically bound to GRPR in human, mouse, and rat at comparable nanomolar potency of 8.5, 7.2, and 10.6 nM respectively. In biodistribution analyses, LY4257496 exhibited favorable pharmacokinetics with rapid tumor targeting and prolonged retention (% ID/g 22.6 at 1h, 11.6 at 24h), fast clearance from normal organs (all tissues below 3.5 % ID/g at 24h), and > 50% renal excretion. LY4257496 was well tolerated at 10, 20 and 30MBq (Q14DX2), and efficacy was dose dependent in T47D xenografts (26, 72, and 72 % TGI, respectively). Efficacy was additive when 20MBq (Q14DX2) LY4257496 dose was given in combination with standard-of-care (SoC) therapies including imlunestrant, fulvestrant, and abemaciclib resulting in 40, 32, and 38% tumor regression, respectively at end of treatment (day 28). No tumor regression was observed with SoC therapies alone. LY4257496 also potently inhibited tumor growth in 3 HR+ breast cancer PDX models; 92% TGI (HER2+, PIK3CA:H1047R, and ESR1:Y537S), 58% TGI (HER2-), and 56% TGI (HER2+). These findings demonstrate that LY4257496 is a promising targeted radioligand therapy for tumors with GRPR expression. OMNIRAY, a phase 1 study evaluating LY4257496 in patients with GRPR+ advanced or metastatic disease is ongoing (NCT07114601).

#7187 Preclinical evaluation of BRP-020063, a first-in-class peptide based radiopharmaceutical for the treatment of nectin4-positive cancers.

Maoyi Lei, Lei Peng, Bo Shan

Boomray Pharmaceuticals, Co., Ltd., Suzhou, China

Background: Nectin-4 is aberrantly overexpressed in multiple solid tumors (e.g., bladder, breast, and non-small cell lung cancers, etc.), while showing limited expression in normal tissues. This specific expression reveals that it is a promising drug target for Radionuclide Drug Conjugates (RDC). Here, we describe the preclinical evaluation of BRP-020063, a novel peptide binder based RDC with excellent drug-like properties.
Methods: The protein binding affinity and selectivity of BRP-020063 were determined by surface plasmon resonance (SPR). Cell binding and internalization were characterized in PC3 cells engineered to express human Nectin4 (PC3-Nectin4) by radioligand binding assays using ^{177}Lu[Lu]-BRP-020063. Both of SPECT/CT imaging and *ex vivo* biodistribution studies in PC3-Nectin4 tumor-bearing mice were performed to evaluate the pharmacokinetics of ^{177}Lu[Lu]-BRP-020063. In addition, in vivo antitumor efficacy studies of ^{177}Lu[Lu]-BRP-020063 were also performed in the same cell derived xenograft (CDX) model to assess the therapeutic effect.
Results: SPR studies showed BRP-020063 exhibited picomolar to nanomolar binding affinity to Nectin4 protein of human, mouse, rat, and cynomolgus monkey, and no binding to other members of the human Nectin-family (hNectins1-3, K_D > 10 μmol/L). Potent cellular binding was confirmed in PC3-Nectin4 cells with nanomolar affinity. Cell uptake studies on PC3-Nectin4 cells and parent PC3 cells (PC3-WT) showed ^{177}Lu[Lu]-BRP-020063 specific bound to Nectin4. Meanwhile, ^{177}Lu[Lu]-BRP-020063 gave efficient internalization on PC3-Nectin4 cells. The SPECT/CT imaging of ^{177}Lu[Lu]-BRP-020063 demonstrated high tumor uptake and long-term tumor retention. The tumor uptake reached the peak (54.91±6.43% ID/g) at 24 h post-injection, and still remained 6.22±1.31% ID/g at 240 h post-injection. *Ex vivo* biodistribution studies further confirmed the remarkably robust and sustained tumor uptake of ^{177}Lu[Lu]-BRP-020063, the tumor uptake reached the inspiring 61.18±9.96% ID/g at 24 h post-injection, and maintained 25.50±5.10% ID/g at 72 h post-injection. The resulting tumor-to-kidney ratios were 2.34 at 24 h and 2.15 at 72 h post-injection. In addition, a single dose of 0.5 mCi or 1 mCi ^{177}Lu[Lu]-BRP-020063 per mouse led to robust and sustained tumor regression and prolonged animal survival.
Conclusion: The preclinical *in vitro* and *in vivo* data demonstrate that ^{177}Lu[Lu]-BRP-020063 possesses excellent target specificity, favorable pharmacokinetic properties, and potent antitumor efficacy. These findings strongly support further investigation of the novel therapeutic ^{177}Lu[Lu]-BRP-020063 as a treatment for patients with Nectin4-positive solid tumors.

#7188 Theranostics targeting the calcitonin gene-related peptide receptor (CGRPR) demonstrate efficacy in a preclinical mouse model of human cancer.

Prabhakar Eeka[1], Darpan N. Pandya[1], Andrew F. Russo[2], Yusuke Shiozawa[3], Thaddeus J. Wadas[1]

[1]Radiology, University of Iowa, Iowa City, IA,[2]Molecular Physiology and Biophysics, University of Iowa, Iowa City, IA,[3]Cancer Biology, Wake Forest University Health Sciences, Winston-Salem, NC

Introduction: Recent literature demonstrates that the CGRPR, and its primary ligand, calcitonin gene-related peptide (CGRP) are implicated in 9 of the 14 hallmarks of cancer and contribute to the development of multiple primary cancers. Here, we developed a theranostic strategy for the SPECT imaging and targeted radiotherapy of CGRPR-positive tumors.

Methods: The CGRPR-specific bioconjugate DOTA-Bn-NCS-FV-Tic-TDVGPFAF (ACP) was radiolabelled with ^{111}In (SPECT: $t_{1/2}$ = 2.8 d; $E_{e\text{-}max}$ = 0.245 MeV) or ^{177}Lu (β - emitter: $t_{1/2}$ = 6.7d; $E_{\beta\text{-}max}$ = 0.497 MeV). Biodistribution studies in CGRPR+ HTB-10 tumor-bearing mice were conducted using [^{111}In]In-ACP and radioactivity in tissue was quantified against a known radioactivity standard. Therapy studies with [^{177}Lu]Lu-ACP in the same tumor bearing model were also completed. As animals reached clinical endpoints, the animals were euthanized and processed for histology. QuPath software was used to quantify immunohistochemistry images, while survival and statistical analysis was accomplished using GraphPad Prism v.10.2.

Results: The acute biodistribution of [^{111}In]In-ACP revealed rapid excretion from blood, liver, kidney and bone suggesting effective clearance that may lead to acceptable dosimetry in dose-limiting organs such as the kidney and bone marrow. A tumor-to-muscle ratio of 39 at 4 h p.i., which was reduced to 12 with peptide blockade suggests that the radiopharmaceutical interacts with the CGRPR through a receptor mediated mechanism. Radiotherapy studies revealed that CGRPR+ HTB-10 tumor bearing mice injected with [^{177}Lu]Lu-ACP experienced a survival benefit when compared to animals receiving control treatments ($p = 0.036$). When analysed histologically, tumor sections from animals receiving the radiotherapy exhibited decreased Ki-67 staining (proliferation marker) but higher caspase-3 (apoptosis marker) staining when compared to tumor sections of untreated animals.

Conclusion: Although the CGRPR/CGRP axis is implicated in cancer development, no theranostic strategies exist currently that target this receptor for imaging and therapy. Available data with [^{111}In]In-ACP revealed effective tumor targeting and rapid clearance from normal tissues, while radiotherapy studies with [^{177}Lu]Lu-ACP demonstrated effective tumor growth control. These results suggest targeting the CGRPR/CGRP axis warrants further exploration as a promising new strategy for the imaging and therapy of cancer.

#7189 Innovative theranostic Trop2 antibody-radionuclide conjugates (ARCs) for precision medicine.

Shih-Hsien Chuang[1], Wei-Ting Sun[1], Michael Evans[2], Haibo Xu[2]

[1]HoneyBear Biosciences, Inc., Taipei, Taiwan,[2]University of California San Francisco, San Francisco, CA

Theranostic antibody conjugates are an emerging class of therapeutics that combines an antibody with radionuclides that can both diagnose and treat disease. We have developed a site-specific Trop2 antibody-radionuclide conjugate (ARC), incorporating 89Zr for imaging and 225Ac for therapy. The imaging ARC, leveraging the long half-life of 89Zr, demonstrates strong tumor accumulation and favorable tumor-to-normal tissue (T/N) ratios across multiple xenograft models, including triple-negative breast cancer and non-small cell lung cancer. The therapeutic ARC, carrying an alpha-emitting radionuclide, effectively suppresses tumor growth in the corresponding xenograft models. This ARC is currently in preclinical development, with an investigational new drug (IND) application planned for 2026.

#7190 Novel peptide radioligands targeting CAIX for theranostic applications in clear cell renal cell carcinoma (ccRCC).

Weiliang (Timo) Xu, Jin Zhang

PepLib, Metuchen, NJ

Carbonic anhydrase IX (CAIX) is a hypoxia-inducible transmembrane enzyme highly expressed in clear cell renal cell carcinoma (ccRCC) and several other solid tumors, making it an attractive target for radiotheranostic development.Using PepLib's peptide discovery and optimization platform, we identified a monocyclic peptide ligand, 4B043 (19 amino acids, one disulfide bond) as a high-affinity CAIX binder. 4B043 exhibited sub-nanomolar affinity to human CAIX ($K_D \approx 86$ pM) and strong cross-species binding to canine, mouse, and cynomolgus monkey CAIX. In Balb/c nude mice bearing VMRC-RCW tumor models, ^{68}Ga-4B043 showed high tumor uptake (~55 %ID/g) with a tumor-to-kidney (T/K) ratio ≈ 0.5 at 4 h post-injection. After structural optimization, ^{68}Ga-2B002 maintained high tumor uptake while significantly reducing kidney accumulation (T/K ≈ 2 at 4 h). Encouraged by these preclinical data, ^{68}Ga-4B043 was advanced into a human IIT. In ccRCC patients, ^{68}Ga-4B043 demonstrated high uptake in renal tumor lesions. Due to CAXI expression in normal gastric and small intestinal tissues, ^{68}Ga-4B043 also showed notable uptake in these organs in patients. Notably, kidney uptake was remarkably low in patients, with a tumor-to-kidney ratio > 8 at 2 h, in clear contrast to the CDX model.4B043 and its optimized derivative 2B002 represent a novel class of CAIX-targeted peptide radioligands with excellent tumor uptake, favorable biodistribution, and promising translational potential. These data support their further development as theranostic agents for imaging and targeted radioligand therapy in CAIX-expressing tumors, including ccRCC.

#7191 6-thio-dG enhances standard-of-care radiation therapy by reprogramming the tumor microenvironment in glioblastoma multiforme.

Anthony Alexander Grichuk[1], Merve Yilmaz[1], Summer Barron[1], Priya Darbha[1], Shannon M. McCabe[2], Jerry W. Shay[3], Kristin Huntoon[4]

[1]Cell Biology, UTSW, Dallas, TX,[2]Neurosurgery, University of Arizona, Tucson, AZ,[3]Professor, Dept. of Cell Biology, UT Southwestern Medical Ctr., Dallas, TX,[4]UA faculty member, Neurosurgery, University of Arizona, Tucson, AZ

Background/Objectives - Glioblastoma multiforme (GBM) remains highly lethal, with a five-year survival rate of only 6.9%. Standard-of-care treatments such as ionizing radiation (IR) and temozolomide frequently fail to produce durable responses due to poor drug penetration across the blood-brain barrier (BBB) and the immunosuppressive tumor microenvironment (TME). 6-thio-2'-deoxyguanosine (6-thio-dG) is a telomerase-mediated telomere-targeting guanine analog that induces telomeric DNA damage selectively in telomerase-positive tumor cells. This process activates the cGAS-STING pathway, triggers innate and adaptive immune responses and has previously resensitized resistant tumors to immunotherapy in a Phase 2 NSCLC clinical trial. We hypothesized that 6-thio-dG penetrates the BBB and enhances the therapeutic efficacy of IR by reprogramming the GBM TME.
Methods - GBM models were treated with 6-thio-dG alone, IR alone, or sequential 6-thio-dG followed by IR. Immune signaling, microglia/macrophage phenotypes, and tumor responses were assessed via molecular, histological, and functional analyses.
Results - Sequential 6-thio-dG + IR treatment significantly increased type I interferon (IFN-I) activation and shifted microglia/macrophages toward a pro-inflammatory M1 phenotype. This TME reprogramming resulted in a statistically significant anti-tumor effect relative to monotherapy.
Conclusions - 6-thio-dG enhances IR efficacy in GBM by inducing telomere-driven immune activation and promoting an anti-tumor TME. These findings support 6-thio-dG as a promising adjuvant to standard-of-care and justify further investigation of telomere-targeted combination strategies.

#7192 FLASH reduces radiation-induced oral mucositis in a mouse model of Fanconi anemia.

Phoebe Loo[1], Margaret Pan[1], Man Zhao[1], Stavros Melemenidis[2], Dixin Chen[1], Kerriann M. Casey[1], Michael Epperly[3], Joel S. Greenberger[4], Billy W. Loo[1], Erinn Rankin[1]

[1]Stanford University School of Medicine, Stanford, CA,[2]University of Colorado Anschutz, Aurora, CO,[3]University of Pittsburgh, Pittsburgh, CA,[4]University of Pittsburgh Shadyside Medical Center, Pittsburgh, PA

Patients with Fanconi anemia (FA) are particularly susceptible to developing squamous cell carcinomas of the head and neck regions due to impaired DNA repair pathways. However, their hypersensitivity to DNA damaging agents can limit effective treatment with standard radiotherapy due to severe side effects and complications. In pre-clinical models, ultra-rapid FLASH radiotherapy (FLASH) has been demonstrated to reduce radiation-induced toxicity to multiple normal tissues while maintaining similar tumor control compared to conventional dose rate radiotherapy (CONV) in a wild-type background. Here, we investigated the safety of FLASH for treatment of the head and neck region in a mouse model of FA. The oral cavity of 129/Sv wild-type (WT) and Fanca-knockout (KO) mice was irradiated with a single dose of electron beam FLASH or CONV to evaluate radiation-induced toxicity in non-tumor bearing mice. Fanca WT and KO mice were irradiated with 25 and 18 Gy, respectively, of FLASH (190 Gy/sec) or CONV (0.2 Gy/sec), and tongues were harvested at 12 hours (hpi) and 10 days (dpi) post-irradiation. Following excision, tongues were stained with toluidine blue to visualize ulceration. At 10 dpi, FLASH-irradiated tongues in both genetic backgrounds demonstrated a reduced area of ulceration, expressed as a fraction of total tongue area, at the dorsal surface compared to CONV-irradiated counterparts. Histopathological analysis of the tongue revealed lower mucositis severity scores, reflected by decreased epithelial thinning and ulceration, in FLASH-irradiated tongues compared to CONV-irradiated ones. Analysis of γ-H2AX foci formation at 12 hpi demonstrated a decreased number of foci in the WT background with FLASH compared to CONV and a similar trend in the KO background. These findings suggest a potential normal tissue sparing effect with FLASH and hold important clinical implications for the treatment of patients with Fanconi anemia and head and neck cancers.

#7193 Short exposure to TTFields potentiates radiation response in glioblastoma via downregulation of DNA repair pathways.

Anat Klein-Goldberg[1], **Tali Voloshin**[1], Aviv Meir[1], Efrat Zemer-Tov[1], Hila Ene[1], Lena Lifshitz[1], Kerem Wainer-Katsir[1], Adi Haber[1], Moshe Giladi[1], Uri Weinberg[2], Yoram Palti[1]

[1]Novocure Ltd, Haifa, Israel,[2]Novocure GmbH, Baar, Switzerland

Background: Tumor Treating Fields (TTFields) therapy, which delivers low-intensity, alternating electric fields to disrupt cellular processes crucial for cancer cell division, is an FDA-approved modality for patients with newly diagnosed and recurrent glioblastoma (GBM). Beyond its established antimitotic effects, TTFields have been shown to interfere with DNA damage repair pathways, suggesting potential synergy with radiation therapy (RT). In this study, we explored whether brief exposure to TTFields can sensitize GBM cells to radiation.
Methods: U87-MG GBM cells were exposed to 2 Gy radiation, to TTFields (200 kHz, 2h), or to TTFields followed by radiation, and colony formation was tested. RNA extracts from control and TTFields-treated cells were examined by PCR for changes in DNA damage response genes. Western blot analyses assessed changes in protein levels of DNA repair genes FANCD2, FANCJ, FANCA, FANCB, BRCA1, and BRCA2. C57BL/6 mice were intracranially implanted with GL261-mCherry glioma cells and tumor growth was confirmed by MRI on day 17 post-implantation. Mice were then randomized into treatment groups receiving TTFields (200 kHz), RT (6 Gy) or the two modalities together with various sequencing: TTFields pre-RT, TTFields post-RT, or TTFields both pre- and post-RT. Tumors were harvested for single-cell suspension preparation, and DNA damage was quantified by flow cytometry using γH2AX staining.
Results: Short exposure to TTFields alone was insufficient to reduce colony formation of the cells. However, when TTFields were applied prior to RT, colony formation was decreased relative to that for RT alone. The TTFields-treated cells demonstrated downregulation of genes and proteins associated with DNA damage repair. In mice, while TTFields post-RT had negligible effects on tumor DNA damage levels relative to application of RT alone, TTFields prior to RT resulted in increased DNA damage and reduced expression of DNA repair protein within tumor cells, with no elevation of DNA damage in tumor infiltrating immune cells. When TTFields were applied both pre- and post-RT, increased DNA damage was demonstrated in the tumor.
Conclusions: Our findings demonstrate that GBM can be radiosensitized by short exposure to TTFields, and that timing and sequencing are important for maximizing the effect.

#7194 Inhibiting glutamine metabolism in combination with radiation disrupts mitochondrial function and impairs homologous recombination.

Scott Bright[1], Yogesh Rai[1], Rishab Kolachina[2], Hadil Elldakli[1], Mark D. Wasley[1], Gabriel O. Sawakuchi[1]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]Augusta University, Augusta, GA

A mainstay of lung cancer treatment is radiotherapy. With our ever-increasing ability to genomically stratify patients, it is now possible to identify biomarkers that contribute to radioresistance or radiosensitivity. Mutations in the gene Kelch-like ECH-associated protein 1 (KEAP1) are associated with resistance to radiotherapy resulting in greater local recurrence and poorer patient outcomes. Mutations in KEAP1 lead to Nuclear Factor (erythroid-derived) 2-like Factor (Nrf2) nuclear translocation where it acts as a transcription factor promoting the formation of antioxidant proteins. However, while tumors harboring KEAP1 mutations are more resistant to therapy, they also rely heavily on the amino acid glutamine, which is processed by the enzyme Glutaminase-1 (GLS1) to meet the metabolic demands associated with the constitutive activation of Nrf2. Disrupting glutamine metabolism in KEAP1 mutant cells and tumors using small molecule inhibitors has shown promise as a radiosensitizing strategy. At a basic mechanistic level this has been attributed to a reduced glutamate level, leaving cells unable to produce the antioxidant glutathione, therefore increasing oxidative stress following radiotherapy. This in turn contributes to greater levels of DNA damage and more cell death. Our data support the radiosensitizing effect of GLS1 inhibition in KEAP1 mutant cells, for both photons and protons, with associated increases in oxidative stress, specifically mitochondrial superoxide. In addition to this basic concept, we hypothesize that the profound metabolic disruption induced by inhibiting glutamine metabolism has implications for not only DNA damage induction but also DNA repair. To investigate this, we first explored DNA damage response (ATM) and pathway specific DNA repair (Rad51) proteins, alongside the comet assay to measure total DNA damage. Our results identified that the inhibitor IACS-6274, which inhibits GLS1, increased total DNA damage measured by the alkaline comet assay but abrogated foci formation for both phosphorylated-ATM and Rad51 (homologous recombination [HR]). We also observed significant synergy when IACS-6274 was combined with PARP or ATR inhibitors in the absence of radiation. In parallel, we determined that mitochondrial membrane potential measured using the dye, TMRM, is significantly reduced along with reduced ATP production in GLS1 inhibited cells.

In summary, our results show that KEAP1 mutant lung cancer cells treated with a GLS1 inhibitor can be significantly radiosensitized to radiotherapy, and this in part maybe attributable to reduced HR proficiency. We propose that either bioenergetic crisis prevents fueling of HR processes or that impaired TCA cycle anaplerosis reduces α-ketogluterate levels, which is an important co-factor for chromatin remodeling preventing DNA end resection and resulting Rad51 foci formation.

#7195 Blocking hERG1 enhances radiation sensitization in glioblastoma.

Hannah E. Goen[1], Naya Ohuabunwa[2], Jonathan D. Rodgers Gochicoa[3], Tingting Huang[4], Kelli B. Pointer[4]

[1]Mount Holyoke College, South Hadley, MA,[2]Washington University in St. Louis, St. Louis, MO,[3]Dartmouth College, Hanover, NH,[4]Dartmouth Cancer Center, Lebanon, NH

Background: Glioblastoma (GBM) is the most aggressive primary brain tumor in adults, with a median survival of less than two years. Poor outcomes are driven in part by glioma stem cells (GSCs) that resist radiation and repopulate the tumor. The voltage gated potassium channel hERG1 (KCNH2) is upregulated in GBM and linked to therapy resistance, suggesting that its inhibition might improve radiotherapy efficacy.
Methods: Human GBM cell line LN-229 and patient derived GSC line GNS144 were cultured as spheres. IC_{50} values for the selective hERG1 inhibitor E-4031 were determined (192.9 µM for LN-229, 94.23 µM for GNS144). Cells were treated with the respective IC_{50} concentration of E-4031 (or vehicle) and irradiated with a single fraction of 0 Gy or 10 Gy. Sphere formation assays were performed and quantified 7-14 days later. Cell-cycle distribution was assessed by flow cytometry. All experiments were performed in triplicate; statistical significance was evaluated with Tukey's or Fisher's LSD tests ($p < 0.05$).
Results: In LN-229 spheres, combination therapy with E-4031 and radiation reduced sphere formation more than radiation alone (+14.4 %, $p = 0.0041$) or E-4031 alone (+23.56 %, $p = 0.0002$). In GNS144, the combination also performed better than radiation alone (+25.80 %, $p = 0.0303$) and E-4031 alone (+26.15 %, $p = 0.0283$). Cell cycle analysis of LN-229 showed that E-4031 decreased the S-phase population by 5.95 % ($p = 0.0054$) compared with controls, and when combined with radiation it reduced the S-phase population by an additional 7.36 % ($p = 0.0016$).
Conclusions: Selective blockade of hERG1 with E-4031 markedly radiosensitizes GBM cells, producing synergistic reductions in sphere forming capacity, a surrogate for stemness. Moreover, hERG1 inhibition decreases the radioresistant S-phase cell population. These findings suggest that hERG1 blockade may be beneficial for radiosensitization in GBM, and further exploration of hERG1 targeted strategies could improve outcomes for patients diagnosed with glioblastoma.

#7196 Detection of radiopharmaceuticals and their cold surrogates by Imaging Mass Cytometry enables assessment of single-cell functional response, therapeutic biodistribution, and modulation of the immune microenvironment.

[1]Lunenfeld-Tanenbaum Research Institute, Toronto, ON, Canada,[2]Department of Immunology and Theranostics, Beckman Research Institute of City of Hope, Duarte, CA,[3]Department of Chemistry & Chemical Biology, McMaster University, Hamilton, ON, Canada,[4]Standard BioTools, Markham, ON, Canada,[5]Department of Molecular Genetics and Radiology & Nuclear Medicine, Erasmus Medical Center Cancer Institute, Rotterdam, Netherlands,[6]Flow Cytometry Core Facility, Leiden University Medical Center, Leiden, Netherlands,[7]Centre for Discovery in Cancer Research, McMaster University, Hamilton, ON, Canada,[8]Radiology & Nuclear Medicine, Erasmus Medical Center, Rotterdam, Netherlands

Radiopharmaceuticals (RPT) can improve therapeutic responses while decreasing adverse reactions through targeted radiation delivery to the tumor. While localized radionuclide uptake can currently be measured, these techniques lack the resolution to examine biodistribution at the single-cell level or capacity to simultaneously assess multiple measures of response. Here, we show that Imaging Mass Cytometry (IMC), a technique combining immunostaining with laser ablation-enabled inductively coupled plasma mass spectrometry, can measure the spatial distribution of RPT metal, as well as the therapeutic response within multiplexed measurements. Testing the abilities and limitations of this approach, we benchmarked IMC and autoradiography readouts, compared isotope-labelling approaches and dosing necessary for IMC detection, and provide examples of a variety of unique single cell readouts of RPT distribution and cellular response. Using both hot and cold labelling strategies, we measured the distribution of either carrier-added metal or cold surrogate and matched target for two tumor-directed RPTs, seeing clear differences in on- and off-target distributions within the tumor. Metal from carrier added [^{177}Lu]Lu-DOTA-RW03, a fully humanized CD133 antibody, co-localized with CD133 expression in certain regions of the tumor, with CD133^{+} RPT metal^{-} regions interspersed. A cold analog of an engineered antibody fragment against the prostate stem cell antigen (^{169}Tm-PSCA A2DM) was observed in both the tumor mass and peripheral areas of collagen-rich stroma in a syngeneic model using human PSCA expressing cells. Over a 28-day time course, on- versus off-target ratios improved with time, and varying therapeutic dose was shown to change single cell RPT amounts with analog doses as low as 10 µg detected by IMC, highlighting its sensitivity. Diving deeper, IMC enabled functional assessments of response showing higher single-cell positivity for markers of DNA damage and apoptosis in regions with higher RPT exposure. Finally, we show the ability of IMC to assess the RPT-initiated immune response and impact of radioisotope selection by comparing lymphocyte and myeloid cell infiltration in response to alpha or beta emitters conjugated to the same targeting reagent. These findings show the potential of IMC quantification of RPT dose, distribution, and response, which will expand our understanding of localized absorbed dose, how radioisotope selection impacts response, and inform future pre-clinical therapeutic design.

#7197 Molecular characteristics of MP0712, a clinical stage ^{212}Pb-based Radio-DARPin candidate for targeted anti-DLL3 radiotherapy of small cell lung cancer (SCLC).

Stefanie Riesenberg[1], Amal Saidi[2], Francesca Malvezzi[1], Aaron Schatzmann[2], Christian Reichen[1], Tania Stallons[2], Nicole Pina[1], Aline Eggenschwiler[1], Amy Wong[2], Madlaina Mettier[1], Jitka Rantanen[1], Marcela Guzman-Ayala[1], Julien Torgue[2], Daniel Steiner[1]

[1]Molecular Partners AG, Zurich-Schlieren, Switzerland,[2]Orano Med, Plano, TX

Introduction

Delta-like ligand 3 (DLL3) is an inhibitory Notch ligand aberrantly expressed on SCLC cells and largely absent in healthy tissues, making it a promising therapeutic target. However, low DLL3 surface density may limit tumor accumulation of a targeted radiopharmaceutical. MP0712, a half-life extended DLL3-targeting DARPin (Designed Ankyrin Repeat Protein) molecule combined with the short-lived alpha-emitting therapeutic isotope ^{212}Pb, showed favorable safety, biodistribution, and antitumor efficacy in mice (Croset et al. AACR 2025). Under South Africa's Section 21 compassionate care framework, MP0712 was administered for imaging with ^{203}Pb to patients with SCLC and other DLL3-positive neuroendocrine cancers (NECs). Initial human imaging data indicate specific tumor uptake, supporting MP0712's intended mode of action (Steiner et al. TRP EU 2025). Here, we describe MP0712's molecular features, focusing on binding properties, internalization, and circulatory half-life.

Methods

DLL3-expressing SCLC cell lines and xenograft models were used to evaluate MP0712 biodistribution *in vivo*. Internalization was assessed using flow cytometry and confocal microscopy. PK/PD properties were determined in mice. The affinity to DLL3 protein was determined by Surface Plasmon Resonance.

Results

We identified sub-nanomolar affinity as a critical parameter for achieving efficient tumor uptake. MP0712 comprises a high-affinity, DLL3-specific DARPin (K_D of 0.2 nM) that binds efficiently and selectively to DLL3+ SCLC cells. Given the low surface density of DLL3, we reasoned that to maximize accumulation in tumor, rapid and repeated internalization of a Radio-DARPin would be beneficial. Consistent with this hypothesis, we could demonstrate that up to 80% of surface-bound DLL3-DARPin internalizes within 30 min into SCLC cells *in vitro*. Importantly, we observed progressive intracellular accumulation over time upon continuous supply of DLL3-targeting DARPins, suggesting that repeated cycles of internalization occur. Finally, we hypothesized that extending systemic exposure of the DLL3-targeting DARPin would further enhance tumor uptake by leveraging these internalization dynamics. Indeed, we observed that intermediate half-life extension with an albumin-binding moiety improved tumor accumulation in xenograft models compared to non-half-life extended molecules.

Conclusions

MP0712 demonstrates a compelling preclinical profile that suggests it may benefit from rapid receptor turnover-mediated intracellular accumulation, offsetting the effects of low DLL3 surface density. Together with emerging ^{203}Pb-imaging data from compassionate care, these findings support further clinical evaluation of MP0712 therapeutic application with ^{212}Pb-payload in patients with SCLC and other DLL3-positive NECs.

#7198 Synergistic effects of next-generation Tumor-Treating Fields technology and cinnamaldehyde/cinnamon oil on apoptosis, cell cycle arrest and growth suppression in triple-negative breast cancer cells.

