Southwest Asian/North African communities (SWANA) make up over 3-4% of immigrants in the U.S. and yet their health status is largely unknown because these ethnic groups are misclassified within the U.S. racial schema as White, deeming them ‘invisible minorities’. Administrative forms specify that White includes Middle-Eastern but SWANA persons may also self-identify as Black, Asian, and Other. With the rise of Islamophobia and increased US intervention in the Middle Eastern region, SWANA Americans face unique challenges that require a deeper understanding of their health status.One methodology to obtain cancer statistics on SWANA is using naming algorithms. Similar to SWANA, the Latine population was invisible in administrative data prior to the 1970’s. Grassroots efforts and advocacy from the Latine community led to the development of validated Latine surname algorithms which have been implemented by the National Cancer Institute. Similarly, SWANA activists have advocated for the creation of a federal identification category for over 50 years arguing that SWANA communities are not perceived as White due, in large part, to a long-standing history of political racism in the United States.The purpose of this study was to develop a SWANA Surname Algorithm (SSA) to inclusively identify SWANA in cancer health data. We used surnames by country of descent to leverage interpretable decision trees to effectively distinguish SWANA from non-SWANA individuals by iteratively selecting the best surname roots at which to split the data to maximize the separation of SWANA individuals from others based on their surname. We integrated these patterns into our SSA so that when presented with a new surname, the algorithm simply follows the decision patterns down to the leaf nodes, otherwise known as the predicted class (SWANA vs non-SWANA).We developed a preliminary SWANA Surname List (SSL) using publicly available naming databases by country of origin (N=71,300). We cross-referenced the SSL against the VCU Massey Cancer Center data repository and found 4.9% of all cancer patients from 2016 to 2020 matched as SWANA. Notably, the prevalence of SWANA patients has been increasing over the last few decades, 3.8% in 1991-1995, to 4.2% in 2001-2005, and then most recently 4.9% in 2016-2020. We will use our SSA to validate these findings. These preliminary findings underscore the valuable insights that naming algorithms can provide in elucidating the true demographic composition of cancer patients. Lack of racial/ethnic disaggregation perpetuates existing inequities in access to essential health resources among SWANA communities. The inclusion of SWANA in cancer disparities research would allow researchers to better examine the cancer health status of this underrepresented but growing community while also aligning with the true racialization of SWANA in the United States.

#0821 Uptake of cervical cancer screening services by women living with HIV in Kajiado County Kenya.

C. Kamau[1], A. Njoroge[1], **F. Makokha**[1], K. T. Ashing[2];
[1]Mount Kenya University, Thika, Kenya, [2]City of Hope National Medical Center, Duarte, CA

Background: This project is an African Caribbean Cancer Consortium (AC3) facilitated study: Women living with HIV (WLHIV) are more susceptible to cancer due to their immune-compromised status. The Kenya Ministry of Health recommends that women diagnosed with HIV should be screened for cervical cancer annually by either visual inspection with acetic acid (VIA) or visual inspection with Lugol's iodine (VILI), cytology and testing for HPV once every two years.
Objective: We determined the uptake of cervical cancer screening and HPV testing by women living with HIV (WLHIV) in Kajiado County in 2022.
Methodology: The electronic health information system was used to abstract data for WLHIV in Kajiado county. Kajiado county has 57 antiretroviral (ART) facilities. However, our analysis accessed data from 38 facilities whose data is captured in the health information system. Authorized health care workers from the county were requested to abstract redacted data from the health information system. No personal identifiers were collected from the system as a means of protecting the privacy of individuals and abiding with the Kenya's data protection law. Authorization to access the county was obtained from the county's department of health while ethical approval was obtained from Mount Kenya University's Institutional Scientific and Ethics Review Committee.
Results: A total of 16,827 people living with HIV were enrolled for care at the 38 ART selected sites in 2022. Out on the total population that was enrolled for care, 11,785 (70%) were women with an age range of 15 to 49 years. A total of 3342 WLHIV, representing 28.36% of the target population, were screened by using visual inspection with acetic acid (VIA). Data for other methods of screening and HPV testing was not available in the health information systems. Of those screened, 3240 (97%) tested negative, 78 (2.3%) had positive results while 24 (0.7%) had suspicious lesions.
Conclusion: Our analysis shows low uptake of cervical cancer screening services with only 28.36% of the targeted women being screened in 2022. The only available testing method (VIA) is less robust as compared to cytology and HPV testing. We also found a gap in reporting of HPV testing in the county. We thus recommend implementation science research examining the systemic barriers to HPV testing and reporting to better inform best practice HPV-related cancer prevention and control policy and practice to reduce cancer-related morbidity and mortality among WLHIV.

#0822 A retrospective study on the disparities of hepatocellular carcinoma.

X. Zhou[1], B. Aldridge[1], N. Rahmanov[1], Z. Liu[2], J. Mao[3], N. Varshney[1];

[1]University of Mississippi Medical Center, Jackson, MS, [2]Shanxi Medical University, Taiyuan, China, [3]Tougaloo College, Jackson, MS

Background: Hepatocellular carcinoma (HCC) is the most common type of primary liver cancer in adults and the third leading cause of cancer-related deaths worldwide. Studies report that the incidence of, and mortality from HCC vary significantly by age, sex, and race/ethnicity; however, disparities in the expression level of tumor biomarkers, liver functions, lipid profiles, and comorbidities have not been thoroughly investigated among subpopulations of patient with HCC.
Methods: A retrospective study was conducted to review 247 serial HCC cases enrolled in the University of Mississippi Medical Center during June 2000 to May 2023. The entire HCC population was stratified into subpopulations by race, gender, age and BMI. Then comparisons were performed between two corresponding subpopulations in the expression level of HCC-related biomarkers including Alpha-FP, liver functions including albumin, ALT, AST, and ALP, plasma lipid profiles including cholesterol, and comorbidity conditions including cirrhosis in benign liver tissues, smoking, alcohol using, and illness with viral hepatitis. Two-tailed Student's T-test was used to calculate the difference in mean values, and Chi-Square Test was used to compare the difference in rates or percentages. The significant p value was set at $p<0.05$.
Results: In total 247 HCC cases, males were 178 (72.1%) and females were 69 (27.9%) with a male to female ratio of 2.6:1; black patients were 108 (43.7%), white patients were 127 (51.4%), and others were 4.9%. The mean age was 59.6 years and mean BMI was 27.04. AFP was the only one of detected tumor biomarkers showing disparities: it was significantly higher in patients of male ($p=0.026$), younger age ($p<0.0001$), lower BMI ($p=0.039$), smokers ($p=0.0325$) and illness with viral hepatitis ($p=0.0007$). Disparities in liver functions included: 1) AST was significantly higher in Black HCC patients ($p=0.027$); 2) no statistical difference of liver functions in gender; 3) younger HCC patients had significantly lower level of Albumin ($p=0.006$), and higher levels of ALT ($p=0.014$) and AST ($p=0.0032$); 4) HCC patients with lower BMI also had lower level of Albumin ($p=0.015$), and higher levels of AST ($p=0.0480$ and ALP ($p=0.0057$). There was no statistical difference of plasma lipid profiles between subpopulations, Black HCC patients except that Black HCC patients had significantly higher levels of cholesterol ($p=0.0006$) and HDL ($p=0.048$). In comorbidity, Black HCC patients had higher rates of alcohol using and existence of cirrhosis; and male HCC patients had higher rates of smoking, alcohol usage and viral hepatitis.
Conclusions: HCC patients are greatly disparate in the expression level of tumor biomarkers, liver functions, plasma lipid profiles and comorbidity conditions between subpopulations stratified by race, gender, age and BMI. These results could provide useful information for clinical management and prognosis of patients with HCC.

#0823 Parent-endorsed potential interventions to improve language disparities in pediatric cancer.

M. Stall[1], N. Winick[1], E. Kaye[2];
[1]University of Texas Southwestern Medical Center, Dallas, TX, [2]St Jude Children's Research Hospital, Memphis, TN

Introduction: Children with cancer whose parents speak languages other than English (LOE) experience disparities including underrepresentation on clinical trials, decreased access to resources and inadequate interpretative services. Few studies in pediatric oncology have investigated the communication experiences of families who speak LOE, and rarely have studies sought parental recommendations for improvement. In this study, we aimed to characterize the experiences of parents of children with cancer who speak LOE and identify stakeholder-driven interventions to improve deficiencies.
Methods: We enrolled parents of children with cancer who spoke any LOE and conducted semi-structured interviews about perceptions of medical care, communication and support from the medical team within 3 months of a new cancer diagnosis and 6-12 months post-diagnosis. Inductive content analysis was performed, with iterative transcript review and memo-writing informing the development of codes. Code frequency, temporal duration and distribution across language subtype were calculated and reported as descriptive statistics. Analysis was organized in MAXQDA, a mixed-methods data analysis software.
Results: Twenty-eight parents, representing 7 different languages, were enrolled. All parents completed first interviews and 14 have completed second interviews to date. Parents described frequent problems with interpretation and felt their child's care would be improved if they spoke English. Parents made suggestions on how to improve their experience and understanding of their child's medical care (Table 1).
Conclusion: Challenges related to language interpretation are pervasive and parents who speak LOE believe their child's cancer care would be improved if they spoke English. Parents identified preferred communication practices and specific interventions that may be useful in promoting understanding of their child's medical care and overall enhance supportive resources.

Parent-endorsed communication practices and potential interventions to improve language disparities

Preferred communication practices	Use simple terms	Limit conversations between providers when no interpreter present	Speak to English and non-English speakers equally	Always automatically use professional interpreters	Take your time
	Repeat	Demonstrate	Rephrase	Use drawings	Point
	Ask for preferred language	Be specific and detailed	Speak slowly	Use short phrases	Allow time for interpretation
Requested resources in preferred language	Educational videos	Written educational materials	Translated hospital documents	List of supportive resources	List of financial resources
	List of reliable websites	Language matched parent buddy support system		Side by side instructions in English and preferred language	
System-level changes	Increased in-person interpreter staffing	Staff education on approach to LOE encounters	Patient advocate to review medications and check labels	Interpreter use at all points of contact	Provision of language concordant providers

#0824 Comparing experiences of Spanish and non-English/non-Spanish speaking parents of children with cancer.

M. Stall[1], N. Winick[1], E. Kaye[2];
[1]University of Texas Southwestern Medical Center, Dallas, TX, [2]St Jude Children's Research Hospital, Memphis, TN

Introduction: Children with cancer whose parents speak languages other than English (LOE) experience disparities including underrepresentation on clinical trials and decreased access to resources. Few studies in pediatric oncology have investigated the communication experiences of families who speak LOE, particularly for languages other than Spanish. The primary objective of this study was to characterize the experiences of parents of children with cancer who speak LOE.
Methods: Parents of children recently diagnosed with cancer who spoke LOE were enrolled concurrently in two cohorts, Spanish speaking and non-English/non-Spanish speaking. Semi-structured interviews were conducted about parent perceptions of medical care, communication and support from the medical team within 3 months of a new cancer diagnosis and 6-12 months post-diagnosis. Inductive content analysis was performed, with iterative transcript review and memo-writing informing the development of codes. Code frequency, temporal duration and distribution across language subtype were calculated and reported as descriptive statistics. Analysis was organized in MAXQDA, a mixed-methods data analysis software.
Results: Of the 28 parents enrolled, 20 spoke Spanish and 8 spoke other languages including Dari, Nepali, Karan, Cantonese, Chuukese and French. All parents completed first interviews and 14 have completed second interviews to date. All parents described challenges with interpretation, but difficulties were reported more often by non-Spanish speakers: 67% of non-Spanish speakers encountered interpreters who spoke a different dialect (vs. 35% of Spanish speakers), 33% had interactions where no interpreter was available via any modality (vs. 0%), and 75% of their children were asked to interpret by the medical team (vs. 12%). Additionally, non-Spanish speakers lacked access to written educational materials or hospital documents in their language and they were unable to build rapport with interpreters, whereas Spanish speakers described regular access to these resources. Spanish speakers also frequently reported incorrect interpretation that was recognized by providers who understood some Spanish. This was never reported by non-Spanish speakers as no medical team members spoke their languages.
Conclusion: Nearly 40% of the United States population speaks a language other than English or Spanish at home, yet their needs are significantly underrecognized and understudied. Our findings demonstrated that challenges related to interpretation are pervasive, and non-English/non-Spanish speakers may face greater difficulties. Overall, parents who speak LOE report receiving disparate care and deficient resources. An urgent need exists to provide equitable communication and resources, particularly for non-Spanish speakers who report significant obstacles in receipt of high-quality pediatric cancer care.

#0825 Adverse childhood experiences and history of depression among cancer survivors.

O. A. Babatunde[1], V. Collucielli[2], M. S. Jefferson[3], S. A. Adams[4], C. Hughes Halbert[5], J. Obeysekare[1], F. Clark[1], A. Nagar[1], N. Osazuwa-Peters[6], E. Adjei Boakye[7];

[1]Prisma Health, Greenville, SC, [2]University of South Carolina School of Medicine, Greenville, SC, [3]Medical University of South Carolina, Charleston, SC, [4]University of South Carolina, Columbia, SC, [5]University of Southern California, Los Angeles, CA, [6]Duke University School of Medicine, Durham, NC, [7]Henry Ford Health System, Detroit, MI

Introduction: Adverse Childhood Experiences (ACEs) are stressful life events that are associated with an increased risk of depression. Depression is experienced by 25% of cancer survivors in the US. While previous studies have examined the associations between ACEs and depression in the general population, studies on cancer survivors are lacking. We aimed to examine the predictors of depression with a primary focus on ACEs among cancer survivors.
Methods: Using a cross-sectional data from the 2020 Behavioral Risk Factor Surveillance System for 19,241 cancer survivors aged 18 and above, we categorized ACEs based on severity. The ACE categories (zero, one, two-three, ≥four) included questions assessing exposure to eight types of ACEs before age 18 years. The outcome is self-reported history of depression diagnosis (yes/no). Weighted multivariable logistic regression models estimated odds of depression by ACEs as the primary variable and covariates were age, gender, smoking status, income, education, marital status, body mass index, health status and race.
Results: In this sample of cancer survivors, 41%, 22%, 21% and 16% reported having experienced zero, one, two-three, and ≥4 ACEs respectively. Personal history of depression was reported by 21% of survey respondents. In the adjusted model, survivors with 1 ACE (aOR: 1.6, 95% CI. 1.2- 2.0), 2-3 ACEs (aOR: 1.7, 95% CI. 1.3- 2.1), or >=4 ACES (aOR: 4.4, 95% CI. 3.4- 5.7) had higher odds of depression compared with those with zero ACEs. Additional notable predictors of higher odds of depression are younger age, 18-39 (aOR: 2.7, 95% CI. 1.8- 4.0), middle age, 40-64 (aOR: 1.6, 95% CI. 1.3- 1.9) compared with those aged 65 and older; females (aOR: 2.1, 95% CI. 1.7- 2.5) compared with males; obese respondents (aOR: 1.5, 95% CI. 1.2- 1.9) compared with respondents with normal body mass index; current smokers (aOR: 1.5, 95% CI. 1.2- 2.0) compared with respondents who never smoked; and poor or fair health status (aOR: 3.2, 95% CI. 2.6- 3.9) compared with respondents with excellent/good health status.
Conclusion: Adult cancer survivors who experience ACEs as children represent an important targeted prevention group to reduce risk of depression. Variation by age, obesity, female gender, current smoking status, and poor health associated factors that may reduce the risk of depression warrants additional studies regarding potential for identification of resilient factors; and this may inform future selective prevention strategies, as well as identify a pathway between ACE and depression among cancer survivors.

POPULATION SCIENCES: Environmental and Occupational Risk Factors, Infection, and Aging
Poster Session

#0828 Associations of perfluoroalkyl substances with breast cancer incidence risk and mediation role of mitochondrial DNA copy number: A prospective case-cohort study.

Y. Feng, H. Guo;
Department of Occupational and Environmental Health, State Key Laboratory of Environmental Health (Incubating), School of Public Health, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China

Background: Perfluorinated carboxylic acids (PFCAs) and perfluorinated sulfonic acids (PFSAs), notable representatives of perfluoroalkyl substances (PFASs), are synthetic persistent chemicals widely accumulated and detected in humans. Short-chain PFASs [PFCAs with carbon number <8 and PFSAs <6, e.g. perfluoroheptanoic acid (PFHpA)] are considered less bioaccumulative and increasingly used in commercial products, yet their health impacts are rarely investigated. Perfluorooctanoic acid (PFOA) has been categorized as a possible human carcinogen (group 2B) and a potential mammary toxicant. However, few population studies explored the prospective associations of PFOA and other common PFASs with breast cancer risk nor the underlying mechanisms.
Methods: Hence, we conducted a case-cohort study within the DongFeng-Tongji Cohort, compromising 226 incident breast cancer cases and a random sub-cohort of 990 individuals. Plasma concentrations of four PFCAs [PFOA, perfluorononanoic acid (PFNA), perfluorodecanoic acid (PFDA), and PFHpA] and two PFSAs [perfluorooctane sulfonic acid (PFOS) and perfluorohexane sulfonic acid (PFHxS)], as well as peripheral blood mitochondrial DNA copy number (mtDNAcn) levels, were measured at baseline.
Results: Using Barlow-weighted Cox regression, we found 35% and 20% increased incident risk of breast cancer for each 1-unit ln-transformed increase in PFOA and PFHpA, respectively [HR (95% CI) = 1.35 (1.03, 1.78) and 1.20 (1.02, 1.40)]. Quantile g-computation analysis revealed a 19% increased incident risk of breast cancer along with each simultaneous quartile increase in all ln-transformed PFCA concentrations [HR (95% CI) = 1.19 (1.01, 1.41)], driven mainly by contributions from PFOA (56%), PFNA (24%), and PFHpA (20%). Besides, mtDNAcn was positively associated with PFHpA levels [β (95% CI) =0.027 (0.005, 0.048)], but not with PFOA or PFNA (P>0.05). We also found significantly higher breast cancer risk in participants with the highest mtDNAcn (Q4, ≥1.52) than those with the lowest (Q1, <0.87) [HR (95% CI) =2.92 (1.69, 5.04)], and that mtDNAcn mediated 12.77% of PFHpA-breast cancer association [Indirect effect, HR (95% CI) =1.02 (1.00, 1.04)]. No significant mediation effect of mtDNAcn was observed in associations of PFOA and PFNA with breast cancer (P>0.05).
Conclusions: Our work unveiled the relationship of short-chain PFHpA with increased incident risk of breast cancer for the first time and highlighted the intermediate role of mtDNAcn in this association, providing a research clue for exploring the potential mechanisms of PFAS-induced breast cancer. Moreover, co-exposure to PFASs was observed as a risk factor for breast cancer, shedding light on breast cancer prevention by regulating PFASs as a chemical class.

#0829 Phthalate exposure results in circadian rhythm-induced BBB dysfunction increasing the risk for breast cancer brain metastasis.

D. Tiburcio, S. Adolphe, I. B. Akpu, T. Teglas, O. Naranjo, S. H. L. George, M. J. Toborek;
University of Miami Miller School of Medicine, Miami, FL

Phthalates, classified as plasticizers, represent a group of chemicals pervasive in the general U.S. population, with notably higher levels in non-Hispanic Blacks compared to non-Hispanic Whites. These persistent organic pollutants (POPs) have been identified for their impact on the circadian rhythms of the brain and vascular system. Several studies indicate that phthalates can elevate neuroinflammation and reduce levels of the junctional protein ZO-1 in the hypothalamus, home to the master circadian clock known as the suprachiasmatic nucleus (SCN). The SCN regulates cellular and tissue circadian rhythms, including tight junction proteins essential for the blood-brain barrier's (BBB) main barrier function. Interestingly, experimental studies reveal that prolonged chronic circadian rhythm disruption (CRD) in mice leads to increased breast cancer metastasis. However, the effects of phthalates on CRD concerning brain cancer and metastasis remain poorly understood. Given their significant prevalence and biological impact, we hypothesize that phthalate exposure induces CRD through hypothalamic dysregulation, resulting in BBB dysfunction and an elevated risk of brain metastasis.
Results. We developed an in vitro BBB model using endothelial cells and exposed them to an environmentally relevant mixture of five phthalates simulating chronic low-grade exposure. Analysis showed dysregulation of critical clock genes (Bmal1 and Clock), along with a substantial decrease in BBB tight junction proteins (claudin-5 and occludin) at the protein and mRNA levels. The tumor trans-endothelial migration assay using breast adenocarcinoma cells along with endothelial cells demonstrated an increased metastatic potential following phthalate exposure.
Conclusion. These findings offer crucial insights into the molecular mechanisms underlying phthalate exposure, suggesting potential targets for future brain metastasis treatments. Additionally, they hold implications for the future regulation and management of phthalate usage and policy. This work was supported by the University of Miami U-LINK Resilience Challenge grant.

#0830 Michigan cancer and research on the environment study (MI-CARES) cohort: Baseline methods and participant characteristics.

Lilah Khoja[1], Maxwell Salvatore[1], Minh Tung Phung[1], Isabella De Sa[1], Heatherlun Uphold[2], Justin Colacino[1], Alison M. Mondul[1], Bhramar Mukherjee[1], Dana Dolinoy[1], Celeste Leigh Pearce[1]

[1]University of Michigan, Ann Arbor, MI,[2]Michigan State University, East Lansing, MI

Michigan has a long history of adverse environmental exposures, many of which are still ongoing, like the Flint water crisis, extreme air pollution burden, and widespread PFAS exposure. Michigan is also home to a diverse population of Latinx, Black, White, and Middle Eastern/North African (MENA) Americans. Because minority populations are underrepresented in environment and cancer research despite being at greater risk of being exposed to environmental hazards and having worse cancer outcomes, Michigan is uniquely positioned for studying the associations between environmental exposures and cancer risk. In June 2022, the Michigan Cancer and Research on the Environment Study (MI-CARES) began recruitment with a goal of establishing a cohort of over 100,000 Michiganders to examine these associations. Any Michigander aged 18-49 is eligible to enroll in MI-CARES. By focusing on this age range, we will capture exposures during important windows of susceptibility prior to the onset of most cancers.While recruitment is open to all state-wide, efforts are focused on six environmental injustice hotspots, identified using the MiEJScreen tool, a relative summary score capturing pollution burden and population vulnerability: the metro areas of Kalamazoo, Grand Rapids, Flint, Lansing, Detroit, and Bay City-Saginaw.MI-CARES will enroll equal numbers of Black, Latinx, MENA, and White participants. To support participation in diverse communities, study materials are available in Arabic, English, and Spanish. MI-CARES has employed a multifaceted community engagement strategy and is recruiting from these communities directly and with the help of community partners. An incentive of $10 is also provided to participants who successfully complete the questionnaire.To democratize participation, MI-CARES enrollment can be completely remote, but in-person and paper-based enrollment is available. Enrollment includes a baseline questionnaire, consent for data linkage, and annual follow-up surveys. Participants are also asked to provide saliva and blood spot samples via a mailed at-home biospecimen collection kit. Biospecimens will be analyzed for environmental exposures like heavy metals and for intermediate cancer markers including inflammation, cellular aging, immune function, and altered metabolism. Participant data will be linked to neighborhood-level exposure databases, administrative databases like cancer registries and death indices, and to the Michigan Neonatal Biobank. More than 4,000 Michiganders have enrolled in MI-CARES. Data on initial cohort members including environmental exposure history and demographic characteristics will be presented. MI-CARES is part of the Cohorts for Environmental Exposures and Cancer Risk (CEECR) consortium, which is funded by the National Cancer Institute and the National Institute for Environmental Health Sciences.

#0831 Occupational-related exposure to benzene and risk of breast cancer: Systematic review and meta-analysis.

V. DeStefano[1], D. Shah[1], V. Shah[2], M. Sadat Seyyedsalehi[3], M. Bonetti[3], P. Boffetta[1];
[1]Stony Brook University, Renaissance School of Medicine, Stony Brook, NY, [2]Northeastern University, Boston, MA, [3]University of Bologna, Bologna, Italy

Purpose: Benzene is a recognized carcinogen as evidenced by its association with leukemia; however, its association with breast cancer is not well established. Hence, a meta-analysis of cohort and case-control studies was performed to determine the association between benzene exposure and the risk of breast cancer.
Methods: A systematic literature review was conducted and 7221 publications were identified, from which 21 cohort and case-control studies were retained, and evaluated using meta-analyses (fixed effects model). PECOS criteria and STROBE guidelines were followed, and the study protocol was registered in the PROSPERO database (Registration No. 379720). Study quality was assessed using a modified Newcastle-Ottawa scale (NOS).
Results: The summary relative risk (RR) for ever-benzene exposure was 1.08 (95% CI=1.02-1.14, I^2=43.6%, n=21); corresponding RR for cancer incidence and mortality were 1.08 (95% CI=1.02-1.14, I^2=58.6%, n=15) and 1.09 (95% CI=0.87-1.38, I^2<0.001%, n=9), respectively. These main results were confirmed in sub-analyses by geographical region, industry type, publication year, and levels of exposure. No heterogeneity was detected amongst geographical regions (p-het=0.19), industry of employment (p-het=0.05) or and duration of the dose (low, high; p-het=0.64). Studies published before 2003 reported a summary RR of 1.24 (95% CI=1.13-1.37), compared to a summary RR of 1.02 (95% CI=0.95-1.08) for studies published later (p-het=0.001). Heterogeneity was observed when evaluating studies at and above, or below the NOS mean (p-het=0.00), with a summary RR of 1.25 (95% CI=1.13-1.28, I^2<0.001%, n=9) for studies below the median NOS score. Sub-group analysis of study design demonstrated heterogeneous results (p-het=0.001) with a summary RR of 1.19 (95% CI=1.10-1.29, I^2<0.001%, n=16) for cohort studies while compared to the findings of case-control studies. Publication bias was detected (p=0.04).
Conclusions: Our meta-analysis identified an association between occupational benzene exposure and risk of breast cancer. The association was restricted to studies published before 2003, below the median NOS score, and cohort studies. Residual confounding variables cannot be excluded, which, together with potential bias, prevents conclusions of causality.

#0832 Gender differences in urinary tract cancer susceptibility associated with radon in water: A population based study from Finland.

P. Y. Li;
Max Planck Institute for Demographic Research (MPIDR), Rostock, Germany

Background: Radon as a common source of environmental radiation, while its carcinogenic effect on urinary tract cancer has not been fully investigated.
Methods: Men and women who have continuously lived in Finland from year 1987 onward and reached 40+ years old at the beginning of 2017 were followed up for urinary tract cancer, including bladder cancer (ICD-O 3 code C67) and kidney cancer (C64-C66 and C68) for 5 years until the end of 2021. The residential location and type of buildings of the cohort members were traced from year 1987 until 2016 annually and linked to the average cumulative exposure of radon concentration in well water on municipality level. Newly diagnosed UTC cases were identified based on the Finnish cancer register. Pre-existing health conditions, such as hypertension, diabetes, chronic kidney disease, calculus of kidney and lower urinary tract, family history of cancer, as well as socioeconomic factors were ascertained from multiple registry databases. Data were analyzed with Cox proportional hazards model conditional on birth cohorts and adjusted with available covariates.
Findings: Among 1,019,331 men and 1,192,960 women with 30-years average radon exposure, 4206 and 2226 urinary tract cancer cases were diagnosed during follow-up period from 2017 until correspondingly. Men with higher radon exposure (>500 Bq/m^3) had about 14% higher risks of UTC in total (HR 1.14, 95% CI 1.07-1.21), 19% higher risks of bladder cancer (HR 1.19, 95%CI 1.09-1.32), 10% higher risks of kidney cancer (HR 1.10, 95%CI 1.02-1.20) comparing with lower exposed samples. Women with higher radon exposure had about 1% higher risks of UTC in total (HR 1.01, 95%CI 0.93-1.10), 3% higher risks of bladder cancer (HR 1.03, 95%CI 0.88-1.22), 1% higher risks of kidney cancer (HR 1.01, 95%CI 0.92-1.11). In the sub-population who only lived in houses during the 30-years exposure period, men with higher radon exposure had about 24% higher risks of UTC (HR 1.24, 95% CI 1.12- 1.36), 30% higher risks of bladder cancer (HR 1.30, 95%CI 1.12-1.51), 20% higher risks of kidney cancer (HR 1.20, 95%CI 1.06-1.36). No significant association was observed in women who only lived in houses during exposure period.
Conclusions: For men, higher radon exposure was significantly associated with elevated risks of UTC. No significant association was observed in women. Further investigates were needed to explore the mechanisms of gender differences in UTC susceptibility associated with radon exposure.

#0833 No association between air pollution and lung cancer incidence in a 2 million South Korean cohort.

S.-Y. Kim[1], J. Park[2], O.-J. Kim[3], M. Shin[1], S. Kang[4], S.-s. Hwang[4], Y. Kim[1], Y.-J. Cho[5];

[1]National Cancer Center - Korea, Goyang, Korea, Republic of, [2]Yonsei University, Seoul, Korea, Republic of, [3]National Institute of Environmental Research, Incheon, Korea, Republic of, [4]Seoul National University, Seoul, Korea, Republic of, [5]Seoul National University Bundang Hospital, Seoul, Korea, Republic of

Background: Accumulating evidence has consistently suggested long-term exposure to air pollution as a risk factor of lung cancer incidence. Our previous study of long-term exposure to particulate matter air pollution and lung cancer incidence in a South Korean cohort showed no association with hazard ratios greater than one. This inconsistent finding with those from previous cohort studies could be due to limited exposure assessment relying on district averages and a relatively small sample size of 80 thousand people. The present study aimed to overcome the two major limitations and re-analyzed the association for long-term exposure to particulate matter ≤ 10 μm and 2.5 μm in diameter (PM10 and PM2.5), nitrogen dioxide (NO2), and ozone. Specifically, we improved our exposure assessment for individual exposure using 100-meter grid addresses, and increased the population size to 2 million people based on the National Health Insurance Database (NHID) composed of the entire South Korean population.

Methods: Our study population included 1,976,265 people who aged 30 years or older, had no history of cancer for 2002-2006, underwent health screening for 2005-2007, and resided in the Seoul Metropolitan Area. We defined lung cancer incidence as the first diagnosis based on the International Classification of Diseases 10th revision code and identified the incidence for 10 years of follow-up from 2007 through 2016. We estimated individual long-term exposure to PM10, PM2.5, NO2, and ozone as five-year average concentrations on each year at 100-meter grid addresses of participants' homes by using previously-validated exposure prediction models. Finally, we applied time-varying Cox proportional hazard model to estimate hazard ratios (HRs) and 95% confidence intervals (CIs) for a 10 μg/m3 or 10 ppb increase of each of the four pollutants after adjusting for individual- and area-level characteristics.

Results: Out of 1,976,265 people, 15,707 people (0.79%) developed new cases of lung cancer for 10 years of follow-up. In all analyses for long-term exposure to four pollutants and lung cancer incidence, we did not find an association (PM10: HR= 0.999 [95% CI=0.956 - 1.044]; PM2.5: 0.890 [0.787 - 1.006]; NO2: 1.002 [0.967 - 1.037]; ozone: 1.027 [0.978 - 1.077]). Our stratified analyses by individual and area-level characteristics as well as 79 districts showed that the null findings in the total population were not derived by specific subpopulations.

Conclusion: Despites the considerable improvement in exposure assessment and population size, our findings are contradictory to previous evidence. In addition to the possibility of no association, our null findings could be due to a relatively short period of exposure, the lack of histological information, and exposure measurement error resulting from indoor-outdoor difference and time activity. Future studies should overcome these limitations and re-examine the association.

#0834 Farm animal exposures and the oral microbiome in the Agricultural Health Study.

V. C. Chang[1], V. Purandare[1], R. Sinha[1], G. Andreotti[1], S. Li[2], X. Hua[3], Y. Yano[1], K. R. Dalton[4], M. Lee[4], C. G. Parks[4], S. J. London[4], D. P. Sandler[4], M. H. Gail[1], J. Shi[1], J. N. Hofmann[1], C. C. Abnet[1], E. Vogtmann[1], L. E. Beane Freeman[1];

[1]National Cancer Institute, Bethesda, MD, [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, [3]Fred Hutchinson Cancer Center, Seattle, WA, [4]National Institute of Environmental Health Sciences, Research Triangle Park, NC

Raising farm animals involves a variety of exposures, including microbes, antimicrobial agents, bioaerosols, and pesticides that may influence the human microbiome. Exposure to farm animals has also been associated with some cancers including lower risk of lung cancer and elevated risks of certain hematologic malignancies, with heterogeneity by animal species. Increasing epidemiologic evidence suggests that changes in the oral microbiome contribute to cancer development. Few human studies have investigated the potential influence of farm animal exposures on the oral microbiome. We investigated associations between farm animal exposures and the oral microbiome in 1245 Iowa and North Carolina farmers and spouses from the Agricultural Health Study. Participants provided information on types and numbers of farm animals raised in telephone interviews close to the time of oral wash sample collection. DNA was extracted from oral wash specimens and analyzed using 16S rRNA gene (V4 region) sequencing. We evaluated associations between farm animal exposures and alpha diversity metrics [e.g., observed amplicon sequence variants (ASVs)] using linear regression and assessed differences in beta diversity metrics (e.g., weighted Unifrac) using permutational multivariate analysis of variance. In addition, we evaluated associations with the presence and relative abundance of specific genera using zero-inflated negative binomial regression. All analyses adjusted for potential confounders (e.g., sex, age, state of residence, smoking). Overall, 63% of participants reported raising any animals, most commonly cattle (46%) and hogs (20%). Raising sheep/goats was associated with lower alpha diversity [e.g., 18 (95% confidence interval: 3-33) fewer observed ASVs compared to not raising sheep/goats], with an exposure-response trend for increasing number of sheep/goats (13 and 24 fewer observed ASVs for 1-29 and ≥30 sheep/goats vs. none, respectively; P_{trend} = 0.048). Increasing numbers of hogs and poultry were associated with higher and lower alpha diversity, respectively. Associations were similar after mutual adjustment for other farm animal types. Based on beta diversity analyses, we did not observe statistically significant differences in microbial compositions between participants with and without farm animals. After adjusting for multiple testing, having any farm animal was associated with an increased relative abundance of *Porphyromonas*, and several genera were more likely to be absent with specific animal exposures (e.g., *Capnocytophaga* for cattle and sheep/goats; *Corynebacterium* and *Abiotrophia* for sheep/goats). To our knowledge, this was the largest investigation of farm animal exposures and the human microbiome to date. Our preliminary findings suggest that animal farming may alter the oral microbiome and provide new insights into the potential role of animal exposures in cancer etiology.

#0835 Occupational-related exposure to benzene and risk of female genital cancers: Systematic review and meta-analysis.

D. Shah[1], V. DeStefano[1], V. Shah[2], M. S. Seyyedsalehi[3], M. Bonetti[3], P. Boffetta[1];
[1]Renaissance School of Medicine at Stony Brook University, Stony Brook, NY, [2]Northeastern University, Boston, MA, [3]University of Bologna, Bologna, Italy

Purpose: The IARC monograph has classified benzene as a class I carcinogen, as evidenced by its association with hematological malignancies. However, its association with female genital cancers (ovarian, uterine, cervical) has not been characterized. Therefore, a meta-analysis of cohort studies was performed to determine the possible correlation between occupational benzene exposure and the risk of female genital cancers.
Methods: A systematic literature review was conducted that identified 7221 relevant publications. A total of 9 cohort studies detailing occupational exposure to benzene and correlated risk of ovarian, uterine, and cervical cancers were retained, and a meta-analysis (using fixed effects model) was performed. PECOS criteria and STROBE guidelines were followed, and the study protocol was registered in the PROSPERO database (Reg. No. 379720). Study quality was assessed using a modified Newcastle-Ottawa scale (NOS).
Results: The summary relative risk (RR) for ever-benzene exposure was 1.22 (95% CI=1.03-1.44, I^2<0.001%, n=19); corresponding RR results for female genital cancers incidence and mortality were 1.09 (95% CI=0.92-1.29, I^2=5.0%, n=17) and 1.69 (95% CI=1.18-2.4, I^2<0.001%, n=9), respectively. These findings were confirmed in sub-analyses by geographical area, industry type, publication year, and levels of benzene exposure. Heterogeneity was detected amongst industries of employment (p-het=0.012) which included petroleum, chemical, printing, and mixed industries categories. Notably, the printing industry (compositors, press operators, and bookbinders) had a summary RR of 2.56 (95% CI=1.45-4.52, I^2=35.0%, n=2). However, no heterogeneity was observed for geographical regions (p-het=0.77), duration of benzene exposure (p-het=0.73), publication year (p-het=0.89), or among varying study quality (< or ≥ median NOS score; p-het=0.14). No publication bias was detected (p=0.43).
Conclusions: Our meta-analysis identified an association between occupational benzene exposure and the risk of female genital cancers. The association was restricted to the industry of employment. Effects of residual confounding variables cannot be excluded, however, given the present association, there is a potential for causality, especially in workers employed in the printing industry.

#0836 Long-term particulate matter and mortality in cancer patients and survivors compared to general population.

M. Shin[1], O.-J. Kim[2], S.-A. Choe[3], Y.-J. Choi[1], H. Kim[4], W. Lee[4], H. Lee[1], S.-Y. Kim[1];

[1]Graduate School of Cancer Science and Policy, National Cancer Center, Goyang, Korea, Republic of, [2]National Institute of Environment Research, Incheon, Korea, Republic of, [3]College of Medicine, Korea University, Seoul, Korea, Republic of, [4]Graduate School of Public Health, Seoul National University, Seoul, Korea, Republic of

Background and Aim Exposure to particulate matter (PM) has been reported as a major environmental hazard to human health. Although many studies found the associations with mortality and its susceptibility in patients with diabetes and heart diseases, few studies paid attention to cancer. In addition, there were no studies that compared these associations in cancer patients and survivors with those in healthy people from the same population. The aim of this study is to compare the association between long-term exposure to PM with all-cause and cause-specific mortality between the general population and cancer patients and survivors both of which were selected from the same cohort in the Seoul Metropolitan Area (SMA), South Korea.

Methods Using the National Health Insurance Services-National Sample cohort, we selected the subjects who received health screening during 2005-2007, had full address information, and were aged 30-80 without severe disability. We defined cause-specific mortality based on the International Classification of Disease, 10^{th} reversion from 2007 to 2015. Using a previously-validated prediction model, we estimated annual-average PM concentrations at participants' district-level addresses and assessed individual long-term exposure as the average concentrations in the previous 5 years on each year during the follow-up. Then, we performed time-varying Cox proportional hazards model to estimate hazard ratios (HRs) and 95% confidence intervals (95%CI) per 10 ug/m^3 increase in $PM_{2.5}$ and PM_{10} adjusting for sociodemographic characteristics, family history of cancer, and health behaviors.

Results Our study population of 98,493 adults include 94,494 (95.9%) general population and 3,999 (4.1%) cancer patients and survivors in the SMA at baseline. In the general population, we observed the associations with deaths from all causes ($PM_{2.5}$: HR=1.31, 95% CI: 1.10-1.55; PM_{10}: 1.07, 1.00-1.15), non-accidental causes ($PM_{2.5}$: 1.51, 1.24-1.84; PM_{10}: 1.10, 1.02-1.20), and cardiopulmonary diseases ($PM_{2.5}$: 1.57, 1.07-2.31); PM_{10}: 1.22, 1.04-1.43). In contrast, although all HRs of all-cause and cause-specific mortality were not statistically significant, cancer patients and survivors showed much higher HRs for all-cancer and lung-cancer mortality ($PM_{2.5}$: 1.57 and 1.99; PM_{10}: 1.01 and 1.33) than those for all or other cause-specific mortality as well as those of cancer-related mortality in the general population.

Conclusions Our findings provided suggestive evidence of the different causes of deaths associated with long-term exposure to air pollution between the general population and cancer patients and survivors. While PM could behave as a risk factor of cardiopulmonary deaths in the general population, after diagnosed with cancer, exposure to PM may increase the risk of dying of cancer.

#0837 Carbaryl use and cancer incidence in the agricultural health study - An updated analysis.

P. A. Erickson[1], G. Andreotti[1], R. Remigio[1], C. G. Parks[2], D. P. Sandler[2], P. S. Albert[1], K. H. Barry[3], J. N. Hofmann[1], L. E. Beane Freeman[1];
[1]National Cancer Institute, Rockville, MD, [2]National Institute of Environmental Health Sciences, Durham, NC, [3]University of Maryland School of Medicine, Baltimore, MD

Background: Carbaryl is a carbamate insecticide with widespread residential and agricultural uses. Previous epidemiologic investigations, including in the Agricultural Health Study (AHS), have suggested potential associations between carbaryl use and cancer risk. In this analysis, we updated a previous AHS evaluation of carbaryl and cancer risk by incorporating additional exposure information and follow-up time.
Methods: The AHS is a prospective cohort study of licensed pesticide applicators in North Carolina (NC) and Iowa (IA). Information on lifetime pesticide use, including carbaryl, was reported on questionnaires at enrollment (1993-1997) and follow-up (1999-2005). We evaluated cancer risks associated with ever-use and intensity-weighted lifetime days (IWLD) of carbaryl use, comparing those who reported use to those who did not. For IWLD, carbaryl exposure was categorized (quartiles, tertiles, or the median) among users, depending on the number of cases. Among 52,625 applicators, 8,713 incident cancers were identified from linkages with state cancer registries through 2014 (NC) or 2017 (IA). We used Poisson regression to estimate risk ratios (RR) and 95% confidence intervals (CI), controlling for confounders, and evaluated lagged exposures.
Results: Approximately 50% of applicators reported use of carbaryl. Among cancer cases, 53% reported carbaryl use. Increasing IWLD of carbaryl use was associated with stomach cancer (RR_{T3}=2.15, 95% CI: 1.11-4.15, *p*-trend=0.02), which persisted across lags up to 15 years. Carbaryl users in the highest quartile of IWLD had an increased risk of leukemia (RR_{Q4}=2.12, 95% CI: 1.05-4.29, *p*-trend=0.08); this risk remained elevated, though attenuated, when exposure was lagged by 5-years (RR_{Q4}=1.86, 95% CI: 0.91-3.81, *p*-trend=0.14). Ever-use of carbaryl was also suggestively associated with both esophageal (RR=1.45, 95% CI: 0.98-2.14) and tongue (RR=1.87, 95% CI: 0.93-3.74) cancers.
Conclusion: This study provides novel evidence of associations between carbaryl use, leukemia, and stomach cancer, as well as suggestive evidence of elevated risks of esophageal and tongue cancers. With more than 7,000 added cancer cases and up to 14 additional years of follow-up time as compared to a previous analysis in the AHS, we were able evaluate cancer sites not previously examined, making this the largest prospective study of carbaryl and cancer risk to date. Our findings highlight the need for additional studies of this widely used insecticide.

#0838 Population attributable fraction of occupational carcinogens for cancer incidence among Korean adults in 2020.

E. Kim[1], D.-H. Koh[2], S. Park[3], Y.-J. Choi[4], H. Seo[4], I. Kim[5], J.-S. Im[4];

[1]National Health Insurance Service, Wonju, Korea, Republic of, [2]International St. Mary's Hospital, Incheon, Korea, Republic of, [3]Seoul National University College of Medicine, Seoul, Korea, Republic of, [4]National Cancer Center, Goyang, Korea, Republic of, [5]Hanyang University College of Medicine, Seoul, Korea, Republic of

Assessing the level and scope of exposure to occupational carcinogens on a country-specific basis presents challenges, and as a result, it has been appraised as uncertain when compared with other factors in the estimation of the burden of cancer. The Korean CARcinogen Exposure (K-CAREX) developed in 2021 is utilized to estimate the population at risk in industrial work environments in Korea (Koh et al., 2021). Our goal is to estimate preventable cancer incidence attributable to occupational carcinogens in Korea, utilizing the K-CAREX program and employing appropriate methodology. Among the exposures classified as Group 1 factors by IARC, considering the possibility of occupational exposure. Population attributable fractions (PAFs) were computed using Levin's Formula (1953), considering a latency period of 15 years between exposure and cancer in our assessment. The prevalence of exposure was calculated using K-CAREX program and census data. The relative risk (RR) for incidence was derived from a meta-analysis of literature. It was possible to calculate PAFs for 11 occupational factors linked with 8 cancer types. This estimation was chosen based on a combination of exposure and sufficient evidence of human carcinogenicity. As a result, Population attributable fractions (PAFs) for cancer incidence associated with occupational carcinogens was estimated at 1% in 2020. Lung cancer (approximately 90%) was found to be the most prevalent type of cancer attributable to occupational factors, as widely acknowledged. The prevalence of exposure to occupational carcinogens was 22%, with Diesel engine exhaust being the most significant source for both genders. Since the early 2000s, the exposure levels of asbestos, subject to usage prohibition and restriction measures, were estimated to be at a lower level compared to other countries. It is evident that these estimates reflect the characteristics of the Korean industry. This is anticipated to provide a foundation for the development of methodologies and indicators essential for measuring the burden of occupational cancer in the country.

#0839 Interaction between solvent exposure and genetic susceptibility and risk for bladder cancer.

D. Tadesse[1], N. Rothman[1], S. Xie[1], L. Hurwitz[1], M. C. Friesen[1], D. Baris[1], M. Schwenn[2], A. Johnson[3], M. Karagas[4], D. T. Silverman[1], S. Koutros[1];
[1]National Cancer Institute, Rockville, MD, [2]Formerly Maine Cancer Registry, Augusta, ME, [3]Formerly Vermont Department of Health, Burlington, VT, [4]Giesel School of Medicine at Dartmouth, Hanover, NH

Introduction: Recent studies have reported an increased bladder cancer risk with occupational exposure to organic solvents, including exposure to benzene, toluene, and xylene (BTX). The metabolism of solvents is known to be influenced by genetic susceptibility. Here, we evaluated the association between BTX and bladder cancer, stratified by genotype in known bladder cancer susceptibility loci and in variants shown to impact the metabolism of solvents.
Methods: We evaluated if single-nucleotide polymorphisms (SNPs) modified the association between BTX exposure and bladder cancer risk in 1182 cases and 1408 controls from a population-based case-control study in New England. Ever and cumulative lifetime exposure to BTX was assessed using occupational histories obtained by personal interviews and exposure-oriented modules in conjunction with a job-exposure matrix. Genotyping was conducted using Illumina arrays and *GSTM1* and *GSTT1* deletion were determined using melt curve/copy number assays. We used multivariate logistic regression to calculate odds ratios (ORs) and 95% confidence intervals (CIs) for the association between BTX exposure and bladder cancer, stratified by genotype and to calculate p-values for multiplicative interaction.
Results: Ever exposure to BTX was more strongly associated with bladder cancer risk among individuals with the *GSTT1* null (deletion) genotype (OR 3.53, 95% CI 1.26-9.89), while exposed individuals with the *GSTT1* active genotype had a diminished risk (OR 1.40, 95% CI 0.93-2.10, P-interaction = 0.06). The association between benzene exposure and bladder cancer was similarly modified by *GSTT1* genotype (carriers of the deletion: OR 5.19, 95% CI 1.91, 14.13; carriers of one or two copies: OR 1.22, 95% CI 0.79, 1.89, p-interaction=0.008).
Conclusion: *GSTT1* genotype has been shown to impair the metabolism of solvents, particularly for benzene**.** Here we show that bladder cancer risk is higher among those exposed to solvents who also harbor a common deletion in *GSTT1,* adding to the evidence of a plausible link between BTX exposures and bladder cancer risk.

#0840 Serum concentrations of per- and polyfluorinated substances and risk of non-Hodgkin lymphoma.

J. Rhee[1], J. Koponen[2], J. N. Sampson[1], A. P. Keil[1], M. H. Ward[1], J. N. Hofmann[1], W.-Y. Huang[1], D. T. Silverman[1], P. Rantakokko[2], M. P. Purdue[1];
[1]National Cancer Institute, Rockville, MD, [2]Finnish National Institute of Health and Welfare, Helsinki, Finland

Per- and polyfluoroalkyl substances (PFAS) are persistent organic pollutants, some immunotoxic, that are detectable in the serum of most U.S. adults. Some studies of highly-exposed individuals have suggested positive associations between PFAS and non-Hodgkin lymphoma (NHL); however, it is unknown whether associations exist at lower exposure levels that are more common in the general population. To address this knowledge gap, we conducted a nested case-control study investigating serum PFAS concentrations and NHL within the Prostate, Lung, Colorectal and Ovarian Cancer Screening Trial. We measured pre-diagnostic serum concentrations (collected between 1993-2001) of five PFAS among 706 cases and 706 controls individually matched on the basis of age at baseline, sex, self-reported race and ethnicity, study center, calendar year of blood collection, and number of prior serum thaws. We estimated odds ratios (ORs) and 95% confidence intervals (CIs) for PFAS concentrations in relation to NHL, both overall and for selected histologic subtypes [diffuse large B cell lymphoma (DLBCL), follicular lymphoma (FL), lymphoplasmacytic lymphoma (LPL), and marginal zone lymphoma (MZL)] using conditional logistic regression. We found no evidence of a positive association with NHL for any of the five PFAS in analyses adjusting for all measured PFAS. In analyses of histologic subtypes, we observed a positive association between perfluorohexane sulfonate (PFHxS) and DLBCL (OR per doubling in concentration=1.27, 95% CI=1.07, 1.50) which remained for cases diagnosed ≥10 years after blood collection (OR=1.34, 95% CI=1.09, 1.64). We also observed inverse associations with PFNA for all subtypes (DLBCL, OR=0.84, 95% CI=0.72, 0.98; FL, OR=0.86, 95% CI=0.69, 1.08; LPL/MZL, OR=0.86, 95% CI=0.66, 1.12), although these associations were null among participants with blood drawn prior to 1997 (DLBCL: $OR_{<1997}$=0.95, $OR_{\geq 1997}$=0.67, $P_{interaction}$=0.001; FL: $OR_{<1997}$=1.01, $OR_{\geq 1997}$=0.77, $P_{interaction}$ =0.08; LPL/MZL: $OR_{<1997}$=1.26, $OR_{\geq 1997}$=0.88, $P_{interaction}$ =0.03). In conclusion, our findings from a cohort study with PFAS serum concentrations comparable to that of the general population do not support an association with increased risk of NHL overall. The suggestive evidence of a positive association between PFHxS and DLBCL warrants further investigation.

#0841 Fine particulate matter exposure during breast cancer treatment among older women associated with increased mortality.

B. Bates[1], R. Nethery[2], M. Rua[1], H. Iyer[3], E. Bandera[3], S. Setoguchi[1];

[1]Rutgers Institute for Health, Health Care Policy, and Aging Research, New Brunswick, NJ, [2]Harvard T.H. Chan School of Public Health, Boston, MA, [3]Rutgers Cancer Institute of New Jersey, New Brunswick, NJ

Background: Fine Particulate Matter ($PM_{2.5}$) is associated with higher mortality among people with chronic conditions. Breast cancer (BC) survivors may be particularly vulnerable during cancer treatment. We assessed the association between $PM_{2.5}$ during 9-months following BC diagnosis and all-cause and BC-mortality using policy relevant $PM_{2.5}$ cut-offs.

Methods: Using SEER-Medicare linked with a high-resolution model-based $PM_{2.5}$ by residential zipcode (2007-2016), we assembled a cohort of women ≥66 years with incident stage I-IV BC. We assessed $PM_{2.5}$ exposure, categorized as <8 μg/m^3 (low), 8-12 μg/m^3 (moderate) and >12 μg/m^3 (high—above air quality standard), and types of cancer treatments (surgery [SX], chemotherapy [CTX], radiation therapy [RTX]) during a 9-month landmark period. We identified all-cause and BC death within 5 years of diagnosis. We fit multivariable Cox proportional hazard models to assess associations with $PM_{2.5}$ exposure adjusting for individual-level characteristics (demographics, tumor characteristics, comorbidities), neighborhood SES, SEER state, and long-term $PM_{2.5}$ exposure. We also evaluated the association between $PM_{2.5}$ exposure and mortality by treatment types (SX, SX + RTX, SX + CTX, SX + RTX + CTX, and RTX and/or CTX). We used multiple imputation to account for missing variables (race, ER status, HER2 status, grade).

Results: Among 72,798 women (mean age 75 years, 83% white, 56% stage I, 32% II, 9.2% III, 2.9% IV), 41%, 32%, 13%, 8.4%, and 5.1% received SX + RTX, SX only, SX + Chemo + RTX, SX + Chemo, and CTX and/or RTX. The mean $PM_{2.5}$ level was 8.8 μg/m^3 [36%, 52% and 11% were exposed to <8, 8-12, and >12, respectively]. We observed 12,163 all-cause and 4,729 BC deaths during follow-up. Compared to those exposed to low levels, higher levels of $PM_{2.5}$ exposure were associated with increased all-cause mortality for both moderate $PM_{2.5}$ [HR 1.03 (95%CI:1.00-1.05)] and high $PM_{2.5}$ [HR 1.09 (95%CI: 1.06-1.14)] but not BC-specific mortality. Among treatment subgroups, $PM_{2.5}$ was associated with higher all-cause mortality in SX+RTX for moderate [HR 1.24 (95%CI:1.18-1.32)] and high $PM_{2.5}$ [HR 1.36 (95%CI: 1.25-1.48)] and SX+RTX+CTX for high $PM_{2.5}$ [HR 1.33 (95%CI: 1.17-1.51)]. There were no association between moderate/high $PM_{2.5}$ with all-cause mortality in SX only and SX+CTX. Among the SX+RTX subgroup, BC-specific mortality was elevated for both moderate [HR 1.50 (95%CI:1.35-1.66)] and high $PM_{2.5}$ [HR 1.81 (95%CI: 1.55-2.12)].

Conclusion: Even below EPA regulatory thresholds ($PM_{2.5}$ <12 μg/m^3), we observed increased risk of death in BC survivors who had high $PM_{2.5}$ exposure during treatment period. The elevated mortality primarily occurred among women who received RTX and was present for all-cause and BC-specific mortality. The potential interaction between RTX and $PM_{2.5}$ exposure, even after adjusting for tumor subtype and stage, warrants further evaluation.

#0842 Maize consumption and circulating aflatoxin B_1 levels in Mexican adults.

M. Lajous[1], O. Solis-Martinez[2], A. Monge[1], J. Groopman[3], K. A. McGlynn[4], M. Romero[1], C. Batis[1], H. Lamadrid-Figeuroa[2], H. Riojas-Rodriguez[2];
[1]Instituto Nacional de Salud Publica, Ciudad de Mexico, Mexico, [2]Instituto Nacional de Salud Publica, Cuernavaca, Mexico, [3]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, [4]National Cancer Institute, Rockville, MD

Objective: To estimate the impact of maize consumption on aflatoxin B_1 [AFB_1] levels, a potent carcinogen, in Mexican adults living in south and eastern Mexico.
Methods: Study participants were women and men ≥40 years of age living in five high hepatocellular carcinoma burden states who participated in Mexico's 2018 National Health and Nutrition Survey, a stratified, multi-stage, and cluster survey probability sampling household survey that is representative of the Mexican population. We estimated the consumption of maize intake in grams per day using a previously validated semi-quantitative food frequency questionnaire with a time reference of the previous seven days. We determined circulating AFB_1-albumin lysine adduct [AFB_1-lys] levels in serum using liquid chromatography. Guided by subject-matter knowledge we fit multivariable linear regression models that considered the survey design and included age, sex, residence, ethnicity, education, socioeconomic status, and foods known to be contaminated with aflatoxins including peanuts, rice, dried chili, milk, and cheese.
Results: Among the 915 participants, median maize consumption was 307 grams per day [Q1-Q3: 165 - 554]. Maize *tortillas* contributed 80% of the total maize consumption. The median maize *tortillas* consumption was 252 grams per day [Q1-Q3: 120 - 462], approximately 8 tortillas per day. Prevalence of AFB_1-lys detection was 92% and median levels were 0.127 pg/µL [Q1-Q3: 0.052 - 0.449]. After adjusting for factors that may affect aflatoxin levels, for every 100 grams of maize consumption AFB_1-lys levels were 7.4% [β: 0.071, 95% CI: 0.030 - 0.112] higher. And for every tortilla consumed [30 g of maize], we observed a 2.0% [β: 0.020, 95% CI: 0.006 - 0.034] higher level of circulating AFB_1-lys.
Conclusion: These findings indicate that maize and maize *tortillas* may be an important source of AFB_1 exposure in the Mexican population. Mexico requires effective public health interventions to mitigate exposure to AFB_1.

#0843 The burden of Merkel cell carcinoma attributable to immunosuppression, ultraviolet radiation, and Merkel cell polyomavirus in the United States.

J. T. Tribble[1], K. Volesky-Avellaneda[1], Q. Luo[1], M. R. Sargen[1], I. Brownell[2], E. K. Cahoon[1], M. Shiels[1], R. Pfeiffer[1], A. Moreno[3], B. Y. Hernandez[4], E. Engels[1]; [1]National Cancer Institute, Rockville, MD, [2]National Institute of Arthritis and Musculoskeletal and Skin Diseases, Bethesda, MD, [3]Texas Department of State Health Services, Austin, TX, [4]University of Hawai'i Cancer Center, Honolulu, HI

Background: Merkel cell carcinoma (MCC) is a rare, aggressive skin cancer. No published study has estimated the contribution of the major potentially modifiable risk factors, such as immunosuppression, ultraviolet radiation (UVR) and infection with Merkel cell polyomavirus (MCPyV), to the burden of MCC in the US. We estimated the population attributable fractions (PAFs) for MCC associated with immunosuppression (HIV and organ transplantation), MCPyV, and UVR in the US during 2001-2020.

Methods: We calculated PAFs for immunosuppression and UVR using the formula: prevalence in cases (Pc)*[(Relative risk, RR-1)/RR]. The proportion of MCC cases among organ recipients and people with HIV (Pc) were derived from US cancer registries in the HIV/AIDS Cancer Match Study, Transplant Cancer Match Study, and the Surveillance Epidemiology and End Results (SEER) Program data. To approximate the RRs, we calculated standardized incidence ratios (SIRs) comparing MCC incidence in people with HIV and organ recipients to the general population. We merged SEER data on MCC cases by county with data on ambient UVR levels in order to create population quintiles of UVR exposure. Since only non-Hispanic White individuals showed elevated IRRs for increased ambient UVR exposure, we estimated the PAF of UVR by calculating incidence rate ratios (IRR ≈ RR) comparing MCC incidence in non-Hispanic White individuals to all other races/ethnicities (at any UVR level) as the reference; here, Pc was the proportion of non-Hispanic White patients in each quintile. To estimate the PAF of MCPyV, we meta-analyzed US studies reporting on MCPyV prevalence in MCC tissues (here PAF ≈ Pc).

Results: Over the study period (2001-2020), 40,571 MCCs were diagnosed in the US. Compared to the general population, organ recipients had 13 times higher (SIR=12.7, CI: 11.3-14.2) and people with HIV had three times higher (SIR=2.78, CI: 2.01-3.75) risk of MCC. Due to the rarity of these exposures (HIV Pc = 0.4%; Transplant Pc = 1.9%), only 0.2% of MCC cases were attributable to HIV and 1.7% were attributable to organ transplantation. Compared with people in other racial/ethnic groups, the IRRs of non-Hispanic White individuals at the various levels of ambient UVR for MCC arising on the head and neck ranged from 4.24 to 5.03 and for other primary sites ranged from 2.81 to 3.36. After combining the PAFs for these sites, the overall PAF for UVR was 65.8%. Meta-analyzing 20 studies with 984 MCC cases combined, we found that 66.1% (CI: 58.0-72.2%) of MCCs were attributable to MCPyV.

Conclusions: While a small proportion of MCCs were due to immunosuppression from HIV infection and organ transplantation, UVR and MCPyV played a major role in MCC burden. Future research is required to assess the combined impact of these risk factors on MCC incidence.

#0844 DNA methylation-derived immune cell profiles and risk of cancers in Black participants in the ARIC Study.

C. S. Semancik[1], N. Zhao[1], D. Koestler[2], E. Boerwinkle[3], J. Bressler[4], K. Kelsey[5], E. A. Platz[6], D. S. Michaud[1];
[1]Tufts University School of Medicine, Boston, MA, [2]University of Kanas Medical Center; University of Kansas Cancer Center, Kansas City, KS, [3]Human Genetics Center, School of Public Health, University of Texas Health Science Center at Houston; Human Genome Sequencing Center, Baylor College of Medicine, Houston, TX, [4]Human Genetics Center, School of Public Health, University of Texas Health Science Center at Houston, Houston, TX, [5]Brown University, Providence, RI, [6]Johns Hopkins Bloomberg School of Public Health; The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Baltimore, MD

Background: Prior cohort studies assessing cancer risk based on immune cell subtype profiles have predominantly focused on White populations. This limitation can obscure vital insights into how cancer risks vary across races, ethnicities, or exposures. This study was designed with the purpose of examining associations between pre-diagnostic immune cell profiles and cancer risk in Black participants.
Methods: In this study, DNA methylation was measured in blood samples collected between 1993 and 1995 from a subset of 2,467 Black participants in the Atherosclerosis Risk in Communities (ARIC) prospective cohort study. Immune cell subtype proportions were estimated using deconvolution based on leukocyte DNA methylation markers. The analysis included 668 incident cancers ascertained between time of blood draw and 2015. Cox proportional hazards regression models were used to analyze the association between immune cell subtype proportions and cancer incidence (all cancers; lung, breast, and prostate cancers). Models controlled for age, sex, BMI, self-reported smoking status, self-reported and methylation-derived smoking pack-years, postmenopausal hormone use, and batch effect, along with other cancer-specific factors.
Results: Increased T regulatory cell (Treg) proportions were associated with significantly higher risk of lung cancer (HR: 1.22, 95% CI = 1.06, 1.41 per percent increase; n = 84 cases) and suggestively higher risk of all cancers. Increased B memory cell proportions were associated with significantly higher risk of prostate cancer (HR: 1.17, 95% CI = 1.04, 1.33; n = 173 cases), all cancers (HR: 1.13, 95% CI = 1.05, 1.22), and suggestively higher risk of lung cancer. Increased CD8+ naïve cell proportions were associated with suggestively lower risk of lung cancer and all cancers, and significantly lower risk of all cancers in participants over the median age of 55 years (HR: 0.91, 95% CI = 0.83, 0.98). Cancer risks for other immune cell subtypes were null.
Conclusions: These results in Black participants align closely with prior findings in largely White populations. Deconvolution allowed for the extension of work on cancer immunity (which has largely focused on major immune cell types) to immune cell subtypes like B memory cells and CD8+ naïve cells. The results are consistent with Tregs initiating and accelerating cancer development by impeding the usual protective immune response. A large reservoir of CD8+ naïve cells may allow for a more targeted and efficient elimination of malignant clones. Further studies should assess these relationships in other cancer types and better elucidate the interplay of B cells in theorized mechanistic processes. This study provides insight into the role of immune cell subtypes in cancer risk among Black men and women.

#0845 Population attributable fraction of cancer incidence due to infectious agents in 2020 in the Republic of Korea.

K.-S. Lee[1], H. Lee[2], Y.-J. Choi[1], M. Ki[1], A. Shin[3], J.-H. Kim[4], S.-K. Park[3], S.-S. Sung[3], S. Moon[3], H. Seo[1], J.-K. Oh[1], J.-S. Im[1];
[1]National Cancer Center - Korea, Goyang-si, Gyeonggi-do, Korea, Republic of, [2]National Medical Center - Korea, Seoul, Korea, Republic of, [3]Seoul National University College of Medicine - Korea, Seoul, Korea, Republic of, [4]Sungkyunkwan University School of Medicine- Korea, Suwon, Korea, Republic of

Purpose: Earlier in 2009, National Cancer Center Korea estimated population attributable fraction (PAF) of cancer incidence due to infectious agents as 24.5% in men and 15.4% in women. This study aimed to investigate the proportion of cancer incidence attributable to infectious agents in the Korean population as of 2020.
Materials and Methods: We organized the Consensus Committee to establish strategy and methodology of PAF estimation. Based on the consensus, infectious agents and cancer sites for PAF estimation were selected according to the IARC List of classification with sufficient evidence in human. As a result, infectious agents included hepatitis B and C virus (HBV and HCV), *Helicobacter pylori* (*H. pylori*), human papilloma virus (HPV), *Clonorchis sinensis* (*C.sinensis*), Epstein Barr virus, and human immunodeficiency virus, and cancer sites included hepatocellular carcinoma (HCC), cholangiocarcinoma (CCC), gastric cancer, pancreatic cancer, cervical cancer, and non-Hodgkin lymphoma. The PAF was calculated by using Levin's formula including exposure prevalence and relative risks (RRs). Exposure prevalence data were collected from literature review of studies in Korean population in 2005 or earlier, assuming at least 15 years of latent period from risk exposure to cancer development. We performed systematic review for cohort studies and case-control studies which investigated RRs or ORs of cancer due to infectious agents in Korean population. Pooled RRs were estimated by meta-analysis of RRs or ORs by using random-effects model.
Results: The fractions of all cancer incidence attributable to infectious agents were estimated to be 13.5% and 7.1% in men and women, respectively. The reduction in PAFs of cancer incidence due to infection in 2020 compared to 2009 is considered due to decrease in exposure prevalence. The major findings regarding infectious agents with large PAFs are as the following. We found that the fractions of HCC cases attributable to HBV infection were 47.7% and 38.4% for cancer incidence in men and women, respectively. The estimated PAFs of gastric cancer due to *H. pylori* were 40.4% in men and 38.2% in women. *C. sinensis* was related to 9.8% of CCC cases in men and 5.2% in women. A total of 77.7% of cervical cancer incidence was attributed to HPV infection.
Conclusion: Although the total PAF due to infection has decreased over the last decade, infection still contributes a substantial fraction to cancer incidence in Korea. These recent estimates of cancer burden due to infection are important for planning and evaluating the national cancer prevention programs.Funding Sources: This work was supported by the National Cancer Center Grant (NCC-2210840).

#0847 Association of methylation-based stem cell divisions with lifetime cancer risk and cancer progression.

Y. Wu[1], C. Thompson[2], F. Schumacher[1];

[1]Case Western Reserve University School of Medicine, Cleveland Heights, OH, [2]Penn State College of Medicine, Hershey, PA

Cancer initiation arises from the accumulation of somatic mutations acquired during stem cell mitotic events mediated by carcinogenic risk factors. On an ecological level, Tomasetti and Vogelstein (2015) demonstrated that lifetime risk of solid tumor cancer types were strongly correlated with total number of stem cell divisions estimated from tissue-specific cell lines. Recently, several mitotic clocks (MC) have been developed to estimate stem cell division rates (SCDR) based on whole-genome methylation arrays. Here, we compare estimated SCDR for several tissue types with tissue-specific cancer incidence and lifetime risk estimates. Furthermore, we assess the link between SCDR with cancer progression and survival.

Array-based methylation data derived from normal adjacent tissue in TCGA was used to estimate SCDR for 15 cancer types. A Pearson correlation test was performed to assess the association between SCDR and cancer-specific incidence and lifetime risk for each cancer type overall and stratified by self-reported race (*e.g.* White and Black). SCDR was estimated in tumors from TCGA for 4 common cancers and subtypes: breast (BRCA), prostate (PRAD), lung adenocarcinoma (LUAD), and lung squamous cell carcinoma (LUSC). A Spearman correlation test was used to identify potential trends between SCDR and pathological stage. Cox proportional hazard (PH) models adjusted for age at diagnosis and treatment status (*e.g.* surgery, radiation, *etc.*) were used to evaluate the association of time to death with SCDR terciles across different cancer stages.

We observed a similar trend between SCDR and overall incidence (cor=0.61, p=0.01), aligning with earlier findings. Stratified-specific trends between cancer incidence and SCDR was consistent for both Black and White populations (cor=0.62 vs 0.66). Tumor analysis revealed a significant correlation between SCDR and pathological stage (*e.g.* stage 1, 2, and 3/4) for BRCA ($p<0.001$) and pathological stage (*e.g.* stage 2, 3 and 4) for PRAD ($p<0.001$), suggesting its potential as a marker of cancer progression. However, the correlation between LUAD, LUSC and pathological stage was insignificant. Based on Cox PH model, within stage III BRCA, SCDR significantly contributed to explaining variability in survival (p=0.04), emphasizing its potential prognostic value beyond cancer stage.

Our study supports earlier findings applying methylation based SCDR estimates and shows that this association is consistent across racial groups. This implies that SCDR may act as a biological marker of a combination of various genetic and environmental risk factors underlying disease etiology. Further analyses will be extended to all cancers in TCGA. Lastly, we demonstrate that MC-based SCDR estimation has the potential to serve as a clinical tool to identify individuals at elevated risk of cancer initiation, track progression, and complement cancer stage for predicting survival.

#0848 Influence of young age at diagnosis on the clinical presentation of disease and survival among patients with multiple myeloma.

K. L. Ong, K. D. Arnold, G. Ravi, L. J. Costa, E. E. Brown;
University of Alabama at Birmingham, Birmingham, AL

Background: Age is an important prognostic factor for multiple myeloma (MM). We evaluated the influence of age on the clinical presentation and outcomes among newly diagnosed patients with MM to optimize risk stratification.
Methods: In 850 patients with first primary confirmed MM prospectively enrolled in the Integrative Molecular And Genetic Epidemiology (IMAGE) study (2009-2020), we evaluated the presence of diagnostic myeloma-defining events (MDE), progression free survival (PFS) and overall survival (OS) by young age at diagnosis (≤50 years). We evaluated the association of young age with the prevalence of diagnostic MDE, clinical features and chromosomal abnormalities using the prevalence odds ratio (OR) and corresponding 95% confidence interval (CI) calculated from multivariable logistic regression. Median PFS and OS were graphically examined using Kaplan-Meier survival curves with log-rank tests used to compare survival by diagnostic age group. Risks of disease progression and all-cause mortality were estimated using hazard ratios (HR) and corresponding 95% CI calculated from multivariable Cox proportional hazard models.
Results.: Of the 850 patients, 15.4% were diagnosed at ≤50 years of age, 54% were male and 40% self-identified as Black. Compared to patients diagnosed with MM over the age of 50, young patients were more likely to self-identify as Black (59.5% vs 40.5%; P<0.0001) and to report a negative smoking history (66.2% v 56.4%; P=0.01), and less likely to present with age-dependent comorbidities including hypertension, hyperlipidemia and diabetes mellitus type II (P≤0.0001). In multivariable analyses, young patients, compared to older patients, were more likely to present at diagnosis with higher median percent bone marrow plasma cells (70% v 55%; P=0.02) and to undergo autologous stem cell transplant (ASCT) as part of their first-line treatment (82.0% v 67.6%; P=0.01) after controlling for sex, race, body mass index, smoking status and comorbidities. We did not observe significant associations of young age with the prevalence of any other MDE, clinical feature or chromosomal abnormality evaluated. The median OS was 106.9 months (range, 0.23-356.1). OS was significantly longer in young patients with MM compared to patients aged greater than 50 years (159 v 99 months, respectively; P<0.001) leading to a suggestive 1.5-fold decreased risk of mortality among younger newly diagnosed patients (HR=0.67, 95% CI 0.39-1.14; P=0.14) after adjusting for sex, International Staging System-stage, adverse cytogenetic abnormalities, and ASCT. We did not observe associations with age and PFS (P=0.81).
Conclusions: Findings suggest that newly diagnosed younger patients with MM are more likely to self-identify as Black, present with more bone marrow plasma cells, have less age-dependent comorbidities, and undergo ASCT leading to a suggestive survival advantage.

#0849 Deciphering the link between aging, lobular involution, and breast cancer risk: The role of LIFR/pSTAT3 signaling.

J. C. Lue[1], D. Radisky[2], M. Stallings-Mann[2], M. Sherman[3], A. Degnim[3], B. McCauley[3], T. Hoskin[3];

[1]Mayo Clinic Graduate School of Biomedical Sciences, Jacksonville, FL, [2]Mayo Clinic, Jacksonville, MN, [3]Mayo Clinic, Rochester, MN

Background: Age-related lobular involution (ARLI), characterized by regression of breast epithelial tissue during the peri-and post-menopausal period, plays a crucial role in breast cancer risk. Delayed or incomplete ARLI is linked with increased postmenopausal breast cancer susceptibility.This study focuses on unraveling the molecular mechanisms of ARLI, drawing parallels with the well-characterized postpartum involution (PPI). Our aim was to discover biomarkers differentiating women who progressed through ARLI from those with stagnant ARLI.

Methods: We utilized the Mayo Clinic Benign Breast Disease (BBD) cohort, analyzing 108 perimenopausal women aged 45-55 who had a subsequent benign biopsy between 2-15 years later. We assessed Lobular Involution (LI) status by comparing the number and size of lobules in initial and subsequent biopsies. RNA profiling of initial biopsies was performed using NanoString 10360 and BC360, identifying differentially expressed genes between ARLI progression and stagnation. Immunohistochemistry (IHC) mapped the expression of these biomarkers in epithelial lobules.

Results: We identified 37 genes with significant differential expression, highlighting Leukemia Inhibitory Factor Receptor (LIFR) as upregulated in ARLI stagnant samples. LIFR, part of the IL-6 cytokine signaling pathway, is known for its role in the induction of apoptosis during PPI via pSTAT3 activation. Our IHC analyses of initial biopsies of women who differentially progress through ARLI confirmed differential expression of LIFR that is coordinately regulated with pSTAT3.

Conclusion: Our findings reveal significant parallels between ARLI and PPI. Future research will assess how LIFR/pSTAT3 signaling is linked to induction of apoptotic markers in perimenopausal women and will investigate how anomalies in the LIFR/pSTAT3 pathway might contribute to heightened breast cancer risk in women with delayed or incomplete ARLI. This study not only sheds light on the complex biological processes of aging in breast tissue but also opens new avenues for breast cancer risk assessment and prevention strategies.

#0850 Androgenic alopecia and risks of overall and aggressive prostate cancer: An updated meta-analysis.

S. Amar[1], D. Hanelin[2], **I. Agalliu**[2];
[1]Yeshiva University, New York, NY, [2]Albert Einstein College of Medicine, Bronx, NY

Background: Androgenic alopecia, known as male pattern baldness (MPB), is a common hair loss disorder among men. MPB has similar risk factors with prostate cancer (PrCa) including advancing age, family history, and sex hormones. Several studies have examined the associations between MPB and PrCa but the evidence remains unclear. We carried out a meta-analysis of epidemiological studies that examined the relationship between patterns of baldness: frontal, vertex, or both and PrCa risk.
Methods: A literature search was performed in October 2022 using PubMed and Web of Science databases for epidemiological studies published between 1/1/2000 and 10/31/2022, which examined the above hypothesis. From each eligible study, relevant data were extracted on study design, population, sample size, prevalence of MPB at various ages, and corresponding associations with risks of total and aggressive PrCa. Pooled relative risks (RR) and corresponding 95% confidence intervals (CI) were calculated using the DerSimonian and Laird random-effects models. Heterogeneity across studies was assessed by I^2 statistic.
Results: A total of 14 studies: 14,573 cases and 132,434 controls/non-cases were included. The prevalence of MPB increased from 5% to 70% with aging and varied across studies. Vertex MPB at ages 40 years or older was associated with a pooled RR of 1.08 (95%CI 1.00-1.17) of total PrCa, but there was no association with frontal MPB. The onset of MBP at younger ages was also associated with RR=1.10 (95% CI 0.93 - 1.29) of PrCa, although results were not statistically significant. Results were similar when data were stratified by clinical features of PrCa, although there was large heterogeneity in the definition of aggressive PrCa across studies.
Conclusions: Men with vertex MPB may have modest increased risk of PrCa. However, the majority of studies were conducted in Caucasian men and they did not evaluate effect modifications by genetic variations in androgen metabolism pathway genes or changes in serum levels of androgens. Further, large well-designed prospective cohort studies are needed to better understand the complex relationship between genetic susceptibility, endogenous hormones, MBP and risk of PrCa.

#0851 Uncovering a novel role of succinate metabolism in tregulatory cells of aged epithelial ovarian cancer mice.

M. Udumula, H. Singh, F. Rashid, M. Hijaz, S. Giri, R. Rattan;
Henry Ford Health System, Detroit, MI

Epithelial Ovarian Cancer (EOC), the most fatal gynecologic cancer is a disease of older women, with median age of 63 years at diagnosis. Reduced naive T cell generation and a rise in immunosuppressive regulatory T (Treg) cells are hallmarks of aging, which are strongly correlated with advanced cancer stage. Aging also alters host and cellular metabolism, which can influence Treg number and function. Although metabolic alterations are known to impact ant-tumor immune response, the relationship between age-related metabolic dysfunction and immune cells is not fully understood. We utilized young (2 months) and old (18 months) female C57/B6 mice, and were injected intraperitoneally with $5x10^6$ mouse epithelial ovarian cancer $ID8^{p53-/-}$ cells. Old mice with EOC showed decreased survival compared to young mice (median survival 49 vs 65 days). Old mice with EOC presented with decreased $CD4^+$ and $CD8^+$ T cells, but a significant increase in $CD4^+CD25+FoxP3^+$ Treg cells in tumor micro environment (TME) and in blood. The Tregs from old mice displayed enhanced expression of IL10 and TGFβ, which corelated with their increased suppression of CD4 and CD8 T cells compared to Tregs isolated from young EOC mice. The CD4+ and CD8+ T cells also displayed decreased effector makers including CD4+IFNγ, CD8+IFNγ and CD8+ Granzyme B, compared to young EOC mice in TME and in blood. The tumor promoting role of Treg was validated by depleting Tregs using anti-CD25 antibody which resulted in decreased tumor burden and improved overall survival, of both young and old mice, more significantly in old EOC mice. Tregs from old mice with EOC displayed enhanced metabolic activity, reflected in increased oxidative phosphorylation (OXPHOS) compared to young EOC mice. Further, on inhibition of OXPHOS, the Tregs from old mice showed decreased expression of immunosuppressive markers Foxp3 and IL10. Targeted metabolomics of TCA cycle in the Tregs, revealed a 5-fold increase in succinate levels in old EOC Tregs compared to young. Succinate treatment enhanced the immunosuppressive Treg function along with an increase in levels of IL10 and TGFβ, while inhibition of succinate synthesis reversed the increase in FOXP3, IL10 and TGFβ. We identified fibroblast growth factor 21 (FGF-21), a hormone essential for T cell development, to be significantly decreased in ascites and plasma, of old mice. Supplementing FGF21 decreased Treg survival, number, and suppressive ability, resulting in increased $CD4^+$ and $CD8^+$ cells in aged EOC mice. FGF21 treatment decreased OXPHOS and succinate levels in aged Tregs. Overall, our observations indicate Tregs to be vital in driving aggressive EOC in old mice. The hyper-suppressive Tregs in old mice reprogram succinate metabolism to drive their suppressive ability which may be negatively regulated by FGF21. Thus, Treg-succinate-FGF21 may be a potential actionable pathway in precision targeting of EOC in the older population.

#0852 Measuring the level of knowledge and awareness about radon in Northeast Tennessee.

K. Al ksir[1], S. Stanifer[2], M. Quinn[1], H. Mamudu[1], D. Slawson[1];
[1]East Tennessee State University, Johnson City, TN, [2]University of Kentucky, Lexington, KY

Introduction: Radon, a radioactive gas found in soil and rocks, is the second leading cause of lung cancer in the United States (1). Despite its significant health risks, radon awareness and knowledge remain low (2). In Tennessee, where geological factors contribute to elevated radon levels, understanding the levels of awareness and knowledge about radon is crucial (3). This study focuses on Northeast Tennessee, an area known for its high radon concentrations.
Methods: This cross-sectional study, conducted from September to November 2023, aims to assess radon awareness and knowledge among participants from seven Northeast Tennessee health councils. These councils play a critical role in public health initiatives and provide access to individuals actively involved in health-related discussions. A convenience sample of 150 participants was chosen from an email listserv of 650 health council members. Participants, aged 18 or older, affiliated with the health councils in the study area, and physically present in the US, were eligible to participate. Demographic data, radon knowledge and awareness were assessed. Additional questions evaluated information sources, concern levels, and willingness to inform the community about radon.
Conclusion: This research addresses a significant knowledge gap regarding radon awareness and knowledge in Northeast Tennessee, an area with unique geological factors that elevate radon exposure risks. The study's findings will contribute to the development of targeted educational campaigns and interventions, ultimately promoting awareness and proactive measures to mitigate radon exposure in the region. With the potential to inform policy and public health efforts, this study holds the promise of reducing the health risks associated with radon in Northeast Tennessee.

#0853 Assessment of racial and ethnic disparities in environmental exposure-related cancer burden.

J. R. Bobbitt[1], F. Liu[1], J. Cullen[1], R. A. Keri[2];

[1]Case Western Reserve University School of Medicine, Cleveland, OH, [2]Lerner Research Institute, Cleveland Clinic Foundation, Cleveland, OH

The United States Environmental Protection Agency designates superfund sites as regions contaminated with hazardous waste. These sites have previously been associated with adverse health outcomes, including an increased incidence of cancer. Historically, communities with racial and ethnic minorities and people of low socioeconomic status have served as prime locations for these sites, as these communities have lacked the ability to advocate against this land use. Here, we ask whether racial and ethnic minorities are disproportionately exposed to these sites or other regions of hazardous waste in our catchment area at the Case Comprehensive Cancer Center, and in the state of Ohio. Further, we are examining whether areas of high exposure are associated with adverse health outcomes including higher cancer incidence and mortality. We utilized the Environmental Justice Index (EJI) database from the Centers for Disease Control and Prevention to assess, on a census tract level, the percent of racial and ethnic minorities in a region, defined as all persons except white, non-Hispanic individuals. We also queried hazardous and toxic waste sites including regions with a national priority list site, a toxic release inventory site, treatment, storage, and disposal sites, risk management plan sites, coal mines, and lead mines. We intersected these data and found that census tracts with a higher percentage of minority persons were more likely to be exposed to hazardous and toxic sites. Our current studies are assessing whether this high environmental burden is contributing to disproportionately worse cancer burden for these individuals. We will test this by comparing EJI data with data from the Ohio Cancer Incidence Surveillance System database to assess cancer incidence and mortality in Ohio. This will also provide an avenue for identifying specific exposures that may contribute to different cancer types. Further, we plan to assess if persons with low socioeconomic status or those living with disabilities are disproportionately affected by environmental burden. Overall, understanding environmental burden and health outcomes will facilitate the prioritization of communities at greatest need, contributing to greater health equity.

BIOINFORMATICS / COMPUTATIONAL BIOLOGY / SYSTEMS BIOLOGY / CONVERGENT SCIENCE: Application of Bioinformatics to Cancer Biology 1 Poster Session

#0857 Identify ROR1 expression in healthy human tissues using single-cell RNA sequencing.

Mingyang Feng[1], Sirui Tan[1], Yue Chen[1], Qiu Li[1], Yongsheng Wang[2]

[1]Department of Medical Oncology, Cancer Center, and State Key Laboratory of Biotherapy, West China Hospital of Sichuan University, Chengdu City, China,[2]Thoracic Oncology Ward, Cancer Center, and State Key Laboratory of Biotherapy, West China Hospital of Sichuan University, Chengdu City, China

Introduction: The Receptor Tyrosine Kinase-like Orphan Receptor 1 (ROR1) is a receptor for Wnt5a and is considered a tumor-specific antigen. Researchers are actively exploring the development of antibodies and adoptive cell therapies targeting ROR1, while the potential "on-target, off-tumor" toxicity is still a major concern. Previous studies have provided inconsistent results regarding the expression of ROR1 in normal tissues, highlighting the complexity of its expression profile. Therefore, we are conducting this study to address this challenge through the detection of ROR1 mRNA expression via single-cell RNA sequencing (scRNA-seq) and the evaluation of ROR1 protein levels by immunohistochemistry (IHC).
Methods: We retrieved the Gene Expression Omnibus (GEO) database and downloaded the scRNA-seq data of each organ. We used the Seurat package to normalize data, perform dimensionality reduction and conduct clustering. The differentially expressed genes of each cell cluster were identified, and the cell clusters were then manually annotated. We further conducted the IHC on the tissue microarray (TMA), and evaluated the ROR1 immunostaining.
Results: We analyzed the scRNA-seq data of 908,941 cells from 14 types of healthy human organs, and 132,837 (14.61%) of cells expressed ROR1. Cell clusters in which the organ's ROR1 positive rate was >1% included the human Heart (Overall 25.99%, Ventricular cardiomyocyte 70%, Atrial cardiomyocyte 50%, Mesothelial 37% and Adipocytes 27%), Pancreas (Overall 9.36%, Beta cell 12.4%, Alpha cell 9.1%, Duct cell 7.3%, Acinar cell 7.2% and Delta cell 7.2%), Colon and small intestine (Overall 6.09%, Paneth 14.9%, Intermediate absorptive enterocyte 14.4%, Transit amplifying 13.8% and Enteroendocrine cell 12.5%), Lung (Overall 3.86%, Alveolar type I 23%, Ciliated cells 5.8% and Alveolar type II 5.4%), Bladder (Overall 2.73%, Fibroblasts 6.8% and Myofibroblast 6.4%), Esophagus (Overall 1.93%, Epithelial suprabasal 5% and Epithelial basal 4.4%) and Stomach (Overall 1.31%, Gland mucous cell 3% and Pit mucous cell 1.9%). The ROR1 expression was found relatively low (<1%) on Adipose, Kidney, Ileum, Liver, Spleen, Bone marrow and PBMC. For the IHC, ninety normal tissues were prepared and used. Consistent with the scRNA-seq results, we found relatively high ROR1 protein on the Heart, Lung, Stomach, Duodenum and Colon and low ROR1 protein on Liver and Ileum. However, ROR1 protein was not detected on Bladder, Pancreas or Esophagus during the IHC process.
Conclusion: Our findings suggest that some healthy human tissues may be at risk of "on-target, off-tumor" toxicity when utilizing ROR1-targeted therapies, including Heart, Colon and small intestine, Lung and Stomach. Close monitoring of possible toxicities related to the high ROR1 expressing organs should be considered in future clinical trials.

#0858 A functional atlas of cancer mutation-rewired protein interactome networks.

A. Agrawal[1], D. McGrail[2], N. Sahni[3], S. Yi[1];
[1]University of Texas at Austin, Austin, TX, [2]Cleveland Clinic, Cleveland, OH, [3]University of Texas MD Anderson Cancer Center, Houston, TX

Somatic mutations in cancer can exert effects on protein-protein interactions (PPIs), leaving some wild-type (WT) interactions perturbed while others unperturbed. The type of PPI perturbations can be used to link the mutation to its phenotypic effects. Here, we apply a technique known as functional variomics to characterize PPI profile changes for around 1,000 cancer missense mutations. Remarkably, our results reveal 5 distinct classes (edgotypes) of mutations: mutations losing PPIs compared to WT (edgetic), gaining PPIs (gain), gaining & losing PPIs (gain/loss), losing all PPIs (quasi-null), and those that do not perturb PPIs (quasi-WT). Notably, gastroenterological cancers have a greater proportion of edgetic mutations, whereas reproductive cancers have a greater proportion of gain edgotype mutations, demonstrating the link between edgotype and cancer type. We further show that more severe cancer stages are associated with interaction-perturbing mutation edgotypes, and the gain/loss edgotype is the most deleterious of all. In addition, pathway enrichment analysis suggests that the edgotypes are predictive of biological effects. For example, mutation edgotypes with loss of interactions are involved in apoptotic process and DNA damage repair, consistent with the expected loss of such functions in cancer. Meanwhile, gain edgotype is linked with cell division and G2/M transition. To our knowledge, this represents the first attempt to perform systematic interactome profiling for cancer mutations. As our results can reveal specific phenotypic attributes and biological functions that are altered for different PPI profiles, our functional platform is important for cancer precision medicine. Our study strengthens the link between genotypes and phenotypes while illustrating the significance of edgotypes in complex disease modeling.

#0859 Development of non-smoking lung cancers by indoor carcinogenic aerosols through epigenetic reprogramming of lung stem cells: Bioinformatics and artificial intelligence analysis..

J. Anderson[1], M. Delgado[1], M. Lovett[1], M. Saunders[1], G. Lake[1], S. Darko[1], R. M. Stiffin[1], A. Huisso[1], M. Sherman[1], L. Appleton[1], A. Mihnea[1], S. Das[2], M. M. Algahtani[3], R. Vadapalli[4], B. Basu[5], A. Biswas[6], N. Neha[7], M. Das[7], M. A. Ruiz[8], M. Doke[9], **J. K. Das**[1];
[1]Florida Memorial University, Miami Gardens, FL, [2]Miami Coral Park Senior High School, Miami, FL, [3]King Saud University, Riyadh, Saudi Arabia, [4]University of Miami, Coral Gables, FL, [5]Chittaranjan National Cancer Institute, Kolkata, India, [6]University of Kalyani, Kalyani, India, [7]Palm Beach Sate College Lake Worth Campus, Lake Worth, FL, [8]Baptist Health Miami Cancer Institute, Miami, FL, [9]University of Miami, Miami, FL

Several scientific studies discovered the toxic effects of indoor aerosols on different organs' adult stem cells of the human body. The most importantly, the indoor toxic aerosols comprised of numerous carcinogens namely, sodium dodecyl sulfate, phthalic acids from floor cleaners, formaldehyde, acetaldehyde, benzene, toluene, ethyl benzene, xylenes, from air fresheners, Hydramethylnon, Pyrethrins, imiprothrin, cypermethrin, tetramethrin, prallethrin and permethrin from ant and roach Killer. However, there was a lack of analysis revealing the mechanism of toxic effects and epigenetic reprogramming of human lung stem cells and development of non-smoking lung cancers. In this study, we analyzed the toxic effects of these chemicals and the mechanism of epigenetic reprograming on lung epithelial cells using Comparative Toxico-genomics Database (CTD), database of Environmental Health Perspectives (EHP), National Institute of Environmental Health Sciences (NIEHS), Google search browser with generative artificial intelligence (AI) and other biological informatics methods (Reactome, Cytoscape PSICQUIC services, and ChEMBL database). We observed from CTD analysis that the chemical gene interactions as risk factors from indoor aerosols showed transcriptionally highly expressed of 31 common genes, by phthalic acids, sodium dodecyl sulfate, from the total of 1347 genes, 107 common genes by formaldehyde, acetaldehyde from the total of 4193 genes and all other toxic ingredients of indoor aerosols. The epigenetic mechanism of histone modifications (H3K4me3, H3K9me3, H3K27me3, H3K27ac, H3K36me3, H3K4me1, Hsa-mir-1301 of lung epithelial, and miRNAs have been revealed by NIH Roadmap Epigenomics Mapping Consortium and the lung tissue arrays were analyzed with AI and matplotlib program. The heterogenic adult stem cell reprogramming is regulated by epigenetic bivalent histone modifications at transcript starts sequences (TSS) of target genes and our current study revealed that CD44, CD80, ALDH2, ALDH3A1, ALDH3B2 are epigenetically reprogrammed with close interaction of other genes by these toxic ingredients of indoor aerosols. Therefore, our results are significant for the carcinogenic effects of indoor aerosols causing for development of lung cancer epigenetically, which may give a clue for the prevention and treatment of nonsmoking lung cancer.

#0860 Pan-tissue master regulator inference reveals mechanisms of MHC alterations in cancers.

M. N. Gondal, R. Mannan, Y. Bao, J. Hu, M. Cieslik, A. M. Chinnaiyan;
University of Michigan, Ann Arbor, MI

Introduction: Major histocompatibility complex (MHC) genes are an integral part of the adaptive immune system. The T-cells can detect and kill cancer cells through the recognition of mutant peptides on the cell surface via the MHC. As a result, many cancers evade the immune system by altering their MHC regulation which can also lead to resistance to immune checkpoint blockade (ICB). Therefore, understanding MHC regulation in both baseline (normal state) and cancer is critical for uncovering mechanisms behind MHC alterations. Here, we have undertaken a pan-tissue evaluation to comprehensively decode MHC transcriptional regulation in healthy tissues and various cancers using a large compendium of single-cell RNA-seq (scRNA-seq) datasets.
Methods: To study MHC class I (MHC-I) and MHC class II (MHC-II) transcriptional regulation at baseline we leveraged a large-scale scRNA-seq dataset encompassing 18 tissues and 124 epithelial cell types. Upon re-clustering and annotation, we investigated MHC expression across cell types and tissues and quantified its heterogeneity using the Gini coefficient. Next, we sought to identify transcription factors (TF) predictive of MHC-I and MHC-II expression, for that, we employed a master regulator inference that utilizes uni- and multi- regression models. Further, to investigate MHC and nominated TFs dysregulation in cancer, we curated a compendium of scRNA-seq datasets comprising 43 datasets, 20 cancer types, across 538 patients.
Results: In normal epithelial cell types, we observed a large range (~8 fold) in MHC-I expression. We also detected MHC-II expression in unexpected cell types such as club cells in the prostate. We found that lung epithelial cells showed elevated MHC-II expression. Immunohistochemistry was performed to validate these findings. Using master regulator inference, we nominated 104 and 107 TFs which predict MHC-I and MHC-II expression, respectively. The nominated TFs showed significant enrichment ($p < 0.001$) for known TFs, alongside putative novel transcriptional regulators such as YBX1 (MHC-I $p < 2e-16$, MHC-II $p = 8e-07$) and XBP1 (MHC-I $p < 2e-16$, MHC-II $p = 7e-04$). Using our single-cell compendium of 20 cancer types we also observed a pan-cancer repression in MHC genes ($p < 0.001$). Next, we utilized an ICB cohort to identify specific TFs that could predict therapeutic benefits. Interestingly, XBP1 ($p < 1e-16$) and SP100 ($p < 2.2e-08$) were strong predictors of patients' survival. We also observed a large heterogeneity in MHC-II expression among colon cancer patients. Upon investigation, we found that patients with high MHC-II expression were mismatch repair deficient, this implicates MHC-II upregulation as an immune evasion mechanism.
Conclusion: In conclusion, we have comprehensively evaluated MHC expression in 124 epithelial cell types and across 20 cancers identifying TFs predictive of MHC-I and MHC-II expression and their effects on patient outcomes.

#0861 Integrative multi-omics analysis enables a comprehensive characterization of prostate cancer and unveils metastasis-associated candidate biomarkers.

M. Villa[1], G. Cazzaniga[1], M. Bolognesi[1], V. Crippa[1], F. Malighetti[1], A. Aroldi[1], G. Bozzini[2], F. Pagni[1], R. Piazza[1], L. Mologni[1], D. Ramazzotti[1];
[1]University of Milano-Bicocca, Monza, Italy, [2]Hospital ASST Lariana, Como, Italy

Prostate cancer (PCa), a common malignancy in men, presents a complex and variable disease landscape, requiring precise evaluation for personalized treatment decisions. Urologists employ a range of assessments, including clinical staging, PSA levels, imaging, Gleason scores, and emerging biomarkers. Nevertheless, the need for additional biomarkers to enhance precision medicine continues. This study utilizes extensive omics datasets to thoroughly profile PCa. We conducted an in-depth analysis of primary PCa data from the multi-omics dataset from The Cancer Genome Atlas studies to identify molecular subtypes showing significant prognostic differences. We conducted integrative clustering analysis on a dataset comprising 341 primary prostate adenocarcinomas with comprehensive multi-omics data, including substitutions, small insertions/deletions, copy number alterations, DNA methylation, gene expression profiles, micro-RNA expression, reverse-phase protein arrays, and microbiome data. The analysis revealed seven distinct clusters (C1 to C7) based on multi-omics features. At the genomic level, recurrent copy number losses and DNA methylation/demethylation were the most prominent alterations across clusters. When looking at survival curves, the 7 clusters could be clearly partitioned into two groups. Therefore, to further investigate multi-omics features specifically linked to prognosis, we grouped clusters with similar prognoses into two macro-clusters. Clusters C1 to C4 formed MC1 (favorable prognosis), while C5 to C7 constituted MC2 (poor prognosis). A comprehensive comparison between MC1 and MC2 revealed molecular differences associated with survival. We performed computational validation of candidate prognostic biomarkers using two external datasets. By utilizing these selected features, we could stratify patients in both the validation datasets into groups with significant differences in survival. The analysis identified six features consistently associated with prognosis across both datasets, including CCNB1, PCNA, RAD51, FOXM1, miR-503-5p (positively associated with risk), and miR-7704 (negatively associated with risk). The practical applicability of these biomarkers was explored through immunohistochemical analysis on biopsy samples obtained at diagnosis and from metastatic sites. Based on their potential relevance according to the literature, we investigated three candidate biomarkers derived from the multi-omics analysis: FOXM1, CCNB1 and RAD51. The expression of these proteins was found to correlate with PCa progression and mark the metastatic stage. In summary, this study highlights the potential of translating comprehensive multi-omics bioinformatic analyses into practical approaches for understanding the molecular mechanisms of tumors and identifying prognostic markers.

#0862 Multi-omic analysis of allelic expression patterns of imprinted and non-imprinted genes in cancer and their association with drug response.

J. Krushkal[1], T. L. Jensen[2], G. Wright[1], Y. Zhao[1];
[1]National Cancer Institute, Rockville, MD, [2]The Emmes Company, LLC, Rockville, MD

Malignant cells undergo a broad array of epigenetic changes, including changes in imprinting patterns. In normal cells, imprinted genes have parent of origin-specific monoallelic expression, which is controlled via epigenetic mechanisms. Imprinted gene loci are often complex and frequently include multiple isoforms, which have different individual patterns of parent-of-origin monoallelic or biallelic expression in the normal tissues. Many imprinted genes promote cell proliferation and body growth, and their expression is important during embryonic and postnatal development. Dysregulation of imprinting in tumors has been suggested to contribute to growth and proliferation of cancer cells. Previously we reported that chemotherapy responses of cancer cell lines from a variety of tumors and of patient-derived acute myeloid leukemia samples were associated with copy number, expression, or DNA methylation of selected imprinted genes. In the current project, we examined allele-specific patterns of expression (monoallelic vs. biallelic) of imprinted genes and isoforms in tumors and studied their potential effect on response of cancer cells to drug treatment. We analyzed expression patterns at the whole gene, isoform, and exon levels of 59,283 autosomal protein-coding genes and ncRNA genes, with a special focus on 94 imprinted genes and their isoforms. We developed a computational pipeline to evaluate monoallelic and biallelic expression patterns of each gene in cancer cell lines and in tumor samples based on available matched RNA-seq expression data, whole exome sequencing information, and copy number data. Our initial analysis included 108 cell lines from the Cancer Cell Line Encyclopedia (CCLE), which had been derived from 9 pediatric and adult tumor histologies. We observed variation of allelic expression patterns of imprinted genes and their isoforms in tumor cell lines, including differences across and within cancer histologies. We also observed predominantly monoallelic expression of multiple additional genes. Some of them (*PRIM2, BCLAF1, MAP2K3,* and *SEC22B*) had been previously reported as potentially imprinted. Monoallelic expression of other genes identified in our analysis (e.g., *GRK2, CBX4,* and additional genes) was likely caused by molecular mechanisms other than imprinting. Allelic expression patterns and overall expression levels of isoforms of multiple imprinted and non-imprinted monoallelically expressed genes (e.g., *CPA4, MAP2K3,* and other genes) were associated with *in vitro* drug response. We also report our ongoing validation of allelic expression patterns of imprinted and non-imprinted genes, isoforms, and exons in primary bladder and breast tumors and in matched solid normal tissue samples using patient data from the Cancer Genome Atlas (TCGA). These results provide new knowledge about epigenetic dysregulation in cancer.

#0863 Scratch: A highly modular pipeline for single-cell cancer research.

Andre F. Fonseca[1], Guangchun Han[1], Marcel Ribeiro-Dantas[2], Enyu Dai[1], Diljot Grewal[3], Matthew Zatzman[3], Eliyahu Havasov[3], Andrew McPherson[3], Break Through Cancer, Data Science TeamLab, Michael N. Noble[4], Rameen Beroukhim[5], Rachel Karchin[6], Sohrab P. Shah[3], Linghua Wang[1]

[1]Genomic Medicine, UT MD Anderson Cancer Center, Houston, TX,[2]Graduate Program in Biotechnology, Potiguar University, Natal, Brazil,[3]Epidemiology and Biostatistics, Memorial Sloan Kettering Cancer Center, New York, NY,[4]Break Through Cancer, Boston, MA,[5]Cancer Biology, Dana-Farber Cancer Institute, Boston, MA,[6]Genomic Medicine, Johns Hopkins Medical Institutions, Baltimore, MD

Background: Single-cell RNA sequencing (scRNA-seq) is a robust approach to facilitate cancer research, revealing insights into tumor heterogeneity, microenvironment, and treatment response. However, scRNA-seq results frequently encounter reproducibility challenges due to i) high data complexity, intensified by human intervention, and ii) insufficient methods standardization, leading to inconsistent findings.
Methods: Here, we introduce SCRATCH (Single-Cell RnA-seq Toolkit and Pipeline for Cancer researcH), a Nextflow-based pipeline designed to improve reproducibility through a layered and modular architecture. SCRATCH follows FAIR principles and guidelines provided by the nf-core community.
Result/Discussion: The pipeline provides three execution modes: end-to-end, iterative, and custom. In the end-to-end mode, the pipeline processes data from raw input to downstream analyses automatically. This mode employs ranking- and aggregation-based approaches. For instance, the ranking approach leverages benchmark metrics to select the most suitable method in distinct steps, e.g., batch correction. Therefore, ensuring a consistent and data-driven selection. On another hand, the aggregation approach uses multiple predictions to increase confidence levels, such as on CNV inference and malignant cell identification. These strategies minimize human intervention, ideal for beginner users, enabling rapid access to preliminary results and biological insights. Alternatively, the iterative mode allows intermediate users to define workflow breakpoints in a layered-based fashion. Users can pause, review results, and adjust decisions at stages (e.g., TME annotation), facilitating a "semi-supervised" approach for a more tailored analysis while retaining the SCRATCH framework. Thirdly, the custom mode enables precise executions based on modules for similar tasks (e.g., trajectory analysis and cell-cell communication), allowing experienced users to bypass the SCRATCH workflow and use it as an on-demand toolkit. This mode leverages pipeline parallelism for efficient processing, perfect for ongoing single-cell projects. SCRATCH produces HTML reports to ensure traceability and reproducibility.
Conclusion: SCRATCH, an evolving project, comprises 05 subworkflows, 18 modules, and 25 tools. We envisage SCRATCH as an open-source tool and invite developers to leverage its modules for their pipelines. For more information, please visit https://break-through-cancer.github.io/btc-scrna-training.

#0864 Pan-cancer analysis of lactic acid metabolism landscape across the Cancer Genome Atlas.

X. Wei[1], L. Cai[2], Q. He[1];

[1]Department of Hepatobiliary Surgery, Shenzhen University General Hospital, Shenzhen, China, [2]Institute of Hepatopancreatobiliary Surgery, Chongqing General Hospital, Chongqing, China

Introduction: Metabolic reprogramming plays an important role in tumor occurrence and progression. Our studies confirmed the survival state of patients with different metabolic systems was heterogeneous and glycolytic metabolism may cause tumor progression. Based on these findings, lactic acid metabolism in glycolysis aroused our interest. This study evaluated the potential association between lactate metabolism gene and tumor clinical process in hepatocellular carcinoma, and proved that it can be used as an effective tool for survival prediction and treatment guidance of 32 kinds of tumor patients by establishing lactate score prognosis model.

Methods: We used the expression profile, proteomics and epigenetics of HCC lactate gene set in the Cancer Genome Atlas Database to systematically describe the changes of lactate related genes. The differentially expressed genes were then verified in 32 clinical tumor data sets. A prognostic model of tumor lactic acid infiltration was constructed to evaluate its correlation with the prognosis of patients. Finally, we analyzed the effects of lame score, immunotherapy and drug response on the clinical process of tumor.

Results: Firstly, we analyzed the differential expression of lactate metabolism genes in HCC and found that the prognosis of patients with high lactate infiltration was significantly lower than that of mild infiltration. AF angiogenesis factor and EMT factor in high infiltration may be the main reason for their differential expression. We constructed a tumor lactic acid prognosis model through six significantly different lactic acid genes, and found that lame score can be used as a predictor of immunotherapy. In addition, we proved the role of lame score in Pan cancer. PGA was positively correlated with lame score in most tumors. The prognosis of 16 tumors with high lame score group was significantly lower than that of low lame score group. There were significant differences in lame score between metastatic and non metastatic cancer groups of Cesc, kirc and kirp. The high and low risk groups of some tumors showed different dryness indices and dampness. At the same time, methylation gene modification has a significant impact on the Lame score of pan cancer, and the Lame score is used to link the drug tolerance and specific pathway enrichment of pan cancer tumor cell lines, confirming the targeted effect of Lame score on tumor treatment. Finally, we used the clinical characteristics and immunohistochemical analysis of a cohort study of real patients with breast cancer endocrine therapy (Tamoxifen) and hepatocellular carcinoma targeted therapy (Lenvartinib) to verify the clinical treatment prediction ability of lame score.

Conclusions: Our study provides a comprehensive analysis of lactate metabolic across cancers and highlights the potential treatment of lactate targeted therapies for cancers.

#0865 Single-cell sequencing identification of malignant cell subpopulations linked to recurrence in hepatocellular carcinoma.

Y. Dong[1], X. Guo[1], X. Wang[1], F. Yang[2], Y. Zheng[2], Y. Chen[1];
[1]Peking Union Medical College, Beijing, China, [2]Peking Union Medical College Hospital, Beijing, China

Introduction: Hepatocellular Carcinoma (HCC) is a highly malignant and challenging-to-treat tumor, with early recurrence affecting up to 35-50% of patients within two years after surgery, significantly impacting prognosis. Identifying high-risk patients for recurrence is critical for guiding postoperative adjuvant therapy. The rapidly advancing field of single-cell RNA sequencing technology offers an unprecedented opportunity to discover clinically relevant cell subpopulations. Here, we harnessed single-cell techniques to unveil a cell subpopulation closely linked with HCC recurrence, highlighting its clinical significance.
Methods and Results: We conducted single-cell RNA sequencing on four HCC samples and harmonized data from three public datasets (GSE112271, GSE125449, CNP0000650) to elucidate the heterogeneity of malignant cells in HCC. Our investigation revealed a distinctive HCC subpopulation enriched in patients with early recurrence (11.4% vs. 3.8%, *P*=0.02). This subpopulation exhibited up-regulated *STMN1* and *EZH2*, signifying high proliferative potential and a propensity for epithelial-mesenchymal transition (EMT). Applying the CIBERSORTx algorithm to the TCGA-LIHC dataset (N=323 patients), we inferred the proportion of this recurrence subpopulation among all malignant cells. Notably, patients with a higher proportion of this subpopulation (N=160) demonstrated significantly shorter recurrence-free survival (31.2 vs. 42.9 months, *P*=0.002), reduced median survival (45.9 vs 55.7 months, *P*=0.03) and a higher rate of microvascular invasion (35% vs. 23%, *P*=0.01). To validate this recurrence-related subpopulation in clinical samples, we conducted multiplex immunohistochemistry staining on paraffin-embedded (FFPE) HCC samples (including CD45, CD31, ARG1, STMN1, EZH2) and used machine learning for its identification. Our findings revealed that patients with a higher proportion of this recurrence subpopulation (N=40) experienced significantly shorter median survival (38.5 vs. 51.0 months, *P*<0.005) and progression-free survival (25.1 vs. 33.4 months, *P*=0.01) compared to a lower proportion (N=40). Multivariate Cox regression analysis confirmed that the proportion of this recurrence subpopulation is an independent predictor of worse prognosis (*P*=0.003).
Conclusion: Through the power of single-cell RNA sequencing technology, we have unearthed and characterized a malignant cell subpopulation intricately connected with HCC recurrence. Importantly, this subpopulation can be identified in FFPE tissue samples and correlates robustly with patient prognosis. Our study underscores the transformative possibility of single-cell techniques in developing cell subpopulation-based biomarkers, emphasizing their clinical relevance and potential utility in guiding postoperative adjuvant therapy for HCC patients.

#0866 Identification of survival-associated epithelial cell markers linked to TROP2 through single-cell and bulk sequencing analysis.

N. N. Al-Bzour[1], A. N. Al-Bzour[1], A. Qasaymeh[1], **A. Saeed**[2], L. Chen[3], A. Saeed[4];

[1]Jordan University of Science and Technology, Irbid, Jordan, [2]University of Vermont Medical Center, Burlington, VT, [3]University of Pittsburgh, School of Medicine \ UPMC Hillman Cancer Center, Pittsburgh, PA, [4]University of Pittsburgh Medical Center (UPMC) \ UPMC Hillman Cancer Center, Pittsburgh, PA

Introduction: Colorectal Cancer (CRC) is known for its aggressiveness and drug resistance. This has increased the interest in antibody-drug conjugates (ADCs) as a possible therapy. In this study, we aim to investigate the effects of the ADC target TROP2, on the level of epithelial cells and its correlation with survival outcomes in CRC patients.

Methods: Single-cell RNA (scRNA) data was downloaded from Gene Expression Omnibus (GEO) for CRC patients and evaluated for TROP2 expression. Patients were grouped into low and high-TROP2 based on median TROP2 expression, and pseudo-bulk analysis was used to find the differentially expressed genes (DEGs). The DEGs were used to find the survival association in the TCGA-CRC cohort. A risk score was built using principal component analysis (PCA) on the TROP2-DEGs and cutoff point was chosen based on survival. Kaplan-Meier curve was used to compare overall survival (OS), progression-free survival (PFS), and disease-free survival (DFS) risk groups. Gene Set Variation Analysis (GSVA) was used to identify the enriched pathways between low- and high-TROP2 in GSE using pseudo-bulk by pooling epithelial cells of individual patients.

Results: Of the 10424 cells of 15 different types for 9 CRC patients retrieved from GSE146771, TROP2 was significantly expressed by epithelial cells (n = 766) with mean expression of 1.64 (SD: 1.96, P-value: 0.003) using pseudo-bulk analysis. Three significant DEGs were obtained which are: KIF13B, UCHL3, and PLAC8. These were evaluated for survival association in resectable stages (I-III) CRC patients (n = 419) using PCA to group the patients into low-risk (n = 88) and high-risk (n = 331), using -1.4 as the cutoff point. High risk group showed a better survival with a 1-year survival probability of 94% compared to 90% in the low group and a 5-year survival probability of 74% vs. 46% in the low group. The Kaplan-Meier curve showed that OS, PFS & DFS were significantly better in the high-risk group (p-value = 0.004, 0, 04, and 0.024 respectively). TROP2 and PLAC8 were significantly associated with worse prognosis, whereas UCHL3 was associated with better prognosis (p-value = <0.001), however, KIF3B did not significantly affect the prognosis. APC gene mutation and TP53 were higher in the low-risk group (p-value = 0.004, 0.007 respectively). KRAS-signaling, IL-18-signaling, MET activation of PTK2-signaling were upregulated in high-TROP2 group, while MYC targets, MTORC1 signaling, DNA repair, reactive-oxygen-species signaling, and TCR-signaling were upregulated in low-TROP2.

Conclusion: In this study we developed a TROP2-associated risk score that significantly predicted OS, PFS, and DFS in patients with resectable CRC by combining single-cell and bulk-RNA-seq datasets and showing predominant expression of TROP2 in epithelial cells. These findings support the development of TROP2 targeting therapeutics in this space.

#0867 Molecular and functional characterization of melanocyte subpopulations in human epidermis based on single-cell RNA sequencing.

Peinan Zhao*[1], Fumihito Noguchi*[1], Christopher Chew[1], Gamze Kuser Abali[1], Pacman Szeto[1], Youfang Zhang[1], Malaka Ameratunga[1], Isobel Leece[1], Jen G. Cheung[1], Miles Andrews[1], Nicholas C. Wong[1], Anthony T. Papenfuss[2], Mark Shackleton[1]

[1]Monash University, Melbourne VIC, Australia,[2]The Walter and Eliza Hall Institute, Melbourne VIC, Australia

The biological and molecular mechanisms that underpin the malignant transformation of normal melanocytes to melanomas are largely unknown. In part, this is due to the limited understanding of normal human melanocyte homeostasis and how melanocytes respond to oncogenic insults such as ultraviolet radiation (UVR). This is particularly true for interfollicular epidermal melanocytes, which have the highest levels of UVR exposure and from whence most melanomas are thought to arise. These knowledge gaps impede the development of strategies for active, targeted prevention of melanoma formation.
We thus evaluated epidermal melanocytes transcriptionally, phenotypically and functionally after isolating them from human skin. Using single-cell RNA sequencing (scRNA-seq), we identified multiple transcriptionally distinct subpopulations within human epidermal melanocytes. RNA velocity analysis revealed subpopulations in different states of melanocytic differentiation, and immunohistochemistry staining demonstrated their distinct anatomical distribution throughout follicular and interfollicular epidermal compartments. Notably, one melanocyte subgroup, marked by increased expression of neurotrophic receptor tyrosine kinase 2 (*NTRK2*) and genes associated with ribosome biogenesis, exhibited molecular characteristics of progenitor cells. This subpopulation displayed human embryonic stem cell (hESC)-derived melanoblast markers, and their anatomical localization corresponded to that of intermediate melanocyte progenitors.
NTRK2+ melanocytes demonstrated enhanced clonogenicity after UVR exposure in primary cell cultures and in ex vivo whole skin explants. In contrast, NTRK2- melanocytes were suppressed by UVR. Furthermore, scRNA-seq data of ex vivo melanocytes after UVR exposure revealed the upregulation of genes associated with cell proliferation within NTRK2-expressing melanocytes. In mouse back skin, the ratio of Ntrk2+ melanocytes increased within 24 hours of UVB irradiation, suggesting a proliferative response in these cells in vivo following UVR.
We thus report the discovery in human epidermis of a putative melanocytic cell hierarchy, and of a candidate melanocyte progenitor subpopulation that responds proliferatively to UVR and is thus a candidate cell of origin of melanoma.

#0868 A novel unsupervised machine learning model applied to neuroblastoma single-cell RNA-seq data reveals a drug-induced mesenchymal-like gene expression program.

R. Chapple[1], **X. Liu**[1], S. Natarajan[1], M. I. M. Alexander[1], Y. Kim[1], A. Patel[1], C. W. LaFlamme[1], M. Pan[1], W. C. Wright[1], H.-M. Lee[1], Y. Zhang[1], M. Lu[1], S. C. Koo[1], C. Long[1], J. Harper[1], C. Savage[1], M. D. Johnson[1], T. Confer[1], W. J. Akers[2], M. A. Dyer[1], H. Sheppard[1], J. Easton[1], P. Geeleher[1];
[1]St. Jude Children's Research Hospital, Memphis, TN, [2]University of Texas Southwestern Medical School, Dallas, TX

High-risk neuroblastoma is one of the most difficult to treat pediatric cancers, with a survival rate of only about 50% and significant long-term consequences from current chemotherapy. Preclinical models such as cell lines and mice are the backbone of drug development and experimental-mechanistic oncology, but the development of new treatments is hampered in part by a lack of understanding of the direct clinical relevance of such data collected in preclinical models. Despite this, few formal methods have been developed to determine how these various models represent/resemble primary patient tumors. Here, we present the first comprehensive single-cell RNA-seq analysis of neuroblastoma across an extensive cohort of patient tumors and a variety of preclinical model systems (n = 126 total samples assembled - the largest cohort of its kind). By building an innovative unsupervised machine learning method, which we term “automatic consensus nonnegative matrix factorization” (acNMF), we have integrated and contrasted the transcriptional landscapes of patient tumors with those of cell lines, patient-derived xenografts (PDX), and genetic mouse models (GEMM).Using these tools, we discovered the dominant adrenergic gene expression programs found in neuroblastoma patient tumors were preserved across all preclinical models. However, the presumptive chemo-resistant mesenchymal-like programs, while identifiable in cell lines, were primarily restricted to subpopulations of cancer-associated fibroblasts and Schwann-like cells in vivo. Surprisingly, a mesenchymal-like program could be acutely chemotherapy-induced in GEMM and was evident in pre-treated patient and PDX samples, suggesting a previously uncharacterized mechanism of therapy escape. In addition to these core findings, our computational tools were able to further delineate the classical neuroblastoma adrenergic and mesenchymal gene expression programs, discovering for example, novel subpopulations of cancer associated fibroblasts. These behaviors were conserved across tumors and most preclinical models, which we validated by RNA in situ hybridization, which is a high resolution ultra sensitive spatial transcriptomics technology. Our work cautions against overreliance on traditional preclinical models without recognizing their limitations and we offer a nuanced, high-resolution view of neuroblastoma pre-clinical systems for advancing therapeutic development. We have launched an open-source web resource, featuring this integrated map to aid the scientific community in further exploration of these data and hypothesis generation (available at http://pscb.stjude.org).

#0869 Single-cell DNA replication dynamics in genomically unstable cancers.

Adam C. Weiner, Marc J. Williams, Hongyu Shi, Ignacio Vazquez-Garcia, Sohrab Salehi, Nicole Rusk, Sohrab P. Shah, Andrew McPherson

Memorial Sloan Kettering Cancer Center, New York, NY

Background: DNA replication and cell cycle regulation are frequently disrupted as part of a cancer's progression toward uncontrolled proliferation, generating somatic copy number alterations (CNAs) and producing intratumoral heterogeneity that drives subsequent evolution. Structural variation and CNAs have been shown to impact epigenetic and chromatin states, but our ability to assess their impact on DNA replication timing (RT) and cell proliferation rates remains limited. Single-cell whole genome sequencing (scWGS) is a powerful method for studying clonal heterogeneity and CNAs, and has the potential to provide greater insight into DNA replication dynamics in aneuploid populations. However, computational identification of S-phase cells and distinguishing inherited somatic CNAs from transient DNA replication changes remain challenging.
Methods: We present a new method, PERT, which uses a Bayesian framework to model read depth as a combination of somatic copy number, replication, and sequencing bias, enabling estimation of DNA replication profiles and cell cycle phase from scWGS data. Unlike previous approaches, PERT provides unbiased estimates of RT and cell cycle phase which allows for analysis of previously uncharacterized cell types using any scWGS platform. These unique properties enable PERT to perform novel analysis such as estimating clone-specific proliferation rates and studying the interplay between RT and somatic CNAs during tumor evolution. We applied PERT to a cohort of >50,000 scWGS cells obtained from a collection of genomically unstable breast and ovarian cell lines, xenografts and primary cancer tissues.
Results: Clone RT profiles correlated with future copy number changes in serially passaged cell lines. Cell type was the strongest determinant of RT heterogeneity, while whole genome doubling (WGD) and mutational signature had weaker RT associations but were associated with accumulation of late S-phase cells. Recurrent CNAs affecting chromosome X had striking impact on RT, with loss of the inactive X allele shifting replication earlier, and loss of inactive Xq resulting in reactivation of Xp. Analysis of time series xenografts illustrated that cell cycle distributions approximate clone proliferation. This relationship enabled us to observe that highly proliferative clones were the most chemosensitive in cisplatin-treated xenografts and, separately, present novel evidence that WGD leads to slower proliferation.
Conclusions: Our analysis implicates cell type as the strongest determinant of RT with chrX being the locus of highest RT variation due to X-inactivation. Separately, quantification of S-phase cells enables interrogation of the on- and off-treatment fitness of genetically distinct subclones. This work leads to better understanding of how DNA replication dynamics drive and are further modulated by genomic instability.

#0871 Unveiling the potential of bispecific antibodies: A comprehensive analysis of efficiency, toxicity, and repurposing in cancer treatment.

B. Wang, S. Madan, A. Schaffer, E. Ruppin;
NIH-NCI, Bethesda, MD

Bispecific antibodies have emerged as promising candidates for cancer treatment, prompting the necessity for a comprehensive understanding of their potential efficacy and toxicity across various cancer types. Leveraging single cell sequencing data, we systematically evaluated the efficacy and toxicity of all cell surface gene pairs across multiple cancers. First, we found that gene pairs involved in successful bispecific antibodies phase I/II clinical trials exhibited significantly higher efficacy scores and lower toxicity scores than gene pairs in those that failed, underscoring the utility of our method in selecting high-quality bispecific pairs. Second, to facilitate the identification of new pairs, we established baseline efficacy and toxicity scores based on successful phase I/II clinical trials, employing these scores to assess the potential of novel combinations. We systematically identified both cancer type-specific and pan-cancer candidate new bispecific antibody pairs. This extensive analysis not only provides valuable insights into the potential of bispecific antibodies to broaden the spectrum of cancer treatments, but also yields a highly confident list of candidate gene pairs capable of constructing effective bispecific antibodies.

#0872 Development of a nomogram and prognostic model based on immune-related genes in kidney renal papillary cell carcinoma.

Adrian Lim, Mouad Edderkaoui, Yi Zhang, Stephen J. Pandol, Yan Ou

Medicine, Cedars-Sinai Medical Center, Los Angeles, CA

Background: Kidney renal papillary cell carcinoma (KIRP) is frequently associated with an unfavorable prognosis for affected individuals. Unfortunately, there has been insufficient exploration in search for a reliable prognosis signature and predictive indicators to forecast outcomes for KIRP patients. Thus, we have used bioinformatics of existing transcriptomic and health data to identify survival-related and prognostic immune genes.
Methods: Processed RNA-seq FPKM data of 289 KIRP and 32 adjacent normal KIRP tissues were downloaded from the TCGA data portal. We downloaded 2499 immune-related genes via the Immunology Database and Analysis portal database and used the Cistrome database to identify and extract 318 total transcription factors (TFs). The differentially expressed immune-related genes and TFs were detected using the Wilcoxon test method. R was used to generate heatmaps and volcano plots. R was also used to perform Gene Ontology (GO) and Kyoto Encyclopedia of Genes and Genomes (KEGG) pathway enrichment analysis. Multivariate Cox regression analysis was implemented to investigate the prognostic value of differentially expressed immune-related genes used to construct the predictive model and nomogram. Kaplan-Meier analysis was performed to compare overall survival. We used Tumor Immune Estimation Resource (TIMER) and the Human Protein Atlas database (HPA) to validate expression and explore associations between a prognostic model and immune cell infiltration. Statistical analyses were performed using R; a p-value < 0.05 was considered to be significant.
Results: A total of 368 immune-related genes and 60 TFs were identified as differentially expressed in KIRP tissues compared with normal tissues. Of the 368, 23 were found to be related to overall survival. GO and KEGG analysis suggested that these prognostic immune-related genes mainly participated in the ERK1 and ERK2 cascades, Rap1 signaling pathway, and the PI3K-Akt signaling pathway - pathways shown to be significantly correlated with the development of cancer. Of these 23 genes, 9 (GRN, PDGFRB, APOH, BIRC5, CCL19, RETN, HTR3A, PTGER1, TRAV39) were identified from Cox regression to be statistically significant prognostic-related genes. Survival analysis showed that a model based on these 9 prognostic-related genes has high predictive performance. Our constructed nomogram has good predictive power and clinical practicability. Immunohistochemistry results show that APOH, BIRC5, CCL19 and GRN were significantly increased in kidney cancer. B cells and CD4+ T cells were positively correlated with risk score model.
Conclusion: We were able to create a prognostic model based on 9 immune-related genes correlated with overall survival in KIRP. We hope that this work helps to provide some insight into therapeutic approaches and prognostic predictors of KIRP.

#0873 Elucidating immune-related gene transcriptional programs via factorization of large-scale RNA profiles.

Shan He, Vakul Mohanty, Matthew Gubin, Hind Rafei, Rafet Basar, Merve Dede, Xianli Jiang, Yukun Tan, Maura Gillison, Katayoun Rezvani, Weiyi Peng, Ken Chen

UT MD Anderson Cancer Center, Houston, TX

Background: Despite the recent success in Immune checkpoint blockade (ICB) therapy, limited patients benefit due to immune-related adverse events or treatment resistance, especially in solid tumors. To overcome these hurdles, understanding the molecular mechanisms behind treatment response is essential. However, the current lack of immune gene transcriptional programs (GTPs) hampers data-driven immunological discovery. Constructing immunity-specific knowledgebases with rigorously curated gene sets (irGSs) and rich immunological language can unlock new insights, enabling interpretation of high-throughput immune microenvironment profiling studies and fostering personalized, effective cancer treatments.
Methods: We collected 83 BulkRNAseq datasets from the ImmuneSigDB. These datasets contain 1826 samples challenged with infections, cytokines or immunological perturbations of different kinds and magnitude, possessing yet-to-be discovered immune functions that lie beneath the transcriptomic profiles. Using non-negative matrix factorization (NMF), we identified gene sets with coordinated expression. We used CITE-seq and selected scRNAseq to annotate the immunological functions of each gene set and validated the clinical utilities of these gene sets from different aspects using data from Cancer Genome Atlas Program (TCGA) pan-cancer, ICB cohorts and a 10X Genomics Visium FFPE Human Breast Cancer spatial slide.
Results: We presented 19 lymphoid-data derived and 9 myeloid-data derived gene sets (irGSs), encompassing a diverse array of immune functions. Through extensive validation using BulkRNAseq, scRNAseq and spatial transcriptomics data, we revealed six irGSs-defined pan-cancer microenvironment subtypes in TCGA with significantly distinct survival patterns regardless of cancer types. Moreover, irGSs are associated with T cell exhaustion phenotypes, which in turn well predicted (classification accuracy of 72%) Nivolumab response using 104 treatment-naïve melanoma patients. Lastly, irGSs simultaneously isolated out tumor regions and highlighted immune infiltration with high specificity in breast cancer spatial transcriptomics H&E image.
Conclusions: These pioneering gene sets, originally derived from non-cancerous experiments, hold tremendous promise for cancer research across diverse contexts. Similarities between cancerous and sepsis immune microenvironments underscore their wide applicability. By studying gene set activities, immunologists can gain profound insights into cancer survival drivers, unravel the intricacies of ICB treatment mechanisms, and potentially conquer therapeutic resistance. These translational utilities herald a transformative era in cancer immunotherapy and open new frontiers in the fight against cancer.

#0874 Expanded detection of *BAP1* alterations in cancer and comparison of tumor type-specific gene expression scores.

Ian R. Sturgill, Jesse R. Raab, Katherine A. Hoadley

UNC Chapel Hill, Chapel Hill, NC

BAP1 is a tumor suppressor gene that was originally studied in uveal melanoma (UVM), kidney renal cell clear cell carcinoma (KIRC), and malignant mesothelioma (MESO). Early analyses focused on single-nucleotide variants, but other alteration types such as larger indels and gene-level copy number (CN) loss can also lead to loss of *BAP1* expression. By incorporating these, we can improve our assessment of cancer type-specific consequences of *BAP1* loss and broaden our findings beyond the initial small subset of cancer types which were studied in the context of mutations alone. We performed integrated multi-omic analyses using data from The Cancer Genome Atlas (TCGA), for 33 cancer types and more than 10,000 individuals. By combining and manually reviewing existing variant calls and new calls derived from a de novo local realignment pipeline across multiple independent variant callers including indel callers, we increased detection of high-quality somatic variant calls by 30% from 85 to 111, including 14 indels ≥5bp. Including CN loss alterations, we found a total of 1561 samples from 32 cancer types to be *BAP1*-altered, with alterations being predominantly CN-driven. We confirmed that expression of *BAP1* was lower in altered versus unaltered tumors ($p<0.001$). Alteration frequencies across cancer types were highly variable, ranging from 0% in thyroid cancer to >30% in KIRC, cholangiocarcinoma (CHOL), UVM, MESO, lung squamous carcinoma (LUSC), and head-neck squamous cell carcinoma (HNSC). Tumor types such as CHOL, UVM, MESO, and liver hepatocellular carcinoma (LIHC) were relatively more mutation-driven whereas other tumor types like KIRC, LUSC, and HNSC were almost entirely CN-driven. To better understand the tissue and context-specific consequences of *BAP1* alteration, we performed differential expression analyses across *BAP1*-altered and -unaltered samples. For each cancer type, we separately computed per-sample *BAP1* alteration signature z-scores summarizing expression of the set of differentially expressed genes. In UVM, we observed distinct patterns of RNA expression, consistent with established literature on *BAP1* loss and serving as a baseline for comparison for the biological effects of *BAP1* loss in other less-studied cancer types. The *BAP1* altered scores for 66% of cancer types were positively correlated with the UVM *BAP1* altered signature, suggesting shared biological responses and affected pathways including immune responses, epithelial-mesenchymal transition, oxidative phosphorylation, and proliferation – all known roles of *BAP1*. In LIHC, we noted enrichment of bile duct gene expression in *BAP1*-altered tumors, suggesting a possible role for *BAP1* in maintaining cell identity distinguishing hepatocytes and cholangiocytes. Our findings broadly emphasize the improvements that are gained by using new computational approaches in large cancer-genome studies such as TCGA.

#0875 Quantitative systems pharmacology modeling of loncastuximab tesirine combined with mosunetuzumab and glofitamab helps guide dosing for patients with DLBCL.

Y. Li[1], **A. K. Wilkins**[1], T. Knab[1], J. P. Boni[2];
[1]Metrum Research Group, Tariffville, CT, [2]ADC Therapeutics America, Murray Hill, NJ

Introduction: CD19 and CD20, B-lymphocyte surface antigens, are clinically validated therapeutic targets for the treatment of B-cell malignancies. Loncastuximab tesirine (loncastuximab tesirine-lpyl [Lonca]) is an antibody-drug conjugate comprising an anti-CD19 antibody conjugated to a pyrrolobenzodiazepine dimer cytotoxin. Mosunetuzumab (Mosun) and glofitamab (Glofit) are CD20 × CD3 T-cell-engaging bispecific antibodies (bsAbs) that redirect T cells to eliminate malignant B cells. These agents target a different B-cell surface antigen than Lonca; hence, combining Lonca with either one of these bsAbs is expected to have additive or even synergistic efficacy. Previously, a novel physiologically-based pharmacokinetic (PBPK)-quantitative systems pharmacology (QSP) model was developed (Utsey K, et al. *Clin Pharmacol Drug Dev*. 2023;12:123-125) and validated with Lonca monotherapy clinical observations in R/R DLBCL (Caimi P, et al. *Blood*. 2022;140:9548-9550). Modeling results of Lonca in combination with Mosun or Glofit in R/R DLBCL are described herein.

Methods: The model was based on the previously validated and published Lonca PBPK-QSP model. This model was reduced in physiological complexity to be compatible with a published minimal PBPK model of Mosun (Hosseini I, et al. *NPJ Syst Biol Appl*. 2020;6:28) while maintaining the core functionality of predicting tumor dynamics during Lonca monotherapy. The following assumptions were made: (1) Lonca or Mosun/Glofit induce healthy and malignant B-cell killing; (2) the tumor comprises malignant B cells and T cells; (3) tumor volume is calculated using malignant B-cell number; and (4) T cells can enter or leave the tumor as they enter or leave other tissues.

Results: Improved tumor growth inhibition (TGI) should result from Lonca + bsAb combination therapy compared with any of the agents as monotherapy. While TGI was predicted to plateau by Cycle (C) 2 with Mosun and Glofit monotherapies, maximum activity of Lonca + bsAb combination therapies may not be observed until C4 or later. Additionally, predicted TGI increased with additional treatment cycles.

Conclusions: Results indicate that treatment by the end of C3 for Lonca + Mosun and by the end of C4 for Lonca + Glofit would promote substantially more TGI compared with any of these agents alone. Increased doses of Lonca in combinations were predicted to have limited additional therapeutic benefit; however, additional cycles of combination treatment were predicted to increase TGI. This model suggests that Lonca doses could be reduced to allow for improved tolerability for longer periods of time, up to the point of maximal benefit, although clinical testing is needed to explore these results. The ongoing LOTIS-7 clinical trial (NCT04970901) evaluates the safety and anticancer activity of Lonca in combination with both Glofit and Mosun.

#0876 *spatialGE*: Empowering researchers to study the tumor microenvironment leveraging spatial transcriptomics.

O. Ospina, R. Manjarres-Betancur, G. Gonzalez-Calderon, A. C. Soupir, I. Smalley, K. Tsai, J. Markowitz, A. Berglund, X. Yu, B. L. Fridley;
Moffitt Cancer Center, Tampa, FL

The use of single-cell RNA-seq (scRNA-seq) to understand the complexity of the tumor microenvironment (TME) has been pivotal in advancing cancer research and treatment strategies. Nevertheless, locating the individual TME components in their spatial contexts is essential to understanding the complexity of the TME, tumorigenesis, metastasis, and drug response. The recent popularity of spatially resolved transcriptomics (SRT) allows researchers to describe the TME and their spatial neighborhoods; however, SRT data analysis can be challenging for non-data scientists. Thus, we have developed *spatialGE*, a point-and-click web application designed to empower researchers in the analysis of SRT data. Our application offers a suite of functionalities, including the visualization of spatial gene expression activity maps, quantification of the spatial heterogeneity, testing of pathway-level spatial aggregation, tissue domain/niche detection, detection of spatial gradients in expression patterns, and differential expression analysis. Furthermore, *spatialGE* allows direct comparative analysis of gene expression with the morphology in tissue images, as well as methods for cell/domain phenotyping. Data input has been streamlined and made flexible to receive outputs from multiple SRT platforms. Analyses and results are stored within user-defined projects to facilitate accessibility at any time. We demonstrate the usefulness of *spatialGE* through its application to leptomeningeal metastatic melanoma (LMM) tissues assayed with the Visium platform. The gene expression tissue domain detection and gradient analysis in *spatialGE* indicated that *SERPINA3* expression is higher in tumor regions closer to stroma. This finding led to cell culture experiments indicating that knocking down *SERPINA3* results in the sensitization of tumors to MAPK-targeting therapy. These results highlight the utility of *spatialGE* for exploring SRT data and the empowerment of cancer researchers to explore the spatial architecture of the TME.

#0877 Molecular and radiographic profiling of lung cancer in never-smokers.

M. Lee[1], A. Yadav[2], G. Liu[1], S. Dubinett[3], J. Beane[1], W. Hsu[3], A. Prosper[3], D. Aberle[3], M. Lenburg[1];
[1]Boston University Chobanian & Avedisian School of Medicine, Boston, MA, [2]University of California, Los Angeles, Los Angeles, CA, [3]David Geffen School of Medicine at UCLA, Los Angeles, CA

Gene expression changes in nasal and bronchial epithelium, and quantitative features from chest CT reflect the presence of lung cancer in current and former smokers and can serve as biomarkers. Between 10-20% of lung cancer cases are diagnosed in patients who have never smoked (<100 lifetime cigarettes) and biomarkers could assist the diagnosis of pulmonary nodules discovered incidentally in this population. We compared lung cancer-associated gene expression and radiomic features in never-smokers and ever-smokers. Nasal epithelial RNA was isolated and sequenced from brushings collected at UCLA from 73 patients presenting to interventional radiology for biopsy for suspected lung cancer. *Limma* was used to identify genes with lung cancer-associated expression in never-smokers by comparing 13 patients with benign nodules with 14 patients diagnosed with lung cancer. Similarities between cancer-associated genes in never-smokers and those previously identified in ever-smokers were assessed by gene set enrichment analysis (GSEA). Next, using all 73 samples, genes whose lung cancer-associated expression is modified by smoking status were identified via an interaction term. Radiomic features for 46 patients (31 ever-smokers, 15 never-smokers) were extracted using *PyRadiomics*, including features from the interior of the nodule and perinodular features generated 10, 15, and 20 mm away from the boundary of the nodule. A binomial model was used to identify features with a significant interaction effect between cancer and smoking status. We identified 74 genes decreased and 84 genes increased in cancer in never-smokers ($p < 0.005$), controlling for age and median TIN. Genes changed in ever-smoker lung cancer patients were significantly enriched among the genes most associated with lung cancer in never smokers (GSEA; $p = 0.0059$ and $p = 4.38e\text{-}15$). Next, there were 51 genes with a p-value < 0.01 for the cancer*smoking interaction term. Lastly, four radiomic features were associated with the perinodular term for cancer and smoking status (FDR< 0.2), including two nodular and two boundary features. These results suggest that lung cancer-associated gene expression differences in ever-smokers are preserved in never-smokers, suggesting the potential relevance of previously derived biomarkers for this population. There may also be never-smoker-specific gene expression patterns associated with lung cancer. Our radiomic findings suggest that both nodular and perinodular characteristics may be important predictors of malignancy.

#0878 Enhancing single-cell RNA sequencing analysis in cancer research: A machine learning framework based on LightGBM for automated cell type annotation.

T. Chuang[1], L.-C. Lai[2], T.-P. Lu[3], M.-H. Tsai[4], H.-H. Chen[5], E. Chuang[1];
[1]Graduate Institute of Biomedical Electronics and Bioinformatics, National Taiwan University, Taipei, Taiwan, [2]Graduate Institute of Physiology, College of Medicine, National Taiwan University, Taipei, Taiwan, [3]Institute of Health Data Analytics and Statistics, National Taiwan University, Taipei, Taiwan, [4]Institute of Biotechnology, National Taiwan University, Taipei, Taiwan, [5]Institute of Computer Science and Information Engineering, National Taiwan Normal University, Taipei, Taiwan

Single-cell RNA sequencing (scRNA-seq) has been widely used in cancer research to understand the complex gene expression diversity and cancer heterogeneity. However, manual annotation of cell types in the scRNA-seq pipeline is time-consuming and depends on the expertise of analyzers, which can significantly influence the results of downstream analyses. To address this problem, we proposed a novel machine learning framework utilizing the LightGBM model for automated and efficient cell-type annotation of scRNA-seq.
Two independent scRNA-seq datasets of non-small cell lung cancer (NSCLC) downloaded from the Gene Expression Omnibus (GEO) were used to train and test our model. A standard procedure is applied to both scRNA-seq datasets for quality control and preprocessing, in which poor-quality cells with low gene expressions or high scores for cellular stress/death were excluded. In addition, Harmony is applied to mitigate batch effects in scRNA-seq that could cause variability due to non-biological factors in experiments. Nine different cell types, including endothelial, epithelial, fibroblast, macrophages, mast, plasma, pulmonary alveolar, B, and T cells, were manually labeled in the two datasets by the providers, which were also examined using gene markers corresponding to different cell types from PanglaoDB and DAVID. These manually labeled cell types were used as the ground truth for training and testing our model. In the training stage, the training dataset (containing 85,000 cells from 44 NSCLC samples) of scRNA-seq was used to train the LightGBM model with its high-variable genes. Then, the model would be evaluated using an independent test dataset (containing 8,000 cells from 18 NSCLC samples) by comparing the automatically predicted and manually labeled cell types.
The training result showed that our model could successfully specify the nine different cell types, achieving an overall average accuracy, F1 score, and precision of 0.86 each respectively. In the independent dataset test, the model demonstrated good generalization, showing high predictive performance across all cell types, with an average accuracy, F1 score, and precision of 0.8, 0.78, and 0.8, respectively. Specific to the predictions in the test dataset, we found that some epithelial cells were mistakenly identified as other cell types. This might be because of the complex gene expression patterns exhibited by tumor epithelial cells, making accurate predictions challenging.
The proposed machine learning framework facilitates cell labeling and unravels the intricate heterogeneity within lung cancer datasets. The combination of LightGBM and standardized preprocessing establishes a benchmark for high-throughput, accurate single-cell analysis, paving the way for discoveries that are more targeted and have significant clinical impact.

#0879 The AVERON Notebook to discover druggable cancer dependencies through the mutant-directed protein-protein interactions.

H. Chen, S. Yeung, B. Revennaugh, H. Fu, A. A. Ivanov;
Emory University, Atlanta, GA

Cancer is a devastating disease that takes more than 10 million lives every year. The genomic alterations, such as mutations in cancer driver genes, can disrupt the essential networks of protein-protein interactions (PPIs), dysregulating major oncogenic pathways and inducing the transformation. While some mutations can disrupt existing PPIs, others can create neomorph PPIs (neoPPIs), which are unnatural for wild-type counterparts. Discovery of such mutant-created neoPPIs is vital for understanding the molecular mechanisms of mutant-driven tumorigenesis and developing new personalized clinical strategies in cancer. However, systematic experimental interrogation of the clinical significance and biological functions of neoPPIs is highly challenging. To address this critical challenge, we develop a novel computational platform called AVERON Notebook for identifying new Actionable Vulnerabilities Enabled by Rewired Oncogenic Networks. The AVERON employs specially designed algorithms and statistical techniques to i) Assess and compare the levels of neoPPIs in cancer patients; ii) Examine their impact on clinical outcomes; iii) Identify distinctive sets of signature genes and oncogenic pathways regulated by individual neomorph PPIs; and iv) Discover clinically significant neoPPI-regulated genes with available clinical compounds and approved drugs. Together, the AVERON Notebook provides a powerful tool for exploring the functional consequences of tumor-driving mutations mediated through the neoPPI networks and sheds new light on previously unexplored clinically actionable dependencies enabled by neomorph PPIs in cancer patients. The AVERON Notebook is freely available onGitHub: https://github.com/aivanovlab/averon_notebook and Code Ocean: https://doi.org/10.24433/CO.7986101.v1

#0880 Identifying ANKRD22 and fostamatinib as a theragnostic target and drug candidate for metastatic pancreatic cancer through in silico analysis.
H. T. Huynh, H. G. Lim, Y.-C. G. Lee, C.-H. Chen, A. T. Wu;
Taipei Medical University, Taipei, Taiwan

Introduction: Pancreatic cancer (PC) presents significant clinical challenges, marked by a low 5-year survival rate and frequent distant metastasis. When PC metastasizes to other organs, it leads to a notable decrease in the 5-year survival rate for PC in metastasis, dropping from 11% to 3%. Despite the effectiveness demonstrated by advanced anti-cancer therapies targeting these mutated genes, the improvement in survival rates remains modest. Another critical consideration is the rising resistance to Gemcitabine, a standard drug used for treating PC. Hence, it is imperative to gain a more profound understanding of the comprehensive mechanisms underlying metastatic pancreatic cancer (mPC) and actively explore novel drugs for its treatment. Methods: First, we reanalyzed the RNA-seq of three of PC's most common metastatic sites, including liver, lung, and peritoneum. Using the Galaxy platform, we identified DEGs (differentially expressed genes) between metastatic sites. After that, we further utilized other web-based tools and databases, such as GEPIA, TIMER 2.0, Alphafold, PubChem, Drugbank, and Chembl, to identify ANKRD22 and perform molecular docking of Fostamatinib binds to this gene. Results: Our research focused on exploring the role of ANKRD22, which contains four copies of L-shaped ankyrin motifs, an emerging oncogenic molecule associated with various cancers. In the current study, we identified that ANKRD22 exhibited significant expression in the pancreatic adenocarcinoma (PAAD) cohort, correlating with deteriorating OS rates in PC patients. Moreover, it displayed distinct expression patterns in advanced stages of the disease compared to early stages, Furthermore, we uncovered a noteworthy correlation between ANKRD22 and the Kras, TP53, CDKN2A, and SMAD4 genetic anomaly, linked to diminished survival rates, as widely recognized, in the initiation and progression of PC, these four genes stand out as the most frequently mutated. Mechanistically, ANKRD22 exhibited associations with KRAS dependency signature, U12 type spliceosome assembly, multivesicular body routing, cell invasion, tumor cell line invasion, and tumor cell line migration, all indicative of PC progression and dissemination. Expanding our investigation through the DrugBank and ChEMBL databases, we delved into fostamatinib, an FDA-approved drug known as a spleen tyrosine kinase (SYK) inhibitor. Molecular docking experiments revealed the potential interaction between ANKRD22 and fostamatinib, suggesting its candidacy to treat mPC. Conclusion: Our findings identify ANKRD22 as a pivotal oncogenic factor promoting metastasis in PC and propose fostamatinib as a potential inhibitory treatment.

#0881 Cell-type-specific gene programs suggest immune and stromal drivers of relapse in colorectal cancer.

Nicholas J. Hornstein[1], Mingshuang Wang[2], Abdelrahman Yousef[2], Saikat Chowdhury[2], Fadl Zeineddine[2], Mohammad Zeineddine[2], Mahmoud Yousef[2], Shuangjie You[2], Betul Gunes[2], David Menter[2], Scott Kopetz[2], John Paul Shen[2]

[1]Medical Oncology Fellowship, UT MD Anderson Cancer Center, Houston, TX,[2]GI Medical Oncology, UT MD Anderson Cancer Center, Houston, TX

Background: Molecular profiling of colorectal cancer (CRC) has demonstrated marked heterogeneity between tumors that appear histologically similar. Although existing classification systems such as the Consensus Molecular Subtypes (CMS) have shown clinical utility, these bulk sequencing-based methods fail to adequately address the intra-tumoral heterogeneity of CRC. To disentangle the complex landscape and identify clinically-relevant properties of CRC we generated a single cell sequencing (scRNASeq) database from 225 tumor samples derived from resection of primary colon or liver metastases. Our analysis defines cell-type-specific gene programs significantly associated with relapse and survival and suggests interventions which may abrogate their effect.
Methods: Utilizing a bio-repository of CRC specimens with an average of 5 years of clinical follow-up, we performed scRNASeq on 225 patient samples comprising ~ 1,000,000 total cells and 2.4 billion gene expression measurements. Following traditional clustering approaches, we then inferred gene expression programs through consensus non-negative matrix factorization (cNMF) to characterize cell activities. Gene program activity was explored on a cell-type-specific level and associated with clinical outcomes such as relapse. Treatment effects were additionally explored.
Results: We identified 56 cell-type specific gene programs significantly associated with relapse in adult CRC patients. Interestingly these programs spanned all cellular compartments with the majority found in stromal or immune, as opposed to tumor cells. Program activity such as the non-canonical Granulocyte Chemotaxis program in B Cells was protective of relapse (relapse median expression 0% activity vs non-relapse activity 40% pAdj $<.05x10^{50}$) whereas the Epithelial Mesenchymal Transition (EMT) program in Cancer Associated Fibroblasts (CAF) was strongly associated with relapse (relapse median expression 16% activity vs non-relapse activity 0% pAdj $<.05x10^{10}$). Cumulative program usage enabled stratification on a patient level to provide an estimate of comparative disease free survival (DFS) and overall survival (OS); gene-programs were significantly associated with outcomes such as the CAF-EMT program which was associated with a DFS HR of 3 (pAdj <.0005). Responses to chemotherapy and treatment effect were also explored; prior treatment with Bevacizumab was associated with a significant reduction in the CAF-EMT program (11% activity in non-exposed patients versus 0% activity in exposed patients pAdj $<.05x10^{10}$).
Conclusions: Analysis of the largest CRC scRNASeq cohort to date identifies a number of previously undescribed cell-type specific gene programs significantly associate with relapse after surgery. These programs provide insights into the underlying mechanisms and suggest that the TME plays an important role in relapse.

#0882 Harnessing single cell multi-omics data to identify predictors of clinical outcome in CD19 CAR T cell therapy.

R. Y. Louie[1], J. Samir[1], C. Cai[1], H. McGuire[2], T. Amos[3], J. Fergsuson[3], I. Deveson[3], T. Adikari[1], M. Bonomi[4], D. Bishop[5], C. E. Mason[6], R. Balderas[7], M. Ruella[8], M. Singh[3], D. Gottlieb[2], E. Blyth[2], K. Micklethwaite[1], **F. Luciani**[1];

[1]UNSW Sydney, Sydney, Australia, [2]University of Sydney, Sydney, Australia, [3]Garvan Institute, Sydney, Australia, [4]University of Bologna, Bologna, Italy, [5]University Sydney, Sydney, Australia, [6]Weill Cornell Medicine, New York City, NY, [7]Beckman Dickinson, San Francisco, CA, [8]UPenn, Philadelphia, PA

Background: Chimeric antigen receptor (CAR) T cell therapy is effective in treating B-cell malignancies, but factors influencing the persistence of functional CAR^+ T cells, such as product composition, patients' lymphodepletion, and immune reconstitution, are not well understood. To shed light on this issue, we conducted single-cell multi-omics analysis of transcriptional, clonal, and phenotypic profiles from pre- to 1-month post-infusion of CAR^+ and CAR^- T cells from patients who received a donor-derived 4-1BB CAR product targeting CD19.

Methods: Longitudinal blood samples and infusion products were obtained from 10 individuals with large B cell lymphoma or B-cell acute lymphoblastic leukemia (CARTELL cohort in Sydney Australia[1]). $CD45^+$ cells and enriched CAR+ T cells were single cell sorted for simultaneous scRNA-seq, 41 barcoded proteins (N=41) and T cell receptors, n= 115,000 cells across 21 samples. Machine learning methods were used to identify subsets of immune cells associated with clinically relevant parameters.

Results: Following infusion, CAR^+ and CAR^- T cells showed similar differentiation profiles with clonally expanded populations across heterogeneous phenotypes, demonstrating clonal lineages and phenotypic plasticity. These findings were validated by performing the same analysis on two publicly available scRNA-seq data sets from two cohorts [2, 3] of paediatric (N=18) and adult (N=32) individual with large B cell lymphoma who received CAR19 T cells. Analysis of mass-cytometry data from our cohort and from 28 patients with B cell lymphoma treated with commercial CAR19 T cells (axi-cel)[4], identified an association of CAR^- and also CAR^+ T cells, both expressing an $2B4^- CD11b^+ CD8^+$ phenotype, with complete remission or progressive disease at 3 and 6 months post-infusion. Finally, we report additional analysis on the immunogenomics of circulating CAR T cells in two patients who developed CAR T cell induced lymphoma and compared it with ascites and CAR-Lymphoma cells.

Discussion:These results suggest that CAR^+ and $CAR^- CD8^+$ T cells share a differentiation trajectory terminating in an NK-like phenotype that is associated with clinical outcome, and that non-CAR-derived signals may influence patients' immune recovery and outcomes.References

#0883 Genetic characteristics between males and females with urothelial bladder cancer.

R. Nair[1], R. Khalife[2], A. Magliocco[2];
[1]University of Central Florida, Orlando, FL, [2]Protean BioDiagnostics, Orlando, FL

Urothelial bladder cancer (UBC) affects the epithelial cells of the urinary tract and is the most common type of bladder cancer worldwide. Statistically, males are four times more likely to develop UBC than females. It is known that decreased expression of the KDM6A gene, coded on the X chromosome, corresponds with a higher incidence of UBC. KDM6A mutations are known to be more prevalent in females with non-muscle-invasive UBC. These mutations are targetable by inhibiting EZH2, an enzyme coded by its namesake gene. On the environmental side, males are at a higher risk of developing carcinogenic complications due to smoking and environmental toxins. However, this discrepancy fails to exist when comparing males and females who smoke similar levels. Though environmental factors may play a role in influencing behavior and altering levels of risk to develop UBC, research suggests that they do not single-handedly explain sex-based disparities in UBC. In this study, we characterize the molecular mechanisms associated with altered overall survival by uncovering previously unreported data on the expression of KDM6A and FGFR3, a commonly altered oncogene, in UBC patients. Our in silico approach consisted of broad survival data analysis through cBioPortal (n=1486), sequencing-based gene expression data through ICGC Portal (n=295), and single nucleotide polymorphism identification with the PLCO Atlas (n=69,429). The 5-year overall survival (OS) curves of 13 therapeutic and/or significantly altered genes between males and females were analyzed. BRCA2 was the only gene associated with worse survival for females with alterations. Interestingly, males with alterations to the following genes had significantly better OS outcomes: ERCC2, KDM6A, BRCA2, FGFR3. However, there was no gene whose alterations were associated with significantly better OS outcomes for females. KDM6A and FGFR3, two genes whose alterations are typically associated with worse OS outcomes in males, exhibit the opposite effect. Additionally, males exhibited significantly worse OS outcomes when presenting with CDKN2A and CDKN2B alterations, while females exhibited significantly worse OS outcomes when presenting with CDKN2A and NTRK1. A majority of European males had SNPs on the following genes: CDKN2B, ERBB2, CREBBP, while a majority of European females had SNPs on BRCA2. Differential expression also revealed 714 genes that were significantly expressed in one sex when compared to the other. Therefore, we suggest that there are unique molecular differences between sex that conflict with previous analyses; further research should be conducted to explore the effect of sex via the tumor-suppressive characteristics of KDM6A as well as oncogenic properties of FGFR3.

#0886 Integrated deep learning model for predicting DNA methylation and tumor types from histopathology in central nervous system tumors.

E. D. Shulman[1], D.-T. Hoang[2], R. Turakulov[1], Z. Abdullaev[1], O. Singh[1], E. M. Campagnolo[1], E. A. Stone[2], M. P. Nasrallah[3], E. Ruppin[1], K. Aldape[1]; [1]NIH-NCI, Bethesda, MD, [2]Australian National University, Canberra, Australia, [3]Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA

Precision in diagnosis of diverse central nervous system (CNS) tumor types is crucial for optimal patient treatment. DNA methylation profiles, which capture the methylation status of thousands of individual CpG sites, are data-driven means to enhance diagnostic accuracy, but this technique is expensive, time-consuming, and not yet routinely available. To address this, we developed DEPLOY, a deep-learning model that predicts 10 major categories of CNS tumors from histopathology. DEPLOY integrates three distinct components: the first classifies CNS tumors directly from histopathology slide images (‘direct model’); the second initially generates predictions for DNA methylation beta values, which are subsequently used for tumor classification (‘indirect model’); and the third classifies tumor types directly from routinely available patient demographics. First, we find that DEPLOY accurately predicted beta values from histopathology images, suggesting that application of inferred methylation data is a promising approach for deep learning histopathology-based classifiers. Using a 10-class model trained on an internal dataset, we apply this model on two independent external test datasets of 1,522 and 348 cases, achieving top-1 accuracies of 96% and 94%, respectively on samples which are predicted with high confidence. Taken together, DEPLOY could assist pathologists in diagnosing CNS tumors, in an equitable very low-cost manner, within a clinically relevant short time frame.

#0887 Fast, interactive, AI-assisted 3D lung tumour segmentation.

M. Patwari[1], Y. Wei[1], M. Xu[1], Z. Zhang[2], K. Sidiropoulos[1], B. Selvaraj[3], G. Hughes[1], N. Garibli[1], K. Ojiako[1], M. Lella[1], L. Fedden[1], J. Parkin[1], M. Parker[1], S. Patel[1], Q. Li[4], K. Patwardhan[4];

[1]ASTRAZENECA UK LIMITED, Cambridge, United Kingdom, [2]ASTRAZENECA, Gaithersburg, MD, [3]ASTRAZENECA AB, Gothenburg, Sweden, [4]ASTRAZENECA, Waltham, MA

Segmentation of lung tumors is an important step in the planning of clinical treatment and operative procedures. Automatic segmentation of advanced lung tumors is challenging due to local invasion and heterogeneous metastasis. Fully automatic deep learning models often fail to accurately delineate advanced disease boundaries and do not allow the user to provide hints to improve segmentation performance. In contrast, interactive segmentation accepts user inputs and is an efficient way to segment lesions while reducing radiologist effort.

This paper describes an interactive segmentation approach for lung lesion segmentation in CT scans. Our pipeline is built atop the SwinUNETR neural network architecture and can be expanded to support alternate models. The backbone model accepts radiologists' hints in the form of mouse clicks that indicate whether a location on the scan corresponds to a lesion. Our approach has the following novel contributions: (1) Context-aware encoding of guidance clicks by combining geodesic and Gaussian smoothing, resulting in improved segmentation of lesion boundaries. (2) An iterative prompting strategy to achieve higher accuracy with fewer clicks at inference time. (3) Guidance-aware Conditional Random Fields to refine the produced segmentation masks. (4) Volume cropping around guidance clicks at inference to improve segmentation precision and inference speed. (5) Linearly scaling our approach on multiple GPUs, to improve inference speed.

On a public non-small cell lung cancer dataset predominantly containing advanced stage cancers (68\% stage III, and 27\% stage IV), our interactive approach delivers a Dice score of 0.74 with a single click, a 21\% improvement from the fully automatic approach (Dice Score = 0.61), and a Dice score of 0.81 with 5 clicks, which is a 33\% improvement. Inference speed is an important metric for an interactive pipeline. On a typical 350 $\times$ 350 $\times$ 150 voxel chest CT scan volume, our interactive approach infers 5 times faster than the original fully automated approach on a single GPU. After scaling to 4 GPUs, we infer in only 0.5 seconds; 20 times faster than the original approach. Qualitative evaluation from three independent radiologists indicates that our interactive pipeline significantly improved their standard clinical segmentation experience.

#0888 Uncovering clinically relevant omics signatures from pan-cancer imaging and multi-omics data integration.

J. Wang, R. Hong, J. Tan, W. Liu, D. Fenyò;
NYU Grossman School of Medicine, New York, NY

Despite advancements in deep learning for histopathology, integrating these insights with multi-omics data to uncover clinically relevant omics pathway-level signatures remains a challenge. Our study addresses this gap by applying unsupervised learning techniques on pan-cancer multi-omics data, leveraging 3,080 Hematoxylin and Eosin (H&E) images from 1,010 patients in Clinical Proteomic Tumor Analysis Consortium (CPTAC) to uncover omics pathway-level signatures that drive discernable morphology phenotypes at the tissue level. First, imaging models were trained to predict clinical and mutation outcomes, and thereafter, integrated with transcriptomic and proteomic expression data using sparse canonical correlation analysis. Our findings reveal that images of TP53 mutated samples exhibited increased nuclear size and dense lymphoplasmacytic infiltration. These morphological changes correlated with neutrophil and macrophage signaling at the proteomic level, and IL-1 mediated signaling at the transcriptomic level, highlighting the complementary perspectives different omics can provide. To further elucidate immune interactions, we applied multi-omics deconvolution to identify 7 immune subtypes, characterizing each with gene set enrichment, germline DNA variations, and kinase activations. We show that imaging models trained to predict these subtypes differentiate tissue morphologies corresponding to immune enrichment (AUROC: 0.84). To further confirm the robustness of our approach, we trained models to predict co-regulated proteomic modules clustered by independent component analysis. We demonstrate a signature in pan-squamous tumors, consisting of T cell markers and interferon-gamma response proteins like CD4, CD48, and GBP5, which imaging models can successfully predict from histopathology. Manual review from pathologists confirmed lymphocytic T-cell density as a differentiator in samples with the highest and lowest T-cell signaling.
Together, these approaches demonstrate that genomic characteristics discovered via unbiased mining of pan-cancer multi-omics data manifest as quantitative imaging phenotypes. These results underscore the potential of multi-omics and digital pathology to integratively uncover and confirm new cancer biology. Our ongoing work will explore predicting drug response and survival from morphology patterns related to multi-omics signatures.

#0889 Machine learning-enhanced targeted versus whole-exome sequencing as a guide to cancer care.

H. Woo, S. S. Chavan, A. J. Hanrahan, A. L. Richards, A. Noronha, A. Zehir, A. Drilon, M. F. Berger, D. B. Solit, M. T. A. Donoghue;
Memorial Sloan Kettering Cancer Center, New York, NY

Targeted DNA sequencing of cancer-associated genes has been widely adopted clinically. In addition, the increasing availability of targeted and whole-exome/genome sequencing (WES/WGS)-derived big data suggests avenues of computationally enhancing power of targeted assays via machine learning. We directly compared targeted (MSK-IMPACT) and WES in a cohort of 1,483 cancer patients using the same DNA libraries. We found high sensitivity and specificity of mutation detection by WES for overlapping genes. Comparatively higher estimates of tumor mutation burden by MSK-IMPACT arose from enrichment of oncogenic mutations in the targeted gene set. WES had minimal value in identifying actionable alterations beyond those from MSK-IMPACT, whereas RNA-sequencing identified additional targetable fusions that led to durable responses. We developed a deep learning-based algorithm (DeepSig) that enhances power of mutational signature detection, enabling detection of a select group of signatures with mutation counts of ~5 or less. Hypermutation-associated signatures, including POLE, temozolomide, and mismatch repair deficiency could be detected robustly using targeted sequencing data. In summary, WES had limited clinical value over targeted sequencing panels and future clinical diagnostic development should focus on transcriptome and WGS that can detect additional signatures and gene fusions.

#0890 Multimodal modeling of digitized histopathology slides improves risk stratification in hormone receptor-positive breast cancer patients.

K. M. Boehm, A. Marra, J. S. Reis-Filho, S. Chandarlapaty, F. Pareja, S. P. Shah;
Memorial Sloan Kettering Cancer Center, New York, NY

In early-stage hormone receptor-positive breast cancer, genomic risk scores identify patients who stand to benefit from up-front chemotherapy but introduce financial and logistical hurdles to care. We assembled a cohort of 5,244 patients with 11,671 corresponding whole-side images of breast tumors stained with hematoxylin and eosin. We developed a multimodal machine learning model to infer risk of distal metastatic recurrence from routine clinical data. Specifically, the model interprets text from the pathologist's report using a large language model and uses self-supervised vision transformers to interpret the corresponding whole-slide image. Tensor fusion joins the modalities to infer Genomic Health's Oncotype DX recurrence score. Inferred recurrence score from the multimodal model correlated with measured score with a concordance correlation coefficient of 0.64 (95% C.I. 0.59 - 0.69) in the withheld test set, compared to 0.55 (95% C.I. 0.49 - 0.61) and 0.56 (95% C.I. 0.52 - 0.60) for the linguistic and visual unimodal models, respectively. The multimodal model attains an area under the precision-recall curve (AUPRC) of 0.69 (AUROC=0.88) for identifying high-risk disease in the full-information setting (when images and pathology reports with quantitative hormone receptor status and grade are available) in a withheld test set, compared to AUPRC of 0.61 and 0.66 for the linguistic and visual models, respectively. By comparison, in the same full-information setting, the clinical nomogram introduced by Orucevic et al. in 2019 achieves an AUPRC of 0.48. We suggest the operating point at which precision is 94.4% and recall is 33.3%. Digitized whole-slide images of routine breast biopsies and their associated synoptic pathology reports contain much of the information necessary to stratify patients by risk of distal metastatic recurrence, when modeled appropriately. Our model could enable hospitals to rapidly triage the need for genomic risk testing, possibly precluding one third of orders without loss of accuracy. This helps allocate scarce resources for genomic tests and valuable weeks prior to beginning therapy while maintaining the standard of precision oncology.

#0891 Turning data into information: Using PD3D® models to guide colorectal cancer therapy by Optim.AI™.

Ulrike Pfohl[1], Masturah Mohd Abdul Rashid[2], **Jhin Jieh Lim**[2], Juergen Loskutov[1], Lena Wedeken[1], Edward Kai-Hua Chow[3], Hugo Saavedra[2], Christoph Reinhard[1], Christian R. A. Regenbrecht[4]

[1]CELLphenomics GmbH, Berlin, Germany,[2]KYAN Therapeutics, Singapore, Singapore,[3]Cancer Science Institute of Singapore, Singapore, Singapore,[4]ASC Oncology GmbH, Berlin, Germany

Colorectal cancer (CRC) is one of the most prevalent and lethal malignancies globally with up to 50 % of patients eventually progressing to metastatic disease. The mitogen-activated-protein kinase (MAPK) pathway emerges as a key player, being one of the most frequently mutated signaling pathways in the oncogenesis of CRC. However, given the numerous genomic aberrations and tumor heterogeneity in CRC, patients may benefit from combinatorial therapies, particularly those who have inoperable or metastatic tumors. In the present study, we investigated the feasibility of combining two platforms, patient-derived 3D (PD3D®) models with Optim.AI™, to identify more effective cancer therapies. PD3D® models can robustly retain the genotypic and histopathologic features of the primary patient tumor, model tumor heterogeneity and were shown to predict a patient's drug response. Optim.AI™ is a hybrid computational-experimental platform that uses small data sets to rationally converge to optimal drug combinations within a defined drug search space. By mapping experimental data points to a second-order quadratic function, Optim.AI™ can predict every possible 531k data points and thus the cell-killing efficacy for all other possible combinations without testing each individual drug-dose combination. Two CRC PD3D® models with different mutation profiles were tested with 155 different combinations of 12 drugs at variant concentrations. The post-treatment cell viability was measured and used for Optim.AI™ analysis to evaluate and compare the best therapies. Optim.AI™ analysis revealed differential drug sensitivity between tested CRC PD3Ds®. The top-ranked drug combinations included SN-38, active compound of commonly used chemotherapeutic irinotecan, paired with MEK-inhibitors trametinib or cobimetinib which we could confirm with both platforms. With this study, we successfully demonstrated the feasibility, the robustness, and the efficiency of combining PD3Ds® and Optim.AI™ in identifying effective drug combination therapies, here for CRC, within one month. This combined technology provides precise insights into tumor treatability and its functional causes of treatment outcomes, leading to new treatment combinations and accelerating the development of new cancer drugs in a time- and cost-effective manner.

#0892 Pan-cancer tumor microenvironment profiling with multiplexed immunofluorescence microscopy and self-supervised learning.

Gantugs Atarsaikhan[1], Isabel Mogollon[1], Katja Valimaki[1], Tuomas Mirtti[2], Teijo Pellinen[1], **Lassi Paavolainen**[1]

[1]Institute for Molecular Medicine Finland (FIMM), University of Helsinki, Helsinki, Finland,[2]University of Helsinki, Helsinki, Finland

Multiplexed immunofluorescence (mIF) microscopy reveals the spatial architecture of cancer tissue and its microenvironment that is not being fully explored with existing analysis methods. Most analysis approaches for mIF microscopy data focus on single-cell or region classification and rely on supervised machine learning. In this work, we present a self-supervised spatial profiling method for mIF images that takes local and global associations into account, and apply this method to profile cancer-associated fibroblasts (CAFs) in a pan-cancer dataset.

We studied a 2-stage self-supervised training scheme to learn the representations of mIF tissue microarray (TMA) images in local and global scales (cellular and long-range associations). During the 1st self-supervised training stage, a Vision Transformer learns the local-scale representations by using small patches from TMA images. Then, the local representations are used as input to the 2nd stage where a similar self-supervised learning strategy is used to learn global patterns in the TMA images.

We applied the method to profile multiple cohorts from three different solid tumors: prostate, renal, and lung cancer. In total, these cohorts include more than 5,000 TMA cores from over 1,750 patients extracted from the tumor center, tumor edge, and adjacent benign areas. The samples were stained with a CAF panel including FAP, aSMA, PDGFRB, pSTAT3/PDGFRA, nuclear and epithelial markers, and imaged with cyclic mIF microscopy.

Samples were studied at the patch-level and TMA core-level. Small patches enable further analysis of associations in the local environment, whereas the core-level enables associations with patient clinical information. Clustering of patch-level (1st stage) and core-level (2nd stage) representations showed independently that self-supervised learning is capable of learning the representations of the mIF images. We were able to identify regions and cases with high pTNM staging from the prostate cancer samples and similar histological subtypes from renal cancer samples. We further validated the clustering using k-NN classification that showed high classification accuracy in all cohorts. Moreover, we developed a stopping criteria for the final model selection that balances between the similarities of samples and patches inside of samples to prevent overfitting.

Our study shows that self-supervised learning enables unbiased discoveries from large-scale mIF microscopy imaging datasets. The developed method uncovers associations between imaging data and clinical information and highlights directly the patterns that are most meaningful for these associations.

#0893 Studying the impact of CNVs on expression at single-cell resolution in HGSOC using autoencoders.

M. Marin Falco[1], T. Narhi[1], E. P. Erkan[2], J. Hynninen[3], A. Vaharautio[1];
[1]University of Helsinki, Helsinki, Finland, [2]Tampere University, Tampere, Finland, [3]University of Turku and Turku University Hospital, Turku, Finland

High-grade serous ovarian cancer (HGSOC) is one of the most lethal gynecological malignancies. Lack of common targetable oncogenic mutations has complicated the development of directed therapies to combat emerging resistance. This malignancy is mainly characterized by the mutation of gene TP53, which promotes genome instability for the emergence of extensive copy number variations (CNVs). However its impact on gene expression at the single-cell level is not well understood. In this study, we aim to investigate the effect of CNVs on transcriptomic signatures by taking advantage of variational autoencoders (VAE) ability for dimensionality reduction, unsupervised learning and feature extraction. The use of VAEs is becoming more popular for the analysis of scRNAseq data, and scVI is one of the most versatile VAE applications performing wide variety of tasks. Here, we used single-cell RNA sequencing (scRNA-seq) data from 90 longitudinal samples of 64 HGSOC patients and inferred CNVs in each cell using inferCNV, an established computational pipeline. Then, we modified scVI algorithm to allow the VAE to reconstruct CNVs from a latent space originated from gene expression profiles and viceversa. Our models were capable of reconstructing CNV profiles accurately from expression data and also remove batch effect. From these models we could observe how, after the integration of genomic information, the latent clusters produced from the transcriptomic space were influenced by the amplifications or deletions of certain genomic regions. Moreover, some of these clusters were characterized by the alteration of important oncogenes in HGSOC, such as KRAS and CCNE1, and allowed us to focus on the transcriptomic consequences of their amplifications. With the results from the approach presented here, we gained a more comprehensive picture of the impact of genomic alterations on HGSOC. As future work, we plan to validate of this results on external cohorts and link the identified signatures to clinically relevant features such as prognosis or chemotherapy response.

#0894 Radiomics at baseline MRI are associated with tumor shrinkage in patients with unresectable renal cell carcinoma treated with neo-adjuvant Cabozantinib.

L. LI[1], E. Nicaise[2], B. Schmeusser[2], A. Midya[1], A. Davarpanahfakhr[1], A. Madabhushi[1], M. Bilen[1], V. Master[2], **R. Shiradkar**[1];
[1]Emory University, Atlanta, GA, [2]Emory University School of Medicine, Atlanta, GA

Background: Neoadjuvant Cabozantinib targeted therapy (nCabo) has been shown to facilitate tumor size reduction in patients with renal cell carcinoma (RCC). However, there is unmet clinical need to identify pre-treatment markers predictive of response to nCabo to limit financial, dose-related toxicity. We investigated computationally derived radiomic signatures from baseline magnetic resonance imaging (MRI) for their association with response to tumor shrinkage following nCabo.**Methods** Seventeen patients with non-metastatic, clinical stage ≥T3, biopsy-confirmed clear cell RCC were enrolled in a phase II clinical trial (NCT04022343) examining primary tumor response to nCabo. Patients underwent 3 Tesla MRI at baseline, 6 and 12 weeks. Partial response (PR) or stable disease (SD) was determined per Response Evaluation Criteria in Solid Tumors at 12 weeks. Tumor regions of interest (ROI) were delineated on axial, arterial phase T1-weighted (T1W) series under the guidance of expert radiologist. T1W were normalized with respect to enhancement in cortex region of kidney. 75 radiomic features quantifying texture heterogeneity were derived from tumor ROI on a per-voxel basis at baseline. Wilcoxon ranksum test was used to evaluate significant differences in radiomics between patient groups PR and SD. **Results**: Following nCabo, 6/17 patients experienced PR. 22 radiomic features from T1W quantifying intensity based heterogeneity showed significant differences between patients with SD and PR after nCabo ($p<0.05$; top 3 in **Table**). None of the clinical variables showed significant differences between SD and PR. **Conclusion**: In this proof-of-concept preliminary study, we observed that radiomics at baseline MRI may allow for identifying RCC patients who would favorably respond to nCabo in terms of tumor shrinkage. Future studies will include analysis on longitudinal data, correlation against survival on large-scale datasets.

#0896 Predicting metastatic transcriptomes of patient tumors with deep learning.

G. Li[1], E. Beal[1], D. Sumner[1], G. G. Galli[1], V. Cremasco[2], J. M. Korn[2], F. Dondelinger[1], **D. Ruddy**[2], A. Kauffmann[1], S. Dimitrieva[1];
[1]Novartis, Basel, Switzerland, [2]Novartis, Cambridge, MA

Metastases are the primary cause of cancer-related death, and improving the means of predicting and targeting their development is one of the major goals in cancer research. While surgical resection and neo-adjuvant therapy can cure well-confined primary tumors, our ability to effectively treat cancer is largely dependent on our capacity to interdict the process of metastasis. The recent accumulation of ‘omics data from metastatic tumors provides an unprecedented opportunity to develop machine learning models to predict the molecular changes during metastasis and explore the patterns of metastasis formation. With this in mind, we developed *MetMapper*, a deep learning model trained on primary and metastatic tumors from > 13 000 patients integrating data from 11 published data resources. MetMapper can predict the transcriptomic changes of a primary tumor when it metastasizes to different distant organs. The results were extensively validated using transcriptomics data from matched primary and metastatic tumor biopsies extracted from the same patients. Furthermore, MetMapper’s predictions revealed that the non-random patterns of cancer metastases can be partly explained by the degree of transcriptome reprogramming needed during metastasis: primary tumors tend to metastasize to organs that require minimal changes to their transcriptomes. Using MetMapper, we derived a metastatic potential score for patient tumors and demonstrate that this score can be used to stratify patients into high and low survival groups across different indications. The predicted metastatic potential of patient tumors significantly correlates with experimentally characterized metastatic potential of cancer cell lines. Additionally, by performing *in-silico* perturbations of genes and oncogenic pathways that can alter the metastatic potential of patient tumors, we identified genomic features that are highly associated with metastases to specific organs, some of which were reported by existing pan-cancer clinical sequencing studies. Our results demonstrate the utility of MetMapper as a novel AI-powered methodology for investigating mechanisms and patterns of metastatic dissemination, as well as forecasting metastatic outcomes of patient tumors.

#0897 Synthetic lethality screening with Recursive Feature Machines.

Adityanarayanan Radhakrishnan[1], Cathy Cai[2], Barbara A. Weir[3], Christopher Moy[4], Caroline Uhler[2]

[1]Harvard University / Broad Institute of MIT and Harvard, Cambridge, MA,[2]Massachusetts Institute of Technology / Broad Institute of MIT and Harvard, Cambridge, MA,[3]Johnson and Johnson Innovative Medicine, Cambridge, MA,[4]Johnson and Johnson Innovative Medicine, Spring House, PA

Synthetic lethality refers to the concept that simultaneous perturbation of gene pairs leads to cell death but individual perturbation does not. Synthetically lethal gene pairs (SL pairs) provide a potential avenue for selective targeting of cancer cells based on underlying genetic vulnerabilities. The rise of large scale gene perturbation screens such as the Cancer Dependency Map (DepMap) offers the opportunity to identify SL pairs automatically using machine learning. Yet, a key difficulty in using machine learning models for this task is the lack of labeled data in the form of known SL pairs. Thus, prior approaches framed SL pair identification as a feature learning problem where the goal is to identify the genomic features most influential for predicting low cellular viability under a gene knockout. These prior approaches have primarily utilized random forests since these machine learning models are one of the only nonlinear models for which feature importances are provided explicitly. On the other hand, if we could identify features learned by state-of-the-art models on screening tasks such as kernel machines, we would be better powered in finding SL pairs. In this work, we present a computationally efficient and effective pipeline for SL pair screening built on a recently developed class of feature learning kernel machines known as Recursive Feature Machines (RFMs). We show that our pipeline more accurately recovers experimentally verified SL pairs than prior work including the best model from the DepMap portal and previous random forest based approaches (see the table below). Moreover, our pipeline identifies several new candidate SL pairs for further analysis, opening new avenues for targeting genetic vulnerabilities in cancer.

Rank of verified SL pairs across unsupervised methods (lower is better with a minimum value of 1).

#0898 Deep learning-based cell types scores in tumor microenvironment estimated by H&E images associated with PD-L1 status in lung adenocarcinoma.

S. Cook[1], H. Shin[1], J. Koh[2], H. Choi[3], K. Na[4];

[1]Portrai, Inc., Seoul, Korea, Republic of, [2]Department of Pathology, Seoul National University Hospital, Seoul, Korea, Republic of, [3]Department of Nuclear Medicine, Seoul National University Hospital, Seoul, Korea, Republic of, [4]Department of Thoracic and Cardiovascular Surgery, Seoul National University Hospital, Seoul, Korea, Republic of

Purpose: The spatial distribution of cell types in the tumor microenvironment (TME) is associated with functional status of tumor immunology and eventually affects the response to immuno-oncology treatment. We have developed a deep learning model that was trained by integrating H&E images of lung adenocarcinoma with spatial transcriptomic data. We applied this model to predict various cell types within the TME using only hematoxylin and eosin (H&E) images to correlate with the PD-L1 status.

Methods: A deep learning model to predict five cell types enrichment score maps from H&E images was trained by spatial transcriptomics data combined with matched H&E images. The five cell types of TME included B cells, T/NK cells, myeloid cells, fibroblasts, and epithelial cells. wAnother dataset based on tissue microarray (TMA) data of H&E images of lung cancer patients (n = 94) was used to predict cell type enrichment scores associated with PD-L1 status estimated by TPS score. The cell type scores derived from the H&E-stained lung cancer images were correlated with the PD-L1 status.

Results: The cell types predicted by the model using H&E image patches showed a significant correlation with those determined through spatial transcriptomic data, serving as an internal validation. All cell types (B cells, T/NK cells, myeloid cells, fibroblasts, and epithelial cells) from TMA cores showed significant differences according to the PD-L1 expression groups. The enrichment scores of B cells, T/NK cells, myeloid cells and fibroblasts were significantly higher in the PD-L1 high group.

Conclusions: Our research introduces a deep learning model for precise cell type mapping within the tumor microenvironment and applied to H&E-stained TMA cores. The relationship between PD-L1 status and the cell type enrichment scores within the tumor microenvironment, as predicted by the deep learning model analyzing H&E images, demonstrates the potential for using H&E-based characterization of the tumor microenvironment as a biomarker in immuno-oncology treatments.

#0899 Development of a deep learning model for cell type mapping in colorectal cancer using H&E images leveraging image-based spatial transcriptomics data.

S. Cook[1], D. Lee[1], M. Lim[1], J. Lee[1], D. Lee[1], H.-J. Im[2], J.-S. Pyo[3], K. Na[4], H. Choi[5];
[1]Portrai, Inc., Seoul, Korea, Republic of, [2]Department of Molecular Medicine and Biopharmaceutical Sciences, Graduate School of Convergence Science and Technology, Seoul National University, Seoul, Korea, Republic of, [3]Department of Pathology, Uijeongbu Eulji Medical Center, Eulji University School of Medicine, Gyeonggi-do, Korea, Republic of, [4]Department of Thoracic and Cardiovascular Surgery, Seoul National University Hospital, Seoul, Korea, Republic of, [5]Department of Nuclear Medicine, Seoul National University Hospital, Seoul, Korea, Republic of

Purpose The tumor microenvironment (TME) is crucial in colorectal cancer as it influences disease progression, treatment response, and patient outcomes, providing valuable insights for personalized therapies and prognostic assessments. Here, we have developed a deep learning model by integrating hematoxylin and eosin (H&E) stained images of colorectal cancer and image-based spatial transcriptomics (Xenium) to infer spatial mapping of cell types in TME only using H&E images.
Methods A total of 30 H&E images of colorectal cancer obtained by tissue microarray were registered with image-based spatial transcriptomics data (Xenium). Utilizing a Variational Autoencoder (VAE) based model and leveraging reference single-cell data enables the acquisition of cell types for individual cells in image-based spatial transcriptomics. A convolutional neural network (CNN) model was developed using H&E image as inputs to predict cell types in H&E-stained tissue image patches of colorectal cancer collected from various patients. The model also estimated the cell types from H&E-stained whole slide tissue image of colorectal cancer of The Cancer Genome Atlas (TCGA-COAD).
Results The accuracy of the model's predictions for cell types using H&E image patches was notably high and exhibited a significant concordance with the results obtained through the validation. The Intersection over Union (IoU) metric for image segmentation indicated a value of 0.66 for epithelial cells and 0.44 for TNK cells. The output of deep learning model for epithelial cells and T/NK cells from TCGA-COAD tissue images showed a correlation with human-labeled regions of cancer epithelium and immune cells.
Conclusions Leveraging image-based spatial transcriptomics, we developed a deep learning model capable of discerning various cell types within the tumor microenvironment solely from H&E images. This clinically translatable approach is valuable for investigating tumor microenvironment to develop biomarkers associated with various cancer therapeutics particularly immuno-oncology drugs. This approach can yield objective deep learning-based models without human labels for characterizing the tumor microenvironment in single-cell resolution, particularly regarding spatial immune distribution.

#0900 Development and validation of an artificial-intelligence-based pathomics biomarker to predict resistance to first-line treatment in metastatic colorectal cancer.

Background: The backbone chemotherapy of first-line standard of care (SOC) for microsatellite stable (MSS) metastatic colorectal cancer (mCRC) combines 5-Fluorouracil to oxaliplatin and/or irinotecan. There are no biomarkers to predict response, which is complete or long-lasting (CR/LLR) in 20-25% of patients, while 10-15% are primary refractory. The aim of this work is to develop a predictive biomarker, based on digital pathology images, that can help stratify patients according to their risk of resistance.

Methods: We trained a supervised bag-of-words artificial intelligence (AI)-based model on a cohort of response outliers mCRC patients classified as “really sensitive” (RS) if they achieved CR or LLR >10 months to any SOC, or “really resistant” (RR) if progression occurred at first disease reassessment. Whole-slide Imaging (WSI) of the resected primary tumors were tiled into patches of 224x224 pixel (0.5µm/pixel). First-order and texture features were subsequently extracted from all tumoral tiles and grouped into homogenous clusters through a k-means algorithm (k=6). For each patient, the percentage of tiles belonging to each tiles’ cluster was computed to represent new features (called bag of words) with whom different machine learning classifiers were trained. Main clinicopathological features were matched to treatment response by Fisher’s exact test.

Results: To date, we analyzed 82 response outlier patients, of whom 35 were classified as RS and 46 RR. Of them, patients identified at Italian centers were used as construction cohort (N=47; 27 RR and 20 RS) and those identified at Spanish centers were used a validation cohort (N=35; 19 RR and 16 RS). The best result was obtained using a stepwise logistic regression, reaching a negative predictive value (NPV) of 90% (18/20; 95% CI=70-97%) and 71% (10/14; 95% CI=49-87%), in the construction and validation sets. No standard clinicopathological features (including stage, *RAS/BRAF* status, histology and sidedness) was associated with the chance of being RR.

Conclusions: We demonstrated that a pathomics signature has the potential to predict resistance to SOC in MSS mCRC. Further validation of these preliminary findings on a larger cohort of response outlier patients is ongoing.

#0901 BATCHIE: An active learning platform for scalable combination drug screens.

C. Tosh[1], M. Tec[2], J. White[1], J. F. Quinn[1], G. Ibanez Sanchez[1], P. Calder[1], A. L. Kung[1], F. S. Dela Cruz[1], W. Tansey[1];
[1]Memorial Sloan Kettering Cancer Center, New York, NY, [2]Harvard University, Cambridge, MA

Large-scale combination drug screens are largely considered intractable due to the immense number of possible combinations. Existing approaches use ad hoc fixed experimental designs then train machine learning models to impute novel combinations. We introduce BATCHIE, an orthogonal approach that adaptively conducts experiments in batches. BATCHIE uses information theory and probabilistic modeling to design each batch to be maximally informative based on the results of previous experiments. BATCHIE is fully modular, allowing any Bayesian probabilistic model to be used and any study constraints to be incorporated while maintaining optimality guarantees.

Results: In retrospective simulations on public combination screens, BATCHIE saved 10s of thousands to 100s of thousands of experiments relative to non-adaptive baselines. We conducted a prospective study focusing on pediatric sarcomas with BATCHIE. Our study covered 16 cell lines spanning Ewing sarcoma (EWS), osteosarcoma, rhabdomyosarcoma, as well as non-sarcoma cancers and non-cancer lines. We used a drug library of 206 drugs at two doses. After 15 rounds of BATCHIE-driven data collection, we observed 54K unique combinations, covering 4% of the experimental landscape. On unobserved validation data, the BATCHIE model predictions were highly accurate (Pearson's rho=0.91, p<10-30) and detected the rare (0.004%) combinations with significant synergy (AUC of ROC=0.85, p<10-5). We further investigated 10 combinations that BATCHIE predicted to have high therapeutic index (TI) for a broad selection of EWS lines, meaning a large differential effect between the predicted viabilities of the control lines and the target lines. We found that the TI scores for the top hits were significantly larger than the rest of the screen ($p<10^{-}50$), with the median top hit TI score lying in the 98th percentile of observed TI scores. We further validated 6 of the top hits in an ex vivo study on 2 patient-derived EWS samples, again finding significantly large TI values (p<10-13), with the median ex vivo TI score lying in the 96th percentile of observed TI scores. The top hits also exhibited biologically plausible rationales including combining PARP inhibitors with topoisomerase 1 inhibitors and alkylating agents, despite our model utilizing no prior knowledge on the molecular targets of our drug library. Combining PARP inhibitors with topoisomerase 1 inhibitors comprise 3 of the 6 currently open phase II clinical combination trials for EWS.

#0902 Explainable AI: Graph machine learning for response prediction and biomarker discovery.

J. Cohen-Setton[1], K. Bulusu[1], J. Dry[2], B. Sidders[1];
[1]AstraZeneca UK, Cambridge, United Kingdom, [2]Tempus AI, Boston, MA

Accurately predicting drug sensitivity and understanding what is driving it are major challenges in drug discovery. Graphs are a natural framework for capturing diverse pharmacological data for efficacy predictions, thanks to their ability to integrate multimodal data and represent relationships such as gene-gene or drug-target interactions as edges. They have also had proven success across a range of other drug discovery tasks including repositioning and target identification. In this study, we sought to address the explainability challenges of drug response predictions. Recent developments in the field of Graph AI have led to improvements in interpretability mechanisms that highlight parts of a graph which are driving predictions. We have conducted a comprehensive review of multiple major approaches for tackling drug efficacy prediction using graph methods, benchmarking the performance and interpretability of these algorithms across indications.

Methods: We assembled a combined dataset of GDSC1 and GDSC2 drug response data in cell lines, with multiomic cell line data and drug target and chemical structure data. We then applied graph-based approaches for the prediction of binarized IC50 on an indication-by-indication basis. Approach 1 involved the creation of a ‘GDSC knowledge graph’, where drug response and cell line ‘omic information is represented in an unweighted knowledge graph: cell lines are connected to genes expressed in them, drugs are connected to genes they target, and so on. We then used state-of-the-art graph embedding techniques to predict IC50 using paired drug and cell line embeddings. In Approach 2 we used a weighted knowledge graph instead, and generated embeddings using heterogeneous graph neural networks (HGNNs). In Approach 3, we modelled response prediction as a graph classification task, where one single graph captures one drug-cell line interaction. The graph classifier and HGNN models both have in-built interpretability mechanisms, including graph attention, that can signify the genes in the cell line which were most important for the eventual prediction. We can also integrate biomedical prior knowledge with all these models by capturing gene-pathway and gene-gene data in the graphs.

Results: Our models outperformed benchmark models including DNNs and GBMs, and identified both established and novel response biomarkers in NSCLC cell lines (AUC = 0.94, Accuracy = 89%). We have also applied our models to Breast Cancer, Pancreatic Cancer, Colorectal Cancer and Haematological malignancies with similar predictive performance and explainability.

Conclusions:Our graph analytical framework for response predictions showed better performance than benchmarking models and provided insights from explainability. This framework is easily extendable to response and ‘omic data from any disease model and patient studies.

#0903 AURIGIN: A comprehensive single-cell OMICs atlas of human development and an AI/ML framework to classify and identify the drivers of tumor plasticity and altered cellular state.

J. DeBartolo III, H. Wilson, K. S. Straley, M. Bhatta, S. Sharma, S. Sinicropi-Yao, J. Neef, B. Chan, A. McRiner, M. Bittinger, L. Antipov, K. E. Yen, T. G. Graeber, D. S. Millan;
Auron Therapeutics, Newton, MA

Altered cellular state and plasticity have been increasingly identified as drivers of poor prognosis and treatment-resistance in cancer. Identifying therapeutics that correct altered cellular state and plasticity meets a broad need in the field of oncology, particularly in tumors resistant to standard-of-care therapy. Tumor plasticity and altered cellular states encompass many potential configurations, including dedifferentiated and transdifferentiated tumors, so classifying tumors based on their specific cell state profile is critical to identifying the gene drivers that are specific to that altered state. For that reason, we have developed AURIGIN - a platform that combines a comprehensive single-cell OMICs atlas of human development with an AI/ML framework that can classify cell state plasticity and identify the genes and pathways that drive those specific altered cellular states. AURIGIN is more comprehensive than previously disclosed single cell atlases in that it focuses and enriches the diverse stem, progenitor, and developmental states commonly involved in plastic cell states of cancer. The platform standardizes and integrates these states with multiple atlases of differentiated adult tissues to create a unified atlas of human development. In addition, the AI/ML paradigm of AURIGIN is embedded with developmental biology models that enable it to deconvolute state heterogeneity within tumor indications for precise identification of the most relevant gene targets for novel therapies. AURIGIN also unifies classified plasticity across tissue types by identifying altered cellular states that span multiple indications. Furthermore, we present the implementation of AURIGINDRIVE ML models that integrate pathway information, physical interaction datasets, and regulatory annotations to accurately predict the gene targets at the top of hierarchy of control of tumor plasticity. AURIGIN also enables and accelerates target validation by identifying models that map to the relevant classified plastic states. Similarly, AURIGIN defines clinically relevant patient selection and treatment efficacy biomarkers that are specifically defined from the classified plastic cellular state. We demonstrate the success of AURIGIN for therapeutic discovery. In sum, AURIGIN amplifies the value of multiOMIC tumor data in cellular state and plasticity target discovery by mapping the data into a developmental biology-informed ML framework.

#0904 AI platform provides an EDGE and enables state-of-the-art identification of peptide-HLAs for the development of T cell inducing vaccines.

J. Klein, D. Sprague, M. Lane, M. Hart, O. Petrillo, I. do Valle, M. Davis, A. Ferguson, A. Allen, K. Jooss, **A. Dhanik**;
Gritstone bio, Inc., Emeryville, CA

T cell inducing vaccines are key for the development of effective therapies against cancer and infectious diseases. Peptides, presented by Human Leukocyte Antigens (HLAs), are the targets of T cells, and their identification is therefore critical to the development of such vaccines. Here, we present the latest improvement in our EDGE^{TM} (Epitope Discovery for GEnomes) platform to address this critical need. EDGE is comprised of AI models that can predict peptide presentation by HLA class I and class II. Although the models are trained primarily using immunopeptidomics data, EDGE scores are predictive of peptide-HLA immunogenicity. There are three class I presentation models in EDGE: an allele-specific model, a pan-specific model, and a model specific for infectious diseases. The allele-specific model is applicable to a large but pre-defined set of HLA alleles. On a large test dataset, the allele-specific model achieved an average precision (AP) of 63% (PPV40=79%) compared to the AP of a standard best-available public model of 21% (PPV40=28%). A Ph1/2 clinical study of personalized cancer vaccines encoding neoantigens predicted from the allele-specific model demonstrated a ~50% molecular response (defined as >=30% reduction in circulating tumor DNA relative to baseline) rate with associated extended overall survival (vs non-responders) in metastatic, microsatellite stable colorectal cancer patients. We observed that ≥50% of the mutations were able to elicit T cell responses. The pan-specific class I model uses HLA sequences as input feature when training and, therefore, is applicable to any HLA. On the same test dataset as above, it achieved an AP of 65% (PPV40=81%) and performed better on average for ~40 less-common HLA alleles. Prediction of viral peptide presentation by HLA class I is challenging due to the lack of immunopeptidomics data. The class I model for infectious diseases was specifically optimized to predict for viral peptides and, therefore, performed better than available class I models on published HIV and Influenza A datasets. Prediction of peptide presentation by HLA class II is challenging due to the flexibility in how the longer peptides interact with open HLA grooves as well as the lack of immunopeptidomics data as compared to the class I peptides. The class II model in EDGE, EDGE-II, uses the latest developments in protein large language models, a novel learned HLA allele-deconvolution strategy, and in-house immunopeptidomics data, resulting in improved prediction of peptide presentation by HLA class II and immunogenicity driven by $CD4^+$ T cells. On a benchmark validation dataset, EDGE-II achieved an AP of 71% as compared to AP of 62% of a leading published model. In summary, EDGE^{TM} provides a comprehensive state-of-the-art platform for the development of vaccines that can induce both $CD8^+$ and $CD4^+$ T cell responses to provide durable benefit to patients.

#0905 ML quantification of tumor-Infiltrating lymphocytes distinguishes immune-phenotypes and reveals phenotypic heterogeneity.

N. Le[1], B. Rahsepar[1], J. Hipp[1], J. Conway[1], Y. Gerardin[1], E. Krause[1], C. Shen[1], R. Biju[1], M. Nercessian[1], N. Indorf[1], S. Degryse[1], M. Markey[1], V. Mountain[1], P. Vaidya[2], W. Wijaya[2], A. Shrotre[2], P. Caplazi[2], D. Inzunza[2], J. Palma[2], E. Huntzicker[2], C. Tribouley[2], D. Chen[2], R. Prediou[2], F. Chen[2], K. Kolahi[2];
[1]PathAI, Inc., Boston, MA, [2]AbbVie, Chicago, IL

Immune phenotypes (IP), defined by the tumor-infiltrating lymphocyte (TIL) distribution within the tumor microenvironment (TME), is prognostic and predictive of treatment response. Here, machine learning (ML) models that characterize the TME were deployed in non-small cell lung cancer (NSCLC) and head and neck squamous cell carcinoma (HNSCC) to exhaustively label TILs directly from hematoxylin and eosin (H&E)-stained whole slide images (WSI), compute IP and quantify TIL distribution, tasks which are manually untenable.

ML-powered TME models (PathAI, Boston, MA; commercially available as PathExplore™) for NSCLC and HNSCC that quantify tissue regions (e.g. tumor, epithelium, and stroma) and cells (e.g. lymphocytes) in H&E-stained WSI were deployed on 126 NSCLC and 103 HNSCC commercial samples. Ground truth CD3 and CD8 scores were obtained from paired immunohistochemically-stained WSI (HALO, Indica Labs, Albuquerque, NM). Inflamed, desert, or excluded IPs (based on data-driven cutoffs) were inferred from the mean TIL density in epithelium and stroma (slide-level IP, sIP), and from the fraction of “hot” patches in all 100um x 100um patches tiling the tumor and stroma areas (patch-level IP, pIP). TIL spatial distribution was measured by the Morisita-Horn index that computes the patch-wise overlap between TILs and cancer cells (MHI, ranging from 0 to 1), and epithelial-stromal interface distance index (EDI) indicating the hot stromal patch bias toward the epithelium (-EDI) or stroma (+EDI).

ML-predicted TIL densities highly correlated with ground truth CD3+ and CD8+ cell densities (NSCLC/HNSCC CD3, CD8: tumor Pearson r= 0.88/0.85, 0.74/0.74; epithelium r= 0.76/0.71, 0.88/0.62; stroma r= 0.74/0.87, 0.61/0.76). High s- and pIP agreement was seen (NSCLC 93% and HNSCC 83%); 6/26 discordant cases were driven by TIL hotspots with high density (116%-310% of the cutoff) but few (median = 26%) hot patches in the epithelium. MHI was higher for the inflamed vs excluded IP ($p < 0.0001$ for NSCLC and HNSCC) and intra-group variability was high (NSCLC/HNSCC inflamed: 0.66±0.11/0.31±0.14, excluded: 0.51±0.12/0.26±0.17, desert: 0.48±0.09/0.28±0.17; mean±std). EDI was lowest and negative in inflamed IP but near zero in desert and excluded IP (NSCLC/HNSCC inflamed: -43±4um/-184±19um, excluded: 1.6±4um/-41±13um, desert: 18±4um/-14±13; mean±sem). Excluded and desert IPs had roughly equal + and - EDI cases (NSCLC +/-: 57/46; HNSCC +/-: 39/29).

ML-powered IP prediction using TIL distribution enables accurate and rapid profiling of the TME using routine histopathology. pIPs were concordant with sIPs and highlight TIL heterogeneity. Spatial markers (MHI and EDI) reveal differences between IP classes and intra-group heterogeneity relevant for drug discovery and patient stratification. Investigating prognostic associations of these markers is a promising direction for future studies.

#0906 Large-scale surface protein abundance prediction from single-cell transcriptomes with a zero-shot model and its applications to cancer research.

R. Chen, B. Chen, J. Zhou;
Michigan State University, East Lansing, MI

We develop SPIDER, a zero-shot model which can predict the abundance for a large scale (>2,000) of surface proteins from single-cell transcriptomes in various contexts. This is to overcome the challenges in current single-cell protein abundance quantification tools (e.g., flow cytometry, CITE-seq) and computational models (e.g., totalVI, Seurat, cTPnet), where routinely only <300 surface proteins can be quantified or predicted. Comprehensive benchmarking on four external validation sets shows that the prediction accuracy of SPIDER outperforms other state-of-the-art methods including Seurat, totalVI, and cTPnet, with a prediction accuracy elevated as much as 42.5% in new contexts. We further conduct case studies in cancers by applying SPIDER to predict the abundance of >2,500 surface proteins on scRNA-seq datasets of hepatocellular carcinoma (HCC) and colorectal cancer liver metastasis (RCRLM), where the predicted surface protein abundance data is analyzed to demonstrate the broad downstream applications of SPIDER including facilitating cell type annotation, disease biomarker/target identification, and cell-cell interaction (CCI) inference. For instance, in these datasets we find that SPIDER can reveal (novel) disease biomarkers that are overlooked by solely observing transcript expression, such as CD44/PIK3IP1 in hepatocytes/ γδ2 T cells as a positive/negative HCC biomarker, demonstrating the capability of SPIDER to compensate for the limitations in the RNA modality. In conclusion, we propose the SPIDER model which can provide valuable information on the abundance of a large scale of surfaceomes in single cells, and can be further used to gain new insights into cancers via promoting cell type annotation, disease biomarker/target identification, and CCI inference.

#0907 ScreenDL: A transfer learning framework integrating tumor omics and functional drug screening for personalized clinical drug response prediction.

C. Sederman, T. Di Sera, Y. Qiao, X. Huang, B. E. Welm, A. L. Welm, G. Marth;
University of Utah, Salt Lake City, UT

Precision oncology hinges on accurate prediction of patient-specific treatment response from tumor molecular inputs. While deep learning (DL) models achieve state-of-the-art response prediction in cell lines, existing methods do not readily translate to the clinic where training data is limited. Here, we have developed and validated ScreenDL, a novel DL framework designed explicitly for use in clinical precision oncology applications. The underlying architecture of ScreenDL consists of two fully connected branches dedicated to learning rich embeddings of a drug's chemical structure and a tumor's transcriptomic profile respectively. These tumor omic and drug molecular embeddings are fed into a shared response prediction subnetwork which outputs predicted ln(IC50) values. The ScreenDL training schema incorporates three phases, each designed to improve clinical response prediction: (1) an initial pretraining phase leverages large-scale cell line pharmacogenomic datasets to extract patterns/relationships linking tumor omics and drug response; (2) subsequent transfer learning integrates pharmacogenomic data from patient-derived models of cancer, adapting the pretrained model to a more patient-relevant context; (3) patient-level omics and drug screening data (e.g., from matched patient-derived organoid (PDO) models) is integrated through patient-specific fine-tuning, generating a patient-specific response prediction model. Importantly, biomaterial from surgical tumor resection is often available for organoid establishment and patient-specific drug screening in practical clinical scenarios. To assess the utility of our ScreenDL framework for clinical response prediction, we applied ScreenDL to predict treatment response in 50 advanced/metastatic triple negative breast cancer (TNBC) patient-derived xenograft models (PDX). We leveraged tumor omics profiles for each PDX and drug screening data from matched PDX-derived organoids (PDxOs), mirroring the combination of patient-level tumor omic characterization and functional drug screening in matched PDOs, a protocol currently being piloted in Functional Precision Oncology trials at the University of Utah Huntsman Cancer Institute. After cell line pretraining, ScreenDL achieves a modest median Pearson correlation per drug of 0.15 relative to 0.03 for the leading compared model. However, transfer learning and subsequent PDX-specific fine-tuning significantly improve performance, producing median Pearson correlations per drug of 0.39 and 0.51, respectively. These results demonstrate the ability of our ScreenDL framework to dramatically improve response prediction in clinically relevant domains, bringing DL-based precision treatment selection closer to clinical application.

#0908 SeNMo: A self-normalizing deep learning model for enhanced multi-omics data analysis in oncology.

A. Waqas[1], **A. Tripathi**[1], S. Ahmed[1], A. Mukund[1], P. Stewart[1], M. Naeini[2], H. Farooq[3], G. Rasool[1];
[1]Moffitt Cancer Center, Tampa, FL, [2]University of South Florida, Tampa, FL, [3]University of Minnesota, Minneapolis, MN

Multi-omics research has enhanced our understanding of cancer heterogeneity and progression. Investigating molecular data through multi-omics approaches is crucial for unraveling the complex biological mechanisms underlying cancer, thereby enabling more effective diagnosis, treatment, and prevention strategies. However, predicting patient outcomes through integration of all available multi-omics data is still an under-study research direction. Here, we present SeNMo (Self-normalizing Network for Multi-omics), a deep neural network that ensures the zero mean and unit variance of activations across network layers using the self-normalizing technique. Such normalizing techniques are critical in stable and robust learning of deep learning models. SeNMo is particularly efficient in handling multi-omics data characterized by high-width (many features) and low-length (fewer samples) attributes. We trained SeNMo for the task of overall survival of patients using pan-cancer multi-omics data involving 28 cancer sites from the Genomic Data Commons (GDC). The training multi-omics data includes gene expression, DNA methylation, miRNA expression, and protein expression modalities. We tested the model's performance on the Moffitt Cancer Center's internal data involving RNA expression and protein expression data. We evaluated the model's performance in predicting patient's overall survival using the concordance index (C-Index), which provides a robust measure of the model's predictive capability. SeNMo performed consistently well in the training regime, reflected by the validation C-Index≥0.6 on GDC's public data. In the testing regime on Moffitt's private data, SeNMo performed with a C-Index of 0.68. The model's performance increased when tested on low-dimensional data or when tested on single omic data such as RNA or protein expression data with a C-Index of 0.7. SeNMo proved to be a mini-foundation model for multi-omics oncology data because it demonstrated robust performance, adaptability across molecular data types, and universal approximator capabilities for the scale of molecular data it was trained on. SeNMo can be further scaled to any cancer site and molecular data type. It can also be fine-tuned for other downstream tasks such as treatment response prediction, risk stratification, patient subgroup identification, and others. Its ability to accurately predict patient outcomes and adapt to various downstream tasks indicates a new era in cancer research and treatment. For future research, SeNMo offers a powerful tool for uncovering deeper insights into the complex nature of cancer and sets a precedent for how artificial intelligence can be leveraged to handle the vast and intricate data in the biomedical field. We believe SeNMo and similar models are poised to transform the oncology landscape, offering hope for more effective, efficient, and patient-centric cancer care.

#0909 Enhancing genomic analysis in cancer diagnostics: A machine learning approach for removing artifacts in FFPE specimens.

J. Lim[1], S. Park[1], W.-C. Lee[2], R. Kim[1], S. Lee[2], J. Lee[1], B.-L. Oh[1], Y. Ju[1];
[1]Genome Insight Technology, Inc., Daejeon, Korea, Republic of, [2]Genome Insight, Inc., San Diego, CA

Formalin-Fixed Paraffin-Embedded (FFPE) specimens, widely utilized in clinical cancer diagnostics, present significant challenges by introducing artifacts into genomic data. This study aimed to profile these FFPE-induced genomic alterations, with a particular focus on single-nucleotide variants (SNVs), small insertions and deletions (indels), and copy-number variations (CNVs), and to develop computational methods for filtering out such artifacts. Our primary focus was twofold: first, to comprehensively characterize the unique error profile of FFPE specimens observed through whole-genome sequencing (WGS), and second, to construct artifact classifiers and noise filters for SNV/indels and CNVs. We utilized machine learning (ML) and signal-processing techniques on a dataset of FFPE and matched fresh-frozen (FF) samples. The dataset of 52 FFPE-FF pairs were obtained from four different medical institutes and from various cancers including liver, breast, colon, stomach, and lung cancer, with varied FFPE archiving times. We also analyzed additional FFPE-only samples to refine our methods. Our methodology incorporated advanced computational approaches, including stacking ensemble, transfer learning, and wavelet transform, to enhance robustness and accuracy. The method's design was centered around the notion of not only achieving high performance in distinguishing true signals from FFPE-induced artifacts but also addressing the real-world challenges posed by the varying quality and conditions of clinical FFPE samples. In the analysis, we found peculiar patterns of FFPE-specific error profile, including well-known cytosine deamination and novel mutational signatures. The classifier, building on our findings, effectively differentiated true genomic variants from FFPE-induced artifacts for both SNVs and indels, demonstrating a sensitivity of 0.97, specificity of 0.87, and an F1 score of 0.94 for SNVs. For indels, it achieved a sensitivity of 0.91, specificity of 0.91, and an F1 score of 0.91. The CNV filter notably enhanced the signal-to-noise ratio (SNR) of CNV depth profiles, increasing it from 13dB to 17.5dB on average. Furthermore, we conducted evaluations on two critical measures in cancer and clinical genomics: homologous recombination deficiency (HRD) and tumor mutational burden (TMB), achieving post-filtering concordance rates of 0.99 for HRD—correctly identifying all 8 HRD-positive patients in our dataset—and 0.96 for SNV-based TMB and 0.87 for indel-based TMB. Additionally, a post hoc procedure for sensitive detection of cancer driver mutations resulted in concordance rates of 0.94 for SNVs, 0.91 for indels, and 0.95 for oncogene amplification. Taken together, our study advances FFPE WGS analysis in cancer diagnostics by effectively filtering artifacts and addressing challenges with older, degraded samples, enhancing clinical applicability.

#0910 Clinical inference and biological dissection of tumor ploidy and heterogeneity in cutaneous melanoma for immunotherapy response using deep learning.

M. Glettig, G. Tarantino, T. Aprati, H. Elmarakeby, D. Liu;
Dana-Farber Cancer Institute, Boston, MA

Background: Tumor ploidy and heterogeneity demonstrated to be pivotal in predicting immunotherapy response in cutaneous melanoma in several independent cohorts (Liu NatMed2019, Tarantino BioRXiv2022). Their estimation can guide more personalized and rational utilization of these immunotherapies. However, 1) the biology underpinning ploidy and heterogeneity is unknown; and 2) these findings were derived in patients using retrospective research tumor-normal paired whole exome sequencing which is not performed for clinical management.
Methods: This study addresses this gap by employing deep learning models to predict these crucial markers using routinely available clinical assays, including H&E images. Attention-based computer vision models enable the identification of key morphological features in H&E slides. Segmentation of tumor tissue to perform automated masking, enhances ploidy inference.Moreover, biologically informed neural networks (P-Net, Elmarakeby Nature2021) uncover transcriptional and genomic features linked to ploidy and tumor heterogeneity. Our models are trained on publicly available data (e.g., Liu et al Nature Medicine 2019; TCGA SKCM) from melanoma cohorts and further validated in independent cohorts to ensure robustness.
Results: We developed and validated automated tumor tissue masking, enabling the prediction of Whole Genome Doubling (WGD) from H&E Slides with an AUC > 0.75. Attention-based models identify distinct Tumor Microenvironment (TME) structures predictive of high tumor heterogeneity. P-Net application revealed the Calmodulin pathway, previously associated with regulating proliferation in cancer and targeted with chemotherapy, as intricately linked to high tumor heterogeneity, providing valuable insights into underlying mechanisms.
Conclusion: In conclusion, our study strategically harnesses and integrates existing datasets to rigorously test, refine, and validate hypotheses concerning the biological and therapeutic implications of genomic heterogeneity and ploidy. Notably, our predictive models with automated tumor masking demonstrate a remarkable AUC >0.75 for biomarkers traditionally challenging to derive from clinical assays. This breakthrough opens avenues for novel therapeutic strategies targeting genomic heterogeneity and ploidy, providing a transformative potential to enhance patient care and outcomes.

#0911 Automatic identification of subjective appetite or weight loss in clinician notes empowers studies of cachexia.

T. Park, K. Pichotta, C. J. Fong, N. Schultz, P. Iyengar, J. Jee, E. Reznik;
Memorial Sloan Kettering Cancer Center, New York, NY

Cachexia is a debilitating syndrome characterized by loss of skeletal muscle tissue that affects over 50% of cancer patients. Defining cachexia for the purposes of epidemiologic analyses has historically been determined by specific weight loss over specific time, and more recently relied on technically challenging interpretation of imaging studies. Subjective appetite or weight loss (AWL) as documented from clinician notes may offer another method of defining a similar phenotype. Although annotation of free-text notes at scale is challenging, we hypothesized that natural language processing (NLP) might successfully annotate AWL from cancer diagnosis medical notes and that such annotations would follow patterns expected from classic cachexia studies.

We created a gold-standard dataset for NLP training and validation by manually labeling AWL in a cohort of 762 free-text initial consultation notes that were extracted from lung and pancreatic adenocarcinoma electronic health records. Using these labels, we fine-tuned a pre-trained neural Longformer model to classify whether a patient has symptoms of cachexia.

The AWL model was evaluated on a cohort of 391 pan-cancer notes independent of the training cohort and achieved an AUC of 0.92, precision of 0.88, recall of 0.95, and accuracy of 0.94. To test whether the labels generated by this model behaved as expected from classic cachexia studies, we applied the model to 46,980 initial consultation notes from a pan-cancer cohort of patients with tumor genomic profiling from MSK-IMPACT, an FDA-authorized tumor sequencing assay. Overall, AWL was present in 28% of the patients and it was associated with gastrointestinal cancers, which is expected from previous studies of cachexia. Our analysis revealed that esophagogastric and pancreatic cancer patients had the highest rates of cachexia at around 67%. We also observed that patients with cachexia symptoms have a reduced overall survival compared to patients without (HR=1.80, 95% CI=[1.75, 1.85]), which held in several specific cancers including NSCLC (HR=1.79, 95% CI=[1.66, 1.94]), pancreatic cancer (HR=1.34, 95% CI=[1.22, 1.47]), and colorectal cancer (HR=1.71, 95% CI=[1.55, 1.89]). Cachexia symptoms were more prevalent in male patients than in female patients. Underweight patients by BMI at presentation were most likely to have cachexia symptoms.

These results reciprocate well-established information about cancer cachexia, demonstrating that our text classification NLP model can be reliably used to predict AWL from free-text medical notes. AWL may thus be a viable means of studying correlates of cachexia at scale in real-world cohorts.

#0912 CheckpointPx, an interpretable radiology AI tool, predicts checkpoint blockade benefit independent of PDL1 status in non-small cell lung cancers (NSCLC): A multi-institutional validation study.

A. Hiremath[1], S. Lee[2], J. Lee[2], P. Kim[3], K. Zhang[1], S. Lee[4], M. Yadav[5], M. Chuchuca[5], T. Um[5], M. Nam[6], L.-Y. Chung[5], H. Kim[5], J. Yu[7], T. Djunadi[8], L. Kim[9], Y. Oh[10], S. Yoon[5], Z. Shah[11], Y. Kim[5], I. Hong[12], G. Kang[12], J. Jang[12], A. Cho[12], S. Lee[13], C. Nam[12], T. Hong[12], Y. S. Velichko[5], A. Gupta[14], V. Velcheti[15], A. Madabhushi[1], N. Braman[1], Y. Chae[5];

[1]Picture Health, Cleveland, OH, [2]Kyungpook National Univeristy, Daegu, Korea, Republic of, [3]The University of Texas at Austin, Austin, TX, [4]School of Medicine at UCI, Irvine, CA, [5]Feinberg School Of Medicine, Northwestern University, Chicago, IL, [6]Lincoln Medical Center, Bronx, NY, USA, New York, NY, [7]Dignity Health - St. Rose Dominican Hospital, Henderson, NV, [8]Richmond University Medical Center, Staten Island, NY, [9]Ascension Saint Francis, Evanston, IL, [10]John H. Stroger, Jr. Hospital of Cook County, Chicago, IL, [11]Roswell Park Comprehensive Cancer Center, Buffalo, NY, [12]Northwestern University, Chicago, IL, [13]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, [14]University Hospitals Cleveland Medical Center, Cleveland, OH, [15]Laura and Isaac, New York, NY

Background: Immune Checkpoint Inhibitors (ICIs) are a cornerstone in the treatment of cancers such as Non-Small Cell Lung Cancer (NSCLC). Despite the standard use of biomarkers such as PD-L1 expression for selecting ICI regimens, recent studies suggest missed opportunities for benefit in PD-L1 low/negative patients. Therefore, there is an urgent need for new biomarker strategies capable of guiding the use of ICIs in NSCLC. We introduce and validate an AI-powered radiology tool for ICI patient selection that provides interpretable predictions by quantifying aspects of tumor biology on baseline CT scans directly associated with ICI efficacy, such as tumor heterogeneity and twistedness of the tumor-associated vasculature.

Methods: We analyzed CT scans of 439 patients treated with ICI at 4 institutions (D1-D4) using the Picture Health Px platform. Experienced radiologists and physicians across institutions delineated target lesions on baseline CT scans. A deep learning model was used to segment pulmonary vessels. CheckpointPx v1.11, an interpretable neural network incorporating quantitative features extracted from within the tumor and its vasculature, was trained to predict ICI response (defined as disease control per RECIST best overall response) on n=247 patients (D1-D3). It was assessed with respect to response and progression free-survival (PFS) on 192 patients (D2-D4), with D4 (n=105) being an external validation set. CheckpointPx was also evaluated within PDL1 subsets among testing set patients where available (n=138).

Results: The cohort was predominantly late stage (Stage 3/4) (>85%) and was mixed with respect to ICI line of treatment (1st-4th). 122 of 247 (49%) and 119 of 192 (62%) were responders in training and test cohorts respectively. CheckpointPx included 16 features, such as entropy-based heterogeneity and quantitative vessel tortuosity (twistedness). The model predicted response to ICI with an AUC=0.65 on the test set. The CheckpointPx High Risk group significantly stratified patients by PFS (HR=1.67 [1.22-2.28], p=0.001). This separation remained significant within the subset of PDL1-negative (HR=2.71 [1.35-5.44], p=0.005) and PDL1-positive patients (HR=2.05 [1.22-3.46], p=0.007).

Conclusions: From baseline radiology, CheckpointPx was shown to strongly predict ICI outcomes across multiple institutions, NSCLC stages, and lines of ICI. Furthermore, the tool stratified patients by ICI benefit within both PDL1-positive and negative subsets - suggesting the potential of CheckpointPx to address critical gaps in the NSCLC biomarker landscape. CheckpointPx is driven by interpretable imaging biomarkers, and thus its predictions are tied to specific and quantifiable phenotypic attributes of the tumor and its microenvironment.

#0913 Automated reasoning artificial intelligence (AI) to model the cell-cell biochemical and cellular interactions in the tumor microenvironment (TME) of oral cancer (OC).

K. Mahtouk[1], M. Vincent[2], Y. Le Meitour[1], B. Vanbervliet-Defrance[1], S. Canjura[1], C. Degletagne[1], L. Tonon[3], L. Michon[1], J. Bouaoud[1], A. Excoffier[3], P. Zrounba[3], R. Boutonnet[2], A. Amara[2], **P. Saintigny**[3];

[1]Cancer Research Center of Lyon, Lyon, France, [2]Turing Biosystems, Lyon, France, [3]Center Leon Berard, Lyon, France

Our goal was to study the spatial complexity of HPV negative OC by integrating scRNAseq and spatial transcriptomics from 11 samples including 5 from never smokers never drinkers (NSND). We used Turing Biosystems proprietary graph database engine and automated reasoning AI to analyze and model the cell-cell biochemical and cellular interactions in the TME. The tumors H&E images, Visium 10X, and single cell 10X data were pre-processed using standard methods. QC-based genes and cells filtering, gene expression normalization, dimensionality reduction, clustering of Visium spots, and identification of spatially variable genes were performed. We generated multiple networks from tumor data and prior biological knowledge to integrate different layers of information: single-cell and spatial transcriptomics data, cell-cell interactions networks, cell neighboring, spatial correlation networks. We first used a novel network-based technique to identify the spatial distribution of any cell subtypes (e.g. CAF, T cells), by integrating differentially expressed genes from scRNAseq, prior knowledge and prior data (e.g. TCGA). We used a multilayer network approach to integrate the different networks of data and an automated reasoning AI analysis which allows to interpret the results based on a reasoning on biological and clinical knowledge in opposition to machine learning methods based on statistical patterns. We identified CAFs/T cells/IFN-g to be strongly correlated within the tumor islets interacting with the stroma in NSND while they were more correlated within the stromal regions in smokers. We also identified 2 or 3 subtypes of tumor islets areas based on their functional states (e.g., immune pathways activated or metabolic differences), allowing us to unravel a more detailed map of the intratumoral heterogeneity when compared to histopathology annotations. In order to get some insights into the functional impact of the spatial distribution of cells, the tumors were then represented as multilayer networks to identify all possible cell-cell interactions in the TME. This was followed by a spatial simulation of these interactions using logic (e.g., inhibition, activation) and correlative (e.g., gene expression, imaging features correlations) interactions in the networks to identify spatial interactions. From that we analysed all the possible known protein-protein and metabolite-protein interactions between the cell types analysed and mapped the tumors with the gene expressions corresponding to the pairs of interacting proteins (or enzymes linked to metabolites). We found an interaction between CAF and Tregs via CXCL12 (CAFs) and CXCR4 (Tregs). In conclusion, automated reasoning AI integrating scRNAseq and spatial transcriptomics allows an in-depth analysis of cells spatial distribution and its functional impact in OC.

#0914 Combination analysis of tumor-associated collagen frameworks and tumor immune phenotype of lung carcinomas using virtual staining.
S. Alexanian, Y. Rivenson, N. Xuan, B. Cone, Z. Fang, S. Meyering, L. A. V. Carvalho, D. Palacios, R. Kozikowski;
Pictor Labs, Inc., Los Angeles, CA

An emerging predictive parameter of immunotherapy response is the patient's tumor immune status, generally classified as "inflamed", "immune excluded" and "desert". Historically, classification was performed semi-quantitatively with somewhat subjective parameters as evidenced by the recent Delphi Workshop consensus. There are a variety of approaches to classifying immune status, most based upon analysis of H&E images (counting tumor infiltrating lymphocytes, TILs), or counting subpopulations of immune cells using immunologic staining. However, use of multiplexed or multiple stains has recently been explored to better quantify the counts and types of immune cells in individual tissue compartments. While the immune microenvironment represents an important parameter in predicting patient response, other regions such as the extracellular matrix (ECM) may yield complementary information, as collagen-rich ECMs may present a barrier to drug diffusion and the orientation of fibers may direct the migration of malignant cells.
Here we present a proof of concept virtual staining enhanced image analysis pipeline, which converts autofluorescence signals from a single tissue section into virtual H&E and Masson's Trichrome along with virtual detection of pan cytokeratin (AE1/AE3/PCK26) and CD45 (LCA) positive cells. We apply image analysis to the panel of virtual stains to study the spatial and case-by-case heterogeneity of tumor collagen frameworks and immune phenotype.
Using a standard slide scanner (Axio Scan Z1, Zeiss), multiple autofluorescence images were captured from unstained sections (4-6um thick) of lung tissue. The virtual staining was performed by four deep neural networks trained in a supervised learning fashion. Select chemical stains were performed on previously scanned tissues and reviewed by pathologists side-by-side with virtual stains to ensure consistency and quality control. Four perfectly registered WSI virtual stain images were generated from each tissue section. The multi-stain results were rendered from a variety of lung cancers, including tissue microarray slides. Image analysis was performed using HALO (Indica Labs) and custom python scripts. We identified unique areas of tumor and adjacent stroma with heterogeneous immune phenotype and collagen characteristics, suggesting that an interplay might exist that could be utilized to improve patient selection or prognosis when deploying advanced AI tools. Future work includes applying this virtual stain technique retrospectively to cases with known immunotherapy treatment responses to determine the prognostic significance of the combined immune/ECM phenotype.

#0919 Veterans Health Administration: Decentralized clinical trials.

A. Press[1], J. Ordman[1], J. Boreland[1], Z. Burningham[2], S. Schoenborn[1], T. Stewart[1], B. Oberg[1], P. Pepperman[1], H. Morris[1], S. Bloemers[1], N. Kutub[1], S. Elam[1], M. J. Kelley[1], D. Friedman[1];

[1]Durham VAMC, Durham, NC, [2]Salt Lake City VAMC, Salt Lake City, UT

Purpose: The Veterans Health Administration (VA) created National TeleOncology (NTO) service in 2019 to provide telehealth cancer care to Veterans and to augment care provided at VA facilities through a hub and spoke model. More recently, VA established a Decentralized Clinical Trials (DCTs) infrastructure to support clinical trials (CTs) that rely on telehealth, where research staff are at different locations, and/or where a single IRB provides oversight even when subjects are at different locations.

Brief Description: Research support and infrastructure is variable across VA facilities resulting in uneven access to cancer CTs in the VA system. Veterans often live in rural areas or have transportation challenges, which are barriers to participate in CTs. The COVID-19 pandemic resulted in increased telehealth use in clinical care and in CTs, providing the rationale for a focused effort in DCTs. DCTs have the potential to reduce barriers to CT involvement at the facility- and patient-level and may be more representative of real-world clinical scenarios.

Summary of Data: Since its inception, NTO has provided hematology and oncology telehealth care to over 10,000 Veterans, of which 47.5% live in rural or highly rural areas, 76.5% are white and 13.2% are black or African American. Because the NTO program provides clinical care via telehealth modalities, patients who receive care through NTO may be more comfortable with participating in CTs that use telehealth, and thus are part of a pool of potentially eligible subjects.Since creation of the DCT program, three cancer DCTs have been conducted in the VA (1) BNT001 Digital Therapeutic Feasibility Pilot Study, (2) Cemiplimab Survivorship Epidemiology (CASE) Study, and (3) Proof-Of-ConcepT DEcentralized CliNical TrIAL (POTENTIAL) study. The BNT study enrolled 24 Veterans, 19 were male, 22 were white, 13 lived in rural areas, and the median age at enrollment was 68 years, including numerous cancer diagnoses. Veterans enrolled in the BNT study received cancer care at seven VA facilities. The CASE study has enrolled 24 male Veterans, 23 were white, 5 lived in rural areas, and the median age at enrollment was 74 years. The POTENTIAL study enrolled 4 male Veterans, 3 were white, 2 lived in rural areas, and the median age at enrollment was 72 years. Upcoming DCTs will focus on the following disease types: metastatic non-small cell lung cancer, multiple myeloma, and relapsed/refractory diffuse large B-cell lymphoma.

Conclusions: The VA provides clinical cancer care to Veterans through the NTO program. The DCT program builds upon the existing clinical infrastructure to conduct CTs on a national scale. The NOP DCT team is a component of the VA's Enhance Equity and Access to Clinical Trials (ENACT) initiative, which is part of Cancer Moonshot. The DCT program intends to expand CT opportunities to Veterans with cancer, minimize barriers to CT activation and enrollment, and improve access to cancer CTs for all Veterans.

#0920 Insights from the National Cancer Institute's request for information on existing data sharing processes for NIH-funded research.

M. Ghosh, N. Boyd, S. Jagu;
National Cancer Institute, Rockville, MD

Data sharing plays a crucial role in accelerating biomedical research discoveries, promoting rigorous and reproducible research, enabling research data reuse, and fostering public trust. To facilitate data sharing, a coordinated, sustainable, and streamlined infrastructure is required to store, preserve, retrieve, and make data findable, accessible, interoperable, and reusable. Starting January 25, 2023, researchers funded by the National Institutes of Health (NIH) are required to comply with the NIH Data Management and Sharing Policy (https://sharing.nih.gov/data-management-and-sharing-policy/about-data-management-and-sharing-policies/data-management-and-sharing-policy-overview) and indicate how research data funded by the NIH will be managed and broadly shared. As institutions prepare to meet these requirements, the National Cancer Institute (NCI) is looking to understand the existing processes of data storage, preservation, and sharing including what infrastructure and services are available to facilitate data sharing. To carry out this goal, the NCI's Office of Data Sharing (ODS), dedicated to promoting responsible and efficient sharing of cancer research data, issued a Request for Information (RFI) to understand the existing data sharing processes for NIH-Funded Research. The RFI was designed to collect information on services (e.g. guidance on data standards and file formats), technologies (e.g. storage, compression, retrieval, archival, analysis tools, workbenches), and processes (e.g. governance, communication, education, outreach) that promote data sharing. ODS utilized the RFI to gather input from stakeholders involved in facilitating data sharing. This included personnel from various fields such as research laboratories, scientific instrumentation core facilities, offices of research and/or sponsored programs, provost offices or other research administration, libraries, information technology, and institutional review boards. We also engaged with bioinformaticians and data scientists who are actively contributing to data curation, formatting, and analysis. Here, we present analysis of the responses received, including insights relating to gaps and challenges in data sharing, and proposed next steps and recommendations.

#0921 The value of cancer genomic data sharing.

S. Nelson, C. Caga Anan, E. Gillanders;
National Cancer Institute, Rockville, MD

Our understanding of and ability to combat cancer relies on the generation, analysis, and sharing of data. The Epidemiology and Genomics Research Program in the National Cancer Institute's Division of Cancer Control and Population Sciences (DCCPS) has supported generation of large genomic data sets and advocated for and/or required broad sharing of this data. One of DCCPS's scientific priorities is focused on data strategies namely, "the use, enhancement, expansion, and accessibility of new and existing DCCPS-supported data resources to accelerate cancer control research" (https://cancercontrol.cancer.gov/overview-highlights/2022/future_directions.html).EGRP funded the Genetic Associations and Mechanisms in Oncology (GAME-ON) Initiative, a multidisciplinary collaboration of researchers focused on understanding the genetic architecture, biology, and clinical and epidemiologic utility of common cancer risk variants. This program focused on 5 common cancer types - breast, colorectal, lung, ovarian, and prostate - and required research that incorporated multiple research domains and sharing of any data generated. A major accomplishment of this program was development of the OncoArray genotyping chip, which used information from genetic epidemiology studies, biological/functional analyses, and clinical and epidemiologic insights to create a comprehensive, high-density genotyping array for pan-cancer studies that has led to the discovery of hundreds of new cancer predisposition variants. This chip was used in a massive, coordinated genotyping effort that culminated in the generation of 7 datasets comprising genotyping data for nearly 500,000 individuals. All the data were deposited in dbGaP between 2014 and 2021 and are available (via controlled access) to any investigators. To understand the secondary use of these data, we determined the number of times the data had been downloaded, who downloaded the data, and types of research for which it was used. We also identified publications using OncoArray data and characterized the publications by research type, cancer type, and other details. Through this analysis, we explore how well the GAME-ON initiative and the OncoArray projects promote the DCCPS scientific priority of optimizing secondary research by making the data findable, accessible, interoperable, and reusable (FAIR).

#0922 Comparison of adverse effects of different combination therapies of immune checkpoint inhibitors and radiotherapy: A systematic review and meta-analysis.

