Background: Cancer immunotherapy such as immune-checkpoint inhibitors or CAR-T cell therapy has emerged as an effective therapeutic modality for some cancers such as hematological malignancies. However, they still show little efficacy for many solid tumors, because of their immune suppressive microenvironment. BC-PIV is a replication-deficient viral vector derived from human parainfluenza virus type 2, that can convey two ectopic genes simuoltaneously and uniquely display ectopic proteins with intact steric structure on the surface of viral particles. Furthermore, BC-PIV itself can induce maturation of dendritic cells with efficient induction of CD80/86. These unique characteristics of BC-PIV make it an attractive tool for improving anti-tumor responses under immunesuppressive milieu of solid tumors.
Aim and Methods: To develop novel immunotherapy using BC-PIV, we have introduced various immunomodulatory molecules into BC-PIV and tested their anti-tumor efficacy *in vivo*. To activate CD4/8 positive T cells, we introduced genes for OX-40L, 4-1BBL, GITRL, CD30L, OX40L/4-1BBL, OX40L/GITRL, or 4-1BBL/GITRL (collectively, TNFRSF ligands) to BC-PIV. All gene products were effectively presented on BC-PIV envelope. For expansion of T, B, and NK cells, or for promoting migration of immune cells, genes for IL-7, CCL19, IL-7/CCL19, IL-7/CCL21, or IL-12 (P40/P35) were introduced. CT-26 murine colon cancer cells ($5X10^5$) were implanted into syngeneic Balb/c mice at one or both side(s) of their ventral wall. Approximately 10^7 viral particles derived from BC-PIV carrying immunomodulatory molecules were directly injected into tumors that had grown to 5-7mm in diameter, and the anti-tumor efficacy was assessed by monitoring the tumor size.
Results: In the mice treated with BC-PIV carrying TNFRSF ligands, tumor regression was observed at the virus administered site, but also at the non-treated, distant site, possibly due to the Abscopal effect. Moreover, these mice maintained efficient anti-tumor responses and rejected tumors when they were re-challenged with CT-26 cells at 8 months after the initial BC-PIV treatment, showing that BC-PIV/ TNFRSF ligands induced sustained anti-tumor immunity. In the BC-PIV/IL-7/CCL19-treated mice, the tumors began to shrink about six days after the single injection of the virus. This effect was even more enhanced by concurrent administration of anti-PD-1 antibody.
Conclusions: BC-PIV carrying TNFRSF ligands, cytokines or chemokines induced efficient, sustained anti-tumor immunity and eradicated tumors in *in vivo* solid tumor model. Unique characteristics of BC-PIV, being able to deliver two genes simultaneously and to display ectopic proteins with intact steric structure on the viral surface, make this vector an attractive, novel platform for next generation cancer immunotherapy.

#3254 Development of novel luminescent assays for sensitive and specific quantitation of double-stranded RNA in mRNA vaccines.

R. Moravec, J. Wang, J. Hartnett, M. Cong, **J. Grailer**;
Promega, Madison, WI

mRNA-based therapeutics have shown clinical efficacy, evidenced by the success of the mRNA vaccines for SARS-CoV-2. Personalized mRNA vaccines containing patient-derived tumor mutations are now entering the clinic and have shown promise. Delivery of mRNA-encoded therapeutic proteins (e.g., antibodies) is also under development. mRNA drug substance is typically generated by in vitro transcription (IVT). One byproduct and contaminant of IVT is the formation of double-stranded RNA (dsRNA). dsRNA is highly immunogenic, can induce inflammation and cell death, and inhibit protein translation, including the protein encoded by the therapeutic mRNA. As such, dsRNA must be measured for all IVT products to ensure safety and efficacy. However, existing dot bot and ELISA technology to detect dsRNA is neither sensitive nor quantitative. Herein, we describe the development of novel assays for sensitive and specific quantitation of dsRNA in IVT products and following encapsulation of IVT products in lipid nanoparticles (LNPs). First, NanoBiT® split luciferase technology was applied to detect dsRNA in IVT products. dsRNA binding domains were genetically attached to either SmBiT or LgBiT. In the presence of dsRNA, the SmBiT and LgBiT constructs bind via the dsRNA binding domains, resulting in dimerization and the complementation of functional NanoBiT® luciferase. NanoBiT® then generates light which is proportional to the amount of dsRNA in the sample. The assay detects dsRNA greater than or equal to 30 base pairs and is independent of the size and sequence of the dsRNA contaminant. The assay does not cross-react with single-stranded RNA or DNA and is highly sensitive, with a limit of detection less than 100 pg/ml. As a complementary tool to the biochemical assay, we developed a cell-based bioassay to detect dsRNA encapsulated in LNPs. dsRNA/LNPs are taken up by endocytosis where Toll-like receptor 3 (TLR3) detects dsRNA. Activation of TLR3 initiates a signaling pathway that is detected by a TLR3 pathway-specific promoter driving luciferase expression. This pathway likely represents the most physiologically-relevant readout of dsRNA bioactivity. Both assays are developed in “add-mix-read” format with no wash steps or media transfer, and exhibit robust, sensitive, and repeatable performance for specific detection of dsRNA in mixed solutions.

#3255 Targeting CD4+FOXP3+ Tregs to enhance anti-tumor immunity.

T. Akimova[1], L. Wang[2], Z. Bartosh[2], E. Eruslanov[3], S. Albelda[3], S. Singhal[3], V. Aishwarya[4], **W. W. Hancock**[1];
[1]University of Pennsylvania and Children's Hospital of Philadelphia, Philadelphia, PA, [2]Children's Hospital of Philadelphia, Philadelphia, PA, [3]University of Pennsylvania, Philadelphia, PA, [4]AUM LifeTech, Philadelphia, PA

We strive to improve the outcomes of cancer immunotherapy by using a new generation of chemically modified self-delivering antisense oligonucleotides (ASO), termed FANA ASO, to target the key T-regulatory (Treg) cell transcription factor, FOXP3. We tested five murine FANA in 2 murine tumor models (TC1, MC38) and studied 19 human FANA FOXP3 in vitro with human healthy donor PBMC, followed by use of clinical samples from lung cancer patients and patients with mesothelioma, as well as testing in humanized mice (hu-PBMC-NSG). In murine studies, we treated mice on day 7 after tumor inoculation with Scramble control or murine FANA FOXP3, 50 mg/kg for 14 days, i.p. In the TC1 lung tumor model, we found an average 38% decrease of tumor volumes, p = 0.0007, and 22% of tumors were completely resorbed. In the MC38 colon carcinoma model, we found a 49% decrease of tumor volumes, p = 0.0182, and 13.6% of tumors were completely resorbed. In both tumor models, we observed an ~50% decrease of Foxp3 mRNA by qPCR, and decreased numbers of intratumoral Tregs by flow cytometry. This was accompanied by significant decreases ($p<0.05$) of the mRNA and protein intratumoral levels of multiple exhaustion markers: LAG-3, CTLA-4, PD-1, Tim-3, Tigit, CD244, CD160 and VISTA, and increased expression of perforin and granzyme-b by intratumoral T cells. In addition, there were no changes in FOXP3 mRNA expression or in the numbers of Tregs in draining lymph nodes and in spleens of tumor bearing mice, suggesting that intratumoral Treg have enhanced sensitivity to FANA FOXP3 in vivo. We identified the best 5 of 19 human FANA FOXP3 and showed these had no toxic effects on cell viability or division, and downregulated FOXP3 expression over 50% in PBMC from healthy donors ($p<0.05$). Human Treg, pre-incubated with FANA FOXP3 for 3 hours, retained only 60.3% of their suppressive function in vitro. FANA FOXP3 treatment of lung cancer tumor samples and mesothelioma pleural effusion samples resulted in a 56.4% decrease in FOXP3 mRNA expression and a 61.5% decrease in Treg numbers (all $p<0.05$). Moreover, tumor FOXP3+ Treg had 36.7% less FOXP3 protein per cell, and downregulated CD39 expression compared to Scramble control. Targeting of cancer samples with human FANA FOXP3 in vitro was associated with increased division of CD4+ and CD8+ cells, and with downregulation of multiple exhaustion molecules, including CTLA-4, Tim-3, PD-1, LAG-3 and TIGIT. Humanized mice, treated with two human FANA FOXP3 compounds (50 mg/kg, 7days), demonstrated an absence of apparent toxic effects and human FOXP3 mRNA was downregulated by 47.4% in the blood, by 74.2% in lymph nodes and by 51.8% in the spleens (all $p<0.05$). Hence, targeting of intratumoral Tregs using FANA FOXP3 results in enhanced immune responses to solid tumors without inducing autoimmunity, and studies are underway in combination with checkpoint inhibitors and/or CAR-T cell therapy.

#3256 Novel SOX2-targeting bioPROTACs for the treatment of cancers.

J. Choi, S. Lim, X. Bai, H. Song, Y. Oh, Y. Yong, S. Lee;
EPD Biotherapeutics Inc., Seoul, Korea, Republic of

Targeted protein degradation (TPD) technology has been developed showing the therapeutic potential to modulate historically 'undruggable' disease-associated proteins. Currently, proteolysis targeting chimeras (PROTACs) using small-molecule binders represent the TPD field, and PROTAC-induced proximity between target proteins and E3 ligases enables specific degradation of target proteins. However, substantial amounts of clinically relevant cancer targets such as transcription factors lack active sites or allosteric binding pockets for small molecules which challenges the development of classical PROTACs for these targets. SOX2 is one of the pluripotency transcription factors and has been well-known for its crucial role in tumor development through promoting cancer cell survival, metastasis, stemness, and drug resistance. Numerous studies have also reported SOX2 amplification and overexpression in various tumor tissues. Thus, SOX2 has been validated as an attractive anticancer target, but directly targeting SOX2 has been proved to be difficult since SOX2 is an "undruggable" transcription factor. EPD Biotherapeutics develops EPDeg™, a next-generation engineered protein degrader platform in order to overcome the limitations of small molecule-based PROTAC. Here we report a series of SOX2-targeting bioPROTACs, being composed of a nanobody against SOX2 with high affinity and several ubiquitin E3 ligases with deletion of natural substrate binding domain to allow highly selective degradation of SOX2 protein. To evaluate the in vitro efficacy, SOX2 bioPROTACs were generated by mRNA IVT with CleanCap ® and modified uridine. First, robust degradation of SOX2 with a half-maximal degradation concentration (DC_{50}) of the picomolar range was observed with the treatment of SOX2 bioPROTACs in multiple SOX2-overexpressing cancer cell lines. The degradation was ubiquitin- and proteosome-dependent manner, and neither nanobody nor ubiquitin E3 ligase alone affected SOX2 protein level. Then, SOX2 bioPROTACs led to significant cancer cell growth inhibition caused by apoptotic cell death with a half-maximal growth inhibition concentration (GI_{50}) of the picomolar range. Notably, chemo-resistant cancer cell lines expressing SOX2 protein in high levels were sensitized to chemotherapy in combination with our SOX2 bioPROTACs. Furthermore, i.v. injection of one of our lead candidates formulated with LNP significantly inhibited tumor growth in the A549 xenograft model, proving the in vivo anti-tumor efficacy of SOX2 degraders for the first time in the world. Taken together, EPD's SOX2 bioPROTACs show potent in vitro and in vivo anti-tumor efficacy as first-in-class SOX2 degraders and provide new insights for the therapeutic potential of transcription factor-degrading strategies.

#3257 Unleashing immune power: How mRNA-encoded modulators suppress tumor growth.

D. Wang, z. zhang, p. wang, b. duan, x. qiang, q. gu;
WuXi App Tec, Shanghai, China

Subsequent to the emergence of the COVID-19 pandemic, an increased number of nucleic acid-based therapeutics have secured clinical endorsement. Unlike conventional protein-targeted therapies, nucleic acid therapeutics provide the potential for long-lasting effects and can be further categorized into oligonucleotides, single-guide RNA (sgRNA), and messenger RNA (mRNA). In this study, we aim to explore the anti-tumor properties of mRNA-encoded CD3-EpCAM Bispecific Antibody (BsAb) and mRNA-encoded IL-12 protein.

We conducted qPCR, flow cytometry, and ELISA analysis to assess the dynamic concentration of mRNA-encoded CD3-EpCAM BsAb and mRNA-encoded IL-12 protein within tumor cells post-transfection. We then accessed their effects on anti-tumor and immune activation in vitro via flow cytometry and ELISA. Furthermore, using in vivo imaging system (IVIS), we were able to determine the biodistribution of mRNA-encoded BsAb in vivo. Efficacy was evaluated in subcutaneous tumor xenograft models with mRNA content in tumors examined via qPCR. Moreover, we analyzed the activation of tumor-infiltrating immune cells post mRNA-encoded IL-12 treatment. Finally, to ascertain the preliminary safety of mRNA-encoded BsAb and mRNA-encoded IL-12 protein, we conducted serum biochemistry analysis and histopathological examination of various organs.

In this comprehensive preclinical evaluation, we found that both mRNA-encoded BsAb and mRNA-encoded IL-12 promoted the activation and cytotoxicity of human T cells, exhibiting significant inhibitory effects on tumor growth in vivo while maintaining a favorable safety profile. Our findings provide compelling evidence that mRNA therapeutics hold significant research value and exhibit promising potential for clinical applications.

#3258 A potential oncogenic role and immunoregulatory mechanisms of MZB1 in melanoma.

G. Chhabra, C. A. Shirley, J. M. Krien, M. A. Ndiaye, N. Ahmad;
University of Wisconsin-Madison, Madison, WI

While immune checkpoint blockade (ICB) therapies have drastically improved melanoma treatment, a majority of patients fail to achieve a durable response. Thus, there is a critical need to advance our understanding of melanoma immune evasion mechanisms and identify novel targets capable of enhancing ICB responses. MZB1 (Marginal Zone B and B1 Cell Specific Protein), an immune regulator gene, is differentially expressed in metastatic melanoma compared to primary melanoma or normal skin. In a limited number of cancers, MZB1 has been shown to function as either an oncogene or a tumor suppressor. However, its role and significance in melanoma is not known. In this study, we determined the functional significance and immunoregulatory mechanisms of MZB1 in human melanoma cell lines using MZB1 overexpression (OE) (in SK-MEL-2, and SK-MEL-28) and CRISPR knockout (KO) (in A375 and Hs294T) lines. MZB1 OE significantly increased melanoma cell proliferation and expression of the proliferation markers Ki67 and PCNA, while MZB1 KO yielded the opposite effect. To identify immunoregulatory mechanisms associated with MZB1, we performed differential gene expression analysis of 770 immune-related genes using NanoString nCounter technology. nSolver analysis identified 153 differentially expressed genes (DEGs) as a result of MZB1 knockout in Hs294T cells (adjusted $p < 0.05$, 1.5-fold change cutoff). MZB1 KO strongly reduced the expression of the HLA class-II family genes and altered the expression of various cytokines, suggesting an immunoregulatory role of MZB1. Further, MZB1 KO significantly downregulated genes related to cancer progression and metastasis promotion. Additionally, MZB1 KO reduced expression of common “cancer stem cell” genes, such as RXRG, ALDH1A1, AQP1, NFATC2, LPAR1, indicating MZB1 expression in melanoma may promote a dedifferentiated or neural crest-like state. In addition, an Ingenuity Pathway Analysis (IPA) of the DEGs revealed many cancer-related functions altered upon MZB1 KO (p adjusted < 0.05) and displayed a negative enrichment for cancer-promoting pathways including tumor growth, metastasis, and proliferation. IPA regulatory analysis predicted MZB1 KO to decrease the activation of oncogenic signaling components including PI3K, MEK, and ERK1/2. Further, IPA predicted that MZB1 inhibition could positively sensitize melanoma cells towards higher immune responses by activating mechanisms associated with T cell proliferation and activation, leukocyte migration, and macrophage activation. Overall, our study suggests MZB1 promotes oncogenic signaling in melanoma to drive proliferation and dedifferentiation, as well as regulates a wide range of immune-related genes that may be responsible for immune evasion in melanoma cells. Thus, MZB1 merits further investigation to determine if the immune consequences yielded by targeting MZB1 can complement ICB approaches in the management of melanoma.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Mechanisms of Drug Resistance 2
Poster Session

#3261 Improving targeted therapy in female patients with lung squamous cell carcinoma.
M. Momcilovic, D. Shackelford;
UCLA - University of California Los Angeles, Los Angeles, CA

Non-small cell lung cancer (NSCLC) will claim the lives of ~60,000 female patients in the US in 2023. Lung squamous cell carcinoma (LUSC) is a subtype of Non-Small Cell Lung Cancer (NSCLC) that comprises ~30% of NSCLC and is characterized by high metabolic activity. Specifically, LUSC typically exhibits elevated rates of both glucose and glutamine metabolism driven by the PI3K-AKT-mTOR and KEAP1/NRF2 pathways. Further, a paucity of identifiable genetic drivers in LUSC has resulted in a lack of effective targeted therapies for patients with this devastating disease. Despite recent advances in therapy, the 5-year survival rate for patients with advanced NSCLC is 6%, underscoring the need for better treatment options. Importantly, no significant sex bias is seen in the newly diagnosed cases of lung cancer (~50%M/~50%F) (American Cancer Society, 2023), yet there are no sex-specific therapeutic approaches in clinical use. We demonstrated that the catalytic mTOR kinase inhibitor TAK228 can be utilized to effectively treat LUSC tumors via inhibition of glycolysis, an approach that is currently being evaluated on two phase I/II clinical trials (NCT02417701, NCT04250545), launched as a direct result of our pre-clinical work. However, our pre-clinical data suggests that despite the potential benefit of TAK228 inhibition in LUSC, a subset of tumors are resistant to TAK228 despite on-target activity of mTOR inhibitor, leading to the rationale of the current hypothesis, namely the possibility that sex-specific differential effects of TAK228 may exist. To evaluate this hypothesis, we have generated preliminary data demonstrating that sex is a determinant of TAK228 response in LUSCs, whereby male mice are significantly more sensitive to mTOR inhibition than females. Follow-on experiments have demonstrated that the anti-estrogen therapy (Letrozole) sensitized previously resistant female mice bearing LUSCs to TAK228, suggesting an estrogen-related link to TAK228 resistance in females. Additionally, RNASeq and biochemical analyses identified pathways that are upregulated in TAK228 resistant female mice with LUSC tumors. These results suggest that the estrogen may play a key role in the observed pattern of female resistance to mTOR inhibition. As such, the goal of the current proposal is to evaluate the catalytic mTOR kinase inhibitor TAK228, in combination with anti-estrogen therapy as a therapeutic strategy to treat LUSC in females.

#3262 Elucidating the mechanism of resistance to tyrosine kinase inhibitors in *ROS1*-and *ALK*-fusion non-small cell lung cancer: The role of CD74.

V. Ho, M. Izumi, M. Lee, D. Shibahara, I. S. Kobayashi, S. S. Kobayashi;
Beth Israel Deaconess Medical Center, Boston, MA

The therapeutic landscape in treating advanced oncogene-mutated non-small cell lung cancer (NSCLC) was revolutionized with the advent of tyrosine kinase inhibitors (TKIs). Despite the efficacious breakthrough and improved patient outcomes, disease progresses once more due to the seemingly inevitable development of drug resistance in tumor cells. This poses a considerable predicament in the clinical management of oncogene-mutated NSCLC and signifies the importance of elucidating the mechanism of resistance in tumor cells that harbor these genomic alterations which give rise to oncogenic drivers. Recent evidence suggests that drug-tolerant persister (DTP) cells, which are tolerant to initial exposure to TKIs give rise to acquired drug-resistant cells. Currently, the mechanism by which tumor cells undergo a drug-tolerant state is not well understood in NSCLCs driven by *ALK* or *ROS1* fusion. Previously, we identified *CD74* as a gene that may play a role in a drug-tolerant state in *EGFR*-mutated lung cancer via single-cell RNA-sequencing (scRNA-seq). Here, we sought to determine whether the CD74 signaling also leads to resistance to TKIs in NSCLCs with *ALK* or *ROS1* fusion. We showed that CD74 expression increased at both the mRNA and protein levels after treatment with respective TKIs in *ALK* and *ROS1* fusion cells lines. Notably, the *ALK* and *ROS1* fusion cell lines also exhibited an increase in mRNA expression levels of upstream and downstream genes of CD74. Additionally, we generated CD74 knock-out and overexpression models in two cells lines, HCC78 (*SLC34A2-ROS1* fusion) and H2228 (*EML4–ALK* fusion), to further examine the role of CD74 expression in DTP cells. We demonstrated that resistance to TKIs were dependent on CD74 expression. Furthermore, it was determined that anti-CD74 antibody-drug conjugates, in combination with TKIs, synergistically induced apoptosis in these cell lines. In conclusion, our data suggest that CD74 can be a therapeutic target in NSCLC with *ALK* or *ROS1* fusion.

#3263 VEGFA mediates traditional EGFR-TKI resistance in non-small cell lung cancer with EGFR exon 20 insertions.

Y. Yang[1], C. Liu[1], G. Yang[2], H. Xu[1], S. Lei[1], Y. Wang[1];

[1]Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China, [2]Department of Respiratory Medicine, Shandong Cancer Hospital and Institute, Shandong First Medical University and Shandong Academy of Medical Sciences, Jinan, China

Background: Epidermal growth factor receptor (EGFR) exon 20 insertions (Ex20ins) accounted for 4%-12% of EGFR mutations and showed primary resistance to EGFR tyrosine kinase inhibitors (EGFR-TKIs) which is an urgent issue to be solved. In our previous studies, we found that antiangiogenetic therapy had certain advantages for patients with Ex20ins in the real-world practice. Previous research showed the tumor microenvironment has been associated with resistance to targeted therapy in sensitive mutations. However, the mechanism of resistance of EGFR-TKIs and the advantage of antiangiogenetic therapy in patients with EGFR Ex20ins were still unclear.

Methods: In this study, patients with EGFR exon 19 deletion (19del), exon 21 p.L858R (21L858R), and Ex20ins were collected to identify the efficacy of EGFR-TKIs. Stable cell lines expressing were established and used to compare signaling pathway activation. Matrigel angiogenesis assay was conducted in different cell lines. Next, we evaluated the efficacy of various treatments combined with antiangiogenetic agents or not in mouse models.

Results: We collected 23 patients with EGFR sensitive mutations and Ex20ins, respectively, and found Ex20ins presented primary resistance to TKIs and poor survival outcomes. Based on the RNA sequence of stable cell lines, it was found that Ex20ins had a higher level of VEGFA expression and enriched in MAPK pathway compared to EGFR 19del and 21L858R. Immunohistochemical studies also revealed that a higher level of VEGFA expression was observed in a cohort of NSCLC patients with Ex20ins mutation compared with 19del or L858R. Matrigel angiogenesis assay has shown consistent result that Ex20ins promoted angiogenesis *in vivo*. Further experiments in mouse models identified that in the group of Osimertinib, mobocertinib alone, chemotherapy alone, mobocertinib or chemotherapy combination with bevacizumab, Osimertinib achieved the worst efficacy and additional utility of antiangiogenetic agents had a more favorable efficacy.

Conclusion: Our study highlights the potential of VEGFA as a mechanism of resistance to EGFR-TKIs and induces immunosuppression microenvironment in NSCLC with Ex20ins. Furthermore, the findings suggested that antiangiogenetic therapy could be a promising therapeutic approach.

Keywords: VEGFA, targeted therapy, resistance, EGFR exon 20 insertions, non-small cell lung cancer

#3264 Characterization of EGFR ectodomain mutation in acquired resistance to cetuximab in colorectal cancer.

N. Joshi[1], R. G. Deal[1], G. Bogatcheva[1], J. N. Higginbotham[1], M. Ramirez[1], B. P. Brown[2], Q. Liu[1], J. Meiler[2], B. Singh[1];
[1]Vanderbilt University Medical Center, Nashville, TN, [2]Vanderbilt University, Nashville, TN

Colorectal cancer (CRC) remains the second leading cause of cancer-related deaths in the United States (US). Individuals with surgically unresectable stage four CRC have a five-year overall survival rate of 13%. Targeting of the receptor tyrosine kinase (RTK), EGF receptor (EGFR) with therapeutic monoclonal antibodies (cetuximab, panitumumab) is approved for use in wild-type (WT) KRAS/NRAS/BRAF (RAS/RAF) advanced CRC. However, these antibodies as a single agent have response rates of 12-17% and expected progression-free survivals of only 3-4 months. Accordingly, resistance may be present at the outset (de novo resistance) or develop during treatment (acquired resistance). Here, we report the identification of an EGFR ectodomain missense mutation acquired *in vitro* in response to treatment with anti-epidermal growth factor receptor (EGFR) antibody cetuximab. Using 2D and 3D drug sensitivity assays, our results demonstrate that this EGFR ectodomain mutation in addition to being resistant to cetuximab and panitumumab, also could not be targeted by the oligoclonal antibody cocktail MM-151. To determine whether this EGFR ectodomain mutation is necessary and sufficient to impart cetuximab resistance, we engineered CRC lines to inducibly overexpress mutant EGFR and showed that this was sufficient to induce cetuximab resistance. Further structural, and functional characterization is underway for this ectodomain mutation that confers resistance to cetuximab and will be shared during the meeting. These findings necessitate the need for additional treatment strategies for a subset of subjects with mCRC who do not respond to treatment with cetuximab/panitumumab and MM-151.

#3265 Secretome core fucosylation drives clonal drug resistance expansion and hypoxic control of metastasis.

M. D. Aldonza, K. Son, J.-Y. Cho;
Seoul National University, Seoul, Korea, Republic of

Cancer secretome is a reservoir for aberrant glycosylation. How therapies alter this post- translational cancer hallmark and the consequences thereof remain elusive. Here, we show that an elevated secretome fucosylation is a pan-cancer signature of both response and resistance to multiple targeted therapies. Large-scale pharmacogenomics revealed that fucosylation genes display widespread association with resistance to these therapies. In cancer cell cultures, xenograft mouse models, and patients, targeted kinase inhibitors distinctively induced core fucosylation of secreted proteins less than 60 kDa. Label-free proteomics of N-glycoproteomes identified fucosylation of the antioxidant PON1 as a critical component of the therapy-induced secretome (TIS). N-glycosylation of TIS and target core fucosylation of PON1 are mediated by the fucose salvage-FUT8-SLC35C1 axis with PON3 directly modulating GDP-Fuc transfer on PON1 scaffolds. Core fucosylation in the Golgi impacts PON1 stability and folding prior to secretion, promoting a more degradation-resistant PON1. Global secretome and PON1-specific de-N-glycosylation both limited the expansion of resistant clones in a tumor regression model. We defined the resistance-associated transcription factors (TFs) and genes modulated by the N-glycosylated TIS via a focused and transcriptome-wide analyses. In a spontaneous lung metastasis mouse model, global secretome and PON1-specific core fucosylation functionally drive hypoxia and hypoxic selection of drug-resistant clones. Our findings demonstrate that core fucosylation is a common modification indirectly induced by targeted therapies that paradoxically promotes resistance and metastasis.

#3266 Plk1 promotes Pdcd4 degradation to enhance enzalutamide resistance in prostate cancer.

Q. Wang, Q. Zhang, Y. Zhang, X. Liu, H.-S. Yang;
University of Kentucky, Lexington, KY

The androgen receptor (AR) signaling pathway plays critical role in the development of prostate cancer (PCa), including castration-resistant prostate cancer (CRPC). As a result, androgen signaling inhibitors (ASIs) like abiraterone and enzalutamide (ENZ) have emerged as the first-line treatment for CRPC. Nevertheless, the limited success of ASIs underscores the urgency of developing new approaches for managing CRPC patients who have become unresponsive to ASIs. Programmed cell death 4 (Pdcd4) is a tumor suppressor, which is frequently down-regulated during PCa progression. It has been shown that reduced Pdcd4 expression promotes both AR-dependent and AR-independent growth in PCa. In this study, we found that down-regulation of Pdcd4 led to acquisition of ENZ resistance in PCa. We also observed that down-regulation of Pdcd4 resulted in activation of mTORC2 activity. Additionally, knockdown of Rictor, a component of mTORC2 complex, enhanced sensitivity to ENZ treatment in PCa. These findings suggested that activation of mTORC2 due to Pdcd4 loss contributes to ASI resistance in PCa. To understand how Pdcd4 is down-regulated in the PCa, we identified that polo-like kinase (Plk1) phosphorylated Pdcd4 at Ser239. Phosphorylation of Pdcd4 by Plk1 led to ubiquitin-mediated proteasomal degradation of Pdcd4. Over-expression of the phosphomimic Pdcd4(S239D) in 22Rv1 cells promoted tumor cell growth in cultured cells and mice. Taken together, our data suggest that targeting Plk1/Pdcd4/mTORC2 signaling axis holds promise as a strategy to overcome ENZ resistance in PCa.

#3267 Understanding the role of dNTP pool on double-strand break and resistant to therapy in quiescent hypoxic glioblastoma.

E. R. Usoro, D. Monroe, K. Carver, E. Steinbeck, A. Williams, S. Aycox, W. Daddacha;
Augusta University, Augusta, GA

Glioblastoma (GBM) is the deadliest type of primary brain tumor. After surgical resection of GBM, chemotherapy and radiotherapy (RT) are used as treatment modalities to induce double-strand breaks (DSBs), the most cytotoxic and lethal form of DNA damage. However, an inadequate oxygen supply and the high metabolic demand in rapidly growing solid tumors like GBM result in severe hypoxic regions, contributing to altered cellular metabolism and resistance to these cancer therapies. These subpopulations of resistant and refractory hypoxic cancer cells are clinically significant as they lead to poor prognosis and adverse clinical outcomes in patients. Ionizing radiation (IR) and chemotherapeutics such as temozolomide induce DNA damage, such as base deletions, single-strand breaks (SSBs), and DSBs. Rapidly replicating cells are more sensitive to these therapeutic agents partly due to replication-induced conversion of SSB and other manageable damages to highly lethal DSB. A balanced deoxyribonucleoside triphosphate (dNTP) is crucial for DNA replication, repair, and maintenance of genomic stability. Cellular dNTP is mainly regulated by ribonucleotide reductase (RNR) and the SAM- and HD-domain-containing protein (SAMHD1). RNR boosts the cellular dNTP pool through the *de novo* synthesis, while SAMHD1 depletes the pool by hydrolyzing dNTPs. Also, previous studies have shown that hypoxic cancer cells have low dNTP levels due to oxygen dependency of its rate-limiting RNR enzyme, which could result in reduced DNA replication and cell cycle arrest. Here, we show the direct relationships between dNTP levels, DNA replication, and DSB induction in hypoxic GBM cancer cells, which is currently unknown. To bridge this knowledge gap, we exposed GBM cells to severe hypoxia and utilized cellular dNTP analysis to demonstrate that their dNTP pool can be elevated. Our results show that elevating the cellular dNTP pool relieved hypoxia-induced cell cycle arrest as determined by flow cytometry and increased their DNA replication. A single-cell microscopic analysis also revealed that increasing the dNTP pool significantly enhanced the induction of DSBs following exposure to IR and bleomycin. Furthermore, we detected an increased efficacy of DSB-inducing agents in hypoxic GBM, as demonstrated by apoptosis pathway activation. Our result suggests that increasing the intracellular dNTP pool in hypoxic GBM will stimulate DNA replication, increase genotoxin-induced DSB, and improve DSB-inducing therapeutic efficacy. In conclusion, this study provides a preclinical justification for using cellular dNTP modulation as a novel therapeutic strategy and an adjunct to classical DSB-inducing agents in hypoxic GBM.

#3268 A novel signaling axis of APE1-redox-sensitive SOX9 activation underlying reflux-condition-associated chemoresistance in esophageal adenocarcinoma.

H. Lu[1], L. Chen[1], F. Ballout[1], D. Peng[1], Z. Chen[1], J. Que[2], S. Chen[1], O. G. McDonald[1], A. Zaika[1], W. El-Rifai[1];
[1]University of Miami, Miami, FL, [2]Columbia University, New York, NY

Chronic gastroesophageal reflux disease (GERD), characterized by the reflux of acidic bile salts (ABS) into the esophagus, stands as the primary risk factor for esophageal adenocarcinoma (EAC). EAC, known for its aggressive nature and limited response to therapy, exhibits a disheartening 5-year survival rate of less than 20%. Overcoming drug resistance remains a pressing challenge in achieving optimal therapeutic outcomes for EAC patients. Previous studies from our team have unveiled that exposure to ABS leads to the overexpression of Apurinic/apyrimidinic endonuclease (APE1), which orchestrates various oncogenic pathways in EAC cells. In this study, we delve into the influence of ABS in driving APE1-redox-mediated activation of the SOX9 pathway, thus contributing to the chemoresistance observed in EAC. To identify the enrichment of the SOX9 pathway and the heightened downstream target genes in EAC, we analyzed RNA sequencing data and public databases. Cell models, patient tissue arrays, pL2-IL1β transgenic mice, and de-identified xenografts derived from EAC patients (PDXs) were employed to investigate the signaling axis of APE1-redox-SOX9 in oxaliplatin resistance of EAC. Our analysis of public databases unveiled a significant enrichment of the SOX9 pathway in EAC patients. RNA sequencing data from EAC cells exposed to ABS, with or without APE1-knockdown, suggested APE1's involvement in the GERD-activated SOX9 signaling pathway. Immunohistochemistry staining of human patient tissue arrays, along with immunofluorescent staining of L2-IL1ß transgenic mice, confirmed the co-overexpression of APE1, SOX9, and ALDH1A1 in EAC. Furthermore, APE1 silencing led to the downregulation of SOX9 and exhibited synergistic effects with oxaliplatin in chemo-resistant EAC cells. Mechanistically, we uncovered that APE1's redox function is crucial for AKT-GSK3ß-mediated SOX9 stability. Treatment with the APE1-redox-specific inhibitor, APX2009, sensitized patient-derived xenograft (PDX) tumors to oxaliplatin by repressing SOX9-regulated chemoresistance genes. This study sheds light on a novel signaling axis involving APE1-redox-AKT-GSK3ß-SOX9 in Barrett’s carcinogenesis. The pharmacological inhibition of APE1-redox function presents itself as a promising therapeutic approach to target the previously intractable SOX9 signals, potentially overcoming chemoresistance in EAC.

#3269 APE1/NF-κB/PRDX2 activated by reflux conditions mediates chemoresistance in esophageal adenocarcinoma by suppressing ferroptosis.

L. Chen[1], H. Lu[1], F. Ballout[1], D. Peng[1], Z. Chen[1], J. Que[2], S. Chen[1], O. McDonald[1], A. Zaika[1], W. El-Rifai[1];
[1]University of Miami Miller School of Medicine, Miami, FL, [2]Columbia University, Miami, FL

Background: Esophageal adenocarcinoma (EAC) stands out as one of the most lethal malignancies, characterized by a discouragingly low 5-year survival rate of less than 20%. Accumulating lines of evidence indicate that ferroptosis, a novel type of cell death, can regulate drug resistance. Peroxiredoxin 2 (PRDX2), an antioxidant enzyme, plays an antioxidant protective role in the cells under stress by regulating redox homeostasis. We aimed to elucidate the role of PRDX2 in regulating reactive oxygen species (ROS), ferroptosis, and chemoresistance in EAC.
Methods: In this investigation, we analyzed RNA sequencing data and public databases to uncover the aberrant overexpression and potential chemoresistance function of PRDX2 in EAC. We employed transient acidic bile salts exposure (ABS) and repeated ABS exposure (rABS) to mimic gastroesophageal reflux disease, the main risk factor for EAC, in *in vitro* cell models. EAC cells and 3D organotypic culture (OTC) served as platforms to delve into the anti-ferroptosis function and regulatory mechanisms of PRDX2. The findings were validated using patient-derived xenografts (PDX) and human EAC tissue microarrays (TMA).
Results: Elevated PRDX2 level was observed in both EAC patients and cell lines exhibiting poor responsiveness to chemotherapy. Intrinsic overexpression of PRDX2 emerged as a crucial factor in the recovery from ABS-exposure-induced lipid peroxidation. Silencing PRDX2 heightened the sensitivity of EAC cells to Oxaliplatin by inhibiting ferroptosis in a GPX4-dependent manner. Mechanistically, we found ABS activate the APE1/redox/NF-kB signal axis, leading to the upregulation of PRDX2 transcription. The co-overexpression of APE1 and PRDX2 was identified through both immunofluorescent staining in cells/OTC and immunohistochemistry staining in TMA. Moreover, the APE1-redox-specific inhibitor, APX2009, significantly sensitized EAC cells to Oxaliplatin by repressing PRDX2 and inducing ferroptosis. Remarkably, the combination therapy of Oxaliplatin and APX2009 achieved a synergistic effect in EAC-PDX tumors.
Conclusion: The study unveils a novel signaling axis, APE1/NF-kB/PRDX2, linking disease-associated ROS unbalance and ferroptosis-related chemoresistance. Targeting PRDX2 signaling by APE1-redox-specific inhibition provides a potential novel strategy for combined chemotherapies in refractory EAC.

#3270 SH3GLB1 is involved with hydrogen peroxide/akt signaling in glioblastoma multiforme cells.

C.-H. Chien[1], K.-Y. Chang[2],

[1]School of Medicine, I-Shou University, Kaohsiung City, Taiwan, [2]National Institute of Cancer Research, National Health Research Institutes, Tainan City, Taiwan

Glioblastoma (GBM), a malignant brain tumor, has poor survival outcomes due to recurrence or drug resistance. In our previous studies, it was found that superoxide dismutase 2 (SOD2) was associated with temozolomide (TMZ) resistance. Moreover, SOD2 can convert $O_2^{\bullet-}$ to H_2O_2, and H_2O_2 redox signaling is vital for physiological reactions and promotes tumor progression. We used cell lines, patient primary cells and pharmacological inhibitors/activators to confirm the significance of H_2O_2 signaling. We used the cultured cells to verify roles of H_2O_2 signaling in the plasticity of cell fate and did animal experiments to identify the optimal treatment strategy. In the present study, SOD2 was found to be the upstream mediator, and combining SOD inhibitor and TMZ, the cells showed reduced SH3GLB1 and autophagy levels. We then found that SH3GLB1 was regulated by H_2O_2 through AKT signaling using experiments of regulating redox homeostasis. The change of intracellular H_2O_2 levels in mitochondria following the treatments is similar to that in cytosol, however, the cell fate of parental or resistant cells was quite diverse. Notably, CCCP, a mitochondrial membrane potential disrupter, increased endogenous H_2O_2 production, and TMZ-increased SH3GLB1 levels can be reversed by $HgCl_2$, reflecting the aquaporin function. In animal models, a combination of TMZ and 4-hydroxynonenal reduced growth of the SH3GLB1-knockdown resistant cells, along with suppressed autophagy levels. Our results characterizing the mechanism of H_2O_2-SH3GLB1 axis signaling in acquired TMZ resistance of GBM cells will provide new therapeutic strategies against the disease in the future.

#3271 The casein kinase 2/IKZF1 axis attenuates ceramide accumulation through up-regulation of acid ceramidase: Implications for use of CK2 inhibitors in high-risk pediatric B-cell acute lymphoid leukemia.

J. A. Hengst[1], D. Bastihalli Tukaramrao[1], T. Fox[2], A. Sharma[1], D. Desai[1], S. Dovat[1];
[1]Penn State College of Medicine, Hershey, PA, [2]University of Virgina School of Medicine, Charlottesville, VA

Casein Kinase II (CK2), a growth-promoting non-oncogene, is frequently over-expressed in pediatric high-risk B-cell acute lymphoblastic leukemia (B-ALL) leading to proliferation and survival. CK2 phosphorylates the tumor suppressor IKZF1 (IKAROS) resulting in a loss-of DNA-binding activity. Loss of IKZF1 function is associated with poor prognosis in high-risk B-ALL. As such, inhibition of CK2 using silmitasertib (CX-4945), to restore IKZF1 function, is being therapeutically investigated in high-risk B-ALL. CK2 also phosphorylates/activates the mammalian ceramide synthases to increase production of the pro-apoptotic sphingolipid, ceramide (Cer). Therefore, we hypothesized that inhibition of CK2 with CX-4945 would exert both pro-death (restoration of IKAROS function) and pro-survival (decreased Cer production) effects on B-ALL cells. Moreover, this suggests that targeting the sphingolipid metabolic pathway in tandem with CX-4945 could be a novel strategy for treatment of high-risk B-ALL. To this end, we examined the effects of CX-4945 on sphingolipid levels and the enzymes of the sphingolipid metabolic pathway. Unexpectedly, we determined that CX-4945 dose-dependently increased expression of ceramide synthase 1 (CERS1) and acid ceramidase (AC) proteins, in an IKZF1 dependent manner. Increased CERS1 expression/production of C18:0 Cer has been linked to enhanced mitophagy (i.e., lysosomal clearance of damaged mitochondria) in head and neck squamous cell carcinoma. Induction of mitophagy by CX-4945 was confirmed by western blot analysis of mitofusin-1 and Drp-1 levels. Up-regulation of AC, a lysosomal protein, metabolizes C18:0 Cer to sphingosine for recycling and prevents Cer-induced lysosomal membrane permeabilization. Thus, induction of mitophagy and metabolic breakdown of Cer could potentially reduce the apoptotic efficacy of CX-4945 in B-ALL cell lines. We, therefore, tested whether inhibition of AC would synergize with CX-4945 to enhance B-ALL cell death. Indeed, synergy was observed with the AC inhibitor, SACLAC, in multiple cell lines. Consistent with the observation of synergy between CX-4945 and SACLAC, the combination also enhanced cleavage of PARP indicating an enhancement of cell death. We are currently testing the efficacy of a combination of CX-4945 and AC inhibitors in cell-line derived xenograft models of human B-ALL. Together, these findings indicate that simultaneous targeting of CK2 and AC represents a rationally selected combinatorial therapeutic strategy that overcomes the ability of cancer cells to adapt to single agent targeted therapies by altering pro- and/or anti-apoptotic pathways.

#3272 PJA1 inhibits docetaxel-induced pyroptosis and results in chemoresistance in nasopharyngeal carcinoma.

N. Liu, Y.-Q. Li, S.-Y. Huang;
Sun Yat-sen University Cancer Center (SYSUCC), Guangzhou, China

Background: Nasopharyngeal carcinoma (NPC) is highly prevalent in South China. More than 70% of patients are diagnosed with locoregionally advanced NPC (LA-NPC) at initial presentation, and the addition of induction chemotherapy (IC) to concurrent chemoradiotherapy is recommended for these patients. However, chemoresistance is a main reason for treatment failure in NPC patients, and the exact regulatory mechanism underlying chemoresistance in NPC remains to be elucidated.

Methods: A gene expression dataset and STRING database were used to identify core module and gene that are related to the efficacy of docetaxel-cisplatin-5-fluorouracil (TPF) IC in NPC patients. *In vitro* and *in vivo* functional experiments were used to test the effects of PJA1 on docetaxel chemoresistance of NPC cells. The flow cytometric analysis, western blot, and lactate dehydrogenase (LDH) release assays were performed to determine the effects of PJA1 on GSDME-mediated cell pyroptosis. Co-immunoprecipitation, mass spectrometry, immunofluorescence staining, and ubiquitination assays were performed to explore the regulatory manners between PJA1 and PGAM5-DRP1 axis. Finally, multiplex immunofluorescence and immunohistochemical staining were used to evaluate the clinical significance of PJA1 -PGAM5-DRP1 axis in patients with NPC.

Results: PJA1 was identified as a key E3 ligase of the top-ranked module ubiquitin-proteasome system dysregulation that involved in NPC chemoresistance, which was highly expressed in NPC patients with nonresponse to the TPF IC. PJA1 facilitated the docetaxel resistance of NPC cells through inhibiting the GSDME-mediated pyroptosis. Mechanistically, PJA1 promoted the degradation of the mitochondrial protein PGAM5 by increasing its K48-linked ubiquitination at K88, further increasing the phosphorylation of DRP1 at S637 and reducing the mitochondrial reactive oxygen species (ROS) production, in turn resulting in a suppressive of GSDME-mediated pyroptosis. PGAM5 knockdown fully restored the docetaxel sensitization effect of PJA1 knockdown. Moreover, RTA402, a pharmacological inhibitor of PJA1, enhanced the docetaxel sensitivity of NPC cells. Clinically, high PJA1 expression indicated resistance to TPF IC an inferior survival in NPC patients.

Conclusions: Our study emphasizes the essential role of E3 ligase PJA1 in regulating chemoresistance in NPC and provides new therapeutic strategies for NPC patients based on targeting the ubiquitin-proteasome system.

#3273 Tirapazamine sensitizes homologous recombination-proficient cancers by enhancing DNA damage andferroptosis.

Y. Jiang, H. Estephan, Y. Wang, F. Aljarbou, N. V. Lopera, E. Moon, E. M. Hammond, A. J. Giaccia;
Oxford Institute for Radiation Oncology, Department of Oncology, University of Oxford, Oxford, United Kingdom

Despite its success in HR-deficient tumors, the application of PARP inhibitors (PARPis) in HR-proficient cancers is very limited. Since the majority of cancers are HR-proficient, there is a need for developing strategies to extend the use of PARPis to HR-proficient cancers. We investigated whether the hypoxic cytotoxin, tirapazamine (TPZ) sensitizes HR-proficient cancer cells to PARPis under normoxia and hypoxia (2% O_2), and found that TPZ enhanced PARPi cell killing to a greater extent under hypoxia compared to normoxia. Mechanistically, this enhanced killing was due to the induction of DNA double-strand breaks and free radicals that lead to ferroptotic cell death. To determine the role of hypoxia in the anti-tumor effect of the combination treatment, we examined the efficacy of TPZ and PARPi treatment in hypoxic spheroids and subcutaneous xenograft models derived from a panel of HR-proficient human non-small cell lung cancer (NSCLC) cells. We found that PARPis combined with TPZ significantly inhibited the growth of the hypoxic NSCLC spheroids. In addition, the combination treatment significantly inhibited the growth of A549 and CORL105 xenografts that possess significant hypoxic fractions, but did not significantly inhibit the growth of well-oxygenated Calu3 and H3122 xenografts. Taken together, this study demonstrates that TPZ can sensitize HR-proficient tumor cells to PARPi through the introduction of DNA strand breaks and free radicals, suggesting that TPZ treatment can broaden the usage of PARPi to HR-proficient cancers.

#3274 Trefoil factor 1 suppresses stemness and enhances chemosensitivity of pancreatic cancer.

J. Yamaguchi, T. Kokuryo, Y. Yokoyama, M. Sunagawa, T. Baba, T. Ebata;
Nagoya Univ. Graduate School of Medicine, Nagoya, Aichi, Japan

Background and Aims: Pancreatic cancer is one of the most lethal malignancies, partly due to resistance to conventional chemotherapy. The chemoresistance of malignant tumors is associated with epithelial-mesenchymal transition (EMT) and the stemness of cancer cells. The aim of this study is to investigate the availability and functional mechanisms of trefoil factor family 1 (TFF1), a tumor-suppressive protein in pancreatic carcinogenesis, to treat pancreatic cancer.
Methods: To investigate the role of endogenous TFF1 in human and mice, specimens of human pancreatic cancer and genetically engineered mouse model of pancreatic cancer (KPC/TFF1KO; Pdx1-Cre/ LSL-$KRAS^{G12D}$/ LSL-$p53^{R172H}$/ $TFF1^{-/-}$) were analyzed by immunohistochemistry (IHC). To explore the efficacy of extracellular administration of TFF1, recombinant and chemically synthesized TFF1 were administered to pancreatic cancer cell lines, a xenograft mouse model and a transgenic mouse model.
Results: The deficiency of TFF1 was associated with increased EMT markers of cancer cells (Snail and Zeb1) in mouse models of pancreatic cancer, KPC. Analysis of the survival of patients who underwent chemotherapy for recurrent pancreatic cancer revealed that the expression of TFF1 in cancer cells was associated with better survival. Also, in the mouse model of pancreatic cancer, KPC mice showed improved survival when treated with gemcitabine, the KPC/TFF1KO mice did not. Pancreatic cancer cell lines were administered with gemcitabine and/or chemically synthesized TFF1, revealing that addition of TFF1 downregulated gemcitabine-induced EMT markers (Snail, Slug, ZEB1, and αSMA), Wnt pathway activation (β-catenin, TCF7, and EPHB3). In addition, TFF1 inhibited the expression of cancer stemness markers (CD133 and NANOG3) and the ability to form tumor sphere. Importantly, TFF1 accelerated the apoptosis of cancer cells induced by gemcitabine *in vitro*. *In vivo*, combined treatment of gemcitabine and subcutaneous administration of TFF1 arrested tumor growth in xenograft mouse model. Also, KPC mice with combined treatment showed the better survival rather than gemcitabine-alone treatment, with lower expression of CD133, high expression of ZEB1, and lower nuclear translocation of β-catenin.
Conclusion: These results indicate that TFF1 can contribute to establishing a novel strategy to treat pancreatic cancer patients by enhancing chemosensitivity.

#3275 PHGDH-mediated serine-glycine-one-carbon metabolism drives ferroptosis- and chemotherapy-resistance in colorectal cancer.

G. Liang[1], J. Chen[1], X. Wen[1], Z. Zhang[1], Z. Chen[1], Y. Chen[1], Z. Xian[1], X. He[1], X. Wu[2], P. Lan[1], T. Hu[1];
[1]The Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China, [2]Sun Yat-sen Memorial Hospital of Sun Yat-sen University, Guangzhou, China

Background and Aim: Ferroptosis is an iron-dependent form of programmed cell death characterized by lipid peroxidation, with the potential as a novel cancer therapy. The application of ferroptosis-inducers has been limited to preclinical studies due to toxic side effects and drug-resistance. Our study aims to explore the metabolic mechanism in regulating ferroptosis-resistance, thereby identifying combinational therapeutic target for ferroptosis-inducers.
Methods: The ferroptosis-resistant CRC cell lines were induced by chronic exposure to ferroptosis inducer Erastin and verified by cell viability assay. Metabolomics and transcriptomics were performed to identify the metabolic characteristics in ferroptosis-resistant CRC cells. Quantitative RT-PCR and western blot was applied to confirm the differentially expressed serine-glycine-one-carbon metabolism (SGOC) enzymes. The MTT cell viability assay, colony formation assay, 3D spheroid formation assay and cell derived xenograft (CDX) model were carried out to investigate the therapeutic effect of targeting SGOC key enzyme-phosphoglycerate dehydrogenase (PHGDH) in combination of ferroptosis inducers. Gene set enrichment analysis (GSEA) was performed to identify molecular mechanism for the upregulation of SGOC enzymes based on RNA-seq data from TCGA-COAD cohort.
Results: Metabolomic and transcriptomic data revealed that SGOC metabolism was significantly increased in ferroptosis-resistant CRC cells. Moreover, the mRNA and protein level of SGOC key enzyme-PHGDH were remarkably upregulated in ferroptosis-resistant CRC cells. PHGDH inhibitor NCT-503 or knockdown of PHGDH exhibited a great synergistic effect with ferroptosis inducers for CRC cells in vitro or in vivo. Additionally, targeting PHGDH could dramatically restore the sensitivity of ferroptosis-inducers in ferroptosis-resistant cells. The RNA methyltransferase-like 3 (METTL3) was identified as the upstream regulator responsible for the upregulation of PHGDH in an m^6A-dependent manner. The ferroptosis stress induced deacetylation of METTL3, thereby promoting its nuclear translocation and enzyme activity.
Conclusions: In summary, we have uncovered that CRC cells resisted ferroptosis inducers via METTL3-PHGDH axis. Targeting PHGDH combined with ferroptosis inducers exhibited with synergistic effect for CRC in vitro and in vivo. Our findings identified the metabolic vulnerability in ferroptosis-resistant CRC cells, which could serve as a novel therapeutic target.

#3276 The effects of extracellular ATP signaling on the anticancer activities of macrophages.

J. M. Manouchehri, L. M. Marcho, M. A. Cherian;
The Ohio State University Wexner Medical Ctr., Columbus, OH

Among cancers in women worldwide, breast cancer has the highest incidence and the highest mortality. Patients with triple negative breast cancer (TNBC) have a markedly worse outcome in comparison to patients diagnosed with hormone-dependent and human epidermal growth factor receptor-positive breast cancers due to the aggressive and rapidly progressive nature of the disease and the deficit in specifically targeted therapies available. Therefore, there is a need for new therapeutic approaches. Extracellular ATP has been shown to cause cell death in an autocrine and paracrine manner and is also a known danger signal that causes immune activation. Our published data reveals that at high micromolar concentrations extracellular ATP (eATP) can induce cell death through the eATP-gated ion channels, purinergic P2RX7 and P2RX4 receptors. We also showed that in the context of chemotherapy treatment, eATP modulates TNBC cell death at submicromolar concentrations. A feature of the tumor microenvironment is a pronounced increase in the concentrations of eATP (micromolar) to levels that are closer to the threshold for cytotoxicity than in normal tissues (nanomolar). In addition, we discovered that chemotherapy induces the release of eATP from TNBC cells, further augmenting its concentration. Despite this, eATP is rapidly degraded to adenosine by extracellular ATPases (eATPases). It should be noted that extracellular ATP release and activation of its receptor, P2XR7, are prerequisites for the activation of a complex of proteins known as the NLRP3 inflammasome that is critical for IL-1β and IL-18 secretion and the induction of a highly inflammatory form of programmed cell death known as pyroptosis. The objective of this study was to evaluate if augmenting eATP levels using extracellular ATPase inhibitors will increase the efficacy of chemotherapy against THP-1 and differentiated THP-1 cells to undergo an inflammatory form of cell death known as pyroptosis. We treated THP-1 and differentiated THP-1 cells with increasing concentrations of the chemotherapeutic agent paclitaxel in the presence of eATPase inhibitors POM-1 and PSB 069 with eATP content and cell viability being assessed. Additionally, we examined NLRP3 inflammasome activation by immunoblot analysis. We analyzed the oligomerization of NLRP3 and ASC, the cleavage of caspase 1 and gasdermin and the secretion of IL-1β and IL-18, all components of pyroptosis. These results reveal that eATP modulates the chemotherapeutic response in the monocytic THP-1 and differentiated THP-1 cells, which could be exploited to augment the anticancer effects of macrophages on TNBC cells. These preclinical experiments could be applied to develop effective therapies that increase the depth and length of responses to chemotherapy and immunotherapy in TNBCs by augmenting pyroptosis of tumor associate macrophages through enhanced eATP.

#3277 PAI-1 mediates resistance to MET-targeted therapy in non-small cell lung cancer.

T. Higashihara[1], Y. Thu[1], K. Suzawa[2], K. Date[1], A. Matsuoka[1], D. Mizuno[1], R. Yoshichika[1], N. Hayashi[1], F. Mukohara[1], M. Yoshikawa[1], K. Shien[2], H. Yamamoto[2], S. Toyooka[1];

[1]Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan, [2]Okayama University Hospital, Okayama, Japan

[Purpose] The mesenchymal epithelial transition factor receptor (MET) is a potential therapeutic target in various cancers, including non-small cell lung cancer (NSCLC). In NSCLC, the activation of MET pathway is thought to occur through diverse mechanisms that influence properties affecting cancer cell survival, growth, and invasiveness. These tumors show oncogene addiction to MET and exhibit remarkable responses to MET-Tyrosine Kinase Inhibitors (TKIs). However, the long-term effectiveness of MET-TKIs is usually limited due to acquired drug resistance. The mechanisms underlying primary and acquired resistance to MET-TKIs in the management of NSCLC remain unclear. In this study, we investigated the mechanisms acquired for crizotinib in *MET*-amplified lung carcinoma cell lines. [Experimental Designs] Two *MET*-amplified lung cancer cell lines, EBC-1 and H1993, were established for acquired resistance to MET-TKI crizotinib and were functionally elucidated. The factors contributing to the resistance mechanism were assessed by genomic and transcriptomic data, and the alterations hypothesized to confer resistance were validated. [Results] Multiple mechanisms underlay acquired resistance to crizotinib in *MET*-amplified lung cancer cell lines. In EBC-1-derived resistant cells, the drug resistance mechanism was mediated by the overexpression of *SERPINE1* , the gene encoding plasminogen activator inhibitor-1 (PAI-1). Crizotinib resistance was overcome by combination therapy with PAI-1 inhibitor and PAI-1 knockdown. Another mechanism of resistance in different subline cells of EBC-1 was evaluated as epithelial to mesenchymal transition (EMT) with the upregulation of antiapoptotic proteins. In the H1993-derived resistant cells, the phosphorylated forms of MEK and ERK were observed to be upregulated and MEK inhibitors could be a potential therapeutic strategy for overcoming the resistance. [Conclusions] In this study, we revealed the different mechanisms of drug resistance to MET-TKI treatment and presented some possible strategies to overcome the resistance.

#3278 Analysis of the mechanism of resistance to selpercatinib in thyroid cancer cells with *RET/PTC1* fusion gene.

M. Amitani, K.-i. Ito;
Shinshu University, Matsumoto, Japan

Purpose: Precision oncology, in which molecularly targeted drugs are selected based on genetic mutations, has begun in thyroid cancer, and drugs targeting *BRAF*, *RET*, and *NTRK* are already in clinical use. However, as with previous therapeutic agents for malignant tumors, there have been cases of resistance to these drugs either initially or during treatment, and the mechanisms of drug resistance need to be elucidated. So far, little is known about the mechanisms of resistance to molecularly targeted drugs in thyroid cancer. To overcome resistance to the RET inhibitor, selpercatinib (SEL), and to consider next therapeutic strategies, we aimed to elucidate the mechanisms of resistance to SEL.
Method: We used papillary carcinoma cell lines TPC-1 and CUTC48, which harbor the *RET/PTC1* fusion gene. We established an SEL-resistant subline (TPC-1/SELR) in TPC-1 by long-term exposure to SEL. The growth inhibitory effect of drugs was analyzed using the WST assay. The alteration of intracellular signal transduction was analyzed by western blotting.
Result: The 50% inhibitory concentration (IC_{50}) for SEL in the parental TPC-1 was 3 nM, while growth inhibition in TPC-1/SELR did not reach 50% even at more than 100 nM of SEL. On the other hand, growth inhibition by SEL in CUTC48 did not reach 50% even at more than 100 nM of SEL. The sensitivity to SEL in CUTC48 was comparable to that in TPC-1/SELR, and CUTC48 showed an intrinsic resistance to SEL. TPC-1/SELR showed increased phosphorylation of EGFR, Erk, Akt, and mTOR compared to TPC-1. In CUTC48, phosphorylation of EGFR and Erk was not increased compared to that of TPC-1, while phosphorylation of Akt and mTOR was increased. We investigated the growth inhibitory effect of an mTOR inhibitor everolimus and found that TPC-1 (IC_{50}: 1.3 nM), TPC-1/SELR (5 nM) , and CUTC48 (9.4 nM) were all highly sensitive to everolimus.
Discussion: Our results showed that Akt and mTOR phosphorylation were elevated in the SEL-resistant TPC-1/SELR and the SEL-intrinsic resistant CUTC48 in common, suggesting the involvement of activation of the Akt-mTOR pathway in SEL resistance in thyroid cancer. The inhibition of the Akt-mTOR pathway in parallel with RET may have therapeutic potential to overcome SEL resistance in thyroid cancer.

#3279 MUC1 is necessary for the inflammatory memory response to osimertinib resistance in NSCLC cells.

N. Haratake[1], A. Bhattacharya[1], A. Nakashoji[1], H. Ozawa[1], M. Shimokawa[2], D. Kufe[1];
[1]Dana-Farber Cancer Institute, Boston, MA, [2]Yamaguchi University, Yamaguchi, Japan

Emergence of resistance is an invariable outcome in cancer progression that may involve memory of cancer cells to treatment. The oncogenic MUC1-C protein confers pleotropic resistance of cancer cells to diverse cytotoxic and targeted agents by unclear mechanisms. We demonstrate that MUC1-C regulates the interferon (IFN) type I/II pathways in H1975 non-small cell lung cancer (NSCLC) cells selected for osimertinib resistance (H1975-OR). Targeting MUC1-C in H1975-OR cells suppressed STAT1 and inflammatory IFN signaling in association with reversing the osimertinib-resistant phenotype. Studies of H1975-OR cells selected for growth in the absence of osimertinib demonstrate that revertant H1975-RT cells retain MUC1-C-dependent memory necessary for recalling osimertinib resistance. Mechanistically, osimertinib treatment of H1975-RT cells activates the *MUC1* gene at a (i) promoter-like signature (PLS) by MUC1-C and STAT1, and (ii) proximal enhancer-like signature (pELS) by PBAF and JUN/AP-1. Targeting MUC1-C in osimertinib-treated H1975-RT and MGH170 NSCLC MET-amplified cells isolated from a patient refractory to osimertinib treatment suppressed induction of STAT1 and downstream IFN-stimulated genes (ISGs) encoding MX1, OAS1 and ISG15. Targeting MUC1-C, STAT1, PBRM1/PBAF and JUN/AP-1 further confirmed their dependencies for reemergence of osimertinib resistance in H1975-RT and MGH170 cells. In support of these results, high MUC1-C protein expression analyzed by IHC is associated with shorter progression free survival for patients treated with osimertinib. These findings and the demonstration that MUC1-C is upregulated in NSCLC cells from patients refractory to osimertinib indicate that MUC1-C drives osimertinib resistance in NSCLC cells by promoting an inflammatory memory response.

#3280 ASCL2$^{\pm}$ tumor cells modulate the response of colorectal cancer to MAPK targeting therapy.

O. E. Villarreal, H. M. Lee, H. Tran, A. Machado, J. Alshenaifi, C. W. Wong, O. Coker, R. Minelli, M. Peoples, A. Hernandez Martinez, N. Fowlkes, P. Kanikarla, K. Lin, C. Bristow, A. Viale, J. R. Marszalek, J. P. Shen, S. Kopetz;
The University of Texas MD Anderson Cancer Center, Houston, TX

Colorectal cancer (CRC) is commonly treated with MAPK pathway inhibitors (MAPKi) including EGFRi, BRAFi, and most recently KRAS G12C inhibitors. However, clinical trials repeatedly demonstrate that durability of benefit is short-lived in many patients. While genomic mechanisms of acquired resistance have been described, this explains a small minority of patients and further research is needed to determine the underlying biology limiting MAPKi therapy durability in CRC.

Potential responsible mechanisms were explored using transcriptomic data from patients treated with MAPKi combination therapy, showing upregulation of stem-related signatures in nonresponders (FDR<0.001), therefore CRC stem markers with the greatest expression increase were identified. The top markers (ASCL2, LGR5, LRIG1) were evaluated using a metacohort of single cell RNAseq (scRNAseq) data from patients with CRC (n=72), and ASCL2 was selected for further study due to its high marker coexpression and tumor cell specificity (OR=8.27, p<0.0001). Additionally, ASCL2 expression increased in multiple patient-derived organoid and xenograft (PDX) models that were treated with a spectrum of MAPKi therapies (BRAFi, EGFRi, G12Ci, MEKi, SOSi). As such, we postulated that ASCL2$^{\pm}$ tumor cells play an important role in the limited response durability of MAPKi therapy in CRC.

To investigate, ASCL2 reporter models were treated with MAPKi therapy, resulting in the significant enrichment of ASCL2$^{\pm}$ tumor cells, independent of driver mutation or treatment regimen used. Using Single Cell BarcodeSeq, by combining molecular barcoded PDXs with single cell transcriptomics, we found that MAPKi therapy engaged intrinsic cellular plasticity resulting in cells transitioning into the ASCL2$^{\pm}$ phenotype. Additional patient-level data confirmed enrichment of the ASCL2$^{\pm}$ transcriptomic signature at progression while on MAPKi therapy. Characterization of ASCL2$^{\pm}$ cells showed higher stem cell frequency ($p=9.7x10^{-62}$), clonogenic capacity (p<0.0001), expression of stem-related genes, and retention of phenotypic plasticity, indicating ASCL2$^{\pm}$ tumor cells feature stem-like abilities, as previously described, which include therapy resistance. Lastly, depletion of ASCL2$^{\pm}$ tumor cells resulted in improved initial response to MAPKi therapy (p<0.0001) and, more importantly, prolonged cell growth inhibition.

Overall, we observe that MAPKi therapy enriches stemness programs in CRC and demonstrate MAPKi drives cells into a transient ASCL2$^{\pm}$ stem-like state with limited sensitivity to MAPK inhibitors. Further studies are underway to identify vulnerabilities that will enable targeting of ASCL2$^{\pm}$ tumor cells. Ultimately these findings will help guide future optimization of MAPKi regimens to prolong response durability and improve outcomes for patients with CRC.

#3281 Silencing of necroptosis related genes in endocrine-resistant breast cancer cells causes PFKFB3 induced arrest of necroptosis and contributes to resistance.

B. C. Jones[1], T. Onal[2], S. Sengupta[2], C. M. Sevigny[3], L. Jin[2], P. R. Pohlmann[4], A. Shajahan-Haq[5], **R. Clarke**[2];
[1]Lombardi Comprehensive Cancer Center, Georgetown University Medical Center, Washington DC, Washington, DC, [2]The Hormel Institute, University of Minnesota, Austin, MN, [3]The Jackson Laboratory, Bar Harbor, ME, [4]MedStar Georgetown University Hospital, Washington, DC, [5]Lombardi Comprehensive Cancer Center, Georgetown University Medical Center, Washington, DC

Approximately 70% of newly diagnosed breast cancer patients are estrogen receptor positive. Patients treated with approved treatment strategies may develop resistance to these therapies. Because of this problem in treatment, new treatment regimens need to emerge. Altered reprogramming of metabolism and an intense dependence on glycolysis are hallmarks of cancer, which is necessary to support the high energy demand of rapidly proliferating cancer cells. Rapidly dividing cancer cells are known to have increased energy requirements and altered reprogramming of glucose metabolism, leading to an increased reliance on glycolysis. The conversion of fructose-6-phosphate to fructose-1,6-bisphosphate, a critical rate-limiting step in the glycolysis pathway, is greatly influenced by an allosteric activator produced by the enzyme PFKFB3 (6-phosphofructo-2-kinase/fructose-2,6-bisphosphatase 3), thus making PFKFB3 an important regulator of glycolytic flux. Furthermore, PFKFB3 has been shown to be overexpressed in many human cancers, including breast cancer, and upregulated by estrogen. In our previous studies, we have shown that endocrine-resistant BC cells growth is strongly reduced by PFKFB3 targeting using PFKFB3 inhibitors, glucose uptake is reduced, triggered to necroptosis by RIPK1 and MLKL phosphorylation, and PFKFB3 inhibition reduces tumor size in mouse xenografts. In this study, we showed that silencing of RIPK1 and MLKL, genes involved in necroptosis, by siRNAs followed by inhibition of PFKFB3 by PFK158 did not induce necroptosis in endocrine-resistant BC cells. Furthermore, we further confirmed that phosphorylation of MLKL and RIPK occurs with PFKFB3 inhibition. In summary, this study reveals that necroptosis induced by PFKFB3 inhibition contributes to resistance by arresting necroptosis in endocrine-resistant BC cells after silencing of necroptosis-related genes.

#3282 Endocrine resistance genes driving cross-resistance to current combination therapies in HR-positive breast cancer.

Z. Huang, N. Wortelboer, C. Beaufort, S. N. Ortak, D.-w. Chan, H. H. Dag, J. Helmijr, J. Martens, M. Jansen;
Erasmus MC Cancer Institute, Rotterdam, Netherlands

Introduction: Treatment failure to multiple treatment lines in hormone receptor positive (HR+) patients brings cross-resistance into the stage. The study aimed to determine if tamoxifen resistance genes cause cross-resistance to commonly employed metastatic breast cancer (combination) treatments.
Materials & Methods: Parental and tamoxifen resistant MCF7A models (BCAR3, BCAR4, EGFR, AKT1 and AKT2) were cultured for 10 days with different concentrations of tamoxifen and fulvestrant (endocrine therapy), ribo-, abema-, and palbociclib (CDK4/6 inhibitors) and alpelisib (PIK3CA inhibitor). Compounds were tested as mono- and combination therapy in replicate experiments estimating cell growth using the Sulforhodamine B assay and half maximal inhibitory concentration (IC50) was calculated by Graphpad PRISM v5 software. Resistance was declared when IC50 was significantly different from parental ($p<0.05$, Mann-Whitney U test).
Results: The BCAR3, BCAR4 and EGFR models were not only resistant to tamoxifen but also to fulvestrant monotherapy (see table). In the two AKTs models the initial results could not be reproduced and were excluded from the study. The BCAR4 model was also resistant to all CDK4/6- and PIK3CA-inhibitors monotherapy. Analysis of the combination regimens demonstrated cross-resistance in the BCAR4 model for all compound combinations tested, in the EGFR model for all combinations except fulvestrant combined with alpelisib, and in the BCAR3 model only for tamoxifen combined with alpelisib.
Discussion/Conclusion: Tamoxifen resistance genes BCAR3, BCAR4 and EGFR show various degrees of cross-resistance to other breast cancer treatments. It might be worthwhile to evaluate these genes or their associated biological pathways as predictive biomarkers for cross-resistance in HR+ breast cancer patients treated with the mentioned (combination) therapies.

#3283 Role of HA, HAS3, UGT1A9 in metastatic renal cell carcinoma and sorafenib resistance.

A. K. Sharma, K. Aguilar, C. S. Panda, V. B. Lokeshwar;
Augusta University, Augusta, GA

Introduction: Despite numerous available treatments, metastatic renal cell carcinoma (mRCC) remains highly lethal, with over 90% of patients succumbing within 5 years. Sorafenib (SF), a second-line treatment for mRCC, exhibits modest efficacy, and the underlying molecular basis for its failure is elusive. Hyaluronic acid (HA), implicated in promoting cell proliferation, invasion, and motility through CD44 and RHAMM receptors, represents a potential player in SF resistance. Hymecromone (HC), a non-toxic dietary supplement, is known to inhibit HA synthesis and downregulate CD44 and RHAMM mRNA levels. This study investigates the elusive mechanisms of SF resistance and evaluates the effectiveness of the HC+SF combination as a targeted therapy for advanced RCC, providing insights into a novel and potentially impactful treatment approach.

Methods: HA levels were measured in normal and tumor kidney specimens using ELISA-like assay and IHC. Similarly, HAS3 and UGT1A9 (A9) levels and SF glucuronidation were measured by qPCR and a glucuronidation assay using tumor microsomes. Response to SF+HC combination was examined in A9 and HAS3 knockdown and overexpression cell lines (transfectants) and primary RCC spheroids by proliferation, apoptosis, motility, and invasion assays. Target analysis was performed by immunoblot. Treatment efficacy was evaluated in subcutaneous and orthotopic xenograft mouse models, with bioluminescence imaging.

Results: SF failure in mRCC was linked due to its glucuronidation and inactivation by A9. Tumor microsomes from patients who developed mRCC glucuronidated SF 5-fold higher than from non-mRCC patients. A9 levels were elevated (8-10 folds) in mRCC patients' tumor along with HA and HAS3 (5-10 folds) as compared to non-mRCC patients and normal kidney tissues. HC treatment downregulated A9 promoter activity and inhibited SF-glucuronidation in RCC cells. SF (5uM) and HC (20, 40ug/ml) combination inhibited RCC cell and primary tumor spheroid proliferation (>90%), motility/invasion (>80%), and induced apoptosis (5-fold) and downregulated HAS3 expression (>80%), and HA synthesis in RCC cells. While A9 and HAS3 transfectants both were resistant to SF+HC treatment, A9 and HAS3 - KO transfectants were sensitive to SF. Endothelial cells co-cultured with either A9 or HAS3 transfectants were resistant to SF+HC treatment. SF+HC upregulated apoptosis effectors, but downregulated CD44, RHAMM, and phospho-Met levels in EV but not in A9 or HAS3 transfectants. HC (100 or 200mg/kg) and SF (30mg/kg) oral combination abrogated Caki-1 tumor growth (>80%), without serum/tissue toxicity. HC+SF treatment decreased A9, HA and HAS3 levels, Ki67 index and microvessel density. Both A9 and HAS3 overexpressing tumors were resistant to treatment.

Conclusion: This study demonstrates the mechanism of SF failure in mRCC and proposes a safe, oral adjunct combination for effective treatment.

#3284 Transcription factor YBX1 elevating the sorafenib IC50 in hepatocellular carcinoma cell lines.

D. Kwabiah[1], A. AyalaPazzi[2], K. Doxtater[1], S. Leslie[1], M. K. Tripathi[1];
[1]University of Texas Rio Grande Valley, McAllen, TX, [2]UT SouthWestern Medical Center, Dallas, TX

Hepatocellular carcinoma (HCC) is the most common form of liver cancer which accounts for more than 90% of occurrences of liver cancer cases. Surgical therapies such as liver transplantation and hepatectomy may help cure hepatocellular carcinoma diagnosed in its early stages. Advanced stages of the disease have a poor prognosis and a high refractoriness because of drug resistance. Sorafenib is a tyrosine kinase inhibitor that has been approved for the systemic treatment of patients with advanced HCC. However, the efficacy of this medication has shown a limited prolongation of the overall survival in patients with advanced HCC. The mechanism of resistance to sorafenib in advanced HCC is poorly understood. The TCGA analysis of the HCC patient cohort shows an elevated expression of YBX1 in tumors as compared to normal. The expression is also correlated with progression, metastasis, and poor survival of HCC patients. Transcription factor YBX1 is involved in the regulation of drug resistance in different cancers, especially breast and colorectal cancers. Our lab is interested in understanding if YBX1 is involved in sorafenib resistance in HCC. Different HCC cell lines procured from ATCC SK-Hep1, Huh-7luc, and C3A, were analyzed for their IC50 values for sorafenib using MTT assays, at different time points. SK-Hep1 showed 8.780µM and 8.174µM, HepG2luc 4.659µM and 3.596µM at 48 and 72 hrs respectively. Overexpression of YBX1 in the SK-Hep1 cell line increased the cell survival and IC50 value of sorafenib at 48 and 72 hrs at 13.19µM and 10.64µM respectively. This supports the hypothesis which demonstrates the role of YBX1 in mediating resistance to sorafenib in advanced HCC. YBX1 could be a major therapeutic target and by inhibiting its action could improve the sensitivity of advanced HCC to sorafenib. We have developed YBX1 overexpressing and knockdown (GFP expressing) cell lines, FACS sorted and Puromycin selected for further mechanistic studies. We are also further developing the sorafenib-resistant HCC cell lines to understand the mechanism underlying sorafenib resistance in HCC. Protein and RNA analyses revealed a relative increase in YBX1 overexpression in sorafenib-resistant cell lines as compared to its parental cell lines. Understanding the mechanism of YBX1-induced drug resistance to sorafenib and its associated signaling pathways could help improve the sensitivity of advanced hepatocellular carcinoma to treatment by sorafenib and thus improve the livelihood of its patients.

#3285 Elevated expression of breast cancer stem cell marker alpha6-integrin is associated with reduced anti-estrogen efficacy in breast cancer.

G. Viteri[1], S. Angeloni[2], U. Soto[2], E. J. Brantley[2];
[1]Loma Linda Univ. School of Pharmacy, Loma Linda, CA, [2]Loma Linda Univ. School of Medicine, Loma Linda, CA

Most women diagnosed with breast cancer have tumors expressing the estrogen receptor and are prescribed agents such as aromatase inhibitors or the anti-estrogens tamoxifen or fulvestrant. However, up to 40% of these patients will experience relapse due to endocrine therapy resistance even when these agents are used in combination with cyclin dependent kinase inhibitors. A small population of cells within tumors known as breast cancer stem cells are generally resistant to endocrine therapy and are believed to promote patient relapse. We previously found that breast cancer stem cell marker α6-integrin is expressed at elevated levels in cells that are resistant to the anti-estrogen tamoxifen. We thus hypothesized that elevated levels of α6-integrin confer resistance to anti-estrogens. Quantitative PCR analyses revealed that tamoxifen-resistant and fulvestrant-resistant mammospheres (breast cancer spheroids) exhibit increased α6-integrin expression as compared to antiestrogen-sensitive mammospheres. Cells with enforced α6-integrin expression were less responsive to tamoxifen and fulvestrant than control cells. Further, pharmacological or genetic inhibition of α6-integrin enhanced anti-estrogen efficacy. Our data suggest that targeting α6-integrin represents a viable strategy to overcome endocrine therapy resistance.

#3286 Synergistic impact of long non-coding RNA TUG1 depletion in overcoming temozolomide chemoresistance in glioblastoma.

Hidekazu Kito, Yuji Kibe, Miho Suzuki, Keiko Shinjo, Yutaka Kondo

Nagoya University, Nagoya, Japan

Glioblastoma (GBM) stands out as the most prevalent and aggressive primary brain tumor in adults, marked by a high mortality rate. Standard therapy involves temozolomide (TMZ) chemotherapy, an alkylating agent. However, most cases develop resistance to TMZ, necessitating the development of new treatment options to overcome TMZ-resistant GBM. Long non-coding RNAs (lncRNAs) constitute a class of RNA molecules that, despite not encoding proteins, play pivotal roles in regulating diverse cellular processes. Overexpression of specific lncRNAs in cancer is linked to crucial aspects of cancer progression, such as cell proliferation, apoptosis, and metastasis. Taurine upregulated gene 1 (TUG1) is a highly expressed lncRNA in GBM, playing a crucial role in preventing excessive DNA replication stress and associated DNA damage (Nat Commun 2023).This study aimed to investigate the combined effects of TUG1 depletion and TMZ in TMZ-resistant GBM. First, we established a TMZ-resistant U251MG cell line, U251MG-R, characterized by a low DNA methylation level of the O6-methylguanine-DNA methyltransferase (MGMT) promoter. We observed that TMZ increased DNA replication stress in the U251MG-R. Depleting TUG1 by using antisense oligonucleotide (TUG1-ASO) sensitized U251MG-R cells to TMZ. Treatment with TMZ or TUG1-ASO alone inhibited cell proliferation, with the most significant inhibition observed when both were combined. Next, we employed a xenograft mouse model to evaluate the efficacy of intravenous TUG1-ASO treatment coupled with a tumor-specific drug delivery system (antiTUG1-DDS). The combination of antiTUG1-DDS with TMZ displayed the most effective suppression of tumor growth compared to either TMZ or antiTUG1-DDS alone. Targeted therapy aimed at TUG1 may be a promising approach for overcoming TMZ resistance in GBM.

#3287 Learning to target CDK4/6 inhibitor resistance via a breast cancer-specific atlas of cellular mechanisms.

A. Yaari[1], E. Farias[1], F. Guedes[1], O. Priebe[1], L. McDaniel[1], T. Earnest[1], T. Ideker[2], **M. A. Sherman**[1];
[1]Serinus Biosciences Inc., New York, NY, [2]University of California, San Diego, San Diego, CA

Development of resistance to targeted, chemotherapeutic, and immune-oncology treatments alike is a major barrier to long-term remission in advanced cancer patients. We developed an integrated computational-experimental platform to mitigate treatment resistance by identifying therapeutics that selectively target clinical resistance mechanisms. The key innovation is the computational framework that comprehensively maps tumor-specific mechanisms of response and resistance to a treatment based on clinicogenomic and/or preclinical pharmacogenomic data. It then screens for drugs or targets that are synthetically lethal with these resistance mechanisms. Here we present the identification of therapeutic options that mitigate resistance to CDK4/6 inhibitors as a case study. Leveraging a breast cancer-specific atlas of cellular architecture, our framework learned genetic mechanisms of CDK4/6 inhibitor resistance from a high-throughput phenotypic screen of ~700 cell lines treated with the clinical CDK4/6 inhibitor palbociclib. The learned mechanisms formed a parsimonious set of hierarchically linked protein complexes that coordinate G1-to-S transition ($P=5.6\times10^{-12}$). The mechanisms unified distinct resistant populations such as samples resistant due to CDK4/6-Rb checkpoint bypass and those resistant due to growth factor receptor activation. Applied to 70 ER+ metastatic breast cancer patients in a real-world dataset, the learned resistance mechanisms accurately predicted patient response to palbociclib ($P=3\times10^{-4}$, log-rank test). Computationally screening 20K clinical-grade small molecules and gene targets for therapeutic options synthetically lethal with the learned resistance mechanisms identified the known CDK4/6 resistance targets CDK2, CCNE1, and E2F. It also identified a target that, to our knowledge, has not previously been rigorously evaluated for its potential to mitigate CDK4/6 inhibitor resistance. In-vitro, monotherapy inhibition of the target by siRNA selectively decreased growth of breast cancer cell lines resistant to CDK4/6 inhibitors by 52% compared to CDK4/6i sensitive cell lines (P=0.023, Mann-Whitney U-test). As a combination therapy, inhibition of the target by siRNA selectively increased the sensitivity to palbociclib by nearly an order of magnitude in an otherwise resistant breast cancer cell line (expected vs observed IC_{50}: 9.7 uM vs. 1.3 uM) while not having a substantial effect in a palbociclib-sensitive cell line (expected vs observed IC_{50}: 0.57 uM vs. 0.56 uM). Finally, while monotherapy inhibition of the target and CDK4/6 induced cell cycle arrest, the combination strongly induced apoptosis in cell lines resistant to CDK4/6 inhibitors. These results highlight how computational deconvolution of tumor resistance mechanisms enable algorithmic identification of therapeutic options to target treatment-resistant cell populations.

#3288 Identification of Annexin A1 as a novel driver of lenvatinib resistance in hepatocellular carcinoma.

C. GU, C. LEUNG, T. LEE;
Hong Kong Polytechnic University, Hong Kong, Hong Kong

Hepatocellular carcinoma (HCC) is the third leading cause of cancer-related deaths worldwide. Lenvatinib has recently been approved by the FDA for front-line treatment of HCC patients at advanced stages. However, the survival benefit of lenvatinib is modest due to the development of acquired drug resistance. In this study, we aimed to investigate the mechanisms underlying lenvatinib resistance in HCC and to identify potential therapeutic targets to combat lenvatinib resistance. For this purpose, we established a lenvatinib-resistant (LenR) HCC patient-derived tumor xenograft (PDTX) by administering four rounds of lenvatinib treatment, and their genetic profiles were analyzed using single-cell RNA sequencing (scRNA-seq). Based on single-cell regulatory network inference and clustering (SCENIC) analysis, Annexin A1 (ANXA1), the top gene that was enriched in the HCC cell-like cluster of LenR tumors, was identified and was consistently observed in LenR HCC cell lines and LenR tumors derived from *Tp53*^{KO}/*C-Myc*^{OE} and RIL175 HCC mouse models. Using an *in vitro* differentiation model, limiting dilution assay, apoptosis assay and correlation analysis, we demonstrated the role of ANXA1 in the regulation of cancer stemness-driven lenvatinib resistance. Mechanistically, ANXA1 regulates cancer stemness and drug resistance by driving the STAT3/S100A6 signaling cascade, and ANXA1 expression is regulated by SOX2 via promoter activation, as demonstrated by a chromatin immunoprecipitation (ChIP) assay. Using the same set of scRNA-seq data, we showed that LenR HCC tumors reshaped the tumor microenvironment (TME) by inducing M2 macrophage polarization, as evidenced by a higher M2/M1 ratio of tumor-associated macrophages (TAM) in LenR HCC tumors than in their mock counterparts. Based on this observation, we further demonstrated the *in vitro* role of secretory ANXA1 in LenR HCC cells in inducing macrophage polarization towards the M2 phenotype. In conclusion, ANXA1 may regulate lenvatinib resistance intrinsically via the promotion of cancer stemness and extrinsically via the induction of an immunosuppressive TME.

#3289 APOBEC3A drives tumor evolution through activation of ERVs in non small cell lung cancer.

H. Isozaki, R. Sakhtemani, N. Nikpour, S. Monroe, M. Lawrence, A. Hata;
Massachusetts General Hospital, Charlestown, MA

Acquired drug resistance to even the most effective anti-cancer targeted therapies remains an unsolved clinical problem. Although many drivers of acquired drug resistance have been identified, the underlying molecular mechanisms shaping tumor evolution during treatment are incompletely understood. We recently demonstrated that lung cancer targeted therapies commonly used in the clinic induce the expression of cytidine deaminase APOBEC3A (A3A), leading to sustained mutagenesis in drug-tolerant cancer cells persisting during therapy. Preventing therapy-induced A3A mutagenesis by gene deletion decreased the chromosomal aberration events and delayed the emergence of drug resistance. Thus, inhibition of A3A may represent a potential therapeutic strategy to prevent acquired resistance. Understanding the regulatory mechanisms of A3A may provide alternative approaches to inhibit A3A mutagenesis. Using a panel drug screen, we found that DNA methyltransferase (DNMT) inhibitor remarkably induces A3A in non-small cell lung cancer cells. RNA-seq profiling revealed that targeted therapy as well as DNMT inhibitor treatment activate expression of distinct classes non-coding repetitive RNA elements, including endogenous retrovirus (ERVs), in drug-tolerant persister cells. Activation of intracellular viral sensing pathways by introduction of exogenous nucleic acids mimicking viral elements induced A3A expression. While the transcription factor NFkB was acutely activated by targeted therapy, TBK1-IRF3 signaling was activated at later time points. These findings suggest that reactivation of ERVs may underlie A3A mutagenic activity and tumor evolution during targeted therapy.

#3290 FTO mediates tumor growth and resistance to erlotinib in NSCLC.

A. Rastogi, R. Qiu, **N. Puri**;
University of Illinois College of Medicine (Rockford), Rockford, IL

Lung cancer, among the most common cancer types, ranks first in cancer associated deaths. Nearly 85% of the lung cancer cases are non-small cell lung cancer (NSCLC). Epidermal growth factor receptor (EGFR), an established marker for NSCLC, is frequently overexpressed on the cell surface. Amplifying mutations often render these receptors activated in a ligand independent manner, therefore, therapies such as erlotinib, an EGFR tyrosine kinase inhibitor (EGFR-TKI), target these activating mutations and inhibit tumor growth. Nevertheless, patients acquire resistance to EGFR TKI within 9-14 months of treatment. Recent studies show that fat mass and obesity- associated (FTO) gene, initially identified to increase the body mass index, plays a major role in cancer development and acquired therapy resistance in several cancer types. FTO demethylates m6A mRNA and modulates tumorigenesis, and drug resistance. In this study, we explored the functions of FTO in EGFR TKI resistance in NSCLC. To study the expression of FTO in erlotinib resistant cells, we used wildtype-EGFR NSCLC cell lines (H2170, H358) and mutant EGFR NSCLC cell lines (H1975, PC9) that were rendered resistant to erlotinib. Our RT-qPCR results demonstrated that FTO was upregulated by 1.7-3.0 fold in erlotinib resistant H2170, H358, PC9 and H1975 cells. FTO protein was upregulated by 1.3-1.6 fold as seen by western blotting, and by 1.7 to 2.6 fold in the nucleus of erlotinib resistant H1975, H2170 and PC9 cell lines by immunofluorescence. Furthermore, we investigated FTO inhibition with Dac51 (FTOi) on cell viability and cell migration properties. MTT cell viability assay showed a 9-17% decrease in cell viability when treated with a combination of Dac51 and erlotinib compared to Dac51 alone in erlotinib resistant H2170 and PC9 cells, respectively. The combinatory treatment showed an additive effect compared to the Dac51 and erlotinib treatments alone. Wound healing assay revealed an 18% open wound area after 48-hour treatment with both Dac51 and erlotinib compared to 0.1% after treatment with erlotinib alone in erlotinib resistant H2170 cells. To evaluate the effect of siRNA mediated FTO (siFTO) knockdown on cell viability and energy metabolism, MTT and luciferase assays were performed. MTT assay showed a 21-28% decrease in viability in erlotinib resistant H1975, H2170, PC9 cells, demonstrating increase in the erlotinib efficacy, as compared to the mock siRNA treatment. Luciferase assay showed an inverse relationship between the FTO and ATP, where the latter was upregulated by 1.3 to 3.4 folds in erlotinib resistant H1975, H2170 and PC9 cells, when treated with siFTO, suggesting its involvement in the energy requirements of the NSCLC cells. In conclusion, our study suggests FTO was upregulated in erlotinib resistant NSCLC cells on both the gene and protein levels. FTO could mediate resistance to EGFR TKI possibly through cell proliferation and migration and help with prognosis of NSCLC patients.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Molecular Glues
Poster Session

#3294 The GSPT1 molecular glue degrader MRT-2359 is active against prostate cancer.

R. Tiedt[1], M. Schillo[1], A. Osmont[1], D. Bonenfant[1], R. Narayan[2], O. Wallace[2], M. Warmuth[2];
[1]Monte Rosa Therapeutics, Basel, Switzerland, [2]Monte Rosa Therapeutics, Boston, MA

We have previously described our GSPT1 molecular glue degrader MRT-2359, which was optimized to achieve preferential antiproliferative activity in non-small cell lung cancer (NSCLC) and small cell lung cancer (SCLC) expressing high N-MYC or L-MYC mRNA. A clinical trial with this new drug candidate is ongoing (NCT05546268). Here, we present pre-clinical profiling of MRT-2359 across hundreds of cancer cell lines representing multiple cancer types, aiming at identifying other cancers where preferential sensitivity is associated with high expression of a MYC family member. These studies showed that prostate cancer cell lines clearly segregate into groups that are either sensitive or insensitive. Sensitive prostate cancer cell lines could be further divided into two subgroups: (1) androgen receptor positive cell lines displaying higher c-MYC mRNA expression levels than the other prostate cancer cell lines, (2) neuroendocrine prostate cancer cell lines with or without high N-MYC. The latter is in line with our previous observation that the neuroendocrine phenotype is generally associated with heightened sensitivity to MRT-2359 independently of MYC status. The insensitive cell lines were androgen receptor and neuroendocrine negative and displayed lower c-MYC mRNA levels. GSPT1 degradation in androgen receptor-positive cell lines led to rapid and deep loss of c-MYC protein as well as reduction of androgen receptor, including the splice variant AR-V7 that is associated with resistance to agents targeting androgen signaling. In androgen receptor-negative cell lines, the levels of c-MYC protein decreased only modestly upon GSPT1 degradation. Finally, in immunocompromised mice, xenografts of the AR-V7-positive cell line 22RV1 and the neuroendocrine prostate cell line NCI-H660, both of which are sensitive to MRT-2359 in vitro, were treated with several MRT-2359 dose regimens including continuous as well as intermittent (5 days on / 9 days off) dosing. Most regimens led to marked tumor regression. Tumors of both models fully regressed after a 4-week course of 10 mg/kg MRT-2359 once daily, and no tumor regrowth could be detected after cessation of treatment. No significant in vivo response was observed for xenografts of the insensitive cell line PC-3. These data support the clinical investigation of MRT-2359 in prostate cancer.

#3295 Pharmacological characterization of CYRS1542: A potent and orally available GSPT1 molecular glue degrader for the treatment of neuroendocrine solid cancer with a favorable safety profile.

Min Sung Joo[1], JaeYung Lee[1], Joonhyung Lee[1], Eun-Jung Kim[1], Seogbeom Song[1], Jeonghyeon Lee[1], Joonwoo Nam[1], Heuijoon Park[1], Jaewoo Park[2], Keon Wook Kang[2], Wooseok Han[1]

[1]Cyrus Therapeutics, Seoul, Korea, Republic of,[2]College of Pharmacy, Seoul National University, Seoul, Korea, Republic of

Neuroendocrine cancers (NECs) are relatively rare compared to other malignancies, but their clinical behavior can be exceptionally aggressive. Two particularly challenging subtypes of NECs, Small Cell Lung Cancer (SCLC) and Neuroendocrine Prostate Cancer (NEPC), are worthy of attention due to their rapid progression, limited treatment options, and high mortality rates. At the molecular level, SCLC and NEPCs necessitate the presence of TP53 and RB1 mutations (Beltran et al., 2016; George et al., 2015). The frequency of TP53 mutations in SCLC is particularly noteworthy, with studies consistently reporting a high incidence (89~92%) (Chen et al., 2022; Sivakumar et al., 2023). A recent study has unveiled intriguing parallels between NECs and hematological malignancies, shedding light on their shared genetic features and analogous patterns of therapeutic susceptibility (Balanis et al., 2019). GSPT1, a translation termination factor, plays a key role in releasing the complete polypeptide from the ribosome. As cancer cells are dependent on translation processes to express elevated levels of oncoproteins, GSPT1 degradation would have lethal consequences. Specific CRBN modulators possess the capability to induce GSPT1 degradation via the ubiquitin-proteasome pathway. GSPT1 degradation leads to a halt in translation termination, activating the Integrated Stress Response (ISR) and subsequently triggering TP53-independent apoptosis. Despite GSPT1 degradation in cancer cells is appealing due to its potential to disrupt the production of critical proteins necessary for cancer cell survival and growth, the challenge lies in doing so without causing excessive harm to normal cells, as GSPT1 is also indispensable for their vital cellular functions. Remarkably, the ongoing development of GSPT1-targeted agents in clinical trials has raised intriguing questions about the mechanisms by which a therapeutic index can be established. Recently, we have identified CYRS1542 as an orally bioavailable GSPT1 molecular glue degrader (MGD) (Joo et al., 2023). Here, we present a pharmacological characterization of CYRS1542 as a potent and orally bioavailable GSPT1 MGD with the ability to effectively treat aggressive neuroendocrine cancers. In various NEC in vivo models, including an orthotopic model, CYRS1542 demonstrated dose-dependent and excellent anti-tumor efficacy comparable to the clinical stage GSPT1 MGD. Furthermore, it demonstrates improved safety profiles in a broad spectrum of normal cells, resulting in a higher therapeutic index compared to the clinical GSPT1 MGD.

#3296 IK-595, a best-in-class MEK-RAF molecular glue, drives broad and potent anti-tumor activity across RAS-MAPK pathway-altered cancers as a monotherapy and in combination.

E. Haines, R. Catterall, V. De Jesus, D. Hidalgo, J. Cavanaugh, M. Sanchez-Martin, J. D. Manna, M. Burke, B. Li, S. R. Wessel, A. Yang, S. Santillana, J. Ecsedy, X. Zhang, S. K. Ruppel;
Ikena Oncology, Boston, MA

Alterations in the RAS/RAF/MEK/ERK pathway are the most common drivers of oncogenesis. Although MEK is a clinically validated cancer target and several MEK inhibitors have been approved by the FDA, their clinical utility has been limited to BRAF V600 mutant cancers and NF1 mutant neurofibromas. We developed the molecular glue, IK-595, a potent inhibitor of the MEK-RAF complex, to overcome the limitations of available MEK inhibitors. IK-595 traps MEK in an inactive complex with all RAF isoforms, as well as mutant forms of BRAF (Class I, II, and III), and blocks RAF-dependent MEK phosphorylation, thereby alleviating CRAF-mediated MEK reactivation that limits the efficacy of approved MEK inhibitors in RAS/RAF-driven tumors. We demonstrate that IK-595 leads to potent and prolonged inhibition of MEK and ERK1/2 phosphorylation in RAS-mutant cancer models. Importantly, IK-595 has a much slower off-rate binding to MEK and retains CRAF longer in an inactive complex with MEK than other MEK/RAF inhibitors, allowing for prolonged target engagement and durable pathway inhibition in RAS/RAF mutant cancer cells. IK-595 exhibits potent single agent activity across a wide range of cancer model indications harboring various RAS/MAPK pathway alterations, including KRAS, NRAS, BRAF and NF1 mutations, and BRAF and CRAF fusions. The benefits of combining IK-595 with inhibitors targeting key resistance mechanisms both within the RAS/MAPK pathway and across parallel survival pathways has also been observed in multiple models. Additionally, IK-595 improved the response of KRAS-driven tumor models to standard of care chemotherapeutic agents, expanding the potential clinical opportunity for IK-595. Key to the design of IK-595 is its PK profile that enables transient high plasma drug exposure and flexible dosing schedules. Intermittent dosing of IK-595 every other day (QOD) or every three days (Q3D) in KRAS-mutant mouse tumor models shows similar efficacy and improved tolerability compared to daily dosing (QD), affording a larger therapeutic window. Preclinical pharmacology studies provide clear guidance to the clinical development plan of IK-595, where flexible dosing schedules, multiple expansion cohorts in RAS/RAF altered patient populations, and combination therapies with mediators of resistance will be explored. IK-595 is a novel MEK-RAF molecular glue that prolongs pathway inhibition, minimizing the potential for resistance, while providing an optimal therapeutic window for patients with RAS/RAF-driven cancer.

#3297 Discovery and evaluation of GT19870, a GSPT1/Myc molecular glue drug (MGD) with oral bioavailability for targeting c-Myc and n-Myc-addictive blood cancer and solid tumors.

L. Ma, Y. Tong, Z. Yang, Q. Zhou, H. Yan, R. Xu, D. Chen;
Kintor Pharmaceutical Limited, Suzhou, China

c-Myc and n-Myc are oncogenic transcriptional factors driving tumor initiation, progression and poor prognosis in a variety of blood cancers and solid tumors, such as acute myeloid leukemia (AML), B-cell malignancies, castration resistance prostate cancer (mCRPC), small cell lung cancer and (SCLC) and neuroblastoma. Both c-Myc and n-Myc dysregulations have been directly linked to the poor clinical outcome in some of these cancers which are addictive to deregulated Myc proteins. Therefore, it is highly warranted to discover and develop novel therapeutical agents for targeting Myc-addictive cancers. GT19870 was discovered through a SAR effort for Myc degradation with improved bioavailability (F % 92.52) from GT19630, a GSPT1/Myc degrader series [1-4]by using phenotypic screenings with c-Myc-addictive HL-60 AML cells and growth factor-dependent hematopoiesis progenitor TF-1 cells, followed by c-Myc ELISA and Western blot assays. GT19870 selectively inhibited the proliferation of HL60 cells with an IC_{50} of 2.6 nM as compared to an IC_{50} of 70.03 nM (26.5-fold selectivity) and effectively degraded c-Myc protein with an IC_{50} of 2.54 nM and IC_{90} <10 nM in HL-60 cells, as compared to an IC_{90}>30 nM in CD3/CD28-stimulated PBMC assays. GT19870, as a MGD, was confirmed to selectively degrade GSPT1, a neo-substrate, by proteomic and Western Blot assays. Further, GT19870 was tested in SCLC, triple negative breast cancer (TNBC) and brain cancer cell panels, in which GT1987 was revealed potent anti-proliferation activities with an IC_{50}<50 nM in 9 of 19 SCLC, 8 of 13 TNBC, and 7 of 24 brain cancer cell lines tested. Importantly GT19870 was also shown potent antitumor activities with IC50 of ≦5.4 nM in 8 of 8 SCLC patient derived organoids. Furthermore, GT19870 (salt form-GT19884) was demonstrated to induce target-engaged (c-Myc and n-Myc) tumor regression in AML, SCLC, mCRPC and neuroblastoma xenograft and PDX models with in a dose ranges of 3-12 mpk/qd/po. In brief, GT19870 is an oral MGD degrading GSPT1/c-Myc/n-Myc. This novel MGD has been demonstrated target-engaged antitumor activities in vitro and in vivo with selectivity of c-Myc degradation in c-Myc-addictive cancer cells as compared to growth factor-stimulated TF-1 cells and CD3/CD28 activated PBMC. GT19870 has been progressing IND enabling stage. References 1. Ma L et al, ASH, 2021 2. Ma L et al, AACR, 2022 3. Nishida Y et al, ASH, 2022 Nishida Y et al, ASH, 2023

#3298 Unlocking the potential of OPM-383: A novel LRRK2 inhibitor in cancer therapy.

M. Riveiro, P. Blom, K. Shoji, J. Hoflack;
ONCODESIGN PRECISION MEDICINE (OPM), Dijon, France

Background: Leucine-rich repeat kinase 2 (LRRK2) plays a pivotal role in regulating various cellular processes, such as cell proliferation, survival, and inflammation. LRRK2 exhibits dual functionality as a serine-threonine kinase and as a GTPase. It is involved in the modulation of multiple signaling pathways, including WNT, MAPK, NF-kB and mTOR. Germline mutations in LRRK2 are associated with an increased risk of cancer, particularly hormone-related and colorectal cancers. LRRK2 also promotes tumor cell growth and survival in papillary renal and thyroid carcinomas, DLBCL and cholangiocarcinoma cells. OPM has designed and developed a novel oral LRRK2 inhibitor, OPM383, using its proprietary Nanocyclix® technology. In this study, we have evaluated the pharmacokinetic (PK) properties, efficacy and tolerability of OPM383 in a colon carcinoma model and a panel of patient-derived organoids.
Materials and Methods: In vitro potency of our Type I inhibitor, OPM383, against full-length wild-type LRRK2 and the G2019S pathogenic LRRK2 mutant was assessed in in a Lanthascreen cell assay. For PK studies, we analyzed OPM383 plasma levels using UPLVC/MS-MS. Evaluation of inhibition of LRRK2 phosphorylation (Ser935) was assessed by western blot. MC-38 cells were inoculated into C57BL/6 mice. When tumor masses reached 75 mm^3, mice were randomized to receive OPM383 (50 mg/kg, orally, daily), anti-PD1 antibody (10 mg/kg, ip, twice weekly), or their combination. OPM383 was also evaluated in patient-derived organoids using the SEngine-Paris® platform.
Results: OPM-383 inhibited wild-type LRRK2 and LRRK2[G2019S] with an IC_{50} of 42 nM and 33 nM, respectively. OPM383 is highly selective among a panel of >400 protein kinases (only 6.7% cross-reactivity at 100 nM). The compound is permeable, metabolically stable and possesses drug-like properties. OPM-383 exhibited a favorable pharmacokinetic profile in mice (AUC of 11858 h*ng/mL and T max of 3 hours at a dose of 30 mg/kg via oral administration). Preliminary e-ADME results indicated moderate inhibition of CYP3A4BFC but no significant inhibition of CYPs 1A2, 2D6, 3A4BQ, 2C19, and 2C9 by OPM-383. After 90 minutes of oral administration in CD1 mice, we observed the inhibition of LRRK2 phosphorylation (Ser935) in the brain, kidney, and PBMCs. In assessing its potential antitumor effects, OPM383 was tested on a panel of patient-derived organoids. Notably, OPM383 inhibited the proliferation of 7 out of 29 patient-derived organoids after 6 days of exposure at various concentrations (<10 µM). In mice bearing subcutaneous MC38 tumors, OPM383 significantly inhibited tumor growth compared to the vehicle-treated group.
Conclusion: This study characterizes a potent first-in-class LRRK2 inhibitor in cancer models. The findings suggest that OPM383 could serve as an attractive lead scaffold for designing and synthesizing a new class of kinase inhibitors for potential applications in cancer therapy.

#3299 Harnessing PIKfyve as a therapeutic vulnerability in neuroendocrine prostate cancer.

Y. Zheng[1], K. G. Rogers[1], A. G. Kamat[1], S. N. Yee[1], R. Mannan[1], X. Jiang[1], R. Kannaiyan[1], X. Cao[1], Y. Wang[2], Y. Qiao[1], A. M. Chinnaiyan[1];
[1]University of Michigan, Ann Arbor, MI, [2]University of British Columbia, Vancouver, BC, Canada

Neuroendocrine prostate cancer (NEPC) represents an aggressive subtype characterized by the independence on androgen receptor (AR) signaling and the acquisition of neuroendocrine features. Despite its rarity among prostate cancer cases, NEPC carries a particularly poor prognosis with limited treatment options. Our prior investigation demonstrated the heightened efficacy of targeting PIKfyve with ESK981 in AR- prostate cancer models, prompting further exploration. In this study, we expanded our investigation to assess the efficacy of ESK981 monotherapy across five NEPC models, encompassing one cell line xenograft and four patient-derived xenografts (PDXs). Our findings revealed consistent tumor inhibition and notable regression in select models. Comparative analysis highlighted the superior effectiveness of ESK981 in NEPC compared to AR+ prostate cancer, as evident through percent tumor growth inhibition (%TGI) assessments. Early evaluations post five days of treatment (PD5) unveiled that PIKfyve inhibition induced apoptotic cell death specifically in NEPC models, confirmed through immunoblotting and TUNEL staining in a time-dependent manner. Intriguingly, PD5 TUNEL positivity correlated with endpoint %TGI, suggesting its potential as a predictor for long-term efficacy. To further delineate the role of PIKfyve in NEPC, we successfully established two novel ex vivo NEPC cell lines from these PDXs, overcoming the constraint of limited publicly accessible NEPC cell lines, and confirmed their NEPC characteristics. Employing a doxycycline-inducible PIKfyve knockdown system in these cells demonstrated significant tumor inhibition in xenograft models, albeit with a lower %TGI compared to ESK981 monotherapy. In conclusion, our results illuminate the preferential cytotoxicity of PIKfyve inhibition in NEPC tumors compared to AR+ prostate cancer, advocating PIKfyve as a compelling therapeutic target. This study provides a strong rationale for advancing ESK981 into clinical trials for NEPC patients, underscoring its potential in addressing this challenging malignancy.

#3301 Translational research of CDK12/13 inhibitor, CTX-439, informing clinical trial strategy.

H. Yamakawa[1], S. Ebara[1], A. Mizutani[1], M. Yoshida[1], M. Sugiyama[1], K. Yamamoto[2], D. Komura[3], M. Kakiuchi[3], S. Ishikawa[3], K. Yusa[4], **D. Morishita**[1]; [1]Chordia Therapeutics Inc., Fujisawa, Japan, [2]MetCoding, Ibaraki, Japan, [3]The University of Tokyo, Tokyo, Japan, [4]Kyoto University, Kyoto, Japan

Gene dysregulation is a hallmark of cancer, arising from genetic alterations that invariably lead to dysregulated transcriptional programs. This dysregulation renders cancer cells highly dependent on certain gene expression regulators, leading to a potential for novel therapeutic strategies. Consequently, ongoing research aims to develop small molecules targeting RNA transcriptional processes. Cyclin-dependent kinase 12/13 (CDK12/13) is a member of the cyclin-dependent kinase family of serine/threonine protein kinases. CDK12/13 regulates the RNA transcription elongation by phosphorylating RNA polymerase II and promotes the elongation of transcripts, specifically those involved in DNA damage responses, such as BRCA1/2. The inhibition of CDK12/13 is expected to exert a synergistic effect when combined with PARP inhibitors and chemotherapeutic reagents. Therefore, we developed a novel small molecule inhibitor, CTX-439 (former name: CRD-1835439). Additionally, we demonstrated that CTX-439 exhibits a preclinical efficacy *in vitro* and *in vivo* [*Cancer Res*. (2022) 82 (12_Supplement): 5485]. To identify potential strategies for a clinical trial of CTX-439, in the current study, we conducted translational research to elucidate (1) pharmacodynamics (PD) markers to monitor the suppression of CDK12/13 in humans, (2) patient selection biomarkers to determine sensitivity to CTX-439, and (3) combination strategies with other key medications. Firstly, to identify PD markers of CTX-439, we performed a comprehensive analysis employing RNA-seq, Pol II-ChIP-seq, and Poly(A)-seq. We confirmed that CTX-439 induced the usage of intronic polyadenylation sites by inhibiting CDK12, resulting in the production of shortened mRNA. Of these transcripts, PCF11 emerged as a potential PD marker for clinical trials, which was confirmed using qPCR analysis of human blood. Secondly, to clarify the indication of CTX-439, we performed an *in vitro* survey involving 400 cell lines and 100 PDX-derived organoids (PDXOs) to identify biomarkers displaying sensitivity and insensitivity to CTX-439. Furthermore, a significant anti-tumor effect of CTX-439 was revealed in PDX models that showed sensitivity in the survey. CTX-439 exhibited a synergistic effect in combination with PARP inhibitors both *in vitro* and *in vivo*, highlighting its potential for use in combination strategies. Additionally, CTX-439 showed an anti-tumor effect when combined with other chemotherapy and molecular-targeted drugs. Collectively, the results from these translational research studies provide a foundation for developing a clinical trial by clearly defining PD monitoring, patient stratification biomarkers, and combination strategies. These findings highlight the therapeutic potential of CTX-439 as a single-agent and in combination with inhibitors, such as PARP, for the treatment of cancers characterized by transcriptional addiction.

#3303 Paralogue selective p300 degraders induce synthetic lethality in pre-clinical models of CBP-deficient and p300-dependent malignancies.

S. Thiyagarajan, C. Abbineni, K. Chaitanya T, A. Apte, I. Iqbal, N. Kumar R, A. A B, A. Kumar, D. Madhu Babu, S. Shwetha, A. Manna, M. Mandal, R. Panigrahi, S. Marappan, S. Gore, M. Fairus, L. Jin, S. Mukherjee, G. Daginakatte, S. Chelur, K. Nellore, M. Ramachandra, **S. Samajdar**;
Aurigene Oncology Limited, Bangalore, India

EP300 (or p300) acts as histone acetyltransferase (HAT) and transcriptional adapter or co-activator regulating transcription via chromatin remodeling. Both histone and non-histone proteins are acetylated by p300. In addition to HAT function, p300 has crotonyl-transferase activities, and that p300-catalyzed histone crotonylation directly stimulates transcription to a greater degree. p300 functions by scaffolding or as co-activator and enhancer of different transcription factors like HIF1a, BRCA-1, p53, NFκB, c-Myc, estrogen receptor (ER) and androgen receptor (AR) and other proteins such as PD-L1 and FOXP3. Selective targeting of p300 is expected to lead to therapeutic efficacy in CBP-mutant and p300-dependent malignancies with high degree of tolerability because of sparing of the other paralog CBP in normal cells. CBP mutant cancers comprise of several solid and hematological malignancies including 10% to 15% of non-small cell and small cell lung cancers harboring loss-of-function (LOF) aberrations. p300-dependent malignancies include prostate cancer, in which p300 plays a major role for androgen-dependent and -independent transactivation of the AR, MYCN-amplified neuroblastoma and ER+ breast cancers. Since the conventional CBP/p300 inhibitors do not discriminate between CBP and p300 proteins due to high sequence homology, we adopted a degrader approach, which has the potential to lead to paralog selectivity due to differentiated ternary complex formation. Herein we report best-in-class novel, potent and paralog selective p300 degraders with excellent selectivity over CBP and and other bromodomain containing proteins such as BRD4 by implementing molecular modeling, iterative medicinal chemistry and SAR based approaches. Synthetic lethality has been demonstrated while selectively degrading p300 in the cell lines having LOF mutation of another paralogue, CBP. Identified selective p300 degraders displayed excellent selectivity towards p300 degradation across tested cell lines and are orally bioavailable. Selective antiproliferative activity was observed in a panel of cell lines with CBP mutations or p300 dependency including AR+ / ER+ cell lines along with the downregulation of target genes. In summary, we have identified highly selective degraders of p300 with desirable profile. Efforts are underway to advance them further towards nominating a development candidate.

#3304 Modulation of enhancer accessibility by SMARCA2 PROTACs synergize with TEAD inhibitors to suppress growth of SMARCA4 mutant lung cancers.

S. Kotagiri, N. Blazanin, M. Qudrattulah, Y. Xi, J. Wang, **Y. Lissanu**;
UT MD Anderson Cancer Center, Houston, TX

The SWI/SNF chromatin remodeling complex is frequently mutated in non-small cell lung cancer with a frequency of 33% in advanced stage disease, making it the most commonly altered complex in lung cancer. Among the various subunits of the SWI/SNF complex, *SMARCA4* and *ARID1A* are by far the most frequently mutated. Importantly, multiple clinical reports have shown that *SMARCA4* mutant lung cancers have one of the worst prognosis among genetically defined lung cancer subtypes and lack response to both immunotherapy and KRAS G12C inhibitors. Recent reports, and our own data, have identified the paralogue *SMARCA2* to be synthetic lethal to *SMARCA4* suggesting SMARCA2 could be a high value therapeutic target. Unfortunately, the discovery of selective inhibitors of SMARCA2 has so far been challenging. To overcome this hurdle, we have recently developed novel, potent and selective SMARCA2 degrading small molecules based on proteolysis targeting chimera (PROTAC) technology. We demonstrated that YD23, our lead SMARCA2 PROTAC, potently and selectively induced degradation of SMARCA2. Importantly, we showed that YD23 selectively inhibits growth of *SMARCA4* mutant lung cancer cells. Mechanistically, we demonstrated that YD23 decreased chromatin accessibility only in *SMARCA4* deficient cells. In particular, SMARCA2 degradation profoundly decreased chromatin accessibility at enhancers of a number of genes with cell cycle and cell growth regulatory roles. Gene expression profiling and pathway analysis indicated that cell cycle genes were downregulated by YD23 consistent with the reduced chromatin accessibility at their *cis*-regulatory regions. We further showed that YD23 robustly inhibited growth of *SMARCA4*-mutant xenograft tumors. While this is promising, SMARCA2 degradation by itself does not induce regression of tumors highlighting the need for identification of efficacious combination strategies. Using integrative gene expression, ATAC-Seq and CUT&RUN assays, we uncover a critical role for YAP/TEAD transcription factor signaling axis in mediating pro-growth phenotypes in *SMARCA4* mutant tumors. Finally, we show that the combination of TEAD inhibitors synergizes with YD23 to induce profound tumor growth inhibition. In conclusion, our study provides a mechanistic basis for the anti-tumor action of SMARCA2 degraders and introduces a novel combination strategy for future clinical development against a genetically defined subtype of lung cancer with dismal prognosis.

#3305 Golcadomide (CC-99282) is a novel CELMoD® agent with antiproliferative activity and combinatorial potential in disease models of chronic lymphocytic leukemia.

A. Lopez-Girona[1], M. Jimenez-Nunez[2], D. Sobradillo[2], S. Carrancio[1], P. Janardhanan[1], G. Deb[1], L. Groocock[1], D. Pierce[1], N. Bence[1], M. Rolfe[1]; [1]Bristol Myers Squibb Company, San Diego, CA, [2]Bristol Myers Squibb Company, Seville, Spain

Chronic Lymphocytic Leukemia (CLL) is an adult leukemia characterized by the accumulation of incompetent B lymphocytes expressing CD19, CD20, CD23, and CD5. Current therapies include chemotherapy and combination with targeted therapies such as ibrutinib (Bruton's tyrosine kinase inhibitor), venetoclax (BCL2 inhibitor), and obinutuzumab (anti-CD20). The tumor microenvironment promotes CLL development and drug resistance. Golcadomide (GOLCA, CC-99282) is an oral cereblon E3 ligase modulator (CELMoD®) agent with immunomodulatory and tumor cell-autonomous activities under clinical investigation for R/R non-Hodgkin lymphomas and CLL/SLL. Here we investigated the effect of GOLCA on inhibiting proliferation and inducing apoptosis of CLL preclinical models by degrading Ikaros and Aiolos. We also studied its combination with other anti-CLL agents. A panel of 10 CLL cell lines and 15 primary CLL patient samples were used to assess efficacy of GOLCA alone or in combination with ibrutinib (Ibru), venetoclax (Ven), and obinutuzumab (Obi). Primary CLL cells were grown ex vivo in a co-culture system with CD40L expressing fibroblasts designed to mimic the CLL lymph node microenvironment. Substrate degradation, viability, cell cycle and immunophenotyping were assessed by flow cytometry. GOLCA showed potent in vitro antiproliferative activity on 6 out of 10 CLL cell lines, including those with high-risk features, with IC_{50} of 1-20 nM. It also inhibited CLL stimulated cell proliferation and induced apoptosis in all evaluated patient samples in the co-culture system, with low to sub-nanomolar IC_{50}, independent of IGHV mutation status and other chromosomal characteristics. Cell-cycle analysis confirmed inhibition of proliferation in the 5 patient samples evaluated after 3 days of treatment with GOLCA, with a dose-dependent decrease in the fraction of cells in the S phase. GOLCA also demonstrated degradation of the proximal substrates Ikaros and Aiolos in tumor and T cells from CLL patient samples. In combination with Obi, Ven, and Ibru, GOLCA led to synergistic or additive tumor cell toxicity in most patient samples evaluated, suggesting potential clinical benefit of these targeted agent combinations. Additive tumor toxicity was observed in two out of four patient samples when GOLCA was combined with Ibru. We have previously demonstrated that GOLCA induces immune activation in T cells from healthy donor PBMCs. In co-cultures of CLL PBMCs and CD40L-expressing fibroblasts, GOLCA increased T cell numbers and activation characteristics. Ven inhibited this immune activation, while Obi or Ibru maintained the immune activation. Collectively, these findings suggest that GOLCA, alone or in combination with targeted agents, may produce clinical benefit in CLL patients.

#3306 RGT-M001, a first-in-class small molecule mRNA degrader of the oncogenic transcription factor c-Myb, demonstrated remarkable single agent anti-tumor efficacy in cancer patient-derived xenograft model.

N. Lu[1], **P. Soulard**[1], K. Li[1], H. Sadlish[1], C. Yates[1], X. Gu[1], I. Kays[1], J. Lee[1], S. Hasson[1], Z. Weng[2], S. Xi[1], T. Wager[1];
[1]Rgenta Therapeutics, Inc., Woburn, MA, [2]University of Massachusetts Medical School, Worcester, MA

Dysregulated transcription factors (TFs) represent a unique class of drug targets that drive aberrant gene expression programs involved in the major hallmarks of cancers. However, developing drug-like small molecules targeting TF proteins for clinical purposes has proven to be extremely challenging. Here, we present a novel and innovative approach to degrade the RNA transcript of the master oncogenic transcription factor C-MYB, thereby preventing its undesirable expression, using potent and orally available small molecules.

C-MYB is a transcription factor that regulates differentiation and proliferation programs in normal cells, including hematopoietic, stem and epithelial cells. In numerous cancer types, such as adenoid cystic carcinoma (ACC), leukemia, colorectal cancer, and breast cancer, C-MYB is a well-established oncogenic transcription factor, overactivated via different mechanisms, including chromosomal translocations and gene amplification.

Here, we leveraged our integrative RNA-targeting platform to identify and validate actionable cryptic exon target sites in the human *C-MYB* gene. We identified RGT-M001, a potent small molecule that can selectively induce the inclusion of the cryptic exon into the final *C-MYB* transcripts, resulting in a robust decrease of *C-MYB* canonical transcripts and C-MYB protein in cells. In a functional assay, we demonstrated that RGT-M001 has potent cell-killing activity against a large panel of cancer cell lines overexpressing *C-MYB* (EC50 ~ 20 - 300nM), while sparing normal cells. To confirm RGT-M001's on-target effect, we demonstrated a robust correlation between RGT-M001 cell-killing activity and the knockdown of C-MYB RNA and protein.

We further investigated the anti-tumor activity of RGT-M001 in an ACC patient-derived xenograft (PDx) mouse model harboring *C-MYB-NFBI* fusion. Recurrent or metastatic ACC is a malignant neoplasm of predominantly salivary gland origin for which effective approved therapies are lacking; the best reported ORR being 15.6% for lenvatinib. As a single agent, RGT-M001 reduced in vivo *C-MYB* transcript levels by >80% at peak drug exposure and induced a remarkable tumor growth inhibition response (~70% TGI) in the ACCX11 PDx mouse model, surpassing the therapeutic benchmark Lenvatinib (40% TGI). Importantly, the RGT-M001 regimen was well tolerated. Finally, we showed that the combination of RGT-M001 with the Notch Inhibitor AL-101 resulted in complete inhibition of tumor growth.

In conclusion, these data demonstrate that small molecules targeting RNA are a safe and effective approach to address previously undruggable protein targets. Down-regulation of *C-MYB* by our RNA-targeting small molecules is an attractive therapeutic strategy to treat ACC and other cancers driven by *C-MYB* dysregulations.

#3307 c-Met targeting chaperone-mediated protein degrader for therapeutic intervention in NSCLC.

H. Chae[1], J. Kim[2], S. Lee[1], H. Yoo[1], H.-K. Kim[2], Y.-J. Yu[2];
[1]Oncozen Co.,Ltd., Seoul, Korea, Republic of, [2]Jeonbuk National University, Jeonju, Korea, Republic of

The interaction between E3 ligases and chaperones is crucial for proteostasis, regulating more than 10% of total proteasomes and over 30% of human E3 ligases (Kevei, 2017). Chaperones also can recognize their substrates and direct them to degradation by the ubiquitin-proteasome system (UPS). Developing a targeted protein degradation (TPD) technology that utilizes these advantageous attributes of chaperones, termed chaperone-mediated protein degradation (CMPD) technology, would broaden the range of disease-causing target proteins and would efficiently degrade them by recruiting various intracellular E3 ligases through interaction with chaperones, compare to other TPD approaches. The c-mesenchymal-epithelial transition (c-MET) is recognized as primary cause of drug-resistance to EGFR inhibitors in non-small cell lung cancer (NSCLC). Herein, to degrade the c-MET, we synthesized bifunctional small molecule compound inducing c-MET and chaperones in proximity, termed CMPD-MET degrader, and evaluate it in MET-mutant NSCLC cell lines and mouse xenograft models.
The efficacy and potency of CMPD-MET degrader were assessed using H596 and H1437 cells *in vitro*. Cell proliferation was measured using MTT assay and c-Met degradation assay was conducted, along with the examination of proteasome-dependent degradation via western blot. An *in vivo* H596 xenograft model gauged impact of CMPD-MET degrader via I.P. administration.
In NSCLC with MET Exon 14 skipping mutation cell line H596 and H1437, treatment a OZD-MET degrader resulted inhibition of cell proliferation with IC_{50}< 5 μM and subsequent proteasome-dependent c-MET degradation with DC_{50} ranging from 4-6 μM for 24h. The degradation of c-MET levels significantly induced by OZD-MET degrader, especially, the c-Met was degraded by 70.4% and 51.7% at 5 μM for 24h in H596 and H1437 cells, respectively. Also, OZ-MET degrader effectively suppressed c-MET mediated signaling and showed cleavage of PARP-1 in a dose-dependent manner. OZD-MET degrader induced selective degradation of c-MET showing at least more than about 5-fold selectivity over other chaperones-regulated client proteins.In the H596 xenograft model, OZD-MET degrader was administered in 5 dosage groups (minimum dose is 2.5 mg/kg) resulted in dramatic reduction in tumor size compared to the vehicle-treated group. Remarkably, administration of OZD-MET degrader revealed more than 90% degradation of c-Met in tumor tissues compared to the vehicle groups via western blots and fluorescence image. In contrast, c-MET inhibitor treated group showed no effect on degradation of c-MET in tumor tissues.
In summary, we developed a novel c-Met targeting chaperone-mediated protein degrader, showed highly potent and selective proteasome-dependent c-MET degradation and notable inhibition of tumor size in xenograft models. These results provide a strong foundation for further evaluation in clinical trials.

#3308 A selective FGFR1/2 degrader overcomes endocrine resistance in ER+/*FGFR1-amplified* and*FGFR1/2*-mutant breast cancer.

Y. Uemoto[1], C.-C. Lin[1], B. Wang[2], D. Ye[1], E. Bikorimana[1], A. Servetto[3], L. Formisano[3], F. Napolitano[1], R. Chica Parrado[1], S. Mendiratta[1], C. Chen[2], A. B. Hanker[1], C. L. Arteaga[1];

[1]Harold C. Simmons Comprehensive Cancer Center, Dallas, TX, [2]UT Southwestern Medical Center, Dallas, TX, [3]University of Naples "Federico II", Naples, Italy

FGFR1 amplification and *FGFR1/2* activating mutations are associated with resistance to antiestrogens in the estrogen receptor-positive (ER+) breast cancer. In this study, we investigated selective degradation of FGFR1/2 using the proteolysis-targeted chimera (PROTAC) DGY-09-192 as a novel therapeutic strategy to overcome resistance to antiestrogens in ER+ breast cancers harboring *FGFR1*-amplification or *FGFR1/2* activating mutations.

Treatment of ER+/*FGFR1*-amplified CAMA1 and MDA-MB-134 breast cancer cells with DGY-09-192 degraded FGFR1 and suppressed phosphorylation of FGFR1 and its downstream targets FRS2, AKT, and ERK1/2. DGY-09-192-mediated FGFR1 degradation were rescued by a proteasome inhibitor, MG132, suggesting that the antitumor activity of DGY-09-192 depends on proteasome-mediated degradation. Growth of CAMA1 and MDA-MB-134 cells were modestly inhibited by single-agent DGY-09-192 or the ER degrader fulvestrant, but the combination completely arrested cell proliferation. Treatment of female NSG mice bearing established ER+/*FGFR1*-amplified patient-derived xenografts (PDXs) with single-agent DGY-09-192 (40 mg/kg/day, i.p.) or fulvestrant (5 mg/week, s.c.) delayed tumor growth, respectively. However, treatment with DGY-09-192 + fulvestrant induced tumor regression in all mice (n=7), suggesting that a FGFR1 degrader plus an antiestrogen can serve as an effective therapeutic combination for ER+/*FGFR1*-amplified breast cancer.

Next, we examined whether ER+ breast cancer cells harboring *FGFR1/2* hotspot mutations are sensitive to DGY-09-192. Ectopic expression of $FGFR1^{N546K}$, the most common *FGFR1* mutation in breast cancer, activated FGFR1 signaling and induced resistance to fulvestrant compared to MCF7 cells transduced with wild-type *FGFR1*. EFM-19 cells harboring $FGFR2^{K659E}$ exhibited resistance to fulvestrant *in vitro.* Treatment of both cell lines with DGY-09-192 degraded the mutant $FGFR1^{N546K}$ and $FGFR2^{K659E}$, respectively, blocked phosphorylation of the FGFR downstream targets, and markedly inhibited cell proliferation. These results suggest that PROTAC-mediated degradation of FGFR1/2 effectively blocks the growth of ER+, F*GFR1/2*-mutant breast cancers resistant to antiestrogens.

Conclusions: DGY-09-192 induced FGFR1/2 degradation and blocks FGFR downstream signaling in ER+/*FGFR1*-amplified and *FGFR1/2*-mutant breast cancer cells. The combination of DGY-09-192 and fulvestrant exhibited superior antitumor effects relative to each monotherapy alone *in vitro* and/or *in vivo*. Therefore, PROTAC-mediated FGFR1/2 degradation represents a promising therapeutic strategy for ER+ breast cancers harboring *FGFR1*-amplification or *FGFR1/2* activating mutations.

#3309 Discovery of potent and selective bivalent CDK2 degraders that demonstrate activity in CCNE1^{amp} driven tumors.

A. Gerson-Gurwitz, P. Yang, **S. Fish**, G. Blanco, H. Gao, K. Hayashi, M. Hocker, A. Jamborcic, A. Richters, M. E. Spalding, J. Toth, D. Tran, L. Yang, S. You, A. Burritt, A. Campos, G. Parker, K. Freeman-Cook, P. A. Thompson, S. Bailey;
Plexium, San Diego, CA

Introduction: The Cyclin-Dependent Kinases (CDKs) with their cyclin binding partners, are associated with cell cycle progression and transcriptional regulation. Targeting CDKs is a key oncology therapeutic strategy with CDK4/6 inhibitors demonstrating significant clinical benefit in HR^{+}/HER2^{-} metastatic breast cancer, the most prevalent subtype. However, 30% of patients develop acquired resistance in the clinic with cyclin E1 (CCNE1) amplification/overexpression and CDK2 activation implicated as a major resistance mechanism to CDK4/6i breast cancer therapy. Additionally, CCNE1/CDK2 activation has also been associated with poor prognosis in ovarian and endometrial cancers. Selective targeting of CDK2 using small molecule inhibitor-based approaches have recently advanced into the clinic. Targeted protein degradation of CDK2 provides an alternative strategy that has the potential to eliminate the activity of the CCNE1/CDK2 complex, as well as CDK2 complexed with other cyclins, including cyclin A, and provide improved clinical benefit.

Results: Discovery efforts at Plexium have identified CDK2 bivalent degraders that consist of a CDK2-binding moiety, a linker and a high affinity cereblon-binding ligand. Cereblon binding potency was found to correlate with potent and deep degradation of CDK2. Degradation was blocked in the presence of a proteasome inhibitor as well as in a cereblon knock-out cell line, confirming that CDK2 degradation is mediated by the ubiquitin proteasome system and through engaging cereblon. Proteome-wide analysis demonstrated that CDK2 was selectively depleted without significantly modulating other CDKs or known cereblon neo-substrates. Selective degradation was achieved despite lack of selectivity for binding/inhibition of other CDKs and was confirmed to be dependent on the formation of a CRBN-CDK2 ternary complex. Dose dependent CDK2 degradation resulted in dose dependent inhibition of Rb phosphorylation, cell cycle arrest, senescence-associated phenotypes and antiproliferative activity in CCNE1 amplified cancer cell lines. The *in vitro* data was used to evaluate the PK/PD drug exposure-response relationship *in vivo* and deep CDK2 degradation was demonstrated both *in vitro* and *in vivo*.

Conclusions: These data provide validation for CDK2 degradation as a therapeutic approach. Potent and selective CDK2 bivalent degraders were exploited as tools for studying the sensitivity of CCNE1 amplified tumor models to CDK2 degradation and dependence on E3 ligase. This proof-of concept study supports Plexium's current approach of discovering novel CDK2 molecular glue degraders for the treatment of CDK4/6 inhibitor-naïve and -resistant HR^{+}/HER2^{-} breast cancer, and CCNE1 amplified ovarian and endometrial cancers.

KRAS mutations represent one of the most common genetic alterations in many cancers including non-small cell lung cancer (NSCLC), pancreatic ductal adenocarcinoma (PDAC), and colorectal cancer (CRC). While Sotorasib and Adagrasib, KRAS G12C inhibitors, have received approval, they exhibit limited responsiveness in clinical trials and are not applicable to various other KRAS mutation types. SOS1 (Son of Sevenless 1) functions as a guanine nucleotide exchange factor (GEF) on RAS, facilitating the transition of inactive GDP-bound RAS to its active GTP-bound state. In addition, SOS1 plays a pivotal role in negative feedback by actively contributing to the reactivation of ERK during treatment with inhibitors targeting the RTK/RAS/MAPK pathway. Inhibiting SOS1, which impedes the reactivation of ERK, has the potential to enhance the effectiveness of inhibitors targeting the RTK/RAS/MAPK signaling cascade and prevent the emergence of resistance mechanisms via H-RAS and N-RAS bypass pathways. Therefore, combining the inhibition of SOS1 with inhibitors targeting the RTK/RAS/MAPK pathway may enhance outcomes and mitigate relapse associated with observed resistances. Here, we present the discovery of a potent, selective, and orally bioavailable small molecule SOS1 inhibitor that effectively disrupts the interaction between SOS1 and RAS. It has demonstrated remarkable synergy effects with RTK/RAS/MAPK pathway inhibitors, significantly impeding the growth of tumors carrying KRAS or EGFR mutations *in vivo*. Overall, our development candidate has demonstrated significant therapeutic potential in combination with inhibitors targeting the RTK/RAS/MAPK pathway for cancers bearing activating mutations in this pathway.

#3314 Molecular profiling of covalent menin inhibitor, BMF-219, in KRAS-mutated solid tumors.

A. A. Momin, T. Rughwani, N. Tanataweethum, K. Mordec, R. Lin, M. Chin, D. Lu, P. Somanath, M. Balakrishnan, T. Butler;
Biomea Fusion, Inc., Redwood City, CA

Menin is an epigenetic protein that drives oncogenic function through transcriptional control directed by its various cofactors such as MLL1 (KMT2A) and MYC. BMF-219 is a covalent menin inhibitor currently under investigation in a dose-finding study evaluating safety and tolerability in adults with KRAS-driven Non-Small Cell Lung Cancer (NSCLC), Pancreatic Adenocarcinoma (PDAC), or Colorectal Cancer (CRC) (NCT NCT05631574). We previously showed that BMF-219 induces effective killing of solid tumor cells irrespective of their KRAS mutation subtype (AACR 2022, abstract 2665) and perturbs genomic binding of MYC and its binding partner MAX, in acute leukemia cells (ASH Abstract 2021). To probe into the underlying mechanism and the potential pathways engaged, BMF-219-induced effects were evaluated in CRC, PDAC and NSCLC cell lines. Cells treated with relevant concentrations of BMF-219 versus vehicle were assessed for menin and MYC protein levels, along with treatment effects on cell cycle and induction of apoptosis. In addition, bulk RNA-seq analysis was performed on the cell lines treated with BMF-219 in a time course study. BMF-219 induces a dose-dependent decrease in menin protein levels in the solid tumor cell lines tested following 24 hours treatment, with the least impact observed in a KRAS WT cell line. The effect of BMF-219 on c-MYC protein levels were variable and highly cell-type dependent, with the CRC metastatic tumor cell line SW620 exhibiting the highest reduction. Differential expression (DE) analysis of bulk RNA-seq data comparing BMF-219 treated versus vehicle treated cells, identified significant alterations in transcript abundance at 6- and 24-hours post treatment. The magnitude of change in the transcript abundance showed a dose-dependent response without significant alteration of a panel of housekeeping genes. GSEA analysis identified pathways associated with cell cycle, cell division and MYC-regulated were significantly differentially expressed across multiple cell lines. These data suggest similar molecular pathways are altered by BMF-219 across KRAS-mutated solid tumor cells. Additional insights into key pathways and modulators will be reported. Collectively, these data suggest that the functional pathway alterations induced by BMF-219 in solid tumor cells are likely pan-KRAS and are similar across different solid tumor indications. This provides further support for advancing the clinical investigation of BMF-219 in KRAS-driven solid tumors.

#3315 Preclinical studies of TSN1611, a potent, selective, and orally bioavailable KRAS^{G12D} inhibitor.

E. Shang, B. Zhong, T. Zhang, C. Dong, S. Ma, A. Yang, Z. Jia, R. Zheng, J. Li, H. Fu, L. Lai;
Tyligand Bioscience (Shanghai), Ltd., Shanghai, China

Background: KRAS mutations are the most frequently encountered driver oncogene, involved in ~25% of all human cancers [1,2]. KRAS^{G12D} is the predominant KRAS mutation isoform, detected in approximately 35% of pancreatic cancer, 13% of colorectal cancer, and 5% of NSCLC [3]. Compared to KRAS^{G12C}, targeting KRAS^{G12D} has proven to be more challenging since the target protein lacks a reactive amino acid residue for irreversible inhibitory modification by a ligand. Herein, we disclose TSN1611, a potent and selective KRAS^{G12D} inhibitor, which possesses favorable oral PK profiles and demonstrates significant *in vitro* and *in vivo* anti-tumor activity in various KRAS^{G12D}-mutant models.

Method: Biochemical HTRF assay was used to measure the inhibition of TSN1611 to both GDP-bound and GTP-bound state of KRAS^{G12D}. Biophysical SPR method was used to directly measure the binding of TSN1611 to GDP-bound KRAS^{G12D} and KRAS^{WT}. Cell based activities were evaluated in a series of *in vitro* cell proliferation assay utilizing Ba/F3 cells engineered with KRAS^{G12D} or non-KRAS^{G12D} mutations and tumor cell lines harboring KRAS^{G12D} mutation. Human cancer cell-derived xenograft models of HPAC (pancreatic) and GP2D (colorectal) were used to evaluate its *in vivo* antitumor effect. *in vitro* and *in vivo* PK studies were performed in mouse, rat, and dog. Systematic nonclinical safety evaluations, including safety panel screen testing, safety pharmacology studies, and repeat-dose toxicity studies were carried out to assess its preliminary toxicity profile.

Results: TSN1611 inhibited both active (GTP-bound) and inactive (GDP-bound) forms of KRAS^{G12D} protein at IC_{50} 1.23 and 1.49 nM, respectively; the K_D value of its direct binding to KRAS^{G12D} protein is 1.93 pM in SPR assay. TSN1611 demonstrated potent anti-proliferation activity against several tumor cell lines harboring KRAS^{G12D} mutation, and excellent selectivity over cells of NRAS, HRAS, and other KRAS isoforms. It also showed dose-dependent anti-tumor efficacy in GP2D and HPAC models. Mechanism of action studies concluded that the antitumor effect of TSN1611 is resulted from its effective inhibition of KRAS signaling pathway. Oral bioavailability and safety profile across multiple species supported its further development.

Conclusion: TSN1611 is a selective KRAS^{G12D} inhibitor. It exhibited excellent selectivity and activity both *in vitro* and *in vivo*; it demonstrated favorable physicochemical properties, oral PK profiles, and brain penetration potential; it also showed acceptable margins of safety. The preclinical data supports further development. Pending regulatory submission and review, the phase I/II study is planned to start in H1 of 2024.

#3316 LY3962673, an oral, highly potent, mutant-selective, and non-covalent KRAS G12D inhibitor demonstrates robust anti-tumor activity in KRAS G12D models.

X. Gong[1], H. Gao[1], M. H. Bender[1], W. Ming[1], Y. Zhang[1], T. R. Stewart[1], C. Yu[2], W. Xu[2], A. X. You[2], W. Bian[2], B. Li[1], T. Wang[1], H. Bian[1], M. Tandon[1], A. Capen[1], R. N. Cavitt[3], B. D. Anderson[3], W. Bocchinfuso[3], A. Klippel[4], C. Iyer[1],
[1]Loxo@Lilly, Indianapolis, IN, [2]Loxo@Lilly, Shanghai, China, [3]Eli Lilly and Company, Indianapolis, IN, [4]Loxo@Lilly, New York, NY

KRAS G12D mutations are activating oncogenic events that occur in approximately 35%, 13%, and 4% of pancreatic, colorectal, and non-small cell lung cancers, respectively, and less commonly in other cancers. We previously demonstrated that LY3962673 is a highly potent inhibitor of KRAS G12D and is selective against wild-type (WT) KRAS in mutant -cell lines and -*in vivo* models. Here, we describe the mechanism by which LY3962673 inhibits KRAS G12D and report a more comprehensive evaluation of LY3962673 activity across a panel of genetically and histologically diverse cancer cell lines, as well as in multiple patient-derived xenograft (PDX) models.