Annulis[2], Abdu Mohammed[1], Kiran Khurshid[1], Noor U. Huda[1], Aaron P. Provenzano[4], Jason R. Henderson[5], Daniel Kuebler[2], Joseph A. Pathakamuri[2], John J. O'Connell[6]

[1]Trinity Health System, Steubenville, OH,[2]Department of Biology, Franciscan University of Steubenville, Steubenville, OH,[3]Department of Bioengineering, Swanson School of Engineering, University of Pittsburgh, Pittsburgh, PA,[4]Hillman Cancer Center, University of Pittsburgh Medical Center, Pittsburgh, PA,[5]Quiverent, LLC., Greenville, SC,[6]University of South Carolina School of Medicine Greenville, Greenville, SC; Department of Medicine, Prisma Health Cancer Institute, Greenville, SC

Background: Triple-negative breast cancer (TNBC), one of the most aggressive subtypes of breast cancer, accounts for 10-20% of breast cancers. Tumor-Treating Fields (TTF), disrupt mitotic spindle formation and induce apoptosis in TNBC cells. Cinnamaldehyde (CA), the active component of cinnamon, inhibits TNBC proliferation and promotes apoptosis. This study evaluated whether CA or cinnamon oil (CO) acts in synergy with TTF to enhance growth suppression, apoptosis, and cell-cycle arrest in TNBC cells.

Methods: MDA-MB-231 TNBC cells were seeded at 75,000 cells/mL and treated with CA (150 μM), CO (1:300 dilution), or vehicle controls. Frequency-modulated TTF (FM-TTFields) were applied continuously for 72 hours at 150 kHz (±10 kHz modulation using an 8.3 mHz triangle wave), 1.2 V_{RMS}/cm. Cell proliferation was assessed by CyQUANT assay and Celigo imaging; apoptosis and cell-cycle distribution were analyzed by Annexin V/PI flow cytometry. Synergy was quantified using Bliss independence and Highest Single Agent (HSA) models.

Results:
Cell death synergy: Cell death from combined treatments TTF+CA (96.7%) and TTF+CO (96.3%) exceeded single agents CA (93.6%), CO (86.1%), and TTF (40.0%). Synergy analysis by HSA and Bliss models confirmed synergy, stronger for TTF+CO (HSA Δ = +10.3 ± 2.5 points (pts), p = 0.02; Bliss Δ = +4.7 ± 1.7 pts, p = 0.042) than TTF+CA (HSA Δ = +3.2 ± 1.4 pts, p = 0.06; Bliss Δ = +0.9 ± 1.0 pt, p = 0.27). Combining TTF with CA or CO yields synergistic benefits, with TTF+CO showing the greatest effect.

Apoptosis synergy (Annexin V/PI): TTF+CO (49.9%) and TTF+CA (65.5%) greatly surpassed CA (20.6%), CO (13.9%), and TTF (1.4%). Combinations increased apoptosis ~36-fold (TTF+CO) and ~48-fold (TTF+CD). Synergy was highest for TTF+CA (HSA Δ = +44.3 pts; Bliss Δ = +43.2 pts) versus TTF+CO (HSA Δ = +35.1 pts; Bliss Δ = +33.9 pts). Combining TTF with CA or CO substantially enhances apoptosis, with TTF+CA most effective.

Cell-cycle modulation: CA and CO enriched the S phase relative to DMSO (Δ%: CO +10 pts; CA +8 pts). TTF induced strong G2/M accumulation (+18 pts). Combining TTF with CO further increased G2/M (+12 pts) with minimal S-phase change (+1 pt), while CA+TTF produced only a small G2/M shift (+2 pts). These patterns suggest mechanistic complementarity: CA and CO primarily arrest cells in the S phase, whereas TTF induce mitotic arrest (M phase).

Conclusions: Combining FM-TTFields with cinnamon oil or cinnamaldehyde enhances TNBC cell death and apoptosis through complementary mechanisms—S-phase arrest and mitotic disruption—resulting in significant synergy for FM-TTFields combined with cinnamon oil or cinnamaldehyde. These findings support a novel, combinatorial strategy for treating TNBC. Future studies should validate these results *in vivo* and explore clinical translation.

#7199 From simulation to reality: Evidence supporting safe high-dose TTFields delivery with the LB10000.

Ze'ev Bomzon[1], Scott Krywick[1], Matthew Travers[1], Kenneth L. Watkins[1], Martin Pribula[1], Michael Winegar[2], Peter Travers[1]

[1]Lifebridge Innovations, Longwood, FL,[2]Winegar Consulting Inc, Maple Grove, MN

Introduction: Tumor Treating Fields (TTFields) are a noninvasive cancer therapy that employ alternating electric fields in the 100-500 kHz range to disrupt tumor cell division. TTFields are clinically approved for glioblastoma, mesothelioma, and non-small cell lung cancer. The LB10000 is a novel TTFields device designed to deliver high-dose fields adaptively across large body regions. Unlike existing systems that use four fixed transducer arrays, the LB10000 employs a large matrix of programmable transducers whose phases can be dynamically switched between 0°, 180°, and off. This enables dynamic field shaping, targeted delivery to multiple anatomical sites, and effective thermal management. We present both in-vivo and in-silico evidence demonstrating the safety of this new system.

Methods: Six female Yucatan pigs were treated with the LB10000. Arrays were removed daily between 7-9 a.m. and reapplied between 12-3 p.m., targeting ≥16 hours of active treatment per day for 24-32 days within a period of 40 days from treatment initiation. If a pig reached the desired quota of per-protocol days, treatment was stopped and the animal euthanized. During treatment, skin temperature, treatment duty cycle, current, and voltage were continuously monitored, and animal well-being was evaluated daily by a veterinarian. Following euthanasia, gross examination of major organs was performed. To assess safety in humans, computational modeling was performed using the Sim4Life (ZMT Zurich, Switzerland) ohmic solver. Virtual LB10000 arrays were applied to anthropomorphic phantoms—DUKE (adult male), ELLA (adult female), and FATS (obese male)—and electric field delivery simulated at 200 Vpp, the device's maximum output. Specific Absorption Rate (SAR) distributions were calculated to evaluate potential heating.

Results: In vivo, the LB10000 delivered fields continuously at 130 V and 6 A (~100 W) with 78-90 % on-time per animal. Five of six pigs completed the full protocol(24-32 day with 16hr/day treatment), totaling 2,780 hours of treatment without adverse events or tissue injury. Gross examination revealed no abnormalities. In silico, SAR values in superficial skin layers were 10-100× higher than in internal organs, indicating that any potential heating is localized beneath the transducers. The risk of thermal damage to tissues increases drastically when tissue temperatures exceed 109°F (43°C). The LB10000 continuously monitors skin temperature below the transudcers and controls delivered power to maintain skin temperature below a safety threshold of 105 °F. Together, these findings demonstrate that the LB10000 operates safely at high doses in vivo and that the risk that the device will cause thermal damage in humans is negligible.

Conclusion: These results provide key evidence supporting advancement toward first-in-human clinical evaluation.

#7200 High-dose adaptive tumor treating fields (TTFields): Expanding the boundaries of electric field therapy.

Ze'ev Bomzon[1], Scott Krywick[1], Matthew Travers[1], Kenneth L. Watkins[1], Martin Pribula[1], Michael Winegar[2], Peter Travers[1]

[1]Lifebridge Innovations, Longworrd, FL,[2]Winegar Consulting Inc/, Maple Grove, MN

Introduction: Tumor treating fields (TTFields) are a non-invasive cancer therapy employing alternating electric fields in the 100-500 kHz range to disrupt mitosis. Current TTFields systems use four fixed transducer arrays positioned on the skin near the tumor. This static configuration imposes two critical limitations: (1) electric fields remain confined between arrays, precluding treatment of multifocal or metastatic disease. (2) Delivery of TTFields through the skin leads to localized heating of the skin below the transducers. To avoid thermal damage to tissue, the power delivered must be controlled in a manner that maintains skin temperature below a safety limit of around 105°F, and if skin temperature exceeds this threshold, the device must temporarily halt field delivery until the skin cools to a safe temperature, leading to a reduction in delivered dose. The LB10000 system was engineered to overcome these barriers. It comprises a large array of individually addressable transducers whose phases can be dynamically modulated between three states (0°, 180°, off). This enables adaptive field steering, effective heat dispersion, and targeted energy delivery across the body. We present experimental and computational evidence demonstrating that the LB10000 delivers TTFields to multiple targets at doses substantially exceeding those achievable with existing systems.

Methods: The LB10000 was applied to six female Yucatan pigs for 30-40 days to assess sustained high-dose delivery. Arrays were removed daily between 7-9 a.m. and reapplied between 12-3 p.m., targeting ≥16 hours of treatment per day. Skin temperature, treatment duty cycle, and current-voltage output were continuously recorded. To assess dose-delivery in humans, simulations were performed using the Sim4Life (ZMT Zurich, Switzerland) platform. Virtual arrays were applied to the DUKE (adult male), ELLA (adult female), and FATS (obese male) anatomical phantoms, with power levels matched to those measured in vivo. Electric field distributions were computed for tumors in multiple organ sites.

Results: In vivo, the LB10000 delivered continuous fields at 130 V and 6 A (≈100 W[SK1]) with 78-90[SK2] [3ב] % on-time, maintaining skin temperatures within safety limits and confirming robust thermal control. Simulations demonstrated that the LB10000 achieved mean intratumoral field intensities exceeding 2 V/cm in lung and liver targets—representing at least a two-fold increase over reported values from existing TTFields devices.

Conclusions: The LB10000 enables adaptive, high-dose TTFields delivery with effective thermal regulation and extended coverage, supporting treatment of disseminated or multifocal disease. This technology represents a new paradigm for TTFields therapy, with the potential to significantly broaden its clinical impact.

#7201 Preclinical evaluation of click-cleavable radioimmunoconjugates for enhanced treatment efficacy in radioimmunotherapy.

Marleen H. M. E. van Stevendaal[1], Kim E. de Roode[1], Luc H. M. Zijlmans[1], Jenne T. Meinema[1], Hendrina M. de Wert-Wattimury[1], Renate C. van Daalen-Bruens[1], Bianca Matthee[1], Mark W. Konijnenberg[2], James Nagarajah[3], Raffaella Rossin[1], **Marc S. Robillard**[1]

[1]Tagworks Pharmaceuticals, Nijmegen, Netherlands,[2]Erasmus Medical Center, Rotterdam, Netherlands,[3]Radboud University Medical Center, Nijmegen, Netherlands

Targeted radiotherapy (TRT) with radiolabeled antibodies is hampered by long circulation times, resulting in dose-limiting toxicity. Tagworks developed a novel TRT approach based on its Click-to-Release platform, comprising an internalizing mAb functionalized with a chelator via a click-cleavable trans-cyclooctene (TCO) linker, and a small-molecule trigger (tetrazine). The radiolabeled mAb is administered and allowed to internalize into tumor cells. Then, a non-cell permeable trigger is injected that selectively reacts with the residual circulating mAb, releasing a small fast-clearing radioactive fragment. This approach is envisioned to unlock the treatment benefits of TRT with long-lived potent beta- (^{177}Lu) and alpha (^{225}Ac) radionuclides, minimizing toxicity to the patient's marrow and kidney while delivering a high therapeutic radioactive dose to the tumor. Tagworks' TGW211 program in Phase 0/1 aims at increasing the therapeutic index of radiolabeled trastuzumab (TGW211-DC), targeting HER2+ tumors. In addition, this approach is being applied to mAbs directed to various other targets in a preclinical setting. Chelate-conjugated mAbs were radiolabeled with ^{111}In or ^{177}Lu and release of the radiolabeled-DOTA was measured upon reaction with trigger. Binding and internalization were characterized using BT-474 cells. Pharmacokinetics and biodistribution were determined in nude mice +/- BT-474 xenografts. Patient dosimetry with different radionuclides was modelled using clinical data for [^{89}Zr]Zr-trastuzumab using IDAC-Dose 2.1 and OLINDA. The trigger rapidly released ^{111}In/^{177}Lu-labeled DOTA in PBS and plasma (e.g. 91.8% in 5 min for [^{111}In]In-TGW211-DC). [^{111}In]In-TGW211-DC demonstrated high-affinity in vitro (KD = 8.4 nM), and efficient internalization. In healthy mice, [^{111}In]In-TGW211-DC was highly stable with >20d TCO isomerization half-life, while trigger effectively released the fast-clearing ^{111}In-fragment in blood. In tumor bearing mice, radioactivity was largely retained inside tumor cells, but cleared from blood by the trigger, reaching maximum tumor-to-blood-ratios (T/B) of 16.3, 24h p.i. and 34.8, 72h p.i. Similar results were obtained for [^{177}Lu]Lu-TGW211-DC. Dosimetry projections indicate maximal healthy tissue dose decrease when trigger is administered 24 hrs post TGW211-DC, reaching up to 92% for ^{225}Ac and 88% for ^{177}Lu in marrow. In kidney this resulted in 89% dose decrease for ^{225}Ac. Finally, this click-cleavable TRT approach could be effectively applied to other internalizing mAb-target combinations. In conclusion, the click-cleavable TRT approach has demonstrated strong platform potential and markedly improved the T/B in mice for TGW211. Moreover, beneficial dosimetry of click-cleavable TRT was projected for TGW211. A First-in-human Phase 0/1 study with HER2+ cancer patients has recently been initiated.

#7202 Comparative evaluation of ^{225}Ac-PSMA-Trillium with other ^{225}Ac-PSMA-SMOL assets in a preclinical prostate cancer xenograft model.

Urs B. Hagemann[1], Maria Spelling[1], Shankari Nair[1], Martin Kohs[1], Meike Fehder[1], Stefan Stargard[1], Sabine Zitzmann-Kolbe[2], Dmitry Zubov[1], Ming Xu[1]

[1]Bayer AG, Berlin, Germany,[2]Life Molecular Imaging, Berlin, Germany

Prostate-specific membrane antigen (PSMA) is a transmembrane glycoprotein highly expressed on prostate cancer cells, making it an ideal target for novel prostate cancer therapies. Currently, there are several actinium-225 (^{225}Ac)-PSMA-targeting small molecules (SMOL) in clinical development for treating patients with metastatic castration-resistant prostate cancer. ^{225}Ac-PSMA-Trillium (BAY 3563254), is a novel PSMA-targeting molecule which comprises a highly specific PSMA-binding motif, an albumin-binding domain to optimize tumor uptake and retention, and a Macropa™ chelator complexed with the alpha-emitter ^{225}Ac. Here, we compared ^{225}Ac-PSMA-Trillium with three other ^{225}Ac-PSMA-SMOLs, i.e., ^{225}Ac-PSMA-617, ^{225}Ac-PSMA-R2 and ^{225}Ac-PSMA-I&T, which all utilize a DOTA chelator for complexing ^{225}Ac. All assets were synthesized and radiolabeled at Bayer AG. Binding to PSMA was confirmed using a surface plasmon resonance (SPR) assay. *In vitro* cytotoxicity in LNCaP cells was evaluated using CellTiterGlo®. The antitumor effects of ^{225}Ac-PSMA-SMOLs were investigated in male SCID mice with subcutaneous LNCaP tumors. Mice were randomized and treated with a single i.v injection of ^{225}Ac-PSMA-Trillium or the other ^{225}Ac-PSMA-SMOLs at different dose levels (100-400 kBq/kg, 375 kBq/nmol). Tumor growth and body weights were monitored for 4 weeks post injection. ^{225}Ac activity in various organs and tumors was measured using a high purity germanium detector or autoradiography. ^{177}Lu-PSMA-617 SPECT imaging was performed to evaluate tumor uptake. All PSMA-SMOLs exhibited strong binding affinity to recombinant PSMA as demonstrated by SPR. When radiolabeled with non-radioactive lanthanum as surrogate for ^{225}Ac, the target residence time of PSMA-SMOLs was weakened, except for PSMA-Trillium. All ^{225}Ac-labeled assets induced potent cytotoxicity in LNCaP cells *in vitro*. Radio-HPLC and iTLC confirmed the integrity and high radiochemical purity, respectively. ^{225}Ac-PSMA-Trillium at 400 kBq/kg showed higher tumor uptake compared to other ^{225}Ac-PSMA-SMOLs, homogeneous tumor accumulation 60 hours after injection, and fast clearance from the kidneys based on autoradiography. Furthermore, ^{225}Ac-PSMA-Trillium at all doses inhibited LNCaP tumor growth and decreased tumor weights in a dose-dependent manner, whereas the antitumor response was restricted to the higher doses for all other compounds. In summary, ^{225}Ac-PSMA-Trillium showed the highest tumor uptake and the strongest tumor growth inhibition with a clear dose response compared with the other ^{225}Ac-PSMA-SMOLs. These data support the clinical development of ^{225}Ac-PSMA-Trillium (NCT06217822).

#7203 ^{212}Pb-based CEA pretargeted radioimmunotherapy demonstrates tumor targeting and potent TGI in immunodeficient and humanized mouse models, informing a FIH study in mCRC.

Sofia H. L. Frost[1], Alexandre Pichard[2], Annabelle Mouchotte[2], Agnes Colmont[2], Sara Colombetti[3], Alexander Haas[4], Hans Peter Grimm[3], Birgit Kittel[3], Stephen Fowler[3], Bernhard Reis[3], Vincent Wolowski[3], Uta Sweere[3], Michael Hettich[3], Wolfgang Jacob[4], Frederic Prince[3], Christian Klein[5], Pablo Umana[5], Julien Torgue[6], **Axel Boehnke**[3]

[1]Roche Pharma Research and Early Development, Roche Innovation Center Welwyn, Roche Products Ltd, Welwyn Garden City, United Kingdom,[2]Institut Roche, Roche S.A.S., Boulogne-Billancourt, France,[3]Roche Pharma Research and Early Development, Roche Innovation Center Basel, F. Hoffmann-La Roche AG, Basel, Switzerland,[4]Roche Pharma Research and Early Development, Roche Innovation Center Munich, Roche Diagnostics GmbH, Penzberg, Germany,[5]Roche Pharma Research and Early Development, Roche Innovation Center Zurich, Roche Glycart AG, Schlieren, Switzerland,[6]Orano Med LLC, Plano, TX

Background: Alpha particles (α) are exceptionally cytotoxic, inducing complex DNA damage and bystander effects. Targeted α-therapy demonstrated a favorable therapeutic index (TI) in certain cancers. To improve the TI and expand to other indications, we developed a ^{212}Pb-based carcinoembryonic antigen-related cell adhesion molecule 5 pretargeted radioimmunotherapy (CEA-PRIT 2.0), involving two complementary SeParated v-domains LInkage Technology antibodies (SPLIT Abs) and ^{212}Pb-DOTAM. Each CEA-targeted SPLIT Ab carries half of a DOTAM binding v-domain that, when combined upon target binding, forms concentration-dependent stable complexes with ^{212}Pb-DOTAM. While unbound ^{212}Pb-DOTAM undergoes rapid renal clearance, ^{212}Pb-DOTAM captured by the SPLIT Abs leads to α emission at CEA-expressing cells with minimal systemic irradiation. Here, we report key preclinical data informing a planned first-in-human (FIH) CEA-PRIT 2.0 study in metastatic colorectal cancer (mCRC) patients.

Methods: We assessed CEA-PRIT 2.0-induced tumor growth inhibition (TGI), biodistribution, and tolerability in 3 CEA-expressing human xenograft models. SCID mice bearing BxPC3 (pancreatic) or LS174T (colorectal) tumors received up to 5 treatment cycles, and BRGS-CD47 mice (humanized and non-humanized) bearing HPAF-II (pancreatic) tumors received up to 3 cycles. Each cycle consisted of the two SPLIT Abs (1-5 mg/kg each) given on day 1 to allow for accumulation on CEA-expressing cells before giving ^{212}Pb-DOTAM (20 µCi) on day 8.

Results: Average ^{212}Pb tumor uptake in all models was 10-43% injected activity per gram of tissue (IA/g) at 24 h, with low blood and kidney retention (<3% IA/g). In the BxPC3 model, TGI was SPLIT Ab dose-dependent, while the LS174T model showed potent TGI already at the lowest dose (1 mg/kg). The SPLIT Ab dose-dependence of the TGI in the HPAF-II model was abrogated in huBRGS-CD47, suggesting secondary immune responses contribute to the therapeutic effect.Manageable body weight (BW) loss was observed in the SCID BxPC3 model. More pronounced BW loss in LS174T (SCID) and HPAF-II (BRGS-CD47/huBRGS-CD47) models was observed, but minimal BW gain or actual BW loss in controls suggests tumor burden toxicity or strain-specific sensitivity were contributing factors.Utilizing the preclinical data, we designed a FIH study, starting with ^{203}Pb-DOTAM as a surrogate for therapeutic ^{212}Pb-DOTAM tumor uptake and healthy tissue distribution, SPLIT Ab pharmacokinetics, and tumor CEA expression to inform optimal SPLIT Ab dosing and interval to ^{212}Pb-DOTAM, before initiating the ^{212}Pb-DOTAM activity escalation and potential cancer immunotherapy combinations.

Conclusions: CEA-PRIT 2.0 showed favorable tumor-to-healthy tissue radiation exposure and potent TGI with a favorable toxicity profile. A FIH study in mCRC is planned in H1 2026.

#7205 A universal duplex sequencing approach for accurate detection of somatic mutations.

Shuvro Prokash Nandi[1], Yuhe Cheng[2], Shams Al-azzam[3], Safa Saeed[2], Isabella R Stuewe[1], Zichen Jiang[2], Luka Culibrk[4], Maria Zhivagui[5], Xiaoxu Yang[6], Rachel M. Wise[7], Foster C. Somatic mutations arise from endogenous and exogenous mutagenic processes, accumulating over time and contributing to aging and disease. Detecting these rare mutations in non-clonal tissues remains a significant challenge due to the high error rates, limited genome coverage, and substantial DNA input requirements of existing sequencing approaches. Here, we introduce UDSeq, a high-accuracy, cost-effective, single-molecule duplex sequencing protocol designed to overcome these limitations. We place UDSeq in the context of existing duplex sequencing approaches, demonstrating that it achieves an exceptionally low error rate of ~2.5×10^{-9} per base pair, supports whole-genome and targeted capture sequencing from as little as 100 picograms of DNA, and delivers up to four times more usable duplex molecules than current state-of-the-art methods from the same input. We demonstrated the broad applicability of UDSeq through a series of in vitro and in vivo mutagenesis experiments, accurately capturing known mutational signatures induced by environmental carcinogens in human cell lines, rodents, and non-model organisms. We further applied UDSeq to normal tissues from a 70-year-old individual, revealing organ-specific mutational burdens and the activity of distinct mutational processes. With its high accuracy, low input requirements, and wide applicability, UDSeq provides a powerful and scalable tool for studying mutational processes across diverse biological contexts. Its versatility supports applications in cancer research, aging, and environmental exposure, expanding our capacity to characterize somatic mutations in both healthy and diseased tissues.

#7209 Chromosome 3p mutations drive unique and non-redundant transcriptional programs in primary ccRCC.

Parker D. Mathews[1], Eric Knoche[2], Martin W. Schoen[3], Russell Pachynski[2]

[1]Internal Medicine Residency Program, Washington University in St. Louis School of Medicine, St. Louis, MO,[2]Division of Oncology, Washington University in St. Louis School of Medicine, St. Louis, MO,[3]Saint Louis University & St. Louis VAMC, Saint Louis, MO

Background: Chromosome 3p genes (tumor suppressor VHL and chromatin modifiers BAP1, SETD2, PBRM1) are frequently altered in ccRCC and may have prognostic significance, though the mechanism by which they drive ccRCC pathogenesis is incompletely understood. Therapies with novel mechanisms, for example belzutifan targeting hypoxia via HIF, increase the relevance of these mechanisms.
Methods: The Tempus Lens Platform (Tempus AI, Chicago, IL) was used to identify a cohort of de-identified ccRCC cases. Data was analyzed in Tempus Workspaces using the tempusverse suite of R packages. GSEA was applied to differential RNAseq expression data using the msigdbr (“hallmarks”) and clusterprofiler R packages. GSEA pathways are presented as normalized enrichment score with adjusted Q-value.
Results: We identified 166 ccRCC pts with solid tumor DNA and wtRNAseq genomic profiling, excluding biopsies from distant metastatic sites. Median age at diagnosis was 57 (IQR 47.2-66.0). The cohort was 63% male (n=101). Within the cohort, VHL SNV/indels were present in 52% (n=86), PBRM1 in 24% (n=39), BAP1 in 7% (n=12), and SETD2 in 10% (n=17). Copy number changes and structural alterations were not included. As expected, BAP1 and PBRM1 mutations were mutually exclusive (Fisher’s p = 0.037). VHLmut tumors demonstrated a clear hypoxic phenotype (hypoxia 1.50, q 2.27e-02, G2M checkpoint -2.37, q 4.00e-09). The other 3p mut tumors showed distinct phenotypes. BAP1mut was notable for an “immune-hot” signature (allograft rejection 2.83, q <7.37e-10, IFN-g response 2.49, q<7.37e-10, E2F targets 2.33 q<7.37e-10). PBRM1mut tumors were “immune-cold” with hallmarks of metabolic dysregulation (allograft rejection -2.13, q 1.96e-7, inflammatory response -1.92, q 1.22e-5, fatty acid metabolism 1.54, q 6.00e-3). Interestingly, SETD2mut tumors were notably distinct from VHLmut tumors, with downregulation of hypoxia, NFKB, and p53, and upregulation of cell cycle hallmarks, necessitating further investigation (hypoxia -2.15, q 1.57e-7, TNFa signaling -2.43, q 3.05e-9, G2M cell cycle 1.96, q 3.82e-6, p53 pathway -1.73, q 5.25e-4).
Conclusions: New treatments are emerging via rational design efforts enabled by a more detailed understanding of ccRCC pathogenesis. Here we leveraged real-world genomic data to characterize the landscape of 4 common, related genetic alterations known to be pivotal to ccRCC biology. Non-VHL altered patients were overrepresented in our cohort relative to prior studies, though only SNV/indels were captured here. We observed that non-VHL cases frequently have alterations in other chromosome 3p genes, which may drive ccRCC development, progression, and resistance via cellular processes distinct from the classic VHL-HIF-hypoxia axis. As HIF directed therapies become more widely utilized, chromosome 3p alterations have the potential to provide additional predictive and prognostic value to ccRCC patients.

#7210 Frequent intra-regional PLAP expression heterogeneity in gastric adenocarcinomas.

Morton Freytag[1], Eike C. Burandt[1], Florian Viehweger[1], Viktor Reiswich[1], Christina Tsourlakis[1], Ronald Simon[1], Claudia Hube-Magg[1], Martina Kluth[1], Waldemar Wilczak[1], Fiete Gehrisch[1], Thorben W. Fruendt[2], Thomas Roesch[3], Philip Dautel[3], Guido Sauter[1], Till S. Clauditz[1], Nina Schraps[1], Stefan Steurer[1], Clara Luehr[1]

[1]Institute of Pathology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany,[2]Gastroenterology and Hepatology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany,[3]Department of Interdisciplinary Endoscopy, University Medical Center Hamburg-Eppendorf, Hamburg, Germany

Placental alkaline phosphatase (PLAP), also known as alkaline phosphatase, placental type (ALPP) is a membranous protein which is thought to play a role in guiding migratory cells and transport specific molecules over the plasma membrane. In normal tissues, PLAP expression is almost exclusively seen in the placenta. In cancer, PLAP expression is a hallmark of testicular germ cell tumors but can also be found in up to 38% of gastric adenocarcinomas. The membranous location of PLAP in combination with the absence or only very low levels of PLAP expression in vital normal tissues of (non-pregnant) humans, makes PLAP a potentially useful therapeutic target. For targeted therapy, both the therapeutic success and the quality of the diagnostic assessment generally may critically depend on the degree of heterogeneity of target protein expression in a cancer. To study the extent of intratumoral heterogeneity of PLAP expression in gastric cancer, a gastric cancer heterogeneity tissue microarray was analyzed by immunohistochemistry (IHC). The TMA contained 0.6 mm tissue samples from 9 areas each of the primary cancers of 113 gastric cancer patients and 3-9 samples from matched lymph node metastases from 61 of these patients. There were 59.0% of 113 evaluable cancers without any PLAP positivity in all samples while a heterogeneous PLAP positivity was seen in 38 (34.0%) of patients. In most of the samples, heterogeneity occurred within individual TMA spots (intraregional heterogeneity) while only few cancers had a combination of distinctly negative spots and spots with a majority of unequivocally positive cells (regional heterogeneity). Intraregional heterogeneity was mostly caused by an admixture of cancer areas with a glandular growth pattern showing apical/luminal PLAP staining while solid areas of the same cancers were PLAP negative. The PLAP status of metastases was often comparable to the respective primary tumor. PLAP positivity of at least one metastasis spot was observed in 74.0% of 27 PLAP positive, but in only 6.3% of 34 PLAP negative primary tumors. Discrepancies in individual cases were again mostly caused by differences in the growth patterns. Metastases with a more solid tumor growth than seen in the primary tumors, tended to be less PLAP positive, than metastases with a glandular growth pattern. To what extent the common intraregional heterogeneity of PLAP expression will disturb the efficiency of targeted anti-PLAP therapies in gastric cancer remains to be seen.

#7211 High intratumoral homogeneity and tumor specificity makes uroplakin 3b (Upk3b) a promising therapeutic targetin malignant mesothelioma.