H. Zhou[1], Z. Guo[2], T. Wang[2], L. Cai[2], P. You[3], **Z. Jiang**[4];

[1]Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou, China, [2]The First Affiliated Hospital of Guangdong Pharmaceutical University, Guangzhou, China, [3]Nanchang University, Nanchang, China, [4]University of California, Berkeley, Berkeley, CA

Background: Numerous ongoing trials are investigating cancer treatment combinations based on the combination of radiotherapy and immune checkpoint inhibitors. Understanding the toxicity profile of treatment-related adverse events is crucial. The purpose of this study is to comprehensively investigate the incidence and overview of treatment-related adverse events in different combination therapies involving radiotherapy and immune checkpoint inhibitors.
Methods: We conducted a systematic review and meta-analysis of different combination therapies involving radiotherapy and immune checkpoint inhibitors. We searched English-language articles published between January 1, 2000, and May 31, 2023, in Pubmed, Embase, and the Cochrane database, investigating globally approved therapies based on PD-1, PD-L1 inhibitors, or CTA-4. Only prospective trials reporting overall incidence rates or lists of treatment-related adverse events data were included, and studies recruiting fewer than 10 patients were excluded. Retrospective studies were also excluded to minimize the risk of bias. The primary outcomes were the overall incidence and overview of treatment-related adverse events of all grades and grade 3 or higher. Heterogeneity among studies was assessed using the I^2 statistic. The summary measure for primary outcomes was incidence rate (95% CI). This protocol is registered in PROSPERO (CRD42023390147).
Results: We identified 1300 records, of which 50 studies (1655 patients) met the inclusion criteria. The incidence of treatment-related adverse reactions in the concurrent group was 76.0% (95% CI 73.5-78.4), and the incidence of grade 3 or higher adverse events was 23.5% (21.1-25.9). In the sequential group, the incidence of treatment-related adverse reactions was 75.9% (70.8-80.6), and the incidence of grade 3 or higher adverse events was 22.5% (18.0-27.5). In the induction group, the incidence of treatment-related adverse reactions was 72.8% (65.0-79.8), and the incidence of grade 3 or higher adverse events was 37.1% (29.4-45.3). The most common specific adverse event in the concurrent group was Fatigue (27.8% [25.2-30.6]); in the sequential group, it was Fatigue (43.3% [33.3-53.7]); in the induction group, it was Fatigue (71.4% [56.7-83.4]). Grade 3 or higher adverse events in the concurrent group was Lymphocyte Count Decreased (7.2% [5.4-9.4]); in the sequential group, it was Pneumonitis (11.1% [5.7-19.0]); in the induction group, it was Fatigue (10.5% [5.6-17.7]).
Conclusion: Our study provides comprehensive data on treatment-related adverse events in different combination therapies involving radiotherapy and immune checkpoint inhibitors. Our results provide an essential reference of toxicity profiles of radiotherapy combined with immune checkpoint inhibitors for clinicians in routine practice of cancer care.

#0923 Biomarker use in oncology approvals in the US.

Y. Dou[1], C. Grimstein[2], J. Wang[2], J. Mascaro[2];
[1]AstraZeneca, Mississauga, ON, Canada, [2]AstraZeneca, Gaithersburg, MD

Introduction: Precision medicine through the use of biomarkers has revolutionized the way we understand and combat cancer. We are summarizing the current state and challenges of biomarker use in the context of cancer therapeutic products approved by the United States Food and Drug Administration (FDA).
Methods: We curated a dataset of oncology therapeutic products approved by the FDA through the regular and accelerated pathways from 2011 to 2022, based on publicly available FDA database, approval letters and reviews, prescribing information, publications, and clinicaltrial.gov.
Results: During the period of 2011 to 2022, the FDA granted 132 accelerated and 331 regular approvals for 80 and 144 oncology therapeutic products with 133 and 340 new indications, respectively. The percentage of approvals for a biomarker-defined population was higher in accelerated approvals in comparison to regular approvals (i.e., 51% vs. 39%). The five disease sites with the highest number of approved indications were leukemia, lung, non-Hodgkin lymphoma, breast, and skin. The vast majority of lung and breast cancer indications were approved in a biomarker-defined population through a range of different biomarkers. Overall, HER2-, EGFR-, BRAF-, HR-, and ALK-defined populations received the highest numbers of approvals. The most common biomarkers linked to the approval of a specific cancer type include Philadelphia chromosome for leukemia, EGFR/ALK for lung cancer, HER2/HR for breast cancer, BRAF for skin cancer, and BRCA for ovarian cancer. Multiple myeloma, kidney cancer, and Hodgkin lymphoma did not have any approval with a biomarker-defined population. Non-Hodgkin lymphoma had a large number of approvals, but the percentage approved for a biomarker-defined population was small. dMMR, MSI-H or dMMR, BRAF mutation, NTRK fusions, TMB H, and RET fusions are biomarkers linked to tissue-agnostic indications approved for solid tumors only through the accelerated pathway.
Conclusion: To the best our knowledge, the analysis represents the most comprehensive overview of the current landscape on integration of biomarker in oncology therapeutic products approved by the FDA through both the accelerated and regular pathways. Our analysis shows that the FDA has increasingly approved indications based on biomarkers, particularly through the accelerated approval pathway. Biomarkers are reshaping cancer therapy under an evolving regulatory landscape with a growing emphasis on precision medicine that promises continued progress in personalized cancer care.

#0924 Patterns of specialty referral in cancer patients treated with immunotherapy regimens.

A. Chen, S. Dusza, D. Faleck, N. Shah, M. E. Lacouture;
Memorial Sloan Kettering Cancer Center, New York, NY

Background: Specialty referral rates have been steadily increasing, as much as 94% within a 10-year period (1). Previous studies have shown the benefits of specialty referral in oncology management in specific populations such as lung cancer patients (2). However, there have yet to be larger-scale studies on general trends in specialty referral in oncology. In particular, patients on immune checkpoint inhibitors frequently develop immune-related adverse events (irAEs) affecting a variety of organ systems and may benefit from specialty care (3).
Objectives: To evaluate the patterns of specialty referral in patients treated with immune checkpoint inhibitors and identify referral patterns that affect patient outcomes.
Methods: This was a retrospective study of all specialty referral for patients on an immunotherapy regimen from 6/1/2022-6/1/2023 at a single-institution cancer center. The specialties consulted included cardiology, dermatology, endocrinology, gastroenterology, infectious disease, neurology, pulmonology, and nephrology.
Results: In total, there were 5,602 patients on an immunotherapy regimen, of whom 3,519 patients (62.8%) were referred to a specialist. Of these patients, 2,017 (57.3%) attended a specialist appointment. A majority of the patients were male (n=1038, 51.5%), had a mean age of 64.1 years (SD=13.8) at initial consult, and were White/non-Hispanic (n=1414, 70.1%). The mean and median number of consults per patient were 1.7 (SD=1.3) and 1 (IQR=1), respectively. The maximum number of consultations for a patient was 17. Dermatology was the most commonly consulted service (n=841, 25.9%), followed by neurology (n=781, 24.0%), and endocrinology (n=446, 13.7%). For dermatology, the most common reason for consultation was evaluation of a rash (n=500, 59.5%). Dermatology also had the highest ratio of outpatient to inpatient consultations at 10.4 to 1. The next closest service was endocrinology at 3.0 to 1. The pulmonary service had the shortest time between consult request and patient visit (10 days), followed by dermatology (13 days), and gastroenterology (15 days). Prior to their initial consultation, the vast majority of patients (82.6%) were on a single therapy, and the most common single therapy was pembrolizumab (n=1589, 59.2%). The most common combination therapy was ipilimumab plus nivolumab, accounting for 59.3% of combinations. Fifty percent of patients (n=1008) who saw a specialist were able to continue their immunotherapy regimen.
Conclusions: There is a range of specialty and multidisciplinary care that is necessary for the management of patients on immunotherapy regimens.

#0925 Continuing anti-EGFR treatment prolonged survival in mCRC patients receiving conversion liver resection.

Y.-Y. Hsieh[1], C.-W. Tsai[2], T-CARE Group, **Y.-H. Liang**[3];
[1]Taipei Medical University Shuang Ho Hospital, Ministry of Health and Weldare, New Taipei City, Taiwan, [2]Taipei Medical University, Taipei City, Taiwan, [3]National Taiwan University Hospital, Taipei City, Taiwan

Introduction: Anti-EGFR monoclonal antibody plus doublet chemotherapy is the mainstay of first-line treatment of RAS/BRAF wild-type metastatic colorectal cancer (mCRC) patients. Some of these patients might undergo secondary resection. However, there is no standardized suggestion on whether colorectal cancer liver metastasis patients should keep target therapy after secondary resection. NCCN guidelines suggest chemotherapy only in patients receiving primary liver resection. Whether we could spare the use of target therapy after secondary resection is the main aim of our study.
Methods: Using Taiwan's National Health Insurance Research Database, we established a cohort of KRAS wild-type mCRC patients treated with first-line anti-EGFR therapy plus doublet chemotherapy between 2013 and 2018. Secondary surgery was defined as either resection of liver metastases or radiofrequency ablation.
Results: 5694 stage IV mCRC patients received anti-EGFR MAb plus doublet chemotherapy as a first-line treatment between 2013 and 2018. 174 patients were enrolled in the final analysis, with 153 continuing anti-EGFR MAb after secondary resection and 21 patients without anti-EGFR MAb. Compared with those who without anti-EGFR therapy after secondary resection, patients who continued anti-EGFR MAb exhibited significantly longer overall survival (OS; median, 43.8 vs. 31.9 months, $p = 0.031$) but not in time to treatment failure (TTF; median, 22.2 vs. 26.6 months, $p = 0.841$). The OS benefits of continuing anti-EGFR MAb remained regardless of left-sided or right-sided primary tumors (40.9 vs. 43.0 months, $p = 0.980$). The patient cohort from 2016 to 2018 showed more prolonged survival than from 2012 to 2015 (not reached vs. 40.450, $p = 0.0305$). TTF has no statistical difference when considering patient cohort or primary tumor location. In multivariate analyses, continuing first-line anti-EGFR MAb therapy after secondary resection remained an independent predictor of longer OS.
Conclusion: For mCRC patients who received secondary resection after first-line anti-EGFR and doublet chemotherapy, continuing anti-EGFR MAb after resection was associated with significantly longer OS regardless of primary tumor sidedness.

#0926 Adaptive universal platform for real-world observational studies (AUPROS): An emerging model for clinical, epidemiologic, and precision oncology research.

S. H. Barghout, S. Raptis, L. J. Zhan, F. Al-Agha, M. C. Brown, D. Patel, G. Liu;
Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada

Background: Adaptive Universal Platform for Real-world Observational Studies (AUPROS) is an emerging study design and platform for the generation of real-world evidence (RWE) particularly in malignancies with rare molecular aberrations. Here, we evaluate the efficiency of AUPROS as an innovative model for real-world observational studies in oncology.
Methods: We conducted a mixed-methods study to evaluate three AUPROS studies at Princess Margaret Cancer Centre either locally or as a part of national and international collaborations: 1) METAL (Molecular Epidemiology of ThorAcic Lesions; n=11,378), 2) THANKS (Translational Head And NecK Study; n=3,506), and 3) CARMA (Canadian Cancers with Rare Molecular Alterations; NCT04151342; n=3,879). Specifically, we reviewed data collected, study elements, protocol language, coordination, institutional review boards (IRBs), and contracts. We also performed stakeholder-directed survey and discussions, analysis of funding, research output, and collaborations, as well as a Strengths-Weaknesses-Opportunities-Threats (SWOT) analysis.
Results: AUPROS is an innovative study design that borrows design elements from master protocol trials, adaptive trials, and master observational trials as well as retrospective and ambispective designs, enabling comprehensive data collection. The universality of AUPROS allowed for multi-purpose analyses of various real-world data (RWD) including epidemiological, clinical, patient-reported outcomes, biospecimens, and imaging data. The adaptive nature created opportunities for multi-source funding (e.g., academic, pharmaceutical, philanthropic, among others), as well as national/international collaborations and involvement in consortia (e.g., ILCCO, TCGA, BEACON, and INHANCE). Additionally, AUPROS has allowed the development of an expanding national RWE platform that involves collaborations among medical and radiation oncologists and surgeons across different tumor sites. As assessed by research output analyses, AUPROS provided a platform for enhanced research productivity in different areas and utilizing various data sources (METAL=130; THANKS=31; CARMA=5 publications). Our survey and SWOT analysis identified several cost and operational benefits of AUPROS over conventional observational studies, as well as several challenges pertinent to ethics approvals, sustainability, complex coordination, and data quality.
Conclusions: AUPROS is an innovative model for real-world observational studies with significant logistical and methodological benefits over conventional RWD study designs. Our findings may help broaden the use of AUPROS to address emerging needs in the scope of precision oncology and clinico-epidemiological research.

#0927 Real-world (RW) biomarker characteristics and clinical outcomes in pre-treated non-MSI-H/dMMR metastatic colorectal cancer (mCRC) patients.

M. M. Amonkar[1], S. Sura[2], K. Desai[1], R. Jain[1], Z. Liu[3], N. Niehoff[2], T. W. Wilson[2], G. Patton[2], D. Cosgrove[4];
[1]Merck & Co., Inc., Rahway, NJ, [2]Ontada, Irving, TX, [3]Eisai Inc., Nutley, NJ, [4]Compass Oncology, Vancouver, WA

Introduction: Given sparse RW evidence, we assessed biomarker characteristics & clinical outcomes in community oncology practices among pre-treated non-MSI-H/dMMR mCRC patients.
Methods: This retrospective cohort study used structured & chart review data from iKnowMed, The US Oncology Network electronic health record data & included non-MSI-H/dMMR adult mCRC patients pre-treated with standard of care (SoC) chemo who initiated subsequent systemic anticancer treatment (SACT), best supportive care (BSC) or neither from 1/1/2016 - 12/31/2021. Index date for SACT users was the regimen start date post SoC chemo & for patients on BSC & no SACT/BSC, it was last chemo administration date. Patients were followed from index date until 8/31/2022 for overall survival (OS) & real-world progression-free survival (rwPFS). KM analyses assessed outcomes, overall & stratified by treatment, RAS status & metastasis sites.
Results: Of mCRC patients with ≥2 visits, 70.9% received MSI/MMR testing. In 292 eligible chart review patients, 69.5% received SACT in pre-treated setting (regorafenib 14.8%, trifluridine/tipiracil (TAS-102) 12.3%, other 72.9%), 28.8% received BSC & 1.7% neither. 76.7% reported KRAS/NRAS testing with 60.7% wild-type & 39.3% mutant. Common metastasis sites were liver-only (44.2%), liver & lung (10.3%) & lung-only (8.9%). Median (range) duration of follow-up was 5.2 (2.7, 10.0) months for regorafenib, 5.3 (2.5, 8.6) for TAS-102 & 10.7 (5.3, 18.0) for the other treatments group. Median OS was 7.4 (95% CI: 5.8, 8.8) months & median rwPFS was 3.5 (95% CI: 3.2, 4.3) months (outcomes data in Table).
Conclusions: 29.1% pre-treated, mCRC patients did not receive guideline recommended MSI/MMR testing, highlighting the need to improve testing. Outcomes varied by treatment, RAS status, & metastatic sites. The modest RW clinical benefit for SoC regorafenib & TAS-102, was consistent with trials & other RW studies; all highlighting an unmet need.

Cohorts	**Median (95% CI) OS (months)**	**Median (95% CI) rwPFS[1] (months)**
Overall	7.4 (5.8, 8.8)	3.5 (3.2, 4.3)
Regorafenib	5.6 (3.1, 9.7)	2.4 (1.8, 3.0)
TAS-102	5.9 (3.4, 8.6)	3.0 (2.1, 3.4)
Other SACT[2]	12.8 (9.8, 17.2)	4.9 (3.7, 5.8)
BSC	2.4 (1.8, 3.2)	-
RAS mutation		
Wild-type	8.6 (6.6, 11.5)	4.0 (3.3, 4.9)
Mutant	5.4 (3.4, 9.5)	3.2 (2.1, 4.6)
Metastatic sites		
Liver only	8.0 (5.7, 11.7)	3.9 (3.0, 4.9)
Lung only	17.0 (7.8, 35.6)	7.9 (3.3, 10.5)
Liver & lung only	5.4 (2.4, 7.2)	3.5 (2.1, 5.4)
Other	6.7 (4.1, 9.4)	3.2 (2.7, 3.9)

Abbreviation: CI: confidence interval, TAS-102: trifluridine/tipiracil, OS: overall survival, rwPFS: real-world progression-free survival, SACT: systemic anticancer treatment [1]Overall rwPFS was calculated among patients receiving subsequent SACT only (n = 203) [2]Top 2 “other SACT” included irinotecan- or oxaliplatin-based treatment

#0928 Real-world comparison of first-line treatments for metastatic clear cell renal cell carcinoma (mccRCC).

O. Yazdanpanah, S. Dwabe, G. Harada, S. Seyedin, N. Mar;
University of California, Irvine, Irvine, CA

Multiple regimens are available for management of mccRCC including either immuno-oncology doublet (IO/IO) or combinations of IO and tyrosine kinase inhibitors (TKI). Clinical trials have compared these regimens to sunitinib, with no direct comparison between them. As such, there is ambiguity among physicians about preferred first-line for mccRCC. We performed a single-institution retrospective study of adults treated in first-line for mccRCC between 1/1/2017 and 1/1/2023. Regimens included IO/IO (ipilimumab/nivolumab [I/N]) or IO/TKI (pembrolizumab/axitinib [P/A], nivolumab/cabozantinib [N/C], or pembrolizumab/lenvatinib [P/L]). We compared efficacy and toxicity endpoints, using Kruskal-Wallis test for medians and Chi-square for categorical variables. 42 patients with median age of 61 (range: 36-95) were included. Patient distribution in IO/IO vs IO/TKI group was 20.0% vs 30.8% in International Metastatic Database Consortium (IMDC) favorable risk, 46.7% vs 38.5% in intermediate-risk, and 33.3% vs 30.8% in poor-risk group. 78.6% vs 66.6% of patients had WHO grade 3/4 ccRCC, 18.8% vs 15.4% had sarcomatoid features in the IO/IO vs IO/TKI, respectively. 38% (16/42) received I/N, 7% (3/42) N/C, 52% (22/42) P/A, and 2% (1/42) P/L. Median follow-up was 109 weeks. Table-1 compares the efficacy of IO/IO vs IO/TKI. IO-related toxicity, TKI-related toxicity, treatment interruptions, dose reductions, and need for steroids were not significantly different between IO/IO and IO/TKI (p= 0.240, p=0.372, p=0.923, p=1.00, and p=0.248, respectively). Genomic characteristics will be reported in poster.

Variable	**IO/IO**	**IO/TKI**	***p*-value**
Median treatment duration (weeks)	8.3	59.4	<0.001
Disease control rate (complete response + partial response + stable disease) (%)	50.0	91.7	0.024
Time from 1st line to 2nd line therapy (weeks)	14.6	57.1	0.001
Median overall survival (weeks)	63.6	Not reached	0.001

Despite small sample size, our real-world data showed that patients treated with IO/IO had significantly worse outcomes compared to those treated with IO/TKI. While this difference may stem from a more aggressive disease in IO/IO group but further insights needs to be obtained through future prospective studies comparing IO/IO and IO/TKI regimens.

#0929 Characterizing first- & second-generation follow on drugs: Clinical trial & development timelines of Bruton tyrosine kinase (BTK) inhibitors.

A. Varma[1], W. B. Feldman[2], A. S. Kesselheim[2], E. R. S. Cliff[2];

[1]University of Texas Health Science Center, San Antonio, TX, [2]Program on Regulation, Therapeutics and Law, Brigham and Women's Hospital, Harvard Medical School, Boston, MA

Once a promising new cancer therapy emerges, other manufacturers often develop drugs with the same molecular target. Some follow on drugs offer meaningful benefit via improved efficacy or reduced toxicity, but others offer minimal benefit. We hypothesized there are two cohorts of follow on drugs: those developed concurrently before efficacy & safety of the therapy is established (first generation) & those developed as follow ons after that point (second generation). We analyzed BTK inhibitor (BTKi) development to evaluate patterns of concurrent & follow on development.

Methods BTKis from 1996-2023 were identified in Pharmaprojects (Citeline, NY). We collected drug development information including indications pursued, development phase reached, & outcome (ongoing development, discontinued development, or completed development with FDA approval). We constructed timelines including the first publicized report of the drug, Phase 2 initiation & date of development discontinuation or FDA approval.

Results We identified 19 BTKis targeting CLL, of which 6 (32%) were concurrent and 13 (68%) were follow-ons relative to ibrutinib's 2014 approval. A cluster of new agents began development immediately after ibrutinib approval, suggesting two distinct groups in this case. We identified 10 BTKis for MCL, of which only 2 (20%) were concurrently developed drugs, and 8 (80%) were follow on, based on ibrutinib's 2013 approval for MCL, with similar clustering to CLL.

Conclusions Among BTKis, market entry progressed in two phases. In a first phase, a smaller group of sponsors attempted to demonstrate safety & efficacy of the novel class. After proof of safety & efficacy, lowering risks for later competitors, a follow on phase of development began in which multiple sponsors sought to enter the market. Knowledge of which drugs belong to which class can aid with evaluation of trial design as part of regulatory approval decisions & with drug price negotiation.

Bruton Tyrosine Kinase inhibitors in Clinical Stage Development in Chronic Lymphocytic Leukemia

Drug	Sponsor	Entry Date	Date of approval/ discontinuation	Outcome
Ibrutinib	AbbVie / J&J	12/12/2007	02/13/2014	Approved (first in class)
Spebrutinib	Bristol Myers Squibb	12/12/2008	01/16/2014	Discontinued
Vecabrutinib	Biogen/ Viracta	04/07/2011	03/23/2016	Discontinued
Tirabrutinib	Gilead/Ono	01/14/2012	09/19/2023	Discontinued
Fenebrutinib	Roche	11/26/2013	Unknown	Discontinued
Pirtobrutinib	Eli Lilly	12/27/2013	08/08/2023	Approved
Acalabrutinib	Acerta/AstraZeneca	01/01/2014	06/11/2019	Approved

CLINICAL RESEARCH: Application of Precision Medicine for Cancer Care
Poster Session

#0933 Single-cell inference and validation of heterogeneous drug sensitivity in cholangiocarcinoma reveals dacinostat as novel therapeutic candidate.

A. Obradovic[1], L. Tomassoni[1], D. Yu[2], C. G. Drake[1], F. D. Cruz[2], A. Kung[2], A. Califano[1];
[1]Columbia University Irving Medical Center, New York, NY, [2]Memorial Sloane Kettering, New York, NY

Cholangiocarcinoma is a rare, aggressive malignancy with limited treatment options, due to a paucity of actionable mutations and low response to immune checkpoint inhibitors. Furthermore, its extreme heterogeneity prevents identification of actionable dependencies from bulk-tissue profiles, such that transformed cells themselves represent as little as 10% of cells comprising the complex micro-environment of these tumors. To address these challenges, we introduce a highly generalizable, single-cell framework for the mechanism-based prioritization of drugs to treat rare, heterogeneous tumors. Analysis of tumor cells isolated by single-cell RNA-Sequencing across six patients and two independent data sources using protein activity inference has revealed three molecularly distinct subphenotypes of cholangiocarcinoma cells, present to varying degrees across patients but with highly conserved proteomic signatures, and predicted to be sensitive to four drugs by regulatory network analysis. A seventh independent patient recapitulated these phenotypes, and drug sensitivity predictions at single-cell level for this patient were validated in low-passage, patient-derived xenografts from the same patient, which confirmed tumor growth rate control by two of these drugs (plicamycin and dacinostat) and further validated predicted subpopulation-specific effects, such that dacinostat alone inhibited tumor growth across all three tumor subphenotypes, while plicamycin preferentially inhibited some but not all, allowing the remaining phenotypes to reconstitute a treatment-resistant tumor. This approach suggests dacinostat as a promising candidate for follow-up clinical trials in cholangiocarcinoma, either alone or in combination with current standard-of-care chemotherapies, and is highly generalizable to elucidate complementary dependencies of other aggressive, heterogeneous tumors.

#0934 RNA-based precision medicine predicts sensitivity to selinexor in select pancreatic ductal adenocarcinoma patients.

A. Curiel-Garcia, L. Tomassoni, T. C. Dalton, A. R. Decker-Farrell, C. F. Palermo, D. R. Ross, S. A. Sastra, U. N. Wasko, I. M. Goncalves, P. S. Mundi, B. S. Bakir, R. A. Safyan, H. Hibshoosh, G. A. Manji, A. Califano, K. P. Olive;
Columbia University Irving Medical Center, New York, NY

Sensitivity to therapeutic agents is impacted both by genetic heterogeneity between patients or among clones within a tumor and by heterogeneity of epigenetic cell states. Prior work demonstrates that human pancreatic tumors comprise malignant cells in a mixture of multiple cell states with distinct genetic dependencies, leading to a reservoir of chemoresistance across the tumor; targeting just one or two malignant cell states is insufficient to achieve durable therapeutic responses. One approach to overcome this challenge is to identify agents with efficacy against malignant cells in multiple cell states. However, in the absence of genetic distinctions between cell states, identifying therapeutic vulnerabilities for each malignant cell state present in a patient's tumor in real time remains a challenge. OncoTreat is a CLIA certified algorithm that matches drugs to patients based on tumor gene expression profiles. The approach utilizes regulatory network analysis, a systems biology framework that transforms gene expression data into regulatory protein activity profiles, in a manner that facilitates the identification of master transcriptional regulators of cell state. We carried out a Phase 1 clinical trial of the OncoTreat framework to examine feasibility for implementing RNA-based precision medicine in patients with metastatic pancreatic ductal adenocarcinoma (2^{nd} line and beyond). Patient-derived xenografts were established from subjects prior to 1^{st} line therapy, and selected agents matched by OncoTreat were assessed co-clinically while subjects received standard of care regimens, with the potential for subsequent treatment with successful agents upon progression. Two subjects in the study matched to selenexor, an XPO1 inhibitor that is FDA approved for multiple myeloma. Co-clinical studies of selinexor in patient-derived xenograft models generated from the matched subjects showed prolonged survival compared to control regimens. Single-cell RNA sequencing analysis of these tumors found that the activity of master regulators confirmed that the activity of selinexor-responsive master regulators were inverted in response to treatment *in vivo*, reducing the fraction of malignant cells in the tumors. Strikingly, selenexor treatment was associated with significant inhibition of RAS/MAPK signaling, suggesting a potential novel role for selinexor targeting Ras. Together, these data indicate a potential therapeutic vulnerability for a subset of PDAC patients that can be predicted by a CLIA-certified RNA-based precision medicine platform.

#0935 Co-clinical endometrial cancer (EC) patient-derived organoids (PDO) to assess functional effects of replication stress (RS)-targeting agents.

E. Ivanova[1], A. L. Saldanha[1], S. Roychoudhury[1], B. Kochupurakkal[1], A. P. Zlota[1], C. E. Padrick[1], H. V. Vo[1], E. K. Greenberg[1], H. Sawyer[1], C. Feeney[1], C. H. Qi[1], S. Narayan[1], J. D. Curtis[1], N. Tayob[1], M. R. Nucci[2], P. Konstantinopoulos[1], D. Chowdhury[1], G. Shapiro[1], C. P. Paweletz[1], U. A. Matulonis[1], J. F. Liu[1]; [1]Dana-Farber Cancer Institute, Boston, MA, [2]Brigham and Women's Hospital, Boston, MA

Background: EC is the most commonly diagnosed gynecologic cancer in the US and has both rising incidence and mortality. Uterine serous cancer (USC) and uterine carcinosarcoma (UCS) are high grade ECs characterized by *TP53* mutation and molecular alterations suggesting high replication stress (RS) and cell cycle dysregulation. These molecular alterations could engender sensitivity to RS-targeting strategies such as WEE1 inhibition. In a single arm phase 2 of 35 patients, the WEE1 inhibitor adavosertib demonstrated clinical activity in recurrent USC, with an overall response rate of 29.4%. To support the development of predictive biomarkers of sensitivity to RS targeting agents, we report on the establishment of co-clinical EC PDOs from pre- and on-treatment biopsies from patients with USC or UCS enrolled to a translational trial of adavosertib.

Methods: Patients with USC or UCS consented for trial participation underwent pre- and on-treatment biopsies while receiving adavosertib monotherapy. Biopsies were dissociated and passaged as 3D organoid cultures in Matrigel in an optimized media. Established PDOs were seeded in 3D microfluidic devices, treated with adavosertib in a dose-dependent manner and assessed for viability after 6 days of treatment by dual labeling live/dead imaging. IC50 values were calculated using log(inhibitor) vs response - variable slope (four parameters) model in GraphPad Prism. To assess the effect of adavosertib on replication fork speed, DNA fiber assays were conducted with PDOs treated with adavosertib for 72 hours. Finally, FFPE blocks were created from PDOs for assessment of DNA damage repair biomarkers by IHC.

Results: 19 biopsies were obtained from 11 participating patients. 6 biopsies did not yield sufficient tumor cells for PDO generation. From the remaining 13 samples, 5 PDOs were successfully established (3 USC and 2 UCS), with a higher success rate when 3 biopsy cores were received (3 of 4; 75%) compared to when 2 biopsy cores were received (2 of 9; 22 %). Dual labeling live/dead imaging of PDOs treated with adavosertib resulted in IC50 values ranging from 113nM to 856nM. DNA fiber assays revealed consistent decrease in fork speed with adavosertib exposure, consistent with the hypothesized effect of adavosertib in increasing RS in these cells. A dose dependent effect on replication fork speed was observed, with greater decreases in fork speed with increasing concentrations of adavosertib. Due to the limited number of samples and the number of PDOs generated from on-treatment as opposed to pre-treatment biopsies, clinical correlation between PDO adavosertib sensitivity and clinical activity was not formally assessed. IHC analysis of potential DNA damage biomarkers is ongoing.

Conclusions: We describe the successful establishment of co-clinical EC PDOs for functional evaluation of sensitivity to RS targeting agents.

#0936 Targeted proteomics and next-generation sequencing (NGS) for biomarker discovery in metastatic colorectal cancer (mCRC).

William J. Kelly[1], Barrett Nuttall[1], Marlon Rebelatto[2], Marcus Schick[3], Armin Meier[3], Steve Sweet[4], Beom-Jun Kim[2], David Chain[4], Yeoun Jin Kim[4], Zhongwu Lai[5], Ying Wang[6], Todd H. Creasy[7], Ramya Gurrapu[8], Sakshi Gulati[9], Alice Barkell[10], Brian Dougherty[1], Danielle Carroll[10], Fabiola Cecchi[2]

[1]Translational Medicine, AstraZeneca, Waltham, MA,[2]Translational Medicine, AstraZeneca, Gaithersburg, MD,[3]Computational Pathology, AstraZeneca, Munich, Germany,[4]Diagnostic Proteomics, AstraZeneca, Gaithersburg, MD,[5]Bioinformatics, AstraZeneca, Waltham, MA,[6]Oncology Data Science, AstraZeneca, Waltham, MA,[7]Oncology Data Science, AstraZeneca, Gaithersburg, MD,[8]R&D IT, AstraZeneca, Chennai, India,[9]Oncology Data Science, AstraZeneca, Cambridge, United Kingdom,[10]Translational Medicine, AstraZeneca, Cambridge, United Kingdom

Background: Multi-omics analysis is widely used in cancer diagnosis, prognosis and prediction of treatment response. Here we introduce the use of targeted proteomics coupled with NGS as tools to assess oncogenic alterations along with quantitative protein expression in patients with mCRC. Our proteomics panel included proteins that are antibody drug conjugates (ADCs) targets (ERBB 1-4, TROP2, CEACAM5 etc.) as well as proteins involved in sensitivity to ADC payload (SLFN11, drug efflux pump, TOP1 etc.).
Methods: The HORIZON III trial (NCT00384176) evaluated FOLFOX + bevacizumab or cediranib as first-line treatment in patients with mCRC (Schmoll *J Clin Oncol* 2012). In the current analysis, a subset of samples from the HORIZON III trial were assessed for molecular alterations using NGS and proteomics. Pre-existing HER2 IHC scores were used as previously referenced (Cecchi *J Clin Oncol* 2023). Samples were processed (n=135) with an automated extraction and library preparation method, then sequenced with both a Whole Exome and targeted-custom gene panel. NGS analysis had a success rate of 116/135 samples (87.3%). Absolute quantitation of protein targets was performed using parallel reaction monitoring (PRM) mass spectrometry after collecting tumor epithelial cells by laser microdissection and punch biopsies (n=60) followed by trypsin digestion.
Results: The NGS analysis showed that patients had mutated *RAS* (50%), *BRAF* (10%), *PIK3CA* (16%), and TMB-H (18%) and MSI-H (5%) status. A distinguished pattern of mutual exclusivity among *KRAS*, *NRAS*, and *BRAF* mutations is evident. The HER2-positive patients were wildtype *RAS*, *BRAF*, and *PIK3CA*, MSS and TMB-L. Samples that were IHC HER2-positive matched those with NGS *ERBB2* amplification. Using PRM, nearly all the evaluable samples had detectable HER2. HER2 IHC 3+ sample showed the highest protein expression at 30,000 amol/ug (equivalent to 1M receptors/cell). Within the HER2-negative patients, HER2 protein expression showed broad dynamic range. CEACAM5 and HER2 are the only ADC targets that reached the level of 1M receptors/cell. Highest TROP2 protein expression is 5 times lower than the highest HER2 value.
Conclusions: Our preliminary findings for this cohort indicate the benefit of the use of multi-modal methodologies to inform better strategies for patient stratification and precision medicine, though further assessment of proteogenomic characteristics is needed. This data may inform future clinical development and guide patient eligibility to clinical trials and possible treatment sequencing for ADCs.

#0937 Prioritizing treatment targets for an adolescent with metastatic processive malignancy using proteomics and personalized xenograft models within an actionable timeframe.

G. D. Barnabas[1], T. A. Bhat[1], V. Goebeler[1], P. Leclair[1], N. Azzam[2], N. Melong[2], J. N. Berman[3], J. A. Chan[4], D. L. Senger[5], S. Parker[1], C. A. Maxwell[1], G. S. Reid[1], J. Bush[1], C. Strahlendorf[1], R. Deyell[1], C. Lim[1], **P. F. Lange**[1];

[1]University of British Columbia, Vancouver, BC, Canada, [2]Children's Hospital of Easern Ontario, Ottawa, ON, Canada, [3]Children's Hospital of Eastern Ontario, Ottawa, ON, Canada, [4]Universtiy of Calgary, Calgary, AB, Canada, [5]Lady Davis Institute for Medical Research, Montreal, QC, Canada

Translation of precision oncology data into feasible precision therapies for hard-to-cure childhood, adolescent and young adult malignancies remains a significant challenge. Identifying therapeutic targets at the protein and pathway level and demonstrating treatment response in personalized models hold great promise, particularly for combination therapies, but may be considered complex and time consuming. Here, we present the case of an adolescent with metastatic, progressive spindle epithelial tumor with thymus-like differentiation (SETTLE) and evaluate how proteomics combined with rapid patient-derived models can identify treatment options not apparent at the genome or transcript level.

Mass spectrometric proteome analysis of macro-dissected tumor and adjacent normal from formalin fixed paraffin embedded sections was completed within two weeks of biopsy and identified key proteins involved in one-carbon metabolism, including SHMT2 and DHFR as possible targets for single or combination therapy. Elevated SHMT2 levels were validated by immunohistochemistry and compared to levels across AYA tumors. Based on the suitability for an innovative therapy trial, we prioritized single-agent sertraline, a commercially available anti-depressant medication that inhibits SHMT2, and confirmed a positive drug response in both chicken chorioallantoic membrane (CAM) and larval zebrafish xenografts generated from the patient. Retrospective expansion in a murine xenograft enabled metabolic tracing on isolated SETTLE- patient-derived xenograft cells using $^{13}C_6$-glucose confirming SHMT2 activity and response to *in vitro* treatment. Following failure of cytotoxic chemotherapy and second-line sorafenib treatment, a monotherapy trial of sertraline was initiated by the patient but stopped after 8 weeks after evidence of progressive disease. Possible combination therapies were evaluated further in the patient-derived models. Combining sertraline with the common antibiotic trimethoprim, resulted in enhanced growth inhibition of SETTLE cells in the larval zebrafish xenografts.

Significance: Overall, we demonstrate that proteomics and personalized xenograft models may provide supportive pre-clinical data in a clinically meaningful timeframe to support medical decision-making and impact clinical practice.

#0938 Screening the entire kinase-directed, FDA-approved pharmacopeia against the largest collection of wild-type and mutant kinases reveals many opportunities for drug repurposing and targeted therapy.

C. M. Loch, S. Liang, J. Wu, M. Eason, A. Goupil, A. Acinapura, J. Purcell, M. Dominguez;
Reaction Biology Corporation, Malvern, PA

We sought to screen all FDA approved, cancer-indicated, kinase targeting drugs using the gold standard radiometric biochemical activity assay (HotSpot) against the largest collection of kinases in the world (>100 drugs against 735 total kinases including 395 wild type and 340 mutants). Virtually every drug examined exhibits polypharmacology inhibiting many kinases. Rarely does the intended target represent the greatest inhibition observed from a drug. Furthermore, most drugs inhibit a select group of mutant kinases, including especially mutants of kinases distinct from the intended target. Within a given kinase, each cancer-identified mutation is often as distinct as the different wild-type kinases are from each other, in terms of inhibition profile. Considering mutants, then, the cancer-relevant druggable kinome is many thousand distinct targets, not 518 “plus a few”. Exposing this reality is a first step towards developing all the therapeutic tools necessary to ultimately defeat cancer. Here, we reveal vast and specific repurposing opportunities among the existing pharmacopeia for tumors that are driven by kinases not previously recognized as targets for certain drugs, and for tumors that have become chemotherapy-resistant through mutation of specific kinases. The most exciting and clinically relevant opportunities were confirmed in cell-based assays, results of which will also be presented.

#0939 Comprehensive genomic and transcriptomic analysis to guide therapy for patients with metastatic solid tumors.

B. Uzunparmak[1], F. Su[1], A. M. Johnson[1], K. Nomie[2], N. Fowler[2], L. Kontselidze[2], A. Bagaev[2], A. Butusova[2], E. E. Dumbrava[1], J. Rodon-Ahnert[1], S. Fu[1], D. S. Hong[1], T. A. Yap[1], A. Naing[1], S. A. Piha-Paul[1], D. D. Karp[1], P. R. Pohlmann[1], A. M. Tsimberidou[1], K. P. Patel[1], F. Meric-Bernstam[1];
[1]UT MD Anderson Cancer Center, Houston, TX, [2]BostonGene, Waltham, MA

Introduction: Precision oncology, which aims to profile tumors for identifying actionable alterations to guide therapy has become mainstream in cancer clinics. While most approaches focus on DNA aberrancies on targeted panels, not all patients' tumors show targetable genomic alterations in these limited gene sets, indicating a need for more comprehensive methodologies combining whole exome (WES) and transcriptome sequencing (RNAseq) to direct a larger fraction of patients to therapies. Here, we aimed to compare the feasibility and utility of BostonGene's (BG) analytical platform with WES and RNAseq to two targeted exome panels in identifying actionable alterations and therapy selection for patients with metastatic solid tumors.
Methods: Study enrolled patients with solid tumors who have had next-generation-sequencing (NGS) testing with one of two tissue-based targeted exome sequencing panels, Oncomine (ThermoFisher, 148 genes), or MDA-MAPP (615 genes) with identification of no College of American Pathologists Tier-1 actionable DNA alterations between August 2022 and November 2023. Patients' tissue and blood/saliva samples were subjected to BG's NGS platform. An alteration-level actionability analysis was done upon receipt of WES results to inform treatment decision making, based on functional and therapeutic effects of the alterations detected.
Results: A total of 64 patients were enrolled; testing was cancelled for 7 patients (10.9%) with samples showing <10% tumor content, while 5 patients' reports were pending at the time of data analysis. Median turn-around time from consent to sample acquisition (SA) and from SA to available genomic profile were 8 and 15.5 days, respectively. 52 patients had NGS results representing a diverse group of tumor types, including sarcoma (*n*=11, 21.2%), head and neck (*n*=*9*, 17.3%) and mesothelioma (*n*=*5*, 9.6%). BG reported DNA alterations (mean: 3.75; median: 4) not shown by prior testing for 94.2% (49/52) of patients, whereby the most common alteration types included SNVs (43.1%), deletions (23.6%) and amplifications (11.8%). BG identified additional actionable DNA alterations (referred to as "AAs"; mean: 1.9, median: 2) in 32 (61.5%) patients, whereby majority of AAs were deletions (59.7%) and amplifications (27.4%). BG detected AAs in 58.8% (10/17) vs 62.9% (22/35) of patients for whom the same vs different samples were used across different tests compared (*P*=0.8). Of 32 patients with AAs, 7 (21.9%) were directed to DNA-informed treatments within 6 months based upon the new genomic findings reported by BG, 14 (43.8%) are being followed for treatment matching, while 11 (34.4%) were deceased.
Discussion: Our results show the feasibility and utility of comprehensive molecular testing to match patients to WES-informed treatments within a clinically relevant time frame. Assessment of the additional benefit of RNA expression analysis is forthcoming.

#0940 Integrated analysis of cfDNA fragmentomics, DNA methylation and cfRNA transcription in metastatic castration-resistant prostate cancer (mCRPC).

C. Dai, L. Zhu, Y. Huang, G. Bonora, K. Zhou, S. Jia, P. Du;
Predicine, Newark, CA

Background Liquid biopsies based on cell-free DNA (cfDNA) analysis provide non-invasive clinical diagnostic insights. Recently, cfDNA fragmentomics has emerged as a tool for inferring epigenomic and transcriptional information from tumor-derived cfDNA. We conducted a comprehensive profiling of cfDNA fragmentomics, whole transcriptome sequencing (WTS), and genome-wide DNA methylation on two metastatic castration-resistant prostate cancer (mCRPC) samples to systematically investigate molecular aberrations in mCRPC.
Methods Two mCRPC patient plasma samples were extensively profiled using high-depth 150x whole-genome sequencing (WGS), 30x whole-genome methylation, and cfRNA WTS. CfDNA fragmentomics analysis was performed to assess androgen receptor (AR) transcriptional activity. We calculated fragment coverage around AR binding sites (ARBS) and quantified ARBS nucleosome profiling abnormality scores (ARBS scores) by comparing centric fragment coverage with normal plasma background. Additionally, we calculated fragment size entropy around AR promoter and enhancer regions to reflect AR gene expression activity. Fragmentomics-inferred gene activity was validated through promoter-targeted panels and WTS profiling of matched mCRPC samples.
Results Both mCRPC plasma samples exhibited significant ARBS nucleosome depletion. Sample A showed a higher ARBS score compared to Sample B. Interestingly, AR enhancer activity inferred from high-depth WGS and targeted panels was high in both samples, while AR promoter activity was high only in Sample A. Genome-wide DNA methylation revealed hypo-methylation in AR enhancer and ARBS regions in both samples, with Sample A showing more pronounced hypo-methylation. Copy number variation analysis indicated AR amplification in Sample A and RB1 loss in Sample B. Collectively, these findings suggest that Sample A may represent androgen receptor-dependent prostate cancer (ARPC), while Sample B may have developed resistance to androgen therapy, possibly indicating neuroendocrine prostate cancer (NEPC).
Conclusions This study, to our knowledge, is the first to combine high-depth WGS, promoter-targeted panels, WTS, and genome-wide DNA methylation to systematically study epigenomic and transcriptional dysregulation in mCRPC. The integration of mutation, copy number variation, fragmentomics, and DNA methylation profiling holds potential clinical utility for inferring prostate cancer subtypes, facilitating patient stratification, and guiding treatment selection.

#0941 Patient-derived model systems of endometrial cancers for disease modeling and drug sensitivity testing.

T. Li[1], X. Huang[2], R. Rosenmeyer[1], S. Robinson[1], K. Salsabil[3], Y. Xiong[1], X. Meng[1], S. Yang[1];
[1]The University of Iowa, Iowa City, IA, [2]Nanjing Medical University, Nanjing, China, [3]California State University, Los Angeles, CA

Background: Endometrial cancer (EC) is the most common gynecological cancer in the US, with increasing incidence and mortality rates. The survival rate lags behind four decades ago (81% vs 87%), underscoring the critical need for more effective treatment strategies. The heterogeneous nature of EC contributes to varied outcomes with current treatments. This project aims to establish reliable EC models for characterizing each individual tumor, distinguish optimal drug treatment, and determine specific drug effect mechanisms for personalized therapy.
Methods: Freshly collected tumors were used for patient-derived xenograft models (PDXs) and patient-derived primary cancer cells (PDCs). Immunohistochemistry (IHC) staining was used to confirm the tumors grown in mice faithfully replicate the characteristics of patient tumor tissues. FDA-approved anticancer drugs were used to screen the optimal drugs to inhibit tumor cell proliferation and further utilized to inhibit tumor growth using PDXs.
Results: We have collected 26 EC tumors and characterize them by DNA mutation and RNA-seq analysis. We implanted them in NSG mice, and 16 tumor samples have successfully grown in mice with a success rate of 61%. Most PDXs can be faithfully passaged to three generations. From the 16 PDXs, we created six novel PDCs. Using 2D and 3D spheroid cell culture, we screened 133 FDA-approved oncology drugs in the EC-PDC models. The drug screening results clearly highlighted several standout drugs, including CUDC-907 (a dual PI3K/HDAC inhibitor), two histone deacetylase (HDAC) inhibitors including romidepsin and panobinostat, four topoisomerase II (TOP II) inhibitors including mitoxantrone, daunorubicin, doxorubicin, and epirubicin, two proteasome inhibitors including carfilzomib and bortezomib, 2 DNA-directed RNA synthesis inhibitor dactinomycin and plicamycin, omacetaxine mepesuccinate (protein synthesis inhibitor), and valrubicin (DNA synthesis inhibitor). These drugs have demonstrated a significant capacity to inhibit tumor cell proliferation. Our pilot studies using single drugs, CUDC-907, romidepsin and mitoxantrone, achieved moderate drug effects. Combine mitoxantrone with romidepsin or CUDC-907 show surprisingly synergistic effects in multiple PDC models. The combination strategy will be tested in PDXs in the near future.
Conclusion: Our unique PDXs and PDCs are excellent models for representing various characteristics of EC and testing novel therapeutics. This current study presents a promising direction for developing personalized therapy options for EC patients and provides a platform for further investigation of drug mechanisms and tumor development. Future studies will also involve etiology, such as chronic psychological stress, DNAm age and intratumoral microbiome. This information will help with endometrial cancer prevention, diagnosis, and prognosis.

#0942 Response to systemic therapies in patient-derived cell lines from primary and recurrent adult granulosa cell tumors.

G. Brink[1], N. Hami[1], S. Mertens[1], W. Hofhuis[2], J. Piek[3], C. de Kroon[4], C. Lok[5], E. Roes[6], L. van Lonkhuijzen[7], H. Nijman[8], H. Snippert[1], J. Groeneweg[1], P. Witteveen[1], R. Zweemer[1];

[1]University Medical Center Utrecht, Utrecht, Netherlands, [2]Franciscus Gasthuis & Vlietland, Rotterdam, Netherlands, [3]Catharina Hospital, Eindhoven, Netherlands, [4]Leiden University Medical Center, Leiden, Netherlands, [5]Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands, [6]Erasmus MC Cancer Institute, Rotterdam, Netherlands, [7]Amsterdam University Medical Center, Amsterdam, Netherlands, [8]University Medical Center Groningen, Groningen, Netherlands

Introduction: In patients with adult-type granulosa cell tumor (aGCT), a rare subtype of ovarian cancer, surgery is the preferred treatment for both primary and recurrent disease. However, the probability of complete resection decreases after multiple recurrences, in which case systemic treatment is an alternative option. Response rates of systemic therapy are variable, resistance is a problem and it is difficult to predict which therapy will work in which patient. Drug screen testing on patient-derived aGCT cell lines may offer a solution.

Methods: In a national prospective study on aGCT, fresh tissue was collected immediately after surgery. Tumor tissue was cultured and developed into 2D cell lines. Both clinically applicable and experimental drugs were tested on the patient-derived cell lines and two control cell lines. Dose-response curves and synergy were calculated using GraphPad Prism and Compusyn software.

Results: We cultured 34 patient-derived cell lines from tissue of seven patients with primary aGCT and from 13 patients with recurrence. In eight patients multiple sites were cultured. A total of 27 drugs were tested, including 10 monotherapies and 17 combinations. Carboplatin/gemcitabine showed efficacy and synergy 33 of 34 patient-derived cell lines (97%), in contrast to the regular carboplatin/paclitaxel and carboplatin/etoposide combinations (50% and 74%, respectively). The experimental combinations alpelisib/fulvestrant and alpelisib/gemcitabine showed efficacy of more than 75%. Testing of anti-hormonal therapy was not sufficiently reliable with this technique.

Conclusion: Drug screening on patient-derived tumor cell lines adequately reflects the reality of the variable response to systemic therapy in aGCT. In future research, this technique could be used to personalize the systemic treatment of aGCT patients. The response to carboplatin/gemcitabine in our patient-derived cell lines is striking.

#0943 Identification and validation of unusual drug combinations identified from combination databases.

R. Grant[1], **M. Pinheiro**[2], R. Weller Roska[1], R. Felix[2];
[1]Bio-Techne Corporation, Minneapolis, MN, [2]Bio-Techne Corporation, Bristol, United Kingdom

There is a noted trend in the identification and subsequent approval of rational drug combinations to treat various diseases, particularly cancer. When applied in a clinical setting, synergistic combinations can have significant benefits including improved patient response and avoiding or overcoming drug resistance. Although multiple strategies have been successfully implemented to identify rational drug combinations, extensive validation is initially required to confirm a combination as synergistic. The existence and growing use of web-based repositories containing comprehensive drug combination data is a key resource and can be a valuable starting point for identifying synergistic combinations. However, are synergistic combinations from these datasets expected or rational and can they be validated experimentally? By mining available drug combinations from the DrugCombo database, we wanted to identify unusual drug combinations reported as synergistic and experimentally validate these with dose-response assays. In addition, we set out to establish if cytokines could be used as an inhibition biomarker to easily assess synergy. We found multiple unexpected synergies including a predicted synergy between the JAK1/2 inhibitor Ruxolitinib with Maraviroc, a CCR5 antagonist, or Levetiracetam, an SV2A binding anti-epileptic reported in the lymphoma cell line, L-1236. Experimentally, these predicted synergies could not be validated. In the context of synergistic drug combinations, this work shows that experimental validation is crucial, particularly for combinations with uncertain biological mechanisms.

#0944 Pre-clinical activity of the Wnt pathway inhibitor RXC004 in combination with MAPK pathway inhibitors in GI cancer models.

S. A. Woodcock, D. Keppel, C. Eagle, J. Kelly, E. Flanagan, E. Bishop, I. Bhamra, C. D. Jones, R. Armer, J. Robertson, C. Phillips;
Redx Pharma Plc, Manchester, United Kingdom

Background: Gastrointestinal (GI) cancers cause more cancer deaths than any other body system, with 3.4 million related deaths in 2018. Wnt pathway activation is common in GI cancers, with the pathogenic upstream Wnt pathway variant sub-population (RNF43 loss of function / RSPO gain of function) showing a combined prevalence of 4.7% in GI cancer patients; pre-clinically this sub-population shows exquisite sensitivity to RXC004, a small molecule Porcupine inhibitor. A striking co-occurrence of upstream Wnt pathway variants with MAPK pathway driver mutations (KRAS, BRAF, NRAS) was detected in 77% of Microsatellite stable (MSS) GI cancers, suggesting co-inhibiting these pathways could enhance clinical activity in these patients.
Methods: *In vitro* proliferation assays were performed in pre-clinical models of upstream Wnt pathway mutated MSS GI cancer (SNU-1411, HPAF-II and AsPC-1) using Wnt (RXC004) or MAPK (Trametinib) pathway inhibitors at multiple concentrations as single agents or in combination. Control cells with downstream Wnt pathway mutations (WiDr and HCT116) were also tested. Synergistic combination effects were detected by BLISS scores. RXC004 (1.5mg/kg QD) and Trametinib (0.3mg/kg QD) were evaluated in an RSPO-fusion xenograft model (SNU-1411) as single agents or in combination. Efficacy was measured by tumour volume and weight; PD markers were assessed in end of study tumour samples. Relative *AXIN2* and *DUSP6* gene expression changes were determined upon inhibitor treatment by quantitative Polymerase Chain Reaction (qPCR).
Results: RXC004 in combination with Trametinib demonstrated strong anti-proliferative synergy in SNU-1411 cells and moderate synergy/additivity in HPAF-II and AsPC-1 cells; no synergy was observed in control cells. *In vivo*, RXC004 and Trametinib monotherapy led to significant moderate tumour growth control ($p<0.05$) at the doses tested, whereas their combination led to significantly enhanced efficacy ($p<0.05$). Gene expression analysis demonstrated a reciprocal Wnt/MAPK signaling mechanism; RXC004 strongly suppressed Wnt signaling (AXIN2) but increased MAPK signaling (DUSP6), whilst Trametinib strongly suppressed MAPK signaling (DUSP6) but increased Wnt signaling (AXIN2). Combination of RXC004 and Trametinib sustained inhibition of both Wnt and MAPK signalling. Similar effects were observed with inhibitors of other MAPK pathway components.
Conclusion: Wnt and MAPK pathways are frequently co-activated in GI cancers, particularly in the upstream Wnt pathway mutated sub-population. Pre-clinically we show that Wnt and MAPK pathways act as potential reciprocal resistance mechanisms following single agent inhibition of either pathway; co-inhibition of these pathways leads to synergistic effects *in vitro* and enhanced efficacy *in vivo.* This provides a clear rationale to assess this combination approach in the clinic.

#0945 *In vivo* anti-tumor activity of onvansertib, a PLK1 inhibitor, combined with gemcitabine or carboplatin in platinum- resistant ovarian carcinoma patient-derived xenograft models.

M. Chiappa[1], F. Guffanti[1], I. Mengoli[1], M. Ridinger[2], G. Damia[1];
[1]Istituto di Ricerche Farmacologiche Mario Negri IRCCS, Milan, Italy, [2]Cardiff Oncology, San Diego, CA

Background: The standard treatment for high grade ovarian carcinoma (HGOC) is cytoreductive surgery followed by a platinum based therapy. Despite an initial high rate of complete remission, most of the patients relapse with a platinum resistant disease. Patients with resistant tumors have few options, including monotherapy with gemcitabine, and new effective therapeutic alternatives are needed. The Polo-like kinase 1 (PLK1) is a master regulator of mitosis and recent evidences suggest its role in interfering with several DNA repair mechanisms. We investigated the effect of onvansertib (ONVA), a highly selective ATP-competitor PLK1 inhibitor, in combination with carboplatin (CARBO) and gemcitabine (GEM) in platinum-resistant HGOC patient-derived xenografts (PDXs).
Methods: The combination of ONVA with either CARBO or GEM was investigated in two platinum-resistant HGOC PDXs, one intrinsically resistant to platinum (MNHOC#315), the other made resistant after repeated *in vivo* treatments with cisplatin (MNHOC#266R). Tumors were subcutaneously (s.c.; MNHOC#315) or orthotopically (i.p.; MNHOC#266R) transplanted in nude mice, mice were treated for 4 weeks with vehicle, single agents or drug combinations and followed for tumor growth (s.c. model) and survival.
Results: CARBO- and GEM-ONVA combinations were well tolerated, with a maximum body weight loss of 6.6%. Both combinations showed strong anti-tumor activities in the two tested models. In MNHOC#315 PDX, CARBO- and GEM-ONVA combinations caused a tumor stabilization that extended beyond the dosing period and resulted in a higher tumor growth inhibition as compared to vehicle and single agents treated mice. In i.p. MNHOC#266R PDX, single agents were inactive, while a statistically significant increase in survival was observed in CARBO/ONVA and in GEM/ONVA treated mice as compared to vehicle treated mice, with a 6.6- and 7-fold increase in mean survival time, respectively. Pharmacodynamic studies are ongoing to decipher the mechanisms underlying the synergic effects of both combinations.
Conclusions: The combinations of ONVA with either CARBO or GEM showed potent anti-tumor activities in two platinum-resistant HGOC PDXs. Additional studies in other HGOC platinum-resistant models, both *in vivo* and *in vitro*, as well pharmacodynamic studies are ongoing to validate these results and to get insights in the mechanisms underlying their efficacy.

#0946 Landscape of HRD aberration in EGFR mutated lung cancer and the role of PARP-inhibitor in EGFR mutated lung cancer with HRD aberration.

J. Kim[1], H. Choi[2], L.-Y. Chung[3], Y. Chae[3];

[1]University of Vermont, Larner School of Medicine, Burlington, VT, [2]The Queen's Medical Center, Honolulu, HI, [3]Northwestern University, Feinberg School of Medicine, Chicago, IL

Introduction: Olaparib, an oral poly polymerase (PARP) inhibitor has received approval for treating malignancies displaying homologous recombination deficiency (HRD). Current data is insufficient in establishing the role of PARP inhibitors in non-small cell lung cancer (NSCLC) in the setting of third generation EGFR tyrosine kinase inhibitor (TKI) use. Preclinical investigation suggests heightened PARP inhibitor sensitivity of TKI-resistant EGFR mutant NSCLC cells compared to TKI-sensitive cells.

Methods: We utilized The Cancer Genome Atlas (TCGA) to investigate the prevalence of HRD gene mutations in patients with NSCLC harboring EGFR mutations. We also present a case demonstrating a favorable response to the dual therapy of olaparib and osimertinib in NSCLC harboring EGFR, RAD50, and ARID1A mutations that progressed on osimertinib.

Results: There were 2298 patients in the NSCLC cohort (MSKCC database). Among 687 patients with EGFR mutations, 24 patients (3.5%) exhibited ARID1A mutations, 8 patients (1.2%) had BRCA1 mutations, 11 patients (1.6%) had BRCA2 mutations, and 5 (0.7%) had RAD50 mutations. A 71-year-old female presented with stage IV adenocarcinoma of the lung. She had recurrent malignant pericardial effusion requiring pericardiocentesis for previous cardiac tamponade. Computed tomography (CT) of the chest revealed a 3cm irregular left hilar mass with bilateral mediastinal and hilar lymph nodes. Tissue next generation sequencing (NGS) at baseline identified EGFR exon19 deletion along with RAD50 R726H which is a HRD pathway gene. Circulating tumor DNA (ct-DNA) NGS (Guardant360) showed EGFR E746_A750del 4.8%. The patient achieved partial response to osimertinib for 28 months. Follow-up CT showed disease progression. Olaparib 200mg twice daily was added to osimertinib based on repeat ct-DNA NGS indicating a new ARID1A alteration (splice site SNV) along with the known BRCA1 mutation. Follow up scans currently have consistently demonstrated ongoing partial response for 19 months. Combining olaparib with osimertinib can be effective in an osimertinib-resistant NSCLC patient with EGFR mutation and HRD aberration. The favorable response could be attributed not only to pre-existing RAD50 mutation but also to acquired mutations in ARID1A HRD genes.

Conclusion: HRD aberrations are uncommon in EGFR mutated lung cancer patients. Further investigation on the role of PARP inhibitor in EGFR mutated lung cancer is warranted.

#0947 A nanodroplet cell processing platform for identifying synergistic drug combinations for neuroblastoma treatment in TH-MYCN transgenic mice.

Y.-T. Liao[1], Z.-K. Yu[1], C.-T. Kuo[2], W.-M. Hsu[3], Y.-X. Huang[1], H. Lee[1];
[1]Department of Life Science, National Taiwan University, Taipei City, Taiwan, [2]Department of Mechanical and Electro-Mechanical Engineering, National Sun Yat-sen University, Kaohsiung Cty, Taiwan, [3]Pediatric Surgery, National Taiwan University Hospital, National Taiwan University, Taipei City, Taiwan

Neuroblastoma is the most common pediatric extracranial solid tumor and contributes to more than 15% of child mortality. It is characterized by extreme heterogeneity and high-risk tumors often resulting in poor prognosis. Currently, chemotherapy is a prevailing standard treatment for neuroblastoma. However, it is plagued by multiple challenges such as drug resistance and debilitating side effects. Synergistic drug combination is proposed as an innovative approach to potentially improve clinical outcomes of single-agent chemotherapy. We propose a novel approach to screen for effective chemo-synergistic drug combinations using Bioinspired nanodroplet processing (BioNDP) screening platform. This platform overcomes the limitations of conventional drug screening approaches, including the requirement for large cell numbers and the low translation rate from bench to bedside. In this study, we utilize TH-MYCN transgenic mice, a well-known genetically engineered mouse model of neuroblastoma that recapitulates critical genetic and clinical aspects of high-risk MYCN-amplified neuroblastoma. With its genetically homogeneous background and spontaneous tumor development, TH-MYCN mice offer a valuable comparison to traditional xenograft mouse models. We have also developed an optimal procedure of primary murine tumor isolation using both negative and positive selection approaches. The purity of the isolated cells was verified with GD2 expression, one of well-known marker of neuroblastoma. In addition, we have successfully identified an effective drug combination of cyclophosphamide, doxorubicin, and vincristine, using primary neuroblastoma tumor samples derived from TH-MYCN transgenic mice as a target. The *in vitro* synergistic effect of primary mouse tumor cell cytotoxicity was confirmed by using luminescent cell viability assay. Further *in vivo* experiments have demonstrated the therapeutic efficacy of this selected drug combination in suppressing tumor growth and improving survival rate in all TH-MYCN transgenic mice treated. To sum up, we aim to establish a future patient-centric paradigm by which minimal primary cell samples from a personalized biopsy of patients may undergo drug screening, leading to the identification of a tailored drug combination. The BioNDP platform we developed may become a pivotal resource for personalized therapy to ensure a faster and more efficient treatment strategy for patients.

#0948 A novel combinatorial therapy for lethal neuroendocrine prostate cancer.

M.-E. Wang[1], W.-L. Tu[1], Y. Lu[1], J. Wu[1], A. Bawcom[1], A. J. Armstrong[1], Q. Wang[1], Y. Wang[2], J. Huang[1], M. Chen[1];
[1]Duke University School of Medicine, Durham, NC, [2]University of British Columbia, Vancouver, BC, Canada

Background: Neuroendocrine prostate cancer (NEPC) is a highly aggressive subtype of prostate cancer that can arise *de novo*, but more commonly develops after hormone therapies for advanced prostate adenocarcinoma. Current treatment options for NEPC are only palliative, and most patients die within several months. Additionally, single-agent clinical trials targeting NEPC so far have only produced disappointing results, highlighting the clear need to develop effective combinatorial therapies for NEPC. *RB1* loss, a pivotal event in the development of NEPC, can sensitize cancer cells to ferroptosis in multiple cancer cell types, including prostate cancer. Here, we aim to identify an optimal combinatorial therapy for NEPC based on targeting ferroptosis.
Methods: We determined the cell-killing efficacy of ferroptosis inducers and several current and emerging treatment regimens for NEPC as single agents, then performed drug synergism analyses of the above two potent treatments. Lastly, we investigated the molecular mechanisms of drug synergism by examining the major types of cell death induced by combinatorial treatment through molecular and biochemical assays.
Results: Our results demonstrated that both ferroptosis inducers and BCL2 inhibitors as single agents led to robust cell death in NEPC cell lines tested. In contrast, cisplatin, the standard of care for NEPC, and Aurora kinase A inhibitor showed modest to no cell-killing effect. Furthermore, suboptimal doses of ferroptosis inducers and BCL-2 inhibitors synergistically induced cell death in NEPC cell lines. Unexpectedly, we found that low-dose ferroptosis inducer led to increased production of mitochondria ROS, which in turn exacerbated BCL-2 suppression-induced apoptosis.
Conclusions: Our findings reveal a novel combinatorial therapy for NEPC. Based on our in vitro data, we will further test the *in vivo* therapeutic efficacy of ferroptosis inducers combined with BCL-2 inhibitors against NEPC growth.

#0949 A single stranded DNA library preparation workflow used for hybridization capture based WES assay showed superior uniformity.

J. Chu, R. Schell, F. Wu, M. Krawczyk, D. Whang, S. Jung, H. Nam, K. B. Thomas, F. J. Lopez-Diaz, V. Funari, J. A. Mayer, S. Kulkarni, J. Guo, S. P. Lau-Rivera;
NeoGenomics, Aliso Viejo, CA

Introduction: In many instances in Precision Oncology Medicine fragmented DNA from formalin-fixed paraffin-embedded (FFPE) samples is the only option. The majority of such degradedsamples need to be sequenced using next generation sequencing (NGS) [1]. Standardizedguidelines highlight that a minimum of 500× coverage depth is required for tissue analyses [2].However, coverage isn't the only metric required for a successful NGS analysis. Highly uniformDNA libraries allow clinical labs to generate more hits from their screens, saving both time andmoney across the course of diagnosis therefore ultimately benefits patient care. The commerciallyavailable single stranded DNA library prep kit tested in this study renders all input moleculessingle-stranded before ligation therefore it recovers template molecules containing DNA nicks andlabile lesions thus maximizing library complexity.
Method: 10 solid tumor FFPE derived DNA samples went through three different NGS workflows:100ng of DNA input in an amplicon-based assay 325 gene panel (Assay A), 60ng input for a 500gene mechanical sheared-based double strand DNA library preparation with hybridization captureassay (~500 gene panel, Assay B), 50ng and 10ng input for a enzymatic shear-based singlestranded DNA library preparation with hybridization capture assay (WES with 1000+ enhancedgene content, Assay C). Data from assays A and C was processed with in-house bioinformaticpipeline, while Assay B's data was processed with a commercially available bioinformatic pipelinethat was bundled with the assay. NGS QC metrics were compared across the three datasets.
Results: This novel single stranded DNA library preparation with hybridization capture workflowshowed superior QC metrics compared to the other two workflows, especially on coverageuniformity and percent target above 100X, with as low as 10ng input.
Conclusion: Employing a novel commercially available DNA library preparation workflow in anNGS assay, NeoGenomics was able to rescue poor quality samples that had previously failed tomeet our internal uniformity metric on other NGS assays and generate robust and reportableresults with as low as 10ng DNA input.[1] Nagahashi et al., *J Surg Res*. 2017 Dec; 220: 125-132.[2] Cappello et al., J Pers Med. 2022 May; 12(5): 750.

#0950 Functional characterization of atypical somatic variants in the Gundersen Precision Oncology Cohort.

P. Feiszt, **P. A. Kenny**;
Gundersen Medical Foundation, La Crosse, WI

The generation and widespread sharing of large somatic mutation datasets has revolutionized our understanding of genetic mechanisms driving cancer initiation and progression. For well-understood mutations, this has created the opportunity for individualized therapeutic intervention in a wide range of malignancies. Beyond these well-characterized mutations, there exists a wide range of alterations that remain poorly understood and which require some kind of functional genomics analysis to determine whether such patients are eligible for the targeted therapy used for more typical mutations in that gene, whether these alterations are passenger mutations that don't affect throughput on the associated signaling pathway, or reflect another more nuanced phenomenon. Whether using ectopic overexpression in cell lines or generation of genetically modified mice, addressing this problem at scale using functional genomics approaches is challenging. A key limitation is the absence of the original tissue context in which that variant co-evolved with other genetic alterations as well as data on the clinical response of the patient to successive lines of therapy. This can be addressed, in part, by the banking of tissue from patient cohorts who have had comprehensive genomic profiling as part of their routine clinical care.

The Gundersen Precision Oncology Cohort is a growing dataset of FFPE specimens and longitudinal clinical data from more than 750 patients who have had comprehensive cancer genome profiling using assays from a wide range of diagnostic companies. We use this resource for biomarker discovery and functional classification of many atypical cancer variants. Current subgroups include atypical point mutations in BRAF, ERBB2 and ERBB3, as well as fusions affecting BRAF, PIK3CA and ROS1. We present examples illustrating the value of this approach for classification of variants detected in a range of tumor types.

#0951 3D-PREDICT - An *ex vivo* precision oncology and clinical trial enrichment platform by Nilogen Oncosystems.

J. Ehrhart, S. Currlin, M. Ataya, A. Humphrey, R. Chakraborty;
Nilogen Oncosystems, Tampa, FL

Background: Immuno-oncology (IO) therapy with checkpoint inhibitors has demonstrated a higher response rate, duration of response, and overall survival than chemotherapy. However, predicting which FDA approved IO therapies or pharmaceutical agents, as well as best combinations and delivery sequence, will have optimal patient response remains a significant challenge for personalized medicine. Nilogen Oncosystem's 3D-PREDICT is a novel *ex vivo* therapeutic investigative platform that provides a functional model of a patient's tumor to investigate susceptibility to different therapeutic approaches directly. Derived from core biopsies, the 3D-PREDICT model captures the tumor heterogeneity while preserving the tumor microenvironment by retaining stromal components and cell-cell and cell-extracellular matrix interactions. Here, we employed the 3D-PREDICT platform to compare the efficacy of different immunotherapeutic approaches in various solid tumor indications *ex vivo*.
Methods: Tumoroids from 18-gauge core biopsies from solid tumors were generated using Nilogen Oncosystems's proprietary mechanical process forgoing any enzymatic digestion or propagation while keeping the spatial contexture of stroma intact. Pooled tumoroids were treated *ex vivo* for 72 hours with various standard-of-care mono or combo therapy (carboplatin, anti-programmed death-ligand 1 (PD-L1) antibody atezolizumab, anti-CD47 antibody magrolimab, anti-programmed cell death receptor-1 (PD-1) antibody nivolumab, or a combination of magrolimab and atezolizumab). Treatment-mediated immune modulation in tumor microenvironment were analyzed to predict patient response to subjected therapies.
Results: Treatment-mediated tumor cell killing activity was evaluated using 3D high throughput confocal imaging and Nilogen Oncosystems's proprietary algorithm for data analysis. The *ex vivo* response to checkpoint inhibitors was correlated with retrospective patient clinical information. Tumoroid samples treated with atezolizumab and magrolimab demonstrated enhanced tumor cell killing. Approximately 20% of tumors showed increased CD8 T-cell activation upon *ex vivo* treatment, correlating with proinflammatory cytokine release in conditioned media.
Conclusions: The 3D-PREDICT *ex vivo* tumoroid platform provides a unique resource to predict patients' response to treatment, potentially serving as a clinical diagnostic to guide clinical care and stratifying patient procurement into clinical trials. This would allow prospective assessment of therapeutic efficacy *ex vivo* to match each patient to the most effective and least toxic, to improving outcomes, reducing costs, and assigning therapeutics on a more rational basis.

#0952 *Ex vivo* drug testing identifies a potentially effective drug in 94% of cases for 403 patients in 42 tumor types.

R. Rosati[1], A. C. Rajevski[1], P. Chatterjee[1], L. R. Appleyard[1], A. Cordero Schmidt[1], S. Pereira[1], R. L. Diaz[1], B. Bernard[1], B. Bernard[2], C. Grandori[1], C. J. Kemp[3];

[1]SEngine Precision Medicine, Seattle, WA, [2]Earle A. Chiles Research Institute, Providence Cancer Institute, Portland, WA, [3]Fred Hutchinson Cancer Research Center, Seattle, WA

Objective: To determine whether patient derived tumor cells (PDTC) could be derived from a variety of solid tumors and used to select effective therapies, we developed a CLIA certified assay, the PARIS® test, to quantify drug sensitivities using PDTCs.

Methods: Oncologists referred patients for the PARIS® test and patients had the option to consent to SEngine Precision Medicine's IRB protocol. Samples were obtained from multiple cancer centers across the US and abroad. Patients were at all stages in their clinical journey ranging from treatment naïve to late stage, recurrent/refractory disease settings. Fresh specimens obtained from surgical resections, core biopsies, or body fluids arrived at our CLIA laboratory within 48 hrs from collection. Tumor origin and driver mutations were confirmed by IHC or DNA sequence in 88% of the cases.

Results: PDTCs derived from 403 patients diagnosed with 42 different solid tumor types, including both common and rare tumors, were subjected to the PARIS® assay. An average of 67 oncology drugs (ranging from 6-307), including chemotherapies and targeted agents, were tested for each patient sample. A report ranking drug sensitivities was provided to the oncologist with an average turnaround time of less than 3 weeks. Drug sensitivity was classified as exceptional/good, moderate/low and no responses. Remarkably, 94.2% of the PDTCs exhibited selective exceptional/good responses to at least one, and typically several drugs, despite the majority of PDTCs being derived from patients with drug resistant, metastatic disease. The drug sensitivity profiles showed highly individualized responses as well as tumor type specificity. While known biomarkers/drug sensitivity associations were confirmed, many samples exhibited sensitivity to targeted agents in the absence of known biomarkers. For example, HER2+ breast cancers demonstrated sensitivity to HER2/EGFR inhibitor and a subset of luminal B and triple negative breast cancers demonstrated HER2/EGFRi responses without underlying genetic alterations. Functional testing was also useful in the rare tumor types. For example, low grade serous ovarian cancer (LGSOC) cells, differentiated from high grade by their response to specific receptor tyrosine kinase inhibitors and estrogen antagonists, but a poor response to standard of care, as is observed in the clinic. Three patients with LGSOC that were treated with the PARIS test top scoring drugs had a positive clinical response and cases from other tumor types will be presented.

Conclusions: Functional testing of PDTCs from both common and rare tumor types is feasible, even for those that have failed standard of care. We provide an unprecedented view of patient-specific, actionable vulnerabilities to current oncology drugs. Personalization of cancer care will require improved access to off-label drugs.

#0953 Integration of functional precision medicine assay for high grade glioma management: A single institution experience.

G. Guzman[1], S. Bettadapura[1], W. J. Shelton-Correa[1], T. Brooks[2], M. Rayner[2], C. Wardell[1], A. Rodriguez[1];
[1]University of Arkansas for Medical Sciences, Little Rock, AR, [2]Kiyatec, Inc., Greenville, SC

Despite the advances in precision oncology, genomic approaches have not significantly improved outcomes for high grade gliomas (HGGs) as once was anticipated. Recurrent HGG pose even greater therapeutic challenge. The integration of functional precision medicine (FPM), in which drugs screens are performed on live tissue, into clinical routine practice presents a promising alternative by offering personalized treatments based on the unique characteristics of the patient's tumor. Here, we present our institutional experience of integrating a spheroid-based drug screening assay (3D Predict^{TM} Glioma) in the treatment management of HGG patients to evaluate its feasibility and efficacy as a therapeutic tool in a clinical setting. We also sought to determine factors that related to assay success. Tissue from intracranial lesions of patients with presumed HGG and planned surgical resection at our institution were collected for ex vivo 3D cell culture and challenged with 12 drug agents to determine patient-specific response parameters. The impact of potential variables, such as ki67, tumor pathology, and shipment timing, on the assay's success was evaluated. Clinical correlation was established between ex vivo response and clinical response in HGG patients. 57 samples, including 24 upfront HGGs, 32 recurrent HGGs, and one medulloblastoma, were sent for spheroid formation and drug testing. In total, 57.9% (33/57) or 23% (13/57) of the assays were successful and resulted in complete or partial functional profiling data, respectively. We conducted a multivariable analysis of our cohort to determine which variables (i.e. tumor volume sent, ki-67 proliferation index, tumor percentage determined by DNA sequencing by Tempus Lab, recurrent status, sample shipment time) were predictive of assay success. The only variable significantly associated with assay success was tumor percentage with samples comprised of >70% tumor leading to assay success, 40%-70% leading to 60% chance of success, and <40% having 0% success. Among 46 patients with partial or complete assay success, 26 patients (56.5%) had a targetable mutation and 17/26 yielded a moderate or full response to one or more of their corresponding targeted drugs in the assay. Treatments were newly administered or altered from prior treatments in 40/57 patients (70%) based on FPM results. Our study demonstrates the technical feasibility of incorporating FPM approaches in the development of treatment regimens for patients with HGG. Success was correlated to tumor percentage present in the sample which indicates intraoperative communication between surgeon and pathologist can lead to improved assay results. Our institutional protocol demonstrates that Integrating FPM into routine clinical practice is possible and can serve as a valuable guide in the refinement of therapeutic recommendations for HGG patients.

#0954 An evaluation of the combination of metformin and Y15 for the treatment of platinum-resistant ovarian cancer.

M. A. Duarte[1], K. Garcia[1], M. A. Arriaga[1], S. Chew[1], A. S. Levy[2], I. Mendez[1];
[1]University of Texas Rio Grande Valley, Brownsville, TX, [2]Nova Southeastern University, Fort Lauderdale, FL

Ovarian cancer is the fifth leading cause of cancer mortality among women. This high mortality rate is linked to the development of resistance to first-line chemotherapy with platinum compounds which has been attributed in part to increased activity of focal adhesion kinase (FAK). The anti-diabetic drug Metformin was previously shown to inhibit the proliferation and migration of ovarian cancer cells and thus, the combination of a FAK inhibitor, Y15, and Metformin may be a promising treatment for platinum-resistant ovarian cancer (PROC). The objective of this study was to evaluate the combination of Y15 and Metformin on PROC cell viability and the mechanism of cell death. An MTT assay was used to analyze cell viability in PROC OVCAR3 cells after 48 h of treatment by measuring the absorbance at 570 nm with a microplate reader. Western blot was used to determine the protein levels of the apoptosis marker cleaved PARP and the autophagy marker LC3B-II. The exposure of OVCAR3 platinum-resistant ovarian cancer cells to Metformin (4.5 mM) + Y15 (5.5 μM) resulted in a significantly enhanced cytotoxicity (32.6 ± 1.8%) compared to single drug treatment with either Metformin (4.5 mM) (65.0 ± 4.2%) or Y15 (5.5 μM) (66.0 ± 4.8%). A combination of Metformin (7.8 mM) + Y15 (5.5 μM) also resulted in a significantly enhanced cytotoxicity (22.8 ± 1.5%) compared to single drug treatment with either Metformin (7.8 mM) (50.7 ± 3.7%) or Y15 (5.5 μM) (66.0 ± 4.8%). Cells treated with the combination of Metformin and Y15 for 24, 48, and 72-hours showed an increase in cleaved PARP compared to the control, Metformin alone and Y15 alone. For Metformin alone, there was an increase in cleaved PARP compared to the control at all timepoints and increased from 24 hours to 72 hours. For Y15 alone, the amount of cleaved PARP was also higher compared to the control at all time points, however, decreased over time from 24 hours to 72 hours. Cells treated with Metformin, Y15, and a combination of Metformin and Y15 showed no conversion of LC3B-I to LC3B-II, which occurs during autophagy. Thus, it is concluded that the mechanism of cell death for both Metformin and Y15 is through apoptosis and not autophagy and apoptosis is enhanced with the combination of the drugs. The delivery of Metformin and Y15 can result in an additive effect on cell viability through apoptosis and can be further explored as a promising approach for the treatment of PROC.

#0955 Double-targeting of pancreatic ductal adenocarcinoma (PDAC): Unveiling the potent combination of NMS-873 and BAY-876.

E. R. Eppinger, C. Schneeweis, D. Saur;
TranslaTUM, Munchen, Germany

Pancreatic ductal adenocarcinoma (PDAC) stands out as one of the most aggressive and challenging-to-treat cancers known. Consequently, the development of effective therapeutic strategies holds significant importance in enhancing patient outcomes. In contrast to single-drug treatments, combination therapies offer the potential for improved results by addressing multiple pathways. This approach not only reduces the likelihood of drug resistance but also encourages synergistic effects, all while permitting the use of lower individual drug doses, thus minimizing potential side effects. In this study, we subjected a panel of PDAC cell lines with varying degrees of sensitivity to a high-throughput combinatorial drug screen. Mitochondrial complex 1/p97 inhibitor NMS-873 was tested in combination with 95 other compounds, revealing remarkable synergy when paired with Glut1 inhibitor BAY-876. In order to affirm the validity of these findings, we conducted further experiments involving multi-dose drug combinations within long-term clonogenic assays. These supplementary investigations also demonstrated significant synergistic effects between BAY-876 and NMS-873, as quantified through the calculation of Bliss and Zip scores. Notably, this combination exhibited superior efficacy when confronting PDAC cell lines that are more resistant to NMS-873, highlighting the potential of this combination to overcome therapy resistance. To gain insights into the underlying mechanisms behind these outcomes, we performed a gene enrichment analysis which revealed that the more sensitive cell lines exhibited elevated rates of cell division, while the more resistant ones demonstrated heightened cRNA processing and increased metabolic activity, particularly in protein, phospholipid, and lipid synthesis. The combination of BAY-876 and NMS-873 presents a promising avenue for the targeted treatment of PDAC. This study underscores the remarkable synergy observed in mouse PDAC cell lines with a particular emphasis on the heightened efficacy against cell populations that are more resistant to NMS-873. These results warrant further investigation to elucidate the underlying molecular mechanisms and validate these findings in clinical settings.

#0956 NCX 4040 and napabucasin synergistically inhibits stemness in human prostate cancer (PCa) cellular models and potently targets transgenic murine PCa cells via inducing oxidative stress.

S. Shah, G. Munirathinam;
University of Illinois College of Medicine (Rockford), Rockford, IL

Prostate cancer (PCa) continues to have a substantial impact on men's wellbeing and quality of life regardless of recent progress in diagnosis and treatments and it continues to have the second highest occurrence rate following lung cancer. The strategy of combination drug therapy has gradually become a valuable choice for treating various cancer types, addressing the heterogeneity within tumors, and surpassing the constraints of existing treatment methods. In our previous work, when we combined two drugs NCX 4040 (an oxidative stress inducer) and napabucasin (a STAT3 signaling inhibitor), we discovered that the combination treatment synergistically works to inhibit the malignant characteristics of human PCa cells. Also, the combination upregulated the cGAS-STING immunogenic pathway in PCa cells which could potentially activate the cancer-targeting cytotoxic T-cells. In the current study, we aimed at investigating the anti-stemness properties of the drug duo which can not only inhibit cancer cell differentiation but also can be effective in preventing cancer relapse. We used two cell lines i.e., BPH-Cd which served as a model of cadmium induced PCa and DU145 as a model of advanced PCa to examine the anti-stemness properties of the drug combination. Based on western-blot analysis, we found the downregulation of transcription factors such as Oct4, Sox2, Nanog, β-catenin and cell surface markers like CD44, CD133 and ALDHA1, which are responsible for stem-cell like properties. In addition, we have tested the combinatory anticancer effects in transgenic mouse derived PCa cell line (Myc-Cap) as a prelude to conduct future studies in FVB mouse syngeneic model to evaluate the tumor suppressive and the antitumor immunogenic responses of combination treatment as it activated cGAS-STING pathway. By performing the cell viability assay, we found that the IC_{50} value of NCX 4040 is ~10μM and that of napabucasin is ~1μM, however when used in combination, ~90% inhibition is seen at 10μM of NCX and 250nM of napabucasin dual treatment. The drug combination also showed synergy in inhibiting tumorigenicity in clonogenic assay and migratory potential in wound-healing assay. By investigating the ROS production, cell death and cell cycle mechanism using flow cytometric analysis, it was observed that the combination therapy synergistically induces cellular oxidative stress which causes cancer cells to undergo late apoptosis and halts the growth of Myc-Cap cells in G2M phase of cell cycle. In conclusion, our data suggests that combination therapy of NCX 4040 and napabucasin can be potential treatment strategy for PCa warranting further evaluation in *in vivo* models.

#0960 Improved cfDNA methylation profiling through correction of misrepaired jagged-ends.
R. Wang, E. G. Hamilton, D. Almanza, A. Hui, M. Diehn, A. A. Alizadeh;
Stanford University School of Medicine, Palo Alto, CA

Background: Profiling cfDNA methylation enables early cancer detection and classification, but challenges arise from "jagged ends" (JEs) for ~90% of cfDNA molecules, as well as for FFPE samples and partially degraded genomic DNA. Repair of these jagged ends introduces erroneous methylation signals, especially in shorter cfDNA fragments enriched for tumor derived molecules. Separately, DNA conversions during 5mC profiling hamper accurate simultaneous ctDNA genotyping of somatic mutations. To meet these needs, we developed a method preserving double-stranded cfDNA molecules without error-prone end-repair at jagged ends. This enables superior methylation profiling including hemimethylation detection, and simultaneous ctDNA SNV genotyping.
Methods: We present JEEPERS (Jagged-End Error Polishing of Enzymatically misRepaired Sequences), a novel method for correcting errors in double-stranded library preparation for methylation profiling. JEEPERS detects and quantifies enzymatic repair errors at JEs, correcting them in silico. Leveraging duplex UMIs, it utilizes complementary strands and sibling reads from cfDNA families without jagged ends. The method exploits the 5' to 3' polarity of ER-associated errors and JE length profiles for correction. JEEPERS introduces anchor CpGs for precise correction of rare signals and enables accurate SNV calling at non CpG sites, addressing the challenge of differentiating true SNVs from conversion artifacts leading to C>T/G>A changes in sequencing data.
Results: Analyzing 248 cfDNA samples (139 NSCLC patients, 109 healthy controls) by methylation profiling (EM-Seq) and ctDNA mutation genotyping (CAPP-Seq), JEEPERS correction efficiently addressed distortions, even at low tumor concentrations. Limiting dilution experiments demonstrated JEEPERS achieving a LOD95 of ~0.2% with 95% specificity (n=300). Despite ~50% lower molecular depth, JEEPERS-corrected cfDNA EM-Seq enabled accurate simultaneous methylation profiling and ctDNA genotyping, correlating strongly with CAPP-Seq genotypes ($R=0.998$, $n=30$). As expected, mutant ctDNA molecules were shorter than wild-type in both CAPP-Seq and EM-Seq data. cfDNA methylation patterns varied by oncogene vs. tumor suppressor status; EGFR mutants showed increased methylation ($p<0.01$), while TP53 mutants had lower methylation levels ($p<0.05$).
Conclusions: Our method effectively corrects cfDNA methylation data, even at low tumor concentration, ensuring enhanced methylation signal accuracy and proficient SNV calling capabilities. This integrated approach offers a powerful means for investigating the link between SNVs and DNA methylation, significantly enhancing the accuracy of cancer detection using cfDNA, especially for early-stage tumors. This paves the way for a deeper understanding of the molecular mechanisms driving cancer initiation and progression.

#0961 Detection of minimal residual disease in lymph predicts recurrence in HPV-negative head and neck cancer patients.

W. Winckler[1], Z. Gu[1], D. Whitfield[1], N. Earland[2], A. Harmon[1], M. Long[1], P. Harris[2], Z. Xu[3], R. Ramirez[2], S. Gerndt[2], M. Pacula[1], M. S. Francis[1], J. P. Zevallos[3], A. A. Chaudhuri[2];

[1]Droplet Biosciences, Inc., Cambridge, MA, [2]Washington University School of Medicine, St. Louis, MO, [3]University of Pittsburgh Medical Center, Pittsburgh, PA

Background: Locoregional cancer relapse remains a major cause of failure in head and neck squamous cell carcinoma (HNSCC), particularly for HPV-negative patients whose 2-year locoregional failure rate is up to 50%. There is unmet need for an accurate diagnostic test that predicts risk of recurrence prior to adjuvant therapy selection. We present a novel proximal assay for minimal residual disease (MRD) profiled in lymphatic exudate collected via surgical drains (“lymph”).
Methods: Lymph, plasma, and blood were collected from 46 HPV-negative HNSCC patients postoperatively at 24 hours along with resected tumor. Cell-free DNA was extracted from lymph and plasma and sequenced using the TruSeq Oncology 500 panel to a depth of >100 million reads. Somatic mutations were identified by exome sequencing (200x) tumor and blood. Five patients had <2 mutations in tumor and were excluded. Two patients were censored due to lack of clinical data, yielding 18 patients with disease recurrence (REC) and 21 with no evidence of disease (NED) with >1 year of follow-up. Tumor-specific variants were force-called in lymph and plasma using a custom pipeline. Patients were considered MRD positive if the mean variant allele fraction (mVAF) was greater than 0.015% (the estimated limit of detection). The Kaplan-Meier (KM) estimator with log-rank test and Cox proportional-hazards model were used for survival analyses. Logistic regression model was performed with 5-fold cross-validation.
Results: KM survival analyses showed lymph accurately predicts recurrence (sensitivity (SN) = 78%, specificity (SP) = 67%; p = 0.003, Hazard ratio (HR) = 4.7), while plasma was not significant (p = 0.92) at this postoperative timepoint. Performance was enhanced for locoregional relapse (SN = 92%, SP = 67%; p = 0.001, HR = 13.9. N=33). We also observed accurate recurrence prediction (SN = 83%, SP = 69%, p = 0.03, HR = 7.7) in the 19 N0 patients (node-negative by pathology). Lymph MRD outperformed individual pathology features (extranodal extension, perineural invasion, lymphovascular invasion, and nodal disease status) for recurrence prediction (HR = 3.4, 0.88, 2.5, 2.4, respectively). A logistic regression model combining lymph MRD with these 4 high-risk pathologic features showed superior performance over lymph alone or pathology alone (SN = 89%, SP = 67%; p = 0.0007, HR = 8.6).
Conclusions: ctDNA analysis of lymph from surgical drains represents a novel proximal MRD approach in HPV-negative HNSCC. Postoperative lymph significantly outperforms plasma for prediction of recurrence, particularly in patients with locoregional relapse. Accurate MRD identification in patients with lower risk pathologic features suggests that lymph MRD testing has potential to augment traditional pathology and provide more personalized adjuvant treatment decision-making in patients with HPV-negative HNSCC.

#0962 Monitoring on-treatment tumor molecular dynamics using plasma whole genome sequencing (pWGS) and whole exome sequencing (pWES) of circulating tumor DNA (ctDNA) in advanced esophageal cancer: An exploratory analysis of KEYNOTE-590.

M. Shah, E. Dettman, A. Albright, C. Chen, J. Kobie, S. Shah, C. Pena, R. Cristescu, Z. Cao;
Merck & Co., Inc., Rahway, NJ

Background: We evaluated on-treatment tumor molecular dynamics using ctDNA-based pWGS and pWES in patients (pts) with locally advanced or metastatic esophageal cancer that responded to pembro + chemo or chemo alone and later experienced PD in KEYNOTE-590 (NCT03189719). **Methods:** Pts with locally advanced, unresectable, or metastatic esophageal or Siewert type 1 gastroesophageal junction cancer were randomized 1:1 to first-line pembro 200 mg or placebo + chemo (5-fluorouracil + cisplatin) Q3W for ≤35 cycles. Cell-free DNA (cfDNA) was isolated and sequenced from plasma samples collected at baseline (BL), during on-treatment response (cycle 5 [C5]), and at PD (discontinuation [D]) from pts with response and subsequent PD. ctDNA burden (tumor fraction [TF]) was estimated using low-pass pWGS by quantifying tumor aneuploidy in cfDNA. All samples with TF >1.5% underwent high-depth pWES. ctDNA burden from pWES was estimated as maximum somatic allele frequency (MSAF). Associations of TF with MSAF were assessed using Spearman correlation coefficient *r*. For each subject, Jaccard index (JI) was calculated to evaluate the overlap of variants between BL and D. Variant allele frequency (VAF) and normalized VAF (nVAF) were used to determine variant clonality. **Results:** 108 pts (pembro + chemo, 59; chemo, 49) with initial response and subsequent PD had plasma samples available from BL, C5, and D. Samples from 94 pts had TF >1.5% by pWGS and underwent pWES. MSAF correlated with TF at BL (r = 0.84), C5 (0.56), and D (0.86). ctDNA TF was lower at C5 than at BL and D, with a mean of 4.4% (C5) vs 20.9% (BL) and 14.0% (D) with pembro + chemo and 4.0% (C5) vs 15.8% (BL) and 15.5% (D) with chemo. In variant-level analyses of pWES data from samples with high TF (≥2.5%) at BL and D (n = 65), 39.2% and 44.2% of variants were shared between BL and D with pembro + chemo and chemo, respectively. Higher overlap was observed for variants between BL and D for the chemo arm (JI: median, 0.54; range, 0.04-0.91) vs pembro + chemo (0.37; 0.01-0.92). Shared variants between BL and D had higher clonality compared with variants at BL-only or D-only with pembro + chemo (BL and D mean nVAF = 0.50 vs BL-only = 0.39, and D-only = 0.38) and chemo (0.49 vs 0.38 and 0.38). In pooled variant analyses, *TP53* was the most commonly observed mutation and was rarely lost or acquired at D. **Conclusions:** Comprehensive pWES was feasible with sufficient ctDNA burden (TF ≥2.5%). ctDNA burden dynamics followed high disease burden at BL and D, consistent with radiographic determination of response/PD. Tumor variants at BL and D generally had a common clonal trunk and a higher overlap of variants was observed at D in the chemo arm. These results provide preliminary molecular evidence of immune editing in pts receiving immunotherapy that warrants further study.

#0963 Comprehensive epigenomic profiling from plasma to inform therapy selection: A proof-of-concept study in cancer.

T. Clark[1], J.-H. Seo[2], A. D'Ippolito[1], A. Gorthi[1], J. Beagan[1], J. Guess[1], A. Donahue[1], M. Greene[1], A. Lau[1], F. Ramirez[1], K. Cibulskis[1], H.-H. Jeong[1], M. Davidsohn[2], G. Lakshminarayanam[2], M. Coyne[1], B. Tran[1], T. Tamakloe[1], H. Sawaengsri[1], M. Eid[2], K. Semaan[2], B. Fortunato[2], C. A. Painter[1], **J. Chmielecki**[1], T. K. Choueiri[2], J. Barrett[1], G. Otto[1], M. L. Freedman[2], M. L. Eaton[1], S. C. Baca[2];

[1]Precede Biosciences, Inc., Boston, MA, [2]Dana-Farber Cancer Institute, Boston, MA

BACKGROUND: Analysis of genomic alterations in circulating tumor DNA is gaining traction in clinical oncology and can provide insights into tumor biology without the need for invasive tissue sampling. In addition to genetic alterations, epigenomic reprogramming leads to transcriptional dysregulation and drives cancer phenotypes including molecular subtypes, histologic subtypes, and mechanisms resistance. As current liquid biopsy assays fail to effectively capture transcriptional biology, new approaches are needed to examine the transcriptional status of therapeutic gene targets and pathways including those relevant to rapidly emerging classes such as antibody-drug conjugates (ADC) and radio-conjugates.

METHODS: We developed a novel multimodal assay that reveals genome-wide transcriptional activity of promoters, enhancers from chromatin and surveys the DNA methylome using 1ml of patient plasma. We applied this assay to patient plasma samples from across 15 tumor types generating 7000 genome-wide transcriptional profiles.

RESULTS: We confirmed a significant correlation between epigenomic signals of transcriptional activation and gene expression from RNA-seq (Promoter vs RNA-seq: ρ =0.95, $p<0.05$; DNA methylation vs RNA-seq: ρ=-0.16, $p<0.05$). We identified transcriptional activation in cancer patient plasma of well-established cancer-associated biomarkers (e.g. MET, DLL3, PSMA) in a tumor-specific manner. Epigenomic profiling simultaneously inferred the expression of multiple pertinent ADC targets currently under investigation (MET, HER2, HER3, TROP2, B7H4 in breast cancer), and SLFN11, a known biomarker for sensitivity to these agents. Unlike targeted panels, the platform assesses transcriptional regulation genome-wide, enabling the assessment of transcriptional activity of select genes as well as related pathways. For example, a multimodal classifier robustly predicted HER2 status across metastatic breast cancer plasma samples based on features both within the *HER2* amplicon as well as *HER2*-distal genes that are activated in HER2+ cancers (AUC = 0.93, 0.84-1.0 95% CI). The multimodal classifier out-performed individual analyte-based classifiers ($AUC_{Promoter+Enhancer}$ = 0.85, 0.72-0.98 95% CI; $AUC_{DNA\text{-}methylation}$ = 0.69, 0.48-0.90 95% CI). Epigenomic signatures were also used to delineate multiple mechanisms of resistance to androgen receptor signaling inhibition in prostate cancer, including reactivation of the androgen receptor, glucocorticoid signaling bypass, and histological transformation to a neuroendocrine subtype.

CONCLUSION: This comprehensive epigenomic liquid biopsy assay provides a platform for simultaneous genome-wide transcriptional assessment of disease and therapy relevant genes and pathways, representing a paradigm shift in our ability to longitudinally monitor cancer in individual patients.

#0964 Updated results of a prospective observational multicenter study on resistance mechanisms to osimertinib using circulating tumor DNA analyses in EGFR-mutated non-small cell lung cancer patients (ELUCIDATOR study).

M. Osuga[1], A. Tamiya[2], D. Harada[3], Y. Mizumori[4], S.-i. Isa[2], Y. Taniguchi[2], K. Nakamura[5], T. Shinohara[6], H. Yanai[7], K. Nakatomi[8], M. Oki[9], M. Mori[10], T. Kuwako[11], K. Yamazaki[12], A. Tamura[13], M. Ando[14], Y. Koh[1];

[1]Wakayama Medical University, Wakayama, Japan, [2]National Hospital Organization Kinki-Chuo Chest Medical Center, Sakai, Japan, [3]National Hospital Organization Shikoku Cancer Center, Matsuyama, Japan, [4]National Hospital Organization Himeji Medical Center, Himeji, Japan, [5]National Hospital Organization Asahikawa Medical Center, Asahikawa, Japan, [6]National Hospital Organization Kochi Hospital, Kochi, Japan, [7]National Hospital Organization Mito Medical Center, Higashiibaraki, Japan, [8]National Hospital Organization Ureshino Medical Center, Ureshino, Japan, [9]National Hospital Organization Nagoya Medical Center, Nagoya, Japan, [10]National Hospital Organization Osaka Toneyama Medical Center, Toyonaka, Japan, [11]National Hospital Organization Shibukawa Medical Center, Shibukawa, Japan, [12]National Hospital Organization Kyushu Medical Center, Fukuoka, Japan, [13]National Hospital Organization Tokyo National Hospital, Kiyose, Japan, [14]Nagoya University Hospital, Nagoya, Japan

Background: Although osimertinib (Osi) is the key standard therapy for patients (pts) with advanced non-small cell lung cancer (NSCLC) harboring sensitizing epidermal growth factor receptor (EGFR) mutations, most of cases experience the progressive disease (PD) after initial response to the treatment. Therefore, understanding the Osi resistance mechanisms and identifying the poor responders are essential to develop better treatment strategies. Thus, we conducted a prospective observational multicenter study and analyzed serially collected circulating tumor DNA (ctDNA). Here we report the results from updated analyses focusing on the association between genetic information from ctDNA and clinical outcome.

Methods: Patient eligibility criteria were as follows: a definitive diagnosis of non-squamous NSCLC confirmed through biopsy or cytology, EGFR exon 19 deletion (19del) or L858R mutation, Osi planned as first-line treatment, and pts who could provide blood specimens. Paired plasma DNA samples were collected before starting Osi as baseline (BL) and at PD and analyzed to investigate Osi resistance by next-generation sequencing (NGS). Correlations between genetic information obtained from ctDNA and clinical outcome such as progression free survival (PFS) and overall survival (OS) were evaluated. The median follow-up time was 33.1 months.

Results: One hundred eighty-eight pts were enrolled between May 2019 and January 2021, and 125 (66%) were female, 96 (51%) were EGFR 19del mutation, and 109 (58%) were never smoker. Among those, 178 pts were included in the analyses, and 111 experienced PD. In consistent with previous reports, median PFS (mPFS) and median OS (mOS) were 19.1 months and 36.0 months, respectively. The efficacy of Osi differed between 19del and L858R in both PFS and OS, with 19del being longer outcome [mPFS, 23.3 months vs. 17.2 months, HR: 1.56 (95%CI: 1.08-2.26), mOS, 40.3 months vs. 30.4 months, HR: 1.54 (95%CI: 0.98-2.45)]. Univariate analysis revealed that the presence of TP53 mutations and MET amplification (amp) at BL was a predictive factor of shorter PFS and OS. Multivariate analysis also revealed that the TP53 mutations at BL was a predictive factor of shorter PFS and OS. Plasma samples from 85 pts were available for ctDNA analysis. New adaptive mutations or amp at PD were detected in genes such as PIK3CA in 3 cases, MET amp in 4, TP53 in 4, BRIMP3 in 2, APC in 1, and BRAF in 2. Secondary EGFR C797S resistance mutation was detected in 1 case.

Conclusions: TP53 mutation at BL could be predictive of poor response to Osi. MET amp and PIK3CA mutations were detected as the most common resistance mechanisms, and secondary EGFR resistance mutations were observed less frequently than previous reports.

#0965 Urine cell-free DNA multi-omics combining copy number analysis with fragmentomics to detect minimal residual disease in bladder cancer patients.

Arpit Panda[1], Irfan Alahi[2], Pradeep S. Chauhan[2], John Sheng[2], Nathan Colon[2], Cayce Nawaf[2], Alexander Shiang[3], Peter K. Harris[2], Faridi Qaium[2], Eric H. Kim[2], Melissa A. Reimers[2], Woodson Smelser[2], Zachary L. Smith[2], Aadel A. Chaudhuri[2]

[1]University of Chicago, Chicago, IL,[2]Washington University in St. Louis, St. Louis, MO,[3]Cedars-Sinai Medical Center, Los Angeles, CA

Background: Standard-of-care for patients with localized muscle-invasive bladder cancer (BC) is neoadjuvant chemotherapy followed by radical cystectomy (RC). Bladder-sparing treatments are limited by our current inability to sensitively detect minimal residual disease (MRD). Here, we analyzed urine, a noninvasive and proximal biofluid, from patients with bladder cancer and utilized an approach that incorporates copy number-derived tumor fraction as well as fragmentomics to sensitively detect MRD and predict pathologic complete response (pCR).
Methods: We acquired urine preoperatively from 51 BC patients (80% muscle-invasive) on the day of standard-of-care RC, and after neoadjuvant chemotherapy in 57% of patients. We performed whole genome sequencing (WGS) of urine cfDNA (median depth: 10X) from all 51 BC patients and 13 healthy adults. Tumor fraction level based on genome-wide copy number alterations was estimated using ichorCNA. We inferred fragment size and genomic coverage of urine cfDNA using Picard Tools. Then, we computed the short-to-long (S/L) fragment ratio for genomic bins in each sample. The S/L ratio per bin was derived by partitioning the genome into 100 kb bins and evaluating the ratio of GC-corrected short fragments (50-150 bp) to long fragments (151-250 bp) within each bin. A normalized genome-wide S/L score was calculated by averaging across all bins.
Results: In our cohort of 51 BC patients, 45% of patients achieved pCR (n = 23) while 55% had residual disease detected in their surgical sample (no pCR; n = 28). Patients with no pCR had significantly higher copy number-derived tumor fractions in urine compared to patients with pCR (median 10.6% vs 1.9%, p = 0.0002) and healthy adults (n = 12) (median 10.6% vs 1.8%, p = 0.003). Tumor fraction achieved an AUC of 0.89 for classification of No pCR from pCR with sensitivity of 82% and specificity of 92%. Presumed cancer-free patients (healthy and pCR) had significantly longer urine cfDNA median fragment sizes than patients with no pCR (median 177 bp vs 156 bp, p = 0.002). Presumed cancer-free patients (healthy and pCR) also had significantly lower S/L ratio scores than no pCR patients (mean .98 vs 1.5, p = 0.007). The top 100 bins with maximally differential S/L ratio between these two patient groups were enriched for genes involved in KEGG pathways implicated in cancer and immune signaling (autophagy, transcriptional misregulation in cancer, Th1 differentiation) indicating biological relevance.
Conclusion: Copy number alteration-derived tumor fraction inference combined with fragmentomic analysis of urine cell-free DNA can enable sensitive detection of MRD to predict pCR and reveal potentially onco-relevant pathways.

#0966 Longitudinal comparative analysis of circulating tumor DNA and matched tumor tissue DNA in patients with metastatic colorectal cancer receiving palliative first-line systemic anti-cancer therapy.

J.-W. Kim[1], S.-b. Lee[2], H.-G. Kim[2], S.-H. Hwang[1], K.-J. Kim[1], J. Lee[3], J. Seo[1], M. Kang[1], E. Jung[1], K. Suh[1], S. Kim[1], J. Kim[1], Y. Kim[1], J. Kim[1], N.-J. Kwon[2], K.-W. Lee[1];

[1]Seoul National University Bundang Hospital, Seongnam, Korea, Republic of, [2]Macrogen, Inc., Seoul, Korea, Republic of, [3]Hankuk University of Foreign Studies, Yongin, Korea, Republic of

Background: Plasma circulating tumor DNA (ctDNA) analysis has become an attractive method for precision oncology. This study compared mutational landscapes of ctDNA with matched tumor tissue DNA (ttDNA) to explore clinical applicability and to better understand clonal evolution in patients with metastatic colorectal cancer receiving palliative first-line systemic anti-cancer therapy (SACT).

Methods: We performed unique molecular identifier-based targeted sequencing of 88 cancer-associated genes using the following samples: ttDNA, germline DNA, ctDNA at baseline (baseline-ctDNA), and ctDNA at progressive disease (PD-ctDNA).

Results: Of the 208 consecutively enrolled patients, 84 were selected (41 males; median age 59, ranging from 35 to 90) with access to all four samples. Excluding duplicated mutations, a total of 202 driver mutations were discovered in 34 genes. ttDNA exhibited the highest occurrence of mutations (N=232), followed by baseline-ctDNA (N=155) and PD-ctDNA (N=117). Genotype concordance for the ten most mutated genes was highest between baseline-ctDNA and PD-ctDNA, at 94.3%, while the concordance rates for ttDNA were 85.5% with baseline-ctDNA and 83.6% with PD-ctDNA. Overall, 40 of the 84 patients (47.6%) benefited from sequencing ctDNA in addition to ttDNA as it identified additional mutations. Compared to ttDNA and baseline-ctDNA, PD-ctDNA identified 13 novel mutations in ten patients (11.9%). Notably, 7 mutations in five patients (6.0%) were missense or nonsense mutations in *APC*, *TP53*, *SMAD4*, and *CDH1* genes. In baseline-ctDNA, patients with maximal variant allele frequency (VAF) values of >0.059 showed significantly worse progression-free survival (median 10.5 vs. 17.1 months, P=0.036) and overall survival (median 18.1 vs. 40.3 months, P=0.010). Moreover, overall survival was significantly worse in those with higher VAF values of *APC* (median 18.1 vs. 36.8 months, P=0.012), *TP53* (median 24.7 vs. 40.3 months, P=0.012), and *KRAS* (median 13.7 vs. 27.6 months, P=0.005) mutations.

Conclusions: While ttDNA remains more sensitive than ctDNA, our unique molecular identifier-based ctDNA platform demonstrated the validity and potential value when ttDNA was unavailable. Furthermore, post-SACT analysis of PD-ctDNA revealed new pathogenic mutations, indicating the clonal evolution of cancer. In addition, the VAF values of baseline-ctDNA predicted prognosis after SACT.

#0967 Clinical applicability of targeted panel sequencing in liquid biopsies for disease diagnosis and monitoring of patients with pediatric solid tumors.

E. Christodoulou, V. Yellapantula, K. O'Halloran, L. Xu, J. L. Berry, F. Navid, D. Ostrow, J. A. Biegel;
Children's Hospital Los Angeles, Los Angeles, CA

Liquid biopsy assays based on sequence analysis of cell-free DNA (cfDNA) have the potential to transform patient care. We recently validated a liquid biopsy platform, LBSeq4Kids, for patients with retinoblastoma, brain tumors and solid tumors using low pass whole genome sequencing (LP-WGS) of cfDNA from aqueous humor (AH), cerebrospinal fluid (CSF), and plasma (PL) to detect Copy Number Alterations (CNAs) in circulating tumor DNA (ctDNA). Herein, we present phase 2, a high-depth comprehensive Next-Generation Sequencing (NGS) panel using cfDNA that allows us to detect SNV's, indels and gene fusions in clinically relevant genes for pediatric solid and brain tumors. Seventy-four cfDNA specimens have been analyzed to date, using plasma from 43 patients with solid tumors, CSF from 25 patients with brain tumors and AH from six patients with ocular tumors including retinoblastoma. cfDNA was extracted at diagnosis, during therapy, at remission and/or relapse. Sequencing libraries were constructed with the xGen Prism DNA Library Prep Kit using 5ng of cfDNA. For the detection of recurrent mutations and fusions we designed a custom panel using a hybridization-based capture method (Twist Bioscience) that included full coverage of the exons of 136 genes harboring recurrent mutations and selected introns for five genes with recurrent rearrangement breakpoints including *BRAF, EWSR1, SYT, FOXO1* and *NTRK1*. Hybridized libraries were paired-end sequenced (Illumina NextSeq 500) at an average 1000x collapsed coverage. Mutations identified in cfDNA were compared with those in the primary or metastatic tumors profiled with our OncoKids® NGS panel. A total of 35/43 (81%) plasma specimens were positive for either an SNV, deletion or fusion with the most common events being a somatic missense variant in *TP53* (13/35, 37%) or translocation involving *EWSR1* (9/35, 26%). A total of 16/25 (64%) CSF specimens were positive for SNVs and fusions, most often involving *KIAA1549::BRAF* (7/25, 28%) in low grade gliomas. A germline variant in *RB1* was detectable in two AH specimens from the left and right eye of a patient with bilateral retinoblastoma while plasma from a patient with metastatic retinoblastoma demonstrated clinically relevant variants in *RB1* and *DICER1*. Serial cfDNA profiling revealed a clinically reported *TP53* c.746G>C missense variant in the plasma of a patient with osteosarcoma at multiple timepoints through the disease course, with evidence for relapse prior to standard imaging. These data suggest that clinical implementation of a second version of LBSeq4Kids that combines CNA and mutation analysis allows for diagnosis, residual disease detection and risk stratification for pediatric patients with diverse tumor types, regardless of histologic grade, with a variety of pediatric solid and brain tumors.

#0969 Tumor-agnostic ctDNA monitoring in patients with metastatic HR+/HER2- breast cancer receiving first-line CDK4/6 inhibitor and endocrine therapy.

M. J. Elliott[1], J. Fuentes-Antrás[2], A. Dou[1], N. Gregorio[1], E. Shah[3], E. Van de Laar[3], G. Yalamanchili[4], L. M. Drusbosky[4], E. Amir[1], M. B. Nadler[1], C. Yu[3], H. K. Berman[5], L. L. Siu[1], P. L. Bedard[1], D. W. Cescon[1];

[1]UHN Princess Margaret Cancer Centre, Toronto, ON, Canada, [2]NEXT Oncology, Hospital Universitario Quironsalud Madrid, Madrid, Spain, [3]Cancer Genomics Program, Princess Margaret Cancer Centre, Toronto, ON, Canada, [4]Guardant Health, Inc., Redwood City, CA, [5]Department of Pathology and Laboratory Medicine, University Health Network, Toronto, ON, Canada

Introduction: CDK4/6-inhibitors (-i) in combination with endocrine therapy are first-line treatment for metastatic HR+/HER2- breast cancer (mBC). Baseline circulating tumor DNA (ctDNA) burden and changes on therapy are prognostic in mBC. GuardantINFINITY is a tumor-agnostic platform which measures aggregated epigenomic methylation signals that can distinguish ctDNA from non-tumor derived signals and permits the detection of somatic alterations in a 753 NGS panel. Longitudinal measurement of ctDNA quantity and characterization of emerging mutations may permit early identification of resistance and allow for intervention prior to clinical/radiographic progression.

Methods: Patients with HR+/HER2- mBC receiving CDK4/6i were enrolled in a prospective cohort study from 2018 onwards. Plasma samples were collected at baseline (prior to initiation of CDK4/6i) and regularly in clinical follow up. Samples were analyzed using the GuardantINFINITY platform. Clinical information, pathologic characteristics, and dates of clinical progression were collected.

Results: 57 patients with 350 clinical timepoints (median of 5 per patient, range 2-15) were evaluated. Median follow up was 28.6m (range: 0.9-64.3m). Median age at diagnosis of mBC was 59 (range: 38-88). CDK4/6i received included 42/57 (73%) palbociclib, 14/57 (25%) ribociclib and 1/57 (2%) abemaciclib; 40/57 (70%) were in combination with an aromatase inhibitor and 17/57 (30%) with fulvestrant. 5/350 (1.4%) of samples failed analysis related to low cfDNA input. ctDNA was detected (by methylation) in 49/57 (86%) at baseline (1 fail, 7 not detected), and 208/345 (60%) of all samples. Median methylation-based tumour fraction (TF) at baseline was 0.0132 (range: 0.000875-0.433); a higher baseline methylation TF (≥1%) was associated with worse CDK4/6i-PFS (14.7m vs. 26.7m; HR: 2.27, 95%CI: 1.12-4.62, p=0.023). 19/49 patients had ctDNA clearance, which was associated with improved CDK4/6i-PFS (34.4m vs. 13.9m; p<0.0001). In longitudinal sampling, methylation TF rose prior to clinical progression and genomic alterations associated with CDK4/6i-resistance were detected, including copy-number loss in *RB1*.

Conclusion: Baseline methylation TF and ctDNA clearance as measured by GuardantINFINITY were prognostic in this cohort. Longitudinal sampling permitted genomic characterization and detection of alterations conferring acquired-resistance prior to clinical progression. Clinical correlates of ctDNA detection, clearance, and further serial genomic analyses will be presented.

#0970 Liquid biopsy-informed precision oncology clinical trial to evaluate the utility of ctDNA comprehensive genomic profiling.

M. Fatteh[1], M. Conroy[1], T. Wanchoo[1], S. Shiqing Teh[1], J. Wehr[1], A. Balan[1], R. Karchin[1], E. Verner[2], K. Karaindrou[1], R. Xian[1], C. Gocke[1], M.-T. Lin[1], P. Fitzpatrick[1], C. L. Hann[1], J. C. Murray[1], V. K. Lam[1], J. L. Feliciano[1], J. R. Brahmer[1], K. A. Marrone[1], P. M. Forde[1], K. Fiallos[1], D. Petry[1], T. Botsis[1], M. Sausen[2], t. Molecular Tumor Board Investigators[1], J. Canzoniero[1], J. Tao[1], V. Anagnostou[1];

[1]Johns Hopkins School of Medicine, Baltimore, MD, [2]Personal Genome Diagnostics/Labcorp, Baltimore, MD

Background: The expanding role of next-generation sequencing (NGS) in precision oncology has led to a paradigm shift towards genotype-targeted therapies, with liquid biopsies (LBs) offering a minimally invasive means of comprehensive genomic profiling.
Methods: This is an observational LB-informed precision oncology clinical trial with primary endpoints to assess feasibility and determine the prevalence of actionable mutations in LB informing genotype-targeted therapeutic recommendations by the Johns Hopkins Molecular Tumor Board (JH MTB; NCT05585684). Secondary endpoints are progression-free and overall survival, ctDNA dynamics assessment, and concordance between plasma and tumor NGS. Target enrollment is 150 patients with advanced solid tumors who have progressed on at least one line of systemic therapy. Serial LB-derived genotypes are obtained at baseline, early on therapy, and upon progression using a CLIA ultra-sensitive 33-gene panel NGS assay (Elio Plasma Resolve, Personal Genome Diagnostics/Labcorp). Variant actionability is assessed by an ensemble knowledgebase, registry, and computational characterization approach, and results are reviewed by the JH MTB, followed by treatment recommendations.
Results: The trial's pre-specified interim analysis included 30 enrolled patients with evaluable LBs; 30 baseline, 13 on-therapy, and 6 progression LBs were analyzed. Twenty-five patients had non-small cell lung cancer among which 9 were EGFR-mutated, 1 patient had small cell lung cancer, 3 patients had gastro-esophageal cancer, and 1 patient had a neuroendocrine tumor. In total, 74 variants were identified across all time points; these were cross-referenced in somatic and germline registries, variant knowledgebases, and the biomedical literature, together with computational characterization of functional consequence to assign mutation actionability. Tumor-confirmed variants comprised 36% of baseline and 42% of both on-therapy and progression variants. At baseline, 20% of the variants were putatively clonal hematopoiesis-derived with similar findings at the on-therapy timepoint. Thirty percent of baseline variants and 33% of variants at progression were deemed actionable. Upon JH MTB review, 29% of patients received a genotype-matched therapeutic recommendation based on LB results, with MTB recommendations followed in 38% of the patients. In analyzing ctDNA dynamics, of the 13 patients with on-therapy samples, 23% showed ctDNA clearance, 31% showed persistence, while 46% had undetectable ctDNA at both time points. Among patients with LBs at the time of progression, a third showed ctDNA emergence, a third had ctDNA persistence, and the remainder had undetectable ctDNA throughout the follow-up period.
Conclusion: Our findings highlight the clinical relevance of liquid biopsies in guiding treatment selection and monitoring.

#0971 Validation of a tumor-naïve circulating tumor DNA (ctDNA) response monitoring panel in advanced non-small cell lung cancer (aNSCLC).

A. C. Chiang[1], R. W. Madison[2], Y. Huang[2], A. Fine[2], D. X. Jin[2], G. R. Oxnard[3], J. Hughes[2], Z. J. Assaf[4], Y. Cao[4], V. Antic[5], O. Gjoerup[2], A. Young[2], D. Fabrizio[2], S. Lakhanpal[6], R. Zuniga[7], K. Schulze[4], L. W. Pasquina[2];

[1]Yale School of Medicine, Dept of Medicine, New Haven, CT, [2]Foundation Medicine, Inc., Cambridge, MA, [3]Boston Medical Center, Boston, MA, [4]Roche/Genentech, South San Francisco, CA, [5]F. Hoffmann-La Roche, Basel, Switzerland, [6]Alabama Oncology, Birmingham, AL, [7]New York Cancer & Blood Specialists, New York, NY

Introduction: Monitoring of ctDNA can be a minimally invasive complement to tumor imaging for assessing treatment effect. Technical limitations require methods to distinguish tumor signal from clonal hematopoiesis (CH), often including non-tumor sequencing. We developed a tumor-naïve panel (FoundationOne® Monitor) to quantify ctDNA tumor fraction (TF). TF analytical validation used peripheral blood mononuclear cell (PBMC) sequencing. We then leveraged plasma collected serially from patients with aNSCLC in the real-world (rw) Prospective Clinico-Genomic (PCG; NCT04180176) study to investigate the utility of TF for monitoring therapy (tx) response.

Methods: TF was quantified using a combination of aneuploidy and variant allele frequencies of genomic alterations (GAs), while excluding CH mutations and aneuploidy using fragmentomic signal from cfDNA. In the PCG study, data from consenting patients were collected from electronic health records from 23 participating Flatiron Health Research Network sites. We analyzed plasma collected 6-15 weeks after start of tx in exploratory and validation cohorts per prespecified criteria. We defined molecular response (MR) as undetectable TF on tx regardless of baseline TF. Hazard ratios (HR) and 95% confidence Interval (CI) were calculated with univariate Cox proportional hazard regression.

Results: For TF validation, 1135 samples separate from the PCG study with paired PBMC results were included. Overall, 24/4274 (0.56%) CH derived non-aneuploidy GAs detected in 1134 samples were falsely classified as somatic. Of these, 4 were detected among 317 samples with no tumor signal, resulting in a false positive TF value (specificity = 98.7%). CH derived aneuploidy was observed in 27 PBMCs and was appropriately filtered during TF estimation in all cases. Assessing the impact of CH aneuploidy filtering on sensitivity, we only identified 1/320 (0.31%) samples where non-CH derived aneuploidy was omitted. To assess clinical validity, 222 patients were analyzed from the PCG study. MR was assessed after a median of 10.8 weeks of tx (IQR 8.9-12.0). In a subset of 152 patients treated with physicians' choice, MR was associated with favorable rw progression free survival (rwPFS: 9.4 v 2.8 months [mo]; HR = 0.30; 95% CI: [0.21-0.44]) and rw overall survival (rwOS: 22.0 v 7.5 mo; HR = 0.33 [0.22-0.49]). We validated this finding on 70 patients receiving immunotherapy (50 with chemo). Again, MR was associated with favorable rwPFS (9.0 v 2.8 mo; HR = 0.28 [0.16-0.51]) and rwOS (20.2 v 9.4 mo; HR = 0.42 [0.23-0.78]).

Conclusions: We describe a highly specific tumor naïve algorithmic filtration of non-tumor signal to enable high confidence ctDNA quantification and MR assessment. On tx MR is associated with favorable outcomes. These findings may enable personalized tx approaches tailored to a patient's risk of progression and downstream cancer morbidity.

#0972 Non-invasive detection of homologous recombination deficiency in metastatic prostate cancer patients.

G. Vlachos, T. Moser, A. Eberhard, L. Glaswitch, J. Blatterer, E. Bauernhofer, N. Monsberger, K. Kashofer, J. Geigl, T. Bauernhofer, E. Heitzer;
Medical University of Graz, Graz, Austria

Background: The recent endorsement of poly ADP ribose polymerase inhibitors (PARPi) has been a breakthrough in managing prostate cancer (PCa) with homologous recombination deficiency (HRD). However, due to its propensity to metastasize to the bone, HRD assessment in tissue biopsy poses a challenge in advanced PCa. Circulating tumor DNA (ctDNA) as a tumor surrogate may be a promising substitute for pinpointing patients who may benefit from PARPi treatment.
Methods: To test whether causes and consequences of HRD can be detected non-invasively in plasma, we pre-selected 139 plasma samples from PCa patients based on aneuploidy screening (mFAST-SeqS). We then applied targeted sequencing using a QIAseq panel including homologous recombination repair (HRR)-related genes as well as genes involved in cell cycle regulation (*TP53, RB1, PTEN*). Putative, pathogenic germline variants were sequencing in constitutional DNA using Sanger sequencing. Moreover, we performed low pass whole genome sequencing to determine the levels of genomic instability using the shallow HRD (sHRD) algorithm.
Results: In our cohort, at least one pathogenic mutation was detected in 68/139 (48.9%) of the patients, of which the majority consisted of alterations in *PTEN*, *TP53* or *RB1* (44/139, 31.7%). Pathogenic *BRCA1*/2 mutations were detected in 13/139 patients (9.4%), the majority of which originated from the germline. In 8/139 patients (5.6%) a pathogenic variant in other HRR genes could be observed and in 3/139 patients (2.2%) *CKD12* mutations were detected. As expected, samples with pathogenic HRR mutations and elevated tumor fraction, presented high sHRD scores (<20) in plasma DNA. In contrast, the majority of high ctDNA samples with mutations in *PTEN*, *TP53* or *RB1* had sHRD score below the cut-off of 20. However, the detection of genomic instability was clearly depending on tumor fractions. Conclusion: Our study indicates that a non-invasive assessment of root causes and subsequent effects of the HRD phenotype in prostate cancer is feasible, and that mutations in HRR correlate with a high genomic instability. However, to detect and quantify genomic instability in plasma, elevated ctDNA levels are required. Based on in-house data from mFAST-SeqS aneuploidy screening of over 900 plasma samples from advanced prostate cancer, approximately 30% of cfDNA samples would have sufficiently high ctDNA fractions for a combined assessment of causes and consequences of HRD, which might be most informative to direct PARPi treatment in PCa.

#0973 Plasma a*ndrogen receptor (AR)* copy number gain at progression in patients randomized in the STAMPEDE phase 3 abiraterone acetate, prednisolone (AAP) and enzalutamide (ENZ) trial: An ancillary biomarker study.

G. Leone[1], F. Orlando[2], S. Thakali[1], S. Lall[1], D. Wetterskog[1], A. Wingate[1], N. W. Clarke[3], N. D. James[4], F. Demichelis[2], G. Attard[1];
[1]University College London (UCL) Cancer Institute, London, United Kingdom, [2]Department of Cellular, Computational and Integrative Biology, University of Trento, Trento, Italy, [3]Christie and Salford Royal NHS Foundation Trusts, Manchester, United Kingdom, [4]Institute of Cancer Research, London, United Kingdom

Addition of ENZ or AAP to androgen deprivation therapy (ADT) as first-line treatment for advanced prostate cancer improves survival compared to ADT alone. Genomic alterations in *AR* associate with resistance to ENZ/AAP when started for castration-resistant prostate cancer (CRPC). We aimed to test whether early use of AAP/ENZ altered the incidence of *AR* alterations at progression. Between July 2014 and March 2016, 1976 patients with metastatic or high-risk locally advanced prostate cancer were randomized to ADT or ADT+ENZ+AAP in the STAMPEDE trial (NCT00268476). Consenting patients were given the option to donate blood for the ancillary biomarker study at trial-defined progression and prior to start of the next line of treatment. We focused on patients who progressed within 4 years from the end of recruitment (early progressors), as these patients represent the greatest unmet need. We obtained plasma DNA at emergence of CRPC from 115 early progressors (ADT n=63, ADT+ENZ+AAP n=52). We performed liquid biopsy-focused, custom, high-coverage targeted enrichment sequencing (PCF-SELECT, Orlando et al, NAR Cancer 2022). We used a bespoke computational pipeline, leveraging allelic imbalance and fragmentome analysis, to detect circulating tumor DNA (ctDNA) in plasma samples and copy number changes. Of 108 samples that passed quality control, 94 were positive for tumor (ADT n=52, ADT+AAP+ENZ n=42). The detection rate and ctDNA fractions were similar between the two treatment groups [ADT: 86.7% (52/60), mean ctDNA fraction 0.18; ADT+ENZ+AAP: 87.5% (42/48), mean ctDNA fraction 0.21; p=0.34]. The proportion of plasma with detectable ctDNA and *AR* gain was significantly higher with ADT+AAP+ENZ vs ADT alone (15/42, 35.7% vs 8/52, 15.4%, p=0.03). We then implemented the same approach on plasma collected from patients progressing on ENZ started for metastatic CRPC in a prospective Phase 3b trial (PRESIDE, NCT02288247): we confirmed a high prevalence of *AR* gain in plasma samples with detectable ctDNA (47.7%, 95% CI 38.8-54.9) in the CRPC setting. Significant copy number aberrations in relevant prostate cancer-related genes/pathways (deletions of *TP53*, *RB1*, *PTEN* or DNA repair genes, or gain of *PI3K*/*AKT1*) were identified in 9 out of 42 evaluable samples in the ADT group and 18 out of 38 evaluable samples in the ADT+ENZ+AAP group (21.4% vs 47.4%, p=0.014). Treatment with ADT+ENZ+AAP increases detection of plasma *AR* gain at emergences of CRPC in early progressors compared to ADT alone. Detection of plasma *AR* gain increases at progression on ADT+ENZ regardless of the treatment setting. The impact of early use of ENZ/AAP on the detection of copy number aberrations, especially homozygous deletions, in other prostate cancer-related genes in plasma requires further investigation.

#0974 DNA methylation and gene expression as determinants of genome-wide cell-free DNA fragmentation.

M. Noe, A. V. Annapragada, Z. H. Foda, J. E. Medina, D. Mathios, S. Cristiano, C. Cherry, D. C. Bruhm, N. Niknafs, V. Adleff, L. Ferreira, H. Easwaran, S. Baylin, J. Phallen, R. B. Scharpf, V. E. Velculescu;
Johns Hopkins University, Baltimore, MD

Cell-free DNA (cfDNA) in the bloodstream is increasingly gaining attention as a diagnostic tool for the early detection of cancer. Nevertheless, the characteristics and sources of cfDNA fragmentation in the blood remain poorly understood. In this study, we sought to unravel the impact of DNA methylation and gene expression on the naturally occurring genome-wide fragmentation of cfDNA. We performed a comprehensive analysis of plasma samples from 969 individuals, including 182 individuals diagnosed with cancer (pancreatic, colorectal, ovarian, lung and breast cancer). In healthy individual cfDNA fragmentation patterns like DNA motifs at cfDNA fraqgments ends, recurrent cfDNA fragment start sites, cfDNA coverage and cfDNA fragment size were compared to publicly available data on cfDNA methylation and gene expression from myeloid cells. We discovered that the ends of cfDNA fragments, particularly those containing CGs or CCGs, displayed a distinct pattern of enrichment or depletion, respectively, at methylated CpG positions throughout the genome. This phenomenon is consistent with structural models suggesting an increased interaction of CG fragment ends with nucleosomes. cfDNA fragments were more prevalent (up to 3.7 fold) and of larger sizes (up to 4-5 base larger) when derived from regions of methylated CpGs or transcriptional start sites of genes that were not actively expressed. Differences in cfDNA fragmentation reflected specific biological pathways associated with their tissue of origin (like E2f transcription factors and blood cell metabolism genes in cfDNA from healthy individuals). Through analyses of cfDNA from patients with cancer, we identified a connection between tumor-related hypomethylation, increased gene expression, and a global reduction in cfDNA fragment size. This connection may offer an explanation for the generally smaller cfDNA fragments found in individuals with cancer. We found that cancer-specific methylation at CpG sites from pancreatic cancers were associated with widespread changes in cfDNA fragment ends, particularly for patients with pancreatic (test statistic = Welch two sample t-test; $p<2.2e-16$) and other cancers. These findings establish a direct link between epigenetic modifications and cfDNA fragmentation that may have implications for non-invasive detection of cancer.

#0975 Genomic landscape of circulating tumor DNA in cervical cancer in Asia: NCCH1905/A-TRAIN trial.

Prathepamalar Yehgambaram[1], Yuki Kojima[2], Kazuki Sudo[2], Shu Yazaki[2], Momoko Tokura[2], Munehiro Ito[2], Mai Hoshino[2], Wong Yoke Fui[3], Pei Jye Voon[4], David SP Tan[5], Arb-aroon Lertkhachonsuk[6], Anh Tuan Pham[7], Thinh Dang Huy Quoc[8], Wan Zamaniah Wan Ishak[9], Hiroshi Yoshida[2], Shinji Kohsaka[10], Yukari Nagasaka[2], Ryunosuke Machida[2], Tomomi Hata[2], Kenichi Nakamura[2], Kan Yonemori[2]

[1]Hospital Kuala Lumpur, Kuala Lumpur, Malaysia,[2]National Cancer Center Hospital, Tokyo, Japan,[3]National Cancer Institute, Putrajaya, Malaysia,[4]Sarawak General Hospital, Sarawak, Malaysia,[5]National University Hospital, Singapore, Singapore,[6]Ramathibodi Hospital, Bangkok, Thailand,[7]National Cancer Hospital, Hanoi, Viet Nam,[8]Ho Chi Minh City Oncology Hospital, Ho Chi Minh, Viet Nam,[9]University Malaya, Kuala Lumpur, Malaysia,[10]National Cancer Center Research Institute, Tokyo, Japan

Background: Cervical cancer is the second most common cancer among women worldwide, with over 500,000 new cases diagnosed annually and a 50% mortality rate in Asia. The incidence and prevalence of cervical cancer is high in Asia due to limited screening, awareness of HPV infection, and access to vaccines. The purpose of this study is to evaluate the comprehensive genomic profiles of circulating tumor DNA (ctDNA) in Asian cervical cancer patients with different histological subtypes and their association with clinicopathological features.
Methods: This is an Asian multicenter prospective observational study conducted by nine institutions in Japan, Singapore, Malaysia, Thailand, and Vietnam (NCT05099978, ClinicalTrials.gov). Eligible patients had histological diagnosis of cervical cancer with metastatic or recurrent disease. Patients on chemotherapy or radiotherapy were excluded. ctDNA was analyzed in blood samples collected at newly initial diagnosis of metastatic disease and/or at disease progression. Genomic profiling was conducted by Guardant360 (Guardant Health).
Results: Ninety-nine samples from 101 cervical cancer patients were analyzed. ctDNA was detected in 70 (70.7%) samples; median time to test results was 11 days. The median number of genomic abnormalities was 1 (range, 0-22). The most frequently altered genes were *PIK3CA* (n=28. 28.3%), *TP53* (n=18, 18.2%), *KRAS* (n=12, 12.1%) and *STK11* (n=6, 6.1%). Clinical trial-related genomic abnormalities were detected in 59 patients (59.6%) with 40 associated with approved drugs in other indication, including those targeting *PIK3CA* mutation (n=28), homologous recombination deficiency (*BRCA1/2*, *ATM* and *CDK12* mutation) (n=5), *ERBB2* amplification (n=4) and *FGFR3*alterations (n=3). In squamous cell carcinoma (n=59), commonly altered genes were *PIK3CA* (n=21, 35.6%), *TP53*(n=12, 20.3%), *ERBB2* (n=5, 8.5%), *NOTCH1* (n=5, 8.5%) and *ARID1A* (n=5, 8.5%). In adenocarcinoma (n=36), commonly altered genes were *KRAS* (n=7, 19.4%), *PIK3CA* (n=6, 16.7%) and *TP53* (n=5, 13.9%). The number of patients with genomic alterations relevant for clinical trials was 39 (66.1%) and 19 (52.8%) for squamous cell carcinoma and adenocarcinoma, respectively. There were no differences in the number of genomic alterations according to prior chemotherapy or radiation therapy.
Conclusion: Comprehensive genomic profiling using liquid biopsy can rapidly identify potential candidates for targeted therapy in cervical cancer patients, regardless of histopathology. Clinical studies of precision medicines in Asia are encouraged for such patients.

#0976 Detection of circulating tumor DNA predicts survival in advanced HCC patients treated with personalized therapeutic DNA cancer vaccine in combination with immune checkpoint blockade.

J. Yan[1], B. Li[2], J. Northcott[2], C. W. Abbott[2], R. M. Pyke[2], R. Perales-Linares[1], N. Cooch[1], S. Rochestie[1], J. Peters[1], E. J. Gane[3], M. Yarchoan[4], T. U. Marron[5], S. M. Boyle[2], I. Csiki[1], R. Chen[2], N. Y. Sardesai[1];

[1]Geneos Therapeutics, Inc., Philadelphia, PA, [2]Personalis, Inc., Fremont, CA, [3]University of Auckland, Auckland, New Zealand, [4]Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins University School of Medicine, Baltimore, MD, [5]Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, NY

Circulating tumor DNA (ctDNA) has enabled the non-invasive monitoring of molecular residual disease (MRD) which reflects therapeutic response/resistance prior to conventional imaging approaches. However, little is known about the applications of ctDNA in the neoantigen-targeted personalized cancer vaccine setting, potentially due to the limited sensitivity of current ctDNA assays. NeXT Personal®, an ultra-sensitive tumor-informed ctDNA assay was used to longitudinally track ctDNA in advanced hepatocellular carcinoma (HCC) patients treated with GNOS-PV02 (a personalized therapeutic DNA cancer vaccine) in combination with pembrolizumab.

Advanced unresectable or metastatic HCC patients that progressed on, or were intolerant to, first-line TKI therapy were enrolled into the Phase 1b/2a GT-30 study [NCT04251117]. Whole exome/transcriptome tumor sequencing was used for the design of GNOS-PV02. Patients were treated with GNOS-PV02 (1mg; Q3W x 4, Q9W) and plasmid-encoded IL-12 (0.3mg; Q3W x 4, Q9W) in combination with pembrolizumab (200mg; Q3W). Clinical Response was evaluated by RECIST 1.1 at baseline and Q9W. The ctDNA analysis and tracking for progression was performed as an exploratory objective.

Over 200 prospective baseline and on-treatment plasma samples from 31 patients were collected and analyzed using NeXT Personal. WGS was performed to identify up to ~1,800 selected tumor variants to create a personalized panel for MRD detection. NeXT Personal has been analytically validated to detection thresholds down to 1-3 parts per million (PPM) of ctDNA with >99.95% specificity.

ctDNA was detected in 152 of 207 plasma samples with a dynamic range of 1.76 - 166,968 PPM. The limit of ctDNA detection ranged down to 1.05 PPM. 96% (24/25) of patients were baseline ctDNA+. The percentage change of ctDNA relative to baseline at week 9 (C4D1) significantly correlated with best overall response (CR/PR/SD vs. PD: p = 0.0076). The ctDNA change from baseline to week 9 was predictive of OS (P=0.008), with 31.2% 2-yr OS (95% CI: 13.2 - 73.7%) for molecular non-responders vs 100% 2-yr OS (95%CI: 100 - 100%) for molecular responders. In addition, the ctDNA levels at week 9 were predictive of best overall response (P = 0.017). ctDNA burden at week 9 was significantly correlated with overall survival (HR = 5.46, 95%CI: 1.79 - 16.65; P=0.003; C-index = 0.886). ctDNA clearance was observed in all 3 CR patients with a lead time of 483, 126 and 105 days compared with MRI.

This ultra-sensitive ctDNA assay shows significant association between ctDNA change and clinical response and survival, and can be used to accurately predict clinical outcome. The convenience of non-invasive liquid biopsy and rapid availability of data could enable the use of ctDNA to allow real-time monitoring of personalized cancer immunotherapy.

#0977 Germline BRCA1/2 mutations detected by circulating tumor DNA testing in breast cancer patients: A retrospective mutiinstitutional analysis.

Letizia Pontolillo[1], Carolina Reduzzi[1], Andrew A. Davis[2], Arielle J. Medford[3], Annika Putur[3], Lorenzo Gerratana[4], Katherine Clifton[2], Whitney L. Hensing[2], Marko Velimirovic[5], Surbhi Warrior[6], Mara S. Serafini[1], Eleonora Nicolo[1], Laura Munoz-Arcos[1], Jeannine Donahue[1], Charles S. Dai[3], Jennifer C. Keenan[3], Amir Behdad[7], William J. Gradishar[6], Diana Giannarelli[8], Emilio Bria[9], Cynthia X. Ma[2], Aditya Bardia[3], Massimo Cristofanilli[1]

[1]Department of Medicine, Division of Hematology-Oncology, Weill Cornell Medicine, New York, NY,[2]Department of Medicine, Washington University in St Louis School of Medicine, Saint Louis, MO,[3]Massachusetts General Hospital Cancer Center / Harvard Medical School, Boston, MA,[4]CRO Aviano, National Cancer Institute, IRCCS,, Aviano, Italy,[5]Cleveland Clinic, Cleveland, OH,[6]Department of Hematology, Oncology, Robert H. Lurie Comprehensive Cancer Center, Northwestern University, Chicago, IL,[7]Pathology and Laboratory medicine,, Cleveland Clinic, Cleveland, OH,[8]Facility of Epidemiology and Biostatistics, Fondazione Policlinico Universitario A. Gemelli IRCCS,, Roma, Italy,[9]Department of Medical Oncology, Fondazione Policlinico Universitario A. Gemelli IRCCS,Universita' Cattolica del Sacro Cuore, Roma, Italy

Background: The use of circulating tumor (ct) DNA testing allows to detect resistant and actionable somatic alterations and it could be associated with the incidental identification of germline mutations. An univocal variant allele frequency (VAF) threshold to distinguish germinal form somatic mutations has not been assessed yet. We aimed to correlate BRCA1/2 ctdNA detected mutations with germline mutational status to determine potential VAF cutoff.
Materials and methods:We retrospectively analyzed the incidence of both somatic (*s*) and germinal *(g) BRCA1/2* alterations in a multiinstitutional retrospective breast cancer (BC) cohort to assess the VAF threshold for the likelihood of germline mutations' detection by ctDNA next-generation sequencing (Guardant 360) testing. Clinical variables were analyzed using descriptive analyses and receiving operating characteristic (ROC) curves were generated to determine the VAF cutoff.
Results: Two hundred and fourteen patients (pts) with *sBRCA1/2* mutations (including variant of uncertain significant and synonymous) detected by ctDNA testing, referred to the enrolling centers between January 2015 to May 2023 were included in the analysis. The median age at diagnosis was 50 years old (Interquartile range (IQR)43,5-61.5), 43% had a family history of cancer. Hormone receptor positive/HER2 negative was the most represented subtype (68%) followed by the HER2 positive (16%) and triple negative (16%) ones. At ctDNA baseline, 95.8% of pts had a metastatic disease; the main sites of metastases were bone (67.4%) and visceral (59.3%). Ninetyfour (43.9%) and 137 (64%) pts had a *sBRCA1* and *sBRCA2* alterations respectively, while 17 (7.9%) had a co-mutation in *BRCA1* and *BRCA2*. The mean VAF value for *sBRCA1* alterations was 10.1% (standard deviation (SD) 19.5%, range [0.04%-84.3%]) while for *sBRCA2* alterations was 10.8% (SD 18.9%, range [0.21%-80.3%]). The germinal testing, performed per standard of care, was available for 100 pts (46.7%). Among these, 42 (42%) had at least a pathogenic variant detected. A *gBRCA1* mutation was present in 11 (11%) pts while 25 (25%) had a *gBRCA2* mutation. Comparing the somatic and germinal testing, 9/100 pts had a concordance for *BRCA1* detection, the 2 discordant cases had both a low allele frequency *sBRCA2* alterations; the concordance for *BRCA2* detection was instead 100%. An optimal cutoff of 38.4% (AUC 0.98) for *BRCA1* and 19.5% (AUC 0.96) for *BRCA2* was assessed by ROC analysis as the likelihood of a germline meaning of a somatic mutation detected by ctDNA analysis.
Conclusion: The identification of *BRCA1/2* alterations in ctDNA could guide the use of germline testing. The VAF cutoff identified for the likelihood of a germinal mutation is lower than expected, suggesting that a wider population should be screened for germinal mutation with relevant impact on the therapeutic choices and family screening.

#0978 Functional characterization and a real-world clinical laboratory pilot of the Foundation for the National Institutes of Health's (FNIH) circulating tumor DNA (ctDNA) quality control materials (QCMs).

C. P. Paweletz[1], T. D. Forbes[2], G. A. Heavey[1], L. M. Yee[3], H.-J. He[4], Z. He[4], D. E. Connors[5], D. Stetson[6], S. Keating[7], K. D. Cole[4], G. J. Kelloff[3], R. T. McCormack[8], M. P. Williams[2], C. Karlovich[2];

[1]Dana-Farber Cancer Institute, Boston, MA, [2]Frederick National Laboratory for Cancer Research, Frederick, MD, [3]National Cancer Institute, Bethesda, MD, [4]National Institute of Standards and Technology, Gaithersburg, MD, [5]Foundation for the NIH, Bethesda, MD, [6]AstraZeneca, Waltham, MA, [7]CCS Associates, Inc., McLean, VA, [8]Independent, Chester, NJ

Background: Analysis of ctDNA now permits assessment of targetable mutations (e.g. *EGFR* L858R/Ex19del) using noninvasive blood tests. There are several FDA-approved tests using digital PCR (ddPCR) or next-generation sequencing (NGS) and many more laboratory developed tests in use. The FNIH Biomarkers Consortium identified the absence of validated standards to qualify the performance of ctDNA assays as a critical need and set out to aid in the characterization of QCMs. Here we report on a commutability study comparing the performance of three commercial QCMs to clinical samples at or above LoD (limit of detection) and update on a real-world assessment of these QCMs by 11 clinical laboratories spanning 4 continents and 3 assay modalities.

Methods: QCMs were provided by Horizon Discovery (H), Thermo Fisher (T) and SeraCare (S). Clinical samples with known *EGFR* L858R and Ex19del mutations were prepared by diluting specimens at known concentrations into cell-free DNA (cfDNA) from healthy donors. The functional characterization compared detection of the mutations in QCM to clinical samples and consisted of 2 parts: (1) Evaluation of *EGFR* L858R/Ex19del (range 0.1% to 5% allele frequency [AF]) by ddPCR, amplicon and hybrid-capture NGS; (2) Evaluation near the LoD of the amplicon NGS assay at the assay LoD95 of 0.3% AF. For the clinical pilot, participants were sent QCM pools formulated at 0.5% and 1% AF by ddPCR. Some participants also tested clinical specimens with *EGFR* L858R and Ex19del at 0.5% and 1% AF by ddPCR. All participants were blinded to AF and identity of the manufacturer.

Results: For Part 1, QCM results from hybrid-capture NGS of *EGFR* L858R were similar to ddPCR; for Ex19del, QCM AF trended lower compared to ddPCR. In contrast, L858R clinical samples showed a strong positive bias compared to ddPCR. For amplicon NGS, QCMs performed similarly to clinical samples, with amplicon NGS AF closest to ddPCR AF for T QCM. For Part 2, the observed hit rates mostly approximated expected values. For H QCM, observed LoD95 (10% for EGFR L858R; 50% for Ex19del) and subsequent dilution hit rates were lower than expected. For the clinical pilot, median Ex19del AF of amplicon NGS were higher than for hybrid-capture NGS for both the 1% QCM formulations and 0.5% QCM formulations. Median QCM L858R AF were similar for amplicon and hybrid-capture NGS, with greatest contributor to variance being inter-lab differences.

Conclusions: This project, unprecedented in the number of participants and analytical rigor, revealed unexpected differences in performance of both assays and QCMs. These findings merit consideration by laboratories that rely on QCMs to develop and perform assays for ctDNA testing as diagnostics.

#0979 Cell-free DNA fragmentomics and second malignant neoplasm risk in patients with *PTEN* hamartoma tumor syndrome.

D. Liu[1], L. Yehia[2], A. Dhawan[3], Y. Ni[3], C. Eng[2];

[1]Cleveland Clinic Lerner College of Medicine, Cleveland, OH, [2]Cleveland Clinic Lerner Research Institute, Cleveland, OH, [3]Cleveland Clinic, Cleveland, OH

Individuals with *PTEN* hamartoma tumor syndrome (PHTS) harbor germline *PTEN* variants that confer a significantly increased lifetime risk of various organ-specific cancers, and a 7-fold increased risk of second primary malignant neoplasms (SMNs). Currently, there is no reliable biomarker that can accurately predict which individuals with PHTS will develop malignancies, let alone SMN. Currently, there is no reliable biomarker that can accurately predict which individuals with PHTS will develop malignancies, let alone SMN. Despite the highly promising value of cell-free DNA (cfDNA) as a biomarker for underlying sporadic cancers, the utility of cfDNA in individuals with hereditary forms of cancer remains poorly understood. Thus, we performed a retrospective study in prospectively accrued patients with PHTS investigating whether plasma cfDNA profiles can be leveraged as a predictive marker of cancer risk. We performed ultra-low pass whole genome sequencing of cfDNA of archived plasma samples from patients with PHTS without cancer (N = 50), and those with cancer (N = 49). Those with cancer included patients with only a single primary malignant neoplasm (PMN, N = 23) and patients with second malignant neoplasms (SMN, N = 26). To investigate cfDNA profiles in patients with PHTS and subclinical cancer, we included nine patients with plasma archived before their cancer diagnosis. We observed that patients with PHTS and SMNs have significantly decreased proportion of di- and tri-nucleosome-associated cfDNA fragments compared to patients with PMNs and those without cancer. Furthermore, SMN status was associated with increased genome-wide fragmentation (ratio of short to long fragments) of mono- (OR 2.37, 95% CI [1.09, 7.27]; P = 0.025) and di-nucleosome-associated (OR 3.03, 95% CI [1.07, 15.7]; P = 0.029) cfDNA fragments, even after controlling for age at plasma draw and phenotypic burden. Fragment end profiling was performed by calculating the frequencies of the first 4-nucleotide sequence (4-mer end motif) at each 5' end of cfDNA fragments. We identified 35 differentially abundant 4-mer end motifs when comparing patients with SMN to those without cancer. Patients with PHTS and SMNs were characterized by a decrease in A-end motifs with concurrent increases in G- and T-end motifs. Increased frequency of C-motifs—namely CC- and CA-end motifs—appeared to be unique to patients who had plasma drawn before their SMN diagnosis, a potential marker for active cancer. Our findings provide evidence that cfDNA fragmentomic features can be leveraged as a potential marker of individual SMN risk in PHTS. These results may facilitate earlier cancer detection and intervention as well as prevent unnecessary high-risk cancer surveillance and prophylactic surgeries in this vulnerable population.

#0980 Plasma tumor fraction is an independent prognostic marker of response to front line chemotherapy in high-grade serous epithelial ovarian cancer: The MITO-16a/MANGO-OV2a/ clinical trial experience.

S. Marchini[1], L. Paracchini[1], L. Arenare[2], G. Scambia[3], C. Pisano[4], R. Zadro[1], L. Mannarino[1], A. Ferrero[5], P. Chiodini[6], D. Califano[7], S. Pignata[8], M. D'Incalci[9]; [1]Humanitas Research Hospital, Milano, Italy, [2]Clinical Trial Unit, Istituto Nazionale Tumori, IRCCS, Fondazione G. Pascale, Naples, Italy, Naples, Italy, [3]IRCCS Policlinico Gemelli,, Rome, Italy, [4]Istituto Nazionale Tumori, IRCCS, Fondazione G. Pascale, Naples,, Naples, Italy, [5]University of Torino, Mauriziano Hospital, Tourin, Italy, [6]Universita degli Studi della Campania, Naples, Italy, [7]Istituto Nazionale Tumori IRCCS e Fondazione G. Pascale, Naples, Italy, [8]Istituto Nazionale Tumori, IRCCS, Fondazione G. Pascale, Naples, Italy, [9]Humanitas University, Milano, Italy

Background. Although 80% of high grade serous ovarian cancer (HGSOC) patients are initially responsive to platinum (Pt)-based chemotherapy, the majority of them experience relapse with a progressive Pt-resistant disease. One of the most challenging issue that hampers the possibility to effectively treat relapsed disease is the lack of biological information about tumor recurrence. To date, the Pt-free interval (PFI), an empirical measure of the time lagging between the end of front-line chemotherapy and relapse, is the only and widely accepted parameter to predict patient outcome and sensitivity to Pt second-line chemotherapy. We have previously demonstrated that analysis of circulating tumor DNA (ctDNA) by low pass whole genome sequencing (sWGS) is a suitable tool to predict patient outcome and to intercept early signs of relapsed disease (Paracchini et al . PMID:33323403). In the present study, we quantified the percentage of tumor fraction (TF) in plasma of patients enrolled within the frame of a phase III clinical trial (MITO-16A/MaNGO-OV2A-EUDRACT number: NCT01706120) to demonstrate, at baseline, the prognostic value of untargeted ctDNA analysis.

Methods. 172 eligible patients enrolled with the frame of the MITO-16A/MaNGO-OV2A clinical trial, for whom plasma sample was collected at chemotherapy before chemotherapy, were selected for the study. For each plasma sample, circulating-free DNA (cfDNA) was purified and whole genome libraries (HyperPlus, Roche) sequenced (mean coverage 0.5X). ichorCN algorithm was used to infer the percentage of TF, as previously published (Paracchini et al . PMID:33323403).

Results. In 168 out of 172 plasma samples analyzed, the TF was detectable and it ranged from 2.4% to 47%. Cox-model univariate analysis with patients' overall survival (OS) and Progression-Free Survival (PFS), indicates association of TF levels with both OS and PFS ($p<0.001$). The prognostic relevance of TF was also confirmed in multivariate analysis, where, considering CA-125, residual tumor, stage of disease, histology and age as co-variables, TF maintained its statistical significance in PFS (HR = 2.1, CI 95%, p-value < 0.003).

Conclusion. Retrospective analysis of baseline plasma samples collected within the frame of the MITO-16A/MaNGO-OV2A clinical trial, demonstrated that the percentage of TF is an independent prognostic marker of relapse. This finding confirms the importance of liquid biopsy analysis based on untargeted sWGS tool as an innovative approach to predict response to front line therapy and patient's outcome

#0981 Robustness of fragmentation-based cell-free DNA approaches to clonal hematopoiesis.

S. Cristiano[1], B. Alipanahi[1], J. E. Medina[1], L. Rinaldi[1], N. Dracopoli[1], R. B. Scharpf[2], A. Leal[3], V. E. Velculescu[2], J. Tom[1];
[1]Delfi Diagnostics, Baltimore, MD, MD, [2]Johns Hopkins University, Baltimore, MD, MD, [3]New York University Grossman School of Medicine, New York, NY, NY

INTRODUCTION: Clonal hematopoiesis (CH) is the result of the clonal expansion of hematopoietic stem cells which acquire and pass on somatically gained mutations, including SNVs as well as arm level losses and gains, defined here as mosaic deletions and amplifications (mDAs). The proportion of blood cells in circulation containing CH alterations increases with age and environmental exposures such as smoking, leading to a higher prevalence in many high-risk cancer screening populations. CH remains a major confounder for mutation-based liquid biopsy tests evaluating circulating cell-free DNA (cfDNA), since these assays are unable to discriminate between mutations originating from the tumor as opposed to CH. While the impact of CH mutations on fragmentation-based methods of detecting ctDNA appears to be limited, the effect of mDAs has not yet been explored.

METHODS: To assess the impact of mDAs on screening efforts using whole genome sequencing (WGS) of cfDNA, we performed copy number analyses on cfDNA from plasma collected from 895 individuals consisting of high-risk individuals meeting the USPSTF guidelines for annual lung cancer screening using low-dose computed tomography. From a subset of 203 available donors (157 without cancer and 46 with lung cancer), matched genomic DNA from white blood cells (WBCs) were extracted from the isolated buffy coat and WGS was performed to evaluate whether ploidy in cfDNA plasma is derived from WBCs. Genome-wide fragmentation features (short to long ratios and fragment size densities), coverage-based statistics, and copy number (CN) statistics adjusting for mDAs were calculated (CN_{adj}). Machine learning models to calculate the probability of cancer based on these features were then derived.

RESULTS: 3.8% (95% CI 0.9%-6.8%) of individuals without cancer had an mDA in their WBCs that were also observed in the plasma ($p < 0.01$, permutation test). Fragmentation features were not different in regions with mDAs in individuals without cancer ($p = 0.619$; permutation test) but were altered in regions of tumor-derived chromosomal changes in patients with cancer ($p < 0.01$; permutation test). Coverage-based statistics were impacted by mDAs ($p < 0.01$; Wilcoxon test). Machine learning models fit with CN_{adj} showed improved performance over CN. However, machine learning models fit with fragmentation features compensated for this difference overall showing robustness to mDAs ($p = 0.45$; bootstrap) demonstrating the robustness of cfDNA fragmentomes for detecting lung cancer.

CONCLUSIONS: While coverage-based statistics of WGS analyses of cfDNA may be affected by mDAs, fragmentation-based approaches relying on cfDNA fragment length are robust to effects of CH. CN_{adj} is an improved statistic for detecting tumor-derived chromosomal copy number changes in cfDNA, providing increased specificity by conditioning on fragment size distributions.

#0982 Variation of cell-free DNA concentrations in liquid biopsies.

S. Short[1], A. V. Annapragada[1], J. E. Medina[1], Z. H. Foda[1], D. Mathios[2], C. Hruban[1], E. J. Chiao[1], K. Boyapati[1], A. Bartolomucci[1], K. Boyapati[1], V. Adleff[1], R. B. Scharpf[1], V. E. Velculescu[1], J. Phallen[1];

[1]Johns Hopkins Sidney Kimmel Comprehensive Cancer Center, Baltimore, MD, [2]Washington University School of Medicine Siteman Comprehensive Cancer Center, St. Louis, MO

Introduction: Liquid biopsies are promising noninvasive tools for cancer detection. Variation in cell-free DNA concentrations (cfDNA-conc) has been observed between individuals with and without cancer. We assessed cfDNA-conc in 2287 treatment-naive individuals including those without cancer, with benign or high-risk conditions, or with one of eight cancer types.

Methods: Plasma (0.3 to 9.8 mL) was separated from whole blood collected in Streck or EDTA tubes from individuals with bile duct, breast, colorectal, gastric, ovarian, liver, lung, pancreatic, or metastatic cancer (n=23, 54, 28, 26, 264, 75, 180, 31, 22, respectively) as well as benign or high-risk conditions (n=550, 133, respectively) such as cirrhosis or hepatitis B or C virus infection (HBV/HCV), and without cancer (n=901). cfDNA was extracted using the Qiagen QIAamp Circulating Nucleic Acid Kit. Quality and quantity were assessed using the High Sensitivity DNA assay on the Agilent Bioanalyzer. Total amount (ng) of cfDNA from all nucleosomal peaks was evaluated per volume (mL) of plasma to assess significance across cohorts using unpaired two-sample Wilcoxon tests.

Results: We observed that in individuals without cancer, cfDNA-conc increased with age (Pearson R^2=0.59; 18-40yrs vs 41-55yrs, vs 56-65yrs, vs 66-85yrs; p=2.31E-09, 1.50E-12, 8.31E-17, respectively). No difference was observed between cfDNA-conc from EDTA and Streck plasma from the same individual (n=9, p=0.359, Wilcoxon signed-rank test two-tailed). Individuals with benign adnexal masses or cirrhosis had similar cfDNA-conc compared to those without cancer while individuals with benign lung lesions or HBV/HCV had significantly different cfDNA-conc (p=0.70, 0.35, 6.96E-04, 1.88E-09, respectively). These observations were not affected by age. Individuals with cancer had significantly higher cfDNA-conc compared to those without cancer (bile duct p=2.08E-14, breast p=4.44E-16, colorectal p=6.04E-10, gastric p=5.93E-04, ovarian p=9.99E-16, liver p=1.22E-15, lung p=0, pancreatic p=8.57E-03, metastatic p=1.18E-06). Ovarian cancer exhibited higher cfDNA-conc than benign adnexal masses which was more pronounced in later stage disease (I/II p=3.83E-06, III/IV p=8.18E-08). Compared to cirrhosis or HBV/HCV we observed a stepwise increase in cfDNA-conc in liver cancer with progressing stage (0/A p= 6.50E-04, B p= 5.69E-10, C p= 1.47E-08). Higher cfDNA-conc were also observed with higher stage of lung cancer compared to benign lung lesions (I/II p=4.99E-03, III/IV p=3.89E-06). Using cfDNA-conc (ng/mL) as a single feature, we distinguished individuals with and without cancer with an AUC of 0.72 (95% CI=0.70-0.75).

Conclusions: In a cohort of 2287 individuals, we observed cfDNA-conc increases with age and cancer stage that varied across cancer types. As a classifier, cfDNA-conc can be predictive of cancer status, yet further work is needed to understand the contribution of other comorbidities.

#0983 Epigenomic analysis of plasma cell-free DNA identifies stemness features associated with worse prognosis in AR-altered lethal metastatic castration resistant prostate cancer.

P. S. Chauhan[1], I. Alahi[1], S. Sinha[1], R. Mueller[1], A. L. Shiang[1], J. Webster[1], H. X. Dang[1], D. Saha[1], L. Greiner[1], B. Yang[1], E. M. Ledet[2], R. K. Babbra[3], W. Feng[1], P. K. Harris[1], F. Qaium[1], E. B. Jaeger[2], P. J. Miller[2], S. A. Caputo[2], O. A. Sartor[4], R. K. Pachynski[1], C. A. Maher[1], A. A. Chaudhuri[1];
[1]Washington University in St. Louis, St. Louis, MO, [2]Tulane University School of Medicine, New Orleans, LA, [3]Wilmot Institute Cancer Center, University of Rochester Medical Center, Rochester, NY, [4]Mayo Clinic, Rochester, MN

Background: Metastatic castration-resistant prostate cancer (mCRPC) resistant to androgen receptor (AR)-targeted agents is often lethal. Unfortunately, biomarkers for this deadly disease remain under investigation, and underpinning mechanisms are ill-understood. Here, we applied epigenomic approaches to identify cell-free (cf) DNA features associated with these lethal AR-resistant mCRPC patients.
Methods: Plasma from 99 mCRPC patients was collected from two independent institutions, either prior to first-line AR-targeted therapy (n = 63) or during treatment (n = 36). We applied EnhanceAR-Seq to detect alterations in the *AR* locus including the upstream enhancer. We then applied genome-wide cfDNA epigenomics to 43 pre-treatment plasma samples and performed both fragmentomics and methylation sequencing to delineate the biology of *AR*/enhancer-altered lethal mCRPC. Finally, we identified stemness genes by applying CytoTRACE to external single-cell RNA-seq data from mCRPC, and applied these to cfDNA via promoter-level methylation analysis. We then assessed these stem-associated genes in tumor bulk RNA-seq data from an independent mCRPC cohort.
Results: *AR*/enhancer alterations were detected in 44% of pre-treatment cfDNA samples and correlated with significantly worse progression-free survival (PFS) (HR = 2.12, P = 0.01) and overall survival (OS) (HR = 2.48; P = 0.02). *AR*/enhancer alterations were detected in 19% of on-treatment cfDNA samples and were also associated with profoundly worse PFS (HR = 15.38, P = 0.0003) and OS (HR = 15.53, P = 0.002). Further, genome-wide cfDNA fragmentomic analysis revealed that binding sites for developmentally relevant transcription factors such as *FOXA1*, *NKX-3* and *HOXB13* were significantly more accessible in *AR*/enhancer-altered lethal mCRPC patients. Gene set enrichment analysis of the 20 most accessible transcription factors revealed several pathways associated with stem cell development. Interestingly, the 10 most stem-associated genes obtained using CytoTRACE applied to an external cohort of single-cell RNA-seq data from mCRPC (He et al. 2021) were promoter-hypomethylated in the plasma cfDNA of *AR*/enhancer-altered lethal mCRPC patients (P = 0.005). Further, metagene analysis of these stem-associated genes revealed worse PFS by Kaplan-Meier analysis (P = 0.04), which was confirmed by multivariate cox proportional hazards modeling. Our stemness metagene further stratified overall survival (P = 0.03) when applied to an external cohort of 80 mCRPC patients from Abida et al. 2019.
Conclusions: Alterations in *AR* including the upstream enhancer are remarkably prognostic in mCRPC with pre-treatment predictive potential. The mechanism can be inferred via cfDNA epigenomic analysis and appears to involve increased tumor cell stemness in *AR*-altered lethal mCRPC.

#0984 Optimizing first-line systemic therapy selection in advanced hepatocellular carcinoma (HCC): A biomarker approach using circulating cell-free DNA (cfDNA) (atezolizumab plus bevacizumab vs. lenvatinib vs. sorafenib).

S. Park[1], B. Kim[2], Y.-e. Lee[3], J. Shim[1], D. Lee[1], J. Choi[1], E.-H. Cho[3];
[1]Asan Medical Center, University of Ulsan, Seoul, Korea, Republic of, [2]National Cancer Center, Goyang, Korea, Republic of, [3]GC Genome, Yongin, Korea, Republic of

Background: With the emergence of new immune checkpoint inhibitors and tyrosine kinase inhibitors for advanced HCC, determining the optimal first-line therapy is challenging due to the lack of precise biomarkers. This underscores the urgent need for biomarker-based strategies for treatment decisions.
Methods: This prospective biomarker study analyzed plasma cfDNA from 267 advanced HCC patients treated with first-line sorafenib (S) (n=212), lenvatinib (L) (n=32), or atezolizumab plus bevacizumab (AteBev) (n=23). Low-depth whole-genome sequencing was performed on cfDNA to identify genome-wide copy number alterations (CNAs). The 'I-score' was established to quantify genomic instability, calculated as the sum of absolute Z-scores of sequenced reads for each chromosome. The treatment outcomes of the three different therapies were compared based on the I-score. The I-score cutoff to differentiate high from low genomic instability was set the level separating progressive disease (PD) from non-PD at the first response evaluation
.Results: Patient demographics and disease characteristics were predominantly male (90.6%) with a median age of 59 years. The majority had an ECOG performance status of 1 (55.4%), HBV etiology (81.3%), and were classified as Child-Pugh class A (88.8%), with most presenting at BCLC stage C (95.1%). The high I-score group (n=164) exhibited a higher prevalence of macrovascular invasion (56.8% vs. 24.6%; p<0.001), lymph node metastasis (39.6% vs. 27.2%; p=0.038), and bone metastasis (14.6% vs. 4.9%; p=0.012) but lower peritoneal metastasis (5.5% vs. 12.6%; p=0.039) compared to the low I-score group (n=103). The high I-score group showed a worse disease control rate (50.6% vs. 74.8%; p<0.001), shorter time to progression (TTP) (median, 2.1 vs. 4.3 months; p<0.001), and poorer overall survival (OS) (6.0 vs. 18.5 months; p<0.001) compared to the low I-score group. Treatment efficacy varied within the high I-score group, with AteBev showing the most favorable outcomes: the median TTP was 6.0 months for AteBev vs. 4.1 months for L vs. 1.8 months for S (p=0.005), and the median OS was not reached for AteBev vs. 7.6 months for L vs. 5.4 months for S (p=0.036). However, in the low I-score group, there were no significant differences in TTP and OS among the treatment types: the median TTP was 9.4 months for AteBev vs. 3.9 months for L vs. 4.2 months for S (p=0.665), and the median OS was not reached for AteBev vs. 9.9 months for L vs. 18.8 months for S (p=0.412).
Conclusions: The I-score, reflecting genome-wide CNA in cfDNA, has potential as a prognostic biomarker for outcomes in advanced HCC patients receiving first-line treatments. It may be instrumental in guiding the selection of the most appropriate therapy.

#0985 An effective cfDNA methylation-based assay in discriminating primary liver cancer from cirrhosis or chronic hepatitis virus infection: marker discovery, phase I pilot, and phase II clinical validation.

Yang Tian[1], Yanan Wang[2], Mingxin Pan[3], Lei Zhang[4], Qiancheng You[4], Bingsi Li[4], Shangli Cai[4], Feng Shen[1], Guoyue Lv[5]

[1]Department of Hepatobiliary Surgery, Eastern Hepatobiliary Surgery Hospital, Navy Medical University, Shanghai, China,[2]Phase I Clinical Trials Unit, First Hospital of Jilin University, Changchun, China,[3]Department of Hepatobiliary Surgery II, General Surgery Center, Zhujiang Hospital, Southern Medical University, Guangzhou, China,[4]Burning Rock Biotech, Guangzhou, China,[5]Department of Hepatobiliary and Pancreatic Surgery, General Surgery Center, First Hospital of Jilin University, Changchun, China

Background: Early detection of primary liver cancer (PLC) in individuals with liver cirrhosis (LC) or chronic hepatitis virus infection (CHVI) improves survival. Timely, effective, and affordable tools with high sensitivity are urgently needed in clinical practice.
Methods: Tissue and/or plasma samples from 159 healthy individuals and 89 PLC, LC, or CHVI patients were sequenced by a targeted methylation panel (~70,000 CpGs) to screen candidate methylated DNA markers (MDMs). In phase I, the performance of each selected MDM was validated in 175 plasma samples (PLC, n=101; LC/CHVI, n=74) by a CO-methylation aMplification rEal-Time PCR (COMET) assay. Logistic models were then trained and validated in phase II with 310 plasma samples (hepatocellular carcinoma [HCC], n=212; combined hepatocellular-cholangiocarcinoma [cHCC-CC], n=12; LC/CHVI, n=106; training vs. validation, 2:1).
Results: The methylation levels of eleven selected MDMs with top performance showed a significant increase in PLC compared with LC/CHVI in both tissue and plasma samples ($P<0.05$). In phase I, eight of the above eleven MDMs with an area under the curve (AUC) over 0.80 to differentiate PLC and LC/CHVI were chosen for further investigation. In phase II, the MDM-based logistic model achieved sensitivity of 87.2% (95% confidence interval [CI], 80.8%-92.4%) and 88.0% (78.4%-94.4%), at respective specificity of 97.1% (90.1%-99.7%) and 100% (90.3%-100%) in the training and validation sets. In the validation set, sensitivity in patients with BCLC stage 0, diameter<3 cm, AFP-negative, and PIVKA-II-negative was 90.0% (55.5%-99.7%), 88.9% (65.3%-98.6%), 80.6% (64.0%-91.8%), and 81.3% (54.4%-96.0%), respectively. The classifier achieved similar sensitivity in patients with or without HBV/HCV infection (88.2% vs 90.0%). Additionally, our model detected 19 of 24 (79.3%, 57.8%-92.9%) intrahepatic cholangiocarcinoma. Combining AFP and PIVKA-II, the model achieved higher sensitivity of 93.3% (85.1%-97.8%) and specificity of 100.0% (90.3%-100%).
Conclusion: In conclusion, the present study demonstrated the feasibility of using an easy-to-implement cfDNA methylation assay (COMET) to discriminate early-stage liver cancer from other liver diseases, with superior accuracy over AFP and PIVKA-II. Notably, the combination of the COMET, AFP, and PIVKA-II increased the overall sensitivity, indicating the potential benefit of integrating these approaches in clinical practices. Moving forward, further investigation is needed to validate these findings in larger prospective clinical studies.
Keywords: primary liver cancer, early detection, liver cirrhosis, chronic hepatitis virus infection, methylated plasma DNA marker.

#0986 Mathematical modeling of ctDNA dynamics to predict utility of ultrasensitive MRD assays in early stage non-small cell lung cancer (NSCLC).

J. S. Goldstein[1], C. Abbosh[2], A. A. Alizadeh[1], M. Diehn[1], D. M. Kurtz[1];
[1]Stanford University, Stanford, CA, [2]AstraZeneca, Cambridge, United Kingdom

***Background*:** ctDNA assay use for minimal residual disease (MRD) detection in early stage NSCLC has been limited by suboptimal sensitivity of first generation assays. It is unclear how improving assay limit of detection (LOD) would translate to improvements in clinical sensitivity. Here, we performed mathematical modeling of ctDNA dynamics after curative-intent treatment in early stage NSCLC to predict the clinical impact of MRD assays with improved analytical sensitivity.
***Methods*:** We analyzed a recently reported dataset of post-surgical ctDNA MRD surveillance in early stage NSCLC (Abbosh et al., Nature 2023) to investigate ctDNA growth dynamics. Of 70 relapsed patients in this cohort, 23 had 3 consecutive ctDNA-positive samples with no intervening therapy. We used these to generate patient-specific mathematical models for ctDNA variant allele fractions (VAF) over time, initially assuming exponential growth. We assessed this assumption by creating log-linear models for ctDNA increase in these cases. Using slopes of the log-linear models, we calculated patient-specific doubling times and assessed their relation to stage, histology, and outcome. We used the log-linear models to simulate a VAF distribution each day after surgery, enabling projection of clinical sensitivities and estimation of lead times for recurrence detection at varying LODs.
***Results*:** For the 23 cases with 3+ consecutive ctDNA positive samples, we developed log-linear models for ctDNA VAF growth, which were strongly correlated ($r > 0.5$) in 18/23 (78%) patients (median $r = 0.89$), supporting that ctDNA can be modeled as exponential growth. We calculated ctDNA doubling times for the 18 patients with exponential ctDNA kinetics and 10 patients with 2 consecutive ctDNA positive samples. Doubling times were remarkably consistent with median 51 days (IQR 40-79). Doubling times were longer for stage I tumors compared to stage II/III ($p = 0.04$) but were not different between NSCLC subtypes. Doubling time correlated with time to clinical relapse, with patients having more rapid ctDNA growth relapsing earlier ($r = 0.52$, $p=0.03$).
Finally, we used patient-specific log-linear models to project ctDNA VAFs at a landmark 30 days after surgery. By improving the LOD for ctDNA detection from 10^{-4} to 10^{-6}, the projected clinical sensitivity doubled (from 43% to 86%). Simulations predicted that this improvement in sensitivity would increase median lead time from 183 days for LOD=10^{-4} to 349 days for LOD=10^{-6} ($p<0.0001$).
***Conclusion*:** For most relapsed NSCLC patients, the natural history of ctDNA MRD growth can be reliably modeled with exponential growth kinetics. ctDNA doubling time is associated with stage and clinical outcome. Ultrasensitive MRD assays with LOD of 10^{-6} are predicted to meaningfully improve clinical sensitivity at the post-surgical landmark and to increase the lead time for MRD detection before relapse.

#0987 Novel ALK mutations in EML4::ALK+ NSCLC resistant to TKIs identified by liquid biopsy.

Federica Malighetti[1], Matteo Villa[1], Elisa Sala[2], Geeta Sharma[1], Giulia Arosio[1], Maria Gemelli[2], Chiara Manfroni[1], Diletta Fontana[1], Nicoletta Cordani[1], Raffaella Meneveri[1], Alfonso Zambon[3], Rocco Piazza[1], Fabio Pagni[1], Diego Cortinovis[1], Luca Mologni[1]

[1]University of Milano-Bicocca, Monza, Italy,[2]Fondazione IRCCS San Gerardo dei Tintori, Monza, Italy,[3]University of Modena and Reggio Emilia, Modena, Italy

The identification of Anaplastic Lymphoma Kinase (ALK) chromosomal translocations led to the development of effective targeted therapies in a subset of Non-Small Cell Lung Cancer (NSCLC) patients. Several drugs are currently in clinical practice for advanced ALK+ NSCLC. However, resistance remains a challenge in these patients. The possibility to analyze circulating tumor DNA (ctDNA) with non-invasive methods can greatly improve prognostic capabilities, by allowing early detection of relapse and of drug-resistant mutations from peripheral blood. We report a series of 15 consecutive relapsed NSCLC patients (12 ALK+, 3 ROS1+) treated at the Fondazione IRCCS-San Gerardo dei Tintori (Monza, Italy) that were investigated by liquid biopsy at tyrosine kinase inhibitor (TKI) failure, through amplicon deep sequencing of the *ALK/ROS1* kinase domains. Median DNA yield was 4.8 ng per ml of plasma and mean fragment size was 176 bp. Mutational hotspot coding regions of ALK and ROS1 genes were amplified by high-fidelity PCR and sequenced. Mean coverage of called variants was 24,687x. The threshold for mutation calling was set at 0.6%, after correcting for mapping quality, minimum coverage, and strand bias. Analysis of background signal on healthy control DNA identified 0.0024 mismatches per mapped base. Overall, plasma ctDNA analysis detected an ALK mutation in 7/18 relapse samples from 7/15 patients. No ROS1 mutations were found in ROS1 fusion-positive patients. Among 12 patients carrying an EML4::ALK fusion, 10 variants potentially driving resistance were found. Along with mutations that were previously identified (L1196M/G1202R, E1154K, F1174L), novel ALK variants were detected such as L1198R, T1211I, C1235R, C1237Y, L1196P. Mutations were characterized for sensitivity to ALK inhibitors in a BaF3-EML4::ALK cell model, using cell proliferation assays and western blotting to evaluate the effects on ALK phosphorylation. C1237Y and L1196P mutants appeared to resist all TKIs; hence, we further tested their sensitivity to novel investigational drugs, zotizalkib and repotrectinib. Both mutants demonstrated resistance, suggesting that these two mutations confer broad resistance to TKIs. Molecular modelling of C1237Y and L1196P mutants was run to elucidate the mechanisms of resistance. The ADP-C1237Y complex showed a much smaller root-mean-square deviation than ADP-WT, indicating a higher affinity/activity of the mutant. L1196 interacts hydrophobically with a methyl group of lorlatinib, P1196 is predicted to lose such interaction, while ATP binding is not affected. The presence of C1237Y and L1196P variants, is a relevant finding due to their resistance, even after the exposure to the fourth-generation inhibitor zotizalkib. The clonal selection of these mutations, made by second/third generation ALK TKIs may lead to a complete refractory status, which would then render TKIs useless in a sequential therapeutic strategy.

#0988 Genome-wide repeat landscapes in cancer and cell-free DNA.

A. Annapragada, N. Niknafs, J. R. White, D. C. Bruhm, C. Cherry, J. E. Medina, V. Adleff, C. Hruban, D. Mathios, Z. H. Foda, J. Phallen, R. B. Scharpf, V. E. Velculescu;
Johns Hopkins University School of Medicine, Baltimore, MD

Introduction: Repeat sequences comprise >50% of the human genome and structural and epigenetic changes in these regions are implicated in cancer. However, no systematic analysis of the compendium of repeat sequences has ever been performed in human cancer or cell-free DNA (cfDNA), largely due to the inability to identify and quantify repeat sequences genome-wide. We describe here the first comprehensive analysis of genome-wide repeat landscapes in cancer and demonstrate their utility in cfDNA liquid biopsies.
Methods: We developed ARTEMIS (Analysis of RepeaT EleMents in dISease) an alignment-free, genome-wide approach for analyzing repeat landscapes in short read sequencing. This approach uses a *de novo* search of short sequences (kmers) in the telomere to telomere (chm13) reference genome to identify 1.2 billion 24-mers uniquely defining 1280 individual repeat types occurring genome-wide across 57 subfamilies and 6 families. We analyzed ARTEMIS kmers in whole genome sequences of 525 matched tumor/normal pairs from breast, colorectal, liver, lung, ovarian, cervical, prostate, thyroid, head and neck, gastric, and bladder cancers in the Pan Cancer Analysis of Whole Genomes (PCAWG), and in low coverage (1-2x) whole genome sequences of 1450 cfDNA samples from individuals with and without 8 types of cancer.
Results: Analysis of ARTEMIS kmer repeat landscapes in 525 PCAWG tumors identified changes in all 1280 repeat element types, including 820 novel elements not previously known to be altered in cancer. A median of 807 repeat elements (range 246-1280) were altered in each tumor compared to its matched normal. The majority of changes were in repeat elements not previously described as altered in tumorigenesis and were most frequently found within Satellites, LINEs and SINEs, though changes were also observed in LTRs, Transposable Elements, and RNA Elements. A cross-validated cfDNA model using repeat landscapes (ARTEMIS) and fragmentation features (DELFI) detected individuals in a diagnostic cohort (n=287) across all stages of lung cancer with high performance (AUC 0.91, 95% CI 0.88-0.95) and was externally validated in a separate population (n=513). The locked model generated scores that correlated with circulating tumor mutant allele fractions for patients (n=19) undergoing targeted lung cancer therapy ($r=0.80$, $p<2.2e-16$), and stratified progression-free survival ($p<0.001$). ARTEMIS repeat landscape analyses of cfDNA also detected liver cancer in a high-risk cohort (n=208) of individuals with cirrhosis or viral hepatitis (AUC 0.91, 95% CI 0.87-0.95), and identified tissue of origin among seven tumor types (n=423).
Conclusions: ARTEMIS reveals genome-wide repeat landscapes in human cancer, including in 820 novel elements not previously known to be altered in tumorigenesis. These repeat landscapes that can now be described are evaluable in the circulation and provide an avenue for noninvasive detection and characterization of cancer.

#0991 Unraveling the role of nicotinamide adenine dinucleotide precursors in pancreatic cancer biology.

F. Nakazzi[1], M. Zarei[1], H. J. Graor[1], A. W. Loftus[2], O. Hajihassanni[1], J. M. Winter[2];
[1]Case Western Reserve University, Cleveland, OH, [2]University Hospitals, Cleveland, OH

Introduction: Pancreatic cancer has the lowest 5-year survival rates among all cancers because of the challenges with early detection, its aggressive nature, and resistance to chemotherapy; this makes prevention a promising approach for reducing related mortalities. The disease is predominantly diagnosed in individuals over 60, suggesting that age-related physiological decline impacts its onset; therefore, delaying aging hallmarks may delay its onset. Nicotinamide dinucleotide (NAD+) precursors may hold a unique advantage over other geroprotectors because they target multiple aging hallmarks. Heron, we investigated how NAD+ supplementation impacts normal human pancreatic ductal epithelial cells (HPDE) under stress as a surrogate for cancer prevention in vitro. We also examined the paradoxical impact of NAD+ precursor supplementation on pancreatic cancer growth during chemotherapy.
Methods: In vitro, we mimicked age-related NAD+ decline in the media. We stressed HPDE cells under these conditions and evaluated the effect of supplementation with the NAD+ precursor, Nicotinamide mononucleotide (NMN). We assessed cell viability using the PicoGreen assay, mitochondrial function, and reactive oxygen species (ROS) using the Seahorse XF Analyzer and the mitoSox kit, respectively, DNA repair and DNA damage using a western blot for Poly ADP ribose (PAR) and gamma H2AX, respectively, and SIRT3 expression was determined using a western blot. To evaluate the impact of NAD+ supplementation on pancreatic cancer cells, we treated pancreatic cancer cells with NMN and oxaliplatin. We then assessed the mitochondrial function, ROS levels, DNA damage, and repair. We implanted MiaPaCa-2 xenografts into athymic nude mice and treated them daily with 300mg/Kg of NMN and biweekly 5mg/kg of Oxaliplatin.
Results: Experiments revealed that NMN is not toxic to HPDE cells, even at high concentrations. There was increased cell survival of HPDE cells under stress (nutrient deprivation and alkylating agents) following NMN supplementation. We also noted reduced ROS levels, increased SIRT3 expression, and PARylation. Pancreatic cancer cells were less sensitive to Oxaliplatin following NMN supplementation and showed an increased oxygen consumption rate, increased PARylation, and reduced ROS levels. There was reduced sensitivity to oxaliplatin treatment in the mice with MiaPaCa-2 xenografts treated with NMN.
Conclusion: These findings demonstrate a cytoprotective role of NAD+ precursor supplementation in normal pancreatic ductal epithelial cells, with implications for possible cancer prevention. NAD+ supplementation also rescued cancer cells under cytotoxic stress, meaning that geroprotectors like NMN, in conjunction with chemotherapy, may unintentionally promote cancer progression. Future studies will directly test NAD+ precursor supplementation in genetically engineered pancreatic cancer models.

#0992 The impact of tamoxifen on autophagic and epigenetic regulation in endometrial cancer.

S. Thota, R. Begum, N. Chintala, A. Pandit, B. Sapkota, J. Francis;
Louisiana State University, Baton Rouge, LA

Background: Endometrial cancer, predominantly endometrioid adenocarcinoma, ranks as the fourth most common cancer in women globally, with an increasing incidence over the last two decades. Tamoxifen, well-known for its antiestrogenic characteristics in the treatment of breast cancer, paradoxically increases the risk of endometrial cancer. Understanding this dual role of tamoxifen is crucial for optimizing breast cancer therapy while mitigating endometrial cancer risk. This study aims to elucidate the molecular alterations induced by tamoxifen in endometrial thickening and its potential to induce cancer, particularly focusing on autophagy, epithelial-mesenchymal transition (EMT), and cancer stem-like cells (CSCs).
Methods: In this study, female BALB/c mice were administered tamoxifen (20 mg/ml) orally for five consecutive days. We monitored changes in EMT markers, autophagy-related genes, and stem cell markers over 1 to 5 months. Furthermore, we investigated the epigenetic modulation of key genes involved in these processes.
Results: Tamoxifen treatment led to altered expression of both epithelial and mesenchymal EMT markers, autophagy-related genes (p62, LC3B, Beclin-1, mTOR, ATG12, ATG16), and stem cell markers (Nanog, SOX2, ALDH1). Notably, we observed significant epigenetic changes, including increased methylation of E-cadherin and decreased methylation of Twist. Furthermore, we observed hypermethylation (a process often linked to the silencing of tumor-suppressing genes) in MGMT (Methylguanine methyltransferase), a DNA repair enzyme involved in chemoresistance, and DAPK (Death-associated protein kinase), a kinase associated with apoptosis, autophagy, and inflammation. We also observed hypermethylation in the CpG promoter regions of autophagy-related genes (Beclin-1 and LC3B) highlighting a potential mechanism for tamoxifen-induced tumorigenic changes.
Conclusion: Our findings demonstrate tamoxifen's influence on cellular and molecular pathways, highlighting the complex interplay between drug treatment and cancer progression. The observed epigenetic changes provide insight into the mechanisms by which tamoxifen may contribute to endometrial cancer risk, suggesting potential targets for therapeutic intervention.

#0993 Comprehensive immunophenotypic strategies to enable equity in remote settings for improved cancer prognosis.

N. J. Smith[1], M. Cohen[2], J. Alipaz[2], C. Loh[2], D. King[2], B. Fazekas de St Groth[1], **H. M. McGuire**[1];
[1]The University of Sydney, Sydney, Australia, [2]Standard Biotools, South San Francisco, CA

Improved cancer prognosis begins with insights obtained from high quality data during clinical trials. Execution of longitudinal clinical trials in flow cytometry is complex, primarily due to logistical challenges in high quality sample collection. For instance, highly remote indigenous population centers are both disadvantaged in access to healthcare and often underrepresented in clinical trials. This paradox is highlighted in the case of Australian First Nations communities, for which lung cancer prevalence peaks in males at twice the magnitude of the general population. Our group has developed a novel blood “immune signature” that robustly predicts failure to make a clinical response to checkpoint therapies targeting the PD-1/PD-L1 pathway. Encouraged by these groundbreaking findings, which were achieved through applying a comprehensive 38-plex immunophenotyping CyTOF panel to biobanked cancer samples, recent advances in CyTOF technology now give us the opportunity to expand our clinical implementation to remote settings, with a further expanded panel to 50+ markers. CyTOF is the only technology that allows easily implemented remote asynchronous sample collection and the largest immunophenotyping panel that yields reproducible results. Asynchronous collection is uniquely enabled using a stable lyophilized large-scale staining panel and achieving comprehensive marker coverage in one panel minimizes blood sample required. Furthermore, the new technology enables a highly simplified workflow including blood collection and processing in remote locations to enable the simplest clinical trial infrastructure complexity and cost, easily implemented in current hospital lab environments. As such, this study is designed to ultimately demonstrate both clinical impact of the large panel and utility of CyTOF technology for highly simplified and robust workflow for multi-site clinical trials. This project has 3 phases; i) implementation and evaluation of the collection, analysis technique and data management of this new approach across multiple sites, ii) collection of samples for analysis both pre- and post- initiation of therapy to establish efficacy and optimize as necessary, and iii) blinded clinical trial. We will report on the first phase of this project which is implementing new workflow across clinical collection site, data integration and analysis. This workflow would enable highly simplified collection to access indigenous and under-served populations spread across remote sites in Australia.

#0995 Preservation of patient whole blood preserves cancer immune cell biology at single cell resolution.

K. Martin, C. Kunihiro, J. Abousoud, T. Drennon, Y. Li, S. Marrache, N. Raman, V. Rodriguez, P. Lund, J. Durruthy Durruthy, S. Taylor, A. Kohlway, P. Smibert, D. Walter, J. Herschleb;
10X Genomics, Pleasanton, CA

Blood is an easily accessible clinical sample type that helps inform treatments, investigate disease mechanisms, and monitor outcomes. Logistical challenges in the transportation and processing of blood samples impact data output from single cell RNA sequencing (scRNA-seq). Recent scRNA-seq studies have shown that significant changes in gene expression and immune cell populations occur in as little as a few hours post collection. Thus, there is a need for rapid preservation of blood upon collection before biological changes can occur. Existing preservation approaches compromise the cell membrane, making samples incompatible with single cell transcriptomic analyses. Here, we describe a novel workflow for fixation and long-term storage of whole blood, and isolation of peripheral blood mononuclear cells (PBMCs) from the fixed blood using a readily available, low-cost, high-throughput procedure. We then profile the gene expression of these cells using the fixation-compatible Single Cell Gene Expression Flex workflow. Importantly, this novel blood collection and preparation workflow eases blood transportation logistical constraints, allowing distributed sample collection and batched shipping of blood samples for scRNA-seq and potentially enabling large-scale translational research studies. We compared whole blood fixed immediately after collection using our workflow with clinical blood samples stored at ambient temperature. This revealed that immune cell populations and biological pathways shift significantly as early as five hours following sample collection, if not immediately stabilized. Across a time course of ambient temperature storage of whole blood without immediate stabilization, we observe significant upregulation of stress-related genes (FOS, JUN, CIRBP) in samples using Single Cell Gene Expression Flex profiling. Additionally, expression of a proto-oncogene TNFAIP3 was upregulated in whole blood stored at 20°C compared to samples stored at 4°C for the same lengths of time, unless samples were stabilized using the novel workflow shown here. This novel whole blood fixation method, coupled with automatable cell isolation methods and Single Cell Gene Expression Flex-enabled multiplexed single cell sequencing, will usher in a new age of economical, large-scale translational research studies that result in valuable clinical insights.

#0996 Predicting early mortality in a large ethnically diverse phase I clinical trial program.

H. Erfani[1], S. Woll[1], A. Luong[1], G. Guerra[1], A. Kharrat[2], R. Umayam[1], A. Martynova[1], L. Brunette[1], L. Roman[1], N. Izadian[1], T. Bustos[1], D. Hanna[1], A. El-Khoueiry[1], J. Thomas[1];

[1]USC - University of Southern California, Los Angeles, CA, [2]Brown University, Providence, RI

Background: Various scoring systems are developed to optimize patient selection for phase I clinical trials. We evaluated the Royal Marsden Hospital (RMH), Princess Margaret Hospital Index (PMHI), and MD-Anderson Cancer Center (MDACC) prognostic scores and compared their power to predict 90-day mortality (90DM) in an ethnically diverse population enrolled in the USC Norris Comprehensive Cancer Center (NCCC) Phase I Program.

Methods: We queried our database of patients enrolled in phase I clinical trials at the NCCC from 2015-2022 which includes demographics, treatment details and outcomes. The enrollment occurred at all NCCC sites including the Los Angeles General Medical Center, a safety net hospital. Prognostic scores were calculated: RMH (albumin < 35 g/L, LDH > ULN, > 2 metastatic sites), PMHI (albumin < 35 g/L, ECOG > 0, > 2 metastatic sites), MDACC (albumin < 35 g/L, LDH > ULN, ECOG > 0, > 2 metastatic sites, GI tumor type). Kaplan-Meier analysis was used to calculate median survival in each group. ROC analysis was performed to assess the 90DM prediction.

Results: 611 patients (15 breast, 344 GI, 20 GU, 29 GYN, 110 Lung/H&N, 88 other) were accrued to 88 phase I trials. Patients had a median age of 61 (25-87) and a median of 3 prior lines of therapy (0-10). 31.9% of pts were Hispanic, 44.1% non-Hispanic white, 3.7% black, and 20.4% Asian. The 90DM rate was 24.9%. The objective response rate was 8.3%, and 41.5% had stable disease. For all systems, higher scores had shorter survival (p<0.001). The MDACC system had the largest AUC to predict 90DM (AUC: 0.678, p < 0.001). Score of 4-5 (high risk) per MDACC system corresponds to a specificity of 94.5% (91.1-97.2) and positive likelihood ratio of 3.6 (1.8-7.2).

Conclusion: In our highly diverse phase I population, higher scores on the RMH, PMHI, and MDACC scoring systems were associated with worse prognosis and 90DM. Careful consideration should be given to potential patients with higher scores prior to enrollment in phase I trials.

Characteristics and outcomes of the study participants (N = 611).

Variable		**Median (IQR)/ N (%)**	**Scoring system**		**N (%)**	**Median survival days (95% CI)**	**p-Value**

#0997 Bringing the first prehabilitation program to American Indian cancer patients.

J. Erdrich[1], A. Hernandez[2], J. W. Bea[2], C. A. Thomson[2];
[1]University of Arizona, College of Medicine, Tucson, AZ, [2]University of Arizona, Mel and Enid Zuckerman College of Public Health, Tucson, AZ

Purpose. American Indian/Alaska Native (AI/AN) people have the worst cancer survival rates of any US racial group, are underrepresented in clinical trials and research, and have never been recruited for participation in any published prehabilitation (prehab) intervention conducted prior to cancer surgery.
Description of Procedure. We are collaborating with tribal partners to design the first prehab translational clinical trial for AI patients diagnosed with obesity-related cancer, to be implemented prior to surgical resection of the tumor. Program components have been developed with community input through semi-structured interviews and guidance from the sponsoring tribal health facility, the San Carlos Apache Healthcare Corporation. Patients preparing for cancer surgery will engage in a 3-week multimodal intervention that entails home-based exercise, supervised fitness sessions, promotion of anti-inflammatory foods, and health education materials adapted for and by community members. Serum and tissue biomarkers, as well as lifestyle behavioral measures, will be compared pre and post intervention to assess responsiveness. In respect of tribal sovereignty, the experimental procedure includes protocol refinement and approval by the tribal health facility's IRB and tribal council.
Summary of Data. Our qualitative data reveal AI cancer survivors from the partnering tribal community have high interest in prehab and attest they would have participated if offered (100%). Their consensus feedback fashioned the specifics of the prehab translational clinical trial: 30 minutes daily walking, 60 minutes supervised resistance training twice weekly, 2 ounces walnut consumption daily, nutrition counseling, transportation assistance, and education/encouragement from staff and peers. Biospecimen sampling can be a sensitive topic for AI audiences, which we addressed early and found 75% of the interviewed survivors agreed to biospecimen collection without stipulation; this increased to 100% support once the rationale for biospecimens was explained.
Conclusions: Published prehab studies in other populations administered for 3-5 weeks between diagnosis and surgery have shown improvements in functional capacity, attenuation of surgery-induced losses, alterations of inflammatory biomarkers, and patient safety. Our community-informed prehab translational clinical trial for AI patients is the first of its kind, and anticipated to demonstrate feasibility, patient acceptability, behavioral changes in lifestyle, and the potential to modulate inflammatory biomarkers.

#0998 Pursuing leadership in literacy to ameliorate head and neck cancer disparities.

Joni D. Nelson[1], Irene M. Lubker[2]

[1]Biomedical and Community Health Sciences, The Medical University of South Carolina, Charleston, SC,[2]Academic Affairs, MUSC Libraries , The Medical University of South Carolina, Charleston, SC

Overview of Proposed Research. Head and neck cancers are a deadly cancer that ranks among the six most common cancers worldwide. (American Cancer Society, 2021). Studies have shown greater disease burden among minority populations for head and neck cancer, higher mortality rates and lower oral cancer knowledge, but limited evidence has defined the underlying causes of late stage diagnoses and access to the healthcare system (Suzuki et al, 2019). More specifically, in comparison to the national rates, South Carolina is among the top ten for head and neck cancers (Community Outreach, Hollings Cancer Center, MUSC, 2019). Dental and primary care play a critical role delivering quality patient education, prevention, risk reduction and treatment regimes. However, there is a paucity of information published on the value of designing and implementing a health literacy program to prioritize head and neck cancer screening and prevention. Rural communities face unique challenges to achieving optimal oral health, impacted mainly by geographic location and socioeconomic status (IOM&NRC, 2011). More specifically, rural southern states such as SC continues to have a tremendous shortage of primary care providers. SC currently has 44 of 46 counties designated as geographic Primary Care and Dental Health Professional Shortage Areas and approximately 25% of SC citizenry are living in rural areas (HRSA, 2018). Because the vast majority of the state has challenges with availability of primary care and dental providers, this potentially exacerbates access to care inequities for rural and underserved minority populations. To enhance the quality and equity of oral cancer prevention in rural SC, it is critical that we prioritize strategies to elevate the significance of head and neck cancer risks. Therefore, the need to design and deliver innovative strategies to increase opportunities that intersect the healthcare system and community is inevitable. In this regard, we propose PULL A-HEAD, Pursuing Leadership in Literacy to Ameliorate HEAd and neck cancer Disparities. PULL A-HEAD is aimed to develop and implement a community-centered approach design for increasing the health literacy and efficacy of navigating the healthcare system for early detection of head and neck cancers. In this presentation we will share outcome and impact results of a community-centered, health literacy program in collaboration with our Regional Medical Library - Region 2 (RML2), National Library of Medicine partners at the Medical University of South Carolina. The program (i.e. PULL A-HEAD) will emphasize the delivery of health literacy education and health systems navigation tools to improve the early detection of head and neck cancers.

#0999 Clinical trial matchmaking: Connecting sites to sponsors.

L. Griffin[1], L. Shivakumar[1], L. Boehmer[1], S. Dodson[1], E. Plotkin[1], S. Pal[2], A. B. Benson III[3];
[1]Association of Community Cancer Centers, Rockville, MD, [2]City of Hope Comprehensive Cancer Center, Duarte, CA, [3]Robert H. Lurie Comprehensive Cancer Center of Northwestern University, Chicago, IL

Background: Oncology programs may encounter many challenges engaging in clinical trials. The Association of Community Cancer Center's (ACCC) Community Oncology Research Institute (ACORI) conducted a survey to gather insights on barriers to clinical trial provision and implementation, patient recruitment, and identifying resources to support cancer programs.
Methods: A survey of 29 questions was administered via Qualtrics. The survey focused on research-naïve sites (i.e., sites with little to no clinical research experience). Survey recipients were identified from ACCC's membership database, and the survey was open from May 5 to October 10, 2023. One survey response was captured per program.
Results: Of the 350 respondents, most were physicians, investigators, or oncology fellows (20%), directors/administrators (16%), patient navigators (12%), and APPs (12%). Responding programs were categorized as a comprehensive community cancer program (28%), community practice (26%), or academic medical center (21%). Eighty percent of respondents indicated their program currently conducts clinical research. The most common challenges included: patient recruitment (40%), limited staffing (36%), limited clinician time (32%), and lack of training in research administration and conduct (25%). The top 3 resources desired were communication about clinical research opportunities (65%), connections to clinical trial sponsors (49%), and clinical research coordinator training (41%).
Conclusions: Survey results showed a clear need for improved communication regarding clinical research opportunities, connections to clinical trial sponsors, and education around clinical trial implementation. Data from this survey will be used to match sites with trial sponsors, especially sites that serve patients with cancer from under resourced geographic, socioeconomic, racial, and ethnic groups. Future efforts will seek to engage clinical trial sponsors in improving trial engagement and feasibility, workforce support, training, and clinical mentorship.

#1000 Clinician and clinical trial staff perspectives on factors that impact enrollment of Black women in breast cancer trials.

Christen Sandoval[1], Eliza Brumer Cohn[2], Leslie R. Carnahan[3], Vida Henderson[2], Tigist Mersha[1], Neha Hippalgaonkar[4], Joe Horowitz[5], Sarah Khan[6], Kauthar Salum[2], Ana Williams[3], Lolita Coleman[7], Beluah Brent[7], Anne Marie Murphy[1], Paris Thomas[8], Paramjeet Khosla[6], Kent Hoskins[3], Ryan Nguyen[3]

[1]School of Public Health, University of Illinois Chicago, Chicago, IL, [2]Fred Hutch Cancer Center, Seattle, WA, [3]University of Illinois Cancer Center, Chicago, IL, [4]Division of Hematology/Oncology, University of Illinois Chicago, Chicago, IL, [5]College of Medicine, University of Illinois Chicago, Chicago, IL, [6]Sinai Chicago, Chicago, IL, [7]Sisters Working It Out, Chicago, IL, [8]Equal Hope, Chicago, IL

Background: Black women (BW) are more likely to present with advanced-stage disease and to die following a breast cancer (BC) diagnosis compared with women from other racial and ethnic groups, yet BW are underrepresented in BC clinical trials (CT). Clinicians and CT staff play a key role in patient participation in CT, however, there is limited data on their perspectives on facilitators and barriers for BW in BC trials.
Objective: The goal of the FOR ME (Fostering Opportunities in Research through Messaging and Education) study is to develop, optimize, and test a decision-aid intervention (web-based video) for clinical care teams to use with BW who have been recently diagnosed with BC to promote shared decision-making and CT participation. We provide insight into the facilitators and barriers from clinicians and CT staff to effectively discuss and enroll BW in BC trials. The identified themes will be used to inform video content and dissemination strategies.
Methods: Key informant interviews (KIIs) (n=20) were conducted by phone and video conferencing. Each KII was recorded and professionally transcribed. Thematic analysis and inductive coding approaches were used to analyze the data. First, a subset of transcripts was annotated, and then annotations were compiled into a preliminary codebook. Inter-coder reliability was established to improve quality and to establish the final codebook. Dedoose was used to analyze quotations and code co-occurrences, application frequencies, and relationships.
Results: In total, 16 clinicians and 4 clinical trial staff across academic and community practices were interviewed. Participants expressed multiple opportunities and barriers to CT participation. Facilitators included formal training on communication around clinical trials among clinical trial staff, previous exposure to discussing and enrolling patients in CT during fellowships and other training, institutional support for CT databases, reviewing CTs during tumor boards, and the presence of dedicated research support staff. Barriers included a lack of formal training in communicating CT to patients among clinicians, lack of institutional investment in CT infrastructure, time constraints of clinical visits, and the clinician's perception of the patient's willingness and ability to complete a CT.
Conclusions: Clinicians and clinical trial staff have a unique and important role to play in CT participation for BW who have BC, however, there are barriers, including training, time, awareness of available trials, and institutional support. Clinical trial staff report formal training in communicating clinical trial information to patients, while there is a lack of this type of training for clinicians. Future research in the FOR ME study will integrate patient, clinician, care team, and advocate perspectives into a web-based decision aid.

#1001 Association between oral cancer screening and knowledge of head and neck cancer symptoms and risk factors among Arab Americans.

N. Al-Antary, R. Siddiqui, M. Gilbert, L. Fakhoury, M. Nair, F. Siddiqui, E. Adjei Boakye;
Henry Ford Health System, Detroit, MI

Background: Head and neck cancer (HNC) has been increasingly affecting individuals of different ages, significantly contributing to the annual cancer burden in the US. While most HNC cases present at late-stages and are more likely to require aggressive surgical interventions with higher mortality, those who present with premalignant clinical signs or early-stages have a 5-year survival of 70%-90%. Moreover, current HNC public awareness is poor with lack of data on cultural and ethnic minorities. This study evaluated the association between oral cancer screening (OCS) recommendation and receipt and HNC symptoms and risk factors knowledge among Arab Americans in Michigan.

Methods: This was a cross-sectional study of adult Arab Americans conducted between March and July 2023. Surveys were available in English and Arabic per participants preference. Outcome variables were knowledge of three main HNC risk factors—alcohol, cigarette smoking, and HPV— and four of the most common HNC symptoms—nonhealing oral ulcers, dysphagia/odynophagia, voice changes and neck/throat masses—defined as yes/no. OCS was captured as receiving provider-given recommendation for screening and undergoing a screening test (yes/no). Multivariable logistic regression models estimated the associations between OCS and HNC symptoms and risk factor knowledge adjusting for socioeconomic factors.

Results: A total of 295 respondents were included in the study, 9% had received recommendation for OCS and 11% had undergone a screening test. In adjusted models, respondents who *did not* correctly identify nonhealing oral ulcers (aOR=0.20; 95% CI 0.06-0.67) as HNC symptoms or HPV (aOR=0.15; 95% CI 0.04-0.55) as risk factor of HNC were less likely to have received provider-given recommendation for OCS compared to those who identified the symptom and risk factor. Similarly, respondents who *did not* correctly identify nonhealing oral ulcers (aOR=0.13; 95% CI 0.04-0.42), dysphagia or odynophagia (aOR=0.22; 95% CI 0.07-0.70), voice changes (aOR=0.27; 95% CI 0.09-0.81), and neck/throat masses (aOR=0.24; 95% CI 0.06-0.91) as HNC symptoms or HPV (aOR=0.07; 95% CI 0.02-0.29) and alcohol (aOR=0.17; 95% CI 0.05-0.58) as HNC risk factors were less likely to have undergone OCS compared to those who identified the symptoms and risk factors.

Conclusion: Respondents who reported limited knowledge of HNC symptoms and risk factors were less likely to be exposed to screening recommendations or testing. Combining screening with education on premalignant and early-stage clinical signs and risk factors might facilitate reduction of HNC incidence and late diagnosis. Further interventions are needed to increase Arab Americans education and identification of high-risk groups by their providers. As HNC screening efficacy remains controversial, future efforts should be directed towards deepening our understanding in this area.

#1002 The historically black colleges and universities cancer trial consortium: A way forward to diversifying cancer clinical trials.

S. L. HOLDER[1], R. A. Winn[2], W. S. El-Deiry[1];
[1]Legorreta Cancer Center, Providence, RI, [2]Massey Comprehensive Cancer Center, Richmond, VA

The National Comprehensive Cancer Center Network cancer guidelines state that the best management for a cancer patient is on a clinical trial. However, the demographics of 74 registration trials for oral cancer therapies from 2009 - 2019 show only 2.5% of participating patients were Black. Similarly, of the 3,593 patients enrolled in all registration trials for new cancer drugs approved by the FDA in 2019, only 4% were Black patients. A third analysis showed that between 2008 and 2018, only 3.1% of cancer trial patients were Black.

The underrepresentation of Black patients in cancer clinical trials is a complex issue that requires a multifaceted solution. Complicated, interdependent causes include, but are not limited to system, provider, and patient bias. Increasing globalization of clinical trials also contributes to a widening gap in Black patient enrollment. Achieving diversity among clinical trial participants requires intention in study design regarding accrual sites and outreach, and involvement of a diverse trial workforce.

The ideal clinical trial system would minimize system, provider, and patient biases. Such a system already exists in the Historically Black Colleges and Universities (HBCU) system. HBCUs represent 3% of institutions of higher education in the USA, yet they enroll 16% of Black students and confer 24% of all baccalaureate degrees earned by Black students. 40% of Black engineers, 50% of Black lawyers, 70% of Black physicians, and a staggering 80% of Black judges attended an HBCU. HBCUs are exceptional at impacting communities of Color and have been doing so for centuries.

The HBCU Cancer Trials Consortium (HBCU CTC) is a network of HBCUs and Ally institutions that aims to bring innovative cancer clinical trials to historically underserved communities and honor the legacy of HBCUs, which have consistently and successfully served underserved communities for over a century. The HBCU CTC will oversee and conduct cancer clinical trials at member institutions. We envision founding flagship members to include HBCUs that provide graduate medical education and training, such as Howard, Meharry, Charles Drew, and Morehouse. Non-HBCUs committed to the mission are invited to join the consortium as Ally institutions (eg. MSIs). Membership is not exclusive of membership in other cancer consortia. The HBCU CTC will provide shared resource services for member institutions that lack expertise or funding to conduct services locally (eg. data management, DSMB, biostatistics, a cancer focused IRB, central radiology, and central pathology). The Consortium will also work to develop local infrastructure support for the conduct of cancer clinical trials at member institutions.

#1003 Contact registry for health-related cancer research: Promoting inclusion in research.

F. Webb[1], I. Guzman[2], B. Hensel[2], E. Ibarra[3], C. Aristizabal[3], J. Luque[4], R. Barahona[3], D. Wilkie[5], M. C. Stern[3], L. Baezconde-Garbanati[3], S. Suther[4]; [1]University of Florida, Jacksonville, FL, [2]University of Florida, Orlando, FL, [3]University of Southern California, Los Angeles, CA, [4]Florida A&M University, Tallahassee, FL, [5]University of Florida, Gainesville, FL

Contact Registries can serve as key tools in connecting community members to cancer health research opportunities. Members of underrepresented groups who enroll in a contact registry can choose to participate in studies they find interesting, provided they are an ideal candidate for participation. However, limited information exists regarding the types of studies underrepresented groups would want to participate in. The Florida-California Cancer Research, Education, and Engagement (CaRE^2) Health Equity Center Community Outreach Core (COC) created a contact registry of community members self-identifying as Black/African American (B/AA) and/or Hispanic/Latinx (H/L) persons who are interested in learning about future research studies conducted at CaRE^2 institutions. The CaRE^2 Contact Registry was implemented in August 2022 by the CaRE^2 COC, one of the six (6) key cores within the CaRE^2 Center. COC's primary objective is to increase the number of persons participating in cancer research, which ultimately produces findings more applicable to the broader, diverse population of B/AA and H/L communities in both Florida and California. Our study team promotes the registry at local community events and through our center's social media accounts and website (https://care2healthequitycenter.org/the-care2-contact-registry/). Recruitment consists of both in-person and online methods provided in both Spanish and English with data stored on REDCap, an online data repository system. For in-person enrollment, a consent/authorization form and OPT-IN survey are completed; meanwhile, our online recruitment requires additional screening to ensure eligibility. Eligibility requires that the person resides in 1) either California or Florida, 2) be 18+ years old, and 3) identify as B/AA or H/L. In addition to collecting contact and demographic information, participants can choose their research study interests. For example, they can choose to participate in surveys, community forums, focus groups, a cancer advocacy training program, and/or to provide a hair, saliva, or blood sample. A $10.00 gift card, either in a physical or electronic format, was provided to each confirmed enrollee. As of November 13, 2023, 1,269 persons have enrolled, representing 63% of the 2,000 enrollment goal. While 92% of registry enrollees are willing to participate in health research involving surveys, only 20% are willing to participate in health research studies requiring saliva (23%), hair (22%), or blood (20%) donations. In conclusion, registry enrollees, regardless of race or ethnicity, have a high interest in participating in studies involving completing surveys or attending focus groups. However, efforts must continue to increase participation willingness for research involving biospecimen donation. Future efforts will also include connecting enrollees to cancer health-related research studies of their interest.

#1004 Establishing lung adenocarcinoma cell lines to mitigate lung cancer health disparities.

S. Lugo[1], C. Leon[1], M. Gladstone[1], C. Yan[1], N. S. Lamango[2], I. A. Offringa[1], K. Ofosu-Asante[2], Y. Huang[3], J. K. Mensah-Mamfo[2];
[1]University of Southern California, Los Angeles, CA, [2]Florida A&M University, Tallahassee, FL, [3]University of Florida, Gainesville, FL

Lung cancer remains the leading cause of cancer death worldwide and is a pronounced source of cancer health disparities. Black/African American (B/AA) individuals demonstrate the highest lung cancer death rates when compared to other ethnic/racial groups. B/AA males exhibit a 15% higher lung cancer death rate and a 12% higher lung cancer incidence when compared to White males. Lung adenocarcinoma (LUAD) is the most common histological subtype in all races including B/AA. To study lung cancer and its related disparities, essential tools such as lung cancer cell lines are important; they can be used for molecular studies of lung cancer development, progression, development of new therapies and pre-clinical drug testing. We reviewed the literature (Leon *et al.* 2023, Frontiers in Oncology, Vol. 13, p. 1187585, 2023) and identified only 30 unique B/AA cell lines out of ~800 cell lines available, with the majority of cell lines being from White and Asian patients. Moreover, only 6 B/AA cell lines were derived from patients with LUAD. We are in the process of developing additional LUAD cell lines from patients as well as alveolar epithelial cell lines that can be used to model LUAD development. In addition, we are generating multiple independent isogenic cell line variants from existing lung cancer cell line NCI-H23, derived from a B/AA male patient harboring a $KRAS^{G12C}$ heterozygous mutation. We are using CRISPR/Cas-9-based genome editing to replace the $KRAS^{G12C}$ mutation with other *KRAS* mutations found in B/AA patients, including $KRAS^{G12V}$, $KRAS^{G12D}$, $KRAS^{G12A}$, and $KRAS^{G13C}$. We will perform whole genome sequencing to exclude off target effects of the CRISPR engineering. We will use isogenic cell lines to test the efficacy of polyisoprenylated cysteinyl amide inhibitors (PCAIs) and other drugs on cell lines bearing the different *KRAS* mutations. PCAIs were developed to target cells carrying mutant *KRAS*. Our efforts will provide tools to limit cancer health disparities and serve as a foundation for future research.

Supported by grants U54CA233396, U54CA233444, and U54CA233465 from the National Institutes of Health (NIH)/National Cancer Institute (NCI) and the Norris Comprehensive Cancer Center core grant, award number P30CA014089 from the NIH/NCI.

#1005 A three-decade-long community-based participatory research among India and Bhutan's ethnic minorities led to the discovery of 32 unique medicinal plants having anti-cancer properties.

S. Sandhya[1], R. Das[2], P. Dutta[2], A. Chowdhury[2], P. Das[3], S. Das[4], T. Baishya[5], L. Pathak[1], D. Dutta[1], N. Das[1], P. Sarma[2], I. Pulu[6], U. Mahanta[7], D. Bora[8], H. Bhai[9], **B. Das**[10];

[1]KaviKrishna Laboratory, IIT Guwahati Research Park, Guwahati, India, [2]KaviKrishna Center of Indian Knowledge System, Sualkuchi, Assam, India, [3]KaviKrishna Center of Indian Knowledge System, Sualkuchi, India, [4]Thoreau Laboratory for Global Health, Lowell, MA, [5]KaviKrishna Telemedicine Care, Sualkuchi, Assam, India, [6]Research Institute of World Ancient Traditions Cultures and Heritage, Roing, Arunachal Pradesh, India, [7]Sri Sri Ishwar Hatisatra, Sualkuchi, Assam, India, [8]Ek Saran Bhagawati Samaj, Nagaon, Assam, India, [9]Shanti Sadhana Ashram, Guwahati, India, [10]KaviKrishna Laboratory, Research Park, Indian Institute of Technology, Guwahati, India

The country of Bhutan, and India's Northeast is an economically deprived region inhabited by diverse groups of indigenous and underserved communities. They live in mostly rural areas, where cancer disparity is very high. On the other hand, they have rich traditional knowledge systems including tantra philosophies (remnant of the Vedic age philosophy), herbal medicinal practice, and spiritual practices that can be traced back to India's Vedic age. To harness this traditional knowledge to reduce cancer disparity, we have taken an indigenous knowledge system (IKS) based approach (1) and initiated a community-based participatory research (CBPR) program in 1998 to conduct public health research in tuberculosis and cancer (2,3). Using this CBPR program, we have unraveled a Vedic age philosophy of Vedic Jiva Upkara Cikitsha Tantra (Vedic altruism-based medicinal system) (2,3). Specially, using the CBPR program we seek to identify novel herbal medicinal agents having anti-cancer activities.

Methodologies: We used the CBPR methodologies of focused group discussion (FGD), debate, and community social work with various indigenous communities living in the Sualkuchi-Hajo cultural complex of Assam, Roing of Arunachal Pradesh, and Mongar of Bhutan. Since 1994, BD has conducted CBPR through the KaviKrishna Telemedicine Care. We have retrospectively analyzed the data of FGD, and suppositional reasoning (tarka) with the community healers, various Hindu, and Buddhist ethnic spiritual organizations of the region. Thematic analysis and the grounded theory method were applied to organize the data. The resulting database of herbal medicinal plants was searched in the scientific database to find the scientific names. Out of the 36 medicinal plants, we have prepared herbal extracts of 10 medicinal plants and then tested for their anti-cancer efficacy at the KaviKrishna Laboratory.

Results: We have found the names of 32 plants used by the indigenous healers practicing the Vedic Jiva Upakara Cikitsha Tantra. We also found that these healers used curd-made whey protein concentrate, special soil, and fecal extracts to treat cancer (3). Our CBPR process also led to the research capacity building in the Sualkuchi-Hajo community.

Conclusion: The study unraveled a unique cancer-care-related philosophy of Vedic Altruism. Our work indicates that IKS-based CBPR can equitably involve researchers and community members to develop a partnership for the process of knowledge emergence. We found that CBPR-based research takes new meaning because of the unique perspectives that inform the ways that research studies take shape for knowledge emergence.

#1006 Revitalizing the accrual of women and minorities: Unique drivers of therapeutic clinical trial enrollment for underrepresented patients with diffuse glioma.

M. Mehari[1], G. Warrier[1], S. Reihl[2], A. Dada[1], A. Kabir[1], M. Negussie[1], C. Nava Gonzales[1], U. Chukwueke[3], A. Porter[4], S. Hervey-Jumper[1];
[1]University of California, San Francisco, Department of Neurosurgery, San Francisco, CA, [2]University of California, Los Angeles, Department of Neurosurgery, Los Angeles, CA, [3]Center for Neuro-Oncology, Dana-Farber Cancer Institute, Department of Neurology, Harvard Medical School, Boston, MA, [4]Mayo Clinic, Division of Neuro-Oncology, Department of Neurology, Phoenix, AZ

Introduction: Despite the enactment of the 1993 NIH Revitalization Act to improve accrual of women and minorities in clinical trials, these groups remain underrepresented. This study aims to uncover drivers of therapeutic clinical trial enrollment that are unique to women and minority patients with low- and high-grade glioma.
Methods: Adult glioma patients who received care from the UCSF Brain Tumor Center between 1997-2017 were identified in a prospective registry. Dividing the cohort into subgroups by gender and NIH-designated minority status, factors associated with therapeutic clinical trial enrollment on univariate logistic regression ($p<0.2$) were selected for multivariate logistic regression.
Results: There were 351 trial participants (41% women, 12% minority) and 627 non-trial participants (44% women, 17% minority). Among women only, seizure at presentation (OR 2.10, p=0.008) was associated with increased odds of trial enrollment. In contrast, among men only, higher median household income (OR 1.09 per $10,000 increase, p=0.006), higher WHO tumor grade (OR 1.89, p=0.045), and occupational status according to the International Standard Classification of Occupations [professionals (e.g., physicians) vs managers (e.g., supervisory positions), OR 2.87, p=0.043] were associated with increased odds of trial enrollment. Among both women and men, lack of insurance (women: OR 0.49, p=0.02; men: OR 0.55, p=0.031) and no treatment with chemotherapy (women: OR 0.18, p=0.001; men: OR 0.34, p=0.002) were associated with decreased odds of clinical trial enrollment, whereas higher KPS (women: 90 vs <80, OR 3.16, p=0.003; men: 90 vs <80, OR 3.15, p=0.002) was associated with increased odds of trial enrollment. Among NIH-designated minority patients, older age (OR 0.66 per 10-year increase, p=0.033) and non-English preferred language (OR: 0.30, p=0.035) were associated with decreased odds of trial enrollment on univariate analysis, but not on multivariate analysis. Among non-minority patients, lack of insurance (OR 0.58, p=0.008) and no chemotherapy treatment (OR 0.25, p<0.001) were associated with decreased odds of trial enrollment, whereas seizure at presentation (OR 1.80, p=0.001), higher neighborhood household income (OR 1.07 per $10,000 increase, p=0.004), higher WHO grade (4 vs 2-3, OR 1.86, p=0.015), higher KPS (90 vs <80, OR 3.21, p<0.0001), and lower extent of tumor resection (80-89% vs 100%, OR 2.16, p=0.047) were associated with increased odds of trial enrollment.
Conclusion: Drivers of trial enrollment differed for women and minority patients with glioma. Non-English-speaking minority patients may face additional barriers to trial enrollment requiring targeted interventions. Our findings can revitalize and tailor efforts to recruit women and minority patients to therapeutic clinical trials in neuro-oncology.

#1007 Breast cancer related lymphedema patient characteristics and treatment patterns in a Hispanic majority population.

S. A. Shaker, L. P. Rahman, M. Mazo Canola;
University of Texas Health Science Center San Antonio, San Antonio, TX

Background: Studies have shown an increased risk of Breast Cancer Related Lymphedema (BCRL) in Hispanic populations, however there are limited studies examining factors specific to BCRL in this minority population. This retrospective study aims to characterize and analyze treatment and demographic related factors associated with BCRL in the Hispanic majority population of San Antonio.

Methods: This is a retrospective, single institution study of patients with BCRL between 2017-2020 at Mays Cancer Center in San Antonio, Texas, a city with a majority minority Hispanic population.**Results:** 110 subjects with BCRL were identified with a median age of 62 years old. 52.7% were Hispanic while 47.3% were non-Hispanic. The median BMI was 31 with over 75% of subjects with BCRL categorized with BMIs of overweight or obese. 89.1% received some form of chemotherapy, whether neoadjuvant or adjuvant, and 80.9% were exposed to some form of taxane. The majority underwent more invasive procedures and surgeries: 69.1% had axillary lymph node dissection and 71.2% underwent mastectomy. The median number of lymph nodes removed were 12. 62.7% of BCRL patients were exposed to nodal radiation. Regarding BCRL severity, 29.4% were classified as grade 1 while 11% classified as grade 3. Of note, there was a statistically significant correlation between more severe lymphedema (grade 2 and 3) and use of chemotherapy (P-value = 0.04.)**Conclusion:** The demographic composition of patients with BCRL closely mirrors the ethnically diverse population of San Antonio, with a large Hispanic predominance. Within this cohort of patients of BCRL, a large portion demonstrated factors of elevated BMI, more invasive surgical interventions, and exposure to chemotherapy, specifically taxane. The examination of these factors in a Hispanic-centric urban setting such as San Antonio offers crucial insight into a patient population at heightened risk for developing BCRL.

#1008 Pilot evaluation of an online course for primary care providers on preparing patients for cancer discussions with their oncologists.

A. Crowe[1], E. S. Weiss[2], M. Michaels[3], D. Durante[4], M. Sae-Hau[2], A. Cassells[5], C. L. Fisher[1], J. Arnold[4], T. Vasquez[6], A. Natale-Pereira[7], R. Mailhot[1], Z. Zhang[8], C. L. Bylund[1];

[1]University of Florida College of Medicine, Gainesville, FL, [2]The Leukemia & Lymphoma Society, Rye Brook, NY, [3]Health Access & Action Consulting, Boston, MA, [4]University of Florida College of Education, Gainesville, FL, [5]Clinical Directors Network, New York, NY, [6]University of Florida College of Journalism and Communications, Gainesville, FL, [7]Rutgers New Jersey Medical School, Newark, NJ, [8]University of Florida Health Cancer Center, Gainesville, FL

Introduction: Cancer clinical trial (CCT) accrual is only 5-8%, and barriers to participate can be more acute for underserved groups. Enrollment of racial/ethnic minorities, older adults, adolescents, and young adults is not adequate to understand treatment outcomes unique to these populations. Education before seeing an oncologist can increase patients' willingness to ask and consider receiving treatment through a CCT. Because primary care providers (PCPs) interact with patients during diagnosis, provide ongoing care, and are a trusted source of information, they can educate and normalize inquiries about therapeutic CCTs. The aim of this study was to pilot test an innovative, tailored online CCT course for PCPs.

Methods: To participate, PCPs (MD, DO, NP, or PA) had to provide care in an outpatient setting, refer patients to a cancer treatment specialist in the past year, and be an English speaker residing in the U.S. or its territories. PCPs were recruited from Clinical Directors Network, University of Pennsylvania, and University of Florida. The 1-hour online course includes four modules hosted by a PCP and radiation oncologist with video segments of a CCT expert who summarized CCT recruitment research. Participants interact with patient scenarios and learn about the patient's cancer diagnosis and medical/personal background. Videos of actors playing the roles of patient and doctor demonstrate communication skills taught in the course. PCPs completed short surveys prior to and immediately after completing the course.

Results: 28 PCPs participated. PCPs were mainly MDs (88.9%), residents (17, 60.7%), White (46.4%), non-Hispanic/Latino (92.9%), and 50% women. Mean *knowledge of CCTs scores* (0-100%) increased significantly from pre (M=56.7, SD=17.5) to post (M=82.1, SD=12; p<.001) indicating that PCPs answered more true/false statements about CCTs correctly after training. Using a 1-5 scale with 5=strongly agree, PCPs' *attitudes and beliefs scores* also increased significantly from pre (M=4.2, SD=.6) to post (4.7, SD=.4, p<.001) indicating that PCPs were more likely to agree they have a role in their patients' cancer treatment, including CCTs, after training. Using the same scale, PCPs' *willingness to communicate about CCTs* increased significantly from pre (M=4.4, SD= .5) to post (M=4.7, SD=.5, p=.007), indicating that PCPs were more willing to engage with patients diagnosed with cancer before referring them to a cancer specialist after training.

Conclusions: Significant pilot findings in knowledge, attitudes and beliefs, and communication scores demonstrate that the online course was effective at educating PCPs about CCTs, and improving PCPs' attitudes about the CCT referral process, and their willingness to engage in their patients' cancer care. Future research will include a larger sample and explore the course's impact on PCP's referral behavior.

#1009 Direct partnering with employers and unions diversifies cancer center access.

Michele Waters, Greg Crewse, Cole Manship, Abigail Baldwin-Medsker, Chris Fong, Nikolaus Schultz, Sergio Giralt, Benjamin Roman, Michelle Johnson, Francesca Gany, Carol Brown, Bob T. Li, Justin Jee

Memorial Sloan Kettering Cancer Center, New York, NY

Treatment at academic cancer centers can further research and improve patient outcomes. Interventions improving access to treatment across racial, ethnic, and socioeconomic boundaries might increase the generalizability of studies conducted at such centers and reduce healthcare inequities. Memorial Sloan Kettering (MSK) is an academic cancer center based in New York and New Jersey (NY/NJ). Like many other NCI-designated cancer centers, it has historically served a population within its geographic catchment, with limited diversity. MSK Direct is a national cancer benefits program that partners with employers and unions to provide a direct referral service for their employees or members and their families, including in-person care and remote second opinions outside NY/NJ. Whether such programs diversify access to academic cancer care is understudied.

To evaluate whether the service diversifies access to academic cancer care, we examined the self-identified race and ethnicity, geographic composition, and imputed socioeconomic status (Yost Index) of MSK Direct and non-MSK Direct (Control) patients with at least one assessment note at MSK since program inception in 2016 until September 21, 2023. We further stratified MSK Direct patients based on referral by employers vs. unions. Groups were compared using Chi-square or Student T tests.

The MSK Direct patient population (N=8,604) was more racially diverse than the Control population (N=283,434), with 9.0% Black/African American patients compared to 6.9% Control ($p<0.001$) patients and 9.3% Asian-Far East/Indian Subcontinental patients compared to 7.5% Control patients ($p<0.001$). Of MSK Direct patients, 10.5% identified as Hispanic or Latino vs. 7.5% of Control patients ($p<0.001$). Among MSK Direct patients, 14.2% of union-member patients self-identified as Black vs. 6.1% of non-union members, while Asian patients comprised 12.1% of company-referral patients vs. 5.8% of union patients. Hispanic patients represented 17.4% of union-referral patients vs. 6.5% of company referrals. The median Yost Index of union MSK Direct patients was 25 vs. 12 (non-union) and 17 (Control, $p<0.001$), signifying a less privileged socioeconomic status for union-referred patients. A total of N=336 MSK Direct patients received guidance through remote second opinions across 41 states, with the most common home states being Georgia, Arizona, and Florida.

Addressing healthcare disparities in diverse populations is a complex and systemic challenge. Direct partnerships with employers and unions are a new paradigm that may expand access to academic cancer care outside a center's usual geographic and sociodemographic catchment. Different partnering strategies may enhance the representation of specific patient populations.

#1010 Feasibility of serial microbiome collection in a multi-site neoadjuvant pancreatic cancer clinical trial allowing for a diverse patient population.

S. Rogers[1], R. Thomas[1], I. Nassour[1], I. Sahin[1], B. Ramnaraign[1], K. Russell[2], S. Hughes[1], K. Hitchcock[1], O. Kayaleh[3], A. Turk[4], M. Ratcliff[1], T. George[1];
[1]University of Florida College of Medicine, Gainesville, FL, [2]Tallahassee Memorial Hospital, Tallahassee, FL, [3]Orlando Health, Orlando, FL, [4]Indiana University, Indianapolis, IN

Background: Pancreatic cancer portends a very poor prognosis. It is the third leading cause of cancer deaths in the United States. African Americans have a 50-90% increased incidence of pancreatic cancer in comparison to other racial groups. 20% of patients present with operable disease and will have a median overall survival of 2.5 years if able to undergo surgical resection. There is a desperate need to discover novel ways of treating pancreatic cancer. Understanding of the microbiome may be informative to overcoming chemotherapy resistance, toxicity and improving outcomes and disparities. The aim of this study is to (1) identify changes in the microbiota during neoadjuvant treatment of pancreatic ductal adenocarcinoma that correlate with treatment response and (2) identify changes in the microbiota during neoadjuvant treatment of pancreatic ductal adenocarcinoma that correlate with treatment toxicity in a diverse patient population.
Methods: Patients with resectable or borderline resectable pancreatic cancer who are enrolled in a multi-site clinical trial (NCT03483038) receiving neoadjuvant NEO-Nali-IRI (oxaliplatin, liposomal irinotecan and 5- FU) followed by surgical resection were asked to provide serial microbiome collections of saliva, urine (collected in clinic), and stool with a dietary log during the following four (or five) time points: at baseline, mid-therapy (after C4), at completion of chemotherapy (after C8), after radiation if applicable, and at 4-6 weeks post-operative. Participants were given stool collection kits during clinic visits for home sample acquisition. All stool samples were mailed to the University of Florida Health Cancer Center Microbiome Biorepository. Demographics, stage, medical history and concurrent medications including antimicrobics and probiotics, chemotherapy dose-reductions, delays, discontinuations, adverse events, safety adverse events, attribution of causality, and hospitalizations were obtained. Outcomes include imaging response using RECIST criteria, CA 19-9 trend, development of metastatic disease, and the ability to proceed to definitive surgical resection. DNA will be extracted from stool and analyzed using 16S rRNA sequencing methods to determine signatures and alpha/beta biodiversity. Descriptive statistics and correlative analysis will be reported. Continuous and categorical variables will be compared with Student's t-test and Chi-squared test. Multiple groups will be compared by ANOVA. Kaplan-Meier logistic regression will be performed to compare outcomes between the different microbiota groupings.
Conclusion: Serial microbiome collection from a multi-site clinical trial is feasible during neoadjuvant chemotherapy for pancreatic cancer and can increase the diversity of the sample population.