LY3962673 is a non-covalent KRAS G12D inhibitor with high affinity binding to KRAS G12D-GDP (Kd 0.071 nM) compared to KRAS G12D-GTPγS (Kd 26.7 nM). In a panel of cancer cell lines with KRAS G12D mutations, non-G12D mutations or KRAS WT, LY3962673 selectively suppressed MAPK signaling and inhibited the growth of KRAS G12D mutant cancer cells while sparing KRAS WT and non-G12D mutant cells. Sensitivity to LY3962673 varied among the KRAS G12D-mutant cells tested, suggesting that not all cell lines share the same dependence on KRAS G12D for their growth and survival. Furthermore, in multiple KRAS G12D-mutant PDX models representing diverse tumor types, LY3962673 demonstrated anti-tumor activities, ranging from tumor growth inhibition to robust tumor regression. LY3962673 also showed enhanced efficacy when combined with other anti-cancer agents.

Taken together, the findings underscore the potential of LY3962673 as a monotherapy or in combination with other anti-cancer agents, as a promising oral therapeutic option for a range of cancer types with KRAS G12D mutations.

#3317 KRAS^{multi} inhibitor BI 3706674 shows efficacy in KRAS-driven preclinical models of cancer that supports clinical testing in patients with tumors harbouring KRAS^{G12V} mutations and KRAS wild-type amplifications.

A. Tedeschi[1], D. H. Peng[2], F. Schischlik[1], L. Herdeis[1], O. Schaaf[1], V. Santoro[1], D. Gerlach[1], F. Savarese[1], J. Lipp[1], C. Haslinger[1], F. Rocchetti[1], J. Popow[1], H. J. Huber[1], B. Wilding[1], M. Treu[1], J. Fuchs[1], J. Broeker[1], T. Wunber[1], M. Gmachl[1], K. Rumpel[1], M. Rees[3], M. Ron[3], J. Roth[3], M. Williams[2], C. Deckard[2], V. Ramamoorthy[2], J. R. Daniele[2], J. A. Ajani[2], F. Meric-Bernstam[2], S. Kopetz[2], M. Kim[2], D. L. Gibbons[2], C. P. Vellano[2], J. R. Marszalek[2], T. P. Heffernan[2], D. McConnell[1], M. Pearson[1], N. Kraut[1], D. Rudolph[1];

[1]Boehringer Ingelheim RCV GmbH & Co KG, Vienna, Austria, [2]The University of Texas MD Anderson Cancer Center, Huston, TX, [3]Broad Institute of MIT and Harvard, Cambridge, MA

Alterations in KRAS are a main cancer driver. Amplifications of the KRAS wild-type (wt) allele account for ~7% of all KRAS-driven cancers and are frequent in gastric (~5%), esophageal (~13%) and gastroesophageal junction cancers (~12%). KRAS^{G12V} mutations account for ~28% of pancreatic cancers, 9% of colorectal cancers and 6% of lung adenocarcinoma. There is an urgent medical need to identify targeted therapies for these frequent KRAS alterations. Herein, we describe BI 3706674, a novel, potent and orally bioavailable small molecule inhibitor of the KRAS oncogene for clinical testing in patients with tumors harboring KRAS^{G12V} mutations and KRAS wild-type amplifications. BI 3706674 binds non-covalently to multiple KRAS mutant alleles, including the KRAS wt allele, in the GDP-bound state and thereby disrupts oncogenic signaling. Importantly, BI 3706674 is highly selective for KRAS vs HRAS or NRAS, and it is therefore expected to be well-tolerated in normal tissues. In two large cancer cell line panels (PRISM and Horizon), BI 3706674 shows sensitivity across a wide range of KRAS alleles (KRAS wt amplifications and KRAS mutations e.g., G12A/C/D/V, G13D and Q61H). The strongest sensitivity was observed for cell lines with KRAS wt amplifications (relative copy number (CN) of > 10) followed by cell lines with KRAS^{G12V} mutations along with significant pharmacodynamic (PD) biomarker modulation (e.g., down-regulation of DUSP6 mRNA). *In vivo*, BI 3706674 was well-tolerated and showed dose-dependent efficacy in cell line-derived and patient-derived xenograft models of human gastric cancer with KRAS wt CN > 10 and diverse tumor types with KRAS^{G12V} mutations. A twice daily oral dose of 30 mg/kg induced significant tumor regression and PD biomarker modulation. Combination of BI 3706674 with standard of care therapies and novel agents are being tested in preclinical models to guide clinical development. Results of the ongoing pre-clinical analysis will be shared. A Phase I clinical trial is in preparation in patients with advanced solid cancers harboring KRAS^{G12V} mutations and KRAS wt amplifications to evaluate safety, tolerability, pharmacokinetic and pharmacodynamic properties, and efficacy of BI 3706674.

#3318 GFH375 (VS-7375): An oral, selective KRAS G12D (ON/OFF) inhibitor with potent anti-tumor efficacy.

Feng Yan[1], Tao Jiang[1], Tao Liang[1], Lijian Cai[1], Leitao Zhang[1], Xiaoming Xu[1], Yanhui Zhao[1], Xiaoling Lan[1], Xiaohui Zhang[1], Meng Liu[1], Qiang Liu[1], Jinting Gao[1], Fubo Xie[1], Xueyan Gao[1], Li Wang[1], Jingyang Zhang[1], Hongcan Ren[1], Dong Liu[1], Siyuan Le[1], Lili Tang[1], Silvia Coma[2], Yaofeng Cheng[2], Nathan Sanburn[2], Jonathan A. Pachter[2], **Fusheng Zhou**[1], Jiong Lan[1], Qiang Lu[1]

[1]Genfleet Therapeutics, Shanghai, China, [2]Verastem Oncology, Needham, MA

Background: KRAS is the best-known oncogene but had long been considered ‘undruggable’ until the approval of the first KRAS G12C inhibitor sotorasib in 2021. However, most current clinical-stage KRAS inhibitors target the KRAS G12C mutation. Inhibitors of other KRAS mutants such as KRAS G12D, the most frequent KRAS mutation in human cancer, are needed for patients. We have developed GFH375 (VS-7375), an oral, selective KRAS G12D inhibitor targeting both “ON” (GTP-bound) and “OFF” (GDP-bound) states of KRAS proteins. The in vitro potency, selectivity, and in vivo efficacy of monotherapy and combination therapy with avutometinib, a unique RAF/MEK clamp, were evaluated in preclinical studies.

Methods: Biochemical and cellular assays were used to investigate inhibition to KRAS cycling and signaling. CellTiter-Glo assay was performed to determine the effects on proliferation of tumor cell lines. Several KRAS G12D CDX tumor models were employed to study the in vivo pharmacodynamic and anti-tumor effects.

Results: GFH375 inhibited both nucleotide exchange on GDP-bound KRAS G12D and interaction between GMPPNP-bound KRAS G12D with RAF1 with single-digit nanomolar IC_{50} values. GFH375 suppressed phosho-ERK1/2 (p-ERK) level with sub-nanomolar IC_{50} values and potently inhibited cell proliferation across a panel of KRAS G12D tumor cell lines. GFH375 showed high selectivity for KRAS G12D relative to non-G12D KRAS variants, KRAS wild type cells, and NRAS, HRAS, or BRAF mutated cells. Following a single oral dose, GFH375 produced deep and durable inhibition of p-ERK in KRAS G12D CDX tumors. GFH375 demonstrated dose-dependent anti-tumor activity with tumor regressions at 10 or 30 mg/kg given orally twice daily in multiple KRAS G12D PDAC and CRC CDX tumor models. GFH375 also showed strong anti-tumor efficacy in an intracranial KRAS G12D tumor model starting as low as 10 mg/kg orally twice daily. Strong synergy between GFH375 and avutometinib was observed in vitro and was validated in vivo as anti-tumor activity of GFH375 was further enhanced by avutometinib.

Conclusions: GFH375 is a highly potent and selective orally active inhibitor of KRAS G12D (ON/OFF) and demonstrated promising anti-tumor activity in multiple KRAS G12D tumor models. GFH375 was also effective in an intracranial tumor model. GFH375 showed strong synergy with avutometinib in vitro and in vivo. GFH375 is currently in IND-enabling development in preparation for clinical studies of monotherapy and potentially in combination with other agents for patients with KRAS G12D mutant tumors.

#3319 The MTA-cooperative PRMT5 inhibitor, MRTX1719, demonstrates increased anti-tumor activity in combination with KRAS mutant-selective inhibitors in *MTAP* del,*KRAS*-mutant cancers.

L. Waters, R. Aranda, X. Helu, L. Vegar, K. Moya, A. Calinisan, A. Hebbert, J. Hallin, D. Vanderpool, D. M. Briere, J. G. Christensen, **P. A. Olson**, L. D. Engstrom;
Mirati Therapeutics, San Diego, CA

MRTX1719 is an MTA-cooperative PRMT5 inhibitor that leverages the increased concentration of the metabolite MTA in cancer cells harboring a homozygous deletion of the *MTAP* gene (*MTAP* del) under investigation in clincial trials. MRTX1719 preferentially binds to the PRMT5•MTA complex to selectively inhibit PRMT5, an essential gene for all cells, in *MTAP* del cancer cells while sparing PRMT5 activity in normal *MTAP*-wildtype cells. *MTAP* del occurs in ~10% of all cancers, and these patients exhibit remarkably poor survival. Among pancreatic cancer, *MTAP* del occurs in ~ 25% of patients and of these ~30% have co-occurring *KRAS* G12D mutations. In addition, ~15% of lung adenocarcinoma patients harbor *MTAP* del and of these ~13% harbor *KRAS* G12C. While recently approved KRAS G12C mutant selective inhibitors demonstrate anti-tumor activity, strategies to address drug resistance and maximize clinical benefit are warranted. Combination of MRTX1719 with adagrasib or the KRAS G12D inhibitor MRTX1133 in CDX models harboring both a *KRAS* mutation (G12C or G12D) and homozygous *MTAP* deletion resulted in increased anti-tumor activity compared to either single agent. This includes the pancreatic KP4 model in which initial tumor regression in response to single agent MRTX1133 was observed, followed by adaptative resistance and tumor progression with monotherapy while co-administration with MRTX1719 continued to result in marked tumor regression. Mechanistically, combination treated animals demonstrated strong inhibition of both PRMT5 and RAS pathway signaling and combinatorial targeting of these pathways converged on enhanced inhibition of RB-1 phosphorylation. We also characterized this combination treatment in the context of resistance to KRAS selective inhibitors or MRTX1719 to evaluate the benefit of combination over sequential treatment. Finally, an *NF1* mutant, *MTAP* del malignant peripheral nerve sheath tumor (MPNST) PDX model was treated with MRTX1719, the SOS1 inhibitor MRTX0902, or the combination, and a similar increase in anti-tumor activity was observed in the combination treatment compared to either monotherapy alone. These results suggest that the combination of an MTA-cooperative PRMT5 inhibitor with a KRAS mutant selective or KRAS pathway inhibitor may lead to deeper and more durable responses in *MTAP* del cancer patients with co-alterations in the KRAS pathway.

#3320 *In vivo* and *in vitro* experience with novel direct Pan-RAS inhibitors.

Tariq Arshad[1], Howard Donninger[2], Goeff Clarke[3], Joe Burlison[3], Rob Monsen[3], Mike Sabo[3]

[1]Qualigen Therapeutics, Carlsbad, CA,[2]Dept. Pharmacology and Toxicology University of Louisville,, University of Louisville, Louisville, KY,[3]University of Louisville, Louisville, KY

RAS oncogenes are frequently activated by mutations in human cancer, where they act as driving elements of the disease. Mutation rates can range from ~25% of Non Small Cell Lung cancers to over 90% of pancreatic cancers. RAS proteins can also be hyper-activated to drive cancer at a significant frequency in the absence of RAS gene mutations when their protein regulatory systems are damaged. Thus, RAS may be the most frequently activated oncoprotein in cancer. We have developed a series of novel, direct, RAS inhibitors with a unique binding site on RAS. The binding of the agents alters the structure of the RAS effector loop and blocks the association with RAS downstream effectors. We used in silico library screening followed by Medicinal Chemistry optimization to develop the compounds. We have validated the agents using Microscale Thermophoresis and NMR to quantify binding to recombinant RAS protein. We have used mutant and wild type RAS driven tumor cell lines in 3D growth and protein-based RAS signaling assays to quantify and characterize the action of the family of inhibitors. We have used xenograft assays to demonstrate compound anti-tumor activity in RAS driven cell lines and pdx systems. We have identified compounds that can bind mutant and wild type K, H, N and M-RAS. We can suppress the association of mutant and wild type RAS protein with its effector RAF-1 in treated cells. The compounds can suppress 3D growth of mutant or wild type RAS driven tumor cell lines and repress tumor development in vivo. The compound family bind to a different site than either clinical agent AMG-510 (K-RAS G12C specific) or MRTX-1133 (K-RAS G12D specific). They exhibit distinct RAS signal inhibition patterns compared to these agents. They can also co-operate with the clinical agents and reduce drug resistance effects.

#3321 KRAS^{multi} inhibitor BI 3706674, an orally bioavailable, direct inhibitor of diverse oncogenic KRAS variants drives tumor regression in KRAS^{G12V}-driven preclinical models.

David Hwa Peng[1], Antonio Tedeschi[2], Lorenz Herdeis[2], Otmar Schaaf[2], Fabio Savarese[2], Francesca Rocchetti[2], Johannes Popow[2], Heinrich J. [1]TRACTION, UT MD Anderson Cancer Center, Houston, TX, [2]Boehringer Ingelheim, Vienna, Austria

Alterations of KRAS are observed in approximately one in seven of all human tumors, making KRAS one of the most prevalent oncogenic drivers. Gain-of-function missense mutations in KRAS, leading to its aberrant activation, are found in ~90% of pancreatic cancer, ~40% of colorectal cancer and ~30% of lung adenocarcinoma, with KRAS^{G12V} mutations accounting for ~28%, 9% and 6% of the cases, respectively. The poor outcome associated with these tumor types as well as the lack of targeted inhibitors for the KRAS^{G12V}-mutant allele calls for the urgent need to identify therapies able to effectively address this allele. BI 3706674 is a novel, potent and orally available small molecule inhibitor of the KRAS oncogene. BI 3706674 binds non-covalently to multiple KRAS mutant alleles, including KRAS^{G12V}, in the GDP-bound state, and blocks downstream oncogenic signalling. Here, we show that BI 3706674 has a strong anti-proliferative activity in a panel of KRAS^{G12V}-mutant cancer cell lines *in vitro*, along with significant pharmacodynamic (PD) biomarker modulation (including inhibition of ERK1/2 phosphorylation and down-regulation of DUSP6 mRNA). *In vivo,* a twice daily oral dose of 30 mg/kg was well tolerated, while inducing tumour regression in several mutant KRAS^{G12V} patient-derived xenograft (PDX) models across multiple different tumor types. Feedback activation of upstream signalling pathways including receptor tyrosine kinases, such as the EGFR, has been suggested to limit the efficacy of GDP-KRAS-targeting compounds in preclinical studies. Clinical combination trials involving KRAS^{G12C} inhibitors such as adagrasib and sotorasib and anti-EGFR modalities are further supporting these findings. Here we show that a combination with anti-EGFR antibodies (e.g., Cetuximab) potently enhances the response observed for BI 3706674 in models of KRAS^{G12V}-mutant colorectal cancer. The deeper response observed upon combination of BI 3706674 with Cetuximab across multiple xenograft models provides a strong rationale for the clinical investigation of this combination therapy. Moreover, based on our *in vitro* mechanistic studies and *ex vivo* organoid platform we have identified prospective mechanisms of resistance and opportunity for novel drug combinations with BI 3706674 that can potentially translate into clinical trials.

#3322 Sigma-2-Erastin inhibits PC tumor growth through lipid ROS-DUSP6-MAPK signaling.

K. S. Bishnupuri[1], K. F. Newcomer[1], Q. Gong[1], L. Ye[1], S. Vangveravong[1], R. Takchi[1], B. T. Keller[2], D. M. Spitzer[1], W. G. Hawkins[1];
[1]Washington University School of Medicine in St. Louis, St. Louis, MO, [2]Accuronix Therapeutics, Inc., St. Louis, MO

Introduction: Pancreatic cancer (PC) is a malignancy with poor prognosis and high mortality with a very low 5-year survival rate. Currently, apoptosis and autophagy are the central mechanisms of programmed cell death (PCD) that maintain cellular homeostasis and regulate cell fate. With the recent emergence of 'ferroptosis' as a new type of PCD and its close association with the pathophysiological processes of many diseases including tumors, it is viewed as a potential mechanism to improve systemic treatment of PC. Considering the opportunity to regulate both apoptosis and ferroptosis by a single agent, our group has developed a cancer-targeted small molecule consisting of a sigma-2 ligand (a known apoptotic inducer) delivery moiety linked to an inhibitor of the cystine importer xCT (dm-Erastin, a known ferroptotic inducer) and named it as Sigma-2-Erastin (S2E) or ACXT-3102. The study presented here is aimed at determining the efficacy of ACXT-3102 in PC and defining its underlying mechanism of action.
Methods: Using *in vitro* and *in vivo* tumor xenograft models of human PC, we determined the effects of ACXT-3102 treatments in regulating PCD of PC cells and defined the signaling pathway involved in mediating the effects.
Results: As assessed by TitreGlo assays, we observed dose-dependent inhibition of PC cell (BxPC-3, AsPC-1 & PANC-1) viability. Following the WES-analysis of signaling proteins, we observed that ACXT-3102 induces PC cell death by combinatorial regulation of apoptotic and ferroptotic PCD via lipid ROS-DUSP6-MAPK/ERK-mediated signaling pathway. Interestingly, the results of this study demonstrated a hyperactivation of MAPK/ERK signaling by increased phosphorylation instead of inhibition involved in inducting apoptotic cell death as represented by significant increases in expression of cleaved Capase-3/7 and PARP. In addition, ACXT-3102 treatments deceased GPX4 expression along with an increase in lipid ROS production as key markers of inducing ferroptotic cell death. Results from the murine model of human tumor xenografts using AsPC-1 cells further demonstrated significant decreases in tumor volume and increases in survival proportions in ACXT-3102-treated mice.
Conclusions: ACXT-3102, an orally administered conjugate of sigma-2 ligand and Erastin induces PCD of human PC by uniquely regulating apoptosis and ferroptosis together. Therefore, ACXT-3102 offers a novel and improved therapeutic strategy for treating patients of fatal human carcinomas, especially those, which are difficult to diagnose at an early stage.

#3323 Novel Pan-RAS inhibitor ADT-007: A unique mechanism of antitumor selectivity in pancreatic and colorectal carcinoma models.

J. Wang[1], A. B. Keeton[1], S. Ramesh[1], P. Johnson[1], Y. Y. Maxuitenko[1], J. B. Foote[2], C.-H. Huang[1], K. L. Berry[1], K. Fadlalla[1], B. D. S. Reddy[2], G. P. Nagaraju[2], E. Nurmemmedov[3], I. Babic[3], V. Gaponenko[4], X. Chen[1], B. F. El-Rayes[2], D. J. Buchsbaum[2], G. A. Piazza[1];

[1]Auburn University Harrison College of Pharmacy, Auburn, AL, [2]University of Alabama at Birmingham, Birmingham, AL, [3]Nerd Bio, San Diego, CA, [4]University of Illinois Chicago, Chicago, IL

Multiple types of RAS mutations activate RAS isoforms, HRAS, NRAS, or KRAS, that drive oncogenic signaling leading to uncontrolled cell proliferation and tumor development. RAS mutations occur de novo in approximately one-third of all human cancers, and are especially prevalent in pancreatic, colorectal, and lung tumors. Where RAS mutations are less frequent in other cancers, such as breast cancer, RAS can be pathologically activated by growth factor receptors that engage numerous downstream effectors.

The currently FDA-approved KRAS-targeted drugs are designed to covalently inactivate only G12C KRAS mutants, however, this mutation is only prevalent in lung cancer. The most common mutations in pancreatic ductal adenocarcinoma (PDAC) are KRAS-G12D, KRAS-G12V, and KRAS-G12R. Our novel class of pan-RAS inhibitors, exemplified by ADT-007, addresses the urgent need for pan-RAS inhibitors with antitumor activity in cancers harboring these common mutations. These pan-RAS inhibitors have unique pharmacological properties that allow for selective killing of cancer cells harboring RAS mutations. ADT-007 inhibited growth of an array of carcinoma tumor cell lines in vitro with single digit nM IC50 values regardless of RAS mutant allele, and inhibited RAS activation and MAPK/AKT signaling. Because it is a pan-RAS inhibitor, ADT-007 may not be susceptible to commonly reported mechanisms of resistance to covalent KRAS inhibitors, such as activation of wild type (WT) alleles or secondary RAS mutations. Differentiated normal epithelial or hepatic cells, and tumor cells with WT RAS were insensitive to ADT-007 due to enzymatic detoxification of ADT-007 via glucuronidation, representing a novel mechanism of tumor selectivity. An orally bioavailable prodrug of ADT-007 (ADT-1004) is well tolerated in vivo, and produced sustained concentrations of ADT-007 well above IC50 values in plasma and even higher levels in tumors. Daily oral administration of ADT-1004 significantly inhibited RAS signaling and tumor growth in orthotopic and PDX mouse models of pancreatic cancer.

#3324 Discovery of a novel SOS1 inhibitor, AIG01012, targeting pan-KRAS mutant cancers.

J. Kim, S. Park, S. Kim, S. Lee, K. Yoo, H.-J. Lee, J. Kang, K.-O. Lee;
AIGEN Sciences, Seoul, Korea, Republic of

Targeting the SOS1-KRAS interaction represents a pivotal strategy in mitigating aberrant KRAS signaling, which is implicated in numerous malignancies. At AIGEN Sciences, Inc., we have harnessed an advanced human-in-the-loop (HITL) AI-based drug discovery platform (AIGEN ChemTailor). This innovative platform allows online learning through expert feedback, optimizing our drug development endeavors. We designed a potent SOS1 inhibitor, AIG01012 using AIGEN ChemTailor in combination with fragment-based drug discovery (FBDD) and molecular modeling techniques. We conceived numerous compounds and shortlisted the leading candidates for extensive testing after meticulous computer simulations. AIG01012 manifested substantial inhibitory effects against several KRAS mutant interactions with SOS1, specifically SOS1-KRAS WT, SOS1-KRAS G12C, SOS1-KRAS G12D, SOS1-KRAS G12V, and SOS1-KRAS G13D. However, its inhibitory capacity did not extend to the SOS2-KRAS G12C interaction. AIG01012 demonstrated remarkable inhibitory effects in 3D cell proliferation assays across various cell lines, including H358, MIA-PaCa2, SW837, AsPC-1, A427, SW620, Capan-2, A549, DLD-1, MKN-1, and H1666. Moreover, AIG01012 showed synergistic antiproliferative effects when combined with approved drugs such as sotorasib (for lung cancer with KRAS mutations), trametinib (a MEK inhibitor), and Osimertinib (targets specific EGFR mutations) in either H358 or PC-9 cell lines. Mouse studies further confirmed its favorable pharmacological properties, and its efficacy was evaluated in subsequent mouse tumor model. In summary, utilizing our human-in-the-loop (HITL) AI platform, AIGEN ChemTailor, we have efficiently derived AIG01012 as a potent SOS1 inhibitor that targets a wide range of KRAS interactions. With its notable in vitro and in vivo outcomes, AIG01012 is set for further exploration and prospective clinical trials as a significant contender in KRAS-targeted cancer treatments.

#3325 HBW-012-D and HBW-012-E are novel, potent, selective, safe, and bioavailable KRAS G12D inhibitors with superior anti-tumor efficacy in mice.

N. Lee, Y. Li, G. Liu, J. Li, J. Ren;
Chengdu Hyperway Pharmaceuticals, Chengdu, China

Purpose: This study is to characterize newly identified KRAS G12D small molecule inhibitors HBW-012-D and HBW-012-E, both showing improved oral bioavailability than MRTX1133, the known clinical compound with poor bioavailability. Method: Through our medicinal chemistry efforts, we have aimed to design novel small-molecule KRAS G12D inhibitors that are orally bioavailable. The compounds were screened via pERK and cell viability (CTG) assays in multiple cell types. The optimized compounds were further evaluated based on their pharmacokinetic (PK) properties and toxicity. The anti-tumor efficacy of the leads was confirmed in the GP2D (colorectal carcinoma with KRAS G12D mutation) mouse xenograft tumor model. Result: As shown in the table, HBW-012-D and HBW-012-E have significantly better potency and PK characteristics than MRTX1133. In the mouse GP2D model, comparing head-to-head with the same vehicle and protocol (50 mg/kg, twice daily, orally), MRTX1133 hardly inhibited tumor growth, whereas HBW-012-D inhibited tumor growth well (58 % tumor growth inhibition), and HBW-012-E not only completely inhibited tumor growth but also further regressed tumor size by around 40%. Preliminary toxicity tests showed that HBW-012-D and HBW-012-E are safe: weak inhibition of CYP450 enzymes, negative mini-Ames test, excellent kinase selectivity, and no obvious abnormalities in the 14-day rat or mouse toxicity test. Conclusion: New KRAS G12D inhibitors, HBW-012-D and HBW-012-E, were identified. Their preclinical profile, including potency, efficacy, and PK data, are all superior to MRTX1133, and their safety meets the criteria of clinical development. They show potential as a preferred oral treatment option for patients with tumors mediated by the KRAS G12D mutation, such as pancreatic cancer that still lacks effective treatments.

in vitro data

IC 50 (nM)	**MRTX1133**	**HBW-012-D**	**HBW-012-E**
AGS (G12D, stomach, pERK)	1	0.8	0.46
AsPC-1 (G12D, pancreas, 3D CTG)	10.88	3.09	
GP2D (G12D, colon, 3D CTG)	1.38	0.67	0.69
MKN-1 (WT, stomach, 3D CTG)		>3000

AUC0~t (mg.h/mL)	20	258	5724

#3326 PMR-116, a second generation RNA Polymerase I inhibitor.

L. Furic[1], N. Hein[2], R. Ferreira[3], K. Panov[4], A. Huglo[1], R. Rebello[1], E. Kusnadi[1], D. Drygin[5], M. Haddach[5], R. Hannan[2],
[1]Peter MacCallum Cancer Centre, Melbourne, Australia, [2]ANU, Canberra, Australia, [3]ANU, Melbourne, Australia, [4]Queen's University Belfast, Belfast, United Kingdom, [5]Pimera Inc, San Diego, CA

Introduction: Inhibition of RNA Polymerase I, the enzyme responsible for the synthesis of ribosomal RNAs, the nucleic scaffold of ribosomes, has been proven as a novel therapeutic target as most cancer cells are "addicted" to ribosome biogenesis.
Methods: In collaboration with Pimera Inc, we developed and tested the efficacy of a second generation RNA polymerase I inhibitor, PMR-116, in various pre-clinical cancer models. On-target activity of PMR-116 was confirmed in peripheral blood cells isolated from patients with solid tumors enrolled in a phase I trial of PMR-116.
Results: PMR-116 potently inhibits Pol I transcription with ~200 fold higher selectivity towards Pol I compared to Pol II transcription. PMR-116 inhibits rRNA synthesis by stalling the Pol I complex at the rDNA promoter preventing promoter escape and consequently elongation. PMR-116 anti-cancer activity was evaluated against a panel of over 100 cancer cell lines representative of 20 major types of solid and haematological malignancies. This new Pol I inhibitor exhibited broad anti-proliferative and cytotoxic activity with an IC50 ranging from 32-4500nM and a median IC50 of 300nM. In contrast, cells derived from normal tissues were significantly less sensitive (IC50 ranging from 6-33µM).
In vivo, PMR-116 significantly improved survival and reduce tumor burden in several preclinical models such as Vk*MYC transgenic model of indolent multiple myeloma, CT26 xenograft model of colorectal cancer, MMTV-PyMT transgenic model of metastatic breast cancer, mixed-lineage leukemia (MLL)-eleven nineteen leukemia (ENL)+Nras acute myeloid leukemia (+/-p53 mutation) and patient-derived xenografts of prostate cancer and AML.
In a phase I trial of PMR-116, on-target activity of PMR-116 was observed in cells derived from the peripheral blood.
Conclusion: PMR-116 significantly reduced cancer growth in a wide range of tumor models, including GEMM, syngeneic and PDX models. PMR-116 is undergoing clinical testing in phase I in solid tumors with the objective to determine maximum tolerated dose and identify a phase II dose.

#3327 L-pampo™, a TLR2/3 agonist, enhances anti-tumor immune responses and synergistically improves the anti-tumor efficacy of immune checkpoint inhibitors in cold tumors.

Guentae Kim[1], Yoonki Heo[1], Hye Jung Kim[1], Sejung Park[1], Byung Cheol Ahn[1], Won Suk Lee[2], Chan Kim[2], Hong Jae Chon[2], Eunyoung Chun[1], Jung Sun Yum[1]

[1]CHA Vaccine Institute, Seongnam-si, Korea, Republic of,[2]CHA Bundang Medical Center, CHA University School of Medicine, Seongnam-si, Korea, Republic of

Introduction: Immunotherapy is a promising therapeutic approach for a wide range of cancers. However, some tumors called "cold tumors" lack infiltrating T-cells and are not responsive to immune checkpoint inhibitors (ICIs), leading to worse clinical outcomes. This study demonstrates that L-pampo, a novel TLR2/3 agonist, promotes an anti-tumor immune response in cold tumors. Also, combining L-pampo with ICIs can improve the anti-tumor efficacy more safely than standard-of-care (SoC) chemotherapies.

Method: We utilized syngeneic tumor models using CT26 colon cancer and 4T1 triple-negative breast cancer (TNBC). L-pampo was administered alone or in combination with ICIs such as anti-PD-1 (aPD-1) and anti-CTLA-4 (aCTLA-4) antibodies to tumor-bearing mice (n=8/group). Tumor size was measured every three days, and the survival rate was monitored until day 60. On day 21 or 27 after transplantation, we analyzed the tumor weight and tumor-infiltrating immune cells. Furthermore, we assessed the respective anti-tumor efficacies and safety of L-pampo and SoC chemotherapies (FOLFOX and paclitaxel).

Result: In the CT26 colon cancer model, L-pampo effectively reduced the tumor size compared to the vehicle group (83.7%). The combination of L-pampo and ICI reduced tumor size by 86.1% (with aCTLA4) and 90.5% (with aPD-1), while the ICI alone did not effectively inhibit tumor growth (aPD-1; 17.3%, aCTLA-4; 23.6%). Notably, the triple concurrent treatment with L-pampo, aPD-1 and aCTLA-4 reduced tumor size by 96.6% and induced completed tumor regression in 1 out of 8. In the 4T1 TNBC model, L-pampo reduced tumor size by 64.2% compared to the vehicle treatment, and combined treatment with L-pampo and a-PD-1 suppressed tumor growth compared to aPD-1 alone (9.6% vs. 61.5%). Additionally, L-pampo improved median overall survival in each tumor model (CT26; 25.5 vs. 35.5, 4T1; 29.5 vs. 53.5 days). To compare the anti-tumor efficacy of L-pampo and conventional cytotoxic chemotherapy, we treated tumor-bearing mice with FOLFOX or paclitaxel as SoC regimen, respectively. Compared with each chemotherapy, L-pampo revealed comparable antitumor efficacies (Tumor growth inhibition CT26; 75.6% vs. 70.6%, 4T1; 65.5% vs. 58.8%). Interestingly, L-pampo inhibited tumor growth without significant adverse effects. In contrast, conventional chemotherapies induced acute hematological side effects such as leukopenia/neutropenia/thrombocytopenia and rapid weight loss. Furthermore, L-pampo increased the active cytotoxic T-cells infiltration through antigen-presenting cells stimulation within the tumors.

Conclusion: This study suggests that L-pampo, a novel TLR2/3 agonist, can be a potent anti-tumor agent, improving the anti-tumor efficacy of ICIs in cold tumors with enhanced anti-tumor immunity and minimal toxicities than conventional chemotherapies.

#3328 Oridonin derivative compounds target STATs to inhibit triple-negative breast cancer.

G. Vontz[1], J. Li[2], Z. Liang[1], R. Ma[3], P. Wang[2], H. Chen[2], J. Zhou[2], Q. Shen[1];
[1]LSU Health New Orleans, New Orleans, LA, [2]University of Texas Medical Branch, Galveston, TX, [3]University of Georgia, Athens, GA

Breast cancer remains the second leading cause of cancer related deaths in women. Despite the development of targeted treatments and immunotherapies, triple-negative breast cancer (TNBC) continues to evade effective treatment. TNBC lacks sufficient expression of druggable markers, ER, PR, and Her2, and exhibits especially aggressive characteristics including later diagnosis, lower survival rate, and higher rates of metastasis and reoccurrence. Currently, cytotoxic chemotherapy and radiation remain the standard of care for TNBC. Our work utilizes compounds from nature to develop therapies for TNBC with improved efficacy and safety. Oridonin, a natural kaurene-type diterpenoid enriched in the medicinal herb *Rabdosia rubescens*, is a promising anticancer agent, but exhibits limited bioavailability and potency. Our team successfully developed oridonin derivative CYD0618 compound that exhibits significantly improved solubility and anticancer activity. This study aims to characterize the mechanism of action of CYD0618 on TNBC cells. We found that CYD0618 reduces the proliferation of TNBC cells *in vitro* with IC_{50}s at the nanomolar level. We also found CYD0618 has high potency against TNBC *in vivo*. Within a xenograft mouse model, CYD0618 suppresses the growth of TNBC tumors and extends animal survival. Using Western blot to probe for putative targets, we found CYD0618 reduces activation of STAT3, a transcription factor critically involved in proliferation, survival, and transformation of epithelial cells. Because STAT3 is constitutively active in ~70% of human cancers, there has been a tremendous effort to develop STAT3 targeting therapies; however, none has achieved FDA approval. In addition to STAT3, we show CYD0618 also suppresses other STAT transcription factors. Compared to selective STAT3 degradation by PROTAC treatment, poly-STAT targeting by CYD0618 exhibits superior activity against TNBC cells. Our study identifies CYD0618 as a novel poly-STAT inhibitor with promising activity against TNBC.

#3329 Development of HM-001 as a therapeutic drug for non-muscle invasive bladder cancer.

Shinji Mima[1], Monta Sakaki[1], Noriaki Kiya[1], Atsunari Kawashima[2], Norio Nonomura[2], **Chihaya Kakinuma**[1]

[1]HOIST Co., Ltd., Osaka, Japan,[2]Department of Urology Graduate School of Medicine, Osaka University, Osaka, Japan

HM-001 is a drug containing sodium chlorite as the active ingredient that is being developed as a drug for non-muscle invasive bladder cancer (NMIBC), and is currently undergoing physician-led clinical trials. It has been discovered that sodium chlorite generates radicals in an acidic environment, and phosphatidylserine on the surface of tumor cells acts as a Lewis acid to generate radicals. HM-001, like other anticancer drugs and BCG, is intended to be injected into the bladder, retained, and then excreted. GLP studies using the same administration method has been completed, and no toxic changes have been observed in human trial doses. The efficacy of HM-001 against NMIBC was evaluated using an orthotopic transplantation model of UM-UC-3, a bladder cancer cell line. In the model, cells were transplanted into the bladder of SCID mouse after epithelial removal with trypsin, 600, 800, 1,600, and 3,200 ppm of HM-001 were administered once a week, and the weight of the excised bladder was calculated. After 4 weeks, the tumor weight was calculated and the tumor weight suppression rate in the control group was evaluated. As a result, the medicinal efficacy was confirmed at concentrations of 800ppm or higher. On the other hand, the UM-UC-3 model is a commonly used model, but it mimics CIS (carcinoma in situ) and can only partially mimic NMIBC. That is, other models are needed to evaluate efficacy for low- and high-grade NMIBC other than CIS. Therefore, we established high-grade and low-grade PDX and evaluated the effectiveness of HM-001 against low- and high-grade PDX through ex vivo testing. First, patient-derived tissue was transplanted into SCID mice, allowed to grow, and then removed. After extraction, they were cut into 2 mm3 pieces, exposed to HM-001 at 800, 1600, and 3200 ppm for 2 hours, and then transplanted into SCID mice. As a result of comparing the tumor size after transplantation with the control group, a dose-dependent tumor regression effect was confirmed in high-grade and low-grade PDX. NMIBC is divided into low-, medium-, and high-risk categories, with different treatment methods and drugs used for each. In particular, low-grade forms are restricted to low- and intermediate-risk groups. The results of this study show that HM-001 is effective not only for high-risk (including CIS) NMIBC but also for low- and intermediate-risk (low-grade) NMIBC.

#3330 BPP, a dual functional inhibitor, targets MLL-rearranged acute myeloid leukemia: Unraveling mechanisms and expanding therapeutic horizons.

T.-L. Chen[1], T.-L. Su[2], T.-C. Lee[2];

[1]National Chung Hsing University, Taichung, Taiwan, [2]Academia Sinica, Taipei, Taiwan

Refractory/recurrent acute myeloid leukemia (AML) poses a formidable clinical challenge, with MLL translocations implicated in approximately 10% of AML cases and a staggering 75% in infant leukemia, bearing an unfavorable prognosis. Our investigation focuses on BPP, a dual-functional inhibitor capable of inducing DNA cross-linking and suppressing angiogenesis. In a diverse panel of solid tumor and leukemic cells, BPP exhibited exceptional sensitivity against MLL-rearranged AML cell types. In MOLM13 and MV4-11 xenograft models, BPP showcased outstanding tumor suppression, with some tumors even achieving complete remission. In-house acute toxicity testing, BPP treated group showed excellent safety margin in both blood chemistry and pathological examination. Remarkably, BPP demonstrated significant cytotoxicity not only in FLT3-WT AML but also in FLT3-ITD AML. Delving into the mechanism, BPP was found to induce FLT3-ITD and MLL degradation by triggering DNA damage and ER stress. Comet assays revealed a dose-dependent accumulation of DNA fragments in MLL cells upon BPP exposure.The involvement of the KMT2A gene in chromosomal translocation in THP1 cells was highlighted, with BPP treatment resulting in a significant increase in Heat-shock protein. Notably, the combination of ganetespib, an FDA-approved HSP90 inhibitor, with BPP exhibited synergistic effects in both in vitro and in vivo models, inducing synthetic lethality and inhibiting HR repair. Furthermore, BPP not only reduced leukemic stem cells in colony formation assays but also demonstrated sensitivity in relapsed/refractory (R/R) and multiple drug-resistant patient samples. These findings collectively position BPP as a promising candidate for the treatment of MLL-rearranged AML, offering multifaceted therapeutic potential.

#3331 Preclinical combination of ONC206 with radiotherapy and temozolomide in a GBM mouse orthotopic model.

L. Zhou, L. Zhang, J. Zhang, S. Zhang, W. S. El-Deiry;
Brown University, Providence, RI

Glioblastoma multiforme (GBM) is the most common form of primary malignant brain tumor in adults. It is also the most aggressive and lethal. Standard of care therapy comprises maximal safe surgical resection followed by adjuvant alkylating agent temozolomide (TMZ) and radiotherapy (RT). There have only been five drugs and one device ever approved by the FDA for the treatment of GBM. The five-year survival rate for GBM patients has shown no notable improvement in the last three decades. We previously reported that the first-in-class imipridone small-molecule Dordaviprone (ONC201) decreases protein chaperone ClpX to unleash mitochondrial protease ClpP activity, integrated stress response and cell death. Preclinical combination of ONC201 (100 mg/kg weekly) with radiotherapy and Temozolomide in a GBM mouse orthotopic model results in reduced tumor burden and prolonged survival. The second generation imipridone ONC206 also activates integrated stress response and decreases ClpX in GBM cells but ONC206 is approximately 20 times more potent than its parent imipridone ONC201. ONC206 0.08 uM in combination with 12.5 uM TMZ and 2 Gy RT reduced the cell viability of GBM cells significantly compared to all single treatments and double treatments. During a short-term treatment of a GBM mouse orthotopic model, ONC206 (50 mg/kg weekly, half of ONC201 doses) synergizes with TMZ and RT to induce more tumor cell apoptosis and inhibits more tumor cell proliferation compared to other groups with single or double treatments. There are two ongoing clinical trials with ONC206: single weekly or multiple-day weekly dose regimens of single-agent, oral ONC206 in patients with recurrent, primary central nervous system (CNS) neoplasms (NCT04541082) and ONC206 alone or in combination with radiation therapy in treating patients with diffuse midline gliomas that is newly diagnosed or has come back (recurrent) or other recurrent primary malignant CNS tumors (NCT04732065). Future studies evaluating the role of immune function, mitochondrial metabolism, dopamine receptors, the ISR and TRAIL pathway in the synergistic effect would support further development of the triple combination regimen of ONC206, TMZ and radiation therapy for GBM clinical trial.

#3332 Kalkitoxin thiol amide suppresses the breast cancer metastasis to bone and brain.

Y. Soh, S. Shrestha, S. Kim;
Graduate School_Jeonbuk National University, Jeonju, Korea, Republic of

Introduction: Breast cancer is the primary frequently diagnosed cancer worldwide, with a high fatality rate. Metastasis resulting from advanced breast cancer increases mortality in patients. MDA-MB-231 is triple-negative breast cancer that does not have any of the receptors that are commonly found in breast cancer. The lipopeptide toxin kalkitoxin thiol amide (KTA), generated from the marine cyanobacterium Moorena producens (formerly Lyngbya majuscule), has a wide range of biological and pharmacological effects. Its promise as a therapeutic agent for treating bone metastases from breast cancer is still uncertain. This study aimed to determine whether KTA could prevent breast cancer from metastasis to mice's bones and to elucidate any potential mechanisms causing this inhibition.
Experimental Procedures: MDA-MB-231 cells were transfected with pGL4.50 (Luc2/CMV/Hygro) vector using LipofectamineTM 2000. Positive clones of MDA-MB-231 cells were selected after treatment with 300 µg/ml hygromycin for one week. After cancer implantation to the heart, bioluminescent imaging of femurs was measured upto 5 weeks and signal intensity of KTA-treated groups was compared with the vehicle group.
Summary: KTA decreased breast cancer cell proliferation, migration, and invasion. KTA prevented MDA-MB-231 cells from breast cancer metastasizing to the bone and brain via inhibiting MAPK and STAT signaling. The epithelial-mesenchymal transition markers, which are responsible for distant metastasis, are highly opposed by KTA. Compared to mice in the control group, mice receiving KTA displayed considerably less bone and brain metastasis, a lower tumor burden, and less bone destruction in the murine breast cancer bone metastasis model.
Conclusion: KTA has new inhibitory effects on cancer cell invasion and migration both *in vitro* and *in vivo*. From these findings, KTA may have therapeutic promise for treating breast cancer patients with distant metastases.

#3333 Targeting the MDM2-p53 interaction: Time- and concentration-dependent studies in tumor and normal human bone marrow cells reveal strategies for an enhanced therapeutic index.

Elaine Willmore[1], Maria Ahn[2], Suzanne Kyle[1], Yan Zhao[1], Huw Thomas[1], Kenneth S. Rankin[1], Luke Bevan[2], Lynsey Fazal[2], Keisha Hearn[2], Nicola Wilsher[2], Justyna Kucia-Tran[2], Nicola Ferrari[2], Nicola Wallis[2], Neil Thompson[2], John Lyons[2], Duncan Miller[1], Celine Cano[1], Martin E. M. Noble[1], Ian R. Hardcastle[1], Steven Howard[2], Gianni Chessari[2], John Lunec[1], David R. Newell[1], **Steve R. Wedge**[1]

[1]Newcastle University, Newcastle upon Tyne, United Kingdom,[2]Astex Pharmaceuticals, Cambridge, United Kingdom

Aim We aimed to design an MDM2-p53 antagonist with a differentiated tolerability profile that could be used to treat patients with wild-type *TP53* malignancies. As part of an alliance between Newcastle University, Astex Pharmaceuticals, and Cancer Research Horizons, we discovered ASTX295, a potent inhibitor of the MDM2-p53 interaction that is currently under clinical investigation in patients with solid tumors (NCT03975387). We selected ASTX295 as a compound with a predicted short plasma half-life, which we hypothesised would help to mitigate the dose-limiting neutropenia and thrombocytopenia observed with earlier MDM2-p53 antagonists in clinical studies. To examine this hypothesis *in vitro*, we determined time- and concentration-dependent responses to ASTX295 treatment in healthy volunteer-derived human bone marrow cells, megakaryocytes, and in a panel of human tumor cell lines.

Methods Samples containing bone marrow cells from healthy patients undergoing hip surgery were obtained under the ethical approval of the Newcastle Biobank (REC 12/NE/0395). Following Lymphoprep™ separation, cells were treated *ex vivo* with ASTX295 and seeded for Granulocyte-macrophage (GM) colony-forming assays in methylcellulose. Megakaryocytes were obtained from *in vitro* differentiation of CD34+ stem/progenitor cells. Human tumor cell lines (including *MDM2*-amplified SJSA-1) were treated with ASTX295 *in vitro* and seeded at low density for colony-forming assays. Exposures of 6, 12, or 24h were examined, and the data plotted to calculate LC_{50} values.

Results The clonogenic survival of tumor cells was time-dependent, with LC_{50} values (mean ± SEM) in SJSA1 cells being 238 ± 46nM and 75 ± 7nM respectively (n = 3-4), following a 12h or 24h exposure to ASTX295. Time-dependent effects were also evident in five human bone marrow samples but with LC_{50} values of 1.9, >3, >10, >10, and >10uM being achieved at 12h, and 860 ± 268nM at 24h. Megakaryocytes showed similar time-dependent sensitivities in which daily treatment of 2 or 6h over three days did not induce apoptosis while significant cell death was observed when the treatment time was extended to 16-24h daily. In contrast, short, daily pulse treatment of 2-6h in cell lines (MV4-11, MOLM-13, SJSA-1) over three days was sufficient to induce cell death.

Conclusions ASTX295 is a potent antagonist of the MDM2-p53 interaction. Collectively, our *in vitro* data suggest that a shorter exposure to ASTX295 (up to 12h), may help to spare healthy bone marrow cells whilst killing tumor cells. Hence, intermittent exposure to an MDM2-p53 antagonist could favourably modulate its therapeutic index. The predicted short plasma half-life of ASTX295 should provide flexibility in controlling the duration of exposure *in vivo*, potentially enabling a more bone-marrow sparing approach to MDM2-p53 antagonism to be utilised.

#3334 Combined treatment with PG3 and Nelfinavir induced synergistic apoptosis though sustained activation of integrated stress response.

X. Tian, W. S. El-Deiry;
Brown University, Providence, RI

Integrated stress response (ISR) activation has been linked to many human diseases, including cancer and neurological diseases. The ISR controls protein synthesis and proteostasis. ISR main effector ATF4 transcriptional factor regulates the balance between survival and cell death. Under acute ISR, ATF4 promotes cell adaptation and survival. Sustained ISR leads to ATF4-mediated apoptosis. In many cancers, mutations or overexpression of oncogenes, results in enhanced cell proliferation and increased protein synthesis, which activate the ISR. Therefore, protein translation is reduced to maintain proteostasis. In other words, many cancers are primed by the ISR. Therefore, additional push by small molecule ISR-inducers will disrupt the balance and force cancer cells to enter apoptosis. Nelfinavir activates ATF4 through inhibition of eIF2α specific phosphatases CReP and GADD34. PG3 upregulates ATF4 through the HRI/eIF2α/ATF4 pathway. We hypothesize that combined treatment of PG3 and Nelfinavir will sustain upregulation of ATF4, and lead to ATF4-mediated cell apoptosis. Cell viability assays indicated that the combined treatment potently and synergistically inhibited cell viability in colorectal cancer cell lines HT29, SW480 and HCT116 $p53^{-/-}$, osteosarcoma cell line U2OS and breast cancer cell lines MCF7 and T47D. The combined treatment sustained the induction of ATF4 and enhanced the expression of its proapoptotic target genes, CHOP and PUMA, and cell apoptosis. We confirmed that the enhanced induction of ATF4, CHOP and PUMA is through the ISR because ISRIB (ISR inhibitor) blocked the combined treatment-induced upregulation of ATF4, CHOP and PUMA.

#3335 A novel and potent IRE1α RNase inhibitor, HM100168 as a promising therapeutic strategy in solid cancers.

J. Kim, S. Jung, M. Kim, W. Park, J. Byun, S. Park, M. Lee, Y.-Y. Kim, J. Park, S. Hong, M. Kim, Y. Ahn;
Hanmi Pharmaceutical Co., Ltd., Hwaseong-si, Korea, Republic of

Protein folding homeostasis in the endoplasmic reticulum (ER) is regulated by a signaling network called the unfolded protein response (UPR). Inositol-requiring enzyme 1α (IRE1α) is an ER membrane-resident kinase/RNase that mediates signal transmission in the most evolutionarily conserved way of the UPR. The IRE1α-XBP1 pathway, one of the most essential branches of the UPR, is activated in various types of cancer. When IRE1α is activated, the spliced form of XBP1 (XBP1s) is generated to activate the transcription of many pro-survival genes to prevent cellular death and relieve cellular stress. IRE1α plays an instrumental pro-tumoral role in various cancers, such as glioblastoma, myeloma, lung adenocarcinoma, and breast cancers, as well as high IRE1α activity is associated with poor prognoses. Moreover, IRE1-XBP1 plays an essential role in the UPR and ER stress responses, which have been implicated in the development of drug resistance. Thereby, blockade of the IRE1α-XBP1 pathway is crucial as it is considered as a potential anti-cancer strategy. Here, we developed a potent and selective IRE1α RNase inhibitor, which have a hydroxy-aryl-aldehydes (HAA) moiety that binds to IRE1α within the RNase catalytic site. Our lead compound, HM100168, potently inhibited the RNase activity of human IRE1α at nanomolar concentrations without affecting its kinase activity. Experiments were performed on MCF7 breast cancer cells to confirm the inhibitory effect in the mRNA and protein levels of XBP1s, which was increased by tunicamycin (TM), a ER stress inducer. HM100168 strongly inhibited XBP1s levels in a dose-dependent manner, displaying the potent IC_{50} values. We tested cell growth inhibition activity in 3D as well as 2D cell culture condition of various cancer cell lines. Interestingly, HM100168 effectively inhibited cell proliferation of diverse cancer cell lines in both 2D and 3D culture condition. In addition, we explored the promising anti-cancer effects of HM100168 and its synergistic potential when combined with anti-tumorigenic agents. As a result, HM100168 in combination with anti-tumorigenic agents significantly enhanced suppression of tumor growth in human cancer cell transplanted mice. In conclusion, we have identified a novel compound with unique properties that specifically blocked the endonuclease activity of IRE1α. HM100168 inhibited IRE1α endonuclease activity, without affecting its kinase activity after endoplasmic reticulum stress *in vitro*. The identification of this novel IRE1α inhibitor supports the hypothesis that the IRE1α-XBP1 axis is a promising target for anticancer therapy. Also, co-targeting of IRE1α-XBP1 in combination with anti-tumorigenic agents can be considered a novel approach to overcome cancer resistance. Further preclinical studies will be performed and reported soon after the establishment of a preclinical candidate.

#3336 Regulation of liver X receptor protein stability by novel ligands in pancreatic cancer cells.

A. Bagchi, K. T. Gamage, S. R. Gilbertson, C.-Y. Lin;
University of Houston, Houston, TX

Liver X Receptors (LXRs) are nuclear receptors that act as ligand-modulated transcription factors. LXRs are overexpressed in various cancers, including pancreatic cancer, and targeting LXR with small molecule ligands has emerged as a promising therapeutic strategy in cancer. Current small molecule LXR ligands were originally developed for the treatment of atherosclerosis and other metabolic diseases. To identify ligands specifically targeting cancer cells, we screened a focused library of drug-like molecules predicted to bind to LXR using molecular docking. In the screen, novel LXR ligand GAC0001E5 (1E5) exhibited significant anti-proliferative effects in human pancreatic ductal adenocarcinoma (PDAC) cell lines. Functionally, 1E5 is an LXR inverse agonist which decreases LXR target gene expression and a “degrader” of LXR proteins following prolonged treatment. We posit that this novel ligand inhibits PDAC cells by downregulating the expression of LXR target genes. To test this hypothesis, we treated cancer cells with the previously described LXR inverse agonist SR9238 and examined its effect on cancer cell proliferation. Interestingly, treatments with SR9238 had no effect on pancreatic cancer cell proliferation as compared to the novel ligand 1E5 and the 1E5 derivative KD-95, suggesting that LXR inverse agonism was insufficient to inhibit cell proliferation. To determine whether SR9238 has similar effects on LXR protein levels as novel ligands, we performed western analysis of protein expression following ligand treatment. In contrast to the novel ligands 1E5 and KD-95, treatments with SR9238 increased LXR protein levels. Furthermore, time-course studies in cycloheximide treated cells indicated that novel ligands decreased protein stability whereas SR9238 had the opposite effect. Inhibition of proteasomal degradation and autophagy abolished the effects of 1E5 and KD-95 in a cell line-dependent manner. Related to these observations, previously published data revealed that knockdown of LXR expression greatly diminished PDAC cell proliferation. Taken together, these findings indicate that LXR expression is essential in pancreatic cancer cells and suggest that the novel ligands may disrupt its involvement in protein-protein interactions and non-genomic mechanisms.

#3337 Inhibition of KIF18A leads to mitotic arrest and robust anti-tumor activity in chromosomally instable tumors.

M. S. Lynes, S. Khan, T. Hotz, B. A. Sparling, M.-M. Zablocki, D. Gotur, P. Boriack-Sjodin, K. W. Duncan, S. J. Blakemore, S. J. Silver, R. A. Copeland; Accent Therapeutics, Lexington, MA

KIF18A is a plus-end directed kinesin known to play a role in mitosis by facilitating chromosome alignment and spindle microtubule dynamics. Knockdown or knockout of KIF18A has been shown to inhibit proliferation in cells with whole genome doubling or aneuploidy, cellular states characterized by chromosomal rearrangements. These alterations render cells particularly vulnerable to disrupted mitosis upon KIF18A loss. As such, KIF18A is a compelling target in a subset of tumors with chromosomal instability (CIN), which have ongoing chromosomal segregation defects. We have identified potent and selective small molecule inhibitors of KIF18A. A proprietary tool compound, ATX020, inhibits KIF18A ATPase activity with an IC_{50} of 14.5 nM; KIF18A is selectively inhibited over other kinesins including CENPE (IC_{50} > 10 µM) and EG5 (IC_{50} 5.87 µM). ATX020 exhibits robust cellular activity, with anti-proliferative activity observed in chromosomally instable ovarian cancer cell lines such as OVCAR-3 (IC_{50} 53.3 nM) and OVCAR-8 (IC_{50} 0.54 µM). Upon treatment with ATX020, Annexin V is robustly induced in sensitive cell lines, demonstrating that KIF18A-dependent cell lines undergo apoptosis upon KIF18A inhibition. In KIF18Ai sensitive cells, a dose-dependent upregulation of phospho-Histone H3 and gamma-H2AX is observed upon ATX020 treatment in OVCAR-3 and OVCAR-8 cells, consistent with the induction of mitotic arrest and DNA damage. In contrast, CIN negative Ovarian cancer cells that are insensitive to KIF18A loss, such as A2780 and OVK18, proliferate normally upon ATX020 treatment, and Annexin V, phospho-Histone H3, and gamma-H2AX are not induced. In sensitive cell lines, ATX020 induces a dose-dependent cell cycle arrest in G2/M, consistent with the role of KIF18A in facilitating mitosis. OVCAR-3 cells treated with ATX020 exhibit fragmented nuclei and malformed mitotic spindles, in contrast to A2780 cells where cell division is unaffected, suggesting that KIF18A is dispensable in CIN negative cells. This selective dependency is also observed *in vivo*, where administration of ATX020 leads to dose-dependent tumor growth inhibition in an OVCAR-3 cancer cell line-derived xenograft model, with significant tumor regression observed at 100 mpk/day. In contrast, OVK18 tumors are unaffected by ATX020 administration, as expected based on the lack of cell cycle and proliferation effects in that cell line. Together, these data demonstrate a critical role for KIF18A in facilitating mitosis in a subset of chromosomally instable cells. These effects are selective, with KIF18A-independent cell lines proceeding through the cell cycle normally in the presence of inhibitors. Small molecule inhibition of KIF18A is therefore expected to have robust efficacy in solid tumors with high levels of chromosomal instability such as Ovarian cancer.

#3338 Development of a CK2α inhibitor for treatment of wnt-driven colorectal cancer.

D. Cawkill;
Apollo Therapeutics Ltd, Cambridge, United Kingdom

A novel, potent and highly selective orally bioavailable small molecule inhibitor of Casein Kinase 2α (CK2α) has been developed and validated in pre-clinical models of wnt-driven colorectal carcinoma; and is poised to enter clinical development.CK2α is considered as a positive regulator of wnt signaling and tumorigenesis. The wnt pathway is known to be sensitive to and amplified by CK2α activity at multiple nodes and can be inhibited by loss of CK2α function. The human genetics of colorectal cancer (CRC) have been well characterized and approximately 80% tumors are identified as being wnt pathway mutation driven. CRC tumors can be further stratified into consensus molecular subtypes (CMS), with iCMS2 representing 37% of CRC patients, being characterized by ongoing wnt pathway upregulation. Development of CK2α inhibitors as a targeted therapy for CRC is therefore mechanistically well aligned to the wnt signaling drive and may serve as a promising therapeutic strategy for this cancer. A novel small molecule binding site on CK2α has been exploited to design and develop an inhibitor with K_i of 95 pM and exquisite selectivity over the kinome. This inhibitor has been comprehensively characterized using *in vitro*, *ex vivo* and *in vivo* pharmacology studies. Cellular mechanism of action studies in CRC cell lines have quantified the potency of target engagement, inhibition of known CK2α phospho-sites, inhibition of tumorigenic wnt pathway activity, and induction of apoptosis. This CK2α inhibitor was also profiled in a high content screen of CRC patient-derived organoids established from various driver mutation backgrounds. Use of these *ex vivo* models has validated the potent cytotoxic activity of CK2α inhibition in tumor samples with wnt-driven characteristics and highlights the potential therapeutic efficacy of CK2α inhibition in this setting. *In vivo* CRC xenograft studies have confirmed anti-tumor efficacy and developed the understanding of pharmacokinetic pharmacodynamic relationship between free plasma concentration of drug and inhibition of CK2α-specific biomarker in the tumor. The preclinical data presented establishes the strong rationale for clinical development of a novel CK2α inhibitor for the treatment of locally advanced or metastatic solid tumors, with an emphasis on wnt-driven CRC.

#3340 RMC-5127, a first-in-class, orally bioavailable mutant-selective RASG12V(ON) inhibitor is central nervous system (CNS)-penetrant and demonstrates anti-tumor activity in a preclinical intracranial xenograft model.

Z. Chen, A. Eriksson, B. Lee, J. Dinglasan, N. Montazer, J. Cregg, A. Edwards, K. Sanders, J. A. M. Smith, D. Wildes, M. Singh, Z. Wang, J. Jiang; Revolution Medicines, Inc., Redwood City, CA

Patients with advanced cancers harboring activating mutations in RAS, particularly those with non-small cell lung cancer, often develop brain metastases leading to increased morbidity and mortality. $KRAS^{G12V}$ is the second most frequent RAS mutation in RAS-addicted cancers, including pancreatic cancer (34 %), colorectal cancer (21 %), and non-small cell lung cancer (19%). RMC-5127 is an orally bioavailable, mutant-selective tri-complex inhibitor of the GTP-bound (ON) form of RAS^{G12V}. RMC-5127 non-covalently binds to an abundant intracellular chaperone protein cyclophilin A (CypA), resulting in a binary complex that engages RAS^{G12V}(ON) to form a high-affinity tri-complex that sterically inhibits RAS binding to effectors. RMC-5127 drove deep suppression of RAS pathway activity, inhibited cell proliferation, and induced apoptosis in a panel of $KRAS^{G12V}$ mutant human cancer cells *in vitro* but only caused submaximal inhibition in the panel of K/N/HRAS wildtype cancer cells, indicative of selectivity for $KRAS^{G12V}$ over K/N/HRAS wildtype. Repeated oral dosing of RMC-5127 resulted in profound and durable anti-tumor activity in subcutaneous CDX and PDX models of $KRAS^{G12V}$ mutant NSCLC, PDAC, and CRC *in vivo*. Dose-dependent exposure of RMC-5127 was observed in the whole brain of naïve mice, indicating the compound is brain penetrant. An intracranial xenograft model of $KRAS^{G12V}$ tumors was established in immunodeficient mice to assess the CNS anti-tumor activity of RMC-5127. The intracranial tumor exposure of RMC-5127 was comparable with that observed in the whole brains of naïve mice and was sufficient to drive robust pharmacodynamic responses in the brain tumor. Moreover, RMC-5127 exhibited profound and durable anti-tumor activity in the intracranial model, with tumor regressions at well-tolerated doses. The anti-tumor activity of RMC-5127 in intracranial tumors was consistent with that in subcutaneous tumors at equivalent tumor exposures. In conclusion, these preclinical data demonstrate that RMC-5127 is a CNS-penetrant RAS^{G12V}(ON) inhibitor and support further study to determine the potential to benefit patients with advanced RAS^{G12V}-mutated cancers, including those that have developed or are at risk of developing brain metastases.

#3341 Targeting CXCR4 via the small molecule inhibitor NMX1 as a therapeutic strategy to treat high-risk malignancies.

Patrick Sipila[1], Son Tran[1], Chunfen Zhang[1], Laura G. Corral[2], Kyle W. H. Chan[2], Cathy A. Swindlehurst[2], Aru Narendran[1]

[1]Department of Oncology, University of Calgary, Calgary, AB, Canada,[2]NovoMedix, San Diego, CA

Introduction: Cytokines are secreted by various cells of the immune system, endothelium, and stroma that play a critical role in cell survival. The activation of C-X-C chemokine receptor type 4 (CXCR4) by its ligand SDF-1 leads to signaling by the AKT and mTOR pathways. CXCR4 is highly expressed in several types of cancer and contributes to tumor growth, metastasis, and resistance to therapy. Interleukin 11 (IL-11) is a cytokine that often drives disease progression, as well as contributing to tumor immune evasion. NMX1 (NovoMedix) is a novel oral small molecule that inhibits mTOR signaling, CXCR4 expression, IL-11 secretion, and activates AMPK. In animal models of breast cancer, NMX1 effectively prevented tumor growth and metastasis, while also protecting from doxorubicin-induced cardiotoxicity. In this study, we investigated the anticancer activity of NMX1 in preclinical models of high-risk pediatric and adult malignancies.
Methods: Cell viability assays using alamar blue were performed in a panel of pediatric and adult cancer cells, including leukemia, brain, breast, lung, neuroblastoma, and sarcoma. Cells were treated with increasing concentrations of NMX1 ranging from 250 nM to 16 µM for 96 hours, followed by determination of half maximal inhibitory concentrations (IC_{50}). To validate target modulation, the level of IL-11 and CXCR4 was determined by ELISA and immunoblot, respectively. Protein kinase activity was assessed by phosphorylation levels. Induction of apoptosis was confirmed by caspase-mediated PARP cleavage. To identify effective drug combinations, NMX1-treated cells were screened with a comprehensive drug library. Synergy was evaluated in the top candidates by dose-response matrices and SynergyFinder. Safety and tolerability was tested in animal models.
Results: NMX1 treatment induced cytotoxicity at micromolar concentrations in diverse types of cancer, with IC_{50} values ranging from 0.2-8.7 µM and 0.4-4.4 µM for leukemia and solid tumor cells, respectively. NMX1 induced cancer cell death by PARP cleavage and apoptosis. Mechanistically, CXCR4 expression, mTOR signaling, and IL-11 secretion were decreased upon treatment with NMX1, validating effective target modulation. The drug combination screen identified several candidates in a tumor type-dependent manner. Synergistic effects were observed using NMX1 combined with clinically relevant concentrations of rucaparib, linsitinib, and crizotinib, which target PARP, IGFR, and c-MET, respectively.
Conclusions: Our study shows antitumor activity by NMX1 through inhibition of CXCR4, IL-11, and mTOR signaling, providing an effective therapeutic strategy for high-risk and refractory malignancies. Preclinical data on feasible drug combinations and biological correlates of activity support development of early phase clinical studies involving NMX1.

#7277 Discovery of INV-9956, an orally available and highly selective Cyp11A1 inhibitor for the treatment of castration-resistant prostate cancer with drug resistant AR mutations.

C. Bai, D. Chen, Z. Xia, S. Huang, L. Lin, Z. Zeng, J. Su, Y. Sun;
IONOVA Life Science Co., Ltd., Shenzhen, China

Androgen Receptor (AR) signaling plays a profound role in prostate cancer and development. Efforts in harnessing androgen and AR axis for castration-resistant prostate cancer treatment have led to discovery of several therapeutics, including AR antagonists and Cyp17 inhibitors. However, resistance to these approved therapeutics has emerged, and remained a significant unmet medical need. Among the prominent resistance mechanisms of action are restored androgen signaling via AR amplification and overexpression, and gain-of-function mutations occurring at AR ligand binding domain that can be agonized by existing AR antagonists and/or non-androgenic steroids such as glucocorticoids. Targeting Cyp11A1 that catalyzes the formation of pregnenolone is effective to ablate biosynthesis of androgens and all steroids and thus holds promise to deliver coverage of a significant percentage of drug resistant AR mutations and benefit CRPC patients post treatment with AR antagonists or Cyp17 inhibitors. Here we present discovery and characterization of INV-9956, an orally available, selective, and potent Cyp11A1 inhibitor with well-acceptable pharmacokinetic properties. INV-9956 potently inhibits biosynthesis of pregnenolone and other androgens in H295R cells with IC50 at single-digit nanomolar, suppresses proliferation of prostate cancer cell lines harboring major clinically acquired drug resistant AR LBD mutations, such as AR L702H using coculture assays. Orally administered INV-9956 showed consistent dose dependent PK/PD correlations across animal species. Particularly, INV-9956 displayed pronounced tumor inhibition superior to known competitors in a CRPC VCaP xenograft model and in a “humanized” animal model. Furthermore, INV-9956 displayed a good tox profile in 14-day repeated dosing rat and dog studies, supported by a high selectivity to Cyp11A1 over other Cyp family members, clean hERG and mini-Ames, and no significant off-target activity in a safety panel screen. The promising preclinical profiles of INV-9956 lend strong support to its potentials in addressing unmet needs in CRPC treatments and warrant clinical development.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Novel Therapeutics
Poster Session

#3344 Widespread *BRCA1/2*-independent homologous recombination defects are caused by alterations in RNA binding proteins.

B. Kaundal[1], D. J. McGrail[2], Y. Li[1], R. S. Smith[3], B. Feng[4], H. Dai[1], L. Hu[1], B. Dennehey[1], S. Awasthi[1], M. L. Mendillo[3], A. K. Sood[1], G. B. Mills[5], S.-Y. Lin[1], S. Yi[6], N. Sahni[1];

[1]UT MD Anderson Cancer Center, Houston, TX, [2]Center for Immunotherapy and Precision Immuno-Oncology, Cleveland Clinic, Cleveland, OH, [3]Northwestern University Feinberg School of Medicine, Chicago, IL, [4]GSK Oncology Experimental Medicine Unit, Waltham, MA, [5]Knight Cancer Institute, Oregon Health and Sciences University, Portland, OR, [6]Livestrong Cancer Institutes, Department of Oncology, Dell Medical School, The University of Texas at Austin, Austin, TX

Summary: Defects in homologous recombination DNA repair (HRD) both predispose to cancer development and produce therapeutic vulnerabilities, making it critical to define the spectrum of genetic events that cause HRD. However, we found that mutations in *BRCA1/2* and other canonical HR genes only identified 10-20% of tumors that display genomic evidence of HRD. Using a networks-based approach, we discovered that over half of putative genes causing HRD originated outside of canonical DNA damage response genes, with a particular enrichment for RNA binding protein (RBP)-encoding genes. These putative drivers of HRD were experimentally validated, cross-validated in an independent cohort, and enriched in cancer-associated GWAS loci. Mechanistic studies indicate that some RBPs are recruited to sites of DNA damage to facilitate repair, whereas others control the expression of canonical HR genes. Overall, this study greatly expands the repertoire of known drivers of HRD, with implications for basic biology, genetic screening, and therapy stratification.

#3345 PP1 phosphatase complex at the hub of the integrated stress response: A potential therapeutic target in multiple myeloma.

S. Xiong[1], J. Zhou[2], T. Tan[2], S.-M. Toh[2], T.-H. Chung[2], T. Sanda[2], W. Chng[3],

[1]Department of Medicine, Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore, [2]Cancer Science Institute of Singapore, National University of Singapore, Singapore, Singapore, [3]Department of Hematology-Oncology, National University Cancer Institute of Singapore, National University Health System, Singapore, Singapore

Protein phosphatase-1 (PP1) is a class of eukaryotic enzyme that catalyzes more than half of the phosphoserine/threonine dephosphorylation reactions, and plays essential roles in cell division, glycogen metabolism and protein synthesis. The substrate specificity of PP1 holoenzyme complex is mediated by PP1-interacting proteins and its catalytic subunits. Of note, PPP1R15B/CReP and PPP1R15A/GADD34 are regulatory subunits of PP1 complex that regulates global protein synthesis and mRNA translation through eIF2α dephosphorylation. Notably, PPP1R15B is constitutively expressed, whereas the expression of PPP1R15A is stress-inducible. Previous studies showed that multiple myeloma (MM), a hematological malignancy arising from immunoglobulin-secreting plasma cells, is characterized by continual ER stress and high dependency on the unfolded protein response (UPR). The integrated stress response (ISR) activated by eIF2α phosphorylation is the fastest reaction pathway of the UPR; however, its functional role and therapeutic potential in MM remains largely unknown.

In this study, we performed gene expression analysis and super-enhancer (SE) profiling in MM cell lines, primary patient samples, normal CD138+ plasma cells and memory B cells. we found that PPP1R15B is highly expressed in MM cells as compared to healthy controls, but did not observe significant upregulation of PPP1R15A in MM cells. In addition, higher expression of PPP1R15B predicted poor overall survival of MM patients, suggesting its clinical relevance in MM pathogenesis. Depletion of PPP1R15B significantly reduced cell viability, proliferation and induced G2/M phase cell cycle arrest. Gene Ontology analysis of downregulated genes in response to PPP1R15B knockdown indicates significant association with the UPR pathway. Immunoblot analysis showed activation of ER stress pro-apoptotic executors PUMA, NOXA, and cleavage of caspase-12 in PPP1R15B knockdown cells.

Furthermore, we examined the therapeutic effects of eIF2α dephosphorylation inhibitors, Salubrinal and Raphin1, on MM cells. Raphin1 is a selective inhibitor of PPP1R15B that binds strongly to the PPP1R15B-PP1c complex, whereas Salubrinal inhibits both PPP1R15A-PP1c and PPP1R15B-PP1c complex. Our data showed that both Salubrinal and Raphin1 inhibited MM cell proliferation in a dose-dependent manner, while sparing normal plasma cells. MM cell lines with elevated PPP1R15B expression level were more sensitive to Salubrinal or Raphin1 than those with lower PPP1R15B level. Similar changes in the expression patterns of ISR-related genes were observed in response to eIF2α dephosphorylation inhibitors. Taken together, our study suggests that targeting PPP1R15B-PP1c complex or maintaining eIF2α hyperphosphorylation may serve as a new therapeutic approach in MM, which warrants further investigation.

#3346 JMJD6 as a novel tumorigenic factor and therapeutic target in group 3 (MYC-driven) medulloblastoma.

M. Kling[1], D. Kumar[2], S. Ray[2], S. Joshi[2], D. Coulter[2], **N. K. Chaturvedi**[2];
[1]Creighton University, Omaha, NE, [2]University of Nebraska Medical Center, Omaha, NE

Medulloblastoma (MB) is the most common type of childhood brain cancer worldwide. Although current treatment with surgery and extensive chemoradiation has led to increased survival rates, many MB patients still die from the disease. Moreover, surviving patients suffer severe long-term side effects as a consequence of treatment. It is therefore crucial to develop more effective and less toxic therapies. The most aggressive subtype of MB tumors often exhibits amplification or overexpression of the MYC oncogene. Patients with MYC-amplified MB exhibit a high frequency of cerebrospinal tumor dissemination, often experience treatment resistance and have extremely poor prognoses. While the MYC oncogene is established as the oncogenic driver in Group 3 MB, it has remained undruggable. Thus, targeting regulatory components of MYC and the signaling pathways regulated by it is of great potential therapeutic value. Studies have revealed that MB has very few germline mutations in cancer predisposition genes, suggesting that dysregulated epigenetic pathways might be critical in MB pathogenesis. Particularly, dysregulation of epigenetic modifiers, including histone methyltransferases and histone demethylases, is very common in Group 3 MB, compared to other MB subgroups. Therefore, it is important to identify such epigenetic modifiers that may have controls on MYC and its tumorigenic activities and explore these as the epigenetic drug-candidate targets in Group 3 (MYC-driven) MB. In this regard, we found that protein arginine demethylase Jumonji C domain-containing protein 6 (JMJD6), an emerging key epigenetic enzyme in cancers, is a novel regulator of MYC expression in MYC-driven MB. We observed high levels of JMJD6 that not only mirror MYC expression in the most aggressive MB but also correlate with poor outcomes in these patients. Knockdown of JMJD6 decreased MYC expression, cellular proliferation/survival and stemness in MYC-amplified MB cells. Mechanistically, our results revealed that JMJD6 forms complexes with proteins involved in maintaining and regulating the promoter-pause at super-enhancers, suggesting that JMJD6 can regulate MYC at the transcription level. Moreover, our in vivo analyses of JMJD6 inhibition, either with inducible gene knockdown or a pharmacologic small molecule inhibitor, demonstrated anti-MB potential with suppressed MYC expression. Based on this background and preliminary observations, we hypothesize that JMJD6 plays crucial roles in the most aggressive MB by regulating MYC expression and hence MYC-driven tumorigenesis. Accordingly, we hypothesize that targeting the JMJD6-MYC axis by JMJD6 inhibition can serve as a powerful therapeutic strategy for MYC-driven MB.

#3347 KIFC1 inhibition elicits antineoplastic activity in small cell lung cancer by inducing anaphase catastrophe.

N. Nakagawa[1], M. Tokunaga[1], M. Ka[1], Y. Sugiura[1], T. Iida[1], T. Ando[1], K. Watanabe[1], X. Liu[2], E. Dmitrovsky[2], H. Kage[1], M. Kawakami[1];
[1]University of Tokyo, Tokyo, Japan, [2]Frederick National Laboratory for Cancer Research, Frederick, MD

Cancer cells often have more than two centrosomes (supernumerary centrosomes) and this is one of the hallmarks of cancer. We previously demonstrated that CDK2 antagonism inhibits clustering of supernumerary centrosomes at mitosis leading to multipolar cell division and apoptotic death in non-small cell lung cancer. This antineoplastic process was designated anaphase catastrophe. Anaphase catastrophe can preferentially affect cancer cells sparing normal cells with two centrosomes. On the other hand, as CDK2 functions in normal cell cycle progression, its inhibition can also affect normal and malignant cells. Identification of a novel drug target that would preferentially cause anaphase catastrophe is needed. The motor protein KIFC1 affects centrosome clustering. Small cell lung cancer (SCLC), known for its poor prognosis with limited therapeutic options, displays disruptions in the cell cycle checkpoint mechanism due to inactivation of p53 and RB. We hypothesized SCLC was susceptible to mitotic abnormalities, including anaphase catastrophe. In this study, we explored the possibility of KIFC1 as a novel therapeutic target that triggers anaphase catastrophe in SCLC. In-silico GEO database analysis revealed elevated levels of KIFC1 and PLK4 in SCLCs compared with other cancers and normal tissues. PLK4 plays a key role in centrosome amplification. Our in-silico analysis results imply that centrosome amplification and their clustering frequently occur in SCLC. We performed in-vitro functional analysis of KIFC1 inhibition in SCLC cell lines (NCI-H146, SHP77, NCI-H209, and NCI-H524 cells), using siRNAs and CRISPR-Cas9 system for genetic inhibition and AZ82, a specific KIFC1 inhibitor, for pharmacologic inhibition of KIFC1. Cell proliferation was measured by the CellTiter-Glo Luminescent Assay and apoptosis was scored by annexin V and PI staining followed by flow cytometry analysis. Cell growth was reduced and apoptosis was statistically significantly increased after genetic inhibition of KIFC1 by siRNAs and by use of the CRISPR-Cas9 system in SCLC cell lines. These antineoplastic effects also occurred after AZ82 treatments, in a dose-dependent manner in these SCLC cell lines. To examine the mitotic status of SCLC cells after KIFC1 inhibition, SCLC cells were stained with α-tubulin antibody and DAPI before analysis with a fluorescence microscope. Besides normal bipolar mitotic cells, multipolar mitotic cells were observed, and their population was increased after KIFC1 knockdown with siRNAs. This indicated that clustering of supernumerary centrosomes was inhibited by targeting KIFC1 in SCLC cells. Taken together, KIFC1 is a potential therapeutic target to induce anaphase catastrophe in cancer cells. Targeting KIFC1 is a novel therapeutic strategy to consider for SCLC that currently has limited treatment options.

#3348 Identification of circSPINT2 as a tumor suppressive circular RNA sensitizing lung cancer to 3rd generation EGFR-TKI treatment.

M.-L. Wang[1], S.-H. Shiou[1], Y.-C. Chen[1], M.-L. Tsai[1], N. Verusingam[1], A.-K. Ong[2];
[1]Taipei Veterans General Hospital, Taipei, Taiwan, [2]Universiti Tunku Abdul Rahman, Selango, Malaysia

Introduction: Lung cancer remains a high incidence and mortality globally. Adenocarcinoma is the most common type of lung cancer with around 50% of patients in Asia expressing mutated EGFR, which makes EGFR an effective therapeutic target to treat lung adenocarcinoma (LAC). Unfortunately, resistance to EGFR-TKI often occurs in patients through either dynamic EGFR mutation, driver oncogenic pathway shift, or transdifferentiating to evade EGFR-TKI treatment. circRNAs are a type of RNA molecule with a circular shape. Their importance in several biological processes and disease progression was intensively studied recently, and have emerged as promising diagnostic, prognostic, and monitoring biomarkers for diseases like cancer. CircRNAs' unique circular structure and resistance to degradation make them robust candidates for non-invasive diagnostics of cancers.

Aims: This study aimed to identify and investigate the involvement of a novel circular RNA (circSPINT2) in acquired resistance against the 3rd generation EGFR-TKI Osimertinib.

Materials & Methods: Comparative circRNA sequencing (circRNA-Seq), qRT-PCR, sanger sequencing, and RNase R treatment were applied to identify and verify the identity of Osimertinib-resistance-related circRNA. Biotinylated circRNA pull-down assay, miRNA-seq, and in-silico analysis were employed to delineate the downstream miRNA-mRNA regulatory axis. Osimertinib-resistant mouse xenograft model was established to explore the molecular mechanisms associated with both circSPINT2 and Osimertinib resistance.

Results: We identified circSPINT2 as particularly downregulated in Osimertinib-resistant cell lines (OR) using circRNA-Seq. Overexpression of circSPINT2 in resistant cells increased cellular sensitivity to Osimertinib, whereas knockdown of circSPINT2 conferred Osimertinib resistance in parental cells. The circSPINT2-dependent regulation of Osimertinib sensitivity is mediated through modulating apoptosis. *In-vitro* analysis indicated high circSPINT2 increased tumor suppressor RBP1 expression by sequestering oncogenic hsa-miR-1296 further improving Osimertinib sensitivity. Molecular and histologic analysis of subcutaneous xenograft tumors corroborated our *in-vitro* results.

Conclusion: Our study demonstrated circSPINT2 functions as a tumor suppressor, improving Osimertinib sensitivity via the hsa-miR-1296/RBP1 axis. circSPINT2 may serve as a prognostic and cancer biomarker to monitor Osimertinib resistance in LAC patients.

#3349 Identification of new potential vulnerabilities for differentiation-based therapeutic strategies against osteosarcoma.

C. Cascini[1], D. Lecis[1], V. Cancila[2], K. Scotlandi[3], C. Tripodo[2], M. P. Colombo[1], **C. Chiodoni**[1];
[1]Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy, [2]University of Palermo School of Medicine, Palermo, Italy, [3]IRCCS Istituto Ortopedico Rizzoli, Bologna, Italy

Osteosarcoma (OS), a mesenchymal bone tumor affecting mainly children and adolescents is characterized by a particularly aggressive behavior, with 20% of patients showing lung metastasis already at diagnosis. Current OS treatment strategies rely on multi-drug chemotherapy, and the prognosis for metastatic cases remains grim, underscoring the pressing need for novel therapeutic approaches. OS is considered a differentiation-related disorder, stemming from the inability of mesenchymal stem cells or osteoblastic progenitors to progress towards terminal differentiation. In our study we explored the impact of targeting ZEB1, a transcription factor known to play a pivotal role in maintaining mesenchymal and stemness characteristics in cancer, on OS cells. We employed CRISPR-Cas9 and shRNA interference techniques to inhibit ZEB1 expression in mouse immune competent OS models. In vitro, ZEB1 deficiency significantly diminished the stemness potential of OS cells, as assessed by spheroid formation assays, while promoting osteogenic differentiation. In vivo, ZEB1 deletion in OS cells led to a significant reduction in primary tumor growth. Tumors originating from ZEB1 KO cells exhibited a more differentiated morphology and higher extracellular matrix deposition compared to controls. Intriguingly, the absence of ZEB1 in tumor cells also influenced the immune infiltrate, with ZEB1-deficient tumors showing significantly fewer pro-tumoral CD206+ M2-like macrophages. This observation is in line with the significant down-modulation of CCL2 expression we detected in ZEB1 KO cells. When injected intravenously, ZEB1-deficient cells produced fewer and smaller lung metastases than control cells. Transcriptional changes induced by ZEB1 deletion were investigated by gene expression profile (GEP) and identified 849 down-regulated and 1093 up-regulated genes in ZEB1 knockout (KO) clones versus ZEB1-competent controls. Gene set enrichment analysis showed a down-modulation of pathways related to cellular proliferation and survival, such as MTORC1 signaling, MYC targets, GM2 checkpoint, E2F targets and oxidative phosphorylation in the absence of ZEB1. Single gene analysis identified among the most up-regulated genes in ZEB1-deficient cells Sfrp1, a negative regulator of the WNT/b-CAT pathway, which in turn regulates MYC, whose pathway is indeed repressed in ZEB1 KO cells. We hypothesize that a high expression of SFRP1 could vicariate the effects of ZEB1 inhibition on OS cell stemness, differentiation state, and in vivo aggressiveness, and therefore could act as a tumor suppressor, which could be potentially exploited for therapeutic strategies.

#3350 The pan-quadruplex drug QN-302 targets up-regulated genes in pancreatic cancer and in other cancer types and correlate with poor patient prognosis.

S. Neidle[1], A. A. Ahmed[1], T. Arshad[2];

[1]University College London (UCL), London, United Kingdom, [2]Qualigen Therapeutics Inc, Carlsbad, CA

We have previously disclosed (Ahmed et al, ACS Med Chem Lett, 2020) a novel small molecule G-quadruplex binding compound, QN-302, that is highly potent in pancreatic ductal adenocarcinoma (PDAC) cells and in several in vivo models for this disease. QN-302 was invented at University College London UK and has been subsequently developed by Qualigen Therapeutics Inc. It was cleared by the FDA in August 2023 for clinical evaluation and is currently in a Phase 1 clinical trial at select oncology centers in the USA. Genes that are significantly down-regulated by QN-302 are mostly up-regulated genes in human PDAC. We report here that some of these genes are also up regulated in other cancer types, whose expression frequently correlates with poor patient prognosis. We have used human cancer data from https://www.proteinatlas.org which contains pathology information based on mRNA and protein expression data from 17 different forms of human cancer, together with millions of in-house generated immunohistochemically stained tissue sections, images and Kaplan-Meier plots showing the correlation between mRNA expression of each human protein gene and cancer patient survival. We have revisited the RNA-seq data for QN-302 in PDAC MIA-PACA2 cells exposed to QN-302 for 24 hrs. (GSE151741 at https://www.ncbi.nlm.nih.gov/geo/) in detail and now identify a small group of eleven down-regulated genes, all with >3-fold expression changes. Interestingly all these genes and their gene products have been previously identified as playing a role in human PDAC (they also have varying roles in other cancer types). Some have been validated as anticancer targets. 10/11 of these genes (https://www.proteinatlas.org/) have been previously reported as being over-expressed in significant fractions of large (>150) groups of human cancer patients from The Cancer Genome Atlas (TCGA) project. Members of the PDAC susceptible gene panel are mostly disfavored in prostate, lung and breast cancer. However, the patient data does not discriminate between cancer sub-types nor does it show resistant data. They are especially favored in colorectal, liver and renal cancers, suggesting that QN-302 may have anticancer effects in these cancers as well as in PDAC. We also do not exclude the strong possibility that each cancer type also has its own group of G-quadruplex containing genes that are sensitive to QN-302.

#3351 Identifying novel therapies from unbiased screens in AML with MECOM re-arrangement.

C. E. Birdwell[1], W. C. Fiskus[1], C. P. Mill[1], T. M. Kadia[1], N. Daver[1], C. D. DiNardo[1], K. Sasaki[1], J. A. Davis[1], K. Das[1], H. Hou[1], M. Cerebelli[2], K. N. Bhalla[1]; [1]UT MD Anderson Cancer Center, Houston, TX, [2]NCATS, NIH, Bethesda, MD

EVI1 is a transcriptional regulator encoded from the MECOM locus (3q26.2). Aberrant EVI1 expression is observed in ~10% of *de novo* AML, of which about half are due to inv3(q21;q26.2) or t(3;3)(q21;q26.2) chromosomal rearrangements [3q26.2-r]. 3q26.2-r AMLs generally have a stem-like phenotype, are refractory to current therapy options and exhibit poor overall survival. Therefore, there is an unmet need to develop novel targeted therapies with improved efficacy in repressing EVI1 and its targets, thereby improving outcomes in AML with EVI1 overexpression. We conducted an unbiased high-throughput drug screen, utilizing a library of mechanistically annotated drugs (NCATS Mechanism Interrogation Plates [MIPE 5.0]), against seven AML cell lines (3q26.2-r: UCSD-AML1, HNT-34, AML191, AML194; non-3q26.2-r AML: SET-2, MV4-11, OCI-AML3). This exploited the mechanistic redundancy in the library to identify druggable, target-level dependencies in 3q26.2-r AML, exhibiting absolute potency and relative activity as compared to other AML subtypes. BRD4 was identified as an absolute dependency in 3q26.2-r AMLs. An unbiased epigenetic modifier CRISPR screen in UCSD-AML further confirmed BRD4 as a dependency, confirming previous reports of BET inhibition (BETi) efficacy in 3q26.2-r AML. Comparison of 3q26.2-r versus other AML cell lines also identified XIAP, mTOR, PIK3CA and Bcl-xL as druggable vulnerabilities in 3q26.2-r AML. In follow-up experiments, IAP family inhibitors/SMAC mimetics induced significantly more dose-dependent apoptosis in 3q26.2-r versus the other AML cell lines, which was associated with reduction of IAP proteins, p-ERK, MCL1 and Bcl-xL, but increase in levels of cleaved caspase-3 and PARP. BETi (mivebresib) also induced dose-dependent apoptosis, and reduced EVI1, c-Myc, c-Myb, IAP proteins, and CDK4/6, while increasing levels of HEXIM1 and cleaved PARP. Consistent with this, co-treatment of mivebresib with SMAC mimetic birinapant or IAP inhibitor LCL161 was synergistically lethal against 3q26.2-r cells. Co-targeting the other identified druggable vulnerabilities from the drug screen with BETi (mTOR/PI3K with BGT-226 and dactolisib, Bcl-xL with navitoclax and A1155463, as well as CBP/p300 (with GNE781, identified through the CRISPR screen), exerted synergistic lethality in 3q26.2-r AML cells. Finally, in a xenograft model of 3q26.2-r AML in immune-depleted mice, while monotherapy with LCL161 or dactolisib significantly reduced the AML burden with minimal toxicity, co-treatment with mivebresib and LCL161 or dactolisib was superior in reducing AML burden in the xenograft model. These findings demonstrate promising preclinical activity of BETi and IAP protein or mTOR/PI3K antagonists in the cellular models of AML with EVI1 overexpression. This supports the rationale to determine *in vivo* efficacy of these BETi-based combinations against this therapy-resistant AML sub-type.

#3352 A CRISPR-enabled function genomics profiling platform in acute leukemia: Updates from a pilot study of Function (Fx) Heme utilizing fresh patient samples.

K. C. Dykes[1], T. R. Tan[1], K. Hodel[2], K. Tran[2], M. Meyers[2], L. Hagmann[2], M. Baltay[2], P. Kilfeather[2], Y. Li[2], C. Schmedt[2], S. Sampath[2], S. Sampath[2], T. N. Tanaka[1], S. Corbel[2];

[1]UC San Diego Moores Cancer Center, San Diego, CA, [2]Function Oncology, San Diego, CA

Introduction: In this study we utilized a novel primary cell CRISPR/Cas9 profiling approach to identify gene dependencies in fresh acute myeloid leukemia (AML) and acute lymphoid leukemia (ALL) patient samples. The primary aim of this prospective study was to demonstrate the feasibility of the CRISPR-based personalized functional genomic testing with fresh patient samples in the clinical setting.

Methods: AML and ALL patient peripheral blood samples (10-16 mL) were obtained at time of initial diagnosis and/or at relapse, and if feasible post-treatment. Primary cells were transduced with lentivirus harboring Cas9 enzyme and a 'drug targets' sgRNA panel. Transduced cells were harvested at early (input) and Day 8 timepoints, and sgRNA distribution was assessed by amplicon sequencing of DNA barcodes. Changes in barcode abundance were quantitated and aggregated to calculate gene-level phenotype scores, enabling identification of gene dependencies.

Results: 37 patients were included in the study, 23 with AML, 9 with Philadelphia (Ph) (+) ALL, 5 with Ph (-) ALL. The majority of patients had adverse or poor risk disease. The average age of patients was 52.6, range 18-84. 23 were male, 14 female; 20 identified as white, 17 as other. 20 patients were sampled at initial diagnosis, 12 were sampled at time of relapse and 5 at time of refractory disease. Serial samples were collected from 9 patients. 34 patients received treatment following sample collection. The majority of patients received intensive chemotherapy or a hypomethylating agent with venetoclax, however 15 patients received some form of targeted therapy. At the time of the abstract submission, Fx Heme results were available for 23 patients and among these, we identified potential treatment targets in 10 samples (43%). Importantly, 60% of the positive samples have a dependency on a gene clinically targetable by an approved leukemia drug. In addition, our profiling platform enabled the discovery of novel druggable dependencies in 100% of the positive samples.

Conclusions: With this pilot study we demonstrated that utilizing small volume fresh patient samples to assess CRISPR-defined gene dependencies on targeted therapies in AML and ALL is feasible, timely, and results in clear Fx Heme dependency gene output. Our data indicates that CRISPR-based comprehensive functional profiling has the potential to add valuable information beyond traditional NGS methods to determine the optimal therapy for patients with AML and ALL. Future directions include translating further into the clinical setting and correlating Fx Heme dependence with response to targeted treatment in acute leukemia patients.

#3353 The emerging role of extracellular HSP90 in prostate cancer progression to a metastatic phenotype.

K. O'Neill, J. Zigmond, R. Bergan;
University of Nebraska Medical Center, Omaha, NE

Background: Metastasis is the central cause of lethal prostate cancer (PCa). Mechanisms regulating metastasis represent high-potential therapeutic targets for preventing development of lethal PCa. Inhibitors of extracellular heat shock protein 90 (eHSP90) have been shown to inhibit prostate cell motility. In contrast to the intracellular HSP90 (iHSP90), whose biology has been extensively studied, and whose therapeutic targeting is associated with systemic toxicity, the biology of extracellular HSP90 is not well understood. We undertook a series of investigations to better understand eHSP90 biology in PCa.
Methods: Human PCa cells were subjected to cellular stress by heat shock combined with serum starvation. Resultant conditioned media was probed for matrix metalloproteinase 2 (MMP-2) by zymography and subject to scratch-wound and Boyden chamber invasion assays. Expression of HSP90 and CDC37 was measured by Western blot. Plasma from patients with PCa and healthy controls was probed for eHSP90 by ELISA.
Results: We have examined expression of iHSP90 and eHSP90 after cellular stress, induced by heat shock and serum starvation, in human PC3, LNCaP, C4-2B, 1532NPTX and 1532CPTX PCa cell lines. Cell stress induces increased eHSP90 in all PCa cell lines examined. This is associated with a decrease in MMP-2 activity in conditioned media. Conditioned media from stressed cells was also shown to decrease invasion of PC3 cells, consistent with changes in MMP-2. Of high interest, the addition of protease inhibitors to conditioned media led to a complete reversal of the MMP-2 response: its activity increased with cellular stress. When measuring HSP90α in plasma from healthy controls (N = 20) and patients with PCa (N = 40, 20 localized and 20 metastatic), we demonstrated a significant (p=.001) >2 fold increase in PCa compared to control. Further, a significant increase in HSP90α was observed when low versus high T stage lesions were compared. There was no statistically significant difference in HSP90α for those with metastasis to regional lymph nodes, non-regional lymph nodes, bone, or liver.
Conclusion: We demonstrate that increased eHSP90 due to cellular stress is a response observed across all PCa cell lines examined and should be considered typical. Its association with extracellular MMP-2 activity is dependent on the presence of other proteases and indicates a complex regulatory mechanism. Examination of eHSP90 in humans supports its association with aggressive disease. These factors support further investigation of underlying biology and therapeutic opportunities.

#3354 Capturing tumor heterogeneity to personalize therapy in young patients with hormone receptor positive breast cancer.

I. Segatto[1], M. Mattevi[1], A. Dall'Acqua[1], L. Musco[1], F. Ruggiero[1], G. Di Giustino[1], A. Favero[1], G. Rampioni Vinciguerra[2], N. Crestan[1], L. Pellizzari[1], R. Spizzo[1], R. Bomben[1], F. Vit[1], A. Vecchione[2], L. Gerratana[1], F. Puglisi[1], S. Massarut[1], T. Perin[1], G. Baldassarre[1], **B. Belletti**[1];

[1]Centro di Riferimento Oncologico (CRO) di Aviano, IRCCS, Aviano, Italy, [2]Universita degli Studi di Roma La Sapienza, Roma, Italy

Background: Breast cancer (BC) in young women (Y) is a distinct entity in terms of prognosis. Although triple negative and HER2 positive subtypes are enriched in Y patients, the hormone receptor (HR) positive subtype (luminal, LBC) remains the most common. A thorough understanding of LBC biology in Y women has not been reached yet, also hampered by lack of appropriate models that faithfully recapitulate these tumors in molecular and preclinical studies.
Methods: To investigate molecular determinants of progression and therapeutic resistance, we collected a large panel of fresh specimens (N=226) from Y (< 40 years) and nY (>55 years) LBC patients, characterized by targeted sequencing and used to generate Patient-Derived Organoids (PDO) and Xenografts (PDX). A selected panel of Y and nY LBC patients (N=96), sharing similar clinical-pathological features, was used for whole exome sequencing (WES) and transcriptomic analyses.
Results: We generated stable LBC PDO (N=32, 13 from Y patients), with a success rate of 50% and stable LBC PDX (N=15, 11 from Y patients), with a success rate 17%. Our targeted panel of NGS, covering most mutated genes in LBC at high coverage (1000x), revealed a significantly higher number of Y patients displaying mutations in PIK3CA and in PIK3CA+TP53. However, these data were not observable in WES analyses (200x), likely because many of those mutations displayed a VAF < 5% (20% of PIK3CA and 30% of TP53). The transcriptomic analysis showed an enrichment in signatures of aggressiveness in the Y LBC subgroup. The EGF family member AREG (Amphiregulin) was the most enriched gene in tumors from pre- versus post-menopausal patients. Following validation in a larger panel of LBC, both at RNA and protein level, we tested the impact of AREG in LBC cell lines. AREG expression was timely induced by growth factor and hormonal stimulation. Furthermore, stimulation using amphiregulin induced the activation of EGFR and its downstream pathway, creating a positive feedback loop. Relevant to the Y LBC phenotype, a consistent and time dependent induction of AREG transcription was induced following estrogen and progesterone stimulation, indicating that, in LBC, AREG might act as a transcriptional target of ESR1. Finally, high levels of amphiregulin reduced response to tamoxifen and CDK4/6 inhibitors in LBC cells and PDOs.
Conclusions and Perspectives: Our study provides valuable molecular and biological insights into LBC in Y women. We identified distinct genetic and transcriptomic profiles, including PIK3CA and TP53 mutations and AREG overexpression, which may be exploited to plan more targeted and efficient treatments. The establishment of a living biobank of PDO and PDX from LBC patients of Y age will enable preclinical trials, facilitating discovery of biomarkers and therapeutic strategies tailored to the unique biology of Y LBC.

#3355 Unraveling the molecular mechanisms of glioma migration: Exploring the role of cell intrinsic and stromal ephrin receptor-ligand signaling.

J. Moon[1], X. Gao[1], P. Ding[1], F. Bilal[1], S. Rindhe[1], N. Gao[1], D. P. Dave[2], M. Henkemeyer[1], E. A. Maher[1], R. M. Bachoo[1];
[1]UT Southwestern Medical Center, Dallas, TX, [2]University of Texas at Arlington, Arlington, TX

Diffuse invasion, a hallmark of malignant gliomas, makes these tumors surgically incurable and is the ultimate cause of death. While glioma cells can migrate along blood vessels and in neuron-rich regions, their preferred route of migration is along white matter (WM) tracts, which allows tumor cells to spread to the contralateral hemisphere with devastating neurocognitive consequences. The underlying mechanisms of in vivo glioma cell migration are poorly understood. There is emerging evidence that glioblastoma multiforme (GBM) cells may hijack migration mechanisms used during brain development. Accordingly, we used a neonatal plasmid electroporation GBM model (CRISPR-Cas9, -Cre,gRNAs targeting NF1, p53, PTEN, and piggyBac-glast) to generate a highly penetrant diffusely invasive glioma models with preference for migration along myelinated fiber tracts including the corpus callosum (CC). To test the in vivo role of integrin-mediated migration, tumors were generated using conditional integrin β1f/f (ITGB1) or focal adhesion kinase (FAKf/f) mice. Both ITGB1 and FAK null GBM cells (confirmed by western blot analysis) showed diffuse infiltration similar to WT mice, suggesting that integrin signaling is not essential for in vivo GBM cell migration. Next, we tested the role ephrin-signaling using a series of transgenic neonatal mice, including EPH-B1-/-, -B2-/-, -B1/2-/-, -kinase-dead (KD) and a gain-of-function mutant). EPH1/2-/- GBM, but not the other genetic models, consistently formed tumors which showed no diffuse single-cell infiltration, but rather grew as a solid expanding mass. An extensive panel of in vitro studies comparing WT and EPHB1/2-/- GBM patterns of growth and migration, including time-lapse random walk, neurosphere radial migration, migration along patterned surfaces, and laminin-coated confined 3D channels, showed similar patterns of migration, despite the marked differences in vivo. These contrasting in vivo and in vitro results raise the possibility that EPH-B1/2 receptors may require their cognate ephrin ligands to facilitate migration through the WM tracts. To test this hypothesis, we are using Ephrin-B1f/f, B2f/f mice for in vivo cell-type specific deletion in WM tract stroma cells and primary astrocytes derived from these mice for ex vivo co-culture studies. Our preliminary data suggest that EPH/EPHRIN interactions may regulate GBM cell migration.

#3356 Inhibiting phospholipase D1 reduces pancreatic carcinogenesis in mice.

H. A. Addassi[1], K. Matsukuma[2], G. G. Mackenzie[1];
[1]UC Davis, Davis, CA, [2]UC Davis, Sacramento, CA

New therapeutic targets are needed for pancreatic ductal adenocarcinoma (PDAC), a leading cause of cancer-related death worldwide. Phospholipase D (PLD) is a lipid-signaling enzyme that appears to play a critical role in cell proliferation, survival/apoptosis, and downstream oncogenic transformation. Elevated PLD1 or PLD2 (the two classical mammalian isoforms) activity has been shown to promote tumor progression in various cancer types, however, the role and mechanisms of PLD in pancreatic cancer are not yet understood. Thus, the objective is to determine the role of PLD1 regulation in pancreatic carcinogenesis through genetic and pharmacological inhibition. To evaluate the role of PLD1 in tumor growth, we subcutaneously transplanted human MIA PaCa-2 pancreatic cancer cells expressing endogenous PLD1 levels (Ctr KD cells), or MIA PaCa-2 cells in which PLD1 was knocked down (Pld1 KD cells), into immunodeficient nude mice. After 18 days post implantation, tumors that arose from Pld1-KD cells presented a significantly smaller tumor size ($p<0.05$) and had reduced levels of Bcl-xL and Bcl-2, compared to controls (Ctr KD). Then, to assess the role of PLD1 in the tumor microenvironment, we implanted KPC pancreatic cancer cells into C57BL/6 wild-type (WT) or C57BL/6 PLD1 knockout (*Pld1*$^{-/-}$) mice with and without treatment with gemcitabine. Fourteen days after tumor implantation, the growth of KPC tumors was attenuated in *Pld1*$^{-/-}$ mice by 49% ($p<0.05$). Treatment with gemcitabine reduced tumor growth by 51.6% ($p<0.05$) in WT mice and by 79.5% ($p<0.03$) in *Pld1*$^{-/-}$ mice. Moreover, we evaluated the effects of PLD1 genetic ablation by crossing *LSL-Kras*$^{G12D/+}$*; Ptf1Cre/+* (*KC*) mice into PLD1 knockout (*Pld1*$^{-/-}$) mice to generate *KC; Pld1*$^{-/-}$ mice. At 8 months of age, *KC; Pld1*$^{-/-}$ mice had significantly smaller pancreases ($p<0.05$) compared to *KC* mice. Interestingly, PLD1 ablation increased phosphorylation of ERK and c-Jun in *KC; Pld1*$^{-/-}$ mice compared to *KC* mice. Finally, to assess whether pharmacological inhibition of PLD can inhibit pancreatic carcinogenesis, *KC* mice received daily intraperitoneal injections of a small molecule inhibitor of PLD1 and PLD2 (FIPI) at a dosage of 3 mg/kg of body weight for a duration of 5 weeks. Treatment with FIPI reduced acinar-to-ductal metaplasia ($p<0.05$) and reduced cell proliferation ($p<0.01$), when compared to vehicle-treated KC controls. Additionally, FIPI treatment was safe demonstrating no significant differences in body weight between the groups and no significant alteration in the serum levels of liver enzymes, including aspartate aminotransferase, alanine aminotransferase and alkaline phosphatase. In conclusion, these findings reveal PLD1 plays a critical role in pancreatic carcinogenesis and might represent a novel therapeutic target.

#3357 Identifying mechanisms of acquired resistance to lorlatinib utilizing a genome-wide CRISPR-Cas9 screen.

Joshua Renn Kalna[1], Smita Matkar[1], Emily O'Drisoll[2], Skye Balyasny[1], Matteo Calafatti[1], Mark Gerelus[3], Dave Groff[1], Tina Acholla[1], Colleen E. Casey[1], Paul Kamitsuka[3], Grant Li[1], Steven J. Pastor[4], Gabriela Witek[1], Kateryna Krytska[1], Jarrett Lindsay[3], Ophir Shalem[5], Yael P. Mosse[6]

[1]Oncology Research, Children's Hospital of Philadelphia, Philadelphia, PA,[2]Genetics and Epigenetics, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA,[3]Pharmacology, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA,[4]Bioinformatics, Children's Hospital of Philadelphia, Philadelphia, PA,[5]Pathology and Laboratory Medicine, Children's Hospital of Philadelphia, Philadelphia, PA,[6]Oncology, Children's Hospital of Philadelphia, Philadelphia, PA

Survival rates for neuroblastoma (NB), a predominantly pediatric solid tumor arising from the sympathoadrenal neural crest, have improved incrementally from 25% to 50% over three decades with dramatic escalation in therapy intensity. Gain-of-function mutations in anaplastic lymphoma kinase (*ALK*), of which 85% occur at residues F1174, F1245, and R1275, confer inferior survival compared to patients with wild-type *ALK*. Lorlatinib, a third generation ALK inhibitor, has completed Phase 1 testing in the NANT Consortium and has moved to frontline therapy in the Children's Oncology Group. The robust and sustained activity observed with minimal toxicity is transient in relapse patients harboring *MYCN* amplification and ALK activation. We aim to elucidate and target mechanisms of acquired resistance that emerge from lorlatinib treatment. We utilized the Brunello library, a genome-wide CRISPR-CAS9 loss of function screen targeting 19,114 genes (4 sgRNA per gene), which allows for a high confidence of detection of hits. We screened four clinically representative cell lines: Kelly (ALK^{F1174L}, *MYCN*-amplified, $p53^{P117T}$), SMS-SAN (ALK^{F1174L}, *MYCN*-amplified), LAN5 (ALK^{R1275Q}, *MYCN*-amplified), and SY5Y (ALK^{F1174L}, *MYCN*-nonamplified). sgRNAs were ranked according to the degree of depletion or enrichment. We validated top depleted targets through cell-based assays and immunoblotting. We identified several actionable targets across multiple NB cell lines that, when depleted, increase the efficacy of lorlatinib, including *FGFR2*, *BCL2L1*, *SOX11*, *SMARCA2*, and *SMARCD2*. Genetic knockout of *FGFR2* led to a 40% reduction ($p<0.05$) in KO cells upon lorlatinib treatment compared to control. PROTAC degradation of the anti-apoptotic BCL-xL (*BCL2L1*) revealed the combination of lorlatinib and the PROTAC led to a decrease in IC50 *in vitro*. Additionally, we identified conserved core components of the SWI/SNF complex, a subfamily of ATP-dependent chromatin remodelers, as well as SOX11, a regulator of the SWI/SNF complex and transcription factor of the core regulatory circuitry in adrenergic high-risk NB. In conclusion, we identified actionable targets across four NB cell lines that, when depleted, increase the efficacy of lorlatinib. Depletion of FGFR2 led to increased sensitivity to lorlatinib, however enzymatic inhibition showed minimal effect. Future investigation into dual targeting of ALK and FGFR2 through novel alternative methods is warranted. Furthermore, we observed a synergistic relationship between lorlatinib and a BCL-xL PROTAC *in vitro*. Ongoing *in vivo* studies will test the combinatorial efficacy in lorlatinib-naïve and resistant models. Finally, we are investigating epigenetic remodeling by the SWI/SNF complex and its regulators in NB cells during lorlatinib treatment through targeted genetic manipulation of *SOX11* to understand its role as a master transcriptional regulator of *MYCN* and *FGFR2*.

#3358 Tribbles 1 (TRIB1) pseudokinase forms a complex with and activates Akt in GBM cells.

K. Singh, C. Han, H. Manring, S. J. Haque, A. Chakravarti;
The Ohio State University, Columbus, OH

Glioblastoma (GBM; WHO grade 4) is the most aggressive form of glioma with a dismal 5-year survival rate. The current therapies are largely ineffective and therapy resistance is commonly encountered. We have recently shown that TRIB1, a Ser/Thr pseudokinase contributes to therapeutic resistance in GBM cells by activating both ERK and Akt pathways. Here we show that, increased expression of TRIB1 contributed to RT/TMZ resistance by activating pro-survival Akt signaling resulting in increased viability of GBM cells. High level of Akt phosphorylation/activation is correlated with poor prognosis of GBM patients. Many pan Akt inhibitors have been developed which are currently in various phases of clinical trials. The three Akt isoforms (1, 2 and 3) are known to play a role in cancer during proliferation, transformation and metastasis. A previous report has shown that TRIB1 interacts with Akt1 in *Drosophila* and blocks its activation. In this study we show that Akt binds and forms a complex with TRIB1 in GBM cells and this interaction could be isoform and cell line specific.

We utilized patient derived xenograft (PDX) GBM cell lines and established GBM cell lines in this study. Stable TRIB1 overexpressing cell lines were generated by antibiotic selection. Co-immunoprecipitation (Co-IP) was performed utilizing Anti-FLAG or anti-c-Myc magnetic agarose beads to evaluate protein-protein interactions. Western blotting was done to detect protein levels. The FLAG tagged TRIB1 deletion mutants were a generous gift from Dr. Takuro Nakamura (Division of Carcinogenesis, The Cancer Institute, Tokyo, Japan). Cells were transfected using Lipofectamine 2000 reagent.

Co-IP studies showed that TRIB1 formed a complex with Akt in PDX GBM cell lines. We then transiently transfected respective TRIB1 deletion mutants lacking either N and C terminal residues in HEK 293 cells and performed Co-IP with Anti-FLAG magnetic agarose beads. We observed that all TRIB1 deletion mutants except TRIB1-ΔN2 (lacking first 160 amino acids) were able to pull down Akt. The western blot results showed that each Akt isoform had a variable protein expression across different cell lines. Co-IP studies in the PDX cell lines showed that TRIB1 interacted with all three Akt isoforms in T08-387 cells whereas TRIB1 consistently interacted with only Akt3 but not Akt1/2 in GBM30 cells that lack wild-type p53 expression.

Our data suggest that TRIB1 forms a complex with Akt in PDX GBM cell lines. The potential Akt binding site on TRIB1 lies between 90-160 amino acids. TRIB1 can interact with different Akt isoforms in a cell type dependent manner thereby playing a role in their activation and consequent tumorigenic processes. Therefore, targeting TRIB1 mediated Akt activation could be considered a better therapeutic option over targeting Akt directly, which may decrease Akt's oncogenic activities without risking the toxicity associated with available Akt- specific inhibitors.

#3359 *HEY1::NCOA2 fusion* disturbs the transcriptional program of chondrogenic differentiation and activates oncogenes in mesenchymal chondrosarcoma tumorigenesis.

W. Qi, W. Rosikiewicz, B. Xu, **L. Wang**;
St. Jude Children's Research Hospital, Memphis, TN

Mesenchymal chondrosarcoma (MCS) is a rare high-grade mesenchymal neoplasm occurring in bone and soft tissue. It accounts for 2%~10% of all chondrosarcomas and affects mainly adolescents and young adults. Genetically, this tumor is characterized by the recurrent HEY1::NCOA2 fusion. To functionally characterize the fusion in MCS tumorigenesis, we generated stably transduced iPSC-derived mesenchymal stem cells (iPSC-MSC) with inducible expression of HEY1::NCOA2. We previously demonstrated that the expression of HEY1::NCOA2 significantly enhanced cell proliferation, upregulated PDGFB/PI3K/AKT signaling, and induced genes that are involved in chondrocyte differentiation. In this study, we evaluated the impact on chondrogenic lineage differentiation and dysregulated pathways resulting from HEY1::NCOA2 expression and further elaborated oncogenic pathways in MCS tumorigenesis. We first successfully established the differentiation culture of inducing iPSC-MSC on chondrogenic lineage differentiation, showing an increase in glycosaminoglycans and the expression of differentiation markers (COL1A1, COL2A1, ACAN, COMP, SOX9 and COL10A1) at 7-, 14-, and 21-days post treatment with differentiation medium. The iPSC-MSC-HEY1::NCOA2 cells and control cells were cultured for chondrogenic lineage differentiation. During differentiation culture, we collected cells from each condition at multiple time points to (1) monitor the expression of differentiation markers and (2) perform transcriptomic profiling. Principal component analysis showed that cells with the expression of *HEY1::NCOA2* possessed a distinct feature from parental cells and control cells, however, *HEY1::NCOA2* did not simply suppress chondrogenic differentiation. The differential gene expression indicated that HEY1::NCOA2 fusion disrupted genes related to fine tuning of chondrogenic differentiation (*SOX9*, *COMP*, and *IGF1*) and activated oncogenes (*PDGFB, BCL2, CCND1, IGF2*, etc.). Notably, we demonstrated that both *BCL2 (*an anti-apoptotic protein) and *COMP (*possess antiapoptotic function that protects chondrocytes against death and blocks activation of caspase 3) were directly targeted and consistently upregulated by *HEY1::NCOA2* fusion. In addition, the functional classification of genes (n=86) consistently increased with HEY1:: NCOA2 expression through differentiation of the chondrogenic lineage demonstrated that the PI3K / AKT pathway was the most significantly enriched, which further supports targeting the PDGFB/PI3K/AKT axis in MCS therapy. Together, this study sheds light on how *HEY1::NCOA2* fusion shapes key mechanisms of chondrogenic differentiation and exerts oncogenic activation. Our findings provide the rationale for anti-apoptosis along with anti-PDGFB/PI3K/AKT signaling in the treatment of mesenchymal chondrosarcoma.

#3360 Myristoylated alanine-rich C-kinase substrate (MARCKS) as a target for pathological tunneling nanotubes in glioblastoma.

Lauren C. Nassour-Caswell[1], Nicholas J. Eustace[2], Shane T. Rich-New[3], Taylor L. Schanel[1], Hasan Alrefai[1], Andee M. Beierle[1], Manoj Kumar[1], Patricia H. Hicks[1], Johsua C. Anderson[1], Christopher D. Willey[1]

[1]Radiation Oncology, University of Alabama at Birmingham, Birmingham, AL,[2]City of Hope, Pasadena, CA,[3]Biochemistry and Molecular Genetics, University of Alabama at Birmingham, Birmingham, AL

Background: Glioblastoma (GBM) is a lethal brain malignancy with a median survival of <2 years due to relapse in 100% of cases. Tunneling nanotubes (TNTs) facilitate the development of treatment resistance by establishing tumor-promoting networks between GBM and surrounding cells. Only having emerged in 2004, many key players remain to be identified which is why we propose that MARCKS regulates TNT directionality through phosphorylation of its effector domain (ED).

Methods: We quantified TNT sinuosity, numbers, branching points, and average length in (3) PTEN-null doxycycline-inducible U87-MARCKS-mutant models in serum-free conditions. Mutants overexpress MARCKS as wild-type (U87-WT), non-phosphorylated (U87-NP), or pseudo-phosphorylated (U87-PP). TNTs were characterized using immunofluorescence, confocal imaging, ICY manual TNT plugin, and negative staining. We also investigated a cytotoxic peptide derived from MARCKS-ED, termed MED2, on PTEN-null brain tumor-initiating cell (BTIC) TNTs. Statistical analysis was conducted with one or two-way ANOVA and multiple comparisons.

Results: The most striking difference between all mutants is the loss of rigidity and directionality in U87-NP TNTs. Negative staining revealed U87-NP TNTs have deformed bodies with clubbed tips compared to ordered filaments in U87-WT and U87-PP. 4h MED2 treatment in non-mutated BTICs results in cytotoxicity as well as truncated TNTs that phenotypically resemble U87-NP.

Conclusions: This is the first report supporting MARCKS to be a novel regulator of TNTs through ED phosphorylation. Future directions will investigate the functionality of TNTs in U87 mutants to determine if the lack of MARCKS phosphorylation renders TNTs nonfunctional. Defining MARCKS' role in GBM TNTs not only advances the field of cellular communication but also offers a new perspective on GBM treatment.

Quantitative TNT Characterization

	Sinuosity	TNT Number	Branch Points	Average Length	MARCKS/F-actin Correlation
U87-WT	1.00 +/- 0.00	29.0 +/- 2.94	17.0 +/- 2.94	9.80 +/- 1.74	R^2=0.9245

#3361 Surfaceome and cancer testis antigen profiling of lung adenocarcinoma by large-scale transcriptomic analysis.

S. Andrew[1], A. Elliott[2], G. W. Sledge, Jr.[2], S. V. Liu[3], B. Halmos[4], V. K. Lam[5], T. K. Owonikoko[1];
[1]UPMC Hillman Cancer Center, Pittsburgh, PA, [2]Caris Life Sciences, Phoenix, AZ, [3]Lombardi Comprehensive Cancer Center, Washington, DC, [4]Montefiore Medical Center, Bronx, NY, [5]Johns Hopkins University School of Medicine, Baltimore, MD

Background: The emergence of improved modalities to target tumor specific and tumor associated antigens in solid tumors (e.g. antibody-drug conjugates, bi-specific antibodies, and adoptive cell therapy) underscores the need to efficiently identify and validate new therapeutic targets.
Methods: We examined differential expression of surfaceome genes (Fonseca et al., 2016) and cancer testis (CT) antigen genes (Almeida et al., 2009) among major lung adenocarcinoma genomic subtypes; conducting comprehensive surfaceome/CT antigen profiling of 9002 NSCLC adenocarcinoma samples using data generated by RNA sequencing (whole transcriptome) at Caris Life Sciences (Phoenix, AZ). NSCLC tumors were stratified into 5 subgroups based on the presence of specific driver mutations: *ALK* fusion (N=325), *EGFR* mutant (N=1739), *KRAS* mutant (no *STK11* or *KEAP1* mutation; N=2561), *KRAS* + *STK* or *KEAP1* mutation (N=1264), and Pan-WT (no mutation in *ALK*, *EGFR*, *KRAS*, *STK11*, or *KEAP1* detected; N=3113). Fold-change in expression was calculated by dividing the median value for a specific subgroup by the median of all other groups combined. Significance was tested by Mann-Whitney U test, with p-values adjust for multiple hypothesis testing (Benjamini-Hochberg).
Results: Surfaceome genes with the highest median expression overall included *CD74*, *TMBIM6*, and *CD44*, while the highest median expression among CT antigens was observed for *SPAG9*, *KIAA0100*, and *RQCD1*, yet the expression of these genes across the 5 driver mutation-based subgroups was similar (fold-changes ranged 0.93-1.06). To identify driver-associated candidate genes with relatively high expression, genes with subgroup-specific median expression >75th-percentile and with significant differences when compared to all other groups were ranked by fold-change. While several candidate surfaceome genes were associated with a specific subgroup, *CLDN10* was identified among the top 3 candidates for both *ALK* fusion and *KRAS* + *STK11*/*KEAP1* mutant subgroups: *ALK* fusion (*GRIN2A*, 3.03-fold; *CLDN10*, 2.53-fold; *SLITRK6*, 1.86-fold), *EGFR* mutant (*SFTPC*, 3.82-fold; *MUC21*, 1.99-fold; *ATP13A4*, 1.60-fold), *KRAS* mutant (*VSIG1*, 1.86-fold; *AREG*, 1.47-fold; *C15orf48*, 1.25-fold), and *KRAS* + *STK11*/*KEAP1* mutant (*ABCC2*, 4.03-fold; *MUC13*, 3.21-fold; *CLDN10*, 3.00-fold). The top driver-associated CT antigen candidates included *LEMD1* (1.42-fold) in *ALK* fusion, *TMEM108* (1.27-fold) in *EGFR* mutant, *XAGE1D* (1.7-fold) in *KRAS* mutant, and *CABYR* (1.52-fold) in *KRAS* + *STK11*/*KEAP1* mutant subgroups.
Conclusion: Our analysis revealed several surfaceome and CT antigen candidate genes with relatively high expression across lung adenocarcinoma, as well as differential expression of candidate genes within specific genomic subtypes. These findings can help prioritize the validation and development of novel therapeutic targets in lung adenocarcinoma.

#3362 Describing the molecular landscape of cervical cancer metastases: Implications for future therapeutic targets.

M. J. Hadfield[1], S. Wu[2], A. Farrell[2], M. Oberly[2], G. Sun[1], P. Thaker[3], J. Wellcome[4], M. Anderson[4], D. Dizon[1];
[1]Brown University/Legorreta Cancer Center, Providence, RI, [2]Caris Life Science, Phoenix, AZ, [3]Washington University/Siteman Cancer Center, St. Louis, MO, [4]University of South Florida, Tampa, FL

Introduction: Cervical Cancer (CC) is a heterogenous disease with multiple histological sub-types. Early screening has led to a reduction in disease related mortality, but a significant number of patients present with or progress to advanced disease. Studies between the molecular and immune alterations in CC primaries (CCP) and CC metastases (CCM) are needed to explore potential therapeutic strategies.
Methods: Relationships of CCM and alterations detected by NGS (592, NextSeq; WES, NovaSeq) were investigated in 2,668 (1,393 primary Cervix samples, 383 local metastatic GYN samples, and 892 distant metastatic samples) CC samples (Caris Life Sciences, Phx, AZ). PD-L1+ was tested by IHC (22c3, >1%). Tumor mutational burden (TMB) was measured by summing somatic mutations per tumor (H: >10 mt/MB). Immune infiltrates estimated by deconvolution of WTS data (NovaSeq) using Quantiseq. Statistical significance determined by chi-square and Mann-Whitney U and adjusted for multiple comparisons ($q<0.05$).
Results: Hierarchical clustering of CCM sites by alterations (mutations, amplifications and fusions) frequency revealed CCM to Liver (n=77) and Lymph Nodes (n=265) as the most distinct from CCP while Vagina/Vulva (V/V) (n=196) and Lung (n=115) CCM were most similar. Lymph Nodes had decreased *TP53*-mt (6.6% vs 14.7%) and *ARID1A*-mt (4.53% vs 8.27%) but higher *BRCA1*-mt (3.03% vs 0.87%) compared to CCP ($p<0.05$). Liver had higher *BRCA1*-mt (6.67% vs 0.87%), *ASXL1*-mt (8.47% vs 2.96%) and *APC*-mt (4% vs 0.65%) compared to CCP ($p<0.05$). CCM to Lymph Nodes had higher median TMB (median [range]: 6 [0-101] vs 5 [0-460], $q<0.05$) and HPV16/18+ rate compared to CCP (81.2% vs 66.8%, $p<0.05$). CCM to Liver had lower expression of *CTLA4* compared to CCP (1.67-fold decrease), similarly, Ovary/FT had significantly lower expression of immune checkpoint (IC) gene expression (*CD80*, *CD86*, *CD274*, *PDCD1*, *PDCD1LG2*, *CTLA4*, *HAVCR2*, *IDO1*, *LAG3*, *IFNG*: 2.23-4.66-fold decrease) ($q<0.05$). While Lymph Nodes had higher expression of the IC genes compared to CCP (1.30-1.49-fold, $q<0.05$). CCM to Liver and Ovary/FT had lower median infiltration of immune cells while Lymph Nodes had higher compared to CCP of Macrophage M1 (2.7% vs 1.03% vs 3.35% vs 3.1%), B cells (3.7% vs 3.5% vs 5.6% vs 4.3%), CD8 T cells (0% vs 0% vs 1.01% vs 0.75%), and Tregs (1.6% vs 0.74% vs 2.86% vs 2.5%) ($q<0.05$). CCM to Liver and Ovary/FT had lower median IFN score while Lymph Nodes had higher median IFN score ($q<0.05$) compared to CCP, similarly, Ovary/FT had a lower % of T-cell inflamed tumors with Lymph Nodes having higher T-cell inflamed tumors compared to CCP (7.89% vs 47.4% vs 29.3%, $q<0.05$).
Discussion: CCM to Lymph Nodes and Liver had the most distinct molecular and immune landscape compared to CCP while Ovary/FT had a similar molecular profile but a distinctively cold immune profile compared to CCP. Additional studies to evaluate the potential therapeutic targets are warranted.

#3363 LIG1 inactivation selectively inhibits growth of BRCA1 mutant cells in vitro and in vivo.

L. Martires, L. G. Ahronian, C. Pratt, N. Das, X. Zhang, D. A. Whittington, H. Zhang, B. Shen, J. Come, P. McCarren, M.-S. Liu, C. Min, T. Feng, H. Jahic, E. Brophy, D. Aird, J. N. Andersen, A. Huang, F. Li, W. D. Mallender, **H. E. Nicholson**;
Tango Therapeutics, Boston, MA

Women harboring a mutation in the *BRCA1* gene have a >7X increased risk of developing breast cancer and >35X increased risk of developing ovarian cancer in their lifetime compared to women lacking such mutations. While PARP1/2 inhibitors are efficacious in the *BRCA* mutant setting, this efficacy is limited and resistance develops readily. Additional therapeutic targets beyond PARP1/2 are needed to treat cancer patients with *BRCA* mutations. We performed CRISPR screens in 11 *BRCA1/2* wild-type and 2 *BRCA1* mutant cancer cell lines to identify targets that are synthetic lethal with *BRCA1* mutations. In addition to USP1, PARP1 and POLQ, we identified the DNA ligase gene *LIG1* as a novel target that when knocked out kills *BRCA1* mutant cells selectively. Internal analysis of *BRCA* mutations in breast and ovarian cancer cell lines in the Project Achilles database further validated the hyperdependence of *BRCA1* mutant cells on *LIG1*. Single-gene perturbation of *LIG1* using CRISPRn, CRISPRi, and RNAi confirm the lethal effect of *LIG1* inactivation in *BRCA1* mutant cell lines, but not *BRCA1/2* wild-type cell lines. This loss of viability could be rescued by complementing with an exogenous wild-type *LIG1* cDNA, demonstrating the on-target nature of the genetic tools. Using a degradable DNA Ligase I fusion protein, we demonstrate a strong correlation between DNA Ligase I protein level and viability in *BRCA1* mutant cells. Enzymatically inactive DNA Ligase I mutant protein (LIG1^{K568A}) was unable to rescue the loss of viability caused by endogenous *LIG1* depletion supporting the tractability of this target from a small molecule inhibitor perspective. These data were reproduced *in vivo* using *BRCA1* mutant MDA-MB-436 derived tumors, in which tumor growth was inhibited >80% upon loss of *LIG1*.Mechanistically, DNA ligase I plays a critical role in DNA replication and damage repair by sealing nicks in the phosphodiester backbone of DNA. When these nicks are not repaired, they are marked by the addition of PAR chains. Consistent with this mechanism, we demonstrated that inactivation of *LIG1* leads to increased PARylation. The induction of PARylation was proportional to the level of inactivation of LIG1 protein, supporting a correlation between LIG1 activity and DNA nick repair. Together, these data support DNA ligase I as a synthetic lethal target in the context of *BRCA1* mutations.

#3364 PELO is a synthetic lethal target in chromosome 9p21-deleted or MSI cancers.

E. M. Chan[1], P. Borck[2], N. Bick[2], K. Jankovic[1], I. Boyle[2], L. Parker-Burns[1], K. Foster[2], A. Lau[2], A. Borah[2], J. Dempster[2], F. Vazquez[2];
[1]Columbia University Irving Medical Center, New York, NY, [2]Broad Institute, Cambridge, MA

Homozygous deletion of chromosomal region 9p21.3 is one of the most frequently observed somatic copy number alterations in cancers, occurring in approximately 15% of all cancers. Many of the 9p21.3-deleted cancers are further characterized by poor clinical outcomes including subsets of glioblastoma, pancreatic, esophageal, and urothelial cancers. Large deletions of chromosomal regions may also provide unique therapeutic opportunities. Specifically, cancer-specific therapeutic opportunities can arise from co-deletions of passenger genes neighboring tumor suppressors. As such, we sought to identify novel therapeutic targets associated with Ch9p21.3 loss in cancers and identified the pelota mRNA surveillance and ribosome rescue factor (PELO) as the top preferential dependency in 9p21.3-deleted cancers. Intriguingly in another analysis, we identified PELO to be amongst the top preferential dependencies in cancers with microsatellite instability (MSI), which accounts for subsets of colorectal, endometrial, gastric, and ovarian cancers. Given the strength of PELO as a candidate synthetic lethal target in two distinct cancer subsets, we performed focused validation with CRISPR interference across multiple cell lines. Knockdown of PELO preferentially impaired the viability of MSI or 9p21-deleted as compared to control (9p21-proficient and microsatellite stable) cells. Further validation with patient-derived organoid and in vivo xenograft models confirmed these findings. We next sought to refine the predictive biomarkers for PELO dependency and identified loss of FOCAD (a 9p21.3 gene and an interactor of the SKI mRNA surveillance pathway) as necessary and sufficient for PELO dependency in the 9p21.3-deleted context. Our findings implicate splicing alterations involving TTC37, a key protein in the SKI mRNA surveillance complex, as the underlying cause of PELO dependency in MSI cancers. Together, we found that loss of large deletions of 9p21.3 and MSI independently impair the SKI complex, uncovering a dependency upon PELO and highlighting a novel functional interaction between PELO and the SKI complex. Furthermore, the strength of this synthetic lethal interaction in a broad range of cancers with poor outcomes underscores the potential of PELO as a promising drug target for patients with 9p21.3-deleted or MSI cancers.

#3365 Reliable detection of potentially therapeutically actionable ecDNA using clinical-grade NGS in a large pan-cancer cohort.

Matteo Repetto[1], Klaus Wagner[2], Shalabh Suman[3], Peter Krein[2], Pavitra Rao[3], Maria Arcila[3], Christian Hassig[2], Mark Donoghue[4], Alexander Drilon[1], Michael Berger[3]

[1]Early Drug Development Service, Memorial Sloan Kettering Cancer Center, New York, NY,[2]Boundless Bio, Inc., San Diego, CA,[3]Pathology and Laboratory Medicine, Memorial Sloan Kettering Cancer Center, New York, NY,[4]Memorial Sloan Kettering Cancer Center, New York, NY

Background Focal high-level oncogene amplifications (FH-amp) (e.g., *MYC, EGFR*) frequently occur on extrachromosomal DNA (ecDNA), highly transcribed units of circular non-chromosomal DNA. FH-amp on ecDNA promote intra-tumoral heterogeneity, resistance to therapies, and poor prognosis. Recently, a Phase 1 clinical trial exploring ecDNA-directed treatments has begun. However, to date, bioinformatic detection of ecDNA has relied on whole-genome sequencing data, and no standard method exists to detect ecDNA on targeted NGS. We thus sought to explore the feasibility of detecting ecDNA in a large cohort of patients with solid tumors sequenced with the targeted NGS panel, MSK-IMPACT, and describe the pan-cancer prevalence of oncogenes amplified on ecDNA.
Methods We utilized a novel bioinformatic ecDNA-diagnostic algorithm, ECHO, to determine the presence of oncogene FH-amp on ecDNA (including HSR) vs. chromosomal in clinical-grade NGS data. 72,651 tumor samples profiled by MSK-IMPACT were queried for high level oncogene FH-amp (*AR, CCNE1, CDK4/6, EGFR, FGFR1-4, KRAS, MDM2, MDM4, MET, MYC, MYCL*, and *MYCN*) above a fold-change of three, and subsequently annotated with ECHO. Patients with concomitant oncogenic driver mutations or fusions (e.g., *EGFR L858R, EML4-ALK*) were excluded based on the hypothesis that they might be mutually exclusive with oncogene FH-amp.
Results FH-amp of any above listed oncogene were found in 3065 (4.2%) samples. Cancer types with frequent FH-amp without concomitant driver alterations were liposarcoma (LPS) (61% FH-amp; 43% were ecDNA+), glioblastoma (GBM) (22%; 72%), gastroesophageal adenocarcinoma (GE AD) (10%; 57%) squamous cell lung cancer (7%; 18%), and breast cancer (BRCA) (7%; 23%). Among tumors with oncogene FH-amp, GBM and GE AD had high frequencies of ecDNA+ FH-amp of *EGFR* (39% and 15% of all EGFR ecDNA+). LPS had the highest frequency of ecDNA+ FH-amp of *CDK4* (64%), followed by GBM (15%). The majority of ecDNA+ *FGFR1* and *FGFR2* FH-amp were in BRCA (75% and 47%). *EGFR* in GBM and EGFR or *FGFR2* in GE AD were ecDNA+ in more than 90% of patients, while *CDK4* in LPS and *FGFR1* in BRCA were ecDNA+ in 45% and 39% respectively.Evaluation the relationship between ecDNA+ by ECHO and amp FC range showed higher ecDNA+ in samples with higher level amp (FC > 5; 58% ecDNA+) compared to lower level amp (FC 4~5; 12%, FC 3~4; 6% ecDNA+).
Conclusions A novel ecDNA clinical diagnostic tool, ECHO, was successfully applied to a large clinical cohort of patients enriched for actionable oncogene amplifications sequenced with MSK-IMPACT. The results demonstrate that detection of ecDNA using clinical-grade NGS assays is feasible and that key oncogene FH-amp on ecDNA (e.g., *EGFR, FGFR2*) are common in select tumor types. ECHO may be developed as a clinical trial device to prospectively identify patients with oncogene ecDNA+ FH-amp for clinical testing of ecDNA-directed therapies.

#3366 FoRx-06-428 is a novel PARG inhibitor with potent anti-tumor efficacy in preclinical cancer models.

O. Querolle[1], U. Lucking[1], L. Iacovino[1], A. Freudenmann[1], G. Rossetti[1], M. Gysin[1], S. Bologna[1], V. Dionellis[1], M. Malattia[1], A. Potenza[1], N. Bocquet[1], I. Konstantinova[1], A. Goutopoulos[1], S. Sotiriou[1], T. Halazonetis[2], T. Bashir[1], F. Zenke[1];

[1]FoRx Therapeutics AG, Basel, Switzerland, [2]University of Geneva, Geneva, Switzerland

The formation of poly(ADP-ribose) (PAR) chains from NAD+ precursors by PARP enzymes is a characteristic posttranslational modification during DNA damage repair. PAR chains function as docking platforms for DNA repair proteins that are required to resolve DNA lesions. Equally important is the subsequent removal of PAR chains from protein substrates to conclude the repair process and restore genomic integrity. Poly(ADP-ribose) glycohydrolase (PARG) is the key enzyme in this process and has recently garnered significant attention as a novel cancer target. FoRx-06-428 is a novel, orally bioavailable and highly potent, low molecular weight PARG inhibitor. It binds to the catalytic domain of human PARG with high affinity, as evidenced by surface plasmon resonance (SPR), and displays potent inhibition of enzymatic activity. FoRx-06-428 shows selective reduction of viability in a panel of cancer cell lines highlighting therapeutic potential in multiple cancer indications. Pharmacological inhibition of PARG leads to accumulation of PAR chains and is indicative of target engagement, accompanied by modulation of DNA damage response markers, such as phosphorylation of replication protein A (pRPA) and phosphorylation of H2AX (γH2AX). Compelling anti-tumor efficacy as single agent was observed in several xenograft models (breast and gastric cancer) with excellent tolerability. Dose-dependent accumulation of PAR chains was demonstrated *in vivo* and constitutes a tractable target engagement biomarker for clinical exploration. Sensitivity to PARG inhibition is partly driven by distinct genomic instabilities, such as defects in homologous recombination (HR) repair, however the activity of PARG inhibitors is also influenced by aberrations in other cancer-relevant pathways. This report represents the first disclosure of the pharmacological characterization of FoRx-06-428 and highlights the value of PARG inhibition as a novel targeted approach to treat DNA repair-deficient cancers.

#3367 R-loop type determines the orientation of transcription-replication conflicts attenuated by transcription factor IIS.

R. C. Duardo[1], J. Marinello[1], M. Russo[1], S. Morelli[1], S. Pepe[1], F. Guerra[1], B. Gomez-Gonzalez[2], A. Aguilera[2], **G. Capranico**[1];
[1]University of Bologna, Bologna, Italy, [2]Centro Andaluz de Biologia Molecular y Medicina Regenerativa-CABIMER, Seville, Spain

During human Topoisomerase I (Top1) catalytic activity, a transient Top1-DNA cleavage complex (Top1cc) forms to allow DNA relaxation. Top1ccs can be stabilized by antitumor Top1 poisons, such as clinically-effective camptothecin analogs. Camptothecin-stabilized Top1ccs can lead to R-loop-dependent transcription-replication conflicts (TRCs), single-end DNA double-strand breaks (seDSBs) and genome instability in cancer cells. To define the genomic location of TRCs and the underlying mechanisms, we integrated genomic maps of Top1cc-induced DNA cleavage by END-seq and DNA:RNA hybrids by DRIP, determined the cell-cycle specificity of micronuclei formation and the effects of elongation transcription factor IIS (TFIIS). We have defined the genomic sites of both seDSBs and increased R-loop levels (gains) induced by Top1ccs. seDSBs are highly enriched at regions with R-loop gains at highly-transcribed genes in early replicating zones. Kinetics analyses of R-loops and genomic ChIP data of RNA polymerase II (RNAPII) revealed that R-loop gains can either be upstream or downstream of RNAPII. TFIIS effects showed that downstream R-loop gains can follow RNAPII backtracking and arrest. seDSB strandness showed that co-directional TRCs occur mainly at downstream hybrid-associated RNAPII, whereas head-on TRCs occur mainly at upstream hybrid-associated RNAPII. Therefore, Top1ccs can increase two structurally-different R-loops and R-loop-associated backtracked RNAPII causes co-directional TRCs at higher rate than head-on collisions. Moreover, Top1ccs trigger micronuclei formation at G1/early S, but not late S/G2, which are attenuated by TFIIS. Thus, our findings establish a role of RNAPII backtracking at highly-transcribed genes in Top1cc-induced co-directional TRCs and micronuclei formation. The findings can accelerate the development of new effective strategies to treat cancer patients. #3368 Combination of a chk1/2 dual inhibitor (prexasertib) and gemcitabine reveals a novel intrinsic synergy mechanism in head and neck squamous cell carcinoma.