Sonke von Weihe[1], Frank Elsholz[1], Philipp Busch[2], Fiete Gehrisch[3], Nina Schraps[3], Martina Kluth[3], Maria C. Tsourlakis[3], Katharina Moller[3], Maximilian Lennartz[3], Veit Bertram[3], Florian Viehweger[3], Florian Lutz[3], Birgit Hantzsch-Kuhn[1], Till Olchers[1], David B. Ellebrecht[1], Christoph Fraune[3], Ronald Simon[3], Guido Sauter[3], Martin Reck[1], **Stefan Steurer**[3]

[1]Department of Thoracic Oncology, Airway Research Center North, German Center for Lung Research, LungenClinic, Grosshansdorf, Germany,[2]General, Visceral and Thoracic Surgery Department and Clinic, University Medical Center Hamburg-Eppendorf, Hamburg, Germany,[3]Institute of Pathology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany

Uroplakin 3B (Upk3b) is one out of 5 known uroplakin (Upk) proteins that cooperatively form the apical asymmetrical unit membrane (AUM) plaques which play a pivotal role in the stabilization and strengthening of epithelial cells that line organs exposed to mechanical stress. In a previous study involving 608 normal tissues and 17,693 cancers we had found that Upk3b expression was limited to membranes of only three cell types which are all subjected to periodical massive distension. These include the apical membrane of the most superficial cell layer of the urothelium (umbrella cells), amnion cells covering the membrane that forms a part of the amniotic sac surrounding the developing fetus in the uterus during pregnancy, and mesothelial cells. Among cancers, Upk3b expression was largely limited to malignant mesothelioma and - less commonly - ovarian carcinomas. The combination of membranous expression in tumor cells and a lack of expression in drug-accessible vital normal cells makes Upk3b a potential therapeutic drug target in malignant mesothelioma. For targeted therapy, both the therapeutic success and the quality of the diagnostic assessment are likely to critically depend on the degree of heterogeneity of target protein expression in individual cancers. Cancers with Upk3b expression in all cancer cells are most likely to be correctly diagnosed as “Upk3b positive” in small biopsies and these tumors may also respond optimally to therapy as all tumor cells carry the drug target. To study the extent of intratumoral heterogeneity of Upk3b expression in malignant mesothelioma, all tumor containing tissue blocks from 58 consecutive patients with a diagnosis of malignant mesothelioma were examined for Upk3b expression by immunohistochemistry. A total of 109 tissue blocks was analyzed (average 2.02 per patient, range 1 - 9). With respect to their Upk3b staining 39 patients (72.2%) were homogeneously positive, 4 (7.4%) were heterogeneously positive and 11 (20.4%) were homogeneously negative. It is concluded from our data that a homogeneous Upk3b expression occurs in about 70.0% of patients with a malignant mesothelioma. This finding supports the notion that UpK3b may represent a promising therapeutic target for malignant mesothelioma, warranting further efforts in drug development.

#7212 MRE11 deficiency occurs in a small group of cancers from various different tumor entities.

Viktor Reiswich[1], Henry Recksiek[1], Katharina Moller[1], Florian Lutz[1], Florian Viehweger[1], Nina Schraps[1], Fiete Gehrisch[1], Christina Tsourlakis[1], Georgia Makrypidi-Fraune[1], Martina Kluth[1], Claudia Hube-Magg[1], Christian Bernreuther[1], Guido Sauter[1], Andreas H Marx[2], Ronald Simon[1], Till Krech[1], Stefan Steurer[1], Christoph Fraune[1], Sarah Minner[1], Viktoria Chirico[1], Bertram Veith[1], Clara Luehr[1], Cosima Volkel[1], Morton Freytag[1], Natalia Gorbokon[1], Maximilian Lennartz[1], Eike C. Burandt[1], Anne Menz[1], Clara von Bargen[1]

[1]Institute of Pathology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany,[2]Department of Pathology, Academic Hospital Fuerth, Fuerth Germany, Fuerth, Germany

The double-strand break repair protein MRE11 forms the core of the MRE11/RAD50/NBS1 (MRN) complex. The MRN complex acts as an early DNA damage response element which is involved in different repair pathways including homologous recombination (HR), non-homologous end joining (NHEJ) and microhomology-mediated end joining (MMEJ) repair. In cancers, altered MRE11 expression has been described in various tumor entities (e.g. carcinoma of the prostate, colon and stomach) and both up- and downregulation was associated with adverse tumor features. Most of the clinical interest comes from studies highlighting the predictive role of MRE11 expression. MRE11 overexpressing cancers have been described to be more radioresistant while low-expressors were more sensitive to radiation and chemotherapy with camptothecin and gemcitabine. Several MRE11 inhibitors are currently being investigated in clinical trials as radiosensitizers. To better understand the role of MRE11 expression in cancer, a tissue microarray containing 14,966 samples from 134 different tumor entities was analyzed. In normal tissues, a strong nuclear MRE11 staining occurred in almost all cell types. Most cancers had a nuclear MRE11 staining that was strong in 11,797 (91.0%), moderate in 1,018 (7.9%), weak in 86 (0.7%), and completely absent (MRE11 deficiency) in 55 (0.4 %) of the 12,956 informative tumor samples. More than one case of MRE11 deficiency was only seen in 6 tumor entities including hepatocellular carcinoma (10 of 292; 3.4%), gastric adenocarcinoma, intestinal type (4 of 208; 1.9%), endometrioid endometrial carcinoma (5 of 268; 1.9%),pulmonary adenocarcinoma (2 of 165; 1.2%), colorectal adenocarcinoma (CRC, 16 of 2,183; 0.7%), and clear cell renal cell carcinoma (ccRCC, 7 of 1,011; 0.7%). Reduced MRE11 staining was associated with mismatch repair deficiency (dMMR) in CRC ($p<0.0001$ each) and in gastric adenocarcinoma ($p<0.0001$), advanced pT stage ($p=0.0003$) and L1 status ($p=0.0019$) in testicular seminoma, high grade ($p<0.05$), advanced pT ($p<0.0001$), and high UICC stage ($p=0.0014$) in ccRCC, advanced pT stage in high-grade serous ovarian carcinoma ($p=0.0396$), and nodal metastases in papillary thyroid cancer ($p=0.0332$). High MRE11 expression was linked to nodal metastasis in hepatocellular carcinoma ($p=0.0258$). It is concluded that MRE11 is highly expressed in most cancers and its reduced expression is associated with an aggressive phenotype in multiple cancer types. The potential to exploit MRE11 deficiency as a target for synthetic lethality deserves to be further explored.

#7213 Evaluation of folate receptor-alpha antibody-drug conjugate mirvetuximab soravtansine-gynx in ovarian cancer PDXs.

Daniel Ciznadija[1], Hsiu-Wen Tsai[2], Marianna Zipeto[2], Markus Hippich[2], Gilad Silberberg[2], **Stefano Cairo**[2], Michael Ritchie[2]

[1]Champions Oncology, Hackensack, NJ,[2]Champions Oncology (Rockville, MD), Rockville, MD

Epithelial ovarian cancer (EOC) remains one of the most lethal gynecologic malignancies, with approximately 20,000 new cases and over 12,000 deaths annually in the United States. Despite initial responsiveness to platinum-based combination chemotherapy, most patients relapse with platinum-resistant disease. Folate receptor-alpha (FRα), a membrane glycoprotein responsible for folate transport, is minimally expressed in normal tissues but highly expressed in ovarian and certain other epithelial cancers, making it an attractive therapeutic target. Elevated FRα expression correlates with reduced overall survival across tumor types, reinforcing its clinical relevance. Mirvetuximab soravtansine-gynx (Elahere®) is an FRα-targeting Antibody-drug conjugate (ADC) that couples an anti-FRα antibody with the cytotoxic maytansinoid derivative DM4. Preclinical models and clinical trials have demonstrated its potent activity in FRα-positive ovarian tumors, leading to regulatory approval in 2022. To evaluate Elahere® in translational preclinical systems, FRα RNA expression was profiled across Champions' patient-derived xenograft (PDX) models. Expression patterns mirrored clinical data, with the highest levels detected in ovarian, kidney, and non-small cell lung cancers. Immunohistochemistry confirmed that models with high FRα RNA display strong membrane staining, whereas FRα-negative models lack detectable expression. Selected ovarian PDX models were treated intravenously with Elahere®. Tumor growth inhibition analyses revealed no response in the FRα-negative model, while FRα-positive tumors displayed variable degrees of sensitivity consistent with patient outcomes, where roughly 43% of FRα-positive individuals respond to therapy. These findings confirm that FRα expression is a strong negative predictor for response when absent, but expression level alone does not discriminate responders from non-responders. To explore potential resistance mechanisms, single-sample gene set enrichment analysis of RNA sequencing data identified enrichment of gene ontology terms related to glutathione and xenobiotic transport in non-responding FRα-positive models, implicating ATP-binding cassette (ABC) transporters such as ABCC1 and ABCC2 in drug efflux-mediated resistance. Additionally, upregulation of cell-cycle checkpoint regulators in non-responders suggests a possible mechanism of mitotic evasion that limits Elahere®'s microtubule-disrupting activity. Collectively, these studies highlight the value of Champions' PDX and bioinformatics platforms in modeling ADC activity. Such translational approaches are essential for optimizing ADC development and improving outcomes for patients with platinum-resistant ovarian cancer.

#7214 LymphGen-based stratification of DLBCL PDX models mirrors clinical tumor complexity.

Marianna Zipeto[1], Mike Ritchie[1], Markus Hippich[1], Daniel Ciznadija[2], Gervaise Henry[1], **Stefano Cairo**[1], Gilad Silberberg[1]

[1]Champions Oncology (Rockville, MD), Rockville, MD,[2]Champions Oncology, Hackensack, NJ

Diffuse Large B-Cell Lymphoma (DLBCL) is a highly heterogeneous malignancy whose biological diversity is best captured by modern molecular classifications. The Cell of Origin (COO) system divides tumors into Germinal Center B-cell-like (GCB) & Activated B-cell-like (ABC) groups, reflecting fundamental differences in differentiation state, signaling reliance, & clinical behavior. Building on COO, the LymphGen classification provides a more granular view by defining genetically coherent subtypes such as MCD, driven by MYD88L265P & CD79B lesions that promote chronic active BCR signaling; BN2, characterized by BCL6 translocations & NOTCH2 mutations typical of marginal-zone-like biology; N1, marked by NOTCH1 activation; A53, enriched for TP53 loss & chromosomal instability; EZB, defined by EZH2 mutation, BCL2 rearrangement, & germinal-center-associated epigenetic rewiring; & additional groups such as ST2, harboring SOCS1 mutations & JAK-STAT pathway alterations. These genomic clusters reveal distinct oncogenic circuits, & potential therapeutic vulnerabilities. In this study, the LymphGen 2.0 classifier integrates somatic mutations, copy-number alterations, & structural variants to assign samples to seven genomic subtypes. To molecularly characterize Champions Oncology's lymphoma PDX & ex vivo models, we applied LymphGen to generated mutation, CNV, & fusion data.

Forty lymphoma models with complete genomic profiling were formatted according to LymphGen 2.0 requirements & submitted via the online data portal. Models were assigned to the following categories: MCD, BN2, N1, EZB, ST2, A53, hybrid subtypes, or Other/Unclassified. Subtype assignments were examined in the context of available clinical metadata & functional datasets.

Among the 40 lymphoma models analyzed, the distribution demonstrate a remarkable ability to reproduce not only the full distribution of LymphGen subtypes but also the detailed combinations of structural variants, driver mutations, & pathway lesions observed in clinical tumors. The presence of multiple hybrid calls reflects either overlapping genomic features or incomplete rule satisfaction, consistent with prior reports on LymphGen behavior in heterogeneous or partially altered samples. This stratification highlights biologically representative diversity across the lymphoma models cohort, enabling subtype-aware selection of models for translational studies, including evaluation of BTK inhibitors in MCD-like backgrounds & EZH2-directed therapies in EZB-assigned models.

Application of LymphGen to Champions Oncology's lymphoma models provides robust subtype resolution that mirrors clinically observed molecular heterogeneity. This integration supports rational preclinical model selection, enhances interpretability of drug-response studies, & lays the foundation for expanded multi-omic subtype refinement across the hematologic pipeline.

#7215 The OTP, CD44, Ki67 biomarker panel predicts prognosis in preoperative lung NET biopsy specimens.

Tijmen JJ van Weert[1], Laura Moonen[1], Lisa M. Hillen[1], Jan von der Thusen[2], Michael A. den Bakker[3], Lisa MV Lap[1], PALGA Group[4], Ronald A. Damhuis[5], Wieneke A. Buikhuisen[6], Anne-Marie C. Dingemans[2], Jules L. Derks[2], **Ernst Jan M. Speel**[2]

[1]Maastricht University, Maastricht, Netherlands,[2]Erasmus MC Cancer Institute, Rotterdam, Netherlands,[3]Maasstad Hospital, Rotterdam, Netherlands,[4]PALGA Foundation, Utrecht, Netherlands,[5]Comprehensive Cancer Association, Utrecht, Netherlands,[6]Netherlands Cancer Institute, Amsterdam, Netherlands

Introduction: Previously OTP, CD44 and Ki-67 have been identified as prognostic biomarkers in resected lung neuroendocrine tumors (lung NETs, also known as lung carcinoids (LCs)).
Aims: We aimed to examine the prognostic value of biomarkers OTP, CD44 and Ki-67 in preoperative LC biopsies.
Methods: Patients with LC (reclassified TNM 8 stage I-III, 2003-2022) who underwent a curative resection were selected from Dutch pathology archives (PALGA). Matching resection (Rx) and biopsy (Bx) specimens were identified and immunohistochemistry (IHC) for OTP, CD44 and Ki-67 was performed. Pathology revision was carried out by three pathologists according to the WHO 2021 classification. OTP and CD44 immunostaining were assessed (H-score), and Ki-67 proliferation index (PI) by eyeball estimation with hot-spot scoring. Bx cases diagnosed as typical carcinoid (TC) or carcinoid not otherwise specified (NOS) were grouped as low risk (i.e. non-atypical carcinoid or non-AC). The biomarker panel was classified as low-risk (OTP≥50, CD44≥30, Ki-67<5%) or high-risk (all others).
Results: In total 98 patients were eligible, including 19 patients with a relapse after a median follow-up of 83.3 months. The biomarker panel correctly identified high-risk in 89% (n=17/19) of relapses, outperforming WHO classification, which assigned only 11% (n=2/19) of relapses as AC. Negative predictive value (NPV) of the biomarker panel was 0.96 compared to 0.82 for WHO. Biomarker risk stratification also showed higher inter-rater agreement (biomarker panel: κ=0.673; WHO: κ=0.276, both $p<0.001$) and improved inter-specimen concordance (biomarker panel: κ=0.584, $p<0.001$; WHO: κ=0.169, $p=0.037$).
Conclusion: An OTP, CD44 and Ki-67 IHC biomarker panel substantially improves identification of patients with low-risk LCs and is applicable on biopsy specimens, outperforming the prognostic value of WHO classification. This may influence the choice of surgical treatment strategy.

#7216 HMGB1 expression is linked to unfavorable tumor features and poor prognosis in colorectal cancers.

Nina Schraps[1], Katharina Moller[1], Viktor Reiswich[1], Florian Viehweger[1], Maria Christina Tsourlakis[1], Georgia Makrypidi-Fraune[1], Claudia Hube-Magg[1], Martina Kluth[1], Till Krech[1], Christoph Fraune[1], Andreas H Marx[1], Fiete Gehrisch[1], Baris Mercanoglu[2], Nathaniel Melling[2], Thilo Hackert[2], Ronald Simon[1], Guido Sauter[1], Morton Freytag[1]

[1]Institute of Pathology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany,[2]General, Visceral and Thoracic Surgery Department and Clinic, University Medical Center Hamburg-Eppendorf, Hamburg, Germany

High-mobility group box 1 (HMGB1) is a chromatin-associated protein with a key role in DNA damage repair and genome stability, involved in DNA replication, transcription, and chromatin remodeling. The translocation of HMGB1 from the nucleus to the cytoplasm may confer additional functions regarding the interplay between autophagy, apoptosis and mitochondrial function. By regulating multiple signaling pathways HMGB1 contributes to critical characteristics of cancer cells including inflammation, angiogenesis, proliferation, migration and invasion, as well as tumor energy metabolism. Both increased and reduced expression of HMGB1 have been found to be linked to unfavorable tumor features, presumably depending on its cellular location and tissue type. To gain further insight into the potential significance of HMGB1 in colorectal cancer, a tissue microarray containing 3,456 colorectal cancers was analyzed by immunohistochemistry for nuclear and cytoplasmic HMGB1. A significant nuclear HMGB1 immunostaining was seen in all normal cells of the colorectal epithelium. However, the level of nuclear HMGB1 was variable in cancers. Among 2,601 interpretable cancers, nuclear HMGB1 was completely lost in 8 cases (0.3%) while the staining was 1+ in 179 (6.9%), 2+ in 684 (26.3%), and 3+ in 1,730 (66.5%) tumors. Strong nuclear HMGB1 was significantly linked to distant metastasis (p<0.0001), lymph node metastasis (p=0.0438), blood vessel invasion (p=0.0365), absence of BRAF V600E mutations (p=0.0107), and shortened overall survival (p=0.0118). Nuclear HMGB1 was markedly reduced in mismatch repair (MMR) deficient (43.8% strong) as compared to MMR proficient tumors (73.4%, p<0.0001). Within MMR proficient tumors, high nuclear HMGB1 was linked to V+ (p=0.0089) and L1 status (p=0.0054). Cytoplasmic HMGB1 was less common (16.7%) and unrelated to the histopathologic tumor phenotype. In summary, our data demonstrate that HMGB1 expression is variable in colorectal cancer and that a high nuclear HMGB1 staining level is associated with aggressive tumor features and poor outcome while reduced nuclear HMGB1 is strongly linked to MMR deficiency.

#7217 Homogeneity of mesothelin expression is tightly linked to its levels of expression in non-small cell lung cancer.

Philipp Busch[1], Fiete Gehrisch[2], **Nina Schraps**[2], Katharina Moller[2], Seyma Buyucek[2], Maximilian Lennartz[2], Florian Viehweger[2], Christoph Fraune[2], Christian Bernreuther[2], Ronald Simon[2], Guido Sauter[2], Till Olchers[3], Florian Lutz[2], Martina Kluth[2], Georgia Makrypidi-Fraune[2], Stefan Steurer[2], Martin Reck[3], Sonke von Weihe[3]

[1]General, Visceral and Thoracic Surgery Department and Clinic, University Medical Center Hamburg-Eppendorf, Hamburg, Germany,[2]Institute of Pathology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany,[3]Department of Thoracic Oncology, Airway Research Center North, German Center for Lung Research, LungenClinic, Grosshansdorf, Germany

Mesothelin is a membrane protein which is commonly expressed in lung cancer as well as in other cancer types while it is only rarely seen on the surface of normal cells. Therefore, mesothelin represents an attractive molecule for targeted cancer therapies employing CAR-T cells, monoclonal antibodies, recombinant immunotoxins, antibody-drug conjugates and other drugs. For targeted therapy, both the therapeutic success and the quality of the diagnostic assessment generally may critically depend on the degree of heterogeneity of target protein expression in each individual cancer. Cancers with mesothelin expression in all cancer cells are most likely to be correctly diagnosed as “mesothelin positive” in small biopsies and may also respond optimally to therapy as all tumor cells carry the critical target signature. To study the extent of intratumoral heterogeneity of mesothelin expression in non-small cell lung cancer (NSCLC), a NSCLC heterogeneity tissue microarray was analyzed by immunohistochemistry (IHC) in a tissue microarray (TMA) format. The TMA contained 0.6 mm tissue samples from 8 areas each of the primary cancers of 130 patients and up to 4 samples (1 sample per nodal metastasis) from matched lymph node metastases from 60 of these patients. Mesothelin positivity was observed in 411 of 1,007 (40.8%) evaluable samples. On a patient level, mesothelin positivity occurred in 56.2% (n=73) while the highest mesothelin staining intensity was strong in 30.0% (n=40), moderate in 9.2% (n=12), and weak in 16.2% (n=21) of patients. Heterogeneity analysis was based on 7.7 samples per patient on average (range 2-12) and revealed a homogeneous mesothelin positivity (observed in all evaluable samples) in 21.5% (n=28), a heterogeneous mesothelin positivity in 34.6% (n=45), and a homogeneous lack of mesothelin staining in 43.8% (n=57) of patients. Homogeneous mesothelin positivity was tightly linked to a high level of mesothelin expression. Among 73 patients with detectable mesothelin positivity in their cancers, positivity was homogeneous in 67.5% (27 out of 40) of patients with at least one strongly positive sample, 8.3% (1 out of 12) with only moderate positivity and not seen (0 out of 21) in patients with only weak mesothelin positivity ($p<0.0001$). It is concluded that NSCLC patients with high level mesothelin expression do mostly exhibit a homogeneous positivity across their cancer while the likelihood for heterogeneous findings increases in patients with a more equivocal mesothelin positivity. These findings could further support the concept that a high level of mesothelin staining could be related to a favorable response to anti-mesothelin drugs in NSCLC patients.

#7218 Preliminary exploration of the synergistic mechanism between EBV LMP1 and MYD88 L265P mutation on the efficacy of PD-1 Inhibitors in ABC-DLBCL.

Chang Wang, Yingtao Lin, Jiesong Wang

Lymphoma, Fujian Cancer Hospital, Fuzhou, China

Background: Activated B-cell-like diffuse large B-cell lymphoma (ABC-DLBCL) is aggressive with poor prognosis. Epstein-Barr virus (EBV) infection and the MYD88 L265P mutation are key molecular drivers in ABC-DLBCL, typically exhibiting mutual exclusivity, potentially due to functional overlap. PD-1 inhibitors show limited efficacy in unselected relapsed/refractory DLBCL patients. However, our retrospective analysis of relapsed/refractory non-GCB DLBCL patients suggested that rare "double-positive" (EBV-positive/MYD88 L265P mutant) patients had higher response rates to PD-1 inhibitors.
Objective: This study investigated how EBV LMP1 modulates intracellular signaling in the context of MYD88 L265P mutation (causing constitutive JAK/STAT activation) and evaluated its synergistic effect with the PD-1 inhibitor tislelizumab.
Methods: Clinical data from 54 relapsed/refractory non-GCB DLBCL patients treated with PD-1 antibodies were analyzed. Patients were stratified by EBER ISH (EBV) and MYD88 sequencing. The HBL-1 cell line (MYD88 L265P mutant, EBV-negative) was used. LMP1 was overexpressed via transfection. Groups: control, tislelizumab alone, LMP1 overexpression, LMP1+tislelizumab. qPCR measured mRNA levels of NF-κB p65, MMP9, c-Myc, TLR3, STAT3, JAK3, LMP1, PD-1, PD-L1. Western blot detected protein expression and phosphorylation of key molecules.
Results: Among 21 patients with complete molecular data, both "double-positive" patients achieved an objective response (100%), compared to 22.2% in EBV-negative/MYD88 mutant (n=9) and 60.0% in EBV-positive/MYD88 wild-type (n=5) groups. HBL-1 cells showed high baseline p-JAK3 and p-STAT3. LMP1 overexpression suppressed p-JAK3 and p-STAT3. HBL-1 cells expressed tumor cell-intrinsic PD-1 mRNA. Tislelizumab alone inhibited p-JAK3/p-STAT3 phosphorylation. The combination of LMP1 overexpression and tislelizumab showed the strongest inhibition, indicating synergy.
Conclusion: MYD88 L265P mutation may cause tumor cell addiction to STAT3 activation maintained by tumor cell-intrinsic PD-1 signaling. LMP1 co-existence adds inhibitory pressure, potentially enhancing this dependency. Tislelizumab blockade may yield a synthetic lethal effect. Combined EBV status and MYD88 profiling could predict PD-1 inhibitor sensitivity in DLBCL, requiring further validation.

#7219 Nectin-4 expression is abundant in many different cancer entities.

Luehr Clara[1], Pia Lehmke[1], Katharina Moller[1], Florian Lutz[1], Florian Viehweger[1], Georgia Makrypidi-Fraune[1], Martina Kluth[1], Claudia Hube-Magg[1], Nina Schraps[1], Fiete Gehrisch[1], Christian Bernreuther[1], Guido Sauter[1], Andreas H Marx[2], Ronald Simon[1], Stefan Steurer[1], Christoph Fraune[1], Viktoria Chirico[1], Till S. Cauditz[1], Bertram Veit[1], Clara Von Bargen[1], Cosima Volkel[1], Morton Freytag[1], Nathalia Gorbokon[1], Maximilian Lennartz[1], Eike C. Burandt[1], Anne Menz[1], Till Krech[1], Maria C. Tsourlakis[1], Sarah Minner[1]

[1]Institute of Pathology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany,[2]Department of Pathology, Academic Hospital Fuerth, Fuerth, Germany

Nectin-4 is a type I transmembrane protein with a crucial role in calcium-independent cell-cell adhesion and a critical involvement in several signaling pathways including the PI3K/AKT and the JAK2-STAT5a pathways. Based on these interactions, Nectin-4 is involved in the regulation of migration, adhesion, and proliferation of tumor cells. In several cancer entities, unfavorable prognosis has been described for Nectin-4 positive cancers. Most of the current significance of Nectin-4 is driven by its role as a drug target for enfortumab vedotin (EV) which has been FDA approved for advanced urothelial carcinoma. EV and several other anti-Nectin-4 drugs are currently being investigated in clinical trials on bladder cancer as well as in several other tumor entities. To better comprehend the prevalence of Nectin-4 expression in different cancer types, Nectin-4 was analyzed by immunohistochemistry (IHC) on tissue microarrays (TMAs) containing 2,418 samples from 43 different tumor types. A total of 35 of 43 tumor categories showed Nectin-4 expression in at least one case, and 22 tumor categories contained at least one strongly positive case. A moderate or strong Nectin-4 positivity was most seen in basal cell carcinoma of the skin (50.0%), squamous cell carcinomas of the larynx (45.8%), vulva (44.3%), anal canal (41.0%), penis (39.0%), floor of the mouth (36.5%), skin (32.5%), pharynx (27.6%), uterine cervix (24.4%), vagina (23.3%), esophagus (20.0%), and the lung (14.5%), muscle-invasive urothelial carcinoma (39.1%), clear cell carcinoma of the ovary (33.3%), pulmonary adenocarcinoma (22.9%), endometrioid carcinoma of the ovary (17.2%), lobular carcinoma of the breast (16.7%), invasive breast carcinoma of no special type (13.3%), carcinosarcoma of the uterus (10.5%) and the ovary (6.3%), ductal adenocarcinoma of the pancreas (9.9%), mucinous carcinoma of the ovary (9.1%), gastric adenocarcinoma of diffuse (5.6%) and intestinal type (2.9%), and prostatic adenocarcinoma (2.6-4.3%). It is concluded from these data that Nectin-4 expression occurs commonly in a broad range of different cancer entities. Thus, anti-Nectin-4 cancer drugs may be applicable in multiple applications beyond bladder cancer.

#7220 Claudin-6 (CLDN6) expression is abundant in many different cancer entities.

Veit Bertram[1], Anin Sharifi[1], Katharina Moller[1], Florian Lutz[1], Florian Viehweger[1], Christina Tsourlakis[1], Georgia Makrypidi-Fraune[1], Martina Kluth[1], Christian Bernreuther[1], Guido Sauter[1], Andreas H. Marx[2], Ronald Simon[1], Fiete Gehrisch[1], Nina Schraps[1], Stefan Steurer[1], Christoph Fraune[1], Viktoria Chirico[1], Clara von Bargen[1], Cosima Volkel[1], Morton Freytag[1], Natalia Gorbokon[1], Maximilian Lennartz[1], Eike C. Burandt[1], Anne Menz[1], Till Krech[1], Sarah Minner[1]

[1]Institute of Pathology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany,[2]Department of Pathology, Academic Hospital Fuerth, Fuerth, Germany

Claudin-6 (CLDN6) is a member of the claudin membrane protein family, which are crucial components of tight junctions, regulating paracellular permeability and maintaining cell polarity. CLDN6 is early expressed in embryonic stem cells and in specific fetal tissues such as kidney, lung, pancreas, and stomach, but is not expressed in corresponding adult tissues. While CLDN6 expression is largely lacking on normal tissues, it is highly expressed in several cancers. Therefore, CLDN6 is considered a potential therapeutic target. Studies evaluating CLDN6 as a target for monoclonal antibodies, antibody-drug conjugates, bispecific antibodies, and CAR-T cells are underway. To better comprehend the prevalence of CLDN6 expression in different cancer types, CLDN6 was analyzed by immunohistochemistry (IHC) on tissue microarrays (TMAs) containing 4,464 samples from 101 different tumor types. A total of 39 tumor categories showed CLDN6 expression in at least one case, and 21 tumor categories contained at least one strongly positive case. At least weak CLDN6 positivity was most commonly seen in embryonal carcinoma (100%), seminoma (97.8%), and yolk sac tumor of the testis (97.6%), serous high-grade (76.4%), endometrioid (41.0%) and clear cell carcinoma (31.6%) of the ovary, carcinosarcoma of the ovary (66.7%) and the endometrium (36.0%), basal cell carcinoma of the skin (44.4%), adenocarcinoma of the ampulla Vateri (20%), endometrioid endometrial carcinoma (18.9%), adenocarcinoma of the cervix uteri (17.4%), adenocarcinoma of the esophagus (13.9%), gastric adenocarcinoma, intestinal type (11.6%), mucinous carcinoma of the ovary (9.1%), ductal adenocarcinoma of the pancreas (8.9%), muscle-invasive urothelial carcinoma (6.9%), cholangiocarcinoma (5.9%), squamous cell carcinomas of the esophagus (4.5%), vulva (4.3%), skin (4.1%), larynx (3.1%), penis (2.8%), pharynx (2.3%), anal canal (1.7%), oral cavity (1.2%), and the cervix uteri (1.2%), Brenner tumor of the ovary (3.6%), invasive breast carcinoma of no special type (3.5%), hepatocellular carcinoma (2.0%), gastric adenocarcinoma, diffuse type (1.8%), colorectal adenocarcinoma (1.7%), and diffuse large B cell lymphoma (1.0%). Our tumor cohorts were large enough to compare CLDN6 expression with tumor phenotype in ovarian, endometrial and pancreatic cancer. CLDN6 positivity was associated with advanced pT stage ($p<0.0001$) and high grade ($p=0.0003$) in ovarian cancer and with high grade in endometrial carcinoma ($p=0.0179$) but was unrelated to phenotype in pancreatic ductal adenocarcinoma. It is concluded that CLDN6 is expressed at significant levels in many different tumor types. Once anti-CLDN6 drugs are approved as safe and efficient, patients with many different cancer types may benefit from these new therapies.