#1011 A comprehensive comparative analysis of African Americans' early onset and late onset colorectal cancer: A 60 year study in underserved population serving hospital.

S. Challa[1], M. Deverapalli[1], N. Farjana[1], L. Gayathri Chirumamilla[1], R. Oskrouchi[2], S. Mynedi[3], M. Rashid[1], k. senthilvelan[3], B. Shokrani[3], R. Zafar[3], A. Kibreab[3], F. Aduli[3], A. Laiyemo[3], z. Sharif[3], H. Brim[1], **H. Ashktorab**[1];
[1]Howard University, Bethesda, MD, [2]Kuwait, Kuwait, Kuwait, [3]Howard University, Washington, DC

Background: The incident of early onset of colorectal cancer (EOCRC) is increasing in adults including in African Americans (AA).
Aim: To investigate differences between EOCRC compared to late onset colorectal cancer (LOCRC) in AA patients.
Methods: We reviewed demography, pathology and colonoscopy records of patients seen at Howard University Hospital from 1959 to 2023. This retrospective cohort consists of 175 EOCRC cases (<45 years) and 2025 LOCRC cases (>45 years). The age-adjusted rates for EOCRC and LOCRC were calculated for the age categories <45 and above 45.
Results: The cohort comprised predominantly AA individuals (>85%). Gender distribution showed slightly more females (1074, 53%) than males, with no significant difference observed between EOCRC and LOCRC groups (p=0.94). Initial symptoms at presentation were prevalent in both EOCRC (93.8%) and LOCRC (92.6%). Notably, EOCRC exhibited a higher incidence of abdominal pain (23.3% vs. 17.2%, p=0.05) and changes in bowel habits (24.4% vs. 14%, p=0.05) compared to LOCRC. However, other symptoms such as melena, hematochezia, weight loss, and anemia were less prevalent in EOCRC than in LOCRC. Additionally, comorbidities like hypertension (HTN), diabetes mellitus (DM), and inflammatory bowel disease (IBD) were less frequent in EOCRC compared to LOCRC. Family history of colon cancer in first-degree relatives was notably higher in EOCRC (15.5%) compared to LOCRC (3.2%, p=0.01). Pathology reports indicated a higher occurrence of neuroendocrine tumors in EOCRC (2.8%) than in LOCRC (1.4%). Complications such as gastrointestinal bleeding and abdominal CT abnormalities were more frequent in EOCRC. Location-wise, EOCRC was primarily observed in the left sigmoid and rectosigmoid regions (p=0.01). Metastasis to other organs was more prevalent in EOCRC than in LOCRC (p=0.04) suggesting more aggressive and advanced lesions. Surgical interventions were slightly more common in EOCRC (80.4%) than in LOCRC (79.1%). Type of polyps and stage distribution showed some variations between the two groups. Interestingly, the incidence of colorectal cancer showed fluctuations over the years, peaking between 1980 and 1989 before declining in recent years, probably as a result of colonoscopy popularization.
Conclusion: CRC incidence is increasing among young AA who display highly advanced and more metastatic tumors in comparison with LOCRC. While current screening programs seems to have decreased CRC prevalence in individuals older than 45, special attention needs to be addressed to young AA adults as well, to counter the observed trend, as they have the highest incidence of CRC among young population groups by race/ethnicity. Detailed analysis of the molecular landscape of EOCRC AA tumors is needed to understand the differential pathways and mechanisms defining these early onset cancers.

#1012 Colorectal cancer in the American Indian and Alaska Native community: A holistic review.

A. R. Monetathchi, W. Carson, A. Little, F. M. Cordova-Marks, J. Erdrich;
University of Arizona, Tucson, AZ

Colorectal cancer (CRC) is ranked third in the United States for both cancer incidence and mortality. Despite a decline in both categories, CRC continues to be a great concern in American Indian/Alaska Native (AI/AN) communities. AI/AN populations have also experienced the largest increase in early-onset colorectal cancer, have the second highest CRC incidence rates, and the AN community has the highest rates of CRC worldwide. AI/AN populations face numerous barriers and are susceptible to risk factors that may contribute to these findings. Currently, a significant amount of research is on screening efforts. Through conducting a literature review of 63 articles, as well as an additional 11 supplemental sources, this manuscript aims to look at several aspects of CRC including demographics, diet, screening, and the impact of geography. This review presents and organizes available research on CRC in the AI/AN population and explores research beyond screening because a more comprehensive and population-specific fund of knowledge on the totality of the subject is critical to directing more effective prevention, earlier detection, and management. Evaluating different components of CRC honors the holistic approach to health practiced by AI/AN communities.

#1013 Strengths, weaknesses, opportunities, and threats of conducting clinical trials in Nigeria: The IRONMAN study.

O. O. Bolajoko[1], P. Fathi[1], O. Toye[2], D. D. Fulwood[1], A. Popoola[3], C. Ogo[4], H. Dogo[5], O. Fatiregun[6], A. Sowumi[7], P. Jibrin[3], M. A. Jimoh[8], F. Mohammed[9], F. Odedina[1], Prostate Cancer Transatlantic Consortium;

[1]Mayo Clinic, Jacksonville, FL, [2]Prostate Cancer Transatlantic Consortium, Ilorin, Nigeria, [3]University of Ilorin Teaching Hospital, Ilorin, Nigeria, [4]Federal Medical Center, Abeokuta, Nigeria, [5]University of Maiduguri Teaching Hospital, Maiduguri, Nigeria, [6]Lagos State Teaching Hospital, Lagos, Nigeria, [7]Lagos University Teaching Hospital, Lagos, Nigeria, [8]Lagos State University Teaching Hospital, Lagos, Nigeria, [9]Amadu Bello University, Zaria, Nigeria

Background: The need to increase understanding of prostate cancer (CaP) is ever increasing. Unfortunately, there is limited understanding of how CaP affects men of African ancestry (MAA) despite significant disparities in CaP prevention, diagnosis, and treatment due to genetic and sociobehavioral factors. Conducting CaP clinical trials (CTs) in Africa presents multiple opportunities to improve upon collective knowledge of CaP in MAA experiences, expand patient access to CTs, and provide opportunities for African scientists and urologists to contribute to research on the global stage. The International Registry of Men with Advanced Prostate Cancer (IRONMAN) seeks to reduce CaP disparities by sponsoring sites throughout Africa. Four Prostate Cancer Transatlantic Consortium (CaPTC) institutions in Nigeria currently participate in IRONMAN: University of Ilorin Teaching Hospital, Federal Medical Center, University of Maiduguri, and Lagos State University Teaching Hospital. Because CTs of this scale are infrequently conducted in Africa, there are special considerations when conducting CTs in low-middle-income countries (LMICs) like Nigeria.

Methods: Hourlong interviews dedicated to site staff were conducted via Zoom in Spring 2023 (four total). Interviews utilized a Strengths, Weaknesses, Opportunities, and Threats (SWOT) analysis approach. Each interview was recorded, transcribed, and validated by study staff for accuracy. Themes from each were inductively coded and then collated across all four sites.

Results: The urologists, oncologists, phlebotomists, pathologists, nurses, research coordinators that make up the study teams identified the holistics of conducting the IRONMAN study at their sites. Strengths included a large patient population to recruit from and appropriate resources to conduct the study (ex., lab space, clinical knowledge, staffing levels). Weaknesses included the social determinants of health that negatively impact patient participation, limited biorepository space to store samples, and the need for patient-physician trust. The greatest opportunity presented was Nigerian institutions joining more CTs in the future, particularly multi-site global trials. Described threats included staff turnover, national stability, and increased economic disparities.

Discussion: While increasing the overall number of CTs in Africa is a noble cause, sponsors and institutions should note the unique circumstances in implementing CTs in Africa when designing CTs and recruiting sites. Listening to the experiences of study teams is pivotal in ensuring CTs are Africa-minded - they will be complimentary to established research infrastructure, appropriately funded, and culturally responsive all in the name of equitable research. By doing so, ethical compliance and quality data collection will ensue and reduce disparities at the micro, mezzo, and macro levels.

#1014 Disparities of triple negative breast cancer in Mississippi.

N. Kaur[1], J. A. Khan[1], J. Mao[2], D. Melvin[3], M. M. Hassan[1], X. Zho[1];
[1]University of Mississippi Medical Center, Jackson, MS, [2]Tougaloo College,, Tougaloo, MS, [3]Tougaloo College, Tougaloo, MS

Background: Triple-negative breast cancer (TNBC) accounts for about 10-15% of all breast cancers nationwide with disparities of incidence and outcomes among races, geographic locations, and other factors. This study is aimed to analyze the differences in the rate of TNBC, patient conditions at time of diagnosis, and death from TNBC among women in Mississippi.
Methods: A retrospective study was conducted to serially review breast cancer cases diagnosed in the University of Mississippi Medical Center during May 2016 to May 2023. The entire breast cancer population was then stratified by race. The rate of TNBC, age and BMI at time of diagnosis, the rate of expiration were compared between African American (AA) and Caucasian American (CA) women with breast cancer. Two-tailed Student's T-test was used to calculate the difference in mean values, and Chi-Square Test was used to compare the difference in rates or percentages. The significant p value was set at $p<0.05$.
Results: In total 291 women with breast cancer, AA patients were 195 (67.01%), CA patients were 88 (30.24%), and other were 8 (2.75%). The mean age of all patients was 58.3 years-old (ranged 24-97). The mean BMI was 31.19. The patients with TNBC were 109 (37.46%) in entire studied population. A total of 32 (1.6%) patients, including 14 TNBC and 18 non-TNBC were expired with an average age of 61.84 and an average survival time of 20 months from diagnosis to expiration. As compared to CA patient population, AA breast cancer patients had onset at younger age (58.08±0.88 vs. 59.18±1.36), had a higher BMI (31.79±0.62 vs. 28.25±1.05, p=0.017), higher percentage of TNBC (41.54% vs. 30.68%, p=0.082 and OR=1.605), and higher rate of expiration (11.28% vs. 9.1%). Also, as compared to CA expired patients with breast cancer, AA expired patients had higher BMI (29.57 vs. 28.61), shorter survival time (17.5 months vs. 19.4 months), and died at younger age (61.84-year old vs. 66.38-year old) with a higher proportion of TNBC subtype (54.6% vs 12.5%, p=0.045, OR=9.6).
Conclusions: Breast cancer is greatly disparate racially between AA and CA and geographically between Mississippi and US national average. The disparities are manifested in the proportion of TNBC subtype, age at onset of breast cancer, BMI at time of diagnosis, and death rate.

#1015 Potential of kava in reducing lung cancer risk and associated disparities: Mechanism-based biomarker discovery and analysis.

C. Xing[1], B. Freeman[1], J. Mamallapalli[1], A. Lynch[1], N. Fujioka[2], R. G. Salloum[1], J. Malaty[1], F. Orlando[1], Z. Huo[1];
[1]University of Florida, Gainesville, FL, [2]University of Minnesota, Minneapolis, MN

Background: Lung cancer is the leading cause of cancer-related deaths. Tobacco smoke is well-recognized as the dominant risk factor. Stress, lung inflammation, air pollution and other factors also contribute to the risk of developing lung cancer Racial/ethnic disparities in lung cancer risks exit as well. The quantitative contributions of different these risk factors to lung cancer and associated disparities, however, have not been systematically characterized. One major barrier is the lack of tools to non-invasively and objectively quantify these risk factors, which precludes the identification of high-risk individuals and the development of effective prevention. Data from our group, particularly results from a pilot clinical trial, suggest that kava, traditionally consumed in the South Pacific Islands as a beverage to reduce stress and promote relaxation, may holistically reduce lung cancer risk by impacting multiple factors that contribute to lung cancer risk.

Aim: This study aims to discover mechanism-based non-invasive biomarkers reflective of different lung cancer risk factors and explore their potential roles in lung cancer risk disparities. Such biomarkers are also employed to characterize the holistic effects of kava in reducing lung cancer risk and its potential in mitigating associated disparities.

Results and Analysis: One-week of kava significantly reduced the level of nicotine exposure among smokers, quantified by the Total Nicotine Equivalents (TNE) in the 24-h urine sample. Excitingly the reduction in TNE appeared to be higher among African American smokers in comparison to participants of other race/ethnicity. Biomarkers for stress (plasma cortisol and urinary total cortisol equivalents (TCE)) were significantly reduced upon one-week kava use, which may mechanistically contribute to the reductions in tobacco use. The reduction in plasma cortisol and TCE were higher among African American smokers as well. One-week kava exposure also increased urinary excretion of total NNAL and reduced urinary 3-methyladenine (3-mA) in participants, suggestive of its ability to reduce the carcinogenicity of nicotine-derived nitrosamine ketone (NNK). Kava effects on NNAL and 3mA were again more pronounced among African American smokers.

Conclusion and future directions: These results demonstrate the potential of mechanism-based biomarkers in investigating lung cancer risks and associated disparities. Such biomarkers may also facilitate the translational development of effective and targeted interventions, such as kava, which may not only reduce lung cancer risk but also mitigate the associated disparities. Additional mechanism-based biomarkers on other tobacco carcinogens and inflammation are currently under development. Two clinical trials are ongoing that the current clinical samples will help validate these discoveries.

#1016 Food insecurity among patients with cancer in the US.

A. R. Marrero-Gonzalez[1], A. Crawford[1], F. Draper[2], A. Incudine[2], S. T. Lindau[3], E. M. Graboyes[1];
[1]The Medical University of South Carolina (MUSC), Charleston, SC, [2]Family Reach, Boston, MA, [3]The University of Chicago, Chicago, IL

Introduction: Food insecurity (FI) is common among cancer patients and can lead to decreased treatment adherence, worse quality of life, and increased recurrence and mortality. Although some studies suggest that patients with cancer are particularly susceptible to FI, these studies have been limited by their small sample size, narrow sampling of cancer types and stages, and limited geographic scope. To address this gap, this study leverages data from a supportive care organization to characterize FI prevalence and associated risk factors in a nationwide sample of patients with diverse types of cancer.
Methods: This cross-sectional study included adults with cancer undergoing treatment referred to Family Reach, a national organization that provides financial support to cancer patients and their families, from 2020-2023. The primary outcome was FI, defined as a self-reported concern that the family would run out of food before getting enough money to buy more. Estimates of FI were provided for the cohort stratified by cancer type; multivariable logistic regression was used to evaluate the association of cancer type (primary independent variable) with FI, adjusted for oncologic and demographic covariates.
Results: Of 6,615 patients with cancer, 62.9% reported FI. Across cancer types, FI prevalence ranged from 56% (brain) to 68% (gynecologic). FI did not vary significantly by cancer type on multivariable logistic regression adjusted for oncologic, geographic, and demographic factors (**Table 1**). A variety of demographic factors were associated with FI (**Table 1**).
Conclusion: Nearly two-thirds of patients with cancer served by a large national cancer support organization reported FI. FI was common across all types of cancer and was associated primarily with demographic characteristics. These FI prevalence and risk factor data can be used by researchers, clinicians, and community-based organizations to understand and address FI among patients with cancer.

Table 1. Characteristics of Patients with Cancer With Food Insecurity Referred to Family Reach and Factors Associated with Food Insecurity Using Multivariable Logistic Regression Analysis.

#1017 Characterizing immune cell infiltration in colorectal cancer tumor microenvironment among Native Hawaiians.

Y. Fu, G. Quintal, M. Nasu, M. Jijiwa, S. K. Rai, I. Mohd-Ibrahim, Y. Chen, H. Yang, Z. Wang, C. Wai, O. Chan, B. Y. Hernandez, Y. Deng;
University of Hawaii at Manoa, Honolulu, HI

Background Colorectal cancer (CRC) is recognized as a heterogeneous disease, ranking third in new cancer diagnoses and second in cancer-related deaths globally and nationally. CRC incidence is higher in the state of Hawaii compared to the U.S. overall. This study focuses on profiling immune cell infiltration in Native Hawaiian(NH)-specific CRC tumor microenvironments. Identifying the race-specific tumor infiltrating microenvironment may uncover potential mechanisms for CRC development in the NH population.

Methods Deidentified, archival formalin-fixed paraffin-embedded tumor samples from Native Hawaiian patients diagnosed with primary CRC between 1990 and 2006 were obtained from the Hawaii Tumor Registry. RNA was extracted from tumor and adjacent normal tissues. RNA-seq data from Caucasian American (CA) CRC samples were obtained from The Cancer Genome Atlas (TCGA) and the Gene Expression Omnibus (GEO). Differentially expressed genes for each cohort were identified via DESeq2 with Benjamini-Hochberg multiple testing q-value<0.05 and a cutoff of 2-fold change. From the gene expression profiles, we applied the ESTIMATE algorithm to calculate the overall immune cell infiltration score for each sample. Based on a deconvolution algorithm, known as CIBERSORT to estimate the abundance of 22 immune cell types, we profiled the tumor-infiltrating immune cells present in each cohort's paired samples, respectively. To improve the accuracy, p-value and root mean squared error were counted for each sample. Data with $p<0.05$ were filtered and selected for the next analysis. The fraction of immune cell subpopulations was evaluated and compared between paired tumor and adjacent normal tissues in NH and CA cohorts.

Results In the NH cohort, we found the overall immune cell infiltration score was significantly lower in cancer tissues than the adjacent normal tissues ($p<0.05$), and there were significantly higher fractions of activated dendritic cells, resting natural killer (NK), and follicular helper T cells in tumor tissues compared to adjacent non-tumor tissues ($p<0.05$). Furthermore, the fractions of activated NK cells and plasma cells were significantly lower in tumor tissues than in adjacent non-tumor tissues in NH ($p<0.05$). Resting NK cells are upregulated in both the NH and the CA cohorts, while plasma cells are the only immune cell type downregulated in either cohort. In the NH cohort, activated dendritic cells and follicular helper T cells are exclusively upregulated, while activated NK cells are downregulated relative to the CA cohort.

Conclusion This study demonstrates that the NH cohort displays distinctive immunological variances between tumor and adjacent non-tumor tissues which distinguishes them from the CA cohort. This emphasizes the significance of acknowledging population-specific genetic variations which may help understand race specific difference in CRC.

#1018 Characteristics and outcomes of patients with cystic fibrosis and pancreatic cancer: A population-based comparative analysis.

S. Manchkanti[1], S. J. Gaddam[2], **U. S. Grewal**[3];

[1]Carver College of Medicine, University of Iowa, Iowa City, IA, [2]Louisiana State University Health Sciences Center, Shreveport, LA, [3]University of Iowa Hospitals and Clinics, Iowa City, IA

Introduction: Advancements in diagnosis and treatment of cystic fibrosis (CF) has allowed improvement in overall survival which also in part explains the increasing incidence of malignancies among these patients, particularly, gastrointestinal cancers. Existing data related to the characteristics and outcomes of patients with CF and pancreatic cancer (PC) are limited to small case series. We sought to investigate the same using a large population-based database.
Methods: We used TriNetX, a national database comprising approximately 74 million patients across 54 healthcare organizations in the United States. We retrospectively identified patients with CF who also had a diagnosis of PC (using ICD-10 codes). We then performed an age, sex and race-matched analysis to compare patients with CF+PC to patients with CF alone. To study the impact of CF diagnosis on PC-related outcomes, we performed a propensity matched analysis between cohorts of patients with CF+PC and patients with PC alone. Kaplan Meier estimates were used for survival analysis. A p-value of <0.05 was considered statistically significant.
Results: We identified a total of 41,655 patients with CF, out of which 198 patients had a diagnosis of PC (0.48 %). A total of 180 patients were included in the propensity matched comparative analysis. Patients with CF and PC had a significantly higher prevalence of type 2 diabetes mellitus (42.8% vs 5.6%, p<0.001), hypertension (58.3% vs 5.6%, p<0.001) and hyperlipidemia (40% vs 5.6%, p<0.001) than patients with CF with no PC. No differences in the prevalence of liver cirrhosis were noted (8.9% vs 5.6%, p=0.22). Patients with PC and CF had a significantly lower prevalence of bronchiectasis (15.8% vs 28.7%, p=0.004). In a propensity matched analysis between patients with CF and PC and PC alone, CF did not impact survival among patients with resectable [HR=1.042 (0.35-3.11), p=0.79] or unresectable/advanced PC [HR=1.17 (0.62-2.22), p=0.09].
Conclusion: To our knowledge, this is the largest analysis investigating the characteristics and outcomes of patients with CF and PC. The prevalence of PC in patients with CF is higher than reported prevalence among general population. We found a significantly higher prevalence of diabetes, hypertension and hyperlipidemia and a significantly lower prevalence of bronchiectasis among patients with CF and PC. CF does not appear to impact overall survival among patients with resectable or unresectable or advanced PC. Our findings may inform risk prediction models for PC among patients with CF.

#7454 Cognitive function in older breast cancer survivors after chemotherapy.

R. Kim, K.-P. Liao, S. Peterson, D. Zorzi, L. Li, M. Chavez MacGregor, S. Giordano;
UT MD Anderson Cancer Center, Houston, TX

Background: In the United States, over 60% of breast cancer survivors are 65 years and older; however, little is known about patient-reported symptoms and the effect that cancer treatments could have on survivors years after their primary treatment and diagnosis. This study evaluated perceived cognitive function in older breast cancer survivors and whether prior chemotherapy was associated with cognitive outcomes.
Methods: Breast cancer patients aged 65 years and older, diagnosed 2012-2013, with local and regional stage disease, were identified through the linked Texas Cancer Registry-Medicare dataset (TCR). Survivors were mailed a survey to assess their cognitive function through the Functional Assessment of Cancer Therapy-Cognitive Function (FACT-Cog V3) instrument (section G of the survey). The survey also collected demographic and clinical data and was collected between April 2018 and October 2019. Utilizing the data from the self-administered questionnaires, TCR, and Medicare claims, the cognitive function and quality of life among elderly patients were evaluated to assess whether prior chemotherapy and/or endocrine therapy impacts long-term health. A linear regression model was used to examine the significance of receiving chemotherapy to FACT-Cog V3 primary score while controlling for respondent sociodemographic and clinical variables.
Results: Of 4,448 eligible patients, 1,954 (43.9% response rate) responded to section G. Of these, 1,065 respondents completed all 4 sections, 37 questions. Eighty of those 1065 respondents self-reported disease recurrence which excluded them from the analyses in order to avoid biases, leaving a total of 985 cases for this study. Median time from diagnosis to survey completion was 68 months (IQR 62-73). Receipt of chemotherapy was associated with a slightly lower FACT-Cog score. In total, those with chemotherapy scored, on average, 105.6 (SD 21.2) while those without scored 107.1 (SD 22.3). The largest difference in mean scores is attributed to the Perceived Cognitive Impairment subsection (scored from 0-72) where those with chemotherapy scored, on average, 57.2 (SD 13.8) and those without scored 58.7 (SD 14.0).
Responsible Conduct Of Research: We need to ensure that the privacy of our patients will be protected when using their information from the surveys.
Conclusion: Adjuvant chemotherapy was associated with more self-reported cognitive impairment in older breast cancer survivors, even 5-6 years after diagnosis. However, the difference between patients who received chemotherapy versus those who did not was modest, suggesting limited clinical significance. Further research is needed to determine the long-term impact of cancer treatments, particularly in older cancer survivors.

CLINICAL RESEARCH: Diagnostic Biomarkers 1
Poster Session

#1021 Defining total protease activity profiles in pancreatic cancer using a FRET substrate array.
M. Stewart, A. Quentel, J. Montoya Mira, E. Manalo-Hall, S. Ranganathan, B. Branchaud, F. Civitci, E. Tu, J. Fischer, Y.-J. Chiu, A. Yildirim;
Knight Cancer Institute, Oregon Health & Science University, Portland, OR

Proteases are an important component of many biological processes in the human body, and as such makes them a well-known subject to explore when investigating a variety of disease states from cancer to cardiovascular disease. In all stages of cancer, including early development, proteases play critical roles in almost every aspect for processes such as invasion, promotion of tumor growth, and metastasis. This makes screening of circulating proteases a potentially powerful tool for early detection and prognosis for a variety of cancers. The human proteome, however, is very complex, with around 600 proteases in total, and at least 234 of them found in circulation. Additionally, proteases often act on more than one substrate, cross reactively cleaving several substrates at different rates, further adding to the complexity of cleavage patterns of the human proteome. Previous liquid biopsies for cancer detection based on protease cleavage patterns focused mainly on detecting the activities of specific proteases, using single substrates to examine the effects of well-studied cancer-related proteases such as MMPs and cathepsins. In this study, we developed a method for screening cleavage patterns of proteases active in plasma samples that deviated from this norm. Due to the complexity of the human proteome, rather than developing a specific substrate for a specific protease, we utilized a large array of substrates to screen for cleavage patterns in plasma samples of cancer patients aimed at not one specific protease, but a wide range that may be present. In this proof of concept study, we used a commercially available internally quenched set of 360 substrates composed of 8 amino acids and a FRET pair. Initially, we optimized this assay to measure protease activity in the complex plasma environment. Next, we screened several plasma samples collected from patients with pancreatic ductal adenocarcinoma (PDAC) or pancreatitis, and screen negative samples using the 360 substrate set assay and identified 5 top substrates that were proficient in identifying PDAC from other conditions. Finally, we performed a validation study with a larger cohort (45 screen negative, 26 PDAC, 19 pancreatitis) using the selected substrates to determine the diagnostic performance of the assay. All five of the selected substrates showed 1.3-1.8-fold increase in fluorescence signal in PDAC compared to screen negative and pancreatitis. Amongst the cancer samples, the substrates showed no significant difference between stage, supporting possible applications for early detection. Additionally, area under the curve analysis of the five substrates gave a score of 0.8. In summary, in this study, we reported a novel approach for the detection of cancer exploiting the protease cleavage patterns in plasma samples. We believe that this approach holds great potential for detecting substrates and proteases for early detection of PDAC and other cancers.

#1022 Integration of cerebrospinal fluid methylome and proteome can obviate the need for biopsy in central nervous system lymphoma.

A. P. Landry[1], J. A. Zuccato[1], V. Patil[2], M. Voisin[1], J. Z. Wang[1], Y. Ellenbogen[1], C. Gui[1], A. Ajisebutu[1], F. Nassiri[1], G. Zadeh[1];
[1]University of Toronto, Toronto, ON, Canada, [2]University Health Network, Toronto, ON, Canada

Background: The diagnosis of intra-axial brain tumors requires histopathological examination of tissue obtained by neurosurgery in current clinical practice, which comes with inherent risks. Some patients, particularly those with primary CNS lymphoma (PCNSL), only undergo surgery to obtain a diagnosis and do not derive any therapeutic benefit from surgical resection or debulking. Less-invasive techniques for diagnosis, such as liquid biopsy, therefore provides an opportunity to mitigate surgical risk in these patients.
Methods: Patients with histopathology confirmed glioblastoma (GBM, IDH wild type), brain metastases (BM), and PCNSL with accompanying cerebrospinal fluid (CSF) samples were included in our study. Cell-free DNA methylation profiling and shotgun proteomics were obtained for all patients and used to train classifiers to distinguish each tumour entity from others. Specifically, binomial elastic net regression models were built by combining both data modalities using established early and late integration paradigms and performance was compared to classifiers built from individual data types alone. Each model was repeated 100 fold and performance assessed on an untouched testing subset.
Results: Our cohort includes 20 patients with GBM, 17 with BM, and 14 with PCNSL, each with matching CSF cell-free DNA methylation and shotgun proteomic profiling. We show that these data can be integrated to fully discriminate PCNSL from its major diagnostic counterparts with a perfect median AUC of 1.00 (95% CI 1-1) and 100% specificity. Integrated "lymphoma vs other" models significantly outperform models trained on methylation or protein data alone, though the same dramatic improvement was not demonstrated in GBM or BM, suggesting synergistic biological information is specific to lymphoma.
Conclusions: There is a critical need to diagnose patients with intra-axial tumours, particularly PCNSL, without relying on invasive and costly surgery. We present the most specific and accurate CNS lymphoma classifier to date by integrating the methylome and proteome of CSF. This has the potential for immediate clinical utility, eliminating the need for biopsy in an important subset of these patients.

#1023 Whole-genome methylation analysis using liquid biopsy for pancreatic cancer diagnosis.

T. Ito[1], T. Iwasawa[2], S. Takeda[2], C. Okamoto[2], T. Motohashi[2], S. Ueda[1], H. Kato[1], R. Yamamoto[1], A. Koizumi[1], Y. Murai[1], K. Nihei[1], M. Itakura[1], R. Akima[1], M. Sakurada[1], K. Tanaka[1], T. Kushida[1], K. Sato[1];

[1]Juntendo Shizuoka Hospital, Juntendo Univ. School of Medicine, Izunokuni-shi, Japan, [2]Shizuoka Medical Research Center for Disaster, Juntendo Univ. School of Medicine, Izunokuni-shi, Japan

Objective: Pancreatic cancer is one of the highly malignant tumors. Its diagnosis requires invasive ultrasound endoscopic biopsy or endoscopic retrograde cholangiopancreatography (ERCP). However, these methods are limited by false-positive results and complications. Liquid biopsy, which uses blood to detect *KRAS* mutations in cancer, can be used to overcome these hurdles. However, only about 30% of cases can be detected as a diagnostic marker by *KRAS* mutations using plasma from patients with stage I-II pancreatic cancer, and its clinical application remains a challenge. Therefore, in this study, we focused on diagnosing pancreatic cancer using methylated DNA in plasma cell-free DNA (cfDNA) obtained from pancreatic cancer and non-cancer patients.
Subjects: Plasma was collected before the start of the treatment from six patients diagnosed with pancreatic cancer from 2019 to 2023 at our hospital, and six non-cancer patients simultaneously.
Methods: Whole-genome bisulfite sequencing (WGBS) using next-generation sequencing (NGS) was performed using the cfDNA obtained from the plasma of pancreatic cancer and non-cancer patients.
Results: The cfDNA fragments obtained by WGBS revealed that promoter regions were mostly deleted, and no difference was observed between cancer and non-cancer patients. The methylation rate of cfDNA fragments by WGBS differed between cancer and non-cancer patients, with multiple methylation sites (>100 sites) in intergenic regions.
Discussion: Although attempts have been made to diagnose cancer using genetic mutations and liquid biopsy, only a few studies are available on using methylation markers in the plasma cfDNA of pancreatic cancer patients, and the effectiveness of this method remains unclear. In the present study, we found that promoter regions were deleted by WGBS, and several distinct hypermethylated regions were present in the intergenic region between pancreatic cancer and non-cancer samples, suggesting the presence of certain markers that can distinguish between pancreatic cancer and non-cancer patients.
Conclusion: This small number of cases suggests that hypermethylation of the intergenic regions could be helpful in the diagnosis of pancreatic cancer. We will need more cases in the future to verify the usefulness of hypermethylation of intergenic regions in the diagnosis of pancreatic cancer.

#1024 Differential gene expression of colorectal cancer biomarkers in Hispanic individuals.

E. V. Caraballo-Rivera[1], **H. Centeno-Girona**[1], G. De Jesus-Astacio[2], C. Zenon-Melendez[1], B. Torres-Velasquez[1], M. Martir-Ocasio[1], M. R. Cruz-Correa[3]; [1]University of Puerto Rico Comprehensive Cancer Center, San Juan, PR, [2]Ponce Health Sciences University, San Juan, PR, [3]University of Puerto Rico, San Juan, PR

Colorectal cancer (CRC) is a leading cause of cancer death among men and women in Puerto Rico and the United States. About 60-70% of CRC cases are found at advanced stages (III/IV), suggesting limited adherence to available screening methods. Several molecular biomarkers have been identified as discriminatory for CRC (e.g., KRAS, NRAS, MSI), improving CRC management and patient outcomes. This study evaluates the differential expression patterns of DKK3, PKM2, IGFBP2, and SEPT9 genes between matched CRC tumors and adjacent mucosa samples. The secondary outcome was to examine the association between the presence of the selected biomarkers in tissue compared to blood samples. Using a retrospective study design, we examined 112 tissue samples of Hispanic individuals with a pathology-confirmed CRC diagnosis recruited throughout the Puerto Rico Familial Colorectal Cancer Registry (PURIFICAR). We quantified expression levels of target genes by RT-qPCR normalized with endogenous control GAPDH, using TaqMan Gene Expression Assay in the QuantStudio 3 (Applied Biosystems). Wilcoxon signed-rank test was used to calculate differences between gene expression from tumor and adjacent mucosal tissue samples. Additionally, 39 paired blood and tissue samples were analyzed to explore the association between biomarkers in these two types of samples. Protein biomarkers were measured using a commercially available ELISA kit according to manufacturer protocols (Thermo Scientific Federick, MD and Biosource San Diego, CA). mSEPT9 was measured using the Epi proColon® 2.0 CE test. The association between biomarker presence in tissue and blood samples was assessed using the Chi-square test of independence, with biomarker concentrations dichotomized at the median value. Statistical analyses were performed using Stata 17 and R version 4.3.1. DKK3 and IGFBP2 expression levels were higher among CRC tumor samples. However, expression levels of PKM2 and SEPT9 genes were slightly lower. DKK3 was the only target gene significantly different ($p<0.05$) when comparing overall gene expression between the matched samples. Upon comparison between early and advanced CRC stages, DKK3 expression levels were higher in advanced-stage tumor samples when compared to adjacent mucosal tissue samples ($p<0.05$). Moreover, a significant association between IGFBG2 presence in tissue compared to blood was detected at a 90% confidence level (p-value<0.10). This association was evident in early-stage CRC cases; there is a relationship between IGFBG2 biomarker presence in tissue and IGFBG2 biomarker presence in blood ($p<0.05$). Our findings indicate DKK3 and IGFBP2 as potential biomarkers for CRC progression and early detection. The study's insights into the differential expression patterns of these biomarkers can inform targeted screening strategies. Further research is needed to assess their potential to enhance early tumor detection in Hispanics.

#1025 An AI based CT scan classifier for predicting extranodal extension and nodal metastasis of HPV-associated oropharyngeal carcinoma.

B. Song[1], k. yang[2], S. Pan[1], L. Li[1], Q. Liu[3], J. Lee[2], S. Stock[2], N. F. Saba[1], M. Bilen[4], M. R. Patel[4], A. Madabhushi[1];
[1]Emory University, Atlanta, GA, [2]Cleveland Clinic, Cleveland, OH, [3]California State University, Los Angeles, CA, [4]Winship Cancer Institute, Atlanta, GA

Background: Pathologic extranodal extension (ENE) and nodal metastasis (NM) are of prognostic significance in human papillomavirus (HPV)-associated oropharyngeal squamous cell carcinoma (OPSCC). The pretreatment identifications of these two factors through computed tomography (CT) imaging are of clinical importance since they could guide treatment de-escalation protocols and select candidates suitable for surgery. In an effort to enhance pretreatment decision making, we developed and validated an AI model (specifically a multi-layer perceptron (MLP)-based deep learning model) to predict radiologic NM and pathologic ENE in HPV-associated OPSCC patients.

Methods: Radiographic CT scans for 290 OPSCC patients treated with definitive chemoradiation were acquired from The Cancer Imaging Archive (TCIA) and divided into training (D_1) and validation (D_2) cohorts for NM prediction. Radiologic NM for D_1 and D_2 were reviewed by two radiologists. Only nodes with concordant NM judgments from both radiologists were included for analysis. An additional 46 OPSCC patients treated with surgery at Emory Winship Cancer Institute were collected to form the test cohorts (D_3) for ENE prediction. The largest metastatic or normal nodes were annotated for D_1 and D_2 while all visible nodes with pathology confirmation of ENE from D_3 were annotated. We present a novel deep-learning model utilizing U-shaped multi-layer perceptron mixer (MLP-Mixer) to capture both global and local feature representations by spatially aggregating image patch information through a procedure called token-mixing. The model was trained for 20 epochs with learning rate of0.0001 and batch size of 64. The diagnostic performance of the AI model was evaluated on D_2 and D_3 using accuracy and area under the ROC curve (AUROC).

Results: There were 121 NM negative and 130 NM positive nodes in D_1, 14 NM negative and 25 NM positive nodes in D_2 and 46 ENE negative and 20 ENE positive nodes in D_3. On D_2 for NM prediction, the AI model achieved overall accuracy of 0.77 and AUROC of 0.78. On D_3 for ENE prediction, the AI model achieved overall accuracy of 0.71, AUROC of 0.69, positive predictive value of 0.52 and negative predictive value of 0.86.

Conclusions: The new AI--based deep learning model was able to identify HPV-associated OPSCC NM and ENE with satisfactory diagnostic performance and shows promise to assist clinicians in treatment decision-making. Additional, multi-site prospective validation of the approach is warranted.

#1026 Post-surgery sequelae unrelated to disease progression and chemotherapy revealed in follow-up of stage III colon cancer patients.

A. Kudriavtsev[1], A. Mirandola[1], C. I. Cofre Munoz[2], R. Comas Navarro[3], M. Macagno[4], B. Pastor[1], E. Pisareva[1], M. Sanchis Marin[3], J. Gonzalo Ruiz[3], A. Sapino[4], A. Bartolini[4], M. Di Maio[5], C. Sanchez[1], Y. Gricourt[6], X. Capdevila[7], G. Lossaint[8], E. Crapez[8], M. Ychou[8], R. Salazar Soler[2], E. Fenocchio[4], P. X. Fernandez Calotti[2], P. Cuvillon[6], T. Mazard[8], C. Santos Vivas[2], E. M. E. Elez[3], F. Di Nicolantonio[4], **A. R. Thierry**[1];

[1]INSERM U896 - IRCM (Montpellier), Montpellier, France, [2]Institut Catala d'Oncologia (ICO) - IDIBELL,, Barcelona, Spain, [3]VHIO Vall d'Hebron Institute of Oncology,, Barcelona, Spain, [4]Istituto di Candiolo - Fondazione del Piemonte per l'Oncologia - IRCCS,, Candiolo, Torino, Italy, [5]University of Torino, Torino, Italy, [6]Centre Hospitalo-Universitaire (CHU), Nimes, France, [7]Montpellier University Hospital, Montpellier, France, [8]Institut du Cancer de Montpellier, ICM, Montpellier, France

A gap currently exists in our understanding of causes of elevated total circulating DNA (cirDNA) levels in cancer patients following tumor resection, and the influence of anesthesia or surgery on cirDNA release. Indeed, the post-surgery dynamics of cirDNA have been largely overlooked to date, despite their importance in determining the optimal timing for assessment of minimal residual disease (MRD). Since cirDNA levels were recently found to be associated with neutrophil extracellular traps (NETs) formation in various cancers, we investigated NETs and cirDNA post-surgery.We conducted two clinical studies to explore the dynamics of cirDNA quantity and of neutrophil extracellular traps (NETs) markers: (1) a peri-surgery study over a duration of up to 72 hours, which involved stage I-III colon (n=10), prostate (n=10), and breast (n=9) cancer patients; and (2) a post-surgery study that extended up to two years post-surgery, and which involved 74 stage III colon cancer patients. We assessed plasma levels of cirDNA using qPCR, and assessed two protein markers of NETs using ELISA, in both cancer patients and control group of healthy individuals (HI) (N=114). This second study is the first prospective, multicenter, blinded study of the dynamics of the total cirDNA post-surgery, for a period of up to two years.We observed that (i), NETs formation contributes to post-surgery conditions; (ii), peri- and post-surgery cirDNA levels were highly associated with NETs formation in colon cancer; (iii), each tumor type showed a specific pattern of the peri-surgery dynamics of cirDNA and NETs markers; peri-operative levels of these markers are significantly lower in breast cancer patients as compared to prostate and colorectal cancer patients; (iv), a significant proportion of patients showed pre- (58.1%) and post-surgery (80.4%) median marker values higher than in HI, even after 2 years following tumor resection, (v) these markers were either equal to or greater (23.2%) than their pre-surgery counterparts; and (vi), elevated values of these markers did not derive from chemotherapy toxicity.We provide evidence that, for cancer patients in the post-surgery period, cirDNA originates mainly from NETs. This finding calls into question the current method of assessing MRD according to the fraction of mutant cirDNA, given that the level of NETs formation appears to be patient dependant. The peri-surgery dynamics of NETs formation and cirDNA release vary according to the surgical procedure and cancer type. In a significant part of patients with colon cancer, NETs continue to persist for more than a year after surgery, irrespective of disease progression or chemotherapy use. Nevertheless, cirDNA and NETs marker levels vary in cases with post-surgery inflammatory/thrombotic adverse events. Our work highlights the existence of long-lasting “sequelae” effects of cancer, previously unreported.

#1027 Immunohistochemistry (IHC) to assess tumor cell-associated OX40 expression in lymphoma PDXs.

J. Lin[1], X. Tu[1], L. Zhang[1], H. Yu[1], C. Jiang[1], T. Yang[2], **H. Q. Li**[2];
[1]Crown Bioscience, Suzhou, China, [2]Hanx Bio, Hangzhou, China

Background. Tumor necrosis factor receptor superfamily member 4, or OX40, is an immunostimulatory receptor usually expressed in activated T-cells. The OX40-OX40L (ligand of OX40) interaction plays a crucial role in the enhancement of T-cell proliferation, survival, and cytokine production, including those in tumor microenvironment (TME) leading to increased anti-tumor immunity[1]. OX40 agonist antibodies have been widely tested for immunotherapy for solid tumors[2,3]. Interestingly, in the treatment of lymphoma, the situation may become more complicate, where OX40 could also be found to be expressed on lymphoma cells, in addition to TME. This phenomenon might or might not impact OX40 agonist therapy. This report aims at developing an immunohistochemistry (IHC) assay to assess tumor-associated OX40 by utilizing morphology approach to understand OX40 expression in lymphoma cells, as opposed on tumor-infiltrate T-lymphocytes (TILs) present in TME. FFPE samples from patient-derived xenografts (PDXs), recapitulating the main pathological features of the original tumors, but exclusive of human TILs, were used as the first stage of the assay development, avoiding TIL interference prior to human sample testing.

Methods. Ninety leukemia and lymphoma PDXs are comprehensively annotated, including RNAseq and histopathology (HuBase™; *https://hubase.crownbio.com*). IHC staining of PDX FFPE slides or TMA (tissue microarray) of various cancers was performed using a commercial OX40 antibody (CST, #61637) and Bond RX Automated IHC/ISH Staining System (Leica Biosystems), followed by whole slide imaging by NanoZoomer NDP2.0-HT Digital Slide System (Hamamatsu) and quantitative analysis by HALO™ image analysis software (Indica labs). OX40 IHC scores were also compared to the RNA expression determined by RNAseq.

Results. A total of 90 leukemia and lymphoma PDXs were comprehensively evaluated. RNASeq data (human mRNA) indeed revealed OX40 gene expression (cutoff as Log2 (FPKM)>3) in 8.9% of models (8/90 models); on the other hand, IHC data also confirmed these OX40 protein expression; and the IHC scores largely correlated with the RNA data. Together, our data firmly confirmed the expression of OX40 in certain hematological cancers, beyond just in TME. The ongoing studies is investigating the characteristics of the OX40 positive lymphoma/leukemia, and the preliminary data will be presented in the annual conference. Furthermore, we are also using the same assay to explore other cancer types beyond hematological cancers.

Conclusion. A tumor associated OX40 expression IHC workflow was preliminarily established and validated to facility the OX40 immunotherapy development.

#1028 Assessment of the diagnostic accuracy of Oncuria-Detect® for detection of upper tract urothelial carcinoma.

T. Sakatani[1], **S. Tanaka**[1], K. Fujita[2], J. Linehan[3], K. Murakami[1], R. Lee[4], I. Pagano[4], C. J. Rosser[1], H. Furuya[1];
[1]Cedars-Sinai Medical Center, Los Angeles, CA, [2]Kindai University, Osaka, Japan, [3]Saint John's Cancer Institute, Santa Monica, CA, [4]University of Hawaii Cancer Center, Honolulu, HI

Introduction and Objective: Due to insufficient accuracy, urine-based assays currently have a limited role in the management of patients with upper tract urothelial carcinoma (UTUC). The application of a robust urine-based multiplex assay, Oncuria-Detect®, to aid in the detection of UTUC has the potential to address this deficiency and to assist with accurate, non-invasive diagnosis.

Methods: To evaluate the performance of Oncuria-Detect®, a multiplex immunoassay capable of querying a voided urine sample for 10 protein biomarkers associated with urothelial carcinoma (A1AT, APOE, ANG, CA9, IL8, MMP9, MMP10, PAI1, SDC1 and VEGFA). Its application to UTUC was evaluated in a multi-institutional cohort of 35 prospectively collected subjects presenting for evaluation of upper tract mass along with 46 prospective collected matched controls (i.e., non-tumor bearing). The ability of the test to identify patients harboring UTUC was assessed. UTCU status was confirmed by endoscopy and tissue biopsy or definitive surgery. Diagnostic performance was assessed using ROC curves.

Results: Oncuria-Detect® provided an AUC of 0.886 (95% CI: 0.807-0.964) with an overall sensitivity of 91.4%, specificity of 73.9%, NPV 91.9% and PPV 72.7%. Sensitivity values of the diagnostic panel for low-grade UTUC, high-grade UTUC, non-invasive UTUC and invasive UTUC were 86.7%, 90.9%, 88.9% and 94.1%, respectively. Urinary cytology or selective ureteral washing/cytology was associated with an overall sensitivity of 54.2%, specificity of 100%, NPV 63.3% and PPV 100%. Sensitivity values of cytology for low-grade UTUC, high-grade UTUC, non-invasive UTUC and invasive UTUC were 100%, 100%, 100%, and 77.8%, respectively.

Conclusions: Urinary levels of a biomarker panel enabled the accurate discrimination of UTUC and controls non-tumor bearing individuals. The multiplex Oncuria-Detect® test can achieve the efficient and accurate detection of UTUC in a non-invasive patient setting.

#1029 Role of *PCDHGA12*/*PRRX1* methylation for the diagnosis of lung cancer using bronchial washing fluid.

J. Son[1], T. Oh[2], M. Lee[1], C. Park[3], S. An[2];

[1]Konyang Univ. College of Medicine, Daejeon, Korea, Republic of, [2]Genomictree, Inc., Daejeon, Korea, Republic of, [3]Ulsan University Hospital, University of Ulsan College of Medicine, Ulsan, Korea, Republic of

Bronchoscopy is a frequently used initial diagnostic procedure for patients with suspected lung cancer (LC). Cytological examinations of bronchial washing (BW) samples, obtained during bronchoscopy, often yield inconclusive results in the diagnosis of LC. Aberrant DNA methylation has previously been shown to be a useful biomarker for LC. DNA methylation analysis in BW specimens could serve as a valuable clinical adjunct to cytology. In this study, to identify potential methylation biomarkers for LC, methylation microarray analyses were performed on primary tumors and compared with adjacent non-tumor tissues of 13 patients with LC at various stages (I - IV). A stepwise validation process using bisulfite-pyrosequencing of cell lines and tissues identified six methylated genes (*ADAMTS20*, *FOXC2*, *NKX2-5*, *OLIG3*, *PCDHGA12*, and *PRRX1*) associated with LC. To assess methylation in BW samples, a highly sensitive and accurate 3-plex Linear Target Enrichment (LTE)-quantitative methylation-specific PCR (qMSP) in a single closed tube was developed. Clinical validation was performed using BW samples from patients with LC (*n* = 68) and non-LC (benign) (*n* = 33) and identified *PCDHGA12* and *PRRX1* methylation as the best performing marker combination for detecting LC. The 2-marker combination exhibited a sensitivity of 82.4% and a specificity of 87.9%, with an area under the curve of 0.891. Notably, its sensitivity was 100% for small cell LC. The 2-marker combination had a positive predictive value of 93.3% and a negative predictive value of 70.7%. Its sensitivity outperformed cytology. The methylation status of the 2-marker showed no correlation with gender, age or stage, but was associated with tumor location and histology. In conclusion, we identified *PCDHGA12* and *PRRX1* methylation as high potential biomarkers for LC diagnosis. This study shows that these biomarkers could be used as a diagnostic adjunct to cytology in the clinical practice for diagnosing LC in BW specimens.

#1030 Concordance between the DESTINY-Breast04 clinical trial assay (4B5[CDx]) and other HER2 IHC assays for HER2-low breast cancer in real-world practice: First phase of a large-scale, multicenter global ring study.

H.-U. Schildhaus[1], S. Badve[2], C. D'Arrigo[3], G. Farshid[4], A. Lebeau[5], V. Peg[6], F. Penault-Llorca[7], J. Rueschoff[1], W. Yang[8], N. Atkey[9], J. Baumann[10], E. Beyerlein[11], **A. Hanlon Newell**[12], A. Penner[1], A. Moh[12], G. Viale[13];

[1]Discovery Life Sciences Tissue Biomarker Services GmbH, Kassel, Germany, [2]Emory University School of Medicine, Atlanta, GA, [3]Poundbury Cancer Institute, Dorchester, Dorset, United Kingdom, [4]Royal Adelaide Hospital, Adelaide, Australia, [5]University Medical Centre Hamburg-Eppendorf, Hamburg-Eppendorf, Germany, [6]University Hospital Vall d'Hebron, Barcelona, Spain, [7]Centre Jean Perrin, Universite Clermont Auvergne, INSERM, Clermont-Ferrand, France, [8]Fudan University, Shanghai, China, [9]Diaceutics PLC, Belfast, United Kingdom, [10]AstraZeneca, Gaithersburg, MD, [11]Daiichi Sankyo Europe GmbH, Munich, Germany, [12]Daiichi Sankyo Inc., Basking Ridge, NJ, [13]IEO European Institute of Oncology IRCCS, Milan, Italy

Background: DESTINY-Breast04 (DB-04) showed that trastuzumab deruxtecan improves survival vs chemotherapy in patients with human epidermal growth factor receptor 2 (HER2)-low (immunohistochemistry [IHC] 1+ or IHC 2+ with in situ hybridization negative) metastatic breast cancer (BC). The VENTANA 4B5(CDx) IHC assay, now approved in the United States (US) as a companion diagnostic, was used as the clinical trial assay (CTA) in DB-04. Real-world differentiation of HER2-low vs HER2 IHC 0 BC with non-CTAs is difficult. This is the first phase of a study assessing agreement between CTA and non-CTA scores.

Methods: 50 clinical BC samples with HER2 IHC scores of 0, 1+, 2+, and 3+ were sent to laboratories in Europe, Canada, and the US for HER2 IHC testing per ASCO/CAP 2018 guidelines. After routine protocol scoring, pathologists were trained and rescored the samples 2 weeks later. Post training scores were compared with reference CTA scores determined by a central laboratory and a panel of experts. The primary endpoint was positive percentage agreement (PPA) and negative percentage agreement (NPA) between CTA and non-CTA scores, assessed after training, considering HER2-low as positive and HER2 IHC 0 as negative.

Results: A total of 3449 post training non-CTA scores were available for analysis. PPA for HER2-low vs HER2 IHC 0 was 87.5% and NPA was 61.9%, with Cohen κ of 0.51 (Table). HER2-low vs HER2 IHC 0 agreement between CTA and non-CTA varied across subgroups. PPA >95% was shown with 4B5 Laboratory Developed Tests (LDTs) and HercepTest (Omnis), NPA of 80% with Leica, and overall agreement >80% with HercepTest (Link48), 4B5 LDTs, and German, French, and Italian laboratories.

Conclusions: The degree of concordance between the CTA and non-CTAs varied among assay types and laboratory locations. A low NPA for some non-CTAs suggests the need for further assay optimization for HER2 IHC 0 evaluation.

Post training non-CTA results		**HER2-low vs HER2 IHC 0 BC Post training scores**

#1031 Targeting genomic biomarker in voided urine for prostate cancer detection.

M. L. Thakur, V. S. Tomar, E. Dale, L. G. Gomella, H. T. Navarro, O. Kolesnikov, J. Leong, O. Dahlgren, E. J. Trabulsi;
Thomas Jefferson University, Philadelphia, PA

Introduction: Prostatic cancer (PCa) is the second most prevalent disease in men globally. In 2020 it lead to >14 million new cases and >375,000 deaths worldwide. Despite numerous detection methods, detecting PCa reliably and non-invasively continues to be challenging. PCa malignant cells (MC) express VPAC (combined for Vasoactive Intestinal Peptide and Pituitary Adenylate Cyclase Activating Peptide) in high density. A VPAC specific PACAP analogues ($Kd=3.1x10^{-8}M$) developed in our laboratory was conjugated with a fluorophore and named TP4303. The goal was to assess if TP4303 will image PCa-MC shed in voided urine and present severity of PCa as grade group (GG).

Method: Consenting PCa patients (N=110) scheduled for radical prostatectomy provided voided urine. Urine was cyto-centrifuged. Cells on glass slide were fixed, incubated with TP4303, washed, treated with DAPI (4,6-diamidodino-2-phenylindole), cover slip placed and analyzed with Zeiss Axio Observer microscope, coupled with ZENN Microscopy software. The software determined percentage of PCa MC shed by each patient. The results were corroborated as per GG, determined by post-surgical histopathology and analyzed statistically.

Results:TP4303 imaged PCa in all subjects. The percent MC shed in urine increased from 13.1±14.4% for GG1 to 25.3±21.07% for GG3 ($p=0.05$) to 50.5±26.7% for GG5 ($p=0.002$). Similarly, the fluorescence intensity increased from 43.8±2.2 for GG1 to 48.8±7.0 for GG3 ($p=0.01$) to 51.5±14.4 for GG5 ($p=0.15$).

Conclusions: The data strongly suggests that TP4303 may not only detect PCa reliably and noninvasively, but may also predict the severity of PCa.

#1032 Development of a novel companion diagnostic immunohistochemistry antibody for claudin 18.2-targeted therapies.

J. Chen[1], S. Bai[1], Y. Bai[1], Z. Hu[1], P. Chen[2], J. Mei[3], B. Shan[3], **B. Hou**[3];
[1]Antengene Biologics Co., Ltd., Hangzhou, China, [2]Antengene Corporation Co., Ltd., Shanghai, China, [3]Antengene Corporation Co., Ltd., Shaoxing, China

Background: CLDN18.2, the isoform 2 of CLDN18, is physiologically confined to gastric mucosa tight junctions, the epitopes of which would be exposed on the cancer cell surface upon malignant transformation and is highly expressed in a significant proportion of cancers, e.g., gastric and pancreatic adenocarcinomas, which makes it a promising drug target for cancer therapy. Currently, multiple drug modalities, such as monoclonal antibodies, ADCs, and CARTs targeting CLDN18.2 are being evaluated in clinical trials. A substantial correlation exists between the expression of CLDN18.2 and the efficacy of the these therapies. However, to date, no companion diagnostic (CDx) antibodies that are specific to CLDN18.2 have been approved. Therefore, it is important to promptly develop an anti-CLDN18.2 CDx antibody with a high specificity, sensitivity, and suitability for immunohistochemistry (IHC). In this study, we present the discovery and validation of a novel, highly sensitive IHC antibody that selectively identifies CLDN18.2.
Methods: 3 CLDN18.2 specific peptide fragments from extracellular domain of human CLDN18.2 were conjugated with KLH. Antibodies were discovered by immunizing BALB/c and SJL mice with these peptides-KLH conjugates. Screening and selection process was relied on positive ELISA results against the immunogen, as well as FACS and Acumen Explorer Microplate staining of CLDN18.2-experssing cells. Hit antibodies were evaluated for IHC on formalin-fixed paraffin-embedded CHOK1 cells expressing full-length CLDN18.2 or CLDN18.1. The antibodies were further validated on human gastric cancer tissue samples to establish the analytical sensitivity and specificity of the IHC assay.
Results: The mAb clone 43F11 exhibited binding to a fusion polypeptide comprising the first extracellular loop of human CLDN18.2 (aa32-53) at a half maximal effective concentration (EC50) of 0.212 nM. 43F11 showed positive cell surface IHC staining on CLDN18.2-experssing cells after fixation but demonstrated no staining on CLDN18.1-experssing cells. The IHC test method was established by utilizing clinical tumor tissues and PDX samples that had predetermined expression levels of CLDN18.2. The 43F11 antibody accurately identified the expression level of CLDN18.2 in the IHC assay, with a minimum concentration of 0.25 µg/mL. When compared to the commercial CLDN18.2 IHC antibody EPR19202, 43F11 demonstrated greater sensitivity, allowing for positive staining on cancer tissues that have significantly lower levels of CLDN18.2 expression.
Conclusion: 43F11 exhibits specific recognition of human CLDN18.2 in IHC assays, while showing no reactivity towards CLDN18.1. It demonstrated superior sensitivity compared to the benchmark antibody. These data suggest that 43F11 has the capacity to serve as an effective diagnostic tool for identifying patients who positively express CLDN18.2.

#1033 Evaluation of autoantibodies to proteins encoded by cancer driver genes as biomarkers for prostate cancer.

C. Qiu[1], X. Wang[1], C. A. Casiano[2], J.-Y. Zhang[1];
[1]The University of Texas at El Paso, El Paso, TX, [2], Loma Linda University School of Medicine, Loma Linda, CA

Prostate cancer (PCa) is a complex disease driven by genomic alterations, and understanding the immune response to these alterations can provide valuable insights into its pathogenesis. This study aimed at exploring the immunogenicity of proteins encoded by PCa driver genes and identifying corresponding autoantibodies as potential PCa biomarkers. Bioinformatics analysis, enzyme-linked immunosorbent assay (ELISA), and immunohistochemistry (IHC) were conducted in this study. A comprehensive screening process involving bioinformatics analysis and published studies identified a set of PCa driver genes for further investigation. Three strategies were employed to identify candidate driver genes: (1) utilizing the IntOGen database (Martínez-Jiménez et.al, Nature Reviews Cancer 2020), nine cohorts comprising 1503 primary PCa patient samples were analyzed, resulting in the identification of 63 PCa driver genes, with the top 20 genes exhibiting high mutation rates and frequencies in these cohorts; (2) employing the Kyoto Encyclopedia of Genes and Genomes (KEGG) database, 16 driver genes that were enriched in prostate cancer pathways were identified from the initial 63 genes; (3) referring to a published article (Dietlein et.al, Nature Genetics 2020), the top 17 driver genes that highly related to prostate cancer across 28 tumor types were selected. A final set of 15 PCa driver genes, which appeared in at least two of the screening strategies, were included in subsequent analyses. ELISA was then performed to assess the presence of autoantibodies targeting proteins encoded by these 15 PCa driver genes. Autoantibodies were evaluated using serum samples from 203 PCa patients and 93 normal controls. The results revealed that seven out of the 15 autoantibodies showed significantly elevated levels in the sera of PCa patients compared to normal controls. Notably, the autoantibody targeting SPOP (speckled-type POZ protein) exhibited the highest frequency of 42.4%, followed by the autoantibody to PTEN (phosphatase and tensin homolog) at 37.4% in the PCa group. Finally, the SPOP protein was analyzed by IHC on the prostate tissue microarray containing PCa tissues, prostate simple hyperplasia tissues, cancer adjacent prostate tissues, and normal prostate tissues further to explore the consistency of SPOP expression in antigen-antibody reactions. High expression of SPOP protein was found in the PCa tissues. These findings suggest that proteins encoded by PCa driver genes may possess immunogenic properties due to neoepitopes possibly generated by mutations, leading to the production of corresponding autoantibodies. Identifying specific autoantibodies associated with PCa driver genes could offer novel opportunities for discovering autoantibody-based biomarkers in PCa. Further validation of these autoantibodies is warranted to evaluate their diagnostic potential in PCa.

#1034 SIGMAR1 as a novel potential prognostic biomarker that regulates PD-L1 expression in oral cancer.

P. Shimaoka Chagas, Sr.[1], G. da Silva[1], G. Ribeiro de Sousa[1], C. Bernadelli Garcia[1], L. Oliveira Sousa[1], R. Cabral Marcelino[2], R. Luiz Lobo da Silva Souza[1], L. Luongo de Matos[3], L. Paulo Kowalski[3], E. da Silva Lopes Salles[4], L. P. Wang[4], B. Baban[4], A. Machado Leopoldino[1];

[1]University of Sao Paulo, Ribeirao Preto, Brazil, [2]Federal University of Alfenas, Alfenas, Brazil, [3]University of Sao Paulo, Sao Paulo, Brazil, [4]Augusta University, Augusta, GA

Background: The SIGMAR1 receptor is a regulator of immunity and inflammation. Together, these key processes can support or restrain cancer progression and response to therapy. Nevertheless, the effect of SIGMAR1 on the modulation of oral cancer (OC) immunity is largely unknown. Here, we investigated not only the prognostic value of SIGMAR1 in OC but also, its impact on antitumor immunity response.

Methods: Were included in this study data from TCGA (Pan-Cancer analysis), multiple large datasets of OC (GSE30784; GSE42743; GSE37991, GSE31056, our cohort-based study of human OC samples and OC cell lines. Taken together, were used to performed the bioinformatics analysis and the experimental verification by several in vitro assays. The CIBERSORT analysis and Luminex assay were used to evaluate the infiltration degrees of different immune cells and also to validate the presence of chemokines and immune-stimulators, respectively, in human OC samples. To assess the role of SIGMAR1 in the modulation of the -PD-L1 expression, SIGMAR1-shRNA OC cell lines were used.

Results: We found that overexpression of SIGMAR1 was associated with poor survival rates in OC. Further, we observed that SIGMAR1 deficiency inhibited Ca2+ influx and clonogenic growth and decreased chemoresistance to cisplatin in human OC cells. Next, the SIGMAR1 expression levels were associated with infiltration degrees of M1 macrophages, Natural Killer cells and T cells (memory and helper CD4+ activated, and CD8+ cytotoxic T cells). Regarding comparison of the analytes between patients with SIGMAR1 high/low expression group, we found significant differences in the CX3CL1 (chemokine), and in immune-stimulators as CD27, CD40, and PD-L1 expression level. Importantly, this research also showed that SIGMAR1 inhibition in human OC cell lines decreases the abundance of PD-L1, both at the total protein and surface expression levels.

Conclusions: Our findings suggests SIGMAR1 not only as an emerging biomarker with promising therapeutic values to OC patients, but also gave a new insight into a potential immunotherapy strategy.

Keywords: Oral cancer; SIGMAR1; PD-L1, Immune checkpoint inhibitors.

#1035 Identification of fibroblast growth factor receptors (FGFRs) alterations (alts) at DNA and RNA-level by one-step next-generation sequencing (NGS) panel.

M. Qing[1], X. Chen[2], W. Su[2], X. Zhuo[3], T. Shen[1], C. Xiong[1], X. Lyu[1], R. Tate[4], Q. Wu[1], L. Zhou[1], S. Thomas[4], W. Ning[2], J. Wang[2], H. Yan[2], Z. Yin[2], Z. Huang[2], Y. Xue[2], **C. Zhu**[2];

[1]Janssen Research & Development, Shanghai, China, [2]Amoy Diagnostics, Xiamen, China, [3]Janssen Research & Development, Beijing, China, [4]Janssen Research & Development, Spring House, PA

Background: FGFR inhibitors are currently in clinical development or approved for urothelial cancer and cholangiocarcinoma with *FGFR* fusion (FUS) or/and mutation (MUT). AmoyDx FGFR 1-4 NGS Panel (FGFR-P) was developed for FGFR alts detection based on both DNA and RNA. The goal of this study is to validate and assess the performance of FGFR-P in pan-cancer *FGFR* alts detection by comparing with an AmoyDx comprehensive genomic profiling test (CGP) and a health authority approved DNA-based NGS panel (DNA-P).

Methods: Both FGFR-P and CGP are DNA (MUT) and RNA (FUS) based for detecting *FGFR* alts with optimized bioinformatics pipeline to eliminate baseline noise caused by deamination events, which is commonly found in aged FFPE samples. Cell lines, cell line/patient derived xenografts (CDXs/PDXs) and 397 samples of 26 cancer types (90 samples >10 years) were used for validation of FGFR-P. Total 382 and 50 pan-cancer samples were respectively tested to compare FGFR-P with CGP and DNA-P.

Results: To validate accuracy, 36 FFPE samples from cell lines and CDXs/PDXs with known FGFR status (25 FUSs, 5 MUTs, 6 wild-types) were tested by FGFR-P with concordance rate 100%. In clinical sample testing, FGFR-P also showed high agreement with CGP (99.5%) and DNA-P (98.0%). Conflicting result confirmed by FISH revealed 1 FUS missed by DNA-P but detected by FGFR-P, which demonstrated advantage of *FGFR* alts detection by DNA+RNA. In addition, an optimized bioinformatics pipeline by mimic samples with deamination events effectively filtered out C:G>T:A false positive signals. FGFR-P achieved high success rate in testing pan-tumor samples (89.9%) including samples >10 years (75.6%).

Conclusions: FGFR-P provides a novel opportunity to identify *FGFR* alt pan-cancer patients using a robust DNA+RNA NGS platform, which shows high success rate even in aged samples and will be a potent tool for sensitive and reliable detection of *FGFR* alts for clinical diagnostics.

#1036 Development of a comprehensive RNA-based NGS panel for detecting tyrosine kinase fusion genes associated with primary hypereosinophilia.

B. Lee[1], A. Chern[1], A. Zhang[1], C. M. Lu[2], M. Y. Sha[1];
[1]DiaCarta, Inc., Pleasanton, CA, [2]University of California and VA Health Care System, San Francisco, CA

Hypereosinophilia (HE) is a medical condition diagnosed when the count of eosinophils in the blood is greater than $1.5X10^9$ per liter. Primary HE is a clonal stem cell disorder manifesting as myeloid and/or lymphoid malignancies and is typically driven by aberrant fusion genes involving a tyrosine kinase (TK) gene (e.g., PDGFRA, PDGFRB, FGFR1, JAK2, FLT3, ABL1). The precise identification of the underlying molecular genetic abnormalities is crucial for timely diagnosing and managing primary HE. There has been no HE-specific assay that can concomitantly detect all known or novel TK fusion genes. We've developed an RNA-based panel for detecting TK fusion genes in HE. This panel, developed using 5' RACE technology, allows for the identification of fusion transcripts in total RNA extracted from whole blood sample. It covers 48 known TK fusion genes and also has the capability of detecting novel gene fusions. We balanced and optimized the panel using an in-house fusion RNA mix containing 11 fusion transcripts. We additionally validated the panel using samples from five patients with hematopoietic neoplasms and two fusion-positive cell lines to ensure its accuracy. The Limit of Detection (LoD) was established by analyzing the in-house RNA mix and normal whole blood RNA. It was found that the minimum RNA input required to detect all 11 fusion transcripts was 3540 copies in the presence of a background of 10 ng normal whole blood RNA. The panel successfully identified two fusion transcripts using 10 ng of total RNA obtained from cancer cell lines. The panel was then used to test five patient RNA samples extracted from whole blood. We successfully confirmed the presence of BCR-ABL1 fusion in 3 patient samples and ETV6-PDGFRB fusion in 1 patient sample, respectively. In summary, we developed HE-specific NGS panel for detecting all known and novel TK fusion genes and demonstrated its analytical accuracy and clinical effectiveness. The next phase of our study is to further validate the tests on a large patient cohort.

#1037 Clinical application of next-generation digital PCR capable of real-time analysis to HER2 measurement as a novel diagnostic in breast cancer: A multicenter retrospective study.

H. Kim[1], S. Park[1], S. Yang[1], M. Song[1], D. Kim[1], J. Chang[2], Y. Kim[2], H.-J. Choi[2], N. Heo[3], H.-Y. Won[4], J.-H. Park[4], M. Song[4], S.-S. Shin[4], D. Lee[4], S.-H. Jang[3], J.-Y. Lee[2], H. Ryu[1];

[1]Seoul National University, Seoul, Korea, Republic of, [2]Hanyang University, Seoul, Korea, Republic of, [3]Soonchunhyang University Cheonan Hospital, Cheonan-si, Korea, Republic of, [4]OPTOLANE Technologies Inc., Seongnam-si, Korea, Republic of

HER2 testing is still challenging due to the subjective natures of immunohistochemistry (IHC) and in situ hybridization (ISH), standard methods for determining HER2 status. Here, we developed a clinically reliable HER2 testing method enabling ultra-fast detection of HER2 gene amplification with high accuracy by using the digital real-time PCR (drPCR) system. To test the clinical validity and standardize procedures of drPCR-based HER2 status evaluation, three independent breast cancer cohorts from different institutions were enrolled, which assigned as a training (SCHU hospital, n = 103) and two validation sets (SNU hospital, n = 170; CNUH hospital, n = 45), and the drPCR assay was compared with current standard HER2 testing methods. In the training cohort, the HER2/CEP17 ratio values from FISH and drPCR tests were highly correlated (r^2 = 0.81; *P* < 0.001), and the drPCR results displayed 98.1% concordance to HER2 status defined by IHC and/or FISH with 92.6% sensitivity and 100% specificity. Eight samples further verified by targeted NGS showed 100% concordance of dPCR to NGS. Consistently, two validation cohorts also showed high concordance of drPCR to IHC and/or ISH results (accuracy = 97.1% and 97.8% in SNU and CNUH cohorts, respectively). The optimal cutoff for HER2 positivity in the drPCR assay was set as a HER2/CEP17 ratio ≥ 1.9 with AUC of 0.963 based on the results from training cohort, and the same cut-off for drPCR was applicable to two independent validation cohorts, supporting the clinical validity of our drPCR-based HER2 assessment. In some discordant cases, low tumor purity (≤ 25%) was observed and microdissection partly improved the drPCR results. The discordance between drPCR and ISH results was also found in marginal HER2+ cases with HER2/CEP17 ratio 2-3, but these cases showed inter-observer variability when re-evaluating the ISH/IHC data due to intratumoral HER2 heterogeneity. Of note, in HER2 IHC3+ cases with negative drPCR results, re-evaluation of IHC using an artificial intelligence (AI)-based HER2 scoring system revised the HER2 IHC 3+ score to 2+, and ISH assessment also confirmed that these cases are indeed HER2-negative, proving the high accuracy of HER2 CN drPCR assay. In conclusion, given the advantages of drPCR-based HER2 assessment with high accuracy, sensitivity, and simplicity, the drPCR assay could be a complementary or alternative method to IHC and ISH to greatly improve current HER2 testing.

#1038 Identification of diagnostic biomarkers for colon adenocarcinoma by analyzing proteins in human-derived extracellular vesicles and particles.

Y. Seo[1], Y. Han[2], L. Bojmar[3], K.-A. Kim[1], Y. Seo[1], D. Lyden[4], H. Kim[1];

[1]Graduate School of Medical Science, Brain Korea 21 FOUR Project, Yonsei University College of Medicine, Seoul, Korea, Republic of, [2]Yonsei University College of Medicine, Seoul, Korea, Republic of, [3]Linkoping University, Linkoping, Sweden, [4]Drukier Institute for Children's Health, Meyer Cancer Center, Weill Cornell Medicine, New York, NY

There is an unmet medical need for circulating biomarkers to improve early cancer detection in colon adenocarcinoma (COAD). We investigated the proteomic profile of extracellular vesicles and particles (EVPs) from the colon tissue explants and plasmas in COAD. The research aims to overcome the limitations of traditional serum Carcinoembryonic Antigen (CEA) testing and invasive procedures like colonoscopy. We analyzed EVPs sourced from tumor and adjacent non-tumor tissues and preoperative and postoperative plasma in COAD patients to identify potential EVP-based tumor diagnostic markers. In the Discovery phase with 50 COAD patients, we conducted a proteomic analysis using liquid chromatography-tandem mass spectrometry (LC-MS/MS), identifying approximately 50 markers each from tissue explants and plasma. These markers were validated in an independent cohort of 104 participants, including 84 COAD patients and 20 healthy controls. We utilized ELISA to quantify 11 selected EVP proteins. Notably, seven of these proteins exhibited significant differential expression in preoperative and postoperative plasma, highlighting their diagnostic relevance. These seven proteins also showed marked elevation in preoperative plasma compared to healthy controls, reinforcing their potential as diagnostic markers. The study extended to evaluate the diagnostic accuracy of these seven proteins, referred to as "EV-7 levels", across various stages of COAD. Their performance was compared with serum CEA levels and plasma cfDNA mutation rates, as detected by an FDA-approved liquid biopsy assay. The EV-7 levels demonstrated superior detection rates in the early stages of COAD, particularly in Stages I and II, in contrast to the serum CEA method. Among the 84 patients, 73 (86.9%) exhibited EV-7 levels exceeding the established cut-off. In the validation cohort, EV-7 levels were more accurate across different COAD stages than serum CEA levels and cfDNA mutation rates. CEA levels above 5 ng/ml were 27%, 45%, 42%, and 64% for Stages I through IV. cfDNA somatic mutation rates were 60%, 80%, 75%, and 75%. EV-7 levels exceeding the cut-off were 73%, 100%, 88%, and 84%, respectively, with Stages I and II having the highest detection rate among the three methods. ROC curve analysis for EV-7 levels in Stages I to IV showed statistically significant, with AUC values of 0.913, 1.000, 0.985, and 0.984, respectively. Our findings indicate that the seven EVP proteins are significantly present in the plasma of early-stage COAD patients. Integrating these markers with current diagnostic approaches could improve early cancer detection, showing promise for practical application in clinical settings.

#1040 Development of a novel RNA-based microsatellite stable predictive response signature (MSS-PRS) to identify MSS colorectal cancer (CRC) patients with a microsatellite instability-high (MSI-H) molecular phenotype.

K. Pappan, G. Mayhew, J. Shepherd, Y. Guo, K. Beebe, **J. Eisner**, M. Milburn;
GeneCentric Therapeutics, Inc., Durham, NC

Introduction: MSI-H and mismatch repair deficient (dMMR) tumors are associated with favorable immune checkpoint inhibitor (ICI) responses (PMID: 3326454). However, up to 95% of CRC tumors are MSS/proficient MMR (pMMR) leading to poorer prognosis and treatment outcomes than MSI-H/dMMR patients (PMID: 12867608, 26028255). In MSS/pMMR metastatic CRC, multiple combination therapies are being investigated despite a lack of biomarkers to guide therapy. Therefore, we developed an RNA-based MSS-PRS with a primary objective to identify MSS tumors that have MSI-H/dMMR molecular features indicative of ICI response.

Experimental Procedures: The MSS-PRS was developed using the TCGA CRC cohort (COAD; n=268). Training labels were assigned using the MSI Mantis score and mutation status from 8 genes with reported MSI association. Samples called “activated” had both a gene mutation and an MSI Mantis score > 0.4 (i.e., MSI-H), and samples called “non-activated” were wild type for all genes and had MSI Mantis score < 0.4. All other samples were designated “ambiguous” and excluded from training. Two thirds of the non-ambiguous samples were assigned to the classifier training set and all remaining samples were assigned to the test set. Using ClaNC software (PMID: 16269418) and cross-validation in the training set, a nearest centroid classifier was developed from a set of high mean, high variance candidate genes to select an optimal gene set to separate activated and non-activated groups. The classifier performance was evaluated in the test set.

Results: The MSS-PRS contained 112-genes enriched for mismatched DNA binding, DNA damage repair, PD-L1, innate and adaptive immune response, cellular immunity, and cytokines. In the test set, the classifier called 44 of 46 MSI-H samples activated; of the remaining 77 samples that were MSS tumors, 38 were called activated and 39 were called not activated. Visual inspection of heat maps of tumor by MSI/MSS-PRS status and their association with TMB and CRC-related mutations suggest greater differences between MSS tumors called activated and MSI-H tumors than between MSS tumors called activated and MSS tumors called not activated. In contrast, immune marker expression profiles in MSS tumors called activated were markedly more similar to MSI-H tumors compared to MSS tumors called non-activated.

Summary and Conclusions: Herein we described the development of a novel MSS-PRS that captures an MSI-H/dMMR-like molecular phenotype in a subset of patients with MSS tumors despite their lack of high TMB or overt MSI defects. Based upon these initial findings, further development of the MSS-PRS and its clinical validation as a tool to select patients with MSS tumors who may benefit from ICI-containing treatment regimens is warranted.

#1041 Spatial concordance between genome and proteome in oncology: A systematic review.

Laura K. M. Sysivirta, Franziska Niemeyer, Veera Kurki, Inkalilja Pirinen, Laura Savolainen, Ceren Seref-Vujaklilja, Andrew Erickson

University of Helsinki, Helsinki, Finland

We recently reported that spatial transcriptome data can be used to spatially detect copy number alterations (Erickson et al., Nature, 2022). Given that copy-number alterations may also be reflected by altered protein expression in human cancers, we sought to determine what the empirical concordance of the spatial proteome and genome in human cancer samples. We performed a systematic review of Immunohistochemistry (IHC) & Fluorescence/Chromogenic In-Situ Hybridization (FISH/CISH) across human cancers. We performed a PUBMED query for records up to April 1st, 2023, yielding 9,294 records. Our inclusion criteria included human sample studies that performed both IHC and FISH/CISH against the same target, with a minimum of two samples. We excluded case reports, RNA ISH- and non-human studies, studies without IHC/ISH performed on the same target, and articles not in English or inaccessible. We screened 9,294 PUBMED article abstracts using the AS Review active learning model (van de Schoot et al., 2021), and used a pre-defined threshold of 5 % consecutive irrelevant abstracts to stop screening. A total of 1,309 abstracts were manually excluded using the AS Review, directing the active learning model to automatically exclude 3,413 abstracts out of the original 9,294. Of the 4,572 articles assessed for full-article screening, 1,167 were excluded for being out of scope, 303 for access issues, 227 for language incompatibility, and 236 for imprecise information, primarily due to non-representative samples or incorrect gene/protein target identification. Ultimately, out of 2,413 articles assessed for eligibility, 2,294 did not meet inclusion criteria, leaving 119 studies for our analysis. From these articles, we manually extracted kappa values for analysis and visualization in R. We identified articles from 19 different cancers with the majority studying Breast Cancer, Non-Small Cell Lung Cancer, Gastric Cancer, and Mesothelioma. We observed high Cohen's Kappa values in Breast Cancer (median = 0.76), Non-Small Cell Lung Cancer (median = 0.91) and Mucinous Ovarian Carcinoma (median = 0.93). We identified studies from 14 different genes with majority being HER2, ALK and MYC. We observed high Cohen's Kappa values in HER2 (median = 0.80), ALK (median = 0.80), ROS1 (median = 0.95) and MDM2 (median = 0.72). Our preliminary analysis indicates significant heterogeneity between tumor types for protein expression and copy-number alterations. To our knowledge, there are no previously reported systematic reviews that have empirically assessed the spatial concordance of proteome and genome, in human cancer samples. The authors often reported IHC/FISH results at patient, or section level, potentially introducing selection bias by not accounting for intra-tumoral heterogeneity at single-cell resolution. Future efforts are needed to spatially resolve gene-copy number and protein expression at single-cell resolution.

#1042 Multi-exposure high dynamic range microscopy obviates the requirement for matching camera exposure to reagent concentration in high-plex spatial biology applications.

J. S. Schwarz, M. H. Ingalls, X. Meshik, A. Northcutt, O. Braubach;
Canopy Biosciences-A Bruker Company, St. Louis, MO

High-plex immunofluorescence imaging allows researchers to perform deep cellular phenotyping with spatial context. However, high-plex immunofluorescence imaging requires the end user to painstakingly optimize antibody concentrations and image acquisition settings before producing reproducible imaging data with sufficient and quantifiable dynamic range. Mismatches of reagent concentration and camera exposures will result in under and over-saturated images, and both outcomes are detrimental for signal quantification and downstream interpretation. As the number of markers deployed in spatial biology increases, it becomes necessary to develop strategies that streamline or automate parameter setting that is needed to capture data with optimal dynamic range.
The CellScape™ platform for Precise Spatial Multiplexing, featuring ChipCytometry™ technology, utilizes multi-exposure high dynamic range (HDR) microscopy as a tool to produce data with consistent and reliable detection of biomarker signals. CellScape replaces the standard single exposure with an exposure series calibrated to the physical limitations of the detector system. Each exposure series captures linear data, ranging from the dimmest to the brightest signals that the system can detect, as well as everything in between. HDR capture is thus akin to capturing an image at every possible exposure length, and it thus includes data from the ‘optimal’ matched exposure. By these means, HDR obviates the need for exposure selection by covering the entire exposure gamut.
Here, we use CellScape to collect a high-plex immunofluorescence spatial biology dataset. Analysis of the dataset highlights the extended linear dynamic range of the integrated luminance HDR data, including a calculation of the expected ‘best-matched’ exposure. Further, we extend this analysis to show how HDR can handle biological variation and allow normalization that is not possible with single exposure imaging. Finally, we examine a reagent concentration series to demonstrate how HDR can be used to maximize the sensitivity of the assay by allowing increasing detection reagent concentration without compromising overall dynamic range for the signal. Our data demonstrates that HDR microscopy supports the deployment of spatial biology as a tool to interrogate the tumor microenvironment, unravel responsiveness to drug treatments and cell therapies, and ultimately stratify patients for targeted treatment and clinical trial enrollment.

#1043 Identification of the novel immune synapse-localized proteome for immuno-oncology using Microscoop-induced targeted photo-biotinylation.

W.-M. Chong, C. Li, C.-K. Huang, C. Cheung, H.-J. Chang, C.-W. Chung, J.-C. Liao;
Syncell Inc., Taipei, Taiwan

Although tens of immune synapse (IS) protein species are known, there remain many unknown IS-localized protein species. Understanding the proteome of the IS between a target cell and a lymphocyte is crucial for advancing immuno-oncology. The low abundance of ISs and the lack of a definitive enrichment marker have limited efficient proteomic profiling. Here, we used Microscoop™, an innovative system that integrates microscopy, machine learning, and targeted photo-biotinylation to enable precise and spatially specific enrichment of IS proteins, thereby facilitating proteomic discovery of the IS. We utilized Raji B cells as antigen-presenting cells (APCs) and induced IS formation with Jurkat T cells. The system first employed immunofluorescence imaging of CD3, a common IS marker in Jurkat T cells, and used a convolutional neural network-based deep learning algorithm to train the recognition of ISs from CMTPX-stained Raji B cells. Our automated system then successfully achieved spatially-targeted biotin-tagging of proteins at ISs through thousands of fields of view of imaging, deep learning-driven pattern generation, and photochemical labeling. Subsequent streptavidin pull-down and mass spectrometry analysis enabled the identification of IS-specific proteins. Remarkably, our spatial proteomic approach led to the isolation and identification of hundreds of different species at the IS interface, including proteins associated with key components of T-cell receptor (TCR) signaling pathways such as the TCR/CD3 complex, Src and Tec family tyrosine kinases, and pivotal NF-kB signaling proteins. Beyond these, we also identified a significant enrichment of proteins not previously associated with the IS. Our study not only illuminates previously unknown aspects of immune regulation at the IS interface, but also shedded light on proteins potentially important for immuno-oncology. These insights have significant implications for cancer research, particularly in understanding and manipulating immune responses for therapeutic purposes.

#1044 Low-cost, high-sensitivity InSituPlex® mIF assays on the Parhelia Omni-Stainer™.

K. Hwang[1], L. Duro[1], A. Veith[1], N. Wedin[2], N. Samusik[2], J. H. Lee[1];
[1]Ultivue, Inc., Cambridge, MA, [2]Parhelia Biosciences, Austin, TX

Background: Multiplex immunofluorescence (mIF) is an important tool for extracting complex phenotypic information from normal or diseased tissues, and provides accurate and predictive insights on the tissue microenvironment faster. For patient samples in translational and clinical research, high sensitivity, specificity, and reproducibility are critical; however, throughput and cost considerations are also important in designing clinical studies. Enabling an easy-to-use high-performance assay such as InSituPlex® on robust and affordable auto-stainers like the Parhelia Omni-Stainer™ can allow researchers to gain a deeper understanding of the tissue micro-environment through high-quality multiplexed biomarker detection in a fraction of the time and cost.
Methods: We performed Ultivue InSituPlex® assays with OmniVUE™ panels using the Parhelia Omni-Stainer™, a low-cost, high-throughput tissue auto-stainer with reduced requirements for reagents with a minimal dead volume. We compared the whole-slide staining performance across replicates using human tonsil and tumor tissue arrays across multiple independent runs over multiple days. The stained slides were scanned using the Zeiss AxioScan.Z1 high-throughput imaging system, and image batches were processed using Ultivue's UltiStacker.AI and UltiAnalyzer.AI software.
Results: Tighter temperature control of the slide in the Omni-Stainer supports optimal InSituPlex® signal amplification. Intra-run and inter-day analysis on serial sections of human tonsil and tumor tissue arrays demonstrated a high degree of consistency in InSituPlex® assay performance, specifically with marker-specific signal intensities and cell densities. The Omni-Stainer facilitates the use of low reagent volumes at each step of the assay due to its efficient reagent use, thus lowering the cost of reagents per slide.
Conclusions: This study demonstrated a fast, simple and robust workflow to perform high-performance InSituPlex® mIF assays on the low-cost, high-throughput Parhelia Omni-Stainer™. Ultivue's configurable OmniVUE™ mIF panels can be run on the Omni-Stainer with reduced associated reagent costs per slide. This workflow can support larger clinical and translational studies in a more cost-effective fashion, leading to in-depth analysis of tissue microenvironment through highly precise multiplexed biomarker detection.

#1045 A freely expandable 20-plex immuno-oncology antibody core panel for spatial biology experiments on human FFPE cancer sections: REAplex IO Core for MICS technology.

J. Femel[1], E. C. DiBasio[2], K. Schonborn[1], M. Buttner[1], T. Duking[1], **M. Habich**[1], T. Wantenaar[1], S. Eulitz[1], A. Bosio[1];
[1]Miltenyi Biotec B.V. & Co. KG, Bergisch Gladbach, Germany, [2]Miltenyi Biotec North America, Inc., Waltham, MA

Spatial biology is integral to understanding the dynamics of immune cells, tumor microenvironment (TME), and therapeutic responses in cancer research. Ultra-high-plex immunofluorescence has transformed deep phenotyping and cell neighborhood analysis, providing unprecedented insight into complex and heterogeneous samples such as the TME. Many spatial biology platforms reduce operator hands-on time by automating image acquisition. However, determining the most appropriate markers to distinguish key cell types, finding application-compatible antibody clones and optimizing their dilution remains a tedious manual process. To streamline the panel-building process, we have developed a series of pre-defined, commercially available antibody panels for the MACSima™ Imaging Cyclic Staining (MICS) technology. So far, these have covered the spectrum from ultra-high-plex screening panels with up to 205 antibodies (REAscreen™ MAX) to the more focused REAscreen Immuno Oncology antibody panel with 61 cancer and immune-related antibodies for the comprehensive analysis of various different human FFPE samples. Here, we introduce a new, 20-plex, pre-defined antibody panel. Organized along essential marker groups, it can function as a stand-alone panel that allows the identification of the major tumor-infiltrating leukocyte populations with a focus on T-cells, and providing insight into TME architecture, tumor neovascularization, and cellular activity. Because it can be combined and expanded with any number of antibodies or even entire panel modules, it can be used as a standardized basis for highly multiplexed custom panels optimized for the research question at hand. We demonstrate its performance and broad applicability across several cancer types analyzed with the MICS technology. Finally, preset template examples for panel-specific data processing with MACS iQ View analysis software demonstrate the simplicity yet power of an integrated end-to-end workflow.

#1046 Prevalence of MTAP deficiencyin human cancer: A tissue microarray study on 17,078 cancers from 149 different tumor types.

N. Gorbokon[1], **M. Lennartz**[1], D. Hoeflmayer[1], S. Dwertmann Rico[1], S. Kind[1], V. Reiswich[1], F. Viehweger[1], F. Lutz[1], C. Fraune[1], A. M. Luebke[1], C. Hube-Magg[1], F. Buscheck[1], A. Menz[1], R. Schlichter[1], T. Krech[1], A. Hinsch[1], E. Burandt[1], G. Sauter[1], R. Simon[1], S. Steurer[1], A. H. Marx[2], P. Lebok[1], D. Dum[1], S. Minner[1], F. Jacobsen[1], T. S. Clauditz[1], C. Bernreuther[1], M. Kluth[1];

[1]University Medical Center Hamburg-Eppendorf, Hamburg, Germany, [2]Academic Hospital Fuerth, Fuerth, Germany

The S-methyl-5′-thioadenosine phosphorylase (MTAP) gene is located at 9p21 and is often co-deleted with CDKN2A. Because homozygous MTAP deletions result in a complete expression loss, MTAP immunohistochemistry (IHC) can be used for detection of homozygous deleted cells. MTAP IHC is of diagnostic utility for the distinction of mesotheliomas (often 9p21 deleted) from benign mesothelial proliferations. Moreover, evidence is emerging that MTAP deficiency results in a critical vulnerability of cancer cells towards drugs targeting several different pathways that depend on a functional MTAP gene and also causes resistance to immune checkpoint inhibitors.

To determine the prevalence of complete MTAP expression loss and to assess the diagnostic utility of MTAP IHC, a tissue microarray containing 17,078 samples from 149 different tumor entities and 608 samples of 76 different normal tissue types was analyzed by IHC. All cases with complete MTAP loss were validated by fluorescence in situ hybridization (FISH).

In normal tissues, MTAP was ubiquitously expressed resulting in a cytoplasmic and nuclear MTAP staining. At least one case with a complete MTAP expression loss was observed in 87 of 149 (58%) tumor categories. MTAP staining was most commonly lost in neuroendocrine neoplasms of various sites (up to 80%), Hodgkin's lymphoma (38%), mesothelioma (24-30%), bilio-pancreatic adenocarcinomas (9-36%), urothelial neoplasms (19-29%), malignant melanoma (14-21%), mucinous carcinoma of the ovary (27%), squamous cell carcinomas of various organs of origin (up to 24%), various types of sarcomas (up to 20%), adenocarcinoma of the lung (11%), gastro-esophageal adenocarcinomas (2.6-11%), and in various types of non-Hodgkin's lymphomas (up to 14%). FISH validation identified homozygous 9p21 deletions in 90-98% of cases with MTAP expression loss in most tumor categories including urothelial neoplasms, mesotheliomas, and pancreatic cancers, and others. There were, however, also tumor types such as neuroendocrine tumors and Hodgkin's lymphomas that always lacked 9p21 deletions.

In summary, our data provide a comprehensive overview on MTAP expression in cancer and show a strong link between MTAP expression loss and homozygous 9p21 deletions in most tumor entities. These cancers might most benefit from cancer drugs targeting MTAP deficiency. The absence of 9p21 deletions in other entities with frequent MTAP expression loss demonstrates that other mechanisms can cause significant MTAP downregulation. Whether these tumors benefit from targeting MTAT deficiency remains to be determined.

#1047 Expression of TYMS in cancer: A tissue microarray study involving 6,613 cancers from 127 tumor entities.

F. Lutz[1], N. Leege[1], K. Moller[1], F. Viehweger[1], R. Schlichter[1], A. M. Luebke[1], M. Kluth[1], C. Hube-Magg[1], A. Hinsch[1], C. Bernreuther[1], G. Sauter[1], D. Dum[1], A. H. Marx[2], R. Simon[1], T. Krech[1], T. S. Clauditz[1], F. Jacobsen[1], E. Burandt[1], S. Steurer[1], P. Lebok[1], C. Fraune[1], S. Minner[1], N. Gorbokon[1], **M. Lennartz**[1];
[1]University Medical Center Hamburg-Eppendorf, Hamburg, Germany, [2]Academic Hospital Fuerth, Fuerth, Germany

Thymidylate synthase (TS, TYMS) is an enzyme that catalyzes the conversion of deoxyuridine monophosphate (dUMP) to deoxythymidine monophosphate (dTMP) which is one of the nucleotides forming the DNA. TYMS is thus essential for DNA synthesis and represents an important target for several chemotherapeutic drugs including 5-fluorouracil (5-FU) and methotrexate. It has been suggested that tumors with low-levels of TYMS may show a better response to 5-FU than those with high-level expression. Literature data on TYMS expression in different cancer types is controversial, however. To better comprehend the role of TYMS expression in cancer, TYMS was analyzed by immunohistochemistry (IHC) on tissue microarrays (TMAs) containing 9,015 samples from 127 different tumor types as well as 8 samples each of 6 different normal tissue types. TYMS immunostaining was always cytoplasmic and/or nuclear. It was only detectable in a minority of normal cell types and was strongest in a subset of lymphoid cells, especially in germinal centers and in the thymus as well as in hematopoetic cells of the bone marrow. Detectable TYMS staining occurred in 3,749 (46.7%) of the 8,030 analyzable tumors, including 2,958 (36.8%) with weak, 609 (7.6%) with moderate, and 182 (2.3%) with strong positivity. A total of 114 of 127 tumor categories showed TYMS expression in at least one case, 64 tumor categories showed TYMS staining ≥50% of cases, and 47 tumor categories included at least one case with strong TYMS positivity. The frequency of TYMS positivity was highest in various subtypes of B- and T-cell lymphoma (80-100%), sarcomas, carcinosarcomas and sarcomatoid carcinomas (33.3-100%), primary and metastatic malignant melanoma (70.5-90.7%), adenocarcinoma of the uterine cervix (78.3%), squamous cell carcinomas of various sites of origin (57.1-77.9%), and testicular germ cell tumors (19.4-67.4%). In all four tumor entities for which clinico-pathological data could be assessed, high TYMS expression was associated with features of aggressive disease. High TYMS expression was linked to high histologic grade ($p<0.0001$) in endometrioid endometrium carcinoma, advanced pT stage ($p=0.0061$) in high-grade serous ovarian carcinoma, poor histologic grade ($p<0.0001$) in squamous cell carcinomas of 11 different organs of origin, and to advanced stage ($p<0.0001$), tumor invasion in blood and lymph vessels ($p\leq0.0064$) as well as microsatellite instability ($p<0.0001$) in colon cancers. TYMS is often overexpressed as compared to normal tissues in a broad range of different cancer entities. Our data suggest that high-level of TYMS expression is a feature of cancer aggressiveness in many different cancer types.

#1048 Loss of MTAP expression is strongly linked to homozygous 9p21 deletion, unfavorable tumor phenotype and non-inflamed microenvironment in urothelial bladder cancer.

N. Gorbokon[1], N. Wo?ner[1], V. Ahlburg[1], S. Schallenberg[2], H. Plage[2], S. Hofbauer[2], K. Furlano[2], S. Weinberger[2], P. G. Bruch[2], F. Ro?ner[2], S. Elezkurtaj[2], **M. Lennartz**[1], N. C. Blessin[1], A. H. Marx[3], H. Samtleben[3], M. Fisch[1], M. Rink[4], M. Slojewski[5], K. Kaczmarek[5], T. Ecke[6], S. Hallmann[6], S. Koch[6], N. Adamini[7], S. Minner[1], R. Simon[1], G. Sauter[1], H. Zecha[7], D. Horst[2], T. Klatte[2], T. Schlomm[2], M. Kluth[1];

[1]University Medical Center Hamburg-Eppendorf, Hamburg, Germany, [2]Charite - Universitatsmedizin Berlin, Corporate Member of Freie Universitat Berlin, Humboldt-Universitat zu Berlin and Berlin Institute of Health, Berlin, Germany, [3]Academic Hospital Fuerth, Fuerth, Germany, [4]Marienhospital Hamburg, Hamburg, Germany, [5]Pomeranian Medical University, Szczecin, Poland, [6]Helios Hospital Bad Saarow, Bad Saarow, Germany, [7]Albertinen Hospital, Hamburg, Germany

9p21 deletions are common in urothelial carcinoma and mostly include S-methyl-5′-thioadenosine phosphorylase (MTAP) a critical enzyme for DNA and RNA synthesis. Homozygous MTAP deletions result in a complete loss of expression which can be visualized by immunohistochemistry (IHC). Evidence is emerging that MTAP deficiency results in a critical vulnerability of cancer cells towards drugs targeting multiple different pathways that depend on a functional MTAP gene and causes resistance to immune checkpoint inhibitors. To determine the prevalence and clinical significance of MTAP deficiency and its relationship with the tumor microenvironment in urothelial bladder carcinomas, more than 2,500 tumors were analyzed by fluorescence in-situ hybridization (FISH) and IHC in a tissue microarray format, and the data were compared with existing data on intratumoral lymphocyte subsets and PD-L1 expression. The cohort included 1,826 patients that underwent radical cystectomy for muscle-invasive disease (pT2-4). 9p21 deletion was homozygous in 364 (21.3%) and heterozygous in 334 (19.5%) of 1,711 analyzable tumors. The rate of 9p21 deleted tumors increased from pTa G2 low (9.2% homozygous, 25.8% heterozygous) to pTa G2 high (32.6%, 20.9%; p<0.0001) but was slightly lower in pTa G3 (16.7% each). In pT2-pT4 carcinomas, 9p21 deletions were homozygous in 23.3% and heterozygous in 17.9%. Within muscle-invasive cancers, 9p21 deletions were tied to high pT (p=0.0014) and poor overall survival (p=0.0461). MTAP expression loss was strongly linked to homozygous 9p21 deletions. Complete absence of MTAP staining was seen in 96.1% of homozygous deleted cancers while only 4 of 249 MTAP negative cancers had retained at least one 9p21 copy (p<0.0001). Accordingly, absence of MTAP staining was also linked to advanced pT status and poor overall survival (p<0.05 each). Tumors with heterozygous 9p21 deletion did often show preserved but low-level expression of MTAP. 9p21 deletions were associated with low numbers of PD-L1 positive tumor cells (p<0.0001), CD8 (p=0.01) and CD4 positive lymphocytes (p=0.009), M2-macrophages (p<0.0001), and dendritic cells (p=0.0007). A similar tendency was observed for MTAP expression loss, but the level of significance was only reached for PD-L1 positive tumor cells (p<0.0001), M2 macrophages (p=0.001) and dendritic cells (p=0.012). Complete MTAP expression loss is common in urinary bladder cancer and strongly tied to homozygous 9p21 loss, aggressive disease, and non-inflamed microenvironment. Drugs targeting MTAP-deficiency may be highly useful in bladder cancer. MTAP IHC is an excellent surrogate for the detection of MTAP deficiency in this tumor entity.

#1049 Prevalence of KDM6A expression loss in human cancer: A tissue microarray study on 6,560 cancers from 114 different tumor types.

F. Viehweger[1], N. Gorbokon[1], **M. Lennartz**[1], V. Reiswich[1], F. Lutz[1], T. Krech[1], A. M. Luebke[1], C. Hube-Magg[1], G. Sauter[1], R. Simon[1], S. Steurer[1], A. H. Marx[2], C. Bernreuther[1], M. Kluth[1], S. Minner[1];

[1]University Medical Center Hamburg-Eppendorf, Hamburg, Germany, [2]Academic Hospital Fuerth, Fuerth, Germany

KDM6A, also known as UTX (ubiquitously transcribed X chromosome tetratricopeptide repeat protein) is an epigenetic regulator constituting a critical part of the COMPASS-like complex. KDM6A mutations occur commonly in cancer. These are of interest because KDM6A loss results in a dependency on EZH2, a potential therapeutic target. Most data on KDM6A have been obtained by next generation sequencing (NGS). However, since most KDM6A mutations are truncating and KDM6A is located on the X chromosome, many mutations result in a complete expression loss which can be detected by immunohistochemistry (IHC). To learn more on the prevalence of KDM6A expression loss and its role in cancer, a tissue microarray containing 6,560 samples from 114 different tumor entities and 608 samples of 76 different normal tissue types was analyzed. In normal tissues, KDM6A staining was rather ubiquitously seen in nuclei. In cancer, KDM6A staining was considered weak (1+) in 581 (11.2%), moderate in 1,927 (37%), and strong in 2,362 (45.4%) of 5,206 interpretable tumors. A complete loss of KDM6A staining occurred in 336 (6.5%) of tumors. At least one case with a complete KDM6A expression loss was observed in 51 of 114 tumor categories. KDM6A staining was most commonly lost in different categories of urothelial carcinomas (19.5-39.2%), squamous cell carcinomas of the esophagus (27.1%), hepatocellular carcinoma (18.4%), gastric carcinoma (3.2-12.5%), papillary renal cell carcinoma (9.5%), adenocarcinoma of the prostate (5.9-9.4%), chromophobe renal cell carcinoma (8.9%), Ewing sarcoma (8.3%), pheochromocytoma (8.3%), and metastatic malignant melanoma (8%). A KDM6A expression loss in less than 8% of cases was observed in 32 further tumor entities. KDM6A expression loss was more than twice as frequent in tumors from male (8.4% of 2,526) than in tumors from female patients (3.9% of 2,024; $p<0.0001$). It is concluded that KDM6A IHC is a suitable method for the detection of truncating KDM6A mutations, especially in males. These make up for about 2/3 of all KDM6A mutations and may exert specific biological effects than differ from the various KDM6A missense mutations known to also occur.

#1053 The Influence of PD1 and TIM3 Expression on CD4+CD103+ and CD8+CD103+ Cells in Glioblastoma Progression.

L. Gabriele[1], G. Romagnoli[1], Q. G. D'Alessandris[2], I. Capone[1], A. Tavilla[1], I. Canini[1], C. Lapenta[1], M. Buccarelli[1], M. Giordano[2], V. Tirelli[1], M. Sanchez[1], A. Fragale[1], S. Giannetti[3], R. Di Bonaventura[2], L. Lauretti[2], M. Biffoni[1], L. Ricci-Vitiani[1], R. Pallini[2];
[1]Istituto Superiore di Sanita, Rome, Italy, [2]Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome, Italy, [3]Universita Cattolica del Sacro Cuore, Rome, Italy

Glioblastoma (GB), IDH-wildtype, is the most common and aggressive high-grade primary malignant brain tumor with extremely poor outcome. Although the use of immune checkpoint inhibitors (ICIs) in GB has shown disappointing results, the identification of a small subgroup of responders underpins the role of the intratumoral immune contexture, in particular tumour-infiltrating lymphocytes (TILs), in determining disease outcome. This study aims to define the features of TIL subpopulations correlating with GB prognosis, and to establish in parallel the predictive roles of peripheral T cell subsets. A single cohort observational study, including patients undergoing GB resection and standard therapeutic and follow-up approaches in Neuro-Oncology, was conducted. Of the 45 patients, histologically confirmed WHO grade 4, 26 had MGMT promoter methylation (60.0%), 24 were male (53.3%) and the median age of young patients (≤63 years) vs elderly patients (>63 years) was 57 vs 71, respectively. Predictors of OS were KPS (≥70 vs <70: 14.7 vs 7.5 months, p=0.0007) and GTR (GTR vs non-GRT: 15 vs 9 months, p=0.004) whereas patients with methylated MGMT promoter had non-significant longer median OS compared to those with unmethylated promoter (14.5 vs 10.5 months). Patients were characterized for the expression of lineage, differentiation, memory, activation, and inhibition markers on intratumoral and peripheral CD4+ and CD8+ T cell subpopulations, and the correlation of an array of CD4+ and CD8+ T cell subsets with OS or PFS was evaluated by multiparametric flow cytometry and uni/multivariate analyses. Intratumoral immune infiltrate was positively associated with CD8+CD103+ tissue-resident memory T cells (Trm), and in particular with CD8+CD103+ Trm expressing PD1 and TIM3 rather than CD4+ Trm. Low CD8+CD103+PD1+ Trm resulted significantly associated with better OS and PFS (p=0.02 and 0.0031, respectively) and even higher significant was the correlation with better OS and PFS of low CD8+CD103+TIM3+ Trm (p=0.0002 and 0.0033, respectively) and CD8+CD103+PD1+TIM3+ Trm (p<0.0001, both). On multivariate analysis, low CD8+CD103+PD1+TIM3+ Trm and KPS ≥70 were confirmed to be the most predictive independent factors associated with longer OS (hazard ratios - HR [95%CI]: 0.14 [0.04 - 0.52] p<0.001, 0.39 [0.16 - 0.96] p=0.04, respectively). Moreover, CD8+CD103+ Trm subpopulations resulted age-related predictors for GB survival. Consistent with this finding, in vitro PD1 and TIM3 blockade released the capability of intratumoral T cells to produce the effector cytokines IFN-γ and TNF-α, and the cytotoxic factor GrzB. Conversely, T cells expressing PD1 and TIM3 of peripheral blood did not show any prognostic significance. In conclusion, low frequency of Trm expressing PD1 or TIM3 or both markers defined TIL subsets as independent positive prognostic factors for patient survival.

#1054 Reciprocal circRNA-miRNA expression axes indicative of early tumor initiation in breast.

N. A. H. Maatouk, S. H. H. Marei, A. B. A. Kurdi, N. S. K. Hamade, R. R. Nasr, R. S. Talhouk;
American University of Beirut, Beirut, Lebanon

Cancer prevention and early detection are the most effective tools for cancer control. In this study, we adopt a novel approach of identifying a network of proteins/mRNA-circRNA-miRNA axes. We hypothesize that mutation of oncogenes or tumor suppressor genes during pre-oncogenic stage result in aligned change in levels of circular RNAs-derived genes, as well as, reciprocally, in corresponding sponged miRNAs. These epigenetic risk predictive proteins/mRNA-circRNA-miRNA axes serve as potential tool for early detection of changes leading to breast cancer (BC) and can be further used as non-invasive screening biomarkers of patients' blood in populations susceptible to cancer. BC patients in GDC Data Portal, TCGA-BRCA project are selected based on several criteria such as their age at diagnosis (20-50 years old), early clinical stage of cancer (stage I) and disease type (ductal and lobular neoplasms). Differentially expressed genes are acquired from mRNA sequencing data by comparing Stage I Breast cancer versus normal primary tissues using R Studio. Then, mRNAs whose expression is aligned with the differentially expressed circRNAs and their host genes acquired from Gene Expression Omnibus (GEO) (GSE182471, Triple Negative Breast cancer tissues versus normal tissues) are selected. Differentially expressed miRNAs, in reciprocal expression with circRNAs, are defined using miRNA sequencing data of the same previously chosen TCGA BRCA patients. Selected miRNAs are hypothesized to be sponged with high confidence by selected circRNAs based on a context percentile binding score in CircInteractome. Using KM Plotter, the survival analysis of corresponding miRNAs in grade I BC patients is examined. The predicted miRNA expression was correlated with lower survival rates among stage I BC patients in KM Plotter. MiRNA-enrichment analysis is used to further validate the involvement of selected miRNAs in early tumorigenic events through exploring in which molecular pathways their downstream genes are enriched. We have constructed more than 20 potential proteins/mRNA-circRNA-miRNA axes for non-invasive screening of patients' body fluid (i.e. Blood) in populations susceptible to BC using RNA and miRNA sequencing data available in online databases and further validate the proposed axes using in-silico tools. The described axes, once validated in clinical samples could provide a potential tool for early-stage BC prediction and prevention.

#1055 ORF1p expression from LINE-1 occurs in clear cell ovarian carcinoma precursors and is detectable in patients' plasma samples.

P. R. de Santiago[1], S. Sato[1], Y. Zhuravlev[1], H. S. Rendulich[1], M. S. Taylor[2], C. Wu[3], M. C. Dougher[4], L. Schwartz[4], D. R. Walt[2], K. H. Burns[5], R. Drapkin[1]; [1]University of Pennsylvania, Philadelphia, PA, [2]Mass General Brigham, Boston, MA, [3]Life Sciences Institute, University of Michigan, Ann Arbor, MI, [4]Hospital of the University of Pennsylvania, Philadelphia, PA, [5]Dana-Farber Cancer Institute, Boston, MA

Long interspersed element 1 (LINE-1) retrotransposons are repetitive genomic sequences able to move across the genome by an autonomous "copy and paste" mechanism. Given the mutagenic potential of LINE-1, benign cells restrict its expression, although the molecular mechanisms involved are usually impaired in cancer. Clear cell ovarian carcinoma (CCOC) accounts for ~5-10% of ovarian cancers and is believed to arise from endometriosis. Women have a poor prognosis when it presents at an advanced stage, which emphasizes the need for a better understanding of the disease. In the present study, we found that ~85% of CCOC tumors express ORF1p, one of two proteins encoded by LINE-1. We show that CCOC cell lines retain ORF1p expression and release it into the extracellular media. By using single molecule array (Simoa) assays, we detected ORF1p in patient plasma, proposing ORF1p as a non-invasive biomarker for this disease. Finally, we found that LINE-1 retrotransposon de-repression is an early event in CCOC, as ORF1p is enhanced during the transition from typical to atypical endometriosis and that is retained in the invasive cancer.

#1056 Development of a B-cell epitope classifier for early detection of renal cell carcinoma.

Thomas W. Campbell[1], Christian R. Hoerner[2], Elizabeth Alli[3], John T. Leppert[4], John C. Shon[1], Alice C. Fan[2]

[1]Serimmune Inc., Goleta, CA,[2]Division of Oncology, Department of Medicine, Stanford School of Medicine, Stanford, CA,[3]Department of Cancer Biology, Wake Forest University School of Medicine, Winston-Salem, NC,[4]Department of Urology, Stanford University, Goleta, CA

A blood biomarker for early detection of renal cell carcinoma (RCC) would help decrease the burden of 15,000 deaths annually in the U.S. (1). Antibodies against tumor (neo)antigens are thought to arise early in cancer development and might serve as a more sensitive biomarker for RCC than tumor-derived biomolecules. Serum Epitope Repertoire Analysis (SERA) of human serum/plasma uses a random bacterial peptide display library and next generation sequencing to allow for unbiased highly multiplexed profiling of B cell epitopes. In combination with bioinformatic methods and machine learning, a classifier was trained to predict the presence of RCC using a cohort of 163 treatment-naïve patients (median age 62, stage: I 35%, II 5%, III 20%, IV 40%) with clear cell RCC (ccRCC) and 438 age-matched healthy controls (median age 61). Classifier performance was evaluated by sensitivity, specificity, and receiver operator curve (ROC) area under the curve (AUC) analysis in an independent validation cohort of 43 treatment-naïve patients with ccRCC (age 22-86, median 63, stage: I 33%, II 2%, III 26%, IV 39%) and 1,759 healthy controls (age 18-89, median 40). A total of 1,465 individual B cell epitope features were discovered and enriched in ccRCC vs. controls and included in a random forest model. In the validation cohort, the ROC-AUC was 0.65, and sensitivities of 9%, 16%, 30%, and 36% were achieved at specificities of 99%, 98%, 95%, and 90%, respectively. Performance was better in both early stage ccRCC and low tumor grade (grade 1 or 2). For stage I, the ROC-AUC was 0.88, and sensitivities of 7%, 14%, 36%, and 57% were achieved at specificities of 99%, 98%, 95%, and 90%, respectively. For low tumor grade, the ROC-AUC was 0.86, and sensitivities of 10%, 20%, 50%, and 60% of were achieved at specificities of 99%, 98%, 95%, and 90%, respectively. The classifier did not miscategorize benign renal lesions as ccRCC (Mann-Whitney p-value 0.52, ROC-AUC 0.54) in a separate cohort of 23 patients with benign renal tumors vs. the 1,759 healthy controls. This preliminary performance for a B cell epitope-based classifier is promising: the better performance in early stage ccRCC suggests that B cell epitope biomarkers may complement the lower sensitivity of cell-free DNA for detecting early-stage cancer (2). Future work will further validate these results in larger multi-institutional cohorts to improve classification performance and explore if B cell epitope biomarkers can be combined with existing assays to develop an early detection composite biomarker for RCC and tumor grade.

#1057 A blood-based multi-omics test for multicancer early detection: Combined retrospective and prospective studies.

M. Mao[1], S. Li[1], Q. Ren[2], Y. Luan[3], W. Liang[4], S. Geng[5], D.-L. Huang[1], D. Zhu[5], Y. Chang[5], W. Wu[1], Y. Zhang[4], L. Zhang[4], Y. Wang[4], Y. Feng[1], B. Wei[6], J. Ma[6], C. Duan[3], G. Long[2];

[1]Research & Development, SeekIn Inc, Shenzhen, China, [2]Peking University Shenzhen Hospital, Shenzhen, China, [3]Sun Yat-sen Memorial Hospital, Sun Yat-Sen University, Guangzhou, China, [4]The First Affiliated Hospital of Zhengzhou University, Zhengzhou, China, [5]Clinical Laboratories, Shenyou Bio, Zhengzhou, China, [6]Henan Cancer Hospital, The Affiliated Cancer Hospital of Zhengzhou University, Zhengzhou, China

Background: Recent studies have demonstrated that blood-based multi-cancer early detection (MCED) approaches may hold promise for identifying asymptomatic cancer patients from general population. However, most studies only exploit a single aspect of cancer hallmarks, which is challenging for the biological reasons as cancer is a heterogenous disease with a wide spectrum of pathological and clinical behaviors. Here we report a multi-omics MCED assay named SeekInCare, a CE-IVD Mark blood test, which incorporates genomic hallmarks: copy number aberrations, fragment size, end motifs and oncogenic viruses via shallow whole genome sequencing from cfDNA, and seven plasma protein tumor markers in 8 ml blood.

Methods: SeekInCare was developed using several retrospective cohorts and the method has been described in a publication (DOI: 10.1016/j.jmoldx.2021.06.003) IF: 4.1 Q2 .

Results: We present the validation in a retrospective cohort consisting of 584 non-cancer individuals and 617 cancer patients covering 27 cancer types. SeekInCare achieved 65.5% sensitivity at 97.9% specificity, resulting in an AUC of 0.936. The sensitivities were 46.9%, 60.0%, 68.9%, 81.8% in stage I, II, III, IV patients. The sensitivities of 10 common cancer types are as the following: breast (46.2%), stomach (46.4%), colorectum (56.5%), gallbladder (60.0%), lung (62.8%), pancreas (64.7%), lymphoma (68.5%), esophagus (70.0%), liver (77.5%), and leukemia (86.7%). These cancer types account for 73.5% of cancer incidence and 81.8% of cancer-related mortality in China. We prospectively evaluated SeekInCare in a real-world cohort consisting of 1203 individuals who received the test as a laboratory developed test (median follow-up time: 753 days) in which it achieved 60.0% sensitivity, 96.1% specificity, 11.5% PPV and 99.7% NPV.

Conclusion: The performances of SeekInCare in both retrospective and prospective studies demonstrate that SeekInCare is an effective blood-based MCED test with similar performance as Grail’s Galleri test, which paves the way for clinical utility as a cancer screening test in average-risk populations.

#1058 Immune biomarkers for recurrence in stage II and III melanoma to guide patient stratification.

Gerardo A. Espinoza[1], Chenxin Zhang[2], Jee-Young Moon[2], Divya B. Kenchappa[1], Matteo Abbruzzese[3], Lydia Bioh[1], Yadriel M. Bracero[1], Sharmin Sultana[1], Ajay Singh[1], Thazin Aung[4], John J. Krolewski[5], Robyn D. Gartrell[6], Larisa J. Geskin[7], Lawrence W. Leung[1], Tammie Ferringer[8], Rui Chang[9], Basil Horst[10], Kent Nastiuk[11], **Yvonne M. Saenger**[1]

[1]Cancer Center, Albert Einstein College of Medicine, Bronx, NY,[2]Epidemiology and Population Health, Albert Einstein College of Medicine, Bronx, NY,[3]Medicine, Albert Einstein College of Medicine, Bronx, NY,[4]Pathology, Yale School of Medicine, New Haven, CT,[5]Biology and Interdisciplinary Unit for Data Science & Analytics, Buffalo State University, Buffalo, NY,[6]Pediatrics, Columbia University Irving Medical Center, New York, NY,[7]Dermatology, Columbia University Irving Medical Center, New York, NY,[8]Dermatopathology, Geisinger Medical Laboratories, Danville, PA,[9]Nuerology, University of Arizona College of Medicine, Tuscon, AZ,[10]Pathology and Laboratory Medicine, The University of British Columbia, Vancouver, BC,[11]Cancer Genetics and Genomics, Roswell Park Comprehensive Cancer Center, Buffalo, NY

Stage II-III melanoma patients lack needed biomarkers to avoid over-treatment and determine need for combination immunotherapy. A “hot” tumor immune micro-environment (TIME) is predictive of survival and immunotherapy benefit in multiple tumor types. We have previously identified the ratio of CD8+/CD68+ cells as well as a 53-gene melanoma immune panel (MIP) as indicative of a favorable “hot” TIME. CD8/CD68 ratio and MIP were evaluated in specimens from 213 previously untreated patients including 164 from Roswell Park Comprehensive Cancer Center (RPCCC) and 49 from Geisinger Health Systems (GHS, n=36). Tumors were stained with Sox10, CD8, CD68, MPO, PDL1 and HLA-DR using the MOTiF workflow (Akoya Biosciences, AB). Image analysis was completed using inForm software (AB). RNA was extracted and NanoString analysis performed using published methods. Receiving Operator Curves (ROC) were generated and KM curves using cutoffs selected using maximally selected log-rank statistics to quantify survival benefit. We tested whether the CD8/CD68 ratio correlated with disease specific survival (DSS) and distant metastatic recurrence (DMR). In the RPCCC cohort (n=164), 138 specimens were evaluated by a pathologist and stained of which 15 were excluded based on tissue quality, and inForm analysis was completed on 80. Of these 80, 16 had DMR of whom 8 had died. ROC showed CD8/CD68 ratio to correlate with DMR (p=0.0397). KM analysis showed high CD8/CD68 ratio correlated with DMR free survival (p=0.00079). Within the GHS samples, 36 of 49 patients had sufficient quality tissue, of whom 13 had died. DMR data was not available. A high CD8/CD68 ratio correlated with DSS by ROC curve (p=0.027) and KM analysis (p=0.0009). MIP was run on 166 patients of whom 147 passed quality control for analysis. MIP correlated with DSS in the RPCCC cohort by ROC analysis (p=0.025) and cutoff defined based on prior cohort showed correlation with DSS (p=0.01) and trend towards correlation with DMRFS (p=0.065). To include diverse samples in the training set, MIP was retrained with the addition of 81 patients from Columbia University (CUMC). KM analysis performed using the retrained signature showed a favorable signature correlated with DSS (p=0.032) and DMRFS (p=0.00077). Immune based biomarkers including CD8/CD68 ratio and immune gene signature have potential to assist clinicians in selecting early-stage melanoma patients for more intensive immunotherapy regimens. Full analysis of the data from the RPCCC and GHS cohorts will be presented at the conference.

#1059 Biomarkers analysis on samples from patients in EVT801 clinical trial: Patient characterization and immunomonitoring.

L. Davenne[1], M. Fitzgerald[2], P.-B. Ancey[1], O. Delpuech[1], C. Poussereau-Pomie[1], M. Esquerre[1], M. R. Paillasse[1], M. Mandron[1], P. Rochaix[3], M. Ayyoub[3], C. Scarlata[3], C. Caux[4], C. Caux[4], P. Cassier[4], C. Gomez-Roca[3], J.-P. Delord[3], J. Friend[2], **P. Fons**[1];
[1]Evotec International GmbH, Toulouse, France, [2]Kazia Therapeutics, Sydney, Australia, [3]Institut Universitaire du Cancer Toulouse-Oncopole, Toulouse, France, [4]Centre Leon Berard, Lyon, France

Introduction: EVT801 is a highly selective small molecule inhibitor of VEGFR3 that acts by inducing tumor (lymph)-angiogenesis normalization in and around the tumor. EVT801 has shown compelling activity in a wide range of cancer models showing a decrease of tumor hypoxia and an increase of $CD8^{pos}$ T-cells infiltration into the tumor micro-environment. EVT801 was well-tolerated in preclinical toxicology studies. A phase I study is underway focusing primarily on understanding the safety, tolerability, and pharmacokinetics of EVT801 across a range of doses (NCT05114668).
Methods: The first stage of the phase I trial aims to determine the maximum tolerated dose (MTD) and recommended Phase II dose (RP2D) for EVT801. Clinical samples from enrolled patients have been collected to explore preliminary signals of the biological activity of the drug and characterize tumor phenotypes. Patient characterization includes histology and mRNA signature in archival biopsies. Target engagement and pharmacodynamics effects are investigated by immunomonitoring as well as assessment of a defined set of proteins as markers of inflammation and angiogenesis as identified in preclinical *in vivo* models.
Conclusion: Our first biomarkers analyses on a subpopulation of patients with High Grade Serous Ovarian Cancer (HGS-OC) enrolled in the first stage of the study showed that levels of VEGFR3 expression had a negative correlation with CD8 positive T-cells infiltration in the tumor microenvironment and a tendency to positive correlation with a PD1 mAb resistance signature. VEGFR3 expression also tends to be correlated with higher levels of hypoxia (CAIX labelling). Our working hypothesis is that patients with hypoxic HGS-OC tumors with high VEGFR3 expression may benefit from EVT801 treatment; this will need to be reinforced by inclusion of additional patients in dedicated PD biomarkers cohorts during stage 2 of the clinical trial.

#1060 Circulating early myeloid derived suppressor cells as biomarkers for early detection of lung cancer.

O. Fortunato[1], B. Bassani[2], M. Lecchi[1], P. Verderio[1], U. Pastorino[1], G. Sozzi[1], M. Colombo[1], **S. Sangaletti[1]**;
[1]Istituto Nazionale dei Tumori, Milano, Italy, [2]Multimedica, Milano, Italy

Background. Lung cancer (LC) patients, despite innovative cancer treatments such as target and immune-therapies, still have the poorest five-year survival rate. In this context the possibility of an early detection can anticipate therapeutic intervention, avoiding aggressive therapies thus prolonging disease-free and overall survival. Therefore, the identification of new circulating early biomarkers still represents a relevant clinical need.
Methods. Lung cancer (LC) patients (n=63) and heavy smokers (HS) cancer free-subjects (n=52) were evaluated for the enrichment of specific subtypes of myeloid cells. Circulating early myeloid derived suppressor cells (eMDSCs) and low-density neutrophils (LDNs) were assessed by flow cytometry on peripheral blood mononuclear cells (PMBCs). Early MDSCs were defined as CD11b+CD33+CD15-CD14- cells among Lineage negative (Lin-) HLA-DR- PBMCs, whereas LDNs were defined as CD66b+CD15+ cells within the gate of CD11b+ PBMCs. Mature and immature subtypes were discriminated according to the expression of CD10.
Results. Performing a sex- and smoking -matched case-control analysis in 39 LC and 39 HS subjects we were able to compare the capacity of specific myeloid population to discriminate lung cancer patients from heavy smokers. The analysis showed significantly higher values of eMDSC (OR=1.12; 95% Confidence Interval (CI) 1.03-1.21), total LDN (CD66b+CD15+; OR=1.23; 95%CI 1.04-1.45) and of mature CD10+ LDN (OR=1.30; 95%CI 1.05-1.61). Moreover, within the overall cohort of 63 LC patients, we analyzed the distributions of the different myeloid populations according to stage (I-II vs III-IV). In this comparison, total LDN (CD66b+CD15+; Kruskal-Wallis (KW) Test p-value=0.014), and mature CD10+ LDN (KW test p-value=0.006) showed significant different distributions according to tumor stage, observing higher values in patients with advanced stage. On the contrary, no difference among stages was observed for the eMDSC population.
Conclusions. These findings point to eMDSCs as an early marker for lung cancer detection whereas LDN could be as well associated with disease progression.

#1061 Diagnostic application of a novel blood CDH17 immunoassay in the detection of colorectal adenoma.

N. Lui[1], F. Hon[2], S. Sun[2], P. Leung[2], D. Ho[2], J. M. Luk[3], **D. C. Foo[1]**;
[1]The University of Hong Kong, Hong Kong, Hong Kong, [2]Tiberias Technology (HK) Limited, Hong Kong, Hong Kong, [3]Arbele Corp, Seattle, WA

Background: Colorectal cancer (CRC) is the most prevalent gastrointestinal (GI) cancer and contribute significantly to global cancer deaths. The mechanism of CRC development is a complex multistage process from hyperplastic lesions to the formation of adenomas, followed by the progression into malignancy. Hence, early detection during hyperplastic and adenomatous stages warrants new screening tests for effective interception of malignancy progression. Cadherin-17 (CDH17) is a biomarker characterized by its overexpression in several GI cancers, but restricted expression in intestinal mucosal epithelium of normal tissues. We have developed a blood immunoassay using a panel of RUO grade antibodies that unveiled CDH17 as a potential marker with high detection sensitivity and specificity for detecting adenomas. Our immunoassay is useful in identifying high-risk individuals with adenomas that may develop into CRC, which can significantly improve the diagnostic efficiency of colonoscopy that is currently lacking.
Methods: The study recruited 66 patients (54 adenoma and 12 hyperplasia) and 39 normal samples (no abnormality by colonoscopy). CDH17 level in plasma samples were measured using the CDH17 immunoassay.
Results: The novel CDH17 diagnostic assay showed an operating dynamic range from 90ng to 123pg. We observed a progressive and significant increase in the circulating CDH17 level from normal samples to the hyperplasia group, followed by the adenoma group (mean: 1.66ng/mL, 3.20ng/mL, 4.93ng/mL, respectively P<0.0001). The assay performance by ROC curve demonstrated an AUC of >0.9, with a sensitivity of 85% and specificity of 86%. NPV and PPV were 84% and 87%, respectively. The assay outperforms two market available FIT-DNA tests at predicting adenomas (Table. 1).
Conclusion: The novel CDH17 immunoassay is potentially a powerful tool for the detection of aberrant plasma CDH17 expression, improving the surveillance and the detection of high-risk individuals for CRC.

CDH17 immunoassay outperforms market availalble FIT-DNA tests at detecting hyperplasia and adenoma

		FIT-DNA test 1	FIT-DNA test 2	CDH17 blood immunoassay
		Age 40-74	Age 50-84	Age 45-93
Sensitivity (%)	Advanced adenoma	63.5	42.4	85.0
	Non-advanced adenoma (i.e Hyperplasia)	Unavailable	17.2	58.3
Specificity (%)	Normal control (no abnormality by colonoscopy)	87.1	89.8	86.1

#1062 Clinical validation: A blood-based biomarker for early lung cancer detection based on circulating DNA fragmentomics.

P. Mazzone[1], P. B. Bach[2], **L. B. Cotton**[2], C. A. Schonewolf[2];
[1]Cleveland Clinic, Cleveland, OH, [2]DELFI Diagnostics, Inc., Baltimore, MD

PURPOSE: Screening for lung cancer using a biomarker blood test has the potential to overcome the currently low adherence rates in the US, offering patients a convenient and accessible option. Integrating routine blood draws into lung cancer screening could boost participation, mirroring the success of non-invasive tests in colorectal screening. Numerous proof-of-concept studies indicate that analyzing genome-wide cfDNA fragmentation patterns can effectively distinguish between individuals with and without lung cancer. We conducted a multi-institutional case-control study to train and validate a fragmentome based cfDNA classifier for lung cancer early detection.
METHODS: The DELFI-L101 study (NCT04825834) is a prospective, multi-site, observational case-control study designed to develop and validate an early detection test for lung cancer. The DELFI (DNA Evaluation of Fragments for Early Interception) method utilizes low-pass whole genome sequencing, a cost-effective approach that examines cell-free DNA (cfDNA) fragmentation patterns associated with lung cancer. Enrolled participants were aged ≥50 y, smoking history of ≥20 pack-years, and had undergone or had planned chest CT imaging. Medical histories were documented, and blood samples were collected for DELFI analysis. A classifier, developed through supervised machine learning, was created to distinguish between samples from individuals with lung cancer and those without. Performance was assessed through repeated 10-fold cross-validation in the training set and then subsequently assessed in an independent split-study clinical validation set. The classifier was optimized for the sensitivity detection of lung cancer in the screening-eligible population. Performance was evaluated across patient and tumor characteristics, adjusting the stage distribution to match that of LDCT screening populations.
RESULTS: In an analysis of 958 participants from both the lung cancer and non-cancer control groups, the sensitivity of the test remained consistent across various participant demographics, comorbidities, and tumor characteristics, increasing with higher group, T, and N stages. The stage weighted sensitivity for the screening population was 80% (95% CI: 75%-86%), with a specificity of 53% (95% CI: 43%-64%). At a prevalence of 0.7%, the negative predictive value was 99.7%.
CONCLUSIONS: Clinical validation of the DELFI-based blood test demonstrates its potential to detect lung cancer within the screening eligible population. A negative result is associated with a high negative predictive value. Given the limited adoption of low-dose computed tomography (LDCT) screening, especially among socio-economically disadvantaged individuals, this clinically validated, blood-based cfDNA test could significantly increase LDCT screening participation.

#1063 IsomiR relative proportion (IRP) within miRNA family as an efficient biomarker for noninvasive colorectal cancer detection.

Y. Hu[1], W. Lu[1], C. Liu[1], X. Dai[2], J. Xu[1], X. Kong[1], Y. Zhu[3], Y. Ye[1], L. Chen[1], X. An[2], F. Wu[2], S. Ma[2], N. Wang[2], Q. Xiao[1], J. Liu[2], **K. Ding**[4];
[1]Ministry of Education, The Second Affiliated Hospital, Zhejiang University School of Medicine, Zhejiang University Cancer Center, Hangzhou, China, [2]New Horizon Health Research Center, Hangzhou, China, [3]Haining Hospital of Traditional Chinese Medicine, Haining Cancer Prevention and Treatment Research Institute, Haining, China, [4]The Second Affiliated Hospital, Zhejiang University School of Medicine,Center for Medical Research and Innovation in Digestive System Tumors, Ministry of Education, Cancer Center of Zhejiang University, Hangzhou, China

Background: Cell free miRNA has been widely used for disease diagnosis, particularly in cancers. The latest research has also demonstrated that isomiRs (isoform miRNAs) can serve as superior markers, displaying enhanced diagnostic performance in cancer diagnosis. However, the low detection sensitivities of miRNA/isomiRs in previous methods in plasma have limited their broad implementations for screening purpose. In this study, we propose a new isomiRs feature of isomiR relative proportion (IRP), which was validated with high performance in Colorectal Cancer (CRC) early diagnosis.
Methods: A total of 1036 participants were enrolled from the National Colorectal Cancer Cohort (NCRCC), and 836 participants were eligible for plasma collection, including 238 controls, 373 CRC patients, 41 inflammatory bowel disease (IBD), 5 intramucosal carcinoma (Tis) and 179 advanced precancerous lesions (APL). Total circulating small RNA was extracted, followed by library preparation using UMI-based approach. Subsequently, small RNA sequencing was conducted using DNB-seq, and bioinformatic analysis was performed thereafter. The samples were randomly assigned into training (49%), test (30%) and validation (21%) sets. Models based on isomiR relative proportion (IRP), isomiR relative expression (IRE) or both features were constructed by beam search and random forest algorithms in training and test sets, and results were verified in validation set.
Results: Differential IRP or IRE features were identified between cancer and controls. IRP identified 132 specific differential expressed isomiRs. Models constructed using either IRP or IRE features showed high performance (both AUC > 0.9). However, there was improvement in IRP feature model in the validation set (sensitivity of IRP: 0.923, sensitivity of IRE: 0.859) compared with IRE model. We then found that there may be complementarities between IRP and IRE features, and the combination model (34 IRP+IRE features) improved cancer detection performance (AUC: 0.953). Finally, the risk scores predicted by this combination model increased gradually across CRC progression (R=0.921), and the sensitivity of APL was 0.626.
Conclusion: We improved the small-RNA sequencing method and developed an IRP method, and present that IRP as a new feature not only demonstrate the ability of CRC early detection, but also revealed the CRC progressing process. Besides, the combination of IRP and IRE improved the performance of diagnosis. These results highlight the potential value of the IRP feature in early cancer detection.

#1065 Two-step method for early detection of ovarian cancer with high specificity via platelet RNA.

E. Ahn[1], S. Kim[2], S. Park[1], S. Kim[1], Y. Kim[3], E. Huang[3], S. Lee[3], D. Hwang[2], H. Kim[4], H. Jo[4], U. Cho[4], J. Lee[5], T. Ahn[3], Y.-S. Song[6];
[1]ForetellMyHealth, Inc., Seoul, Korea, Republic of, [2]Seoul National University College of Medicine, Seoul, Korea, Republic of, [3]Handong Global University, Pohang, Korea, Republic of, [4]Cancer Research Institute, Seoul National University College of Medicine, Seoul, Korea, Republic of, [5]Cancer Research Institute, Seoul National University College of Medicine,, Seoul, Korea, Republic of, [6]Myongji Hospital, Goyang, Korea, Republic of

Owing to lack of disease-specific symptoms and screening methods, most of patients with ovarian cancer are diagnosed at an advanced stage. Recent technology based on platelet RNA aids in detection of tumors at the early stages. Also, for population screening of low-prevalence diseases like cancer, accurate detection with high specificity is essential to improve diagnostic methods. Thus, we proposed platelet RNA-based early ovarian cancer detection with great specificity. It is a two-step method for detecting ovarian tumors with more than 99% specificity using exon-exon junction features and sampling invariant normalization and finding their malignancy with more than 99% negative predictive value using exon-exon junction and hematology parameters. First, we downloaded public platelet transcriptome data of gynecological cancer including ovarian cancer (n=151), benign tumor (n=30), and healthy counterparts (n=218) from GEO (GSE158508, 89843, and 183635). Second, we prospectively enrolled patients with gynecological cancer (n=31), benign tumors (n=20), and healthy women (n=18) at Seoul National University Hospital (SNUH) and Boaz Medical Center and obtained platelet transcriptome data (FMH data). Feature selection and model development were conducted using public training set (n=243), public validation set (n=156), and FMH training/validation set (n=47). The batch-invariant normalization was performed, and 198 splice junctions were selected as features from training/validation set for the bootstrap aggregation of the SVM model diagnosing the existence of an ovarian tumor. The model performance was assessed from a separate test set only composed of FMH data (n=22). Our model that demonstrated 96.8% sensitivity, 100.0% specificity, with a predetermined cut-off value. Next, FMH training/validation set was used for model development of following malignancy test. 10 splice junctions and 19 hematology parameters were selected and SVM models were separately developed for splice junctions and hematology parameters using 5-fold cross validation. The predictions were combined using a logical OR operation to obtain the final prediction result. The result showed its diagnostic performance with 100% sensitivity or NPV, and 50.0% specificity in the test data set with a predetermined cut-off value. We proposed a two-step method to operationally improve the existing protocol for ovarian cancer screening. Our model initially excludes most healthy individuals who do not have ovarian tumors and excludes patients with benign ovarian tumors who do not necessitate medical testing. To conclude, our model allows physicians to identify a subset of ovarian tumor patients with a higher risk of malignancy even at early stages; it exhibits potential in enhancing early diagnosis of ovarian cancer, leading to increase of treatment effectiveness and ultimately augmenting the survival of patients with ovarian cancer.

#1066 Colocalization of ovarian cancer-associated biomarkers in tumors, cancer cells and extracellular vesicles.

A. D. Couvillon[1], E. S. Winn-Deen[1], S. Thornton[2], S. Liu[2], M. DeRan[3], M. Pacula[4], S. Banerjee[1], D. Gusenleitner[1], L. T. Bortolin[1], J. Grosha[1], T. Santos-Heiman[1], G. [1]Mercy Bioanalytics, Waltham, MA, [2]University of British Columbia, Vancouver, BC, Canada, [3]Diamond Age Data Science, Somerville, MA, [4]Flagstaff Solutions, Acton, MA

Introduction: We have previously shown that ovarian cancer can be detected with high specificity and sensitivity by interrogating colocalized membrane-associated cell-surface biomarkers on single tumor-associated extracellular vesicles (EVs). Our blood based Ovarian Cancer Test (OC Test) is composed of 5 cancer-associated biomarkers (BST-2, FOLR1, MUC-1, MUC-16, and sialylated Thomsen-nouveau antigen (sTn)) known to be overexpressed in ovarian cancer relative to healthy tissues. The test employs these 5 biomarkers in 3 combinations to capture and detect EVs from human plasma to distinguish high-grade serous ovarian carcinoma (HGSC) from both benign ovarian tumors and normal samples. Using super-resolution microscopy on ovarian cancer cell lines and EVs and multiplex immunohistochemistry of ovarian benign and tumor tissue, our study aimed to show that the 5 ovarian cancer biomarkers show 1) colocalization on ovarian cancer cells, 2) colocalization on the surface of EVs, and 3) colocalization on cancer cells within ovarian tumor biopsies.

Methods: Super-resolution microscopy was employed to visualize stained biomarkers on the cell surface of a collection of ovarian cancer cell lines as well as on the surface of extracellular vesicles released by these cell lines. 58 HGSC (17 Stage I, 30 Stage II, and 10 Stage III) and 17 benign ovarian tumor K_2EDTA plasma samples and paired FFPE tissue were sourced from the Ovarian Cancer Research Program (OVCARE, Vancouver BC, Canada). A tumor microarray from identical tissue samples was stained with an Opal multiplex-IHC (mIHC) assay comprised of antibodies to BST2, MUC1, sTn, and pan-cytokeratin and a DAPI counterstain. Machine learning based image analysis was utilized to determine colocalization of the biomarkers at the cellular level within benign and tumor tissue. RNA sequencing was carried out to assess expression levels of the biomarkers in each FFPE tissue sample. OC Tests were run on each plasma sample.

Results: Super-resolution microscopy showed colocalization of OC Test combination biomarkers on ovarian cancer cells and EVs derived therefrom. Machine learning-based image analysis of tumor and benign tissue microarrays stained for BST2/MUC1/sTn using mIHC, showed strong evidence for colocalization of these biomarkers on single cells within ovarian tumor tissue, particularly in early-stage tumors, but not on benign tissue. RNA sequencing analysis showed good correlation of biomarker RNA expression levels and with the OC Test results.

Conclusions: The results presented here demonstrate that the OC Test biomarkers are colocalized on tumor tissue, ovarian cancer cells, and EVs from ovarian cancer cell lines. RNA and protein expression levels show good correlation with OC Test results. These results provide further evidence that colocalized biomarkers on EVs can be utilized for early detection of cancer.

#1067 Label free Raman spectroscopy of extracellular vesicles for early stage liquid biopsy cancer detection.

R. P. Carney[1], M. Navas-Moreno[2], A. Birkeland[1];
[1]UC Davis, Davis, CA, [2]illumifyDx, Broomfield, CO

Aim: To improve patient outcomes, there remains a critical need to develop faster, less invasive platforms capable of identifying biomarkers. Multi-omics approaches, while promising, are high in cost and complexity, low throughput, slow, and require large sample volumes, thus are impractical for many stages of clinical care. Raman spectroscopy (RS) addresses many of these needs: it requires little to no sample preparation, is non-destructive, does not need exogenous dyes or labelling agents, and can be performed directly in aqueous solutions. Surface enhanced Raman spectroscopy (SERS) offers further improvements in terms of sensitivity but increases complexity. In this study we carried out comprehensive RS and SERS measurements on a >100-person cohort of blood and saliva from head and neck cancer (HNC) patients and benign controls. Analyses were carried out on whole biofluids, in addition to extracellular vesicles (EVs) isolated from the biofluids to investigate the added value. EVs are emerging biomarkers of interest found in high numbers in circulating biofluids with great promise to increase the specificity of diagnostic platforms.
Results: We analyzed a robust clinical dataset of HNC patient saliva and plasma to build a diagnostic model. We found distinct Raman and SERS signatures of metabolites in all cancer samples uniquely present compared to non-cancer controls. Raman spectral measurements fused together for EVs and whole biofluids across saliva and plasma delivered accuracies of >95% using a novel machine learning module based on convolutional neural networks. Our platform features an automated method to isolate EVs amenable to rapid clinical use.
Conclusions: The results of this study indicate an exciting step in validating Raman as a robust diagnostic tool revealing that complementary chemical information spread out across biofluids and biomarkers of interest can strongly improve simple, quick Raman based diagnostics of whole biofluids and EVs.

#1068 Plasma metabolite biomarkers for EGFR-mutated non-small cell lung cancer (NSCLC).

L. Thamlikitkul[1], S. Manocheewa[1], S. Limjiasahapong[1], K. Wanichthanarak[1], A. Panya[2], N. Poungvarin[1], Y. Pomyen[3], S. Khoomrung[1];
[1]Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand, [2]National Center for Genetic Engineering and Biotechnology (BIOTEC), Pathumthani, Thailand, [3]Chulabhorn Research Institute, Bangkok, Thailand

Background: Lung cancer is the leading cause of cancer death. More than half of the patients are diagnosed in the advanced stage for which the 5-year survival is below 10%. Lung cancer screening using low-dose CT scan reduced lung cancer mortality among heavy smokers. However, no standard screening method exists for non-smokers. Up to 35% and 90% of male and female lung cancer patients in Southeast Asia, respectively, do not smoke. Half of NSCLC patients in this region harbor EGFR mutations, which is common in women and non-smokers. Thus, we sought to explore novel biomarkers that help to identify lung cancer patients and those who have EGFR mutation. Metabolic reprogramming is one of the hallmarks of cancer. It leads to changes in metabolite levels in the blood. Hence, we conducted plasma metabolomic analysis to identify potential metabolite biomarkers in lung cancer patients.
Methods: Plasma samples were collected from 69 lung cancer patients at Siriraj hospital and 10 healthy individuals during 2018-2022. Plasma metabolites from 29 treatment-naïve EGFR-mutated NSCLC patients, 30 treatment-naïve EGFR-wild-type NSCLC patients, 10 treatment-resistant EGFR T790M-mutated NSCLC patients, and 10 healthy individuals were profiled using GC-MS and untargeted LC-MS with Metlin database matching. EGFR mutation was detected from plasma ctDNA using real-time PCR. Negative plasma EGFR mutation results were confirmed with corresponding tumor tissues. Metabolomics data were processed by the metabox R package.
Results: Among 114 candidate metabolites that passed the variable importance in projection (VIP) cutoff of 1.5, the top ten metabolites that differentiate NSCLC patients with EGFR mutation from those without were shown in Table 1. Many of them can also separate between NSCLC patients and healthy individuals.
Conclusions: Plasma L-Histidinol, tryptophan, PC(20:0/24:0), and formic acid are potential metabolite biomarkers for NSCLC patients harboring EGFR mutation.

Table 1. ROC curve analysis

Discriminant metabolites (Mutated EGFR vs Wild-type EGFR NSCLC)	**AUC**	**Accuracy**	**Sensitivity**	**Specificity**

#1069 Interrogating the role of the cGAS/STING pathway fallopian tube transformation.

D. H. Al-Rawi, D. Norkunaite, S. Bakhoum, S. Shah;
Memorial Sloan Kettering Cancer Center, Manhattan, NY

Ovarian Cancer is the deadliest gynecologic malignancy. Despite recent advances in cancer diagnostics, it is a cancer that is often detected late and the vast majority of patients are diagnosed at Stage III and Stage IV. After treatment with debulking surgery and chemotherapy, 80% of patients have tumor relapse with increasing resistance. Early detection efforts have been largely unsuccessful and the only effective prevention strategy in high risk patients is surgical removal of the fallopian tube and ovaries. Careful pathologic studies of prophylactic risk reducing bilateral salpingo-oophorectomy (RRSO) has demonstrated that HGSC originates in the fallopian tube. Within the fallopian tube, secretory cells within the fimbriae are believed to be the origin of HGSC based on numerous lines of correlative evidence including the identification of histologically and molecularly abnormal regions in the fallopian tube called serous tubal intraepithelial cancer (STIC) in 3-5% of patients undergoing RRSO, and the presence of STIC in approximately half of patients undergoing debulking surgeries for HGSC. Finally, p53 mutations have been found to be identical in STIC and in the concurrent invasive disease indicating that HGSC and the STIC likely arise from the same clone. TCGA analysis has demonstrated that HCSC is a disease characterized by genomic and chromosomal instability harboring copy number alteration, including amplifications, deletions and more complex chromosomal rearrangements which impact multiple genes and pathways. Aberrantly segregating chromosomes that lag behind the spindle apparatus fail to become part of the primary nucleus (PN) and are instead enclosed by a self-assembled nuclear membrane, creating a structure called the micronucleus (MN). Spontaneous breakdown of the MN causes cytoplasmic DNA sensing and activation of the cGAS-STING pathway, an important innate cellular defense mechanism to foreign cytoplasmic DNA. To better understand the early genomic and signaling events in the development of HGSC, we are interrogating tissue from our archives from MSKCC patients who have undergone RRSO, hormone ablation surgeries or surgical debulking and were found to have benign fallopian tube, STIC lesions or invasive HGSC with STIC. We have performed a pilot experiment of 20 patient samples of different germline genetic backgrounds. Intriguingly, cGAS signaling was observed only rarely in the STICs indicating low rates of CIN in STICs we have evaluated, however we note that even in early invasive disease, we observe cGAS positivity. Taken together, these data are consistent with a model where CIN and subsequent cGAS/STING pathway activation drives the transition from pre-invasive to invasive disease.

#1070 Overcoming deficiencies in the early detection of high grade serous ovarian cancer: Evaluating exosomal proteins as novel biomarkers of disease.

M. Lightfoot[1], **K. Dorayappan**[2], L. Yu[2], C. Hisey[2], T. Sakaue[3], M. Anbalagan[4], C. M. Cosgrove[2], L. G. Maxwell[5], P. Thaker[6], B. Y. Karlan[7], D. O'Malley[2], R. E. Pollock[2], D. E. Cohn[2], R. Gogna[8], S. Karuppaiyah[2];

[1]NYU Grossman School of Medicine, New York, NY 10016, NY, [2]The Ohio State University, Columbus, OH, [3]Kurume University School of Medicine, Kurume, Japan, [4]Tulane University School of Medicine, New Orleans, LA, [5]Inova Fairfax Hospital, Virginia, VA, [6]Washington University School of Medicine, St. Louis, MO, [7]University of California, Los Angeles, CA, [8]Virginia Commonwealth University, Richmond, VA

Introduction: High-grade serous ovarian cancer (HGSOC) accounts for over 75% of all epithelial ovarian cancer and has a high mortality rate due to a lack of early detection methods. Many biomarkers have been proposed; however, none have been shown to improve detection at an early stage in this patient population. The purpose of this study is to assess whether there are unique extracellular vesicle (EV) protein signatures of early-stage HGSOC that could serve as early detection biomarkers.

Methods: 250 serum samples were obtained from a multi-institutional retrospective cohort of patients with all stages of HGSOC and healthy controls. LC-MS/MS and PEA of serum samples from patients with early-stage HGSOC identified differentially expressed EVs proteins in HGSOC versus controls. Tob candidate proteins are validated by ELISA.

Results: We have identified the top 10 EVs candidate proteins based on their fold change and statistical significance. When comparing early-stage HGSOC and controls using ELISA, CFH, PCP, and CCNE1 exhibited the highest Area Under the Curve (AUC) values of 0.94, 0.91, and 0.83, respectively. In contrast, MUC16 (also known as CA-125) exhibited an AUC of only 0.42 in whole serum. Furthermore, MUC16 distinguished between controls and both early and advanced-stage HGSOC in EVs, while in whole serum, it was only differentially expressed between controls and advanced-stage disease. Our results demonstrate that the predictive performance of the combined biomarkers surpasses that of any individual biomarker. Further, we integrated the ten aforementioned biomarkers, deriving the optimal combination biomarker by maximizing the corresponding Sum of Harmonic Means (SHUM) function by utilizing data from all 70 patients, results showed the optimal coefficients of the biomarkers, which maximize the diagnostic accuracy for early-stage HGSOC. The overall true positive rate (TPR) of 0.943, false positive rate (FPR) of 0.000, and Mathew's correlation coefficient (MCC) were presented for both the combined biomarker approach and individual biomarkers. The results demonstrated that the predictive performance of the combined biomarkers surpassed that of any individual biomarker.

Conclusion: Expression of EV-based protein biomarkers is significantly different in early-stage HGSOC compared to both control and late-stage HGSOC. This work can be readily translated to clinical use and potentially improve the early detection of HGSOC substantially.

#1071 Circulation of rare events in the liquid biopsy for early detection of lung mass lesions.

A. Shah, K. Resnick, J. Mason, P. Kuhn, J. Nieva, S. Shishido;
USC - University of Southern California, Los Angeles, CA

Lung cancer screening with low-dose CT scans (LDCT) has reduced mortality for patients with high-risk smoking histories. However, this method of screening remains imperfect. High rates of false positive scans expose patients to additional morbidity as they pursue subsequent diagnostic evaluation. Real-world application of screening LDCT remains low. Finally, current screening guidelines exclude those without smoking histories, a population which comprises up to a quarter of lung cancer patients. We sought to explore the utility of liquid biopsy (LBx) in lung cancer patients and its use in early cancer screening and diagnosis. Using the third generation High-Definition Single Cell Assay (HDSCA3.0) workflow, we analyzed 99 peripheral blood samples divided into three cohorts: Normal Donors (ND, n=50) who were healthy volunteers with no known pathology, Screening CT patients (CT, n=25) who underwent standard LDCT screening with resultant Lung-RADS 1-2, Biopsy patients (BX, n=24) who had abnormal CT scans requiring tissue biopsy. The ND group was used to characterize baseline epithelial, mesenchymal, endothelial, and immune cells, alongside acellular events (oncosomes). For the CT and BX patients, demographic information including age, gender, and average BMI was roughly equivalent, however average pack-years smoked differed owing to 10 (42%) patients in the BX group who had no prior smoking history. A total of 14 (58%) BX patients were diagnosed with primary lung cancer (BX+), of which 11(75%) were adenocarcinoma, 2 (19%) were squamous cell carcinoma and 1 (6%) was small cell. Across the cohorts we observed intra- and interpatient heterogeneity of rare events including multiple phenotypic rare cell populations and oncosomes. The comparison of the rare event enumerations between the ND, CT, BX+, and BX- cohorts revealed a greater incidence of total events, total rare cells and oncosomes, as well as specific cellular phenotypes in the CT and BX cohorts compared to the ND cohort. LBx analytes were detected at a significant elevation in the BX samples compared to the CT samples, but there was no significant difference between BX+ and BX- samples. The data supports the utility of the LBx in distinguishing patients with an alveolar mass lesion from those without, providing a mechanism for screening prior to LDCT to better inform clinical workup and avoid unnecessary radiation exposure and biopsy.

#1072 The *EsomiR* project: A case control study to assess the role of exosomal miRNAs in breast cancer cancerogenesis.

B. Cardinali[1], P. Piccioli[1], F. Boccardo[2], A. Rubagotti[2], L. Zinoli[1], A. Sciutto[1], S. Coco[1], G. Chiorino[3], P. Ostano[3], E. Sehovic[3], Z. Cavalieri[1], C. Bruzzo[1], S. Marconi[1], R. Tasso[2], R. Quarto[1], D. Ceresa[1], P. Malatesta[2], L. Del Mastro[1];

[1]IRCCS Ospedale Policlinico San Martino, Genova, Italy, [2]University of Genova, Genova, Italy, [3]Fondazione Edo ed Elvo Tempia, Biella, Italy

Introduction: One of the unmet needs in Breast Cancer (BC) prevention is how to identify women at higher risk of developing this disease, who might benefit from periodic surveillance and/or from chemoprevention. The goal of this retrospective study is to assess the role miRNAs isolated from extracellular vesicles (EV-miRNAs) as possible early biomarkers for identifying patients with higher risk of developing BC, in order to personalize their screening programme. To this goal, EV-miRNAs from cyst fluid derived from women with Gross Cyst Disease of the Breast (GCDB - a benign disease of the mammary gland associated with a 2-4-fold increase in the risk of developing BC) have been analysed.

Methodology: Cyst fluids have been selected among samples from a cohort of 600 patients diagnosed with GCDB between 1985 and 1993, some of whom developed BC during follow-up. EV-miRNAs have been extracted from cyst fluid using the exoRNeasy midi kit (Qiagen), qualitatively evaluated by Bioanalyzer (Agilent) and quantified by Qubit™ using the microRNA Assay Kit (Thermo Fisher Scientific). The MiRNome profiles have been assessed by microarray using an optimised protocol on Agilent platform (labelling and hybridization on SurePrint Human miR Microarrays 8×60 K and images acquisition by G2565CA scanner).

Results: A total of 117 samples (58 cases and 59 controls, paired on the bases of clinical and pathological variables) have been analysed. Single variable logistic regression analysis on the most expressed EV-miRNAs (logFC >= 6 (n=329)), selected six EV-miRNAs (miR-6076, miR-202-3p, miR-6872-3p, miR-769-3p, miR-5195-3p, miR-4443) and one (miR-4713-3p) negatively and positively associated with BC development, respectively (raw p-value <0.05). A risk score combining the seven EV-miRNAs was derived by multivariable logistic regression modelling and reported an AUC=0.73 (95% [CI] 0.6427-0.8231). The model was refined including clinical variables and applying step-wise logistic regression analysis. The combination of 3 EV-miRNAs (miR-6076, miR-6872-3p, miR-5195-3p) with menopausal status, familiarity and type of cyst yielded an AUC of 0.8 (95% [CI] 0.7015-0.8847). Logistic regression was also performed on Type I cysts (n=78), that are correlated with a higher risk of developing BC, pointing in evidence 3 EV-miRNAs with a negative (miR-6076, miR-6872-3p) or positive (miR-4515) correlation with BC development risk (AUC = 0.74, 95% [CI] 0.6278-0.8475). In the model comprehensive of clinical variables, two of those EV-miRNAs (miR-6872-3p, miR-4515) together with familiarity and menopausal status were selected, giving an AUC of 0.8 (95% [CI] 0.6961-0.8991).

Conclusion: This study allowed the identification of a EV-miRNA-based BC risk signature obtained by liquid biopsy on cyst fluid. The final purpose of this project is to transfer this signature in the clinic by testing it prospectively on plasma samples.

#1073 AI-assisted high-dimensional cytological single cell analysis distinguishes normal and malignant urine samples using cell morphology images with high accuracy at the single cell level.

T. P. P. van den Bosch[1], G. J. van Leenders[1], S. Sinnadurai[1], Z. Lian[2], R. Carelli[2], M. Nakaki[2], V. Lu[2], M. Ray[2], J. Cruz[2], K. R. Miller[2], M. Salek[2], M. Masaeli[2], **P. J. van der Spek[1]**;

[1]Erasmus Medical Center, Rotterdam, Netherlands, [2]Deepcell, Inc, Menlo Park, CA

Background: Urothelial cancer (UCC) is the 4th most common malignancy in men. The current clinical problem in UCC management is the high interobserver variability of tissue UCC grading and the low sensitivity of urine cytology for early detection of recurrences and progression. We hypothesize that assessing urine samples and UCC tissues with detailed quantitative image analysis based on artificial intelligence has strong potential in both urine-based early detection of tumor recurrence and progression as well as tissue-based pathological grading.

Methods: Here, we utilized the Deepcell® Human Foundation Model (HFM), a self-supervised deep learning model, to assess a cohort of urine samples from 54 normal healthy cases, 19 atypical cases, and 4 UCC cases. High resolution images of label-free single cells were captured and analyzed using the HFM to identify distinct morphological characteristics of cells from different urine origins. The urine samples were loaded onto a single-use microfluidic cartridge as part of the Deepcell® REM-I platform and brightfield images of single cells were captured in real-time. For data analysis, images of all cells run through the REM-I instrument are automatically sent to the Deepcell® Axon Suite, which provides an analysis platform to visualize cell images from specific runs, generate UMAPs of the embedding space, and run additional deep neural network models on samples in silico.

Results: High-dimensional analysis of 115 deep learning and morphometric features reveals 12 morphotypes among the pooled urine samples, as represented by morphology UMAP plots. Morphology analysis reveals distinct morphotypes in normal compared to pathological urine samples. Confusion matrix showed deep learning model performance in classifying atypical versus UCC with 89.1% (Atypical (n = 8642), UCC (n = 12637)). This indicates high model performance accuracy for AI prediction of atypical versus UCC samples at the single cell level.

Conclusions: The Deepcell® REM-I platform performs well with urine samples and identified numerous cell clusters among normal and pathological urines. AI-assisted high-dimensional morphology analysis distinguishes atypical urine samples from UCC cases with 89.1% accuracy at the single cell level. Future applications of this study include early detection or monitoring of UCC cases using non-invasive patient samples such as urine.

#1074 Plasma EV profiling facilitates low abundance biomarker discovery in pancreatic cancer.

S. Bansal[1], S. Wang[1], Y. Li[1], S. Bansal[1], J. Smith[1], J. B. Tyburski[2], k. Unger[1], **A. Cheema**[1];
[1]Georgetown University Medical Center, Washington, DC, [2]Nelson Scientific Labs, Gaithersburg, MD

The lack of reliable biomarkers for early detection of pancreatic ductal adenocarcinoma (PDAC) results in poor prognosis due to advanced disease at diagnosis. Biopsies for pancreatic cancer are known to be particularly difficult to perform because of the location of the pancreas and low volume of primary tumors that metastasize aggressively. Currently, there is no blood test or other screening modality in use, for stratification of individuals with higher-than-average risk (5-8-fold) of developing PDAC in their lifetime. Given this existing void in the US and worldwide, an FDA-compliant, minimally invasive, quantitative biomarker test for the early detection of PDAC would be critical for screening subpopulations with, a) inherent genetic or familial predisposition; history of chronic pancreatitis; c) precursor lesions of pancreas; and d) older patients (>50 years) with new onset diabetes or sudden weight loss. Extracellular vesicles (EVs) are shed by normal and cancer cells and carry a rich molecular cargo that can be leveraged for biomarker discovery. Whereas molecular profiling of bio-fluids poses intrinsic limitations for detection of low abundant, disease-specific biomarkers due to matrix effects; EVs, on the other hand, offer promise as a robust and minimally invasive biomarker resource. Mass spectrometry data were developed in our laboratory, based on multi-omics (proteomics, lipidomics and metabolomics) analyses of plasma EVs derived from patients diagnosed with early-stage PC (N=60), pancreatitis (N=39), precursor lesions of pancreas (N=45) as well as normal controls (N=50). These clinically annotated samples were made available by the Georgetown University Medical Center (GUMC) repository. Feature selection using a training-validation design allowed the development of a multiplexed biomarker panel comprising of 12-analytes (5-lipids, 2-metabolites and 5-proteins) that can robustly stratify early-stage PC from normal controls with high accuracy (AUC>95%). Availability of a FDA compliant, multi-analyte-based classification algorithm that can stratify patients with precursor lesions of the pancreas that are at potential risk of progression to PC with > 90% specificity and sensitivity is a critical clinical need. Refinement of panel to improve positive predictive value as well as identification of markers predictive of progression of precursor lesions to malignant transformation is ongoing.

#1075 Buccal mucosal remodeling predicts esophageal cancer risk.

A. Yokoyama[1], T. Hirano[1], K. Watanabe[1], M. Tamaoki[1], K. Hirohashi[1], Y. Ishida[1], Y. Inoue[1], Y. Takeuch[1], Y. Kishimoto[1], S. Kim[2], C. Katada[1], Y. Nanya[3], H. Seno[1], S. Ogawa[1], M. Muto[1], N. Kakiuchi[1];

[1]Kyoto University, Kyoto, Japan, [2]Kobe Asahi Hospital, Kobe, Japan, [3]The University of Tokyo, Tokyo, Japan

Lifestyle habits, including alcohol consumption, tobacco smoking, and germline variants of *ALDH2* and *ADH1B*, increase the risk of developing esophageal squamous cell carcinoma (ESCC). However, current prediction methods that rely on self-reported lifestyle information lack accuracy. We previously demonstrated that driver-mutated clones remodel the esophageal epithelium with age and that this remodeling is accelerated in heavy drinkers and smokers. Nonetheless, predicting cancer from clonal expansion in normal tissues remains challenging, due to limited sample availability beyond the blood. The squamous epithelium continuously covers the esophagus, throat, and oral cavity. Therefore, we evaluated buccal mucosal remodeling by mutant clones and its potential as a predictive biomarker of ESCC. A total of 387 buccal mucosa samples were collected from 110 subjects, including 62 with ESCC and 48 without, using swabs of three different sizes, followed by error-corrected sequencing targeting 26 driver genes that showed positive selection in samples from ESCC and physiologically normal esophageal tissues, as well as *ALDH2* and *ADH1B*. Somatic mutations were detected in all samples (median, 27 (1-134)). In total, 13,235 mutations, including 12,085 nonsynonymous and 1,150 synonymous mutations, with VAFs ranging from 0.0016-0.12 (median, 0.0025), were detected. Ten of the 26 genes, *TP53*, *CHEK2*, *NOTCH1*, *CDKN2A*, *NOTCH2*, *FAT1*, *AJUBA*, *PPM1D*, *ARID1A*, and *ZNF750* showed positive selection (dN/dS >1, q<0.1). Correlation analysis demonstrated that driver mutations in *TP53*, *FAT1*, and *PPM1D* were positively correlated with not only germline risk variants of ALDH2 but also alcohol consumption. The impact of alcohol consumption on the number and sum of VAFs of mutations in each of the three genes was analyzed and stratified by the presence or absence of the germline risk variant of *ALDH2*, and positive correlations were observed only among subjects with risk variants. Compared to subjects without ESCC, patients with early-stage or advanced ESCC displayed significantly higher numbers and sums of VAFs of driver mutations (p<0.05). These results indicated that buccal mucosal remodeling driven by positively selected mutations is associated with lifestyle and germline risk factors for ESCC, thus motivating the establishment of a predictive model for ESCC using genetic swab data. The prediction model for ESCC using sequencing data outperformed a model using self-reported lifestyle and alcohol flushing reaction and a model using lifestyle and germline risk variants (AUC of 0.94, 0.72, and 0.88, respectively). In conclusion, this is the first study to use clonal expansion in normal tissues to predict the presence of solid organ cancer, and our study successfully established a prediction model for ESCC based on buccal mucosal remodeling and germline variants.

#1076 Single nucleus RNA-sequencing using normal human salivary glands revealed a potential etiologic relationship between each salivary gland cell and salivary gland malignancies.

T. Nakagawa[1], C. Nasamran[2], J. Hu[2], P. Sen[2], T. Guo[2], K. Fisch[2], J. Califano[2];
[1]Chiba Univ., Chiba, Japan, [2]UC San Diego, La Jolla, CA

Salivary glands are composed of several types of cells, and each cell type is predicted to be involved in the carcinogenesis of different types of cancers including Adenoid cystic carcinoma (ACC), Acinic cell carcinoma (AciCC), salivary duct carcinoma (SDC), myoepithelial carcinoma (MECA) and other histology. In this study, we performed single nucleus RNA-seq on three human salivary gland samples to clarify the gene expression profile of each complex cellular component of the salivary glands and related these expression patterns to expression found in salivary gland cancers (SGC) to infer cell of origin. By single nucleus RNA-seq, total 13,643 salivary gland cells were stratified into four clusters: acinar cells, ductal cells 1, ductal cells 2, and myoepithelial cells/stromal cells, with differentially expressed genes of each group. The localization of each cell group was anatomically validated by IHC of each cluster marker gene, and one group of ductal cells was found to represent intercalated ductal cells labeled with HES1. Gene ontology analysis for this group included “epithelial cell differentiation” confirming the intercalated duct. Furthermore, to elucidate the potential etiologic relationship between normal salivary glands cell type and salivary gland carcinoma histology, we compared the expression of each cluster marker to SGC public RNA-seq data. In comparison between AciCC and ACC, we used normalized RNA-seq data of 54 ACC and 21 AciCC. ACC had significantly less expression of acinar cells markers (STATH, CST2, and LPO) compared to other markers expression(***$P = 4x10^{-51}$), unlike AciCC ($P = 0.54$), suggesting a possible contribution of acinar cells to the carcinogenesis of AciCC. In another cohort, we compared 16 SDC, and 38 MECA with publicly available RNA-seq data. Remarkably, HES1 and ELF3, each of two different ductal cell markers, were significantly upregulated in SDC consistent with origin of SDC from ductal cells (P=0.001, P=0.0007, respectively). Consistent with bulk RNA-seq results, expression of HES1 in IHC using clinical human SDC and MECA samples was higher in SDC than MECA, suggesting that the expression of the derived cells is involved in salivary gland carcinogenesis. Cell type expressions in specific SGC histology are similar to those found in normal salivary gland populations, indicating a potential etiologic relationship. On the other hand, there was no significant difference in myoepithelial marker ACTA2 expression between SDC and MECA, suggesting that the markers of origin are not always highly expressed, depending on cancer subtypes. Although publicly available SGC RNA-seq data used in this study are limited, the results remarkably reflect the diverse modes of carcinogenesis of SGC. These findings might provide a better understanding of the molecular basis of SGC and treatment strategies for SGC.

CLINICAL RESEARCH: Pediatric Sarcomas and Other Solid Tumors: Translational
Poster Session

#1080 Using genome-wide CRISPR screening to develop novel combination therapies for high-risk Ewing's sarcoma.

D. Ravindrarajah[1], S. Krishan[1], K. Simpson[2], T. Gulati[2], B. B. Cheung[1], G. M. Marshall[1];
[1]Children's Cancer Institute Australia, Sydney, Australia, [2]Peter MacCallum Cancer Centre, Melbourne, Australia

Ewing's sarcoma (EWS) is an aggressive bone and soft-tissue cancer, characterized by a hallmark fusion oncoprotein comprising the amino terminus of a FET gene and the carboxy terminus of an ETS gene, most commonly (85%), the EWSR1-FLI1 t (11,22) fusion.TK-216 is a first-in-class EWSR1-FLI1 inhibitor currently in phase II clinical trials for EWS. Although TK-216 was designed to target the fusion protein interaction directly, it has demonstrated limited efficacy as a monotherapy. Thus, more effective TK-216 combination therapies are needed. We have used genome wide Clustered Regularly Interspaced Short Palindromic Repeats (CRISPR) Knockout screening in EWS cells treated with TK-216 to identify novel synthetic lethality. We have identified 97 genes whose deletion potentially enhances the action of TK-216 in EWS cells. We have also identified several druggable targets, such as USP9X and the oxidative phosphorylation (OXPHOS) pathway as synthetic lethal interactions for TK-216. USP9X is known to deubiquitinate and stabilize the EWS-FLI1 fusion protein. USP9X and EWS-FLI1 protein expression levels were found to be positively correlated in EWS clinical specimens. USP9X siRNA-mediated gene silencing reduced EWS cell viability. Most importantly, USP9X siRNA-mediated gene silencing sensitized EWS cells to TK-216 treatment. In addition, inhibition of USP9X with a small-molecule inhibitor WP1130, led to significant cell death in EWS alone and in combination with TK-216 with wide therapeutic indices. The molecular mechanism of synergy and *in vivo* efficacy of the novel TK-216 combination will be determined in our study for future clinical translation.

#1081 A role for the oncogenic driver fusion protein EWS-FLI1 in the targeting of DR5 by INBRX-109 in Ewing sarcoma.

C. C. Parker[1], L. M. Gaetano[1], E. A. Boguslawski[1], S. Kinn-Gurzo[1], R. Kaufman[1], M. C. Stout[1], C. Deveraux[2], P. J. Grohar[1];
[1]Children's Hospital of Philadelphia, Philadelphia, PA, [2]Inhibrx, Inc., La Jolla, CA

Background: Tumor necrosis factor receptor superfamily member 10b (TNFRSF10b, also known as DR5) agonists are attractive targeted agents for cancer cells because these agents activate cellular apoptosis. Ewing sarcoma (ES) is a bone and soft-tissue sarcoma occurring in adolescence defined by a t(11;22)(q24;q12) balanced chromosomal translocation that results in chimeric transcription factor and oncogenic driver protein, EWS-FLI1. Independent studies and unbiased cell line screens have reported ES to be sensitive to DR5 targeting. INBRX-109 is a tetravalent, DR5-targeted antibody. Here, we analyzed the sensitivity of ES models to DR5 targeting by INBRX-109 and explored how the EWS-FLI1 transcriptional program impacts the continuum of sensitivity-resistance to this targeting.
Methods: In a panel of 11 ES lines, in vitro sensitivity was assessed to both single agent and INBRX-109 combinations. A screen of 1,363 FDA approved compounds identified cooperative combinations that were prioritized mechanistically. Differential sensitivity for single agent and in combination with irinotecan was confirmed in vivo in xenograft models. Resistant clones were isolated from in vivo experiments and evaluated for DR5 expression and sensitivity. Cellular factors associated with sensitivity and resistance were determined by siRNA knockdown and Cleavage Under Targets and Tagmentation assay (CUT and Tag).
Results: ES models showed variable sensitivity to INBRX-109, with a GI90 as low as 10 picomolar in some models. All models showed robust expression of DR5, but absolute expression of DR5 did not correlate with sensitivity. In vitro sensitivity was replicated in vivo, with all 7 mice bearing RD-ES xenografts demonstrating initial complete tumor regression and 3 of 7 mice demonstrating no recurrence beyond 90 days. Importantly, cells isolated from recurrent tumors showed a novel mechanism of resistance: direct repression of DR5 by EWS-FLI1. INBRX-109 was ineffective as a single agent at 10 nM in resistant ES models. However, there was striking synergy in vitro with SN38, the active metabolite of irinotecan, and this effect translated into tumor regressions of a resistant TC32 xenograft in vivo. The FDA compound screen captured novel synergy with a panel of agents.
Conclusion: INBRX-109 is an exciting candidate for ES as a single agent in subsets of tumors or in combination with irinotecan, which is currently being evaluated in the clinic. Investigation of the exact relationship between EWS-FLI1 and sensitivity to DR5 targeting is ongoing. Initial findings suggest EWS-FLI1, combined with other disease modifying mutations, is a key mediator of this sensitivity. Further, EWS-FLI1 plays a direct role repressing DR5 in the setting of therapeutic challenge in one model in vivo. These findings highlight the potential for INBRX-109 in combination with irinotecan or novel candidates as therapies for ES patients.

#1082 Exploiting lurbinectedin-driven nucleolar relocalization of EWS-FLI1 to develop novel combination therapies for Ewing sarcoma.

S. M. Veluvolu[1], **R. D. Lopez**[1], J. M. Gedminas[2], E. A. Boguslawski[1], E. R. Wilson[1], B. P. Caiello[3], M. E. Murphy[4], P. J. Grohar[1];
[1]Children's Hospital of Philadelphia, Philadelphia, PA, [2]University of Iowa Stead Family Children's Hospital, Iowa City, IA, [3]University of Pennsylvania, Perelman School of Medicine, Philadelphia, PA, [4]The Wistar Institute, Philadelphia, PA

Background: Ewing sarcoma (ES) is a malignant bone tumor characterized by the oncogenic fusion protein EWS-FLI1. EWS-FLI1 acts as an aberrant transcription factor, inducing and silencing genes involved with increasing cell proliferation and survival. We have previously shown that lurbinectedin, a trabectedin analog, effectively inactivates the transcriptional activity of EWS-FLI1 by redistributing it within the nucleus to the nucleolus. Interestingly, this process activates a gene signature like that of the DNA damage response (DDR) to UV light, which was also shown to induce nucleolar translocation of WT Ewing sarcoma breakpoint 1 (EWSR1). However, the mechanism governing the nucleolar translocation of EWS-FLI1 induced by these drugs has yet to be elucidated. In addition, novel approaches to exploit this relocalization mechanism as a means to broaden the therapeutic window have yet to be established.
Methods: We used immunoblotting, RT-qPCR, viability assays, cell fractionation, confocal microscopy, proximity ligation assays (PLA), mass spectrometry, genomics, and immunoprecipitation to investigate the mechanism of action of trabectedin/lurbinectedin-induced nucleolar relocalization of EWS-FLI1.
Results: Through interrogation of the pathways triggered by trabectedin/lurbinectedin, we found that this mechanism is in part mediated by HSP70. Viability assays also revealed profound synergy between HSP70 inhibitors (HSP70is) and lurbinectedin. Immunoprecipitated EWS-FLI1 subjected to mass spectrometry revealed an association of EWS-FLI1 and several HSP70 isoforms after trabectedin treatment which was confirmed with PLA. Trabectedin/lurbinectedin treatment also revealed an upregulation of EWS-FLI1-suppressed targets and suppression of induced targets. Confocal microscopy showed that EWS-FLI1 “trapping” in the nucleolus was potentiated by combination treatment with HSP70is.
Conclusion: Our results underscore the synergistic effect of combining HSP70is with trabectedin or lurbinectedin treatment to attenuate several aspects of ES tumorigenesis *in vitro*. *In vivo* experiments with patient-derived xenografts are underway to corroborate the synergy of HSP70is and trabectedin/lurbinectedin. Together, our data highlights the potential for a novel “EWS-FLI1 nucleolar trap” as a means to inhibit and sustain EWS-FLI1 repression with this class of compounds.

#1083 Cell membrane-anchored and tumor-targeted IL12 T-cell therapy destroys cancer-associated fibroblasts and disrupts extracellular matrix in heterogenous osteosarcoma xenograft models.

J. Hu, A. Lazar, W.-L. Wang, W. Zhang, Z. Jia, D. Ragoonanan, J. Wang, X. Xia, K. Mahadeo, R. Gorlick, S. Li;
UT MD Anderson Cancer Center, Houston, TX

Background: The extracellular matrix (ECM) and cancer-associated fibroblasts (CAFs) play major roles in tumor progression, metastasis, and the poor response of many solid tumors to immunotherapy. CAF-targeted CAR-T cell therapy cannot infiltrate ECM-rich tumors such as osteosarcoma.
Method: In this study, we used RNA sequencing to assess whether the recently invented membrane-anchored and tumor-targeted IL12-armed (attIL12) T cells, which bind cell-surface vimentin (CSV) on tumor cells, could destroy CAFs to disrupt the ECM. We established an *in vitro* model of the interaction between osteosarcoma CAFs and attIL12-T cells to uncover the underlying mechanism by which attIL12-T cells penetrate stroma-enriched osteosarcoma tumors.
Results: RNA sequencing demonstrated that attIL12-T cell treatment altered ECM-related gene expression. Immunohistochemistry staining revealed disruption or elimination of high-density CAFs and ECM in osteosarcoma xenograft tumors following attIL12-T cell treatment, and CAF/ECM density was inversely correlated with T-cell infiltration. Other IL12-armed T cells, such as wild-type IL12- or tumor-targeted IL12-T cells, did not disrupt the ECM because this effect depended on the engagement between CSV on the tumor cell and its ligand on the attIL12-T cells. Mechanistic studies found that attIL12-T cell treatment elevated IFNγ production upon interacting with $CSV^{\pm}$ tumor cells, suppressing TGFβ secretion and in turn upregulating FAS-mediated CAF apoptosis. CAF destruction reshaped the tumor stroma to favor T-cell infiltration and tumor inhibition.
Conclusions: This study unveiled a novel therapy—attIL12-T cells—for targeting CAFs/ECM. These findings are highly relevant to humans because CAFs are abundant in human osteosarcoma. **What is already known on this topic:** As the major source of ECM factors in tumors, the $FAP^{\pm}\alpha SMA^{\pm}$ subtype of CAFs within tumors induce production of ECM factors, preventing antitumor T cells from accessing the core regions of tumors. **What this study adds:** Our group demonstrated that attIL12-T cell transfer (US Patent: 11421010) induced T-cell infiltration into and eliminated large osteosarcoma PDX tumors. Comparison of gene expression in sensitive or resistant PDX models to attIL12-T cell therapy elucidated the ECM-targeting mechanism of attIL12-T cells. Our *in vitro* system further determined that the CSV-attIL12 interaction mediated IFNγ upregulation, which triggered FAS induction in CAFs to induce CAF apoptosis. In sum, attIL12-T cell treatment shifts tumor stroma from a TGFβ-dependent CAF-promoting phenotype to an IFNγ-induced immune-inflamed phenotype. **How this study might affect research, practice or policy:** attIL12-T cell transfer is a novel anti-ECM strategy that renders ECM-rich tumors more susceptible to T cell-mediated tumor killing.

#1084 Preclinical testing of a cell adhesion molecule 1 (CADM1) targeting antibody-drug conjugate in osteosarcoma and other pediatric solid tumor models.

Z. Zhang[1], Y. Wang[2], W. Zhang[1], X. Tian[1], Q. Wang[1], R. Lazcano Segura[1], M. Roth[1], J. Gill[1], D. Harrison[1], Z. Xu[1], Y. Yi[1], S. Jusu[1], G. Longo[1], X. Zhou[1], J. Wang[1], R. Gorlick[1];

[1]UT MD Anderson Cancer Center, Houston, TX, [2]Boston University Boston Medical Center, Boston, MA

Introduction: Survival outcomes of osteosarcoma have remained stagnant for decades, emphasizing the urgent need to identify new cell surface targets and develop novel therapies. Antibody-drug conjugates (ADCs), known for their targeted delivery of cytotoxic agents to specific targets, present an attractive therapeutic class for potential use in osteosarcoma.

Methods: We previously identified Cell Adhesion Molecule 1 (CADM1) is highly expressed on the cell surface in osteosarcoma using an integrated proteomic and transcriptomic surfaceome profiling approach. As a proof of concept, a humanized CADM1 antibody (clone PTA021-A1) was conjugated with Tesirine (SG3249), a pyrrolobenzodiazepine (PBD) dimer payload. The antitumor activity of this CADM1 ADC was validated in vivo in 8 osteosarcoma patient-derived xenografts (PDXs). CADM1 is also highly expressed in other pediatric solid malignancies such as neuroblastoma and Wilms tumor. The CADM1 ADC was tested in vitro in neuroblastoma and Wilms tumor models. Negative controls included a CD19 targeting ADC with the same payloads and CADM1 negative Ewing sarcoma models.

Results: The expression of the CADM1 was validated by flow cytometry in osteosarcoma, neuroblastoma, and Wilms tumor cell lines, and by immunohistochemistry (IHC) in osteosarcoma patient samples and PDX models. In vivo testing of CADM1 ADC in 8 osteosarcoma PDX models showed that the ADC was well-tolerated and significantly prolonged progressive-free survival in all osteosarcoma models. Complete response (CR) and maintained CR was observed in 3 models. In vitro testing for neuroblastoma and Wilms tumor is ongoing, and preliminary data suggest promising antitumor activities.

Conclusions: CADM1 is highly expressed in osteosarcoma and other pediatric solid tumors. CADM1 ADC demonstrated promising antitumor *in vitro* and *in vivo* activity in osteosarcoma, and initial *in vitro* studies in neuroblastoma and Wilms tumor show similarly promising responses. These data support the need for further studies assessing the potential of a CADM1 ADC as a novel agent for the treatment of pediatric solid cancers.

#1085 Exploiting bioenergetic vulnerabilities in chemotherapy resistant osteosarcoma.

Valerie U. Nguyen[1], Laurie Graves[2], Veronica Colmenares[3], Abol Macabangon[4], Casey Syal[4], Kelsey Fisher-Wellman[5], William C. Eward[6], So Young Kim[7], Jason A. Somarelli[1]

[1]Department of Medicine, Duke Cancer Institute, Durham, NC,[2]Department of Pediatrics, Division of Hematology/Oncology, Duke University Medical Center, Durham, NC,[3]Duke Cancer Institute, Durham, NC,[4]Department of Medicine, Duke University, Durham, NC,[5]Department of Physiology, East Carolina University, Greenville, NC,[6]Department of Orthopedic Surgery, Duke University Medical Center, Durham, NC,[7]Department of Molecular Genetics and Microbiology, Duke University, Durham, NC

BACKGROUND: Osteosarcoma (OS) is the most common bone cancer in children and young adults. Standard treatment involves chemotherapy and surgical resection, yet nearly 4 in 10 patients experience disease relapse, and almost all of these patients are resistant to additional chemotherapy. Therefore, there is an urgent need to understand the biology of chemo-resistant OS and identify new therapeutic strategies to treat this therapy-resistant disease state.
METHODS: Using a CRISPR-Cas9 based lineage tracing system, RNA sequencing, and Seahorse XF assays in chemo-naïve, -resistant, and -released human 143b and patient-derived 173x OS cell lines, we modeled the evolution of chemoresistance and release from the selective pressure of chemotherapy in osteosarcoma. The phenotype of each cell state was assessed through *in vitro* and *ex vivo* cell proliferation assays, a comparison of cell viability upon re-challenge to standard-of-care chemotherapy, and comparison of cell viability in response to novel therapies targeting alterations in cell respiration.
RESULTS: Chemo-resistant OS cells demonstrate a decrease in expression of proliferation-associated gene pathways and shift their resources toward expression and maintenance of multi-drug resistance ABC transporters. Chemo-released cells maintain elevated expression of ABC transporters while re-activating proliferation. Across the spectrum of chemotherapy exposure, OS cells demonstrate changes in respiratory capacity, with unique bioenergetic phenotypes observed in chemo-naïve, -resistant, and -released cells.
CONCLUSIONS: Chemo-resistant and chemo-released OS cells demonstrate unique bioenergetic patterns that correlate with gene expression signatures and growth phenotypes. Evolution imposed by the selective pressure of chemotherapy may render OS cells vulnerable to therapies that disrupt cellular energetics and exploit multi-drug resistant ABC transporters.

#1086 ZFP36L2 is expected to be a potential prognostic marker in IL-1β+ osteosarcoma patients.

P. Hao[1], P. Luo[1], Z. Ren[1], S. Xu[2], J. Han[1], X. Nan[1];

[1]Anhui Medical University, Hefei, China, [2]Department of Orthopedics, The First Affiliated Hospital of Anhui Medical University, Hefei, China

Background: Osteosarcoma (OS) is the most common bone malignancy affect children and young adults. For decades, the long-term survival for patients with recurrences and metastases remains ~30%. There's an urgent need for new prognostic marker and therapeutic options. ZFP36L2, a member of the tristetraprolin (TTP) family of CCCH zinc finger proteins, stands out for its pivotal role in post transcriptional modifications and modify tumor microenvironment (TME). Notably, ZFP36L2 contributes to the recruitment of macrophages, specifically the M1 subtype, which are known for their ability to secrete IL1β and exhibit anti-tumor functions. Our study reveals that, ZFP36L2 can be used as a predictor of prognosis in OS patients with enriched IL1B expression. This study aims to elucidate the interaction between ZFP36L2 and IL1B in modification of TME and shed light on its potential of prognosis prediction and therapeutic in IL1β positive OS patients.

Methods: Firstly, we conducted a comprehensive exploration of ZFP36L2 expression across TCGA cohorts. Then, we performed IHC staining to confirm the evaluated expression of ZFP36L2 in cancerous tissues. Immune infiltration analysis, including QUANTISEQ, TIMER, and CIBERSORT, was conducted. KM plot was employed to analyze the prognosis of OS patients. Finally, qPCR and western blot were used to validate transcriptional and translational changes of key molecules across OS cell lines.

Results: Our findings demonstrate that ZFP36L2 exhibits specific expression across various cancer types, with a notable elevation in sarcoma tissues, as confirmed by IHC. Importantly, this high expression of ZFP36L2 in sarcoma tissues is correlated with metastasis. We found ZFP36L2 significantly correlates with tumor metastasis but failed in patient overall survival. Immunoinfiltration analysis indicates a significant correlation between ZFP36L2 and macrophages, as well as T cells, suggesting a role in the TME. Prognostic analysis reveals that ZFP36L2 can serve as a predictive marker for IL1β positive patients. The wetlab experiments demonstrated that ZFP36L2 leads to IRGM mRNA degradation, ultimately affecting $IL1\beta^{\pm}$ macrophages.

Conclusion: This study delineates the tumor-specific elevated expression of ZFP36L2 and its potential as a prognostic marker in $IL1\beta^{\pm}$ OS patients. We hypothesize that ZFP36L2 affects $IL1\beta^{\pm}$ macrophages through IRGM degradation. Besides, IRGM also has an impact on cytotoxic T cells. Therefore, the ZFP36L2-IRGM axis plays an important role in remodeling OS TME. These results indicated ZFP36L2, not only serves as a marker, but also can be a therapeutic target in IL1β enriched patients.

#1087 Synergistic mechanisms against pediatric bone sarcoma models: Trabectedin enhances oncolytic virotherapy intratumoral spread and antitumor immune activation.

E. Ringwalt[1], M. Currier[2], A. Glaspell[2], M. V. Cannon[2], C.-Y. Chen[2], A. C. Gross[2], M. Cam[2], P.-Y. Wang[2], R. D. Roberts[1], T. P. Cripe[1];
[1]Nationwide Children's Hospital & Ohio State University, Columbus, OH, [2]Nationwide Children's Hospital, Columbus, OH

Osteosarcoma and Ewing sarcoma are the most common pediatric bone malignancies and, despite decades of research, efforts to treat patients with advanced disease remain dismal. To address this inadequacy, we leverage oncolytic herpes simplex virotherapy as a double-edged attack against tumors through 1) tumor cell-specific lysis and 2) antitumor immune stimulation. However, previous trials of oncolytic herpes simplex virotherapy in pediatric sarcomas displayed limited responses, likely due to the observed presence of immunosuppressive monocytes and macrophages. To improve efficacy, we combined oncolytic herpes simplex virotherapy with trabectedin, an FDA-approved DNA-binding agent known to disrupt gene expression and deplete monocytes and macrophages. Surprisingly, we found that the efficacy of this combination far surpassed our predictions, inducing complete and partial regressions in multiple models of Ewing sarcoma and osteosarcoma. To explore potential mechanisms driving this high degree of synergy, we performed single cell RNA sequencing on tumors of mice treated with monotherapy or combination therapy. Interestingly, trabectedin synergized with the oncolytic virotherapy through two unexpected mechanisms. Our analysis revealed that trabectedin increased intratumoral oncolytic virus spread by disrupting expression of the intrinsic antiviral response in human Ewing sarcoma cells. Additionally, trabectedin not only reduced immunosuppressive macrophages but also stimulated cytotoxic granzyme expression in infiltrating T and NK cells in immunocompetent osteosarcoma models. These effector NK and T cells were necessary for the regressions of osteosarcoma allografts treated with trabectedin and oncolytic virotherapy. Thus, trabectedin enhanced both the oncolytic effect of herpes simplex virotherapy and the effector function of cytotoxic lymphocytes that become activated in response to the virus. The combination of trabectedin and oncolytic herpes simplex virotherapy offers the potential to unite these mechanisms against bone tumors to achieve better outcomes for children.

#1088 An evaluation of patritumab deruxtecan (HER3-DXd, U3-1402) against pediatric PDX models for hepatoblastoma and rhabdomyosarcoma - A report from the NCI PIVOT Program.

R. Kurmasheva[1], P. Houghton[1], V. Del Pozo[1], S. Ghilu[1], R. Nakamura[2], P.-D. Fan[3], E. Jocoy[4], T. Stearns[4], S. Neuhauser[4], J. Chuang[4], C. J. Bult[4], B. A. Teicher[5], M. A. Smith[5],

[1]UT Health San Antonio, San Antonio, TX, [2]Daiichi-Sankyo Co., Ltd., Tokyo, Japan, [3]Daiichi-Sankyo Co., Ltd., Hillsdale, NJ, [4]The Jackson Laboratory, Bar Harbor, ME, [5]National Cancer Institute, Bethesda, MD

Introduction: HER3-DXd is an ADC consisting of a fully human monoclonal antibody to HER3 attached to a topoisomerase I inhibitor payload (DXd, an exatecan derivative) that has demonstrated clinically meaningful efficacy with durable responses in adults with non-small cell lung cancer. Two childhood cancers with HER3 expression are rhabdomyosarcoma (RMS) and hepatoblastoma (HB), and the goal of this work was to evaluate the activity of HER3-DXd against PDX models for these cancer types.

Methods: IHC testing was conducted on FFPE tissue (slides or TMA) using HER3/ErbB3 (D22C5) XP rabbit mAB and membrane expression was determined. HB models were evaluated using HER3-DXd and control IgG ADC (C-ADC) with a DXd payload, both at 10 mg/kg weekly x 3. RMS models were evaluated using HER3-DXd and C-ADC at 3 mg/kg and 10 mg/kg administered weekly x 3. Activity was assessed by the PIVOT objective response measure (ORM) targeting partial, complete, or maintained complete responses (PR, CR, and MCR) as compared to stable disease (SD) or progressive disease, with or without growth delay (PD2 and PD1, respectively).

Results: For 11 HB models, HER3 expression was 0 (n=2), 1+ (n=5), 2+ (n=1), and 3+ (n=3). For 8 RMS models, median IHC scores were 0 (n=1), 1+ (n=5), and 2+ (n=2). HER3-DXd activity by ORM is shown in the table. Three of 4 HB models treated with HER3-DXd showed MCR, while one had PD. The 3 HB models with MCR responses to HER3-DXd showed lesser responses to C-ADC. HER3-DXd was highly active against RMS models at 3 and 10 mg/kg with most models having MCR. C-ADC was also highly active against RMS models at both dose levels. At 10 mg/kg HER3-DXd, 2 of 4 HB models and 3 of 6 evaluable RMS models had time to event > 100 days.

Conclusions: Many HB and RMS models show HER3 expression by IHC. HER3-DXd is highly active against both HB and RMS models. The high activity of C-ADC for RMS models suggests exquisite sensitivity of RMS models to the DXd payload

Treatment response categories to treatment of pediatric PDX models with HER3-Dxd

	PD1	PD2	SD	PR	CR	MCR
HB (HER3-Dxd, 10 mg/kg)	1	-	-	-	-	3
HB (C-ADC, 10 mg/kg)	2	1	-	1	-	-
RMS (HER3-Dxd, 3 mg/kg)	-	1	-	-	-	5
RMS (C-ADC, 3 mg/kg)	-	-	-	1	2	2
RMS (HER-Dxd, 10 mg/kg)	-	-	-	-	-	6
RMS (C-ADC, 10 mg/kg)	-	-	-	-	2	4

#1089 Endogenous HiBiT-tagging of PAX3-FOXO1 reveals downregulation of the fusion oncogene by CDK inhibitors and has synergy with vincristine.

Y. Kim[1], k. Jia[1], M. Churiwal[1], T. Hawley[2], S. Pomella[1], C. Evans[3], R. Chari[3], D. Milewski[1], R. Sinniah[1], Y. Song[1], H.-C. Chou[1], X. Wen[1], C. Thomas[4], M. Ceribelli[4], J. Wei[1], R. Hawley[5], J. Khan[1];

[1]National Cancer Institute, Bethesda, MD, [2]National Institute of Allergy and Infectious Diseases, Bethesda, MD, [3]Frederick National Laboratory for Cancer Research, Frederick, MD, [4]National Center for Advancing Translational Sciences, Bethesda, MD, [5]George Washington, Washington, DC

Background: Oncogenic fusion genes are attractive therapeutic targets due to their tumor-specific expression and driver roles in cancers. PAX3-FOXO1 (P3F) is the dominant oncogenic driver of fusion-positive rhabdomyosarcoma (FP-RMS) with no current targeted therapy. We developed methods to directly measure endogenous P3F protein levels amenable to high-throughput drug screens.

Method: HiBiT tag, an 11 amino acid peptide of NanoLuc luciferase, was inserted into the endogenous P3F using CRISPR in FP-RMS cell lines RH4 and SCMC. Western blot was used for HiBiT tag validation. RNA-seq and ChIP-seq were used to assess transcriptomics and DNA binding of HiBiT-tagged P3F (P3F-HiBiT). High-throughput drug screen using Nano-Glo luciferase assay was performed using the Mechanism Interrogation PlatE (MIPE 5.0) drug library, a 2,480 drug library with known mechanisms of action. CellTiter-Glo was used to monitor cell viability. Mouse xenograft models of FP-RMS were used to investigate in vivo efficacy.

Results: We validated HiBiT tagging of P3F by Western. Both P3F-HiBiT and unmodified P3F activated the same gene sets in fibroblasts by RNA-seq Gene Set Enrichment Analysis (GSEA). ChIP-seq using HiBiT antibody for P3F-HiBiT matched the genomic locations from ChIP-seq with P3F antibody in RH4 and SCMC. Using a cutoff value of > 90 (Area Under the Curve (AUC) of CellTiter-Glo minus AUC of Nano-Glo), in both RH4 and SCMC, we identified 182 compounds which downregulate P3F before cell death. Filtering for drugs with ≥ 3 hits for the same target identified 14 drug classes that suppressed P3F including HDAC inhibitors (3), BRD4 inhibitors (3), and CDK inhibitors (8). FP-RMS was sensitive to CDK1/2, CDK4/6, CDK9, and multi-CDK inhibitors. A multi-CDK inhibitor TG02, currently in human trials, downregulated P3F and RNA-seq GSEA showed marked suppression of P3F targets. TG02 also significantly delayed tumor progression in mouse xenograft model of FP-RMS without weight loss. Interestingly, the commonly used chemotherapeutic Vincristine (VCR) also downregulated P3F in vitro. TG02 with VCR showed synergy by Loewe analysis. In vivo, testing showed significant delay in tumor progression by the combination compared to TG02 or VCR alone. Of note, tumor RNA-seq GSEA following treatment with TG02, or VCR alone, and in combination significantly downregulated P3F targets.

Conclusion And Future Directions: By HiBiT tagging the fusion oncogene P3F, we identified 182 drugs that suppress P3F levels of which TG02 was a top hit. TG02 showed in vivo efficacy indicating that FP-RMS is susceptible to CDK inhibition. We also found synergy between TG02 and VCR, resulting in a significant delay in FP-RMS tumor progression compared to single agents. Interestingly, we found that VCR alone can downregulate P3F and its targets. Combination therapy of TG02 with VCR shows promise for clinical translation in FP-RMS.

#1090 GPC2 directed CAR T cells are efficacious against fusion-positive and fusion-negative rhabdomyosarcomas.

R. Shraim[1], P. M. Schuerch[1], A. Giudice[1], K. L. Conkrite[1], A. K. Weiner[1], A. B. Radaoui[1], B. Mooney[2], R. T. Kurmasheva[3], P. J. Houghton[3], G. B. Morin[2], Y. B. Mosse[1], P. H. Sorensen[2], B. A. Garcia[4], A. Sacan[5], J. M. Maris[1], K. R. Bosse[1], S. J. Diskin[1];

[1]Children's Hospital of Philadelphia, Philadelphia, PA, [2]BC Cancer Research Institute, Vancouver, BC, Canada, [3]The University of Texas Health Science Center at San Antonio, San Antonio, TX, [4]Washington University School of Medicine, St. Louis, MO, [5]Drexel University, Philadelphia, PA

Background: Rhabdomyosarcoma (RMS) is an aggressive pediatric solid tumor with poor survival and new targeted therapies are needed.
Aims: Using an integrative proteogenomic quantitative approach, we sought to identify candidate immunotherapeutic targets then validate top targets in RMS preclinical models.
Methods: We first performed plasma membrane enrichment followed by mass spectrometry (MS) to define the surfaceome of 7 fusion-positive (FP) and 14 fusion-negative (FN) RMS patient-derived xenograft models. Surface proteins were scored by IMMUNOTAR, our custom pipeline which extracts and integrates quantitative features from diverse proteogenomic and annotation datasets to provide a score for each protein, using mean-average-precision for score optimization. Cell surface expression of IMMUNOTAR-prioritized proteins was validated using flow cytometry, focusing on targets with immunotherapies in development. CAR T cells targeting the lead protein were engineered and studied in RMS preclinical models.
Results: A total of 847 and 882 high confidence cell surface proteins were detected in FP and FN RMS surfaceome, respectively, with 94% of proteins overlapping the phenotypes. IMMUNOTAR ranked anaplastic lymphoma kinase (ALK), a putative immunotherapeutic target in FP RMS, as the top FP target. Glypican 2 (GPC2), a differentially expressed cell surface proteoglycan identified in neuroblastoma and other neural-derived tumors, targetable with CAR T cells and antibody-drug conjugates [Bosse et al. Cancer Cell 2017], ranked as the top protein in FN and 5th protein in FP RMS. Overall, GPC2 was abundantly expressed in 16 of 21 RMS models profiled. Flow cytometry revealed expression of GPC2 comparable to neuroblastoma in 5 of 8 RMS cells lines. Additionally, both FP and FN GPC2+ RMS cell lines (FN: RH36, SMS-CTR; FP: RH41, RH30) activated GPC2 CAR T cells with either a CD28 or a 4-1BB costimulatory domain, inducing release of IFN-gamma and IL-2 upon co-incubation across different E:T ratios as quantified by ELISA. Further, GPC2 CAR T cells induced potent RMS cell cytotoxicity compared to control CD19 CAR T cells with near 100% specific cytotoxicity at 1:1 E:T ratio. In a pilot study, GPC2 CAR T cells with 4-1BB costimulatory domains induced significant tumor regression ($p=0.03$) and prolonged progression-free survival ($p=0.01$) compared to CD19 CAR T cells in an established murine RH41 flank xenograft model.
Conclusion: In summary, we probed the RMS surfaceome using MS and identified candidate proteins amenable for immunotherapeutic targeting using our IMMUNOTAR algorithm. We validated GPC2 as a candidate target in FP and FN RMS and are corroborating our findings in additional pre-clinical RMS models. Demonstration of GPC2 CAR efficacy in these models could lead to inclusion of RMS in our ongoing phase 1 clinical trial (NCT05650749) in a planned expansion phase.

#1091 Distinct mechanisms of orthotopic tumor control by alpha$_V$beta$_3$and HER2 CAR Ts support development of a bispecific CAR T cell therapy for pediatric rhabdomyosarcoma.

A. M. Lulu, N. Park, J. J. Caruso, D. A. Cobb, D. W. Lee;
University of Virginia, Charlottesville, VA

Goal: Evaluate αvβ3 and HER2 as antigens for a bispecific chimeric antigen receptor T (CAR T) cell therapy in pediatric rhabdomyosarcoma.
Background: Current treatments are ineffective against relapsed/refractory or metastatic rhabdomyosarcoma (RMS). Antigen loss or modulation on tumor cells commonly leads to tumor escape across diverse cancer types after CAR T therapy targeting different antigens. We hypothesize that simultaneously targeting two RMS antigens with a bispecific CAR T will reduce the likelihood of tumor escape. The integrin alpha$_V$beta$_3$ (αvβ3) plays a role in cancer progression, metastasis and neovascularization in several malignancies. HER2 also contributes to cancer progression and metastasis.
Methods: Control of intramuscular RMS tumors by αvβ3 or HER2 CAR Ts was assessed in NSG mice, with non-specific CD19 CAR Ts as controls. Tumor burden was assessed weekly by bioluminescence imaging. Persistence and phenotype of CAR Ts were evaluated by flow cytometry. CAR T cell infiltration, tumor antigen expression and residual disease were determined by immunohistochemistry.
Results: Six of six pediatric patient-derived RMS cell lines express αvβ3 and/or HER2. αvβ3 and HER2 CAR Ts kill RMS cells *in vitro* at low effector-to-target ratios. αvβ3 and HER2 CAR Ts independently control—and nearly eliminate—orthotopic RMS tumors. Fewer HER2 CAR Ts ($5x10^6$) are needed to control tumors than αvβ3 CAR Ts ($10x10^6$), but this is not due to lack of persistence or exhaustion of αvβ3 CAR Ts. Tumor control by αvβ3 CAR Ts is delayed (>21 days) compared to that by HER2 CAR Ts (7 days), and is robust, despite initial tumor progression following treatment. Importantly, despite strong tumor control by both CAR Ts, at 7 weeks post-treatment residual tumor nests are evident by histology. At this time, CAR Ts are still abundant, are not exhausted and express memory markers, suggesting that the remaining tumor cells are no longer susceptible to CAR T killing. We are currently evaluating the hypothesis that the remaining tumor cells have down-regulated antigen expression. Delayed tumor control by αvβ3 CAR Ts was ameliorated by engineering αvβ3 overexpression in RMS tumors.
Conclusions: αvβ3 and HER2 CAR Ts control orthotopic RMS tumors by distinct mechanisms with changes in αvβ3 antigen expression, likely due to tumor progression, one prevalent factor. This is consistent with our prior reports of αvβ3 CAR Ts preventing breast cancer metastases, which naturally upregulate αvβ3 compared to the primary tumor. Despite near elimination of tumors, residual nests of tumor cells are likely to rebound as CAR T resistant tumors, similar to what is seen in patients treated with monospecific CAR Ts. These data support the incorporation of αvβ3 and HER2 CAR Ts into a bispecific CAR T approach to mitigate antigen escape. Our data also support investigation into the role of αvβ3 in RMS.

#1092 RUNX2 inhibition alters PAX3::FOXO1 driven fusion-positive rhabdomyosarcoma cell state and growth.

Elizabeth A. Mendes[1], Audrey L. Chambers[1], Samantha J. Weitzel[1], Michael Deel[2], Aanandi Munshi[2], Christopher M. Counter[1], Seth Zimmerman[1], John Bushweller[3], Corinne M. Linardic[2]

[1]Pharmacology and Cancer Biology, Duke University School of Medicine, Durham, NC, [2]Pediatric Hematology/Oncology, Duke University School of Medicine, Durham, NC, [3]Molecular Physiology and Biophysics, University of Virginia Medical School, Durham, VA

Investigation: Fusion-positive rhabdomyosarcoma (FP-RMS) is an aggressive pediatric cancer of skeletal muscle lineage. While the incidence of RMS is ~4.5 patients per million individuals aged <20 years, 5-year survival for high-risk children is <30%, and <8% when metastatic. The *PAX3::FOXO1 (P3F)* fusion gene, resulting from *t*(2:13), is the most prominent fusion oncogene that drives FP-RMS. P3F is a fusion transcription factor and supports FP-RMS by keeping it in a persistent myoblastic state. We found P3F functions in part by suppressing MST kinase activity in the Hippo tumor suppressor pathway, a developmental pathway involved in cell fate and organ size. To investigate how this may rewire gene expression to support FP-RMS, we performed ATAC-seq analysis of a myoblast-based model of FP-RMS in which MST was further inhibited and found the *RUNX2* gene locus was more accessible. Since RUNX2 is a pioneer transcription factor known to interact with the "WW" domains of Hippo pathway members to support mesenchymal cell fate, we hypothesize that RUNX2 maintains these relationships to support FP-RMS cell state and survival.

Methods & Results: Inquiry of in silico databases and previously published literature unveiled that sarcomas including RMS have a high dependency on RUNX2 and that P3F directly binds a RUNX2 enhancer. Interrogation of a proximity labeling proteomics study from our collaborators in the Counter lab found that RUNX2 was part of the protein interactome of 7/7 FP-RMS fusions including P3F. Additionally, Co-IP experiments confirmed that there is a direct protein-protein relationship between RUNX2, P3F, and TAZ. Next, we performed *in vitro* genetic loss of function (LOF) of RUNX2 using RNAi, which showed that suppression of RUNX2 caused cell death, growth inhibition, increased TAZ expression, and induction of both myogenic and osteogenic markers. We also performed complementary pharmacologic LOF using two available small molecules, AI-14-91 (Bushweller lab) *in vitro,* and CADD522 (commercially available) *in vitro* and *in vivo*. We found that these partially phenocopied the genetic LOF and that CADD522 reduces tumor volume and growth.

Conclusions: RUNX2 is a vulnerability in RMS based on *in silico*, *in vitro,* and *in vivo* investigation, and may act to prevent osteogenic and myogenic differentiation via protein-protein relationships in the Hippo pathway. The next step will be assessing mechanistic relationships between the Hippo pathway and RUNX2, as well as the genome wide changes upon RUNX2 LOF by performing ChIP-seq, RNA-seq, and scRNA-seq experiments.

#1093 Small molecule inhibitors of the PAX3::FOXO1 fusion protein in rhabdomyosarcoma.

T. Shaw, K. Nakazawa, P. Tiwari, E. Nelson, J. Formen, C. Wolf, J. Toretsky, A. Uren;
Georgetown Lombardi Comprehensive Cancer Center, Washington, DC

Rhabdomyosarcoma (RMS) is the most common pediatric soft tissue sarcoma. It is commonly divided into subtypes based on histopathological appearance. The oncogenic fusion proteins PAX3::FOXO1 or PAX7::FOXO1 are present in the alveolar subtype of RMS (ARMS). These chimeric proteins are formed by reciprocal chromosomal translocations and consist of an N-terminal portion of the PAX3 or PAX7 transcription factor fused to a C-terminal portion of the FOXO1 transcription factor. These fusion proteins have been shown to drive malignant transformation in ARMS, and patients with fusion-positive ARMS have a worse prognosis than patients with fusion-negative ARMS and embryonal RMS. We recently reported that piperacetazine, a phenothiazine derivative and first-generation antipsychotic, is capable of binding to and inhibiting the transcriptional activity of PAX3::FOXO1, reducing the expression of PAX3::FOXO1 target genes, and inhibiting the ability of fusion-positive RMS cells to grow in soft agar. We hypothesize that other phenothiazine derivatives may have stronger binding affinity for PAX3::FOXO1 and greater ability to reduce tumor growth in vivo. We employed a structure-activity relationship campaign to develop new phenothiazine derivatives that may be more potent inhibitors of PAX3::FOXO1 than piperacetazine. We synthesized and tested 10 new compounds, in addition to 9 existing FDA-approved phenothiazine derivatives, for their ability to bind to PAX3::FOXO1 and inhibit its transcriptional activity and target gene expression as well as inhibiting the growth of fusion-positive RMS cells in 3D culture. Seven derivatives inhibited PAX3::FOXO1 reporter activity better than piperacetazine, nine of them performed worse, and three of them showed comparable activity to piperacetazine. We demonstrated that piperacetazine does not alter PAX3::FOXO1 levels, subcellular localization, binding to a PAX3::FOXO1 target DNA sequence, or phosphorylation at Ser256 in the FOXO1 portion of the fusion protein. We therefore hypothesize that piperacetazine may be disrupting interactions between PAX3::FOXO1 and its partner proteins. We are employing a proximity-based biotinylation method to identify proteins that are competed away from PAX3::FOXO1 by piperacetazine. Our data suggest that it is possible to target PAX3::FOXO1 protein using small molecules that can directly bind to it and inhibit its activity in fusion-positive RMS cells.

#1094 Utilizing CRISPR-Cas13 as a novel functional genomics tool to characterize PAX3-FOXO1 in alveolar rhabdomyosarcoma.

A. Zhao[1], L. M. Brown[1], M. Fareh[2], P. G. Ekert[1];
[1]CCIA, Sydney, Australia, [2]Peter MacCallum, Melbourne, Australia

Background: CRISPR-Cas13 (Cas13) is an RNA editing system that can knockdown gene transcripts with higher efficiency and specificity than RNA interference technologies. We are exploring the utility of Cas13 as a robust novel functional genomics tool to understand the biology of the PAX3-FOXO1(P3F1) gene fusion in alveolar rhabdomyosarcoma (ARMS). Our goal is to identify gene dependencies and novel druggable targets. [LB1]
Aim: This study aims to functionally characterize P3F1 in paediatric cancer cell lines using Cas13. [LB2]
Methods & Results: Transient transfection and viral transduction of Cas13 vector systems were used to demonstrate that Cas13 knockdown of target gene expression can be achieved in ARMS cell lines. We developed guides to specifically target P3F1 expression and tested their efficiency in HEK293T cells. Cas13 function was validated with a mCherry knockdown proof-of-concept expression in the ARMS cell lines Rh5 and Rh30. 90-95% knockdown efficiency was seen over three independent experiments. Ten P3F1 breakpoint targeting guides were designed and screened first in a HEK293T P3F1 overexpression model to select optimal high efficiency targeting guides. The highest efficiency targeting guide showed a GFP reduction of 70% in three independent experiments. High-efficiency Cas13 guides were taken forward into Rh5 cells to knockdown endogenous P3F1 expression which were validated by western blotting and RT-PCR. Western blots of Cas13 sorted Rh5 cells showed that guide 1150 was able to knockdown P3F1 protein expression by ~70%.
Discussion/Conclusion: These findings demonstrate the high efficiency and specificity of the Cas13 system to silence P3F1, and other oncogenic fusion drivers. Further studies will utilize Cas13 to characterize the molecular and cellular consequences of P3F1 gene-silencing in patient-derived ARMS cell lines.

#1095 Prox1 transcription factor and its downstream signaling - A new therapeutic target for rhabdomyosarcoma.

N. Y. Gizaw, T. Bohling, M. Sampo, K. Alitalo, R. M. Kivela;
University of Helsinki, Helsinki, Finland

Rhabdomyosarcoma (RMS) stands as the predominant soft tissue sarcoma in children, characterized by a high-grade neoplasm composed of cells resembling skeletal myoblasts. Despite being prevalent, patients with metastatic or recurrent rhabdomyosarcoma still experience poor outcomes, underscoring the necessity for novel treatments. We have recently shown that PROX1 is a critical factor in RMS tumor growth and myogenic characteristics (Gizaw NY, et al. PNAS 2022). As PROX1 has previously been associated with tumor metabolism in colorectal cancer, we investigated further its role in RMS metabolism. Our findings demonstrate that PROX1 plays a crucial role in regulating RMS cell metabolism. Specifically, silencing of PROX1 resulted in decreased lipid and oxidative metabolism, which was accompanied by an increase in glycolysis and triglyceride accumulation. RNA sequencing and Gene Set Enrichment Analysis revealed downregulation of all genes involved in the cholesterol synthesis pathway in PROX1-silenced RMS cells. Our studies further reveal that inhibiting cholesterol synthesis, akin to PROX1 silencing, can effectively inhibit RMS cell growth. Our results provide novel insights into the role of PROX1 in RMS metabolism and highlight the potential of PROX1-regulated metabolic pathways as promising targets for the development of novel RMS therapies.

#1096 Enhancing effector function in T cell adoptive cell therapy in murine models of pediatric sarcomas.

J. P. Sanchez[1], E. Davila[2], B. H. Ladle[1];

[1]Johns Hopkins University, School of Medicine, Baltimore, MD, [2]University of Colorado, Anschutz Medical Campus, Aurora, CO

New treatment approaches for high-risk pediatric sarcomas are desperately needed. Immunotherapy advances with adoptive cell therapy in hematologic malignancies have not yet translated to pediatric solid tumors including sarcomas. Hallmarks of the immune microenvironment in pediatric sarcomas include the presence of immunosuppressive cytokines and immune cells and a lack of potent T cell activation. We are seeking ways to overcome these barriers to effective adoptive cell therapy in pediatric sarcoma. We are exploring introduction of a novel synthetic co-receptor, CD8a:MyD88, that can augment tumor-specific T cell effector function and potentially improve outcomes in murine models of sarcoma. Tumor-antigen specific T cells or tumor-infiltrating T cell populations are transduced ex vivo to express the CD8a:MyD88 synthetic co-receptor resulting in MyD88 signaling when T cells encounter their cognate MHC I/epitope complex. We have studied the effects of CD8a:MyD88 expression on cytokine production and lytic activity against murine sarcoma cell lines in vitro. Initial experiments utilized the OT1 T cell model (specific to the model antigen chicken ovalbumin) which we introduced into our murine sarcoma cell lines (KPSarc pleomorphic sarcoma and M3-9M rhabdomyosarcoma). Using GFP as a marker of T cell transduction, the production of effector cytokine interferon gamma was measured following T cell activation compared with GFP-negative non-transduced T cells. CD8a:MyD88 expressing T cells expressed higher levels of interferon gamma at basal levels and following antigen-specific activation when co-cultured with Ova-expressing sarcoma cells. Improved tumor-specific lytic function in CD8a:MyD88 expressing T cells was also observed in co-culture experiments compared to untransduced or control vector- transduced T cells. We further hypothesized that skewing T cell differentiation toward an effector phenotype with the addition of interleukin-12 during T cell expansion would increase the anti-tumor effect of the CD8a:MyD88 expressing T cells. Co-culture with our murine sarcoma cell lines showed increased tumor-lytic function in T cells primed with IL-12. We have ongoing experiments studying the in vivo effects of the CD8a:MyD88 expressing T cells in model antigen-expressing murine sarcoma models. In addition, the ability of the CD8a:MyD88 co-receptor to augment the effector function of polyclonal sarcoma infiltrating T cells is being explored. These results will further define the obstacles and potential solutions to successful adoptive T cell therapy for pediatric sarcomas.

#1097 CD73 contributes to the pathogenesis of fusion-negative rhabdomyosarcoma through the purinergic signaling pathway.

K. G. Cano Hernandez, A. Shah, V. Lopez, V. Tagliabracci, K. Chen, L. Xu, R. Bassel-Duby, E. Olson, N. Liu;
University of Texas Southwestern Medical Center, Dallas, TX

Rhabdomyosarcoma (RMS) is the most common type of soft tissue sarcoma in children and adolescents. Fusion-Negative RMS (FN-RMS) accounts for more than 80% of all RMS cases. The long-term event-free survival rate for patients with high grade FN-RMS is below 30%, highlighting the need for improved therapeutic strategies. CD73 is a 5' ectonucleotidase that hydrolyzes AMP to adenosine and regulates the purinergic signaling pathway. We found that CD73 is elevated in FN-RMS tumors that express high levels of TWIST2. While high expression of CD73 contributes to the pathogenesis of multiple cancers, its role in FN-RMS has not been investigated. We found that CD73 knockdown decreased FN-RMS cell growth while upregulating the myogenic differentiation program. Moreover, mutation of the catalytic residues of CD73 rendered the protein enzymatically inactive and abolished its ability to stimulate FN-RMS growth. Overexpression of wildtype CD73, but not the catalytically inactive mutant, in CD73 knockdown FN-RMS cells, restored their growth capacity. Likewise, treatment with an adenosine receptor A_{2A-B} agonist partially rescued FN-RMS cell proliferation and bypassed the CD73 knockdown defective growth phenotype. These results demonstrate that the catalytic activity of CD73 contributes to the pathogenic growth of FN-RMS through the activation of the purinergic signaling pathway. Therefore, targeting CD73 and the purinergic signaling pathway represents a potential therapeutic approach for FN-RMS patients.

#1098 Identification of SUMO2 as a novel therapeutic target for synovial sarcoma.

R. Iyer, P. Akula Bala, R. Murad, A. J. Deshpande;
Sanford Burnham Prebys Medical Discovery Institute, San Diego, CA

Synovial Sarcoma (SySa) is a rare soft tissue sarcoma that accounts for 5 - 10% of all soft tissue sarcomas. It disproportionately affects children, adolescents and young adults with tumors emerging in muscles, tendons, nerve tissue and joints. Current treatment involves radiation and radical surgery including limb amputation with overall survival around 50% highlighting the urgent need to develop targeted therapies for these patients. In this study, we hypothesized that the fusion SS18-SSX protein found in SySa transcriptionally rewires the tumor cells creating a dependence on specific genes that if uncovered can be exploited therapeutically. To study genes that are selectively essential to SySa, we analyzed the dependency maps (DepMap) whole genome RNAi and CRISPR screening datasets consisting of ~1750 human cancer cell lines including 9 SySa cell lines. We identified 368 target genes that specifically impact the proliferation of SySa when compared to other tumor cell lines. To interrogate these genes systematically, we designed pooled CRISPR libraries and conducted *in vitro* as well as *in vivo* screens in SySa cell line HS-SY-II. Our screens revealed that Small Ubiquitin like-modifier 2 (SUMO2) was one of the most significant dependencies in both the *in vitro* as well as *in vivo* screens. We tested the SUMO2 inhibitor, TAK-981, a clinical stage small molecule inhibitor specific for E1 SUMO-activating enzyme (SAE), against a panel of SySa cell lines with HS-SY-II and SYO1 showing an EC_{50} in the low nanomolar range. Furthermore, TAK-981 treatment potently induced apoptosis and reduced the proportion of cycling cells in both HS-SY-II as well as SYO1 cell lines. Strikingly, transcriptomic studies on HS-SY-II and SYO1 cell lines showed that TAK-981 treatment substantially altered the oncogenic signatures of SySa. This was evident both in the HS-SY-II cell line expressing the SS18-SSX1 fusion as well as the SYO1 cell line expressing the SS18-SSX2 fusion protein. These data strongly indicate that SUMO2 is critical for the transcriptional activity of the different SS18-SSX chimeric oncoproteins. In addition, TAK-981 treatment showed a highly significant downregulation of genes associated with cell cycle progression as well as a modulation of genes of the BAF and PRC1/PRC2 complexes that have been implicated in SySa pathogenesis. Taken together, we developed an integrated computational and experimental screening approach to prioritize and validate selective dependencies in synovial sarcoma. Our studies identify SUMO2 as a novel, selective vulnerability in this cancer and since SUMO2 inhibitors are currently in Phase 1/2 clinical trials for other malignancies, our findings present a novel potential avenue for targeted treatment of synovial sarcoma.

#1099 Combined MEK and RET inhibition overcomes resistance to single agent RET inhibition in medullary thyroid cancer.

Arwa Fallatah[1], Abdelrahman Rahmy[1], Sophia Khan[2], Hsien-chao Chou[3], Kerstin Heselmeyer-Haddad[3], Darawalee Wangsa[3], David Milewski[3], Yong Kim[1], Robert Hawley[3], Young Song[3], Xiaohu Zhang[4], Craig Thomas[4], Jun S. Wei[3], Jong-In Park[5], John Glod[2], Javed Khan[3]

Medullary thyroid carcinoma (MTC) is a rare neuroendocrine cancer, caused by activating mutations in the *RET* proto-oncogene, contributing to 13% of all thyroid cancer mortalities. Patients with metastatic MTC treated with RET inhibitors (RETi) can develop resistance through mechanisms currently being investigated. We aim to understand the molecular mechanisms of acquired resistance to RETi and develop novel combination therapies to circumvent resistance to these drugs. We used TT, an MTC cell line, to develop vandetanib-resistant (VanR) lines, at two independent sites, the Medical College of Wisconsin (MCW) and the Pediatric Oncology Branch (POB) at the NCI. We applied a multiomic approach to investigate the mechanisms of resistance, including Spectral karyotyping (SKY) and multiplex interphase Fluorescence in situ Hybridization (miFISH) to study the karyotype, ploidy, and heterogeneity at a single-cell level. Whole exome and RNA-sequencing was done to identify genetic alterations such as acquired mutations, copy number variations, and gene expression changes. In parallel, we performed genome-wide CRISPR gene knockout (KO) in TT cells treated with selpercatinib or vehicle to develop potential synergistic targeted combination therapy with RETi. Additionally, we performed a cytotoxicity screening using the Mechanism Interrogation Plate (MIPE6.0) library containing 2803 investigational drugs, novel agents, and FDA-approved drugs with known mechanisms of action. SKY and miFISH results showed that, for the parental TT_POB cell line, there were 4 copies of chromosome 10 (location of the *RET* gene), whereas there were 3 copies in TT_POB VanR. This was associated with an increase in the *RET* variant allele frequency, indicating a loss of heterozygosity of the wildtype allele as a mechanism of resistance, which was confirmed by whole exome sequencing. For TT_MCW VanR, we identified a new *RET* solvent front (G810S), as well as an increased copy number of *RET* with an increase in expression. CRISPR KO demonstrated that the knockout of NF1 led to resistance and survival to selpercatinib treatment. The MIPE6.0 screening confirmed resistance to RETi in TT_MCW VanR and sensitivity to multiple MEK inhibitors. *In vivo* testing in a xenograft mouse model confirmed the synergistic/additive activity of combined selpercatinib with trametinib, a MEK inhibitor. In conclusion, using a multiomic approach, we show that resistance to RETi occurs by an adaptive increase in RET signaling through secondary mutations in *RET*, and an increase in expression or dose of the mutant *RET* allele. These genetic events are associated with an activation of RAS signaling, in VanR cell lines, through the ERK/MAPK pathway. Furthermore, we demonstrate that the combination of RET and ERK/MAPK inhibition is synergistic against *RET*-mutant MTC. Future plans include translating our findings through clinical trials at the NCI.

#1100 Fascin-1 inhibitor decreases hepatoblastoma cells tumorigenicity via YAP 1.

L. DIF, A. Martin, S. Basbous, G. Manaud, V. Moreau;
Bordeaux Institut of Oncology, Bordeaux, France

Introduction: Hepatoblastoma (HB) is a liver tumor that arises in children. It's a sporadic malignancy that is often overly aggressive. The current treatment consists of chemotherapy. However, chemotherapy in young patients has disastrous and long-term side effects such as ototoxicity, cardiomyopathy, and infertility. Thus, alternative strategies are needed. One hint is to target the most common mutations in HB. It has been demonstrated that 90% of HB tumors are mutated for the Wnt pathway effector ß-catenin. This mutation leads to an aberrant constitutive activation of Wnt/ß-catenin signaling. Here, we investigate one of ß-catenin transcriptional targets, Fascin-1 that is found up-regulated in many tumors. Fascin1 affects actin organization into bundles, and this leads to cell migration and invasion. Whereas Fascin-1 is absent from normal hepatocytes, we found its expression associated to the poor prognosis C2 subtype of HB. In both human and murine HB samples, Fascin-1 is associated to undifferentiated tumor cells. We further demonstrated that Fascin-1 expression modulates tumor hepatocyte differentiation status through gene expression. In this study, we investigate how Fascin-1 can regulate tumor cell plasticity and whether Fascin-1 is a druggable target in HB tumors.
Methods: We use two classical HB model cells Huh6 and HepG2 and 3 Patient-Derived-Xenograft cell lines. We explore the effect of Fascin-1 actin-bundling activity impairment by using inhibitors, on invasion and migration using Trans-well and wound-healing assays. We follow proliferation and cell death by Flow cytometry and investigate gene expression by PCR and reporter assay. We investigate Fascin modulation of the kinome with PamGene technology.
Results: We show that the inhibition of Fascin actin-binding activity decreases cell invasion and migration as well as proliferation. We show an increase of cell death in Huh6/HepG2 cells but not in the PDX models. A cell cycle arrest is induced, and the cells become senescent. Differentiation genes are overexpressed and EMT genes are repressed. Yap expression is downregulated; Yap promoter activity is downregulated, and Yap is found translocated into the cytoplasm upon Fascin-1 inhibition. These data suggest that Fascin inhibition decreases tumors cell invasion, induces cell senescence, and favors a switch towards a differentiated and these effects on the cells are mediated via the Hippo pathway. The kinome is also modulated.
Conclusion: Fascin-1 is an interesting target in hepatoblastoma, commercialized phase-2 drugs are available, and this study will confirm the potential use of those drugs in HB treatment and elucidate by which mechanism Fascin-1 inhibition impacts tumors.

#1101 A patient-derived xenograft in vitro platform identifies panobinostat as the most efficient drug to treat high-risk hepatoblastoma patients.

S. Demir[1], E. Indersie[2], S. Branchereau[3], E. Hiyama[4], S. Cairo[5], **R. Kappler**[1];
[1]Ludwig Maximilians University, Munich, Germany, [2]XenTech, Evry, France, [3]Bicetre Hospital, Paris, France, [4]University Hospital, Hiroshima, Japan, [5]Champions Oncology, Rockville, MD

Hepatoblastoma is the most common pediatric liver tumor, and the treatment of patients with preoperative chemotherapy and surgical resection of the tumor has led to survival rates of up to 83%. However, resistance of the primary tumor towards chemotherapy and the persistence of metastases still represents major challenges to achieve complete remission in high-risk patients, which is associated with poor prognosis. In order to identify new treatment options, we have used a newly developed in vitro drug-testing platform comprised of conventional cell lines and cultures from dissociated patient-derived xenografts of pediatric liver cancers to test standard-of-care medications used in the current PHITT trial as well as compounds targeting a wide range of different cellular pathways. We identified histone deacetylase (HDAC) inhibitors as a promising drug family to reduce tumor cell growth in a dose-dependent manner, with panobinostat being the most effective drug tested. Subsequent in vitro assays showed that panobinostat reduced short- and long-term proliferation, retarded three-dimensional spheroid growth and ultimately induced apoptosis of hepatoblastoma cells. RNA sequencing indicated that panobinostat results in downregulation of MYC target genes and upregulation of the dual specificity phosphatase 1. Of clinical relevance, the combination of panobinostat with doxorubicin revealed a strong synergistic effect, even stronger than the one of cisplatin and doxorubicin, which is currently given to high-risk hepatoblastoma patients. Moreover, increased expression of *HDAC4* and *HDAC11* in primary tumor tissues was significantly associated with metastatic disease. Our results strongly suggest panobinostat to be used in future therapeutic trials for high-risk hepatoblastoma patients, especially when combined with doxorubicin.

#1102 Amentoflavone enhances regorafenib-induced apoptosis and -inhibited invasion via inactivating STAT3/NF-KB signaling pathway in Hepatocellular carcinoma.

Y. TSAI[1], Y.-T. Chen[2], F.-T. Hsu[1], J.-J. Tsai[3], Y.-C. Liu[4];
[1]China Medical University, Taichung City, Taiwan, [2]National Yang Ming Chiao Tung University, Taipei City, Taiwan, [3]Taipei Veterans General Hospital, Yuan-Shan/Su-Ao Branch, Taipei City, Taiwan, [4]Chang Bing Show Chwan Memorial Hospital, Changhua City, Taiwan

Hepatocellular carcinoma (HCC) is an aggressive tumor and ranks as the third leading cause of cancer-related deaths worldwide. Amentoflavone, a biflavonoid compound, possesses antiviral, angiogenesis-inhibitory, and anticancer properties. Prior studies have illustrated that amentoflavone effectively restrains tumor growth and promotes apoptosis in various cancers, including brain cancer and osteosarcoma. Regorafenib, a small molecule inhibitor of multi-kinases, can inhibit angiogenesis, tumor growth, and anti-tumor metastasis. While regorafenib is a targeted drug approved for the treatment of metastatic colorectal cancer and has also been approved for use in HCC, its effectiveness in HCC is limited. Consequently, our goal is to investigate whether amentoflavone may enhance the sensitivity of regorafenib in treating HCC and explore the underlying mechanisms. In our study, through the combined treatment and combination index analysis, we proved that the combination of regorafenib and amentoflavone may induce cytotoxicity more effectively compared to monotherapy, as assessed by the MTT assay in Huh7 and HepG2 cells. The invasion and migration assays also demonstrated a superior inhibitory effect in the combination group. Additionally, apoptosis markers such as "cleaved caspase-3, -8, -9, Fas and FasL" assayed by flow cytometry, confirm that the combination treatment may induce the extrinsic/intrinsic apoptosis pathway in HCC. In our Western blotting analysis, we observed that the phosphorylation of STAT3 and NF-κB proteins was effectively suppressed by the combination of regorafenib and amentoflavone in Huh7 and HepG2 cells, respectively. Furthermore, our in vivo study confirmed a superior tumor inhibition rate and control rate with the combination of regorafenib and amentoflavone. Importantly, no signs of general toxicity were observed in any of the treatment groups, as evidenced by body weight monitoring and Hematoxylin and Eosin stain (H&E) pathology evaluation. We believe that the combined treatment of these two drugs effectively triggers cell death and suppresses metastatic patterns through the inactivation of the STAT3/NF-κB signaling pathway. These results suggest that amentoflavone has the potential to serve as an adjuvant that sensitizes regorafenib for the treatment of HCC without causing any side effects.

#1103 Molecular signature for treatment-responsive and recurrent Wilms tumors.

J. Jiang, D. B. Allison, R. Burikhanov, S. Ganguly, R. A. Goettl, J. Liu, C. Wang, A. F. Saltzman, T. Tucker, P. H. Spielmann, E. B. Durbin, J. A. D'Orazio, V. M. Rangnekar;
University of Kentucky, Lexington, KY

Wilms tumor is the most common solid renal malignancy in children. To better understand the biology of Wilms tumors and develop drugs especially against tumors that relapse, we sought to identify mutations in the exome, differential gene expression patterns, and tumor suppressor expression status of Wilms tumors in Kentucky. The Kentucky Cancer Registry (KCR) Virtual Tissue Repository identified 29 cases of Wilms tumor diagnosed between 2015 and 2021 at hospitals across the Commonwealth of Kentucky. The Markey Cancer Center Biospecimen Procurement and Translational Pathology Facility prepared tumor microarrays (TMAs) using Wilms tumor and matching normal tissue cores for immunohistochemistry (IHC) analysis. RNA-Seq analysis performed at the Markey Cancer Center Oncogenomics Facility identified a gene signature that was further validated by IHC and reverse-transcription quantitative-PCR (RT-qPCR). Outcome data provided by KCR indicated that increased expression of an anti-apoptotic protein in the tumor counter-intuitively provided better prognosis and outcome to treatment, indicating that the treatments either directly or indirectly targeted this protein. Loss of function of the tumor suppressor proteins in Par-4/PAWR, WT1 and p53 did not explain the higher expression of the cell survival protein. Our multidisciplinary team approach involves basic science/translational researchers, population scientists, biomedical informaticists, and clinicians and has resulted in well-characterized, Wilms tumor tissue microarrays. The next phase of the study is generating patient derived xenografts (PDXs) for a better understanding of Wilms tumor biology in children.