V. C. Palve, H. L. Walker-Mimms, R. Chaudhary, V. Izumi, N. Chaudhary, B. Fang, J. Koomen, J. A. Guevara, P. C. Rodriguez, C. H. Chung, D. R. Duckett; Moffitt Cancer Center, Tampa, FL

Head and neck squamous cell carcinoma (HNSCC) presents a challenging clinical scenario due to its recurrence propensity despite existing treatments. Altered intrinsic signaling pathways significantly contribute to therapeutic resistance, demanding exploration of novel strategies to induce tumor cell demise. Dysregulated cell cycle and DNA damage repair constitute pivotal events driving HNSCC progression, offering potential therapeutic targets.CHK1 and CHK2, pivotal regulators of the DNA replication checkpoint, are promising targets in HNSCC. The convergence of DNA-damaging agents with DNA checkpoint inhibitors represents a burgeoning paradigm in cancer management. Our study delves into elucidating the intrinsic signaling mechanisms triggered by the synergistic action of the CHK1/2 dual inhibitor (Prexasertib) and the nucleoside analog (Gemcitabine) in HNSCC.Our study unveiled a robust synergistic effect between Prexasertib and Gemcitabine, inducing substantial cell death in multiple HNSCC cell lines and mouse model. Remarkably, the combination rapidly induced DNA damage and reduced tumor growth in vivo. To unravel the underlying intrinsic signaling mechanism provoked by the Prexasertib/Gemcitabine combination, we conducted comprehensive molecular analyses.Proteomic profiling uncovered distinct alterations in key signaling pathways upon combination treatment. We identified unique overexpression of an embryonic stem cell-specific transcription factor pivotal in genomic stability regulation, solely induced by single-agent Prexasertib. Specifically, the combination therapy showcased unique modulation of critical genes involved in DNA repair, replication, and cell cycle regulation. These alterations included overexpression or suppression of key genes associated with DNA stability and cell proliferation pathways, accompanied by evidence of CHK1/2 inhibition-mediated DNA damage response accompanied by cleavage of CHK-2 and caspase-3 proteins, validated through Western blots.Additionally, functional assays including the colony formation assays demonstrated markedly reduced survival rates with the combination treatment compared to single-agent therapy. Cell cycle analysis revealed a replication catastrophe and increased pH2AX across multiple HNSCC cell lines following combination treatment.Our findings highlight the significance of CHK1/2 inhibition coupled with nucleoside analog-induced DNA damage in unveiling novel intrinsic signaling mechanisms in HNSCC. These insights offer a promising avenue for targeted therapeutic strategies to enhance treatment efficacy and outcomes in HNSCC.This work has been supported by the MGC, FC, P&MC, and BBSR at the H. Lee Moffitt Cancer Center & Research Institute, a comprehensive cancer center designated by the National Cancer Institute (P30-CA076292).

#3369 Dual inhibition of ATR and PI3K pathways promotes cell death in platinum-resistant endometrial cancer cells by increasing DNA damage.

K. R. Ibanez[1], T.-T. Huang[1], S. Sotiriou[2], Y. G. Lin[3], J.-M. Lee[1];

[1]Center for Cancer Research, National Cancer Institute, National Institutes of Health, Bethesda, MD, [2]Roche Pharma Research and Early Development (pRED), Roche Innovation Center Basel, F. Hoffmann-La Roche Ltd., Basel, Switzerland, [3]Genentech, Inc., South San Francisco, CA

Background: Endometrial cancer (EC) is the most common gynecologic malignancy with increasing incidence and mortality in the U.S. Among the four subtypes characterized by the Cancer Genome Atlas, the serous-like copy number high (CNH) subtype which occurs in 15-25% of EC is associated with poor prognosis and platinum resistance, requiring alternative treatment options. ~85% CNH EC cases have impaired G1/S checkpoint regulation, making cells rely on ATR-mediated G2/M cell cycle checkpoints for optimal DNA replication and repair. Additionally, over 80% of ECs exhibit PI3K pathway activation (e.g., *PIK3CA* mutations), linked to enhanced DNA repair and drug resistance. Therefore, we hypothesized that dual ATR and PI3Kα inhibition would enhance DNA damage, increasing cell death in EC.

Methods: CNH EC cell lines included platinum-resistant (KLE, MFE280, HEC1A, ARK2) as well as platinum-sensitive (ARK1) lines used to evaluate the activity of ATR inhibitor (ATRi) camonsertib and PI3Kα inhibitor (PI3Kαi) inavolisib. Cell growth was assessed by 3-day XTT and 9-12-day colony-forming assays. The degree of combination synergy, additivity, or antagonism was calculated using SynergyFinder with a reference highest single agent (HSA) model. An HSA synergy score > 10 indicates synergy, -10 to 10 suggests additivity and < -10 represents antagonism. DNA damage endpoints were measured by alkaline comet assay and immunoblotting for γ-H2AX. Data were repeated in triplicate, analyzed using one-way ANOVA test, and shown as mean ± SD. $P < 0.05$ was statistically significant.

Results: All tested EC cell lines showed sensitivity to clinically attainable doses of ATRi monotherapy (IC_{50} 0.09 - 0.98 μM), but varying sensitivity to PI3Kαi monotherapy (IC_{50} 0.03 - 67.01 μM) unrelated to their *PIK3CA* mutation status. Combination treatment using clinically attainable concentrations (camonsertib < 6 μM; inavolisib < 10 μM) yielded additivity in all cell lines independent of platinum sensitivity (HSA synergy scores -0.8-10.0). Notably, increased cytotoxic effects were observed in both *PIK3CA* wild-type (KLE) and *PIK3CA*-mutant (MFE280 and HEC1A) platinum-resistant lines by colony-forming assays (4.8- to 15.4-fold decrease in colony-forming ability relative to ATRi; 1.5- to 3.5-fold decrease relative to PI3Kαi). ATRi and PI3Kαi combination induced greater DNA damage, evidenced by elevated mean comet tail moment relative to ATRi (increased 2.5- to 6.7-fold; $P < 0.01$) or PI3Kαi (increased 2.1- to 5.6-fold; $P < 0.01$) regardless of *PIK3CA* mutation status. Increased γ-H2AX levels were found in HEC1A cells with combination treatment (3.2-fold increase relative to ATRi; 16-fold increase relative to PI3Kαi).

Conclusion: Our results suggest that dual inhibition of ATR and PI3K pathways induces greater cell death by increasing DNA damage in platinum-resistant EC cells independent of *PIK3CA* mutation status.

#3370 Anti-tumor activity of Debio 0123 in combination with sacituzumab govitecan in preclinical models of breast cancer.

L. Piggott, E. Rodrigo Imedio, F. Staehli;
Debiopharm International S.A., Lausanne, Switzerland

Background: Debio 0123 is a WEE1 inhibitor that has previously shown significant preclinical efficacy in combination with DNA damaging agents and is currently being investigated in phase 1 clinical studies either as a monotherapy or in combination with different standard therapies. Sacituzumab govitecan (SG) is a TROP2 directed antibody-drug-conjugate (ADC) carrying an SN38 payload that has recently gained approval in TNBC and ER+ve breast cancer after demonstrating improvements in survival versus standard therapies. Despite these promising data some patients still do not respond to SG treatment, develop resistance or experience toxic side effects. Herein we present preclinical data that demonstrates Debio 0123 improves tumor response to SG in breast cancer models and provides sustained complete responses and anti-metastatic activity.

Methods: Synergy between Debio 0123 and SG was evaluated in breast cancer cell lines, with varying levels of TROP2 expression, *in vitro* using standard cytotoxicity assay in a matrix combination format. Efficacy of Debio 0123 and SG as monotherapies or in combination was further assessed *in vivo*, in both $TROP2_{high}$ and $TROP2_{low}$ subcutaneous breast cancer xenograft models at different doses.

Results: *In vitro*, Debio 0123 in combination with SG demonstrated synergistic tumor cell killing in all 4 breast cancer cell lines tested, at all concentrations. *In vivo*, $TROP2_{high}$ MDA-MB-468 breast cancer xenograft tumors treated with Debio 0123 at 30mg/kg QD resulted in minimal anti-tumor activity as a monotherapy but completely regressed 100% of the tumors in combination with SG. Furthermore, 40% of these complete regressions were sustained for up to 100 days post-treatment initiation. These data were then further replicated at a reduced dose of SG. In the $TROP2_{low}$ MDA-MB-231luc model, Debio 0123 significantly improved response to SG resulting in a 2-fold improvement in tumor growth inhibition. Additionally, combination treatment significantly inhibited metastasis of these tumors to the lung and lymph nodes as monitored by bioluminescence. Collectively, these results lead to a significant improvement in animal survival as a combination compared to either treatment as a monotherapy.

Conclusion: These results demonstrate that Debio 0123 synergizes with, and significantly improves breast cancer tumor cell response to, SG regardless of TROP2 expression levels (both *in vitro* and *in vivo*), leading to complete regressions and inhibition of metastasis. Collectively these data support Debio 0123 in combination with SG could be a potential therapeutic approach for improving responses in patients with breast cancer.

#3371 PRMT blockade induces defective DNA replication stress response via ATR suppression and synergizes with PARP inhibition.

D. Bisht[1], Y. Li[1], L. E. Dobrolecki[2], C. Sallas[2], X. Zhang[1], T. D. Kerr[3], Y. Wang[1], S. Awasthi[1], B. Kaundal[1], S. Wu[1], W. Peng[4], M. L. Mendillo[5], Y. Lu[1], C. R. Jeter[1], G. Peng[1], J. Liu[1], S. N. Westin[1], A. K. Sood[1], M. T. Lewis[2], J. Das[6], S. Yi[7], M. T. Bedford[1], D. J. McGrail[8], N. Sahni[1];

[1]The University of Texas MD Anderson Cancer Center, Houston, TX, [2]Baylor College of Medicine, Houston, TX, [3]Center for Immunotherapy and Precision Immuno-Oncology Cleveland Clinic, Cleveland, OH, [4]University of Houston, Houston, TX, [5]Northwestern University Feinberg School of Medicine, Chicago, IL, [6]University of Pittsburgh School of Medicine, Pittsburgh, PA, [7]The University of Texas at Austin, Austin, TX, [8]Center for Immunotherapy and Precision Immuno-Oncology, Cleveland Clinic, Cleveland, OH

Aberrant protein arginine methylation has been observed in multiple cancer types, making it an attractive drug target. Proteins can undergo asymmetric arginine methylation by type I protein arginine methyltransferases (PRMTs), predominately by PRMT1 and to a lesser extent PRMT4, or symmetric arginine methylation by type II PRMTs, predominately PRMT5. Here, we performed targeted proteomics following inhibition of PRMT1, PRMT4, and PRMT5 across cancer cell lines. We found that inhibition of both type I and type II PRMTs suppressed levels of total and phosphorylated ATR protein in cancer cell lines, and down-regulated expression of the ATR gene. Loss of ATR from PRMT inhibition resulted in defective DNA replication stress response activation in following exogenous replication stress. Since PARP inhibitors are known to induce replication stress, we next combined PRMT inhibition with PARP inhibition and found inhibition of PRMT1 or PRMT5 greatly exacerbated PARP inhibitor induced DNA damage. Based on this observation, we assessed the combination of PARP and PRMT inhibition in a panel of cell lines. While inhibition of both type I and type II PRMTs were synergistic with PARP inhibition in both cells with intact and deficient homologous recombination, type I PRMT inhibition resulted in higher toxicity in non-malignant cells. Therefore, we validated the synergy of combined PARP/PRMT5 inhibition in primary patient-derived organoids. Finally, we demonstrate that the combination of PARP and PRMT5 inhibition improves overall survival in both BRCA-mutant and wild-type patient-derived xenograft models without any detectable hematological toxicities typically associated with PARPi combination therapies. Taken together, these results demonstrate that PRMT5 inhibition may be a well-tolerated approach to improve tumor sensitivity to PARP inhibition.

#3372 Clinical genetic testing results in metastatic prostate cancer patients.

T. Crawford[1], E. Barrett[1], T. Al-Saleem[2], M. Tayeb[1], H. Symecko[1], C. Orr[1], V. Narayan[1], S. Takvorian[1], R. Parikh[1], Y.-N. Wong[1], K. Robinson[1], L. Aiello[2], C. Wolfe[1], D. Mann[1], K. Spielman[1], S. Domchek[1], K. Maxwell[1];

[1]University of Pennsylvania, Philadelphia, PA, [2]Corporal Michael Crescenz Veterans Affairs Medical Center, Philadelphia, PA

Background: A proportion of prostate cancers (PCa) are hereditary, driven by likely pathogenic/pathogenic germline variants (PGVs) in DNA repair genes. PGVs in *BRCA2* contribute to aggressive prostate cancer biology and overall poorer survival. Genetic testing and targeted sequencing panels help identify PGV carriers who are susceptible to aggressive PCa and may be candidates for targeted therapy with PARP inhibitors. Prior research suggested a high rate of 10-20% of metastatic PCa (mPCa) patients have PGVs in DNA repair genes; however, many of these studies reported highly selected research cohorts. The real-world rate of DNA repair PGVs and whether any genotype-phenotype correlations exist in broader, more racially diverse clinical populations are not well understood.

Patients and Methods: We studied two prospective cohorts of males with PCa who presented for genetic testing due to meeting NCCN personal history genetic testing criteria for prostate cancer (metastatic or high risk/very high risk localized). We report PGV frequencies of mPCa patients who underwent genetic testing in a point of care model at the Basser Center within Penn Medicine (Penn-POC, n=596), and a cancer genetics practice at the Corporal Michael Crescenz VA Medical Center in Philadelphia (VA-GT, n = 171). PGVs were identified in *ATM, BRCA1, BRCA2, CHEK2, EPCAM, HOXB13, MLH1, MSH2, MSH6*, *NBN, PMS2, TP53*.

Results: The Penn-POC and VA-GT cohort included 437 (73.3%) and 59 (34.5%) self-identified white patients, respectively, and 121 (20.3%) and 107 (62.6%) self-identified black patients, respectively. In the Penn-POC and VA-GT cohorts, 7.2% and 7.6% patients were found to carry a PGV, respectively, and 11.9% and 18.1% of patients had variants of uncertain significance (VUS), respectively. The most common PGVs in the Penn-POC cohort were in *BRCA2* (2.2%), *ATM* (1.9%), and *BRCA1* (1.3%). The most common PGVs in the VA-GT cohort were in *BRCA2* (2.9%), *ATM* (1.1%), and *CHEK2* (1.2%). PGV rates were not statistically different between self-identified white and black patients in either cohort (Penn-POC p= 0.4036; VA-GT p=0. 0.4061). Overall PGV frequencies between the Penn-POC and VA-GT cohorts are not statistically different. There is a correlation between carrier status and age at diagnosis with a significant difference between carriers and non-carriers (p=0.0433) as well as with family history of first degree relatives with PCa (p=0.0184). However, there was not a significant correlation between carrier status and clinical stage at diagnosis, Gleason grade group, or other clinical variables.

Conclusions: We report a lower rate of DNA repair PGVs in two prospectively ascertained, racially diverse cohorts of mPCa patients, approximately 7%, compared to the previously reported rates of 10-20%. Our results suggest age and family history, but not other pathological variables are clinical predictors for carrying a PGV in mPCa patients.

#3373 Protein kinase D1 alleviate etoposide induced DNA damage through up regulation of alpha-catenin.

S. Shukla, S. Serrano, M. Al-Toubat, T. Osumi, K. Balaji;
University of Florida, Jacksonville, FL

Interaction between E-cadherin and β-catenin at cell-cell adherens junctions is pivotal in cell adhesion, and dysregulation of these genes is associated with disease progression in various solid tumors, notably in prostate cancer. α-catenin acts as a physical linker between the cadherin/β-catenin complex and actin cytoskeleton, through its mechanosensory properties has potential to modify interactions between cadherins and cytoskeleton and results in sensitivity of cells to DNA damage and toxicity. Membranous β-catenin interacts with the cellular cytoskeleton through threonine 120 (T120) phosphorylation and its association with α-catenin. We want to investigate the role of protein Kinase D1 (PrKD1) in DNA damage response, using various prostate cancer cell lines; PrKD1-silenced cells (LNCaP sh-PrKD1) and overexpression of PrKD1 (C4-2 PrKD1). PrKD1 silence and overexpress cells were treated with PrKD1 inhibitor and Etoposide to observe the effect of DNA damage repair altering various genes in prostate cancer cells. Silencing α-Catenin increased p-γH2AX (ser-139) expression in C4-2 PrKD1 cells. Conversely silenced PrKD1 (LNCaP sh-PrKD1) cells represented decreased α-Catenin expression, and increased p-γH2AX (ser-139). Overexpression of PrKD1 in prostate cancer cells increased α-catenin levels and conferred resistance to etoposide-induced DNA damage. Silencing PrKD1 compromised DNA damage protective effect. Furthermore, we elucidate the role of Protein kinase D1 (PrKD1), a unique serine-threonine kinase that phosphorylates β-catenin at T120, in this interaction. We treated C4-2 and C4-2 PrKD1 cells with PrKD1 inhibitor and immuno-precipitated β-Catenin complex represented decrease in β-Catenin (T-120) and α-Catenin than untreated C4-2 PrKD1 cells. We observed crosstalk between α-catenin and PrKD1 in DNA damage repair. In-silico analysis affirmed that the loss of T120 phosphorylation disrupts β- and α-catenin interaction. PrKD1 inhibitor decreased cell viability in dose response fashion, and also decrease the p-γH2AX (ser-139) in C4-2 PrKD1 cells than C4-2 cells. In vitro findings were corroborated in a mouse prostate cancer PDX xenograft model by inhibiting PrKD1 kinase activity, resulting in reduced β-catenin T120 phosphorylation and α-catenin levels. In vivo experiments with PrKD1 inhibitor represented tolerability in mice and its efficacy in modulating α-catenin and PrKD1 expression to inhibit tumor progression. Study for the first time provides a mechanistic basis of the protective role of PrKD1 against DNA damage.

PREVENTION / EARLY DETECTION / INTERCEPTION: Animal and Cellular Models of Cancer Prevention and the Study of Biological/Biochemical Mechanisms
Poster Session

#3377 Exploring the role of obesity-induced exosome secretion and associated proteins in endometrial cancer pathogenesis: A roadmap for prevention through exosome inhibition.

T. Sakaue[1], **K. Dorayappan**[2], R. Zingarelli[2], W. Khadraoui[2], M. Anbalagan[3], J. Wallbillich[4], M. Wascovich[2], P. Paramita[2], A. Suarez[2], C. Cosgrove[2], L. G. Maxwell[5], H. Koga[1], D. O'Malley[2], D. Cohn[2], S. Karuppaiyah[2];
[1]Kurume University School of Medicine, Kurume, Japan, [2]The Ohio State University, Columbus, OH, [3]Tulane University School of Medicine, New Orleans, LA, [4]Wayne State University, Detroit, MI, [5]Inova Fairfax hospital, Virginia, VA

Introduction: Endometrial cancer (EC) is the leading gynecologic malignancy in the U.S., with obesity implicated in 57% of cases. This study explores the molecular workings of oncogenic protein expression (TMEM205, STAT5, and FAS) and their role in regulating exosome secretion. Understanding these mechanisms is crucial for unraveling pathways involved in obesity-related EC, informing the development of innovative strategies for prevention and treatment.
Methods: The isolated exosomes were quantified using nanoparticle tracking analyzer (NTA) and their size measured by Transmission electron microscopy (TEM). TMEM205, STAT5, FAS and PIAS3 expression was confirmed by IHC, ELISA and RT-PCR in patient and high fat diet treated mouse tissue. Endometrial hyperplasia was developed in immunocompetent mice using high fat diet (HFD; 45 kcal% fat diet) for 16 weeks.
Results: Our study investigates exosome secretion and the regulation of oncogenic proteins in adipose and uterine tissues from obese EC patients compared to non-obese EC samples. Analyzing the effects of a 45% kcal high-fat diet (HFD) on mice over 24 weeks, we observed higher body weight and increased adipose tissue in the HFD group, along with enlarged uterine horns and heightened inflammation. This correlated with elevated exosome secretion and increased expression of TMEM205, FAS and STAT5, while the tumor suppressor gene PIAS3 was downregulated. The identified small molecule inhibitor, DAP-5, selectively targeting TMEM205 and exosome secretion, demonstrated a significant reduction in body weight and adipose tissue accumulation when administered to HFD mice. Additionally, DAP-5 treatment restored normal uterine morphology and reduced the expression of exosome-related proteins.
Conclusion: This study offers central insights into the mechanisms underlying obesity-mediated TMEM205 expression and exosome secretion, shedding light on their role in the pathogenesis of EC. Additionally, it provides pre-clinical evidence supporting the initiation of the first in-human studies for exosome-targeted therapies aimed at preventing obesity-mediated EC.

#3378 Acinar cell susceptibility for tumor development in the pancreas: Targeting the critical regulators for therapy.

Z. Pan[1], J.-L. Van den Bossche[1], E. Rodriguez-Aznar[1], P. Janssen[1], O. Lara[1], G. Ates[1], A. Massie[1], D. Luc De Paep[2], I. Houbracken[1], M. Mambretti[1], I. Rooman[1];

[1]Vrije Universiteit Brussel (VUB), Jette, Belgium, [2]Universitair Ziekenhuis Brussel, Jette, Belgium

Acinar to ductal metaplasia (ADM) or acinar cell dedifferentiation is one of the most notable features of chronic pancreatitis. It is also considered the initial step of pancreatic cancer development when oncogenic mutations accumulate. However, its precise mechanism and regulatory pathways remain unclear. This study profiled the transcriptome of dedifferentiated acinar cells from both humans and mice. Differential expression analysis integrated with a systematic literature search revealed several potential regulators (e.g., GDF15, GFRA1, MXRA5, CXCL17), of which the expression pattern over time was validated by qRT-PCR. We also focused on multiple conserved pathways of cell survival, among which SLC7A11 (xCT) is transiently upregulated in both species. The xCT subunit, integral to the cystine/glutamate antiporter system xc-, plays a critical role in cell survival across various cell types. To elucidate its role in acinar dedifferentiation, we employed gene silencing, pharmacological inhibition, and a knock-out mouse model. Acinar cells with diminished xCT function exhibit increased ferroptosis linked to lipid peroxidation. Antioxidants such as N-acetylcysteine and ferroptosis inhibitors like Ferrostatin-1 can mitigate lower glutathione levels and lipid ROS accumulation. Similarly, in mouse acute pancreatitis, xCT prevents lipid peroxidation. Our findings indicate that xCT fuels the glutathione pool and maintains ROS balance during ADM, thereby preventing pancreatic acinar cells from ferroptosis, a form of cell death rarely reported in relation to ADM. Next to xCT, a future and similar comprehensive study of the aforementioned genes could provide valuable insights into the dynamic changes that occur during acinar cell dedifferentiation and pave the way to the discovery of new intervention targets to suppress tumorigenesis in chronic pancreatitis.

#3379 Single-cell profiling reveals dynamic epithelial and immune cell interactions in the progression of lung adenocarcinoma.

H. Chen[1], B. Zhu[1], J. Fujimoto[1], Y. Tian[1], J.-R. Li[2], C. Li[1], P. Chen[1], A. Reuben[1], M. Nilsson[1], X. Le[1], A. Poteete[1], S. M. Hubert[1], D. L. Gibbons[1], I. I. Wistuba[1], J. Wu[1], C. Cheng[2], J. V. Heymach[1], J. Zhang[1];

[1]The University of Texas MD Anderson Cancer Center, Houston, TX, [2]Baylor College of Medicine, Houston, TX

Background: Lung adenocarcinoma (LUAD) is a leading cause of cancer-related deaths. Our understanding of LUAD initiation and progression is limited, impeding early diagnosis and effective treatment. A comprehensive single-cell transcriptomic analysis, unraveling the malignant transformation from normal lung to LUAD, will provide key insights into the initiation and development of this challenging disease. However, human tissues are not amendable for such analysis.

Methods: We generated two mouse models, a genetically engineered mouse model with $Kras^{G12D}$ activating mutation (GEMM) and a carcinogen urethane-induced mouse tumor model (CITM) in the same 129S4 background. Single-cell transcriptome sequencing was conducted on lung tissues collected at five time points after induction for each model. The LUAD and its precursors were defined by experienced lung cancer pathologists as normal lung, hyperplasia, adenoma and adenocarcinoma. This analysis aimed to characterize the dynamic interaction between epithelial and immune cells, providing insights into the initiation and progression of LUAD.

Results: A comprehensive analysis identified a total of 12 major cell types, revealing a gradual increase in the proportion of epithelial cells during LUAD progression. EpiC 1, 2, 5 and 8 were consistently found in normal lung epithelium and various stages of abnormal epithelia, indicating their role as background components in lung tissues. In contrast, EpiC 4 emerged from hyperplasia and EpiC 0 and 3 emerged from early adenoma, while EpiC 6 and 7 were predominantly present in adenocarcinoma. Further investigation into the developmental trajectory of AT2 cells indicated a clear separation between normal (EpiC 1, 2, 5 and 8) and tumor cells (EpiC 0, 3, 4, 6 and 7). Cancer hallmark analysis revealed that tumor clusters exhibited higher scores in KRAS_SIGNALING_UP, HYPOXIA, APOPTOSIS, and P53_PATHWAY compared to normal epithelial clusters, suggesting the potential activation of these pathways in the tumorigenesis. Furthermore, the proportion of Macro_C1qc increased over time, accompanied by Macro_C1qc exhibiting the highest M2 signature score. This indicates a unique enrichment of M2-like macrophages in LUAD tissues. Remarkably, a notable increase in ligand-receptor pairs contributed significantly to the signaling from macrophages to tumor cells during progression. The dynamic regulatory interplay between Macro_C1qc and tumor cells was notably mediated by Thbs-Sdc1, App-Cd74, Spp1-Cd44 and other L-R pairs across various time points.

Conclusion: We constructed a single-cell LUAD developmental atlas of dynamic tumor-immune cell interactions, which sheds light on the initiation and progression of LUAD. Notably, our findings underscore a potential crucial role of macrophages, particularly M2 in lung tumorigenesis.

#3380 HER2 overexpression induces breast tumorigenesis in a non cell autonomous manner by inducing oxidative stress in the tissue microenvironment.

S. B. Gurler, O. Wagstaff, L. Dimitrova, F. Chen, R. Pedley, W. Weston, I. Donaldson, B. A. Telfer, D. Novo, K. Pavlou, G. Taylor, Y. Ou, K. Williams, A. Gilmore, K. Brennan, A. Ucar;
University of Manchester, Manchester, United Kingdom

Breast cancer is the most common cancer type in the world. Approximately 70% of pre-malignant breast tumours, known as ductal carcinoma *in situ* (DCIS), and 20% of invasive breast tumours overexpress HER2. Although molecular mechanisms of HER2 function in breast tumour cells have been extensively studied, our knowledge on how HER2 drives breast tumourigenesis at its pre-malignant stage is quite limited. Here, we investigate the HER2-overexpression driven cellular events at the earliest stages of breast tumourigenesis using *in vitro*, *in vivo and ex vivo* models. Using mouse models of HER2+ breast cancer and clinical samples of patients with DCIS, we showed that breast cancer stem cells (BCSCs) reside in HER2-negative population of tumour cells and arise from a HER2-negative cell-of-origin. Proteomics and metabolomics analyses of mammary ducts isolated from the MMTV-Neu mice at the pre-cancerous stage showed that *HER2/Neu* overexpression alters the energy metabolism in mammary epithelial cells *in vivo*. Furthermore, we have observed an accumulation of reactive oxygen species levels in pre-cancerous mammary ducts, which consequently causes oxidative stress induction and DNA damage in both HER2-positive and HER2-negative epithelial cells. Collectively, our findings indicate that HER2 overexpression in normal mammary epithelia may lead to a genotoxic tissue microenvironment that may consequently result in the accumulation of further somatic mutations in HER2-negative cell populations, which contain BCSCs and their cell-of-origin. Our findings therefore illustrate a novel mechanism explaining the HER2-driven breast tumour initiation and thus provide new avenues of research for developing novel preventive approaches against breast cancer.

#3381 Diversifying the breast cancer cell line repository with ACRJ-BC24, ACRJ-BC24α, and ACRJ-BC24β: Novel TNBC cell lines derived from an Afro-Caribbean patient.

I. Allen[1], S. Clarke[1], J. Ravix[2], A. P. Sanchez Covarrubias[3], A. Omotoso[2], D. Cornwall[1], S. N. Chin[1], S. Harrison[4], C.-H. Claude-Henry Volmar[2], S. Saigh[2], B. B. Cortes[1], E. Smith[2], R. Thompson[1], C. Ragin[4], S. George[2], **S. A. Badal[1]**;

[1]Univ. of the West Indies - Mona Campus, Kingston 7, Jamaica, [2]University of Miami, Miami, FL, [3]University of Miami, Kingston 7, FL, [4]Fox Chase Cancer Center, Philadelphia, PA

Breast cancer is a leading global health burden; however, women of African ancestry are disproportionately affected and have an increased risk of developing more aggressive breast cancer, triple-negative breast cancer (TNBC), and consequently suffering poorer outcomes. One factor contributing to this cancer disparity is the lack of diverse representation in preclinical models and clinical trials. Cell lines are widely used preclinical models, though of the breast cancer cell lines commercially available, only 8% are derived from women of African ancestry, compared to 90% from women of European ancestry. Thus, diversifying cancer cell lines would better represent the population as a whole and strengthen the translatability of results. The aim of this study was to develop and characterize three novel breast cancer cell lines derived from a woman of African-Caribbean ancestry, ACRJ BC24 parent, ACRJ BC24α, and ACRJ BC24β. Characterization assays included cell line authentication, growth curve analysis, western blots, immunohistochemistry staining, flow cytometry, whole-genome sequencing (WGS), RNA-sequencing (RNA-seq), xenografts, and karyotyping. Short tandem repeat profiling confirmed the novelty and human origin of the cell line. WGS confirmed the cell lines to be of 100% African ancestry. The ACRJ-BC24 parent, α, and β lines have been passaged over 70 times in vitro with a doubling time of 70 hours, 133 hours, and 70 hours, respectively. All cell lines were confirmed triple-negative, CD49f+ and EpCAM-, as well as CD44+ and CD24-, suggesting a basal-like subtype. Additionally, all the ACRJ BC24 cell lines expressed vimentin but not E-Cadherin, suggesting a mesenchymal phenotype. Expression of N-cadherin is demonstrated in the parent and α line, but not in the β line, showing varying levels of epithelial-mesenchymal transition amongst the lines. Additionally, varying intensity of expression of CD49f was observed between the three ACRJ BC24 lines, further confirming a biological distinction. Cytotoxicity of 10 chemotherapy drugs was assessed against the 3 novel cell lines and established lines (MCF7, T47D, HCC70, and HCC1806). Differential viability was observed among the cell lines as gemcitabine and docetaxel were most potent against ACRJ BC24α with IC_{50}s of 4.6 nM and 10 nM respectively compared to all other cell lines. Our findings confirm the need for increased representation of Black breast cancer cell lines among the preclinical panel for drug screens. The inclusion of these three novel Afro-Caribbean breast cancer cell lines in preclinical models will provide further insight into the current disparities among Black and White breast cancer cell lines.

#3383 Growth suppression and selective disruption of actin by alpha-santalol in human melanoma SK-MEL2 cells.

A. Bommareddy, **R. Chandrasekaran**, M. Lu, D. Penate;
Florida Atlantic University, Boca Raton, FL

Alpha-santalol, a major component of sandalwood oil has been shown to have chemopreventive and anti-tumor effects in different pre-clinical cancer models. The present study was undertaken to determine the *in vitro* efficacy of alpha-santalol on SK-MEL2 human melanoma cells and an immortalized human keratinocyte cell line (HACaT). In this study, we employed MTT assay, Trypan blue assay, wound healing assay, and confocal microscopy for imaging phalloidin/DAPI stained cells to investigate the cytotoxicity, cell viability, migratory potential respectively of the cells treated with different concentrations of alpha-santalol and DMSO for given time periods. Results showed that alpha-santalol treatment significantly decreased SK-MEL2 cell viability, wound healing, while only affecting HACaT cells at higher concentrations. Alpha-santalol treatment also disrupted actin cytoskeleton in SK-MEL2 cells, whereas HACaT cells were more resistant to this effect. In conclusion, the present study reveals selective growth inhibitory and anti-migratory effects of alpha-santalol in human melanoma cells and warrants future studies to systemically explore the mechanistic details involved in its growth inhibitory and antimigratory effects.

#3384 Rapid and automated tumor cell phenotyping based on annexin-mediated enforce blebbing response.

W. Huang[1], Z. Wang[1], D. W. Au[2], B. Tang[1], B. Qi[1], **W. C. Cho**[2], Y. Lin[1];
[1]The University of Hong Kong, Hong Kong SAR, China, [2]Queen Elizabeth Hospital, Hong Kong SAR, China

Introduction: Accumulating evidence supports the tight correlation between the physical characteristics of cells (including morphology, mechanical, and electrical properties) with the progression of cancer. Cellular blebbing, a distinctive feature observed during apoptosis and cell migration, has gained significant recognition. However, existing tools such as atomic force microscopy and optical tweezers have limitations in terms of throughput and complexity. Microfluidics has emerged as a promising technology to overcome these limitations.
Methods: In this study, we developed a novel microfluidic device with a double-layer compression mechanism to induce controlled blebbing of cells. We implemented a convolution-based tracing program to enhance the accuracy and efficiency of cell area measurement. The device was used to examine the enforced blebbing response of two human breast cancer cell lines (MDA-MB-231 and MCF-7) and investigate the potential of blebbing as a marker for drug resistance using a human lung cancer cell line (HCC4006). Additionally, we elucidated the role of annexin-6 (A6) in enforced blebbing and its underlying mechanism.
Results: Our microfluidic device successfully implemented a double-layered design that induced cell deformation through compression from the second pressurized polydimethylsiloxane layer. The findings revealed that highly invasive cell lines, such as MDA-MB-231 and osimertinib-resistant HCC4006, required significantly higher critical compression levels compared to their non-invasive counterparts (MCF-7 cell line) or osimertinib-sensitive cells. Moreover, the drug-resistant groups exhibited a greater compression strain requirement for blebbing compared to the control group, indicating their enhanced resilience against disruptive forces and superior survivability. Prior studies have demonstrated that A6 protein is recruited to the site of membrane injury and facilitates the formation of blebs, thereby contributing to cellular repair processes. Our further investigation into the role of A6 protein demonstrated its involvement in cell blebbing. Knockdown of A6 resulted in a notable 27% reduction in cellular volume, reflecting reduced intracellular pressure, and a corresponding 1.7-fold increase in the critical compressive strain necessary for inducing blebbing.
Conclusion: Our microfluidic device allows for rapid and simultaneous testing and automated analysis of hundreds of cells, making it suitable for applications such as cell sorting, highly invasive and drug-resistant cancer cell detection, without the need for labeling. Furthermore, it serves as a powerful tool for fundamental studies of membrane and cytoskeleton dynamics. The label-free nature of the device, coupled with its high throughput capabilities, highlights its potential in future applications, including cancer monitoring and drug-resistance screening.

#3385 Modeling evolutionary fitness in resistant cancers based on a common adaptability trait.

B. Singh, V. N. Sarli, A. Lucci;
UT MD Anderson Cancer Center, Houston, TX

Cancer is composed of a major subpopulation of proliferative cells and a minor subpopulation of highly adaptable cells. Although it is evident that cancer is an evolution like process driven by rare adaptable cancer cells that persist under various selection pressures, most of our knowledge about cancer comes from studying proliferative cancer cells. To overcome the hurdle in modeling adaptable cancer cell state that defeats all currently offered therapies, we are exploiting a linkage that exists between different adaptability substates such as metabolic, regulatory, and structural substates. Our studies, thus far carried out with aggressive triple-negative breast cancer and melanoma cell lines, suggest that it is feasible to apply severe metabolic challenges as realistic selection pressures/bottlenecks for modeling highly abnormal and highly adaptable cancer cells that drive cancer evolution and therapy resistance. The most significant aspect of our approach is an ability to model rare resistant cells (approximately 0.01% of cells) that survive in reversible quiescence under selection pressures. Monitoring of cells under microscope for several weeks under a severe and prolonged metabolic challenge, for example, a lack of glutamine in culture medium, revealed perhaps most interesting and cancer-relevant cells that survive in quiescence for weeks and then advance to generate therapy-resistant cells. Such microscopic monitoring revealed a significant heterogeneity among surviving cells. As examples, 1) surviving cells differ in the depth of quiescence, some cells trying to proliferate sooner than others; 2) as cells progress from quiescence to proliferation, their fate is far from certain: cells may progress to yield few cells, tiny colony, or large colony and then stop proliferating and in most instances die (abortive attempts at evolution). Of significance, the cell lines derived inflammatory breast cancer (IBC), an aggressive subtype of breast cancer, possessed a higher evolutionary fitness than non-IBC cell lines. This approach also eliminates 99.99% of cells that proliferate in cell culture but would not survive selection pressures in the body. The adaptable cells that survived the bottleneck and then proliferated indefinitely were highly resistant and metastatic. Molecular analyses of adaptable cells, including gene expression microarrays, CGH microarrays, and whole genome sequencing revealed mechanisms for their plasticity (exemplified by markers of high EMT), and for generating cellular diversity by altering epigenome (exemplified by low TET2) and by structural modifications in transcriptome (exemplified by high FTO). We conclude that the phenotype-based approach described here is good at modeling deep intrinsic resistance and may be useful in developing strategies for improving outcomes in resistant cancers. Supported by a State of Texas Grant for Rare and Aggressive Cancers.

#3386 Changes in extracellular vesicle miRNAs from three-dimensional ovarian cancer cell models reflect physiological changes and cancer survival.

N. Godbole[1], A. Ravichandran[2], D. Guanzon[1], A. Lai[1], F. Carrion[3], P. Kalita de Croft[1], L. Perrin[4], J. Hooper[4], L. Bray[2], C. Salomon[1];
[1]University of Queensland, Brisbane City, Australia, [2]Queensland University of Technology, Brisbane City, Australia, [3]Universidad del Alba, Santiago, Chile, [4]Mater Research Institute, Brisbane City, Australia

Ovarian Cancer (OC) is the most common gynaecological malignancy and the eighth most diagnosed cancer in females worldwide. Currently, it is the fifth leading cause of cancer-related mortality among patients globally, largely due to delayed diagnosis, chemotherapy resistance, high metastasis rates, and subtype heterogeneity. Recent OC research highlights extracellular vesicles (EVs) as pivotal contributors to intercellular communication and disease progression, elucidating the intricacies of OC pathology. EVs, diverse membrane-derived vesicles released by most cells, carry molecular cargoes containing proteins and nucleic acids. Studies indicate that the biogenesis, packaging, and release of EVs are highly dependent and sensitive to the cellular microenvironment and depend on the in-vitro and in-vivo modelling systems. Labs use varied model systems—2D monolayers, animal models, and innovative 3D models—to investigate EVs' ovarian cancer roles. Therefore, in this study we aimed to compare the miRNA profiles associated with EVs in 3D ovarian cancer cell models, and to identify the pathophysiological relevance of the EVs isolated from these models to the patient derived EVs.In this study, two OC epithelial cell lines, SKOV-3 and OVCAR-, were initially cultured as 2D monolayers and embedded within Gelatin Methacryloyl hydrogels. Over nine days, multiple assays observed spheroid formation within the cell-laden hydrogels. EVs isolated from the cell-conditioned media were characterized per MISEV 2018 guidelines. Small RNA sequencing identified statistically significant miRNAs, subject to gene ontology and gene rank analyses. EVs from a cohort of 60 OC patients were used to identify survival-associated miRNA profiles.Our findings in the cell-laden hydrogels demonstrated OC cell growth, proliferation, and aggregation into spheroidal structures, establishing an ideal 3D model. The isolated EVs were characterized for size, concentration, morphology, and surface markers. Small RNA sequencing revealed 18 significantly different EV-associated miRNA species across 3D vs 2D models, influencing apoptosis, angiogenesis, migration, and proliferation in ovarian cancer. Notably, 3D model-derived EV-associated miRNAs mirrored patient-derived EV-associated miRNA profiles, indicating their pathophysiological relevance.This study establishes a robust 3D OC model in hydrogels, showcasing growth, proliferation, and aggregation capabilities. Differential miRNA profiles between 3D and 2D model EVs highlight the critical roles of these miRNAs in essential ovarian cancer processes. Moreover, similarities between 3D model and patient-derived EV-associated miRNA profiles emphasize the clinical relevance of our model.

#3387 Spatial analysis revealed distinct molecular and immune landscape in genetic versus carcinogen-induced lung adenocarcinoma precancer mouse models.

B. Zhu[1], P. Chen[1], J.-R. Li[2], M. Aminu[1], C. Li[1], H. Chen[1], Y. Tian[1], F. R. Rojas[1], P. Edwin Roger[1], O. Shi[1], M. B. Nilsson[1], A. Poteete[1], S. M. Hubert[1], K. B. Khan[1], W. Lu[1], X. Song[1], J. Zhang[1], D. L. Gibbons[1], L. M. Solis Soto[1], I. I. Wistuba[1], J. V. Heymach[1], C. Cheng[2], J. Wu[1], J. Zhang[1];
[1]UT MD Anderson Cancer Center, Houston, TX, [2]Baylor College of Medicine, Houston, TX

Introduction: Our understanding of early carcinogenesis of lung adenocarcinoma (LUAD) is still rudimentary. Single-cell technologies have unveiled the intricate interaction between tumor cells and tumor microenvironment (TME) with unprecedented precision. However, the spatial context of single-cell phenotypes within TME during LUAD early carcinogenesis remain poorly understood. Here, we sought to characterize human-relevant murine LUAD precancer models to elucidate the molecular and immune changes in the spatial context during early LUAD carcinogenesis to inform lung cancer interception strategies.
Methods: We have developed genetically engineered mouse models (GEMMs) (129S4 KrasG12D) and carcinogen-induced LUAD precancer model (CITM) (129S4 Urethane). Lung tissues were collected at various time points after induction and analyzed using whole exome sequencing (WES), imaging mass cytometry (IMC), and spatial transcriptomics (10x Visium).
Results: Pathological image analysis demonstrated a significantly higher tumor burden ($p<0.01$) in the 129S4 KrasG12D model compared to the 129S4 Urethane model across different time points. WES revealed a progressive increase in tumor mutation burden (TMB) from precancers to invasive LUADs in both models, with the CITM model having significantly higher TMB ($p<0.05$) at matched timepoints than GEMM model. IMC assessed 39 biomarkers in 284 regions of interest (ROIs) and identified 1.4 million individual cells with 17 major cell types. Macrophages were the most prevalent immune cell type in TME, representing 9.00% of total cells in GEMM and 8.29% in CITM. The percent immune cells of the total cells progressively decreased from early-stage hyperplasia to late-stage adenocarcinoma in both models. The CITM exhibited a significantly ($p<0.05$) higher immune proportion than the GEMM model at hyperplasia and adenoma stages, with no significant difference at the invasive adenocarcinoma tumor cores between these 2 models. On the other hand, CITM had a significantly higher overall immune proportion ($p<0.05$) and the CD8 T cell and B cell proportions than GEMM tumor adjacent lung tissues at the adenocarcinoma stage leading to a significantly higher immune cell gradient between tumor adjacent lung tissues and tumor cores in CITM models. Spatial transcriptomics (ST) data demonstrated an increased presence of immune response signaling at the tumor adjacent lung tissues compared to the tumor core in the latest stage.
Conclusion: Spatial analysis revealed different molecular and immune landscapes in the genetic and carcinogen-induced LUAD precancer models, leading to distinct cellular spatial arrangements within the tumor microenvironment in each model. Overall, innate immunity, particularly macrophage, probably plays critical roles during early carcinogenesis of LUAD regardless of carcinogen exposure.

#3388 Targeting liver specific βII-Spectrin to prevent the development of metabolic dysfunction associated steatohepatitis (MASH) through CEACAM1 axis.

K. Bhowmick[1], K. Ohshiro[1], X. Xiang[1], S. John[1], X. Yang[1], N. Beauchemin[2], M. I. Hassan[3], T. Mohammad[3], **L. Mishra**[1];
[1]Feinstein Institute for Medical Research, New York, NY, [2]The Rosalind and Morris Goodman Cancer Institute, Montreal, QC, Canada, [3]Jamia Millia Islamia, New Delhi, India

Background: Obesity and pro-inflammatory alteration of the gut microbiome are risk factors for gastrointestinal (GI) cancers, including liver cancer (HCC). Dysregulated TGF-β signaling and loss of CEACAM1 activity are implicated in fatty liver disease. Clinically, 40% of human liver and GI cancers have genetic alterations in the TGF-β pathway members. CEACAM1 expression is significantly decreased in the liver of patients with Metabolic dysfunction-associated steatohepatitis (MASH). In contrast, in hepatocellular carcinoma (HCC), high CEACAM1 is associated with invasion, metastasis and poor prognosis. We hypothesized that TGF-β signaling and βII-Spectrin modulate MASH and HCC through CEACAM1.
Methods: Wild type and the liver-specific βII-Spectrin (*Sptbn1*) knockout (LSKO) mice fed a high-fat diet (HFD) or Western diet (WD) and analyzed for *Ceacam1* expression, changes in immune cell population, liver inflammation, and cancer. We used Alphafold and molecular modeling to identify the CEACAM1 and SPTBN1 interaction sites.
Results: Single cell sequencing analysis of MASH mice liver revealed that Ceacam1 expression is significantly decreased in hepatocytes. Interestingly, we found that CEACAM1 levels are restored to normal in tissues from liver-specific βII-Spectrin knockout (LSKO) mice. Transcriptomic and multiplex imaging analysis suggest that proinflammatory TGF-β signaling is activated and infiltration of CD11b+ cells is increased in MASH liver. These phenotypes are blocked in LSKO mice. Furthermore, siRNA-knockdown of βII-Spectrin blocks diet-induced obesity, fibrosis, lipid accumulation, tissue damage, and cancer susceptibility. We have also found that CEACAM1 interacts with the Smad3 adaptor, βII-Spectrin. Furthermore, structural analysis of CECAM1 and βII-Spectrin revealed critical residues involved in the interaction.
Conclusion: These data suggest that βII-Spectrin regulates CEACAM1 expression in the liver and is a potential target for therapeutic intervention to treat MASH and prevent progression to HCC.

#3389 Intraductal ablative procedure for local preventive intervention in rat models of breast cancer.

E. Zaluzec[1], M. Ashry[1], E. G. Phelps[1], **K. Kempinska**[1], E. Kenyon[1], L. Kenny[1], M. Volk[1], K. Powell[1], J. M. Hix[1], C. Mallett[1], M. Kiupel[2], E. M. Shapiro[1], L. F. Sempere[1];

[1]Michigan State University, East Lansing, MI, [2]Michigan State University, Lansing, MI

There are limited options for primary prevention of breast carcinoma (BC). Prophylactic mastectomy and systemic hormonal therapy are only recommended for high-risk individuals. Prophylactic mastectomy is a drastic surgery that removes the entire breast, including the epithelial cell-lined ductal trees where BC arises but also uninvolved stroma. Even with a 90% risk reduction, many women are deterred from prophylactic mastectomy due to its associated risk of infection, lymphedema, painful recovery time, and mental health toll. Hormonal therapies, tamoxifen and raloxifene, reduce BC risk by upwards of 50% but also increase the risk of uterine cancer and stroke. Thus, new interventions to reduce the risk of BC and minimize deterrents are necessary. Intraductal (ID) injection is a minimally invasive procedure that avoids systemic toxicity by cannulating a needle directly into the ductal tree opening to directly administer a solution to the epithelial cells. We previously reported that ID infusion of 70% ethanol (EtOH) as a cell-killing solution prevents tumor formation in an aggressive genetically engineered mouse model of BC with minimum collateral tissue damage. Here, we investigated the therapeutic efficacy of EtOH-based ablative solutions in a Methyl-N-Nitrosourea (MNU) chemically induced rat model of BC to assess scalability of this procedure towards clinical trials. Two weeks after tumor induction, rats received ID infusions of a solution containing 70% EtOH to ablate epithelial cells, ethyl cellulose (EC) to minimize collateral tissue damage, and/or Tantalum Oxide (TaO_x) to visualize infused ductal trees via micro-CT imaging. EtOH-infused glands had the longest tumor latency (273 days vs 97 days in control group, $p < 0.0001$). No statistically significant differences were noted in epithelial ablation or collateral tissue damage between treatment groups receiving ID injections of 70% EtOH with varying concentrations of EC, but there was a trend to lower collateral damage with EC-containing solutions. Local clearance of TaO_x in infused mammary glands enabled post-procedure MR imaging surveillance after 15 d of ID procedure. This preclinical study demonstrates that ID injection of a refined solution containing 70% EtOH and TaO_x is an efficacious and scalable procedure for primary prevention of BC.

#3390 Development of hypoxia responsive targeted polymersomes drug therapy validated using patient derived xenograft of triple negative breast cancer.

Y. S Ramakrishnan[1], S. Ambhore[1], C. Edvall[1], J. Mohammed[1], S. Mallik[1], D. M Tuvin[2], V. Sathish[1];
[1]North Dakota State University, Fargo, ND, [2]Sanford Broadway Clinic, Fargo, ND

Introduction: Eliminating triple-negative breast cancer (TNBC) resistance to neoadjuvant chemotherapy is a critical unmet clinical need. TNBC accounts for 20% of breast cancer and is more aggressive due to increased metastasis, high recurrence rate, and significant resistance to chemotherapy (e.g., Doxorubicin, DOX). Napabucasin (NAPA, a small organic molecule) is recognized to kill cancer stem cells by targeting the transcription factor STAT3 pathway and is currently in clinical trials. Our previous *in vitro* results showed significant effects with hypoxia-responsive targeted polymersomes compared to control in MDA-MB-231 and Patient-Derived Xenograft (PDX) TNBC cells. Further, we observed increased NRP-1 expression in TNBC patient-derived xenograft (PDX) cells under hypoxic (0.2% oxygen) conditions compared to normoxia (21% oxygen). Hence, we hypothesize that targeted hypoxia-responsive polymersome drug therapy would reduce the tumor growth of the PDX mouse model of triple-negative breast cancer *in vivo*.

Methods: We have established the TNBC PDX mouse model with two major phases, initial propagation (F1-F3) and final study phase (F3-F6), for *in vivo* study (TNBC tumor samples received from Sanford Broadway Clinic, Fargo, IRB approved). We utilized 3-6 months old female adult NSG mice (Jackson Lab) weighing 18-25 g. PDX tumor-bearing female NSG mice were administered polymersome-encapsulated drug (doxorubicin and other groups) by intravenous injection twice a week for 4 weeks and then observed the animals for an additional week. The percentage of tumor volume growth was calculated on these treatment groups and compared to vehicle. The tumors from all the groups were excised and dissected after the treatment and fixed in 10% formalin for histological evaluation. Tumors from all the groups after treatment were stained using hematoxylin and eosin to analyze the tumor core necrosis, and the average area of necrosis was compared among all the groups.

Results: The TNBC PDX mouse model treated with DOX alone and a combination of encapsulated DOX with NAPA showed significant weight loss compared to the control (over 4 weeks). DOX-alone treated mice have shown reduced tumor growth and exhibited a significant difference compared to the control group. Notably, the targeted DOX-encapsulated polymersome demonstrated a much lower tumor volume and displayed a marked difference compared to non-targeted vehicles, free-DOX, and saline. In the initial analysis, we observed a higher necrosis in the tumor of the targeted DOX-encapsulated polymersome compared to the control.

Summary and Conclusion: Overall, the hypoxia-responsive targeted polymersomes showed potent antitumor activity in the novel TNBC PDX animal model. With further developments, the targeted polymersomes might have translational potential as drug carriers for treating TNBC.

#3391 Effects of repeated psychological stress on NNK-induced lung cancer development in young female mice.

F. Jenkins[1], L. P. Stabile[1], J. R. Nedrow[1], K. Day[1], J. D. Latoche, Jr.[1], P. M. Tarwater[2], J. Manculich[1], **D. H. Bovbjerg**[1];
[1]UPMC Hillman Cancer Center, PIttsburgh, PA, [2]Texas A&M University, College Station, TX

Lung cancer is the second most common cancer in both men and women in the US and the leading cause of cancer death. Among younger US women, lung cancer incidence rates have in recent years become higher than rates seen in men, despite comparable histories of tobacco use. The possible contribution of stress to higher lung cancer risk in young women has received little research attention despite preclinical evidence that exposure to stress-related neuroendocrine responses can cause DNA damage. The present study used a well-established lung cancer model in young female mice (*in vivo* exposure to NNK) along with a mouse stress model to explore their independent and combined effects on lung cancer development. In addition, we explored one possible biological pathway by chronic administration of a beta-adrenergic receptor blocker (propranolol). We also tested the use of *in vivo* imaging for repeated monitoring of tumor development over time. Cohort 1 (n=60) had 4 groups: Home cage control, NNK treatment alone, repeated stress (RS) alone and NNK+RS. Cohort 2 (n=60) had the same 4 groups with the addition of administration of propranolol in drinking water. Cohort 3 (n=48, imaging cohort) had 3 groups: Home cage control, NNK alone and NNK+RS. FVB/N (4-6 wk) were purchased from a commercial supplier and acclimated with gentle handling for two weeks. The repeated stress protocol began week-3 and continued for the duration of the study. It combined two well-established rodent models: social disruption stress via changes in cage mates at the time of cage cleaning (2x/week) and a 90-minute restraint stress immediately prior to cage change (1x/week). NNK or saline treatment began on week-4 (IP; 2x/week; 3 mg/injection) and continued for 4 weeks. 21 weeks after stress initiation, the mice in cohorts 1 and 2 were sacrificed, lungs removed, inflated and tumors counted and sized. Mice in cohort 3 were imaged by Hounsfield-calibrated micro-CT (μCT) at baseline, 14, 19 and 23 weeks. The entire lung space, excluding the heart, was defined as a volumetric region of interests (VOIs). The VOIs were subjected to thresholding to segment the lungs into air space and tissue space compartments. The volume of tissue space of each animal was ratioed against its own baseline tissue space volume. Results from Cohort 1 revealed significantly greater numbers and overall size of lung tumors in stressed mice that received NNK. No significant effects were seen in the absence of NNK. Results from Cohort 2 revealed no significant differences between stressed and unstressed groups treated with propranolol. Cohort 3 revealed a pattern of results with stressed mice generally showing the highest lung tumor volume levels (Hounsfield Units), which reached significance at 19 weeks in preliminary analyses.
Conclusion: In this study, we found that repeated stress increased lung tumor burden in female mice treated with NNK, and that a beta-adrenergic pathway may be involved.

#3392 Generation and characterization of transgenic oncopig model for lung cancer.

Kirtan Joshi[1], Nagabhishek Sirpu[2], Amanda Schmelzle[3], Ravikanth Poonooru[3], Benjamin Nelson[3], Pradeep Subramanyam[3], Colleen Garrett[4], Mariana Sponchiado[3], Sarah Schlink[4], Samantha Gerb[4], Jesse Porter[5], Dae Kim[6], Jeffrey Kunin[5], Jeffrey Bryan[7], Timothy Hoffman[8], Bhanu Telugu[3], Jussuf Kaifi[9], Satyanarayana Rachagani[10]

[1]Department of Medicine and Surgery, University of Missouri - Columbia, Columbia, MO,[2]Roy Blunt NextGen Precision Health Institute, University of Missouri - Columbia, Columbia, MO,[3]National Swine Resource and Research Center, University of Missouri - Columbia, Columbia, MO,[4]Veterinary Medicine And Surgery, University of Missouri - Columbia, Columbia, MO,[5]Department of Radiology, University of Missouri - Columbia, Columbia, MO,[6]Department of Veterinary Pathobiology, University of Missouri - Columbia, Columbia, MO,[7]Department of Veterinary Medicine and Surgery, University of Missouri - Columbia, Columbia, MO,[8]Department of Medicine-Division of Hematology and Oncology, University of Missouri - Columbia, Columbia, MO,[9]Department of Surgery-Section for Thoracic Surgery, University of Missouri - Columbia, Columbia, MO,[10]Department of Veterinary Medicine And Surgery, University of Missouri - Columbia, Columbia, MO

Lung cancer (LC) is the leading cause of cancer-associated death in the United States. Preclinical findings in small animal models do not translate into human clinics. There is an urgent need to develop relevant preclinical large animal models for LC. We describe a novel method to induce LC in transgenic pigs carrying Cre-inducible $Kras^{G12D}$ and $TrP53^{R167H}$ mutations (Oncopigs).

The Oncopigs (n=12; 9 females, and 3 males) at 9 weeks of age were anesthetized and adenovirus ($1x10^{11}$ PFU) carrying Cre recombinase gene (Ad-Cre) ± polybrene (1:100) ± IL-8 (5 ng/ml) was injected via flexible bronchoscopy with two techniques: (1) Bronchial lavage (n=6) and (2) Transbronchial needle injection (n=6) into different lung lobes. As controls, a combination of polybrene ± IL-8 was injected without AdCre into the contralateral lobes in the same pigs (n=8). Oncopigs were monitored via clinical monitoring, blood counts, basic metabolic panel, and contrast-enhanced computed tomography (CT) imaging for LC progression and metastasis at 3-, 4-, 7-, 10-, 16-, and 26 weeks post-intervention.

All animals tolerated the injections with expected weight gains. Blood counts and metabolic panels remained normal during LC progression. At the site of injection/lavage, lung masses were detected on CT imaging at 3 weeks post-injections. However, a decrease in masses was observed on CT at 7 weeks post-intervention. The decrease in size of the lung masses coincided with increasing attenuation. No distant metastases were observed on CT imaging. Lavage-based lesions appeared to be more heterogeneous with surrounding inflammatory changes. Transbronchial-injection-based lesions appeared more consolidated and coin-shaped without surrounding inflammatory changes. Control injection sites did not show any mass growth on CT imaging.

Immunohistochemistry analysis on lung tumors revealed increased pancytokeratin, trichrome, E-cad, Ki-67, IBA, and CD3 expression. Further, immunofluorescence revealed decreased E-Cad, CK-19, and Zo-1 expression, whereas increased expression of N-Cad, FN1, snail, CD44, α-SMA, and γ-catenin, was observed in the LC and metastatic tissue compared to normal.

We successfully generated and characterized a novel transgenic Oncopig LC model. There is robust tumor production status post AdCre delivery. One of four Oncopigs had carcinomatous metastatic skin growth. The remaining 7 Oncopigs are monitored longitudinally for tumor growth and development of metastasis.

#3393 Deciphering colorectal cancer: A model to study sex-based differences and role of estrogen amidst obesity.

P. Wele, H. Shi, X. Wu;
Miami University, Oxford, OH

Worldwide statistics indicate that obesity is increasing globally, mostly due to the consumption of Western diet. The literature points out that obesity is a potent risk factor for the development of colorectal cancer (CRC). Interestingly, CRC incidence is higher in men compared to women, and the sex hormone estrogen protects reproductive-age females from CRC despite obesity. In this project, we aim to understand the sex-based differences and protective role of estrogen in obesity-influenced CRC. An improved mouse model was devised where the effects of obesity and estrogen in CRC could be meticulously studied. We deployed 4-5-week-old male and female FVB/NJ mice and performed either sham surgery (males and females) or bilateral ovariectomy (OVX) (females). Post one week of recovery, all mice were randomly sub-grouped into either low-fat diet (LFD, 10% fat) or high-fat diet (HFD, 60% fat) groups, weekly injected with a colon-specific carcinogen azoxymethane (AOM; 5 mg/kg for week 1, 10 mg/kg for weeks 2-6), and cyclically every 4-5 days injected 17-beta-estradiol (E2; 4 µg/mouse) to a group of OVX mice for the study period of 22 weeks. The body weight of all mice was tracked every week. A whole-body composition analysis after 22 weeks showed that males and OVX females are more obese compared to females with sham surgery and OVX females with E2 injection (OVX+E2), respectively. Additionally, mice on HFD had a higher body weight compared to those on LFD; however, the absence of estrogen in OVX females led them to have higher body weight compared to sham and OVX+E2 females. Moreover, a significant difference was observed in the tumor size between males and females, females and OVX females, and OVX and OVX+E2 females. Study models have rarely incorporated both sex-dependent differences and diet-induced obesity in understanding CRC. With the current study model, it is anticipated to learn more about these differences at molecular, cellular, and metabolic levels.

#3394 Participation of molecular iodine and PPARG in prostate cancer progression and neuroendocrine differentiation.

C. Montes de Oca, L. Alvarez, C. Aceves, B. Anguiano;
Universidad Nacional Autonoma de Mexico (UNAM), Queretaro, Mexico

Introduction: Advanced prostate cancer (PCa) therapy is based on androgen deprivation; however, cancerous cells develop resistance, and can develop a highly aggressive neuroendocrine (NE) phenotype. Molecular iodine (I_2) has antitumoral effects in breast cancer models, in which PPARG receptors represent the main mechanism of action described. In PCa though, PPARG is considered pro-tumoral and I_2 effects have not been fully studied. Hence, the aim of this study was to analyze I_2 individual and combined effects with androgen deprivation by using both androgen dependent (AD) and independent (AI), *in vitro* and *in vivo* PCa models.

Methods: *In vitro.* I_2 effects in cell viability and invasion were analyzed in AD (LNCaP) and AI (DU145, PC3) PCa cells. LNCaP cells were also treated with androgen receptor (AR) antagonists. PPARG participation in I_2 effects was assessed with GW9962 (antagonist) and rosiglitazone (agonist). NE phenotype was induced in LNCaP by prolonged culture under androgen-depleted conditions and was assessed by measuring the growth and length of neurite-like projections. RT-qPCR was employed to assess the expression of NE markers (*SYP, ENO2*), and lipogenic genes (*FASN, SREBF1*). *In vivo.* Eighteen weeks-old TRAMP mice were subjected to sham surgery or castration, and were provided or not with I_2 (0.025%, drinking water) for four weeks. Prostates were subjected to histopathological analysis (H&E and Masson's trichrome) and IHC (AR, SYP, PPARG). Scoring systems were used to grade the severity of high proliferative intraepithelial lesions (HPIN), and desmoplasia.

Results: I_2 decreased the cell viability and invasion capacity of all PCa cells tested, and when supplied with AR antagonists further enhanced their antiproliferative effects in LNCaP cells. I_2 failed to induce the expression of PPARG target genes, and GW9662 did not prevent I_2-induced decrease in cell viability. Like androgen deprivation, I_2 also caused NE-like morphology in LNCaP cells, but unlike androgen deprived LNCaP cells, I_2 treated cells had decreased expression of NE markers. In TRAMP mice, I_2 increased the presence of HPIN, reduced nuclear AR protein detection, and had no effect on PPARG. As expected, castration reduced HPIN, caused epithelial atrophy and desmoplasia; decreased total AR levels and PPARG nuclear levels. However, the number of NE (SYP-positive) cells did not change. The addition of I_2 to castration did not modify the score of epithelial lesions but increased the desmoplasia and the presence of NE cells.

Conclusions: I_2 exhibited *in vitro* antineoplastic effects over epithelial cells, however, these effects did not translate into the *in vivo* model. PPARG did not seem to mediate I_2 effects. Overall, our data suggest that tumoral microenvironment may interfere with I_2 epithelial-specific antitumoral effects.

Funding: PAPIIT-UNAM (IN217223, IN202322) and CONAHCYT (774791).

#3395 Polyisoprenylated cysteinyl amide inhibitors: Effects on RAS signaling pathway intermediates and viability of mutant *KRAS* African American lung cancer cell line.

Justin K. Mensah-Mamfo[1], Kweku Ofosu-Asante[1], Jassy Mary S. Lazarte[1], Amarender Goud Burra[1], Sofia A. Lugo[2], Yong Huang[3], Ite A. Offringa[2], Nazarius S. Lamango[1]

[1]Florida A&M University, Tallahassee, FL,[2]University of Southern Carlifornia, Los Angeles, CA,[3]University of Florida, Gainesville, FL

Mutated *KRAS* is the most common cancer driver gene in lung adenocarcinomas in all racial and ethnic groups, including Blacks/African Americans (B/AAs). Drugs developed to combat KRAS-driven cancers become less effective due to intrinsic changes in the cells resulting in resistance and relapse. Due to the enormous challenges encountered in developing direct KRAS inhibitors, agents targeting alternative downstream RAS mediator kinase enzymes of the MAPK and PI3K/AKT signaling pathways have been developed. However, other avenues that directly target KRAS and similar cancer drivers must be explored to obtain alternative effective therapies. PCAIs constitute a group of potential anticancer agents that we developed to specifically disrupt and suppress signaling by hyperactive G-proteins such as mutated KRAS. In previous studies, PCAIs stimulated MEK1/2, ERK1/2, p90RSK and AKT phosphorylation resulting in cell death. The present study aims to determine whether specific inhibitors of the kinases can reverse PCAIs-stimulated phosphorylation and cell death. PCAIs were thus tested against the KRAS mutant NCI- cell line H23 (from a B/AA patient) and compared to $KRAS^{G12C}$ inhibitor Sotorasib and other kinase inhibitors drugs. The EC_{50} values for the PCAIs NSL-YHJ-2-27 and NSL-AB-45 were 4.1 ± 0.3 and 5.5 ± 0.1 µM, respectively, compared to Gefitinib (EGFR), Sotorasib ($KRAS^{G12C}$), Dabrafenib (BRAF), Selumetinib (MEK1/2), Ulixertinib (ERK1/2) and Ipatasertib (AKT) whose EC_{50} values were 83 ± 12.9 µM, 38 ± 5.5 µM, 33 ± 1.2 µM, 71 ± 5.3 µM, 11 ± 0.2 µM, 12 ± 1.0 µM, respectively. The results indicate that the PCAIs are more effective against NCI-H23 than the other kinase inhibitor drugs. Future work will determine the effects of co-treating cells with the PCAIs and the respective kinase inhibitors on cell viability and PCAIs-induced phosphorylation of the kinases. Supported by grants U54CA233396, U54CA233444, and U54CA233465 from the National Institutes of Health (NIH)/National Cancer Institute (NCI) and the Norris Comprehensive Cancer Center core grant, award number P30CA014089 from the NIH/NCI

PREVENTION / EARLY DETECTION / INTERCEPTION: Cancer Control and Survivorship
Poster Session

#3399 Prediction of cardiac adverse events (AE) in trastuzumab treated breast cancer patients (pts) via a comprehensive genomic and DNA methylation blood based assay.

S. Gordon, C. Barbacioru, D. Gaile, D. Tolkunov, N. Zhang, C. Espenschied, J. Wang, T. Dinman, K. Banks, A. Das, H.-Y. Chuang, H. Eltoukhy; Guardant Health, Redwood City, CA

Background: *ERBB2* (HER2) targeted therapy is an important therapeutic class used to treat HER2-positive breast cancer (BC) but has been associated with a risk of cardiotoxicity. Identifying pts likely to experience this AE could allow for early intervention and/or a change in treatment plan. Previous studies have demonstrated the ability to detect changes in methylation patterns of pts who had cardiotoxicity from anti-HER2 therapy. Here, we report a retrospective study assessing the feasibility of using the Guardant Infinity platform (genomic and epigenomic NGS analysis) to predict severe cardiac AE in pts treated with trastuzumab.

Methods: Samples (n=46) from female pts with BC undergoing treatment with trastuzumab without prior record of heart failure and with a blood sampling <300 days prior to a documented heart failure event defined a positive case cohort. 70 blood samples were matched to the positive case cohort in all above attributes but without record of patient heart failure to comprise a negative cohort. The >20K differentially methylated regions on Guardant Infinity platform may be useful for detection of specific disease attributes such as treatment-associated AE. To explore this, mixture models were first trained using 880 BC samples unrelated to heart failure to distinguish methylation signals coming from tumor versus non-tumor cfDNA. The resulting normalized methylation signals represent the posterior probabilities of the region molecules to be derived from tumor cells. A subset of methylation regions were selected based on significance of association between heart failure status and normalized methylation signals in the positive and negative AE cohorts. A penalized logistic regression model was then trained on the normalized signals of the selected methylation regions to predict whether a patient would have future cardiac AE.

Results: A 10-fold cross validation of the penalized logistic regression models trained on normalized methylation signals produced an area under the curve of 0.78 for predicting heart failure status, suggesting feasibility of using blood-based methylation signals to predict cardiac AE on this platform. The differentially methylated regions selected as model predictors show a clear separation in hypermethylation status between positive versus negative cohorts.

Conclusion: Our results show the prediction of cardiac AE in BC pts undergoing trastuzumab treatment in advance of documented heart failure using a blood-based assay designed for simultaneous comprehensive genomic and epigenomic profiling. Given the relatively small sample size within this study, further refinement and validation of the classification models is warranted and ongoing.

#3400 Single-cell proteogenomics analysis of AML samples treated with decitabine and venetoclax reveals divergent treatment escape mechanisms.

Y. Kim, Z. Li, A. Maiti, T. Tanaka, H. Uryu, K. Furudate, K. Hayes, N. Daver, N. Pemmaraju, T. M. Kadia, F. Ravandi, N. J. Short, M. Ohanian, G. Borthakur, N. Jain, G. C. Issa, L. Masarova, S. M. Kornblau, W. G. Wierda, S. Loghavi, S. A. Wang, G. Garcia-Manero, H. Kantarjian, C. D. DiNardo, M. Y. Konopleva, K. Takahashi;

The University of Texas MD Anderson Cancer Center, Houston, TX

The combination therapy of hypomethylating agents and venetoclax (HMA+Ven) has emerged as a standard of care for acute myeloid leukemia (AML) patients unfit for intensive chemotherapy. Nonetheless, significant clinical challenges persist including relapse and treatment resistance, to which our understanding remains incomplete. Previous studies have revealed genetic (RAS/RTK pathway mutations and *TP53* mutations) and phenotypic (monocytic differentiation) resistance mechanisms. In this context, we hypothesized that integrative assessment of both genetic and phenotypic factors could further unveil the contributors of HMA+Ven resistance. To determine the predictors of treatment response, we first analyzed the baseline characteristics of 208 newly diagnosed, secondary, and relapse/refractory AML patients treated with Decitabine and Venetoclax (Dec+Ven). While complex cytogenetics, KRAS and TP53 mutations were significantly associated with treatment resistance, phenotypic factors such as bone marrow cell compositions or French-American-British (FAB) classifications were not. To identify the factors of resistance at the cellular level, we performed a single-cell targeted DNA-antibody sequencing (DAb-seq) on a subset of 33 patients. In total, 60 multi-timepoint bone marrow samples were analyzed, which included five patients with paired baseline-relapse timepoints. From all five patients, we identified that stem-like cells were largely eradicated and replaced by more differentiated cells such as monocyte-like or erythroid-like cells. At relapse, we identified three patterns of phenotypic shifts: monocytic shift, erythroid shift, and mixed monocytic/erythroid shift. The phenotypic shifts were not always associated with the expansion of new genetic mutations, except for in two cases: one patient had monocytic shift accompanied by the expansion of *KRAS* mutation, and another patient had erythroid shift accompanied by the expansion of *NRAS* mutation. To examine the mechanisms behind the phenotypic shifts, we performed a single-cell RNA sequencing on three of the relapsed patients. As a result, we confirmed the upregulation of BCL2L1 in the patient with erythroid shift (N=1), and MCL1 in the patients with monocytic shifts (N=2), but not BCL2 in both. These findings are consistent with known dependency of these cells on non-BCL-2 anti-apoptotic proteins such as MCL-1 and BCL-xL. To summarize, we conclude both genetic and phenotypic factors play a role in Dec+Ven resistance. Most importantly, we report that divergent phenotypic transitions, from stem-like toward more differentiated phenotypes (monocytic or erythroid), were frequently observed in AML relapse following Dec+Ven therapy. Close monitoring of phenotypic alterations during HMA+Ven treatment may facilitate the precise identification of AML patients predisposed to relapse.

#3401 Uncovering virus induced dysregulated processes in cancer and their impact on outcomes.

M. Soleimanpour moghadam, A. Khosh, D. Ebrahimi;
Texas Biomedical Research Institute, San Antonio, TX

The National Cancer Institute has designated several viruses such as EBV, HBV, HCV, HIV, HPV, and HTLV as agents that either cause cancer or increase the risk of developing cancer. However, extensive analyses of tumor genome and transcriptome datasets have identified numerous additional virus types, the functional implications of which remain largely unknown. Viral infection often dysregulates unique molecular processes within tumor cells and alters the composition of immune cells in the tumor microenvironment. For instance, HPV-positive tumors have been shown to exhibit a significantly elevated expression of the DNA editing enzyme APOBEC3B compared to HPV-negative tumors. Furthermore, HPV positive tumors display and increased number of C-to-T mutations induced by this protein. The genome and transcriptome of tumor tissue biopsies contain a wealth of information about these virus-associated signatures. However, advanced signal processing approaches are needed to extract these viral signatures from complex tumor datasets, and elucidate their specific roles in cancer. Here, we developed a quantitative approach to investigate the link between viral infection and dysregulation of a seven-membered A3 enzyme family (A3A/B/C/D/F/G/H). The primary role of these enzymes is to restrict viral infections by inducing C-to-U mutations in viral genomes. However, at least three members of this enzyme family (A3A/B/H) can also induce mutations in cellular DNA, and drive tumor formation and evolution. We used NMF (Nonnegative Matrix Factorization) to deconvolute the expression profiles of A3 enzymes in >10,000 bulk RNAseq datasets from diverse TCGA tumors. This analysis revealed the expression profiles of A3 enzymes within tumor and tumor microenvironment cells including various immune cells. Next, we conducted an association analysis to identify the link between the presence of viral infection and the proportion of each of these tumor and tumor microenvironment expression profiles. As expected, our analyses revealed strong associations between tumor-specific A3 expression profiles and infections by oncolytic viruses such as HPV. Notably, and somewhat unexpectedly, our analyses also revealed associations with viruses about which little is known in the field of cancer. For example, in certain tumors, we identified a robust association between bacteriophages and a tumor-specific A3 expression profile characterized by A3B upregulation. Taken together, our analyses provide evidence for the link between A3 dysregulation and infection by viruses including bacteriophages.

#3402 Integration of microRNAs and transcriptome signatures identifies the persistent infection of hepatitis C virus-induced hepatocellular carcinoma.

W.-H. Su, C. S. Shabangu, S.-C. Wang;
Kaohsiung Medical University, Kaohsiung, Taiwan

MicroRNAs (miRNAs) are short non-coding RNAs (ncRNAs) of ~22 nucleotides that mediate gene expression through various functions, including gene silencing, which can lead to translation repression and degradation of target mRNAs. Dysregulation of miRNA function has been associated with numerous diseases, particularly cancer, including hepatocellular carcinoma (HCC). During the progression of HCV-HCC, the function of miRNAs may be altered thereby altering gene expression to favor HCC. Therefore, the involved miRNA-mRNA interaction needs to be further studied. In addition, there are many clinical studies have shown that HCV patients who do not adequately control their diet which are prone to fatty liver accumulation (steatosis), it may increase the possibility of liver cirrhosis. In the current study, we aim to investigate the function and effects of persistent HCV-induced miRNAs expression in liver hepatocellular carcinoma progression and gene expression and to explore the mechanisms and regulatory genes of liver steatosis caused by HCV patients in a high-fat environment. We used the Huh751 cell line and the infected with the HCV JFH1 replicon of low-viral load S2 cells. We used an HCV miRNA array for initial identification of potential candidates. These miRNAs were analyzed for KEGG pathways via DIANA. Next, we identified miRNA-mRNA targets in 3 databases (miRDB; miRPathDB; TargetScan) and analyzed the targets for KEGG pathways using ShinyGO. The target miRNA-mRNA candidate genes were then compared with long-term JFH1 replicon infectious cell (L-HCV) NGS mRNA data to integrate miRNA-mRNA. The identified genes were analyzed in The Cancer Genome Atlas (TCGA) for survival, biological process, and expression in LIHC Big Data. Hsa-miR-215, hsa-mir-10b, and hsa-let-7a of L-HCV miRNAs group showed high significance for LIHC overall survival with a hazard ratio >1.0. Moreover, miRNAs associated with L-HCV survival were LIHC-specific but not in other cancers. Through systematic integration of these findings, we identified HMOX1 and BMF genes as being specifically associated with HCC and regulated by hsa-miR-215-5p, hsa-miR-10b-5p, and hsa-miR-7a-5p. In addition, we also found that the expression of the adipogenesis genes, FABP4 and adipogenesis gene, SREBP1, as well as the viral non-structural protein, NS3, was significantly increased in the HCV-high-fat group; and the expression of the gene IRS1, which is involved in hyperinsulinemia, showed a decreasing trend. The main cause of HCC is that HCV inhibits the expression of hsa-miR-215-5p, hsa-miR-10b-5p, and hsa-miR-7a-5p, leading to alter the expression of target genes, these have a significant effect on survival, suggesting that an essential role in virus-related liver cancer. In the future, we will further explore the regulatory mechanisms between these genes and HCV in a high-fat environment.

#3403 Disentangling the obesity paradox in high-grade serous epithelial ovarian cancer.

Evan W. Davis[1], Nancy Barone[1], Charles Roche[2], Gyorgy Paragh[3], Andre Klein[4], **Rikki Cannioto**[1]

[1]Cancer Prevention and Control, Roswell Park Comprehensive Cancer Center, Buffalo, NY,[2]Diagnostic Radiology, Roswell Park Comprehensive Cancer Center, Buffalo, NY,[3]Dermatology; Cell Stress Biology, Roswell Park Comprehensive Cancer Center, Buffalo, NY,[4]Information Technology, Roswell Park Comprehensive Cancer Center, Buffalo, NY

Background: Previously published evidence suggests an 'obesity paradox' in epithelial ovarian cancer, where excess adiposity is linked to better survival. However, prior studies did not jointly consider skeletal muscle, a key prognostic factor in cancer. Addressing this gap, our study examines the combined effects of adiposity and muscle phenotypes on mortality in high-grade serous epithelial ovarian cancer (HGSOC), offering novel insights into the role of body composition in patient outcomes.

Methods: 343 HGSOC patients from the Body Composition and Epithelial Ovarian Cancer (BComES) Cohort at Roswell Park were included in this analysis. Body composition was derived from sliceOmatic software using computed tomography images obtained prior to chemotherapy. Body composition was quantified as surface area (cm^2) at L3 for intermuscular adipose tissue (IMAT), visceral adipose tissue (VAT), subcutaneous adipose tissue (SAT), total adipose tissue (TAT), and skeletal muscle index (SMI). SMI<38.5 cm^2/m^2 was defined as low SMI, a proxy for sarcopenia. For each adipose depot, phenotypes were categorized as: 1) low adiposity/high SMI (optimal/referent); 2) high adiposity/high SMI; 3) high adiposity/low SMI (e.g., sarcopenic obesity); and 4) low adiposity/low SMI (e.g., cancer cachexia). Multivariable Cox models adjusted for age, tumor stage, and surgical debulking status were used to estimate Hazard Ratios (HR) and 95% Confidence Intervals (CI) representing associations of each body composition phenotype with mortality.

Results: High IMAT and VAT were associated with increased mortality in patients with high SMI (HR=1.80, 95% CI: 1.18-2.74 and HR=1.96, 95% CI: 1.27-3.04, respectively) and low SMI (HR=1.65, 95% CI: 1.05-2.61 and HR=1.70, 95% CI: 1.04-2.80). High SAT and TAT were also associated with increased mortality in patients with high SMI (HR=1.74, 95% CI: 1.14-2.67 and HR=2.04, 95% CI: 1.31-3.18), but associations were shy of significance for patients with low SMI (HR=1.37, 95% CI: 0.85-2.23 and HR=1.58, 95% CI: 0.95-2.61). Lastly, low SMI and low adiposity was associated with increased mortality for VAT (HR= 1.65, 95% CI: 1.01-2.70), SAT (HR=1.88, 95% CI: 1.14-3.10), TAT (HR=1.97, 95% CI:1.19-3.26) and IMAT (HR=1.46, 95% CI: 0.85-2.53).

Conclusions: In this study, we observed no support for an obesity paradox. Rather, we observed compelling evidence linking high adiposity phenotypes with striking increases in HGSOC mortality, regardless of SMI. Notably, as the cachectic phenotype was also linked to substantial increases in mortality, unwittingly assigning patients with low adiposity and low muscle to a reference group in adiposity research could falsely induce an ‘obesity paradox’. Importantly, as body composition can be modified through diet and exercise, our data establishes it as a potential therapeutic target alongside chemotherapy to improve outcomes in this deadly disease.

#3404 Body weight trajectory among patients with non-small-cell lung cancer receiving immune checkpoint inhibitors.

T.-Y. D. Cheng, B. Kinder, R. T. Akasheh, C. M. Mahenge, C. J. Presley, P. G. Shields, X. Nguyen, A. Shendre, Z. Li, L. Li;
The Ohio State University, Columbus, OH

Objectives: Body weight is an important prognostic factor in patients with lung cancer. As immunotherapy involves toxicities, body weight may be affected during the treatment course. The objective of this study is to examine the trajectory of weight changes at 180 and 365 days after the initiation of immune checkpoint inhibitors (ICIs) among patients with NSCLC.

Methods: Retrospective chart review and data extraction were performed among patients receiving ICIs at the Ohio State University Comprehensive Cancer Center between 2015 and 2021. Patients with NSCLC were included in this study if their initial treatment entailed a PD-1/PD-L1 ICI), either alone or in combination with chemotherapy/targeted cancer drugs, and if they also had their body weights recorded on ICI initiation and 180 days after (± 30 days) treatment initiation. A subset of these patients who had body weight data on day 365 of ICI initiation were included in additional analysis. Percentages of change in body weight relative to pre-ICI were calculated ([weight at 180 or 360 days minus pre-ICI weight] divided by pre-ICI weight x 100%) and examined by treatment regimen and pre-ICI body mass index (BMI) using t-tests. A sensitivity analysis was performed by excluding 11 patients with cachexia defined by the presence of ICD-9 (799.4) or 10 (R64) codes in their medical records.

Results: A total of 554 patients with NSCLC received any ICI; 139 patients met the inclusion criteria, of which 96 had body weight data on day 365. The mean age of diagnosis was 63.8 (SD=10.1); 80% were White and 18.7% were Black. The median time on ICI was 195 days (inter-quartile range, 55-392 days) among patients with ICI only and 255 days (inter-quartile range, 126-479 days) among patients with ICI combined with chemotherapy or targeted cancer drugs. Among patients receiving ICI only, body weight increased among those with normal weight (BMI <25.0; mean change = +7.57%, P=0.013) but decreased among those classified as overweight (BMI = 25.0 to 29.9; −5.2%, P=0.037) or obese (BMI ≥30; −6.5%, P=0.025). Decreases in weight were also observed for patients with obesity and receiving a combined treatment (−9.65%, P=0.043). After one year of treatment, weight changes among patients receiving ICI only remained significant in the normal weight group (+15.6%, P=0.007), but not among patients with other BMIs and treatment regimens. These associations remained similar after excluding the patients with cachexia.

Conclusions: Body weight change during ICI therapy may vary by treatment regimen and pre-ICI BMI among patients with NSCLC. Whether the weight changes are related to toxicities and survival warrants further research to shed light on weight management, ICI efficacy, and prevention of treatment-related adverse events. Funding: The study was in part funded by NIH/NCI R37CA248371, OSUCCC CCSG P30CA016058, and Pelotonia Institute for Immuno-Oncology (PIIO) at OSUCCC.

#3405 CT-assessed body composition and tumor immunologic characteristics in patients with non-small-cell lung cancer.

T.-Y. D. Cheng, **C. M. Mahenge**, R. T. Akasheh, A. S. Yilmaz, B. Kinder, X. Nguyen, M. Pietrzak, C. J. Presley, P. G. Shields;
The Ohio State University, Columbus, OH

Objectives: Obesity is associated with higher immunotherapy efficacy, but body mass index is a convoluted marker of adipose and muscle tissue. We conducted a discovery scale study to assess the association of skeletal muscle and adipose tissue areas annotated on computed tomography (CT) scan images with selected tumor immunologic characteristics among patients with non-small-cell lung cancer (NSCLC).

Methods: We analyzed publicly available data from 102 patients (mean age = 67.2, 47.1% female, and 70.6% stage I-II) who had diagnostic CT images in The Cancer Image Archive. All patients had the 12th thoracic vertebra (T12) image, and a subset (62 patients) had the 3rd lumber vertebra (L3) image. Paravertebral muscle areas on T12 and skeletal muscle and adipose tissue areas on L3 were annotated using Slice-O-Matic. RNA-seq data were provided by The Cancer Genome Atlas and Clinical Proteomic Tumor Analysis Consortium; percentages of CD8, regulatory T cells, and activated NK cells were identified using the CIBERSORT. ESTIMATE algorithm was used to derive the stromal score and the immune score. Differences in the immune markers were examined using ANOVA adjusting for stage, histology, and study.

Results and Conclusion: Patients with higher paravertebral muscle area (3rd tertile) had the lowest stromal scores, compared to the 2nd and 1st tertile ($P<0.05$). Patients in the 2nd tertile of paravertebral muscle areas had the highest immune score and *CD274* (*PD-L1*) gene expression. Among the body composition types classified using L3 images, low muscle/high adiposity was associated with lower stromal scores, and low muscle was associated with lower immune scores, compared to high adiposity and high muscle/low adiposity types. Other immunological markers did not differ across the body composition types.

Significance: These findings suggest associations between deconvoluted skeletal and adipose tissue components and tumor markers relevant to immune checkpoint inhibitor efficacies in NSCLC. Further validation using immune phenotyping in a large patient sample is warranted. Funding: The study is in part supported by NIH/NCI R37CA248371 and OSU Comprehensive Cancer Center - James.

#3406 Transcriptomic analysis reveals differentially expressed pathways in colon tumors of cancer patients with vs without obesity: Results from the ColoCare Study.

V. M. Bandera[1], T. Lin[1], C. Himbert[2], E. M. Glenny[3], A. Tan[4], J. Ose[1], C. Warby[1], O. Aksonova[1], A. Carpanese[5], C. Stubben[1], D. Nix[1], K. Boucher[4], P. Schirmacher[6], I. Strehli[1], J. Jedrzkiewicz[1], L. C. Huang[4], J. N. Cohan[4], A. Brobeil[6], M. A. Schneider[6], C. Kahlert[6], E. M. Siegel[7], A. T. Toriola[8], D. Shibata[9], C. I. Li[10], J. C. Figueiredo[11], B. Gigic[6], J. Roper[5], S. Hursting[3], C. M. Ulrich[1];

[1]University of Utah Huntsman Cancer Institute, Salt Lake City, UT, [2]Massachusetts General Hospital, Boston, MA, [3]University of North Carolina at Chapel Hill, Chapel Hill, NC, [4]University of Utah, Salt Lake City, UT, [5]Duke University, Durham, NC, [6]Heidelberg University Hospital, Heidelberg, Germany, [7]Moffitt Cancer Center, Tampa, FL, [8]Washington University School of Medicine, St. Louis, MO, [9]University of Tennessee Health Science Center, Memphis, TN, [10]Fred Hutchinson Cancer Center, Seattle, WA, [11]Cedars Sinai Medical Center, Los Angeles, CA

Despite the rise of global obesity rates and obesity's implication in increased colon cancer risk, the understanding of mechanisms underlying these associations and opportunities for interception are limited. This work leveraged transcriptomic data from colon tumors to identify pathways and biologically relevant functions that characterize the tumors among obese vs nonobese individuals. Fresh-frozen colon tumor samples were collected from 155 patients who underwent surgery without neoadjuvant treatment as part of the ColoCare Study at Huntsman Cancer Institute, Utah, and Heidelberg University Hospital, Germany. RNA was sequenced using the NovaSeq X. The DESeq2 R package identified differentially expressed genes stratified by body mass index (BMI) at diagnosis (>30 kg/m^2 vs <30 kg/m^2) adjusting for age, sex, study site, and tumor stage. Genes with *padj* < 0.2 were entered into Ingenuity Pathway Analysis (IPA) software for pathway and expression analyses. Significant pathways were identified using Fischer's Exact Test as the probability of molecules' association with canonical pathways due to chance. The analysis was also repeated testing a median BMI categorization of >27.7 kg/m^2 vs <27.7 kg/m^2 using *padj* < 0.1 for IPA entry. Patients were 49% female, 63±14 years old, 47% stage III with a mean baseline BMI of 28.8±6.0 kg/m^2. In colon tumors of those with >BMI 30 kg/m^2, 213 genes were differentially expressed compared to BMI <30 kg/m^2. IPA identified five upregulated pathways (neurovascular coupling signaling, adrenergic receptor signaling, activation of N-methyl-D-aspartate receptors and postsynaptic events, response to elevated platelet cytosolic Ca^{2+}, docosahexaenoic acid signaling) and one downregulated pathway (WNT/B-catenin signaling) in patients with vs without obesity (p <0.05). The top predicted functional pathways, based on activation z-scores, identified in expression analysis included significant activation in chromosomal instability and aberration, size of body, phosphorylation of L-tyrosine, protein kinase cascade, and cell death and survival categories among colon tumors in obese patients. Using a median BMI categorization, 458 genes and 35 pathways were differentially expressed in those with BMI > 27.7 kg/m^2 vs < 27.7 kg/m^2. Both BMI models had good agreement with 5 pathways consistently significantly (z-score > |2|) up- or down-regulated, including predicted downregulation of organismal death and increased body size and phosphorylation of L-tyrosine in the higher BMI group. Colon tumors from patients with a higher BMI had pathways associated with more aggressive tumors, such as increased chromosomal instability and decreased cell death. Our ongoing work investigates the role of the adipose-tissue tumor microenvironment among patients, and the potential for interception using parallel mouse models.

#3407 Physical activity and post-menopausal breast cancer in the Multiethnic Cohort Study.

J. K. Gill[1], G. Maskarinec[2], S.-Y. Park[2], L. Wilkens[2], L. Le Marchand[2];
[1]California State University, Fullerton, Fullerton, CA, [2]University of Hawai'i Cancer Center- University of Hawaii at Manoa, Honolulu, HI

Much research has been conducted on the relationship between physical activity and breast cancer, with meta-analyses showing 10 – 21% reduction in breast cancer risk for postmenopausal women with high compared to low level of physical activity. However, few studies have explored this relationship in non-Caucasian women. We analyzed data from 74,177 post-menopausal African American, Caucasian, Japanese American, Latina, and Native Hawaiian women in the Multiethnic Cohort in Hawaii and California. Data on physical activity (hours and metabolic equivalents (METs)) was based on a self-administered questionnaire at baseline (1993–1996). Multivariate Cox proportional hazards models provided estimates of hazard ratios (HRs) and 95% confidence intervals (CIs) adjusted for risk factors. We observed no associations between breast cancer risk and hours of moderate/vigorous activity per week (HR=1.01, 95% CI: 0.91-1.10, Ptrend=0.71), MET-hours of moderate/vigorous activity per week (HR=1.03, 95% CI: 0.94-1.13, Ptrend=0.92), and total METs-measured as average MET level per day multiplied by 7 (HR=0.94, 95% CI: 0.86-1.03, Ptrend=0.37) when comparing the highest quartile to the lowest. When examining the data across race/ethnicity, we observed a reduction in risk of breast cancer for total METs (HR=0.75, 95% CI: 0.61-0.94, Ptrend=0.05) among Latina women. Analysis across strata of BMI showed no differences across subgroups. In this study, we did not observe any consistent protective association between physical activity and breast cancer risk.

#3408 'Survivor mentality': The meaning of survivorship among Black cancer survivors.

Nathaniel Woodard, Jingle Xu, Deirdre F. Lea, John L. Milner, Paulette Duggins, Karia Coleman, Ashley L. Bryant, Carmina G. Valle, Stephanie B. Wheeler, Jessica Carda-Auten, Tammy A. Triglianos, Rachel Hirschey

University of North Carolina at Chapel Hill, Chapel Hill, NC

Purpose: To explore how Black adults who have been diagnosed with cancer perceive and interpret the term 'cancer survivor'.
Procedures: This study is a secondary analysis of qualitative data from a project identifying physical activity determinants among Black U.S. residents living past a cancer diagnosis. Semi-structured telephone interviews began with an inquiry into perceptions of the term 'cancer survivor.' Eligible participants were age 18 or older, self-identified as Black, and were living beyond a cancer diagnosis. Interviews were audio recorded and transcribed verbatim. Applying directed content analysis, 5 researchers independently applied a codebook generated from the interview guide to a subset of transcripts. The codebook was refined through iterative discussions to address coding discrepancies and achieve replicability. Remaining transcripts were then coded and a report of grouped narrative summaries was generated. Themes and subthemes were organized to present the meaning and significance of 'cancer survivorship' among the sample. The partnering community advisory board aided in and reviewed the interpretation of study findings.
Results: Participants were 19 survivors of nine different types of cancer. Most participants were women (89.5%), 68.4% held a bachelor's degree or greater, and the mean age was 56 (SD=12). Emergent themes describing perceptions of 'cancer survivorship' included 1) cancer 'survivor' terminology preferences, 2) outset of cancer 'survivorship,' 3) 'survivor mentality' and mental fortitude, and 4) advocacy for those affected by cancer. Many participants identified as 'cancer survivors' and preferred this to 'in remission,' but some preferred different terms or identities (e.g., warrior or thriver). Many believed survivorship began once an individual completed cancer treatment, but some felt survivorship began at cancer diagnosis. Survivor mentality was raised as a mindset providing some individuals the mental fortitude to complete cancer treatment, especially among those embracing a survivor identity during treatment. Some participants raised advocacy, providing support to others diagnosed with cancer, and sharing cancer information and their experience as part of what it means to be a survivor.
Conclusions: Acceptance of the term "cancer survivor" and what it means to be a "survivor" vary among Black individuals living past a cancer diagnosis. The identities held by those diagnosed with cancer may have implications for their cancer experiences and outcomes. Many Black cancer survivors may perceive working to improve the lives of others with cancer as part of what it means to be a survivor. Partnering with Black cancer survivors in cancer prevention and control efforts may be mutually appealing and beneficial to improve the lives of individuals living past a cancer diagnosis.

#3409 AGEing and lifestyle after a cancer diagnosis: A balanced equilibrium for survivorship?.

D. P. Turner[1], B. A. Krisanits[1], M. E. Ford[2], L. L. Peterson[3], S. E. Steck[4], P. D. Bos[1], V. J. Findlay[1];
[1]Virginia Commonwealth University, Massey Cancer Center, Richmond, VA, [2]Medical University of South Carolina, Charleston, SC, [3]Washington University, St Louis, MO, [4]University of South Carolina, Columbia, SC

In the US, over 18 million people are living with a cancer diagnosis and that number may double by 2050. There is a need to unite research across the cancer continuum to address the needs of cancer survivors to ensure optimal quality of life and improve mortality outcomes. Health constructs that influence cancer survivorship are multifactorial, highly dynamic, and vary across the lifespan. This makes assigning their impact on the well-being and future outcomes of cancer survivors challenging. As a pathophysiological process that lies at the intersection between societal, environmental, and biological constructs, it is proposed that the irreversible accumulation of metabolites called advanced glycation end products (AGEs) can inform on quality of life and mortality outcomes for cancer survivors. It is proposed that AGE accumulation as a result of societal, environmental, and biological constructs overwhelm the fragile equilibrium that maintains AGE homoeostasis to impact tumor biology and cancer outcomes. The relationships between health constructs and AGE exposure are epitomized by nutritional behavior. The consumption of cheaper unhealthier often ultra-processed foods are inherently AGE laden and the excessive consumption of foods high in fats and sugars that promote obesity and increase cancer risk readily provide reactive intermediates that fuel AGE formation in cells and tissues. Our collaborative epidemiological studies assign high levels of AGE consumption with increased breast cancer risk, aggressiveness, and mortality, which is supported by translational studies showing that circulating AGE levels in breast cancer patients correlate with worse disease-free survival and other poor prognosis indicators. Critically, this group has also shown that chronic AGE consumption by mice increases prostate tumor growth ($p<0.001$), and causes a rapid progression through prostate intra-epithelial neoplasia ($p=0.049$), adenocarcinoma ($p=0.042$) and metastasis ($p=0.001$). Consumption of the high AGE diet caused a regulatory program of stromal activation conducive for tumor growth. As a bio-social determinant of health AGE accumulation and its pathogenic effects serve as informative and/or functional markers indicative of the current health status and well-being of cancer survivors and may inform of potential future outcomes. Our studies show that physical activity and dietary intervention (cardiac rehabilitation) reduced systemic AGE levels in breast cancer survivors. Therefore, prevention and control interventions aimed at reducing AGE exposure represent viable strategies for improving quality of life and disease recurrence for cancer survivors.

#3410 Financial toxicity among patients with advanced prostate cancer in the United States.

I. Singh[1], B. Vaselkiv[1], E. Rencsok[1], K. Autio[2], D. Enting[3], A. Morgans[4], J. Nowak[5], K. Kensler[6], D. Nanus[6], R. Dreicer[7], B. Lewis[8], O. Sartor[9], E. Heath[10], P. Kantoff[11], D. Kaye[12], D. George[12], L. Mucci[1];

[1]Harvard School of Public Health, Boston, MA, [2]Memorial Sloan Kettering Cancer Center, New York, NY, [3]Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom, [4]Dana Farber Cancer Institute, Boston, MA, [5]Cancer ABCs, Brooklyn, NY, [6]Weill Cornell Medical College, New York, NY, [7]University of Virginia School of Medicine, Charlottesville, VA, [8]Tulane University School of Medicine, New Orleans, LA, [9]Mayo Clinic, Rochester, MN, [10]Karmanos Cancer Institute, Detroit, MI, [11]Convergent Therapeutics, Cambridge, MA, [12]Duke University School of Medicine, Durham, NC

Background: Advanced prostate cancer is defined as metastatic hormone-sensitive prostate cancer (mHSPC) or castration-resistant prostate cancer (CRPC). Newer and aggressive treatments are leading to increasing lifespans in this population. As such, studying quality of life could have a large impact on the survivorship experience. An important component of quality of life is financial toxicity, defined as the financial burden and distress that can arise for patients and their families because of cancer treatment.

Objectives: To understand the prevalence and predictors of financial toxicity in advanced prostate cancer.

Methods: IRONMAN (International Registry of Men with Advanced Prostate Cancer) is a prospective cohort of patients with newly diagnosed mHSPC or CRPC enrolling in 15 countries. Financial toxicity was collected using the EORTC QLQ-C30 (“has your physical condition or medical treatment caused you financial difficulties?”) at enrollment and every three months thereafter. For this analysis, we studied 997 patients cared for at 37 US sites enrolled from 7/2017 to 7/2023. We examined baseline and longitudinal reports of financial toxicity across clinical and demographic factors: age at enrollment, race and ethnicity, disease state, marital status, education, employment, military status, and type of health center. We conducted adjusted risk difference analysis and multivariable regression modeling to identify predictors of financial toxicity using a generalized estimating equations approach to calculate odds ratios (OR and 95% confidence intervals, CI).

Results: At enrollment, 125 (13%) patients reported experiencing “quite a bit” or “very much” financial toxicity. 21% of Black patients experienced toxicity compared to 10% of White patients. Even after incorporating all other predictors, Black patients experienced 5% (95% CI: 0, 11) greater toxicity than White patients. Independently of other predictors, patients >75 experienced 11% (CI: -17, -4) lower toxicity compared to those <65 years (while patients in the 65-74 group experienced 6% less, CI: -12, 1). Toxicity was 6% greater in patients with mHSPC (CI: 2, 10) than in patients with CRPC, and disabled or unemployed patients were at substantially higher risk. In the multivariable longitudinal analyses, older age (> 75) remained associated with significantly lower odds for financial toxicity (OR: 0.30, 0.15-0.61) while mHSPC (OR: 1.91, 1.14-3.20) and being unemployed (OR: 2.69, 1.03-6.99) or disabled (OR: 5.14, 2.29-11.6) were associated with higher odds.

Conclusions: Financial toxicity is prevalent in advanced prostate cancer, especially in patients who are Black, younger than 75, diagnosed with mHSPC, or unemployed/disabled. These results may inform identification of patients at high risk for financial toxicity to support delivery of patient-situation-informed care by clinicians and targeted aid for patients at highest risk.

#3411 Health-related quality of life trajectories in older breast cancer survivors and noncancerous controls over ten years: SEER-MHOS analysis.

E. Lee[1], M. Azevedo Daruge[1], K. Ferdowsi[1], J. Zhu[2];
[1]University of Central Florida, Orlando, FL, [2]Advent Health, Orlando, FL

Background: The adverse effects of cancer treatment on health-related quality of life (HRQOL) are the primary concern of older women diagnosed with breast cancer. The interplay of transient and progressive functional impairments caused by cancer therapies alongside the accelerated physical declines associated with the normal aging process are all negatively correlated to HRQL, yet it remains unclear whether this is an effect of cancer or solely aging; therefore, this study examined HRQL trajectory over ten years after diagnosis between cancer cases and controls.
Methods: The cancer group included 1467 women (age ≥ 65) diagnosed with primary breast cancer in 1998 - 2012, registered in the Surveillance, Epidemiology, End Results (SEER) cancer registry, and completed Medical Health Outcomes (MHO) surveys before and after cancer diagnosis. Propensity score-matched controls were randomly selected with a 1:1 ratio. Participants reported their HRQOL using SF-36/VR-12. It was summarized into two summary scores (Physical Component Summary [PCS] and mental component summary [MCS]) and eight domain scores (physical functioning [PF], role limitation due to physical health [RP], bodily pain [BP], general health [GH], vitality [VT], social functioning [SF], mental health [MH], and role limitation due to emotional problem [RE]). Hierarchical linear modeling was utilized to assess the main effects of time and group and the interaction effect between time and group on HRQOL trajectory.
Results: At diagnosis, cases fared worse than controls for all HRQOL domains and summary scores. Over the ten years, PCS, PF, GH, RP, SF, and VT worsened over time (all *P* for time < 0.05), while MCS, MH, and RE remained relatively constant over time (all *P* for time ≥ 0.05). Older women with breast cancer had lower HRQL over time than controls in PCS, GH, and RP domains, while they showed higher HRQOL than controls post 4 - 7 years in PF, SF, RE, and VT domains (all *P* for group < 0.05). However, only RE showed a statistically significant interaction effect (*P* =0.035), improving over time in cases but worsening in controls.
Conclusions: This research shows both older women with breast cancer and propensity-matched controls experiencing deterioration of HRQOL, particularly physical health domains, over ten years after baseline, with cases' HRQOL kept lower than controls over time. Needs assessment and more efficient interventions to improve physical health HRQOL among older women are warranted.

#3412 Benralizumab for treatment of eosinophil-related cutaneous adverse events associated with checkpoint inhibitors and anticancer targeted therapies: Phase 2 study.

Mario E. Lacouture[1], **Tara Maier**[1], Alexander Pan[1], Anna Chen[1], George Dranitsaris[2], Neil J. Shah[3], Sarat Chandarlapaty[4], Chau Dang[4], Devika Gajria[4], Allison Gordon[1], Neil Iyengar[4], Pedram Razavi[4], Mark Robson[4], Ezra Rosen[4], Serena Wong[4], Ucalene Harris[1], Kwami Ketosugbo[1], Cindy Bravo[1], Manu Jain[1], Alina Markova[1]

[1]Dermatology Service, Department of Medicine, Memorial Sloan Kettering Cancer Center, New York, NY,[2]Department of Public Health, Falk College, Syracuse University, New York, NY,[3]Sidney Kimmel Center for Prostate and Urologic Cancers, Memorial Sloan Kettering Cancer Center, New York, NY,[4]Evelyn H. Lauder Breast Center, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Eosinophil-related cutaneous adverse events (ercAEs) are common toxicities of PI3K inhibitors, antibody drug conjugates (ADCs), checkpoint inhibitors (CPIs), and targeted cancer therapies. While systemic corticosteroids are effective, their use is limited by additional toxicities and high recurrence. Benralizumab is an anti-IL-5Rα monoclonal antibody that induces eosinophil depletion via antibody-dependent cellular cytotoxicity, and is FDA-approved for severe eosinophilic asthma but has not been studied for ercAEs.

Methods: We conducted a single-center, single-arm, Phase 2 trial (NCT04552288) of benralizumab in cancer patients with Grade 2/3 ercAEs from PI3K inhibitors, ADCs, CPIs or targeted therapies. Patients received benralizumab 30 mg subcutaneously every 4 weeks for 3 doses, then every 8 weeks for 3 doses. The primary endpoint was clinical response, defined as reduction in ercAE Grade to 0/1 at Week 4. Secondary endpoints included changes in quality of life, rash body surface area (BSA), cytokines and eosinophil biomarkers, as well as adverse events (AEs).

Results: Forty-seven patients were enrolled, predominantly with breast (55.3%), bladder (10.6%), melanoma (10.6%), or kidney (6.4%) cancer. Baseline ercAEs were Grade 2 (48.9%) and Grade 3 (51.1%), most often from PI3K inhibitors (46.8%), CPIs (21.3%), tyrosine kinase inhibitors (8.5%) or ADCs (8.5%). Overall, 32 of 42 evaluable patients (76.2%) had clinical response by Week 4, with decreased ercAE grade (mean 2.4 to 0.9, $p<0.0001$), improved quality of life, reduced rash BSA, decreased peripheral and skin eosinophils (all $p<0.0001$), and cytokine changes. Clinical response by Week 4 was seen in all patients with ercAEs from alpelisib (PI3K inhibitor; n=18) or enfortumab vedotin (ADC; n=4); p-value for both: $p<0.05$. Mild-to-moderate mucositis, diarrhea, and xerosis were the most common AEs, all unrelated to benralizumab.

Conclusions: Benralizumab demonstrated favorable safety and efficacy for Grade 2/3 ercAEs from cancer therapies, especially alpelisib and enfortumab vedotin. Larger placebo-controlled trials are warranted to confirm these preliminary findings.

#3413 Physical activity and sedentary behavior of cancer survivors compared to individuals without cancer in NHANES.

A. Pavy, S. E. Steck;
University of South Carolina, Columbia, SC

INTRODUCTION: Physical activity may improve quality of life and reduce mortality among cancer survivors. As cancer death rates continue to decrease, the population of cancer survivors is expected to grow, therefore making it important to study their health behaviors. Research has been conducted on prevalence of physical activity and sedentary behaviors of survivors of certain cancers, however, little research has been conducted comparing cancer survivors to individuals without cancer. The purpose of this study was to update previously published results from earlier National Health and Nutrition Examination Survey (NHANES) cycles (2007-2010) with more recent data comparing physical activity and sedentary behavior among cancer survivors and individuals without cancer.
METHODS: Using the NHANES 2011-2018, we identified 1320 cancer survivors and 19,109 participants without cancer who provided data on recreational, work-related, and transportation-related physical activity and sedentary behavior. The included participants were over 20 years of age, not pregnant at the time of the survey, and were more than three years from their cancer diagnosis, if applicable. Comparisons between cancer survivors and individuals without cancer were conducted for duration of total physical activity (min/day) and sedentary time per day. To account for the complex sampling design, weighted multivariable analysis was used to calculate odds ratios (ORs) and 95% confidence intervals (CIs).
RESULTS: Compared to individuals without cancer, cancer survivors reported less average ± standard error physical activity minutes per day (190.06 ± 5.24 and 147.29 ± 13.14, respectively), and slightly more sedentary hours per day (6.95 ± 0.09 and 7.56 ± 0.36, respectively). However, after adjusting for age, race and ethnicity, sex, educational status, body mass index, and smoking status, there was no association between physical activity duration or sedentary time and cancer survivor status. The OR (95%CI) for more than 60 minutes per day of physical activity was 1.00 (0.83, 1.20) compared to no physical activity, and for more than 8 hours of sedentary time per day was 1.00 (0.82, 1.21) compared to less than 5 hours per day.
DISCUSSION: In a previous publication of earlier cycles of NHANES (2007-2010), cancer survivors reported higher physical activity but also higher sedentary time per day compared to individuals without cancer. However, these results were not supported in this updated analysis using more recent NHANES cycles (2011-2018). After adjustment for important covariates, we did not find differences between cancer survivors and individuals without cancer in reported physical activity or sedentary time. Further research in other populations is needed to corroborate these findings and document whether they reflect a growing awareness of the negative impact of sedentary behavior in cancer survivorship.

#3417 Dissecting tumor microenvironment to predict clinical outcome in prostate cancer.

Aritri Bhattacharjee[1], Manjusha Biswas[1], **Amjad Husain**[1], Asim Kr Das[2], Sourav Karmakar Karmakar[2], Tapan Mondal[2], Pinaki Roy[2], Manas Kr Mondal[2], Badal Kumar Sahu[2], Nabendu Murmu[3], Partho Nath[3], Chandra C. Ghosh[1], Pradip Kumar Majumder[1]

[1]CanFinis Therapeutic Private Limited, Kolkata, India,[2]Nilratan Sircar Medical College and Hospital, Kolkata, India,[3]Chittaranjan National Cancer Institute, Kolkata, India

Prostate cancer is one of the major causes of cancer death in males, and its prevalence is particularly high in developed countries such as the United States and Western Europe. However, death rates in developing and underdeveloped countries are greater, presumably, due to a lack of routine clinical check-ups, poor health awareness, inadequate screening resources, and clinical intervention. Much progress has already been made using cutting-edge technologies like whole genome sequencing, RNAseq, phosphoproteomics, and targeted transcriptomic Nanostring profiling, etc. However, understanding of the prostate tumor microenvironment as a whole in clinical samples remains very limited. Here we use the latest genomic, proteomics, and metabolomic tools not only to understand the biology of prostate cancers but also their correlation with patient demography and clinical outcome. We recruited 80 patients from both tertiary research hospitals and clinical centers in the eastern region of India. All of their demographic information is collected along with their clinical outcome. Pathological evaluation revealed only 50 patients with positive Prostate Carcinoma. We performed a detailed analysis using experimental data (from genomic, and proteomic) in a cohort of patients' routine biomarkers (PSA and PSMA), histopathology, and clinical outcome. Our data demonstrate no linear correlation of any of the individual markers or parameters like AR status, PSA, Prostate Specific Acid Phosphatase, Prostate-Specific Membrane Antigen (PSMA), Alpha-methylacyl-CoA racemase (AMACR), Mesothelin, PD-L1, and other potential genomic and proteomic alterations or any histopathological readouts. However, a clear understanding of the relationship between these multiparameter data, disease pathology, and clinical outcomes in a group of patients has been established. The heterogeneity of these individual data for tumor microenvironments will lead us to identify novel biomarkers for the clinical response of targeted drugs, accelerating personalized treatment strategies.

#3418 Preoperative nutritional status and overall survival among non-metastatic colorectal cancer patients: The ColoCare Study.

B. Gigic[1], V. Damerell[1], T. Lin[2], J. Ose[2], C. Kahlert[1], J. C. Figueiredo[3], C. I. Li[4], M. Schneider[1], D. Shibata[5], E. M. Siegel[6], A. T. Toriola[7], C. M. Ulrich[2]; [1]Heidelberg University Hospital (UKHD), Heidelberg, Germany, [2]University of Utah and Huntsman Cancer Institute, Salt Lake City, UT, [3]Samuel Oschin Comprehensive Cancer Institute, Cedars-Sinai Medical Center, Los Angeles, CA, [4]Fred Hutchinson Cancer Research Center, Seattle, WA, [5]University of Tennessee Health Science Center, Memphis, TN, [6]H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL, [7]Washington University St. Louis, St. Louis, MO

Introduction: Preoperative malnutrition in colorectal cancer (CRC) patients undergoing major abdominal surgery is a common and serious issue that affects postoperative recovery and clinical outcomes. The aim of this study was to evaluate the associations between preoperative nutritional status and overall survival (OS) of prospectively followed, non-metastatic CRC patients.

Methods: The target cohort consisted of 415 patients with newly-diagnosed stage I-III CRC who underwent curative surgery at the Heidelberg University Hospital in Germany. Nutritional status was evaluated using predefined accessible laboratory parameters (haemoglobin, albumin, total protein, and thrombocytes), and the Geriatric Nutritional Risk Index (GNRI), a screening tool to identify patients with malnutrition: *(GNRI) = 14.89×serum albumin concentration (g/dl) + 41.7×present weight/ideal weight*. Ideal weight was calculated as follows: *height(cm)-100-[(height(cm)-150)/4]* for men and *height(cm)-100-[(height(cm)-150)/2.5]* for women. Patients were categorized into normal *vs.* out of normal range for laboratory parameters and into four grades of nutrition-related risk: major risk (GNRI: <82), moderate risk (GNRI: 82 to <92), low risk (GNRI: 92 to ≤98), and no risk (GNRI: >98). Vital status has been obtained through study-specific follow-ups or the tumor registry. OS was calculated as the interval between the date of surgery and the date of death from any cause or the last follow-up examination. Using Cox proportional hazards regression, we examined associations of the nutritional status with OS. Models were adjusted for potential confounders.

Results: After a median follow-up of 2.24 years for OS, 13% (54) of the 415 patients died. Of all patients, 35.1%, 3.4%, 12.5%, and 10,8% had values out of the normal range for haemoglobin, albumin, total protein, and thrombocytes, respectively. Further, 6.4%, 33.8%, 29.7%, and 30.2% of the patients had major, moderate, low, and no nutrition-related risk, respectively. Patients with out of normal range haemoglobin and thrombocyte values had a significantly increased risk of death (HR_{Hb}: 2.8; 95% CI, 1.6-4.9, p<0.001 and HR_{Thr}: 3.0; 95% CI, 1.5-6.1, p=0.003). The major nutrition-related risk group had a significantly increased risk of death compared to the no nutrition-related risk group (HR_{GNRI}: 7.2; 95% CI, 2.7-19.3, p<0.001). We did not observe significant associations between preoperative albumin and total protein values and OS among CRC patients.

Conclusion: Patients with out of normal range levels of preoperative haemoglobin and thrombocytes had a significantly worse OS. Further, the GNRI may have a close relationship with the prognosis in non-metastatic CRC patients. Findings from this study yield important clinical information that could help to strategically combat malnutrition prior to surgery in order to improve clinical outcomes.

#3419 Demographic, health history, and lifestyle factors in association with biomarkers of colorectal cancer prognosis: A pilot study.

U. Zanif[1], I. Tai[1], S. Yip[2], S. Babinszky[3], K. Milne[3], P. Watson[3], R. Murphy[1], P. Bhatti[1];
[1]BC Cancer Research Centre, Vancouver, BC, Canada, [2]BC Cancer Agency, Vancouver, BC, Canada, [3]BC Cancer Research - Deeley Research Centre, Victoria, BC, Canada

Background/Objectives: Multiple demographic, health history, and lifestyle factors have been associated with prognosis of colorectal cancer (CRC), but the mechanisms underlying these associations remain poorly understood. Knowledge of these mechanisms could reveal new strategies to improve outcomes among CRC patients. The primary objective of this project was to explore the association of these factors, which were assessed pre-diagnostically, with expression of two biomarkers in CRC tumors, SPARC and PD-L1, for which lower and higher levels of expression, respectively, have been previously associated with poorer CRC prognosis.
Methods: Participants were drawn from the British Columbia Generations Project (BCGP). At the time of recruitment, they completed a detailed questionnaire that ascertained demographic factors (e.g., biological sex and household income), health history (e.g., personal history of CRC screening), and lifestyle factors (daily fruit and vegetable consumption and alcohol consumption). Formalin-fixed paraffin-embedded blocks (FFPE) with adequate volumes of tumor were obtained for 49 incident CRC cases diagnosed within the BCGP. Cores were extracted from the blocks to create tumor tissue microarrays (TMAs). Slides created from thin sections of the TMAs were stained with SPARC and PD-L1 antibodies and then imaged and analyzed to calculate H-scores as measures of expression in both epithelial and non-epithelial tissues. Linear regression analyses were conducted to evaluate associations between the various factors and ln-transformed H-scores.
Results: Compared to non-smokers, smokers, on average, had 47% lower SPARC H-scores (p=0.05) in the epithelial tissues of their CRC tumors. Individuals with incomes higher than $74,999/year had 33% higher SPARC H-scores (p=0.04) in their CRC tumor non-epithelial tissues than those who earned less than $74 999/year. Females had 2.8-fold greater PD-L1 H-scores (p=0.005) in their CRC tumor epithelial tissues than males. Compared to those without a history of CRC screening, those with a history of CRC screening had 2.2 and 2.0-fold greater PD-L1 H-scores in their epithelial and non-epithelial CRC tumor tissues, respectively.
Conclusion: Larger-scale studies with prognostic data are needed to confirm our findings, but our results suggest that differences in the expression of SPARC and PDL-1 may contribute to the previously observed impacts of some demographic, healthy history, and lifestyle factors on CRC prognosis.

#3420 Androgen receptor $(CAG)_n$ polymorphism: A genomic marker for prostate cancer prognosis independent of histopathological parameters.

G. M. Pascual[1], A. Sabater[2], J. Bizzotto[1], R. Seniuk[1], P. Sanchis[1], C. M. Roggero[3], C. Scorticati[4], O. Mazza[4], E. Vazquez[1], A. Toro[1], G. Gueron[1], J. Cotignola[1];

[1]CONICET - IQUIBICEN, Ciudad Autonoma de Buenos Aires (CABA), Argentina, [2]1-CONICET - IQUIBICEN. 2-Universidad Argentina de la Empresa (UADE), Instituto de Tecnologia (INTEC), Ciudad Autonoma de Buenos Aires (CABA), Argentina, [3]CONICET-IHEM, Ciudad de Mendoza, Argentina, [4]Universidad de Buenos Aires, Hospital de Clinicas Jose de San Martin, Departamento de Urologia, Ciudad Autonoma de Buenos Aires (CABA), Argentina

The androgen receptor (AR) serves as a pivotal transcription factor in prostate cancer (PCa) development. Its transcriptional activity is linked to the number of glutamines in the N-terminal domain. While current screening for PCa and prognostic biomarkers include serum prostate-specific antigen (PSA) levels and histopathological characteristics (specifically, ISUP grade and margin involvement), the heterogeneity of these tumors underscores the need for additional markers to enhance clinical management.

Thus, this study aimed at characterizing an Argentinian PCa patient cohort based on the CAG polymorphism $(CAG)_n$ in *AR* and establish associations between genotypes and clinical-pathological characteristics to refine disease prognosis.

We designed a hospital-based case-case study for PCa patients to determine the association between *AR* polymorphisms and PCa biochemical relapse after radical prostatectomy (RP). We retrospectively recruited 112 patients histologically diagnosed with PCa at the Hospital de Clínicas José de San Martín, Buenos Aires, Argentina. All patients underwent RP as their primary therapeutic strategy. All patients were, by definition, Hispanics, predominantly of Caucasian ancestry and, at a lesser extent, Amerindian or African. Written informed consent and institutional review board approval were acquired.

Blood samples were collected post-RP for genomic DNA extraction using the CTAB method. $(CAG)_n$ in *AR* was genotyped by fluorescent PCR followed by capillary electrophoresis, and correlations between genotypes and clinical-pathological variables were analyzed using R.

Results categorized patients into three subgroups based on the length of the CAG tandem repeat in *AR*: long (>23 repeats, n=29), medium (20-23 repeats, n=44), and short (<20 repeats, n=38). No associations were found between the length of the polymorphism and age of diagnosis, pre-RP PSA serum values, ISUP grade, and margin involvement. However, patients with family cancer history had a higher frequency of the intermediate-length allele (p=0.02). Moreover, among patients with pre-RP PSA <10 ng/ml and intermediate-length allele had 2.72-fold risk of biochemical recurrence (BCR) (HR=2.72, 95%CI=1.05-7.03, p=0.039). Furthermore, multivariable BCR analysis including the ISUP grade and margin involvement as co-variates showed that the $(CAG)_n$ in *AR* was independent of these histopathological parameters (HR_{adj}=3.37, 95%IC=1.24-9.10, p_{adj}=0.017).

Altogether, the *AR* polymorphism is associated with family history of cancer. Consequently, determining the number of CAG repetitions in *AR* through a blood sample could serve as an independent prognostic marker in patients with PSA <10 ng/ml prior to PR, independent of the histopathological features.

#3421 Associations of circulating levels of tryptophan-kynurenine metabolites and inflammation biomarker neopterin with overall survival among patients with stage I-III colorectal cancer.

Introduction: Dysregulation of the kynurenine pathway of tryptophan metabolism has been linked to the development of inflammation-related chronic diseases, such as colorectal cancer (CRC). Circulating concentrations of certain kynurenine metabolites, the kynurenine/tryptophan ratio (KTR), and the pro-inflammatory marker neopterin increase during inflammation, particularly in response to interferon-gamma. However, comprehensive data on the associations between inflammation markers and kynurenine metabolites and clinical outcomes in CRC patients are lacking. To address this gap in knowledge, we investigated associations of circulating kynurenine metabolites and neopterin with overall survival (OS) in prospectively followed non-metastatic CRC patients.

Methods: Pre-surgery blood samples from 2,101 stage I-III CRC patients participating in the international FOCUS consortium were used to measure circulating levels of nine tryptophan-kynurenine pathway metabolites and neopterin using liquid chromatography-tandem mass spectrometry. Multivariable linear regression models and Spearman partial correlation analyses were conducted to quantify associations between kynurenine metabolites and neopterin. Based on the results from correlation analyses, a subset of patients (n=984) was categorized into different groups (‘kynurenine metabolite/neopterin‘; i.e. ‘low/high‘, ‘high/high‘) using the median biomarker concentration as cut-off. Associations of biomarkers with OS were assessed using Cox proportional hazards regression models. All models were adjusted for age at diagnosis, sex, tumor stage, tumor site, circulating creatine levels and cohort.

Results: Tryptophan was inversely correlated with neopterin ($r=-0.21$, $\beta=-0.48$, $P_{linear}<0.001$). Neopterin was positively correlated with kynurenine (kyn) ($r=0.25$, $\beta=0.57$, $P_{linear}<0.001$), the KTR ($r=0.42$, $\beta=0.87$, $P_{linear}<0.001$), 3-hydroxykynurenine ($r=0.26$, $\beta=0.32$, $P_{linear}<0.001$), anthranilic acid ($r=0.29$, $\beta=0.36$, $P_{linear}<0.001$), and quinolinic acid (QA) ($r=0.41$, $\beta=0.56$, $P_{linear}<0.001$). After a median follow-up of 3.2 years for OS, 14% (141) patients deceased. While patients with ‘high neopterin’ levels had a 43% increased risk of death (HR, 1.43, 95%CI 0.95-2.16), the ‘high kyn/high neopterin‘ patient group had a 52% increased risk of death (HR, 1.52, 95%CI 1.04-2.22). Similarly, the ‘high QA/high neopterin‘ and ‘high KTR/high neopterin‘ patient groups had a 85% and 89% increased risk of death, respectively ($HR_{QA/Neopt}$, 1.85, 95%CI 1.24-2.75, $HR_{KTR/Neopt}$, 1.89, 95%CI 1.27-2.80).

Conclusion: Tryptophan-kynurenine pathway activation correlates with inflammation marker neopterin in CRC. Combined associations of kynurenine metabolites and neopterin may be a promising predictor for OS among stage I-III CRC patients.

#3423 Spatial-resolved single-cell analysis of the tumor microenvironment in Alaska Native colorectal cancer patients.

H. Yin[1], D. Redwood[2], K. Smythe[3], D. Jones[3], M. Houghton[3], K. C. Barry[3], A. L. Koehne[3], E. Donato[3], C. Yeung[3], M. Lin[3], J. J. Tiesinga[4], T. A. Harrison[1], S. S. Thomas[3], L. Hsu[3], J. C. Figueiredo[5], L. Li[6], T. K. Thomas[2], C. Li[3], U. Peters[3], J. R. Huyghe[3];

[1]University of Washington, Seattle, WA, [2]Alaska Native Tribal Health Consortium, Anchorage, AK, [3]Fred Hutchinson Cancer Center, Seattle, WA, [4]Alaska Native Medical Center, Anchorage, AK, [5]Cedars-Sinai Medical Center, Los Angeles, CA, [6]Ochsner Health Foundation, New Orleans, LA

Tribal Health Organizations recognize the high rates of colorectal cancer (CRC) among Alaska Native peoples and are undertaking initiatives to address it. The tumor microenvironment (TME) is a complex ecosystem including tumor, stromal, and immune cells. Understanding the cell composition and spatial organization of the TME among Alaska Native patients with CRC will provide new insights into disease progression. We performed spatial profiling on 3 tissue microarrays (TMA) from 37 patients using the Akoya Biosciences' s PhenoCycler system. Patients with CRC were selected from a nested case-control study which includes 16 patients who died of CRC and 21 patients who lived as long as patients with lethal CRC and matched on age at diagnosis, sex, tumor site and tumor stage. We designed a 40-antibody panel that captured tumor, epithelium, stromal, vascular, and immune cells, as well as cell functional states (e.g., PD1). Initial images were processed using QuPath for image stitching, artifact removal, background subtraction, cell segmentation, and measurement of average intensity of each marker per cell. Cell quality control (QC) was performed to filter out low quality cells based on cell size and log10-transformed sum of intensity. After quantile normalization and arcsinh transformation, cells that passed QC were clustered using the R package 'Seurat' and manually annotated based on the cell type and function marker intensities for each cluster. We identified 1.17 million cells and 15 cell types. Those cell types included 3 stromal and vascular cells, 1 epithelium, 1 mixed immune cluster, and 10 different immune cells. We quantified each cell type as a fraction of total cells on a per-patient basis. Among the subset of immune cells, the proportions of macrophages, CD4+T cells, and CD8+T cells were high (21%, 11.2%, and 14.5%, respectively), and the proportion of B cells was low (5.1%). We also identified regulatory T cells, cytotoxic CD8+T cells, and monocytes at 1-3%. We observed differences in the composition of cell clusters by CRC-specific death. The frequency of epithelium was higher among patients with lethal CRC, and the frequency of CD4+T cells and CD8+T cells were higher among patients without lethal CRC. In summary, the overall composition of tumor and immune cells varies between patients with and without CRC-specific death, indicating TME heterogeneity. Further investigation of spatial domains and relationships with clinical molecular features may facilitate discovery of novel predictors of CRC-specific death among Alaska Native peoples. We are clustering cell types into different cellular neighborhoods using spatial information and conducting statistical analysis integrating RNA sequencing data from the same patients. Further, we are generating spatial profiling data for an additional 5 TMAs comprising 60 additional patients and will present results of the combined data analyses.

#3424 Assessing a DNA methylation-based telomere length estimator in individuals with a heavy smoking history.

L. Grieshober[1], S. Graw[2], M. J. Barnett[3], G. E. Goodman[3], C. Chen[3], D. C. Koestler[4], C. J. Marsit[5], J. A. Doherty[1];
[1]Huntsman Cancer Institute, University of Utah, Salt Lake City, UT, [2]Everest Clinical Research Corporation, Markham, ON, Canada, [3]Fred Hutchinson Cancer Center, Seattle, WA, [4]University of Kansas Medical Center, Kansas City, KS, [5]Rollins School of Public Health, Emory University, Atlanta, GA

Telomere length (TL) and DNA methylation are associated with age and smoking exposure, as well as aging-related outcomes including lung cancer and mortality. A DNA methylation-based TL score (DNAmTL) was developed to estimate TL using DNA methylation array data, both in blood. DNAmTL effectively estimates telomere-related aging using 140 CpGs that are moderately enriched in sub-telomeric regions and not included in existing epigenetic clocks. We examined DNAmTL in individuals with a heavy smoking history (mean 56 pack years, range 11-185) in a nested lung cancer case-control study of 350 cases and 350 controls from the β-Carotene and Retinol Efficacy Trial identified through 2005. Twenty-two controls became cases with additional follow-up through 2013, so 328 controls and 372 cases were considered for these analyses. Leukocyte TL was measured using quantitative polymerase chain reaction (T/S ratio, log2-transformed), and DNA methylation was assayed on the Illumina EPIC array, in blood samples obtained on average 4.9 years prior to diagnosis in cases. We observed weak positive Pearson correlations between DNAmTL and TL in cases (r=0.19, p=0.0003) and controls (r=0.14, p=0.009) that persisted after age-adjustment: r=0.16, p=0.002 and r=0.14, p=0.014, respectively. Age-adjusted DNAmTL, but not TL, was longer for female compared to male cases (T=3.6, p=0.0004) and controls (T=2.2, p=0.03), and for those in the placebo compared to the intervention arm in cases (T=2.1, p=0.03) and controls (T=2.3, p=0.02). Linear regression models of TL and DNAmTL adjusted for age, sex, and race and ethnicity were not statistically significant for smoking variables at blood draw (pack years, current vs former smoking status, cigarettes smoked per day during smoking history, years smoked, years since quit), nor asbestos exposure in either cases or controls. Longer age-adjusted DNAmTL was associated with a lower hazard ratio (HR) for time to lung cancer death (0.60, 95% Confidence Interval (CI): 0.37-0.97) among cases (n=313 lung cancer-specific mortality events) in Cox proportional hazards models adjusted for age, sex, race and ethnicity, and time from blood draw to diagnosis with stage as a stratification variable (early I/II, advanced III/IV, unknown). Analogous age-adjusted TL model showed a similar direction but did not reach statistical significance (HR 0.86, CI: 0.71-1.05). Further adjustment of these models by DNA methylation-estimated leukocyte proportions of granulocytes, monocytes, natural killer, CD8+T, and CD4+T (excluding B cells) yielded similar results for age-adjusted DNAmTL (HR 0.54, CI: 0.31-0.92) and age-adjusted TL (HR 0.87, CI: 0.71-1.05). Our results illustrate that while DNAmTL may not be closely associated with smoking exposure among heavily exposed individuals, shorter DNAmTL may be more strongly associated with lung cancer mortality than TL in individuals with a heavy smoking history.

#3425 Genetic predisposition to obesity and survival in women with breast cancer.

C. Bodelon, A. Lori, M. Landry, J. Hodge, P. P. Choudhury, Y. Wang, L. E. McCullough, A. V. Patel, L. R. Teras;
American Cancer Society, Atlanta, GA

Background. Higher body mass index (BMI) is associated with poor survival after breast cancer diagnosis. BMI is a heritable trait. A polygenic risk score (PRS) for BMI has been associated with cardiometabolic traits and found to modify weight loss interventions. Whether BMI genetic scores affect survival in women with breast cancer is unknown.

Methods. This analysis was conducted in the Cancer Prevention Study II Nutrition cohort. Women diagnosed with non-metastatic breast cancer between 1992 and 2017 were included in the analysis if they had genotype data. Analyses were restricted to unrelated, postmenopausal women at the time of diagnosis who were of European ancestry (N=3,566). Deaths through 2020 were identified through linkage with the National Death Index. Primary cause of death was based on the International Classification of Disease codes. Pre-diagnosis BMI was self-reported (median 1.3 years from BMI measurement to diagnosis, interquartile range (IQR): 0.6, 1.9). We constructed a PRS using findings from a published meta-analysis of BMI genome wide association studies (GWAS) that included ~700,000 individuals and the PRSice tool.Hazard ratios (HR) and 95% confidence intervals (CI) between the PRS and all-cause mortality were estimated using Cox proportional hazards regression and Fine and Gray models for cause-specific mortality to account for competing risks. Models were adjusted for age and GWAS-specific statistically significant (P<0.05) principal components for population stratification. Mediation was estimated using the mediation R package.

Results. The median age at diagnosis was 71.5 years (IQR: 66.3, 76.8). Most women were overweight (33.5%) or obese (18.4%) and were diagnosed with localized stage (63%) and estrogen receptor positive (65%) breast cancer. During a median follow-up of 14.5 years (IQR: 9.7-19.8), there were 1,825 (51.2%) deaths, including 301 breast cancer and 337 cardiovascular disease (CVD) specific deaths. In multivariable models, a 5 Kg/m^2 increase in BMI was associated with increased risks of all-cause mortality (HR=1.09, 95% CI: 1.04, 1.15), breast cancer-specific mortality (HR=1.27, 95% CI: 1.13, 1.42), and CVD-specific mortality (HR=1.25, 95% CI: 1.11, 1.41). The PRS was highly predictive of pre-diagnostic BMI (P<0.001). A 1-standard deviation increase in the PRS was associated with statistically increased risk of all-cause mortality (HR=1.06, 95% CI: 1.02, 1.11). Risks of breast cancer (HR=1.07, 95% CI: 0.96, 1.19) or CVD (HR=1.01, 95% CI: 0.90, 1.12) specific mortality did not reach statistical significance. We estimated that 27% of the PRS and all-cause mortality association was mediated by BMI (95% CI: 12%, 91%; P=0.004).

Conclusions. Women with breast cancer predisposed to higher BMI were at increased risk of all-cause mortality. A BMI-related PRS may be a useful tool to identify women with breast cancer in need of additional interventions and/or surveillance.

#3426 Real-world biomarker testing rates and trends among patients with advanced non-small cell lung cancer in the US.

Y. Chen, A. Carlson;
University of Minnesota, College of Pharmacy, Minneapolis, MN

Background: Broad biomarker profiling before treatment initiation for non-small cell lung cancer (NSCLC) is recommended. Patients may not receive or receive inadequate biomarker testing before treatment initiation. This study assesses rates and trends of biomarker testing in community and academic oncology practices in the US.
Methods: A descriptive cohort study was conducted using electronic health records from an NSCLC registry. Patients who initiated NSCLC treatment following diagnosis of advanced NSCLC (stage IIIB/IIIC/IV) from 01/01/2015-12/31/2021 were identified. Patient demographics (age, gender, race, region) along with histology type (squamous/non-squamous) and hospital type (academic/community) were included. The percentage of patients receiving tests for any of the nine biomarkers before and during therapy was calculated and compared.
Results: 8,769 patients were identified with advanced NSCLC; 65.9% having non-squamous cell carcinoma; 22.4% having squamous cell carcinoma; 11.7% unknown. 13.4% of patients were from academic centers, 78.7% from community hospitals, 8.0% unknown. The majority (59%) were 65+ years; 47.3% were female. Overall, 83.2% had biomarker testing at some point in treatment; only 66.3% before treatment initiation. Over time, biomarker testing rates prior to treatment initiation increased (46.9% in 2015 to 73.8% in 2021). The use of biomarker testing in non-squamous cell carcinoma was greater than in squamous cell carcinoma. The most frequent biomarker testing before treatment initiation were PD-L1 (52.2%), EGFR (51.6%), and ALK (50.7%), followed by ROS1 (46.9%), BRAF (39.5%), and KRAS (34.1%). Testing rates for the newest biomarkers NTRK, MET, and RET were 20.4%, 28.4%, and 28.0%, respectively. Testing rates were similar between academic centers and community-based hospitals, except for the newest biomarkers, where use in academic settings was greater. Biomarker testing rates were higher among female patients (χ^2 P-value<0.001); rates by race were similar (χ^2 P-value=0.83).
Conclusion: While the use of biomarker testing in advanced NSCLC is growing, 26% of patients remained untested before treatment initiation. Biomarker testing in non-squamous cell carcinoma is higher than in squamous cell carcinoma, in keeping with the guideline emphasis on biomarker testing for that histology type. Results suggest that further dissemination of guideline recommendations to obtain biomarker test results prior to treatment initiation is important to optimize treatment decisions in the NSCLC landscape.

#3427 Serum metabolites and pancreatic ductal adenocarcinoma in two prospective cohorts.

T. Zhang, S. C. Moore, S. Fu, K. Wang, D. Albanes, S. J. Weinstein, K. Yu, R. Z. Stolzenberg-Solomon;
National Cancer Institute, Rockville, MD

Objective: Metabolomics may provide insight to understand the etiology and potential mechanisms for pancreatic ductal adenocarcinoma (PDAC) development beyond established risk factors of smoking, diabetes, and adiposity. We extended our previous metabolomic study by including additional participants from the Prostate, Lung, Colorectal, and Ovarian Cancer Screening Trial (PLCO) with the aim to examine prospective associations between serum metabolites and incident PDAC.

Method: We measured 1483 known metabolites in pre-diagnostic serum (up to 24 years) in two PDAC nested case-control studies within the PLCO (360 cases-control pairs) of mostly non-smoker men and women and Alpha-Tocopherol, Beta-Carotene Cancer Prevention Study (ATBC, 372 cases-control pairs) male smokers using liquid chromatography, high resolution/accurate mass spectrometry. Controls were incidence-density sampled and matched to cases by age, blood draw date, sex, race/ethnicity, and cohort. We used conditional logistic regression to calculate odds ratios and 95% confidence intervals for PDAC per standard deviation increase in $\log_{10}$-metabolite levels in each cohort and combined using fixed-effect meta-analyses and stratified by follow-up time. We also performed ElasticNet regression in each cohort to identify metabolites. We assessed associations of 72 predefined metabolic pathways with PDAC by comparing Fisher's statistic of metabolite p-values per pathway with a null distribution based on 500,000 permutations.

Results: Sixty-six metabolites were associated with PDAC at a false discovery rate (FDR)<0.05 with 26 below the Bonferroni threshold ($P<3.4\times10^{-5}$). Among the 66 metabolites, 14 and 15 were selected in ElasticNet regressions in ATBC and PLCO, respectively, with two in both cohorts. Notable findings include: fibrinopeptide B(1-9); seven modified, di- or poly-peptides; eight xenobiotics related to tobacco smoke; amino acids, carbohydrates, and TCA cycle metabolites known to be regulated by mutant KRAS (aspartate, glutamate, lactate, pyruvate, and α-ketoglutarate); four secondary bile acids and three aromatic amino acids (tryptophan, phenylalanine, and tyrosine) that were positively, while four fibrinogen cleavage peptides were inversely associated with PDAC. Among the top identified metabolites, aspartate, α-glutamyltyrosine, pyroglutamylglutamine, and Glu-Gly-Asn-Val showed time-varying associations overall ($P\leq0.05$) with greater magnitudes within the first 5 years after blood draw. Thirteen metabolic pathways were associated with PDAC (Bonferroni $P\leq0.05$).

Conclusion: Our study suggests pre-diagnostic circulating metabolites, particularly those potentially related to subclinical disease, microbiome, and tobacco metabolism are associated with PDAC. The identified metabolites along with other known risk factors might be useful in algorithms to model disease risk and progression.

#3428 Association of adipokines and inflammation biomarkers with cancer risk in men.