#7221 LncRNA SNHG14 remodels cholesterol metabolism to inhibit pancreatic ductal adenocarcinoma via recruiting USP20 and down-regulating miR-105-5p through IRF1-SNHG14-USP20-HMGCR axis.

Zhu Ke[1], Dong Yan[2], Yingying Tong[1], Yurong Cheng[1], Chan Zhang[1]

[1]Beiijing Luhe Hospital Affiliated to Capital Medical University, Beijing, China,[2]UT MD Anderson Cancer Center, Beijing, China

Introduction: Lipid metabolism disorders are closely linked to pancreatic cancer progression, with intricate interactions underlying this association. Small nucleolar RNA host gene 14 (SNHG14), a long non-coding RNA with oncogenic properties, has been implicated in the progression of various malignant tumors including pancreatic cancer. However, its specific contribution to tumor lipid metabolism, particularly in pancreatic cancer, remains unclear.

Methods: Pancreatic cancer models with SNHG14 overexpression or knockdown were established to assess its effects in vitro. Quantitative RT-PCR and Western blotting evaluated SNHG14's influence on the downstream target USP20, while cholesterol detection assays examined its role in regulating intracellular cholesterol. In vivo, a nude mouse subcutaneous xenograft model was used to study tumor growth following SNHG14-knockdown cell injection, confirming its role in pancreatic cancer progression. Tumor tissues were analyzed for USP20 expression and cholesterol content, further supporting SNHG14's regulatory function. Molecular mechanisms were explored via dual luciferase reporter assays and RIP, confirming the interaction between SNHG14 and miR-105-5p, and its regulation of USP20 mRNA stability through the ceRNA pathway. Co-IP revealed the USP20-HMGCR interaction, while ChIP identified IRF1's binding to SNHG14, elucidating its nuclear regulatory pattern.

Results: SNHG14 significantly upregulated USP20 mRNA and protein expression, consistent with its effects in vitro and in vivo. SNHG14 overexpression promoted pancreatic cancer cell proliferation, invasion, and xenograft growth, while SNHG14 knockdown inhibited these effects, confirming SNHG14's oncogenic role via USP20 upregulation. In vivo, SNHG14 knockdown reduced cholesterol levels in pancreatic tumors, identifying SNHG14 as a key regulator of cholesterol metabolism linked to cholesterol accumulation in pancreatic cancer. In the cytoplasm, SNHG14 acts as a molecular sponge for miR-105-5p, competing with it to regulate USP20 mRNA stability and enhance USP20 expression. As a deubiquitinating enzyme, USP20 promotes HMGCR stability and activates the cholesterol synthesis pathway. In the nucleus, IRF1 binds to the SNHG14 promoter, facilitating its transcription. SNHG14 amplifies HMGCR expression via the miR-105-5p/USP20 axis, remodeling cholesterol metabolism and accelerating disease progression.

#7223 Evaluating treatment-related estrogen signaling and molecular subtype heterogeneity in a racially diverse HR-positive breast cancer cohort.

Abigail M. Fielder[1], Gregory Dyson[1], Julie Ruterbusch[1], David Carr[2], Julie Boerner[1], Ann G. Schwartz[1], Kristen S. Purrington[1]

[1]Oncology, Wayne State University School of Medicine, Detroit, MI,[2]Pathology, Wayne State University School of Medicine, Detroit, MI

African American women (AAW) with hormone receptor-positive (HR+) breast cancer have ~50% higher mortality than European American women (EAW), and AAW are twice as likely to have weakly HR+ tumors (1-10% positivity). Although women with weakly HR+ tumors have 60% higher mortality and may still benefit from endocrine therapy (ET), they are less likely to receive ET. Clinical HR staining may not consistently reflect endocrine activity, and better characterization across HR positivity could help ensure optimal treatment.

We performed targeted RNA sequencing on 118 tumors (54 EA, 64 AA) enrolled in the Detroit Research on Cancer Survivorship (ROCS) cohort and the Karmanos Cancer Institute Biobank to assess functional estrogen signaling with the Sensitivity to Endocrine Therapy (SET) index and heterogeneity in molecular subtypes using the Breast Cancer Consensus Subtype (BCCS) panel. Clinical HR staining was grouped as strongly (>90%), moderately (11-90%), and weakly (1-10%) HR+. RNA-seq data were normalized and $\log_2$-transformed. SET values were grouped into low, intermediate, and high tertiles. BCCS subtypes were assigned using the BCCSclassifier R package, yielding five subtypes: ER-negative (ER-) non-basal, ER- basal, ER+ proliferative, ER+ stromal infiltration, and ER+ strong tumor signaling. Relationships between gene expression, SET score, HR categories, and race were evaluated using ANOVA and chi-square tests. Subtype distribution across HR categories and race was tested with multinomial logistic regression ($\alpha = 0.05$).High SET scores were enriched among strongly HR+ tumors ($\chi^2 = 11.9$, $p = 0.018$). Further, 7% of weakly HR+ tumors had high SET scores, while 15% of strongly HR+ tumors had low SET scores, indicating discordance between clinical staining and treatment-related endocrine activity. Tumors from EAW vs. AAW had higher median SET values among those with intermediate (AA median= -0.21 vs. EA median= 0.017, p=0.028) and high (AA median=0.97 vs. EA median=1.88, p=0.16) SET scores. Considering BCCS, weakly HR+ tumors were more likely to have the ER-negative basal subtype compared to strongly HR+ tumors (OR=38.5, p=0.002) and to moderately HR+ tumors (OR=4.9, P = 0.044). Moderately HR+ tumors were also more likely to be classified as ER- basal (OR = 7.9, p = 0.024) compared to strongly HR+ tumors. The proportion of HR+ tumors assigned an ER-negative subtype differed significantly in AA vs EA patients overall (48.3% vs. 26.1%, p = 0.035), and similar trends were seen among the 1-10% (94% vs 67%, p=0.18) and 11-90% (52% vs 20%, p=0.11) HR groups. We observed meaningful differences in hormone signaling phenotypes between AAW and EAW, suggesting that clinical HR staining may not fully capture the underlying endocrine activity. This emphasizes the need for deeper molecular characterization to guide targeted treatment strategies and address disparities.

#7224 Nuclear/cytoplasmic translocation of β-Catenin protein is a strong predictor of unfavorable patient prognosis in ERG negative but not in ERG positive prostate cancer.

Florian Lutz[1], Osman Gokalp[1], Ronald Simon[1], Hans Heinzer[2], Alexander Haese[3], Sarah Minner[1], Guido Sauter[1], Thorsten Schlomm[4], Martina Kluth[1], Claudia Hube-Magg[1]

[1]Institute of Pathology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany,[2]Martini-Clinic, Prostate Cancer Center, University Medical Center Hamburg-Eppendorf, Hamburg, Germany,[3]Martini-Clinic, Prostate Cancer Center, University Medical Center Hamburg-Eppendorf, Hamburg, Germany,[4]Department of Urology, Charite - Universitatsmedizin Berlin, Hamburg, Germany

β-Catenin (CTNNB1) alterations are of potential interest as a prognostic feature and an option for therapeutic targeting in cancer. β-Catenin (CTNNB1) is a dual function protein with roles in cell cohesion and gene transcription as a critical intracellular signal transducer in the Wnt signaling pathway. Cytoplasmic and nuclear translocation of the β-Catenin protein results in an increased transcription of multiple cancer promoting genes. Aberrant nuclear β-Catenin translocation is especially caused by loss of function mutations of genes encoding proteins of the β-Catenin destruction complex or by gain of function mutations of CTNNB1. Affected cancers can be recognized by immunohistochemistry (IHC) due to their aberrant nuclear/cytoplasmic β-Catenin staining. To study the prevalence and the potential role of aberrant β-Catenin staining patterns, more than 6,000 adenocarcinomas of the prostate were analyzed by immunohistochemistry (IHC) in a tissue microarray format. All patients had been treated by radical prostatectomy. Clinical follow-up data were available for 4,895 patients. Among 6,114 evaluable cancers, membranous β-Catenin staining was considered strong in 2,893 (47.3%), moderate in 2,737 (44.8%), and weak in 326 (5.3%) while additional 158 (2.6%) showed unequivocal nuclear/cytoplasmic translocation of β-Catenin protein. Strong membranous β-Catenin staining was more common in 1,926 tumors with (61.4%) than in 2,617 tumors without (37.7%) *TMPRSS2:ERG* fusion ($p<0.0001$). Strong membranous β-Catenin staining was significantly associated with advanced pT stage as well as a high traditional ($p<0.0001$) and quantitative Gleason grade ($p<0.0001$). A comparison of β-Catenin staining data with PSA recurrence revealed only minimal differences between tumors with weak, moderate, and strong membranous staining but a significantly increased risk for PSA recurrence for patients with nuclear/cytoplasmic β-Catenin translocation ($p=0.0448$). A subgroup analysis of 1,258 ERG positive and 1,672 ERG negative cancers revealed that the unfavorable prognostic impact of nuclear/cytoplasmic β-Catenin translocation was only seen in the ERG negative group ($p<0.0001$) while there was even a tendency towards better patient outcome in case of nuclear/cytoplasmic β-Catenin translocation in ERG positive cancers. It is concluded that nuclear/cytoplasmic β-Catenin translocation as detected by IHC is rare in prostate cancer and occurs in about 3% of patients. Only in ERG negative cancers, nuclear/cytoplasmic translocation of β-Catenin is strongly linked to unfavorable disease course. The strong prognostic role of the β-Catenin status could potentially be exploited for clinically relevant disease course prediction.

#7225 TROP2 expression is abundant in primary and recurrent prostate cancer.

Joanthan Jeutner[1], **Ronald Simon**[2], Maximilian Lennartz[2], Sarah Minner[2], Eike Burandt[2], Fiete Gehrisch[2], Nina Schraps[2], Martina Kluth[2], Guido Sauter[2], Natalia Gorbokon[2], Florian Viehweger[2], Hans Heinzer[3], Alexander Haese[3], Thorsten Schlomm[1], Markus Graefen[3], Stefan Steurer[2], Ria Schlichter[2], Christian Bernreuther[2], David Dum[2], Andreas Lubcke[2], Neele Heckmann[3]

[1]Department of Urology, Charite - Universitatsmedizin Berlin, Corporate Member of Freie Universitat Berlin, Humboldt-Universitat zu Berlin and Berlin Institute of Health, Berlin, Germany,[2]Institute of Pathology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany,[3]Martini-Clinic, Prostate Cancer Centre, University Medical Center Hamburg-Eppendorf, Hamburg, Germany

The membrane glycoprotein Trophoblast cell surface antigen 2 (TROP2) is the molecular target of sacituzumab govitecan (SG), an antibody-drug conjugate that has been approved for treatment of breast cancer and urothelial carcinomas. To assess the prevalence and clinical significance of TROP2 expression in primary and recurrent prostate cancer, a tissue microarray containing 17,627 primary and 258 recurrent prostate cancer samples was analyzed by immunohistochemistry (IHC). A positive TROP2 immunostaining was seen in 100% of 12,807 interpretable primary prostate cancers and was rated strong in 94.5%, moderate in 3.5%, and weak in 2.0% of cases. The intensity of TROP2 staining decreased significantly with high tumor stage and Gleason grade. Among 12,669 evaluable primary prostate cancers, TROP2 staining was strong in 95.3% of pT2, 94.0% of pT3a, and 93.2% of ≥pT3b (p=0.0011) as well as in 95.2% of Gleason 3+3, 95.8% of Gleason 3+4, 92.7% of Gleason 4+3, and 90.2% of Gleason ≥8 (p<0.0001). Among 250 evaluable recurrent prostate cancers, TROP2 staining was strong in 57.6%, moderate in 31.6%, weak in 8.4%, and negative in 2.4%. Accordingly, TROP2 staining was significantly less intense in recurrent prostate cancer than in primary tumors (p<0.0001) and also less intense than in Gleason ≥8 primary cancers (p<0.0001). Among primary prostate cancers, TROP2 staining was significantly more intense in cancers harboring the *TMPRSS2:ERG* fusion (98.8% moderate or strong positivity) than in ERG fusion negative tumors (97.5%; p<0.0001). Low TROP2 expression was significantly linked to early biochemical (PSA) recurrence in ERG positive (p=0.0165) but not in ERG negative cancers (p=0.3271). A comparison with 11 of the most frequent genomic deletions (*PTEN*, 3p13, 5q21, 6q15, 13q14, 18q21, 8p21, 12p13, 12q24, 16q24, 17p13) did only reveal marginal associations of reduced TROP2 expression with deletions of 6q15 and 8p21 in ERG negative and with 17p13 and *PTEN* in ERG positive cancers. It is concluded from our data, that TROP2 is always expressed at significant levels in newly diagnosed prostate cancers and that a significant expression is retained in most recurrent cancers although reduced levels of TROP2 expression occur commonly after systemic therapy. Absence of strong associations with chromosomal deletions argues against a relationship between TROP2 expression levels and genomic instability.

#7226 Tumor cell ICAM-1 expression is frequent in many tumor entities and linked to unfavorable tumor phenotype in renal cell carcinomas.

Clara von Bargen[1], Finn Wickel[1], Katharina Moller[1], Florian Lutz[1], Florian Viehweger[1], Georgia Makrypidi-Fraune[1], Martina Kluth[1], Claudia Hube-Magg[1], Christina Tsourlakis[1], Christian Bernreuther[1], Guido Sauter[1], Andreas H Marx[2], Ronald Simon[1], Stefan Steurer[1], Christoph Frauen[1], Nina Schraps[1], Fiete Gehrisch[1], Viktoria Chirico[1], Bertram Veith[1], Clara Luehr[1], Cosima Volkel[1], Morton Freytag[1], Natalia Gorbokon[1], Maximilian Lennartz[1], Eike C. Burandt[1], Anne Menz[1], Till Krech[1]

[1]University Medical Center Hamburg-Eppendorf, Hamburg, Germany,[2]Academic Hospital Fuerth, Furth, Germany

Intercellular Adhesion Molecule 1 (ICAM-1; CD54) is a transmembranous glycoprotein with roles in immune surveillance, inflammation, cell signaling, and apoptotic processes. ICAM-1 is considered a stemness marker in cancer which is often expressed on cancer cells. It can modulate anti-cancer immune response or facilitate metastasis through interactions with immune cells and the extracellular matrix. Because of its surface expression, ICAM-1 is also being explored as a therapeutic target. To better comprehend the role of ICAM-1 expression on tumor cells in different cancer types, ICAM-1 was analyzed by immunohistochemistry (IHC) on tissue microarrays (TMAs) containing 5,946 samples from 105 different tumor types. A total of 85 of 105 tumor categories showed ICAM-1 expression in at least one case, and 70 tumor categories contained at least one strongly positive case. Strong ICAM-1 positivity was most seen in several subtypes of lymphomas (up to 98.0%), metastatic malignant melanoma (87.7%), clear cell renal cell carcinoma (ccRCC; 79.8%), clear cell (tubulo) papillary RCC (75.0%), squamous cell carcinomas of the penis (68.5%), oral cavity (62.8%), esophagus (56.7%), pharynx (54.5%), larynx (54.0%), anal canal (53.4%), urinary bladder (47.6%), cervix (46.3%), and the vulva (43.0%), hepatocellular carcinoma (55.3%), muscle-invasive urothelial carcinoma of the bladder (47.4%), papillary RCC (pRCC; 40.6%), cholangiocarcinoma of the liver (27.3%), intestinal type gastric adenocarcinoma (25.7%), and in serous high-grade ovarian carcinoma (25.4%). Within 1,337 evaluable ccRCCs, ICAM-1 positivity was considered strong in 79.7%, moderate in 11.7%, weak in 6.7%, and absent in 1.9%. High ICAM-1 expression was associated with unfavorable ISUP grade ($p<0.0001$), advanced pT stage ($p<0.0001$), high UICC stage ($p=0.0002$), and distant metastasis (M1, $p=0.0181$). Within 370 pRCCs, ICAM-1 positivity was strong in 40.0%, moderate in 21.1%, weak in 25.9%, and absent in 13.0%. High ICAM-1 positivity was associated with poor ISUP grade ($p<0.0001$) and also tended to correlate with high pT stage ($p=0.0861$) and UICC stage ($p=0.0890$). It is concluded that ICAM-1 expression on tumor cells occurs commonly in many cancer entities. That high ICAM-1 expression was linked to unfavorable tumor features in RCCs supports the concept of a role of ICAM-1 expression for cancer progression.

#7227 *NECTIN4*-amplified breast cancer targeted by Zelenectide Pevedotin: Amplification and expression are frequent, concordant, and stable.

Alexander Azizi[1], Niklas Klumper[2], Emma Colliver[1], Alexander Quaas[3], Birgid Schoemig-Markiefka[3], Arndt Hartmann[4], Christoph Kuppe[5], Manuel Ritter[2], Viktor Grunwald[6], Michael Holzel[7], Chris Bailey[1], Gustavo Arruda Bezerra[8], Nicholas Guthertz[8], Sergey Nikolaev[9], Fabrice Andre[9], Charles Swanton[1], Johannes Braegelmann[3], Markus Eckstein[10]

[1]The Francis Crick Institute, London, United Kingdom,[2]University of Bonn, Bonn, Germany,[3]University of Cologne, Cologne, Germany,[4]Inst. of Pathology, University Hospital Erlangen, Erlangen, Germany,[5]RWTH Aachen, Aachen, Germany,[6]Essen University Hospital, Essen, Germany,[7]University Medical Centre Bonn, Bonn, Germany,[8]Bicycle Therapeutics, Cambridge, United Kingdom,[9]Gustave Roussy, Villejuif, France,[10]FAU Erlangen-Nurnberg, Nurnberg, Germany

Background

NECTIN4 amplification (amp) can predict response to Nectin4-targeted therapy. In the Phase I/II Duravelo-1 trial (NCT04561362), *NECTIN4*-amp breast cancer (BC) showed higher response rates to the Bicycle® Drug Conjugate (BDC™) zelenectide pevedotin (zele, formerly BT8009) versus non-amp tumors (57.1% vs. 6.3%) (Klümper et al, SABCS 2024). These findings led to FDA Fast Track designation and the Phase II Duravelo-3 trial in *NECTIN4*-amp BC (NCT06840483). To further characterize *NECTIN4* and its targetability, we assessed its prevalence, biology across BC datasets, and describe its structure-activity based targeting.

Methods

Public, multi-omic primary BC data from METABRIC (n=2173), TCGA (n=1079), and TRANSNEO (n=166) were analyzed. Proprietary primary tissue data (Cologne cohort, n=252) linked high *NECTIN4* copy number (CN; amp/polysomy via FISH) with expression and BC subtypes. Metastatic analyses were conducted on META-PRISM (n=59). High *NECTIN4* CN was defined as >2× ploidy (amp) or ≥6 copies (polysomy). Structural and biophysical studies (crystallography, SPR) assessed zele's binding.

Results

High *NECTIN4* CN was observed in 21.1% (METABRIC), 30.8% (TCGA), and 29.5% (TRANSNEO) of cases, ranking in the 97.5th percentile for amp (TCGA, all genes). By subtype, HR+, HER2+, and TNBC tumors exhibited high CN in 21%, 19%, and 20% (METABRIC) and 30%, 29%, and 36% (TCGA), respectively. CN correlated with elevated mRNA ($p < 2 \times 10^{-16}$) and protein expression ($p = 2 \times 10^{-6}$). No differences were observed by immune infiltrate or germline BRCA status. In the Cologne cohort, high *NECTIN4* CN (19.1%) strongly correlated with membranous Nectin-4 expression (median H-score 150 vs 0, $p = 8.8 \times 10^{-28}$). In META-PRISM metastases, high CN prevalence was similar (29%) and correlated with RNA expression ($r^2 = 0.34$, $p < 0.00001$). Zelenectide pevedotin binds Nectin-4 domain 1 with high affinity (Kd 2.5 ± 1.5 nM) and minimal conformational change (RMSD 0.435 Å). Its compact bicyclic scaffold (4.2 kDa, surface area 1900 Å^2) provides a smaller footprint than conventional antibodies while maintaining strong target engagement, and rapid renal clearance (t½ <1 h), which should support rapid tumor penetration, and efficient delivery of the MMAE payload.

Conclusions

NECTIN4 amplification is frequent, concordant with high RNA and protein expression, and stable in frequency between primary and metastatic BC. Nectin-4 can be effectively engaged by the BDC zelenectide pevedotin with high affinity. The frequency and stability of *NECTIN4* amplification across breast cancer subtypes supports its evaluation as a biomarker for patient selection in Nectin-4-targeted trials.

#7228 A novel digital PCR assay can detect MLH1 variants in patients with hereditary colorectal cancer.

Matthew Moldenhauer[1], Aditya Mahadevan[2], Cameron Hom[3], Valeria Rangel[3], Sophie Hasson[4], Farshid Dayyani[3], Ning-Hsiang Hsu[3], Deepika Nathan[3], Vishal Chandan[5], Selma Masri[6], Feng Qiao[3], Nicholas Pannunzio[3], **Jennifer Brooke Valerin**[3]

[1]UC San Diego, La Jolla, CA,[2]UCSF, San Francisco, CA,[3]UC Irvine, Orange, CA,[4]Ohio State University, Columbus, OH,[5]University of California, Irvine, Orange, CA,[6]University of California, Irvine, Irvine, CA

Background: Lynch syndrome significantly increases the risk of developing colorectal cancer (CRC) due to an inherited defect in mismatch repair (MMR). Early detection relies on identification of pathogenic mutations in patients, but few canonical Lynch mutations exist. We describe two separate colon cancer patients with identical mutations in the *MLH1* gene (*MLH1* c.2054C>T) and later determined to be cousins as well as a third relative diagnosed with several cancers with the same mutation. Despite a strong family history of cancer, the *MLH1* mutation was labeled discordantly on different NGS panels and required several weeks to obtain results delaying patient care. This highlights a need for improved diagnostics with faster turn-around time, increased cost effectiveness, and ability to screen for non-canonical Lynch variants. We designed a novel, customizable digital PCR (dPCR) assay to rapidly detect *MLH1* gene variants. We also conducted in-depth molecular modeling, mutational signature analyses, and *Saccharomyces cerevisiae* based functional assays to demonstrate that the *MLH1* mutation likely disrupts the interaction with binding partner PMS2, impairing MMR; defining a novel *MLH1* mutation.

Methods: NGS: DNA was isolated. The NovaSeq platform was used for sequencing. Data analysis was performed on the RTA software. Digital PCR: TaqMan probes were created for *MLH1* using a FAM labeled probe for wild type alleles and a HEX labeled probe for mutants. Quantification of fluorescent signal used Thermo Quantstudio software with total signal converted to a percentage to determine the VAF. Yeast assay: In *S. cerevisiae*, *mlh1* and *pms1* knockout (*mlh1Δ* and *pms1Δ)* strains were obtained through the fragment insertion technique. Yeast expression plasmids encoding the human versions of *mlh1-2054*, *MLH1*, and *PMS2* were obtained via the LR clonase technique. Plasmids were transformed into the heterozygous diploid knockout yeast strain to make the genetic construct for the assay CHT8 and CHT9 in which fresh segregants are dissected into haploids for our 5-FOA assays.

Results: We designed two fluorescently labelled probes, one that recognizes the wild-type *MLH1* allele and one specific for c.2054C>T (*mlh1-2054).* We can detect *MLH1* and *mlh1-2054* alleles in equal amounts, consistent with a heterozygous germline mutation in all 3 patients. We observed a significant increase in mutation frequency in yeast transformed with the *mlh1-2054* variant compared with *wild-type hMLH1*, which reflected the difference in mutation frequency we observed in comparing *MLH1 PMS1* yeast and *mlh1Δ pms1Δ* yeast. This suggests the *mlh1-2054* variant present in all patients is pathogenic due to the resulting MMR defect we see in our yeast genetic model.

Conclusion: This study emphasizes the need for improved diagnostic tools to identify pathogenic mutations in diverse populations and establishes a novel *MLH1* hereditary mutation.

#7229 TM-PAP, everywhere you need it: Cross-species, multi-host panel for fast readouts.

Yue Huang, Xiaomeng Gou, Yao Peng, Jinying Ning, **Feng Hao**

Kyinno Biotechnology Co., LTD, Beijing, China

Prostatic acid phosphatase (PAP, a.k.a. ACP3) is a convenient, druggable antigen for rapid assay development when displayed on the cell surface as TM-PAP (membrane-localized PAP). Compared with ad-hoc antigen systems, a standardized, cross-species TM-PAP panel enables reliable head-to-head testing of antibody and small-molecule formats across hosts and species barriers. Such models accelerate mechanism confirmation (binding, internalization), effector biology (ADCC/ADCP/CDC), payload delivery (ADC, RIC), and analytical assays (qFACS titering, IHC controls), while providing clean negative controls via isogenic ACP3-KO backgrounds.We assembled 15 engineered models spanning four species variants (human, mouse, rat, cynomolgus) across eight host lineages: human cancer and producer lines (LNCaP, VCaP [pools], PC3, HT-1080, 293T) plus bioproduction/rodent oncology backbones (CHO-K1, MC38, CT26). The panel includes LNCaP-ACP3-KO (isogenic negative control); human TM-PAP in PC3, HT-1080, 293T, CHO-K1, MC38, and CT26; ortholog panels in 293T/CHO-K1 for mouse, rat, and cynomolgus TM-PAP; and LNCaP-ACP3 and VCaP-ACP3 for rapid screening when single-cell cloning is unnecessary. The platform now supports both in vitro and in vivo workflows: multiple hosts (e.g., LNCaP, PC3, HT-1080, MC38, CT26) are established for murine xenograft/syngeneic studies, and the remaining lines are compatible with in-vivo deployment or serve as system controls, enabling end-to-end evaluation from binding/internalization to pharmacology and efficacy.Species-matched TM-PAP cDNAs were integrated to generate stable lines (clones or pools), with expression verified by flow cytometry (FACS) and routine QC (mycoplasma-free, STR-authenticated where applicable). The ACP3-KO line was created by CRISPR/Cas9. Typical readouts include high-throughput binding EC_{50}, pH-sensitive internalization, and Fc-mediated functions using human or rodent effectors, plus analytic controls for IHC/ELISA. This panel lets teams (i) standardize antigen-centric screening across species, (ii) de-risk cross-reactivity and matrix effects before animal work, and (iii) compress assay setup time from weeks to days—bringing “TM-PAP, everywhere you need it” to early discovery, CMC-adjacent analytics, and translational method development.

#7230 A paclitaxel-induced rat model of chemotherapy-induced alopecia.

Simonetta I. Gaumond[1], Joaquin Jimenez[2]

[1]Department of Biochemistry and Molecular Biology, University of Miami Miller School of Medicine, Miami, FL,[2]University of Miami Miller School of Medicine, Miami, FL

Chemotherapy-induced alopecia (CIA) is one of the most visible and distressing toxicities of cancer therapy, disproportionately affecting women with breast and ovarian cancers, where paclitaxel remains a cornerstone treatment. Despite its widespread use, no standardized animal model exists to study paclitaxel-induced alopecia or evaluate protective strategies. Here, we report the first reproducible rat model of paclitaxel-induced alopecia. Fourteen-day-old Sprague-Dawley rats were randomized to control (n = 20), low-dose paclitaxel (n = 10), or high-dose paclitaxel (n = 10), administered subcutaneously for three consecutive days. Animals were monitored daily, with peak alopecia observed after two weeks. Alopecia severity was graded by blinded assessors using a quintile grading scale (0 = no hair loss, 4 = complete alopecia). Safety endpoints (weight, grooming, activity) were recorded. On day 28, animals were euthanized and a representative biopsy from each group was acquired, formalin-fixed, paraffin-embedded, and stained with H&E. Alopecia severity differed significantly across treatment groups ($p < 0.0001$, Kruskal-Wallis). Median alopecia scores were 3 in controls, 1 in low-dose paclitaxel ($p = 0.0015$, Dunn's post hoc), and 1 in high-dose paclitaxel ($p < 0.0001$), with no significant difference between paclitaxel doses. Dermoscopy demonstrated localized alopecia at the medial rump injection site. Histopathology revealed reduced follicular density and follicular miniaturization, consistent with classical CIA. Paclitaxel administration reliably induced localized alopecia replicating key clinical and histologic features of CIA. This represents the first standardized paclitaxel rat model of CIA and addresses a critical gap in preclinical dermatology and oncology research. This model provides a biologically relevant platform for mechanistic studies and therapeutic testing, particularly relevant to women, for whom alopecia carries substantial psychosocial burden and may influence treatment adherence.

: Chromatin Architecture and Regulatory Landscapes

#7234 A SWI/SNF-specific Ig-like domain, SWIFT, is a transcription factor binding hub.