CLINICAL RESEARCH: Radiation Oncology
Poster Session

#1107 Prospective observational study to evaluate the efficacy of oxygen saturation endoscopic imaging for radiotherapeutic response in head and neck squamous cell carcinoma.

K. Tomizawa[1], A. Motegi[1], H. Hirata[1], H. Yamashita[1], H. Sunakawa[1], W. Okano[1], T. Enokida[1], T. Fujisawa[1], S. Zenda[1], M. Nakamura[1], H. Hojo[1], S. Abe[2], M. Sakuramachi[2], H. Igaki[2], Y. Saito[2], K. Matsuura[1], M. Tahara[1], T. Yano[1], T. Akimoto[1];
[1]National Cancer Center Hospital East, Kashiwa, Japan, [2]National Cancer Center Hospital, Tokyo, Japan

Background: Radiotherapy (RT) has a pivotal role in the management of head and neck squamous cell carcinoma (HNSCC), providing effective tumor control and functional preservation. Hypoxia is a cause of radioresistance in HNSCC. We have developed an oxygen saturation endoscopic imaging (OXEI) method to assess real-time tissue oxygenation levels. However, the clinical significance of OXEI in patients with HNSCC receiving RT remains unclear. We evaluated the association between pretreatment tumor oxygen saturation (StO_2) quantified by OXEI and clinical outcomes of patients with HNSCC receiving RT.
Methods: We prospectively recruited patients with HNSCC scheduled to receive RT at 2 institutions. The primary endpoint was the association between pretreatment tumor StO_2 and complete response (CR) rate 8 weeks after completion of RT. Secondary endpoints evaluated the impact of StO_2 on 1-year overall survival (OS) and progression-free survival (PFS) rates after RT initiation. We also evaluated the cumulative incidence of local failure (LF). To explore the relationship between tumor hypoxia assessed by OXEI and gene expression profile, we performed RNA sequencing of 4 tumor samples collected from 2 patients (2 samples/patient) before RT. The hypoxia score for each sample was calculated by gene set variation analysis based on HNSCC mRNA-based hypoxia signatures. We performed gene set enrichment analysis (GSEA) to evaluate whether the biological pathways (Hallmark, Reactome, and KEGG gene sets) showed significant associations with tumor hypoxia.
Results: Of the 50 patients enrolled from March 2019 to February 2022, we analyzed 37 who underwent RT and OXEI. Thirty-six (97%) patients received current platinum-based chemotherapy. The median (range) pretreatment tumor StO_2 of 60 (45-84)% was lower than that of normal mucosa, 66 (56-84)% ($P < 0.01$). Patients with tumor $StO_2 < 60\%$ were classified as the hypoxia group (n =19), and those with tumor $StO_2 \geq 60\%$ as the non-hypoxia group (n =18). The CR rate 8 weeks after RT was not significantly different between the hypoxia and non-hypoxia groups (84% vs. 100%, respectively; $P = 0.23$). After a median (range) follow-up of 33 (9-45) months, the hypoxia group had worse 1-year PFS (74% vs. 94%, $P = 0.017$) and OS (89% vs. 100%, $P = 0.015$) and higher LF rates (21% vs. 6%, $P = 0.036$) compared with the non-hypoxia group. RNA sequencing confirmed that tumor StO_2 reflected expression-based hypoxia scores. GSEA showed upregulation of reactive oxygen species (ROS) and KEAP1-NFE2L2 pathways in hypoxic samples (StO_2 of 59%) compared with non-hypoxic samples (StO_2 of 70%; adjusted $P < 0.01$), consistent with the fact that hypoxic stress increases ROS production.
Conclusion: Our findings suggest that pretreatment tumor StO_2 quantified by OXEI correlates with 1-year PFS, OS, and LF rates of patients with HNSCC receiving RT.

#1108 The impact of adjuvant radiotherapy (ART) and survival prediction by machine learning in intracranial hemangiopericytoma (HPC).

S. Alshwayyat[1], A. A. Al-Khalili[1], A. Erjan[2], H. Kamal[1], T. Abdulsalam[1], M. Alshwayyat[1];
[1]Jordan University of Science & Technology, Irbid, Jordan, [2]King Hussein Cancer Foundation, Amman, Jordan

Background: Intracranial HPC is a rare brain tumor that accounts for less than 1% of all primary central nervous system malignancies. Surgery is the primary treatment, and while radiation may reduce the risk of local recurrence, its overall effectiveness remains uncertain. Therefore, it is crucial to develop reliable predictions for personalized care and improved management. In this study, we used machine learning (ML) techniques to predict the survival of patients with intracranial HPC.

Methods: Data were obtained from the Surveillance, Epidemiology, and End Results (SEER) database (2000-2019). Patients with other malignancies or lack of pathological diagnosis were excluded. T-tests and chi-square tests compared variables, while Kaplan-Meier, log-rank tests, and Cox regression identified prognostic factors for overall survival (OS) and cancer-specific survival (CSS). Patient records were randomly divided into training (80 %) and validation (20 %) sets. Univariate Cox regression and least absolute shrinkage and selection operator were used to identify the significant factors linked to survival, which were used to establish a nomogram for predicting the 3- and 5-year OS and CSS.

Results: Of the 367 included patients, 121 underwent surgery and 246 underwent surgery + ART. The median survival time was 54 months. Patients who underwent surgery had 5-year OS rates of 61% and 86% for CSS, while those treated with surgery + ART had 81% and 96% survival rates, respectively. The two treatment groups showed significant differences in the OS and CSS ($p<0.022$ and $p<0.017$, respectively). Age ≥ 50 years was a poor prognostic factor for OS, whereas ART, localized stage and regional stage were good prognostic factors. No significant factors were associated with CSS. To construct the OS Nomogram, three predictors, age, stage, and treatment method, were chosen. In the training and validation sets, the C-indices are 0.799 and 0.736, respectively. The receiver operating characteristic curves (AUCs) for the 3- and 5-year OS in the training set were 0.594 and 0.617, respectively, whereas those in the validation set were 0.56 and 0.59. For the CSS nomogram, two factors, age and stage, were utilized. The C-indices for the training and validation sets are 0.814 and 0.774, respectively. In the training set, the AUCs for 3- and 5-year CSS were 0.585 and 0.605, respectively, and 0.563 in the validation set. The most important risk factor was the distant stage, while the most important protective factor was age less than 50 years.

Conclusion: This study shows that ART has a significant impact on the treatment of Intracranial HPC and provides better survival outcomes. ML has been used to create prediction models to support personalized patient care. These findings provide valuable insights into the management of this rare brain tumor and the potential of data-driven approaches to improve treatment and outcomes.

#1109 LINC01770 stabilizes TEAD1 expression to mediates nasopharyngeal cancer radiation resistance rendering tumor cells vulnerable to ferroptosis.

Q. Xu, C. Sun, S. Zhang, X. Li, L. Chen, M. Chen;
Sun Yat-sen University Cancer Center, Guangzhou, China

Background: Long noncoding RNAs (lncRNAs) regulate various essential biological processes, including cell proliferation, differentiation, apoptosis, migration, and invasion. However, in nasopharyngeal carcinoma (NPC), the clinical significance and mechanisms of lncRNAs in malignant progression are unknown.
Methods: LINC01770 expression was determined using quantitative real-time reverse transcription PCR, and its prognostic value was evaluated using Kaplan-Meier survival analysis. RNA sequencing and bioinformatic analysis were used to determine the potential function of LINC01770, and its biological effects were investigated using *in vitro* and *in vivo* experiments. Mass spectrometry-coupled RNA pull-down assays and western blotting identified LINC01770 interacting proteins, followed by confirmation using RNA immunoprecipitation (RIP) assays. Ferroptosis and lipid peroxidation were detected using flow cytometry.
Results: LINC01770 was overexpressed in NPC tissues according to microarray screening. Patients with NPC showing high LINC01770 expression experienced shorter survival and worse prognosis. *In vitro* and *in vivo* experiments suggested that knockdown of LINC01770 expression significantly inhibited the proliferation, migration, and invasion of NPC cells. Sequencing and functional complementation experiments showed that LINC01770 regulates the proliferation and metastasis of NPC through TEA domain transcription factor 1 (TEAD1). Meanwhile, RIP and PCR experiments suggested that LINC01770 and TEAD1 were common targets of microRNAs miR-615-5p and miR-1293. Overexpression of LINC01770 promoted ferroptosis *in vitro* and *in vivo* through the TEAD1/Acyl-CoA synthetase long chain family member 4 (ACSL4)/transferrin receptor (TFRC) pathway.
Conclusions: LINC01770 is a prognostic biomarker for NPC and participates in the regulation of TEAD1 signaling pathway through competitive binding to miRNA-615-5p and miRNA-1293, resulting in NPC metastasis and progression. Radiation resistant cells are in a delicate balance between lipid peroxidation and increased vulnerability to ferroptosis, suggesting that ferroptosis could be used to kill NPC cells and reverse their radiotherapy resistance during the malignant progression of NPC caused by high expression of LINC01770. Thus, inducing ferroptosis could be used to treat recurrent and refractory NPC.

#1110 Estrogen receptor β signaling induced radio-resistance in bladder cancer.

H. Ide[1], T. Murakami[1], E. Kashiwagi[2], S. Kitaoka[3], A. Komatsuda[3], C. Nishimura[3], S. Funakoshi[3], M. Oya[1], H. Miyamoto[4];
[1]Keio University, Tokyo, Japan, [2]Kyushu University, Fukuoka, Japan, [3]Saiseikai Central Hospital, Tokyo, Japan, [4]University of Rochester Medical Center School of Medicine and Dentistry, Rochester, NY

Introduction and Objective: Although radiotherapy (RT) combined with chemotherapy shows comparable outcomes to surgery, women tend to have higher mortality from bladder cancer (BC) compared to men. Emerging evidence indicated the involvement of estrogen receptorβ (ERβ) signaling in BC progression and the association of ER signaling with DNA repair pathways which are involved in radio-resistance. Therefore, we evaluated the association between ERβ signaling and the sensitivity to BC cells.
Methods: We compared the inhibitory effect of RT on BC cell viability between ERβ positive [5637 and T24 expressing control short-heparin RNA (shRNA)] and ERβ negative (5637 and T24 expressing ERβ-shRNA) cells. Moreover, we compared DNA double-strand breaks (DSB) via γ-H2AX foci formation, as well as the expression levels of DNA repair genes, in these cells after RT. Finally, in a mouse xenograft model, we evaluated it on the growth of ERβ positive tumor treated with radiation combined with mock or tamoxifen treatment.
Results: *In vitro* experiment showed that ionizing radiation reduced the numbers of viable cells in ERβ negative cells more significantly than those in ERβ positive cells. Moreover, tamoxifen treatment reduced the numbers of viable cells more than mock treatment in ERβ positive cells, while tamoxifen didn't show significant effects in ERβ negative cells. The down-regulation of ERβ resulted in a delay in DSB repair 4-24 hours after RT. We then established radio-resistant cells and confirmed considerable elevation of the expression of ERβ as well as DNA repair genes including RAD51 and RAD54. Estradiol treatment induced the expression of these genes and tamoxifen abolished these effects. Finally, in vivo experiment showed that tamoxifen enhanced the cytotoxic effects of RT in xenograft bearing mice.
Conclusions: These results indicated that ERβ signaling inversely correlated with sensitivity to RT in BC. Thus, ERβ inhibition have a potential of enhancing the cytotoxic effects of radiation, especially in ERβ positive BC cells.

#1111 Poor radiation sensitivity and potential radiosensitizers for betel-nuts related head and neck squamous cell carcinoma in Taiwan.

J.-P. Chen, J.-Y. Chang, R.-L. Hong;
National Taiwan University Hospital, Taipei, Taiwan

Background: Betel nut chewing might contribute to strong invasion & treatment refractoriness in HNSCC from Taiwan. Betel-nuts exposed HNSCC cell line, TW2.6, had high PDL1, defective p53 mutation, p16 loss, & BCL2 overexpression. In our studies, PI3K/AKT/mTOR inhibitors, anti-angiogenesis therapies, CDK4/6 inhibitors, DDR interventions, epigenetic modifications, and immunotherapy-containing regimens will be future combination options. The genomic signature of TW2.6 has been figured out in our study(AACR2020 & 2023), too, mainly with PIK3CA H1047R mutation, high TMB(8.42 muts /Mb)/MSS, VEGF-A amplification, p53/MYC/HRAS/DDR2/ PDGFRbeta/EPHB1/ATM mutations, FAT1 loss, amplification of TERT/ FGF10/CCND3/SOX9/IL-7R/SDHA/RICTOR/FLCN, CDK12/PTPRD loss of function, CDK8 mutation, & deletions of STK11/ARID1B/MITF/TNFAIP3 and molecularly-guided novel interventions will be designed. Purpose & Methods: Polo-like kinase 1 inhibitor(volasertib), gluconate(blocking citrate transport & glucose metabolism), IAP inhibitor(Debio1143), glutaminase 1 inhibitor(CB839) were tested on TW2.6 to evaluate synergistic effects with radiation. Results: TW2.6 was resistant to volasertib, gluconate, or radiation alone; but sensitive to Debio1143 and CB839. Volasertib significantly enhanced radiation. The flow cytometry revealed volasertib and radiation resulted in a significant G2/M arrest. Western blotting showed volasertib and radiation increased p-histone3, p-CDK1, & cyclin B levels and induced apoptosis. Gluconate, CB839, or Debio1143 each had significant synergistic effects with radiation. The radiosensitization efficacy would be volasertib>gluconate>CB839>Debio1143. Conclusions: In Taiwan, patients with R/M HNSCC progressing within 3 months after CCRT could be rescued by early ICIs. Recently, sequential CCRT followed by ICI or Debio-1143 with CCRT showed potential survival benefits. In our studies, novel agents such as PLK inhibitor, gluconate, and CB839 had even better radiosensitization compared with Debio1143. Sequential CCRT with novel agents followed by ICI will be the future trend, esp. in biology-aggressive betel-nuts related locally advanced HNSCC in Taiwan.

#1112 Modulated dNTP pools and their influence on DNA repair mechanisms and apoptosis in therapy resistant cancers.

D. Monroe, M. Kehinde-Ige, E. Usoro, A. Williams, E. Steinbeck, S. Aycox, H. Shi, W. Daddacha;
Augusta University, Augusta, GA

Glioblastoma (GBM) is a deadly primary tumor of the brain, accounting for almost half of all diagnosed malignant gliomas. Ionizing radiation (IR) and some chemotherapeutics strategically target cancer cells by causing DNA double-strand breaks (DSBs). However, cancers like GBM often develop resistance to DSB-inducing therapeutics due to dysregulated DNA repair. Homologous Recombination (HR) is an error-free DSB-repair process consisting of proteins that are often dysregulated in GBM, causing overactive DNA-repair, therapy resistance, and poor patient outcomes. Proteins involved in the HR-repair process have been extensively investigated; however, therapeutic resistance remains common. Here, we provide an alternative approach to target DSB-resistant GBM by modulating the dNTP pool instead of solely targeting DNA-repair proteins. Our goal is to understand the interplay between dNTP pools and DSB- repair. dNTPs are a necessary constituent to repair DSBs; however, the role of the dNTP pool in DNA damage repair is not fully understood. Previous research shows that the dNTP pool remains unchanged after inducing DSBs, highlighting the importance of a tightly regulated dNTP pool. Using a neutral comet assay, we quantified accumulated double-stranded breaks in different treatment groups. We then analyzed these groups using immunofluorescent microscopy to examine distinct proteins involved in HR-mediated repair. We carried out RNA sequencing analysis to determine differential gene expression. We quantified cell viability and apoptotic cell populations via flow cytometry and Alamar blue assays. We determined protein interactions using immunoblotting and immunoprecipitation assays. We found that increasing the dNTP pool prior to IR treatment led to impaired DNA DSB repair in GBM cells as determined by a neutral comet assay. When analyzing key proteins involved in HR via immunofluorescence, we observed a significant decrease in RPA70 localization to the DNA damage site, indicating a disruption in end resection, a necessary phase of HR. Our RNA sequencing results show that increasing the dNTP pool in LN229 GBM cells prior to IR treatment caused significant changes in gene expression when compared to IR treatment alone. The most impacted pathways most were apoptosis, p53 cell cycle arrest, and DNA repair. The pathway analysis has identified genes of interest in the synergistic dNTP + IR treatment model. Significant increases in apoptosis and decreases in viability were observed 48 hours after inducing DSBs in LN229 cells with elevated dNTP pools. Not only do these data suggest that HR efficiency is reduced due to end resection impairment, but they also show that as a result, cell viability is destabilized due to prolonged DNA damage, resulting in apoptosis. The identification of this impairment may be essential in finding novel therapeutic approaches to sensitize therapy resistant GBM.

#1114 Evaluating strategies to harness metabolic vulnerabilities in cervical.

Julie K. Schwarz[1], Nishanth Gabriel[1], **Aunannya Banik**[2]

[1]Washington University School of Medicine, St Louis, MO,[2]Sweet Briar College, Sweet Briar, VA

Tumor cells frequently alter their metabolism to generate biomolecular intermediates for tumor maintenance and proliferation. Previous reports from Dr. Julie Schwarz's laboratory have shown that cervical cancer cells with altered AKT/mTOR pathways show increased reliance on glucose and exogenous glutamine. The laboratory has introduced PIK3CA E545K mutation and PTEN null mutation in cervical cancer cell line SiHa. Further, to evaluate the role of glutamine metabolism in these genotypes, these cells were cultured in sequentially lower levels of glutamine until these cells were able to proliferate without exogenous glutamine supplementation. These isogenic long-term glutamine-deprived (QD) cells allow us to tease out the role of these specific mutations in cellular metabolism. In our study, long-term glutamine deprivation inhibits the proliferation of rapidly proliferating PI3K-AKT-altered cell lines. Even though glutamine is required for GSH synthesis, which quenches reactive oxygen species, QD cells were refractory to cisplatin and irradiation. Since PI3K-AKT altered were dependent on exogenous glutamine, it was expected that QD cells would have lower GLS levels to inhibit glutaminolysis. However, GLS levels in WT and QD were similar. Altogether, these data indicate that in PI3K-AKT altered cervical tumor glutamine antagonists can reduce tumor proliferation. Further glutamine reduction does not alter GLS levels and hence GLS can be targeted as well to further improve treatment outcomes. To evaluate the alternate metabolic dependencies in cervical cancer tumors, both cellular as well as secreted metabolites were evaluated. To identify alternative pathways that are activated in these glutamine-deprived cell lines, we cultured these cells in uniformly labeled 13C glucose. Mass spectrometric studies also evaluated the protein levels of various metabolic intermediates in glutamine-deprived cell lines compared to control cells. To confirm our observations, we used kit-based assays to evaluate metabolites in the cells. To further confirm the change in the metabolite pathway we evaluated changes in transcriptional changes of regulating proteins/enzymes. This pre-clinical study reinforced efforts that are anticipated to reveal new metabolic vulnerabilities of cancer cells that can be targeted by therapeutic interventions. This study also helped us evaluate druggable metabolic targets that can be targeted for effective tumor eradication along with conventional treatment. This understanding will help advance the pre-clinical trials persistent to the cure of cervical cancer.

#1115 Enhancing lung cancer sensitivity to chemotherapy, radiation, and chemo-radiation through inhibition of a mitotic checkpoint kinase BUB1.

S. Thoidingjam, S. Sriramulu, S. L. Brown, F. Siddiqui, B. Movsas, S. Gadgeel, S. Nyati;
Henry Ford Health, Detroit, MI

Non-small cell lung cancer (NSCLC) and small cell lung cancer (SCLC) represent two major subtypes of lung cancer, marked by challenging treatment resistance. Our study explores the inhibition of BUB1, a critical mitotic checkpoint kinase, in conjunction with radiotherapy and chemotherapy. This approach has the potential to overcome resistance, thus enhancing the efficacy of treatment and improving treatment outcomes for lung cancer patients. We analyzed BUB1 expression in lung cancer using TCGA datasets and patient tissue microarrays (TMAs). In vitro experiments used four NSCLC and two SCLC cell lines with BUB1 inhibitor (BAY1816032), Paclitaxel, Cisplatin and Olaparib. Cells were irradiated (2, 4, or 6 Gy), and assays measured proliferation, long-term effects, DNA damage, and repair. Bioinformatic analysis in NSCLC subtype, lung adenocarcinoma (LUAD) demonstrated marked overexpression of BUB1, correlated with cancer stage, tumor grade and survival. Lung cancer TMAs revealed elevated expression of BUB1 protein in SCLC that correlated with poorer survival. BUB1 inhibition (BUB1i) induced cytotoxicity in LUAD cell lines at micromolar concentrations, while nanomolar concentrations enhanced cell death significantly when combined with radiation. Furthermore, BUB1i sensitized LUAD cells to different classes of chemotherapy (Paclitaxel, Cisplatin), and PARP inhibitor (Olaparib) alone (chemo-sensitization) or with radiation therapy (chemo-radiosensitization). H2030 and H1975 demonstrated higher chemo-radiosensitization efficacy compared to A549, likely due to genetic differences, potentially including a p53 mutation that improves sensitivity by affecting DNA repair and cell cycle regulation. Preliminary investigations revealed DNA double-strand breaks, indicated by prolonged γH2AX foci, and the inhibition of the NHEJ DNA damage repair pathway after BUB1 ablation. Among SCLC cell lines, NCI-H1876 demonstrated higher radiosensitivity upon BUB1 ablation compared to NCI-H2198, potentially due to genetic differences/mutations affecting radiation response. The study highlights the potential of BUB1i in enhancing the sensitivity of NSCLC and SCLC cells to radiotherapy and chemotherapy and provide rationale to explore BUB1i as a novel approach to enhance lung cancer therapy in clinical trials.

#1117 To investigate the effect of fluoxetine combined with radiation therapy on hepatocellular carcinoma.

B.-X. Chen[1], T. Liao[2], R.-E. Lu[1], F.-T. Hsu[1], Y. Chang[3],

[1]China Medical University, Taichung, Taiwan, [2]National Yang Ming Chiao Tung University, Taipei, Taiwan, [3]Taipei Medical University-Shuang Ho Hospital Ministry of Health and Welfare, New Taipei City, Taiwan

Hepatocellular carcinoma (HCC) is a highly prevalent and lethal primary liver tumor. It commonly occurs in individuals with chronic liver diseases, such as hepatitis B or C related cirrhosis. Despite conventional treatments, such as surgery and chemotherapy, the prognosis for HCC remains poor. The optimal treatment for patients with HCC is contingent on various factors, including the size and location of the tumor, the functional capacity of their liver, and their overall health status. Radiation therapy (RT) is a prevalent cancer treatment modality that targets rapidly dividing tumor cells by utilizing high-energy radiation. It is frequently administered alongside other treatments, such as surgery and chemotherapy, to improve the likelihood of successful cancer management. The timing of RT may vary, as it can be delivered before, during, or after other therapies depending on the patient's specific clinical situation. It's important to note that there are limits to the amount of radiation a patient's body can safely receive over their lifetime. For this reason, RT is often combined with other cancer treatments to enhance its effectiveness in sensitizing HCC cells. Fluoxetine is an anti-depressant drug that has also been shown to inhibit the growth of HCC. However, the potential role of fluoxetine in combination with RT for the treatment of HCC remains uncertain. In this study, we aim to identify whether fluoxetine may sensitize HCC to RT and evaluate its underlying mechanism. In this study, we employed the MTT assay and colon information to assess the cytotoxic effects of fluoxetine and radiotherapy (RT) at varying doses on HCC. Our findings, obtained through flow cytometry, revealed that the combination treatment can elicit extrinsic/intrinsic apoptosis in HCC cells. Specifically, this combination led to the loss of mitochondrial membrane potential, activation of cleaved-caspase-3, -8, -9, Fas, and FasL. Additionally, flow cytometry analysis showed an increase in the activation of PARP-1 and TUNEL, signifying DNA damage induction. Furthermore, we observed that fluoxetine not only enhances this DNA damage but also inhibits DNA repair, as shown through flow cytometry by the suppression of p-ATM and p-CHK2. Our western blotting assay confirmed that fluoxetine effectively inhibits HCC progression by activating LC3B, indicating the induction of autophagy in HCC cells. Moreover, the combined treatment, as demonstrated by transwell and wound healing assays, significantly reduced the migration and invasion capabilities of HCC cells. To conclude, the induction of apoptosis, DNA damage, and autophagy emerges as a crucial mechanism contributing to the heightened sensitivity of HCC cells to RT when combined with Fluoxetine. These results suggest that the combination of Fluoxetine with RT presents a promising novel approach for the treatment of HCC.

#1118 Mitigating radiation-induced lymphopenia using interleukin-15: Preclinical rationale for clinical translation.

Priti Gupta, Min Wang, Steven Lin

Radiation Oncology, UT MD Anderson Cancer Center, Houston, TX

Background: Radiation therapy is a common treatment for cancer patients, with nearly 50% of them undergoing this procedure. While radiation is effective at targeting tumor cells, it also has the unintended consequence of killing lymphocytes, which are among the most sensitive cells to radiation within the erythroid, myeloid, and lymphoid lineages. This phenomenon is known as radiation-induced lymphopenia (RIL) and is considered a negative prognostic factor in various malignant solid tumors. It occurs severely in over 40% of solid tumor patients who receive radiotherapy. Some previous studies have shown promising results with IL15 therapy in increasing circulating lymphocytes in cancer patients. However, until now, no studies have investigated the impact of IL15 in the context of radiation-induced lymphopenia. Our study aims to investigate whether IL15 can boost lymphocyte numbers and decrease tumor burden following radiation treatment in a mouse model.

Methods: To conduct our study, we subcutaneously injected TSA tumor cells into the flank region of mice. Once the tumors reached a palpable size, approximately 50mm^3, we divided the mice into four groups: Control (Con), Irradiation (IR), Control with IL15 (Con+IL15), and Irradiation with IL15 (IR+IL15). The irradiated mouse groups received a radiation dose of 2 Gray in the thorax and 1 Gray in the spleen for five consecutive days, simulating the severe radiation-induced lymphopenia observed in cancer patients. After the radiation treatment, the IL15-treated groups received IL15 in combination with recombinant IL15 in a 1:6 ratio weekly. Throughout the experiment, we monitored the circulating lymphocytes and tumor growth. After two weeks following the last radiation dose, we euthanized the mice, collected blood, spleen, and tumor samples, and identified immune cells using flow cytometry.

Results: The radiation treatment significantly increased tumor growth while decreasing the number of lymphocytes, including B cells, T cells, and NK cells, in the blood. IL15 administration led to an increase in the number of lymphocytes both in the blood and within the tumor compared to the irradiated group. We observed a trend toward reduced tumor growth in the group that received both IL15 and radiation (IR+IL15) compared to the group that received radiation alone (IR).

Conclusion: IL15 effectively boosted the number of lymphocytes in both the bloodstream and tumors, resulting in slower tumor growth in the IL15-treated group compared to the irradiated group. This study is of significant importance as it demonstrates the potential of IL15 to counteract radiation-induced lymphopenia in mice with TSA tumors. Further testing of these findings is currently underway in MC38 tumor-bearing mice, a cell line known to be more radiation-sensitive.

#1119 Novel fibroblast activation protein targeting radioligand for imaging and radiotherapy of solid tumors.

R. Mukkamala, L. D. Spencer, C. J. Daniel, P. Tudi, M. N. Kaine, A. Horner, S. Madduri, P. S. Low;
Purdue University, West Lafayette, IN

Fibroblast activation protein has emerged as an attractive biomarker for the imaging and therapyof ~90% of human epithelial cancers due to its expression on cancer associated fibroblasts (CAFs), but not on fibroblasts in healthy tissues. Not surprisingly, several small molecules and peptide-based radioligands that target FAP have been introduced into human clinical trials, but preclinical and clinical data suggest that these radioligand therapies suffer from inadequate tumor uptake, short tumor residence times, or unwanted uptake in the healthy tissues. Hence, there remains an unmet need for development of new FAP-targeted radioligands with improved therapeutic properties. For this purpose, we have designed and synthesized a higher affinity and specificity FAP-targetingligand (FAP8) and linked this ligand via a PEG spacer to both a well-known metal chelator (DOTA)and a 4(-iodo)-phenyl butyric acid pharmacokinetic extender to yield the trifunctional conjugate, FAP8-IP-DOTA. Binding affinity and FAP specificity studies reveal that FAP8-IP-DOTA exhibits high affinity and selectivity for FAP (IC_{50} = 1.6 nM) relative to its ubiquitous homologs' prolyloligopeptidase (IC_{50} = 16.5 nM) and dipeptidyl peptidase-IV (IC_{50} = 865.0 nM). Moreover, ^{177}Luand ^{111}In radiolabeled forms of the conjugate were found to bind a FAP-transduced cell line (HEK-FAP) with a K_d = 3.0 ± 2 nM, and this binding was completely suppressed upon co-incubation with unlabeled conjugate, i.e., further confirming FAP's specificity. SPECT/CT imaging studies following intravenous injection of ^{111}In labelled FAP8-IP-DOTA into mice expressing HT29, MDA-MB-231, KB or 4T1 tumors then demonstrated high tumor uptake and remarkably prolonged tumor retention of >8 days. Biodistribution studies of the ^{177}Lu labelledFAP8-IP-DOTA conjugate in mice implanted with either FAP-negative 4T1 tumor cells or FAP-transduced HEK tumor cells at different time points further revealed declining tumor radioactivity from 12.0 to 2.0 % ID/g and 21.0 to 12.0 %ID/g between 1h and 168h post injection, respectively. Importantly, uptake of the same conjugate in the healthy tissues was minimal over this time course, with most radioactivity clearing rapidly. Comparative dosimetry analyses showed tumor: healthy tissues ratios of >5-fold for all major organs. Finally, analysis of tumor inhibiting activity demonstrated that ^{177}Lu-FAP8-IP-DOTA suppressed tumor growth between 60% and 100% in all xenograft models tested (HT29, MDA-MB-231, KB and 4T1), with remarkably improved overall survival rates compared to untreated groups. Based on these promising results, we suggest that FAP8-IP-DOTA warrants further evaluation for possible translation into human clinical trials.

#1120 CD8 ImmunoPET imaging identifies an immunogenically active tumor microenvironment following radiotherapy in primary TNBC.

P. N. Song[1], S. E. Lynch[1], C. T. DeMellier[1], A. Mascioni[2], J. Fang[2], A. G. Sorace[1];
[1]University of Alabama at Birmingham, Birmingham, AL, [2]Imaginab, Inglewood, CA

Background: Tumor immune composition has been shown to drive therapy response in triple negative breast cancer (TNBC). Radiation is a component of standard-of-care treatments for TNBC, however immune populations have not been studied in the context of radiation resistance in breast cancer. Positron emission tomography (PET) allows for quantifying molecular signatures of the tumor microenvironment, which can precede anatomical changes in tumor volume. Recently, development of immune-targeted imaging approaches has allowed for noninvasive quantification of immune cells, allowing for quantification and long-term therapy response. Preclinical studies have demonstrated that combining therapies, such as radiotherapy and immunotherapy, could be beneficial in treating cancer. The goal of this study is to quantify changes in immune infiltration with [^{89}Zr]-CD8 ImmunoPET following radiation therapy to determine variations in immune activation that can affect therapeutic response in radiation sensitive or radiation resistant tumors.

Methods: Syngeneic radiation sensitive 4T1 or a radiation-resistant 4T1 tumors were treated with fractionated radiation (2 Gy/day) from day 0-5, injected with [^{89}Zr]-CD8 minibody on day 6, and imaged with [^{89}Zr]-CD8 PET on day 7. Following imaging, tumors were excised for biological assays (N = 20) or monitored for longitudinal changes in tumor volume (N = 15). Biological assays included CD8 immunofluorescence or assessment of immune population differences with flow cytometry against T-cells (CD3, CD4, CD8, IFN-gamma), macrophages (CD45, F4/80, CD86 and CD206), and natural killer cells (CD56 and CD16). A non-parametric T-test was used to assess for statistical differences.

Results: In radiation sensitive tumors, [^{89}Zr]-CD8 PET indicated that radiation significantly increases CD8 immune infiltration ($p = 0.02$) compared to controls, which was correlated with immunofluorescence ($p < 0.01$). Immune infiltration was increased in radiation sensitive tumors when treated with radiation therapy (4.6-fold increase in CD86+ M1-like macrophages, 4.7-fold increase in CD206+ M2-like macrophages, 5.3-fold increase in CD8 T-cells and 4.3-fold increase in CD4 T-cells) compared to control tumors. Radiation was observed to increase cytotoxic CD8 immune infiltration in radiation sensitive tumors. In radiation resistant tumors, no significant difference was observed in either CD8 immune infiltration or tumor volume in treated tumors compared to controls ($p = 0.63$).

Conclusions: [^{89}Zr]-CD8 ImmunoPET reveals significant increases in CD8 immune infiltration in a radiation sensitive model of TNBC and identifies an immune altered tumor immune microenvironment. Fractionated radiotherapy was also observed to significantly increase the infiltration of innate and adaptive immune cells.

#1121 Targeting the DNA damage response in high-risk medulloblastoma.

A. DeCarlo, C. Fernandes da Silva, L. Shen, V. Ramaswamy, U. Tabori;
SickKids, Toronto, ON, Canada

Medulloblastoma (MB) is the most common malignant pediatric brain tumour and is currently treated with surgery, external beam radiation and chemotherapy however, current treatments are woefully inadequate, with survival of only 50% but morbidity approaching 100%. A very-high risk group of SHH-activated MB harboring TP53 mutations (TP53mut-SHH) account for a substantial proportion of treatment failures after radiotherapy with a uniformly fatal outcome. Through optimizing radiation as a selection pressure and employing a functional genetic approach through whole-genome CrisprCas-9 dropout screening, the present study aims to identify drivers of radiation resistance and uncover unique vulnerabilities to sensitize these tumours to therapy. The dropout screen was conducted across a panel of established in vitro models of sporadic murine TP53mut-SHH, which resemble the human disease with profound radio-resistance. Initial results reveal that targeting the DNA damage response confer radiation sensitization. However, consistent hits across all models demonstrate non-homologous end-joining (NHEJ) as being synthetically lethal with radiation specifically in TP53mut-SHH. Genetic knockout experiments confirm genes encoding main proteins involved in NHEJ are synthetically lethal in combination with radiation. A small molecule drug screen targeting NHEJ revealed such vulnerabilities may be therapeutically exploited in TP53mut-SHH and are able sensitize these tumours to radiation. Using our unique approach of leveraging newly established models of TP53mut-SHH with a combination of functional genetic screening and small-molecule drug screening, this study highlights the genetic mechanisms of treatment resistance and reveals novel approaches for radiation sensitization. Here, we develop a novel approach to identify targets that are synthetically lethal with radiotherapy and identify multiple synthetically lethal targets at the genetic level which can be therapeutically targeted, allowing the development of new treatments to overcome current barriers.

#1122 Inhibition of HDAC6 enhanced radiation therapy induced antitumor response in melanoma.

X. Li[1], M. Suresh[1], H. Coulibaly[1], D. Quiceno-Torres[1], N. Gajendran[1], K. Tan[1], S. Noonepalle[1], S. Grindrod[2], A. Dritschilo[2], A. Villagra[1];
[1]Georgetown University, Washington, DC, [2]Shuttle Pharmaceutical Inc, Gaithersburg, MD

Patients with advanced melanoma are often treated with radiation therapy (RT) in combination with immunotherapies. Immunogenic tumor cell death induced by radiation is known to activate innate and adaptive immunity. Macrophage activity in the irradiated tumor microenvironment (TME) has been implicated to play a critical role in post-RT innate immune responses. However, tumor-associated macrophages (TAMs) due to their phenotypic plasticity convert from initial antitumor M1 phenotype to protumor M2 macrophages resulting in relapse and metastasis of any surviving tumor cells. Therefore, strategies regulating tumor macrophages post-radiation can enhance the therapeutic effectiveness of radiation therapy. Here, we report targeting HDAC6 function with a novel selective inhibitor (SP-2-225) as a potential therapeutic candidate for combination with RT. When administered intraperitoneally at a dose of 25mg/kg, SP-2-225 resulted in significant tumor suppression in the immunocompetent SM1 murine melanoma model. Phenotyping of tumor immune infiltrate indicated a profound decrease in M2 macrophages resulting in an M1/M2 macrophage ratio and an increase in CD8 effector memory T-cells. Further, in-vitro co-culture studies using trans-well assays indicated that irradiated tumor cells attract M2 macrophages, and treatment with SP-2-225 abrogated the M2 macrophage migration but did not alter M1 macrophage migration. In addition, 24 hours post-RT, intratumor administration of SP-2-225 treated M1 macrophages as adoptive cell therapy resulted in diminished tumor growth. The combination of conditioned M1 macrophages with an irradiated tumor microenvironment resulted in an increased M1/M2 ratio and infiltration of effector memory and central memory CD8 T-cells underscoring the influence of transplanted macrophages on the local antitumor immunity. Therefore, our findings demonstrate the ability of HDAC6 inhibitors to regulate macrophage function and phenotype as a cell therapy for use in combination with radiation therapy.

#1123 Genomic characterization of radiotherapy-associated bladder cancer.

N. Wijetunga[1], K. H. Gessner[1], K. Kanchi[1], S. E. Wobker[1], D. Corcoran[1], M. D. Galsky[2], M. I. Milowsky[1], W. Y. Kim[1], T. L. Rose[1], **J. S. Damrauer[1]**;
[1]University of North Carolina, Chapel Hill, NC, [2]Icahn School of Medicine at Mount Sinai, New York, NY

Background: Bladder cancer (BCa) is the 4th most common cancer diagnosed in men, with 82,290 new cases predicted in 2023. As BCa frequently occurs at an advanced patient age, its diagnosis may follow radiotherapy (RT) for the treatment of prostate cancer. Currently, data is limited regarding the influence of RT on the clinical course and genomic landscape of subsequent BCa, mainly due to a paucity of samples. From prior studies, pelvic radiation confers an increased risk of BCa, with resulting tumors that are largely genomically similar to non-RT tumors with the exception of an increase rate of genomic insertions. Our current study looks to expand on these findings by characterizing the genomes of the largest cohort of RT-associated bladder cancers to date.
Methods: We identified BCa cases from patients with a prior history of pelvic radiation for prostate cancer, and tumor only targeted sequencing was performed using Foundation Medicine (FMI) on FFPE tissue (n=41). For control cases (CTRL), patients with no prior record of pelvic radiation and who had previously underwent standard of care FMI sequencing were included (n=41). Sequencing data were re-aligned to hg38 and mutation calling was performed on the newly aligned sequences.
Results: CTRL and RT cohorts had similar distributions of patients based on race and smoking status. While cT stage was similar between the two cohorts, the CTRL cohort was biased toward higher cN and cM stages with no difference in overall survival (median OS: CTRL = 20m, RT = 23m), though the advanced stage of the CTRL cohort could mask a worse prognosis in the RT cohort. Latency specific analysis revealed short latency tumors (<10 years from RT) had a significantly shorter overall survival than long latency tumors ($p<0.01$, HR=5.59, CI=1.81-17.3), and a numerically, but not significantly, shorter survival than CTRL patients ($p=0.17$, HR=1.55, CI=0.82-2.94). Long latency tumor patients had a significantly longer overall survival than CTRL patients ($p<0.01$, HR = 0.22, CI=0.07-0.63). In line with prior studies, RT samples had increased numbers of insertions ($p<0.01$). In addition, we also detected an increase in SNVs in the RT samples ($p<0.01$). Of note, *KDM6A* alterations were enriched within the RT cohort (CTRL = 10/41, RT = 30/41, $p<0.001$), with series of splice site mutations exclusive to RT samples ($p<0.001$).
Conclusion: Patients diagnosed with BCa within a short interval following pelvic radiation have a worse prognosis. Genomic analysis showed RT-associated tumors having an increased number of insertions, SNVs, and *KDM6A* splice site mutations compared to non-RT tumors. Overall, the spectrum of recurrent alterations within the cohorts were consistent with previous studies, with the exception of the KDM6A mutations. To our knowledge, this is the first report of a RT-associated alteration in a specific gene in bladder cancer and additional studies will be needed to validate and understand the consequences of this finding.

#1124 Prevention of radiation-induced malignancies in Li-Fraumeni syndrome.

P. Psarianos[1], N. Fischer[2], D. Malkin[2];
[1]University of Toronto, Toronto, ON, Canada, [2]The Hospital for Sick Children, Toronto, ON, Canada

PURPOSE: Li-Fraumeni Syndrome (LFS) is a genetic disorder associated with a significant risk of early-onset cancer. This condition is driven by germline mutations in the *TP53* gene which plays a primary role in the regulation of the radiation response. Aberrant TP53 function contributes to radiation vulnerability and a greater risk of secondary, radiation-induced malignancies (RIMs). As a result, therapeutic options for LFS patients are often limited to exclude radiotherapy (RT), which may otherwise be beneficial for the treatment of certain primary tumors. Data from our lab demonstrate an aberrant transcriptomic response to irradiation (IR) in mutant p53 patient skin fibroblasts compared to wildtype; however, it is unknown whether reprogramming this radiation response can decrease the risk of RIM in LFS. Metformin, a commonly prescribed anti-diabetic drug, is associated with lower cancer incidence and may decrease cancer-related mortality in murine LFS models. In addition to its potential anti-tumorigenicity, studies have shed light on the ability of metformin to prevent IR-induced damage in normal tissue; hence, we hypothesize that metformin can reprogram the radiation response to protect against radiation injury and delay the onset of RIM in LFS.
METHODS: To establish a murine model of RIM in LFS, and to investigate whether metformin can delay tumor onset in this model, whole-body or localized IR were administered to mice harboring a hotspot *Trp53*$^{R172H/+}$ mutation in the presence and absence of metformin. Serial MRI was conducted to monitor for tumor development. To understand the effect of metformin on the mutant p53 radiation response *in vivo*, a similar murine workflow was established and irradiated skin was collected longitudinally from untreated and metformin-treated cohorts for whole transcriptome sequencing. Sequencing data were functionally validated in a separate cohort of mice using flow cytometry. In parallel, we performed RNA sequencing on LFS patient fibroblasts to characterize the effect of metformin on the human radiation response.

RESULTS: We demonstrate that IR decreases tumor latency in TP53$^{R172H/+}$ mice, and that metformin significantly delays tumor onset within the radiation field. Moreover, transcriptomic data revealed that metformin upregulates apoptosis following IR in TP53$^{R172H/+}$ mice. Flow cytometry analysis of the radiation response validated these findings, demonstrating that metformin promotes the apoptosis-driven clearance of damaged, potentially tumorigenic cells following IR. Transcriptomic data from patient cell lines will be presented.
CONCLUSIONS: Overall, we show that metformin may delay RIM in LFS mice, and have begun to characterize the biology underpinning this reprogrammed response to IR. This study is the first to highlight metformin as a radioprotective agent in the context of germline mutant p53, with the potential to broaden RT treatment options for LFS patients.

#1125 TNIK induced chemoradiation resistance in small cell lung cancer.

D. Dutta Chowdhury[1], E. Imada[2], N. Connis[3], T. Nguyen[1], J. Chang[1], D. Council[1], A. Lafargue[1], M. Rezaee[4], P. T. Tran[1], L. Marchionni[2], C. L. Hann[3]; [1]University of Maryland School of Medicine, Baltimore, MD, [2]Weill Cornell Medicine, New York, NY, [3]Johns Hopkins University School of Medicine, Baltimore, MD, [4]Johns Hopkins University, Baltimore, MD

Chemoradiation (CRT) is the standard first-line therapy for limited stage small cell lung cancer (LS-SCLC), which is characterized by early metastasis, intrinsic-acquired CRT resistance and tumor recurrence. CRT confers a 20-25% 5-year overall survival in patients with LS-SCLC. In this study, we utilized patient-derived xenograft (PDX) models to demonstrate CRT resistance of SCLC and identified CRT resistance candidate genes from various SCLC PDX that represent the majority of molecular subtypes (n=4 that include SCLC-A and SCLC-N subtypes). RNA-seq data identified *TNIK* (Traf2- and Nck-interacting kinase) as one such gene that is consistently upregulated in SCLC PDXs exposed to CRT compared to single modality treatments. Copy number gains of *TNIK* were also present in human SCLC samples. Overcoming this CRT resistance is crucial in improving treatment outcomes and patient survival. Genetic depletion or pharmacological inhibition of TNIK reduced the *in vitro* clonogenic survival of $TNIK^{high}$ SCLC cells, NCI-H446 and makes them increasingly sensitive to CRT. *In vivo,* pharmacological inhibition of TNIK with the inhibitor NCB-0846, enhances the CRT sensitivity of NCI-H446 cell line-derived xenografts (CDX) in NOD SCID immunodeficient mice. Furthermore, pharmacological inhibition of TNIK *in vivo* demonstrated sensitivity to CRT in LX33 PDX. In conclusion, our results indicate that *TNIK* plays a role in conferring resistance to CRT *in vitro* in SCLC cell lines and *in vivo* in SCLC CDX and PDX models and therefore, can be a potential therapeutic target in limited stage SCLC.

#1126 Extracellular vesicle mediated radioresistance in H3K27M-diffuse midline glioma.

V. Oza, S. Sampathi, Y. Chernyavskaya, K. Flores, J. Blackburn;
University of Kentucky, Lexington, KY

H3K27M-Diffuse Midline Gliomas (DMGs) are a subset of uncurable malignant pediatric gliomas and the deadliest form of brain tumors in children worldwide. Radiation therapy, the current standard of care, is initially effective but all tumors become resistant within 4-6 months. H3K27M-DMGs are heterogenous, comprised of an average of 6 genetically distinct subclones. Some subclones harbor mutations in genes previously linked to radiation resistance, such as *TP53*. We have found subclones are also functionally distinct, with some clones harboring intrinsic radiation resistance. Extracellular signaling between clones is linked with therapy resistance and tumor progression in other tumors, and we hypothesized that radioresistant H3K27M-DMG release small extracellular vesicles (sEVs) that impact the radiosensitivity of neighboring tumor cells. We found that all patient-derived H3K27M-DMG samples examined (n=6) produced sEVs (< 220nm), indicating this is a common feature in this tumor type. We isolated sEVs from a radioresistant (RR) patient-derived H3K27M-DMG cell line and used them to treat radiosensitive (RS) DMG cells. Using flow cytometry to profile sEV uptake dynamics, we found that RR-sEVs are internalized by RS cells within 2 hours of exposure and are retained at 18 hours ($p<0.001$, compared to control). This uptake can be significantly abrogated by proteinase K treatment of the sEVs, ($p<0.001$), indicating that uptake involves sEV surface proteins. We then applied a biosensor approach to assess single-cell phenotypic changes in RS DMG after RR-sEV treatment on radiation-induced cell death, DNA damage, and cell senescence, three dynamic processes. Using a genetically encoded death indicator (GEDI), we found that RR-sEVs significantly enhanced the survival of RS cells after acute radiation exposure ($p<0.001$). This was due to enhanced DNA damage repair as measured by 53BP1 foci ($p<0.01$). Small RNA sequencing of sEV cargo demonstrated that RR-sEVs express multiple miRNAs that are involved in oncogenic signaling such as the miR-7 family, miR-1246, and miR-1290 at several log fold higher than RS-sEVs. Overall, this data reveals the first functional role for sEVs in the context of radiation induced tumor transformation in DMG. We plan to further investigate the primary route of sEV uptake and define the mechanism through which sEV cargo alters radiosensitivity. This study provides new insight into the impact of heterogeneity and sEVs in mediating radioresistance in H3K27M-DMG and may lead to the development of novel radiosensitizers, which are critically needed for all patients.

#1127 Single cell network-based analyses reveal dose-dependent increase in myeloid suppressive cell sub-populations in response to radiation therapy.

A. Krishnan, S. Bansal, S. Sarti, M. D. Kissner, C. Karan, A. Califano, A. Z. Obradovic, C. S. Spina;
Columbia University Irving Medical Center, New York, NY

Background: More than half of all cancer patients undergo radiation therapy (RT) with curative or palliative intent. With the widespread use of immunotherapy to treat cancer, immune effects of radiation are an important consideration in design of sequential and combination therapies. While radiation has been found to deplete lymphocytes, less is known about its effects on the myeloid compartment, which includes both immune activating and suppressive populations. We hypothesized that a network-based analysis of single cell proteogenomic data generated from tumor-infiltrating immune cells can identify druggable proteins in pathways driving unwanted immunosuppressive changes with radiation, particularly among myeloid cells.
Methods: Proteogenomic (CITE-Seq) analysis was conducted on CD45+ immune cells from unirradiated and irradiated orthotopic 4T1 murine mammary tumors three- and ten-days after tumor irradiation (8 Gy x 1 or 8 Gy x 3). Based on expression of select surface proteins, analysis of the CITE-Seq data resulted in eight distinct immune clusters, including three myeloid clusters — monocytes, macrophages, and granulocytes. Using VIPER (virtual inference of protein activity by enriched regulon), an algorithm that infers protein activities from weighted expression on each protein's downstream targets, we identified distinct functional subpopulations within these eight clusters. Further profiling subclusters enriched by RT using the OncoTarget algorithm, we identified druggable proteins with significant inferred activity as potential targets of therapeutic interest.
Results: As expected, lymphocytes were persistently depleted after RT on both radiotherapy schedules. However, three distinct subclusters of myeloid cells with immune-suppressive phenotype became enriched following tumor irradiation, with greater enrichment at the lower radiation dose of 8 Gy x 1: TAM2, PMN1, and PMN4. Surface protein expression enabled us to define the immunophenotype and isolate these three cell clusters from murine 4T1 tumors as well as human renal cell carcinoma tumors for further functional analyses. OncoTarget identified a number of druggable targets, including PARP1 for the PMN1 subcluster.
Conclusion: Suppressive myeloid subpopulations induced by radiation were identified among the immune cells. Combining radiation therapy with inhibitors of these cell populations may provide therapeutic benefit over radiation therapy alone or in combination with checkpoint inhibitor immunotherapies. Future work will experimentally determine if inhibition of druggable protein targets in these myeloid subpopulations improves the overall efficacy of RT.

#1128 Association between gut microbial change and acute gastrointestinal toxicity in patients with prostate cancer undergoing definitive radiation therapy.

B.-S. Jang[1], **D. Lee**[2];
[1]Seoul National University Hospital, Seoul, Korea, Republic of, [2]College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic of

Purpose: This prospective cohort study investigated the association between gut microbial changes and acute gastrointestinal toxicities in prostate cancer patients undergoing definitive radiation therapy (RT).
Methods: Seventy-nine fecal samples were analyzed. Stool samples were collected at the following timepoints: pre-RT (prRT), 2 weeks after the start of RT (RT-2w), 5 weeks after the start of RT (RT-5w), 1 month after completion of RT (poRT-1m), and 3 months after completion of RT (poRT-3m). We computed the microbial community polarization index (MCPI) as an indicator of RT-induced dysbiosis.
Results: Patients experiencing toxicity had lower alpha diversity, especially at RT-2w (P=0.037) and RT-5w (P=0.003). Compared to patients without toxicity, the MCPI in those experiencing toxicities was significantly elevated (P=0.019). In terms of predicted metabolic pathways, we found linearly decreasing pathways including carbon fixation pathways in prokaryotes (P=0.035) and the bacterial secretion system (P=0.005), in patients who experienced toxicities.
Conclusions: We showed RT-induced dysbiosis among patients who experienced toxicities. Reduced diversity and elevated RT-related MCPI could be helpfully used for developing individualized RT approaches.

#1129 A multifaceted study of X-Ray radiation therapy across diverse mouse tumor models.

J. Huang, W. Li, X. He, W. Cheng, L. Zhang, G. Li, Q. Li, Y. Wang, X. Ren, Z. Wei, L. Shi, Y. Wei, J. Jin, L. Li, W. Yun;
Pharmaron, Inc., Beijing, China

In this study, we showcase the application of X-ray radiation therapy of tumor-bearing mice across 13 syngeneic tumors, one intracranial tumor, and in combination with radiosensitizing drugs, aiming to develop potent cancer treatment strategies. 1.We examined the effects of different radiation levels on multiple tumor models using a therapeutic device delivering targeted radiation to the tumor site. 2.We investigated the combined benefits of radiation with the radiosensitizer Gemcitabine on the H22 liver tumor model. 3.We assessed the impact of radiation sensitization on the HCC1975-luc intracranial tumor model in combination with AZD0156, a drug that cannot cross the blood-brain barrier. The integrity of the blood-brain barrier and the presence of the pharmacodynamic marker pRAD50 of AZD0156 were evaluated. The results show that X-ray radiation has anti-tumor effects across diverse models, with combination drug treatment with both Gemcitabine and AZD0156 showing enhanced therapeutic effects. Furthermore, pRAD50 showed decreasing trend in the single dose PD study in HCC1975-luc intracranial model. We conclude that our platform provides robust methods for evaluating the therapeutic effects of X-Ray radiation, offering invaluable insights for the creation of new cancer therapies.

#1134 Dissecting pancreatic cancer tumor-immune microenvironment crosstalk using spatial transcriptomics.

A. Pankaj[1], M. J. Raabe[1], B. K. Patel[1], E. R. Lang[1], J. R. Kocher[1], K. H. Xu[1], L. T. Nieman[1], W. L. Hwang[2], A. C. Kimmelman[3], D. P. Ryan[2], T. S. Hong[2], M. J. Aryee[4], **D. T. Ting**[1];

[1]Massachusetts General Hospital, Charlestown, MA, [2]Massachusetts General Hospital, Boston, MA, [3]NYU Langone Health, New York, NY, [4]Dana-Farber Cancer Institute, Boston, MA

Background: Pancreatic ductal adenocarcinoma (PDAC) often fails to respond to immune therapies due to various factors, including the role of Epithelial to Mesenchymal Transition (EMT) plasticity in conferring broad resistance to diverse therapies. However, the relationship between cancer cell heterogeneity and the tumor immune microenvironment remains unclear. To address this, we utilized single cell RNA-seq and spatial transcriptomics to uncover the landscape of these cell-cell interactions in human PDAC. Here, we applied to specimens from a clinical trial testing Losartan, an indirect TGF-beta inhibitor with FOLFIRINOX chemotherapy and nivolumab (anti-PD1) in a randomized multi-institutional clinical trial for PDAC (NCT03563248).
Methods: Using the NanoString GeoMx Digital Spatial Profiler, we selected multiple regions of interest in formalin-fixed paraffin-embedded (FFPE) human PDAC specimens. Immunofluorescent antibody-guided isolation of RNA and protein from cancer cells (pan-cytokeratin), cancer-associated fibroblasts (alpha-SMA), and immune cells (CD45) were performed. Utilizing the whole transcriptome assay (WTA; 18,000+ protein-coding genes) and a new IO Proteome Atlas (IPA; 500+ plex proteins), we ventured to understand the relationship between tumor cells and the surrounding microenvironment.
Results: PDAC cells, CAFs, and immune cells were successfully characterized using NanoString GeoMx in clinical trial specimens. Analysis revealed associations between cancer cell plasticity, TGF-beta signaling mesenchymal subtypes in PDAC cells. These TGF-beta enriched mesenchymal PDAC cells were enriched in Arm 1 (FOLFIRINOX) compared to Arm 2 (FOLFIRINOX+losartan). Immune deconvolution analysis identified variations in immune infiltrates, showing an anti-correlation between macrophages and T-cells. The IPA analysis revealed lower MHC I protein levels in short compared to long term survivors in Arm 3.
Conclusions: Spatial transcriptomics and proteomics reveal insights into the spatial relationship between PDAC tumor cell EMT plasticity, CAFs, and immune infiltrates. This enables the discovery of novel immune response biomarkers and potential therapeutic avenues to target tumor and microenvironment interactions.
Trial Registration: DF/HCC protocol 18-179: Losartan and Nivolumab in Combination With FOLFIRINOX and SBRT in Localized Pancreatic Cancer. NCT03563248
Ethics Approval: All studies presented were approved by the Dana-Farber/Harvard Cancer Center IRB protocols 18-179.

#1136 Tumor genomic and transcriptomic profiling of patients (pts) with metastatic castration sensitive prostate cancer (mCSPC) who do versus do not achieve an optimal PSA response to androgen deprivation therapy intensification (ADTi).

V. Mathew Thomas[1], B. Chigarira[1], G. Gebrael[1], C. Chehade[1], A. Narang[1], N. Sayegh[1], N. Tripathi[1], Y. Jo[1], C. Tandar[1], A. Srivastava[1], R. Ji[1], E. Dal[1], G. Fortuna[1], H. Li[2], B. L. Maughan[1], U. Swami[1], N. Agarwal[1];

[1]University of Utah Huntsman Cancer Institute, Salt Lake City, UT, [2]University of Kansas Cancer Center, Salt Lake City, UT

Background: Pts with mCSPC receiving ADTi and achieving PSA nadir ≤0.2 ng/mL (PSA-L) have better overall survival (OS) compared to those with a PSA nadir > 0.2 ng/mL (PSA-H). We investigate differences in genomic and transcriptomic profiling between PSA-L and PSA-H.

Methods: In this IRB-approved retrospective study, eligibility criteria included confirmed mCSPC receiving ADTi and having comprehensive genomic profiling (CGP) performed by a CLIA-certified lab (Foundation Medicine and Tempus). Transcriptomic profile was evaluated from Tempus cohort. Pts were divided into 2 groups: PSA-L and PSA-H based on achieving a PSA nadir ≤0.2 ng/mL at any time during treatment course. The DEseq2 pipeline was used to analyze differentially expressed genes between the groups. The data included the Log2 fold change, Wald-Test p-values, and Benjamini-Hochberg adjusted p values (q values) for each differentially expressed gene. These results were subjected to Gene Set Enrichment Analysis (GSEA) to identify pathways enriched in each cohort. All bioinformatic analysis was undertaken using R studio v4.2.

Results: 248 pts were eligible for genomic analysis (PSA-L=166, PSA-H=82). The top 5 most commonly altered genes were *TMPRSS2, TP53, PTEN, APC,* and *SPOP.* Genomic analysis did not reveal significant differences between PSA-L and PSA-H. 78 pts were eligible for transcriptomic analysis (PSA-L=55, PSA-H=23). Table shows differences in the expression of pathways between PSA-L and PSA-H.

Conclusion: While there were no significant differences in genomic aberrations between PSA-L and PSA-H, gene expression profiling showed significant variations in crucial pathways, particularly the AR pathway, which might explain the better outcomes in PSA-L. After external validation, these findings may help personalize medicine prior to initiation of therapy.

Differential gene set expression scores in PSA-L vs. PSA-H

Pathway	**Normalized Enrichment Score (NES)***	**p-value**	q-value
TNF-α signaling via NFKB	2.5	<0.01	<0.01
Androgen Response	1.7	<0.01	<0.01

#1137 Spatial expression profile of mucinous cystic neoplasm indicates a divergent malignant marker patterns in ductal and stromal regions.

A. Ghodrati, C. S. Gopinath, A. Parvizi, M. Gnanamony, L. Demirkhanyan, C. S. Gondi;
University of Illinois College of Medicine (Peoria), Peoria, IL

Mucinous cystic pancreatic neoplasms (MCPN), initially characterized as benign, present a unique challenge, with the five-year survival rate dropping from 100% to 57% if malignancy occurs. In this study, we using spatial genomic expression analysis of MCPN, and focus on the correlations between marker expression patterns in stroma and ductal region. Tissues obtained from surgical samples of a 69-year-old patient with a pancreatic head cystic mass and a history of pancreatitis (staged as T3N1Mx) were embedded in paraffin. These tissues were then sectioned, collected onto subbed slides, and subjected to probe hybridization, ligation, and extraction onto Visum slides following the manufacturer's instructions (10X Genomics). Genomic expression was extracted using established protocols, processed through SpaceRanger, and further visualized in Loupe Browser (10X Genomics). A comparison was conducted between the ductal and stromal regions, both with and without cystic involvement. Our study reveals a significant 5.1 $\log_2$ fold increase in MUC5AC expression in the ductal region, regardless of cystic involvement, suggesting implications for apoptosis regression and cadherin-dependent cell adhesion in MCPN progression. Further analysis indicates a significantly higher expression of TMSB4X exclusively in the ductal region, extending into the surrounding stroma, potentially stimulating MCPN progression by fostering pro-inflammatory cytokine environments. The novel marker IGKC, indicating favorable prognosis and PDAC treatment efficacy, shows high expression in the stroma (1.8 $\log_2$ fold higher). However, around the duct with cystic involvement, its expression is notably reduced (-1.7 $\log_2$ fold lower), suggesting pathways that may contribute to MCPN's progression towards a more invasive PDAC phenotype. Additionally, our study reveals a 1.9 $\log_2$ fold elevated expression of FN1, a biomarker associated with poor outcomes in PDAC patients, in the stroma around the cyst, hinting at a possible pathogenic role of FN1 in cell adhesion, migration, and progression of MCPN to PDAC. Co-expression of FN1 with COMP and TIMP3 within MCPN suggests a concerted effort in the microenvironment, influencing tissue development, maintenance, and extracellular matrix remodeling. Co-localization of FN1 with COMP and TIMP3, particularly within degenerating acinar cells, hints at a potential mechanism in the intricate progression of MCPN to PDAC. These findings contribute to a deeper understanding of the molecular landscape of MCPN, offering potential avenues for targeted interventions to thwart its progression to PDAC, guiding novel diagnostic and therapeutic strategies for pancreatic neoplasms. Further expression data will be presented.

#1138 A single-cell spatially resolved atlas of immune-mediated control of lung adenocarcinoma using 1,000-plex single-cell spatial molecular imaging in a transgenic mouse model.

T. Panciera[1], F. Zanconato[1], M. Cordenonsi[1], M. Forcato[1], G. Vanni[1], S. Bicciato[1], J. Preciado[2], S. Ilcisin[2], K. V. Raay[2], M. Hoang[2], M. Patrick[2], **S. He**[2], J. Beechem[2], S. Piccolo[1];

[1]University of Padua School of Medicine, Padua, Italy, [2]Nanostring Technologies, Seattle, WA

Background: Lung adenocarcinoma is one of the leading causes of cancer-related mortality. One of the most frequently occurring mutations in lung cancer is KRAS mutations. Recent development of chemical inhibitors that specifically target oncogenic variants of Ras, particularly the commonly mutated KRAS-G12D isoform, represents a significant breakthrough in targeted therapeutics. The tissue-level mechanisms underlying the cell-autonomous and non-cell-autonomous effects of KRas-G12D inhibitors are poorly understood. Additionally, the effectiveness of KRas-G12D inhibitors in lung cancer models remains unknown. To address these gaps in knowledge, we analyzed the spatial interactions between cancer cells and the surrounding tissue microenvironment during the process of tumor eradication mediated through KRas-G12D inhibitors.

Methods: We utilized a genetic mouse model of non-small cell lung cancer (NSCLC), driven by the activation of KRas-G12D in combination with the loss of p53. We investigated the immune-mediated tumor recognition following the targeting of KRas-G12D in an immunocompetent setting. Lung samples were collected from control mice and treated. Spatial transcriptomic analysis (CosMx™ SMI 1,000-plex Mouse Universal Cell Characterization Panel) were employed to obtain a high-plex, single-cell, temporal and spatially resolved molecular atlas of lung tumor regression.

Results: Prior to Kras inhibitor treatment, mice displayed both LuAD and lung adenomas. Lesion size and histological grade progressively decrease during pharmacological treatment with Kras inhibitor. 906 unique genes were detected above background on intact FFPE tissue slides, along with 4 protein markers for optimal single-cell segmentation results. Concordance between CosMx SMI and scRNAseq was assessed and demonstrated high assay sensitivity and specificity of the CosMx assay. LUAD cell subtypes were identified and showed distinct spatial features. Molecular states, and receptor-ligand interactions, within niche-specific signaling networks were investigated to underline molecular mechanism of immune attack and eventual eradication of tumors.

Conclusion: This study provides novel insights into the temporal and spatial dynamics of KRas-G12D inhibitor-mediated tumor regression in lung cancer, shedding light on the previously unknown cell-cell interactions occurring during this process. By investigating these spatiotemporal aspects, we aim to enhance our understanding of lung cancer biology and potentially identify new immunotherapeutic biomarkers. Moreover, the research tools used in this study have implications for the design of future preclinical studies exploring the potential of immuno-oncology combination therapies. FOR RESEARCH USE ONLY. Not for use in diagnostic procedures.

#1139 Unravelling tumor heterogeneity in patients with HER2-low hormone receptor-positive breast cancer using spatial transcriptomics.

D. Fimereli[1], M. Serra[1], M. Rediti[1], F. Lifrange[2], N. Occelli[1], L. Collet[1], D. Vincent[1], G. Rouas[1], L. Craciun[1], D. Larsimont[1], D. Venet[1], M. Vikkula[3], F. P. Duhoux[4], F. Rothe[1], C. Sotiriou[1];

[1]Institut Jules Bordet, Brussels, Belgium, [2]University Hospital Center of Liege, Liege, Belgium, [3]de Duve Institute, Brussels, Belgium, [4]Institut Roi Albert II, Cliniques universitaires Saint-Luc, Brussels, Belgium

Background: The current binary distinction between HER2-positive and HER2-negative breast cancer (BC) has recently been challenged by the emergence of the HER2-low entity. Antibody-drug conjugates targeting HER2 have shown efficacy in both HER2-positive and HER2-low BC, while some preliminary evidence showed efficacy also in patients with HER2-zero BC. Here, by combining spatial transcriptomics (ST) and morphological annotation, we aimed to investigate the inter- and intra-tumor heterogeneity of ERBB2 expression in relation to breast cancer IHC subtypes.

Methods: We performed ST (Visium 10X Genomics) on frozen tumor samples from patients with hormone receptor positive (HR+) ductal BC with HER2 IHC staining and FISH. Hematoxylin/eosin slides were morphologically annotated integrating manual and machine learning-based approaches reaching single-cell resolution (QuPath software). The relative histomorphological categories composition of each spot across the ST slide was computed as percentage of pixels. Spots were defined as tumoral if the percentile of pixels in that spot surpassed the 80th percentile of all the tumor spots in the cohort.

Results: Our cohort consisted of 56 HER2-zero (IHC 0), 30 HER2-low (IHC 1+) and 20 HER2-positive (IHC 2+/FISH positive or IHC 3+) samples. HER2-zero samples contained a significantly higher percentage of acellular stroma spots compared to HER2-low (pvalue=0.04), while no other morphological annotation showed a difference, including tumor spots. Only tumor spots were retained for downstream analysis. A difference in the ERBB2 gene expression was found at the spot level, with a higher expression in HER2-low samples compared to HER2-zero samples (median expression 0.4, 0.7 and 3.1 in HER2-zero, HER2-low and HER2-positive, respectively). Inter-sample heterogeneity was observed, with 27% of the HER2-zero samples having equal or higher mean ERBB2 expression that the mean ERBB2 expression of the HER2-low cohort. Variability within individual samples was observed, revealing two peaks in ERBB2 expression, one characterized by low levels and the other by medium-high levels. This pattern was frequently observed in samples classified as HER2-zero and HER2-low, indicating the existence of tumor spots with diverse ERBB2 expression.

Conclusions: Our results revealed inter- and intra-tumor heterogeneity of ERBB2 expression in HER2-zero and HER2-low BC. The use of spatial transcriptomics can provide more details of the spatial distribution of ERBB2. Further validation is warranted.

#1140 A spatially mapped gene expression signature for intestinal stem-like cells identifies high-risk precursors of gastric cancer.

I. A. Wichmann[1], R. J. Huang[1], A. Su[2], A. Sathe[1], M. V. Shum[1], S. M. Grimes[1], R. Meka[1], A. Almeda[1], X. Bai[1], J. Shen[1], Q. Nguyen[2], M. Amieva[1], J. Hwang[1], H. P. Ji[1];

[1]Stanford University School of Medicine, Stanford, CA, [2]The University of Queensland, Brisbane, Australia

Gastric intestinal metaplasia (GIM) is a precursor lesion for the intestinal subtype of gastric cancer (GC). A risk stratification tool is the Operative Link on GIM (OLGIM), a system that relies on histopathologic annotation of gastric biopsies. Advanced OLGIM (stages III and IV) have the highest risk of progression to GC. Molecular biomarkers for advanced OLGIM are lacking. We explored transcriptomics biomarkers for advanced OLGIM to aid risk assessment efforts among GC precursors.We used clinical and genomic data from four cohorts: 1) GAPS, a cohort of OLGIM-staged patients (N=303); 2) a subset of confirmed intestinal-type GC from The Cancer Genome Atlas (TCGA, N=198); 3) a compilation of scRNA-seq data (N=40), and 4) a spatial transcriptomics cohort (N=5) with annotated H&E-stained histopathology slides from GC or OLGIM-staged patients.We separated the GAPS bulk RNAseq gene expression dataset into independent discovery (N=88) and validation (N=215) sets. Through a combination of differential expression analysis and co-expression analysis, we identified a discrete set of 100 significantly upregulated genes characterizing advanced OLGIM that were confirmed in the validation set. Importantly, these genes were overexpressed both in the corpus and antrum of the stomach. We leveraged spatial transcriptomics assays to refine this signature to genes overexpressed specifically in GIM foci. We interrogated the TCGA dataset and confirmed these genes to be also expressed in gastric tumors. The final high-risk signature included 26 genes. Single-cell RNAseq analysis revealed these genes to be expressed by aberrant intestinal-like lineages. Further, reference-mapping identified cells resembling mature enterocytes and goblet cells that expressed 16 of these genes, whereas 10 genes from the high-risk signature pinpoint immature intestinal stem-like cells at varying stages of differentiation (duodenum stem cells, duodenum differentiating stem cells, and duodenum transit amplifying cells). Finally, we confirmed expression of 12 of these genes by single-molecule fluorescence *in situ* hybridization (smFISH), that distinguish differentiated from stem-like lineages in metaplasia and are absent in normal gastric glands in intact tissue sections from GC precursors.Our study identified as signature of 26 genes that are: i) characteristically over-expressed in advanced OLGIM stages, ii) localize specifically to metaplasia, iii) are expressed in gastric tumors, and iv) distinguish differentiated from stem-like cells in GIM. These results provide transcriptomics biomarkers that indicate the establishment and expansion of intestinal stem-like cells in advanced OLGIM, with profound translational implications, as these cells may harbor and expand mutations that predispose advanced OLGIM patients to GC.

#1141 Spatial-specific gene signatures to predict immunotherapy outcomes in lung cancer.

T. N. Aung[1], M. Moutafi[2], I. Trontzas[1], A. Kulasinghe[3], J. Monkman[3], N. Gavrielatou[2], I. Vathiotis[4], J. H. Warrell[5], D. L. Rimm[1];

[1]Department of Pathology, Yale University School of Medicine, New Haven, CT, [2]School of Medicine, National and Kapodistrian University of Athens, Anthens, Greece, [3]Frazer Institute, Faculty of Medicine, The University of Queensland, Brisbane, Australia, [4]Oncology Unit, 3rd Department of Internal Medicine, Sotiria Hospital, National and Kapodistrian University of Athens, Anthens, Greece, [5]Department of Molecular Biophysics and Biochemistry, Program in Computational Biology and Bioinformatics, Yale University, New Haven, CT

The widespread use of immunotherapy in lung cancer, and its more recent approval for early stages, underscores the need for biomarkers that can identify the most responsive patients. Spatial transcriptomics, which maps gene expression in its spatial tissue context, offers a unique approach over bulk transcriptomics. By incorporating spatial information, the predictive power of the signature can be enhanced. Here, we aim to develop spatially informed gene signatures that could be translated into clinical RNA in situ assays, distinguishing patients unlikely to benefit from immunotherapy and thereby sparing them unnecessary side effects. We utilized the NanoString GeoMX Whole Transcriptome Atlas for spatially resolved transcriptomic profiling of retrospectively collected lung cancer tissue samples from patients treated with immunotherapy in an advanced-stage setting (N=60). By targeting 18,190 genes within distinct areas of interest (AOIs)—including stromal (macrophages/CD68+ and leukocytes/CD45+) and tumor (cytokeratin, CK+) cells—we developed AOI-specific gene signatures to predict objective responses. These were derived from a robust computational framework employing LASSO logistic regression on a split-sample approach, yielding predictive models for treatment outcome.We achieved high predictive accuracy on the training set, with the area under the curve (AUC) exceeding 0.86 for all AOI-specific spatial signatures, indicating strong potential for clinical application. Validation against an independent cohort (N=42) corroborated the efficacy of these signatures. Our 6-gene tumor signature was validated with an AUC of 0.73 (95% CI: 0.67-0.89, p = 0.009**), while the CD45 5-gene signature showed an AUC of 0.75 (95% CI: 0.53-0.97, p = 0.022*). Our 18-gene CD68 signature trended towards validation but lacked statistical significance. A combined CD68 and CD45 signature predicted outcomes with greater accuracy, achieving an AUC of 0.79 (95% CI: 0.62-0.98, p = 0.0088*). Following gene set enrichment analysis on our differentially expressed and signature genes, we identified genes with positive coefficients in both tumor and stroma signatures that were associated with glucocorticoid response and glycolytic processes linked to T-cell homeostasis, while genes with negative coefficients were associated with epithelial cell differentiation and cytokine production. These associations are concordant with the observation that genes with positive coefficients are predictors of treatment response, while those with negative coefficients indicate resistance.Our findings indicate that AOI-specific signatures predict the immunotherapy outcome in lung cancer with high accuracy, suggesting that spatial assessment can provide substantial predictive information. The high performance of these signatures indicates their potential for prospective clinical applications.

#1142 Spatial decomposition of lung adenocarcinoma expression subtypes reveals tumor microenvironment characteristics.

S. He[1], C. Alba[2], S. Kounelis-Wuillaume[3], T. J. Franks[4], M. L. Doughty[3], R. F. Browning[5], C. D. Shriver[5], C. L. Dalgard[6], APOLLO Research Network, M. D. Wilkerson[6];

[1]John P. Murtha Cancer Center Research Program, Uniformed Services University; Henry M. Jackson Foundation for Military Medicine, Bethesda, MD, [3]Department of Anatomy Physiology and Genetics, Uniformed Services University, Bethesda, MD, [4]Pulmonary & Mediastinal Pathology Department of Defense, The Joint Pathology Center, Silver Spring, MD, [5]John P. Murtha Cancer Center Research Program, Uniformed Services University, Bethesda, MD, [6]Center for Military Precision Health, The American Genome Center, Uniformed Services University; Department of Anatomy Physiology and Genetics, Uniformed Services University, Bethesda, MD

The expression subtypes of lung adenocarcinoma (LUAD) capture tumors with distinct pathway activity, mutations and histopathology and also differentiate clinical outcomes. The microenvironments of these subtypes, proximal-inflammatory (PI), proximal-proliferative (PP), and terminal respiratory unit (TRU), have been described generally as immune hot, immune moderate and immune cold, respectively, but otherwise have not been analyzed at high resolution. Here, we aimed to characterize and compare tumor microenvironments between LUAD subtypes. Using spatially barcoded arrays and cDNA libraries (10x Genomics), we sequenced the spatial transcriptomes of a 6.5mm^2 plane of 14 LUAD tumors from the Applied Proteogenomics and Organizational Learning Outcomes (APOLLO) program. Spatial transcriptomes had a median of 3,560 spots and a median of 4,026 genes detected per spot. First, collapsing the spatial array to a bulk measurement per sample, we applied our published expression subtype predictor classifying 4 PI, 5 PP, and 5 TRU cases. We then decomposed each tumor's spatial expression profile by unsupervised clustering, followed by signature scoring and collapsing into tumor, immune, and stroma tumor microenvironment (TME) components. Twelve of the fourteen tumors harbored multiple components while two tumors had one component. The region areas of TME components showed trends among the subtypes, with PI having the greatest immune area and PP having the greatest tumor area. Within each tumor, we calculated differentially-expressed genes between each TME component. Comparing TME genes to the subtype predictor genes, we found significant overlap (chi-square $p << 0.001$). This indicates that genes that are variable among bulk tumors also have variability within tumors. We then predicted expression subtype for decomposed compartments. Five tumors had the same expression subtype across their TME components, which we refer to as single subtype tumors. However, six tumors had more than one expression subtype prediction among the tumor's TME components, which we call 'multi-subtype tumors'. Multi-subtype tumors had lower bulk subtype prediction scores than single-subtype tumors ($p < 0.01$), indicating that the TME diversity among tumors affects the bulk expression subtype. Interestingly, the six multi-subtype tumors were in the PP and PI subtypes, suggesting greater TME component diversity than TRU. Calculating the spatial compactness of the tumors through continuity indices, we found that PI subtype trended with greater intermixing of TME components. In summary, the bulk LUAD expression subtypes capture differences between tumors and within tumors related to the tumor microenvironment. The views expressed in this abstract are solely of the authors and do not reflect the official policy of the Departments of Army/Navy/Air Force, Department of Defense, USUHS, HJF, or U.S. Government.

#1143 Dissection of melanoma and cutaneous lymphoma spatial molecular architecture by multimodal single-cell and spatial transcriptomics with generative AI.

Z. Liu[1], X. Song[2], J. He[3], J. He[3], J. Balasi[4], J. H. Chuang[1], P.-L. Chen[4];
[1]The Jackson Laboratory for Genomic Medicine, Farmington, CT, [2]H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL, [3]Vizgen, Cambridge, MA, [4]Moffitt Cancer Center, Tampa, FL

Advances in single-cell multiomic technologies have revolutionized our understanding of how heterogeneous cell types and cell states shape the tumor microenvironment (TME). However, dissociated single cell profiling lacks spatial context. To resolve the organization, cell-cell communication, and granular structures in the TME, new single-cell spatial transcriptomic (ST) characterizations are needed. Here, we dissected the spatial molecular architecture of the melanoma (30 tumors, 30 patients) and transformed cutaneous T-cell lymphoma (tCTCL, 12 tumors, 6 patients) TMEs by Multiplexed Error-Robust FISH (305 gene MERFISH), with benchmarking scRNAseq data from matched tissues (6 melanoma scFFPEseq, 6 tCTCL scVDJ/RNAseq) for cross-platform validation. We profiled 565,122 cells in melanoma and 92584 cells in tCTCL by MERFISH. We interrogated both datasets using a novel computational framework that includes cell typing by Leiden clustering and marker genes, spatial neighborhood and receptor-ligand (R-L) analyses, and spatial/scRNA imputation via deep learning. In the melanoma dataset, we identified tumor cells, major TME cell types, and rare immune cell types (TCF7+ stem-like T-cells and CD3+TCRα+PAX5+CD79a+ B/T dual-expressor lymphocytes enriched in tertiary lymphoid structures). All cell types were validated in scFFPEseq. As immune R-L interactions are critical therapeutic targets, we developed a novel computation method to quantify spatial R-L interactions by accounting for cell-cell distance, identifying spatially informed R-L pairs that differ from dissociation-based inferences. CNV inference from melanoma scFFPEseq revealed intratumoral heterogeneity (ITH). We therefore adapted the conditional variational autoencoder ENVI to simultaneously incorporate scRNA and MERFISH spatial data into a unified latent embedding. ENVI-ITH successfully learned ITH subgroup information, enabling imputation of phylogenetic lineages on spatial MERFISH. CTCL MERFISH data revealed major TME cell types, yet separation of malignant vs benign T-cells by clustering and marker approaches is hindered by their overlapping gene expression. To overcome this barrier, we deployed ENVI to impute patient-specific malignant and benign TCR clonotypes by training on the matched scVDJ/RNA data, yielding an ENVI-TCR pipeline that can delineate malignant vs benign T-cells *in situ*. We validated the spatial pattern of malignant T-cells by patient-specific *in situ* TCR probes. In sum, we have interrogated the melanoma and CTCL TME by MERFISH and presented a novel computational framework for robustly co-embedding scRNA data with imaging-based ST to spatially resolve melanoma ITH and malignant/benign T-cell populations. We believe this approach will be highly impactful for melanoma and CTCL and can be broadly applied to other solid tumors and lymphomas.

#1144 Glioblastoma cells increase expression of neurodevelopmental programs and synaptic connectivity in the tumor periphery.

D. Harwood[1], V. Pedersen[1], N. S. Bager[1], A. Y. Schmidt[2], T. O. Stannius[2], A. Areskeviciute[2], K. Josefsen[2], D. S. Noroxe[1], D. Scheie[1], H. E. Rostalski[1], U. Lassen[1], F. O. Bagger[2], J. Weischenfeldt[1], D. H. Heiland[3], K. Vitting-Seerup[4], S. R. Michaelsen[1], B. W. Kristensen[1];

[1]University of Copenhagen, Copenhagen, Denmark, [2]Rigshospitalet, Copenhagen, Denmark, [3]University of Freiburg, Freiburg, Germany, [4]Technical University of Denmark, Copenhagen, Denmark

Glioblastoma remains one of the deadliest brain malignancies. First-line therapy consists of maximal surgical tumor resection, accompanied by concomitant and adjuvant temozolomide chemotherapy and radiotherapy. Malignant cells escape surgical resection by migrating into the brain parenchyma, where they give rise to the recurrent tumor. Based on gene expression, the tumor core can be subtyped into mesenchymal, proneural and classical areas, each being associated with differences in genetic alterations and cellular composition. In contrast, the tumor periphery where migrating tumor cells infiltrate brain parenchyma is less characterized in patients. Using spatial transcriptomics (n = 11), we show that specific malignant states colocalize in tumor core areas with necrosis and microvascular proliferation. Malignant cells within proneural or mesenchymal subtyped cores displayed, as expected, many differences in genetic expression, although such differences disappeared in the tumor periphery. Malignant cells residing in the tumor periphery had increased expression of genes related to neurodevelopmental pathways and synaptic connectivity. Our findings show similarities in cellular states across tumor subtypes with implications for post-operative treatment and provide an updated view of the spatial landscape of glioblastomas.

#1145 Comparative spatial transcriptomic analysis of tumor microenvironment responses to conventional chemotherapy and immunotherapy in triple-negative breast cancer.

D.-E. Gu[1], J. Hyeon[2], E. Seo[2], H. Jung[2], J. Yu[2], S. Kim[2], Y.-H. Im[2], J.-Y. Kim[2], W.-Y. Park[2];
[1]Sungkyunkwan University, Seoul, Korea, Republic of, [2]Samsung Medical Center, Seoul, Korea, Republic of

Background: In triple negative breast cancer (TNBC), pembrolizumab in combination with cytotoxic chemotherapy has proven its efficacy and improved survival outcome. Previous studies demonstrated that PD-L1 expression, tumor mutational burden as well as certain neo-antigens were associated with response to pembrolizumab but there were no biomarkers predicting the response of pembrolizumab of TNBC in neoadjuvant setting. Therefore, tumor microenvironment (TME) evaluation would be warranted to understand the mechanism of action of pembrolizumab in TNBC.
Methods: We employed the Xenium In Situ platform, a cutting-edge spatial transcriptomics tool, capable of mapping hundreds of transcripts within individual cells. Using a 380-plex gene panel, we analyzed formalin-fixed, paraffin-embedded TNBC sections treated with weekly paclitaxel with carboplatin followed by doxorubicin with cyclophosphamide (CTx) with/without pembrolizumab in neoadjuvant setting. We analyzed detailed cellular compositions of tumors, encompassing immune and stromal cells, across over one million cells and we attempted to identify various cell types and states, previously characterized through single-cell RNA sequencing, and assess their spatial heterogeneity within the TME with regard to treatment strategy and the response to treatment.
Results: We collected 19 serial samples from 13 patients including 12 pre-treatment and seven post-treatment samples. Among seven post-treatment samples, one was collected after three weeks of the first treatment and one was after disease relapse. Of 13 patients, seven patients had received pembrolizumab with cytotoxic chemotherapy and four out of seven have achieved pathologic complete response (pCR). In six patients treated with only cytotoxic chemotherapy, only two achieved pCR. Our analysis revealed significant alterations in the spatial organization of cells in both the pembrolizumab with CTx and CTx-only groups. Notably, an increase in CD8 T cells and plasma cells following treatments was pronounced in post-treatment samples from patients in the pembrolizumab with CTx group. We also observed treatment-specific variations in ligand-receptor interactions between immune cells and cancer cells.
Conclusion: This study provides an in-depth analysis of the TME in TNBCs in response to pembrolizumab with CTx. Utilizing the Xenium In Situ platform, we uncovered significant disparities in the immune cell population according to the application of pembrolizumab. Our findings underscore the complexity of TME responses and highlight the potential of spatial transcriptomics in informing tailored treatment strategies for TNBC.

#1146 Pan-cancer characterization of cancer cell state and plasticity using spatially resolved transcriptomics.

G. Pei[1], K. S. Cho[1], Y. Liu[1], S. Alejandra[1], R. Lazcano[1], E. Dai[1], G. Han[1], F. Peng[1], D. Zhang[2], Y. Chu[1], A. F. Sinjab[1], J. Jiang[1], M. Li[2], C. Yee[1], A. Futreal[1], A. Lazar[1], H. Kadara[1], J. Gao[1], L. M. Soto[1], A. Maitra[1], J. Ajani[1], L. Wang[1];

[1]UT MD Anderson Cancer Center, Houston, TX, [2]University of Pennsylvania, Philadelphia, PA

Cancer cell state heterogeneity constitutes a foundational characteristic of cancer, posing a formidable barrier to the discovery of biomarkers and the efficacy of therapeutic interventions. However, current understanding of cancer cell heterogeneity and plasticity remains limited, especially in the spatial context. Previous studies underscored that cancer cell states are not strictly governed by genetics, but rather display a remarkable degree of plasticity. Recent pan-cancer single-cell studies have unveiled dozens of recurrent cancer cell states. Nevertheless, the relationship between these cancer cell states and tumor microenvironment (TME) remains poorly understood, especially when considering the diversity across different tumor types. Recent advancements in spatial transcriptomics (ST) have paved the way for a novel approach to spatially profile cell location, organization, and interaction within the tumor microenvironment. In this study, we curated ST data (Visium, 10x Genomics) from public repositories and in-house datasets, encompassing a total of >200 tissue sections across 11 cancer types. By incorporating histological annotations and inferred copy number variations, we systematically investigated the spatial heterogeneity of cancer cell states and inferred clonal architectures of cancer cell-enriched spots. Non-negative matrix factorization was applied to identify highly recurrent cancer states and transcriptional hallmarks associated with intra-tumor heterogeneity. By employing this approach, we uncover a diverse curated gene set of meta-programs. Notably, we observe a high level of reproducibility of these meta-programs when compared to the findings from single-cell level. Furthermore, we observe significant variations of cell states across different cancer types, even among two cancer subtypes within a specific tissue. We noted a unique distribution of 'hypoxia' and 'epithelial-mesenchymal transition' in the basal lineage tumor. Following this, we perform single-cell and ST co-embedding using available tools, including CellTrek and CytoSPACE. We noticed the cell type composition of tumor's neighbor spots play a significant role in influencing tumor states, especially for myofibroblastic CAFs and the tumor state in epithelial-mesenchymal transition. These findings contribute valuable insights into the relationship between cancer cell state plasticity and interactions with the TME, offering potential targets for further exploration and therapeutic intervention.

#1147 Sub-cellular spatial resolution of immune and stromal interactions underlying prostate cancer progression.

C.-K. Mo, R. G. Jayasinghe, A. Abedin do, X. Li, C. Weimholt, E. H. Kim, R. Pachynski, F. Chen, L. Ding;
Washington University in St. Louis, St. Louis, MO

Prostate cancer boasts a complex morphological structure and diverse cellular composition, yet current technology falls short in resolving the detailed spatial interactions among cells within the environment. In this study, we employed the Xenium platform, coupled with the 3D reconstruction tool Mushroom, to examine high-resolution spatial cellular interactions within the prostate cancer microenvironment. Our investigation focused on the transition of molecular characteristics from normal to high-grade prostatic intraepithelial neoplasia (HGPIN, pre-cancer), spanning the spectrum of Gleason Grades 3 to 4 and advancing to metastatic prostate cancer. We identified genes with unique spatial and grade-dependent expression profiles, including MYC, CP, and UHCL1. Evaluating sub-cellular imaging facilitated a comprehensive characterization and quantification of immune and stromal interactions, unveiling distinct spatial niches across transition stages. These findings underscore the nuanced immune interactions within the tumor microenvironment and offer crucial insights into the development of immunotherapeutic approaches tailored to the specific spatial and immune dynamics observed in advanced prostate cancer. This research contributes to the evolving understanding of prostate cancer progression, providing a foundation for the development of targeted therapies that disrupt specific cellular interactions.

#1148 Multimodal spatial transcriptomics and proteomics analysis of the resectable NSCLC ecosystem following neoadjuvant chemoimmunotherapy.

Z. Rahal[1], T. Zhou[1], S. Yang[1], A. Serrano[1], J. Feng[1], A. Sinjab[1], J. T. Le[1], X. Sun[1], M. Wang[1], W. Hu[1], J. Zang[1], T. Bruno[2], H. T. Tran[1], S. G. Swisher[1], C. H. Leung[1], H. Y. Lin[1], J. J. Lee[1], J. Wang[1], J. V. Heymach[1], D. L. Gibbons[1], I. I. Wistuba[1], A. Weissferdt[1], J. K. Burks[1], L. M. Solis Soto[1], H. Kadara[1], T. Cascone[1];

[1]The University of Texas MD Anderson Cancer Center, Houston, TX, [2]University of Pittsburgh, Pittsburgh, PA

Neoadjuvant and perioperative immunotherapy with checkpoint inhibitors (ICIs), combined with chemotherapy (CT), have improved outcomes for patients with resectable non-small cell lung cancer (NSCLC). Pathologic tumor response has been utilized in clinical trials as a surrogate of clinical efficacy. Yet, over half of treated patients experience non-response, highlighting the need for novel markers to identify those who are most likely to derive therapeutic benefit.

To dissect the spatial complexity of the tumor-associated immune landscape following neoadjuvant chemoimmunotherapy (CT+ICI), we selected patients (n =3) with a range of residual viable tumor (%RVT) - pathological complete response (pCR; 0% RVT), partial response (20% RVT), and no-response (100% RVT). We performed multimodal spatial transcriptomics (ST) and proteomics (using a 35-plex protein panel) on the same tissue sections using the Visium CytAssist from 10X Genomics. We also examined spatial patterns of 20-plex panel of immune and stromal markers at single-cell resolution in the same samples using the COMET Lunaphore platform. In the pCR patient, we studied two tumor areas to assess the impact of tumor response heterogeneity on the immune landscape.

Our analysis identified distinct immune profiles across three patients with varying %RVT, reflecting the heterogeneity of the immune response. We found robust gene-protein correlation, such as *MS4A1* gene expression and CD20 protein levels, in our multimodal spatial-omics analysis. Intriguingly, the arrangement of B cells and their interaction with surrounding plasma cells (PCs) varied notably across patients. Unlike in the patients with partial or no response, pronounced tertiary lymphoid structure (TLS) formation and signatures were observed in the pCR patient, with the CXCL13-CXCR5 axis overlapping with the TLS profile, suggesting a functional interplay that may be crucial in mediating response to therapy. Intriguingly, in the pCR patient, PCs uniquely arrayed around dense B cell aggregates, marked by *MS4A1*, *CR2*, *FCER1*, and *CXCL13*. PCs were not only less abundant in non-PCR patients but they also did not array around lymphoid aggregates.

Our high-resolution and multimodal analysis identified spatially-resolved expression and patterns for B lineage cells that may be associated, and thus, underlie response of resectable NSCLC to neoadjuvant CT+ICI. Ongoing efforts on this expanding cohort will shed further light on transcriptional states and immunogenomic roles of B lineage cells in neoadjuvant CT+ICI-treated NSCLC.

#1149 Spatial transcriptomic analysis of tumor microenvironment in patients with triple negative breast cancer with residual disease after neoadjuvant chemotherapy with immune checkpoint inhibitor.

J.-Y. Kim[1], K. Park[2], Y. Choi[1], J. Lee[1], B. Chae[1], J. Yu[1], S. Kim[1], S. Nam[1], J. Ahn[1], W.-Y. Park[2], Y. Park[1];
[1]Samsung Medical Center, Seoul, Korea, Republic of, [2]Samsung Genome Institute, Seoul, Korea, Republic of

Recent advance of treatment strategy for triple negative breast cancer (TNBC) including immune checkpoint inhibitor improved survival outcome. Especially, adding pembrolizumab on neoadjuvant chemotherapy (NAC) increased pathologic complete response (pCR) rate at the time of curative surgery. Previous studies suggested that PD-L1 expression in both tumor and immune cells was associated with the response of pembrolizumab in TNBC, but PD-L1 expression state were not associated with pembrolizumab response in NAC setting. In addition, neoadjuvant pembrolizumab increased event-free survival (DFS) rate after NAC even though they had not achieved pCR. However, there were no biomarker for EFS increasement of using pembrolizumab. We designed prospective translational research for evaluating tumor microenvironment (TME) of residual TNBC which had treated with NAC followed by curative surgery. We collected formalin fixed paraffin embedded (FFPE) surgical specimens after NAC with or without pembrolizumab. TNBC samples were used for spatial transcriptomics (ST) analysis, with H&E staining and inspection by an experienced pathologist. Libraries were prepared using Visium Spatial Gene Expression Reagent Kit protocol for FFPE (10x Genomics). Sequencing was conducted on the NovaSeq 6000 System (Illumina). From February 2023 to October 2023, 23 TNBC specimens from 22 patients were collected. Twenty specimens were breast tissues and three were lymph nodes, 18 TNBCs had been treated with NAC with pembrolizumab and four with only NAC, and five had residual cancer burden(RCB) class I, 11 of RCB class II and one of RCB class III. We collected BC and LN samples from BC with class III. Of 23 samples, we performed spatial transcriptomic analysis in 12 samples. In intrinsic subtyping, eight specimens were categorized into normal like, two of basal like and two of luminal A BC subtypes. In TNBC subtyping, mesenchymal stem cell like (MSL) were in six specimens, three of stem cell like (SL), two of luminal androgen receptor (LAR) and one of immunomodulatory (IM). We also performed cell type annotation with unsupervised method and categorized into 11 cell types; three cancer cell types, two macrophages, B and T cells, adipocytes, normal epithelium and perivascular-like and cancer associated fibroblasts. Among these 11 cell types, increasement of immune cells including B cells, T cells and macrophage proportions was associated with pembrolizumab treatment in NAC setting. In our study, we evaluated TME state of TNBC after NAC with or without pembrolizumab. We suggested that MSL or SL TNBC subtypes were associated with residual disease after NAC regardless of pembrolizumab use and pembrolizumab may recruit more immune cells in TME of TNBC. For concreating our suggestion, further analyses would be warranted.

#1150 Unveiling the spatial landscape of tumor and stroma heterogeneity in colorectal cancer with spatial transcriptomics.

J. Zhou[1], T. B. Sheridan[2], S. Domanskyi[1], S. L. Cowles[2], S. Park[1], I. Putra[2], O. Anczukow[1], J. H. Chuang[1], J. C. Rubinstein[3];
[1]The Jackson Laboratory for Genomic Medicine, Farmington, CT, [2]Hartford Hospital, Hartford, CT, [3]Hartford HealthCare Cancer Institute at St. Vincent's Medical Center, Bridgeport, CT

Heterogeneity in colorectal cancer (CRC) manifests in the diversity and interactions among tumor cells, support stroma, and immune components, critically impacting patient prognosis and therapeutic efficacy. In this study, spatial transcriptomics (ST, 10x Genomics Visium Spatial Gene Expression) was performed on 40 retrospectively collected CRC samples, along with detailed clinicopathological parameters and long-term clinical outcomes, with the goal of unraveling the molecular topography of the tumor and surrounding stromal compartments, and associating their spatial interactions to clinical outcomes. Five primary RNA groups were identified through unsupervised clustering on ST data, correlating with tissue classes detected in H&E-stained images via a pre-trained deep learning model. Markers and pathways specific to these tissues were identified. Furthermore, immune cell infiltration in these regions was deconvoluted using reference single-cell RNA sequencing (scRNA-seq) data. Sub-clustering within the tumor groups revealed five major tumor subtypes, each characterized by a distinct set of differentially expressed marker genes. Enrichment analysis across these subtypes highlighted distinct activation and suppression in pathways including KRAS, p53, MAPK, and Integrin. Tumors exhibited intra- and inter-tumoral heterogeneity. Location-specific tumor subtypes were observed, with those in right-sided CRC displaying increased immune cell infiltration, linked to enriched pathways such as Type II Interferon Signaling and Cytokine Signaling. Conversely, left-sided CRC subtypes had reduced immune cell presence, and were characterized by enhanced pathways related to vascular development, Hypoxia, and p53 Signaling. Inferred clonal lineages from copy number variation (CNV) using ST suggested a spatially structured phylogenetic organization corresponding to transcriptional clusters. Additionally, the ST data unveiled distinct spatial distribution patterns across various cancer-associated fibroblast (CAF) phenotypes, such as matrix, inflammatory, vessel-associated, tumor-promoting, and antigen-presenting CAFs. Transcriptional patterns uncovered through scRNA-seq, including epithelial-mesenchymal transition (EMT) signatures and consensus molecular subtypes (CMS), displayed unique spatial layouts within the tumor microenvironment. To our knowledge, this is the most comprehensive study to date on spatial transcriptomic heterogeneity within CRC patients, revealing distinct tumor, stroma and immune compositions and spatial structures. This spatially detailed map provides novel insights into CRC heterogeneity, critical for advancing personalized treatment.

#1151 Reconstruction of the spatial ecosystem of glioblastoma reveals relationships between tumor cell states and microenvironment.

B. Adabbo[1], S. Migliozzi[1], L. Garofano[1], F. D'Angelo[1], P. Davila[1], S. H. Gultekin[1], D. Bilbao Cortes[1], B. Currall[1], S. L. Williams[1], M. Sanson[2], F. Bielle[2], A. Di Stefano[3], M. Ceccarelli[1], A. Lasorella[1], A. Iavarone[1];

[1]University of Miami Sylvester Centr.-I, Miami, FL, [2]Sorbonne University, Paris, France, [3]Ospedali Riuniti di Livorno, Livorno, Italy

Glioblastoma multiforme (GBM) is the most aggressive form of primary brain tumor, with no curative treatment options. Multiple studies have characterized at single cell resolution the GBM as being composed of transcriptional cell states interconnected with components in the tumor immune microenvironment (TME). Our group proposed and validated the first single cell guided functional classification of GBM in four tumor-intrinsic cell states which informed clinical outcome and delivered therapeutic options. However, single cell technologies are unable to unravel the spatial relationships among the cell states of GBM and between GBM cell states and TME. Spatially resolved transcriptomic technologies are emerging as powerful tools to reconstruct the spatial architecture of a tissue. We performed spatial transcriptomics of multicellular regions of interest (ROI) in 6 primary IDH wild-type GBM and 2 recurrent GBM with both CosMx Spatial Molecular Imager, which analyzes 1,000 RNA probes and 64 proteins at single cell resolution, and GeoMx Digital Spatial Profiler which profiles the whole transcriptome (~18,000 genes) at ROI resolution. The development of computational tools aimed to integrate spatial proximity and CosMx derived single-cell transcriptomics revealed spatial segregation of the tumor cell clones and cellular states and highlighted recurrent patterns of cell states, distinct TME cell types associated with coherent histopathological features across multiple samples. The development of a spatial informed intercellular communication algorithm and the reconstruction of ligand-receptor-target networks will allow the discovery of tumor cell states-TME cross-talks and the biological signaling regulated by these interactions that are driving the heterogeneity of GBM and therefore potentially therapeutically targetable. Analysis of matched regions of interest profiled by GeoMx and spatial proteomics with CosMx further cross-validated the spatial ecosystem of glioblastoma as reconstructed at single-cell resolution. Our studies established a scalable approach to resolve the transcriptional heterogeneity of GBM and reconstruct the architecture of GBM cell states and tumor microenvironment.

#1152 Pan-cancer single-cell and subcellular characterization of lymphoid aggregates and tertiary lymphoid structures using high-plex spatial molecular imaging.

Y. Liu[1], Y. Zhang[1], G. Han[1], G. Pei[1], K. Cho[1], E. Dai[1], Y. Chu[1], J. Jiang[1], A. Sinjab[1], L. M. S. Soto[1], A. Serrano[1], J. Gao[1], H. Kadara[1], C. Fridman[2], W. H. Fridman[2], L. Wang[1];

[1]UT MD Anderson Cancer Center, Houston, TX, [2]Universite de Paris, Paris, France

Tertiary lymphoid structures (TLSs), clusters of immune cells that form in non-lymphoid tissues, are frequently identified in a wide range of solid tumors. They function as immunological “hubs”, driving anti-tumor responses. Previous studies have demonstrated that the presence of TLSs is often associated with improved responses to immunotherapy and superior clinical outcomes. Despite these insights, our understanding of their phenotypic diversity, spatial organization, intercellular communication, and interactions with cancer cells and the tumor microenvironment remains incomplete. Existing methods lack the resolution, depth, and scale required for a thorough understanding of these complex structures. We have obtained in-house and public spatial multi-omics data generated on various tissues across 9 different cancer types using the cutting-edge single-cell spatial transcriptomics and high-plex spatial molecular imaging platforms. We have developed innovative computational approaches for the detailed characterization of TLSs at single-cell and subcellular resolution and carried out an extensive analysis of lymphoid aggregates (LAs) and TLSs in tissue sections across these different solid cancer types. We defined the phenotypic state of each individual cell within TLSs including B/ plasma cells, follicular helper/regulatory/stressed/exhausted T cells, follicular dendritic cells, fibroblasts and high endothelial venules. Then, we performed unbiased phenotyping and classification of TLSs based on their cellular states, compositions and organization patterns across various types of tissues. Additionally, we performed spatial neighborhood analysis, characterized the neighboring cells of each TLS and analyzed their cell-cell communication networks. Our approach allowed an unprecedented examination of the spatial phenotypes of TLSs in large, complex tissues at super resolution, in ways that were not previously described. We comprehensively characterized TLSs across different solid tumor types. Our analysis revealed a high degree of spatial and phenotypic heterogeneity in LAs and TLSs. We created a comprehensive spatial atlas of LAs and TLSs across solid tumor types, profiled TLSs at various maturation states with distinct cellular composition and organization patterns, and discovered new TLS states. Notably, we observed distinct communication networks associated with TLS phenotypic states. Our innovative methods and analytical approaches offer a more comprehensive way to study LAs and TLSs, enhancing detection capabilities and providing deeper insights into their spatial interaction and functional phenotypes. This research holds the potential to significantly advance our understanding of TLSs and their roles in immunobiology and immunotherapy responses across a broad range of cancers and diseases.

#1153 Using spatial transcriptomics to dissect cell to cell cooperation in lung adenocarcinoma.

R. Jamshidi, L. Griffiths, R. Johnston, V. Parihar, F. Schneider, A. Marcus;
Winship Cancer Institute, Emory University School of Medicine, Atlanta, GA

Lung cancer is the second most common cancer in the United States and the leading cause of cancer related deaths in this country. Unfortunately, efficacious treatments for lung cancer remain suboptimal. Lung cancer is characterized by several distinct subtypes of which lung adenocarcinoma is the most common, comprising about 40% of this malignancy. The hallmark gene mutations of lung adenocarcinoma include *TP53*, *RAS*, and *STK11*. LKB1 is a serine-threonine kinase (coded by the gene *STK11*) that largely functions as a tumor suppressor, and is mutated in 20-30% of non-small cell lung cancers (NSCLCs). The diversity between and within lung cancer subtypes, as well as within a patient (i.e. metastases vs primary tumor), makes treating this cancer very challenging. Lung adenocarcinoma, in particular, has collective invasion packs of cells adjacent to the primary tumor that correlate with metastatic disease in mouse models. We hypothesize that the transcriptomic profile of the collective invasion packs in lung adenocarcinoma patients varies significantly from the adjacent primary tumor and represents a targetable metastatic sub-population. This work will help to identify specific cell signaling pathways that have the translational potential to develop novel therapeutics for metastatic disease, ultimately improving patient outcomes through precision medicine. Utilizing patient lung adenocarcinoma samples with KRAS and KRAS+LKB1 mutations, we identified regions of interest including bulk tumor and surrounding invasion packs. Then, using GeoMx digital spatial profiling technology (by Nanostring) and next-gen sequencing, we generated transcriptomic profiles from bulk tumor and invasion packs. Preliminary results indicate region specific transcriptomic differences, highlighting the heterogeneity of these cell populations. More specifically, collective invasion packs exhibit upregulation of gene networks involving immune cell differentiation, function, oxidative phosphorylation, tumor invasiveness, and mitochondrial structure. To discern the metastatic potential, transcriptomic profiles and biological functions will be compared between invasion packs, tumor bulk vs invasion packs, and finally, inter-patient differences. Successful completion of this project will characterize transcriptomes of metastatic lung cancer and has the potential to ultimately identify biomarkers of aggressive disease. Lastly, this foundational study will pave the way for future studies on the transcriptomic landscape of metastatic pediatric cancers and cancer predisposition syndromes.

#1154 Spatial profiling of the tumor microenvironment in head and neck squamous cell carcinoma revealed immune cell type infiltration into the TME as a predictor of immunotherapy response.

H. Sadeghirad[1], C. Tan[2], N. Liu[2], J. Monkman[1], C. Cooper[3], K. O'Byrne[3], M. Davis[2], B. Hughes[4], A. Kulasinghe[1];
[1]The University of Queensland, Brisbane, Australia, [2]The Walter and Eliza Hall Institute (WEHI), Melbourne, Australia, [3]The Princess Alexandra Hospital, Brisbane, Australia, [4]The Royal Brisbane and Women's Hospital, Brisbane, Australia

Background: Immunotherapy has shown promising results in advanced head and neck cancer patients, however, only a subset of patients are responsive to immune checkpoint blockade therapy. The molecular and cellular characterization of the tumor microenvironment (TME) may reveal clues as to why some head and neck tumors are responsive or resistant to the therapy.
Methods: Formalin-fixed paraffin-embedded (FFPE) tissue samples were collected from 34 patients at two major Queensland Hospitals with advanced head and neck squamous cell carcinoma (HNSCC), prior to immunotherapy. To investigate the cellular and molecular characteristics of the HNSCC TME, we used the Nanostring GeoMx Digital Spatial Profiler (DSP) spanning modules in an immune-oncology panel, which included immune cell typing and profiling, cell death, PI3K/AKT signaling, drug target, immune activation, and pan tumor protein biomarkers. A deeper structural analysis was performed using the Nanostring whole transcriptome atlas (WTA) panel of tertiary lymphoid structures (TLSs) and germinal centers (GCs).
Results: Out of 34 patients, 3 had a complete response (CR), 7 had a partial response (PR), 5 had stable disease (SD), and 19 had progressive disease (PD), based on the Response Evaluation Criteria in Solid Tumors (RECIST). When we compared patient responders (patients with CR, PR, and SD) to patient non-responders (patients with PD), we found that the former had a higher infiltration of immune cell type markers representatives of $CD8^{+}$ T cells, dendritic cells, and macrophages, into their tumor microenvironment than the latter. Then, to investigate differentially expressed genes between patients with complete response and patients with partial response to immunotherapy, we performed DE analyses and we found that patients with PR had higher Ki-67 expression than those with CR. Spatial transcriptomic mapping of TLS's (peripheral, intra-tumoral) and normal germinal centers revealed interferon pathway enrichment in the TLS's. In a subset, these appear to be linked with HPV viral infection.
Conclusion: In this study, we found that immune cell type infiltration into the tumor microenvironment of head and neck cancers could be predictive of response to immunotherapy. Furthermore, it was revealed that patients with a high expression of Ki-67 might be less likely to respond completely to immunotherapy. Spatially resolved whole transcriptome analysis of HNSCC tissues revealed the presence of tertiary lymphoid structures with a higher enrichment of interferon pathway genes.

#1155 Spatial colocalization and molecular crosstalk of myofibroblastic CAFs and tumor cells shape lymph node metastasis in oral squamous cell carcinoma.

K. Furudate[1], S. Kasai[1], T. Yoshizawa[1], Y. Sasaki[2], K. Fujikura[3], S. Goto[1], R. Ito[1], T. Tanaka[2], H. Kijima[1], K. Kubota[1], K. Itoh[1], W. Kobayashi[1], K. Takahashi[2]; [1]Hirosaki University Graduate School of Medicine, Hirosaki, Japan, [2]The University of Texas MD Anderson Cancer Center, Houston, TX, [3]Kobe University Graduate School of Medicine, Kobe, Japan

Lymph node metastasis (LNM) is a critical prognostic factor for patients with oral squamous cell carcinoma (OSCC). While previous research has implicated partial epithelial-to-mesenchymal transition (p-EMT) of tumor cells and cancer-associated fibroblasts (CAFs), specifically myofibroblastic CAFs (myCAFs), in LNM, the underlying molecular mechanisms remain poorly understood. Furthermore, the lack of diagnostic and prognostic biomarkers related to LNM has impeded the improvement in clinical outcomes for patients with OSCC. Here, we conducted a comprehensive molecular analysis integrating original and publicly available OSCC data of the bulk genome and transcriptome analyses, single-cell transcriptome profiling, and spatial transcriptome analyses. We found that myCAFs were both quantitatively and functionally activated in LNM-positive samples and spatially colocalized with OSCC cells within the invasive tumor front (ITF), providing a niche that may facilitate LNM. We validated spatial colocalization of myCAFs and OSCC cells using 50 additional Immunohistochemistry (IHC) samples. Mechanistically, myCAFs provided increased extracellular matrix (ECM) signals, such as *COLLAGEN*, *Fibronectin1(FN1)*, and *LAMININ* to OSCC cells. Consequently, OSCC cells upregulate ECM receptors such as *αβ integrins (ITGA-B)*, *syndecans (SDC)*, and *CD44*, leading to upregulating stemness-related genes in OSCC cells. Further analysis using CRISPRGeneEffect data from DepMap found that *ITGB1*, *ITGA3*, and *CD44* are among the most essential genes for the survival and growth of OSCC cells. By analyzing the spatial transcriptomic data of matched primary tumor sites (HUH001-P1 and HUH001-P2) and metastatic site (HUH001-met) from the same patient, we identified the origins of metastatic cells in the primary tumor site. We further extracted a 23-gene signature from the metastatic origin in ITF, where OSCC and myCAFs colocalize. This spatially-resolved 23-gene signature predicted LNM status and poor overall survival (OS) in clinical OSCC patients. The prognostic significance of the 23-gene signature we extracted from the spatial analysis was also validated in separate clinical cohorts from TCGA study and two other microarray datasets. Our findings provide novel insight into the molecular crosstalk between myCAFs and OSCC cells that facilitates LNM and identifies clinically valuable biomarkers for better prognostication in patients with OSCC.

#1156 A systematic comparison of common multiplex immunohistochemistry (mIHC) methodologies to the novel SignalStar™ assay in the characterization of the tumor microenvironment (TME).

J. Ziello, D. Papalegis, L. Vu, K. Goldman, J. Loebelenz, S. Sponaugle, S. Tkachev, S. Klein;
Cell Signaling Technology, Inc., Danvers, MA

The emergence of an increasing number of immunotherapy biomarkers and their importance within the spatial context of the TME has resulted in a concomitant need for reliable and accurate mIHC assays. Many of the currently available mIHC technologies do not offer amplification, resulting in the loss of detection of low expressing cells, while others require deposition and cycling of antibodies, which can lead to epitope masking and degradation, respectively. The SignalStar mIHC assay from Cell Signaling Technology is a novel methodology used to label, amplify and visualize up to 8 targets within the same formalin fixed, paraffin-embedded carcinoma (FFPE) tissue section without the need for fluorophore deposition or antibody cycling.

In this study, the SignalStar mIHC assay was used to simultaneously label 8 targets including TIM-3, PD-1, PD-L1, LAG3, CD3, CD68, CD8 and Pan-Keratin in FFPE carcinoma tissue. A network of complementary, fluorescently-labeled oligonucleotides was used to amplify the signal of the first 4 antibody-oligo conjugates followed by tissue imaging. The fluorescent signal was then removed, and the process repeated.The resulting two 4-plex images were then computationally aligned with QuPath. This methodology was compared to the Tyramide Signal Amplification (TSA) deposition assay, as well as to indirect and direct immunofluorescent detection with respect to mean fluorescence intensity (MFI) per cell and percent positivity of cells in matched regions of interest in serial sections. All mIHC strategies were in turn compared to the canonical chromogenic IHC assay. Furthermore, the fluorescent signal from the 8-plex SignalStar assay was removed and the same tissue was stained with fluorescent direct conjugates to achieve even higher plex.

Our data demonstrates that the SignalStar assay detected similar percentages of cells when compared to chromogenic and TSA staining. Alternatively, the SignalStar assay often outperformed indirect and direct immunofluorescent detection. SignalStar was also successfully combined with a panel of direct Alexa Fluor® dye conjugates, showing the complementarity of these assays in such a way that both plex and flexibility can be increased. Ultimately, we demonstrate that SignalStar mIHC is a useful tool in the characterization and analysis of the complex TME. SignalStar mIHC outshines existing technologies as it does not require deposition in order to amplify the signal of multiple colocalizing targets, including low abundance proteins, while also maintaining dynamic range.

#1157 Molecular signatures associated with the progression from DCIS to IDC.

S. Chen, A. Karpova, P. Lal, E. Storrs, R. Jayasinghe, M. Iglesia, A. Houston, Y. Zhao, A. Shinkle, C.-K. Mo, J. Herndon, F. Chen, W. Gillanders, L. Ding; Washington University School of Medicine in St. Louis, St. Louis, MO

Patients with ductal carcinoma in situ (DCIS) are frequently overtreated. Identifying markers that accurately predict which cases of ductal carcinoma in situ (DCIS) would progress to invasive ductal carcinoma (IDC) is crucial to personalized medicine but remains a challenge. Deciphering the process of DCIS progression at cellular, molecular and genetic levels helps identify biomarkers, allowing for better informed clinical decision-making. To study molecular signatures associated with the progression from DCIS to IDC, we collected samples from breast cancer patients with co-occurring DCIS and IDC, and performed Visium spatial transcriptomics (ST), single-nucleus RNA sequencing and multiplex imaging on these samples. We identified *MGP*, *SLC39A6*, *PLAT*, *MLPH*, *AZGP1*, *TFF1* and *TFF3* as showing significant differential expression levels in DCIS compared to IDC from ST analysis, which was confirmed with snRNA analysis. Notably, in multiplex imaging, MGP and PLAT showed consistently higher expression in DCIS compared to IDC at the protein level. Moreover, we evaluated these molecular signatures using MMTV-PyMT genetic mouse models at various breast cancer progression stages (3, 6, 12, 15, and 20 weeks) with snRNA-seq and multiplex imaging platforms. Collectively, our findings highlight the importance of identifying biomarkers at the molecular level, and provide potential predictive biomarkers for DCIS progression.

#1158 Spatially resolved cell profiling unveils tumor metabolic states associated with immunotherapy response in NSCLC.

James Monkman[1], Rotem Czertok[2], Shai Bookstein[3], Becky Arbiv[4], Yuval Shachaf[5], Ron Elran[5], Kenneth Bloom[5], Oscar Puig[5], Ken O'Byrne[6], Ettai Markovits[5], **Arutha Kulasinghe**[1]

[1]University of Queensland, Brisbane, Australia,[2]NucleAI, Tel Aviv, Israel,[3]NucleAI, Tel-Aviv, Israel,[4]Nucleai, Tel-Aviv, Israel,[5]Nucleai, Tel Aviv, Israel,[6]Princess Alexandra Hospital, Brisbane, Australia

Background. Only a subset of non-small cell lung cancer (NSCLC) patients benefit from immune checkpoint inhibitors (ICIs). Thus, there is a clinical need to develop predictive biomarkers for ICIs. Deeper insights from the tumor microenvironment (TME) can lead to identification of spatial features associated with clinical responses to immune checkpoint inhibitors (ICI). In this study, we investigated functional profiles within cell subtypes as a surrogate for ICI clinical endpoints.

Methods. We profiled a retrospective cohort of 39 NSCLC tissue cores from 27 patients treated with ICI, using highly multiplexed immunofluorescence (mIF) stained by the Phenocycler Fusion platform (Akoya Biosciences) capturing 45 proteins. Utilizing a deep learning based multiplex imaging analysis pipeline, cells were classified to 15 cell types by known marker expression and were further subclassified by unsupervised clustering. Cells were assigned to the tumor area or TME and more than 1000 spatial features were calculated based on cell type, marker positivity, and area assignments, and were compared between responders and non-responders to ICI therapy using Fisher's exact and logrank tests.

Results. Unsupervised cell subtyping of the 15 cell types identified 43 cell subsets, which were mostly segregated by their metabolism and activation status. Interestingly, all lymphocytes showed a similar pattern of clustering resulting in two clusters of metabolically active and inactive cells. The most significantly differentially expressed proteins between these cell types were oxidative phosphorylation proteins such as CS, SDHA and ATPA5, and other metabolic enzymes such as HK1, GLUT1 and LDHA. We found a direct connection between metabolic state, effector functions and tissue localization as the metabolically active lymphocytes exhibited higher levels of PD-1, MHC class I and II and CD44 positivity, and were more abundant within tumor infiltrating lymphocytes (TILs) and tertiary lymphoid structures (TLS). Unsupervised clustering of tumor cells demonstrated segregation to three main metabolic states - OXPHOS+, OXPHOS- and a third cluster (PPP+) which was characterized by upregulation of ASCT2, a glutamine transporter, as well as pNRF2 and G6PD, regulators of the pentose phosphate pathway. These cells also exhibited higher proliferation rate and CD44, a tumor stemness marker, positivity. All tumors with high content of PPP+ tumor cells (>40%) were resistant to PD-1 blockade (0/8 vs. 10/18 response rate in other tumors, p=0.009) and showed reduced overall survival (OS) rates (median OS of 27.6 vs 90.3 months, p=0.02).

Conclusions. Taken together, this study reveals connections between metabolic states, effector functions, and immunotherapy outcome and contributes to the evolving landscape of predictive biomarkers for ICI therapies.

#1159 Machine learning integrating spatial omics uncovers humoral immunity patterns in intratumoral tertiary lymphoid structures in pancreatic cancer pathologic responders.

D. N. Sidiropoulos, S. M. Shin, A. Girgis, D. H. Shu, J. Montagne, A. Deshpande, J. A. I. Johnson, L. Dequiedt, V. Jacobs, A. Ogurtsova, G. Mo, X. Yuan, G. Stein-O'Brien, M. Yarchoan, Q. Zhu, A. Kiemen, E. M. Jaffee, L. Zheng, W. Ho, R. Anders, E. J. Fertig, L. T. Kagohara;
Johns Hopkins University, Baltimore, MD

Background: In pancreatic ductal adenocarcinoma (PDAC), rare long-term survivors correlate with high intratumoral tertiary lymphoid structure (TLS) density. This finding prompted our investigation of clinically viable strategies to induce TLS in patients with immune-excluded tumors. We previously reported the induction of intratumoral TLS following administration of a neoadjuvant GM-CSF-secreting allogeneic vaccine (GVAX) to PDAC patients (NCT00727441). However, no clinical benefit was observed, likely owing to immune tolerance mechanisms governing the PDAC tumor microenvironment (TME). We previously observed upregulation of both the PD-1 and 4-1BB pathways with GVAX, and thus in a subsequent neoadjuvant trial combined GVAX with PD-1 blockade and 4-1BB agonism (NCT02451982) which was associated with pathologic responses. We hypothesized this combination strategy induced TLS of higher maturity and anti-tumor activity compared to GVAX alone.

Methods: To explore how this therapeutic strategy affected TLS morphology and intercellular crosstalk, we leveraged the Visium spatial transcriptomics platform and a 35-marker customized TLS panel for imaging mass cytometry. We generated cellular and molecular maps of the TME after neoadjuvant treatment in 26 PDAC patients (GVAX n=19, GVAX+aPD1 n=2, GVAX+aPD1+a41BB n=5). To compare TLS maturation in parallel with secondary lymphoid organ-mediated tumor immunity, we also profiled tumor-adjacent lymph nodes. We applied unsupervised learning with non-negative matrix factorization (NMF) and trained AI-enabled image classification models to characterize cellular states within tissue structures of interest.

Results: We identified spatial gene expression NMF patterns in PDAC TLS spanning across distinct morphologies and neoadjuvant treatment arms. Intratumoral TLS after GVAX were found to propagate activated B cells expressing immunoglobulins that infiltrated into malignant cellular niches. TLS NMF patterns were also associated with autoimmune disease signatures, such as diabetes, in a subset of patients. We scored TLS using tumor-draining lymph nodes as a reference and found increased maturation of TLS after PD-1 blockade, while addition of 4-1BB agonism significantly boosted the cytotoxic NK/T cell compartment compared to GVAX alone.

Conclusions: We present machine learning approaches for spatial multi-omics analysis to characterize the TLS-enriched TME. We mined genome-wide spatial TLS gene expression patterns elucidating the spatial dynamics of humoral immunity of rare immunotherapy pathologic responders in PDAC. Altogether our findings shed light on the plasticity of TLS in neoadjuvant immunotherapy and suggest future immunotherapy approaches should target both humoral and cytotoxic NK/T cell compartments to augment responses in solid tumors.

#1160 Investigating spatial gene expression profiling in colorectal cancer: Tumor and stroma comparison between primary lesions and matched liver metastases.

J. Lee[1], Y. Kim[1], H. Ryu[1], J. Sim[1], C. Kim[1], J. Park[1], A.-R. Lim[1], J. Kim[1], H. Sung[1], X. Guo[2], J. Choi[1], **J. Choi**[1];
[1]Korea University Medical Center, Seoul, Korea, Republic of, [2]Vanderbilt University Medical Center, Nashville, TN

The nanoString GeoMx® Digital Spatial Profiling (DSP) enables the investigation of spatial assessment of tumors through high-plex profiling at the RNA and protein levels. Recent genomic analyses have revealed the intertumor heterogeneity between primary and metastatic lesions in colorectal cancer (CRC) patients. In CRC with liver metastases, current treatment strategies are mainly based on the parameters of primary tumors, and metastatic heterogeneity is a challenge since molecular heterogeneity contributes to therapeutic resistance. Furthermore, spatial intratumor heterogeneity exists within a single tumor between cancer cells (tumor) and their microenvironment (stroma) in human cancers. However, whether there are distinct spatial gene expression patterns of tumor and stroma between primary lesions and liver metastases remains unclear in CRCs.

We examined 24 formalin-fixed paraffin-embedded tissue samples, including primary lesions and matched liver metastases from 12 patients (6 with synchronous and 6 with metachronous metastases) using NanoString GeoMx® DSP. The best regions of interest (ROI) with the invasive front boundary of the tumor were selected by pathologists. The ROI was segmented into PanCK-positive (tumor) and PanCK-negative (stroma), followed by a collection of indexed oligonucleotides and sequencing on Illumina instrument. Differential expression and pathways enrichment analyses were performed using R BioConductor package standR, limma, and GSEABase. Statistical significances were based on $|\text{Log}_2$ fold change$| > 1$ and Benjamini-Hochberg-corrected $P < 0.05$. Immune cell abundance was estimated using the SpatialDecon package.

In 12 metastatic patients (mean age, 61 years ± 7 [standard deviation]), liver metastatic stroma was associated with 68 upregulated and 93 downregulated genes compared to the primary stroma, with enrichment of 'Immune response' terms in gene set enrichment analysis (GSEA). A higher proportion of CD4 T memory cells and increased expression of cytotoxic genes (*IL7R* [2.02-fold], *CD3E* [1.75-fold], *KLRB1* [1.68-fold], and *GZMK* [1.54-fold]) were observed in liver stroma compared to primary stroma. Conversely, liver metastatic tumors were associated only with 23 upregulated and 6 downregulated genes compared to primary tumors, with 'humoral response' terms enriched in GSEA. Similar patterns were observed in stratified analyses with synchronous and metachronous metastases, although a more prominent ‘immune response’ was observed in synchronous metastatic stroma compared to the primary stroma.

We revealed that higher immune cell proportion and cytotoxic activity were observed in liver metastatic stroma compared to CRC stroma, providing novel insights into a unique etiology and may yield clinical implications for developing targeted treatment modalities for liver metastatic CRC patients.

#1161 Deep spatial proteomics: A new approach for obtaining insight into the glioblastoma microenvironment.

K. Saxena[1], R. Daucke[2], V. Pedersen[1], P. H. klausen[3], E. Schoof[2], B. W. Kristensen[1];
[1]University of Copenhagen, Kobehavn N., Denmark, [2]Technical University of Denmark, Lyngby, Denmark, [3]Copenhagen University Hospital, Rigshospitalet, Kobehavn N., Denmark

Glioblastoma is the most frequent and malignant brain tumor, with a median survival of approximately 14 months. The tumor microenvironment is composed of different cell types and is known to support the glioblastoma cells and contribute to poor patient prognosis. Since accumulating studies report discordance between mRNA and protein abundances both on population and single-cell levels, and since proteins are the effector molecules of the cells and the actual target molecules of most drugs, our aim is to dissect the tumor microenvironment by spatial LC-MS based proteomics. Glioblastoma formalin-fixed paraffin-embedded (FFPE) tissue was sectioned and placed on membrane glass slides suitable for laser capture microdissection (LCM), followed by precise isolation of single cells from the heterogeneous tumor microenvironment. We used the Zeiss Palm MicroBeam laser microdissection instrument, combined with an Orbitrap Eclipse Tribrid Mass Spectrometer running our in-house sensitivity tailored Data Independent Acquisition method (WISH-DIA) to analyze and quantify the proteomes. We obtained up to 3000 proteins out of only 100 cells and were able to demonstrate the feasibility of collecting and analyzing various cell types at the single-cell level. The proteins identified belonged to many different classes/families of proteins and were able to distinguish the different cell types. In conclusion, this on-going study demonstrates our ability to isolate single cells from the highly heterogeneous tumor microenvironment of glioblastoma with ultra-high sensitivity, thereby allowing the characterization of the proteome of the glioblastoma microenvironment followed by identification of potential therapeutic and/or diagnostic targets.

#1162 Tumor-immune microenvironment associated with obesity in triple-negative breast cancer in the Mayo Clinic cohort.

S. Pang[1], Y. Liu[1], Y. Ma[1], Z. Li[1], R. A. Leon-Ferre[2], D. Zahrieh[2], D. W. Hillman[2], J. C. Boughey[2], J. N. Ingle[2], K. R. Kalari[2], F. J. Couch[2], M. P. Goetz[2], K. L. Knutson[1], S. Chumsri[1], E. Thompson[1];

[1]Mayo Clinic, Jacksonville, FL, [2]Mayo Clinic, Rochester, MN

Background: Previous studies demonstrated that obesity is associated with poor outcomes and significantly worse pathological complete response (pCR) in triple-negative breast cancer (TNBC) treated with conventional chemotherapy. Emerging studies described a phenomenon termed the obesity paradox, which referred to improved outcomes observed in obese patients treated with immune checkpoint inhibitors (ICIs). Our study aimed to determine distinct immune features in TNBC across body mass index (BMI).

Methods: Characteristics and outcomes of TNBC patients treated with neoadjuvant pembrolizumab-based chemotherapy at Mayo Clinic were collected. Normal BMI was defined as 18-25 kg/m^2, overweight 25-30, and obese BMI ≥ 30. NanoString CosMx, a spatial multi-omics single-cell imaging (SMI), was performed in 75 samples from the Mayo Clinic TNBC cohort (Leon-Ferre BCRT 2018). Differential expression as log 2-fold change (FC) was estimated from the linear mixed model with significance defined as two-sided p< 0.05.

Results: Between 2021-2023, there were 108 TNBC patients treated with neoadjuvant pembrolizumab. 25.9% were obese, 32.4% were overweight, and 41.7% had normal BMI. In contrast to previous studies with conventional chemotherapy, obese patients numerically had a higher pCR rate of 71.4% with pembrolizumab-based chemotherapy compared to 55.6% in normal and 62.9% in overweight patients. However, this difference did not reach statistical significance (obese vs. normal weight, OR 2.26, 95%CI 0.89-6.06, p 0.094). We further evaluated spatially-resolved immune features associated with obesity using CosMx SMI in 75 samples from the MC TNBC cohort. Obese patients had significantly higher intratumoral B cells (log2FC 1.88, p 0.017), stromal B cells (log2FC 2.79, p 0.001), stromal plasmablasts (log2FC 1.94, p 0.047), and stromal macrophages (log2FC 1.80, p 0.017) compared to patients with normal BMI. Obese patients also had significantly lower intratumoral myeloid dendritic cells (mDC) (log2FC -1.27, p 0.037). Similar trends were observed after standardizing cell counts per 100 tumor or stromal cells, including higher intratumoral B cells (log2FC 3.00, p 0.001), intratumoral plasmablasts (log2FC 2.00, p 0.006), intratumoral natural killer (NK) cells (log2FC 1.66, p 0.044), and stromal B cells (log2FC 1.50, p 0.008). Differential gene analyses for intratumoral B cells revealed that genes (CD74, HLA-C, HLA-DRB1, HLA-DRA, HLA-DRB) associated with the positive regulation of type 2 immune or chemokine response were upregulated.

Conclusions: Using in-depth analysis with spatially defined context, our study showed that obese TNBC patients had significantly higher B cell infiltration, which is associated with improved outcomes with ICIs. Future research on how obesity alters the immune microenvironment is needed to identify potential pathways to improve outcomes with ICIs in TNBC.

#1163 Increased spatial coupling of integrin and collagen IV in the immunoresistant clear cell renal cell carcinoma tumor microenvironment.

A. C. Soupir[1], M. T. Hayes[1], T. C. Peak[1], O. E. Ospina[1], N. H. Chakiryan[2], A. E. Berglund[1], P. A. Stewart[1], J. Nguyen[1], C. M. Moran-Segura[1], N. L. Francis[1], P. M. Ramos-Echevarria[1], J. Chahoud[1], R. Li[1], K. Y. Tsai[1], J. A. Balasi[1], Y. Caraballo-Perez[1], J. Dhillon[1], L. A. Martinez[1], W. E. Gloria[1], N. Schurman[3], S. Kim[3], M. Gregory[3], J. J. Mule[1], B. L. Fridley[1], B. J. Manley[1];

[1]H. Lee Moffitt Cancer Center, Tampa, FL, [2]Knight Cancer Center, Portland, OR, [3]Nanostring, Seatle, WA

Immunotherapy (IO) has improved the survival of patients with clear cell renal cell carcinoma (ccRCC); however, most patients will not have a durable complete response and will die from their disease. Our understanding of the development of IO resistance for ccRCC is very limited. We employed spatial transcriptomics (ST) with single cell resolution on patients with IO naïve tumors and IO exposed tumors to characterize spatial properties and differences between these two populations. Fourteen matched tumor and adjacent stromal fields of view (FOV) from surgically resected primary kidney specimens were analyzed using CosMx Spatial Molecular Imager (SMI). Non-tumor cell phenotyping was performed using the Kidney Cell Atlas. A generalized linear model was developed to identify malignant tumor cells in kidney tissues and validated by a pathologist. Differential cell abundance, clustering, and gene expression for each cell phenotype were compared between the two groups. Spatial gene set enrichment (GSEA) of modified hallmark gene sets were also compared. CD8+ T cells were more abundant in IO exposed vs IO naïve tumor FOVs. *YES1* expression in the malignant tumor cells was significantly higher in IO exposed samples compared to IO naïve samples (false discovery rate [FDR] = 0.084). Spatial GSEA showed significant clustering of many gene sets (cells of high enrichment closer together than expected by chance), most notably epithelial-mesenchymal transition (EMT) pathway. Next, a post-hoc analysis of genes belonging to known ligand-receptor pairs in the EMT pathway was completed using bivariate Moran's I to estimate spatial autocorrelation. We found significantly higher spatial autocorrelation of *ITGAV-COL4A1* in the stroma of IO exposed FOVs than IO naïve FOVs (FDR = 0.008). Cell types with the highest expression of *ITGAV* and *COL4A1* were found to be fibroblasts, endothelial, and tumor cells. Protein validation with multiplex immunofluorescence (mIF) confirmed cells positively stained for anti-integrin alpha-V were more abundance on stromal FOVs ($p < 0.001$) in IO exposed samples. Fibroblast (SMA+) cells in stromal FOVs were more likely to be positively stained for anti-integrin alpha-V ($p < 0.001$) in IO exposed than IO naïve FOVs. ITGAV protein is involved in migration from primary to metastatic disease in several cancers, and its inhibition increases T cell killing indicating ccRCC endothelial and tumor cells may be using this signaling for immune evasion and disease progression. Further, collagen and cancer associated fibroblasts (CAFs) play a role in tumor growth. To our knowledge, this is the first study to leverage single-cell resolution ST to identify potential ways by which ccRCC tumors become resistant to IO therapy.

CLINICAL RESEARCH: Tumor Immune Response 1
Poster Session

#1167 Prospective analysis of pretreatment circulating CD4 memory T cell features associated with severe immunotherapy toxicity.

A. Usmani[1], N. Earland[1], W. Zhang[2], P. K. Harris[1], A. Bacchiocchi[3], C. M. Sachs[1], A. Nene[3], D. Y. Chen[1], M. Sznol[3], R. Halaban[3], A. M. Newman[2], A. A. Chaudhuri[1];

[1]Washington University in St. Louis, St. Louis, MO, [2]Institute for Stem Cell Biology and Regenerative Medicine, Stanford University, Stanford, CA, [3]Yale University School of Medicine, New Haven, CT

Introduction: Immune checkpoint inhibitors (ICIs) have revolutionized melanoma treatment, significantly improving outcomes. Nevertheless, too many melanoma patients undergoing ICI treatment experience severe and often debilitating immune-related adverse events (irAEs). In a retrospective melanoma cohort treated with ICIs, we previously found that elevated baseline levels of circulating CD4 effector memory T (TEM) cells were associated with the development of severe irAEs, irrespective of the affected organ system (Lozano et al., Nature Medicine, 2022). Here, we present data from an extended prospective validation cohort from 47 patients across two academic medical centers.
Methods: Of 47 patients, 26 received combination anti-PD1/anti-CTLA4 ICIs, 3 combination anti-PD1/anti-LAG3 ICIs, 17 anti-PD1 ICI, and 1 anti-CTLA4 ICI. Peripheral blood mononuclear cells (PBMCs) were prepared from pretreatment (Cycle 1 Day 1) blood samples obtained from all patients. We performed mass cytometry (CyTOF) on PBMCs using a 38-marker panel to deeply profile immune subsets. We further leveraged bulk RNA-seq from 24 patients to (i) deconvolve CD4 memory T cell abundance using CIBERSORTx and (ii) determine T cell receptor (TCR) diversity using Shannon entropy following MiXCR clonotype assembly. irAEs were graded on a 5-point scale using the Common Terminology Criteria for Adverse Events v5.
Results: After treatment initiation, 14 patients experienced severe irAEs (grade 3+) at a median of 12.1 weeks (range 4-54), including 4 with life-threatening (grade 4) irAEs. CyTOF revealed elevated circulating CD4 TEM cells in patients that developed severe irAEs ($P<0.0001$; AUC=0.87), including those treated with combination ICIs ($P=0.0001$; AUC=0.89). We further observed a continuous relationship between increasing CD4 TEM levels and irAE grade ($P=3e-6$, Jonckheere-Terpstra test). We then combined CD4 memory T cell abundance and TCR diversity derived from bulk RNA-seq on 24 of these patients using logistic regression (trained on data from Lozano et al.) to yield a composite model score. The pretreatment composite model score was strongly associated with severe irAE development ($P=0.0009$, AUC=0.88), and in a median split, identified patients with shorter time to severe irAE development (3 months vs. not reached; $P=0.006$; HR=10.5). Notably, composite model features and the overall score had no significant association with immunotherapy benefit.
Conclusion: In this prospective study, both circulating CD4 TEM levels determined by CyTOF and a composite model score measured by RNA-seq were strongly associated with severe irAE development, independent of response status. These findings hold promise for future pretreatment risk stratification of ICI therapy.

#1168 Anti-CSF1R antibody monotherapy inhibits minimal residual disease in a novel immunocompetent murine colorectal cancer metastasis model.

A. M. T. Mohamed, K. Cho, M. Soeung, A. Anderson, J. Alshenaifi, G. Manyam, O. Villareal, J. Davis, W. Norton, S. Gao, C. Bristow, F. Carbone, S. Napolitano, O. Coker, I. Khanduri, J. Huang, D. M. Maru, M. Di Pilato, R. Sun, L. Wang, D. G. Menter, G. Genovese, G. Draetta, N. Fowlkes, S. Kopetz;
The University of Texas MD Anderson Cancer Center, Houston, TX

Background: The high mortality rate of colorectal cancer (CRC) is primarily due to metastatic disease. Microscopic minimal residual disease (MRD) detected in patients by circulating tumor DNA (ctDNA) may remain radiographically undetectable and persist following therapeutic intervention, resulting in recurrence. Preclinical models are urgently needed to elucidate the mechanisms whereby MRD escapes anti-tumor immune surveillance. We have developed and characterized a preclinical liver MRD model that recapitulates immune response, with the goal to discover novel strategies to improve outcomes for patients with ctDNA+ MRD.

Methods: We generated genetically engineered mouse colonic organoids CDX2 CRE; Rosa26 LSL-CAS9-GFP with APC and TP53 mutation and performed intrasplenic injection in syngeneic C57BL/6 mice to recapitulate microsatellite stable CRC metastasis to the liver. Mice were monitored for radiographically detectable disease using MRI. Tumors were resected at various timepoints, with comparison between metastases at various sizes of development (dichotomized as micro- and macro-metastases). We performed multiplex immunofluorescence staining, single cell RNA seq, and spatial transcriptomic analysis to delineate the immune compartments of micro- and macro-metastasis in untreated mice. After identifying colony stimulating factor -1 receptor (CSF1R) as a target, we performed a vehicle controlled anti-CSF1R monotherapy study for 4 weeks. Treatment began at either 7 days before metastasis is radiographically detectable to mimic treatment of MRD, or 21 days post tumor engraftment.

Results: Immune exclusion was confirmed through intratumoral CD45+ leukocyte densities, with transition to an immune excluded phenotype occurring above 0.5mm in size (defined as macro-metastases). In our preclinical model, immunosuppressive populations of macrophages (IBA1+CD163+) dominated in the micro-metastases. This observation was confirmed in 13 patients with paired micro- and macro-metastases to the liver ($p=0.0065$). Strikingly, anti-CSF1R treatment in the murine model eradicated IBA1+CD163+ macrophages ($p<0.0001$) and induced complete remission of liver micro-metastasis (0/7 mice with residual disease), in contrast to limited efficacy for macro-metastases (5/5 mice with progressed radiographically disease). Additionally, a long-term study confirmed 100% survival (5/5 mice) and no evidence of disease via MRI at 6 months upon anti-CSF1R treatment compared to vehicle (0/5 mice).

Conclusions: We established a reproducible preclinical model of MRD with similar immunopathological features of MRD in patients. Our data further identified infiltration of immunosuppressive macrophage populations as an early determinant of MRD progression and indicated CSF1R as a potential new clinical therapeutic target for ctDNA+-defined MRD patients.

#1169 Increased immunotherapy sensitivity associated with damaging IFN-gamma pathway mutations in NSCLC.

Alexander Azizi[1], Arvind Ravi[1], Natalie Vokes[2], Stephen-John Sammut[3], Justin Gainor[4], Gad Getz[1]

[1]The Broad Institute of Harvard and MIT, Cambridge, MA, [2]Department of Thoracic/Head and Neck Medical Oncology, MD Anderson Cancer Center, Houston, TX, [3]Breast Cancer Now Toby Robins Research Centre, The Institute of Cancer Research, London, United Kingdom, [4]Henri and Belinda Termeer Center for Targeted Therapies, Massachusetts General Hospital, Cambridge, MA

Introduction: In vivo CRISPR screens across multiple murine models of malignancy revealed that loss of interferon gamma (IFN-γ)-mediated sensing predisposes to immune elimination. We assessed the association between damaging mutations in the IFN-γ pathway and clinical outcomes after immune checkpoint inhibition in the Stand Up to Cancer-Mark Foundation non-small cell lung cancer (NSCLC) cohort.

Methods: The sensitizing IFN-γ pathway genes were defined as *IFNGR1*, *IFNGR2*, *JAK1*, *JAK2*, *STAT1*, *IRF1* & *IRF9*. Damaging mutations (including missense mutations) in any of these genes was considered as loss of pathway activity. We used the best observed response (measured by RECIST v1.1 criteria across time points) to define outcome. Complete and partial response were categorized as responses (R), while stable and progressive disease were categorized as non-responses (NR). The percentage change in target lesions (CTL) was also assessed. Response data was analyzed using additive logistic (LogR) and linear regression (LinR). Overall survival (OS) and progression-free survival (PFS) were analyzed using Cox proportional-hazards models. Three predictor variable groups were established; the final models comprised IFN-γ pathway loss, tumor mutational burden (TMB), programmed death-ligand 1 (PD-L1) tumor proportion score (TPS), prior platinum chemotherapy, age, sex, histological subtype, initial tumor stage, and smoking pack years.

Results: 309 patients had evaluable whole-exome sequencing data, treatment with PD-(L)1 inhibitor regimens, and matched radiological responses (121 R [39%], 188 NR [61%]); 306 had matched OS data; 297 had matched PFS data; and 227 had matched CTL data. 27 (7%) patients had damaging mutations in the IFN-γ pathway [*IFNGR1* (3); *IFNGR2* (1); *JAK1* (6); *JAK2* (8); *STAT1* (3); *IRF1* (1); *IRF9* (3); and *JAK2* & *IRF9* (1)]. Significant relationships were observed in univariable models between IFN-γ pathway loss and both response (LogR: OR 0.17, $p=2x10^{-4}$*; LinR: OR 0.70, $p=4.8x10^{-4}$*) and survival (PFS: HR 0.45, p=0.0067*; OS: HR 0.51, p=0.037*). IFN-γ pathway loss is significantly associated with TMB ($p=9.7x10^{-8}$*, Wilcoxon signed rank test). Multivariable models incorporating TMB and PD-L1 TPS confirmed the significance of IFN-γ pathway loss in both response (LogR: OR 0.29, p=0.050*; LinR: OR 0.71, p=0.0052*) and survival (PFS: HR 0.37, p=0.036*; OS: HR 0.27, p=0.030*). These relationships persisted in the final multivariable models (LogR: OR 0.32, p=0.11; LinR: OR 0.69, p=0.012*; PFS: HR 0.39, p=0.068; OS: HR 0.15, p=0.0038*). Random gene sets, of similar total protein coding sequence length, significantly associated with TMB but not with multivariable models of response or survival.

Conclusion: In this NSCLC cohort, damaging IFN-γ pathway mutations associate with increased immunotherapy sensitivity, independently of TMB and other co-variates, as evidenced by multiple clinical outcomes.

#1170 An off-the-shelf vaccine activates mutant KRAS-specific T cells in patients with resected pancreatic cancer.

A. L. Huff, A. Girgis, S. D. Haldar, E. Davis-Marcisak, T. Heumann, G. Longway, L. Andaloori, A. Hernandez, M. F. Konig, B. Mog, L. Danilova, L. T. Kagohara, J. M. Nauroth, A. M. Thomas, E. J. Fertig, W. Ho, E. M. Jaffee, N. Azad, N. Zaidi;
Johns Hopkins University, Baltimore, MD

Background: Oncogenic mutations in KRAS (mKRAS) are expressed in up to 90% of pancreatic ductal adenocarcinomas (PDAC) therefore representing a promising immunotherapeutic target. We developed a pooled mKRAS peptide vaccine targeting the 6 most common mutations in PDAC: G12V, G12A, G12C, G12R, G12D, or G13D (NCT04117087). In a phase I study, we evaluated mKRAS-specific T cell responses raised by the vaccine when given in combination with immune checkpoint inhibitors to PDAC patients following resection and adjuvant chemotherapy.

Materials and Methods: Patients received the pooled mKRAS peptide vaccine (0.3mg/peptide and 0.5mg poly-ICLC weekly for 4 doses in combination with ipilimumab and nivolumab followed by boosters every 8 weeks with nivolumab. To detect vaccine-induced mKRAS-specific T cells, pre- and post-vaccine peripheral blood mononuclear cells (PBMCs) were restimulated with control or individual mKRAS peptides and IFNγ release was measured by ELISPOT. mKRAS-specific T cell activation, proliferation, memory, and exhaustion profiles were assessed by CyTOF and cytokine secretion was determined by ELISA. For a subset of patients, mKRAS-specific T cells were expanded *in vitro* and T cell receptor (TCR) β chain sequencing and scRNA/TCRseq were used to identify the KRAS mutation-specific TCR repertoires and define their phenotypes in circulation.

Results: mKRAS-specific T cells were detected by IFNγ ELISPOT post-vaccination for all patients, although magnitude and mutation-specific responses varied between patients. CyTOF analysis identified mKRAS-specific Th1 CD4+ central memory (cm, CCR7+IFNγ+) and effector memory (em, CCR7-IFNγ +IL2+ TNFα+) responses as well as CD8+ effector (eff, CD137+GZMBhiKi67hi) and effector memory (CCR7-CD137+GZMB+) responses. mKRAS-specific T cells were also detectable in the extended booster phase of treatment (>1 year post initial vaccination). *In vitro* expanded mKRAS-specific T cells mapped to CD4+ Tcm/em and CD8+ Tem populations within single cell datasets of unstimulated PBMCs collected post-vaccine. 5-25% of the mKRAS-specific T cells significantly expanded to more than one mKRAS antigen suggesting potential cross-reactive T cell clonotypes. In addition, shared public mKRAS-specific T cell clonotypes were identified across patients.

Conclusions: This study demonstrates mKRAS vaccine induction of *de novo*, high quality mKRAS-specific polyfunctional CD4+ and CD8+ T cells. mKRAS-specific TCR analysis identified shared public TCRs across vaccinated patients that have important implications for future “off the shelf” adoptive therapy approaches. Ongoing studies are aimed to validate antigen specificity and map HLA-restriction of mKRAS-specific T cells. Overall, this study demonstrates a positive immunogenic signal of this pooled mutant KRAS vaccine that may be amenable for interception vaccination strategies against PDAC.

#1171 Estimating sensitivity of exploratory cellular biomarkers in oncology clinical trials.

C. Xue, C. D. Swenson, T. W. Mc Closkey;
ICON Clinical Research, Inc., Farmingdale, NY

Background: In the prolonged and complex process of assessing immunotherapeutic oncology drug candidates, flow cytometry plays an essential role. In oncology studies, biomarker measurement requires robust and reliable flow cytometric assays. A crucial element of these assays is to understand the lower limits of measurable surface biomarkers.
Methods: We incorporated into the development and validation of flow cytometry assays the measurement of the lower limit of quantitation (LLOQ). The LLOQ is the lowest number of a reportable parameter in a blood or bone marrow study sample that can be quantitatively determined with acceptable precision and accuracy. Two steps are necessary to determine the LLOQ. First in these assessments a measurable range of lower limits of a particular cell type or receptor is estimated. That is, in validating an assay LLOQ, there are three options to select cells expressing target surface biomarkers of interest: using cultured or bioengineered cells, using samples of known high expression of a biomarker, or using pre-titered positive samples. Then decreasing concentrations of the target cell or receptor may be used to precisely determine the LLOQ of a specific assay reportable parameter.
Results: By acquiring at least ten negative control sample results, the limit of the blank (LOB) and limit of detection (LOD) of a biomarker is determined. LOB is calculated as mean +1.645 SD, and LOD as mean +3 SD. The negative control samples either lack the fluorescent monoclonal antibodies against the markers of interest or lack the target cell population. Different reportable parameters, detected by one or more biomarkers have varying LLOQ. The LLOQ for a reportable parameter is a precise measurement of a parameter above or equal to the LOD. We found that typical LLOQ values are from 4 to 145 positive cells, with a frequency of 0.01 to 0.1% among a parent population. For example, in the case of tetramer assays, flow cytometry can reliably detect as few as 25 CD8+ antigen-specific cells among three million lymphocytes.
Conclusions: LLOQ determinations for exploratory flow cytometry biomarkers are required for clinical research in cancer immunotherapy and cancer vaccine development. This valuable information allows for interpretation of data at the low end of a measurable range.

#1172 Association between CD8+ PD-1+ T cell infiltration levels and improved response to total neoadjuvant therapy in mismatch-repair proficient locally advanced rectal cancer.

C. Lee, C.-T. Chen, N. Urganci, F. Wu, C. Firat, H. Williams, E. Seffar, P. Malekzadeh, W. K. Chatila, J. Shia, J. Garcia-Aguilar, F. Sanchez-Vega;
Memorial Sloan Kettering Cancer Center, New York, NY

Background: The tumor microenvironment plays a major role in colorectal cancer progression, dissemination, and response to therapy. As a mechanism of tumor immunity, CD8+ tumor infiltrating lymphocytes have been shown to express PD-1 in response to clonal neoantigens of tumors. We hypothesized that high levels of CD8+ PD-1+ T cell infiltration prior to treatment initiation may correlate with improved response to total neoadjuvant therapy (TNT) in patients with locally advanced rectal cancer (LARC).
Methods: We analyzed untreated endoscopic biopsies from 159 patients diagnosed with stage II (n=25) or III (n=134), mismatch-repair proficient rectal adenocarcinoma. All patients were treated with TNT, consisting of either induction chemotherapy followed by chemoradiation (n=108) or chemoradiation followed by consolidative chemotherapy (n=51). FFPE blocks from each biopsy were sectioned into slides for H&E and immunohistochemistry staining with antibodies for CD8 and PD-1 in a CLIA certified lab. CD8+ and PD-1+ cells were quantified using established protocols from the College of American Pathologists. We evaluated associations between response to TNT and tertiles of intratumoral CD8 and PD-1 expression (low/mid/high). Disease free survival (DFS) from the start of TNT and rate of sustained complete response (CR, either clinical or pathologic) were used as primary endpoints.
Results: Median follow-up was 40.3 months. The overall CR rate was 42% and the 5-year DFS rate was 77%. Intratumoral CD8 levels were significantly correlated with improved response rates (56% in the top tertile vs. 27% in the bottom tertile, p=0.003, Fisher's test) and improved 5-year DFS (92% vs. 67% for the top vs. bottom tertiles, respectively; p=0.006, log-rank test). Patients in the highest tertile of intratumoral PD-1 expression also had improved response (56% vs. 25%, p=0.002) and DFS (88% vs. 67%, p=0.034). CD8 and PD-1 levels were strongly correlated with each other (R=0.72, p<0.001, Spearman correlation). Finally, the 41 patients who met criteria for top tertiles of CD8 and PD-1 expression had higher CR rates (66% vs. 32%, p<0.001) and better 5-year DFS (97% vs. 70%, p=0.002) than the other patients.
Conclusions: Higher levels of CD8+ and PD-1+ tumor infiltrating lymphocytes on pre-treatment biopsies are associated with improved response to TNT and disease free survival in LARC patients.

#1173 T cell receptor diversity in buffy coat samples from subsets of breast and ovarian cancer patients.

Corinna Keup[1], Cornelia Kolberg-Liedtke[1], Song Tian[2], Samuel J. Rulli[2], Siegfried Hauch[3], Paul Buderath[1], Oliver Hoffmann[1], Rainer Kimmig[1], Sabine Kasimir-Bauer[1]

[1]Essen University Hospital, Essen, Germany,[2]QIAGEN GmbH, Frederick, MD,[3]QIAGEN GmbH, Hilden, Germany

Background: Immunotherapy, mainly by the use of immune checkpoint inhibitors (ICI), has been established as a standard option for both, solid tumors and hematological malignancies. Unfortunately, this success has only been replicated in a subset of patients (pts) with gynecological cancers. In ovarian cancer (OC), response rates to ICI monotherapy were low and in breast cancer (BC), only the subgroup of triple-negative BC (TNBC) pts showed an improved outcome by the addition of ICI. One reason for limited success of immunotherapy might be an impaired immune system. In this regard, monitoring the T cell receptor (TCR) repertoire could provide key insights into adaptive immune responses to ultimately understand disease initiation, progression and treatment response. Here we elucidated TCR alpha, beta, gamma and delta in buffy coats of pts with non-metastatic OC as well as non-metastatic and metastatic TNBC and compared the results with healthy donors (HDs).

Methods: RNA was isolated from buffy coat samples of 20 HDs, 10 treatment-naïve primary OC pts, 14 treatment-naïve, non-metastatic TNBC pts (participating in the phase II neomono trial) and 19 pts with metastatic TNBC by a modified QIAamp RNA Blood Mini protocol. A survey of the TCR diversity and mapping of common and unique TCRs was done using the QIAseq Targeted RNA Panel Human TCR panel for all known T-cell receptors (alpha, beta, gamma, delta).

Results: Regardless of the cancer entity, a significant reduction in TCR diversity was observed compared to HDs with the greatest differences observed in the delta receptors. When OC samples were compared with HDs, the difference in diversity was highly significant for all TCR subtypes (TCRalpha: p=0.013; TCRbeta: p=0.008; TCRgamma: 0.008; TCRdelta: 0.006). Similar results were obtained for non-metastatic TNBC (TCRalpha: p=0.0002; TCRbeta: p=0.0001; TCRgamma: p=0.002; TCRdelta: p=0.002) as well as metastatic TNBC patients (TCRalpha: p=0.001; TCRbeta: p=0.001; TCRgamma: p=0.005; TCRdelta: p=0.003) when their TCR diversity was compared to HDs. Interestingly, no significant differences in diversity were obtained when treatment-naïve non-metastatic TNBC pts were compared with heavily pretreated metastatic TNBC pts. The lowest diversity was found in BC pts compared to the OC pts.

Conclusion: We have initiated a survey of the TCR diversity in TNBC and OC patients. Further evaluations will include the correlation of these findings with clinical characteristics and outcome. Whether the reduced TCR diversity represents T cell exhaustion or T cell specialization cannot yet be deduced from the results. Nevertheless, the addition of a TCR diversity score could provide an additional metric which may help provide patient guidance when integrated into a multi-modal molecular test.

#1174 Incorporation of multisector analysis into the design of personalized DNA vaccines for patients with newly diagnosed glioblastoma.

E. A. R. Garfinkle[1], K. E. Miller[1], A. J. Livingstone[2], R. Perales-Linares[3], N. Cooch[3], A. Perales-Puchalt[3], S. Rochestie[3], J. Peters[3], N. Y. Sardesai[3], W. E. Gillanders[2], E. R. Mardis[1], G. P. Dunn[4], T. M. Johanns[2];

[1]Nationwide Children's Hospital, Columbus, OH, [2]Washington University School of Medicine, St. Louis, MO, [3]Geneos Therapeutics, Plymouth Meeting, PA, [4]Massachusetts General Hospital, Boston, MA

Glioblastoma (GBM) is the most common malignant central nervous system (CNS) tumor in adults. Despite multimodality treatment including surgery, radiation, and chemotherapy, patients with GBM have a median survival of less than 2 years. Recent clinical trials have reported promising results using cancer vaccines to stimulate a tumor-directed immune response in several histologies. The majority of trials targeted tumor neoantigens derived from a single tumor sample, which limits the antigen pool in spatially heterogeneous cancers like GBM. Our group previously implemented multisector sequencing into the design of personalized peptide vaccines to increase the candidate pool of targetable neoantigens (NCT03422094). Although the peptide vaccine treatment was successful in stimulating an effector T cell response, it was limited by a long turnaround time from vaccine design to administration and a low peptide production rate. Therefore, we incorporated multisector sampling into the design of a personalized DNA-based GBM vaccine (NCT04015700). An average of 33% of the candidate targetable neoantigens were spatially restricted to a single sampled region, which would have been missed without multisector sequencing. DNA-based vaccines are potentially advantageous over peptide-based vaccines because they enable a higher neoantigen payload and faster manufacturing time with potent immunogenicity. Here, we report the results from 9 subjects enrolled onto the study. Spatially distinct tumor regions were subjected to whole exome sequencing (WES) and RNA-sequencing (RNA-seq), data from which were used to identify neoantigens through the pVACseq algorithm (http://pvactools.org). An average of 32 neoantigens were included in each DNA vaccine, compared to an average of only 9 for the peptide vaccine, and the turnaround time from date of surgery to administration of the DNA vaccine was about half the time. Three subjects had radiographic evidence of tumor progression prior to vaccination, highlighting the aggressive nature of GBM and the need for short manufacturing timeframes. PBMCs pre- and post-DNA vaccination were collected from 7/9 subjects. All subjects presented detectable responses and 6/7 tested revealed a sustained increment in T cell reactivity against tumor neoantigens post-treatment by IFN-γ ELISpot. Intracellular staining showed a neoantigen-specific antitumor CD8/CD4 T cell cytolytic (CD69+, CD107a+) and proliferative (Ki67+) profile. Post-vaccination tumor resections were performed for 2 subjects who also were treated with PD1 blockade upon progression, providing an opportunity to explore vaccine-induced changes in the tumor microenvironment. Herein, we demonstrate the advantages of incorporating multisector sequencing into the development of DNA-based GBM vaccines and provide insights into the resulting immune responses.

#1175 Differential patterns of immune infiltration in the tumor immune microenvironment associate with therapeutic response in primary prostate cancer following chemohormonal therapy.

E. Heninger, J. M. Sperger, K. Weinstein, B. P. Johnson, P. G. Geiger, S. Wells, S. Y. Cho, W. Huang, P. Tsourkas, S. McIlwain, I. M. Ong, S. C. Kerr, D. F. Jarrard, D. J. Beebe, J. M. Lang;
University of Wisconsin, Madison, WI

There is a critical need to develop novel therapeutic strategies and diagnostic tools to precisely deliver treatments to improve survival for men with prostate cancer. To support this development, improved strategies are needed to better understand heterogenous tumor microenvironments and tumor biology that associate with variable treatment responses. We hypothesized that the tumor immune microenvironment (TIME) plays a critical role in treatment resistance. In this study we aimed to evaluate TIME signatures of treatment response and resistance utilizing a novel, integrated technological tool to identify response patterns and enable precision sampling for comparative cellular and molecular analysis.

30 patients with newly diagnosed, locally advanced, high-risk, primary prostate cancer underwent ^{18}F-DCFPyL PSMA PET/MRI with multiparametric MRI scans followed by 3 cycles of chemohormonal therapy (NCT03358563). Repeat PSMA PET/MRI was performed prior to prostatectomy and scans were used to categorize lesions as complete response (CR), partial response (PR), no response (NR) or normal tissue. MRI scans were used to print a 3D mold of the prostate to allow microdissection of regions of interest from the resected prostate. Cellular infiltrates were analyzed by flow cytometry in 3 to 5 tissue specimens per patient. Statistical analysis was performed with One-way ANOVA with Tukey-correction.

The frequency of CD8$^{\pm}$ T cells in the total CD45$^{\pm}$ infiltrate was highest in normal and CR areas and was significantly reduced in PR vs CR ($p<0.01$). CXCR3$^{\pm}$CD8$^{\pm}$ and CD103$^{\pm}$CD8$^{\pm}$ T cell frequencies were also reduced in PR vs CR foci ($p<0.01$, $p<0.05$, respectively). Meanwhile, the frequency of CXCR3$^{\pm}$CD8$^{\pm}$ T cells was highest and significantly elevated in CR vs normal tissue. A tendency of reduced CCR6$^{\pm}$, CXCR5$^{\pm}$, and CCR4$^{\pm}$CD8$^{\pm}$ T cells was observed in PR vs CR foci, while those frequencies remained higher in normal and CR areas. An increase in total CD8$^{\pm}$ and CD103$^{\pm}$CD8$^{\pm}$ T cells associated with longer progression-free survival. Additionally, the analysis of EpCAM$^{\pm}$ cells showed a significant increase in B7H3 expression in PR vs CR lesions ($p<0.05$) and a tendency of reduced HLA I expression in foci that associated with treatment resistance. We are currently integrating analysis of myeloid cells and transcriptomic analysis of sorted CD4$^{\pm}$, CD8$^{\pm}$ and CD11b/CD14$^{\pm}$ cells to further dissect patterns of therapeutic response in our study cohort.

In conclusion, PSMA/PET MRI based precision sampling of tumor tissue associated with differential therapeutic response patterns captured differences in the TIME infiltrates and these observations may provide hypothesis to test biological mechanisms to expedite discovery of targetable mechanisms to improve tumor stratification and targeting in high-risk prostate cancer.

#1176 Identification of circulating and spatial dynamics of immune cells response to to immune checkpoint inhibitors in triple-negative breast cancer at single-cell resolution.

E. Seo, H. Jung, K. Kim, K. Park, E. Ko, B. Chae, J. Lee, E. Cho, J.-Y. Kim, W.-Y. Park;
Samsung Medical Center, Seoul, Korea, Republic of

Background: Triple-negative breast cancer (TNBC) have had significantly worse survival outcome compared to other BC subtypes even though treatment strategies of TNBC have been advanced. The advent of immune checkpoint inhibitors (ICIs), especially pembrolizumab, a PD-1 inhibitor, has started to revolutionize TNBC treatment, showing encouraging effects in improving survival outcomes regardless of treatment settings. In neoadjuvant setting, pembrolizumab with cytotoxic chemotherapy achieved 13.6 % of pathologic complete response rate improvement and 36% of three-year event reduction. Therefore, pembrolizumab has highlighted new dimensions of TNBC's immunogenic characteristics. However, no immunogenic characteristics to predict the response of pembrolizumab have not been revealed.

Methods: This study was designed as prospective, translational research for stage II or III TNBC patients scheduled for neoadjuvant chemotherapy with or without pembrolizumab followed by curative surgery. Tissue and blood samples were collected at baseline, 1 or 3 weeks after the first treatment initiation and curative surgery. We employed various single-cell and bulk RNA techniques for our multiomic analysis, including peripheral blood mononuclear cell (PBMC) single-cell RNA sequencing, T cell receptor sequencing (scTCR), high-resolution single-cell spatial transcriptomics (Xenium) targeting 380 genes, and bulk PBMC and tissue TCR analysis

Results: From March 2023 to October 2023, 37 patients were enrolled in this study. Of 37 patients, we collected 36 blood and BC tissue samples at baseline, as well as 35 blood and 14 BC tissues at follow-up. These samples were analyzed and also compared with sex and age-matched healthy controls (n = 65). Of 37 patients, two patients were treated with only cytotoxic chemotherapy without pembrolizumab. We observed substantial increases in both systemic and localized immune responses, primarily marked by an upsurge in activated T cells and a decrease in regulatory T cells. A notable rise in TCR diversity post one week of treatment was followed by clonal expansion of activated T cells after three weeks in both blood and tissue. In addition, we observed a significant enrichment of pathways related to inflammatory response in classical monocytes following treatment.

Conclusion: The findings from this study significantly enhance our understanding of the dynamics of circulating and local immune cells in TNBC, analyzed at a single-cell level with spatial information. These insights reveal how pembrolizumab alters the immune landscape and correlates these changes with treatment responses. Importantly, the data provide valuable indicators for predicting which TNBC patients are more likely to respond to neoadjuvant pembrolizumab therapy.

#1177 The chronology of immune-related adverse events (irAEs)-mechanistic implications.

F. Mazahreh, H. Safar, L. Mazahreh, A. Safar;
University of Arkansas for Medical Sciences, Little Rock, AR

Immune Oncology (IO) is a novel component of the oncology armamentarium given its distinct mechanism of action, and by extension, unique mechanisms of toxicity (Tx). To recognize these unusual Txs, the term irAEs was popularized in clinical trials. Most organs have been involved by irAEs and autoimmunity has been implicated commonly by practicing oncologists. The onset of irAEs has not been studied well, however. We reasoned that autoimmune phenomena would be expected early after IO, since this is the timeframe within which T-cells expand to exert their effects on tumor and other 'self' tissues. It follows that if autoimmunity is the sole mechanism of irAEs, such toxicities should be reported early. Mechanism(s) of irARs may prove important for IO duration discussions. In some cases, tumor antigenic epitopes may mimic self-tissues, and in such cases irAEs develop early after initiation of IO. We *hypothesized* that irAEs have distinct chronology: earlier events representing autoimmunity (unavoidable); later events reflecting an intercurrent exposure to an antigen (e.g., virus) and therefore are avoidable by limiting duration of IO. Methods: We reviewed published IO monotherapy trials if individual patient data (swimmers' plot) were reported. We derived the timing and frequency of Tx. We used therapy discontinuation without progressive disease as a surrogate for Tx if reported before the planned 24 months IO therapy.Results: Table depicts the data on included clinical trialsConclusion: The emergence of irAEs after IO extends over a protracted periods with 86% of events occurring beyond 4 months of IO. Though responses occasionally develop late after IO, for Tx consideration, T-cell expansion starts within days of IO initiation, and if autoimmunity is the mediator of Tx, irAEs would emerge only early. Our results suggest dual mechanisms and provide one more impetus to consider shortening IO duration.

Tumor	Author	Discontinued IO (n)	Months of IO Discontinuation

#1178 Tissue nanomechanics as a novel, clinically translatable predictive early biomarker of response in combination immunotherapy.

G. Srivastava[1], S. Nizzero[2], M. Wasley[2], M. Kim[3], K. Graham[2], P. D. Ndiaye[1], M. Gachechiladze[1], N. Puebla-Osorio[4], P. Oertle[1], T. Appenzeller[1], V. Cristini[5], M. Loparic[1], M. Plodinec[1], J. W. Welsh[4];

[1]Artidis AG, Basel, Switzerland, [2]Artidis Inc, Houston, TX, [3]MD Anderson, Houston, TX, [4]MD Anderson Cancer Center, Houston, TX, [5]Houston Methodist Research Institute, Houston, TX

Background: Recently, the successful integration of immunotherapy with other treatment modalities has demonstrated its efficacy in enhancing immune activation and suppressing tumors in solid cancers. The most promising of such efforts include the use of low dose radiation (LD-XRT) to prime the tumor microenvironment and enhance the T cell infiltration and activation [Barsoumian HB, et al., 2020; Patel RR, et al., 2021; He K, et al., 2023]. With these advancements, there is an urgent need to develop clinical biomarkers to predict response and optimize treatment decisions. Recent evidence underscores the importance of nanomechanical alterations within the tumor microenvironment as mechanistic indicators of aggressiveness [Plodinec M, et al., 2012]. This study aims to demonstrate the value of ARTIDIS nanomechanical signature as early predictor of elucidate of response to combination LD-XRT/immune checkpoint inhibitors (ICI). Our measurement protocol in mice follows the same settings for biopsies acquired in routine biopsy collection protocol, thus supporting prompt clinical translation and integration.

Methods: We established a mouse model of 344SQ lung adenocarcinoma tumors that exhibited resistance to anti-PD1 treatment in 129Sv/Ev mice. These mice underwent treatment protocols involving a combination of anti-PD1 and anti-CTLA4 antibodies, both with and without LD-XRT pre-treatment. Throughout the study, we closely monitored survival rates and tumor growth across diverse experimental groups. Employing the ARTIDIS platform, a cutting-edge technology that integrates atomic force microscopy with proprietary artificial intelligence algorithms, we extracted a multiparametric nanomechanical signature and we evaluated its outcome prediction value. This signature was then complemented by histopathology, multiplex immunofluorescence, and Nanostring assays to elucidate mechanisms of stroma remodulation and immune infiltration.

Results: This study identifies the unique nanomechanical signature predictive of response to immunotherapy alone or in combination with radiation. Using the tissue nanomechanical signature as a predictive biomarker, we achieved precise differentiation between responders and non-responders, boasting a 90% sensitivity, 99.1% specificity, and a 96% AUC. To our knowledge, this study is the first to demonstrate the response-predicting power of a tissue derived nanomechanical signature for immune checkpoint inhibitors administered in combination with LD-XRT. These findings support clinical translation of the ARTIDIS nanomechanical signature as a pivotal tool for clinically predicting and evaluating responses to integrated radiation and immunotherapy approaches.

#1179 A single-cell atlas of human gastric malignancy reveals CD8+ T cell rejuvenation as a mediator of immunotherapeutic response.

H. Liang[1], J. Chen[2], Y. Luo[3], M. Kang[2], W. Liu[1], L. Wang[2];
[1]UT MD Anderson Cancer Center, Houston, TX, [2]Zhejiang University, Hangzhou, China, [3]Baylor College of Medicine, Houston, TX

Immune checkpoint inhibition (ICI) has emerged as a mainstream treatment for patients with advanced stage gastric cancer (GC). Cellular heterogeneity in the tumor microenvironment (TME) has a profound impact on the therapeutic responses to ICI. Here we characterize the kinetics of tumor-infiltrating immune populations in GC patients treated with anti-PD-1 using single-cell RNA and TCR sequencing (scRNA/TCR-seq), including primary tumors and metastases. Integrated with public GC scRNA-seq datasets, we construct the largest multi-omic atlas of GC cell states to date that captures the full trajectory of GC malignancy and comprises >320,000 cells derived from 73 samples. We demonstrate the rejuvenation of exhausted CD8$^{\pm}$ T cells into a proliferative state marked by the loss of *LAYN* expression as a major mediator of ICI response in the TME. In parallel, we observe enhanced immunogenicity of cancer cells in post-ICI tumors, thus highlighting the coordination between tumor-intrinsic and microenvironmental factors elicited by ICI. Our study provides a valuable resource of investigating the tumor response to anti-PD-1 treatment and suggests novel strategies for combination therapy and patient stratification.

#1180 Asparagine deprivations enhance CD8+ T cell antitumor activity and ICB immunotherapy via ROS-mediated NFAT nuclear localization.

Hsuan Chia Chang, Kwang-Huei Lin, Huang Yu Yang

Chang Gung University, Taoyuan City, Taiwan

Metabolic reprogramming plays a crucial role in the differentiation and activation of T cells. Both oxidative phosphorylation (OXPHOS) and glycolysis are upregulated to meet the high energy demands. However, the impact of amino acid metabolism on T cell activation remains unclear. Our study demonstrates that asparagine deprivation enhances the antitumor activity of CD8+ cytotoxic T lymphocytes (CTLs) and increases the flux of glycolysis and the tricarboxylic acid (TCA) cycle. Mechanistically, asparagine deprivation induces the production of reactive oxygen species (ROS) through mitochondrial complex I deficiency and leads to nuclear localization of NFAT, subsequently affecting cytokine production and T cell activation. In the animal model, we found that the clinical drug leunase exhibits antitumor activity that relies on the immune response of T cells. Leunase treatment promotes the activation of tumor-infiltrating lymphocytes (TILs) in vivo. Furthermore, the combination therapy of leunase and anti-PD1 demonstrates a synergistic effect. In patients with nasopharyngeal carcinoma (NPC), leunase therapy enhances the cytokines production and activation of CD8+ T cell. In summary, our findings offer valuable insights into how T cells adapt to changes in their nutritional environment.

#1181 Therapeutic efficacy by *Streptococcus salivarius* as a probiotic in a preclinical model of oropharyngeal carcinoma.

J. Diaz[1], M. R. Rivera[1], K. A. A. Del Valle[1], E. E. A. Pinero[1], F. G. Vitorino[1], J. R. G. Ortiz[2], S. M. D. Estremera[1];
[1]University of Puerto Rico - Medical Sciences Campus, San Juan, PR, [2]University of Puerto Rico - Comprehensive Cancer Center, San Juan, PR

Streptococcus salivarius is a gram-positive, non-pathogenic bacteria found in the oral cavity and upper respiratory tract. This bacterium has been shown to possess antimicrobial properties with the potential to cause activation of natural killer (NK) cells and induction of anti-tumorigenic cytokines such as interferon-gamma and interleukin-12 (IL-12). There is a high abundance of this bacteria in the saliva in oral squamous cell carcinoma patients. Moreover, *Streptococcus-reactive* cytotoxic T cells were associated with recurrence-free survival. Nevertheless, there is a considerable lack of information regarding the impact of *S. salivarius* on intratumoral immune responses and its potential as a cancer therapeutic. This study aimed to characterize the immune responses in the tumor microenvironment by *S. salivarius* in combination with programmed cell death protein 1 (anti-PD-1) therapy and its therapeutic efficacy. We expect that *S. salivarius* will cooperate with immune checkpoint inhibitors, activating antitumor immune responses. For this project, we used a preclinical murine model where an HPV+ oropharyngeal cancer cell line named mEER was implanted subcutaneously or in the tongue of the mice. We treated with or without *S. salivarius* and/or anti-PD-1. First, *S. salivarius* was administered intratumorally on subcutaneous tumors and treated or not with anti-PD-1 therapy administered intraperitoneally. We measured tumor volume and quantified different immune cells by flow cytometry. While anti-PD-1 treated mice showed a continuous increase in tumor volume, the ones treated with anti-PD-1 and *S. salivarius* reduced the growth rate starting at day 20. Mice treated with anti-PD1 and *S. salivarius* showed increased CD4+ T cells and myeloid-derived suppressor cells (MDSCs) compared to anti-PD-1 treatment alone. Secondly, we implanted the mice with tongue tumors and applied *S. salivarius* topically in the oral cavity with or without anti-PD-1. The use of *S. salivarius* contributed to an increase in CD4+T cells and activation of CD8+T cells and NK cells. The combination of anti-PD-1 with *S. salivarius* did not further enhance the activation of these cells. Nevertheless, 80% of mice receiving anti-PD-1 with *S. salivarius* responded to the therapy, whereas 63% responded while receiving only anti-PD-1. In conclusion, *Streptococcus salivarius* as a probiotic, affected tumor development and immune cell infiltration in oropharyngeal cancer. Future analyses will allow us to explore the effect of the probiotic on the tumor microenvironment and improve colonization in the oral cavity.

#1182 PDC*lung01: An innovative therapeutic cancer vaccine induces specific immune responses in combination with anti- PD-1 treatment in patients with non-small cell lung cancer.

We have developed an innovative cancer vaccine for the treatment of advanced NSCLC patients in combination with checkpoint inhibitors. This PDC*lung01 product based on an irradiated plasmacytoid dendritic cell line loaded with HLA-A*02:01 restricted peptides (NY-ESO-1, MAGE-A3, MAGE-A4, Multi-MAGE-A, MUC1, Survivin and Melan-A) is able to prime and expand peptide-specific CD8+ T cells *in vitro* and *in vivo*, and is synergistic with anti-Programmed Death (PD)-1 (Plumas et al, 2022; Hannani et al, 2023, NCT03970746). In study PDC-LUNG-101 with EudraCT number 2018-002382-19, PDC*lung01 is injected intravenously and subcutaneously for 6 times at two dose levels, 14 million, or 140 million cells in stage II/IIIA (cohort A1 & A2, monotherapy) or stage IV with TPS≥50% (cohort B1 & B2; in combination with pembrolizumab) patients. We report here the analysis of immune response of 3 cohorts (A1, A2, B1) of patients and the first 19 patients out of 42 (cohort B2) treated with high dose of PDC*lung01 in combination with Pembrolizumab at baseline and 3 timepoints post injection. Several circulating immune parameters have been evaluated at different times before and after vaccination using different assays we have developed: leukocyte count and determination of circulation peptide specific CD8+ T cells by flow cytometry using multimer tools without prior *in vitro* culture. The assay made on purified CD8+ T-cells allowed us to define a limit of quantification (LOQ) to accurately assess the fold changes of the cell expansion. In addition, tumor microenvironment (TME) was analyzed by multiplex fluorescence immunochemistry. The data of 42 patients for who an immune response has been evaluated (cohorts A and B) will be presented. No major changes in circulating main lymphocyte frequencies (B cells, NK cells, CD4+, CD8+, or Treg T cells) were observed during treatment. In addition, no major cell activation (CD25+, CD54, or DR+) was noted. In contrast, in a significant number of patients, PDC*lung01 induced circulating peptide-specific CD8+ T cell expansion in all 4 cohorts at different levels and time points against at least one out of seven peptides used. The percentages of patients for who an expansion of antigen-specific T-cell were observed were 50%, 64%, 66.7% and 68.4% in A1, A2, B1 and B2 cohorts respectively. The intensity of the immune response was proportional to the dose of PDC*lung01 and to the combination with pembrolizumab. When possible, total and peptide-specific CD8+ T cells were sorted for analysis of TCR repertoire, illustrating the modelling and dynamics of the immune response. The TME features will also be illustrated. To conclude, treatment with PDC*lung01 induces an anti-tumor immune response in a significant number of patients which appears to be enhanced by the combination with pembrolizumab.

#1183 A first-in-class and SHP1 allosteric inhibitor, SB8091, shows a good efficacy and safety profile in preclinical models.

J. Kim, K. Ryu, J. Cho, D. Kim, D. Seong, K. Kim, I.-S. Jang, J. Shin, S. Jeong, M. Jang, H. Han, J. Hwang, D. Lee, C. Ryu, S. Lee, H. Kim, H. Lee, H. Lee, T.-D. Han, S. Yang, H. Doh;

Introduction: Src homology 2 domain-containing phosphatase 1 (SHP1) is a cytoplasmic protein tyrosine phosphatase (PTP) that is primarily expressed in hematopoietic cells and is commonly recognized as a negative regulator of multiple signaling pathways[1]. Previously, we showed that inhibition of the phosphatase activity of SHP1 by a novel SHP1 allosteric inhibitor, SB6299, results in the activation of innate and adaptive immune cells and enhanced anti-tumor immune responses[2]. Here, we report SB8091, an advanced SHP1 allosteric inhibitor with a promising initial safety profile and improved pharmacokinetic properties.

Methods: SHP1 inhibitors were developed through a structure-based drug design approach, and optimized for cellular activity on target, in vitro ADME, and in vivo pharmacokinetic properties. Pharmacokinetic (PK) and preliminary toxicity studies were performed with mice. The lead series was assessed in in-vitro studies with mouse or human primary immune cells. *In-vivo* efficacy and pharmacodynamic data were generated using mouse syngeneic tumor models.

Results: Structurally, SB8091 seemed to stabilize the autoinhibitory form of SHP1 as an allosteric inhibitor, in a nanomolar range and which can explain the outstanding selectivity compared to other PTP enzymes, including SHP2. In several human primary immune cell types, SB8091 significantly increased cytokine responses and demonstrated significantly enhanced activity in NK cells and macrophages against various cancer target cells. As a single agent, this compound exhibited inhibitory effects on tumor growth when administered orally, and the efficacy was further enhanced when co-administered with anti-PD1 antibodies in various syngeneic tumor models. Notably, this effect was associated with a pharmacodynamic response marked by increased levels of phosphorylated substrates regulated by SHP1. SB8091 exhibited favorable pharmacokinetic properties for oral administration, and SafetyScreen data showed a very low potential for off-target activity and drug-drug interactions. Additionally, during a 2-week repeat pilot toxicity study in mice, SB8091 demonstrated excellent tolerability even at high doses, indicating a high therapeutic index (TI > 100).

Conclusion: Our advanced compound, SB8091, is a potent, highly selective, and orally bioavailable allosteric inhibitor of SHP1. It has demonstrated excellent efficacy as a monotherapy or in combination with immune checkpoint blockers, with favorable drug properties and safety profiles. Research to advance to the clinical stage is being conducted.

#1184 Combination pembrolizumab and radiotherapy induces anti-tumor immune responses in immunologically-cold non-small cell lung cancer.

J. Huang[1], W. S. M. Theelen[2], Z. Belcaid[1], M. Najjar[1], C. Cherry[1], A. Balan[1], J. R. White[1], N. Niknafs[1], J. Wehr[1], M. van den Heuvel[3], R. Karchin[1], P. Baas[2], V. E. Velculescu[1], V. Anagnostou[1];

[1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]Netherlands Cancer Institute, Amsterdam, Netherlands, [3]Radboudumc, Nijmegen, Netherlands

Introduction: Primary resistance to immune checkpoint inhibition (ICI) is in part driven by a “cold” tumor microenvironment in the context of low PD-L1 expression, low tumor mutation burden or oncogenic mutations that drive tumor immune exclusion. Radiation has the potential to sensitize tumors to ICI through extra-tumoral T cell activation in response to tumor antigens released from irradiated cancer cells (abscopal effect). Here, we investigate tumor microenvironment and T cell repertoire reshaping leveraging serial biospecimens from a phase 2 randomized clinical trial of stereotactic body radiation therapy followed by pembrolizumab (SBRT arm) vs. pembrolizumab alone (control arm) in non-small cell lung cancer (NSCLC; NCT02492568).

Methods: We employed whole exome sequencing, RNA sequencing and T cell receptor (TCR) sequencing to analyze 293 serial tumor and peripheral blood samples collected at baseline and after 8 weeks of treatment from 72 patients in the control (n=35) and SBRT (n=37) arms. Immunologically-cold tumors were defined as low TMB (<300 mutations per exome, n=43), PD-L1 null (0% expression on immunohistochemistry, n=41), or WNT-activated (presence of mutations affecting genes in the WNT pathway, n=10). TCR clonotypic differential abundance analyses and RNA sequencing deconvolution and gene set enrichment analyses were performed on baseline and on-therapy blood and tumor samples from the control and SBRT arms.

Results: Patients with immunologically-cold tumors in the SBRT arm had significantly longer progression free survival compared to the pembrolizumab monotherapy arm (log rank p=0.029 for TMB-low, p=0.022 for PD-L1-null, p=0.037 for the WNT-activated subsets). Induction of interferon-gamma, interferon-alpha, antigen processing and presentation, and inflammatory response gene sets was significantly enriched on-therapy in the SBRT arm (FDR adjusted p<0.01 for TMB-low, PD-L1-null, and WNT-activated tumors). We observed greater enrichment in newly expanded TCR clones on-therapy intratumorally and in peripheral blood in the SBRT arm compared to the control arm (mean 16.17 vs 7.54 clonotypes, p=0.022 in tumor; mean 4.56 vs 1.00, p=0.039 in blood; Mann-Whitney U test). Similarly, we noted greater expansion of pre-existing TCR clones in the SBRT arm than within the control arm (mean 34.83 vs 18.69, p=0.021 in tumor; mean 21.61 vs 8.15, p=0.009 in blood; Mann-Whitney U test). Within the SBRT arm, there was no significant difference in T cell expansion between TMB-stratified (<300 mutations vs >=300 mutations) or PD-L1-stratified (0% vs >= 1% expression) groups.

Conclusions: SBRT followed by pembrolizumab was associated with priming and augmenting anti-tumor immune responses in immunologically-cold NSCLC, which opens a therapeutic window of opportunity for radiotherapy to overcome primary resistance to immune checkpoint inhibition.

#1185 Novel association of an autoimmune-related axis and anti-CTLA-4-based toxicities in adjuvant immunotherapy-treated melanoma patients.

K. R. Monson[1], R. Ferguson[1], J. Handzlik[1], J. Xiong[1], S. Dagayev[1], L. Morales[1], V. Chat[1], A. Bunis[1], C. Sreenivasaiah[1], S. Dolfi[2], D. Tenney[2], I. Osman[1], J. Weber[1], T. Kirchhoff[1],

Intro: Immune checkpoint inhibition (ICI) for metastatic unresectable melanoma has markedly improved survival, and has shown benefit as adjuvant (AT) and neoadjuvant (NAT) therapy. Although ICI treatments confer survival benefit, they frequently induce immune-related adverse events (irAEs), which are a substantial clinical problem, particularly in AT/NAT, where ICI is used in less advanced disease to prevent recurrence. As such, the biomarkers predicting irAE risk, in particular in AT/NAT, are urgently needed to improve patient outcomes.

Methods: We assessed RNA from pre-treatment peripheral CD4+ and CD8+ T cells from adjuvant clinical trial patients (CheckMate-915; n=212 patients) treated with Nivolumab (n=130) or Ipilimumab/Nivolumab (Combo) (n=82). We performed RNA-seq differential expression analysis to identify baseline differences in the immune profiles of patients with no/mild toxicity (grade 0-2) versus severe toxicity (grade 3-5).

Results: Gene ontology analysis of the differentially expressed genes (DEGs) among those with severe toxicity reveals significant enrichment of immune-related pathways (IL-2, IFN-gamma, T-cell receptors, Toll-like receptors). These are shared among cell types (CD4+/CD8+) and between treatments (Nivo/Combo). From predicted DEG protein-protein interactions, we identified a treatment- and cell-type-specific expression signature associated with irAE development in CD4+ cells from Combo-treated patients. This signature, involving genes in the spleen tyrosine kinase (SYK) pathway, correctly predicts severe irAE patients with 73% accuracy (chi-squared p-value=0.001). The signature also identifies patients with mild to moderate irAEs in organ systems previously found in autoimmune traits to be associated with SYK upregulation (including skin, GI, liver, and pancreas), with 96% of all predicted patients experiencing at least one of these SYK-related toxicities, and 79% experiencing two or more. Importantly, the signature is not associated with disease recurrence (p=0.79).

Conclusions: We have identified baseline expression differences in key immune pathways in peripheral T cells from ICI-treated patients with severe irAEs, and defined an SYK-related gene signature correctly identifying over half of severe irAE patients in the Combo-treated cohort. This finding aligns with our previous work linking anti-CTLA-4 irAEs with a germline variant associated with high SYK expression. This gene signature may not only serve as a baseline biomarker of severe irAEs, but it may also help guide treatment decisions, reducing toxicity while retaining efficacy, which will be particularly important in the adjuvant setting.

#1186 Moving beyond conventional autoimmune thyroiditis autoantibodies to predict immune checkpoint inhibitor induced hypothyroidism.

K. Blenman[1], O. Blaha[1], C. Gibson[1], S. Qiu[1], H. Rushmeier[1], M. Ibrahim[2], S. Qiu[2], M. Krosgsgaard[2], I. Osman[2];
[1]Yale University, New Haven, CT, [2]NYU Langone Health, New York, NY

INTRODUCTION
Treatment emergent adverse events (TEAEs) thyroiditis/thyrotoxicosis and hypothyroidism occur in up to 40% of patients treated with immune checkpoint inhibitors (ICIs). Conventional autoimmune thyroiditis autoantibodies (AutoAbs) (thyroglobulin (TG); thyroid peroxidase (TPO)) do not predict these TEAEs. We previously reported that pretreatment serum AutoAb profiles were associated with all severe TEAEs for melanoma patients treated with ICIs. Herein, we test if pre-existing AutoAbs could predict ICI induced hypothyroidism (TEAE ThyDis).
METHODS
NYU Melanoma Program patients with stage IV metastatic melanoma treated with ICIs (Ipilumumab, Pembrolizumab, Nivolumab, or Combination) who had TEAE ThyDis (N = 14) or No TEAE (N = 11) were included. The HuProt™ human proteome microarray was used to profile proteins on cell surfaces or preferentially in extracellular spaces (N = 1061) in pretreatment and posttreatment (within ~4 months of ICI start) serum. Wilcoxon Rank Sum test was used to determine statistical significance ($p < 0.05$).
RESULTS
17 pretreatment pre-existing AutoAbs were detected (**Table**). All were higher in patients with TEAE ThyDis versus those with No TEAE. The pre-existing AutoAbs impacted immune cells (41%), extracellular matrix (ECM) (65%), or both (24%). P3H4 ($p = 0.01$) and ABCA2 ($p = 0.01$) were the only pre-existing AutoAbs that were statistically different posttreatment and were >10x higher in patients with TEAE ThyDis. They are both associated with intracellular vesicles but can be found in plasma membranes and extracellular spaces. No pre-existing AutoAbs were higher in patients with No TEAE ThyDis compared to those with TEAE ThyDis. However, posttreatment there was an increase in CSF1 AutoAbs that were not pre-existing ($p = 0.05$).
CONCLUSIONS
Our data suggest that serum AutoAbs beyond TG and TPO can predict ICI TEAE ThyDis. Larger studies in other cancers (e.g., Breast) are required to validate these results.

Pretreatment VS Posttreatment

#1187 Sensitization to chemo-immunotherapy by targeting TGF-β in preclinical triple negative breast cancer models.

Laura Kalfeist[1], Fanny Ledys[1], Stacy Petit[1], Samia Kada-Mohammed[1], Mickael Rialland[2], Francois Ghiringhelli[1], Emeric Limagne[1], Sylvain Ladoire[1]

[1]Centre Georges-Francois Leclerc, Dijon, France, [2]U1231 INSERM University of Burgundy, Dijon, France

Metastatic triple-negative breast cancer (mTNBC) is refractory to anti-PD-(L)1 immunotherapy. In order to sensitize it, preclinical data show the value of adding chemotherapy treatment for its ability to induce immunogenic cancer cell death (Kroemer et al, 2013). This would enable the recruitment of cytotoxic T-CD8^{+} lymphocytes (CTL) and thus initiate an antitumor immune response to sensitize tumors to immunotherapy. Nevertheless, the results of clinical trials using chemo-immunotherapy combinations are divergent (IMpassion 130 and 131). The IMpassion 130 trial demonstrated the efficacy of nab-paclitaxel and atezolizumab (anti-PD-L1) in PD-L1^{+} patients, but unfortunately, IMpassion 131 with paclitaxel did not replicate these results. The choice of chemotherapy to combine with immunotherapy appears to be crucial for inducing an antitumor immune response. Optimizing chemo-immunotherapy combinations is a major challenge in the management of TNBC.

The initial aim of this project was to evaluate the immune effects of an experimental chemotherapy doublet, based on two drugs used in mTNBC: cisplatin (CDDP) and eribulin. The idea was to find an alternative to the use of taxanes in combination with anti-PD-(L)1.The effect of the two molecules, alone or in combination, was evaluated on immunogenic death stigmata, modulation of effector or immunosuppressive immune populations and stromal populations, and sensitization to anti-PD-L1 immunotherapy in the immunologically "cold" model: 4T1. The *in vivo* studies has been realized by generation of orthotopic 4T1 tumors, the analysis of the immune infiltration was performed by RT-qPCR, IHC and flow cytometry.

In vitro, our results indicate that CDDP, and more intensely in combination with eribulin, significantly induces the various immunogenic death stigmas. *In vivo,* the therapeutic effect of chemotherapies is limited, with a superior effect of CDDP and the combination. Nevertheless, CTL recruitment and functionality induced by CDDP are significantly enhanced by eribulin. Despite these data pointing to a potential therapeutic synergy with anti PD-L1 immunotherapy, chemo-immunotherapy treatment fails to induce a superior treatment effect. The significant increase in a TGF-β signature induced by the combination in parallel with CTL recruitment explains this resistance. The results show that inhibition of TGF-β, combined with chemo-immunotherapy in the 4T1 model, leads to a reduction in tumor immunosuppression and intratumoral fibrosis, as well as an increase in CTL infiltration and cytotoxicity, enabling tumor sensitization.

Overall, this project highlights the benefits of using an experimental doublet of CDDP and eribulin-based chemotherapies. This project demonstrates that management of chemo-induced immunosuppression mechanisms is necessary to overcome tumor resistance to immunotherapy.

#1188 Identification of CXCL10-inducing chemotherapy/targeted therapy combinations for PD-1 blockade sensitization in “cold” triple negative breast cancer.

L. Kalfeist[1], S. Petit[1], L. Galland[1], C. Poirrier[1], R. Aucagne[2], F. Ghiringhelli[1], S. Ladoire[1], E. Limagne[1];
[1]Centre Georges-Francois Leclerc, Dijon, France, [2]University Hospital Francois Mitterand, Dijon, France

Metastatic triple-negative breast cancer (mTNBC) currently has the poorest prognosis among subtypes, with limited treatment options due to molecular characteristics that render conventional targeted therapies ineffective. Immunotherapy, specifically anti-PD-(L)1 (ICIs), has revolutionized certain cancer treatments, but its efficacy in mTNBC has been disappointing. To enhance tumor responses to ICIs, combining them with immunogenic chemotherapy has been explored. Studies like IMpassion130 and KEYNOTE 522 indicate benefits of chemo-immunotherapy based on taxanes, especially in PD-L1^{+} tumors. PD-L1 expression often correlates with TILs infiltration, particularly cytotoxic T lymphocytes (CTLs), indicating an activated immune response in the tumor. However, tumors with poor CTL infiltration, known as "Cold" phenotype, are often associated with a lack of induction of CXCR3-associated chemokines (CXCL9, 10, and 11), crucial for CTLs recruitment in the tumor microenvironment. The limited efficacy of chemo-immunotherapy in PD-L1-negative tumors may stem from chemotherapy's inability to induce immunogenic cancer cell death, CXCR3-associated chemokines, and CTL recruitment. Internal data from a 4T1 TNBC murine model demonstrated that the taxane paclitaxel failed to induce CXCL10, CTL recruitment, and sensitization to PD-L1 blockade. The preclinical research project aimed to identify a combination therapy, inspired by current clinical practices, capable of inducing CXCL10 expression and restoring CTL recruitment in the 4T1 "cold" mTNBC model. We initially screened standard TNBC chemotherapies and selected carboplatin for its *in vitro* potential to induce CXCL10 production and its clinical use in association with ICIs in the TNBC. Combining carboplatin with a library of over 400 targeted therapies, we identified histone deacetylase (HDAC) inhibitors as significantly enhancing CXCL10 secretion. *In vivo*, this combination demonstrated therapeutic additivity, increasing immune recruitment, particularly CD8+ T lymphocytes, with the therapeutic effect reduced by CXCR3 blockade. Mechanistic exploration in vitro revealed that the combination activated the type I interferon pathway, inducing CXCL10 secretion. *In vivo* confirmation validated the role of the type I interferon pathway and CXCL10 in the combination's efficacy. This data outlines a chemotherapy and HDAC inhibitor combination capable of inducing CTL recruitment via increased CXCL10 production. Future project phases will focus on understanding HDACi's mechanism of action on CXCL10 production and the combination's potential to sensitize tumors to ICIs. Overall, this project underscores the role of epigenetic modifications in amplifying carboplatin-induced CXCL10 secretion, potentially converting "cold" ICI-resistant tumors into a "hot" phenotype.

#1189 Modulation of the MSS and MSI colorectal cancer immune microenvironment with FOLFOX and FOLFIRI -/+ anti-PD-1 immunotherapy.

L. Carlsen, **M. Pinho-Schwermann**, L. Zhang, A. Elliott, K. E. Huntington, W. J. MacDonald, B. Verschleiser, L. Jinxuan Wu, W. S. El-Deiry;
Brown University, Providence, RI

Metastatic colorectal cancer (mCRC) is a deadly disease with a five-year survival rate of 14%. Most patients receive 5-FU (F) and folinic acid (FOL) combined with oxaliplatin (OX), irinotecan (IRI), or both (OXIRI). Immune checkpoint inhibitors (ICIs) are effective against microsatellite instable (MSI) tumors, but 95% of mCRC tumors are microsatellite stable (MSS) and ICI-resistant. Though the primary targets of 5-FU, irinotecan, and oxaliplatin are well-understood, their effects on the tumor microenvironment (TME) remain incompletely characterized. Chemotherapy-mediated immune stimulation in MSS CRC has been observed in preclinical models and clinical trials. We hypothesize that combination chemotherapy treatment modulates the immune microenvironment of CRC -/+ ICI, with differences across subtype and treatment regimen. Chemotherapy-dependent changes in cancer cell gene expression, PD-L1 levels, cytokine secretion, and T cell activation were measured using *in vitro* models of MSS and MSI CRC. A preliminary evaluation of spleen and tumor T cells and dendritic cells (DCs) in murine models of MSS and MSI CRC after immunotherapy -/+ chemotherapy was conducted. CD8+ T cells, DCs, PD-L1, CD69, and GM-CSF expression were measured in clinical specimens of chemotherapy-treated MSS mCRC patients. In MSS CRC, FOX increased GM-CSF and activated CD8+ T cells *in vitro* and activated splenic CD8+ and CD4+ T cells *in vivo*. FOX and FIRI suppressed an anti-PD-1-mediated enhancement of type 1 cDCs in the tumor *in vivo*. FOLFOX was associated with increased tumor CD8+ T cells and decreased GM-CSF in MSS mCRC biopsies. FIRI treatment increased PD-L1 *in vitro*. FOLFIRI was not associated with increased tumor CD8+ T cells in MSS mCRC biopsies. In MSI CRC, FOX increased tumor CD8+ T cells *in vivo*. Here, we elucidate novel effects of clinically relevant chemotherapy combinations on the TME in MSS and MSI CRC. These data point to a FOX-specific mechanism by which CD8+ T cell infiltration into MSS mCRC tumors is enhanced, but their activation is halted potentially by GM-CSF suppression and/or type 1 cDC depletion in the TME. These findings contribute to our understanding of the mechanisms of chemotherapy-dependent immune modulation and bring the field closer to harnessing these effects for therapeutic gain.

#1190 NK cell subsets as potential correlates of antitumor immunity in HPV+ cancers.

M. O'Hara, J. Sastry;
The University of Texas MD Anderson Cancer Center, Houston, TX

High-risk type human papillomaviruses (HPV) are associated with genital and oral cancers, and the incidence of head and neck squamous cell cancers is fast increasing in the USA and worldwide. Survival rates for patients with locally advanced disease are poor and variable after standard of care (SOC) chemoradiation treatment (CRT). Identifying the antitumor host immune mediators important for treatment response and designing strategies to promote them are essential for improving clinical outcome. Antitumor immunity comprises of adaptive and innate immune effectors. The immediate innate immune response by natural killer (NK) cells is a critical component for antitumor efficacy. The effector function of NK cells is modulated by various receptors via a wide array of activation or inhibitory signals. Among these receptors is HLA-DR, a recognized activation marker on CD8 T and NK cells. Literature studies refer to HLA-DR+ NK cells as pre-mNK. Preclinical data demonstrated therapeutic vaccine mediated induction of pre-mNK equivalent to contribute to tumor-free long-term survival. In our studies with clinical samples from HPV+ cancer patients, we've observed a dysfunctional phenotype of circulating pre-mNK when compared to healthy donors, demonstrated by flow cytometry methods. The correlates for dysfunction include increased PD-1 expression, a known inhibitory receptor, and reduced CD16, an NK receptor for Antibody Dependent Cellular Cytotoxicity (ADCC). Further, we observed circulating pre-mNK cells in HPV+ head and neck patients gain functionality post-treatment, as shown by significant increases in granzyme B and CD16, both known contributors for NK cytotoxicity. In cervical cancer patients, we had the opportunity to analyze the tumor microenvironment (TME). Interestingly, we found a significant increased frequency of cytotoxic pre-mNK cells, shown by granzyme B, in the TME that was not present in circulation. Overall, pre-mNK represent a uniquely activated immune subset for antiviral and antitumor immunity.

#1191 Personalized neoantigen DNA vaccine GNOS-PV02 and pembrolizumab as second-line treatment for advanced hepatocellular carcinoma.

M. Yarchoan[1], E. J. Gane[2], T. U. Marron[3], R. Perales-Linares[4], J. Yan[4], N. Cooch[4], D. Shu[1], E. J. Fertig[1], L. T. Kagohara[1], G. Bartha[5], J. Northcott[5], J. Lyle[5], S. Rochestie[4], J. Peters[4], J. Connor[6], E. Jaffee[1], A. Perales-Puchalt[4], D. B. Weiner[7], I. Csiki[4], N. Y. Sardesai[4];

[1]Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins University School of Medicine, Baltimore, MD, [2]University of Auckland, Auckland, New Zealand, [3]Icahn School of Medicine at Mount Sinai, New York, NY, USA, New York, NY, [4]Geneos Therapeutics, Philadelphia, PA, [5]Personalis, Inc., Fremont, CA, [6]Confluence Stat, LLC, Cooper City, FL, [7]The Wistar Institute, Philadelphia, PA

Background: PD-1 inhibitors have modest efficacy as monotherapy in hepatocellular carcinoma (HCC). A personalized therapeutic cancer vaccine (PTCV) tailored against neoantigens identified in an individual's tumor may enhance responses to PD-1 inhibitors through the induction of tumor-specific immunity. Here, we present results from a single-arm Phase Ib/2a trial evaluating a DNA plasmid (GNOS-PV02) encoding up to 40 neoantigens co-administered with plasmid-encoded IL-12 (pIL12) in combination with pembrolizumab (PEMBRO) in patients (pts) with advanced HCC.**Methods**: Pts were eligible for study therapy upon progression or intolerance with a 1L tyrosine kinase inhibitor (TKI). The PTCV [GNOS-PV02 (1mg) and pIL12 (0.34mg)] was administered intradermally via in vivo electroporation Q3w x 4 doses, and Q9w thereafter. PEMBRO was administered at 200mg IV Q3w. The primary endpoints were safety and immunogenicity. To evaluate the secondary endpoint of ORR per RECIST 1.1 by investigator review with a null hypothesis of an ORR of 16.9% (KN-240, *Finn et al ASCO 2019*), 36 pts were included to provide 80% power to reject the null hypothesis at the one-sided 0.10 level, assuming the true ORR rate of 33.1%. The data cut date was August 18, 2023.**Results**: Among the 36 enrolled pts who received at least one dose of treatment, there were no DLTs or treatment-related grade ≥3 events. The most common treatment-related adverse events were injection site reactions, observed in 41.6% of pts. ORR (mITT) per RECIST 1.1 was 30.6% (11/36; 9 confirmed and 2 unconfirmed) with 8.3% (3/36) of pts achieving a CR. This achieved statistical significance with a one-sided p-value = 0.031 (1-sided 90% CI 20.4%-100%) The mOS was 19.9 months. ctDNA changes correlated with radiographic responses and preceded them. A complete molecular response (100% ctDNA clearance) was detected in 7 pts including the 3 radiographic CRs, and 4 additional pts who continue to show durable tumor control (3PR, 1 SD). Immunological analyses confirmed the induction of neoantigen-specific T cell responses by IFNγ-ELISpot in 19/22 (86.4%) evaluable pts, and pts with a larger ELISpot response showed a trend towards longer OS. Multi-parametric cellular profiling and single-cell analysis revealed active, proliferative, and cytolytic vaccine-specific CD4+ and CD8+ effector T cells in the blood of immunized pts. In 14/14 (100%) of pts with paired pre- and on-treatment blood and tumor biopsies, we identified by TCRβ bulk sequencing expanded T cell clones in the peripheral blood that also trafficked into the tumor. **Conclusions**: Our results show that a PTCV plus PEMBRO is well tolerated and has clinical activity in pts with advanced HCC, and support the PTCV mechanism of action based on the induction of anti-tumor T cells in peripheral blood and tumor. A confirmatory phase 3 clinical study assessing OS is planned.

#1192 Diversity of TCR repertoire on peripheral CD8$^{\pm}$PD-1$^{\pm}$ T-cell predicting the PFS of chemoradiotherapy followed by durvalumab maintenance in unresectable locally advanced NSCLC patients..

M. Shirasawa[1], T. Yoshida[1], Y. Takeyasu[2], T. Matsutani[3], S. Yagishita[4], S. Kitano[5], H. Kuroda[6], T. Hida[6], T. Kurata[2], Y. Ohe[1];

[1]National Cancer Center Hospital, Tokyo, Japan, [2]Kansai Medical University Hospital, Hirakata, Japan, [3]Repertoire Genesis, Inc., Osaka, Japan, [4]National Cancer Center Research Institute, Tokyo, Japan, [5]The Cancer Institute Hospital of JFCR, Tokyo, Japan, [6]Aichi Cancer Center Hospital, Nagoya, Japan

Background: Chemoradiotherapy (CRT) followed by Durvalumab consolidation has been the standard treatment for unresectable locally advanced non-small cell lung cancer (LA-NSCLC) patients. This study aimed to evaluate how CRT changes TCR repertoire on peripheral CD8$^{\pm}$PD-1$^{\pm}$ T-cells, and the change affects the clinical outcomes of CRT followed by durvalumab treatment.

Methods: This was a prospective cohort study conducted from November 2019 to May 2021 in three institutes (National Cancer Center Hospital, Kansai Medical University Hospital, and Aichi Cancer Center Hospital) in Japan. We revealed the diversity of TCR repertoire (diversity evenness 50 [DE50]) on PD-1$^{\pm}$CD8$^{\pm}$ T cells, and CD8$^{\pm}$ T cell phenotype in PBMCs before and after CRT treatment.

Results: A total of 40 patients treated with CRT were included. Of these patients, 32 patients received durvalumab consolidation treatment after CRT (Durva cohort). The diversity and usage of T cell Receptor Beta Variable (TRBV) and T-cell receptor beta joining gene (TRBJ) usage were significantly positively correlated before and after CRT (TRBV usage: r=0.62, p<0.001, TRBJ usage: r=0.55, p<0.001). Regarding the association of TCR repertoire diversity with CD8$^{\pm}$ T cell phenotype, DE50 and frequencies of CD8 naive were significantly positively correlated before CRT (p=0.049), while there was no correlation between PD-L1 expression and TCR repertoire before CRT (r=0.03, p=0.89) In Durva cohort, DE50 in patients with non-recurrence was higher than those with recurrence both before and after CRT (Before CRT: 0.0032 vs. 0.0019, p=0.13, After CRT: 0.0026 vs. 0.0014, p=0.06). The progression-free survival (PFS) of patients with $DE50_{High}$ before CRT was significantly greater than those with $DE50_{Low}$ (NR vs. 14.3 months; p=0.01). Moreover, when the patients were exploratory classified based on the PD-L1 expression status and the diversity of TCR repertoire, the PFS of the CRT followed by durvalumab apparently differed ($DE50_{High}$, PD-L1 TPS≥1%, NR, and $DE50_{Low}$, PD-L1 TPS<1%, 5.9 (4.6-7.3) months, p=0.001).

Conclusions: TCR diversity of peripheral CD8$^{\pm}$PD-1$^{\pm}$ T-cell predicted the recurrence in unresectable locally advanced NSCLC patients treated with chemoradiotherapy followed by durvalumab maintenance. Additionally, the TCR diversity combined with PD-L1 expression status could more accurately predict the efficacy of the CRT followed by durvalumab.

#1193 Peripheral immune analyses from phase I trial of HPV vaccine PRGN-2009 in combination with bintrafusp alfa in patients with HPV-associated cancers.

M. Goswami[1], C. S. Floudas[1], J. Strauss[1], D. E. Brough[2], A. R. Lankford[2], C. Jochems[1], J. L. Gulley[1], J. Schlom[1], R. N. Donahue[1];
[1]National Cancer Institute (NCI), Bethesda, MD, [2]Precigen Inc., Germantown, MD

Background: PRGN-2009 is a novel gorilla adenovirus vaccine targeting HPV16/18, and bintrafusp alfa (BA) is a bifunctional anti-PD-L1/TGFβ fusion protein. Patients with pretreated advanced HPV-associated malignancies received PRGN-2009 vaccine ($5x10^{11}$ particle units, subcutaneous administration) q2 weeks for 3 administrations and biweekly 1200mg BA followed by q4 weeks vaccine and biweekly BA (NCT04432597), with an overall response rate of 30%. We report here correlative analyses from this first-in-human Phase I study using peripheral blood from 10 patients with HPV16+ (n=8), HPV18+ (n=1), or HPV45+ (n=1) disease to identify immune correlates associated with clinical response.

Methods: Peripheral HPV-specific T cell responses, HPV circulating tumor DNA (ctDNA) from plasma, serum cytokines and soluble factors, and peripheral immune cell subsets were assessed to evaluate changes induced with treatment and peripheral correlates associated with clinical activity. Patients with complete response (CR, n=1), partial response (PR, n=2; 1 confirmed) or stable disease (SD, n=1) (n=4 total) were compared to patients with progressive disease (PD, n=6).

Results: Eighty percent (8/10) of patients developed either HPV16 or HPV18-specific T-cell responses after repeat administration of PRGN-2009 with BA. Eight of 10 patients had detectable HPV16 or 18 ctDNA at baseline and changes in ctDNA load with treatment generally correlated with outcomes. Early transient increases in IL-8, TNFα, and IFNγ occurred, with greater increases in IL-8 at 2 weeks and TNFα at 4 weeks in patients with PD compared to CR/PR/SD. The patient who achieved a durable CR had HPV45+ disease, and had a) a 50% increase in CD8+ T cell frequency at 2 weeks, b) increases in frequencies of CD8+ naïve T cells expressing Ki67+ and central and effector memory T cells expressing 4-1BB, PD-1, or TIM-3, and c) considerable increases in HPV18-specific T cell responses through 484 days after treatment start, indicating durable antigen-specific T cell activity.

Conclusions: The majority of patients developed HPV16/18 specific T-cell responses after repeat administration of PRGN-2009 in combination with BA. Transient increases in IL-8 and TNFα 2-4 weeks after start of treatment were associated with worse outcomes, suggesting that early changes in cytokines may reflect disease course. Furthermore, the early expansion of CD8+ T cell subsets in the patient developing a CR with HPV45+ disease after receiving a vaccine targeting HPV16 and HPV18 epitopes suggest a broadening and boosting of T cell responses that enabled potent anti-tumor activity. A high degree of homology between HPV18 and HPV45 may have contributed to the expansion of HPV18 specific T cells in the patient with CR. These data highlight the importance of assessing peripheral blood in immunotherapy trials to reveal important immunological phenomena.

#1194 Understanding radiation and immunotherapy induced cell state shifts in the pancreatic tumor microenvironment.

M. Parikh[1], R. Park[1], A. R. Parikh[2], J. L. Koenig[2], L. Pappas[2], M. Sade-Feldman[1], L. Bi[3], N. Carzo[2], T. M. Grillo[2], I. Baiev[2], O. Asupoto[4], I. Gushterova[2], T. LaSalle[2], A. Gonye[2], E. Blaum[2], D. P. Ryan[2], D. T. Ting[2], T. S. Hong[2], D. Pe'er[5], N. Hacohen[2], A. Mehta[1];

[1]Broad Institute of MIT and Harvard, Cambridge, MA, [2]Massachusetts General Hospital, Boston, MA, [3]Harvard Medical School, Boston, MA, [4]Boston Medical Center, Boston, MA, [5]Sloan Kettering Institute, New York, NY

Pancreatic ductal adenocarcinoma (PDAC) is a lethal disease with few effective treatment options. It is characterized by a highly desmoplastic tumor microenvironment and a paucity of dendritic cells, leading to low immune cell infiltration and poor outcomes with immunotherapy treatments that are highly effective in other cancers. In a recent pilot study, metastatic PDAC patients who had progressed on chemotherapy were treated with a combination of dual immune checkpoint blockade (ICB) therapy and radiation which resulted in an 18% overall response rate (ORR) and 29% disease control rate (DCR). This led to a phase 2 study in order to further test this combination with the goal of deep correlative analysis to understand the determinants of immunotherapy response and resistance. In this follow up there was a 3.6% ORR, 10.7% DCR, progression free survival (PFS) of 2.3 months, and a single patient with complete response. We collected 36 samples from 23 patients including primary pancreas tumor tissue and liver metastases, and 13 pairs of pre and on treatment biopsies. We performed single-nucleus and paired single-cell RNA and TCR sequencing on these samples to provide comprehensive insight into the cell types and biology present in this unique tumor microenvironment. Using supervised non-negative matrix factorization we have identified both previously established and novel gene programs that co-vary between cell types. Within the various tissue sites we have identified differing proportions of basal to classical tumor cell types and a distinct shift towards the classical state post-radiation. Of particular interest is a group of interferon related gene programs present within epithelial cell subtypes, C1QC+ and MHCII+ macrophages, and CD14+/CD16+ monocytes that indicate cell type specific responses to treatment. Focusing on the T cells, we found a distinct shift towards exhausted or proliferating states on treatment and using TCR sequencing data we have identified novel and expanding clones on treatment, largely consisting of those same cell subtypes. We also collected spatial transcriptomics data on a subset of patient samples, and analysis is ongoing to further confirm the cell type relationships identified in single-cell resolution data, along with spatial localization of basal to classical tumor states. This vast multimodal dataset allows us novel insight into the radiation and dual ICB induced cellular state shifts in the tumor microenvironment.

#1195 Prospective study for the identification of nivolumab biomarkers via analyses of pre-treatment plasma exosome mRNAs from head and neck cancer patients (BIONEXT).

M. Masuda[1], S. Toh[1], M. Matsuo[2], M. Sugasawa[3], K. Yamazaki[4], U. Yushi[5], T. Nakashima[6], H. Uryu[6], T. Ono[7], T. Ueda[8], H. Umeno[7], S. Kano[9], K. Tsukahara[10];

[1]National Kyushu Cancer Center, Fukuoka, Japan, [2]Graduate School of Medical Science, Kyushu University, Fukuoka, Japan, [3]International Medical Center, Saitama Medical University, Hidaka, Japan, [4]NiNigata University Graduate School of Medical and Dental Sciences, Niigata, Japan, [5]Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan, [6]National Hospital Organization Kyushu Medical Center, Fukuoka, Japan, [7]Kurume University School of Medicine, Kurume, Japan, [8]Graduate School of Biomedical and Health Sciences Hiroshima University, Hiroshima, Japan, [9]Faculty of Medicine and Graduate School of Medicine, Hokkaido University, Fukuoka, Japan, [10]Tokyo Medical University, Tokyo, Japan

Nivolumab paved a new way in the treatment of recurrent or metastatic (RM) head and neck squamous cell carcinoma of (HNSCC). However, the limited rates of long-term survivors (< 20%) demand a robust prognostic biomarker. This nationwide multi-centric prospective study aimed to identify a plasma exosome (PEX) mRNA signature, which serves as a companion diagnostic of nivolumab and as well provides a biological clue to develop effective therapies for a majority of non-survivors. Pre-treatment plasmas (*N* = 104) were subjected to comprehensive PEX mRNA analyses for prognostic marker discovery and validation. In parallel, paired treatment naïve tumor and plasma samples (*N* = 20) were assayed to elucidate biological implications of the PEX mRNA signature. A combination of 6 candidate PEX mRNAs plus neutrophil-to-lymphocyte ratio precisely (*P* = 0.000124) distinguished non-survivors from >2-yr survivor (0% vs 57.7%) with a high hazard ratio (2.878; 95% confidence interval 1.639-5.055; *P* = 0.0002348). In paired samples, high PEX *HLA-E* mRNA (a non-survivor-predicting marker) reflected the increased HLA-E protein expression (*P* = 0.0191) and the dense population of tumor-infiltrating NK cells (*P* = 0.024) in the corresponding tumor. It is estimated that the effects of PD-1blockade is canceled by the HLA-E-NKG2A immune checkpoint in patients with high PEX *HLA-E* mRNA. The combination of NKG2A antibody (i.e., monalizumab) and nivolumab may be a promising strategy for non-survivors predicted by a RT-qPCR-based pre-treatment measurement of PEX mRNAs. A candidate companion diagnostic of nivolumab that indicates a possible treatment option is identified.

#1196 Peripheral immune analyses correlate with clinical outcome: A phase II trial of nivolumab, capecitabine, or the combination in patients with triple negative breast cancer.

N. J. Toney[1], F. Lynce[2], C. Mainor[3], C. Isaacs[4], J. Schlom[1], R. N. Donahue[1];
[1]National Cancer Institute, Bethesda, MD, [2]Dana-Farber Institute, Boston, MA, [3]MedStar Georgetown University Hospital, Boston, MA, [4]Georgetown University, Bethesda, MD

Introduction: Patients with triple negative breast cancer (TNBC) with residual disease after neoadjuvant chemotherapy have a higher risk of recurrence and worse outcomes than patients achieving pathologic complete response. Here, we report on immune correlates from the OXEL study (NCT03487666), an open label randomized phase II trial in TNBC patients with residual disease following neoadjuvant chemotherapy, who were treated with post-neoadjuvant nivolumab (360 mg intravenously every 3 weeks, Arm A), capecitabine (1,250 mg/m^2 orally twice daily on days 1-14 of each 3-week cycle, Arm B), or the combination of nivolumab and capecitabine (Arm C). The primary endpoint was to assess the immunologic effects of nivolumab, capecitabine, or the combination.
Methods: Peripheral blood mononuclear cells were evaluated at baseline and after 6 and 12 weeks of therapy in patients from Arm A (n=15), B (n=14), and C (n=13) by flow cytometry to identify 158 immune cell subsets. Peripheral immunoscores reflective of enhanced immune cell function were calculated to evaluate changes in the immune profile induced by each therapy, and the association between the immune profile at baseline and disease recurrence.
Results: At 6 weeks versus baseline, an increase in immune cell function was seen in patients on Arms A+C compared to Arm B. Additional distinct immune subsets showed statistical changes after 6 and 12 weeks of therapy that were specific to each arm. At baseline, a higher peripheral immunoscore was associated with a lack of eventual disease recurrence in patients on Arm A or Arms A+C, but not for patients on Arm B. Patients on Arm A (p=0.0003) or Arms A+C (p=0.0085) with a peripheral immunoscore above the median also had a longer interval of disease-free survival than patients at or below the median; this association was not seen in Arm B. Distinct immune subsets at baseline also associated with development of recurrence in each arm; higher levels of naïve CD8$^+$ T cells and HLA-DR$^+$ Tregs and lower levels of NKp30$^+$ NK and PD1$^+$ NKT cells associated with recurrence in Arm A, while in Arm B, greater levels of intermediate and nonclassical monocytes associated with recurrence. In Arm C, higher frequencies of multiple Treg subsets were associated with recurrence.
Conclusions: Patients receiving nivolumab, with or without capecitabine, showed enhanced immune cell function. A peripheral immunoscore based on the immune profile at baseline was associated with disease recurrence only in patients receiving immunotherapy. These data highlight the importance of assessing peripheral blood to reveal important immunologic phenomenon and potential associations with clinical outcome.

#1200 A novel algorithm for deconvolving cancer allele-specific clone copy number and copy number evolution.

P. Pawlik[1], K. K. Grigoriadis[2], A. Bunkum[1], S. Zaccaria[1], N. McGranahan[1], C. Swanton[2];
[1]University College London (UCL) Cancer Institute, London, United Kingdom, [2]The Francis Crick Institute, London, United Kingdom

Both single nucleotide variants (SNVs) and somatic copy number alterations (SCNAs) accumulate in cancer cells during tumor development, fuelling clonal evolution. However, accurate inference of their coevolution from bulk DNA sequencing is challenging. We present ALPACA (ALlele-specific Phylogenetic Analysis of clone Copy number Alterations), a novel algorithm to allow the practical inference of SNV and SCNA coevolution. ALPACA is framed as an optimisation problem, that takes as input bulk tumor sample copy number mixtures and the tumor phylogenetic tree constructed from SNVs, and deconvolves the optimal, allele-specific integer copy number profiles for every distinct clone present in the tumor. To circumvent the challenge of joint SNV/SCNA inference, we postulate that in high mutation burden tumors all relevant SCNA clones are identifiable by their unique SNVs, hence ALPACA leverages phylogenetic trees constructed from bulk tumor sequencing data using SNVs. Secondly, to restrict the clone-specific copy number search space, ALPACA leverages constraints imposed by multisample sequencing, specifically in cases where clones are present across multiple samples or clones from different samples are phylogenetically related. Finally, ALPACA relies on parsimony and biologically informed constraints to further guide the deconvolution process.
We demonstrate that ALPACA infers the copy number evolution of complex simulated tumors with higher accuracy than current state-of-the-art methods. We apply ALPACA to the large, multisample non-small cell lung cancer (NSCLC) cohort from the recent longitudinal, prospective TRACERx421 study, and show that ALPACA uncovers loss of heterozygosity and amplification events in minor subclones that were previously missed using standard approaches. ALPACA's assignment of SCNA driver events to branches of the phylogenetic tree reveals the evolutionary ordering of SNVs and SCNAs during NSCLC tumor evolution, such as late focal amplifications affecting the TERT gene locus occurring in subclones which expand and dominate a tumor sample. ALPACA enables an in-depth analysis of the coevolution of mutations and SCNAs in the tumor's evolutionary history, revealing distinct patterns of copy number evolution. Notably, ALPACA identifies common patterns of copy number changes across the genome characterizing metastatic seeding clones, revealing that they harbor an increased number of SCNAs compared to clones that do not metastasize. Additionally, ALPACA uncovers subclonal enrichment for CCND1 amplification in primary tumor subclones that seed metastasis, and an overall increase of SCNA events occurring in both tumors with polyclonal seeding and extrathoracic metastases.
Clone-level results obtained with ALPACA can offer new clinical insights and enable new types of analysis, e.g. copy number signature analysis including temporal order of SCNA acquisition.

#1201 Pervasive HLA disruption fuels cancer evolution.

C. Puttick[1], T. P. Jones[2], M. Leung[2], O. Pich[1], F. Galvez Cancino[2], J. Liu[2], M. Varas-Godoy[2], A. Rowan[1], C. Martinez-Ruiz[2], R. Bentham[2], K. K. Dijkstra[3], R. Rosenthal[4], N. Kanu[2], K. Litchfield[2], R. Salgado[5], D. A. Moore[1], P. Van Loo[6], M. Jamal-Hanjani[2], S. A. Quezada[2], N. McGranahan[2], C. Swanton[1];
[1]The Francis Crick Institute, London, United Kingdom, [2]University College London, London, United Kingdom, [3]Netherlands Cancer Institute, London, Netherlands, [4]Achilles Therapeutics, London, United Kingdom, [5]Peter MacCallum Cancer Centre, Melbourne, Australia, [6]MD Anderson Cancer Center, London, TX

Disruption of the human leukocyte antigen (HLA) molecules has important implications for immune evasion and tumor evolution. However, although genomic loss of HLA is frequent in non-small cell lung cancer (NSCLC) and in some types of breast cancer, the extent and importance of transcriptomic disruption to HLA presentation, including transcript repression and alternative splicing (AS), remains unclear. To address this, we developed MHC Hammer, a tool to call HLA allele-specific mutations, loss of heterozygosity (LOH), transcriptional repression, and alternative splicing.

We first assessed HLA allelic expression and the prevalence of AS in normal tissue. Applying MHC Hammer to 510 normal lung samples and 407 normal breast samples from the Genotype-Tissue Expression cohort, we identified extensive heterogeneity in HLA allelic expression depending on both the allele and tissue type. In addition, HLA allelic AS, occurring in at least 20% of the allele transcripts, was observed in 19% of normal lung and 13% of normal breast samples.

Next, we applied MHC Hammer to 413 TRACERx NSCLCs and 743 TCGA breast tumours. While mutations were uncommon, HLA LOH was a frequent event, occurring in 32% of lung adenocarcinomas (LUAD) and 57% of lung squamous cell carcinomas (LUSC). We observed a similar rate of HLA LOH in estrogen receptor positive (ER+) and negative (ER-) tumors (ER+: 14%, ER-: 15%), while in triple negative breast tumours we observed a higher rate of LOH (31%). Due to the heterogeneity in HLA expression observed in the normal samples, to measure tumor specific HLA repression and alternative splicing, we restricted our analysis to tumours with WES, tumor and tumor-adjacent normal RNAseq data. This resulted in a cohort of 88 NSCLCs from the TRACERx study as well as 44 ER+ breast tumours from the TCGA cohort. 61% of LUAD, 75% of LUSC and 35% of ER+ tumours harbored class I HLA transcriptional repression that could not be explained by underlying genomic loss. 27% of LUAD, 7% of LUSC and 55% of ER+ breast tumor patients exhibited no HLA disruption. Tumor specific AS affecting HLA exons 2, 3 or 4, potentially disrupting HLA antigen presentation, was identified in 8% of LUADs, 11% of LUSC and 7% of ER+ breast tumours. Tumor specific AS of exon 5, yielding soluble HLA molecules without a transmembrane domain was identified in 20% of LUAD, 14% of LUSCs and 18% of ER+ breast tumours.

LUAD and LUSC tumor regions without HLA LOH or repression were enriched for somatic HLA AS events and alleles with somatic HLA AS had a higher neoantigen burden than those without. We found no relationship between survival and HLA expression or AS in the normal tissue. However, consistent with the importance of HLA dysfunction in tumor evolution, LUADs with low HLA expression in at least one tumor region were associated with shorter disease-free survival, HLA LOH was more common in LUAD's that metastasized and HLA repression was enriched in LUSC primary regions seeding metastases.

#1202 Signatures of selection for biallelic inactivation in tumor suppressor genes across cancer types.

Mark R. Zucker[1], Maria A. Perry[2], Arielle Elkrief[2], Anton Safonov[2], Rohit Thummalapalli[2], Samuel I. Gould[3], Debyani Chakravarty[2], Rose Brannon[2], Marc Ladanyi[2], Pedram Razavi[2], Mark T. A. Donoghue[2], Yonina R. Murciano-Goroff[2], Francisco J. Sanchez-Rivera[3], Yuan Chen[2], Ronglai Shen[2], Sarat Chandarlapaty[2], David B. Solit[1], Nikolaus Schultz[2], Michael F. Berger[1], Adam J. [1]Epidemiology and Biostatistics, Memorial Sloan Kettering Cancer Center, New York City, NY, [2]Memorial Sloan Kettering Cancer Center, New York City, NY, [3]Massachusetts Institute of Technology, Cambridge, MA

Background: The canonical model of tumor suppressor gene (TSG)-mediated oncogenesis, Knudson's "two hit hypothesis," posits that loss of both alleles is necessary for TSG inactivation. Many key TSGs accordingly exhibit near universal biallelic loss in associated cancers (e.g., APC in colorectal cancer and RB1 in retinoblastoma). However, because the majority of large-scale cancer genomics studies have utilized non-allele-specific copy number analysis methods, neither the extent of biallelic inactivation across TSGs, nor patterns of selective pressure for biallelic inactivation of TSGs, nor the functional and translational consequences of biallelic inactivation, are well-understood.

Methods: Here, through allele-specific analysis of sequencing data from 48,179 cancer patients, we define the prevalence, selective pressure for, and functional consequences of biallelic inactivation across TSGs. We classify TSGs according to their patterns of selection for or against biallelic inactivation across cancer types. Finally, we investigate in detail the association of biallelic status with gene expression and clinical outcome for two TSGs, KEAP1 (in lung adenocarcinoma) and APC (in lung and prostate adenocarcinoma).

Results: TSGs largely assort into distinct classes associated with either pan-cancer (Class I) or lineage-specific (Class II) patterns of biallelic loss, while some TSGs, mostly transcription factors, were predominantly monoallelic (Class III/IV). We discover that gene expression and co-mutation patterns indicate selection for biallelic losses in noncanonical contexts, including *APC* in lung and prostate adenocarcinomas. Selection for biallelic inactivation is also significantly elevated among variants of unknown significance (VUS) of several TSGs, including in *KEAP1* in lung adenocarcinoma, nominating these VUS as worthy of in depth functional characterization. Patients with KEAP1 VUS also show similarly poor survival and response to chemoimmunotherapy to patients with known KEAP1 driver mutations, indicating that *KEAP1* VUSs phenocopy established *KEAP1* oncogenic alleles, and that zygosity, rather than variant classification, is prognostic of therapeutic response.