D. DeMoulin, H. Cai, Q. Cai, W. Zheng, X.-O. Shu;
Vanderbilt University Medical Center, Nashville, TN

Using pre-diagnosis fasting plasma samples from 4,040 participants of the Shanghai Men's Health Study which enrolled 61,464 men ages 40-70 during 2001-2006, we prospectively evaluated the associations of adipokines and inflammation biomarkers with cancer risk. Levels of leptin, resistin, adiponectin, plasminogen activator inhibitor type-1 (PAI-1), interleukin-6 (IL-6), interleukin-8 (IL-8), tumor necrosis factor-alpha (TNFa), monocyte chemoattractant protein-1 (MCP-1), and insulin were measured by Luminex assays, and C-reactive protein (CRP), measured by ACE Clinical Chemistry System. Biomarker levels were categorized by tertile distribution. The Cox regression model was applied to derive hazard ratios (HR) and 95% confidence intervals (CI) for cancer risk in association with biomarkers with adjustment for potential confounders. Principle component analysis (PCA) was performed to assess associations with multiple biomarkers, and tertile scores for each component were used in analyses. During 15-years of follow-up, 318 cancer cases were identified, including 85 lung, 49 gastric, 17 liver, and 61 colorectal cancer (CRC) cases. Analyses adjusted for age, education and income showed that 3rd vs 1st tertile of TNFa (HR=1.7, 95%CI=1.0-3.0) and adiponectin (HR=4.0, 95%CI=1.1-14.4) was associated with lung and liver cancer risk, respectively. High levels of leptin, insulin, and CRP were each associated with CRC risk: respective HRs were 2.3 (95%CI=1.1-4.7), 2.1 (95%CI=1.0-4.2), and 2.0 (95%CI=1.1-3.9). After further adjustment for known cancer risk factors, TNFa-lung cancer (HR=1.8, 95%CI=1.1-3.1); leptin-CRC (HR= 3.2, 95%CI=1.3-7.7); insulin-CRC (HR=2.1, 95%CI=1.0-4.5); and CRP-CRC (HR=2.0, 95%CI=1.0-4.0) associations remained statistically significant. The adiponectin-lung cancer association lost significance. PCA identified 4 principal components (PC). High PC1 score (main loadings: TNFa, leptin, and insulin) was associated with CRC risk (HR=2.3, 95%CI=1.1-5.0 for 3rd vs 1st tertile p_{trend}=0.02). High PC2 score (main loadings: adiponectin, IL-8, MCP-1) and PC3 (main loadings: resistin and PAI-1) were associated with liver cancer risk: HR=5.2 (95%CI=1.1-24.3) for the 3rd vs 1st tertile, p_{trend}=0.03 and HR=4.7 (95%CI=1.0-21.7), for the 3rd vs 1st tertile, p_{trend}=0.03, respectively. High PC4 score (main loadings: IL-6 and CRP) was associated with lung cancer risk (HR=1.7, 95%CI=1.0-3.0, for the 3rd vs 1st tertile, p_{trend}=0.04). These associations, except the PC1-CRC association, lost significance after further adjustment of known cancer risk factors. Our study found that high plasma levels of insulin, CRP, and their combination were associated with CRC risk, high resistin and adiponectin levels with liver cancer risk, and high TNFa levels with lung cancer risk. Some biomarker-cancer associations may be explained by their correlations with known cancer risk factors, especially smoking.

#3429 Using metabolomics to identify biomarkers mediating the associations of adiposity in childhood and early adulthood with mammographic breast density in premenopausal women.

Kayla R. Getz[1], Myung Sik Jeon[1], Lili Liu[2], Lei Liu[2], Chongliang Luo[1], Jingqin Luo[1], Adetunji T. Toriola[1]

[1]Public Health Sciences, Washington University School of Medicine in St. Louis, St. Louis, MO,[2]Biostatistics, Washington University School of Medicine in St. Louis, St. Louis, MO

Introduction: Mammographic breast density (MBD), a strong predictor of breast cancer risk, is highly influenced by body mass index (BMI) in childhood and early adulthood, but the mechanisms elucidating this relationship are undetermined. To our knowledge, no study has explored the mediating role of biomarkers on the relationship between early-life adiposity and MBD. The goal of this study is to discover metabolites that mediate the relationship between BMI at ages 10 and 18 with MBD in premenopausal women.

Methods: This study includes premenopausal women who had their screening mammogram at Washington University in St. Louis, MO, and provided a fasting blood sample. Metabolon performed untargeted metabolomic profiling, detecting 1,074 metabolites. Metabolites missing >300 observations were excluded, leaving 828 metabolites; the other missing values were imputed using the nearest neighbor method. To mitigate batch effect, we normalized the metabolite peak area data using ComBat. Volumetric percent density (VPD) was calculated in 700 women using Volpara software. BMI at age 10 was estimated using the Stunkard pictogram, and BMI at age 18 was calculated from self-reported weight at 18 and height at study initiation. To assess the mediating role of the 828 metabolites, we performed high dimensional mediation analysis using the *hima* R package adjusting for potential confounders. Missing values in the covariates and BMI measures included in the mediation analysis were imputed using multivariate imputation by chain equations. Associations were considered significant if FDR p-value <0.1.

Results: Four metabolites (glutamate, beta-cryptoxanthin, phytanate, and cortolone glucuronide (1)) mediated the relationship between BMI at age 10 and VPD; and 2 metabolites (glutamate, beta-cryptoxanthin) mediated the relationship between BMI at age 18 and VPD. Glutamate and beta-cryptoxanthin significantly mediated the relationship between both BMI measures and VPD, but glutamate was the strongest mediator across both time points. Glutamate mediated 6.7% (FDR p-value=0.06) and 9.3% (FDR p-value=0.008) of the total effect between BMI at age 10 and 18, respectively, on VPD. Beta-cryptoxanthin mediated 4.1% (FDR p-value=0.06) and 6.3% (FDR p-value=0.04), of the total effect between BMI at age 10 and 18, respectively, on VPD. Additionally, phytanate mediated 2.6% (FDR p-value=0.06) and cortolone glucuronide (1) mediated 2.0% (FDR p-value=0.07) of the total effect between BMI at age 10 and VPD.

Conclusion: Amino acid, lipid, cofactor/vitamin, and xenobiotic metabolites mediated the associations of BMI in early-life and VPD in premenopausal women. This innovative study offers insight into the biological mechanisms underlying the link between early-life adiposity and MBD, which can support future research into breast cancer prevention.

#3430 Mosaic loss of the Y chromosome is associated with prostate cancer risk.

R. L. Kelly, W. Zhou, K. M. Barnao, C. D. Young, A. K. Hubbard, S. M. Khan, W.-Y. Huang, S. J. Chanock, M. J. Machiela;
National Cancer Institute, Rockville, MD

Mosaic loss of the Y chromosome (mLOY), a type of clonal hematopoiesis, is the most frequent chromosomal alteration observed in leukocytes of aging men. mLOY is a putative biomarker of genomic instability with evidence of associations with risk of some solid tumors, but more studies are needed to refine associations and identify potential mechanisms for cancer risk. Prostate cancer (PCa), the most common non-cutaneous cancer in males, is also associated with aging. To further investigate potential relationships between mLOY and PCa, we examined DNA derived from leukocytes of male participants in two large biobanks: the UK Biobank (UKBB; N = 210,103) and the Prostate, Lung, Colorectal, and Ovarian Cancer Screening Trial (PLCO, N = 26,795). Of the 236,898 male participants without previous cancer diagnosis, 14,253 (6.0%) were diagnosed with incident PCa after DNA collection. High-density genotyping array data collected during the studies were used to create virtual karyotypes for detecting mLOY in whole blood samples utilizing a phase-based detection method in MoChA software. Analyses were restricted to men without cancer at genotyping and multivariable regression models were adjusted for age, smoking status, and genetic similarity. Men with detectable mLOY were older (mean = 62 vs 56 years) and more likely to be smokers (14.8% vs 9.7%) than men without mLOY. A total of 3,848 (27.0%) men with PCa and 42,835 (19.2%) men free of PCa had detectable mLOY. mLOY clonal fraction ranged from 0.01% to 72.1% of total leukocytes. 18.7% of PCa cases and 13.6% of men free of PCa had high clonal fraction mLOY, defined as greater than 10% of leukocytes with mLOY. Fixed effect meta-analysis of multivariable models from UKBB and PLCO produced evidence for a positive association between mLOY in leukocytes and incident PCa; (Odds Ratio (OR) = 1.062, 95% Confidence Interval (CI) [1.020, 1.107], P-Value (p) = 0.004). The effect estimate was the same in men with low clonal fraction of mLOY (OR = 1.062, 95% CI [1.012, 1.113], p = 0.014) and men with high clonal fraction of mLOY (OR = 1.065, 95% CI [0.998, 1.137], p = 0.057). Age at PCa diagnosis was not associated with mLOY or the clonal fraction of mLOY. A sub-analysis of separate participants from PLCO with mLOY detected in buccal cells (n = 18,011) also showed a small positive effect between mLOY and PCa risk, but the relationship did not reach statistical significance (OR = 1.036, 95% CI [0.877, 1.224], p = 0.673)). Our investigation of the relationship between mLOY and PCa in two large prospective studies provides additional evidence for an association between mLOY detected in the blood and increased PCa risk, meriting additional studies of potential biologic mechanisms underlying the relationship.

#3431 Genetically determined circulating lactase/phlorizin hydrolase concentrations and risk of colorectal cancer: A two-sample mendelian randomization study.

S. Han[1], J. Yao[1], H. Yamazaki[2], S. Streicher[3], J. Rao[4], R. Nianogo[1], Z.-F. Zhang[1], B. Huang[5];
[1]UCLA Fielding School of Public Health, Los Angeles, CA, [2]Graduate School of Medicine, Kyoto University, Kyoto, Japan, [3]University of Hawaii Cancer Center, University of Hawaii at Manoa, Honolulu, HI, [4]UCLA David Geffen School of Medicine, Los Angeles, CA, [5]Keck School of Medicine of USC, Los Angeles, CA

Background: Colorectal cancer (CRC) ranks as the third most common cancer worldwide. Despite its established connection with genetic, dietary, and lifestyle factors, gaps remain in the understanding of its etiology. Lactase-phlorizin hydrolase (LPH) plays a critical role in milk digestion and influences crucial nutrient absorption and gut microbiota composition. A direct relationship of CRC risk with LPH level remains unexplored. Our study aims to elucidate the potential causal link between genetically determined LPH levels and CRC risk.
Methods: We applied a two-sample Mendelian Randomization (MR) strategy to investigate the causal link between elevated LPH levels and CRC risks. Genetic instruments for LPH (one *cis*-variant and three *trans*-variants) were derived from the Fenland Study, and CRC-associated summary statistics for these instruments were extracted from the FinnGen Study, PLCO Atlas Project, and Pan-UK Biobank. Primary MR analyses focused on a *cis*-variant (rs4988235) for LPH levels, with results integrated via meta-analysis. MR analyses using all variants were also undertaken. This analytical approach was further extended to assess CRC subtypes, specifically colon and rectal cancer.
Results: Meta-analysis across the three datasets illustrated an inverse association between genetically predicted LPH level and CRC risk (OR: 0.92 [95% CI, 0.89-0.95]). Subtype analyses revealed associations of genetically predicted elevated LPH levels with reduced risks for both colon cancer (OR: 0.92 [95% CI, 0.89-0.96]) and rectal cancer (OR: 0.92 [95% CI, 0.87, 0.98]). Consistency was observed across varied analytical methods and different datasets.
Conclusions: Our study suggests an inverse relationship between genetically determined LPH level and CRC risk. Further exploration is warranted to unveil the underlying mechanisms and validate LPH's potential role in CRC prevention.

#3432 Blood metabolomic profile of glioma risk: A pooled, multi-cohort analysis in COMETS.

J. Huang[1], B. Zhao[1], S. J. Weinstein[2], M. L. Neuhouser[3], S. C. Moore[2], H. Eliassen[4], D. J. Cote[5], L. Le Marchand[6], L. Mucci[4], Y. Yang[7], V. Stevens[7], W. Zheng[8], X.-O. Shu[8], **D. Albanes**[2];

[1]National Clinical Research Center for Metabolic Diseases, Changsha, Hunan, China, [2]National Cancer Institute, Bethesda, MD, [3]Fred Hutchinson Cancer Center, Seattle, WA, [4]Harvard TH Chan School of Public Health, Boston, MA, [5]Keck School of Medicine of the University of Southern California, Los Angeles, CA, [6]University of Hawaii Cancer Center, Honolulu, HI, [7]American Cancer Society, Atlanta, GA, [8]Vanderbilt University Medical Center, Nashville, TN

Although gliomas are relatively rare, they are among the most lethal malignancies. Yet, with the exception of ionizing radiation and family history, their etiologic factors remain largely unknown. We conducted an untargeted metabolomics investigation pooling nested case-control studies from 9 prospective cohorts (median age 63 years, 59% women) in the Consortium of Metabolomics Studies (COMETS). One cancer-free control was individually matched to each of the 803 glioma cases based on age, sex, self-identified race/ethnicity, and blood collection date. Using an ultrahigh-performance LC-MS/MS platform (Metabolon, Inc.), we identified 874 known metabolites in pre-diagnostic serum or plasma, and logistic regression models conditioned on the matching factors) estimated odds ratios (ORs) and 95% confidence intervals for the associations between 1-SD increases in circulating metabolites and glioma risk (Bonferroni corrected significance threshold $P=5.7\times10^{-5}$). A total of 58 metabolites were associated with glioma ($P<0.05$), with the top three being 3-methylglutarylcarnitine (OR=1.19; P=0.001), cholate (OR=0.85; P=0.001) and a sphingomyelin (SM) (d18:2/21:0, d16:2/23:0, OR=1.19; P=0.002). Analysis restricted to cases diagnosed >5 years after blood collection showed 51 metabolites associated with risk ($P<0.05$), including SM d18:2/23:1 (OR=1.32; $P=5.2\times10^{-5}$), and two other SMs (d18:2/21:0, d16:2/23:0 and d17:1/24:1(15Z)) (ORs=1.27 and 1.26, respectively; $P<5.6\times10^{-4}$). Our findings were not materially altered with further adjustment for smoking, BMI, height and diabetes. Analysis restricted to high-grade glioma cases (n=595) showed similar associations, whereas low-grade glioma (n=207) showed fewer metabolites related to risk (top signals of sphingosine, sphinganine and *L*-glutamic acid, each inversely associated). We did, however, observe that the 2-hydroxyglutarate/alpha-ketoglutarate ratio was significantly associated with low-grade disease (OR=2.9; P=0.0008), which was most pronounced among cases diagnosed >10 years following blood collection (OR=9.99; P=0.003). Glioblastoma (n=485) showed similar positive risk estimates including for 3-methylglutarylcarnitine which achieved Bonferroni significance (OR=1.35; $P=3\times10^{-5}$) and several SMs. In contrast, the top metabolite for astrocytoma risk (n=88) was tyrosine (OR=0.55; P=0.002). Gene-set and principal components analyses confirmed that the sub-pathways of SM, dihydro-SM, fatty acid, and dihydroceramide metabolism were significantly associated with overall glioma risk, and dihydro-SM, dihydroceramide, SM, lactosylceramide, glutathione, and purine metabolism were associated with high-grade glioma (all P values <0.05). These novel findings regarding altered metabolic pathways/dysregulation occurring years before glioma diagnoses may be related to etiologic factors or subclinical disease.

#3433 Characterization of co-occurring clonal hematopoiesis to identify high risk clones associated with hematologic cancer risk.

K. M. Barnao[1], A. K. Hubbard[1], W. Zhou[1], I. Chan[2], D. Tran[2], Y. Cao[2], S. J. Chanock[1], K. L. Bolton[2], M. J. Machiela[1];
[1]National Cancer Institute, Bethesda, MD, [2]Washington University School of Medicine, St. Louis, MO

Clonal hematopoiesis (CH) is the age-related clonal expansion of hematopoietic cells as a result of acquired mutations in driver genes, commonly referred to as clonal hematopoiesis of indeterminate potential (CHIP), or due to large-scale mosaic chromosomal alterations (mCAs). While the type and genomic location of CH exhibits varying associations with hematological parameters as well as lymphoid and myeloid malignancy risk, few studies have examined the co-occurrence of CH types. We characterized the frequency of co-occurring CH and examined the association of co-occurring CH with various cancer-related phenotypes to identify potential high-risk clones associated with hematologic cancer risk.

We analyzed sequencing and genotyping array data from 453,807 participants in the UK Biobank to detect CHIP and mCAs. In total, 83,240 (18.3%) individuals had at least one detectable type of CH, with increasing age strongly associated with increasing frequency of CH ($P < 2\times10^{-16}$). The most common type of CH was mCAs (N= 67,081 (14.7%)), with mosaic loss of the Y (mLOY) and X (mLOX) chromosomes being most frequently observed in males and females, respectively. We noted inverse associations between mLOY or mLOX with autosomal mCAs, but positive associations between some autosomal mCAs (e.g., chr3 and chr18 mCAs). CHIP was detected in 20,354 (4.5%) individuals, with mutations in *DNMT3A*, *TET2*, and *ASXL1* most common. Similar to mCAs, some forms of CHIP were inversely associated (e.g., *DNMT3A* CHIP with most other CHIP mutations) while others displayed positive associations (e.g., *JAK2* CHIP with *NFE2* CHIP), suggesting both instances of mutual exclusivity as well as cooperation. We likewise noted several instances of CHIP and mCAs co-occurring (e.g., *MYD88* and chr18 mCAs) and overlapping (e.g., *JAK2* and 9p24 mCAs) more frequently than expected.

Compared to those with no CH, participants with CH had notable alterations in blood cell counts, leukocyte telomere length (LTL), and elevated hematologic cancer risk even after adjusting for age, sex, smoking, and genetic ancestry. Furthermore, co-occurring CH had more pronounced associations, with the greatest alterations and hematologic cancer risk generally noted in participants with overlapping CHIP and mCAs (e.g., *MYD88* and 3p22 mCAs). These findings highlight substantial enrichment in CH co-occurrences, particularly in the positional overlap of CHIP and mCAs, and indicate an increased risk of hematological malignancies when CH types overlap (HR = 29.5, 95% CI [24.0, 36.3], $P < 2\times10^{-16}$). Overall, this study details the landscape of co-occurring CH and nominates high risk co-occurrences with strong implications for future hematological malignancy risk.

#3434 Effect modification by levels of sex hormones in the association between adiposity and cancer incidence in the UK Biobank.

L. Lucas, Y. Lu, E. L. Giovannucci, M. Song;
Harvard T.H. Chan School of Public Health, Boston, MA

Introduction: The association between adiposity and cancer risk differs between sexes for some cancer types.
Methods: We prospectively examined adiposity in relation to cancer incidence according to sex hormones in the UK Biobank. Adiposity was assessed by body mass index (BMI) and visceral adipose tissue (VAT), the latter predicted using determinants of age, height, weight, hip circumference, waist circumference, and race. Serum sex hormone binding globulin (SHBG), testosterone, and estradiol were measured using a biochemistry assay and were classified as high or low based on median levels. Cancer incidence was ascertained using ICD-10 codes through cancer registry linkage. For cancer types showing a sex difference in the association between adiposity and cancer incidence, we assessed multiplicative and additive interaction with sex hormones in men and women separately and corrected for multiple testing using false discovery rate. We used Cox regression to calculate the multivariable hazard ratio (HR) of cancer per increase between the 90^{th} to 10^{th} percentile of adiposity (BMI or predicted VAT).
Results: During a median follow-up of 13.1 years, we documented 23,964 and 21,045 incident cancer cases among 217,460 men and 256,163 women, respectively. Adiposity showed a much stronger association with higher risk of colorectal, esophageal, and liver cancers in men than women. In men, BMI was more strongly associated with higher risk of colorectal cancer in low vs. high levels of SHBG (HR (95%CI) of 1.47 (1.31-1.64) vs. 1.12 (0.94-1.33) (adjusted $P_{interaction}$ = 0.027). In contrast, BMI showed a stronger association in high vs. low levels of SHBG with esophageal (HR = 2.39 vs. 1.62) and liver cancers (HR = 3.24 vs 1.96) in men (adjusted $P_{interaction}$ = 0.038 and 0.027, respectively). Among women, BMI was associated with a higher risk of esophageal cancer in those with low SHBG (HR=1.68) but not in those with high SHBG (HR=0.64) (adjusted $P_{interaction}$ = 0.025). Similar patterns were observed for predicted VAT. Men with high SHBG levels and high adiposity (BMI and predicted VAT) had 7.63 (5.08-11.46) and 8.92 (5.72 to 13.90), respectively, times higher risk of liver cancer compared to men with low SHBG levels and low adiposity. No effect modification by estradiol or testosterone was detected for any of the cancers studied.
Conclusions: The association between adiposity and colorectal, esophageal, and liver cancer differed by sex. SHBG may be an important factor underlying these differences.

#3435 History of breastfeeding in relation to circulating inflammatory biomarkers.

N. Lin[1], J. M. Mongiovi[2], L. V. Farland[3], T. Huang[1], H. Eliassen[2], M. K. Townsend[2], S. S. Tworoger[2], K. L. Terry[1], N. Sasamoto[1];
[1]Brigham and Women's Hospital, Boston, MA, [2]Harvard T.H. Chan School of Public Health, Boston, MA, [3]University of Arizona, Tucson, AZ

Background: History of breastfeeding has been associated with reduced risk of various chronic diseases in which chronic inflammation is involved in disease etiology, including cardiovascular disease, type II diabetes, breast cancer, and ovarian cancer. However, few studies have investigated the long-term impact of breastfeeding on systemic inflammation. Thus, we aimed to examine the associations between breastfeeding history and circulating inflammatory biomarkers at midlife.
Methods: We conducted a cross-sectional analysis including 3,448 parous women with plasma inflammatory biomarkers in the Nurses' Health Study and Nurses' Health Study II. We examined self-reported history of ever breastfeeding (ever vs. never) and lifetime total duration of breastfeeding (never, < 6 months, 7-11 months, 12+ months) prior to the time of blood draw. We calculated the geometric means of eight inflammatory biomarkers [i.e., high sensitivity C-reactive protein (hsCRP), interleukin-6 (IL6), sIL6Rα, IL8, IL10, sIL2-receptor-α(Rα), soluble tumor necrosis factor α receptor 2 (sTNFR2), B-cell activating factor (BAFF), C-X-C motif chemokine ligand 13 (CXCL13)] by self-reported history of breastfeeding status adjusted for age, body mass index (BMI), smoking status, duration of oral contraceptive use, parity, proinflammatory diet, analgesic use, menopausal status, and cohort. Tests for trend were calculated using the median value of each lifetime breastfeeding duration category and modeling as a continuous variable. We also conducted stratified analyses by menopausal status and BMI (< 25kg/m^2 vs. ≥ 25kg/m^2) at blood draw.
Results: Overall, we did not observe statistically significant differences in circulating inflammatory biomarker levels by history of breastfeeding among parous women. When stratifying by menopausal status at blood draw, total breastfeeding duration was inversely associated with sTNFR2 levels among premenopausal women (P-trend = 0.03) but not among postmenopausal women. Plasma IL8 levels were suggestively inversely associated with breastfeeding duration among postmenopausal women (P-trend = 0.07) but not among premenopausal women. Among women with BMI ≥ 25 kg/m^2, plasma BAFF levels were lower in parous women who ever breastfed compared to those who never breastfed [1382.5 (95%CI = 1242.0 - 1539.0) pg/ml vs. 1611.9 (95%CI = 1424.9 - 1823.4) pg/ml; p = 0.03], and suggestively inversely associated with total breastfeeding duration (p-trend = 0.07) but no statistically significant association was observed in women with BMI < 25kg/m^2. IL10 was inversely associated with total breastfeeding duration among women with BMI ≥25 kg/m^2 (P-trend = 0.007), but not in women with BMI < 25kg/m^2.
Conclusion: Overall, history of breastfeeding was not associated with inflammatory biomarkers at mid-life, however the association may vary by menopausal status and BMI.

#3436 Circadian rhythm dysregulation with risk of gastrointestinal cancers: A large-scale prospective analysis.

Y. Kang, S. Mok, X. Zong, Y. Cao;
Washington University in St. Louis, St Louis, MO

Introduction: The incidence of multiple gastrointestinal (GI) cancers has been rising among younger adults with unknown etiology. Circadian rhythm dysregulation due to increasing exposures to artificial lighting, irregular work hours, and frequent travel, has been recently linked with multiple diseases. Disruption of the circadian clock drives *Apc* LOH to hyperactivate Wnt signaling and enhances MYC-dependent glycolytic metabolism to accelerate colorectal cancer progression. However, the association between circadian rhythm dysregulation, quantified by relative amplitude (RA)--a parameter derived from rest-activity patterns, and risk of colorectal and other GI cancers has not been evaluated in epidemiologic studies.

Methods: We prospectively examined the associations between RA and risk of incident GI cancers among 87,653 UK Biobank participants who wore an Axivity AX3 triaxial accelerometer over 7 days (2013-15) with follow-up to 2021. RA was derived and averaged across all valid days, using the difference between the mean activity levels during the most active 10-hour period and the least active 5-hour period. Cox models were used to estimate relative risks (RRs) and 95% confidence intervals (CIs).

Results: During 512,074 person-years, 1,079 incident GI cancer cases occurred. After multivariable adjustment, lower RA was associated with an increased risk of overall GI cancer (RR per SD [standard deviation] = 1.12, 95% CI 1.04-1.21, P for trend = 0.01). Compared to individuals in the highest tertile (T1), those with RA in the lowest tertile (T3) had a 25% increased risk of overall GI cancer (RR = 1.25, 95% CI 1.05-1.50). The positive associations with GI cancers were mainly driven by gastric cancer (RR per SD = 1.33, 95% CI 1.02-1.74, P for trend= 0.04) and colon cancer (RR per SD = 1.13, 95% CI 1.00-1.28, P for trend = 0.03).

Conclusion: In this large-scale, prospective analysis of accelerometer data, circadian rhythm dysregulation was associated with subsequent risk of GI cancers, primarily gastric and colon cancer. To our knowledge, this is among the first population-based studies reporting the positive link between circadian rhythm dysregulation with cancer risk.

#3437 Stromal tumor-infiltrating lymphocytes in association with body size and composition among Black and White women with breast cancer.

Rand T. Akasheh[1], Thaer Khoury[2], Song Yao[2], Angela Omilian[2], Chi-Chen Hong[3], Elisa V. Bandera[4], Bonnie Qin[4], Nur Zeinomar[4], Christine Ambrosone[2], Ting-Yuan David Cheng[1]

[1]Internal Medicine, The Ohio State University Wexner Medical Center, Columbus, OH,[2]Roswell Park Comprehensive Cancer Center, Buffalo, NY,[3]Roswell Park Comprehensive Cancer Center, Bufalo, NY,[4]Rutgers Cancer Institute of New Jersey, New Brunswick, NJ

Background: Obesity is a major risk factor for breast cancer and negatively affects disease prognosis. Tumor-infiltrating lymphocytes (TILs) in the stroma of breast tissue play a major role in eliminating cancer cells and modulating immunotherapy efficacy. We aim to study the association between body size and composition with stromal TILs in breast tumor tissue by race.
Methods: The study included 920 Black and 395 White women with newly diagnosed invasive breast cancer who have stromal TIL scores from the Women's Circle of Health Study (WCHS). Body mass index (BMI), waist circumference (WC), and waist-to-hip ratio (WHR) were measured during the home interview. Pre-treatment H&E-stained tumor tissue sections were reviewed by our study pathologist and stromal TILs were scored on a scale of 0-100% at 10% increment according to the recommendations of the International TILs Working Group. Linear regressions adjusting for age at diagnosis, tumor grade, stage, and molecular subtype were used to test the differences in TILs across the categories of body size and composition indicators separately for Black and White women.
Results: A higher stromal TILs score was associated with more aggressive breast cancer features, including higher grade, larger tumor size, more advanced stage, hormone receptor (HR) negativity, and human epidermal growth factor receptor 2 (HER2) positivity in both Black and White women (all $P<0.05$). Among Black women, WHR >0.90 vs ≤0.85 was associated with lower TILs overall ($\beta = -3.5\%$, $P = 0.045$) and in triple-negative tumors ($\beta = -12.3\%$, $P = 0.003$). Among White women, BMI 25.0 - 29.9 vs <25 was associated with higher TILs in HR-/HER2+ tumors ($\beta = 28.1\%$, $P = 0.031$). A pattern suggested that BMI ≥30 vs <25 was associated with lower TILs in both HR-/HER2+ ($\beta = -10.2$, $P=0.52$) and triple-negative ($\beta = -12.8$, $P=0.14$) tumors, although the associations were not significant. No association was observed between TILs and any of the body composition parameters in women with HR+ tumors.
Conclusions and Relevance: Body size and composition correlate with stromal TILs mainly in patients with HR- tumors, and this relation may be race-dependent. These findings suggest that body size and composition potentially modulate breast cancer treatment outcomes at least in part through TILs-dependent mechanisms. Funding: This work was in part supported by grants from the US National Institutes of Health (P01CA151135, R01CA100598, R01CA185623, P30CA016056, P30CA072720, K07CA201334, and R37CA248371), US Army Medical Research and Material Command (DAMD-17-01-1-0334), the Breast Cancer Research Foundation (CBA), and the Philip L. Hubbell family.

#3438 Associations between estimated endotoxin exposure and circulating immunological markers among male farmers.

S. C. Ezennia, L. E. Beane-Freeman, V. C. Chang, S. Xie, G. Andreotti, M. C. Friesen, J. N. Hofmann;
NIH-NCI, Bethesda, MD

Occupational exposure to endotoxin has been associated with reduced lung cancer risk. Farmers who perform certain tasks (e.g., raising hogs) can be highly exposed to endotoxin. The mechanisms through which endotoxin could confer a lower risk of lung cancer, while likely to be immune mediated, are not clear. To address this gap, we evaluated associations between estimated endotoxin exposure and circulating immunologic markers among male farmers in the Biomarkers of Exposure and Effect in Agriculture (BEEA) study. Our investigation included 122 non-smoking farmers from Iowa, oversampling those raising hogs (n=61). We evaluated 58 serologic markers, including some linked to lung cancer, that were measured using multiplex bead-based assays. Based on an algorithm linking personal air measurements in BEEA and published data to reported farming tasks, we estimated cumulative endotoxin exposure in the last 30 days and 12 months before sample collection. We used multivariable linear regression to estimate geometric mean ratios of immune markers across exposure quartiles, overall and by season of sample collection. Higher endotoxin exposure in the last 30 days was associated with increased levels of FGF-2, MIP-3A/CCL20, and sIL-4R ($P_{trend} \leq 0.02$), and with decreased levels of MDC/CCL22 ($P_{trend} = 0.02$). In analyses stratified by season, the positive associations with FGF-2 and MIP-3A/CCL20 were most apparent in the winter ($P_{trend} = 0.002$ and 0.03, respectively); we also observed an inverse association with sCD27 levels in the summer ($P_{trend} = 0.03$). Similar patterns were observed for endotoxin exposure in the last 12 months. This study is the first to use novel algorithm-based endotoxin exposure estimates to evaluate associations with intermediate lung cancer-related markers. Several markers were associated with endotoxin levels in an exposure-response manner. Our findings suggest possible biological mechanisms through which endotoxin may reduce risk of lung cancer.

Table 1. Associations between estimated endotoxin exposure in the last 30 days and selected serum im

#3439 Factors affecting the performance of existing epigenetic clocks to predict chronological age in colorectal tumor and normal tissues.

C. L. Benson II[1], F. Moratalla-Navarro[2], A. Diez-Villanueva[2], M. A. Devall[3], V. Moreno[2], S. L. Schmit[4], F. R. Schumacher[1];
[1]Case Western Reserve University, Cleveland, OH, [2]Catalan Institute of Oncology (ICO), Barcelona, Spain, [3]University of Virginia, Charlottesville, VA, [4]Cleveland Clinic, Cleveland, OH

Epigenetic age (EA) may serve as a risk stratification biomarker for early-onset colorectal cancer (EOCRC, <50 years old), which has been rising substantially in recent decades. We utilized publicly available data in a descriptive analysis to compare epigenetic clocks in colorectal tissue and to investigate differences between chronological age (CA) and biological age, as measured by EA, in relation to demographic and clinical features. We analyzed DNA methylation (DNAm) array data on 144 participants (96 CRC cases, 48 healthy controls) from the Colonomics Study (CLX; Barcelona, Spain) and 331 CRC cases (51 EOCRC, 316 average-onset (≥50) colorectal cancer (AOCRC)) from The Cancer Genome Atlas (TCGA) as well as corresponding demographic and clinical variables. Among CLX participants, the 96 CRC cases provided colon tumor and paired normal mucosa samples, while the 48 controls provided healthy colon mucosa samples. TCGA included primary tumor samples from 331 cases with colon or rectal adenocarcinoma (TCGA-COADREAD). The 2013 Horvath clock estimated EA based on CA, while epiTOC, estimated the relative stem cell division rate from tissue biospecimens. We examined the correlations between CA and EA stratified by case/control status, sample type, sex, and age of onset (TCGA only). Tissue from CLX controls demonstrated a strong, positive correlation ($r>0.9$) between CA and EA for both the 2013 Horvath and epiTOC clocks. Using the Horvath clock, CA and EA correlations in normal mucosa and tumor tissue samples from CLX varied, with $r = 0.74$ and $r = 0.41$, respectively, and were weaker using the epiTOC clock, with $r = 0.26$ (normal) and $r = 0.10$ (tumor). When CLX cases were stratified by sex, the CA and EA (Horvath) correlations among female cases were $r = 0.80$ (normal) and $r = -0.12$ (tumor), while the correlations for males were stronger at $r = 0.58$ (normal) and $r = 0.31$ (tumor). This is in comparison to the epiTOC clock with females showing correlations of $r = -0.02$ (normal) and $r = 0.41$ (tumor), while males had $r = 0.06$ (normal) and $r = 0.11$ (tumor). In TCGA, correlations for EOCRC were $r = -0.20$ (Horvath) and $r = -0.08$ (epiTOC) and for AOCRC were $r = 0.29$ and 0.20, respectively. By sex, correlations for females with EOCRC for Horvath and epiTOC were $r = -0.09$ and $r = -0.07$, respectively, while correlations for males with EOCRC were $r = -0.02$ and $r = -0.08$, respectively. For TCGA cases with AOCRC, the correlations between CA and EA were $r = 0.35$ and $r = 0.22$ for females, and $r = 0.26$ and $r = 0.20$ for males, respectively for Horvath and epiTOC. This study revealed substantial variability in the ability of existing epigenetic clocks to accurately predict chronological age, with tissue type and sex strongly influencing the resulting correlations. Our findings highlight the importance of considering these factors when choosing an epigenetic clock.

#3440 Etiology of prostate cancer with the *TMPRSS2:ERG* fusion: A systematic review of risk factors.

Colleen B. McGrath[1], Alaina H. Shreves[2], Megan R. Shanahan[1], Hannah E. Guard[1], Manelisi V. Nhliziyo[1], Kathryn L. Penney[1], Tamara L. Lotan[3], Michelangelo Fiorentino[1], Konrad H. Stopsack[1], Lorelei A. Mucci[1]

[1]Harvard T.H. Chan School of Public Health, Boston, MA,[2]Division of Cancer Epidemiology and Genetics, National Cancer Institute, Bethesda, MD,[3]Johns Hopkins University School of Medicine, Baltimore, MD

Background: The *TMPRSS2:ERG* gene fusion is the most common somatic alteration in primary prostate cancer and an early event in carcinogenesis. There are emerging data highlighting etiologic differences in prostate cancer by *TMPRSS2:ERG* status. This systematic review synthesized evidence from epidemiologic studies on prostate cancer risk factors for tumors with and without the *TMPRSS2:ERG* fusion.

Methods: A systematic literature search was performed in Ovid MEDLINE, EMBASE, and Web of Science without language restriction for studies published by September 27, 2022. Studies that assessed associations between epidemiologic and genetic factors and prostate cancer risk by tumor *TMPRSS2:ERG* (ERG) fusion status in human populations were included.

Results: Of 3,071 records identified, 20 publications comprising prospective cohort and case-control studies from five study populations (published 2009-2022) were included. Risk factors included germline genetic variants, circulating hormones, diet, lifestyle factors, and medications. The included studies suggested that taller height and higher total and free circulating testosterone levels tended to be associated with higher risk of ERG-positive, but not ERG-negative prostate cancer. CAG repeat length in the androgen receptor (*AR*) gene, related inversely to transcriptional activity, appeared to be associated with a lower risk of ERG-positive, but not ERG-negative prostate cancer. There was statistical evidence for etiologic differences for several germline single nucleotide polymorphisms (SNPs) by ERG status. Excess body weight, greater vigorous physical activity, greater lycopene intake, and calcium channel blocker use appeared to specifically be associated with a lower risk of ERG-positive tumors. Associations of other potential etiologic factors, including diabetes mellitus, baldness, aspirin use, circulating antioxidant levels, and sex hormones other than testosterone, with ERG-positive prostate cancer were null or inconclusive. Most associations had low precision, and the results were based on few distinct study populations, highlighting a need for replication.

Conclusions: Prostate cancer with the *TMPRSS2:ERG* fusion may be an etiologically distinct subtype impacted by certain modifiable and hormonally-acting risk factors that align with the established mechanistic role of this gene fusion in androgen, insulin, and growth factor pathways. The findings suggest a potentially distinct genetic predisposition to prostate cancer with or without the *TMPRSS2:ERG* fusion. More broadly, these findings suggest that considering molecular subtypes of prostate cancer, beyond *TMPRSS2:ERG*, may strengthen etiologic understanding of prostate cancer and evidence for prevention.

#3441 Application of a maternal comorbidity index to predict childhood cancer risk: A population-based case-control study in Denmark.

T. Adenekan[1], J. E. Heck[1], C. Yin[1], J. Hansen[2];
[1]University of North Texas, Denton, TX, [2]Danish Cancer Institute, Copenhagen, Denmark

Background: Maternal health has been found to be an indicator of children's health and has also been found to affect the risk of childhood diseases. Children are especially susceptible to in-utero exposures. A mother's health conditions before and during pregnancy could have important consequences for her child's health, including cancer development, as was observed in some prior studies.
Objectives: This study aimed to identify the impact of varying maternal comorbidities on the development of childhood cancers. This study applied an Obstetric Comorbidity Index (Bateman et al, 2013) to examine maternal comorbid conditions in childhood cancer risk.
Methods: Using maternal and birth records, and cancer records from the Danish Cancer Registry, we conducted a population-based case-control study with two population groups- the first population included cases (n=2578) and controls (n=64450) with ICD-10 diagnoses from 1994-2013, and the second population included cases (n=8339) and controls (n=208475) with ICD-8 and 10 diagnoses from 1977-2013. Maternal comorbidities were ascertained from the National Patient Register using the Obstetric Comorbidity Index. We estimated the risk of childhood cancer using conditional logistic regression.
Results: Multiple gestation pregnancy (OR=1.17, 95% CI 1.05, 1.30), maternal pre-existing diabetes (OR=1.68, 95% CI 1.14, 2.48), congenital heart disease (OR=2.62, 95% CI 1.13, 6.09) and previous cesarean delivery (OR=1.35, 95% CI 1.03, 1.75) showed an increased risk of childhood cancers (all types combined). Children born to mothers between the ages of 35 and 39 also had a higher risk of cancer as compared to those born before. In the 1977-2013 population, there was an increased risk of acute lymphocytic leukemia (ALL; OR=1.08, 95% CI 1.04, 1.13) and rhabdomyosarcoma (OR=1.13, 95% CI 1.01, 1.27) for each unit of increase on the Obstetric Comorbidity Index. There was also an increased risk of retinoblastoma (OR=1.16, 95% CI 1.01, 1.32) for each unit of increase on the maternal comorbidities index in the 1994-2013 population. Examining mothers that had a score of one or more in the Obstetric Comorbidity Index, there was a higher risk of ALL (OR=1.43, 95% CI 1.26, 1.62), non-Hodgkin lymphoma (OR=1.50, 95% CI 1.17, 1.91), Burkitt lymphoma (OR=1.71, 95% CI 1.12, 2.61), and rhabdomyosarcoma (OR=1.58, 95% CI 1.10, 2.26) for children whose mothers with at least one maternal comorbidity. A similar trend was observed in the 1994-2013 population for ALL, non-Hodgkin lymphoma, and Burkitt lymphoma.
Conclusion: The results of the study show varying effects of exposure to one or more maternal comorbidities on individual pediatric cancer types, and an overall increased risk of most cancers development in children with exposure of mothers to 1 or more maternal comorbidities.

#3442 Factors modifying the association between hormonal contraception and risk of early-onset breast cancer.

L. R. Teras[1], E. L. Deubler[1], M. E. Sherman[2], C. Bodelon[1], L. E. McCullough[1], J. M. Hodge[1], S. Chantaprasopsuk[1], A. V. Patel[1];
[1]American Cancer Society, Atlanta, GA, [2]Mayo Clinic College of Medicine and Science, Jacksonville, FL

Breast cancer rates among women younger than 50 years-old have been steadily increasing since the mid-1990s. There is consistent evidence that use of combination estrogen and progesterone oral contraceptives (OCs)—including contemporary formulations with lower estrogen—increases breast cancer risk. It is unclear, however, if this risk varies by factors such as progestin type in the OC formulation, timing of OC use, histopathologic characteristics of the breast cancer, or individual patient characteristics. This study included premenopausal women aged <50 years and cancer-free when they enrolled in the U.S.-based American Cancer Society Cancer Prevention Study-3 cohort between 2006 and 2013 (n=101,838 women). At enrollment participants responded to a detailed life history questionnaire including questions about type, brand, duration, and recency of OC use. Incident breast cancers diagnosed between 2006-2018 were identified through cancer registry linkages (n=759). Participants were followed until the first of 1) breast cancer diagnosis, 2) age >50 years, or 3) December 31, 2018. Multivariable hazard ratios (HRs) and 95% confidence intervals (CIs) were used to estimate associations between OC use and breast cancer risk. On average, participants were 39.3 years at baseline and were followed for 5.7 years (up to 12.3 years). Current versus never use of OCs for 10+ years was associated with a higher risk of breast cancer (10-<20 years: HR=1.46, 95% CI: 1.03-2.07; 20-<30 years: HR=1.66, 95% CI: 1.14-2.41; 30+ years HR= 2.51, 95% CI: 0.77-8.16). Cessation of OC use progressively attenuated the association down to the null 15 years after discontinuation of use (HR=1.04, 95% CI: 0.73-1.49). Associations with current OC use varied by generation of progestin in the formulation (first generation: HR=1.37, 95% CI: 0.93-2.02; second: HR=1.79, 95% CI: 1.20-2.67; third: HR=1.65, 95% CI: 1.13-2.42; fourth: HR= 0.91, 95% CI: 0.49-1.67). The strongest associations were observed for use of formulations with norgestrel: HR=2.82, 95% CI: 1.54-5.19; norgestimate: HR=1.80, 95% CI: 1.19-2.72; and levonorgestrel: HR=1.56, 95% CI: 1.00-2.43. The OC-breast cancer associations were primarily limited to localized, grade 1 or 2, and ER+ disease. Race, income, body mass index, physical activity, alcohol use, cigarette smoking, parity, and breastfeeding did not appear to modify the associations. There were also no clear differences in the associations based on age at first or last OC use or timing relative to pregnancy. Current, long-term OC use was associated with increased risk of early-onset breast cancer. These data suggest that risks may vary with progestin content, and future studies are needed to define formulations that minimize breast cancer risk while still maximizing protection against other female cancers.

POPULATION SCIENCES: Risk Prediction Modeling, Screening, Early Detection, and Preneoplastic and Tumor Markers
Poster Session

#3446 Associations of non-steroidal anti-inflammatory drug use and circulating inflammatory proteins with gallbladder dysplasia.

L. Rosa[1], P. Cook[2], R. M. Pfeiffer[3], T. J. Kemp[4], A. Hildesheim[3], B. Pehlivanoglu[5], V. Adsay[6], E. Bellolio[7], J. Araya[8], L. Pinto[4], C. Ferreccio[1], G. Aguayo[9], E. Vinuela[10], J. Koshiol[3];

[1]Advanced Center for Chronic Diseases (ACCDiS), Pontificia Universidad Catolica de Chile, Santiago de Chile, Chile, [2]University of North Carolina, Chapel Hill, NC, [3]National Cancer Institute, Rockville, MD, [4]National Cancer Institute, Frederick, MD, [5]Dokuz Eylul University, Izmir, Turkey, [6]University School of Medicine and Koc, University Research Center for Translational Medicine, Istanbul, Turkey, [7]Universidad de La Frontera, Temuco, Chile, [8]Universidad de La Frontera & Hospital Dr. Hernan Henriquez Aravena, Temuco, Chile, [9]Pontificia Universidad Catolica de Chile & Hospital Sotero del Rio, Santiago de Chile, Chile, [10]Pontificia Universidad Catolica de Chile & UDA Hospital Sotero del Rio, Santiago de Chile, Chile

Background: Most gallbladder cancer (GBC) cases arise from the metaplasia-dysplasia-GBC sequence, and chronic inflammation has been associated with its development. The use of non-steroidal anti-inflammatory drugs (NSAIDs) has been associated with reduced risk of GBC; however, little is known about these associations with preneoplastic lesions. We thus aimed to study the associations of the use of NSAIDs and inflammatory proteins with gallbladder dysplasia, a precursor to GBC.

Methods: Associations of NSAIDs and gallbladder dysplasia were evaluated in 1,925 Chilean cholecystectomy patients, 82 with dysplasia and 1,843 with gallstones but not dysplasia. In addition, we measured 33 circulating inflammatory proteins in a subsample of 68 dysplasia cases diagnosed at the time of sample selection and 136 gallstone controls. Age- and sex-adjusted odds ratios (ORs) and 95% confidence intervals (95% CIs) were calculated, and associations of inflammatory proteins and gallbladder dysplasia were analyzed.

Results: NSAID use was inversely associated with gallbladder dysplasia (OR: 0.48, 95% CI: 0.26-0.83). Comparing the highest versus lowest category of each immune-related protein, eight proteins were inversely associated with dysplasia with ORs ranging from 0.30 (95%CI: 0.12-0.77) for IL-33 to 0.76 (95%CI: 0.59-0.99) for MIP-1B. Of those, GRO remained associated with dysplasia (OR: 0.64, 95%CI: 0.45-0.91) and BCA-1 was borderline-associated (OR: 0.74, 95%CI: 0.54-1.01) in the multivariable logistic regression model additionally adjusted for sex, age and NSAID use.

Conclusion: NSAID users were less likely to have gallbladder dysplasia, suggesting that NSAIDs might be beneficial for gallstones patients. Prospective studies are needed to understand the inverse association of immune-related markers and dysplasia, and to evaluate the biological effect of NSAIDs in GBC.

#3447 Potential for reduction in invasive cancer incidence by interception of preneoplastic lesions.

P. Pradhan[1], I. Ghobrial[2], C. Marinac[2], B. O'Donnell[2], S. Syngal[2], T. Rebbeck[1];
[1]Harvard T.H. Chan School of Public Health, Boston, MA, [2]Dana-Farber Cancer Institute, Boston, MA

Background: Preneoplastic lesions (PNL) are morphologically identifiable lesions lack the ability to invade surrounding tissue but can progress to invasive cancer. Thus, PNL present an opportunity to identify individuals at elevated cancer risk and identify opportunities for early detection and interception of cancer.
Objective: We used published data sources to estimate the impact of intercepting progression of PNL to invasive cancer across multiple anatomic sites. We estimated the hypothetical number of cancers that could be avoided in the United States population if interception was successful in preventing a percentage of individuals with PNL from progressing to invasive cancer.
Methods: Estimates of prevalence, latency, and probability of percent progression of PNL to invasive cancer were obtained from literature. We considered PNL associated with invasive tumors of the breast, bladder, cervix, colorectum, esophagus, liver, lung, oropharynx, pancreas, prostate, skin (melanocytes), skin (squamous cells), and stomach as well as precursors to leukemia and myeloma. We modeled a cohort of 100,000 individuals from which we estimated the number of cases that could be avoided if interception of a PNL before it progressed to an invasive cancer case was successful. Results were stratified for race and sex; positive- and negative-predictive values were calculated.
Results: For PNL with a higher prevalence and percent progression per year, there were more invasive cancers that could be avoided if interception was successful. Detection of PNL associated with pancreas, stomach, oral, and prostate cancers had the greatest potential to avoid invasive cancers in the US population. For example, if 95% of pancreatic intraepithelial neoplasia lesions were detected, 15% progressed to pancreas cancer, and assuming a 43% prevalence over a 5-year latency period, 1,226 potential invasive pancreatic cancer cases could be avoided per year. Similarly, 998 potential invasive stomach cancer cases could be avoided earlier if 95% of gastric intestinal metaplasia lesions were detected assuming 42% progressed to invasive cancer with a 19% prevalence and a 4-year latency period. Additionally, if we could intercept 5% to 95% of all PNL from becoming invasive cancer, we would avoid between 176 to 8,515 number of invasive cases being diagnosed. When stratified by race, symptomatic multiple myeloma can be avoided in individuals with monoclonal gammopathies of undetermined significance if this condition is detected earlier among Black individuals.
Conclusion: By detecting PNL and preventing them from advancing to invasive cancer, we can avoid substantial mortality as well as the costs and morbidities associated with treating more advanced cancers.

#3448 A novel liquid biopsy lung cancer detection method using a coverage and fragment end motif machine learning analysis.

B. Leatham, M. Salmans, M. Smith, M. Wang, A. Carson, K. Fathe, B. Lee;
Genece Health, Inc., San Diego, CA

Lung cancer remains the leading cause of cancer death in the United States. One reason for this high mortality is that >40% of cases are diagnosed at a late stage, where the 5-year survival rate is low. Liquid biopsy molecular testing has transformed lung cancer care through the identification of driver mutations when tissue is inaccessible. It also has promise as a tool in early detection and diagnosis, thereby reducing mortality. The existing paradigm for lung cancer screening and diagnosis includes low dose CT (LDCT) scans and tissue biopsy. LDCT scans yield a visualization of lung abnormalities. However, many of these abnormalities are difficult to characterize and next steps are often unclear to physicians. One option is to continue to monitor the patient, which may risk a delay in cancer treatment. Up to 15% of all individuals who are put on a monitoring regime will ultimately be diagnosed with lung cancer. A second option is to biopsy the nodule, which risks unnecessary invasive procedures and expenses to patients. 42-62% of indeterminate nodules detected by LDCT are found to be benign after biopsy. Furthermore, 15% of transthoracic needle biopsies result in complications. Genece Health aims to decrease uncertainty in cancer diagnosis and improve patient outcomes through a minimally invasive liquid biopsy assay that detects the presence of lung cancer. The technology utilizes a proprietary algorithm that leverages machine learning models to detect lung cancer signals in low-pass whole genome sequencing (LP-WGS) of patient cfDNA isolated from plasma. To establish assay performance, 50 clinical lung cancer samples from a commercial biobank, and 100 presumed normal samples were collected in Streck cfDNA BCT Devices. Following cfDNA extraction from plasma, LP-WGS was performed. Sequencing data was then processed to generate fragment end-motif and size (FEMS) and fragment coverage data that was input into Genece Health's proprietary machine learning classifier to generate a final cancer prediction score. In addition, a limit of detection was determined using three late-stage lung cancer samples, with tumor fractions estimated using whole exome sequencing and ichorCNA scores. Our results show >80% specificity, >90% sensitivity, and a limit of detection of <1% tumor fraction. Through this testing, we demonstrate the assay's ability to detect lung cancer across various lung cancer stages, including early stage disease, and histologies. Genece has developed a highly sensitive and specific lung cancer detection liquid biopsy assay. We present this assay as a cost-effective approach to discriminate between benign and malignant nodules identified by LDCT. In addition, this assay has the potential to be applied across the cancer care continuum. For example, future work will involve characterizing the assay's ability to be applied in early cancer screening.

#3449 Is AI-enhanced breast ultrasound ready for breast cancer screening in low-resource environments? A systematic review.

A. Bunnell[1], D. Valdez[1], F. Strand[2], Y. Glaser[3], P. Sadowski[3], J. A. Shepherd[1];
[1]University of Hawai'i Cancer Center, Honolulu, HI, [2]Karolinska University Hospital, Solna, Sweden, [3]University of Hawai'i at Manoa, Honolulu, HI

Purpose. Screening mammography is unavailable in many low-resource areas. We ask if the state-of-the-art in artificial intelligence (AI)-enhanced breast ultrasound (BUS) is sufficiently accurate to be used for primary breast cancer screening in low-resource regions.
Background. Since the 1980s, high-income countries have implemented mammographic screening programs, leading to breast cancer mortality reduction in screened women.[1] Mammography is unavailable in many low-resource regions, such as the USAPI. Furthermore, travel difficulties and lack of radiologists hinder implementation. AI combined with portable BUS may address limitations of the high-income paradigm. In this systematic review, we ask if AI-enhanced BUS can detect/segment lesions (Objective 1) and classify lesions as cancerous (Objective 2).
Methods. Two reviewers independently assessed articles from 1/1/2016 to 8/6/2023 from PubMed, Google Scholar, and citation searching. Studies which report on AI development and report performance on a patient-wise, held-out test set met the inclusion criteria. Studies were characterized by AI task and clinical application time. Dataset composition and performance were examined via narrative data synthesis. QUADAS-2 bias assessment was performed using criteria for each AI task. Success in (2) is defined by meeting minimum screening performance guidelines.[2,3]
Results. PubMed yielded 281 studies, Google Scholar yielded 225 studies, and a manual citation search yielded 41 studies. From 382 unique full texts evaluated, 52 articles met all inclusion criteria: 3 frame selection, 2 real-time detection, 2 combination, 14 segmentation-only, and 31 classification-only. Lesion segmentation-only models achieved a 90th percentile Dice similarity coefficient of 0.913 on generally small datasets. The best evidence for lesion cancer classification reported 0.976 area under the curve. All studies faced elevated bias and applicability concerns under QUADAS-2.
Conclusion. Reported performance for (1) is insufficient to introduce AI-enhanced BUS for breast cancer screening. Evidence supporting AI-enhanced BUS for (2) is dependent on few studies relying on internal datasets, limiting generalizability. Geographically diverse clinical trials are needed to confirm and improve robustness of performance of AI-enhanced BUS for (1) and (2).

#3451 Association of multi-level factors with cervical cancer screening in healthcare settings.

R. Rathod[1], E. Hu[1], S. Pruitt[1], J. A. Tiro[2], J. Chubak[3], J. Haas[4], S. J. Atlas[4], G. Kruse[5], A. E. Hughes[1];
[1]UT Southwestern Medical Center, Dallas, TX, [2]The University of Chicago, Chicago, IL, [3]Kaiser Permanente Washington, Seattle, WA, [4]Massachusetts General Hospital, Boston, MA, [5]University of Colorado School of Medicine, Aurora, CO

Background- Few studies have examined the independent contribution of patient, clinician and system factors associated with completing cervical cancer screening.

Methods- Using a large retrospective cohort created from electronic health record data, we examined the association of patient- and provider-level characteristics with cervical cancer screening among unknown- and average-risk, screen eligible women who entered the cohort at a primary care visit in 1 of 3 U.S. healthcare systems (Kaiser Permanente Washington, Parkland Health, Mass General Brigham) between 2010-2019. The outcome was time, in days, from cohort entry to screening. We fit piecewise exponential (PWE) survival models, nesting patients hierarchically within provider seen and the facility at the time of their analytic cohort entry visit. We excluded patients whose visit was with providers at their non-principal facility (principal defined as the facility that they saw most patients in 2010). The analysis was stratified by healthcare setting.

Results- Median time from cohort entry until screening varied across settings (202-1063 days) and across providers and clinics (between cluster variance= 0.11-0.77, 0.06-1.18, respectively). Many patient-level characteristics (age, cohort entry year, race/ethnicity, number of comorbidities, smoking status, primary care visit within 12 months before cohort entry, and insurance), some of the provider-level characteristics (provider specialty and sex) and social determinants of health measures (Local Isolation Score Hispanic) were associated with time to screening. In the adjusted PWE models, for all three settings: a) Younger patients (21-49 years old) (vs older patients (50-65 years)); b) Hispanic and Non-Hispanic Asian/Pacific Islander (vs Non-Hispanic White); and c) patients seeing ob-gyn providers (vs family medicine providers) had shorter time to screening. Patients with a) higher (vs lower) comorbidity burden, and b) Medicare insurance (vs Commercial) were less likely to receive screened.

Conclusion- By identifying characteristics at multiple levels that are associated with the outcome, our results help us identify targets for interventions to improve and increase timely cervical cancer screening in healthcare settings.

#3452 Senescence-associated secretory phenotype (SASP) aging index is associated with cancer risk in the Atherosclerosis Risk in Communities (ARIC) Study.

S. Wang[1], Z. Rao[1], A. H. Blaes[1], J. Coresh[2], C. E. Joshu[2], J. S. Pankow[1], B. Thyagarajan[1], P. Ganz[3], E. A. Platz[2], W. Guan[1], A. Prizment[1];
[1]University of Minnesota, Minneapolis, MN, [2]Johns Hopkins University, Baltimore, MD, [3]University of California, San Francisco, San Francisco, CA

Background: The accumulation of senescent cells, which release SASP proteins damaging neighboring cells, contributes to aging and age-related diseases, such as cancer. Therefore, SASP proteins could be used as biomarkers for individuals' aging process, but no studies have tested if SASP protein-based aging index is associated with cancer risk. We created a SASP-aging index based on the 72 SASP proteins reported in Tanaka et al. [2018] and examined its association with cancer risk in the ARIC study.
Methods: ARIC is an ongoing cohort of White and Black females and males initiated in 1987, followed for cancer until 2015 (median follow-up=17.3 yrs). At Visit 2 (1990-92), 5000 plasma proteins were measured using SomaScan -- an aptamer-based assay in 10,834 participants (aged 46-70 yrs, 55% female, 76% White): 3,347 participants developed cancer during follow-up and 7,487 participants stayed cancer-free. In the training set of 67% randomly selected cancer-free participants, we constructed the SASP-aging index by applying Ridge regression to train the 72 SASP proteins against chronological age. The SASP-aging index was validated in the remaining 33% of cancer-free participants (test set). We calculated age acceleration as residuals after regressing the SASP-aging index on age in participants after excluding the training set. We used Cox proportional hazards regression to estimate hazard ratio (HR) and 95% confidence intervals (CI) for the risk of any type of cancer per 5 years increase in age acceleration, employing Barlow's method [1994] to account for the exclusion of the training set. HR was adjusted for age, sex, race, center, education, BMI, smoking status, alcohol intake, aspirin use, diabetes, and eGFR. We also estimated HRs for obesity-related, smoking-related, and the most common cancers (breast, prostate, colorectal, and lung).
Results: In the test set, Pearson correlation coefficient between the SASP-aging index and age was 0.50. Age acceleration was significantly associated with the risk of any type of cancer [HR (95% CI) per 5 years=1.21 (1.08-1.36)]. There was a suggestion of a higher HR for any type of cancer in females [1.26 (1.07-1.48)] than males [1.18 (1.00-1.39)] [p-interaction=0.08], but HRs were similar across race and smoking status [p-interaction>0.50]. Age acceleration was significantly associated with the risk of obesity-related cancers [1.36 (1.20-1.54)]. A significant association was also found with smoking-related cancers [1.43 (1.24-1.65)] and this association remained significant even among never smokers [1.39 (1.07- 1.82)]. Age acceleration was also significantly associated with colorectal [1.34 (1.03-1.75)] and lung cancer risk [1.63 (1.31-2.02)] but not with breast or prostate cancer risk.
Conclusion: SASP protein-based aging index shows promise as a potential biomarker for cancer risk.

#3453 U.S. Geographic and socio-demographic characteristics of Voyage Study participants.

A. M. Berry, J. A. Grimm, C. R. Kirt, E. J. Kirsch, R. E. Dixon, W. Z. Fan, K. A. Bohn, J. St. Sauver, K. J. Yost, L. J. Finney Rutten, J. E. Olson;
Mayo Clinic, Rochester, MN

The Voyage Study is a large-scale, prospective cohort study of long-term health outcomes among participants with a valid multi-target stool DNA (mt-sDNA) test order. Recently, the Voyage Study achieved its enrollment target of 150,000 participants. The intent of this descriptive analysis is to provide baseline geographic and socio-demographic characteristics of Voyage Study participants to set the stage for future comparisons to the broader mt-sDNA user population.
Participants were randomly selected from all persons in the U.S. or Puerto Rico who had a valid order for mt-sDNA screening during the enrollment period (10/18/2019 - 10/17/2023). Enrolled participants completed a baseline questionnaire that collected socio-demographic and health information. Participant characteristics and baseline survey answers were compared between regions using chi-square tests where appropriate. Regional geographic data was aggregated for the broader mt-sDNA user population during the enrollment period, though no formal comparisons were made between the broader population and the Voyage population at this time.
Analyses were limited to 139,369 participants with available baseline questionnaire data. Voyage participants were more likely to reside in the Midwest, Northeast, or Southeast (29.9%, 22.5%, 22.6% respectively) and less likely to reside in the Southwest and West (11.6%, 13.4%). During the enrollment period, differential participation was also observed in the mt-sDNA user population, with the Midwest, Northeast, and Southeast having the greatest proportion (25.4%, 22.2%, 26.7%) and the Southwest and West having the lowest proportion of mt-sDNA users (13.8%, 11.9%). In the Voyage cohort, Midwest participants reported the lowest education attainment as characterized by years of school completed (14.1% high school or below, 59.2% college or greater), while participants in the West reported the highest education attainment (7.9% high school or below, 67.3% college or greater). The West also had the highest percentage of participants reporting an income of $100,000 or greater (51.6%), with the Southeast being the lowest (42.2%), as compared to the other regions.
We report here early results of geographic and socio-demographic characteristics from a new research resource that will enable future analyses of health outcomes and behaviors in a population of mt-sDNA users. We observed that the greatest percentage of Voyage participants resided in the Midwest, Northeast, or Southeast, and that there was differential socio-demographic participant characteristics based on region. Future analyses will compare long-term healthcare outcomes and differences in colorectal cancer incidence and mortality between the broader mt-sDNA user population and the Voyage cohort.

#3454 Cell-free DNA methylation and fragmentomic signatures identify tissue damage and predict cancer risk.

N. Cheng[1], K. Skead[2], T. Oullette[1], S. Bratman[3], D. De Carvalho[3], D. Soave[4], P. Awadalla[1];
[1]Ontario Institute for Cancer Research, Toronto, ON, Canada, [2]Regeneron Genetics Center, New York City, NY, [3]Princess Margaret Cancer Centre, Toronto, ON, Canada, [4]Wilfrid Laurier University, Toronto, ON, Canada

Cell-free DNA (cfDNA) epigenetic and fragmentomic profiling has emerged as prominent non-invasive approaches for early cancer detection and subtyping. However, owing to difficulties in observing the early development of human malignancies, most cancer biomarker and evolution studies to date have primarily examined biologics following a diagnosis. Utilizing cfDNA as a screening tool for early disease detection requires assessment of blood plasma samples collected from asymptomatic individuals prior to the diagnosis of cancers. Here, we leverage the Ontario Health Study (OHS), a prospective longitudinal population cohort, to assess cfDNA profiles in blood plasma collected from participants that developed breast (n=476), prostate (n=342) and pancreatic (n=32) cancers throughout the study follow up time between 2009 and 2019. We performed cell-free methylated DNA immunoprecipitation and high-throughput sequencing (cfMeDIP-seq) on baseline plasma samples from incident cancer cases up to eight years prior to diagnosis, in addition to matched controls (n=404) with no history of cancer through follow-up. Genome-wide plasma cfDNA differential methylation analysis revealed significantly hypermethylated regions, particularly among CpG island and shore regions, were predictive of early breast cancers, and overlapped hypermethylated regions in solid cancer tissues relative to adjacent normal tissues and peripheral blood leukocytes. Using a repeated cross-validation strategy we found that as few as 200 hypermethylated regions can identify individuals with breast cancer in blood up to seven years prior to diagnosis among discovery set samples (AUC=0.725) and are highly generalizable to samples processed in separate batches (AUC = 0.650). Remarkably, integrating biomarker hypermethylated regions with fragmentomic features including fragment length and 5' tetranucleotide motif proportions further increased accuracy for detecting individuals with early prostate cancers (AUC=0.804). In addition, we observed shared genome-wide cfDNA methylome changes associated with aging and heavy alcohol consumption in cfDNA. We identified increased shedding of tissue-specific methylation markers from liver and pancreatic tissue among individuals consuming more than three drinks a week relative to non-drinkers, reflective of potential signatures of tissue damage.

#3455 Prevalence of monoclonal gammopathy of undetermined significance (MGUS) in a Western Nigerian population.

C. M. Vachon[1], C. Allmer[1], D. Moonen[1], A. Norman[1], J. Cook[1], S. Slager[1], O. A. Rotimi[2], O. C. De Campos[2], T. M. Dokumu[2], D. Murray[1], S. Kumar[1], E. Brown[3], L. B. Baughn[1], **S. Rotimi**[2];

[1]Mayo Clinic, Rochester, MN, [2]Covenant University, Ota, Nigeria, [3]University of Alabama, Tuscaloosa, AL

Monoclonal gammopathy of undetermined significance (MGUS) is a premalignant condition characterized by plasma cell production of monoclonal (M) protein and is a requisite precursor to multiple myeloma (MM). African American (AA) individuals have a two-fold higher incidence of MGUS and MM compared to White individuals. However, data are limited on individuals from Africa, especially using sensitive MGUS detection methods. We examined the prevalence of MGUS in a sample of the general population in Nigeria. Individuals aged 40 and over (n=343) were recruited through health promotion events in Ado-Odo Ota Local Government Area of Ogun State, Nigeria, and provided informed consent, a blood sample, and a short questionnaire. Serum was screened at Mayo Clinic for heavy chain (HC)-MGUS using the matrix-assisted laser desorption/ionization-time of flight (Mass-Fix) assay, which has high sensitivity for detection of M-proteins; serum free light chains (FLC) were also measured. FLC was abnormal if the kappa (>0.26 mg/dL) or lambda (>0.33 mg/dL) light chain (LC) was elevated and FLC ratio (kappa/lambda) was outside the reference range (0.26-3.10). LC-MGUS was defined as an abnormal FLC in the absence of a HC. Age- and sex-adjusted prevalence rates were directly standardized to 2010 United States (US) population for comparison to published studies. Logistic regression was used to examine the association of age, sex, and BMI with HC-MGUS. The mean age of participants was 55 years (SD=10.9), and 74.6% were female. Of these, 216 (63%) had both parents from the Yoruba tribe, 89 (26%) from the Igbo tribe and 38 (11%) from other tribes. Overall, 33 participants (9.6%) had HC-MGUS, with 8 (2.3%) having an M-protein above 0.2 g/dL; 6 (1.7%) had LC-MGUS. HC-MGUS was predominantly IgG isotype (48.5%), followed by IgA (27.3%), biclonal (15.2%) and IgM (9.0%). Prevalence of HC-MGUS was 8.3% for ages 40-49, 7.7% ages 50-69 and 22% ages 70 and above. Standardized to the US population, age and sex adjusted MGUS prevalence ages 50 and older was 17.3% (95% CI: 9.8%-24.9%) and HC-MGUS was 14.7% (95% CI: 7.7%-21.8%), similar to previously published rates of HC-MGUS using Mass-Fix screening of AA individuals (16.5%, 95% CI: 12.2%-20.8%) (PMID: 35316833). In models that included age, sex and BMI, older age was positively associated with HC-MGUS (OR=3.1, 95% CI: 1.1-8.7 for ages 70+ compared to <50), while female sex (OR=0.53, 95% CI: 0.24-1.2) and overweight/obesity (OR=0.34, 95% CI: 0.16-0.75 for BMI > 25 vs. <25) were inversely associated with HC-MGUS. We observed similar prevalence of HC-MGUS at ages 50 and above among Western Nigerian and AA populations when screened using mass-spectrometry. Older age was positively associated with HC-MGUS while overweight and obesity were inversely associated. Studies of MGUS in indigenous African populations may provide insight to unique cancer risk factors compared to other populations.

#3456 The role of particulate matter exposure in racial differences in colorectal cancer mortality in metropolitan Detroit.

Natalie Gail Snider[1], R. Blake Buchalter[2], Theresa Hastert[1], Gregory Dyson[1], Carina Gronlund[3], Elena M. Stoffel[4], Ed Peters[5], Laura Rozek[6], Ann Schwartz[1], Kristen Purrington[1]

[1]Oncology, Wayne State University School of Medicine, Detroit, MI,[2]Case Comprehensive Cancer Center, Cleveland, OH,[3]Epidemiology, University of Michigan, Ann Arbor, MI,[4]Internal Medicine, University of Michigan Health System, Ann Arbor, MI,[5]Epidemiology, University of Nebraska Medical Center, Omaha, NE,[6]Oncology, Georgetown University School of Medicine, Washington, DC

Colorectal cancer (CRC) is the third most diagnosed cancer in the United States and the third leading cause of cancer-related deaths. Non-Hispanic Black (NHB) individuals have the highest rates of CRC incidence and mortality in the United States. These disparities are highly influenced by social determinants of health (SDOH). Neighborhood quality, a well-established SDOH, has been shown to influence cancer outcomes, oftentimes more heavily in minorities. Additionally, neighborhood quality is known to influence an individual's risk of exposure to harmful environmental contaminants including ambient air pollution as a result of systemic racism such as segregation and historic redlining, leading to environmental injustices. Fine particulate matter (PM2.5) exposure has been shown to increase the risk of CRC mortality, however, its effects by race have not yet been examined. We sought to understand whether higher rates of exposure to PM2.5 played a role in racial differences in CRC survival in metropolitan Detroit. Patient data including census tract at diagnosis, demographics, and clinical features were obtained from the metropolitan Detroit cancer surveillance system registry. Ambient PM2.5 concentration data at the census tract were obtained from the Environmental Protection Agency (EPA) Remote Sensing Information Gateway (RSIG) and converted to annual averages to use in an interval-censored Cox proportional hazards regression model. We found that PM2.5 exposure partly attenuated the effect of race on overall mortality in all patients (NHB vs NHW: Hazard Ratio (HR) = 1.24, 95% Confidence Interval (CI) 1.20 - 1.27, $p < 0.0001$, NHB vs NHW after accounting for PM2.5: HR = 1.19, 95% CI = 1.16 - 1.23 $p < 0.0001$) and the effect was stronger among patients under 50 than over 50, though still significant in both models. Additionally, the effect of PM2.5 on mortality was much stronger among NHB patients than NHW patients (NHB HR = 1.30, 95% CI = 1.17 - 1.45, $p < 0.0001$; NHW HR = 1.06, 95% CI = 1.02 - 1.11 $p = 0.008$) and especially strong among NHB patients under 50 (HR = 2.51, 95% CI = 2.38 - 3.38, $p < 0.0001$) compared to any other group. We conclude that ambient air pollution, particularly PM2.5, disproportionately affects mortality risk in NHB CRC patients. These results highlight the importance of environmental justice research in biomedical research, and the need for a better understanding of environmental impact on tumor biology to prevent tumor progression and mortality among all patients.

#3457 Distinct signatures of tumor-associated macrophage subpopulations predict survival in renal cell carcinoma.

Youngsoo Han[1], Aidan Shen[2], Zhaohui Wang[2], Aliesha Garrett[2], **Chongming Jiang**[2]

[1]Bioengineering Department, University of California, Los Angeles, Los Angeles, CA, [2]Terasaki Institute for Biomedical Innovation, Los Angeles, CA

Background: Comprising 90% of renal cancer cases in adults, renal cell carcinoma (RCC) is marked by significant heterogeneity in its tumor microenvironment. This study aims to test the hypothesis that tumor-associated macrophages (TAMs) play a role in modulating RCC progression and patient response to treatment. We explored the prognostic implications of TAM signatures on RCC survival, leveraging immunomics to decipher TAM-related alterations in the tumor microenvironment.

Methods: Utilizing independent single-cell RNA-seq data from human RCC samples, we crafted 8 distinct RCC TAM signatures reflective of TAM presence. A LASSO Cox regression model was developed to prognosticate survival, tested against the TCGA dataset and independently validated across multiple RCC cohorts. Model performance was corroborated through Kaplan-Meier survival plots, receiver operating characteristic (ROC) curves, principal component analysis, and t-SNE analyses.

Results: We identified two TAM signatures that correlate positively with patient survival, indicative of the abundance of specific subsets of TAMs in RCC. These signatures showed a strong association of specific TAM markers and macrophage infiltration. Survival analysis demonstrated that specific TAM signature gene expressions are significant prognostic markers. Forest plots underscored their prognostic relevance. A 32-gene risk score model was established, successfully stratifying patients into distinct risk categories, with low-risk patients exhibiting markedly improved overall survival.

Conclusions: The study underscores the positive association between abundance of specific TAM subsets of and RCC patient survival. The precision of our LASSO Cox regression model, informed by novel abundance markers of specific TAM subsets, advances our understanding of TAM roles in TIME and RCC progression. These TAM signatures could potentially provide additional insights and targets to enhance the efficacy of RCC treatments.

Keywords: Tumor associated macrophage, renal cell carcinoma, prognosis, tumor microenvironment, immunomics.

#3458 DNA methylation-predicted blood protein levels and breast cancer risk.

J. K. Kresovich[1], **B. Reid**[1], D. A. Byrd[1], K. M. O'Brien[2], Z. Xu[2], C. R. Weinberg[2], D. P. Sandler[2], J. A. Taylor[2];
[1]H. Lee Moffitt Cancer Center, Tampa, FL, [2]National Institute of Environmental Health Sciences, Durham, NC

Background: Blood DNA methylation (DNAm) profiles can be used to predict a variety of human physiologic traits that are associated with breast cancer incidence and plasma concentrations of over 100 proteins, including those involved in inflammation, coagulation, metabolism, and growth. DNAm predictions of circulating proteins, here referred to as "DNAm proteins," may be useful in providing molecular insights into breast cancer etiology and could be a valuable resource for personalizing breast cancer risk prediction.
Methods: The Sister Study is a nationwide, prospective cohort of 50,884 women with a family history of breast cancer designed to identify novel environmental and biological risk factors for breast cancer. Epigenome-wide DNAm data were previously generated using the HumanMethylation450 or MethylationEPIC arrays on baseline blood samples collected from two case-cohort samples, for a combined sample of 4,479 women. This sample included 2,151 (48%) women who were selected because they were diagnosed with breast cancer (1,673 invasive cancer and 478 ductal carcinomas *in situ*) in the 15 years (mean: 7.9 years) following blood draw. Blood levels of 109 DNAm proteins were estimated from DNAm profiles using the method developed by Gadd et al. (eLife, 2022). Weighted Cox regression models were used to estimate associations between these DNAm proteins and incident breast cancer; associations were considered statistically significant at a False Discovery Rate (q) ≤ 0.10.
Results: In age and platform adjusted models, higher breast cancer rates were associated with higher DNAm-predicted blood concentrations of RARRES2, IGFBP4, and CCL21 and lower predicted concentrations of F7, SELL, CXCL9, CD48, and IL19. The strongest associations were observed for RARRES2 (per 1-SD increase, HR: 1.24, 95% CI: 1.10, 1.40, P= 6×10^{-4}, q= 0.03) and F7 (per 1-SD increase, HR: 0.82, 95% CI: 0.74, 0.91, P= 3×10^{-4}, q= 0.03). Estimates were similar after adjustment for known breast cancer risk factors and excluding those diagnosed within two years of their blood draw. Associations appeared stronger for invasive breast cancer.
Conclusions: Using novel DNAm-based estimates of blood proteins, we identified associations between circulating proteins and breast cancer incidence. IGFBP4 and RARRES2 have previously been reported to be higher in newly-diagnosed breast cancer patients. We also identify new potential protein biomarkers related to immune response (CCL21, SELL, CXCL9, CD48, and IL19).

#3460 Predicting cessation of immune checkpoint inhibitor therapy due to severe adverse events with an integrated autoimmune disease polygenic risk score.

P. Middha[1], R. Thummalapalli[2], Z. Quandt[1], Princess Margaret Lung Group, M. A. Gubens[1], C. M. Lovly[3], G. Liu[4], M. C. Aldrich[5], A. J. Schoenfeld[2], E. Ziv[6]; [1]University of California San Francisco, San Francisco, CA, [2]Memorial Sloan Kettering Cancer Center, New York, NY, [3]Vanderbilt University Medical Center and Vanderbilt Ingram Cancer Center, Nashville, TN, [4]Princess Margaret Cancer Centre, Temerty School of Medicine, Dalla Lana School of Public Health, University of Toronto, Toronto, ON, Canada, [5]Vanderbilt University Medical Center, Nashville, TN, [6]Helen Diller Family Comprehensive Cancer Center, Institute for Human Genetics, University of California San Francisco, San Francisco, CA

Background: Immune checkpoint inhibitors (ICIs), including anti-PD1/PD-L1 and anti-CTLA4 agents, have changed the landscape of cancer therapy. However, 6-30% of patients treated with ICIs can develop severe immune-related adverse events (irAEs) depending on the type of therapy used, often leading to cessation of treatment. Hundreds of genetic variants have been associated with autoimmune disorders, and recent genetic studies have developed polygenic risk scores (PRS) for composite risk of autoimmune disease (PRS_{AID}). We used data from an ongoing observational study of patients with non-small cell lung cancer (NSCLC) treated with ICIs to evaluate the association between PRS_{AID} and cessation of ICI therapy due to severe irAEs.

Methods: Our cohort comprises 1,316 advanced NSCLC patients who received ICI therapy from four institutions between 2009 and 2022. Genotyping was performed using the Affymetrix Precision Medicine Array, and imputation was performed using 1000 Genomes Reference. To evaluate cessation of therapy due to severe irAEs, we conducted a thorough review of electronic health records. We identified permanent discontinuation of ICIs due to irAEs as cessation for at least 6 months without any disease progression. We tested the association of a previously published PRS_{AID} (PMID: 35393596) with cessation of ICI due to any severe irAE. PRS_{AID} was converted to a standard normal distribution. We conducted an unconditional logistic regression model to evaluate the association between a standardized PRS_{AID} and discontinuation of ICI therapy due to severe irAEs. All models were adjusted for age at diagnosis, sex, type of ICI therapy, recruitment site, and 5 ancestry-informative principal components.

Results: Of the 1,316 participants with genotype and outcome data, 171 (13.5%) of patients stopped ICI therapy due to severe irAEs. The most common irAEs leading to discontinuation were colitis, hepatitis, and pneumonitis. The PRS_{AID} predicts the cessation of therapy due to severe irAEs with an odds ratio (OR) per standard deviation (SD) of 1.20 (95% confidence intervals [CI]=1.02-1.41, p=0.03). The association was stronger in individuals with high genetic risk (top 25th percentile compared to bottom 75th percentile of the PRS_{AID}) (OR=1.60, 95% CI = 1.11-2.28, p=0.01). When we stratified the analysis by therapy type, we found an OR of 1.17 (95% CI-0.98-1.39, p = 0.08) for the anti-PD1/PD-L1 monotherapy groups and an OR of 1.48 (95% CI=0.94-2.40,p=0.09) for the dual anti-PD1/PD-L1 and anti-CTLA4 therapy group.

Conclusions: An integrated PRS for autoimmunity can predict the cessation of ICI therapy due to severe irAEs in patients with advanced cancer. These findings suggest that PRS may help determine which patients may benefit from careful monitoring or even preventative measures for irAEs during ICI therapy.

#3461 Shorter leukocyte telomere length and higher risk of primary liver cancer in a prospective cohort study.

S. Karnam[1], K. Demanelis[1], K. B. Beckman[2], R. Wang[3], J. Adams-Haduch[3], W.-P. Koh[4], J.-M. Yuan[1];
[1]University of Pittsburgh, Pittsburgh, PA, [2]University of Minnesota, Minneapolis, MN, [3]University of Pittsburgh Medical Center, Pittsburgh, PA, [4]National University of Singapore Yong Loo Lin School of Medicine, Queenstown, Singapore

Background: Telomeres are conserved tandem repeats at chromosome ends that are vital to maintaining chromosomal stability and preventing degradation. Shorter telomere lengths (TL) are typically associated with older biological age or poor health status and can activate programmed cell death, whereas longer telomere lengths can be indicative of younger age or abnormal replication processes with oncogenic mutations. Previous research has identified a link between telomere length and carcinogenesis, but relatively few studies have investigated TL and primary liver cancer (PLC) risk despite it being one of the leading causes of cancer worldwide. The goal of this analysis was to study this association in a large prospective cohort.
Methods: Data was extracted from the Singapore Chinese Cohort Health Study, a cohort of 63,257 men and women aged 45-74 years at enrollment during 1993-1998. Telomere length was measured in peripheral leukocytes of 26,540 participants who provided baseline blood samples, using a validated quantitative polymerase chain reaction (qPCR) method. PLC incidence and death among cohort participants was annually surveilled using the nationwide Singapore Cancer Registry and the National Birth and Death Registry from study enrollment to 2015. For statistical analysis, a *t* test was performed to examine the differences in TL between participants who developed incident PLC and those who remained free of PLC. Cox proportional hazard method was used to estimate the hazard ratios (HRs) and their 95% confidence interval (CI) of PLC incidence according to TL quartiles.
Results: Over a 12-year follow-up, 199 participants developed incident PLC. The relative TL was significantly lower in participants with incident PLC than those without (-6.7%, $p < 0.001$). Multivariate Cox regression model showed an inverse association between TL quartile and risk of PLC (p for trend = 0.009). Compared with the lowest quartile, HRs (95% CIs) of PLC for the 2nd, 3rd, and highest quartile of TL were 0.78 (0.54-1.12), 0.75 (0.51-1.11), and 0.57 (0.37-0.88), respectively, after adjustment for age, sex, alcohol use, body mass index, and smoking status.
Conclusion: The present analysis demonstrated a statistically significant association between shorter telomere length and increased risk of PLC in a large prospective cohort of Singaporean Chinese. This inverse association for PLC is different from those for other cancer types in the same cohort. These results warrant further studies such as using Mendelian randomization to quantify genetic variation in TL with PLC development.

#3462 Mendelian randomization analysis of 27 cardiometabolic trait related polygenic scores identifies genetic risk for cardiometabolic and cardiovascular events in a large prospective study of breast cancer survivors.

P. N. Fiorica[1], H. Sheng[1], C. A. Laurent[2], J. M. Roh[2], V. S. Lee[2], A. Zimbalist[2], I. J. Ergas[2], Q. Zhu[1], R. K. Cheng[3], E. Rillamas-Sun[4], C. Iribarren[2], J. S. Rana[2], M. Nguyen-Huynh[2], D. L. Hershman[5], L. H. Kushi[2], C. B. Ambrosone[1], M. L. Kwan[2], H. Greenlee[4], S. Yao[1];
[1]Roswell Park Comprehensive Cancer Center, Buffalo, NY, [2]Kaiser Permanente Northern California, Oakland, CA, [3]University of Washington School of Medicine, Seattle, WA, [4]Fred Hutchinson Cancer Center, Seattle, WA, [5]Herbert Irving Comprehensive Cancer Center, New York, NY

Background: CVD is the most common cause of non-cancer death in breast cancer patients. Due to cancer treatment-related cardiotoxicities, breast cancer survivors are at increased risk of cardiometabolic disease (CMD) and cardiovascular disease (CVD). In addition to treatment-related factors, behavioral risk factors such as diet, smoking, and obesity are shared between CVD and breast cancer. While clinical factors influencing the risk of CVD in breast cancer patients are well studied, the effects of genetic factors are less known.

Methods: To investigate genetic factors contributing to risk of CMD and CVD in women with a history of breast cancer, we performed a Mendelian randomization analysis to explore the relationships between 27 polygenic scores (PGS) for CMD and CVD phenotypes selected from the PGS Catalog and literature and 13 incident CMD and CVD events in a large prospective cohort of 3,699 breast cancer survivors in the Pathways Study. Fine-Gray sub-distribution hazard ratios (HRs) and 95% confidence intervals (CIs) associated with one standard deviation of PGS were derived with adjustment for epidemiologic, clinical, and treatment factors. The time scale was defined as time since date of breast cancer diagnosis to first of incident event, health plan disenrollment, death, or end of study (12/31/2019). The proportional hazards assumption was tested using Schoenfeld residuals, and no violation was found.

Results: We identified 19 PGS-CMD/CVD associations that met Bonferroni significance ($P<1.17\times10^{-4}$). Five PGS were associated with increased risk of dyslipidemia: apolipoprotein B (HR=1.52, 95% CI,1.38-1.65), LDL cholesterol (1.49, 1.36-1.63), total cholesterol (1.43, 1.31-1.56), triglyceride levels (1.24, 1.14-1.34), and coronary artery disease (1.22, 1.13-1.33). Four PGS were associated with increased risk of hypertension: systolic blood pressure (1.36, 1.25-1.48), diastolic blood pressure (1.21, 1.11-1.32), fasting glucose adjusted for BMI (1.19, 1.09-1.30), and hypertension (1.41, 1.29-1.54). PGS for atrial fibrillation was associated with increased risk of arrhythmia (1.40, 1.25-1.57) and any cardiovascular disease (1.22, 1.12-1.32). PGS for coronary artery disease and myocardial infarction were both associated with increased risk of ischemic heart disease (1.43, 1.21-1.70 and 1.38, 1.17-1.62, respectively).

Conclusion: Our study provides strong evidence for the potential use of PGS to predict the risk of CVD and CMD in women with a history of breast cancer. Future studies may explore the use of PGS to identify women with breast cancer at high risk of CVD-related outcomes and strategies to mitigate this risk.

#3463 Beyond staging systems in cutaneous squamous cell carcinoma: Validation of two thresholds for a model-estimated metastatic risk.

O. F. Steijlen[1], L. Pozza[2], B. Rentroia-Pacheco[1], C. J. Eggermont[1], D. Bellomo[2], S. Alex[2], J. Dwarkasing[2], A. L. Mooyaart[1], L. M. Hollestein[1], M. Wakkee[1]; [1]Erasmus Medical Centre, Rotterdam, Rotterdam, Netherlands, [2]SkylineDx, Rotterdam, Netherlands

Background: Cutaneous squamous cell carcinoma (cSCC) is the second most common skin cancer, therefore causing a death toll comparable to that of melanoma, despite its low propensity to metastasize (2-5%). We recently developed a clinicopathological (CP) model that predicts absolute metastatic risk in cSCC patients. We have recently shown that, in a nationwide Dutch cohort, the model enhances the risk stratification provided by the American Joint Committee on Cancer, eighth edition (AJCC) and the Brigham and Women's Hospital (BWH) staging systems. The current study aims to evaluate the refined risk stratification and designed risk thresholds in an independent, nationwide UK cohort.

Methods: In the Dutch cohort, we defined patients at increased risk within the low-risk group (AJCC: T1-T2, BWH: T1-T2a) as those with an estimated risk above 1%; and in the high-risk group (AJCC: T3-T4, BWH: T2b-T3), as those with a risk above 3.5%. Both risk thresholds were evaluated in the nested case-control (NCC) cohort (n=696), sampled from the nationwide UK cohort (n=31981). The CP model was applied to the NCC cohort and results were binarized as CP Low-Risk or CP High-Risk. Weighted metrics were computed to adjust for the difference in proportion of cases and controls between NCC and nationwide cohorts.

Results: In the low-risk group as per AJCC (T1-T2) and BWH (T1-T2a), the metastatic risk is respectively 0.93% and 1.07%. Within this group, CP High-Risk patients represent respectively 1.69% and 6.11% of the AJCC and BWH groups and have increased metastatic risk of 7.54% in AJCC and 5.36% in BWH. In the high-risk group as per AJCC (T3-T4) and BWH (T2b-T3), the metastatic risk is respectively 7.79% and 13.80%. Within this group, CP High-Risk patients represent respectively 7.42% and 24.40% of the AJCC and BWH groups. They have an increased metastatic risk of 27.92% in AJCC and 24.07% in BWH.

Conclusions: This study validates the designed risk thresholds in an independent nationwide cohort. Differences in performance compared to the Dutch cohort can be explained by the exclusion of patients with multiple missing variables and worse annotation of pathological features in the UK cohort. Additionally, this study confirms that our risk model can enhance cSCC staging systems by a refined risk stratification in both low-risk and high-risk groups. Specifically, the CP High-Risk subgroup within the staging systems' low-risk group might benefit from heightened surveillance and diagnostic screening, such as lymph node ultrasonography. Similarly, the CP High-Risk subgroup within the staging systems' high-risk group could be considered for intensified surveillance and (adjuvant) treatment. In conclusion, adding the CP model to current cSCC staging systems would enable more personalized decisions about follow-up and treatment, while also facilitating the management of healthcare resources.

#3464 Development and prospective validation of an estrogen receptor positive breast cancer risk model to identify women who could benefit for risk-reducing therapies.

T. U. Ahearn[1], S. Mukhopadhyay[1], J. Balasubramanian[1], N. Chatterjee[2], M. Garcia-Closas[3], P. Pal Choudhury[4];
[1]National Cancer Inst. Div. of Cancer Epidemiology & Genetics, Rockville, MD, [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, [3]Institute of Cancer Research, London, United Kingdom, [4]American Cancer Society, Atlanta, GA

Background: Breast cancer risk-reducing therapies such as tamoxifen and aromatase inhibitors are effective for ER-positive (ER+) but not for ER-negative disease. As these therapies have side effects it is important to identify women at risk of ER+ disease. We developed and validated ER-specific risk prediction models in a prospective cohort and evaluated the expected gains of predicting ER+ vs overall disease.
Methods: The iCARE-Lit model integrates established questionnaire-based risk factors and a 313 variant polygenic risk score. We reparametrized the iCARE-Lit model to estimate risk of ER+ and ER- disease separately by obtaining relative risks from published literature for ages at menarche, menopause, first childbirth, and parity to account for their heterogeneous associations with risk of ER-defined subtypes. We estimated 5-year (yr) absolute risk (AR) for ER+ disease using an overall and ER+ model. We evaluated model performance in the Prostate, Lung, Colorectal and Ovarian (PLCO) Cancer Screening Trial prospective cohort. This included evaluation of calibration (expected-to-observed (E/O) ratio) and discrimination (area under the receiver operating characteristic curve (AUC)), among 46,571 self-reported non-Hispanic White women aged 50-75 yrs (1,052 ER+ cases with 5 yrs of follow-up from enrollment). We compared projected risk stratification of the overall and ER+ models among eligible US women in terms of proportions of women and future ER+ cases identified above the 3% 5-yr AR threshold recommended for risk-reducing interventions in the US.
Results: In predicting ER+ disease in PLCO, on average the overall and ER+ AR were well calibrated; however, models overpredicted risk at the ≥3% 5-yr AR threshold, (E/O = 1.31 (1.20, 1. 42) and 1.23 (1.13, 1.34), respectively. Risk discrimination was similar from the overall and ER+ models (AUC=0.65 (0.64-0.67) and 0.66 (0.64-0.67), respectively. The overall model projected that 16% of women in the US could be eligible for risk-reducing therapies, compared to 11% when using ER+ model, resulting in ~1.4 million less women crossing the risk threshold when using the ER+ score. However, the percentage of ER+ cases in the US population projected to occur within 5-yrs among eligible women was larger for the overall (38%) than ER+ (32%) risk score.
Conclusion: Findings suggest that ER-specific risk scores might not offer a substantial advantage compared to overall risk scores to identify women eligible for risk-reducing therapies. Further risk-benefit analyses are needed to quantify the potential gains of predicting ER+ vs overall breast cancer.

#3465 Association with total reproductive year and the risk of biliary tract cancer in women.

C. Maeng[1], K. Han[2], J.-H. Park[3], J. Hong[4];

[1]Kyung Hee University, Seoul, Korea, Republic of, [2]Soongsil University, Seoul, Korea, Republic of, [3]Korea University, Ansan, Korea, Republic of, [4]Sungkyunkwan University, Seoul, Korea, Republic of

Background: Many studies have reported that female reproductive factors, such as parity, age at menarche or menopause, breastfeeding, or age at first birth, were associated with or not associated with the development of biliary tract cancer (BTC). Our study was planned to determine whether a long-term rather than transient exposure was associated with the risk of BTC, including total reproductive year, which was defined as the time from menarche to menopause throughout the life cycle.

Methods: This nationwide cohort study included 1,059,533 women with natural menopausal women aged 40-69 years who underwent the periodic health check-up provided by the Korean National Health Insurance System in 2009. The median follow-up period was 9.3 years. Cox proportional hazard regression analysis was performed to estimate the risk of BTC based on the female reproductive factors.

Results: During the 9,867,152 person-years of follow-up, 4,198 patients (0.4%) were newly diagnosed with BTC. The incidence of BTC was significantly increased in subjects younger than 40 years at menopause compared with those aged 40 years or older (HR 1.341, 95% CI, 1.095-1.642). This trend was consistent even when menopause age was subdivided into 5-year intervals (<40 vs. 40−44, 45−49, 50-54, and ≥ 55 years) for those aged 40 years or older. When compared by categorization into four quartiles, the incidence of BTC tended to be numerically lower than that of the bottom 25% with the lowest age of menopause (designated as Q1 reference group). Compared to those with total reproductive year of 30 years or more, the incidence of BTC increased significantly in the group with less than 30 years of total reproductive year (HR 1.106, 95% CI, 1.014-1.206). This tendency was significantly reproduced in comparison by categorizing the entire group into quartiles. Compared to the lower 25% group (designated as Q1 reference group), the risk of BTC showed a significant linear inverse correlation with the longer total reproductive year. Q1 group has significantly higher incidence of BTC compared to the other groups ($p < 0.001$). This trend was repeated in various subgroup analysis.

Conclusions: In conclusion, this study demonstrated that women under the age of 40 at menopause had an increased risk of BTC compared to those over 40 years of age. Similarly, a longer period of total reproductive year was associated with a lower risk of BTC, suggesting a protective female hormonal effect on BTC. Total reproductive year may be more reliable indicator in that it reflects the actual lifetime exposure to female hormones.

#3466 Prognostic implications of lymph node micrometastasis in patients with gastric cancer.

A. Yamamoto, H. Okamoto;
Tsuru Municipal General Hospital, Tsuru, Japan

Purpose: The clinical significance of lymph node micrometastasis (LNMM) remains controversial in gastric cancer (GC). In this study, we investigated the prognostic impact of patients with LNMM GC.Methods: A total of 624 patients with pathologically lymph node metastasis negative (pN0) and N1 status (pN1) who underwent gastrectomy between 2004 and 2018 were enrolled in this retrospective study. The diameter of tumor cell clusters in metastatic lymph nodes was measured in 120 patients with pN1 GC. Results: Patients with lymph node tumors of diameter < 1500 μm (LNMM) had significantly better prognosis than those with tumors of diameter ≥ 1500 μm ($p = 0.012$; log-rank test). Cox's proportional hazards model revealed that LNMM ($p = 0.016$), several dissected lymph nodes ($p = 0.049$), and the provision of adjuvant chemotherapy ($p = 0.002$) were independent prognostic factors for overall survival of patients with pN1 GC. There was no significant difference in overall survival between patients with LNMM who received chemotherapy and those who did not ($p = 0.332$). Conclusions: LNMM is associated with favorable prognosis and could be an independent prognostic marker in patients with pN1 GC. LNMM in GC may be considered as one of the factors preventing adjuvant chemotherapy.

#3467 Tumor immune and microbial characteristics of colorectal cancer according to age at diagnosis and detailed anatomical location.

T. Ugai[1], Y. Takashima[1], Y. Zhong[1], J. P. Vayrynen[2], D. Buchanan[3], J. Huyghe[4], L. Hsu[4], C. Qu[4], S. Thomas[4], C. Thomas[4], S. Gallinger[5], R. Grant[6], U. Peters[4], A. I. Phipps[7], J. Nowak[1], S. Ogino[1];

[1]Brigham and Women's Hospital, Boston, MA, [2]University of Oulu, Oulu, Finland, [3]University of Melbourne, Melbourne, Australia, [4]Fred Hutchinson Cancer Center, Seatle, WA, [5]University of Toronto, Toronto, ON, Canada, [6]Ontario Institute for Cancer Research, Toronto, ON, Canada, [7]Fred Hutchinson Cancer Center,, Seatle, WA

Background: Colorectal cancer is a heterogeneous disease, exhibiting spectra of tumor characteristics that vary across age at diagnosis and anatomical location. We hypothesized that tumor immune and microbial characteristics of colorectal cancer might change with age at diagnosis and detailed anatomical location.

Methods: We utilized a pooled dataset of colorectal cancer cases (N= 958 to1413 depending on variables) with available immune cell density or microbial data in the Nurses' Health Study, Health Professionals Follow-up Study, and Ontario Familial Colon Cancer Registry. We examined whether there were statistically significant trends in tumor immune and microbial according to age at diagnosis and detailed primary tumor location (cecum, ascending, hepatic flexure, transverse, splenic flexure, descending, sigmoid, rectosigmoid, rectum) using Spearman's correlation test. The densities of immune cells were determined by using multiplex immunofluorescence, including T cells (CD3, CD4, CD8, CD45RA, CD45RO, FOXP3) and macrophages (CD68, M1-like, and M2-like) in tumor intraepithelial and stromal regions. We conducted stratified analyses by microsatellite instability (MSI) status.

Results: The density of memory (both $CD4^{\pm}$ and $CD8^{\pm}$) T cells in tumor epithelial areas continuously increased as age at diagnosis increased (P for trend <0.005). Compared to later-onset colorectal cancer, early-onset colorectal cancer had a lower density of memory T-cells. With respect to tumor site, $CD3^{\pm}CD4^{\pm}$ and $CD3^{\pm}CD8^{\pm}$ T densities in tumor epithelial areas were highest in the cecum compared to other subsites, and there was a statistically significant decreasing trend from the cecum to rectum (P for trend <0.005). We also observed significant decreasing trends for CD68+, M1-like, and M2-like macrophage densities in combined tumor (intraepithelial and stromal) regions from the cecum to rectum (P for trend <0.005). The proportion of *F. nucleatum*-positive colorectal cancers gradually decreased from the cecum to rectum (P for trend <0.005). Similar trends were observed in separate analyses in non-MSI-high cases.

Conclusions: This study suggests that certain tumor immune and microbial characteristics in the tumor microenvironment, specifically T cell and macrophage densities and *Fusobacterium nucleatum* positivity, change gradually according to age at diagnosis and/or detailed anatomical location. Age and anatomical location spectra in tumor immune and microbial characteristics will shed light on the etiology of colorectal cancer (including early-onset colorectal cancer), leading to better-personalized cancer prevention and treatment.

#3468 Emerging lessons from patient-reported hospital discharge experiences among hospitalized cancer patients with frequent emergency department use.

S. Kurteva, R. Tamblyn;
McGill University, Montreal, QC, Canada

Background: While teamwork is essential to providing high-quality patient-centered care, challenges in interprofessional collaboration and decision-making in the hospital settings are common, especially for cancer patients. The purpose of this study was to identify emerging themes related to hospital discharge experiences among patients hospitalized for cancer who became frequent emergency department (ED) users following their hospital discharge.
Design & Methods: A cohort of cancer patients discharged from an academic health center in Montreal (Canada) between October 2014 and November 2016 was assembled. Frequent ED (FED) users were identified as patients who had a > 4 ED visits in the year following hospital discharge using health administrative claims from the provincial universal health care program. Qualitative analysis of telephone interviews conducted with patients 30 days' post-discharge were used for in-depth exploratory analyses to characterize hospital discharge experiences and transition process from the hospital to the community.
Results: A cohort of 1253 cancer patients was formed. The mean age was 70.9 (SD=11.8) and the most frequent cancers included 488 (38.9%) respiratory and 309 (24.6%) upper digestive cancer. Overall, 14.5% (n=182) of patients became FED users. Content analyses revealed the most common emerging themes from the FED patients interviews on hospital discharge experiences. These included:1. Early hospital discharge putting patients at high risk of being re-admitted and going back to the ER shortly after that. Some patients mentioned post-discharge complications and emerging of new health issues that could have been avoided if patient was kept in the hospital for longer.2. Lack of communication between different specialists at the hospital. Some patients mentioned the help of a nurse as crucial during inpatient stays in maintaining communication between doctors. 3. Lack of communication of medications prescribed. Some patients mentioned the lack of communication of what doses was modified, what medications were stopped and which ones were newly prescribed.4. The need to schedule follow-up appointments at the time of hospital discharge. This becomes especially important for vulnerable patients who have been on pain medication during the hospital stay, affecting their cognitive abilities and making post-discharge planning more difficult.
Conclusions: This study using integrated data from administrative claims and patient interviews provided insights into the challenges related to hospital discharge experiences and transition into community among hospitalized cancer patients with frequent emergency department use. Application of our findings could assist in hospital discharge preparation and improvement in healthcare delivery and health outcomes.

#3469 Exploring the impact of a giant inflatable colon on the level of awareness, knowledge, and intent for colorectal cancer screening among men attending two state fairs in the Midwest.

A. E. Sedani[1], K. K. Rifelj[1], M. S. Bevel[2], C. L. McCall[1], M. Rogalla[1], L. Laliberte[3], K. Ellis[4], R. J. Pratt[5], C. R. Rogers[1];
[1]Medical College of Wisconsin, Milwaukee, WI, [2]Medical College of Georgia, Augusta, GA, [3]MNGI Digestive Health, Minneapolis, MN, [4]Masonic Cancer Center, Minneapolis, MN, [5]University of Minnesota, Minneapolis, MN

Purpose: This study aimed to evaluate the influence of an interactive inflatable colon as an effective educational tool to increase colorectal cancer (CRC) awareness, knowledge, and screening intention among men attending the Wisconsin (WI) and Minnesota (MN) state fairs.
Methods: Eligible study participants were self-identified men aged 18-75 who spoke English, were residents of WI or MN, and able to read in English. The study was employed during the final operating weekend of both the 2023 WI State Fair (August 11-13) and the MN State Fair (September 1-3). Eligible participants completed: (1) a pre-survey, (2) an unguided tour of the inflatable “Super Colon”, and then (3) a post-survey. The primary outcomes of interest were change in awareness (two items), knowledge (four items), and behavioral intent to obtain CRC screening (one item) from pre- to post-survey. Chi-square tests were used to examine study site differences and to explore the association between demographics and behaviors (awareness, knowledge, intentions) before entry to the Super Colon. McNemar’s test were employed to test if there were significant differences in the distributions from pre- to post-survey.
Results: A total of 940 eligible participants were included in the study sample. The men self-identified their race/ethnicity as Non-Hispanic (NH) White (72%), followed by NH other (12%), NH Black (9%), and Hispanic (8%). Race and ethnicity significantly varied by study site (<.0001) with participants from WI more likely being members of racial/ethnic groups that are often medically underserved (33% vs. 24% in MN). Only 13% of participants had walked through an inflatable colon before. Of those who were screening-age appropriate (age 45 or older), 89% had been screened for CRC previously. With the exception of one question, baseline CRC knowledge was relatively high among our study sample. Interestingly, having higher confidence of their awareness level was inversely associated with higher knowledge. As a result of touring the Super Colon, a significant improvement in confidence in individuals’ knowledge of CRC (<.0001), knowledge regarding a colon polyp (<.0001), and intentions to be screened in the future (<.0001) were observed. Most participants (95%) agreed that the Super Colon is an effective educational tool to teach people about CRC.
Conclusion: Since both encouraging CRC screening uptake and increasing research study participation among men can be a difficult task, these findings emphasize the crucial role of community-based educational initiatives in achieving these goals. Our findings affirm how the three-dimensional interior of the Super Colon is as an effective educational tool for promoting CRC early detection screening behaviors among men and increasing their awareness.

#3470 Evaluation of the association between sickle cell disease and breast cancer using the *All of Us* Research Program dataset.

I. T. Jubilee II, L. K. Evans, K. P. Lemieux;
Xavier University of Louisiana, New Orleans, LA

Background: The *All of Us* Research Program (AoURP) dataset was used to evaluate pharmacological treatment modalities in patients with both breast cancer (BC) and sickle cell disease (SCD). This study aims to identify treatment strategies for sickle cell patients with BC that may inform improved treatment options for patients living with either or both conditions, as there is an imminent need in this patient population.
Methods: We investigated the relationship between SCD and BC using the AoURP dataset. Criteria were female patients with a confirmed diagnosis of concomitant SCD and BC were selected. Hematologic, antineoplastics, and immunomodulating agents prescribed to patients were identified. Analysis was conducted in a Jupyter Notebook environment by way of R. Using FDA-approved and off-label indications, medication use patterns were used to reverse-engineer patient information and identify trends between SCD and BC.
Results: Nine female patients had concomitant diagnoses of SCD and BC, which aligned with the inclusion criteria. African Americans were significantly represented in this cohort, making up sixty-seven of patients. Twenty-two percent of patients did not indicate race, while eleven percent of patients identified as Caucasian. All patients included in the study were prescribed anemic therapy. Eleven percent of patients were prescribed an FDA-approved medication for SCD. Seventy-eight percent of patients were prescribed hormone-targeted BC medications. Thirty-three percent of patients were prescribed the immunotherapy regimen, Dinutuximab with adjunctive interferon-alpha. Eleven percent of patients were prescribed cytotoxic therapy.
Conclusion: Further investigation is warranted for dinutuximab use in BC treatment, specifically the triple negative subtype, as currently no targeted therapeutic options exist, and prognosis is poor. The data suggests dinutuximab with adjunctive interferon-alpha may be promising for triple-negative BC patients with SCD.

#3471 Predictors of cancer related distress among patients with colorectal cancer.

C. N. Zivanov[1], R. Kalbfell[1], J. Zarate Rodriguez[1], S. Sathe[1], J. Vetter[1], M. Jeon[1], D. Chao[1], K. A. Ohman[1], J. Ose[2], B. Gigic[3], E. M. Siegel[4], D. Shibata[5], C. I. Li[6], J. C. Figueiredo[7], C. M. Ulrich[2], A. T. Toriola[1];

[1]Washington University in St. Louis, St. Louis, MO, [2]Huntsman Cancer Institute, Salt Lake City, UT, [3]Heidelberg University Hospital, Heidelberg, Germany, [4]Moffitt Cancer Center, Tampa, FL, [5]University of Tennessee Health Science Center, Memphis, TN, [6]Fred Hutchinson Cancer Center, Seattle, WA, [7]Samuel Oschin Comprehensive Cancer Institute at Cedars-Sinai Medical Center, Los Angeles, CA

Background: Colorectal cancer (CRC) incidence among patients under age 50 has increased drastically over the past few decades. Given that increased cancer-related distress is associated with worse oncologic outcomes, studies are needed to assess the psychosocial wellbeing of CRC survivors across the shifting demographic and socioeconomic landscape.

Methods: The ColoCare Study is a prospective cohort study of newly-diagnosed CRC patients enrolled across six US and European sites. We analyzed ColoCare data from the Washington University site, which has high accrual of Non-Hispanic Black (NHB) patients. Cancer-related distress was measured using a validated Cancer and Treatment Distress (CTXD) tool with 4-point Likert scales ranging from 0-3 with higher scores indicating greater distress. Covariate-adjusted linear regression analyses were used to evaluate sociodemographic, lifestyle, and clinical factors as predictors of cancer-related distress 12 months following CRC diagnosis.

Results: This analysis included 156 participants enrolled from April 2017 to September 2022 who completed a 12-month CTXD questionnaire: 51.4% male; mean age 55.3 (SD 13.1) years; 64.8% Non-Hispanic White; 33.1% NHB; mean 12-month CTXD score 0.75 (SD 0.70). In covariate-adjusted models, predictors of increased distress at 12 months (Table 1) included recurrence or new metastasis (regression coefficient (β)=0.63, 95% confidence interval (CI)=0.35-0.91), stage II ((β=0.49, 95% CI=0.15-0.84) or stage III (β=0.37, 95% CI=0.02-0.72) disease, current smoking (β=0.33, 95% CI=0.10-0.56), female gender (β=0.22, 95% CI=0.00-0.44) and age (β= -0.01, 95% CI -0.02-0.00). Race and social vulnerability index were not predictors of distress in this analysis.

Conclusion: Among CRC survivors, those with younger age, female gender, active smoking, advanced stage, and disease progression may benefit from targeted cancer-related distress assessment and interventions.

Multiple Linear Regression Analysis Estimating 12-Month CTXD Scores

Variable	Regression Coefficients	95% Lower CI	95% Upper CI	P-value
Age	-0.01	-0.02	0.00	***0.015**
Gender: Female vs. Male	0.22	0.00	0.44	***0.050**
Race: Black vs. White	0.01	-0.26	0.29	0.933
Race: Other vs. White	-0.17	-0.91	0.57	0.650
Social Vulnerability Index	0.15	-0.26	0.56	0.463
BMI	0.00	-0.02	0.02	0.908
Smoking Status: Current vs. Former/Never	0.33	0.10	0.56	***0.006**
Stage II vs. Stage I	0.49	0.15	0.84	***0.006**
Stage III vs. Stage I	0.37	0.02	0.72	***0.040**
Stage IV vs. Stage I	0.41	-0.08	0.91	0.100

Adjuvant Treatment: Yes vs. No	-0.23	-0.53	0.07	0.133
Stoma at 6 months: Yes vs. No	-0.21	-0.68	0.25	0.364
Recurrence or New Metastasis: Yes vs. No	0.63	0.35	0.91	***<0.001**

#3472 Tailored cancer outreach efforts of a community outreach core working with Native Hawaiian and Pacific Islanders in Hawai‘i.

Mark Lee Willingham Jr.[1], **Kevin D. Cassel**[1], Angela Sy[2], Munirih Taafaki[2], Tressa P. Diaz[3], Antoinette Kleiner[3], Angelina G. Mummert[4]

[1]University of Hawai'i Cancer Center, Honolulu, HI,[2]John A. Burns School of Medicine, University of Hawai‘i at Mānoa, Honolulu, HI,[3]University of Guam, Margaret Perez Hattori-Uchima School of Health, Mangilao, Guam,[4]Cancer Research Center, Mangilao, Guam

Background The Community Outreach Core (COC) of the Pacific Island Partnership for Cancer Health Equity (PIPCHE) aims to improve health equity for historically underserved populations including Native Hawaiians and other Pacific Islanders (NHOPIs), and Filipinos. PIPCHE is a partnership between the University of Hawai'i Cancer Center and the University of Guam whose efforts are focused in Hawai'i, Guam and the U.S. Affiliated Pacific Islands (USAPI). The COC directly addresses the disproportionately high rates of health disparities and cancer incidence and mortality found within NHOPIs often due to multiple complex historical, social, cultural, and environmental factors. Cancer is the second leading cause of death in Hawai'i between 2014-2018, as well as the second most common cause of death in nearly all USAPI jurisdictions. The COC uses research-tested, community-engaged approaches to modify determinants of cancer in these groups.

Methods Outreach efforts have addressed NHOPI cancer inequities by raising awareness of high cancer burdens experienced by these underserved communities. Efforts include resource sharing and data collection at various venues in Hawai‘i such as health/wellness fairs, public housing, and Pacific Islander churches. Outreach Advisory Council meetings were held biannually with community health leaders to discuss ongoing and future initiatives/resource sharing. The COC provided health providers and students with cultural competency training on more efficient strategies to work with these unique NHOPI groups. The COC provided presentations and short talks across the U.S, including a Health Providers Symposium on lung cancer across the Pacific. Outreach efforts have included tailored NCI-based Screen to Save (S2S) colorectal cancer education to NHOPIs.

Results Forty-seven major outreach events were conducted from 2021 to November 2023. These include: 1 Health Providers' Cancer Symposium, 5 Outreach Advisory Council meetings, 5 Cultural Competency trainings and class lectures, 11 conference/community and short talk presentations, and 25 community outreach events. There were 1,900 attendees reached during these regional and national outreach activities. The COC works with professional audiences at the national level to inform these groups about cancer and the health burdens of NHOPIs. A total of 97 Pacific Islanders received the S2S education and completed a pre-posttest with positive increases in means found for all 14 questions.

Conclusion The PIPCHE COC has been able to reach NHOPIs though community partnerships to deliver culturally tailored cancer prevention education and efforts within Hawai‘i, as well as shed light nationally of the cancer burdens these populations face. The S2S education has been able to raise awareness of cancer screenings and holds promise as a potential strategy to address cancer burdens of NHOPI communities.

#3473 Bringing cancer information and resources to our diverse vulnerable populations: Cancer Wellness Hubs pop-up model.

Elena Nieves[1], Rosa Barahona[1], Marya Shegog[2], Dana Dornsife[2], **Lourdes A. Baezconde-Garbanati**[1]

[1]Keck School of Medicine of USC, Los Angeles, CA,[2]Lazarex Cancer Foundation, Danville, CA

Background: To achieve cancer health equity, we must provide a safe space where we recognize the cultural and cancer challenges among the communities that we serve. The Lazarex Cancer Foundation, in collaboration with USC NCCC, has established the Cancer Wellness Hubs pop-up model to provide information in a culturally sensitive and language specific way. This leads to making educated, accurate and timely decisions in the cancer journey. The actions we take allow us to help reduce the cancer burden. We bring education and connection to cancer support services into the neighborhoods of our most vulnerable populations.

Methods: During the period of 08/2021 - 07/2023 we teamed up with several YMCAs across LA County including East LA, Koreatown, and South LA, as well as with other community-based organizations to bring cancer information to the community. The hubs have supported culturally specific community events such as Chinese New Year, Dia de los Muertos, and Celebration of Life. A speaker series was developed to provide education, guidance, consultation, comfort, and support to enhance the community members' trust and reduce their fear regarding cancer, cancer screening, treatment, clinical trials, and survivor skills. Our cancer experts responded to frequently asked questions on cancer to manage a variety of topics including the importance of clinical trial participation. Holistic wellness workshops were provided to engage the community members in mind-body, health practices.

Results: We provided cancer information to 5,000+ individuals between 08/2021-07/2023. The majority identified as females (79%), including survivors, family members, and caregivers. Over 1,200 have attended our speaker series, and 3,773 have received information. We have supported organizations such as Celebrate Life Cancer Ministry and the Men's Cancer Network, Inc. and their support groups reaching 260 individuals. From Jan-July 2023, 112 community members received individualized follow-up to support increase knowledge and access services such as establishing a medical home, cancer screening, genomic testing, clinical trials & navigation, financial planning and mental, social, or emotional support.

Conclusion: By creating a safe space and inviting environment for our community members, our diverse communities in LA County are becoming better informed about cancer. Considerable education has been provided to help equip our vulnerable diverse communities with the knowledge needed throughout a cancer journey. Information provided includes screening guidelines, the importance of participation diversity in clinical trials, self/ patient advocacy, and accessing trustworthy, reliable sources. This pop-up model is reaching communities in their own *backyard* enhancing our ongoing effort to reduce cancer disparities and create health equity.

#3474 Racial disparities in receipt of surveillance mammography after breast cancer diagnosis.

J. G. Wilkerson[1], F. Wang[2], Y. Raveendran[1], T. Akinyemiju[3];

[1]Duke Cancer Institute, Durham, NC, [2]Duke University Cancer Institute, Durham, NC, [3]Duke University School of Medicine, Durham, NC

Background: The 5-year survival rate for breast cancer (BC) stands at an estimated 91%, with approximately 3.8 million BC survivors in the U.S. This large population of breast cancer survivors remains at risk of loco-regional recurrence, with variations noted across racial groups. White survivors face a locoregional breast cancer recurrence rate of 1.8%, whereas Black, Asian, and Hispanic survivors experience higher rates of 3.9%, 3.6%, and 3.1%, respectively. Notably, Black BC survivors with recurrent breast cancer exhibit a median survival time of 1.8 years compared with 3.6 years observed for White BC survivors. Current recommendations from the U.S. Preventative Services Task Force and the American College of Radiology advocate for surveillance through annual mammography and routine clinical visits following breast-conserving surgery and lumpectomies. However, there are gaps in the data available regarding disparities in the utilization of surveillance mammography by race/ethnicity. Thus, the goal of this study is to estimate race/ethnic disparities in surveillance mammography utilization and its impact on survival among breast cancer survivors at a large comprehensive cancer center.

Methods: A retrospective cohort study of female breast cancer survivors ≥19 years diagnosed and/or treated at the Duke Cancer Institute (DCI) between 2014 and 2022 was conducted. Data was abstracted on patient socio-demographics, cancer type (invasive ductal and ductal in situ carcinomas) and utilization of surveillance mammography within 2-5 years post initial breast cancer diagnosis. Chi-squared testing will be used to analyze rates of mammography surveillance receipt among different races presenting with BC at DCI. Kaplan-Meier estimates will be used for analysis on survival.

Results: A total of 10,904 women with a mean age of 43.7 years were included in the study. The study cohort is comprised of 69% non-Hispanic (NH) White, 24% NH Black, 2.2% Hispanic, 0.5% NH Native American, 1% NH other, and 3.2% NH Asian women. There were 1,791 cases of ductal in situ carcinomas and 9,113 invasive ductal carcinoma cases. NH Black women had the lowest 5-year relative survival rate (81.5%) of all represented racial groups: NH White 89.1%, Hispanic 95.3%, NH Native 87.8%, Asian 97.9%, and NH Other 88.0%. Ongoing analysis will be completed to estimate disparities in the use of post-treatment surveillance mammography amongst breast cancer survivors.

Conclusions: This study will inform efforts to increase post-treatment surveillance and improve adherence to survivorship guidelines with the ultimate goal of reducing mortality disparities among breast cancer survivors.

#3475 Prediction of nausea or vomiting, and fatigue or malaise in cancer care.

R. Vienne, Q. Filori, V. Susplugas, H. Crochet, L. Verlingue;
UNICANCER Centre Leon Berard, Lyon, France

Introduction : Natural language processing has recently achieved unprecedented performances for several medical tasks, but requires additional improvements in oncology. Moreover, very few projects have assessed the potential of language models to help prevent the most frequent serious or severe medical events in medical oncology. We aim at predicting nausea or vomiting (ICD10 code R11), and fatigue or malaise (ICD10 code R53) from patients' medical reports.
Material and methods: The study included all the patients of Centre Léon Bérard between 2000 and 2023 that have not refused to share their data for this analysis. We have retrieved all the clinical notes and manual coding of hospitalization stays in ICD10, in French. We have pretrained a BERT language model with a masking strategy on this data and then fine-tuned it and compared it to several medical pretrained open source models (DrBert and K-memBERT). The labels were medical events leading to or associated with a hospitalization in the 90 days after every patients' notes. For OncoBERT, we included sequential reports from the patients' history, along with a time-encoding layer, and integrated it in a final transformer layer.
Results: We analyzed 140,523 patients, representing 2,515,957 pseudo-anonymized text reports and 6.6M hospitalizations codes in total. The medical texts were consultations reports (56%), end-of-stay reports (17%) and hospitalization summaries (9%). The most frequent types of oncology treatments received by the patients at each time point were 18.8% for chemotherapy, 10.8% for targeted therapies and 1.3% for immunotherapies. The most frequent medical events were nausea or vomiting (20% of patients with 1 or more events), and fatigue or malaise (18% of patients with 1 or more events). In the final dataset, nausea and vomiting (R11) accounted for 16% of the labels while malaise and fatigue (R53) accounted for 24.7% of the labels. We performed random undersampling of reports without any event to balance the label dataset. The fine-tuning on R11 and R53 achieved the performances of 0.58 macro-aucpr (OncoBERT) and 0.50 macro-aucpr (best open-source model) on the validation set.
Conclusion: The language models achieved high performance on the prediction of the most frequent serious medical events in our hospital dedicated to cancer care. We plan to validate the external performances of these models on collaborating hospitals and prospectively and improve the interpretations that we will present at the congress.

BIOINFORMATICS / COMPUTATIONAL BIOLOGY / SYSTEMS BIOLOGY / CONVERGENT SCIENCE: Application of Bioinformatics to Cancer Biology 3 Poster Session

#3479 Evaluation of subclonal deconvolution pipelines using reference cell-lines and patient plasma samples.

X. Dong, Y. Huang, T. Zhang, S. Jia, P. Du;
Predicine Inc., Hayward, CA

Background: Intratumor heterogeneity plays a pivotal role in treatment resistance, emphasizing the need for a comprehensive understanding of tumor clonal architecture. While various methods exist for extracting this information from bulk tumor sequencing data, few studies have evaluated the entire workflow, from sample processing to subclone calls.
Methods: To address this gap, we utilized cell lines with known copy number changes and somatic mutations, constructing 12 ground truth sample sets with varying cellular proportions and tumor purities. These cell lines underwent NGS pipeline using PredicineWES+ with increased sequencing depth across ~600 cancer-related genes. Subclonal analysis workflows, including FACETS, PyClone, and ECLIPSE, were implemented to to assess variant assignment and cellular fractions. The subclone analysis was extended to 91 plasma samples from cancer patients.
Results: Our findings indicate that subclonal decomposition effectively segregates mutations from distinct cell lines. Notably, analyzing multiple samples with different proportions of the same subclones outperformed deconvolution from single mixture samples. In plasma samples from cancer patients, nearly one-third exhibited subclonal clinically actionable variants.
Conclusions: The established subclonal deconvolution pipeline enhances biomarker analysis from assays utilizing WES with boosted sequencing depth for selected genes.

#3480 Alterations in the tumor microenvironment and key signaling pathways in naturally-occurring canine gliomas mirror those seen in human patients.

N. A. Lanman[1], S. Utturkar[1], H. Kothandaraman[1], D. Dhawan[1], D. Liu[1], M. Zhang[2], M. Beyers[3], D. W. Knapp[1], R. T. Bentley[4];
[1]Purdue University, West Lafayette, IN, [2]University of California, Irvine, Irvine, CA, [3]Leidos Biomedical Research, Inc., Frederick National Laboratory for Cancer Research, Frederick, MD, [4]University of Liverpool, Liverpool, United Kingdom

Background: Malignant gliomas are the most common type of primary brain tumors, with patient outcomes that are generally dismal. Recently, pet dogs have been assessed as a valuable model in which to study gliomas. Gliomas in pet dogs occur at similar rates to those seen in humans, and a recent study comparing canine and human gliomas identified high similarity in terms of mutational rates, aneuploidy, the timing of mutations, and methylation patterns. Here, we further compare naturally-occurring canine and human gliomas, focusing on the tumor microenvironment (TME) and key pathways dysregulated in human gliomas.

Methods: Spontaneously occurring gliomas from adult and pediatric human, and canine patients were utilized for this study. RNA, whole genome/whole exome, and bisulfite sequencing data from adult and canine samples were downloaded from the Genomic Data Commons and the National Cancer Institute's Integrated Canine Data Commons, respectively. Pediatric tumor RNA-seq and genomic data were obtained from the Gabriella Miller Kids First database. Normal adult human and canine brain tissue served as control tissue. Only tumors with a clear diagnosis of astrocytoma, oligodendroglioma, or oligoastrocytoma were included in this study.

Results: Overall, we found that key canonical pathways that are altered in human gliomas are also altered in canine gliomas. A comparison of high-grade gliomas in pet dogs to normal canine brain tissues showed significant abnormal gene expression in 3 canonical oncogenic pathways of human GBM: the TP53, RB1, and RTK/RAS/PI3K pathways. Similarities between species included increased expression of PDGF, and receptors PDGFRA and PDGFRB. Frequent copy number alterations and mutations were also observed in PDGFRA and EGFR. Differences between species include the mutation rate of TP53, which we found to be mutated frequently in adults but not in pediatric or canine gliomas, however, expression of TP53 as assessed by RNA-seq was significantly increased in both adult and canine gliomas. IDH1, which drives methylation, was significantly overexpressed in adults but underexpressed in canine. Correspondingly, each of the promotor regions of TERT, PD1 and MGMT was hypermethylated in adults, but hypomethylated in canine. Although an analysis of the TME from RNA-seq data revealed an influx of immune cells in adult, pediatric and canine gliomas, there was a concurrent influx of immunosuppressive cells. Gene expression profiles of astrocytomas and oligodendrogliomas show differences in alterations of immune-related and TME-specific pathways.

Conclusion: We found that similar TME and pathway alterations were observed between human and canine gliomas, and that TME alterations were different between canine astrocytomas and oligodendrogliomas. The canine TME, like that in humans, appears to be immunosuppressive.

#3481 Comparative spatial transcriptomic analysis of monoclonal antibodies targeting the same molecule: A comparison between cetuximab and panitumumab.

J. Choi[1], J. Park[1], M. Lim[1], D. Lee[1], J. Lee[1], H. Choi[2], H.-J. Im[3];

[1]Portrai, Inc., Seoul, Korea, Republic of, [2]Portrai, Inc. / Seoul National University Hospital, Seoul, Korea, Republic of, [3]Portrai, Inc. / Graduate School of Convergence Science and Technology, Seoul National University, Seoul, Korea, Republic of

Background: In recent years, multiple therapeutic monoclonal antibodies have been developed that target the same molecules. Examples include trastuzumab and pertuzumab for HER2, cetuximab (CTX) and panitumumab (PNT) for EGFR, as well as pembrolizumab and nivolumab for PD-1. Currently, comparative studies between different monoclonal antibodies with same target primarily focus on comparing their efficacy, which makes it challenging to discern the factors contributing to their varied effectiveness. In this study, we conducted a comparative analysis of CTX and PNT using integrated data of fluorescence imaging and spatial transcriptomics (ST) to explore their distribution, as well as the associated cell types and genes in tumor tissues.

Method: A FaDu cancer cell line, which has high EGFR expression, was used to establish tumor model in BALB/C nude mice. In the tumor model, fluorescence dye-conjugated CTX or PNT was intravenously administered. In vivo fluorescence imaging was conducted at 0, 2, and 40 hours. Tumor tissues at 2 and 40 hours were dissected for drug distribution images and 10X Visium ST. SPADE algorithm [1], CellDART [2], and Stopover analysis [3] were employed for integrative analysis, cell type deconvolution, and topological association of interesting genes.

Results: In vivo imaging demonstrated that both antibodies exhibited high tumor uptake at 2 hrs, with further increase observed at 40 hrs post-injection. Initially, CellDART analysis confirmed that in the 2 hrs sample, both CTX and PNT exhibited a distribution similar to cancer cells among the various cell types. However, in the 40 hrs sample, the distribution pattern resembled that of cancer cells and inflammatory macrophages for both antibodies. A stopover analysis revealed a higher concordance between CTX distribution and EGFR expression in both the 2 and 40 hrs samples compared to that of PNT. Lastly, the top 100 up-regulated differentially expressed genes which are highly associated with drug distribution were identified through SPADE analysis. Notably, when we checked the intersection between CTX and PNT administered samples for these genes, there was 83% discordance in the associated genes in the 2 hrs sample and 93% in the 40 hrs sample.

Conclusion: In the examination of the distribution patterns of two distinct therapeutic antibodies targeting EGFR within cancer tissues, a notable observation was made: while the cell types exhibited similarity, the associated genes demonstrated divergence, with different degrees of alignment with the intended target. This analytical approach, scrutinizing the distribution of different antibodies within tissue sharing a common target, holds promise as a widely applicable method for elucidating divergent therapeutic effects.

#3482 Single-cell transcriptome analysis reveals that PLK4 signature genes are highly associated with cancer proliferation and hotspot mutations in non-small cell lung cancer (NSCLC).

Y. Kim[1], J. Hwang[1], Y. Park[2], D. Kim[3], K. Na[1], S. Lee[3], S. Baek[1], S.-s. Kang[4], S. Yang[1], M. Kim[1], H. Han[1], C. Lee[1], Y. Han[1], M. Hong[5], J. Lee[5], S. Lim[5], K.-H. Pyo[2], B. Cho[5];

[1]Department of Research Support, Yonsei Biomedical Research Institute, Yonsei University College of Medicine, Seoul, Korea, Republic of, [2]Yonsei New Il Han Institute for Integrative Lung Cancer Research, Yonsei University College of Medicine, Seoul, Korea, Republic of, [3]Brain Korea 21 PLUS Project for Medical Science, Yonsei University College of Medicine, Seoul, Korea, Republic of, [4]JEUK Institute for Cancer Research, JEUK Co., Ltd, Gumi, Korea, Republic of, [5]Division of Medical Oncology, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, Korea, Republic of

Background: Polo-like kinase 4 (PLK4) is a member of the polo-like kinase family known for its precise regulation during the cell cycle and its key role in centriole duplication, which is essential for proper cell division. Dysregulation of PLK4 is associated with abnormal centriole number, genomic instability and cancer development. In our previous study, we proposed PLK4 as a potential therapeutic target and biomarker for LUAD patients with *TP53* mutations by bulk RNA-seq analysis and confirmed its association with drug resistance. In this study, we analyzed the expression of *PLK4* and its association with cell cycle at the cellular level by scRNA-seq in NSCLC data.

Methods: In a previous study, we analyzed NSCLC data from The Cancer Genome Atlas (TCGA) database using the UCSC Xena data portal. In this study, we analyzed E-MTAB-6653 dataset from the single cell expression atlas(https://www.ebi.ac.uk/gxa/sc/home).

Results: In the previous study, we demonstrated that *PLK4* expression is higher in primary tumors compared to normal tissues in NSCLC. Higher *PLK4* expression in patients is associated with an unfavorable prognosis. Using genes highly correlated with *PLK4*, we confirmed a significant association between *PLK4* and *TP53* mutation by statistical analysis. Using the Drug Gene Interaction database, we observed an association between the drug resistance-related genes *PBK* and *BIRC5* with *PLK4*, and these genes were also correlated with *TP53* mutation. In this study, we investigated the association between *PLK4* and the cell cycle using single cell RNA-seq. First, we performed data pre-processing to selectively isolate NSCLC cells. Using a set of 87 PLK4 signature genes obtained from previous research, we stratified the samples into *PLK4* high and low groups based on the expression of these genes. We then analyzed cell cycle related genes in both groups and observed a higher expression of G2/M phase related genes in the *PLK4* high group compared to the *PLK4* low group. We also examined the expression of *PLK4* signature genes based on pathological differences and found higher expression in tumor tissue compared to normal tissue. There was also an increasing expression gradient from the tumor margin to the tumor core. Finally, using Gene Ontology analysis of both groups, we confirmed the upregulation of genes associated with transcription and translation, as indicated by the GO terms obtained.

Conclusion: In a previous study, the association between *PLK4* expression, *TP53* mutation and drug resistance was identified by bulk RNA-seq. In the current study, we used single cell RNA-seq to verify the correlation between *PLK4* and cell cycle in NSCLC. In addition, we observed that the expression of *PLK4* signature genes increased towards the tumor core based on pathological differences.

#3483 SIRT7 as a potential therapeutic target for drug resistance in lung adenocarcinoma: Insights from histone modification-related genes.

K.-H. Pyo[1], Y. Park[1], G.-T. Lee[2], J. Ahn[3], S.-J. Choi[2], Q. Kejia[2], T. Lee[2], Y. Kim[2], J. Hwang[2], B. Cho[4];

[1]Yonsei New Il Han Institute for Integrative Lung Cancer Research, Yonsei University College of Medicine, Seoul, Korea, Republic of, [2]Department of Research Support, Yonsei Biomedical Research Institute, Yonsei University College of Medicine, Seoul, Korea, Republic of, [3]Severance Biomedical Science Institute, Yonsei University College of Medicine, Seoul, Korea, Republic of, [4]Division of Medical Oncology, Department of Internal Medicine and Yonsei Cancer Center, Severance Hospital, Yonsei University College of Medicine, Seoul, Korea, Republic of

Background: Lung cancer is one of the leading causes of cancer-related deaths worldwide. Understanding the molecular mechanisms underlying its development and progression is crucial for the development of targeted therapies. In recent years, histone modification has emerged as a key player in the epigenetic regulation of gene expression, and its involvement in lung cancer has gained significant attention. Histone modifications, including methylation, acetylation, phosphorylation, and ubiquitination, influence chromatin structure and, consequently, gene transcription. Aberrant histone modifications can lead to dysregulated gene expression patterns, contributing to the initiation and progression of lung cancer. In this study, we investigated the expression patterns of 55 histone modification-related genes and identified an epigenetic tumor regulator as a potential therapeutic target.

Methods: We obtained 55 histone modification-related genes from dbHiMo (http://hme.riceblast.snu.ac.kr/). Transcriptomic (n= 576), clinical data (n=706) and survival data (n=641) of lung adenocarcinoma (LUAD) were downloaded from XenaTCGA database (https://xenabrowser.net/). The transcriptomic and IC50 values with 87 lung cancer cell lines and 310 drugs were downloaded from DepMap portal (https://depmap.org/portal/). RNA-seq data of GSE197555 was downloaded from GEO database (https://www.ncbi.nlm.nih.gov/geo/). All statistical analysis was performed using R.

Results: Among a total of 55 genes related to histone modifications, 6 genes including *KAT2A*, *SIRT7*, *CARM1*, *KDM5B*, *HDAC1* and *PRMT3* were significantly overexpressed in tumor tissues in LUAD transcriptome data from TCGA. Out of these 6 genes, 3 (*KAT2A*, *SIRT7* and *CARM1*) showed significant differences in survival analysis with disease-free interval in the adjuvant therapy-received TCGA LUAD dataset. All three demonstrated that as their expression levels increased, the prognosis became worse. The expression levels of *SIRT7* and *KAT2A* were highly positively correlated with the IC50 value of trametinib, which is MEK inhibitor. Among these two genes, the expression level of *SIRT7* was up-regulated in trametinib-treated group in resistance to MEK inhibitor in the H460 cell line. However, sensitive to MEK inhibitor in A549, the *SIRT7* expression level was down-regulated in the trametinib-treated group.

Conclusion: The histone modification-related gene *SIRT7* was found to be associated with resistance to trametinib. In this study, these findings suggest that SIRT7 may serve as a potential therapeutic target related to drug resistance in combination therapy with dabrafenib and trametinib.

#3484 Mechanism of BRAF V600E resistance revealed by cell panel screening and bioinformatics.

K. Hu, Q. Yang, P. Pan, F. He;
Pharmaron, Inc., Beijing, China

The BRAF V600E mutation is pivotal target in the treatment of melanoma. Dabrafenib, one of the most potent inhibitors approved by the FDA, exhibits differential sensitivity across different cancer types. To explore the underlying mechanisms responsible for the resistance of certain cancers to Dabrafenib, we tested a panel of 20 BRAF V600E positive cancer cell lines. Our results showed that 15 of these cell lines demonstrated sensitivity to Dabrafenib, whereas the remaining 5 exhibited resistance. We then investigated the correlation between Dabrafenib potency and gene expression patterns based on public high throughput sequencing data via bioinformatics methods. The results uncovered that the cell lines resistant to Dabrafenib showed low expression of MAP3K1, alongside with elevated expression of G0S2 and PIK3CG. These alterations are known to promote tumor cell proliferation, migration, and invasion, thereby contributing to a reduced sensitivity to BRAF inhibitors. Subsequent in vitro experiments validated the findings derived from our analysis. This unbiased, bioinformatics-driven approach provides valuable insight into the reasons behind treatment resistance and aids in the development of next-generation treatment approaches for inhibitor-resistant cancers.

#3485 Global DNA methylation level is associated with the sensitivity of cytotoxic and senotherapeutic drugs in gastrointestinal tumors.

K. Lin, X. Wang, Y. Luo, **H. Yu**;
The Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China

Background: Gastrointestinal cancer has become a severe burden around the world. Marker-guided treatment and clinical trials with sensitive anti-tumor drugs are critical for improving cancer survival. The decreasing DNA methylation levels of repetitive elements, such as LINE-1 and ALU, have been identified as the common biomarkers in cancer and aging. However, it remains unclear whether the methylation levels of repetitive elements can imply the drug sensitivity in gastrointestinal cancer. We investigated the association of LINE-1 and ALU methylations with the sensitivity of cytotoxic and senotherapeutic drugs in gastric cancer (GC) and colorectal cancer (CRC).

Methods: The profiles of DNA methylation and gene expression were obtained from GC and CRC patients from the TCGA cohorts. Then, we calculated the averaging methylation level of two repetitive elements (LINE-1 and ALU) to quantify the global methylation levels by using the probes targeting the repetitive elements in 450K methylation array. The sensitivity of anti-tumor drugs, including the cytotoxic (oxaliplatin and fluorouracil) and five senotherapeutic agents (Dasatinib, Nutlin-3a, Navitoclax, Rapamycin, ABT737), were inferred with Oncopredict R package based on the gene expression profile. The Pearson analysis was conducted to test the correlation between DNA methylation and drug sensitivity.

Results: The ALU methylation was associated with the sensitivities of cytotoxic (oxaliplatin: r = 0.171, P = 0.001; fluorouracil: r = 0.158, P = 0.002) and senotherapeutic agents (Dasatinib: r = 0.162, P = 0.002, Nutlin-3a: r = 0.109, P = 0.037, Navitoclax: r = 0.007, P = 0.931, Rapamycin: r = 0.144, P = 0.006, ABT737: r = 0.054, P = 0.523) in GC, while the association of LINE-1 methylation with drug sensitivities was observed in less drugs with weak correlation, including the cytotoxic (oxaliplatin: r = 0.132, P = 0.013; fluorouracil: r = 0.122, P = 0.019) and senotherapeutic agents (Dasatinib: r = 0.129, P = 0.014, Nutlin-3a: r = 0.109, P = 0.037, Rapamycin: r = 0.110, P = 0.034). In CRC, there was no correlation between DNA methylation levels of repetitive elements and drug sensitivity except Dasatinib (ALU: r = -0.107, P = 0.043).

Conclusion: DNA methylation of repetitive elements could serve as a biomarker for cytotoxic and senotherapeutic drugs in GC. In addition, our findings suggested the promising value of ALU and LINE-1 methylation-guided chemotherapy with senotherapeutics in GC.

#3486 Triple hormone receptor signatures as novel prognostic markers in breast cancer.

Mohamed Omar[1], J. Chuck Harrell[2], Rulla M. Tamimi[3], Luigi Marchionni[1], Tan Ince[1]

[1]Pathology and Laboratory Medicine, Weill Cornell Medicine, New York, NY,[2]Virginia Commonwealth University, Richmond, VA,[3]Department of Population Health Sciences, Weill Cornell Medicine, New York, NY

Background: Tumor phenotype across various cancers, including breast cancer, is predominantly shaped by a synergy between genomic alterations and the cell-of-origin from which the tumor originates. These elements collectively influence crucial aspects like tumor aggressiveness, treatment response, and patient prognosis. While existing research highlights that the role of cell-of-origin in shaping the molecular architecture of breast cancer, leveraging this information for actionable clinical insights has proven challenging. Here, we introduce two robust models leveraging cellular ancestry signatures of breast luminal cells to improve patient stratification and outcome prediction.