Siddhant U. Jain[1], Kaylyn E. Williamson[1], Alexander Ying[1], Aasha M. Turner[1], Jerry R. Jiang[2], Shaunak Raval[3], Kevin So[1], Maxwell J. Allison[1], Akshay Sankar[1], Daniel Guerra[1], Nazar Mashtalir[1], Henry H. Rohrs[2], Cheryl F. Lichti[4], Malvina Papanastasiou[3], Joao A. Paulo[5], Steven Gygi[5], Michael L. Gross[2], Cigall Kadoch[1]

[1]Pediatric Oncology, Dana-Farber Cancer Institute and Harvard Medical School, Boston, MA,[2]Department of Chemistry, Washington University in St. Louis, St. Louis, MO,[3]Broad Institute of MIT and Harvard, Cambridge, MA,[4]Washington University at St. Louis, St. Louis, MO,[5]Department of Cell Biology, Harvard Medical School, Boston, MA

Mammalian SWI/SNF (BAF) chromatin remodeling complexes modulate DNA accessibility and gene expression, however, the mechanisms by which they are targeted on chromatin remain incompletely understood. Here, we define SWIFT (SWI/SNF Ig-Fold for Transcription Factor Interactions), found on the SMARCD family of subunits within the mSWI/SNF core module as an evolutionarily conserved, universal transcription factor (TF) binding platform. SWIFT is necessary and sufficient for direct interaction with the transactivation domain of a lineage-specific TF, PU.1, in vitro and in cells, with a single amino acid mutation in SWIFT able to disrupt PU.1-mSWI/SNF binding, inhibit site-specific complex targeting and activity, and attenuate oncogenic gene expression and proliferation of PU.1-dependent acute myeloid leukemia (AML) cancer cells. Further, dominant expression of the SWIFT domain in isolation sequesters TFs from mSWI/SNF complexes and “poisons” TF-addicted cancer cells across different lineages. Finally, we uncover striking preferences of lineage-specific TFs for the SWIFT domains of specific SMARCD subunit paralogs. These SMARCD paralog-specific affinities of TFs align with their tissue- and differentiation state-specific expression patterns across human cells and tissues, suggesting that that switches in mSWI/SNF subunit composition fine-tune affinities for TFs that govern specialized cell state transitions during normal differentiation and tumorigenesis.In conclusion, this work unmasks a novel mSWI/SNF biochemical interface amenable to targeted therapeutic modulation in a diverse collection of transcriptionally addicted cancers.

#7235 Integrated spatial multiomic profiling of 3D genome architecture and transcriptome-wide gene expression in breast cancer models.

Yi Cui[1], Huy Nguyen[2], Andrea Floris[2], David King[2], Serdar Tulu[2], David Castillo[2], Shanshan He[1], Shyamtanu Chattoraj[2], Jude Dunne[2], Mirko Corselli[1], John Lyssand[1], Joseph M. Beechem[1]

[1]Bruker Spatial Biology, Seattle, WA,[2]Bruker Spatial Genomics, San Jose, CA

Disruption of 3D genome organization profoundly influences gene expression, driving disease and cancer progression. Mechanisms such as oncogene amplification, deletion, and chromatin domain misfolding are key contributors to tumorigenesis. However, conventional approaches like whole-genome sequencing (WGS), RNA-seq, and Hi-C typically assess these changes at the bulk level, masking cell-to-cell heterogeneity. To dissect these mechanisms with single-cell and spatial resolution, we leverage the PaintScape™ system to visualize 3D genome architecture in situ, within single cells. We then correlate changes in genome structure to gene expression and phenotype measured in parallel samples using a spatial multiomic assay on the CosMx® Spatial Molecular Imager (SMI) to generate a comprehensive multi-modal dataset. Using normal (MCF10a) and cancerous (MCF7) breast cell lines, the PaintScape assay enabled high-resolution visualization of chromosomal territories and gene regions involved in cancer-associated pathways, including cell cycle regulation, apoptosis, and chromatin remodeling. We identified cell type-specific structural alterations such as translocations, extrachromosomal DNA (ecDNA) formation, locus copy number variation and shifts in topologically associating domain (TAD) boundaries. Parallel CosMx SMI multiomic imaging revealed transcriptome-wide signatures and subcellular localization patterns of key molecular markers. Upon exposure to Estradiol, an estrogen receptor (ER) agonist, we observed transcriptional upregulation of MYC, CCND1, and E2F1 in ER+ MCF7 cells, contrasting with minimal response in ER- MCF10a cells. PaintScape profiling further revealed spatial clustering of distant estrogen response elements (DEREs) near Chr17q and Chr20q, while CosMx SMI quantified local transcriptional activation, highlighting complementary insights from the two platforms. Together, the PaintScape system and CosMx SMI enable an integrated, single-cell, and spatially resolved interrogation of genome architecture, transcriptomics, and proteomics. This multi-modal approach uncovers cell populations with distinct genomic and phenotypic states, offering a powerful framework to elucidate how 3D genome organization and transcriptional regulation jointly drive cancer heterogeneity and progression.

#7236 Defining and targeting drivers of lineage plasticity in stem cell-like prostate cancer.

Chen Khuan Wong[1], Dan Li[1], Ekta Khurana[2], Yu Chen[1]

[1]Memorial Sloan Kettering Cancer Center, New York, NY,[2]Weill Cornell Medicine, New York, NY

Prostate cancer depends on androgen receptor (AR) signaling for growth, which is why androgen deprivation (castration) therapy is effective at early stages. However, many tumors eventually progress to a lethal form known as castration-resistant prostate cancer (CRPC). A subset of CRPC tumors bypass dependency on AR signaling by acquiring lineage plasticity, where prostate cancer cells transdifferentiate into alternate cellular states through epigenetic reprogramming. Neuroendocrine (NE) prostate cancer represents one well-known lineage plasticity phenotype. Nevertheless, most AR-independent tumors do not exhibit NE features and are defined as AR-negative/NE-negative or “double-negative prostate cancer” (DNPC). In a collaboration with Dr. Ekta Khurana’s computational genomics lab at Weill Cornell Medicine, we recently classified CRPC into four epigenetic subtypes, including the well-established 1) AR and 2) NE, as well as the novel DNPC subgroups 3) WNT and 4) stem cell-like (SCL) (PMID: 35617398). We focused on the SCL subtype as it is the second most common group in CRPC patients and lacks therapeutic targets. Using functional genomic approaches, we found that YAP/TAZ/TEAD cooperates with FOSL1 to drive the SCL lineage and growth of SCL models. We therefore hypothesize that the heightened dependency on the YAP/TAZ/TEAD/FOSL1 transcriptional program represents a therapeutic vulnerability in CRPC-SCL. To test this, we exposed CRPC models to TEAD inhibitors and found robust growth suppression in SCL cells compared to non-SCL cells in vitro. To evaluate whether the TEAD inhibitors are on-target, we performed transcriptomic profiling in SCL models and observed downregulation of YAP/TAZ gene signature as well as FOSL1 expression, which phenocopies the effects of YAP/TAZ double knockdown. To define the cistromes of these factors upon TEAD inhibition, we performed ChIP-seq and observed reduced co-occupancy at consensus sites, suggesting the disruption of the YAP/TAZ/TEAD/FOSL1 transcriptional circuit by the small molecule compound. To determine whether these phenotypes are recapitulated *in vivo*, we will treat mice harboring CRPC-SCL xenografts with TEAD inhibitors to assess growth response and evaluate epigenetic and transcriptional response using single-nucleus Multiome (ATAC+RNA). These studies will establish whether small molecule inhibition of TEAD is a promising strategy for the treatment of CRPC-SCL and allow high-resolution analysis of cell state transitions, with a focus on loss of SCL-specific signatures and potential emergence of AR/NE programs as adaptive resistance mechanisms.

#7237 LDB1-dependent enhancer connectivity constrains a metabolic synthetic lethality in T-cell acute lymphoblastic leukemia.

Rahul S. Bhansali[1], Juan S. Long[2], Siqing Wang[2], Ahnaf Tausif[2], Shuo Zhang[3], Petri Polonen[4], Sarah Skuli[1], Nicholas Aboreden[5], Zhuangzhuang Geng[2], Belinda M. Giardine[6], Cheryl A. Keller[6], Ross C. Hardison[6], Charles G. Mullighan[4], Gerd A. Blobel[2]

[1]Hospital of the University of Pennsylvania, Philadelphia, PA,[2]Children's Hospital of Philadelphia, Philadelphia, PA,[3]University of Pennsylvania, Philadelphia, PA,[4]St. Jude Children's Research Hospital, Memphis, TN,[5]Dana Farber Cancer Institute, Boston, MA,[6]Penn State University, University Park, PA

LDB1 and LMO2, two proteins frequently overexpressed in T-cell acute lymphoblastic leukemia (T-ALL), form a chromatin architectural complex that promotes chromatin looping between enhancers and/or promoters. Here, we defined LDB1-driven oncogenic enhancer connectivity in T-ALL and examined its impact on therapeutic vulnerabilities.

To identify proximal LDB1 targets in T-ALL, we engineered isogenic T-ALL cell lines (LOUCY [ETP-ALL] and KOPT K1 [non-ETP-ALL]) with dTAG degrons at the endogenous LDB1 loci. Treatment with dTAG-V1 ligand for 4 hours reduced LDB1 protein levels and chromatin occupancy by >90%. Acute LDB1 loss disrupted spatial enhancer connectivity at critical leukemic oncogenes in both LOUCY (e.g. *HHEX, MYB, MYCN*) and KOPT K1 (e.g. *DUSP6, STAT4*), resulting in their downregulation and subsequent reduction in cell growth. CRISPRa-mediated restoration of select LDB1-dependent oncogenes, such as *MYB*, in LDB1-depleted cells rescued cell expansion.

Nascent transcript profiling further revealed that acute LDB1 loss affected distinct gene sets in LOUCY and KOPT K1, consistent with their distinct identities. Notably, however, several cholesterol biosynthetic genes (*HMGCS1, MVD, MVK*) were upregulated in both cell types. These changes were not driven by altered expression or subcellular localization of SREBP2—the canonical transcriptional regulator of these genes. Instead, they were caused by altered enhancer-promoter connectivity in the absence of LDB1. Specifically, LDB1 loss disrupted connectivity of nearby enhancers for different genes, thereby liberating them to form de novo contacts with *HMGCS1, MVK,* and *MVD* gene promoters to activate them. Hence, by clustering regulatory elements, LDB1 not only enables the expression of genes but also constrains enhancers from making inappropriate contacts. Importantly, the native LDB1-dependent loops are detected in primary samples from patients with T-ALL based on published H3K27ac HiChIP data.

Functionally, we found that cholesterol flux and expression of upstream regulators, like *SREBP2*, increased with prolonged LDB1 depletion, suggesting a feed-forward regulatory mechanism on cholesterol homeostasis in T-ALL. Using both LDB1 degron and knockout models, we observed that LDB1 loss sensitizes leukemic cells to rosuvastatin and pitavastatin by 2-5-fold. This was recapitulated in several T-ALL cell lines with distinct molecular drivers upon LDB1 knockout. Furthermore, statin sensitization was rescued by spike-in of mevalonate or geranylgeranyl pyrophosphate, confirming that this phenotype is driven by altered cholesterol metabolism.

Together, our study illustrates a paradigm by which LDB1 loss enables illegitimate spatial connections of enhancers with cholesterol biosynthetic gene promoters. This, in turn, creates a new metabolic addiction in leukemic cells, which may be targeted with statins.

#7238 Cis-regulatory role of alternative promoters in cancer.

Emily R. Wilson, Xiaoyang Zhang

University of Utah Huntsman Cancer Institute, Salt Lake City, UT

Alternative promoters are increasingly recognized as critical regulators in cancer, with differential promoter usage driving transcriptional shifts that can support oncogenic activity. While promoters are traditionally viewed as transcription initiation sites, emerging evidence suggests they can also act as cis-regulatory elements, enhancing or compensating for the expression of neighboring genes. Our 3D genomics data reveal that alternative promoters of the same gene interact with each other at the chromatin level, yet it remains unknown whether these interactions play a functional cis-regulatory role in regulating the gene's expression. Through analysis of TCGA data, we discovered that minor alternative promoters exhibit enhancer-like histone modification signatures and cancer-type-specific chromatin accessibility. To mechanistically interrogate their cis-regulatory potential, we employed CRISPR interference (CRISPRi) and CRISPR activation (CRISPRa) to modulate minor promoter activity and assess the impact on major isoform expression in cancer-related genes such as EGFR. We also found that this cis-regulatory enhancer function of minor promoters is driven by lineage-specific transcriptional master regulators. Additionally, CRISPRi-mediated repression of the major promoter led to increased minor isoform expression, suggesting a compensatory function of minor promoters. We will further investigate this compensatory activity using high-resolution chromatin interaction mapping (HiChIP) to determine whether shifts in enhancer interactions contribute mechanistically to compensation. Currently, the field lacks a clear understanding of how alternative promoters function as cis-regulatory elements, limiting our ability to define how cancer cells exploit these promoters to promote oncogenic activity. These studies will delineate mechanisms by which alternative promoters regulate oncogenic gene expression through enhancer-like and compensatory functions and will generate a resource of cancer-type-specific alternative promoters with cis-regulatory activity, offering potential therapeutic targets and a new framework for modulating oncogene expression.

#7239 A genomic deletion variant controls super-enhancer-driven overexpression of LINC00636 and CD47 to promote tumor cell survival in breast cancer.

Carolina Di Benedetto, Amelia Tsark, Alysia Thach, Anmol Singhal, Anthony Rodriguez, **Paola Betancur**

University of California, San Francisco, San Francisco, CA

Dysregulated gene expression in cancer is often driven by epigenetic reprogramming of non-coding regions such as super-enhancers (SEs). These large enhancer clusters are rarely active in normal tissues but can drive overexpression of genes that promote malignant traits, including immune evasion. Previously we have shown that SEs are linked to chemotherapy resistance and anti-apoptotic gene expression in triple-negative breast cancer (TNBC). Although SEs are promising therapeutic targets, their large size makes them difficult to target effectively in cancer therapy. This limitation underscores the need to identify smaller, functionally critical regions within SEs that can serve as precise therapeutic entry points.The goal of this research is to define and functionally validate core elements within breast cancer–specific SEs that are necessary and sufficient to drive immune escape. We hypothesize that these core elements, alone or in combination, act as molecular drivers of malignancy by aberrantly activating the immune-suppressive gene *CD47* and the regulatory long non-coding RNA *LINC00636*.Our rationale stems from the discovery of a breast cancer–specific SE harboring a germline insertion/deletion (InDel) variant that regulates *CD47* and *LINC00636* expression. CRISPR deletion of this variant in engineered breast cancer cells increased chromatin accessibility of the SE region, leading to upregulation of *CD47* and *LINC00636*, enhanced resistance to nutrient-deprivation–induced apoptosis (via *CD47*), activation of senescence (driven by elevated *LINC00636*), and delayed cell death. RNA-seq analyses of cells lacking the insertion and cells with high *LINC00636* expression revealed a shared immunosuppressive and pro-survival transcriptional program, including increased *CXCL17, STAT1, CXCL8*, and *ANGPTL4*—genes associated with tumor immune signaling, senescence and apoptosis resistance. In macrophage-competent xenograft models, deletion of the variant reduced anti-tumor macrophage infiltration, supporting activation of an immune-evasive state. Clinically, breast cancer patients carrying the insertion allele show improved progression-free survival when compared to patients homozygous for the deletion—demonstrating the clinical relevance of discrete SE elements.Together, our findings identify a common InDel variant as a minimal core element that fine-tunes the regulatory activity of a bifunctional SE controlling *CD47* and *LINC00636*. Our work provides new insight into SE-mediated gene dysregulation in breast cancer and highlights the therapeutic potential of targeting discrete SE components rather than entire enhancer clusters.

#7240 Multi-omic analysis identifies BACH2 transcription factor as key epigenetic and transcriptional repressor driving drug-tolerance to targeted therapy in EGFR-mutant lung adenocarcinoma.

Yoshimasa Kudo[1], Althaf Singhawansa[2], Yong Zeng[2], Catherine O'Brien[3], Scott Bratman[4], Geoffrey Liu[1]

[1]Department of Medical Biophysics, University of Toronto, Toronto, ON, Canada,[2]Princess Margaret Cancer Center, University Health Network, Toronto, ON, Canada,[3]Department of Laboratory Medicine and Pathobiology, University of Toronto, Toronto, ON, Canada,[4]Department of Radiation Oncology, University of Toronto, Toronto, ON, Canada

RATIONALE Drug resistance poses a significant challenge for EGFR-mutant lung cancer patients treated with osimertinib, a 3rd-generation EGFR tyrosine kinase inhibitor. Non-mutational mechanisms, particularly epigenetic alterations in drug-tolerant persister (DTP) cells, enable survival under lethal drug pressure and seed resistance. A deeper understanding of these mechanisms is required to evaluate whether targeting epigenetic changes in DTP cells may represent a promising therapeutic strategy.

METHODS We conducted a preclinical multi-omic study to map the epigenetic and transcriptional changes driving DTP in EGFR-mutant lung cancer. Using PC9-DTP cell line exposed to osimertinib for 14 days, we employed a combination of single-cell and bulk omics assays to profile genome-wide DNA methylation, chromatin accessibility, and transcriptomic landscapes defining the DTP state. Top epigenetic regulators were nominated from integrative analyses, and public datasets from other EGFR-mutant lung cancer models were analyzed for validation.

RESULTS DTP cells displayed global DNA hypermethylation across the vast majority (88.7%) of differentially methylated regions. Hypermethylation in cis-regulatory regions were strongly associated with closed chromatin and reduced transcription ($R=-0.64$, $p<2.2e-16$), reflecting coordinated epigenetic silencing. Gene regulatory network analysis and *in silico* perturbation, leveraging paired transcriptomic and chromatin features from single-cell multi-omic assay, identifies BACH2 - transcriptional and epigenetic repressor - as the top repressive transcription factor in DTP-specific networks. Additionally, chromatin remodeler HMGA1 was among the target genes most strongly repressed by BACH2. Based on motif enrichment analysis, BACH2-specific DNA-binding motifs were enriched in hypermethylated ($p<1e-4$) and closed chromatin regions ($p<1e-6$), accompanying the downregulation of corresponding target genes, including HMGA1. Furthermore, pathway analysis of BACH2-repressed target genes revealed enrichment in oxidative phosphorylation and ATP synthesis, indicating a metabolic shift. Finally, analyzing public transcriptomic datasets from other cell line models, patient-derived organoids (PDOs), xenografts (PDXs), and patient tumor samples confirmed consistent BACH2 upregulation in DTP and residual disease state, as well as downregulation of HMGA1 and other target genes.

CONCLUSION These findings position BACH2 as a key contributor of epigenetic silencing and metabolic reprogramming in osimertinib-induced DTP state. Overall, our multi-omic approach provides high-resolution insight into drug-tolerance mechanisms and nominates BACH2 as a priority target, potentially informing novel therapeutic strategy for improved patient outcome.

#7241 Decoding 3D enhancer architecture identifies hierarchical oncogenic regulatory programs in prostate cancer.

Huan Cao, Zexun Wu, Baixi Ji, Seolyn Yang, Leonardo Gonzalez-Smith, Andrew Vu, Suhn K. Rhie

Department of Cancer Biology, Keck School of Medicine of USC, Los Angeles, CA

Aberrations in non-coding DNA regions, particularly those located in regulatory elements, are increasingly implicated as a hallmark of prostate cancer. Yet, mapping enhancers that underpin tumor-specific transcription remains challenging. Here, we developed an integrative workflow to prioritize prostate cancer-specific enhancers (PSEs) by analyzing 204 H3K27ac ChIP-seq datasets from prostate tumor and normal tissues, alongside prostate cell lines. We connected the differentially activated enhancer landscape to three-dimensional (3D) chromatin organization in prostate cancer by identifying key oncogenic topologically associating domains (TADs) from Hi-C datasets. We selected a previously uncharacterized but high-priority locus at chr6q24.1 for in-depth study. To define cancer-specific 3D architecture at chr6q24.1, we generated Region-Capture Micro-C (RCMC) maps at nucleosome resolution in RWPE-1 (normal) and 22Rv1 (cancer) cells. This revealed highly nested enhancer-promoter (E-P) interactions, which we termed multi-connected enhancer hubs, that were prominent in cancer but absent in normal, exceeding the sensitivity of conventional Hi-C for enhancer-centered contacts. CRISPR/Cas9 deletion of individual enhancers across the locus, followed by multi-omic profiling, revealed two distinct enhancer classes. Central PSEs (cPSEs) function as core regulatory organizers, whose deletions weakened activities of other PSEs, collapsed locus-wide chromatin interactions, reduced target gene expression, and impaired cancer cell proliferation without broadly altering CTCF/cohesin architecture. In contrast, redundant PSEs (rPSEs) are buffered by neighboring rescuing enhancers to preserve transcription via compensatory rewiring that strengthens alternative E-P contacts. Our data also suggest that these two classes of enhancer behaviors are associated with differential activity of FOXA1, a pioneer transcription factor in prostate cancer. Together, our study revealed cancer-specific, multi-connected enhancer hubs essential for prostate tumorigenesis and uncovered the regulatory hierarchy of enhancers, providing a framework to functionally characterize and validate oncogenic non-coding DNA regions that sustain prostate cancer phenotypes. This study advances our understanding of non-coding regulatory regions and offers future opportunities for developing novel precision epigenome-based clinical interventions for prostate cancer.

#7243 In-situ direct single-cell visualization of 3D genome architecture in ER+ and HER2+ breast cancer cell lines using PaintScape™ system.

Huy Nguyen[1], Sophie Pribus[2], Zhicheng Ma[2], David King[1], Johnson Huynh[1], Serdar Tulu[1], Marc Glazer[1], Brian Smart[1], David Castillo[1], Kenny Chung[1], Shyamtanu Chattoraj[1], Jude Dunne[1], Doug Werner[1], Christina Curtis[2], Mark Munch[1]

[1]Bruker Spatial Genomics, San Jose, CA,[2]Stanford University, Stanford, CA

Breast cancer (BC) is highly heterogeneous, and classification based on ER, PR, and HER2 expression alone does not fully capture its clinical diversity or therapeutic vulnerabilities. In particular, the aggressive HER2 positive (HER2+) and estrogen receptor positive (ER+) subtypes are driven by complex genomic and cellular dynamics-including epithelial to mesenchymal transition (EMT), chromosomal instability, and 3D genome reorganization that contribute to metastasis, therapy resistance, and poor prognosis. Bulk studies such as WGS and Hi-C have revealed key genomic features in BC sub-types such as focal amplifications (e.g. CCND1-HER2 co-amplification in HER2+ BC; Chr 20q alterations in ER+ BC), A/B compartment switching, TAD boundary disruptions and associated oncogenic rewiring. However, these approaches remain ex-situ and bulk-based obscuring the spatial and cellular heterogeneity and fail to capture the full spectrum of structural and functional interactions within individual cells which is critical to understanding disease progression. To overcome these limitations, in-situ single-cell technologies capable of resolving dynamic 3D genome changes are essential for uncovering resistance mechanisms and enabling precision therapies tailored to the unique genomic landscape of each tumor cell.

Here we present the PaintScape™ system enabling simultaneous in-situ visualization of the 3D genome structure in single BC cells. Over 1,000 targets relevant in several important cancer pathways including Cell Cycle and Apoptosis, Transcriptional Regulation and Chromatin Structure are visualized across all chromosomes using our OncoPaint™ Oncogenic Pathways Panel in ER+ MCF7 and HER2+ HCC 1954 cell lines. We identified common and cell line specific unique 3D genome alterations between MCF7, HCC 1954 and other breast cell lines, and relate these to patterns of genomic rearrangement inferred from patient samples. In ER+ MCF 7, we identified distributions in copy gain/loss of specific chromosome arms e.g. Chr 20q, individual targets including regions of clustered breakpoints, unique ecDNA and distal estrogen response elements (DEREs), at the single cell, and sub-population level. In HER2+ HCC 1954, we identified focal amplification of Chr 8q and directly visualized ecDNA amplification, rearrangement and nuclear localization of key oncogenes such as MYC and CCND1. We simultaneously show A/B compartment switching and TAD boundary disruption of key oncogenic regions in MCF7 and HCC 1954 in-situ, showing consistency with up/down regulation of genes between the cell lines.

The PaintScape system enables simultaneous in-situ 3D genome mapping within single cells revealing structural differences linked to gene dysregulation across BC sub-types, offering an integrated view of how genome architecture influences cellular processes during disease progression.

#7244 AMPK interacts with PRC1.1 complex on chromatin to regulate NADK expression in response to metabolic stress in acute lymphoblastic leukemia.

Anna Shvab[1], Guy J. Leclerc[1], Julio C. Barredo[2]

[1]Pediatrics, University of Miami Miller School of Medicine, Miami, FL,[2]Div. Director, Pediatric Hem./Onc., University of Miami, Miami, FL

Acute lymphoblastic leukemia (ALL) remains a leading cause of pediatric cancer-related mortality. ALL cells are particularly vulnerable to metabolic stress following activation of AMP-activated protein kinase (AMPK), a master regulator of cellular energy homeostasis. We and others have demonstrated that AMPK interacts with chromatin-associated proteins to modulate gene expression in response to energy stress. A comprehensive AMPK interactome analysis using TurboID proximity labeling proteomics identified the non-canonical Polycomb Repressive Complex 1.1 (PRC1.1) as an AMPK-associated complex. Co-immunoprecipitation confirmed interactions between AMPK and PRC1.1 components (PCGF1, RING1, KDM2B, BCOR, BCORL1, USP7, SKP1, and RYBP) in KASUMI-2 (Bp-ALL) and KE-37 (T-ALL) cells, which were enhanced following treatment with allosteric AMPK activators (PF-06409577, 991). To evaluate the functional consequence of AMPK activation on PRC1.1 activity, we measured H2AK119ub levels under metabolic stress and observed a marked increase. In contrast, AMPKα1/α2 double knockout (DKO) HEK293T cells treated with AMPK activators exhibited no change, confirming AMPK dependency. ChIP-seq analysis in KASUMI-2 and KE-37 cells identified *Nicotinamide adenine dinucleotide kinase* (*NADK*) as an AMPK-associated chromatin target. ChIP-qPCR demonstrated accumulation of AMPK, BCOR, and KDM2B at the *NADK* promoter under metabolic stress, correlating with increased H2AK119ub and reduced RNA polymerase II occupancy, indicative of transcriptional repression. RT-qPCR and immunoblot analyses confirmed NADK downregulation in ALL cells exposed to metabolic stress, while pharmacological inhibition of AMPK (BAY-3827) or RING1 (PRT4165) upregulated NADK expression. Similarly, NADK repression was abrogated in HEK293T AMPKα1/α2-deficient cells, and pharmacological inhibition of USP7 (CDDO-Me and Eupalinolode B) increased NADK expression in ALL cells. NADK catalyzes phosphorylation of NAD^+ to $NADP^+$, supporting NADPH generation essential for anabolic metabolism and redox homeostasis. NADK inhibition depletes NADPH, induces oxidative stress, and suppresses proliferation. We propose that AMPK-mediated transcriptional repression of NADK represents an adaptive mechanism to enforce metabolic homeostasis under energy stress. Consistently, combined treatment with the AMPK activator ASP4132 and the NADK inhibitor thionicotinamide induced synergistic cytotoxicity in ALL cells, suggesting a potential therapeutic strategy targeting AMPK-PRC1.1-NADK signaling.

#7245 Mechanistic dissection of ABI1 as DNA-binding transcriptional regulator in cancer cells.

Kate Livingston[1], XIANG Li[2], Kevin M. Lin[1], Leszek Kotula[1]

[1]SUNY Upstate Medical University, Syracuse, NY,[2]UT Southwestern Medical Center, Dallas, TX

Background: ABI1 (Abelson interactor-1) is classically recognized as a multifunctional adaptor protein with homeostatic roles in cancer biology. It functions as a tumor suppressor in some cancer such as prostate cancer, yet exhibits oncogenic activity in other cancers such as for example breast cancer. Historically, ABI1 has been studied for its actin-cytoskeleton-associated functions—including cell-cell adhesion, cell motility, and lamellipodia formation—as well as its role in regulating major signaling hubs such as c-Abl, PI3K, and Src. Our recent findings reveal an unanticipated function of ABI1: direct DNA binding mediated by a conserved homeodomain homology region (HHR). This discovery led us to hypothesize that ABI1 may act as a previously unrecognized transcriptional regulator. Here, we sought to define the molecular mechanisms through which ABI1 contributes to transcriptional control.
Methods: To determine sequence specificity and genomic occupancy, we performed ChIP using HHR-intact and HHR-mutant ABI1 constructs, complemented by in vitro DNA binding assays using purified proteins. Subcellular fractionation and chromatin enrichment assays assessed ABI1 nuclear localization and association with chromatin. ABI1-interacting transcriptional machinery was identified through co-immunoprecipitation (co-IP). RNA-seq comparing cells expressing wild-type ABI1 versus an HHR-defective DNA-binding mutant defined ABI1-dependent transcriptional outputs.
Results: ABI1 binds DNA both in vitro and in vivo and displays reproducible sequence motifs from integrated ChIP and in vitro binding analyses. ABI1 variants containing an intact HHR domain localize preferentially to the nucleus and chromatin fractions. Co-IP studies identify ABI1 as a component of a defined transcriptional complex. RNA-seq analyses reveal that HHR-mediated DNA binding is required for a discrete ABI1-dependent transcriptional program.
Conclusions: We identify ABI1 as a novel DNA-binding protein with sequence preference and transcriptional regulatory capacity mediated through its HHR domain. These findings expand the functional repertoire of ABI1 beyond actin regulation and kinase signaling, providing the first mechanistic framework for ABI1-driven transcriptional control.

#7246 Transcriptional control of myeloid differentiation trajectories in AML.

Sagarajit Mohanty, Jieun Jeong, Soumya Sharma, Daniel Cizin, Jun Ho Lee, Wenbin Xiao, Richard Koche, Thomas Norman, Hans-Guido Wendel

Memorial Sloan Kettering Cancer Center, New York, NY

Across different subtypes, Acute myeloid leukemia (AML) is a malignancy of proliferating myeloid cells that fail to differentiate. The failure of AML cells to respond to physiological differentiation cues remains a critical challenge despite extensive efforts, with few exceptions. We performed a CRISPR screen for transcriptional and epigenetic regulators of differentiation in AML cells. Our findings identified the roles of multiple components of the mediator complex, STAGA complex, and different transcription factors. We applied a Perturb-seq strategy which revealed how each lesion affects differentiation trajectories, uncovering shared and unique pathways in AML. Interestingly, we found multiple distinct transcriptional trajectories of differentiation in AML cells. We have validated these findings through additional in vitro and in vivo evaluations and are exploring their therapeutic relevance. Together, our results highlight key components of transcription regulatory complexes that are required to maintain the differentiation block in AML and pinpoint new targets for interventions.