Conclusion: TSGs vary significantly in their patterns of biallelic inactivation, and can be classified according to whether and how consistently, across cancer types, they are selected for loss of both copies. Additionally, taking into account the zygosity of TSG alteration events is often necessary to understand their phenotypic and clinical consequences, and can be useful in identifying novel driver events.

#1203 Mushroom: a tool for identification of 3D cellular neighborhoods in multi-modal spatial datasets.

E. Storrs, S. Chen, C.-K. Mo, A. Houston, A. Shinkle, A. Southard-Smith, F. Simin, A. Targino, X. Li, A. Abedin, R. Jayasinghe, A. Karpova, J. Liu, J. Herndon, D. Fenyo, F. Chen, R. Fields, T. Ju, B. Raphael, L. Ding;
Washington University School of Medicine in St. Louis, Saint Louis, MO

A comprehensive understanding of the spatial localization of cellular processes is necessary to fully describe tissue biology. Numerous techniques exist to identify cellular neighborhoods in spatial datasets, however, these techniques are limited in that they either only capture two-dimensional phenomena - and can't describe the full, 3-dimensional tumor volume, or they are restricted to one spatial technology (i.e. IF, 10X Visium, Xenium, MERFISH, etc.). To address this, we developed Mushroom, a tool for identification of three-dimensional cellular neighborhoods in serial-sectioned multi-modal datasets. Mushroom's methodology consists of two main steps: 1) registration of multi-modal technologies taken in serial sections (such as multiplex imaging, H&E, or spatial transcriptomics), and 2) identification of 3-dimensional cellular neighborhoods comprising the tissue volume that has been serially sectioned. Keypoint registration is performed with BigWarp, after which the resulting dense displacement field (DDF) is used to register neighboring serial sections - including those from different data modalities. We then implement a neural network to identify three dimensional cellular neighborhoods. The network is a variational autoencoder (VAE) with a vision transformer (VIT) backbone that has been adapted to work with multiple spatial data modalities. Features extracted from the VIT backbone are then clustered to identify cellular neighborhoods unique to each input data type. With 3D neighborhoods in hand, biological questions not answerable in traditional 2D approaches can be investigated, such as z-dimensional changes in morphology and cellular interactions. Further, seamless characterization of cellular neighborhoods by simultaneous technologies at multiple levels of spatial and genomic resolution becomes possible.

#1204 Neoantigen MHC presentability ratios influence the tumor microenvironment and response to immunotherapy.

T. J. Sears[1], K.-H. Lee[1], M. Pagadala[1], A. Castro[2], M. Zanetti[1], H. Carter[1];
[1]University of California San Diego - UCSD, San Diego, CA, [2]University College London, London, United Kingdom

Introduction: Recent literature suggests that neoantigens presented via MHC-II induce a CD4+ T Cell mediated immune response, and MHC-I presented neoantigens expand CD8+ cytotoxic T Cells populations. We developed an algorithm to stratify patients into MHC-I Reliant and MHC-II Reliant immune checkpoint blockade (ICB) responders.
Experimental Procedures: Our algorithm generates patient mean harmonic best rank scores (PHBR) of each neoantigen in a tumor to estimate the proportion of neoantigens that are likely well presented by each MHC complex, given a patient's specific HLA alleles. From there, the ratio of neoantigens presented by each MHC (class-I and class-II) can be used to stratify patients into MHC-I or MHC-II Reliant groupings. The primary goals of our study were to investigate tumor immune microenvironment and survival differences between these groups. First, we used CIBERSORTx infiltration estimates of the ratio of these CD4/CD8 T cell populations across our MHC Reliance categories and by response vs nonresponse in two separate cohorts: Discovery (110) and Validation (77).
Results: We first observed that the CD4/CD8 ratio is higher in MHC-II responders than in MHC-I responders (Fig 6. A, P=~0.0057 Discovery; P=0.025 Validation), but no such a difference was found in nonresponders. Using an alternate digital cytometry tool (xCell) we obtained similar results (MHC-II vs MHC-I responders discovery P=0.44; validation P=0.0015) (Fig. S7). We applied an identical methodology to immune-hot ICB-naive cancer samples from TCGA and found that there was a powerful protective effect of the CD4/CD8 ratio in TCGA MHC-II Reliant patients (Fig S6. HR=-0.76, P=0.0092), there was a significantly harmful effect of that same ratio in TCGA MHC-I Reliant patients (Fig S6 HR=0.59, P=0.0352). These data demonstrate a benefit to having some level of concordance between CD4/CD8+ T cell infiltration and MHC-II/MHC-I neoantigen presentability ratios. Since CD4 memory based immune responses have a longer duration of action over more transient CD8 cytotoxic immune responses (cite), we compared the survival of responders in MHC-II vs MHC-I Reliance groups. MHC-II Reliant responders had a significantly longer overall survival in both discovery and validation cohorts (Fig 6. B-C, discovery P=0.0073; validation P=0.0398).
Conclusions: While neoantigens are already used in ICB stratification in the context of tumor mutational burden, we demonstrate that the balance of which MHC is presenting a set of neoantigens is relevant to immune infiltration and treatment outcome.

#1205 Inferring allele-specific copy number aberrations and tumor phylogeography from spatially resolved transcriptomics.

C. Ma[1], M. Balaban[1], J. Liu[2], S. Chen[2], L. Ding[2], **B. J. Raphael**[1];
[1]Princeton University, Princeton, NJ, [2]Washington University, St Louis, MO

Tumors evolve through the acquisition of somatic mutations over time and across space. While the temporal aspects of tumor evolution can be inferred by applying phylogenetic techniques to bulk or single-cell DNA sequencing data, the spatial aspects of tumor evolution remain understudied. Spatially resolved transcriptomics (SRT) measures gene expression at thousands of spatial locations in a tumor, but does not directly measure genetic aberrations. Thus, SRT data has not yet been fully utilized for tumor evolution studies. We introduce CalicoST, an algorithm that simultaneously infers allele-specific copy number aberrations (CNAs) and derives a phylogeographic model of tumor evolution from SRT data. By modeling CNA-induced perturbations in both gene expression and allele frequencies, CalicoST identifies important types of CNAs - including copy-neutral loss of heterozygosity (CNLOH) and mirrored subclonal CNAs - that are invisible to total copy number analysis. On SRT data from nine patients from the Human Tumor Atlas Network (HTAN), CalicoST achieves an average accuracy of 86%, approximately 21% higher than existing methods. On two of these patients with multiple adjacent slices, CalicoST reconstructs a tumor phylogeography that describes the spread of cancerous clones in three-dimensional space. CalicoST analysis of multiple SRT slices from a cancerous prostate organ reveals five spatially coherent clones, with mirrored subclonal CNAs distinguishing clones on the two sides of the prostate, and a bifurcating phylogeography in both genetic and physical space that suggests a polyclonal cancer.

#1206 Three-dimensional immune atlas of pancreatic cancer precursor lesions reveals large inter- and intra-lesion heterogeneity.

Immunotherapies are generally ineffective in pancreatic ductal adenocarcinoma (PDAC). Paradoxically, inflammation is believed to play a key role in PDAC development and invasion: patients suffering from chronic pancreatitis have a 13-fold increase in risk of developing PDAC. PDAC cells are surrounded by a dense network of fibrotic tissue containing immunosuppressive cells such as regulatory T cells, tumor-associated macrophages, and cancer-associated fibroblasts. Better understanding of the role of inflammation in PDAC could lead to the design of effective immunotherapies. Pancreatic intraepithelial neoplasia (PanIN) is a precursor to PDAC. While most of us will develop PanINs, few of these lesions will progress to invasive cancer. Efforts to determine which PanINs are likely to progress have shown that the size, incidence, and genetic variation of these lesions is high. Here, we add to these efforts through in-depth quantitative analysis of the pancreatic immune microenvironment. CODA is a novel 3D imaging technique used extensively to study the structure, transcriptomic signatures, and genetic heterogeneity of PanINs. In serial histological samples, CODA integrates image registration, cell detection, and segmentation of nine pancreatic structures: PanIN, normal ducts, islets, acini, nerves, vasculature, fat, stroma, and immune aggregates. Through integration with CD45, CD3, and FoxP3 labelled images, we explored immune infiltration in 48 large (cm^3) samples of human pancreas tissues containing >1,000 PanIN lesions to describe spatial correlations between local immune hotspots, 3D tumor morphology, and the surrounding pancreas structures. We quantified inter- and intra-sample heterogeneity in immune response to pancreatic cancer precursor lesions. We determined that this cohort varied greatly in both the number of PanIN (range 3 - 92 per cm^3) and overall immune cell density (range 3,000 - 40,000 immune cells / mm^3). We determined that, while PanIN size is not related to local immune cell density, overall PanIN burden is highly correlated to global immune cell density. This suggests that PanIN content does not have a short-range relationship to inflammation, but does have a long-range relationship with pancreatic structures and immune infiltration. As chronic inflammation in the pancreas shows correlation with development of pancreatic cancer, increased knowledge of the heterogeneous, local immune cell environment in precancerous samples will help us determine the role of inflammation in reacting to and controlling malignant progression.

CLINICAL RESEARCH: Biomarkers Predictive of Therapeutic Benefit
Minisymposium

#1207 Immune subtyping identifies a subset of HR+HER2- early-stage breast cancer patients with a very high likelihood of response to neoadjuvant immunotherapy (IO): Results from 5 IO arms of the I-SPY2 TRIAL.

Background: Neoadjuvant immunotherapy (IO) has become standard of care for early-stage triple negative breast cancer (TNBC). I-SPY2 was the first randomized trial to examine the efficacy of IO therapy in high-risk HR+HER2- breast cancer, where most IO arms showed improved efficacy relative to control. We also previously showed immune-gene expression signatures associate with pathologic complete response (pCR) in HR+HER2- treated with IO; and developed a clinically applicable Immune classifier (ImPrint) predicting response to IO that is now being used in I-SPY2.2 as part of the Response Predictive Subtypes. Here we report the performance of ImPrint in HR+HER2- patients from 5 IO arms.
Methods: 204 HR+HER2- (MammaPrint high risk) patients from 5 IO arms (anti-PD1, anti-PDL1/PARPi, anti-PD1/TLR9 dual-IO, and anti-PD1 +/- LAG3 dual-IO) and 191 patients from the control arm were included in this analysis. Patients were classified ImPrint+ (likely sensitive) vs. ImPrint- (likely resistant), by Agendia, Inc, using pre-treatment mRNA. Performance of ImPrint for predicting pCR to IO was characterized and compared to that of MammaPrint (ultra) High2 risk (MP2) and tumor grade (III). Based on the DRFS of pCR vs. non-pCR HR+HER2-/ImPrint+ patients (median follow up ~4.5yr), we predicted the DRFS in the IO vs. control arms using an exponential model as a function of the pCR rates.
Results: Overall, the pCR rate over the 5 IO arms was 33%. 28% of HR+HER2- patients were ImPrint+; and pCR rates with IO were 76% in ImPrint+ vs. 16% in ImPrint-, with the highest pCR rate >90% in a dual-IO arm. In the control arm, pCR rates were 33% in ImPrint+ and 8% in ImPrint-.
Based on the pCR rates in the IO vs. control (76% vs. 33%), the predicted DRFS of HR+HER2-/ImPrint+ patients are 91% vs 80% at 5 years, respectively. This translates to a risk reduction of 52% for the IO arm relative to standard chemotherapy in HR+HER2-/ImPrint+ patients.
We also compared MP2 and tumor grade (III) to ImPrint+ as pCR predictors, as these markers have been used or proposed as selection markers for neoadjuvant IO trials in HR+HER2-. The pCR rates for MP2, Grade III, at 56%, 45%, respectively, are much smaller than that for ImPrint+ at 75% pCR; thus ImPrint appears to be a more precise predictive biomarker for neoadjuvant IO therapy in the HR+HER2- breast cancers.
Conclusion: These results suggest that a subset of high risk HR+HER2- breast cancers is highly sensitive to immunotherapy, and by using a specific and sensitive selection strategy patients could achieve pCR rates similar to what is seen with best neoadjuvant therapies in TNBC and HER2+ (i.e., pCR rate > 65-70%). ImPrint, an FDA IDE-enabled assay currently being further evaluated in I-SPY2, may represent the way to identify patients for IO that best balances likely benefit vs risk of serious immune-related adverse events.

#1208 Plasma proteomics-based models for predicting therapeutic benefit and immune-related adverse events in non-small cell lung cancer patients treated with immunotherapy.

Background: Immune checkpoint inhibitors (ICIs) have significantly improved outcomes for patients with metastatic non-small cell lung cancer (NSCLC). However, clinical management is challenging. The PD-L1 biomarker does not optimally guide the choice between ICI monotherapy and combination ICI-chemotherapy, and there are currently no biomarkers to predict immune-related adverse events (irAEs). Here, we describe a versatile platform based on plasma proteomics and machine learning for generating predictive tools to support treatment decisions.

Methods: Pre-treatment plasma samples were collected from 616 NSCLC patients receiving ICI-based therapy (NCT04056247). Clinical benefit (CB) data and irAEs were recorded. Proteomic profiling of plasma samples was performed using the SomaScan® assay, covering ~7000 proteins per sample. Proteins associated with Clinical Benefit (progression-free survival at 12 months) were classified as resistance-associated proteins (RAPs). Proteins associated with grade ≥3 irAEs occurring within the first 100 days of treatment were classified as toxicity-associated proteins (TAPs). RAPs and TAPs were integrated into two separate machine learning-based models, yielding CB and irAE probabilities, respectively. The CB model used a CB probability threshold to assign patients a PROphet-positive or PROphet-negative result. Bioinformatic analysis was performed on RAPs and TAPs.

Results: CB and irAE models displayed strong predictive performance with a high correlation between predicted probability and observed CB or irAE rate (CB model: R2=0.98; p-value<0.0001; irAE model: R2= 0.92; p-value <0.0001). In the CB model, patients classified as PROphet-positive achieved significantly longer overall survival (OS) than PROphet-negative patients, with a median OS of 25.9 vs. 10.8 months (hazard ratio, HR = 0.51; p-value<0.001). Furthermore, patients with PD-L1 ≥50% tumors and a PROphet-negative result had significantly longer OS with ICI-chemotherapy in comparison to ICI monotherapy (HR=0.23, p-value = 0.0003), suggesting that combination therapy is preferable for such patients despite high PD-L1 levels. Bioinformatic analysis showed that RAPs related to immune regulation, angiogenesis, chemo-resistance, and other potential resistance mechanisms displayed higher expression levels in patients who did not benefit from treatment. Neutrophil- and inflammation-related proteins were significantly enriched in patients who experienced irAEs.

Conclusions: We describe two machine-learning based predictive tools that may be used separately or in combination to inform treatment decisions based on the patient's likelihood to benefit from ICI therapy and to develop serious irAEs. Our findings also provide biological insights related to treatment resistance and immune-related toxicity.

#1209 Tumor informed circulating tumor DNA monitoring for early treatment response and survival outcomes on trastuzumab + pertuzumab.

R. Kurzrock[1], M. Childress[2], W. Li[3], A. Muse[3], J. Malato[4], Y. Wang[4], M. Liu[5], A. Aleshin[5], R. S. P. Wang[3], J. Thierauf[3], C. J. Sweeney[6], J. Hainsworth[7], T. Szado[4], A. Young[3], K. Schulze[4], D. Spigel[7], F. Meric-Bernstam[8], C. Swanton[9], H. A. Burris III[7];

[1]Medical College of Wisconsin, Wauwatosa, WI, [2]Foundation Medicine, Inc., Nashville, TN, [3]Foundation Medicine, Inc., Boston, MA, [4]Genentech, San Francisco, CA, [5]Natera, San Carlos, CA, [6]South Australian Immunogenomics Cancer Institute, Adelaide, Australia, [7]Sarah Cannon Research Institute, Nashville, TN, [8]MD Anderson Cancer Center, Houston, TX, [9]Francis Crick Institute, London, United Kingdom

Background: Advances in cancer treatment have led to the rise of targeted therapies as practice-changing modalities, demonstrating significant efficacy in molecularly selected patients. However, depth of response and survival benefit is variable. Limitations in radiographic imaging create challenges in determining a clinical response. Circulating tumor DNA (ctDNA) is a promising minimally-invasive, predictive biomarker. Here we explore the utility of tumor-informed, on-treatment ctDNA dynamics for early response monitoring and prognostication in patients with HER2-positive tumors of various histologies receiving trastuzumab + pertuzumab on the phase II basket trial, MyPathway (NCT02091141).

Methods: In this retrospective study, 58 patients were included based on availability of tissue comprehensive genomic profiling (CGP) results and baseline/on-treatment plasma. FoundationOne® Tracker was utilized to detect and quantify ctDNA, selecting 2-16 tumor-derived variants from tissue CGP and monitoring the corresponding patient's plasma with multiplex PCR. ctDNA was assessed at baseline and Cycle 3 Day 1 (C3D1) of therapy. Correlations between ctDNA changes and objective response, progression-free survival (PFS) and overall survival (OS) were made using Kaplan Meier analyses and landmarked at C3D1. Patients ctDNA- at baseline and C3D1 were excluded.

Results: Of the 58 patients, personalized ctDNA assays were successfully designed for 52 (89.7%) representing 14 unique tumor histologies. Of 52, 48 (92.3%) had ctDNA results available for baseline analysis with a median of 100.7 mean tumor molecules per mL (MTM/mL); 89.6% were ctDNA+ with a median of 119.5 MTM/mL. A total of 39 patients had both baseline and C3D1 results for ctDNA response analyses. On-treatment ctDNA decline >90% (N=10) was associated with longer survival compared to <90% decline (N=16) or any increase (N=13) in ctDNA (OS: NR, 9.4 months (mo); P= 0.007). CtDNA dynamics remained predictive in a disease specific analysis of colorectal cancer (N=18; OS: NR, 10.2 mo; P= 0.04). Similar results were seen when stratifying patients by baseline ctDNA level (above/below median MTM/mL) or HER2 *(ERBB2)* mutation vs amplification. ctDNA increase at C3D1 preceded radiographic progression by a median of 1.3 mo. In patients with stable disease, >90% decline in ctDNA was associated with longer OS compared to <90% decline or any increase (NR, 9.4 mo; P= 0.01).

Conclusion: Tumor-informed ctDNA monitoring provides insight into early treatment response and survival outcomes in patients with diverse HER2 amplified or mutated tumors receiving HER2 targeted therapy. On-treatment ctDNA dynamics refine and can potentially detect response/progression ahead of standard of care response assessments, suggesting early ctDNA monitoring as a valuable complementary tool for real-time treatment response monitoring.

#1210 High-throughput time-resolved single-cell analysis of T-cell activation.

S. J. J. Kwok[1], S. Forward[1], E. Assita[1], T. Brown[1], M. Fahlberg[1], P. Chattopadhyay[2];
[1]LASE Innovation, Woburn, MA, [2]Talon Biomarkers, Whippany, NJ

How immune cells respond to stimuli is fundamental in developing adoptive cell therapies, vaccines, and other immunotherapies. T cells dynamically undergo activation, exhaustion, expansion, phenotype switching, and cell killing. Flow cytometry is the gold standard method for characterizing these at high throughput, typically by comparing T cell populations before and at different timepoints after treatment. This approach is limited to population-level analyses and overlooks any heterogeneity of individual T cell responses over time, which may contribute to variability in response. Here, we describe the development of a novel flow cytometry-based method (Time-lapse flow™) to characterize immune cell responses over time at the single cell level.

To measure the same cells repeatedly on a flow cytometer, we employed a new optical barcoding technology called laser particles (LPs) that provide individual cells with a unique spectral signature that can be tracked over the course of multiple measurements. Using a custom flow cytometer with fluorescence and LP detection, we performed a multi-day assay to capture how T cell marker expression changes over time after CD3/CD28 activation. Specifically, we used releasable antibodies to quantify PD1, CD69 and CD25 at each time-point and correlated these expression kinetics with cell function at the end of the assay by measuring cytokine secretion (IFNg, IL2, TNFa) after PMA/ionomycin stimulation.

We found significant cellular heterogeneity in kinetic profiles of PD1, CD69 and CD25 expression, with different dominant ‘kinetic modes’ present for each marker. For example, while a large proportion of PD1 expression was transient (positive on day 1, but not on days 2 and 3), nearly all cells that express CD69 on day 1 retained their expression on day 2. We also found that T cells with late expression of PD1 had significantly more cytokine secretion compared to cells that were initially positive for PD1. These results were replicated with at least 3 replicate samples for multiple donors. Differences in kinetic phenotypes were not explained by conventional phenotyping with CD4, CD8, CD45RA and CCR7.

To date, immune cell phenotyping with flow cytometry involves classifying cell types through their marker expression profiles at a single time-point. Here, we introduce a novel approach for acquiring time-resolved single-cell data with a flow cytometer and applied it to study T cell activation. We found novel kinetic phenotypes of T cells defined by their marker expression over time, which also correlated to their functional potential (cytokine secretion). These kinetic phenotypes could not be identified with conventional flow cytometry. Our approach could have significant implications for immunotherapy development, particularly in identifying the most suitable cell populations to use, understanding mechanisms of exhaustion and persistence, and elucidating the basis of donor variability.

#1211 Biomarker analysis of pembrolizumab and ramucirumab neoadjuvant therapy for PD-L1-positive stage IB-IIIA lung cancer: EAST ENERGY trial.

K. Nomura[1], S. Kumagai[1], S. Koyama[1], K. Aokage[2], Y. Shimada[3], K. Yoh[2], M. Wakabayashi[2], M. Fukutani[2], H. Furuya[2], T. Miyoshi[2], K. Tane[2], J. Samejima[2], T. Taki[2], T. Hayashi[4], J. Matsubayashi[3], G. Ishii[2], N. Ikeda[3], H. Nishikawa[1], M. Tsuboi[2];

[1]National Cancer Center, Kashiwa, Japan, [2]National Cancer Center Hospital East, Kashiwa, Japan, [3]Tokyo Medical University, Tokyo, Japan, [4]Juntendo University School of Medicine, Tokyo, Japan

Background: Neoadjuvant treatments with novel combination immunotherapies for resectable non-small cell lung cancer (NSCLC) are being developed. Combination therapy with antiangiogenic agents and anti-PD-1/PD-L1 antibody has shown enhanced antitumor effects. EAST ENERGY is a single-arm multicenter phase 2 trial of neoadjuvant pembrolizumab and ramucirumab in patients with PD-L1-positive stage IB-IIIA NSCLC (NCT04040361). In this study, we aimed to identify biomarkers that predicts the efficacy of the neoadjuvant therapy. Furthermore, we aimed to elucidate the effect of the neoadjuvant therapy on the tumor microenvironment (TME).

Methods: Patients enrolled in the EAST ENERGY trial (n=24) for whom pre- and post-treatment specimens were available (n=20) were included in this study. RNA-sequencing and multiplex immunohistochemistry (mIHC) were used to examine the association between the immunological phenotype of the TME and major pathological response (MPR), and changes in the TME before and after treatment.

Results: MPR was achieved in 50.0% (12/24) of patients. Biomarker analyses with RNA-sequencing revealed that high expression of cancer-associated genes, and upregulation of interferon-gamma and interferon-alpha response in pre-treatment tumor were associated with MPR (q value<0.001). mIHC in pre-treatment samples revealed that abundance of $CD8^{\pm}$ T cells in the pre-treatment TME was associated with MPR (p=0.039). On the other hand, infiltration of immunosuppressive cells such as Treg or M2-macrophages were not associated with resistance for the treatment (p=0.836, 0.639, respectively). Next, to clarify the effect of the neoadjuvant therapy on the TME, comparative analyses of pre- and post-treatment samples was performed. In gene set enrichment analysis, the neoadjuvant therapy enhanced gene set associated with interferon-gamma response (q value=0.051). Furthermore, angiogenesis-related gene set were downregulated after the treatment (q value=0.090). mIHC analyses revealed that the number of $CD8^{\pm}$ T cells in the TME was significantly increased after the neoadjuvant therapy (p<0.001). Notably, Tregs / $CD8^{\pm}$ T cells ratio and the number of M2-macrophage in the TME were significantly decreased after the neoadjuvant therapy (p=0.032, 0.003, respectively).

Conclusion: In the neoadjuvant therapy with pembrolizumab and ramucirumab, immune-activated status before treatment serves as a potential biomarker for predicting treatment response. Moreover, combining ramucirumab with pembrolizumab reduced immunosuppressive cells in the TME and inhibited tumor angiogenesis. These results suggest that this combination therapy modifies the TME and augments antitumor immunity. Larger clinical trial is warranted to assess the efficacy of neoadjuvant therapy with ramucirumab and pembrolizumab in patients with PD-L1-positive NSCLC.

#1212 Impact of KEAP1/STK11 co-mutations and NRF2 signaling on resistance to adagrasib in advanced NSCLC.

M. V. Negrao[1], D. Molkentine[1], A. G. Paula[1], L. Hover[2], M. Nilsson[1], N. Vokes[1], L. Engstrom[3], A. Calinisan[3], L. Waters[3], D. M. Briere[3], J. Hallin[3], G. R. Blumenschein[1], F. Skoulidis[1], S. E. Kopetz[1], D. S. Hong[1], D. L. Gibbons[1], P. Olson[3], J. Christensen[3], J. V. Heymach[1];
[1]UT MD Anderson Cancer Center, Houston, TX, [2]Monoceros Biosystems, San Diego, CA, [3]Mirati Therapeutics, San Diego, CA

Background: KRAS G12C inhibitors (G12Ci) are revolutionizing the therapeutic landscape of advanced NSCLC, but mechanisms of limited clinical efficacy observed in some patients (pts) merit continued exploration. In the largest cohort of advanced KRAS G12C-mutant (K^{G12C}) NSCLC pts treated with G12Ci, we demonstrated *KEAP1* and *STK11* co-mutations are enriched in early progression to G12Ci. Yet the independent predictive role of *KEAP1* and *STK11* co-mutations and the impact of enhanced NRF2 signaling in clinical outcomes to G12Ci remains incompletely characterized.
Methods: Clinico-genomic data were collected from 129 pts with advanced K^{G12C} NSCLC treated with adagrasib (ada) (KRYSTAL-1 - NCT03785249). NRF2 signaling was estimated by NRF2 score (*HTG transcriptome panel*). Kaplan-Meier estimates of PFS and OS were assessed with log-rank test. Hazard ratios (HR) were estimated using Cox regression model. K^{G12C} NSCLC cell lines and CDX/PDX models were used for pre-clinical experiments.
Results *KEAP1* and *STK11* co-mutations were each associated with significantly shorter survival upon ada treatment (*KEAP1*: PFS 4.1 vs 9.9 mo, HR 2.7, p<0.01; OS 5.4 vs 19.0 mo, HR 3.6, p<0.01; *STK11:* PFS 4.2 vs 11.0 mo, HR 2.2, p<0.01; OS 9.8 mo vs not reached [NR], HR 2.6, p<0.01). $KEAP1^{WT}/STK11^{WT}$ status identified a group of pts with significantly longer PFS (16.85 mo) and OS (NR) upon treatment with ada. In cell viability and colony formation assays, KEAP1 re-expression sensitized all $KEAP1^{MUT}/STK11^{MUT}$ K^{G12C} NSCLC cell lines to ada treatment. Similar results were observed with *STK11*/LKB1 re-expression. $KEAP1^{MUT}$ was linked to limited response to ada across a broad panel of NSCLC PDX/CDX. *In vivo* drug anchored CRISPR screens in the ada-sensitive LU99 cell line identified *KEAP1* as the most significant gene promoting resistance to ada. *KEAP1* KO in the LU99 model determined early onset of ada resistance. *In vitro* drug screens showed high synergy scores and higher anti-tumor activity for mTOR inhibitor (mTORi) and ada combinations in K^{G12C} $KEAP1^{MUT}/STK11^{MUT}$ NSCLC. High NRF2 score was associated with significantly shorter survival with ada (PFS: 4.2 vs 8.4 mo, HR 2.0, p=0.02; OS: 6.5 vs 19.0 mo, HR 2.8, p<0.01) even in $KEAP1^{WT}$ NSCLC pts. Integration of $KEAP1^{WT}$, $STK11^{WT}$ and low NRF2 score status identified pts - 32% - with significant and meaningfully longer survival when treated with ada (PFS 12.0 vs 4.2 mo, HR 0.2, P<0.01; OS NR vs 8.0 mo, HR 0.1, p<0.01).
Conclusions: Co-mutations in *KEAP1* and *STK11* and NRF2 signaling define a subgroup of K^{G12C} NSCLC pts with markedly distinct outcomes upon treatment with ada. The mTORi and ada combination shows high efficacy for targeting K^{G12C} NSCLC harboring *KEAP1* and *STK11* co-mutations. The clinical safety and efficacy of mTORi nab-sirolimus and ada will be determined in the ongoing KRYSTAL-19 trial (NCT05840510).

#1213 Tissue-specific thresholds and microenvironment correlates of tumor mutation burden associated with immunotherapy benefit and prognosis in microsatellite stable cancers.

M. Muquith[1], M. Espinoza[1], A. Elliott[2], J. Xiu[2], A. Seeber[3], W. El-Deiry[4], E. S. Antonarakis[5], S. Graff[4], M. J. Hall[6], H. Borghaei[6], D. S. Hoon[7], S. V. Liu[8], P. C. Ma[9], R. R. McKay[10], T. Wise-Draper[11], J. Marshall[8], G. W. Sledge[2], D. Spetzler[2], H. Zhu[1], D. Hsieh[1];

[1]UT Southwestern, Dallas, TX, [2]Caris Life Sciences, Dallas, TX, [3]Medical University of Innsbruck, Innsbruck, Austria, [4]Brown University, Providence, RI, [5]Masonic Cancer Center, Minneapolis, MN, [6]Fox Chase Cancer Center, Philadelphia, PA, [7]Saint John's Cancer Institute, Santa Monica, CA, [8]Georgetown University, Washington, DC, [9]Penn State Cancer Institute, Hershey, PA, [10]Moores Cancer Center, San Diego, CA, [11]University of Cincinnati, Cincinnati, OH

Background: Immune checkpoint inhibitors (ICIs) targeting anti-PD-1/L1 have expanded the treatment landscape against cancers, but are only effective in a subset of patients across all cancer types. Tumor mutation burden (TMB) is postulated to be a generic determinant of ICI dependent-tumor rejection. Here, we clarify the association between TMB and survival outcomes among microsatellite-stable cancers in a real-world clinicogenomic cohort including 70,698 patients distributed across 27 histologies.

Methods: Patients were segregated into mutually exclusive anti-PD-1/L1 (N=14,736, immune checkpoint inhibitor, ICI) and non-ICI cohorts (N=55,962) if they had received pembrolizumab, nivolumab, atezolizumab, durvalumab, avelumab, or cemiplimab, and non-ICI therapies, respectively, during the course of treatment for individual cancer types. Patients treated with chemo-immunotherapy combination regimens were included in the ICI cohorts, but anti-CTLA-4 agents were excluded from both cohorts. For both ICI and non-ICI cohorts, patients were reiteratively categorized as TMB-high or -low using increasing TMB thresholds up to the 90th percentile TMB for individual cancer types. Outcomes were then assessed using Cox regression analyses of overall survival (OS).

Results: Across 27 histologies, 12 cancer types had at least one TMB cutoff associated with survival benefit upon ICIs (melanoma, NSCLC, SCLC, bladder, cervical, colorectal, gastric, ovarian, head and neck, vulvar cancers, as well as carcinoma of unknown primary, and sarcoma), and these associations were generally conserved across sex and age groups, although not necessarily significant in all cases. In two cancer types (cholangiocarcinoma and neuroendocrine tumors), TMB cutoffs were associated with worse OS with ICIs. The lowest TMB cutoff in which a survival benefit could be detected with ICIs ranged from 2 mut/Mb in melanoma to 9 mut/Mb in colorectal cancer. TMB thresholds with the greatest predictive value (defined as the lowest survival hazard ratio) were frequently near the highest TMB examined for individual cancer types, suggesting that TMB may scale with ICI benefit.

Conclusion: TMB was associated with survival benefit or detriment depending on tissue and treatment context. Detectable survival benefits were noted over a broad range of TMB cutoffs across cancer types, and a dose-dependent relationship between TMB and outcomes was observed in a subset of cancers. These results may have implications for cancer-agnostic and universal TMB cutoffs to guide the use of anti-PD-1/L1 therapies, and underline the importance of tissue context in the clinical development of ICI biomarkers.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Biological Therapeutic Agents
Minisymposium

#1214 Investigating therapeutic strategies to promote immune rejection of KRAS^{G12C} inhibitor-resistant subpopulations in lung cancer.

M. Tomaschko, C. Moore, C. E. Pillsbury, K. Ng, S. de Carne, S. Rana, A. de Castro, P. Anastasiou, **M. Molina-Arcas**, J. Downward;
The Francis Crick Institute, London, United Kingdom

Oncogenic KRAS signaling not only promotes progression and survival of cancer cells, but it can also play a major role in suppressing anti-tumor immunity through several mechanisms, including secretion of cytokines, reduction of antigen presentation and suppression of tumor-intrinsic interferon responses. Consequently, treatment with KRAS^{G12C} inhibitors alleviates oncogenic KRAS driven immune suppression, resulting in a profound remodeling of the tumor microenvironment (TME). In immunogenic mouse models, these changes can lead to the generation of some complete responses which are dependent on the engagement of the immune system. In this project we aim to investigate whether the induction of immune responses triggered by KRAS^{G12C} inhibition can effectively target inhibitor-resistant subclones. To achieve this, we mimic the development of drug resistance by combining reporter-traced isogenic KRAS^{G12C} and KRAS^{G12D} mutant lung cancer cells, where the KRAS^{G12D} mutant cells are inherently resistant to KRAS^{G12C} inhibitors. Growth of resistant cells was monitored via in vivo luciferase imaging and end point flow cytometry. KRAS^{G12C} inhibition as monotherapy, either with the active-state KRAS^{G12C} inhibitor RMC-4998 or the inactive-state inhibitor adagrasib, led to a proliferative advantage of the drug-resistant subpopulation, suggesting that any immune response to KRAS^{G12C} inhibition in the bulk tumor population was insufficient to target the resistant cell subclones. To investigate if immune mediated elimination of resistant cells could be achieved using combinations, we assessed two strategies commonly evaluated in clinical trials with KRAS^{G12C} inhibitors: anti-PD1 blockade and SHP2 inhibition. Of note, KRAS^{G12D} mutant cells do not respond to these therapies when grown subcutaneously. Treatment of RMC-4998 in combination with either anti-PD1 or the SHP2 inhibitor RMC-4550 was able to induce complete eradication of both KRAS^{G12C} and KRAS^{G12D} mutant lung cancer cells, despite the resistant cells being insensitive to these therapies when treated in the absence of sensitive cells. Furthermore, both combinations induced immune memory towards the resistant cells. These long-term effects were dependent on the immune system as they were not observed in immune deficient mice. Immune profiling of treated tumors revealed that both combinations can result in a more profound remodeling of the TME and potentiate the immune responses. Overall, our preclinical results demonstrate that the anti-tumor responses generated by the combination of KRAS^{G12C} inhibitors with SHP2 inhibition and/or immune checkpoint blockade can result in the bystander immune mediated killing of subclones of KRAS^{G12C} inhibitor resistant cells, providing a paradigm for the development of therapeutic combinations that may be more able to counter the development of inhibitor resistance.

#1215 DIRAS3 inhibits oncogenic RAS signaling and RAS-dependent cell growth driven by prevalent KRAS hot spot mutations.

G. Bildik[1], J. Liu[2], W. Mao[1], H. Yang[1], J. F. Hancock[2], R. C. Bast, Jr.[1], Z. Lu[1];
[1]The University of Texas MD Anderson Cancer Center, Houston, TX, [2]The University of Texas Medical School at Houston, Houston, TX

RAS mutations are found in 30% of human cancers and are characterized by hotspot mutations at codons G12, G13, and Q61. This results in constitutively activated RAS proteins. Despite recent advances in drug design and the emergence of covalent inhibitors, effectively targeting mutant RAS remains challenging. Our group previously identified the tumor suppressor protein DIRAS3, which directly binds Ras and inhibits its function by disrupting KRAS dimers/nanoclusters and blocking effector activation. DIRAS3 expression reduced cancer cell growth in pancreatic and ovarian cancers. To determine whether DIRAS3 plays a definitive role in inhibiting mutant KRAS, we comprehensively characterized DIRAS3's RAS-inhibitory effects using RASless mouse embryo fibroblast (MEF) cells as a model system lacking endogenous RAS isoforms. We ectopically expressed various KRAS mutations in these cells and then examined DIRAS3's effect on each KRAS mutant clone. We analyzed downstream RAS signaling, colony formation, cell viability, and toxicity. Our results showed that DIRAS3 significantly inhibited RAS-dependent colony formation in KRAS mutant (G12C, G12D, G12V, G13D, G12R, Q61R, Q61L) but not wild-type KRAS clones. However, when we added epidermal growth factor (EGF) to the medium, DIRAS3 expression inhibited wild-type KRAS activity, decreasing colony formation. This suggests that DIRAS3 selectively affects the active, GTP-bound form of KRAS and downstream signaling. Additionally, DIRAS3 expression decreased Erk1/2 phosphorylation in MEF cells with mutant KRAS, but not in the cells with a BRAFV600E mutation. This indicates that DIRAS3 specifically inhibits the KRAS-mediated MEK/ERK signaling, cell proliferation, and cytotoxicity. Moreover, to determine the critical region for DIRAS3's RAS-inhibitory function, we compared wild-type DIRAS3 and deletions (ΔNTE, ΔCTE, ΔNCTE). Our results showed both termini are required to effectively suppress clonogenic growth, emphasizing the requirement for DIRAS3 to anchor to the plasma membrane and interact with the RAS dimer interface to inhibit RAS-dependent tumor growth. In conclusion, our findings underscore the potent and specific inhibitory effects of DIRAS3 on RAS-driven oncogenesis, positioning it as a promising pan-RAS inhibitor for RAS-mutant cancers.

#1216 Pan-RAS inhibition by a tumor-targeted biotherapeutic.

G. L. Beilhartz[1], H. Liang[1], M. Udaskin[2], C. Ng[1], N. Radulovich[2], R. A. Melnyk[1];
[1]The Hospital for Sick Children, Toronto, ON, Canada, [2]University Health Network, Toronto, ON, Canada

Oncogenic RAS signaling drives tumor growth in about 30% of human malignancies. In recent years the first mutant-specific inhibitors of KRAS G12C (sotorasib and adagrasib) entered the clinic. While some durable responses were noted in KRAS-mutant non-small cell lung cancer, the clinical experience of KRAS G12C inhibitors is marked by rapid drug resistance, either intrinsic or acquired, causing re-activation of the MAPK pathway. Common resistance mechanisms include compensatory signaling through the related RAS isoforms NRAS and HRAS, as well as the selection of non-G12C KRAS mutations, among others. The bacterial peptidase RRSP potently cleaves all RAS mutants and isoforms in the conserved Switch I region. We have shown that receptor-mediated intracellular delivery of RRSP using an engineered protein delivery system (RASx) can inactivate all RAS signaling in a cell, causing apoptosis in RAS-addicted tumor cells *in vitro* and *in vivo*. Since systemic pan-RAS inhibition is not likely to be tolerated therapeutically, precise tumor targeting is a necessary feature of a true pan-RAS inhibitor. Here, we describe the unique ability of the RASx system to specify the cell surface receptor used by RRSP to enter cells, allowing exquisite targeting and killing of KRAS, NRAS and HRAS-driven tumor cells while sparing healthy tissues. We screened a panel of patient-derived tumor organoids (PDOs), to demonstrate broad tumor cell killing across pancreatic and colorectal cancer-derived PDOs. 97% of KRAS mutant organoids were sensitive to RASx, independent of the specific mutation. Intriguingly, 46% of wildtype RAS PDOs were sensitive to RASx, including organoids with activating mutations in EGFR. In contrast, PDOs with mutations downstream of RAS such as BRAF V600E were resistant to RASx. Indeed, RASx is effective not only against RAS-addicted tumors, but also wildtype RAS tumors driven by upstream receptor tyrosine kinases, potentially expanding the clinical utility of this platform. RASx is a first-in-class, tumor-targeted pan-RAS inhibitor that represents a unique entry into the growing armamentarium against oncogenic RAS.

#1217 Defining the anti-tumor activity and immune effects of the RAS^{MULTI}(ON) inhibitor RMC-7977 in preclinical models of NRAS-mutant melanoma.

L. A. D. Carvalho, M. S. Phadke, K. S. Smalley;
Moffitt Cancer Center, Tampa, FL

Introduction: Mutations in the small GTPase NRAS are the second most common oncogenic driver in cutaneous melanoma, being found in ~25% of cases. Targeted therapy strategies are currently lacking for NRAS-mutant melanoma. Here, we characterized the anti-tumor activity and immune effects of RMC-7977, a RAS^{MULTI}(ON) preclinical tool compound, representative of the investigational agent RMC-6236, in preclinical mouse and human models of NRAS-mutant melanoma.

Methods: The *in vitro* potency of RMC-7977 was determined using mouse and human NRAS-mutant melanoma cell lines. Recovery of signaling was quantified by Western Blot and receptor tyrosine kinase (RTK) arrays. *In vivo* anti-tumor activity of RMC-7977 was determined in two syngeneic mouse melanoma models (SW1 NRAS^{G13D} and NRAS#5 NRAS^{Q61R}), and tumor immune infiltrate quantified using multiplexed IHC and flow cytometry. Mechanisms of resistance were defined using RNA-seq.

Results: RMC-7977 had good activity *in vitro* against human cancer cell lines and in mouse models of NRAS-mutant melanoma. Time-course studies demonstrated RMC-7977 rapidly inhibited phospho-ERK signaling, which then began to recover after 8 hr of treatment. There was also evidence of adaptive receptor tyrosine kinase signaling by 48 hr. In syngeneic mouse models of NRAS-mutant melanoma, RMC-7977 led to a rapid inhibition of tumor growth, increased expression of tumor MHC class I and PD-L1 and an increase in CD4+ and CD8+ T cell infiltrate into tumors. Therapeutic escape was associated with decreased CD4+ and CD8+ T cell infiltration and increased numbers of immunosuppressive MDSCs. Cells collected from tumors resistant to RMC-7977 *in vivo* did not show any shift in sensitivity to the inhibitor when re-challenged *in vitro*, suggesting that the resistance observed *in vivo* resulted from mechanisms specific to the tumor microenvironment, for example adaptive RTK signaling or immune escape. RNA-seq and IHC analysis suggested that resistance was associated with decreased MHC expression and antigen presentation, as well as reduced co-stimulation of T cells. Combination studies of RMC-7977 with anti-PD-1 are ongoing to identify potential synergistic interactions in these preclinical models.

Conclusion: RMC-7977 has anti-tumor activity in syngeneic mouse models of NRAS-mutant melanoma, associated with a robust immune response.

#1218 CDK9 inhibitors modulate the transcriptional landscape of colorectal cancer to suppress MAPK signaling and synergizes with BRAF inhibitors to treat BRAF-mutant colorectal cancer.

C. Kuang[1], N. Wei[1], M. Mohammadi[1], M. A. Bhat[1], T. Li[1], P. Patil[2], O. Wiltz[1], R. Huang[1], K. Ooka[1], M. Quintal[1], E. Chu[1];
[1]Montefiore Einstein Comprehensive Cancer Center, Bronx, NY, [2]Montefiore Medical Center, Bronx, NY

Background: Colorectal cancer (CRC) is the second leading cause of cancer deaths in the US, and it remains a significant public health burden. Metastatic CRC (mCRC) is usually treated with combination chemotherapy and targeted therapy regimens, but eventually becomes chemotherapy refractory. Thus, novel and more effective treatments for mCRC are urgently needed. Cyclin-dependent kinase 9 (CDK9) is a key activator of RNA Pol II transcription and promotes the expression of many cancer driver genes, making CDK9 a promising target for cancer therapy.
Methods: Human CRC cell lines, patient-derived organoids (PDOs), cell line xenografts, and patient-derived xenografts were used to investigate the efficacy and mechanisms of action of the CDK9 inhibitors AZD4573, enitociclib, and NVP-2, as well as the BRAF inhibitors encorafenib and dabrafenib. *In vitro* viability was measured by chemical cell proliferation assays and *in vivo* tumor sizes were measured by calipers. *In vitro* mechanisms of action were assessed by RNA sequencing, real time polymerase chain reaction, and Western blotting. *In vivo* mechanisms of action were assessed by immunohistochemistry.
Results: CDK9 inhibitors potently inhibited CRC cells and PDOs. In contrast to hematologic malignancies, we did not observe consistent suppression of the oncogenes c-MYC and MCL-1 by CDK9 inhibitor treatment. Instead, CDK9 inhibitors suppressed several other key cancer pathways in CRC, such as MAPK, mTOR, and PI3K signaling pathways. Importantly, multiple targets within the MAPK pathway were strongly suppressed, including EGFR, KRAS, and BRAF. We hypothesized that combination treatment with CKD9 inhibitors and MAPK pathway inhibitors can synergistically treat CRC. As proof-of-concept, we investigated the combination of CDK9 and BRAF inhibitors in models of BRAF-mutant CRC, a particularly aggressive type of CRC. We found this combination to synergistically suppress CRC growth *in vitro* and *in vivo*. Compared to single agents, combination treatment led to significantly stronger induction of apoptosis and suppression of MAPK pathway signaling. Our results suggest that concurrent treatment with CDK9 inhibitors plus established MAPK pathway inhibitors, such as BRAF inhibitors, can significantly improve upon single agent treatment. Conclusions: We have found CDK9 inhibitors to potently suppress CRC growth and survival through a unique mechanism of action, by vertical suppression of the MAPK signaling pathway. We demonstrate that CDK9 inhibitors can synergize with BRAF inhibitors in the treatment of BRAF-mutant CRC models. Thus, CDK9 inhibitors are a promising class of drugs warranting further investigation, including early-phase clinical trials, in mCRC.

#1219 In vivo delivery of CRISPR-Cas9 using lipid nanoparticles enables ATAD3A gene depletion to enhance RAS-targeted therapy.

F. Chen[1], L. Lang[2], Y. Li[3], W. Zheng[1], **Y. Teng**[1];

[1]Emory University, Atlanta, GA, [2]Augusta University, Augusta, GA, [3]Upstate Medical University, Syracuse, NY

Targeting mitochondrial oncoproteins presents a new concept in developing effective cancer therapeutics. ATAD3A is a nuclear-encoded mitochondrial enzyme that contributes to mitochondrial dynamics, cholesterol metabolism, and signal transduction. Our previous study has demonstrated elevated expression of ATAD3A in head and neck squamous cell carcinoma (HNSCC) primary tissues and cultured cell lines. Loss of function suppresses HNSCC cell growth and elicits tumor regression in orthotopic tumor-bearing mice. Mechanistically, ATAD3A interacts with ERK1/2 in the mitochondria of HNSCC cells in the presence of VDAC1, and the ATAD3A-ERK1/2 signaling axis drives HNSCC development in a RAS-independent fashion. CRISPR-Cas9 has revolutionized genome engineering and has been intensively used to modify cancer-associated genes. However, challenges remain as CRISPR editing components must be transported into cells to exert their function. There is a need to explore effective in vivo delivery systems to accelerate the clinical use of CRISPR-Cas9. As no drug is available to target ATAD3A directly, we developed CRISPR-based ATAD3A-targeting nanodrugs by loading Cas9 mRNA and anti-ATAD3A sgRNAs into lipid nanoparticles (LNPs) that have become clinically acceptable delivery system due to low toxicity and high delivery efficacy and biocompatibility. As expected, treatment tongue tumors established in NSG mice with LNP-sgATAD3A remarkably repressed tumor growth. Most interestingly, the addition of LNP-sgATAD3A to the RAS inhibitor salirasib potentiated anticancer activity for HNSCC compared with the efficacy resulting from single-arm treatment. These novel and significant findings demonstrate a novel approach to inhibiting ATAD3A in tumor cells and provide a possible therapeutic strategy to enhance the success of multimodality therapy in cancer patients.

#1220 Deep mutational scanning of EGFR reveals potential domain-specific TKI sensitivities in lung cancer and glioblastoma.

T. Hayes[1], E. Aquilanti[2], E. Kim[2], N. Persky[3], L. Brenan[3], A. Goodale[3], T. Sharpe[3], D. Alan[3], R. Shue[2], L. Golomb[4], B. Silverman[2], Y. Li[2], L. Westlake[3], F. Piccioni[5], A. [1]UCLA - University of California Los Angeles, Los Angeles, CA, [2]Dana-Farber Cancer Institute, Boston, MA, [3]Broad Institute, Cambridge, MA, [4]Dana-Farber Cancer Institute, Los Angeles, MA, [5]Merck, Boston, MA, [6]Moffitt Cancer Center, Tampa, FL, [7]Bright Peak Therapeutics, San Diego, CA, [8]Massachusetts General Hospital, Boston, MA, [9]Novartis, Cambridge, MA, [10]Brigham and Womens Hospital, Boston, MA

The epidermal growth factor receptor, EGFR, is frequently activated in lung cancer and glioblastoma by genomic alterations including missense mutations. The different mutation spectra in these diseases are reflected in divergent responses to EGFR inhibition: significant patient benefit in lung cancer, but limited in glioblastoma. Here, we report a comprehensive mutational analysis of EGFR function. We performed saturation mutagenesis of EGFR and assessed function of ~22,500 variants in a human EGFR-dependent lung cancer cell line. This approach revealed enrichment of erlotinib-insensitive variants of known and unknown significance in the dimerization, transmembrane, and kinase domains. Multiple EGFR extracellular domain variants, lacking approved targeted therapies, were sensitive to dacomitinib. Strikingly, at least two glioblastoma patients with G598V dimerization domain mutations showed responses to dacomitinib treatment together with subsequent off-target resistance in one case. In summary, this comprehensive screen reveals novel functional EGFR variants and suggests broader clinical investigation of EGFR inhibition for cancers harboring extracellular domain mutations.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Conquering Drug Resistance by Innovative Research Minisymposium

#1221 Selective translational activation of PBK (PDZ- binding kinase) reveals a molecular vulnerability of drug-tolerant persister cells to targeted therapies in *EGFR*-mutant lung adenocarcinoma.

In lung adenocarcinoma (LUAD), EGFR-targeted therapies often result in incomplete tumor responses followed by disease progression caused by acquired resistance. As *EGFR* mutations are truncal (*i.e.*, present in every cell of a tumor), it remains unclear why a fraction of tumor cells can survive in the presence of drug treatment. It is increasingly recognized that drug-tolerant persister cells (DTPCs) can escape selective drug pressure and are important drivers of therapy failure and tumor relapse. The mechanisms underlying tumor cell adaptation and survival of DTPCs during therapy are not fully understood.Using *EGFR*-mutant LUAD cell lines treated with osimertinib, we unexpectedly observed that DTPCs display uncoupled mRNA and protein variations of PBK (PDZ Binding Kinase), a spindle assembly serine/threonine protein kinase. Mechanistically we discovered that although global protein synthesis is decreased upon osimertinib treatment, *PBK* translation is selectively maintained in DTPCs.The establishment and survival of DTPCs following EGFR inhibition is critically dependent on PBK, as genetic depletion of *PBK* reduces persistence to osimertinib treatment *in vitro*. PBK knockout leads to suppression of ERK1/2 reactivation following EGFR inhibition, and results in decreased expression of ZEB1 and Vimentin, key effectors of epithelial-to-mesenchymal transition (EMT), a hallmark of the DTPC phenotype. Consistently, combined treatment with osimertinib and OTS514 (PBK inhibitor) *in vitro*, reduces the DTPC fraction and decreases the enrichment of EMT-related transcriptional signatures. Similar results were obtained in LUAD patient-derived organoids, used to recapitulate the phenotype of residual disease in patients. In PDX treated with osimertinib, PBK is activated at both residual disease and acquired resistance. Concordantly, combined EGFR/PBK pharmacological inhibition was also effective in reverting osimertinib acquired resistance *in vitro*. Finally, in matched diagnosis and relapse samples from 7 *EGFR*-mutant LUAD patients treated with EGFR inhibitors, we observed increased PBK activation at the time of acquired resistance in 5 cases, including 3 $EGFR^{T790M}$-positive cases, suggesting that PBK activation may co-occur with genetic resistant alterations.Our findings unveil a novel mechanism by which *EGFR*-mutant lung cancer DTPCs selectively translate *PBK* mRNA as an adaptive survival mechanism to persist during osimertinib treatment; and provide a therapeutic target of non-genetic drug resistance otherwise unlooked-for in routine transcriptomic analyses. A deeper understanding on the mRNA translational reprogramming in DTPCs is currently performed to uncover therapeutic vulnerabilities to reduce residual disease and delay or revert the emergence of acquired resistance.

#1222 Mechanisms of succinate-mediated drug resistance in ER+ breast cancer.

J. HOGSTROM[1], B. Petrova[2], C. Perea[1], M. Ward[1], G. Wulf[1], L. Collins[1], N. Kanarek[2], T. Muranen[1];
[1]Beth Israel Deaconess Medical Center, Boston, MA, [2]Boston Children's Hospital, Boston, MA

Breast cancer is the most prevalent cancer among women worldwide with estrogen receptor-positive (ER+) cancer constituting 70% of all breast cancers. Although ER+ breast cancers initially respond well to ER-targeted therapies and CDK4/6 inhibitors, approximately 30% patients acquire resistance to targeted therapies. In addition to intrinsic resistance that tumors develop, cancer-associated fibroblasts (CAFs) residing in the tumor microenvironment, also contribute to treatment-resistance and poor survival. The role of secreted metabolites by CAFs has been poorly studied in the context of targeted drug resistance. Therefore, to investigate the mechanism of stroma-mediated resistance to CDK4/6-inhibitors, we propagated patient-derived organoids (PDOs) and CAFs from treatment-naïve and treatment-resistant ER+ breast tumors. Our data show that the CAF conditioned media containing the polar metabolite fraction stimulates resistance to CDK4/6 inhibitors. Therefore, to identify metabolites that drive resistance, we performed an untargeted metabolomics on CAF conditioned media. We observed that the CAF conditioned media was enriched for TCA cycle intermediates, including succinate. Succinate is an oncometabolite that has an essential function in energy metabolism. Aside from causing metabolic reprogramming, succinate can be transported out of the mitochondria to perform other biological processes, such as epigenetic modifications and pseudohypoxia. Furthermore, succinate in the extracellular space binds to the succinate receptor SUCNR1 and induces G-protein coupled receptor-mediated signaling in cells expressing SUCNR1. To assess mechanism of resistance that these metabolites might induce, we treated breast cancer cells with the most enriched metabolites we had identified in our metabolomics assay. These experiments identified succinate as driver of CDK4/6 inhibitor resistance in ER+ breast cancer cells. Furthermore, treating tumor cells with SUCNR1 antagonist increased their sensitivity to CDK4/6-inhibitors, showing that succinate mediated resistance is conveyed via SUCNR1. This suggests that CAF secreted succinate plays a role in supporting a pro-tumor environment by promoting drug resistance towards CDK4/6 inhibitors. Defining this mechanism of resistance will elucidate potential therapeutic targets to augment patient response to therapy.

#1223 KDM6A orchestrates NK cell response *via* CD38/48 regulation in multiple myeloma.

J. Liu[1], L. Xing[2], J. Li[3], k. Wen[1], N. Liu[4], Y. Liu[1], A. Gulla[1], N. Munshi[1], T. Hideshima[1], K. C. Anderson[1];
[1]Dana-Farber Cancer Institute, Boston, MA, [2]Shandong Cancer Hospital and Institute, Shandong First Medical University and Shandong Academy of Medical Sciences, Jinan, China, [3]The Seventh Affiliated Hospital of Sun Yat-Sen University, Shenzhen, China, [4]Shanghai Ocean University, Shanghai, China

Daratumumab (Dara), a first-in-class humanized monoclonal antibody targeting CD38, demonstrates notable efficacy in both newly diagnosed and relapsed/refractory multiple myeloma (MM) when administrated alone or in combination with other agents. However, the development of Dara resistance and subsequent relapse is common.To identify the tumor-intrinsic genes involved in resistance to NK-mediated cytotoxicity in the presence of Dara in MM cells, we conducted an *in vitro* genome-wide CRISPR-Cas9 knockout (KO) screen and found 433 genes exhibiting a positive correlation with MM cytotoxicity elicited by Dara and primary NK cells. Remarkably, 16 of these genes demonstrated a consistent correlation with cytolytic activity across the majority of the 36 cancer types in the TCGA database.The efficacy of Dara is closely linked to the expression of CD38, with nonresponders exhibiting low CD38 expression. Therefore, we conducted another CRISPR screen to identify the genes whose KO resulted in diminished CD38 expression. The genes that overlapped in these two screens are implicated in regulating both Dara-mediated ADCC and CD38 expression. Our focus turned to KDM6A among the overlapping genes. We validated that *KDM6A* KO significantly decreased CD38 expression and that reintroducing *KDM6A* into *KDM6A* KO cells restored the expression of CD38 and Dara-induced cytotoxicity.KDM6A demethylates lysine 27 of histone H3 (H3K27) to promote gene expression. Our ChIP-seq data unveiled that *KDM6A*-KO cells exhibited an increased H3K27me3 level at the CD38 promoter area than control cells. Remarkably, this pattern was consistent with Dara-resistant cell lines, which displayed reduced CD38 expression alongside elevated levels of H3K27me3 at the CD38 promoter. Interestingly, we found that CD38 overexpression only partially restored the sensitivity of *KDM6A* KO cells to Dara treatment, implying the existence of an additional mechanism. We performed RNA-seq in *KDM6A* KO cells and found CD48, an NK-activating ligand, was significantly repressed. Overexpression of CD48 in *KDM6A* KO cells resulted in a substantial increase in the secretion of Granzyme B and Perforin by NK cells and restored the activity of NK cells and re-sensitized *KDM6A* KO cells to Dara treatment. These data suggest that KDM6A mediates Dara-mediated ADCC sensitivity through the dual regulation of CD38 and CD48. KDM6A acts to oppose the EZH2/PRC2 complex by demethylating H3K27me3, and we found that Tazemetostat (Taze), an FDA-approved EZH2 inhibitor, increased the expression of CD38 and CD48, especially in *KDM6A*-KO cells. Importantly, Taze also restored the sensitivity of *KDM6A* KO cells to Dara-mediated NK cell cytotoxicity. In summary, our findings illuminate the dual role of KDM6A in enhancing the efficacy of Dara in MM. Imitating KDM6A function using an FDA-approved inhibitor holds promise in overcoming Dara resistance and improving patient outcomes in MM.

#1224 3D models of chemotherapy- and PARPi-resistant ovarian cancer indicate essential roles for JAK/STAT signaling in mediating drug resistance.

E. Rodman, X. Wang, H. Smith, X. Hou, S. Kaufmann, J. Weroha, J. Hawse;
Mayo Clinic, Rochester, MN

Ovarian cancer is the deadliest gynecological cancer with a low 5-year overall survival rate that affects over 300,000 women globally each year. Given lack of routine screening procedures, ovarian cancer patients are frequently diagnosed with late-stage disease that rapidly progress despite initial responses to front line therapy. PARPi and VEGFi targeted therapies have improved progression free survival in small subsets of patients but have largely failed to improve overall survival. Since the robust uptake of PARPis in the front line setting, resistance to this class of drugs is a growing problem. The literature is filled with many novel treatment approaches, but the vast majority fail to gain traction in pre-clinical models and early phase trials. A contributing factor to these disappointments relates to the prevalent use of 2D monoculture model systems that do not recapitulate the tumor microenvironment. To address this issue, we utilized the Rastrum 3D cell printer to grow ovarian cancer cells and PDX models in bio-functional matrices which provide optimal stiffness and extracellular matrix components specific to the ovarian tumor microenvironment. We found that ovarian cancer cells grown under these conditions exhibit dramatic up-regulation of the JAK/STAT signaling pathway, including autocrine/paracrine signaling factors, which correlated with increased sensitivity to JAK/STAT inhibitors. This affect was lost when STAT1 and STAT3 knockout cell lines were grown in this 3D environment. Ovarian tumors are known to be rich in cancer-associated fibroblasts (CAFs) and tumor-associated macrophages (TAMs). We incorporated primary CAFs into this 3D culture system and found they could promote ovarian cancer cell growth only in cancer cells with intact JAK/STAT signaling further indicating the essential role of this pathway in mediating tumor progression. Co-culture with M2 macrophages was also found to induce ovarian cancer cell growth, particularly in resistant models. Conversely, co-culture with M1 macrophages inhibited treatment naïve ovarian cancer cell growth but not resistant cell line growth. Single-cell RNAseq of the complex 3D cultures elucidated profound differences in the cross-talk between these cell types that is dependent on cancer cell sensitivity to standard-of-care agents. Finally, the addition of JAK/STAT inhibitors was found to substantially alter this cross-talk between cell types and inhibit cancer cell viability. These data further implicate the importance of JAK/STAT signaling, specifically in clinically relevant 3D models, in supporting ovarian cancer progression and response to chemotherapy and PARPi treatment. Ongoing studies are aimed at confirming these findings in pre-clinical mouse models and to elucidate the most effective JAK/STAT inhibitors *in vivo* with the goal of informing the design of future clinical trials.

#1225 Novel cellular barcoding to dissect melanoma heterogeneity and drug resistance.

H. Li, Y. Chen, J. Kaster, N. Promi, M. Herlyn;
The Wistar Institute, Phialdelphia, PA

Melanoma is the most common cause of death in skin cancer. While the development of targeted therapies (MAPK pathway inhibitors) led to a substantial improvement in overall survival of patients with melanoma harboring the BRAFV600E mutation, approximately 40% of treated patients acquire resistance and experience tumor recurrence after one year. Melanoma drug resistance is mediated by drug-tolerant persister (DTP) cell subpopulations present in tumors. DTP cells are either intrinsically rare sub-populations pre-existing prior to therapies, or adaptive sub-populations that acquire genetic and epigenetic alterations during treatments. Our lab has established six PDX models that responded to the treatment of BRAF/MEK inhibitor combination then relapsed in six to 40 weeks. We combined cell lineage barcoding and single-cell transcriptomics to trace the emergence of DTP cells in melanoma recurrence. The recent development of cellular barcoding facilitates the labelling of tens to millions of cancer clones and enables the identification of the complex mechanisms associated with clonal fate in response to therapy and in different microenvironments. We have constructed a library of approximately 15 million barcodes into a lentiviral vector. Melanoma cells were infected with the barcode library to ensure each cell carried a unique barcode. Labelled melanoma cells were injected into NSG mice, which were then treated with BRAF/MEK inhibitors, and they developed drug resistance with prolonged treatments. Treated tumors were harvested at different timepoints until relapse. The barcodes are localized close to the polyA tail of the expressed mRNA, the 3' end sequence of which could be retrieved simultaneously through single-cell RNA sequencing (scRNAseq). Thus, we can trace the clonal information from the relapsed tumor back to earlier timepoints such as the treatment naive tumor and minimal residual disease (MRD) stage. Our data showed that the diversity of barcodes in MRD stage had no significance compared to treatment naive tumor, while the diversity of barcodes in the relapsed tumor decreased around 10-fold from the MRD stage. The most dominant sub-populations in MRD arose from minor sub-populations in the treatment naive tumor, while most of the dominant sub-populations in the relapsed tumor were daughter cells from minor sub-populations in MRD stage. The top three sub-populations dominated 25% of the relapsed tumor. The three dominant drug-resistant sub-populations shared a similar phenotype shown by scRNAseq clusters. The data indicate that the heterogeneity of melanoma is maintained in the early treatment stage but is lost in acquired resistance. And the lineages of DTP cells change continuously under prolonged BRAF/MEKi drug pressure.

#1226 Genomically encoded lineage plasticity drives resistance to EGFR targeted therapy in lung adenocarcinoma.

M. Zatzman, A. Quintanal-Villalonga, S. Salehi, C. Falcon, N. Ceglia, S. P. Shah, C. M. Rudin, H. A. Yu;
Memorial Sloan Kettering Cancer Center, New York, NY

EGFR-mutant lung adenocarcinoma (LUAD) represents 20% of all non-small cell lung carcinomas, with most patients presenting with incurable metastatic disease. Treatment with mutant-selective EGFR tyrosine kinase inhibitor (TKI) therapies such as osimertinib, the current standard of care for metastatic EGFR-mutant LUAD, results in greater overall and progression-free survival. However, all patients eventually relapse. Uncovering the mechanisms driving primary and acquired resistance to osimertinib is therefore critical to improving disease management. Here, we use clinical genomic sequencing (n=47) and single-nucleus RNA (snRNA) sequencing (n=62) to profile a cohort of unmatched treatment-naïve (n=26), on-treatment (n=6), and post-treatment relapsed (n=30) EGFR-mutant LUADs treated with osimertinib. Relapsed tumors are marked by increased tumor mutation burden, along with elevated rates of genome doubling and loss-of-heterozygosity. We derived expression-based signatures of LUAD, lung squamous cell carcinoma (LUSC), and small cell lung carcinoma (SCLC) and applied them to tumor cells across our cohort. Relapsed tumors had a marked decrease in LUAD gene signature expression compared to untreated tumors and accompanying increases in epithelial-mesenchymal transition (EMT) and stemness markers, consistent with dedifferentiation. Notably, tumors harboring secondary mutations to EGFR, MET, or other MAPK pathway genes and showing sustained MAPK signaling retained a more differentiated state. Patients lacking these secondary on-target or bypass mutations were more likely to experience relapse with histological transdifferentiation, marked by complete loss of LUAD signatures, and accompanying increases in LUSC or SCLC signatures. Phenotype matching of tumor cells to normal cells from the developing fetal lung revealed enrichment of airway progenitor populations in non-histologically transformed treatment-resistant patients, in contrast to a proportion of late bud-tip and club-like epithelial cells which predominated in treatment-naïve samples. In rare cases, we observed subpopulations of basal stem-like progenitors in otherwise well-differentiated pre-treatment tumors. In summary, single-cell mapping of histological and developmental phenotypes has revealed divergent evolutionary trajectories during the acquisition of resistance to osimertinib, defined by MAPK signaling reactivation or by loss of LUAD identity and histological transformation respectively.

#1227 Novel combination therapies to overcome non-genetic/adaptive menin inhibitor resistance in AML with MLL1r or mtNPM1.

W. C. Fiskus[1], C. P. Mill[1], J. Piel[2], M. Hentemann[2], C. E. Birdwell[1], K. Das[1], J. A. Davis[1], H. Hou[1], T. M. Kadia[1], N. Daver[1], S. Loghavi[1], B. Cuglievan[1], C. D. DiNArdo[1], K. N. Bhalla[1];

[1]UT MD Anderson Cancer Center, Houston, TX, [2]Foghorn Therapeutics, Cambridge, MA

In AML with MLL1 rearrangement or MLL1 fusion proteins (FP), the N-terminus of MLL1 becomes fused to over 80 partner proteins resulting in an aberrant leukemic transcriptional program including dysregulated expression of HOXA9, MEIS1, PBX3, FLT3, MEF2C and CDK6. On the other hand, in mutant NPM1 AML cells, wild type MLL1 is the main regulator of HOXA9, MEIS1 and FLT3, promoting self-renewal of myeloid progenitor cells. Menin inhibitors have been developed that disrupt the binding of Menin to MLL1 leading to reduced activity of HOXA9 and MEIS1 and repression of MLL1 or MLL1-FP target genes. Clinical trials have demonstrated that Menin inhibitors (MI) are well-tolerated and clinical remissions have been observed in patients with relapsed/refractory AML harboring MLLr. Unfortunately, most patients either fail to respond or eventually relapse. MI-resistance in AML with MLL1r or mtNPM1 is either due to recently described mutations in the MI-binding domain of Menin or is non-genetic/adaptive, due to dysregulated epigenome/transcriptome/proteome. In the present studies, through repeated shocks with LD_{90} dosing of MI, followed by drug washout and recovery, we have generated MLL1r (MV4-11-MITR) and mtNPM1 (OCI-AML3-MITR) AML cell lines that are tolerant/resistant (TR) to MI with LD_{50} values greater than 1 μM. Whole exome sequencing confirmed that these cells were lacking in new driver mutations. We determined that resistance in the MITR cells was not due to presence of hotspot mutations in Menin. ChIP-Seq analysis of H3K27Ac showed that the activities of super enhancers and core transcriptional regulatory circuitry was altered in both MITR cell types. Non-genetic/adaptive resistance to MI also concordantly reduced genome wide ATAC-Seq and RNA-Seq peaks in the OCI-AML3-MITR cells with significant depletion of MEIS1, IGF2BP2, BCL2, and PBX3, with concomitant induction of leukemia stem cell associated CLEC12A and CD244 expressions. A domain-specific CRISPR screen in MV4-11-MITR cells identified several druggable co-dependencies (e.g. EP300 and MOZ) and co-enrichments (SMARCA4, CREBBP and BRD4) with MI, suggesting them as potential mechanisms of non-genetic/adaptive MI resistance. Consistent with these findings, co-treatment with SMARCA2/SMARCA4 (chromatin remodeler ATPases) inhibitor FHD-286 and the BETi OTX015 or the MI SNDX-50469 exerted synergistic lethality in MV4-11-MITR and OCI-AML3-MITR cells as well as in PD MITR AML cells with MLL1r or mtNPM1. Co-treatment with CBP/p300 inhibitor GNE049 or GNE781 was also synergistic with MI in these cells. In vivo treatment with FHD-286 and OTX015 or SNDX-5613 significantly reduced the AML burden in mice bearing OCI-AML3-MITR xenografts. These findings underscore preclinical activity of epigenetically-targeted agent-based combinations and highlight their promise in overcoming MI resistance in AML with MLL1r or mtNPM1.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Novel Antitumor Agents 1

#1228 Selective FGFR4 inhibitor Irpagratinib (ABSK011) exhibits broad synergistic and combinatory anti-tumor effects with other therapeutic agents in preclinical HCC models.

N. Zhang, B. Shen, Z. He, C. Dai, J. Wang, J. Zhang, M. Liu, Y. Zhang, Z. Chen;
Abbisko Therapeutics Co., Ltd., Shanghai, China

Background: Hepatocellular carcinoma (HCC) is the most common primary liver cancer, ranking as the sixth most prevalent cancer and the third leading cause of death worldwide. Approved therapeutic drugs, including chemotherapy, anti-angiogenesis agents and immunotherapy-based combination regimen (atezolizumab plus bevacizumab), have shown suboptimal clinical benefits for patients with HCC. There are critical unmet medical needs for additional therapeutic options to address this challenge. Deregulation of FGF19-FGFR4 signaling accounts for roughly 30% of HCC and plays a pivotal role in driving HCC tumorigenesis. To date, several FGFR4 inhibitors have advanced to the clinical stage for the treatment of HCC patients. Among them, a recently discovered novel and highly selective inhibitor, Irpagratinib (ABSK011), has demonstrated the potential to become a first-in-class or best-in-class FGFR4 inhibitor. It showed promising anti-tumor activity in an ongoing phase Ib clinical study, with an ORR of 40.7% observed in FGF19 overexpressed late line HCC patients in cohorts treated with BID regimens. To further expand the therapeutic potential of irpagratinib, we carried out an array of combination treatments and revealed its broad synergistic effects with various immune and targeted agents in treating HCC.
Methods: We evaluated the combination effects of Irpagratinib with a variety of therapeutic agents, covering both targeted and immune-oncology agents, in preclinical HCC *in vivo* models. The tested agents, including lenvatinib, atezolizumab plus bevacizumab, anti-PD-(L)1, SHP2 inhibitors and EGFR antagonists, were assessed across a range of preclinical models, such as cell-derived or patient-derived xenografts, engineered syngeneic models and humanized models.
Results: Synergistic anti-tumor effects of irpagratinib were observed in combination with the indicated agents, demonstrating more profound effects than either single agent alone in the selected preclinical *in vivo* models. This resulted in significant effects on inducing tumor regression or inhibiting tumor progression.
Conclusions: In summary, these findings collectively illustrate very broad synergistic anti-tumor effects of irpagratinib when combined with various other therapeutic agents. These results may pave the road for potential novel combinatory therapeutic strategies that could expand the utility of irpagratinib and provide innovative and more effective therapies to HCC patients.

#1229 BDTX-1535: A MasterKey EGFR inhibitor targeting classical and non-classical oncogenic driver mutations and the C797S acquired resistance mutation to address the evolving molecular landscape of EGFR mutant NSCLC.

E. Dardenne[1], M. O'Connor[1], M. Nilsson[2], J. He[2], X. Yu[2], J. V. Heymach[2], X. Le[2], E. Buck[1];
[1]Black Diamond Therapeutics, Cambridge, MA, [2]MD Anderson Cancer Center, Houston, TX

The molecular landscape of EGFR mutated NSCLC has evolved over time in response to changing treatment practices with EGFR inhibitors and through the expanding use of NGS. With the replacement of first-generation reversible EGFR tyrosine kinase inhibitors (TKIs) by the third generation covalent TKI osimertinib as front-line therapy for patients with NSCLC expressing classical EGFR mutations, acquired resistance mutations have shifted with the near disappearance of EGFR-T790M and the emergence and growing incidence of EGFR-C797S. Our understanding of the EGFR mutation landscape has also continued to mature with comprehensive sequencing across all EGFR exons and with the vast majority of patients now undergoing sequencing. We now see how classical oncogenic drivers represent only a subset of oncogenic EGFR driver mutations and where other non-classical driver mutations are numerous and represent a major unmet medical need. Furthermore, there is a growing appreciation of the differences between the classical EGFR-L858R and EGFR-Ex19 deletion (Ex19del) mutations. For patients expressing L858R, many co-express non-classical drivers and this may explain the weaker relative activity for osimertinib in patients expressing L858R versus Ex19del. For patients expressing Ex19del, the co-expression of non-classical mutations is less common. In contrast, patients with Ex19del more often gain C797S as an acquired resistance mutation. Using the Foundation Medicine's FoundationInsights™ web-based platform, we present real world evidence (RWE) to define the molecular landscape of classical, non-classical, and acquired resistance mutations from a survey of >80,000 sequenced cases of NSCLC, including >12000 EGFR altered cases. We further present the profile for BDTX-1535 as a MasterKey EGFR inhibitor designed to address this evolved EGFR mutational landscape and tested against over >50 EGFR mutations. We also show how BDTX-1535 can address classical EGFR mutations in addition to on target mechanisms of resistance post osimertinib with potency against C797S as well as non-classical mutations affecting both the intracellular and extracellular domains, including L718X, E709X, S784F, V834L and A289V.

#1230 MTX-531, a first-in-class pan-PI3K inhibitor spares hyperinsulinemia yielding durable tumor regressions and resilience to adaptive resistance.

C. E. Whitehead[1], E. K. Ziemke[2], C. L. Frankowski-McGregor[2], R. A. Mumby[2], J. Chung[2], J. Li[3], N. Osher[3], O. Coker[4], M. Norris[5], S. Kopetz[4], V. Baladandayuthapani[3], M. Hollingshead[5], S. Verma[5], **J. S. Sebolt-Leopold**[2];

[1]Mekanistic Therapeutics, Inc., Ann Arbor, MI, [2]University of Michigan Medical School, Ann Arbor, MI, [3]University of Michigan School of Public Health, Ann Arbor, MI, [4]MD Anderson Cancer Center, Houston, TX, [5]NCI, Rockville, MD

Adaptive resistance mechanisms compromise the long-term effectiveness of kinase-targeted agents dictating the need for strategic combination approaches. MTX-531 was computationally designed to selectively target both PI3K and wild type EGFR. MTX-531 exhibits low nanomolar potency against the PI3K isoform family and EGFR with a high degree of specificity predicted by co-crystal structural analyses. Full kinome screening confirmed that MTX-531 is exquisitely selective for its intended targets. We evaluated the pharmacological profile of MTX-531, whereupon single agent treatment with this lead molecule elicited a high incidence of durable tumor regressions in a broad panel of PIK3CA mutant CDX and PDX squamous head and neck (HNSCC) models. The combination of MTX-531 with RAS pathway inhibitors, including agents directed against KRAS G12C, led to durable regressions of KRAS mutant colorectal and pancreatic xenografts, resulting in striking increases in median survival. MTX-531 is exceptionally well tolerated in mice and uniquely does not lead to hyperglycemia and hyperinsulinemia commonly seen with predecessor pan PI3K inhibitors. MTX-531 acts as an agonist of PPARγ, a structural feature of the molecule that is thought to mitigate hyperglycemia induced by PI3K inhibition. This unique attribute of MTX-531 confers a favorable therapeutic index not typically seen with PI3K inhibitors. To the best of our knowledge, MTX-531 is the first reported pan-PI3K inhibitor that does not lead to hyperglycemia. The pharmaceutical profile of MTX-531 includes favorable cross-species oral bioavailability, microsomal stability, and a facile 3 step chemical synthesis. MTX-531, which has the unique capability of concurrently and selectively inhibiting PI3K and EGFR, illustrates the power of rational computational drug design to target multiple adaptive resistance mechanisms in a single molecule. The versatility of MTX-531 in both the single agent and combination settings offers a breadth of development strategies that continue to evolve as new combination candidates become available. MTX-531 is currently undergoing advanced preclinical development for anticipated first in human clinical trials in late 2024.

#1231 First-in-class AR-V7/AR-fl small molecule molecular glue degrader for prostate cancer treatment.

C. C. Au[1], C. Estrella[1], P. Vatsa[1], M. Naidoo[1], M. Miller[2], P. T. Meinke[2], D. M. Nanus[3], P. Giannakakou[3];
[1]Weill Cornell Medicine, New York, NY, [2]Tri-Institutional Therapeutics Discovery Institute, New York, NY, [3]Meyer Cancer Center, Weill Cornell Medicine, New York, NY

Metastatic castration resistance prostate cancer (mCRPC) is a lethal disease due to the development of treatment to androgen receptor (AR) signaling inhibitors (ARSi) and taxane chemotherapy. Treatment resistance occurs partly due to the expression of AR splice variants that lack the ligand binding domain (LBD) and are constitutively active in the nucleus. AR-V7 is the most prevalent variant conferring clinical resistance to both ARSi and taxanes. Currently, there is no selective AR-V7 inhibitor leaving patients with limited therapeutic options. Thus, the development of selective AR-V7 inhibitors is a high priority, clinically unmet need. To identify AR-V7 pharmacologic inhibitors, we performed a high throughput small molecule phenotypic screen using enzymatic complementation and nuclear AR-V7 as the assay endpoint. Our primary screen of ~170K compounds (z score = 0.8), followed by a cell-toxicity counter screen and a secondary GFP screen identified hit **compound 7907**, **as a dual AR-V7/AR-fl protein degrader**, with unique chemotype compared to all known AR modulators. Hit to lead optimization by medicinal chemistry/SAR studies identified **lead compound 15,** with increased potency compared to 7907. Mechanistically, we showed that compound **15** shortened AR-V7 protein half-life by activating the ubiquitin-proteasome pathway and inducing proteasomal degradation of both AR-V7/AR-fl, without affecting their transcription. Importantly, compound **15** induced degradation occurred within 3hr of treatment and was blocked by the clinically approved proteasome inhibitor, bortezomib. TurboID proximity ligation assay identified distinct E3 ligases, uniquely interacting with AR-V7 or AR-fl. Using AR-V7/AR-fl deletion mutants we further showed that compound **15** activity is mediated by the N-terminal domain of AR, present in both proteins. Remarkably, compound **15** sensitized LNCaP95 cells (endogenous AR-V7/AR-fl expression) to enzalutamide suggesting potential therapeutic synergism and ability to reverse enzalutamide resistance. Ongoing studies aim to narrow down the binding site of compound **15** as well as identify the E3 ligases mediating its activity. Together, these data support a molecular glue degrader mechanism of action, consistent with published studies showing that molecular glue degraders are ideal for targeting classically “undruggable” proteins lacking an LBD or containing intrinsically disordered domains, as is the case for AR-V7. Currently, all AR-directed therapies target the LBD of AR-fl, inhibiting AR signaling. AR-V7 expression is a direct outcome of this inhibition, leading to AR-fl and AR-V7 co-expression in patient tumors. We posit that our drug candidate, by offering **dual AR-V7/AR-fl inhibition in a single treatment**, has the potential to not only benefit patients with mCRPC but also patients with hormone-sensitive disease, and delay AR-V7 expression.

#1233 Novel inhibitor targeting triple integrated stress response kinase HRI, PERK, and GCN2 provides new insights into overcoming resistance to proteasome inhibitors in multiple myeloma.

Y. Inoue[1], K. Hikami[2], S. Ebara[2], M. Sugiyama[2], R. Oda[2], A. Mizutani[2], M. Yoshida[2], H. Yamakawa[2], S. Yagishita[3], A. Hamada[3], H. Hayashi[1], M. Ri[4], S. Iida[4], **D. Morishita[2]**;

[1]Nagoya City University, Nagoya, Japan, [2]Chordia Therapeutics Inc., Fujisawa, Japan, [3]National Cancer Center Research Institute, Tokyo, Japan, [4]Nagoya City University Graduate School of Medical Sciences, Nagoya, Japan

The introduction of novel treatments for Multiple myeloma (MM), particularly proteasome inhibitors (PI) such as bortezomib (BTZ), has greatly improved outcomes. However, many patients eventually experience relapse. Therefore, new approaches for managing patients with resistance to PI should be explored. The integrated stress response (ISR) is an evolutionarily conserved intracellular signaling network that is activated in response to both intrinsic and extrinsic stresses. Stresses are sensed by four specialized kinases: HRI, PERK, PKR, and GCN2, which converge on the phosphorylation of eIF2α. This phosphorylation triggers the translation of ATF4, thus promoting cell survival and homeostasis. Recent studies investigating the contribution of the four ISR kinases in overcoming resistance to PI treatment, have revealed the potential of a selective GCN2 inhibitor to overcome this resistance. Here, we observed that PI simultaneously induced mitochondrial stress, ER stress, and amino acid starvation, leading to the activation of HRI, PERK, and GCN2, respectively. However, the contribution of crosstalk among ISR kinases has not been considered thus far. To gain a comprehensive understanding of ISR kinases in BTZ resistance, we generated single or combination patterns of double and triple KO of the four ISR kinases and reevaluated their contribution to BTZ treatment. Sensitivity screening using the HAP1 single, double, and triple KO cell library showed that HRI primarily, and to a lesser extent, PERK and GCN2, contribute to BTZ resistance. Consistent with the HAP1 KO screening, MM cell line-derived KO cells revealed a similar dependency on these three kinases. Building upon our observation of the significance of the HRI/PERK/GCN2 triple kinase, we developed a novel and orally available small molecule, CRD-1367799, which inhibits these triple kinases in cells. CRD-1367799 effectively dampened the activity of these ISR kinases, leading to a complete inhibition of eIF2α phosphorylation and ATF4 activation. Additionally, we observed a distinct anti-growth effect when combined with BTZ in vitro and in vivo, which was not replicated by the GCN2 or PERK-selective inhibitor. Furthermore, we uncovered the mechanism of cell death induction in combination with proteasome inhibitors. Notably, the apoptosis inducers NOXA and CHOP were upregulated, but the mechanism did not seem to rely on previously known processes such as ATF4-mediated transcriptional induction. In summary, our novel findings on the contribution of the triple ISR kinase provides us with new insights for overcoming resistance to proteasome inhibitors with HRI/PERK/GCN2 inhibitor. To the best of our knowledge, the use of a triple kinase inhibitor in this context has not been reported thus far, making CRD-1367799 a new therapeutic strategy for MM with PI.

IMMUNOLOGY: Tumor-Targeted Immune Cell Engagers
Minisymposium

#1235 Impact of anti-CD3 and tumor-target binder affinities on *in-vitro* potency, *in-vivo* efficacy, and cytokine release.

O. Abdelmotaleb[1], A. Schneider[1], T. Hofer[1], J. Sam[1], M. Lechmann[2], I. Waldhauer[1], A. Bransi[1], M. Eigenmann[3], A. Freimoser-Grundschober[1], C. Gassner[2], A. Odermatt[4], P. Brunker[1], S. Colombetti[1], C. Klein[1];
[1]Roche Innovation Center Zurich, Schlieren, Switzerland, [2]Roche Innovation Center Munich, Penzberg, Germany, [3]Roche Innovation Center Basel, Basel, Switzerland, [4]University of Basel, Basel, Switzerland

Background: First generation T cell bispecifics (TCBs) were developed by utilizing high CD3 and tumor target binder affinities to induce a potent response. Instrumentalizing this, TCBs have clinically proven to elicit efficacious target cell killing and anti-tumor efficacy, but they encountered hurdles related to cytokine release. Recent studies suggested that reducing CD3 binder affinity could lead to an efficient tumor killing with lower cytokine levels. However, the answer to whether cytokine release is mainly dependent on CD3 binder affinity or a multifactorial phenomenon remains ambiguous. Here, we aim to characterize the efficacy-safety relationship of different TCBs through investigating the interplay between CD3 binder affinity and the affinity of the tumor target-specific binder. For that purpose, a series of TCBs with varying CD3 affinities, and two target binders of high and low affinities were generated in the 2:1 TCB format, resulting in a bivalent binding to the tumor antigen and a monovalent one to CD3, which offers a unique opportunity to enhance the activity of TCBs.
Methods: Firstly, 2:1 TCBs comprising either the high or low affinity target binder and varying CD3 binder affinities were co-cultured *in-vitro* with human peripheral blood mononuclear cells (PBMCs), and human tumor cell lines, in order to assess T cell mediated cytotoxicity and cytokine release at different time points. Additionally, the impact on *in-vivo* efficacy, cytokine release, and pharmacokinetics was assessed in humanized mice implanted with a patient-derived xenograft model.
Results: Based on the dose-response in the cytotoxicity assay, the CD3 binders were classified into high, intermediate, and low levels of affinity. As expected, we observed that the *in-vitro* T cell cytotoxicity, *in-vivo* tumor growth inhibition (TGI), and cytokine release levels were maximal with the highest affine CD3 binder. Simultaneously, we have observed a decrease in cytotoxicity response with decreasing CD3 affinity compared to the high affinity binder. However, this was accompanied by an atypical decrease in cytokine release. Particularly, the TCB comprising the intermediate CD3 affinity binder illustrated a comparable *in-vitro* cytotoxicity and *in-vivo* TGI to the high affinity binder with a marked decrease in cytokine release [4x reduction *in-vitro* and 6x reduction *in-vivo*]. Upon testing the TCBs comprising the low affinity target binder with the same CD3 binders, we observed an additional decrease in cytokine release with the decreasing CD3 affinity.
In conclusion, we designed and generated TCBs with varying affinities in both the CD3 and target binding arms. Reducing cytokine release while maintaining adequate efficacy is feasible through CD3 binder affinity attenuation; however, the target binder affinity should be taken into consideration when interpreting our findings and designing new molecules.

#1236 Characterization of CBX-250, a first-in-class TCR-mimetic-based T-cell engager targeting a cathepsin G peptide-HLA complex for the treatment of myeloid leukemia.

G. Paulus[1], B. Lee[1], P. Sankaran[1], T. Rahman[1], J. Jimenez[1], D. O'Connor[1], S. Yue[1], Y. Huang[1], M. Bikowitz[1], S. Jaffe[1], S. O'Malley[1], B. Ban[1], G. Gabriely[1], T. Wang[1], A. Mak[1], M. Princiotta[1], C. Shi[2], H. He[2], N. Feng[2], J. Yan[2], T. Heffernan[2], G. Alatrash[2], J. Molldrem[2], D. Wiederschain[1];
[1]Crossbow Therapeutics, Inc., Cambridge, MA, [2]The University of Texas MD Anderson Cancer Center, Houston, TX

While T-cell engaging therapies have demonstrated clear clinical benefit in the treatment of B-cell malignancies, their application to myeloid malignancies remains a challenge due to the limited repertoire of suitable tumor specific surface antigens. Targeting HLA-restricted peptides (pHLA) derived from intracellular cancer antigens provides an opportunity to explore the entire cancer proteome. CG1 (FLLPTGAEA) has been validated as an HLA-A*02:01 restricted leader peptide from Cathepsin G (CTSG) and is abundantly presented by leukemic versus normal myeloid cells. TCR-mimetic (TCRm) antibodies are ideally suited to target pHLA with high potency and specificity and can be engineered and manufactured using standard antibody technologies. Here we report the preclinical characterization of CBX-250, a novel CG1/HLA-A2 TCRm-CD3 bispecific T-Cell Engager (TCE).

CBX-250 induced potent T-cell activation and T-cell mediated killing of leukemia cell lines with varying levels of target antigen density with sub-nM EC50 *in vitro*. *In vivo*, a closely related precursor of CBX-250 demonstrated potent tumor control in various AML and CML CDX models at doses as low as 0.01mpk.

Although CTSG is a serine protease stored in neutrophil azurophilic granules, the CG1 peptide is preferentially presented by leukemia cells, as validated by mass spectrometry. Moreover, when co-culturing PBMCs with HLA-A2 neutrophils, we did not observe any CBX-250-mediated T-cell activation or IFNγ production.

In silico predictions identified HLA-A2-restricted human peptides that share sequence or structural similarity to CG1. We determined the cross-reactivity risk of CBX-250 to be low, based on T-cell activation and T-cell mediated cytotoxicity assays against cells pulsed with supra-physiological concentrations of these peptides. Moreover, we observed no activity against target-negative cancer cells, including a CTSG-KO cell line. To further assess the specificity of CBX-250, we screened a panel of normal cells and found no meaningful T-cell activation or IFNγ production at CBX-250 concentrations exceeding its EC90. Finally, the CBX-250 precursor molecule demonstrated favorable safety in a double transgenic mouse model expressing human HLA-A2 and CG1.

Following sequence optimization, CBX-250 demonstrated robust serum and pH stress stability and a favorable melting temperature, while retaining excellent potency and specificity. A full suite of analytical and biophysical assessments supports CBX-250's favorable developability profile.

In summary, these data provide strong preclinical evidence of the potency, specificity, safety, and developability of CBX-250, a novel, first-in-class, off-the-shelf, TCRm-based TCE for the treatment of myeloid malignancies.

#1237 IGM-2644, a CD38xCD3 bispecific IgM T cell engager, shows enhanced anti-tumor activity compared to daratumumab in preclinical models of multiple myeloma.

K. C. Hart, D. Santos, K. Li, R. Yun, M. Chai, A. Kabai, G. Li, P. Yakkundi, R. P. Funke, Y. Guan, T. Manley, L. Liu, A. M. Sinclair, A. F. Candia, B. Keyt, M. F. Kotturi;
IGM Biosciences, Inc., Mountain View, CA

Multiple myeloma (MM) is a hematologic malignancy characterized by the accumulation of monoclonal plasma cells in the bone marrow. CD38 is an attractive therapeutic target for MM due to its high expression on plasma cells, but it is also expressed on multiple subsets of normal immune cells. Approved therapies including anti-CD38 monoclonal antibodies such as daratumumab are available, however resistance inevitably develops, and toxicities such as reduced immune cell counts put patients at increased risk for infections. To address this and other issues associated with current therapies, we are developing IGM-2644, an engineered high affinity, high avidity bispecific anti-CD38xCD3 IgM T cell engager (TCE) antibody for the treatment of plasma cell disorders. IGM-2644 kills CD38-expressing tumor cells through complement-dependent cytotoxicity (CDC) and T cell-dependent cellular cytotoxicity (TDCC). Live cell imaging of tumor cells in the presence of normal human serum as a source of complement has shown that IGM-2644, compared to daratumumab, has exhibited superior CDC with faster kinetics and higher maximal killing, as well as increased activity on tumor cell lines that express low levels of CD38. IGM-2644 also has displayed enhanced cellular dependent cytotoxicity over daratumumab across tumor cell lines with a range of CD38 expression levels in vitro. In ex vivo assays with MM patient bone marrow mononuclear cells (BMMC), IGM-2644 has shown superior tumor cell depletion compared to daratumumab even with low T cell to tumor cell ratios. Furthermore, IGM-2644 can deplete tumor cells in BMMC from daratumumab-refractory MM patients. Similarly, using in vivo humanized xenograft tumor mouse models with various levels of CD38 expression, greater anti-tumor activity with IGM-2644 over daratumumab was observed. When compared to daratumumab, IGM-2644 demonstrated lower immune cell fratricide in an in vivo xenograft tumor mouse model, suggesting a potentially differentiated safety profile. In summary, IGM-2644 is a bispecific anti-CD38xCD3 IgM TCE antibody that demonstrates superior tumor cell killing when compared to daratumumab in vitro and especially in xenograft tumor models in vivo with low CD38 expression while having low immune cell depletion, potentially reducing the risk of infections. The safety and efficacy of IGM-2644 has been initially studied in a phase 1 clinical trial for relapsed/refractory (r/r) MM. Applicability of IGM-2644 for the treatment of other plasma cell disorders is currently being explored, including autoimmune diseases.

#1238 ISB 2001, a BCMA and CD38 dual targeting T cell engager, demonstrates superior cytotoxicity relative to teclistamab in the samples of patient relapsing from CD38 and BCMA targeted immunotherapies.

L. Carretero-Iglesia[1], M. Pihlgren[1], J. Berret[1], A. Drake[1], D. Pais[1], C. Dreyfus[1], V. Menon[2], T. Matthes[3], C. Edwards[4], J. Edwards[4], C. Pellat-Deceunynck[5], P. Moreau[6], C. Touzeau[6], T. Matsuura[7], P. van der Graaf[7], L. Pacaud[2], C. Konto[2], E. Zhukovsky[1], **M. Perro**[1];

[1]Ichnos Sciences Biotherapeutics SA, Epalinges, Switzerland, [2]Ichnos Sciences Biotherapeutics SA, New York, NY, [3]University Hospital Geneva, Geneve, Switzerland, [4]University of Oxford, Oxford, United Kingdom, [5]Nantes Universite, Nantes, France, [6]Service d'Hematologie Clinique, Unite d'Investigation Clinique, Nantes, France, [7]Certara UK Limited, Canterbury, United Kingdom

Immune therapies targeting single tumor associated antigens (TAA) demonstrated efficacy against multiple myeloma (MM). However, durable responses are still limited[1] potentially due to expansion of clones with low target expression[2] We have previously demonstrated that simultaneous targeting of BCMA and CD38 on MM tumor cells with heterogenous expression of these antigens using dual targeting ISB 2001, enables superior killing relative to mono-targeting T cell engagers (TCE) [3]. Here we present a further characterization of a dual targeting TCE utilizing bone marrow aspirates from multiple myeloma patients. In relapsed/refractory (r/r) patients, which received CD38 targeted therapy, daratumumab cytotoxicity was substantially reduced due to low CD38 expression. Teclistamab is considered the next line of treatment in such patients. However, ISB 2001 consistently demonstrated increased cytotoxicity compared to teclistamab in both newly diagnosed patient and r/r patient samples. Remarkably, ISB 2001 also induced stronger cytotoxic response in one patient relapsing after BCMA targeted therapy, suggesting that the dual targeting ISB 2001 TCE can overcome the escape mechanisms. ISB 2001 was also compared to the combination of teclistamab and daratumumab in cytotoxic assay using healthy donors. ISB 2001 shows superiority to both teclistamab and daratumumab as single agents, as well as when they were used in combination. Additionally, ISB 2001 was compared against a combination of daratumumab and teclistamab in a humanized mouse model of multiple myeloma with a low expression of both CD38 and BCMA, mimicking potential tumor escaping clones. ISB 2001 induced complete eradication of the tumors in almost all animals, whereas the combination only showed partial tumor protection, underscoring that dual targeting by a TCE is superior to two therapeutic agents individually targeting the same antigens. Based on the promising preclinical in vitro, ex vivo and in vivo data, we have advanced ISB 2001 into clinical studies. For calculating the first-in-human (FIH) dose, we have developed a quantitative systems pharmacology (QSP) model. The calculated FIH dose was 50-100 fold higher than that generated by a traditional minimum anticipated biological effect level calculation. Therefore, using this approach will substantially reduce patient exposure to sub-efficacious doses of ISB 2001. This plan was accepted by the HREC in Australia and the FDA in the US to initiate a Phase 1 FIH study of ISB 2001 for the treatment of relapsed/refractory multiple myeloma (NCT05862012)[4].

Background: Claudin-6 (CLDN6), one of over 20 known human CLDN family members, is upregulated in many solid tumors but shows minimal or no expression in healthy adult tissues. This makes it an ideal target for cancer therapy. Although several therapeutic modalities targeting CLDN6 are currently under investigation—including T cell engagers (TCE), CAR-T, and antibody drug conjugates—a more potent therapeutic option is still desirable. TCEs are a promising avenue within cancer immunotherapy, but their current efficacy and safety must be improved, particularly against solid tumors.

Methods and Results: To enhance immune activation and achieve successful clinical outcomes against solid tumors expressing CLDN6, we generated SAIL66, a CLDN6-targeting next generation TCE, using a new technological format called Dual-Ig®. SAIL66 is a tri-specific monoclonal antibody designed to bind to CLDN6 on cancer cells with one Fab arm and to both CD3 and CD137 with the other Fab arm. The preclinical characterization of SAIL66 was performed in a series of in vitro and in vivo studies which included comparisons to a conventional TCE targeting CLDN6 and CD3. SAIL66 demonstrated high specificity for CLDN6 despite its similarity to CLDN3, CLDN4, and CLDN9, suggesting a lack of off-target toxicity in patients. Using a Jurkat cell system harboring NFAT or NF-κB reporter genes, we confirmed that SAIL66 exerts CD3 and CD137 signal induction activity depending on CLDN6 expression. SAIL66 induced activation of T cells, release of cytokines, and lysis of CLDN6-positive cancer cells. In vivo studies with a humanized mouse (huNOG) model showed that SAIL66 had better anti-tumor efficacy in eliminating CLDN6-positive cancer cells than a conventional TCE. Flow cytometry analysis in the huNOG model revealed that SAIL66 also more significantly increased CD3+ T cell infiltration of tumor tissue and resulted in a smaller percentage of exhausted T cells in tumor. Moreover, transcriptome analysis in the huNOG model showed that both SAIL66 and the conventional TCE increase expression of genes associated with immune activation, with a durable increase observed especially with SAIL66. Further, we clarified that T cells repeatedly stimulated with SAIL66 had a greater ability to inhibit the growth of CLDN6-positive cancer cells than T cells stimulated with the conventional TCE in vitro.

Conclusion and Discussion: Our study shows that SAIL66 has better anti-tumor efficacy against CLDN6-positive cancer cells than a conventional TCE. This is due to effective immune activation by SAIL66 which triggers CD3 signaling (signal 1) combined with CD137 co-stimulatory signaling (signal 2) in T cells. Thus, SAIL66 represents a promising therapeutic option for solid tumors expressing CLDN6. A clinical trial for CLDN6-positive cancer patient is now ongoing (NCT05735366).

#1240 Enhancing NK cell function in the 'cold' tumor microenvironment of prostate cancer with a novel tri-specific killer engager.

S. Phung, Y. Soignier, N. Zorko, R. L. Waller, J. Walker, T. Nelson, C. Selleck, L. Bendzick, P. Kennedy, J. S. Miller, M. Felices;
University of Minnesota, Minneapolis, MN

Introduction: Natural killer (NK) cells are associated with good prognosis in patients with metastatic castration-resistant prostate cancer (mCRPC). However, NK cell function is hindered in the immunosuppressive and hypoxic tumor microenvironment (TME) of mCRPC. To improve NK cell-mediated responses against mCRPC, we designed a novel Tri-specific Killer Engager (TriKE®) that engages with NK cell activating receptor CD16, binds to prostate-specific membrane antigen (PSMA) that is highly and specifically expressed on mCRPC, and has an interleukin (IL)-15 moiety that is essential for NK cell survival, proliferation, and priming.

Methods: PSMA TriKE was produced using the mammalian expression system and tested using healthy donor and prostate cancer patient-derived NK cells. Flow cytometry-based functional and dye dilution proliferation assays were used to compare activation and proliferation of NK cells treated with PSMA TriKE or IL-15. NK cell cytolytic capacity against C4-2 cells, a PSMA-expressing prostate cancer line, was measured using IncuCyte live cell imaging. In various assays, hypoxic (1% oxygen) culture condition and cytokine-induced myeloid-derived suppressor cells (MDSC) were incorporated to better examine PSMA TriKE function in the physiological setting of mCRPC. In vivo testing of the PSMA TriKE was performed using C4-2 xenograft model and expanded NK cells in NSG mice.

Results: PSMA TriKE significantly enhanced expansion of peripheral blood NK cells derived from healthy donors up to 8-fold. Additionally, PSMA TriKE induced significantly higher NK cell degranulation and intracellular IFNγ and TNFα buildup, when compared to IL-15 treatment, after incubation with C4-2 cells. Responses of NK cells derived from prostate cancer patients were equivalent to healthy controls. Although NK cell activation was not observed against PSMA knockout (KO) C4-2, indicating specificity of PSMA TriKE treatment, bystander killing of PSMA-KO C4-2 was achieved with PSMA TriKE treatment when wildtype C4-2 cells were cocultured. This suggests potential PSMA TriKE benefit in controlling tumor antigen escape, through natural cytotoxicity once primed. In settings that mimic the TME of mCRPC, NK cells treated with PSMA TriKE in prolonged exposure to hypoxia showed retention of cytotoxicity against C4-2 while IL-15 treated NK cells showed greatly impaired cytotoxicity. Similarly, MDSC suppressed NK cell cytotoxicity in the presence of IL-15, but PSMA TriKE treatment abrogated MDSC-induced suppression. Finally, PSMA TriKE enhanced tumor control and improved survival of mice as compared to IL-15 and no treatment groups in vivo.

Conclusion: PSMA TriKE demonstrates potential in overcoming suppression of NK cells in the TME of mCRPC and is a promising candidate for advanced prostate cancer therapy.

#1241 Enhancing NK cell therapy for head and neck cancer within the solid tumor microenvironment using a B7H3-targeting tri-specific killer engager (TriKE).

M. Khaw[1], N. A. Zorko[1], C. Selleck[1], L. Bendzick[1], Z. Davis[1], P. Hinderlie[1], M. Shackelford[1], A. Lu[2], J. Lim[2], N. Fujioka[1], M. MacMillan[1], J. Wagner[1], M. Felices[1], J. S. Miller[1];

[1]University of Minnesota, Minneapolis, MN, [2]Xcell Biosciences, San Francisco, CA

With an annual incidence rate exceeding 660,000 cases, and a death toll surpassing 325,000 per year, head and neck cancer (HNC) ranks as the seventh most common cancer in the world. Surgery, radiation and chemotherapy are used to treat HNC patients with modest and variable clinical success. However, these treatments prove less effective for human papillomavirus negative (HPV-) HNC patients, a subset of HNC patients with markedly worse prognosis. While significant advancements have been made in cancer immunotherapy over the past decade, its success also remains elusive for HNC due to factors such as the hypoxic solid tumor microenvironment (TME). To address the critical need for an improved therapeutic intervention, we leveraged the ability of natural killer (NK) cells in killing cancer cells without prior sensitization by developing a novel tri-specific killer engager (TriKE) that can direct NK cell killing of tumor within the hypoxic solid TME. The TriKE is composed of three domains: a humanized nanobody arm binding the activating receptor CD16 on NK cells, an interleukin (IL)-15 moiety that can drive expansion of NK cells, and a nanobody arm binding B7H3, a protein which high expression can be negatively correlated with overall survival of HPV- HNC patients. B7H3 is a prime target candidate because it is highly expressed on HPV- HNC cells, but minimally expressed on healthy tissues. *In vitro* testing using HPV- HNC patient blood samples revealed that B7H3 TriKE enhances activation (measured by NK cell degranulation and interferon-gamma production) and expansion of NK cells from these patients at levels equivalent to those observed in healthy controls. Furthermore, B7H3 TriKE is efficacious in its ability to drive high NK cell cytotoxicity in both acute (<48-hours) and prolonged (7-days) hypoxic (1% oxygen) models of HNC. Under acute hypoxia, B7H3 TriKE induces significantly more killing of targets by NK cells compared to IL-15 treatment, where NK cell cytotoxicity is impaired. In addition, B7H3 TriKE can boost the killing efficacy of NK cells exposed to prolonged hypoxia, surpassing limitations seen with IL-15 treatment. These findings strongly suggest that the B7H3 TriKE can bypass hypoxic suppression of NK effector functions in the solid TME. *In vivo* studies using immunocompromised mice engrafted with HPV- HNC cells revealed that B7H3 TriKE treatment significantly extends the survival of mice, compared to IL-15 treatment. Moreover, NK cells persisted in the blood of B7H3 TriKE-treated mice 28 days post-NK cell injection, highlighting the promising clinical translation of this immunotherapy. More in-depth characterization of NK cells from HPV- HNC patients are underway but altogether, these robust pre-clinical data present a novel avenue for the management of HNC for these patients. We plan to translate results from these studies to clinical trials in fall 2024.

MOLECULAR/CELLULAR BIOLOGY AND GENETICS: Cancer Epigenetics
Minisymposium

#1242 Foxa1/2-dependent epigenomic reprogramming drives lineage switching in lung adenocarcinoma.
K. Gillis, W. Orellana, E. Wilson, G. Fort, H. Essel Dadzie, T. Parnell, X. Zhang, E. Snyder;
University of Utah Huntsman Cancer Institute, Salt Lake City, UT

The ability of cancer cells to alter their identity is essential for tumor survival and progression. Loss of the pulmonary lineage specifier NKX2-1 within KRAS-driven lung adenocarcinoma (LUAD) enhances tumor progression and results in a pulmonary-to-gastric lineage switch that is dependent upon the activity of pioneer factors FoxA1 and FoxA2; however, the underlying mechanism remains largely unknown. Here, we perform transcriptional and epigenetic assays to show that FoxA1/2 reprogram the chromatin landscape of NKX2-1-negative LUAD to facilitate a gastric differentiation program. Using sequential recombination models, we find that FoxA1/2 are required for demethylation of gastric-defining genes after *Nkx2-1* deletion. FoxA1 colocalizes with TET3, an enzyme that mediates DNA demethylation, in NKX2-1-negative tumors. Deletion of *Foxa1/2* results in loss of TET3 occupancy at key gastric marker genes, indicating that FoxA1/2 recruit TET3 to lineage-specific sites. H3K27ac ChIP-seq and HiChIP show that FoxA1/2 also control the activity of enhancers and promoters as well as their 3D interactions at gastric target genes following NKX2-1 loss. Furthermore, oncogenic KRAS is required for the FoxA1/2-dependent epigenetic reprogramming in NKX2-1-negative LUAD. This work demonstrates the role of FoxA1/2 in rewiring the methylation and histone landscape and cis-regulatory dynamics of NKX2-1-negative LUAD to drive cancer cell lineage switching.

#1243 Shifted mSWI/SNF complex assembly and function underlie therapeutically targetable dependencies in endometrial carcinoma.

Jessica Diane St. Laurent[1], Grace Xu[2], Alexander Ying[2], Bengul Gokbayrak[3], Ajinkya Patil[2], Akshay Sankar[2], Chae Young Shin[4], Daniel Same Guerra[2], David Kolin[5], David Huntsman[6], Yemin Wang[4], Cigall Kadoch[2]

[1]Brigham and Women's Hospital/ Dana Farber Cancer Institute/Harvard Medical School, Boston, MA,[2]Dana Farber Cancer Institute/Harvard Medical School, Boston, MA,[3]University of British Columbia, Vancouver, BC, Canada, BC, Canada,[4]University of British Columbia, Vancouver, BC, Canada,[5]Brigham and Women's Hospital/Harvard Medical School, Boston, MA,[6]University of British Columbia, Vancouver, BC

The mammalian SWI/SNF (mSWI/SNF) family of chromatin remodelers govern cell type-specific chromatin accessibility and gene expression and assemble as three distinct complexes: canonical BAF (cBAF), Polybromo-associated BAF (PBAF), and non-canonical BAF (ncBAF). ARID1A and ARID1B are paralog subunits that specifically nucleate the assembly of cBAF complexes and are the most frequently mutated mSWI/SNF components in human cancer, including in endometrial cancer. However, the biochemical and functional impacts of ARID1A/B loss, and hence cBAF complex disruption, on remaining PBAF and ncBAF complex activities, chromatin architecture, and gene expression remain poorly understood. Here, we define the molecular consequences of complete cBAF loss in models of aggressive de-differentiated endometrial carcinoma (DEC) harboring dual ARID1A/ARID1B mutations. Notably, re-expression of ARID1A in DEC cellular model systems biochemically restores cBAF complex assembly while reducing that of PBAF and ncBAF complexes, implicating functional contributions of differential mSWI/SNF family stoichiometry. We observe genome-wide increases in DNA accessibility at distal enhancer regions following ARID1A rescue, coupled with transcriptional changes at nearest genes including those associated with epithelial lineage differentiation, estrogen receptor signaling, and PI3K/AKT pathway signaling. Importantly, differential gene regulatory changes aligned with simultaneous cBAF restoration and reduction in ncBAF, and PBAF complex function mirror signatures derived from well-differentiated (WEC) and dedifferentiated (DEC) compartments of a collection of n= 15 primary human DEC cases profiled. Reduced ncBAF- and PBAF-mediated chromatin regulation resulting from either ARID1A rescue or ncBAF/PBAF genetic disruption attenuated oncogenic gene signature features such as MYC target genes, cell cycle checkpoint and DNA repair pathways and significantly reduced proliferative capacity. Finally, treatment of ARID1A/1B-mutant and ARID1A-mutant endometrial cell lines in culture and PDX models in vivo with a clinical-grade SMARCA4/2 ATPase inhibitor, FHD-286, markedly attenuated both cell proliferation and tumor growth. Further, FHD-286 synergized with carboplatin, leading to significant reduction in tumor burden in ARID1A- and ARID1A/B-mutant PDX models. Taken together, these findings reveal the oncogenic contributions of shifted of mSWI/SNF family complex abundance and chromatin-level gene regulatory function and suggest therapeutic utility of mSWI/SNF complex small molecule inhibitors in endometrial carcinoma and other cBAF-disrupted cancer types.

#1244 Exploiting the pathogenesis of endogenous retrovirus to tackle squamous cancers.

Y. Lyu, **Y. Ge**;
UT MD Anderson Cancer Center, Houston, TX

Retrotransposons are the evolution relic of ancestrally invaded retroviruses interspersed through our genome. Mostly domesticated as host regulome, retrotransposons shape lineage gene expressions or donate coding functions. A few rare evolutionarily young species remain virally active, leading to germline mutations and modulating immune functions. Aberrant retrotransposon activities have been widely observed in adult diseases, although the extent to which they ensue active viral form and function under those contexts is unclear. Their molecular trigger in adult pathophysiology is poorly defined. To address these questions, we use murine skin as our model, given its well-characterized, abundant and highly accessible adult stem cells, not only mediating postnatal remodeling and homeostatic regeneration, but also responding to stress by driving tissue repair and adaptations. By analyzing a genetic model lacking a known retrotransposon suppressor, histone methyltransferase Setdb1, which we found to be essential in the adult skin, we saw hair loss and hair follicle stem cell exhaustion phenotype, accompanied by a robust and selective surge of endogenous retroviruses (ERVs). When combined with squamous cell carcinoma drivers, Setdb1 loss significantly blocked tumor progression in vivo. Interestingly, compared to relatively mild or no induction of commonly observed evolutionarily young ERVs, the most induced species in our model is a class I ERV, murine leukemia virus (MuLV). We detected abundant retroviral peptides originated from its full-length copies through mass spectrometry and viral-like particles through transmission electron microscopy that are immunoreactive to a monoclonal MuLV *env* antibody. Similar viral-like particles were broadly evident across several epithelial tissues beyond skin, implicating its conserved function across squamous cancers. Epithelial originated ERVs elicit tissue wide inflammatory response, and can be ameliorated by pharmacological or genetic inhibition of retroviral activity. Physiologically, viral-coding ERVs arise as the epigenetic machinery declines in response to age-associated stress, and plummet when host safeguard prevails in UV induced skin hyperplasia. As an evolutionary conundrum, viral-coding ERVs pose a threat to host fitness and yet, they've resisted extinction persisting in the mammalian genome. Our findings suggest viral-coding ERVs wrestle with the host surveillance programs to regulate adult tissue physiology and pathology, thus providing a key target in eliciting innate immunity and tackling squamous cancers.

#1245 The histone methyltransferase KMT2D mediates subtype-specific transcriptional regulation and therapeutic response in prostate cancer.

S. Kittane[1], E. Ladewig[2], T. Li[3], J. Love[4], A. Arruabarrena-Aristorena[5], X. Guo[6], M. Sallaku[7], L. Garcia-Martinez[8], R. Blawski[3], J. Carmona Sanz[9], C. Simpkins[3], W. Chen[3], B. Basque Foundation for Science, Bilbao, Spain, [6]University of Southern California, Los Angeles, CA, [7]Loxo Oncology at Lilly, New York, NY, [8]University of Miami-Miller School of Medicine, Miami, FL, [9]Vall d? Hebron Institute of Oncology, Barcelona, Spain, [10]KU Leuven, Belgium, Belgium, [11]SUNY Optometry, New York, NY, [12]NYU Grossman School of Medicine, New York, NY, [13]AstraZeneca, Gaithersburg, MD

Primary prostate cancer is characterized by its dependence on androgen receptor (AR) and often has hyperactive PI3K signaling, most frequently through loss of PTEN. PI3K/AKT pathway inhibitors are in late-stage clinical development in combination with anti-AR therapy. Androgen deprivation therapy is a cornerstone of treatment for advanced prostate cancer, but the development of castration-resistant prostate cancer (CRPC) eventually occurs. CRPC remains largely dependent on AR for growth with a subset of CRPC that lose AR dependence. There is an urgent need to study the molecular pathways leading to AR activation and the loss of AR reliance in order to identify therapeutic targets. KMT2D is a histone methyltransferase and an important regulator of gene expression. Here we found that KMT2D establishes the chromatin competence necessary for the recruitment of AR and FOXA1 transcription factors (TFs) to activate AR-dependent transcription in AR-high prostate models. In AR-low models such as the stem cell-like (SCL) subtype, KMT2D controls residual AR-FOXA1 gene expression programs and AP-1 TFs such as FOSL1, a driver of the SCL subtype. In SCL, single cell RNA-seq and single cell chromatin assays confirm a key role for KMT2D in the maintenance of a mixed lineage cell state through the regulation of AP-1 and FOXA1 TFs. Combined suppression of PI3K/AKT and KMT2D reduces cell proliferation in prostate cancer cells and patient derived organoids, providing a rationale for epigenetically informed combination therapies with PI3K/AKT inhibitors in PTEN-deficient prostate cancer. Together, these data establish KMT2D as a major mediator of subtype-specific chromatin accessibility and transcriptomic landscape in CRPC, required for prostate cancer growth and therapeutic response.

#1246 Erg-driven prostate cancer emerges from a basal subset of cells with luminal transcriptomic features.

E. Ladewig, W. Feng, C. Leslie, C. Sawyers;
Memorial Sloan Kettering Cancer Center, New York, NY

Translocations of the ETS family transcription factor *ERG* are found in nearly 150,000 newly diagnosed prostate cancers (PCas) each year in the United States underscoring the importance of defining the mechanism by which *ERG* promotes prostate epithelial transformation. A consequence of nearly all *ERG* translocations is the aberrant expression of ERG in prostate luminal cells under transcriptional control of *TMPRSS2*. Multiple lines of evidence implicate *ERG* translocations as an initiating event in prostate cancer. *ERG* expression is seen in prostatic intraepithelial neoplasia (PIN) and proliferative inflammatory atrophy; expression in cancers is typically uniform; and, in the context of PI3K pathway activation, *ERG* is sufficient to induce cancers in mice. Yet, despite extensive research the mechanism by which *ERG* initiates prostate cancer is unclear. To gain insight into how ERG translocations cause prostate cancer, we performed both transcriptional profiling (scRNA-seq) and chromatin accessibility via Assay for Transposase-Accessible Chromatin using sequencing (snATAC-seq) in single cells of an autochthonous mouse model at an early stage of disease initiation. Surprisingly, we observed in prostate epithelial cells broadly expressing *ERG* enhanced proliferation primarily in a hybrid subpopulation of cells having basal identity but with luminal morphology and cytokeratin expression. Through a series of lineage tracing and primary prostate epithelial transplantation experiments, we confirmed tumor initiating activity resided within a subpopulation of basal cells expressing luminal genes (e.g., *Tmprss2* and *Nkx3-1*). A trajectory analysis from single-cell Chromatin accessibility indicated Erg+ cells began to lose basal (*Trp63*) accessibility and gained in *STAT/NFAT* TFs while retaining the ability to rapidly differentiate into luminal cells that reflect the lineage of *ERG*-positive cancers. These findings help resolve a preexisting debate about the cell of origin of *ERG*-driven prostate cancer and narrow the focus for future mechanistic studies to a basal-luminal subpopulation of tumor initiating cells.

#1247 PPARsing epigenetic memory in intestinal stem cells: High-fat diet and oncogenic susceptibility.

D. R. Saiz, T. Hartley-McDerrmott, Y. Barrera-Millan, K. F. Castro-Ochoa, A. Shukla, M. Torel, M. D. Mana;
Arizona State University, Tempe, AZ

Diet has a profound impact on health and susceptibility to cancer. Adaptation to a Western diet is strongly associated with increased colorectal cancer (CRC) and obesity prevalence. This study demonstrates the epigenetic changes in intestinal stem cells (ISCs) induced by a pro-obesity high-fat Western diet (HFD) and the heightened risk of oncogenic transformation. A HFD induces a phenotype characterized by increased ISC frequency, proliferation, regenerative capacity, and ability to initiate adenomas. We hypothesized that a HFD generates lasting epigenetic alterations in ISCs thereby enhancing oncogenic susceptibility. We evaluated the chromatin landscape of intestinal stem cells (ISCs) and the reversibility of the epigenetic changes. Mice carrying a fluorescent reporter of the ISC marker Lgr5, were subjected to a control diet, HFD, or HFD with a return to control. We isolated ISCs by flow cytometry and used an assay for transposase-accessible chromatin sequencing (ATAC-seq) to identify differentially accessible genomic regions correlated with the ISC phenotype. We found that a HFD induces distinct changes in the chromatin landscape that persist after removal from the HFD. These accessible regions are associated with genes involved in lipid metabolism and are enriched with PPAR (Peroxisome Proliferator-Activated Receptor) binding motifs. We demonstrate that these lipid metabolism regulators, PPAR-delta and PPAR-alpha, are necessary for the majority of significant accessible regions. We further show that HFD-induced accessibility significantly correlates with early chromatin alterations seen by loss of tumor suppressor APC. Our data supports a mechanistic pathway for diet-induced epigenetic reprogramming due to PPAR activity and suggests that the HFD imposes a preneoplastic stem cell chromatin state that stokes the risk of oncogenic change.

#1248 The BRD8/p53 epigenetic switch re-establishes tumor suppression in glioblastoma.

Xueqin Sherine Sun, **Alea A. Mills**

Cold Spring Harbor Laboratory, Cold Spring Harbor, NY

Glioblastoma (GBM) is the most common and deadly adult primary brain malignancy. Median survival is just 12-14 months, with only about 5% of GBM patients surviving 5 years after diagnosis. This picture has not substantially improved over decades and there is an urgent need to discover more specific and effective treatments for this deadly malignancy. We discovered the bromodomain-containing chromatin regulator BRD8 as essential to GBM lacking p53 mutations *(TP53*^{WT}*)*, which make up ~71% of cases (1). BRD8 maintains malignancy by crippling p53-mediated tumor suppression in a way distinct from previously described mechanisms: it reprograms the p53 network through the EP400 histone acetyltransferase complex and by bromodomain-directed occupancy of the histone variant H2AZ at p53-induced targets, enforcing a repressive chromatin state that prevents p53-mediated transactivation. Importantly, targeting BRD8 in *TP53*^{WT} GBM remodels chromatin by evicting H2AZ and enhancing chromatin accessibility, enabling p53 to bind and transactivate its targets. This chromatin remodeling cascade (referred to as the “BRD8/p53 epigenetic switch”) re-establishes p53 activity in *TP53*^{WT} GBM, normalizing gene expression, evoking cell cycle arrest, inhibiting gliomagenesis, and prolonging survival in xenograft models of *TP53*^{WT} GBM. Our recent work: (i) reveals that BRD8 opposes p53 function in non-malignant brain cells; (ii) shows that the bromodomain of BRD8 is unique amongst the bromodomain-containing protein family, as it is the only one that selectively reprograms the p53 network; and (iii) demonstrates that targeting BRD8 works synergistically with MDM2 inhibition. Our findings present a previously unappreciated mechanism by which cancer cells side-step p53, indicate that targeting BRD8 re-establishes p53-mediated tumor suppression in *TP53*^{WT} GBM, highlight unique features of the bromodomain of BRD8, and propose therapies using co-inhibition of BRD8 and MDM2 as a dual-level tactic for boosting up p53. Thus, our work sheds light on new principles of chromatin biology and offers new promise for treating patients with this devastating malignancy.

cBioPortal for Cancer Genomics is an open-source platform for interactive, exploratory analysis of large-scale clinico-genomic data. cBioPortal provides a suite of user-friendly visualizations and analyses, including OncoPrints, mutation lollipop plots, variant interpretation, group comparison, survival analysis, expression correlation analysis, alteration enrichment analysis, cohort and patient-level visualization.

The public site (https://www.cbioportal.org) is accessed by >35,000 unique visitors each month and hosts data from >390 studies spanning individual labs and large consortia. All data is available in the cBioPortal Datahub: https://github.com/cBioPortal/datahub; in 2023 we added 35 studies (~16,000 samples). In addition, >86 instances of cBioPortal are installed at academic institutions and companies worldwide.

We also host a dedicated instance for AACR Project GENIE, enabling access to the GENIE cohort of >197,000 clinically sequenced samples from 19 institutions (https://genie.cbioportal.org). The GENIE Biopharma Collaborative (BPC) enables the collection of comprehensive clinical annotations including response, outcome, and treatment history, which can all be visualized in cBioPortal. BPC cohorts for non-small cell lung cancer (~2,000 samples) and colorectal cancer (~1,500 samples) are available, with more cancer types to come.

This past year, we significantly enhanced existing features. Group comparison now includes a Mutations tab showing a mirrored lollipop plot and outcomes analysis now supports hazard ratios and landmark analysis. Arm-level copy number can now be compared across groups, as can any data in the generic assay format.

We also enhanced the study view. Users can now add charts to summarize the copy number of a specific gene across the cohort. The option to add custom data charts now supports numerical data as well as categorical data. Filters in study view can now be manually submitted, which provides a performance improvement when applying multiple filters in a large cohort. Larger-scale performance improvements are currently underway.

We continue to improve support for multimodal datasets incorporating derived data elements, including cell type counts and fractions per sample from imaging or single cell data. The MSK-SPECTRUM ovarian cancer study has samples profiled with bulk sequencing, scRNASeq, H&E and mpIF imaging. Through integrations with CELLxGENE (single cell data) and Minerva (imaging), users can explore these data modalities in detail in isolation and query them jointly in cBioPortal.

cBioPortal is open source (https://github.com/cBioPortal/). Development is a collaborative effort among groups at Memorial Sloan Kettering Cancer Center, Dana-Farber Cancer Institute, Childrens Hospital of Philadelphia, Princess Margaret Cancer Centre, Caris Life Sciences, Bilkent University and The Hyve. We welcome open source contributions from others in the cancer research community.

#1250 Activating *PIK3CA* mutations and hedgehog signaling may confer resistance to KRAS inhibition in colorectal cancer.

S. Chowdhury[1], J. Ahmed[2], V. Haridas[1], D. S. Hong[1], S. Kopetz[1], J. Shen[1];

[1]UT MD Anderson Cancer Center, Houston, TX, [2]National Cancer Institute (NCI), National Institute of Health (NIH), Bethesda, MD

Background: Treatment with $KRAS^{G12C}$ inhibitors results in an objective response in only small fraction of patients with $KRAS^{G12C}$ mutant colorectal cancer (CRC) (7.1% and 22% objective response rates (ORR) in two prospective trials), in contrast to lung cancer where the ORR exceeds 35%. We hypothesize that co-mutation of other oncogenes and/or transcriptomic factors may contribute to the resistance of $KRAS^{G12C}$ CRC to KRAS inhibitors.

Methods: Mutation profiles of CRC patients were obtained from the AACR Project-GENIE v14 CRC cohort (N = 9441). The impact of *KRAS* knockout in 59 CRC cell lines was queried from the DepMap database. $KRAS^{G12C}$-mutant CRC cell lines SW837 and SW1463 were treated with Sotorasib ($KRAS^{G12C}$ inhibitor), Vismodegib and Taladegib (Hedgehog inhibitors), and cell viability was measured up to 96 hours after treatment.

Results: In the AACR Project-GENIE CRC (N = 9441) cohort, $KRAS^{G12C}$ tumors (2.6%, 245/9441) were significantly co-mutated with $PIK3CA^{mut}$ (19.2%, 47/245; Odds ratio = 1.7 (95% CI: 1.2 - 2.4), Chi-Square test, p-value = 0.002). Dependence on *KRAS* in CRISPR knockout viability assays was higher in $KRAS^{mut}$ vs. wildtype CRC cell lines (median CERES score -1.3 vs -0.5, p-value < 0.001). Interestingly, $KRAS^{mut}$ cell lines with *PIK3CA*-co-mutation (n=10) were more resistant to *KRAS* knockout than $PIK3CA^{wt}$ cells (n=22) (median -1.0 vs -1.4, p-value = 0.03). The SW837 and SW1463 cell lines initially displayed high sensitivity to Sotorasib (IC50: 0.92 µM and 0.90 µM). However, overexpression of $PIK3CA^{E545K}$ mutant induced resistance to the same treatment (IC50: 5.18 µM and 6.45 µM). Furthermore, gene set enrichment analysis (GSEA) showed that Hedgehog signaling was significantly enriched in *KRAS* knockout resistant $KRAS^{mut}$ CRC cell lines. SW837 cell line treated with Sotorasib (S) and a fixed dosage of 25 µM of Vismodegib (V) or Taladegib (T) showed higher sensitivities in combination treatment assays (IC50 decreased: ~11 folds in S+V vs S; and ~15 folds in S+T vs S) as compared to Sotorasib (S) treatment alone. Similar results were seen for the SW1463 cell line (IC50 decreased: ~18 folds in S+V vs S; and ~15 folds in S+T vs S).

Conclusion: Resistance in CRC to $KRAS^{G12C}$ inhibitors may be attributed to activated *PIK3CA* mutations and the Hedgehog signaling pathway. The future study will focus on detailed investigations involving comprehensive transcriptome and exome profiles in tumors and PDX models treated with anti-KRAS drugs in monotherapy and combination therapy.

#1251 Tobacco smoke alters the adaptive landscape of lung adenocarcinoma and influences the strength of epistatic interactions.

Krishna Dasari, Jorge Alfaro-Murillo, Jeffrey Townsend

Biostatistics, Yale University, New Haven, CT

Tobacco smoke produces both mutagenic and physiological effects, altering the mutation rate of cells and the selection acting on them in the damaged lung environment, and facilitating its role in driving cancer progression. In addition to these gene-by-environment interactions, gene-by-gene epistatic interactions also shape the adaptive landscape, influencing the evolutionary trajectories of cancer. Understanding the influence of tobacco smoke on the epistatic trajectories of lung cancer progression would help guide the development of targeted therapies that are more effective for smoker or never-smoker populations. To address this need, we constructed a continuous-time Markov chain model for the evolutionary trajectories of lung adenocarcinoma (LUAD), the most common subtype of lung cancer and the most frequent subtype among never-smokers. Using thousands of tumor sample sequences aggregated across studies, we profiled the trajectories of LUAD in smokers and never-smokers and estimated the rates at which mutations are gained from each possible set of pre-existing mutations, or genetic states. We then accounted for differences in baseline mutation rates to quantify the selective benefit of mutations. We find that epistasis is prevalent in LUAD, with several strong synergistic interactions—such as between RB1 and EGFR mutations- and antagonistic interactions-such as between EGFR and KEAP1 or KRAS mutations. Additionally, we identify non-additive epistatic effects: STK11 mutations are synergistic with KEAP1 and KRAS mutations but do not experience additional selection when both are mutated. In contrast, GNAS mutations are not synergistic with KEAP1 or RBM10 mutations alone but are synergistic with their co-mutation. Smoking has a large influence on the adaptive landscape, with several common mutations being preferentially selected in never-smoker cancers, including EGFR, SMAD4, GNAS, and PIK3CA mutations. KEAP1, STK11, and KRAS mutations are preferentially selected in smoker cancers. Smoking's physiological influence also affects the strength of certain epistatic interactions, such as between STK11 and KEAP1 mutations. Overall, we find that smoking not only increases the mutation rate of lung cells but also substantially alters the adaptive landscape of lung adenocarcinoma, leading to clinically relevant differences in selection on mutations between smoker and never-smoker cancers. We additionally detect frequent pairwise and higher-order epistatic effects in LUAD that may inform the personalized application of targeted therapies.

#1252 AI-derived predictions improve identification of real-world cancer driver mutations.

T. N. Tran, C. Fong, K. Pichotta, A. Luthra, R. Shen, Y. Chen, M. Waters, S. Kim, G. Riely, D. Chakravarty, N. Schultz, J. Jee;
Memorial Sloan Kettering Cancer Center, New York, NY

AI-based variant effect predictors (VEPs), such as AlphaMissense, which is based on the protein structure prediction method AlphaFold, have gained significant attention for their potential to predict pathogenic effects of mutations. However, the utility of these methods for identifying pathogenic mutations in cancer remains unknown.

We sought to quantify the prevalence of variants of unknown significance (VUSs) across the pan-cancer, multi-institution AACR GENIE cohort (N=160,965 samples) and test the utility of VEPs (SIFT, PolyPhen, MutationAssessor, REVEL, CADD, and AlphaMissense), using publicly available mutation annotations from each method, for 1) Annotating known pathogenic somatic cancer variants across the GENIE cohort, using known benign single nucleotide polymorphisms as negative controls 2) Identifying VUSs associated with overall survival (OS) in two cohorts of patients with non-small cell cancer (NSCLC), the MSK-IMPACT NCSLC (N=8,690) and non-MSK AACR GENIE Biopharma Collaborative NSCLC (N=977) cohorts, and 3) Identifying VUSs associated with known genomic patterns of mutual exclusivity in the MSK-IMPACT NSCLC cohort.

In the GENIE cohort, 79% of mutations identified were VUSs according to an FDA-recognized molecular knowledge database, with a wide range of VUS frequencies across genes. Among VEPs trained without prior human-annotated knowledge, CADD and AlphaMissense had the highest AUROCs (0.940, 95%CI 0.937-0.943 and 0.917, 95%CI 0.913-0.922 respectively) for predicting known cancer drivers, demonstrating the power of protein structure modeling or functional genomic data for enhancing cancer drivers prediction. All VEPs identified known driver mutations in tumor suppressor genes more accurately than oncogenes, highlighting the challenge in identifying gain-of-function mutations.

We tested whether VUSs reclassified as pathogenic by VEPs are associated with prognosis using inverse probability of treatment-weighted Cox's propensity hazard models controlling for tumor mutational burden, treatment history, and other factors. VUSs reclassified as pathogenic by AlphaMissense and other VEPs in KEAP1 and SMARCA4 correlated with worse OS, comparable to that of known oncogenic mutations in those genes. Patients with tumors containing VUSs annotated as benign had similar OS to patients without analogous driver mutations. Finally, VUSs reclassified as oncogenic by AlphaMissense in genes within the RTK/RAS and NRF2 pathways followed expected patterns of mutual exclusivity, further suggesting biological validity.

Despite not being trained to predict somatic effects in cancer, AI-derived mutation annotations can broaden the subset of annotated pathogenic variants in cancer and contribute to a more complete understanding of cancer genetics. Real-world outcomes and alteration patterns are additional benchmarks to consider when assessing the utility of VEPs in cancer.

#1253 Pan-cancer comparative and integrative analyses of driver alterations using Japanese and international genomic databases.

Sara Horie[1], Yuki Saito[2], Yasunori Kogure[2], Kota Mizuno[3], Yuta Ito[2], Mariko Tabata[4], Koichi Murakami[3], Junji Koya[2], Keisuke Kataoka[3]

[1]Department of Gastroenterology, Keio University School of Medicine, Tokyo, Japan,[2]Division of Molecular Oncology, National Cancer Center Research Institute, Tokyo, Japan,[3]Division of Hematology, Department of Medicine, Keio University School of Medicine, Tokyo, Japan,[4]Department of Urology, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan

Recent large-scale pan-cancer genome projects have broadened our understanding of the cancer genome. However, these projects mainly consisted of White patients, with a limited focus on Asian populations. In addition, while pairwise relationships between driver alterations can provide valuable functional insights, the majority of these analyses are limited to those using The Cancer Genome Atlas (TCGA) dataset.

Here we present a pan-cancer landscape of driver alterations in Japanese patients with advanced solid tumors using targeted sequencing data of 48,627 samples from the Center for Cancer Genomics and Advanced Therapeutics (C-CAT) in Japan. This data set had a greater number of samples from Asian-prevalent cancer types, such as intrahepatic cholangiocarcinoma and stomach adenocarcinoma, compared to the Genomics Evidence Neoplasia Information Exchange (GENIE) cohort. In the C-CAT cohort, the most frequently mutated gene was *TP53* (56%), followed by *KRAS* (25%), *APC* (17%), and *PIK3CA* (12%). Gene fusions were detected in 1,166 samples (2%), including *ERG* fusions in prostate adenocarcinoma (*n* = 129), and *RET* and *ALK* fusions in lung adenocarcinoma (*n* = 30 and 32). At least one clinically actionable genetic lesion was found in 16% of patients, with well-differentiated thyroid cancer having the highest proportion.

A comparative analysis of somatic mutation frequencies was conducted between the C-CAT cohort and the White population in the GENIE cohort. Among 352 driver gene-cancer type combinations, 14 and 4 were significantly higher and lower in the C-CAT cohort (> 10% difference with *q*-value < 0.01). Notably, *TP53* mutation frequencies were elevated in the C-CAT cohort across 10 cancer types, suggesting racial differences in *TP53* mutation frequencies.

We then integrated C-CAT, GENIE, and TCGA data consisting of more than 150,000 patients to conduct a meta-analysis of co-occurring and mutually exclusive relationships between 1,790 cancer-driver combinations. This analysis not only validated 215 previously reported relationships but identified 484 novel ones. Interestingly, we found significantly co-occurring mutations within the epigenetic pathway, with 13 epigenetic regulators co-occurring in ten cancer types. Gene set enrichment analysis using RNA-sequencing data in TCGA revealed that accumulation of mutations in epigenetic regulators causes increased proliferation-related transcriptomic signatures. In addition, loss-of-function mutations in epigenetic drivers suppresses proliferation in wild-type cell lines, but this effect is reduced in cells with mutations in both the same and other epigenetic drivers.

Our multi-cohort analyses uncover differences in the driver landscape between Asian and White populations, provides valuable resources for precision cancer medicine, and offers insights into epigenetic regulator-associated oncogenesis.

#1254 Integration of human omics analysis and new syngeneic tumor organoid models reveals that aberrant RAS/PI3K crosstalk triggers refractoriness in high-grade serous carcinoma.

T. Tamura[1], K. Masuda[1], S. Nagai[1], K. Imaeda[1], J. Yamasaki[2], E. Sugihara[2], H. Nobusue[2], Y. Otsuki[2], R. Yamaguchi[3], K. Sakurada[1], W. Yamagami[1], H. Saya[2], O. Nagano[2];

[1]Keio University School of Medicine, Shinjuku, Japan, [2]Fujita Health University, Toyoake, Japan, [3]Aichi Cancer Center Research Institute, Nagoya, Japan

Refractory high-grade serous carcinoma (HGSC) is one of the most severe clinical problems in gynecology, but we have barely grasped the underlying mechanism of aggressiveness and chemo-resistance. Previous study has shown that homologous recombination genes, *BRCA1/2*-unmutated HGSC patients possess the potential to be in refractory condition, and their primary response to chemotherapy was heterogenous; thus, there can be subtype-specific determinant factors hatching refractoriness in *BRCA1/2*-unmutated HGSC patients. To explore the determinant factors, we performed gene set variation analysis and comprehensive log-rank tests on TCGA advanced serous ovarian cancer datasets. As a result, regulation of small GTPase signaling prominently correlated with poor prognosis uniquely in *BRCA1/2*-unmutated HGSC patients (p-value < 0.001), and eventually, pathway clustering analysis by variational Bayesian Gaussian mixture model discovered aberrant RAS/PI3K crosstalk as peculiar poor prognostic signature of *BRCA1/2*-unmutated HGSC patients. To elucidate the mechanism of poor progression triggered by RAS/PI3K, we utilized our syngeneic HGSC organoid models newly established from murine fallopian tube epithelium by making *Myc* overexpressing, and knocking out *Trp53* and *Rb1*; as a supplement, the propriety of these genetic alterations to develop HGSC models was backed up by genetic profiles of high-grade serous ovarian cancer patients in AACR Project GENIE. After that, we knocked out *Nf1* and *Pten* whose deletions were detected relatively with high frequency in HGSC to induce aberrant RAS/PI3K crosstalk in the primitive HGSC model. *In-vivo* evaluation and growth comparison indicated that aberrant RAS/PI3K crosstalk transformed *Brca1/2*-unmutated HGSC modeling cells into aggressive phenotypes such as poor survival (p-value < 0.01) and high growth rate (p-value < 0.001). Chemo-sensitivity assay also showed that the genetic manipulation made *Brca1/2*-unmutated HGSC modeling cells more tolerant to anti-tumor agents like carboplatin (p-value < 0.001), paclitaxel (p-value < 0.01), and olaparib (p-value < 0.01). To investigate biological processes that induce the aggressive and chemo-resistant phenotype, we performed gene set enrichment analysis among our HGSC models. The result showed that aberrant RAS/PI3K crosstalk induces cell cycle acceleration and downregulation of apoptosis in the HGSC cells, which backed up aggressive phenotype and chemo-resistance in our HGSC models. In conclusion, aberrant RAS/PI3K crosstalk transforms *Brca1/2*-unmutated HGSC modeling cells more aggressive and chemo-resistant, which was well recapitulated by our HGSC modeling organoids. The integration of our computational approach and experimental models will lead us to detect peculiar therapeutic targets against refractory HGSC.

MULTIDISCIPLINARY: Genetic and Cellular Mediators of Tumor Progression
Minisymposium

#1256 RPL22 is a tumor suppressor in MSI-high cancers and a key splicing regulator of MDM4.

H. N. W. Weinstein[1], K. Hu[1], L. Fish[1], Y.-A. Chen[1], P. Allegakoen[1], K. S. F. Hui[1], J. H. Pham[1], M. B. Baco[2], H. Song[1], A. O. Giacomelli[3], F. Vazquez[2], M. Ghandi3[2], H. Goodarzi[1], F. W. Huang[1];

[1]University of California - San Francisco, San Francisco, CA, [2]Broad Institute of MIT and Harvard, Boston, MA, [3]Princess Margaret Cancer Center, Toronto, ON, Canada

Microsatellite instability high (MSI-H) tumors are marked by 30% or more mutations in microsatellite regions and are generated by somatic or germline alterations in DNA mismatch repair machinery. Despite a high tumor mutational burden, MSI-H tumors do not frequently harbor mutations in TP53. Notably, a frameshift mutation (*p.K15fs*) in the gene *RPL22* is among the most recurrent mutations in MSI-H tumors. RPL22 and its paralog, RPL22L1, form part of the large subunit of the 60S ribosome and are known to affect protein synthesis as well as splicing of genes and transcription factors that affect development and tumorigenesis. Here we explore the result of *RPL22* loss on the regulation of MDM4, an upstream target of p53. MDM4 protein expression is mediated through alternative mRNA splicing of its sixth exon, which leads to two isoforms, the exon 6-inclusive MDM4-FL and the exon 6-exclusive MDM4-S, which is prone to degradation. To date, no mutational events have been associated with this alternative splicing event. We show the prevalence of *RPL22fs* mutations is more than 70% in certain MSI-H cell lines (e.g. colon, endometrial) and tumors (e.g. stomach adenocarcinoma) in the CCLE and TCGA. *RPL22* copy number loss and *RPL22* frameshift mutations are strongly correlated with MDM4 exon 6 inclusion in TCGA samples, and *RPL22* knockout increases *MDM4* exon 6 inclusion and MDM4 protein in multiple cell lines. *RPL22* loss increases cell proliferation and augments resistance to the MDM inhibitor Nutlin-3a. Downstream targets of p53 (p21, BBC3) are downregulated due to *RPL22* loss and Nutlin-3a inhibition, suggesting mutation of *RPL22* and subsequent overexpression of MDM4 promotes resistance to Nutlin-3a. CLIP-seq revealed that RPL22 binds the *MDM4* 3'-UTR. We find that *RPL22* loss is associated with an alternative 3'-splicing event in *RPL22L1* adjacent to exon 3 and results in the expression of the full-length transcript of *RPL22L1*. In summary, we identify RPL22 as a key modulator of *MDM4* splicing through an alternative splicing switch in exon 6. Furthermore, RPL22 represses the expression of its paralog, RPL22L1, by mediating the splicing of a cryptic exon corresponding to a truncated functional transcript. Therefore, we propose that damaging mutations in *RPL22* drive oncogenic MDM4 induction and reveal a common splicing circuit in MSI-H tumors that may inform therapeutic targeting of the MDM4-p53 axis and oncogenic RPL22L1 induction. Our results also suggest that the presence of RPL22 may act as a rheostat to maintain *MDM4* exon 6 skipping under normal cellular contexts.

#1257 CHD5 suppresses glioblastoma by inhibiting MYC.

X. Sun, A. Mills;
Cold Spring Harbor Laboratory, Cold Spring Harbor, NY

Fundamentally, cancer is a disease caused by genetic and epigenetic alterations that converge to reprogram gene expression networks, leading to unrestrained proliferation. Glioblastoma (GBM) is the most prevalent and aggressive primary brain cancer, median survival being approximately one year and the 5-year survival rate being only 5%. Despite decades of effort, this devastating picture has not appreciably improved and effective therapies have been elusive for GBM patients. A better understanding of GBM biology is essential for developing more effective therapies. Although several genetic alterations have been implicated in gliomagenesis, driving genetic factors responsible for GBM are still obscure, and the interplay between genetic alterations and epigenetic dysregulation is largely undocumented during the gliomagenic process. Here, we show that *CHD5* — a gene mapping to the 1p36 chromosomal region that is notoriously deleted in many cancers, is recurrently deleted in over 20% of GBM cases and is further downregulated through epigenetic means. To delineate how CHD5 loss promotes gliomagenesis, we established a glioma-prone mouse model harboring conditional alleles of *Pten*, *Trp53*, and *Chd5*. We developed an engineered mouse neural stem cell (NSCs)-based strategy to elicit glioma formation, as NSCs are the major cell-of-origin for GBM. We show that Chd5 loss significantly impairs NSCs differentiation while promoting proliferation, transformation, and gliomagenesis *in vivo*. Mechanistically, Chd5 forms a Chd3-containing but Chd4-independent NuRD complex that directly binds the *Myc* promoter and super enhancers to govern *Myc* expression in normal NSCs, with the Snf2 domain of Chd5 playing the most critical chromatin regulating role in the context of GBM. Chd5 loss triggers the remodeling of chromatin, enhances accessibility, and augments *Myc* expression, leading to the formation of highly aggressive glioma. Furthermore, reactivating CHD5 in human GBM xenograft models significantly extends survival. This work demonstrates the tumor suppressive role of CHD5 in gliomagenesis, providing therapeutic insights for cancers with 1p36 deletions. In parallel, this work presents a powerful strategy for rapidly interrogating gene function during gliomagenesis using engineering NSCs, and the generation of novel mouse models with classic clinical features of GBM, offering new approaches for elucidating GBM biology that can inform on therapeutic opportunities for treating patients with GBM.

#1258 A cholesterol metabolite can modulate neutrophil-derived extracellular vesicles to promote breast cancer cell epithelial to mesenchymal transition (EMT) and stemness.

N. J. Krawczynska[1], Y. Wang[1], A. Das Gupta[1], J. Drnevich[1], J. Ostrander[2], E. R. Nelson[1];
[1]University of Illinois at Urbana-Champaign, Urbana-Champaign, IL, [2]University of Minnesota Medical School, Minneapolis, MN

Breast cancer is the second leading cause of cancer-related death in women, with mortality most often due to metastatic recurrence. Elevated cholesterol is associated with poor prognosis, with several potential mechanisms proposed. Work in murine models found that many of the pro-metastatic actions of cholesterol required the enzymatic conversion of cholesterol to 27-hydroxycholesterol (27HC), which functions as a ligand for both the estrogen receptors (ERs) and liver X receptors (LXRs). Importantly, we have found that 27HC promotes metastasis, in part through its actions on neutrophils. When examining mechanisms, we have made the observation that 27HC resulted in increased secretion of small extracellular vesicles (sEVs) from neutrophils. These 27HC-neutrophil-sEVs independently promote metastatic colonization. Since we have found that breast cancer cell lines can take up neutrophil-derived sEVs, we hypothesized that 27HC results in altered cargo within sEVs which leads to functional changes within cancer cells, the ultimate consequence of which being their increased metastatic potential. Using a non-biased small RNA-seq approach we have found that sEVs from 27HC-treated neutrophils had an altered miRNA signature. Bioinformatic analysis revealed several downregulated miRNAs from the let-7 subgroup. Let-7 miRs are known to target several genes associated with the WNT/β-catenin pathway, a pathway strongly implicated in epithelial to mesenchymal transition (EMT) and cancer cell stemness. Strikingly, breast cancer cells treated with sEVs from neutrophils treated with 27HC lost their adherent properties and adopted a mesenchymal and stem-like phenotype. In order to elucidate the mechanism by which these sEVs promote EMT and stemness, we performed comprehensive transcriptomics through time. Weighted gene co-expression network analysis (WGCNA) confirmed these phenotypic shifts, and implicated the WNT/β-catenin pathway, providing support to our hypothesis that the loss of let-7 miRs is the upstream mediator. Collectively, our data suggests that 27HC increases metastasis in part through its effects on neutrophils, by shifting sEVs cargo towards a loss of protective microRNA, resulting in increased EMT and stemness, and thus the ability of cancer cells to migrate, invade and metastasize. Funding: National Cancer Institute (ERN: R01CA234025) Department of Defense (ERN: BCRP Era of Hope Award), and Beckman Institute for Advanced Science and Technology (NK)

#1259 HMGA1: An epigenetic gatekeeper of Wnt signals during colon tumorigenesis and regeneration.

B. West[1], L. M. Resar[1], L. Z. Luo[1], L. Xian[1], I. Herrera[1], S. Wu[1], J.-H. Kim[1], Y. Feng[2], J. Calderon-Espinosa[1], E. R. Fearon[2], C. Sears[1];
[1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]University of Michigan Medical School, Ann Arbor, MI

Cancer cells undergo epigenetic reprogramming to co-opt stem cell networks and drive tumor progression, although how this occurs remains unclear. The *High Mobility Group A1* (*HMGA1*) gene encodes an architectural transcription factor that binds to DNA at AT-rich sequences where it recruits chromatin complexes to modulate gene expression. *HMGA1* is highly expressed during embryogenesis and in adult stem cells, but silenced in differentiated cells. *HMGA1* becomes re-expressed in aggressive cancers where high levels portend adverse outcomes. In colorectal cancer (CRC), *HMGA1* is among the genes most highly overexpressed compared to normal colon epithelium. We previously discovered that *HMGA1* is required for oncogenic phenotypes in CRC cell lines by inducing genes involved in an epithelial-mesenchymal transition. *Hmga1* transgenic mice also develop aberrant proliferation and polyposis of small intestinal epithelium where Hmga1 amplifies Wnt signals to enhance self-renewal. To determine how HMGA1 functions in colon epithelial homeostasis and tumorigenesis, we examined mouse models with overexpression or deficiency of *Hmga1*. Here, we uncover a previously unknown role for HMGA1 as an epigenetic gatekeeper of Wnt signals in colon epithelial cells, both during tumorigenesis driven by mutant *APC* or stress-induced tissue repair. Strikingly, loss of just a single *Hmga1* allele within the colon epithelium disrupts tumorigenesis while prolonging survival in two models of colon tumorigenesis driven by *APC* mutation, including *CDX2P-CreER*^{TC}*Apc*$^{fl/fl}$ and *APC*^{Min} mice inoculated with pro-carcinogenic, enterotoxigenic *Bacteroides fragilis*. Single cell RNA sequencing in *Apc* mutant crypt epithelial cells reveals that intact Hmga1 is required for expansion in the *Lgr5*$^{+}$ stem cell pool, deep secretory cells, and tuft cells during tumorigenesis. *Hmga1* deficiency impacts the stem cell pool the greatest, decreasing Lgr5+ stem cells with skewing to more proliferative, transit amplifying-like cells. Single cell transcriptomic analyses together with assays of single cell chromatin accessibility demonstrate that Hmga1 maintains accessible chromatin to activate gene loci involved in Wnt signals, including *Ascl2*, a stem cell master regulator, Wnt agonist receptors, and Wnt downstream effectors. Surprisingly, either depletion or overexpression of *Hmga1* has no impact on colon epithelial regeneration under homeostatic conditions, although *Hmga1* overexpression enhances tissue repair and survival following injury induced by inflammation or irradiation. Together, our results establish HMGA1 as an epigenetic gatekeeper of Wnt signals in colon stem cells during APC-driven tumorigenesis or injury, but not steady state homeostasis, highlighting its role as a promising therapeutic target for both cancer and regenerative medicine.

#1260 Collapse of cancer cell micronuclei from oxidative damage.

M. Di Bona[1], Y. Chen[1], A. Agustinus[1], M. Deyell[2], M. A. Duran[1], C. Hong[1], J. Hickling[1], D. Bronder[1], S. Martin[3], N. Riaz[1], B. Diplas[1], M. Jalan[1], N. Lee[1], A. Ordureau[1], B. Izar[4], A. Laughney[2], S. Powell[1], S. Santaguida[3], J. Maciejowski[1], T. Jeitner[2], S. Bakhoum[1];
[1]Memorial Sloan Kettering Cancer Center, New York, NY, [2]Weill Cornell Medicine, New York, NY, [3]European Institute of Oncology, Milan, Italy, [4]Columbia University, New York, NY

Chromosomal instability, a hallmark of aggressive cancers, disrupts genome integrity through multiple hits by ongoing missegregation of chromosomes. These chromosomes, inherited only by one daughter cell, are subsequently encapsulated in micronuclei (MNi). Micronucleation is detrimental for replication fidelity not only because it sustains chromosomal missegregation, but also because MNi frequently undergo irreversible collapse during interphase exposing their enclosed chromatin to the cytosol. This exposure catalyzes chromosomal rearrangements and heritable epigenetic abnormalities that have been shown to further bolster cancer evolution and therapeutic resistance. Moreover, MNi collapse is known to promote distant metastasis and poor prognosis through eliciting a non-canonical response of otherwise inflammatory signaling pathways. Despite the fundamental role played by MNi catastrophe in compromising genome integrity and sustaining cancer progression, and the subsequent therapeutic potential of targeting this process, the mechanisms underlying MNi collapse are poorly understood. Here, we identify mitochondria-derived reactive oxygen species (ROS) as the main cause of MNi rupture. Notably, we observe that MNi that locate closer to mitochondria are more prone to rupture. Accordingly, increasing ROS chemically and by H_2O_2 addition increment rupture in a panel of 5 different tumor cell lines, while decreasing ROS using pan-cellular or mitochondrial specific scavengers reduce the frequency of ruptured MNi. By using a combination of advanced super-resolution microscopy, proteomics, transcriptomics, *in vitro* biochemistry assays, and extensive mutagenesis, we reveal the exact pathway leading to MNi collapse. We demonstrate that ROS promote a noncanonical function of the membrane repair ESCRT-III complex scaffolding protein, CHMP7. ROS reduce CHMP7 interaction with ESCRT-III promoting CHMP7 oligomerization and its binding to the inner nuclear membrane protein, LEMD2. CHMP7, while aggregating, physically pulls the micronuclear envelope together with the LEMD2-associated lamina, thereby disrupting MNi integrity. Finally, we show that hypoxic conditions promote ROS-dependent CHMP7-LEMD2 interaction, inducing MNi rupture and inflammatory signaling. Thus, we observe that human tumors characterized by hypoxia have a significantly increased predominance of ruptured MNi, providing a mechanistic link between tumor hypoxia and downstream processes that drive cancer progression.

#1261 *In vitro* medulloblastoma leptomeningeal metastasis models reveal adhesion signaling as a therapeutic vulnerability.

L. Jimenez Garcia, A. C. Gross, R. D. Roberts, J. B. Reinecke;
Nationwide Children's Hospital, Columbus, OH

Introduction: How tumor cells colonize an inherently distinct environment and survive the pressures of therapeutic treatment during metastasis is incompletely understood. In patients with medulloblastoma, the most common malignant pediatric brain tumor, mortality is almost exclusively dictated by metastasis to the leptomeninges, the inner covering of the brain and spinal cord. We aim to mechanistically understand the molecular drivers of leptomeningeal colonization, including how leptomeningeal adhesion mediates therapy resistance.

Experimental approach: Progress in leptomeningeal metastasis research has been hindered by the scarcity of matched primary and metastatic tissue from patients given the lack of clinical benefit to obtaining metastatic tissue. Furthermore, end points from pre-clinical human xenograft mouse models are often driven by primary cerebellar tumors, not leptomeningeal dissemination. These barriers underscore the necessity for novel *in vitro* leptomeningeal metastasis models that allow for rigorous experimental analysis. These models must simultaneously recapitulate tumor cell-host and tumor cell-environment interactions driving colonization to produce translatable findings. Accordingly, our lab has developed two novel *in vitro* leptomeningeal metastasis models that allow for cell-based experimental analysis: a primary meningeal cell-medulloblastoma organotypic co-culture and an acellular leptomeningeal matrix mimetic monoculture.

Results: Proteomic analysis identified that leptomeningeal cells promote medulloblastoma chemotactic honing to the leptomeninges through CXCL12-CXCR4 signaling. Additionally, loss of CXCL12/CXCR4 signaling impaired medulloblastoma adhesion to the leptomeninges. CXCL12/CXCR4 are known to mediate adhesion of stem cells in stromal niches via activation of integrin receptor ITGA4/ITGB1 (VLA4) binding to stromal VCAM1. Indeed, the VLA4-VCAM1 axis is required for medulloblastoma leptomeningeal adhesion and requires activation by CXCL12/CXCR4 signaling. From a translational perspective, we found that leptomeningeal adhesion promotes therapy resistance and that inhibition of adhesion signaling sensitized adherent medulloblastoma cells to therapy.

Conclusions: These findings provide proof-of-concept that appropriate *in vitro* models of metastasis can be developed and utilized to define the biology driving adhesion and chemotherapy resistance in medulloblastoma metastasis. Furthermore, we show that medulloblastoma leptomeningeal adhesion is mediated by a CXCL12/CXCR4-VLA4/VCAM1 axis. Finally, we demonstrate the therapeutic potential of targeting this axis in sensitizing medulloblastoma metastases to current therapies.

#1262 Comparative analysis of *TP53* alleles in pancreatic ductal adenocarcinoma.

A. Tang[1], S. Agabiti[2], H. Chung[2], M. D. Muzumdar[2];
[1]Yale University, New Haven, CT, [2]Yale University School of Medicine, New Haven, CT

The transcription factor p53 is a tumor suppressor capable of inducing cell cycle arrest, senescence, and apoptosis. Both truncating loss-of-function mutations and point mutations of the *TP53* gene (mouse gene *Trp53*), which encodes for the p53 protein, are frequently observed across human cancers. While point mutations in p53 result in loss of canonical tumor suppressor function, recent studies suggest that these mutated proteins acquire pro-tumorigenic gain-of-function properties. For example, $Trp53^{R172H}$ mutations (the murine homolog of $TP53^{R175H}$, the most common human *TP53* variant) enhance metastatic spread relative to deletion mutations in mouse models of advanced pancreatic ductal adenocarcinoma (PDAC). To further explore the differential functions of p53 point and deletion mutants in cancer progression, we performed a rigorous comparative analysis of *Trp53* alleles *in vivo* using **M**osaic **A**nalysis with **D**ouble **M**arkers (MADM) in mice. MADM uses stochastic mitotic recombination to induce two genotypically distinct daughter cells - created at 1-to-1 ratios - expressing different *Trp53* variants dependent on the genotype of the mouse (+/+ vs. -/-, *R172H/R172H* vs. +/+, *R172H/R172H* vs. -/-) and simultaneously label them with unique genetically encoded fluorescent markers (TdTomato vs. GFP). We integrated MADM into a faithful *Kras*-driven model of pancreatic tumorigenesis and used fluorescence microscopy to trace subclonal populations with various p53 alleles within the same mouse. By analyzing the ratio of TdTomato+ to GFP+ cells, we studied the functional differences between alleles in driving pancreatic cancer at various stages of progression. We found that $Trp53^{-/-}$ cells exhibited greater tumor initiation of preinvasive pancreatic intraepithelial neoplasia (PanINs) and early PanIN cell expansion compared to $Trp53^{+/+}$ cells. Surprisingly, $Trp53^{R172H/R172H}$ cells were comparable in number to $Trp53^{+/+}$ cells in early PanINs but were outcompeted by $Trp53^{-/-}$ cells.In contrast, both $Trp53^{R172H/R172H}$ and $Trp53^{-/-}$ cells were capable of facilitating the transition to advanced PDAC with comparable survival times. These phenotypic differences imply that $p53^{R172H}$ retains tumor suppressive properties in early pancreatic tumorigenesis, but similar to the loss of p53, it is incapable of constraining progression to advanced disease, arguing that $p53^{R172H}$ is a separation of function mutation *in vivo*. Ongoing studies examining the molecular differences between *Trp53* alleles by fluorescence-activated cell sorting and RNA-sequencing will shed further light onto the underlying mechanisms that explain these phenotypic differences.

PREVENTION / EARLY DETECTION / INTERCEPTION: Multi-Cancer Early Detection Testing: Where Are We?
Minisymposium

#1263 Interim results from a large-scale, prospective cohort study (JINLING) for multi-cancer early detection test in average-risk asymptomatic patients.

S. Yang, H. Bao, X. Chen, M. Wu, S. Tang, R. Yang, D. Zhu, X. Wu, W. Tang, S. Chang, P. He, X. Xu, Y. Jiang, S. Wu, S. Liu, X. Zhang, X. Wu, Y. Shao; Nanjing Geneseeq Technology Inc., Nanjing, China

Background: Previously, we reported that a multi-cancer early detection (MCED) test CanScan, which utilizes plasma cfDNA genome-wide fragmentomics-related features that can detect cancer signals and tissue of origin (TOO) signals across thirteen cancer types at 99% specificity in individuals with cancer. Here, we report the interim results of a first large-scale prospective clinical study in an asymptomatic population with average risk of cancer, the JINLING Cohort (NCT06011694).
Methods: This ongoing prospective clinical study is enrolling participants aged between 45 and 75 years old without cancer-related symptoms, initiated in June 2022. Each participant will undergo peripheral blood collection for CanScan test and annual routine physical exams once a year for three consecutive years, with an additional two years of follow-up. The primary objective of the study was to evaluate the diagnostic performance of the CanScan test in the early detection of multiple cancers. Secondary objectives include the evaluation of TOO accuracy, its efficiency and clinical utility, lead-time relative to clinical diagnosis, and participants' attitudes and adherence to this test compared to standard care screening methods.
Results: By June 2023, a total of 3724 participants with analyzable samples were included in the analysis. At the data cut off time of Sept 2023, 29 participants were clinically diagnosed with cancer, including 8 that were not in the 13 targeted cancer types. The majority of the cancers were found in the early stages (Stage I or II; 89.6%, 26/29). The CanScan test detected a cancer signal at a sensitivity of 55.2% (16/29; stage I: 10/21, 47.6%; stage II: 4/5, 80.0%; stage III: 2/3, 66.7%). For detected cancers, the prediction accuracy of the top predicted origin was 61.5% (95% CI [38.5%,84.6%]; stage I: 62.5% [5/8]; stage II: 1/3, 33.3%; stage III: 2/2, 100%). The accuracy was 84.6% (95% CI [61.5%,100.0%]; I: 87.5% [7/8]; II: 66.7% [2/3]; III: 100.0% [2/2]) when taking into account the top two predicted origins. Specificity was 97.9% (3619/3695) in non-cancer participants.
Conclusions: In this one-year interim analysis of the large-scale, prospective, clinical cohort study, we investigated the efficacy of the MCED test within an asymptomatic population with an average-risk of cancer. the CanScan test demonstrates capability in detecting a wide range of cancer types and predicting TOO at early stages, highlighting an exceptional level of sensitivity and accuracy while maintaining a high level of specificity. Therefore, the MCED test holds significant potential for early cancer screening in asymptomatic populations, potentially transforming preventative healthcare and improving patient outcomes.

#1264 A targeted methylation-based multi-cancer early detection blood test preferentially detects high-grade prostate cancer and minimizes overdiagnosis.

B. Mahal[1], M. Margolis[2], E. Hubbell[2], C. Chen[2], J. M. Venstrom[2], J. Abran[2], J. J. Karlitz[2], A. W. Wyatt[3], **E. A. Klein**[2];
[1]University of Miami Miller School of Medicine, Miama, FL, [2]GRAIL, LLC, Menlo Park, CA, [3]University of British Columbia, Vancouver, BC, Canada

Background: Indolent prostate cancer (PCa) is prevalent in men in the intended use population (adults aged 50-79 years) for blood-based multi-cancer early detection (MCED) tests. It is thus important to understand detectability of PCa by MCED tests across the spectrum of disease aggressiveness, including detection of indolent disease.
Methods: PCa detectability by a targeted methylation-based MCED test that interrogates circulating cfDNA was assessed in 2 studies: 1) the Circulating Cell-free Genome Atlas (CCGA, NCT02889978), a case-control study (Substudy 3) that demonstrated detection of a shared cancer signal across > 50 cancer types and accurate prediction of cancer signal origin (CSO) with an observed false positive rate of 0.5%; and 2) PATHFINDER (PF, NCT04241796), a return of results cohort study in the intended use population without clinical suspicion of cancer. MCED test performance was assessed by Gleason grade group (GG) and clinical stage, and the association between tumor methylated fraction (TMeF) and cancer detectability was investigated.
Results: The CCGA3 study included 420 recently diagnosed PCa cases with a median age of 65 years (IQR, 59-70). Test sensitivity for PCa was 11.2% (47/420), and CSO accuracy was 91.5% (43/47). Median PSA was higher in detected cases (14 ng/dL, IQR 7-38 vs 6 ng/dL, IQR 5-9, $p < 0.05$). The MCED test detected no low grade (GG1, 0/58), 1.9% (3/157) of favorable intermediate grade (GG2), 5.1% (4/78) of unfavorable intermediate grade (GG3), and 31.9% (36/113) of high grade (GG4 & GG5) cancers. Clinical staging showed detection of 3.2% (3/95) of Stage I, 4.7% (11/235) of Stage II, 14.9% (7/47) of Stage III, and 81.5% (22/27) of Stage IV cases. Non-detected cases had better overall survival (HR 0.263, CI 0.104 - 0.533, $p<0.05$), and detected cases had similar survival (HR 0.672, CI 0.323 - 1.21, $p=0.2$) compared to SEER estimates matched for age, stage and GG. Median TMeF was higher for detected cases (0.002106, IQR 0.000350 - 0.024376 vs 0.000024, IQR 0.00001 - 0.000038, $p < 0.05$). Performance was similar in PF (median age 66 years, IQR 58 -70) with overall sensitivity for PCa of 5.9% (1/17), including no (0/12) detected GG1-2 cases and one of five GG3-5 cases. No Stage I or II (0/15) and 1/2 (50%) Stage III & IV cases were detected.
Conclusion: In two independent prospective studies, this MCED test preferentially detected high grade, clinically significant PCa. A cancer signal detected test result with a prostate CSO prediction generally indicates the presence of aggressive PCa and should lead to a prompt diagnostic work-up. Use of this test in population-based screening programs is unlikely to exacerbate overdiagnosis of indolent PCa.

#1265 Comparison of mortality- vs. stage-based endpoints in randomized trials of cancer screening: A systematic review with implications for multi-cancer screening trials.

X. Feng[1], H. Zahed[1], J. Onwuka[1], M. Johansson[1], R. Etzioni[2], M. E. J. Callister[3], **H. A. Robbins**[1];
[1]International Agency for Research on Cancer, Lyon, France, [2]Fred Hutchinson Cancer Center, Seattle, WA, [3]Leeds Teaching Hospitals, Leeds, United Kingdom

Background: Randomized controlled trials (RCTs) assessing the endpoint of late-stage cancer incidence, rather than the gold-standard of cancer-specific mortality, are proposed for evaluation of multi-cancer early detection tests.
Methods: We conducted a systematic review to assess whether stage-based endpoints can provide a valid alternative for mortality-based endpoints (registration: PROSPERO CRD42023411132). We searched PubMed to identify RCTs of cancer screening interventions published in English before January 20, 2023. Inclusion required that RCTs report, by study arm, numbers of cancer-specific deaths and cancer cases distinguishable between stages I-II vs. III-IV. Data extraction was done by 2 separate reviewers and included the numbers of cancer cases, deaths, and participants by study arm. For each trial, we calculated the percentage reduction in the cumulative (a) late-stage cancer incidence and (b) cancer-specific mortality between the intervention and control arms. We compared these two endpoints based on Pearson correlation coefficients, fixed-effects meta-analysis, and binary statistical significance.
Results: We analyzed 41 trials ranging in size from 2,500 to 409,000 participants. Correlation between the reduction in cancer-specific mortality vs. stage III-IV cancer was strong for lung (Pearson's ρ=0.92, n=12), breast (ρ=0.70, n=6), and 'other' cancers (ρ=0.69, n=8) but weak for colorectal (ρ=0.39, n=11) and prostate cancers (ρ<0, n=4). The overall correlation by fixed-effects meta-analysis across cancer types was 0.71 (95%CI=0.47-0.86) (I^2=0.55). In larger trials, there was a smaller deviation between the observed reduction in cancer-specific mortality and that predicted, by cancer type, based on the trial's reduction in stage III-IV cancer (p=0.02). Of 12 trials demonstrating a statistically significant reduction in stage III-IV cancer incidence (p<0.05), 5 also showed reduced cancer-specific mortality (42%).
Conclusions: In screening RCTs, reductions in late-stage cancer vs. cancer-specific mortality are correlated, but with important differences by cancer type. Screening interventions that reduce late-stage cancer incidence do not necessarily reduce cancer-specific mortality.

#1266 Development and performance of a multi-cancer early detection test utilizing plasma cfDNA fragmentomics: A large-scale, prospective, multicenter study.

H. Bao, X. Chen, M. Wu, S. Tang, X. Wu, W. Tang, D. Zhu, S. Yang, S. Chang, P. He, X. Xu, J. Zhang, Y. Shen, S. Wu, Y. Jiang, S. Liu, X. Zhang, X. Wu, Y. Shao;
Nanjing Geneseeq Technology Inc., Nanjing, China

Background: The implementation of the multi-cancer early detection (MCED) test offers a valuable adjunct to existing screening methods, enabling more efficient detection of cancer and potentially leading to improved treatment outcomes and prognoses for patients. Here, we report on the performance of an MCED test, which utilizes plasma cfDNA and leverages genome-wide fragmentomics-based characteristics to identify cancer signals and predict the signal origin across a diverse range of cancer types.
Methods: Plasma cfDNA from evaluable blood samples was analyzed using an MCED blood test called MERCURY, a robust machine learning classifier leveraging the low-coverage whole-genome sequencing and a comprehensive set of genome-wide features derived from cfDNA fragmentomics. A carefully selected cohort of 3076 cancer patients representing 13 cancer types, in addition to 3477 healthy controls, were pre-specified into the training and internal validation sets to train and internally validate the models to assess cancer and tissue of origin (TOO). The classifier was trained to a target specificity of 99% and locked before analysis of the independent validation set. The independent validation was enrolled prospectively and consists of 1465 participants (cancer: n= 732; non-cancer: n= 733).
Results: The performance metrics in the internal validation set demonstrated that the sensitivity and specificity for cancer detection were 0.865 (95% CI [0.840, 0.887]) and 0.989 (95% CI [0.980, 0.994]), respectively. These impressive results were further substantiated in the independent validation set, where the overall sensitivity and specificity were found to be 0.874 (95% CI [0.848, 0.897]) and 0.978 (95% CI [0.965, 0.987]) respectively. Notably, the sensitivity showed an incremental increase with the stage of cancer (Stage I: 0.769, 95% CI [0.708, 0.821]; Stage II: 0.840, 95% CI [0.784, 0.886]; Stage III: 0.923, 95% CI [0.874, 0.954]; Stage IV: 0.971, 95% CI [0.901, 0.995]. Regarding the TOO model, a total of 10 cancer types with more than 100 patients in the model construction cohort were considered. The TOO model achieved a prediction accuracy of 83.5% (95% CI [80.7%, 86.6%]) and 91.8% (95% CI [89.6%, 94.1%]) for the top predicted origin and the top two predicted origins, respectively, amongst the true positive cases in the independent validation set.
Conclusions: In this pre-specified, large-scale study, the MCED test, utilizing cfDNA fragmentomics, demonstrates its remarkable ability to assess cancer signal with an elevated level of sensitivity and specificity across 13 distinct types of cancer. Moreover, it displays noteworthy accuracy in predicting the tissue of origin. The performances are to be further validated in a prospective cohort study (NCT06011694).

#1267 Projected impact of liquid biopsy screening strategies with high sensitivity in focused populations and high specificity in broad populations.

P. B. Bach, N. U. Trivedi, L. Cotton;
Delfi Diagnostics, Baltimore, MD

Purpose: Two 'liquid biopsy' cancer screening approaches exist: Focused and Broad. The Focused approach targets specific cancers and populations lacking adequate screening, emphasizing high sensitivity. The Broad approach aims to detect various cancers in the population, prioritizing high specificity to minimize false-positives but potentially compromising sensitivity. The public health impact and testing burden of these approaches remain unexplored.
Methods: Projected cancer mortality reduction and annual test volumes are based on published data for liquid biopsy tests. Focused screening is modeled for patients not undergoing guideline-recommended screening for lung, liver, and colorectal cancers. Broad screening is modeled for individuals aged 50-80, assuming the detection of all cancer types. Averted deaths are calculated by combining published mortality reduction estimates or assumed at 20% if not available. Reductions are adjusted for reported test sensitivities. Liquid biopsy cannot prevent deaths from cancers recommended for screening if the person has already undergone the recommended test.
Results: Focused and broad screening strategies annually prevented around 20,000 cancer deaths. Focused screening necessitated testing only one-fifth of the people compared to broad screening (30MM vs. 150MM). The projected reduction in mortality for focused testing relied entirely on randomized studies, while the equivalent statistic for the broad strategy was 53%.
Conclusions: Equivalent reductions in cancer deaths can be achieved with focused screening at high sensitivity and broad screening at high specificity, with only one-fifth of the testing burden. The influence of false positives in focused testing and false reassurance in broad testing may impact these findings, which could also be influenced by testing and follow-up costs.

Table 1

Annual cancer deaths averted (thousands)	Focused cancer testing	Broad cancer testing
Lung	10-12	4-8
Liver	4-5	1
Colorectal	3-4	1
Other screened cancers*	Not modeled	1-2
Unscreened cancers	Not modeled	6-10
Total	17-20	14-22
Annual test volume (millions)	30	150
*Other screened cancers includes prostate, breast, cervical. Range reflects the application of reported Stage I or overall sensitivity, respectively.		

#1268 Immune activation characterization via amino acid concentration signatures for multi-cancer early detection and CDKi treatment response prediction.

C. Tang[1], P. Corredeira[1], S. Casimiro[1], W. Sukdao[2], L. Costa[1], E. Yates[2], G. Bernardes[3];
[1]Instituto de Medicina Molecular Joao Lobo Antunes, Lisbon, Portugal, [2]Proteotype Diagnostics Ltd, London, United Kingdom, [3]Yusuf Hamied Department of Chemistry, University of Cambridge, Cambridge, United Kingdom

Early detection of cancer can increase survival rates by 5-10 times. In the US, a significant portion of cancers are still detected at a late stage, for example, 32.1% of breast cancer, 45.5% of lung cancer, 22.8% of colon cancer patients were diagnosed at advanced stage. Early detection is challenging because many cancers are asymptomatic in early stages, although cancer screening can detect cancer before symptoms emerge. Current standard-of-care screening programs are limited and directed to single types of cancer. Non-invasive multi-cancer early detection (MCED) is urgently needed because it can screen for several cancer types with a single blood test, increasing cancer screening coverage while avoiding cumulative false positive rates.
Developmental MCED approaches usually rely on detection of circulating tumor DNA (ctDNA) released from tumors. However, ctDNA signals scale with tumor burden limiting sensitivity and specificity, particularly for early-stage cancers, while also limiting applicability to precision oncology.
Here we report a MCED approach with superior sensitivity and specificity, which can also be used to predict treatment response. We introduce a novel strategy for detecting cancers from blood plasma, profiling the immune response to disease development rather than relying on detection of emerging diseased tissue. The platform is designed to detect alterations in the ratio of immunoglobulins and albumin, as well as class-switching among immunoglobulins, by measuring the overall concentration of amino acid residues incorporated into proteins in patient plasma. By using our biorthogonal chemistry labeling tool, we were able to measure and characterize amino acid concentration signatures (AACS) within the neat blood samples, including cysteine, free cysteine, lysine, tryptophan and tyrosine, which allowed us to observe distinct signatures for varying cancers including breast, prostate, colorectal and pancreatic cancers. We could identify 84% of cancers with <0.5% false positive rate (N=93). In this study, cancer AACS signatures were distinct from signatures measured with non-cancerous immune activation, including autoimmune diseases and infection.
Moreover, AACS was also correlated to clinical features, such as cancer metastatic statuses and therapy response. With Cyclin-dependent Kinase 4/6 Inhibitors-treated advanced breast cancer patients as an example, we achieved 100% correct prediction of responding patients and 91.7% accurate predictions of non-responding patients by using AACS in treatment-naïve samples.
Altogether, the novel AACS approach is a powerful combination of bioorthogonal chemistry and machine learning analysis in clinical practice, and it can be potentially used for cancer screening and support clinical decisions for treatment selection and patient stratification in new indications.

#1269 Large-scale validaton studies of a blood-based effective and affordable test for multicancer early detection.

M. Mao[1], B. Wei[2], Q. Xu[2], Y. Shen[2], R. Brandao[3], S. Li[1], W. Wu[1], P. Xing[4], Y. Chang[4], D. Zhu[4];

[1]Research & Development, SeekIn Inc, Shenzhen, China, [2]The Affiliated Cancer Hospital of Zhengzhou University and Henan Cancer Hospital, Zhengzhou, China, [3]First Clinic, Sao Paulo, Brazil, [4]Clinical Laboratories, Shenyou Bio, Zhengzhou, China

Cancer early detection aims at reducing cancer deaths. Unfortunately, many established cancer screening methods are not suitable for use in low- and middle-income countries (LMICs) due to cost, complexity, and dependency on extensive medical infrastructure. Nearly 10,000 participants (2003 cancer cases and 7888 non-cancer cases) were divided into one training and five independent validation cohorts across different races, sample types and platforms. One tube of peripheral blood was collected from each participant and quantified using a panel of seven protein tumor markers (PTMs) consisting of AFP, CA125, CA15-3, CA19-9, CA72-4, CEA and CYFRA 21-1 by common clinical immunoassay analyzers. An algorithm named OncoSeek was established using artificial intelligence (AI) to distinguish cancer cases from non-cancer cases by calculating the probability of cancer (POC) index based on the quantification of the seven PTMs and clinical information including sex and age, and to predict the possible affected tissue of origin (TOO). The conventional clinical method that relied only on a single threshold for each PTM would make a big problem when combining the results of those markers as the false positive rate would accumulate as the number of markers increased. Nevertheless, OncoSeek was empowered by AI to significantly reduce the false positive rate, increasing the specificity from 54.0% to 93.0%. The overall sensitivity of OncoSeek was 51.7%, resulting in 84.6% accuracy. The performance was consistent in the training and the five validation cohorts from three countries (Brazil, China and United States) including two sample types (plasma and serum) and three different platforms (Roche, Luminex and ELISA). The sensitivities ranged from 39.0% to 77.6% for the detection of the nine common cancer types (breast, colorectum, liver, lung, lymphoma, oesophagus, ovary, pancreas and stomach), which account for 59.2% of global cancer deaths annually. Furthermore, it has shown excellent sensitivity in several high-mortality cancer types for which there are lacking routine screening tests in the clinic, such as the sensitivity of pancreatic cancer was 77.6%. The overall accuracy of TOO prediction in the true positives was 65.4%, which could assist the clinical diagnostic workup. OncoSeek significantly outperforms the conventional clinical method, representing a novel blood-based test for multicancer early detection (MCED) that is non-invasive, easy, efficient and robust. Moreover, the accuracy of TOO facilitates the follow-up diagnostic workup. OncoSeek is affordable (~$20) and accessible requiring nothing more than a blood draw at the screening sites, which makes it adoptable in LMICs.

#1270 p53-R172H mutation confers gain-of-function properties and promotes metastasis in squamous cell carcinoma.

G. Efe[1], K. Cunningham[1], R. Navaridas Fernandez de Bobadilla[1], K. J. Dunbar[1], K. Sugiura[1], N. Nishiwaki[1], S. Carcamo[2], L. Resnick-Silverman[2], D. Hasson[2], A. J. Klein-Szanto[3], A. M. Taylor[1], J. J. Manfredi[2], C. Prives[4], A. K. Rustgi[1];
[1]Columbia University Irving Medical Center, New York, NY, [2]Icahn School of Medicine at Mount Sinai, New York, NY, [3]Fox Chase Cancer Center, New York, NY, [4]Columbia University, New York, NY

INTRODUCTION: Metastasis is associated with more than 90% of cancer-related mortality, and thus, there is a compelling need for innovative therapeutic breakthroughs. *TP53* mutations are present in 60-70% of human cancers, especially in squamous cell cancers. For example, *TP53* mutations are detected in up to 80% of esophageal squamous cell carcinomas (ESCCs). Accumulating evidence suggests that certain missense mutant forms of p53 such as R175 (R172 in mouse), R273 and R282 can acquire neomorphic pro-oncogenic activities that are referred to as gain-of-function (GOF). To elucidate novel mutant p53-dependent mechanisms in promoting metastasis, we conducted RNA-Seq, p53 ChIP-Seq and H3K27ac CUT&RUN-Seq on primary and metastatic tumor cells harvested from our mouse model of ESCC harboring *Trp53*$^{R172H/-}$, *Trp53*$^{-/-}$ and *Trp53*$^{+/+}$. Herein, we have identified p53-R172H gene targets in metastatic ESCC. One of the dominant effectors of p53-R172H-mediated metastasis was Colony stimulating factor-1 (Csf-1) signaling through its cognate receptor (Csf-1r), which we recently published in Cancer Discovery (PMID: 37676642). Overall, this study aims to investigate the GOF properties and mediators of mutant p53 in promoting ESCC metastasis.

RESULTS/DISCUSSION: Using *ex vivo* cultures and *in vivo* tail-vein injections, we demonstrated increased colonization and metastatic capabilities of ESCC cells harboring p53-R172H in comparison to the tumor cells with null and wild-type p53. p53-R172H occupies more genes in the metastatic ESCCs than in the primary tumors that is independent of p53 expression levels. We identified 72 unique targets of p53-R172H with altered gene occupancy and expression that occurs during the transition from primary tumor to metastasis. Such targets in metastatic ESCC are exemplified by *Csf-1* and *Birc5* (encoding anti-apoptosis protein Survivin) that are also enriched with H3K27ac in their promoters. They are upregulated during metastasis compared to the primary tumors dependent upon p53 mutation status, which is reinforced by TCGA data and ESCC patient-derived tissue microarrays (TMAs). Interestingly, other frequently detected “hotspot” p53 mutations including R282W and R273C, which we introduced into the ESCC cells using base editing promote differential pro-tumorigenic activities. Indeed, the analysis of SCC datasets in TCGA reveals that specific p53 mutations are associated with altered overall survival, as well as differences in the enriched pathways.

CONCLUSION: We have demonstrated GOF properties and mediators of p53-R172H in promoting ESCC metastasis that may be applicable to other SCCs. We are further expanding our analyses to additional “hotspot” p53 mutations to dissect the mechanisms of distinct p53 mutations in fostering ESCC metastasis, which can open up new avenues for therapeutic applications.

#1271 PMEPA1 acts as a switch to modulate cooperative cellular invasion and drive NSCLC tumor progression.

T. O. Khatib[1], B. A. Pedro[2], C. M. Knippler[1], V. Y. Matsuk[1], S. F. Webster[1], S. Bombin[1], B. Dwivedi[1], J. Kowalski[3], H. R. Johnston[1], J. K. Mouw[1], A. I. Marcus[1]; [1]Emory University, Atlanta, GA, [2]Johns Hopkins School of Medicine, Baltimore, MD, [3]University of Texas at Austin, Austin, TX

Metastatic disease drives cancer patient mortality. One primary mode of metastasis is collective invasion, whereby cohesive groups of cells invade into the adjacent stroma while maintaining cell-cell contacts. Importantly, these cellular packs harbor genetically and phenotypically heterogeneous subpopulations that cooperate to drive invasion. To deconstruct how phenotypic cellular heterogeneity facilitates distinct molecular profiles within a single tumor, we established the technique Spatiotemporal Cellular and Genomic Analysis (SaGA). SaGA is an image-guided approach that optically highlights phenotypically defined cell(s) for live fluorescence-activated cell sorting and analysis. To elucidate the transcriptional heterogeneity across invasive packs within a 3D physiologically-relevant microenvironment, we combined SaGA with single cell RNA sequencing for isolation and analysis of actively invading cells. This novel single cell transcriptomics approach reveals that - during cellular invasion into the microenvironment - the follower subpopulation supplies TGFβ to heterogeneously stimulate both autocrine canonical and paracrine noncanonical signaling pathways. This cooperative exchange facilitates a symbiotic relationship between tumor subpopulations in non-small cell lung carcinoma both *in vitro* and *in vivo*. *In vitro*, we determine that PMEPA1 protein levels mitigate TGFβ downstream effector signaling within heterogeneous tumor cells to modulate JAG1 expression and activity. *In vivo*, we show that a reduction in JAG1 levels decreases primary tumor cell invasion and progression. We mechanistically define a TGFβ-PMEPA1-JAG1 signaling axis across leader and follower subpopulations critical for tumor cell invasion and cancer progression. Together, these data highlight the importance of cellular heterogeneity and subpopulation communication required for tumor progression.

#1272 Spatial profiling of human colorectal cancer brain metastasis identifies chromosomal instability with adaptive niche cellular reorganization and reprograming.

A. Sathe[1], A. Khan[1], J. Kang[1], R. Meka[1], S. M. Grimes[1], A. S. Luksik[2], M. Lim[1], C. Petrisch[1], C. M. Jackson[2], H. Vogel[1], M. Gephart[1], S. Han[1], H. P. Ji[1]; [1]Stanford University School of Medicine, Palo Alto, CA, [2]Johns Hopkins University School of Medicine, Baltimore, MD

Brain metastasis in colorectal cancer (mCRC) poses a significant clinical challenge with poor outcomes. Our study, the largest spatial analysis reported to date, aimed to uncover unique cellular and genomic features facilitating metastatic lesion development. Employing spatial transcriptomics on 60 patients' surgical resections, we validated our findings with single-cell RNA sequencing (scRNA-seq), whole-genome sequencing (WGS), and *ex vivo* functional studies in tumor slice cultures. We obtained spatially distinct gene expression profiles of metastatic tumor cells, tumor microenvironment (TME) and brain parenchymal lineages. Our analysis identified spatially heterogenous upregulation of PI3K, MAPK, EGFR, p53, and TGFβ signaling in metastatic tumor cells. Tumor cells had high levels of chromosomal instability (CIN) marked by recurrent amplifications in chromosomes 6, 7, 17, and 20. WGS from three independent cohorts revealed significantly higher CIN in mCRC brain compared to primary CRC or mCRC from other organs. Spatial neighborhood analysis identified an immune desert phenotype with lack of proximity between lymphocytes and metastatic tumor cells. However, mCRC brain contained abundant plasma cells identifying a unique TME niche feature. Significant proximity between tumor cells and endothelial cells underscored their potential role in tumor seeding and growth. Spatially aware differential expression analysis demonstrated adaptive responses in the brain parenchyma. This included increased Golgi-ER processing and Rho GTPase signaling in neurons and astrocytes adjacent to metastatic tumor cells, respectively. Macrophages were characterized by high expression of pro-fibrogenic genes. Increased *SPP1* ligand expression from these macrophages interacted with corresponding receptors on spatially proximal fibroblasts, identifying a key niche reorganization feature that can promote metastatic lesion growth. To evaluate the translational potential of our findings, we examined the effects of perturbating the metastatic niche using scRNA-seq. We established a tumor slice culture from a mCRC brain surgical resection, which maintained all original cell states. Despite elevated signaling pathway activity, metastatic tumor cells were resistant to regorafenib, a multi-receptor tyrosine kinase inhibitor. In contrast, pirfenidone, an anti-fibrotic and anti-inflammatory small molecule, successfully reduced extracellular matrix-associated gene expression programs in fibroblasts in the TME. Our analysis identified distinct properties of mCRC brain that can serve as therapeutic targets, including high levels of chromosomal instability, remodeling of brain parenchyma, lymphocyte evasion, plasma cell abundance and macrophage-fibroblast interactions.

#1273 Tumor progression and tumor microenvironment of pancreas cancer ascites revealed by scRNA-seq and spatial transcriptomics.

S. Umeda, E.-R. Karnoub, F. Balogun, A. Jimenez-Sanchez, C. A. Iacobuzio-Donahue;
Memorial Sloan Kettering Cancer Center, New York, NY

Peritoneal metastasis of pancreas cancer is one of the ultimate modes of spread in the cancer. Little is known about how cancer cells spread into abdominal cavity and what is different from hematogenous metastasis. It is also not well characterized how tumor microenvironment prevent cancer cells from spreading in abdominal cavity. We performed single-cell RNA-seq analysis and special transcriptomic analysis to clarify the progression and environment of the cancer. We collected and processed ascites samples of 20 PDAC samples from 19 patients. Sixteen ascites samples were obtained from abdominal paracentesis and two cases in the postmortem period. For one patient ascites was collected both pre and postmortem. All but one patient received chemotherapy prior to ascites collection. Routine clinical cytology evaluation of ascites samples from 17 patients indicated it was malignant in 11 patients and nonmalignant in six patients. All ascites samples were purified by gradient centrifuge using Ficoll-Paque Plus to remove erythrocytes and necrotic debris. For the platform, we adopted the 10x Genomics Chromium Single Cell Gene Expression platform for single-cell RNA-seq library preparation. Spatial transcriptomics was performed for eight FFPE samples from the two autopsy patients with paired cancer ascites using 10x Visium. The CytAssist was used to transfer transcripts of pre-sectioned and pre-stained tissues with 11 x 11 mm Visium Capture Area slides. The sample locations were metastatic tumors to bowel wall, rib bone, mesentery, iliac nerve, diaphragm, peritoneum, pelvis, and primary pancreas tumor. A total of 248,263 cells were analyzed in single-cell RNA-seq. Cell population in pancreas cancer ascites consisted of macrophages, lymphocytes, dendritic cells, plasma cells, plasmacytoid dendritic cells, mesothelial cells, and cancer cells. Cancer cells were detected in twelve samples whereas no cancer cells were detected in eight samples. Gene ontology and gene set enrichment analyses showed macrophages in ascites with cancer cells involved neutrophil activation while those in ascites without cancer cells retained antigen presentation capacity and inducing interferon gamma pathway. Mesothelial cells in ascites with cancer cells showed more apoptosis and lymphocyte proliferation while those in ascites without cancers cells triggered fibrosis and mitosis. These data suggest that macrophage and mesothelial cells could be categorized into anti-tumor cells and tumor associated cells. Ongoing investigations are exploring ligand-receptor relationships. We are going to compare the expression profile of tumor cells in ascites fluid and in tissue from various organs by integrating single cell RNA-seq data and special transcriptomics data.

#1274 Investigating PLOD2 as a therapeutic target to overcome metastasis in radiorecurrent prostate cancer.

Gavin Frame[1], Hon Leong[2], Roni Haas[3], Xiaoyong Huang[2], Jessica Wright[1], Paul C. Boutros[3], Thomas Kislinger[4], Stanley K. Liu[2]

[1]Medical Biophysics, University of Toronto, Toronto, ON, Canada,[2]Sunnybrook Research Institute, Toronto, ON, Canada,[3]University of California, Los Angeles, Los Angeles, CA,[4]University Health Network, Toronto, ON, Canada

Prostate cancer (PCa) is the second most common cancer in males, with 1 in 8 men developing the disease in their lifetime. For PCa, a common treatment strategy is external beam radiation therapy to the prostate. However, when cancer recurs (radiorecurrent PCa), it often behaves aggressively by invading into surrounding organs or spreading distantly. Radiorecurrent PCa metastasis is therefore a significant cause of morbidity and mortality that must be overcome to improve survival of advanced PCa patients. Proteomic analysis revealed the procollagen enzyme Lysyl Hydroxylase 2 (PLOD2) to be upregulated in our radiorecurrent, and highly aggressive, conventionally fractionated DU145 (DU145-CF) PCa cell line. Given its established function as a mediator of invasion in various other cancers, we sought to characterize the role of PLOD2 in the aggressive phenotype of our radiorecurrent PCa cells. Bioinformatic analysis of clinical data revealed PLOD2 genomic amplification to be significantly associated with biochemical recurrence in PCa patients. Upon further examination in vitro, it was revealed that PLOD2 knockdown significantly reduces matrigel invasion and migration in our radiorecurrent DU145-CF cell line, in addition to numerous other PCa cell lines, including primary cells we derived directly from PCa patients. Using the in vivo chick Chorioallantoic Membrane (CAM) model, we confirmed that PLOD2 knockdown significantly reduces the ability of DU145-CF cells to extravasate from the CAM vasculature into the surrounding stroma, a critical step of the metastatic cascade. To explore mechanisms of metastatic cellular reprogramming downstream of PLOD2, RNA sequencing of DU145-CF cells was conducted; a total of 681 genes were discovered to be dysregulated by PLOD2 knockdown, with their functional analysis suggesting changes in cellular metabolism and respiration. Finally, since PLOD2 is known to be regulated by hypoxia-induced protein HIF1α, we explored whether PLOD2 expression could be inhibited by the HIF1α inhibitor, PX-478. Treatment with PX-478 reduced both HIF1α and PLOD2 protein expression, and significantly reduced invasion, migration, and in vivo extravasation in DU145-CF cells, thereby indicating its potential as a pharmacological inhibitor of HIF1α-associated PLOD2 in radiorecurrent PCa. Together, our results demonstrate for the first time the role of PLOD2 in radiorecurrent PCa invasiveness, and point towards its potential as a therapeutic target to reduce metastasis and improve survival outcomes in PCa patients.

#1275 *In vivo* functional CRISPR screens identifies metabolic dependencies mediating triple negative breast cancer lung metastasis.

Xiaoyong Wang, Shu-ting Chou, Verra Ngwa, Yoonha Hwang, Breelyn Karno, Deanna Edwards, Jin Chen

Medicine, Vanderbilt University Medical Center, Nashville, TN

Metastasis is responsible for about 90% of cancer-related mortality. Throughout the metastatic cascade, cancer cells requires substantial metabolic rewiring to adapt the nutrient micro-environmental changes enabling dissemination and seeding in distant organs. Recent insights into importance of the tumor-intrinsic metabolic reprograming has been implicated in immune escape, yet altered immune responses imposed by tumor metabolism during metastasis are poorly understood. Here, we generated genetic perturbations in triple-negative breast cancer cells using metabolism-focused CRISPR knockout library and performed in vivo screens in both immunocompetent and immunodeficient mice. By comparing enriched sgRNAs in lung metastases or primary tumors, we identify loss of one gene related to long chain fatty acid (LCFA) β-oxidation (FAO) potentiates metastatic dissemination in immunocompetent mice but no in immunodeficient mice, suggesting that impaired FAO in tumor cells promotes breast cancer lung metastasis through an lymphocytes-dependent manner. We confirmed individual sgRNAs targeting this FAO gene from the primary screen dramatically accelerate metastasis in different breast cancer orthotopic models. Specifically, we find that low expression of this gene in primary tumors of advanced breast cancer patients with high grade tumors and positive lymph nodes (LN+) is associated with reduced overall survival. In addition, deletion of this gene generates an immunosuppressive microenvironment in the lung metastatic tumors with increased neutrophils, monocytes and decreased $TNF\alpha^{+}$-$IFN\gamma^{+}$ $CD8^{+}$ T cells. Mechanistically, impaired FAO in tumor cells causes mitochondria imbalance under lipid metabolism stress, consequently triggers inflammatory response on establishing a neutrophil-rich metastatic niche via mitochondrial nucleic acid-driven innate immunity. Altogether, our data provides a new insight on how tumor cell lipid metabolism impacting immune interplay during metastatic progression, nominating potential anti-tumor immunotherapies.

#1276 Kindlin-2: a novel target of Parkin regulating cancer metastasis.

M. Yeon, I. Bertolini, D. C. Altieri;
The Wistar Institute, Philadelphia, PA

Although targeted therapies in prostate cancer have clinically shown successful outcomes, resistance to these therapies and acquisition of lineage plasticity pose challenges for fully treating prostate cancer. Among several microscopic perspectives to solve these obstacles, much evidence has emerged indicating that mitochondria dynamics are closely associated with tumor metastasis and tumor progression in various types of cancer.

The E3 ubiquitin ligase Parkin is associated with PINK1-mediated mitophagy, allowing cells to control mitochondria damages and generate the needed energy to survive in harsh physiological conditions.

Interestingly, we found that Parkin potentially ubiquitinates proteins independently of PINK1-associated mitophagy. By SALIC analysis, we found that K681 and K582 of Kindlin-2 is one of the potential ubiquitination sites by Parkin in prostate cancer cells.

Kindlin-2 is a cytoskeletal membrane protein and is a component of the focal adhesion complex. Computational modeling suggested that N-terminal region of Kindlin-2 binds to Parkin, with K581 and K582 of Kindlin-2 exposed outside for ubiquitination. Our studies showed that Kindlin-2 is ubiquitinated and degraded by wild-type Parkin but not by the catalytic site, C431S, mutant Parkin. Furthermore, K581A and K582A mutant Kindlin-2 did not exhibit poly-ubiquitination under conditions of Parkin overexpression. Surprisingly, in our immunofluorescence study, Kindlin-2 was recruited to the mitochondria and co-localized with Parkin. From a mitochondrial functional perspective, wild-type Kindlin-2 reduced mitochondria dynamics, whereas mutant Kindlin-2 didn't in the presence of Parkin. This suggests that the cytoskeletal protein Kindlin-2 might play a role in mitochondrial dynamics that mediates tumor metastasis.

Wild-type Kindlin-2 reduced both focal adhesion generation and decay, unlike mutant Kindlin-2 under Parkin-induced condition. Additionally, this pattern was observed in the single cell lamellipodia dynamics through live cell imaging. 2D and 3D cell invasive assays supported the evidence that Parkin decreases tumor metastatic potential by ubiquitinating Kindlin-2 and regulating mitochondria and focal adhesion dynamics.

Our findings indicate that Parkin reduces tumor metastatic potential by ubiquitinating Kindlin-2 and demonstrate the possibility as a therapeutic agent for advanced and immune suppressive tumors. Furthermore, Parkin could be a promising agent for Parkin suppressed tumor patients in line with personalized cancer therapy development.

TUMOR BIOLOGY: Microbes and Tumors: Time for Mechanisms
Minisymposium

#1277 Unveiling the impact of intratumoral microbiota in the treatment efficacy of soft tissue sarcoma.

L. Tiraboschi[1], D. Braga[2], A. Melacarne[1], V. Ferrari[3], G. Vella[1], A. Mozzarelli[4], A. Lo Cascio[1], G. Fornasa[1], M. Lizier[1], S. Carloni[5], G. Martano[1], S. Timo[1], A. Bernardinello[1], S. L. Renne[5], F. Cananzi[5], A. Bertuzzi[1], G. Penna[1], M. Rescigno[5];

[1]IRCCS Humanitas Clinical and Research Center, Rozzano, Milan, Italy, [2]Institute of Oncology Research, Bellinzona, Switzerland, [3]Institute for Research in Biomedicine, Bellinzona, Switzerland, [4]New York University, Langone Health, New York, NY, [5]Humanitas University, Rozzano, Milan, Italy

Tumor resident microbiota is an emerging component of the tumor microenvironment with unclear biological function. Among all microorganisms harbored within tumor tissue, bacteria are currently the most studied due to their ability to interact with the host. To date, the tumor microbiome is reported as composed of tumor type-specific bacteria, commonly found within host cells, which can affect tumor biology as well as play a role in cancer formation, progression, and response to therapy. So far, the contribution of intratumoral microbiota in the context of soft tissue sarcoma (STS) has been underestimated; therefore, this project aims to characterize the STS microbiota and understand if it can impair the sensitivity to chemotherapeutic regimens. STS are heterogeneous cancers with more than 100 histological subtypes, different in molecular alterations, which make its personalized therapy very complex. Thus, doxorubicin is the gold standard of chemotherapy for advanced STS but it is effective for less than 50% of patients. Doxorubicin is a natural anthracycline produced by different strains of *Streptomycetaceae* which exploit the toxic properties of this molecule for inter-specific competition. Hence, the hypothesis that certain bacteria developed drug-inactivating mechanisms seems evolutionarily plausible. Targeting the bacterial 16S rRNA gene through a Fluorescence in situ hybridization, we were able to detect bacteria within different histotypes of sarcoma. In addition, we analyzed the microbiome composition of sarcoma tissues and adjacent healthy tissues showing that sarcomas harbor a distinct microbiome composition. Besides, comparison of different sarcoma histotypes revealed that microbiome composition seems to be shaped according to histological features. Moreover, we isolate live bacteria harbored within sarcoma tissues. To date, isolated bacteria were mainly strictly or facultative anaerobes; thus, well adapted to live in the hypoxic environment of tumors. These bacteria gave us the opportunity to investigate their ability to interfere with chemotherapy. We exposed several sarcoma-isolated bacteria strains to doxorubicin, we found that certain bacteria strains were responsible for drug degradation. This result was confirmed with functional experiments evaluating drug toxicity after bacterial exposure. In addition, we showed *in vivo* that the intratumoral presence of doxorubicin-degrading bacteria is sufficient to provoke the occurrence of chemoresistance in a doxorubicin-sensitive mouse model of fibrosarcoma. This study offers new insights about the relationship between the intratumoral microbiota and the occurrence of chemoresistance in cancer therapies, suggesting that microbial communities hosted within the tumor should be deeply investigated, and then manipulated, to improve the outcome of therapies.

#1278 Differential urinary microbiome and its metabolic footprint in bladder cancer patients following BCG treatment.

Kyungchan Min[1], Xuan-Mei Piao[2], Young Joon Byun[2], Chuang-Ming Zheng[2], Seon-Kyu Kim[3], Seong-Hwan Park[3], Sungmin Moon[4], Kyeong Kim[4], Ho Won Kang[4], Won Tae Kim[4], Seok Joong Yun[4], Hansoo Park[1]

[1]Gwangju Institute of Science and Technology, Gwangju, Korea, Republic of,[2]Department of Urology, Chungbuk National University College of Medicine, Cheongju, Korea, Republic of,[3]University of Science and Technology, Department of Bioscience, Daejeon, Korea, Republic of,[4]Department of Urology, Chungbuk National University Hospital, Cheongju, Korea, Republic of

Introduction & Objectives: Recent insights reveal a urinary microbiome, challenging prior beliefs about urine's sterility. Using 16S rRNA gene sequencing, a pivotal tool in mapping this microbiome, our study delves into the interplay between bladder cancer (BCa), BCG therapy, and the urinary microbiome. We analyzed bacterial profiles in benign and malignant samples, considering various clinical parameters.

Materials & Methods: A total of 88 patients participated in the study, comprising 30 individuals with benign diseases and 58 BCa patients. Urine samples were collected from patients with benign conditions and from BCa patients before and after BCG treatment. Malignant samples obtained before the completion of the intravesical BCG induction cycle were labeled 'Pre-BCG', while those collected after this cycle were termed 'Post-BCG'. Following collection, DNA was extracted and underwent 16S rRNA gene sequencing. The sequencing data was then utilized for bioinformatic analyses, which included metagenomic profiling and metabolic pathway inference.

Results: Significant differences in bacterial compositions were observed between benign and malignant samples, with a metabolic signature suggesting toluene degradation pathway may mitigate bladder cancer development. In the post-BCG samples, we inferred elevations of 2-oxoglutarate, a BCG derivative, and L-methionine, which is associated with therapeutic benefits, compared to their pre-BCG counterparts. Furthermore, post-BCG samples showed microbial differences in responders and increased quinolone synthesis compared to non-responders. This is of significance due to quinolone's role in modulating DNA topoisomerase and mitochondrial functions, both pivotal in bladder cancer progression.

Conclusions: Utilizing 16S rRNA gene sequencing, we drew comparisons between the urinary microbiomes of benign and malignant samples and suggested a potential pathway for bladder cancer occurrence. Following intravesical BCG treatment, certain microbial metabolic pathways seemed to offer therapeutic benefits to responders. Our study provides insights into the microbial influences on bladder cancer development and the varying responses to BCG treatment.

#1280 Role of the tumor microbiome in the lung adenocarcinoma immune microenvironment through multi meta-omics analysis.

I. Valdes[1], A. Martin[2], E. Martinez[3], d. Carvajal Hausdorf[4], E. Riquelme[1];
[1]Pontificia Universidad Catolica de Chile, Santiago, Chile, [2]Universidad San Sebastian, Santiago, Chile, [3]Corporacion CGNA, Temuco, Chile, [4]Clinica Alemana Santiago, Santiago, Chile

Lung cancer is the leading cause of death by cancer worldwide. The tumor microbiome has shed light on its role, influence, and modulation in cancer immunosurveillance, where the tumor-bacterial component emerges as a potential mediator for the antitumoral-immune response. Nevertheless, the complexities and functional mechanisms underlying this interaction remain elusive. Here, we outline how the tumor microbiota can impact the host´s immune response to lung adenocarcinoma (LUAD). We explored the microbiome within LUAD tumors and non-tumoral adjacent tissues (NAT) from Chilean patients. We used 10 paired (LUAD and NAT) fresh-frozen samples, 20 exclusively tumor fresh-frozen samples, and 40 exclusively tumor formalin-fixed paraffin-embedded samples. Using 16S rRNA gene sequencing, we assessed revealed variations in alpha diversity, with an intra-tumoral microbiome enriched in *Gammaproteobacteria* and *Actinobacteria*, particularly genera *Pseudomonas* and *Corynebacterium* in undifferentiated LUAD samples. Notably, a consistent depletion of *Verrucomicrobiota* with genus *Akkermansia* was evident in samples where cell differentiation was lost. Metaproteomics analysis revealed bacteria-associated peptides from *Pseudomonas* and *Streptomyces* enriched in the tumor, linked to Major facilitator superfamily (MFS) transporters and Glutathione S-transferase N-terminal domain-containing protein, both associated with transport activity and negatively correlated with cancer. The bacterial metabolic analysis uncovered 10 enriched microbial-associated metabolites in the tumor, highlighting adenosine and inosine, two known inducers of immunosuppression on T-cells in the tumor microenvironment. Host proteomics gene-ontology analysis highlighted an enrichment of proteins in the Interferon pathways. Concurrently, a downregulation of proteins like T-cell surface-glycoprotein CD8 and HLA-class I histocompatibility antigen was observed, linked to MHC protein complex binding function, and associated with immune evasion through diminished antigen presentation. Furthermore, upregulated proteins such as macrophage migration inhibition factor (MIF) and eIF-2-alpha kinase GCN2, known to stimulate cell proliferation, were identified. In summary, our multi-omics and bioinformatic analyses unveil a distinct intra-tumoral microbiome and microbe-derived metabolites could induce immune suppression, altering the metabolic profile in the LUAD tumor microenvironment and collectively contribute to tumor progression.

#1281 Antibiotics aerosolization shrinks intratumoral Tregs and impairs lung tumor growth by perturbing the taxonomic structure of tumor-associated microbiota.

Giancarla Bernardo[1], Valentino Le Noci[2], Elena Montanari[2], Emerenziana Ottaviano[3], Giorgio Gargari[4], Elisa Borghi[3], Simone Guglielmetti[4], Federico Ambrogi[5], Tiziana Triulzi[2], Elda Tagliabue[2], Serenella M. Pupa[2], Michele Sommariva[1], Lucia Sfondrini[1]

[1]Department of Biomedical Sciences for Health, University of Milan, Milano, Italy,[2]Department of Experimental Oncology, Fondazione IRCCS Istituto Nazionale dei Tumori, Milano, Italy,[3]Department of Science of Health, University of Milan, Milano, Italy,[4]Department of Food, Environmental and Nutritional Sciences (DeFENS), University of Milan, Milano, Italy,[5]Department of Clinical Sciences and Community Health,, University of Milan, Milano, Italy

The lung has been traditionally regarded as a sterile environment. Emerging evidence has overturned this belief unveiling the existence of a specific lung microbiota that plays a pivotal role in modulating lung immune tolerance. Recent research also sheds light on how the tissue microbiota is significantly altered by the presence of a growing tumor. Here, we investigated the compositional changes in lung-colonizing bacterial populations associated with the growth of LLC1 lung carcinoma cells in C57BL/6 mice, by analyzing the lung 16S rRNA profiling. While overall microbial diversity and structure were similar in tumor-bearing and healthy lungs, abundance analysis of amplicon sequence variants (ASVs) revealed that 48 ASVs were differentially modulated at significant level (FDR ≤ 0.05). Notably, local treatment with aerosolized vancomycin/neomycin antibiotics starting 4 days after tumor injection caused a different representation of 47 ASVs (FDR ≤ 0.05), mostly reducing those ASVs specifically emerging in the lung by the tumor growth, belonging to Bacterioidales, Clostridiales, Lactobacillales and Enterobacteriales. A different microbial composition was also suggested by the results of Partial Least Squares Discriminant Analysis (PLS-DA) that clustered lung tumor samples as saline or antibiotic-aerosolized. Based on the reported ability of some bacteria belonging to these orders to induce immunosuppressive cells in the gut, we examined the impact of antibiotic aerosol on tumor-associated Tregs in the lung. The presence of the tumor promoted the appearance of Tregs expressing CD69 and PD-1 activation markers, but vancomycin/neomycin aerosol treatment strongly dropped Treg frequency in tumor-bearing lungs, compared to saline. In a therapeutic setting, aerosolization of antibiotics starting 4 days after LLC1 tumor intravenous injection significantly reduced the number of lung metastases (p=0.0116). This effect was associated with an increased cytotoxic activity of immune infiltrating effector cells suggesting that the modulation of the lung microbiota impairs tumor growth and enhances antitumor immune response. Some cultivable bacterial strains, that were in agreement with metataxonomic profile results, were isolated from tumor-bearing lungs, but not from healthy lungs. Ongoing experiments suggest an effect of their in vivo transfer in the lung by aerosol on tumor growth and the ability to induce Treg expansion in vitro. Overall, this study unveils that the growth of the murine LLC1 tumor shapes the lung microbial composition by favoring the expansion of microbes with potential immunosuppressive activity eventually affecting the tumor progression. Moreover, our findings unravel the therapeutic potential of localized antibiotics to revert the immunosuppressive microenvironment by targeting tumor-associated bacteria.

#1282 Gavage with *Candida albicans* leads to fungal colonization of colorectal tumors and decreased response to radiotherapy.

D. J. Grencewicz III[1], A. Loncar[1], R. Hoyd[1], A. Pallerla[1], N. Williams[1], M. Benej[1], M. Kreamer[1], Y. Mehra[1], S. Jahanbakhshi[1], M. Anderson[2], N. Denko[1], D. Spakowicz[1];

[1]The Ohio State University College of Medicine, Columbus, OH, [2]University of Wisconsin-Madison, Madison, WI

The host microbiome in the gut and tumors have been shown to affect tumor growth and therapeutic response in cancer. Furthermore, the presence of specific fungal taxa are associated with tumor hypoxia, tumor progression, therapeutic response, and clinical outcomes in colorectal cancer (CRC). Preliminary data from our group found that the presence of *Candida* species increased tumor hypoxia and decreased overall survival in CRC. However, whether intratumoral *Candida* drive, support, or simply inhabit tumors with poor prognoses remains unclear. Here, we investigate a casual role for *Candida albicans* in tumor progression and therapy response using a syngeneic mouse model of microsatellite-instability high (MSI-H) colorectal cancer.

We subcutaneously implanted MC38 colorectal cancer cells into C57BL/6 mice and then orally gavaged these mice with *C. albicans*, *Saccharomyces cerevisiae*, or PBS. The site of tumor formation was locally irradiated once (7.5 Gy), and growth of the tumor was measured over time. Differences in tumor volume were assessed by longitudinal mixed-effect models. Tumor sections were stained for fungi using calcofluor white (CFW) and underwent bulk RNA sequencing to detect differential gene expression, which were interpreted using gene set enrichment analysis (GSEA).

Mice gavaged with *C. albicans* showed decreased response to radiation compared to mice gavaged with either *S. cerevisiae* ($p<0.05$) or PBS ($p<0.001$). Additionally, hyphae were observed in murine tumors gavaged with *C. albicans*, suggesting translocation of gavaged *C. albicans* from the gut to tumors. Further, tumors from mice gavaged with *C. albicans* displayed unique gene expression profiles, including decreased interferon alpha and IL-6 and STAT3 signaling, decreased oxidative phosphorylation, and decreased apoptosis-related gene expression.

Here, we show that *C. albicans* may confer resistance to radiation therapy and affects immune and cancer cell activity in the MC38 (MSI-H) syngeneic *in vivo* model of colorectal cancer. Further, we show that hyphal fungi can be visualized in heterotopic murine tumors from our *C. albicans* gavage condition. These data establish that fungi can translocate from the gut to distal tumor sites, and that upon translocation, changes in gene expression and therapy response are observed. Future directions will explore the mechanism by which these effects occur and whether these findings can be leveraged to improve radiotherapy outcomes.

#1283 Digital spatial profiling of metastatic brain tumors reveals association of the tumor microbiome with immune alterations in the tumor microenvironment.

G. Morad, A. V. Damania, B. Melendez, M. C. Wong, P. V. Sahasrabhojane, S. B. Johnson, M. Chelvanambi, F. Dimitriou, J. S. Losh, N. J. Ajami, S. D. Ferguson, J. A. Wargo;
UT MD Anderson Cancer Center, Houston, TX

Introduction: Metastatic brain tumors are associated with significant morbidity and mortality. The microbiome has emerged as a novel hallmark of cancer, with a prominent role in tumor immunity and response to treatment. However, the role of the microbiome in brain tumors, and in particular brain metastasis, is largely unknown. We hypothesized that distinct microbial communities are associated with alterations in the tumor microenvironment in metastatic brain tumors.
Methods: To evaluate the role of different microbial communities in brain metastasis, matched stool, saliva, and tumor samples were collected prospectively from patients with metastatic brain tumors who underwent surgical tumor resection at the University of Texas MD Anderson Cancer Center. Stool and saliva samples were sequenced via metagenomic shotgun sequencing and tumor samples were analyzed through 16S rRNA gene sequencing. The tumor microbiome was further characterized through confocal and electron microscopy and culture techniques. Lastly, we conducted digital spatial profiling using the NanoString GeoMx® platform to determine the spatial association of the tumor microbiome with tumor and immune transcriptome. Spatial single-cell transcriptome analysis of bacteria-positive and bacteria-negative cells within the tumor microenvironment is currently in progress using the CosMx® platform (NanoString Inc.).
Results: Our computational and experimental analyses demonstrated that bacterial signals could be detected in metastatic brain tumors and exhibit an intracellular localization. Interestingly, we found that the tumor bacterial signatures in brain metastases were composed of commensal oral bacterial taxa but had limited overlap with the gut microbiome. Spatial transcriptome analysis demonstrated that tumor areas with high bacterial signal were associated with innate-immune mediated anti-bacterial responses, suggesting an active host response to intra-tumoral bacteria in metastatic brain tumors.
Conclusion: Overall, this work demonstrates the presence of intracellular bacterial signal coupled with an anti-bacterial response within the tumor microenvironment of brain metastases. These findings offer a new perspective on the dynamic interaction between cancer, microbiome, and the brain microenvironment and can inform future mechanistic and translational studies to improve the outcome of brain tumor patients.

SCIENCE AND HEALTH POLICY: Science and Health Policy
Poster Session

#1287 The ACCESS consortium: Advancing childhood cancer experience, science and survivorship in Canada.

C. J. Williams[1], S. A. Grover[2], A. Co-Dyre[3], D. Malkin[2], J. A. Whitlock[2], on behalf of the ACCESS consortium;
[1]Ontario Institute for Cancer Research, Toronto, ON, Canada, [2]The Hospital for Sick Children, Toronto, ON, Canada, [3]King's University College at Western University, London, ON, Canada

In Canada, >4,300 children, adolescents and young adults are diagnosed with cancer each year. 1/3 have refractory/metastatic disease or will relapse with an expected 5-year survival rate of <15%. The prognosis for most pediatric cancers has stagnated in the past 30 years and Canada trails the US and Europe in providing accessible clinical trials and improved outcomes. Advocacy for change by patients and families led to a federal government investment of $30M in pediatric cancer research. $23M was allocated to establishing a national pediatric cancer consortium. “ACCESS: advancing childhood cancer experience, science and survivorship” is the new multi-stakeholder network created with a vision that every Canadian child with cancer has access to the latest scientific advances, diagnostic tools, therapies and supportive care leading to better outcomes and quality of life.
ACCESS will connect the Canadian pediatric cancer community, build partnerships, leverage research and clinical expertise across cancer types and ages, implement transformative change and create a unified national strategy. To date, >350 clinicians, researchers, policymakers, advocates, people with lived experience (PWLE; patients, families and survivors) and other stakeholders have been engaged, with a goal of representing Canada's ethno-cultural, socioeconomic and geographic diversity. ACCESS is building partnerships between children, families, professionals, and existing programs to collaborate in coordinated research and knowledge mobilization. The goal is to implement transformative change in the delivery of fair, fast, effective and safe cancer care for all Canadian children.
ACCESS has developed a statement of its values that includes patient/survivor and family centred; collaborative; anti-oppressive; innovation and excellence; accountable. Uniquely, ACCESS is an interdisciplinary and inclusive organization that directly engages and collaborates with PWLE at all levels of research and governance.
ACCESS is organized into 7 themes that will address gaps, advance research and educate through all phases of the pediatric cancer journey: cancer biology; clinical trials; access to innovative therapies and optimal care; regulation, policy and economics; education and training; ethical, legal, societal implications and implementation science; and psychosocial and survivorship. In addition, there are two cross cutting groups focusing on Knowledge mobilization and Social justice, Indigenization and Inclusion.
Collaborations with local, provincial, national and international initiatives are being established through the development of a partnership strategy. Cross-consortium priorities are being implemented, and a data management strategy is in development. The publication of a strategic and sustainability plan for ACCESS is anticipated in 2024.

#1288 Evaluating gender and country of origin diversity on editorial boards in thoracic, gastrointestinal, and breast oncology journals.

Z. L. Arter[1], R. Hsu[2], D. Benjamin[3];

[1]University of California Irvine medical center/Chao Family Comprehensive Cancer Center, Orange, CA, [2]University of Southern California/Norris Comprehensive Cancer Center, Los Angeles, CA, [3]Hoag Family Cancer Institute, Newport Beach, CA

Background: The composition and diversity of editorial board members in oncology journals are critical indicators of the field's inclusivity and global perspective. Despite a historical trend of female underrepresentation on editorial boards of peer-reviewed medical journals, the extent of diversity within oncology's various subspecialties remains less understood. This study aims to elucidate the landscape of gender and economic diversity among editorial boards in three major oncology subspecialties: thoracic, gastrointestinal (GI), and breast oncology.

Methods: 5 top oncology journals in thoracic, GI, and breast oncology were selected based on 2022 Journal Citation Reports impact factors (Clarivate). Editorial board members, identified from each journal's website, were assessed for economic diversity using the World Bank's 2024 high-income country classification and gender based on academic profile data. Chi-square tests evaluated the gender and economic diversity differences.

Results: A total of 762 editor positions from 15 journals were analyzed across the 3 subspecialties. In thoracic oncology, 64.6% were men, 33.5% women, with 7.3% from non-high-income countries. In GI oncology, 84.5% were men, 10.5% women, with 11.1% from non-high-income countries. In breast oncology, 59.3% were men, 39.7% women, with 2.8% from non-high-income countries. Significant disparities in gender and geographical origin were noted ($\chi^2 < 0.01$). A majority of GI oncology journal editors are based in Asia (66.1%), while in thoracic and breast oncology, most editors are located in North America and Europe. Among 17 editors-in-chief, 88.2% were men, all from high-income countries.

Conclusion: The study highlights a significant gender imbalance and a predominance of editors from high-income countries in oncology journals. This imbalance underscores the need for greater inclusivity and diversity in the editorial boards of prominent oncology journals.

Gender and country of origin representation among thoracic, GI, and breast oncology Journals

Editors in Subspecialties	Male	Female	Unknown Gender	Originating from High-Income Country	Originating from Middle- or Low-Income Country	Continent
Thoracic Oncology (N=206)	133 (64.6%)	69 (33.5%)	4 (1.9%)	191 (92.7%)	15 (7.3%)	Asia: 37 (18.0%) Africa: 1 (0.5%) Australia: 7 (3.4%) Europe: 73 (35.4%) North America: 86 (41.7%) South America: 2 (1.0%)
GI oncology (N=342)	289 (84.5%)	36(10.5%)	17 (5%)	304 (88.9%)	38 (11.1%)	Asia: 226 (66.1%) Africa: 1 (0.3%) Australia: 2 (0.6%) Europe: 71 (20.8%) North America: 40 (11.7%) South America: 2 (0.6%)
Breast Oncology (N=214)	127 (59.3%)	85 (39.7%)	2 (0.9%)	208 (97.2%)	6 (2.8%)	Asia: 10 (4.7%) Australia: 10 (4.7%) Europe: 63 (29.4%) North America: 130 (60.7%) South America: 1 (0.5%)

#1289 Disparities in healthcare utilization and access among female cancer survivors in Maryland.

A. E. Connor[1], M. Jin[2], K. Visvanathan[1];

[1]Johns Hopkins Bloomberg Sch. of Public Health & Sidney Kimmel Comprehensive Cancer Center, Baltimore, MD, [2]University of North Carolina, Chapel Hill, Chapel Hill, NC

Background: Healthcare utilization can be defined as how often healthcare is used, through what venue, and if access is available. There are medically vulnerable groups of cancer survivors, such as racial/ethnic minorities and economically disadvantaged populations, that may underutilize healthcare throughout cancer survivorship compared to non-vulnerable groups. Factors associated with survivorship care access/utilization should be evaluated to identify at-risk groups and reduce risk of poor health outcomes. Among female cancer survivors in Maryland, we examined the associations between race/ethnicity, obesity, measures of economic stability, and healthcare utilization-related outcomes (including access to care providers, type of doctor provides majority of care, and unmet health care needs because of cost).

Methods: Survey data were analyzed for 1,353 non-Hispanic white (NHW) and 280 non-Hispanic Black (NHB) women with a self-reported history of cancer living in Maryland who completed the Maryland Behavioral Risk Factor Surveillance Survey between 2011-2020. Multivariable logistic regression models were used to estimate odds ratios (ORs) and 95% confidence intervals (CI) for the associations between independent factors and healthcare utilization outcomes.

Results: On average, survivors were 66.8 (standard deviation (SD)=12.8) years of age at time of survey and 53.5 (SD=15.6) years of age at time of cancer diagnosis. Breast cancer was the most common cancer reported (58.9%). While most women reported being retired (50.6%), 30.6% reported being employed and 10% were unemployed. Most women were homeowners (81.5%) and 40.1% had household incomes >$50,000/year. Overall, race/ethnicity was not associated with any of the outcomes. Unemployed survivors (compared to employed) were 3.90 times more likely (95% CI 1.38-11.04, p=0.01) to report not being able to see a doctor because of cost. Survivors who were not homeowners (compared to homeowners) were 0.39 times less likely (95% CI 0.22-0.67, p <0.001) to report having a general/family practitioner for majority of cancer survivorship care. Survivors with household incomes ≤$50,000/year (compared to >$50,000/year) were 2.36 times more likely (95% CI 1.20-4.65, p=0.01) to not have seen a doctor in the past year. Lastly, obese survivors, compared to non-obese, were 0.25 times less likely (95% CI 0.07-0.84, p=0.02) to not have at least one healthcare provider.

Conclusions: While race/ethnicity was not associated with healthcare access/utilization, our results do demonstrate various disparities in access to care and healthcare utilization during cancer survivorship by employment status, home ownership, and income. Our findings can inform interventions in collaboration with healthcare providers caring for female cancer survivors to address challenges associated with access to survivorship care among medically underserved survivors in Maryland.

#1290 Racial and ethnic representation and disparities on clinical guideline panels in oncology.

J. M. Loree[1], A. Dasari[2], M. Shaheed[3], H. Gothwal[4], K. Singh[5], H. Shaheed[6], R. Mangal[4], S. Gothwal[7], J. Willis[2], M. J. Overman[2], S. Kopetz[2], **K. P. Raghav**[2]; [1]BC Cancer, Vancouver, BC, Canada, [2]The University of Texas MD Anderson Cancer Center, Houston, TX, [3]McMaster University, Hamilton, ON, Canada, [4]Adesh Institute of Medical Science and Research, Bathinda, India, [5]Government Medical College, Patiala, India, [6]The University at Buffalo, Buffalo, NY, [7]Texas A&M University, College Station, TX

Purpose: Culturally competent diverse workforce is critical to equitable and progressive cancer care. Yet, racial bias, permeates practice and research in oncology. The National Comprehensive Cancer Network (NCCN) panels recommend guidelines that determine standards for patient care in the United States (US). We investigated the extent of racial/ethnic representation/disparity amid this higher echelon of cancer leadership.

Methods: We collected data from publicly available NCCN (https://www.nccn.org) guidelines (version: 1.2023-5.2023) published between 11/2022-11/2023. Six research team members extracted data. Race/ethnicity (NIH categories: White, Black, Hispanic/Latinx, Asian) was identified by advanced AI detection software tools (Namsor and Kairos, utilizing names and facial recognition to infer US race). Gender was determined using name/pronoun (if available). All information was confirmed using online databases (institutional profiles, biographical paragraphs, social media) and group consensus (in case of discrepancies). Data regarding active US physicians was obtained using Association of American Medical Colleges (AAMC) 2022 physician specialty data report. The primary objective was to determine the racial/ethnic composition of panels and association between race/ethnicity and chairs/co-chairs/vice-chairs (lead positions or leads) within panels. Descriptive statistics were used. Proportions were compared using Fisher-exact or Chi-squared test (odds-ratio [OR] and 95% confidence intervals [95%CI] were reported).

Results: We reviewed 63 panels corresponding to 63 distinct disease sites. A total of 1223 unique individuals [475 (38.8%) females and 748 (61.2%) males] accounted for 2162 panel members with a median of 34 members (range: 25-42) per panel. Racial/ethnic representation was 1455 (67.3%) Whites, 570 (26.4%) Asians, 93 (4.3%) Hispanics/Latinx, and 44 (2.0%) Blacks, which was comparable to racial/ethnic makeup of active US physicians (64%, 21%, 7% and 6%, respectively). Among these 2162 member positions, 129 (6.0%) were lead positions. In these leads, racial/ethnic representation was 105 (81.4%) Whites, 5 (11.4%) Blacks, 17 (3.0%) Asians, and 2 (2.2%) Hispanics/Latinx. Notably, no significant difference was seen between proportion of female (5.2%) and male (6.4%) leads (OR: 0.80; 95%CI:0.55-1.16; P=0.26). However, the proportion of Whites in lead positions was significantly higher than Non-whites (7.2% vs. 3.4%; OR: 2.2; 95%CI: 1.4-3.5; P < 0.001).

Conclusions: Although, overall membership of NCCN panels shows favorable racial/ethnic diversity, underrepresentation and bias appear to subsist for non-White race/ethnicity, when it comes to leadership positions within this key decision-making body that influences cancer care. Further efforts to improve this disparity within oncology is an essential step to shaping equity within the field.

#1291 ASPIRE: Advocates and Scientists Partner in Research Education.

Laurie Betts[1], Jennifer Potter[2], Veronica Carlisle[2], Patricia A. Spears[3]

[1]Patient Advocates for Research Council, UNC Lineberger Comprehensive Cancer Center, Mebane, NC,[2]UNC Lineberger Comprehensive Cancer Center, Chapel Hill, NC,[3]Patient Advocates for Research Council, UNC Lineberger Comprehensive Cancer Center, Chapel Hill, NC

UNC Lineberger Comprehensive Cancer Center (LCCC) has a robust and growing cancer patient advocacy community. UNC Lineberger is the flagship publicly funded comprehensive cancer center in North Carolina. We are constantly looking for ways to educate patient and community advocates on recent advances in cancer biology research and clinical trials. Our advocates are also valuable partners for our basic and clinical researchers that may be early in their career. We developed and implemented an inaugural research education program for new advocates. We model this program partly on the highly successful and popular AACR Scientist Survivor Program that recently celebrated it's 25th anniversary. Some of the UNC LCCC advocates participate in the SSP and were motivated to develop our own local program.

We will showcase our pilot 2024 ASPIRE education program that brings together cancer patient and community advocates and cancer researchers to learn from each other. The basic itinerary of the ASPIRE program is:

1.Three separate one-hour online presentations by UNC Lineberger researchers with a patient advocate moderator. The topics covered are:

Cancer 101 : cancer biology, diagnosis, staging, treatment.

Clinical Trials 101: clinical trials, phases, patient protection, progress with for example accrual of representative populations.

Research 101: bench research, bioinformatic, AI, how research works and how it may lead to new treatments. To showcase a tissue donation program being developed by UNC Patient Advocates that will benefit researchers.

2.The lecture series is followed by a breakfast roundtable discussion for all the participants to discuss their experiences. There will be short presentations and discussions in small groups of researchers and cancer patient advocates.

We will summarize our ASPIRE pilot experience, how our participation in the SSP program motivated this local program, and how we plan to incorporate feedback from participants to inform future programs. We hope this will lead to more informed patient advocates that can then be even more powerful in research advocacy.

#1292 ProTALKS: A community outreach project founded by a graduate of the CaRE^2 Community Scientist Research Advocacy training program, Mrs. Lynn Jones-Turpin.