Methods: In this study, we developed a unique gene signature anchored in the expression levels of triple hormone receptors (THR)—namely androgen (AR), estrogen (ER), and vitamin D (VDR)—in breast cancer cells. Building on this, we formulated two distinct mRNA markers, THR-50 and THR-70, aimed at categorizing breast tumors based on their THR expression profiles. These markers were rigorously validated across 65 independent breast cancer studies, involving a total of 6,679 patients, utilizing Kaplan-Meier survival curves, Cox proportional hazards models, and unsupervised clustering analyses.

Results: Our findings indicate that both THR-50 and THR-70 are robustly associated with overall survival and recurrence-free survival in breast cancer patients across all datasets evaluated. Importantly, these THR signatures demonstrate broad applicability across various breast cancer subtypes, grades, and treatment phases—unlike existing prognostic markers that tend to be subtype-specific. Additionally, the THR signatures have revealed four unique patient clusters with divergent survival outcomes, three of which are ER-positive and one is ER-negative. Additionally, we developed an immune-based signature (i20) which can further categorize patients within the ER-negative cluster into two subgroups: one with a highly favorable prognosis, comparable to the ER-positive subtypes, and another that is characterized by exceedingly poor survival outcomes.

Conclusion: The THR-based cellular ancestry signatures open a new avenue in understanding the intricacies of breast cancer biology. These signatures offer a robust and stable framework for developing other prognostic markers, thus providing an enhanced stratification of existing breast cancer categories as well as creating new classifications with more distinct survival estimates.

#3487 Molecular dynamic simulations of RAS family protein interactions: Mutant KRAS binding with wildtype HRAS and NRAS.

I. Silverman[1], M. S. Gerber[2], A. Shaykevich[1], Y. F. Stein[1], A. Siegman[1], S. Goel[3], R. Maitra[1];
[1]Yeshiva University, New York, NY, [2]Albert Einstein College of Medicine, Bronx, NY, [3]Rutgers Cancer Institute of New Jersey, New Brunswick, NJ

Introduction: Mutations in the *KRAS*, *HRAS*, and *NRAS* genes are frequently associated with worse patient outcomes. Previous analyses of the structure and function of the associated proteins have been explored but not conclusively. The actual binding conformations of the three isoforms, especially when mutated are essential in designing inhibitory drugs. Recent studies have identified important interactions between the three isoforms that affect the oncogenic strength of the others when they are mutated. We use a bioinformatics approach to examine the modifications of the structural properties, mechanisms, and kinetic energies of eight KRAS mutants interacting with wildtype HRAS, and again with wildtype NRAS.
Methodology: AlphaFold AI predicted models of KRAS, HRAS, and NRAS were downloaded from Uniprot and relevant mutations were induced using PyMOL. Pairs of KRAS mutants and either HRAS or NRAS were submitted to ClusPro for docking. PyMOL was used to separate proteins by chain identities before being repaired in GROMACS. Molecular dynamics simulations (MDS) were performed between proteins using GROMACS, a Linux based MDS software that renders a topology regulated by Newton's Laws. XmGrace was used to analyze structure, *MMPBSA.py* was used to derive energy calculations, and VMD was used to visualize the interaction mechanisms.
Results: RMSF data indicated C-terminus residues in KRAS mutants and WT-HRAS and WT-NRAS are the most mobile in their interactions. Notably, when WT-HRAS interacts with G12R, G12S, G12V, and Q61H, its C-terminus decreases fluctuation. G13D had the greatest binding strength and strength fluctuation with WT-HRAS. G12V had the greatest binding strength with WT-NRAS. All other mutants had weaker binding with WT-NRAS than WT-KRAS. WT-HRAS had stronger binding at residue Val187 with WT-KRAS than all mutants did. WT-HRAS residues Cys184, Lys185, and Cys186 each had weaker binding energies with WT-KRAS than most mutants did. WT-KRAS residues Gln25 and Lys117 both exhibited stronger binding energy in interactions with WT-HRAS than most mutants did. WT-NRAS had stronger binding at residues Met182 and Met189 with WT-KRAS than all mutants did. Residue Pro185 in WT-NRAS did not have significant interaction with WT-KRAS, but had a strong interaction with all mutants. WT-NRAS residue Val187 had weaker binding energy with WT-KRAS than most mutants. WT-KRAS residues Tyr32 and Asp38 both exhibited weaker binding energy in interactions with WT-NRAS than most mutants did.
Conclusion: MDS between KRAS mutants and WT-HRAS and WT-NRAS present notable structural modification and binding kinetics. In each KRAS mutation, different segments of the protein complexes are involved in the interaction, indicating unique inhibitory methods are required to approach each mutant.

#3488 Decoding splicing isoforms and adaptive evolution in melanoma brain metastases through single cell long-read RNA sequencing.

L. Lu[1], C.-K. Shiau[1], K. Fukumura[2], H. Lin[1], Y. He[1], T. Pan[1], L. Norberg[2], J. Ritchie[2], J. T. Huse[2], R. Gao[1];
[1]Northwestern Univ. Feinberg School of Medicine, chicago, IL, [2]The University of Texas MD Anderson Cancer Center, houston, TX

Melanoma brain metastasis (MBM) is the third most common origin of metastasis to the brain, with a median overall survival of 8.9 months. Alternative splicing plays a critical role in cancer pathogenesis through altered protein coding complexity in tumor cells, which however has been poorly studied in MBM due to technical limitations. Long-read single cell RNA sequencing has the unique strength of measuring transcript isoforms and mutations simultaneously in individual cells due to its capacity of measuring full-length transcripts. In this study, we employed high throughout single cell long-read RNA sequencing (scNanoRNAseq) onto patient-matched MBM and extracranial metastasis (ECM) tumor pairs to evaluate the extent to which splicing isoforms impact adaptive clonal evolution in MBM. Our results showed that MBM tumors had distinct genetic alterations and ecological cellular compositions compared to matched ECM tumors, indicating that tumor clones were adaptively expanded in brain microenvironment. Comparative isoform analysis revealed that hundreds of genes expressed different combinations of isoforms (DCIs) involved in glucose and lipid metabolic pathways. Interestingly, our data demonstrated that ~10% of splicing related genes themselves were alternatively spliced including both spliceosome members and splicing activators. Furthermore, we calculated temporal changes of isoform usages along with tumor cell evolutionary lineages to quantify their impact on adaptive clonal expansion in MBM. Taken together, our work improves the understanding of transcriptional and splicing dynamics inherent in the adaptive evolution of MBM, providing evidence for developing new therapeutics targeting tumor cell-specific and MBM-specific splicing isoforms.

#3489 MetFlow: Automated nextflow pipeline for Ion AmpliSeq methylation assay designs.

R. Bedre, D. Kaul, A. Sharma, A. Hatch, L. Pickle, N. Li, F. Hyland;
Thermo Fisher Scientific, Carlsbad, CA

Introduction: DNA methylation plays a crucial role in development and progression of cancer. Identification of DNA methylation profiles in cancer is indispensable for early detection. To address this research need, Ion AmpliSeq™ offers targeted next-generation sequencing (NGS) methylation community amplicon panels for DNA methylation profiling in cancer-associated genes. However, the process of designing custom methylation amplicon panels using the Ion AmpliSeq primer design pipeline is intricate, labor-intensive, and time-consuming. Here, we developed a one-step, fully automated, faster, and reproducible nextflow-based primer design pipeline (MetFlow) for development of custom Ion AmpliSeq™ methylation panels. MetFlow streamlines the development of custom methylation panels for cancer-related genes, and thus significantly reduces the time and effort traditionally required for amplicon design.

Methods: The fully automated MetFlow pipeline is implemented using Nextflow. MetFlow necessitate an input configuration file for the execution of methylation Ion AmpliSeq™ designs. The configuration file specifies the essential parameters, including target CpG input, reference genome, pool number, and amplicon lengths, which are required for designing the amplicons. The MetFlow pipeline designs candidate amplicons for CpG targets on both Watson and Crick strands, facilitating the subsequent creation of files required for the generation of a methylation panel.

Results: The fully automated MetFlow pipeline has been used for designing the customized Ion AmpliSeq™ methylation amplicon panel(s) for cancer and age-related genes. The amplicons lengths in these AmpliSeq™ methylation panels were ranged from 125 bp to 175 bp for formalin-fixed, paraffin-embedded (FFPE) research samples. These customized methylation panels were run on the Ion GeneStudio™ S5 sequencer followed by performance analysis using Ion Torrent™ Suite. The published data for these custom amplicon panels suggest that the Ion AmpliSeq™ has sufficient read depth and mapping efficiency, higher sensitivity and accuracy for methylation measurement, and strong correlation (r=0.993) for methylation profiling among sample replicates.

Conclusion: We present MetFlow, an advanced automated primer design pipeline for designing the custom Ion AmpliSeq™ methylation amplicon panels tailored to targeted NGS applications in cancer research. The custom designed Ion AmpliSeq™ methylation panels exhibited sufficient read depth, higher sensitivity and accuracy, and reproducibility.

For Research Use Only. Not for use in diagnostic procedures.

#3490 Unveiling sex differences in lung adenocarcinoma through multi-omics integrative protein signaling networks.

C. Chen[1], E. Saha[1], D. L. DeMeo[2], J. Quackenbush[1], C. M. Lopes-Ramos[1];
[1]Harvard T.H. Chan School of Public Health, Boston, MA, [2]Harvard Medical School, Boston, MA

Sex differences in lung adenocarcinoma (LUAD) are evident in incidence rates, prognostic outcomes, and therapy responses, yet the underlying molecular mechanisms driving these disparities remain underexplored. In this study, we conducted a comprehensive proteogenomic analysis encompassing 38 females and 73 males with LUAD from the Clinical Proteomic Tumor Analysis Consortium (CPTAC) dataset. Employing Transcription Inference using Gene Expression and Regulatory data (TIGER), we inferred sex-differentially activated transcription factors (TFs) from The Cancer Genome Atlas (TCGA) LUAD gene expression data and identified sex-differentially activated kinases using CPTAC protein phosphorylation data. We further constructed a comprehensive kinase-TF signaling network by integrating these sex-differentially activated kinases with TFs, identifying all paths shorter than 3 in the protein interaction networks to highlight druggable pathways. Our analyses revealed that many proteins exhibit not only sex-biased abundance but also sex-biased phosphorylation and acetylation. Furthermore, these sex-biased proteins were associated with critical biological pathways including cell proliferation, immune response, and metabolism. Using kinase-TF signaling networks, we found substantial sex bias in the activities of clinically actionable TFs and kinases, including the glucocorticoid receptor (*NR3C1*), *AR*, *AURKA*, *CDK6*, and *MAPK14*. Leveraging the PRISM cancer cell line screening database, we identified several small-molecule drugs, such as glucocorticoid receptor agonists and aurora kinase inhibitors, potentially exhibiting sex-specific efficacy as LUAD therapeutics. Our findings showed that the activity of some clinically relevant TFs and kinases differ by sex in LUAD, underscoring the need to consider sex as a biological variable and the utility of multi-omics integrative protein signaling networks in advancing our understanding of cancer biology and the development of sex-aware therapeutics.

#3491 Tumor subtype classification of HPV-associated head and neck cancers is central to key clinically relevant variables.

B. F. Garb[1], S. Li[1], T. Qin[1], E. Lopez[1], S. Soppe[1], S. Patil[1], L. Rozek[2], N. D'Silva[1], M. Sartor[1];
[1]University of Michigan, Ann Arbor, MI, [2]Georgetown University, District of Columbia, DC

Cancer types are typically categorized according to the cell of origin, but within these groupings there exists vast heterogeneity. Thus, subtypes based on molecular features are often defined that have clinical utility as prognostic biomarkers, aid in selection of therapeutic strategies, or are associated with treatment response. Head and neck cancer (HNC) is the seventh most common cancer globally and projected to have 54,540 new cases in the U.S. in 2023. Within the US, HPV(+) HNC is now more prevalent than HPV(+) cervical cancer, and it is expected to continue to rise. Although there is wide morphologic and epigenetic diversity within HPV(+) HNC, tumor subtyping is not yet widely used for this cancer population, largely because of HPV(+) HNC's unique tumorigenesis process. Unlike other cancers that are driven by specific genetic signatures, HNC is driven by viral gene mechanisms. Given the large degree of heterogeneity among HPV(+) HNC cases and the lack of key mutations to define subtypes, the classification of HPV(+) HNSC subtypes requires a more sophisticated approach.
In this study, we introduce a robust, ensemble machine learning (ML) classifier for subtyping HPV(+) HNC that was trained on multiple cohorts and gene feature sets from RNA-seq data, and rigorously tested to ensure high reproducibility. The results classify HPV(+) HNC into the two main recognized subtypes: IMU (immune strong) and KRT(highly keratinized). Using a cohort of 227 patients, we show that the IMU/KRT classification is highly correlated with key clinically relevant variables in HNC. Of 41 molecular, clinical, and epidemiologic variables tested, 24 significantly associated with subtype. The IMU subtype was significantly associated with CD8 T-cells (p-value = 4.21×10^{-9}), Dendritic cells (p-value = 1.65×10^{-8}), B-cells (p-value = $2.20E^{-8}$), and epithelial to mesenchymal transition (p-value = 0.00013146). The KRT subtype is significantly associated with keratinization (p-value = 7.11×10^{-9}), HPV integration (p-value = 3.14×10^{-6}), radiation resistance (p-value = 0.00307), female sex (p-value = 0.00641), and high T stage (p-value = 0.0324). Genetic, epigenetic, and HPV gene-related variables were also among those significantly associated with subtype.
HPV(+) HNC subtypes have been shown to be associated with survival, with KRT-like patients having worse clinical outcomes than IMU. Given the different carcinogenic processes underlying IMU and KRT tumors, our ensemble ML subtype classifier web tool will help inform future studies of HPV(+) HNC. Future work to assess how HPV(+) subtypes can be incorporated into precision treatment strategies is well-motivated by our findings.

#3492 Comprehensive analysis of hematological malignancies with optical genome mapping and Bionano VIA™Software.

J. Wisotsky, A. Raski, W. Sherman, M. Roytman, S. Al-Saffar, J. Hauenstein, A. Wing Chun Pang, V. Wasnikar, N. Miller;
Bionano Genomics, San Diego, CA

The current standard for analysis of samples with suspected hematological cancer is karyotyping, fluorescence in situ hybridization (FISH), and/or chromosomal microarray (CMA). However, these methods have several limitations for the detection of structural variants (SVs) or copy number variants (CNV) that are smaller than 5 Mbp (karyotyping). Additionally, they are limited in their ability to detect low allele fraction (LAF) events and cannot detect the absence of heterozygosity (AOH) or the loss of heterozygosity (AOH/LOH - FISH and karyotyping).

Optical genome mapping (OGM) from Bionano can enable accurate detection of SV and CNV events of sizes down to 5 kbp, with high sensitivity to detect LAF events down to 5% variant allele fraction. Bionano's VIA™ software provides visualization and analysis support for OGM SV events including an improved Circos plot and ideogram for whole genome review. VIA incorporates CNV calling from OGM data using the SNP-FASST3 algorithm which also allows for accurate copy number calling at allele fractions as low as 10%. CNV detection performance was evaluated using 280 CNV events ranging in size from 175 kbp to 8 Mbp on the 22 autosomal chromosomes. Sensitivity and PPV were calculated for each size range separately.

Using SNP-FASST3, VIA also adds the ability to detect AOH/LOH events from OGM data. By analyzing locations where known SNPs disrupt the specific nucleotide sequence motif used by the DLE-1 labeling enzyme, a B-allele frequency can be calculated and enable AOH/LOH detection at low allelic fractions. AOH/LOH performance using SNP-FASST3 was evaluated using a cohort of constitutional and cancer samples analyzed with orthogonal methods as well as with simulated events. Sensitivity for 20-25 Mbp AOH events was 92% with PPV greater than 90% at 25% aberrant cell fraction.

The VIA 7.0 release also includes the ability to create a customizable decision tree using supplied reference annotation files for CNV, AOH and SV event pre-classification. VIA resources include a panel of target variants derived from various medical societies for clinical analysis guidelines specific to Acute Myeloid Leukemia (AML), Myelodysplastic Syndrome (MDS) and an aggregation of all hematological malignancy guidelines (pan-heme). These methods, combined with tools for expert review and reclassification of variants, allow users to conduct whole genome interpretation and report results.

These new features in VIA provide a streamlined workflow for analyzing heterogeneous hematological cancer samples and demonstrate the analytical performance of updated approaches for detection of CNV and AOH/LOH regions at low allele fractions using optical genome mapping alone.

#3493 Read-level methylation pattern extraction for high-multiplex large-scale targeted NGS assay.

M. Jin[1], M. Kaneko[2], S. Cen[2], H. Li[2], W. Guo[1], X. Zhou[2], A. Fujihara[2], T. Iwata[2], L. Storino Ramacciotti[2], D. Paralkar[2], G. Cacciamani[2], M. Aron[2], O. Ukimura[2], I. Gill[2], G. Liang[2], A. L. Abreu[2], J. Bhasin[1], **X. Yang**[1], X.-Y. Jia[1];

[1]Zymo Research Corp., Irvine, CA, [2]University of Southern California, Los Angeles, CA

The abnormal changes in DNA methylation are linked to the early stages of carcinogenesis. Identifying these epigenetic changes in circulating tumor DNA (ctDNA) can reveal potential biomarkers for the early diagnosis of various cancers. However, analyzing such data poses bioinformatics challenges due to the lack of sensitivity in detecting the low abundance ctDNA signals in biopsy samples, which are often overwhelmed by the complexity of libraries containing hundreds of targeted regions. Read-level methylation analysis holds the promise of more in-depth DNA methylation detection due to the wide coverage and high sensitivity of rare signals. However, this approach is hindered by the absence of a standardized workflow capable of generating interpretable reports suitable for both bench scientists and professional bioinformaticians. Here, we present a bioinformatics workflow that examines next-generation sequencing (NGS) data and characterizes the read-level methylation patterns of amplicons. Compared to other currently available tools, our method is designed to work with high-multiplex, large-scale targeted assays. It effectively eliminates the undesired noise derived from sequencing byproducts such as false CpG calls, dimers, and off-target alignments. Additionally, to accommodate the substantial volume of data generated by state-of-the-art NGS platforms, the workflow enables parallel processing of samples compatible with both cloud-based and on-premises computing resources. This workflow provides a comprehensive per-sample visualization of DNA methylation patterns and reports read-level methylation results in a “pattern-as-a-feature” table. In this table, the occurrence of an amplicon epiallelic haplotype (pattern) for every sample is represented as a “feature column” and is aggregated with all patterns discovered in the experiment. These read-level patterns, along with other information, can be used to develop machine learning algorithms to reiteratively harvest true predictive features and penalize confounding signals in predicting cancer diagnosis.

#3494 KINOMO: A non-negative matrix factorization framework for recovering intra- and inter-tumoral heterogeneity from single-cell RNA-seq data.

S. Tagore, Y. Wang, J. Biermann, E. K. D'Souza, K. D. Luthria, R. Rabadan, E. Azizi, B. Izar;
Columbia University, New York, NY

Single-cell RNA-sequencing (scRNA-seq) is a powerful technology to uncover cellular heterogeneity in tumor ecosystems. Due to differences in underlying gene load, direct comparison between patient samples is challenging, and this is further complicated by the sparsity of data matrices in scRNA-seq. Here, we present a factorization method called KINOMO (Kernel dIfferentiability correlation-based NOn- negative Matrix factorization algorithm using Kullback-Leibler divergence loss Optimization). This tool uses quadratic approximation approach for error correction and an iterative multiplicative approach, which improves the quality assessment of NMF-identified factorization, while mitigating biases introduced by inter-patient genomic variability. We benchmarked this new approach against nine different methods across 150 scRNA-seq experiments and find that KINOMO outperforms prior methods when evaluated with an adjusted Rand index (ARI), ranging 0.82-0.91 compared to 0.68-0.77. Thus, KINOMO provides an improved approach for determining coherent transcriptional programs (and meta-programs) from scRNA- seq data of cancer tissues, enabling comparison of patients with variable genomic backgrounds.

#3495 Multi-omic landscape of squamous cell lung cancer.

I. Y. Narvaez-Bandera, A. Lui, E. Welsh, D. Ercan, V. Rubio, H. Ackerman, G. Li, L. Darville, M. Liu, B. Fang, S. Eschrich, B. Fridley, J. Koomen, E. Haura, G. M. DeNicola, E. Flores, P. Stewart;
Moffitt Cancer Center, Tampa, FL

Patients with lung squamous cell carcinoma (LSCC) require new drug targets and improved biomarkers due to a lack of targetable genomic drivers and low response rates to immune checkpoint blockade. In a previous study, we analyzed a cohort of 108 LSCC patients by integrating DNA copy number variation, somatic mutations, RNA-sequencing, and expression proteomics. The principal discovery was the identification of three proteomic subtypes, with the majority (87%) of tumors comprising two of these subtypes. The "Inflamed" subtype showed enrichment for B-cell-rich tertiary lymphoid structures, while the "Redox" subtype exhibited enrichment for redox pathways and NFE2L2/KEAP1 alterations but had notably lower immune infiltration. We hypothesized that these subtypes would result in distinct metabolic signatures. Using ultra-high-performance liquid chromatographic separation on a HILIC column, followed by analysis on a Q Exactive HF high resolution mass spectrometer, we performed untargeted metabolomics on 87 tumors from the same LSCC proteogenomics cohort. A total of 7,392 features were obtained from this analysis, leading to the identification of 446 metabolites through m/z and retention time matching against an internal reference library. To understand if metabolomics could recapitulate our proteomic subtypes, we applied consensus clustering and non-negative matrix factorization (NMF) and assessed the resulting clusters using a Random Forest (RF) supervised classifier. Area Under the Curve (AUC) values for consensus clustering (5 clusters, AUC = 0.72), NMF (4 clusters, AUC = 0.73), and proteomics subtypes (Stewart et al. Nature communications. 2019:10:3578) (3 clusters, AUC = 0.74) suggest that metabolite abundances do indeed recapitulate the proteomic subtypes. Differential expression between Redox and Inflamed yielded 29 differentially expressed metabolites (p-value < 0.05 and 1.5 fold change). Glutathione, a key redox metabolite, was modestly elevated in the Redox proteomic subtype (0.58 log2 ratio, p = 1.14E-05). Notably, we identified glutathione metabolism (p = 1.29-5) and arginine biosynthesis (p = 5.22-4) as among the most significant pathways among differentially expressed metabolites. Glutathione, a key redox metabolite, was modestly elevated in the Redox proteomic subtype (0.58 log2 ratio, p = 1.14E-05). In conclusion, metabolomics recapitulates the proteomic subtypes, and there are distinct differences between these subtypes at the metabolite level. Ongoing work is developing a novel, network-based analysis framework to integrate these data quantitatively.

#3496 EpigenPlot: A tool for the gene-level methylation analysis of colorectal tumors.

D. Muller, B. Gyorffy;
Semmelweis University, Budapest, Hungary

Introduction. Aberrant DNA methylation patterns are frequent in colorectal adenocarcinoma (CRC) tissues. The investigation of this layer of epigenetic regulation holds the promise of a better understanding of tumour progression and the identification of novel biomarker candidates.
Purpose. Our goal was to collect and analyse publicly available DNA methylation data of colorectal samples and create a user-friendly tool for exploring and visualizing the CRC methylome.
Methods. We used Illumina Infinium Methylation Arrays, which is a popular platform for genome-wide methylation analysis of large cohorts. Gene Expression Omnibus database (GEO) and TCGA-COAD (The Cancer Genome Atlas Colon Adenocarcinoma) datasets including normal colorectal mucosa, adenoma, and adenocarcinoma samples were systematically collected and filtered. Differentially methylated regions were identified using the Kruskal-Wallis test. Genes with significant methylation changes were further analysed using ROC (Receiver Operator Characteristic) analysis. Finally, we established a web application using the shiny R package.
Results. We assembled a database including methylation data of 2,586 samples. Adenoma and adenocarcinoma samples were globally hypomethylated. Hypermethylation ($p < 0.05$, $\Delta\beta >= 0.2$) in adenocarcinoma samples was predominantly present in regions near proximal promoters. Out of the 74 previously proposed biomarkers examined, 50 had a cross-validated AUC of over 0.8. FDA-approved biomarkers BMP3, NDRG4, and SEPT9 have shown the highest performance in the TSS200 region (cvAUC = 0.8, 0.83, and 0.76, respectively). Genes with the highest performance were ITGA4 (5'UTR, first exon: cvAUC = 0.9), MDFI (5'UTR: cvAUC = 0.9), CNRIP1 (5'UTR, first exon: cvAUC = 0.89). The established web application can visualize methylation at CpG sites and gene regions, and KEGG pathway genes. The platform is available at https://epigenplot.com.
Conclusion. We collected and analysed a sizeable database of colorectal tissue data. Gene regions with the best performance include previously proposed and novel diagnostic biomarker candidates. The web platform provides an tool for the efficient exploration of the assembled data.

#3497 Glioma Immune Microenvironment Composition Calculator (GIMiCC): A method of estimating the proportions of eighteen key cell types from human brain tissue assayed using Illumina DNA methylation microarray technology.

S. C. Pike[1], J. K. Wiencke[2], Z. Zhang[1], A. M. Molinaro[2], D. C. Koestler[3], B. C. Christensen[4], K. T. Kelsey[5], L. A. Salas[4];
[1]Dartmouth College, Hanover, NH, [2]University of California San Francisco, San Francisco, CA, [3]University of Kansas Medical Center, Kansas City, KS, [4]Dartmouth-Hitchcock Medical Center, Lebanon, NH, [5]Brown University, Providence, RI

Precise detection of both tumor subclass and immune composition is critical in the pursuit of personalized immunotherapeutic treatment strategies for glioma. DNA methylation (DNAm) biomarkers are promising on both fronts. DNAm-based biomarkers for molecular classification have been developed and integrated into World Health Organization (WHO) diagnostic criteria. However, prediction of the tumor microenvironment is not as well defined. To fill this gap, we present GIMiCC, an approach for cellular deconvolution of DNAm microarray data for four WHO 2021 tumor subclasses: glioblastoma, oligodendroglioma, grade 2/3 astrocytoma and grade 4 astrocytoma. Using data from 17 isolated cell types, we describe the derivation of the deconvolution libraries and test the method on independent datasets from the Cancer Genome Atlas (TCGA) and the DKFZ molecular neuropathology classifier (PMID: 29539639). We utilize GIMiCC to illustrate that DNAm-based glioma classification is unlikely to be biased by compositional variation. In addition, we utilize GIMiCC to identify composition independent DNAm alterations that are associated with high immune infiltration. Our future work aims to optimize GIMiCC and advance the clinical evaluation of glioma with this new tool.

#3498 A novel combination of tissue-informed, comprehensive genomic profiling (CGP) and non-bespoke blood-based profiling for quantifying circulating tumor DNA (ctDNA).

T. Driessen, C. Lo, W. Zhu, R. Tell, J. Freaney, H. Nimeiri, K. Sasser;
Tempus, Chicago, IL

Background: Estimating quantitative circulating tumor fraction in liquid biopsy samples is a promising area of clinical development for monitoring therapeutic molecular response and correlates with patient outcomes. Here we introduce a sensitive measure of estimating ctDNA tumor fraction (ctDNA TF) using a novel combination of tissue-informed CGP with a non-bespoke, blood-based liquid biopsy panel.
Methods: Advanced pan-solid tumor samples were sequenced with both the Tempus xF/xF+ (105/523 gene, liquid biopsy) and Tempus xT (648 genes, solid-tumor with matched buffy coat) NGS assays (samples collected within 90 days). A normal distribution was fit against the somatic variants detected in solid-tissue and variants with variant allele fractions (VAF) within two standard deviations were used as selected biomarkers in the corresponding liquid biopsy to calculate a tumor-informed ctDNA TF for each sample.
Results: In the initial validation set (n=79 samples also sequenced with low-pass whole genome sequencing), the linearity of tumor-informed ctDNA TF was compared to mean VAF (R^2=0.26, slope=0.55), ichorCNA (R^2=0.84, slope=0.84), and tumor-naive ctDNA TF (R^2=0.71, slope=0.90). In a larger validation set (n=12,080), 37.5% samples had no variants detected in both xF and/or xT. Of the remaining samples, the linearity of tumor-informed ctDNA TF was compared to mean VAF (R^2=0.21, slope=0.55) and tumor-naive ctDNA TF (R^2=0.65, slope=0.81). In a follow-up analysis, we required 5 or more variants be detected in both xF and xT (n=1,659 samples) and compared the linearity of tumor-informed ctDNA TF to mean VAF (R^2=0.37, slope=0.64) and tumor-naive ctDNA TF (R^2=0.68, slope=0.98). In samples that received xF+ profiling (n=567), 24.3% had no variants detected in both xF+ and xT. The linearity of tumor-informed ctDNA TF of the remaining samples was compared to mean VAF (R^2=0.01, slope=0.26) and tumor-naive ctDNA TF (R^2=0.63, slope=1.02). Increasing the required number of variants to 5 or more had marginal improvement in linearity of tumor-informed ctDNA TF to mean VAF (R^2=0.12, slope=0.47) and tumor-naive ctDNA TF (R^2=0.67, slope=1.13).The limit-of-blank of the tumor-informed ctDNA TF approach was established to be 0% in both xF and xF+, and the limit-of-detection was ≤0.1% demonstrating that tumor informed ctDNA TF is a sensitive measure in detecting tumor fraction at low concentration levels.
Conclusion: Here we introduce a novel sensitive and specific tumor-informed, non-bespoke approach for estimating ctDNA TF. Linearity improves with increased panel size and increased variant number. These results suggest that a tumor-informed ctDNA TF can be utilized to improve the sensitivity of existing methods for estimating tumor fraction to help in treatment decisions using Tempus' tissue and liquid comprehensive NGS genomic profiling platform.

#3499 Non-small cell lung cancer (NSCLC) histology classification using DNA methylation data captured from liquid biopsies.

L. Tung[1], D. Tolkunov[1], C. Barbacioru[1], D. Kale[1], S. Shell[1], J. Tsai[1], L. Drusbosky[1], K. Parikh[2], H.-Y. Chuang[1];
[1]Guardant Health, Redwood City, CA, [2]Mayo Clinic, Rochester, MN

Background: Non-small cell lung cancer (NSCLC) makes up ~85% of lung cancers, and its major subtypes are adenocarcinoma (AD) and squamous cell carcinoma (SC). The histology classification of NSCLC has significant therapeutic and prognostic implications. As liquid biopsies are rapid and non-invasive, computational methods to classify NSCLC subtypes using cell-free DNA (cfDNA) are desired.
Methods: Using The Cancer Genome Atlas (TCGA) NSCLC methylation data, we developed a method to classify AD and SC subtypes from cfDNA samples. We mapped TCGA methylation data to Guardant Infinity's promoter regions and transformed them to allow for the transfer of the TCGA trained model to Infinity cfDNA epigenomic data. An advantage of this approach is that TCGA training data originates from the primary tumor, while cfDNA samples have low tumor fraction (TF) and may also contain signals from metastatic tumors. We trained a penalized Logistic Regression model with LASSO. To better fit the model to Infinity cfDNA data, we performed region filtering.
Results: Our model effectively classified AD and SC subtypes from TCGA samples (AUC 0.97) (10-fold cross validation; Table 1). When evaluating on cfDNA samples with epigenomic TF ≥ 1%, the final model shows reasonable performance (AUC 0.94) (Table 1); the performance decreases when reduced to TF > 0.05% (AUC 0.89) as expected (Table 1). When evaluating cfDNA from uncategorized lung samples, the predicted AD probabilities have significant association with *KRAS* mutations (p-value = 0.027).

Table 1: Model evaluation on tissue TCGA samples and cfDNA Infinity samples (different TF cutoffs)

Sample type	N samples	AUC	Accuracy	Sensitivity	Specificity	Precision	F1 score
tissue TCGA	907	0.97	0.93	0.94 +/- 0.02	0.93 +/- 0.02	0.94 +/- 0.02	0.94 +/- 0.01
cfDNA Infinity	17 (TF ≥ 1%)	0.94	0.88	0.83 +/- 0.3	0.91 +/- 0.17	0.83 +/- 0.3	0.83 +/- 0.21
cfDNA Infinity	29 (TF > 0.05%)	0.89	0.83	0.88 +/- 0.23	0.81 +/- 0.17	0.64 +/- 0.28	0.74 +/- 0.2

Conclusion: Our results show that the penalized Logistic Regression model trained with tissue TCGA methylation data through mapping, transformation, and region selection can classify NSCLC subtypes from cfDNA samples. This method may offer a fast, non-invasive tool to inform subtype-based clinical decisions, especially in the setting of poorly-differentiated carcinomas, and to identify subtype switches upon resistance to targeted therapies.

#3500 Refining diagnosis of renal cell carcinoma subtypes through single-cell resolution transcriptomic signatures.

M. Kim, A. Madrigal, Z. Mehrjoo, K. I. Glennon, M. Arseneault, M. Park, F. Brimo, S. Tanguay, H. S. Najafabadi, Y. Riazalhosseini;
McGill University, Montreal, QC, Canada

A remaining challenge in the field of renal cell carcinoma (RCC) is diagnosis of rare or mixed subtypes, which hampers the delivery of the most effective healthcare to patients. While a new classification scheme, integrating molecular characteristics of tumors, is emerging, it requires a deep understanding of the tumor heterogeneity and etiopathogenesis of each subtype. We have generated and analyzed single-cell transcriptome profiles of 38 human RCCs and normal kidneys 16 RCCs with diverse histological subtypes and established gene signatures specific to each cell type. We have applied these gene signatures to bulk RNA-sequencing data of 1000 RCC tumors with different histological subtypes and normal kidneys from The Cancer Genome Atlas (TCGA) to characterize different cancer types and cellular origins. Unsupervised clustering analysis of TCGA data shows diagnostic discrepancies for 9.3% cases and subclassifies each major subtype (clear cell, papillary and chromophobe) into clusters with differential clinical outcomes.[KM1] . The pathological marker expression in misdiagnosed tumors is consistent with clustering-based classification, not their original diagnosis. Notably, using unique and subtype-specific gene signature patterns, we identified clear cell papillary renal cell tumor (ccpRCT), which is a newly classified benign entity and the main tumor type representing the mis-diagnosed tumors. These observations have further been confirmed by reviewing histological images of the tumors by an experienced genitourinary pathologist. Interestingly, our gene signatures reveal that ccpRCT does not originate from proximal tubule cells unlike clear cell and papillary RCCs. Taken together, our approach suggests a potential new classification method connected to clinical behaviors and drug responses based on overall transcriptomic differences.

#3501 Concurrent amplification of TBXT and highly activated enhancers in extrachromosomal DNA (ecDNA) drives chordoma tumorigenesis.

B. Zhao[1], M. Ines[1], L. Ye[1], X. Wu[1], A. Soragni[2], A. Futreal[1], K. Akdemir[1];
[1]UT MD Anderson Cancer Center, Houston, TX, [2]UCLA, Los Angeles, CA

Chordoma, a rare bone cancer characterized by limited actionable clinical targets, exhibits a pivotal hallmark in the activation of the developmental transcription factor gene TBXT (Brachyury) through its association with highly active enhancers. TBXT amplification emerges as a major causative factor in familial chordomas, yet the amplification mechanism and its consequential impact on genomic instability remain inadequately elucidated. In this study, we conducted a comprehensive analysis of multiple genomic and epigenomic sequencing datasets, including WGS-seq, H3K27ac ChIP-seq, and ATAC-seq in six chordoma cell lines, and HiC data in two of them, to unravel the mechanisms of structural variations and their biological implications. Notably, our focus extends to JHC7 cells, which exhibit extrachromosomal amplification of a 2.4M region encompassing TBXT and the associated enhancers. The existence of such extrachromosomal DNA (ecDNA) in JHC7 was further validated through DNA FISH and Sanger sequencing. Comparing JHC7 with CH22, a chordoma cell line lacking TBXT amplification, revealed heightened chromatin relaxation and increased DNA rearrangements in JHC7. Interestingly, FISH results showed significant genomic ploidy heterogeneity within JHC7 cells, a finding demonstrated by nucleus FACS sorting. Single-cell multiomic analysis, combining snRNA-seq and snATAC-seq, demonstrated heterogeneous gene expression and distinct copy number variations among JHC7 cells. However, the amplification of the TBXT locus was observed in nearly all cells examined, indicating the rapid genomic evolution in the cultured JHC7 cells. These results collectively show that TBXT is extensively amplified through the formation of ecDNA, providing a fitness advantage to chordoma cells and concurrently exacerbating genomic instability. The findings in this study provide an insight for understanding the pathogenesis of chordoma and may inform the development of targeted therapeutic strategies.

#3502 Multi-omics approach to cholangiocarcinoma-related biology and development of precision medicine.

W. Kwon, I. Kang, S. Lee;
Laboratory of Integrative Precision Oncology, Seongnam-si, Korea, Republic of

Introduction: Cholangiocarcinoma is a diverse tumor entity characterized by distinct tumor biology and clinical phenotypes, which are influenced by the unique tumor microenvironment (TME) and anatomical location—whether intrahepatic, peri-hilar, or distal extrahepatic. Consequently, there is a clear need for a precision strategy that relies on cancer-specific, multi-omic features, moving away from traditional molecular subtypes derived from bulk RNA sequencing.
Methods: We conducted thorough multi-omic analyses utilizing data from the Cancer Dependency Map (DepMap) project. This encompassed cancer-specific molecular characterization through various omics data, genome-wide loss-of-function screening employing the CRISPR-Cas9 system, and drug sensitivity assessments via compound screening. These efforts aimed to reveal cancer-specific molecular subtypes with clinical relevance. The identified cancer-specific molecular signatures were subsequently validated in independent translational cohorts.
Results: Through integrative profiling of the transcriptome in bile duct cancer cell lines (n=39) obtained from the Cancer Cell Line Encyclopedia (CCLE), we unveiled cancer-specific molecular subtypes exhibiting distinct tumor biology across all omics layers, coupled with clinical relevance and prognostic significance. The major molecular features of each subtype demonstrated reproducibility in validation cohorts. Additionally, subtype-specific molecular biomarkers, encompassing mutational signatures and metabolites, were identified. Finally, we analyzed target drugs with subtype-specific genetic dependencies to formulate a precision strategy tailored to the distinct molecular characterizations of each subtype.
Conclusions: A thorough analysis utilizing a multi-omics dataset uncovered precision strategies founded on cancer-specific molecular subtypes of cholangiocarcinoma, both in terms of tumor classification and discriminative therapeutic opportunities. It is imperative to conduct prospective translational studies in conjunction with clinical trials, all centered around the cancer-specific molecular subtypes, to establish a precision strategy for effectively managing cholangiocarcinoma.

#3503 New generation drug development from *in-silico* identification to preclinical evaluation in glioblastoma.

Mahesh Arunachalam, Shreyas Gaikwad, Sharavan Ramachandran, Sanjay K. Srivastava

Immunotherapeutics and Biotechnology, Texas Tech University Health Sciences Center, Abilene, TX

Glioblastoma(GBM) is the most common malignancy of the central nervous system in adults. Despite medical advancements, stagnant survival rate improvements (<13%) and failure of conventional treatments such as temozolomide, have warranted the need for novel drug discovery methodologies. Considering the enormous potential of drug repurposing, we developed a method to identify a safe, active, and effective treatment for GBM. This method comprises two key stages, drug-target prediction and preclinical functional evaluation. Stage 1 fabricated a novel five phase in-silico pipeline for drug-target prediction against Ephrin-Type-A Receptor 2, chosen through preliminary literature and genomic analysis. Around 1562 FDA approved drugs were screened against the developed criterion and analyzed for bond type, location, repulsion, Gibbs free energy, stability, interactions over time, blood brain barrier permeability, and possible false positives (PAINS). Our results provided five plausible hits: Empagliflozin, Mycophenolate mofetil, Canagliflozin, Rivaroxaban, and Carvedilol. We subsequently evaluated the anti-proliferative effects of these hits using Sulforhodamine-B cytotoxicity assay on glioblastoma cell lines U251 and SF295. Our results demonstrated that Canaglifozin and Empagliflozin reduced the proliferation of GBM cell lines with IC50 value ranging from 30-40 µM. On the other hand, Mycophenolate mofetil (IC50: 5µM) and Carvedilol (IC50:16µM) also exhibited significant cytotoxic effects. Effects of Mycophenolate mofetil and Carvedilol were further evaluated in pancreatic cell line SUIT-2 where results exhibited cytotoxic responses similar to those observed in GBM. Furthermore, Annexin V/FITC analysis showed apoptosis in SUIT-2 cells by Carvedilol. Taken together, our results show the anti-cancer repurposing candidates extracted from our in-silico pipeline show significant cytotoxic effects of compounds identified through in-silico screening. Further studies are currently underway in our laboratory to delineate the anti-cancer mechanism, toxicity and off-target effects of these compounds.

#3504 ARS2 and paraspeckle interactions: A nexus for lncRNA mediated drug resistance and cancer progression in hepatocellular carcinoma.

G. Thillainadesan, H. S. Leong, O. Alawamry;
Sunnybrook Research Institute, Toronto, ON, Canada

Paraspeckles, elaborate sub-nuclear assemblies composed of the lncRNA *NEAT1-2* and a cohort of RNA-binding proteins, have a noted association with cancer progression and drug resistance. The specific mechanisms, however, have remained obscure. Our investigation into Hepatocellular Carcinoma (HCC) reveals a critical interaction: the sequestration of ARS2—an RNA-binding protein vital for the suppression of mRNA transcripts and the maturation of miRNAs—within paraspeckles. This sequestration leads to increased levels of *NEAT1-2*, derails miRNA processing, and diminishes the gene-silencing function of ARS2, thereby enhancing the expression of oncogenic genes. This discovery positions the ARS2-paraspeckle axis as a pivotal factor in cancer biology and a promising target for future treatments.

#3505 Classification of cancer subtypes by cfDNA fragmentomics analysis.

L. Zhu[1], C. Dai[1], S. Gan[2], S. Jia[1], P. Du[1];
[1]Predicine, San Francisco, CA, [2]Predicine Huidu (Shanghai) Medical Sciences, Shanghai, China

Introduction Fragmentation patterns of cell-free DNA (cfDNA) from whole genome sequencing offer insights into nucleosome occupancy, providing a tool to infer epigenomic and transcriptomic information. The nucleosome complex, the primary protector of cfDNA, is reflected in the size distribution of cfDNA fragments, with a mode fragment size of 167 bp corresponding to the wrapping of DNA around a single nucleosome. Nucleosome occupancy patterns at transcription factor binding sites (TFBS) exhibit differences between circulating tumor DNA in cancer patients and normal plasma controls, as well as among different tumor subtypes. Therefore, cfDNA fragmentomics can be employed for cancer subtyping analysis.
Methods We utilized the Griffin framework to classify tumor subtypes based on nucleosome profiling of cancer-specific TFBS and tumor subtype-specific chromatin accessibility regions from low-pass whole genome sequencing data of cfDNA. For prostate cancer subtyping, AR and ASCL1 binding sites were used to distinguish between androgen receptor-dependent prostate cancer (ARPC) and neuroendocrine prostate cancer (NEPC). ER and ERBB2 were employed for breast cancer subtyping to differentiate between ER-positive and ER-negative tumor subtypes.
Results Nucleosome profiling patterns at AR binding sites (ARBS) were compared among over 500 prostate cancer plasma samples and 42 normal plasma backgrounds. The ARBS nucleosome profiling abnormality score (ARBS score) was quantified by comparing its GC-corrected fragment central coverage with the normal background using a standard Z-score.Majority of prostate cancer samples with a high ARBS score could be classified as ARPC. For 12 samples with high tumor fraction but low ARBS score and no AR copy number amplification, we found that 8 had a high ASCL1 nucleosome profiling abnormality score. All these samples also exhibited RB1 copy number loss, suggesting that these 8 samples likely belong to NEPC. Nucleosome profiling of 171 breast cancer plasma samples at breast cancer-specific ER binding sites revealed that majority of samples had a high ERBS abnormality score, indicating likely ER-positive breast cancer.
Conclusion Our results demonstrate that nucleosome profiling of tumor cfDNA exhibits distinct patterns across different tumor types. Integrating nucleosome profiling at cancer-specific transcription factor binding sites can facilitate cancer subtyping, highlighting its potential clinical utility for patient stratification.

#3509 Using generative AI for filtering and comprehension of drug target discovery screen results.

A. Rech[1], **Y. Goltsev**[2], N. Samusik[2], A. Kaznadzey[2];
[1]University of Pennsylvania, Philadelphia, PA, [2]Cellformatica, Inc., Menlo Park, CA

Recent advancements in generative AI, including models such as GPT-4 and LLAMA2, have been rapidly integrated into cancer research. Cellformatica, Inc. has developed a pipeline designed to enhance the accuracy of functional and genomic drug target discovery screens by reducing the incidence of false positives and refining the interpretation process. This pipeline is capable of conducting comprehensive investigations, including genome-wide analyses, and is accessible via web and API interfaces. At the core of the pipeline is the use of the extensive global corpus of scientific literature to assess the relevance of each gene within the context defined by the experimental design of the screen. To address the issue of AI-generated inaccuracies, often referred to as 'hallucinations,' the pipeline incorporates a custom-tuned language model (LLM) component within the generative AI framework. This fine-tuning process is specifically tailored to the gene set under investigation. The pipeline's multi-agent architecture is a distinctive feature. It scores candidates based on three orthogonally-tuned criteria: effectiveness, confidence, and novelty. In benchmarking tests, this multi-agent scoring system has outperformed GPT-4 and has proven particularly adept at identifying candidate targets that may have been overlooked in previous research. These candidates are recognized for their significant therapeutic potential and are corroborated by existing scientific findings. The versatility of the Cellformatica pipeline is demonstrated through its application in three distinct areas of cancer research. First, it has been employed to optimize chimeric antigen receptor (CAR) T-cell therapies, a form of immunotherapy for cancer treatment. Second, the pipeline has been used to elucidate the network of chemotactic molecules that orchestrate immune cell infiltration and tissue remodeling in the lungs of patients with COVID-19. Third, it has been used to spatially define signaling pathways in humanized xenograft murine tumor experiments, for which existing cross-species database knowledge is limited. These applications underscore the pipeline's potential to contribute to the understanding and treatment of complex diseases.

#3510 A radiogenomic approach for triple-negative breast cancer risk stratification.

H. Noor[1], Y. Zheng[1], A. Mantz[1], R. Zhou[1], A. Kozlov[2], W. B. DeMartini[1], S.-t. Chen[3], S. Okamoto[4], D. Ikeda[1], S. Mattonen[5], S. Napel[1], M. L. Telli[1], G. Sledge[1], A. Kurian[1], M. Satoyoshi[1], O. Gevaert[1], H. Itakura[1];

[1]Stanford University School of Medicine, Stanford, CA, [2]University of Utah, Utah, UT, [3]Department of Diagnostic Radiology, Chang Gung Memorial Hospital, Taiwan, Taiwan, [4]St. Marianna University School of Medicine, Kawasaki, Japan, [5]Western University, London, ON, Canada

Background: Triple-negative breast cancer (TNBC) is an aggressive disease that accounts for 15-20% of all breast cancers. Expressions of ER, PR and HER2 receptors are lacking in this disease, and thus targeted therapies are not effective. TNBC has a shorter relapse-free survival, higher metastasis rate and decreased overall survival compared with other breast cancers. However, when undergoing standard treatment, some patients respond well, while others have poor outcome, suggesting TNBC heterogeneity. Early stratification of patients with long versus short survival could identify the subgroup of patients who would not benefit from exposure to toxicity of chemotherapy treatment. Here, we developed a non-invasive radiogenomic approach for TNBC risk stratification.
Methods: A transcriptomic-based prognostic gene signature was previously developed using the TCGA-BRCA cohort (n=860). Briefly, LASSO Cox regression model analysis with the 'glmnet' R package was used to identify the transcriptomic signature gene-set consisting of 50 genes. We tested this signature to prognosticate overall survival in a Stanford cohort (n=63) and a previously published SCANB cohort (n=604). The patients were stratified into high- and low-risk groups based on the median risk-score. Next, we developed a machine learning model that identified a radiomic feature set to predict the prognostic transcriptomic risk-groups. Radiomic features were extracted from pre-treatment breast MRI. Radiomics features were extracted using PyRadiomics. The model utilized Decision Tree Classifier and LeaveOneOut method was used for cross-validation.
Results: The transcriptomic signature low-risk group was significantly associated with improved overall survival in the two TNBC cohorts, with hazard ratios of 0.11 [95% CI: 0.01-0.88] for the Stanford cohort and 0.71 [95% CI: 0.52-0.97] for the SCANB cohort (log-rank p-values p=0.012 and p=0.032, respectively). Including this transcriptomic signature in a multivariate analysis, which adjusted for clinical features (patient age, grade, stage and Ki67%), the transcriptomic prognostic signature remained a significant prognostic factor ($p<0.05$). The radiomic feature set (consisting of 20 features) predicted the high- and low-risk transcriptomic groups with a mean accuracy of 72.2% and a mean AUROC of 71%. The precision, F1 and recall scores were 67%, 74% and 82%, respectively. In an independent dataset consisting of 116 Stanford TNBC patients, we used this model to predict risk groups based on the MRI radiomics features, and evaluated the prognostic effects of predicted risk groups. The overall survival of the predicted high-risk group was significantly poorer than the predicted low-risk group (p=0.013).
Conclusions: We present a prognostic model that can non-invasively stratify TNBC patients for low versus high mortality risk using radiomic features derived from pre-treatment patient MRI data.

#3511 iQC: machine-learning-driven prediction of surgery reveals systematic confounds in cancer whole slide images from hospitals by protocol.

A. J. Schaumberg[1], M. S. Lewis[2], R. Nazarian[2], A. Wadhwa[2], N. Kane[2], G. Turner[1], P. Karnam[1], P. Devineni[1], N. Wolfe[1], R. Kintner[1], M. B. Rettig[2], B. S. Knudsen[3], I. P. Garraway[2], S. Pyarajan[1];

[1]VA Boston Healthcare System, Boston, MA, [2]VA Greater Los Angeles Medical Center, Los Angeles, CA, [3]University of Utah, Salt Lake City, UT

Problem: This 21st century has produced an eruption of research using AI for the detection and diagnosis of cancer. Yet, an often-unspoken core premise in this field of computational pathology is that a glass slide suitably represents the patient's disease. Here, we report systematic confounds may dominate slides from a medical center, such that slides are unsuitable for diagnosis.

Methods: We mathematically define high quality data as a whole slide image set where the patient's surgery may be accurately predicted by an automated system. Our system "iQC" accurately distinguished biopsies (i.e. thin strands of tissue) from nonbiopsies, e.g. transurethral resections (TURPs) or prostatectomies, only when the data appeared high quality, e.g. bright histopathology stains and few artifacts. Thus, when the data are of high quality, iQC (i) accurately classifies pixels as tissue, (ii) accurately generates stats that describe the distribution of tissue, and (iii) accurately predicts surgical procedure from those stats. We compare iQC against the published HistoQC tool.

Results: iQC holds all data to the same objective quality standard. We validate this standard in five Veterans Affairs Medical Centers (VAMCs) and the public Automated Gleason Grading Challenge (AGGC) dataset. For the surgery prediction task, we report an AUROC of 0.9966-1.000 at VAMCs that produced high quality data and AUROC=0.9824 for AGGC. In contrast, we report AUROC=0.7115 at the VAMC that produced poor quality data. A pathologist found poor quality may be explained by faded histopathology stains and VAMC protocol differences. Supporting this, iQC's novel stain strength statistic finds this VAMC had weaker stains ($p < 2.2e-16$, two-tailed Wilcoxon rank-sum test; Cohen's $d=1.208$) than the VAMC that contributed most of the slides. Additionally, iQC recommended only 2 of 3736 (0.005%) VAMC slides for review due to inadequate tissue. In contrast, HistoQC in its default configuration excluded 89.9% of VAMC slides because tissue was not detected, but we reduced this to 16.7% with our custom HistoQC configuration.

Conclusion: Our surgery prediction AUROC may be a quantitative indicator positively associated with data quality for a dataset. Unless data are poor quality, iQC accurately locates tissue in slides and excludes few slides. iQC is, to our knowledge, the first automated system in computational pathology that validates quality against objective evidence, e.g. surgical procedure data available in the EHR/LIMS, which requires no efforts or annotations from anatomic pathologists.

#3512 Joint probabilistic modeling of multimodal metabolic data with UnitedMet.

A. X. Xie, C. Bradshaw, C. Tosh, W. Tansey, E. Reznik;
Memorial Sloan Kettering Cancer Center, New York, NY

Metabolites play a crucial role in the functioning of biological systems. Measurements of metabolite abundances by metabolomics and metabolic pathway activity by isotope-tracing are powerful approaches to study metabolic phenotypes. However, large-scale measurements of metabolite levels and pathway activity remain extremely scarce due to the technical challenges. Motivated by the strength of RNA-metabolite covariation, we present UnitedMet, a Bayesian probabilistic method for end-to-end joint modeling of RNA-sequencing and metabolic datasets that is capable of dimensionality reduction, data integration and metabolic modality prediction. UnitedMet demonstrates high accuracy predicting metabolite levels and isotopologue distributions from gene expression data in human tumor samples. To evaluate UnitedMet's efficacy in clinical applications, we inferred metabolomic profiles and isotope labeling patterns from the RNA sequencing data of clear cell renal cell carcinoma (ccRCC) patients enrolled in TCGA and clinical trials. Correlation analysis between genetic mutations and predicted metabolic phenotypes revealed that BAP1 mutations were associated with increased contribution of glucose to TCA cycle in ccRCC. Increased TCA cycle activity was found to be associated with disease progression and poorer clinical outcome. UnitedMet, therefore, provides a solution that could be broadly applicable to enhance multimodal metabolomic datasets and facilitates comprehensive study of interplays between metabolic profiles, molecular alterations and human phenotypes.

#3513 A CNN-based approach with efficient transfer learning improves microRNA-mRNA prediction.

Chen-Hao Peng[1], Hui-Yu Chen[1], Da-Chuan Cheng[1], Eric Y. Chuang[2], Chien-Yueh Lee[3]

[1]Department of Biomedical Imaging and Radiological Science, China Medical University, Taichung City, Taiwan, [2]Graduate Institute of Biomedical Electronics and Bioinformatics, National Taiwan University, Taipei, Taiwan, [3]Innovation Frontier Institute of Research for Science and Technology, National Taipei University of Technology, Taipei City, Taiwan

MicroRNAs play a crucial role in post-transcriptional regulation, influencing over 60% of human protein-coding genes by targeting specific mRNA sites to suppress protein translation. Various predictive algorithms aim to discern potential microRNA-mRNA pairs. Current approaches primarily employ sequence alignment, machine learning, and deep learning, yet encounter challenges such as complex data pre-processing, time-consuming model generation, and limited binding site precision. Additionally, some methods rely on inefficient RNN-based models, resulting in sluggish predictions. To address these issues, we proposed a CNN-based algorithm combined with transfer learning for direct and precise prediction of microRNA-mRNA binding sites, eliminating the need for extensive preprocessing. We introduced two models in this study: the per-based model and the miRNA-target binding decision model. The former screens potential target sites on 3'-UTR sequences, while the latter guides the decision-making process for miRNA-target pairs. The per-based model utilized a public database, extracting 786,447 human microRNA-mRNA pairs verified by CLIP-seq. It employed sequence alignment approaches to determine putative binding sites and per-base binding states. MicroRNA sequences and seed regions served as the initial convolutional kernels in the deep learning model, combined with encoded full-length 3'-UTR sequences of mRNAs as inputs for the fine-tuned U-Net architecture. For the miRNA-target binding decision model, we excluded the per-based model's decoder and initialized a new classification layer for target-site prediction. Leveraging experimental validation datasets from public databases, we extracted 2,846 binding and 1,058 non-binding human microRNA-mRNA pairs. The pre-trained model was fine-tuned on these 3,904 pairs. Both models underwent training with cycle learning rate, focal loss, gradient clipping, and weighted decay to address dataset imbalances. The dataset was split into 80% training and 20% testing data, with balanced accuracy as the evaluation metric. The per-based model achieved a robust 82.14% balanced accuracy on the test data, excelling in handling imbalanced datasets in per-based tasks. It swiftly and accurately identified nucleotide binding states. The miRNA-target binding decision model outperformed existing methods with a balanced accuracy of 80.39% on the test data. In contrast to many deep learning methods requiring additional preprocessing, our algorithm directly predicts per-base binding states from full-length sequences. It seamlessly transfers knowledge from the per-based to the miRNA-target model. Importantly, our approach relies solely on seed regions, eliminating the need for prior knowledge and enhancing microRNA target prediction reliability. This advancement holds promise for biomedical and clinical researchers, offering valuable insights.

#3514 A deep learning model for detection and characterization of tertiary lymphoid structures in H&E-stained images from pancreatic ductal adenocarcinoma.

C. Zhao[1], J. Jia[2], M. Lv[2], J. Feng[1], Y. Wang[1], Y. Liu[1];

[1]Renji Hospital affiliated with Shanghai Jiao Tong University School of Medicine, Shanghai, China, [2]Shanghai Jiao Tong University, Shanghai, China

Tertiary lymphoid structures (TLSs) are ectopic aggregates of a number of immune cells in nonlymphoid tissues under chronically inflamed environments and cancer. Emergence evidence suggested that TLSs were found in diverse cancers and TLSs have been referred as an independently predictive biomarker for immunotherapy response, especially immune checkpoint inhibitors. Moreover, the density and mature status of TLSs often positively associated with the favorable outcomes in cancers. Pancreatic ductal adenocarcinoma (PDAC) is one of the leading causes of cancer-related mortality with low survival rate in the whole world. Here, we developed a multi-resolution machine learning model for detection of TLSs from hema-toxylin and eosin (H&E) stained digital pathology slides as a potential clinical biomarker in PDAC. We selected 120 H&E slides (patients) with a total of 1,896 TLSs manually annotated as immature or mature TLSs by two pathologists. We also used immunohistochemistry (IHC) for CD20 and CD23 markers as a reference standard for H&E-based manual annotations. Our model mainly included detection and segmentation of individual TLSs. First, we used a transformer convolutional neural network to build a classification task to detect the presence of immature or mature TLSs. Then the instance segmentation model was applied to quantify the number of lymphocytes per unit square to validate the presence and maturation of TLSs. F1-score, calculated by the harmonic mean of precision (positive predictive value) and recall (sensitivity), was finally used to quantitatively evaluate the performance of model for each H&E slide. In validation dataset with 250 H&E slides (patients), we selected 50 slides to calculate F1-score, suggesting that our machine learning model achieved high F1-scores for detection and classification of immature TLSs (mean = 0.87, range from 0.79 to 0.95), and mature TLSs (mean = 0.92, range from 0.86 to 0.97). We further stratified 370 PDAC patients into three groups with mature TLSs (23%), immature TLSs (16%), and no TLSs (61%), respectively. Combined the clinical information, survival analysis revealed that patients with mature TLS had better survival outcomes than those without TLS (HR = 0.63; 95% CI, 0.44 - 0.90; P = 0.010). We developed a machine learning model that can accurately detect and classify TLSs in PDAC, and also demonstrated the prognosis value of predictive TLSs in H&E slides by automatedly machine learning model. These data highlight the promise of machine learning model for automated identification and quantification of the TLS on H&E slides in PDAC pathology.

#3515 SynAI: An AI-driven cancer drug synergism prediction platform.

K. Yan[1], R. Jia[2], S. Guo[2];

[1]Crown Bioscience, Inc., Leiden, Netherlands, [2]Crown Bioscience, Inc., Suzhou, China

Introduction: The SynAI solution is an adaptive AI-driven *in silico* drug synergism screening solution aiming to discover the potential therapeutic value of compounds at an early development stage. Given one of both compound inputs in SMILE sequences, SynAI can predict the potential Bliss score of compounds in any given cell line without the need for compound synthesis or structural analysis.The evaluation version of SynAI is accessible at https://synai.crownbio.com
Methods: The AI core of SynAI was constructed using the MLP (multi-layer perceptron) network under the PyTorch machine learning framework. The AI core of SynAI was trained against NCI-Almanac and DrugCombDB datasets. In total, these datasets consist of over 12 million *in vitro* synergism tests across 150 cancer cell lines of different origins. On average, each cell line is tested against over 6000 two-compound combinations of FDA-approved cancer drugs. One MLP network was trained for each cell line. Essentially, these networks predict the Bliss score for any combination of SMILE-based feature sets known as molecular fingerprints. The networks were trained against the NCI Almanac set and verified against NCI and DrugCombDB using n-fold cross-validation to avoid model overfitting. During the training, a hyperparameter tuning (HT) study was performed for SynAI and other popular algorithms; allowing an objective comparison of SynAI performances.
Results: Compared to existing synergism prediction platforms, SynAI yields similar performance in all categories (cf. Table 1) but provides more flexibility for data input using SMILE sequences directly. In addition, the AI core of SynAI can be constantly updated with new inputs from different cell lines and drug combinations. Table 1. Pearson cross correlation (PCC) between measured and predicted Bliss scores of NCI test set

PCC Score	**Cell Lines**		
Algorithm	**MCF7**	**OVCAR-8**	**SK-MEL-5**
SynAI	**0.68 ± 0.02**	**0.56 ± 0.07**	**0.86 ± 0.02**
RF	0.64 ± 0.02	0.55 ± 0.03	0.89 ± 0.02
GBX	0.66 ± 0.02	0.48 ± 0.05	0.88 ± 0.02
RNN	0.54 ± 0.12	0.43 ± 0.06	0.83 ± 0.08

Conclusions: Its adaptive and dynamic nature allows SynAI to learn from new data feeds from future studies and has significant potential in reducing the time and cost of synergism screening.

#3516 AI-derived features of 3D glandular networks are associated with likelihood of biochemical recurrence post radical prostatectomy.

J. Salguero[1], H. Abdeltawab[1], K. Hammouda[1], G. Corredor[1], S. Hawley[2], P. Mutha[1], R. Dhamdhere[1], S. Medina[1], T. Pathak[1], K. Bishop[3], R. Serafin[3], T. Mirtti[4], P. Lal[5], L. True[3], J. Liu[3], A. Madabhushi[6];

[1]Emory University, Atlanta, GA, [2]Canary Foundation, Palo Alto, CA, [3]University of Washington, Seattle, WA, [4]University of Helsinki & Helsinki University Hospital, Helsinki, Finland, [5]University of Pennsylvania, Philadelphia, PA, [6]Emory University and Georgia Institute of Technology, Atlanta, GA

Introduction: Prostate cancer is the most common cancer in American men and is mainly diagnosed from two-dimensional histology sections. Recently, three-dimensional (3D) prostate histopathology has emerged as a valuable strategy to enhance the understanding of the disease by increasing microscopic sampling of specimens. This strategy enhances the microscopic examination of specimens by facilitating the analysis of the volumetric shape of cells and glands, as well as the pathway structures through entire biopsies and other morphological features. These aspects hold the potential to be linked with biochemical recurrence (BCR) outcomes. This study highlights the potential of features derived from the 3D structure of glands in samples of patients with prostate cancer for identifying patients who are at higher risk of BCR.

Methods: Radical prostatectomy specimens were collected from 50 patients along with 5-year postoperative BCR follow-up from the University of Washington. A total of 118 *ex vivo* whole-biopsy 3D pathology images were obtained from RP by an open-top light-sheet microscopy platform. Images were converted into a synthetic CK8 immunofluorescence dataset using an image-sequence translation model. From these 3D images, a glandular structure mask was generated by a computer-vision algorithm. The 3D structure of prostate glands was modeled through a Tree-structure Extraction Algorithm for Accurate and Robust Skeletons (TEASER), which provides a simplification of the length of the gland, its shape, and its pathway. 91 features were then extracted from the glandular skeleton architecture. A 3-fold cross-validation approach was used in which patients were divided into training (D_1) and test (D_2) sets of 33 and 17 patients, respectively. Fisher's score, used to select features based on their correlation to the outcome, was applied to D1 to identify the top 5 features most correlated with BCR. We then utilized these features to train a K-Nearest Neighbors classifier on D_1, aimed at predicting whether a patient would experience BCR. The model's performance was evaluated on D_2 and averaged across all folds.

Results: The classifier was able to accurately differentiate between BCR+ and BCR- patients, achieving an average ROCAUC of 0.73 (±0.04) in D_2. Significant differences in 3D skeletal features were observed between BCR+ and BCR- groups ($p<0.05$). Among the five selected features, three were related to the length and diameter of the gland, with the longest glands observed in BCR- patients. The remaining two features pertained to gland curvature and tortuosity, revealing more twisted glands in BCR+ patients.

Conclusion: Features derived from a skeleton model of the 3D glandular structure of biopsies showed promise in identifying patients with prostate cancer who are at a higher risk of BCR. Additional, multi-site independent validation of these findings is warranted.

#3517 A deep learning-based virtual staining system with multimodal-attention for precision medicine.

Z. Zhou[1], Y. Jiang[2], R. Li[1], L. Xing[1];
[1]Stanford University, Stanford, CA, [2]Wake Forest University School of Medicine, Winston Salem, NC

Purpose: This study introduces a novel multimodal-attention-based virtual mIF staining (MAS) system designed for efficient, reliable virtual mIF staining from label-free fluorescence images. Our goal was to overcome the performance bottleneck and time-cost limitations associated with traditional mIF techniques and thereby enhance their clinical utility.
Method and Materials: Our approach involved developing a cutting-edge MAS model. This model is built upon a sophisticated end-to-end generative convolutional neural network (CNN) architecture. It ingeniously leverages autofluorescence and 4',6-diamidino-2-phenylindole (DAPI) slides as inputs to generate mIF images. To achieve this, we equipped the model with feature extractors enhanced by pretrained masked auto-encoders (MAEs) and a self-attention combination strategy. These components worked harmoniously to extract antigen-label-related features and precisely locate specific cells within the images.
Results: In our comprehensive study, we engaged 94 gastric cancer patients, utilizing the MAS system for automated virtual mIF staining of seven biomarkers, namely CD3, CD20, FOXP3, PD1, CD8, CD163, and PDL1, in both cancerous and non-cancerous tissues. Importantly, the MAS-produced virtual mIF stains matched the quality of traditional manual stains. Furthermore, we validated the prognostic accuracy for gastric cancer using these virtual mIF images, demonstrating their ability to provide clinical information that is as reliable and valuable as that obtained from manually stained mIF images.
Conclusions: Our study identifies the MAS system as an important advancement in mIF staining, enhancing personalized medicine with its efficiency and quality. This tool holds significant potential to enable personalized medicine efficiently and cost-effectively, streamlining the process of diagnosing diseases, making prognoses, and developing treatment plans.

Quantitative Comparison of Ablation Experiments for MAS system in predicting multiple biomarkers

Biomarkers	Index	U-Net (Avg±Std)	ReU-Net (Avg±Std)	Att-ReU-Net (Avg±Std)	MAS (Avg±Std)

#3518 Next generation H&E cell modeling: Using same-slide multiplex immunofluorescence (mIF) data to train H&E.

B. Arbiv, A. Bart, T. Dankovich, R. Elran, S. Bookstein, A. Laniado, T. Dicker, S. Dagan, O. Puig, K. Bloom, E. Markovits;
Nucleai, Chicago, IL

Haematoxylin & Eosin (H&E)-based deep learning algorithms require a large number of human-based cell annotations for model training, and are limited by what a human eye can see. Multiplex immunofluorescence (mIF) offers a more comprehensive and accurate method for classifying cells because annotations are based on cell status, i.e. whether a cell expresses certain markers or not. In this study, we leverage mIF-based cell type predictions[1] to enhance H&E model performance.We used a publicly available CODEX/PhenoCycler dataset[2] consisting of 140 tissue cores obtained from 35 patients with colorectal cancer, which were stained with 56 protein markers and subsequently with H&E. mIF data was used to create over 60,000 prediction-based annotations on the corresponding H&E-stained images that were used to train deep learning H&E classifiers.

The final model performance reached AUC of 0.91 when evaluated on the H&E test annotations and 0.90 on the mIF predictions. Notably, the mIF annotations-based H&E model surpassed the manual annotations-based H&E model in effectively identifying challenging cell types, demonstrating its superior performance. These findings highlight the potential of leveraging mIF cell type predictions to train accurate and automated H&E models.

[1]Markovits et al, BioRxiv, https://doi.org/10.1101/2022.11.09.515776[2]Schürch et al, Cell. 2020,182(5): 1341-1359.PMID: 32763154

#3519 Reconstructing a latent representation of gene expression from genomic alterations to improve clinical utility of real-world clinicogenomics data.

M. Baron, S. Kumar, F. Kuperwaser, D. Tracy, E. Vucic, J. Sherman;
Zephyr AI, McLean, VA

Background: Molecularly and clinically well-annotated patient datasets are ideal for studying tumor biology and developing robust machine learning (ML) models for predicting outcome and treatment response. These data however rarely exist in real-world settings or in sufficient quantities within research contexts. Large publicly available datasets like The Cancer Genome Atlas (TCGA) which provid multi-omic profiles for diverse cancer types, have profoundly advanced cancer research and facilitated development of novel therapies and personalized medicines. However, the absence of patient outcome data tied to treatment limits the applicability of these data for understanding and modeling treatment response. Real-world clinicogenomics cohorts, such as the AACR Project GENIE, on the other hand are typically very rich in clinical annotations, including treatment regimens and outcomes measures. These data are however sparsely annotated for patient tumor molecular profiles, rarely exceeding ~100's of genes profiled. We hypothesized that it would be possible to reconstruct latent tumor mRNA representations from limited genomic and clinical data available in real-world clinicogenomic cohorts, and that these reconstructed expression profiles would be useful for a variety of clinically meaningful downstream applications.

Methods: We developed an ML model, called Mut2Ex, to reconstruct tumor gene expression profiles using genetic information available on commercial next generation sequencing panels using a Principle Label Space Transformation (PLST) we adapted to regression problem, along with embeddings from clinical information (OncoTree code, sex and stage) generated by a language model. Mut2Ex was trained on ~1200 cell lines from DepMap representing 26 cancer types, to generate ~2000 reconstructed mRNA gene profiles that were applied to a variety of clinical tasks. We used Mut2Ex to reconstruct mRNA profiles for ~10,000 tumors from TCGA and ~180,000 tumors from AACR Project GENIE.

Results: Reconstructed mRNA expression by Mut2Ex was highly correlated with true expression in cell lines (rho = 0.926, [0.924-0.928 95% CI, N = 1184]). Compared to true expression, reconstructed profiles recapitulate sub-clusters within cancer types, PAM50 subtyping in breast tumors, survival signatures in colorectal tumors and multiple oncogenic signatures in a pan-cancer manner. Analysis of reconstructed expression for AACR Project GENIE tumors revealed expected enrichment of known driver genes within expression subtypes and enrichment of oncogenic signatures associated with distinct clinical outcomes in a cancer type specific manner.

Conclusions: Our flexible analytic framework for reconstructing gene expression profiles from clinicogenomics data substantially augments the clinical utility and value of data acquired in real-world settings.

#3520 A scalable single cell RNA-seq pipeline leveraging machine learning and high-quality references for cell-type prediction.

A. Dasgupta[1], G. Duclos[2], R. Miragaia[3], B. Manry[1], E. Jacob[2], N. Markuzon[2], A. Rotem[2];
[1]AstraZeneca US, Gaithersburg, MD, [2]AstraZeneca US, Waltham, MA, [3]AstraZeneca UK, Cambridge, United Kingdom

Single cell RNA-seq (scRNA-seq) technology transformed our understanding of biology at the cell level. Inferring cell types provide insights into the relative abundance of, and genomic differences between, different cell types. Current methods leverage known cell type markers and genomic similarity measures to attribute cell types to groups of cells.

We present a scalable machine learning-based pipeline that can leverage high quality reference annotation data to infer cell types quickly for multiple scRNA-seq experimental samples. This pipeline leverages two machine learning technologies: variational autoencoders (VAE) to create a low-dimensional representation of the reference transcriptome; and, supervised learning methods that use this representation to learn cell types from the reference data. This pipeline can quickly score new experimental data using GPU-enabled computing platforms and provide probabilities of a cell being each cell type present in the reference data.

This novel pipeline is evaluated using 5 public reference data sets. We evaluate whether VAE-based representations benefit supervised learning, compared to PCA and t-SNE. We next evaluate different supervised learning methods for predictive performance. Finally, we compare the pipeline's performance with commonly-used cell type prediction algorithms (Seurat, scANVI). We find that using a VAE is generally better than both PCA and t-SNE for feature generation to predict cell type. Using the VAE representation, there is no significant difference in accuracy between logistic regression and other supervised learning algorithms. Finally, using logistic regression as the learning machine, this pipeline is as accurate as Seurat and better than scANVI, while running about 2-5x faster than Seurat.

Algorithm	PBMC (10X)	HLCA	Eraslan snRNA	Blueprint Breast	Blueprint Lung
Our pipeline	92 (87-95)	92 (88-93)	93 (90-97)	89 (80-96)	97 (95-99)
Seurat	96 (95-97)	90 (94-98)	94 (93-97)	96 (87-98)	98 (94-99)
scANVI	91 (84-95)	72 (78-86)	92 (88-96)	94 (80-97)	88 (86-100)

Table 1 Balanced accuracy (%) from leave-one-subject-out cross-validation across 5 public data sets. Intervals are the range of the metric across the cross-validation folds.

#3521 Robust inference of PTEN deletion in prostate cancer from routine histopathology whole slide images using attention-based deep learning.

F. Scarfo[1], M. Omar[2], L. Marchionni[2];

[1]IRCCS Ospedale San Raffaele, Milan, Italy, [2]Weill Cornell Medicine, New York City, NY

The diagnostic workup of prostate cancer (PCa) requires a thorough manual histopathological inspection of prostate tissue specimens stained with hematoxylin and eosin (H&E). While immunohistochemistry and advanced molecular tests like FISH could uncover key genetic alterations, they are not cost-effective and often require special training, necessitating the development of more effective tools that can accurately infer the status of such alterations directly from the tissue morphology depicted in routine H&E-stained glass slides. PTEN deletion, which is present in 15-20% of PCa, is significantly associated with tumor aggressiveness and negative prognostic impact. Deep learning (DL) models can be trained to predict the presence of PTEN deletion on routine whole slide images (WSIs) and select patients that could benefit from further treatment. In this study, we trained and tested the performance of a weakly supervised, multiple-instance learning network on a cohort of 449 WSIs radical prostatectomy specimens stained with hematoxylin & eosin. Our model demonstrated robust performance in predicting PTEN loss based on tumor morphology alone. Through the model, we also generated attention heatmaps of the most informative tiles of each slide, allowing us to quantify the different cellular components, thus inferring the morphological features associated with PTEN loss. This study shows that DL is a potential tool that can assist the pathologist in accurately inferring the molecular status of key genetic alterations using the tissue morphology depicted in histopathology slides. Moreover, the morphological information that can be obtained by attention-based models can be leveraged to close the gap between the pathologist's morphological analysis and the interpretability of artificial intelligence models.

#3522 Application of large language models to nucleotide sequences for profiling signaling pathway disruptions in ovarian cancer patients.

D. K. Chebanov, N. S. Tatevosova;
BioAlg Corp., Covina, CA

Ovarian cancer is a challenging disease, often exhibiting recurrence after initial treatment. The complexity arises from simultaneous disruptions in multiple signaling pathways within tumor cells, rendering targeted inhibitors ineffective in providing sustained therapeutic impact. While targeted sequencing panels can identify specific therapeutically relevant events, they often fail to capture the complete picture of targetable tumor driving aberrations, and provide biomarkers relevant to disease resistance and/or recurrence. A potential solution lies in comprehensively defining the landscape of signaling pathway alterations by identifying molecular triggers underlying their dysregulation. While individual DNA mutations sometimes may not lead to carcinogenesis or changes in tumor cell behavior, combination of deactivating mutations in suppressor genes, can influence tumor development and prognosis, warranting a comprehensive delineation of their effect on the broad signaling network level. To this end, we propose the Large Language Models (LLMs), which have been successful in natural language processing, particularly in understanding context. Such tools are essential for discerning the effect of mutation combinations, their physical proximity to other mutations, and functional gene regions. We obtained mutation annotation files for 177 ovarian cancer patients from the TCGA database, reconstructing consensus nucleotide sequences using a reference genome. To input this data into LLMs, we generated embeddings for these sequences using the Nucleotide Transformer algorithm, pre-trained on 500 million variants of the reference genome. Additionally, we extracted data on detected disruptions in 10 signaling pathways (Cell Cycle, HIPPO, MYC, NOTCH, NRF2, PI3K, RTK RAS, TP53, TGF-Beta, WNT) for these patients from TCGA. Each pathway was associated with the percentage of its alteration. We trained a deep learning algorithm on these data to predict a combination of 10 numerical values, each corresponding to the percentage of disruption for a given signaling pathway. Our findings revealed that nearly half of the patients exhibited disruptions in 5 or more signaling pathways. The algorithm developed enables the determination of the extent of disruption in each pathway based on whole exome sequencing results. This approach facilitates more informed treatment strategy planning and enhances the efficient development of new drugs for ovarian cancer treatment.

#3523 Self-supervised foundation model captures high-dimensional morphology data from single cell brightfield images.

K. Saini, S. Zhang, R. Carelli, K. B. Jacobs, A. Wong-Thai, C. Luengo, V. Lu, A. Mavropoulos, A. Jovic, J. Mei, T. Vollbrecht, S. C. Boutet, M. Salek, M. Masaeli; Deepcell Inc., Menlo Park, CA

Our knowledge of cancer biology has advanced with the characterization of distinct cell types and cell states within heterogeneous tumor environments. Many methods for imaging and sorting tumor cells require biomarker labels that alter cell characteristics and create a selection bias. The use of label-free single-cell methods should further improve cancer studies involving viable, unperturbed cells for downstream assays such as RNA-Seq, cell culture expansion, and functional assays. To eliminate biomarkers and enable broader assessment of cells, we developed REM-I, a platform that characterizes and sorts unlabeled single cells based on high-dimensional morphology. Cells are captured with brightfield imaging and processed in real-time by self-supervised deep learning models to generate quantitative AI embeddings representative of cell morphology. A significant technical challenge in building REM-I was developing an AI model based on extracted features from cell images without prior knowledge of cell types, cell preparation, or other application-specific knowledge. Accordingly, we developed the Human Foundation Model (HFM), a hybrid architecture that combines self-supervised learning (SSL) and morphometrics (computer vision) to extract 115 dimensional embeddings representing cell morphology from high-resolution REM-I cell images. SSL produces a foundation model with high generalization capacity that enables hypothesis-free sample exploration and efficient generation of application-specific models. Meanwhile, computer vision extracts features that represent measurable and interpretable concepts (e.g., cell size, shape, texture, intensity). The training process for the HFM self-supervised backbone model utilizes the discriminatory power of supervised tasks. Using synthetic cells and three cancer cell lines, we trained and then validated the reproducibility and generalization capabilities of the resulting model. Results show combining deep learning and morphometrics improve interpretability of data and enable rapid characterization and classification of tumor cells with high accuracy. We also report on the Deepcell® Axon data suite, a tool to analyze data and customize reusable workflows. This includes the ability to store and manage data, visualize high dimensional data as low-dimensional projections, and train classifiers to identify and sort cell populations. To enable compatibility with user-preferred downstream analysis pipelines, Axon provides data export options for images, plots, and embeddings. Our approach allows users of all skill levels to access and interpret AI-enabled morphological profiling. Applications of REM-I include hypothesis-free evaluation of heterogeneous tumor samples, label-free cancer cell enrichment, characterization of distinct cell states, and multi-omic integration.

#3524 Leveraging ChatGPT for literature-based inference of drug-gene relationships in cancer.

Y. Shin, **M. Ning**, L.-J. Wang, Y. Huang, Y.-C. Chiu;
UPMC Hillman Cancer Center, Pittsburgh, PA

Approximately 5,000 new articles are indexed by PubMed daily, many providing critical insights into novel gene-drug relationships. However, searching and distilling the wealth of biomedical literature to infer specific pharmacogenomic relationships between a gene and a drug poses a significant burden for researchers. Recent advances in large language models, such as ChatGPT, offer a promising solution to tackle this challenge. This study aims to prototype a literature-based inference for drug-gene relationships in the context of cancer using ChatGPT, marking an exploratory effort in this emerging domain. Our approach involves developing an automated pipeline that integrates the Application Programming Interfaces (APIs) of PubMed and ChatGPT, specifically GPT-3.5. Given a gene, a drug, and a disease, the pipeline searches PubMed for relevant articles and extracts their abstracts. Leveraging prompt engineering techniques, we formulated a prompt that facilitates accurate summarization of these abstracts. The output of our pipeline includes three key components: 1) a concise, one-sentence summary elucidating the relationship between the drug-gene pair; 2) a step-by-step explanation of the inference process; and 3) the confidence level associated with the generated summary. Our approach was able to confirm well-known gene-drug relationships in cancer, such as palbociclib and *CDK4*. We further examined a challenging case of CX-5461, an inhibitor of ribosomal RNA synthesis currently under clinical investigation for various cancers. Until recent evidence emerged in 2021, this drug was mischaracterized as an RNA-Pol I inhibitor, whereas it primarily targets topoisomerase II beta (*TOP2B*). Notably, our pipeline correctly identified *TOP2B* as the primary target of CX-5461, despite an extensive body of literature prior to 2021 supporting the RNA-Pol I relationship. To evaluate the sensitivity of our pipeline, we conducted a systematic assessment using a mixture of relevant and irrelevant abstracts. Utilizing bevacizumab, VEGF, and hepatocellular carcinoma as a demonstrating example, we showed that ChatGPT achieved nearly 95% accuracy even when only 30% of the abstracts were relevant to the case. In summary, this pilot research serves as a foundational step towards the utilization of large language models in the field of drug discovery and development. Our ongoing efforts involve the rigorous evaluation of our approach across a diverse spectrum of drug targets and cancer types, as well as the optimization of prompts through state-of-the-art prompt engineering techniques.

#3525 Towards the efficient design of shared neoantigen peptide cancer vaccines using artificial intelligence.

G. Zhang[1], J. Du[1], X. Gao[1], T. Wang[1], Z. Wang[1], Q. Zhang[1], T. Liu[1], D. Chen[1], R. Zhu[1], Y. Zhao[1], C. Li[2], M. Toh[2], **L. Lai**[1];
[1]Xtalpi, Beijing, China, [2]CK Life Sciences Development Limited, Hong Kong, Hong Kong

Background: The advent of immune checkpoint inhibitors has improved morbidity and mortality for some cancers, and recent breakthroughs in gene & cell therapy have shed light on curing some types of blood cancers. However, many cancers remain intractable and the development of novel, effective and safe therapies continue to be a priority. Cancer vaccines as a cancer immunotherapy approach has seen a resurgence in recent years, due to the success of mRNA vaccines for the COVID-19. However, the accurate prediction of immunogenicity of cancer vaccines remains elusive.
Methods: Our models predict the probability of a given peptide derived from the protein of interest to be presented by MHC-I or MHC-II. For MHC-I antigen presentation model development, over 17 million entries in the dataset were collected from published literature and available databases, e.g., IEDB, with peptide lengths ranging from 8 to 11. The peptides were restricted to 150 unique MHC-I alleles. Similarly, ~4 million entries with peptide lengths ranging from 13 to 21 were collected for MHC-II antigen presentation model development, and the peptides were restricted to 19 unique MHC-II alleles. To develop advanced antigen presentation models, a language model was chosen as the backbone network and contrast learning was used to better discriminate the peptide-MHC match versus mismatch. Overall, both MHC-I and MHC-II presentation models were constructed with about 30 million parameters. To validate the model prediction accuracy, automated peptide synthesis and surface plasmon resonance (SPR) technologies were applied.
Results: Using open-sourced data, our developed AI models surpassed the performance of state-of-the-art prediction algorithms, the latest versions of NetMHCpan and MixMHCpred, for both MHC-I and MHC-II antigen presentation. Furthermore, to validate the algorithm accuracy and the peptide immunogenicity, 28 predicted patentable peptides derived from mutated TP53 protein were synthesized and their binding to respective common HLA alleles were validated using SPR. We found that greater than 80% of the peptides display binding affinities that are stronger than the positive control, suggesting that AI significantly improves neoantigen peptide vaccine design.
Conclusions: We developed advanced AI algorithms to rapidly design shared neoantigen T cell epitopes with predicted strong binding affinity to MHC-I and MHC-II. We envision that the epitopes predicted and designed by our AI algorithms possess great potential in advancing the field of off-the-shelf cancer vaccine development and hold the promise of significantly benefiting patients, once translated into the clinic.

#3526 GAIN-BRCA: A graphical explainable AI-net framework for breast cancer subtype classification using multiomics data.

J. Patel, S. K. Shakyawar, S. Sethi, C. Guda;
University of Nebraska Medical Center, Omaha, NE

Higher standards for precise distinction and classification among the four breast cancer subtypes, i.e., Luminal A, Luminal B, HER-2-enriched, and Basal, are essential to delivering customized treatment in precision oncology. The effective integration of readily accessible multi-omics datasets from the same patient may improve the accuracy of subtype prediction algorithms and help decipher reliable molecular features for the prediction and prognosis of breast cancer. Previous models for predicting breast cancer subtypes relied mostly on concatenation and autoencoder methods but rarely utilized graph-based integration to leverage the biological associations among omics datatypes. To overcome these limitations, we developed a graph-based multi-omics integration method using features from mRNA, DNA methylation, and miRNA data and synthesized features from their interactions. GAIN-BRCA computes weightage scores from miRNA-mRNA and DNA methylation-mRNA interactions to derive a new transformed feature vector without compromising biological information. The neural network architecture was designed and trained on the transformed features to classify breast cancer subtypes. Neural network prediction accuracies were compared using concatenated, autoencoder, and GAIN-BRCA-based integrated datasets. GAIN-BRCA outperforms the existing similar models MOGONET (Acc: 0.72) and moBRCA-net (Acc: 0.86) with an accuracy of 0.91. These transformed features were then processed using SHAP, and the top 357 features were selected for functional characterization and pathway analysis. We identified specific pathways and genes related to each breast cancer subtype separately. The most enriched pathways found in each subtype are ribonucleotide reductase signaling and glucocorticoid signaling pathways in luminal A, PFKB4 signaling pathway in luminal B, adipogenesis and DNA methylation and transcriptional signaling in HER2+, and the role of OCT4 in mammalian embryonic stem cell pluripotency in basal. Similarly, the most discriminated gene features are BRAF, ESR1, KRAS, MAPK1, SMARCE1, PPP3CA, and TGFBR2 in luminal A, TGFB3 and NCOA3 in luminal B, HNF4A, SIN3A, and SOX9 in HER2+, and POU5F1 and FOXA2 in basal subtypes. The GAIN-BRCA framework, combined with SHAP, weighs independent omics as cross-disciplinary rather than multidisciplinary and presents a distinctive picture for each subtype. As a result, the framework presents the importance of features about the corresponding subtype, which might lead to a greater understanding of the molecular basis of breast cancer subtypes.

#3527 Application of a deep learning based drug sensitivity prediction model on a novel anticancer drug.

N. M. Chand, V. Vishnudas, M. A. Kiebish, A. Thakurta, N. R. Narain, S. Gesta, G. M. Miller;
BPGbio Inc., Framingham, MA

Discovery of a candidate drug molecule through the preclinical stages is an iterative multiparametric process until a candidate is selected for investigational new drug submission enabling studies. This iterative approach takes up significant time and effort to design, synthesize, and test new compounds. A specific testing step is evaluation of half maximal inhibitory concentration (IC50) of compounds on cell line (CL) models. To augment CL testing, computational approaches predicting the IC50 of a drug can be used to guide choice of optimization as the molecule goes through hit to lead optimization onto candidate selection. DeepDSC [1] is a deep learning (DL) model developed to predict the IC50 in a specific CL of a given drug by integrating public data from large-scale drug screens and high-throughput RNAseq profiling. The Cancer Cell Line Encyclopedia (CCLE) [2] and Genomics of Drug Sensitivity (GDSC) [3] projects compiled pharmacological profiles of 23 and 139 drugs across 491 and 655 cancer CLs, respectively. A 10-fold cross validation (CV) approach was employed to train DeepDSC on the datasets independently and reported the average root mean squared error (RMSE) and the coefficient of determination (R^2) on the held-out sets across the folds. However, the model's generalizability to novel compounds not in the dataset, specifically compounds that are structurally dissimilar, is yet to be tested. In this regard, the DeepDSC model was retrained, with modifications, on a subset of the GDSC dataset - GDSC2 - to access the generalizability of DL models on BRG399, a proprietary microtubule targeting agent (MTA) developed by BPGbio Inc. GDSC2 was used since data generated for BRG399 and GDSC2 share the same potency assay (CellTiter-Glo [6]). The GDSC2 set was split into training and held-out sets using a 80-20 random split. Further, we chose to optimize the learning rate for both the autoencoder and feed forward networks (FFN), and the L2 regularization factor for the FFN only. Hyperparameters were optimized using 5-fold CV on the training set. Finally, we evaluated the predictive performance of the model on BRG399, which was not present in the training set. We encoded each compound in GDSC2 (n=234) using Circular Fingerprints [4] and observed an average Jaccard (or Tanimoto) distance (JD) [5] of 0.892 across 27261 drug pairs. BRG399 showed an average JD of 0.873 across 234 drug pairs, with the most similar compound JD of 0.785. Our retrained DeepDSC model had RMSE 1.15 and R^2 0.82 on the training set and RMSE 1.19 and R^2 0.86 on the held-out set. However, on BRG399 tested CLs (n=101) model had RMSE 1.84 and $R^2 < 0$, which indicated that predictions were on average worse compared to a mean-predictor model for BRG399. These results suggest that DL models that can generalize predictions to a held-out set for compounds that were present in the training set may not accurately predict IC50 of novel compounds not in the training set.

#3528 Constructing knowledge graph of N^6-methyladnosion regulations in cancer from literature using ChatGPT-4.

S. Jo[1], X. Wu[1], Y. Zeng[2], A. Das[2], T.-H. Zhang[2], D. A. Spellman[2], A. Ferris[2], S.-J. Gao[2], J. Zhang[3], Y.-C. Chiu[2], Y. Huang[2];
[1]University of Pittsburgh, Pittsburgh, PA, [2]University of Pittsburgh School of Medicine, Pittsburgh, PA, [3]The University of Texas at San Antonio, San Antonio, TX

N^6-methyladenosine (m^6A) is the most abundant mRNA modification with a crucial role in cellular processes. Its involvement in cancers is well-established. Dysregulation of m^6A is linked to cancer initiation, progression, and therapy resistance, impacting the tumor microenvironment (TME) and promoting metastasis. Understanding m^6A's regulatory role in cancer is essential for identifying new therapeutic targets. We considered the construction of a knowledge graph (KG) representing molecular regulatory mechanisms (MRMs) of m^6A in healthy conditions and different cancers from PubMed papers. Such a KG consists of interconnected triplets of (head node, regulatory relationship, tail node), each denoting regulation between genes or a gene and a phenotype/process. Advances in natural language processing (NLP) have provided tools such as SemRep and GNBR to automate the extraction of these triplets from the literature. However, these methods don't extract contextual information, such as the type of cancers or cells in which these MRMs occur, leading to contradictory regulations in the constructed KG. In addition, existing approaches were designed to extract generic regulatory relations and therefore struggled in properly capturing unique concepts associated with m^6A regulatory mechanisms. To tackle this challenge, we designed a novel ChatGPT-4 prompt to extract relational graphs from papers tailored for m^6A regulatory mechanisms. An annotated dataset of 400 titles on m^6A-related MRMs were created to evaluate the performance. We then applied the prompt to 1023 papers to create a m^6A Molecular Regulatory Mechanism Knowledge Graph (m6A-MRM-KG). This graph illuminates m^6A's roles in gene expression regulation, especially in cancer and immunity. Anticipated to enhance our understanding of cancer development, it provides insights into potential therapeutic strategies. The m6A-MRM-KG not only organizes information but also empowers researchers to uncover novel insights in the dynamic relationships of m^6A modifications in diverse biological contexts.

#3529 Leveraging deep learning for fully automated analysis of pre-clinical mouse positron emission tomography.

H.-Y. Lee, M. Goryawala, T. Sproul, M. Louie, D. Suhy;
Earli Inc., Redwood City, CA

Turning early-cancer diagnosis into actionable treatment often relies on highly accurate and sensitive imaging techniques to guide surgical intervention or to monitor therapeutic efficacy. Earli is developing a highly sensitive, orthogonal approach that uses genetic constructs to usurp dysregulated cancer pathways to force the tumor to produce a PET reporter gene, enabling the use of radiotracers amenable to positron emission tomography/computed tomography (PET/CT) to guide precision imaging. However, analysis of PET/CT images using standard manual and semi-automated methods is challenging resulting in reduced experimental throughput and user variability, highlighting the need for a fully automated PET/CT analysis pipeline using Deep Learning (DL). To increase pre-clinical throughput and reduce inter-user variability, we developed an automated DL processing pipeline in Python to perform three major tasks: separation of multi-mouse bed data for PET uptake quantification by mouse, segmentation of tumors and background organs, and quantification of PET signal for PK/PD analysis. Preclinical PET/CT data was acquired using a 4 animal, multi-mouse bed and separated into individual mice by co-registering the reconstructed CT image against a multi-mouse bed reference mask using a rigid 3D Euler transformation algorithm and cropping at fixed indices. Following mouse separation, a 3D nnUNet architecture is used to perform semantic segmentation of regions of interest (ROI) on CT for bi-hemispheric subcutaneous tumors, lungs, liver, kidneys, spleen, and the bladder. nnUNet was trained on PET/CT of 311 mice consisting of a mixture of naïve and tumor-bearing animals subcutaneously implanted with H1299 cells using a five-fold cross-validation strategy with 1000 epochs per fold. Model performance was evaluated by comparing the network prediction to the reference manually annotated masks using the Dice coefficient. PET uptake is reported as percent injected dose per milliliter (%ID/mL) or standardized uptake value (SUV). Segmentation performance results for the hold-out set identified mean Dice scores greater than 0.80 for all ROIs, reflecting the similarity between model predictions and human annotations. The automated pipeline reduced the analysis time from 5.5-6 hours per mouse when using traditional manual/semi-automatic approaches to approximately 15 minutes. In summary, we developed a fully automated DL-based PET/CT quantification pipeline for pre-clinical mouse studies that provides accurate ROI segmentation and PET uptake quantification, significantly increasing experimental throughput and reducing inter-user variability. Further improvements to model inference include loss functions weighted for poor performing ROIs and addition of lung nodule segmentation for eventual translation to humans as an accompaniment to Earli's theranostic programs.

#3531 PRESS*NET*: Patient stratification and biomarker discovery using multi-modal knowledge graph framework.

K. C. Bulusu[1], J. Cohen-Setton[1], I. Kagiampakis[2], M. Goncalves[1], G. Edwards[1], S. Jayabalan[3], S. Shikare[1], K. Tsang[1], B. Sidders[1], E. Jacob[3];
[1]AstraZeneca UK, Cambridge, United Kingdom, [2]AstraZeneca US, San Francisco, CA, [3]AstraZeneca US, Waltham, MA

Background: Multiomics data is critical to obtain a near comprehensive picture of disease progression and drug response. In addition, the generation of response and survival biomarkers, and the segmentation of patients into subtypes with distinct, actionable 'omic signatures and survival trajectories, is vital for personalised medicine research and successful trial design. However, as the volume and diversity of data increases, so too does the challenge of effective multiomic data integration. Knowledge graphs (KGs) can capture heterogeneous data and relationships between entities in a flexible and scalable data structure, making them suitable for this domain. We have developed PRESS*net*, a framework for building Patient KGs and analysing clinical data for novel patient stratification hypotheses and clinical biomarker discovery.

Methods: PRESS*net* is an end-to-end framework that turns raw patient data into graph-derived insights. Firstly, the user chooses which modality files to include, what assumptions to make about data processing, and which graph algorithms to use. PRESS*net* then automatedly creates a patient KG of the input data, where nodes represent patients and their associated features. In addition, biomedical prior knowledge, for example in the form of gene-pathway or gene-gene relationship data, is also integrated with the graphs. Insights are generated from the KG via community detection, graph embedding generation, and graph neural networks; these generate hypotheses for novel patient subtypes or biomarkers for clinical outcomes. As graph algorithms capture interrelationships between nodes, PRESS*net* offers biomarkers that are composite, i.e. that can contain features from multiple 'omics and clinical features.

Results: We applied PRESS*net* to the MSK 2022[1] cohort of IO-treated LUAD patients, and it uncovered prognostic composite biomarkers that stratified biomarker-positive patients from the whole cohort with a p value < 0.001 (95% CI) for OS, including known markers of poor prognosis such as STK11, RBM10, KRAS and KEAP1 mutations, and high neutrophil/lymphocyte ratio. We also generated embeddings of patients in the cohort and predicted survived/deceased status with an AUC of 0.82, outperforming published state-of-the-art.

Conclusions: We have successfully developed a generalisable framework for generating insights from patient data using state-of-the art knowledge graph data science. PRESS*net* can generate novel stratification and biomarker hypotheses that can potentially inform the next generation of IO targets and clinical biomarkers.

#3532 Transforming genomic data into images for enhanced deep learning in precision oncology.

M. Islam, L. Xing;
Stanford University School of Medicine, Palo Alto, CA

Purpose: In the realm of cancer treatment and research, the analysis of genomic data stands as a cornerstone for diagnosis and therapy. Recognizing this, our study embarks on an ambitious journey to revolutionize how we interpret such data. By converting complex genomic data into a two-dimensional (2D) image format leveraging feature correlations, we pave the way for more profound insights and applications in clinical decision-making. This innovative approach utilizes 2D convolutional neural networks (CNNs) to analyze these structured images, promising a leap forward in the accuracy and utility of such data.

Methodology: The core of our method involves a novel transformation of tabular genomic data into an image format. We start with m patient samples, each characterized by n genes, and calculate a pairwise correlation matrix to capture the intricate relationships between these genes. Concurrently, we generate an Euclidean distance matrix that represents the distances between n points in a 2D grid. The next step involves the optimization of the Gromov-Wasserstein discrepancy to align these two matrices, resulting in a transformation matrix, T. When applied to the tabular data, T transforms it into m distinct, informative images. These images are then processed using a 10-layer CNN, comprising a convolutional layer (3x3 kernel), three dense layers, two relu layers, and a dropout layer.

Data Sources: We created images, termed 'genomaps', from genomic data collected from three diverse patient groups: 130 individuals (cancerous and normal) from Stanford Hospital, 230 breast cancer patients from The Cancer Genome Atlas (TCGA), and a larger group of 1572 patients from the Memorial Sloan Kettering (MSK) Cancer Center. The created genomaps are visually interpretable, offering clear differentiation between cancerous and non-cancerous samples, which is pivotal for accurate analysis.

Outcomes: Our method demonstrates a remarkable 8% improvement in survival prediction accuracy in comparison to the existing methods. The employment of DeepSHAP in our analysis has allowed us to identify critical genes with greater precision than conventional methods. The p53 gene family, notably TP53 and TP63, was identified as significantly mutated in over 50% of all cancer types analyzed. Another critical discovery was the ERBB gene family, encompassing EGFR, ERBB2, ERBB3, ERBB4, which plays a dual role in tumor proliferation and influencing the immune response against tumors, a factor critical for immunotherapy strategies.

Conclusion: This research introduces a transformative approach to represent genomic data, utilizing 2D CNNs for in-depth analysis. It sets a new benchmark in classification and regression accuracy, offering a more interpretable pathway for biomarker discovery, significantly contributing to the field of personalized medicine and cancer research.

#3533 Spatially Resolved Laser-Activated Cell Sorting (SLACS) and AI integration for enhanced pathological analysis and biomarker discovery.

H. Jang[1], A. C. Lee[2], S. Lee[2], S. Kwon[1];

[1]Seoul National University, Seoul, Korea, Republic of, [2]Meteor Biotech, Seoul, Korea, Republic of

This study focuses on the integration of Artificial Intelligence (AI) with Spatially Resolved Laser-Activated Cell Sorting (SLACS) for enhanced pathological analysis and biomarker discovery. The primary approach involves using AI to automatically analyze slide images, identifying critical areas associated with diseases such as cancer or cells emitting specific signals. AI algorithms efficiently segment these significant regions or cellular groups, facilitating targeted analysis.

Following the AI-driven segmentation, SLACS comes into play, isolating the identified cells from the slide for further examination. This precise sorting allows for the focused study of cells relevant to disease processes, enhancing the efficiency and accuracy of pathological analysis.

The separated samples obtained through SLACS are then subjected to detailed analysis. This step is crucial for understanding the cellular mechanisms at play in disease states and for the identification of potential biomarkers. These biomarkers are vital for developing targeted therapeutic strategies and advancing personalized medicine.

By combining AI's advanced image processing and pattern recognition capabilities with the precision of SLACS, this integrated approach significantly improves the identification and analysis of disease-related cellular characteristics. It streamlines the process of isolating and studying specific cell populations, contributing to a deeper understanding of disease mechanisms and progression.

In conclusion, the synergistic application of AI and SLACS represents a significant advancement in pathological research and biomarker discovery. This methodology not only enhances the accuracy of disease marker identification but also opens new avenues for research and clinical application.

#3534 GeneLLM: Unveiling gene functions through literature-driven transformer embeddings.

A. Jararweh, K. Virupakshappa, O. S. Macaulay, A. Segura, O. M. Oyebamiji, Y. Hu, A. D. Sahu;
University of New Mexico, Albuquerque, NM

INTRODUCTION: Our understanding of gene properties has advanced through representation learning such as Alpha fold. Representation learning involves encoding the relationships between genes by embedding them into a numerical space. These embeddings, which capture complex genetic interactions and characteristics, can then be leveraged by machine learning models to predict various gene properties. Current embeddings derive from transcriptome or sequence data. Over the past 150 years, numerous experimental assays have uncovered gene functions and interactions- comprehensive knowledge documented in the literature but not always evident in transcriptome or sequence data. It has been posited that leveraging this knowledge to create gene embeddings; however, could result in machine learning models biased towards well-studied genes.

METHODS AND RESULTS: We tested this hypothesis by developing a novel knowledge-embedding framework, GeneLLM. During training, GeneLLM learns to comprehend summaries of every gene- a compressed form of published knowledge- using Large Language Models (LLMs), fine-tuned for downstream tasks mapping cellular properties and biochemical processes. Despite the expected bias towards well-known genes, GeneLLM surprisingly showed high predictive power for an array of gene properties. Compared to baseline models, GeneLLM boosted an increase in performance of 20.3% correlation in gene conservation across species, 8.6% and 57.2% prediction accuracy in subcellular localization and gene ontology respectively. GeneLLM also showed competitive results on solubility prediction with 0.91 accuracy and a correlation of 0.71 for tissue-specific expression levels for 1001 cell lines. We also showed that the bias toward well-known genes could be mitigated by combining GeneLLM representation with transcriptome or sequence-based embedding. The combined embeddings exhibited superior performance to their individual components which suggests that GeneLLM extracts views complementary to existing embedding methods.

CONCLUSION: The GeneLLM framework demonstrates the ability of LLMs to extract information from the rich knowledge available about the nexus of genes and their cellular traits. It also illustrates how bias in knowledge representation is complementary to other transcriptome and sequence-based information. This ability of GeneLLM to advance our understanding of genes, their roles in cellular processes, and their impact on oncogenesis, as well as in response and resistance mechanisms, highlights its potential in cancer research.

#3535 Seeking novel therapeutic targets in oncology using machine learning.

M. Quazi[1], S. Sirimulla[1], C. G. Bologa[2], A. Pushechnikov[1], N. Savchuk[1], **T. I. Oprea**[1];
[1]Expert Systems, Inc., San Diego, CA, [2]University of New Mexico School of Medicine, Albuquerque, NM

We developed 42 machine learning models using Knowledge Graphs (KGML), informed by data from Pharos (1), based on major resources like DepMap (2), Reactome (3), and STRING (4). Focused on 41 blood cancers, we utilized cancer-specific positive genes and 440 shared negative genes, using metapath and XGBoost (5).

Analysis of the top 500 genes from each model revealed 3,842 genes strongly linked to cancers, with 519 classified as “Tchem,”i.e., small molecule modulators are known (6). We focused on Tchem proteins given the notion that small molecules perturbing these proteins are already known, which accelerates drug discovery. A separate, 1SVM (one-class support vector machine) model was built using mode-of-action drug targets (6) (Tclin, N = 704) as input. This 42nd model evaluates the likelihood that a gene shares the characteristics of Tclin targets (“Tclin-like”). Of the 519 Tchem genes, 132 have “Tclin-like” probability above 50%. The top five “Tclin-like” genes are GAPDH, AKT1, HRAS, TLR4 and TP53, respectively; their role in cancer is well studied.

Our focus shifted to 19 genes that have limited or no known cancer associations, as evaluated by the DISEASES platform (7) - see Table 1. Three genes (LPAR5, GPR18 and FCER2) are associated with primary bone diffuse large B cell lymphoma, and 2 (ADCY1 and PLD1) with B cell prolymphocytic leukemia. Additional studies may elucidate their role in these malignancies. Five genes (IRAK3, EPHB1, ITPKB, ACVR2B and CAMK2D) are predicted to be relevant in 10 or more blood cancers. Machine learning may uncover overlooked, but potentially promising drug targets for leukemias, lymphomas and myelomas.

#3536 Paracell: A high throughput, deep learning-based pipeline for single-cell phenotypic profiling.

D. L. Nguyen[1], J. T. Chao[2];
[1]Queen's University, Kingston, ON, Canada, [2]Sunnybrook Research Institute, Toronto, ON, Canada

Variants of uncertain significance constitute the vast majority of missense variants, hampering the utility of genetic testing, despite its remarkable impacts on clinical diagnosis and decision-making. Although the sequencing and interpretation of genetic variants have been drastically improved in recent years, only about 2% of novel missense variants are currently clinically actionable. Therefore, a robust and scalable pipeline is desperately needed to provide functional evidence critical for variant interpretation. In this work, we demonstrate Paracell, a deep learning-based phenotypic profiling pipeline that leverages subcellular segmentation, high-dimensional single-cell phenotyping, and machine learning to classify the functional impact of variants. Paracell captures heterogeneity in cellular phenotypes and protein colocalization between variants and their signaling partners, as well as subcellular markers, and enables analysis at a single-cell resolution. Using a classification model trained on single-cell features extracted by Paracell, we were able to accurately classify cells from loss-of-function (LoF) variants based on their impact. After aggregating cellular profiles on a variant level, our pipeline was able to distinguish LoF variants from functional ones with high sensitivity and specificity. Our work demonstrates that Paracell is a robust and scalable method that can sensitively detect differences in single-cell phenotypic profiles. The systematic application of this pipeline will provide valuable functional evidence for variant interpretation, enhancing their clinical utility and accelerating personalized cancer care.

#3537 Assessing machine learning models of drug response predictions using orthotopic patient-derived xenograft.

Y.-H. Chien, R. Pippa, W. Andrews, J. Rodriguez, K. Buck, D. Gorospe, E. Valencia, B. Carapia, E. Eastwood, J. Sperry, J. Nakashima, L. Do;
Certis Oncology Solutions, San Diego, CA

Accurate prediction of drug response using machine learning (ML) remains a significant challenge in drug development as well as in personalized cancer therapy. Furthermore, there is a scarcity of rigorous external validation studies for evaluating drug response prediction models. Even when available, such validations are often confined to in-vitro studies. Orthotopic patient-derived xenograft (O-PDX) mice serve as essential preclinical models that closely replicate the human tumor microenvironment and assess the therapeutic response to cancer treatments. We present CertisAI^{TM}, a novel ensemble of machine learning models that have been trained on a vast array of experimental high-throughput screenings of both monotherapies and combination therapies, incorporating over 4500 investigational and FDA-approved drugs across 10 major cancer indications. The results of our ML drug response prediction models show an average R^2 of 0.75 and RMSE of 0.62 (across internal 5-fold cross-validation) for all 10 cancer prediction models. Our evaluation of CertisAI's drug response predictions within O-PDX pharmacology studies has shown a notable overall correlation between actual observed tumor growth inhibition (TGI) and predicted TGI, with an r value of 0.45 across seven indications. The most accurate prediction model achieved an r value of 0.7 for colorectal cancer, encompassing 37 treatments in 6 O-PDX studies. Altogether, these results highlight CertisAI’s potential in enhancing pre-clinical model selection as well as personalized treatment strategies in oncology.

Poster Session

#3541 Systematic assessment of the mechanism of action landscape of glue compounds.
L. Hu, C. Karan, A. Califano;
Columbia University Irving Medical Center, New York, NY

We have recently completed a large-scale project to elucidate the Mechanism of Action (MoA) of clinically relevant compounds in over twenty tumor specific contexts. Many novel, translationally relevant findings have arisen from this work, including (a) the identification of context-specific inhibitors of many proteins considered to be poor pharmacologic targets—including transcription (co-)factors and undruggable signaling proteins; (b) graph theory-based elucidation of drug polypharmacology; and (c) identification of MoA overlap between previously unrelated drugs. However, a limitation of the study is it relies on the existing repertoire of small-molecular inhibitors that is heavily biased towards specific target classes. Compounds that inhibit master regulators (MR) of tumor state are missing or under-represented. In this new project, we explore an extra molecular space of “molecular glues”, as they might be more effective modulators of MRs. Similar to our prior oncology drug study, we will leverage the automated PLATE-Seq technology and the VIPER algorithm to characterize compound MoA in a proteome-wide fashion. Specifically, we will first generate genome-wide RNA-Seq profiles of patient-matched cell lines using a panel of ~150 glue compounds, including a subset of them named PROteolysis TArgeting Chimeras (PROTACs) that were designed to degrade therapeutic targets by recruiting them to E3 ligases. We will analyze the PLATE-seq perturbational profiles with a set of complementary algorithms including the VIPER, which, akin to a multiplexed, tissue-specific gene reporter assay, can accurately measure the differential activity of over 6,000 regulatory/signaling proteins, by assessing the enrichment of their transcriptional targets in differentially expressed genes. Current effort of this project is focused on six PDA cell lines including three MAPK-pathway dependent (M+) and three MAPK-pathway independent (M-) contexts, each one representing the gastrointestinal lineage state (GLS), morphogenic state (MOS), and acinar to ductal metaplasia-like state (ALS). Using this data, we explore similarity-based connections between PLATE-seq perturbational profiles and the Connectivity Map (CMAP) that contains transcriptional consequences of chemical and genetic perturbations. We will also compare PLATE-seq perturbational profiles to tissue-specific differential expression signatures that distinguish cell lines sensitive to compounds in the Cancer Therapeutics Response Portal (CTRP) and Broad Repurposing Hub, each of which houses results from exposing hundreds of compounds exposed to dozens to hundreds of cell lines. Taken together, the data and analyses will help understand MoAs and polypharmacologies/off-targets of molecular glues, which also serve to enable interpretation and prioritization of new candidate MoA for molecular glues by comparing them to compounds with known targets and MoAs.

#3542 The Chemical Probes Portal: An essential resource providing expert advice on chemical tools for cancer research.

Domenico Sanfelice[1], Albert Antolin[2], Alisa Crisp[1], Yi Chen[1], Paul Brennan[3], Susanne Muller[4], Bissan Al-Lazikani[5], Aled Edwards[6], Paul Workman[1]

[1]The Institute of Cancer Research, Sutton, United Kingdom,[2]ProCURE, Catalan Institute of Oncology, Oncobell, Bellvitge Institute for Biomedical Research (IDIBELL), Barcelona, Spain,[3]University of Oxford, Oxford, United Kingdom,[4]Institute of Pharmaceutical Chemistry, Johann Wolfgang Goethe University; Structural Genomics Consortium (SGC), Buchmann Institute for Life Sciences, Johann Wolfgang Goethe University., Frankfurt, Germany,[5]Department of Genomics Medicine and the Institute of Data Science in Oncology, MD Anderson Cancer Center, Houston, TX,[6]Structural Genomics Consortium, University of Toronto, Toronto, ON, Canada

Background: The Chemical Probes Portal (Portal) serves as a vital resource in the realm of cancer research and biomedical science generally - offering expert guidance on high-quality chemical tools, usually protein inhibitors, crucial for studying physiological and pathological processes and validating therapeutic targets. Researchers often grapple with selecting suitable chemical probes, inadvertently utilizing tools ill-suited for their purpose, and not following best practice, thereby contaminating the scientific literature and wasting valuable time and resources. To address this challenge, the Portal (https://www.chemicalprobes.org) was established as a non-profit, independent online platform, meticulously curating, annotating, and scoring the quality of chemical probes and providing associated information and advice.

Results: The Portal stands apart as the sole expert-curated public resource evaluating the quality and utility of small-molecule chemical tool compounds for use in cancer research and wider biomedical research. More than 250 experts, comprising scientific leaders in chemical biology, medicinal chemistry, pharmacology, and related fields, contribute their experience and insights to assess featured chemical probes. Since 2021, a progressively updated and enhanced version of the Portal has been operational, housing over 1000 compounds targeting 500+ proteins across diverse families, now including PROTACs and molecular glues. We also flag 254 ‘Unsuitables’, which are compounds that should not be used to interrogate a specific protein target. Additionally, the Portal now offers informative pages, providing advice delineating guidelines for selecting well-validated compounds, including those suitable for rodent studies, necessitating specific pharmacokinetic and pharmacodynamic properties. Best practice use requires employing high-quality chemical probes from more than one distinct chemical class that target the same protein, incorporating an inactive control compound, and following the recommended concentration range - all aimed at mitigating off-target risks.

Conclusion: The enhanced Chemical Probes Portal provides a vital platform for researchers to navigate and evaluate chemical probes, easily and effectively. It employs a rigorous expert review to ensure the quality of the probes listed. The resource not only aids high-quality probe selection but also provides advice through an Information Centre, offering guidelines, FAQs, and additional information on probe criteria and use. The continuous expansion and outreach efforts aim to make the Portal an indispensable tool for cancer researchers and the broader biomedical research community. Researchers are encouraged to participate in the Portal's development and contribute to the robustness of chemical probe use in scientific endeavors.

#3543 TWNeoDB: A web-based database for tumor neoantigens in the Taiwanese population.

Y.-H. Tseng[1], C.-H. Wu[1], C.-Y. Sung[1], H. K. Yang[2], M.-H. Tsai[1], L.-C. Lai[1], T.-P. Lu[1], K. C. Chao[2], E. Y. Chuang[1], C.-Y. Lee[3];
[1]National Taiwan University, Taipei, Taiwan, [2]China Medical University, Taichung, Taiwan, [3]National Taipei University of Technology, Taipei, Taiwan

Tumor neoantigens are highly immunogenic. Two types of neoantigens have been reported for their ability to be shared among patients. One is a mutated tumor-specific antigen (mTSA) derived from somatic mutations in tumor cells. The other is an aberrantly expressed TSA (aeTSA), influenced by epigenetic changes or abnormal RNA splicing. Tumor neoantigens can bind with the major histocompatibility complex (MHC) and be recognized by the T cell receptor (TCR). Consequently, they can trigger the immune system to attack cancer cells. Until now, some neoantigen databases have been available, they mostly focus on the Western population and primarily contain peptides derived from mTSAs. In contrast, our database provides peptides not only from mTSA but also from aeTSA with a strong emphasis on the Taiwanese population.

Initially, we obtained public sequencing raw data from the NCBI database and employed a neoantigen pipeline for analysis, identifying potential neoantigens. The data collection criteria included samples from Taiwanese individuals, with paired DNA-seq or RNA-seq from both normal and tumor tissues of the same patients. RNA sequencing datasets were utilized to identify aeTSAs and mTSAs, whereas DNA sequencing datasets served for mTSA identification. Additionally, human leukocyte antigen (HLA) genotyping was performed for every sample. The identified peptides were further compared to previously validated data available on IEDB. This data was used to develop a web-based database with several functionalities. Users can search for specific peptides and download relevant data from the website. The website also included data cross-referenced and validated with IEDB. In addition, we incorporated clinically validated peptides capable of stimulating T cells to release cytotoxins or interferons. A machine-learning-based LightGBM model was trained to predict immunogenicity for these peptides through a series of cross-validations based on random data splitting. Users can access comprehensive information on tumor-specific peptides in the online database.

We collected sequencing data from 243 patients, spanning five different types of cancer. The predominant HLA genotype is HLA-A*11:01, a common allele in the Taiwanese population. Peptide characteristics, such as hydrophobicity, binding affinity, and binding stability, have been calculated and stored in the database. Notably, the LightGBM model excelled in predicting immunogenicity, achieving an AUC of 0.95 on the training dataset and 0.8 on the testing dataset. Implemented in the online database, this model allows users to forecast their own candidates. The state-of-the-art database serves as a comprehensive platform for gathering Taiwanese-specific neoantigens, contributing to the advancement of personalized cancer vaccines and immunotherapies.

#3544 OncoKB™, MSK's precision oncology knowledge base: 2023 updates.

S. P. Suehnholz, **M. Nissan**, H. Zhang, R. Kundra, C. Lu, A. Dhaneshwar, N. Fernandez, B. Preiser, M. E. Arcila, M. Ladanyi, M. F. Berger, A. Syed, A. Brannon, R. Levine, A. Dogan, A. Drilon, D. B. Solit, N. Schultz, D. Chakravarty;
Memorial Sloan Kettering Cancer Center, New York, NY

OncoKB™ is Memorial Sloan Kettering Cancer Center's (MSK) FDA-recognized precision oncology knowledge base that contains detailed, evidence-based information about the oncogenic effect and therapeutic implications of individual somatic mutations and structural alterations present in patient tumors. Since its public release in 2016, OncoKB™ has expanded to include annotation for >7,500 alterations in ~820 cancer-associated genes. OncoKB supports variant interpretation by the cBioPortal for Cancer Genomics, is used to annotate >15,000 MSK patient sequencing reports annually and its data is publicly available through the website (www.oncokb.org). Programmatic access to OncoKB™ data via its web-based API is freely available to users in an academic setting while users from commercial and hospital settings require a fee-based license.

OncoKB™ utilizes its Therapeutic Levels of Evidence system to classify variants based on their tumor type-specific sensitivity or resistance to matched standard care or investigational targeted therapies. To date, OncoKB includes 49 Level 1 genes as well as MSI-H and TMB-H (included in the FDA drug label), 24 Level 2 genes (included in professional guidelines), 35 Level 3A genes (predictive of drug response in well-powered clinical studies), 27 Level 4 genes (predictive of drug response based on compelling biological evidence), and 11 R1/R2 resistance genes. In 2023, OncoKB™ captured the following notable changes in precision oncology drug development: Level 1 annotation of *ESR1* ligand-binding domain mutations in breast cancer and promotion from Level 2 to Level 1 of *ERBB2* amplification in colorectal cancer following the FDA drug approvals of elacestrant and tucatinib + trastuzumab, respectively. Additionally, KRAS G12C became a Level 2 biomarker in pancreatic and colon cancers with the listing of adagrasib and sotorasib as systemic therapy options for *KRAS G12C*-mutant disease in the NCCN pancreatic and colon cancer guidelines. *IDH1/2* mutations in low grade glioma were annotated as Level 3A based on compelling clinical evidence demonstrating response to the *IDH*-specific inhibitor vorasidenib. Lastly, noting emerging data with the *KRAS* G12X-specific inhibitor, RMC-6236, OncoKB™ included all alleles at *KRAS* position G12 as Level 4.

In sum, six novel clinically actionable biomarkers (all Level 1) and 14 follow-on precision oncology therapies for existing leveled biomarkers were added to OncoKB™ in the past year. OncoKB™'s current focus includes coverage of additional cancer-associated genes, annotation of germline alterations and incorporation of OncoKB™ data into an electronic health record system.

#3545 Atlas of therapeutic targets: Evolution of druggable proteome.

I. Babic, **E. Nurmemmedov**;
Nerd Bio, San Diego, CA

Selection of therapeutic targets and modalities is of fundamental importance in drug discovery, as it can have a direct impact on the economics of drug discovery as well as its success rate. With the advancement of chem-bio and proteomics methods together with advent of artificial intelligence, the scope of the druggable proteome is expanding. The choice of drug targets gains further importance as we link it to potential clinical efficacy and safety, genetic variation and patient populations. Drug targets are often selected based on inadequate understanding of target biology, tractability by existing toolbox of therapeutic modalities and insufficient insight into possible clinical outcome. We have developed an “Atlas of Therapeutic Targets”, an interactive resource that provides classification of drug target families with linked information on clinical and investigational drugs. The atlas also provides key insights and score for tractability of targets with various therapeutic modalities. Particularly, our scoring system grades the targets on dimensions such as ligandability, involvement in protein-protein complexes, structural disorder, hotspot analysis and cross-referencing with known targets, thus yielding a total tractability score of 1-10. Dissection of targets based on such dimensions, enables critical evaluation therapeutic modalities as well tools and methodologies needed for their conversion into successful drug discovery programs. We curate 900+ human drug targets, analysis of which indicates the continued dominance of privileged target families across disease areas, but also the growth of novel first-in-class mechanisms. This atlas will be available as a resource for the wide drug discovery community.

#3546 Putting genes in context by linking gene signatures to established cancer hallmarks.

O. Menyhart, W. Kothalawala, B. Győrffy;
Semmelweis University, Budapest, Hungary

The concept of the "Hallmarks of Cancer" provides a valuable framework for understanding fundamental organizing principles common to various types of cancers. However, the absence of a consensus gene set for cancer hallmarks poses data comparison and integration challenges, resulting in diverse biological interpretations across studies.

Here, we first established a consensus cancer hallmark-gene set by merging data from available mapping resources. We searched the scientific literature for relevant publications from which a list of hallmark genes could be reconstructed. By consolidating data from seven publications, we identified 6,763 candidate cancer hallmark genes associated with ten cancer hallmarks. Of these, 1574 genes were part of at least two resources, forming a "core" hallmark gene set.

Then, we compared the enrichment of cancer hallmarks by analyzing the prognostic genes associated with overall survival across twelve solid tumor types. Notably, the hallmark "tissue invasion and metastasis" was most prominent in the stomach (p=1.2E-11), pancreatic (p=1.5E-09), bladder (p=1.8E-08), and ovarian cancers (p=0.0002), aligning with their heightened potential to spread. "Sustained angiogenesis" predominated in lung squamous carcinomas (p=4.5E-08), while "genome instability" showed strong enrichment in lung adenocarcinomas (p=1.3E-09), liver (p=1.4E-10), pancreatic (p=1E-5) and kidney cancers (p=0.0025). Compelling evidence links lifestyle choices like alcohol consumption and smoking to genomic instability across tumors, suggesting a potential common underlying mechanism of tumorigenesis.

Pancreatic cancers displayed the highest enrichment of hallmarks (8 out of 10), emphasizing the disease's complexity, while in melanomas, liver, and kidney cancer, a single hallmark („genomic instability") was enriched among the prognostic markers of survival. These findings underscore the utility of the hallmark concept as an effective organizational tool, particularly when establishing a clear connection between genes and biological functions.

Finally, we integrated the data into a publicly accessible and user-friendly online tool (available at www.cancerhallmarks.com) that allows users to identify the most relevant cancer-associated "candidate hallmark genes" in their datasets.

In summary, we have established a consensus list of genes associated with cancer hallmarks. The analysis of survival-associated genes revealed a unique pattern of hallmark enrichment for each tumor type.

#3547 The ISB Cancer Gateway in the Cloud (ISB-CGC): Access, explore and analyze large-scale cancer data through the Google Cloud.

F. Seidl[1], L. Hagen[2], J. Wilson[1], B. Aguilar[2], D. Bleich[1], L. Wolfe[2], P. Gundluru[1], P. Venkatesan[1], M. Tian[2], S. Paquette[2], E. Lee[2], D. Huffman[1], D. Pot[1], W. Longabaugh[2];

[1]ISB-CGC, Rockville, MD, [2]ISB-CGC, Seattle, WA

Rapid growth of cancer data in recent decades has made data discovery and wrangling difficult for the average cancer research lab. Our mission at the ISB Cancer Gateway in the Cloud (ISB-CGC), part of the NCI's Cancer Research Data Commons ecosystem, is to democratize access to large cancer datasets. Funded by the NCI, we have performed ETL processes on data from GDC and PDC projects such as TCGA, TARGET, and CPTAC. We generated hundreds of BigQuery tables containing data such as mutations, gene expression, and protein abundance, which enable data analysis in the cloud via SQL. BigQuery analyses are inexpensive and rapid even when scaled to petabyte sized inputs, for example we ran 6.6 billion correlations in 2.5 hours with a total cost of about one dollar. These data can also be accessed affordably from Google Cloud VMs where researchers can develop analysis pipelines in Python, R, and workflow languages such as CWL. We present two recent collaborations: In one BigQuery was used to develop machine learning algorithms that calculated genetic risk scores from TCGA glioblastoma and ovarian cancer copy number variation. In another example researchers combined SQL queries of our BQ tables with data from the ISPY2 Trial initiative and generated an R shiny app that can dynamically create data visualizations for genes of interest in different TCGA cohorts.

#3548 OKAIN: A comprehensive oncology knowledgebase for the interpretation of clinically actionable alterations.

Z. Yang, M. Wang, H. Qin, Y. Yu, Y. Zheng, Z. Li, X. Meng, X. Dong, L. Wang, K. Wang, A. Wang;
OrigiMed Co., Ltd, Shanghai, China

Background: The increased use of Next-Generation Sequencing (NGS) in clinical genetic testing has resulted in the identification of several genetic variations with possible therapeutic implications. Several knowledgebases, such as OncoKB, have been curated to better understand the clinical implications of somatic mutations in cancer. While thorough annotation of gene variations of Chinese pharmaceuticals is not recorded in the majority of those databases. As a result, we developed OKAIN (https://szcube.origimed.com), an algorithm tool that assesses clinically actionable mutations using a precision oncology knowledge database.
Methods: OKAIN employs a weighted evidence analysis system to deliver final clinical annotation outcomes for intricate variations. This process commences with a weighted analysis of all therapeutic efficacy evidence for a specific genomic variant related to a particular drug, to determine the highest degree of efficacy for that drug. The top efficacy level is then assessed against numerous variants of the gene, resulting in efficacy data for all variants of the gene in relation to the medication.
Results: To date, OKAIN has collected 15,654 pieces of evidence on 471 genes associated with cancer. This comprises 2,600 pieces of Level A evidence (included in FDA/NMPA labeling or clinical professional guidelines) on 66 genes, 180 Level B evidence (included in extensive retrospective studies or prospective investigations) on 31 genes, 676 Level C evidence (included in small-scale retrospective studies or early-stage prospective studies) on 81 genes, and 5,562 Level D evidence (included in case reports and preclinical studies) on 188 genes. For Level A evidence, 864 pieces of evidence were derived from either the NMPA label or CSCO guidelines. As an illustration, Befotertinib was approved by NMPA as a first-line treatment for locally advanced or metastatic non-small cell lung cancer (NSCLC) in adult patients with either *EGFR* exon 19 deletion or L858R mutation. This indicates that adult Chinese patients with locally advanced or metastatic NSCLC who have *EGFR* exon 19 deletion or L858R mutation can potentially experience benefits from administering Befotertinib.
Conclusion: OKAIN acts as a precision oncology knowledgebase for the assessment of clinically actionable alterations, integrating exhaustive data related to cancer-associated genomic variants and therapeutic efficacy. It is a beneficial tool for medical professionals and patients, providing an enhanced means of understanding and approaching precision oncology.

#3549 PMed-TRIAL PDX database: Integrated multidimensional information to facilitate new drug development.

X. Chen, Y. Guo, L. Van, J. Caggiula, X. Gu, **D. Wen**;
Shanghai LIDE Biotech Co., Ltd., Shanghai, China

PDX models play a crucial role in pre-clinical research for new drugs. In recent years, research based on PDX models has entered the 'Big Data Era.' On the one hand, there are numerous factors influencing drug responses, such as cancer types, genetic backgrounds, clinical treatment histories, and more. Therefore, selecting the appropriate PDX models for drug efficacy testing based on relevant information has become increasingly important. On the other hand, conducting in-depth genomics and transcriptomics analyses on PDX models allows us to gain a deeper understanding of the mechanisms of drug efficacy and drug sensitivity. After years of effort, LIDE have successfully built and maintained over 1800 PDX models from 40 different cancer types. And in this year (2023), we launched LIDE's PMed-TRIAL PDX database website. As a comprehensive database of PDX models, it includes fundamental PDX clinical information, medication history, growth curves, and standard of care (SOC) data. It also contains whole exome sequencing data and RNA-seq data. Cancer is a complex and heterogeneous disease characterized by tumor heterogeneity, encompassing both inter-tumor diversity (between patients) and intra-tumor variability (within a single patient), thereby complicating drug responsiveness. PDX models preserve heterogeneity of individual patients, and a robust PDX cohort is essential for accurately representing inter-tumor heterogeneity. LIDE's PDX cohorts effectively capture representative molecular subtypes across various major cancer types, highlighting their potential as a valuable resource for pre-clinical trials. LIDE's PMed-TRIAL PDX database comes with a concise and efficient web user interface. Users can search and filter models using keywords, such as drug names, gene symbols, and other information. The website can now be accessed via the following URL (https://pmed.lidebiotech.com:8000/).

#3550 PerturbDB: A resource for revealing gene functions and cancer-associated phenotypes.

B. Yang, M. Zhang, Y. Shi, Y.-M. Dong, X. Ma, J. Zhang, D. Lu, J.-Y. Liao, **D. Yin**;
Sun Yat-Sen University, Guangzhou, China

Perturb-seq is a high-throughput technique that combines clustered regularly interspaced short palindromic repeats (CRISPR)-based screens with single-cell RNA sequencing (scRNA-seq) readouts for high-content phenotypic screens to comprehensively map the transcriptional effects of genetic perturbations, showing great advantages in revealing disease-associated gene functions and mechanisms in high volumes. Despite the rapid accumulation of Perturb-seq datasets, no dedicated database exists for reusing these valuable information. In this study, we developed a platform called PerturbDB (http://research.gzsys.org.cn/perturbdb) to facilitate users to unveil genotype-phenotype relations, especially gene functions and regulatory networks involved in several classical cancer associated phenotypes using 37 Perturb-seq datasets from 15 studies. By reanalyzing 3,429,829 single-cell transcriptomes from the knockdown of 3214 genes across 10 different cell lines, we identified 749 classical cancer phenotype-related genes and 373 functional gene clusters annotating potential novel functions. Utilizing Marker genes scoring and the InferCNV algorithm, we identified genes involved in 9 malignant phenotypes, which consists of sustaining proliferative signaling (362 genes), resisting cell death (120 genes), inducing angiogenesis (145 genes), tissue invasion and metastasis (321 genes), enabling replicative immortality (160 genes), deregulating cellular metabolism (247 genes), avoiding immune destruction (95 genes), unlocking phenotypic plasticity (231 genes), and chromosome instability (231 genes). Additionally, functional clusters were calculated utilizing Principal Component Analysis (PCAs) and the HDBSCAN package to introduce unknown gene functions related to the cancer associated phenotypes. Perturbation clusters (PCs) were identified by comparing similarities in the transcriptomes of perturbed cells, suggesting individual genes in the same functional cluster perform similar gene functions, and therefore novel functions of 735 genes can be inferred from the known functions of neighboring genes. The PGSEA tool was developed to facilitate functional analysis of genes not yet included, which helps users to predict gene functions through a combination of PerturbDB datasets and personalized RNA-seq datasets. This study will greatly expand our understanding of genes involved in emblematic cancer associated phenotypes and their coordinated functions and regulatory networks.

#3551 Continued analysis of extensive data towards Genome in a Bottle benchmarks for a new tumor normal pair.

J. Wagner[1], J. McDaniel[1], G. L. Rosen[2], N. D. Olson[1], V. Patel[1], C. Xiao[3], A. Liss[4], J. Zook[1];
[1]National Institute of Standards and Technology (NIST), Gaithersburg, MD, [2]Drexel University, Philadelphia, PA, [3]NIH/NLM/NCBI, Bethesda, MD, [4]Massachusetts General Hospital, Boston, MA

Here, we detail in-progress genome-scale measurements from a variety of technologies of the first tumor normal benchmark from the Genome in a Bottle (GIAB) consortium. We created the first broadly-consented tumor cell line from a pancreatic ductal adenocarcinoma with matched normal pancreatic and duodenal tissue. Data is being collected from a large homogeneous batch of the tumor cell line and paired normal tissues. As we receive data we make it publicly available on the NCBI hosted GIAB FTP site, https://ftp.ncbi.nlm.nih.gov/ReferenceSamples/giab/data_somatic/. When complete, this dataset will include WGS measurements from Illumina, ONT, Hi-C, Bionano, single cell WGS, PacBio HiFi and Onso, and Element. Analysis and development of a variant calling benchmark using this data is ongoing in collaboration with an open working group of the GIAB consortium.

Initial Hi-C and optical mapping data from the tumor cell line indicates substantial aneuploidy from translocations that cause large deletions. We found roughly 17 large inversions and translocations and 16 chromosomes with extensive loss of heterozygosity due to missing >30% of one copy, in addition to a few smaller duplications. Low coverage single cell sequencing that provides ploidy estimates across chromosomes showed that most of the large deletions appear in all or nearly all cells with some variation in a few cells. These observations are consistent with bulk WGS analyses from two batches of cells. Additionally, many of the observed large deletions correspond to deletions seen in the population of TCGA chromosomal Loss of Heterogeneity samples. Examining somatic SNVs in non-repetitive regions, we find that close to 60% occur in almost all cells in diploid regions, 30% occur in almost all cells in haploid regions, and 5% in only some cells in diploid and haploid regions, respectively. We take these results to indicate the cell line is relatively homogeneous and stable with most CNVs being deletions. As such, we plan to explore using long reads, ultralong reads, and Hi-C data to generate a near-complete genome assembly of the dominant tumor clone as well as a complete diploid assembly of the normal. With this personalized genome assembly, we will explore aligning tumor and normal reads to each haplotype of the normal to characterize somatic variants, including variants in minor clones. Building on the methods GIAB and T2T have developed to polish diploid assemblies of GIAB's normal genomes and mosaic variant characterization, we will develop benchmarks for somatic variants against the normal assembly as well as standard references.

#3553 OralDB, A integrative data portal for oral and oropharyngeal cancer omics and clinical research.

J. Wang, P. Lam,, Y. Su, J. Wang;
The University of Hong Kong, Pokfulam, Hong Kong

Oral and oropharyngeal cancer is one of the more common cancers worldwide, with a poor prognosis in advanced stages and a higher incidence in Asian populations than in other regions. Its affected Affected areas include the lips, gums, tongue, the inside of the cheeks, the roof of the mouth, the floor of the mouth, the tonsils, and the oropharynx. Currently, the distribution of RNA expression data and clinical data in oral and oropharyngeal cancer is fragmented, impeding effective data mining for the discovery of novel biological markers and testing of new hypotheses. We constructed an oral and oropharyngeal cancer-specific database with expression dataRNA expression and clinical data from more than 4,356 patients in 41 studies. The RNA Expression data from 23 genome-wide platforms are carefully processed and quality-controlled, while clinical data is standardized and tightly managed. With the support of this oral and oropharyngeal cancer-specific database oral cancer-specific database, we have created an open-access web resource, the Oral and Oropharyngeal Cancer Browser, to facilitate researchers interested in oral and Oropharyngeal cancer to quickly access and analyze all currently published RNAoral cancer expression data and clinical data. Users can perform a meta-analysis of Oral and oropharyngeal oropharyngeal cancer to quickly understand the results of tumor versus non-malignant tissue (normal), differential gene expression, and expression-survival associations. Flexible options for survival analysis, comparative analysis, and correlation analysis based on a single dataset are also available. At the same time, the database also accepts the user's own input data and allows the user to do theircarry out their own analysis by combining the input data with the existing data in the database.

#3554 Using All of Us cancer data on the Researcher Workbench to advance career development.

Karriem S. Watson[1], Rubin Baskir[1], Division of Engagement and Outreach, All of Us Research Program, Karen Hubbard[2], **Hannah L. Park**[3], Lin Zhu[4]

[1]All of Us Research Program, National Institutes of Health, Bethesda, MD,[2]City College of New York, New York City, NY,[3]University of California, Irvine, Irvine, CA,[4]Temple University, Philadelphia, PA

This session will provide an overview of the All of Us Research Program (All of Us) dataset, discuss a mechanism to build the capacity of research institutions using the All of Us dataset, and outline the career benefits researchers experienced from using the dataset. All of Us is building a national health dataset to accelerate medical breakthroughs. It is used by cancer researchers to advance health research and career development. This dataset is large and diverse, both in the data types available as well as the demographics of participants: as of April 2023, health data from 413,450+ participants is available to researchers, from a variety of distinct data types, including survey responses, physical measurements, electronic health records, whole genome sequencing, wearable data, and genotyping arrays, with 75% of participants self-identifying as underrepresented in biomedical research and about 45% of participants self-identifying as racial and ethnic minorities. Researchers already leverage this dataset, with All of Us data used in more than 210 publications across peer-reviewed journals. In addition, this dataset is useful for cancer researchers - All of Us EHR data indicates over 60,700 participants are diagnosed with at least one type of cancer, and more than 10% of research projects underway (725/6,945 as of September 2023) using the All of Us dataset are cancer-related, making it the top condition studied by researchers. To help build capacity at research institutions, All of Us collaborated with the NCI Center to Reduce Cancer Health Disparities (CRCHD) Partnerships to Advance Cancer Health Equity (PACHE) to develop a Notice of Special Interest (NOSI) titled Administrative Supplements to Support "All of Us" and Health Disparities-Related Pilot Research Projects at NCI CRCHD-Funded PACHE Partnerships. The focus of this NOSI was on P20 and U54 awards associated with research projects led by PACHE researchers interested in exploring the connections between social determinants of health outcomes and populations experiencing cancer health disparities. NIH awarded investigators at the following institutions: City College of New York, University of California, Irvine, and Temple University.