#7247 BPTF regulates androgen receptor activity in prostate cancer.

Hee-Young Jeon[1], Sudeep Khadka[1], Majid Pornour[1], Hyunju Ryu[1], Hegang Chen[1], Arif Hussain[1], Hung-Ming Lam[2], Eva Corey[3], Htoo Zarni Oo[4], Martin E. Gleave[5], Xiaofang Che[6], Christopher E. Barbieri[7], **Jianfei Qi**[1]

[1]University of Maryland School of Medicine, Baltimore, MD,[2]University of Washington Medical Center, Seattle, WA,[3]University of Washington, Seattle, WA,[4]Department of Urologic Sciences, Vancouver Prostate Centre, BC Cancer Agency Vancouver Center, Vancouver, BC, Canada,[5]Distinguised Professor, Dept. of Urological Sciences, University of British Columbia, Vancouver, BC, Canada,[6]Department of Medical Oncology, The First Hospital of China Medical University, Shenyang, China,[7]Resident, Weill Cornell Medical College, New York, NY

BPTF, the scaffolding subunit of the nucleosome remodeling factor (NURF) complex, has been implicated in the progression of several malignancies, but its role in prostate cancer (PCa) remains unclear. Here, we show that BPTF is upregulated in aggressive PCa and promotes disease progression. BPTF knockdown inhibits PCa cell proliferation, while CRISPRa-mediated upregulation promotes androgen-independent growth. To investigate BPTF function, we performed RNA-seq, ChIP-seq and ATAC-seq analyses in BPTF-knockdown PCa cells. RNA-seq analysis reveals that BPTF primarily upregulates androgen receptor (AR) target gene expression. ChIP-seq data show that BPTF facilitates AR binding to enhancers, super-enhancers as well as promoters. ATAC-seq data indicates that BPTF enhances chromatin accessibility at AR-binding sites, partly via SMARCA1, a catalytic subunit of the NURF complex. Notably, BPTF ChIP-seq peaks exhibit strong enrichment of FOXA1 motifs but weak enrichment of AR motifs. We find that BPTF interacts with both FOXA1 and AR to form a protein complex in which FOXA1 anchors BPTF-AR to chromatin, while BPTF stabilizes the AR-FOXA1 interaction. Importantly, BPTF interacts with AR through its bromodomain, and a bromodomain inhibitor disrupts this interaction, leading to impaired AR signaling and suppressed PCa cell growth. In summary, our findings establish BPTF as a key regulator of AR activity by enhancing chromatin accessibility and stabilizing the AR-FOXA1 complex, highlighting BPTF as a potential therapeutic target for prostate cancer.

#7249 RUNX1T1 as an early driver in treatment-induced neuroendocrine transdifferentiation .

Yuchao Ni[1], **Mingchen Shi**[2], Dong Lin[2], Yen-Yi Lin[3], Hui Xue[4], Xin Dong[4], Liangliang Liu[3], Funda Sar[3], Rebecca Wu[4], Tunc Morova[3], Anne Hargert[3], Robert Bell[3], Xinyao Pang[2], Adam Classen[2], Yu Wang[2], Junru Chen[5], Stephan Le Bihan[3], Wei Dong[6], Vickie Wang[7], Ning Xu[8], Nathan Lack[3], Martin E. Treatment-induced neuroendocrine prostate cancer (t-NEPC) is a lethal form of castration-resistant variant arising primarily through neuroendocrine (NE) transdifferentiation of prostate adenocarcinoma following androgen deprivation therapy (ADT) and androgen receptor pathway inhibitors (ARPI). Despite its clinical relevance, the early molecular events initiating this transition remain poorly defined. Leveraging the first and only longitudinal patient-derived xenograft (PDX) model capturing adenocarcinoma-to-NEPC transdifferentiation (LTL331/331R), we performed single-cell RNA sequencing (scRNA-seq) across seven key stages spanning pre-castration, post-castration/ transitional phases, and relapsed NEPC.Clustering analysis identified 15 major cell populations and revealed a previously unrecognized intermediate transitional cell state enriched for epithelial-mesenchymal transition (EMT), stemness, metabolic activity, and HDAC-related regulatory signatures, highlighting a unique window of lineage plasticity. Two terminal NEPC subclusters with reciprocal ASCL1/FOXA2 expression patterns reflected intratumoral heterogeneity at relapse.Transcriptional interrogation of the transitional population identified **RUNX1T1** as a central regulator emerging early during plasticity. Functional assays revealed that RUNX1T1 overexpression markedly accelerates AR pathway inhibition-induced NE transdifferentiation and confers resistance to ARPI therapy in prostate adenocarcinoma models. Conversely, RUNX1T1 knockdown reduces NE-related pathway expression, suppresses NEPC cell growth, and induces apoptosis. These findings position RUNX1T1 as an essential factor for both NEPC development and progression.Mechanistically, rapid immunoprecipitation and mass spectrometry (RIME) uncovered that RUNX1T1 interacts with multiple repressive epigenetic factors including HDAC-containing complexes and heterochromatin-related genes. These results support a role for RUNX1T1 in mediating transcriptional silencing and regulatory network reprogramming during NEPC development.In summary, this study delineates the temporal evolution of t-NEPC at single-cell resolution, identifies an intermediate transitional state during NE transdifferentiation, and reveals heterogeneity within terminal NEPC. The identification of RUNX1T1 as an early and persistent driver of this trajectory positions RUNX1T1 and its associated repressive complexes as promising candidates for therapeutic intervention.

#7250 SYMPK regulates *AR* alternative polyadenylation and AR variant expression in advanced prostate cancer.

Kiel T. Tietz, Conor R. Miller, Jamie L. Van Etten, Scott M. Dehm

Masonic Cancer Center, University of Minnesota, Minneapolis, MN

Localized prostate cancer can be cured by radiation or surgery but advanced prostate cancer continues to be a clinical challenge. Advanced prostate cancer can initially be controlled by endocrine therapies that target the androgen receptor (AR), however, these tumors will inevitably develop resistance. This stage of the disease, termed castration-resistant prostate cancer (CRPC), is responsible for practically all prostate cancer-specific deaths. Truncated AR variant (AR-V) proteins are expressed in CRPC cells, and can function as ligand-independent, constitutively active transcription factors that promote resistance to endocrine therapies. Several well-characterized AR-Vs, such as AR-V7 and AR-V9, arise from splicing of *AR* exon 3 to different cryptic exons (CEs) located within *AR* intron 3. Splicing of these CEs is coordinated by a consensus AAUAAA poly(A) site located at the end of *AR* exon CE3. To define sequence elements in *AR* pre-mRNA required for usage of the CE3 poly(A) site, we designed inhibitory antisense oligomers to target regions upstream and downstream of the core AAUAAA motif. We found that sequences directly flanking the AAUAAA motif positively regulated AR-V expression, whereas sequences ~50 nucleotides downstream of the CE3 poly(A) site negatively regulated AR-V expression. To identify trans-acting factors that recognize and drive usage of the CE3 poly(A) site, we performed RNA-immunoprecipitation (RIP) using an RNA bait containing the CE3 poly(A) site or an RNA bait with the AAUAAA motif mutated. Proteins that preferentially bound the CE3 poly(A) site in RIP experiments were identified using mass spectrometry. We identified the scaffold protein SYMPK as a factor that bound specifically to RNA bait containing the CE3 poly(A) site. Consistent with a functional role for this binding event, knockdown of SYMPK reduced AR-V expression and inhibited growth of CRPC cell lines. We have also found SYMPK regulates the growth of AR negative prostate cancer cell lines, demonstrating AR-independent functions for SYMPK in regulating the growth of prostate cancer cells. This work highlights SYMPK as a novel regulator of AR-V expression and a therapeutic target for the treatment of multiple subtypes of advanced prostate cancer.

#7251 Pioneer round of translation factor CTIF regulates tumor immunity in drug-tolerant persister cells.

Yuqing Wang[1], Mengyao Wang[2], Kaixiu Li[2], Shensi Shen[2]

[1]Institute of Thoracic Oncology and Department of Thoracic Surgery, National Clinical Research Center for Geriatrics, Frontiers Science Center for Disease-related Molecular Network, West China Hospital, Sichuan University, Chengdu, China,[2]Institute of Thoracic Oncology and Department of Thoracic Surgery, National Clinical Research Center for Geriatrics, West China Hospital, Sichuan University, Chengdu, China

Background: Tumor cell plasticity enables cancer cells to alter their phenotype through coordinated epigenetic, transcriptional, and translational changes. Drug-tolerant persister cells (DTPs) represent a key plastic state associated with therapy resistance and minimal residual disease (MRD). Newly synthesized mRNAs undergo a pioneer round of translation (PRT) for quality control, yet how PRT influences tumor plasticity and immune evasion remains unknown. We hypothesize that the PRT-associated initiation factor CTIF, a core component of CBP80-CBP20-dependent translation machinery, regulates the immunosuppressive phenotype of DTPs and contributes to MRD-associated immune escape.

Methods: We integrated the bulk RNA-seq datasets across LUAD, BRCA, SKCM and COAD to define cross-cancer DTP transcriptional features. DTP models and isogenic CTIF-knockdown (KD) cells were established across multiple cancer types. We examined PRT-related factor expression, drug IC50, proliferation, and translational output via polysome profile and ribosome sequencing (Ribo-seq). Functional relevance of CTIF was evaluated in vivo using syngeneic immunocompetent and immunodeficient models.

Results: Cross-cancer analyses revealed treatment-specific DTP signatures with convergence on shared pathways, including altered expression of CTIF and additional PRT-related factors. CTIF-KD had minimal effects on drug resistance or proliferation in vitro, but polysome profiling and Ribo-seq indicated altered ribosome translation landscape. Integrated RNA-seq and Ribo-seq demonstrated that CTIF-KD selectively upregulated immune-related transcripts at the translational level, suggesting a previously unrecognized role in immune modulation. In vivo, CTIF-KD did not affect tumor growth in immunodeficient mice but significantly impaired tumor progression in immunocompetent hosts, consistent with enhanced immune recognition.

Conclusions: Our study uncovers a non-canonical, immune-regulatory role of CTIF. Although dispensable for proliferation and drug tolerance in vitro, CTIF is essential for tumor growth in vivo in an immune-dependent manner. We propose that CTIF shapes the tumor translatome to sustain immune evasion, and that targeting PRT, particularly CTIF, may offer a novel strategy to overcome immune suppression and eliminate MRD-associated persister states within the tumor immune microenvironment.

#7252 The landscape of alternative splicing in hepatocellular carcinoma and its association with TP53 mutation.

Xueqing Fang[1], Kui Wu[2], Man Tong[1]

[1]The Chinese University of Hong Kong, Hong Kong, China,[2]BGI Genomics, Shenzhen, China

Alternative splicing (AS) is a key mechanism of post-transcriptional regulation and is crucial for the formation of proteomic diversity in eukaryotes. Splicing dysregulation is increasingly recognized as a new hallmark in cancer development and progression. These aberrant splicing events are not only promising biomarkers for diagnosis and prognosis, but also novel targets for drug development. Hepatocellular carcinoma (HCC), which is the most common primary liver tumor, is characterized by significant tumor heterogeneity, which poses a major challenge for effective treatment. Therefore, there is a need to explore post-transcriptional mechanisms, such as AS, as a novel approach to identify new prognostic biomarkers and therapeutic targets. To explore post-transcriptional mechanisms, we uncovered the landscape of AS in HCC, investigated its clinical implications, and explored its association with key driver gene mutations. Differential AS events between HCC and adjacent normal samples were identified, which enabled patient stratification into two subgroups with different prognoses. The poor-prognosis subgroup exhibited a higher *TP53* mutation frequency and lower AS values. Through cross-dataset analysis, we identified three consensus differential events that were distinct between *TP53*-mutant and wild-type samples. These consensus differential AS events were highly correlated with differentially expressed splicing factors between the *TP53* groups. In conclusion, our study demonstrates that alternative splicing is extensively dysregulated in HCC and has significant prognostic implications. We provide evidence that *TP53* mutation, a key genetic driver in HCC, is associated with distinct AS patterns, potentially through the transcriptional regulation of specific splicing factors.

#7253 Regulation of TbRIII expression and ectodomain shedding via the sheddase, PRSS8, and ERG transcription factor.

Benjamin Michael Greulich, Kaitlyn Eidson, Logan Baker, Hannah Fitzgibbons, Shreya Sudakar, Emma Teng, Cion Kim, Huy Lam

Biology, Mercer University, Macon, GA

TGF-β signaling is frequently dysregulated in cancer and can contribute to cancer-associated phenotypes including immune evasion, migration, and metastasis. Unfortunately, attempts to inhibit TGF-β have had limited success, likely due to the critical roles of TGF-β in normal tissue. For this reason, this work aims to more fully understand the regulation of TGF-β signaling. The co-receptor, TβRIII, can bind ligand and stimulate the TβRI/TβRII complex. Conversely, TβRIII can be shed from the cell surface where it can sequester TGF-β ligand and prevent TβRI/TβRII activation. However, the identity of the enzyme that sheds TβRIII and the regulatory mechanisms that govern TβRIII shedding are unknown. This work aims to address two aspects of TβRIII shedding regulation: firstly, what enzyme is responsible for producing shed TβRIII, and secondly, what novel transcriptional networks are responsible for regulating the expression of TβRIII and its sheddase. PRSS8 increased TβRIII shedding, decreased expression of TGF-β target genes and EMT markers, and decreased TGF-β associated phenotypes of EMT, migration, and invasion. PRSS8 overexpression also sensitized cells to chemotherapy. Furthermore, PRSS8 expression could be induced pharmacologically with lovastatin to elicit similar reductions in TGF-β associated phenotypes. Treatment with cholesterol was able to increase migration of these cells, but PRSS8 overexpression prevented this effect of cholesterol. These data suggest cholesterol homeostasis pathways may regulate PRSS8 expression and therefore alter TGF-β signaling activity. Taken together, this establishes a novel cholesterol-PRSS8-TGF-β axis of regulation. Current work aims to identify novel transcriptional networks that are regulating TβRIII and its shedding. RNA-seq data between prostate cell lines with and without ERG overexpression has revealed ERG increased expression of pro-TGF-β signaling genes and suppressed genes associated with down-regulating TGF-β. In cervical cancer cell lines, knockdown of ERG has reduced phenotypes such as migration, invasion, and chemoresistance. ERG knockdown has also increased TβRIII shedding. ERG ChIP-seq in cervical cancer is being performed in the presence and absence of TGF-β activation to determine the effect of TGF-β on ERG binding. SMAD2/3 ChIP-seq will be performed with and without ERG knockdown to reveal if ERG affects SMAD2/3 binding to the genome. By discovering new transcriptional regulators of TβRIII, such as ERG, new possibilities for rescuing TβRIII expression and reducing dysregulated TGF-β signaling are revealed. Therapies directed at cholesterol homeostasis or ERG may be able to be repurposed and applied to cancers experiencing TGF-β dysregulation.

#7254 Post-transcriptional upregulation of GPC3 via CSTF2-driven 3'UTR remodeling promotes hepatocellular carcinoma progression.

Suk Woo Nam, Soyoung Jeon, Jin Woong Ha, Min jeong Na, Sang Yean Kim

Catholic University of Korea, College of Medicine, Seoul, Korea, Republic of

Alternative polyadenylation (APA) is a widespread post-transcriptional mechanism that generates mRNA isoforms with variable 3′ untranslated regions (3′UTRs), influencing transcript stability and translation. Aberrant 3′UTR shortening frequently occurs in cancer, allowing oncogenic transcripts to evade microRNA (miRNA)-mediated repression. However, the global landscape and functional impact of APA alterations in hepatocellular carcinoma (HCC) remain incompletely defined. We performed transcriptome-wide APA profiling across a multistage human liver cancer cohort to identify genes exhibiting significant 3′UTR alterations during hepatocarcinogenesis. Differential Poly(A) Site Usage Index (ΔPDUI) analysis was applied to detect APA-driven isoform shifts. Candidate genes were validated using independent HCC datasets and correlated with clinical outcomes. Functional assays—including RNA interference, overexpression, and proliferation/apoptosis measurements—were conducted in HCC cell lines to define mechanistic and phenotypic consequences. Approximately 77% of APA-affected mRNAs displayed 3′UTR shortening in HCC compared to normal liver tissue. Among these, Glypican-3 (GPC3) emerged as one of the most prominently upregulated transcripts, with high expression levels strongly associated with poor patient prognosis. Manipulation of GPC3 expression confirmed its oncogenic role, as silencing GPC3 suppressed proliferation and enhanced apoptosis, whereas ectopic expression promoted growth. Among core APA regulators, Cleavage Stimulation Factor 2 (CSTF2) was markedly upregulated in HCC and positively correlated with both GPC3 expression and poor clinical outcomes. CSTF2 overexpression induced 3′UTR shortening of GPC3 and elevated its protein levels, while CSTF2 knockdown lengthened the GPC3 3′UTR and decreased expression. Mechanistically, truncation of the GPC3 3′UTR eliminated binding sites for miR-96-5p and miR-140-5p, relieving translational repression and sustaining oncogenic GPC3 expression. Our findings reveal that CSTF2-driven APA remodeling serves as a key post-transcriptional mechanism promoting GPC3 activation in HCC. CSTF2 overexpression shortens the GPC3 3′UTR, abrogating miRNA-mediated repression and enhancing tumorigenic potential. This CSTF2-GPC3 axis underscores APA dysregulation as a pivotal driver of hepatocarcinogenesis and highlights CSTF2 as a promising therapeutic target for liver malignancies.

#7255 RNA binding proteins mediated oncogenic adaptions in cancer cells.

Jasmine George, Pradeep Chaluvally Raghavan

Medical College of Wisconsin, Wauwatosa, WI

Introduction: Ovarian cancer remains a major contributor to cancer-related deaths in women, underscoring the urgent need for novel therapeutic strategies. Fragile X-related protein 1 (FXR1), frequently amplified and overexpressed in ovarian and other malignancies, plays a central role in driving oncogenesis through translational regulation of multiple cancer-promoting genes. We have determined that the oncogene c-MYC is a direct target of FXR1 both in ovarian cancer cells and in cells within the tumor microenvironment. Tumor-derived extracellular vesicles (EVs) are known to play a critical role in reprogramming the tumor microenvironment (TME). We observed that FXR1 mRNA enriched EVs are taken up by surrounding stromal and immune cells, where they modulate protein translation in ways that promote tumor progression. Building on this background, we aim to investigate the mechanism by which FXR1 mRNA is incorporated into EVs and to elucidate its functional impact on the TME.
Methods: We performed a Surface Sensing of Translation (SUnSET) assay to demonstrate that FXR1 enhances global protein translation in cancer cells. RNA electrophoretic mobility shift assays (REMSA) and proximity ligation assays were conducted to show that FXR1 binds to the AU rich elements (ARE) within the 3′UTR of c-MYC. Intriguingly, we found that FXR1 mRNA is packaged into EVs derived from ovarian cancer cells. RNA immunoprecipitation assays also showed that FXR1 interacts with the exosomal markers TSG101 and CD63. Finally, flow cytometry-based immunophenotyping and single-cell RNA sequencing (scRNA-seq) of tumor-derived ascites from mice were performed to characterize how FXR1 influences overall translation in tumor cells and reshapes the TME.
Results: Our previous data demonstrated that FXR1 plays a crucial role as an oncoprotein and is significantly involved in the pathophysiology of ovarian cancer. We identified that FXR1 stabilizes cMYC mRNA by binding to specific sequences of AREs within its 3′UTR. We further demonstrated that FXR1 mRNA is highly enriched in tumor-derived exosomes, which are transferred into macrophages in the TME. In a corollary, FXR1 enriched EVs resulted into the reprogramming of cells in the tumor microenvironment, favoring tumor growth by inducing macrophage polarization and T-cell inactivation.
Conclusion: Our studies have identified that FXR1 promotes oncogenic translation in cancer cells and in the cells in tumor microenvironment. Our data suggest that FXR1 mediated macrophage polarization and T-cell inactivation is an important mechanism for cancer growth and metastasis.

#7256 Enhancer reprogramming establishes ETS1-RUNX1-FOSL1 as an oncogenic and immunosuppressive transcriptional circuitry in gallbladder carcinoma.

Jiaxi Sun[1], Xing He[2], Yuntan Qiu[1], Zhenyu Zhou[3], Daning Lu[1], Shiru Tang[1], Wenbin Li[2], Dong Yin[1], **Lehang Lin**[1]

[1]Guangdong Provincial Key Laboratory of Malignant Tumor Epigenetics and Gene Regulation, Sun Yat-Sen Memorial Hospital, Sun Yat-sen University, Guangzhou, China,[2]Department of Biliary and Pancreatic Surgery, Sun Yat-Sen Memorial Hospital, Sun Yat-sen University, Guangzhou, China,[3]Department of Hepatobiliary Surgery, Sun Yat-Sen Memorial Hospital, Guangzhou, China

Background: Gallbladder carcinoma (GBC) is a highly aggressive malignancy with poor prognosis and limited therapeutic options. Enhancers and super-enhancers (SEs) are critical regulators of cell type-specific transcription and oncogenic programs, yet their roles in GBC progression remain poorly defined.
Objective: We aimed to map enhancer and SE reprogramming in GBC and identify master transcription factors (TFs) driving these transcriptional programs. Design: Chromatin immunoprecipitation sequencing and RNA sequencing were performed on normal, inflammatory, and tumorous gallbladder tissues, as well as GBC cell lines. Integrative analyses of enhancer remodeling, TF motif enrichment, expression, and transcriptional connectivity were conducted to identify SE-driven master TFs. Functional assays and immunohistochemistry were used to evaluate their oncogenic and immunomodulatory functions.
Results: GBC exhibited extensive enhancer and SE reprogramming relative to non-tumorous gallbladder tissues, with gained enhancers and SEs preferentially enriched in oncogenic pathways. ETS1, RUNX1, and FOSL1 were identified as SE-driven master TFs that form an interconnected regulatory circuitry co-occupying SEs, including those of *CD274* (encoding PD-L1), to promote oncogenic transcription and immune evasion. Perturbation of this circuitry suppressed GBC cell proliferation, migration, and tumor growth *in vitro* and *in vivo*. Clinically, elevated expression of these master TFs correlated with reduced $CD8^+$ T cell infiltration, poorer patient survival, and diminished responsiveness to immunotherapy in GBC.
Conclusion: This study delineates enhancer and SE reprogramming during gallbladder malignant transformation, identifies an ETS1-RUNX1-FOSL1 master TF circuitry, and highlights FOSL1 as a key driver of oncogenic transcription and immune evasion, providing mechanistic, prognostic, and therapeutic insights into GBC.

#7257 Identification of KDR as a novel effector downstream of ETS variant transcription factor 4 in NSCLC.

Su Hyeon Yu, Jiyoon Kang, Ji Won Kim

Jeju Research Institute of Pharmaceutical Sciences, College of Pharmacy, Jeju National University, Jeju, Korea, Republic of

The ETS family comprises transcription factors characterized by a highly conserved DNA-binding domain that recognizes a central GGA(A/T) motif. Among these, ETV4, the predominant member of the PEA3 subfamily, has been strongly associated with advanced disease stage and poor prognosis in multiple malignancies, including non-small cell lung cancer (NSCLC) and hepatocellular carcinoma (HCC), largely through its MAPK-dependent transcriptional activity. Despite its clinicopathologic significance, the downstream effectors and genome-scale regulatory circuitry governed by ETV4 remain incompletely defined. Here, we aimed to define the ETV4-driven transcriptional landscape. We identified KDR/VEGFR2 as a direct ETV4-promoted target, with ETV4 overexpression markedly elevating KDR transcripts and protein levels. Through chromatin immunoprecipitation and complementary binding assays, we demonstrated physical occupancy of ETV4 at the KDR promoter. Although KDR/VEGFR2 is classically characterized as an endothelial receptor that amplifies angiogenic signaling, accumulating evidence indicates that cancer cell-intrinsic KDR supports vasculogenic mimicry and aggressive structural remodeling through VEGF/VEGFR2 paracrine and autocrine circuits. Pharmacologic suppression of ETV4 significantly attenuated KDR expression and impaired epithelial-mesenchymal transition, migration, and invasion, phenotypes that were recapitulated by genetic silencing of either ETV4 or KDR. Collectively, these findings define a previously unrecognized transcriptional axis in which ETV4 directly activates KDR/VEGFR2 to potentiate malignant behavior, positioning the ETV4-KDR pathway as a targetable therapeutic vulnerability across ETV4-high tumors.

: Genomic Approaches to Define Tumor Biology and Clinical Stratification

#7261 Comprehensive multi-omics profiling reveals molecular heterogeneity and developmental signatures in solid pseudopapillary neoplasm of the pancreas.

Dong-Ju Shin[1], Jin Ho Choi[2], Sang Hyub Lee[2], In Rae Cho[2], Kyung-Min Lee[2], Ji Kon Ryu[2], Woo Hyun Paik[2], Jin-Ku Lee[1]

[1]Department of Anatomy and Cell Biology, Seoul National University College of Medicine, Seoul National University, Seoul, Korea, Republic of,[2]Department of Internal Medicine and Liver Research Institute, Seoul National University Hospital, Co, Seoul National University, Seoul, Korea, Republic of

Solid pseudopapillary neoplasm (SPN) of the pancreas is a rare, low-grade malignant tumor that predominantly affects young women. Although previous studies have applied omics approaches, including whole-exome sequencing, transcriptomics, and DNA methylation profiling to characterize SPN, its tumorigenesis and cell of origin remain elusive. Apart from the recurrent *CTNNB1* hotspot mutation, which is currently considered the only canonical driver, SPN is typically diploid and exhibits few recurrent genomic alterations. Moreover, because of its low incidence, previous small-cohort studies have been insufficient for robust molecular subtyping or integrative analysis.

To comprehensively characterize the molecular landscape of SPN, we performed multi-omics analyses on 80 tumors using whole-genome sequencing (WGS), whole-transcriptome sequencing, and whole-genome enzymatic methyl-sequencing (EM-seq). Unsupervised hierarchical clustering based on the top 1,000 genes ranked by median absolute deviation (MAD) across transcriptomes identified two robust molecular subtypes: a *developmentally reprogrammed* type and an *immune-enriched* type: The immune-enriched subtype exhibited significant activation of immune-associated pathways, including immunoglobulin-mediated and adaptive immune responses, whereas the developmentally reprogrammed subtype showed enrichment of embryonic skeletal system development and morphogenesis signatures. Furthermore, SPN tumors displayed a genome-wide hypermethylated pattern compared with normal pancreatic tissues, highlighting their distinct epigenetic state. Beyond expression-based stratification, we systematically examined fusion events, genome-wide somatic mutations, structural variants, mitochondrial genome alterations, numtogenesis, retrotransposon activity, and methylation entropy across the cohort. Notably, a recurrent *TVP23C-CDRT4* fusion was detected in 61% of cases, suggesting a potential novel genomic hallmark of SPN. This study represents the largest integrative multi-omics analysis of SPN to date, revealing distinct transcriptomic and epigenomic subtypes, a recurrent fusion event, and marked molecular heterogeneity. Ongoing integrative analyses aim to clarify the developmental origin and oncogenic evolution of this rare pancreatic neoplasm.

#7262 A fully automated walkaway system programmed with a novel library prep target enrichment protocol for detection of ultra-low frequency mutations in liquid biopsy and tumor samples.

Saharnaz Bigdeli[1], Jan Godoski[1], Bernd Buehler[1], Bahram Arezi[1], Brandyn Clark[1], Denise Rhodes[1], schryl castaneda[1], Bonita Lam[2], Yun Bao[2], ji zhu[1], Gilbert Amparo[2], Neelima Mehendale[2], Khine Win[2], Karen Chapman[1]

[1]Agilent Technologies, La Jolla, CA,[2]Agilent Technologies, Santa Clara, CA

Liquid biopsy has transformed oncology through high sensitivity detection of genomic alterations from circulating cell-free DNA (cfDNA). Issues such as sensitivity, PCR bias, contamination, reproducibility, and long and laborious workflows are yet to be resolved. Here, we have fully automated the workflow for a novel library preparation and target enrichment probe technology, Agilent Avida, that tackles some of the existing challenges by being highly optimized to work with circulating tumor DNA (ctDNA). Our automated protocol using pre-aliquoted reagents, was developed on the Agilent Magnis NGS Prep System for a wide range of DNA inputs (1-100 ng) and various sample types (intact, FFPE DNA, and cfDNA). Using this platform, we construct libraries with a high sample recovery that scales linearly with the input amount and is capable of high sensitivity variant detection without a need for pre-enrichment PCR, minimizing the GC bias. Our automated protocol generates up to eight target-enriched Illumina sequencing-ready DNA libraries in about 8 hours without the need of any user intervention, thus minimizing potential contamination. We have generated data using both Avida catalog and custom panels covering a broad range of target sizes to determine assay sensitivity. Using these probes, we were able to reliably detect cancer-associated genomic alterations, including SNVs, indels, CNVs, and translocations across key oncogenes using well characterized cfDNA and formalin compromised reference standards as well as real ctDNA samples. For example, using 15 ng of SeraCare V4 ctDNA sample enriched with Avida DNA Onco LB panel (1.17 Mb covering 164 pan-cancer-associated genes) and sequenced with a budget of 100 M read pairs, we were able to detect SNP frequencies down to 0.25%. Furthermore, in our automated runs, we obtained high reproducibility across 8 technical replicates. For example, for 5 independent Magnis runs (40 samples) of various sample types and inputs per run using the Avida DNA Onco LB panel, the % Coefficient of Variation (CV) ranged from 0.8 to 2.3% for on-target rate, 1.9 to 8.2% for library complexity (unique molecular identifier UMI recovery), 1 to 3.2% for base coverage, and 0.03 to 0.09% for uniformity.