Lynn Jones-Turpin[1], Ileana Guzman[2], Brooke Hensel[2], Fern Webb[1]

[1]University of Florida, Jacksonville, FL,[2]University of Florida, Orlando, FL

ProTALKS was created and led by a community member committed to reducing prostate cancer health disparities. ProTALKS stands for Prostate Cancer Outreach, Opinions, and Opportunities and is designed to increase awareness of prostate cancer prevention, research, and treatment as well as highlight the health disparities observed in Black communities. According to the Florida Department of Health, prostate cancer incidence and mortality rates among Black men living in Duval County are higher compared to men of other races and ethnicities. Therefore, there is a need for programs like ProTALKS that focus on early detection strategies and promoting community resources. In collaboration with the Prostate Health Education Network (PHEN), The American Legion Post 197, and Florida Blue, ProTALKS has increased access to services such as prostate cancer screening and evidence-based information. Community events implemented by ProTALKS bring together oncologists, researchers, key community leaders, health educators, and providers to educate and promote positive health behavior changes among high-risk communities. In addition to hosting health fairs, ProTalks has hosted grilling competitions and community awareness walks to further educate the community about prostate cancer prevention, screening, and research. ProTALKS also shares information through the local newspaper, *The Jacksonville Free Press*, The Lynn & Friends radio show, and social media platforms. Since its start in 2021, with support from the Florida-California Cancer Research, Education, and Engagement (CaRE^2) Health Equity Center, ProTALKS has implemented more than 10 community events with over 1,000 community members from Jacksonville, Florida. ProTALKS, in collaboration with CaRE^2, continues to disseminate information about cancer screening, the importance of clinical trial participation, and donating biospecimens for cancer research. Although ProTALKS has been successful in its mission, there have been challenges throughout its implementation. For example, one challenge has been increasing the number of community members attending events and using appropriate marketing techniques to promote ProTALKS' activities. Future implications to avoid challenges include recruiting more volunteers, and partnering with other community organizations in Duval County.

#1293 Uncovered: The breast cancer journey of a Black woman from advocacy to awareness to action.

M. Audoin;
Michelle Audoin (Individual Patient Advocate), Toronto, ON, Canada

Background: There have been 3 significant life events guiding my journey from being a young, Black mother with stage 4 breast cancer and thyroid cancer to an engaged patient partner. The first was having a benign breast tumor removed at age 14. The second was my 2017 mBC diagnosis, including my bilateral mastectomy and the lack of images and information available for Black women concerning reconstruction and scar management. The third is exclusion from and the lack of diversity in clinical trials.
Objective: In order to address the disparities in cancer and my unmet needs, I use my story and experiences as a catalyst for change primarily in three forms, which have evolved over time: advocacy, awareness, and action.
Methods: Advocacy: To unburden myself from the shame about my breast health and the scar from my surgery at age 14, I vocalized my concerns and needs as an adult navigating my breast reconstruction options after my 2017 cancer diagnosis. Ongoing frustration that my needs were not being addressed led me to create Uncovered: A Breast Recognition Project, in collaboration with Rethink Breast Cancer. Uncovered, a digital and print resource, shines a light on the disparities and challenges that Black, Indigenous and people of color face in breast cancer care.
Awareness: The 2020 edition started with my story and those of 7 Black women. After Uncovered launched, other racialized women reached out with similar experiences. The resource was expanded in 2021 to include stories and images of an Inuk woman, Black women, and women of color. This confirmed a systemic need to raise awareness and address racialized communities and inequities in breast cancer care.
Action: As a result of the slow progress towards systemic change, I, along with the women of Uncovered, co-created the Wish List in 2021. The Uncovered Wish List is 6 accessible and actionable items that should be a priority for ending disparities in breast cancer care. Due to the complexity of my diagnosis, which limits my clinical trial options, and the historical underrepresentation of racialized communities in clinical trials, I now partner with cancer institutions and organizations that focus on research to address ongoing unmet needs with the goal to improve equity, diversity and inclusion.
Results: Uncovered is a first-of-its-kind resource in Canada. To date, it has had a global reach of over 70 million through conferences, panels, podcasts, resource links, presentations, and various media. The recognition of my story, Uncovered, and the Wish List allows me to form collaborative connections, and become an engaged patient partner committed to systemic change.
Conclusion: Despite systemic barriers, it is possible for Black women with breast cancer to advocate, raise awareness and take action towards change in meaningful ways.

#1294 Cancer related fatigue and the additive effect of treatment in the context of lymphoma and CLL: An analysis of Lymphoma Coalition's 2022 Global Patient Survey.

S. E. Kalloger, A. Watson, S. Sajkowski, L. Warwick;
Lymphoma Coalition, Kingston, ON, Canada

Introduction: Cancer related fatigue (CRF) continues to be a challenging phenomenon that is often underreported and poorly understood. With etiologies in both disease and treatment manifesting as a symptom and a side-effect respectively, CRF is highly incident and presents a significant clinical problem that impacts survivorship. We sought to explore CRF in a large multinational cohort of patients with lymphoma and Chronic lymphocytic leukemia (CLL).
Methods: Lymphoma Coalition deployed the Global Patient Survey in 2022 targeting patients with lymphoma and CLL and their caregivers. Responses were collected from 8637 respondents over 79 countries. Respondents indicated if they experienced fatigue as a symptom, side-effect or both. Data were enumerated and segregated into the following categories: No Fatigue / Treated (A), No Symptom / No Treatment (B), Symptom / No Treatment (C), Symptom Only / Treated (D), Side-effect Only (E), Symptom and Side-Effect (F). Data were stratified across lymphoma subtypes and categorical percentages were computed. An approximation of the contribution of treatment to CRF was calculated using the following equation: (F) + (E) - (D).
Results: Valid responses were obtained for 6758 respondents. The majority of respondents for most subtypes reported CRF as both a symptom and a side-effect of treatment. Across the 13 subtypes examined, the attributable incidence of CRF related to treatment was found to be highest in: DLBCL (58%), Hodgkin (54%), Peripheral T- Cell (53%) and Mantle Cell (50%). The subtypes with the lowest attributable incidence of CRF included: Chronic Lymphocytic Leukemia (3%), Hairy Cell (12%), Cutaneous (25%) and Marginal Zone (26%).
Conclusions: The majority of patients in this study cited CRF as a significant issue. The calculated fraction of fatigue attributable to treatment suggests that certain treatments may have a larger effect on fatigue than others. A limitation of this study is that we are relying upon patient reported outcomes and we acknowledge that patients may be unable to reliably differentiate fatigue from being a symptom or a side-effect. Our future work in this area will seek to map the intensity of fatigue from diagnosis through treatment in order to get a better understanding of the dynamic nature of this phenomenon. However, we are of the opinion that the compounding effect of CRF related to both disease and treatment yields opportunities to individualize treatment to patients based upon their symptomatic CRF.

#1295 CancerCare coping circle workshop for patients with cancer and covid-19.

Christine Verini[1], **Sarah Paul**[1], Rebecca Ashkenazy[2], Brittany Wolf Gianares[2]

[1]CancerCare, New York, NY, [2]Pfizer, New York, NY

Background: Despite an end to the US COVID-19 public health emergency, COVID-19 remains an ongoing public health priority (1). Patients with cancer can be at increased risk of progression to severe COVID-19 due to their cancer type or to receipt of immunosuppressives or treatment (2). Their mental and emotional well-being have also been impacted negatively (3). There is a need for awareness and education on managing and navigating risk of COVID-19 infection in patients with cancer.

Method: Coping Circle Workshop series webinar 'Navigating the Ongoing Impact of COVID-19 on Cancer Patients' was designed for patient/caregivers to reduce feelings of isolation caused by ongoing challenges associated with COVID-19; provide attendees with the tools to communicate effectively with medical teams; offer tips on utilizing and enhancing their support systems; and help develop adaptive coping mechanisms and provide resources for support. Pre- and post-webinar polls were analyzed to assess webinar impact. Training was provided by a social worker and a mindfulness practice was incorporated.

Results: Webinar had 11 attendees; 91% had skipped a cancer medical appointment due to COVID-19. Post-webinar, all participants responded that the webinar provided new topic information or insights at a level of ≥3 (scale 0-5; Table 1). Attendees' confidence in understanding and managing their potential risks associated with COVID-19 infection increased from 5.8±1.3 (mean± standard deviation) pre-survey to 8.2±1.8 post-survey (scale 0-10).

Conclusions: Delivery of COVID-19 education by an aligned provider supports enhanced scientific discourse and disease management resource utilization and awareness. It may also serve to reduce time and resource burden on oncology providers when engaging in educating patients and improve patients COVID-19 care and management. Conclusions are limited by small participation size.

#1296 Evaluating the accuracy and reproducibility of ChatGPT models in answering lung cancer patient queries.

A. Allibhai[1], **A. Allibhai**[1], A. Brade[2], Z. Allibhai[1];
[1]Southlake Hospital, Newmarket, ON, Canada, [2]University of Toronto, West Mississauga, ON, Canada

Large language models (LLMs) such as ChatGPT can imitate human conversation and produce rapid, coherent responses, which may mask their potential for inaccuracies. With patients increasingly turning to the internet for medical information, the use of LLM chatbots for cancer-related queries risks spreading misinformation. Our study assessed ChatGPT's accuracy and reproducibility in offering valid information and treatment advice for lung cancer in line with established guidelines.

In the evolving landscape of AI-driven healthcare support, the ability of language models to provide accurate and reliable information is crucial. Our study delves into the effectiveness of OpenAI's ChatGPT models (versions 3.5 and 4.0) in responding to patient inquiries about lung cancer across various domains including general information, clinical presentation, risk factors, screening, diagnosis, staging, treatment options, prognosis, post-treatment follow-up, lifestyle recommendations, and psychosocial/educational aspects.

We conducted a structured assessment, posing identical sets of questions to both ChatGPT 3.5 and 4.0. A total of 47 questions were posed with each query being repeated twice per model to evaluate both the accuracy and reproducibility of the responses. The scoring system focused on the accuracy and comprehensiveness of each response.

Our findings revealed a notable disparity in the performance of the two models. GPT 4.0 demonstrated higher consistency and accuracy, with 41 out of 47 (87.2%) responses deemed accurate and comprehensive, compared to 36 out of 47 (76.6%) for GPT 3.5. In terms of reproducibility, both models exhibited strong performance: 42 out of 47 (89.3%) for GPT 3.5 and 45 out of 47 for GPT 4.0 (95.7%). When comparing responses between the models, we observed good reproducibility in 38 out of 47 questions (80.8%).

A key observation was that GPT 4.0 significantly outperformed its predecessor GPT 3.5 in terms of both accuracy as well as reproducibility within its own responses, indicating a more reliable and consistent performance. The area most lacking in accuracy for both models was lung cancer staging, indicating a need for further refinement in this domain. Another key observation was the models' tendency to incorporate empathetic language, often beginning responses with expressions of sympathy and consistently advising confirmation with a medical professional.

Our study underscores the potential and limitations of current AI models in patient education and support, highlighting areas for improvement and the importance of empathetic communication in AI interactions with patients. As the model continues to be trained on a larger and more comprehensive set of data, it is reasonable to anticipate further improvements in its ability to provide precise, detailed, and contextually appropriate responses.

#1297 Patient engagement: Improving the at home care for cancer patients in treatment.

R. Blomquist;
CareBOX Program, Austin, TX

CareBOX Program is an Austin-based non-profit founded in 2014 to address a serious gap in cancer care for patients in the Central Texas area. It provides essential nutritional supplements and supplies to help prevent malnutrition, infections, and injuries from falls as patients continue at-home recovery during treatment and following surgery. About 80 percent of the supplies CareBOX Program provides are not covered by insurance. Many patients could not afford to purchase these items on their own. Volunteers deliver the CareBOXes to the clients' homes. CareBOX Program has always been an inclusive organization. We operate on the basis that all cancer patients in Central Texas in need of our services will receive them as long as we have the funding to do so. Our youngest patient has been 3 months old and our oldest patient has been 93 years old. Currently we are serving more women (61%) than men (39%). Approximately 67% of patient households report annual income of less than $35,000. To date, CareBOX program volunteers have delivered more than 3,800 CareBOXes

#1298 Assessing the impact of Medicaid expansion on colorectal cancer preventative services utilization.

P. Omeaku;
VCU Massey Comprehensive Cancer Center, Richmond, VA

Introduction: Colorectal cancer (CRC) is the second leading cause of cancer mortality. CRC screening rates have steadily risen and incidence rates around the nation have declined. To date, forty-one states have expanded Medicaid across the United States, with 9 states remaining that have not expanded. Although, access through insurance has increased, colorectal disparities in screening and mortality persist. Other studies have shown that screening guideline concordance can be inconsistent based on insurance type. Data suggests Medicaid enrollees are more likely to present advanced-stage cancers than those privately enrolled. The screening differences throughout the United States emphasize how complex colorectal cancer disparities are and how insurance may play a role.
Aims: Our study aims to investigate the impact of Medicaid expansion on timely CRC screenings, specifically examining whether these effects differ by African Americans, Hispanics, and White Americans.
Methods: Data was utilized from the Behavioral Risk Factor Surveillance System (BRFSS) to analyze timely CRC screening data of adults below 138% of the federal poverty level (FPL) of states with different Medicaid expansion statuses. Most recently available data was used in our analysis spanning the years 2014-2022 in all 50 states. States were stratified by dummy variables for Medicaid expansion and non-expansion status. Timely CRC screenings were determined by eligible respondent responses. Difference-in-difference analyses were used to study the effect of Medicaid expansion on timely CRC screenings in states with different Medicaid expansion statuses.
Results: Our sample included 60.52% White Americans, 12.22% African Americans, and 16.41% Hispanics in both Medicaid expanded and non-expanded states. Sex and race had significant associations to Medicaid expansion status and timely CRC screenings, particularly when analyzing race for Hispanics and White Americans. Between 2014 and 2022, timely CRC screening for low-income adults in Medicaid expansion states was at 33.15% compared to 23.17% from non-expansion status states. Notably, adults aged 45-64 demonstrated the highest differences in timely CRC screenings for Medicaid-expanded states (12.26% and 18.98%) compared to non-expanded states (9.27% and 13.96%, respectively).

#1299 Cost-effectiveness analysis of circulating tumor DNA-based molecular profiling platforms for the detection of *EGFR* mutations in lung cancer.
P. Rozendal, P. van der Leest, E. M. J. van der Logt, N. Rifaela, I. Platteel, F. J. G. Scherpen, H. J. M. Groen, L. C. L. van Kempen, E. M. D. Schuuring; University Medical Center Groningen, Groningen, Netherlands

Background The detection of mutations in circulating tumor DNA (ctDNA) in blood plasma of lung cancer patients can be used to monitor the tumor-response to therapy and for the early detection of resistance mechanisms. In 2017, the Roche Cobas® EGFR Mutation Test v2 for the detection of the *EGFR* c.2369C>T p.(T790M) mutation in plasma-derived ctDNA was FDA-approved to identify patients eligible for osimertinib treatment. Today, different platforms are available for *EGFR* mutation testing in plasma-derived cell-free DNA (cfDNA). In this study we compared the clinical utility of five platforms for the detection of *EGFR* mutations in cfDNA offering insights into their operational costs, target coverage, hands-on-time and turn-around-time.
Methods Four PCR-based platforms and one NGS-based approach for the detection of *EGFR* mutations were compared. Operational, maintenance, material and personnel costs were calculated for each platform and used as input variables for our recently developed ctDNA micro-costing framework (doi.org/10.1016/j.jmoldx.2022.10.004). This was compared to target coverage and turn-around-time of each platform in the context of therapy resistance.
Results Per sample costs decreased for all platforms at maximal weekly throughput. The BioCartis Idylla™ demonstrated the shortest turn-around-time while the Roche Cobas® was the least expensive. Despite being the most expensive and time-consuming, the AVENIO ctDNA Expanded kit covered the most known resistance mechanisms to *EGFR* inhibitors, many of which are targetable with other TKIs.
Conclusion *EGFR* ctDNA mutation analysis is only cost-effective when the throughput is high. This implies that centralization of cfDNA-testing is necessary to optimize cost-efficiency. With the advent of ctDNA analysis beyond *EGFR* in the context of targeted therapies for lung cancer, multigene detection assays will become more cost-effective with high throughput.

Overview of results

Platform	Turn-around time at maximal weekly throughput	Per sample cost at maximal weekly throughput	Coverage of resistance mutations in *EGFR* [1]Additional testing necessary	Coverage of genome-wide resistance mutations to *EGFR*-TKI [1]Additional testing necessary
BioCartis Idylla™ ct*EGFR* Mutation Assay	2,5 hours	€571	33%	12%[1]
Roche Cobas® *EGFR* Mutation Test v2	4 hours	€497	33%	6%
Bio-Rad QX200 droplet digital PCR (ddPCR)	7,5 hours	€766	100%[1]	24%[1]
Agena MassARRAY® UltraSEEK® Lung Panel	2 days	€613	53%	12%
Roche AVENIO ctDNA Expanded kit	1 week	€1551	100%	65%

#1300 A collaborative approach to enhance tissue donation for cancer research; the UNC Patients and Researchers Together (PART) Program.

P. A. Spears, M. Van Lokeren, V. Branch, J. A. Potter, R. Robinson, Patient And Researchers Together (PART) Team;
University of North Carolina at Chapel Hill, Chapel Hill, NC

Introduction: Tumor tissue-based cancer research is essential to translate scientific discoveries to improve treatments for cancer. Tissue donation programs require a partnership: patients donating tissue and researchers using tissue for translational research. Lineberger Comprehensive Cancer Center (LCCC) has established a program called Patients and Researchers Together (PART) to value and increase the number of patients who agree to donate tissue for research. The PART Program is a patient-centered partnership between patients, community members, oncologists, surgeons, researchers, as well as staff and faculty from the clinical trials office, tissue procurement facility and UNC health communications to increase tissue donations for cancer research by valuing the patient's contribution.

Methods: The PART program began in 2021 by convening a group of diverse partners with a common goal of valuing patients as partners in biospecimen research. Creating an environment of bidirectional communication and exchange of ideas to 1) inform patients about the benefits of donating tissue for research, 2) inform the public about the importance of tissue to help researchers learn more about cancer, and 3) ensure researchers at UNC have access to tissue for their research. In the initial phase, the PART team evaluated the tissue research needs at LCCC by conducting surveys, interviews and focus groups with key partners. This set the foundation for the focus of current activities. One of the key focus areas is to communicate to patients and the public about the value of using tissue in research. The PART program established a working group to develop patient materials. The working group developed a template for educational materials, study summaries and a rigorous review process. The development of materials and iterative review process includes content experts, health literacy experts, patients and community members, and communications experts.

Results: The PART working group developed a series of educational materials about tissue donation for research. Understanding the importance of donating tissue for research is the first step in engaging with patients. The team developed a template and a multi-step process to review documents. PART used this information to develop a website to promote tissue donation for research to the public. The team has been developing summaries of studies focused on tissue donation. We developed or consulted on 2 general education flyers and 8 study summaries in a variety of cancer types. There is a continuous queue of studies in progress and plans to develop more general education materials.

PART patients and community members are leading the effort to educate patients and the public about tissue use in research. LCCC values patients who donate their tissue to research to improve the lives of all cancer patients.

#1301 Comparing VA and safety-net hospital patient-reported care metrics and provider recommendations to address social determinants of health and demographics.

N. Hippalgaonkar[1], M. Weinfeld[1], C. Weldon[2], J. Trosman[2], C. Chan[3], S. Khan[4], S. Paduri[4], V. Reddy[4], A. Sakhuja[4], P. Khosla[4], M. Pasquinelli[1], L. Feldman[1]; [1]University of Illinois at Chicago, Chicago, IL, [2]Center for Business Models in Healthcare, Glencoe, IL, [3]Jesse Brown VA Medical Center, Chicago, IL, [4]Sinai Chicago, Chicago, IL

Background: The Jesse Brown Department of Veterans Affairs Medical Center (JBVA) and Sinai Chicago, a safety-net hospital nearby, serve veterans and patients with significant social needs on Chicago's South and West sides. Both institutions are adopting the 4R Oncology Model (Right Info/Care/Patient/Time) for patient-facing care planning and self-management, proven to enhance supportive and health maintenance care delivery (Trosman JCOOP 2021). This abstract depicts a baseline survey of JBVA veterans' and Sinai Chicago patients' experiences in planning and delivering guideline-directed supportive and health maintenance care for new cancer diagnoses, informing 4R implementations.
Methods: Patients at JBVA and Sinai Chicago were surveyed from February to September 2023 with participants receiving a $25 gift card. An analysis was conducted using Fisher's two-tailed exact test.
Results: The two institutions yielded a 67% survey response rate. Key patient demographics and oncologic and supportive care metrics are outlined in the table below. At JBVA, fewer than 50% of veterans knew their cancer stage at diagnosis, and 63% were aware of their care goals. Furthermore, only 17% of veterans received recommendations for support services offered by JBVA. "Emotional distress or worry" support recommendations were received by < 50% of patients at both institutions.
Conclusions: The baseline survey uncovered gaps in care planning, supportive services, and health maintenance care in both institutions, catering to patients with challenging social determinants of health. The implementation of the 4R Oncology Model is designed to address these gaps, providing a personalized care sequence that establishes a clear roadmap through the patient's care trajectory, ultimately enhancing patient-centered care. Further results will be shared when available.

Metric	Combined% of pts(n=60)	JBVA% of pts (n=30)	SINAI% of pts(n=30)	PVALUE
Patient knew stage of their cancer	67	43	86	**0.0005**
Patient knew goal of their care	77	63	86	**0.0442**
Cancer care provider recommended to:				
Get Nutrition consult about how to eat during cancer treatment	35	27	42	0.2997
Talk to your primary care provider about staying as healthy as possible during care treatment	62	57	67	0.4523
Get support for transportation, food, housing, insurance, or other practical needs	44	17	67	**0.0001**
Get help to stop smoking or vaping*	29	28	31	1.0
Get help for emotional distress or worry*	37	24	46	0.1078
Demographics				
Age	59	66	53	**0.0001**
Male	69	93	39	**0.0004**
Black	59	83	39	**0.0001**
Hispanic	32	0	58	0.1103
High School education or less	68	57	78	0.1854
Household income less than $30,000 **	70	59	81	0.1305
Live Alone	37	47	29	**0.0001**

*of those who reported needing help, **of those who shared income level

#1302 Development and implementation of a systematic approach to measure patient-reported outcomes in early-phase cancer trials.

A. L. King, J. E. Levine, E. Vera, Y. Gandhi, E. Novakovich, T. Yu, S. Berhanu, C. Locke, K. Julmeus, T. Mendoza, T. S. Armstrong;
National Cancer Inst. - Bethesda Campus, Bethesda, MD

Background: There has been a shift in the clinical trial landscape toward early-phase studies where data from well-designed and pivotal phase I/II trials is leading to accelerated drug approval. Our goal was to develop a standardized approach to the measurement and reporting of patient-reported outcomes (PROs) in early-phase trials to improve assessment of tolerability, address noted barriers to inclusion, and enhance patient-provider communication to inform treatment decisions and ultimately improve outcomes.

Methods: The Office of Patient Centered Outcomes Research (OPCORe) was established in 2022 within the Center for Cancer Research at the National Cancer Institute (NCI) with the mission to advance understanding of the clinical benefit and tolerability of cancer therapies by integrating patient-centered approaches into CCR clinical trials by fostering education and collaboration with stakeholders. Implementation of regulatory/consortia guidelines related to use of core constructs, assessment frequency, and hypothesis-driven objectives and analysis plans through protocol template, development of data capture, email-based alerts and data visualization for clinical providers was developed and standardized templates for protocol language, research staff education, tools for workflow, and tracking implemented.

Results: The OPCORe protocol template includes measurement of 3 constructs, including tolerability, clinical benefit and disease-specific impact, as well as anchors of meaningful change. Core symptomatic toxicities are measured to inform understanding across trials with agent/class-specific symptomatic toxicities added to assure relevance. Baseline and standardized weekly electronic capture of tolerability during early cycles with alerts to clinical research staff if moderate-severe toxicities reported helps facilitate patient check-ins. Repeat PROs assessments in later cycles are expanded to include disease-specific assessments and align with disease evaluation to further inform clinical impact. To date, we have collaborated with 7 research groups and developed approaches for first-in-human, phase I, and phase II studies with trial start-up and data collection in process.

Conclusion: The value of including PROs in cancer trials is increasingly recognized by regulators, clinicians, patients, and advocates to advance understanding of the clinical benefit & tolerability of emerging therapies. Standardization and incorporation of PROs in earlier phase trials may enable PROs to be optimized, improve later phase trial design, and help inform health policy, support drug approval, and promote shared decision making between providers and patients to inform treatment decisions.

#1303 Harness the power of data to improve cancer care - Understanding the complex landscape of health policies and regulations.

Y. Huang, H. Basehore, E. S. Boja, J. M. Guidry Auvil;
National Cancer Institute, Rockville, MD

In the era of big data and artificial intelligence, biomedical research and healthcare have been presented with unprecedented opportunities for improving the understanding of cancer biology. In addition, the Open Science Initiative aims to shift the current paradigm of research practice towards broad sharing and public access to research findings as the norm. Big data in oncology usually includes a combination of genomic sequencing, proteomics, medical imaging, electronic health records, payor records, and other data sources from pharmaceutical research, wearables, and medical devices. While combining, linking, and analyzing data from different sources across research and healthcare enterprises is key to realizing the promise of big data and a health learning system, it poses tremendous challenges for researchers and implementers to understand the nuances of relevant policies, laws, and regulations while striving for broad, equitable, timely and responsible data sharing, as well as tackling issues in data quality, harmonization, interoperability, and security. Herein, we aim to shine a light on the ever-evolving landscape of data privacy regulations, laws, and policies that govern different touch points of a patient's journey where data are collected for research and healthcare purposes throughout the lifecycle that would impact data-sharing outcomes. We hope the illumination of a complex landscape of data governance framework to consider for many data sources will facilitate broad community engagement including data scientists and technologists, patients and advocacy groups, and policymakers to maximize open data and science while protecting patient privacy and confidentiality.

#1304 Employing widening funds to address inequity in cancer research - example of the STEPUPIORS collaborative rectal cancer project.

M. Cavic[1], A. Djuric[1], M. Marinkovic[2], A. Stanojevic[1], M. Tanic[1], S. Bjelogrlic[1], J. Spasic[1], A. Damjanovic[1], M. Djordjic Crnogorac[1], A. Vuletic[1], K. Mirjacic Martinovic[1], M. Radulovic[1], S. Stojanovic-Rundic[2], A. Krivokuca[1], R. Jankovic[1], S. Castellvi-Bel[3], J. Zoidakis[4], R. J. A. Fijneman[5];
[1]Institute for Oncology and Radiology of Serbia, Belgrade, Serbia, [2]Institute for Oncology and Radiology of Serbia; Faculty of Medicine, University of Belgrade, Belgrade, Serbia, [3]Fundacio Clinic per la Recerca Biomedica-Institut d'Investigacions Biomediques August Pi i Sunyer (FRCB-IDIBAPS), Centro de Investigacion Biomedica en Red de Enfermedades Hepaticas y Digestivas (CIBERehd), Hospital Clinic, University of Barcelona, Barcelona, Spain, [4]Biomedical Research Foundation, Academy of Athens; National and Kapodistrian University of Athens, Greece, Athens, Greece, [5]The Netherlands Cancer Institute-Antoni van Leeuwenhoekziekenhuis, Amsterdam, Netherlands

Introduction: Treatment of locally advanced rectal cancer (LARC) using neoadjuvant chemoradiotherapy (nCRT) improves local control and survival, but response varies. Patients treated at the Institute for Oncology and Radiology of Serbia (IORS) who undergo surgery upon complete response might be exposed to risks and poor quality of life. A consortium dedicated to redefining prognostic and predictive biomarkers in rectal cancer was formed within the framework of the STEPUPIORS Horizon Europe project. The current study evaluated whether employing collaborative widening funds might lead to sustainable strategies for cancer treatment, lowering inequity and steering societal impact, especially in countries with limited resources, using a pilot rectal cancer project.
Patients and Methods: The analysis was performed in the period Oct 01, 2022, to Oct 01, 2023, with a Serbian coordinating institution and partners from Spain, Greece, and the Netherlands as expert twinning centers. RT was administered to 75 patients with LARC using volumetric modulated arc therapy-simultaneous integrated boost approach/concomitant chemotherapy (5FU/Leucovorin, week 1&5) for the first time in Serbia. A comprehensive approach towards building human capacities on biobanking, multiomics analyses and project management was developed through intensive training and expert visits. Consensus consortium decisions were reached on regular partner meetings.
Results: Patients with clinical complete response (16.0%) and initially distant-located tumors were enrolled in the watch and wait approach and are under follow up. Developed pipelines for multiomics analyses led to 4 high-quality papers on new predictive biomarkers to nCRT in LARC and the deposition of omics data in open-science repositories following FAIR data principles. A first Serbian cancer biobank was successfully installed. Fifteen IORS researchers (87% female), were certified in biobanking. A grant management office was established to provide and support the sustainability of future research projects. This led to 5 new grant applications and enrollment of 1 female project member in a Masters program for Management in the Health Care System.
Conclusion: This study showed that even within the first 12 months, implementation of a 3-year collaborative grant dedicated to a specific research problem, might significantly change educational and treatment strategies enabling better patient care (OCEBM level of evidence 3). The results highlight that disparities in cancer outcomes and health equity might only be addressed by progressing beyond descriptions of said outcomes and taking specific action. Systematic, long-term strategic initiatives and collaborations among relevant stakeholders and ethical, legal and societal structures are needed in more countries.
Acknowledgements: Horizon Europe Project STEPUPIORS (101079217).

#1305 Comparison of HPV-DNA testing to PET-CT imaging as prognostic test following definitive treatment for cervical cancer: A retrospective proof-of-concept study.

C. Huddleston, A. Fakhreddine, S. Stroever, R. Young, N. Sah, K. Palle, M. Reedy;
Texas Tech University Health Sciences Center, Lubbock, TX

Cervical cancer is a significant global health issue, with oncogenic HPV-High Risk (HPV) responsible for over 99% of cases. Despite the prevalence of HPV-related malignancies, current guidelines by the National Comprehensive Cancer Center (NCCN) do not recommend post-treatment HPV-DNA testing. Instead, PET-CT imaging is recommended as a prognostic test. This retrospective proof-of-concept study aims to evaluate current NCCN guidelines and examines whether post-treatment HPV-HR DNA testing is a cost-effective, reliable alternative to PET-CT imaging in cervical cancer prognosis.

Methods: The study included female patients diagnosed with cervical or vaginal carcinomas (2011-2021), ensuring comprehensive records of both pre-treatment and post-treatment high-risk HPV (HPV-HR) testing, alongside PET-CT imaging results. Utilizing the FDA-approved HPV-HR DNA test, capable of detecting 14 oncogenic HPV strains, the study conducted rigorous statistical analyses via STATA software to determine significance of the study results.

Results: Our analysis of 53 patients who met the inclusion criteria demonstrated that post-treatment assessments using both HPV status and PET-CT imaging exhibited high levels of sensitivity and specificity, as well as impressive negative and positive predictive values (NPV and PPV, respectively). There was a statistically significant correlation between the likelihood of cancer recurrence and the results obtained from HPV status and PET-CT imaging post-treatment (p-value < 0.001). A critical observation was the superior sensitivity and improved NPV of post-treatment HPV status compared to PET-CT scans. Specifically, the sensitivity for HPV status post-treatment was quantified at 92.31, surpassing the 76.92 sensitivity rating of PET-CT scans. Furthermore, the NPV for post-treatment HPV status was measured at 97.44, which is better than the 92.31 NPV for PET-CT scans. Notably, no patients with negative post-treatment HPV-HR tests had a recurrence.

Discussion: The results of this study underscore the clinical significance of assessing HPV-HR DNA status post-treatment, particularly when HPV-HR DNA is negative. If future prospective studies confirm these findings, it may eliminate the need for post-treatment PET-CT scans, providing significant survivorship benefits for patients by reducing follow-up visits and eliminating unnecessary imaging. This would also result in substantial financial savings, estimated to be over $75,000,000 per year in the US alone, based on 2023 data. The limitations of the study include small sample size, single-institution data, and biases associated with retrospective studies. Future multi-institutional prospective studies are necessary to improve current guidelines further and validate the findings of this study.

#1306 Preferences for survivorship care among AYA cancer survivors and challenges of cancer specialist-led follow up.

Y. Kojima, Y. Ando, Y. Nogami, S. Iwata, T. Suzuki, E. Satomi;
National Cancer Center Hospital, Tokyo, Japan

Background: The number of cancer survivors is increasing substantially. Survivorship care, including long-term health care, for adolescent and young adult (15-39 years) (AYA) cancer survivors is not standardized. AYA cancer survivors have unique challenges that differ from those of other generations. The purpose of this study was to highlight challenges regarding survivorship care for AYA cancer survivors.
Methods: This study assessed survivorship care challenges for AYA cancer survivors based on questionnaire data in two configurations. We surveyed AYA cancer survivors diagnosed with various cancer types at our hospital regarding the actual status and challenges of survivorship care. Questionnaires assessed schooling and employment status, place of residence, length of hospital visits, cost of transportation to hospital, department and reason for visits, and issues related to survivorship care. We then surveyed cancer specialists who provide survivorship care about the actual status and challenges of survivorship care, including issues identified in the AYA cancer survivor survey.
Results: Ninety-eight AYA cancer survivors responded; 42 survivors (42.9%) were aged 20-29 and 45 (45.9%) were aged 30-39. The median time since completion of cancer treatment was 3.7 years. Most survivors (85.7%) hoped for long-term follow-up for surveillance of cancer recurrence. There were 27 survivors (27.6%) who received survivorship care in more than one department, and 26 (26.5%) received survivorship care in cooperation with other departments in the other hospital. Due to schoolwork and jobs, 52.0% of survivors felt that time for outpatient visits was scarce, and 51.0% of survivors indicated that they would prefer online survivorship care. On the other hand, the survey for cancer specialists was completed by 45 respondents (70.3%). More than 60% of cancer specialists providing follow-up care for AYA cancer patients felt that knowledge and experience in reproductive medicine and life events was necessary. Furthermore, regarding the challenges of long-term follow-up care for AYA cancer patients, more than 80% of physicians felt that mental, endocrine-related, and sexual function-related care and management were difficult in their own practices.
Conclusion: AYA cancer survivors with schoolwork and jobs felt that they had challenges in visiting outpatient clinics for survivorship care. Meanwhile, cancer specialists found it difficult to provide mental, endocrine, and reproductive care for AYA cancer survivorship care on their own. These require standardization of medical treatment content and systems for survivorship care for AYA.

#1307 Community-driven support platform BlueHQ: An innovative solution to address the needs of patients with colorectal cancer.

K. L. Newcomer;
Colorectal Cancer Alliance, Washington, DC

Background: Colorectal cancer (CRC) is the third-most commonly diagnosed cancer and the second-leading cause of cancer death in men and women combined in the United States. To manage the disease, patients and caregivers turn to various tools and resources for financial assistance, information dissemination, emotional and peer support, and treatment planning, among other critical issues and needs they face. The Colorectal Cancer Alliance (the Alliance) created BlueHQ to provide patients and caregivers with a resource solution encompassing all potential areas of need.
Methods: A survey aimed at understanding needs, barriers, and quality improvement opportunities was disseminated via the Alliance's Blue Hope Nation community for two weeks and by email. One hundred sixty-seven colorectal cancer patients and forty caregivers of colorectal cancer patients completed the survey.
Results: Patients and caregiver respondents report reliance on external tools and resources to manage disease and support information. Of the support methods, patient respondents reported using social media (46.11%); notebooks, journals, and planners (45.41%); online articles (44.91%); the Blue Hope Nation Facebook group (41.32%); cancer discussion boards (35.33%); and spiritual or religious advice (29.94%). Patients sought financial assistance, local peer support and groups, and mental health help to minimize diagnosis-related stressors. To provide more efficient care and limit stress, the community suggested financial help, communication and support from other patients and caregivers, and informational resources.
Conclusions: These survey results are consistent with other published learnings about patient and caregiver reliance on support tools and highlight the myriad resources that patients and caregivers currently use for managing CRC. BlueHQ is a support solution that provides patients and caregivers with access to information and resources tailored to users' specified profiles, including molecular characteristics of the tumor. Users can also store documents and information from healthcare encounters, creating a longitudinal record and tracking disease progression. In the age of precision oncology, BlueHQ ensures patients and users are presented with personalized educational materials and multimedia resources to help manage their disease and bridge the gaps in patient support. BlueHQ was explicitly designed to connect the CRC community to the latest therapeutic and clinical research resources to improve outcomes and quality of life for all CRC patients.

#1308 Policy guiding secondary findings from genome sequencing pertinent to cancer: Results from a systematic review.

S. Majeed[1], C. Johnston[1], S. Saeedi[2], C. Mighton[1], V. Rokoszak[2], I. Abbasi[2], S. Grewal[2], V. Aguda[2], D. Malkin[3], Y. Bombard[1];
[1]University of Toronto, Toronto, ON, Canada, [2]Unity Health, Toronto, ON, Canada, [3]The Hospital for Sick Children, Toronto, ON, Canada

Background: While genomic sequencing has personalized patient care across disciplines like oncology, secondary findings (SFs) unrelated to the primary indication are a common complicating factor. SFs relevant for oncology are categorized as cancer-related potentially leading to a cancer diagnosis (CA-SFs) or non-cancer findings revealing important medical conditions, predispositions, or carrier status in cancer patients (NC-SFs). These SFs can inform disease prevention, early detection, or management decisions, but may cause distress, overdiagnosis, and overuse of resources if actionability is limited. There is a lack of consensus for identifying, analyzing, and interpreting the clinical relevance of SFs. This significantly impacts cancer care, where paired tumor-normal sequencing is standard practice. Widespread practice variation can lead to detrimental impacts on patient outcomes and overall health. We synthesized policy guiding the clinical investigation of SFs for cancer to help providers navigate decisions regarding SFs.
Methods: We carried out a systematic review of international guidance directing the identification, analysis, and management of SFs from genomic sequencing, and analyzed the subset of policies specifically relating to oncology. We searched the grey literature (IFHGS members) and academic databases including MEDLINE, Embase and Cochrane. Two reviewers independently assessed policy documents for screening, data extraction and quality assessment (using AGREE-II).
Results: We identified 7 policies guiding the investigation of SFs relating to cancer across the general population (n=4), adults (n=1), pediatrics (n=1) and research (n=2) contexts. Most policies included guidelines for SF variant selection (identification; n=5) and management (n=4), with a minority detailing analysis processes (n=2). Recommended CA-SFs included medically actionable cancer predisposition variants, while suggested NC-SFs were variants important for drug therapies *(identification)*. Laboratories were advised to ensure adequate coverage and read depth during SF analysis *(analysis)*, while policies recommended that a medical genetics healthcare provider return results, specifically discussing their clinical utility *(management)*.
Conclusions: To our knowledge, our review is the most comprehensive synthesis of policy guiding SFs for cancer. Policies outline the types of SFs to investigate from genome sequencing in cancer and non-cancer patients, and related strategies for disclosure. However, best practices for SF analyses and patient follow-up including SF surveillance, treatment, etc. remain poorly described. This synthesis will help cancer care providers navigate critical decision points based on current evidence and direct policymakers on gaps to fill in the future.

#1309 Assessment of geographic and socioeconomic factors in primary brain tumor patient accrual to a natural history study.

Y. Kim[1], M. L. Stockdill[2], E. Vera[2], H. Miller[2], J. B. Vo[2], M. R. Gilbert[2], T. S. Armstrong[2], O. Celiku[2];

[1]Wayne State University School of Medicine, Detroit, MI, [2]National Cancer Institute, National Institutes of Health, Bethesda, MD

Purpose: To better understand neuro-oncology trial access barriers in the United States (US), we assessed the role of geography, population density, and socioeconomic factors in the accrual of adult primary brain tumor patients in the Natural History Study (NHS, NCT02851706) at the National Institutes of Health (NIH).

Methods: Participant addresses were linked to zip code geography and population data from the US Census and the Neighborhood Atlas Area Deprivation Index (ADI; 1 to 100 from least to most disadvantaged). Locations with population density greater than 1000 inhabitants per square mile were considered urban. Locations were categorized based on their distance from NIH as local (<50 mi), short-distance (50-200mi) and long-distance (>200 mi). T-tests, chi-square tests, and multivariate logistic regression compared socioeconomic and urbanity factors.

Results: 667 NHS participants arrived from 43 states and territories, with the majority (61%) from Maryland and neighboring states, and other states contributing no more than 5% of the participants each. The home locations of the participants were disproportionately urban (60% versus 19% of all US locations, p <0.001) and socioeconomically advantaged (mean ADI 26.94 versus 57.30 across all US locations, p<0.001). Local participants (49%) had greater racial and ethnic diversity (73% White, 11% Black, 9% Asian, 2% other; 11% Hispanic/Latino) compared to short-distance participants (11% total; 96% White, 3% Black, 0% other; 0% Hispanic/Latino) and long-distance participants (39% total; 89% White, 3% Black, 3% Asian, 2% Other; 6% Hispanic/Latino). Local participants lived in the most socioeconomically advantaged locations (mean ADI 16.39) compared to short-distance (mean ADI 40.88, p<0.001) and long-distance (mean ADI 39.69, p<0.001) participants. Short-distance participants were from disproportionally non-urban areas (69%) compared to local (28%, p<0.001) and long-distance (46%, p<0.001) participants. Multivariate analysis also confirmed that local participants were more likely to live in more advantaged areas than short-distance (OR=0.90, p<0.001) and long-distance (OR=0.93, p<0.001) participants, and short-distance participants were less likely to live in urban areas compared to local (OR=0.19, p<0.001) and long-distance (OR=0.44, p=0.008) participants.

Conclusion: The trial enrolled patients across the US, albeit with most participants arriving from neighboring states and socioeconomically advantaged, urban areas. Greater rural patient participation from nearby areas reflects the positive impact of NIH subsidies in reducing the financial challenges linked to participating in clinical trials. Current trends indicate that continued and targeted efforts to enable participation from local disadvantaged communities can ameliorate access to neuro-oncology clinical care and research.

#1310 Social determinants of migrant health factors impacting prostate cancer care and survivorship among sub-Saharan African immigrant men diagnosed with prostate cancer.

E. Kaninjing[1], G. Asiedu[2], K. Van Voorhis[1], M. Young[3], E. Erefah[4], E. Agboola[4], F. Odedina[3], R. Dronca[3], K. Ashing[5], S. Rotimi[6], C. Ngufor[2], A. Merriweather[7], J. McCall[5], A. Hill[3];

[1]Georgia College & State University, Milledgeville, GA, [2]Mayo Clinic, Rochester, MN, [3]Mayo Clinic, Jacksonville, FL, [4]Florida A&M University, Tallahassee, FL, [5]City of Hope, Duarte, CA, [6]Covenant University, Otta, Nigeria, [7]American Legion, Jacksonville, FL

Background: Sub-Saharan African Immigrants (SSAI) represent one of the fastest-growing segments of the immigrant population in the United States (US). Between 2010 and 2018, the SSAI population in the US increased by 53%, significantly outpacing the 12% growth rate for the overall foreign-born population in the US during that time frame. Despite these growing numbers, little is published about the extent to which SSAIs adapt to health behaviors more common in the US or remain immersed in the values, beliefs and practices reflective of their country of origin. Importantly, no study has comprehensively examined the Social Determinants of Health (SDOH) among this population relative to their migration experiences and their influence on health-seeking behaviors and decision-making regarding prostate cancer care and treatment options.

Methods: This qualitative study employed grounded theory and the social determinants of migrant heath framework to better understand the needs of SSAI prostate cancer survivors in the United States and how to effectively support these survivors. In-depth interviews were conducted with 8 survivors who live in the states of Florida and Minnesota.

Findings: Some participants reported limited access to care and financial challenges paying for drugs. In terms of coping with diagnosis and treatment, most of the participants relied on their faith, a positive outlook about survivorship and support of family members. Some participants relied on the coaching and support of a loved one who experienced prostate cancer in the past. Erectile dysfunction severely impacted the sexual life of most participants as they experienced difficulty getting an erection.

Conclusion: Participants expressed the benefit of belonging to support groups with other survivors for social and emotional support. As the number of immigrants from sub-Saharan continue to rise, so too will the demand for culturally tailored care to address and reduce disparities in survivorship among this sub-population.

#1311 Planning for health equity in oncology trials: Expectations and feasibility.

H. G. Skinner, C. Marra, A. I. Alexandrow, H. L. Subramaniam, N. C. Nussbaum, J. B. Franklin, E. P. Simard, A. P. Abernethy;
Verily Life Sciences LLC, South San Francisco, CA

Achieving diverse representation in oncology studies is an ongoing challenge., Responding to calls to advance health equity in clinical trials, Congress amended the Food Drug and Cosmetic Act to require trial sponsors to submit a “diversity action plan” to the FDA with a study’s protocol. This requirement to plan for diverse trial recruitment drives a need to innovate approaches for site selection and trial recruitment that go beyond mirroring race-ethnicity distributions from the US Census or disease prevalence. We present a novel framework that nests clinical trials in a longitudinal patient registry to achieve diverse representation across multiple domains, evaluate site-selection and recruitment strategies, and examine health equity across the cancer patient journey.

Implementing a registry to support longitudinal data collection (i.e., a cohort study), we establish a continuous view of participant characteristics including demographic and social determinants of health, treatment received, and relevant outcomes. Nesting clinical trials within the structure of the cohort, we can select sites and recruit for diverse representation to achieve equity goals. This framework involves a multi-layer analysis of external population statistics and internal reference registry to gauge the pool of eligible participants and calibrate the sampling strategy and recruitment expectations to the realities of clinical representation. Moreover, where clinical representation differs from population statistics, the registry offers an opportunity to report benchmarks for diversity and compare to site-level and study-level realized enrollment and feasibility.

In conclusion, the path to health equity in oncology trials depends on a capacity to ask and answer the right questions in planning. What specific aspects of diversity are we aiming to capture? How do these aspects impact outcomes? We advocate for a dynamic planning process that continuously reevaluates goals and strategies in the face of enrollment data and evolving population demographics. By utilizing a registry with longitudinal follow-up, we can set forth clear expectations, transparently report on the progress of inclusion efforts, and candidly address feasibility challenges. We present a structured framework for trial sponsors to not only comply with the forthcoming requirement for diversity action plans, but ultimately to advance the goal of equitable cancer care through research that truly reflects the complex intersectional diversity of those impacted by the disease.

#1312 A study of the clinical utility of NTRKs only vs. comprehensive gene fusion panel testing from a single assay platform.

C. Duong, S. Lau-Rivera, R. Jackson, P. Kanagasunderam, R. Hariri, N. Montgomery, D. Lyle, F. Lopez Diaz;
NeoGenomics, Fort Myers, FL

Background: Gene fusions have important implications for therapeutic selection and patient quality of care, and though they have a low prevalence individually, many fusions are targeted effectively, agnostic of any tumor type. Unfortunately, patients in the community oncology setting are most often only tested for NTRK fusions, which have a prevalence of around 1%. Here, we compared side by side the actual clinical actionability differences using real-world testing data between broad vs. NTRK fusion only panels offered by our clinical laboratory, both with identical assay performance characteristics, reimbursement, and cost levels.

Methods: Clinical samples(n=8307) from 33 tumor types were tested for known and novel RNA fusions using our hybridization capture RNA-seq based Solid Tumor Fusion Panels in our clinical laboratory, which targets RNA breakpoints at 1104 genes. Deidentified results were analyzed before or after filtering for fusions based on either a Targeted Solid Tumor NGS fusion Panel (16 drug targetable genes) or only NTRKs fusions. Deidentified patient data presented was analyzed according to an IRB-approved protocol.

Results: The prevalence of fusions in the cohort was 30.5% involving any of the 1104 targeted genes by the assay (27% in frame, 20% out of frame, and 41% others). Druggable fusions were present in 5.1% (422) of patients, where 53% were female with a median age of 68 years old, and 47% were male with a median age of 70. However, when filtering only for NTRK fusions, only 104 patients had an NTRK fusion (38 NTRK1, 10 NTRK2, 56 NTRK3), while an additional 318 patients had detected fusions from the Targeted Panel. These druggable fusions had the following prevalences; ALK 0.6 %, BRAF 0.3%, FGFR1 0.2%, FGFR2 0.3%, FGFR3 0.4%, FGFR4 0.0% n=4, MET 0.4%, NOTCH1 0.0% n=1, NOTCH2 0.2%, NRG1 0.2%, PDGFB 0.0% n=3, PDGFRA 0.1%, PDGFRB 0% n=0, RAF1 0.2%, RET 0.5%, ROS1 0.2%, excluding NTRK positive cases. The incidence of NTRK 1/2/3 fusions was 1.25%, while 3.8% of patients have other fusions included on the Targeted Panel in the absence of an NTRK fusion. Two (2, 0.02%) patients had both an NTRK fusion and an additional fusion covered on one of the other 16 genes in the Targeted NGS fusion panel.

Conclusion: Actionable fusions showed a combined prevalence in the clinical setting of 5.1%. This study demonstrates that when fusion testing is performed, four times more patients can benefit from a therapeutic option than when testing for these 16 genes compared to the widespread panel of the current clinicians' favorite choice of only NTRK fusions. More data and education are needed to change the testing paradigm of treating physicians to test broader sets of fusions when assay performance and financial considerations are equal to increase cancer care access.

#1313 Racial disparities in colorectal cancer incidence across US ethnic groups: A comprehensive analysis.

A. Chaudhuri, R. Gray;
Stillman College, Tuscaloosa, AL

Colorectal cancer (CRC) ranks as the third most prevalent global cancer and the fourth leading cause of cancer-related deaths. Racial disparities in CRC within the United States pose a significant public health concern, affecting incidence, mortality rates, and screening rates. This study investigates the impact of racial disparities on CRC incidence across various US states, utilizing CRC data from the National Cancer Institute (NCI) at the Centers for Disease Control and Prevention (CDC). Analysis with GraphPad Prism 5 software and Student's t-test reveals a consistent trend of higher CRC incidence in males compared to females, irrespective of ethnicity. Notably, the Black and American Indian ethnic groups demonstrate the highest CRC incidences among all races, especially in individuals aged 65 and above. Certain states, including Iowa and Mississippi for Black populations, and Alaska, Minnesota, Montana, Oklahoma, and South Dakota for American Indian populations, exhibit significantly elevated CRC incidences compared to the national average. County-specific analysis in Alabama reveals varying CRC incidence rates across ethnic groups, with higher rates in specific counties, such as Clarke County for Black males. Limited reports for American Indian, Asian Pacific, and Hispanic ethnic groups indicate potential disparities in access to testing, awareness, and funding for CRC detection and prevention. This study concludes that Black and American Indian males and females experience a higher incidence of colorectal cancer, possibly influenced by genetic factors or other variables contributing to CRC development. The observed disparities are multifaceted, arising from a combination of social, economic, and healthcare system factors. Addressing these complexities is crucial for mitigating CRC disparities and promoting equitable healthcare access and outcomes. Additional research, including molecular screening studies, is essential to substantiate disparities in cancer-related health and enhance public health and cancer awareness within the community.

Key Words: Cancer, Colorectal Cancer, Health Care, Racial Disparities

#1314 SCHEQ Foundation (STEMM & Cancer Health Equity): Increasing STEMM diversity and outcomes for patients navigating cancer.

E. Manley, Jr.;
SCHEQ Foundation, New York, NY

Health inequities are estimated to cost $320B annually, while racial and ethnic disparities are estimated to cost $42B in productivity. There are systemic issues at play that contribute to these disparities. These include lack of diversity in Science, Technology, Engineering, Mathematics, and Medicine (STEMM) fields; bias in healthcare delivery and access; underinsurance in patients from low-income backgrounds; and lack of training that advances those from historically underrepresented groups. The SCHEQ Foundation (STEMM & Cancer Health Equity) is a black-founded nonprofit organization that seeks to increase STEMM workforce diversity and improve outcomes for underrepresented, underserved, marginalized, and invisible populations across the cancer care continuum. Herein we describe the formation of SCHEQ Foundation and our core domains that we seek to make change. We seek to increase STEMM access and exposure, increase STEMM workforce diversity, and improve outcomes for underserved populations navigating the cancer care continuum. This will be accomplished in part by 1) engaging professional in STEMM from their lived background and experiences, 2) developing training, mentoring, and professional developing programs across the academic continuum to increase success of minoritized scholars; and 3) providing information and resources in culturally responsive manners to help underserved patient navigate cancer and advocate for the standard of care they deserve. We will change how we convey content, information, and resources to underserved populations by utilizing a combination of multimedia, infographics, webinars, info sheets, and community engagement. The goal is to increase survival for groups that historically have the greatest cancer disparities.

#1319 In vivo programming of natural killer cells and T cells using mRNA delivered cytotoxic chimeric antigen receptors.

N. Diwanji, D. Getts, Y. Wang;
Myeloid Therapeutics, Cambridge, MA

Introduction: Current generation of adoptive cell therapy relies on ex vivo engineering of immune cells with tumor-targeting chimeric antigen receptors. In addition to manufacturing challenges, ex vivo engineered cells such as CAR-NK and CAR-T show limited tumor infiltration and persistency within tumor microenvironment. A method leveraging mRNA-based delivery for in-vivo engineering of these cells could address these issues but has not been established. Conventional mRNA/LNP when infused systemically result in significant accumulation in liver tissue and the CAR has no immune cell specificity in their expression or function.

Method: Many immune receptors are heterodimeric complexes composed of a ligand binding subunit (e.g. CD16 and TCR) and a signaling adaptor containing Immunoreceptor Tyrosine-based Activation Motif (ITAM) (e.g. FcRγ and CD3ζ). Notably, the cell surface expression of the ligand binding subunit often depends on the expression of the ITAM adaptor. Based on this we fused HER2-targeting scFv to multiple activating receptors whose expression is restricted to NK cells and T cells, and evaluated their expression and anti-tumor function.

Results: We developed a series of Natural Cytotoxic Receptor (NCR)-based in vivo CAR constructs by fusing HER2-targeting scFv to the native extracellular and transmembrane sequences of the receptor NKp30, NKp44 and NKp46, These CARs engage signaling adaptor FcRγ or DAP12 expressed in NK cells, and exhibit potent tumoricidal activity against HER2+ ovarian cancer cells as well as mediate tumor-induced cytokine and chemokine response. Using Huh7 liver cell as a model for off-target expression in hepatocytes, we found that NKp44 and NKp46-based CAR requires their cognate signaling adaptors for stable cell surface expression. We also showed that similar strategy can be used to design receptors for selective expression on the surface of T cells utilizing CD3ε chain fused with tumor targeting scFv.

Conclusion: These results demonstrated the feasibility of engineering primary NK cells with CARs based on the NCR family of receptors NKp44 and NKp46, whose expression requires the immune-restricted signaling adaptors. These CAR-NK receptors do not contain intracellular signaling motifs but can engage and activate their signaling natural adaptors to initiate tumor killing and cytokine response. An mRNA/LNP based delivery of NKp44-based CAR for cancer treatment is currently under clinical development.

#1320 Engineered expression of HLA-E and HLA-G protects iPSC-derived cells from killing by primary NK cells.

A. Lebid, D. Kim, G. Greco, H. Jessup, A. Suarez, S. Brown, N. Alexander, M. Desai, B. Gurung, B. Morse, D. J. Perry, M. F. Naso, H. Levitsky; Century Therapeutics, Philadelphia, PA

Background: A major challenge to off-the-shelf allogeneic cell therapies is the HLA-targeted elimination of genetically dissimilar cells. To combat this, HLA Class I can be deleted through transgene insertion at the beta-2 microglobulin (B2M) locus, while HLA Class II can be deleted by disruption of the gene encoding MHC Class II Transactivator (CIITA). Lack of HLA Class I expression, however, marks cells for elimination by natural killer (NK) cells, which normally receive inhibitory signals from this protein family. HLA-E and HLA-G are non-classical HLA Class I molecules that are far less polymorphic than HLA-A/B/C. They can inhibit natural killer cell-mediated activation by engaging NKG2A, KIR2DL4, ILT2, and ILT4. The objective of this study was to assess allo-evasion from NK cells by iPSC-derived cells engineered to overexpress HLA-E and -G.

Methods: Allo-evasion by HLA-E, -G or both was first assessed in the chronic myelogenous leukemia K562 cell line, which expresses very low HLA Class I and is highly susceptible to NK-mediated killing. K562 cells were engineered using CRISPR/CAS9 to express chimeric molecules encoding either HLA-E or HLA-G heavy chains tethered to a defined nominal self-peptide and B2M, or HLA-E/peptide/B2M-P2A-HLA-G/peptide/B2M. Along with parental K562, these were used as targets in co-cultures with allogeneic PBMCs (n=22 donors) at different E:T ratios. Target killing was observed using flow cytometry and normalized to parental K562. Phenotyping of effector PBMCs for NK frequency and expression of HLA-E and -G receptors (NKG2A, KIR2DL4, ILT2, and ILT4) was performed to study correlations with killing efficiency and allo-evasion. IPSCs with endogenous B2M knocked out were also engineered to overexpress HLA-E and -G with the constructs described above. These were then differentiated into NK cells and gamma delta T cells using proprietary processes. Allo-evasion of these cells from killing by the same PBMC cohort was evaluated by flow cytometry.

Results: While NK cells across donors expressed heterogeneous combinations of HLA-E and -G receptors, the strongest correlation with PBMC allo-responsiveness was NK frequency. K562 and iPSC-derived cells lacking HLA were susceptible to killing by PBMCs. Overexpression of HLA-E and -G offered protection to K562 and iPSC-derived cells against all tested donors. HLA-E offered more protection than HLA-G, and the combination of both HLA-E and -G was most potent.

Conclusion: When genetically dissimilar HLA Class I protein family must be deleted to prevent graft rejection, expression of the more-conserved HLA-E and -G can effectively protect allogeneic drug products from elimination. These Allo-evasion^{TM} edits may increase the in vivo persistence and enable multi-dosing of our iPSC-derived allogeneic cell therapies.

#1321 *In vivo* immune cell programming using mRNA-LNP chimeric antigen receptors.

S. Argueta, F. K. Melber, M. Gorgievski, N. Divangi, E. Cochran, T. Chu, Y. Wang, J. Ding, D. Getts;
Myeloid Therapeutics, Cambridge, MA

Introduction: The tumor microenvironment (TME) is a dynamic and multifaceted system that comprises largely myeloid lineage immune cells including monocytes, neutrophils, macrophages, and dendritic cells. Reprogramming the myeloid compartment within the context of cancer therapy presents an attractive strategy to overcome current limitations in solid tumor treatment. We have developed a novel approach that harnesses the natural ability of Myeloid cells to take up mRNA loaded lipid nanoparticles, to reprogram these cells with chimeric antigen receptors (CAR's) that arm these cells to recognize and kill tumor cells.
Methods: Current LNPs technology is sufficient to deliver significant mRNA cargo to numerous cell types, including B cells, T cells and myeloid cells. Leveraging this phenomenon we have developed a new class of chimeric antigen receptors (CARs), using protein biology that imparts targeted immune cell expression and functionality, specifically in Myeloid cells. These CARs harness Immunoreceptor Tyrosine-based Activation Motif (ITAM) signaling adaptors expressed exclusively in immune cells, achieving immune cell-type specific CAR-directed tumor lysis and cytokine responses. With a FcaR I (CD89) based CAR design, we have developed a CAR that is dependent on the common Fc receptor gamma chain, primarily restricted to myeloid cells, for stable expression and function.
Results: We have demonstrated specific expression of CD89-based CAR in myeloid cells in mouse and monkey following systemic mRNA/LNP delivery, and in human myeloid cells following *in vitro* treatment with mRNA/LNPs. Systemic mRNA/LNP delivery of CD89-based CAR has demonstrated robust anti-tumor efficacy against multiple tumor antigens in various xenograft mouse models of human breast cancer, hepatocellular carcinoma, and ovarian cancer. Furthermore, in syngeneic mouse tumor models, robust anti-tumor immune responses, characterized by tumoral infiltration of activated CD8+ T cells, diminished tumor-associated Tregs, systemic enhancement of dendritic cells and anti-tumor IgG production, were observed for treated animals.
Conclusions: Taken together, we present CAR designs that achieve expression and function in targeted immune cell populations, capable of eliciting anti-tumor efficacy against multiple target antigens by leveraging innate and adaptive immune responses, and demonstrating a class of novel CAR designs to overcome limitations faced by current *in vivo* mRNA/LNP delivery strategy. A phase I clinical trial is currently on-going to assess the safety and preliminary efficacy of CD89-based CAR against TROP2+ epithelial malignancies.

#1322 A cryopreserved allogeneic anti-BCMA CAR-NK cellular therapy exhibits both innate and CAR-mediated MM cell killing *in vitro* and *in vivo*.

L. Talarico[1], C. Wong[1], C. Pang[1], T. Hickman[1], C. Hu[1], A. Shaw[1], E. Wisniewski[1], S.-C. Lai[1], P. Sharma[1], S. Moore[1], L. Nguyen[1], K. Rhuda[1], S. Patel[1], P. Lin[2], R. Basar[2], S. Cogan[1], K. Sofjan[1], A. Ramamurthy[1], A. Handler[1], K. Fraser[1], Y. Wang[1], K. Rezvani[2], M. D. Curley[1];

[1]Takeda Pharmaceutical Company Ltd. (U.S.), Cambridge, MA, [2]The University of Texas MD Anderson Cancer Center, Houston, TX

Introduction Multiple myeloma (MM) is the second most prevalent hematopoietic malignancy with an overall 5-year survival rate of 58%. B cell maturation antigen (BCMA) is selectively expressed on normal and malignant plasma cells, making it an attractive MM target. Anti-BCMA chimeric antigen receptor (CAR) T cell therapy and T cell engagers have shown promise as treatment options for certain MM patients; however, potential toxicities associated with these anti-BCMA therapies, such as cytokine release syndrome (CRS), have limited broader utilization. Much like T cells, natural killer (NK) cells are cytolytic and have demonstrated an innate capacity to reduce tumor burden while exhibiting a more favorable safety profile in clinical testing. To that end, we developed a cryopreserved allogeneic cell therapy comprised of genetically modified human umbilical cord blood-derived (CB) NK cells transduced with a gammaretroviral vector, which incorporates genes for an anti-BCMA CAR and soluble human interleukin-15 (sIL-15). Referred to hereafter as anti-BCMA CAR-NK, it exhibits both innate NK- and CAR-mediated killing *in vitro* and robust *in vivo* activity against established MM tumors.

Methods CBNK cells were isolated from donor cord blood units, propagated using feeder cells, transduced with a gammaretroviral vector to express an anti-BCMA CAR and soluble human IL-15, and propagated further before harvest and cryopreservation. Donor-equivalent untransduced (UTD) NK cells were generated via the same process but without the transduction step. Cryopreserved anti-BCMA CAR-NK and UTD NK cells were used for in vitro studies, including short-term killing, as well as for evaluation of activity against established MM tumors *in vivo* using the MM.1S-Luc4 model.

Results The anti-BCMA CAR was successfully expressed across all batches of anti-BCMA CAR-NK generated. Results from an *in vitro* cytotoxicity assay indicated that anti-BCMA CAR-NK kills BCMA expressing MM.1S-Luc4 tumor cells and secretes IFNγ, TNFα, and granzyme B at greater amounts compared to donor-equivalent UTD NK. Anti-BCMA CAR-NK and UTD NK cells also demonstrated equivalent cytotoxicity towards BCMA non-expressing cell lines, JJN3-Luc BCMA KO and NCI-H520, in an effector:target cancer cell dependent manner, highlighting the potential for treatment with anti-BCMA CAR-NK post-prior BCMA therapy. In *in vivo* studies, anti-BCMA CAR-NK exhibited robust anti-tumor activity in an MM.1S-Luc4 NSG mouse xenograft model, with no signs of anti-BCMA CAR-NK related body weight loss.

Conclusion A cryopreserved allogeneic anti-BCMA CAR-NK cellular therapy exhibits both innate and CAR-mediated killing in vitro and robust in vivo activity in MM tumor models. Preclinical data supports future clinical evaluation in relapsed/refractory MM patients who have received prior BCMA therapy and IND enabling studies are ongoing.

#1323 Anti-B7-H3 chimeric antigen receptor NK cells suppress the growth of atypical teratoid/rhabdoid tumor orthotopic xenografts.

J. Choe, S. Chakravarti, N. Holl, R. Rahnama, M. Zinsky, D. G. Jones, S. Vorri, A. Modi, E. H. Raabe, C. L. Bonifant;
Johns Hopkins University School of Medicine, Baltimore, MD

Background: Atypical teratoid/rhabdoid tumors (AT/RTs) are the most common malignant CNS tumor in infants. AT/RT patients have a 5-year overall survival rate of ~35% and high rates of relapse, emphasizing a dire need for new safe and effective therapies. These therapy-resistant tumors frequently overexpress the immune checkpoint cell surface molecule B7-H3 (CD276). CAR-T cell studies have an established safety profile in pediatric patients. We developed B7-H3 targeted chimeric antigen receptor (CAR) natural killer (NK) cells as a tumor-specific cell therapy for aggressive pediatric brain tumors. CAR-NK cells have several advantages over CAR-T cells. NK cells can be obtained from healthy donors and produced as an “off-the-shelf” product. NK cells also have a lower risk of inflammatory toxicity and graft-versus-host disease compared to T-cells when transferred across the HLA barrier from healthy donors to patients.
Methods: We have designed a library of variable affinity B7-H3-targeted CARs, produced replication incompetent γ-retroviral vector, and used this for generation of B7-H3 CAR-NK cells. We verified B7-H3 expression in a panel of AT/RT cell lines, and further engineered firefly luciferase expressing AT/RT (CHLA06.ffLuc, BT12.ffLuc, BT37.ffLuc) as well as a CHLA06-derived B7-H3 knockout. We developed an orthotopic CHLA06.ffLuc xenograft model. We tested CAR-NK cell functionality using *in vitro* co-culture and cytotoxicity assays. *In vivo* study was performed in our xenograft with intratumoral delivery of CAR-NK cells.
Results: B7-H3 targeted CAR-NK cells demonstrate target-specific cytotoxicity when compared to untransduced NK cells (36.8±12.5% vs. 72.4±24.2% at effector:target ratio of 1:1, n=3). CRISPR/Cas9 mediated knockout of B7-H3 in target cells abolished the difference in CAR vs. no-CAR NK-mediated target killing. When delivered intracranially to CHLA-06 orthotopic xenograft bearing mice, B7-H3 CAR NK cells eliminate tumor cells and prolong survival, whereas unmodified NK cells did not (log-ranked median survival = 20 vs. 84 days, $p<0.0001$). We are currently testing intracranial delivery of our B7-H3 CAR NK against other AT/RT orthotopic xenografts.
Conclusions: Targeting pediatric brain tumors with an anti-B7-H3 CAR-NK cell therapy may provide a safe and effective treatment for patients who have extremely limited therapeutic options. Direct intracranial injections of cell therapies into pediatric patients is currently being explored in clinical trials. As B7-H3 is a tumor associated antigen found to be overexpressed in a large variety of tumor types, this strategy may also be useful for treatment of other B7-H3 expressing cancers.

#1324 Superior anti-tumor activity of GL205, an allogeneic anti-CD5 CAR-NK for treating T-cell malignancies.

Miyoung Jung, Seung Min Kim, Eunsol Lee, Hyunseung Sun, Jaeyoung Yoo, Hwi Wan Choi, Subin An, Sunglim Cho, Bokyung Min

GC Cell, Yongin-si, Gyeonggi-do, Korea, Republic of

T cell malignancies are rare and intractable diseases with fewer treatment options and higher unmet needs compared to B-cell lymphomas. Chemotherapy such as CHOP has been used as the standard therapy for treatment of T cell malignancies, but clinical outcome is not a promising and alternative treatments are needed. Currently, Brentuximab Vedotin, an antibody-drug conjugate that targets CD30 is widely used for Hodgkin lymphoma, ALCL and CTCL. However, the application is limited to specific subtypes because CD30 expression is restricted to some subsets of T-cell lymphoma. CD5 is an attractive target for cancer immunotherapy because it is commonly expressed in most of T cell malignancies. Although CD5 CAR-T cell products have demonstrated the anti-cancer efficacy, there are several disadvantages including 1) challenges due to difficulties in manufacturing process caused by fratricide, 2) product contamination by CAR-introduced patient's malignant T cells, 3) severe side effects such as CRS and neurotoxicity. Therefore, CD5 CAR-NK as allogeneic anti-tumor therapy can be an alternative for treatment of T cell malignancies. GL205, cord blood-derived CD5 CAR-NK, is genetically modified to express CD5-directed CAR and simultaneously produce IL-15 which supports the NK survival and proliferation. GL205 is ex-vivo expanded, cryopreserved cell therapy product comprising of pure NK cells (> 99%) with high CD5 CAR expression (> 90%). GL205 showed significantly higher *in vitro* direct-killing efficacy against $CD5^{\pm}$ tumor cells compared to donor matched CBNK. IFN-γ and IL-15 release from GL205 was significantly increased after co-incubation with $CD5^{+}$ tumor cells. In xenograft mouse model, GL205 administration exhibited a greater survival rate and low tumor burden compared to vehicle group. In addition, GL205 was detected in blood for 3 months, demonstrating *in vivo* long-term persistence. In conclusion, GL205 could be a valuable and off-the-shelf allogeneic therapeutic option for treating T cell malignancies.

#1325 CD19 CAR-expressing iPSC-derived NK cells effectively enhance migration and cytotoxicity into glioblastoma by targeting to the pericytes in tumor microenvironment.

D. Kong[1], D. Kwon[2], B. Moon[2], D.-H. Kim[3], K.-S. Kang[1];
[1]Seoul National University, Seoul, Korea, Republic of, [2]Research Institute in Maru Therapeutics, Seoul, Korea, Republic of, [3]Sungshin Women's University, Seoul, Korea, Republic of

In cancer immunotherapy, targeting specific antigens with chimeric antigen receptors (CARs) has emerged as a potent tool for cell-based therapy. After being accessed by CARs, the selective anticancer lysis by CAR-natural killer (NK) cells through ‘missing-self’ and ‘induced-self’ mechanisms can mitigate off-tumor toxicity, a contrast to CAR-T cells. This specificity can be advantageous in the heterogeneous milieu of solid tumors. In the tumor microenvironment of glioblastoma (GBM), pericytes not only support tumor growth but also contribute to immune evasion, underscoring their potential as therapeutic targets in GBM treatment. Indeed, we examined and observed the presence of CD19-positive pericytes derived from GBM in patient samples, particularly within the perivascular niche, highlighting CD19 as a possible therapeutic target. Given this context, our study aimed to target the GBM tumor microenvironment, with a special focus on pericytes expressing CD19, to evaluate the potential effectiveness of CD19 CAR-iNK cells against GBM. In this study, we generated induced pluripotent stem cell-derived NK (iNK) cells with CD19 CAR. To determine whether CD19 CAR targets the tumor microenvironment pericytes in GBM, we developed GBM-blood vessel assembloids (GBVA) by fusing GBM spheroids with blood vessel organoids. When co-cultured with GBVA, CD19 CAR-iNK cells migrated towards the pericytes surrounding the GBM, inducing tumor lysis through NKp44 upregulation. Using a microfluidic chip, we observed that post-infused CD19 CAR-iNK cells targeted pericytes in a perfusion-like setting, facilitating an examination of CD19 CAR-driven migration and their tumor-specific cytotoxicity on the GBM. Therefore, we conclude that CD19 CAR-iNK cells may effectively target the pericytes in the GBM tumor microenvironment, suggesting their potential therapeutic value for GBM treatment.

#1326 Pre-clinical development of ARB011: A CDH17 targeting allogeneic nonviral RNA-based *"Flash"* CAR-NK therapy for gastrointestinal cancer.

J. Roy[1], N. Lin[1], K. Chow[1], C. Y. Yang[2], J. C. Lin[2], J. M. Luk[3], K. F. Wong[1];

[1]Arbele Limited, Hong Kong SAR, Hong Kong, [2]Medigen Biotechnology Corp., Taipei City, Taiwan, [3]Arbele Corporation, Seattle, WA

Background: Treatment for advanced gastrointestinal (GI) cancers has remained challenging, therefore, novel immunotherapies using chimeric antigen receptor (CAR)-T cells are being developed as a new hope for the patients. However, despite the clinical successes in hematologic malignancies, the overall safety and efficacy against solid tumors of CAR-T cells have yet to be established, and the manufacturing of autologous CAR-T cells requires lengthy cell expansion and viral transduction processes. In view of these technical challenges, we have developed ARB011, an RNA-based allogeneic CAR-NK therapy targeting GI cancers expressing cadherin-17 (CDH17), a promising therapeutic target with its overexpression associated with poor prognosis in patients with GI cancers. The use of allogeneic NK cells would mitigate the risk of graft-versus-host disease. Moreover, engineering NK cells with nonviral CAR-encoding mRNA would provide a rapid large-scale manufacturing platform with minimal risk of abnormal genetic alteration mediated by viral integration.

Methods: To generate the ARB011 CAR-NK cells, ex vivo expanded human peripheral blood NK (Magicell-NK, Medigen, Taiwan) cells were electroporated with mRNA encoding a humanized anti-CDH17 scFv fused with transactivation domains. Flow cytometry, in vitro cytotoxicity assay, and cytokine release assay were performed to evaluate the expression and functionality of ARB011. To examine the developability of ARB011 as an off-the-shelf cell product, cryopreservation and large-scale electroporation were also studied.

Results: Flow cytometry analysis revealed efficient electroporation with a high level of CDH17 CAR expression (>80%) and optimal CAR-NK cell viability (60%-80%). Following electroporation, cytotoxicity of ARB011 was tested against gastric (AGS and NCI-N87), colorectal (DLD-1 and T84), and liver (MHCC-97H) cancer cells by co-culturing at 1:1 and 2:1 effector/target ratio for 12-24h. ARB011 showed significant cytotoxicity against CDH17+ but not CDH17- cancer cells. The CDH17-sepcific cytotoxicity was accompanied with elevated levels of CD107a or LAMP-1 expression on CAR-NK cells and IFN-γ and TNF-α releases. Interestingly, cryopreserved ARB011 maintained optimal cell viability, CAR expression, and potent CDH17 target-specific cytolytic activity. Lastly, large-scale electroporation showed the establishment of up-scaling process of ARB011 production for clinical application.

Conclusions: Overall, the findings suggest that ARB011 could be a novel off-the-shelf, CAR-NK therapy that warrants further studies in animal models and in clinical trials.

#1327 Affinity tuning anti-CD123 chimeric antigen receptor natural killer cell therapy to treat acute myeloid leukemia.

M. Kizerwetter[1], H. Yang[2], R. Rahnama[1], C. Bonifant[1], J. Spangler[1];
[1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]Johns Hopkins University, Baltimore, MD

Acute myeloid leukemia (AML) is a highly prevalent blood and bone marrow cancer characterized by the uncontrolled growth of abnormal myeloblasts. Current treatments for AML often result in systemic toxicities for patients, many of whom will still experience relapse. There is thus an unmet need to develop safer and more effective therapies targeting AML. Chimeric antigen receptor (CAR) T cells, which are engineered to express a cancer-targeting extracellular antibody single-chain variable fragment (scFv) linked to an intracellular T cell-activating domain, have shown promise in treating B cell leukemias, but their success has been limited in myeloid leukemias. This is due in part to the lack of AML-specific target antigens. Moreover, impaired T cell function, a hallmark of AML, is also problematic when relying on autologous T cell activation upon reinfusion. We overcame the limitations of CAR T therapy in AML by developing CAR-expressing natural killer (NK) cells targeting CD123. While present on both healthy and AML cells, CD123 is expressed at >10-fold higher levels on malignant cells. Furthermore, use of NK allows use of fully functional allogeneic cells from healthy donors, since NK cells do not induce graft-versus-host-disease. To optimize the tumor cell selectivity of CAR NK cells, we employed the yeast display directed evolution platform to isolate anti-CD123 scFvs with varying affinities and are identifying and characterizing clones that maximize the interaction with $CD123^{high}$ AML cells over healthy $CD123^{low}$ cells, as determined by binding, cytotoxicity, cytokine secretion, and intracellular signaling studies. Collectively, our efforts introduce a new paradigm for engineered cell therapeutics with significant promise for AML treatment.

#1328 AccuBase™ (ceBE), a second-generation high-fidelity base editor, can proficiently modify genes in a human primary NK cells with minimizing off-target effect.

H. Ying[1], C. Yao[2], C. Fang[2], G. Li[3], L. Wang[2], Y. Zhou[2], C. Gong[2], J. Li[3], Y. Wang[3], W. Fan[3], F. Lv[3], X. Shao[3], H. Zhao[3], L. Wang[3], J. Yan[3], T. Xu[3], S. Zhu[2]; [1]Base Therapeutics (US) Co., Ltd., San Mateo, CA, [2]Shanghai University of Traditional Chinese Medicine, Shanghai, China, [3]Base Therapeutics (Shanghai) Co., Ltd., Shanghai, China

Natural Killer (NK) cells hold great promise for cancer therapy owing to their innate ability to detect cells expressing signs of stress or infection. However, NK cell-based therapeutics face significant challenges: limited expansion and genetic modification resistance. In response to these challenges, we present our pioneering work in the development of Base Editing-Directed NK (BED-NK) cell products, referred to as NK510, which is an off-the-shelf allogeneic cell therapy product containing peripheral blood mononuclear cell (PBMC)-derived TIGIT knock-out NK cells. Through a meticulously planned optimization process, we have achieved over 80% editing efficiency in NK510s using our high-fidelity Base Editor, AccuBase™. By knocking out TIGIT (an inhibitory receptor in NK cells), we have prompted tumor cell-derived CD155 (an inhibitory ligands in tumor cells) to engage with CD226 (an activating receptor in NK cells), triggering activating signals in NK510s. Our results showed that CD155 positive tumor cells were more susceptible to NK510s than CD155 negative tumor cells. And target killing percentage is positively related to CD155 expression level in tumor cells. This transformation effectively converted an inhibitory ligand into an activating one, resulting in tumor regression in multiple mouse models, including non-small cell lung cancer (NSCLC) and sarcoma. We developed a GMP-compliant NKBoost+ expansion system to generate a millionfold expansion of NK510 within a 21-day expansion protocol. To investigate the safety of NK510 product, we conducted repeated dosing toxicity, tumorigenicity, and oncogenicity study in a GLP facility, and the results validated the safety of NK510. Additionally, we developed an analytical protocol based on Droplet Digital PCR (ddPCR) technology to investigate the pharmacokinetics (PK) and biodistribution of NK510s in NSCLC tumor-bearing mice. We observed an enrichment of NK510-derived genomic DNA (gDNA) in lung tissues of tumor-bearing mice at day 1. The concentration of NK510-derived gDNA was up to 2000 copies/ug DNA. The concentration of NK510-derived gDNA sharply decreased from day 2 to day 6, and then decreased to below the lower limit of quantification (LLOQ). Distinct from the PK data of NK510s, the concentration of NK510-derived gDNA started low at day 1 and reached peak concentration at day 2 (in blood samples) and at day 4 (in liver tissues), respectively. These results demonstrated the efficacy and safety of BED-NK product and underscore the feasibility of combining base editing with ex vivo expansion of NK cells, significantly enhancing their therapeutic potential in clinical settings.

#1329 Development of the first optimised “off the shelf” MAGE-A4 targeting TCR-NK cells for advancement into the clinic for the treatment of solid tumors.

S. Vollmers, A. Cieslar-Pobuda, J. Kmiecik, G. Malachin, M. L. Satersmoen, F. Hosoien Haugen, M. Boieri, M. Sandve, D. Clement, I. Cardoso, P. Wanichawan, M. E. Haugstoyl, A. Oldenburg, L. Christ, P. Oberoi, L. Mora-Velandia, A. Holm, N. J. Hassan, E. Gauthy, J. Ino, S. Pollmann, L. U. Weigand; Zelluna Immunotherapy AS, Oslo, Norway

T cell receptor (TCR)-T based therapies, such as MAGE-A4 TCR-T cells, have shown compelling data demonstrating effective infiltration into and targeting of solid tumors with clinical responses across various solid cancers. However, heterogeneity and down-regulation of target antigen and HLA expression limit the durability and curative potential of these types of treatments. On the other hand, owing to their clinical potency, favorable safety profile and applicability as “off the shelf” therapy, natural killer (NK) cells have emerged as promising modalities in recent years. Unguided NK cells have shown limited potential against solid cancers, due to lacking infiltration into tumors. With our proprietary TCR-NK platform, we combine the solid tumor targeting capabilities of TCRs with the pan-cancer sensing and cytotoxic potential of highly potent killer cells, redirecting and arming NK cells with a fully functional TCR-CD3 complex. Here we present our lead product, an optimized TCR-NK cell product, ZI-MA4-1a, expressing an affinity enhanced TCR (KVL-a) directed to the HLA class I-restricted clinically validated cancer-testis antigen MAGE-A4, that is broadly expressed across solid tumors. The KVL-a TCR was successfully engineered from a naturally occurring wild-type TCR, increasing the affinity to MAGE-A4-peptide-HLA complex and resulting in enhanced recognition of tumor cells expressing the target antigen. ZI-MA4-1a is produced by transducing healthy peripheral blood derived NK cells with the full CD3 complex, the KVL-a TCR and a CD8 coreceptor. The process has been optimized to enrich TCR-NK cells, increasing process robustness, diminishing the impact of donor variability, and producing a higher performing TCR-NK cell product. We show the dual functionality of ZI-MA4-1a: TCR driven cytotoxicity as well as innate NK sensing of antigen knockout or HLA negative cancers. We demonstrate killing of heterogenous tumor cell models in vitro, as well as the multifunctionality of ZI-MA4-1a with killing, degranulation and multicytokine secretion. Interestingly, we observe enhanced proliferation of ZI-MA4-1a cells after activation by MAGE-A4 expressing tumor cells, indicating that TCR-NK cells acquire further proliferative capacity when the TCR is triggered. Finally, we demonstrate higher activity of ZI-MA4-1a compared to KVL-a and benchmark TCR transduced T cells against antigen positive targets, and activity against antigen negative tumor cells escaping TCR-T cell recognition.

#1330 Universal and potent chimeric antigen receptor-natural killer (upCAR-NK) cells for B-cell malignancy treatment.

D. Kwon[1], B. Moon[1], M. Han[1], T.-W. Lee[1], J.-H. Lee[1], K.-S. Kang[2];

[1]Maru Therapeutics Co., Ltd., Seoul, Korea, Republic of, [2]Seoul National University, Seoul, Korea, Republic of

Patient-specific CAR-T cells treatment is an innovative new drug that has shown excellent therapeutic effects against B cell blood cancer. However, side effects such as cytokine release syndrome and immune effector cell-associated neurotoxicity syndrome and ultra-high treatment costs must be overcome, and off-the-shelf CAR-NK cells can be a good alternative. The purpose of this study was to combine cellular reprogramming, gene editing, and differentiation technologies to produce full-off-the-shelf NK cells derived from iPSCs and verify their efficacy and safety. To this end, somatic cell-derived iPSCs were produced, seven genes were edited using CRISPR/Cas9 technology (5 kinds of knockout and 2 kinds of overexpression), and differentiated into NK cells. upCAR (universal and potent chimeric antigen receptor)-iPSCs with seven genes edited showed bialleic INDEL in the coding sequence of five genes and no off-target effect. In addition, normal transcriptome and genetic stability were maintained. High-efficiency differentiated upCAR-NK cells showed a very high differentiation yield, *in vitro* proliferation, and freezing / thawing were possible. In addition, upCAR-NK cells secrete interferon-γ when they meet cancer cells, showing cytotoxic effects *in vitro* and *in vivo*. upCAR-NK cells themselves showed no obvious toxicity *in vivo*. In conclusion, this study developed upCAR-iPSCs and upCAR-NK cells platform technologies that are less likely to have side effects and can be economically developed for B cell blood cancer than CAR-T. In the future, this technology can be useful in developing full-off-the-shelf CAR-NK cells anti-cancer immune cell therapy with low side effects, high efficacy, and low price.

#1331 MiNK-215, an IL-15 armored FAP-targeting CAR iNKT cell therapy, effectively treats human organoid models of treatment-refractory MSS colorectal cancer (CRC) liver metastases.

S. Krishnan[1], B. Joshi[1], J. Keith[1], R. Frazier[1], B. Kalinowska[1], J. Choi[2], S. Sanders[2], S. Boi[3], O. Le Tonqueze[3], N. Kushner[3], K. Soh[1], R. Stein[1], T. J. Curiel[4], M. A. van Dijk[3], E. Kim[2], E. Chantzoura[3], N.-P. Rudqvist[1], D. Chand[1];

[1]Agenus Inc, Lexington, MA, [2]Biorg, Winston-Salem, NC, [3]MiNK Therapeutics, New York City, NY, [4]Agenus Inc and Dartmouth-Hitchcock Medical Center, Lexington, MA

The presence of liver metastases in patients with microsatellite-stable (MSS) or mismatch repair proficient (pMMR) colorectal cancer (CRC) is associated with poor response to current pharmacological treatments, including immune checkpoint blockade (ICB). The tumor microenvironment (TME) of CRC liver metastases is characterized by a highly immunosuppressive phenotype that includes poor immunogenicity, a paucity of dendritic cells, elimination of tumor-specific effector T cells, and an abundance of immunosuppressive intrahepatic Kupffer cells and myeloid-derived suppressor cells. This underscores the urgent need for innovative therapeutic approaches targeted specifically to patients with CRC liver metastases. Here we describe MiNK-215, an IL-15 armored FAP-targeting CAR iNKT cell therapy, derived from the AgenT-797 allogeneic iNKT platform, as a potential novel therapeutic approach for patients with CRC liver metastases.

To better model ICB refractory human MSS CRC liver metastases, we developed an ex vivo human organoid model that recapitulates the histological and immunological features of human disease. Organoids were comprised of MSS CRC cells engineered to express nuclear GFP and HLA-A2-NY-ESO-1, hepatocytes, Kupffer cell-enriched non-parenchymal cells, and HLA-matched peripheral blood mononuclear cells (PBMCs) supplemented with NY-ESO-1-reactive T cells. Organoid models of CRC lung metastases, which are traditionally more responsive to ICB therapy were also developed to compare the models to clinical experience and further validate their usefulness. Models were treated with Fc-enhanced anti-CTLA-4 (botensilimab) and anti-PD-1 (balstilimab) antibodies, or MiNK-215 to assess tumor killing and immune activation.

Botensilimab and balstilimab enhanced T cell activation and cytotoxicity of CRC tumor cells in the absence of “normal” liver cells and in lung organoids. However, they were less effective in organoid models of CRC with liver metastases consistent with clinical observations. In contrast, MiNK-215 potently enhanced tumor killing by T cells in models of CRC with liver metastases. Tumor killing in CRC liver organoid models by MiNK-215 was associated with depletion of immune suppressive FAP-expressing stellate cells and increased $CD8^{\pm}$ T cell infiltration.

Our findings demonstrate that in treatment-refractory CRC-liver metastatic organoid models, MiNK-215 overcomes the limitations of ICB therapy to home to sites of disease, reprogram the TME, recruit tumor-reactive T cells and enhance tumor killing. *Ex-vivo* human CRC liver and lung metastatic organoid models are a novel platform that can be leveraged to rapidly identify new therapeutic approaches for potential clinical evaluation.

#1332 Allogeneic CD19-directed CAR-iNKT cells and their phenotypic subsets for the treatment of CD19+ hematological malignancies.

K. Ponnusamy[1], S. Poon[2], N. van der Weerden[2], R. Dossa[2], M. J. Baker[2], M. Bharathan[2], A. Karadimitris[1];
[1]Imperial College, London, United Kingdom, [2]Arovella Therapeutics, Victoria, Australia

Invariant Natural Killer T (iNKT) cells are a unique subset of innate lymphocytes, constituting <1% of human T cells. iNKT cells express a semi-invariant TCR (iTCR) recognizing glycolipids presented by the monomorphic, MHC-like molecule CD1d. Previous studies indicate that due to distinctive TCR constitution and antigen recognition properties, iNKT cells do not induce acute graft-versus-host disease. Based on the CD4 and CD8 expression, mature human iNKT cells can be classified into CD4+CD8-, CD4-CD8- & CD4-CD8+ subsets with overlapping and distinct functions. The functional profiling of CAR19-iNKT cell subsets serves the dual purpose of ensuring their safety and efficacy as a therapeutic intervention. Here we characterized the phenotypic and functional profile of CD4+ and CD4- CAR19-iNKT cells. iNKT cells were isolated with >99% purity from healthy donors' peripheral blood and were transduced with a CD19 CAR-encoding 3rd generation lentivirus. After expansion, the CAR19-iNKT cells were cryopreserved and later analyzed post-thawing. Differential expression of CD27 and PD1 was noted in CAR+CD4+ and CAR+CD4- iNKT cells compared to other markers. For functional profiling, CAR+CD4+ iNKT cells were positively selected, and 24h cytotoxicity assays were performed using several tumor cell lines including SEM, Ramos and C1R-CD1d (+/- α-GalCer). The CAR+CD4- iNKT cells exhibited superior cytotoxicity to multiple tumor cell lines compared to that of CAR+CD4+ iNKT cells from two donors. However, both subsets lysed α-GalCer pulsed C1R-CD1d cells in a comparable manner indicating the potential of these subsets to recognize antigen through the iTCR. Subsequently, we assessed the proliferation ability of the CAR+CD4+ and CAR+CD4- subsets by exposing the cells to three rounds of stimulation, 24h apart, using SEM (CD19+CD1d-) or K562 (CD19-CD1d-) tumor cells with or without IL-15. Proliferation was assessed seven days following the first stimulation. The CAR+CD4+ subset of CAR19-iNKT cells demonstrated faster proliferation than CAR+CD4- cells in the presence of IL-15 after repeated exposure to tumor cells. Ongoing RNA seq analysis of CAR+CD4+/CAR+CD4- cells will further elucidate differences between these subsets. The outcomes of these studies have shown encouraging results, indicating the potential benefit of having diverse subsets among CAR19-iNKT cells for treating CD19+ cancers. The therapeutic potential of CAR+CD4+ iNKT cell subset could be enhanced to match that of CAR+CD4- subset with the use of α-GalCer. In summary, inclusion of both CD4+ and CD4- iNKT cells is critical for the functionality of allogeneic CAR-iNKT cell therapy. Extensive characterization is crucial for clinical translation, but additional research, including preclinical and clinical trials, is essential to determine the safety and effectiveness of CAR19-iNKT cell therapy in real-world applications.

#1333 Preclinical data supporting the Phase 1 trial design of SENTI-202, a next generation allogeneic logic-gated selective CAR NK cell therapy, engineered to overcome key limitations of first generation cell therapies in AML.

D. Kaveri, P. Chinta, E. Leitner, L. Naitmazi, G. Yucel, M. Tian, N. Almudhfar, H. Deng, Y. Li, A. Lam, C.-T. Lee, E. Hong, R. Emery, B. Garrison, **A. N. Nguyen**, K. Rajangam;
Senti Biosciences, South San Francisco, CA

First generation natural killer (NK) and chimeric antigen receptor (CAR) NK cell products are well-tolerated and have clinical activity (~20-60% CR) in patients with AML. CRs generally increase with the inclusion of CARs or cytokines, increased cell doses, and when Flu/Ara-C lymphodepletion (LD) is used for conditioning. Key clinical limitations have been low PK of the infused NK cells, short durability of the observed responses potentially due to immune evasion of leukemic stem cells (LSCs), and manufacturing challenges precluding higher or multiple doses.

SENTI-202 is a next generation allogeneic logic-gated selective CAR NK cell therapy specifically designed to address these limitations and to augment endogenous NK anti-AML activity. SENTI-202 expresses a bivalent activating CAR (aCAR) that targets CD33 and FLT3 on bulk AML blasts and LSCs. As FLT3 is also expressed on healthy hematopoietic stem cells (HSCs), SENTI-202 is further engineered to express an inhibitory CAR that recognizes endomucin expressed on HSCs, thereby conferring protection from aCAR-mediated cytotoxicity even in the presence of FLT3/CD33. SENTI-202 expresses a calibrated-release IL15 that provides both auto- and paracrine cytokine support, mediating expansion, activation, and persistence of SENTI-202 and host immune cells. SENTI-202 demonstrated robust and specific killing of primary AML blasts, LSCs, and AML cell lines in vitro. SENTI-202 protected HSCs from CAR-mediated cytotoxicity while preserving their function. In vivo, SENTI-202 revealed robust efficacy that increased with higher E:T ratio and with 3 weekly vs 1 dose. Preclinically, 3 doses of SENTI-202 that were > 60-fold the planned starting clinical trial dose were well tolerated in acute and chronic toxicology studies with no CAR NK-related body weight, laboratory, or histopathology findings. SENTI-202 non-clinical PK revealed greater than dose proportional exposure, which was ~2-fold greater compared to non-engineered NK cells. Pretreatment of CD33/FLT3 negative AML cell lines with Ara-C resulted in upregulation of CD33 and FLT3 expression, sensitizing cells to robust SENTI-202-mediated killing, providing additional rationale for the use of Ara-C-based LD. In the presence of exogenous IL2, persistence, cytotoxicity, and serial killing activity of SENTI-202 were increased, supporting the use of low dose IL2 to further augment SENTI-202 clinical activity.

Taken together, these results support the Phase 1 trial design of SENTI-202-101 in patients with R/R CD33 and/or FLT3 positive malignancies including AML, which uses Flu/Ara-C as LD followed by 3 weekly doses of SENTI-202 and includes the option of enrolling patients into cohorts that additionally receive low dose IL2 following SENTI-202 administration.

#1334 Evaluation of NK cell combination therapies in mouse models of cancer.

K. Franciszkiewicz[1], P. Rettman[1], B. Gauthier[2], L. Noblet[1], C. Nicolazzi[1], A. Kunert[3], R. Igarashi[3], L. Calvet[1], V. Fantin[4], **S. Sidhu**[1];
[1]Sanofi R&D, Vitry-sur-Seine, France, [2]Sanofi R&D, Montpellier, France, [3]Sanofi R&D, Amsterdam, Netherlands, [4]Sanofi R&D, Cambridge, MA

Adoptive immunotherapy with natural killer (NK) cells has emerged as a promising innovative approach against hematological malignancies and solid tumors. To enhance the functional aspects of NK cells and to achieve stronger, sustained anti-tumor responses, combination strategies are under development. They are focused on optimization of NK cell potency, persistence and tumor targeting using monoclonal antibodies, multi-specific NK cell engagers and immune modulators like cytokines. SAR445419 is a universal off-the-shelf allogeneic human NK cell (hNK) product made using Sanofi's proprietary platform with potential broad application across hematologic and solid tumor indications. We evaluated the therapeutic potential of these NK cells in combination with internal assets and standard of care treatments in preclinical mouse models. The studies were performed in immunodeficient NOG mouse strains transgenic for hIL-15, supporting long-term engraftment of functional hNK cells. We demonstrated the therapeutic advantage of NK cell combination with an anti-CD20 monoclonal antibody (mAb) in a disseminated lymphoma model. We also reported prolonged lifespan of leukemia-bearing animals treated with NK cells and pegenzileukin, a PEGylated non-alpha rhIL-2 variant engineered to preferentially bind to the IL-2 βγ receptors and promote NK cell function. The anti-tumor response correlated with pegenzileukin-induced increase in NK cell numbers in the blood. A combination of CD38KO NK cells with an anti-CD38 mAb was also investigated in a model of multiple myeloma (MM). FcγR-KO immunodeficient mice were used in these studies to limit the confounding contribution of residual murine immune cells engaging with the Fc-competent therapeutic antibody and to specifically detect hNK-cell mediated activity. The comparison of CD38KO versus WT NK cell numbers in the blood of animals treated with an anti-CD38 mAb showed a significant decrease in CD38-expressing NK cell count that was mitigated by the genetic deletion of CD38. Obtained results suggest that CD38KO NK cells are resistant to anti-CD38 mAb-mediated fratricide and provide a rationale for the combination of CD38KO NK cells with anti-an CD38 mAb against MM. Overall, these preclinical in vivo studies have a pivotal role in the evaluation of NK cell combination therapies against cancer and reveal their therapeutic potential.

#1335 Generating functional CAR-NK cells for cancer immunotherapy.

Karina Di Gregoli[1], Henry Leonard[1], Dan Rocca[1], William Morley[2], Sabrina de Munnik[3], Gemma Moiset[3], Raluca Dumitru[4], Wassim Basheer[4], Brianna Schoen[4], Robert Nunan[1], Lauren Schewitz-Bowers[1], **Louise Brackenbury**[1]

[1]Charles River Laboratories, Bristol, United Kingdom,[2]Charles River Laboratories, Portishead, United Kingdom,[3]Charles River Laboratories, Leiden, Netherlands,[4]Charles River Laboratories - Cell Solutions, Northridge, CA

Chimeric Antigen Receptor-Natural Killer (CAR-NK) cells are rapidly emerging as a promising cellular therapeutic overcoming the potential life-threatening adverse events that may result from CAR-T therapy, including cytokine release syndrome (CRS), neurotoxicity and graft-versus-host disease (GVHD). Due to their intrinsic characteristics, NK cells can kill tumor cells without the requirement for recognition of antigen in the context of MHC. This removes the constraint of HLA matching and supports antigen independent cytotoxicity through NK cell intrinsic mechanisms. As such CAR-NK cells kill via both CAR-dependent and -independent mechanisms. For these reasons, they offer the advantage of being an “off-the-shelf” product; satisfying the requirement for large-scale production of cancer immunotherapies, with the potential to reach more patients at a reduced cost. The frequency of NK cells in the blood is low (~ 2-5%), therefore improving their *in vitro* expansion is key to generating sufficient material to offer a viable CAR-NK cell therapy. Here we outline an *in-vitro* method to generate, expand, and test primary human CAR-NK cells using engineered feeder cells, and go on to demonstrate the efficacy of the CAR-NK against target cancer cells. Primary human NK cells were cultured and expanded in the presence of irradiated K562 cells (iK562) modified to express 4-1BBL and membrane bound IL-21. Following initial expansion, NK cells were transduced with a clinically tested CD19-targeting CAR lentiviral vector (LV) or GFP expressing LV; as an empty vector transduced control. Following transduction, CD19 CAR-NK and GFP-NK were enriched by FACS sorting to reach >80% purity and further expanded in the presence of 4-1BBL/mbIL21 iK562 feeder cells. Following sufficient expansion, cytotoxicity of fresh or cryopreserved CD19 CAR-NK cells was tested *in vitro* in a Tumor Killing Assay (TKA) against CD19+ or CD19- target cells. As expected, CD19 CAR-NK cells showed increased on-target cytotoxicity, increased degranulation and IFNγ secretion compared to controls. This effect was not observed with CD19 negative cancer cells, strongly suggesting CD19 CAR engagement of the target antigen to mediate killing. Taken together these data show the generation, expansion, and enrichment of CD19 CAR-NK cells with enhanced cytotoxic activity towards CD19+ target cells. This approach provides a platform for *in vitro* characterization of novel CAR-constructs, allied with *in-vitro* safety assessment and *in vivo* pharmacology testing. Together, this offers the potential to further develop new and more widely available cellular therapeutics to treat cancer.

#1336 Verification of the effect of human allogeneic iPS cell-derived gene-engineered NK cells (eNK cells HLCN061) on mesothelioma.

S. Matsumoto[1], Y. Fujita[1], K. Goto[2], Y. Sato[2], F. Nishigaki[2], Y. Higashi[2], H. Kimura[2], K. Tamura[2];
[1]Hyogo Medical University, Nishinomiya, Japan, [2]HEALIOS K.K., Kobe, Japan

Malignant pleural mesothelioma is a malignant tumor that is caused by exposure to asbestos. Because it is a rare cancer, there are few drugs that can be used to treat it. Healios is developing iPSC-derived NK cells (eNK cells) (HLCN061) engineered with NKG2D, DAP10, IL-15, CD16, CCL19, and CCR2B genes for the treatment of refractory solid tumors. This study evaluated the antitumor effect of eNK cells against human malignant pleural mesothelioma cell lines.(Method) The antitumor effect of eNK cells on human malignant pleural mesothelioma cell lines in vitro was evaluated using the Viability/Cytotoxicity Multiplex Assay Kit (WST-8/LDH).In vivo, immunodeficient mice were subcutaneously inoculated with human malignant pleural mesothelioma cell lines. After subcutaneous tumor formation, eNK cells were inoculated into or near the tumor, the size of the subcutaneous tumor was measured, and the tumor volume was compared with that of an untreated group. After the study was completed, the tumors were removed and the tumors in the untreated group and the eNK cell-administered group were analyzed using RNA-seq.(Results) The antitumor effect of eNK cells against human malignant pleural mesothelioma cell lines was confirmed in vitro. In a mouse subcutaneous tumor model, the eNK cell treatment group suppressed tumor growth compared to the untreated group ($p \leqq 0.05$). RNA-seq showed increased expression of granulysin, IL2RB, cathepsin W, etc. in subcutaneous tumors treated with eNK cells.

#1337 Characterization of anti-AXL CAR-NK cell therapy for the treatment of melanoma.

W. Hibler, G. Merlino, Y. Yu;
NIH-NCI, Bethesda, MD

AXL is a receptor tyrosine kinase (RTK) that is commonly expressed in metastatic melanoma and several other forms of cancer. Activation of AXL signaling is linked to tumor cell growth, invasion, metastatic transformation, drug resistance, and immune response regulation. However, treatment of metastatic melanoma continues to present clinical challenges due to its capacity to rapidly develop drug resistance, which manifests under the influence of AXL signaling. As such, AXL may be a viable antigen target for immunotherapies. Despite their successes in hematological malignancies, chimeric antigen receptor (CAR)-T cell therapies remain limited by their susceptibility to causing off-target toxicity. In contrast, natural killer (NK) cells are not associated with such risks, which makes them clinically appealing as an alternative to T cells. However, studies on the application of CAR-NK cells to treat solid tumors remain acutely scarce. To explore the clinical viability of CAR-NK cells for the treatment of metastatic melanoma, AXL-specific CAR-NK cells were generated by transfecting NK cells obtained from NK cell lines. Preliminary data from a cytotoxicity assay indicated that the cytotoxicity of CAR-NK92-MI cells against AXL-positive melanoma cell lines was significantly stronger (up to a 10-fold difference) than the corresponding parental cells. Further in vitro characterization of this CAR-NK cell line and other CAR-NK cell lines, as well as in vivo evaluation of their efficacy in a mouse xenograft model of melanoma metastasis, is underway.

#1338 Novel activation domains coupled to chimeric ILT receptors (CIR) enhance NK cell targeting of HLA-G$^{\pm}$leukemic and solid tumor cells.

M. Duong, J. Park, R. Ognar, S. Wain-Hobson, **H. Bayle**;
NKILT Therapeutics, Houston, TX

Human leukocyte antigen-G (HLA-G) suppresses lymphoid and myeloid immune systems by binding ILT2 and ILT4 respectively and activating ITIM signaling. HLA-G is abundantly expressed in placental cytotrophoblasts to block fetal rejection. HLA-G is not expressed in most normal cells but is derepressed in in about 50% of malignancies. We engineered ILT2 and ILT4 to produce activating signals as Chimeric ILT Receptors or CIR. Preliminary results indicated robust killing of Acute Myeloid Leukemia (AML) cells by Natural Killer (NK) cells expressing either ILT2 or ILT4 CIRs. Here, we evaluated the effect of alteration of activating domains in the CIR constructs to produce signals that mimic the effect of IL-18 signaling in CIR-NK cells to enhance cytotoxicity, NK cell growth and persistence. Further, HLA-G expression and CIR-NK cell targeting of primary human cell types were rigorously screened.

Activated NK cells derived from peripheral blood (2 to 5 donors) were transduced with γ-retroviruses directing expression of CIR proteins (CIR.X.Y or CIR.Y.X) where X stimulates cytotoxicity through CD3ζ, DAP10 or DAP12, and Y directs coactivation through 4-1BB, fusion of the MyD88 death domain or recruitment of endogenous MyD88 with receptor-derived TIR domains and soluble IL-15. CIR-NK cells were cocultured with GFP*ffluc*-expressing AML and solid tumor target cell lines or normal primary human cells. NK cell proliferation and cytotoxicity of CIR-NK cells was monitored by Incucyte microscopy and supernatants were analyzed for cytokine release by ELISA.

At low E:T (1:20 - 1:40) in 7-day cocultures, mock-transduced NK cells displayed innate killing activity against HLA-G$^{\pm}$ Molm13 and Kasumi1 AML cells that was augmented by CIR constructs containing direct fusions of MyD88 and DAP10 or DAP12 (mock = 2.06E7 ± 4.53E6 vs. CIR-ILT4.MyD88.DAP10 = 1.03E7 ± 5.46E6) with 7-fold elevation of IFN-γ production. CIR constructs that recruited endogenous MyD88 signaling through the TLR2 TIR domain (4-1BB.DAP10.TLR2) also exhibited enhanced anti-HLA-G activity (9.13E6 ± 5.33E6). Against HLA-G$^{\pm}$ HT-1376 bladder cancer cells (E:T = 1:10-1:20), CIR-NK cells also displayed enhanced tumor cell killing with enhanced NK cell growth. Conversely, CIR-enhanced killing was not observed against HLA-G^{-} HCT-116 colorectal cancer cells. The persistence of CIR-NK cell potency after 4 weeks of expansion varied markedly with different activation domains employed. When screened against primary human cells (cardiomyocytes, hepatocytes, hepatic endothelial cells, corneal, colon and lung epithelial cells), no CIR-specific targeting was observed at high E:T ratios (1:1 and 1:5).

In conclusion, CIR-NK cells exhibit potent and specific anti-tumor activity against HLA-G$^{\pm}$ solid and leukemia cells. Alteration of CIR-NK cell intracellular signaling can optimize the potency and persistence of NK cell anti-tumor activity.

#1339 Pre-clinical development of IAMA-004, a tri-specific antibody targeting innate immune receptors and tumor targets.

L. Liu, Z. Han, Y. Fan, Q. Pan;
Nanjing JSIAMA Biopharmaceuticals, Ltd., Nanjing, China

Immune check-point inhibitor (ICI) such as anti-PD1 or anti-PDL1 antibody, which enhances the adaptive immunity via re-energizing exhausted T cells, has become the foundational therapy for many cancers. However, due to variety of other immunosuppressive tumor microenvironments, it is efficacious only in 15-30% of the patients. It is well known both the innate immunity and the adaptive immunity are required for full control of cancer growth. Thus, therapeutics harnessing the innate immunity will be complementary to ICI and improve the cancer response rate when used in combination. Currently therapeutics harnessing the innate immunity mainly involve bispecific antibodies with one arm targeting tumor antigen and one arm connecting to innate effector cells such as NK cells or macrophages, represented by CD30-CD16a bispecific and Her2-CD47 bispecific respectively. Considering that cancer patient's immune status are heterogenous, varying from T cell exhaustion, macrophage disfunction (M2 bias), Treg cell presence to NK cell deficiencies, it would be advantageous to combine several innate immunity enhancers into one therapeutic molecule. Here we describe a long-acting tri-specific antibody termed IAMA-004 that targets Her2 as the primary target and CD47 and CD16a as effector cell engagers. CD47 is also a co-target on some tumor cells (CD47-Her2 double positive tumors). We have characterized this molecule both *in vitro* and *in vivo*. The *in vitro* experiments tested the molecule's ability to kill Her2 high, Her2 low and Her2 negative tumor cell lines including BT-474, SK-OV-3, NCI-N87, OE19, HCC1954, MDA-MB-231, MDA-MB-468, in human PBMC ADCC assays with DS-8201 and Trastuzmab as the comparator molecules. In all of these ADCC experiments, IAMA-004 showed superior tumor cell killing activities to those mediated by DS-8201 or Trastuzmab. When combined with IAMA-005 (a Fc-IL2-IFN-α fusion cytokine), the tumor cell killing activities were dramatically increased. In addition, IAMA-004 was also tested in patient-derived *Ex-Vivo* fluids (one malignant pleural effusion and one malignant asities) and demonstrated tumor cell killing efficacies; and the killing activity could be attributed to the specific arms of the molecule. These results suggest that it is feasible to combine more than one innate engager in one molecule to carry out specific functions in the heterogeneous immune status for the treatment of advanced cancer patients.

#1340 Modulation of the natural killer cell immune response to tumor with a synthetic tumor -immune cell agonist, NK-TICA™.

F. Dufort, T. Ezell, A. Rezvaya, K. Ho, C. Leitheiser, P. Brandish, K. McDonnell, N. Keen;
Bicycle Therapeutics, Cambridge, MA

Natural Killer (NK) cells are highly responsive cytotoxic immune cells of the innate immune system with well characterized anti-tumor properties. Their ability to directly kill malignant cells and elicit an adaptive immune response makes them a promising candidate for a precision guided immunotherapy in oncology. Bicycle® peptides are small (ca.1.5kDa), chemically synthetic, structurally constrained peptides discovered via phage display and optimized using structure-driven design and medicinal chemistry approaches. We have applied the Bicycle® platform technology to discover and evaluate a new class of fully synthetic molecules termed NK tumor immune cell agonists (NK-TICA™). The NK-TICA™ consists of chemically coupled Bicycle® peptides that bind specifically to the key activating receptor, NKp46, and to tumor antigens, that results in highly potent, antigen-dependent receptor activation and NK cell function. We demonstrate potent, selective binding of our Bicycle® peptides to receptor-expressing cells and the capability of the bifunctional molecule to induce NK cell function in vitro. With Bicycle's novel NK-TICA™ compound, we demonstrate the engagement of NK cells, the specific activation and function of NK cells, and enhanced tumor cytotoxicity in a tumor target- and dose-dependent manner. In conclusion, NK-TICAs drive NK cell-mediated tumor cell killing and cytokine production in vitro and as such have the potential to catalyze the development of durable anti-tumor immunity in tumor types not well served by current therapies. We hypothesize that utilization of Bicycle® NK-TICA™ as a multifunctional immune cell engager will promote the modulation and anti-tumor activity of peripheral and intra-tumoral NK cells to solid tumors.

#1341 SM2235: A bispecific EGFR x CD16A innate immune cell engager for enhanced treatment of EGFR-expressing solid tumors, regardless of RAS mutation status.

H. Geng, W. Song, X. Liu, S. Lu, H. Zhou, S. Yang, S. Xie, Y. Wei, X. Zhang, S. Zhou, **Y. Liang**;
Beijing StarMab BioMed Technology, Ltd., Beijing, China

Background: Monoclonal antibodies (mAbs) targeting the epidermal growth factor receptor (EGFR) are frontline therapies for numerous EGFR-dependent epithelial tumors. However, their efficacy faces challenges due to on-target skin toxicity and intrinsic or acquired resistance. Within the tumor microenvironment, innate immune cells, including macrophages and natural killer (NK) cells, play a significant role but are hindered by the lack of specific cancer cell targeting and a suppressive microenvironment. To enhance innate immune cell cytotoxicity, we have developed SM2235, a humanized tetravalent bispecific VHH antibody. SM2235 partially blocks EGFR and EGF interaction while conditionally activating innate immune cells through CD16A upon engagement with cancer cells.
Methods: SM2235 was engineered by combining a partially blocking EGFR single-domain antibody with a high-affinity CD16A-activating single-domain antibody on an inactivated human IgG1 Fc backbone. The binding affinity and specificity were confirmed using bio-layer interferometry and ELISA with recombinant proteins, followed by flow cytometry with EGFR+ human cancer cell lines and CD16A+ primary NK cells. SM2235's efficacy in blocking EGFR-EGF interaction and downstream signaling was assessed through competitive ELISA and proliferation assays in both EGFR-dependent and independent cancer cell lines. Its ability to induce target-dependent NK cell and macrophage activation was evaluated through activation markers as well as cytotoxicity and phagocytosis assays. In vivo efficacy of SM2235 against EGFR+ human tumors was measured using xenograft assays in NSG mice, covering cetuximab-sensitive and resistant cancer cell lines. Preliminary pharmacokinetics and safety studies were conducted in cynomolgus monkeys.
Results: SM2235 exhibits sub-nanomolar affinity for EGFR+ human cancer cell lines and CD16A+ primary human NK cells. It partially inhibits EGFR-dependent cancer cell proliferation. Compared to cetuximab, SM2235 significantly enhances target-dependent CD16A-mediated NK cell and macrophage activation and cytotoxicity against EGFR+ cancer cells in ADCC and ADCP assays in vitro. SM2235 effectively inhibits EGFR+ xenograft tumors in vivo, irrespective of KRAS mutation status. In cynomolgus monkeys, SM2235 demonstrates excellent tolerance with a 20-hour serum half-life of approximately 20 hours and no dose-dependent skin toxicity.
Conclusions: Preclinical characterization of SM2235 shows promising in vivo efficacy against EGFR+ human cancers, regardless of KRAS mutation, with a favorable safety profile marked by minimal skin toxicity.

#1343 BSI-111, a highly selective anti-CD16a monoclonal antibody with potent agonist activity for building a NK cell engager platform.

J. Liu[1], W. Dai[1], H. Li[1], **X. F. Liu**[2], J. Li[1], S. Xia[1], Q. Lyu[1], H. M. Davis[2], M. Chen[1], Z. Peng[1];
[1]Biosion, Inc., Nanjing, China, [2]Biosion USA, Inc., Newark, DE

Background: Natural killer cells (NK) are innate lymphocytes endowed with the ability to recognize and kill cancer cells. CD16a, a well-characterized activating receptor predominantly expressed on NK cells, is a low-affinity receptor for the IgG Fc domain and is crucial for stimulating NK cell-mediated tumor cell killing. Unlike CD16a, CD16b is mainly expressed on granulocytes as a GPI-anchored receptor and is not involved in the lysis of tumor cells although CD16a and CD16b share 97% sequence identity in their extracellular domains. Due to the high homology of extracellular domains of CD16a and CD16b, it is extremely challenging to develop CD16a-specific agonistic antibodies without binding $CD16b^{\pm}$ granulocytes, the most abundant subset in leukocytes. Here we report the development of an anti-CD16a-specific monoclonal antibody with potent NK cell activation.

Experimental procedures: Humanized mice were immunized with recombinant CD16a-ECD-Fc. The Biosion proprietary H^3 (High-throughput, High-content and High-efficiency) antibody screening platform was used to identify an anti-CD16a monoclonal antibody lead candidate - BSI-111. The target binding specificity, binding activity, and affinity of BSI-111 were evaluated by protein-based ELISA, cell-based FACS and Biacore-based SPR. A cell-based agonist reporter assay and a primary NK cell activation assay were used to evaluate the bioactivity of BSI-111.

Summary: BSI-111 is a fully human monoclonal antibody with the following critical properties: (1) specifically binds to CD16a without recognizing CD16b; (2) binds the two allelic variants of CD16A - 158F and 158V with similar high affinities; (3) shows cross-reactivity to cynomolgus CD16a; (4) can significantly activate NFAT signaling in a cell-based reporter assay; (5) exhibits strong activity on activating primary NK cells; and (6) has potentially longer half-life and silenced Fc-effector function through Fc-engineering.

Conclusion: BSI-111 demonstrates great biophysical properties and functional characteristics, supporting the development of anti-CD16a-based NK cell engagers for potential benefit of cancer patients.

#1344 Improvement of the anti-tumor activity of NK cells and the efficacy of anti-CD20 monoclonal antibodies in the therapy of B cell-derived malignancies..

A. Zerrouqi[1], A. Zdanowicz[1], A. Torun[1], A. Ciechanowicz[1], B. Pradhan[1], G. Rymkiewicz[2], D. Efremov[3], **B. Pyrzynska[1]**;
[1]Medical University of Warsaw, Warsaw, Poland, [2]Maria Sklodowska-Curie National Research Institute of Oncology, Warsaw, Poland, [3]International Centre for Genetic Engineering and Biotechnology, Trieste, Italy

Resistance of tumor cells to immunotherapy with monoclonal antibodies (mAbs) often relies on the reduced level of the antigen targeted by the particular mAb. We have therefore screened for the compounds able to upregulate selected antigens on the surface of lymphoma/leukemia cells, to minimize the possibility of resistance acquired by the tumor cells. We have found that members of a specific class of antibiotics, known as cation carriers, namely salinomycin (SAL), monensin (MON), narasin, and nigericin exhibit great CD20 antigen-upregulating abilities. A variety of Burkitt's lymphoma and diffuse large B-cell lymphoma (DLBCL) cell lines as well as patients-derived primary malignant cells, such as DLBCL and chronic lymphocytic leukemia (CLL) cells exhibited upregulation of surface CD20 upon the treatment with SAL and MON at concentrations as low as 250nM and 50 nM, respectively. As a consequence, these compounds appeared to be beneficial for the therapy of lymphoma/leukemia with anti-CD20 mAbs, both *in vitro* and in animal models.Moreover, the proteomics analysis revealed that besides CD20, cation carriers upregulated a number of different proteins on the surface of tumor cells, including proteins implicated in the interaction with immune cells. These included ICAM1, HLA-A/B/C, CD155, CD80, CD86 and ULBP2/5/6. Particularly important appears to be the upregulation of antigens interacting with the activating receptors on NK cells, helping them to overcome the inhibitory signals and stimulate the lysis of tumor cells. Thus, the results of proteomics analysis explained why SAL- or MON-pretreated tumor cells were efficiently eliminated by NK cells, even in the absence of therapeutic mAb. In light of our discoveries, it seems reasonable to consider the cation carriers as promising drug candidates for the improvement of NK cell anti-tumor activity and potential treatment of B-cell non-Hodgkin lymphoma patients, in combination with anti-CD20 mAbs.Funding: National Science Centre (NCN, Poland), grants 2019/35/B/NZ5/01445 and 2020/39/B/NZ6/03513.

#1345 NAV-201, an orally bioavailable small molecule NK cell activator enhancing antibody-mediated cancer therapies.

N. C. Nicolaides, L. Grasso, J. Kline;
Navrogen, Glen Mills, PA

Tumors employ a number of mechanisms to suppress a patient's immune anti-tumor responses. Recently, we uncovered an immunosuppression mechanism that tumors employ to avoid humoral immune responses that involves tumor-produced proteins, called Humoral Immuno-Oncology (HIO) factors. These HIO factors are able to suppress antibody-mediated tumor cell killing via direct binding to antibodies that alter their Fc domain interactions with the C1q protein to suppress complement dependent cytotoxicity (CDC) and reduce antibody engagement with CD16a Fc receptors on immune-effector cells, including NK cells, to suppress antibody dependent cellular cytotoxicity (ADCC). HIO factor immunosuppression of ADCC appears to involve the reduced binding affinity of antibody to CD16a Fc receptors. In an attempt to identify agents that may enhance antibody-CD16a binding affinity to overcome HIO factor immunosuppression, we sought to identify agents that can restore this interaction by screening natural small compound libraries via an IgG1-CD16a based ELISA assay. One lead compound was identified that was subsequently optimized by structural activity relationship analysis. This compound, named NAV-201, specifically binds CD16a and enhances the affinity of antibody binding to both the low affinity CD16a-158F and high affinity CD16a-158V allotypes. Moreover, we found that NAV-201 can also bind to the mouse CD16a ortholog and enhance its antibody binding affinity, making NAV-201 suitable for efficacy testing in mouse models. *In vivo*, NAV-201 was found to be well tolerated up to at least 120 mg/kg when administered orally and daily to mice, have a serum half-life of 18 hours, enhance systemic levels of the NK cell produced INF-γ and TNF-α cytokines, and enhance the therapeutic efficacy of antibodies in mouse xenografts. Together, these data support the further development of NAV-201 for human testing to improve and/or enhance the efficacy of antibody-based therapies in HIO factor positive cancers.

#1346 Combined role of interleukin-15 stimulated natural killer cell-derived extracellular vesicles and carboplatin in Osimertinib resistant H1975 lung cancer with EGFR mutations.

A. Nathani[1], L. Sun[2], I. Khan[1], M. Aare[1], A. Bagde[1], Y. Li[3], M. Sachdeva[1];

[1]Florida A&M University College of Pharmacy & Pharmaceutical Sciences, Tallahassee, FL, [2]Florida State University, Tallahassee, FL, [3]FAMU-FSU College of Engineering, Tallahassee, FL

Extracellular vesicles (EVs) derived from immune cells (e.g., NK cells, dendritic cells) may be able to treat malignancies that are resistant to other treatments (e.g., chemotherapy) relying on the hypothesis that EVs carry almost the same cargo of the parent cells. In this study, we evaluated IL-15 stimulated natural killer cell-derived EVs (NK-EVs) as therapeutic agents in vitro and in vivo in Osimertinib resistant lung cancer (H1975R) with EGFR mutations(L858R). NK-EVs were isolated by ultracentrifugation and nanoparticle tracking analysis revealed a size distribution of 89.5 ± 3.4 nm, zeta potential of -31.38 ± 0.25 mV. Atomic force microscopy imaging revealed vesicles with a spherical form and comparable sizes, meeting the criteria of exosomal EVs. Further, western blot studies demonstrated the presence of regular EV markers along with specific NK markers (perforin and granzyme). EVs were also characterized by using proteomic analysis which demonstrated that EVs had proteins for natural killer cell mediated cytotoxicity (Granzyme B) and T cell activation (Perforin and Plastin-2). Gene oncology (GO) analysis also showed that these are differentially expressed proteins (DEPs) that are involved in programmed cell death and positive regulation of cell death. Further, isolated NK-EVs ($1*10^{11}$ particles/mL) were cytotoxic to H1975R cells in vitro with 55% and 68% cell viability in 2D and 3D cell cultures respectively against control. Carboplatin's IC_{50} was reduced by approximately 1.9 and 1.7-fold (p less than 0.001) in 2D and 3D cell culture respectively when combined with NK-EVs. The EVs were then combined with carboplatin (25 mg/kg) and administered by i.p. route to H1975R tumor xenografts and significant reduction in tumor volume in vivo (≈1000 mm^3 compared to ≈2000 mm^3 of control group, p less than 0.001) was observed after 10 days. Our findings show for the first time that NK-EVs target the PD-L1/PD-1 immunological checkpoint and induce apoptosis and anti-inflammatory response by downregulation of SOD2, PARP, BCL2, SET, NF-κB and TGF-ß. MicroRNAs regulating cytotoxic proteins like perforin, granzyme and plastin were also identified using sequencing and the miRNAs: hsa-miR-5193/149-5P/3133/193-5p are picked for further studies. These miRNAs have been encapsulated in NK-EVs by electroporation and will be evaluated against Lung PDX xenografts along with carboplatin loaded NK-EVs. These miRNAs are directly involved in T cell or NK cell mediated cytotoxicity and are being currently investigated. The ability to isolate functional NK-EVs on a large scale and using them with platinum-based drugs may lead to new clinical applications. The results of the present study suggest the possibility of the combination of NK-cell-derived EVs and carboplatin as a viable immunochemotherapeutic strategy for resistant cancers.

IMMUNOLOGY: Immune Checkpoints and Inhibitory Molecules 1

#1350 KD6001: A promising new anti-CTLA-4 human monoclonal antibody for cancer therapy.

Y. Chen[1], P. Li[2], G. Fang[2], H. Wu[2], C. Zhang[2], Z. Cai[1];
[1]Shanghai Kanda Biotechnology Co. Ltd., Shanghai, China, [2]Shanghai Celgen Bio-Pharmaceutical Co. Ltd., Shanghai, China

Cytotoxic T lymphocyte antigen-4 (CTLA-4) is a crucial immune checkpoint that negatively regulates T cell activation. Inhibiting this negative regulation through CTLA-4 blockade has emerged as a promising therapeutic strategy against cancer. Herein, we present the preclinical pharmacology study of KD6001, a novel anti-CTLA-4 IgG1 kappa human monoclonal antibody with superior properties compared to ipilimumab, a currently approved anti-CTLA-4 mAb. Surface plasmon resonance (SPR) analysis revealed that KD6001 exhibits a higher affinity for CTLA-4 compared to ipilimumab (KD = 0.57 nM vs 1.20 nM). Competition ELISA experiments demonstrated that KD6001 is significantly more potent than ipilimumab in disrupting CTLA-4 interactions with CD80 (IC50 = 16 ng/mL vs 93 ng/mL) and CD86. Further, amino acid point mutation analysis indicated that two specific residues following the CD80/CD86 binding site (99MYPPPY104) are critical for ipilimumab binding, whereas mutation of the two residues had minimal impact on KD6001's CTLA-4 binding activity. These findings suggest that KD6001 and ipilimumab bind distinct epitopes on CTLA-4. In vitro experiments demonstrated that KD6001 enhances the production of IL-2 and IFNγ in PHA-activated human lymphocytes and exhibits synergistic anti-tumor effects when combined with anti-PD-1/L1 antibodies. Moreover, in vivo studies utilizing syngeneic murine tumor models established in human CTLA-4 gene knock-in mice revealed that KD6001 effectively inhibits or delays tumor growth in colon cancer MC38, melanoma B16, and hepatocellular carcinoma Hepa1-6 models. Additionally, KD6001 demonstrated synergistic anti-tumor effects when combined with a mouse anti-PD-1 antibody or ibuprofen. Toxicity evaluation in cynomolgus monkeys revealed that KD6001 was generally well-tolerated at doses ranging from 1 mg/kg to 10 mg/kg administered intravenously once weekly for four weeks. The primary pathological changes observed were lymphocyte/monocyte infiltration or increased lymphocyte/monocyte infiltration in several organs, consistent with KD6001's mechanism of action. Notably, the similar affinity of KD6001 for human and cynomolgus monkey CTLA-4 suggests that the toxicity profile observed in monkeys accurately reflects the dose-toxicity relationship in human. The promising preclinical data presented herein support the further clinical development of KD6001 as a potential therapeutic agent for cancer treatment. Currently, clinical trials evaluating KD6001 in patients with advanced melanoma are ongoing.

#1351 Preclinical characterization of BMS-986288, a novel non-fucosylated (NF) anti-cytotoxic T lymphocyte antigen-4 (anti-CTLA-4) Probody® therapeutic.

A. Jhatakia[1], M. Nasser[1], A. Mukhopadhyay[1], K. Kang[1], C. Newsome[2], N. Gupta[1], R. Z. Mandawe[1], F. Findeisen[1], J. A. Lohre[1], L. Leung[1], Y. Wei[1], J. Dobroff[1], K. Price[2], J. Engelhardt[1], M. Selby[1], A. J. Korman[1], N. Wilson[1];

[1]Bristol Myers Squibb, Redwood City, CA, [2]Bristol Myers Squibb, New Brunswick, NJ

Introduction: Blockade of the CTLA-4 pathway with ipilimumab (IPI), alone and in combination with nivolumab (anti-programmed death-1 antibody), has shown clinical benefit in multiple tumor types. However, not all tumors respond to IPI ± nivolumab, and peripheral effects can lead to immune-related adverse events. To enhance the therapeutic index of CTLA-4-directed therapy, a proprietary Probody® therapeutics technology platform was used to develop a modified version of IPI. BMS-986288 is an anti-CTLA-4 antibody that combines a Probody® therapeutic masking peptide and protease-cleavable linker, designed to localize anti-CTLA-4 activity to the tumor microenvironment, with an NF Fc region hypothesized to enhance antigen-presenting cell (APC)-mediated T-cell priming and regulatory T cell (Treg) modulation via increased binding to the FcγRIIIA (CD16) receptor. Here, we present the characterization of the mechanism of action and pharmacodynamic (PD) response of BMS-986288 in preclinical models.

Methods: APC-mediated T-cell priming and antigen-specific responses were evaluated in a superantigen model using peripheral blood mononuclear cells (PBMCs) and human CTLA-4 knock-in (KI) mice. Antitumor activity and immune cell population changes were assessed in an MC38 tumor model implanted in human CTLA-4 KI mice. Intratumoral Treg depletion was further investigated using patient-derived dissociated tumor samples as a physiologically relevant model. Peripheral PD effects and tolerability of BMS-986288 were evaluated in a non-human primate (NHP) Ad5 vaccine model.

Results: Protease-cleaved BMS-986288 demonstrated enhanced APC-mediated T-cell priming compared with IPI in superantigen-stimulated PBMCs. Similarly, administration of superantigen staphylococcal enterotoxin B (SEB) peptide elicited an increased antigen-specific T-cell receptor (Vβ8+) T-cell response after treatment with cleaved BMS-986288 vs IPI in human CTLA-4 KI mice. In the MC38 tumor-bearing mouse model, BMS-986288 showed enhanced antitumor activity as compared to IPI, with tumor clearance in all mice. Although BMS-986288 enhanced intratumoral CTLA-4+ Treg depletion in the MC38 model, limited Treg depletion was observed in the patient-derived dissociated tumor model with an NF anti-CTLA-4 antibody without the masking peptide, potentially reflecting differences in CTLA-4 expression on human vs mouse Tregs. BMS-986288 reduced PD effects in the peripheral blood compartment and increased tolerability in NHP relative to IPI.

Conclusion: BMS-986288 leverages unique characteristics to differentiate it from IPI, enhancing APC-mediated T-cell priming and anti-tumor activity while also reducing peripheral activity in preclinical models. These data support an ongoing phase 1/2 clinical trial of BMS-986288 (NCT03994601) in patients with advanced solid tumors.

#1352 Computational design of a cyclic peptide that inhibits the CTLA4 in T cells and the growth of lung carcinoma in mice.

R. Thakkar[1], D. Upreti[2], S. Ishiguro[2], G. Magnin[2], K. Sudasinghe[2], A. Hall[2], **S. DeVader**[2], M. Tamura[2], J. Comer[2];
[1]University of California, Berkeley, CA, [2]Kansas State University, Manhattan, KS

Proteins involved in immune checkpoint pathways, such as CTLA4, PD-1, and PD-L1, have become important targets for cancer immunotherapy; however, the development of small molecule drugs targeting these pathways has proven difficult due to the nature of their protein-protein interfaces. Here, using a hierarchy of computational techniques, we designed a cyclic peptide that binds CTLA4 and follow this with experimental verification of binding and biological activity, using bio-layer interferometry, cell culture, and a lung cancer mouse model in immunocompetent mice. Beginning from a template excised from the x-ray structure of the CTLA4:B7-2 complex, we generate several peptide sequences using Rosetta, a protein modelling program. These peptides are cyclized head-to-tail to improve structural and proteolytic stability and screened using molecular dynamics simulation and MM-GBSA calculation. The standard binding free energies for shortlisted peptides are then calculated in explicit-solvent simulation using a rigorous multistep Binding Free Energy Estimator (BFEE). The most promising peptide, cyc-EIDTVLTPTGWVAKRYS (hereafter CTLA4-ip), yields the standard free energy -6.6 ± 3.5 kcal/mol, which corresponds to a dissociation constant of 15 μmol/L. The binding affinity of this peptide for CTLA4 is measured experimentally (31 ± 4 μmol/L) using bio-layer interferometry. Pharmacokinetics of CTLA4-ip in a cell culture with Lewis lung carcinoma (LLC) cells and in mice revealed that this peptide is significantly more stable in both cell culture and in mice as compared to a control non-cyclic scrambled-sequence. Treatment with CTLA4-ip inhibited cancer cell growth in a co-culture of LLC cells and LLC cell-antigen primed murine T cells. Intraperitoneal administration of the CTLA4-ip (10mg/kg/day, every other day totaling 4 doses) markedly inhibited lung tumor growth in mice with an orthotropic LLC allograft model. Efficacy of the tumor growth inhibition by the CTLA4-ip was similar to that by an anti-PD-L1 antibody (10mg/kg/day, every two days totaling 3 doses). These results strongly suggest that this novel CTLA4-ip works as an immune checkpoint inhibitor to CTLA4 and is usable for lung cancer treatment. This research was supported by Kansas State University Johnson Cancer Research center (MT), Midwest Biomedical Accelerator Consortium (MT, JC), National Cancer Institute MT, JC) and the National Science Foundation (JC).

#1353 Potentiating salvage radiotherapy in radiorecurrent prostate cancer through anti-CTLA4 therapy: Implications from a syngeneic model.

H. Wang[1], L. Gong[1], X. Huang[2], S. D. White[1], H. T. Chung[3], D. Vesprini[3], T. N. Petchiny[1], E. Fokas[4], H. He[1], R. S. Kerbel[5], S. K. Liu[6];
[1]University of Toronto, Toronto, ON, Canada, [2]Sunnyrook Research Institute, Toronto, ON, Canada, [3]Sunnybrook Health Science Centre, Toronto, ON, Canada, [4]Goethe University Frankfurt, Frankfurt, Germany, [5]Sunnybrook Research Insitute, Toronto, ON, Canada, [6]Sunnybrook Research Institute, Toronto, ON, Canada

Background: Advanced prostate cancer (PCa) is a leading cause in cancer death and can elicit significant morbidity and mortality. A common treatment modality for advanced PCa is radiation therapy (RT). Currently, salvage of local disease recurrence after RT is a major clinical problem. Emerging evidence indicates the importance of the immune system in governing RT response. In support of this, immune checkpoint inhibitors (ICIs), which enhance immune activation, have demonstrated clinical therapeutic promise in combination with RT in certain advanced cancers. Irradiation (IR) combined with ICIs may prime the immune system to recognize and target recurrent cancer.
Purpose: Investigate the therapeutic efficacy of ICIs in combination with RT for radiorecurrent PCa in a syngeneic pre-clinical model.
Methods: TRAMP-C2 cells were treated with 10 Gy of radiation over 5 fractions (similar to clinical hypofractionated (HF) schedule) to generate TRAMP-C2 HF cells. Immune-competent mice were transplanted subcutaneously with TRAMP-C2 HF cells. Once tumors reached palpable size, mice were administered either ICIs (anti-PDL1 or anti-CTLA4) alone or in combination with RT. Tumor volume was monitored to determine the treatment effect. Correlative studies on excised tumors and secondary lymphoid organs included flow cytometry and NanoString gene expression panel to evaluate immunological mechanisms that contribute to anti-tumor effects.
Results: TRAMP-C2 HF cells were validated for radiation resistance and exhibited a more aggressive phenotype (reduction in senescence, increase in clonogenicity) similar to clinically recurrent PCa. Radiation resistance of TRAMP-C2 HF tumors was validated in vivo. Administration of anti-PDL1 and anti-CTLA4 as monotherapy or in combination did not achieve significant tumor growth delay compared to control. IR alone produced an observable tumor growth delay compared to ICIs alone. The combination of anti-PDL1 and IR did not yield additional growth delay compared to IR alone. Strikingly, significant tumor growth delay was seen with the combination of IR and anti-CTLA4 compared to IR alone, while also resulting in complete cure in a third of the mice. mice. Lymph nodes and tumors from mice treated with IR and anti-CTLA4 vs. IR and isotype control demonstrated differential expression of genes in T cell functions and enrichment in both CD4+ and CD8+ T cell populations.
Conclusion: We generated the first syngeneic radiorecurrent PCa model and demonstrated that combining anti-CTLA4 and IR results in synergistic tumor response. Combined therapy resulted in augmented immune response, most notably enhancement of CD8 T cell activity.
Significance: These findings contribute to our understanding of immunological events associated with RT and ICIs in the context of radiorecurrent PCa and support new avenues for salvage therapy in clinical trials.

#1354 Anti-CTLA-4 generates memory T-cells with greater expansion and functionality than anti-PD-1.

S. Mok, H. Liu, N.-A. A. Anang, J. J. Mancuso, D. A. Cobanoğlu, J. P. Allison;
UT MD Anderson Cancer Center, Houston, TX

Distinct effects on T-cell differentiation arise from immune checkpoint inhibition targeting cytotoxic T-lymphocyte-associated antigen 4 (CTLA-4) and programmed death 1 (PD-1). However, the effect of these immunotherapies on the immunological memory response remains unclear. Our investigation into the effects of anti-CTLA-4 and anti-PD-1 on memory T-cell formation in mice revealed that anti-CTLA-4 generates a more effective memory antitumor response than anti-PD-1. Memory T-cells arising after anti-CTLA-4 treatment exhibit greater expansion, cytokine production, and antitumor activity than those from anti-PD-1. Notably, anti-CTLA-4 preserves more TCF-1+ T-cells during priming, while anti-PD-1 leads to more TOX+ T-cells. Experiments using conditional TCF-1- or TOX-knockout mice highlight TCF-1 is essential for memory response generated by anti-CTLA-4, whereas TOX deletion alone in T cells has no effect on response to anti-PD-1. Deepening our understanding of how checkpoint inhibition affects memory response is crucial for advancing our understanding of the enduring impacts of these immunotherapies on the immune system.

#1356 The VISTA blocking antibody HMBD-002 promotes type-I interferon signaling and drives anti-tumor responses through macrophage reprograming and cytotoxic CD8+ T cell activation.

B. Dharmadhikari, O. Zharkova, D. Thakkar, R. Tirado-Magallanes, K. Paszkiewicz, P. J. Ingram, J. D. Boyd-Kirkup;
Hummingbird Bioscience Pte Ltd, Singapore, Singapore

VISTA, a predominantly myeloid immune checkpoint, promotes an immunosuppressive tumor microenvironment and has been associated with resistance to approved checkpoint therapies. While blockade of VISTA with antibodies has shown anti-tumor efficacy in preclinical models, the biological mechanisms that underlie this effect remain poorly understood. To investigate the mechanistic basis of anti-tumor responses, we performed single-cell RNA sequencing of tumor infiltrating leukocytes from the cell-derived murine colon carcinoma xenograft model, CT26, which is known to be sensitive to VISTA blockade. We used HMBD-002, a uniquely blocking but non-depleting clinical-stage IgG4 anti-VISTA antibody, to identify the key immune cells and pathways impacted by VISTA blockade in the absence of Fc-mediated cell depletion. The translatability of these findings was validated in a human PBMC mixed leukocyte reaction assay. Subsequently, targeted depletion or inhibition of the identified immune populations and pathways was performed to confirm their contribution to the anti-tumor efficacy of HMBD-002.The blockade of VISTA by HMBD-002 significantly increased CD8+ T cells in the CT26 tumors, promoting an activated cytotoxic Tc1 program without inducing exhaustion. Concurrently, a substantial increase in proinflammatory M1 tumor-associated macrophages (TAMs) was noted within treated tumors, while other immune cell populations remained unaffected. Among the signaling pathways, the type-I interferon (IFN) response exhibited a significant upregulation, particularly in TAMs, indicating a type-I IFN-driven M1 reprogramming by HMBD-002. Validation experiments further demonstrated that the depletion of TAMs or CD8+ T cells, but not CD4+ T cells, abrogated the efficacy of HMBD-002. Moreover, blocking the type-I IFN signaling effectively impeded HMBD-002-induced TAM reprogramming and subsequent anti-tumor efficacy, thus confirming the pivotal roles of CD8+ T cells, TAMs, and type-I IFN signaling in driving the anti-tumor response to VISTA blockade. In conclusion, VISTA blockade with HMBD-002 promotes an anti-tumor response by type-I IFN mediated reprogramming of TAMs and activation of cytotoxic CD8+ T cells.

#1358 Elucidating the contribution of T cell-intrinsic VISTA to the suppression of antitumor T cell immunity.

Sachin Patnaik[1], Elizabeth Delaney[1], Cassandra Gilmour[1], Keman Zhang[1], Amin Zakeri[1], Hieu M. Ta[1], Prerana B. Parthasarathy[2], Tyler Alban[2], Timothy Chan[2], Li Lily Wang[1]

[1]Department of Translational Hematology and Oncology Research, Cleveland Clinic Foundation, Cleveland, OH,[2]Center for Immunotherapy and Precision Immuno-Oncology, Cleveland Clinic Foundation, Cleveland, OH

Immune checkpoint receptors (ICRs) negatively regulate antitumor immune responses. While significant advances have been made in understanding the mechanisms of well-established ICRs such as PD-1 and CTLA-4, other checkpoint proteins remain incompletely characterized and may be targeted to synergistically boost antitumor immunity. One such protein is V-domain immunoglobulin suppressor of T-cell activation (VISTA), an ICR whose expression curtails the function of several lymphoid and myeloid lineages, including tumor-reactive cytotoxic T cells. Globally blocking VISTA elicits potent T cell-mediated antitumor immunity and systemic myeloid cell-mediated inflammatory responses. Mechanistically, VISTA has been shown to inhibit T cell activation by acting as an inhibitory ligand on antigen-presenting cells. However, the impact of T cell-intrinsic VISTA on modulating tumor-reactive T cell responses has not been thoroughly investigated, and it remains unclear whether blocking T cell-specific VISTA is adequate for revitalizing T cell-mediated tumor control. In this study, we utilized VISTA conditional knockout mice models to examine the relative contribution of T cell-intrinsic VISTA versus myeloid-derived VISTA in the regulation of antitumor immunity. We present evidence that blocking VISTA on T cells alone is insufficient to induce strong antitumor immune responses, whereas blocking VISTA on myeloid cells counteracts its dominant role in orchestrating T cell suppression.

#1359 Rewiring CD8$^{\pm}$T cell responses to PD-1 immune checkpoint blockade in PDAC by preventing terminal exhaustion via the inhibitory receptor PSGL-1.

J. L. Hope[1], Y. Zhang[2], H. A. F. Hetrick[2], G. Romano[1], S. Roy[2], M. Lin[2], A. B. Palete[2], S. Maganti[2], D. C. Otero[2], C. Commisso[2], L. M. Bradley[2]; [1]Drexel University College of Medicine, Philadelphia, PA, [2]Sanford Burnham Prebys Medical Discovery Institute, La Jolla, CA

Pancreatic ductal adenocarcinoma (PDAC) is an aggressive, poorly immunogenic cancer with increasing incidence and a poor 5-year survival rate of 12%. PDAC tumors are refractory to all currently available treatments, including immune checkpoint blockade (ICB) therapies, and demonstrate limited infiltration of cytotoxic CD8$^{\pm}$ T cells that kill tumor cells. There is therefore an urgent, unmet need for novel therapeutic options. Analysis of single-cell RNA-sequencing data of patient PDAC revealed high expression of the novel immune checkpoint, PSGL-1, on infiltrating CD8$^{\pm}$ T cells. We hypothesize that PSGL-1-mediated immune suppression is a critical barrier to effective anti-tumor immunity in PDAC. To test this, we utilized a preclinical model of PDAC where orthotopic injection of the KPC.4662 tumor cell line into pancreata recapitulates patient tumor responses with limited T cell infiltrates and uncontrolled tumor growth in C57BL/6 (wildtype) control mice and compared to PSGL-1^{KO} (C57BL/6 background) mice. At endpoint, tumor burden in PSGL-1^{KO} mice was reduced by >50% compared to controls, with 45% of PSGL-1^{KO} animals exhibiting >70% reduction. Total immune infiltration (CD45$^{\pm}$) was 2-fold greater in tumors from PSGL-1^{KO} mice, with a significant increase in infiltrating CD3$^{\pm}$ T cells. Detailed analyses revealed that infiltrating CD8$^{\pm}$ T cells from PSGL-1^{KO} mice were not only more abundant, but also less differentiated towards terminal exhaustion with sustained TCT-1 expression compared to controls. Moreover, PSGL-1^{KO} mice showed protection against metastatic disease. Since our data support a critical role for T cell driven anti-tumor immunity to PDAC, we transiently depleted CD4$^{\pm}$ T cells, CD8$^{\pm}$ T cells, or both just prior to tumor cell implantation. While depletion of CD8$^{\pm}$ T cells did not impede tumor control by PSGL-1^{KO} mice, depletion of all T cells or only CD4$^{\pm}$ T cells resulted in the loss of PDAC tumor growth inhibition, demonstrating a key role of CD4$^{\pm}$ cells in the response. Given our previous studies demonstrating an intrinsic role for PSGL-1 in development of terminal T cell exhaustion in melanoma, including loss of TCF-1$^{\pm}$ CD8$^{\pm}$ T cells, we hypothesized that PSGL-1-deficiency would promote responsiveness to PD-1 ICB, which is ineffective as a monotherapy in PDAC patients and mouse models. To test this prediction, PD-1 ICB was therapeutically administered to control and PSGL-1^{KO} mice. While treatment with anti-PD-1 had no effect on the tumor growth in the control animals, PD-1 ICB resulted in complete tumor ablation in 85% of PSGL-1^{KO} animals, demonstrating a profound synergistic effect of PD-1 inhibition in the absence of PSGL-1. From these studies, we conclude that PSGL-1 is a critical inhibitor of T cell anti-tumor responses in PDAC. PSGL-1 therefore represents a novel ICB target with high translational potential for promoting immune responses to PDAC tumors.

#1360 TIGIT blockade combined with local radiotherapy and PD-1 blockade in a murine triple-negative breast cancer model.

S. Kim[1], S. Jeon[2], I. Kim[2],

[1]Integrated Major in Innovative Medical Science, Seoul, Korea, Republic of, [2]Seoul National University Bundang Hospital, Seongnam, Korea, Republic of

Background: Immune checkpoint blockades (ICB) improve outcomes of patients with some solid tumors such has melanoma and lung cancer, however the efficacy of ICB alone showed limited efficacy in many other tumors such as breast cancer. Radiation therapy is a promising combination partner of ICB as a strong immune stimulator so called *in situ* tumor vaccine, however it also can increase immune suppressive repertoires. TIGIT (T cell Immunoglobulin and ITIM domain) is an inhibitory receptor expressed on activated T cells and NK cells. We evaluated the effects of TIGIT blockade in addition to local RT and PD-1 blockade as a strategy to overcome therapeutic resistance of ICI in a murine breast cancer model. Materials and Methods: 4T1-Luc tumors were treated with various strategies including control, RT, anti-PD-1, anti-TIGIT, RT+anti-PD-1, RT+anti-TIGIT, anti-PD-1+anti-TIGIT, and RT+anti-PD-1+anti-TIGIT. A total of 24 Gy in 3 fractions at 1 week was delivered to the tumor at hindlimb (primary tumor) while the tumor at flank (secondary tumor) was left unirradiated. 10 mg/kg of anti-PD-1 blocking antibodies and 10 mg/kg of anti-TIGIT blocking antibodies were intraperitoneally injected for 6 times for 2 weeks. Flow cytometry, IHC staining, and ELISA were performed to assess the immunologic status after treatments.

Results: The triple combination therapy (TCT) group showed the most superior growth delay of primary and secondary tumor growth among treatments. The number of metastatic lung nodule was significantly reduced by TCT as well. Plasma levels of interferon-β and interferon-γ were the highest after TCT. Moreover, TCT significantly increased the proportion of splenic $CD8^+$ dendritic cells among myeloid cells, and effector-memory ($CD44^+CD62L^-$) cells among splenic $Foxp3^-$ non-regulatory $CD4^+$ and $CD8^+$ T cells. Furthermore, expression of CD226, which is an activating counter-receptor of TIGIT, on splenic $CD8^+$ T cells was elevated by TIGIT blockade, possibly suggesting the activation of systemic immune response by addition of TIGIT blockade to local RT and PD-1 blockade. Meanwhile, TCT decreased splenic $Foxp3^+$ regulatory T cells, as well as the expression of CD39 on splenic $Foxp3^+$ regulatory T cells. The increase of $CD8^+$ T cell infiltration in primary and secondary tumors was most prominent in TCT group.

Conclusion: TIGIT blockade elicits systemic immune responses in a murine triple-negative breast cancer model. when combined with local RT and PD-1 blockade, which were correlated with significant delay in the growth of both irradiated and unirradiated tumors. These results suggest that TIGIT blockade could be a viable approach to increase the efficacy of RT and immune checkpoint inhibitors in breast cancer which is a relatively immunologically cold tumor. #1362 IOMX-0675, a LILRB1 and LILRB2 cross-specific antibody, effectively repolarizes immunosuppressive myeloid cells and activates T cells leading to potent tumor cell killing.

C. Hartl, J. Zantow, I.-P. Maser, M. Stebegg-Wagner, S. Friedrich, J. Schilz, S. Kaden, R. Milde, E. Korotkova, M. Maraslis, B. Langer, M. Swiat, C. Ginzel, C. Ammerhauser, L. Albert, L. Majunke, A. Huth, K. Sudan, M. Yule, C. Rothe, H. Loferer, M. Aigner, A. Marziale, **S. Bissinger**;
iOmx Therapeutics AG, Martinsried / Planegg, Germany

Recently, myeloid checkpoints in the tumor microenvironment have gained increased attention in the context of tumor immune evasion. LILRB1 (ILT2) and LILRB2 (ILT4) are immunosuppressive receptors of the leukocyte immunoglobulin-like receptor (LILR) family that recognize both classical and non-classical MHC-I molecules (e.g., HLA-G). While tumor-infiltrating myeloid cells express both LILRB1 and LILRB2, lymphoid cells are restricted to LILRB1 expression. LILRB1 and LILRB2 are frequently co-expressed with immune-activating LILR family members LILRA1 and LILRA3 in several tumor indications and upregulated in patients non-responsive to T cell checkpoint blockade. Furthermore, the non-classical MHC-I molecule HLA-G, a major ligand of LILRB1 and LILRB2 in the tumor environment, is overexpressed and associated with poor prognosis in multiple solid cancer types.
IOMX-0675, a fully human, Fc-silenced, monoclonal immunoglobulin G1 (IgG1) antibody with a highly differentiated binding profile, that binds selectively with high affinity to the inhibitory receptors LILRB1 and LILRB2, while binding only weakly to the closely related immune-activating LILR family members LILRA1 and LILRA3, was identified from iOmx' proprietary phage display library. A high-resolution Fab-based Octet assay was established to monitor the IOMX-0675-mediated blocking of LILRB1 or LILRB2 binding to HLA-G. The LILRB1/2 cross-specific antibody promotes phagocytic and pro-inflammatory activity of various macrophage subtypes, which was monitored by flow cytometry and cytokine profiling. In co-cultures of monocyte-derived macrophages with autologous T cells, IOMX-0675 shows high potential to reprogram dose-dependently immunosuppressive macrophage, to further activate pro-inflammatory macrophage subtypes and thereby rescues the activity of the lymphoid immune compartment. Even in environments dominated by LILRA1/A3, IOMX-0675 shows a strong binding capacity to the immunosuppressive LILRB1/B2 receptors and significantly repolarizes the immune environment.
In summary, we discovered IOMX-0675, a cross-specific antibody antagonizing both LILRB1 and LILRB2 with high selectivity, that exhibits potent reprogramming of the immunosuppressive myeloid compartment and restores cytotoxic T cell activity in the tumor microenvironment. Negligible binding to immune-activating LILR family members by IOMX-0675 could unleash full anti-tumor activity. The differential binding profile of IOMX-0675 provides best-in-class potential and may maximize anti-tumor efficacy for the benefit of patients with high-unmet medical need, who are resistant to T cell checkpoint blockade.

#1363 Blocking inhibitory receptor ILT3 by an antibody with enhanced Fc function promoted adaptive immunity against hematopoietic malignancy independent of ADCC.

S. Ye[1], D. Zhang[1], M.-Z. Wu[1], H. Raghu[1], D. Cohen[1], M. Romero[1], S.-S. Tan[1], D. Choi[1], J. Hickson[2], J. Engelhardt[1], A. Shoemaker[2];
[1]AbbVie Bay Area, South San Francisco, CA, [2]AbbVie Inc., North Chicago, IL

Immunoglobulin-like transcript 3 (ILT3) is an inhibitory receptor that is expressed by mature monocytes, dendritic cells (DC), plasma blasts, and the malignant cells arising thereof including acute myeloid leukemia (AML), B cell lymphoma and multiple myeloma (MM). We developed an anti-ILT3 blocking monoclonal antibody (mAb) 17G8 to test the hypothesis that blockade of ILT3 on hematopoietic malignant cells might drive anti-cancer responses through several mechanisms such as cell migration, ADCC, and T cell driven immune responses. Blockade of ILT3 using 17G8 without Fc effector function impaired AML cell line THP1 dissemination into distant sites *in vivo* and using 17G8 with enhanced Fc function through afucosylation further reduced the tumor burden. This effect of afucosylated 17G8 appears to be mediated by a mechanism other than ADCC, since afucosylated 17G8 showed modest tumor inhibition in ICR mice carrying ILT3 positive AML and MM xenografts. In immune competent mice carrying murine syngeneic AML cell C1498 expressing human ILT3, 17G8 also showed modest anti-tumor effects as a single agent, however, when combined with anti-PD1, afucosylated 17G8 increased $CD8^{+}$ effector memory T cells, reduced proportion of cells with an exhausted phenotype and significantly improved survival when compared to different controls. Since T cells don't express ILT3, the effects of 17G8 on T cells are hypothesized to be mediated by blocking ILT3 expressed on myeloid cells. The expression of ILT3 on immature human monocyte-derived DC (moDC) is higher than on mature moDC. Blocking ILT3 with afucosylated 17G8 on immature moDC potentiated maturation of moDC when compared to the controls *in vitro*. Surprisingly, afucosylated 17G8 stimulated IFNγ production from moDC during maturation. The enhanced DC function induced by afucosylated 17G8 was subsequently found to be translated into enhanced T cell function in an allogeneic mixed lymphocyte reaction (allo-MLR) assay, in which afucosylated 17G8 significantly increased IFNγ production when combined with anti-PD1. The activation of effector T cells was also monitored through a cytotoxicity assay by mixing THP-1 cells with human PBMC in culture. Afucosylated 17G8 induced strong cytotoxicity on THP-1 cells with minimal effects on normal ILT3 positive cells such as monocytes or moDC, suggesting that blockade of ILT3 with afucosylated 17G8 induced more potent T cell mediated allogeneic cytotoxicity than innate cell mediated ADCC killing. In summary, ILT3 is a highly selective M4/M5 AML target. Developing a blocking antibody with enhanced Fc function could add an additional therapeutic strategy of inducing host anti-tumor immunity to current AML treatments which induce direct tumor killing, such as chemotherapy, targeted therapy, and antibody drug conjugate.

#1364 Characterization of CHS-1000, an Fc-modified anti-ILT4 monoclonal antibody for reprogramming suppressive myeloid cells in solid tumors.
N. Rajasekaran, X. Wang, S. Klakamp, S. Ravindranathan, S. Tatarewicz, J. Du, B. Nguyen, K. Widmann, N. Hawkins, D. J. Chin, T. LaVallee, V. Kapoor; Coherus Biosciences Inc., Redwood City, CA

Tumor resident immunosuppressive myeloid cells play a significant role in inducing resistance to cancer immunotherapy and are associated with poor prognosis in several solid tumors. The leukocyte immunoglobulin-like receptor B2 (LILRB2), also known as ILT4, is primarily expressed on myeloid cells and is a negative regulator of myeloid cell activation. ILT4 and its primary ligands (HLA-G, HLA-A) are widely expressed in various solid tumors and are associated with disease progression, tumor metastasis and poor clinical outcome. Abrogating inhibitory signals mediated through ILT4 and its ligands is a promising strategy to reprogram suppressive myeloid cells and enhance efficacy of immune checkpoint therapies. Here we report IND-enabling preclinical characterization of CHS-1000, a novel recombinant humanized Fc-modified IgG1 antibody with attenuated Fc-gamma receptor (FcγR) binding, that specifically targets immunoglobulin-like transcript 4 (ILT4). CHS-1000 selectively binds to human ILT4 with high affinity and potently blocks ILT4 interactions with its primary ligands (HLA-A, HLA-G). Functionally, CHS-1000 promotes re-polarization of suppressive myeloid cells to a pro-inflammatory phenotype and enhances activation of dendritic cells and T cells. Combinations of CHS-1000 with PD-1 inhibitors or other immunotherapy agents hold particular promise for enhanced anti-tumor activity. These preclinical characterization data support clinical development of CHS-1000 in combination with toripalimab (a commercial stage anti-PD-1 antibody) as an immunotherapy treatment for patients with solid tumors.

#1365 INB03: a new immune checkpoint inhibitor that reprograms macrophage polarization, boosts ADCP and reverts T-cell exhaustion markers.

S. Bruni, M. F. Mercogliano, R. Schillaci;
Instituto de Biologia y Medicina Experimental, Buenos Aires, Argentina

Trastuzumab resistance is an important clinical issue in HER2+ breast cancer (BC), and few actionable targets are available. We demonstrated that soluble TNF (sTNF) upregulates mucin 4 (MUC4) expression, which shields trastuzumab epitope on HER2 hindering its therapeutic effect, and that sTNF blockade with INB03 decreases MUC4 expression which, together with trastuzumab, triggers an effective antitumor immune response based on antitumoral macrophage-NK cell collaboration. Because immune checkpoint molecules (ICP) and T cell exhaustion foster tumor immune escape, we addressed whether INB03 could modulate macrophage polarization, T cell exhaustion, and ICP expression in both populations to boost an antitumor immune response. For *in vitro* assays, human monocytes and T cells were isolated from buffy coats and enriched with specific RosetteSep. Macrophages (Mϕ) were differentiated for 6 days with M-CSF (10 ng/ml) to M0, and polarized for 48h to the M1-like subtype with LPS (50 ng/ml)+IFNγ (20 ng/ml), or to the M2-like subtype with IL-4 (20 ng/ml)+IL-10 (20 ng/ml). Then, INB03 was added (10 µg/ml) for 96h with corresponding cytokines to already-polarized Mϕ to test its ability to revert polarization. Also, Mϕ antibody-dependent cellular phagocytosis (ADCP) against human HER2+ breast cancer cell line JIMT-1 was assessed. T cells were activated with CD3/CD28 beads and cultured for 7 or 14 days. INB03 was added at those times for 48h to test its ability to modulate ICP and exhaustion markers. For *in vivo* assays, tumor-free mice or bearing the HER2+ C4HD tumor were treated with vehicle or INB03 (10 mg/kg, i.p.) for 21 days. Polarization, exhaustion and ICP markers were studied in Mϕ and T cells from spleen and tumor. Adding INB03 to already-polarized human Mϕ enhanced polarization towards M1-like ($CD86^{\pm}CD206^{-}$). Polarized Mϕ exposed to INB03 showed decreased PD1 and PDL-1 expression. Also, the expression of ADCP-inhibitory markers B7H4 and SIRPα was diminished when INB03 was present. These Mϕ exhibited increased ADCP against JIMT-1 cells treated with INB03, which showed downregulation of the inhibitory signal CD47. Murine Mϕ from tumor-bearing mice treated with INB03 showed increased polarization to the M1-like phenotype. Human $CD8^{\pm}$ T cells showed decreased expression of PD1, PD-L1, LAG3, TIM3 and TIGIT. However, only TIM3 and PD1 were downregulated in murine $CD8^{\pm}$ T cells of tumor-bearing mice treated with INB03. In all, sTNF blockade skews Mϕ to the M1-like phenotype and reprograms already-polarized pro-tumoral M2-like Mϕ to antitumoral ones. INB03 can tailor the tumor microenvironment by promoting Mϕ ADCP against tumor cells and by acting as an ICP inhibitor for $CD8^{\pm}$ T cells, possibly relieving their exhaustion. $HER2^{\pm}MUC4^{\pm}$ BC patients could benefit from the administration of INB03 to boost targeted therapy efficacy and overcome tumor-induced macrophage and T-cell immune escape.

#1366 Dual immune checkpoint inhibition enhances the anti-tumor activity of trastuzumab deruxtecan in preclinical models.

Liam Jenkins[1], Laura Kazlauskas[1], Matt Wilson[2], Scott A. Hammond[3], Theresa Proia[1], Jerome Mettetal[1]

[1]AstraZeneca, Waltham, MA,[2]AstraZeneca, Cambridge, United Kingdom,[3]AstraZeneca, Gaithersburg, MD

Background

Trastuzumab deruxtecan (T-DXd) is an antibody-drug conjugate (ADC) composed of an anti-human epidermal growth factor receptor 2 (HER2) antibody, a cleavable tetrapeptide-based linker, and a topoisomerase I inhibitor payload. Recent clinical trials such as BEGONIA have highlighted the potential therapeutic benefit in combining T-DXd with immuno-oncology (IO) agents such as the PD-L1 inhibitor durvalumab. Here, we report preclinical findings demonstrating enhanced anti-tumor activity when T-DXd is combined with dual immune checkpoint inhibition.

Methods

HER2-expressing human cancer cell lines were treated in vitro with T-DXd and assessed for induction of immunogenic cell death (ICD) markers and expression of NK cell-activating ligands. Human macrophages and T cells were incubated with supernatants from treated cancer cells, and their activation status evaluated via flow cytometry. In vivo, the effects of T-DXd in combination with inhibitors of PD-L1, CTLA-4, and a monovalent bispecific anti-PD-1/TIGIT antibody - a murine surrogate of rilvegostomig - on tumor growth were evaluated in BALB/c mice bearing human HER2-low EMT6 murine mammary tumors. The anti-tumor activity of T-DXd in combination with volrustomig, a monovalent bispecific antibody targeting PD-1 and CTLA-4, was also assessed in hu-CD34+ NSG mice bearing HER2-low Caki-1 renal cell carcinoma tumors.

Results

In vitro, T-DXd induced ICD via DXd-mediated extracellular release of inflammatory mediators ATP and HMGB1, and cell surface exposure of calreticulin. This was associated with a greater than 2-fold increase in expression of NK cell-activating ligands, and activation of both macrophages and T cells. In immunocompetent mice bearing human HER2 expressing EMT6 tumors, T-DXd treatment drove tumor growth inhibition (53%, P <0.001) that was associated with an increase in tumoral T cells (2.6-fold, P <0.05) and increased CD8+ T cell expression of the immune checkpoints PD-1, TIGIT, and TIM-3. Tumor growth inhibition relative to vehicle-treated mice was enhanced when T-DXd was combined with inhibitors of PD-L1 (108%, P <0.001), PD-L1 plus CTLA-4 (172%, P <0.001), or a bispecific PD-1/TIGIT inhibitor (181%, P <0.001). Pharmacodynamic analysis revealed how the combination of T-DXd and PD-1/TIGIT inhibition increased tumoral NK cells (3.2-fold, P <0.001) and CD8+ T cells (3.8-fold, P <0.001) relative to vehicle. Consistent with findings in syngeneic models, the combination of T-DXd with a bispecific PD-1/CTLA-4 inhibitor also enhanced tumor growth inhibition in a humanised Caki-1 model (121%) compared to T-DXd alone (72%) (P <0.001).

Conclusions

These data provide insight into the clinical activity observed with T-DXd and provide scientific rationale for combination strategies with novel, bispecific IO agents targeting CTLA-4 or TIGIT in addition to the PD-1/PD-L1 axis.

#1367 PD1 signaling uncovers a pathogenic subset of cytotoxic T cells.

S. Bukhari[1], S. Lerrer[1], J. Straube[2], R. Winchester[1], B. Henick[1], M. Dragovich[1], **A. Mor**[1];
[1]Columbia University Irving Medical Center, New York, NY, [2]Martin Luther University Halle-Wittenberg, Halle, Germany

PD-1 drives its fame for serving as a pivotal immune checkpoint receptor on T cells. Within the realm of cancer immunotherapy, blocking this receptor triggers the T cell activation, leading to the immune response against tumors. Conversely, in autoimmunity, PD-1 agonist is a prime candidate for effectively suppressing the T-cell-driven auto-reactivity and self-tissue damage. Despite a decade of exploration and unlike cancer immunotherapy, the efficacy of PD-1 agonists in treating autoimmunity remains a challenge. To overcome this hurdle, innovative methods must be devised to look beyond the PD-1 receptor engagement and uncover the downstream effectors involved in PD-1 signal transduction. A comprehensive genome-wide CRISPR/Cas9 screen was also conducted to pinpoint genes linked to PD-1 signaling. An in-depth exploration of genes associated with PD-1 signaling was undertaken, utilizing publicly accessible bulk and single-cell RNA sequencing datasets of patients with melanoma treated with PD-1 blockade and in patients with inflammatory arthritis. We employed flow cytometry of T cells derived from peripheral blood and synovial fluid to validate the results.Our screening process validated established regulators in the proximal PD-1 signaling pathway and unveiled an additional 1,112 unique genes associated with PD-1's capacity to hinder T-cell functions. These genes demonstrated a robust correlation with the response of cancer patients to PD-1 blockades and exhibited high scores for tumor immune dysfunction and exclusion, affirming their downstream involvement in PD-1 signaling. Functional annotation underscored the significance of these genes in established immune regulation processes. Intriguingly, T cells isolated from patients with inflammatory arthritis exhibited a significant downregulation of the same genes, emphasizing their overarching inhibitory role. Examining single-cell RNA sequencing data revealed that five specific genes, KLRG1, CRTAM, SLAMF7, PTPN2, and KLRD1, were notably downregulated in activated and effector T cells from synovial fluids. Back-gating these genes to canonical cytotoxic T cell signatures identified PD-1^{+} HLA-DR^{HIGH} KLRG^{LOW} T cells as a novel inflammatory T cell subset that should be targeted with immunotherapies. Our findings suggest that PD-1 $^{+}$ HLA-DR^{HIGH} KLRG^{LOW} T cells are promising targets for prospective PD-1 antagonists and agonists in treating inflammatory diseases. This study not only reveals novel genes linked to PD-1 downstream functions but also serves as a valuable resource, offering insights for further investigations essential to delineate the role of PD-1 within immune responses.

#1368 Novel mRNA encoding anti-PD-L1 monoclonal antibodies for cancer immunotherapy.

E. Chung, Y. Bong, R. Chen, M. Zhang, S. Long, **D. Shen**;
RNAimmune, Inc., Baltimore, MD

The difficulties with antibody-based therapies stem from their steep costs, complex procedures, and contamination risks. We investigate the use of in vitro transcription (IVT) for mRNA production, presenting a novel approach to traditional antibody treatments by promoting internal protein or antibody synthesis. We aim to create innovative mRNA-based anti-PD-L1 antibodies with strong immunotherapeutic effectiveness. The study begins with mouse immunization and hybridoma generation. Immunizing mice with the glycosylated extracellular domain of PD-L1 produces mouse antibodies against human PD-L1. Hybridomas, derived from post-immunization splenocytes, yield monoclonal antibodies screened for PD-L1 binding affinity via flow cytometry. A neutralizing assay identifies 22 antibodies with similar IC50 values and shared binding epitopes. M1, chosen for glycospecificity, affinity, and neutralizing activity, undergoes additional evaluation for the expression and anti-tumor efficacy of mRNA-encoded antibodies. The expression of M1 and atezolizumab antibodies is facilitated through an mRNA-lipid nanoparticles (LNPs) delivery system. Following intravenous administration in mice, sustained serum levels of M1 (ranging from 100 to 700 μg/mL at 24 hours post-injection) are observed. Serum concentrations of M1 and atezolizumab antibody peak at the first timepoint (24 or 48 h) after mRNA-LNP injection, respectively, and then significantly decrease within the next 4 days, with a gradual decline over the next 2 weeks. Conversely, the serum concentrations of M1 or atezolizumab protein decline significantly 24 hours post-injection and consistently stay at a baseline level (t1/2 of 94 and 4 h for M1 mRNA-LNP and protein, respectively). This indicates that the injection of encoded mRNA in mice can stably and continuously express antibodies.Administering Atezolizumab mRNA-LNP through two intravenous injections leads to a significant decrease in MC38 tumor growth, exhibiting a dose-dependent effect (TGI% = 8.1, 43.1, and 62.8 for doses of 0.2, 0.6, and 1 mg/kg, respectively). A complete tumor regression was observed up to day 19 following injection with a 2 mg/kg dose of mRNA-LNP (TGI% = 90.8%). Remarkably, a 3 mg/kg dose of atezolizumab antibody demonstrates a similar reduction in tumor growth as 0.6 mg/kg of the mRNA-LNP formulation in this model. In conclusion, this research underscores the potential of LNP-formulated mRNA as a transformative approach, converting the human body into a site for the continuous, stable expression of antibodies, offering a promising alternative to traditional protein-based therapies for combating cancer. This innovative approach shows promise in overcoming the limitations associated with traditional antibody production and clinical utilization.

#1369 PD-1 directly suppresses macrophage metabolism to restrict anti-tumor immunity in an obesity-cancer connection.

J. Bader, J. Rathmell;
Vanderbilt University Medical Center, Nashville, TN

Obesity has been established as a leading risk factor for many cancers and can drive tumor progression and metastasis. Paradoxically, obesity has in some cases been associated with better survival and improved response to immune checkpoint blockade therapies. The role of the immune system in the obesity-cancer connection and how obesity affects immunotherapy responses, however, have been unclear. Here we show that obesity enhanced PD-1 expression on macrophages to reduce phagocytosis and antigen presentation to T cells that correlated with reduced T cell expansion and function. This obesity associated immune dysfunction, however, primed for enhanced anti-tumor response to PD-1 blockade. Single cell RNAseq showed obesity remodels myeloid and T cell populations but does not impact non-immune cell populations such as fibroblasts and epithelial cells. Specifically, obesity increased the overall number of tumor-associated macrophages (TAM) while effector T cells were decreased in abundance. Interestingly, the frequency of macrophages expressing PD-1 increased, while the remaining T cells maintained similar or reduced PD-1 expression and appeared less activated. Further, T cell depletion from the tumor microenvironment, enhanced macrophage PD-1 expression and worsened PD1-associated TAM dysfunction in an obesity enhanced manor. Obesity associated cytokines and adipokines including IFN-ã, leptin and insulin induced PD-1 expression on macrophages. This expression is associated with mTOR and c-myc activation signaling pathways; as such inhibiting these signaling pathways blocked PD1 expression. Bulk RNA sequencing analysis revealed PD-1^{+} TAMs had an altered gene profile compared to PD-1^{-} TAMs. PD1 expressing macrophages exhibited increased mitochondrial respiration and expression of oxidative phosphorylation, increased lipid uptake and increased cell cycling related genes. Conversely PD1- TAMs exhibited increased phagocytosis and antigen presentation. PD-1/PDL1 interaction directly regulated TAMs, as recombinant PDL-1 reduced glycolysis and phagocytosis in purified macrophages, and these effects could be reversed with blocking PD-1 antibody. Conversely, PD-1$^{-/-}$ TAMs had reduced lipid uptake but high rates of glycolysis, phagocytosis, and expression of MHC-II. Myeloid-specific PD-1 deficiency correlated with slower tumor growth and decreased LAG3 and increased CD69 on CD8 T cells. In addition, myeloid specific PD1 deficiency enhanced TAM antigen presentation through OVA specific CD8 T cell activation. These findings identify PD-1 as a metabolic regulator in TAM dysfunction and reveal a unique PD-1 mediated and macrophage-specific mechanism for immune tumor surveillance and checkpoint blockade. This may contribute to improved immunotherapy response in TAM-enriched tumors and obesity.

#1371 SLAMF9 promotes tumor progression and immunotherapy resistance by reshaping the tumor microenvironment.

T. Fan, C. Xiao, Z. Deng, W. Cai, H. Tian, L. Wang, C. Li, J. He;
National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Bei jing, China

Tumor prognosis and immunotherapy efficacy coincides with the infiltration ratio and functional status of immune cells in the tumor microenvironment (TME). Signaling lymphocytes activating molecule factors (SLAMFs) has been reported to play a key role in regulating tumor immunity. Herein, using multi cohorts, in vitro and in vivo experiments, we showed that SLAMF9 worsens tumor and suppresses immune therapy responses by remodeling TME. A pan-cancer analysis showed that SLAMF9 had relatively high transcriptional levels within tumor tissues compared with normal tissues across most cancer types. High SLAMF9 expression is associated with poor prognosis and anti-PD-L1 therapy resistance in advanced clear cell renal cell carcinoma cohorts and metastatic urothelial cancer cohorts. SLAMF9 expression was markedly upregulated in anti-CTLA-4-resistant murine B16 melanoma compared with parental tumors. In particular, SLAMF9 expression was generally negatively correlated with CD8+T cell infiltration score in 12159 patients of 40 cancer types even using different immune cell infiltrating algorithms. Although in vitro experiments have shown that SLAMF9 knockdown has almost no effect on the malignant phenotype of tumor cells, subcutaneous melanoma and lung adenocarcinoma with SLAMF9 deficiency grew slowly, which featured with increased infiltration of CD8+T and PD-1+cells. More importantly, SLAMF9-knockdown significantly increases the sensitivity of subcutaneous melanoma to anti-CTLA-4 inhibitor or anti-PD-L1 antibodies and improved the survival benefits of tumor-bearing mice. This work highlights SLAMF9 as a new target in reshaping the tumor immune microenvironment by controlling the functional status of CD+8 T cells and to improve the efficacy of immunotherapy.

#1372 BTN1A1 regulates T cell-mediated cancer immunotherapy by interacting with Galectin-9, PD-1, and TIM3.

S. Lee, Y.-S. Kim, C. Wu, A. Park, S. S. Yoo;
STCube Pharmaceuticals Inc., Gaithersburg, MD

Butyrophilin 1A1 (BTN1A1) is a novel immune checkpoint protein belonging to the butyrophilin family and is expressed on immune cells such as macrophages, B cells, or activated CD8 T cells and in human tumors. Our results indicate that BTN1A1 and PD-L1 expression are mutually exclusive in various human solid tumors. Furthermore, it was observed that BTN1A1 had a significantly higher detection level than PD-L1 in cancer patient samples. We have reported that BTN1A1 plays an immunomodulatory role in T cell activation and proliferation. BTN1A1 inhibited the proliferation of T cells that are activated by anti-CD3 and anti-CD28 antibodies *in vitro*. Overexpression of BTN1A1 in PC3 cells also inhibits T cell-mediated killing of cancer cells. BTN1A1 is a bona fide immune checkpoint inhibitor and has anti-tumor activity in a human immune setting. BTN1A1 represents a novel cancer immunotherapy target that goes beyond the low expression levels of PD-1/PD-L1 in tumors. BNT1A1 is an immune checkpoint and cell membrane protein that, together with its binding partners, serves as a starting point for signaling pathways. The BNT1A1 complex, which has various abilities by combining with a specific partner, plays a vital role as an immune checkpoint. In this study, we identified binding partners of BTN1A that regulate immune activity in a mutually interaction relationship with BTN1A1 in various ways. We identified binding partners for the extracellular domain of human BTN1A1 using cell microarrays from Retrogenix (Whaley Bridge, UK). Through this screening approach, we found that BTN1A1 binds to galectin-1 (Gal1), galectin-9 (Gal9), and neuropilin 2 (NRP2). These three putative binding partners could specifically bind to wild-type BTN1A1 but not to this protein's unglycosylated (2NQ) form. Of these three targets, immunoprecipitation and Biacore binding assays revealed that Gal9 exhibited the greatest affinity for human BTN1A1. Since Gal9 is a known PD-1 and TIM3 binding protein, we predicted the potential formation of a BTN1A1/Gal9/PD-1 or BTN1A1/Gal9/TIM3 complex. Indeed, it reveals that immunoprecipitation and confocal microscopy assays performed using cells expressing Myc-tagged versions of these four proteins demonstrated the formation of BTN1A1/Gal9, PD-1/Gal9, TIM3/Gal9, BTN1A1/Gal9/TIM3, and BTN1A1/Gal9/PD-1 complexes. In T cell activation assay using these complexes, when present BTN1A1 alongside the complex inhibits activated T cells. As high Gal9 expression levels are correlated with poor prognosis in multiple cancers, our results highlight this BTN1A1-Gal9-PD-1 or BTN1A1-Gal9-TIM3 axis as a novel therapeutic target for immunotherapeutic drug development.

#1373 Gene expression correlation of immune checkpoint molecules Siglec-15 and PD-L1 varies widely by cancer indication.

K. Watkins, L. Diao, M. Crochiere, J. Pinkas;
Pyxis Oncology, Boston, MA

Siglec-15 is a novel target for immunotherapy in cancer and exhibits low mRNA expression in normal tissues but broad expression across cancer indications, specifically on tumor-associated macrophages and tumor cells [1]. Expression of Siglec-15 and the immune checkpoint molecule PD-L1 have previously been reported to be mutually exclusive [1][2]. However, a large-scale meta-analysis of this claim has not been undertaken across cancer indications. Here, RNA-Seq analyses were performed across single cells, cell lines, and bulk tumor samples for Siglec-15 and PD-L1 mRNA expression. Data and meta-data from TCGA, CCLE, and primary tumor samples from 62 studies were obtained through OmicSoft OncoLand and single cell analysis was performed on the BioTuring Talk2Data platform. Analyses were limited to non-small cell lung cancer (NSCLC), cholangiocarcinoma, breast, thyroid, head and neck, colon, rectal, bladder, kidney, and endometrial cancers. Expression values were binned separately into percentiles across all indications and samples in increments of 10%. These analyses revealed individual gene expression levels of Siglec-15 and PD-L1 in bulk tumor samples varied substantially by indication, while co-expression of Siglec-15 and PD-L1 varied across indications. Analysis of gene expression of Siglec-15 and PD-L1 from the TCGA database showed a positive correlation in several indications including NSCLC, head and neck, kidney, and thyroid cancers. Analyses from additional studies in primary tumor samples confirmed co-expression of Siglec-15 and PD-L1 in NSCLC and head and neck cancer. Cell lines showed a similar trend of positive correlation with varying levels of Siglec-15 and PD-L1 expression. However, when examining expression at the single cell level (not bulk tumor), in 30 single cell studies spanning >1.3M cells, only 731 cells in 20 studies were found to co-express Siglec-15 and PD-L1 on the same cell while each gene was expressed individually on other cells. The majority of the cells co-expressing the genes were macrophages (n=~350), followed by CD4 (n=~115) and CD8 T cells (n=~50). This study demonstrates that at the bulk tumor level, Siglec-15 and PD-L1 mRNA expression are not broadly mutually exclusive across cancer indications and instead expression of each gene varies broadly within a given indication. Additionally, their expression is frequently positively correlated, including in NSCLC, head and neck, kidney, and thyroid cancers. These results also demonstrate that Siglec-15 and PD-L1 are rarely found co-expressed on same cell. These associations enable a better understanding of the landscape of target expression in patients across a wide variety of cancer indications and can inform combination strategies with anti-Siglec-15 therapies. [1] Sun J, et al. *Clin Cancer Res*, 2021;27(3):680-688. [2] Wang J, et al. *Nat Med,* 2019;25(4):656-666.

#1374 Targeting CD47/SIRPα axis in urologic cancer triggers enhanced phagocytosis of tumor cell and induces tumor growth inhibition.

F. Shen, M. Praharaj, A. J. Lee, T. R. Nirschl, X. Wang;
Johns Hopkins University School of Medicine, Baltimore, MD

Signal regulatory protein-α (SIRPα; CD172a or SHPS-1) is a transmembrane molecule that highly expressed on myeloid population. Binding of CD47 (integrin-associated protein, IAP) to SIRPα inhibits phagocytosis in macrophages, which acts as a mechanism of maintaining homeostasis. Tumor cells however, often time upregulate CD47 to evade immune response. Using publicly available dataset, we found that human prostate cancer cells upregulate expression of both CD47 and calreticulin, a “eat me” signal when engaged with Low density lipoprotein receptor-related protein 1 (LRP1). In addition, macrophages, monocytes and dendritic cells in human prostate cancer do have relatively high level of SIRPα and LRP1 expression. This finding provides the rationale of targeting CD47/SIRPα axis in prostate cancer to shift the balance between pro-phagocytosis and anti-phagocytosis signaling. We then moved to RM1 and B6Cap, two syngeneic prostate cancer models in immunocompetent mice. Significant tumor growth inhibition was seen in both models with anti SIRPα blocking antibody. Furthermore, we observed in vitro that CD47 or SIRPα blockage led to enhanced PC3 cell line phagocytosis by human monocyte derived macrophages (HMDMs). Same finding was found using mouse bone marrow derived macrophages (BMDMs). We then utilized ovalbumin expressing MB49 bladder cancer cell line and cocultured those with BMDMs. CD8+ T cell from OT1 mice exhibited higher expression of activation makers when cocultured BMDMs treated by either anti CD47 or SIRPα antibody, indicating that enhanced phagocytosis subsequently increases antigen cross presentation in macrophages. In summary, we identified that CD47 is overexpressed in human prostate cancer; blocking CD47/SIRPα did inhibit tumor growth through enhanced phagocytosis and antigen presentation.

#1375 Abundance of *KLRB1*+ (CD161) T cells in anti-PD1 non responders coupled with enhanced tumor cytotoxicity of anti-CD161 (IMT-009) with anti-PD1 makes it a rational target for combination with anti-PD-(L)1 immunotherapy.

A. Kar[1], T. Nieuwenhuis[2], M. Duan[3], S. Tabrizi[1], M. Huggins[1], E. Scanlon[1], C. Hession[1], M. Bernstein[1], M. Ross[1], M. Tang[1], S. Malu[1];
[1]Immunitas Therapeutics, Inc., Waltham, MA, [2]AstraZeneca, Waltham, MA, [3]Novartis Institute of Biomedical Research, Cambridge, MA

Background: Intra-tumoral CD4+ and CD8+ T cells expressing inhibitory receptor CD161 have an effector memory phenotype with high cytotoxic potential. CD161 inhibits T and NK cell function in the presence of its ligand, CLEC2D. This suppression can be recovered by treatment with IMT-009, a first in class anti-CD161 antibody. Single cell transcriptomic analysis of anti-PD1 refractory microsatellite stable colorectal tumors identified presence of CD161+ CD4+ cytotoxic T cells and CD161+ PD1+ exhausted CD8 T cells suggesting that anti-CD161 treatment may provide benefit in these tumors both as a monotherapy and in combination with anti-PD1. It was also observed that CD161+ CD4/CD8T cells are more abundant in anti-PD1/L1 non responders compared with responders in hepatocellular carcinoma, cutaneous squamous cell carcinoma, clear cell renal carcinoma and breast cancer, providing a rationale for targeting CD161. Using engineered ex-vivo tumor models and dissociated human tumors, we have demonstrated that IMT-009 reverses CLEC2D mediated inhibition and restores primary T cell function. Additionally, co-treatment of IMT-009 with anti-PD1 further enhanced T cell mediated cytotoxicity, providing rationale for studies combining IMT-009 and anti PD1 in the clinic.

Methods: Using the Snakemake pipeline developed in house, we processed publicly available scRNAseq data. Cells were clustered by Louvian method followed by cell type annotation by Seurat, and gene expression and gene signature levels per cluster were plotted. For ex-vivo assays, antigen specific CD8 T cells expanded from HLA-A2:01 donors were co-cultured with HLA-A2:01 expressing MDA-MB 231 triple negative breast cancer cell line or Raji Burkitt Lymphoma model with HLA-A2:01 allelic overexpression. Target tumor cells were engineered to express the ligands CLEC2D or PDL1. These cell lines were made to overexpress luciferase for monitoring target cell death using a luminescence readout. Additionally, dissociated tumor cells (DTCs) were cultured in presence of the treatment molecules. Intracellular staining of cytotoxic T cells along with detection of IFNγ, IL-2, TNFα and Granzyme B levels in culture supernatants by MSD/ELISA were used to assess activation profile of tumor infiltrated T cells.

Results: Combining anti-PD1 and IMT-009 significantly enhanced cytotoxic benefit compared to individual monotherapy in both Raji and MDA-MB-231 target cell line models. IFNγ levels in supernatants of DTCs treated with this combination were elevated as compared to individual monotherapy. Together with scRNAseq data of increased abundance of *KLRB1* (CD161) expressing T cells in anti PD1 non-responder patients, our data provide rationale for testing combination of IMT-009 with anti-PD1 in patients that may not respond to anti PD1 alone.

#1376 Engineered exosomes for the delivery of PD-L1 siRNA for lung cancer immunotherapy.

R. Kandimalla[1], D. N. Moholkar[2], M. Wallen[3], C. Ding[1], R. C. Gupta[1], F. Aqil[1];

[1]Brown Cancer Center, University of Louisville, Louisville, KY, [2]University of Louisville, Louisville, KY, [3]3P Biotechnologies, Louisville, KY

Cancer immunosurveillance involves a dynamic interplay between the host's innate and adaptive immunity. The regulation of programmed death ligand-1 (PD-L1) expression on cancer cells has emerged as an attractive approach for cancer treatment. However, challenges such as the immunosuppressive tumor microenvironment, ineffective trafficking, and tumor antigen heterogeneity limit the applications of cancer immunotherapy for solid tumors. Small interfering RNA (siRNA) against PD-L1 presents a compelling alternative to antibody treatment to reduce *PD-L1* presentation on cancer cells, thereby enhancing T-cell detection and preventing tumor progression. Bovine milk/colostrum serve as a biocompatible source for exosomes for delivery biologics such as siRNA. Here, we demonstrate exosomes mediated delivery of si*PD-L1* for lung cancer immunotherapy. Exosomes were isolated from bovine colostrum powder using ultracentrifugation. The average particle size of exosomes was 66 ± 2.5 nm, with polydispersity index (pdi) 0.27 ± 0.01 and a zeta potential -9.2 ± 0.70 mV, as analyzed by Zetasizer and validated by atomic force microscopy (AFM) and transmission electron microscopy (TEM). Formulations of exosomes with polyethyleneimine (EPM) and siRNA (1 - 20 µg), when mixed with 5'-^{32}P-labeled siRNA as a tracer resulted in over 90% entrapment of siRNA. Biodistribution studies of exosomes and EPM, with or without the tumor-targeting ligand folic acid (FA), revealed predominantly similar distribution patterns. Notably, FA-EPM exhibited enhanced tumor accumulation compared to EPM, attributed to the overexpression of folate receptors on tumor cells.To assess the functionality of EPM-siRNA, we screened 4 different siPD-L1 sequences in LLC-1 and A549 lung cancer cells. Following 48 h of EPM-siPD-L1 treatment, cells were harvested. Analysis of protein lysates by western blot showed a significant downregulation of the PD-L1 expression, ranging from 55% - 80% in LLC-1 cells and over 80% in A549 cells. *In vivo* mouse study with orthotopic Lewis lung carcinoma (LL/2-Luc2) tumors is underway to validate the effective silencing of PD-L1 and its effect on tumor inhibition and immune markers. In summary, our targeted EPM technology represents a novel nanoplatform for siRNA therapeutics delivery. As milk/colostrum are the most abundant sources of exosomes, clinical translatability of this novel approach is eminent.

Funding: This research work was supported from the Kentucky Lung Cancer Research Program (GB170558) and Immunotherapy CCII CoBRE pilot project (P20GM135004).

#1377 The role of TIM3 and PD1 blockades in head and neck cancer.

M. Shaikh, A. Karimi, P. Zeng, H. Pan, J. Barrett, A. Nichols;
University of Western Ontario, London, ON, Canada

Background: Our group has recently developed and validated a novel prognostic score for human papillomavirus (HPV+) oropharyngeal cancer called UWO3, which stratifies patients into low risk (immune rich), intermediate risk (immune mixed), and high risk (immune desert) groups. The high-risk immune desert group had a paucity of immune cells, however, that population of lymphocytes expressed high levels of the checkpoint molecule TIM3. To follow up on this, we assessed the therapeutic effect of anti-TIM3 mAb alone and in combination with anti-PD-1 in a syngenic murine HPV+ head and neck cancer model using the mERR. T-cell immunoglobulin mucin 3 (TIM3) and Programmed death 1 (PD-1) are negative immune checkpoint receptors that are expressed on tumor-infiltrating lymphocytes (TIL), play a crucial role in tumor-induced immune suppression. Given the critical role that the tumour microenvironment (TME) has on the prognosis of head and neck squamous cell carcinoma (HNSCC), immune checkpoint inhibitor immunotherapy approaches, specifically anti-PD1 and/or anti-TIM3 antibody therapy, may be very effective treatment strategies and may offer improved survival outcomes.

Methods:Immunocompetent C57BL/6 mice were injected in one flank with the syngeneic mouse HPV+ cell line, mEERL (10^6 cells), for tumour generation. Mice were then treated with either IgG2a isotype control, anti-PD1 (200µg), anti-TIM3 (200 µg) antibodies or a combination of anti-PD-1 and anti-TIM3 were administered via intraperitoneal injection 3 times per week following tumour establishement for 6 weeks (n = 7 mice per arm, total of 28 mice). Tumour volumes were measured every 2 days. Three representative tumors from each treatment group were collected for bulk RNA sequencing, scRNA-seq, and flow cytometry to characterise immune cell populations and transcriptional changes and monitor their impact on the TME of HNSCC.

Results:Anti-PD1 and anti-TIM3 both restricted tumour growth by size and weight relative to the IgG2a control ($p<0.01$, linear mixed model [lmm]). The combination of anti-PD1 and anti-TIM3 was more effective than either monotherapy alone ($p<0.05$, lmm). RNA sequencing analysis revealed differential abundance in CCL6, CCL9, CFD, and MAP3K5 transcripts relative to control for anti-PD1, anti-TIM3, and combination checkpoint inhibition.

Conclusion:Targeting both PD-1 and TIM3 enhanced the anti-tumor immune response in HPV+ head and neck tumours, providing further support for dual targeting of these molecules for more effective cancer immunotherapy. Our results suggest that immune checkpoint inhibitor therapy (PD1 and TIM3 blockades) could be a promising treatment strategy for HPV+ HNSCC, and the expression of these immune checkpoint molecules could serve as a predictive biomarker of patient outcome in HPV+ HNSCC.

IMMUNOLOGY: Inflammation and Cancer in Metastasis
Poster Session

#1381 Characterization of the 12-lipoxygenase expression in the megakaryoblastic cell line, Dami.

L. H. Boudreau[1], V. L. Gauvin[1], J. Richard[1], M.-F. N. Soucy[1], M. P. Hebert[1], E. P. Allain[2];
[1]Universite de Moncton, Moncton, NB, Canada, [2]Vitalite Health Network, Moncton, NB, Canada

Megakaryocytes are myeloid cells produced primarily in the bone marrow and are best known for releasing platelets in the blood stream. In the platelet production process, megakaryocytes transfer their bioactive content, including the 12-lipoxygenase (12-LO) enzyme, into newly formed platelets. The 12-LO has been shown to be implicated in platelet activation and is overexpressed in several chronic inflammatory conditions, including several types of cancers. The 12-LO is responsible for the conversion of the arachidonic acid into the 12(S)-hydroxyeicosatetraenoic acid (12(S)-HETE), a key lipid mediator implicated in several steps of the metastatic cascade. While 12-LO is expressed in mature human megakaryocytes, we recently identified two megakaryoblast cell lines isolated from leukemia patients lacking 12-LO expression. However, only one of the two cell lines expresses functional 12-LO protein upon megakaryocyte maturation. The goal of this study is to characterize the 12-LO expression during the megakaryocyte maturation process. We hypothesize that 12-LO expression is increased during cell maturation and that inhibition of the 12-LO expression will result in dysfunctional platelets. Both the Dami cell and MEG-01 cells were induced with the co-incubation of both phorbol myristate acetate and eltrombopag, a thrombopoietin receptor agonist. The maturation and viability of the cells were confirmed by flow cytometry. Expression of the 12-LO was assessed by RT-qPCR and immunoblot. Quantification of the 12(S)-HETE was performed by reversed-phase high performance liquid chromatography. Platelet release was quantified by flow cytometry using CD41 fluorescent labelled antibodies. We observed a 3-fold increase in 12-LO protein expression following cell maturation in the Dami cell line. Interestingly, mRNA expression between the undifferentiated Dami cells and mature Dami cells remained unchanged. Furthermore, we did not detect any 12-LO protein expression in the MEG-01 after the cell's maturation. Finally, we identified a specific 12-LO antisens non-coding RNA that is implicated in the regulation of the protein expression in megakaryocytes. Our study reports the first mechanistic regulation of 12-LO expression implicated in the megakaryocyte maturation process. Since both platelets and platelet-specific 12-LO play an important role in cancer biology, it is important to better understand how megakaryocytes package the enzyme inside these small cells. It remains elusive whether 12-LO enrichment in platelet correlates with the disease severity.

#1382 Activation of the cGAS-STING pathway by large oncosomes induces type I IFN inflammation in mesenchymal stem cells that triggers an immunosuppressive phenotype in neutrophils.

Taylon F. Silva[1], Diana Kitka[1], Blandine Victor[1], Chen Qian[1], Minhyung Kim[1], Tatyana Vagner[1], Giorgia Guerra[1], Catherine Grasso[1], Sungyong You[1], Fayyazz Sutterwala[1], Caroline Jefferies[1], Paola de Candia[2], Michael Freeman[1], Helen Goodridge[1], Karen Cavassani[1], Jlenia Guarnerio[1], Dolores Di Vizio[1]

[1]Cedars-Sinai Medical Center, Los Angeles, CA,[2]University of Naples Federico II, Naples, Italy

Extracellular vesicles (EVs) have been recognized as key players in cancer progression and metastasis, particularly large oncosomes (LO), secreted by invasive cancer cells, represent a distinct class of EVs with unique features. Previous research by the Di Vizio lab revealed LO's ability to alter recipient cell behavior, induce vascular morphogenesis, and carry cancer-specific biomolecules. Our preliminary studies point to a new mechanism of intercellular communication that involves the release of LO-containing DNA from PC cells. Notably, LO from prostate cancer exhibits enhanced potency in reprogramming bone marrow-derived mesenchymal stem cells (BM-MSCs) compared to exosomes (Exo) as observed by RNAseq. When evaluating the response to LO and Exo of BM-MSC, which are emerging as important drivers of bone metastasis, LO induces a robust inflammatory response, including metastasis-relevant chemokines and transcription factors involved in type I IFN response such as IRF7 and RASD2. Further, REACTOME pathway analysis of the differentially expressed genes revealed enrichment of the cGAS-STING pathway in BM-MSCs treated with LO, indicating a potential link between DNA/RNA sensors and the inflammatory response. BM cells isolated from WT and mutant Sting1gt/J mice demonstrated that up-regulation of IRF3 and IFNA1 genes induced by LO is inhibited when STING is absent. Suggesting that nucleic acid sensors engage in the LO-induced immune response in BM cells. Gene ontology analysis (GO) also identified several chemokines involved in neutrophil chemotaxis. In line with the observation from GO, neutrophil chemotaxis was significantly promoted by PC-derived LO-treated BM-MSC. Interestingly, human blood-derived neutrophils exposed to a conditioned medium from EVs-treated BM-MSC significantly increased the percentage of a population of LOX-1^{high} and CD62L$^{low/-}$ after 6h of culture. This was observed in concert with increased expression of Arginase1 and IL-10, suggesting their differentiation into polymorphonuclear-myeloid-derived suppressor cells (PMN-MDSC). An experimental orthotopic model using the breast cancer bone metastatic 4T1.2 cell line, with increased capacity to shed LO, demonstrated an increase in the presence of PMN-MDSC in the bone marrow of tumor-bearing mice in addition to a complete lack of lymphocyte populations, indicating their immunosuppressive activity that could lead to a pre-metastatic niche formation. This comprehensive study unveils the molecular pathways underlying the immune response to LO in the bone marrow, shedding light on mechanisms that could influence metastatic progression in prostate cancer. The findings underscore the unique role of LO in modulating the BM microenvironment, providing potential targets for therapeutic intervention and biomarkers for early disease detection.

#1383 Investigation of biological role and cytokine axis of cancer-associated fibroblast (CAF) in lung cancer brain metastasis.

N. Kim, S. Salam, E. Jahan, E.-J. Ahn, T.-Y. Jung, J.-H. Lee, J. Rhee, S. Kim, **K.-H. Lee**, K.-S. Moon;
Chonnam National University Medical School, Jeollanam-do, Korea, Republic of

Background: Brain metastases (BM) are among the most lethal forms of cancer globally. Lung cancer BM are frequently encountered and are associated with poor prognosis, decreased survival rates, and therapeutic resistances. Cancer-associated fibroblasts (CAFs) have emerged as important players of the brain metastases tumor microenvironment (TME). Mechanistic roles of brain metastases CAFs (hBM-CAFs) in tumorigenesis and therapeutic resistances remain unclear.

Material and Methods: In the present study, the patient's BM surgical sample was subjected to primary culture to isolate CAF. The hBM-CAF induced EMT and stemness phenotype was investigated by western blot. Biological role of hBM-CAF in tumorigenesis was evaluated using indirect co-culture method in vitro. FACS analysis was performed to investigate the changes in cisplatin cytotoxicity and radiation susceptibility of lung cancer cell lines when co-cultured with hBM-CAF. CX3CL1 and IL26 expression was confirmed by ELISA along with transcriptomic analysis of hBM-CAF. Molecular events were validated by using neutralizing CX3CL1 and IL26. The tumorigenicity and response to chemotoxicity of lung cancer cells were examined by co-injecting them with hBM-CAF in a mouse xenograft model.

Results: Our experiments demonstrated that hBM-CAFs significantly enhanced EMT and stemness phenotype by upregulating transcription factor SNAIL1, TWIST1, Slug and CD133, CD44 respectively in lung cancer cells. We also observed that hBM-CAFs decreased cisplatin cytotoxicity and enhanced radiation resistance, as measured by FACS analysis of apoptotic cells. *In vivo* experiments using xenograft mouse models revealed that co-injection of lung cancer cells with hBM-CAFs led to faster tumor growth and increased cisplatin resistance. Transcriptomic analysis of hBM-CAFs revealed a distinct genomic signature compared to normal fibroblast (hNFs), with significant overexpression of IL26 and CX3CL1 genes in the hBM-CAFs secretome, as validated by ELISA. Moreover, we found that lung cancer cells expressed high levels of the IL26 receptor IL10Rβ and ILR20α, and CX3CL1 receptor CX3CR1. Our hBM-CAF significantly upregulated JAK-STAT3 and Akt-mTOR pathway. Eventually, we have confirmed that neutralizing IL26 and CX3CL1 inhibit phosphorylation of JAK-STAT3 and Akt-mTOR respectively and revoked the IL26-CX3CL1 induced EMT and stemness phenotype of lung cancer cells.

Conclusion: Patient derived hBM-CAF promote aggressive phenotype of lung cancer cells by upregulating EMT and stemness transcriptome factors. Overexpression of IL26 and CX3CL1 cytokine led to the therapeutic resistance through JAK-STAT3 and Akt-mTOR signaling pathway respectively. Targeting IL26-CX3CL1 might be a novel therapeutic efficacy for lung cancer brain metastasis patients.

#1384 Highly metastatic PDAC adopts mesenchymal morphology and spatially coordinates endothelial cells with macrophages.

N. E. Gross, S. Charmsaz, J. W. Lee, C.-C. Huang, A. G. Hernandez, S. M. Shin, E. M. Coyne, C. Cannon, X. Yuan, L. D. Wood, E. M. Jaffee, W. Ho; Johns Hopkins University School of Medicine, Baltimore, MD

Background: Patients with pancreatic ductal adenocarcinoma (PDAC) often have metastatic disease at diagnosis and are highly resistant to cytotoxic and immunotherapies. Increased presence of myeloid cells, specifically high myeloid-to-T cell ratios, correlates with worse prognoses. However, mechanisms by which myeloid cells regulate cancer invasion and metastasis remain poorly understood. To study the role of immunosuppressive myeloid cells in driving metastasis, we employed murine PDAC models in conjunction with organoid systems and imaging mass cytometry (IMC).

Methods: We used two murine cell lines driven by *Kras*^{G12D} and *Trp53*^{R172H} under *Pdx1*-Cre, KPCY 2838c3 and KPCY 6419c5, which exhibit low-metastatic and high-metastatic propensities, respectively. To characterize differences in the metastatic cascade between these cell lines, flow cytometry, histological analysis, and 3D organoid modeling were used. IMC was also used to interrogate the tumor microenvironment and identify spatial relationships.

Results: These cell lines were orthotopically injected into syngeneic C57BL/6J mice to generate tumors that naturally metastasize to the liver. Flow cytometry analysis of livers from mice bearing 2838c3 or 6419c5 pancreatic tumors validated the higher propensity for metastasis with the 6419c5 cells ($p=0.0484$). Furthermore, the steps along the metastatic cascade contrasted significantly between 6419c5 and 2838c3. Highly metastatic PDAC adopted mesenchymal rather than collective invasion, increased intravasation, and more robust metastatic outgrowth. Notably, IMC revealed that highly metastatic PDAC had increased endothelial cell abundance (***$p \leq 0.001$), lower cytotoxic CD8+ T cell to CD4+ regulatory T cell ratios (***$p \leq 0.001$), and lower M1-like to M2-like tumor associated macrophage (TAM) ratios (*$p \leq 0.05$). Furthermore, spatial analysis demonstrated that highly metastatic PDAC excluded lymphocytes from the tumor and situated Arginase-1+ TAMs near Ki67+ tumor cells and CD31+ endothelial cells. In contrast, low-metastatic PDAC had closer lymphocyte proximities to tumor and greater distances between Arginase-1+ TAMs, tumor, and endothelial cells.

Conclusions: The highly metastatic PDAC tumor line utilizes mesenchymal invasion, has increased intravasation, and robust metastatic outgrowth compared to the low-metastatic PDAC cells. The TME of the highly metastatic model had disproportionate abundances of T regulatory cells and M2-like macrophages, poor lymphocyte infiltration, and enhanced vascularization. These overabundant M2-like macrophages (Arginase-1+) were also spatially coordinated with proliferating tumor cells and vasculature, suggesting a potential role for macrophages in tumor cell invasion and/or angiogenesis.

#1385 Crosstalk between hepatocyte and myeloid-specific IL17 signaling in colorectal cancer metastasis.

Katarzyna Chojnacka[1], Dan Kamen[1], Katrina M. Reyes[2], Hana Tomizawa[2], Sergei I. Grivennikov[1]

[1]Department of Medicine and Department of Biomedical Sciences, Cedars-Sinai Medical Center, Los Angeles, CA, [2]University of California Los Angeles, Los Angeles, CA

Advanced colorectal cancer (CRC) is resistant to current immunotherapies and prone to metastasis. Chronic inflammation mediated by cytokines such as interleukin (IL)17 activates the oncogenic pathways in cancer cells, promoting sporadic and inflammation-associated CRC. Increased levels of IL17A in early stages of CRC portends poor prognosis indicating its potential involvement into metastasis. We and others previously showed that IL17A signaling is required for early CRC tumorigenicity in a variety of models and that in early CRC, its ability to signal to epithelial cells is essential. What remains unknown is whether IL17 signaling to other cell types within the tumor microenvironment (TME) is essential to control tumor progression and metastasis. Using a model of colitis-associated cancer (CAC) we found that “late” IL17A neutralization decreases tumor burden, possibly acting through regulation of myeloid cells and chemokine network essential for the control of immunosuppressive TME. Next, using models of colorectal cancer liver metastasis (CRLM) including intraportal cell injection and cecum transplantation of organoids with distinct set of oncogenic mutation we found that IL17 neutralization reduces metastasis. FACS analysis revealed that IL17A promotes the recruitment of tumor-associated macrophages and other key myeloid subsets into the metastatic liver environment. Interestingly, ablation of IL17RC (receptor) in myeloid cells only (using *Il17rc*$^{f/f}$-LysMCre mice) led to reduction in metastasis and reshaping of metastatic myeloid cell compartments. Meanwhile, IL17 signaling in hepatocytes was required for early metastasis and pre-metastatic niche formation, as the ablation of IL17RC in hepatocytes (using *Il17rc*$^{f/f}$-AlbCre mice) led to a reduction of metastatic numbers but not growth. This coincided with reduced neutrophil recruitment and enhanced activation of cytotoxic innate lymphoid cells and CD8 T lymphocytes, indicating the role of hepatocyte specific IL17 signaling in blunting anti-tumor immunity. Our findings illuminate the role of inflammatory cytokine IL17 into CRC progression and metastasis and imply its distinct cell type specific role within the metastatic liver TME.

#1386 CD1d-restricted iNKT cells promote liver metastasis from colon cancer.

Marc Nater[1], Giulia Lucchiari[1], Michael Brugger[2], Tomas Valenta[2], Virginia Cecconi[1], Geo Forni[1], Stephan Benke[3], Maries van den Broek[1]

[1]Institute of Experimental Immunology, Universitat Zurich, Zurich, Switzerland,[2]Department of Molecular Life Sciences, Universitat Zurich, Zurich, Switzerland,[3]Flow Cytometry Facility, Universitat Zurich, Zurich, Switzerland

The liver is a prominent site for metastasis, yet little is known about the role of liver immunity in antimetastatic defense. Compared to other organs, the liver harbors a unique immune environment characterized by the abundance of innate cell lineages, including CD1d-restricted invariant natural killer T (iNKT) cells. To investigate the influence of iNKT cells on metastasis, we established an orthotopic model of colorectal cancer (CRC) with spontaneous dissemination to the liver. We induce the primary tumor by implanting CRC organoids into the colon mucosa of syngeneic C57BL/6 mice, resulting in hepatic macrometastases within 5 weeks. We observed that liver metastasis hardly occurred in mouse strains lacking iNKT cells (*Cd1d*$^{-/-}$ and *Traj18*$^{-/-}$ mice), while the growth of the primary tumor was comparable to that in wild-type mice. These results indicate a tumor-promoting function for hepatic iNKT cells. We uncovered that hepatic iNKT cells respond to disseminating cancer by producing IL-4 and IL-13, two cytokines known to activate hepatic stellate cells (HSCs) into fibrogenic myofibroblasts. Indeed, we saw rapid activation of HSCs and deposition of extracellular matrix upon arrival of cancer cells in the liver of wild-type but not iNKT cell-deficient mice. We propose that hepatic iNKT cells contribute to the formation of a supportive niche for disseminated tumor cells by activating HSCs early in the development of hepatic metastasis. Taken together, our findings highlight an essential tumor-promoting role for iNKT cells during the development of liver metastasis and contribute to our understanding of immune regulation of metastasis.

#1387 SETD2 loss promotes macrophage infiltration and metastasis in RCC.

E. N. Arner[1], M. M. Wolf[2], L. Vlach[2], J. C. Rathmell[1], W. Rathmell[1];
[1]Vanderbilt University Medical Center, Nashville, TN, [2]Vanderbilt University, Nashville, TN

Across human cancer, tumors that are high grade, poorly differentiated, and have undergone epithelial-to-mesenchymal transition (EMT) carry a worse prognosis with a high likelihood of metastasizing to distant organs. Despite significant research efforts, metastatic cancers and relapse remain the primary cause of cancer related deaths. In renal cell carcinoma (RCC), metastasis is present in one-third of patients at the time of diagnosis, and one-third of patients who initially present with locally advanced disease eventually develop local or distant recurrence following resection of the primary tumor, highlighting the need for new RCC therapies and further insight into the metastatic process. Using RCC patient biopsies, we found that patients with more epithelial tumors have a significantly lower risk of recurrence. Additionally, tumors that had a mesenchymal protein signature had significantly increased macrophage infiltration, which was significantly associated with a higher stage at diagnosis and worse overall survival, suggesting that macrophages may play an important role in EMT and metastasis in ccRCC. Whole exome sequencing of these patient samples revealed that mutational loss of SETD2, a histone methyltransferase that is lost in about 20% of RCC patients, correlated strongly with increased macrophage infiltration within the primary tumor and was necessary for the correlation between macrophages and EMT. SETD2 loss in syngeneic kidney cancer mouse models confirmed that SETD2 loss within tumor cells resulted in increased EMT, macrophages within the primary tumor microenvironment (TME), and spontaneous metastasis, further supporting the role of macrophages in promoting metastasis in the absence of SETD2. Further characterization of the gene signatures and immune cell infiltrate in RCC will lead to a better understanding of metastasis in an oncogene- and tissue-specific manner and thus lead to more efficacious therapies for metastatic patients.

#1388 Spatial transcriptome analysis of EMT trait and corresponding immune composition study in HNSCC.

C.-H. Chung, M.-H. Yang;
National Yang Ming Chiao Tung University, Hsinchu, Taiwan

Head and neck squamous cell carcinoma (HNSCC) is a prevalent malignant cancer worldwide. Conventional treatments for this type of cancer involve surgical resection, radiation therapy, and chemotherapy. However, in cases where the tumor recurs or metastasizes distantly, rendering surgical resection or radiation therapy impractical, the only viable option is the utilization of targeted drugs in conjunction with chemotherapy. Despite such interventions, the prognosis remains grim. Hence, the identification of genetic characteristics or biomarkers associated with easy metastasis or recurrence in the early stages of the tumor has become imperative for effective head and neck cancer treatment. The objective of this study is to analyze tumor specimens from the primary site and lymph node metastasis post-surgical resection in HNSCC patients. We employed the GeoMx Digital Spatial Profiler (DSP) for imaging-based digitized gene expression analysis. The DSP provides gene expression information at specific locations we selected, such as the primary tumor center core, primary tumor invasion borders, and lymph node metastasis specimens. The GeoMx DSP spatial analysis tool illustrates the cancer transcriptome atlas (CTA), encompassing the expression of 1825 genes related to cancer and immunity from the primary site to the metastatic site. We identified tissue-specific EMT gene expression patterns in paired tumor regions of interest (ROIs). ITGB1 emerged as the most significant co-expression marker in the primary outer tumor and metastatic tumor. Distinct EMT signature genes expressed in the HNSCC primary site and lymph node metastatic site were also discovered. Additionally, we conducted CTA profiling in correlated stroma ROIs. Through myeloid activity analysis in HNSCC paired samples, we identified distinct myeloid activation signatures in primary and metastatic site stroma cells. These results will provide crucial insights into head and neck cancer treatment strategies based on different tumor site characteristics.

#1389 Understanding the differential role of an IL-6 family cytokine in varying subtypes of breast cancer patients for novel therapeutic intervention.

C. L. Wolf, K. Tawara, C. L. Jorcyk;
Boise State University, Boise, ID

In the United States, it is estimated that over 295,000 women will be diagnosed with breast cancer, and over 43,000 breast cancer deaths in 2023. Mortality in breast cancer is due in large part due to distant metastasis to organs such as the bone, lung, liver, and brain. Our laboratory has identified that the IL-6-family cytokine oncostatin M (OSM) plays a crucial role in initiating metastasis by secreting pro-metastatic molecules such as VEGF, LOXL2 and IL-6, and increasing circulating tumor cell numbers and metastases to bone and lung *in vivo*. More recent work within our lab has identified unique roles for OSM in varying subtypes of breast cancer patients, particularly between estrogen receptor positive (ER+) and ER- patients. It is well known that patients with ER- breast cancer, specifically triple negative breast cancer (TNBC; ER- PR- HER2-), have limited therapeutic options. However, the divergent role OSM plays in ER+ and ER- breast cancer and the mechanism by which this occurs has yet to be fully understood. Thus, we aimed to fully elucidate the difference between OSM in ER+ versus ER- breast cancer. RNA sequencing analysis on OSM-treated human ER+ cells and ER- TNBC cells discovered significant differences in gene expression between both cell lines upon treatment with OSM, including alteration in DNA-replication and cell cycle pathway genes. Afterwards to evaluate the correlation between OSM and DNA synthesis and this role on metastasis, we evaluated the role of a novel anti-OSM therapeutic and its correlation with decreased metastasis. This research aims to elucidate the unique role OSM plays in ER+ and ER- breast cancer and will provide a molecular understanding of how this occurs and will provide detailed information on which patients will benefit most from anti-OSM therapeutics.

#1390 Pulmonary viral infection promotes the awakening of dormant metastatic breast cancer cells in lungs.

S. Chia[1], B. Johnson[1], M. Boorgula[1], V. Sreekanth[1], A. Goodspeed[1], B. J. Davenport[1], J. Hu[1], D. Gao[1], M. Papanicolaou[2], T. E. Morrison[1], J. A. Aguirre-Ghiso[2], M. Rincon[1], J. V. DeGregori[1],

[1]University of Colorado Anschutz Medical Campus, Aurora, CO, [2]Albert Einstein College of Medicine, New York, NY

Background: Breast cancer is the most common form of cancer and the second cancer-causing death in females. Although remission rates are high if detected early, survival rates drop substantially when breast cancer becomes metastatic. The most common sites of metastatic breast cancer are bone, liver, and lung. Respiratory viral infections inflict illnesses on countless people, as evidenced by annual flu seasons and the latest pandemic caused by SARS-CoV-2. Respiratory viral infections result in increased inflammation with immune cell influx to facilitate viral clearance. Prior studies have shown that inflammation can contribute to dormant cancer cells awakening and outgrowth. However, how respiratory viral infections contribute to breast cancer lung metastasis remains to be unraveled.

Methods: MMTV/NEU mouse model of dormant breast cancer was used, with influenza virus as the model respiratory virus. Lungs and bronchoalveolar lavage fluid were harvested for immunohistochemistry, flow cytometry, cytokines, and single-cell RNA-seq analysis. Flatiron Health Database was mined for epidemiological data to assess the risk of breast cancer metastasis to lung with COVID infection.

Results: We have shown a dramatic increase in disseminated cancer cell (DCC) awakening in the lungs following influenza and SARS-CoV-2 infections. Influenza infection results in loss of a pro-dormancy mesenchymal phenotype and increased proliferation of DCC in the lungs within days post-infection, with a more than 1000-fold expansion of carcinoma cells over a couple of weeks. Strikingly, by 15 days post-infection, the lesions that expanded from solitary HER2$^{\pm}$ DCCs almost homogeneously return to a quiescent state. Our preliminary data indicate that post-infection increases in IL-6 are required for DCC expansion post-influenza. Acute influenza infection also contributed to an accumulation of CD4$^{\pm}$ T cells around expanding tumor cells for as long as 28 days after the initial infection. Depletion of CD4$^{\pm}$ T cells but not CD8$^{\pm}$ cells during infection with influenza virus prevents the expansion of the DCCs in the lung. Co-depletion of CD8 cells with CD4 cells partially restored the DCC burden in the lungs, indicating a role for CD8 cells in eliminating DCCs when released from CD4-mediated suppression. Single-cell RNA-seq analyses of CD8$^{\pm}$ T cells with CD4 depletion showed an increased IL2/STAT5, MTORC1, and Ox/Phos activation by 15 dpi. The analyses also showed an immunosuppressive effect by the tumor cells. Finally, analysis of female breast cancer patients who tested positive with SARS-CoV-2 after their initial diagnosis exhibited a hazard ratio of 1.44 (p=0.043) for subsequent diagnosis of metastatic breast cancer in lungs.

Conclusions: These studies reveal the potential risks to cancer survivors who experience respiratory viral infections, with mechanistic insight that could lead to novel prevention or intervention strategies.

#1391 Therapeutic salmonella induces long-term protective trained immunity in NK cells against metastasis.

L. Rong, J. Huang;
The University of Hong Kong, Hong Kong, Hong Kong

Immune memory is a trait commonly associated with adaptive immunity. Nevertheless, it has been observed that activation of the innate immune system can also result in enhanced responsiveness to subsequent triggers, a form of innate immune memory known as trained immunity. This *phenomenon* has been primarily explored in the context of host defense against infectious disease, where myeloid cells, including monocytes, macrophages, and their precursor cells, are conditioned by specific stimuli such as β-glucan, LPS, or the bacillus Calmette-Guérin (BCG) to boost protection against microbial pathogens. However, the induction of trained immunity in innate lymphocytes, particularly through these known or yet-to-be-discovered stimuli and its explicit contribution to tumor immunity, remain insufficiently characterized. Metastasis accounts for 90% of cancer-related deaths, and no effective clinical therapies are currently available to halt the metastatic cascade. Based on multiple cancer metastasis mouse models and immunological analysis, we found that a single dose of therapeutic Salmonella YB1, an engineered oxygen-sensitive strain, provides extensive and persistent protection against metastasis by inducing protective trained immunity in NK cells, consistently observed irrespective of the mouse genetic background or cancer cell lines. Following inflammatory resolution, salmonella YB1-trained NK cells exhibit an enhanced capacity to release IFN-γ upon secondary stimulation and increased cytotoxicity towards cancer cells, which is associated with epigenetic changes. Further investigation using single-cell transcriptomic profiling indicates that the formation of long-term anti-metastatic trained immunity in NK cells by Salmonella YB1 is dependent on IL12 and IL18. Additionally, Salmonella YB1-trained NK cells outperform common immune checkpoint therapies like PD1 blockade and TIGIT blockade in suppressing metastasis. In summary, our results revealed a novel anti-metastatic function of trained NK cells induced by therapeutic Salmonella, suggesting the induction of trained immunity in NK cells as a potential anti-tumor strategy.

#1392 Neutrophil extracellular trap (NET)-induced pancreatic tumor metastasis requires integrin-linked kinase (ILK) signaling.

P. C. McDonald[1], S. J. Awrey[1], H. Tavakoli[1], R. Carroll[1], Z. J. Gerbec[1], J. M. Karasinska[2], D. F. Schaeffer[2], D. J. Renouf[2], S. Dedhar[1];
[1]BC Cancer Research Institute, Vancouver, BC, Canada, [2]Pancreas Centre BC, Vancouver, BC, Canada

Neutrophil extracellular traps (NETs) are an important contributor to the immunosuppressive tumor microenvironment and facilitate metastasis of solid cancers. NETs have been shown to stimulate breast and colon cancer cell metastasis through a mechanism potentially involving an interaction between integrin-linked kinase (ILK) and the cell surface receptor coiled-coil domain containing protein 25 (CCDC25). Here, we have interrogated whether ILK is required for NET-induced metastasis in pancreatic ductal adenocarcinoma (PDAC), an inflammation-driven tumor that is difficult to treat. Evaluation of the circulating neutrophil to lymphocyte ratio (NLR) in the blood samples of patients presenting with metastatic PDAC showed that a higher baseline NLR is associated with significantly shorter overall patient survival. Western blot and immunofluorescence analyses demonstrated that human PDAC cell lines, patient-derived xenograft cells, cells derived from the KPCY genetic model of PDAC and patient-derived organoids co-express CCDC25 and ILK. Co-immunoprecipitation analyses showed that CCDC25 and ILK associate in both mouse and human PDAC cells, and that exposure of the cells to NETs results in an increased amount of ILK associated with CCDC25. Exposure of human and KPCY mouse PDAC cells to NETs increases phosphorylation of GSK3-β and ERK, increases activation of Rac1 and Cdc42 and upregulates markers of epithelial-to-mesenchymal transition (EMT), including ZEB1 and Snail, in a time and concentration-dependent manner. Furthermore, time-lapse imaging using Incucyte-based wounding assays showed that exposure to NETs induces pseudopodia-like protrusions, migration and invasion by these cells. RNAi-mediated suppression of ILK expression or inhibition of ILK activity using a highly selective inhibitor of ILK, QLT-0267, significantly inhibits the NET-induced increase in GSK3-β phosphorylation, Rac1/Cdc42 activation, migration and invasion of PDAC cells. *In vivo*, co-localization of CCDC25 and ILK is observed in tumors and metastases from KPCY mouse and MIA PaCa-2 human PDAC xenograft models stained by multispectral immunofluorescence and analyzed by confocal microscopy. Tumors and metastases show the presence of infiltrating neutrophils and NETs as indicated by staining for myeloperoxidase and citrullinated histone H3. Importantly, doxycycline-inducible shRNA-mediated suppression of ILK expression by luciferase-positive PDAC cells following injection of these cells through the tail vein of mice administered LPS intranasally results in a significant reduction in metastasis as measured by bioluminescence-based imaging, compared to control animals. Collectively, these data identify NET-induced ILK signaling as an important contributor to PDAC progression and suggest the potential for targeting this axis to prevent PDAC progression and metastasis.

#1393 Tumor-infiltrating monocyte-like cells create metastasis-promoting immunosuppressive microenvironment via THBS1 production in aggressive colorectal cancer.

M. Omatsu[1], Y. Nakanishi[1], K. Iwane[1], N. Aoyama[1], T. Maruno[1], H. Kasashima[2], M. Yashiro[2], A. Fukuda[1], H. Seno[1];
[1]Kyoto Univ. Graduate School of Medicine, Kyoto City, Japan, [2]Osaka Metropolitan Univ., Osaka City, Japan

Mesenchymal subtype of colorectal cancer (CRC) is characterized by high metastatic potential, poor prognosis and an immunosuppressive tumor microenvironment (TME). Although tumor-infiltrating myeloid cells constitute the primary population of immune components in the TME, targeting myeloid cells remains highly challenging owing to the developmental and functional heterogeneity of their subsets. Thus, a deeper understanding of how tumor-infiltrating myeloid cells contribute to the creation of a tumor-promoting TME is needed to identify rational strategies against CRCs with aggressive phenotypes. Recent studies have revealed that multiple inflammatory signatures are elevated in mesenchymal CRCs, suggesting a strong association between inflammation and stromal activation. In this study, we focus on thrombospondin-1 (THBS1), which is a matricellular protein, typically expressed in inflammatory processes. Immunostaining and RNA in situ hybridization on human CRC samples revealed a clear localization of THBS1 expression in tumor stroma. Analyses of the cancer genome atlas (TCGA) and tissue microarray of human CRCs show a positive correlation between increased expression of THBS1 and the mesenchymal phenotype, immunosuppression, and poor prognosis in human CRCs. Utilizing immunocompetent orthotopic implantation systems with aggressive mouse tumor organoids (MTO) on wild-type and *Thbs1* knockout (*Thbs1*$^{-/-}$) mice, we demonstrated that loss of THBS1 in the TME suppressed metastatic formation accompanied by an increased infiltration of tumor-infiltrating CD8^{+} T cells. Depletion of CD8^{+} T cells by neutralizing antibody restored metastases in MTO-bearing *Thbs1*$^{-/-}$ mice, indicating that THBS1 promotes metastatic formation by suppressing CD8^{+} T cell-mediated anti-tumor immunity. Analyses of single cell RNA sequencing data of human CRCs and orthotopic MTO tumors revealed that bone marrow (BM)-derived monocyte-like cells are the primary source of THBS1. This notion was further supported by analyzing the orthotopic MTO tumors in chimeric mice generated by bone marrow transplantation. Finally, we identified stroma-derived CXCL12 as a key chemokine for the recruitment of THBS1-producing monocyte-like cells by analyzing orthotopic MTO tumors treated with CXCL12 inhibitor. Our study contributes to a better understanding of the processes underlying THBS1 production by monocyte-like cells that mediates immune evasion that confer aggressive features to CRCs. These findings provide insights for the treatment of this poor-prognosis malignancy.

#1394 The CXCL10-CXCR3 axis as Jekyll and Hyde: A regulator of metastasis and immune response in osteosarcoma.

B. B. Gyau[1], X. Chen[1], J. Wang[1], M. A. Clement[1], A. M. Major[2], J. Xu[1], M. Hicks[1], T.-K. Man[1];
[1]Baylor College of Medicine, Houston, TX, [2]Texas Children's Hospital, Houston, TX

The CXCL10-CXCR3 axis is known to promote tumor growth and metastasis via autocrine signaling, while it can also elicit anti-tumor responses by paracrine signaling. However, its roles are still elusive in osteosarcoma (OS), the most common malignant bone tumor in children. In this study, we utilized in vitro assays, mouse models, and gene expression analysis to characterize the roles of the CXCL10-CXCR3 axis in OS. To understand the autocrine signaling, we performed in vitro phenotypic assays on three OS cell lines with and without CXCL10. The results showed that the chemokine increased AKT phosphorylation and tumor cell migration. Using a CRISPR-based CXCR3 deletion mutant, we demonstrated that the lack of the receptor inhibited OS tumor growth and pulmonary metastasis in an orthotopic xenograft mouse model. The results indicate that the CXCL10-CXCR3 axis is sufficient and necessary to promote aggressive phenotypes in OS via autocrine signaling. Next, using gene expression datasets from two cohorts of OS patients, we showed that high expression of CXCL10 or its cognate receptor CXCR3 was associated with a better prognosis. Since CXCL10 is known to recruit CXCR3+ immune cells to fight against cancer, we further found that the expression of the T cell marker CD3D was associated with a better prognosis. These results suggest that the chemokine may also play a protective role in osteosarcoma by recruiting anti-tumor immune cells via paracrine signaling. Lastly, we have previously reported that a high circulating level of CXCL10 correlates with a poor prognosis in osteosarcoma patients. In this study, we demonstrated that increasing the circulating CXCL10 level in immunodeficient orthotopic xenograft mouse models of OS did not significantly promote the development of pulmonary metastases, suggesting circulating CXCL10 may exert its chemotactic effect mainly on immune cells, not on tumor cells. Taken together, we propose a model that tumor expression of CXCL10 promotes osteosarcoma growth and metastasis development via autocrine signaling. The increase of the local level of CXCL10 attracts CXCR3+ immune cells to the tumor site and promotes anti-tumor function via paracrine signaling. Metastatic cells colonize the lungs and cause tissue damage and inflammation, which increases the production of CXCL10 in the circulation. The higher circulating CXCL10 recruits T cells away from the primary tumor site and indicates the occurrence of metastasis and, hence, correlates with a worse outcome in patients. Our research highlights the importance of understanding the opposite effects of CXCL10 on tumor and immune cells as well as in the tumor microenvironment and circulation. Identification of the mechanistic differences in the CXCL10-CXCR3 signaling between tumor and immune cells will provide a novel therapeutic approach against tumor cells while promoting anti-tumor immune response in OS.

#1395 Unraveling the interplay between tumor heterogeneity and microenvironment in pancreatic ductal adenocarcinoma evolution and its clinical implications.

H. Kim[1], H.-o. Jeong[2], S.-H. Lee[1], K. Lee[1], K. Lee[1], J. Lee[1], M. Lee[1], S. Lee[2], J. Park[1];
[1]Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of, [2]Ulsan National Institute of Science and Technology, Ulsan, Korea, Republic of

Intratumoral heterogeneity (ITH) and tumor microenvironment (TME) of pancreatic ductal adenocarcinoma (PDAC) play important roles in tumor evolution and patient outcomes. However, the precise characterization of diverse cell populations and their crosstalk associated with PDAC progression and metastasis is still challenging. We performed single-cell RNA sequencing of primary PDAC samples with and without paired liver metastasis samples to understand the interplay between ITH and TME in the PDAC evolution and its clinical associations. We discovered that even a small proportion (~30%) of basal-like ductal cells in primary PDAC was associated with poor chemotherapy response and patient survival and that epithelial-mesenchymal transition programs were largely subtype specific. The clonal homogeneity significantly increased with more prevalent and pronounced copy number gains of oncogenes, such as KRAS and ETV1, and losses of tumor suppressor genes, such as SMAD2 and MAP2K4, along PDAC progression. Diverse immune cell populations, including naive SELL^{hi} regulatory T cells (Tregs) and activated TIGIT^{hi} Tregs, contributed to shaping immunosuppressive TMEs of PDAC through cellular interactions with malignant ductal cells. The proportion of basal-like ductal cells negatively correlated with that of immunoreactive cell populations, such as cytotoxic T cells, but positively correlated with that of immunosuppressive cell populations, such as Tregs. Overall, our study provides a valuable resource for better understanding the roles of ITH and TME in PDAC evolution and their clinical relevance in the treatment of PDAC.

#1396 Targeting immune suppressive myeloid cells in prostate cancer recurrence and metastasis.