Principal investigators of these awards will provide an overview of their work, describe how they analyze the All of Us dataset, and discuss how their use of the dataset has helped advance their career as cancer researchers:

Karen Hubbard (City College of New York)

Project Title: Relative and Intersectional Analysis of social determinants of Lung Cancer Risk among Black and Hispanic All of Us respondents

Hannah Lui Park (University of California, Irvine)

Project Title: Improving breast cancer risk assessment and prevention in Asian American women

Lin Zhu (Temple University)

Project Title: Elucidating the Roles of Metabolic Syndrome and Non-Alcoholic Fatty Liver Disease among Asian American Patients with Chronic Hepatitis B

#3555 COSMIC: two decades of curating somatic variants in cancer.

Zbyslaw Sondka, Madiha Ahmed, Joanna Argasinska, David Beare, Nidhi Bindal Dhir, Denise Carvalho-Silva, Manpreet Singh Chawla, Stephen Duke, Ilaria Fasanella, Muhammed Fouzan, Avirup Guha Neogi, Susan Haller, Bhavana Harsha, Balazs Hetenyi, Leonie Hodges, Alex Holmes, Steven Jupe, Rachel Lyne, Madhumita Madhumita, Thomas Maurel, Karen McLaren, Sumodh Nair, Helder Pedro, Amaia Sangrador-Vegas, Helen Schuilenburg, Zoe Sheard, Michael Starkey, Rebecca Steele, Sari Ward, Jennifer Wilding, Siew Yit Yong, Jon Teague

COSMIC, Wellcome Sanger Institute, Cambridge, United Kingdom

In 2004, COSMIC was one of the first initiatives to integrate global data on somatic mutations in cancer. At the time it was explicit that the fragmentation of genetic datasets was a major obstacle to understand the processes driving cancer. A team of expert curators and bioinformaticians was tasked with identifying and cataloguing data related to somatic variants, as well as relevant demographic, clinical, and patient information from published studies and making these data easily accessible to the research community. Over the last two decades we have witnessed the incredible progress in cancer genomics enabling whole genome studies, resulting in the exponential growth of data generated by cancer research. During its first year, COSMIC integrated data from 1672 scientific papers, cataloguing 1755 unique mutations across 21 genes. At present, twenty years later it is common for a single publication to describe tens of thousands of genome-wide mutations and now COSMIC includes 24 million genomic variants collected from more than 1.5 million patient samples acquired from over 29,000 scientific publications. Today, an important part of COSMIC's mission is to help translate this information for improving cancer treatment and patient care. To achieve this, the main catalogue of somatic mutations is supported by 6 accompanying resources that focus on different aspects of molecular oncology. The Cancer Gene Census and Cancer Mutation Census describe the roles of genes and mutations in oncogenesis, based on literature curation and analysis of the core mutation catalogue. COSMIC 3-D visualises mutation frequency in the context of the protein structure, and Mutational Signatures catalogues the mutagenic processes behind the nature of mutations at the genome level. To help target molecular alterations in clinical practice, Actionability and the catalogue of mutations causing drug resistance inform the availability of therapeutic options for cancer and how their efficacy is influenced by the genetic profile of the cancer. The ongoing development of sequencing techniques and new diagnostic methods as well as computational approaches, including deep learning and use of generative AI, give us hope that the next 20 years will be equally revolutionary for data-driven oncology. However, the abundance of new sources of diverse datasets makes data fragmentation an evolving challenge for the whole research community. Developing and adopting common standards for data formats, management and usage will be critical to assure inclusive, efficient, and effective translation of genomic research into a clinical practice.

#3556 A pan-cancer *ex vivo* drug screen database for next-generation pharmacogenomics and functional precision oncology.

A. Markus[1], K. Pichotta[1], J. Quinn[1], J. White[1], C. Tosh[1], J. Liu[2], E. Coyne[1], W. Tansey[1];

[1]Memorial Sloan Kettering Cancer Center, New York City, NY, [2]Weill Cornell Medicine, New York City, NY

Large-scale drug screens across thousands of drugs and biological models enable pan-cancer analyses that can reveal novel insights into therapeutic response and resistance. Existing databases, such as the Cancer Dependency Map only screen established 2D cell lines, which are known to poorly translate to patients. Ex vivo models such as patient-derived cells, spheroids, and organoids, have consistently demonstrated superior translatability from drug screening responses as they better replicate the original tumor. However, the cost, complexity, and difficulty of developing and screening ex vivo models has thus far prevented the establishment of any large-scale database comparable to existing cell line databases. We present the pan-preclinical (PPC) project, a large pan-cancer database of ex vivo drug responses comprising 2.1M raw dose-response measurements with curve-level summary statistics and metadata. The PPC database is assembled from over 30 previously published ex vivo studies and contains 2,880 ex vivo models spanning 106 cancer subtypes tested against subsets of 3,023 drugs. Compounds are harmonized across studies and paired with detailed chemoinformatics derived from PubChem. Each ex vivo sample is matched to an underlying patient and paired, where available, with genomics, transcriptomics, and clinical information such as sex, treatment history, and overall survival. Two thirds of the underlying studies did not originally make the underlying drug screening data available at publication time, making the PPC database a novel resource beyond data integration. Results: To investigate the power of the PPC database, we developed a preliminary computational modeling and statistical analysis pipeline. A hierarchical Bayesian factor model was developed to estimate dose-response curves, remove batch effects across studies, and impute missing drugs. Low-dimensional projections of ex vivo drug responses show biologically meaningful clustering. Statistical analyses of both observed and imputed drug responses recapitulate standard of care drugs as significantly effective across several cancer types. Overall, we envision the PPC project laying the foundation for the next generation of large-scale pharmacogenomic analyses and aiding in the coming era of functional precision oncology.

#3557 A pancancer gamma delta T cell repertoire atlas.

X. Yu[1], S. Li[2], L. Cen[1], X. Wang[1];
[1]Moffitt Cancer Center, Tampa, FL, [2]Dartmouth College, Lebanon, NH

While representing only a small portion of T cell population, Gamma delta (γδ) T cells have unique contributions to both innate and adaptive immunity. Compared to αβ T, γδ T cells have a more diverse TCR repertoire, allowing them to recognize a broader range of tumor antigens. Recent breakthrough discoveries indicate that the antitumor efficacy of γδ T cells can be potentiated or rescued through targeted therapeutic approaches. Despite their functional and translational significance, a comprehensive understanding of the γδ T cell repertoire within tumor tissues has yet to be fully achieved.In this work, we generated a pan-cancer γδ T cell repertoire Atlas through reanalyzing RNA-seq data from more than 11,000 tumors in TCGA utilizing TRUST4, an advanced computational method for reconstruction of TCR repertoires. This allowed us to offer the most accurate and comprehensive examination of the γδ TCR landscape spanning 33 cancer types, marking it the largest collection of γδ clones on human cancer to date. We processed 660 billion RNAseq reads, identified ~3 million CDR3 reads, applied a series of stringent filtering criteria to remove biologically implausible, ambiguous sequences, and out-of-frame TCRs, which resulted in 22,205 unique γδ TCR clones from 6,751 tumors. TCR gene enrichment scores were calculated to represent overall expression of γδ in each tumor. The γδ enrichment is highly variable between and within cancer types. As expected, tumors traditionally classified as immune-cold (UVM and GBM) show the lowest scores. Cancers intrinsically related to lymphatic system (LAML, THYM and DLBC), exhibit the highest scores. Beyond THYM, the top five solid-tumor cancers carrying the highest enrichment are PRAD, KIRC, TGCT, LUAD and KICH. We further profiled the clone counts, spectrum of clone sizes, CDR3 length, V-J pair usage, and clonality in 33 cancers. Overall, a dominant presence of large clone segment is not observed in most cancers. The most prevalent V-J pairs are TRGV10/9/2-TRGJ1 for γ, and TRDV1-TRDJ1 for δ chain. Cancers including LAML, KIRC, LUAD, SKCM, CESC, LUSC, STAD, display a relatively higher proportion of intermediate to larger clones. THYM exists the highest γδ diversity, with the lowest clonality and most diverse V-J pairs. In addition, we evaluated the prognostics value of γδ genes by multivariate Cox regression, adjusting for age, sex, stage, and tumor purity, and identified 38 γδ genes associated with patient survival with $p<0.05$ in 25 cancer types. Finally, within HNSC, we observed higher γδ gene enrichment ($p=1.6e-9$) and clone diversity ($p=0.014$) in HPV+ vs. HPV- tumors. The γδ gene enrichment is also found associated with patients' survival ($p=0.002$) in HPV+, but not in HPV- HNSC. Similarly, COAD tumors with high Microsatellite Instability (MSI) shows higher γδ gene enrichment and clone diversity compared to MSI low COAD. Collectively, our findings serve as a foundational resource for γδ T cell research in oncology.

.

#3558 An integrated data platform to support the international alliance for cancer early detection.

B. Walsh[1], L. Beckman[1], J. Burchett[1], M. Peterkort[1], J. Lee[1], M. Fitzsimons[2], P. Vassilatos[2], B. Bajracharya[2], C. Barnes[2], J. Qureshi[2], R. Grossman[2], C. Yakura[1], Y. Lu[3], S. Burge[4], D. Kelberman[3], E. Watson[1], **K. Ellrott**[1];

[1]OHSU, Portland, OR, [2]University of Chicago, Chicago, IL, [3]University College London, London, United Kingdom, [4]Cambridge, Cambridge, United Kingdom

Cancer early detection is one of the most critical areas of cancer research, as it offers the greatest potential for improving patient outcomes. The International Alliance for Cancer Early Detection (ACED) is a global partnership of world-leading cancer research institutions in the UK and US, established in 2019 to accelerate and revolutionize research in this field. ACED brings together the expertise of the Canary Center at Stanford University, the University of Cambridge, the Knight Cancer Institute at Oregon Health and Sciences University, University College London, and the University of Manchester, together with Cancer Research UK, with the goal of catalyzing new collaborations and research in the field of early detection. One of the major challenges to enabling international collaborations across different institutions is the ability to collect, share and discover datasets between researchers and institutions. To enable collaboration on innovative data science, fundamental functions include, 1) controlled data sharing mechanisms; 2) structured metadata to enable data exploration and data discovery; and 3) enabling easy computational access to that data. To advance researchers' collaboration, ACED began development of an Integrated Data Platform (IDP). The ACED-IDP is based on the Gen3 software platform developed by the University of Chicago's Center for Translational Data Science. Based on software systems originally developed for the NCI's Genomic Data Commons, Gen3 has been used in several other data projects including The Blood Profiling Atlas in Cancer (BloodPAC), Australian BioCommons and numerous other research data platforms. The unique nature of ACED required unique innovations to be made for the development of the IDP. Each of the member institutions within the alliance has different existing computer infrastructures, separate authentication platforms and heterogeneous data types forming the basis of their research. The IDP sought a cloud-ready strategy, while still being cognizant of the extreme costs associated with cloud egress fees that hamper researchers' ability to download data. Additions were made to the Gen3 platform to allow for hybrid cloud support, allowing on-premises as well as cloud object storage systems to be linked to the platform. This innovation permits each institution to share files using the mechanisms that they see fit. To unify the various datasets, the standard Gen3 schema was replaced with one derived from the Fast Healthcare Interoperability Resources (FHIR) standard. To support import from clinical data sets, tooling to enable import and export Observational Medical Outcomes Partnership (OMOP) data has been integrated. With this platform in place, we hope to advance international collaborations and accelerate early cancer detection research.

#3559 A validated bioinformatics tool-set for predicting TCR specificity.

A. Wilm, F. Schmidt, M. Wirawan, M. Cooray, K. Wu, K. Fink, D. MacLeod;
ImmunoScape, Singapore, Singapore

Background: The T-cell receptor (TCR) is a transmembrane receptor on T cells, which is responsible for recognizing any foreign antigen derived peptide, presented on infected or abnormal cells by the MHC-I complex. Predicting TCR specificity computationally is a long-standing problem. Many methods leverage large libraries of TCR sequences and cognate epitopes as input for machine learning and predict specificity from sequence alone. Most methods generally do not perform very well, especially in the case of unseen peptides, i.e. for cases where peptides were not part of the input library.
Methods: Here we describe three independent but interacting in-silico modules for TCR discovery. 1) The first module predicts specificity from deep phenotypic T cell profiles. We produce these profiles using a high-throughput pipeline, which combines multiplexed CyTOF with subsequent VDJ CITE-Seq. The generated multiomics data is aggregated into a database called TCAPS, which is the basis for machine learning models. These models can predict T cell specificity from the deep phenotype alone, i.e. without TCR sequence information. The resolution however is limited to the target class and hence the actual epitope has to be determined through subsequent deorphanization. This deorphanization step is augmented by the other two modules also described here. 2) The second module enables ultrafast sequence similarity search, which is used to find similar TCRs with known epitope specificity 3) The third module ranks TCR candidates for prioritisation for in-vitro validation. This is achieved by running the Alphafold-based structure prediction program TCRDock.
Results: 1) We demonstrate how TCR specificity can be correctly predicted from multiomics deep T-cell profiles and specifically highlight two in-vitro validated predictions, for which the corresponding epitope/antigen were not part of the input panel. 2) Using a recently published TCR clustering benchmark TCRScapes, we demonstrate the superior performance of our ultrafast sequence similarity search. 3) We furthermore showcase TCRdock-directed experiments on TCRs specific for SF3B1mut-induced splice variants. TCRdock correctly ranked TCR candidates, including artificial combinations, whose functionality we prove through in-vitro validation.
Conclusions: We describe three modules for TCR discovery and demonstrate their utility by benchmarking and in-vitro validation of multiple predictions, including two examples against unseen epitopes/antigens.

#3560 Quantified kinematics and wearable sensors to predict serious adverse events in patients undergoing cancer therapy trials.

E. Tran[1], L. Nocera[2], A. Kolatkar[2], A. El-Khoueiry[2], J. Thomas[2], P. Kuhn[2], A. Zeng[2], M. Kai[3], M. Karuturi[3], J. Nieva[2],
[1]UCSD School of Medicine, San Diego, CA, [2]USC Norris Comprehensive Cancer Center, Los Angeles, CA, [3]MD Anderson, Houston, TX

Background: Serious adverse events (SAEs) are a critical determinant of drug toxicity in clinical trials. However the drivers of toxicity may be related to patient factors as much or more than drug related factors. Prior studies have shown that time in non-sedentary activity predicted toxicity in cancer patients receiving highly emetogenic chemotherapy. SAEs are a critical determinant of drug toxicity in clinical trials. However, predicting SAEs using conventional PS scales measurements, such as ECOG is challenging because measurements can vary among observers. Prior studies have used activity trackers to measure physical activity and showed that time spent in non-sedentary activity predicted toxicity in cancer patients receiving highly emetogenic chemotherapy. Here, we sought to extend these findings to early phase clinical trial participants by examining data collected in two single-arm, observational, prospective studies at USC Keck and MD Anderson centers. We explored the use of out-of-clinic wearable sensors as an objective metric of frailty so as to identify patients at risk for therapy complications.

Methods: Adult patients diagnosed with cancer and enrolled in early stage clinical trials across USC Keck and MD Anderson centers were included in parallel single-arm, observational, prospective studies. Patients used a consumer grade wearable activity tracker (Fitbit) and the study examined associations between the number of severe adverse events to activity levels measured by metabolic equivalents (METs) and get-up-go times across the first 30 days. Trends were assessed using t-tests.

Results: 36 eligible patients were included in METs activity analysis. There was a total of 16 recorded incidences of SAEs within the first 30 study days, with 10 patients experiencing at least one SAE. The median non-sedentary time for patients with no SAEs was 27.5 hours above 1.5 METs per week, compared to 21.5 hours for those with at least one SAE occurrence (p-value=0.0146, r^2=0.1629). The median get-up-go times for those without SAEs was 10.0 seconds (n=26) and with SAEs was 9.8 seconds (n=10), (p-value=0.828, r^2=0.0014).

Conclusions: Non-sedentary time, as an objective measure of activity, can be used to identify those patients who are at greatest risk for SAEs in clinical trials. Widely available and inexpensive consumer grade sensors can be used as a stratification tool. Findings should be confirmed in larger patient cohorts across a wider variety of trial settings.

Figure 1: Weekly non-sedentary hours vs. presence of SAE in first 30 days of trial enrollment

#3562 Comparison of spatial co-localization measures for studying the tumor immune microenvironment with application to ovarian cancer.

B. L. Fridley[1], A. Soupir[2], J. Wrobel[3], C. Colin-Leitzinger[2], M. K. Townsend[2], A. B. Lawson[4], K. L. Terry[5], J. M. Schildkraut[3], S. S. Tworoger[2], L. C. Peres[2]; [1]Children's Mercy Hospital, Kansas City, MO, [2]Moffitt Cancer Center, Tampa, FL, [3]Emory University, Atlanta, GA, [4]Medical University of South Carolina, Charleston, SC, [5]Brigham And Women's Hospital, Boston, MA

Introduction: The spatial contexture of the tumor immune microenvironment (TIME) has been associated with survival among cancer patients, including women with high-grade serous ovarian cancer (HGSOC). However, an assessment of statistical approaches to quantify the spatial characteristics of the TIME has not been conducted. Moreover, it is unknown which statistical approach is most sensitive in identifying spatial co-localization of two cell types in the TIME.
Methods: Using the R package scSpatialSIM that simulates spatial single-cell protein data (i.e., multiplex immunofluorescence data), we completed a simulation study to compare four methods for assessing co-localization of cell types in the TIME (Ripley's K, Nearest Neighbor G, Dixon's segregation statistic, and a spatial interaction variable). The simulation study varied the cell abundance (e.g., low vs high), the co-localization (e.g., co-localization, random, segregation), and the variation in the marked point process. In addition to the simulated data, we assessed the four methods in large epidemiological studies (Nurses' Health Study [NHSI/NHSII], New England Case Control Study [NECC], African American Cancer Epidemiology Study [AACES], and North Carolina Ovarian Cancer Study [NCOCS]) including 756 women with HGSOC. Multiplex immunofluorescence was conducted using AKOYA Biosciences OPAL™ platform to measure cytotoxic T cells (CTLS) and regulatory T cells (Tregs). Cox proportional hazards regression models were fit to estimate the association of spatial co-localization of CTLS and Tregs with overall survival.
Results: In the simulation study, we found that Ripley's K was the most powerful approach for assessing co-localization for a variety of simulation scenarios. Surprisingly, the other approaches (Nearest Neighbor G, Dixon's Segregation statistic, and spatial interaction statistic) were unable to detect the simulated co-localization of two cell types in most simulation scenarios. In the analysis of women with HGSOC in the epidemiological cohorts, we were able to detect significant co-localization of CTLS and Tregs in 40.2%, 12.2%, 21.2%, and 17.0% of samples using Ripley's K, Nearest Neighbor G, Dixon's statistic, and the interaction variable methods, respectively. However, the level of co-localization was not associated with survival.
Conclusions: We found that Ripley's K was the most powerful at detecting simulated co-localization of two cell types in the TIME. Similarly, Ripley's K identified the highest level of significant spatial co-localization of CTLS and Tregs in the application to HGSOC. However, we did not observe an association of co-localization of CTLS and Tregs with overall survival. Future work is needed to develop powerful approaches for quantifying the spatial contexture of the TIME, along with assessment of the statistical properties of these methods.

#3563 Multi-modal mutational signatures elucidate the comprehensive consequences of mutational processes.

C. D. Steele, L. Alexandrov, A. Khandekar;
University of California San Diego - UCSD, San Diego, CA

The development of mutational signatures defined individually in the contexts of single/double base substitutions, insertions and deletions, structural variants and copy number variation have led to improved understanding of cancer mutagenesis and potential for improved patient stratification. We hypothesized that combining these contexts into a multi-modal mutational signature framework may improve the accuracy of assigning mutational processes to samples, and provide a holistic view of the full repertoire of mutations conferred from such processes. In order to develop multi-modal signatures, bespoke feature engineering was required for each mutational modality to enhance signal, in addition to individual modality matrix normalization so that the data could be harmonized and analyzed as a whole. These methods, and subsequent signature extraction were developed on 2,438 whole genome sequenced cancers from 21 distinct cancer types from the PCAWG consortium for which all modalities of data were available, incorporating a 348 channel signature definition. Deployment of these methods identified multi-modal signatures that encompass multiple mutation types known to associate with specific processes, for example SBS, indel and rearrangement channels defining a signature of homologous recombination deficiency. In contrast, some signatures remain defined by a single mutational modality, highlighting the distinction between broadly mutational processes, and more focused mutation processes. Multi-modal signatures show promise in increasing accuracy for difficult to assign signatures, such as those for homologous recombination deficiency, and therefore in improving patient stratification for life-saving treatment.

#3564 Survival-based grouping of genetic variants: A novel statistical framework with an application to *TP53* mutations.

X. Liu[1], H. Shi[2], E. Montellier[3], P. Hainaut[3], W. Wang[1];
[1]UT MD Anderson Cancer Center, Houston, TX, [2]Rice University, Houston, TX, [3]Univ. Grenoble Alpes, Grenoble, France

Advancements in genotyping and sequencing techniques, coupled with the growing magnitude of genome databases, have led to comprehensive investigations into the impact of genetic variants on human diseases, including cancers. It is commonly acknowledged that genetic variants have homogeneous effects on clinical outcomes, i.e., variants exhibit similar effects within a certain group but are distinct from those in other groups. However, such grouping information is typically unknown, and identification of the underlying genetic variation groups is crucial for understanding their functional consequences, facilitating patient management, and improving risk prediction. To resolve this challenge, we introduce a novel statistical framework called Survival-based Clustering of Predictors (SCP) in Cox regression to group genetic variants based on patient survival outcomes. Built upon a penalized Cox regression model, SCP considers different genetic variants, as well as additional patient-specific features if needed, as survival predictors and then searches for homogeneity among the coefficients for individual variants to recover the underlying grouping structure. Focusing on *TP53*, the most frequently mutated gene in cancer that has resulted in a wide range of functions and clinical outcomes, we apply SCP to group *TP53* germline mutations with the age of cancer diagnosis as the time-to-event. Using datasets from four Li-Fraumeni syndrome (LFS) cohorts at MD Anderson, NCI, and DFCI, we obtained 75 recurring *TP53* germline mutations from 513 patients and clustered these mutations into high-, medium-, and low-risk groups. Hotspot mutations such as R175H, R248Q, G245S, and R273C are in the high-risk group as supported in many *TP53* studies, while several non-hotspot mutations such as R290H, V218G, and G244D also exhibit strong positive effects and are grouped together with hotspot mutations. Overall, mutations in all three risk groups, obtained through applying SCP, are highly consistent with a yeast functional assay-based approach for grouping *TP53* mutations, supporting the utility of SCP for survival-based grouping of genetic variants. The contribution of our study is three-fold. Statistically, our method fills a critical gap in the survival analysis literature, offering a novel statistical framework for clustering predictors in Cox regression based on survival outcomes. Clinically, we provide a timely solution to the patient outcome-based grouping of *TP53* mutations, facilitating clinical management of *TP53* mutation carriers. Biologically, we bring fresh insights into knowledge for the most frequently observed genetic variants in cancer, providing new hypotheses to *TP53*-related biological research.

#3565 The Cox proportional hazards mixed model enables accurate estimation of the total effect somatic SNVs have on treatment outcomes.

K. Taraszka, A. Gusev;
Dana-Farber Cancer Institute, Boston, MA

Heritability is the variation in disease susceptibility attributed to genetic variation and is a fundamental parameter for interpreting disease architecture and making predictions. In the context of germline genetics, variance component models are commonly used to estimate heritability for continuous or case-control phenotypes (under the liability threshold model, LTM). However, models for time-to-event (TTE) outcomes have been largely unstudied. This has limited the characterization of age-of-onset and treatment response phenotypes, the latter particularly relevant for clinical studies. Here, we propose and evaluate a Cox proportional hazard Mixed Model (COXMM) to enable accurate estimation for TTE phenotypes with censoring. We apply these methods to Real World data from the Profile cohort from Dana-Farber Cancer Institute, a large prospectively collected tumor sequencing cohort with detailed clinical annotation. We implemented an efficient COXMM with a random effect modeled by the genetic relatedness across individuals, and benchmarked its performance in extensive simulations. We simulated phenotypes according to generative models reflecting either LTM or TTE models. For TTE phenotypes, data followed various Weibull distributions with independent censoring. Across TTE simulations, COXMM produced unbiased estimates while the classic case-control heritability estimator showed significant downward bias. Likewise, restricting only to cases and estimating the heritability of age-of-onset as a normalized continuous phenotype produced biased estimates, due to the artificial exclusion of controls. For example, for an age-of-onset with heritability of 0.8 and 40% of individuals in the study being cases, COXMM correctly inferred the heritability to be 0.80 +/- 0.007, compared to 0.32 +/- 0.004 for a conventional case-control model, and 0.09 +/- 0.02 for a conventional case-only age-of-onset model. In the Profile cohort, we analyzed the impact of somatic SNVs on progression free survival (PFS) and overall survival (OS) in patients with non-small cell lung cancer (N=954 and N=1796, respectively). We restricted to somatic SNVs present in at least 5% of patients. For OS, we observed that the COXMM heritability estimate was significantly larger than those computed by case-control status and using a normalized case-only age/duration (COXMM: 0.19 +/- 0.003; Case-Control: 0.07 +/- 0.2; Duration: 0.04 +/- 0.01). We observed a similar phenomenon for PFS as well (COXMM: 0.11 +/- 0.01; Case-Control: 0.03 +/- 0.4; Duration: 0.03 +/- 0.02). These results demonstrate that somatic features are most strongly associated with TTE and can be accurately estimated with COXMM. COXMM enables the efficient quantification of TTE heritability for diverse clinical phenotypes and outperforms existing methods.

#3566 Mohs surgery trends in 104 cases of pediatric melanoma.

Z. G. Brandt, X. Wu, J. Kennard, J. Griffin, P. Silberstein;
Creighton University School of Medicine, Omaha, NE

Background: Cutaneous melanoma is rare in children with a global incidence of two to five cases per million people per year, accounting for roughly 1% of all pediatric malignancies.[5] However, the incidence of pediatric melanoma in the United States is increasing.[1] Mohs Micrographic Surgery (MMS) is a standard treatment for adult skin cancer due to its low recurrence rates and tissue preservation. However, it is less commonly used to treat melanoma in children because the required infrastructure is not widely accessible and many pediatric surgeons are not familiar with MMS.[4] With more limited treatment options for pediatric melanoma, it is important to question the role of socioeconomic factors that may contribute to MMS treatment of pediatric patients with melanoma.[2]
Purpose: The purpose of the study is to investigate pediatric patients with melanoma and assess their tumor characteristics by comparing various skin cancer treatments (Mohs, other treatments [local excision], or no treatment).Methods: This is a retrospective cohort study of pediatric patients (age < 21 years) diagnosed with cutaneous Melanoma who received MMS between 2004 and 2020 in the National Cancer Database (NCDB). Descriptive statistics were collected on the following variables: the year of diagnosis, sex, race, tumor stage, tumor behavior, primary site, and surgical procedure. Overall survival was determined via the Kaplan-Meier test.
Results: 104 cases of pediatric melanoma treated with MMS were identified. Per statistical analysis, it does not appear that surgical frequency has varied yearly from 2004 to 2020 ($r^2 = 0$). The median age of patients analyzed was 18 years old. Most patients were female (64.4%, N = 67), White (100%, N=104), non-Hispanic (100%, N=104), and had private insurance (87.3%, N = 90). 70.2% (N=73) of cases were defined as early-stage (stage 0 or I). 72.1% (N=75) of cases were identified as invasive. 45.2% (N=47) of MMS were performed with a margin of 1 cm or less, 19.2% (N=20) were performed with a margin of 1 cm or more, and the remaining had unspecified margins. The most common primary site for MMS was skin of the trunk (33.7%, N=35), followed by the upper limb and shoulder (16.3%, N=17), and the lower limb and hip (15.4%, N=16). All patients were alive at the last contact, with a median overall survival of 182 months (15.2 years).
Discussion: MMS is used commonly in adults to treat a variety of skin tumors that can have aggressive traits such as melanoma. Although it offers low recurrence rates and tissue-sparing treatment in adult populations, MMS frequency has not changed within the pediatric population. MMS is mainly seen in privately insured, White patients with an early stage of melanoma; this is likely due to lower rates and delayed diagnosis in patients with darker skin that would otherwise present with metastatic disease. Given its clinical advantages and low rate of use, further research should address barriers that affect the availability of MMS in the pediatric population.

#3568 Managing large-scale cancer research data programs.

J. Klenk[1], D. Mikdadi[1], C. Owens[1], A. Maggio[1], B. Singh[1], E. Barner[1], T. Davidsen[2], E. Kim[2];
[1]Deloitte, Arlington, VA, [2]National Cancer Institute, Rockville, MD

Purpose: The National Cancer Institute's (NCI's) Cancer Research Data Commons (CRDC) is a data ecosystem for the cancer research community that provides cloud-based, secure storage and analytic tools for many cancer data types, including genomic, proteomic, imaging, and clinical data. CRDC requires a carefully designed, federated data governance framework to enable CRDC's goals to sustain a collaborative data environment where researchers can access timely, accurate, and relevant cancer data.
Methods: In 2023, CRDC chartered a Data Governance Framework of Committees and Working Groups across all CRDC components to: Enable diverse data type sharing; provide secure data access; optimize common infrastructure components and functions; and adhere to FAIR data principles (Findable, Accessible, Interoperable, and Reusable). We considered many designs for the CRDC Data Governance Framework, including fully centralizing or decentralizing decision-making bodies. Implementing a fully centralized data governance framework for a diverse data ecosystem like CRDC would risk top-down decisions that do not meet the unique needs of the CRDC and cancer research community. A fully decentralized data governance framework risks inconsistencies and compliance challenges. Additional governance design considerations included a federated approach that emphasizes clear roles and responsibilities; prioritizing cross-component policies to ensure consistency and promote operational efficiency; defining measurable performance standards; and keeping data owners, stewards, and users informed, trained, and supported.
Results: We have determined that long term sustainment of CRDC requires a federated governance approach with broad stakeholder participation through Committees and Working Groups. Currently established CRDC governance committees include the Enterprise Architecture Review Team (EART), Submission Review Team, Data Standards Working Group, and Data Advisory Board consisting of cancer research domain experts, researchers, and skilled cloud engineers and developers. In 2023, the CRDC EART defined data lifecycle stages and identified technical optimization opportunities for submission coordination and indexing. The established governance groups are working to identify optimization opportunities for data quality checks, submission review workflows, study acceptance criteria, data submission reviews, and cross-CRDC emerging data standards requirements.
Conclusions: Sustaining large, complex, cancer research data requires a federated governance approach with participation from all relevant stakeholder groups and cannot simply be top-down imposition of policies, standards, and procedures. The newly established CRDC federated governance framework will contribute to improving the long-term sustainability of the CRDC infrastructure and ensuring CRDC data drive meaningful research outcomes.

#3569 Using AI to automatically process data from unstructured health records of patients with lung cancer.

M. Aldea[1], P. Rolland[2], S. Simon[1], A. Poplu[2], M. Wartelle[1], B. Vignal[2], J.-C. Louis[2], F. Lion[1], A. Borie[2], D. Planchard[1], C. Robert[1], S. Michiels[1], F. Andre[1], F. Barlesi[1], F. Le Quay[2], B. Besse[1];

[1]Gustave Roussy, Villejuif, France, [2]Lifen, Paris, France

Introduction: Structured databases created from electronic health records (EHR) are crucial for cancer research. Manual data entry into databases is both labor-intensive and error-prone. We aimed to develop an artificial intelligence (AI)-driven approach for automatically inputting patient information from EHRs.
Methods: A REDCap database for 53 patients with advanced lung cancer treated with first line immuno+/-chemotherapy at Gustave Roussy between 02/2021-06/2023 was manually populated by physicians with demographics, risk factors, cancer history, and treatment data, with 137 variables/patient. Given unstructured medical letters and a schematic description of each variable, generative AI was used to find, quote and process variables into a structured form. We directed large language model actions with prompt engineering and tailored few-shot examples. Mortality data were auto-extracted from the French public registry, INSEE. We assessed consistency between manual (MDE) and automated data entry (ADE), with a secondary manual review for mismatches performed by a senior physician.
Results: In total, 7,261 data points were assessed. ADE averaged 10 minutes per patient inclusive of quality checks vs 1 h for MDA. The concordance rate between ADE and MDE was 90.2% (6,550/7,261) with a discordance of 6.8% (496/7,261). Data was missing in 0.8% (59/7,261) of cases for both methods, 1% (73/7,261) for ADE and 1.1% (83/7,261) for MDA. After checking discordances, ADE correctness was 95.3% (6,922/7,261) (Table), MDE was 93.8% (6,809/7,261). Errors in ADE (207/7,261) were due to algorithm refinement needs (70%) and missing EHR information (30%).
Conclusion: Generative AI has a strong potential for identifying and structuring data from EHRs, yielding consistency superior to manual entry by physicians and 85% reduced amount of time. This may enhance the efficiency, accuracy, and scalability of EHR-to-database conversions. ADE for >1000 patients will be presented at the meeting.

#3572 Role of the gut microbiome in androgen production and prostate cancer treatment resistance.

A. I. Cruz Lebron[1], P. A. Balbuena-Almodovar[1], L. Mummert[1], S. Ernst[1], M. Markowski[1], M. Rudek[1], J. Ridlon[2], K. S. Sfanos[1];
[1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]University of Illinois at Urbana-Champaign, Urbana, IL

Metastatic prostate cancer is often treated via a combination of androgen deprivation therapy (ADT) and the androgen receptor axis-targeted therapies abiraterone acetate + prednisone (AA/P) or enzalutamide. Unfortunately, most individuals undergoing these treatments develop resistance, termed “castration resistance”, through an unknown mechanism. Previous studies demonstrate a potential link between the gut microbiota and the treatment efficacy of endocrine therapy in metastatic castration resistant prostate cancer (mCRPC). This may be due in part to gut bacterial communities with the machinery to synthesize androgens using mechanisms distinct from human cells. For example, the bacterial *desAB* genes (e.g., “desmolase”) that were first described in the gut commensal bacterial species *Clostridium scindens* convert cortisol and prednisone to the androgenic metabolites 11β-hydroxyandrost-4-ene-3,17-dione (11OHAD) and Δ1-adrenosterone (Δ1-AT), respectively. We hypothesize that androgen synthesis by the gut microbiota promotes treatment resistance to AA/P in advanced prostate cancer. This study aims to determine if androgen-converting gut bacterial species as well as circulating and fecal androgen levels correlate with AA/P treatment response in individuals with mCRPC using a combination of metagenomics and metabolomics. We further aim to demonstrate the relationship between gut bacterial androgen production and prostate cancer treatment response using an *in vivo* mouse model. Metagenomic sequencing showed an imbalance in microbial communities and identified the presence of androgen-synthesizing bacteria such as *C. scindens* in fecal samples of individuals undergoing treatment with AA/P. We also demonstrate that the relative abundance of *C. scindens*, as well as other species reported to generate androgens, are significantly enriched during metastatic disease progression on AA/P. Furthermore, targeted quantitative PCR of the bacterial desmolase (*desA*) gene demonstrated that absolute levels of desmolase are significantly higher in AA/P non-responders relative to AA/P responders, and trended higher in individuals with rising prostate-specific antigen (PSA) versus stable PSA while on AA/P. Targeted LC/MS/MS analyses of fecal samples demonstrated the presence of testosterone, dihydrotestosterone, 11OHAD, Δ1-AT, and other androgen metabolites in association with rising PSA levels in the AA/P cohort. Furthermore, we demonstrate that *C. scindens* converts hydrocortisone and prednisone into 11OHAD and Δ1-AT, respectively, *in vitro* at 48- and 72h post-treatment, which recapitulates prior published studies. Finally, we have established a prostate cancer mouse model using a VCaP xenograft in which tumor growth was significantly inhibited by abiraterone acetate in comparison to treatment with ADT alone. Additional studies will use this mouse model to study the effects of androgen metabolism by gut bacteria on AA/P efficacy. Overall, this study ascertains the ability of the human gut microbiota to harbor androgen-synthesizing bacteria, which in turn can be an alternative source of androgens that could impact the efficacy of the anti-androgen therapies used to treat metastatic prostate cancer.

#3574 Cancer testis antigen expression correlates with stromal natural killer cell activation and longer overall survival in small bowel neuroendocrine tumors.

R. I. Ayabe, Y. D. Seo, B. Melendez, R. Lazcano, B. C. Fields, K. Wani, S. Johnson, M. Chelvanambi, C. Hudgens, S. D. Hernandez, N. J. Ajami, J. A. Wargo, A. J. Lazar, D. M. Halperin, J. S. Estrella, J. E. Maxwell;
The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Patients with small bowel neuroendocrine tumors (SBNET) frequently present with metastatic disease and the efficacy of available therapies, including immune checkpoint blockade (ICB), is limited. Toward developing novel immunomodulatory strategies, we interrogated the tumor immune microenvironment of SBNETs using bulk transcriptional and digital spatial profiling (DSP).
Methods: Patients with SBNET who underwent resection at MD Anderson Cancer Center from 2003-2016 were retrospectively analyzed. Overall survival (OS) was assessed using the Kaplan-Meier method and the Cox proportional hazards model was used for multivariate analysis (MVA). Bulk transcriptional profiling was performed using the Nanostring PanCancer-Immune Panel. DSP with whole human transcriptome was performed using PanCK to segment tumor and adjacent stroma; 88 distinct regions were analyzed using differential gene expression and Reactome pathway enrichment pipelines.
Results: Resected SBNET from 42 patients were selected for transcriptional analysis. Unsupervised clustering of gene expression demonstrated dichotomization into high and low cancer testis antigen (CTA) expression. CTA-high patients (n=12) demonstrated elevated expression of type-I interferons (IFN), and CTAs such as PRAME, GAGE1 and MAGEA3 and had significantly longer OS compared to CTA-low patients (n=30; median OS not reached vs 1975 days, p=0.008). MVA controlling for age, sex, stage, and Ki-67% confirmed CTA-high status as an independent predictor of longer OS (hazard ratio [HR] 0.2, 95% confidence interval [CI] 0.05-0.83, p=0.014). A pilot DSP experiment on 4 CTA-high and 4 CTA-low tumors confirmed differential gene expression in the PanCK+ tumor compartment of these samples (R2=0.09, p=0.001). In particular, epigenetic modification genes (e.g., H2BC8, H4C8, H3C1, p<0.001) and epigenetic pathways (e.g., DNA methylation, histone acetylation) were enriched in CTA-high tumors. CTA-high tumors exhibited increased M2 macrophage presence (p=0.025) and increased NK cell activation within the PanCK- stromal compartment (p=0.001).
Conclusions: High CTA and type-I IFN expression in resected SBNET identifies patients with longer survival, agnostic of stage or grade. While CTA expression has been implicated in tumor immunogenicity, this is the first work to identify a clinically relevant signal in SBNET. Increased IFN in CTA-high tumors, corroborated by increased stromal NK cell activation, suggests that enhanced immunogenicity may drive this survival difference. Spatial transcriptomic analysis reveals epigenetic differences in CTA-high tumors and highlights the potential for combination epigenetic modifiers and immunotherapy in future trials.

#3575 The estrogenic endocrine disrupting compounds bisphenol-a (BPA) and alpha-zeranol (aZAL) induce early mammary hyperplasia in female ACI rats.

C. Winz, B. Liu, C. Xie, S. Rohatagi, E. Li, P. Furmanski, N. Suh;
Rutgers University - New Brunswick, New Brunswick, NJ

Endocrine disrupting compounds (EDCs) found in food-grade plastics, drinking water, and foodstuffs, pose a threat to human health. Estrogenic EDCs are capable of binding and activating the estrogen receptor (ER). Since breast tissue relies on estrogen signaling for growth and renewal, excessive estrogen stimulation is associated with breast cancer development. Breast cancer is a leading cause of cancer-related death in women. Only 5-10% of all breast cancer cases can be attributed to genetic causes, and the proportion of breast cancers of the luminal subtype are increasing in the United States for reasons unknown. Estrogenic EDCs may be able to initiate breast cancers through their estrogenic activities. The present study assessed two EDCs: the plasticizer bisphenol-A (BPA) and the mycotoxin alpha-zeranol (aZAL). To assess the estrogenic effects of these EDCs in an *in vivo* model, we utilized the ACI rat strain due to its sensitivity to estrogen-induced mammary carcinogenesis. The hypothesis of this work was that BPA and aZAL will induce mammary gland proliferation and estrogen signaling at early timepoints post-exposure. Estrogen, BPA, or aZAL were implanted into the backs of female ACI rats in silastic tubes at either a 9 gram doses. At a timepoint of 5 days post implantation, we saw no overt toxicity of our treatment. Both BPA and aZAL resulted in increased glandular proliferation and hyperplasia in a comparable manner to estrogen. Immunohistochemistry and qPCR revealed that the estrogen signaling marker progesterone receptor (PGR) was significantly upregulated in the estrogen, BPA, and aZAL treatment groups compared to control. The percent positivity of PGR staining in the mammary glands were 21.5% +/- 4.2%, 25.7% +/- 1.7%, 27.9% +/- 3.8%, and 8.18% +/- 2.5% respectively. Additionally, PCNA, a marker of cell proliferation, was significantly upregulated in the estrogen and aZAL treatment groups. The percent positivity of PCNA staining in the mammary glands were 7.67% +/- 2.56%, 49.6% +/- 5.2%, and 41.0% +/- 11.5% respectively. Additionally, the weight of the pituitary gland, an estrogen-sensitive endocrine organ, significantly increased in both the estrogen and aZAL treatment groups. Overall, this study demonstrated that the estrogenic EDCs BPA and aZAL induced mammary gland proliferation and hyperplasia in a comparable manner to estrogen. This is concerning due to the routine detection of these two compounds in human biosamples. More information is needed to assess the risk of exposure to these compounds as it pertains to breast cancer and other hormonal cancers.

#3576 CRISPR Cas9 mediated MADD deletion can induce autophagy via downregulation of MAPK and PI3K/AKT/mTOR signaling in anaplastic thyroid cancer.

V. Bakthavachalam, M. Madhayan, M. Sanborn, J. Rehman, P. Bellur;
University of Illinois at Chicago, Chicago, IL

Thyroid cancer is a highly prevalent endocrine malignancy with one of the fastest growing incidences of all cancers in the United States. Anaplastic thyroid cancer (ATC) has an incidence of about 1.7% of all thyroid cancers, but it causes over 40% of thyroid cancer-related deaths with a median survival period of less than one year. This is why agents that inhibit the aberrant signaling pathways which drive ATC aggressiveness are of significant interest. MAPK-activating Death Domain-activating protein (MADD) plays a key role in cancer cell survival and proliferation. MADD is constitutively expressed at higher levels in most tumor tissues and cancer cells relative to normal tissues. Studies using shRNA suggest that MADD prevents apoptosis in ATC cells. For a more definitive and mechanistic analysis of MADD in ATC, we used conditional CRISPR-Cas9 gene editing to target MADD. We observed that MADD deletion in ATC cells induced spontaneous apoptosis and also activated the autophagy pathway in human ATC cells through downregulation of ERK and mTOR signals involving the MAPK and PI3K/Akt/mTOR signaling pathways. Transcriptomic analysis of publicly available TCGA data showed several PI3K/AKT/mTOR pathway genes were positively correlated with MADD levels. RNA sequencing data of ATC lines demonstrated that enhanced activity of the PI3K/AKT/mTOR signaling pathway was correlated with a worse prognosis in ATC. Targeted MADD deletion in ATC cells combined with treatment using ERK/PI3K/Akt/mTOR/autophagy inhibitors resulted in enhanced cell death compared with MADD deletion alone. Further, MADD deleted 8505C-ATC cells showed significantly delayed tumor formation in an orthotopic nude mouse model. These findings suggest that combining MADD deletion with inhibitors of PI3K/Akt/mTOR pathway could provide an attractive new therapeutic option for ATC.

#3577 The role of PLXND1 in lineage plasticity and progression to neuroendocrine prostate cancer.

B. Chen, P. Xu, J. C. Yang, S. Ning, L. Wang, C. Nip, A. C. Gao, C. Liu;
UC Davis, Sacramento, CA

Background: Neuroendocrine prostate cancer (NEPC) is a lethal subtype of prostate cancer and is commonly associated with therapy resistance and poor prognosis. Treatment-induced NEPC (t-NEPC) predominantly develops by lineage plasticity from adenocarcinoma in response to androgen receptor signaling inhibitors, such as enzalutamide. However, the mechanisms underlying the lineage plasticity and progression to NEPC are unclear. PLXND1 (PlexinD1) is a cellular receptor of the semaphorin family and has important functions in modulating the cytoskeleton and cell adhesion. However, the role of PLXND1 in lineage plasticity to NEPC development and progression is not well established.
Methods: We performed transcriptomic analysis on NEPC patients' cohorts and the enzalutamide-resistant prostate cancer cell lines. Correlation of PLXND1 with neuroendocrine feature genes and AR-targeting genes was determined. Kaplan-Meier method and the Cox proportional hazards model was used to estimate the correlation between PLXND1 expression level and patients' survival. Immunohistochemistry was used to analyze PLXND1 expression in prostate adenocarcinoma and NEPC. Cell viability was determined in C4-2B MDVR, CWR22Rv1, and H660 cells after knocking down PLXND1 using siRNA or knocking out PLXND1 using CRISPR/CAS9. Organoids viability of patient-derived xenografts was measured after knocking down or knocking out PLXND1.
Results: Our analysis on different patient cohorts suggests that PLXND1 is highly expressed in NEPC patients, and the expression of PLXND1 is positively correlated with neuroendocrine feature genes (CHGA, ENO2, SYP, and NCAM1). Kaplan-Meier survival analysis shows that high expression of PLXND1 is significantly associated with the poor prognosis of prostate cancer patients. PLXND1 is overexpressed and negatively regulated by androgen receptor signaling in enzalutamide-resistant cells and prostate cancer patients' cohorts. Furthermore, downregulation of PLXND1 expression suppressed proliferation of the NEPC cells and viability of the PDX tumor organoids.
Conclusions: PLXND1 expression is elevated in NEPC and correlated with the poor survival of prostate cancer patients, suggesting it is a potential molecular indicator and therapy target for NEPC.

#3578 A systematic NEN spheroid drug screen reveals a novel drug resistance mechanism in small bowel NETs.

C. G. Tran[1], L. C. Borbon[1], D. H. Tow[1], J. Shilyansky[1], G. Li[1], J. Egan[1], S. K. Sherman[1], E. Abusada[1], J. Tang[2], R. govindan[3], R. C. Fields[3], T. A. Braun[1], C. H. Chan[1], C. Chandrasekharan[1], D. Spitz[1], D. E. Quelle[1], A. M. Bellizzi[1], J. R. Howe V[1], **P. Ear**[1];

[1]University of Iowa, Iowa City, IA, [2]University of Helsinki, Helsinki, Finland, [3]Washington University, St. Louis, MO

Neuroendocrine neoplasms (NENs) are rare cancers that arise from neuroendocrine cells. NENs are classified as well-differentiated neuroendocrine tumors (NETs) and poorly differentiated neuroendocrine carcinomas (NECs). Small bowel NETs (SBNETs) and pancreatic NETs (PNETs) are generally slow growing but they commonly metastasize to the liver and can become aggressive cancers. NECs are rapidly growing, and patients have poor prognosis. Little is known about the drug sensitivity profile of SBNETs, PNETs and NECs due to a paucity of cellular and animal models of these malignancies. We have successfully cultured NEN cells from clinical samples as patient-derived spheroids (PDS) and showed that they express appropriate tumor markers. We systematically screened 20 NEN (12 SBNET, 5 PNET, and 3 NEC) spheroid cultures against a library of 175 compounds (147 FDA-approved anti-cancer drugs, 8 lab selected compounds, and 20 structurally diverse molecules) and compared their drug sensitivity profiles to identify the most effective drug classes and to better understand the biology of each NEN subtype. Top drug hits were validated for their anti-tumor properties in NEN PDS and patient-derived xenograft (PDX) mouse models. Our NEN PDS cultures identified common and unique drug sensitivity profiles for each type of NEN. SBNET spheroids were more resistant to many classes of anti-cancer drugs, which was due to overexpression of cytochrome P450 genes. Consistent with clinical findings, PNET spheroids showed increased sensitivity to tyrosine kinase and mTOR/PI3K inhibitors compared to SBNET & NEC spheroids. NEC spheroids showed the broadest sensitivity to many anti-neoplastic compounds. The top candidate drug identified from our screen was romidepsin, a histone deacetylase inhibitor. Romidepsin displayed anti-tumor properties *in vitro* and *in vivo* for all 3 NEN models and was highly synergistic with rapamycin, an mTOR inhibitor similar to the SBNET approved drug everolimus. Excitingly, low-dose romidepsin effectively inhibited tumor growth when combined with low-dose rapamycin in an SBNET PDX mouse model. These NEN PDS drug screens enabled direct drug testing in primary tumor cultures to identify promising drugs that could be used alone or in combination with currently approved-NEN therapies. Histone deacetylase inhibitors, such as romidepsin, may be effective against SBNETs. NEN PDS models also serve as a valuable resource for understanding the unique biology and mechanisms of drug resistance for specific NEN subtypes.

#3580 Understanding and overcoming innate and acquired resistance to type I and II RAF inhibitors in anaplastic thyroid cancer using translational functional genomics.

P. Zeng[1], J. Meens[2], J. Barrett[1], M. J. Cecchini[1], S. B. Ryan[1], N. Pan[1], A. Karimi[1], L. Jarycki[1], A. E. Dawson[1], M. Shaikh[1], D. Palma[1], E. Winquist[1], P. C. Boutros[3], L. Ailles[2], A. C. Nichols[1];

[1]Western University, London, ON, Canada, [2]University of Toronto, Toronto, ON, Canada, [3]University of California, Los Angeles, Los Angeles, CA

Anaplastic thyroid cancer (ATC) is one of the most lethal human cancers, with some patients succumbing to the disease within weeks of diagnosis. Despite a subset of *BRAF*^{V600E} mutant ATC patients responding to monomeric type I RAF inhibitor (RAFi) dabrafenib in combination with MEK inhibitor (MEKi) trametinib, almost all patients rapidly develop adaptive or acquired resistance. These patients, along with those who do not harbor the *BRAF*^{V600E} alteration, have limited treatment options. To understand the mechanism of resistance to dabrafenib and trametinib, we utilized multi-region whole genome sequencing and single nuclei profiling of ATC patient tumors to unravel genomic, transcriptomic, and microenvironmental evolution during type I RAFi and MEKi therapy. Single-cell nuclei sequencing of matched primary and resistant ATC patient tumors identified transcriptomic reactivation of MAPK-pathway, along with immunosuppressive macrophage proliferation, underlie the development of acquired resistance. Our translation genomics led us to hypothesize that deeper inhibition of the MAPK-pathway can be efficacious in overcoming treatment resistance. Screening of a panel of type II RAFis revealed that ATC cell lines are exquisitely sensitive to the type II RAFi naporafenib. We further demonstrate that naporafenib in combination with MEKi trametinib can durably and robustly overcome both innate and acquired treatment resistance to dabrafenib and trametinib using ATC cell lines and patient-derived xenograft models, including in a PDX model from an ATC patient who developed acquired resistance to dabrafenib and trametinib. Finally, we describe a novel mechanism of acquired resistance to type II RAF inhibitor and MEK inhibitor through compensatory mutations in *MAST1*. Taken together, our work using translational and functional genomics have unraveled the differential mechanisms of treatment resistance to type I and type II RAFi in combination with trametinib, and rationalizes the clinical investigation of type II RAFi in the setting of thyroid cancer.

#3581 IGFR1 and MEK inhibition synergize to mediate anti-tumor activity in adrenocortical carcinoma.

S. Kumar, N.-Y. Sun, Y. Arakawa, D. Varghese, C. D. Hoang, J. M. Hernandez, Y. Pommier, C. Thomas, J. Del Rivero, N. Roper;
National Cancer Institute Center for Cancer Research, Bethesda, MD

Adrenocortical carcinoma (ACC) is an aggressive and rare endocrine malignancy with limited treatment options and poor prognosis. IGF2, the ligand for IGFR1, is highly expressed in ACC. However, linsitinib, an IGFR1 inhibitor, failed to improve overall survival over placebo in a randomized, phase 3 clinical trial of metastatic ACC. We hypothesized that combination therapy with IGFR1 inhibition may have greater anti-tumor efficacy in ACC than IGFR1 inhibition alone. To test this hypothesis, we performed high-throughput cell toxicity screening of 2803 clinical-stage compounds with linsitinib in an ACC cell line. MAPK inhibitors were among the top screening hits. MEK inhibitors were chosen for further evaluation given the safety, tolerability, and broad clinical activity of these FDA-approved agents. IGFR1 and MEK inhibitors were strongly synergistic in cytotoxicity across ACC cell lines, ACC organoid short-term cultures derived from surgical tissue resections (PDOs), and PDX-derived organoids (PDXOs). Genetic depletion of IGF2 significantly inhibited growth with cobimetinib and genetic depletion of MEK1 inhibited growth with linsitinib in ACC cell lines. Combination IGFR1 and MEK inhibition downregulated ERK phosphorylation and increased apoptosis compared to either IGFR1 or MEK inhibition alone. Linsitinib combined with cobimetinib significantly reduced tumor growth compared to either linsitinib or cobimetinib alone in an ACC xenograft model. Our study provides preclinical support for testing the combination of IGFR1 and MEK inhibition in patients with ACC.

#3582 PPAR gamma acetylation governs mammary adenocarcinoma tumor growth via acetylated residues that determine DNA sequence-specific binding.

L. Tian[1], X. Jiao[2], C. Wang[1], A. Ertel[1], R. Soccio[3], E. R. Chen[3], B. Győrffy[4], G. Di Sante[2], Z. Zhong[1], S. Addya[1], P. A. McCue[1], A. V. Kossenkov[5], J. Achinger-Kawecka[6], S. Clark[6], **R. G. Pestell**[2];

[1]Thomas Jefferson University, Philadelphia, PA, [2]Baruch S. Blumberg Institute, Wynnewood, PA, [3]Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA, [4]Semmelweis University, and RCNS Cancer Biomarker Research Group, Budapest, Hungary, [5]The Wistar Institute, Philadelphia, PA, [6]Garvan Institute of Medical Research, Darlinghurst, Australia

Background: HER2/neu overexpression in breast cancer confers a lipogenic phenotype. Although the introduction of anti-Her2 therapies has led to dramatic improvements in survival, nearly all patients with metastatic Her2-positive breast cancer will progress on treatment suggesting the importance of developing coextinction approaches targeting multiple pathways. Peroxisome proliferator-activated receptor γ (PPARγ), which is expressed in a variety of malignancies, governs biological functions through transcriptional programs. PPARγ binds additional DNA cis elements associated with other transcription factors, including C/EBPs, NFκB and AP-1 proteins, to promote non-canonical signaling. Defining the mechanisms governing the selection of canonical versus non-canonical PPARγ binding sequences may provide the opportunity to design regulators with distinct functions and side effects. PPARγ1 acetylation at K268/293 participates in the regulation of adipose tissue differentiation (1), and the conserved lysine residues (K154/155) govern lipogenesis in breast cancer cells (2). Although Cre based *Ppary1* gene deletion in mammary tumor oncomice showed *Ppary1* participates in the onset and progression of ErbB2-induced mammary tumorigenesis (3), the molecular mechanisms and the post-translational modifications of PPARγ governing *Ppary1* tumorigenic function remained to be determined.

Methods: Herein, we defined the role of PPARγ1 acetylation in breast cancer growth in immune-deficient mice using distinct breast cancer cell lines (MCF10-Ras, MCF10A-NeuT). Furthermore, using ChIP and ChIP-Seq we show that the acetylated residues of *Ppary1* altered preference of *cis*-element binding in chromatin to augment *Ppary* non-canonical binding.

Results: Herein, the PPARγ1 acetylated residues K154/155 were shown to be essential for the induction of transcriptional modules governing growth factor signaling, cellular apoptosis, and autophagy in mice. The K154/155 residues determined the selection of genome-wide DNA binding sites, altering the selection from canonical to non-canonical (C/EBP) DNA sequence-specific binding. The gene signature reflecting the acetylation-dependent genomic occupancy provided predictive value in patient survival outcomes.

Conclusions: Endogenous *Ppary1* promotes mammary tumor onset and progression. PPARγ1 breast tumor induction involves K154/155, which governs transcriptional programs (growth, apoptosis, and autophagy) via transcriptional complex binding to canonical *vs.* non-canonical regulatory elements. *Ppary1* acetylation participates in ErbB2-induced breast cancer tumor growth and inflammation and may represent a relevant target for therapeutic coextinction.

#3583 Enzalutamide and flutamide induce cytotoxicity in desmoplastic small round cell tumor independent of the androgen receptor.

J. W. Magrath[1], I. N. Goldberg[1], D. D. Truong[2], A. B. Hartono[1], S. Sampath[1], C. E. Jackson[1], A. Ghosh[1], D. L. Cardin[1], H. Zhang[1], J. A. Ludwig[2], S. B. Lee[1]; [1]Tulane University School of Medicine, New Orleans, LA, [2]The University of Texas MD Anderson Cancer Center, Houston, TX

Desmoplastic Small Round Cell Tumor (DSRCT) is a rare, pediatric cancer caused by the EWSR1::WT1 fusion protein. DSRCT predominantly occurs in males, which comprise 80-90% of the patient population. While the reason for the male prevalence remains unknown, one hypothesis is that the androgen receptor (AR), when stimulated by testosterone in males, plays a critical role in DSRCT tumor growth. As a rare pediatric cancer, DSRCT model systems including cell lines and patient-derived xenografts are scarce. Further, DSRCT cell lines have been thought to seed xenograft tumors poorly, with studies commonly using 5-10 million cells for one xenograft. Using a recently established DSRCT cancer stem cell (CSC) model, we sought to establish DSRCT xenografts from fewer cells to enable large-scale xenograft feasibility and reliability. To our surprise, we were able to consistently seed tumors with as few as 100 cells, not only from CSC spheres but also from standard adherent cells. We hypothesized that mouse sex may explain our ability to seed xenografts with so few cells, as many previous studies have utilized female mice. This observation led us to comprehensively investigate the role of the AR in DSRCT. Here, we demonstrate that AR is highly expressed in DSRCT relative to other fusion-driven sarcomas and that the AR antagonists - enzalutamide and flutamide - reduce DSRCT growth. We further elucidate a novel interaction between AR and EWSR1::WT1, which may explain their co-occupancy in a subset of regulatory genomic regions. However, despite these findings, which suggest an essential role for AR in DSRCT, we find that DSRCT cell lines can form xenografts in female mice at the same rate as male mice and AR depletion does not significantly alter DSRCT growth *in vitro*. Further, we demonstrate that AR antagonists remain effective in DSRCT cells depleted of AR, establishing an AR-independent mechanism of action. Intriguingly, high-dose enzalutamide treatment reduces EWSR1::WT1 oncoprotein expression and could explain its toxicity. DSRCT cells express high levels of NR3 nuclear receptors, including the glucocorticoid receptor (GR). Enzalutamide was shown to act on GR in AR-negative prostate cancer cell lines, which could possibly explain its effect on DSRCT independent of AR. Further examination of this mechanism may provide promising therapeutic implications for DSRCT and other fusion proteins driven by the EWSR1 promoter.

#3584 Context matters: Genomic profiling of PR isoform-specific actions in breast cancer stem cells reveals novel therapeutic insights for ER+ breast cancer.

N. E. Gillis[1], T. H. Truong[1], J. Finlay-Schultz[2], C. A. Sartorius[2], C. A. Lange[1];
[1]University of Minnesota, Minneapolis, MN, [2]University of Colorado Anschutz Medical Campus, Aurora, CO

Exposure to progesterone is a recognized risk factor for breast cancer, and *PGR* polymorphisms are associated with various malignancies. The two progesterone receptor (PR) isoforms, full length PR-B and truncated PR-A, are expressed from the *PGR* gene in breast tissue and play crucial roles in normal physiology. An imbalance in the expression ratio of these isoforms, favoring increased levels of PR-A, is common in breast cancer and is associated with resistance to tamoxifen in Luminal A-type tumors. Notably, PRs have recently been implicated in promoting endocrine resistance and driving the expansion of cancer stem-like cell (CSC) populations implicated in early dissemination and maintenance of metastatic populations. Because prior gene expression studies were primarily conducted in 2D culture conditions, the isoform-specific molecular and epigenetic mechanisms underlying PR actions in advanced ER+ breast cancer remain elusive. Our goal was to define progesterone-driven gene expression in CSC cells by employing transcriptomic profiling of T47D cells cultivated in spheroid-culture conditions (3D) expressing exclusively PR-A or PR-B. Utilizing CUT&RUN, we have mapped the genomic binding sites unique to each PR isoform and identified shared sites. This genomic data has been integrated with phenotypic studies in cells expressing a single PR isoform. Our findings indicate that PR-A acts as a regulator of the cell cycle and senescence, while PR-B plays a pivotal role in cell metabolism and intracellular signaling. We find little overlap between PR-regulated gene sets derived from the same hormone-treated cells harvested from 2D relative to 3D conditions. Our genomic profiling of PRs in this 3D model system has unveiled novel strategies to combat CSC outgrowth and late recurrence in luminal breast cancer patients. This work has shifted our prior understanding of the role of PRs in gene regulation within the CSC population, and offers potential insights for therapeutic interventions in ER+ breast cancer.

#3585 DNA-PK inhibition to enhance radiation sensitivity in metastatic pancreatic neuroendocrine cancer.

P. G. Rychahou[1], A. Chauhan[2], Z. Chow[1], T. Izumi[1], Q. Chen[1], E. Y. Lee[1], D. Napier[1], L. Anthony[1], M. J. Cavnar[1], C. M. Townsend, Jr.[3], B. Evers[1]; [1]University of Kentucky, Lexington, KY, [2]University of Miami, Miami, FL, [3]University of Texas Medical Branch, Galveston, TX

Gastroenteropancreatic (GEP) neuroendocrine tumors (NETs) are neoplasms originating from the gastrointestinal track and pancreas. Unfortunately, most patients at the time of diagnosis have extensive metastatic disease and are not candidates for curative surgical resection of metastatic tumors. In such cases, targeted radiation therapy (RT) can slow the progression of metastatic disease, but eventually tumors develop resistance to radiation therapy. In this study, we examined whether DNA-PK inhibition could sensitize pancreatic NETs to radiation therapy and enhance the radiation therapy effect in a preclinical model of pNET metastasis.

Methods. We used 96-well clonogenic assays to evaluate the efficacy of the DNA-PK inhibitor peposertib in combination with RT *in vitro* in QGP-1 and BON pancreatic NET cell lines. Double-strand break-induced DNA repair was visualized with confocal laser scanning microscopy using γ-H2AX immunofluorescence after peposertib treatment alone or in combination with RT. Western blot analysis was used to confirm inhibition of DNA-PKcs (pDNA-PKcs S2056) combination RT. The efficacy of peposertib in combination with RT was evaluated in QGP-1 and BON human xenograft models in athymic nude mice and a BON preclinical lung metastasis model.

Results. Clonogenic assays demonstrated absence of cytotoxicity from peposertib alone at doses below 1000 nM and a strong radiosensitizing effect at 200 nM in both QGP-1 and BON cell lines. Pretreatment with peposertib or treatment within 2 h after RT suppressed colony formation; treatment at later timepoints did not enhance radiotherapy. Immunofluorescence analysis revealed high numbers of γH2AX foci with peposertib therapy alone at 96 h or when given 2 h after RT. Western blot analysis confirmed inhibition of DNA-PK Ser2056 after RT in combination with peposertib. DNA-PK inhibition in combination with RT led to remarkable repression of pNET growth both in subcutaneous xenografts (>90%) and in the preclinical lung metastasis model (>90%).

Conclusions. Our results showed several advantages of targeting DNA-PK to enhance radiation sensitivity in high-grade pNETs: (1) DNA-PK inhibition alone disrupts DNA damage response in pNETs as demonstrated by strong H2AX phosphorylation. (2) DNA-PK inhibition is most effective at enhancing radiotherapy either right before or after radiation therapy administration. This demonstrates that extended DNA-PK inhibition is not necessary to achieve marked responses during pNET radiotherapy. (3) DNA-PK inhibition 30 min before radiation therapy is sufficient to greatly reduce pNET tumor growth or metastasis progression in pNET preclinical models. In summary, selective DNA-PK inhibition provides a potent therapeutic strategy for disruption of non-homologous end joining DNA double-strand break repair and may offer a novel therapeutic approach in advanced NET radiotherapy.

#3586 A Hedgehog-dependent signaling axis drives neural plasticity and oncogenic reprogramming in gastroenteropancreatic neuroendocrine tumors.

S. Duan[1], R. A. Sontz[1], M. Deymier[2], J. L. Merchant[1];

[1]University of Arizona College of Medicine, Tucson, AZ, [2]Arizona Genetics Core, Tucson, AZ

Background: Neuroendocrine tumors (NETs) represent heterogenous malignancies whose origins and etiology remain poorly understood. *Men1*-driven reprogramming of neural crest-derived glial cells was recently implicated in NET development. In these studies, aberrant Sonic hedgehog (SHH) pathway activation known to pattern neural cell fate coincided with the neuroendocrine phenotype in mice. Here, we investigated the hypothesis that loss of menin encoded by the *MEN1* gene drives SHH-dependent oncogenic reprogramming of NETs by modulating the neural crest cell fate.

Methods: Glial cell specific *Men1* deletion was accomplished by expressing *Cre* recombinase downstream of the human glial fibrillary acidic protein promoter (*GFAP*$^{\Delta Men1}$). Hedgehog (HH) activation of *Men1*-deficient glial cells was blocked by deleting the gene encoding primary ciliary protein *Kif3a* required for transducing SHH signaling. The resulting *GFAP*$^{\Delta Men1}$ mice were evaluated for NET development and dysregulated hormone profiles. To identify aberrant SHH activation leading to neuroendocrine reprogramming, we performed single cell RNA- and Assay for Transposase Accessible Chromatin sequencing on *GFAP*$^{\Delta Men1}$ NETs and primary glial cultures. Hyperactivation of SHH in human gastroenteropancreatic (GEP)-NETs was confirmed by immunofluorescent staining and western blot. Lastly, primary mouse and human NET organoids were treated with an agonist and inhibitors of HH signaling and evaluated for ERK/AKT activation, proliferation, and transcript fluctuations indicative of neural crest cell reprogramming.

Results: *GFAP*$^{\Delta Men1}$ mice developed NETs in the pancreas, pituitary, and small intestine. Astonishingly, impaired SHH activation in GFAP^{+}/*Men1*$^{-/-}$ cells abolished the development of NETs and restored hormone levels to that of wild type mice. *GFAP*$^{\Delta Men1}$ NETs and glial cultures showed increased SHH signaling and chromatin accessibility of HH pathway genes, whereas additive *Kif3a* deletion blocked HH activation. Moreover, menin negative glial cells demonstrated a phenotypic shift in neuroglial lineages that suggested SHH-mediated reprogramming of neural crest-derived cells following the loss of menin. Consistent with hyperactive SHH activation in the *GFAP*$^{\Delta Men1}$ mice, human GEP-NETs overexpressed SHH and downstream signaling targets. Functionally, SHH induced ERK/AKT activation, cell proliferation, and neuroendocrine transcript expression in human and mouse NET organoids, whereas pharmacological inhibition of HH signaling reversed these effects.

Conclusions: Our observations implicate neural crest-derived glial cells as potential neuroendocrine cell precursors that are susceptible to transformation through increased HH signaling. These studies warrant future investigation into the delivery of Hedgehog inhibitors in the adjuvant setting for NET treatment.

#3587 Evidence that membrane progesterone receptors (mPR) play a key role in cancer metastases in most cases of metastatic cancer.

J. H. Check[1], D. Check[2], B. Neumann[3], C. Wilson[2],

[1]Cooper Medical School of Rowan University (CMSRU), Melrose Park, PA, [2]Cooper Institute for Reproductive Hormonal Disorders, Mt. Laurel, NJ, [3]Inspira Health Network, Vineland, NJ

An immunomodulatory protein called the progesterone induced blocking factor (PIBF) is essential for the fetal semi-allograft to escape immune surveillance. Many cancer cell lines make both mPRs for PIBF and the protein itself. The progesterone receptor (PR) antagonist mifepristone added to cancer cell line cultures down-regulated mRNA for PIBF and the PIBF protein. This IRB approved study (that required a compassionate use IND from the FDA) evaluated oral mifepristone 200mg per day (majority) or 300mg in patients with very advanced cancers with no more treatment options available. Patients would remain under the care of their primary oncologists (FDA requirement). Because the nuclear (n) PR may be protective against cancer spread, only patients with cancers negative for the nPR were treated. Patients with the following types of cancers received mifepristone: non-small cell lung cancer (NSCLC) (n=9), small cell lung cancer (SCLC) (n=2), colon (n=3), pancreatic (n=2), thymic epithelial cell (n=1), transitional cell carcinoma of the renal pelvis (n=1), malignant fibrous histiocytoma (n=1), glioblastoma multiforme stage IV (n=1), leiomyosarcoma (n=1). All 21 patients showed significant palliative benefits, especially but not limited to, marked reduction in pain and marked improvement in energy, decreased dyspnea on exertion, and return of mental clarity. For those who had repeat CT evaluation no one failed to show shrinkage and decrease in malignant lesions and 2 (leiomyosarcoma and SCLC) showed complete remission after a few months on mifepristone. Five patients (3 females, 2 males) with SCLC (1), NSCL (n=3) and fibrous osteosarcoma (n=1) survived at least 5 years with 2 dying from cancer unrelated causes (SCLC and NSCLC). Two are still alive (NSCLC with EGFR mutation and brain metastases). The male with fibrous osteosarcoma died after stopping mifepristone in favor of a new drug recommended by his oncologist. Two patients lived over 2 years. Most would have lived longer had they not stopped mifepristone. Other observations: significant palliative benefits are seen within 3 weeks of taking mifepristone before any evidence of significant tumor regression. After a period of time, some lesions (especially in the primary location) may start growing slowly, but this is not a sign of loss of drug efficacy and long good quality life is still probable if one remains on the drug. The cancer spreads rapidly if one stops the mifepristone. The usual reason for stopping the drug was intervention by the primary oncologist suggesting a new clinical trial because there has not been complete remission of the cancer or some tumor growth (usually slow) or finances. Not one patient had a side effect. Hopefully this study will generate interest in treating patients with advanced cancer with mifepristone, especially those devoid of the nPR. These data support the role of mPRs in cancer proliferation.

#3588 Androgen synthesis disruption, ferroptosis induction and prostate cancer inhibition by androgen and vitamin D combination.

B. Park, J. Vaquiz, O. Igbekoyi, **B. Chatterjee**;
UT Health Science Center at San Antonio, San Antonio, TX

Background: Metastatic castration-resistant prostate cancer (CRPC) is a fatal condition that progresses to end-of-life within two years, and it is the fifth leading cause of cancer death in men globally. New avenues for preventing or delaying lethal CRPC progression are a critical unmet need. Hormonal vitamin D_3 (calcitriol) inhibits prostate cancer - both castration sensitive and castration resistant - in preclinical models, as documented widely. However, vitamin D as an anti-cancer therapeutic is clinically untenable since prostate tumor suppression in patients requires hormone dosing at a supraphysiologic level which induces hypercalcemia and other toxicities.

Results: Herein we provide the first evidence that a subnanomolar, non-calcemic calcitriol dose can inhibit CRPC cell proliferation, G1 to S phase transition, clonal growth, migration, and invasion *in vitro*, and xenograft growth *in vivo*, only upon concurrent dosing with 5α-DHT at a physiologic or subphysiologic level. Calcitriol as a single treatment is non-inhibitory at a subnanomolar dose. HSD3β1, a hydroxysteroid dehydrogenase, was markedly induced by calcitriol, while DHT cotreatment reduced the induction. HSD3β1 catalyzes conversion of dehydroepiandrosterone, an adrenal androgen, to androstenedione (AED) - a rate-limiting step in the androgen biosynthesis pathway. AKR1C3, an aldo-keto reductase which promotes androgen biosynthesis, was also reduced by calcitriol/DHT cotreatment. In contrast, AKR1D1, an androgen-inactivating 5β-reductase, was robustly induced by a non-calcemic calcitriol dose in the presence of DHT, not by calcitriol singly. AKR1D1 converts AED and testosterone to 5β-diols. HSD3β1 and AKR1C3 are elevated in CRPC. Disruption of androgen biosynthesis and net reduction of the intratumor androgen pool are expected outcomes of reduced HSD3β1 and AKR1C3, and elevated AKR1D1. The hormone pair led to LC3B induction, ferritin degradation, and induction of *ALOX-5* and *NCoA4* - the genes which regulate ferroptosis, indicating autophagy mediated ferroptosis (ferritinophagy). Apoptosis and necroptosis were absent. We conclude that vulnerabilities created by combined androgen and non-calcemic vitamin D dosing can lead to cell death by ferroptosis, and this hormone pairing may be a new avenue for arresting CRPC clinical progression.

Significance: The translational potential of our results is bolstered by the precedent that supraphysiologic testosterone improved serum PSA scores and other clinical parameters for a subset of therapy-inert CRPC patients who received repeated cycles of once-a-month single testosterone dosing- a protocol known as bipolar androgen therapy (BAT)[1]. Our findings may offer a strategic framework for enhancing the efficacy of BAT by including oral dosing of a non-calcemic level of vitamin D_3. W81XWH-21-1-0307 (DoD); IK6 BX004207 (VA). Ref 1: Nat Rev Urol 2023; PMID 36543976

#3589 Understanding the role of Pax5 in development of taxane-resistant NE-like prostate cancer.

S. Bhattacharya, R. Islam, S. Bodas, J. Mishra, D. Das, K. Datta, S. Dutta;
University of Nebraska Medical Center, Omaha, NE

Background: Resistance to the existing Androgen Receptor Signaling Inhibitor (ARSI) therapies led to higher incidences of aggressive therapy-induced neuroendocrine-like prostate cancer (t-NEPC) with predominant small cell-like characteristics, dismal overall survival, and an ultimate resistance to taxane chemotherapies. t-NEPCs are mostly treated with platinum-based drugs with etoposide and/or taxane but have less selectivity and high systemic toxicity, which often limits their clinical and therapeutic potential. During t-NEPC transformation, upon chromatin reprogramming associated with epigenetic alterations and altered transcriptional activity, adenocarcinoma loses its luminal features to adopt neurobasal characteristics. The following study aims to unravel the mechanism of developing t-NEPC taxane resistance upon acquiring such adaptive neuronal characteristics.
Objective: The primary objective is to delineate how chromatin modifications along with epigenetic regulation facilitates the adaptive neuronal characteristics and dictates the development of t-NEPC taxane resistance.
Methods: We generated various t-NEPC cell lines either by genetic modification (DKD) or therapeutic pressure (C4-2BER). We performed RNA-Seq, ATAC-Seq and acetylated Histone (H3K18 and H3K27) ChIP-Seq in our developed t-NEPC models and compared with adenocarcinoma. We next compared ATAC Seq and Acetylated histone ChIP Seq with RNA Seq in C4-2B and C4-2BER and performed functional assays.
Results: Our ATAC Seq and acetylated histone footprints (Ac H3K18 and Ac H3K27 ChIP Seq) analyses revealed an enhanced chromatin accessibility during t-NEPC transformation. Overlapping RNA seq suggested newly transcribed neuronal genes with higher extent of promoter accessibility. Transcription Factor mapping among newly accessible gene promoters revealed preferential Pax5 binding, whose expression occurs selectively in t-NEPC unlike adenocarcinoma. Pathway analysis of differentially expressed neuronal genes in t-NEPC suggested an involvement of Pax5 in axonal guidance, neurotransmitter regulation, and neuronal adhesion, which are essential for strong cellular communication. Furthermore, Pax5 depletion disrupts cellular interaction in t-NEPC, thereby, sensitizing them to taxane therapies.
Conclusions: Our study concludes that continuous AR ablation with ARSIs, leads to chromatin alterations with epigenetic changes, thereby allowing Pax5 transcriptional activation in t-NEPC. This altered transcriptional activity promotes gene expression necessary to govern taxane-resistant t-NEPC development.

#3590 Tumor intrinsic production of glucocorticoids in ovarian carcinoma.

P. Hanjra[1], E. Stur[1], S. Cole[2], S. Lutgendorf[3], A. Sood[1];
[1]UT MD Anderson Cancer Center, Houston, TX, [2]University of California, Los Angeles, Los Angeles, CA, [3]University of Iowa, Iowa City, IA

Background: Cortisol is a glucocorticoid (GC) known to be produced by the hypothalamic-pituitary-adrenal (HPA) axis. Dysregulation of the HPA axis is prevalent in patients with ovarian cancer. These patients have elevated nighttime levels of cortisol and increased tumoral expression of the glucocorticoid receptor (GR); both of which correlate with shortened overall survival (OS). We hypothesize that outside the HPA axis, ovarian cancer may have tumor-intrinsic production of GC. In this study, we examined whether 11 beta-hydroxysteroid dehydrogenase 1 (11β-HSD1; enzyme which activates cortisone to cortisol) has steroidogenic activity in the ovarian cancer tumor microenvironment (TME).
Methods: We used the Genotype-Tissue Expression (GTex) Portal and the Cancer Cell Line Encyclopedia (CCLE) to determine expression of steroidogenic enzymes in the ovary and ovarian cancer cell lines. We further performed UMAP analysis of a single-cell RNA-seq dataset of tumor samples from patients with ovarian carcinoma to cluster for cell type. ELISAs were performed to quantify cortisol production and secretion by cells stimulated with metabolite, cortisone. Subcellular fractionation and Western blotting were performed to measure protein expression of 11β-HSD1, GR, and phospho-Ser 211 GR.
Results: HSD11B1 mRNA (which encodes 11β-HSD1) is detectable in bulk ovarian tissue at a median expression of 78.19 transcripts per million (TPM) as measured in the GTex data. *In vitro*, primary human ovarian fibroblasts express functional 11β-HSD1 and produce and secrete cortisol upon cortisone stimulation in a time-dependent manner, with a mean total secretion of 17.91 ± 0.21 ng/ml at 12 hours. Analysis of scRNA-seq data identifies that cancer-associated fibroblasts (CAFs) may be a source of HSD11B1 in the ovarian TME, with roughly 9% of CAFs expressing HSD11B1. In HeyA8 ovarian cancer cells (positive for 11β-HSD1), cortisone stimulation *in vitro* results in cortisol production with a mean total secretion of 22.04 ± 5.46 ng/ml at 12 hours. Moreover, this cortisol results in GR activation in an 11β-HSD1-dependent manner.
Discussion: We identify 11β-HSD1 as a potential mechanism of GC production within ovarian cancer, with CAFs being a putative source. We further show that 11β-HSD1 activity can lead to activation of the GR within cancer cells.

#3591 Upregulation of CXCL8 is an early step in the oncogenic transition of human thyroid cells by *BRAF*^{V600E}.

R. Sarkar, P. Bolel, J. Klubo-Gwiezdzinska, M. C. Gershengorn;
NIH National Institute of Diabetes and Digestive and Kidney Diseases (NIDDK), Bethesda, MD

Introduction: BRAF^{V600E} is one of the most common oncogenic mutations in human thyroid cancers, especially in papillary thyroid carcinoma (PTC). However, the early molecular changes caused by this mutation have not been studied previously in human thyrocytes *in vitro*.

Methods: Primary cultures of cells derived from noncancerous thyroid tissue of patients (at least n=3) were infected with *BRAF*^{V600E} adenovirus to mimic the mutated condition. Changes induced by the infection were measured at early times (<24h). Transcriptome analysis was performed on infected thyrocytes (n=6) to determine the highest differentially expressed genes between the control and infected groups, which were then verified at the gene and protein levels. RNAi downregulation experiments were performed to determine the cross-regulatory function of the genes.

Results: The induction of *BRAF*^{V600E} mutation, confirmed at the protein level, increased proliferation of the cells, and morphological changes were observed at approximately 24h post-infection. The decreased expression of thyroid-specific genes, viz. TSHR, TG, and TPO were observed after >72h post-introduction of *BRAF*^{V600E} mutation. Transcriptome and protein expression analysis of *BRAF*^{V600E}-positive thyrocytes showed the overexpression of chemokines *CXCL8* and *CXCL12*, and upregulation of endothelial cell-specific molecule 1 (ESM1). These molecules are known to be associated with increased neoangiogenesis and proliferation. Functional studies showed that siRNA knockdown of *CXCL8* decreased the expressions of *CXCL12* and *ESM1*, whereas knockdown of either *CXCL12* or *ESM1* did not decrease the expression of *CXCL8*.

Conclusion: Increased proliferation, de-differentiation, upregulation of chemokines, and endothelial-specific factor are effects associated with *BRAF*^{V600E}-driven thyroid carcinogenesis. CXCL8 appears to play an important early regulatory role in this process.

CLINICAL RESEARCH: Adoptive Cellular Therapy 1
Poster Session

#3595 A retrospective analysis of the clinical characteristics of metastastic solid cancer patients with cytokine-induced killer cells combined immune checkpoint inhibitor immunotherapy.

J. Choi[1], J. Kim[1], D. Yang[2], G. Nam[3];

[1]Konyang Univ. Hospital, Daejeon, Korea, Republic of, [2]Konyang Univ. College of Medicine, Daejeon, Korea, Republic of, [3]GC Cell Corp., Yongin City, Korea, Republic of

Background: Cytokine-induced killer cells (CIKs), obtained through ex vivo expasion from peripheral blood mononuclear cells, are phenotypically and functionally shared with both T and NK cells. Within the T cell group, it can be classified into a group that simultaneously expresses CD3 and CD56 molecules (range: 30% to 70%) and a group representing CD3+ CD56- phenotype (range: 20% to 60%). It also contains a small population (< 30%) of CD3 CD56+ NK cells. They can exhibit potent MHC-unrestricted cytotoxicity for both hematologic and solid tumors, but they are not harmful in hematopoietic precursors and normal tissues. Anti-programmed death-1 (PD-1) antibodies reinvigorate T cell-mediated antitumor immunity. PD-1 blockade antibody might significantly increase the cytotoxic potency of CIK cells via increasing proliferative capacity and IFN-r secretion. This retrospective study is the first to combine CIK cells with PD-1/PD-L1/CTLA-4 blockade(Immune checkpoint inhibitors, ICIs) in patients with metastatic solid cancers.
Methods: We analyzed 225 heavily treated metastastic solid cancer patients receiving CIK cell (Immunecell-LC, GC cell inc provide.) and with ICIs. Blood Sampling for CIK cells production was performed after 3 days after ICIs administration. Patients received a single intravenous infusion of activated autologous CIK cells every 2 weeks. ICIs was administered according to the protocol of each drug regardless of the CIK cells administration date. The primary end points were safety and adverse event (AE) profiles. Objective responses, overall survival (OS), progression-free survival (PFS), and diseae control rate were secondary end points.
Results: Treatment-related AEs occurred in 154/225 patients. Grade 3 or 4 toxicities, including fever and chills, were observed in 28 patients. All treatment-related AEs were tolerable and no death due to autoimmune disease. When administration ICIs, CIK cells exhibited excellent antitumor properties and increased IFN-γ secretion. Objective responses (complete or partial responses) were observed in 67 of the 225 patients. One patients with hepatocellular carcionma had complete response. In most patients who showed an objective response, the effectiveness was maintained for more than 6 months. The overall disease control rate in the patients was 58.9%. At the time of this report, the median OS and PFS were 18.6 and 7.1 months in hepatocellular carcinoma patients and were 13.1 and 6.5 months in triple negative breast cancer patients, respectively.
Conclusion: Treatment with activated autologous CIK cells and ICIs was safe and exerted encouraging antitumor activity in metastastic solid cancers. Phase 2 clinical studies for each tumor type will be conducted.
Keywords: Cytokine-induced killer cells, Immune check inhibitors, Safety, Objective response

#3596 Metabolic reprogramming of the tumor microenvironment to enhance the functionality of TCR-edited T cell in colorectal cancer and liver metastases.

A. Potenza, C. Balestrieri, M. Spiga, L. Albarello, F. Pedica, A. Ferrari, O. A. Botrugno, B. Camisa, E. Tiziano, C. Sirini, M. Casucci, C. Iozzi, D. Abbati, U. Elmore, G. Di Lullo, G. Casorati, C. Doglioni, G. Tonon, P. Dellabona, R. Rosati, L. Aldrighetti, P. Monti, E. Ruggiero, C. Bonini;
IRCCS San Raffaele Scientific Institute, Milan, Italy

In solid malignancies, T cells functionality is intertwined with metabolic reprogramming within the tumor microenvironment (TME), which supports the increased energy request of cancer cells and suppresses the effector function and cytokines production of the immune infiltrate. In primary colorectal cancer (CRCs) and related liver metastases, we revealed extensive transcriptional remodeling across tumors, being metabolic pathways among the major drivers of this variance. Accordingly, extracellular adenosine, accumulating in the TME for the hydrolysis of ATP by CD39 and CD73, has been recognized as a novel inhibitory mediator, which binds preferentially to the A2A receptor (A2Ar) to exert its immunosuppressive activity. By high dimensional flow cytometry, we revealed that CD39 is a major driver of T-cell exhaustion in primary and metastatic CRCs. Therefore, we sought to disrupt CD39 in TCR-edited T cells (TCR_{ED}). By CRISPR/Cas9, we disrupted both the α and β chains of the endogenous TCR together with *ENTPD1*, the gene encoding for CD39, and redirected T cell specificity against the HER2 antigen. $TCR_{ED}CD39_{KO}$ T cells outperformed their competent counterpart in eliminating patient-derived organoids (PDOs) from primary and metastatic tumors both *in vitro* and *in vivo*. Given the role of CD39 in starting the biochemical cascade leading to adenosine production, we aimed at investigating the direct role of adenosine on the functional advantage observed with $TCR_{ED}CD39_{KO}$ T cells. We challenged our cellular products with target cells in the presence or absence of adenosine and observed that $TCR_{ED}CD39_{KO}$ T cells are superior to their competent counterpart in the ability to release cytokines, while the effect is completely abolished when adenosine is present. Also, when $TCR_{ED}CD39_{KO}$ T cells were challenged with PDOs, the exogenously added adenosine nullifies the functional killing advantage given by the $CD39_{KO}$. To gain more insights into the pathway, we also generated $TCR_{ED}A2Ar_{KO}$ T cells. In line with the different roles of CD39 and A2AR on the ATP/adenosine pathway, the disruption of the adenosine receptor resulted in a significant advantage in PDO killing in the presence of adenosine only. We then evaluated the influence of $CD39_{KO}$ in the metabolic capacity of T cells and revealed that $TCR_{ED}CD39_{KO}$ T cells have a greater potential to rely on the mitochondrial other than glycolytic functions, which explains higher functionality and persistence. Further evaluation on the metabolic effect of $CD39_{KO}$ are currently ongoing. Overall, we showed that the ATP/adenosine cascade is relevant for T cells functionality and metabolic status and can be harnessed in adoptive cell therapy strategies to counteract the immunosuppressive TME.

#3597 Multimodal γδ T cell cytotoxicity overcomes cellular therapy reprogramming.

C. B. Nattress[1], D. Fowler[2], P. Vlckova[1], C. Hutton[3], M. Ramos Zapatero[1], J. Sufi[1], F. Cardoso Rodriguez[1], A. Campbell[1], A. Kanouta[2], M. Buschhaus[1], K. Chester[1], J. Anderson[2], V. Li[3], M. Barisa[2], J. Fisher[2], C. Tape[1];

[1]University College London (UCL) Cancer Institute, London, United Kingdom, [2]University College London-Great Ormond Street Hospital (UCL-GOSH) Institute of Child Health, London, United Kingdom, [3]The Francis Crick Institute, London, United Kingdom

Colorectal cancer (CRC) is a devastating disease that kills ~700,000 people worldwide annually. Current immunotherapies struggle against both microsatellite stable (MSS) disease and the immunosuppressive CRC tumor microenvironment (TME). Despite these challenges, tumor infiltrating γδ T cells confer a prognostic benefit to CRC patients and can kill cancer via antibody independent cytotoxicity (AIC) and antibody-dependent cellular cytotoxicity (ADCC). We hypothesized that γδ T cells can be exploited as an 'off-the-shelf' anti-CRC biotherapeutic but their complex interactions within the CRC TME need to be elucidated. To explore the patient-, donor-, and mechanism-specific interactions of γδ T cells with CRC, we performed single-cell profiling of >1,000 CRC patient-derived organoid (PDO) and human Vγ9Vδ2 T cell cultures. γδ T cells from multiple donors were used either unmodified or engineered to secrete a modified IL-15 cytokine (stIL15-γδs). The addition of anti-tumour IgG further allowed us to study anti-PDO ADCC, with antigen specificity assessed with antigenKO PDO models. Using 126-plex Thiol Organoid Barcoding in situ (TOB*is*) mass cytometry (MC) (Qin et al., Nature Methods, 2020) (Sufi and Qin et al., Nature Protocols, 2021), we measured cell-type specific signaling across multiple γδ donors and CRC PDOs, including post-translational modifications (PTMs), cell-state, and immunological phenotype. We found that stIL15-γδs exhibit superior proliferation, purity and viability both *in vitro* and *in vivo*. stIL15-γδs demonstrated significant cytotoxicity against all CRC PDOs tested, commonly outperforming standard-of-care chemotherapies even when challenged against our previously-defined chemorefractory MSS patients (Zapatero et al., Cell, 2023). The susceptibility of PDOs to ADCC differs substantially and is not associated with antigen density and %positivity or PDO tumor mutational burden. Minimal differences in ADCC capability were seen between stIL15-γδs donors which were not associated with γδ phenotype or pre- and post-experiment FcγR CD16 expression. Crucially, we found that stIL15-γδ signaling is reciprocally regulated in a PDO-specific manner, with significant regulation of stIL15-γδ cell-state, PTM signaling and immunological phenotype observed. Increased dysregulation of stIL15-γδs during AIC negatively correlates with PDO cytotoxicity — indicating PDOs negatively reprogram γδ T cellular therapies. However, when γδ T cells engage in ADCC (via anti-tumour IgG), stIL15-γδ signaling recovers, leading to substantial anti-PDO cytotoxicity. Furthermore, stIL15-γδs could perform significant cytotoxicity against all chemoresistant MSS PDOs tested, representing the patient population with greatest unmet clinical need. These results demonstrate that multimodal γδ T cell cytotoxicity can overcome tumor-specific cellular therapy reprogramming.

#3598 A new strategy for T cell therapy: T cells secreting TCR anti-CD3 bispecific T-cell engager.

Hanli Sun, Jiao Huang, Kai Zhan, Wanli Wu, Xianqing Tang, Min Liu, Shanshan Guo, Hongjun Zheng, Yingjie Huang, **Shi Zhong**

XLifeSc Ltd., Guangzhou, China

TCR-engineered T (TCR-T) cells and TCR-anti-CD3 bispecific T-cell engagers (TCEs) are potent TCR-based therapeutic agents with distinct advantages and limitations in tumor treatment. TCR-T cells offer durable persistence within patients but necessitate personalized manufacturing and lack the capacity to harness bystander T cells. Conversely, TCEs are readily available as "off-the-shelf" products and can recruit bystander T cells, yet they exhibit a shorter lifespan. In our study, we sought to merge the merits of both approaches by engineering T cells to secrete a TCR-anti-CD3 TCE specific for alpha fetoprotein (AFP), a tumor-associated antigen abundantly expressed in hepatocellular carcinoma (HCC). We initially identified a TCR with specificity for the $AFP_{158-166}$ peptide bound to HLA-A*02:01 and enhanced its affinity to picomolar via phage display. To facilitate efficient secretion by T cells, we adapted the high-affinity TCR to a single-chain format (scTCR) and fused it with a CD3-specific single-chain antibody fragment (scAFP-TCE). Our findings demonstrated that scAFP-TCE effectively redirected bystander T cells to engage in the lysis of HCC cells. Moreover, scAFP-TCE could be secreted by T cells transduced with lentiviral particles encoding the TCE gene. These transduced T cells exhibited potent antitumor activity both independently and by enlisting bystander T cells. This innovative T cell strategy, combining the bystander-recruiting ability of fusion proteins with the durable persistence seen in T cell therapy after a single infusion, presents a promising alternative to conventional TCR-based therapeutic agents. We anticipate that this novel approach may hold substantial potential for enhancing HCC treatment and expanding the scope of TCR-based immunotherapies.

#3599 Recombinant chimeric antibody-based gamma-delta TCR targeting GPC3 induces potent antitumor response against hepatocellular carcinoma.

D. Li[1], T. Liang[1], Z. Duan[1], H. Zhang[2], C. Liu[2], M. Ho[1];
[1]National Institutes of Health (NIH), Bethesda, MD, [2]Eureka Therapeutics, Inc., Emeryville, CA

Background and Significance: Hepatocellular carcinoma (HCC), a major type of primary liver cancer, is the third leading cause of cancer-related death worldwide. While Glypican-3 (GPC3) is highly upregulated in HCC, it is minimally expressed in normal tissues. The research in our laboratory has been focused on the development of GPC3 as an immunotherapeutic target for liver cancer. Despite many clinical trials, there has not been any approved therapy targeting GPC3 largely due to the combination of antigen heterogeneity, poor tumor penetration, and the inability to induce a durable, potent immune response in the tumor microenvironment (TME). Here, we made a recombinant chimeric antibody-based T cell receptors (named AbTCR) targeting GPC3 and explored its anti-tumor efficacy in xenograft mouse models.
Methods: The AbTCR constructs were built by fusing an antigen recognition domain (hYP7 scFv or HN3 VH) specific for GPC3 to the gamma-delta TCR constant region along with a secondary T cell signaling activation motif. The NFAT-tdTomato reporter cell line was established and used to measure the AbTCR-triggered T cell signaling upon stimulation with tumor cells. Anti-tumor efficacy of AbTCR-T cells was determined via luciferase-based cell killing assay as well as multiple HCC xenograft mouse models.
Results: The hYP7 GPC3 AbTCR-T cell not only enhances antigen-binding capacity and T cell activity, but also induces infiltration and expansion of T cells in the TME, thereby causing robust liver tumor regression in mice.
Conclusion: Our data show that new hYP7-directed GPC3 AbTCR is a promising strategy for treating liver cancer. This work provides a rationale for the use of hYP7 GPC3 AbTCR in clinical studies for treating HCC and other GPC3-positive solid tumors.

#3600 Reversal of iNKT cell dysfunction in cholangiocarcinoma.

K. Htwe, K. Soontrapa, S. Jirawatnotai, S. Prasopporn, P. More-Krong, S. Sampattavanich, A. Wongkajornsilp;
Mahidol University, Bangkok, Thailand

Invariant natural killer T (iNKT) cells are CD1d-restricted unconventional T cells possessing innate and adaptive immunity with high anti-tumor activities. Yet, the effectiveness of iNKT cell therapy in clinical trials is limited due to iNKT cell dysfunction after exposure to the tumor microenvironment. Aggressive cholangiocarcinoma (CCA) cell lines were used to study iNKT cell reactivity. These CCA cell lines lacked CD1d molecules and responded poorly to iNKT cells. The iNKT cells became dysfunctional after the exposure to CCA by 48 h. In this study, we overcame iNKT cell dysfunction by searching for a small molecule to prevent or reverse the gene sets regulating iNKT cell dysfunction, thus prolonging anti-tumor activity. It was found that P53 and estrogen early response pathway gene sets were enriched in dysfunctional iNKT cells which were reversed by vorinostat, an HDAC inhibitor. Anti-CCA activity of iNKT cells was regained with a subtherapeutic dose of vorinostat as protection. Interestingly, vorinostat could not totally recover the anti-tumor effect of iNKT cells that have already developed into the dysfunctional stage. Significant tumor size reduction was seen in the humanized mouse model after iNKT cell adoptive therapy was given in combination with vorinostat compared to monotherapy with either iNKT cell or vorinostat alone. This study demonstrated that inhibiting the gene sets regulating iNKT cell dysfunction by vorinostat could prevent iNKT cell dysfunction, and prolong its anti-tumor activities. This combination could be a novel treatment option for CD1d-negative CCA patients resistant to standard chemotherapy.

#3601 Improving killing of renal cell carcinoma through the combined effects of TCR engineered CD4+ and CD8+ T cells.

Muna Igboko[1], Long Chen[1], Stefan Barisic[2], Elena Cherkasova[1], David Allan[1], Mala Chakraborty[1], Joseph Clara[1], Angie Parrizzi[1], Kyra Carney[1], Rosa Nadal Rios[1], Robert Reger[1], Richard Childs[1]

[1]NIH National Heart, Lung & Blood Institute, Bethesda, MD,[2]Oregon Health & Science University, Portland, OR

Patients with late-stage kidney cancer have poor long-term survival rates. Our lab isolated a low affinity CD8 dependent TCR named BZ-4 from CTLs of a patient who had immune-mediated regression of renal cell carcinoma (RCC) following an allogeneic stem cell transplant and found this TCR recognized a human endogenous retrovirus type E (HERV-E) derived 10-mer peptide, CT-RCC-1. The BZ-4 clone belongs to the Vβ7.1 family and binds to CT-RCC-1 in an HLA-A11 dependent manner. Adoptive infusion of CD8+ BZ-4 transduced T cells is currently being explored in an NIH phase I trial (NCT03354390). Because CD4+ T cells have been shown to augment the anti-tumor effects of TCR-modified CD8+ T cells, we hypothesized that CD4+ T cells genetically engineered to co-express BZ-4 and CD8 would recognize and kill RCC tumors expressing the CT-RCC-1 and would improve the in vivo proliferation and tumor cytotoxicity of CD8+ BZ-4 T cells. CD4+ T cells isolated from healthy donor PBMCs were transfected via Sleeping Beauty electroporation with the control MART-1 reactive TCR (DMF5), BZ-4, or BZ-4 alongside the CD8 co-receptor (BZ-4-8). CD8+ T cells were similarly transfected with DMF5 or BZ-4. Following magnetic bead enrichment, 66% to 84% (mean 77%) of transfected T cells stained positive for Vβ7.1. TCR engineered T cells were subsequently tested for their ability to lyse a) luciferase transduced HLA A-11 expressing RCC tumors and b) a T2 cell line modified to express both HLA A-11 and luciferase that was peptide-pulsed with decreasing concentrations (5×10^{-1}, 5×10^{-2}, 5×10^{-3} & 5×10^{-4} ug/mL) of CT-RCC-1. CD4+ T cells expressing BZ-4 or BZ-4-8 as well as CD8+ T cells expressing BZ-4 or DMF5 were used either alone or in combination in cytotoxicity assays. For combined T cell groups, the total effector/target ratio was maintained at the same ratio as individual T cell groups. For T-2 targets, CD4+ BZ-4 T cells exhibited no cytolytic activity in contrast to both CD8+ BZ-4 T cells and CD4+ BZ-4-8 T cells, which were highly cytolytic to target cells. For RCC tumor targets, CD4+ BZ-4 T cells exhibited no cytolytic activity at 48, 72 and 96 hours in contrast to both CD8+ BZ-4 T cells and CD4+ BZ-4-8 T cells, which exhibited high levels of tumor killing at these timepoints. Remarkably, CD4+ BZ-4-8 T cells alone or in combination with CD8+ BZ-4 T cells demonstrated tumor cytotoxicity that was comparable to that observed with CD8+ BZ-4 T cells alone. In conclusion, these data show that CD4+ BZ-4 T cells transfected with the CD8 co-receptor acquire the ability to lyse RCC tumors at levels comparable to that observed in CD8+ BZ-4 T cells. Additional experiments are planned to evaluate whether mixtures of CD8+ BZ-4 T cells with CD4+ BZ-4-8 T cells will augment the ability of TCR modified T cells to proliferate in vivo and kill human RCC tumors compared to CD8+ BZ-4 T cells alone in tumor bearing NSG mice.

#3602 TRAIL-NK-92 MI as a novel adoptive therapy for castration-resistant prostate cancer (CRPC): Preliminary *in vitro* results.

M. Schwermann[1], P. Srinivasan[1], W. MacDonald[1], V. Tajiknia[1], A. Schmidt[1], S. Zhang[1], L. Carlsen[1], A. George[2], C. Purcell[1], S. Lu[3], M. Hadfield[3], A. Mega[3], B. Carneiro[3], W. El-Deiry[3];

[1]Legorreta Cancer Center at Brown University, Providence, RI, [2]Yale School of Medicine, New Haven, CT, [3]Legorreta Cancer Center and Lifespan Cancer Institute at Brown University, Providence, RI

Introduction: Natural killer (NK) cell tumor infiltration and higher expression of activating receptors NKp30 and NKp46 are associated with improved clinical outcomes in prostate cancer (PC). Activation of NK cells by androgen receptor inhibitors enhanced the killing of PC cell lines (Schwermann 2023). These findings support the therapeutic potential of strategies inducing NK cell activation to treat CRPC. NK cells induce apoptosis of cancer cells via TNF-related apoptosis-inducing ligand) (TRAIL) binding of death receptor 5 (DR5), which is overexpressed in PC cells. This is the first report of adoptive therapy utilizing high expression of TRAIL as a novel therapeutic strategy.

Methods: We transduced NK-92-MI and CD4+ (Jurkat) cell lines with human TRAIL (pLVX-EF1alpha-TRAIL-IRES-eGFP).Transduced cells were pre-treated with simvastatin or atorvastatin (4uM) for 36h, followed by stimulation (IL-2 100 IU/ml and IL-12 100 ng/ml) for 2h. The eGFP-expressing cells were then sorted by FACS. PC (PC3, DU145, LNCaP, and 22Rv1), fibroblast (IMR-90), and brain endothelial (hCMEC/D3) cell lines were used in co-culture experiments with non-transduced and transduced NK cells and CD4+ cells. These experiments were quantified using the ImageXpress Confocal HT instrument. Viability assays were performed using Annexin-PI and flow cytometry staining for caspases 3/7.

Results: Transduced NK-92 MI cells with TRAIL displayed increased surface expression of TRAIL (control[C]: 4.38%±1; TRAIL-overexpression[NK-TRAIL]: 78.54%±3.76; p<0.001). Co-culture of PC cell lines with TRAIL-NK-92 MI cells resulted in significant tumor-induced apoptosis compared to co-culture with non-transduced NK cells after 48 hours (LNCaP + NK [C]: 16.52%±5, LNCaP + NK-TRAIL: 73.19%±6; PC [C]: 14.4%±3, PC3 + NK-TRAIL: 79%±8; 22Rv1 [C]: 16.78%±1.7, 22Rv1 + NK-TRAIL: 76%±8; DU145 [C]: 13%±4, DU145 + NK-TRAIL: 59.1%±10; p<0.001). This enhanced cytotoxic function was also observed in CD4+ cells expressing high levels of TRAIL. Annexin-PI staining as well as Caspase 3 and 7 showed increased apoptosis in PC co-cultured with NK-TRAIL. Co-culture of NK-TRAIL cells did not affect the viability of the non-malignant cells (IMR-90 and hCMEC/D3) over 48h (IMR-90 + NK: 4.6%±1, IMR-90 + NK-TRAIL: 4.47±2, p=0.9; hCMEC/D3 + NK: 2.7%±0.8, hCMEC/D3 + NK-TRAIL: 2.2±0.5, p>0.99). These results align with the lower expression of DR5 on non-malignant cells compared to PC cell lines (IMR-90: 1.46%±0.5, hCMEC/D3: 1.9%±0.8, LNCaP: 92.3%±4.5).

Conclusion: Transduced NK-92 MI cells with human TRAIL-induced higher levels of apoptosis of PC cell lines compared with non-transduced NK cells in co-culture experiments. The results highlight the potential of TRAIL-expressing adoptive cell therapy for CRPC. Engaging adoptive therapies with specific targets (anti-PSMA CAR) might increase the therapeutic potential of this strategy.

#3603 NKX101, an allogeneic off-the-shelf CAR NK cell therapy targeting NKG2D-Ls, has potent anti-leukemic activity alone or in combination with Ara-C.

C. Cho, N. Kimura, J. Sood, D. Juat, M. Zhang, C. Chan, T. Geng, K. Hansen, J. Trager;
Nkarta Inc., South San Francisco, CA

Introduction: NKG2D-Ligands (NKG2D-Ls) are a family of immunomodulatory proteins that are upregulated on damaged or transformed cells but have limited expression on normal tissues. Natural killer (NK) cells target and eliminate NKG2D-L^{+} cells through NKG2D receptor binding and subsequent activation. NKX101 is an allogeneic, off-the-shelf healthy donor-derived chimeric antigen receptor (CAR) NK cell therapy candidate engineered to express an NKG2D-L targeting CAR and membrane-bound IL-15 for extended persistence. In a clinical trial, NKX101 treatment combined with modified lymphodepletion incorporating cytarabine (Ara-C) has shown promise for the treatment of relapsed/refractory (r/r) AML, including generating complete responses (CR) with MRD negativity (MRD^{-}). To support the rationale of NKX101 combined with modified lymphodepletion, we developed assays to (i) investigate the cytotoxic activity of NKX101 against individual NKG2D-Ls, (ii) determine the effect of Ara-C pre-treatment on NKG2D-L expression on AML cell lines, and (iii) evaluate the combined anti-leukemic activity of NKX101 and Ara-C.

Methods: NKX101 cells were generated from peripheral blood leukopaks from healthy donors. CHO-K1 cells were engineered to stably express individual NKG2D-Ls or transduced with empty vector controls and were combined with NKX101 cells for cytotoxicity experiments. AML cell lines were treated with increasing levels of Ara-C and evaluated for NKG2D-L expression by flow cytometry. To measure NKX101 cytotoxicity against AML cell lines, NucRed™-labeled target cells were pre-treated with Ara-C using IC_{50} and IC_{90} concentrations and co-cultured with NKX101. Specific cell killing of target cells was measured using an Incucyte® instrument for five days. Assessment of the contribution of each agent was determined using a dose-response matrix of increasing concentrations of NKX101 and Ara-C to generate specific cytotoxicity values. Combination effects were analyzed using the SynergyFinder Plus web application.

Results: Expression of a single NKG2D-L was sufficient to trigger NKX101 cytotoxicity against target cell lines, further validating NKG2D-Ls as therapeutic targets. Flow cytometry analysis revealed that pre-treatment with Ara-C upregulated NKG2D-Ls on AML cell lines in a dose-dependent manner. NKX101 showed enhanced anti-leukemic activity against AML cells pre-treated with Ara-C compared to untreated controls, demonstrating that the combination can enhance NKX101 potency. Assessment of the combination of NKX101 and Ara-C using a dose-response matrix revealed that the two modalities combine to potently kill AML cells in a synergistic manner, supporting continued investigation of NKX101 CAR NK cell therapy after lymphodepletion incorporating Ara-C for the treatment of r/r AML.

#3604 NKX101, an allogeneic off-the-shelf NKG2D CAR-NK cell therapy, has potent in vitro cytotoxicity against patient-derived AML leukemic stem cells and non-leukemic stem cell blasts.

K. Hansen, C. Cho, N. Kothari, D. Shook, J. Trager;
Nkarta Inc., South San Francisco, CA

Introduction: Acute myeloid leukemia (AML) is a malignancy of immature myeloid cells characterized by rapid proliferation of abnormal myeloblasts. Treatment options for patients with AML are limited, especially for relapsed/refractory (r/r) disease. Leukemic cells with stem cell features, known as leukemic stem cells (LSCs), have been implicated as the origin of relapse in minimal residual disease positive (MRD^{+}) AML (Khaldoyanidi et al. 2022, Kamel et al. 2022). NKX101 is an allogeneic, off-the-shelf, healthy donor-derived chimeric antigen receptor (CAR) NK cell therapy candidate engineered to express an NKG2D CAR and membrane bound IL-15. In a clinical trial, NKX101 has shown promise for the treatment of r/r AML, including generating complete responses (CR) with MRD negativity (MRD^{-}). In this study, we utilize a flow cytometry-based approach to (i) evaluate the cell surface expression of NKG2D-Ls on normal cells vs. primary AML blasts, (ii) assess the expression pattern of NKG2D-Ls on AML blast subsets, and (iii) determine NKX101 cytotoxic killing of LSC and non-LSC AML blasts.
Methods: NKX101 cells were generated from peripheral blood leukopaks from healthy donors. Cryopreserved bone marrow mononuclear cells (BMMCs) were obtained from AML patients (n=20) and healthy donors (n=10) in accordance with approved IRB protocols. AML somatic mutation status was determined using an Illumina TruSight® Myeloid Sequencing Panel. NKX101 cytotoxicity against patient-derived AML blasts was assessed using a flow cytometry-based assay that measured specific cytotoxicity and AML blast/LSC markers. NKG2D-L expression was determined using flow cytometry with antibodies specific to individual NKG2D-Ls.
Results: Utilizing patient-derived primary samples, we demonstrate that NKG2D-Ls are expressed on AML blast cells and expressed at higher levels on AML blast cells compared to healthy normal hematopoietic cells ($p = 0.002$). Furthermore, we show that NKG2D-Ls are expressed at similar levels on LSCs compared to non-LSC AML blast populations. Target cell specific flow cytometry-based cytotoxicity assays revealed that NKX101 potently kills patient-derived AML blasts in a dose-dependent manner. Moreover, NKX101 had similar cytotoxic potency against both LSC and non-LSC AML blasts.
Conclusions: In summary, we show that NKG2D-Ls are expressed on the surface of both LSC and non-LSC AML blasts and at levels above those observed in normal hematopoietic cells. Additionally, the ability of NKX101 to potently kill AML LSC blasts suggests that NKG2D-L targeting may be a viable mechanism for eliminating LSCs in the blood and bone marrow of patients with r/r AML. Taken together, these data support NKG2D-Ls as promising therapeutic targets for AML and support further investigation of NKX101 CAR-NK therapy for the treatment of r/r AML.

#3605 Phase II study of pembrolizumab in conjunction with lymphodepletion, TIL ACT, and high- or low-dose IL-2 in patients with metastatic melanoma.

M. Hasanov[1], **S. Kiany**[2], M.-A. Forget[2], R. L. Bassett[2], M. A. Davies[2], A. Diab[2], J. E. Gershenwald[2], I. C. Glitza[2], J. E. Lee[2], A. Lucci[2], J. L. McQuade[2], S. P. Patel[2], M. I. Ross[2], H. A. Tawbi[2], J. Wargo[2], M. K. Wong[2], C. Bernatchez[2], P. Hwu[3], C. Haymaker[2], R. N. Amaria[2];

[1]The Ohio State University Comprehensive Cancer Center, Columbus, OH, [2]UT MD Anderson Cancer Center, Houston, TX, [3]Moffitt Cancer Center, Tampa, FL

Background: In metastatic melanoma (MM) patients (pts), adoptive cell transfer (ACT) using tumor-infiltrating lymphocytes (TIL) can yield lasting responses. However, TIL ACT with high-dose IL-2 has notable toxicities. Anti-PD1 (pembrolizumab) is FDA approved for MM treatment. Our study aimed to merge TIL infusion with anti-PD1 in two arms, comparing high (HD, arm 1) and low (LD, arm 2) IL-2 doses.

Methods: After tumor harvest and TIL expansion, pts were lymphodepleted with cyclophosphamide and fludarabine, followed by infusion with their ex-vivo expanded TIL combined with IL-2 (arm 1: 720,000 IU/kg IV q 8 hrs up to 15 doses; arm 2: 2 million IU SC for 14 days). Pts were given 200 mg of IV anti-PD1 starting 21 days post-TIL infusion, followed by doses every 3 weeks for up to 2 years. Blood was taken before lymphodepletion and before the first two anti-PD1 doses for flow cytometry and cytokine analysis The primary endpoint of the study was determination of overall response rate by RECISTS 1.1 criteria. Enrollment aimed for 18 pts per arm, monitoring the primary ORR endpoint using a Bayesian rule. Enrollment would halt in any arm if the ORR dropped below 40%.

Results: The median age was 50 years (n=14: 6 F and 8 M). Of these 14 pts, 8, 2, 2, and 2 had cutaneous, uveal, mucosal, or unknown primary melanoma. Pts had a median of 3 lines of prior therapies (range 1-6), including anti-PD-1 (n=13). In arm 1, one pt had a partial response (PR) for 10 months, 2 had stable disease (SD), 3 had progressive disease (PD), and 1 was not evaluable (NE). In arm 2, one pt had an ongoing PR for over 76 months, 1 had SD, and 5 had PD. Due to ORR <40% in each arm, enrollment was stopped after treatment of 14 pts. There was no significant different in progression-free survival or overall survival between the two arms (p=0.99 and p=0.71, respectively). In general, toxicity levels were comparable in both arms; however, pts in arm 2 had slightly lower grade 3 febrile neutropenia (57% vs. 71%) and shorter hospitalization (median 16 days vs. 18 days) than pts in Arm 1. While no correlation was observed between the phenotype of the TIL product and clinical response, both PR pts received high numbers of TIL (38.6x10^9 and 93.7x10^9; mean: 32.6x10^9 cells), with a high CD8+/CD4+ T cell ratio (284.7 and 2.7; median: 2.7). IL-2 dose did not affect circulating Treg frequency, phenotype, or proliferation by flow cytometry 3 weeks post TIL infusion. IL-2 dose was not associated with CD4+ non-Treg and CD8+ T cell phenotype or proliferation. Addition of anti-PD1 reduced expression of checkpoints but did not boost T cell proliferation.

Conclusion: Our treatment strategy did not yield any distinct difference between low and high dose IL-2, suggesting the potential of low-dose IL-2 as an alternative. Anti-PD1 did not have any appreciable effect on immune states potentially due to the cohorts being comprised of a heavily pre-treated heterogenous pt population.

#3606 Tumor-specific CD8$^{\pm}$ Tc9 cells activate host CD4$^{\pm}$ T cells to control antigen-lost tumors.

L. Xiao, Q. Yi;
Houston Methodist Research Institute, Houston, TX

Cancer immunotherapies relying on targeted destruction of cancer cells by potent antitumor T cells have achieved unprecedented success in recent years. As a main form of cancer immunotherapies, adoptive T cell therapy (ACT) has shown a durable response in certain cancer patients. However, this response is often short-lived and tumor relapse occurs due to the outgrowth of antigen-lost-variant (ALV) tumors and poor antitumor immune response. Here, We reported that adoptively transfer of murine tumor-specific CD8$^{\pm}$ Tc9 but not Tc1/CTL cells achieved long-term control of tumor growth in vivo. Here, we demonstrated that murine tumor-specific Tc9 cells not only killed antigen-expressing primary tumors but also controlled the outgrowth of antigen-lost relapsed tumors by recruiting and activating host effector CD4$^{\pm}$ T cells that recognized relapsed tumors. Tc9 cells secreted IL-24 and recruited CCR7-expressing conventional type-2 dendritic cells (cDC2) into tumor-draining lymph nodes to prime host CD4$^{\pm}$ T cell response against relapsed tumors. Depleting host CD4$^{\pm}$ T cells or deficiency in CCR7 expression impaired Tc9 cell ability to control the outgrowth of relapsed tumor. We also observed that intratumoral *IL24* expression was positively correlated with gene signatures of cDC2 and CD4$^{\pm}$ T cells in human cancers and expression of *IL24* and cDC2 and CD4$^{\pm}$ T cell gene signatures were associated with patient's overall survival. Thus, this study uncovers a novel mechanism underlying activation of tumor-specific CD4$^{\pm}$ T cells in vivo.

#3607 Case study: Efficacy and persistence of autologous T cell therapy targeting SLC45A2 in uveal melanoma.

S. Singh[1], E. Ryu[1], K. M. Campbell[2], **A. Smith**[3], S. Phillips[1], L. Soto[1], I. Lai[4], G. Lizee[1], B. Vincent[5], M. Thompson[3], W. Hoos[3], S. Patel[1], C. Yee[1];
[1]MD Anderson Cancer Center, Houston, TX, [2]University of California, Los Angeles, Los Angeles, CA, [3]H37 Institute, Durham, NC, [4]CTMC, Houston, TX, [5]University of North Carolina at Chapel Hill, Lineberger Comprehensive Cancer Center, Chapel Hill, NC

Background: Metastatic uveal melanoma (UM) is an aggressive cancer, with a 1-year overall survival of < 50%. While the bispecific T-cell engager tabentafusp is approved for HLA-A2+ patients with gp100+ UM, there are limited treatment options for patients who do not express HLA-A2. We present a strategy and proof-of-concept for designing and manufacturing a tumor-selective endogenous T-cell therapy (ETC) for a patient with metastatic UM.
Methods: PBMC were collected by apheresis in 2013 upon first diagnosis with uveal melanoma; 8 years later, following progression, cryopreserved PBMC were used to generate autologous antigen-specific T cells for adoptive therapy. The validated tumor antigen SLC45A2 was found to be overexpressed in the patient's metastatic tumor based on RNA expression profiling. Peripheral blood derived SLC45A2-specific HLA-A2402-restricted central memory CD8+ T cells were generated via a process of in vitro priming, IL-21 treatment, tetramer-guided sorting and cell expansion. Clinical response was assessed via longitudinal CT imaging and ctDNA-based MRD monitoring. Persistence of transferred T cells was measured via serial flow cytometry and RNA-sequencing of PBMCs, along with TCR and RNA sequencing of tumor tissue collected post infusion.
Results: A 39 year old male received SLC45A2-specific ETC therapy and checkpoint inhibitor treatment for advanced metastatic UM (GNAQ (Q209P), BAP1 (E398*, LOF). Bulk RNAseq data from baseline biopsies were queried for known tumor-associated antigens, and *SLC45A2* was expressed at high levels. The patient experienced widespread disease stabilization with minimal toxicity. SLC45A2-specific CD8+ T cells persisted in circulation up to 181 days after the first infusion and 43 days after the second infusion, ranging from 6.7% - 1.5% of total circulating CD3 T cells. T cell clones from the infusion product included the dominating TCR subclone in tumor tissue collected 6 weeks post infusion, comprising 33% of the TCRá and 26% of TCRâ population. SLC45A2-specific T cells were identified in the tumor infiltrating lymphocytes in a separate lesion collected 10 months after the first infusion. A duodenum lesion progressed during treatment, and RNAseq demonstrated reduced expression of genes associated with HLA presentation and *SLC45A2* and reduced TIL infiltration, suggesting tissue-specific immune editing of the tumor cell population.
Conclusions: 1. Tumor-reactive antigen-specific T cells can be isolated and expanded for adoptive therapy using PBMCs cryopreserved for > 8 years. 2. Following infusion, peripheral blood and tumor profiling support the persistence of transferred T cells in a patient with metastatic uveal melanoma. 3. Disease stabilization in aggressive metastatic UM was achieved with minimal toxicity. Overall, our study provides evidence and rationale for utilizing autologous antigen-specific T cells for treating rare cancers.

#3608 Nonpathogenic *E. coli* engineered to surface display human cytokines for enhanced immunotherapy.

Shaobo Yang[1], Michal Sheffer[1], Isabel Kaplan[1], Zongqi Wang[2], Mubin Tarannum[1], Roman Shapiro[1], Yasmin Abdulhamid[1], Rebecca Porter[1], David Barbie[1], Robert Soiffer[1], Jessica Little[1], Jerome Ritz[1], Mengdi Yang[3], Valeria Marquez-Pellegrin[3], Jiahe Li[2], Rizwan Romee[1]

[1]Medical Oncology, DFCI/Harvard Medical School, Boston, MA,[2]Biomedical Engineering, University of Michigan, Ann Arbor, Ann Arbor, MI,[3]Bioengineering, Northeastern University, Boston, MA

Background: Poor trafficking, exhaustion and low persistence of adoptively transferred T and NK cell-based therapies in solid tumors remain major barriers in the field. Leveraging safety, tumor tropism and ease of genetic manipulation in bacteria present potentially a novel approach to overcome these barriers. Prior approaches to bacteria-based biologics delivery encounter issues of low concentration and fast clearance. In this study, we hypothesized that displaying immune-activating cytokines on outer membrane of *Escherichia coli (E. coli)* could modulate immunosuppressive tumor microenvironment (TME) enhancing migration, activation, and tumor control mediated by T and natural killer (NK) cells.

Methods: To investigate our hypothesis, we expressed human and murine cytokines: IL-15, decoy resistant IL-18 (DR-18), and IL-21 on outer membrane of a non-pathogenic facultative bacteria *E. coli* K-12. We first evaluated their ability to activate human mesothelin (MSLN) NK cell CARs *in vitro* and performed gene expression analysis. For the *in vivo* experiments we used C57BL/6 mouse model with syngeneic tumor cell lines MC38 and B16F10. We also assessed the ability of human cytokine-displaying bacteria with human MSLN-CAR NK cells in NSG mice carrying human mesothelioma H226.

Results: OmpA displaying murine DR-18 on bacterial surface was most effective in tumor control. After optimization, intra-tumoral injection of the bacteria resulted in 50% of cured mice bearing MC38 and 30% of cured mice bearing B16F10. Rechallenging these mice with respective cells showed no tumor growth, indicating induction of tumor-specific immune memory. Tumor tissue analysis showed upregulation of CD8 T and NK cells and depletion experiments demonstrated the contribution of these cells to tumor control. When systemically injected, the bacteria inhibited tumor growth with no side effects. Bio-distribution analysis demonstrated bacterial enrichment in TME. Through the utilization of *in vitro* killing assays by NK cells, YiaT232 scaffold with human DR-18 emerged as the optimal candidate. RNA-sequencing demonstrated that bacteria with DR-18 were capable of upregulating IL-12 and oxidative phosphorylation pathway in NK cells. Furthermore, administration of bacteria displaying DR-18 and systemic (IV) MSLN-CAR-NK cells led to better tumor control (vs soluble DR-18 or bacteria alone) in NSG mice carrying mesothelin-high H226.

Conclusions: Here we develop a novel platform for immunotherapy involving surface display of cytokines in non-pathogenic *E. coli*. The bacteria were safe and demonstrated tumor tropism and CD8 T and NK cells were identified as the major effector cells mediating tumor control in immune-competent mice. Subsequently, we could display human DR-18 on these bacteria which resulted in superior tumor control in NSG mice when combined with MSLN-CAR-NK cells, paving the way for clinical translation in the near future.

#3609 Chimeric cytokine receptors increase memory phenotypes and improve expansion and efficacy of CAR-T cell therapies.

J. R. Newcomb[1], J. Ren[1], S. Syed[1], Z. Caruolo[1], L. Webb[1], C. McKay[1], S. Kwei[1], C. Novina[2], F. Mermelstein[1];
[1]Dynamic Cell Therapies, Watertown, MA, [2]Dana Farber Cancer Institute, Boston, MA

Cytokine activation of T cells can promote T cell proliferation, memory and improve T cell function in driving tumor cell killing. However, systemic administration of cytokines at therapeutic doses is also associated with unacceptable toxicities. To overcome this limitation, we have engineered a system of private cytokine signaling to affect T cell homeostasis, identity, and function. Specifically, we have engineered chimeric cytokine receptors (CCRs) composed of single-chain variable fragments (scFvs) that bind specifically to small molecules such as fluorescein or DOTA. These scFvs are fused to transmembrane and intracellular domains of all members of the common gamma-chain (γ-chain) family of cytokine receptors. CCRs that permit private cytokine signaling were introduced into known CAR-T cell therapies and their impact on CAR-T cell phenotype, function, and anti-tumor activity was tested. First, CCR-containing T cells were tested for activation-induced changes in phenotype and expansion following stimulation with small molecule conjugates *in vitro*. The most promising results were obtained using either the IL-7Rα- or IL-2Rβ/γ-containing CCR's. CCR-containing constructs were then transduced into one of two different anti-BCMA CAR-T constructs, ide-cel or cilta-cel, using a lentiviral transduction system. CAR-T cells containing each CCR were then compared with CAR-T cells lacking CCRs for phenotype and function *in vitro*. Results indicated that engineering the IL-7Rα CCR with both of these CAR-T's led to increased expansion, cytokine secretion and improved tumor cell killing. Next, CAR-T cells expressing the IL-7Rα CCR were compared to CAR-T cells lacking CCR for efficacy and durability in a mouse model of human multiple myeloma. IL-7Rα CCR-expressing CAR-T cells demonstrated improved long-term tumor control compared to ide-cel and cilta-cel alone. In addition, IL-7Rα CCR-expression increased T cell numbers in blood, spleen and bone marrow of tumor-bearing mice. These increases were particularly evident in the $CD8^{+}$population of CAR-T cells *in vivo*. These results demostrate that private cytokine signaling using small-molecule activatable CCRs can improve efficacy and durability of CAR-T cells. We are testing these CCRs in mouse models of human solid tumors to assess their ability to overcome the immunosuppressive microenvironment.

#3610 Utilizing fructose metabolism to fuel anti-tumor immunity.

T. Schild[1], R. Chirayil[2], L. Haughton[1], P. Wallisch[1], M. Berishaj[1], D. A. Scheinberg[1], K. R. Keshari[1];
[1]Memorial Sloan Kettering Cancer Center, New York City, NY, [2]Columbia University Medical Center, New York City, NY

Consumption of fructose in the form of high fructose corn syrup is elevated in the western diet, but it is not fully understood how fructose metabolism influences anti-tumor immunity. Fructose is canonically metabolized in the intestine and the liver and can shunt into glycolysis. In certain tumor types, fructose metabolism becomes deregulated, allowing tumor cells to metabolize fructose to power their biosynthetic processes. Similarly, reprogramming immune cells to be able to efficiently metabolize fructose may help us power immunotherapy to work in difficult to treat cancers, especially in individuals who have high fructose in their blood or in the tumor microenvironment (TME). Imparting effector T cells with the ability to use fructose for fuel can overcome one of the major metabolic limitations of the TME: limited nutrient supply. As T cells become activated, they alter their metabolism to support growth and proliferation. Activated CD8+ T cells upregulate their glycolysis which results in increased biosynthetic processes, such as synthesis of macromolecules and effector cytokines. However, tumor cells also consume substantial amounts of glucose, resulting in a glucose-depleted microenvironment, which could be one of the major barriers to immunotherapy working in solid tumors. Therefore, we engineered T cells to overexpress a fructose transporter, GLUT5, which is normally not expressed in the immune compartment at high levels. We hypothesized that increased fructose uptake by CD8+ T cells will ameliorate exhaustion caused by the glucose-low tumor microenvironment. Indeed, we determined that GLUT5 T cells are more efficient in killing in low glucose supplemented with fructose. We also observed that GLUT5 expression restores T cell glycolytic capacity under fructose to that of unexhausted T cells under glucose replete conditions. Similarly, GLUT5-expressing T cells proliferate faster *in vitro* and exhibit an improved ability to control B16 tumor growth *in vivo*. Additionally, combining GLUT5 cell infusion with checkpoint inhibition resulted in durable tumor control and prolonged mouse survival. Further, engineered CD19-targeted CAR T cells with expression of GLUT5 were more metabolically active and cytotoxic in low glucose conditions, mimicking the TME. In conclusion, GLUT5 expression in effector CD8+ and CAR T cells may allow immunotherapy to function in solid tumors under low glucose conditions.

#3611 A patient-derived organoid platform to assess the effectiveness of γδTCR cell therapy in solid tumors.

Andrea Bisso[1], Rene Overmeer[2], Sjoerd Baardman[1], Chris Coomans[1], Cesar Oyarce[2], **Sylvia F. Boj**[2]

[1]Gadeta B.V., Utrecht, Netherlands,[2]HUB Organoids B.V., Utrecht, Netherlands

Recent advances in cancer immunotherapy have positively impacted the life expectancy of patients for an extensive range of clinical indications. With new treatment strategies and druggable targets being identified at an increasing pace, the number of patients eligible for cancer immunotherapy is expected to expand steadily. However, promising therapeutic developments face hurdles in translating preclinical findings into therapy since conventional 2D cancer models hold low clinical predictive value. HUB developed an innovative alternative, building on the discovery that adult stem cells proliferate and organise into three-dimensional organotypic structures when embedded into the extracellular matrix. Patient-derived organoids are generated from healthy and malignant tissues, and they recapitulate complex characteristics of the original parental tissue, including molecular heterogeneity and morphological and functional traits. Cell therapies have achieved positive results in treating haematological cancers. Recently, the unique tumour-targeting properties of γδ T cell receptors have been leveraged to develop safer and more effective strategies. HUB and Gadeta joined efforts to explore the therapeutic potential of GDT002 - i.e. αβ T cells engineered with a Gadeta proprietary new γδTCR - to target solid cancers. A preclinical basket trial was performed using patient-derived organoids from several tumour types (colorectal, breast, head and neck, ovarian cancers) cocultured with GDT002. The results showed broad reactivity of GDT002 against solid tumor PDOs. Interestingly, GDT002 was particularly efficient at killing ovarian cancer-derived PDOs, allowing Gadeta to move GDT002 to clinical trials for this indication confidently. This study reveals that our tumor organoid co-culture with engineered T cells platform holds significant value for the preclinical development of cellular therapies.

#3612 Preclinical & clinical activity of autologous mRNA engineered chimeric antigen receptor monocytes for targeted cancer immunotherapy.

Yuxiao Wang[1], Michele Gerber[1], Michael Gorgievski[1], Josephine D'Alessandro[1], Neha Diwanji[1], Ronald Vale[2], Siddhartha Mukherjee[3], Daniel Getts[1]

[1]Myeloid Therapeutics, Cambridge, MA,[2]HHMI, Cambridge, MA,[3]Columbia Univerisity, Cambridge, MA

Introduction: The tumor microenvironment (TME) is a dynamic and multifaceted system that comprises largely myeloid lineage immune cells including neutrophils, macrophages, dendritic cells and monocytes. When activated, these cells are can effectively infiltrate TME and orchestrate anti-tumor immune response. Reprogramming myeloid cells by arming them with a tumor specific chimeric antigen receptor (CAR) presents an attractive strategy to overcome current limitations in solid tumor treatment. In this study, we present the isolation and mRNA-based engineering of monocytes with chimeric antigen receptors (CARs), followed by their in vivo application for cancer treatment in rodent models and in human T cell lymphoma patients.

Results: Engineered monocytes demonstrated the abilities to infiltrate the TME, undergo activation, and differentiate into macrophages and dendritic cells. Upon CAR activation, these reprogrammed myeloid cells utilized both direct and indirect mechanisms to eliminate tumor cells. This included direct tumor cell killing through phagocytosis and TNF-associated mechanisms. Furthermore, engineered monocytes exhibited the capacity to recruit natural killer (NK) cells and T cells to the TME. In the case of T cells, these engineered myeloid cells facilitated the presentation of neoantigens to T cells and stimulate an adaptive immune response. In patients with T cell lymphoma, treatment with engineered monocytes expressing a CAR targeting CD5 exhibited a favorable safety profile and was associated with TME remodeling, expansion of novel T cell clones, and promising survival outcomes.

Conclusions: These findings underscore the potential of reprogrammed myeloid cells as a novel avenue for cancer immunotherapy, offering hope for improved treatments and outcomes in the fight against cancer.

#3613 Screening iPSC lines for optimal characteristics of differentiation into immune effector cells for clinical programs.

B. A. Morse, Jr., A. Cogburn, A. Chialastri, M. S. Hall, O. Manor, A. Lebid, D. Kim, L. Cocka, D. J. Perry, C. Budd, A. Kolluri, L. Campion, T. Nishimura, M. Naso, H. Levitsky;
Century Therapeutics, Philadelphia, PA

Engineered Induced Pluripotent Stem Cells (iPSCs) are the core foundational technology for Century Therapeutics. In our constant effort to identify iPSC lines with diverse functional activity, we have derived a large panel of clinical-grade peripheral blood mononuclear cell (PBMC)-derived and gamma-delta T cell-derived IPSC lines (PiPSCs and TiPSCs, respectively) from multiple donors. These lines have been screened by multiple criteria to select the top lines for clinical development in our iPSC-derived NK (iNK) and T cell (iT) programs. Initial screening included in-depth genomic and transcriptomic analysis of PiPSC and TiPSC lines to eliminate those with any unwanted genetic abnormalities, as well as to build multi-omics datasets for correlating gene polymorphisms and transcript variation to function. Next, all lines were differentiated to iNK or iT effector cells, and phenotypically characterized throughout the differentiation process. In those studies, 86.5% of PiPSCs and 69.2% of TiPSCs lines were compatible with our protocols and able to be successfully differentiated and acquire NK cell and gamma delta T cell phenotypes respectively. Yield and lineage commitment (%CD56+ for NK cells and %CD3+ for T cells) variability was found to be higher across clones than donors in this initial analysis. Finally, we evaluated in vitro cytotoxicity, cytokine secretion, and persistence for all clones that met differentiation thresholds (>90% lineage commitment). As part of that evaluation, 39 PiPSCs lines were differentiated to iNK cells. Cytotoxicity against tumor lines was observed to be consistently between 85-100% at an effector to target ratio of 1:1. Although no trends in functionality were found to be associated with the PBMC donor, iPSC lines derived from CD34+ enriched PBMCs exhibited higher levels of innate killing as compared to those derived from bulk PBMCs. For this presentation, we will present genetic, transcriptomic , and phenotypic correlations with favorable differentiation and functional efficacy and illustrate how our screening process enables efficient selection of founder lines with the highest therapeutic potential for allogeneic cell therapies.

#3614 T cell receptor-engineered T cell therapy using TCR gene derived from an HLA-A2 hepatoblastoma patient who was completely cured by administration of glypican-3 peptide vaccine.

T. Terada[1], K. Ohnuki[1], M. Shimomura[1], T. Suzuki[1], Y. Amaishi[2], K. Takeichi[2], S. Okamoto[2], N. Fujinami[1], K. Takenouchi[1], N. Tsukamoto[1], K. Shoda[1], T. Yoshikawa[1], T. Nakatsura[1];

[1]National Cancer Center, Kashiwa, Japan, [2]Takara Bio Inc., Kusatsu, Japan

Glypican-3 (GPC3) is highly expressed in many of hepatocellular carcinoma, hepatoblastoma, ovarian clear cell carcinoma, and squamous cell lung carcinoma, but not expressed in almost all normal tissues, making it an excellent target for cancer immunotherapy. We identified each HLA-A24 and -A2-restricted GPC3-derived peptide and had conducted various clinical trials administering these peptides. All five cases of refractory hepatoblastoma, who had repeated relapses and remissions, are surviving for more than 9 years without recurrence by the only administering these peptide vaccines. We established many kinds of peptide-specific CTL clones with high avidity from PBMC of one of the female HLA-A*02:01-positive refractory hepatoblastoma patient treated with GPC3-derived peptide. Through collaborating research with Takara Bio Inc., which has siTCR technology and extensive experience in developing TCR-T cell therapies including NY-ESO-1 TCR-T, we identified most effective two kinds of TCR by creating a viral vector, preparing TCR-expressing T cells, and evaluating them in various in vitro/in vivo experiments. These TCR-gene engineered T cell can kill cancer cells presenting glypican-3-derived peptides, so this TCR-T therapy has proven to be a promising treatment for patients with cancers that are HLA-A2 positive and express GPC3. The development of TCR-T has been overshadowed by the overwhelming increase in the number of CAR-Ts developed in recent years, but while CAR-Ts have struggled in solid cancers, there have been some reports of successful cases in TCR-Ts and remains a promising treatment. Although GPC3 is a membrane protein, it is not necessarily expressed on the cell membrane and is often expressed within the cell, so we believe that TCR-T is more effective than CAR-T, which targets GPC3. TCR-T cell therapy targeting GPC3 has not yet been implemented anywhere in the world, and we hope this TCR-T therapy as an effective treatment for hepatocellular carcinoma, an intractable cancer with a 10-year survival rate of only 15%, refractory childhood hepatoblastoma, ovarian clear cell carcinoma and lung squamous cell carcinoma that are difficult to respond to anticancer drugs. This development was based on an unmet medical need, and HLA-A2 is found not only in 40% of Japanese, but also in many Caucasians, making it versatile and possible for international expansion.

#3615 Targeting high-risk neuroblastoma by TGFβ imprinted natural killer cells.

J. A. Ayala-Cuesta[1], Y. Chu[1], K. Foley[1], M. Tian[1], K. Klose[1], A. S. Mendelowitz[1], T. P. Cripe[2], D. A. Lee[2], M. S. Cairo[1];
[1]New York Medical College, Valhalla, NY, [2]Nationwide Children's Hospital, The Ohio State University, Columbus, OH

Background: Neuroblastoma (NB) is a common malignant extracranial solid tumor in children, responsible for 11% of cancer deaths in pediatric patients under 15 (Smith et al, Cancer, 2014). High-risk neuroblastoma is a metastatic disease in children aged 18 months or older with L2, M, or MS disease with amplification of the MYCN oncogene (Chuang Pediatr Blood Cancer 2021). Recent analyses by COG show that HR Neuroblastoma still has a 5-year event free survival of 51% despite an extensive treatment regimen (Steven et al, ASCO, 2022). To address improved tumor targeting and overcome antigen escape, chimeric antigen receptor (CAR) technology to Natural Killer (NK) cell therapy has been adapted (Chu/Cairo, et al, Frontiers in Oncology, 2019). TGFβ is a potent mechanism of the NK cell anti-tumor resistance and is present at elevated levels in the NB tumor microenvironment (TME) (Foltz, Cancers, 2018). Studies demonstrated that blockade of TGF-β signaling in NK cells caused the accumulation of NK cells that produce IFN-γ and neutralization of TGF-β prevented NKG2D downregulation and also restored NK cell anti-tumor reactivity (Nayyar/Chu/Cairo, et al Frontierls in Oncology, 2018). ROR1, a transmembrane protein is highly expressed on the majority of NB (Rebagay/Yan *Front Oncol*, 2012). Our group has successfully expanded functional and active peripheral blood NK cells (exPBNK) with irradiated feeder cells and electroporated CAR mRNA to exPBNK (Chu/Cairo, et al Cancer Immunol Res, 2015).
Objective: To determine in vitro cytotoxicity against neuroblastoma cells by ex vivo expanded TGFβ imprinting (TGFβi) NK cells.
Methods: TGFβi NK cells are generated by culturing expanded NK cells with irradiated K562-41BBL-mbIL21 in 50 IU/mL IL-2 plus 10 ng/mL TGFβ every 2-3 days for two weeks. NK and TGFβi NK cells specific in-vitro cytotoxicity were compared via luciferase reporter assay against ROR1^{+} NB cell lines as we previously described (Chu/Cairo, et al, JITC, 2022). Cytokine/chemokine levels secreted by NK and TGFβi NK cells were compared using ELISA assays (Chu/Cairo, et al, JITC, 2022).
Results: We have successfully expanded TGFβi NK cells. These TGFβi NK cells showed significantly enhanced in vitro cytotoxicity against NB cells compared to NK cells under TGFβ environment (20±2.4% vs 0%; $p<0.001$) at E:T=3:1 and consistently, TGFβ-imprinting NK secreted significantly high level of TNF-alpha (393.7pg/ml±16.77pg/ml) against NB cells ($p<0.001$) compared to NK cells (79.7pg/ml±14.7pg/ml) under TGFβ environment.
Conclusion: Our data indicate TGFβi NK cells may be a promising novel therapy to overcome the immunosuppression of TGFβ in the tumor microenvironment for pediatric NB tumors. We will further engineer these TGFβi NK cells to express anti-ROR1 CAR to enhance the targeting specificity against NB tumors and investigate the anti-tumor effects of anti-ROR1 CAR TGFβi NK cells against NB tumors *in-vitro* and *in-vivo* (Funded by U54 CA232561).