#7263 Identification of molecular alterations in soft tissue sarcoma patients with combined pan-cancer CGP and bespoke sarcoma fusion detection testing.

Chaugiang Duong[1], Ryan Bender[2], Nathan Montgomery[3], Fernando J. Lopez-Diaz[2]

[1]NeoGenomics, Aliso Viejo, CA,[2]NeoGenomics, San Diego, CA,[3]NeoGenomics, Durham, NC

Introduction: The genomic characterization of soft tissue sarcomas is increasingly applied in patient care to help understand the pathogenesis of these diseases. However, most pan-cancer comprehensive genomic profiling (CGP) tests cover few gene fusions of clinical relevance in sarcomas. Hence, the contribution of all classes of genomic alterations to the pathogenesis of sarcomas often has a methodological bias.
Objective: This study investigates all actionable genomic variants present in soft tissue sarcoma patients using a sarcoma-targeted CGP approach that also interrogates most sarcoma-relevant gene fusions.
Methodology: We screened 20660 test orders for cancer patients with available diagnosis tested by either of two complementary tests: a pan-cancer CGP panel and a sarcoma fusion panel, both routinely performed in our clinical laboratory. The first detects SNV/Indels in 517 genes, CNA in 59 genes, MSI and TMB, and common solid tumor RNA fusions in 55 genes. The second analyzes additional known and novel RNA fusions in 97 genes with high diagnostic, prognostic, and therapeutic value in sarcomas, utilizing fusion enrichment-based RNA-seq. Out of 12885 CGP tested patients, 346 had sarcoma, while 1406 sarcoma patients were tested with the sarcoma fusion panel. Of those, 62 patients were characterized using both tests.
Results: From the 346 sarcoma patients tested with the pan-cancer CGP test, 268 patients had pathogenic DNA alterations, and 22 patients had RNA fusions. Conversely, among 1406 sarcoma patients tested with the sarcoma fusion panel, fusions were detected in 399 patients, with 207 distinct fusions identified. The top 5 genes rearranged were EWSR1, HMGA2, FUS, FLI1, and SS18. We next analyzed the data from the 62 sarcoma patients tested with both assays and found that pathogenic alterations (DNA/RNA) were detected in 56 cases. DNA alterations were found in 54 of them. SNV/indels were present in 53 patients with 86 genes harboring pathogenic mutations, most frequently in TP53, TERT, LRP1B, NF1, TET, and CDKN2A. CNAs were identified in 15 patients, of whom one had only CNAs (KRAS, MDM2, PDGFRA, and KIT). The most frequent CNAs were in MDM2 (n=5), followed by CCND1, CDK4, EGFR, KRAS, and MYC (n=3). Gene fusions were detected in 10 patients. Three (3) patients had fusions detected by both panels, 2 had fusions detected by the CGP panel but not covered by the sarcoma panel, and 5 patients had a fusion only detected by the Sarcoma fusion panel.
Conclusions: Comprehensive genomic profiling of sarcomas with pan-cancer targeted panels unveiled the pathogenic molecular landscape in sarcoma patients from the community. Additional testing with a sarcoma-targeted fusion panel significantly enhanced the identification of pathogenic fusions, enabling a more comprehensive evaluation of the contribution of gene fusions to both pathogenesis and patient care.

#7264 Molecular differences between ovarian and uterine carcinosarcomas.

Kwong-Kwok Wong, Yvonne Tsang

The University of Texas MD Anderson Cancer Center, Houston, TX

Carcinosarcomas, also known as malignant mixed Müllerian tumors (MMMTs), are rare and aggressive neoplasms characterized by the coexistence of both carcinomatous (epithelial) and sarcomatous (mesenchymal) components. These tumors primarily arise in the uterus and less frequently in the ovary. Despite histological similarities, ovarian and uterine carcinosarcomas differ in epidemiology, clinical presentation, prognosis, and treatment strategies. Understanding the molecular differences between ovarian and uterine carcinosarcoma is essential for accurate diagnosis, effective treatment planning, and improved patient outcomes.In this study, whole-exome sequencing (WES) was performed on three ovarian and three uterine carcinosarcomas, along with matched normal blood or tissue DNA. Sequencing libraries were prepared using the Twist Library Preparation and Capture Kit and sequenced on NovaSeq X 25B with 150 bp paired end reads, generating an average of >900 million reads per sample.Somatic variants (missense and indels; n = 1,971-2,542) were identified across samples. Notably, a novel germline mutation in TBC1D32 (p.Thr375Lys) was detected in five of the six carcinosarcomas. TBC1D32 is primarily associated with genetic disorders such as ciliopathies and hypopituitarism, and although mutations have been reported in various cancers, its role as an oncogene or tumor suppressor remains unclear. While the overall number of variants did not differ significantly between ovarian and uterine carcinosarcomas, several somatic variants were unique to ovarian carcinosarcoma, including alterations in ANKDD1A and RPL10. ANKDD1A functions as a tumor suppressor; frequently silenced in glioblastoma via hypermethylation. RPL10 influences cancer through protein synthesis and extra-ribosomal functions; overexpression and mutations linked to tumor development. Validation of these variants in additional carcinosarcoma samples is ongoing. Furthermore, RNA sequencing using the Illumina Stranded Total RNA Prep Ligation with Ribo-Zero Plus Kit and NovaSeq X 25B (100 bp paired-end reads) is being conducted to identify differentially expressed genes between ovarian and uterine carcinosarcomas. Data analysis is currently in progress. In conclusion, we identified a recurrent germline mutation in TBC1D32 (p.Thr375Lys) across both ovarian and uterine carcinosarcomas, as well as somatic variants unique to ovarian carcinosarcoma. Further investigation of these genes may provide insights into carcinosarcoma pathogenesis and inform the development of differential treatment strategies for ovarian versus uterine disease.

#7265 MBCproject: multi-omic profiling of metastatic breast cancer evolution through patient-partnered research.

Diana Garcia-Cortes[1], Esha Jain[2], Mary McGillicuddy[2], Beena S. Thomas[2], Dewey Kim[2], Sara Balch[2], John Navarro[2], Jakob H. Weiss[2], Tania G. Hernandez[2], Michael Dunphy[2], Brett N. Tomson[2], Colleen M. Nguyen[2], Jeremy Johnson[2], Parker S. Chastain[2], Sarah Winnicki[2], Elana Anastasio[2], Diane M. Diehl[2], Todd R. Golub[2], Corrie A. Painter[2], Nikhil Wagle[1], Daniel L. Abravanel[1], Jorge Gomez Tejeda Zanudo[1]

[1]Breast Oncology Program, Dana-Farber Cancer Institute, Boston, MA,[2]Broad Institute, Cambridge, MA

The Metastatic Breast Cancer project (MBCproject) is a patient-partnered research study that has collected clinical, genomic, and survey data through online enrollment. The cohort includes whole exome sequencing from 379 tumor biopsies (bxs) with matched germline from 301 patients (pts) and RNA-seq from 200 bxs (141 pts). In addition to confirming prior observations, this multi-omics cohort has enabled the discovery of novel MBC characteristics. Tumor evolutionary analysis was performed for 56 pts with multiple bxs from different timepoints and sites (115 bxs). Acquired *ESR1* mutations were observed in six pts, all of whom received endocrine therapy between bxs. Mutations in *TP53*, *GATA3*, and *PTEN* were almost always truncal. However, mutations in *PIK3CA*, *CDH1*, and *KMT2C* exhibited complex clonal dynamics with gain/loss events across paired bxs, contrary to the common assumption that such mutations are truncal. For pts with distinct *CDH1* mutant status across bxs, the presence of *CDH1* mutations at the bx level is associated with lobular histology (ILC), and the lack of *CDH1* mutations is associated with ductal histology (IDC). The cohort includes three pts with bilateral breast cancers, which we found to be phylogenetically unrelated. Only one pt harbored a pathogenic germline mutation (*CHEK2*). In one pt, bilateral bxs had distinct histology yet shared copy number variations (CNVs) such as 1q gain and 6q loss. In another, left and right ILCs had distinct *PIK3CA* and CDH1 mutations and dissimilar CNV profiles. The shared altered genes and CNVs from independent tumors in the same pt suggest convergent evolution through tumorigenesis. To further explore evolution over disease progression, we compared treatment-naive primary and treatment-exposed metastatic bxs in the full cohort. *TBX3* mutations were enriched in metastatic bxs ($p=0.024$, FDR<0.25), driven by higher prevalence in HR+/HER2- and HER2+ subtypes, and co-occurred with *CDH1* ($p=0.0016$) and *ERBB2* oncogenic mutations ($p=0.039$). All MBCproject *TBX3-ERBB2* mutant bxs were from pts with ILC and had *CDH1* mutations. MSK IMPACT confirmed *TBX3-CDH1* ($p=4.4e-8$) and *TBX3-ERBB2* ($p=6.1e-5$) co-occurrence and showed *TBX3-ERBB2* mutations also co-occurred in IDC bxs without *CDH1* mutations ($p=9.2e-4$), suggesting that *TBX3-ERBB2* mutations are independent of ILC and *CDH1* status. *TBX3*-only mutant bxs had a proliferation RNA-seq signature score higher than Luminal A bxs ($p=0.032$ MBCproject, $p=0.0047$ TCGA) and more similar to that of IDC than ILC tumors. Overall, this indicates that *TBX3* mutations drive distinct tumor behavior independent of histology and *CDH1* alterations. The MBCproject demonstrates the power of patient-partnered research and multi-omics evolutionary analysis to uncover novel insights into metastatic breast cancer biology.

#7266 Advancing insights into disease biology of non-muscle invasive bladder cancer (NMIBC) through comprehensive multi-omics analysis.

Siew Kee Low[1], Yoshiyuki Nagumo[2], Xuesong Lyu[1], Jiarui Zhang[3], Jie Zhao[1], Kozaburo Tanuma[2], Satoka Kinase[2], Karen Urtishak[3], Neil Beeharry[3], Shibu THOMAS[3], **Longen Zhou**[3], Hiroyuki Nishiyama[2]

[1]Johnson & Johnson, Shanghai, China,[2]Department of Urology, Institute of Medicine, University of Tsukuba, Tsukuba, Ibaraki, Japan,[3]Johnson & Johnson, Spring House, PA

Non-muscle invasive bladder cancer (NMIBC) accounts for approximately 75% of all bladder cancer cases and has high rate of recurrence and potential progression to muscle-invasive disease. Treatment strategies for NMIBC include transurethral resection of bladder tumor (TURBT) followed mainly by Bacillus Calmette-Guérin (BCG) immunotherapy or chemotherapy. Although NMIBC management has progressed, understanding its molecular basis and changes after treatment remains critical for better prognosis, patient stratification and informed treatment strategies. Here, we conducted whole exome and transcriptomic sequencing to elucidate molecular landscape and tumor microenvironment and uncover potential prognostic biomarkers associated with BCG response. Three distinct BCG response subtypes (BRS) were assessed by BCG response subtype predictor using transcriptomic sequencing data. Comparison of genomic alterations' prevalence and transcriptomic signatures in Kyoto Encyclopedia of Genes and Genomes (KEGG) via ssGSEA (single sample Gene Set Enrichment Analysis) between high vs low/intermediate risk were evaluated. Data from 37 pre-treatment NMIBC patients were analyzed (N = 37); including patients treated with TURBT followed by BCG [N = 16], and with TURBT only [N= 21]. Genomic profiling of 37 patients demonstrated mutation frequencies consistent with published literature, with highest prevalence observed in Telomerase Reverse Transcriptase (TERT) (78.4%), followed by Tuberous Sclerosis Complex 1 (TSC1) (64.9%) and Lysine (K)-Specific Methyltransferase (KMT)2D (51.4%). Notably, mutation frequency of Fibroblast Growth Factor Receptor 3 (FGFR3) was higher among low- and intermediate-risk groups (66.7%, N = 15) compared to high-risk groups (36.4%, N = 22). Pathway score calculated using ssGSEA from transcriptomic profiling revealed a markedly higher gene expression profile enriched in cell-cycle pathway in among high- compared to low- and intermediate-risk groups (p = 0.033). Patients with BRS3 tumors exhibited significantly reduced progression free survival (PFS) versus BRS1/2 (p= 0.0095, HR = 5.92), following BCG treatment. BRS3 tumors demonstrated elevated expression of epithelial-mesenchymal transition and basal markers and were characterized by an immunosuppressive profile. We identified that FGFR3 mutation rate is higher among low- and intermediate risk. Cell cycle dysregulation is known to contribute in tumor progression and aggressiveness of bladder cancer; our pathway analysis identified cell cycle pathway enrichment among high-risk NMIBC, which enhances our understanding of NMIBC disease biology. Our data validated BRS3 subtyping in predicting poor BCG response, demonstrating robustness of this classification approach. Further investigation is warranted to confirm these findings, considering smaller cohort in this study

#7267 Genomic architecture of prostate cancer in *BRCA1/2*germline carriers.

Taylor B. Crawford[1], Heena Desai[1], Jiannong Li[2], Ryan Hausler[1], Candace L. Haroldsen[3], Martin W. Schoen[4], Timothy R. Rebbeck[5], Brent S. Rose[6], Michael J. Kelley[7], Bruce Montgomery[8], Nicholas G. Nickols[9], Matthew B. Rettig[10], Kosj Yamoah[11], Isla P. Garraway[12], Kara N. Maxwell[13]

[1]University of Pennsylvania, Philadelphia, PA,[2]Research Scientist, Moffitt Cancer Center, Tampa, FL,[3]University of Utah, Salt Lake City, UT,[4]Saint Louis University School of Medicine, St. Louis, MO,[5]Dana-Farber Cancer Institute, Boston, MA,[6]University of California, San Diego, San Diego, CA,[7]Duke Cancer Institute, Durham, NC,[8]University of Washington, Seattle, WA,[9]University of California Los Angeles, Los Angeles, CA,[10]Professor, UCLA David Geffen School of Medicine, Los Angeles, CA,[11]H. Lee Moffitt Cancer Center, Tampa, FL,[12]UCLA, Manhattan Beach, CA,[13]Perelman School of Med. Univ. of Pennsylvania, Philadelphia, PA

Background: Inherited pathogenic germline variants (PGVs) in *BRCA1 and BRCA2* are significant risk factors for the development of prostate cancer (PCa). Individuals with *BRCA2* PGVs have a 3-4-fold increased risk of developing PCa and demonstrate higher Gleason scores, increased nodal metastases, and overall poorer survival. However, the mechanisms by which *BRCA1/2* loss promotes PCa development is unknown. In this study we aim to summarize somatic genomic alterations of *BRCA1* and *BRCA2* carriers with PCa.

Methods: Germline carriers of PGV or putative PGV *BRCA1/2* variants with PCa were identified in the Veteran Affairs National Precision Oncology Program (VA-NPOP) by either clinical genetic testing or by sequencing of liquid biopsies (VAF≥30%). Controls were patients with no PGV in any cancer risk gene on germline genetic testing. Somatic mutations were identified from tumor tissue or liquid biopsy tests as PCa patients were stratified by hormone sensitive prostate cancer (HSPC) and castration resistant prostate cancer (CRPC) clinical status. Fishers' exact tests were used to compare mutation frequencies in 30 genes, tumor mutational burden (TMB), and microsatellite instability (MSI) scores in *BRCA1* or *BRCA2* carriers vs. germline negative controls.

Results: A total of 85 patients with *BRCA1/2* variants were included in the study (n=70 *BRCA2*, n=15 *BRCA1*) with 1,124 control patients including 844 and 365 PCa patients who had HSPC and CRPC, respectively. Of the HSPC patients who received a tumor tissue test, *BRCA2* carriers had a significantly higher mutation frequency of the *PRKCI* gene compared to controls (13% (n=16) vs n=1% (n=560), p=0.023, respectively). Of the CRPC patients who received a liquid biopsy test, *BRCA2* carriers had a significantly higher mutation frequency of the *KDM6A* gene compared to controls (13% (n=38) vs 2% (n=318), p=0.005, respectively). Additionally, mutations in the *APC* gene were found at a higher frequency in *BRCA1* carriers (22% (n=9) vs 3% (n=318), p=0.027). There was no significant difference in tumor mutational burden and microsatellite instability measurements between *BRCA1* and *BRCA2* carriers and controls regardless of the type of somatic test and sensitivity to hormone therapy. Further work is required to understand mechanisms that contribute to these genomic differences, therefore, we have expanded this study to understand transcriptomic differences between *BRCA2* carriers (n=30) and non-carriers (n=60) with localized PCa by performing bulk DNA and RNA-sequencing and single cell RNA sequencing of fresh *BRCA2* (n=10) prostate tissues and clinically matched control patients (n=20).

Conclusions: We report differences in genomic alteration frequencies in *PRKCI*, *KDM6A*, and *APC* between *BRCA1* and *BRCA2* germline carriers and controls in VA-NPOP. Further work is needed to determine the functional role of genomic and transcriptomic differences in *BRCA1/2* carriers and non-carriers.

#7268 AI-Driven stratification of cancer patients using The Cancer Genome Atlas whole-genome sequencing data.

Jonghoon Lee[1], Chunyang Bao[1], Hansol Park[1], Gang-Hee Lee[1], Yoonsuh Lee[1], Beomki Lee[2], David Lehotzky[3], Ron Solan[3], Antonia Kowalewski[3], Xavi Loinaz[3], Vasuki Narasimha Swamy[3], David I. Heiman[3], Samantha Van Seters[3], Saveliy Belkin[3], Sam Wiseman[3], Andrew D. Cherniack[3], Luis Antonio Corchete Sanchez[3], Brian P Danysh[3], Zachary Everton[3], Chip Stewart[3], Haruna Tomono[3], Gengchao Wang[3], Esther Rheinbay[3], Gad Getz[3], Young Seok Ju[3], Won-Chul Lee[3], Ryul Kim[1]

[1]Inocras, San Diego, CA,[2]Korea Advanced Institute of Science and Technology, Daejeon, Korea, Republic of,[3]Cancer Program, Broad Institute of MIT and Harvard, Cambridge, MA

Recent genomic foundation models have advanced DNA sequence interpretation, yet most remain constrained to local sequence patterns and fail to produce the patient-level insights required for clinical decision-making. To address this limitation, we developed a framework that extends beyond sequence-level inference, enabling robust patient stratification through a Cancer Foundation Model. Our approach begins with “DNAChunker”, which employs a dynamic H-net-based tokenization strategy that divides the genome into variable-length segments, preserving high-resolution detail in regulatory and coding regions while efficiently compressing repetitive sequences. When evaluated on the Nucleotide Transformer and Genomic Benchmarks, DNAChunker achieved performance comparable to the state-of-the-art GENERator (1.2 billion parameters) while using only 156 million parameters. To translate these genomic embeddings into patient-level insights, we implemented a transformer-based Cancer Aggregation Model that integrates mutation embeddings with somatic copy-number alteration (SCNA) features. The framework was evaluated on large whole-genome sequencing (WGS) cohorts, including PCAWG (n=2,040) and CUBRICS breast cancer samples (n=1,053), with TCGA-BRCA (breast cancer; n=920) serving as an external validation cohort. The model effectively stratified patients by cancer type (accuracy, 96.89%), homologous recombination deficiency (HRD; accuracy, 92.83%), and PAM50 subtype (accuracy, 84.05%). Notably, it classified PAM50 intrinsic subtypes using only DNA-level information, eliminating the conventional reliance on RNA-based expression profiling. The Cancer Foundation Model demonstrates that patient-level representation learning from whole-genome data can achieve clinically meaningful stratification across diverse tumor types. By bridging the gap between genomic sequence interpretation and actionable phenotypic classification, this framework establishes a foundation for AI-based precision oncology. With further validation, it will facilitate biomarker discovery and patient stratification in clinical trials directly from WGS data.

#7269 Development and validation of an optimized, bead-based dual nucleic acid extraction method for high-yield genomic profiling of scarce FFPE tumor specimens.

Nripesh Prasad, Rebecca Beatty, Rachel Marshall, Chan-Ho Lee, Elizabeth Coffey, Annamaria Szanto

Discovery Life Science, Huntsville, AL

Formalin-fixed, paraffin-embedded (FFPE) tumor tissues are crucial for retrospective oncology studies, but recovering high-quality nucleic acids (NA) from these samples—especially scarce core needle biopsies (CNBs)—is challenged by chemical crosslinking, fragmentation, and low input volume, often compromising next-generation sequencing (NGS) success. To meet the demand for reliable NGS from limited FFPE material, we developed and validated a Modified Proprietary Dual Extraction Method specifically optimized for low-input and highly degraded FFPE tissues, including CNBs. This novel, bead-based chemistry utilizes a Xylene-free deparaffinization step, followed by Covaris UltraSonication to achieve optimized lysis and de-crosslinking conditions. The method focused on refining key technical parameters, namely lysis buffer concentration and de-crosslinking time/temperature, and was benchmarked against our Internal Standard and a commercial column-based standard (Qiagen AllPrep FFPE Dual Kit). FFPE samples across multiple tumor types (kidney, head and neck, bladder, lung) and varying tissue inputs (0.5 mm^3 to 4.0 mm^3) were tested, including a cohort of known low-quality (LowQ) FFPE samples. We evaluated DNA/RNA yield, integrity (DIN/RIN), and reproducibility across all three methods. The Modified Method demonstrated significantly superior performance: DNA Yield and Recovery: The protocol delivered a dramatic increase in usable DNA yield, with 98.83% of samples meeting the minimum 100 ng NGS threshold, compared to only 73.50% using the commercial kit. DNA Quality: The Modified Method achieved higher DNA yields without compromising DNA integrity and notably improved the quality metrics of challenging LowQ FFPE specimens. RNA Quality: RNA integrity also significantly improved over the AllPrep Kit, enhancing the suitability of the resulting RNA for complex downstream applications like RNA sequencing (RNA-seq) workflows. The protocol exhibited high reproducibility with minimal operator or lot-to-lot variability. This Modified Dual Extraction Method, leveraging optimized bead-based chemistry and sonication, enables superior, high-quality, and reproducible recovery of nucleic acids from the most challenging FFPE tumor specimens. Its validated performance over conventional protocols is critical for advancing reliable genomic profiling in cancer research and precision oncology using archived or limited tissue specimens.

#7270 Comprehensive mutation profiling from The Cancer Genome Atlas (TCGA) whole-genome sequencing datasets.

Chunyang Bao[1], Hansol Park[1], Gang-Hee Lee[1], Ryul Kim[1], Won-Chul Lee[1], Jonghoon Lee[1], Yoonsuh Lee[1], Beomki Lee[2], David Lehotzky[3], Ron Solan[3], Antonia Kowalewski[3], Xavi Loinaz[3], Vasuki Narasimha Swamy[3], David I. Heiman[3], Samantha Van Seters[3], Saveliy Belkin[3], Sam Wiseman[3], Andrew D. Cherniack[3], Luis Antonio Corchete Sanchez[3], Brian P. Danysh[3], Zachary Everton[3], Chip Stewart[3], Haruna Tomono[3], Gengchao Wang[3], Esther Rheinbay[3], Gad Getz[3], Young Seok Ju[1]

[1]Inocras Inc., San Diego, CA,[2]Graduate School of Medical Science and Engineering, Korea Advanced Institute of Science and Technology, Dajeon, Korea, Republic of,[3]Cancer Program, Broad Institute of MIT and Harvard, Cambridge, MA

Cancer arises from the progressive accumulation of genomic alterations. The Cancer Genome Atlas (TCGA), a landmark consortium project, has comprehensively characterized 33 cancer types through multi-omics profiling of over 11,000 tumor-normal pairs. However, most TCGA-based studies had relied on whole-exome sequencing (WES), which covers only ~1-2% of the genome, leaving the majority of the genomic landscape unexplored. To achieve a more comprehensive understanding of cancer genomes, the Broad Institute and Inocras collaboratively analyzed TCGA whole-genome sequencing (WGS) data encompassing over 8,000 tumors across more than 30 cancer types, which were initially analyzed by whole-exome sequencing. To fully leverage this resource, we applied CancerVision, an automated and streamlined bioinformatics pipeline developed by Inocras for clinical-grade WGS interpretation. CancerVision detects diverse genomic variants, including single-nucleotide variants (SNVs), insertions/deletions (indels), somatic copy number alterations (SCNAs), structural variants (SVs), and germline mutations, while also inferring homologous recombination deficiency (HRD) and mutational signatures. Using CancerVision, we performed a comprehensive, harmonized reanalysis of the TCGA WGS dataset and benchmarked our results against the bioinformatics pipelines from the Broad Institute and the official TCGA exome data. Across representative cohorts, ovarian cancer (CNV-driven), thyroid cancer (SNV-driven), and glioblastoma (mixed), CancerVision achieved high concordance, often uncovering additional high-confidence genomic alterations not captured in the existing TCGA resource. By integrating these results, we expand the known landscape of somatic variants, improve driver gene detection, and demonstrate the power of whole-genome-based analytics for actionable insights in precision oncology.

#7271 Clinical genomic and functional genomic support for a role of ARID1A loss in progression of desmoplastic small round cell tumor.

Tom Zhang[1], Andrea Gazzo[1], Christopher A. Febres-Aldana[2], Juan Luis Gomez Martis[1], Lee Spraggon[3], Romel Somwar[1], Marc Ladanyi[1]

[1]Memorial Sloan Kettering Cancer Center, New York, NY,[2]Laboratory of Pathology, National Cancer Institute, National Institute of Health, Bethesda, MD,[3]UCSF READY Center, San Francisco, CA

Background. Desmoplastic small round cell tumor (DSRCT) is a rare, lethal sarcoma defined and driven by the *EWSR1::WT1* fusion. DSRCT has a very low tumor mutational burden (TMB) and few recurrent secondary somatic mutations. Often, the *EWSR1::WT1* fusion is the sole identifiable genetic alteration. We leveraged the Memorial Sloan Kettering Cancer Center (MSK) sarcoma sequencing cohort to conduct a comprehensive profiling of 110 DSRCT cases to better define the genomic landscape and evolution of DSRCT.

Methods. DSRCT samples underwent matched tumor:normal DNA sequencing on the MSK-IMPACT platform (01/2014-12/2023). All cases harbored the *EWSR1::WT1* fusion. A genome-wide, pooled CRISPR-cas9 loss-of-function screen was conducted in 2 DSRCT cell lines (Brunello library, 4 sgRNAs per gene, targeting 19,114 genes). Immunohistochemistry (IHC) was used to assess ARID1A protein expression.

Results. We identified 110 DSRCT samples from 82 patients (pts) after robust filtering and quality control from a starting cohort of 198 samples (123 pts). Pts were predominantly male (85.4%) with a male-to-female ratio of 5.8:1 and a median age of 21.5 yrs (range: 6.5-55.9 yrs). At diagnosis, 50% had localized disease (stage I-II), 28.05% had liver metastasis (stage III), and 21.95% presented with extra-abdominal disease (stage IV). DSRCT samples had a median TMB of 0.8 mutations/Mb (range: 0.0-6.6); indeed, 47.3% had no detectable mutations (muts) among the 505 genes profiled. The most frequent secondary alterations were *ARID1A* inactivating muts (12.2%), followed by *FGFR4* activating muts (7.3%), *TERT* promoter muts (6.1%), and *TP53* muts (4.9%). In the knockout screen, *ARID1A*, *TP53*, and *PTEN* ranked among the top positively selected hits, providing functional genomic support for the clinical genomic findings. Notably, *ARID1A* muts were more common in metastatic lesions (18.5%) than in primary intraabdominal tumors (9.8%), suggesting a role in disease progression. To explore their evolutionary timing, we performed clonal decomposition using cancer cell fraction (CCF) analysis: metastatic samples had significantly higher CCF values (p=0.0067), and clonal muts were predominantly found in metastases (5/7), while subclonal variants were mainly observed in primary tumors (6/8; p=0.021) and their subclonality confirmed by IHC for ARID1A. Two *ARID1A*-mutated patients had both primary and metastatic samples; in one, an *ARID1A* nonsense mutation shifted from subclonal (CCF=0.286) in the primary to clonal (CCF=1.0) in the metastasis. In the 2nd patient, an ARID1A frameshift mutation appeared only in the metastatic lesion.

Conclusions. Late acquisition and metastatic selection of *ARID1A* mutations point to a role for loss of this BAF complex component in DSRCT progression. Future studies will investigate the pathobiology and therapeutic vulnerabilities associated with ARID1A loss in DSRCT.

#7273 Genomic Concordance Patterns Distinguish Multiple Primary Tumors from Metastatic Recurrences.

Brandie Taylor, **Samuel Rivero-Hinojosa**, Sandro Satta, Nicole Scott, Faraz Salmasi, Kevin Manage, Stephanie Woods, Charuta C. Palsuledesai, Ekaterina Kalashnikova, Angel Augusto Rodriguez, Minetta C. Liu

Oncology, Natera, Inc., Austin, TX

Background

Multiple primary cancers (MPC), wherein two or more synchronous or metachronous malignant tumors in the same or different organs are present within a single patient (pt), are observed in ~10-25% of pts with cancer. Differentiating MPCs from metastatic disease has implications for staging, treatment selection and prognosis. Here, we evaluated whole exome sequencing (WES) data of tumor tissues from pts known to have MPCs and metastatic recurrence (MR).