S. Mei, H. Zhang, T. Hirz, N. E. Jeffries, S. Wu, C. Wu, D. M. Dahl, P. J. Saylor, D. B. Sykes;
Massachusetts General Hospital, Boston, MA

Metastatic prostate cancer is a leading cause of cancer-related deaths worldwide and therefore an urgent inadequately addressed clinical problem. We have approached this problem primarily by studying immune cells within the tumor microenvironment rather than the tumor cells themselves. One critical cell subset that seems to be contributing to the aggressive behavior of clinically significant prostate cancers is the immune suppressive myeloid cells (MDSC) within the tumor microenvironment. MDSC have been shown to promote tumor metastases by participating in the formation of pre-metastatic niche, promoting angiogenesis, tumor cell invasion, and mediating immune suppression. Understanding the heterogeneity and function of these myeloid cells is an essential step toward developing effective therapeutic strategies to target them and enhance anti-tumor immune responses that have thus far been so elusive. We utilized previously generated scRNAseq data and combined it with publicly available prostate cancer scRNAseq datasets. The analysis included a total of 96 samples at different disease stages, including healthy prostate tissue, adjacent-normal tissue, low-grade tumors, high-grade tumors, as well as local and bone metastatic tumors. In addition, GeoMx spatial profiling was performed on 24 high-grade prostate cancer patients to assess immune cell spatial infiltration. This meta-analysis provided comprehensive insights into the molecular characteristics of prostate cancer. We characterized multiple MDSC subpopulations and revealed the dynamics of tumor associated macrophages (TAMs) during tumor progression and metastasis. We found that a specific type of TAM, known as APOE+ SPP1+TAM, is significantly enriched in metastatic tumors. They are transcriptionally similar to the TAMs found in the bone metastasis niche of prostate cancer. Moreover, we found APOE+ SPP1+TAMs within primary/localized tumors tumors alone could predict prostate cancer recurrence despite curative-intent local therapy. We validated the accumulation of APOE+ SPP1+TAMs in a prostate cancer mice model. We are currently studying the role of the specific subset of TAMs in tumor metastases by focused analysis of the communication between these TAMs, T cells, and tumors. Additionally, we are exploring the therapeutic potential of blocking APOE+ SPP1+TAMs in a mice model of prostate cancer. Our analyses provide a comprehensive picture of myeloid cell linage across different prostate cancer stages, highlighting the potential for therapeutic targets that disrupt the metastatic process via their effects on tumor associated macrophages.

#1397 Metabolic CRISPR-Cas9 screening identifies loss of mitochondria*Gene M*in triple-negative breast cancer to promote lung metastasis via immune modulation.

S.-T. Chou, X. Wang, D. N. Edwards, J. Chen;
Vanderbilt University Medical Center, Nashville, TN

Triple-negative breast cancer (TNBC) is a heterogenous breast cancer characterized by an aggressive phenotype and high risk of metastatic occurrence. Metastasis is a multifaceted process that involves metabolic reprogramming, selection, and adaptation. Although studies have shown that alterations of metabolic processes can influence TNBC phenotype and sensitivity to treatments, less is known about how changes in metabolic enzymes in the tumor cells affect crosstalk between tumor and immune cells during metastasis. Here, we performed a high-throughput CRISPR-Cas9 screening of metabolic genes in an orthotopic basal-like mammary carcinoma 4T1 mouse model to identify key metabolic enzymes in the tumor cells that are associated with TNBC lung metastasis by affecting the tumor microenvironment (TME). The CRISPR-Cas9 screening showed an enrichment of sgRNA for mitochondria *Gene M* in the metastasized lungs of wild-type mice but not *Rag1*$^{-/-}$ mice, indicating that loss of *Gene M* could modulate adaptive immune cells in the TME or distant organs to promote 4T1 lung metastasis. Further pilot experiments revealed that loss of *Gene M* in 4T1 cells increased murine basal-like carcinoma lung metastasis *in vivo* and decreased population of B cells, CD4+ T cells, M2 macrophages, monocytes, and CXCR2+ neutrophils in the metastasized lungs without affecting the growth rate of the primary tumors. Overall, our preliminary results demonstrated that *Gene M* deficiency in 4T1 cells affects immune cell profile and drives lung metastasis of murine basal-like carcinoma cells, but the molecular and cellular mechanisms by which loss of *Gene M* grant tumor cells with metastatic advantage requires further investigation.

#1398 The role of ST8SIA2 & ST8SIA4 in melanoma progression and metastasis.

Amirali Amirfallah, Kayla Gallant, Maria Cavallo, Zongguan Huang, Edward Hartsough

Drexel University College of Medicine, Philadelphia, PA

Melanoma is the deadliest form of skin cancer; while early detection affords patients a 5-year survival rate greater than 90 percent, survival for metastatic patients is poor. Metastatic dissemination is reliant on melanoma's ability to escape immune surveillance and migrate to distant organs. These processes are heavily influenced by cell surface proteins, which themselves can be regulated by post-translational modifications (PTM) like protein glycosylation. An understudied glycosylation that may affect immune evasion and cancer progression is polysialylation (polySia). Here, a long-chained polymer of sialic acid moieties is formed by the polysialyltransferases ST8SIA2 and ST8SIA4. In silico analysis suggests that compared to normal skin, primary cutaneous melanoma has elevated expression of both ST8SIA2 and ST8SIA4. Interestingly, although ST8SIA4 is upregulated in metastatic samples, its expression is associated with increased survival. Further analysis revealed a positive correlation between CD8+ T cell infiltrates and ST8SIA4 expression. Furthermore, analysis of ST8SIA2 expression shows an inverse correlation with survival and T Cell CD8+ cells infiltration, suggesting ST8SIA2 and -4 differentially regulate the tumor immune microenvironment. One potential polySia modified cell surface protein, mediating these effects is Cell Adhesion Molecule 1 (CADM1). CADM1 is a target of ST8SIA2 and may also be modified by ST8SIA4. Loss of CADM1 increases the invasive properties of melanoma cells and our recent point mutational analysis reveals that the adhesive function of CADM1 might be regulated by polySia at Asp 113. In addition to its role in cancer migration and invasiveness, CADM1 expression may also affect the tumor immune environment. Further investigations are needed to untangle the complex relationship between PolySia modification and melanoma immune evasion and metastasis.

#1399 The role of CCN5 in regulation of tumor-infiltrating lymphocytes (TILS) in triple-negative breast cancer (TNBC) cells.

U. Biswas, A. Kambhampati, N. Haideri, A. De, S. Upadhyay, S. Banerjee, S. Banerjee;
Kansas City VA Medical Center, Kansas City, MO

TNBC accounts for about 15-20 percent of all breast cancer cases, with a high incidence in young and African-American women. TNBC lacks the expression of estrogen receptor, progesterone receptor, and normal human epidermal growth factor receptor type 2 (HER2) copy number with expression. Thus, TNBC is not sensitive to endocrine and targeted molecular therapies. Therefore, surgery and systemic chemotherapy are the primary treatment methods for TNBC. The adjuvant therapy regimen includes anthracycline, paclitaxel, or both in (Neo-) early TNBC. However, this treatment is often ineffective after recurrence or metastasis. Therefore, continuously searching for new targeted therapies and immunotherapies becomes a focus in TNBC treatment in patients with diverse communities. The studies showed that TNBC is more immunogenic than other subtypes of breast cancers with tumor-infiltrating lymphocytes (TILs) in its microenvironment. More importantly, Cytotoxic CD8+ TILs of the adaptive immune system are the most potent effectors in the anticancer immune response and constitute the backbone of cancer immunotherapy. Therefore, a high number of CD8+TILs in TNBC patients' tumors are considered a better prognosis following neoadjuvant chemotherapy. Hence, increasing and activating CD8+ TILs could be an exciting and appropriate approach to treating TNBC. Blocking immune checkpoints can inverse the microenvironment immunosuppressive state and enhance the function of tumor cell clearance. One of the major immune checkpoint therapies has involved a monoclonal antibody against programmed cell death-1 (PD-1)/programmed cell death-ligand 1 (PD-L1), expressed in various tumor cells, including TNBC and immune cells. The studies found that PD-1/PD-L1 negatively regulates CD8+ TILs in cancers, and blockade of PD-1 can induce CD8+ TILs responses in advanced melanoma. Interestingly, PD-1/PD-L1 immunotherapy has also progressed in suppressing TNBC growth and progression. However, the currently available immune checkpoint therapies have therapeutic limitations with the toxicity of the drugs. Thus, new therapeutic options are urgently needed. Our studies found that the expression of CCN5, an anti-invasive gene, correlates with the number of cytotoxic CD8+ TILs in ER+ and HER-2 positive breast cancer samples. Furthermore, we also observed that PD-L1 (programmed death-ligand 1), which was found to have high and low expression in MDA-MB-231 and 4T1, respectively, was suppressed in MDA-MB-231 and 4T1 TNBC cell lines by CCN5 recombinant protein treatment for 48 h. These findings might provide a novel immune checkpoint mechanistic explanation of CCN5 that mediates TNBC growth and progression suppression.

IMMUNOLOGY: Inflammation, Host Factors, and Epigenetic Influences on Cancer Development and Treatment
Poster Session

#1403 The role of Dclk1-expression cells in normal pancreas and in pancreatic tumor progression.
G. Valenti, P. Laise, **F. Wu**, H. Kobayashi, Q. T. Waterbury, R. Takahashi, T. Ruan, Z. Jiang, Y. Ochiai, L. B. Zamechek, T. C. Wang;
Columbia University Irving Medical Center, New York, NY

Background: Tuft cells, marked by Doublecortin-like kinase-1 (Dclk1), are rare in the healthy pancreas but increase markedly during pancreatic tumorigenesis. While Group 2 innate lymphoid cells (ILC2s) are known to modulate inflammation and immunity, their specific roles in cancer-related immunity and immunotherapy interactions with pancreatic tuft cells remain unknown.
Methods: To investigate tuft cells during early pancreatic neoplasia, we used a Dclk1 reporter mouse model and single-cell RNA-seq to study Dclk1-expressing cells in normal pancreas and neoplasia using Mist1/Kras mouse. We treated mice with IL-13 peptides and anti-IL-13 antibodies to explore the IL-13-ILC2 axis in tuft cell regulation.
Results: Within the normal pancreas, Dclk1 expression marked several specialized epithelial cell types, including tuft-like cells, neuroendocrine cells, and a small number of acinar progenitor cells. A notable increase in Dclk1-expressing cells was observed at the onset of early PanIN lesions, with a subsequent decline in advanced PanIN stages and PDAC. Using flow cytometric analysis, we observed an increase in ILC2 cells in the Mist1/Kras pancreas in response to IL33 produced by pancreatic cancer-associated fibroblasts (CAFs). Blocking ILC2 activation with anti-IL33 antibodies reduced Dclk1 cell hyperplasia during PanIN progression. Given the known association between tuft cells, ILC2 cells, and the IL13/IL4 signaling pathways in the intestine, we discovered that Dclk1-expressing cells highly expressed the IL4 receptor (IL4ra). IL-13 levels increased during PanIN progression, and we found that ILC2s comprised the primary source of IL-13 within pancreatic tumors. In vitro, studies showed that the presence of IL-13 maintained the expansion of Dclk1-expressing tuft-like cells in pancreatic organoids derived from Dclk1-DTR-ZsGreen mice. Correspondingly, the in vivo administration of anti-IL-13 resulted in reduced Dclk1 expression.
Conclusion: Previous studies have shown that pancreatic tuft cells inhibit pancreatic cancer progression. Our study reveals a novel regulatory mechanism wherein IL-13 secreted by ILC2s modulates Dclk1 tuft cell expression during pancreatic tumorigenesis. The IL13-ILC2 axis appears to be a potential therapeutic target to regulate Dclk1 cell activity, which could influence the course of pancreatic tumorigenesis. Future investigations will further explore the interaction between the IL13/ILC2 axis and Dclk1 in pancreatic cancer development.

#1404 Blood-based transcriptomics provides novel insights into Sjögren's syndrome-associated lymphomagenesis.

A. Gjyrezi[1], C. Skarlis[2], P. Zumbo[3], D. Betel[3], I. E. Stergiou[2], M. Voulgarelis[2], C. P. Mavragani[2], P. Giannakakou[4];
[1]Weill Cornell Medicine, New York, NY & National Kapodistrian University of Athens, Athens, Greece, [2]National and Kapodistrian University of Athens, Athens, Greece, [3]Weill Cornell Medicine, New York, NY, [4]Meyer Cancer Center, Weill Cornell Medicine, New York, NY

Sjögren's syndrome (SS) is a debilitating autoimmune disorder that carries the highest risk of progressing to lymphoma among all autoimmune diseases, with up to 10% of patients developing SS-associated lymphoma. However, the underlying mechanisms are unknown, and there are currently no actionable targets for prevention and therapeutic intervention.To elucidate the mechanisms associated with SS-lymphoma, we performed RNA-Seq in peripheral blood from SS patients without (n=11) or with lymphoma (n=8). Differential gene expression and pathway analysis identified TNF-α signaling via NF-κB, inflammatory response and interferon gamma (IFN-γ) response as the top pathways enriched in SS-lymphoma patients. Interestingly, the enriched IFN-γ response pathway is consistent with our published work identifying elevated IFN-γ transcript levels in salivary gland tissues from SS patients with lymphoma. Central to SS pathogenesis is the elevation of TNF-α signaling, triggering NF-κB pathway activation and subsequent inflammation, along with inflammasome activation, in line with prior observations. Our data reveal significant upregulation of these pathways in SS-lymphoma patients, which together with the inflammatory response and IFN-γ pathway enrichment, support the idea that persistent autoimmune-related chronic inflammation fosters a microenvironment conducive to lymphomagenesis.Next, we sought to assess the impact of SS immune landscape in SS-lymphoma by performing an immune modular analysis using an established framework of 97 whole blood transcriptomics modules (Pascual), derived from transcripts co-expressed in blood across various autoimmune conditions. This analysis revealed a significant downregulation of T-cell and enrichment of B-cell modules in SS-lymphoma compared to SS patients. These findings are consistent with our biopsy results, showing lower T cell counts in high-grade *vs*. low-grade SS patients. As patients with high-grade SS are more likely to develop SS-lymphoma, these data possibly suggest that suppressed T-cell responses are involved in lymphomagenesis. In addition, the significant enrichment in B-cell transcriptional modules mirrors the observed clinical increase in B cell counts during the transition to SS-lymphoma. Germline mutations in B-cells are thought to drive the clonal expansion of malignant B cells, which may contribute to the observed increase of B cell transcriptomes in SS patients developing lymphoma. We are currently investigating the gene mutation landscape in these datasets to better understand their contribution to SS-lymphomagenesis.This study provides preliminary evidence that chronic inflammation along with dysregulation of T and B compartments in SS significantly contributes to lymphoma progression, emphasizing the need for further research to uncover the molecular basis and develop early diagnostic/intervention tools.

#1405 Development of a humanized anti-IL-22 antibody for cancer and inflammation therapy.

J. Chen, C. Chang, G. Frey, H. Liu, J. Wang, W. J. Boyle, J. M. Short;
BioAtla, San Diego, CA

Interleukin-22 (IL-22) is an inflammatory cytokine involved in the pathology of autoimmune diseases such as psoriasis, atopic dermatitis, and ulcerative colitis. IL-22 has also been shown to promote epithelial cell proliferation, stemness and tumorigenesis in cancer, and is associated with a more aggressive phenotype in a variety of cancers including inflammatory colon cancer models. IL-22 plays a central role in this pathogenic process by driving activation of STAT3 and other signaling cascades. Recent studies demonstrated that neutralization of IL-22 reduced dysplasia and tumor development in preclinical models. However, there has not been a clear application for anti-IL-22 therapy for cancer and autoimmune diseases, likely due to identifying the right disease indication and their low potency and efficacy. Thus, there remains an opportunity to explore the potential of more potent anti-IL-22 therapeutics.

We have developed humanized anti-IL-22 antibodies with high affinities to human, cynomolgus and mouse IL-22 using BioAtla's proprietary antibody discovery and engineering platforms. *In vitro* data demonstrated that our anti-IL-22 antibodies inhibited IL-22-induced p-STAT3 activities. In addition, our antibodies showed a 10-fold increased binding activity to human IL-22 compared to Fezakinumab, which was previously developed by Pfizer for the treatment of autoimmune diseases. To test the functions of our antibodies *in vivo*, we established an inflammation-driven sporadic colitis-associated colorectal (CAC) cancer mouse model. Our humanized anti-IL-22 antibody, a potent, species cross-reactive anti-IL-22 blocking antibody, significantly reduced tumor progression in CAC model. These data suggest that targeting IL-22 reduces tumor occurrence by reducing inflammation-induced tumorigenesis. In addition, we evaluated our anti-IL22 antibodies in an imiquimod-induced psoriasiform skin inflammation mouse model. The mice treated with anti-IL22 antibodies had significantly reduced skin lesions compared to isotype antibody-treated mice. Q-PCR analysis of the mouse skin demonstrated that treatment with our anti-IL-22 antibody led to significantly decreased RNA levels of the imiquimod-induced inflammatory marker CXCL3. In conclusion, the development of a potent, species cross-reactive anti-IL-22 antibody using BioAtla's antibody discovery and engineering platforms addresses the past challenges of anti-IL-22 therapeutics and allows for translational studies in relevant animal efficacy and safety models.

#1406 Plk1 attenuates colon inflammation and tumorigenesis.

Xinyi Wang, Daheng He, Fengyi Mao, Yifan Kong, Chaohao Li, Sai Wu, Jia Peng, Chi Wang, Zhiguo Li, Xiaoqi Liu

University of Kentucky, Lexington, KY

Inflammation-associated colon cancer, linked with long-standing colon inflammation, is often seen in patients with inflammatory bowel diseases (IBD), such as Crohn's disease and ulcerative colitis. Typically, these patients are diagnosed at a younger age compared to those with sporadic colon cancer. Despite some advancements, the detailed molecular mechanisms driving cancer development in IBD remain unclear. Polo-like kinase 1 (Plk1), a serine/threonine kinase and cell cycle regulator, is recognized as an oncogene in various cancers. Intriguingly, higher Plk1 expression correlates with better survival rates in colon cancer patients. Besides, Plk1 also elevates in IBD cases, suggesting its significant role in both colitis and colon cancer. Our study explores Plk1's role in IBD-associated colon cancer using the azoxymethane (AOM)/dextran sulfate sodium (DSS) mouse model, revealing Plk1's suppressive impact on both colitis and related colon cancer.

#1407 Investigating the effect of an aged liver microenvironment on immune surveillance and predisposition to cancer.

A. Aabish Gandhi[1], F. A. Hoffmann[2], M. LaPorte II[3], A. Havas[1], A. Rajesh[1], A. Davis[1], M. G. Teneche[1], J. Proulx[1], S. Kaech[3], P. D. Adams[1];
[1]Sanford Burnham Prebys Medical Discovery Institute, La Jolla, CA, [2]Stanford University, Stanford, CA, [3]Salk Institute of Biological Studies, La Jolla, CA

The incidence of liver cancer is increasing and there is an urgent need for new therapies and preventative strategies. Age is a major risk factor for liver cancer, the reasons for which are not well defined. One of the hallmarks of aging is immune dysfunction which affects liver homeostasis potentially making it prone to cancer. To understand the role of immune dysfunction in aging liver, we analyzed immune cells from young and old livers. As is reported before, in aged livers we observed an increase in $CD101^{\pm}PD1^{\pm}CD8^{\pm}$ T cell population as well as an increase in an $IFN\gamma^{\pm}TNF\alpha^{\pm}$ population suggesting an increase in T cell response in an aging liver. We next sought to understand the cause of T cell exhaustion in aged livers. Cell cluster analysis of the young (4-month-old) and old (22 month old) livers by scRNA seq revealed a cell population unique to the aged livers, showing increased expression of immune checkpoint ligands as well as tumor-initiating cell markers. We validated this data by flow cytometry. We next functionally probed the immune environment of aged liver, by testing the effect of cognate antigen expression in young and old hepatocytes on adoptively transferred activated P14 $CD8^{\pm}$ T cells isolated from a young P14 mouse. Analysis of the *ex vivo* activated P14 $CD8^{\pm}$ T cells from young and old antigen-expressing livers by flow cytometry and scRNA sequencing revealed increased exhaustion and cytokine-deficiency in old mice as compared to the young mice. This study explores the age-associated alterations in the immune cells in the liver, aiming to alter liver-resident immune cells and their metabolic states in a way that promotes anti-tumor immunity in an aging liver.

#1408 Intrahepatic IgA complex induces polarization of cancer-associated fibroblasts to matrix phenotypes in the tumor microenvironment of HCC.

P. Sung;
Catholic University of Korea, Seoul, Korea, Republic of

Background and Aims: Cancer-associated fibroblasts (CAFs) are activated fibroblasts that play key roles in the tumor microenvironment (TME). Immunoglobulin A (IgA) contributes to inflammation and anti-tumor immunity dismantling in the human liver. We investigated the effects of the IgA complex on CAFs in the TME of hepatocellular carcinoma (HCC).
Approach and Results: CAF dynamics in HCC TME were analyzed via single-cell RNA sequencing of HCC samples. CAFs were isolated from 40 HCC samples. The isolated CAFs were treated with mock or serum-derived IgA dimers. Following treatment with the mock or serum IgA dimers in vitro, co-culture experiments were performed using CAF and $CD8^{\pm}$ T cells. Single-cell analysis showed that sub-cluster proportions in the CAF-fibroblast activation protein-α (FAP) matrix were significantly increased in patients with high serum IgA levels. We were performed flow cytometry on fresh surgical tissues and observed a significant increase in the mean fluorescence intensity (MFI) of FAP in the $CD68^{\pm}$ cells from patients with high serum IgA levels compared to those with low serum IgA levels ($p<0.001$). We validated that the transferrin receptor (CD71) is expressed in CAFs ($p<0.01$). IgA-treated CAFs exhibited higher programmed death-ligand 1 (PD-L1) expression levels than mock-treated CAFs ($p<0.05$). Co-culture with CAFs induced the attenuation of the cytotoxic function of activated $CD8^{\pm}$ T cell, and these cells co-cultured with IgA-treated CAFs exhibited increased expression levels of programmed death-1 (PD-1) compared to those co-cultured with mock-treated CAFs ($p<0.05$).
Conclusions: Intrahepatic IgA induces polarization of HCC CAFs into more malignant matrix phenotype and attenuates cytotoxic T cell function. Our study uncovers five dynamic CAF subpopulations within HCC tissues and highlights their potential roles in tumor progression and immune suppression.

#1409 The role of liver receptor homolog 1<LRH-1>in regulating breast cancer progression by modulating the immune response.

Y. Wang[1], B. Duong[1], N. Krawczynska[1], S. V. Bendre[1], C. P. Schane[1], E. Weisser[1], L. Kockaya[1], Y. Fei[1], A. Das Gupta[1], H. E. Vidana Gamage[1], A. T. Nelczyk[2], E. R. Nelson[1];

[1]University of Illinois at Urbana-Champaign, Urbana, IL, [2]Helixon US Inc, Champaign, IL

Breast cancer remains the second leading cause of cancer-related death among American women, with the majority of morality being associated with metastatic disease. At this stage, immunotherapy is only approved for a small subset of patients whose tumors are of the triple negative subtype <TNBC> that stain positive for PD-L1. However, the majority of these tumors prove refractory. Thus, it is imperative to develop novel therapeutic targets to improve the immune response in breast cancer. Since cholesterol metabolism is important for myeloid immune cell function, we launched studies to identify proteins involved in cholesterol homeostasis that are amenable to small molecule intervention. Liver Receptor Homolog 1 <LRH-1/NR5A2> is highly expressed in myeloid cells, particularly neutrophils. We have found that elevated LRH-1 expression in breast cancer patients is associated with increased overall and recurrence-free survival rate. Thus, we hypothesized that LRH-1 acts as an immune modulator in myeloid cells, with subsequent effects on breast cancer progression. We initiated a series of experiments to characterize the role of LRH-1 in important aspects of neutrophil function: migration, NETosis, phagocytosis and influence on T cells. Neutrophils and neutrophil NETosis has previously been implicated in breast cancer progression including reemergence from dormancy and metastatic recurrence. Interestingly, we found that LRH-1 inhibits neutrophil migration towards cancer cells, a finding that may have important implications regarding infiltration of immune-suppressive myeloid cells. Furthermore, neutrophils treated with an LRH-1 agonist demonstrated decreased NETosis, while an antagonist resulted in increased NETosis. On the other hand, LRH-1 agonist treatment strongly decreased the neutrophil phagocytotic ability, while treatment with an antagonist did not significantly impact this process. Finally, T cells had increased expansion when cocultured with neutrophils that had been previously treated with an LRH-1 agonist, and reduced proliferation in the presence of neutrophils pretreated with an LRH-1 antagonist or inverse agonist. This was especially apparent in CD4+ helper T cells and later divisions. Ongoing work is aimed at determining the pathological relevance of these findings.

Collectively, our data indicate that LRH-1 plays important roles in regulating different neutrophils functions, including migration, NETosis, phagocytosis, and T cell expansion. Overall, these findings suggest that LRH-1 in neutrophils regulates the immune response, and therefore can be a potential therapeutic target for cancer patients.

Funding: National Cancer Institute (ERN: R01CA234025) Department of Defense (ERN: BCRP Era of Hope Award)

#1410 An effect of Phenylalanine hydroxylase (PAH) deficiency on cancer development in kidney.

S. Kim[1], J. Park[1], J. Park[1], C. Kang[1], K. Moon[2], S. Han[3], Y. Koh[3], S.-S. Yoon[3];

[1]Seoul National University College of Medicine, Seoul, Korea, Republic of, [2]Seoul National University Hospita, Seoul, Korea, Republic of, [3]Seoul National University Hospital, Seoul, Korea, Republic of

Several studies have noted the importance of amino acid metabolism in cancer progression. Preliminary research using public cancer multi-omics data has revealed associations between heterozygous germline mutations in genes associated with amino acid metabolism and cancer development. In particular, the heterozygous status of the PAH gene enhances the risk of developing kidney cancer by more than three times. Phenylalanine hydroxylase (PAH) is an enzyme that converts phenylalanine to tyrosine. It is highly expressed in the liver and kidneys. Analysis of the blood metabolome in prospectively collected PAH heterozygous carriers indicates that heterozygous status causes metabolome fluctuations in the body. By the way, renal cell carcinoma (RCC) is an immunogenic tumor mainly infiltrated by T cells. Accordingly, we suggest that defects in the PAH gene change the metabolites in the body, leading to a reduction in immune function and an increased risk of developing kidney cancer. First, the expression of the PAH protein was confirmed through immunohistochemistry in a tissue microarray from RCC patients, and the results were then compared with clinical information. Next, we simulated the environment of PAH deficiency in vitro by treating the cells with phenylalanine (Phe) and its metabolite, phenylpyruvate (PRA), which accumulates during PAH dysfunction. The cytotoxicity of Phe and PPA was investigated using the WST assay. The Jurkat T cell line was cultured long-term in a medium containing Phe or PPA and then stimulated with PHA/PMA. Cytokine secretion was confirmed in these supernatants. In addition, purified primary human pan T cells were stimulated with Anti-CD3/CD28 in the medium containing either Phe or PPA. Proliferation was evaluated using CFSE staining. The IHC was performed on 467 tissues from RCC patients aged 29 to 101 years. We classified the cases into three scale scores based on the percentage of PAH intensity. Approximately 73% of cases were PAH-negative, and only 27% were positive (score 1+ or 2+). A comparison of IHC results with clinical information showed that lower PAH expression was associated with a lower relapse-free survival rate. Next, Phe and PPA exhibited minimal cytotoxicity. The secretion of representative proinflammatory cytokines IL-2 and TNF- α were dose-dependent and significantly decreased with Phe and PPA treatment. Additionally, cell proliferation, a critical step in acquiring effector functions of T cells, was inhibited by treatment with Phe and PPA, particularly in the CD8+ T cell population compared to CD4+ T cells. These results suggest that metabolite changes within the tissue microenvironment of the kidney, caused by Pah defects, may suppress anti-tumor immunity by impairing the function of immune cells. This novel discovery may contribute to the importance of the PAH gene as a new biomarker for diagnosing kidney cancer and to the development of kidney cancer therapy.

#1411 Cell-type-specific transcriptomic immune aging clocks reveal clinically relevant associations with chronic illnesses including cancer.

Y. Gurevich-Schmidt[1], **K. Wang**[1], D. Wu[1], S. Madan[1], V. Gopalan[1], S. Sinha[2], B. Wang[1], S. Dhruba[1], A. A. Schaffer[1], E. Ruppin[1];
[1]NIH-NCI, Bethesda, MD, [2]NCI-Designated Cancer Center Sanford Burnham Prebys Medical Discovery Institute, San Diego, CA

The aging of the immune system has profound implications for individual immune responses, yet precise quantification of immune age remains a challenge. Analyzing single-cell peripheral blood mononuclear cells (PBMC) transcriptomics data from 981 healthy individuals, we developed IMMClock (IMMune Clock), a human immune age clock derived from single cell transcriptomics. IMMClock is the first to accurately assess the age of three major immune cell types, CD8+ T cells, CD4+ T cells and NK cells, at the individual level. Testing the ability of these clocks to capture the dynamic aging process, we show that they reliably predict individuals' chronological ages across seven publicly available single-cell transcriptomics datasets and the large Framingham bulk transcriptomics cohort. IMMClock identifies cell type specific age-related pathways including apoptosis, interferon gamma response, and cytokine response. The application of IMMClock reveals several associations between immune aging of different cell-types and key clinical phenotypes during aging: it recapitulates the established observation of higher immune age in males compared to females and uncovers higher immune age in CD8+ T cells of smokers and individuals with chronic illnesses including cancer. Analyzing cancer patients' data, IMMClock readings strongly correlate with CD8+ T cell exhaustion levels, and, quite strikingly, highlights an elevated immune age in the tumor microenvironment compared to blood.

#1412 Immune and metabolic control of Th17 cells by TMEM176B: Potential implication in cancer immunotherapy.

S. Russo, M. Malcuori, M. Segovia, M. Hill;
University of the Republic, Faculty of Medicine, Montevideo, Uruguay

Helper $CD4^{+}$ T cells are key players in the adaptive immune response that differentiate into different subpopulations. One of these subpopulations are T helper 17 (Th17) cells. In cancer, the role of Th17 cells is still controversial. The dual effect that Th17 cells seem to have in cancer can be explained by the great heterogeneity and/or plasticity of these cells. Two different subpopulations of Th17 cells have been reported: regulatory or “non-pathogenic” Th17 cells and effector or “pathogenic” Th17 cells. We currently know that this dual behavior depends on the cytokine microenvironment in which Th17 cells differentiate. However, the molecular basis of how, when, and why Th17 cells differentiate into effector or regulatory populations, as well as its *in vivo* relevance, are still poorly understood. Here we show that intrinsic expression of TMEM176B can determine the fate of Th17 cells. TMEM176b is a druggable immunoregulatory ion channel which function was first described by our team. We have found that in *in vitro* differentiated Th17 cells, *Tmem176b* is over-expressed in regulatory Th17 cells compared to effector Th17 cells, in agreement with its immunoregulatory properties. Furthermore, we found that *Tmem176b* influence Th17 polarity, since Th17 *in vitro* differentiation with IL-6+TGF-β from naïve *Tmem176b*$^{-/-}$ $CD4^{+}$ T cells results in an enhanced IFN-γ production. Same results were obtained by pharmacological inhibition of TMEM176B in WT $CD4^{+}$ T cells. Functional evaluation of these cells showed a decreased regulatory capacity compared to WT Th17 cells. Thus, WT Th17 cells inhibited $CD8^{+}$ T cell proliferation whereas *Tmem176b*$^{-/-}$ Th17 cells showed poor inhibitory capacity. Supporting this effector-like phenotype, *Tmem176b*$^{-/-}$ Th17 cells have higher basal pAKT/AKT ratio compared to WT Th17 cells. Furthermore, *Tmem176b*$^{-/-}$ Th17 cells have a better metabolic fitness than WT Th17 cells, with higher glycolysis and oxidative phosphorylation. It was reported that the effector role of Th17 cells is dependent on the IL-1β production through ASC-NLRP3-caspase 8 activation. Here we show that *Tmem176b*$^{-/-}$ Th17 cells stimulated with ATP have a higher Caspase-8 activation compared to WT Th17 cells. All these results suggest that *Tmem176b* deficiency leads to an effector-like Th17 cell phenotype when cells are differentiated in a regulatory cytokine microenvironment. Moreover, co-culture of *Tmem176b*$^{-/-}$ Th17 cells with *in vitro* generated exhausted $CD8^{+}$ T cells results in a reduction of the frequency of terminal exhausted $CD8^{+}$ T cells and of mitochondrial reactive oxygen species production compared to co-culture with WT Th17 cells. Therefore, *Tmem176b*$^{-/-}$ Th17 may have enhanced anti-tumor properties compared to WT Th17 cells. In conclusion, we have identified a new intrinsic regulator of Th17 cells, TMEM176B, which may constitute a molecular target to pharmacologically modulate these cells.

#1413 BRCA1 loss is synthetic lethal with double stranded RNA: A genome wide CRISPR screen to identify mechanisms of RNASEL independent death.

D. Trastulli, G. Vozza, V. Pinamonti, **L. Mazzarella**;
IEO - European Institute of Oncology, Milan, Italy

Double-stranded RNAs (dsRNAs) are potent immunostimulatory nucleic acids of viral origin but also physiologically produced by mammalian cells. Recent studies demonstrated that elevating dsRNA levels, either exogenously through dsRNA mimetics like Polyinosinic-polycytidylic acid (pI:C) or endogenously through epigenetic modulation of retroviral elements, can elicit anticancer effects. In response to dsRNA, cells elicit a dual response consisting in Interferon (IFN) production and translational shutdown associated, in some cells, with cell death. These two responses are linked in a feed-forward loop in which induced cytokines themselves enhance dsRNA sensing by the death-inducing pathway, complicating our understanding of the cell-intrinsic mechanisms at play. The 2,5-oligoadenylate synthetase (OAS)-RNASEL system is widely thought to be the main responsible for dsRNA-induced cell death, but it remains unclear how its activity leads to cell death.To elucidate these mechanisms, we decided to minimize the impact of interferon modulation by studying dsRNA-induced death in interferon-saturated conditions. RNASEL-KO A549 cells were, as expected, refractory to IFN+pI:C induced cell death; however, inhibiting protein synthesis or RNA transcription with Cycloheximide (CHX) or Actinomycin D (ActD) abolished the need for RNASEL causing RNASEL-KO cells to undergo apoptosis, although CHX/ActD alone had no effect. In addition, HT-29 cells revealed no clear dependence on RNASEL for dsRNA-induced cell death. Transient ablation through siRNA showed that this novel death-inducing pathway is independent of other canonical dsRNA sensors such as RIG-I, MDA5 and PKR. We then performed a genome-wide CRISPR screen for factors involved in dsRNA-induced death in our interferon-saturated conditions in HT29 cells. Pathway enrichment analysis of screen hits revealed that RNA surveillance, RNA Polymerase II Transcription Initiation, Mitochondrial translation and respiratory chain and DNA Repair genes have a protective role against dsRNA increase. In particular, we validated the synthetic lethality of IFN+pI:C with BRCA1 by CRISPR. Ongoing research is aimed at validating this interaction in vivo models.Our work shed light on potential new mechanisms involved in dsRNA dependent cell death, revealing a connection with DNA damage and BRCA1. If confirmed, these findings may pave the way for the use of dsRNA mimetics, possibly in conjunction with immune checkpoint inhibitors, in the treatment of BRCA1-mutated tumors.

#1414 HBM9014, a first-in-class fully human anti-LIFR antibody with excellent preclinical efficacy and safety profile.

Jue Zeng[1], Dongxu Zhang[2], Louis Liu[1], **Lingbing Zhang**[2]

[1]Harbour BioMed, Natick, MA,[2]Yinuoke, Ltd., Nanchang, China

Background: Leukemia inhibitory factor (LIF) and cardiotrophin like cytokine factor 1 (CLCF1) are multi-functional cytokines from IL-6 family. They are reported to be highly expressed in a variety of human cancers such as pancreatic carcinoma, cholangiocarcinoma, NSCLC, GBM, head and neck cancer etc. Their expression is associated with poor prognosis and survival. LIFR is the key component of LIF/CLCF1 receptors. Antibody targeting LIFR has the advantage to block both LIF and CLCF1 pathways thus inhibiting tumor growth more effectively than products to block single cytokines.
Methods: Fully human Anti-LIFR antibodies were generated from H2L2 Harbour Mice® transgenic platform. *In vitro* function of the antibodies was tested for their abilities to block LIF/CLCF1 induced downstream signaling pathway and tumor spheroid proliferation. *In vivo* efficacy was tested in multiple tumor models as monotherapy and in combination with cisplatin. DRF toxicokinetics was evaluated on NHP with a 4-week repeat-dose toxicity study.
Results: HBM9014, a fully human anti-LIFR antibody generated by H2L2 Harbour Mice®, specifically binds LIFR thus blocks the interaction between LIF/CLCF1 and their respective receptors, inhibits downstream STAT3 phosphorylation, and reduces exogenous and endogenous LIF induced tumor spheroid proliferation in vitro. Furthermore, HBM9014 shows potent anti-tumor activity in multiple tumor models in vivo. In a GLP NHP 4-week repeat-dose toxicity study, HBM9014 is well tolerated up to 150 mg/kg with no discernable drug-related toxicity.
Conclusions: HBM9014 specifically binds to the key component of LIF and CLCF1 receptor, LIFR, thus blocks both LIF and CLCF1 signaling pathways. HBM9014 shows significant cell proliferation inhibition alone or in combo with small molecule inhibitors in 3D culture of multiple cancer cell lines. It also shows significant in vivo antitumor efficacy as monotherapy, and enhanced efficacy in combination with Cisplatin in multiple mouse models. Importantly, despite the benefits of double blocking, HMB9014 has an excellent safety profile. Taken together, HMB9014 is a promising drug candidate for advanced cancer with favorable efficacy and safety profiles that warrant clinical validation.

#1415 Reduction in photoimmunotherapy-induced edema with COX-2 inhibition: Combatting clinically relevant adverse events without compromising efficacy.

G. Ma, M. Gordon, J. Lapetoda, A. Lozano, C. M. Amantea, T. Osada, A. H. Thorne;
Rakuten Medical, San Diego, CA

ASP-1929 photoimmunotherapy (PIT), an investigational drug-device combination, consists of an epithelial growth factor receptor (EGFR)-targeting drug, cetuximab, conjugated to a light-activatable dye, IRDye® 700DX, and a laser light. Localized illumination results in rapid and selective tumor necrosis in the preclinical setting, and early clinical studies demonstrate a manageable safety profile in patients with head and neck squamous cell carcinoma. In the ongoing clinical trials, however, edema is a commonly reported adverse event and laryngeal edema, requiring prophylactic tracheostomy, has been noted in some patients. Thus, a critical need exists to provide clinicians with tools to manage ASP-1929 PIT-associated edema to ensure optimal patient outcome. To evaluate edema following cancer-targeted PIT, we developed a mouse tumor model and used it to characterize the mechanism of edema development and evaluate various methods for edema reduction. Briefly, cohorts of mice bearing syngeneic LL/2 tumors engineered to express Ephrin A2 (EphA2) were administered an anti-EphA2 antibody conjugated to IR700 (conjugate) or saline control. Light was applied 24h following administration and edema was measured by caliper. In control mice, light alone did not generate edema; however, mice treated with conjugate plus light showed a light-dose dependent increase in edema volume which peaked at 6h post light delivery. We next evaluated a series of inflammatory cytokines and immune cell populations in the blood and tumor region at the onset (2h), peak (6h), and resolution (24h) of PIT-induced edema. We found a striking increase in neutrophils (500-fold greater than control mice, n=10, $p<0.0001$) in the blood at the peak of edema formation coinciding with a significant increase in IL-6 (n=5, $p<0.001$) and IL-10 (n=5, $p<0.05$), indicating the onset of a heightened inflammatory response. To combat the edema formation, we next evaluated the effect of various anti-inflammatory drugs commonly used in the clinical setting. Cohorts of mice were administered conjugate plus light in the presence or absence of steroids or the selective COX-2 inhibitor meloxicam. Results show there is no reduction in edema by steroids regardless of timing of administration. Conversely, the addition of meloxicam resulted in a significant reduction in edema at all time points and light doses evaluated: 40-50% reduction at both 2h and 6h post-PIT when administered prophylactically and 25% reduction at 6h post-PIT when administered post-light (all settings, n=10, $p<0.0001$). Importantly, we found the reduction in edema with meloxicam was not associated with a loss of therapeutic benefit based on measurement of tumor growth. In conclusion, the use of COX-2 inhibitors may be directly translated to the clinic for the benefit of patients receiving ASP-1929 PIT and should undergo further evaluation.

#1416 Resolvins enhance immunotherapy to induce Fanconi anemia tumor regression via inflammation resolution.

K. Quinlivan[1], H. Yang[2], D. R. Bielenberg[3], S. I. Wells[4], C. N. Serhan[5], D. Panigrahy[1];

[1]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, [2]College of Food Science and Nutritional Engineering, China Agricultural University, Beijing, China, [3]Boston Children's Hospital, Harvard Medical School, Boston, MA, [4]Cancer and Blood Diseases Institute, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [5]Brigham and Women's Hospital, Harvard Medical School, Boston, MA

Fanconi anemia (FA) is a disorder characterized by early-onset solid tumors unresponsive to chemotherapy and radiation. Unresolved inflammation is a hallmark of FA, the mechanisms underlying the initiation and resolution of inflammation in FA are poorly characterized. We hypothesized that FA tumor progression is controlled by dysregulated resolution metabolomes and a systemic pro-inflammatory eicosanoid storm of inflammation-initiating mediators. Using a novel transplantable murine FA tumor model, we show that Fancc-/- HNSCC (head and neck squamous cell carcinoma) progression disrupts the resolution of inflammation via an imbalance between specialized pro-resolving lipid mediators (SPMs) and eicosanoids. Fancc-/- tumor-bearing mice exhibited an increase in eicosanoids, including leukotriene B_4 (LTB_4) and thromboxane B_2 (TXB_2) in the spleen and a 113% increase in prostaglandin E metabolite (PGEM), a marker of PGE_2 production, in the plasma compared to non-tumor-bearing (NT) mice. Fancc-/- tumor-bearing mice exhibited a loss in the SPM/LTB_4 ratio including RvD1/LTB_4, RvD2/LTB_4, and MaR1/LTB_4, compared to NT mice. Given the activity of immune checkpoint blockade in mismatch repair deficient tumors including head and neck cancers, immunotherapy may be relevant to FA-induced cancers. Importantly, the number of absolute T cells and CD4+ T cell function is preserved in individuals with FA. We combined stimulation of the resolution of inflammation (i.e., treatment with RvDs) with immunotherapy in a new transplantable murine FA tumor model. While treatment with RvD4, RvD5, or anti-PD1 immunotherapy alone delayed tumor growth compared to control at treatment day 20, the tumors did escape monotherapy by treatment day 30. Remarkably, RvD4 or RvD5 combined with anti-PD1 immunotherapy induced sustained Fancc-/- tumor regression. Moreover, RvD4 and/or anti-PD1 immunotherapy inhibited orthotopic Fancc-/- tumor growth compared to control. Resolvins and immune checkpoint blockade synergistically induced *Fancc-/-* tumor regression via macrophage phagocytosis of apoptotic debris, counter-regulation of pro-angiogenic cytokines, and inhibition of angiogenesis. Triggering Receptor Expressed on Myeloid cells-2 (TREM2)-antagonism combined with resolvins and immunotherapy restored SPM/eicosanoid ratios in *Fancc*$^{-/-}$ tumor-bearing mice to pre-cancer levels. SPMs and eicosanoids provide potential early biomarkers and biological targets in FA-induced cancer progression. Stimulating the resolution of inflammation via pro-resolution lipid mediators to enhance immunotherapy is a novel host-centric therapeutic approach to prevent FA-induced cancer progression via debris clearance and cytokine suppression. These results provide evidence for targeting the resolution of inflammation via resolvins to enhance immunotherapy to prevent and/or reverse FA-induced cancer progression.

#1417 IRF8 driven reprogramming of the immune microenvironment enhances anti-tumor adaptive immunity and reduces immunosuppression in murine glioblastoma.

Megan Montoya, Sara A. Collins, Pavlina Chuntova, Noriyuki Kasahara, Hideho Okada

Neurological Surgery, UCSF - University of California San Francisco, San Francisco, CA

Glioblastoma (GBM) has an extremely immunosuppressive microenvironment, primarily mediated by the recruitment of immature myeloid cells (IMCs) to the tumor. IMCs suppress T cell function and dampen the anti-tumor response. In this study, we sought to “reprogram” IMCs into antigen-presenting cells (APCs) to enhance anti-tumor T cell responses. To induce IMC differentiation into APCs, we utilized a retroviral replicating vector (RRV) expressing IRF8, a master regulator of type 1 conventional dendritic cell (cDC1) development. We evaluated the impact of IRF8 RRV on *in vivo* tumor growth kinetics, survival, immunosuppression, and immune microenvironment. Because RRV transduction requires the proliferation of target cells, we assessed the proliferative capacity of myeloid cells in murine and human GBM samples. We utilized the SB28 cell line, a poorly immunogenic murine GBM model. We pre-transduced SB28 cells with IRF8 RRV and implanted them intracranially into syngeneic C57BL/6 mice; controls expressed an empty vector. Intratumoral myeloid cells were proliferative in both murine and human samples. In vivo, tumor and myeloid cells are infected proportionately to their respective levels of proliferation. Mice with IRF8 RRV pre-transduced intracranial tumors had significantly longer survival (median 28 days) compared to controls (median 19 days) ($p < 0.0001$). Additionally, tumor growth was delayed in IRF8 RRV mice. IRF8 RRV mice had significant enrichment of dendritic cells ($p = 0.0145$), cDC1s ($p < 0.0001$), T cells ($p = 0.0025$) and CD8+ T cells ($p < 0.0001$). Both monocytic and granulocytic IMCs had decreased expression of the immunosuppressive markers Arginase 1 and IDO1. Further, *ex vivo* co-culture of intra-tumoral myeloid cells with naïve T cells showed a functional decrease in immunosuppression in IRF8 RRV tumors compared to controls ($p < 0.0001$).

To study the mechanism of action, we assessed whether IRF8 transduction of tumor cells alone or both tumor and immune cells, was necessary for the observed survival benefit. To inhibit RRV spread from infected cells to other cells, we treated mice with azidothymidine, a reverse transcription inhibitor. A robust survival benefit and tumor growth inhibition were seen only in mice where the RRV could spread freely ($p = 0.0005$). This finding shows that both tumor and immune cells must be infected to cause the phenotype and suggests that reprogramming immune cells is required for therapeutic efficacy.

Our novel approach used RRV to deliver a myeloid transcriptional regulator in intracerebral GBM. This therapy achieved significant survival benefits and increased intratumoral cytotoxic T cells and APCs, while decreasing myeloid immunosuppression. Further studies will expand upon the mechanism of action and test combination therapies.

#1418 Priming of the glioblastoma tumour microenvironment via copper chelation to enhance the efficacy of immunotherapies.

Tyler Shai-Hee[1], Toni Rose Jue[2], Riccardo Cazzoli[2], Jourdin R. C. Rouaen[2], Filip Michniewicz[3], Jessica Bell[2], Tessa Gargett[4], Michael P. Brown[4], Orazio Vittorio[1]

[1]School of Clinical Medicine, Faculty of Medicine & Health, UNSW Sydney, Kensington, Australia,[2]Children's Cancer Institute, Lowy Cancer Research Centre, UNSW, Kensington, Australia,[3]School of Biomedical Sciences, Faculty of Medicine & Health, UNSW Sydney, Kensington, Australia,[4]Translational Oncology Laboratory, Centre for Cancer Biology, SA Pathology and University of South Australia, Adelaide, Australia

Glioblastoma, a highly aggressive brain tumor with a dismal prognosis necessitates novel therapeutic approaches as current standard treatments yield limited success. Despite the transformative impact of immune checkpoint blockade in various malignancies, its efficacy in glioblastoma remains elusive. Similarly, chimeric antigen receptor T (CAR-T) cell therapy, while successful in hematological malignancies, faces challenges in solid tumors. This study addresses the immunosuppressive barriers hindering the effectiveness of immunotherapies in glioblastoma. Highlighting copper's pivotal role in glioblastoma, our research group demonstrated its elevation and influence on PD-L1 expression. Given the success of copper chelators in treating Wilson's Disease, in which neurological manifestations are alleviated following treatment, we hypothesized that copper chelation therapy could be a promising strategy for glioblastoma, especially when combined with immunotherapies. Flow cytometry analysis revealed a significant increase in the tumor-associated antigen GD2 following treatment with the copper chelator trientine (TETA), suggesting its potential synergy with GD2-targeted immunotherapies. In an immunocompetent murine glioblastoma model, combination therapy with GD2-targeted CAR-T cells and TETA effectively slowed tumor growth, demonstrating enhanced efficacy. Additionally, TETA as a monotherapy significantly improved survival compared to the control. The combination of TETA with anti-PD1 antibody therapy also exhibited promising results in inhibiting tumor growth and subsequently prolonging survival, with some mice demonstrating complete tumor regression. Importantly, TETA decreased copper levels in the brains of the mice, indicating the drug can act on the brain, a crucial therapeutic hurdle that is hampering the efficacy of novel therapies in glioblastoma. Further exploration of immune cell populations using OPAL Multiplex immunohistochemistry following TETA, anti-PD1, and GD2-targeted CAR-T cell treatments will underscore the potential of copper chelation in reshaping the tumor microenvironment. Our findings suggest that copper chelation, with agents like TETA, can be repurposed as a viable anticancer therapy when combined with immunotherapies. This study provides a compelling rationale for further pre-clinical validation, offering a potential breakthrough in the quest for effective glioblastoma treatments.

#1419 Locoregional delivery with engineered stem cells modulates immunosuppressive tumor microenvironment in brain leptomeningeal metastasis.

N. Kanaya[1], W. Seddiq[2], K.-S. Chen[2], Y. Kajiwara[2], L. Moreno Lama[2], S. Kuroda[1], T. Fujiwara[1], H. Wakimoto[3], K. Shah[2];
[1]Okayama University Graduate School of Medicine, Dentistry, and Pharmaceutical Sciences, Okayama, Japan, [2]Harvard Medical School/Brigham and Women's Hospital, Boston, MA, [3]Harvard Medical School/Massachusetts General Hospital, Boston, MA

Leptomeningeal metastasis (LM) is one of the severe disease conditions in brain metastasis (BM) and results in poor prognosis and reduction of quality of life. Immunotherapies such as anti-Programmed cell Death (PD)-1 antibodies have shown improved overall survival against non-small cell lung cancer (NSCLC).. However, the clinical benefit of patients with NSCLC derived LM is still limited due to poor penetration of therapeutic agents into the brain and cerebrospinal fluid (CSF) and lack of understanding of the tumor microenvironment in LM. In this study, we first developed immune-competent mouse models of LM which show significantly decreased immune cells and increased PD-1+ T cells in the tumor microenvironment as compared to primary NSCLC tumors, thus mimicking primary and LM NSCL in patients. Next, we explored the use of oncolytic herpes simplex virus (oHSV) that selectively replicate in tumor cells and illicit an antitumor effect via oncolysis and production of neoantigens for targeting LM NSCLC. Given that virus neutralization, and inefficient extravasation are the major barriers to the effective systemic delivery of oHSV to target metastatic tumor lesions in the brain, we utilized mesenchymal stem cells (SC) and created two population of mesenchymal SC types: one for loading oncolytic herpes simplex virus (oHSV) and another one, engineered with knockout of Nectin-1 receptor by CRISPR/Cas9 technique to be resistant to oHSV, for secreting single-chain variable fragment (scFv) anti-PD-1. We show that locoregional treatment improved therapeutic outcomes by inducing oHSV-mediated immunogenic cell death, and activation of anti-tumor T cell signaling in mouse NSCLC LM tumors. Our novel SCs based immunotherapeutic strategy provides a roadmap towards treatment of lung to brain leptomeningeal metastatic patients.

#1420 Mechanism of NPRL2 gene therapy induced antitumor immunity in KRAS/STK11^{mt} aPD1 resistant metastatic NSCLC.

I. M. Meraz, M. Majidi, R. Song, F. Meng, L. Gao, Q. Wang, J. Wang, E. Shpall, J. A. Roth;
UT MD Anderson Cancer Center, Houston, TX

NPRL2/TUSC4 is a tumor suppressor gene whose expression is reduced in many cancers including NSCLC. Restoration of NPRL2 induces cell cycle arrest and apoptosis. We investigated the antitumor immune responses to NPRL2 gene therapy in aPD1 resistant KRAS/STK11^{mt} NSCLC in a humanized mouse model. Humanized mice were generated by transplanting human cord blood-derived CD34 stem cells into NSG mice. Mice harboring > 25% human CD45 cells were considered humanized. Lung metastases were developed in humanized mice by injecting KRAS/STK11^{mt}/aPD1^{R} A549 cells, which were treated with i.v. injection of NPRL2 nanoparticles (DOTAP-NPRL2) with or without pembrolizumab (aPD1). NPRL2 treatment reduced lung metastases, whereas pembrolizumab was ineffective. The antitumor effect was greater in humanized than non-humanized mice suggesting the role of immune cells. The antitumor effect was associated with increased infiltration of human cytotoxic immune cells and decreased numbers of Treg in tumors. NPRL2+ pembrolizumab was not synergistic in this resistant model but was synergistic in KRAS^{wt}/aPD1^{S} H1299 tumors. Cytotoxic immune cells in tumors were associated with the antitumor effect. Consistent with A549, NPRL2 showed a significantly strong antitumor effect on other KRAS^{mt}/aPD1^{R} syngeneic LLC2 tumors whereas aPD1 was not effective. The antitumor effect of NPRL2 was correlated with HLA-DR$^{\pm}$ DC, CD11c DC, TILs and NK cells in TME. The antitumor effect of NPRL2 was abolished upon in-vivo depletion of CD4, CD8 T, and MΦ in the LLC2 tumor model. However, no effect was found on in-vivo depletion of NK cells. Nanostring analysis on lung metastasis resulted in a distinct pattern of human gene expression by NPRL2. T cell functional genes, including IFNγ, CD8b, CD7, TNFSF18, ITGA1, GATA3 and TBX21 were significantly increased. Conversely, the negative regulatory genes, including FOXP3, TGFB1, TGFB2, and IL-10RA were inhibited. NPRL2 also downregulated T cell co-inhibitory molecules, including CTLA4, ICOS, LAG3, PDCD1, CD274, IDO1, PDCD1LG2, CD47, and KLRB1. Stably expressing NPRL2 clones were established, and tumors in humanized mice with these clones exhibited significantly slower growth compared to controls. TME analysis showed an upregulation of human CD45, CD3, CD8 T, HLA-DR+ DC and a downregulation of Tregs, CD3$^{\pm}$PD1$^{\pm}$T, MDSC, and CD163$^{\pm}$ TAM in tumors expressing NPRL2. The stable cells showed a substantial increase in both colony formation inhibition and apoptosis. Stable clones showed heightened sensitivity to carboplatin in colony formation, apoptosis, and PARP cleavage assays. Stable expression of NPRL2 resulted in the downregulation of both AKT-mTOR and MAPK pathways by inhibition of pAKT, pmTOR, pPRAS40, p4E-BP1, pS6, and pERK1/2. Taken together, NPRL2 gene therapy induces antitumor activity on KRAS/STK11^{mt}/aPD1^{R} tumors through DC-mediated antigen presentation and cytotoxic immune cell activation

#1421 The HDAC6-specific inhibitor AVS100 (SS208) blocks M2 polarization of tumor associated macrophages and potentiates immunotherapy in preclinical tumor models.

D. Kovalovsky[1], S. Noonepalle[2], M. Suresh[2], D. Kumar[1], M. Berrigan[3], A. Horvath[3], A. Kim[3], D. Quiceno-Torres[2], K. Musunuri[1], A. Villagra[2];
[1]Avstera Therapeutics Corp., Malvern, PA, [2]Georgetown University, Washington, DC, [3]The George Washington University, Washington, DC

Inhibition of HDAC6 was associated with an increased proinflammatory tumor microenvironment and an antitumoral response. Here, we show that a highly specific HDAC6 inhibitor AVS100 (SS208), blocks M2 polarization in murine and human macrophages while partially affecting M1 polarization. AVS100 effects were observed as blocked upregulation of M2-related gene signature under M2 polarizing conditions and blocked generation of $CD206^{\pm}$ and $Arg1^{\pm}$ macrophages. Oral administration of AVS100 had an antitumoral effect in SM1 melanoma and CT26 colon cancer models and increased the efficacy of anti-PD1 treatment, leading to complete remission in melanoma and increased response in colon cancer. Flow cytometry and scRNAseq analysis of tumor-infiltrating immune cells revealed an increase of proinflammatory/anti-inflammatory ratio in tumor-associated macrophages as well as an increase of intratumoral CD8 effector T-cells after AVS100 treatment. Interestingly, cured mice didn't relapse and became resistant to a subsequent tumor challenge, suggesting acquired antitumoral T-cell immunity. T-cell repertoire analysis of effector/memory T-cells in cured mice revealed a higher number of immunodominant T-cell clones after AVS100 treatment, indicating increased T-cell expansion. Finally, AVS100 has demonstrated no mutagenicity and a strong safety profile in rats and dogs, leading to its recent U.S. FDA clearance of an Investigational New Drug (IND) application and planned initiation of Phase Ia/b clinical trials targeting locally advanced or metastatic solid tumors in the first half of 2024. Altogether, we have performed the preclinical characterization of a novel small molecule inhibitor targeting HDAC6 for solid cancers. AVS100 had an antitumoral effect as single agent and improved the efficacy of immune checkpoint inhibition by blocking the immunoregulatory tumor microenvironment and increasing T-cell immunity.

#1422 A novel gut microbiota therapeutic approach for enhancing immune checkpoint inhibitor therapy.

P. Del Valle, G. Nguyen, Y. Choi, P. Sabaeifard, W. Li, J. Lichterman, L. Coughlin, N. Poulides, A. Sanjuan, A. Y. Koh;
UT Southwestern Medical Center, Dallas, TX

Immune checkpoint inhibitor therapy (ICT) has revolutionized cancer care, but up to 50% of patients do not respond to ICT. A host factor implicated in variable ICT response is the gut microbiome: a) germfree/antibiotic-treated mice do not respond to ICT; b) human ICT responders have distinct gut microbiome signatures compared to non-responders; and c) fecal microbiota transplants are safe and potentially effective in cancer patients previously unresponsive to ICT. We have previously established that ICT induces translocation of gut microbiota into secondary lymphoid tissues (particularly the mesenteric lymph nodes) and tumor which is required to enhance extraintestinal anti-tumor immunity (PMID: 36867675). Here, we have developed a novel gut microbiota therapy (GMT) which circumvents the challenges and limitations of conventional microbiome therapies that use live microbes. GMT utilizes specific components derived from commensal gut microbiota identified in our published clinical study (PMID:28923537) that can be administered parenterally (subcutaneous/intravenous) to safely and reproducibly enhance ICT efficacy in multiple preclinical cancer models (B16-F10 with anti-PD-1 and/or CTLA-4, MC38 with or without anti-PD-1, humanized mouse with human melanoma and human anti-PD-1). GMT acts by agonizing the pattern recognition receptors hTLR1/2/6, hNOD2 and hSTING. GMT induces anti-tumor cytokines (IL-12) but does not significantly increase sepsis associated cytokines (IL-6, TNFa) in both human immune cells and in non-human primates. Mechanistically, GMT acts via dendritic cells, and potentially through increased expression of delta-like ligand protein 4 (DLL4), a Notch signaling ligand that activates Notch 1/4 in T cells and promotes Th1 and Th17 differentiation. Current efforts to identify the active components of GMT are underway in which we have used serial liquid-liquid extractions (ethyl acetate followed by water:methanol:chloroform) and subsequent reverse phase chromatography to identify the most active fractions and identification of the bacterial components/constituents within these fractions. Together, these results demonstrate that GMT has the potential to serve as an innate immune adjuvant (akin to vaccine adjuvants) that enhances the effect of immunotherapy for possibly many cancer types.

#1423 Harnessing the gut microbiome to modulate immune checkpoint blockade response in triple-negative breast cancer.

Kenysha YJ. Clear[1], Adam S. Wilson[1], Elizabeth R. Stirling[1], Yu-Ting Tsai[2], Valerie Payne[1], David R. Soto-Pantoja[2], Katherine L. Cook[2]

[1]Department of Surgery, Wake Forest University School of Medicine, Winston-Salem, NC,[2]Department of Cancer Biology, Wake Forest University School of Medicine, Winston-Salem, NC

Triple-negative breast cancer (TNBC) is one of the most aggressive subtypes of breast cancer. The discovery that this subtype has the highest levels of tumor-infiltrating immune cells and programmed death ligand 1 (PD-L1) expression in the tumor microenvironment (TME) has propelled the use of anti-PD-1 immune checkpoint blockade (ICB) therapy, in combination with chemotherapy, as a treatment for TNBC patients. This has advantageously impacted TNBC patient outcomes such as survival, yet there remains a need to improve patient response to ICB therapies. The gut microbiome, in particular, increased abundance of *Akkermansia muciniphila* was associated with ICB therapy response in other cancer types. *A. muciniphila* can degrade mucins and produce short-chain fatty acid (SCFA) metabolites. Therefore, we investigated the interplay between *A. muciniphila*, SCFAs, and ICB therapy efficacy in TNBC models. As diet is the main modifier of the gut microbiome, we first investigated diet-gut microbiome interactions on ICB efficacy. Using the EO771 syngeneic murine model of TNBC, female C57BL/6 tumor-bearing mice consuming a low-fat control, or high-fat Western, or Mediterranean diet, were treated with 3 doses of 200µg of IgG or anti-PD-L1 antibodies and tumor progression was monitored. To assess changes in tumoral immune cell populations, end-of-study tumor tissue was used for immunohistochemistry (IHC). To evaluate modulation on the gut microbiome, metagenomic sequencing was performed on DNA isolated from fecal samples collected at the end-of-study, and targeted SCFA metabolomic analysis was performed on plasma collected at the study endpoint. Results show mice consuming a Mediterranean diet treated with anti-PD-L1 had significant increases in the abundance of gut *A. muciniphila* and plasma SCFAs, as well as significantly reduced primary tumor volume and increased immune cell activity within the TME. To then investigate if direct supplementation of *A. muciniphila* or SCFAs could enhance ICB efficacy, EO771 tumor-bearing mice were treated with 3 doses of 200µg of IgG, anti-PD-L1 or anti-PD-1 antibodies with a subset of mice stratified to also receive *A. muciniphila* or exogenoussupplementation of SCFAs. Tumor progression was measured and changes in tumoral immune cell populations were assessed with end-of-study tumor tissue prepared for flow cytometry and IHC. Results show mice supplemented with *A. muciniphila* and treated with anti-PD-L1 therapy demonstrated response to treatment, with a significant reduction in tumor volume as well as increased levels of immune cell populations in the TME. Mice supplemented with SCFAs and treated with a combination of anti-PD-1 and chemotherapy demonstrated enhanced response to treatment, with a significant reduction in tumor volume. In conclusion, data from our lab suggest that increased levels of gut *A. muciniphila* and SCFAs drive ICB efficacy in TNBC.

#1424 Epigenetic activation of tumoral IFNγresponse and pyroptosis overcomes immunotherapy resistance in hepatocellular carcinoma.

Y. Tu[1], H. Wu[1], C. Zhong[2], Z. Xiong[1], J. Wang[1], P. P. Wong[1], W. Yang[1], J. Lu[1], Z. Liang[1], S. Chen[1], L. Zhang[1], S. Chen[1], J. Zhou[1], K.-F. To[1], J. J. Sung[3], S. L. Chan[1], D. Kerr[4], N. L. Thangue[4], A. S. Cheng[1];

[1]The Chinese University of Hong Kong, Hong Kong, Hong Kong, [2]Renji Hospital Affiliated to Shanghai Jiao Tong University, Shanghai, China, [3]Nanyang Technological University, Singapore, Singapore, [4]The University of Oxford, Oxford, United Kingdom

Background: Immune checkpoint blockade (ICB) therapies by antibodies have revolutionized the treatment paradigm for a variety of cancers. Although subsets of people exhibit durable responses, resistance and relapse are common in hepatocellular carcinoma (HCC). We therefore aim to delineate the mechanism underlying the failure of ICB therapy in HCC, and more importantly to identify ICB-sensitizing therapeutic approaches.

Methods: ICB-resistant orthotopic-grafted murine models were established via a serial selection of HCC cells in ICB-treated mice. Integrated multi-omics analysis (single-cell RNA-seq, single-cell ATAC-seq and ChIP-seq) were applied to decode the mechanisms underlying the ICB resistance and an epigenetic-mediated ICB response.

Results: We successfully established the ICB-resistant murine models of HCC, in which tumor intrinsic interferon-gamma (IFNγ) response was most significantly suppressed and characterized by a “cold” tumor microenvironment with decreased lymphocyte activation and intratumoral infiltration. On the other hand, single cell RNA-seq analysis of human HCC biopsies revealed that patients with HDAC1/2/3-high HCC exhibit poor survival upon ICB therapy. Notably, we found that a novel specific HDAC1/2/3 inhibitor CXD101 synergized with PD-(L)1 antibody to induce immunogenic cell death, eradicate tumor and prolong survival in our ICB-resistant mouse models, which was accompanied by enhanced intratumoral infiltration, activation and anti-tumor memory formation of cytotoxic lymphocytes. Mechanistically, CXD101 combined with PD-(L)1 inhibition synergistically reactivated tumor IFNγ pathway via enhancing chromatin accessibility of downstream genes associated with antigen presentation and lymphocytes recruitment. Moreover, the activated immune system induced tumor cell pyroptosis, further igniting antitumor immunity and ICB response.

Conclusions: Our findings suggest that corruption of tumor intrinsic IFNγ signaling may confer ICB resistance upon ICB therapy, which can be rectified by class I HDAC inhibitor mediated IFNγ response and tumor cell pyroptosis. Based on these findings, we have commenced a Phase II clinical study of a new epigenetic immunotherapy (CXD101 plus anti-PD-1) for HCC patients resisting anti-PD-(L)1 alone. This project is supported by the CRF (C4045-18W), GRF (14115820), TRS (T11-706/18-N), Li Ka Shing Foundation, CUHK Strategic Seed Funding for Collaborative Research Scheme. We also acknowledge support (funding and study medications) by Celleron Therapeutics.

#1425 Epigenetic modulation synergizes with a novel TCR β chain directed antibody-fusion molecule to suppress checkpoint-refractory tumors irrespective of MHC I status.

K. E. Lothstein[1], A. S. Khelifa[1], M. Miyamoto[1], C. M. Minnar[1], L. Poppe[1], N. Roller[1], A. Bayliffe[2], K. Liu[2], J. Moisan[2], M. Katragadda[2], Z. Su[2], J. Schlom[1], S. R. Gameiro[1];

[1]National Cancer Institute, Bethesda, MD, [2]Marengo Therapeutics, Cambridge, MA

Background: Epigenetic silencing of MHC-I, and poor T cell infiltration and function in the tumor microenvironment (TME) are prevalent in solid malignancies and associate with lack of response to immune checkpoint blockade (ICB). Novel combination therapies may overcome these barriers, thereby providing clinical benefit across solid tumors. STAR0602 is a first-in-class bifunctional therapeutic molecule, that simultaneously engages a nonclonal mode of T cell receptor (TCR) activation with costimulation to promote activation and expansion of αβ T cell subsets expressing distinct variable β (Vβ) TCR chains. Here, we examined the tumor-suppressive ability and mode of action of a murine surrogate of STAR0602 (mSTAR1302) in combination with the class I HDAC inhibitor Entinostat, an epigenetic modulator that enhances tumor immune cell recognition, in multiple tumor models, including ICB-refractory.

Methods: mSTAR1302 and/or Entinostat were administered to mice bearing ICB-responsive breast EMT6 wild-type (wt) and ICB-refractory EMT6 β2-microglobulin (B2m)-deleted and CT26 (Kras $G12D^{mut}$ colon) tumors. Anti-tumor efficacy, survival, and protective memory were monitored. Immune cell depletion studies were conducted. Comprehensive proteomic and immune profiling of tumor, tumor-draining lymph node (tdLN), and spleen cell populations was conducted. Antigen-specific IFNg T cell responses were evaluated by ELISpot.

Results: Combination therapy demonstrated significant enhancement in tumor suppression and prolonged survival in CT26 ($MHC\text{-}I^{\pm}$), EMT6 wt ($MHC\text{-}I^{\pm}$) and EMT6 β2m-deleted ($MHC\text{-}I^{null}$) tumors relative to single agent therapy, as well as enhanced tumor-specific protective memory responses. Tumor suppression was independent of $CD4^{\pm}$ T cell immunity and associated with sustained activation and expansion of Vβ13 $CD8^{\pm}$ T cells.

Conclusions: Ongoing mechanistic studies indicate combination therapy to elicit complimentary mechanisms of tumor suppression beyond $CD8^{\pm}$ T cells. Ongoing proteomic and single-cell transcriptomic investigation of MHC-I competent and null tumors will provide a deeper insight into the mode of action of this combination therapy. Collectively, these data support the use of STAR0602 in combination with Entinostat for the treatment of solid malignancies, including for patients harboring ICB-refractory tumors devoid of MHC class I.

#1426 Lipid-mediated epigenetic activation of PPAR-gamma signaling promotes immune-checkpoint resistance in hepatocellular carcinoma.

Z. Xiong[1], S. L. Chan[1], J. Zhou[1], X. Zeng[1], W. Yang[1], H. Wu[1], J. Cao[1], J.-T. Low[2], M. W. Chan[2], K. Y. Yip[3], J. J. Sung[4], A. S. Cheng[1];
[1]The Chinese University of Hong Kong, Hong Kong, China, [2]National Chung Cheng University, Min-Hsiung, Taiwan, [3]Sanford Burnham Prebys Medical Discovery Institute, La Jolla, CA, [4]Nanyang Technological University, Singapore, Singapore

Background: Although use of immune-checkpoint inhibitors (ICI) has yielded impressive results in cancer patients, resistance to ICI therapies has increasingly been observed, especially in hepatocellular carcinoma (HCC).
Materials and Methods: We generated a novel anti-programmed death-ligand 1 (PD-L1) treatment resistant mouse hepatoma cell Hepa1-6 (PD-L1R) by 7-generation of *in vivo* selection. To dissect tumor cell-intrinsic resistant mechanism, we performed single-cell RNA-sequencing (scRNA-seq) from anti-PD-L1-treated tumors generated from parental or PD-L1R cells. Expression level of target genes was detected by QPCR, western blot and immunohistochemical analyses. Lipid content and fatty acid uptake was examined by Oil Red O and BIODIPY staining. *Peroxisome proliferator-activated receptor gamma* (*PPARγ*) promoter methylation level was analyzed by bisulfite pyrosequencing. To investigate the tumor cell-extrinsic factors, we profiled the myeloid and lymphoid lineages by flow cytometry.
Results: ScRNA-seq revealed significant gene enrichments in lipid metabolism and PPARγ signaling pathway in PD-L1R tumors, which could be verified in both mRNA and protein levels. Moreover, we observed evident lipid accumulation in the PD-L1R tumors when compared to the parental tumors by Oil Red O staining. Consistently, PD-L1R tumor cells exhibited higher lipid content and enhanced fatty acid uptake *in vitro*, as demonstrated by $BODIPY^{493/503}$ and BODIPY-C16 analyses. Of note, palmitic acid could dose-dependently increase *Pparg* mRNA expression in parental cells to a similar level with the PD-L1R cells, supporting an important role of lipids in inducing PPARγ expression. Pyrosequencing analysis indicated that PD-L1R cells exhibited lower PPARγ methylation level compared with parental cells. Notably, 5-Azacytidine treatment in parental cells significantly reduced the promoter DNA methylation and increased *Pparg* mRNA expression to similar extent with the PD-L1R tumor cells, thus indicating DNA hypomethylation-driven PPARγ up-regulation. Flow cytometry analysis showed that ICI resistance was associated with lower cytotoxic $CD8^{+}$ T cells but higher intermediate Th17 cells, myeloid-derived suppressor cells and T regulatory cells in the tumor microenvironment (TME).
Conclusions: Our study suggested that lipid exposure may epigenetically up-regulate PPARγ transcription in the development of anti-PD-L1 resistance. Detailed investigation on the crosstalk between aberrant lipid metabolism and immunosuppressive TME is ongoing.
Acknowledgment: This study is supported by RGC General Research Fund (14120621 and 14119023), Li Ka Shing Foundation and CUHK Strategic Seed Funding for Collaborative Research Scheme.

TUMOR BIOLOGY: Animal Models of Cancer
Poster Session

#1430 Development of transparent transgenic zebrafish model to study anti-cancer drug induced *in vivo* cardiotoxicity.
S. K. Rajpurohit, T. Gossman, S. Nasanally, K. Bhatt, A. Van Derhei, S. Hotwani, D.-A. Manhiani, R. Pasi, J. Mi, V. Arora, B. Lokeshwar; Augusta University, Augusta, GA

Cardiotoxicity is the second leading cause of death among cancer survivors and can manifest as arrhythmia, acute coronary syndrome, acute heart failure, or pericarditis/myocarditis. Chronic myocyte damage and apoptosis can transition from an asymptomatic phase to adaptive myocardial hypertrophy, followed by decreased left ventricular ejection fraction, and eventual heart failure. Cardio-oncology is an emerging field that studies cancer therapy-associated cardiotoxicities. The development of reliable and effective preclinical models for cardiotoxicity prediction and prevention is essential to improving the long-term cardiac health of cancer patients. Zebrafish are a promising animal model for the field of cardio-oncology and have emerged as an invaluable tool for investigating genetic and molecular aspects of cardiovascular research. Zebrafish heart cells are like human heart cells at the molecular level, making them an ideal system for studying the genetic underpinning of cardiac function. Zebrafish myl7 gene, a myosin light chain-7 gene, is a regulatory gene of heart orthologs to human MYL7. In-vivo imaging is limited due to the opacification of skin and subdermal structures. To conduct in-vivo whole organism imaging studies, skin transparency is a primary requirement, necessitating the blocking of pigmentation. The Zebrafish Casper mutant maintains skin transparency throughout its life, offering the ideal combination of sensitivity and resolution for in-vivo analyses and imaging. In this study, we have developed a novel transparent transgenic zebrafish model and established time-lapse in-vivo confocal microscopy to study cellular phenotype/pathologies of cardiomyocytes. The newly developed homozygous transparent transgenic Casper/ myl7:RFP; annexin-5:YFP/NF-kB: GFP/mpeg1:mcherryFP, allows us to study cell death process (Annexin5) and inflammatory activity (NF-kB) in microglia and cardiomyocytes. We have successfully established in vivo fluorescence and confocal microscopy in this newly developed strain, enabling the study of cellular morphology and function changes under various conditions. This will allow us to elucidate cell death patterns, and cardio-inflammatory and cardiotoxicity pathways.

#1431 Generation of transparent transgenic zebrafish strain to study cardiovascular functionin translational cardio-oncology research.

S. K. Rajpurohit[1], T. Gossman[1], **R. Pasi**[1], S. Nasanally[1], K. Bhatt[1], A. Van Derhei[1], S. Hotwani[1], D.-A. Manhiani[1], K. Kimmerling[2], V. Arora[3], B. L. Lokeshwar[1]; [1]Augusta University, Augusta, GA, [2]FiteBac Technology, Marietta, GA, [3]Medical College of Georgia, Augusta University, AUGUSTA, GA

Transgenic zebrafish lines have been extensive use in biomedical research and their primary applications. The zebrafish has proven to be an ideal tool for direct In-vivo observations of developmental processes. In vertebrates, including zebrafish and humans, the ability to obtain high-resolution, in-vivo imaging is limited due to the natural opacification of skin and subdermal structures. To conduct in-vivo whole organism imaging studies, skin transparency is a primary requirement, necessitating blocking of pigmentation. Zebrafish casper mutant maintains skin transparency throughout its life, offering the ideal combination of sensitivity and resolution for in-vivo analyses and imaging. Our Laboratory is developing a novel transparent transgenic zebrafish model to address basic and translational cardio-oncology and experimental therapeutics. The fli1 promoter in zebrafish having an enhanced expression reporter gene of green fluorescent protein, GFP. This model allows for the in-vivo examination of the vascular system by using fluorescent and confocal microscopy. In this study, we developed transparent transgenic strain of Caspe/fli1:EGFP and integrating with recently developed *casper*/myl7/annexin-*5:YFP and* casper/*fli1:EGFP* strain through crossbreeding of casper and transgenic zebrafish. We have generated F1 generation of newly developed strains of Caspe/fli1:EGFP and *casper*/myl7/annexin-*5:YFP and* casper/*fli1:EGFP.* The presence of fluorescence expressions RFP, YFP and GFP, in crossbred progeny identified through the screening of larvae at 72 HPF stage. Expression of these fluorescent proteins determines the presence of the reporter genes. *Positive transgenic larvae validated by confocal microscopy. The progenies of the F1 generation are heterozygous in nature and allow them to grow into adults to breed transparent transgenic strain to get F2 generation. This process will be continued to F2, F3, F4 and F5 generation until obtain homozygous progeny of newly developed strain.* The development of *casper*/myl7/annexin-*5:YFP x* casper/*fli1:EGFP* will aid new dimensions in Cardio-oncology research for cardiac injury and Vasotoxicity induced by anticancer drug treatment in cancer patients.

#1432 Development of transparent transgenic zebrafish model to study CNS microglia and NF-kB activity in glioblastoma.

S. K. Rajpurohit[1], S. Nasanally[1], **S. Hotwani**[1], T. Gossman[1], K. Bhatt[1], A. Van Derhei[1], R. Pasi[1], D.-A. Manhiani[1], K. Kimmerling[2], B. L. Lokeshwar[1]; [1]Augusta University, Augusta, GA, [2]FiteBac Technology, Marietta, GA

Microglia are resident macrophages of the central nervous system (CNS) and have crucial roles in normal brain homeostasis, function, and immune response. Microglia play key roles in the healthy brain, ranging from phagocytosis of dying neurons and CNS debris to modulating adaptability. The role of microglia has been well documented but their specific contributions to the development and progression of cancers, such as glioblastoma, have recently garnered wide attention. The zebrafish have proven novel tool for modeling innate immune responses. A macrophage-specific marker mpeg1 and its promoter are used in mpeg1-driven transgenes. mpeg1-driven transgenes mpeg1:mCherryFP are expressed in macrophage-lineage cells that do not express neutrophil-marking transgenes. These zebrafish transgenes contribute to the fields of inflammation, infection, and leukocyte biology. We have recently developed a novel transparent transgenic homozygous strain Tg(6xNF-kB:EGFP); Casper(roy−/−, nacre−/−) of zebrafish to the in-vivo study of NF-kB activity under normal and inflammation stage at the cellular, organ-specific and whole organism level. To perform an in-vivo study of microglial function, we are developing Casper;*mpeg1:mCherryFP* microglia specific strain and integrating with newly developed Tg(6xNF-kB:EGFP); Casper(roy−/−, nacre−/−) strain through crossbreeding of Casper and transgenic zebrafish. We have generated F1 generation of newly developed strains of Casper;*mpeg1:mCherryFP and Tg(6xNF-kB:EGFP);Casper*. The presence of fluorescence mCherry and GFP, in crossbred progeny was identified through the screening of larvae at 72 HPF stage. The expression of these fluorescent proteins determines the presence of the reporter genes. *F1 generation confirmed heterozygous and allowed them to grow into adults to breed transparent transgenic strain to get F2 generation. This process will be continued to F2, F3, F4, and F5 generation until achieving homozygous progeny.* This model allows for in-vivo examination of microglia functional morphology by using fluorescent and confocal microscopy. This novel transgenic model will be applied to identify novel anti-inflammatory drug inhibitors in NF-kB pathophysiology for glioblastoma and cardio-oncology experimental therapeutics.

#1433 FOXA1 alterations distinctively drive prostate tumorigenesis or therapy resistance in mice.

S. Eyunni, A. Parolia, E. Young, J. M. George, R. Mannan, S. E. Carson, Y. Zhang, J. Tien, M. Jaber, J. Luo, M. Pang, R. Mehra, X. Cao, F. Su, R. Wang, M. Cieslik, D. K. Lee, J. Xu, A. M. Chinnaiyan;
University of Michigan, ann arbor, MI

Androgen receptor (AR) signaling is critical for survival of prostate cancer (PCa) cells, thus making androgen deprivation therapy (ADT; e.g., castration) as the mainstay for treatment. Notably, oncogenic functions of AR rely on chromatin-binding regulatory proteins, which includes a pioneer transcription factor called FOXA1. FOXA1 de-compacts chromatin to enable AR's binding to the DNA and expression of it's target genes. Recently, our lab found FOXA1 alterations to recur within three distinct structural classes in over 35% of metastatic castration resistant PCa (mCRPC) in Caucasian men. Subsequent studies found FOXA1 mutations to be prevalent in over 40% of primary PCa in Chinese men, positioning FOXA1 as a principal oncogene in this disease. Yet, hitherto, no studies have defined the pathobiology of FOXA1 alterations in mouse models. Here, we have developed the first-in-field transgenic mice with conditional overexpression of FOXA1 mutants in the prostate luminal epithelia. We found truncal FOXA1 Class1-mutants to initiate luminal hyperplasia in a monogenic model, or hyperproliferative prostate adenocarcinoma in a compound Trp53-deficient genetic background. Mechanistically, Class1 mutants concurrently upregulate the AR and mTORC1/2 pathways to drive transformation, with this being the first report of FOXA1-driven PCa formation in mice. In contrast, FOXA1 Class2 mutants—which are acquired in mCRPC—do not drive prostate luminal transformation. Instead, single-cell multi-omics (RNA+ATAC) profiling of Class2-mutant mouse prostate tissue uncovered extensive transcriptional remodeling of epithelial cells into a luminal stem-like cell fate, leading to a dramatic 15-20-fold expansion of the progenitor population vs control tissue. These luminal stem cells are similar to the Club/Hillock cells detected in the human prostate that have been implicated in driving resistance to ADT. Consistently, we found Class2-mutant prostates to show minimal atrophy upon castration, with immunohistological assessment uncovering a higher density of Ki67+ luminal epithelial cells relative to wild type and Class1 tissues. Class2-mutant organoids also showed higher subcutaneous grafting ability in mice in limiting dilution assays. Mechanistically, we found the cistromically-dominant Class2 mutants to pioneer over 40,000 *neo*-enhancer elements harboring motifs of stemness-associated transcription factors, which in turn instruct the ADT-resistant luminal progenitor gene program. Altogether, findings from our mouse models uncover FOXA1's versatility as a driver oncogene that, depending on the mutation type, either activates enhancer-wired luminal tumorigenesis (Class1-initiating event) or therapy resistance-associated stemness (Class2-promoting alteration) gene programs in the mouse prostate tissue.

#1434 Modeling the 3q26 OncCassette using genetically engineered mice.

K. M. Meneses, Y. Liu, C. R. Weems, L. Jamieson, D. T. Nguyen, V. Justilien, N. R. Murray, A. P. Fields;
Mayo Clinic, Jacksonville, FL

Lung squamous cell carcinoma (LUSC) is a devastating disease, accounting for ~30% of all lung cancer diagnoses and ~40,000 deaths annually in the United States alone. LUSC patients suffer from high prevalence of relapse and a dismal 5-year survival of only ~24%. The lack of animal models that reflect the salient features of human disease to assess the safety and efficacy of drugs, and to explore the underlying molecular mechanisms of LUSC tumor biology, is a major impediment for LUSC patients. We have identified concomitant 3q26 copy number gain (CNG) and *TP53* loss as a defining genetic alteration present in ~90% of LUSC tumors. Furthermore, we have identified and characterized three 3q26 oncogenes (*PRKCI, ECT2 and SOX2)* that genetically and biochemically collaborate to drive LUSC tumor formation. Using syngeneic mouse modeling, we have demonstrated that coordinate overexpression of *Prkci, Ect2* and *Sox2*, and loss of *Trp53* in *ex vivo* cultures of lung basal stem cells (LBSCs; a cell of origin for LUSC) drives transformation of these cells into tumors of exclusively LUSC histopathology. These findings lead to the hypothesis that *PRKCI, ECT2* and *SOX2* represent a multigenic driver of 3q26 CNG-driven LUSC, which we term the 3q26 OncCassette. Based in these findings, we have developed and begun characterizing the first autochthonous genetically engineered mouse model (GEMM) to study 3q26 OncCassette-driven tumorigenesis. Our novel immune competent GEMM will provide critical insight into tumor initiation and progression of preneoplastic lesions to malignant LUSC and allow characterization of the immune landscape in these tumors.

#1435 Utilization of CLDN18.2 syngeneic mouse models to study chimeric antigen receptor T cells in immunocompetent mice.

S. Breen, R. Carrasco, K. McGlinchey, B. Janocha, P. Zanvit, L. Ortiz, B. Clark, A. Toloczko, M. Cobbold, G. Moody, E. Bosco, A. Barrett; AstraZeneca US, Gaithersburg, MD

CLDN18.2 expression has been observed in pancreatic, gastric and esophageal cancers, whereas normal tissue expression of CLDN18.2 is mostly restricted to differentiated gastric mucosal epithelial cells. This expression profile renders CLDN18.2 an ideal tumor associated antigen (TAA) for CAR-T targeting and an armored targeted CAR-T, AZD6422, is in clinical development. While CAR-T are beginning to show clinical promise in solid tumors, a consistent challenge is to overcome the immunosuppressive tumor microenvironment (TME) where immune and stromal cells secrete high levels of TGFb. Since the majority of pre-clinical CAR-T efficacy data is generated utilizing immunocompromised mouse models, which lack a proper TME, the team utilized syngeneic xenograft models to circumvent this challenge. In vitro studies showed that CLDN18.2 targeted murine CAR-T cells generated by retroviral transduction induced efficient cytolysis of target positive mouse tumor cells accompanied by cytokine release. To model the clinical scenario, tumor-bearing mice were lymphodepleted with total body irradiation (TBI) to enhance CAR-T engraftment. The dosage of TBI used in these studies was predetermined to have caused leukopenia and minimal impact on tumor growth. We observed substantial tumor control and extended tumor efficacy in mice treated with mCAR-T cells compared to those infused with untransduced T cells or in non-target bearing control tumors in the absence of gross toxicities. This syngeneic mouse model platform will additionally allow us to investigate how mCAR-T cells perform within a fully competent TME in combination with other therapeutic agents targeting cancer cells via altered mechanism of action.

#1436 Cancer associated fibroblast dependency in a model of bladder cancer.

H. Valentine, U. Satyal, L. Bukavina, H. Uddin, Y. Beyamin, R. Arya, P. Abbosh;
Fox Chase Cancer Center, Philadelphia, PA

Introduction: The relationship between genotype and phenotype in targeted therapy has proven to be crucial for most kinase inhibitors. In bladder cancer, the PI3K/AKT/mTOR pathway is widely activated by mutation but untargeted. Our study focuses on developing an immunocompetent, CRISPR-edited bladder cancer mouse model that mirrors common PI3K/AKT/mTOR mutations. We aim to establish genotype-effective kinase inhibitor pairings using *in vitro* CRISPR-edited organoids and Cancer Associated Fibroblasts (CAFs) to create a pro-tumorigenic environment *in vivo*.

Methods and Results: Urothelial cells were isolated from the bladder of Rosa26 Lox-Stop-Lox-Cas9/GFP transgenic mice to develop organoids. These organoids were co-edited for *Trp53* and *Rb1* KO, and further editing of the *Pten* gene resulted in a nine-fold increase in sensitivity to the kinase inhibitor ipatasertib. Despite successful engraftment into mouse bladder, these edited cells regressed before tumor formation, and intradermal injection did not yield subcutaneous tumors. An alternate model featuring a *9p21* deletion with *Trp53* KO also displayed similar regression post-engraftment into bladder or skin. However, co-injection with skin-cancer-derived CAFs subcutaneously yielded palpable subcutaneous tumors that grew for 12 weeks. Enhancing orthotopic model fidelity, we established a BBN bladder-tumor-derived CAF line, leading to the formation of tumors with squamous differentiation upon intramural co-injection with edited organoids. These models displayed immune-excluded architecture and a predominance of M2 over M1 macrophages. Following our accomplishments in establishing bladder tumors, we aimed to enhance our model's adaptability by introducing common PI3K/AKT/mTOR mutations, specifically *TSC1*/*TSC2* KO and *Pik3ca* hotspots, into our *9p21*/*Trp53* KO model. While *TSC1*/*TSC2* KO lines exhibited elevated P-S6K signaling, they displayed resistance to Torin 1, Voxtalisib, and Everolimus—kinase inhibitors targeting mTORC1/2. In parallel, we employed CRISPR-mediated HDR to successfully introduce a *Pik3ca* H1047R hotspot into our *9p21*/*Trp53* KO model, as evidenced by increased Phosphorylation of AKT compared to wild-type *9p21*/*Trp53* KO cell lines.

Conclusions: Our research establishes the crucial role of CAFs in bladder tumor formation. Our now established customizable model of bladder cancer is suitable for direct targeting by kinase inhibitors while providing a platform for understanding the genotype-phenotype relationship in bladder cancer.

#1437 Generating primary mouse models of diffuse midline glioma through a combination of the RCAS/tv-a retrovirus system and CRISPR/Cas9 gene editing.

S. R. Wu[1], H. Q. Liu[2], J. Tolliver[2], S. M. Maingi[2], V. Valentine[2], N. T. Williams[2], Z. J. Reitman[2];
[1]Duke University, Durham, NC, [2]Duke University Medical Center, Durham, NC

Diffuse midline gliomas (DMGs) are deadly brain tumors that arise in the brainstem of children and young adults, resulting in a median survival of less than two years. Genetically engineered mouse models (GEMMs) are critical to studying tumorigenesis and tumor-immune interactions in DMG, which may inform the design of new urgently-needed treatment approaches. One approach to generate DMG GEMMs uses RCAS/tv-a, an avian retrovirus gene delivery system to express transgenes in specific brain cell lineages in the mouse brain. However, this approach often requires resource-intensive breeding to generate mice with the desired genetic alterations in their germline. As a result, we aimed to establish a new approach that combines this system with CRISPR/Cas9 gene editing technology. This methodology has been described for model adult supratentorial gliomas in mice but has not been described for pediatric or brainstem gliomas. To express Cas9 and the avian retrovirus receptor TVA in mouse neural stem cells, we bred mice of genotype Nestin-TVA; Nestin-Cre; LoxP-STOP-LoxP-Cas9-EGFP. RCAS retrovirus plasmids were generated containing various guide RNAs (gRNAs) targeting DMG-relevant genes for disruption by Cas9, including *Trp53*, *Cdkn2a*, *Atm*, *Ppm1d*, *Pten*, and a non-targeting control (Cntl). For each gRNA, two plasmids were generated, one with a platelet-derived growth factor beta ligand (PDGFB) oncogene driver and one with a blue fluorescent protein (BFP) marker. In a pilot experiment, avian fibroblast cells transduced with RCAS-Trp53_gRNA_BFP and RCAS-Cntl_gRNA-PDGFB were injected into postnatal day 4 mouse brainstems of the aforementioned genotype and observed for tumor formation. High grade tumor formation was observed. We also observed high grade tumors in mice of genotype Nestin-TVA; LoxP-STOP-LoxP-Cas9-EGFP when injected with an additional RCAS-Cre construct, indicating that Cre can be expressed from the mouse germline or delivered via a retrovirus payload to drive tumorigenesis. Immunohistochemistry confirmed tumor features that model human DMG, expression of Cas9 and PDGFB, and loss of p53. Thus, RCAS/tv-a and CRISPR/Cas9 can be combined to model pediatric glioma tumorigenesis in the mouse brainstem. This approach to mouse modeling will streamline future GEMM DMG research by allowing new genes of interest to be rapidly perturbed by simply generating RCAS retrovirus constructs. The workflow may also enable sophisticated experiments such as pooled *in vivo* genetic experiments that screen gRNAs targeting various tumor suppressor genes or therapeutic targets.

#1438 Investigating the roles of EMT in small cell lung cancer tumorigenesis and chemoradiation response.

T. Nguyen[1], J. Chang[2], K. Gabrielson[3], A. Shetty[4], Y. Song[4], A. Lafargue[2], S. Jagtap[3], D. Council[2], A. Chan[2], D. Dutta Chowdhury[2], M. Khan[2], N. Connis[3], F. Carrieri[3], E. Imada[5], D. Sforza[3], E. Gardner[5], C. McFarland[6], L. Marchionni[5], M. Rezaee[3], C. Hann[3], P. Tran[2];

[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, [2]University of Maryland School of Medicine, Baltimore, MD, [3]Johns Hopkins School of Medicine, Baltimore, MD, [4]University of Maryland Institute for Genome Sciences, Baltimore, MD, [5]Weill-Cornell Medicine, New York, NY, [6]Case Westerns Reserve University, Cleveland, OH

In this study, we investigated the contributions of the epithelial-mesenchymal transition (EMT) program to small cell lung cancer (SCLC) tumorigenesis and chemoradiation (CRT) response. SCLC is a highly aggressive and deadly neuroendocrine malignancy. Two major factors that contribute to the high mortality of SCLC are (1) early metastasis and (2) rapid development of therapy resistance. Recent research suggests upregulation of EMT and the EMT transcription factor Twist1 correlated with accelerated tumor progression and CRT resistance in SCLC. Due to the lack of suitable animal models, the causal relationship between the EMT program and SCLC tumorigenesis and therapy response has not been rigorously investigated. To this end, we have generated a novel genetically engineered mouse model (GEMM) termed RPGT (*Rb1*^{Flox}*; Trp53*^{Flox}*; ROSA26*$^{LSL\text{-}rtTA\text{-}IRES\text{-}EGFP}$*; Twist1-TetO*$_7$*-Luc*). The RPGT GEMM enables the generation of autochthonous SCLC tumors after induction with Cre recombinase adenovirus. By withdrawing or providing doxycycline to mice, we can control Twist1 expression to activate or inactivate EMT in tumors. Upon characterizing mouse tumor samples with histological and molecular analyses, we observed that both control (no Twist1 overexpression) and Twist1-overexpressing RPGT mice developed neuroendocrine SCLC tumors. While SCLC-A was the predominant subtype in both cohorts, RPGT tumors exhibited more heterogeneity. Importantly, although no difference in tumorigenesis was observed, Twist1 overexpression dramatically increased the metastatic incidence in RPGT (87-100%) compared to control (25-50%) animals, indicating an important role of EMT in SCLC dissemination. Furthermore, transcriptomic profiling of primary tumors and matching metastases in RPGT mice revealed downregulation of Twist1 and EMT in metastases, suggesting that EMT suppression was necessary for metastatic outgrowth. To evaluate the impact of EMT activation on SCLC sensitivity to CRT, we performed *in vitro* viability assays on primary tumor cell lines established from RPGT tumors. We found that repressing Twist1 expression enhanced SCLC susceptibility to CRT. To validate these results *in vivo*, we treated RPGT mice with vs. without Twist1 overexpression with CRT. Consistent with our *in vitro* results, our *in vivo* data indicated that Twist1 overexpression promoted CRT resistance in SCLC tumors. Overall, our data suggest that the EMT program plays an important role in SCLC differentiation, metastasis, and resistance against chemo-radiotherapy.

#1439 Elucidation of the pathogenesis of prostate cancer harboring mutations of epigenetic factor UTX using genetically engineered mice.

N. MURAMOTO[1], M. Iwasaki[2], Y. Sera[2], H. Ide[1], S. Mukai[3], T. Fukushima[4], S. Horie[1], H. Honda[2];
[1]Juntendo University Graduate School of Medicine, Tokyo, Japan, [2]Tokyo Women's Medical University, Tokyo, Japan, [3]University of Miyazaki, Miyazaki, Japan, [4]University of Miyazaki, Tokyo, Japan

Introduction and Objective: Histone modifications are important for tissue homeostasis, and their mutations are involved in carcinogenesis. Mutations in a histone modifier, UTX (KDM6A) are common in prostate cancer (PCa), which is frequently associated with loss of its counterpart UTY (KDM6C). However, mechanisms underlying the development of UTX-deficient PCa are not clear. We aimed to address this issue by generating and analyzing genetically-engineered mice.
Methods: We generated mice with deletion of both *Utx* and *Uty* in the prostate tissue (*Utx*Δ, *Uty*Δ) and crossed with mice with a heterozygous deletion of *p53* (*p53*+/−) to create *Utx*Δ, *Uty*Δ and *p53*+/− compound mice. High-fat diet (HFD) that is known to promote cancer growth was administered to mice. We found that *Utx*Δ, *Uty*Δ, *p53*+/− mice treated with HFD developed PCa with Gleason score (GS) = 3+3. Isolated prostate tissues were subjected to pathologic, molecular, and cellular analyses. In addition, RM-2 mouse PCa cells which do not express UTY were knocked down for *Utx* (si*Utx*) and *control* (si*NC*) by siRNAs to assess changes in the abilities of proliferation and migration.
Results: RM-2 si*Utx* cells showed increased proliferation and migration compared with RM-2 si*NC* cells. By performing high-throughput RNA sequencing (RNA seq) and gene set enrichment analysis (GSEA) using mouse prostate tissues, we found that loss of UTX in the prostate activated inflammatory pathways, whereas inactivated DNA damage repair pathways. Immunostaining prostate tissues with an antibody to a macrophage marker, F4/80, exhibited significant accumulation of macrophages in *Utx*Δ, *Uty*Δ, *p53*+/+ mice compared to *Utx*+, *Uty*Δ, *p53*+/+ mice. In addition, immunofluorescent staining of irradiated prostate tissues with an antibody against a DNA repair marker, γH2AX, revealed that the time required for DNA damage repair was markedly prolonged in *Utx*Δ, *Uty*Δ, *p53*+/+ mice compared with *Utx*+, *Uty*Δ, *p53*+/+ mice.
Conclusions: These results suggest that loss of UTX contributes to prostate cancer development through promoting inflammation and impairing DNA damage repair, which may serve as novel therapeutic targets in PCa patients with UTX mutations.

#1440 Retinoblastoma binding protein 9 regulates intestinal inflammation and inflammation-associated carcinogenesis.

Y. Nakanishi[1], K. Hamada[1], M. Omatsu[1], K. Iwane[1], H. Kitamoto[1], M. Okabe[1], Y. Muta[1], S. Yamamoto[1], A. Fukuda[1], H. Kasashima[2], H. Seno[1];
[1]Kyoto Univ. Graduate School of Medicine, Kyoto, Japan, [2]Osaka Metropolitan University, Osaka, Japan

The intestinal epithelium constitutes the mucosal barrier, and its dysfunction promotes microbial invasion from the gut lumen, which further induces the intestinal inflammation. Chronic intestinal inflammation, as observed in poorly controlled inflammatory bowel diseases (IBD), leads to the development of inflammation-associated cancer. Thus, a deeper understanding of the regulatory system that controls intestinal homeostasis is essential. Retinoblastoma-binding protein 9 (RBBP9) is expressed in a range of human cancer cells. RBBP9 was initially reported to have the ability to regulate the cell cycle pathway. More recent studies have identified RBBP9 as a serine hydrolase (SH) that promotes cancer progression by subverting the anti-proliferative function of TGFβ in a pancreatic cancer model. However, little is known about the roles RBBP9 plays in the development of intestinal cancer. In this study, we investigated the role of RBBP9 in inflammation and inflammation-associated cancer in the intestine. Analyses of surgically resected human samples and publicly available datasets demonstrated that RBBP9 expression was reduced in patient samples of ulcerative colitis (UC) and colitis-associated cancer (CAC). Genetically knockout mice for Rbbp9 (*Rbbp9*$^{-/-}$) were susceptible to experimental colitis induced by dextran sulfate sodium (DSS). Furthermore, *Rbbp9*$^{-/-}$ mice exhibited enhanced azoxymethane/DSS-induced tumorigenesis, a model for human CAC. Mechanistically, RNA sequencing of these tumors showed increased enrichment of inflammation-associated signatures, including interferon signaling pathways. Ex vivo organoid experiments revealed the suppressive function of RBBP9 in interferon signaling-mediated apoptosis of the intestinal epithelium. Simultaneous inhibition of RBBP9 and STAT1, a downstream transcription factor of interferon signaling, reverted the apoptotic phenotype of *Rbbp9*$^{-/-}$ organoids. Collectively, our data provide insight into the understanding of the crucial role of RBBP9 in protecting against intestinal inflammation and inflammation-related tumorigenesis via regulating the interferon signaling-mediated apoptotic pathway.

#1441 Establishing a novel clinically relevant disease model of glioblastoma.

K. Connor[1], K. White[1], J. Clerkin[2], K. Sweeney[2], L. Shiels[1], T. van Brussel[3], I. Arijs[3], D. Lambrechts[3], G. Shankar[3], F. de Smet[3], S. G. Maher[4], L. Marignol[4], P. Dicker[1], J. Prehn[1], D. O'Brien[2], A. T. Byrne[1];

[1]Royal College of Surgeons in Ireland, Dublin, Ireland, [2]Beaumont Hospital Dublin, Dublin, Ireland, [3]KU Leuven, Leuven, Belgium, [4]Trinity College Dublin, Dublin, Ireland

Introduction: GBM is the most common primary malignancy of the CNS. Historically pre-clinical models have failed to predict response in humans, despite promising preclinical data. Moreover, current models seldom incorporate surgical resection and/or standard of care chemotherapy treatment. These models also commonly employ young animals exclusively, whose immune contexture differs from older patients. We therefore sought to establish an improved, orthotopic, preclinical GBM model, which better recapitulates patient response to standard-of-care and targeted treatments.

Methods: NFpp10a-Luc2 GBM cells were orthotopically implanted into C57BL/6-mice (aged[>18months] and young[6-8weeks]) and weekly bioluminescence imaging performed to monitor tumor growth. Overall survival (OS) and tumor growth were assessed in response to (1) Surgical Resection, (2) Temozolomide (TMZ) (3) anti-PD1 (4) neoadjuvant anti-PD1 and (5) Regorafenib (REGO) therapy. Tissue collected post-mortem underwent bulk RNA sequencing followed by analysis via microenvironment cell population counter (MCP) and gene set enrichment (GSEA) to determine changes in the GBM-TME following treatment.

Results: We demonstrated OS advantage in aged mice undergoing surgical resection (Resection:33.5 days vs Non-Resection: 18 days; p=0.0166) and observed age to be a significant prognostic factor (Young:62 days vs Aged: 22 days; p=0.0002). Subsequently, we observed that TMZ and anti-PD1 monotherapies had no impact on NFpp10-Luc2 growth (p=0.9001, p=0.7933) or survival (p=0.3035, p=0.6328). Neoadjuvant anti-PD1 treated mice demonstrated no significant survival advantage compared to IgG control (33 days vs 35 days; p=0.9429). Lastly, REGO treatment demonstrated a trend towards improved OS vs Vehicle (p=0.096). MCP analysis revealed both neoadjuvant anti-PD1 and REGO treatment induced influx of CD8+ T cells, B cells and monocytes into the TME, with neoadjuvant anti-PD1 associated with an upregulation of CXCR3 (p=0.0045).

Conclusions: We have, for the first time, established and characterized response of the NFpp10a-C57BL/6 model to surgical resection, TMZ, anti-PD1 and REGO therapy in both young and aged mice. We have shown the model is markedly insensitive to intervention with chemotherapy and immune checkpoint therapy, mirroring what is seen clinically in patients. The model may therefore be employed in future pre-clinical studies to guide clinical trials in the setting of mesenchymal GBM.

#1442 Establishing a papillary renal cell carcinoma mouse model with activating Met mutation.

Preet Lal[1], Li Ding[2], Feng Chen[1]

[1]Department of Medicine-Nephrology, Washington University In St. Louis, Saint Louis, MO,[2]Department of Medicine-Oncology, Washington University In St. Louis, Saint Louis, MO

Renal cell carcinoma (RCC) is a heterogeneous group of cancers of the nephron. Papillary renal cell carcinoma (PRCC) is the second most common type of RCC. c-Met activating mutations have been associated with Type 1 PRCC which are made up of small cells containing basophilic cytoplasm covering papillae and tubular structures. In patients with PRCC, c-MetH1112Y missense mutations are associated with both somatic and germline mutations. Previous functional studies indicate codon H1112 plays an important structural role in maintaining c-Met in the inactive conformation and alterations at this codon, including H1112Y, likely disrupt this interaction facilitating constitutive activation with increased c-MET activity. A c-MetH1112Y (c-MetHY) transgene with tetO promoter sequence was micro-injected into the mouse oocyte. Transgenic mice carrying this transgene have the ability to express this activated Met protein in cells expressing rtTA (reverse tetracycline-controlled transactivator) and when doxycycline is present. Mutant mice harboring this transgene along with additional trp53 mutations showed glomeruloid like Type 1 PRCC. Our in vivo studies confirmed the expression of c-MetHY gene within the kidney and Lrp2 and Ki67 staining indicated that PRCC arises from PT (proximal tubule). PRCC canonical markers CK7, AMACR and MET expression confirmed the Type1 PRCC in our mouse model. Additionally Pan-CK, E-Cad positive expression in mutant mice further confirmed PRCC arises from epithelial cells. We have generated and described type 1 PRCC mouse model with activating-MetHY mutation. This mouse model will help illustrate the oncogenic mechanism of Met activation and identify the critical events during progression of PRCC.

#1443 The PI3K-AKT-mTOR axis persists as a therapeutic dependency in KRAS^{G12D}-driven non-small cell lung cancer.

W. J. McDaid[1], L. Wilson[1], H. Adderley[2], M. Baker[1], J. Searle[1], T. Budden[1], A. Viros[1], M. Aldea[3], A. Marinello[3], J. Aredo[4], B. Besse[3], H. A. Wakelee[4], C. R. Lindsay[5], A. Malliri[1];

[1]Cancer Research UK Manchester Institute, Manchester, United Kingdom, [2]Department of Medical Oncology, The Christie NHS Foundation Trust, Manchester, United Kingdom, [3]Gustave Roussy, Paris, France, [4]Stanford University, Stanford, CA, [5]The Christie NHS Foundation Trust, Manchester, United Kingdom

Direct inhibitors of KRAS^{G12C} and more recently KRAS^{G12D} are currently under clinical evaluation and may represent the beginning of a major translational breakthrough for non-small cell lung cancer (NSCLC) and RAS addicted cancers in general, targeting the most commonly mutated oncogene in this disease. However early reports of resistance with inactive state-selective KRAS^{G12C} inhibitors have highlighted the pressing need for rational combination partners. While preclinical combination strategies to enhance KRAS^{G12D} inhibition and combat innate resistance have already been reported for pancreatic and colorectal cancer, the application of KRAS^{G12D} inhibitors alongside combination partners in KRAS^{G12D}-driven NSCLC has not been investigated. Here we compared KRAS^{G12C}- and KRAS^{G12D}-initiated lung tumorigenesis using isogenic genetically engineered mouse models and human and mouse cell models of KRAS^{G12C} and KRAS^{G12D}-driven NSCLC initiation to compare oncopotency and signaling of each subtype. We then examined whether signaling differences observed at initiation persist in established tumors. We identified that KRAS^{G12D} is more potent than KRAS^{G12C} in inducing tumor formation. This higher potency was accompanied by co-operative activation of the PI3K-AKT-mTOR signaling axis. Disruption of this pathway using either an AKT inhibitor or mTORC1-specific inhibitor (RMC-6272, a preclinical tool compound representative of the clinical candidate RMC-5552) led to a greater reduction in transformation and proliferation in a KRAS^{G12D}-driven lung initiation model compared to the KRAS^{G12C} counterpart. Although differences between these oncogenic phenotypes become less distinguishable once tumors are established, signaling dependencies and vulnerabilities are still preserved. For instance, KRAS^{G12C}-lung tumor cells are relatively more susceptible to ERK and MEK inhibition, while KRAS^{G12D}-lung tumor cells are more susceptible to AKT and mTORC1 inhibition. Inhibiting the PI3K-AKT-mTOR axis alongside KRAS^{G12D} inhibition (MRTX1133) induced a robust, synergistic apoptotic response in KRAS^{G12D} tumor cell lines of varying sensitivity to KRAS^{G12D} inhibition alone, highlighting a potential combinatorial approach to override intrinsic resistance to KRAS^{G12D} inhibitors. Our preclinical data identify treatment vulnerabilities and suggest patient selection strategies for combination approaches that should be i) contextualized to individual RAS mutants, and ii) tailored to their downstream signaling programs.

#1444 Modeling *Twist1* overexpression in a pancreatic ductal adenocarcinoma mouse model.

M. A. Khan[1], J. Chang[1], T. Nguyen[2], D. N. Council[1], D. Dutta Chowdhury[1], A. Shetty[1], Y. Song[1], A. Chan[1], C. Lam[2], P. Patel[1], L. Tran[1], J. Chen[2], K. Nugent[2], M. Ballew[2], G. Lemtiri-Chlieh[2], F. A. Carrieri[2], R. Malek[2], H. Wang[2], N. R. J. Thielman[3], K. Li[4], L. Zheng[2], K. Gabrielson[2], P. T. Tran[1], A. Lafargue[1]; [1]University of Maryland, Baltimore, MD, [2]Johns Hopkins University, Baltimore, MD, [3]Lake Erie College of Osteopathic Medicine, Erie, PA,, PA, [4]Sichuan university, Chengdu, China

Pancreatic ductal adenocarcinoma (PDAC) is an extremely lethal cancer characterized by very poor survival outcomes. Genomic sequencing of human PDAC tissues and cell lines have identified four molecular subtypes: quasimesenchymal (QM), pancreatic progenitor, immunogenic, and aberrantly differentiated endocrine exocrine (ADEX). QM-PDAC has the worse prognosis, but no *in vivo* models exist for this molecular subtype. Our preliminary analysis using publicly available data demonstrated that the epithelial-to-mesenchymal transition (EMT) transcription factor *TWIST1* is upregulated in QM-PDAC. We hypothesized that the *TWIST1*-dependent plasticity program was a key regulator of QM-PDAC subtype development. We created a tetracycline-inducible tissue specific *Twist1* PDAC genetically engineered mouse model (GEMM). Tumor development in the mouse pancreatic ductal epithelium was directed using the *Pdx1 promoter-Cre* (P) allele leading to stable native expression of the *LSL-Kras*^{G12D} oncogene (R) and *LSL-rtTA-IRES-GFP* (G) alleles. The non-*Twist1* GEMM (PGR) was crossed with the *Twist1-tetO-Luc* (T) mouse to create the PGRT model which allows inducible expression of *Twist1* and *luciferase* in pancreatic epithelium under doxycycline treatment (Tet-ON system). Tumor progression, lineage tracing and metastatic invasion are followed by fluorescence (GFP) and bioluminescence (BLI) imaging. The characterization of this novel PGRT mouse model showed decreased overall survival compared to control non-*Twist1* containing mice (~35 weeks PGRT (n=17) vs ~60 weeks PGR (n=10)). Histological and immunohistochemistry analyses showed the PGRT pancreatic tumors resemble the QM-PDAC subtype and vimentin overexpression correlates with *Twist1*-dependent induction of EMT. We attempted to confirm the QM-PDAC profile via cellular markers: GATA6-, HNF1A-, KRT81+, KRT17+, KRT20+, P63+ and ΔP63+. The PGR and standard KPC (*Kras*$^{+/LSL\text{-}G12D}$*; Trp53*$^{+LSL\text{-}R172H}$*; Pdx1-Cre*) PDAC model were also profiled. We observed that 75% of the PGRT tumors displayed a QM-PDAC profile, contrasting with the absence of such profile in both PGR and KPC tumors. Examining the tumors from PGR and KPC, 100% of the PGR and 72.27% KPC tumors exhibited a non-squamous PDAC profile while an intermediate squamous profile was observed in 25% PGRT tumors and 27.27% KPC tumors. Furthermore, *Twist1* induction resulted in intra-abdominal and lung metastases. We observed that 87.5% of the PGRT mice were positive for metastases while we observed no positivity for PGR mice and 63.64% positivity in KPC mice. In conclusion, these data suggest that *Twist1* overexpression cooperates with *Kras*^{G12D} for PDAC tumor development mimicking the human QM-PDAC subtype to promote progression towards metastasis and early lethality. Potential uses of this novel model include testing treatment strategies to ultimately improve patient outcomes with QM-PDAC.

#1445 Emergence of frameshift mutations during tumorigenesis in VCMsh2 mouse model of Lynch syndrome.

Y. Song[1], L. Wei[2], S. S. Baxter[1], B. Somerville[1], H. Loomans-Kropp[3], C. Sanders[1], R. N. Baugher[1], S. D. Mellott[1], T. B. Young[1], H. E. Lawhorn[1], T. M. Plona[1], Q. Hu[2], S. Liu[2], A. Hutson[2], S. Difilippantonio[1], L. Pinto[1], S. M. Lipkin[4], M. Kloor[5], S. Sei[3], R. H. Shoemaker[3];
[1]Frederick National Laboratory for Cancer Research, Frederick, MD, [2]Roswell Park Comprehensive Cancer Center, Buffalo, NY, [3]National Cancer Institute, Bethesda, MD, [4]Weill Cornell Medical College, New York, NY, [5]University of Heidelberg, Heidelberg, Germany

Monoallelic germline mutations in MMR genes (e.g., *MLH1*, *MSH2*, *MSH6*, and *PMS2*) predispose individuals to Lynch syndrome (LS) with microsatellite instability (MSI) throughout the genome. Mutations at coding mononucleotide repeats (MNR) usually result in frameshift mutations (FSMs). Recurrent FSMs are thought to play a central role in the increased risk of different types of cancer. Neoantigens produced by FSMs have been shown to elicit immune responses, which is the basis for frameshift neoantigen-based vaccines. To develop a prophylactic vaccine and prevention strategy for this high-risk population, we assessed FSMs during tumorigenesis from histologically normal mucosa and fecal DNA of a LS mouse model using targeted sequencing and a panel of FSMs in MNR regions. *Msh2*$^{LoxP/LoxP}$;*Villin-Cre* mice (VCMsh2) started developing detectable tumors at 7-8 months and median survival was 11.5 months with 100% penetrance. Interestingly, FSMs were detectable not only in tumors and mucosa at 7-8 months, but also in young mice (1 month), embryos and pups although FSMs detected and variant allele frequency (VAF) were very low, indicating that FSMs accumulated over time, and FSMs alone may be not sufficient for tumorigenesis since tumors emerge at older age. To determine whether Msh2 was absent in embryos and pups, immunohistochemical (IHC) analysis was performed. Msh2 was lost in almost all intestine epithelial cells in 2-month-old mice but still present in young pups and embryos with very few cells absent of Msh2, indicating that emerging FSMs in these young pups may be due to decreased Msh2 expression because of delayed Cre function. To determine whether low Msh2 expression could lead to the emergence of FSMs, intestine mucosa from 8-, 10-, and 12-month-old *Msh2*$^{LoxP/+}$;*Villin-Cre* heterozygous mice was sequenced. FSMs were detectable with low VAF, although they didn't develop tumors. IHC staining revealed that Msh2 was absent in only a few intestine epithelial cells in these heterozygous mice, suggesting that loss of heterozygosity was a late event and rare at 12 months. To determine whether MSI emerged in young VCMsh2 pups and heterozygous mice due to haploinsufficiency of *Msh2*, MSI was assessed using seven markers and fragment size analysis. One marker (mBat67) showed instability in the intestinal mucosa of heterozygous mice and three showed instability in fecal DNA of one month old VCMsh2 mice. Interestingly, mucosal and fecal samples from a time course study in VCMsh2 mice showed progressive increase in MSI with a good correlation between MSI and FSMs during the tumorigenesis process. In summary, FSMs emerged at an early stage of tumorigenesis in VCMsh2 mice, which correlated with MSI status. Our data indicates that FSMs and MSI status can be used to monitor the tumor development of LS colorectal cancer.

#1446 Gastric cancer with microsatellite instability: Ex vivo generation of syngeneic mouse models.

Daniela Conticelli[1], Gabriele Picco[2], Cristina Migliore[1], Claudia Orru[1], Fabrizio Maina[3], Emanuela Boccuni[1], Simona Corso[1], Silvia Giordano[1]

[1]Department of Oncology, University of Turin, Candiolo Cancer Institute, FPO-IRCCS, Candiolo, Italy,[2]Wellcome Sanger Institute, Hinxton, United Kingdom,[3]Candiolo Cancer Institute, FPO-IRCCS, Candiolo, Italy

The DNA mismatch repair (MMR) system is a highly conserved pathway crucial for maintaining the genomic integrity. MMR impairment in sporadic tumors is due to *MLH1* epigenetic silencing or mutations in other MMR genes (such as *MSH2, MSH6, PMS2*) and leads to microsatellite instability (MSI). Two independent molecular classifications reported the existence of a MSI subgroup in gastric cancer (GC), including 22-23% of all cases. GC MSI inter and intra-tumoral heterogeneity represents a significant challenge for precise patient stratification and treatment. Even if MSI status in GC is usually associated with a good prognosis, some reports described a subpopulation of MSI GC patients displaying a worse outcome. Moreover, while clinical trials testing immune checkpoint inhibitors in MSI tumors showed effectiveness across all treatment lines, the outcomes in GC patients were not as remarkable as in other cancer types. From the analysis of MSI GC patients enrolled in phase III clinical trials testing anti-PD1 monotherapy, it emerged that nearly half of the tumors are intrinsically resistant and complete and long-lasting responses are achieved in very few cases. Tumor mouse immunocompetent models allow to mimic the complex interactions between a fully functional immune system and a developing tumor. MSI GC syngeneic mouse models could thus represent a valuable tool to better understand the molecular complexity and predict the clinical behavior of this subgroup. To obtain MSI GC mouse models, we generated non-transformed organoids from normal gastric mucosa of BALB/c mice as a starting point for the induction of a neoplastic transformation *ex vivo*. To induce MMR deficiency, we inactivated either *Mlh1* or *Msh2* genes using CRISPR/Cas9 genome editing. Importantly, we did not introduce any other alteration in known oncogenes and tumor suppressor genes, thus allowing the natural emergence of driver mutations in the context of the genetic instability. Over time, MMR deficient models, but not the WT controls, exhibited MSI and increased their mutational burden. Furthermore, when cultured in stringent culture conditions (two-dimensional culture, growth factor deprivation), only MMR deficient cells generated tumor masses upon subcutaneous injection in immunodeficient NOD SCID mice. Importantly, cells retrieved from the tumor masses (n = 8) exhibited mutations in a relevant fraction of genes associated with the MSI subgroup by TCGA (21 out of 35) – including *Kras, Arid1a, Erbb3* and *Tpr53* – thus offering a good representation of the human MSI GC mutational landscape. Given the immunogenicity of the Cas9 protein, we finalized our models optimizing the genome editing protocol to avoid a persistent Cas9 expression. Cas9-free MMR deficient models were able to generate tumors in immunocompetent BALB/c mice, thus representing a valuable resource to investigate tumor development, progression and responses to immunotherapy *in vivo*.

#1447 Development of advanced preclinical modeling for a comprehensive characterization of cardiac angiosarcoma biology.

Rosalba Minelli, Luigi Perelli, Benjamin J. Bivona, Sanjana Srinivasan, Desiree Catania, Bianca E. Amador, Frederick S. Robinson, Johnathon L. Rose, Christopher T. Terranova, Alejandro Hernandez Martinez, Charles E. Deckard, Courtney N. Le, Kuo-Shun Hsu, Michael Peoples, Aparna Subramaniam, Hannah C. Beird, Ningping Feng, Joseph R. Daniele, Christopher Vellano, Joseph Marszalek, Vinod Ravi, Alexander J. Lazar, Andrew Futreal, Timothy P. Heffernan, Giannicola Genovese, Virginia Giuliani

UT MD Anderson Cancer Ctr., Houston, TX

Cardiac angiosarcoma (CAS) is an extremely rare malignant cardiac tumor known for its propensity for early metastasis and poor prognosis. CAS frequency is around 1-2% of all angiosarcoma cases and mostly arise in the right atrium. At present, there are no effective treatments and the survival rate is less than 10% at 5 years. Furthermore, the dearth of preclinical models has limited the advancement of biological insights into CAS. To address this challenge, we developed a somatic mosaic genetically engineered mouse model (smGEMM) with the aim of accurately mirroring the biological features of CAS. This model will be a crucial instrument for acquiring in-depth insights into the disease and steering the development of impactful therapeutic strategies. To develop a CAS smGEMM, we leveraged an endothelial-specific CRE recombinase to activate a fluorescent reporter in a tissue-dependent manner and CRISPR/Cas9 technology to engineer somatic drivers of CAS tumorigenesis. Using this strategy, all endothelial cells express tdTomato fluorescent reporter and spCas9. We then administered adeno-associated viral (AAV) particles carrying selected tandem sgRNAs with two different approaches: a direct approach where AAV particles were administered by ultrasound-guided injection in the cardiac wall of the smGEMM; and an *ex-vivo* approach where primary endotheliocytes derived from cardiac tissue of our smGEMM were first transduced with AAV particles *in vitro*, and then transplanted orthotopically by ultrasound-guided injection. With the latter strategy, we successfully generated the first cardiac angiosarcoma model that faithfully recapitulates angiosarcoma features, including lung dissemination. Cell lines from primary and metastatic tumors were also established, characterized and utilized for genome-wide CRISPR Cas9 screening. Current efforts are focused on prioritizing hits for validation, aiming to glean insights that can inform potential therapeutic strategies.

#1448 Investigating the effects of estrogen on the initiation of prostate cancer.

Nash S. Denic, Ashlyn Swift-Gallant, Kenneth R. Kao

Medicine, Memorial University of Newfoundland, St. John's, NL, Canada

Background: Prostate cancer (PCa) is responsible for ~10% of cancer-related deaths in men. *Nkx3.1* is an androgen-regulated gene expressed primarily in the prostate, which encodes a tumor suppressor protein important for male reproductive development. Loss of nkx3.1 is thought to lead to prostatic intraepithelial neoplasia (PIN), the pre-invasive form of prostatic adenocarcinoma. Previous evidence suggests that estrogenic dysregulation and testosterone imbalance play a significant role in PCa initiation and progression.

Objectives/Aims: We aimed to investigate how estrogen impacts the progression of PIN in the anterior prostate of mice lacking nkx3.1.

Methods: To investigate the effect of long-term exposure to 17β-estradiol (E2), nkx3.1$^{+/+}$ and nkx3.1$^{-/-}$ 12-week-old mice were given 2 mg/day of E2 over 90 days by subdermal implantation of 90-day extended-release tablets. After 90 days, the anterior prostate lobes of the mice were harvested and analyzed post-treatment for signs of pre-cancerous tissue. The immediate, early effect of E2 exposure was also investigated by the subcutaneous injection of 8- and 20-week-old mice with 0.300 mg/kg of E2. Within two hours, the anterior prostate lobes were harvested, and ~500 ng/µL of RNA was isolated from the tissues. cDNA was reverse-transcribed, in triplicate, from the RNA and the expression of c-myc, p53, estrogen receptor ERα (ESR1), and ERβ (ESR2) were assessed via qRT-PCR. Three technical replicates from three biological replicates were performed for each treatment.

Results: Nkx3.1$^{-/-}$ mice chronically exposed to elevated E2 developed PIN following E2 treatment, while the placebo group had tissue hyperplasia. Nkx3.1$^{+/+}$ mice had normal prostate tissue regardless of E2 treatment. In response to immediate exposure to E2, the prostates of 8-week-old nkx3.1$^{+/+}$ mice showed reduced c-myc expression. 8-week-old nkx3.1$^{-/-}$ mice showed no changes in expression of any of the four genes assayed, in response to E2 as compared to the placebo treatment. In contrast, regardless of exposure to E2, c-myc, p53, and ESR2 were significantly elevated in these mice compared to the nkx3.1$^{+/+}$ groups. Furthermore, c-myc and p53 expression was suppressed in 20-week-old nkx3.1$^{-/-}$ mice in response to E2, while ESR1 and ESR2 remained unchanged.

Conclusion: Our evidence suggested that prolonged exposure of wild-type mice to E2 had no pathohistological impact on the anterior prostate tissue. In nkx3.1-deficient mice, however, E2 exposure promoted the onset of PIN, and caused immediate differential expression of estrogen-responsive genes, suggesting a role of nkx3.1 in protecting the prostate in the presence of a hormonal imbalance.

#1449 Targeting squalene epoxidase for breast cancer brain metastasis: The evaluation of a new therapeutic target for brain extravasation and colonization using animal models.

P. Y. Lee[1], K.-Y. Lin[1], C.-D. Chang[1], S.-Y. Cheng[1], Y.-W. Hung[1], C.-C. Yang[1], Y.-H. Chang[1], C.-C. Shen[1], J.-Y. Yeh[2], Y.-L. Yu[2], S.-P. Wang[3];
[1]Pharmacology Discovery Services Taiwan, Ltd., New Taipei City, Taiwan, [2]China Medical University, Taichung, Taiwan, [3]Academia Sinica, Taipei, Taiwan

Breast cancer brain metastasis is one of the most common forms of breast cancer metastasis and a major cause of morbidity and mortality. Patients who develop brain metastases tend to be associated with progressive neurologic deficits and short overall survival, which represents an unmet medical need. Extensive research has been conducted to elucidate the mechanism of cancer metastasis with limited information gained as to how cancer cells extravasate and colonize to the brain. Recently, we identified a novel mechanism by which squalene epoxidase (SQLE), the second rate-limiting enzyme in cholesterol biosynthesis, plays a critical role in the process of breast cancer metastasis to the brain. Thus, toward a better understanding of the underlying molecular mechanisms and applications of molecular target(s) for brain metastasis therapy, murine models were employed for investigation of brain extravasation and colonization with intracardiac or direct intracranial injections of GFP/FLuc-labeled human MDA-MB-231 metastatic breast carcinoma cells. The MDA-MB-231 cells were found to metastasize to the brain and other organs following intracardiac implantation into nude mice and were further isolated from each tissue. Interestingly, the isolated brain-metastasized tumor cells (MDA-MB-231-BrM) exhibited a significant upregulation of SQLE expression when compared with those that metastasized to other distal sites. The essential role of SQLE in the specific steps of the breast cancer-to-brain metastatic process was evaluated by *ex vivo* immunofluorescence analysis and immunohistochemistry staining of brain slices from the study subjects. Our data demonstrate that high SQLE expression is essential for MDA-MB-231-BrM to extravasate into the parenchyma, as well as the formation of micro- and macro-metastases in the brain. Interestingly, we found that blood vessel co-option and the surrounding neuronal cells play key roles in supporting MDA-MB-231-BrM to develop brain macro-metastases. *In vitro* blood-brain barrier (BBB) models further demonstrated the critical role of SQLE in promoting tumor cell invasion and penetration through the BBB. To verify SQLE as an oncogenic factor that can be selected as a potential therapeutic target in suppressing breast cancer brain metastasis, we evaluated the inhibitory effects of terbinafine (a SQLE inhibitor) in both the MDA-MB-231-BrM orthotopic and intracardiac mouse models. Pharmacologic inhibition of SQLE by terbinafine suppressed MDA-MB-231-BrM tumor growth at the mammary fat pad and distal metastases to the brain, suggesting that targeting SQLE represents a therapeutic opportunity for breast cancer brain metastasis.

#1450 Novel whole slide imaging modes for imaging mass cytometry reveal cellular and structural composition of mouse glioblastoma.

Q. Raza, N. Zabinyakov, **T. D. Pfister**, N. Parsotam, D. Howell, L. Lim, C. Loh;
Standard BioTools, Markham, ON, Canada

Mouse tumors have become widely used models in translational research of brain malignancies, helping to address the difficulties related to studying the human brain. Mouse brain can be regarded as a miniaturized model of the human brain, permitting visualization of the whole tissue to provide spatial cellular context. Imaging Mass Cytometry™ (IMC™) is a highly relevant tool capable of quantitative evaluation of the multiparametric protein composition in brain tumor microenvironment (TME) without the complications of autofluorescence, tissue degradation, and spectral overlap. The Hyperion XTi™ Imaging System (Standard BioTools™) utilizes IMC technology to simultaneously assess more than 40 individual structural and functional markers in tissue, providing insight into the organization and function of the TME.

We demonstrate the whole slide imaging (WSI) application using a 40-marker panel composed of the Maxpar OnDemand™ Mouse Immuno-Oncology IMC Panel Kit and the Maxpar® Neuro Phenotyping IMC Panel Kit on mouse normal and glioblastoma (GBM) brain tissue. The panel was composed of mouse-specific antibodies, which highlight tumor and immune components of the mouse TME. We performed imaging using two new features of Hyperion™ XTi. Ultrafast preview mode (PM) was applied to rapidly screen entire brain sections for marker expression signatures associated with various immuno-oncology processes. This enabled biomarker-guided selection of areas in tumor tissue that were imaged using region of interest-based IMC and analyzed using single-cell analysis (SCA). In parallel, a high-throughput tissue mode (TM) was applied to perform a detailed whole-slide scan of normal and GBM mouse brain tissues that were quantified using pixel-based analysis (PBA) to unravel the composition of the TME.

Using TM, we were able to successfully visualize the entire coronal and sagittal sections of normal mouse brain as well as mouse GBM tissue. PBA on TM data provided quantitative spatial expression patterns of structural and immune markers across the whole tissue. In normal tissue, we visualized the highly organized structure of the normal brain and detected neurons, oligodendrocytes, vascular-adjacent astrocytes, and axonal tracks. In GBM tissue, necrotic cores, areas with high immune infiltration, extracellular matrix deposits, and activated tumor cells were detected. SCA of GBM tissue demonstrated expansive vascularization, replicating $Olig2^{+}$ cells, activation of Ras signaling, and high abundance of infiltrating immune cells.

Overall, we demonstrate the successful application of two novel WSI modes and highlight the power of IMC technology to simultaneously explore dozens of relevant biological outputs to better understand the TME of GBM and other tumors.

For research use only. Not for use in diagnostic procedures.

#1451 Replication repair deficient mouse models provide insights into gliomagenesis and response to immunotherapy.

Z. Aamir[1], M. Galati[1], E. Gattoni[1], O. Crump[1], N. M. Nunes[1], A. Das[1], N. Fernandez[1], N. Fernandez[1], A. K. Q. Wong[2], J. Fortin[3], L. Stengs[1], V. Bianchi[1], M. Edwards[1], L. Negm[1], C. Hawkins[1], D. Malkin[1], S. Egan[1], U. Tabori[1];

[1]The Hospital for Sick Children, Toronto, ON, Canada, [2]Queen's University, Kingston, ON, Canada, [3]Princess Margaret Cancer Centre, Toronto, ON, Canada

Background: Replication Repair Deficiency (RRD), caused by germline monoallelic (Lynch Syndrome) or biallelic (Constitutional Mismatch Repair Deficiency, CMMRD) mutations in MMR genes, is present in 5-10% of glioblastomas in children, adolescents, and young adults. RRD glioblastomas are chemoradiation-resistant, but respond favorably to immune checkpoint inhibition (ICI). Representative immunocompetent animal models are urgently needed for 3 recently identified subgroups based on specific somatically-acquired mutations, survival, and immunotherapy response (RRD1: MMRD with *POLE* mutations, RRD2: MMRD associated with *TP53* mutations, and RRD3: MMRD harboring *IDH1* mutations).

Methods: Using germline mutations and brain-specific *Cre*-drivers, we genetically engineered mouse models that recapitulate each human RRD-subgroup.

Results: All mouse models robustly developed brain tumors displaying phenotypic variation.

RRD1 (*Nestin-* and *Olig2-Cre*$^{+}$*/ Msh2*$^{LoxP/LoxP}$*/Pole*$^{S459F/+}$ and *LSL-Pole*$^{P286R/+}$): CMMRD-like *Nestin-Cre*-driven mice develop posterior-fossa glioma-like or embryonal (EB)-like tumors at ~2.7 months. *Olig2-Cre*-driven mice display hemispheric gliomas at ~10 months, suggesting distinct cell-of-origin.

RRD2 (*Nestin-Cre*$^{+}$*/Trp53*$^{LoxP/LoxP}$ and *Msh2*$^{LoxP/LoxP}$ or *Mlh1*$^{-/-}$): tumors develop primarily in the hindbrain in germline *Mlh1* mice, and majority arise in the forebrain of *Nestin-Cre/Msh2* mice, highlighting the timeline of mutagenesis. Strikingly, germline *Mlh1* tumors occur earlier than *Nestin-Cre*-driven RRD2 tumors, indicating early developmental mutation accumulation in CMMRD-patients. Lynch-like RRD1/2 mice succumb exclusively to gliomas >13 months ($p<0.0001$).

RRD3 (*Olig2-Cre*$^{+}$*/Msh2*$^{LoxP/LoxP}$*/Trp53*$^{LoxP/LoxP}$*/LSL-Idh1*$^{R132H/+}$): mice succumb to brain tumors at >11 months and are hemispheric.

Significance: These observations recapitulate human data, where CMMRD-patients develop glioblastoma/EB earlier than Lynch-patients (8.6 vs. 14-years; $p<0.0001$), and posterior-fossa glioblastoma/EB presents earlier than hemispheric gliomas ($p=0.04$). Additionally, tumor onset and location vary by subgroup (RRD1: 7.6-years, RRD2: 8.3-years, both hemispheric/posterior-fossa; RRD3: 12-years, hemispheric; $p=0.005$). In both mice and humans, RRD1 exhibits ultra-hypermutation, high immune infiltration, and response to ICI, whereas RRD2 harbors lower mutational burden, are immune-cold, and ICI-monotherapy resistant. Temporal dynamics of RRD tumor development is currently being tracked by serial MRI to define previously undetermined biologically relevant time points of tumor progression.

Conclusion: Our models accurately mimic the human condition and provide unique insights into RRD tumorigenesis, allowing optimization of subgroup-tailored therapeutic approaches.

#1452 A *PIK3CA*-driven mouse model of metaplastic breast carcinoma to assess potential therapeutic strategies.

P. Roa[1], V. Foglizzo[1], M. R. de Marchena[1], S. Chandthakuri[1], E. Cocco[1], P. Castel[2];
[1]University of Miami Miller School of Medicine, Miami, FL, [2]NYU Grossman School of Medicine, New York, NY

Metaplastic Breast Carcinomas (MBC) are rare and aggressive breast cancers with mesenchymal or squamous components. While histologically heterogeneous, MBC are typically triple negative: they lack expression of ER, PR and HER2. Importantly, approximately 40% of MBC harbor oncogenic gain-of-function mutations in *PIK3CA*, the gene encoding for the catalytic subunit of PI3K. These alterations are targetable by an array of inhibitors of the PI3K-AKT-mTORC1 pathway. However, few animal models of MBC are available, and it is currently difficult to study MBC biology and response to therapy. Here, we describe the generation of a new mouse model of MBC driven by the *PIK3CA* H1047R mutation. We histologically and biologically characterize this model and assess potential therapeutic strategies. We used genetically-engineered mouse models to express the human *PIK3CA* H1047R mutation under the control of the MMTV promoter, which is mostly expressed in the mammary epithelium. Tumors developed in mice in about 1 year. We histologically characterized these tumors and generated cell lines, organoids, and tumor grafts in immunocompromised mice. The resulting model, termed MMTV-102, was evaluated for the response to PI3K-AKT-mTOR pathway inhibitors, both *in vitro* and *in vivo*. The MMTV-PIK3CA^{H1047R} tumor was a high grade poorly differentiated MBC negative for ER, PR, and HER2. It presented squamous components, keratin depositions, mitotic figures, and vascular invasion and stained positive for the basal marker CK14. In addition, due to the presence of the *PIK3CA* H1047R mutation, it stained positive for phosphorylated AKT, PRAS40, and S6RP, indicating constitutive activation of the PI3K-AKT-mTORC1 pathway. MBC derived cell lines and organoids were confirmed to be triple negative and could form tumors in mice. In addition, these cellular models were sensitive to PI3Kα, pan-PI3K, and mTORC1 inhibitors *in vitro* and *in vivo*, but the mTORC1 inhibitor everolimus exhibited the strongest effect. When resistance to everolimus eventually developed *in vivo*, we established cell lines from these resistant tumors. In addition, we generated an everolimus resistant cell line following chronic drug exposure *in vitro* (MMTV-102 Par res). Both cellular models were tested for their sensitivity to the next-generation mTORC1 inhibitor RMC-5552 by proliferation and clonogenic assays. We show that our mouse model can originate MBC with an active PI3K pathway. These tumors are amenable to transplantation into immunocompromised mice and to generate cell lines and organoids, allowing us to develop a simple, versatile, and rapid model of MBC. Tumors derived from our model are sensitive to PI3Kα and mTORC1 inhibitors, but eventually develop resistance to these agents. The use of next-generation mTORC1 inhibitors can overcome resistance in some cases, providing a rationale for their implementation in the treatment of patients with MBC.

#1453 Development and evaluation of subcutaneous and orthotopic PC3M metastatic prostate cancer xenograft model in SRG rats for therapeutic assessment.

K. Draheim, E. Rainbolt, B. John, C. Clouse, K. Shinn, J. Avery, K. Aw Yong, C. Hall, P. Fadden, **A. Avrutskaya**;
Charles River Laboratories, Inc., Wilmington, MA

Introduction: Prostate cancer is the most prevalent cause of cancer deaths in American males after lung cancer. The establishment of clinically relevant prostate cancer models is crucial for advancing our understanding of the disease and evaluating potential therapeutics. Oncology studies in rats provide a secondary species to mice with the advantage of extensive longitudinal blood sampling and tumor biopsies in pharmacodynamics analysis. This *in vivo* study evaluates the behavior of subcutaneous and orthotopic luciferase (luc) tagged metastatic PC3M-luc cells in immunodeficient SRG rats (Hera Biolabs) for tumor growth kinetics, metastasis, and response to paclitaxel and carboplatin alone and in combination.
Methods: PC3M-luc cells were implanted subcutaneously into the right flank or orthotopically into the prostate of SRG rats. Subcutaneous tumor progression and treatment responses were monitored using calipers and bioluminescent imaging (BLI), with the capacity to detect developing metastases prior to necropsy. Orthotopic implants were monitored exclusively using BLI. Tolerability was evaluated based on biweekly changes in body weight, daily observations for signs of tumor- or treatment-related clinical signs, necropsy results, and complete blood count (CBC) and clinical chemistry marker comparisons with immunocompetent CD rats.
Results: PC3M-luc prostate carcinoma was successfully established orthotopically and subcutaneously in SRG rats, with similar growth rates and the development of spontaneous metastases to distant organs, modeling metastases observed in prostate cancer patients. Paclitaxel treatment was less tolerated in SRG rats in comparison to nude rats, enhanced toxicity was observed when combined with carboplatin. Comparison of CBC and clinical chemistry blood markers in naïve immunocompetent CD and immunodeficient SRG rats differed mainly in White Blood Cell (WBC) counts that were significantly lower in SRG rats, as expected due to the lack of mature B, T, and NK cells in these animals.
Conclusion: The development of orthotopic and subcutaneous PC3M-luc prostate cancer models in rats provides a valuable alternative platform for assessing the effectiveness of established and novel therapies. This rat-based models offers a secondary species for comparison of prostate cancer behavior in mice, successfully mimics the clinical development of metastases, and provides additional insights into disease progression and therapeutic strategies. Future studies will focus on the assessment of tolerability and combination therapy strategies for improved treatment outcomes.

#1454 Expanding the therapeutic application of PARP inhibitor: AI evaluation of real-word clinico-genomic data from spontaneous canine tumors.

L. Rodrigues[1], K. Wu[2], G. Harvey[1], G. Post[1], A. Hull[1], A. Miller[1], L. Lambert[1], C. Lopes[1], J. Zou[2];
[1]FidoCure - One Health Company, Palo Alto, CA, [2]Department of Biomedical Data Science, Stanford University, Stanford, CA

The widespread application of Poly-ADP ribose polymerase (PARP) inhibitors in anti-cancer therapy is constantly increasing their role as a treatment strategy across various neoplasms, the majority of which are linked with BRCA deficiency. While the most significant advantages are observed in cancers with BRCA1/2 mutations, it is evident that the benefits extend beyond this specific group. Preclinical evidence encourages the exploration of PARP inhibitors in neoplasms demonstrating BRCAness or homologous recombination deficiency (HRD), both as monotherapy and in combination with chemotherapy. This study employs spontaneous canine tumors as a complementary model for cancer research, aiming to seamlessly bridge the transition from preclinical investigations to clinical application. Leveraging the FidoCure® Precision Medicine Platform, we identified biomarkers associated with prognosis and treatment prediction, specifically with the PARP inhibitor olaparib, facilitating a smoother translation from laboratory findings to practical clinical use. Analyzing real-world clinico-genomic data from 1278 dogs with cancer revealed intriguing insights of specific targeted treatments developed for humans showing a positive prognosis when applied to canine tumors with specific genomic alterations. Notably, olaparib exhibited efficacy in TP53 and BRCA1-mutated cases (OS HR 0.34, $P < 0.001$; HR 0.39, $P = 0.004$), while rapamycin (mTOR inhibitor) demonstrated promising outcomes in TP53 and RB1-mutated canine tumors (OS HR 0.73, $P = 0.028$; HR 0.32, $P = 0.024$). Further stratification by tumor types unveiled noteworthy correlations. TP53 mutant osteosarcomas exhibited improved prognosis with olaparib treatment (OS HR 0.11, $P < 0.001$), and soft tissue sarcomas with TP53 mutations demonstrated favorable responses to rapamycin and olaparib therapy (OS HR 0.11, $P = 0.012$; HR 0.07, $P = 0.011$). These findings underscore the potential of leveraging canine tumor models and clinico-genomic analyses to inform targeted treatment strategies, offering valuable insights for advancing precision medicine in both veterinary and human oncology. Further investigation into the association between TP53 mutation and olaparib response is warranted. The intriguing aspect lies in the role TP53 mutation has been linked in previous studies to heightened chromosomal instability and elevated HRD scores. Utilizing real-world evidence and data tools within the FidoCure dataset, we have effectively pinpointed correlations between gene mutations and survival, particularly in relation to responses to targeted therapy treatment. Canine models, mirroring human diseases with intact immune systems and comparable tumor genomic profiles, as verified by the FidoCure database, expedite clinical studies of novel treatments that face significant scalability challenges.

#1455 *In vitro* blood brain barrier model for evaluation of brain metastasis.

S. Noda-Narita, A. Aiba;
The University of Tokyo, Tokyo, Japan

Introduction: Brain metastasis significantly reduces the patient's quality of life and survival, but there are only a few choices of treatment for brain metastasis. The research for brain metastasis is difficult because of its complex and unique microenvironment, including blood-brain barrier (BBB). The BBB maintains strong cell adhesion of the vascular endothelial cells (ECs) to protect the brain parenchyma. The BBB is composed of three cell types: vascular endothelial cells, pericytes, and astrocytes. As the role of pericytes in maintaining the BBB function has become more evident, the reconstituted models of the BBB in which ECs, pericytes, and astrocytes are seeded on the front and back of the insert membrane have gotten our attention. In the field of cancer, the role of not only ECs but also wall cells, corresponding to pericytes in the brain, has been focused on. In this study, we aimed to create the *in vitro* BBB models and elucidate the interaction of the BBB and the metastasizing cancer cells.
Methods: We applied a reconstituted model of the BBB consisting of ECs, pericytes, and astrocytes of human immortalized cells (Ito R, et al. *Mol Pharm* 2019) and created the co-culture system for evaluating brain metastasis. We constructed four co-culture systems and compared the migration ability of MDA231 in those models: EPA model (ECs, pericytes, and astrocytes), E0A model (ECs and astrocytes), EP0 model (ECs and pericytes), and E00 model (ECs only). We also analyzed the migration ability of the pairs of parental and brain metastatic (BrM) cell lines.
Results: The BBB reconstituted model (EPA model), in which ECs were co-cultured with pericytes and astrocytes, showed higher trans-epithelial electrical resistance and lower permeability than the other co-culture models. When cancer cells were seeded, the EPA model strongly inhibited metastatic invasion of cancer cells compared to the other models. It suggests that both pericytes and astrocytes are essential for regulating cancer cell invasion. In addition, when the BrM cells of MDA231 and Ex3LL were seeded, the BrM cells invaded the EPA model more easily than the parental cells. It indicates that this model can reproduce *in vivo* brain vascular functions.
Conclusion: We created the BBB reconstituted model which mimics the brain vascular microenvironment. This model reproduced the *in vivo* BBB function to protect brain from cancer cells and evaluated the brain metastatic ability of the cancer cells. Using this model, we showed that pericytes and astrocytes were essential for the BBB barrier function against the cancer cells. We need further investigation to elucidate the mechanism of brain metastasis using this BBB model.

#1456 First successful engraftment of human liver cancer cell line in highly robust immunocompromised porcine model to test the tumor ablation efficacy by histotripsy.

T. Paul[1], K. Imran[1], J. Gannon[1], B. Trusiano[1], K. Eden[1], H. Ivester[1], M. Mott[1], M. Powar[1], M. Edwards[1], C. Byron[1], S. Clark-Deener[1], K. Lee[2], E. Vlaisavljevich[1], I. Allen[1];

[1]Virginia Tech, Blacksburg, VA, [2]University of Missouri, Columbia, MO

Liver tumor, commonly called Hepatocellular carcinoma(HCC), is the most common type of primary liver malignancy. It is the fourth leading cause of cancer-related deaths. Late diagnosis, location of the tumor, tumor burden, and metastases makes liver tumor very challenging to treat by liver transplantation, surgical procedures, and other ablation techniques like cryoablation and thermal ablation. Also, the absence of a preclinical animal model makes it challenging to develop and explore the feasibility of treatment modalities. Histotripsy is a non-invasive, non-ionizing, non-thermal, image-guided focused ultrasound ablation treatment method that uses high-pressure pulses to create acoustic cavitation, a “bubble cloud,” at the target. The bubble cloud expands and collapses, which ablates the tissue into an acellular homogenate. Pigs are ideal animal models as they closely resemble human anatomy and are significant in improving the translation to human patients. This study aimed to establish the feasibility of successfully ablating liver tumors by histotripsy using an immunocompromised porcine model to generate HepG2 human liver cancer cell line tumors in the liver of the immunocompromised pigs. The orthotopic porcine model was established using RAG2/IL2RG double knockout immunocompromised pigs. HepG2 cells were injected orthotopically into the liver of immunocompromised pigs. Three weeks after the injections, CT images and necropsy indicated successful engraftment and growth of liver tumors in the pigs. The ultrasound images and post-histotripsy treatment histology images showed confirmed ablation zones in the liver. Therefore, in conclusion, our preliminary results in the study could demonstrate, for the first time, a highly robust model of human liver cancer in a large animal model. Soon, we plan to conduct more such studies and explore all the possible utilities of these immunocompromised porcine models to develop therapeutic strategies to increase the efficacy of liver tumor ablation by histotripsy.

#1458 Anti tumoral role of PDX1 on pancreatic ductal adenocarcinoma aggressiveness.

J. Mosna, F. Garde, M. Stinson, C. Pastore, P. Sanchis, A. Carcagno;
CONICET - IQUIBICEN, Buenos Aires, Argentina

Pancreatic ductal adenocarcinoma (PDAC) represents a very aggressive type of pancreatic cancer (9% survival rate at 5 years). PDX1 is an important transcription factor for embryonic development of the pancreas, endocrine lineage differentiation and the maintenance of mature beta cells. Notably, in PDAC patients, the expression of PDX1 is downregulated in tumor cells compared to adjacent non-tumoral tissue. Interestingly, increasing tumor PDX1 expression has been shown to enhance the overall survival rate in PDAC patients. Therefore, our aim was to analyze the role of PDX1 on tumor aggressiveness of PDAC cells. To induce PDX1 expression, PANC1 cells were treated with BRD7552 (a PDX1 inducer) for 9 days. Overexpression of PDX1 was confirmed by Western Blot analysis and no cytotoxic effects were observed by MTT or Trypan Blue exclusion assays on treated cells compared to control. Wound healing and transwell migration assays showed a significant reduction in the migration rate compared to the control group. A higher proportion of cells in G1 phase was observed in treated cells compared to control by propidium iodide staining followed by flow cytometry assay. Furthermore, the cell confluence assay showed a significant reduction in proliferation rate in treated cells compared to control, but no differences were observed on the proportion of $KI67^{+}$ and $PH3^{+}$ cells by immunostaining. To assess the *in ovo* effects of BRD7552, treated PANC1 cells were implanted onto the chorioallantoic membrane of chick embryos and tumor growth was measured at different stages observing a significant reduction in tumor growth in PANC1 cells compared to control between days 3 and 8 post implantation. No significant differences in morphology or color were observed between treated and control implanted cells. Hematoxylin-eosin staining showed reduced invasion of treated cells into the chorioallantoic membrane compared to control. In conclusion, the overexpression of PDX1 affects cell cycle, reduces proliferation rate and inhibits migratory potential *in vitro*. Moreover, in an *in ovo* model this overexpression diminished tumor growth and invasion in PANC1 cells. In conclusion, the overexpression of PDX1 induced by BRD7552 drives pancreatic ductal adenocarcinoma to a less aggressive tumoral phenotype.

#1459 The immuno-AVI-PDX, am innovative patient-derived xenograft model for preclinical immuno-oncology studies.

M. Lacourrege, Jr., C. Costechareyre, Jr., L. Jarrosson, Sr., **R. Teinturier, Sr.**, F. Berget, Sr., C. Delloye-Bourgeois, Sr., V. Castellani, Sr.;
ONCOFACTORY, Lyon, France

Over the last decade, the success of immunotherapy in treating numerous solid and hematological tumors is unprecedent. However, the poor preclinical predictive power of current model systems explains in part the failures during late-stages clinical drug development for the numerous potential immunotherapies. Thus, there is a crucial need for innovative technologies offering fast and reliable evaluation of immunotherapies on patient-derived models. Using its proprietary process of micro-implantation of patient tumor cells within selected organs of series of avian embryos, Oncofactory developed two humanized avian xenograft models, namely IMMUNO-AVI-patient derived xenograft (iAVI-PDX™) and IMMUNO-AVI-cell line derived xenograft (iAVI-cellDX™). These models, consisting in the co-implantation of human peripheral-blood mononuclear cells (PBMC) and human cancer cells were validated through a sequence of experimental steps. First, we found that transplantation of PBMCs into avian tissues exhibited good survival and low allogenicity against the avian embryonic organism. Second, in embryos engrafted with tumoral cells, we established that intravenously injected PBMCs successfully populated the tumor. Third, to reduce the dilution of immune cells in the embryonic tissues and to better standardize the number of implanted cells in between embryos, we optimized the process by direct co-implantation of both PBMCs and cancer cells. We analyzed the immune cell contingent sorted from dissected tumors and found that all major immune cells populations, including T and B lymphocytes, monocytes as well as NK cells were preserved post-grafting, when compared to pre-grafted PBMCs. The AVI-cellDX™ and AVI-PDX™ models initially developed by Oncofactory allows fast and reproducible tumor growth with statistical evaluation of molecule efficacy already at 24 hours post-injection. To assess whether our humanized models retain these advantages, we analyzed the outcome of anti-PD1 antibody (Pembrolizumab) intravenous injection in series of avian embryos co-engrafted with human PBMCs and PDL1-expressing breast and colorectal cancer cell lines. Twenty-four hours post vehicle or Pembrolizumab exposure, we analyzed the tumor volumes in grafted embryos using light sheet microscopy. In all three cancer models, we found a statistically significant reduction of the volume upon pembrolizumab, compared with vehicle. Using a panel of molecular markers in flow cytometry, we found that the Pembrolizumab efficiently targeted T lymphocytes in the tumors. Finally, we validated the efficiency of Pembrolizumab treatment in models of co-implantation of human PBMCs with melanoma and colorectal patient samples. Thus, humanized iAVI-cellDX™ or -PDX™ technology bring powerful and fast alternative to mouse models, to strongly accelerate preclinical developments in immuno-oncology.

TUMOR BIOLOGY: Chemical, Environmental, and Virus-Induced Carcinogenesis
Poster Session

#1463 Characterizing inflammation-induced epigenetic and transcriptomic alterations driving NSCLC using lung organoid models.
N. Wang, K. Lombardo, R. Padaki, R.-W. Chiu Yen, M. V. Brock, L. Cope, H. Easwaran, S. B. Baylin, M. Vaz;
Johns Hopkins University School of Medicine, Baltimore, MD

Chronic inflammation is a major driver of lung cancer and contributes to its pathogenesis by inducing genetic and epigenetic alterations. These, in turn, modulate the microenvironment to facilitate emergence of tumor promoting immune evasive mechanisms. The evolution of epigenetic events and their role, both alone, and in association with lung cancer specific genetic drivers in initiation of lung cancer is not well delineated. Specific pathological subtypes of non-small cell lung cancer (NSCLC) have distinct cells of origin, suggestive of cell type-specific changes in driving their development. We employed lung organoid models with chronic exposure to cigarette smoke condensate (CSC) to elucidate sequential, cell type-specific epigenetic and transcriptomic alterations and their role in co-operating with genetic events to drive development of NSCLC. We examined epigenomic and transcriptomic alterations over a 6-month exposure period by DNA methylation arrays, ATAC-seq, and RNA-seq. We observe that CSC exposure causes distinct morphological changes in organoid structure and composition, accompanied by an increase in proliferative potential. Using flow cytometry and immunofluorescent staining approaches, we demonstrate a chronic inflammation-driven shift in stem cell populations accompanied by reduction in differentiated cell types. Bulk and single-cell RNA sequencing approaches identified distinct temporal changes in transcriptional signatures in CSC exposed organoids suggestive of evolution of an immune evasive and pro-tumorigenic phenotype. Gene set enrichment analysis revealed a downregulation of interferon signaling and upregulation of Myc targets and oxidative phosphorylation pathways in CSC treated organoids. Notably, co-culturing organoids with key immune cell populations, demonstrate the ability of the CSC exposed organoids to modulate shifts in immune cells from a pro- to anti- inflammatory state. In accordance with this shift in immune cell phenotype, CSC treated organoids secreted decreased levels of pro-inflammatory cytokines as measured by multiplex ELISA assays. Genome wide DNA methylation analysis reveal that CSC methylated genes were associated with differentiation and cell fate commitment as well as transcription factor activity. Finally, we demonstrate that introduction of key NSCLC-specific driver events at the 6-month time point sensitize only CSC treated organoids to tumor formation in vivo, leading to the development of distinct genetic driver-specific subtypes of NSCLC. Altogether, our results demonstrate the ability of chronic inflammation to drive key cell type-specific transcriptomic and epigenetic changes leading to the development of distinct subtypes of NSCLC. Our findings will help identify molecular correlates for early detection and aid development of novel therapeutic strategies for disease interception.

#1464 Smoking carcinogen-induced inflammation promotes lung carcinogenesis via IRAK4 activation.

R. K. Aggarwal[1], S. Sidoli[1], S. Sahu[1], S. Aluri[1], C. Vegivinti[1], D. Verma[1], S. Gordon-Mitchell[1], B. Agarwal[2], T. Verma[1], D. T. Starczynowski[3], U. G. Steidl[1], B. Halmos[1], L. M. LaFave[1], H. Cheng[1], A. Verma[1], Y. Zou[1];

[1]Albert Einstein College of Medicine, Bronx, NY, [2]Genome RX, Philadelphia, PA, [3]Albert Einstein College of Medicine, Cincinnati, OH

Lung cancer is globally the most common cancer, and most cases are associated with smoking. Smoking exposes respiratory epithelial tissues to various carcinogens. Evaluating the effects of these carcinogens administered intratracheally in mouse models would allow us to study lung carcinogenesis in a relevant manner and determine therapeutically targetable pathways.

Cigarette smoking exposure was mimicked in vivo using a smoke machine and the condensate was subjected to chemical analysis. In addition to nicotine, cigarette smoking condensate included significant levels of the carcinogens, Nicotine-derived nitrosamine ketone (NNK) and Benzo(α)pyrene (BP). Next, a mouse model of cigarette smoking-induced carcinogenesis was developed by exposing ICR mice to intratracheal exposure to NNK and BP three times a week for 18 months.

Mice chronically exposed to NNK and BP developed epithelial dysplasia at 4 months of exposure and lung cancers at 8-12 mo. of exposure at significantly increased rates relative to controls. Histology revealed myeloid inflammation in murine lung tissues. Exposure of lung epithelial cells to cigarette smoking condensate led to increased production of pro-inflammatory IL-1β. Downstream mediator of IL-1β signaling, Interleukin 1 receptor associated kinase-4 (IRAK4), was overexpressed in murine lung tissues exposed to carcinogens in vivo. Two-thirds of human tissue sections obtained from archived lung cancers also exhibited overactivated IRAK4 expression.

In lung cancer cell lines, IRAK4 immunofluorescence revealed a microtubule like pattern of expression in lung cancer cells. Immunoblotting confirmed IRAK4 colocalization within purified microtubules. Using mass spectrometry on isolated microtubules, we observed that phosphorylation decreased in various tubular proteins after IRAK4 inhibition. Inhibition of IRAK4 using small molecule specific inhibitors resulted in decreased invasion in lung cancer cell lines.

These data show that chronic intratracheal exposure of smoking associated carcinogens leads to dysplasia and malignancies in mouse models. This exposure also leads to myeloid inflammation and activation of IRAK4 in lung tissues. Therapeutic targeting of IRAK4 can have potentially beneficial effects in lung cancer models.

#1465 Studying basal cell adaptation in the airways in response to chronic tobacco exposure.

D. Osuna de la Pena[1], Z. Stoichkova[1], M. Przybilla[2], C. Percival[1], S. E. Clarke[1], K. H. Gowers[1], P. J. Campbell[2], S. M. Janes[1];
[1]University College London (UCL), London, United Kingdom, [2]Wellcome Sanger Institute, Hinxton, United Kingdom

Premalignant lesions in the airways are preceded by the accumulation of cells with a high mutational load, many of which carry driver mutations. Our previous work suggests this is a dynamic process: tobacco smoking increases the size of mutated clones, which contain shorter telomeres and higher Ki67, while smoking cessation appears to be associated with the expansion of clones with near-normal mutational burden and an overall reduction in Ki-67 expression. To understand how these long-term changes take place, we have performed ex vivo functional assays to quantify the competitive advantage imparted by smoke. We have then explored the transcriptomic landscape of these cultures to determine how differential smoke exposure modulates epithelial cell dynamics before and after smoking cessation.

Primary basal cells from bronchial explants were co-cultured following different regimes of exposure to cigarette smoke extract (CSE). We find that, upon acute exposure, pre-exposed cells have a ~20% higher chance of proliferating per week than smoke-naïve cells. To test this in a more physiological model, long-term epithelioid cultures were established with chronic exposure to low-dose CSE for months. As before, we observe that over time, pre-exposed cells outcompete the smoke-naïve, suggesting that smoke imparts a beneficial adaptation on re-exposed cells even at low doses. To elucidate this mechanism, we performed RNA sequencing of 48 different combinations of acute and chronic exposure to CSE. Genes were classified into distinct modules according to their regulation following exposure, re-exposure and cessation. Differential expression analysis and gene set enrichment analysis showed that metabolic pathways, including both nutrient and detoxification pathways, are predominantly enriched in these modules. In particular, following cessation, cells with the highest cumulative exposure to CSE displayed senescent-like features which are suppressed with chronic re-exposure. Further analysis and in vivo validation of these results will help elucidate how these changes affect the likelihood of premalignancy and may provide valuable targets for cancer prevention.

#1466 Tobacco carcinogen impacts redox pathway to facilitate pancreatic ductal adenocarcinoma (PDAC) initiation and progression.

X. Lin[1], M. Stamp[2], A. Fowler[2], C. Bottomley[2], S. Okhovat[2], K. Peck[2], D. Engle[2];

[1]University of California San Diego - UCSD, San Diego, CA, [2]Salk Institute for Biological Studies, San Diego, CA

The 5-year survival rate for pancreatic ductal adenocarcinoma (PDAC) is only 10%. PDAC is projected to soon become the second leading cause of cancer death. Tobacco is one of the main risk factors for PDAC. Incidence of PDAC increases 2-fold among tobacco users, and 20-35% of PDAC cases are attributed to smoking. However, the specific pathways activated by tobacco carcinogens remain elusive.This research project addresses the impact of carcinogens in pancreatic cancer etiology. We hypothesize that carcinogens in tobacco increase reactive oxygen species (ROS), which elevates the Nrf2 redox pathway to facilitate PDAC initiation and progression. Specifically, we focus on two major subclasses of carcinogens: the heavy metal cadmium (Cd) and the polycyclic aromatic hydrocarbon (PAH) benzo(a)pyrene (BaP). Using mouse pancreatic ductal organoid cultures, we found that acute carcinogen exposure increases Nrf2 activity, which is sustained after "intermediate" exposure (5 passages). Intriguingly, chronic exposure (10 passages) downregulates Nrf2 activity, which has been shown to be associated with acquired metastatic potential. Furthermore, we found an upregulation in NFkB and EGFR signaling after intermediate exposure, which are involved in microenvironment remodeling and increased proliferative potential. Overall, we demonstrate that acute carcinogen exposure elevates ROS levels and activates the Nrf2 pathway, whereas prolonged exposure upregulates NFkB and EGFR pathways. Furthermore, we have established a novel carcinogenesis model using 3D organoid culture to recapitulate each step in pancreatic tumorigenesis. Collectively, this project contributes to our understanding of tobacco-related PDAC pathogenesis.

#1467 Contribution of estrogen metabolites to never-smoking lung cancer.

Mitchell Cheung, Lisa A. Vanderveer, Daniel Krzizike, J. Nicholas Bodor, Joseph Treat, Joseph R. Testa, Margie L. Clapper

Fox Chase Cancer Center, Philadelphia, PA

There has been a consistent rise in the incidence of non-small cell lung cancer (NSCLC) among individuals who have never smoked. Remarkably, over 50% of diagnosed female cases and 15-20% of male cases are never-smokers. Notably, NSCLC in never-smokers exhibits distinctive clinical and pathological features, notably a higher incidence of tumors with EGFR mutations, setting it apart from its counterpart in smokers. Despite the improved disease-free survival observed with EGFR-tyrosine kinase inhibitors, eventual relapse and limited responsiveness to immunotherapy are common, underscoring the urgency to comprehend the molecular mechanisms driving the escalating prevalence of NSCLC in never-smokers and develop targeted preventive and interceptive therapeutic strategies. The preponderance of females among NSCLC patients who never smoked has prompted an exploration into the potential contribution of estrogen to lung tumorigenesis. In contrast to prevailing research focused on estrogen receptor-mediated signaling, our investigations have yielded compelling evidence supporting the involvement of estrogen metabolism in lung carcinogenesis among never-smokers. This group is the first to report that estrogen is metabolized extensively in both mouse and human lungs, resulting in the generation of various derivatives, including the potential carcinogen 4-hydroxyestrogen (4-OHE). Notably, recent findings from our laboratory indicate that prolonged exposure of nonneoplastic human bronchial epithelial cells to 17β estradiol or 4-OHE, at concentrations approximating physiological levels, induces the accumulation of double-strand DNA breaks and cellular transformation. A comprehensive analysis was performed to further elucidate the mechanisms underlying the transformation process. Isolated transformed clones obtained after 9, 18, and 22 wks of exposure to 4-OHE were subjected to karyotyping, F.I.S.H., and RNA and exome sequencing. A longitudinal progression of aberrant chromosomal rearrangements and copy number alterations was observed, that increased with time of 4-OHE exposure. In addition, RNA-Seq analyses revealed the epithelial-mesenchymal transition pathway was highly enriched at the early timepoint (9 wks), while replicative stress-related signaling pathways were induced at all timepoints. To determine if the differentially expressed genes were also dysregulated in clinical lung cancer cases, TCGA lung adenocarcinoma (LUAD) data were examined. Interestingly, many of the genes upregulated after estrogen exposure were similarly overexpressed in the LUAD samples and often associated with a worse prognosis. In conclusion, our data support the role of estrogen metabolites in promoting lung cancer among never-smokers. (Supported by CA217161 and generous contributions from the Hellendall Family Foundation, Gregory G. Lawton and the Timothy and Aurora Hughes Cancer Research Fund.)

#1468 Low exposures to amphibole or serpentine asbestos in germline *Bap1*-mutant mice induce mesotheliomacharacterized by an immunosuppressive tumor microenvironment.

Y. Kadariya, E. Sementino, M. Ruan, M. Cheung, A. J. Klein-Szanto, K. Cai, J. R. Testa;
Fox Chase Cancer Center, Philadelphia, PA

The purpose of this study was to determine if minimal exposures to amphibole (crocidolite) and serpentine (chrysotile) asbestos fibers significantly increase the incidence and rate of malignant mesothelioma (MM) onset in mice with a germline heterozygous *Bap1* mutation, and to assess the effect of the resulting gene × environment interactions on the tumor immune microenvironment (TIME). The studies were carried out by chronically injecting intraperitoneally *Bap1*+/- and *Bap1*+/+ (wild-type, WT) mice with minimal doses of asbestos (in some experiments, as low as 0.0125 mg x 8 injections; total, 0.1 mg/mouse) and then monitoring the mice for tumor formation for up to 90 weeks. Pro-inflammatory and pro-tumorigenic factors in the TIME were evaluated by immunohistochemistry (IHC) and immunofluorescence (IF) for immune cell markers. With either type of asbestos and at each dose tested, MMs occurred at a significantly higher rate and earlier onset time in *Bap1*-mutant mice than in WT littermates. MMs from mice injected with chrysotile, but less so with crocidolite, had widespread adhesions in the peritoneal cavity owing to an overwhelming immune response, particularly at the higher dose used. IHC staining demonstrated an increased number of immune cells in granulomas and MMs. In particular, pro-inflammatory M1 macrophages were found mainly in granulomas, whereas pro-tumorigenic M2 macrophages were predominant in MMs. IF staining revealed that the relative number of M2 macrophages was strikingly greater in chrysotile-induced than crocidolite-induced MMs, suggesting that chrysotile induces a more profound immune response. MMs from *Bap1*-mutant mice showed upregulation of both CD39/CD73-adenosine and Ccl2/Ccr2 pathways, which collectively are known to mechanistically create favorable conditions for neoplastic transformation, invasion, and the development of an immunosuppressive TIME, in part by attracting M2 macrophages. This implies that chemoprevention and immunotherapy strategies targeting these pro-tumorigenic immune pathways could be beneficial in *BAP1* mutation carriers. In conclusion, we provide evidence that low-level exposures to either chrysotile or crocidolite in germline *Bap1* heterozygous mice result in a markedly increased risk of MM characterized by an immunosuppressive tumor microenvironment. Drawing parallels to humans, these experimental findings suggest that exposure of *BAP1* mutation carriers to even minimal doses of different forms of asbestos may be associated with significantly enhanced susceptibility to MM.

#1470 Advancing cancer research: A novel PanCancer digital PCR tool for simultaneous detection of multiple hallmark mutations in BRAF and EGFR.

C. Kappmeier, S. Edward, C. Hochstein, E. I. Bruske, F. Di Pasquale, **R. Kellner**;
QIAGEN GmbH, Hilden, Germany

The paradigm shift towards precision medicine in oncology emphasizes the importance of identifying specific genetic mutations driving cancer. Some hallmark mutations in cancer-associated genes, such as BRAF and EGFR, are important in analyzing many cancer types. With the emergence of digital PCR (dPCR) technology, high-sensitivity and quantitative mutation analysis can be performed, lending valuable support to cancer research. In this work, we introduce a new and innovative dPCR method, the dPCR PanCancer assays (RUO), designed for concurrently detecting multiple hallmark mutations in BRAF and EGFR.
This work includes two novel PanCancer assays for BRAF and EGFR, each tailored to target a spectrum of mutations associated with these genes, facilitating a comprehensive mutation analysis. The dPCR assay for BRAF targets multiple V600 hallmark mutations, and the dPCR assay for EGFR targets various important deletions on exon 19. This also includes a reference gene as a control for PCR efficiency in the duplex reaction. Here, we present our initial data from various sample types, including blood, plasma and FFPE samples. Through a meticulously optimized dPCR setup, we achieved exceptional sensitivity and specificity, enabling the detection of multiple mutations in a single channel at allelic frequencies below 1%.
Both dPCR PanCancer Kits (RUO) have potential use in research for pre-screening samples (e.g., prior to next-generation sequencing) or monitoring cancer cells. They simultaneously assess the mutations, reducing time and costs and saving sample material. Additionally, our technology is adaptable to other cancer-associated genes, where similar assays can potentially be developed. Overall, we have demonstrated that our dPCR PanCancer Kits (RUO) provide a robust, fast and efficient technology to identify critical mutations, ultimately enhancing our understanding of BRAF and EGFR-driven cancers.
The dPCR PanCancer Kit is for research use only. Not for the diagnosis, prevention, or treatment of a disease.

#1471 A novel mouse model of upper tract urothelial carcinoma influenced by gut microbiota.

A. Yamamoto[1], A. Kawashima[1], K. Jingushi[2], S. Nesrine[1], Y. Horibe[1], A. Yoshimura[1], M. Tani[1], L. Yutong[1], t. Oka[1], Y. Okuda[1], t. Uemura[1], G. Yamamichi[1], Y. Ishizuya[1], Y. Yamamoto[1], T. Kato[1], K. Hatano[1], N. Nonomura[1];

[1]Graduate School of Medicine Osaka University, Osaka, Japan, [2]Graduate School of Pharmaceutical Science Osaka University, Osaka, Japan

Introduction & Objective: Recently, it has been revealed that bladder cancer (BC) and upper tract urothelial carcinoma (UTUC) are biologically distinct diseases. Mouse models of BC carcinogenesis have been established using N-butyl-N-(4-hydro-oxybutyl) nitorosamine (BBN) for a long time, but there are few reports of UTUC carcinogenesis with high incidence. Therefore, the UTUC carcinogenesis mouse model is expected. The aim of this study is to establish a novel mouse model of UTUC carcinogenesis and to identify the characteristics of this model.

Methods: We used two strains (C57BL/6 and BALB/c) of male and female mice and fed 0.05% BBN from 6 weeks old to the harvest day. Both sides of upper urinary tract from mice drinking BBN or tap water were subjected to whole exome sequencing and whole transcriptome sequencing (WTS) to assess its genetic similarity to human UTUC. Microbiome in gut were assessed by 16S ribosomal RNA gene sequencing (16S rRNA-seq). Metabolic differences in feces, serum and liver between UTUC mice and healthy mice were evaluated by comprehensive metabolomic analysis. Inflammatory mediators were assessed by quantitative polymerase chain reaction (qPCR).

Results: Only BALB/c female showed higher incidence of UTUC than BC, while the other strains rarely had UTUC. This model showed SBS5-like mutational pattern. The frequent mutated gene list showed similarity to human UTUC. In terms of gene expression, this model belonged basal subtype. We detected 593 differentially expressed genes between cancerous side and non-cancerous side of upper urinary tract in this model, which could also classify human UTUC and adjacent normal samples. The cancerous side of upper urinary tract enriched several inflammation related pathways such as Nfkb and Tnf pathway. We validated the upregulation of inflammatory gene expression in upper urinary tract (*Il6*, *Il1b*, *Tnfa*, *Relb*) by qPCR (all: $p < 0.05$). 16S rRNA-seq revealed that *Firmicutes* was enriched in feces. Metabolomic analysis revealed that some amino acids in feces and FAD in serum were upregulated. Feeding with amino acid mediated diet changed gut environment. *Firmicutes* in feces and FAD in both feces and serum were downregulated consistently. This diet suppressed inflammatory gene expression in upper urinary tract (*Il6*, *Il1b*, *Tnfa*, *Relb*, *Cd38*, *Tnfrsf1b* and *Kdm1a;* all: $p < 0.05$). Finally, UTUC was disappeared but not BC in this model treated by BBN with amino acid mediated diet.

Conclusion: We have established a novel mouse model developing UTUC with high incidence that genetically mimics human UTUC. In addition, amino acid mediated diet can change both microbiome and metabolome in gut of this model, downregulate host's inflammatory reaction to BBN in upper urinary trat and suppress the UTUC carcinogenesis.

#1472 APOBEC-induced non-coding hotspot mutations near *LEPROTL1* contribute to the tumorigenicity of bladder cancer via deregulation of *LEPROTL1*, *DCTN6* and *SARAF*.

B. Lone, K. Butler, A. Dobbins, D. Yesudhas, A. Chakraborty, E. Hickman, S. Boudjadi, A. Apolo, R. Banday;
National Cancer Inst. - Bethesda Campus, Bethesda, MD

In bladder cancer, APOBEC3 deaminases are major drivers of genomic mutagenesis, with most of these mutations occurring in synonymous or non-coding regions of the genome. The impact of these mutations on tumorigenesis has not been explored. This study aimed to investigate two non-coding hotspot mutations, likely induced by APOBEC3A near *LEPROTL1*—chr8: 29,952,919 G>A and chr8: 29,952,921 C>T—in bladder cancer. Using dual-luciferase reporter assays, we found that these mutations enhance both promoter and enhancer activities. Employing multi-omics approaches, including RNA-seq, ChiP-seq, and Hi-C, identified *LEPROTL1, DCTN6,* and *SARAF* as target genes co-regulated by a common enhancer where these hotspot non-coding mutations manifest. Isogenic cell lines, generated through CRISPR-mediated base editing to introduce these mutations, exhibited upregulation of target genes, and displayed oncogenic characteristics, such as increased cell growth, proliferation, invasiveness, and resistance to cisplatin. Moreover, these mutations exert their effect on cell proliferation by promoting cell cycle progression. These results suggest that recurrent non-coding somatic mutations upstream of *LEPROTL1* disrupt the coregulation pattern of the three genes, thereby promoting bladder tumorigenesis.

#1473 Exposure of arsenic promotes malignant stemness and induces bladder malignancy in preclinical models.

Bhawna Tyagi, Mohit Vashishta, Neha Tyagi, Balaji Chandrasekaran, Vaibhav Shukla, Ashish Tyagi, Chendil Damodaran

Texas A&M University, College Station, TX

Numerous epidemiological and scientific studies have consistently demonstrated that populations exposed to arsenic (As) concentrations ranging from >10 ppb to 2500 ppb in their drinking water face an elevated risk of urogenital cancers, with a particular emphasis on bladder cancer (BCa). Hence, the goal of the study is to investigate the underlying mechanisms that trigger malignant transformation in the bladder using physiologically relevant arsenic concentrations observed in BCa patients. In our results, we observed significantly elevated levels of arsenic in the urine of BCa patients, ranging from 20 to 50 mg/L, in stark contrast to the levels observed in healthy controls (>10 mg/L) and the recommended guidelines set by the Environmental Protection Agency (EPA) and Centers for Disease Control and Prevention (CDC). We used a median physiological concentration of arsenic (30 PPM) in drinking water-induced bladder hyperplasia in male and female mice over six months. Likewise, chronic exposure of healthy bladder epithelial cells (TRT-HU1) to similar arsenic concentrations (250nM:30 PPM) for 12 months resulted in malignant transformation, and arsenic-transformed cells (AsT) were capable of inducing tumors in xenografted and orthotopic models. Nonetheless, the molecular mechanism responsible for this malignancy remains to be elucidated. Our molecular analysis has pointed towards the activation of stem cells, notably ALDH1A1 (with a 50,000-fold increase), as a pivotal factor driving this transformation. Furthermore, our research has demonstrated that the activation of ALDH1A1 is contingent on the induction of Metal Response Element-Binding Transcription Factor-1 (MTF1). Consequently, silencing MTF1 inhibited the expression of ALDH1A1 and its associated malignant properties in As-transformed cells, strongly suggesting that MTF1 functions as the master regulator in As-induced bladder carcinogenesis. We have also observed similar molecular signatures (MTF1 and ALDH1A1 expression) in arsenic-exposed versus non-exposed mice and bladder cancer patients. In conclusion, our studies suggest that activation of stem cells is a critical step in arsenic-induced bladder carcinogenesis.

#1474 Interleukin-8 and NF-κB mediated signaling axis: A potential driver for cadmium-induced prostate carcinogenesis..

K. Gupta[1], R. K. Singh[2], J. R. Seremak[1], V. B. Lokeshwar[1], B. L. Lokeshwar[1];
[1]Augusta University, Augusta, GA, [2]Integra Biosciences, Princeton, NJ

Cadmium (Cd) is a toxic heavy metal, ubiquitous in nature, and an industrial pollutant. Cadmium exposure can cause irreversible damage to lungs, liver and kidney including cancers. Alarmingly, abnormally high levels of cadmium are found in human prostate tissues. Studies on rodents have shown cadmium exposure causes liver, lung, and prostate cancers. The mechanism of carcinogenesis caused by Cd is multifactorial and specific organ carcinogenesis remains unclear. We and others have reported that the CXC-chemokine IL-8 drives cancer progression in prostate cancer (PCa). We tested a hypothesis that chronic cadmium-exposure induces upregulation of proinflammatory cytokines, such as IL-1β, IL-6, and IL-8, which individually or combined promote carcinogenesis and progression. The study used two non-transformed prostate epithelial cell lines (RWPE-1 and NHPrE1) to test whether continuous exposure to Cadmium chloride ($CdCl_2$) perturbs cytokine expression pattern and selective silencing of elevated cytokines delays carcinogenesis and invasive potential. The $CdCl_2$ exposed cells and culture conditioned media were analyzed regularly for changes in inflammatory milieu and for hallmarks of carcinogenesis. These studies measured changes in cell proliferation, production of cytokines (IL-8, IL-1β, IL-6, IFN-γ, TGF-β, and others), activation of Nuclear Factor-kB (NF-κB), and pro-tumorigenic factors, e.g., vascular endothelial growth factors (VEGF-A and B), cellular motility, and invasive potential, etc. Cells exposed to $CdCl_2$ showed increased cell proliferation and clonogenic potential and specifically, increased expression of IL-8, it's receptors (CXCR1 and CXCR2), IL-1β, and other cytokines & related genes. While un-exposed RWPE-1 cells did not express IL-8, it was the first cytokine to increase when exposed to $CdCl_2$, followed by activation of NF-κB (p65-rel), VEGF-A, & B, CXCR1 and other markers. Gene silencing of IL-8 suppressed motility, invasion, and survival activity. These data supported that immediate-early IL-8 expression probably upregulates NF-κB mediated inflammatory signaling axis which is critical for Cd-induced carcinogenesis and may expose targets for countermeasures to prevent metal-induced toxicity & carcinogenesis.

#1475 Investigating the carcinogenic effects and the mechanism of cadmium exposure on WPMY-1 prostate myofibroblast cell line.

Sakshi V. Bansod, Gnanasekar Munirathinam

Biomedical Sciences, University of Illinois College of Med. at Rockford, ROCKFORD, IL

Prostate cancer (PCa) is the second most common cancer among males with an incidence rate of PCa is 288,300 new cases annually. Risk factors include age, genetics, and lifestyle, but the underlying stimuli remain largely uncertain. One potential emerging cause of PCa is exposure to metal carcinogens as cadmium (Cd) which is now classified as a group I human carcinogen. Chronic exposure to Cd on epithelial cells has been extensively shown to induce carcinogenesis, making it a likely contributor to PCa development. In this study, we expand this information by examining how chronic Cd exposure affects prostate-derived myofibroblast (WPMY-1) cells transforming into a cancer-associated fibroblast like phenotype. To study the transformation, WPMY-1 cells were treated with 500nM of Cd for a period of 11 months establishing the WPMY-1 Cd model. Fibroblasts are a crucial tumor microenvironment (TME) component and potentially contribute to PCa progression when transformed and activated into cancer-associated fibroblasts (CAFs). To begin, we used an MTT assay to measure the effect of Cd toxicity on normal prostate myofibroblasts versus WPMY-1 Cd. The data showed that 10µM Cd solution was toxic to WPMY-1 cells, but WPMY-Cd cells depicted high cell viability at 50 µM dose, conferring to chronic Cd exposure improved resiliency to Cd toxicity. We analyzed the expression of CAF-specific markers in WPMY-Cd cells, such as vimentin, FAP, α-SMA, and PDGFR-β. WPMY-Cd cells showed a distinct upregulation for these markers when compared to untreated WPMY-1 cells, suggesting that chronic exposure to Cd promotes CAF-like phenotypic transformation in WPMY-Cd. To further ascertain the cancer-promoting properties of WPMY-Cd, an *in vitro* 3-D spheroid assay was performed by growing the cells on a Matrigel scaffold. The WPMY-Cd cells formed many more tumor-like spheroid structures than WPMY-1 and exhibited sprouting. The sprouting spheroids displayed lamellipodium and filopodium-like structures, demonstrating the initiation of migratory phenotype in WPMY-Cd. Additionally, previous research suggests that CAFs may play a role in PCa progression by promoting tumor growth via the secretion of cytokines and growth factors. We tested this theory by exposing Cd-treated epithelial (BPH-Cd) cells to conditioned media containing secretions from CAFs and WPMY-Cd. WPMY-1 Cd conditioned media in conferring cell migration on epithelial BPH-Cd cells was confirmed by a wound healing assay wherein BPH-Cd cells treated with WPMY-1 Cd conditioned media led to complete wound closure in 24 hours as compared to WPMY-1 and CAF conditioned media. Overall, there is considerable evidence that Cd exposure in fibroblasts may play a crucial role in PCa disease progression and is a promising area for researching PCa treatment strategies against a crucial component of the tumor microenvironment.

#1476 OSBPL3 facilitates endoplasmic reticulum stress and stemness in triple negative breast cancer.

S. Pu, H. Zhang, Y. Ren, J. He, N. Hao;
First Affiliated Hospital of Xi'an Jiaotong University, Xian, China

Background: Triple negative breast cancer (TNBC) is a type of aggressive breast cancer with a poor survival. Endoplasmic reticulum (ER) stress, induced by exposed to intrinsic (e.g. oncogenes) and external factors (e.g. chemotherapies), is an important factor in both tumor progression and responses to chemotherapies. Recent studies have demonstrated that the progression of ER stress may result in the emergence of cancer stem cells (CSC), which also arise as a consequence of metastasis. However, the mechanism of targeting ER stress signaling in cancer stem cells remains to be investigated.
Aim: (i) To investigate the mechanistic role of Oxysterol binding protein-like 3 (OSBPL3) in TNBC and its links with breast cancer mortality, particularly caused by chemotherapeutic resistance and metastasis; and (ii) to test a hypothesis that OSBPL3 facilitates the abnormal activation of ER stress and cancer stemness, result in the resistance to chemotherapy and metastasis in TNBC.
Methods: The expression level of OSBPL3 in TNBC was determined by immunohistochemical staining and the mRNA expression profiles from the TCGA database. Roles of OSBPL3 in cancer cell growth, metastasis, stemness and activation of ER stress were determined by molecular and cell biology methods. Immunoprecipitation was used to examine the binding of proteins and chromatin immunoprecipitation (ChIP), promoter luciferase reporter assay was included for detecting the transcription of OSBPL3 in TNBC. TNBC xenograft nude mice were used to study the inhibition of tumor development.
Results: OSBPL3 is a novel TNBC target, which is overexpressed in TNBC tissues and significantly associated with clinical pathology of advanced TNM stage and poor prognosis of tumor patients. Mechanistically, Increased OSBPL3 induced ER stress and ER stress agonist (tunicamycin) treatment results in the translocation of XBP1, an ER stress sensor, into the nucleus to induce OSBPL3 expression through direct binding to the OSBPL3 promoter. In addition, OSBPL3 facilitates the stemness induced by ER stress via phosphorylating GSK3β and transporting accumulated β-catenin to the nucleus to promote the expression of stemness-related transcriptional factors, ultimately resulting in tumor metastasis and resistance to chemotherapy. Furthermore, OSBPL3-specific siRNAs encapsulated by jetPEI nanocarriers prominently inhibit tumor growth and epirubicin-induced resistance in vivo.
Conclusion: We identified an important role of OSBPL3-ER stress-XBP1 feedback loop in the stemness and resistance to chemotherapy, representing a future biomarker and therapeutic target of TNBC.

#1477 Acrylamide exposure in obesity enhances mammary epithelial DNA damage via the activity of its metabolite, glycidamide, and increased oxidative stress.

B. Walton, L. Arendt;
University of Wisconsin-Madison, Madison, WI

Obesity is a world-wide epidemic, with 39% of adults considered overweight and 13% obese, and rates are rising. Obese women are at greater risk for developing breast cancer than lean women, however the mechanisms of how obesity increases breast cancer risk are not well understood. There is also limited knowledge on how environmental toxins may interact with obesity to promote breast cancer. Acrylamide, a probable carcinogen, is a biproduct in starchy foods cooked at high temperatures, which are prevalent in the obesity-inducing Western diet. Acrylamide is metabolized by the CYP2E1 enzyme into the epoxide, glycidamide, which is known to induce DNA damage. CYP2E1 activity is elevated in obesity, which could enhance DNA damage in obese individuals. Acrylamide exposure is associated with an increased risk of breast cancer in epidemiologic studies, but the evidence has been contradictory. To investigate how acrylamide impacts DNA damage in the obese mammary gland, three-week-old FVB female mice were randomized to receive a low-fat (LFD; 16% kcal from fat) or high-fat diet (HFD; 60% kcal from fat) and either 0.7 mM acrylamide water or control water. HFD-fed mice gained significantly more weight than LFD-fed mice, and exposure to acrylamide did not impact weight gain compared to respective controls. Mammary epithelial cells from acrylamide-treated mice had increased DNA damage compared to controls measured by COMET assays, with the highest DNA damage present in epithelial cells from obese acrylamide-treated mice. Mammary epithelial cells from acrylamide-treated mice also had enhanced oxidative DNA damage, measured by 8-OHdG adducts, and an additive effect was observed between acrylamide exposure and obesity. To investigate the impact of acrylamide *in vitro*, COMMA-D mammary epithelial cells were treated with vehicle, 9.8 µM acrylamide, or 0.5 mM glycidamide for 24 hours, then COMET assays and immunohistochemistry for markers of DNA damage were performed. COMMA-D cells treated with acrylamide-metabolite glycidamide showed significantly increased double strand DNA breaks compared to vehicle-treated cells, however acrylamide-treated cells did not. Interestingly, acrylamide-treated cells demonstrated significantly higher levels of intracellular reactive oxygen species compared to both glycidamide and vehicle-treated cells. These studies suggest acrylamide exposure enhances DNA damage in mammary epithelial cells via conversion to the genotoxic metabolite glycidamide and through generation of oxidative stress, which is exacerbated by obese conditions. These studies suggest that long-term acrylamide exposure through foods common in the Western diet may enhance DNA damage in mammary epithelial cells, potentially enhancing obesity-induced breast cancer risk.

#1478 Chronic perfluorooctanesulfonic acid exposure promotes proliferation of colorectal cancer cells.

J. Durham, J. Weber Tessmann, B. Hennig, Y. Zaytseva;
University of Kentucky, Lexington, KY

Background: Chronic exposure to long-term exposures to per- and polyfluoroalkyl substances (PFAS), widely known as “forever chemicals”, has been associated with multiple negative health outcomes including increased risk of cancer. Perfluorooctanesulfonic acid (PFOS), a “long-chain” subtype of PFAS, has high bioaccumulation potential with a long elimination half-life. PFOS is frequently detected in drinking water leading to its high absorption through the gastrointestinal tract. Recent studies demonstrate that PFAS exposures promote intestinal inflammation and gut barrier dysfunction. However, how a long-term PFOS exposure affects colorectal cancer (CRC) progression is not known. Therefore, the purpose of this study is to delineate the effect of PFOS exposure on CRC cell proliferation and test the potential mitigation strategy for the harmful effects of PFOS.
Methods: SW480 and HCT116 cells have been treated with 1 ug/mL PFOS and proliferation was measured at 1, 2, and 3 months using the Presto Blue Cell Viability Reagent fluorescence assay. Proliferation markers were assessed by qPCR and Western blot. Control and PFOS exposed cells were treated with sulforaphane, a nuclear factor erythroid 2-related factor 2 (Nrf-2) inducer, at concentration 5, 10 and 20 uM for 72 hours.
Results: We show that chronic, low-dose PFOS exposure promotes proliferation of SW480 and HCT116 cell lines starting at 3 months since the first exposure. The increase in proliferation is associated with upregulation of Cyclin D, pAkt and FASN. We also show that sulforaphane significantly decreases proliferation of HCT116 and SW480 cells, and its efficacy is significantly higher in PFOS exposed CRC cells. The current studies show no effect on sulforaphane on normal colon epithelium cells.
Conclusion: Our studies suggest that chronic PFOS exposure promotes proliferation of CRC cells by increasing pro-carcinogenic gene expression and signaling. Furthermore, our findings suggest that supplementation of diet sulforaphane can potentially mitigate the harmful effects from PFOS exposure. Our studies warrant further investigation of the mechanisms behind the effect of PFOS exposure on cancer progression that would guide development of effective intervention strategies to mitigate the harmful effects of the exposure to “forever chemicals”.

#1479 ABCC3 (MRP3)-mediated export of deoxycholic acid regulates MAPK signaling in colorectal adenoma and adenocarcinoma.

Y. Sato[1], **M. Kobayashi**[1], M. Ohira[2], R. Funayama[1], M. Maekawa[3], H. Karasawa[1], S. Ohnuma[1], M. Unno[1], K. Nakayama[1];
[1]Tohoku University Graduate School of Medicine, Sendai, Japan, [2]Tohoku University School of Medicine, Sendai, Japan, [3]Tohoku University Hospital, Sendai, Japan

ABCC3 (also known as MRP3) is an ATP binding cassette transporter and it works as a bile acids transporter. We previously elucidated that ABCC3 expression is downregulated in colorectal cancer through the Wnt/β-catenin signaling pathway. However, it remained unclear how downregulation of ABCC3 expression contributes to colorectal carcinogenesis. We here explored the role of ABCC3 in the progression of colorectal cancer-in particular, focusing on the regulation of bile acid export. First, we performed experiments with clinical samples of familial adenomatous polyposis (FAP) patients to confirm whether ABCC3 expression is already downregulated in colorectal adenomas. Next, we investigated the effect of ABCC3 expression on intracellular bile acid concentrations using ABCC3 knockdown and overexpression colorectal cancer cell lines (HT-29, SW620). The intracellular concentration of deoxycholic acid, which is known to have carcinogenic effects, was verified with fluorescently labeled deoxycholic acid. Then, we tested whether activation of oncogenic signaling by deoxycholic acid is affected by ABCC3 expression changes. Finally, we examined the effect of nonsteroidal anti-inflammatory drugs (NSAIDs), which have been suggested to inhibit the carcinogenesis of FAP, on the expression of ABCC3 in experiments with colorectal cancer cell lines. Gene and protein expression analysis of colorectal adenomas isolated from FAP patients revealed that ABCC3 were downregulated as early as at the stage of adenoma formation, and many other genes related to bile acid efflux were also downregulated. Knockdown or overexpression of ABCC3 increased or decreased intracellular concentration of deoxycholic acid in colorectal cancer cells, respectively. Forced expression of ABCC3 suppressed deoxycholic acid-induced activation of MAPK signaling. Finally, we found that several NSAIDs increased ABCC3 expression in colorectal cancer cells, suggesting that ABCC3 could be one of the targets for therapeutic intervention of FAP. Our data thus suggest that downregulation of ABCC3 expression contributes to colorectal carcinogenesis through the regulation of intracellular accumulation of bile acids and activity of MAPK signaling.

#1480 Perfluorooctanesulfonic acid exposure promotes pathological changes in normal intestinal tissues which may lead to an increased risk of colorectal cancer development.

J. Weber Tessmann, J. Durham, R. Goettl, D. He, C. Wang, P. Deng, B. Hennig, Y. Zaytseva;
University of Kentucky, Lexignton, KY

Introduction: Long-term exposures to per- and polyfluoroalkyl substances (PFAS) have been increasingly linked to negative health outcomes including metabolic disorders, reduced immune responses, and increased risk of cancer. PFOS, one the most frequently detected PFAS in drinking water, is readily absorbed in the GI tract and distributes predominantly to the plasma and liver. Even though recent studies demonstrate that PFOS can cause an imbalance of cecal gut microbiota, alter microbiota diversity, and promote inflammation and gut barrier dysfunction, there is still not much known about the effects of PFOS exposure on normal and pre-malignant intestinal tissues and its contribution to carcinogenesis. Therefore, the goal of this study is to investigate the effects of PFOS on normal (I) and malignant intestinal cells (II).
Methods: The effect of PFOS on gene expression profile was assessed by RNAseq analysis in intestinal tissue of C57BL/6 mice. Tumor organoids were established from Apc/VillinCre mice (adenoma models). Organoid cultures, colorectal cancer (CRC) and primary normal intestinal cell lines have been treated with 1µg/ml of PFOS. To access the mechanisms involved in PFOS-induced intestinal alterations, qRT-PCR, western blot, immunofluorescence, cytokine array and metabolomics analysis have been performed.
Results: The RNAseq analysis showed that PFOS exposure is associated with transcriptome alterations with exacerbated changes in pathways involved in lipid metabolism, immune system regulation and pro-carcinogenesis signaling. PFOS exposure leads to a significant decrease in expression of 3-hydroxy-3-methylglutaryl-Coa synthase 2 (HMGCS2), a rate limiting ketogenic enzyme, in intestinal tissues. We also showed that PFOS exposure upregulates fatty acid synthase, a key enzyme of *de novo* lipogenesis, programmed death-ligand, an immune checkpoint inhibitor, and altered the levels of pro-inflammatory cytokines and metabolites. Using HMGCS2 knockout cells, we identified the possible contribution of HMGCS2 in cytokine regulation and activation of oncogenic pathways.
Conclusion: In summary, our data suggests that PFOS may induce gastrointestinal pathological changes that can increase the risk of CRC development. Further studies are warranted to determine the functional significance of PFOS-mediated downregulation of HMGCS2 and upregulation of lipid metabolism in intestinal cells. Delineating the effects of PFOS on intestinal epithelium may contribute to development of interventional strategies to eliminate harmful effects of these environmental pollutants.

#1481 Disparity landscapes of HBV integration in hepatocellular carcinoma: Mechanistic characterization and functional implications.

X. Lyu, K. M. Sze, J. M. Lee, A. Husain, I. O. Ng, D. W. Ho;
University of Hong Kong, Li Ka Shing Faculty of Medicine, Hong Kong, China

Hepatocellular carcinoma (HCC) is the most common type of primary liver cancer and is a common malignancy worldwide. About half of all new liver cancers worldwide each year occur in China due to a high prevalence of hepatitis B virus (HBV) infection. HBV DNA integrates into the human genome, disrupting the endogenous tumor suppressors/regulatory genes or enhancing the activity of proto-oncogenes. It would be useful to examine the different NGS-based databases to provide a more unbiased and comprehensive survey of HBV integration. We aimed to take advantage of publicly available datasets of different regional cohorts to determine the disparity landscapes of integration events among sample cohorts, tissue types, chromosomal positions, individual host and viral genes, and genic locations. By comparing HCC tumor with non-tumorous liver, landscape of HBV integration was delineated at gene-independent and gene-dependent manners. Moreover, we performed mechanistic investigations on how HBV-*TERT* integration led to *TERT* activation and derived a score to predict patients' prognostication according to their clonal disparity landscape of HBV integration. We revealed a global geographical disparity of HBV integration that the landscape of HBV integration between HCC and non-tumorous liver varied in regional cohorts, suggesting the different degrees of clonal enrichment. In the Mainland China, Hong Kong and Mongolia cohorts, HCC tumors had higher numbers of events than the non-tumorous livers, whereas in the French and US cohorts, the reverse was true. Moreover, most HBV integrations were positionally enriched at the telomeres and centromeres, and this highlighted the novel co-involvement of HBV integration at these regions, which likely introduces greater genomic instability. Furthermore, we constructed a large meta-cohort of multiple ethnicities to refine the landscape of HBV integration. This enabled the identification of events at key HCC-related genes (e.g., *TERT*, *KMT2B,* and *CCNA2*) and gene families (e.g., cyclin, cadherin, and contactin). As *TERT* is the most frequently integrated gene by HBV, we further investigated the mechanistic modulation of *TERT* transcription activation by combining and analyzing our in-house sample cohort with a previous report and luciferase reporter assays. This revealed the positive concurrent influence by both the orientation and relative distance of HBV integration (closer to transcription start site) from the *TERT* gene. Additionally, we observed clonal disparity of HBV integration among patients and the higher level of the clonal disparity score correlated with poor prognostication of HCC patients. Our study uncovered the different levels of clonal enrichment of HBV integration and identified mechanistic insights and prognostic biomarker. This strengthens our understanding of HBV-associated hepatocarcinogenesis.

#1482 FKBP52 drives diverse HCC phenotypes through context-dependent targeting of p53.

X. Wang, J. Wu, C. Tang, X. Li, L. Zhu, Y. Liu;
Fujian Medical University, Fuzhou, Fujian province, China

p53 is notably the most frequently mutated protein in hepatocellular carcinoma (HCC), one of the major causes of cancer-related fatalities globally. These mutations often result in some of the most adverse outcomes in HCC, making p53 a prime target for therapeutic intervention. The concept of “hyperstability”of p53 is essential in understanding its gain-of-function and dominant-negative effects in tumorigenesis. However, the mechanisms driving this hyperstability are not completely understood. In this study, we have identified FKBP52, a member of the FK506-binding protein family, as a crucial factor in stabilizing and accumulating p53, irrespective of the type of mutation. Furthermore, our study suggests that FKBP52 could be a valuable biomarker for predicting HCC outcomes. We observed a notable link between FKBP52 levels and the histological differentiation in HCC samples. To corroborate these observations, we performed a series of in vitro and in vivo experiments using liver cancer models. These experiments highlighted the dual nature of FKBP52’s impact on hepatocytes, which varies according to cell type. Given its connection to HCC severity, FKBP52 seems to contribute negatively to the disease’s progression. The insights gained from this study on how FKBP52 influences p53 stabilization are critical. We suggest that targeting the processes upstream of FKBP52 could lead to more effective HCC treatments. These findings emphasize the importance of further investigating this pathway, potentially paving the way for new strategies in liver cancer therapy.

#1483 Sugar analogs inhibit KSHV replication by blocking N-glycosylation and inducing the unfolded protein response.

M. Schlesinger[1], **C. McDonald**[1], A. Ahuja[1], C. Alvez-Canete[1], Z. Nunez Del Prado[1], J. Naipauer[2], T. Lampidis[3], E. Mesri[3], N. Shembade[3];
[1]University of Miami Miller School of Medicine, Miami, FL, [2]Universidad de Buenos Aires, Buenos Aires, Argentina, [3]University of Miami, Miami, FL

Background: Kaposi´s Sarcoma (KS) herpesvirus (KSHV) is one of the seven known human oncogenic viruses. KSHV infection precedes the development of KS, an AIDS-associated malignancy. While the incidence of AIDS-KS globally has seen a decline, this endothelial cancer is refractory to treatment. The standard of care for AIDS-KS has gone virtually unchanged for over 20 years and effective treatments against the oncovirus KSHV have yet to be developed. 2-DG (2-deoxy-D-glucose), 2-FDG (2-fluoro-deoxy-D-glucose), and2-DFM (2-deoxy-2-fluoro-D-mannose) are sugar analogs. 2-DG and 2-FDG are D-glucose analogs and strong glycolysis inhibitors. 2-DG is also a D-mannose analog so that can inhibit N-glycosylation. In this work we aimed to further characterize and compare the inhibition of the three drug analogs on KSHV replication and pathogenesis.
Design/Methods: We determined the ability of each drug to inhibit KSHV reactivation and infection by flow cytometry using the KSHV producer cell line iSLK.219 Virus titers were measured by de novo infection of naïve AdHEK293 cells and quantifying the number of AdHEK293 infected cells. We further characterized sugar analog inhibition assessing viral glycoprotein expression by western blot and quantifying virion production by qPCR. To show that N-glycosylation impairment is the main contributor of virus replication inhibition, we carried out D-mannose rescue experiments and analyzed activation of the unfolded protein response (UPR). When UPR cannot be resolved, it leads to either apoptosis or autophagy. For this reason, we analyzed the cellular fate of reactivated sugar analog-treated cells by western blot using apoptotic and autophagic markers. Additionally, we calculated the cell death index using the IncuCyte® machine.
Results: All three sugar analogs negatively affected KSHV replication and virion infectivity, but 2-DFM displayed the strongest inhibition. Viral glycoproteins K8.1 and gB were down-regulated and virion production was diminished especially with 2-FDG and 2-DFM sugar analogs. D-mannose could rescue viral glycoprotein expression and virion infectivity, but could not reverse the number of reactivated cells, indicating that N-glycosylation is the main target of the drugs. In line with this, all analogs triggered UPR and even overcame KSHV-induced suppression of the PERK pathway. Finally, 2-DG, 2-FDG, and 2-DFM played a protective role in reactivated cells, displaying the autophagic marker instead of the apoptotic signature observed in the untreated cells.
Conclusion: Collectively, this work identifies the non-toxic inhibition of N-glycosylation by sugar analogs as an important viral target and reinforces the potential of 2-DG as an antiviral for KSHV and other enveloped viruses. We also found that 2-DFM is a more potent and target-oriented compound and a promising therapeutic antiviral agent against an oncogenic virus.

#1484 5-Aza-4'-thio-2'-deoxycytidine induces C to G transversions in a specific trinucleotide context and leads to acute lymphoid leukemia.

R. M. Bertoli, Y. Chung, M. Difilippantonio, A. Wokasch, M. R. B. Marasco, H. Klimaszewski, S. Garber, Y. Zhu, R. L. Walker, D. Cao, J. Doroshow, P. Meltzer, P. D. Aplan;
NIH-NCI, Bethesda, MD

Myelodysplastic syndromes (MDS) are a diverse group of blood cancers characterized by peripheral blood cytopenias and dysplastic blood cell morphology. Up to 40% of patients with high risk MDS will transform to acute myeloid leukemia (AML), an aggressive blood cancer with significant morbidity and an overall 5-year survival of less than 35%. Both MDS and AML have been linked to hypermethylation of cytosine residues. Hypermethylation in the 5' regulatory region can result in epigenetic downregulation of gene expression, and it has been speculated that hypermethylation of tumor suppressor genes can contribute to malignant transformation. DNA methyltransferase inhibitors (DNMTi), most commonly cytidine analogs, are compounds that are used clinically to decrease 5'-cytosine methylation, with the aim of inducing the re-expression of tumor suppressor genes resulting in a halt of tumor progression. 5-Aza-4'-thio-2'-deoxycytidine (Aza-TdCyd or ATC) is a cytidine analog that incorporates an aza modification (nitrogen in place of carbon) of the cytosine base and a thioether modification of the deoxyribose sugar. ATC is a promising new DNMT1i that has demonstrated efficacy in preclinical studies of solid tumors. Based on these prior studies, we sought to characterize the potential therapeutic effect of ATC in MDS.Mice that express a NUP98::HOXD13 (NHD13) transgene develop an MDS that closely recapitulates all of the key features of human MDS, including pancytopenia, dysplastic morphology, and transformation to AML. We transplanted NHD13 and wild-type (WT) hematopoietic stem and progenitor cells into WT recipients, and used this model of MDS to investigate the therapeutic potential of ATC. We found that ATC treatment led to both T and B lineage lymphoid leukemia (ALL) originating from the NHD13 cells. Surprisingly, ATC treatment also led to T and B lineage ALL in the WT cells, and further experiments demonstrated that non-transplanted, healthy WT mice developed T and B cell ALL after treatment with ATC. In sum, all mice that received at least 8 cycles of ATC therapy at the 1.0 mg/kg dose developed leukemia. Whole exome sequencing of tumors revealed thousands of acquired mutations, almost all of which were C>G transversions in a previously unrecognized, specific 5'-NCG-3' context. These mutations involved a number of genes well-known to be involved in human lymphoid leukemia, such as Notch1, Pten, Pax5, Trp53, and Nf1. Treatment of the human U937 and CEM cell lines in vitro showed thousands of acquired C>G transversions in a similar context. Taken together, these findings demonstrate that ATC can be a potent mutagen in human and mouse cells, both in vitro and in vivo.

#1485 Hallmarks of APOBEC3 mutagenesis in normal, pre-leukemic, and myeloproliferative neoplasm cell populations.

J. M. Isquith, T. Whisenant, J. Pham, L. Alexandrov, C. Jamieson;
UC San Diego School of Medicine, San Diego, CA

Changes in gene expression and subsequent editing patterns of APOBEC3 (apolipoprotein B mRNA editing enzyme catalytic polypeptide-like) cytosine deaminases have been shown to be present in solid tumor cancer evolution, however, the context specificity and mechanisms by which APOBEC3 enzymes promote cancer initiation and progression require further elucidation, especially in the hematopoietic niche. Building on advanced sequencing data of healthy, pre-leukemic, and myeloproliferative neoplasm patient samples, we seek to uncover normal and malignant patterns of APOBEC3C overexpression in hematopoietic cells. Overexpression of lentiviral APOBEC3C and an editase-mutated APOBEC3C in normal cord blood, healthy bone marrow, and MPN patient hematopoietic stem/progenitor cells (HSPCs) allows us to study the effects of deaminase dysregulation in hematopoietic cells. In addition to APOBEC3, we are exploring the upregulation of adenosine deaminase acting on RNA1 (ADAR1), as we have previously shown that these two innate immune deaminases are synchronously upregulated in the high-risk myelofibrosis (MF) stem cell population compared to normal aged bone marrow. These overexpression studies show novel differential gene expression changes, RNA hyper-editing sites, and DNA mutation signatures induced by APOBEC3 mutagenesis, which can be cross-referenced to gene expression and mutation signatures seen in hematopoietic malignancies and solid tumor cancers. In addition to mutation patterns, the regulation of LINE-1 elements has been shown to be another important function of APOBEC3 enzymes. In these studies, we examine the effects of APOBEC3 overexpression on repetitive element expression in hematopoietic cell populations and have found that there are strong cell type and context patterns across the APOBEC3 family and between cell types within the hematopoietic system. We will use this comprehensive study of APOBEC3 deregulation to uncover predictive biomarkers of malignant transformation.

TUMOR BIOLOGY: Contributors to Metastatic Organotropism

#1488 Spatial characterization of the tumor microenvironment of metastatic triple-negative breast cancer.

M. Bhargava[1], J. Kaur[2], G. Saini[1], J. Zheng[3], Y. Xu[3], S.-H. Chen[3], P.-Y. Pan[3], E. Rewcastle[4], U. Kiraz[4], E. A. M. Janssen[4], R. Aneja[1];
[1]University of Alabama at Birmingham, Birmingham, AL, [2]Georgia State University, Atlanta, GA, [3]Houston Methodist Research Institute, Houston, TX, [4]Stavanger University Hospital, Health Stavanger HF, Stavanger, Norway

Triple-negative breast cancer (TNBC) is an aggressive subtype of breast cancer associated with high rates of recurrence and metastasis, which contribute to poor overall survival. The challenges in treating TNBC stem from its high intratumor heterogeneity and lack of expression of the estrogen receptor, progesterone receptor, and human epidermal growth factor receptor 2 druggable targets. The tumor microenvironment (TME) plays a crucial role in disease progression. Within the TME, complex spatial interactions among tumor cells, immune cells, stroma, angiogenesis- and hypoxia-inducing factors collectively contribute to the advancement and spread of TNBC. In-depth understanding of the TME and interactions of the various components within can elucidate newer therapeutic targets, enhancing the prognosis of TNBC patients. Imaging mass cytometry (IMC) enables detailed analysis of cell-cell and cell-matrix interactions within the TME at the single-cell level. In this study, we aim to characterize the spatial relationships among various cell types within the TNBC TME using IMC, while also investigating differences in the TME of TNBC patients who developed distant metastasis (DM) compared to those who remained non-metastatic (NM). IMC was performed on formalin-fixed paraffin-embedded TNBC primary resection tissues (n= 16; DM= 7, NM= 9) from Stavanger University Hospital, Norway, using a panel of 25 metal-conjugated antibodies. Regions of interest were marked by the pathologist and the slides were laser ablated using Hyperion Imaging System. DeepCell was used to segment single cells based on surface markers. Mean intensity values of all markers for each cell were extracted and consolidated in R scripts for unsupervised clustering. Cell clusters were annotated based on phenotypic markers. Normalized expression of markers was compared for each cell type across DM and NM patients, including markers for cell proliferation, angiogenesis, hypoxia, and cell migration. Neighborhood analysis examined spatial associations between different cell types, highlighting differences in DM and NM patients. The IMC panel successfully provided spatial insights into the TME, including the characterization of tumor cells, immune cells (B cells, T cells, macrophages), endothelial cells, and proliferating cells. We identified 18 unique phenotypic cell clusters that were present at different frequencies in DM and NM patients. These clusters demonstrated different expression profiles of functional markers. t-SNE plots revealed distinct patterns of cell type distribution and unique protein expression profiles, highlighting significant differences between the two groups. Our data suggest a distinct spatial organization of the TME in TNBC patients who develop metastasis. This warrants further investigations to determine the role and interplay of TME features in predicting the risk of distant metastasis in TNBC.

#1489 The role of EPAS1 and TEAD1 in gastric cancer liver metastasis.

D. Lee[1], H. Park[2], J.-H. Cheong[1], H. Gee[1];

[1]Yonsei University College of Medicine, Seoul, Korea, Republic of, [2]Yonsei University, Seoul, Korea, Republic of

Gastric cancer ranks fifth in incidence and fourth for cancer-related mortality worldwide. While the liver is widely recognized as the leading site of metastasis in gastric cancer, the intricate mechanisms underpinning its tropism toward the liver and the hematogenous metastasis process remain poorly understood and demand further investigation.

Hematogenous metastasis encompasses the generation of circulating tumor cells from the primary tumor site and their subsequent attachment to the metastatic niche. This process involves the transition between adherent and suspension states. In our investigation of anchorage dependency, we identified 20 transcription factors upregulated in suspension cells compared to adherent cells and 18 transcription factors upregulated in adherent cells relative to suspension cells, respectively.

To investigate factors involved in gastric cancer metastasis, RNA sequencing of paired primary and metastatic tissue samples obtained from 15 patients diagnosed with advanced gastric cancer was conducted, which disclosed the selective upregulation of EPAS1 and TEAD1 in metastatic liver tissue compared to the matched primary tumor tissue and the metastatic tissue originating from other sites.

Through in vitro analysis, we observed a portion of adherent cells transitioning into suspension cells when subjected to a hyperdense environment. We also observed cell reattachment upon harvesting and replating these suspension-state transited cells. Comparing EPAS1 and TEAD1 expression in these states unveiled increased expression of EPAS1 and TEAD1 in reattached cells relative to suspension-state cells.

We established a gastric cancer metastasis mouse model introducing gastric cancer cells into the mouse circulatory system via intracardiac injection to validate our findings. In vivo imaging was utilized to confirm systemic metastasis. After fluorescence-based cell sorting, EPAS1 and TEAD1 expression in cancer cells collected from the blood, liver, and ovary were assessed. We detected higher expression of EPAS1 and TEAD1 in liver metastasis compared to the circulating tumor cells. Furthermore, EPAS1 and TEAD1 were upregulated in liver metastatic cancer cells compared to ovarian metastatic cancer cells.

Our findings underscore EPAS1 and TEAD1 as pivotal factors governing gastric cancer liver tropism and metastasis, offering insights that may contribute to targeted interventions in the clinical landscape.

#1490 Elucidating the effect of glutamine metabolism in breast to bone metastasis.

B. A. Karno[1], Y. Hwang[2], R. Johnson[2], J. Chen[2], D. Edwards[2];
[1]Vanderbilt University, Nashville, TN, [2]Vanderbilt University Medical Center, Nashville, TN

Bone-metastatic lesions will develop in approximately 65-75% of patients with metastatic breast cancer and are associated with high morbidity and mortality. Despite our limited understanding of how breast-to-bone metastases form, the recent emergence of metabolic adaptation as a critical factor in metastasis is a promising development. Breast cancer cells are particularly reliant on glutamine, a key amino acid that is metabolized by the enzyme glutaminase (GLS) to facilitate many downstream metabolic processes. Bone-tropic breast cancer cell lines significantly enhance their glutamine uptake, suggesting that glutamine metabolism may be a significant factor in bone metastasis. In addition to tumor cells, glutamine metabolism is critical for osteoblasts, important bone-resident cells that contribute to the “vicious cycle” of bone destruction during metastatic outgrowth in the bone niche. In this study, we sought to evaluate the role of glutamine metabolism in breast cancer bone metastasis by examining the effect of GLS function in metastasizing tumor cells and bone-native osteoblasts. Using an intracardiac inoculation model of bone metastasis, we found that breast cancer cells lacking GLS (GLS KO) failed to effectively form bone metastatic tumors. We also observed that GLS KO bone tumors show a reduction in osteolysis using a direct intratibial injection model. Mechanistically, we have found that GLS KO breast cancer cells develop a “senescence-like” phenotype that may limit metastatic outgrowth within the bone. To investigate the importance of glutamine metabolism in the bone niche, we developed a conditional genetic mouse model to delete GLS in osterix-expressing in osteoblast progenitors and mature osteoblasts (GLS^{OBKO}). Remarkably, we observed reduced bone destruction in GLS^{OBKO} mice after intratibial injection of syngeneic breast cancer cells. We also report a reduction in the number of osteoclasts at the bone/tumor interface in these mice, suggesting that loss of osteoblast GLS could temporarily halt the “vicious cycle” of bone metastasis. Together, this work suggests that glutamine metabolism may promote breast-to-bone metastasis via both intrinsic and extrinsic mechanisms. These findings raise the possibility of using pre-existing cancer therapies targeting glutamine metabolism to ameliorate bone metastatic burden in breast cancer.

#1491 The enhanced formation of neutrophil extracellular traps (NETs) may contribute to the exacerbation of peritoneal metastasis in a diabetic host.

R. Takahashi, H. Ohzawa, Y. Kaneko, M. Matsumiya, Y. Futoh, K. Tamura, K. Takahashi, Y. Kimura, A. Saito, H. Miyato, N. Sata, J. Kitayama;
Jichi Medical University, Tochigi, Japan

Background: Diabetes is associated with increased risk of cancer development and progression. Recent studies have shown that neutrophils in diabetic patients are prone to forming neutrophil extracellular traps (NETs) which have been reported to capture circulating cancer cells, leading to the promotion of liver and lung metastasis. This study aims to clarify the causative relationship between NETs and the peritoneal metastasis (PM) in diabetic condition.
Methods: Outcome of the diabetic patients who received curative gastrectomy for gastric cancer from 2010 to 2021 in our institute was comparatively investigated with those without diabetes. Neutrophils were isolated from the bone marrow from C57BL/JHamSlc-ob/ob mouse (type 2 diabetes model) and wild type mouse using Ly6G-based positive immunomagnetic selection. The neutrophils were stimulated with 100nM of PMA for 4 hours and NETs formation was evaluated by the addition of Sytox Green under fluorescent microscope. A mouse gastric cancer cell, YTN16P (5×10^5 cells) was intraperitoneally (IP) injected, the number of metastatic nodules on mesentery was comparatively evaluated two weeks later.
Results: Disease-free survival (p=0.004, HR=1.65) and overall survival (p=0.035, HR=1.46) of 203 diabetic patients were significantly worse those of 975 non-diabetic patients. Neutrophils isolated from ob/ob mice produced markedly increased NETs than that from wild-type mice. NETs produced by neutrophils obtained from the peritoneal cavity of ob/ob mice after IP injection of a 9% casein solution effectively captured many YTN16P in vitro. The concentration of double strand DNA (dsDNA) in plasma in ob/ob mice compared with their counterparts (676ng/mL vs 590ng/mL, p=0.036, n=3). The number of PM in ob/ob mice was significantly more than that in wild-type controls (39.1 vs 15.5, p=0.027, n=10).
Conclusion: Enhanced NETs formation in diabetic conditions may be associated with an increased risk of PM in gastric cancer.

#1492 Unveiling the re-programming of choroid plexus and leptomeningeal metastasis.

A. Nobre, H. Wang, R. Estrera, I. Osei-Gyening, A. Boire;
Memorial Sloan Kettering Cancer Center, New York, NY

Leptomeningeal metastasis (LM) is an increasingly common, fatal complication of breast and lung cancer. Despite aggressive treatment, neurologic deficits accumulate rapidly, and patients generally succumb to LM within months. We must expand our limited mechanistic knowledge of this disease.
Under homeostatic conditions, choroid plexus (ChP), highly vascularized structures within the brain ventricles, restrict the entry of macromolecules and cells into the leptomeninges; however, select cancer cells can cross this barrier and grow within the leptomeningeal space. We hypothesize that interactions between cancer and ChP niche cells alter both the niche and the cancer cells, ultimately supporting LM.During neurogenesis, the ChP display substantial extracellular matrix (ECM) remodeling, which is elegantly modulated by dynamic spatiotemporal regulation of MMPs, Wnt signaling, among other effector proteins. Similarly, 2-photon imaging of ChP collected from mice harboring LM revealed a profound ECM remodeling of the ChP when compared with naïve mice. This remodeling was accompanied by increased levels of MMP2 and MMP9 in LM mice. Upon pharmacological inhibition of MMP2 and MMP9 *in vivo*, we observed a decrease in LM burden and increase in overall survival, which correlates with a decrease in ChP permeability. Interestingly, human CSF from patients with leptomeningeal metastases is also enriched in collagen 1 fragments, MMP2, MMP9 and TIMP1. TIMP1, a MMP9 natural inhibitor, is not present in complex with MMP9, suggesting a role of TIMP1 as a cytokine in LM progression. TIMP1 neutralization and knockout from the cancer cells leads to a decrease in LM burden and increase in overall survival. Together, these data suggest a provocative link between proteolysis and inflammation in LM progression.
The use of clinically-annotated human samples and mouse models of LM, and the integration of transcriptomics and proteomics enabled us to identify key signaling pathways, and capture the re-programming of ChP niche and cancer cells that unlock the leptomeningeal space to cancer cells. The timeframe for this evolution will be further revealed by analysis of mouse and human samples at different stages of cancer progression.

#1493 Secretory function of neuroendocrine-like prostate cancer cell enhances therapy resistance and metastatic potential of adjacent adenocarcinoma.

J. Mishra, S. Bodas, S. Bhattacharya, D. Das, S. UnNazir, S. Dutta, K. Datta;
University of Nebraska Medical Center, Omaha, NE

Background: Castration-resistant prostate cancer (CRPC) is advanced non curable disease associated with poor prognosis and survival n patients. Androgen receptor pathway inhibitors (ARSIs) are used to treat advanced prostate cancer, but in majority of patients it progresses by developing resistance to AR-directed therapies and is referred to as CRPC. Adenocarcinoma cells in CRPC tumor often undergoes lineage switch and become neuroendocrine-like cancer cells (NEPC) with small-cell histology, characterized by the loss of Tp53 and Rb1 genes. NEPC cells are frequently present as scattered foci along with prostatic adenocarcinomas and are secretory in nature.
Objective: The primary objective is to determine how these NEPC cells influence surrounding adenocarcinoma and aids in disease progression.
Methods: We performed Mass spec and cytokine array experiments from NEPC conditioned media to determine its secretory phenotype. We orthotopically implanted NEPC and adeno cells in the nude mice and performed colony formation assay on flow sorted adeno cells from the tumor. We also checked the effect of NEPC on the adeno cells and TME components.
Results: Our analysis of the RNA-seq data from SU2C-PCF cohort and NE-like cells revealed that functions related to secretion were significantly enriched in NE-like PCa. NE-like cells gain the ability to secrete neuropeptides, growth factors, and cytokines to establish cell-cell communication. This secretory function is tightly regulated by the Neuropilin2 (NRP2) axis. We studied for the effect of NE-like cells on the adenocarcinoma cells in the mice tumor model and found that the presence of NE-like cells facilitated the adenocarcinoma cells to acquire aggressive characteristics. This could be due to both direct and/or through the modulation of the tumor microenvironment (TME). The direct effect could be by enhancing the therapy resistant ability of the surrounding adenocarcinoma, and the indirect effect is through the tumor microenvironment especially through neurons and macrophages that promote metastatic potential.
Conclusions: Overall, our results prove that NE-like cancer cells influence the adjacent adenocarcinoma cells directly by making them resistant to treatment and indirectly make them more metastatic by utilizing macrophage-neuron axis.

#1494 Clonal dominance defines metastatic dissemination in pancreatic cancer.

I.-L. Ho[1], C.-Y. Li[1], F. Wang[1], L. Zhao[1], J. Liu[1], E.-Y. Yen[1], C. Dyke[1], R. Shah[1], Z. Liu[1], A. Cetin[2], F. Citron[1], S. Attanasio[1], V. Giuliani[1], T. Heffernan[1], K.-A. Do[1], G. Gargiulo[2], G. Draetta[1], A. Carugo[1], R. Lin[1], A. Viale[1];

[1]UT MD Anderson Cancer Center, Houston, TX, [2]Max-Delbruck-Centrum fur Molekulare Medizin, Berlin, Germany

Tumors represent ecosystems where subclones compete during tumor growth. While extensively investigated, a comprehensive picture of the interplay of clonal lineages during dissemination is still lacking. Using patient-derived pancreatic cancer cells, we created orthotopically-implanted clonal replica tumors to trace clonal dynamics of unperturbed tumor expansion and dissemination. This model revealed the multifaceted nature of tumor growth, with rapid changes in clonal fitness leading to continuous reshuffling of tumor architecture and alternating clonal dominance as a distinct feature of cancer growth. Regarding dissemination, a large fraction of tumor lineages could be found at secondary sites each having distinctive organ growth patterns as well as numerous undescribed behaviors such as abortive colonization. Paired analysis of primary and secondary sites revealed fitness as major contributor to dissemination. From the analysis of pro- and non-metastatic isogenic subclones, we identified a transcriptomic signature able to identify metastatic cells in human tumors and predict patients' survival.

#1495 Lipocalin-2 promotes breast cancer metastasis via tumor cell intrinsic and extrinsic mechanisms.

J. Gamez[1], F. Sanchez[1], G. Ortiz-Soto[2], J. Cox[1], A. Gerami[3], **J. A. Kelber**[2];
[1]California State University, Northridge, Northridge, CA, [2]Baylor University, Waco, TX, [3]Western University of Health Sciences, Pomona, CA

While metastasis is the primary factor predicting poor outcomes in solid tumors, survival is lowest in patients initially diagnosed with a localized malignancy that then progresses to metastatic disease. Notably, nearly 25% of early-stage breast cancers (BCs) metastasize during treatment or following an initial positive response to therapeutic intervention. To define the molecular and cellular factors that contribute to metastatic progression of BC, we previously developed the Py230-C57Bl/6 syngeneic experimental metastasis model for interrogating mechanisms by which soluble factors condition premetastatic lung tissue to potentiate BC cell seeding/expansion. Using this model and the TCGA, we identified lipocalin-2 (Lcn2) as a molecular candidate that is upregulated in lung-tropic Py230 cells and other human triple-negative breast cancer (TNBC) cells, and that predicts poor outcomes in human BCs. While Lcn2 has been previously reported to mediate BC progression in genetically engineered mouse models, its mechanism(s) of action remain undefined. Here, we demonstrate that Py230 cell-secreted Lcn2 is necessary for optimal reprogramming of the premetastatic lung during metastatic progression. In agreement with these data, we defined a cell intrinsic role for Lcn2 in BC cell organoid assembly/invasion and expression of proinflammatory factors. To define BC cell extrinsic roles for Lcn2 in remodeling the premetastatic lung, we collected global transcriptome and single-cell spatial proteome data for lung tissue from C57Bl/6 mice systemically educated with mock media or media conditioned with Py8119 ($Lcn2^{low}$) or Py230 ($Lcn2^{hi}$) BC cells. Mice receiving Py230 conditioned media treatments were further divided between two groups – one receiving an isotype control IgG and the other receiving an Lcn2 immunoneutralizing antibody. Global transcriptome data was used to determine novel gene set enrichment signatures and clinically relevant interactomes – notable candidates predicted to cooperate with Lcn2 in decreasing patient survival were affiliated with cilia biogenesis and function. Single-cell spatial proteome data were analyzed for 28 different cell populations within the premetastatic lung. Interestingly, Py230 cell-derived Lcn2 did not affect the percentage of ciliated epithelial cells indicating that the global transcriptome data referenced above represent a real increase in expression of cilia-related genes and not an increase in cilia-positive cell types. Notably, we identified that Lcn2 increased the percentage of $CD45^{neg}/Des^{pos}$ mechanomodulatory cells and proliferating $CD45^{pos}/CD3^{pos}/CD4^{neg}/CD8^{pos}$ cytotoxic T cells in the premetastatic lung. Taken together, these data define new targets around which new therapeutic strategies can be developed to improve BC patient outcomes.

#1496 The role of endothelial ACKR1 in breast cancer metastasis.

S. T. Roach, R. Patel, S. Thomas, C. Ewenighi-Amankwah, J. Dufraine, L. A. Naiche, J. Kitajewski;
University of Illinois at Chicago, Chicago, IL

Background: Tumor cells can co-opt mechanisms of leukocyte extravasation. Atypical Chemokine Receptor 1 (ACKR1) expression in endothelial cells has an established role in promoting leukocyte extravasation; however, the potential for endothelial ACKR1 to facilitate the metastatic process through the extravasation of tumor cells has not been studied.
Methods: To understand ACKR1 function, we investigated endothelial ACKR1 expression at the distant metastatic site of the lung, a common site of breast cancer metastasis. We analyzed lung endothelial ACKR1 expression using immunofluorescent staining of lung vasculature during tumor progression in immunocompetent mice bearing orthotopically implanted E0771.LMB breast tumor cells. We assessed the timing of metastatic tumor cell arrival in the lung and evaluated the spatial relationship between disseminated tumor cells and ACKR1-positive vessels. To investigate secreted tumor factors that may mediate ACKR1 regulation in the lung, we performed intratracheal injections of TNF-alpha. We developed an endothelial cell specific ACKR1 conditional knockout mouse model (ACKR1 ECKO) to understand the impact of endothelial ACKR1 on primary tumor growth and subsequent lung metastasis in breast cancer.
Results: Our results reveal a significant upregulation of ACKR1 in the lung endothelium of mice implanted with breast cancer cells in the mammary fat pad. Tumor-dependent ACKR1 expression was specifically localized to pulmonary venule endothelium, a common site of leukocyte and tumor cell extravasation. Lung endothelial ACKR1 expression became evident by day 13 after implantation, persisting through endpoint at day 28. Notably, ACKR1 upregulation occurred prior to tumor cell arrival in lungs of tumor bearing mice. We observed spatial clustering of disseminated tumor cells in proximity to ACKR1-positive vessels, implying a preferential site of tumor cell extravasation. In the absence of primary tumors, intratracheal delivery of TNF-alpha induced ACKR1 expression within lungs. When tumors were orthotopically implanted into our ACKR1 ECKO mouse model, we observed a marked decrease in lung metastases compared to control mice.
Conclusion/Future Directions: We have determined that pulmonary ACKR1 expression is induced by breast tumors, and vessels expressing ACKR1 appear to act as entry points for lung metastasis. Loss of endothelial ACKR1 reduced metastasis, suggesting that endothelial ACKR1 regulates tumor cell extravasation at distant metastatic sites. We will upregulate lung endothelial ACKR1 expression and directly test its requirement for extravasation using an intravenous tumor cell injection metastasis model.

#1497 Humanized mouse model unveils niche conditioning in gastric cancer peritoneal metastasis.