#3616 *In vivo* expansion patterns of anti-BCMA CAR T-cell in relapsed/refractory multiple myeloma: Comparative immunomonitoring of idecabtagene vicleucel and ciltacabtagene autoleucel.

M. Kocoglu, A. P. Rapoport, E. Gebru, D. Omili, D. Yamoah, R. Mulatu, J. Yared, N. M. Hardy, M. Kallen, A. Z. Badros, **D. Atanackovic**;
University of Maryland Greenebaum Comprehensive Cancer Center, Baltimore, MD

Introduction: Chimeric antigen receptor (CAR) T cell (CAR-T) treatments have revolutionized the treatment of multiple myeloma (MM). Two CAR-T cell products targeting B cell maturation antigen (BCMA) have received approval for the treatment of MM: idecabtagene vicleucel (idecel) and ciltacabtagene autoleucel (ciltacel). A comparative analysis of in vivo CAR-T responses in patients receiving these novel cellular therapies has not been performed, especially not in the real-world setting.
Methods: We prospectively enrolled 23 MM patients treated with idecel or ciltacel in our study GCCC2043. Blood samples were obtained at apheresis, pre-lymphodepleting (LD) chemotherapy, on days 0, +7, +14, +21, +28 and at +3 months post CAR-T. Samples were stained using BCMA or control CAR detection reagents, monoclonal antibodies against T cell surface antigens, and analyzed using flow cytometry.
Results: Baseline clinical characteristics, pre-apheresis and pre-LD absolute lymphocyte counts were comparable between groups. There were no G3 cytokine release syndrome (CRS) events whereas G1/2 CRS and all-grade Immune Effector Cell-Associated Neurotoxicity Syndrome (ICANS) events were not significantly different between cohorts. The global overall response rate (ORR) was 78.3% (n=18) and 60.9% (n=14) at days 30 and 90, respectively. At +1 month, 72.7% (8/11) of idecel and 83.3% (10/12) of ciltacel cohort had an objective response (p=0.625). There was no statistical ORR difference between idecel and ciltacel cohorts at 3, 6, and 9 months. Two-way ANOVA of CAR-T expansion studies revealed a trend towards an effect of treatment type (p=0.0595). Time to peak CAR-T numbers was significantly shorter for idecel (p=0.0127), however, ciltacel showed a significantly more pronounced CAR-T expansion (p=0.043) and longer persistence. Peak CAR-T expansion was associated with clinical responses across cohorts at +1 (p=0.034) and +3 months (p=0.050). Day +30 responses were indicative of Day +90 and Day +180 responses (p<0.001, p=0.011). There was no difference in CD8+ CAR T cell peak levels, however, CD4+ CAR T cell peak levels were much higher (p=0.019) for ciltacel vs. idecel. Similarly, there were significantly higher (p=0.002) CD4+/CD8+ double-positive CAR-T peak levels in ciltacel vs. idecel patients. There was no significant difference in the distribution of T cell memory subtypes at peak level.
Conclusions: We demonstrate here for the first time significant differences in CAR T cell expansion and persistence patterns following infusion of either idacel or ciltacel. Studies are underway at our institution investigating anti-BCMA CAR T cell responses in more detail and larger numbers of patients. Such studies have the potential to identify predictive/prognostic biomarkers and/or lead to further optimization of myeloma-targeting CAR-T.

#3617 Expansion and persistence of anti-BCMA CAR T cells correlates with durability of responses in multiple myeloma patients.

K. Wu, K. Law, G. Ledergor, C. Liu, Z. Fan, V. Gurunathan, A. Lea, M. Clark, S. Kwek, A. Cheung, J. Wolf, A. Chari, A. Kumar, J. Eyquem, T. Martin, L. Fong; UCSF - University of California San Francisco, San Francisco, CA

Background: Chimeric antigen receptor (CAR) T cells targeting B-cell maturation antigen (BCMA) can induce >70% response rates in patients with relapsed/refractory multiple myeloma (RRMM). However, most patients ultimately relapse. There are two FDA-approved CAR T products: ciltacabtagene autoleucel (cilta-cel) and idecabtagene vicleucel (ide-cel), the former having much more durable responses. The mechanisms that mediate more durable responses with these CAR T cells is unknown. Previous studies have shown that specific cell states in the apheresis and infusion products are associated with long-term efficacy of anti-BCMA CAR therapy in MM and the relationship between durability of response and CAR T cell persistence remains unclear.
Methods: We analyzed serial bone marrow and PBMC samples from 20 MM patients who received BCMA CAR T therapy, including cilta-cel, ide-cel, and JCARH125. Flow cytometry and single-cell RNAseq were used to evaluate the features of CAR T cells that are associated with durable clinical responses.
Results: While CAR T cells were detectable but variable among patients at 1-month post infusion, the frequency of CAR T cells in bone marrow at 1-month post-infusion is positively correlated with progression free survival (PFS) in all MM patients (p=0.009). This association was also evident in patients just treated with cilta-cel (p= 0.008). By 6 months, CAR T cells could still be detected by high-throughput flowcytometry in the cilta-cel-treated patients, but CAR T cells were not detectable in most of the patients receiving the other 2 products. Cilta-cel CAR T cells predominantly possessed an effector-like surface phenotype at 1-moth post infusion in both CD8+ and CD4+ compartments in bone marrow. These CAR T cells shifted to effector memory and central memory T cell states by 6 months, respectively. For ide-cel and JCARH125, patients with more durable responses (>6mos) there was a significantly higher proportion of CAR T cells with CD8+ effector memory-like state at 1-month post infusion.
Conclusions: Our data demonstrate that distinct anti-BCMA CAR T cell treatments lead to very different cellular outcomes: Cilta-cel CAR T cell treatment leads to greater expansion and persistence compared to other anti-BCMA CAR T cells. Cilta-cel CAR T cells also shift from the initial effector state to a memory phenotype. These results provide insights into features of more efficacious anti-BCMA CAR T cells that can help guide the future development of more durable treatments for MM.

#3618 High-avidity BCMA CAR and high-affinity, non-cleavable CD16 Fc receptor incorporated in off-the-shelf CAR T cells promote multi-antigen targeting and durable anti-tumor cytotoxicity in the treatment of multiple myeloma.

J. Reiser[1], A. O'Connor[1], B. Hancock[1], S. Markov[1], B. Groff[1], A. Gutierrez[1], M. Meza[1], M. Jelcik[1], Y. Pan[1], A. Garcia[1], B. Goulding[1], M. Denholtz[1], T. Lee[1], R. Abujarour[1], R. Bjordahl[1], A. Rehm[2], R. Clarke[1], J. Goodridge[1], B. Valamehr[1];

[1]Fate Therapeutics, San Diego, CA, [2]Max Delbruck Center, Berlin, Germany

Immune cell therapy has proven highly effective for the treatment of multiple myeloma (MM). However, key challenges remain that include disease relapse, limited patient access, and inability to effectively combine with existing standard-of-care therapies. Rapid progress in the development of off-the-shelf, multiplexed-engineered, induced pluripotent stem cell (iPSC)-derived cell therapies enables large-scale manufacture of immune cells incorporating multiple novel synthetic controls of cell function to improve cell fitness, enhance cell function, and enable synergistic combination with existing effective therapies such as CD38-targeted antibody (mAb) therapy. We have developed an iPSC-derived chimeric antigen receptor T (CAR-iT) cell therapy that uniquely leverages elements of both adaptive and innate immunity by incorporating a BCMA-targeted CAR (BCMA-CAR) derived from a scFv domain exhibiting high-binding affinity in the low nanomolar range, and a high-affinity, non-cleavable CD16 (hnCD16) Fc receptor to enable antibody-dependent cellular cytotoxicity with mAb therapy. The genetic deletion of CD38 gene was also incorporated to eliminate the possibility for CD38-mediated fratricide, and genetic deletion of TRAC gene was introduced to remove the potential risk of graft-versus-host disease in an allogeneic setting. These CAR iT cells, which were generated from a clonally-derived iPSC line, demonstrated homogenous expression of each genetic edit (>95% BCMA-CAR and hnCD16; <1% CD38 and TCR surface expression). Using a stringent, disseminated xenograft mouse model of multiple myeloma, MM.1S, which was allowed to achieve complete systemic engraftment during the initial 4 days, treatment with BCMA-CAR iT cells demonstrated comparable tumor cell clearance ($p=0.0024$ vs. vehicle at Day 17) to primary BCMA-CAR T cells ($p=0.002$ vs. vehicle). In combination with a CD38-targeted mAb to exploit hnCD16 and biallelic CD38 KO, BCMA-CAR iT cells are capable of dual-antigen targeting to address antigen escape and promote durable tumor control. To this end, a single dose of BCMA-CAR iT cells combined with daratumumab exhibited near complete TGI for the duration of the study ($p<0.0001$ vs. vehicle at Day 37). Together, these studies demonstrate CAR iT cells incorporating a high-avidity BCMA CAR and high-affinity, non-cleavable CD16 Fc receptor can uniquely leverage elements of both adaptive and innate immunity and can be combined with CD38-targeted mAb to potentially outcompete primary BCMA CAR T cells. As these CAR iT cells can be administered off-the-shelf, key challenges associated with current immune cell therapy, such as patient access and inability to synergize with standard-of-care therapies, can be addressed for the treatment of relapsed / refractory MM.

#3619 Post CAR-T lymphocytosis as a surrogate of BCMA CAR-T expansion, response, and prognosis in multiple myeloma.

M. Mejia Saldarriaga[1], D. Pan[2], C. Unkenholz[3], T. Mouhieddine[2], J. Fein[1], J. Monge[1], C. Rosenbaum[1], R. Pearse[1], D. Jayabalan[1], C. Gordillo[4], H. Chan[4], M. Mapara[4], G. Inghirami[1], S. Lentzsch[4], R. Reshef[4], A. Rossi[2], S. Parekh[2], S. Jagannath[2], S. Richards[2], R. Niesvizky[1], M. Bustoros[1];

[1]Weill Cornell Medicine, New York, NY, [2]Mount Sinai, New York, NY, [3]Weill Cornell Medicine School of Medicine, New York, NY, [4]Columbia University Irving Medical Center, New York, NY

Introduction: Expansion of chimeric receptor antibody (CAR)-T cells after infusion has been described as important marker in multiple myeloma (MM); however, the phenomenon of overt lymphocytosis has not been reported. We describe the kinetics of absolute lymphocyte count (ALC) after BCMA CAR-T in MM as a marker of depth of response and progression-free survival (PFS).

Methods: 158 patients (pts) were included (93 pts ciltacabtagene autoleucel (cilta-cel) and 65 pts idecabtagene vicleucel (ide-cel) from three institutions. Baseline characteristics, cytokine release syndrome (CRS), immune effector cell-associated neurotoxicity syndrome (ICANS), ALC on day -5 through 14, and outcomes were collected. A cohort of 84 pts who received CD19 CAR-T for non-Hodgkin lymphoma (NHL) as comparator. Peripheral blood (PB) flow cytometry was performed on days 7, 14 and 21 in 4 patients.

Results: Early ALC increase after BCMA CAR-T was frequent, with a median max ALC 1.3 $x10^3$/uL (IQR 1-4.4) from a median baseline of 0. However, when compared to ide-cel, cilta-cel had a higher median Max ALC (2 $x10^3$/uL (1 - 4.4) vs 0.8 (0.7 - 2.8), p < 0.001), longer time-to-max ALC (11 vs 12 days, p = 0.003), and higher absolute ALC increase (2.1 $x10^3$/uL vs 0.7 $x10^3$/uL, p <0.001), while there were no differences in ALC before lymphodepleting conditioning or day 0. Higher max ALC was associated with CRS (OR 4.8, CI 1.3-17.2, p 0.01). Max ALC and absolute increase in ALC were significantly associated with deeper response (VGPR vs PR or less), improved PFS and duration of response (DoR) in univariable analysis. Max ALC >1 $x10^3$/uL (HR 0.4, 0.2-0.7, p <0.001) and non-paraskeletal EMD (HR 2.1, 1.2-.4, p <0.01) remained associated with PFS/DoR in multivariable model after adjusting for CAR-T Product, high-risk cytogenetics, and number of previous lines. PB flow cytometry in 3 responder patients (max ALC range 2-14 $x10^3$) showed expansion of CD3+ BCMA CAR-T from day 7 (BCMA CAR-T <0.2% of CD3+ cells) to day 14 (BCMA CAR-T range 54-88.6%), while a non-responder (max ALC 0.4 $x10^3$) patient had no expansion despite presence of CD3+ BCMA CAR-T at day 7, 14 and 21. BCMA CAR-T had higher max ALC when compared to CD19 CAR-T (median 1.3 $x10^3$ vs 0.4 $x10^3$ (0.2-0.7), p < 0.001), while there were no differences in baseline ALC between BCMA and CD19 CAR-T. Median max ALC did not differ between response status after CD19 CAR-T (0.4 $x10^3$ (0.2-0.7) vs 0.6 (0.3-0.7), p = 0.3).

Discussion: Post-CAR-T lymphocytosis is common after BCMA CAR-T therapy for MM and is associated with response, PFS, and DoR after adjusting for other prognostic variables. A cut-off of max ALC > 1 $x10^3$ identified patients with superior PFS, while max ALC <0.5 $x10^3$ represents high-rates of poor response and early progression. ALC expansion correlated with BCMA CAR-T expansion as assessed by flowcytometry, supporting ALC assessment as an accessible surrogate that is clinically applicable and accessible.

CLINICAL RESEARCH: Biomarkers in Clinical Trials
Poster Session

#3623 Quantifying pharmacodynamic markers of radioligand therapies in tumor by multiplex immunofluorescence and automated quantitative analysis (AQUA) algorithms.

J. Santos[1], V. Nyanchama[1], V. Romanet[2], E. Dammassa[2], L. Kattenhorn[3], Y. Huang[3], J. Lim[3], X. Li[1], J. Deeds[3], L. Iaconis[3], E. Pacia[1], M. McLaughlin[3], N. Dakappagari[1], **J. Bordeaux**[1];

[1]Navigate BioPharma Services, Inc., a Novartis subsidiary, Carlsbad, CA, [2]Novartis Biomedical Research, Basel, Switzerland, [3]Novartis Biomedical Research, Cambridge, MA

Purpose: Due to profound clinical successes observed with radioligand therapies (RLT) across multiple cancers coupled with advances in drug handling and delivery logistics recently, clinical trials investigating RLTs are on the rise. Ionizing radiation produced by radioisotopes linked to antibodies causes double-stranded breaks either directly or via generation of reactive oxygen species. This type of DNA damage is associated with an increase in proteins mediating cell cycle arrest (e.g., p21/CIP1) and repairing damaged DNA (e.g., CHK2 and γH2Ax). Additionally, proliferating cells (identifiable by Ki67) are most susceptible to ionizing radiation as DNA is exposed during the mitotic phase of the cell cycle. We incorporated these biologically verified markers into a multiplexed fluorescence immunohistochemistry (mFIHC) assay for robust quantitation of the pharmacodynamic activity of RLTs and gain insights into the DNA damage response in on-treatment tumor core biopsies.
Study Design: We designed a novel mFIHC assay incorporating antibodies to p21, pCHK2, γH2Ax, Ki67, CK to quantitatively characterize DNA damage across five tumor indications of commercially available ovarian cancer, colorectal cancer, gastric cancer, endometrial (uterine) cancer, and breast cancer formalin-fixed paraffin-embedded (FFPE) tissue blocks. We successfully validated this mFIHC assay using automated staining (Bond RX), imaging (PhenoImager HT), and combined with hypothesis-driven spatial profiling algorithms (e.g., AQUA Technology).
Results: Sensitivity and specificity were confirmed on known positive and negative controls. Reproducibility and precision were observed across instruments, operators, and independent experiments for all markers The frequency of p21 ranged from 5% - 8%, pCHK2 from 3% - 36%, pH2Ax from 0% - 8%, Ki67 from 4% - 61%, and CK cells ranged from 25% to 87%. Over 56 unique parameters were evaluated. The prevalence of p21, pCHK2, and γH2Ax ranged from 0% to >30% across five tumor indications tested and were highly concordant.
Conclusion: The validated mFIHC assay examines the expression of proteins mediating cell cycle arrest and DNA damage in tumor and stromal cells. This panel may be used to further understand the complexity of DNA damage response pathways in tumor and non-tumor areas in the context of RLT clinical trials.

#3624 A low-cost kit for gentle, effective and timely extracellular vesicle (GET EVs) isolation: Accelerating development of RNA-based liquid biopsies for neuroendocrine neoplasms.

B. Su[1], M. Jeyhani[2], X. Yang[3], J. Nanayakkara[3], R. Wunsche[4], N. Renwich[3], S. Tsai[2], H. Leong[1];

[1]Department of Medical Biophysics, University of Toronto, Biological Sciences Platform, Sunnybrook Research Institute, Toronto, ON, Canada, [2]Department of Mechanical and Industrial Engineering, Toronto Metropolitan University, Keenan Research Centre for Biomedical Science, St. Michael's Hospital, Institute for Biomedical Engineering, Science and Technology (iBEST), Toronto, ON, Canada, [3]Laboratory of Translational RNA Biology, Department of Pathology and Molecular Medicine, Queen's University, Kingston, ON, Canada, [4]Department of Mechanical and Industrial Engineering, Toronto Metropolitan University, Toronto, ON, Canada

Extracellular vesicles (EVs) are cell fragments released by all cells, making them promising platforms for cancer biomarker development. Effective isolation of ultra-pure EVs for downstream analyses is key for EV-based liquid biopsy development. However, current EV isolation methods such as ultracentrifugation (UC) and other commercialized EV isolation kits are lackluster because of damage to EVs, length of time required, and low EV recovery rates. In response, we developed an “GET EV” kit which is based on the principles of lipid energy states, also known as the aqueous two-phase system (ATPS) to isolate EVs from any media. Nanoscale flow cytometry (nFC) analysis revealed that ATPS has greater EV enrichment capability (21.4× vs. 10.9× times fold enrichment) and higher EV recovery efficiency (97.6% vs. 69.3% recovery) than UC. Other EV isolation kits were tested and were inferior to ATPS in terms of EV recovery and EV-RNA recovery. EV subpopulations as determined by EV biomarkers (CD9, CD63, CD81, etc.) were confirmed by nFC. “Omics” studies (small RNA sequencing and proteomics) also confirmed the presence of expected EV markers. We developed an RNA-based liquid biopsy for Neuroendocrine Neoplasms (NENs) by quantitating the presence of EVs containing miR-375, an established biomarker for NENs. Using the GET EVs kit, we isolated EVs from healthy volunteer and patient plasma samples of NEN patients. RT-qPCR demonstrated enriched expression of miR-375 in EVs isolated from Lung and GI NEN patient plasma samples. Our study establishes the use of GET EV kits to efficiently, rapidly, and gently isolate EVs from small plasma samples (250 uL). This is a low-cost innovation that will finally enable the development of other RNA-based Liquid Biopsies for other disease sites with significant diagnostic and prognostic implications.

#3625 Metabolic phenotypes of doxorubicin-induced cardiotoxicity in breast cancer patients.

S.-R. Jun[1], K. Wallis[1], R. D. Landes[1], V. K. Todorova[1], L. Su[2], S. Makhoul[3], **P.-C. Hsu**[1];
[1]University of Arkansas for Medical Sciences, Little Rock, AR, [2]UT Southwestern Medical Center, Dallas, TX, [3]CARTI Cancer Center, Little Rock, AR

Background. Doxorubicin (DOX) is a highly effective chemotherapy agent that is commonly used in combination with other chemotherapy regimens to treat a wide range of cancers, including 32% of breast cancer (BC) cases. Although DOX has greatly increased the number of long-term cancer survivors, some DOX recipients have experienced DOX-induced cardiotoxicity (DIC). Currently, there are no validated markers that can predict the early development of DIC. Cardiac troponin released by cardiomyocytes has been used in non-clinical studies as a marker of myocardial injury; however, the false positive rates are high, and the predictive value on cardiotoxicity is limited. Therefore, novel biomarkers of DIC are urgently needed to identify patients who are at an increased risk, allowing early detection of the cardiotoxicity before it causes permanent cardiac damage.

Methods. Untargeted metabolomics profiling was performed for plasma samples from a cohort of 28 breast cancer patients who developed abnormal cardiac function (ABN) and those who maintained normal cardiac function (NML). Blood samples were collected before, during, and after DOX-containing chemotherapy. Using both baseline observations and pre-post changes, machine-learning techniques were used to identify metabolite markers that can be used as early indicators of DIC in BC patients. Area under the receiver operating characteristic curve was reported to evaluate the performance of significant metabolites, and metabolite set enrichment analysis (MSEA) and network analysis were used to extrapolate known associations between metabolites and diseases.

Results. Significant separation of plasma metabolomics profiles between ABN and NML patients at baseline was observed. From 1,124 metabolites, abundance of 59 metabolites were found to differ between ABN and NML patients at baseline. Across all patients, levels of 78 metabolites changed between baseline and after the 1st chemotherapy cycle. Of the 6 metabolites identified in both baseline and pre-post data, ABN patients had higher levels of dicarboxylic acids suberate and sebacate derived from ω-oxidation of fatty acids at baseline than NML patients. Enrichment analysis on the metabolites from the pre-post analysis suggested myocardio injury and carnitine palmitoyltransferase deficiency. Network analysis of metabolite-disease interactions further suggests potential impact on neurological health after chemotherapy.

Conclusion. The metabolomics phenotype identified is indicative of impaired beta-oxidation at baseline for ABN patients. In addition, our findings suggest neurotoxic effect from DOX, implicating the potential brain-heart axis involved behind the cardiotoxicity phenotype.

#3626 Day 21 early bone marrow response does not offer high concordance with response bone marrow in the induction chemotherapy setting of *FLT3* mutant acute myeloid leukemia.

V. Lok[1], S. Hahn[1], N. N. Shah[2], D. A. Kerr[2], I. M. Borrello[2], E. M. Sotomayor[2], D. M. Swoboda[2];
[1]USF Health Morsani College of Medicine, Tampa, FL, [2]Tampa General Hospital Cancer Institute, Tampa, FL

Purpose: Day 14 early bone marrow biopsies are routinely initiated to determine need for reinduction chemotherapy, but poorly predict true response and risk overtreatment. Day 21 (D21) bone marrow biopsies have been performed in the context of trials utilizing *FLT3*-targeted therapies in combination with induction chemotherapy (Stone et al. NEJM 2017). However, the utility of D21 bone marrow responses is not well defined.
Methods: We retrospectively identified 26 newly diagnosed *FLT3* mutant AML patients who underwent induction chemotherapy with midostaurin and Next Generation Sequencing (NGS) of bone marrow aspirate within a week of diagnosis.
Results: 19/26 (73%) of patients had both D21 and response bone marrow biopsy. Of the remaining 7 patients, 4 patients did not have D21 bone marrow, 2 died of unrelated complications prior to response bone marrow, and 1 did not have recovery marrow available for assessment. Our cohort included 13 (50%) men with a median age of 57 years (range, 21 - 73 years). All patients had ECOG of 0 - 1. 96% of cases were de novo AML and 81% had normal cytogenetics. FLT3 ITD mutations were detected in 17 (65%) patients with a median FLT3 ITD ratio of 0.305 (range, 0.03 - 1) and median FLT3 VAF of 23.8% (range, 3.2 - 80.6%). 7 patients (26.9%) underwent additional allogeneic stem cell transplant.
In the 19 patients evaluable for analysis, 13/13 (100%) patients with blast % ≤ 5 at D21 achieved a complete response (CR) based on recovery marrow. 4/6 (67%) patients with blast % > 5 at D21 which were considered to have residual disease based on pathology review (median blast % 11 (range, 6 - 17%) ultimately achieved a CR. The 2 patients that did not achieve a CR has a blast % of 29% and 9% on D21 marrow. Thus, the positive predictive value of D21 early bone marrow response corresponding with the response bone marrow was only 33% in our patient cohort. Of the 4 patients that did not have D21 marrow but had recovery marrows available for review, the CR rate was 100%.
No other significant differences in initial disease characteristics were seen. There were no differences proportion of co-mutations in *NPM1, DNMT3A, TP53, IDH2*, and *IDH1*, and higher FLT3 ITD ratio nor FLT3 VAF corresponded with ability to clear D21 bone marrow. Additionally, there were no differences in minimal residual disease (MRD) and overall survival (OS) between the groups.
Conclusions: Our study suggests early bone marrow response in the context of *FLT3*-mutant disease is not dependent on inherent disease characteristics and does not correspond to overall response to targeted induction chemotherapy. The utility of these marrows in is this population needs to be studied further in a larger cohort to better understand the clinical necessity to avoid unnecessary cost/procedures to patients and even more importantly unnecessary reinductions.

#3627 Volrustomig a novel PD-1/CTLA-4 bispecific antibody leads to robust increase in peripheral and intra-tumoral pharmacodynamic biomarkers in solid tumors from FTiH study.

I. Achour[1], M. Kuziora[1], F. Song[1], S. Eck[1], L. Meinecke[1], J. Blando[1], J. Pearson[1], M. Saraiya[1], C. Eisen[1], F. Segerer[1], M. Schick[1], N. Triltsch[1], M. Surace[1], G. Silva Boos[1], H. Hessel[1], M. Bui[1], K. Pratsch[1], A. Andoni[1], S. D. Gainer[1], D. Freeman[1], D. Subramaniam[1], B. Tran[2];
[1]AstraZeneca US, Gaithersburg, MD, [2]Peter MacCallum Cancer Centre,, Melbourne, Australia

Background: Volrustomig (MEDI5752) is designed to fully inhibit PD-1 while preferentially inhibiting CTLA-4 on activated PD-1+ T cells. In a FTiH trial, volrustomig demonstrated meaningful clinical activity in patients with solid tumors (including 1L RCC and NSCLC), acceptable safety profile, sustained PD-1 receptor occupancy, and T cell proliferation at levels greater than seen with clinically tolerable doses of CTLA-4 inhibitors with co-administration of anti-PD(L)-1. We sought to further characterize volrustomig pharmacodynamic effect in the periphery and tumor to demonstrate its biological activity and inform dose optimization.

Methods: Pre- and on-treatment blood samples from 86 patients enrolled in dose exploration were collected. Peripheral T cell profiling was assayed by flow cytometry, RNAseq, TCRSeq and serum proteomics. Paired tumor biopsies (N=17), pre- and at week 6 on-treatment, were analyzed for T cell infiltration and function using RNAseq and computational image analysis of immune cell marker density detected by histochemistry and multiplex immune fluorescence assays.

Results: Volrustomig achieved dose-dependent peripheral pharmacodynamic changes of biomarkers specific to CTLA-4 blockade at ≥ 225mg. At C1D8 with doses ≥ 500mg, increases in CD4 T cell proliferation (ki67), activation (ICOS), and memory T cells (1516%, 321% and 88%, respectively) were seen, each greater than observed with historical controls of patients treated with tremelimumab 3mg/kg (T3) in combination with durvalumab. Similarly, CD8 proliferation and activation were also higher than T3 at C1D8 with 300% and 161% increase respectively. Additional CD4 and CD8 T cell proliferation and activation was observed at C2D8 supporting the benefit of repeat dosing. Higher peripheral T cell clonal expansion at doses ≥ 500mg was seen and associated with PFS and OS benefit. In patients with paired biopsies, volrustomig achieved robust T cell mediated anti-tumor activity including increases in T cell infiltration (CD8+, 2.3 fold, p=0.04), proliferation (CD8+ Ki67+, 2.1 fold, p=0.04) and, T cell cytotoxicity and activation (GrB+, 2.2 fold, p=0.01; T cell effector and IFNg gene signatures, > 2-fold, p< 0.01). Additionally, volrustomig increased CD8 proliferation in tumor compared to historical control durvalumab alone (>2-fold increase in 70% vs 50% patients).

Conclusion: Voltrustomig demonstrated robust peripheral and intra-tumoral T cell activation and proliferation, broadening the pool of antigen experienced T cells, at levels greater than seen with dual checkpoint blockade currently used in the clinic.

#3628 Combined mek and jak inhibition *in vitro* is an effective strategy in overcoming jak inhibitor resistance in primary myelofibrosis (PMF).

S. B. Reynolds, S. Matono, M. Kandarpa, K. Pettit, M. Ribick, M. Talpaz, Q. Li;
University of Michigan, Ann Arbor, MI

Introduction Primary myelofibrosis (PMF) is a myeloproliferative neoplasm arising from various mutations in myeloid-committed hematopoietic progenitor cells. Treatment of PMF is challenging as Jak inhibitor resistance is common, making the expansion of molecular characterization and novel therapeutic target identification in PMF essential. The main goals of this study are to determine both the presence of Ras activity in PMF and the impact on Ras/MAP Kinase pathway targeting in the disease.

Methods Integrated genomic-transcriptomic sequencing analyses were performed on peripheral blood mononuclear cells (PBMCs) purified from 27 patients with PMF at a single institution; protein was then obtained from whole cell lysates. Ras activity was then assessed by applying Ras binding domain (RBD) to sample in an ELISA and was compared between patients with PMF, essential thrombocythemia (ET), polycythemia vera (PV) and healthy donors. Statistical analyses were conducted using two-way unpaired t-tests. The next set of *in vitro* studies aimed to evaluate the effects of MEK inhibition in PMF. Cell viability studies were first performed on human erythroleukemia (HEL) cells to identify IC50 values. Colony forming assays in methylcellulose-enriched media formulated for the growth of CD34+ cells were then performed in 4 conditions: Ruxolitinib and Cobimetinib monotherapy, combined therapies and untreated sample.

Results As previously reported in our initial study, Ras activity in 21 patients with MF was 1.74 fold higher than healthy donors (13 volunteers, p=0.0304) and 1.64 fold higher than in PV/ET (12 patients, p=0.0462). We also reported previously on Ras activity from differential enrichment of myeloid and lymphoid cells from PBMC samples, where a key observation was that myeloid contribution to Ras activity in PMF patients with *RAS*/MAP Kinase pathway mutations was 3.8 times higher in Ras/MAP Kinase WT patients (p=0.0012), potentially suggesting that *RAS* pathway mutations have a predominance in myeloid cells. In HEL cell viability assays, cobimetinib and ruxolitinib, when utilized in tandem, resulted in more cell growth inhibition than either agent individually. This same finding was recapitulated in colony forming assays in 4 different patients with varying levels of sensitivity to Jak inhibitors, in all of whom ruxolitinib and cobimetinib lead to a greater reduction in colony formation than ruxolitinib monotherapy.

Discussion Data from colony forming assays of bone marrow from patients with PMF identifies at least an additive effect of combined Jak and Ras/MAP Kinase (specifically Mek) inhibition on CD34+ colony formation. The specific observation that Ras pathway inhibition may be utilized as a means of overcoming Jak inhibitor resistance in PMF is a novel finding in this field and may be a valuable avenue for future early-phase clinical trials.

#3629 Prevalence of claudin18.2 expression in gastric/gastroesophageal junction adenocarcinoma among patients in TranStar101 and TranStar102 clinical trials.

Li Shen[1], Carol Mao[1], Alan Lin[1], Ying Gu[2], Jenny Milata[2], Lijuan Zhang[1], Chuan Qi[1], Jenny Yao[2], Steven Yu[1], Changjun Yue[3], Lin Shen[4], Yelena Janjigian[5], Xueming Qian[1], Wen-I Chang[2], Caroline Germa[2]

[1]Suzhou Transcenta Therapeutics Co., Ltd, Suzhou, China,[2]Transcenta Therapeutics, Princeton, NJ,[3]LabCorp Central Lab, Torrance, CA,[4]Beijing Cancer Hospital, Beijing, China,[5]Memorial Sloan Kettering Cancer Center, New York, NY

Background: Claudin18.2 (CLDN18.2) is a tight junction protein highly specific to gastric mucosa, and a validated target for gastric cancer (GC) treatment. Immune checkpoint therapy targeting PD-1 combined with chemotherapy has been approved as the first line therapy of GC. Understanding the expression profiles of CLDN18.2 and PD-L1 could guide the development of combination therapies to maximize the benefits of these two agents. This study investigated the prevalence of CLDN18.2 expression in gastric/gastroesophageal junction adenocarcinoma (G/GEJC) screening samples from studies Transtar101 (NCT04396821 in US) and TranStar102 (NCT04495296 in China), and its correlation with various clinical characteristics and PD-L1 expression.
Methods: CLDN18.2 expression in formalin-fixed, paraffin-embedded (FFPE) G/GEJC tissue samples was prospectively detected by an immunohistochemistry-based LDT using an in-house anti-CLDN18.2 antibody (Clone14G11) on the Leica Bond III stainer. CLDN18.2 expression was assessed by scoring the staining intensity (0, 1+, 2+, 3+) and the percentage of positive tumor cells. Positive CLDN18.2 expression is defined as the cutoff at ≥10% of tumor cell with ≥1+ staining intensity for this evaluation. PD-L1 expression was assessed by combined positive score (CPS) using Agilent's PD-L1 IHC 28-8 pharmDx. Both assays were conducted in CAP/CLIA certified LabCorp central lab.
Results: 547 G/GEJC patient samples had CLDN18.2 results as part of the screening procedures for the clinical trials. Of these patients (454 GC/93 GEJC), 439 (80%) were Asian, 29 (5%) were Caucasian, 2 (0.4%) were other ethnic group, and 77 (14%) were not recorded; 434 (79%) were primary tumors and 113 (21%) were metastasis; 201 (37%) were core needle biopsies (CNB), 108 (20%) were surgical resections (SR) and 238 (44%) had no information. 311 (57%) samples had positive CLDN18.2 expressions (≥10%/≥1+). No significant difference in CLDN18.2 positive rates were found between TranStar101 and TranStar102 studies (p=0.801), Asian and Caucasian (p=0.612), GC and GEJC (p=0.373), primary and metastatic specimens (p=0.055) or CNBs and SRs (p=0.715). Out of 83 TranStar102 specimens that had both CLDN18.2 and PD-L1 results, 15 (18%) had PD-L1 CPS≥5, 59 (71%) had positive CLDN18.2, and 10 (15%) had both positive CLDN18.2 and PD-L1 CPS≥5. No correlation (p=0.393) was observed between PD-L1 scores (CPS<5 or CPS≥5) and CLDN18.2 expression (≥10%/≥1+ or <10%/≥1+).
Conclusions: Data suggested CLDN18.2 expression levels were independent of PD-L1 status, and support the use of Transcenta 14G11 antibody for CLDN18.2 detection regardless of sample collection methods, location, and patient demographics. An anti-CLDN18.2 companion diagnostic device based on 14G11 is being developed (CLDN18.2 IHC 14G11 pharmDx, Agilent Technologies, Inc.).

#3630 Measuring EGFr on extracellular vesicles in human plasma samples.

D. A. Olsen, T. F. Hansen, I. Brandslund, J. S. Madsen;
Lillebaelt Hospital, University Hospital of Southern Denmark, Vejle, Denmark

Introduction: Extracellular vesicles (EVs), secreted extracellularly by almost all types of cells, play a pivotal role in intercellular communication and have emerged as valuable indicators in disease progression. Their potential for cancer diagnostics and monitoring is particularly noteworthy. Epidermal growth factor receptor (EGFr) is a major driver of several cancers and serve as an important target or co-target in cancer treatment. The purpose of this study was to develop an assay for measuring EGFr on EVs directly in plasma samples. Additionally three assays were developed to measure the total concentration of plasma EVs.
Methods: Recognizing the expected low concentrations of EGFr on EVs, the immunoassays were developed using Single molecule array (Simoa) technology, which has shown up to a 1000-fold improvement in sensitivity as compared to conventional immunoassay approaches. Commercial available calibrator material and antibodies against surface markers (EGFr, CD9, CD63 and CD81) were used to develop four assays: CD81-EGFr, CD81-CD9, CD81-CD63, and CD9-CD63. Plasma samples from healthy individuals (n=13) and small cohorts of various cancer patients (n=30, lung, colorectal, ovarian) were used for development, validation and testing.
Results: Each assay was tested for dilution linearity, limit of detection, analytical variation and pre-analytical stability of EVs. EGFr on EVs was lower in cancer patients (median: 489 $x10^6$ EVegfr/mL) compared with healthy individuals (median: 663 $x10^6$ EVegfr/mL). Conversely, total EV concentrations were markedly higher in plasma from cancer patients compared with healthy individuals (CD81-CD9: 9157 vs 4088, CD81-CD63: 3634 vs 1582, CD9-CD63: 9538 vs 1210, median values $x10^6$ EV/mL). Positive correlations were observed among the total EV assays ($r=0.6$, $p<0.0001$).
Conclusion: The developed assays allow measurement of EGFr on EVs and total EVs in human plasma samples. Notable, total EV concentrations were highly increased in cancer as compared with healthy individuals. The assays are now ready for a comprehensive validation using large cohorts of cancer samples.

#3631 Preclinical and clinical pharmacodynamic characterization of BBI-355, a novel, orally bioavailable, and selective CHK1 inhibitor being evaluated in the first-in-human Phase 1/2 POTENTIATE clinical trial of patients with cancer harboring oncogene amplifications.

D. Liao, R. Hansen, S. Chowdhry, E. Holmes, J. Wiese, A. Steffy, A. Pferdekamper, E. Tse, S. Garcia, R. Reynolds, S. Weymer, K. Wagner, C. Hassig, S. Kasibhatla;
Boundless Bio, San Diego, CA

Pharmacodynamic (PD) biomarkers play an integral role in the rational development of novel therapeutic agents. Critically, PD biomarkers enable the measurement and confirmation of a drug's intended effect in early clinical trials. Integration of PD biomarker assessments in early therapeutic development can inform the relationship between drug dose and regimen, target modulation, and biological tumor response, which are fundamental to determining the efficacy and safety of novel therapeutic agents. Boundless Bio is evaluating a novel, orally available, and selective Checkpoint Kinase 1 (CHK1) inhibitor, BBI-355, in the Phase 1/2 clinical trial, POTENTIATE (NCT05827614), in patients with solid tumors harboring oncogene amplification including those on extrachromosomal DNA (ecDNA). ecDNA-enabled oncogene amplification endows cancers with significant genomic plasticity, which can facilitate resistance to targeted therapy (Nathanson et al., 2014), and which is also associated with significantly shorter survival (Kim et al., 2020). While ecDNA provides a fitness advantage to cancer cells, its unique features also confer certain liabilities, including elevated DNA replication stress (RS). Elevated RS results in DNA damage and makes ecDNA+ cancers hyper-reliant on the master regulator of RS, CHK1, which manages DNA replication and repair to maintain cell viability (Chowdhry, 2022). Due to their elevated RS and hyper-reliance on CHK1, ecDNA+ cancer cells are rendered more susceptible to CHK1 inhibition than cancer cells that lack ecDNA. Prior clinical CHK1 inhibitor programs have lacked effective clinical PD biomarker assays. Here, we present preclinical data supporting the use of phosphorylated-CHK1 Ser345 (pCHK1-S345), a proximal marker of RS, as a PD biomarker for CHK1 inhibition by BBI-355. In preclinical studies, BBI-355 treatment induced pCHK1-S345 protein expression by immunoblotting in tumor cell lines in vitro and in xenograft tumors in vivo, which corresponded with tumor cell cytotoxicity. We went on to demonstrate in rats the utility of skin as a tumor surrogate tissue to detect CHK1 inhibitor PD effect through induction of pCHK1-S345 expression by immunohistochemistry. Finally, and for the first time, PD activity of a CHK1 inhibitor in humans was demonstrated by increased pCHK1-S345 expression by immunohistochemistry in skin biopsies from patients enrolled on the POTENTIATE study and treated with BBI-355. In conclusion, pCHK1-S345 is a useful PD biomarker for confirming clinical on-target activity of BBI-355 and may be useful to inform the pharmacologically active range of BBI-355 to support clinical development.

#3632 Cytokine profiles associated with ICI myocarditis using machine learning approaches identifies novel cytokines and implicated pathways.

R. Jaber Chehayeb, D. Hong, N. W. Chen, C. Matute Martinez, R. Jayakrishnan, A. Ferrigno Guajardo, D. Lin, Y. Im, S. Halene, J. VanOudenhove, J. Hwa, A. Jha, J. M. Kwan;
Yale University School of Medicine, New Haven, CT

IntroductionImmune checkpoint inhibitors (ICIs) are effective for a growing number of cancer indications. ICI-mediated T cell activation can lead to immune related adverse effects, including ICI myocarditis, which has up to a 50% mortality. To date, only a few cytokines have been reported to be associated with ICI myocarditis. We evaluated an expansive repertoire of cytokines associated with ICI myocarditis and the pathways they regulate.
MethodsA total of 173 cardio-oncology patients were enrolled in the biomarker study, including 55 who were on ICI. Blood samples of patients who were on ICI for cytokine profiling were sampled when patients presented with symptoms concerning for ICI myocarditis. 71 different cytokines were evaluated and analyzed using Point Biserial correlation analyses and machine learning (XGboost) and explainable artificial intelligence (SHAP) to identify cytokines associated with ICI myocarditis. Analyses were performed to identify pathways associated with ICI myocarditis.
Results28 cytokines were associated with ICI myocarditis and machine learning revealed top features associated with ICI myocarditis in the entire cohort with IL33 being the top feature, Accuracy of 0.895, AUC of 0.902, F1 score of 0.73. SHAP was also used to identify features associated with ICI myocarditis and found IL10, CXCL9, CXCL13, CCL3, were positively associated with ICI myocarditis while CCL22, IL33, TNFSF10, CCL8, and CCL24 were negatively associated with ICI myocarditis. 90% of cytokines identified in the correlation model were also identified in SHAP and XG Boost. Top KEGG and GO pathways associated with ICI myocarditis identified by XGBoost and SHAP features include the cytosolic DNA sensing pathway, response to influenza A, IL17, PI3K-Akt, JAK-STAT and lipid/atherosclerosis pathways
ConclusionsIdentifying pathways associated with ICI myocarditis could provide insights into optimization of immunosuppression strategies

Table of cytokines associated with ICI myocarditis identified by SHAP

Cytokine	Direction
IL10	Upregulated
CXCL9	Upregulated
CXCL13	Upregulated
IL7	Upregulated
CCL3	Upregulated
IFNL2	Upregulated
KITLG	Upregulated
IL27	Upregulated
FLT3LG	Upregulated
CCL22	Downregulated
IL12	Downregulated
CCL2	Downregulated
IL33	Downregulated
TNFSF10	Downregulated
CCL8	Downregulated
CCL21	Downregulated
FGF2	Downregulated
CCL24	Downregulated
CX3CL1	Downregulated

#3633 Multi-parametric characterization of extracellular vesicles in the aqueous humor of uveal melanoma eyes undergoing brachytherapy.

S. Sirivolu[1], C.-C. Peng[2], P. Neviani[2], J. L. Berry[1], L. Xu[1];
[1]Keck School of Medicine, University of Southern California, Los Angeles, CA, [2]Children's Hospital Los Angeles, Los Angeles, CA

Introduction: Aqueous humor (AH), fluid in the anterior chamber of the eye, is a liquid biopsy source of tumor information in uveal melanoma (UM). Extracellular vesicles (EVs) have recently been characterized in the AH of retinoblastoma eyes, however, have not been investigated in UM. EVs are small membrane-enclosed particles secreted by virtually every cell type with a role in intercellular communications. We hypothesize that tumor-derived EVs are detectable in the AH of UM eyes and that understanding the type of vesicles present may help us better understand their function, particularly for cancer. Small extracellular vesicles (sEVs) have been shown to promote tumorigenesis, treatment resistance, and metastasis, leading to the discovery of clinically-relevant biomarkers for multiple cancer types. As the diversity and role of sEVs in the AH of UM patients has never previously been reported, this project is a first step towards investigating new biomarkers of clinical utility. Our aim is to use single particle analysis to characterize sEV subpopulations in the AH of UM patients by quantifying their size, concentration, and phenotypes based on cell surface markers, specifically tetraspanin co-expression patterns.
Methods: sEVs were analyzed from paired pre- and post-brachytherapy AH samples collected from 19 UM patients. AH samples from 5 glaucoma patients served as the control cohort. Unprocessed AH underwent Nanoparticle Tracking Analysis for size quantification and Single Particle-Interferometric Reflectance Imaging Sensor analysis for fluorescent particle count and tetraspanin immunophenotyping; counts were subsequently converted to percentages for analysis. Statistics were performed using Mann-Whitney U, ANOVA, and Tukey's tests.
Results: AH derived from UM eyes (pre-brachytherapy) displayed a broader sEV size distribution than glaucoma eyes, with more diverse sEV subpopulations. Both tumor and nontumor AH samples demonstrated a dominant CD63+ sEV subpopulation. A significantly higher percentage of CD63/81+ sEVs (P= 0.0217) and CD9/63/81+ sEVs (P= 0.0146) were found in post-brachytherapy samples compared to pre-brachytherapy.
Conclusions: sEV subpopulations in UM eyes demonstrate increased heterogeneity in comparison to nontumor eyes. Our results are consistent with prior studies reporting that the CD63+ sEV subtype is an AH-specific biomarker enriched across multiple ocular diseases. The increase in CD63/81+ sEVs and CD9/63/81+ sEVs after brachytherapy is presumably a result of radiation-induced release of these vesicles, suggesting a tumor-derived origin of these subpopulations. CD63/81+ sEV subpopulation was previously reported to also be a tumor-derived subpopulation in AH of retinoblastoma eyes. Further study of the cargo carried by these sEV subpopulations may uncover molecular mechanisms pivotal to UM and other ocular cancers.

#3634 Copy number alterations in chromosome 19 genes associate with reduced immune infiltrate and adverse outcomes in lung cancer.

B. S. Henick, Y. Georgis, B. O. Herzberg, C. P. Concepcion-Crisol, A. M. Taylor;
Columbia University, New York, NY

Deleterious mutations in *STK11/LKB1*, *KEAP1,* and *SMARCA4* have been shown to be associated with adverse response to immunotherapy in several lung cancer cohorts. However, the biological and clinical implications of deletions of these genes, which all reside on chromosome 19p (chr19p), has not been extensively described. We sought to first characterize the association between immune infiltration and these copy number changes in chr19p. To do this, we analyzed mutation, copy number, and gene expression data from non-small cell lung cancer cohorts in the Cancer Genome Atlas (TCGA). Chr19p is frequently deleted across cancers in the TCGA dataset, with higher rates in lung adenocarcinoma. In both lung adenocarcinoma and squamous cell carcinoma, nearly half of TCGA tumors have deletion of chr19p including *STK11*, *KEAP1,* and *SMARCA4*, and these tumors are enriched for *STK11* mutation. Immune infiltrate (estimated by methylation patterns) was not significantly associated with *STK11* mutation but was significantly reduced in tumors with chr19 deletion when controlling for tumor type and overall copy number load. In addition, low-level deletion of any of these genes correlated with decreased expression of immune signaling pathways.

Based on these findings, we next wanted to characterize the association between chr19p copy number and immunotherapy response. We previously reported that low-level deletion of STK11 correlated with an immunosuppressive, treatment-refractory phenotype in samples collected from non-small cell lung cancer (NSCLC) patients with resectable disease in a phase II study of neoadjuvant atezolizumab + chemotherapy. To confirm these findings in a larger cohort, we examined the AACR GENIE NSCLC biopharma collective (BPC) dataset. A subset of this cohort included patients treated with immunotherapy (atezolizumab, nivolumab, and/or pembrolizumab) and with copy number data available or GISTIC analysis of individual genes (n = 204). Here, deletion of any of these three genes correlated with worse overall survival, and this was statistically significant for STK11 deletion. Overall, our data suggests that a broader set of patients, defined by copy number changes in these genes, may experience this adverse immunobiology. Further study to elucidate the mechanistic implications of this association is warranted.

#3635 Insulin-like growth factor receptor predicts poor prognosis in early-stage non-small cell lung cancer.

H. nagamine, M. Yashiro, M. Mizutani, A. Sugimoto, Y. Matsumoto, Y. Tani, K. Sawa, K. Yamada, H. Kaneda, T. Watanabe, K. Asai, S. Suzuki, T. Kawaguchi; Osaka Metropolitan University, Osaka, Japan

Introduction: Insulin like growth factor receptor (IGF1R) is involved in the proliferation and metastasis of various cancers. However, the clinical significance of IGF1R in non-small cell lung cancer (NSCLC) remains to be unclear. In this study, we retrospectively evaluated the correlation between IGF1R expression and clinicopathological features of NSCLC.

Method: A total of 782 specimens of NSCLC patients who underwent surgical resection of primary lung cancer between 2010 and 2019 at Osaka Metropolitan University Hospital was enrolled in this study. Immunohistochemical staining of IGF1R were performed, and the correlation between IGF1R expression and clinicopathological features of NSCLC, especially in recurrence free survival (RFS) and overall survival (OS), was evaluated. We also evaluated an association between IGF1R and programmed death ligand 1 (PD-L1) expression.

Results: IGF1R expression was positive in 279 (35.8%) patients. IGF1R-positive group had significantly longer smoking histories (median smoking index, 1,000 vs 600, p <0.01) and a higher proportion of squamous cell carcinomas (35.1% vs 14.1 %, p <0.01). IGF1R-positive group also significantly expressed PD-L1 (24.4% vs 6.4%, p<0.01). IGF1R-positive group had significantly worse RFS (10-year recurrence-free rate; 42.7% vs 53.7%, p <0.01) and OS (10-year survival rate; 54.4% vs 67.3%, p <0.01). RFS and OS were significantly worse in the IGF1R-positive NSCLC patients at stage 0 and stage I (10-year recurrence-free rate; 49.0% vs 62.9%, p <0.01, 10-year survival rate; 57.4% vs 74.2%, p<0.01), but not in stage II (10-year recurrence-free rate; 52.0% vs 43.8%, p=0.68, 10-year survival rate; 63.4% vs 47.5%, p=0.95) and III (10-year recurrence-free rate; 20.7% vs 20.8%, p=0.77, 10-year survival rate; 38.3% vs 54.6%, p=0.18). IGF1R expression was associated with poorer RFS and OS in early-stage NSCLC.

Conclusion: IGF1R is a predictor of poor prognosis in resected early-stage NSCLC.

#3636 Myeloid cell rebound associated with GD2-CAR-T cell therapy in solid tumor patients.

Michael P. Brown[1], Tessa Gargett[2], Nga T. H. Truong[2], Orazio Vittorio[3], David S. Ziegler[4]

[1]Cancer Clinical Trials Unit, Royal Adelaide Hospital, Adelaide, Australia,[2]Translational Oncology Laboratory, Centre for Cancer Biology, Adelaide, Australia,[3]School of Biomedical Sciences, University of NSW, Sydney, Australia,[4]Kids Cancer Centre, Sydney Children's Hospital, Sydney, Australia

GD2 is a validated cancer immunotherapy target with highly restricted normal tissue expression. Promising activity of GD2-CAR-T cell therapy in diffuse midline glioma and neuroblastoma has promoted interest in this therapy. We initiated three phase 1 clinical trials of escalating doses of intravenously administered autologous GD2-CAR-T cells in patients with advanced GD2-positive solid tumors.

Emerging evidence suggests that CAR-T cells may increase circulating myeloid derived suppressor cells (MDSCs) and that this event may be mediated and/or triggered by CAR-T cell-derived cytokines and chemokines. These findings may help to explain the limited persistence of CAR-T cell therapy in solid tumor patients. Hence, we sought evidence of MDSC generation and secretion of relevant cytokines and chemokines in our clinical trial patients.

The CARPETS trial (www.anzctr.org.au: ACTRN12620000622909) recently closed to recruitment after enrolling 12 patients (7 melanoma, 4 colorectal cancer, and 1 sarcoma). No significant adverse events were attributable to CAR-T cell therapy. We opened two other GD2-CAR-T cell therapy trials in 2023: LEVI'S-CATCH (ACTRN12622000675729) in patients with diffuse midline glioma at Sydney Children's Hospital and KARPOS (ACTRN12622001514796) in adult patients with recurrent glioblastoma at Royal Adelaide Hospital. To date, 3 patients have enrolled to LEVI'S-CATCH with the first patient clearing the dose limiting (DLT) evaluation period. Three patients completed enrolment to the first dose cohort of KARPOS without DLTs.

In all CARPETS patients, CAR-T cell expansion, which was measured by by DNA quantitative PCR and flow cytometry, peaked during the 6-week post-CAR-T infusion DLT evaluation period. In 6 CARPETS patients for whom peripheral blood samples were available, we found by flow cytometry, newly formed or increased size of pre-existing subpopulations of non-classical monocytes and/or MDSCs of mononuclear and/or polymorphonuclear class, which peaked at or after the time of peak CAR-T cell expansion. Typically, serum levels of inflammatory cytokines and chemokines such as TNF, IL-6, IL-8, CCL2, GM-CSF, and CXCL10, were detected only after the CAR-T cell infusion with variable patterns of the timing and concentration of analyte observed among the 12 patients.

At the time of writing, blood samples from the first KARPOS patient showed CAR-T cell expansion and the subsequent increases in circulating myeloid derived suppressor cells and inflammatory cytokines. We expect that full data sets for these parameters will be presented for current and future enrolled patients to both studies.

To improve CAR-T cell persistence in solid tumor patients, these data indicate the need for new therapeutic strategies to mitigate effects of CAR-T cell induced myeloid cells with antitumor activity.

#3637 Ultrasensitive assays for combined detection of CEA$^{\pm}$ extracellular vesicles and soluble CEA.

L. Hebert[1], M. Al-Ameen[1], T. Spriggs[1], C. Nelson[1], E. A. Gizzie[1], J. L. Franklin[2], R. J. Coffey[2], **D. A. Routenberg**[1], J. N. Wohlstadter[1];
[1]Meso Scale Diagnostics, LLC, Rockville, MD, [2]Vanderbilt University, Nashville, TN

Colorectal cancer (CRC) is the third most common cancer worldwide and is the second leading cause of cancer death in the United States. Carcinoembryonic antigen (CEA) is a biomarker commonly used in the management of CRC. It is typically present at low levels in the blood of healthy adults but is elevated in CRC samples and some other cancers. CEA is most commonly used to monitor treatment efficacy and as a critical part of post-treatment surveillance for residual disease, recurrence, and/or progression/metastasis. The CRC recurrence rate averages >25%, and liver metastasis occurs in 25-30% of cases. Improved CEA assays could enable earlier determination of treatment failure, detection of lower levels of minimal residual disease (MRD) after treatment, or earlier detection of recurrence. CEA is a GPI-linked membrane protein secreted from CRC cells mainly by enzymatic cleavage of its GPI anchor. However, we have identified alternative secretion of CEA in association with extracellular vesicles (EVs). We hypothesized that the soluble CEA produced by canonical shedding and the alternatively secreted CEA may provide distinct information about the tumor or its microenvironment and serve as independent but complementary biomarkers of CRC. We developed ultrasensitive, multi-marker electrochemiluminescence (ECL) immunoassays for measuring intact EVs presenting CEA, CD73, or both in human plasma. We observed that plasma levels of CEA$^{\pm}$EVs and CD73$^{\pm}$EVs were elevated in some late-stage CRC samples compared to controls. CEA and CD73 double-positive EV (CEA$^{\pm}$CD73$^{\pm}$EVs) levels were also elevated in the same samples, exhibiting a 3-fold improved separation of these samples with CRC from controls, compared to detection of CEA$^{\pm}$EVs. Additionally, approximately 25% of stage IV CRC samples had elevated CEA$^{\pm}$EV and CEA$^{\pm}$CD73$^{\pm}$EV levels while exhibiting low soluble CEA. We confirmed this result in an independent sample set that included samples across all CRC stages, and also identified a few earlier-stage samples that exhibited high CEA$^{\pm}$EVs and CEA$^{\pm}$CD73$^{\pm}$EVs without elevated soluble CEA. Since CEA$^{\pm}$CD73$^{\pm}$EVs and soluble CEA assays identified different subsets of samples, we combined the two assays into a single classifier for late stage CRC and controls, yielding improved receiver operator characteristic (ROC) with area under the curve (AUC) of 0.975 versus 0.927 for the standard soluble CEA assay or 0.788 for CEA$^{\pm}$CD73$^{\pm}$EVs alone. These results suggest that assaying EVs presenting multiple surface markers can increase specificity for the detection of tumor-derived EVs relative to a single marker and that assaying both soluble and EV-associated forms of CEA in plasma may improve the value of CEA measurement in CRC.

#3638 Pathologic endpoints as surrogates for survival endpoints in neoadjuvant immunotherapy clinical trials for non-small cell lung cancer.

R. B. Cameron[1], J. B. Hines[1], A. Esposito[1], C. Bestvina[1], M. C. Garassino[1], V. Torri[2], R. Thawani[1];
[1]UChicago Medicine, Chicago, IL, [2]Institute Mario Negri, Milan, Italy

Background: The use of neoadjuvant immunotherapy alone or in combination has rapidly evolved in the last 5 years. There is significant debate as to whether pathologic complete response (pCR) or major pathologic response (MPR) can be considered a surrogate endpoint for survival. We therefore performed a systematic review and meta-analysis to evaluate the surrogacy of pCR and MPR for event free survival (EFS) in neoadjuvant clinical trials for early-stage NSCLC.

Methods: We performed a systematic literature search on PubMed and reviewed abstracts of the most relevant international conferences until June 2023. Relevant information relative to response rates, Odds Ratios (ORs) of response, 2-years EFS rates and Hazard ratios (HRs) were retrieved from all eligible clinical trials and the association were analyzed. To evaluate patients level surrogacy the association between response rate and 2-year EFS was evaluated. In trials presenting EFS rates by achievement of pCR and MPR a forest plot with random effect model was also produced. For trial level surrogacy, ORs for pCR and MPR and HRs for EFS were retrieved and analyzed using a linear regression model weighted by sample size. R^2 and linear regression slope were used respectively to estimate the proportion of variation in EFS effect explained by pCR effect and the magnitude of change in EFS effect as a function of the magnitude of change in pCR effect. The R^2 with 95% CI were calculated by bootstrapping approach.

Results: Seven RCTs were identified for a total of 2940 patients. At patient level, the R^2 of pCR and MPR with 2-years EFS were 0.82 (0.66-0.94) and 0.81 (0.63-0.93), respectively, with slopes of 0.96 (0.68-1.19) and 0.64 (0.45-0.85), respectively. At trial level, R^2 for association of OR for response and HR for EFS was 0.58 (0.00-0.97) and 0.61 (0.00-0.97) for pCR and MPR, respectively.

Conclusions: While we were able to show a strong correlation between pCR and EFS, trial level surrogacy was not proven. The lack of surrogacy can be related to the high heterogeneity among clinical trials and the still scarce number of data available. More research to reduce the heterogeneity (e.g., pathological evaluation, surgery, and staging harmonization) must be done to introduce pCR as a primary measure to predict EFS.

#3639 *ARID1* mutations may serve as a predictor of MSI and TMB levels in gastric cancer.

C. Xu[1], B. Lian[1], Y. Dai[1], W. Duan[2], F. Zhao[2], **M. Li**[1];
[1]Department of Gastrointestinal Surgery, Xijing Hospital, Air Force Medical University, Xi'an, China, [2]3D Medicines Inc., Shanghai, China, Xi'an, China

Background: *ARID1A* is a gene that produces a protein called BAF250a, which is a component of the chromatin remodeling complex. This complex plays a critical role in regulating gene expression by altering the structure of chromatin. *ARID1A* mutations and MSI-H are mutually exclusive in endometrial cancer, but not in ovarian cancer. *ARID1A* mutations are associated with high TMB in certain types of cancer, such as endometrial and gastric cancer. The relationship between *ARID1B* mutations and MSI-H/TMB is complex, and this study aims to clarify it in gastric cancer.
Methods: The formalin-fixed paraffin-embedded (FFPE) tissues 337 patients with gastric cancer who have underwent next-generation sequencing (NGS) include 733 genes from Nov, 2019 to Mar, 2023 in 3DMed Clinical Laboratory Inc. were investigated in this study. These patients are still being followed up.
Result: In this study, 337 patients with gastric cancer were analyzed for *ARID1A* and *ARID1B* mutations, MSI-H status, and TMB levels. The results showed that 17.8% of the patients had *ARID1A* mutations, 8.9% had *ARID1B* mutations, and 3.6% had both mutations. Additionally, 7.7% of the all patients had MSI-H. The study found that patients with *ARID1* mutations had significantly higher rates of MSI-H compared to unselected patients. Specifically, 35% of patients with *ARID1A* mutations, 30% with *ARID1B* mutations, and 75% with both mutations had MSI-H, compared to 7.7% in unselected patients. Furthermore, TMB levels were higher in patients with *ARID1A* or *ARID1B* mutations compared to wild-type and unselected patients ($p<0.0001$). There was no significant difference observed between patients with *ARID1A* and *ARID1B* mutation subgroups in terms of TMB levels ($p = 0.3515$). However, TMB levels were lower in patients with *ARID1A* or *ARID1B* mutations compared to patients with both mutations ($p = 0.0036$, $p = 0.0104$). These findings suggest that *ARID1* mutations may cause genomic and chromosomal instability in gastric cancer, leading to higher rates of MSI-H and TMB.
Conclusion: The study highlights the potential clinical significance of *ARID1* mutations as a biomarker for predicting MSI-H and TMB levels in gastric cancer, which could help guide personalized treatment strategies for patients with this disease. However, further research is needed to confirm these findings and to determine the clinical implications of *ARID1* mutations in gastric cancer.

#3640 RAB26 accelerates endometrial cancer cell progression by regulating the Hedgehog signaling pathway.

C. Gao[1], Y. Liu[1], Y. Han[2], F. Xue[1], Y. Wang[1];

[1]Tianjin Medical Univeristy General Hospital, Tianjin, China, [2]First Teaching Hospital of Tianjin University of Traditional Chinese Medicine, Tianjin, China

As one of the most common gynecological malignant tumors, endometrial cancer (EC) is continuously being studied since its etiology is still not clear. RAB26, a member of the RAB family, has been shown to influence cell proliferation, metastasis and other malignant phenotypes in several cancers. However, whether and how RAB26 plays roles in EC remain unknown. Our previous study showed that RAB26 was related to the cell cycle-associated protein IK, which has been shown to contribute to carcinogenesis. Herein, we further explored the clinical significance and biological function of RAB26 in EC. Immunohistochemical staining of 615 endometrial tissue samples was conducted to explore whether RAB26 expression was related to the clinicopathological characteristics of EC. In vitro and in vivo experiments were used to evaluate the role of RAB26 in EC and investigate the underlying mechanism. RAB26 expression was higher in EC than in normal endometrium (NE), hyperplastic endometrium (HE) and atypical hyperplastic endometrium (AHE). High RAB26 expression was positively correlated with tumor histological grade (P=0.010), FIGO stage (P=0.042) and tumor size (P=0.003) in EC. RAB26 attenuation inhibited cell proliferation and metastasis but promoted cell apoptosis and caused G0/G1 arrest. After RAB26 attenuation, RNA sequencing data showed that the Hedgehog signaling (SHH) pathway was enriched. Further western blot results confirmed that the levels of SHH pathway proteins (SHH, PTCH1, smo and Gli1) decreased as RAB26 expression was attenuated. Moreover, an agonist of the SHH pathway, purmorphamine, blocked the inhibitory effect of RAB26 attenuation on EC progression. The results of an in vivo study also showed that RAB26 attenuation exerted a significant antitumor effect. Accordingly, RAB26 may act as an oncogenic protein to promote EC progression through the SHH pathway. RAB26 may be a potential target for the treatment of EC patients.

#3641 Pharmacodynamic and predictive biomarker results from the phase I dose escalation study of NGM707, an ILT2/ILT4 dual antagonist antibody, in patients with advanced solid tumors.

L. K. Blum, H.-I. H. Chen, A. De Costa, A. Iyer, G. W. Stone, N. D. Galicia, J. Chan, B. Dampier, K. Wu, U. Jeffry, K. Zhou, J. Sloan-Lancaster, D. Abhayankar, V. Hanes, H. D. Lieu, D. D. Kaplan, J. M. Roda;
NGM Biopharmaceuticals, Inc., South San Francisco, CA

Background: NGM707 is a dual antagonist antibody that binds a shared epitope of the immune inhibitory receptors ILT2 (LILRB1) and ILT4 (LILRB2). In preclinical studies, NGM707 reprogrammed suppressive myeloid cells via blockade of ILT2/ILT4 and enhanced NK and CD8+ T cell activity via blockade of ILT2; furthermore, NGM707 and pembrolizumab acted additively in vitro to enhance CD4+ T cell activation in mixed lymphocyte reactions. NGM707-IO-101 (NCT04913337) is a first-in-human Phase 1/2 clinical trial of NGM707 monotherapy and combination with pembrolizumab. Here we report pharmacodynamic and predictive biomarker data from NGM707-IO-101 monotherapy and combination dose escalation cohorts.
Methods: Eligible patients with advanced or metastatic solid tumors were enrolled into escalating dose cohorts from 6 to 1800 mg NGM707, alone or in combination with 200 mg pembrolizumab, administered Q3W iv. Biomarker assessments of tumors comprised RNA-sequencing and immunohistochemistry (including ILT2, ILT4, CD163) of archival/baseline (N= 41 IHC, 47 RNA) and paired on-treatment tumor biopsies (N=13 IHC, 21 RNA). Peripheral blood biomarker samples were collected on days 1, 4, 8, and 15 of cycle 1 and prior to dosing at each subsequent cycle. Blood biomarker assessments included circulating cytokines/chemokines, PBMC RNA-sequencing, and flow cytometry immunophenotyping. Baseline biomarkers were associated with anti-tumor activity per RECIST v1.1.
Results: Pre-treatment biopsies from patients with disease control (DC) showed higher expression of genes in the 18-gene tumor inflammation signature (TIS) than patients with progressive disease (PD). A composite gene signature incorporating gene sets related to TIS, NK cell activity, and tumor cell proliferation had a statistically stronger association with DC than TIS genes alone. Baseline ILT2/ILT4 target expression (≥1% of tumor area) was observed in 31 (75.6%) patients, with similar levels observed in patients with DC and PD. Pharmacodynamic changes were observed in tumor samples following treatment, including increased expression of gene signatures that reflect myeloid cell activation and a proinflammatory tumor microenvironment. Decreased protein expression of the immunosuppressive myeloid marker CD163 was observed following treatment in both blood and tumor for a subset of patients. Proinflammatory chemokines including CXCL9 increased in serum following treatment.
Conclusion: Baseline gene expression signatures have shown an encouraging association with clinical benefit from NGM707 and merit further investigation as promising predictive biomarkers. Protein and gene expression changes reflecting the expected modes of action of NGM707 and pembrolizumab were observed in both peripheral blood and tumor biopsies following treatment.

#3642 Phenotypic biomarkers of aqueous humor extracellular vesicles from retinoblastoma eyes.

A. Amacker[1], C.-C. Peng[2], B. J. Reiser[2], J. L. Berry[2], L. Xu[2];
[1]Keck School of Medicine of USC, Los Angeles, CA, [2]Children's Hospital Los Angeles, Los Angeles, CA

Purpose: Retinoblastoma (RB) is the most common pediatric intraocular cancer, yet tumor biopsies are contraindicated. This challenge emphasizes the need for investigation of non-tissue biomarkers. Extracellular vesicles (EVs), which are secretory vesicles containing bioactive molecules, have emerged as promising biomarker candidates due to their ability to be phenotyped using known tetraspanin markers. Aqueous humor (AH) provides an exciting liquid biopsy source for intraocular tumor information, with EVs having recently been identified in AH. Our laboratory has previously proposed that CD63/81+EVs are associated with retinoblastoma, but specific tumor-derived markers have not been linked to AH EVs using traditional tetraspanin assays. In this study, we employed MACSPlex, a high-dimensional magnetic bead-based immunoassay, to further explore RB-EV.
Methods: 7 AH samples consisting of two congenital glaucoma (GLC) samples and five RB samples taken at the time of primary enucleation were analyzed. We utilized Macsplex, a multiplex bead-based flow cytometry assay, to analyze the expression profiles of surface markers found on EVs. With 39 capture beads coated with monoclonal antibodies for 37 different EV surface antigens and two negative controls, the mean fluorescence intensity (MFI) of APC conjugated antibody cocktail from three tetrapanins (CD9, CD63 and CD81) on EVs captured by each surface antigen could be measured by flow cytometry. Enrichment ratios were then calculated by normalizing the fluorescence of each signal to the mean fluorescence of CD9, CD63, and C81.
Results: Macsplex analysis of the 2 GLC AH samples demonstrated a strong CD63 dominance compared with RB AH. The mean CD63 enrichment ratio for GLC samples was 2.6 (S.D. = 0.34), and 1.3 (S.D. = 0.27) in RB samples, with a p-value of 0.069. In comparison to the GLC patients, the analysis of EVs in the AH of the 5 RB samples exhibited a greater co-dominance of CD63/CD81 positivity consistent with past research on RB EVs. The mean CD81 enrichment ratio for the 5 RB samples was 1.5 (S.D. = 0.26), in contrast to 0.3 (S.D. = 0.24) in GLC AH, with a p-value of 0.03. Interestingly, 4 out of the 5 RB AH samples demonstrated very strong CD133 signals, which is a known cancer marker. Deeper investigation into one RB AH sample utilizing single tetraspanin detection revealed higher coexpression of CD63 and CD81 with CD133 than seen with CD9. The CD133 enrichment ratio for the CD81, CD63, and CD9 single channel experiments were 6.6, 3.4, and 1.5 respectively.
Conclusions: Comparison between this study and previous work done by our group demonstrate a high concordance between results utilizing Macsplex and Exoview**.** However, this is the first study identifying the expression of CD133, a cancer stem cell marker, on retinoblastoma-derived EVs in AH. Macsplex technology illustrates an incredible clinical potential of AH EVs for characterizing retinoblastoma phenotype *in vivo.*

#3643 Molecular pathogenesis of lung cancer associated with interstitial pneumonia.

D. Mizuno[1], K. Shien[2], A. Matsuoka[1], M. Ohki[1], S. Tomida[3], R. Yoshichika[1], T. Higashihara[1], F. Mukohara[1], N. Hayashi[1], T. Habu[1], M. Yoshikawa[1], K. Suzawa[2], H. Yamamoto[2], D. Ennishi[3], S. Toyooka[1];

[1]Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan, [2]Okayama University Hospital, Okayama, Japan, [3]Okayama University Hospital, Center for Comprehensive Genomic Medicine, Okayama, Japan

Background: Interstitial pneumonia (IP) is known to be associated with a high risk of developing lung cancer. While common mechanisms have been reported to be involved in the pathogenesis of IP and lung cancer, including genetic and epigenomic alterations or specific signaling pathway activations, many of the molecular mechanisms of lung cancer development in IP lesions remain unknown.

Methods: To clarify the detailed mechanisms of the pathogenesis of lung cancer associated with IP, we performed spatially resolved transcriptomics on lung cancer specimens obtained from usual interstitial pneumonia (UIP) associated lung cancer patients. In a total of 10 patients, including five lung cancers that developed inside the UIP and five lung cancers that originated outside the UIP, regions of interest (ROIs) were selected in the tumoral tissues and their adjacent non-tumor tissues. Then, gene expression profiles were comprehensively analyzed by using GeoMx digital spatial profiler in each ROI.

Results: In the UIP lesions adjacent to lung cancer, increased gene expressions associated with pulmonary fibrosis, such as COL1A1, COL3A1, and APOE, were observed, and gene set enrichment analysis (GSEA) revealed that they were associated with autoimmunity-related pathways. When we compared the tumor lesions developed inside the UIP with outside the UIP, increased gene expressions related to IP mortality were observed in the tumor cells developed inside the UIP. Interestingly, GSEA revealed that the gene set for neutrophil extracellular trap (NETs) formation was found to be upregulated in the tumor cells developed inside the UIP, suggesting that NETs plays an important role in the pathogenesis of lung cancer developed in IP lesion.

Conclusions: In our study, spatially resolved transcriptomics revealed a novel pathway related to the pathogenesis of lung cancer associated with IP.

#3644 Uncover spatial signatures of tumor microenvironment and oncogenic pathways using 6,000-plex single-cell spatial molecular imaging on FFPE skin squamous cell carcinoma.

M. Patrick, **S. He**, S. Ilcisin, D. Kroeppler, P. Danaher, J. Reeves, M. Gregory, H. Zhai, M. Rhodes, J. Beechem;
Nanostring Technologies, Seattle, WA

Background: Tumor progression and therapeutic response are regulated by the tumor microenvironment. Understanding the spatial association and architecture of molecular characteristics and composition of tumor immune microenvironment at single-cell and subcellular resolution encourages improvements in clinical prognosis and immunotherapy benefits. Single-cell Spatial profiling technologies permit the study of transcriptional activity at the spatial, single-cell level and provide abundant, high-resolution information required for the identification of clinical-related features in immuno-oncology.
Methods: We performed an ultra-high-plex RNA assay to detect 6,000 targets simultaneously *in situ* on FFPE human skin squamous cell carcinoma using the CosMx™ Spatial Molecular Imager (SMI). For the selection of regions of interest, four protein markers and DAPI were co-detected on the same tissue slide. Tertiary analysis algorithms were developed for cell typing, co-localization of genes and ligands, cell-cell interaction, and pathway analysis.
Results: Thousands of transcripts were simultaneously detected with high sensitivity and specificity on the FFPE skin squamous cell carcinoma tissue section at single-cell subcellular resolution. We investigated the tumor microenvironment including cell types, their spatial distribution and proportion of diversified immune cells in the tumor compartment. The cell typing results revealed many cancerous subpopulations, which resolved spatially from cells that lacked any defining marker genes. We also assessed distances between immune cells and their nearest functional-related neighbors. Moreover, we revealed the ligands co-localization, as well as spatial patterns of direct cell-cell interactions and signaling pathways. We found that some genes have elevated expression in macrophages which are near cancer compared to those are far from cancer cells, empowering the molecular investigation of novel signaling between immune and cancer cells in tumor immune microenvironment.
Conclusions: Single-cell spatial measurements of 6,000 RNA and four proteins on the same tissue section, along with a large viewing area on archival FFPE tissue, provide a novel tool to reveal the spatial signature of tumor microenvironment and oncogenic pathways, facilitating the next level of cancer and therapeutic research. FOR RESEARCH USE ONLY. Not for use in diagnostic procedures. FOR RESEARCH USE ONLY. Not for use in diagnostic procedures.

#3645 Unraveling spatial complexity of the tumor microenvironment: A whole transcriptomic perspective with Visium HD.

Y. Yin, J. Sapida, D. Sukovich, D. Patterson, A. Tentori;
10x Genomics, Pleasanton, CA

In recent years, advances in spatial transcriptomics have revolutionized our understanding of the tumor microenvironment, providing crucial insights into the complex interplay of different cell types within cancer tissues. In this study, we employed the new, high definition Visium spatial transcriptomics assay (Visium HD) to investigate the intricate molecular landscape of prostate cancer at single-cell scale resolution and across the whole transcriptome. Our research focused on deciphering the spatial heterogeneity of gene expression patterns within the tumor microenvironment, shedding light on the interactions between cancer cells, stromal cells, and vasculature.

The Visium HD assay enables an unbiased exploration of the transcriptome on FFPE tissue sections mounted on standard glass slides. Combining gene expression data with H&E images from the same section, it allows precise characterization of local molecular features and disease states at single-cell scale. We analyzed a set of human prostate adenocarcinoma samples with the Visium HD assay, and identified spatially regulated gene signatures associated with specific cell types and functional pathways. Our findings have recapitulated previously identified molecular markers, including VEGFA and MYC which have been implicated in tumor progression and angiogenesis. The spatial gene expression patterns had good correlation with histological annotations of cancerous and normal tissue within the H&E image. However, Visium HD allowed us to further observe molecular processes and pathways specific to this adenocarcinoma sample. This integrative approach offers valuable implications for personalized cancer therapy and the development of targeted interventions tailored to the spatial context of individual tumors.

Our study underscores the significance of understanding the spatial organization of the whole transcriptome in cancer tissues, and highlights the potential of the Visium HD platform as a powerful tool for unraveling the complexities of the tumor microenvironment. These insights pave the way for the development of innovative therapeutic strategies and precision medicine approaches, ultimately contributing to improved outcomes for cancer patients.

#3646 A spatially resolved single cell proteomic atlas of small bowel adenocarcinoma.

Z. Dereli, B. Bozorgui, H. Wang, J. Weinstein, M. Overman, **A. Korkut**;
UT MD Anderson Cancer Center, Houston, TX

Small bowel adenocarcinoma (SBA) is a rare malignancy associated with poor prognosis. The cellular and proteomic heterogeneity within the tumor immune microenvironment (TIME) of SBA is a likely driver of prognosis, disease progression and response to therapy. There is, however, a major gap in our knowledge of tumor and immune interactions in SBA. Cyclic Immunofluorescence (CycIF), an antibody-based, highly multiplexed imaging technology for spatially resolved single cell level proteomic profiling, is well suited to map the proteomic heterogeneity and organization of TIME in SBA. Here, using CycIF, we have generated a spatially resolved single-cell proteomic atlas of TIME for 136 tumor and normal samples from clinically and genomically annotated SBA patients (N=37). The SBA TIME Atlas covers information on expression levels, spatial position, and cell morphology for > 40 proteomic markers of tumor-intrinsic processes and states, diverse immune cell types, immune checkpoints, and tumor vascularization. In total, we collected proteomics data from > 600,000 cells. Using a hierarchical decision tree of cell type markers, we have generated the cell identity annotations for > 350,000 cells, with positional information. A comprehensive computational analysis of the SBA atlas revealed various spatial and heterogeneity features that may impact the TIME organization in fine detail. Using those features, we have compared the proteomic heterogeneity in tumor vs. normal cell populations, identifying spatial and single-cell correlates of key clinical variables (e.g., patient survival, age, sex, disease stage, metastatic status). We have also performed differential analyses of spatial features involving protein markers and cell types with respect to genomic alteration states and have mapped the spatial enrichment of likely actionable immune check proteins to immune and tumor cells. Such mapping may guide future therapeutic decisions. Overall, we expect that the SBA TIME Atlas will provide a useful resource and inform future translational studies, as well as basic research for better mechanistic understanding and treatment of this disease.

#3647 Digital spatial transcriptomic reveals different epithelial and immune cells signatures across endometriosis-related diseases: From simple ovarian endometriosis to ovarian cancer.

V. Iacobelli, C. Nero, S. Alivernini, G. Scaglione, F. Camarda, F. Sillano, R. Trozzi, A. Piermattei, B. Tolusso, G. Mantini, L. Giaco, G. Anderson, G. Zannoni, E. Gremese, A. Fagotti, G. Scambia;
A. Gemelli University Hospital, University of the Sacred Heart, Rome, Italy

Endometriosis represents a pressing medical concern, imposing a relevant burden on patients including potential malignant transformation into endometriosis-associated ovarian cancer (EAOC). Despite the process of cancer development remains unclear, immune cells abnormalities arose as putative biomarkers in the neoplastic progression. One-third of ovarian endometriosis cases exhibit PD-1/PD-L1 expression levels comparable to those observed in cancer. To substantiate the biological basis of these findings, this study aimed to elucidate the spatial transcriptomic profile of epithelial and immune components from different endometriosis-related conditions, along with their genetic interplay. Formalin-fixed paraffine embedded (FFPE) specimens from 4 ovarian endometriosis (OE) cases, two of which displayed elevated levels of PD-1/PD-L1 expression and were referred to as cancer-like endometriosis (CLE), 1 Clear Cell Ovarian Cancer (CCOC) and 1 Endometrioid Ovarian Cancer (EOC) were cut in 5um section for spatial transcriptomic analysis using GeoMX Human Whole Transcriptome Atlas (WTA) probe-set (>18000 genes). For all sections, the regions of interest (ROIs) were identified using a set of morphology markers: anti-human CD3, CD68 and PanCK antibodies. Spatial transcriptomic analysis revealed condition-specific gene enrichment of epithelial and immune cells across the different conditions. In spite of similar H&E findings, $PanCK^{pos}$ epithelial cells from CLE showed an increased expression of genes involved in stress response and defense regulation pathways (e.g. CXCL6, S100A9, and PECAM-1), when compared to OE, in which $PanCK^{pos}$ cells were enriched in DUSP1/2 and VIM. Interestingly, in CCOC, location-specific gene-enrichment was found in $PanCK^{pos}$ cells, with a significant up regulation of tumor suppressor genes (e.g. EGR-1, NR4A1) in normal-looking peri-tumoral epithelium compared to cancerous intra-tumoral $PanCK^{pos}$ cells. Similarly, in the immune compartment, spatial transcriptomic analysis revealed that $CD3^{pos}$ cells from CLE displayed an up-regulation of genes involved in IL-17 signaling, response to oxydative stress and complement activation (e.g. CXCL6, HMOX1, S100A9, and PECAM-1), when compared to OE. Moreover, in CCOC, $CD68^{pos}$ cells of the tumoral mass showed over-expression of tumor growth and progression markers (e.g. SPP1) compared to their counterpart in the outer area of the tumoral mass. In this first comprehensive spatial transcriptomic study of endometriosis-related diseases with GeoMx WTA, our findings uncovered remarkable differences in epithelial and immune cells among different stages and tissue locations. Importantly, CLE emerged as a transitional entity with a unique immune profile. Ongoing analysis of six additional samples will further refine our results.

#3648 The spatial organization of cells expressing MYC and BCL2 affects immune microenvironment composition and prognosis in DLBCL.

S. Shridar[1], M. M. Hoppe[1], P. Jaynes[1], G. Kumar[2], S. Jasoria[3], Z. Meng[1], V. Rajan[1], K. Kannan[2], C. Tripodo[4], **A. D. Jeyasekharan**[1];
[1]National University of Singapore (NUS), Singapore, Singapore, [2]The University of Texas MD Anderson Cancer Center, Houston, TX, [3]Birla Institute of Technology & Science, Pilani, Pilani, India, [4]University of Palermo, Palermo, Italy

Point process analyses are widely used in ecology and geography to understand the impact and relevance of spatial distribution of points in a complex system. To date, only few studies have explored point process analyses in the context of tumor heterogeneity. Malignancies often show variable patterns of cellular distribution, and the relationship of these topographic variables with underlying biological processes and clinical outcomes is not well understood. Here, we performed spatial point process analyses in diffuse large B-cell lymphoma (DLBCL), leveraging advances in multiplexed immunohistochemistry and cellular phenotyping, with downstream multi-omic and clinicopathological analyses.

We have demonstrated that survival in DLBCL is strongly associated with the fraction of malignant cells showing co-expression of the oncogenes MYC and BCL2 in the absence of BCL6 (M+2+6-). These cells display non-random spatial organization within tumor infiltrates, deviating from a poisson distribution. We therefore modeled the spatial organization of M+2+6- cells within DLBCL, using x-y coordinate information from multiplexed fluorescent immunohistochemistry (mfIHC) in four independent cohorts (N=449 patients). We derived spatial point patterns, upon which Geyers point process models were applied. We observed that patients could be divided into two groups based on these: one group showed “clustered” spatial organization, while the other displayed a “dispersed” M+2+6- cell distribution. Cases with predominantly “dispersed” M+2+6- cells showed shorter overall survival in all analyzed cohorts ($P < 0.05$ in 4/4 cohorts).

We performed multi-omic analyses to identify potential biological explanations for this association between topography and clinical outcome. Using digital spatial profiling of the transcriptome from CD20, CD3 and CD68 compartments in 47 DLBCL samples, we observed that lymphomas with an M+2+6- ‘dispersed’ phenotype had an immunologically cold microenvironment enriched in Tregs and exhausted CD4+ and CD8+ T cells. Through an integration with single-cell transcriptomic analyses (N=22 samples) we observed that malignant B-cells from cases with M+2+6- ‘dispersed’ phenotype expressed genes implicated in cell migration and adhesion, but also in potentially targetable immune checkpoints such as LAG3.

In summary, by integrating multiplexed immunophenotyping and point process analysis with molecular profiling in the setting of DLBCL, we show that a dispersed pattern of distribution of the M+2+6- subclonal fraction uniquely confers poor prognosis, and associates with a potentially reversible immune cold microenvironment composition. This represents the first demonstration that the spatial distribution of malignant cell subpopulations in lymphoma can embody biological and clinical significance.

#3649 A novel spatial multi-omic approach for biological discoveries in colonic diseased tissues using a comprehensive Immuno-Oncology Proteome Atlas and Whole Transcriptome Atlas.

A. Rosenbloom[1], S. Bonnett[1], M. Conner[1], C. Kang[1], E. Piazza[1], B. Filanoski[1], R. Meredith[1], H. Yi[1], L. Hamanishi[1], E. Ignacio[1], N. Nelson[2], M. Prater[2], V. Devgan[1], R. Van Eijsden[1], M. Moon[1], L. Isgur[1], T. Theisen[1], M. Hoang[1], G. Geiss[1], J. M. Beechem[1];

[1]NanoString Technologies, Inc., Seattle, WA, [2]Abcam plc, Cambridge, United Kingdom

The advancement of spatially resolved, multiplex proteomic and transcriptomic technologies has revolutionized and redefined the approaches to complex biological questions pertaining to tissue heterogeneity, tumor microenvironments, cellular interactions, cellular diversity, and therapeutic response. While spatial transcriptomics has traditionally led the way in plex, multiple studies have demonstrated a poor correlation between RNA expression and protein abundance, owing to transcriptional and translational regulation, target turnover, and most critically, post-translational protein modifications. Therefore, a more holistic, ultra-high-plex, and high-throughput proteomic atlas approach becomes critical for the next phase of discovery biology. Here, we present a barrier-breaking, spatial proteomics panel that was designed to accelerate scientific discoveries. A Digital Spatial Profiler platform is uniquely suited to support high-plex proteomics, allowing for the simultaneous analyses of proteins from discrete regions of interest (ROIs) in FFPE tissue sections while preserving spatial context. The assay relies upon abcam antibodies coupled to photocleavable DNA barcodes readout with NGS sequencing, allowing for theoretically unlimited plex. Here we introduce the Human Immuno-Oncology Proteome Atlas (IPA), a 570+ antibody-based proteomic discovery panel, compatible with immunohistochemistry on FFPE tissues with NGS readout. IPA is the highest-plex, most comprehensive, antibody-based multi-omic panel to date focusing on key areas of immuno-oncology, oncology, immunology, epigenetics, metabolism, cell death, and signaling pathway regulation. Here we demonstrate the performance of IPA on various cell lines and tissue. Additionally, we show the power of IPA, using the spatial multi-omic assay along with the GeoMx® Whole Transcriptome Atlas (> 18,000 transcripts), a 40-plex custom antibody panel and microbiome-curated RNA custom spike-in (~220 transcripts) to evaluate 70 different colon disease samples across 5 pathologies including adenocarcinoma, hyperplasia, and chronic inflammation. This is the highest-plex multi-omic (~610-plex proteins and >18,220 genes) study ever implemented for spatial biology. When we compared the diseased tissue to normal tissue, we observed an upregulation of specific pathways associated with tumorigenesis and inflammation. Furthermore, we observed distinct differences in proteomic and transcriptomic landscape between pathologies. The cutting-edge, data-driven, expert-curated IPA panel is at the forefront of spatial proteomics, empowering the researcher for the acceleration of biological discoveries. FOR RESEARCH USE ONLY. Not for use in diagnostic procedures.

#3650 Deep learning-based image cytometry and co-localization index in tumor immune microenvironment.

Tomoki Abe[1], Kimihiro Yamashita[1], Toru Nagasaka[2], Tomosuke Mukoyama[1], Souichirou Miyake[3], Yasuhiro Ueda[3], Masayuki Ando[1], Yuki Okazoe[3], Takao Tsuneki[1], Yukari Adachi[1], Ryunosuke Konaka[3], Ryuichiro Sawada[1], Hironobu Goto[1], Hiroshi Hasegawa[1], Shingo Kanaji[1], Takeru Matsuda[1], Takumi Fukumoto[3], Yoshihiro Kakeji[1]

[1]Division of Gastrointestinal Surgery, Kobe University Graduate School of Medicine, Kobe, Japan,[2]Association of Medical Artificial Intelligence Curation, Nagoya, Japan,[3]Division of Hepato-Biliary and Pancreatic Surgery, Kobe University Graduate School of Medicine, Kobe, Japan

Background: In pathology, digitizing tissue slides has prompted a remarkable development in image analysis using deep learning. This technological advancement is anticipated to aid in pathological diagnosis and to enhance patient management. Deep learning-based image cytometry (DL-IC) enables accurate cell identification and counting and the acquisition of vast amounts of location information from tissue slides. DL-IC can capture information about the diverse and complex tumor immune microenvironment(TIME) and its constituent cells and help identify biomarkers to predict patient treatment efficacy and prognosis. This study will introduce a spatial interaction map and co-localization index (CLI) for the analysis of TIME using DL-IC.

Materials and Methods: Cu-Cyto, a deep learning-based image analysis technology, was used in this study; bit-pattern kernel filtering technology, which can accurately count cells while avoiding the determination of multiple cell counts, was used by Cu-Cyto (Abe T, et al. Anticancer Res. 43:3755, 2023). First, the accuracy of cell counting using Cu-Cyto was evaluated. Second, tumor tissue slides with immunohistochemical (IHC) and hematoxylin-eosin (H&E) staining were prepared from surgical specimens of patients with rectal cancer who had undergone neoadjuvant chemoradiotherapy (NACRT), and the relationship between the co-localization index (CLI) of cancer cells and $CD8^{\pm}$T cells and prognosis was investigated. CLI was defined to predict cell- cell interactions on the basis of the relative distances between different cell types (Nagasaka T. PCT/JP 2021/021455).

Results: The performances of three versions of Cu-Cyto were evaluated according to their learning stages. In the early stage of learning, the F1 score for immunostained $CD8^{\pm}$ T cells (0.343) was higher than that for non-immunostained cells (adenocarcinoma cells [0.040] and lymphocytes [0.002]). In the latest stage of learning, the F1 scores for adenocarcinoma cells, lymphocytes, and $CD8^{\pm}$ T cells were 0.589, 0.889, and 0.911, respectively. Next, we examined the correlation of CLI between cancer cells and $CD8^{\pm}$ T cells with prognosis: patients with a higher CLI significantly prolonged five-year disease-free survival (P=0.038), while there was no substantial difference in five-year overall survival (P=0.57).

Conclusion]: Cu-Cyto performed well in cell determination. In particular, IHC was able to increase the learning efficiencies in the early stages of learning. The CLI calculated using Cu-Cyto ts an objective, reproducible, and innovative quantitative approach for assessing cell-cell interactions, which has been shown to be associated with recurrence-free survival in patients with rectal cancer after NACRT. Its performance is expected to improve even further with continuous learning, and the DL-IC can contribute to the implementation of precision oncology.

#3651 Mutational analysis and spatial phenotyping to decipher racial disparities in pancreatic adenocarcinoma.

D. J. Salas-Escabillas[1], N. Ma[2], B. B. Cheikh[2], A. Pratapa[2], T. Pichardo[3], K. Langley[3], J. Clark[3], N. Steele[3], N. Jhaveri[2], D. Kwon[4], H. C. Crawford[3];
[1]University of Michigan, Ann Arbor, MI, [2]Akoya Biosciences, Inc., Marlborough, MA, [3]Henry Ford Pancreatic Cancer Center, Detroit, MI, [4]Henry Ford Health, Detroit, MI

Background: Pancreatic cancer has a 5-year survival of only 12%. This is due to the lack of effective treatments and virtually no early detection methods. To compound this already poor prognosis, African Americans face a 20% higher incidence and worse mortality compared to non-African American patients. With a substantial portion of the data and tools employed for studying pancreatic cancer failing to adequately represent this demographic we aim to gain more insight into the differences associated with worse outcomes for African Americans with pancreatic cancer. To achieve this, we conducted an in-depth analysis of tumor mutational burden using whole exome sequencing and the cutting-edge PhenoCycler®-Fusion 2.0 spatial biology platform, to uncover disparities in spatial immune and metabolic phenotypes.

Methods: Using an ultrahigh-plex discovery panel of markers encompassing cell lineage, immune checkpoints, tissue architecture, activation, metabolism, proliferation, and stress, we sought to analyze the differences in spatial phenotypes, cellular neighborhoods and functional pathways across the two groups. Additionally, we performed laser capture microdissection on a cohort of patients containing equal numbers of African American and non-African American pancreatic cancer samples. Tumor, stroma, and adjacent normal areas were identified by a board-certified pathologist. These annotations were used to laser capture on 10-micron sections with 7 sections for each patient. We performed whole exome sequencing on these sections and different areas and compared between groups.

Results: Through our investigation using these two technologies, we can find differences in the tumor microenvironment between African Americans and non-African Americans. We can see potential associations in the increased mortality and incidence of this group while also building a foundation of racially diverse data to be used for future studies. Whole exome sequencing has revealed distinct mutational patterns among African American patients, involving common genes that exhibit unique mutation profiles when compared to those previously observed in non-African American patients. Moreover, whole-slide spatial phenotyping reveals the differential tumor-immune landscapes and the key cellular and molecular niches that contribute to tumor progression and prognosis. These findings underscore the imperative need for a more systems biology exploration of the variations within these groups, with the aim of developing more effective and personalized treatment approaches.

#3652 Spatial transcriptomic study of the tumor microenvironment in HNSCC.

C. Schroyer, S. Zhou;
Labcorp, Morrisville, NC

Background: The complex and dynamic nature of the tumor-immune microenvironment (TME) presents challenges for identification of robust and predictive biomarkers in immuno-oncology (IO). Standard multiplex immunohistochemistry (mIHC) or multiplex immuno-fluorescent assays (mIF) allow for the phenotyping on the cellular level but are limited by the number of markers available and the detection systems. Gene expression or next generation sequencing (NGS) platforms provide high-plex bulk data sets about the TME, but the spatial context of the tumor and immune cell interactions is lost. The NanoString GeoMx® Digital Spatial Profiler (DSP) combines spatial context, utilizing fluorescent morphological markers, with molecular profiling capabilities. This combination allows for the quantitative analysis of high-plex analyte abundance which can be traced back to a region of interest within a sample, providing biological inference in the region of interest.

Methods: Formalin-fixed paraffin-embedded (FFPE) specimens from HNSCC patients were cut in 5µm sections for all analyses. Whole section tissue analysis was previously performed utilizing the NanoString nCounter® PanCancer IO 360™ Panel. Tumor inflammation signatures (TIS), an 18-gene signature measuring the adaptive immune response within tumors, was generated for each specimen and categorized each as immune-hot or immune-cold based on predefined parameters. Four specimens were selected based on their TIS score and two sets of cut sections were processed by either Labcorp lab in Morrisville, NC or Nanostring lab in Seattle, WA for precision evaluation, using the GeoMx Human Whole Transcriptome Atlas (WTA) panel (18,000 genes) with the NanoString GeoMx digital spatial profiling technology. The TME regions of interest (ROI) were identified using a set of morphology markers consisting of panCK, CD45 and Syto13; 12 ROIs were selected from each sectioned tumor material. The same ROIs were selected at the two testing sites with matching tissue location and morphology characters.

Results: GeoMx WTA panel provided an unbiased view of 18,000 protein-coding genes at specific TME regions. These counts were successfully mapped to the 12 ROIs on the tissue. A pseudo-TIS score was generated using the same 18 gene signature from the WTA panel for each ROI. The pseudo-TIS scores from ROIs from the four specimens showed consistency with the specimen-wise TIS score, yet variations were observed across different TME/ROI within each specimen. Whole transcriptome expression results showed high correlation between the two testing sites, providing confidence in the reproducibility of the technology. High resolution fluorescent staining images were able to be fed to downstream quantitative digital analysis to generate complementary spatial data.

CLINICAL RESEARCH: Circulating Nucleic Acids 3
Poster Session

#3656 Target enrichment of methylated circulating tumor DNA for colorectal cancer detection.
H.-Y. Huang, R. Vijaya Satya, W.-C. Chan, E. Atolia, J. Babiarz, B. Zimmermann, T. Kawli;
Natera, Inc., Austin, TX

Aberrant DNA methylation changes are one of the earliest signatures of cancer development. Methylation profiling of circulating tumor DNA (ctDNA) from plasma has emerged as a promising approach for early cancer detection (ECD). However, the set of methylation targets that can successfully distinguish cancer through liquid biopsy will vary depending on cancer type and subtype. Here, we explored a methylation target enrichment workflow and developed a methylation-based classification model to distinguish between patients with colorectal cancer (CRC) and healthy individuals. First, CRC-specific CpG targets were identified by comparing the methylation landscape of CRC and normal samples (tissue and blood) available in The Cancer Genome Atlas (TCGA) database and Gene Expression Omnibus (GEO) datasets. This analysis resulted in >800 CRC-specific CpG targets for initial evaluation. To develop and test the classification model, CRC patients and healthy individuals with plasma samples were included. A machine learning model was used to evaluate the highest performing CpG targets that effectively discriminated between CRC patients with detected ctDNA ("CRC ctDNA-positive") and healthy individuals. Correlation between methylation levels of the high performing CpG targets and the variant allele frequency (VAF) among CRC ctDNA-positive patients was calculated. In total, 86 patients were included in this proof of concept study (mean age, 62 ±12 years; male, 55%). 50 CRC ctDNA-positive patients (24% stage I, 40% stage II, 24% stage III, and 12% stage IV) and 36 healthy normals were included in the analysis. We investigated this cohort to identify the highest performing CpG targets among the >800 potential CpG targets that provided effective discrimination between CRC patients and healthy individuals. Using the highest performing CpG targets, observed methylation level was correlated with VAF of single nucleotide variants detected by ctDNA testing (R^2: 0.8). In summary, we developed a cost-effective methylation target enrichment workflow and utilized machine-learning algorithms to demonstrate the potential use of ctDNA methylation markers in early detection. Additional studies are needed to confirm that these and other markers can accurately distinguish between patients with CRC and healthy individuals.

#3657 Customized liquid biopsy assay for monitoring EWSR1 fusions in sarcomas.

A. Li[1], J. C. Thierauf[1], B. Gonda[1], R. Purohit[1], S. T. Kaluziak[1], E. Codd[1], S. N. Dybel[1], E. Choy[2], G. M. Cote[2], J. K. Lennerz[1], A. Iafrate[1];
[1]Massachusetts General Hospital, Harvard Medical School, Boston, MA, [2]Mass General Cancer Center, Massachusetts General Hospital, Boston, MA

Background: Gene fusions involving EWSR1 are involved in certain rare sarcomas and sarcoma-like tumors such as, for example, Ewing sarcoma, clear cell sarcoma, hyalinizing clear cell carcinoma, and clear cell odontogenic carcinoma. EWSR1-FLI1 fusions are found in Ewing sarcoma, while EWSR1-ATF1 and EWSR1-CREB are characteristic of clear cell sarcoma among others. Liquid biopsies involve obtaining tumor-derived materials through minimally invasive methods such as blood or other body fluid collection. Analysis of cell-free DNA (cfDNA) is an attractive method to identify gene fusions and monitor tumor recurrence and minimal residual disease (MRD). However, the structural complexity of oncogenic rearrangements poses challenges for the detection using plasma assays. We present a novel assay to monitor fusion positive tumor DNA in a busy oncology clinic.

Methods and Patients: Patients with EWSR1 fusion positive sarcomas are identified through clinical RNA-based sequencing. Tumor DNA isolated from biopsy or surgical samples is sequenced to map the intronic breakpoint and customized primers spanning the breakpoint are designed for each patient. The breakpoint is subsequently confirmed through PCR. The product length of ~100bp accounts for the small shedding size of tumor cfDNA. A quantitative TaqMan assay is designed to confirm EWSR1 fusions. The limit of detection is determined by a dilution series of tumor DNA. cfDNA is extracted from blood samples of the patients at multiple timepoints, the tumor burden is quantified by TaqMan Assay and subsequently correlated with clinical findings from imaging studies such as tumor progression or remission.

Results: We consented 10 patients with EWSR1 fusion positive tumors to participate in this study. Plasma samples were collected for 8, resulting in 26 total timepoints. Breakpoints were identified in 9 patients and confirmed with PCR on original tumor DNA. TaqMan assays were designed for 5 patients and showed correlation between the tumor burden detected in EWSR1-ATF1 copies in cfDNA extracted from patient blood and the therapeutic response to treatment found through imaging studies. One patient was followed over the period of 9 months, and a total of 5 plasma timepoints were collected. The patient started with a low number of EWSR1-ATF1 copies of <1ng/ul, while on a lurbinectedin/irinotecan therapy and showed a mixed response in the CT scan. After withdrawing from that therapy and starting other therapy regimens, the EWSR1-ATF1 copies increase to 8ng/ul, correlating with tumor progression observed in CT scans.

Conclusion: Our results suggest that ESWR1 fusions in sarcomas can serve as biomarkers to measure tumor burden. Our approach using an individually tailored cfDNA TaqMan assay could provide a valuable monitoring tool to inform clinicians about tumor progression or MRD. With these proof-of-principle findings we can now determine clinical validity and utility.

#3658 Longitudinal tumor-informed ctDNA monitoring with the originally developed OTS-Assay system.

S. S. Nishizuka[1], H. Hiraki[1], A. Yashima-Abo[1], T. Iwaya[2];

[1]Iwate Medical University Institute for Biomedical Sciences, Yahaba, Japan, [2]Iwate Medical University School of Medicine, Yahaba, Japan

Background: Cancer Genome Profiling (CGP) tests are now widely available in daily practice. However, only a very small fraction of patients have the opportunity for genome-guided therapies. Somatic mutations from cancer specimens are unique to individual patients and hold utility as individual tumor markers in blood. We have developed an original circulating tumor DNA (ctDNA) monitoring system, called OTS (Off-The-Shelf)-Assay, at Iwate Medical University Hospital, Yahaba, Japan.

Patients and Methods: Between April 2022 and October 2023, 79 patients who received the OTS-Assay were enrolled in the present analysis. The OTS-Assay includes three steps: (a) OTS-Scan (somatic mutation identification by either tissue or blood), (b) OTS-Select (somatic mutation selection), and (c) OTS-Monitor (periodical somatic mutation quantification as ctDNA). For the OTS-Select, we established an originally developed >90 stepwise selection algorithm. One of the determinants is the availability of appropriate digital PCR (dPCR) probes for individual patients. Here, we search the probes for individual patients from the dPCR probe library, OTS-1000ex, which consists of >1000 probes against frequently reported human somatic mutations (Quantdetect, Tokyo, Japan).

Results: All 79 patients were subject to the analysis. The cancer stage of all the patients was advanced. More than 10 tumor types were enrolled, including esophagus (n=42), colorectal (n=12), breast (n=7), lung (n=4), pancreas (n=3), hematological (n=3), and others (n=8). Fifty patients received OTS-Scan, and 29 patients had received a CGP test before the OTS-Assay (i.e., OTS-Scan was not needed). Seventy-five patients received OTS-Select, meaning that four patients had somatic mutations that were designated for ctDNA monitoring. All 79 patients received at least one OTS-monitor. The number of OTS-Monitors received ranged from 1 to 11 during the 19-month period, and the average interval was 3.0 months. The average pretreatment variant allele frequency (VAF) was 4.96% and the majority of the follow-up VAF was less than 1%. More than 90% of the patients had at least one clinical validity defined by: (a) early relapse prediction, (b) treatment efficacy evaluation, or (c) no relapse corroboration.

Conclusion: The OTS-Assay system provides stable longitudinal ctDNA monitoring at the range of less than 1% of VAF using the originally developed dPCR probe library. The sensitivity and affordability of the OTS-Assay system allows frequent monitoring, which leads to obtaining important clinical information in the context of advanced cancer therapy.

#3659 Development of customized circulating tumor DNA panel for minimal residual disease detection in biliary tract cancer.

Y. Shinohara[1], S.-K. Low[2], T. Nakamura[1], Y. Kimura[3], T. Murakami[3], K. Kiyotani[2], S. Hirano[1];
[1]Hokkaido University Faculty of Medicine, Sapporo, Japan, [2]Japanese Foundation for Cancer Research, Tokyo, Japan, [3]Sapporo Medical University, Sapporo, Japan

Biliary tract cancer (BTC) is a rare type of abdominal cancer and is more frequent in Asian countries than in Western. The 5-year survival rate for BTC is very low 7 to 20% and only 20% of BTC patients could undergo curative-intent surgery. BTC diagnosis based on biopsy and cytology are low in sensitivity that prompted the necessity to identify alternative biopsy. Liquid biopsy, specifically circulating tumor DNA (ctDNA) is known for the accessibility and low invasiveness received great interest for their potential uses in various clinical applications for patients with insufficient tumor tissue, including mutation profiling, treatment monitoring, and cancer detection. However, the panel available in the market up-to-date focused mainly targeted, actionable alterations and thus not suitable for minimal residual disease (MRD) monitoring. In this study, we aimed to develop a customized ctDNA panel for MRD monitoring in BTC. In this study, 124 BTC patients undergone curative resections were enrolled at Hokkaido University and Sapporo Medical University from May 2019 to April 22. All enrolled patients have BTC diagnosis confirmed by pathological diagnosis after surgery, and without other malignant tumors. Genomic profiles of FFPE tissue were conducted using Ampliseq CCP. 13 patients were excluded for high fragmentation. Referring to the genomic profiles of 111 patients in our study and 1924 patients in TCGA established a customized panel using Ion Ampliseq HD technology. The Ampliseq HD panel claims to detect variants at 0.1% LOD for ctDNA detection. It also integrates molecular barcodes to reduce NGS-related errors. The designed panel was 258 Amplicons and 20 genes including eleven therapeutically targetable genes. Clinical characteristics of ctDNA detection were also assessed. Results:The panel validation: concordance of the mutation allele frequency (MAF) between the NGS standard control and Ampliseq HD panel showed a coefficient of determination (R2) of 0.96. Also, concordance of MAF Ampliseq CCP and Ampliseq HD panel on FFPE tumor profiling showed R2 of 0.78. When assessing 70% of BTC patients were covered to have at least one tumor-derived Ampliseq HD panel. When assessing using plasma cell-free DNA, 55% of BTC patients were detected to have at least one tumor-derived ctDNA. Distribution of detected altered top4 genes using Ampliseq HD panels shows TP53 35%, KRAS 10%, SMAD4 5%, ARID1A 2.5%. Clinical characteristics may affected the concordance of plasma and FFPE tumor tissue; stage (P=0.035), size of tumors (P=0.0088), subtype (P=0.013), LN metastasis (P=0.11). Conclusions: A highly sensitive ctDNA customized panel for BTC was established. We also found that clinical characteristics of the BTC affects the detection of ctDNA from blood liquid biopsy. Future study: MRD evaluation using this customized panel.

#3660 Plasma cell free DNA hydroxymethylation profiling reveals anti-PD1 treatment response and resistance biology in non-small cell lung cancer.

G. D. Guler[1], Y. Ning[1], C. Coruh[2], T. Phillips[2], M. Nabiyouni[2], K. Hazen[1], A. Scott[1], W. Volkmuth[1], S. Levy[2];

[1]ClearNote Health, San Mateo, CA, [2]ClearNote Health, San Diego, CA

Background: Treatment with immune checkpoint inhibitors (ICIs) targeting programmed death-1 (PD-1) can yield durable anti-tumor responses, yet not all patients respond to ICIs. Current approaches to select patients who may benefit from anti-PD-1 treatment are insufficient. 5-hydroxymethylation (5hmC) analysis of plasma-derived cell free DNA (cfDNA) presents a novel non-invasive approach for identification of therapy response biomarkers which can tackle challenges associated with tumor biopsies such as tumor heterogeneity and serial sample collection.

Methods: 151 blood samples were collected from 31 non-small cell lung cancer (NSCLC) patients before therapy start and at multiple timepoints whilst on therapy. Blood samples were processed to obtain plasma-derived cfDNA, followed by enrichment of 5hmC-containing cfDNA fragments through biotinylation via a two-step chemistry and binding to streptavidin coated beads. 5hmC-enriched cfDNA and whole genome libraries were prepared in parallel and sequenced to obtain whole hydroxymethylome and whole genome plasma profiles, respectively.

Results: Comparison of on-treatment timepoint to matched pre-treatment samples from same patients revealed that anti-PD-1 treatment induced distinct changes in plasma cfDNA 5hmC profiles of responders, as judged by RECIST, relative to non-responders. In responders, 5hmC accumulated over genes involved in immune activation such as IFNγ and IFNα response, inflammatory response, and TNFα signaling, whereas in non-responders 5hmC increased over epithelial to mesenchymal transition genes. The Molecular Response to anti-PD-1 treatment, as measured by 5hmC changes in plasma cfDNA profiles were observed early, starting with the first cycle of treatment. Comparison of pre-treatment plasma samples revealed that anti-PD-1 treatment response- and resistance-associated genes can be captured by 5hmC profiling of plasma-derived cfDNA.

Conclusions: These results demonstrate that 5hmC profiling can identify response and resistance associated biological pathways in plasma samples, offering a novel method for non-invasive prediction and monitoring of immunotherapy response in NSCLC.

#3661 Non-coding RNAs as biomarkers for early detection of lung cancer.

G. S. Casagrande[1], A. P. Filho[1], A. P. Siqueira[1], R. S. Chiarantano[1], F. d. Vazquez[1], M. A. Molina[2], C. Pedraz-Valdunciel[2], A. Gimenez-Capitan[2], R. M. V. Reis[1], L. F. Leal[1];

[1]Barretos Cancer Hospital, Barretos, Brazil, [2]Hospital Universitari Dexeus, Barcelona, Spain

Introduction: Screening programs proven to reduce lung cancer deaths in high-income countries. Biomarkers detection in body fluids may guide more precise selection of high-risk subjects but this approach has not been currently employed for lung cancer screening. **Aims:** To identify ncRNA-based signatures for early detection of lung cancer in liquid biopsies. **Methods:** This is a case-control prospective study, conducted at the Barretos Cancer Hospital Screening Program. We analyzed miRNAs in plasma and sputum samples from high-risk subjects (n=51), and patients (n=44) diagnosed with non-small cell lung cancer (NSCLC), no metastatic, at Barretos Cancer Hospital (Brazil). We analyzed circRNAs in plasma samples from high-risk subjects (n=100), and patients (n=86) with NSCLC at Hospital Universitari Quiron Dexeus (Spain). Samples were subjected to RNA isolation followed expression analysis, for miRNA expression was used *nCounter Human V3 microRNA* painel, and for circRNA expression was use a nCounter customized painel (NanoString). Counts were normalized by housekeeping, and differentially expressed miRNAs were filtered out according to fold-change (≥|1.5|), p-value (≤0.05). **Results:** All cancer patients were diagnosed with adenocarcinoma (n=68), squamous cell carcinoma (n=41) and others/no information (n=36). No differences were observed related to age, sex, and tobacco exposure between high-risk and cancer groups (p>0.05). For Brazilian group, we observed six differentially expressed miRNAs in plasma able to distinguish cancer from non-cancer samples - three miRNAs upregulated, and three miRNAs downregulated -, and three of them presented with high accuracy (AUC = 0.70). For sputum, we observed four differentially expressed miRNAs able to distinguish cancer from non-cancer samples, and the 4-miRNA signature present with high accuracy (AUC = 0.73). None of miRNAs were shared between plasma and sputum. In both sample types we have miRNAs associated with zinc finger (*ZNF99* and *ZNF268*), that predicted to be involved in regulation of transcription by RNA polymerase II. In Spanish cohort, we observed 4-circRNA signature with high accuracy (AUC = 0.745). These four circRNAs are associated with insulin resistance and proto-oncogenes. **Conclusion:** We identified ncRNA-based biomarkers in biofluids potentially to be employed in lung cancer screening programs to better guide selection of high-risk subjects for early detection of lung cancer.

#3662 Cell-free DNA dynamics following neuroblastoma resection.

Joshua N. Honeyman[1], Andrew Chi[1], Shakeel Modak[2], Fiorella Iglesias Cardenas[2], Michael P. La Quaglia[1], Neerav N. Shukla[2], J. Ted Gerstle[1]

[1]Department of Surgery, Memorial Sloan Kettering Cancer Center, New York, NY,[2]Department of Pediatrics, Memorial Sloan Kettering Cancer Center, New York, NY

Introduction: Prior studies have demonstrated the utility of circulating tumor DNA (ctDNA) as a biomarker in the postoperative period for oncologic risk stratification. However, its utility may be limited in the early postoperative period by surgical trauma causing an increase in total cell-free DNA (cfDNA) due to tissue destruction, inflammation, and wound healing. No studies have identified the optimal timing of postoperative sample collection in pediatric patients undergoing resection of high-risk neuroblastoma. The purpose of this study is to assess the postoperative dynamics of cfDNA following neuroblastoma resection to determine optimal timing for ctDNA investigations.

Methods: An institutional database of banked cell-free DNA samples was retrospectively queried for patients with a diagnosis of neuroblastoma who had blood samples collected prior to resection and postoperative samples collected within 2 months of the operation. Plasma was collected from whole blood samples. cfDNA was extracted from plasma samples using the QIAGEN QIAsymphony SP system, and samples were quantified using the Advanced Analytical Fragment Analyzer Automated CE System with the High Sensitivity Genomic DNA Analysis Kit.

Results: Seventeen patients were identified undergoing 18 total operations and 37 total blood draws yielding cfDNA. There were 12 male and 5 female patients. Median age at operation was 5.5 years (range 1.4y to 20.5y). Two patients were INRG stage L2, and 15 patients were stage M. Operative indications were primary tumor resection in 10 patients and resection of recurrence/progression in 8 patients. Three postoperative samples were drawn within 10 days of the operation, and 16 samples were collected between postoperative weeks 4 and 6. There was a statistically significant difference (p=0.029) in cfDNA yield between each timepoint sampled: preoperative (median 6ng/mL, range 2-30ng/mL), 0-10 days postop (median 34ng/mL, range 15 - 85 ng/mL), and 4-6 weeks postop (median 6ng/mL, range 2 - 17ng/mL). Pairing the pre- and post-operative samples for each patient, those drawn within 10 days had a median increased yield of 180% (range +67% to +652%) while the samples collected at 4-6 weeks had a median decreased yield of 23% (range -55% to +491%; p = 0.047). Of note, there were three outliers in the 4-6 week group who had increases in cfDNA yield of >200%. On further review of these charts, each patient was being treated for obstructive uropathy at the time the postoperative sample was collected.

Conclusion: Plasma cfDNA yield increases in the early postoperative period before dropping by postoperative week 6. Tumor resection may be associated with an overall decrease in total cfDNA. Postoperative renal pathology may cause a persistent elevation in cfDNA. Further studies are necessary to clarify the role of ctDNA in the management of patients with neuroblastoma.

#3663 Extending and analytical validation of a hematological cancer panel for simultaneous detection of driver mutations, copy number variations and translocations in tissue and blood samples.

Y. Huang, T. Zhang, F. Xie, J. Dong, X. Wang, Z. Zhao, S. Luo, K. Zhou, S. Jia, P. Du;
Predicine Inc, Hayward, CA

Background Hematological cancers represent approximately 9.4% of all new cancer cases in the US, with varying prevalence among different age groups. For instance, Acute Lymphocytic Leukemia (ALL) is more prevalent in children (less than 15 years), while Multiple Myeloma and Non-Hodgkin Lymphoma are commonly identified in older population (65 or older). Each hematological cancer subtype has distinct mutation and expression profiles, necessitating the coverage of various variant types, including point mutations, gene copy number variations (CNVs), and translocations. In this study, we extend the PredicineHEME panel to encompass long-range translocation and CNV detections.

Methods The extension of the original PredicineHEME panel involves three key modifications. First, a genome-wide SNP backbone was incorporated to enhance the sensitive detection of both gene and chromosomal-level CNVs and Loss of Heterozygosity (LOH). Second, additional coverage of translocation breakpoint regions was added, considering the panel's application in liquid biopsy samples. Coverage included the most frequently found translocations in major hematological cancers. Third, the driver gene list was supplemented to include genes and mutations treated as active therapeutic targets in clinical studies. Analytical validation was conducted using contrived reference materials, cell lines with known biomarker status, and healthy and clinical samples with known mutations or translocation status.

Results The expanded panel underwent balanced testing with healthy normal saliva gDNA samples to ensure even capture of targeted genomic regions. Assay testing followed CLIA/CAP guidelines on analytical validation materials. The Limit of Detection for SNV/INDEL and known translocation breakpoint reached as low as 0.3%. Our assay detected over 90% of covered and reported translocation breakpoints in the validation materials. Chromosome arm level CNVs reported in the validation materials were detected with 100% sensitivity and specificity.

Conclusions The expansion of the PredicineHEME panel underwent analytical validation, meeting design expectations. With this extension, the assay can effectively detect driver mutations (SNVs/INDELs), CNVs at gene and chromosomal levels, and targeted large translocations in major hematological cancers.

#3664 Evaluation of on-treatment tumor molecular dynamics using plasma whole genome sequencing (pWGS) and whole exome sequencing (pWES) of circulating tumor DNA (ctDNA) in patients (pts) with metastatic non-small cell lung cancer (NSCLC): An exploratory analysis of KEYNOTE-598.

Minita Shah, EJ Dettman, Andrew Albright, Cai Chen, Julie Kobie, Vinay Varadan, Ayman Samkari, Carol Pena, Razvan Cristescu, Z Alexander Cao

Merck & Co., Inc., Rahway, NJ

Background: ctDNA-based pWES is a promising tool to examine tumor genomics using a non-invasive liquid biopsy to serially monitor changes during tumor evolution and treatment. Here, we evaluate on-treatment tumor molecular dynamics using ctDNA-based pWGS and pWES in pts with metastatic NSCLC that responded to pembrolizumab (pembro) monotherapy and later experienced PD in KEYNOTE-598 (NCT03302234).

Methods: In KEYNOTE-598, pts had metastatic NSCLC (PD-L1 tumor proportion score ≥50%) and received first-line pembro ± ipilimumab for ≤35 cycles. Cell-free DNA (cfDNA) was isolated and sequenced from plasma samples at baseline (BL), during on-treatment response (cycle 5 [C5]), and at PD (discontinuation [D]) from pts with objective response to pembro monotherapy and subsequent PD. ctDNA burden (tumor fraction [TF]) was estimated using low-pass pWGS by quantifying tumor content in cfDNA as a function of aneuploidy. All samples with TF >1.5% underwent high-depth pWES. ctDNA burden was estimated from pWES data using maximum somatic allele frequency (MSAF). Correlation between TF and MSAF was evaluated using the Spearman coefficient (r). Variant allele frequency (VAF) and normalized VAF (nVAF) were used to determine variant clonality.

Results: In total, 23 pts with initial response to pembro and subsequent PD had plasma samples available from BL, C5, and D. Samples from 22 pts had TF >1.5% by pWGS and underwent pWES. MSAF by pWES was correlated with TF by pWGS at BL (r = 0.68), C5 (0.80), and D (0.59). ctDNA TFs at BL and D (mean = 8.1% and 4.9%, respectively) were higher than C5 (2.0%). In a pooled variant-level analysis (nVAF >0.25) of samples from pts with high TF (≥2.5%) at both BL and D (n = 10), 786 (46%) of variants were present at BL and D, 391 (23%) were present at BL only, and 540 (32%) were present at D only. Variants shared between BL and D had higher clonality (mean nVAF = 0.46) than BL-only (0.38) or D-only variants (0.4). In general, shared variants had similar nVAFs at BL and D but in some pts nVAFs increased at D, suggesting evolution of tumor subclones during treatment. *TP53* was mutated in 9 of 10 pts with high TF and was shared at BL and D in 6 pts (mean nVAF = 0.49), present at BL only in 1 pt (0.11) and at D only in 2 pts (0.43). *KRAS G12V* and *Q61H* hotspot mutations were observed in 2 pts at D-only and may be related to immune editing.

Conclusions: Comprehensive pWES is feasible with sufficient ctDNA burden (TF ≥2.5%). ctDNA dynamics demonstrated molecular profiles characteristic of recurrence with high TF at BL and D and were consistent with radiographic determination of response/progression. Tumor variants at BL and D generally had a common clonal trunk with clones disappearing or appearing de novo.

#3665 Stratifying prostate cancer patients through circulating genes related to prostate cell subtypes, drug targets, and therapeutic resistance.

Seta Derderian[1], Edouard Jarry[2], Arynne Santos[1], Mohanachary Amaravadi[1], Quentin Vesval[3], Lucie Hamel[1], Raphael Sanchez-Salas[4], Alexis Rompre-Brodeur[4], Wassim Kassouf[4], Raghu Rajan[5], Marie Duclos[6], Fadi Brimo[7], Armen Aprikian[4], Simone Chevalier[8]

[1]Uro-oncology Research Group, Cancer Research Program, McGill University Health Centre Research Institute, Montreal, QC, Canada,[2]Urology, Centre Hospitalier Regional et Universitaire de Lille, Lille, France,[3]Urology, Centre Hospitalier Regional et Universitaire de Rennes, Rennes, France,[4]Deparments of Oncology and Surgery, McGill University, Montreal, QC, Canada,[5]Deparment of Oncology, McGill University, Montreal, QC, Canada,[6]Deparment of Radiation Oncology, McGill University, Montreal, QC, Canada,[7]Deparment of Pathology, McGill University, Montreal, QC, Canada,[8]Deparments of Oncology, Surgery, and Medicine, McGill University, Montreal, QC, Canada

Stratification remains an obstacle for the optimal treatment of prostate cancer (PCa) patients throughout the treatment trajectory. Targeting the androgen receptor (AR) kills the majority of luminal-like cells, which are AR-positive and express Prostate Specific Antigen (PSA). However, a subset of surviving AR-positive cells develop resistance to treatments while AR-negative cells of the neuroendocrine (NE) or stem-like phenotypes emerge through selection. We reported on the clinical relevance of cell-subtype genes in whole blood RNA of advanced PCa patients. Here, we studied an expanded panel of genes to include drug targets and therapeutic resistance as predictive biomarkers to stratify patients at diagnosis and at the advanced stage of disease.Genes were chosen based on literature review, results of clinical trials in PCa, and PCa transcriptomic data. Technical validation of TaqMan RT-qPCR assays was carried out for each gene, including rigorous testing of reproducibility. Whole blood RNA was extracted from 26 healthy controls with no prostatic disease, 16 patients prior to prostatectomy, and 43 blood samples from 28 metastatic cases. Gene overexpression was defined as the 99.5% confidence interval of expression in controls. Clinical data were retrieved from patients' charts.A panel of 64 genes was built, showing overexpression in advanced PCa but low or no expression in normal blood (including whole blood, white and red blood cell populations and platelets). Testing in control blood showed no correlation with age. The proportions of patients' white blood cells did not correlate with gene expression in their blood. Overall, up to 44/64 genes were overexpressed in at least one patient sample. Patients with prostatic intraductal carcinoma at prostatectomy showed more circulating genes, including more NE and stemness genes, and more PCa cell subtypes represented. Intermediate and high-risk patients showed more circulating NE genes. In metastatic patients, signatures of luminal, NE, stemness, and resistance to AR inhibitors or taxanes were associated with progression. PCa-specific luminal genes were associated with shorter overall survival. Treatment resistance genes correlated with lines of treatment and current taxanes. Two targetable NE genes were overexpressed in distinct categories of patients, suggesting that they may benefit from more specific treatments.In conclusion, phenotypic and functional differences in circulating gene patterns of PCa patients correlate with pathological features, treatments, progression. They may be clinically meaningful to stratify patients and predict therapeutic response. Circulating genes encoding drug targets may justify clinical trials to offer personalized treatments and impact on lethal PCa.

#3666 Multi-cancer early detection using metrics of DNA methylation based epigenetic instability.

S.-J. Thursby, Z. Jin, S. B. Baylin, M. Brock, T. Pisanic II, H. Easwaran;
Johns Hopkins University, Baltimore, MD

Cancers present significant changes in DNA methylation, which has proven to be highly useful in cell-free DNA (cfDNA) based cancer detection. Cancer epigenomes are marked by a high degree of intra- and inter-tumor epigenetic variation, indicative of the high level of epigenetic instability. However, the nature of the regions with high epigenetic instability and its utility as biomarker has not been explored. Here we developed a novel methodology and metric to measure the degree of epigenetic perturbation, termed the Epigenetic Instability Index (EII), for multiple cancer screening through cfDNA. Our novel methodology provides a sample specific score of epigenetic perturbation in relation to the expected normal state as opposed to only looking at CpG sites that change between samples. Through machine learning, we have elucidated 269 CpG-island regions which sufficiently capture the epigenetic instability in cancers. We have built classifier models using the EII metrics of these 269 regions and demonstrate that they can efficiently identify breast and lung cancer cases from cfDNA methylation data. Particularly, the models can differentiate even Stage IA of NSCLC with ~75% sensitivity at 95% specificity and early-stage breast cancer at ~68% sensitivity and 95% specificity. The EII metrics perform significantly better than metrics that measure absolute DNA methylation levels. Our studies highlight the potential of measuring epigenetic instability from cfDNA in any given sample in addition to traditional methods of methylation measurement for non-invasive screenings via liquid biopsies.

#3667 Nucleic acid quantification in uveal melanoma aqueous humor.

C. Chang[1], S. Pike[2], M. Reid[3], C.-C. Peng[3], B. Xu[2], J. Berry[3], L. Xu[3];

[1]Univeristy of Southern California, Los Angeles, CA, [2]Keck School of Medicine of the University of Southern California, Los Angeles, CA, [3]Children's Hospital Los Angeles, Los Angeles, CA

Introduction: Uveal melanoma (UM) is the most common primary adult intraocular cancer. Though radiation brachytherapy is often employed for UM treatment, half of UM patients develop systemic metastases. In large tumors with macular involvement, the disease and its treatment can lead to blindness. Clinically, UM prognosis is estimated by tumor size, location, American Joint Cancer Commission (AJCC) staging, and histologic findings. Prognostic UM biomarkers have been established but lesions <2 mm in height, particularly near the fovea, are difficult to biopsy, and thus physicians often do not perform biopsies on such tumors. Therefore, the use of aqueous humor (AH) as a liquid biopsy is a promising methodology. The purpose of the study was to quantify analytes in AH samples collected at diagnosis and post-brachytherapy from UM eyes with varying tumor sizes and AJCC Stages to analyze correlations between analyte (dsDNA, microDNA, and protein) concentrations and tumor features.

Methods: This case series study included 119 UM AH samples from 66 UM eyes and 16 control AH samples collected from age-matched non-UM glaucoma (GLC) eyes analyzed for unprocessed analytes using Qubit fluorescence assays.

Results: Most UM AH samples contained quantifiable analyte concentrations (dsDNA: 94.1%, miRNA: 88.0%, protein: 95.2%) and at higher concentrations than GLC controls (dsDNA, P=0.008; miRNA, P<0.0001; protein, P=0.007). In samples taken at diagnosis, concentrations were higher at more advanced AJCC stages; comparing most advanced Stage III (n=8) to least advanced Stage I (n=24), median dsDNA was 4 times greater (P<0.0001), protein was 3 times greater (P<0.0001), and miRNA was 2 times greater (P=0.001). Analytes were quantifiable in >70% of pre-brachytherapy samples from eyes with tumors <2 mm tall (n=17). Height was positively associated with analyte concentrations at diagnosis (dsDNA: R=0.43, P=0.0007; miRNA: R=0.35, P=0.01; protein: R=0.39, P=0.005). In paired samples (n=53), all analyte concentrations were significantly higher post-therapy compared to diagnosis pre-therapy (Ps<0.01).

Conclusions: Although AH analytes were also quantifiable in smaller, less advanced tumors, AH samples from eyes with larger, more advanced tumors had higher analyte concentrations. The detection of prognostic biomarkers in AH may allow for early UM recognition and guide personalized treatment.

#3668 Plasma cell-free DNA profiling for deciphering cellular origins and immune competence in cancer patients.

L. Andersen, A. Frydendahl, T. V. Henriksen, C. Demuth, M. H. Rasmussen, I. Nordentoft, K. Birkenkamp-Demtroder, J. S. Pedersen, S. Besenbacher, L. Dyrskjot, C. L. Andersen, N. J. Birkbak;
Aarhus University Hospital, Aarhus N, Denmark

Plasma cell-free DNA (cfDNA) originates from apoptotic cells in the blood, providing a real-time insight into the biology of various cell types. The fragment coverage pattern of cfDNA across the genome is known to reflect the distinct chromatin status of originating cells. While extensive research has focused on fragments derived from cancer, known as circulating tumor DNA (ctDNA), for inference about cancer biology, cfDNA fragments from healthy cells have received little attention. Our study explores the potential of cfDNA to decipher the relative abundance of distinct blood cell types, particularly immune system cell types.
We collected a cohort of 273 bladder (BC) and colorectal cancer (CRC) patients and 45 healthy controls for plasma whole genome sequencing and assessed the fragment coverage profile at transcription start sites (TSS) of protein coding genes. A significant negative correlation was observed between TSS coverage and whole blood gene expression (Spearman's rho = -0.65). Furthermore, TSS coverage revealed a bimodal distribution, characterized by modes corresponding to high and low gene expression levels in blood cells. This may suggest the cfDNA coverage profile as a binary expression status classifier to distinguish between expressed and unexpressed genes in blood cells. We further evaluated TSS with differential coverage between age groups of healthy individuals and relapse status of cancer patients. Notably, out of the TSS that significantly differentiated middle-aged (aged 40-65) from older individuals (aged 65+), 31 were also able to distinguish relapse from non-relapse patients. Among these TSS were CD36, SLAMF7, TABBP and PDCD1, known to be involved in immune related pathways. Finally, we evaluated coverage at cell-type specific TSS and found dendritic cells (P-value: CRC = 8e-06, BC = 5.1e-3), monocytes (CRC = 1.6e-04, BC = 2.5e-3), and NK cells (CRC = 8.5e-04, BC = 0.026) to exhibit a significant increase in coverage in the cancer cohorts compared to healthy controls. Conversely, T-cells showed a decrease in coverage (CRC = 0.041, BC = 0.062).
In conclusion, cfDNA coverage profile may identify TSS with differential coverage between patient groups and characterize a shift in blood cell type composition as a response to cancer. Future work may show if fragment coverage quantifies the relative contribution of cfDNA from distinct immune cell types. We anticipate our analysis to illuminate the utility of plasma cfDNA as a biomarker for cancer patient's immune competency, enabling improved patient stratification for treatment, leveraging their distinct immune capabilities.

#3669 Clinical application of urinary DNA methylation biomarkers for identifying patients with non-muscle invasive bladder cancer.

G. Bonora[1], Z. Zhu[1], B. Gould[1], B. Xiang[1], K. Zhou[1], S. Jia[1], R. Li[2], P. Du[1];
[1]Predicine, Inc., Hayward, CA, [2]Moffitt Cancer Center, Tampa, FL

Introduction

Differences in DNA methylation along cell-free DNA (cfDNA) fragments are known to exist between cancer patients and healthy individuals. Profiling these aberrant methylation patterns in urinary cfDNA (ucfNDA) holds great promise for the non-invasive detection and monitoring of bladder tumors, including non-muscle invasive bladder cancer (NMIBC). Here, we analyzed fragment-level DNA methylation patterns in urine samples obtained prior to repeat transurethral resection of a bladder tumor (reTURBT) from a cohort of NMIBC patients. The results were compared to traditional clinical disease assessment and mutation-based tumor fractions. We found a strong concordance between DNA methylation abnormality and clinical diagnosis, as well as tumor fractions, highlighting the potential of epigenetic alterations as a non-invasive indicator of bladder cancer status.

Methods

Patients with high-risk NMIBC (n = 30) were prospectively enrolled prior to reTURBT. The PredicineEPIC™ genome-wide methylation analysis and PredicineBEACON™ MRD profiling was performed on pre-repeat TURBT urine samples. Abnormally methylated genomic fragments were detected against a background model built from a panel of plasma samples from healthy donors.

Results

DNA methylation abnormality was significantly higher ($p = 4.8 \times 10^{-6}$) in samples classified as NIMBC positive by a clinical pathologist (n = 19) compared to negative samples (n = 11), as well as compared to hold-out healthy donor samples (n=24; $p = 7.0 \times 10^{-9}$). Classifying the samples based on a DNA methylation score cut-off derived from healthy donor samples, 24 / 30 samples showed concordant disease status. Furthermore, DNA methylation abnormality scores correlated positively with mutation-based tumor fractions (r = 0.62), with higher grade samples showing a stronger correlation (r = 0.81; n = 13) than lower grade samples (r = 0.54; n = 17).

Conclusion

We demonstrate the utility of methylation patterns extracted ucfDNA samples obtained prior to reTURBT to detect and monitor NMIBC. Urinary DNA methylation patterns were highly concordant with clinical pathology status and as well as tumor fractions determined from mutation analysis.

#3670 Reducing the patient burden for ctDNA biomarkers: Advancing small volume home-based collection technologies.

B. R. Evans[1], R. J. Foley[2], S. M. Townson[1], E. J. Welch[3], C. E. Frame[1], D. D. Donovan[1], J. M. Fahey[1], K. P. Bateman[1];
[1]Merck & Co., Inc., Rahway, NJ, [2]Guardant Healthcare, Palo Alto, CA, [3]Tasso, Inc., Seattle, WA

There is broad consensus from regulatory agencies, clinicians and patients for the need to move to decentralized trials while focusing on patient-centric approaches with the COVID-19 pandemic being the catalyst. This requires the development of new sample collection capabilities and workflows to ensure that the necessary biomarkers can be measured. Circulating tumor DNA (ctDNA) has become an increasingly important biomarker for cancer detection and genetics, and monitoring patients during treatment. Typical measurements of ctDNA involve venous draws of >10mls of whole blood that require patients to be in clinic. Here, we test the feasibility of using a new collection device, Tasso+, to collect capillary blood for ctDNA analysis using the Guardant360 panel. A pilot of whole blood microsamples (< 1 mL) with a cfDNA yield of 0.7-1.4 ng/ml spiked to 0.5% MAF with Seraseq ctDNA reference material. This resulted in detection of ~20% of the total expected variants across variant classes showing the feasibility of using the G360 panel to detect low volume/low MAF samples. Initial testing of Tasso+ collected samples revealed a 5-10x increase in high MW gDNA compared to traditional venipuncture. SPRI bead-based size selection was used in the extraction protocol to remove >95% of the high MW DNA, resulting in a 35% loss of target cfDNA fraction. Traditional venipuncture samples and Tasso+ samples were collected from 5 cancer patients and run using the G360 platform. Microsamples detected 75% of the variants across all variant classes found in venipuncture samples. Tasso+ lost sensitivity of variants when the MAF was <0.5%. To expand usage of Tasso+ to at-home collection of blood for ctDNA analysis, we sought to determine if lyophilization of the Streck DNA BCT RUO tube reagent could still provide stability to samples and a potential framework for at-home collections. Venipuncture and Tasso+ samples were collected from control patients, pooled and spiked with Seraseq cfDNA reference material. Samples were aliquoted into standard liquid Streck tubes or tubes with lyophilized reagent at the concentration per manufacturer's directions and evaluated for stability over time. The Tasso+ samples with a target MAF between 0.5%-2.0% detected ~26% of all variants compared to the standard samples with a similar MAF. Lyophilization of the Streck reagent had minimal effect (<20% reduction in variants detected) on the reagent's performance as there were approximately an equal number of total variants detected when comparing liquid and lyophilized samples for both the standard tubes and Tasso+ samples. Overall, these results provide support and a framework for using a home-based patient-centric sampling approach for monitoring ctDNA from cancer patients in clinical development.

#3671 Analytical performance of the Oncomine™ Dx Express Test, a CE-IVD NGS liquid biopsy assay for identification of clinically relevant variants.

M. Jasti, S. Raut, D. Hassell, N. Ezzedine, D. Garcia, S. Wunsch, N. Siepert, E. Martinez, E. Ostrowska, J. Schagemann, J. Gu, T. Jayaweera, L. He, A. Cheng; Thermo Fisher Scientific, AUSTIN, TX

For in vitro Diagnostic use only. Not available in all regions including the United States.

Introduction

Minimally invasive blood-based liquid biopsy using cell-free total nucleic acid (cfTNA) and next generation sequencing (NGS) has substantially evolved in the field of clinical diagnostics for oncology, for detection of molecular therapeutic targets in non-small cell lung cancer (NSCLC). Here we describe analytical validation results for cfTNA using the CE-IVD Oncomine™ Dx Express Test (ODxET) assay, a qualitative in vitro diagnostic test that uses targeted NGS technology, the Ion Torrent Genexus™ Dx Integrated Sequencer to detect SNV, indel and copy number gain present in 42 genes and fusions in 7 genes from cfTNA isolated from NSCLC plasma samples.