Methods

Pairs of distinct primary tumors from 76 pts with MPCs and primary/metastatic site tumor pairs from 134 pts with MR were compared. Tumor tissue WES was performed as part of either commercial circulating tumor DNA testing (Signatera™, Natera, Inc) or Altera™ Comprehensive Genomic Profiling (Natera, Inc). To enable intertumor comparison, normalization involved restricting variants to shared genomic regions (defined by a BED file) and normalizing variant allele frequencies in each sample by their respective median. Concordance analyses included shared variants (Jaccard index), VAF correlation coefficients, TMB comparisons (mut/Mb) and single-base substitution (SBS) mutational profile. Outlier pairs were identified by >5 mut/Mb TMB difference or Pearson VAF correlation <0.3.

Results

MPC and MR cohorts had 44.7% and 48.9% males, respectively; median pt ages were 69 (40-90) years and 72 (39-90) years, respectively. No primary tumor pairs were from the same organ. MPC tumor pairs exhibited minimal somatic mutation overlap [median Jaccard index = 0.00 (0.00-0.43)], with only 5% of patients having >1 shared driver mutations. Nearly 77% (59/76) MPC tumor pairs had >2-fold differences in TMB. Additionally, the cosine similarity distribution of SBS mutational profiles across MPC tumor pairs was broad and relatively low [median: 0.49 (0-0.95)], indicating distinct mutagenic processes. In contrast, MR tumor pairs demonstrated markedly higher genomic similarity, with high proportion of shared mutations [median Jaccard index = 0.352 (0- 0.965)], high VAF correlations (mean Pearson r = 0.62) in shared mutations, and >1 shared driver mutations in 61.9% of tumor pairs. Further, MR presented a strongly right-skewed distribution of SBS mutational profiles cosine similarity [median: 0.77 (0-0.98)]. TMB was largely concordant between MR paired tumors, though 15% of pairs exhibited divergence >5 mut/Mb.

Conclusions

MPC and MR tumor pairs showed markedly distinct patterns of genomic concordance. MPC tumors have low mutation sharing and minimal similarity in mutational profiles, suggesting independent mutagenic processes. Conversely, MR tumors display high clonal continuity across all genomic metrics, indicating a shared origin. VAF correlation and mutational signature profiling provides a robust framework to molecularly distinguish MPCs from MR, addressing a critical unmet need in tumor classification and precision oncology.

#7274 Structural variant signature discovery across >8,000 TCGA whole genomes using QuantHDP.

Many cancers have inherent defects in DNA damage response (DDR) which influence their sensitivity to tumor-targeting therapies. Examples include increased activity of immunotherapies in cancers with mismatch-repair deficiency and sensitivity to PARP inhibitors and platinum-based therapies in the context of homologous recombination (HR) deficiency. However, we are currently unable to reliably determine which DDR defects are present in a given cancer sample, which severely limits our ability to exploit these therapeutic vulnerabilities. Structural variants (SVs), or genomic rearrangements formed as a product of aberrant double strand break repair, hold promise as biomarkers of DDR state. Indeed, SVs affect a larger proportion of the cancer genome than any other form of genetic alteration and have features that reflect their mechanism of formation. Here, we develop QuantHDP, a novel computational method for detecting SV signatures which leverages complex modeling of genetic features to distinguish between cancers with different DDR alterations and potentially identify clinically relevant biomarkers. QuantHDP models SV features with probability distributions that reflect our knowledge of the biological mechanisms that generate them, accounts for expected differences in signature content by cancer type, and automatically infers the number of signatures present in a given dataset. In addition to recapitulating multiple previously established associations with defects in DDR - including signatures of BRCA1, BRCA2, and CDK12 alterations — we also uncover novel signatures that warrant further investigation.

#7275 Molecular characterization of Latino gastric adenocarcinomas identifies homologous recombination deficiency and TGF-beta pathways as targets for aggressive genomically stable tumors.

Montoya[1], Ana Patricia Estrada-Florez[2], Paul Lott[3], Katherine Chiu[4], Javi Villalpando[2], Shriveda Reddy[2], Jasmine Diaz Sezati[5], Fabian Castro[6], Guadalupe M Polanco-Echeverry[7], Magdalena Echeverry de Polanco[6], Javier Torres[8], Mabel Bohorquez[6], Luis G. Carvajal-Carmona[5]

[1]Biochemistry and Molecular Medicine, UC Davis School of Medicine, Davis, CA,[2]UC Davis, Davis, CA,[3]Genome Center and Department of Biochemistry and Molecular Biology, UC Davis, Davis, CA,[4]Genome Center, UC Davis, Davis, CA,[5]Biochemistry and Molecular Medicine, UC Davis, Davis, CA,[6]Universidad del Tolima, Ibague, Colombia,[7]The Health Equity Leadership, Science, and Community Research Laboratory, UC Davis, Davis, CA,[8]Instituto Mexicano del Seguro Social, Mexico City, Mexico

Background: Gastric cancer (GC) disproportionately affects Latino populations, yet genomic data from these patients remain scarce. This underrepresentation limits understanding of ancestry-specific molecular features that could inform targeted therapies. Tumors characterized by a genomically stable (GS) subtype are associated with worse outcomes and is more prevalent among Asians and Hispanics than among non-Latino White (NLW) and Black populations.

Methods: We analyzed 192 gastric adenocarcinoma tumors from Latino patients (Colombia, Mexico, and U.S.) using low-pass whole-genome sequencing (LP-WGS), or whole-exome sequencing. Molecular subtypes were classified, and somatic alterations were assessed and compared to the NLW cohort from the cancer genome atlas (TCGA).

Results: Similar to previous studies, the GS subtype was predominant (57.8%) in this Latino cohort, significantly higher than the mostly NLW, TCGA-STAD (11.5%, $p < 10^{-29}$). GS tumors had frequent alterations in cadherin/catenin complex genes (CDH1, CTNND1) as well as the DNA damage repair gene ATM, and TGF-β related pathway members TGFBR2 and ELF3. We identified six novel significantly mutated genes in non-hypermutated tumors and subtype-specific drivers that differ in frequency based on self-identified race. Comparative analysis revealed genetic ancestry-linked differences, including greater Indigenous American (IA) ancestry in diffuse histology tumors and higher CDH1 mutation frequency. Analysis of the therapeutically actionable biomarkers were limited in GS tumors (65% lacked targets), but ATM mutations suggest potential benefit from PARP inhibitors.

Conclusions: Latino GC tumors are enriched for GS subtype and harbor unique genomic alterations, including novel drivers and HRR pathway defects. These findings underscore the need for ancestry-informed therapeutic strategies and highlight PARP inhibition as a promising avenue for GS tumors.

#7276 Understanding cutaneous immune-related adverse events at single-cell resolution.

Olivia J. Cheng[1], Nabeela Khan[2], Terri Clister[2], Rebecca Nichols[2], Khanh Doan[2], Connor Hall[2], Rajan Kulkarni[2], Aik Choon Tan[1]

[1]University of Utah Huntsman Cancer Institute, Salt Lake City, UT,[2]OHSU, Lake Oswego, OR

Background: Immune checkpoint inhibitor (ICI) treatment has demonstrated clinical efficacies in various cancers. However, alongside the benefits of ICI's anti-tumor effect, a subset of patients experience immune-related adverse events (irAEs) that could lead to the termination of treatment, and in severe cases, morbidity and mortality. Cutaneous irAEs often occur early and are among the most common irAE in patients treated with ICIs. In particular, combinations of ICI with other anti-cancer agents can heighten the frequency and severity of irAEs. The goal of this study is to understand the molecular factors of immune-related rash (ir-Rash) and identifying biomarkers for early risk prediction and mechanism-based management.

Method: Five prostate cancer patients were treated with pembrolizumab and enzalutamide (androgen receptor blocker), and skin samples were collected for longitudinal single cell RNA sequencing (scRNA-seq) at various post-treatment timepoints: Week 0, Week 12, and Rash for those who developed ir-Rash. Cell type annotation, gene set enrichment, cell proportion and cell-cell interaction analyses were performed to identify cell types and biological pathways associated with ir-Rash risk and temporal development. To identify predictive biomarkers correlated with the risk of ir-Rash, baseline Week 0 samples were compared between the rash (R) and no-rash (NR) groups. To understand the temporal changes and mechanisms of actions through ir-Rash onset and resolution, we compared samples from patients with rash at the three timepoints.

Results: Cell proportion analysis revealed a higher baseline proportion of dendritic cells (DCs) in ir-Rash patients compared to NR patients. Among ir-Rash patients, cytotoxic cell abundance increased at rash timepoint relative to baseline. Single sample gene set enrichment analysis (ssGSEA) of 50 MSigDB hallmark gene sets across 5 conditions (Week0-NR, Week0-R, Rash, Week12-NR, and Week12-R) showed enrichment of pathways including interferon responses and PI3K-AKT-MTOR signaling at Rash. Week0-Rash samples additionally exhibited enrichment of MYC targets, IL2-STAT5 signaling, hypoxia, mTORC1 signaling, and E2F targets. Particularly in DCs, interferon-gamma response was enriched at both Week0-Rash and Rash timepoints. And among cytotoxic cells, notch signaling, MTORC1 signaling, WNT-BETA-Catenin signaling were enriched at the Rash timepoint.

Conclusions: Our results suggest that immune-related rash is associated with an increase in dendritic cell frequency at baseline and an increase in cytotoxic cells at onset, accompanied by enrichment of pathways including interferon responses. These results may help elucidate potential mechanisms underlying cutaneous toxicity during ICI treatment.

#7278 Single-cell RNA-seq analysis reveals distinct tumor and immunosuppressive T-cell phenotypes in CLL patients treated with ibrutinib..

Shanmugapriya Thangavadivel[1], Jami Shaffer[1], Shrilekha Misra[1], Samon Benrashid[1], Britten Gordon[1], Alexander He[1], Wantong Li[1], Konur Oyman[1], Annika Chura[1], Shelby Cabrera[1], Altan Turkoglu[1], Tzung-Huei Lai[1], Kerry Rogers[2], Seema Bhat[2], John C. Byrd[3], James S. Blachly[4], Jennifer A. Woyach[5], Bradley Blaser[6]

[1]The Ohio State University Comprehensive Cancer Center, Columbus, OH,[2]The Ohio State University, Columbus, OH,[3]UPMC Hillman Cancer Center, University of Pittsburgh, Pittsburgh, PA,[4]Duke University (Columbus, OH), Columbus, OH,[5]Assistant Professor of Internal Medicine, Division of Hematology, Ohio State University College of Medicine, Columbus, OH,[6]Division of Hematology, Department of Internal Medicine, The Ohio State University, Columbus, OH

The development of Bruton tyrosine kinase inhibitors and their introduction into clinical practice represents a major advance in the treatment of chronic lymphocytic leukemia (CLL). However, monotherapy with ibrutinib or other BTKis generally does not induce complete remissions or undetectable minimal residual disease even with extended therapy. Therefore, there is a need to understand the differences between ibrutinib sensitive and resistant CLL cells along with the immune microenvironment to identify novel therapeutic approaches for controlling residual disease during BTKi treatment. Here, we investigated the cellular heterogeneity of peripheral blood mononuclear cells from patients with CLL treated with ibrutinib using single-cell RNA sequencing. We identified unique transcriptional heterogeneity within the B cell cluster in the ibrutinib-sensitive and resistant patients. Ibrutinib sensitive cells showed enrichment of B cell populations with upregulation of MHC I molecules and TNF family members. Additionally, we observed that inflammatory response and metabolism related pathways were decreased, whereas cellular response to stress and DNA repair programs were increased in the ibrutinib resistance samples. T cells in ibrutinib-resistant patients showed expansion of Tregs and an exhausted CD8 effector T cell compartment. Furthermore, CD14+ and CD16+ monocytes from ibrutinib resistant patients preferentially expressed a gene expression program of antiviral immunity. At the single-cell level, our findings demonstrate a picture of transcriptional heterogeneity in the tumor compartment and immune milieu. Overall, these findings highlight transcriptional changes in circulating immune cells associated with ibrutinib resistance, suggesting that T cells exhaustion and monocyte polarization accompany, rather than directly drive, resistance during long-term BTKi therapy.

#7279 Beyond HLA LOH: Alternative modes of HLA loss are common and vary by cancer type.

Qidi Yang, Michael Brodie Mumphrey, Wenjin Gu, Taylor Harding, Ariane Lozac'hmeur

Bioinformatics, Tempus AI, Inc., Chicago, IL

The human leukocyte antigen (HLA) genes play a pivotal role in immune surveillance of tumors by presenting tumor-derived antigens to cytotoxic T cells, enabling immune recognition and elimination of malignant cells. Loss of heterozygosity (LOH), somatic mutations, epigenetic silencing and structural variations at the HLA locus are well-characterized mechanisms by which tumors evade immune detection, contributing to disease progression and resistance to immunotherapies. However, those mechanisms are rarely considered in conjunction. A comprehensive understanding of these diverse modes of HLA loss is critical for elucidating tumor-immune escape and optimizing immunotherapeutic strategies.

We developed an integrated workflow leveraging the Tempus xT assay to detect somatic alterations in HLA genes. Germline HLA alleles were first genotyped using a validated proprietary assay. Patient-specific HLA alleles and decoy sequences were used to realign sequencing reads. The realigned reads were fed into standard variant calling and RNA expression quantification workflows to establish HLA variants and HLA expression. HLA variants were filtered to remove artifacts. HLA expression was normalized and bias corrected using machine learning models trained on over 2,000 samples. Total HLA expression loss was defined as the trimmed mean of M values (TMM) being more than 2 standard deviations below the gene- and tumor-purity-stratified mean. HLA LOH was determined using the validated Tempus HLA LOH device. We applied our workflow to 11,000 cancer samples, assessing HLA genotypes, LOH, somatic variants, and expression.

Our HLA loss detection methods showed a high level of concordance, with DNA-based alterations evident at the RNA level. 61% of HLA alleles with LOH and/or loss of function (LOF) variants also displayed loss of HLA RNA expression, which included both allele-specific expression (ASE) and total expression loss from both HLA alleles. 12% of tumors without any DNA loss events displayed RNA-level HLA loss, potentially due to epigenetic regulation, or other causes. The prevalence and molecular mechanisms of HLA loss varied by cancer type. LOH was the dominant mechanism for HLA loss in most cancers, with exceptionally high rates of LOH in head and neck squamous cell carcinoma (46%, 92% of loss events) and lung squamous cell carcinoma (32%, 87% of loss events). Conversely, somatic LOF variants were the dominant mechanism in MSI-H colorectal cancer (22%, 51% of loss events), and expression loss dominated in prostate cancers (21% of cases, 84% of loss events).

As HLA-restricted immunotherapies expand, accurate and comprehensive characterization of HLA gene alterations in tumors is increasingly important. Our findings highlight that, beyond LOH, LOF variants and transcriptional silencing are significant contributors to HLA loss in certain cancers and should be routinely assessed to inform immunotherapeutic decision-making.

#7280 Pan-cancer single-cell RNA sequencing analysis refines multiorigin monocyte and macrophage lineages.

Truc Do Thanh Nguyen[1], Andrew J. Lee[2], Hyun Jung Park[3], Nameeta Shah[4], Bayrta Mandzhieva[1], Dong-Sup Lee[5], Inkyung Jung[2], Woong-Yang Park[1]

Tumor-associated macrophages (TAMs) are central regulators of tumor progression, influencing tissue homeostasis, immune suppression, and angiogenesis. To define their diversity and developmental organization across human cancers, we analyzed a unified single-cell and spatial transcriptomic atlas of myeloid cells from healthy tissues and multiple tumor types. This analysis delineated two principal trajectories of tumor-associated macrophages (TAMs): a resident macrophage-aligned C1QC$^+$ lineage and a monocyte-derived lineage comprising SPP1$^+$ and ISG15$^+$ TAMs. We further identified THBS1$^+$ immature myeloid cells as a precursor population that transitions toward the SPP1$^+$ TAM state and underlies a strongly immunosuppressive and pro-angiogenic program. Clinically, enrichment of C1QC$^+$ TAMs was associated with more favorable outcomes, whereas activation of the THBS1$^+$ MDSC-SPP1$^+$ TAM axis correlated with poor survival and diminished response to immunotherapy. These findings refine the developmental framework of myeloid cells in cancer and underscore a pathogenic macrophage trajectory with potential therapeutic relevance.

#7281 Immune senescence and antigen presentation defects define a pre-existing state of BCG unresponsiveness in bladder cancer.

KyounJun Lee[1], Jee Soo Park[2], Myung Eun Lee[2], Jongchan Kim[3], Hyoung-oh Jeong[1], Minseo Kim[1], Won Sik Ham[2], Semin Lee[1]

[1]UNIST, Ulsan, Korea, Republic of,[2]Yonsei University College of Medicine, Seoul, Korea, Republic of,[3]Yonsei University Health System, Seoul, Korea, Republic of

Background: Bacillus Calmette-Guérin (BCG) is standard therapy for high-risk non-muscle invasive bladder cancer (NMIBC), yet a substantial proportion of patients fail to respond. Although T-cell dysfunction and impaired antigen presentation have been implicated in BCG resistance, their pre-treatment presence and clinical relevance remain unclear. We aimed to define a reproducible, treatment-specific transcriptomic signature of BCG unresponsiveness centered on antigen presentation machinery (APM) deficiency.

Methods: We performed single-cell RNA sequencing (scRNA-seq) on 10 pre-treatment NMIBC tumors to identify cellular programs associated with BCG outcomes. Tumor-intrinsic APM activity and interferon pathway status were quantified at the independent bulk transcriptomic cohorts (UROMOL and BRS). Pre-treatment urine samples were assessed for a targeted chemokine panel (IL-6, IL-8, IFN-γ, CXCL10, CXCL13, CCL5, CCL21) to determine concordance between transcriptomic IFN/APM activity and protein-level immune signaling.

Results: Single-cell profiling revealed that BCG-unresponsive tumors exhibited markedly reduced epithelial APM expression accompanied by suppression of type I/II interferon signaling and loss of plasmacytoid dendritic cell activity. These transcriptomic features were reflected at the protein level: non-responders displayed significantly lower urine chemokine levels prior to BCG instillation. Bulk transcriptomic validation across >350 patients demonstrated that high APM activity robustly predicted improved recurrence-free survival in BCG-treated patients ($p < 0.05$).

Conclusions: BCG-unresponsive NMIBC is defined by a pre-existing antigen presentation defect coupled with suppressed interferon signaling, detectable at both the transcriptomic and urine protein levels. The APM signature exhibits strong, treatment-specific predictive value across multi-cohort datasets and provides a biologically compelling rationale for APM-restoring or IFN-enhancing intravesical immunotherapies as alternatives for patients unlikely to benefit from BCG.

Acknowledgments: The results shown here are in part based upon data generated by the TCGA Research Network: https://www.cancer.gov/tcga. We thank the staff of the Department of Urology and Laboratory Medicine at Yonsei University College of Medicine for their technical assistance. We also thank all the patients who participated in this study. This work was also supported by the National Research Foundation of Korea (NRF) funded by the Ministry of Education (RS-2018-NR031072).

#7282 A comprehensive multiomics atlas of treatment-naïve breast cancer uncovers co-occurring tumor-immune ecosystems driving immune hot and cold phenotypes.

Hani Jieun Kim[1], Beata Kiedik[1], Kate Harvey[1], Sehrish Kanwal[2], James Douglas[1], John Reeves[1], Alexander Lobanov[3], Daniel L. Roden[1], Sophie Van Der Leij[1], Mun N. Hui[4], Aziz Al'Khafaji[5], Elgene Lim[1], Sean M. Grimmond[2], Joakim Lundeberg[6], Charles M. Perou[3], Alexander Swarbrick[1]

[1]Garvan Institute of Medical Research, Darlinghurst, Australia,[2]University of Melbourne, Victoria, Australia,[3]UNC Lineberger Comprehensive Cancer Center, Chapel Hill, NC,[4]Chris O'Brien Lifehouse, Camperdown, Australia,[5]Broad Institute of MIT and Harvard, Cambridge, MA,[6]Science for Life Laboratory, KTH Royal Institute of Technology, Stockholm, Sweden

Breast cancer is a clinically and genetically heterogeneous disease. Whilst single-cell studies have advanced our understanding of the underlying biological diversity of this disease, a major limitation in previous studies is that they fail to capture the broad spectrum of breast cancer subtypes and lack the statistical power to resolve subtype-specific differences. To address this gap, we generated a comprehensive breast cancer single-cell atlas designed to robustly characterise transcriptomic and genomic heterogeneity across all major clinical subtypes.

Focusing on treatment-naïve tissues to capture disease biology prior to therapeutic intervention, we profiled nearly 200 patient samples to generate a comprehensive multiomics atlas of scRNA-seq, whole transcriptome sequencing (WTS), whole genome sequencing (WGS), and clinicopathological data, such as age, histological grade and type, ER/PR/HER2 measurements, and stromal tumour-infiltrating lymphocyte (sTIL) and PD-L1 status.

To quantify inter- and intra-tumoral heterogeneity, we developed a framework of breast cancer archetyping that positions malignant epithelial cells along axes capturing the cancer intrinsic properties. Archetyping successfully resolves biologically meaningful gradients and systematically quantifies transcriptomic heterogeneity. Our results show that luminal cancers—particularly Luminal B—exhibit the largest degree of intra- and inter-tumoural diversity. We define the key gene programs that contribute to this variability and identify immune programs among luminal cancers. Using sTIL status as a measure of immunogenicity, we identified an underappreciated subset of luminal tumours exhibiting high immune infiltration—challenging the prevailing view that luminal cancers are uniformly “immune cold.” Leveraging our single-cell data, we performed integrative analysis to uncover the distinct co-occurring tumour-immune ecosystems associated with immune-hot versus immune-cold phenotypes. These observations were further validated using our matched multimodal WGS, WTS, and spatial transcriptomics data.

Our single-cell multiomics breast cancer atlas spanning all major clinical subtypes provides a high-resolution framework for dissecting the multilayered heterogeneity of breast cancer. By maximizing patient representation and integrating rich clinical and genomic metadata, this resource enables robust identification of subtype-specific biology and reveals striking diversity within luminal breast cancers, including a substantial subset with immune-hot characteristics. Ongoing work will leverage this atlas and our deeply curated metadata, including survival outcomes, to refine breast cancer stratification and identify clinically actionable tumour ecosystems.

#7283 Genomic landscape of IDH-wild-type glioblastoma in a patient treated with TNF-alpha inhibitor: Implications for risk stratification and therapeutic decision-making.

Suryanarayan Mohapatra[1], **Natarajan Ganesan**[2]

[1]Internal Medicine, Kaiser Permanente - Mid-Atlantic Permanente Medical Group, Silver Spring, MD,[2]Biomedical and Anatomical Sciences, New York Institute of Technology, College of Osteopathic Medicine (NYITCOM) at Arkansas State University, Jonesboro, AR

Background:
TNF-α inhibitors, such as adalimumab, are widely used for autoimmune diseases, yet their long-term impact on tumorigenesis in genetically susceptible individuals remains unclear. Glioblastoma multiforme (GBM) is an aggressive IDH-wild-type tumor with well-defined molecular drivers, but genomic characterization of GBM arising in TNF-α inhibitor-treated patients remains extremely limited. We investigated the genomic profile of a GBM that developed after sequential methotrexate, sulfasalazine, adalimumab, and tofacitinib therapy to explore possible mechanistic links between immunomodulation and tumor evolution.
Methods:
Tumor tissue underwent immunohistochemistry, targeted next-generation sequencing, and copy-number analysis at two independent clinical laboratories. Genomic results were interpreted in the context of TNF-α pathway biology, tumor microenvironment (TME) interactions, and known molecular pathways associated with GBM progression.
Results:
The tumor demonstrated GFAP and OLIG positivity, Ki-67 of 45%, and strong p53 expression (>90%). Genomic profiling revealed hallmark alterations of IDH-wild-type GBM, including CDKN2A/B deletions, PTEN deletion, and TP53 mutation. Some unusual variants included a KDM6A frameshift variant, an unexpected ATRX mutation with uncertain pathogenicity, and PDPK1 loss. Notably, the tumor lacked a TERT promoter mutation—present in the majority of IDH-wild-type GBMs—suggesting alternative telomere-maintenance pathways. The combination of PTEN loss, TP53 mutation, and CDKN2A/B deletion indicated a highly aggressive molecular phenotype associated with immune evasion within the TME. Several altered pathways intersect with TNF-α signaling, raising the possibility of altered tumor-immune interactions under TNF-α blockade.
Conclusions:
This analysis identifies both canonical and atypical genomic alterations in a GBM arising after prolonged TNF-α-targeted therapy. The absence of a TERT promoter mutation and the presence of an unusual ATRX variant suggest a nonstandard evolutionary trajectory. Although causality cannot be established, the temporal association with TNF-α inhibitor exposure, combined with pathway overlap between TNF-α biology, PTEN/TP53 signaling, and immune regulation, warrants further investigation. These findings highlight the importance of genomic risk stratification and consideration of germline predisposition before initiating TNF-α inhibitors, as well as the need for systematic genomic profiling of tumors emerging during biologic therapy.

#7284 Clinically significant cancer variants detected by comprehensive genomic profiling test PGDx elio tissue complete.

Kenneth C. Valkenburg[1], Jesse Fox[1], Jennifer Jackson[1], Robert Auber[2], Ann L. Carr[2], Eric Severson[1], Taylor Jensen[3], Shakti Ramkissoon[1], Marcia Eisenberg[1], Brian Caveney[1], Christopher Coldren[2]

[1]Labcorp Corporation of America, Burlington, NC,[2]PathGroup, Brentwood, TN,[3]Labcorp, Fuquay-Varina, NC

PGDx elio® tissue complete (ETC) is an FDA-cleared kitted IVD class II tumor profiling assay that detects somatic cancer-associated genomic alterations in formalin-fixed paraffin embedded (FFPE) tissue from all solid tumors. ETC is a hybrid capture 505-gene next-generation sequencing (NGS) test that reports single nucleotide variants (SNVs), insertions and deletions (indels), copy number amplifications, translocations, microsatellite instability (MSI), and tumor mutation burden (TMB). Tumor-specific variants are reported based on AMP/ASCO/CAP guideline-supported clinical significance. The size and design of the gene panel enable reporting of recognized variants with evidence of clinical significance across 16 tumor types (bladder, breast, cholangiocarcinoma, CNS, colon, gastric, GIST, IMT, melanoma, NSCLC, ovarian, pancreatic, prostate, rectal, thyroid, uterine), including variants that are indicated for all solid tumors, empowering comprehensive clinical utility. These variant classes include the following: SNVs and/or indels in 36 genes (*AKT1*, *ATM*, *ATR*, *BARD1*, *BRAF*, *BRCA1*, *BRCA2*, *BRIP1*, *CDK12*, *CHEK1*, *CHEK2*, *EGFR*, *ERBB2*, *ESR1*, *FANCA*, *FANCL*, *FGFR3*, *IDH1*, *IDH2*, *KRAS*, *KIT*, *MET*, *MLH1*, *MRE11A*, *NBN*, *NRAS*, *NTRK3*, *PALB2*, *PDGFRA*, *PIK3CA*, *PTEN*, *RAD51B*, *RAD51C*, *RAD51D*, *RAD54L*, and *RET*), translocations in 4 genes (*ALK*, *RET*, *NTRK2*, and *NTRK3*), amplifications in *ERBB2*, and 2 genomic signatures (MSI and TMB). In addition, resistance mutations in *ALK*, *EGFR*, *BRAF*, *KIT*, *MET*, and *PTCH1* that impact treatment decisions with targeted therapies are reported. Analytical validation studies assessed the specificity for each variant and the sensitivity, accuracy, and reproducibility for many of them, yielding competitive analytical performance. Clinical validation has been performed for *BRAF* V600E/K in melanoma, demonstrating comparable performance relative to other on-market FDA-approved companion diagnostic tests. Analysis of real-world evidence for approximately 20,000 cases reveals that ETC detects clinically significant variants at expected rates when compared to available cancer variant databases. ETC, due to its large gene panel, provides a more comprehensive view of patients' mutational profile, enabling physicians to make treatment decisions that are more precisely tailored to individual needs. Overall, these results demonstrate the exceptional performance of ETC in FFPE tissue and the power of comprehensive genomic profiling over single gene tests in standard testing workflows and discovery studies.

#7285 Gene expression-based subtypes associated with prognosis in Colombian colorectal cancer.

Wendy Johana Montero Ovalle[1], Diego Felipe Ballen-Lozano[2], Liliana Lopez-Kleine[3], Silvia Juliana Serrano-Gomez[4]

[1]Instituto Nacional de Cancerologia, Bogota, Colombia,[2]Oncology, Instituto Nacional de Cancerologia, Bogota, Colombia,[3]Universidad Nacional de Colombia, Bogota, Colombia,[4]Instituto Nacional de Cancerologia, Bogota, Colombia

In Colombia, colorectal cancer (CRC) is the fifth leading cause of cancer-related death. Molecular alterations linked to clinical-pathological variables are useful for prognosis and guiding treatment. However, current gene expression-based classifications have been developed mostly in non-Latin American populations, leaving Latin Americans underrepresented. To date, no gene expression studies have been conducted in Colombian CRC patients.

Objective: Identify and characterize gene expression profiles and evaluate their association with the prognosis in Colombian patients with CRC.

Methodology: FFPE tumor (n=35) and non-tumor (n=17) samples from CRC patients treated at the National Cancer Institute, Bogotá-Colombia between 2010-2014 were analyzed by RNA-seq. Differential gene expression was assessed with DESeq2 (FDR-adjusted ≤0.05, lfc of 2 and p-value ≤0.05)K-means, NFM and clusGap were used to clustering. Functional enrichment was performed using the ClusterProfiler and KEEG. WGCNA identified hub genes. Differences in the presentation of clinical-pathological variables were evaluated with chi-square and Fisher's tests ($p<0.05$ considered statistically significant). Recurrence-free survival (RFS), metastasis-free survival (MFS), and overall survival (OS) were estimated by Kaplan-Meier method and the log-rank test.