J. J. Zhao[1], D. K. Chia[2], Z. Her[3], H. Ma[4], X. Ong[4], S. Tay[4], J. B. So[2], Q. Chen[3], P. Tan[4], R. Sundar[1];

[1]National University Cancer Institute, Singapore, Singapore, [2]University Surgical Cluster, National University Health System, Singapore, Singapore, [3]Agency for Science, Technology and Research (A*STAR), Singapore, Singapore, [4]Duke-NUS Medical School, Singapore, Singapore

Background: Peritoneal metastases (PM) in gastric cancer (GC) portend a poor prognosis. Yet, biological mechanisms underpinning peritoneal colonization and transcoelomic metastases remain unclear. Utilizing a novel humanized mouse model of GCPM, we seek to understand the evolution of the peritoneum to allow for peritoneal dissemination. The humanized mouse model, defined as mice engrafted with functional human cells or tissues, was selected as the host immune system appears to play a significant role in the mechanisms of transcoelomic metastases.

Methodology: Humanized (humice) and NOD-scid Il2rynull (NSG) mice models were injected with GSU (diffuse type) GC cell lines in the flank (subcutaneous), stomach (orthotopic) and directly into the peritoneum (intra-peritoneal). After 1 month, the mouse models were sacrificed and samples from the primary tumor (PT), PM and adjacent peritoneum were retrieved. The tumors were then harvested, along with normal/adjacent peritoneum and bulk RNA-seq was performed and analyzed.

Results: Fifty-six samples including PT, PM were harvested from 10 humice and 11 NSG models and were analysed with whole transcriptome sequencing. All models with orthotopic inoculation were found to create PM while no gross PM were appreciated in models with flank inoculation. Principal component analysis mapping of samples demonstrated transcriptomic distinction between normal peritoneum from the flank humice model and adjacent normal samples in the orthotopic and intra-peritoneal humice model. Compared to adjacent peritoneum of the intra-peritoneal humanized mouse model, the orthotopic model appeared to be more tumorigenic with enriched epithelial mesenchymal transition (EMT), stromal and immune infiltration, inflammatory response (IL2-STAT5, IL6-JAK-STAT3, TGF-β signaling), IFN-γ response signatures. Enrichment scores of these pathways were likewise more pronounced in adjacent normal peritoneal samples in the orthotopic humanized mouse model when contrasted against other sample types. Higher expression of M2 macrophages, B cells and T regs, dendritic cells (activating and resting) was found in adjacent peritoneum in the orthotopic model. Collectively, these describe a phenomenon in which the adjacent uninvolved peritoneum has evolved into a tumorigenic environment to facilitate transcoelomic metastasis. These unique niche changes of the peritoneum were conversely not appreciated in the NSG model.

Conclusion: We unveil novel insights that delve into the mechanistic role of the host immune system in orchestrating tumorigenic microenvironmental alterations to support peritoneal organotropism. These provide functional proof alluding to the phenomenon of peritoneal niche conditioning in GC PM.

#1498 TGFβ signaling in cancer-associated fibroblasts drives a hepatic gp130-dependent pro-metastatic inflammatory program in CMS4 colorectal cancer.

S. Abudukelimu, T. J. Harryvan, S. G. T. Janson, I. Stouten, E. M. E. Verdegaal, L. J. Hawinkels;
Leiden University Medical Center (LUMC), Leiden, Netherlands

Background: Colorectal cancer (CRC) is characterized by a metastatic pattern that shows tropism towards the liver which is the major cause of CRC-related deaths. The current CRC classification, Consensus Molecular Subtypes (CMS), suggests an association between transforming growth factor (TGF)-β signaling, cancer-associated fibroblasts (CAFs), and the risk of liver metastasis. However, the key downstream effectors of TGFβ signaling in CAFs and their role in hepatic metastases remain poorly understood.
Methods: The aim of this study was to investigate the TGF-β/CAF dependent cross talk with the hepatocytes in pre-metastatic niche formation. CAFs from 18 primary CRC tissues and 7 liver-metastasized CRC were stimulated with TGFβ1 and qPCR arrays/ELISAs were performed to identify differentially expressed genes. Results were cross-referenced with RNAseq expression data of CMS-classified CRC and in fresh samples from CRC patients. To investigate CAF-liver crosstalk hepatocytes were stimulated with the TGFβ primed CAF-derived cytokines and the effect on pro-inflammatory gene expression and neutrophil migration was determined. Subsequently, blockade of these pathways via chemical inhibition and CRISPR/Cas9 genetic ablation was performed to study the molecular mechanism involved in the induction of this hepatic pro-inflammatory program.
Results: TGFβ signaling in primary CRC-derived CAFs leads to increased expression of different IL-6 cytokine family members, which was also reflected in human CRC samples. CAF-derived IL6 family members induce upregulation of myeloid chemoattractants, including SAA1, in hepatocytes and increased neutrophil-to-hepatocyte migration in vitro. Chemical blockade and genetic ablation of the IL-6 family cytokine signaling pathway showed the critical role of the gp130 co-receptor in the regulation of this inflammatory response in hepatocytes and the potential formation of a premetastatic niche.
Conclusion: TGFβ signaling in CAFs actively contributes to the formation of a neutrophil-dependent, pre-metastatic hepatic niche, and this mechanism might play a role in CMS4 subtype CRC.

#1499 Senescent stromal cells drive lung metastases of breast cancer.

A. Melam, J. Ye, S. A. Stewart;
Washington University in St. Louis, Saint Louis, MO

In 2022 in the United States, there were nearly 300,000 women diagnosed with breast cancer (BC) with the risk increasing significantly after age 50. The overall 5-year survival rate dramatically decreases, from 99% for patients with stage I, to a devastating 25% for those with stage IV (metastatic) BC, making distal metastasis the leading cause of BC mortality. This mortality rate has not changed in decades with lungs being one of the most common sites for distal metastasis of BC. The BC microenvironment is a complex mix, consisting of tumor cells and numerous nontumor cells including distinct subpopulations of cancer-associated fibroblasts (CAFs): vascular (vCAFs), inflammatory (iCAFs), and myofibroblastic CAFs (myCAFs), which can play pro- or anti-tumor roles. Senescent fibroblasts, which accumulate with age typically express $p16^{INK4A}$ and can modulate the cells around them via the secretion of a cadre of pro-tumorigenic factors including cytokines, chemokines, and extracellular matrix (ECM) modulating enzymes, collectively called the senescence-associated secretory phenotype (SASP). To investigate how p16+ senescent cells impact tumorigenesis, we mated the well-characterized MMTV-PyMT mouse, to the INK-ATTAC (INK) mouse, wherein treatment with AP20187 (AP) selectively eliminates p16+ senescent cells. Preliminary data showed that elimination of p16+ aSMA+ senescent fibroblasts (senCAF) resulted in a significant decrease in primary tumors, lung tumor foci and lung metastatic burden. Further, we found that senescent CAFs (senCAFs) were the only stromal cells eliminated in the PyMT-INK mouse treated with AP, suggesting that this CAF subtype is a key contributor to tumor progression. To determine if senCAFs directly impacted lung metastasis, EO771-LG Luc mammary tumor cells were injected in the tail vein of INKATTAC mice that were treated with AP to eliminate p16+ senCAFs. We found that metastatic tumor burdens were significantly reduced in INK+ versus control mice and immunohistochemical analysis revealed that tumor burden and foci was significantly reduced, suggesting that senCAFs in the lung promoted tumor cell seeding and outgrowth.

#1500 Breast cancer-derived extracellular vesicles modulate the endocytic metabolism and morphodynamics of the endothelial cells of the blood-brain barrier.

S. Busatto, G. Morad, M. Moses;
Boston Children's Hospital, Boston, MA

Breast cancer, particularly the triple-negative subtype, is the primary cause of brain metastasis in women, affecting 10-20% of breast cancer patients. Breast cancer patients who develop brain metastasis have few treatment options and a dismal prognosis with a median survival time of 6-16 months. We demonstrated, for the first time, that EVs derived from brain-seeking breast cancer cells (BrEVs) breach the intact blood-brain barrier (BBB) via transcytosis and cause a significantly increased incidence of breast-to-brain metastasis. Within this context, we are now studying the interactions between BrEVs and the endothelial cells (ECs) of the BBB. BrEVs were isolated by ultracentrifugation, characterized following the latest guidelines published by the International Society of Extracellular Vesicles (MISEV 2018) and tested *in vitro* using primary human brain ECs and *in vivo* using our mouse model of breast-to-brain metastasis. ECs were treated with BrEVs and analyzed using antibody-based assays, impedance measurements, genetic engineering and fixed and live cell imaging. The imaging results were analyzed using novel machine learning approaches to detect and describe, for the first time, EV-mediated morphodynamic changes at the brain EC barrier level. *In vivo*, we administered BrEVs intravenously to our models of breast-to-brain metastasis, followed by the analysis of mouse brains and their cerebral microvessels to examine microscopic structure and protein expression. Our studies show that (1) BrEVs target BBB ECs both *in vitro* and *in vivo*, causing significant variations of multiple proteins involved in the intracytoplasmic vesicles' long-recycling loop, (2) BrEVs are responsible for specific EC barrier function and morphodynamic changes and (3) BrEVs mediate, at least in part, their effect(s) through the delivery of specific micro RNAs. Taken together, our studies demonstrate that BrEVs have a significant impact on brain EC endocytic metabolism and morphodynamics, promoting transcytosis and sustaining breast-to-brain metastasis. Our findings increase our understanding of the early events that facilitate brain metastasis and have the potential to identify key regulators of brain metastasis formation. These results also inform and contribute to the development of EV-based therapeutic and diagnostic strategies for brain metastasis. (This work was supported by NIH R21 CA253051-01, the Breast Cancer Research Foundation, NIH T32 5T32HL007917-22 and the Nile Albright Research Foundation.)

#1501 Engineering tissue models to elucidate prostate cancer bone metastasis dynamics.

B. Han, Z. Yang, S. Zhao, G. Liang, B. X. Hoang, J. Fang;
Keck School of Medicine of USC, Los Angeles, CA

Prostate cancer (PCa) ranks as the second most frequently diagnosed cancer in men and the fifth leading cause of male cancer-related deaths globally Advanced PCa exhibits a propensity for bone metastasis which significantly contributes to morbidity. It is challenging to understand its mechanisms and develop effective treatments due to complicated tumor microenvironments. The current study addresses this gap by focusing on the construction of in vitro and in vivo models to mimic tissue-specific microenvironments resembling primary prostate tumor sites and metastatic bone tissue, shedding light on the complex processes of cancer cell dissemination, osteomimicry, and bone metastasis. To recapitulate the complex interplay between primary tumor sites and bone microenvironments, the study employs a combination of tunable extracellular matrix mechanics, bone-derived growth factors, and bone marrow-derived stromal cells. These engineered niches emulate the contexts of both primary tumor and bone tissue. LNCAP-C4-2B prostate cancer cells are introduced into these niches to analyze various aspects, including cell proliferation, osteoblastic differentiation, dissemination, and in vivo tumor formation. The study introduces a 3D organoid culture that mimics the pre-metastatic niche, providing a platform for studying PCa cell proliferation and dissemination. A negative relationship is observed between 3D matrix stiffness and cell proliferation, while a positive link is identified with cell dissemination. Bone matrix-derived soluble factors (BMSF) are identified as key modulators of LNCAP-C4-2B cell behavior, suppressing LNCAP-C4-2B proliferation but enhancing osteomimicry in vitro, Notably, bone marrow-derived stromal cells, primed with bone matrix-derived growth factors, amplify tumor cell proliferation and chemotaxis in vitro, contributing to increased tumor formation in vivo. In vivo experiments demonstrate BMSFs eliciting local inflammatory responses and inhibiting in vivo tumor formation. Moreover, osteogenic bone marrow stromal cells are shown to play a promotive role in LNCAP-C4-2B proliferation and migration, emphasizing the influence of the bone microenvironment on the prostate-to-bone progression of PCa cells. In conclusion, this study highlights the potential of the engineered tissue models for dissecting tumor progression and screening therapeutic interventions. By leveraging tissue-engineered soft and hard tissues, our approach offers a versatile toolbox for comprehensively investigating PCa progression and bone metastasis. These insights extend to potential therapeutic screening applications, providing a valuable resource for advancing our understanding of cancer pathogenesis and treatment strategies.

#1502 Deciphering the spatial and temporal dynamics of premetastatic niche in lung mediated by Treg and myeloid cell interactions.

Y. Tian[1], J.-R. Li[2], B. Zhu[1], J. Fradette[1], H. Chen[1], C. Li[1], L. Rodriguez[1], D. Kraushaar[2], L. Solis[1], A. Reuben[1], I. Wistuba[1], D. L. Gibbons[1], C. Cheng[2], J. Zhang[1];

[1]UT MD Anderson Cancer Center, Houston, TX, [2]Baylor College of Medicine, Houston, TX

Introduction: The lung is a frequent site for metastases, where pre-metastatic niches (PMN) form in anticipation of tumor cell arrival. A deeper understanding of the molecular and immune features underlying the PMN formation may facilitate developing innovative strategies to prevent and treat metastasis more effectively in its early stages.

Methods: In this study, we developed mouse models by subcutaneously implanting the 344SQ cell line, derived from the metastasis of a genetically engineered mouse model (GEMM) harboring *Kras*$^{G12D/+}$; *p53*$^{R172H/+}$ mutations, which reliably metastasizes to the lungs. We collected paired samples of the subcutaneous tumors, peripheral blood mononuclear cells (PBMCs), and lung tissue at pre-metastatic, early-metastatic, and late-metastatic phases. These samples were subjected to single-cell RNA sequencing (scRNA-seq), single-cell TCR/BCR sequencing (scTCR/BCR-seq), and spatial gene expression profiling with 10X Genomics Visium technology.

Results: ScRNA analysis revealed large-scale comprehensive longitudinal changes in cell components throughout the invasion and metastasis cascade, which were validated by spatial gene expression. Furthermore, analysis of Visium data deduces the spatial information of these dynamic changes.We identified a subset of tumor-associated Tregs (TA_Tregs, enriched in the subcutaneous tumor tissues) that existed in small amounts in the lung tissue in the pre-metastatic phase when there are no tumor cells detectable in the lung. These cells were characterized by high expression of Treg-associated suppressive genes (Tnfrsf9, Tnfrsf4, Tnfrsf18, Traf1, Nfkbia), inhibitory molecules (Ikzf2, Il2ra, Tight, Pdcd1), cytokines and chemokines (Ccr5, Ccr8, Ccl5, Cxcr6) and other Treg effector molecules (Id2, Hif1a, Rora, Il1r2, Itgav, Stat1, Icos, Areg). The scTCR-seq results and trajectory analysis revealed the TA_Tregs might derive from minor clones of lung resident Tregs (LR_Tregs) and play an active role in remodeling an immunosuppressive microenvironment by closely interacting with other cell components in the TME. We also observed a significant alteration in the ratio of macrophage subpopulations between Macro_Spic and Macro_Vcan. This ratio exhibited a continuous decrease in lung tissues, which could be an early indication of the initiation of pre-metastatic niche (PMN) conditioning.

Conclusion: By simultaneously characterizing cellular gene expression, immune repertoires, and their corresponding spatial information, we revealed the dynamic changes of the lung tissue microenvironment (LTME) during from a normal state to pro-metastasis state at single-cell resolution. The LTME of metastatic organs may be primed before the establishment of metastasis.

#1503 Melanoma-derived lymphatic extracellular vesicles suppress dendritic cell differentiation and maturation in the sentinel lymph node.

S. Suman[1], W. K. Nevala[1], J. W. Jakub[2], R. Guo[2], A. A. Leontovich[1], R. M. Moore[1], C. L. Atherton[1], L. Geng[1], J. E. Johnson[1], S. A. McLaughlin[2], S. N. Markovic[1],

[1]Mayo Clinic, Rochester, MN, [2]Mayo Clinic, Jacksonville, FL

Spread to regional lymph nodes is the most common site of metastasis from melanoma and almost all solid tumors. Lymphatic metastases begin in the first lymph nodes draining from the primary tumor, i.e., the sentinel lymph nodes (SLN), preceded by the development of the premetastatic niche (PMN) initiated by primary cutaneous melanoma. Melanoma mediators are known to play a critical role in developing the PMN through the immune subversion in SLN. The DCs are a vital component of LN immunity that directly relates to eliciting T-cell functions. Our multiplex immunofluorescence (MxIF) analysis of SLNs indicates significantly decreased levels of DCs and cytotoxic-T cells in both core and interface areas of tumors in recurred patients treated with immunotherapy compared to non-recurred melanoma patients. The goal of this study is to determine whether the lymphatic extracellular vesicles (L-EVs) of melanoma patients regulate DC tolerization in SLN in order to stimulate the development of PMN. To identify whether L-EVs stimulate DC suppression, we extracted L-EVs from the lymphatic fluid of patients with melanoma downstream of primary cutaneous melanomas, compared it with controls (non-malignant post-operative fluid collected from the lymph node dissection field, and evaluated their effect on DC maturation by challenging these L-EVs in monocytic (CD14+) and hematopoietic stem cells (CD34+) cells. We found that L-EVs derived from melanoma patients suppress differentiation of CD11c+HLA-DR+ DCs and their maturation (defined by CD83 and CD86) compared to control L-EVs in CD14+ based DC maturation assay. We also found a reduction of conventional type 1 DC (cDC1) in CD34+-based DC maturation assay those challenged with patients' L-EVs compared to control. To understand the mechanism of DC suppression in patients' L-EVs, we also conducted a total RNA sequencing analysis of subsets of DCs from maturation experiments to evaluate differently regulated transcriptomic profiles. The gene ontology analysis indicates that patient-derived L-EVs interfere with tRNA processing, oncostatin M & IL-10 signaling, and other immunoregulatory pathways to alter the hematopoietic cell lineage pathways in the DC maturation. Furthermore, the proteomic analysis of L-EVs also indicated several differentially regulated cargo-identified proteins in patient L-EVs, which are associated with immunomodulation, including regulation of DC function compared to control L-EVs. In conclusion, our study revealed that the patient's L-EVs carry differential proteomic cargoes secreted by cutaneous melanoma, which may be involved in regulating DC differentiation and maturation to diminish their functions and support the developing PMN in SLN.

#1504 Tumor microenvironment-mediated regulation of early dissemination and colonization in breast cancer via BAZ2A-containing remodeling complexes.

Miriam Kokal-Ribaudo[1], Nora Jahnen[2], Saba Sameri[1], Fulvia Ferrazzi[3], Renato Liguori[3], Christoph A. Klein[1], Gernot Langst[2], Hedayatollah Hosseini[1]

[1]Experimental Medicine and Therapy Research, University of Regensburg, Regensburg, Germany,[2]Biochemistry Center Regensburg, University of Regensburg, Regensburg, Germany,[3]Bioinformatics and Computational Pathology, University of Erlangen, Erlangen, Germany

The molecular mechanisms governing invasion, dissemination, extravasation, and early metastatic colonization remain incompletely understood. In the BALB-neuT mouse model, we found that most metastases originate from disseminated cancer cells (DCCs) that left the primary site early in tumorigenesis, i.e. when lesions are still small. Consequently, we investigated whether cellular density and the tumor microenvironment synergize to generate the plasticity needed during metastasis.

RNA-sequencing analyses of murine breast cancer cells in low cellular density (LD) and high cellular density (HD) conditions revealed distinct profiles of differentially expressed genes. Notably, we identified the enrichment of ribosomal RNA (rRNA) and chromatin remodeling pathways in LD conditions. Interestingly, once these cells were treated with Wnt4 and Rankl, factors secreted by the tumor microenvironment, the expression profile of genes involved in proliferation, migration and stemness as well as epigenetic-related factors changed drastically. Specifically, cells in LD conditions treated with Wnt4 and Rankl displayed induced migration and stemness phenotypes, whereas under HD conditions, these signals induced proliferation. Among the chromatin-remodeling pathways, we found that BAZ2A along with the rRNA regulating network were primarily upregulated in migratory cancer cells. Immunostaining of primary and metastatic lesions in murine and human breast cancer samples showed an upregulation of BAZ2A in early/microlesions compared to more advanced and proliferative macroscopic lesions.

Taken together, these results indicate that cell density, tumor microenvironmental factors and BAZ2A-containing chromatin regulating complexes play pivotal roles in regulating cancer cell plasticity in breast cancer. Additional sequencing and functional analyses will be performed to dissect the specific components of this mechanism and evaluate their impact on the *in vivo* colonization of breast cancer models.

#1505 Unraveling diepafitaxis: Investigating ECM stiffness and microarchitecture in tumor spheroid migration.

H.-P. Chen, Y.-C. Tsai, T.-Y. Tu;
National Cheng Kung University, Tainan City, Taiwan

Background: Metastasis, accounting for up to 90% of cancer-related deaths, remains one of the least understood aspects of cancer progression. Recent research has shifted focus from solely biological hallmarks to the physical characteristics of cancer, such as the stiffness and microarchitecture of the extracellular matrix (ECM), which play pivotal roles in metastatic advancement. We previously introduced the concept of 'diepafitaxis' to describe a unique mechanism driving the interface-mediated tropism of tumor spheroids at matrix-surface boundaries. This phenomenon suggests that cancer cells preferentially migrate along a 2D 'interfacial' track formed by heterogeneous 3D ECM structures, facilitating invasion and dispersion. However, the exact mechanisms by which interfacial components, stiffness, and structural attributes influence cell movement remain debated. To investigate this, we have developed a microfluidic chip with a precisely controlled stiffness of the hydrogel matrix-matrix interface (MMI), aiming to shed light on specific diepafitatic behaviors.
Method: We developed a polydimethylsiloxane (PDMS)-based microfluidic chip using a traditional photolithographic process. This chip features three channels, with the center channel designed to precisely control various MMI stiffness combinations: stiff vs soft (t-o), stiff vs stiff (t-t) and soft vs soft (o-o). MDA-MB-231 breast cancer spheroids (BCS), representing an in vitro tumor model, were embedded in the top gel. We observed the dynamic behavior of these cancer spheroids over a 24-h period using differential interference contrast (DIC) microscopy.
Result: The study revealed that BCS exhibited more pronounced dispersion in a soft homogeneous ECM compared to a stiff ECM in 3D environments. Interestingly, when BCS were near an MMI, a stiffer MMI (t-t) significantly enhanced BCS invasiveness and single-cell migration, more so than t-o, and notably more than o-o. We previously described this phenomenon as '2.5D migration,' where cells migrate in a ventral 2D manner within a sandwiched 3D gel structure. This diepafitatic behavior was further analyzed for its response to gravitational effects and the influence of chemotaxis, induced by introducing VEGF on one side of the microfluidic channel.
Conclusion: Conclusively, our study demonstrates that the stiffness and structure of the ECM, particularly at MMI, significantly influence the invasive behavior and migration patterns of BCS, underscoring the critical role of mechanical microenvironments in cancer metastasis.

#1506 Diminished migration potential of MDA-MB-231Br (brain-seeking) breast cancer cell line with integration of keratin 18 gene.

A. Johnson[1], T. Liu[2], P. Lockman[3], G. Szalai[1];

[1]Burrell College of Osteopathic Medicine, LLC, Las Cruces, NM, [2]West Virginia School of Osteopathic Medicine, Lewisburg, WV, [3]West Virginia University School of Medicine, Morgantown, WV

Triple-negative breast cancer is considered to have one of the poorest prognostic outcomes of the breast cancer subtypes, with brain metastasis resulting in a survival rate of less than a year. Determining and eventually targeting the cause of the triple-negative breast cancer cells that seek the brain would improve life expectancy and quality of life by preventing the ramifications of brain pathology. Through a novel mouse model, previous research has demonstrated that one sub-line of the MDA-MB-231 (triple-negative breast cancer cell line) cells, MDA-MB-231Br, preferentially metastasizes to the brain. Additionally, lower levels of expression of the keratin 18 gene were observed in the MDA-MB-231Br cells, which prompted the analysis of the transcriptional control of the keratin 18 gene. In our previous study, we analyzed the pattern of chromatin occupation of transcription factors FLI1 and ETS1 to understand the transcriptional control of keratin 18 within the parental MDA-MB-231 cell line and MDA-MB-231Br brain-seeking counterpart. Notably, the ETS1 transcription factor was enriched in the MDA-MB-231Br cells, and the FLI1 transcription factor was enriched in the MDA-MB-231 cells. In this study, using transient and stable transfection, we incorporated keratin 18 cDNA into the MDA-MB-231Br cells and examined the effect on their migration capabilities. We hypothesized that with the introduction of keratin 18 cDNA into the MDA-MB-231Br cells, their migration capabilities would match that of their parental counterpart.

The MDA-MB-231Br cells were cultured in the Burrell research laboratory, and transfections were performed using Lipofectamine™ 3000 Transfection Reagent by Thermo Scientific with GFP as a control. Migration assays were performed using a transwell migration assay (Millipore) and with a wound healing assay. Ultimately, our results from both migration and wound healing assays demonstrated a diminished migration capability after keratin 18 was re-introduced into the MDA-MB-231Br cells through transfection. In the wound healing assay, the MDA-MB-231Br cells transfected with keratin 18 closely resembled the pattern of migration demonstrated by the parental MDA-MB-231 cells, while the MDA-MB-231Br cells transfected with GFP followed the pattern of the untouched MDA-MB-231Br cells. Additionally, the migration assay showed significantly less migratory capability of the MDA-MB-231Br cells expressing keratin 18 compared to the MDA-MB-231Br cells expressing GFP as a control ($p < 0.05$). The invasion capabilities of these cells with and without the presence of keratin 18 will be evaluated next to further elucidate the effects of re-expressing keratin 18.

#1507 Involvement of GABAergic signaling in enhanced tumor cell invasion in a mechanically dynamic tumor microenvironment.

C. Strelez[1], R. Perez[1], J. S. Chlystek[1], C. Cherry[2], B. Haliday[3], A. Yoon[1], C. Shah[3], R. X. Sun[1], R. Lau[1], A. Schatz[1], J. Neman[4], H. Josef-Lenz[3], J. Katz[1], **S. M. Mumenthaler**[3],

[1]Ellison Institute of Technology, Los Angeles, CA, [2]C M Cherry Consulting, Baltimore, MD, [3]USC - University of Southern California, Los Angeles, CA, [4]University of Southern California, Los Angeles, CA

Metastasis is a major contributor to cancer morbidity and mortality. However, studying this complex, multi-step, multi-organ process is challenging. There is a pressing need to dissect the contributions of the tumor microenvironment (TME) on this process in a controlled and precise manner. Fortunately, the utilization of microfluidic “organs-on-chips” (OOC) in cancer research is facilitating such investigations. Moreover, by combining organoids and organs-on-chips we can enhance the progress of these studies in a patient specific manner. In this study, we have developed a cancer-on-chip model aimed at investigating early metastatic spread within the colon milieu. To achieve this, we employ colorectal cancer (CRC) cell lines as well as patient-derived CRC organoids chosen from our biorepository to encompass diverse representations across race/ethnicity, sex, and mutational profiles. The tumor cells are introduced into the upper chamber of the OOC model, while human microvascular endothelial cells (HIMECs) are introduced into the lower chamber to establish a tube-like structure resembling a blood vessel. These two chambers are separated by a porous membrane, and the chip is flanked by vacuum chambers to introduce stretch-like motions, simulating peristalsis in the gastrointestinal track.

Creating a mechanically dynamic microenvironment facilitates the exploration of neurotransmitters and their impact on tumor cell behavior. Recent studies have suggested that tumor cells may exploit physiological processes, such as neurotransmitter signaling, to their benefit. By utilizing mass spectrometry-based metabolomics we detected dynamic and patient organoid-specific changes in neurotransmitter levels (i.e., serotonin, aspartate, glutamate, γ-aminobutyric acid (GABA)) in the effluent of our CRC-on-chip model. Coupled with live-cell imaging, we discovered tumor cell-derived GABA, a major inhibitory neurotransmitter, serves as an energy source for supporting tumor cell intravasation. This finding was most pronounced in KRAS-mutant tumor cells and further supported by analysis of CRC patient samples from The Cancer Genome Atlas (TCGA) database. We were able to reverse the GABA-mediated invasion effect by inhibiting 4-aminobutyrate aminotransferase (ABAT), the enzyme responsible for GABA catabolism. In summary, our cancer-on-chip model holds promise for exploring various aspects of the metastatic process and uncovering potential therapeutic targets, such as neurotransmitters.

#1508 Membrane heparan sulfate proteoglycans work with cadherins to establish the directional orientation of migrating cancer cells.

Lorenzo Depau, Jlenia Brunetti, Chiara Falciani, Marta Garfi, Maria Francesca Paolocci, Alessandro Pini, **Luisa Bracci**

Department of Medical Biotechnologies, University of Siena, Siena, Italy

A role of heparan sulfate proteoglycans (HSPGs) in cancer cell differentiation, proliferation and migration has been recognized and related to their ability to specifically interact with growth factors, morphogens, and extracellular matrix proteins, mainly through sulfated groups on their glycosaminoglycan (GAG) chains. Due to the considerable diversity of HSPGs and of their GAG chains, and to the lack of specific ligands, a precise molecular characterization of the biological role of HSPGs in cancer cells is still lacking. HSPGs, besides working as coreceptors for growth factors and morphogens, may have a determinant and autonomous role in cancer signaling events, regulating cell adhesion, migration, and invasiveness. Being overexpressed and over sulfated in cancer cells, HSPGs may become attractive tumor targets for cancer diagnosis and therapy. We had used the tetra-branched peptide NT4, which binds sulphated GAG chains of HSPGs, to validate HSPGs as potential tumor associated antigens in different human solid tumors. The same NT4 peptide had been tested as a tumor targeting agent for either cancer cell imaging or therapy, in vitro and in vivo [1]. Once identified the sulfated GAG specificity of NT4, the peptide has also been used as a specific tool for studying the role of HSPGs in cancer cell migration and invasiveness, with the aim of proposing HSPG as potential drug targets for interfering with cancer invasiveness and metastatic potential [2,3]. We found that NT4 inhibits adhesion, oriented migration, and colony formation in different human cancer cell lines. We investigated the role of HSPGs in migration of different human cancer cell lines, displaying either single-cell mesenchymal migration (PANC-1 pancreas adenocarcinoma, and MDA-MB-231 breast adenocarcinoma) or collective migration (MCF-7 breast adenocarcinoma). After assessing the expression of HSPG and of E- and N- cadherin in each cell line, their specific cellular distribution was detected by confocal microscopy in migrating cells, in wound healing experiments. We found that distribution of either E- or N- cadherins on the membrane of migrating cells is complementary to that of HSPG. This is particularly clear in collective migration, where HSPGs are exclusively located on the migration front of leader cells, whereas cadherins are only expressed by follower cells. Our results suggest that HSPG may have a crucial role in defining the front of migrating cells, while cadherin-mediated cell-cell contacts on the opposite site, may contribute to inducing protrusion formation at the front of migrating cells, as already suggested [4]. [1]- Brunetti J et al. Sci. Rep. 2015, 5, 17736; [2]- Brunetti J et al. Sci. Rep. 2016, 6, 27174; [3]- Depau L et al. J Med Chem 2020, 63, 15997; [4]- Grimaldi C et al Nat Commun 2020, 11, 5397

#1509 Microglial dominance in glioma dissemination: Unraveling TAMs' impact and therapeutic implications through modulating cathepsin activity.

S.-Y. Wu, C.-S. Chiang;
National Tsing-Hua University, Hsinchu, Taiwan

Introduction: It is well known that tumor-associated macrophages/microglia (TAMs) play a vital role in brain tumor progression. Our previous studies suggested that the activated microglia could reduce the cytotoxic effect of chemotherapeutic drugs on glioma cells in a 2D/3D model. This study delves into TAMs within diverse brain TME regions, emphasizing the distinction of resident microglia from infiltrating macrophages in invasion areas and their role in glioma migration and invasion.

Material and Method: We employed the murine orthotopic astrocytoma model (ALTS1C1), dissecting brain tumor tissues into normal, invasion, edge, and core regions. Immunofluorescence staining, utilizing TMEM119 and CD68 markers to identify resident microglia and infiltrating macrophages, respectively. The IHC results were analyzed with QuPath software and validated via flow cytometry. Microglia (BV2) and macrophage (RAW264.7) cell lines were directly co-cultured with ALTS1C1 in 2D and 3D migration/invasion models. Bulk RNA sequencing analysis unraveled the differences between BV2 and RAW264.7. Bone marrow-derived macrophages (BMDM) were used for the TAMs activation test, and the cathepsin inhibitor, E64, was applied to elucidate cathepsin's role in microglia within co-culture models.

Results: The IHC results reveal more TMEM119^{+} microglia than CD68^{+} infiltrating macrophages in the tumor invasion area. On the other hand, there are more CD68+ infiltrating macrophages than TMEM119^{+} microglia in the tumor core regions, signifying a specific role of microglia in tumor invasion. Flow cytometry further supported that more CD11b^{+}CD45^{low} microglia prevalence in tumor surrounding tissues than in tumor core. ALTS1C1 astrocytoma cells, in the presence of microglia, exhibited more increased invasion and migration ability than the presence of macrophages in 2D/3D models. RNA sequencing highlighted M2 activation and cathepsin gene upregulation in microglia over macrophages. M2-polarized TAMs enhanced 2D migration, while cathepsin inhibition significantly decreased glioma's 3D invasion potential.

Conclusion: This study identifies microglia as primary TAMs in brain tumor invasion areas and their roles in glioma cell survival and dissemination. Notable differences in activation states and the critical impact of cathepsin in microglia for their roles on brain tumor invasion and survival offer promising therapeutic avenues. Targeting cathepsin in microglia emerges as a novel glioma prevention and treatment strategy. These findings contribute valuable insights to enhance clinical interventions for glioma patients.

#1510 Cell-cell contacts regulate HER2 cellular localization and the transitions between migration and proliferation in breast cancer cells.

H. Hosseini[1], S. Sameri[1], S. Shahrivari[1], C. Fisch[1], M. Kokal[1], M. Schletter[1], P. S. Hahn[1], L. Seider[1], M. Schubel[1], D. Das[2], M. Hoffmann[2], C. Werno[2], K. Weidele[2], V. Milosevic[3], A. Ostman[3], S. Sarhadi[4], J. Wegener[5], S. Michaelis[5], F. Weber[1], A. Bruckmann[1], E. R. Tamm[1], Y. Li[6], C. A. Klein[1];

[1]University of Regensburg, Regensburg, Germany, [2]Fraunhofer Institute for Toxicology and Experimental Medicine ITEM, Regensburg, Germany, [3]University of Bergen, Bergen, Norway, [4]Technical University of Munich, Munich, Germany, [5]Fraunhofer Institute for Electronic Microsystems and Solid State Technologies EMFT, Regensburg, Germany, [6]Shenyang Pharmaceutical University, Shen Yang, China

Introduction: Epithelial-to-mesenchymal transition (EMT) is widely recognized as the primary mechanism regulating invasion and metastatic dissemination in carcinomas. In contrast, the mechanisms triggering single disseminated cancer cells (DCC) to reacquire their epithelial identity at ectopic sites, initiating metastasis formation, remain unclear. Since we had previously noted that HER2 expression levels and cellular density impact on migration and proliferation, we sought to determine whether they are involved in molecular mechanisms regulating transitions between proliferation and migration.

Methods: To control HER2 expression levels we generated inducible cell models. Cell density was assessed by the number of cell-cell contacts or by the number of cells per area. Pathway analyses were performed by gene expression analysis, protein interactions by western blotting and mass spectrometry. Migration and proliferation were analyzed by functional assays including in vitro live cell imaging.

Results: Migrating epithelial cells undergo reduced protein trafficking, resulting in a perinuclear deposition of HER2. This was accompanied by increased calcium ion regulation via phospholipase-C in the endoplasmic reticulum (ER). Upon the establishment of cell-cell contacts, particularly between cells expressing desmosome cadherin proteins, HER2 is redirected to the cell surface through direct physical binding with desmoplakin, facilitating proliferation signals. Then, PIP2 to PIP3 is converted through the activation of the PI3K pathway, concomitant with the upregulation of PDPK1. The PH domain of PDPK1 exhibits a high binding affinity to PIP2 molecules. Consequently, membrane localization of HER2 significantly diminishes PIP2 availability for the PLC pathway, redirecting cells towards proliferation. Patient sample analysis confirmed the loss of membrane-bound HER2 in solitary circulating tumor cells (CTCs), which was paralleled by increased plakoglobin, elevated ZEB1, and reduced KI67 protein levels.

Conclusion: Cell-cell contacts determine the cellular localization and function of growth factor receptors like HER2. Single disseminating cancer cells therefore need to establish such contacts at metastatic sites to activate proliferation programs. Our data are in line with findings that circulating tumor cell clusters are associated with higher metastatic rates, the impact of specific metastatic niches for outgrowth and have implementation for the targeting of single DCC.

TUMOR BIOLOGY: Immune Cells in the Tumor Microenvironment 1
Poster Session

#1514 A novel workflow to assess the T-cell and patient-derived organoid interaction.
Z. Tong, A. Lim, O. Sirenko;
Molecular Devices, LLC (Moldev), San Jose, CA

Immunotherapy is increasingly popular as a type of cancer treatment. These therapies include the use of Chimeric Antigen Receptor-engineered T-cells (CAR T-cells), tumor-infiltrating lymphocytes (TIL), and other genetically modified T-cells to specifically target the cancer cells. Although much success has been achieved with immunotherapy for treatment of blood cancers, its efficacy remains limited in solid tumors. One of the reasons for the low success rate is attributed to the solid tumor microenvironment (TME) where suppressive cytokines limit the tumor killing ability of T-cells. Thus, understanding the role the TME plays in T-cell responses is essential for the development of effective cancer therapies. The benefits of using 3-dimensional (3D) PDOs lie in the physical and chemical cues present within the TME that cannot be mimicked in traditional 2D monolayer cultures. Studies show that PDOs show similar responses to drugs as original tumors, suggesting the value of using PDOs to improve therapeutic outcomes. Thus, PDOs can provide more relevant physiological and pathological cancer models that recapitulate the basic features of primary tumors and is more suited for assessing the effectiveness of T-cell killing than 2D cell models. Despite the benefits associated with the use of PDOs, there are significant barriers to widespread adoption of PDOs in drug discovery. Organoid production is a costly and highly labor-intensive process. Moreover, organoid culture is a skilled manual process, and thus there can be significant variability between operators. To address the challenges associated with the use of PDOs in large scale applications, a semi-automated bioprocess has been developed for the large-scale expansion of assay ready organoids. Here, we developed a method to assess the effectiveness of T-cell invasion in solid tumors using patient derive organoids (PDOs). Using bioreactor expanded patient-derived colorectal cancer organoids (CRCs), activated PBMCs (human peripheral blood mononuclear cells) stained with CellTracker were added to CRCs (stained with MitoTracker) in a 96well microtiter plate and monitored on every 4 hours for 3 days using high content imager. To quantify T-cell invasion, we developed an image analysis method to measure the distance of each T-cell to the nearest organoid (interaction distance). We find that stimulated T-cell resulted in smaller interaction distance than non-stimulated T-cells. The results demonstrate the utility of the bioreactor-expanded organoids in large scale T-cell based screens.

#1515 Tertiary lymphoid structures restrain cancer evolution by supporting stem-like CD8+ T cells for sustained anti-tumor immunity.

P. Wang[1], C. Zhou[2], Z. Wei[2], Y. Wang[1], Y. Gao[2], F. Meng[2], J. Zhou[1], J. Fan[1], Q. Liu[2], Y. Sun[1];
[1]Zhongshan Hospital Fudan University, Shanghai, China, [2]School of Life Sciences and Technology, Tongji University, Shanghai, China

Currently, our understanding of the mechanism underlying the immune response on extending the survival of patients with aggressive tumors remains limited. In this study, we generated multi-regional genomic and transcriptional data coupled with digital pathology from 28 long-term survivors (LTSs) and 34 stage-matched short-term survivors, with intrahepatic cholangiocarcinoma (iCCA). Our investigation unveiled that mature tertiary lymphoid structures (TLSs) within the tumors of LTSs exerted significant immune pressure on the tumor, leading to the restriction in generating clonal mutations and increased subclonal diversity. Employing single-cell profiling, we identified significant enrichment of IgM^{+} naïve B cells and TCF7^{+} stem-like CD8^{+} T cells in TLS-positive tumors. Spatial profiling further highlighted that TCF7^{+} stem-like CD8^{+} T cells preferentially localized in TLS, facilitating reduced vulnerability to unfavorable environmental factors. Functionally, TCF7^{+} stem-like CD8^{+} T cells displayed strong capacity to differentiate into effector subsets while maintaining a diverse T-cell receptor repertoire. Mechanistically, we identified that naïve B cells promote activation and differentiation of stem-like CD8^{+} T cells within the TLS niche through IgM-FcμR axis, which primed these T cells for enhanced anti-tumor immunity. In summary, our findings underscore that TLS plays a pivotal role in orchestrating enduring and effective anti-tumor immunity, which yield strong immune stress on cancer evolution and ultimately contributing to better prognosis of patients.

#1516 Large scale, transcriptome-based analysis of TCR clonality reveals functional immunity in non-small cell lung cancer.

H. Yu[1], A. Magoulopoulou[2], M. Hori[3], A. Lindberg[1], M. Backman[1], H. Brunstrom[4], M. Marincevic Zuniga[1], J. Mattsson[1], A. Saito[5], K. Leandersson[4], M. Nilsson[2], R.-M. Amini[1], P. Micke[1], C. Strell[1];

[1]Uppsala University, Uppsala, Sweden, [2]Stockholm University, Stockholm, Sweden, [3]Kanazawa University, Kanazawa, Japan, [4]Lund University, Lund, Sweden, [5]The University of Tokyo, Tokyo, Japan

Tumor-related T-cell activation and subsequent clonal expansion are essential for an effective anti-cancer immune response. Thus, quantifying the clonal distribution of T-cells in cancer tissue from patients might provide prognostic and predictive information, particularly in high immunogenic tumors like non-small cell lung cancer (NSCLC). We evaluated TCR clonality in the tumor microenvironment of NSCLC, its relation to the *in situ* immune phenotype, and its clinical impact in a cohort of 182 resected NSCLC patients. The α and β TCR clones were determined based on RNA sequencing data, and the Gini index was used to weight individual clonal distribution. We used matched FFPE cancer tissue for multiplex immunofluorescence cell analysis and *in-situ* sequencing of T-cell clones. The analysis revealed a broad spectrum of TCR clonality patterns, including tissue with high TCR diversity and high evenness (low Gini coefficient) and tissue with clonal dominance with low evenness (high Gini coefficient). Highly expended clones were detected in 15/182 patients, whereas 43/182 revealed no clonal enrichment. A low TCR clone evenness (high Gini coefficient) was significantly more frequent in normal lung areas than in the corresponding tumor areas (n=20, p=0.02). In the cancer tissue, a high Gini index further correlated with high tumor mutational burden, indicating neoantigen-induced T cell clone expansions. Correspondingly, high TCR clonality was associated with an inflamed tumor phenotype associated with PD-1+ immune cells, CD3+, CD8A+, CD163+, and CD138+ cells, as well as higher expression of genes connected to immune activation (PRF1, GZMB, GZMH) and T cell exhaustion (PD-L1, LAG3, TIGIT). Cancer tissue with dominant T-cell clones also showed higher numbers of mature tertiary lymphoid structures with germinal centers. *In situ* sequencing suggested a close spatial relation between specific T cell clones and tumor cells. Finally, NSCLC patients with dominant T-cell clones showed strong responses and longer survival when treated with immune checkpoint inhibitors. This suggests that TCR clonality analysis is a strong candidate for precision diagnostics. Plausibly, the dominant clones found in NSCLC are responsible for a specific but malfunctioning anti-tumor response that can be unleashed by immune checkpoint inhibition.

#1517 Tc1 cytotoxic T-cells and Th1 helper T-cell rich tumor microenvironment is a hallmark of MSI colorectal cancers.

T. Mandelkow, Z. Huang, E. Bady, J. H. Muller, G. Sauter, J. Ebner, M. Lennartz, N. Gorbokon, R. Simon, M. Kluth, C. Hube-Magg, S. Minner, N. C. Blessin; University Medical Center Hamburg-Eppendorf, Hamburg, Germany

Background: Microsatellite instability (MSI-h) is a strong biomarker to predict response to immune checkpoint therapy and patient's outcome in colorectal cancer. Although enrichment of distinct T-cell subpopulations, such as type 1 cytotoxic T-cells (Tc1) or type 1 helper T-cells (Th1), have been identified to impact patient's outcome and response to immune checkpoint therapy, only little is known about the underlying changes in the composition of the immune tumor microenvironment.

Material and Methods: To assess the density, composition, degree of functional marker expression, and spatial interplay of T-cell subpopulations in 93 MSI and 1153 microsatellite stable (MSS) colorectal cancers, a tissue microarray as well as large sections were stained with antibodies directed against CD3, CD4, CD8, FOXP3, T-bet, GATA3, RORγT, BCL6, CD27, CD56, TIM3, PD-1, CTLA-4 Granzym B, and Ki67 using our BLEACH&STAIN multiplex fluorescence immunohistochemistry approach. A deep learning-based framework comprising two different convolutional neuronal networks (U-Net and DeepLabv3+) was used for image analysis.

Results: The composition of Type 1 (T-bet$^{\pm}$), Type 2 (GATA3$^{\pm}$), Type 17 (RORγT$^{\pm}$), NKT-like (CD56$^{\pm}$), regulatory (FOXP3$^{\pm}$), and follicular (BCL6$^{\pm}$) cytotoxic (CD3^{+}CD8$^{\pm}$) or helper (CD3^{+}CD4$^{\pm}$) T-cells showed marked differences between MSI and MSS patients. For instance, the density and proportion of Tc1 as well as Th1 was significantly higher ($p<0.001$ each) in MSI compared to MSS patients. In contrast, the density and composition of Tregs, Th2, Th17 T-cells was significantly lower in MSI compared to MSS patients in the intraepithelial tumor compartment. In addition, among the MSI colorectal cancers, NKT-cells showed the highest level of Granzyme B that was significantly higher than in MSS patients ($p<0.05$). The degree of immune checkpoint expression (i.e., TIM3, PD-1, CTLA-4) was significantly higher in MSI compared to MSS patients for most T-cell subpopulations ($p<0.05$ each). The additional analysis of 10 large sections confirmed the observations from the TMA analysis and revealed that the alterations in the T-cell composition seen in the center of the tumor largely reflect the T-cell composition at the invasive margin in both MSI and MSS patients.

Conclusion: This study identified a higher proportion of Tc1 cytotoxic T-cells and Th1 helper T-cells accompanied by a paucity of regulatory T-cell subpopulations, Th17 and Th2 T- helper cells in MSI colorectal cancers compared to MSS patients.

#1518 Understanding the role of VISTA in regulating T cells function and the therapeutic potential of blocking VISTA in triple negative breast cancer.

M. Abudula, Y. Astuti, M. Raymant, T. Luckett, P. Freeman, M. Schmid, A. Mielgo Iza;
University of Liverpool, Liverpool, United Kingdom

Immune checkpoint inhibitors (ICIs) targeting immune modulatory molecules have been widely used and have shown therapeutic efficacy in treating multiple malignancies in the last decade. However, in triple-negative breast cancer (TNBC), only around 5 % of patients showed a durable response to ICIs. While the response rates were increased up to 10% by combining ICIs with conventional chemotherapy, the majority of the patients did not respond to the treatment. Thus, there is a need to improve our understanding of the mechanism underlying unequal response to ICIs in TNBC and develop/discover new treatments to improve patient outcomes. The lack of response to ICIs has been attributed to the increased infiltration of immunosuppressive cells (including MDSCs, neutrophils and TAMs), as well as the presence of additional immune checkpoint receptors/ligands that may further suppress cytotoxic T cells (CD8+ T cells) in the tumor microenvironment (TME). V-domain Ig suppressor of T-cell activation (VISTA) is one of the immune checkpoint molecules attracting increasing attention in the context of anti-tumor immunity due to its broad expression across various cancer types and increased expression upon development of immune checkpoint resistance. However, the role of VISTA in the anti-tumor immune response and its therapeutic potential in TNBC remains unclear. In our study, we observed that VISTA is expressed in TNBC patients, with higher expression in neutrophils and macrophages. In the Py230 murine breast cancer model, VISTA expression increased upon paclitaxel (PTX), anti-PD-L1 and paclitaxel combined with anti-PD-L1 treatment compared to the control group, suggesting its potential role as a resistance mechanism in further inhibiting T cells. In the Py230 model, VISTA blockade increased the infiltration and activation of CD8+ T cells, as evidenced by the higher number of CD8+ T cells, increased CD69+CD8+ T cells, and Granzyme B production, indicating that VISTA blockade improved CD8+ T cells mediated anti-tumor immunity. To functionally test the role of VISTA, we stimulated CD8+ T cells and co-cultured them with naïve macrophages or tumor educated macrophages in the presence or absence of VISTA blocking antibody. Tumor-educated macrophages showed increased immunosuppressive activity which is abrogated with VISTA blockade. Moreover, we found that the immunosuppressive effect of macrophages on T cell activation needs direct cell interaction between VISTA on macrophages and T cells. In conclusion, this study shows the mechanism of action of VISTA in the regulation of T cells mediated anti-tumor immune response, and provides the rationale for blocking VISTA in TNBC.

#1519 Effect of obesity on CD4$^+$ T cells in the tumor immune microenvironment of colorectal cancer.

M. Ando, K. Yamada, M. Saito, K. Yamashita, T. Tsuneki, Y. Adachi, T. Abe, T. Mukoyama, R. Sawada, Y. Koterazawa, H. Harada, N. Urakawa, H. Goto, H. Hasegawa, S. Kanaji, T. Matsuda, Y. Kakeji;
Kobe University Graduate School of Medicine, Kobe, Japan

Background: The number of new cases and deaths from colorectal cancer (CRC) is increasing rapidly, and obesity is considered one of the risk factors. Obesity-associated cancers are related to the overproduction of hormones, induction of reactive oxygen species (ROS) production by free fatty acids, and changes in the gut microbiome. Obesity also promotes immune cell dysfunction in the tumor immune microenvironment (TIME). The increase of fatty acid levels due to obesity causes metabolic reprogramming and decreases the cytotoxic activity of natural killer (NK) cells and CD8$^+$ T cells, which accelerate tumor progression. However, the impact of obesity on CD4$^+$ T cells in the TIME remains unclear. Therefore, this study aimed to clarify how obesity affected the number and the anti-tumor activity of CD4$^+$ T cells in CRC using mouse models.

Methods: Seven-week-old male C57BL/6J mice were randomly divided into two groups and fed the control diet (CD) or high-fat diet (HFD) for nine weeks. Blood samples were collected from the buccal vein of the mice every four weeks after feeding for analysis. MC38 CRC cells of 4×10^6 were subcutaneously inoculated in the middle of the backs of mice to analyze tumor progression. Three weeks after tumor cell inoculation, the mice were sacrificed, and the immune cells of the tumor, blood, and various organs were analyzed.

Results: After nine weeks of feeding, the HFD-fed mice had a significantly increased body weight compared to CD-fed mice. Flow cytometry results revealed that the number and frequency of CD4$^+$ T cells in the blood were significantly reduced in HFD-fed mice compared to those in CD-fed mice, and the expression of programmed death-1 (PD-1) in CD4$^+$ T cells in HFD-fed mice was significantly higher than that in CD-fed mice at eight weeks. Three weeks after tumor inoculation, HFD feeding accelerated tumor growth and decreased the survival rate. The number of CD4$^+$ T cells in the tumors was significantly reduced in HFD-fed mice compared to that in CD-fed mice (55.9 vs 18.2 cells/mg; 95% CI 14.9-60.3 cells/mg; $P = 0.006$). The number of CD8$^+$ T cells in the tumors was also reduced, which was more pronounced for CD4$^+$ T cells than for CD8$^+$ T cells. In addition, the production of cytokines such as IFN-γ and TNF-α was significantly reduced in CD4$^+$ T cells and CD8$^+$ T cells of HFD-fed mice. In a depletion analysis of CD4$^+$ T cells, the feeding-dependent acceleration of tumor growth was not observed in each group. This result indicated that CD4$^+$ T cells were involved in accelerating tumor growth due to HFD-induced obesity.

Conclusion: We showed that the reduced number and dysfunction of CD4$^+$ T cells due to obesity led to a decreased anti-tumor response of both CD4$^+$ and CD8$^+$ T cells, ultimately accelerating the progression of colorectal cancer. Our findings may elucidate the pathogenesis for poor outcomes of colorectal cancer associated with obesity.

#1520 A novel cluster of cytolytic alpha/beta TCR$^{\pm}$CD4^{-}CD8^{-}T cells originating from CD8$^{\pm}$T cells with potent innate-like T cell killing ability: implicating adoptive T cell transfer therapy for hepatocellular carcinoma.

Cheng-Heng Wu[1], Te-Wei Tseng[2], Chen-Yang Huang[3], Ping-Hsun Ou[4], Yi-Chen Lin[4], Pin-Jung Chen[4], Po-Ting Lin[4], Chan-Keng Yang[3], Wei Teng[4], Tsung-Han Wu[5], Yung-Chang Lin[3], Chun-Yen Lin[6]

[1]School of Medicine, Chang Gung University, Taoyuan, Taiwan, [2]Internal Medicine, Chang Gung Memorial Hospital, Taoyuan, Taiwan, [3]Division of Medical Oncology/Hematology, Chang Gung Memorial Hospital, Taoyuan, Taiwan, [4]Division of Gastroenterology, Chang Gung Memorial Hospital, Taoyuan, Taiwan, [5]General Surgery, Chang Gung Memorial Hospital, Taoyuan, Taiwan, [6]College of Medicine, Chang Gung University, Taoyuan, Taiwan

Tumor immunotherapies represent promising strategies for treating various cancers, including hepatocellular carcinoma. In this context, immune cells, including the adoptive T cell transfer treatment, become the focus of interests. Notably, alpha/beta TCR$^{\pm}$CD4^{-}CD8^{-}T (DNT) cells is a subgroup of T cells that is ignored for a long time but was re-focused recently. These DNT cells are a group of cells with opposite functions in different condition, including pro-inflammatory or suppressive functions and possibly originated from over-stimulation of peripheral CD4$^{\pm}$T cells/CD8$^{\pm}$T cells or a special group of T cells formed in thymus. In our research results, we have found these DNT cells increased in murine hepatoma model, especially in the tumor microenvironment. In addition, these DNT cells from tumor microenvironment of murine hepatoma possessed potent tumor-killing ability. Furthermore, we analyzed the transcriptome profile of T cells in tumor microenvironment by single cell RNAseq approach (CITE-seq). We found DNT cells could be categorized into two main clusters, one is cytolytic DNT cells, resemble the potent CD8$^{\pm}$T cells, and another is the CD4$^{\pm}$T cell-like DNT cells. These cytolytic DNT cells are not exhausted but with high expression of cytolytic molecule and low hypoxia-inducible factor-1alpha (HIF-1a) expression. By trajectory analysis, cytolytic DNT cells come from the conventional CD8$^{\pm}$T cells but following a unique developmental pathway that is different from the exhausted CD8$^{\pm}$T cells. Interesting, these cytolytic DNT cells also expressed high level of Fcer1g molecule, a marker of innate CD8+T cells. In addition, these DNT cells could be generated and expanded in-vitro by IL-15 without TCR activation. In conclusion, we identified a cluster of cytolytic DNT cells, originated from CD8$^{\pm}$T cells, exhibits innate T cells behavior and potent killing ability. In addition, these cytolytic DNT cells could be generated and expanded in-vitro for the adoptive T cell transfer treatment of hepatoma.

#1521 Chromatin remodeler ACTL6A in CD8$^{\pm}$ T cells promotes antitumor immunity.

B. Wu[1], W. Thant[1], E. Bitman[1], T. Liu[1], L. W. Ellisen[2];
[1]Harvard Medical School/Massachusetts General Hospital, Boston, MA, [2]Harvard Medical School/Massachusetts General Hospital, Ludwig Center at Harvard, Boston, MA

Chromatin remodeling plays a pivotal role in dictating epigenetic and transcriptomic regulation governing cytotoxic T lymphocyte differentiation and effector function. However, the regulatory mechanisms underlying chromatin remodeler assembly and actions remains unclear. Actin-like gene family members have been implicated in the organization of chromatin landscapes, however their role in T cell functional regulation remains unknown. We identified Actin-like protein 6A/Actl6a as the most upregulated gene within actin-like family members upon CD8$^{\pm}$ T cell activation across multiple species. Additionally, *ACTL6A* is highly expressed in human tumor-infiltrating CD8$^{\pm}$ mitotic tissue-resident memory T cells, suggesting a functional importance of *ACTL6A* in this subset. Deletion of mouse *Actl6a* in mature T lymphocytes impairs immune responses to transplanted syngeneic mouse tumors. T cell-specific *Actl6a* deletion mice exhibit a reduced effector memory population and attenuated cytotoxicity in their tumor infiltrating CD8$^{\pm}$ T cells. Heterozygous deletion of *Actl6a* displays an intermediate reduction of effector memory population and cytotoxicity between that of wildtype and homozygous knockout, indicating that ACTL6A acts in a dose-dependent manner to promote CD8$^{\pm}$ effector cell fate. T cell adoptive transfer further corroborates a CD8$^{\pm}$ T cell-intrinsic role of *Actl6a* on antitumor adaptive immunity. Currently, we are investigating the chromatin landscape and transcriptomic changes upon loss of *Actl6a* using ATAC-seq and RNA-seq. Furthermore, the dose dependency of Aclt6a on CD8$^{\pm}$ T cell effector function suggests that pharmacological or genetic approaches to increase Actl6a expression in CD8$^{\pm}$ T cells may have the potential to boost immune based anticancer therapies including CAR-T therapies.

#1522 Tumor-associated fibrosis leads to an increase in T-cell exhaustion and impairs tumor control in non-small cell lung cancer.

U. Y. Panni, V. Shenoy, B. Knolhoff, F. Ahmed, B. Herzog, W. G. Hawkins, J. A. Olson, D. G. DeNardo;
Washington University in St. Louis, St.Louis, MO

Lung cancer is the leading cause of cancer-related mortality with non-small cell lung cancer (NSCLC) being the most predominant type. Recent studies have shown the efficacy of anti-PD1 inhibitors which improved overall survival. However, this efficacy is limited to a subset of patients due to the intrinsic tumor resistance to immune checkpoint inhibitors. Our group recently demonstrated that tumor-associated fibrosis negatively correlates with T cell-mediated immune response in lung cancer. This is largely dependent on Col13a1-expressing cancer-associated fibroblasts (CAFs), which result in recruiting the immunosuppressive macrophages and regulatory T cells while limiting dendritic cells and CD8 T cell infiltration. Here, we characterize the effect of fibrosis on the TME including TILs and macrophages using an orthotopic KRAS and P53-driven murine NSCLC model (KPL86-mCher model) with FITC-induced fibrosis.Fibrosis significantly increased the number of cancer-associated fibroblasts and collagen density in KPL86-mCher lung tumors. Following carboplatin + pemetrexed and Anti-PD1 treatment, we observed no increase in tumor-infiltrating $CD4^+$ and $CD8^+$ T cells or decrease in tumor burden when compared with the non-fibrotic tumors. Rather, we observed a significant increase in exhausted T cells marked by high Tim3, PD1, and TOX in fibrotic KPL86-mCher tumors. Corresponding to these impaired T-cell responses, we found an increase in tumor-infiltrating alveolar macrophages with immunosuppressive phenotype under fibrotic tumor conditions. Our data suggests that tumor-associated fibrosis leads to an increase in CD8+ T cell exhaustion as well as immunosuppressive macrophage infiltration in our spontaneously derived murine model on NSCLC. Overall, this indicates that targeting tumor fibrosis may significantly improve the efficacy of immunotherapy which would have translational implications for patients with immunotherapy-resistant NSCLC.

#1523 The predictive potential of gamma-delta T cells and germinal B cells in cancer therapy for enhanced clinical outcomes.

A. Segura[1], **M. Dicome**[1], L. Song[2], X. S. Liu[3], A. Sahu[1];
[1]University of New Mexico Health Sciences Ctr., Albuquerque, NM, [2]Geisel School of Medicine at Dartmouth, Hanover, NH, [3]Dana-Farber Cancer Institute, Boston, MA

Introduction: Immune Checkpoint Blockade (ICB) therapy elicits clinical responses in a subset of patients in multiple cancer types, yet predicting response remains an open problem. While CD8-T cells remains to be focus, emerging evidence suggests role of other immune cell subtypes in favorable outcome of patients. This study presents the abundance of gamma-delta T (gdt) cell subpopulations in responders and non-responders. The analysis further contrasts differential abundances under immunotherapy and non-immunotherapy regimens across diverse cancers.
Methods: We performed joint analysis of data from 250 non-immunotherapy cohorts and 17 ICB cohorts. To infer differential abundance in each cohort, we first identified genes robustly upregulated in tumors of patients with favorable outcome, and then unbiasedly evaluated upregulated genes for enrichment for immune cell populations. The topmost differential abundant subpopulations were validated by de novo assembly and single cell analyses.
Results: Our analysis revealed similarities in the immune microenvironment across responders, irrespective of immunotherapy or non-immunotherapy modalities, strongly suggesting shared factors influencing response. Notably, gdt cells emerged as consistent predictors of better prognosis, being associated with favorable responses to ICB therapy and improved long-term survival in non-immunotherapy-treated cancer patients. Two independent validation approaches reinforce these findings. First, taking advantage of the fact that gamma and delta receptors are unique to gdt cells, we obtained precise estimates of gdt cells in tumors from their RNA-seq using de novo assembly. The assessment recapitulated our finding that favorable prognosis of tumors with of gdt cell levels. Second, analysis of several single-cell RNA-sequencing cohorts showed that patients with favorable prognoses consistently exhibit high gdt cell levels within tumors.
Conclusion: The study underscores a strikingly consistent responder immune microenvironment, whether under immunotherapy or non-immunotherapy setting, suggesting a shared response and resistance mechanisms. The likelihood of cross-resistance has implications when clinicians decide whether immunotherapy should be administered before or after the traditional therapies for patients. Our study also elucidates the role of gdt cells as potent biomarkers for ICB therapy and their broader significance in enhancing patient survival across various cancer types. Ultimately, these insights may refine patient selection and inform tailored treatment strategies, could elevating clinical outcomes in the realm of precision oncology.

#1525 Integration of high-plex tumor-Immune phenotyping and checkpoint interactions for deeper spatial characterization of human cancer tissues.

S. Bodbin[1], A. Viratham[2], R. Stad[2], **N. Ma**[2], A. Pratapa[2], N. Nikulina[2], J. Monkman[3], N. Jhaveri[2], H. Elofsson[1], S. Basu[1], A. Zieba-Wicher[1], A. Kulasinghe[3];
[1]Navinci Diagnostics, Uppsala, Sweden, [2]Akoya Biosciences, Marlborough, MA, [3]University of Queensland, Brisbane, Australia

Background: Immune evasion is a key cancer hallmark, and one of the primary mechanisms is the PD-1/PD-L1 checkpoint axis. While immunotherapies that target these interactions have reshaped cancer treatment, the variable efficacy in patients is not fully understood. Due to the weak correlation between PD-1/PD-L1 expression measured by single-plex assays and observed clinical outcomes, there is a need to understand protein interactions at the cellular and subcellular level. Proximity Ligation Assays, detecting spatial interactions between ligand-receptor targets, provide insights into the activation of signaling pathways. Coupled with high-plex spatial phenotyping with tumor and immune profiling biomarkers, the integration of cellular and functional information will be beneficial for a deeper characterization of the tumor microenvironment (TME), understanding immune responses, and identifying spatial signatures for patient stratification and targeted treatment strategies.
Methods: In this study, we phenotyped biopsies from head and neck cancer patients enrolled in immune checkpoint inhibitor therapies. We integrated Naveni® PD-1/PD-L1 proximity ligation assays and a customizable high-plex PhenoCode™ Signature Panel (CD3ε/CD8/CD20/CD68/PanCK) for high-throughput profiling of the TME utilizing the PhenoImager® HT 2.0 platform. Comprehensive bioinformatic analyses were conducted for whole-slide segmentation, identifying cellular phenotypes, spatial neighborhoods, functional interactions, and distinct spatial signatures via the open-source image analysis software QuPath.
Results: Our analyses revealed key differences in the localization of the PD-1/PD-L1 interactions within the TME of head and neck cancers. Areas of PD-1/PD-L1 interactions are associated with immune cell types on the periphery of the tumor and some within the tumor-infiltrating lymphocytes. The PhenoCode Signature panels helped resolve the localization of PD-1/PD-L1 interactions to immune cell types within the TME and provided a dual workflow for spatial co-localization of interacting receptor/ligand interactions and cell phenotypes within the TME.
Conclusions: By combining spatial immune profiling with Akoya's PhenoCode Signature panels and protein-protein interaction data from Navinci's Naveni® PD-1/PD-L1 assay, deep correlative insights of the TME can be applied to improve predictions of clinical outcomes. This innovative approach enriches our comprehension of underlying mechanisms and stands as a promising tool for refining patient selection and optimizing treatment outcomes in immunotherapy.

#1526 The distinct tumor microenvironment of advanced hepatocellular carcinoma with high PVR or high PD-L1 expression.

L.-C. Lu, Y.-H. Lee, T.-h. Liu, Y.-Y. Shao, A.-L. Cheng, C.-H. Hsu;
National Taiwan University Hospital, Taipei, Taiwan

Background: The combination of anti-PD-L1 and anti-VEGF has been the standard-of-care for advanced hepatocellular carcinoma (HCC), while additionally targeting TIGIT is under active investigation. We aimed to explore the expression and clinical significance of PVR (CD155), the ligand of TIGIT, within the tumor microenvironment (TME) of advanced HCC.

Methods: All HCC tumor specimens were obtained at the advanced stage of HCC. Immunohistochemistry (IHC) was employed to evaluate membranous staining of PVR and PD-L1 of tumor specimens, and semiquantitative scores with IHC 0, 1, 2, or 3 were given if < 1%, ≥1% but < 5%, ≥5% but < 10%, or ≥10% of tumor cells (TCs) and tumor-infiltrating immune cells (ICs) were PVR or PD-L1 positive. Selected tumor specimens underwent immune gene expression profiling using the nCounter Analysis System (NanoString Technologies, Inc.) with the PanCancer Immune Profiling Panel.

Results: The study enrolled 67 advanced HCC patients, with median age of 59.2 years (male:female = 57:10). Forty-eight (71.6%) of the patients were hepatitis B virus (HBV) surface antigen positive, and 23 (34.3%) had received sorafenib before the study. Thirteen (19.4%) and 18 (26.9%) tumor tissues showed positive PVR expressions (IHC scores ≥1) in TCs and ICs, respectively; Seventeen (25.4%) and 36 (53.7%) tumor tissues showed positive PD-L1 expressions in TCs and ICs, respectively. The expressions of PVR in TCs or ICs showed no association with clinical factors, such as sex, age, HBV infection, sorafenib treatment, or overall survival. Interestingly, in both TCs and ICs, the intensities of PVR and PD-L1 expression were inversely correlated for those with at least IHC scores ≥1 in either PVR or PD-L1 (TCs, $n = 26$, $r = -0.6966$, $p < 0.0001$; ICs, $n = 46$, $r = -0.4548$, $p = 0.0015$). Immune profiling of the selected tumor specimens showed that those with high PVR but low PD-L1 expressions had significantly lower CD8 T cells scores, lower cytotoxic cells scores, and lower CD8/Treg ratio than those with high PD-L1 but low PVR expressions.

Conclusions: There was an inverse correlation observed between expressions of PVR and PD-L1 in the advanced HCC tissues. The TME of those with high PVR expression was distinct from those with high PD-L1 expression. These findings may have important clinical implications for developing combination immunotherapy in advanced HCC. (This work is supported by grants from the Ministry of Science and Technology, Taiwan, MOST 110-2314-B-002-204-MY3).

#1527 Exploring the role of tertiary lymphoid structure in the tumor microenvironment of cholangiocarcinoma.

S.-Y. Chung[1], M.-H. Chen[1], Y.-C. Yeh[1], Y.-C. Chang[2], Y.-C. Wang[2];
[1]Taipei Veterans General Hospital, Taipei, Taiwan, [2]National Yang Ming Chiao Tung University, Taipei, Taiwan

Cholangiocarcinoma is the second most common hepatobiliary malignant tumor besides liver cancer, grows from bile duct epithelial cells. However, surgery is the only hope for most patients with cholangiocarcinoma, but the effectiveness of treatment is not outstanding. Even though other methods of treatment, such as chemotherapy and radiation therapy, have limited effects. The immunotherapy and precision treatment have become the latest expectations of patients. Here, we analyzed the TCGA and GEO database to classify the cold and hot tumor using hierarchical clustering. The MCP counter results demonstrated that two genes, MS4A1 and CD79A, could identify the hot and cold tumor subgroups after TCGA data training and similar results show in GEO database. We also performed the tissue array for 105 cholangiocarcinoma tissue samples and found patients with high expression levels of MS4A1 or CD79A have better disease free survival (DFS) and progression free survival (PFS) (p value =0.0131 and 0.0017). In addition, we tested the tertiary lymphoid structures (TLS) signatures in tissue array sections, which is associated with the present of MS4A1 and CD79A. The results shows that patients who received the immunotherapy with TLS signatures have longer overall survival (OS) and PFS (p value =0.017 and 0.006). Collectively, B cell lineages or TLS could be an ideal biomarker to lead the clinical treatment and wish can broader applications in other diseases.

#1528 Flowcytometric based approach to investigate prostate tumor microenvironment.

karishma sajnani, Sini Eerola, Konsta Kukkonen, Hanna Rauhala, Tapio Visakorpi, **Alfonso Urbanucci**

Faculty of Medicine and Health Technology, Tampere University, Faculty of Medicine and Health Technology, Tampere, Finland

Prostate cancer (PC) and its tumor microenvironment (TME) are heterogenous and evolving along with the treatment patients are exposed to. Modelling of the TME represents an attractive approach to understand how PC evolves and spreads. Flow cytometry is a technique for quantitative measurement of single cell profiling based on the cell surface as well as intracellular markers. We designed a flowcytometric based approach to investigate the interplay between the PC cells and immune cells in a direct coculture. Cells are fluorescently tagged with a cell tracer and the analysis is performed separately on the adherent and non-adherent cells. To optimize the readout method, we investigate the interplay between Jurkat cells and PC cells (LNCaP) as well as immortalized prostate epithelial cell models modified to mimic early events in prostate carcinogenesis (RWPE-1 cells overexpressing androgen receptor, RWPE-1-AR, and having PTEN deletion, RWPE-1-AR-PTENdel).Jurkat (suspension culture) cocultured with LNCaP (adherent culture) exhibited 40% decrease in viability but only 30% of LNCaP dying cell in the floating population compared to LNcaP only which is 60%. When Jurkat were activated using Phorbol 12-myristate 13-acetate (PMA), we observed an increase in LNCaP cell death. Jurkat viability was not impacted in presence of RWPE-1 neither when exposed to RWPE1-AR-PTENdel. In summary our Flowcytometric-based approach will help to understand the interplay between immune cells and prostate cancer cells.

#1529 Development of lymphoid aggregates in metastatic uveal melanoma tumors treated with tebentafusp.

T. Sato[1], C. Britton-Rivet[2], S. Khakoo[2], A. Easton[3], A. Kazachenka[2], L. Collins[2], E. Leach[2], A. Benlarech[2], S. Stanhope[2], M. O. Butler[4]; [1]Thomas Jefferson University, Philadelphia, PA, [2]Immunocore Ltd., Abingdon, United Kingdom, [3]University of Oxford, Oxford, United Kingdom, [4]Princess Margaret Cancer Centre, Toronto, ON, Canada

Tebentafusp (tebe), targeting gp100, is the first TCR-CD3 bispecific to demonstrate overall survival (OS) benefit and is approved for the treatment of metastatic uveal melanoma (mUM). We have previously shown B cell recruitment into the tumor associates with OS on tebe [1]. We explored further the formation of lymphoid aggregates (LA) within the tumor microenvironment in response to tebe. HLA-A*02:01+ 2L+ adult patients (pts) with mUM were treated with tebe (NCT02570308). Paired tumor biopsies were collected at baseline (n=70), after 3 doses of tebe (n=48), and at radiographical progression (n=17). Presence of B cells, T cells and macrophages was assessed by immunohistochemistry, using antibodies against CD20, CD3 and CD163 respectively, and digitally quantified. Using digital density analysis, aggregates of ≥10 CD20+ B cells within CD3+ T cell area in a 100µm radius were defined as LA. At progression pts were categorized by OS ≥12 or <12 months. Mean fold change (FC) was used. At baseline, B cells were detected in 90% of pts (median 5 B cells/mm^2) with those pts having no more than 2 LA/mm^2 (17% pts with 1 LA/mm^2 and 3% pts with 2 LA/mm^2). The median number of B cells in the biggest LA per sample was 24.B cells were recruited into the tumor after 3 doses of tebe (median 32 B cells/mm^2, FC 3, p=6.5e-05). The LA density increased up to 6 LA/mm2 (23% pts with 1 LA/mm^2, 8% pts with 2 LA/mm^2, 6% pts with 3 LA/mm^2 and 2% pts with 6 LA/mm^2) with a trend for an increase in LA size (median B cell number in biggest LA = 30, p = 0.67). Tumors with a low baseline CD163+ macrophage to CD3+ T cell ratio, which was previously associated with longer OS on tebe, tended to have more LA/mm^2 at baseline and on-treatment than those with a high ratio. At progression, pts with long OS had more B cells in the tumor compared to short OS (median 20 vs 2 B cells/mm^2; FC 5, p=0.05). Additionally, more pts with long OS had LA than pts with short OS (6/12 pts vs 1/5 pts respectively) with a density not exceeding 1 LA/mm^2. LA size was larger in pts with long OS compared to short OS (median B cell number in biggest LA 30 vs 10 respectively). LA in the short OS patient was found in the normal adjacent tissue compared to the LA in long OS patients which were located in the tumor and invasive margin. Tebe enhanced the formation of LA in the tumor microenvironment, notably in the low immunosuppressed tumors, which is consistent with the hypothesis that it results in epitope spread. These observations provide deeper insight into the mechanism of action of tebe and helps to explain prolonged survival of mUM pts beyond radiographical progression. [1] Greenshields-Watson A. et al., 619, SITC 2022

#1530 Tumor cell line-derived xenograft subtype shapes tumor microenvironment composition in BRGSF-HIS mice.

P. Martin-Jeantet, S. Hedir, F. Sonego, G. Martin, Y. Cherifi, **K. Thiam**;
genOway, Lyon, France

The relevance of preclinical models has vastly improved with mice bearing a human immune system, especially in the context of immunotherapy. BRGSF (Balb/C Rag2$^{-/-}$, IL2Rγ$^{-/-}$, SIRPαNOD and Flt3$^{-/-}$) is a highly immunodeficient mouse featuring reduced murine myeloid cells. BRGSF mice reconstituted with human cord blood CD34^{+} cells (BRGSF-HIS) develop functional lymphoid and myeloid compartments. This engraftment is stable for over a year (Labarthe *et al.*, 2019) and mice do not develop GvHD. Myeloid compartment can be transiently boosted with exogenous human Flt3L injections. In contrary to other models overexpressing human cytokines to develop human myeloid cells, Flt3L-treated BRGSF-HIS mice do not show side effects. BRGSF-HIS mice are permissive to mouse and human cancer cell lines engraftment and represent a valuable preclinical model to study cancer development and test novel therapeutics. Effect of Flt3L-induced boost on myeloid compartment is seen in a non-small cell lung cancer (A549) tumor model. A single boost prior to tumor cell inoculation associates with increased tumor-infiltrating T-cells (mainly CD8^{+} T-cells) and myeloid cells, and reduced tumor-infiltrating NK cells in the tumor microenvironment (TME). Human triple negative cancer cell (TNBC) MDA-MB-231 and human pancreatic adenocarcinoma HPAFII cell lines are widely used in cancer research and drug development. We show that upon implantation in BRGSF-HIS mice, *in vivo* growth of human cell line-derived xenograft (CDX) is CD34^{+} donor independent and the TME composition varies according to cell line used. As seen in TNBC patients (Zheng *et al.*, 2021); TME of MDA-MB-231 bearing BRGSF-HIS mice is enriched in myeloid cells, mostly CD206^{+}/CD163^{+} M2 macrophages. CD163-expressing M2 macrophages represent the main tumor-associated macrophages, and are known to promote breast cancer initiation, angiogenesis, invasion, and metastasis by generating an immunosuppressive TME. Interestingly, TME composition evolves over time, with increased T cells frequency in later stage (tumor volume over 1000 mm^3 compared to 500 mm^3) depicting cancer cell plasticity. Conversely, TME of HPAFII bearing mice is mainly composed of T cells enabling T cells-based therapy. Treatment of BRGSF-HIS mice bearing HPAFII tumor cells with combotherapy based on CD3xTAA + CD28xTAA efficiently reduces tumor growth *in vivo* compared to vehicle-treated mice or mice injected with CD3xTAA alone. Induced systemic immunomodulation is observed in the TME where increased numbers of both CD4 and CD8 T cells are observed upon combotherapy. Remarkably, while no CD34^{+} donor effect is observed in CDX growth kinetic, response to treatment appears to be donor dependent with apparition of “weak” and “good” responders. This heterogeneity of response mimics what is observed in clinic and enables further investigations of treatment mode of action and immune escape mechanisms.

#1531 TIL analysis demonstrates different mechanisms underlying PD-1 resistance in animal models.

S. Qiao, Y. Liu, W. Liu, W. Pan, X. Zhou, L. Wang, M. Chai, Y. Liu, H. Yang, **Z. Yu**;
Biocytogen Pharmaceuticals (Beijing) Co., Ltd., Beijing, China

Despite the tremendous success of PD-1 immunotherapy in treating cancer, resistance to the therapy is an inevitable risk. One of the major mechanisms underlying this resistance is alterations in the tumor microenvironment, including tumor-infiltrating lymphocyte (TIL) profiling changes after anti-PD1 treatment. To better understand the mechanism of PD-1 resistance, characterization of TILs in the tumor microenvironment was explored. First, immune cell profiling was performed in syngeneic tumor models established by 19 cancer cell lines without anti-PD-1 treatment. Depending on the tumor model, absolute numbers of $CD45^+$ cells and immune cell subsets varied. Moreover, stratifying the analysis based on tumor size (100 mm^3 to 3000 mm^3) revealed alterations in the proportion of immune cell percentages in MC38 tumors, which implies alterations in TIL frequency during cancer progression. Next, we investigated the TIL profile in two PD-1 resistant models: a hPD-1 antibody-induced resistant model and a syngeneic model in aged mice. The hPD-1 antibody resistant model was induced by multiple rounds of hPD-1 antibody retreatment on MC38 tumor-bearing humanized B-hPD-1/hPD-L1 mice. Efficacy results from this model further validated their resistance to hPD-1 treatment (0% tumor growth inhibition (TGI)), while the control group, which was not serially treated, showed substantial tumor inhibition (82.2% TGI). Next, mPD-1 antibody resistance was evaluated in aged wild-type mice. While mPD-1 efficacy on MC38-bearing young mice was approximately 85.5% TGI, the efficacy of this treatment in aged mice yielded only 6% TGI. TIL analysis in these models was subsequently performed: in the hPD-1-treated control mice that were responsive to anti-PD1 treatment, the numbers of total T cells, cytotoxic T cells ($CD8^+$) and MHC II positive cells were increased, while the anti-tumor effector cells in the serially treated resistant mice were either unchanged (total T cells and MHC II positive cells) or decreased ($CD8^+$ cells); strikingly, an increase in inhibitory myeloid-derived suppressor cell (MDSC) populations was also observed in the resistant model post-treatment. In the anti-PD1 treated aged mice, the frequency of TILs was unchanged upon mPD-1 treatment, suggesting that resistance in aged mice may be due to non-responsiveness of the immune cells. In sum, our results demonstrate different mechanisms underlying anti-PD-1 resistance, and suggest that a more thorough analysis of the TILs present in the tumor microenvironment could predict the responsiveness to PD-1 therapy and inform treatment strategies.

#1532 Improved reproducibility in multiplex immunofluorescence analysis of the tumor microenvironment using a novel quenching solution.

M. Levin, J. Heath, A. Schrank-Hacker, S. Dunn, M.-C. Vu, I. Hamza, D. Schwartz;
Leica Biosystems, Vista, CA

Formalin-fixed, paraffin-embedded (FFPE) tissues are commonly used in histopathology because the fixed tissues are stable and easy to store. In the context of immunofluorescence detection, however, endogenous autofluorescence of FFPE tissues can significantly reduce or mask immunofluorescent signals. The autofluorescence of FFPE tissues is caused by a variety of factors, including the presence of endogenous fluorophores, tissue fixation, and processing. While there are several methods that can be used to quench autofluorescence in FFPE tissues, chemical quenchers, which absorb or scatter light, are most frequently used for multiplex IF. Examples of chemical quenchers commonly used in manual multiplex staining include Sudan Black B and TrueBlack; however, these are not chemically compatible for use on automated platforms such as the Leica Biosystems BOND RX. Due to the need for increased throughput and decreased hands-on time, automation has risen in popularity versus manual staining, leading to a need for a versatile quenching solution compatible with automation. Here we demonstrate that NovaPlex Quenching Solution (NPQS), a novel proprietary quenching agent, reduces the background caused by autofluorescence and enhances the signal of the Cell IDx UltraPlex multiplex immunofluorescent (mxIF) assay across tissue types. Qualitative studies showed a decrease in autofluorescent signal in FFPE mouse spleen stained with antibodies against B220/Foxp3/CD3e, suggesting the utility of NPQS in mouse models of cancer and immunity. Similarly, nonspecific background was decreased across FFPE human tissue types, including lung adenocarcinoma stained for CD8/Foxp3/CD3e/CD4 and tonsil stained for CD8/Foxp3/PD-1/CD4. Further statistical studies in FFPE human tonsil tissue stained with CD8/Foxp3/PD-1/CD4 showed there was no significant decrease in dye intensity across all four markers and channels, resulting in a significant increase in signal-to-noise ratio for both CD8 at 490nm and PD-1 at 650nm ($p<0.05$). These experiments using Cell IDx/LBS UltraPlex mxIF technology demonstrate an effective method to improve the signal-to-noise ratios of fluorophores without reducing signal intensity from any of the target proteins in these parallel multiplex immunofluorescent assays.

#1533 Characterizing tumor-immune surveillance in Li-Fraumeni syndrome.

Camilla Giovino, Nicholas Fischer, Noel Ong, Ashby Kissoondoyal, Ran Kafri, David Malkin

Hospital for Sick Children, Toronto, ON, Canada

Li-Fraumeni Syndrome (LFS) is a cancer predisposition syndrome associated with germline *TP53* mutations and increased lifetime risk of developing multiple cancers. p53, the protein encoded by *TP53*, plays a role in regulating various aspects of immune cell biology. Accordingly, inactivation of p53 in tumor cells shapes interactions with the immune system and influences the anti-tumor immune response. Mutation or deletion of p53 in immune cells also favors tumor development and progression. However, to date, a comprehensive study of immune cell populations and the anti-tumor immune response has not been undertaken in the context of LFS. We hypothesized that germline *TP53* mutation carriers possess dysfunctional immune cells and/or immune responses, supporting LFS-associated tumor progression. Our preliminary data indicate a profound defect in tumor-immune surveillance in an LFS murine model. We observed that MC38 cancer cells develop significantly faster into tumors when injected into LFS mice (harboring a gain-of-function mutation $Trp53^{R172H/WT}$) compared to wildtype (WT) control-mice. Importantly, we identified significant alterations in immune cell compositions and phenotypes within the tumor microenvironment as well as immune organs using flow cytometry. We are currently using *ex vivo* proliferation assays and cytotoxicity assays to investigate the impact of mutant p53 on the tumor-killing ability of immune effector cells. Altogether, an improved understanding of anti-tumor immune dysfunction in the context of germline *TP53* mutation may reveal the potential for innovative therapies to target different facets of the immune system to intercept cancer progression in LFS patients.

#1534 The tumor immune microenvironment at different stages of non-small cell lung cancer.

M. Hansen[1], Q. Zhou[2], Y. S. DeRose[2], M. Kovacsovics[2], B. Brintz[2], B. L. Witt[2], K. L. O'Neill[1], S. Hu-Lieskovan[2];
[1]Brigham Young University, Provo, UT, [2]University of Utah, Salt Lake City, UT

Introduction: To better understand the immune microenvironment in non-small cell lung cancer (NSCLC), we evaluated immune cell populations within the tumor parenchyma and their interaction at the periphery of the tumors at different stages of disease.
Methods: 27 whole tumor slides were collected from NSCLC patients of all stages after surgical resection. Tissue slides were stained with multiplex Opal immunofluorescence for CD8, CD68, CK, PD-1, PD-L1, FoxP3, and DAPI using a Leica Bond automated stainer. Slides were scanned at 20x magnification by Akoya Polaris whole slide scanner and spectrally unmixed. Spatial analyses were performed on the HALO software.
Results: Density of CD8 T cells, T regulatory (Treg) cells, and macrophages were significantly higher ($p=0.001$) in the interface region compared to the tumor and stroma. There is abundant CD8 T cell infiltration in the tumor at early stage I and this decreased significantly ($p=0.05$) at higher stages. PD-1− CD8 T cells significantly dropped with higher stage, while PD-1+ CD8 T cells did not. On the other hand, macrophage infiltration increased as stage increased, with most of the increase driven by PD-L1− macrophages. No statistically significant trends were observed in Treg cells across stages, but they appeared to be higher in stage II. No differences in immune infiltration were observed between the NSCLC subtypes adenocarcinoma and squamous cell carcinoma. No correlation was found between proximity of immune cell subsets to tumor cells and stage.
Conclusion: The tumor microenvironment in NSCLC is rich in CD8+ cells at early stage and their density decreases as the stage of the disease increases, while macrophage infiltration increases as the disease stage progresses.

#1535 Differential immune microenvironments in triple-negative breast cancer and hormone receptor-positive HER2-negative breast cancer: A spatial analysis via multiplex immunofluorescence.

Y. Cha, I. Park, S.-J. Shin;
Yonsei University College of Medicine, Seoul, Korea, Republic of

Objective: To elucidate differences in immune cell (IC) composition and their spatial distribution between triple-negative breast cancer (TNBC) and hormone receptor-positive HER2-negative breast cancer (HR+HER2-BC), and to evaluate the effect of PD-L1 status on these parameters.
Methods: We selected 32 patients with ≥60% tumor-infiltrating lymphocytes (TIL) (TNBC, n=18; HR+HER2- BC, n=14). Multiplex immunofluorescence was employed on resected tumor tissues. Using markers such as CK, CD20, CD8, CD4, and FOXP3, IC types and tumor cells (TC) were identified in both stromal and tumor areas. We analyzed and compared cellular density and proportional distribution of IC, and spatial interactions (both IC-TC and IC-IC) based on tumor subtype and PD-L1 status.
Results: TNBC exhibited a unique IC composition with a higher proportion of CD8+IC (stroma: 27% vs 17%, p<0.001; tumor: 54% vs 31%, p<0.001) and CD4+FOXP3+IC (stroma: 3.9% vs 3.0%, p=0.036) than HR+HER2-BC. Among PD-L1 positive cases, TNBC had a denser stromal population of CD4+FOXP3+IC (146.4±67.1/mm2 vs 114.3±146.9/mm2, p=0.036). Both tumor subtypes displayed varied IC compositions based on PD-L1 status. Density plots revealed a pronounced clustering of IC near TC in TNBC, especially in PD-L1 positive cases. Analysis of cell-cell interactions showed diverse adjacency patterns between TC and various IC combinations with frequencies differing by tumor subtype and PD-L1 status.
Conclusion: The immune landscape, typified by IC composition and spatial distribution, varies between TNBC and HR+HER2- BC, with PD-L1 status further modulating these patterns.

#1536 Deciphering the crosstalk within the tumor microenvironment of NSCLC by a virtual microdissection approach.

S. Parab[1], F. Napoli[1], D. Cora[2], G. Doronzo[1], V. Communanza[1], L. Righi[1], L. Primo[1], V. Monica[1], L. Manganaro[3], B. Selene[3], P. Bironzo[1], G. Scagliotti[1], F. Bussolino[1];

[1]University of Turin, Turin, Italy, [2]Piemonte Orientale University, Novara, Italy, [3]Aizoon Technology Consulting, Turin, Italy

Introduction: Non-small cell lung cancer (NSCLC) is a highly heterogenous disease with the largest number of cancer-related mortality worldwide, one of the reasons for this is the complex and diverse tumor microenvironment (TME) comprising of numerous cell types. Several studies have already highlighted the importance of TME in dictating progression steps and response to therapies; however, a transcriptome-based molecular subtyping of patients in lung adenocarcinomas (LUADs) and lung squamous cell carcinomas (LUSCs) can further determine the distinct tumor immune microenvironment (TiME), which can eventually provide a systematic overview to improve the diagnosis and prognosis of patients.

Material and method: To elucidate such nature of interactions between tumor cells and cells comprising the TME, we exploited the transcriptome of 300 early stages (Ib-IIIa) NSCLC recruited in the prospective observational clinical trial PROMOLE. With the help of a clustering approach, initially we performed a molecular-based virtual stratification/dissection on the NSCLC patients. Next, to elucidate the relative cell-type abundance, a deconvolution approach was applied to identify the possibility of tumor infiltrating immune cells within these subgroups. Immunohistochemistry (IHC) was then used to substantiate these predictions on tumor cells.

Results and discussion: The resulting subgroups of LUADs and LUSCs are biologically well-characterized by mutational and gene expression profiles. Cell-type abundance approach identified samples which are enriched with tumor infiltrating immune cells like Neutrophils, Tcells, macrophages, etc. These findings were positively confirmed by IHC with multiple cell markers such as MPO, CD4, CD8, CD68, etc. Integrating these two results highlighted the proportion of TiME in the two different sub-populations along with shedding some light on the crosstalk happening between different cancer-/immune- cell lines.

Conclusion: The in-silico predictions on bulk RNA data by virtual micro-dissection, distinguished the two distinct NSCLC subtypes, each associated with clinical and molecular features. Furthermore, the immune cells infiltration suggests a possible role of infiltrating tumor immune cells with the prognosis of patients. Our analysis successfully performed an intra-sample and inter-sample comparison, which can unveil new prognostic markers that can provide relevant information for cancer immunotherapy.

#1537 CD63 acts as a key modulator of tumor progression and innate immune evasion in non-small cell lung cancer.

T. Lerbs[1], L. Cui[2], C. De Souza[2], R. Buettner[1], G. Wernig[2];
[1]University Hospital of Cologne, Bonn, Germany, [2]Stanford University, Stanford, CA

Introduction: Lung cancer is a major reason for cancer-related mortality worldwide, causing more than two million cancer deaths per year. Over the last decade, new therapies have allowed long-term survival for patients even in advanced stages. However, only a minority of patients benefits from these therapies and patients often grow resistant over time. An important mechanism that contributes to cancer growth and the development of therapy resistances is the cross-talk between cancer cells and their tissue microenvironment, in particular fibroblasts and macrophages. In this context, we explored whether the tetraspanin CD63 - which is commonly found on intra- and extracellular membranes - stimulates cancer growth and mediates pro-tumorigenic functions of the tissue microenvironment in NSCLC.
Methods: We analyzed patient tissue via immunohistochemistry and in-situ-hybridization. We deleted CD63 in cancer cell lines (A549, H810, LC19) and primary fibroblasts via CRISPR-Cas9. To assess phagocytosis, we used in vitro EdU assays and adaptive transfer models in vivo, and identified changes in cell signaling via mass spectrometry. We used an in vitro phagocytosis assay to determine the effect of CD63 on cancer cell phagocytosis through macrophages and analyzed the expression of M1 and M2-associated surface markers through flow cytometry upon co-culturing PBMC with cancer cells over one week.
Results: In patient sections, cancer tissue did not only express more CD63 on the gene expression and protein level but a stronger CD63 expression also correlated with a denser macrophage infiltrate. Looking for pro-tumorigenic functions, deleting CD63 in three cancer cell lines reduced cancer cell growth both in vitro and in an adaptive transfer model in vivo. Additionally, deleting CD63 impaired the pro-tumorigenic focal adhesion signaling in primary fibroblasts. Concerning the interaction between cancer cells and macrophages, deleting CD63 reduced the macrophage-mediated phagocytosis of cancer cells and co-culturing primary monocytes with CD63-deficient lung cancer cells induced the expression of M1-associated surface markers on the PBMC.
Conclusion: In conclusion, these results demonstrate that the tetraspanin CD63 drives NSCLC growth by stimulating cancer cell proliferation - in part by interfering with focal adhesion signaling - and facilitating immune evasion by preventing cancer cell phagocytosis through macrophages and inducing an immunosuppressive phenotype in macrophages.

#1538 Impact of C-reactive protein on the efficacy of immune checkpoint inhibitors in non-small cell lung cancer.

W. Li[1], H. Guo[2];

[1]The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China, [2]The Second Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China

Background: Immune checkpoint inhibitors (ICIs) therapy has achieved remarkable success in the treatment of non-small cell lung cancer (NSCLC). Clinical studies have suggested a correlation between C-reactive protein (CRP) levels and treatment efficacy, but it remains unclear whether CRP can directly impact the efficacy. Therefore, we investigated the imapct of CRP on the efficacy of ICIs in NSCLC.

Methods: The tumor growth model was established in CRP knockout and wildtype mice by injecting LLC cells to evaluate the effect of CRP on tumor proliferation. The frequencies and phenotypes of macrophages and T cells in mouse tumors were detected by flow cytometry. The impact of CRP on macrophage polarization was evaluated using flow cytometry and IF, while its impact on T cell chemokines CCL5, CXCL9, and CXCL10 was analyzed by ELISA and qRT-PCR. mCRP and α-PD-1 were implemented in C57/BL6 mice injected with LLC cells to evaluate the effect of mCRP on tumor immunotherapy. The frequencies of T cells in mouse tumors were detected by flow cytometry. Expression of mCRP and infiltration of immune cells in human NSCLC tissues were analyzed using IHC.

Results: We found that tumor progression was enhanced and the proportion of tumor-infiltrated M1 macrophages was decreased in CRP knockout mice. Using human PBMC-derived macrophage and RAW264.7 cell lines, we demonstrated that the monomeric form of CRP, known as mCRP, induced M1 polarization of macrophages, leading to increased secretion of CCL5, CXCL9, and CXCL10. In tumor bearing mice, mCRP treatment enhanced anti-tumor immunity and suppressed tumor progression by increasing $CD4^+$ and $CD8^+$ T cell recruitment. Surprisingly, the combined treatment of mCRP and α-PD-1 induced more significant tumor regression than α-PD-1 treatment alone. Additionally, high level of mCRP in NSCLC tissues is correlated with a more inflamed tumor microenvironment phenotype.

Conclusion: mCRP can enhance the efficacy of immune checkpoint inhibitors in NSCLC by activating anti-tumor immunity.

#1539 A comprehensive analytical validation framework for antibodies used in the CellScape multiplex immunofluorescence assay.

C. E. Jackson[1], A. Christians[2], J. Boog[2], M. H. Ingalls[1], X. Meshik[1], A. Northcutt[1], K. E. Cashion[1], J. S. Schwarz[1], O. Braubach[1];
[1]Canopy Biosciences-A Bruker Company, St. Louis, MO, [2]Canopy Biosciences-A Bruker Company, Hannover, Germany

Background: Multiplex immunofluorescence (mIF) is a powerful tool that enables deep phenotyping of cells within the tumor microenvironment (TME). Careful optimization of multiplex antibody panels for specificity, sensitivity and reproducibility is crucial to achieving robust data and is a precondition for assay repeatability and standardization. We describe our validation procedure for VistaPlex™ multiplex assay panels.
Methods: Experiments were performed using the CellScape™ platform for precise spatial multiplexing. The platform enables automated cyclic mIF for readily available fluorophore-conjugated antibodies compatible with fresh frozen or FFPE tissues. The use of high dynamic range imaging further facilitates quantitative phenotyping, while excellent imaging resolution provides single-cell discrimination with high accuracy. To design a ready-to-use panel for immune cell phenotyping, individual antibodies were first screened for specificity and then optimized for labeling sensitivity. Signal-to-noise, inter-assay reproducibility, and intra-assay precision were evaluated across serial sections in a multi-stage testing matrix to validate each antibody in isolation and assembled into a panel. Resulting from this effort, we introduce a 15-plex ready-to-use VistaPlex immune profiling panel for human FFPE tissues.
Results: Image analysis of signal-to-noise ratios demonstrated robust performance of multiplexed antibodies across multiple tissue sections and tissue types. Measurements of both signal and quantitative immune phenotyping across technical replicates showed a high degree of intra-assay precision and inter-assay reproducibility. The 15-plex panel was validated on human tonsil, lung, breast, and colon tissues.
Conclusions: The CellScape platform enables simultaneous detection of multiple protein biomarkers on a single tissue section for deep immune cell profiling in the TME. Rigorously validated VistaPlex panels further streamline this spatial biology workflow and will aid in the generation of consistent and reliable results for end users.

#1540 The dendritic cell receptor DNGR-1 shapes immunity to cancer.

K. H. J. Lim[1], E. Giampazolias[2], B. Frederico[1], N. C. Rogers[1], P. Chakravarty[1], G. Kelly[1], A. Cardoso[1], E. Nye[1], A. Suarez-Bonnet[3], S. Priestnall[3], R. Goldstone[1], C. Science Technology Platform[1], S. Lee[1], O. Schulz[1], J. Strid[4], L. Zapata[5], C. Reis e Sousa[1];

[1]The Francis Crick Institute, London, United Kingdom, [2]Cancer Research UK Manchester Institute, Manchester, United Kingdom, [3]The Royal Veterinary College, Hatfield, United Kingdom, [4]Imperial College London, London, United Kingdom, [5]The Institute of Cancer Research, London, United Kingdom

Background: Central to the success of $CD8^{+}$ T cell-mediated anti-cancer response are type 1 conventional dendritic cells (cDC1s), acting as professional antigen presenting cells. In both mouse and human, DNGR-1 (a.k.a. CLEC9A) is a dedicated cDC1 receptor that, upon binding to its physiological ligand filamentous-actin (F-actin) exposed upon cell death, prime cytotoxic $CD8^{+}$ T cells specifically against dead cell-associated antigens. Here, we interrogate the role of DNGR-1 in shaping the tumor microenvironment during carcinogenesis.

Methods: We utilized two models of chemical carcinogenesis: 3-methylcholanthrene (MCA)-induced sarcoma, and azoxymethane (AOM) and dextran sodium sulfate colitis (DSS)-associated carcinoma. *Rag1*$^{-/-}$ (no B and T cells), *Clec9a*$^{gfp/gfp}$, *Clec9a*$^{cre/cre}$ and WT (wildtype) mice on C57BL/6 background were used. Primary MCA-sarcoma cell lines were generated and subsequently tested in a series of transplantation experiments in naïve syngeneic WT mice. Whole exome and RNA sequencing were performed to elucidate the mutational landscape and decipher the immunopeptidome of these primary cell lines.

Results: Upon challenge with MCA, there is shorter latency for tumorigenesis in DNGR-1-deficient mice (n=46), like in *Rag1*$^{-/-}$ mice (n=43), in contrast to immunocompetent WT hosts (n=59) (median: 95 vs 113 days, hazard ratio: 1.72, 95% CI 1.11-2.68, p=0.008). DNGR-1-deficient mice also display increased susceptibility to AOM-DSS carcinogenesis compared to co-housed WT mice. Majority (n=16/24, 68%) of MCA-induced primary sarcoma cell lines derived from DNGR-1-deficient hosts are highly immunogenic and were controlled/rejected at a similar rate, upon challenge in secondary naïve WT recipients, like those derived from *Rag1*$^{-/-}$ mice (n=13/19, 68%). Whole-exome sequencing of cell lines derived from DNGR-1-deficient hosts revealed that they harbor high mutational burden, including mutations in F-actin-binding proteins that have been previously associated with better survival outcomes in patients with cancer (Giampazolias *et al. Cell*, 2021). Collectively, these data argue that DNGR-1 protects against carcinogenesis and selects for less immunogenic tumor cells. To evaluate the degree of immunoediting which occurred in the respective primary host mice, we applied the evolutionary metric based on the ratio of nonsynonymous to synonymous mutations (dN/dS), and found that they are less immunoedited compared to cell lines derived from WT hosts.

Conclusion: Our findings highlight DNGR-1 as a novel immune checkpoint that couples cell death sensing and (neo-)antigen cross-presentation to functional tumor-specific $CD8^{+}$ T cell responses during cancer immunoediting. Understanding the mechanism by which DNGR-1 sculpts the mutational landscape of tumors may further inform the dynamics of cancer evolution and may have translational therapeutic implications in directing effective immunotherapy strategies.

#1541 Heterogeneity of the hormone receptor-positive breast tumor immune microenvironment according to patient's body mass index.

H.-L. Nguyen[1], T. Geukens[2], M. De Schepper[2], K. Van Baelen[1], M. Maetens[1], G. Zels[1], A. Mahdami[1], E. Isnaldi[1], S. Hatse[1], J. Verbeke[1], C. Matthys[1], B. Thienpont[1], E. Vanderheyden[3], T. Van Brussel[3], R. Schepers[3], G. Philips[3], B. Boeckx[3], D. Lambrechts[3], G. Floris[2], F. Richard[1], C. Desmedt[1];
[1]KU Leuven, Leuven, Belgium, [2]University Hospitals Leuven, Leuven, Belgium, [3]VIB-KU Leuven, Leuven, Belgium

Background: Obesity is a risk factor for postmenopausal hormone receptor-positive (HR+) breast cancer (BC) and is associated with poorer outcomes. "Obesity-paradox", a phenomenon where obesity (BMI ≥ 30) is associated with better outcomes in patients treated with immune checkpoint inhibitors (ICI), has been observed in several cancer types. It is however under-explored in BC, especially HR+ BC. Emerging data from recent trials (KEYNOTE-756 and CheckMate 7FL) have shown the potential benefits of ICI for treating early HR+ BC. This prompted the need for better insights into the biological link between obesity and HR+ BC, particularly its tumor immune microenvironment (TIME).

Patients & Methods: A monocentric cohort of 33 patients (11 lean, 11 overweight, 11 obese) with early HR+ BC was selected for the study, whose tumor tissues were collected and subjected to snRNA-seq. Unsupervised clustering and cluster annotation were performed on the processed data leading to identification of cell types and subtypes. We then performed differential gene expression (DGEA) and gene set enrichment analyses (GSEA) according to BMI category for each of the immune cell types.

Results: We identified a total of 76,773 immune cells belonging to six major cell types, namely B/plasma cell, dendritic cell (DC), mast cell, monocyte/macrophage (mono/macro), T cell, and natural killer (NK) cell. Their proportions varied between patients, however immune cellular composition was not associated with BMI. DGEA and GSEA revealed highly cell type-specific obesity-associated differences in the expression profile of immune cells. Notably, an enrichment of B cell-mediated immune activities, substantiated by the upregulation of Ig genes, was observed in B cells and plasma cells. This was however coupled with an overexpression of the checkpoint *BTLA* in B cells. CD8+ and CD4+ T cells showed a lower level of activation (higher *LEF1, TCF7*, lower *ANXA1, IL4R*), and NK cells a decreased cytokine production (*CD96, CD226*) and conflicting differential expression of cytotoxic molecules (lower *NKG7*, higher granzymes). Checkpoint genes such as *PDCD1, CTLA4, TIGIT, LAG3, HAVCR2* did not show significant changes in their expression in T/NK cells. Mast cells displayed a downregulation of antigen presenting genes (*CD74, HLA-A/B/E*). DC and mono/macro populations also exhibited both up- and down-regulation of genes involved in different immune pathways.

Conclusion: Our current data suggested that obesity was associated with multi-directional changes in the immune activities, possibly implying an unresolved inflammation in the HR+ BC tissue. Further investigation incorporating other cell types and their interaction with immune cells in both tumor and matched normal mammary tissues is warranted and on-going, which could provide more understanding of HR+ breast TIME and lead to speculation on therapeutic implications.

#1542 Epithelial cell adhesion molecule induces canonical Wnt pathway to promote stemness in colorectal cancer.

H.-C. Wu[1], S. Panda[1], K.-C. Chen[1], C.-C. Lee[1], H. Hsieh[2], Y.-J. Su[1];
[1]Academia Sinica - Institute of Cellular & Organismic Biology, Taipei, Taiwan, [2]National Health Research Institutes - Institute of Biotechnology and Pharmaceutical Research, Miaoli, Taiwan

Epithelial cell adhesion molecule (EpCAM) is a pleiotropic type-1 transmembrane glycoprotein and known cancer stem cell marker, yet its tumorigenic mechanisms remain elusive. Cancer stem cells (CSC) have been implicated in cancer progression and recurrence, but targeting them with therapeutics is a major challenge. It is known that EpCAM is highly expressed in CSCs of different cancer types. Here, we studied the role of EpCAM in colorectal cancer (CRC) stemness. First, we show that the extracellular domain of EpCAM (EpEX) functions as a ligand for Wnt receptors, frizzled6/7 and LRP5/6, while the intracellular domain (EpICD) upregulates transcription of these receptors. Further, EpEX-induced Wnt signaling activates TACE and γ-secretase enzymes to augment shedding of EpEX and EpICD, establishing a positive feedback loop. Importantly, we show that the EpCAM-neutralizing antibody, EpAb2-6, targets the Wnt pathway to attenuate stemness characteristics in colorectal cancer (CRC). Our EpCAM-neutralizing antibody (EpAb2-6) and a porcupine inhibitor (LGK974) each partially attenuated cancer stemness, while their combination abolished stemness-related endpoints, induced apoptosis *in vitro* and markedly diminished tumor progression in animal models of human CRC. From these findings, we conclude that EpCAM stimulates Wnt signaling to promote cancer stemness, and the combination of EpAb2-6 and porcupine inhibitors may represent an effective CRC treatment, including for KRAS-mutant cancers. Our findings reveal an opportunity to combat drug resistance in tumor stem cells. Thus, the mechanistic insights gained from our study may be useful to improve existing treatments or to develop novel anticancer therapeutics.

#1543 40-color spectral flow cytometry for comprehensive immunophenotyping of murine cancers.

A. J. Kare, L. Nichols, R. Zermeno, M. N. Raie, S. K. Tumbale, K. W. Ferrara;
Stanford University, Stanford, CA

Introduction: High-dimensional immunoprofiling is essential for studying host response to cancer immunotherapy. Synergistic agents often induce systemic changes in leukocyte abundance/function due to targeting, dosage, or delivery, necessitating multi-tissue analyses to decipher immune response mechanisms. We set out to dissect leukocyte composition in lymphoid tissues and tumors by using spectral cytometry, a multiplexed, high-throughput technology.
Methods: We engineered a 40-color spectral flow cytometry panel to immunophenotype all major leukocytes and their functional subsets. Naïve and tumor-burdened C57BL/6 mice treated with combinations of agonist CD40 (aCD40) and checkpoint inhibitors were sacrificed, and tissues were processed. Stained cells were acquired on a 5-laser CyTEK Aurora. Unmixing accuracy and resolution was validated via 780 NxN plots, and high-dimensional analysis was performed.
Results: Spectral cytometry affords resolution of 43+ parameters compared to 26 or less in conventional systems. We first designed a 25-marker backbone panel to identify all immune lineages. Additional channels were assigned to functional markers, allowing for profiling of migration, maturation, and activation in tumor-infiltrating leukocytes (TILs). In naïve secondary lymphoid tissues (SLTs), 35 distinct $CD45^{+}$ populations were resolved. Germinal center B cells (17% vs. ~0.3% of $CD45^{+}$ in other SLTs) and T follicular cells (31% vs. ~1-5% of CD4+ T cells in other SLTs) were mostly found in the Peyer's patches, representing a hypothesized model tissue for studying tertiary immune structures in tumors. Peripheral blood contained the highest frequency of NK cells (4%), monocytes (6%), basophils (0.3%), eosinophils (4%), and neutrophils (7%) as a percentage of $CD45^{+}$ cells. The spleen held the largest reservoir of CD4/8 central/effector memory cells (5% of $CD45^{+}$) while ~80% of all T cells in the lymph nodes were naïve. In primary lymphoid tissues (PLTs), 12 distinct thymocyte and 7 B cell populations were resolved. Wanderlust trajectory analysis revealed CD24 and CD127 as key developmental regulators in lymphocyte differentiation. Autofluorescence extraction was essential for myeloid phenotyping. With this approach, we found monocytes comprised ~60% of TILs following aCD40 treatment (~8% in non-treatment and checkpoint only controls) and had altered macrophage differentiation fates. aCD40-treated tumors also contained higher frequencies of activated $CD40/80/86^{+}$ DCs (~80/86/60% vs. ~60/51/50% of DCs in NTCs).
Conclusion: This work describes a novel tool that efficiently resolves leukocytes on the axes of time, tissue, and treatment. Applications range from serial monitoring of circulating blood, endpoint analysis, validation of multiplexed-IHC, and cell sorting. PLT and SLT data has been made publicly available to serve as a training tool and reference proteomic atlas in future work.

#6869 Paired single-cell B-cell transcriptomics and receptor sequencing reveal activation states and clonal signatures that characterize B cell immunity in acute myeloid leukemia.

S. Guo[1], **G. S. Mohan**[2], B. Wang[2], T. Li[1], N. Daver[2], Y. Zhao[1], P. K. Reville[2], D. Hao[1], H. A. Abbas[2];
[1]Harbin Medical University, Harbin, China, [2]UT MD Anderson Cancer Center, Houston, TX

Acute myeloid leukemia (AML) is the second most common adult leukemia with a five-year survival rate around 30%. For decades, AML treatment has centered around intensive chemotherapy frequently followed by allogeneic stem cell transplant (Allo-SCT). The power of Allo-SCT to induce lasting remission has been attributed to a potent graft-versus-leukemia effect and has inspired efforts to stimulate host immunity against AML via immune checkpoint blockade (ICB). Thus far, these studies have yielded mixed results. While tumor-infiltrating T-cells have long been the focus of immunotherapy investigations, a growing body of data points to a central role of B-cells in mediating anti-tumor immunity, and a comprehensive assessment of B lymphocytes within the AML immune microenvironment has never been carried out with single cell clonal resolution. We performed paired single-cell transcriptomic and B cell receptor (BCR) analysis on 52 bone marrow aspirate samples. These samples included 6 from healthy bone marrow donors (normal), 24 from newly diagnosed AML patients (NewlyDx), and 22 from 8 relapsed or refractory AML patients (RelRef), who underwent assessment both before and after ICB with azacitidine/nivolumab. We first used transcriptomic data to delineate canonical B-cell subpopulations and observed a reduction in nascent B cells and an expansion of differentiated B cells in AML patients (RelRef>NewlyDx). Overlaying BCR sequencing and clonotypic analysis revealed clonal expansion, low clonotypic diversity, and extensive somatic hypermutation in the RelRef samples, suggesting antigen-driven affinity maturation within the tumor microenvironment. Furthermore, we identified robust AP-1 expression (a marker of activation) in B-cells from NewlyDx patients and a marked loss of AP-1 in RelRef patients, suggesting that B-cell exhaustion may be a key immunologic feature of AML relapse. Importantly, we observed that AP-1 activity is restored and that specific B-cell clones expand after ICB, but only among patients who clinically respond to ICB. In line with these observations, we also noted the clonal expansion of AML-associated plasma cells and loss of clonotypic diversity among ICB clinical responders, pointing to an antitumor role for these clones. Finally, we characterized atypical memory B cells which demonstrate high antigen presentation activity, close interaction with AML cells and are associated with unfavorable clinical outcomes, suggesting that they play a direct role in aiding AML survival and immune escape. Collectively, our findings establish the dynamic landscape of AML-associated B-cells while identifying specific B-cell subpopulations and B-cell-AML interactions that may be targeted by the next generation of AML-directed immunotherapies.

TUMOR BIOLOGY: Metastasis Promoting and Suppressing Genes
Poster Session

#1547 Melanotransferrin (*MELTF*, CD228) as a determinant of melanomagenesis: *MELTF* expression attenuates melanoma progression in the A375-luc2 murine metastasis model and human patients.

J. Jandova, **G. T. Wondrak**;
R Ken Coit College of Pharmacy and UA Cancer Center, The University of Arizona, Tucson, AZ

The cell-surface glycoprotein melanotransferrin (MELTF, CD228) is a member of the iron-binding transferrin superfamily expressed in human melanocytes and other cell types. Dysregulated *MELTF* expression in malignant melanoma has been reported before but its specific role in tumorigenesis has remained elusive. Following our interest in the role of the transferrin receptor (TFRC) in melanomagenesis, our initial TCGA-analysis suggested that high *MELTF* expression is associated with increased melanoma patient survival. In order to explore the mechanistic role of *MELTF* in melanoma we performed CRISPR/Cas9-based *MELTF* deletion in A375-luc2 human malignant melanoma cells. ICP/MS-analysis indicated no difference in iron-content between *MELTF*_WT and *MELTF*_KO cells. NanoString nCounter™ ('PanCancer-Progression-Panel'; 770 genes) comparative transcriptomic profiling (*MELTF*_KO versus *MELTF*_WT) demonstrated an upregulation of EMT-related expression networks in *MELTF*_KO cells, an observation consistent with phenotypic detection of enhanced matrigel invasiveness; likewise, inclusion of recombinant glycosylated MELTF (Gly20-Gly711 His-tag; 92 kDa; 10-100 nM) attenuated invasiveness of *MELTF*_KO cells. In SCID mice, subcutaneous growth of *MELTF*_KO exceeded that of *MELTF*_WT xenografts, and intracardial injection followed by non-invasive bioluminescent monitoring revealed an increase in lung metastatic burden associated with decreased survival of the *MELTF*_KO group. These data support a heretofore unrecognized tumor-suppressive function of *MELTF* expression in melanoma progression, a mechanistic role consistent with a potential survival benefit associated with high *MELTF* expression observed in human melanoma patients.

#1548 Olfactomedin 4 deficiency promote de novo progression of prostate cancer in TRAMP mouse model.

H. Li, W. Liu, J. Zhu, K. Chin, G. P. Rodgers;
NIH National Heart, Lung & Blood Institute, Bethesda, MD

Prostate cancer is the most diagnosed solid tumor and the second leading cause of cancer-related death in American men. Olfactomedin (*OLFM4*) plays tumor suppressor roles and is associated with the initiation, growth, and clinical outcome of human prostate cancer. *Olfm4*-null mouse sporadically developed prostate epithelial neoplasia through up-regulated hedgehog signaling pathways. In this study, we have generated *Olfm4*$^{+/+}$*/GFP/TRAMP* and *Olfm4*$^{-/-}$*/TRAMP* mouse models to investigate *Olfm4* gene biological functions underlying prostate cancer de novo progression. We have observed that *Olfm4*$^{-/-}$*/TRAMP* mice developed more advanced prostate cancer at 47.6% (20/42) compared to *Olfm4*$^{+/+}$*/TRAMP* at 11.9 % (5/42) and had poor survival compared to *Olfm4*$^{+/+}$*/TRAMP* mice ($P<0.01$). Histopathological and immunofluorescent staining revealed that tumor tissues containing more heterogeneous cells such as Ar+/Ck8+ epithelial or Syn+ neuroendocrinal cells or Vim+/Ck8+ epithelium mesenchymal transition cells in the primary tumors obtained from *Olfm4*$^{-/-}$*/TRAMP* mouse. We found more tumor angiogenesis and metastases into lymph nodes, liver, lung, kidney, and soft tissues in *Olfm4*$^{-/-}$*/TRAMP* mice. The accumulations of the dendritic cell population in primary tumor and lung metastasis tumors were detected. The primary tumor was sensitive to androgen deprivation therapy by using castration with both *Olfm4*$^{+/+}$*/GFP/TRAMP* and *Olfm4*$^{-/-}$*/TRAMP* mice. However, castration-resisted EMT tumor cells or expressing neuroendocrine marker cells regrew after castration 7-8 months in both *Olfm4*$^{+/+}$*/GFP/TRAMP* and *Olfm4*$^{-/-}$*/TRAMP* mice. Furthermore, we tested JQ1, a BET bromodomain inhibitor, as an epigenetic targeted therapy reagent and found that JQ1 significantly inhibited tumor cell growth of *Olfm4*$^{-/-}$*/TRAMP* mouse tumor in the organoids culture. Taken together, we have provided novel evidence that *Olfm4* plays a tumor-suppressing role during prostate cancer de novo progression.

#1549 Molecular mechanism of CD146 nanobody in tumor metastasis inhibition mediating by IL-6/JAK/STAT3 signaling in triple-negative breast cancer.

K. Huang[1], H. Sun[1], C. Wu[1], D. Lin[2], J. Chen[1], Y. Chen[1], X. Fang[1], S. Chen[1], Y. Liang[1], H. Lin[1];
[1]First Affiliated Hospital of Shantou University Medical College, Shantou, China, [2]Cancer Hospital of Shantou University Medical College, Shantou, China

Background: CD146, an adhesion molecule involved in inflammatory regulation, is linked to increased aggressiveness in Triple Negative Breast Cancer (TNBC). Yet, the molecular mechanisms of CD1146-driven TNBC metastasis in an inflammatory context remain elusive. We synthesized CD146 nanobody (anti-CD146 #112-2), which degraded CD146 protein specifically, inhibiting IL-6-mediated JAK/STAT3 activation and suppressing TNBC metastasis. This study aims to elucidate the mechanisms of CD146 degradation by 112-2 and the role of CD146 in mediating inflammatory responses leading to TNBC metastasis.
Methods: CD146 knockout and overxpression cell models were created using CRISPR/Cas9 or lentiviral techniques. Lung metastasis was evaluated by injecting luciferase-labeled cells into the tail veins of Balb/c-nu mice, monitored with the IVIS Kinetic system. The impact of CD146 on TNBC metastasis in an inflammatory environment was explored through cell-adhesion assays and trans-endothelial migration assays using CD146 knockout models and HUVEC cells. Transwell assays assessed the influence of IL-6 and 112-2 on TNBC. CD146 mutant vectors with specific truncations were generated to confirm the binding sites between CD146 and 112-2. ELISA and immunofluorescence assays examined CD146 protein internalization. CD146 degradation by 112-2 was confirmed using proteasome inhibitor MG132 and lysosome inhibitor Bafilomycin A1, along with western blotting and immunofluorescence experiments. **Results:** Stimulation of TNBC cells with IL-6 increased CD146 expression and tumor metastasis. Knocking down CD146 significantly reduced IL-6 secretion by TNBC cells, leading to reduced tumor-endothelial cell adhesion and trans-endothelial migration. CD146 knockout or 112-2 treatment inhibited IL-6-mediated JAK/STAT3 activation and tumor metastasis. Experiments with CD146 mutants and molecular docking identified the specific 112-2 binding site at leucine positions 331-332 of CD146 protein. 112-2 treatment led to CD146 protein internalization and cleavage, resulting in an 80 kDa fragment recognized by both 112-2 and C-terminus-specific CD146 antibodies, ultimately inhibiting the activation of IL-6/JAK/STAT3 signaling. Notably, the inhibition of proteasome or lysosome activity failed to reverse the 112-2-induced reduction in CD146 protein levels. However, inhibiting lysosomal acidification resulted in significant co-localization of CD146 with lysosomes, suggesting a potential role of lysosomes in 112-2-mediated cleavage of CD146. **Conclusion:** CD146 promotes TNBC metastasis by modulating IL-6/JAK/STAT3 activation. The nanobody anti-CD146 #112-2 specifically binds to CD146 extracellular domain induces the proteolysis of CD146 protein, thereby inhibiting the tumor-promoting effect of IL-6.

#1550 Identification of a novel squalene epoxidase function in breast cancer brain metastasis.

S.-P. Wang[1], J.-Y. Yeh[2], Y.-L. Lee[3], K.-Y. Lin[3], C.-D. Chang[3], C.-C. Yang[3], S.-Y. Cheng[3], Y.-W. Hung[3], Y.-H. Chang[3], Y.-F. Li[4], Y.-L. Yu[2];
[1]Academia Sinica, Taipei, Taiwan, [2]China Medical University, Taichung, Taiwan, [3]Pharmacology Discovery Services Taiwan, Ltd., New Taipei City, Taiwan, [4]National Defense Medical Center, Taipei, Taiwan

Brain metastases are serious complications of breast cancer, especially in triple-negative breast cancer (TNBC) patients. There is currently no effective treatment due to the unique brain microenvironment and limitation for drugs to cross the blood-brain barrier (BBB). BBB limits access of nutrients from the circulation and thereby makes the brain hypoxic and depleted of metabolites, growth factors and proteins. However, it remains poorly understood how breast cancer cells manipulate for adaption and colonization in the brain. To probe the molecular mechanism of breast cancer brain metastasis (BCBM), we compared gene signatures in primary breast tumors and BCBM tumors, and identified that *SQLE* (encodes squalene epoxidase, the second rate-limiting enzyme in the cholesterol biosynthesis) could be a leading-edge gene in breast cancer brain metastasis. To explore the role of SQLE in BCBM, we established the brain metastatic TNBC MDA-MB-231 (MDA231-BrM) cell line from brain metastatic subpopulation that originated from its parental MDA-MB-231 (MDA231) cell line. We found that SQLE expression was greatly upregulated in MDA231-BrM cells compared with the parental MDA231 cells. Using MDA231-BrM and MDA231 cell lines expressing *SQLE* shRNAs, we evaluated the effects of SQLE loss on cancer cell migration, invasion, and stemness by wound-healing, transwell invasion/migration, and tumorsphere formation assays. While loss of SQLE greatly attenuated cell invasiveness and stemness in both MDA231 and MDA231-BrM cells, loss of SQLE could only affect the cell migration activity on MDA231 cells but not MDA231-BrM cells. Our RNA-seq data further identified a subset of SQLE-affected genes that is uniquely enriched in MDA231-BrM cells and favors brain extravasation and colonization. To explore the potential function of SQLE in brain extravasation and colonization, we established *in vitro* BBB models and *ex vivo* mouse brain slice organotypic cultures. We showed that loss of SQLE inhibited the ability of MDA231-BrM cells to across the BBB-mimic astrocyte-endothelial structures as well as impaired the co-option with blood capillaries in the mouse brain slices. Although SQLE-deficient MDA231-BrM cells could still spread on the surface of the blood vessels, they seemed to undergo apoptosis. Since the ability to invade, migrate, and penetrate is critical for invasion of cancer cells, our results strongly imply the novel function of SQLE in breast cancer cell invasion, penetration, and even colonization in the brain through blood vessel co-option. In summary, our data reveal a novel role for SQLE in two critical requisites for breast-to-brain extravasation and colonization - the ability to penetrate through BBB and to co-opt brain vessels for metastatic expansion. Our findings indicate that targeting SQLE may represent a therapeutic opportunity for breast cancer brain metastases.

#1551 Succinyl-CoA synthetase Beta-A: A novel metastasis promoting factor in lung cancer.

J. Kang, J. Hwang, A. C. Boese, S. Shuff, J. Kim, K. Eun, **S. Kang**;
Emory University, Atlanta, GA

Changes in metabolism occur when cancer cells disseminate from primary sites and metastasize. Mitochondrial metabolism plays an essential role in various biological processes of cancer cells, but the underlying mechanism through which mitochondrial factors contribute to cancer metastasis remains largely elusive. Anoikis is a form of apoptosis induced by loss of cell adhesion, and metastatic tumor cells must be anoikis resistant to survive during circulation before forming metastatic foci in distant organs. We performed an unbiased RNAi screen using a customized mitochondrion shRNA library and identified succinyl-CoA synthetase beta-A (A-SCS, also called SUCLA2), which is known to catalyze the reversible conversion of succinyl-CoA and ADP to succinate and ATP in the TCA cycle as an essential factor that promotes the survival of disseminated cancer cells during metastasis. We demonstrate that A-SCS manages redox balance during tumor metastasis, and this metabolic contribution is independent of its role in the TCA cycle. Mechanistically, A-SCS relocates from the mitochondria to the cytosol and binds to stress granules, promoting stress granules to express the redox-scavenging enzyme catalase upon cell detachment. This mitigates oxidative stress and makes cancer cells survive through anoikis, eventually promoting metastasis. A clinical correlation study comparing primary and metastasized tumors collected from lung cancer patients demonstrated that A-SCS levels align with catalase expression as well as the metastatic progression of lung cancer. Our finding provides an academic basis for developing new treatment targets against metastasis, which strikes elevated mitochondrial metabolism during cancer cell dissemination.

#1552 Tumorigenesis of basal muscle invasive bladder cancer was mediated by PTEN protein degradation resulting from *SNHG1* upregulation.

C. Huang, T. Li, H. Jin;
Oujiang Laboratory and Wenzhou Medical University, Wenzhou, China

hosphatase and tensin homolog deleted on chromosome ten (PTEN) serves as a powerful tumor suppressor, and has been found to be downregulated in human bladder cancer (BC) tissues. Despite this observation, the mechanisms contributing to PTEN's downregulation have remained elusive. In this study, we discovered that mice exposed to N-butyl-N-(4-hydroxybu-tyl)nitrosamine (BBN), a specific bladder chemical carcinogen, exhibited primary basal muscle invasive BC (BMIBC) accompanied by a pronounced reduction in PTEN protein expression *in vivo*. Utilizing a lncRNA deep sequencing high-throughput platform, along with gain- and loss-of-function analyses, we identified small nucleolar RNA host gene 1 (*SNHG1*) as a critical lncRNA that might drive the formation of primary BMIBCs in BBN-treated mice. Cell culture results further demonstrated that BBN exposure significantly induced *SNHG1* in normal human bladder urothelial cell UROtsa. Notably, the ectopic expression of *SNHG1* alone was sufficient to induce malignant transformation in human urothelial cells, while *SNHG1* knockdown effectively inhibited anchorage-independent growth of human BMIBCs. Our detailed investigation revealed that *SNHG1* overexpression led to PTEN protein degradation through its direct interaction with HUR. This interaction reduced HUR binding to ubiquitin-specific peptidase 8 (USP8) mRNA, causing degradation of USP8 mRNA and a subsequent decrease in USP8 protein expression. The downregulation of USP8, in turn, increased PTEN poly-ubiquitination and degradation, culminating in cell malignant transformation and BMIBC anchorage-independent growth. *In vivo* studies confirmed the downregulation of PTEN and USP8, as well as their positive correlations in both BBN-treated mouse bladder urothelium and tumor tissues of bladder cancer in nude mice.Our findings, for the first time, demonstrate that overexpressed *SNHG1* competes with USP8 for binding to HUR. This competition attenuates USP8 mRNA stability and protein expression, leading to PTEN protein degradation, consequently, this process drives urothelial cell malignant transformation and fosters BMIBC growth and primary BMIBC formation.

#1553 S1PR1 directs tumorsphere proliferation in ovarian cancer.

N. Gendrau-Sanclemente[1], A. Figueras[1], K. Gracova[1], E. Alsina-Sanchis[1], J. Marin-Jimenez[1], J. Casas[2], A. Vidal[3], X. Matias-Guiu[3], S. Fernandez-Gonzalez[3], M. Barahona[3], L. Marti[3], J. Ponce[3], F. Vinals[1];

[1]Catalan Institute of Oncology; Institut d'Investigacio Biomedica de Bellvitge (IDIBELL), Barcelona, Spain, [2]Institute for Advanced Chemistry of Catalonia (IQAC-CSIC), Barcelona, Spain, [3]University Hospital of Bellvitge, Barcelona, Spain

Despite the clinical efforts to improve detection and treatment of high-grade serous ovarian cancer (HGSOC), half of diagnosed women will die every year because of this disease. Notably, nearly all of them present with ascites at diagnosis, which is directly associated with poor prognosis. Malignant ascites production occurs when ovarian cancer cells shed from the primary tumor, creating a selective pressure environment that threatens their survival. Therefore, cancer cells cluster into tumorspheres, the main metastatic units in HGSOC. In recent years, valuable insights into the mutational and immunological landscapes of HGSOC have been gained. However, there is scarce evidence on the precise molecular mechanisms that enable tumorspheres to surpass the ascites bottleneck and metastasize. In this work, our group addresses this knowledge gap by deciphering the role of S1PR1 in ovarian tumorsphere biology. In this study, ascites samples and Formalin-Fixed Paraffin-Embedded (FFPE) tumors and peritoneal metastases from a cohort of 32 treatment-naïve HGSOC patients have been used. Furthermore, 3D spheroid models from four different ovarian cancer cell lines have also been developed for *in vitro* and *in vivo* assays. Our results indicate that up to 60% of cells within HGSOC tumorspheres are proliferating due to an increased expression of pro-proliferative receptors. Thus, cancer cells within tumorspheres that overexpress these receptors might benefit from autocrine and paracrine signaling through release of their ligands. In this work, we have identified S1P-S1PR1 as one of these ligand-receptor axes, which promotes an autocrine positive loop that increases the intermediates of sphingolipid metabolism in ovarian cancer spheroids. Here, we demonstrate that S1PR1 is highly expressed in ascites tumorspheres and, in consequence, overexpressed in metastases in comparison with primary tumors. Furthermore, we also report that proliferation levels of ovarian cancer spheroids positively correlate with S1PR1 endogenous expression. Consistently, these levels are significantly reduced when S1PR1 is knocked out or pharmacologically inhibited. In addition, our results indicate that MEK1/2-ERK is the key downstream pro-mitogenic pathway of S1PR1 in HGSOC tumorspheres, and that its pharmacological inhibition is effective in reducing growth and number of disseminations *in vivo*. Conclusively, our group is the first one in reporting that the axis S1P-S1PR1-MEK1/2 is the main proliferative mechanism in HGSOC tumorspheres, providing them with a selective advantage and, consequently, a greater metastatic potential. The preclinical findings presented here may represent an opportunity to further explore targeted therapeutic strategies to hamper disease progression in ovarian cancer patients with the poorest outcome.

#1554 *LIM Domain 7* (*LMO7*) splice variant influences prostate cancer biology.

M. Al Abo[1], D. J. George[2], Z. Wang[3], S. R. Patierno[2], J. A. Freedman[2], A. Jiang[4];
[1]Duke Cancer Institute, Durham, NC, [2]Duke University, Durham, NC, [3]Shanghai Institute for Nutrition and Health, Shanghai, China, [4]Washington University, St. Louis, MO

LIM Domain 7 (LMO7) has been shown to participate in cell-cell junction formation through interaction with afadin and α-actinin. It has also been reported to collaborate with Rho kinase to regulate actin filament formation and to activate the Rho-myocardin-related transcription factor serum response factor pathway. Additionally, LMO7 itself may function as a transcription factor, regulating the expression of genes involved in Epithelial Mesenchymal Transition (EMT). Alternative splicing of *LMO7* has the potential to modulate its function. Previously, we reported *LMO7* as a target that is alternatively spliced in prostate cancer (PCa) between self-reported Black and White patients. In addition, by analyzing expression of *LMO7* splice variants in The Cancer Genome Atlas (TCGA) data, we previously reported increased expression of a *LMO7* splice variant skipping exon 12 in breast, lung and liver cancer compared with paired normal tissues. In the present study, we found that *LMO7* is downregulated in metastatic PCa specimens within the Stand Up To Cancer cohort. To investigate the functional impact of expression of the *LMO7* splice variant skipping exon 12 in PCa, we utilized CRISPR-Cas9 methodology to delete *LMO7* exon 12 in PCa cells and assessed resulting alterations in PCa cell biology. The *LMO7* exon 12 deleted PC3 PCa cells exhibited enhanced migratory potential compared with parental PCa cells. An Immunofluorescence (IF) assay showed weak staining of cell-cell junctions in *LMO7* exon 12 deleted PCa cells compared with parental PCa cells. Moreover, IF staining showed retardation in f-actin in *LMO7* exon 12 deleted PCa cells compared with parental PCa cells. As E-Cadherin is often inhibited during EMT, we assessed the level of E-Cadherin by western blot and real-time polymerase chain reaction (PCR). These analyses revealed that E-Cadherin protein as well as messenger RNA is suppressed in *LMO7* exon 12 deleted PCa cells compared with parental PCa cells. These findings suggest a role for skipping of *LMO7* exon 12 in disrupting PCa cell-cell junctions, down-regulating E-Cadherin in PCa and enhancing PCa cell migratory potential, consistent with EMT.

#1555 Nuclear accumulation of cell surface programmed cell death ligand 1 promotes metastatic outgrowth in triple-negative breast cancer cells.

Y. Gohara, N. Tomonobu, R. Kinoshita, K. Yamamoto, H. Murata, M. Sakaguchi;
Okayama Univ. Graduate School of Med., Dentistry & Pharm. Sci., Okayama, Japan

PD-L1 presented on the cancer cell surface is well known for its role in immune checkpoint regulation by interacting with PD-1 on immune cells. On the other hand, it has been reported that PD-L1 is localized in the cancer cells' nuclei, where the nuclear PD-L1 (nPD-L1) is conducive to cancer outgrowth and motility. However, there has yet to be reported about the mechanistic insight into the event. In this study, we, therefore, aimed to clarify still unidentified points in the nPD-L1-mediated event. Our efforts revealed that the upregulation is induced by a functional suppression of nuclear protein X (tentative name), which we identified as a novel binding protein with nPD-L1 at its cytoplasmic tail. Their nuclear interaction also abolished an aggressive cancer proclivity, epithelial-mesenchymal transition (EMT). The mechanism is helpful to the complex nature of PD-L1 in plural cancer cell behaviors.

#1556 AMIGO2 is associated with the peritoneal dissemination in serous ovarian cancer by enhancing its adhesion to peritoneal mesothelial cells.

Y. Iida, S. Sato, K. Yamamoto, K. Hikino, M. Okawa, M. Hosokawa, M. Sawada, H. Komatsu, A. Kudoh, H. K. Seong, R. Izutsu, M. Osaki, F. Okada, F. Taniguchi;
Tottori University, Yonago, Japan

Amphoterin-induced gene and open reading frame 2 (AMIGO2) has been associated with the prognosis of colorectal, gastric, and cervical cancer. However, its relationship with ovarian cancer remains unclear. This study aimed to clarify the role of AMIGO2 in ovarian cancer. The research involved evaluating AMIGO2 expression in patients with ovarian serous carcinoma using immunohistochemistry. The AMIGO2-high group exhibited significantly shorter progression-free survival (PFS) compared to the AMIGO2-low group. The predictive index of the AMIGO2-high group was considerably higher than that of the AMIGO2-low group. The rate of complete cytoreductive surgery was lower in the AMIGO2-high group than in the AMIGO2-low group. Furthermore, in vitro studies showed that four serous ovarian cancer cell lines expressed AMIGO2 expression and adhesion to mesothelial cells. Adhesion to mesothelial cells was attenuated by AMIGO2 knockdown in SKOV3 cells. Moreover, in a murine model, AMIGO2 downregulation in SKOV3 cells significantly suppressed peritoneal dissemination. These findings suggest that high AMIGO2 expression in serous ovarian carcinoma cells contributes to a poor prognosis by promoting peritoneal metastasis through enhanced cell adhesion to mesothelial cells.

#1557 Loss of lncRNA XIST promote brain metastasis by reshaping tumor lipid metabolism via upregulation of ACSL4.

Y. Liu, M. R. Smith, Y. Wang, R. D'Agostino, Jr., J. Ruiz, G. L. Kucera, L. D. Miller, W. Li, M. D. Chan, M. Farris, D. Zhao, F. Xing;
Wake Forest University School of Medicine, Winston-Salem, NC

Metastatic disease is the main cause of cancer death, and the brain is one of the major sites of breast tumor metastasis. The median survival of breast cancer patients who developed brain metastases (BrM) is less than a year even with the advanced treatment such as stereotactic radiosurgery (SRS). Regardless of high clinical significance, the pathological mechanism of brain metastasis is still poorly understood. Previously, we found that loss of lncRNA XIST robustly promote metastasis and specially brain metastasis in breast cancer. However, the underlying molecular mechanism was not fully understood. In following study, we found that loss of XIST has significantly altered lipid metabolism of breast cancer cells specifically increasing lipid droplet amount and PUFA incorporation. Instead of *de novo* syntheses, XIST^{low} cancer cells acquire fatty acid by uptake from exogenous. We found that one X-linked gene, Acyl-CoA Synthetase Long Chain Family Member 4 (ACSL4) which are highly upregulated after loss of XIST is responsible for the altered lipid metabolism. ACSL4 activated the free polyunsaturated fatty acids (PUFAs) and lead to increased incorporation of PUFAs into phospholipids. On one hand, elevated ACLS4 expression leads to relative low PPAR pathway activation by decreasing the cellular free PUFA level which directly binds and activate PPAR. PPAR pathway is known to inhibit the expression of inflammatory cytokines which are important for cancer cells to establish brain metastasis. On the other hand, elevated ACSL4 expression enable cancer cells to metabolize the abundant PUFAs in the brain environment, thereby gaining survival advantage. However, increased PUFA incorporation into lipids especially phospholipids produce excess lipid ROS and sensitize cells to ferroptosis inducer such as RSL3. Our study has find out that brain microenvironment not only supports the outgrowth of *XIST* ^{low} cells by providing PUFAs for maintaining their metastatic properties but also sensitizes those cells to ferroptosis inducers, a potential therapy for treating this devastating disease.

#1558 Deciphering the role of ribosomal paralogs RPL39/RPL39L in metaplastic breast cancer.

M. F. Chervo, **M. Li**, C. Mancino, K. A. Ortega Martinez, V. V. Shah, W. Qian, J. Zhou, L. Guzman-Rojas, P. Matre, F. Taraballi, K. W. Brannan, J. C. Chang; Houston Methodist Research Institute, Houston, TX

Metaplastic breast cancer (MpBC) is a rare, highly aggressive, and metastatic malignancy that accounts for <5% of all breast cancer diagnoses. Most MpBCs display a triple-negative breast cancer (TNBC) phenotype (ER-/PR-/HER2-). MpBCs exhibit the most dismal prognosis of all breast cancer subtypes. The standard of care for metastatic MpBC remains systemic chemotherapy, despite known resistance to most cytotoxic drugs. MpBCs are enriched with epithelial-to-mesenchymal transition (EMT) and cancer stem cell (CSC) markers. We previously described a unique molecular signature for breast cancer stem cells (BCSCs) derived from patient biopsies and identified ribosomal protein L39 (RPL39) as a critical driver of treatment resistance, BCSCs self-renewal, and lung metastases in TNBC/MpBC. Growing evidence has also demonstrated aberrant expression of the testis-specific ribosomal protein paralog 39L (RPL39L) in several cancer types. Here, we hypothesize that RPL39 and its paralog RPL39L alter ribosome composition and function to initiate a specific translational landscape that promotes tumor growth and enhanced metastatic potential in MpBC. We first examined the relative expression of RPL39 and RPL39L in TNBC/MpBC cell lines and patient-derived xenografts (PDXs) using real-time qPCR. We detected co-expression of RPL39/RPL39L transcripts, however, RPL39L mRNA levels were significantly lower than RPL39. These results suggest that both RPL39 and RPL39L contribute to ribosome heterogeneity in TNBC/MpBC. To investigate the function of RPL39/RPL39L transcripts, we designed a small interfering RNA (siRNA)-strategy targeting their differential 5' untranslated region (5’ UTR). Selective downregulation of RPL39 and RPL39L mRNA inhibited in vitro cell proliferation in TNBC/MpBC models. Notably, combined targeted silencing of both RPL39 and RPL39L further decreased cell proliferation in comparison to individual siRNAs. We next evaluated the efficacy of RPL39/RPL39L dual blockade in vivo using MpBC PDXs. MpBC PDX4664 was implanted into the mammary fat pad of NSG mice. Once tumors were established (100-150 mm^3), mice received phosphate buffered saline (PBS controls) or 0.5 mg/kg RPL39/RPL39L siRNAs encapsulated into liposome-like nanoparticles (NPs) via tail vain (i.v.) injection. Animals were treated thrice a week for 21 days and sacrificed 48 h after the last injection. We found that siRNAs-NP formulation silenced RPL39/RPL39L expression in vivo and significantly reduced tumor growth. Overall, our findings support the notion that RPL39/RPL39L ribosome heterogeneity may confer preferential translation of oncogenic and BCSC-related genes, facilitating tumor progression and metastasis in MpBC. Ongoing studies are directed to validate ribosome heterogeneity by proteomic analysis and evaluate the role of RPL39/RPL39L on global translation by ribosome profiling.

#1559 IKZF1 plays a crucial role in the spread of melanoma.

J. Oh[1], D. Lee[1], S. Lee[1], H. Park[2], H. Gee[1];

[1]Yonsei University College of Medicine, Seoul, Korea, Republic of, [2]College of Life Science and Biotechnology Yonsei University, Seoul, Korea, Republic of

Melanoma is one of the most fatal type of skin cancer. If melanoma has spread to distant sites, it is refractory to existing therapies with the 5-year survival rate declining to 17%. Metastasis remains as the main barrier to successful therapy, persisting as the main cause of cancer-related death. Thus, understanding metastasis mechanism is vital.

First, we confirmed that IKZF1 gene was more increased in circulating tumor cells than primary tumor cells. Using GFP+ B16F10, we generated an orthotopic melanoma mouse model and isolated GFP+ tumor cells of primary footpad, blood, and lung. In single cell RNA sequencing, IKZF1, IRF8, NFE2 genes were more upregulated in circulating tumor cells than primary tumor cells. We also found these correlations in human melanoma cell line orthotopic mouse model and Braf/Pten mouse model.

Next, we conduct intervention study to find causality in IKZF1 and metastasis. IKZF1 KO led to fewer CTCs and IKZF1 inhibitor, lenalidomide, reduced metastasis in mice.

Collectively, we demonstrate that IKZF1 could contribute the formation of CTC and IKZF1 could be a target for metastasis treatment.

#1560 *In vivo* CRISPR/Cas9 transcriptional activation screen leads to discovery of INAFM2, a novel driver of metastasis.

A. Molotkova, E. Deniz, M. Swift, E. Glasgow, J. Toretsky, A. Uren;
Georgetown University Medical Center, Washington, DC

Metastasis is the main cause of mortality in cancer patients and accounts for about 90% of cancer deaths, which has not changed in the past 50 years. This indicates a significant need for further study of metastasis pathways to find novel druggable targets. Ewing sarcoma (ES) is an aggressive childhood cancer that occurs in the bones or soft tissue. The five-year survival rate for Ewing sarcoma patients diagnosed with metastatic disease is still only 25%, making ES a good model for studying metastasis. We performed a genome-wide CRISPR/Cas9 transcriptional activation screen in a zebrafish xenograft model to discover genes whose activation leads to increased metastasis. The screen identified a number of genes that may accelerate ES metastasis; we chose *INAFM2* for further study because multiple unique INAFM2-targeting gRNAs were enriched in the screen and we discovered a potential link to metastasis and patient survival in publicly available clinical data. Overexpression of INAFM2 in six different cancer cell lines (four ES, one hepatocellular carcinoma, and one stomach adenocarcinoma) caused increased cell migration and chemotaxis *in vitro*, and increased intravasation in zebrafish xenografts. INAFM2 knockdown in four cancer cell lines (two ES, one clear cell renal cell carcinoma, and one stomach adenocarcinoma) decreased chemotaxis and rescue of INAFM2 expression restored the cells' ability to migrate. Analysis of patient tumor RNA sequencing data from many different types of cancers revealed correlations between INAFM2 expression and both an increased metastatic phenotype and poor patient survival. Further *in vivo* studies by tail vein injection of ES cells in immunodeficient mice demonstrated significantly increased gross metastases with INAFM2 overexpression and decreased gross metastases with INAFM2 knockdown compared to the respective control groups. This provides strong evidence for a substantial role of INAFM2 in cancer metastasis. Human *INAFM2* is an unstudied gene and our preliminary work has revealed that the INAFM2 protein localizes to the cell membrane, is glycosylated, and may be involved in Wnt and/or MAPK pathway signaling. Inafm2 silencing by morpholino in zebrafish embryos lead to significant mortality, necrosis, and developmental delays/defects including severe cardiac edema. Current studies are focused on further discerning the molecular pathways that mediate the role of INAFM2 in promoting metastasis using *in vitro* and *in vivo* models as well as characterizing the functional significance of the direct protein binding partners and post-translational modifications for INAFM2.

#1561 Identification of tumor-associated macrophages promoting early-stage metastasis during peritoneal dissemination in gastric cancer.

W. Kawase[1], Y. Hiroshima[1], I. Hashimoto[2], S. Onuma[2], M. Furuta[2], N. Machida[2], T. Oshima[2], Y. Miyagi[1];
[1]Kanagawa Cancer Centre Research Institute, Yokohama, Japan, [2]Kanagawa Cancer Centre, Yokohama, Japan

Peritoneal dissemination (PD) is the most frequent metastasis pattern in gastric cancer (GC) and is a significant predictor of poor prognosis. However, the mechanisms underlying PD formation remain unclear, and a PD-specific signature has not been identified. PD development is thought to be influenced by various changes occurring in GC tumor cells and immune cells present in the peritoneal cavity. We previously performed RNA-seq analysis of cell components in cytology-positive (CY1) gastric cancer ascites. The results suggested that tumor-associated macrophages (TAMs) infiltrate the abdominal cavity together with GC tumor cells and might be involved in PD development. In this study, we aimed to identify the specific TAMs responsible for promoting metastasis during the early stage of PD in GC. We demonstrated the abundant presence of TAMs in CY1 GC ascites using flow cytometry analysis and identified several genes that were significantly expressed in CY1 TAMs using single-cell RNA-seq analysis. Furthermore, we evaluated the potential of these genes to serve as therapeutic targets for the treatment of PD in GC.

#1562 HMGA2 regulates GPX4 expression and oxidative stress.

P. E. Dike[1], T. Campbell[2], M. Awolowo[1], V. Odero-Marah[1];
[1]Morgan State University, Baltimore, MD, [2]Clark Atlanta University, Atlanta, GA

Prostate cancer (PCa) is a leading cause of mortality, primarily due to its ability to metastasize to the bone. The High Mobility Group AT-Hook 2 (HMGA2) plays a crucial role in regulating gene expression and has been implicated in tumorigenesis and the metastatic process. Our recent study revealed that overexpression of the wild-type/full-length HMGA2 isoform in PCa cells promotes cancer progression by triggering epithelial mesenchymal transition (EMT), whereas truncated HMGA2 isoform promotes progression through oxidative stress signaling. We hypothesize that HMGA2 regulates GPX4 expression and oxidative stress in PCa. We studied the expression of HMGA2 and GPX4 in various PCa cell lines including enzalutamide resistant cell line (C4-2B MDVR), LNCaP cells overexpressing HMGA2 isoforms (wild type and truncated HMGA2). Our analysis of HMGA2 and GPX4 expression in diverse PCa cell lines, shows an inverse relationship between HMGA2 and GPX4 levels. Elevated HMGA2 expression coincides with reduced GPX4 expression, leading to heightened oxidative stress and susceptibility to ferroptosis. Moreover, treatment of enzalutamide resistant cell line C4-2B MDVR with ferroptosis inducer RSL3, further suppresses GPX4 expression, resulting in decreased cell proliferation. Our results unveils the intricate relationship between HMGA2, GPX4 regulation and oxidative stress in the context of prostate cancer progression. Exploiting this oxidative stress pathway offers a promising therapeutic approach for cancer treatment, especially for enzalutamide-resistant cancer cells.

#1563 Anoikis associated metabolic modulation by UCA1 in CRC.

S. Leslie, K. Doxtater, S. Lopez, B. Hafeez, T. Oraby, T. Loy, M. K. Tripathi;
University of Texas Rio Grande Valley, McAllen, TX

Colorectal Cancer (CRC) is the second most lethal cancer in estimated deaths for 2023 according to the American Cancer Society. This is partially due to the low survival rate once CRC is diagnosed at a distant location. This warrants early diagnostic markers and an understanding of the mechanisms underlying the metastatic process, anoikis resistance being one of them. Our laboratory analysis of the TCGA database comprising 519 human CRC tissues shows lncRNA UCA1 overexpressed in tumors compared to normal, and higher expression of lncRNA UCA1 is responsible for the progression, metastasis, and poor survival of CRC patients. In our anchorage-independent growth model (anoikis resistant), using isogenic (oncogenic and metastatic) cell lines, we observed a very high expression of lncRNA UCA1 along with GluT1 with increased cell survival. Cancer cells, however, appear to rapidly increase their glucose uptake and directly ferment it into lactate, even in the presence of oxygen and functional mitochondria. UCA1 has been found to play an essential role in the development of metastasis and dysregulation of glycolysis in various cancers. To verify if lncRNA UCA1 modulates anoikis resistance and glucose metabolism, we generated SW480+UCA1 overexpression (OE) and SW620+shUCA1 knockdown (KD) stable cell lines using lentiviral transduction. The OE GFP-expressing cell lines were further sorted, and grown in puromycin. The KD cell lines were selected with puromycin for the generation of stable cell lines. The stable cell lines were characterized through different phenotypic assays. UCA1 OE cell lines have a higher glucose uptake and the UCA1 KD cell lines have a lower glucose uptake. The lactate production is high in the KD and low in OE cell lines. The OE and KD cell lines along with the control cell lines were subjected to an anoikis model, and glucose and lactate analysis were performed accordingly. RT-PCR and western blot analysis were performed for the target genes responsible for cell survival, stemness, and glucose metabolism. We are analyzing the Extracellular Acidification Rate (ECAR), Oxidative Consumption Rate (OCR), ATP production rate the rate and potential max rate of glycolysis, and the mitochondrial stress of the recombinant cell lines using the “Agilent Seahorse XF”. The role of lncRNA UCA1 in anoikis resistance leading to metastasis and modulating glucose metabolism will provide new insights into the pathophysiology of CRC metastasis. This information will be beneficial for developing more unique strategies for the treatment of this metastatic disease.

#1564 NEU4-mediated desialylation ignites the oncogenic receptors for the dissemination of ovarian carcinoma.

J. Shi[1], R. Zhou[1], S. Wang[1], Y. Liu[1], B. Tian[1], Y. Liu[1], Y. Chen[1], T. Hu[1], Y. Mu[1], S. Wang[1], X. Shao[1], J. Yan[1], P. Qu[2], W. Ding[2], S. Yang[1], Y. Shi[1], J. Li[1], L. Wang[1];

[1]The School of Medicine, Nankai University, TianJin, China, [2]Department of Gynecological Oncology, Tianjin Central Hospital of Obstetrics and Gynecology, TianJin, China

Background: Glycosylation profoundly influences the interactions between cancer cells and microenvironmental stromal cells during the peritoneal disseminated metastasis of ovarian carcinoma (OC), which is the major cause of cancer-related death. Although the characteristic cancer glycoconjugates are widely used as biomarkers for cancer diagnosis, our knowledge about cancer glycome remains quite fragmented due to the technique limitations in analyzing glycan chains with tremendous structural and functional heterogeneity.

Method: Given the dysregulated cancer glycome is defined by the altered glycosylation machinery, here we performed a systematic loss-of-function screen on 498 genes involved in glycosylation for key regulators of OC dissemination. We identified neuraminidase 4 (NEU4), an enzyme capable of hydrolyzing terminal sialic acid from glycoconjugates, as a vital peritoneal dissemination-promoting modifier of OC glycome. What's more, we also identified membrane proteins whose sialylation was able to be modified by NEU4 in OC cells by pull down and mass spectrum to investigate the functional significance of NEU4-mediated desialylation.

Results: In human patients with high-grade serous OC (HGSOC), increased NEU4 was detected in the disseminated OC cells when compared with that in the primary tumor cells, which significantly correlated with the worse survival. Among three alternative splice-generated isoforms of human NEU4, we revealed that only the plasma membrane-localized NEU4 isoform 2 (NEU4-iso2) and intracellular isoform 3 promoted the peritoneal dissemination of OC by enhancing the cell motility and epithelial-mesenchymal transition. We also identified NEU4-iso2-regulated cell surface glycoproteome and found that NEU4-iso2 desialylated the epithelial growth factor receptor (EGFR), in particular at N196 residue, for the hyperactivation of EGFR and its downstream tumor-promoting signaling cascades.

Conclusion: Our results provide new insights into how the OC glycome is dysregulated by NEU4 during OC progression and reveals a functionally important glycosite on EGFR for its abnormal activation in cancer.

#1565 USP13 influences metastatic features in fallopian tube-originated high-grade serous carcinoma.

B. Mok[1], J. Kwon[1], J. Zhang[1], S. Allsup[1], H. Choi[2], C. Han[1];
[1]Georgetown University School of Medicine, Washington, DC, [2]Konkuk University, Seoul, Korea, Republic of

High-grade serous ovarian carcinoma (HGSOC), originating from the fallopian tube, stands as a formidable challenging gynecologic malignancy with the highest mortality rate worldwide. Ubiquitin-specific peptidase 13 (USP13) has garnered attention due to the highly frequent *USP13* gene copy amplification in human ovarian cancer. However, its precise pathological role in ovarian cancer remained elusive. To uncover the underlying role of USP13 in HGSOC, we developed a novel genetically engineered mouse model (GEMM) of HGSOC. *Ovgp1-iCreER*^{T2};*Trp53*$^{flox/flox}$;*Pten*$^{flox/flox}$ mouse (OPT) was crossed with Rosa26$^{-LSL-Usp13}$ knockin mouse model (U), generating *Ovgp1-iCreER*^{T2};*Trp53*$^{flox/flox}$;*Pten*$^{flox/flox}$; Rosa26$^{-LSL-Usp13}$ mouse model (OPTU). Usp13 overexpression with loss of p53 and Pten was induced specifically in fallopian tube secretory epithelial cells in OPTU mice. OPTU mice demonstrated the development of STIC and early HGSOC in the fallopian tube as well as invasive metastatic HGSOC. While OPT tumors largely retained mucinous and HGSOC subtypes, displaying limited metastatic behavior, OPTU tumors exhibited more complex ovarian tumor subtypes, including mucinous, HGSOC, and Mixed Mesodermal Mullerian Tumor (MMMT) histology. Furthermore, OPTU tumors showed invasive and metastatic phenotypes, characterized by an increased incidence of ovary invasion, metastasis to distant organs, and ascites development. Importantly, OPTU-driven HGSOC tumors closely resemble human HGSOC histology features, making the OPTU model a valuable tool for exploring fallopian tube-originated ovarian cancer. Primary ovarian cancer cells established from ascites of the OPTU mouse reproduced metastatic HGSOC tumorigenesis in the syngeneic mouse study. Stable USP13 knockdown in OPTU cells exhibited reduced cell proliferation and metastatic abilities in 2D and 3D cultures. In summary, this study underscores the pivotal role of USP13 in facilitating metastasis in fallopian tube-originated HGOSC. Our findings may provide a promising avenue for future therapeutic strategies aimed at mitigating the aggressive nature of USP13-amplified fallopian tube-originated HGOSC.

#1566 Cancer metastasis and stemness: The metastasis-inducer MACC1 regulates LGR5 to promote cancer stem cell-like properties in colorectal cancer.

M. Erdem[1], K. Lee[1], M. Hardt[1], J. Regan[2], D. Kobelt[1], W. Walther[1], C. Regenbrecht[3], **U. S. Stein[1]**;
[1]Max Delbruck Center for Molecular Medicine, Berlin, Germany, [2]Charite Berlin, Berlin, Germany, [3]CELLphenomics GmbH, Berlin, Germany

Colorectal cancer (CRC) is one of the leading causes of cancer-related deaths worldwide. The high mortality is directly associated with metastatic disease which is thought to be initiated by colon cancer stem cells according to cancer stem cell (CSC) model. Consequently, early identification of those patients who are at high risk for metastasis is crucial for improved treatment and patient outcome. Metastasis-associated in colon cancer 1 (MACC1) is a novel prognostic biomarker for tumor progression and metastasis formation independent of tumor stage. We previously showed an involvement of MACC1 in cancer stemness in the mouse intestine of our transgenic mouse models. However, the expression of MACC1 in human CSCs and possible implications remain elusive. Here, we explored the molecular mechanisms by which MACC1 regulates stemness and CSC-associated invasive phenotype based on patient-derived 3D cell culture models (PD3D), patient-derived xenografts (PDX) and human CRC cell lines. We showed that CD44-enriched CSCs from PD3D models express significantly higher levels of MACC1 and display higher tumorigenicity in immunocompromised mice. Similarly, RNA sequencing performed on PD3D and PDX models demonstrated significantly increased MACC1 expression in ALDH1(+) CSCs, highlighting its involvement in cancer stemness. We further showed the correlation of MACC1 with CSC markers CD44, NANOG and LGR5 in PD3D models as well as established cell lines. Additionally, MACC1 increased stem cell gene expression, clonogenicity and sphere formation. Strikingly, we showed that MACC1 binds as a transcription factor to the LGR5 gene promoter uncovering the long-known CSC marker LGR5 as novel essential signaling mediator used by MACC1 to induce CSC-like properties in human CRC patients. Our *in vitro* findings were further substantiated by significant positive correlation of MACC1 and LGR5 in CRC cell lines as well as CRC patient tumors. Taken together, this study indicates that the metastasis-inducer MACC1 act as a cancer stem cell-associated marker. Interventional approaches targeting MACC1 would potentially improve further targeted therapies for colorectal cancer patients to eradicate CSCs, prevent cancer recurrence and distant metastasis formation.

#1567 Honing in on the metastasis machinery.

J. Chen, T. C. Fugere, F. Mazahreh, B. Fugere, E. Delgiacco, A. M. Safar;
University of Arkansas for Medical Sciences, Little Rock, AR

A prevailing 'principal' in oncology posits that metastases is the last step in a strict sequence of tumorigenic events. However, despite decades of widespread breast & colon cancer (CA) screening and interceptive surgeries, there hasn't been any decrease in metastatic (M) stages, a discrepancy that undermines the validity of this principle. Others suggested unlinking tumorigenesis from metastasis, supporting an evolutionarily convergent model. We reasoned that cells' ability to circulate (physiologic in white blood cells) is mediated by putative gene(s)-encoded metastatic apparatus (MA), hence subject to alteration during the genomic turmoil of tumorigenesis. It follows that essential components of MA cannot be chromosomally deleted in M CAs; stage I CA may indicate deactivated MA. The overarching goal here is to identify genes encoding the putative MA. Chromosomal deletions are relevant since they are definitive, testable and inform mutational and epigenetic events. Of note, the retained gene list (RGL) in any CA includes cell-viability genes (CVG).
Methods: The Cancer Genome Atlas (TCGA) is a well-curated, clinically annotated public database. We examined copy number variation to determine the RGL1 in stage 1 cancers (CVG); and RGL2 in metastatic CAs. To account for possible heterogeneity or redundancy in MA in different CA types, we performed the RGL2 analysis within organ systems. By TCGA's criteria, deletion was defined as a microarray expression of <-0.3. Regions of interest, therefore, were RGL2 excluding RGL1.
Results: Table lists RGL2 excluding RGL1 per CA site

RGL2 (excluding RGL-1 2,405 regions): unique genes that are never deleted in any of the listed metastatic cases in TCGA per site (n) and the number of overlapping genes for further testing consideration											
Gastrointestinal Exocrine		Gastrointestinal Mucosa		Lung		Genitourinary		Breast		Head & Neck		Thyroid	
Pancreas	392 (100)	Esophagus (49)	1982	Adenocarcinoma (169)	2800	Bladder (216)	434	BC (191)	341	H&N (337)	275	Thyroid (224)	8292

Pan-CA Overlap	ZERO												

Conclusion: We present a plausible mechanistic approach to identify RGL encoding the putative MA for interrogation by gene-editing experiments. Our data suggest plurality of the MA given zero overlap for the entire set. Performing the analysis in additional cases within embryonal ontogeny or by driver oncogene might be useful in this pursuit. This work has implications for screening, diagnostic, prognostic surgical/adjuvant CA therapy, and novel antineoplastics.

#1568 Her2 promotes early dissemination of breast cancer by suppressing the p38 pathway through upregulation of Wip1.

Nan Wang

Wake Forest Baptist Medical Center, Winston-Salem, NC

(a)Metastasis is the leading cause of cancer-related deaths. Increasing evidence shows that cancer cells can disseminate from early primary lesions that are impalpable, but the pathways are poorly understood. Her2 promotes breast cancer early dissemination by suppressing p38, but how Her2 downregulates p38 is unclear. In this study, we investigated the mechanism underlying suppression of p38 by Her2 in breast cancer early dissemination using cell models and xenograft models of early lesions of breast cancer.
(b)We studied the role of Wip1, a p38 phosphatase, in disseminating phenotypes in cell line models of breast cancer early lesions, including cell motility measured in transwell assays, cell invasion measured by percentage of organoids with outward invading cells, and epithelial-to-mesenchymal transition (EMT) measured by levels of EMT markers in Western blotting analysis and immunofluorescence (IF) staining assays.
(c)We demonstrate that high levels of Wip1 correlated with Her2+ status, and reduced phosphorylation of p38 and its downstream effectors MK2 and Hsp27 in tissue samples from early lesions of human breast cancer. In addition, ectopic expression of Wip1 reduced phosphorylation of p38, MK2 and Hsp27 in cell models of breast cancer early lesions.We found that Wip1 promoted migration, invasion and EMT, while Wip1 knockdown abrogated the ability of Her2 to induce these disseminating phenotypes, in cell line models of early lesion breast cancer. Thus, Wip1 induction is both sufficient, and necessary for Her2, to promote migration, invasion and EMT in early lesion breast cancer cells. In an attempt to identify the Wip1 downstream effectors involved in disseminating phenotypes, we found that ectopic expression of the constitutively active mutants of p38 reversed the ability of Wip1 to suppress MK2 and Hsp27 phosphorylation and to induce migration, invasion and EMT in early lesion breast cancer cells. These results suggest that Wip1 promotes breast cancer early dissemination by suppressing p38. We investigate the mechanism by which Her2 induces Wip1 expression. Ectopic expression of Her2 did not alter the level of Wip1 mRNA or the Wip1 protein stability, suggesting that Her2 promote Wip1 expression by regulating its translation. We are currently investigating the mechanism by which Her2 induces Wip1 translation.Moreover, inhibitors of Her2, Wip1 and Skp2 can each reduce the disseminating phenotypes in cells models of breast cancer early lesions ectopically expressing Her2, Wip1 or Skp2.
(d)Our findings identify the Her2-Wip1-p38-Mk2-Hsp27 cascade as a novel mechanism mediating breast cancer early dissemination and provide a basis for new therapies targeting early metastatic dissemination in Her2+ breast cancer using inhibitors for Her2, Wip1 or Skp2.

#1569 Keratin X promotes cell metastasis and sorafenib resistance via the AMPKα/Snail axis in hepatocellular carcinoma.

Y.-H. Lin, C.-T. Yeh;
Chang Gung Memorial Hospital - Linkou branch, Taoyuan City, Taiwan

A great majority of liver cancers are developed from cirrhotic livers. The key molecules involved in cirrhosis-mediated hepatocarcinogenesis have not been clearly defined. Understanding the oncogenic pathways and their associations with cancer growth, metastasis and drug resistance may help scientists devise new effective therapeutic agents. In the present study, we identified the intermediate filament-forming protein keratin X (KRTX) as a key factor in cirrhosis-mediated hepatocarcinogenesis. KRTX was highly expressed in HCC tissues and correlated with poor survival outcomes. Experimental verification revealed that overexpression of KRTX enhanced cell growth, tumor cell metastasis, glycolysis and sorafenib resistance. Conversely, knockdown of KRTX led to opposite effects. Mechanistically, KRTX inhibited AMPKα phosphorylation, thereby enhancing Snail protein stability. Additionally, TGFβ1 positively regulated *KRTX* expression, resulting in a KRTX/AMPKα (Thr172)/Snail axis-mediated increase in cell motility. Treating with 2-deoxyglucose reversed the KRTX-induced metastasis and sorafenib resistance. In clinic, KRTX expression is positively correlated with Snail overexpression and high KRTX/Snail expression had poor prognosis in HCC patients. Our data revealed a signaling pathway from TGFβ1, KRTX, through p-AMPKα (Thr172) to Snail. Targeting KRTX and its pathway may be effective for treating patients with metastatic HCC.

#1570 Lipid metabolism alterations promote TNBC metastasis and immunotherapy resistance via PD-L1 internalization and signaling.

W. O. Wofford, J. Kim, D. Kim, A. H. Janneh, H. G. Lee, F. C. Atilgan, N. Oleinik, E. Hill, O. Saatci, S. Gencer, P. Chakraborty, S. Mehrotra, O. Sahin, B. Ogretmen;
The Medical University of South Carolina, Charleston, SC

Programmed death-ligand 1, PD-L1 (CD274), is an immune checkpoint protein upregulated by cancer cells to facilitate immune evasion. PD-L1 also performs oncogenic functions within cancer cells, but the underlying mechanisms of PD-L1 internalization and signaling remain largely unknown. Here, we report a new mechanism whereby altered ceramide metabolism via ceramide synthase 4 (CerS4) drives PD-L1 internalization to potentiate a TGFβ/Shh/β-catenin signaling axis to drive triple-negative breast cancer (TNBC) migration and metastasis. In response to altered ceramide metabolism, we observed that PD-L1 is internalized via clathrin-mediated endocytosis and depends on S278/S279 in its cytoplasmic domain. Once internalized, PD-L1 directly interacts with Caprin-1, an RNA-binding protein previously unassociated with PD-L1 signaling. Through our analysis of clinical specimens, we established a positive association between PD-L1/Caprin-1 interaction and metastatic progression in human TNBC. In terms of mechanism, we determined that the PD-L1/Caprin-1 complex plays a pivotal role in mediating CerS4-dependent cell migration. This complex selectively binds and stabilizes mRNA, resulting in heightened TGFβ/Shh/β-catenin signaling. Conversely, CerS4 restoration in metastatic TNBC cells impaired cellular migration and the interaction between PD-L1 and Caprin-1. Genetic depletion of CerS4 enhanced lung metastasis derived from 4T1 orthotopic allografts and transgenic MMTV-PyMT breast tumors concomitant with PD-L1/Caprin-1 interaction and TGFβ/Shh/β-catenin signaling. Bioinformatics analysis of clinical datasets was used to validate the impact of the CerS4/PD-L1/Caprin-1 axis on metastatic progression in human TNBC. In alignment with enhanced tumor progression, CerS4 depletion in tumors promoted regulatory T-cell infiltration, suggesting an immunosuppressive tumor microenvironment (TME). Treatment with sonidegib, an FDA-approved Hedgehog (Hh) inhibitor, effectively prevented PD-L1 internalization and its interaction with Caprin-1. We hypothesized that sonidegib could synergize with immune checkpoint blockade to sensitize TNBC to immunotherapy, which typically has low response rates. Sonidegib, in combination with αPD-L1 therapy, was significantly more effective in controlling TNBC primary and metastatic tumor growth, especially when Cers4 was downregulated, compared to αPD-L1 monotherapy. Our data also suggested that this potent anti-tumor effect was due to immunotherapy sensitization after combined flow cytometry, multiplexed immunofluorescence, and bulk RNA-sequencing analyses. Altogether, these findings demonstrate a mechanism to define intracellular PD-L1 signaling in response to altered ceramide metabolism, providing a new therapeutic strategy to target TNBC metastasis and improve response to immunotherapy.

#1571 Upregulation of phosphoglyceric acid mutase (PGAM)-1 is related to lymph node metastasis in gastric cancer.

H. Wang[1], Z. Liu[1], L. Wang[1], Z. Wang[2], C. Jamieson[3], **N. A. Cacalano**[2];
[1]The First Hospital of Jilin University, Jilin, China, [2]UCLA David Geffen School of Medicine, Los Angeles, CA, [3]University of California San Diego, Los Angeles, CA

Gastric cancer (GC) is the most common malignancy of the digestive system, causing over 750,000 deaths worldwide. Gastric cancer mortality is largely due to its high level of invasiveness and metastasis to distal organs. Thus, it is an urgent priority to identify mechanisms underlying GC metastasis to improve cancer diagnosis develop of effective biological targeting agents. In this study, we demonstrate that phosphoglyceric acid mutase-1 (PGAM1) was preferentially over-expressed in lymph node metastasis (LNM) tissues of GC patients and correlated with poor prognosis. PGAM1 knock down in two human GC cell lines resulted in impaired cell proliferation and increased cell cycle arrest. Further, PGAM knockdown inhibited migration of both GC cell lines, which correlated with decreased expression of MMP2, MMP9 and ICAM-1. In a murine xenograft model, GC cells with a PGAM1 knockdown displayed decreased growth capacity *in vivo.* Western blot analysis showed that PGAM1 knockdown in SGC7901 and BGC823 decreased the phosphorylation of Src, FAK and Paxillin relative to the parental cell lines. These results indicate that PGAM1 may play an important role in promoting GC lymph node metastasis by driving cell proliferation and activating cytoskeletal reorganization and cell migration through the regulating Src/FAK/Paxillin pathway.

#1572 *POU5F1B* is a human-restricted ROCK inhibitor-sensitive oncoprotein that restructures membrane nanodomains to increase cell adhesion.

L. Simo-Riudalbas[1], S. Offner[1], L. Abrami[1], E. M. Unterauer[2], J. Duc[1], E. Planet[1], R. Jungmann[2], G. van der Goot[1], D. Trono[1];
[1]Ecole Polytechnique Federale de Lausanne, Lausanne, Switzerland, [2]Ludwig Maximilian University, Munich, Germany

Evolution confers new species with distinctive biological features, which can translate in purely mechanistic speciation or in novel phenotypic traits. *POU5F1B* arose by retrotransposition of *POU5F1 (OCT4)* in the last common ancestor of modern Hominoidae. Its human product is endowed with oncogenic properties, notably promoting gastrointestinal cancer growth and metastasis. Here, we reveal that the oncogenic action of POU5F1B requires ubiquitination of lysine residues found only in the human protein. This post-translational modification is essential for POU5F1B to localize to the cytoplasm and become acylated by the DHHC17 palmitoyltransferase. This leads to POU5F1B association with detergent-resistant membrane subdomains, where it triggers the accumulation of integrins and signaling molecules, and to a stimulation of cell focal adhesion. Finally, we determined that POU5F1B stability is critically dependent on ROCK, a crucial regulator of cytoskeletal dynamics and cell motility.

TUMOR BIOLOGY: Pancreatic Cancer Microenvironment
Poster Session

#1576 The heterogeneity between pancreatic ductal adenocarcinoma with & without lymphovascular invasion.
Y. Zou, Y. Xie, S. Gao, T. Zhou, J. Yu, J. Hao;
Tianjin Medical Univ. Cancer Inst. & Hospital, Tianjin, China

Background Pancreatic ductal adenocarcinoma (PDAC) is one of the deadliest malignant solid tumors, with a five-year survival rate less than 10%. Lymphovascular invasion (LVI) is a poor prognostic indicator for PDAC, yet the difference between tumors with or without LVI is unclear.
Methods We used scRNA-seq analysis on the PDAC tissue of 24 patients obtained from the National Genomics Data Center (Project number: PRJCA001063) to compare T-cell, macrophage, & cancer-associated fibroblast (CAF) heterogeneity between LVI-positive & LVI-negative PDAC. To validate the scRNA-seq results, complementary techniques, including multiple immunofluorescence assays & flow cytometry, were used. Additionally, we analyzed the characteristics of LVI-positive PDAC tumor cells.
Results LVI-positive PDAC thrives in an immunosuppressive microenvironment. We discovered that CD8+ T cells were more deficient in LVI-positive PDAC than in LVI-negative PDAC. Furthermore, the effective & cytotoxic markers (such as GZMB & IFN-γ) of CD8+ T cells also decreased in LVI-positive PDAC. M2 macrophage polarization was found to be higher in LVI-positive PDAC compared to LVI-negative PDAC. In addition, we discovered a more fibrotic TME signature in LVI-positive PDAC. LVI-positive tumor cells, in particular, had a mesenchymal transition phenotype & a hypoxic microenvironment.
Conclusions This study adds to our understanding of the intricate heterogeneity seen in LVI-positive PDAC. It sheds light on the distinct characteristics of LVI-positive PDAC & advances our understanding of its underlying biology.

#1577 Cancer associated fibroblast - tumor cell crosstalk enhances epithelial to mesenchymal transition and promotes a classical to basal switch in human pancreatic ductal adenocarcinoma.

S. Guinn, B. Perez, J. Patel, J. Lee, D. Zabransky, W. J. Ho, E. J. Fertig, E. Kartalia, J. Tandurella, R. Burkhart, J. W. Zimmerman, E. Jaffee;
Johns Hopkins Medicine, Baltimore, MD

Introduction: Cancer associated fibroblasts (CAF) drive a complex tumor microenvironment (TME) in pancreatic ductal adenocarcinoma (PDAC) through incompletely understood interactions. Two major CAF subtypes, myofibroblastic (myCAF) and inflammatory (iCAF), dominate the tumor landscape and have been defined by gene expression profiles. There is significant plasticity between subtypes and alterations in CAF behavior likely drive changes in tumorigenicity and immune evasion. Additionally, PDAC tumor cells usually present with a predominant classical or basal phenotype that is associated with clinical outcomes. We hypothesized that CAF phenotype impacts tumor cell gene expression and alters the clinically-relevant tumor subtyping.

Methods: We interrogated cellular crosstalk in the PDAC TME using a novel three-dimensional, patient-matched coculture system of patient-derived organoids (PDO) and CAFs, established from 12 patients undergoing surgical resection. Molecular characterization included bulk RNA sequencing, proteome profiling (107 factor), flow cytometry, multiplex RNA Scope, imaging mass cytometry (IMC), and RT-qPCR.

Results: PDO gene expression analysis from bulk RNAseq demonstrated CAF coculture induced phenotypic shifts in the Moffitt subtype from a classical to a basal phenotype. Further, CAF coculture enhanced epithelial to mesenchymal transition (EMT) across all patients, even those with a baseline basal phenotype. We hypothesized this could be due to both cell-cell crosstalk and secreted factors. We therefore treated PDO with CAF-conditioned media (CM) and demonstrated that CM is sufficient to drive the observed classical-to-basal shift by RT-qPCR. Secretome analysis of CM derived from 3 CAF lines identified HGF, FGF19, and IL-8 as factors contributing to this transcriptional change. Next, we used spatial - omics (transcriptomics and proteomics) to examine the validity of these findings in source patient tissue. Using RNA Scope, we discovered distinct tumor neighborhoods expressing basal mRNAs KRT17 and KRT6a surrounded by CAFs compared to those expressing classical genes TFF1 and GATA6. We then used IMC to further explore CAF subtypes in patient tumors and found FAP+ myCAF regions corresponded to basal tumor regions, while CXCL12+ iCAFs were found in classical regions.

Conclusions: PDAC tumor biology is likely driven by interactions between cancer cells and CAFs. Potential mediators of these interactions include both cell-cell contact and secreted factors. We introduce a novel approach combining *in vitro* coculture with tissue-based assays, demonstrating that modern culture techniques preserve cell type heterogeneity and plasticity. Together, these data demonstrate that a CAF-rich TME drives tumor cell plasticity not only towards EMT but also a more basal disease phenotype.

#1578 RAS-GTP inhibition modulates Hedgehog signaling, suppressing myCAFs and promoting iCAFs in pancreatic ductal adenocarcinoma.

M. Hasselluhn, L. Tomassoni, U. Wasko, A. Curiel-Garcia, T. Dalton, S. A. Sastra, C. Palermo, A. Califano, **K. P. Olive**;
Columbia University Irving Medical Center, New York, NY

More than 90% of human pancreatic ductal adenocarcinoma (PDAC) cases are driven by activating mutations in KRAS. RMC-7977 is a potent inhibitor of GTP-bound RAS proteins (RAS(ON), including both wild type and mutant variants of KRAS, NRAS, and HRAS. The related investigational agent, RMC-6236, is a first-in-class, potent, orally bioavailable, RAS^{MULTI}(ON) inhibitor currently in Phase 1/1b clinical trials (NCT05379985). We performed preclinical studies in a range of models of PDAC, including the highly chemoresistant K-$ras^{LSL.G12D/+}$, $p53^{LSL.R172H/+}$, $Pdx1Cre^{tg/+}$ (KPC) genetically engineered mouse. RMC-7977 exhibited broad anti-tumor activity at tolerable doses, provoking radiographic responses in KPC pancreatic tumors and extending overall survival by 3-fold, the largest response observed yet in this model. RMC-7977 dosing produced a metronomic effect on RAS signaling in tumor and normal tissues. This yielded tumor-selective effects on apoptosis and proliferation, consistent with RAS oncogene addition in PDAC.

PDAC tumors are characterized by an expansive stroma that harbors multiple subtypes of cancer associated fibroblasts (CAFs) that manufacture a fibrotic, inflammatory extracellular matrix. CAF proliferation is driven by signals emanating from the malignant epithelial cells, such as Sonic Hedgehog (SHH), a secreted ligand that drives downstream Hedgehog pathway signaling in myofibroblastic CAFs (myCAFs). To understand the impact of RAS-GTP inhibition on paracrine signaling to CAFs in PDAC, To understand the dynamic responses of malignant epithelial cells following GTP-RAS inhibition, we performed single cell RNA sequencing (scRNAseq) on KPC pancreatic tumors treated with RMC-7977 or vehicle at multiple timepoints. Using the ARACNe and VIPER algorithms, we performed single cell regulatory network analysis on the expression profiles of >210,000 cells to calculate the activities of thousands of transcriptional regulatory protein in each cell.

We found that the RAS-GTP inhibition blocked SHH expression in malignant epithelial cells, resulting in loss of downstream Hh pathway activity in CAFs within 24 hours of treatment. By one week of treatment, myCAFs were significantly depleted whereas inflammatory CAFs (iCAFs) were significantly accumulated. Strikingly, CAF heterogeneity was restored in KPC pancreatic tumors that acquired resistance to RMC-7977, despite continued suppression of Hedgehog pathway signaling. Consistent with prior studies of Smoothened inhibitors, the depletion of myCAFs from RAS-GTP inhibition was associated with the rapid opening and hypersprouting of intra-tumoral blood vessels. Ongoing studies using the mutant-selective $KRAS^{G12D}$ inhibitor RM-044 should discriminate between direct effects of wild type RAS inhibition in CAFs versus the paracrine consequences of mutant RAS inhibition in malignant epithelial cells.

#1579 Macrophage infiltration and polarization in pancreatic ductal adenocarcinoma following stereotactic body radiation therapy.

E. D. Gonzalez Marrero[1], L. Wang[2], B. R. Schrank[2], A. C. Koong[2];

[1]University of Puerto Rico School of Medicine, San Juan, PR, [2]The University of Texas MD Anderson Cancer Center, Houston, TX

Introduction: Stereotactic body radiation therapy (SBRT) has emerged as a promising treatment modality for pancreatic ductal adenocarcinoma (PDAC) due to its precise delivery and potential to improve local control. Beyond its direct impact on tumor cells, accumulating evidence suggests that SBRT may also modulate the tumor microenvironment (TME), influencing immune responses. Macrophages play a crucial role in the TME with their polarization into pro-inflammatory (M1) or pro-tumoral (M2) phenotypes significantly impacting cancer progression. Studying the TME and developing immune therapies may be helpful for metastatic PDAC, which currently only has non-curative treatment. The TME, in particular the polarization of macrophages, has not been well studied following radiation treatment. Therefore, our work aims to study how SBRT affects the infiltration and polarization of macrophages in the PDAC TME in a time-dependent manner.
Methods: To establish and study PDAC C57BL/6J mice were orthotopically injected with a luciferase-labeled KPC tumor cell line. SBRT was administered to tumor-bearing mice following a schedule of 10Gy radiation per fraction in total of 5 fractions on days 10-14 post tumor implantation. Mice were euthanized on day 1, 3 and 7 after irradiation. Tumor tissues were collected for immunohistochemistry (IHC) staining and flow cytometry with antibodies targeting CD68, CD11b, CD86 (M1 marker), and CD206 (M2 marker). Images were analyzed and quantified using ImageJ and GraphPad Prism.
Results: Via the use of IHC staining, we found no significant difference in the number of cells stained with the CD68 antibody (macrophage marker) when compared throughout groups. Additionally, we found no significant difference in the number of macrophages stained with the M2 marker. However, we did observe a significant increase in the number of macrophages stained with the M1 marker in the group receiving SBRT. Through flow cytometry of the tumor tissues we observed an increasing trend, as time passed, in the number of macrophages expressing the M1 marker. The same trend was observed in macrophages expressing both the M1 and M2 markers. However, a change in the total number of macrophages or those expressing only the M2 marker was not observed.
Conclusions: SBRT does not affect the total number of infiltrated macrophages in the TME or the amount of M2 macrophages. However, we did observe that the percentage of M1 macrophage increases significantly as time passes after SBRT. We theorize that the increase in M1 macrophages may be due to an M2 to M1 transition in the M2 population. Our study provides preliminary rationale to use macrophage-targeted immune therapy to potentiate the efficacy of SBRT for PDAC treatment, though we understand that further follow-up studies with a larger sample size and longer time course are required to obtain significant and meaningful results.

#1580 Investigating the tumor microenvironment of pancreatic ductal adenocarcinoma with BRCA2 mutation.

F. Al-Musawi, C.-i. Hwang;
UC Davis, Davis, CA

Pancreatic ductal adenocarcinoma (PDAC) is one of the most aggressive and deadliest cancers with a survival rate of less than 12% at 5 years. It is estimated that around 14% of human PDAC contain mutations in genes involved in DNA Damage Repair (DDR), including BRCA1/2, ATM, and others. Additionally, PDAC has an extensive network of extracellular matrix components surrounding the tumor in the stroma, such as cancer-associated fibroblasts, which promote cancer cell growth. The interactions of the tumor with its tumor microenvironment and stroma can bring vulnerabilities that could be targeted if identified. New therapeutic strategies to those targets can be developed for specifically PDAC with DDR mutations.

Using publicly available RNA-seq dataset of PDAC patients from The Cancer Genome Atlas (TCGA), I computationally estimated the infiltration of immune and stromal cell types into the tumor. From the analyses, I found that there was a significant difference in the migration of Common Lymphoid Progenitor (CLP) cells into PDAC with mutations to DDR genes. CLP cells usually divide into T-cells, B-cells, and NK cells, suggesting that DDR mutations could cause a more immunogenic environment. There was also a decrease in the infiltration of stromal elements, mainly fibroblasts, into PDAC with mutations to DDR genes.

In the experiment I am currently working on, I hypothesize there are also in vivo differences in the infiltration rates of certain immune cell types and fibroblasts into BRCA2-mutated PDAC, since BRCA2 is the most commonly mutated DDR gene in PDAC.

For my current experimental design, the mice in the experimental group will be orthotopically implanted with PDAC with Brca2 knockout. The control group will have mice orthotopically implanted with PDAC without Brca2 knockout. After letting the tumors grow for 3 weeks, the mice will be sacrificed and the pancreatic tumors will be collected and stained through trichrome staining. Trichrome staining probes for the stromal cancer-associated fibroblasts. Furthermore, immunohistochemistry (IHC) staining will be done to look for specific populations of cells, such as specific types of fibroblasts, effective and immunosuppressive immune cells including T-cells, B-cells, and NK cells. The aim is to see whether the computational findings in regards to the tumor microenvironment are also reflected in vivo. I will have the data from this experiment by the time of the conference in April 2024.

Overall, my project is about investigating the tumor microenvironment and fibroblast abundance in PDAC with BRCA2 knockout mice, using computational data, IHC staining and trichrome staining.

#1581 Colony-stimulating factor-1 receptor as a potential therapeutic target in pancreatic ductal adenocarcinoma.

S. Chaudhuri, D. A. Deming, C. A. Pasch, K. A. Johnson, C. K. Sievers, P. B. Emmerich;
Univ. of Wisconsin Madison Sch. of Med. & Public Health, Madison, WI

Background:
Pancreatic ductal adenocarcinoma (PDAC) is associated with poor prognosis, rising incidence and suffers from limited existing treatment options. Currently, salient features of PDAC are being investigated that can potentially predict immunotherapy outcomes, to identify small patient populations that can benefit from such strategies. Preliminary studies show that colony-stimulating factor-1 receptor (CSF1R), a surface receptor tyrosine kinase that drives survival, function, proliferation and differentiation of several myeloid lineage cell types can be a potentially interesting target for combination immunotherapy.

Methods:
PDAC patients from the TCGA PanCancer Atlas were stratified into $CSF1R^{hi}$ and $CSF1R^{lo}$ cohorts and clinically relevant characteristics were compared between the two. The mRNA expression of CSF1R and immunological markers of interest were evaluated and Gene Set Enrichment Analysis (GSEA) was run on the two groups to analyze differential expression of gene sets.

Results:
mRNA expression z-scores were used to classify 129 patient samples in the TCGA PanCancer Atlas dataset into $CSF1R^{hi}$ (z-score>1, n=20) and $CSF1R^{lo}$ (z-score<0, n=109) cohorts. Both have similar disease staging, MSI MANTIS scores, tumor mutation burden, median diagnosis age, sex and race distribution. However, the $CSF1R^{hi}$ cohort has a distinct, non-conventional PDAC driver gene mutation profile (genomic alteration frequencies in $CSF1R^{hi}$ vs $CSF1R^{lo}$ cohorts respectively: a) *KRAS: 30% vs* 73% b) *CDKN2A*: 15% vs 57% and c) *SMAD4*: 5% vs 42%) (p-value<0.01 for each). CSF1R correlates with markers of CD8+ T-cell function (R^2 values: *CD8A:* 0.683, *GZMB:* 0.508, *PRF1:* 0.673), CD8+ T-cell infiltration (*CXCL9:* 0.596, *CXCL10:* 0.483, *CCL5:* 0.666) and expression of immune checkpoint genes (*PDCD1:* 0.602, *CD274:* 0.544, *CTLA4:* 0.613). *CD8A, GZMB, PRF1, CXCL9, CXCL10, CCL5, PDCD1, CD274, CTLA4* are significantly upregulated in the $CSF1R^{hi}$ group (log2Fold changes respectively: 2.07, 1.57, 1.48, 2.51, 1.71, 1.75, 1.63, 1.34, 1.80). GSEA against the hallmark gene set database shows that *KRAS* signaling, Inflammatory response, IL6 JAK STAT3 and Interferon-gamma signaling are significantly upregulated in the CSF1R high patient group (FDR q-value <0.01 for each).

Conclusion:
Preliminary *in silico* analysis suggests that PDAC patients with higher levels of CSF1R may be more immune infiltrated. Future studies will evaluate the potential of CSF1R as a biomarker to identify an immune infiltrated subset of PDAC patients *ex vivo* and the mechanism of immune infiltration in $CSF1R^{hi}$ PDACs *in vivo*.

#1583 Neutrophil pro-tumorigenic role in progression and therapy resistance in pancreatic ductal adenocarcinoma.

Reegan Sturgeon[1], Esther Johnson[1], Caitlin Molczyk[1], Paran Goel[2], Parker Tinsley[3], Lauren Abrahams[4], Michael Maher[5], Rakesh K. Singh[1]

[1]University of Nebraska Medical Center, Omaha, NE,[2]University of Alabama at Birmingham, Birmingham, AL,[3]Wayne State University, Wayne, NE,[4]Tufts University, Medford, MA,[5]Creighton University, Omaha, NE

Pancreatic cancer (PC) continues to be a challenge for today's therapeutics, with a meager 5-year survival rate of 12%. Due to the pancreas' location, patients often receive diagnosis late, leaving them with limited treatment options. Often, they fail to respond to chemotherapy regimens or develop resistance to those therapies. Tumor-promoting inflammation is a hallmark of cancer, contributing to tumor cells' survival and proliferation. Infiltrating leukocytes and pro-inflammatory cytokines released into the tumor microenvironment (TME) often cause this inflammation. My lab has previously linked increases in pancreatic ductal adenocarcinoma (PDAC) progression and chemotherapy resistance to inflammation and the CXCR2 pathway. In the present study, we examined the role of neutrophil recruitment in PDAC progression using patient samples and KRAS-dependent KC and KPC murine models. Our data suggest a positive association between tumor-associated neutrophils (TANs) and PDAC progression. *In vitro*, we observed neutrophil-PDAC interaction enhancing the survival of both neutrophils and PDAC cell lines. Moreover, this survival was mediated by cellular aggressiveness and therapy resistance. Concerning survival, we saw increased expression of anti-apoptotic genes in the neutrophils upon PDAC cancer cell conditioned media treatment. We also observed modulated expression of immunoregulatory molecules. Our data suggest that increased recruitment of TANs supports PDAC progression and survival, and PDAC cell-neutrophil interaction modulates neutrophil survival and immunoregulatory phenotype.

#1584 The interplay between natural killer cells and pancreatic stellate cells in pancreatic ductal adenocarcinoma.

R. E. A. Fincham[1], P. Periasamy[2], C. R. Joseph[2], J. Meng[2], J. Lim[2], F. Wee[2], K. Stasinos[1], M. R. Goulart[1], J. Ye[2], L. Chong[2], D. Goh[2], J. P. S. Yeong[2], H. M. Kocher[1];

[1]Barts Cancer Institute, London, United Kingdom, [2]Agency for Science, Technology and Research (A*STAR), Singapore, Singapore

Natural Killer (NK) cells have been shown to possess potent anti-tumor activity against multiple cancer types and consequently have been harnessed as a cellular cancer immunotherapy. Furthermore, targeting of pancreatic stellate cells has received increasing interest in the treatment of pancreatic ductal adenocarcinoma (PDAC), with several clinical trials testing the hypothesis that rendering activated pancreatic stellate cells/cancer associated fibroblasts (aPSC/CAF) into a quiescent state (qPSC) can enhance anticancer treatment. Despite this interest, our understanding of the interplay between these two cell types remains limited. We hypothesized that PSC/CAF may exhibit a dynamic interaction with NK cells that may be harnessed for therapeutic strategies and patient stratification. Employing a series of *in vitro* assays, we demonstrate a significant bi-directional interaction between natural killer cells and pancreatic stellate cells in the context of PDAC. NK cells were found to effectively target and eliminate both aPSC and qPSC, with PSC activation conferring some protection from NK-lysis. Furthermore, we highlight a significant myofibroblastic shift in PSCs regardless of previous activation status when cultured with NK cells; an interaction that was direct contact dependent. NK cells were also found to demonstrate cellular modulation of NKG2A and TIM3 in response to PSC co-culture. Drawing on Luminex ELISA analysis, we suggest that engagement of the IFN-γ signaling pathway may be driving phenotypic modulation. Global proteomic analyses demonstrated differential protein changes induced by NK cells in aPSC compared to qPSC, as well as alterations in the NK cell proteome upon such co-culture. Utilizing multiplex immunohistochemical analysis of PDAC patient samples, we highlight differential spatial distribution of phenotypically distinct NK cells and PSC/CAF subtypes in patient samples between long- (n=16) and short- (n=48) survivors. Moreover, NK-PSC proximity, and not total immune infiltrate, was found to play a prognostic role in PDAC. Our work provides a global overview of the cross-talk between NK and PSC in PDAC, demonstrating a significant bi-directional relationship which offers novel insights into potential therapeutic avenues. Furthermore, we demonstrate, for the first time to our knowledge, the prognostic role of NK-PSC proximity in patient survival and suggest its potential for patient stratification.

#1585 Tenascin C in pancreatic cancer-associated fibroblasts enhances epithelial mesenchymal transition and is associated with resistance to immune checkpoint inhibitor.

S. Furuhashi, Y. Morita, A. Matsumoto, S. Ida, R. Muraki, R. Kitajima, M. Takeda, H. Kikuchi, Y. Hiramatsu, H. Takeuchi;
Hamamatsu University School of Medicine, Hamamatsu, Japan

Backgrounds: Tenascin C (TNC) is an extracellular matrix glycoprotein that is abundantly expressed in cancer stroma and its overexpression correlates with tumor progression in various types of cancer including pancreatic adenocarcinoma (PAAD). However, the role of TNC in regards to response to immune checkpoint inhibitor (ICI) still remains to be identified. In this study, we aimed to investigate the potential involvement of TNC in the response to ICI among PAAD patients.
Materials and Methods: Transcriptomic profiles were downloaded by TCGA and GTEx database and TNC mRNA levels were compared between tumors and normal tissues. These transcriptomic data were deconvoluted using CIBERSORTx to identify specific enriched pathways in cancer cells and cancer-associated fibroblasts (CAFs) in PAAD patients. Bioinformatic programs were used to predict paracrine communications between cancer cells and cancer-associated fibroblasts (CAFs), and the Tumor Immune Dysfunction and Exclusion (TIDE) score was calculated to predict response to ICI treatment in PAAD patients. An independent immunotherapeutic cohort was applied to validate prediction values for immunotherapy.
Results: TNC mRNA levels were significantly upregulated in tumors compared to normal tissues in eight cancer types including PAAD. TNC-high (TNC-H) PAAD patients (n = 138) had significant shorter overall survival than TNC-low (TNC-L) patients (n = 40) (p = 0.0125, Log-rank test). Using CIBERSORTx, TNC was estimated to be predominantly expressed in CAFs in PAAD. In pathway analysis, both cancer cells and CAFs had significant enrichments of the epithelial mesenchymal transition pathway in TNC-H patients. Ligand-receptor interaction analysis showed that TNC produced in CAFs had the highest interaction potentials to bind to integrin families such as ITGαV and ITGβ3 in cancer cells. In an independent immunotherapy data cohort, patients with TNC-H and ITGαV-high or ITGβ3-high expression were associated with poor response to ICI treatment and had shorter overall survival than those with both low expressions.
Conclusions: In conclusion, these findings suggest that TNC-high CAFs can play a crucial role in tumor progression and resistance to ICI therapy in PAAD patients, and targeting TNC and its interactions with cancer cells may provide a potential strategy for improving the efficacy of ICI therapy in PAAD.

#1586 Unraveling the importance of pancreatic cancer extracellular signaling to endothelial cells within the tumor microenvironment.

J. M. Finan[1], Y. Guo[1], A. Q. Bartlett[1], K. MacPherson[1], V. Calvert[2], M. D. Hedberg[1], E. Petricoin[2], R. Sears[1], J. R. Brody[1];
[1]Oregon Health & Science University, Portland, OR, [2]George Mason University, Fairfax, VA

In many solid tumors, including pancreatic ductal adenocarcinoma (PDAC), the secretion of extracellular vesicles (EVs) has been shown to support tumor progression, chemotherapeutic resistance, and metastasis. Importantly, PDAC tumors are composed of up to 80% non-tumor cells and an extracellular matrix, yet no studies have been performed to determine which cells within PDAC tumors internalized PDAC EVs. Further, the RNA-binding protein HuR plays an important role in PDAC cells, supporting the stability and translation of transcripts that aid tumor cell stress responses. Our lab has recently found that EVs harbor distinct mRNA and phosphorylated protein cargoes from donor cells. Further, HuR knockout (KO) cells produce EVs with significantly different mRNAs and phosphorylated proteins that EVs isolated from HuR wildtype (WT) cells. Specifically, proteins relating to endothelial function and angiogenesis were significantly differentially phosphorylated. Considering the functional impact of EV cargoes on recipient cells, our study aims to identify the specific cell types in the tumor microenvironment that import PDAC EVs and investigate the role of PDAC cell HuR in this signaling process. We have generated human PDAC and mouse $Kras^{G12D}$ $Trp53^{R172H}$ driven (KPC) PDAC cell lines to express an EV reporter, PalmGRET. Utilizing these cells lines in an immunocompetent mouse model of PDAC, we found that endothelial cells are major importers of PDAC EVs. We next performed bulk RNA-sequencing on endothelial cells sorted from these tumors that have (GFP+) versus have not (GFP-) imported PDAC EVs to assess the functional impact of PDAC EVs. Subsequent studies will focus on delineating the importance of this signaling axis by ablating EV secretion in addition to assessing endothelial cell function when treated with EVs from HuR WT vs. KO cells. Collectively, our study sheds light on the preferential uptake of PDAC EVs by endothelial cells and highlights the potential role of tumor cell-intrinsic HuR in this signaling process. These findings expand our understanding of the interactions between PDAC and the tumor microenvironment, potentially paving the way for targeted therapeutic interventions in this devastating disease.

#1587 Multimodal spatial transcriptomics uncover distinct tumor microenvironment states and cell-cell communication networks in molecular pancreatic cancer subtypes.

S. Baerthel[1], C. Falcomata[2], V. Goelling[3], D. Lucarelli[4], R. Gindra[5], C. Schmitt[1], J. Swietlik[6], F. Meissner[7], M. Schmidt-Supprian[8], D. Saur[1];
[1]DKFZ German Cancer Research Center, Munich, Germany, [2]Icahn School of Medicine at Mount Sinai, New York, NY, [3]Institute of Experimental Hematology, School of Medicine, Technical University of Munich, Munich, Germany, [4]Chair of Translational Cancer Research and Institute of Experimental Cancer Therapy, Klinikum rechts der Isar, School of Medicine, Munich, Germany, [5]Chair of Translational Cancer Research and Institute of Experimental Cancer Therapy, Klinikum rechts der Isar, School of Medicine, Munich, Germany, Munich, Germany, [6]Experimental Systems Immunology Laboratory, Max Planck Institute of Biochemistry, Martinsried, Germany, [7]Institute of Innate Immunity, Department of Systems Immunology and Proteomics, Medical Faculty, University of Bonnr, Bonn, Germany, [8]Institute of Experimental Hematology, School of Medicine, Technical University of Munich, Munich, Germany, Munich, Germany

The tumor microenvironment (TME) presents a complex ecosystem comprising a diversity of immune and stromal cell populations that influence tumor progression, drug delivery and therapy outcome. High levels of inter- and intra-tumor heterogeneity in TME state are driven by molecular tumor phenotypes. Pancreatic ductal adenocarcinoma (PDAC), one of the most lethal cancer types, displays a high genetic heterogeneity along with an immunosuppressive TME. However, it remains largely elusive how distinct TME states are mechanistically influenced, and which molecular processes dictate the emergence of different modes of immunosuppression within the TME of molecular PDAC subtypes.Here, we performed a systematic analysis of functional associations between the major molecular PDAC subtypes, the classical and mesenchymal subtype, and their TME states. We describe the TME composition and complex cell-cell communication networks within PDAC subtypes using a multimodal integration of spatial transcriptomics (ST) with complementary approaches, such as scRNA-seq, MS-based Secretomics and multiplexed histocytometry. We generated ST data sets (Visium) of a tumor cohort derived from a *Kras*-driven PDAC mouse model. To analyze TME composition as well as spatial niches and cell type communities, we computationally enhanced the spot-resolution of ST datasets, followed by cell type deconvolution and cell-cell communication analysis to identify subtype-specific TME communities and communication networks.To this end, we generated a large resource of PDAC mouse models which represent molecular subtypes of the disease and mimic the heterogeneity of TME states found in human PDAC cohorts. This analysis revealed that a set of subtype-specific secreted factors shape the immunosuppressive PDAC TME via direct and indirect communication networks with immunosuppressive myeloid and T cells in molecular PDAC subtypes. Multimodal ST analysis delineated spatial subtype-specific TME communities as well as spatial communication patterns. We functionally investigate the tumor cell intrinsic regulation of the identified subtype-specific secreted factors, providing potential therapeutic vulnerabilities for more effective combinatorial subtype-specific therapies including immunotherapeutic approaches.

#1588 Identification of new signaling pathways between fibroblasts & tumor cells in pancreatic cancer.

A. Al Shoukari[1], M. Batardiere[1], N. Movahed[2], C. beaussier[1], J. Baig[1], M. gonzalez[1], P. Moraille[1], E. Bonneil[1], L. Rousseau[3], S. turcotte[3], K. Delgiorno[4], M. Tan[5], A. Means[5], E. Dianati Ajibisheh[1], Q.-h. Trinh[1];

[1]University of Montreal, Montreal, QC, Canada, [2]Concordia University, Montreal, QC, Canada, [3]CHUM, Montreal, QC, Canada, [4]Vanderbilt University, Tennessee, TN, [5]Vanderbilt University Medical Center, Tennessee, TN

We explore the unstudied role of nanoparticles (NPs), recently discovered secreted non-vesicular nanoparticles, in signaling between pre-cancer associated fibroblasts (preCAF), CAFs, and tumor cells. We generated two novel primary lines preCAF PFUM1 from a patient with high-grade intraductal papillary mucinous neoplasms and CAF FUM2 from a patient with pancreatic ductal adenocarcinoma, all tests performed between passages 2 and 3, fibroblast purity validated by RT-PCR and ACTA2 immunofluorescence. Small extracellular vesicles (sEVs), exomeres, and supermeres (the two main forms of NPs) were isolated by the ultracentrifugation method from PF-UM1 and F-UM2 with n=2-3 experiments. To validate the isolation, we used nanoparticle tracking, electron, and fluid-phase atomic force microscopy. Proteins were quantified by BCA assay. Liquid chromatography-mass spectrometry characterized the cargo from each fraction. Human cancer lines MIAPACA2 and SU8686 were treated with 10 µg of each fraction and cell proliferation was tested by phase-contrast images (Cytation 5), analyzed by Ilastik-based 1.4.0 machine-learning. We performed fluorescent Ki-67 and vimentin staining and quantified in QuPath 0.4.3. Non-parametric statistics were performed in Prism GraphPad.

NPs constitute the major fraction of small particles released by fibroblasts, containing 80.5% (PFUM1) and 77.5% (FUM2) of the protein load by quantification. Mass spectrometry reveals enrichment of growth factors, epithelial-to-mesenchymal (EMT) transition, and metabolism-associated proteins in the NPs compared to sEVs. At 72 hours, cell proliferation for Su8686 reveals a proliferative effect for all fractions from both PFUM1 and FUM2 (19-63% increase compared to controls, p=0.049 to <0.0001). For MIAPACA2, only supermeres from PFUM1 and FUM2 consistently increased proliferation (9.5-35% increase, p=0.0051 to <0.0001). Ki-67 expression in MIAPACA2, increased by 9.6-23.0% following treatment by NPs (all p<0.0001) and by 2.9-9.2% with sEVs (p=0.011 to <0.0001). EMT was estimated by vimentin in MIAPACA2, as all preCAF fractions from PFUM1 reduced vimentin expression (p<0.001), while CAF FUM2 NPs increased vimentin expression (p<0.0001) while sEVs had no effect (p=0.075).

In conclusion, the majority of pancreatic tumor-associated fibroblast small secretome is composed of NPs, exhibiting significant functional pro-tumoral effects.

#1589 Integrated multiomics analysis revealed the significance of Transgelin in driving pancreatic cancer-associated fibroblast-mediated cancer progression.

K. Shinjo[1], X. Wang[1], K. Kumegawa[2], R. Maruyama[2], S. Mii[1], Y. Murofushi[1], M. Suzuki[1], A. Enomoto[1], Y. Kondo[1];
[1]Nagoya Univ. Graduate School of Medicine, Nagoya, Japan, [2]Japanese Foundation for Cancer Research, Tokyo, Japan

Pancreatic ductal adenocarcinoma (PDAC) is primarily characterized by a desmoplastic reaction, mainly consisting of cancer-associated fibroblasts (CAFs). In order to investigate the heterogeneity of CAFs, we initially conducted single-cell Assay for Transposase-Accessible Chromatin with high-throughput sequencing (scATAC-seq) using pancreas tissue from 12-week-old KPC (K-rasLSL.G12D/+; Trp53R172H/+; Pdx-1-Cre) PDAC mouse models. We identified three clusters enriched with myofibroblast CAF (myCAF) gene markers and one cluster enriched with inflammatory CAF (iCAF) gene markers. Next, we performed single-cell RNA sequencing (scRNA-seq) on pancreas tissues from KPC mice. scRNA-seq revealed four distinct fibroblast clusters, each exhibiting characteristic gene expression profiles of normal fibroblasts, iCAF, myCAF and antigen-presenting CAF (apCAF). These findings suggest that CAFs in the myCAF cluster identified in scATAC-seq may have potential to differentiate into either myCAFs or other CAF subtypes based on certain cues. Next, we focus on the expression of myCAF marker genes, particularly two commonly used markers, *Tagln* and *Acta2*. Among myCAFs, two subtypes were identified: *Tagln*-positive and *Acta2*-positive CAFs, and *Tagln*-negative and *Acta2*-positive CAFs. To confirm our findings, we conducted Immunohistochemical analysis (IHC) on KPC pancreas samples. We observed CAFs that were positive for both Talng and αSMA exclusively in close proximity to tumor cells. Fibroblast expressing only αSMA mostly located in normal area. Tagln is known as an actin-binding protein and plays an important role in activated fibroblasts. Orthotopic PDAC mouse models using Tagln homozygous knockout mice showed a significant reduction in tumor weight compared to the wild-type mice (P = 0.0076). Indeed, we found that high *TAGLN* expression in PDAC samples was associated with poor survival, as demonstrated by the analysis of the TCGA dataset. These data suggest that myCAFs expressing TAGLN contribute to the promotion of PDAC growth. Targeting stromal TAGLN might be a potential therapeutic strategy to counteract PDAC progression.

#1590 The role of mucosal associated invariant T (MAIT) cells in pancreatic cancer liver metastasis.

Jugmohit Toor[1], Peter Dimitrion[1], Rachel Krevh[2], Kalpana Subedi[2], Bobby Zuniga[2], Jie Wang[2], Li Zhou[2], Qing-Sheng Mi[2]

[1]Cancer Biology, Henry Ford Health System / Wayne State University, Detroit, MI, [2]Henry Ford Health System, Detroit, MI

Pancreatic cancer liver metastasis (PCLM) is present in 50% of patients diagnosed with pancreatic ductal adenocarcinoma (PDAC) and leads to a median survival of <6 months. Here, we sought to identify urgently needed therapeutic options for treating PCLM by targeting mucosal associated invariant T (MAIT) cells, an invariant T cell restricted to MHCI related protein (MR1). MAIT cells are a unique subset of T cells that are classified as “protumor” MAIT17 and “antitumor” MAIT1 cells. We hypothesize that the PCLM tumor microenvironment (TME) induces direct MAIT cell activation via MR1 which primes MAIT cells towards a “protumor” phenotype. Using publicly available TCGA data, we found that PDAC tumors were enriched for MR1 gene expression compared to healthy tissue and patients with lower tumor MR1 expression had better overall survival. Next, immunostaining of MR1 on tumor samples from primary PDAC and PCLM revealed that that MR1 protein expression is highly enriched in the TME and localized to the surface of tumor cells. This suggests that MAIT cells in the PCLM TME are being activated directly via an MR1 dependent pathway. Next, we performed hemi-spleen injection of mouse pancreatic cancer cells into WT and MR1 KO (lacks MAIT cells) mice to model PCLM. Interestingly, MAIT cells in the WT PCLM mice were shifted towards the “pro-tumor” MAIT17 phenotype. Furthermore, the lack of MAIT cells in MR1 KO mice significantly reduced tumor burden compared to WT mice. Lastly, we found that MR1 KO mice had a reduction in exhausted NK and NKT cells which likely promoted anti-tumor immunity. Overall, we find that the PCLM TME promotes “pro-tumor” MAIT17 cells via MR1 mediated activation and these MAIT17 cells inhibit anti-tumor cells such as NK and NKT cells. This work identifies targeting MAIT cells as a novel immunotherapy approach for PCLM.

#1591 Hepatocytes compensate for the loss of PHGDH in pancreatic cancer cells during liver metastasis.

K. Ganguly[1], K. Yamamoto[2], J. Encarnacion Rosado[1], A. Sohn[1], D. Biancur[1], E. Lin[1], E. White[1], A. C. Kimmelman[1];
[1]NYU Langone Health Perlmutter Cancer Ctr., New York, NY, [2]The University of Tokyo, Bunkyo City, Tokyo, Japan

Background: Pancreatic cancer (PC), one of the deadliest malignancies, exhibits a high rate of distant metastasis that directly correlates with the mortality rate. Liver serves as one of the most predominant sites of metastasis in PC patients. The nutrient availabilities at the metastatic organ and the metabolic dependencies of the invading tumor cells play pivotal role in shaping the metastatic tumor microenvironment (TME) and establishing metastatic colonies. We observed an elevated expression of PHGDH, the first rate-limiting enzyme of the serine (Ser) biosynthesis pathway, in the hepatocytes (most abundant liver-resident cells) isolated from murine pancreatic liver-metastasis (LM), as compared to normal livers. Hence, we hypothesized that hepatocytes may promote the growth of PC cells by sufficing for their Ser-requirement during LM.
Methods: Murine PC line (HY19636 derived from LSL-KrasG12D; p53 L/+, Ptf1a-Cre+ tumors), were used to generate LMs in B6 mice via hemi-splenic route. PHGDH was knocked-out by lentiviral and AAV-mediated delivery of CRISPR-Cas9 gRNAs *in vitro* and *in vivo*, respectively. RNA-seq, immunoblot, immunohistochemistry, confocal microscopy, ELISA, flow cytometry, chromatin immunoprecipitation and promoter-reporter analyses were performed to identify the molecular axis, followed by functional validations using genetic and pharmacologic inhibitions in murine and human lines. Frozen homogenates with matched formalin-fixed sections of LMs from PC patients provided a unique correlative platform for the study.
Results: A significant portion of the LM tissues (68% in our cohort of 32 PC patients) demonstrated no to very low expression of PHGDH in the cancer cells, rendering them as exogeneous Ser (exSer)-dependent. Notably, loss of PHGDH in the tumor cells induced an elevated PI3K/AKT signaling, downstream of a CXCL5/CXCR2 axis, in the neighboring hepatocytes. This led to FOXO3A's cytoplasmic sequestration and decline in its occupancy on PHGDH promoter, causing a transcriptional upregulation of PHGDH in these hepatocytes, which enabled them to supply Ser and support the growth of exSer-dependent cancer cells in the liver. Abrogation of each node in the CXCR2-PI3K-FOXO3A axis and hepatocyte-specific deletion of PHGDH, led to a significant decline in the metastatic burden of exSer-dependent cells in the liver with a significant increase in overall mice survival, particularly under Ser-deprived dietary conditions.
Conclusion: Our findings demonstrate a novel cancer cell-hepatocytes crosstalk necessary for the growth of PC cells in Ser-depleted conditions. Here, we have identified several actionable signaling nodes in the liver that serve as compensatory metabolic allies for PC cells during liver metastasis, and can be considered as potential therapeutic targets in adjuvant setting.

#1592 Single-cell transcriptomics reveals unique stromal and metabolic heterogeneity in liver metastatic pancreatic cancer.

R. Singh, C. Halbrook;
University of California, Irvine, Irvine, CA

Pancreatic ductal adenocarcinoma (PDA) is the 3rd leading cause of cancer related death in the US. This mortality is strongly linked to the complex PDA tumor microenvironment that drives resistance to chemotherapy and immune suppression. Most patients succumb to metastatic disease, with liver being the most frequently colonized organ. Despite this, most pre-clinical studies have focused on primary PDA models to study the disease. Accordingly, the extent that the liver metastatic niche promotes immune evasion and resistance to treatment remains unclear.To directly compare primary vs. metastatic tumors in PDA tumors, we have optimized a syngeneic experimental model to contrast primary vs. metastatic lesions. To define the similarities and differences between cell types present in these tumors, we employed a single-cell transcriptomics approach. Our analysis has identified shared populations of malignant epithelial, stromal, and immune cells between lesions, allowing for a direct comparison of programming. Here, we have observed that the dominant populations of PDA cells in pancreas vs. liver tumors engage in distinct metabolic programs that suggest different actionable vulnerabilities.Beyond these, we also observed fibroblasts and myeloid sub-populations that are exclusive to liver tumors. These data further support our hypothesis that alternative mechanisms of metabolic, immune, and stromal interactions take place in the metastatic tumor microenvironment. To define these crosstalk networks, we employed the interactome tool CellChat, which has uncovered unique signaling interactions between the CAF and cancer cell populations in pancreatic or liver tumors. Overall, these data have the potential to lead to new avenues to directly target cancer cells or engage an effective immune response that can be designed to treat metastatic pancreatic cancer- an urgent clinical need.

#1593 Intercellular network in immune suppressive microenvironment of pancreatic cancer.

K. Aoki, H. Fukuda, Y. Mizoguchi, K. Arai;
National Cancer Center Research Institute, Tokyo, Japan

Despite constant efforts to improve treatment, the prognosis remains poor, with an overall survival rate of 6% (ranges from 2% to 9%) due to lack of efficient chemotherapy, radiotherapy, and targeted therapy. Immune checkpoint inhibitors (ICIs) has been reported to be effective in various solid cancers, such as melanoma, lung cancer, and renal cell carcinoma. However, pancreatic ductal adenocarcinoma (PDAC) is resistant against ICIs. The responsiveness of immune therapy is mainly determined by immune tumor microenvironment (TME) composed of tumor-infiltrating lymphocytes (TIL) and stromal cells. PDAC possesses unique TME, which is abundant of fibrosis, termed of desmoplasia, and the role of fibrosis in constructing immune suppressive TME remains unclear. First, in this study, to examine the immunological characteristics of TME, we constructed an integrated data base of TIL profiling, RNA-seq and whole exome seq using 31 fresh resected tissues of PDAC. An unsupervised clustering of based on numbers and percentages of 12 TIL types analyzed by flow cytometry showed that PDAC was divided into 2 types of cluster (myeloid cell-, T cell-dominant type), and the prognosis of myeloid type was significantly poorer than T cell-type. Myeloid type contained the high frequency of myeloid cell lineage including monocytes, macrophages and myeloid-derived suppressor cells (MDSC). Only MDSCs were significantly associated with poor prognosis among various immune cell types. Furthermore, gene enrichment analysis identified activated and suppressed pathways in each immune type, and in myeloid cell-dominant type, the immune-related pathways were significantly down-regulated. Then, to understand the characteristics of MDSCs infiltrated into pancreatic cancer tissues, single cell RNA-seq with surgical specimens was performed, and the analysis showed that a specific subtype of MDSCs infiltrated into cancer tissues. In addition, activation status of cancer-associated fibroblasts (CAFs) was related with MDSC recruitment and activation, indicating that the interaction between MDSCs and CAFs is crucial to create MDSC-rich TME. Inhibition of interaction between MDSCs and CAFs is expected to overcome immunosuppressive TME can be a therapy in PDAC.

#1594 Pancreatic cancer and T-cell crosstalk-induced MUC4 expression attenuates T-cell-mediated response.

X. Li, I. Khan, R. Kehrberg, Z. W. Alsafwani, R. Bhatia, S. Kumar, S. K. Batra;
University of Nebraska Medical Center, Omaha, NE

Background: While T-cell-based immunotherapy emerged as a promising tool for cancer management, clinical trials and translational studies revealed that cancer cells develop resistance by modulating tumor microenvironment and cell-intrinsic mechanisms. Pancreatic cancer (PC), consisting of dense stroma, immunosuppressive environment, and aberrant mucin expression, has a dismal survival rate and responds poorly to immunotherapies. MUC4, a member of the mucin family, has been reported to block lymphokine-activated killer cells and induce apoptosis of cytotoxic T-cells, suggesting its possible role in immune modulation. However, how the T-cell secretome influences MUC4 expression in PC and its role in modulating the T-cell response is poorly investigated.
Method: The scRNA-seq data analysis and primary T-cell conditioned media (CM) were utilized to investigate the MUC4 and T-cell crosstalk. T-cell CM-treated murine PC cell line (KCT-3266) was analyzed by RNA-seq analysis followed by MUC4 silencing studies to investigate its role in evading T-cell response. The subcutaneous murine model was utilized to investigate the influence of MUC4 KO on immune cells and cytotoxic cell infiltration. The RNA isolated from tumor tissues from $Kras^{G12D/+}$, $Trp53^{R127H/+}$, Pdx-1-Cre (KPC), and Muc4 knockout (KPMC) murine models were used for PanCancer immune profiling.
Results: The scRNA-seq analysis suggests that intratumoral T-cells positively correlate with MUC4 expression in PC patients. The activated T-cell CM consisting of predominantly IL-2, IFN-γ, and TNF-α cytokines, significantly induce the expression of MUC4 transcriptionally and translationally in both human (SW1990 and COLO357) and murine (KCT-3248 and KCT3266) PC cell lines. RNA-seq analysis from T-cell CM-treated cancer cells revealed that T-cell secretome induced the pathways related to cancer cell death. The CRISPR knockout of MUC4 in PC cells showed increased expression of cleaved caspase-3 after T-cell CM treatment, indicating that MUC4 plays a protective role against the T-cell CM-mediated killing. Subcutaneous implantation of MUC4 proficient and deficient PC cells on the flanks of C57BL/6 immunocompetent mice demonstrated a significantly higher infiltration of CD3 positive and cytotoxic T-cell infiltration in the MUC4 deficient tumors, resulting in significantly lower tumor weight. The PanCancer immune profiling also showed that depletion of Muc4 increases the T-cells and cytotoxic T-cell signaling scores in the KPMC tumor tissues compared to KPC.
Conclusion: T-cell secretome induces MUC4 expression in pancreatic cancer cells, and the increased MUC4 expression reduces T-cell infiltration and protects PC cells against T-cell-mediated killing.

#1595 Persistence of fetal gene signatures along the mesenchymal lineage trajectory defines heterogeneity and function of pancreatic cancer associated fibroblasts.

L. Han[1], T. Walter[1], J. Beaudet[1], C. Everett[1], K. Fang[2], M. Zimmermann[2], A. Mathison[2], R. Urrutia[2], V. Jin[2], G. Leone[2], M. Ostrowski[1];
[1]The Medical University of South Carolina (MUSC), Charleston, SC, [2]Medical College of Wisconsin, Milwaukee, WI

In pancreatic ductal adenocarcinoma (PDAC), cancer associated fibroblasts (CAFs) play critical and complex roles in the tumor microenvironment. CAFs are also a major cell type in the desmoplastic stroma in PDAC and may account for half of the entire tumor tissue. Here we aimed to investigate the origin, diversification, and function of CAFs. We constructed a dual-DNA-recombinase mouse genetic model carrying *Kras*$^{G12D/+}$; *Trp53*$^{frt/+}$; *Pdx1*$^{Flpo/+}$; *Isl1*$^{creER/+}$; *R26*$^{Tomato/+}$ alleles, referred to as *KPFIT*. The DNA recombinase FlpO directs expression of an oncogene Kras (G12D mutation) and loss of a tumor suppressor p53 in pancreatic epithelial cells, while creER recombines the Tomato reporter in the splanchnic mesenchyme and its descendants. The splanchnic mesenchyme is a layer of fetal tissue surrounding the endoderm where the pancreatic epithelium arises. This approach capitalized on the independent functions of FlpO/Frt and CreER/LoxP systems, allowing us to lineage trace Tomato labeled splanchnic progenies (via *IT*) in a spontaneous pancreatic cancer model (via *KPF*) within the same mouse. Our study identified the splanchnic mesenchyme as the fetal origin of pancreatic fibroblasts during homeostasis and tumorigenesis. Notably, the other two postulated origins, bone marrow and epithelial cells, have minimal contributions to fibroblasts. Importantly, single cell transcriptomic analysis indicated persistent and dynamic gene expressions along the pancreatic mesenchymal trajectory during development, homeostasis, precancer lesion and cancer. Intriguingly, certain splanchnic factors are expressed in only subtypes of adult pancreatic fibroblasts in temporally and spatially distinct patterns. Furthermore, we constructed mouse genetic models to delete one of the splanchnic factors, *Gata6,* specifically in CAFs, which resulted in increased tumor burden in the pancreas. This suggests a non-cell autonomous function of GATA6 in CAFs to restrain pancreatic cancer progression. In summary, this study delineated a continuous cell trajectory of the mesenchymal lineage in the pancreas across different life stages. Moreover, persistent gene expressions along the mesenchymal trajectory contributes to pancreatic CAF heterogeneity. Importantly, such persistence may constitute an inherent mechanism to suppress pancreatic cancer. The enhancement of this mechanism could be explored further for therapeutic benefits.

#1596 Disrupting local immunosuppression by combined myCAF/myeloid targeting in pancreatic cancer.

M. C. Hasselluhn[1], D. Thomas[2], L. Vlahos[1], A. Curiel-Garcia[1], A. R. Decker-Farrell[1], T. C. Dalton[1], S. A. Sastra[1], C. F. Palermo[1], A. Califano[1], K. P. Olive[1]; [1]Columbia University Irving Medical Center, New York, NY, [2]QuantX Biosciences, Princeton, NJ

Immunotherapy has revolutionized clinical care for many patients, but some cancers, such as pancreatic ductal adenocarcinoma (PDAC) remain stubbornly resistant. Local immunosuppression (LIS) is one of the striking hallmarks of PDAC due to the combined effects of multiple different immunosuppressive cell types in the tumor microenvironment (TME). There is great need for an increased understanding of the cellular crosstalk within tumors to understand how stromal cells coordinate in their suppression of immune responses. Oncogenic KRAS activation in tumor cells promotes the invasion and proliferation of tumor-supporting stromal cells, while excluding cancer-targeted cytotoxic T cells. Prior attempts to reverse LIS in PDAC by targeting individual stromal cell populations have been unsuccessful, alluding to the contributions of multiple distinct cell types. Here we examine the interactions of cancer-associated fibroblasts (CAFs) and myeloid-derived suppressor cells (MDSCs) and how they coordinate to suppress immune responses in the PDAC TME. We interrogate PDAC stromal cell biology by using targeted therapies to perturb various cell populations both *in vivo* using genetically engineered mouse models, and *ex vivo* using PDAC tumor explants. Explants are short-term slice cultures that enable experimental study of intact tumor sections with a full complement of cell types. Importantly, PDAC explants maintain their histopathological architecture and cellular diversity over time. This medium-throughput platform allows for testing of multiple drugs and mechanistic hypotheses in the native PDAC TME. We show in preliminary data that Smoothened inhibition (SMOi) decreases the proliferation and activity of myCAFs, but provokes the expansion of CD11b-positive myeloid cells *in vivo*. Thus, we hypothesize that LIS in PDAC is maintained by a balance between myCAFs and myeloid cells, preventing effective T cell invasion. Single cell RNA-seq data comparing ctrl vs. SMOi-treated murine PDAC elucidates stromal subpopulations involved in the LIS phenotype and guides the identification of myeloid subtypes emerging after SMOi. Strikingly, we demonstrated that simultaneous SMOi and targeting myeloid cells via anti-Gr1 or CCR1 inhibition significantly elevates cytotoxic T cell numbers within the TME. We are currently investigating whether the activity of these T cells may be further potentiated through combination with immunomodulatory agents. By testing various treatment combination in the same TME, we will identify the best synergistic effects for future immunotherapy approaches in human PDAC. In summary, we are elucidating the complex mechanism behind LIS in PDAC by employing our novel explant culture system alongside *in vivo* studies. We aim to develop a translatable regimen to neutralize LIS, reactivating the cytotoxic T cells in the tumor periphery to invade, proliferate, and attack cancer cells.

#1597 CD144$^{\pm}$cancer-associated fibroblasts drive the malignancy of pancreatic cancer via stimulating inflammatory paracrine.

X. Sun, J. Yu, T. Zhao, J. Hao;
Tianjin Medical University Cancer Institute and Hospital, Tianjin, China

Purpose: Cancer-associated fibroblasts (CAFs) are highly heterogeneous in pancreatic ductal adenocarcinoma (PDAC). We previously reported that CAFs can acquire an endothelial phenotype under stress. Thus, we hypothesized that there are CAFs highly expressing endothelial markers and substantiated a novel subtype of CAFs promoting tumor progression.

Experimental design: We performed single-cell RNA sequencing to identify the existence of CD144$^{\pm}$CAFs. The prospective and retrospective analysis were combined to figure out the correlation between CD144$^{\pm}$CAFs proportion and clinical outcome. The proliferation and invasion assay of cell lines, organoids and pancreatic cancer xenograft model were used to detect the effect of CD144$^{\pm}$CAFs on tumor progression. Cytokine array assay, RNA-sequencing, IP-mass spectrum, Ch-IP and luciferase analysis were conducted to elucidate the underlying mechanism. siRNA delivery nanosystem was designed and administrated to precisely target CD144$^{\pm}$CAFs *in vivo*.

Results: CD144$^{\pm}$CAFs were present in tumor microenvironment of PDAC and breast cancer and patients with a higher CD144$^{\pm}$CAFs proportion have worse prognosis in PDAC. CD144$^{\pm}$CAFs can promote the metastasis of PDAC through enhancing epithelial-mesenchymal transition. CD144-β-catenin-STAT3 signaling axis was activated and downstream inflammatory secreted cytokines were transcriptionally upregulated to maintain the functions and phenotype of CD144$^{\pm}$CAFs. A novel CAF-targeting siRNA delivery nanosystem, loading FAPα and siCDH5, was designed and administrated to precisely target CD144$^{\pm}$CAFs, which substantially inhibited the protumoral roles *in vivo*.

Conclusion: CD144$^{\pm}$CAFs can promote the growth and metastasis of PDAC by activating CD144-β-catenin-STAT3 signaling axis and stimulating inflammatory secretion. CAF-targeting siRNA delivery nanosystem can inhibit tumor progression by precisely targeting CD144+CAFs.

#1598 Individualized longitudinal assessment reveals therapy-induced tumor and microenvironment dynamics in preclinical pancreatic cancer models.

Background & Aim: Progression and therapeutic resistance in pancreatic cancer depends on the ability of cancer cells to adopt specific cell states. These phenotypes largely depend on environmental tissue niches. Here, we investigated therapy-induced tumor dynamics in vivo at single-cell spatial and temporal resolution in different subtypes of PDAC using several genetically engineered mouse models, which reflect distinct human PDAC ecosystems.
Methods & Results: We established orthotopic tumor models of pancreatic cancer with distinct tumor microenvironment (TME) formation (reactive vs deserted stroma), which were monitored for tumor growth to define tumor response patterns under MAPK inhibition. Serial ultrasound-guided biopsy sampling was performed to collect tissues from the same tumors at pre-treatment, responsive and recurrence periods.Transcriptomic analysis of biopsies using the Mfuzz algorithm delineated highly dynamic gene and pathway activities during treatment. Reactive, but not deserted, TME showed an upregulation of immune-related pathways (antigen presentation, T cell receptor, NK cytotoxicity) immediately after MAPK inhibition in regressed tumors that dropped dramatically during recurrence of tumors, in which upregulation of TGF-b signaling was observed. In the deserted stroma model, on the other hand, an enrichment in drug metabolic pathways during recurrence was observed.CAF cluster deconvolution analysis revealed an increase in a LRRC15+ CAF cluster, which was TGF-b-driven and immunosuppressive, during recurrence period only in the reactive model. The dynamic changes of immune cells and CAFs were validated at protein level by multiplex immunofluorescent imaging. Cmputational spatial analysis revealed a tumor-encapsulating and CD8+ cytotoxic T cell-repelling pattern exhibited by LRRC15+FAP+ CAFs, implying a potential role of this CAF subset in T cell suppression during recurrence in reactive subtype. Using spectral cell sorting with CellView image technology, specific CAF subsets, tumor cells as well as immune cell subsets based on 30+ markers and cell morphology were isolated, characterized and assessed by *ex vivo* functional assays to confirm the immunosuppressive and tumor protective mechanism mediated by CAFs.
Conclusion: Longitudinal in vivo assessment of distinct PDAC subtypes provides deep mechanistic insights to accurately unlock specific response patterns of tumors with heterogeneous TME dynamics upon therapeutic perturbation, leveraging identification of key nodes for intervention.

#1599 Metabolism as a key regulator of macrophage phenotype in pancreatic cancer.