Methods

Plasma samples from NSCLC patients were screened for variants of interest on several important gene loci. Screening involved isolation of cfTNA from K2-EDTA-derived plasma using the Genexus™ Cell-Free Total Nucleic Acid Purification kit on an automated purification system and sequencing was performed on the Genexus™ Dx integrated sequencer using the ODxET assay. Plasma samples having clinically relevant variants from the set of screened plasma samples were used to perform the validation studies.

Results

Analytical sensitivity and specificity of NSCLC plasma samples were characterized through determination of limit of detection (LOD) and limit of blank (LOB), respectively. The LOD level tested for DNA SNVs, and indels at 5 ng (minimum) input level ranged from 0.62% to 1.82% allelic frequency (AF), while 30 ng (maximum) input shows the LOD level ranging from 0.23% to 0.42% AF. The LOD for the tested RNA fusions ranged from 4.2 to 19.6 molecular counts for 5ng input and 4.9 to 8.0 molecular counts for 30ng input. Furthermore, LOB for the ODxET assay was determined by testing wild type (WT) cfTNA extracted from 30 healthy donor blood plasma samples, which were confirmed to be negative at all variant locations. The analytical accuracy study shows the false positive rate at 0.20% for SNVs, 0% for indel locations and fusion targets. In addition, the analytical reproducibility study shows 99.64% intra-run repeatability call rate for DNA variants and 98.75% for RNA variants.

Conclusion

In conclusion, we establish that the ODxET assay on Ion Torrent Genexus Dx Integrated Sequencer, is fast and efficient while demonstrating high sensitivity, specificity, and reproducibility for testing NSCLC liquid biopsy samples.

#3672 Development of liquid biopsy HPV (Human Papilloma Virus) cell free DNA (cfDNA) based approach for prognosis of cervical cancer.

G. Dagar[1], A. Gupta[1], R. Chauhan[1], A. Shankar[1], D. N. Sharma[1], M. A. Macha[2], A. A. Bhat[3], R. Goyal[4], V. Suri[1], M. Singh[1];
[1]All India Institute of Medical Sciences (AIIMS), New Delhi, India, [2]Islamic University of Science and Technology, Pulwama, Jammu and Kashmir, India, [3]Obesity and Cancer Program, Sidra Medicine, Doha, Qatar, [4]Lady Hardinge Medical College, New Delhi, India

Introduction: Recent progress in the analysis of blood samples for circulating tumor cells or cell-free circulating tumor DNA (ctDNA) has shown that liquid biopsies may have potential applications in the detection and monitoring of cancer. Human papillomavirus (HPV) circulating cell-free (ccf) DNA may act as a unique marker for the prognosis of high-risk HPV-related cancers. However, detection of circulating markers for cervical cancer (CC) requires extremely sensitive techniques that can measure circulating human papillomavirus DNA. Here, we used the sensitive droplet digital PCR (dd PCR) based approach for the detection and quantification of circulating human papillomavirus DNA in plasma from patients diagnosed with cervical cancer at baseline and subsequent follow up with intention of validating its utility as a prognostic marker in CC.

Method: Blood sera form 34 Patients diagnosed with cervical cancer (Stage 1-1V) at AIIMS Delhi was collected at baseline and after 3 months of the treatment. 10 healthy controls were also recruited in the study after due approval from AIIMS IEC. Plasma samples were stored at -80°C. ccf DNA was isolated from 1 ml of plasma and further processed to detect the presence of circulating high risk Human papilloma virus (HPV) i.e., HPV-16 and HPV18 cf DNA using dd PCR.

Result: The median cf DNA concentration was 9.3 ng/uL (range 3-26.6) for all patients while median cf DNA concentration was 7.2 ng/uL (Range 3-57.3) for healthy controls (n=10). Furthermore, the levels of cfDNA decreases post 3 months of treatment with average concentration of 8.07 ng/uL (Range 4.6-19.3). We further processed our samples for dd PCR based screening to detect low copy no HPV cf DNA and ddPCR detection yielded a positive rate of 51% (18/35) for circulating HPV18 DNA while a positivity of 88.5% (31/35) was seen for the circulating HPV16 DNA in the sera of CC patients. By comparing HPV16 and HPV18 genotypes, we observed detection of circulating HPV 16 DNA more frequently than circulating HPV18 DNA in CC patients coming at our center. Furthermore, we found that copies of circulating viral DNA (HPV18 and HPV16) decreased post induction therapy in CC patients indicating progression ability of thid marker.

Conclusion: In the current studies we provide evidence that cell free DNA concentration in CC patient can predict tumor burden and detection of low copy no of circulating HPV DNA could be a promising indicator for prognosis in cervical cancer patients and can predict recurrence of the disease.

#3673 Monitoring treatment response in patients with metastatic colorectal cancer using cfDNA fragmentomics testing: The DOLPHIN trial.

D. E. van Steijn[1], R. J. A. Fijneman[1], G. R. Vink[2], J. M. L. Roodhart[3], M. Koopman[3], M. J. Lahaye[1], M. N. J. Braat[4], V. M. H. Coupe[5], D. A. van den Broek[1], G. A. Meijer[1], H. Wang[5], M. J. E. Greuter[6], B. I. Lissenberg-Witte[6], L. Rinaldi[7], E. Peters[8], A. Konicki[8], N. C. Dracopoli[8], N. F. M. Kok[1], V. E. Velculescu[8];
[1]Netherlands Cancer Institute, Amsterdam, Netherlands, [2]University Medical Center Utrecht, Utrecht University. Netherlands Comprehensive Cancer Organisation (IKNL)., Utrecht, Netherlands, [3]University Medical Center Utrecht, Utrecht, Netherlands, [4]University Medical Center Utrecht, Amsterdam, Netherlands, [5]Amsterdam University Medical Center, Amsterdam, Netherlands, [6]Amsterdam University Medical Centers, Amsterdam, Netherlands, [7]Delfi Diagnostics, Balitmore, MD, [8]DELFI Diagnostics, Baltimore, MD

Background: Accurate monitoring of treatment response in patients with metastatic colorectal cancer (mCRC) is important to decide when to adjust treatment regimen or to proceed to local therapy of metastases. At present, clinical response is determined by computed tomography (CT) imaging-based assessment of changes in tumor size. However, this monitoring approach is constrained by limited sensitivity in detecting lymph node and peritoneal metastases, as well as inter-reader variability. Detection of circulating tumor DNA (ctDNA) is indicative of the amount of neoplastic cells and may have added clinical value to CT imaging for assessment of treatment response and guidance in treatment decision making in mCRC patients. We recently developed a tumor mutation-independent ctDNA test that utilizes low-coverage whole genome sequencing to analyze the plasma cell-free DNA (cfDNA) fragmentome to measure the ctDNA tumor fraction: the DELFI-tumor fraction (DELFI-TF) score.
Aim: The DOLPHIN study aims to investigate whether the DELFI-TF ctDNA assay can provide a sensitive, affordable and broadly applicable ctDNA test to monitor treatment response of mCRC patients.
Methods: The prospective, observational, multi-center DOLPHIN study is a substudy of the Prospective Dutch ColoRectal Cancer cohort (PLCRC). Clinical data, images and blood samples from 400 patients receiving systemic therapy in 8-10 Dutch hospitals will be collected. Blood samples will be drawn longitudinally in conjunction with regularly scheduled CT imaging. Plasma cfDNA will be analyzed for tumor-specific fragmentation patterns using the DELFI-TF score. Droplet digital PCR ctDNA-testing of RAS/RAF hotspot mutations will be performed as reference, when feasible. Primary endpoint is the association between ctDNA changes and clinical response. Secondary endpoints are the association between ctDNA changes and radiological response according to RECIST and to serum carcinoembryonic antigen (CEA) at various time points during systemic treatment, lead time of ctDNA-testing compared to CT imaging to detect progressive disease, and the prognostic value of longitudinal ctDNA-testing.
Results: Since the inclusion of the first patient in March 2023, 117 patients have been included in the DOLPHIN study (November 2023). Seven hospitals throughout the Netherlands are currently open for patient inclusion and more sites have been approached to participate.
Discussion: The DOLPHIN study will assess the added clinical value of longitudinal ctDNA-testing in treatment response monitoring of mCRC patients and whether imaging can be complemented and/or partly replaced by ctDNA-testing. The results of this study may lead to novel strategies for monitoring treatment response and to ctDNA-guided treatment decision making in mCRC patients.

#3674 Blood-based differentiation of malignant and benign pancreatic lesions using analysis of fragmentation patterns in cell-free DNA.

C. T. Marcinak[1], M. D. Stephens[1], B. R. McDonald[1], N. Merali[2], S. M. McGregor[1], S. M. Weber[1], A. E. Frampton[2], S. Sivakumar[3], R. M. Minter[1], M. Murtaza[1]; [1]University of Wisconsin - Madison, Madison, WI, [2]University of Surrey, Guildford, United Kingdom, [3]University of Birmingham, Birmingham, United Kingdom

Pancreatic ductal adenocarcinoma (PDAC) remains lethal, with a five-year survival rate of less than 10%. For patients with pancreatic cystic lesions (PCL), analysis of DNA from cyst fluid has shown promise in determining the risk of malignant transformation. However, obtaining cyst fluid requires an invasive procedure. We recently developed an approach for blood-based cancer detection by analyzing fragmentation characteristics in plasma cell-free DNA (cfDNA). In this study, we evaluate the performance of this method in differentiating between patients with malignant and benign pancreatic lesions. We collected plasma samples from 81 patients at the time of endoscopic evaluation or surgical resection of a PCL. We simultaneously obtained plasma samples from 209 PDAC patients and 56 healthy individuals. Using plasma cfDNA whole genome sequencing data from patients with PDAC and healthy individuals, we trained and cross-validated an ensemble machine learning model based on 10 genomic features capturing plasma cfDNA fragmentation patterns. This model was applied to sequencing data from patients with PCL for independent evaluation of diagnostic performance. In training and cross-validation, the model demonstrated an area under the receiver operating characteristic curve (AUROC) of 0.90 for differentiating PDAC samples from healthy individuals. Of the 81 PCL patients, ten patients (12.3%) were found to have a malignant PCL, with either high-grade dysplasia or invasive carcinoma. The trained model showed an AUROC of 0.78 for differentiating malignant from benign lesions, achieving 50% sensitivity and 62.5% positive predictive value at 95% specificity. Our results are a novel demonstration that a peripheral blood test based on plasma cfDNA analysis can enable differentiation between malignant and benign pancreatic lesions. This approach may improve risk-stratification and clinical decision-making regarding the necessity for surgical resection. Larger studies and clinical trials to validate these results and evaluate their impact on outcomes are warranted.

#3675 Design of high-performance tumor-informed minimal residual disease (MRD) panels from low FFPE tumor input.

M. LaBella[1], A. Acevedo[1], R. Patel[1], K. Haug[1], S. Ganesh[1], E. Buser[1], N. Xu[1], S. Carlson[1], K. Trettin[1], S. Ratzel[1], K. Hara[2], P. Msaouel[3], K. Sircar[3], C. Tang[3], D. Muzzey[1], G. Gould[1];

[1]Myriad Genetics, Inc., Salt Lake City, UT, [2]The University of Texas MD Anderson Cancer Center, Houstin, TX, [3]The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Minimal residual disease (MRD) testing can detect cancer recurrence months to years earlier than the current standard of care, enabling earlier treatment of recurrence and improved patient outcomes. Tumor-informed MRD assays typically utilize formalin-fixed paraffin-embedded (FFPE) tumor tissue, which is available in limited quantities for some patients, for example, following core needle biopsy (CNB), after neoadjuvant treatment or when patients need multiple tests from the same tumor sample. To determine the lower limit of tissue input, we evaluated our MRD assay performance across a range of extracted tumor volumes.

Methods: Resected tumors and CNBs were sectioned, H&E stained, and macro-dissected. Tumor gDNA was extracted, quantified, prepared into libraries and sequenced. Sequenced libraries were aligned and evaluated for depth of coverage, variation of coverage, and duplication rate. Somatic calling was performed on matched tumor and normal samples. Up to 1000 target sites were selected for high-depth targeted sequencing of the tumor and normal gDNA for confirmation of somatic variant calls. The positive predictive value (PPV) was computed as the percent of putative somatic variant sites that were present in the tumor capture library and absent in the normal capture library.

Results: Extracted tumor volumes varied by almost two orders of magnitude, from 0.06mm^3 (equivalent to needle core or fine needle aspirate biopsies) to 5mm^3 (achievable with resected tumor). gDNA amount varied linearly (3.6ng to 1549ng) with tumor tissue input, indicating the low tissue to paraffin ratio did not have an adverse effect on yield. Tumor gDNA inputs into library prep ranged from 2.5ng to 100ng. DNA amounts above 100ng into library prep had no discernable benefit. Below 10 ng, depth of coverage and the coefficient of variation in coverage indicated poor-quality libraries. Samples with ~10 ng of gDNA input into library prep showed depth of coverage comparable to higher inputs and saturated the achievable library complexity. Additionally, PPV of somatic calling was consistent across the range of gDNA inputs from 10-100 ng, demonstrating equivalent assay performance.

Conclusion: Tumor-informed MRD assays have immense potential for increasingly sensitive treatment response and recurrence monitoring that can inform better treatment decisions. FFPE tumor tissue is a critical input into MRD assays but is a limited resource. This study supports a minimum DNA input of 10 nanograms for a single attempt at extraction, corresponding to a tissue volume of 0.2mm^3 or a single 10µm slide with a 20mm^2 area, representing one of the lowest tissue input requirements for an MRD assay. Low FFPE tissue requirements expand the patient population that benefit from MRD testing by utilizing samples that have low tumor content, are post-neoadjuvant therapy or do not meet the tumor volume requirements of competing MRD offerings.

#3676 A circulating tumor fraction DNA biomarker response stratified by *ESR1* mutation status correlates with overall survival in patients with HR+ HER2- metastatic breast cancer.

M. M. Stein[1], **K. Kaneva**[1], S. Hyun[1], C. Sangli[1], M. Ting-Lin[1], R. Ben-Shachar[1], J. Freaney[1], K. Sasser[1], J. Guinney[1], H. Nimeiri[1], M. Cristofanilli[2]; [1]Tempus Labs, Chicago, IL, [2]Weill Cornell Medicine, New York City, NY

Background: *ESR1* mutations (*ESR1m*) are acquired resistance mutations that evolve during treatment with aromatase inhibitor (AI) therapy in approximately 40% of ER+ HER2- metastatic breast cancer (mBC) patients and are indicative of poor outcomes. Patients with *ESR1m* acquired on AI may retain treatment response if switched to selective estrogen receptor degraders (SERDs) like fulvestrant. Circulating tumor DNA (ctDNA) analysis can detect the emergence of *ESR1* mutations and simultaneously determine molecular response to therapy through changes in quantitative ctDNA tumor fraction (ctDNA TF). We used real-world data (RWD) to study the combined effect of acquired *ESR1* mutation status and ctDNA TF dynamics on overall survival in ER+ HER2- mBC.

Methods: Tempus xF Monitor is a ctDNA assay that measures quantitative molecular changes in ctDNA TF by utilizing diverse genomic events, dynamically weighting somatic variant allele frequencies and copy number variants, while using germline information to inform these estimates and providing single nucleotide variant (SNV) results on 105 genes including *ESR1*. Non-responders (NR) were characterized as < 50% reduction in ctDNA TF while responders (MR) experienced ≥ 50% reduction in ctDNA TF. We selected a cohort from the deidentified Tempus multimodal database of 101 HR+ HER- mBC patients with a baseline xF test up to one year prior to or 3 months post AI therapy start. Real-world overall survival (rwOS) was defined as the interval from AI start to death, censored on the last known physician follow-up. Kaplan Meier analysis and Cox proportional hazards models were fitted to evaluate the relationship between *ESR1m* and MR/NR status with rwOS.

Results: In our evaluable cohort, (n=101), median age 59, *ESR1m* was detected in 29.7% (n=30) patients. *ESR1m* patients had shorter rwOS compared to *ESR1* WT patients (median *ESR1m* rwOS 63.8 months, median rwOS not reached for *ESR1* WT; p=0.013, HR=3.45 [1.9-9.2]). Across the cohort, regardless of *ESR1* status, 23.8% (24/101) of patients were characterized as ΔctDNA TF MR, 60.4% (61/101) as NR and 15.8% (16/101) of patients with ctDNA TF values below the limit of blank (b-LOB). Within the NR group, 35.5% (22/61) were also *ESR1m*, while only 20.8% (5/24) and 18.8% (3/16) *ESR1m* patients were in the MR and b-LOB group, respectively. Patients with combined *ESR1m* + NR ΔctDNA TF (n=22) experienced shorter rwOS (p=0.015) compared to MR ΔctDNA TF patients with WT *ESR1* (p=0.024, HR=6.61 [1.3-34.2]).

Conclusions: xF Monitor is a ctDNA assay that tracks changes in quantitative ctDNA TF and simultaneously monitors for the emergence of *ESR1m*, providing a diagnostic that identifies resistance to AI therapy and enables early switch to therapies that could improve outcomes in a patient population with poor prognosis. A larger prospective clinical study is needed to validate these findings.

#3677 Hybrid capture based sequencing from urinary cell free DNA from colorectal cancer patients.

A. Eberhard, T. Moser, L. Ziegler, G. Vlachos, I. Lazzeri, M. Loibner, A. Gerger, E. Heitzer;
Medical University of Graz, Graz, Austria

Background: The study of body fluids other than blood is gaining increasing attention in the field of liquid biopsy. Since urine offers a truly non-invasive sampling method, it is a particularly interesting specimen. Evidence suggests that urine cell-free DNA (ucfDNA) harbors information about renal and bladder cancer. However, not much is known about ucfDNA in colorectal cancer (CRC) patients. Therefore, we aimed to test the feasibility of a hybrid capture based NGS approach with and without preanalytical stabilization of urine samples.
Methods: Urine samples were collected from 20 patients with metastatic CRC (mCRC), aliquoted and stored unstabilized or stabilized (urine collection/stabilization solution under development at PreAnalytiX (QIAGEN/BD company) and Streck urine Preserve) at room temperature. Urine cfDNA was isolated at the day of donation and after 3 days. Matched blood samples were additionally collected in PAXgene Blood ccfDNA Tubes (PreAnalytiX). cfDNA from blood and urine was isolated using the QIAsymphony platform (QIAGEN). cfDNA samples were analyzed using the AVENIO ctDNA Analysis Kit (Roche), a hybrid-capture based approach enriching for 17 clinically relevant genes.
Results: While all stabilized ucfDNA yielded high quality libraries, library preparation failed in 66.7% of unstabilized urine samples, demonstrating that without stabilization ucfDNA rapidly degrades after urine donation. In native samples, in which sequencing data could be obtained, sequencing depth was significantly decreased compared to stabilized samples. For stabilized samples, sequence analysis revealed full concordance between urine and plasma for putative germline variants. However, when using less than 50ng of input material of ucfDNA, a low signal-to-noise ratio with a high number of false positive low level variants was observed. We therefore adjusted the limit of detection for ucfDNA to 0.5%, at which CRC-related mutations were detected in ucfDNA in one patient. Although these variants, were not observed in plasma cfDNA, they could be detected in all stabilized urine samples, which hints to true variants.
Conclusion: Our data demonstrate that a hybrid-capture based analysis approach is feasible for ucfDNA form CRC patients and that urine may provide complementary information about a patient's tumor that may be missed in plasma. Yet, due to degradation and lower concentrations, immediate stabilization of urine after donation is required. Moreover, the limit of detection needs to be adjusted if low amounts of input DNA is available only.

#3678 Beyond detection: AI-based classification of breast cancer invasiveness using cell-free orphan non-coding RNAs.

Mehran Karimzadeh[1], Taylor B. Cavazos[1], Nae-Chyun Chen[1], Noura K. Tbeileh[1], David Siegel[1], Amir Momen-Roknabadi[1], Jennifer Yen[1], Jeremy Ku[1], Selina Chen[1], Diana Corti[1], Alice Huang[1], Dang Nguyen[1], Rose Hanna[1], Ti Lam[1], Seda Kilinc[1], Philip Murzynowski[1], Jieyang Wang[1], Xuan Zhao[1], Andy Pohl[1], Babak Behsaz[1], Helen Li[1], Lisa Fish[1], Kim H. Chau[1], Laura J. Van't Veer[2], Laura J. Esserman[2], Patrick A. Arensdorf[1], Hani Goodarzi[2], Fereydoun Hormozdiari[3], Babak Alipanahi[3]

[1]Exai Bio Inc., Palo Alto, CA,[2]UCSF, San Francisco, CA,[3]Exai Bio Inc., San Francisco, CA

Background: Approximately 1 in 8 women will be impacted by breast cancer in their lifetimes. Earlier detection of breast cancer through screening has improved survival. Liquid biopsies have the potential to complement existing screening methods by enabling earlier detection and differentiating invasive cancer (IBC) from ductal carcinoma in-situ (DCIS). We previously demonstrated high sensitivity and specificity for early detection of IBC by using a blood-based liquid biopsy platform to analyze a novel category of cancer-associated small RNAs, termed orphan RNAs (oncRNAs). Here, we developed a test that could not only detect the presence of cancer, but also classify the invasiveness of breast cancer.

Methods: We utilized The Cancer Genome Atlas (TCGA) small RNA profiles to discover a library of 20,538 oncRNAs that were significantly enriched among 1,103 breast tumors compared to 349 controls from normal tissues spanning multiple tissue sites, limited to female samples. The diagnostic performance of these oncRNAs was assessed in an independent cohort of serum samples from 708 women, including 380 breast cancer patients (221 IBC and 159 DCIS; mean age: 58.0 ± 13.4 years) and 328 age-matched controls (mean age: 58.4 ± 13.7 years). We sequenced the small RNA content from 1 ml of serum from these patients at an average depth of 21.6 million 50-bp single-end reads. We detected 19,736 (96%) of the breast cancer-specific oncRNA library within at least one sample in this cohort. We then trained a multi-class generative AI model using 5-fold cross-validation to predict IBC, DCIS, and absence of breast cancer (IBC or DCIS).

Results: Our oncRNA-based generative AI model achieved an overall AUC of 0.95 (95% CI: 0.94-0.97) for prediction of breast cancer versus cancer-free controls. At 90% specificity, overall model sensitivity is 90.0% (86.5%-92.8%). For DCIS and stage I IBC, the model has a sensitivity of 88.1% (82.0%-92.7%) and 90.4% (81.9%-95.8%) respectively, both at 90% specificity. In the second step, restricting to samples flagged as cancer, we observed an overall AUC of 0.9 (0.87-0.93) and sensitivity of 62.4% (55.3%-69.1%) at 90% specificity for discriminating against invasive breast cancer.

Conclusions: We have demonstrated the potential utility of oncRNAs as the foundation for a liquid biopsy platform for sensitive and accurate early detection of breast cancer. Our liquid biopsy assay has the potential to complement standard of care by not only detecting breast cancer but also differentiating IBC from DCIS.

#3679 Development and validation of prognostic signatures comprising neutrophil-specific long non-coding RNAs (LncRNAs) for predicting survival in urothelial carcinoma.

H. Y. Su, C.-T. Lin, S.-Y. Huang, Y.-H. Chen, C.-W. Kuo;
Kaohsiung Chang Gung Memorial Hospital, Kaohsiung, Taiwan

Background: Tumor-associated neutrophils profoundly influence the tumor immune microenvironment (TME), impacting urothelial carcinoma (UC) progression, metastasis, and survival. Long non-coding RNAs (lncRNAs) have emerged as critical players in cancer biology. Recognizing neutrophils as influential contributors to tumor biology, our study aimed to explore neutrophil-specific lncRNAs and evaluate their prognostic significance in UC.
Methods: In the GSE24890 dataset, 46 lncRNAs were identified with elevated expression in neutrophils compared to other immune cells, thus designating them as neutrophil-specific lncRNAs. To establish a tailored prognostic model, the TCGA BLCA dataset served as the internal training set. Candidate lncRNAs underwent filtration and selection through univariate Cox regression analysis, followed by the construction of a risk score employing LASSO and multivariate Cox regression algorithms. We used IMVigor210 dataset as external validation for this lncRNA model.
Results: Ten lncRNAs exhibiting correlation with overall survival (OS) were initially identified through univariate Cox regression. Following LASSO regression and subsequent multivariate Cox regression analysis, a refined set of 9 lncRNAs was selected to construct the risk model, represented by the formula: Risk score = (-0.096 × FAM13A-AS1 expression level) + (0.157 × FAM27C expression level) + (-0.294 × HCG27 expression level) + (-0.037 × HOTAIRM1 expression level) + (-0.137 × LINC-PINT expression level) + (-0.279 × LINC00612 expression level) + (-0.058 × LINC00967 expression level) + (0.187 × LINC01018 expression level) + (-0.288 × LINC01138 expression level). Kaplan-Meier survival analysis of the BLCA cohort revealed that patients in the high-risk group experienced significantly worse OS compared to those in the low-risk group ($p < 0.001$). The area under the curve (AUC) values at 1, 3, and 5 years were 0.66, 0.67, and 0.66, respectively. In the multivariate Cox regression model, the risk score remained an independent prognostic factor ($p < 0.001$; HR 2.5; 95% CI 1.91-3.30). The validity of the risk score was further confirmed in the IMVigor210 dataset, demonstrating discriminative predictive ability for OS between high- and low-risk groups ($p = 0.027$).
Conclusions: This study underscores the interplay between neutrophils and lncRNAs in UC. Neutrophil-related lncRNAs identified may serve as promising therapeutic targets and prognostic markers for UC.

#3680 Prognostic value of serum biomarkers in pancreatic adenocarcinoma: Results from a Swiss single center cohort analysis.

E. D. Chiru[1], M. Knufike[2], M. Sonderegger-Stalder[1], R. Mosimann[1], A. Sgries[1], R. Rosenberg[1], E. Burri[1], S. Mitrovic[1], M. Voegeli[1], K. Mertz[1], A. Angelini[1], M. Vetter[1];

[1]Cantonal Hospital Baselland, Basel, Switzerland, [2]Eidgenossische Technische Hochschule Zurich, Zurich, Switzerland

Introduction: Inflammatory and nutritional biomarkers, such as neutrophil to lymphocyte ratio (NLR), C-Reactive Protein (CRP), lactate dehydrogenase (LDH) and albumin, are valuable prognostic indicators, refining stratification strategies in oncological patients. This study aims to delineate the impact of these markers on overall survival in patients with pancreatic adenocarcinoma, in order to aid in clinical risk stratification.

Methods: We conducted a retrospective analysis on patients with adenocarcinoma of the pancreas, treated at the Cantonal Hospital Baselland (January 2018 - February 2022). Clinical data, including diagnosis, treatment, and blood markers, were extracted from electronic records. The analysis incorporated the computation of median values for each blood marker, followed by survival analysis and determination of Cox proportional hazard ratios with a 95% confidence interval.

Results: Our cohort included 43 patients, 53% women, 44% men, median age 73 years (IQR 14.75) with adenocarcinoma of the pancreas. Most patients (56%) had advanced distant disease and 25% of these did not receive any oncological therapy. At least one cycle of chemotherapy was administered in 85% of patients. NLR<4 was reported in 63% of cases, normal albumin levels in 72%, normal LDH levels in 79%, and normal CRP levels in 47%. In the multivariate Cox regression analysis, there was a significant higher risk for death with metastatic disease (HR 6.216 CI 2.00-19.28, p=0.002), age ≥75 (HR 4.88, CI 1.65-14.39, p=0.004) and CRP>10 (HR 3.38, CI 1.18-9.66, p=0.023) and lower risk with addition of chemotherapy (HR 0.076, CI 0.02-0.29, p<0.001). NLR, LDH and albumin levels did not significantly correlate with higher HR for death. At a median follow-up period of 8.5 months (IQR 14), the median overall survival was 9 months (IQR 14.5) with a worsening prognostic for increased CRP (p=0.00027), NLR>4 (p=0.051), albumin <35g/l (p=0.0024), LDH >250 U/l (p=0.037). Better survival rates were seen in patients receiving chemotherapy 75% vs 20 for those without chemotherapy (p<0.0001) and in those with local disease 80% vs 60% for metastatic disease p=0.034). Age ≥75 years carried a significant poorer prognostic (p=0.0017), while gender was not relevant. However, due to small sample size, age adjusted survival was not carried out and age was considered not relevant for the survival analysis.

Conclusion: Beyond the expected factors like stage of disease and therapy, an increased CRP appears to carry significant correlation with hazard ratio for death among patients with adenocarcinoma of the pancreas. In our cohort, abnormal CRP, NLR, albumin and LDH levels demonstrated significant association with shorter survival period, underscoring the potential utility of these biomarkers in prognostic stratification and their incorporation into routine oncological assessments.

#3681 Transcribed ultraconserved regions are associated with survival in multiple tumor types.

Ana Carolina Rodrigues[1], Douglas Adamoski[2], Daniela F. Gradia[1], **Jaqueline Carvalho de Oliveira**[1]

[1]Genetics, Federal University of Parana (UFPR), Curitiba, Brazil,[2]Brazilian Biosciences National Laboratory (LNBio), Brazilian Center for Research in Energy and Materials (CNPEM), Campinas, Brazil

Ultraconserved regions (UCRs), encompassing 481 genomic segments identical across humans, mice, and rats, and conserved in other species, are distributed across all human chromosomes except 21 and Y. Over 90% of these regions, termed transcribed ultraconserved regions (T-UCRs) are expressed in at least one human tissue. Although extensively studied in the context of cancer since their discovery, the prognostic significance of T-UCRs in a pan-cancer context has not been explored. For this, TCGA data extracted from the TANRIC platform was utilized, differential expression and survival analysis was performed on different tumor types. Our analysis revealed that approximately 300 UCRs were expressed in the majority of the 20 tumor tissues. Additionally, it was noted that all examined tumor tissues expressed a higher number of UCRs compared to their non-tumor counterparts. Through t-distributed stochastic neighbor embedding (t-SNE) analysis, UCR expression patterns could distinguish primary tumor origins and types. Regarding the prognostic value, we identified 100 (20,8%) T-UCRs associated with disease-specific survival (DSS) and 102 (21.2%) T-UCRs associated with progression-free interval (PFI). Those T-UCRs are particularly important in the survival outcomes of kidney renal clear cell carcinoma (KIRC) and low-grade gliomas (LGC). In addition, we verified that uc.44, uc.48, uc.135, uc.144, uc.153, uc.217, uc.255, uc.256, uc.344, uc.357, uc.390, uc.427 and uc.436 were associated with survival of more than one tumor. Particularly, uc.135 high expression was associated with poor prognosis in Kidney Renal Papillary Cell Carcinoma (KIRP) and LGC, and good prognosis in KIRC. Uc.135 are mapped on MECOM gene, coding an oncoprotein acting as transcriptional regulator and involved in apoptosis, proliferation, and cell differentiation. Our findings suggest that analysis of T-UCRs expression have the potential to be used as predictive biomarkers and can help in studying the mechanisms and specific roles of the highlighted T-UCRs in cancer.

#3682 Pre-surgical blood metabolites associated with ovarian cancer prognosis.

N. Lin[1], O. A. Zeleznik[1], J. Avila-Pacheco[2], C. B. Clish[2], A. F. Vitonis[1], D. W. Cramer[1], K. L. Terry[1], N. Sasamoto[1];
[1]Brigham and Women's Hospital, Boston, MA, [2]Broad Institute of MIT and Harvard, Boston, MA

Background: Ovarian cancer has a poor prognosis with a 5-year survival less than 50%, resulting > 14,000 deaths in the US annually and > 150,000 globally. Identifying prognostic biomarkers at time of diagnosis and elucidating the biological dysregulation among those who are more likely to progress after first-line treatment could inform personalized treatment strategies. Thus, we evaluated metabolites and metabolomic profiles in pretreatment blood associated with survival in women with high-grade serous ovarian cancer, the most common and most deadly histologic subtype.
Method: We examined plasma metabolites in blood samples collected prior to ovarian cancer treatment in 80 high-grade serous ovarian cancer patients who participated in the PreOperative Pelvic Mass Study, a clinic-based study enrolling women undergoing surgery for a pelvic mass. Liquid chromatography tandem mass spectrometry was used to measure 524 known metabolites. We excluded metabolites with coefficient of variation ≥ 25% (n = 104), then removed metabolites with missing in > 20% of the samples (n = 3). Metabolites missing in < 20% of the samples were imputed to be half the minimum value for that metabolite, resulting in 417 unduplicated metabolites. All metabolite values were transformed to probit scores to achieve normality. Cox proportional hazard models were used to calculate the hazard ratios (HRs) and 95% confidence intervals (CIs) adjusting for age at diagnosis, body mass index (BMI), and stage. False discovery rate (FDR) was used for multiple testing correction. Metabolite set enrichment analysis (MSEA) was used to identify metabolite classes associated with prognosis.
Results: Overall, none of the individual metabolites were significantly associated with survival after multiple testing correction (FDR > 0.05). However, 32 metabolites were associated with survival with p< 0.05, with 12 metabolites being associated with worse survival (HR range: 1.38 - 1.98) and 20 metabolites being associated with better survival (HR range: 0.54 - 0.73). MSEA revealed triglycerides (normalized enrichment score (NES) = 3.14), cholesteryl esters (NES = 2.43), and phosphatidylcholines (NES = 2.30) were positively associated with risk of death (FDR < 0.001). Steroids and steroid derivatives (NES = -1.93), sphingomyelins (NES = -2.45), and carnitines (NES = -2.27) were negatively associated with risk of death (FDR < 0.001). Diglycerides (NES = 1.96), lysophosphatidylethanolamines (NES = 1.72), and phosphatidylcholine plasmalogens (NES = 1.58) were positively associated and phosphatidylethanolamines (NES = -1.93) was negatively associated with risk of death with FDR < 0.05.
Discussion: In this study, we explored plasma metabolites associated with mortality in high-grade serous ovarian cancer patients and observed multiple classes of lipid-related metabolites being associated with worse prognosis.

#3683 Prognostic value and biological correlates of LINE1 hypomethylation in oropharyngeal cancer.

M. Casarotto[1], R. Guerrieri[1], P. Boscolo-Rizzo[2], M. Schiappacassi[1], S. D'Andrea[1], V. Lupato[3], S. Chiocca[4], M. Tagliabue[4], R. De Berardinis[4], A. Menegaldo[5], A. Piccinato[6], P. Stritoni[6], M. Ansarin[4], D. Politi[6], G. Fanetti[1], G. Giurato[7], J. Polesel[1], **E. Fratta**[1];

[1]Centro di Riferimento Oncologico di Aviano (CRO), IRCCS, Aviano, Italy, [2]University of Trieste, Trieste, Italy, [3]Santa Maria Degli Angeli General Hospital, Pordenone, Italy, [4]European Institute of Oncology (IEO) IRCCS, Milano, Italy, [5]AULSS 2 Marca Trevigiana, Treviso, Italy, [6]AULSS 3 Serenissima, Mestre, Italy, [7]University of Salerno, Salerno, Italy

Background. We have recently demonstrated that LINE-1 hypomethylation is a negative prognostic factor in oropharyngeal squamous cell carcinoma (OPSCC). HPV-positive patients with LINE-1 methylation <55% showed an almost 5-fold higher risk of death than hypermethylated once, with an overall survival as poor as HPV-negative patients. Somatic *TP53* mutations are a common feature in HPV-negative OPSCC, whereas their presence has been reported in only a small subset of HPV-related OPSCC. At present, little is known about the correlation between LINE-1 methylation and p53 expression status and/or *TP53* mutation in OPSCC. **Methods**. Since 2019, an ongoing prospective study has been enrolling patients with OPSCC in nine cancer centers in Northern Italy. HPV16 E6 DNA was quantified using real-time quantitative PCR (qPCR). LINE-1 methylation was evaluated by methylation-specific qPCR. p53 expression was detected by immunohistochemical staining. *TP53* exon mutations were analyzed by Next Generation Sequencing. **Results**. Up to date, 134 OPSCC patients have been enrolled, including cancer of the tonsil (n=74; 55.2%), base of tongue (n=47; 35.1%), and other subsites (n=13; 9.7%). HPV16 DNA was found in 54.3% of cases: 65.7% in base of tongue, 57.1% in tonsil, and 16.7% in other subsites (p<0.001). LINE-1 methylation was higher in HPV16-positive patients (median: 55.8%, interquartile rage [IQR]: 42.5-68.5) than HPV16-negative ones (median: 40.7; IQR: 23.9-59.1; p=0.003). Nevertheless, the median LINE-1 methylation was lower (50.7%) among HPV-16 OPSCC patients who relapsed than those who did not (56.0%), thus confirming the findings previously reported. However, data from the present investigation are presently not mature to purse the study aims (median follow-up: 12.3 months). The correlation between LINE-1 hypomethylation and p53 expression has also been evaluated in OPSCC patients. p53 expression was categorized into three groups (0%, 1-49%, and ≥50%) based on the overall intensity of nuclear staining of the tumor cells. p53 was considered null, overexpressed, or wild type when its nuclear staining was 0 %, ≥50%, or ranged between 1% and 49%, respectively. Of note, the highest level of LINE-1 methylation was observed in OPSCC tissues with nuclear p53 staining between 1% and 49% (57.8%), whereas OPSCC patients with p53 expression ≥50% showed a decline of LINE-1 methylation levels (40.6; p=0.026). Interestingly, LINE-1 methylation was lower in OPSCC patients harboring *TP53* mutations in both HPV16-negative (24.8%) and HPV16-positive (24.0%) OPSCC patients, even if statistical significance was reached only in the HPV-negative group (p=0.015). **Conclusion**. Preliminary results confirm the potential of LINE-1 methylation to identify HPV16-positive patients with poor prognosis. In addition, this study suggest that *TP53* mutations might influence LINE-1 methylation, irrespective of HPV status.

#3684 Comprehensive error suppressing approach allowing enhanced minimal residual disease detection in lung cancer patients.

H. Bao[1], F. Meng[2], Z. Xia[2], Q. Sun[2], S. Wang[2], W. Tang[1], N. Li[1], M. Wu[1], J. Zhang[1], B. Zhu[1], D. Zhu[1], X. Wu[1], R. Yin[2], Y. Shao[1];
[1]Nanjing Geneseeq Technology Inc., Nanjing, China, [2]Department of Thoracic Surgery, Jiangsu Key Laboratory of Molecular and Translational Cancer Research, Jiangsu Cancer Hospital & Nanjing Medical University Affiliated Cancer Hospital & Jiangsu Institute of Cancer Research, Nanjing, China

Objective: Identifying minimal residual disease (MRD) in postoperative lung cancer patients is crucial for timely cancer intervention. However, current fixed panel methods suffer from low sensitivity, whereas personalized panels face challenges as long yield time and require patient tissue samples. Our objective was to develop an accurate and efficient method for detecting circulating-tumor DNA (ctDNA) in post-surgery lung cancer patients.
Methods: The study retrospectively enrolled 39 lung cancer patients (14 relapse, 25 non-relapse) with 63 post-surgical plasma samples. The mutational profiles of cell-free DNA (cfDNA) were obtained using SHIELDINGTM ULTRA Panel by Geneseeq, covering hotspots in 2365 cancer-associated genes. A comprehensive error suppressing algorithm, which combines intra-run sampling adaptive noise control, cfDNA fragment profiling, normal pool, and white blood cell background, was utilized to eliminate the background artifacts. The plasma ctDNA status were identified under both tumor-informed and tumor-naïve scenarios.
Results: Our method yielded results on par with personalized panels, achieving a sensitivity of 85.7% at the specificity of 92.0%, with a negative predictive value (NPV) of 92.0% in longitudinal analysis. The ctDNA positive patients had a 21-fold increased risk (Hazard Ratio [HR] = 20.7, p = 9.2 ×10^(-5)) compared to the ctDNA negative patients. Remarkably, the landmark analysis using 39 samples (<= 7 days post-surgical) showed a 57.1% sensitivity at 100.0% specificity. Patients with a landmark (<= 7 days post-surgical) ctDNA positive status showed an increased risk of 16.2 times (HR = 16.2, p = 3.5 ×10^(-6)). Furthermore, we found that our approach could maintain its level of performance under tumor-naïve scenario, showing HRs of 12.7 (p = 1.3 ×10^(-4)) for longitudinal ctDNA positive patients and 12.3 (p = 3.7 ×10^(-5)) for landmark ctDNA positive patients. The ctDNA status determined by the tumor-informed and tumor-naïve approaches showed a substantial agreement, yielding a concordance of 90.5% (Cohen's Kappa = 0.738).
Conclusion: Herein, we report a comprehensive error suppressing approach for removing background artifacts by fixed MRD panel, allowing an enhanced MRD detection in post-surgical lung cancer patients. Our approach, which accurately identified ctDNA status at a cost-effective rate, outperformed other fixed panels while showing comparable performance with personalized panels. Furthermore, our method can be utilized under tumor naïve scenarios when personalized panels are unfeasible in the absence of tumor information. Finally, the faster turnout time of fixed panel makes our approach more suitable for clinical landmark MRD detection than a personalized panel.

#3685 Improved detection of minimal residual disease in colorectal cancer patients using adaptive noise cancellation algorithm.

H. Bao, W. Tang, N. Li, M. Wu, J. Zhang, B. Zhu, X. Wu, Y. Shao;
Nanjing Geneseeq Technology Inc., Nanjing, China

Objective: Existing methods for detecting circulating-tumor DNA (ctDNA) through fixed panels exhibit constrained sensitivity, while customized panels are time-consuming and rely on prerequisite tumor mutation profiles. Here, we aimed to introduce an adaptive noise cancellation approach for efficient Minimal Residuals Disease (MRD) detection in colorectal cancer patients employing a fixed panel under both tumor-informed and tumor-naïve situations.
Methods: 108 plasma samples were collected from 52 colorectal cancer patients (11 relapse, 41 non-relapse) at various post-surgical timepoints. Comprehensive mutational profiling of plasma samples was conducted using a fixed MRD panel (SHIELDINGTM ULTRA) that encompasses hotspots in 2365 cancer-related genes. Background errors were removed by an adaptive noise cancellation algorithm relying on DNA fragment profiling, normal pool, and white blood cell background and intra-run plasma sampling. Variants were called both with (tumor-informed) and without (tumor-naïve) the present of tumor tissue.
Results: Our longitudinal analysis of 108 plasma samples yielded 90.9% sensitivity, 97.6% specificity and 97.6% negative predictive value in the tumor-informed scenario. The ctDNA positive patients exhibited significantly higher risk than those with negative ctDNA status (Hazard Ratio = 87.2, p = 3.5×10^(-5)). For landmark analysis, 33 plasma samples (≤7 days post-operation) were assessed, yielding a remarkable performance of 66.7% sensitivity and 100% specificity. Our approach showed robustness under tumor-naïve scenario, illustrating 90.9% sensitivity, 92.7% specificity and 97.4% NPV for the longitudinal analysis. This corresponded to an increased risk of 49 times in the ctDNA positive patients (HR = 49.0, p = 2.2×10^(-4)). Notably, the results of tumor-naïve samples closely aligned with those of tumor-informed samples, showing a concordance of 92.6% and substantial agreement (Cohen's Kappa = 0.691).
Conclusion: Our method stands as an ultra-sensitive tool for identifying colorectal patients at high risk of recurrence. By employing an adaptive noise cancellation algorithm, our fixed panel approach demonstrates superiority over existing fixed panels in accuracy and proves to be a cost-effective alternative to personalized panels. Significantly, it extends potential clinical utilization towards tumor-naïve patients, which is not feasible for personalized panels.

CLINICAL RESEARCH: Circulating Tumor Cells 1
Poster Session

#3689 Optimizing CTC isolation techniques for molecular characterization of circulating tumor cells in clear cell renal cell carcinoma: A comparative study of EpCAM-based and density-based methods.

Joanna Bialek, Anne Muthe, Stefan Yankulov, Felix Kawan, Georgios Gakis, **Gerit Theil**

University Clinic and Outpatient Clinic for Urology, Medical Faculty of Martin Luther University Halle-Wittenberg, Halle (Saale), Germany

Introduction: Renal cell carcinoma (RCC) belongs to the most invasive cancers with the high molecular intrapatient heterogeneity. Circulating tumor cells (CTCs) are cells that detach from the tumor, reflecting the activity of the metastatic procedure. The most popular CTCs isolation methods are based on EpCAM signal detection on epithelial tumor cells. The clear cell RCC (ccRCC) originate from epithelial entity, since that is the EpCAM-based method suitable to isolate CTCs in this cancer. However, the prone of CTCs to EMT is known, which may in consequence downregulate the EpCAM expression and change the cell profile (hybrid phenotype). This is one of the points challenging the CTCs isolation by RCC disease. In our study, we compare the effectivity of antibody-based and density-based isolations technics in ccRCC patients to detect potential markers in CTCs.
Purpose: Our aim was to find a precise and costs effective method to isolate and characterize CTCs from ccRCC patients.
Materials and Methods: Prospective blood samples (3mL) from pulmonary and/or osseous metastatic ccRCC patients were collected during the immunotherapy and from the healthy donors. CTCs were isolated using EpCAM beads (RCC n=13; healthy n=15) or density-based (RCC n=13; healthy n=15) method. Expression of potential RCC biomarkers (mucin-1 (Muc1), androgen receptor (AR)) was identified using qPCR (Real-Time PCR) followed by dPCR (digital PCR), the results status received from both methods was evaluated.
Summary: Based on our prior results, we first isolated CTCs based on EpCAM beads. Using qPCR we analyzed expression of genes, which we previously associated to the RCC (Muc1, PD-L1, AR). The results revealed differences in Muc1 (40% of tested patients positive but none of the healthy donors), when PD-L1 did not differed and AR was not detected. Applying more precise dPCR did neither show any expression. We continued our investigations with isolation of CTCs using density-based method. We confirmed more frequent expression of Muc1 by RCC Patients than by donors, as in our EpCAM cohort. PD-L1 was similar in both groups. Results of AR obtained using qPCR were confusing, showing deviations within same patients. The use of dPCR displayed significant differences in expression between RCC patients (77%; median [range] 0.28 [0.00 - 0.62] and donors (60%; 0.04 [0.00 - 0.51] confirming dPCR as optimal tool for molecular CTC characterization.
Conclusions: Based on our results we demonstrate higher expression of Muc1 and AR in CTCs of metastatic ccRCC patients. The isolation technic should be adapted to the disease status and treatment choice. Further investigations confirming Muc1 and AR as ccRCC biomarkers are required.

#3690 Monitoring prostate specific membrane antigen or androgen receptor expression on circulating stromal cells in advanced prostate cancer patients and their correlation with patient response.

D. M. Kasabwala[1], R. C. Bergan[2], R. Alpaugh[3], D. C. Danila[4], T. L. Chuang[4], B. Y. Hurtado[4], D. L. Adams[5];
[1]Rutgers, The State University of New Jersey, New Brunswick, NJ, [2]University of Nebraska Medical Center, Omaha, NE, [3]Fox Chase Cancer Center, Philadelphia, PA, [4]Memorial Sloan Kettering Cancer Center, New York, NY, [5]Creatv MicroTech, Inc., Monmouth Junction, NJ

Background: Metastatic Prostate cancer (mPCa) mortality rates are high despite numerous treatment options against various mechanisms of action, including targeted therapies, i.e. prostate specific membrane antigen (PSMA)-targeted therapy (Pluvicto) or anti-androgen receptor (AR) (Enzulamide, Biculamide). Further, tumor biomarkers (i.e. PSMA and AR) can change over time and with resistance mechanisms that develop after treatments. This suggests that primary biopsies may not represent later PCa tumors necessitating a way to identify patients that may respond to later line therapies. Blood based biopsies can be used to monitor PCa treatment, which can include circulating tumor cells (CTCs) and the newly discovered cancer associated macrophage like cells (CAMLs), a cancer specific circulating phagocytic stromal cells. Interestingly, while PSMA & AR have been identified in CTCs, they have not been evaluated in CAMLs, nor have PSMA & AR expressions in CTCs & CAMLs been evaluated in anti-AR therapy settings. We measured CAMLs & CTCs in mPCa to evaluate their PSMA & AR expression, including in patients treated with anti-AR therapy.
Methods: We evaluated CAMLs & CTCs in a multi-institutional prospective pilot study using n=30 mPCa patients with progressive disease, prior to starting a new line of therapy (T0). Whole peripheral blood (7.5mL) was filtered for CAMLs & CTCs and stained for PSMA (n=15) & AR (n=15). In addition, 15 patients were treated with anti-AR therapy as standard of care and responses by PET/CT were compared against AR expression. When possible, follow up samples (T1) were also procured.
Results: CTCs were identified in 16% (n=5/30) of patients and CAMLs were identified in 96% (n=29/30), with 53% of patients having hyperengorged CAMLs ≥50 µm (n=16/30). CTCs in patients were not statistically significant for worse outcomes PFS HR= 0.1748, p=0.546 nor OS (HR= 1.303, p=0.865), nor were CAMLs prognostic for PFS or OS. However, patients with ≥50 µm CAMLs did have significantly worse PFS (HR= 5.9, CI95% 2.2-16.3, p=0.001) and worse OS (HR= 3.1, CI95% 1.3-7.1, p=0.016). Further, PSMA CAML/CTC expression was high in 60% (n=9/15) of patients and AR CAML/CTC expression was high in 53% (n=8/15). Of the n=15 patients who received anti-AR therapy after T0, high AR expressing CAMLs/CTCs (n=8/15) had a ~250% better mPFS of 10.3 months (mons) (progressing at 2.2-32.6 mons) vs low AR CAMLs/CTCs mPFS of 4 mons (progressing at 0.2-7.2 mons). Additional mOS analysis from T1 samples and 2-year survival is ongoing.
Conclusion: We utilized liquid biopsies to monitor the expression of two common cell surface receptors (PSMA & AR) in CAMLs and CTCs in mPCa. Further, in a small subset of patients treated with AR therapy, high AR CTC/CAML expression appeared to correlate with better response rates, though larger prospective studies are needed.

#3691 Molecular profiling using next generation sequencing with high purity enrichment of circulating tumor cells.

S. Park, J. Choi, **A. Jeong**, H. Kim, J. Oh, I. Jang, H. Kang, J. Lee, S. Pak, M.-J. Song, J. Kim, H.-C. Lee;
Cytogen Inc., Seoul, Korea, Republic of

Purpose: In the area of liquid biopsy, coupled with next generation sequencing (NGS), circulating tumor cells (CTCs) and circulating tumor DNA (ctDNA) can serve as an alternative substrate to tumor tissue for mutation detection and companion diagnostic purpose. Emerging evidence shows that complementary sequential CTCs and ctDNA profiling provide promising benefit for prognosis and treatment. In contrast to well-established ctDNA extraction methods, the process of isolating intact CTCs for NGS analysis is yet to be fully elucidated. Here, we show that the isolation and harvest of viable CTCs by CytoGen's Smart Biopsy™ System enable the attainment of sufficiently high purity for NGS analysis in metastatic breast cancer.

Methods: Targeted panel sequencing for CTC was developed to detect representative mutated genes, using the Oncomine™ Comprehensive Assay Plus (501 genes) and the Oncomine™ Pan-Cancer Cell-Free Assay (52 genes). Analytical validation was performed with breast cancer cells MDA-MB-231 (50 to 5 cells) which were spiked into 5 mL healthy blood, to mimic CTC. The CytoGen's Smart Biopsy™ system was applied to isolate the CTC. Then, CD45 depletion and whole genome amplification were performed. Sequencing was carried out on Ion S5™ XL systems using an Ion 550™ Chip Kit. Subsequently, sequencing data was analyzed using Ion Torrent software with default configurations.

Results: As a result of targeted panel sequencing using Oncomine™ Comprehensive Assay Plus, representative mutated genes (*BRAF*, *KRAS*, *TP53*, *NF2 and NOTCH3*) in breast cancer were detected in at least 20 MDA-MB-231 cells. In the results using Oncomine™ Pan-Cancer Cell-Free Assay, mutated genes (*BRAF*, *KRAS* and *TP53*) were successfully detected even with only 5 MDA-MB-231 cells. These results suggest that clinical sample of breast cancer could be applied with promising sensitivity and specificity for detection of representative mutated genes.

Conclusion: Molecular analysis of CTCs is a challenge since CTCs are very rare in the blood and there are technical limitations in isolating CTCs with sufficient purity. In this study, we developed the process for NGS analysis on very low number of CTCs with high purity, isolated using CytoGen's Smart Biopsy™ system. Overall, these process could provide information for diagnosis and appropriate treatment of metastatic breast cancer along with the results of our ongoing clinical trials.

#3692 Genomic profiling with the novel single-cell IMPACT assay reveals evidence of genetic heterogeneity among CTCs in late-stage breast cancer patients.

Zbigniew T. Czyż[1], Clara Chaiban[1], Adithi Ravikumar Varadarajan[2], Cacilia Kostler[1], Vadim Dechand[2], Jonas Grote[3], Thomas Ragg[3], Bernhard Polzer[2], Jens Warfsmann[2], Christoph A. Klein[1]

[1]Experimental Medicine and Therapy Research, University of Regensburg, Regensburg, Germany,[2]Division of Personalized Tumor Therapy, Fraunhofer Institute for Toxicology and Experimental Medicine, Regensburg, Germany,[3]quantiom bioinformatics GmbH & Co. KG, Weingarten, Germany

Introduction: Liquid biopsy enables minimally invasive molecular profiling of systemic cancer for diagnosis, therapy selection and longitudinal monitoring of minimal residual disease. Cell-based liquid biopsy methods are particularly well suited to examine the extent of genetic heterogeneity and clonal diversity among metastatic cancer cells, which are believed to be the major determinants of therapeutic failure. However, isolation and molecular profiling of circulating tumor cells (CTCs) from body fluids is challenging due to methodological constrains.

Methods: To overcome these challenges, we have developed a workflow for detection, isolation, and mutational profiling of CTCs. The workflow utilizes the FDA-approved CellSearch System® and a novel method for single-cell Integrated Mutation Profiling of Actionable Cancer Targets (scIMPACT). Our workflow was optimized for reliable detection of copy number variations (CNVs) and single nucleotide variations (SNVs) in single CTCs. The method was then applied to 31 CTCs alongside with 15 matched germline samples.

Results: After implementation of a customized Bayesian neural network based algorithm, accounting for biases introduced during amplification of single-cell DNA and prioritizing the detected mutations, we achieved a sensitivity of 91% and a specificity of 96%, AUC = 0.98. The CTC analysis revealed presence of CNVs affecting known oncogenes and tumor suppressor genes (including *MYC*, *CCND1*, *FGF4*, *TP53* and *RB1*) as well as SNVs classified as pathogenic (e.g., ARID1A Q775*). Notably, in the examined specimens most of the chromosomal aberrations (51-82%) were clonal across all cells of a given patient. In contrast, most of the detected somatic SNVs (67-96%) were sub-clonal and thus present only in a subset of CTCs.

Conclusion: In summary, the novel scIMPACT workflow enabled reliable and accurate genomic profiling of patient-derived CTCs in late-stage breast cancer patients. Our proof-of-concept study revealed evidence of genetic diversity of SNVs among the examined CTCs, which might have been acquired late in progression but relevant for therapy escape in the studied cases. Further analyses are still needed for assessing the generalizability of our finding as well as for deeper understanding of the molecular basis orchestrating the establishment and maintenance of heterogeneous genotypes of CTCs in breast cancer.

#3693 Molecular and functional characterization of circulating CK+/CD45+ cells in breast cancer.

C. Reduzzi[1], E. Nicolo`[1], L. L. Ozimski[2], M. Silvestri[3], L. Gerratana[4], M. S. Serafini[1], E. Molteni[4], N. Bayou[1], A. K. Strickland[1], H. Liu[5], V. Cappelletti[3], N. Aceto[2], M. Cristofanilli[1];

[1]Weill Cornell Medicine, New York, NY, [2]ETH Zurich, Zurich, Switzerland, [3]Fondazione IRCCS Istituto Nazionale Tumori, Milano, Italy, [4]Universita` degli Studi di Udine, Udine, Italy, [5]Northwestern University, Chicago, IL

Background: Circulating tumor cells (CTCs) are considered a key element in metastatic progression and represent a validated prognostic biomarker in breast cancer (BC). CTCs in BC are normally defined as epithelial cells (positive for EPCAM or cytokeratin, CK) lacking the expression of the leukocyte marker CD45. Circulating cells expressing both EPCAM/CK and CD45 (dual positive, DPcells) have however been reported in BC but not investigated. It is believed that DPcells derive from the heterotypic cell fusion of tumor and immune cells, but this hypothesis has not been demonstrated yet. We recently reported, for the first time, the association of DPcells with worse survival in a cohort of 341 BC patients (pts) [Reduzzi et al. ASCO 2022] supporting their tumor origin. Here, we further investigated their malignancy and metastatic potential by molecular profiling and functional experiments.

Methods: The study consisted of 2 components: A) Single CTCs and DPcells were enriched from the blood of BC patients with the CellSearch platform, and isolated with the DEPArray system. Single cells underwent whole genome amplification and lowpass whole genome sequencing for single cell copy number alteration (CNA) profiling; B) DPcells and CTCs were investigated in the blood of immunodeficient (NSG) and immunocompetent (FVB) mouse models using various cell lines (LM2, 4T1, MVT1). To test their metastatic potential, DPcells from the primary tumor of FVB donor mice were transplanted into recipient NSG mice, and the metastatic burden in the lungs and liver quantified, in comparison with control CD45- tumor cells.

Results: We analyzed 73 DPcells and 18 CTCs collected from 16 BC pts: Aberrant genomes were observed in 28% and 93% of evaluable cells, respectively. When collected from the same pt, CTCs showed clonal CNA profiles, while DPcells were highly heterogeneous. *In vivo*, DPcells could only be detected in the blood of FVB mice but not in NSG mice. They were very rare, comprising of only about 3% of the total CTC count. When DPcells and control tumor cells were isolated from the primary tumor of 10 donor mice and transplanted into the tail vein of 10 recipient mice, we observed no significant differences in the metastatic colonization of the lungs and liver by the two population, indicating that DPcells do in fact possess metastatic ability, and to a similar extent as control cancer cells.

Conclusions: DPcells can have an aberrant genome, supporting their malignancy. Contrary to CTCs, DPcells' CNA profiles are not clonal and, i*n vivo*, they can only be observed in immunocompetent models; both observations support the tumor/immune fusion hypothesis. Finally, DPcells show metastatic potential in mice, in line with the association with worse survival we previously observed in BC pts. Overall DPcells seem a new CTC subpopulation that should not be neglected anymore. More studies are needed to better understand their origin and phenotypic/molecular features.

#3694 Genomic profiling of single cancer cells using the novel single-cell integrated mutational profiling of actionable cancer targets (scIMPACT) assay.

C. Chaiban[1], A. Ravikumar Varadarajan[2], J. Grote[3], T. Ragg[3], I. Blochberger[1], V. Dechand[2], J. Warfsmann[2], C. A. Klein[1], Z. T. Czyż[1];
[1]University of Regensburg, Regensburg, Germany, [2]Fraunhofer ITEM-R, Regensburg, Germany, [3]Quantiom Bioinformatics GmbH & Co. KG, Weingarten, Germany

Liquid biopsy provides opportunities to guide therapy decisions using biomarkers such as circulating tumor cells (CTCs) even years after the primary tumor resection. For this, novel methods permitting the genomic profiling of CTCs are needed to characterize systemic cancer spread and identify clinically targetable genomic alterations. Hence, we developed an assay based on the FDA-approved MSK-IMPACT® assay to analyze the genomes of single-cells. We present a series of benchmarking experiments using well-characterized cell lines to demonstrate the performance of our new Single-Cell Integrated Mutation Profiling of Actionable Cancer Targets (scIMPACT) assay.The scIMPACT assay was developed using Ampli1® WGA products of single-cell and pool samples. The workflow consists of an optimized library preparation protocol followed by targeted sequencing with the scIMPACT panel. A bioinformatics mutation calling workflow facilitates the detection of single nucleotide variations (SNVs), indels, and copy number variations (CNVs). To account for WGA associated bias, we developed an in-house proprietary machine learning based classifier algorithm. Two sample collectives were prepared and used for training and validating the workflow. The first collective, including genomic libraries of MDA-MB-453, BT474, BT549 and ZR-75.1 samples, was used for training of the mutation detection workflow. The second collective, consisting of HCC1395/HCC1395BL cell lines representing matched tumor and normal cells, was used to validate the performance of the assay. The scIMPACT assay identified somatic mutations in all WGA products as predicted from bulk gDNA samples and published literature. Notably, evidence of genetic heterogeneity was reported at the single cell level. Pertaining to the SNV detection, the training collective displayed 91% sensitivity and 96% specificity (AUC=0.98) while the validation collective demonstrated similar performance with 84% sensitivity and 96% specificity (AUC=0.90) proving the applicability of our workflow across different datasets. Furthermore, CNV analysis showed high concordance between matching gDNA and WGA samples. Our workflow enables mutational profiling with high specificity and sensitivity and accurate CNV detection in single cells. The scIMPACT assay has been successfully adapted to analyze samples at the single-cell level. Therefore, our method can be applied for the genomic profiling of patient-derived CTCs.

#3695 Monitoring response to immunotherapy using cell free DNA fragmentomes.

B. Alipanahi[1], L. Sivapalan[2], J. Medina[1], Z. L. Skidmore[1], P. Ghanem[2], E. Peters[1], G. Pereira[2], N. Rao[2], K. Velliangiri[2], A. Konicki[1], S. Cristiano[1], L. Millberg[1], J. Carey[1], K. Lumbard[1], N. Niknafs[2], B. Chesnick[1], J. Tom[1], A. Leal[3], B. Levy[2], P. Forde[2], P. Bach[1], N. C. Dracopoli[1], R. B. Scharpf[2], V. Velculescu[2], L. Rinaldi[1], V. Anagnostou[2];

[1]Delfi Diagnostics Inc., Baltimore, MD, [2]The Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins University School of Medicine, Baltimore, MD, [3]NYU Grossman School of Medicine, New York, NY

BACKGROUND: The rapid detection of disease progression in patients receiving immune checkpoint inhibitors (ICIs) is challenging since there are no reliable biomarkers of clinical response. Liquid biopsy assays may address this unmet need by using cell-free DNA (cfDNA) to monitor treatment responses. Current targeted next-generation sequencing cfDNA assays are costly and have limited assay sensitivity for detection of cancer-specific mutations at low mutant allele frequency (MAF). Here, we demonstrate the utility of DELFI Tumor Fraction (DELFI-TF), a tumor- and mutation-independent cfDNA fragmentome approach to monitor treatment response in patients with metastatic non-small cell lung cancer (mNSCLC).

METHODS: Overall, 422 longitudinal blood samples were collected from 141 mNSCLC patients of which 109 were treated with immunotherapy and 32 with targeted therapy (TT). Plasma-derived cfDNA was processed with whole genome sequencing at low coverage (~4x). Circulating tumor burden was quantified as the maximum MAF (maxMAF) of tumor-derived variants detected using a 500+gene panel. Matched white blood cells were used to filter out germline and clonal hematopoietic variants. A random forest regression model was trained with maxMAF as the response using fragmentation-derived features. The accuracy of DELFI-TF was assessed using leave one patient out cross-validation in the ICI cohort and holdout validation in the cohort of patients receiving TT. For survival analyses, we used the median baseline scores to define low/high DELFI-TF and maxMAF.

RESULTS: In the ICI cohort, DELFI-TF scores were strongly correlated with the maxMAF ($r=0.94$, $p<0.001$, Pearson). At baseline, DELFI-TF and maxMAF both differentiate responding from non-responding tumors ($p = 0.01$ and $p = 0.001$ for DELFI-TF and maxMAF respectively; Wilcoxon). Patients with high DELFI-TF or maxMAF had significantly shorter progression-free survival (PFS) compared to low DELFI-TF or maxMAF (17.0 vs 4.7 months, $p < 0.001$; 17.0 vs 4.6 months, $p < 0.001$; Log-Rank respectively) and similar overall survival (OS) (DELFI-TF high 11.4 vs low 34.1 months, $p<0.001$; maxMAF high 10.9 vs low 34.1 months, $p < 0.001$, Log-Rank). Changes in DELFI-TF and maxMAF at the earliest timepoint were highly correlated ($n=109$; $r=0.90$; Pearson). In the validation cohort of TT patients, DELFI-TF at baseline outperformed maxMAF in distinguishing patients with PFS and OS benefits (DELFI-TF PFS 36.4 vs 11.5 months, $p = 0.03$; maxMAF PFS 21.9 vs 15.9 months, $p=0.6$; Log-Rank) (DELFI-TF OS high 37 months vs low not reached (NR), $p < 0.05$; Max MAF OS high 37 vs NR, $p = 0.1$, Log-Rank). The majority of TT patients (81%) had consistent changes with DELFI-TF and maxMAF from baseline to the earliest timepoint.

CONCLUSIONS: DELFI-TF is a tumor and mutation independent approach that is cost-efficient with high performance comparable to current ctDNA assays for estimating tumor burden and monitoring response in cancer patients.

#3696 Liquid biopsy biomarker analysis during treatment with ^{177}Lu-PSMA-617 in castrate resistant prostate cancer.

J. M. Sperger, M. N. Sharifi, L. Nunamaker, V. Carreno, A. H. Chang, S. R. Reese, C. Linebarger, A. K. Taylor, G. C. Bliitzer, J. Floberg, S. G. Zhao, J. M. Lang; University of Wisconsin-Madison, Madison, WI

Background: Prostate-Specific Membrane Antigen (PSMA) is a highly expressed prostate cancer (PCa) cell surface protein regulated by androgen receptor signaling and the target of the recently approved radioligand therapy ^{177}Lu-PSMA-617. While some patients have dramatic responses to this therapy, rates of upfront or acquired resistance are high even in patients with PSMA-PET-avid disease, and better biomarkers of ^{177}Lu PSMA-617 response and resistance are needed to select patients more effectively for this therapy. To address this need, we evaluated the relationship between longitudinal circulating tumor cell (CTC) androgen signaling and PSMA expression to ^{177}Lu-PSMA-617 response or resistance in patients with metastatic prostate cancer. We leveraged a CTC androgen signaling signature that we have previously shown is prognostic for patients with metastatic prostate cancer treated with AR signaling inhibitors.
Methods: Longitudinal blood samples were collected from 20 patients for circulating tumor cell (CTC) analysis at C1D1, C2D1, C4D1, and C6D1. CTCs were isolated with antibodies to EpCAM followed by parallel enumeration, analysis of cell surface expression of PSMA and RNA extraction for AR or neuroendocrine marker transcriptional profiling.
Results: CTC samples were assessed for PSMA cell surface protein expression prior to treatment and on treatment. *FOLH1* (PSMA) gene expression was detected from CTCs at baseline that persisted through treatment. Gene expression representative of AR pathway activation was present in 70% of the cohort at baseline and 50% of patients at C2D1. Concordant with these observations, no significant decrease in CTC number or PSMA protein expression was seen from baseline to C2D1. However, increased CTC AR pathway activation at C2D1 was associated with increased mean serum PSA (155 vs 21.93 ng/ml) and was associated with decreased duration of response.
Conclusions: Improved tools to predict who will respond to ^{177}Lu-PSMA-617 and detect early treatment resistance and disease progression are needed. Here, we show that persistent CTC burden, CTC AR signaling, and CTC PSMA expression are common early in treatment with ^{177}Lu-PSMA-617 and may be associated with lower likelihood of clinical response. Further ongoing studies are needed to elucidate the relationship between these liquid biopsy results and clinical outcomes.

#3697 Proof-of-concept study to enumerate large oncosomes using the RareCyte CTC platform.

E. Papp[1], J. Vandesompele[2], P. B. Vermeulen[3], L. Y. Dirix[3], M. Kockx[2];

[1]CellCarta, Montreal, QC, Canada, [2]CellCarta, Antwerp, Belgium, [3]GZA Hospital Sint-Augustinus & University of Antwerp, Edegem, Belgium

Introduction: Large oncosomes (LO) are produced by tumor cells and can be detected in blood from cancer patients. The clinical utility of enumerating and characterizing LOs along with CTCs has been demonstrated, especially in settings where CTC counts are low. The RareCyte CTC platform has the potential to capture LOs along with CTCs. We performed a pilot study to evaluate the RareCyte CTC platform's potential to analyze LOs using established preanalytical procedures.

Methods: Metastatic breast cancer patients' (N=10) blood smears labelled with RarePlex® Enumeration panel kit were re-evaluated to identify objects with LO-like characteristics at 10x magnification, along with negative control slides (N=5). LO-like objects were annotated and re-scanned at 40x magnification using the CyteFinder® imaging instrument. After establishing the criteria for LO identification, LO enumeration was performed on a cohort of MBC patients (N=6). Sets of five blood smear slides stained with the RarePlex® Enumeration panel kit were reviewed and LO counted. Total LO counts were established by extrapolating LO counts to 7.5 mL plasma. Pearson correlation was used to determine the level of correlation between LO counts and previously obtained CTC counts.

Results: The established identification criteria enabled the consistent enumeration of LOs at 10X magnification. Total LO count was 9.6 on the negative control slides. In MBC patients the mean total LO count was 306.2 (range 3.2 - 792). There was a significant positive correlation between LO and CTC count (r=0.855, p=0.3). In samples with CTC>0 (N=3), the average total LOs count was 588, about six times higher than CTC count. In CTC=0 patient samples (N=3) the mean total LO count was 24.3 (range 3.2-36).

Conclusions: We report a novel protocol to quantify large oncosomes using the RareCyte CTC platform using established preanalytical workflows. The strong CK/EpCam staining in LOs and the strong correlation of LO count with CTC count indicates their tumoral origin. Due to their higher abundance, LOs combined with CTCs offer a more sensitive tool for treatment response monitoring. Due to its broad range, LO counts in patients with CTC=0 may reveal therapy response dynamics undetectable with CTC enumeration alone. Ongoing work focuses on the parallel detection and integrated evaluation of HER2 by immunofluorescent staining of CTCs and LOs, along with digital PCR based HER2 quantification using cfDNA from matched blood plasma samples.

#3698 Characterization of circulating rare events in non-small cell lung cancer.

J. Seo, S. N. Shishido, J. Mason, C. R. Velasco, J. Mullin, R. Prabakar, J. Hicks, P. Kuhn;
USC - University of Southern California, Los Angeles, CA

Non-small cell lung cancer (NSCLC) is the most frequent type of lung cancer, accounting for about 80 - 85% of all diagnoses. Unfortunately, 75% of NSCLC diagnoses are made when cancer has already spread and the prognosis is poor. Therefore, biomarker investigation that might allow for early detection of NSCLC is critical to improving patient outcomes. The purpose of this study is to demonstrate the feasibility of liquid biopsy to detect and identify circulating rare events, such as circulating tumor cells (CTCs), associated with NSCLC. Here we apply our non-enrichment-based High Definition Single Cell Assay (HDSCA) workflow which utilizes an immunofluorescence staining technique and an unsupervised rare event detection algorithm to identify the circulating rare cells and acellular events in samples collected from 206 NSCLC patients and 60 healthy individuals. We detected a heterogeneous population of circulating rare events in NSCLC, including epithelial, mesenchymal, and endothelial cells, as well as acellular events such as oncosomes. Cancer-associated circulating rare events with statistically significant prevalence in NSCLC compared to healthy individuals were observed. Molecular characterization using multiplexed targeted proteomics based on imaging mass cytometry and genomic analysis by single-cell copy number profiling confirmed the phenotypic heterogeneity and genomic profiles of the detected circulating rare events. In this study, our results demonstrate the use of the extended capabilities of liquid biopsy to identify a comprehensive overview of circulating rare events that can provide clinically valuable biomarkers in NSCLC.

#3699 Identifying novel resistance biomarkers in circulating tumor cell-expressed transcriptomes of metastatic castration-resistant prostate cancer patients treated with androgen receptor signaling inhibitors.

H. Cho[1], J. Cha[1], K.-H. Han[1], J.-S. Chung[2];

[1]Inje University, Gimhae, Korea, Republic of, [2]Haeundae Paik Hospital, Busan, Korea, Republic of

Introduction: For individuals with metastatic castration-resistant prostate cancer (mCRPC), therapeutic options include androgen receptor signaling inhibitors (ARSIs) like abiraterone or enzalutamide, as well as taxane-based chemotherapy. Despite this, establishing the best treatment approach is still debated, with varied responses to treatments observed. Notably, around 30%-40% of mCRPC patients either do not benefit from ARSI therapy or quickly become resistant. PSMA PET/CT demonstrates prognostic significance in forecasting responses to ARSI treatments, underscoring its utility in managing mCRPC. Nevertheless, the effectiveness of blood test-measured PSMA expression levels in diagnosing and treating prostate cancer remains uncertain. Consequently, there is a crucial demand for predictive biomarkers, particularly those indicating therapeutic resistance, to customize treatments according to the unique tumor biology of individual patients.

Materials and Methods: We recruited 21 healthy donors and 60 ARSI-treated metastatic castration-resistive prostate cancer patients. We isolate the circulating tumor cells (CTCs) using lateral magnetophoretic microfluidic technology. The EpCAM-labeled CTCs were specifically isolated by microfluidic technology and analyzed for cell enumeration and transcriptomic analysis. Prostate cancer and epithelial-related six genes (PSMA, PSA, AR, AR-V7, EpCAM, and KRT19) were detected by droplet digital PCR (ddPCR) method.

Results: In ARSI-treated groups, the connection between transcript expression and CTC count is differentiated by the presence or absence of a PSA response. Specifically, 41.7% (25/60) of the ARSI group exhibited a PSA non-response, defined as less than a 50% reduction from the baseline level. These patients demonstrated elevated PSA, PSMA, and AR-V7 mRNA expression levels. Kaplan-Meier survival analysis indicated that patients with high PSMA, PSA, and AR-V7 expressions and a higher CTC count experienced poorer PSA-PFS, radiological-PFS, and overall survival (OS) than those with lower expression levels. This trend was echoed in the findings of the proportional hazards model. Notably, patients with higher PSMA mRNA expression faced significantly lower PSA-PFS (HR: 2.28, 95% CI: 1.20-4.33, $p = 0.012$), radiological-PFS (HR: 4.75, 95% CI: 2.27-9.93, $p < 0.001$), and OS (HR: 6.99, 95% CI: 2.93-16.73, $p < 0.001$) than those with lower expression. The Cox model presented analogous results for CTC count and PSA mRNA levels. However, other transcripts, such as AR, KRT19, and EpCAM, did not correlate significantly with the response to ARSI treatment.

Conclusions: The study's conclusion revealed that PSMA, PSA, and AR-V7 are biomarkers resistant to ARSI treatment among the CTC-derived transcriptomic genes.

#3700 Genomic alterations on first-line panitumumab plus FOLFIRI in metastatic colorectal cancer.

A. Avallone[1], F. Giuliani[2], G. Nasti[1], V. Montesarchio[3], G. Santabarbara[4], S. Leo[5], U. Malapelle[6], G. Rosati[7], C. Lotesoriere[8], E. Tamburini[9], A. Colombo[10], F. Pepe[6], C. Cardone[1], A. Leone[1], C. Vitagliano[1], G. Russo[6], G. Troncone[6], D. Giannarelli[11], A. De Stefano[1], A. Budillon[1];

[1]Inst. Nazionale Tumori IRCCS - Found. Pascale, Napoli, Italy, [2]National Cancer Research Centre Istituto Tumori Giovanni Paolo II, Bari, Italy, [3]AORN dei Colli, Napoli, Italy, [4]AORN S.G.Moscati, Avellino, Italy, [5]Ospedale Vito Fazzi, Lecce, Italy, [6]University of Naples Federico II, Napoli, Italy, [7]Ospedale San Carlo, Potenza, Italy, [8]IRCCS Saverio de Bellis, Castellana Grotte, Italy, [9]Tricase City Hospital, Tricase, Italy, [10]Casa di Cura Macchiarella, Palermo, Italy, [11]Fondazione Policlinico Universitario A. Gemelli, Roma, Italy

Background: IMPROVE is a randomized, non-comparative multicenter, phase 2 study evaluating continuous or intermittent FOLFIRI/PANI, in first-line in patients (pts) with unresectable RAS/BRAF wild-type metastatic colorectal cancer (mCRC). In this trial intermittent FOLFIRI/PANI strategy produced a longer progression-free survival (PFS) on treatment, 17.6 months (mts) vs 11.3 mts, a reduced skin severe toxicity, 18% vs 30%, without any detrimental effect on overall survival (OS), 36.2 mts vs 36.2 mts. The trial also included a prospective genomic alterations (GAs) analysis on circulating tumor DNA with the aim to explore emergence of GAs under the selective pressure of FOLFIRI/PANI.

Methods: We analyzed paired plasma samples (basal and PD) by a commercially available NGS panel enabled to simultaneously analyze KRAS, NRAS, BRAF and PIK3CA hotspot mutations from blood samples. Among them, inspecting default calling parameters on proprietary analysis software (Ion Reporter software 5.2.0), only variants with ⩾5X allele coverage and a quality score ⩾20, within an amplicon that covered at least 1000X alleles was considered. As clonality, the threshold of 0.5% of variant allele frequency (VAF) was established to classify mutations as clonal (VAF⩾0.5%) or subclonal (VAF<0.5%).

Results: Of the 137 pts enrolled in the trial, GAs basal analyses were available for 84 pts. Among these, in 55 (65.5%) no GAs were detected (ND). In the remaining cases, the analysis relieved the presence of mutations for PIK3CA (N=14), KRAS (N=12), NRAS (N=2) and BRAF (N=1). According to the clonality threshold, these GAs were classified as subclonal (SC) in 12 cases (14.3%) and clonal (CL) in 17 (20.2%) cases. Survival analysis according to basal GAs clonality showed a median PFS of 16.6 mts (95% IC 13.0-20.2), 12 mts (95% IC 9.1-14.9) and 25.8 mts (95% IC 17.2-34.5) for ND, CL and SC group, respectively. Median OS was 47.7 mts for ND group (95% IC 34.9-60.5), 26.8 mts for CL (95% IC 25.8-27.8) and not reached for SC group. Moreover, we performed GAs analysis on 61 cases of which basal and PD samples were available. Forty-two cases (68.9%) resulted ND, 7 (11.5%) with SC and 12 (19.7%) with CL GAs.At PD, among 42 ND basal cases, 29 remained ND (69%), 8 (19%) and 5 cases (11.9%) developed SC and CL GAs, respectively. In the SC group, 1 kept SC (14.3%), 4 (57.1%) and 2 (28.6%) cases became ND and CL GAs, respectively. In the CL group, 10 (83.3%) kept CL GAs, 1 (8.3%) case became ND and 1 (8.3%) CL.

Conclusions: These findings suggest that classical GAs associated with anti-EGFR resistance are infrequent with up-front use of anti-EGFR/chemotherapy. Moreover, our data show that basal SC GAs rarely evolve to CL GAs at progression disease and do not affect survival of pts with anti-EGFR/chemotherapy treatment. An update will be provided at the congress. NCT04425239

#3701 Urine-based liquid biopsy test for the detection of residual bladder cancer in radical cystectomy patients.

R. Arya, H. Valentine, U. Satyal, R. Chelluri, M. Li, P. Abbosh;
Fox Chase Cancer Center, Philadelphia, PA

The gold standard therapy for muscle-invasive bladder cancer (MIBC) is neoadjuvant chemotherapy followed by radical cystectomy (RC) and urinary diversion. Some patients may have their disease completely eradicated by chemotherapy as ~35% of patients achieve a pathologic complete response (pCR) when evaluated from RC specimens. RC with urinary diversion is a life-altering operation with high complication rates and therefore determining who are complete responders would improve quality of life and could decrease costs and still achieve a high cure rate via RC avoidance. Unfortunately, current methods cannot accurately identify complete responders. Our lab has developed a urine-based liquid biopsy test in which DNA isolated from urine and germline is isolated and subjected to panel exome sequencing for enumeration of somatic variants. This occurs under the premise that tumor DNA identified (as mutant alleles) is a marker of residual disease while the absence of tumor DNA (meaning the absence of mutant alleles) can indicate a pCR.

A 55 gene panel was designed to be used for exonic sequencing of urinary DNA (uDNA) to identify mutations indicative of bladder cancer or therapeutic targets. We have shown that most mutations in tumor tissue are detectable as mutations in urine (Mu). We also showed that the presence or absence of residual Mu after completion of chemotherapy strongly associates with residual disease or pCR at the time of RC, respectively. Therefore, this test could be used after neoadjuvant therapy to better identify patients for RC avoidance.

To optimize this test, we are currently evaluating pre-analytical factors affecting the yield, purity, and integrity of uDNA and the quality of sequencing data using prospectively collected samples from patients with MIBC. We are also testing commercial and novel preservatives to identify one that maintains cell-free DNA integrity, yield, and mutation detection accuracy to enable temporary ambient temperature storage without compromising mutation detection, permitting shipping/centralized testing. Lastly, we are comparing two library preparation approaches: classical hybrid capture-based (Agilent SureSelect XT^{HS}) and amplicon+hybrid capture-based (Agilent HaloPlex^{HS}) to determine which performs the best for identifying the variants in a sample. Our results showed that both sequencing depth and the quality bases mapped was higher when utilizing the SureSelect XT^{HS} kit as compared to HaloPlex^{HS} using approximately the same number of reads. This improvement may also increase the power to detect rare alleles.

Studies described herein will enable liquid biopsy tests to accurately identify patients with pCR after neoadjuvant therapy and might safely avoid radical cystectomy.

#3702 Dissecting circulating tumor cells phenotype in a cohort of locally advanced non-small cell lung cancer patients undergoing neoadjuvant chemotherapy.

R. Leporati, T. Beninato, S. Iadecola, C. Andreon, F. Murianni, M. Balsamo, A. Martinetti, B. Lombardi Stocchetti, L. Mazzeo, S. Manglaviti, M. Occhipinti, M. Brambilla, A. Prelaj, C. Proto, R. Miceli, L. Roz, G. Sozzi, F. De Braud, G. Lo Russo, G. Bertolini;
Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy

Background: Platinum-based neoadjuvant chemotherapy (pb-NACT) is the primary treatment approach for locally advanced non-small cell lung cancer (LA-NSCLC), despite offering only a limited overall survival (OS) gain. Cisplatin-induced cell damage has been shown to activate the SDF-1/CXCR4 axis in preclinical models of NSCLC, resulting in the recruitment of a cell subset co-expressing the stemness marker CD133 and CXCR4 (SDF-1 receptor) at distant sites. These cells, known as metastasis-initiating cells (MIC), exhibit prometastatic activity. By longitudinally monitoring circulating tumor cells (CTC) in the blood of LA-NSCLC patients (pts) undergoing pb-NACT, our objective is to assess the potential prognostic significance of CTC number and phenotype.
Methods: Between February 2019 and August 2023, a total of 61 pts with LA-NSCLC undergoing pb-NACT, were included in the study. Blood samples were obtained at baseline (T1), post-pb-NACT (T2), and post-surgery (T3) for the characterization of CTC, including total CTC, CXCR4+CTCs, and CXCR4+CD133+ MIC. This characterization utilized a validated marker-independent strategy combining Parsortix and DEPArray™ technologies. Logistic regression models were employed to examine the association between CTC subsets and the response to pb-NACT (Disease Control Rate [DCR], Overall Response Rate [ORR]), while Cox-regression models were used to assess their association with survival endpoints (event-free survival [EFS], OS, disease-free survival [DFS]).
Results: Out of the 61 enrolled patients, 34 had available CTC data for analysis. In this population, DCR was 64.7%, and the ORR 29.4%. Surgery was performed in 14 pts (41.2%). At baseline (T1), elevated levels of CXCR4+CTCs were linked to a lower DCR (10 vs 3/mL, odds ratio [OR]=0.02, 95% confidence interval [CI]: 0-0.40, p=0.008), as well as shorter EFS (10 vs 3/mL, HR=4.20, 95% CI: 1.84-9.58, p=0.002) and OS (10 vs 3/mL, HR=3.14, 95% CI: 1.25-7.88, p=0.004). At the post- CT time point (T2), higher levels of MIC were associated with shorter EFS (3 vs 0/mL, HR=1.41, 95% CI: 1.00-1.99, p=0.047) and OS (3 vs 0/mL, HR=1.55, 95% CI: 1.03-2.34, p=0.035). Although the sample size was limited, a higher number of MIC at the post-surgery time point (T3) showed a trend toward reduced DFS.
Discussion: CTC could serve as a novel biomarker for assessing the effectiveness of pb-NACT in LA-NSCLC. Elevated levels of CXCR4+CTC both at baseline and after pb-NACT, along with increased MIC post-pb-NACT and post-surgery, indicate unfavorable prognostic factors for survival. Specifically, a higher baseline of CXCR4+CTCs may be linked to a suboptimal response to treatment, suggesting the potential need for treatment intensification in patients exhibiting elevated CXCR4+CTC baseline levels.

#3703 Utility of circulating tumor DNA (ctDNA) from cerebrospinal fluid (CSF) for prognosis of patients with recurrent high grade glioma.

B. M. Holle[1], S. Nandakumar[1], C. Kreitzer[1], T. Song[1], M. Tartaro[1], C. J. Hertz[2], J. Rafailov[3], C. Campos[1], A. S. Reiner[1], R. Young[1], A. Meng[1], L. Pasquini[1], A. R. Brannon[1], N. D. Socci[1], M. E. Arcila[1], D. B. Solit[1], M. F. Berger[1], N. Schultz[1], I. K. Mellinghoff[1], A. M. Miller[1];

[1]Memorial Sloan Kettering Cancer Center, New York, NY, [2]Weill Cornell Medicine, New York, NY, [3]NYU Grossman School of Medicine, New York, NY

High-Grade Gliomas (HGGs) are the most aggressive primary brain tumors in adults and molecular characterization is crucial for diagnosis and optimal disease treatment. Due to the eloquent location of many HGGs, upfront or repeat tumor sampling may be sub-optimal. Hence, there is an urgent need to develop alternative, minimally-invasive means to obtain diagnostic information and determine the expected clinical behavior. Here we report that circulating tumor DNA (ctDNA) from cerebrospinal fluid (CSF) can be used to identify disease defining genomic alterations and to track clonal evolution. Additionally, we demonstrate that detection of CSF ctDNA is positively correlated with leptomeningeal disease and overall survival suggesting that CSF ctDNA should be integrated into clinical decision making in the clinic.

Our study includes 315 samples from 254 patients with recurrent glioma treated at Memorial Sloan Kettering Cancer Center who underwent CSF collection for routine clinical care and were sequenced using the MSK-IMPACT targeted clinical sequencing assay (468 and 505 genes). Alterations were classified as oncogenic based on OncoKB. 23% of genomic alterations detected were identified using a secondary bioinformatics analysis, following an informed approach with less stringent mutation calling criteria and Gaussian Mixture Model to call copy number events. CSF ctDNA positivity was determined by the presence of at least one oncogenic disease defining alteration or any shared alteration with the tumor.

Within this cohort, we found 198 CSF ctDNA positive (63%) and 117 CSF negative (37%) samples. Of note, CSF ctDNA positivity was the highest amongst histone mutant tumors with 94% CSF ctDNA positivity compared to 56% CSF ctDNA positivity for IDH-WT tumors. We noticed considerable evolution of the cancer genome in patients with sequential biopsies with only 35% of alterations shared between the tumor and the CSF, in particular within the growth signaling pathways (e.g. PDGFRA). The majority of the shared alterations were clonal, and we noticed the emergence of new clonal events in the CSF.

Our cohort demonstrated that patients with positive CSF ctDNA had a significantly shorter overall survival compared to those who were CSF ctDNA negative (4.83 months vs 11.83 months, HR 2.1, $p < 0.001$). In tandem with secondary clinical analysis, radiographic findings also correlated with CSF ctDNA positivity. Specifically, the presence of enhancing disease and contact of the tumor with the ventricular space were positively associated with detection of CSF ctDNA. Additionally, CSF ctDNA was associated with positive cytology in 21/21 cases (100%).

With our improved bioinformatics pipeline we hypothesize ctDNA from CSF may be used as a prognostic biomarker for survival, but confirmation requires further validation in a prospective study.

#3704 Whole genome and targeted proteome analysis of single cancer cells.

A. Alyasin[1], K. Weidele[2], C. Botteron[2], C. A. Klein[1], Z. T. Czyż[1];
[1]University of Regensburg, Regensburg, Germany, [2]Fraunhofer ITEM-R, Regensburg, Germany

The simultaneous genome and proteome analysis of very rare single cells would enable addressing important biological and diagnostic questions particularly in cancer. Here, we introduce a novel genome and proteome (G&P) analytic workflow, a method allowing comprehensive analysis of single-cell DNA and targeted profiling of protein expression in single cells. As a proof of concept, we demonstrate the capability of the method by quantifying copy number of the *ERBB2* gene alongside with protein expression levels of HER2 and phospho-HER2 in single cells. The G&P workflow utilizes antibodies conjugated with DNA oligonucleotides designed to enable their amplification alongside the single-cell genome facilitating parallel genome and proteome profiling by either quantitative PCR (qPCR) or sequencing. We utilized antibodies targeting cytokeratin 8/18/19, HER2 and phospho-HER (Tyr1248). Performance of each DNA-conjugated antibody was assessed by immunofluorescence staining in a variety of breast cancer cell lines (MDA-MB231, MDA-MB453, BT474 and MCF7) and sample types. Stained cells were isolated by manual micromanipulation and subjected to whole genome amplification (WGA). Protein expression levels, derived from quantification of the amplified DNA tags, were measured by qPCR. Shallow whole genome sequencing was employed to facilitate genome-wide profiling of copy number variations (CNVs), including the *ERBB2* locus. We successfully developed and tested a G&P workflow allowing parallel genome-wide CNV profiling and quantification of three target proteins. G&P measurement yielded concordant results to immunofluorescence quantification for all tested markers. Furthermore, the workflow allowed direct correlation of copy numbers of the *ERBB2* gene with HER2 expression in single cancer cells. Notably, the method enabled measurements of cellular and molecular responses at the single-cell level to lapatinib treatment, i.e. monitoring of the HER2 pathway activation level. Our novel multiplex G&P technique is capable of generating multiparametric measurements linking DNA copy numbers and expression levels of selected genes of interest. The method is optimized for analysis of single cells from rare cell populations and is readily translatable to study circulating tumor cells (CTCs) and disseminated cancer cells (DCCs), enabling for the first time pathway analysis via phosphoprotein analyses of these cells.

#3705 Development and analytical validation of a novel assay for HER2 assessment on circulating tumor cells using Parsortix® isolation and BioView imaging technologies.

M. Ciccioli[1], A. Young[1], L. Vlietinck[1], C. Johnson[2], A.-S. Pailhes-Jimenez[1];
[1]ANGLE Europe Limited, Guildford, United Kingdom, [2]BioView, Billerica, MA

Background. HER2 testing in tissue biopsies is extensively performed in breast cancer (BC) patients. However, tissue biopsy is invasive and repeated examination is impractical. Additionally, lack of concordance between primary tumor and metastatic sites are often observed. Liquid biopsy, on the other hand, enables less invasive and recurrent sample collection for ongoing monitoring. In this study, we developed an end-to-end Research Use Only assay for concomitant evaluation of HER2 gene amplification and protein overexpression in circulating tumor cells (CTCs).
Methods. Blood was drawn from healthy volunteers into Streck Cell-Free DNA tubes, spiked with SKBR3 (HER2+) and Hs 578T (HER2-) breast cancer cells and processed on ANGLE's Parsortix® PC1 System, a microfluidic device that captures CTCs from metastatic breast cancer patients' blood based on their size and deformability, without relying on specific markers. Captured cells were harvested and spun onto positively charged slides and stained with the Portrait HER2 immunofluorescence (IF) panel, consisting of a nuclear dye, epithelial and mesenchymal markers, leukocytes' markers, and an antibody targeting HER2. Slides were then de-stained and subjected to HER2 FISH using a commercially available kit. All slides were imaged twice using BioView Allegro Plus, a platform equipped with artificial intelligence for automated imaging, CTC candidate identification and reporting. First, an automated scan after IF was performed to identify CTCs based on marker expression and morphology profiles. Second, an automated relocation of the CTCs based on IF results and reimaging using higher magnification to ensure precise analysis of the FISH signals in single cells. The workflow is being implemented in a cohort of BC patients.
Results. Following IF, HER2 protein expression in SKBR3 cells was significantly higher (p<0.0001) than that of HER2-negative cells, with 100% analytical specificity and sensitivity. Following FISH, 100% of the cells were de-stained and presented sharp HER2/CEP17 foci, with 96% of the SKBR3 cells and only 4% of the Hs 578T cells displaying HER2 amplification. Additionally, in a small cohort of metastatic BC patients', 100% of the identified CTCs are retained and evaluable from IF to FISH.
Conclusions. An assay integrating HER2 identification by IF and FISH to characterize CTCs in metastatic BC patients was successfully developed. The assay enables the identification of both HER2 protein and gene copy information from each target cell with minimal cell loss, with the potential for minimally invasive patient monitoring during treatment and better classification of patients who may qualify and benefit from HER2-targeted therapies. An added value of the assay is the practicality of utilizing preserved blood samples, allowing streamline batch shipping of clinical samples.

#3706 Single cell and cell-free nucleic acid analyses of liquid biopsy specimens from a blood collection tube using a new droplet digital PCR system.

L. Jackson, C. Cochran, C. Gould, S. Kreston, J. Bello, B. D'Alessio, J. Riley, A. Tubbs, G. A. Pestano;
Biodesix, Inc., Boulder, CO

Introduction: Liquid biopsy-based testing has increasingly been adopted by oncologists for biomarker-driven diagnostics, therapy selection, and patient monitoring. Unlike tissue-based approaches, the target analytes in blood specimens are often rare events that must be discriminated from a background of non-tumor derived material. Droplet digital PCR (ddPCR) is an ideal platform for detection of rare nucleic acid markers in the clinic, because it is highly sensitive and specific, robust, and quantitative. Additionally, the workflow is simple to adopt and execute. The QX600 System is a new ddPCR instrument designed for advanced multiplexing which enables simultaneous detection of up to 6 unique fluorophores in a single well. This capability can decrease the sub-sampling needed for detection of multiple analytes. The objective of our study was to develop multiplexed ddPCR assays for detection of cell-based and cell-free circulating biomarkers from a single tube of whole blood.
Methods: Tumor cells were enriched from the buffy coat fraction of whole blood collected in fixative-containing cfDNA BCT based on size and morphology using a microfluidics-based system. Enriched tumor cells were enumerated by immunofluorescence (DAPI+/Pan-CK+/CD45-), and gene expression was measured using the QX600 for a panel of cytokeratins (CK) and PD-L1 in CTC negative, NSCLC donor specimens (n=8). Results were compared to CTC positive, contrived specimens (whole blood spiked with breast tumor cell line MCF7 cells; n=5). For ctDNA analysis of the plasma fraction, a multiplexed ddPCR assay was designed to test for five actionable mutations prevalent in NSCLC, including EGFR del19, L858R, T790M, KRAS G12C, BRAF V600E, and wildtype EGFR. To evaluate performance of the multiplexed assay, concordance evaluation was conducted using cfDNA from 8 mutation-positive NSCLC donors on the QX600 and compared to single assays run on the QX200 system.
Results: CK8 and CK19 were differentially expressed in the cells enriched from the CTC negative NSCLC cohort as compared to the contrived positives ($p=0.0058$, and $p=0.0049$, respectively). All the NSCLC cfDNA samples were positive for the reference variant, and linear regression analysis of the minor variant frequency for ctDNA biomarkers showed good concordance between QX systems ($R^2=0.8847$).
Conclusions: These studies demonstrate proof of concept for single cell and cell-free analysis from a single blood draw into a cfDNA BCT using the QX600 system. Liquid biopsy analysis of CTCs and ctDNA can enable minimally invasive, comprehensive decision making in the diagnostic workup of patients. Future studies will focus on further optimizing the cell enrichment methodology from cfDNA BCT and development of additional multiplexed ddPCR assays for NSCLC-relevant biomarkers on the QX600.

#3707 Characterization of estrogen receptor expression on CTCs during CDK4/6i treatment in HR+/HER2- metastatic breast cancer: Results from the PACE phase II study.

Background Circulating tumor cells (CTCs) are associated with worse survival in metastatic breast cancer (MBC). The PACE study (NCT03147287) enrolled patients (pts) with hormone receptor-positive (HR+)/ human epidermal growth factor receptor 2-negative (HER2-) MBC after progression on CDK4/6 inhibitor (CDK4/6i) and endocrine therapy, and randomized pts to fulvestrant (ful) alone; ful with palbociclib; or ful, palbociclib, and avelumab [Mayer et al., SABCS 2022]. Pts with ≥5 CTCs appear to derive benefit from treatment combinations vs ful alone. In this feasibility analysis, we evaluated estrogen receptor (ER) expression on CTCs to further investigate their monitoring/predictive potential.**Methods** Blood samples were collected from pts enrolled in the PACE study at: baseline (T1), first tumor assessment (T2) and progression (T3). CTCs were enumerated using the CellSearch platform and samples were classified as CTC^{high} or CTC^{low} (cutoff ≥5 CTCs). CTC^{high} samples underwent ER expression quantification with the ACCEPT software [Zeune et al. 2017]. ER expression intensity (ERint) was measured through the *Marker Characterization* function for each CTC; the average was calculated for each sample. **Results** From the 220 enrolled pts, a total of 409 samples (166, 153 and 90 collected at T1, T2, and T3, respectively) were analyzed for ER. Overall, 236 samples were CTC^{low} (T1 = 91, T2 = 97, T3 = 48) and 173 were CTC^{high} (T1 =75, T2 =56, T3 =42). ER was quantified on 3928, 1853, and 2209 CTCs collected at T1, T2, and T3, respectively. Overall, 32.2% of CTCs were ER negative (ER-).The samples' median ERint showed a numerical decrease from T1 to T3 (T1 = 7.27, T2 = 4.58, T3 = 1.31). Similarly, the % of ER positive (ER+) CTCs per sample decreased from baseline to progression: 26.3%, 14.0%, 5.5% at T1, T2, T3, respectively.CTC^{high} samples were then classified as ER+ or ER- (ER+ = mean ER_int >0). At T1, 91 (54.8%) samples were CTC^{low}, 67 (40.4%) were CTC^{high}/ER+, and 8 (4.8%) were CTC^{high}/ER-. At progression, 48 (53.3%) samples were CTC^{low}, 26 (28.9%) were CTC^{high}/ER+, and 16 (17.8%) samples were CTC^{high}/ER-. A numerical increase in the proportion of CTC^{high}/ER- samples was thus observed from baseline to progression (4.8 to 17.8%).**Conclusions** Herein we demonstrated the feasibility of evaluating and quantify ER expression on CTCs with a software-assisted approach to reduce inter-operator variability. In the PACE study, ER expression on CTCs was decreased at progression compared to baseline, possibly suggesting a mechanism associated with treatment resistance. Future analyses are needed to investigate the correlation between ER expression levels on CTCs with survival and treatment response. This, together with information about the mutational status of *ESR1* by ctDNA sequencing, might provide a new perspective on the development of resistance to ful and CDK4/6i in HR+/HER2- MBC.

#3708 Characterization of EpCAM-positive cells for specific detection of disseminated cancer cells in bone marrow of early breast cancer patients.

J. Roth[1], E. Raya[1], S. Hucker[2], H. Koerkel-Qu[1], S. Seitz[1], C. Klein[1];
[1]University of Regensburg, Regensburg, Germany, [2]Fraunhofer ITEM Regensburg, Regensburg, Germany

Obviously, breast cancer cells that disseminated from the primary tumor before surgical resection are responsible for metastasis. However, detection of disseminated cancer cells (DCC) in breast cancer patients during minimal residual disease is still difficult, impeding the study of early systemic cancer and the extraction of clinically relevant diagnostic or therapeutic information. Others and we have shown previously that EpCAM is a suitable DCC detection marker, however not entirely specific in bone marrow. To improve DCC detection, we here compared different methods to enrich DCC exploiting information from our ongoing single cell RNA-seq study. Based on our ongoing scRNA-seq study (see poster of Elia Raya), we generated a qPCR assay to classify candidate DCC based on an expression signature of four genes. This assay categorizes plasma cell-like EpCAM+ cells from healthy donors and candidate DCC from breast cancer patients with high fidelity. With this assay at hand, we compared two enrichment strategies: depletion of CD11b, CD319 and Glycophorin A positive cells from density gradient enriched mononuclear cells (MNC) vs. positive selection of EpCAM+ cells and subsequent addition of markers that separate out DCC among EpCAM+ cells. For this we applied 10x genomics profiling of EpCAM+ cells from bone marrow. We depleted and screened the bone marrow of 221 patients suffering from non-metastatic early breast cancer for EpCAM-positive cells. From 87 patient samples we could isolate EpCAM-positive cells. We performed single cell RNA-sequencing on 64 EpCAM-positive cells from 54 patients of which 84% were classified as cancer cells and 16% of bone marrow origin. Applying the selected gene signature, 76% of isolated cells were classified as DCC, 16% were undefined and 8% as non-cancer bone marrow cell (NCC). Upon positive selection of EpCAM+ cells implementing additional markers, we isolated 53 cells from 14 patients. Of these, 68% showed a DCC or DCC-like-signature, 15 % a NCC and 17% an undefined profile. To get a better understanding of these EpCAM-positive confounder populations we currently perform a scRNA-seq profiling using 10X on the enriched EpCAM+ cells. Our data shows that EpCAM is a promising marker to identify DCCs in the bone marrow of early cancer patients, but it also indicates that we find several groups of confounder cells. To differentiate between these cell types during staining and in our qPCR assay we are currently testing additional markers.

#3709 Single cell analysis from CSF of patients with suspected leptomeningeal metastasis.

C. Koestler[1], G. Feliciello[1], F. Lueke[1], K. Weidele[1], S. Zoubaa[2], P. Hau[2], T. Pukrop[2], M. J. Riemenschneider[2], C. A. Klein[3], **B. Polzer**[1];
[1]Fraunhofer Institute for Toxicology and Experimental Medicine ITEM, Regensburg, Germany, [2]University Hospital Regensburg, Regensburg, Germany, [3]University of Regensburg, Regensburg, Germany

Introduction: Leptomeningeal metastases (LM) are diagnosed in up to 10% of metastatic cancer patients, the most frequent cancers being carcinomas of breast and lung or melanoma. Due to a dismal prognosis and an overall median survival of only four months new approaches for molecular analysis could help to identify individual treatment options. Material and Methods: In this study, we collected 28 cerebrospinal fluid (CSF) samples from patients with different primary tumors but suspected LM. CSF was divided in two parts for standard neuropathologic cytomorphology and detection of circulating tumor cells (CTCs) by using the CellSearch® CTC Kit, respectively. Subsequently, single Cytokeratin-positive CTCs were isolated for whole genome amplification by *Ampli*1™ and molecular analysis. Additionally, we were able to isolate cell-free DNA (cfDNA) from CSF in a subset of patients which we amplified by an adapted *Ampli*1™ library protocol. In a small subset of patients, we collected slices of formalin-fixed paraffin embedded (FFPE) primary tumors and systemic metastases for dissociation and isolation of pure subpopulations by DEPArray™ technology. Isolated CTCs, cfDNA and subpopulations of tumor and stromal cells were analyzed for copy number variations (CNV) applying the *Ampli*1™ LowPass protocol on the Illumina MiSeq™ platform. Results: By comparing results from classical cytomorphology and CellSearch® workflow, we could find high concordance (24/28 samples) with a slightly higher tumor cell detection rate by CellSearch® (11 positive cases vs. 9 by cytomorphology). Importantly, we could confirm the malignant origin of isolated cells by CNV analysis in all patients positive in CellSearch® assay. Moreover, by comparing single cell data with cfDNA analysis of a subset of 20 samples, we could also detect a higher sensitivity for tumor detection in CTC-based analysis (8/20 cases positive) in comparison to cfDNA-based analysis (5/20 cases positive). In a comprehensive analysis of multiple samples of an individual patient, including CTCs and cfDNA from CSF at different time points, CTCs from blood and biopsies from multiple visceral metastasis, we could identify divergent genomic evolution between tumor cells from the central nervous syste Conclusion: In this proof-of-concept study we show that a liquid biopsy-based approach for single cell analysis from CSF holds potential for innovative diagnostic assays for patients with suspected LM. Combining CTC quantification with molecular single cell analysis could enable us to define predictive tests to select novel treatment options for patients with LM in the future.

#3710 Determining the efficacy of blood filtration in patients diagnosed with pancreatic cancer through the liquid biopsy.

D. D. Suresh[1], G. Courcoubetis[1], E. Lin[1], J. Mason[1], N. Nissen[2], S. Gaddam[2], S. Lo[2], S. Pandol[2], P. Kuhn[1], S. Shishido[1];
[1]USC - University of Southern California, Los Angeles, CA, [2]Cedars-Sinai Medical Center, Los Angeles, CA

Cancer becomes lethal as it spreads from the primary site to the rest of the body. Circulating tumor cells (CTCs) are considered a marker of disease progression and have been associated with decreased overall survival. Blood filtration is one such method of removing cancer cells from circulation to improve patient prognosis. This study utilizes the liquid biopsy to assess the efficacy of a proprietary filtration device on the blood of patients with pancreatic ductal adenocarcinoma (PDAC) using the third generation high-definition single cell assay (HDSCA3.0) workflow. Blood samples were collected and analyzed to characterize the CTCs and other rare cells present before and after filtration. Examination of 6 paired portal (PoVB) samples demonstrated a statistically significant decrease in total rare cells, total CK+ cells, and epi.CTCs across all patients due to filtration of the blood. Furthermore, analysis of 2 paired peripheral blood (PB) samples showed a decrease in total rare cells, total CK+ cells, and specific phenotypes of rare cells upon filtration. These preliminary results demonstrate initial proof of concept that this filtration device can remove CTCs from the circulation, which may be used as a potential therapeutic device for PDAC patient care.

#3711 Procedure establishment of EGFR mutation test with circulating tumor cells of lung cancer by in vitro assay.

J. Lee, **H. Kang**, M. Kim, J. Lee, H. Kim, S. Kim, H. Lee, H.-C. Lee, J. Kim;
Cytogen, Inc., Seoul, Korea, Republic of

Introduction: Non-small cell lung cancer (NSCLC) is the most common subtype, accounting for approximately 80% of lung cancer. The treatment for NSCLC has significantly improved since the introduction of targeted therapies. Epidermal growth factor receptor (EGFR) mutations are the most frequently found genetic alterations in NSCLC, and deletion of exon 19 is a representative example. Searching for this mutation may provide important clues to the use of EGFR tyrosine kinase inhibitors in NSCLC. So, the detection of EGFR mutation is important step in cancer diagnosis and determining the drug treatment strategy, but the detection of mutation with tissues has limitations such as clinical challenge to poorly accessible tumor tissues before and after treatment. The aim of this study was to explore the feasibility and utility of implementation of EGFR molecular testing from circulating tumor cells (CTC) in NSCLC. Here, we developed and optimized the procedure of mutated EGFR detection in CTC after isolation with CytoGen's Smart Biopsy™ CTC isolator by cobas® EGFR Mutation Test. This EGFR mutation test in CTC showed the potential to overcome the limitations of tissue biopsy with high sensitivity and specificity in an in vitro assay.
Method: PC-9 cells were used the positive control of EGFR mutation (EGFR exon 19 deletion). Limit of detection (LOD) was performed with PC-9 cells (200 cells to 5 cells, 6 points) spiked into blood sample (5mL, healthy donor) to mimic CTC in the blood of lung cancer patient. CTC were isolated from spiked samples using CytoGen's Smart Biopsy™ CTC isolator, subsequently cobas® EGFR Mutation Test was carried out to detect of EGFR mutation.
Results: In in vitro experiments of recovery test using cell lines spiked into blood from healthy donor, the recovery rate of CytoGen's Smart Biopsy™ CTC isolator showed over 80%. As a result of LOD test, EGFR exon19 deletion mutation of PC-9 cells was clearly detected even in the smallest number of cells were spiked into blood (5 cells in 5mL blood) and was not detected at all in the negative controls. The result suggested that CytoGen's Smart Biopsy™ CTC isolator can isolate CTC with high recovery rate and apply the test of oncogenic mutations including EGFR mutation in CTC.
Conclusions: Confirmation of EGFR mutation is important step in the diagnosis and selection of optimal drug for cancer patients. However, tissue biopsy has several limitations such as difficulties to get tissue samples and inaccurate information due to invasive method and tumor heterogeneity. Detection of EGFR mutation in CTC might overcome and make up for limitations of tissue biopsy. In this study, we optimized the EGFR mutation detection procedure of intact live CTC isolated by CytoGen's Smart Biopsy™ CTC isolator.

CLINICAL RESEARCH: Combination Immunotherapies
Poster Session

#3716 Enhancing anti-tumor responses in triple-negative breast cancer by combining SIRPα inhibition with immunogenic chemotherapy or antibody-drug conjugates.

X. Ma, L.-C. Tsao, T. Wang, C.-X. Liu, M. Gajda, X. Yang, G. Lei, J. Wei, Z. Hartman;
Duke University, Durham, NC

Background: Triple-negative breast cancer (TNBC) is a subtype of breast cancer defined by the absence of hormone receptors and HER2 receptor on tumor cells. Because of a lack of targetable receptors and poor response to PD1/PDL1 immunotherapy, TNBC has limited systemic treatment options. In previous work using a genomic screen (Shuptrine et al., 2017), we identified CD47 as one of the leading factors that contributes to TNBC immune evasion. The CD47-SIRPα axis is an innate immune checkpoint that primarily regulates myeloid cells. In the context of cancer, tumor cells upregulate CD47 to engage SIRPα inhibitory signaling to block phagocytosis. While CD47 or SIRPα blockade alone show limited antitumor effect, therapies that combine blockade of this axis with other treatment agents, such as tumor-antigen specific antibodies, show superior tumor inhibition. Thus, we hypothesize that the addition of SIRPα inhibition to existing TNBC treatments (chemotherapy and Trop2-antibody drug conjugates (ADC)) will improve their treatment efficacy.
Methods: To ascertain the impact of SIRPα inhibition combined with chemotherapy and Trop2-ADC, we utilized and validated a novel SIRPα KO mouse, along with SIRPα mAbs, in our previously utilized models of Triple-Negative Breast Cancer (TNBC) (Crosby et al., 2018). Using both in vitro and in vivo tumor models, we tested the therapeutic impact of SIRPα inhibition/blockade combined with different immunogenic chemotherapies (doxorubicin/cyclophosphamide) and Sacituzumab govitecan (SG) in TNBC.
Results: After validating the loss of SIRPα in KO mice, we found that E0771 TNBC cells had comparable growth rates in WT and SIRPα KO mice. Similarly, we did not observe different anti-tumor responses to Doxorubicin between WT and SIRPα-KO mice. However, we observed more profound suppression of E0771 tumors after cyclophosphamide treatment in SIRPα KO mice than in WT mice. To evaluate the efficacy of SG in inducing antibody-dependent cellular phagocytosis (ADCP), we co-cultured SIRPα KO and WT mouse macrophages with a syngeneic mouse TNBC model (MM3MG-Trop2-WT). We found that SG promotes ADCP in WT macrophages, and SIRPα loss further increased this ADCP, suggesting the potential importance of antibody-mediated phagocytosis as a mechanism of action for SG. *In vivo*, we implanted human TNBC cells (MDA-MB-468) in mice and treated them with SG with and without SIRPα antibody blockade. These studies demonstrated an anti-tumor effect from SG that was potentially enhanced by SIRPα blockade, suggesting the clinical potential of this combination in TNBC.
Conclusion: Our study demonstrates that the addition of SIRPα inhibition to chemotherapy or SG may promote tumor phagocytosis and stimulate stronger antitumor immunity in TNBC. These results support further investigation of SIRPα-targeting combination therapies for TNBC.

#3717 Sudocetaxel Zendusortide (TH1902) triggers the cGAS/STING pathway and potentiates anti-PD-L1 immune-mediated tumor cell killing.

M. Demeule[1], J.-C. Currie[1], C. Charfi[1], A. Zgheib[2], I. Cousineau[2], V. Lullier[2], R. Beliveau[2], C. Marsolais[1], B. Annabi[2];
[1]Theratechnologies, Montreal, QC, Canada, [2]Universite du Quebec a Montreal, Montreal, QC, Canada

The potential impact of the immune tumor microenvironment (iTME) was assessed with respect to the anticancer efficacy of sudocetaxel zendusortide (TH1902), a peptide-drug conjugate internalized through a sortilin (SORT1)-mediated endocytic pathway. In the triple-negative breast cancer (TNBC)-derived MDA-MB-231 immunocompromised xenograft tumor model, TH1902 induced complete tumor regression for more than 40 days after the last treatment. Surprisingly, immunohistochemistry analysis revealed higher staining of CD45 leukocytes and of STING, a master regulator in the cancer-immunity cycle, in comparison to docetaxel. Additionally, in a murine B16-F10 melanoma syngeneic tumor model, weekly administration of TH1902 as a single agent also demonstrated superior tumor growth inhibition than did docetaxel. Although B16-F10 is considered a non-immunogenic “cold” tumor model, we observed a net increase in CD45 leukocyte infiltration within TH1902-treated tumors, especially for tumor-infiltrating lymphocytes and tumor-associated macrophages. Moreover, in TH1902-treated tumors, increased staining of perforin, granzyme B, and caspase-3 was suggestive of elevated cytotoxic T and natural killer cell activities. Combined TH1902/anti-PD-L1 treatment led to increased tumor growth inhibition and median animal survival. Accordingly, TH1902 inhibited cell proliferation and triggered apoptosis and senescence in B16-F10 cells *in vitro*, while inducing several downstream effectors of the cGAS/STING pathway and the cell surface expression of MHC-I and PD-L1. This is the first evidence that TH1902 exerts its antitumor activity, in part, through modulation of the iTME and that the combination of TH1902 with checkpoint inhibitors (anti-PD-L1) could lead to improved clinical outcomes.

#3718 Deciphering the role of TREM2+ tumor-associated macrophages as mediators of immunoresistance in micro-satellite stable colorectal metastases.

M. Mirza[1], M. Cottam[1], M. Raoof[2], K. Idrees[1];

[1]Vanderbilt University School of Medicine, Nashville, TN, [2]City of Hope, Irvine, CA

Introduction: Most Colorectal Cancer (CRC)-related deaths are caused by metastatic disease, and more than 95% of CRC metastases (mCRC) are microsatellite stable (MSS) which respond poorly to Immune checkpoint inhibitors (ICI). Tumor-associated macrophages (TAMs) have been recognized as major drivers of immunoresistance in primary CRC; however, their role in mCRC remains poorly understood. We analyzed primary CRC and major metastatic sites (Liver, Peritoneum, Lungs) using single-cell RNA-sequencing (scRNAseq) to elucidate the TAM driven mechanisms of immunoresistance in the mCRC tumor microenvironment (TME) and used a novel TAM directed targeting strategy to improve responses to ICI in a preclinical orthotopic model of MSS-mCRC.

Methods: Using scRNA-seq, we analyzed 22 samples from 14 patients with mCRC. Target antigens identified were validated using flow cytometry and immunofluorescence (IF). The antitumor activity of anti-TREM2 and anti-PD1 mABs was evaluated in-vivo using CT26 CRC cell line in BALB-C mice, assessing tumor immune response via flow cytometry.

Results: We characterized the TME in MSS-mCRC and identified 17 clusters of malignant epithelial, immune, and stromal cells. Our sub-clustering analysis revealed 6 unique sub-populations of TAMs which were differentially distributed across liver, lung, and peritoneal metastases (PM).Two subsets of TAMs, 5 and 6, were enriched in PM and malignant ascites. TAMs 5/6 expressed canonical lipid-associated genes; TREM2, APOE, and PLTP. TREM2+ TAMs were also enriched in immunosuppressive and pro-angiogenic pathways, and expressed genes known to drive EMT and ECM remodeling in the TME. Thus, TREM2 was identified as a potential therapeutic target. We validated our transcriptomic findings using flow cytometry and IF analysis of MSS-mCRC showing an abundance of TREM2+ TAMs in PM. TREM2+ TAMs co-expressed CD163, known marker for M2-TAMs and stained positive for BODIPY. In an aggressive PM mouse model, treatment with anti-PD1, anti-TREM2, or combination anti-PD1/anti-TREM2 was insufficient to reduce tumor burden. However, a trend towards a reduction in total intratumoral F4/80+CD11b+ TAMs was observed in the combination treatment compared to other groups. All three treatments trended towards increased CD8+ intratumoral T-cell infiltration compared to control mice.

Conclusion: Our study provides new insights into the TME of MSS-CRC metastases at a single-cell level. Our findings indicate that TREM2+ TAMs contribute to the immunosuppressive milieu of MSS-CRC metastases. Targeting TREM2 in combination with anti-PD1 resulted in a modulation of TME via reduction of TAMs paralleled by an increased infiltration of CD8+ T cells. This reprogramming of TME suggests that inhibiting TREM2 might augment response to ICI in MSS-CRC metastases, traditionally resistant to ICI.

#3719 Fasting-mimicking diet plus 2-DG drives antitumor immunity by targeting EDEM3-induced PD-L1 glycosylation.

X. Liu, S. Peng, X. Wang, H. Yu, Y. Luo;
Sun Yat-sen University, Guangzhou, China

The PD-1/PD-L1 axis plays an essential role in immune escape and immunotherapy. Importantly, translated N-linked glycosylation of PD-L1 stabilizes protein, enters the cell membrane binding to PD-1, renders T cells anergic and leads to T-cell exhaustion and dysfunction. Targeting PD-L1 glycosylation as an attractive target by a rational combination of cancer immunotherapies. Cancer-associated fibroblasts (CAFs), a predominant cell component of the tumor microenvironment, exert crucial functions in promoting immune escape and immunotherapy resistance by increasing the tumor PD-L1 expression. However, whether and how CAFs upregulate the glycosylation of PD-L1 has never been reported. This study shows that CAFs can upregulate PD-L1 glycosylation and enhance PD-L1 cell surface expression via glycosyltransferase EDEM3, thus cancer immune evasion. Then, the study delves into the relationship between EDEM3 expression, prognosis and immunogenicity. We demonstrate that EDEM3 plays a role in tumor immunity during tumor progression, as evidenced by EDEM3 expression is only significantly correlated with poor prognosis in the $CD8^+$ T cell-enriched population. In subcutaneous tumor models, we observed high cell-surface PD-L1 expression accompanied by decreased $CD8^+$ T cell infiltration and increased M2 macrophage in immunocompetent mice transplanted with EDEM3 over-expressed CRC cells that promote resistance to PD-1/PD-L1 blockade cancer immunotherapy. By performing bioinformatic analysis, we found that the hexosamine biosynthesis pathway (HBP) is highly affected in EDEM3-upregulated CRC cancer. Subsequently, the production of the UDP-GlcNAc (the end product of HBP metabolic flow), a donor substrate for N-linked glycosylation, is significantly increased in EDEM3 over-expressed CRC cells by LC/MS. Meanwhile, glucose is confirmed to be the primary effector of PD-L1 glycosylation in CRC cells, and the glucose restriction attenuates EDEM3-modified PD-L1 glycosylation by reducing UDP-GlcNAc biosynthesis. Finally, we demonstrate that modulation of glucose metabolism through a fasting-mimicking diet (FMD) in combination with 2-deoxy glucose (2-DG) treatment enhances antitumor immunity, especially in tumors with high-EDEM3 expression that exhibit resistance to immunotherapy. We propose potential therapeutic targets for CRC that inhibit PD-L1 glycosylation through FMD+2-DG and could augment the efficacy of immune checkpoint blockers.

#3720 Utility of oncolytic virus as an immunostimulants and potential for combination therapy with ICIs.

D. Kadowaki[1], S. Kuroda[1], M. Hashimoto[1], N. Kanaya[1], Y. Kakiuchi[1], S. Kikuchi[1], K. Noma[1], H. Tazawa[1], S. Kagawa[1], Y. Urata[2], T. Fujiwara[1];
[1]Okayama Univ. Graduate School of Med., Dentistry & Pharm. Sci., Okayama city, Japan, [2]Oncolys BioPharma Inc., Toranomon, Minato-ku, Tokyo, Japan

Background: Anti-PD-1 antibodies have been approved for a variety of carcinomas, but their efficacy in gastrointestinal cancers is limited. CD8-positive T cells (CD8) of tumor-infiltrating lymphocytes (TILs) and resident memory T cells (TRMs) with long-term anti-tumor immune function have been reported to be associated with the therapeutic efficacy of anti-PD-1 antibodies. Among our oncolytic adenoviruses (OVs), OBP-301, in which the human telomerase reverse transcriptase (hTERT) promoter element drives the expression of the viral E1A and E1B genes, is currently undergoing clinical trials. In the present study, we investigated the usefulness of OVs as immunostimulants and their potential efficacy in combination with anti-PD-1 antibodies.
Methods: The cell lines used were the mouse colon cancer cell line CT26 and the mouse pancreatic cancer cell line PAN02. In vitro, the cytotoxic activity of the OVs and extracellular ATP in the culture supernatant were determined. OBP-502, an OBP-301 variant with the gene cassette of the RGD peptide, and anti-PD-1 antibody were used to examine the antitumor effect on subcutaneous tumors. OBP-702, another OBP-301 variant with the gene cassette of the wild-type p53 tumor suppressor gene, was used to examine the effect of long-term anti-tumor immunity. The effects on memory T-precursor cells (MPEC), CD8 and TRM were immunologically assessed in a rechallenge study.
Results: OBP-502 and OBP-702 showed cytotoxic activity against CT26 and PAN02 cells in vitro, and significantly increased ATP in the culture supernatant. In vivo, the anti-PD-1 antibody/OBP-502 combination therapy significantly increased intratumor CD8 in CT26 and PAN02 subcutaneous tumors compared to each monotherapy. Complete response was achieved in 4 out of 12 mice by the combination therapy against CT26 tumors. When CT26 cells was re-seeded into tumor-free mice cured by the combination therapy, 2 out of 4 mice remained tumor-free. In the CT26 and PAN02 subcutaneous tumor model, OBP-702 increased CD44-positive CD62L-negative MPECs that differentiated into TRMs in the spleen, and this effect was blocked by ATP receptor inhibition. In CT26 and PAN02 bilateral subcutaneous tumor models, OBP-702 had a significant antitumor effect on both OBP-702-treated and -non-treated sides, and TIL analysis showed a significant increase in CD8 and TRM. In a rechallenge study, OBP-702-pretreatment showed significant growth inhibition of re-inoculated tumors.
Conclusion: The OVs showed potent and long-term immune activation by inducing CD8 and TRM in tumors as well as direct anti-tumor effects, and synergistic effects with ICI.

#3721 EZH2 inhibition enhances PD-L1 protein stability through USP22-mediated deubiquitination in colorectal cancer.

J. Yang, J. Huang, Q. Yin, L. Xue;
Peking University Third Hospital, Beijing, China

The regulation of PD-L1 is the key question which largely determines the outcome of the immune checkpoint inhibitors (ICIs) based therapy. The epigenetic mechanism is involved in transcriptional regulation towards PD-L1. However, besides the transcription level, the protein stability of PD-L1 is closely correlated to its function and has drawn more and more attention. In this study, EZH2 inhibition could enhance PD-L1 expression and protein stability, and the deubiquitinase ubiquitin-specific peptidase 22 (USP22) is identified as a key mediator in this process. EZH2 inhibition upregulates the expression of USP22 via canonical mechanism, and upregulated USP22 further stabilize PD-L1. Importantly, a combination of EZH2 inhibitors with anti-PD-1 immune checkpoint blockade therapy could improve the tumor microenvironment, promotes immune cell infiltration, enhances sensitivity to immunotherapy and exerts synergistic anti-cancer effects. In addition, knocking down USP22 could potentially enhance the therapeutic efficacy of EZH2 inhibitor on colon cancer. These findings unveil the novel role of EZH2 inhibitors (EZH2i) in tumor immune evasion by upregulating PD-L1. Although it may be one reason of EZH2i inefficacy due to the fact that it elicits the immune suppressive effect, appropriately utilizing this drawback to arouse PD-L1 expression may convert the tumor into more responsive upon ICI cancer therapy. In addition, the EZH2-USP22-PD-L1 regulatory axis could further facilitating to identify populations sensitive to immunotherapy or provide novel strategy for combined treatment. Therefore, these findings provide valuable insights into the intricate interplay between EZH2 and PD-L1, shedding light on the optimization of combining both immune checkpoint blockade and EZH2 inhibitor based epigenetic therapies to achieve more efficacies and accuracy in cancer treatment.

#3722 Immunotherapy efficacy in advanced hepatocellular carcinoma in a diverse and underserved population in the United States.

F. Bteich[1], L. Bioh[1], K. Desai[1], C. Zhang[2], A. Kaur[3], R. A. Levy[1], A. Wang[1], S. Sultana[1], A. Kaubisch[1], M. M. Kinkhabwala[4], S. Bellemare[4], S. A. Fidvi[2], D. Kanmaniraja[2], R. G. Berkenblit[2], J.-Y. Moon[2], A. A. Adedimeji[2], C. Y. Tow[4], Y. M. Saenger[1];

[1]Montefiore Einstein Comprehensive Cancer Center, Bronx, NY, [2]Albert Einstein College of Medicine, Bronx, NY, [3]Jacobi Medical Center, Bronx, NY, [4]Montefiore Medical Center, Bronx, NY

The incidence of hepatocellular cancer (HCC) in the Bronx is 61% higher than the rest of New York State. Underserved populations are not well represented in clinical trials of immune checkpoint inhibitors. The purpose of this study is to analyze the efficacy of immunotherapy treatment in a diverse and underserved patient population in the Bronx. Study demographics include 194 patients treated with ICI at the Montefiore Einstein Comprehensive Cancer Center (MECCC) between 2017 and 2022. A retrospective electronic medical record (EMR) review was conducted of all adult patients and this sample size was identified as having advanced HCC treated with immunotherapy. Outcome parameters such as overall survival and disease control rate assessed by radiologists using the Modified Response Evaluation Criteria in Solid Tumors (mRECIST 1.1) were reported. Survival was evaluated using parameters such as baseline serum alpha-fetaprotein(AFP) level, its evolution at the 3-month re-evaluation mark, the Child-Pugh(CP) class and MELD-Na score at the time of diagnosis. Categorical variables were analyzed by Chi-squared test and survival was analyzed using Kaplan-Meier (KM) curves. MECCC patients were 40.7% Hispanic and 20.6% Black, compared with 3% and 2% respectively in the landmark IMbrave 150 study. Median overall survival (mOS) on ICI was 9.0 months, 25.0 months for the 100 (51.5%) favorable-prognosis Child Pugh A (CPA) patients included in HCC clinical trials. Disease control rate (DCR) was 58.5% among 123 evaluable patients per mRECIST 1.1. Baseline liver function, as defined by CP and Model for End Stage Liver Disease-Sodium (MELD-Na), correlated with survival ($p<0.001$). Hepatitis C Virus (HCV) and alcoholism were over-represented relative to National Cancer Institute (NCI) data (56.2% vs 4.7% and 38.7% vs 8.2%, respectively). HCV treatment correlated with prolonged survival in infected patients ($p=0.0017$). AFP decline correlated with response ($p=0.001$). Hispanic patients lived longer when clinical variables were controlled for (mOS 52 vs 23 months; $p=0.011$). In summary, our patient population differed significantly in racial composition and etiology of liver disease from clinical trial populations on which ICI was tested. In an underserved HCC population, ICI yielded a DCR of 58.5% and low rates of severe toxicity. This work highlights ICI efficacy in minority groups, a need for earlier HCC diagnosis and for studies of genetics and environmental factors in Hispanics with HCC.

#3724 Targeting the LIFR-LCN2 pathway to sensitize liver cancer to immunotherapy.

Y. Deng, L. Ma;
UT MD Anderson Cancer Center, Houston, TX

Liver cancer, primarily hepatocellular carcinoma (HCC), is highly lethal with limited treatment options and no biomarker to predict therapy response. The current frontline therapies for liver cancer, including sorafenib and the combination of atezolizumab (anti-PD-L1) and bevacizumab (anti-VEGF), have limited therapeutic benefits, which could be attributed, at least in part, to the highly immunosuppressive tumor microenvironment in liver cancer. Leukemia inhibitory factor receptor (LIFR) is frequently downregulated in HCC. My recent studies revealed that in oncogene-induced liver tumors, overexpression of LIFR increased, while knockout of Lifr decreased $CD8^+$ T cell infiltration, which may be mediated by LCN2-dependent inhibition of T cell viability, proliferation, and effector function. In ongoing and future work, I will investigate whether LIFR or therapeutic LCN2 neutralization can sensitize HCC to immunotherapy. If successful, this project will illuminate how to improve liver cancer immunotherapy by targeting the LIFR-LCN2 pathway. Low LIFR expression and high LCN2 expression may be used to select HCC patients who will likely benefit from the combination therapy with the LCN2-neutralizing antibody plus immune checkpoint inhibitors.

#3725 Exosomal Galactin-3 promotes pre-metastatic niche formation that accelerates peritoneal metastases of gastric adenocarcinoma.

Y. Fan, S. Song, M. Pool Pizzi, K. Yoshimura, J. Vykoukal, S. Hanash, J. Ajani;
UT MD Anderson Cancer Center, Houston, TX

Peritoneal carcinomatosis (PC) in gastric adenocarcinoma (GAC) lead to a short median survival (≤6 months). Pre-metastatic niche (PMN) formation, in a distant organ to prepare for tumor seeding and colonization, has long been recognized. However, the precise molecular and mechanistic contributions of exosomes in PMN formation of PC remain unclear. We identify that exosomes promote PMN formation in the peritoneal cavity by patient-derived orthotopic mouse model. Using an in-depth proteomic profiling of paired ascites cells and ascites-derived exosomes from PC patients, we discover that Galectin-3 as the exosomal payload is responsible for PC by promoting PMN formation in both patient-derived orthotopic model and syngeneic mouse model. Inhibition of exosomal Galectin-3 reverses PC. Furthermore, exosomal Galectin-3 activates cancer-associated fibroblasts (CAFs), which further activate the CXCL12/CXCR4 axis to orchestrate the immunosuppressive PMN. Simultaneous inhibition of exosomal Galectin-3, CXCR4, and PD-1 leads to tumor regression and durable anti-tumor responses. Thus, this study provides a rationale for the novel clinical strategy for GAC patients with PC.

#3726 Absence of synergistic effects for PARPi and immunotherapy combinations in ex vivo 3D micro tumor assay for ovarian cancer patients.

L. J. Ceton[1], E. Koedoot[1], T. J. P. Sijsenaar[1], D. J. van der Meer[1], M. Montero Garcia[1], J. van der Valk[1], K. Maad[2], C. de Kroon[3], A. van Altena[4], **W. Vader**[1], J. Kroep[3], N. Ottevanger[4];

[1]VitroScan B.V., Leiden, Netherlands, [2]Oncodia, Uppsala, Sweden, [3]LUMC, Leiden, Netherlands, [4]Radboud University Medical Center, Nijmegen, Netherlands

Introduction: 50% of ovarian cancers are homologous recombination deficient (HRD), with 15% of the patients carrying a BRCA mutation. PARP inhibitors (PARPi) are designed to improve survival in HRD patients, but clinical responses to PARPi often do not match HRD status. In this study, a 3D ex vivo tumor testing platform was applied to quantify patient-specific drug responses to (combinations of) PARPi, chemo- and immunotherapies.

Material and Methods: 81 patients with ovarian cancer eligible for chemotherapy were included in the trial between 2019 and 2022 in the Netherlands (IRB P18.032). Tumor clusters were isolated from ascites and solid tissue, seeded and exposed to three PARPi, standard-of-care chemotherapies and immunotherapies, both single agent and in combination. Ex vivo drug sensitivity was quantified using high-throughput 3D imaging and extraction of morphological features. Bliss scores were calculated for synergy analysis.

Results: Results were generated in two weeks after sample collection. Ex vivo patient-specific response profiles were observed for all drug classes, with a small percentage of patients (7%) showing strong PARPi sensitivity reflected by strong tumor cluster shrinkage upon treatment. Significant correlation of drug sensitivity profiles was observed comparing the different PARPi between themselves, but also comparing PARPi and platinum responses. Interestingly, ex vivo sensitivity to olaparib and immunotherapy combinations demonstrated additive, but no synergistic effects (21 patients, 79 tests). In addition, olaparib responses were shown to be independent of immune responses (SEA).

Conclusion: This study applied a predictive ex vivo 3D micro tumor testing platform to classify patient-specific sensitivity to (a combination of) PARPi, chemo- and immunotherapies in over 80 patients. The current dataset demonstrates the potential of ex vivo testing to identify patients that are responsive to PARPi. No synergistic effects were observed for these drugs in combination with immunotherapies.

Discussion: Evaluation of PARPi responses in a functional 3D micro tumor assay could support identification of responsive patients prior to treatment. Distinct responses were observed for PARPi and immunotherapies. No synergistic but additive effects were measured, suggesting that ovarian cancer patients could benefit from PARPi and immunotherapies. Correlation of clinical and ex vivo drug responses to PARPi in combination with available HRD tests will further validate the platform for predicting patient clinical outcome.

#3727 Synergistic effect of CD47 blockade and EPHA3 treatment on recurrent head and neck cancers.

S. Kim[1], M. Han[1], J. Kim[2], S. Kim[3];
[1]University of Ulsan College of Medicine, Ulsan, Korea, Republic of, [2]Inha University College of Medicine, Incheon, Korea, Republic of, [3]University of Ulsan College of Medicine, Seoul, Korea, Republic of

CD47 acts as a “don’t eat me “signal and suppresses it through its interaction with signal regulatory protein (SIRP-a) on the macrophage. CD47 is expressed in many human cancer cells, including head and neck cancer. Additionally, we reported in a previous study that EphA3 is overexpressed in radioresistant head and neck cancer and may play an important role in the development of radioresistance in head and neck cancer. In our present study, we demonstrated that the blockade of EPHA3 and CD47 attenuates the function of M2-like macrophages and may contribute to macrophage polarization toward the M1 phenotype. Here, we combined a therapeutic strategy of an anti-EPHA3 and an anti-CD47 antibody. Using mRNA sequencing and fluorescence imaging, we showed that the combination treatment could significantly enhance the effectiveness of anti-EPHA3 and anti-CD47 antibodies, in reactivating macrophages and reversing macrophage polarization. In addition to using flow cytometry in vivo, combination treatments can alter the proportion of tumor-associated macrophages (TAMs). Collectively, our findings suggested that the combination treatment of anti-EphA3 and the anti-CD47 antibodies could significantly improve tumor suppression, increase the proportion of M1 macrophages, and decrease the proportion of M2 macrophages.

#3728 Treating pancreatic cancer with "armed" oncolytic adenoviruses and adoptive T-cell therapy.

B. L. Roach, M. Yamamoto;
University of Minnesota, Minneapolis, MN

Introduction: Pancreatic ductal adenocarcinoma (PDAC) is the third leading cause of cancer-related mortalities and is projected to become second by 2030. Although major advancements in cancer treatments have improved outcomes for many cancers, the survival rate for PDAC has not improved in nearly four decades. Two primary features make PDAC refractory. First, the highly immunosuppressive tumor microenvironment (TME) plays a crucial role in impeding the innate and effector arms of the immune system to prevent anti-tumor responses. Second, desmoplasia causes formation of fibrotic tissue within and around tumor tissue, which creates a physical barrier for infiltration of anti-tumor immune cells and therapeutics. The goal of this project is to develop viro-immunotherapies against PDAC that target the immunosuppressive TME and desmoplasia by utilizing “armed” oncolytic adenoviruses (OAds) and adoptive T-cell therapy (CAR T-cells). Three transgenes were selected to “arm” the OAd constructs: i.) TGF-beta blocker, ii.) interleukin-7 (IL-7), and iii.) interferon gamma (IFN-gamma).

Methods: “Armed” replication-deficient adenovirus (Ad) constructs were first generated to isolate transgene function from oncolytic activity. Each transgene was individually cloned into the E1 region of Ad-5 (WT). Viral particles were amplified in 293 cells and purified via ultracentrifugation using a CsCl gradient. Anti-tumor effects were measured using a syngeneic mouse model. C57BL/6 mice were subcutaneously injected with KPC cells (mouse PDAC cell line), and tumors were treated with Ad constructs via intratumoral injection. Tumors were harvested at various time points and stained for immune cell infiltration and fibrosis. Mesothelin-directed CAR T-cells (meso-CARTs) were injected (tail vein) into NSG mice bearing subcutaneous Panc1 tumors after intratumoral injection of Ad constructs.

Results: Tumor growth was significantly inhibited in syngeneic mouse models in the presence of each “armed” Ad construct. Furthermore, significant tumor infiltration of anti-tumor immune cells was induced upon treatment as well as a decrease in fibrosis. Abscopal effects were observed on contralateral tumors after injection of ipsilateral tumors as well as an increase in tumor infiltration of anti-tumor immune cells. Finally, combining meso-CARTs with IFN-gamma-expressing Ad induced the greatest anti-tumor responses.

Conclusions: PDAC is very resistant to conventional therapeutics, so utilizing combination strategies seems essential. The findings in this study have broad implications in the field of pancreatic cancer by shedding light on how the TME can be manipulated to enhance anti-tumor effects to aid in the development of more efficient therapeutics against PDAC. Moreover, therapeutics inducing abscopal effects should be highly valued because most PDAC patients die from metastasis.

#3729 Association between clinical characteristics and treatment outcome of immune checkpoint inhibitor with or without chemotherapy in elderly non-small cell lung cancer patients with high PD-L1 expression.

H. Kawachi[1], S. Takei[1], T. Yamada[1], M. Tamiya[2], Y. Negi[3], Y. Goto[4], A. Nakao[5], S. Shiotsu[6], T. Takeda[7], A. Okada[8], T. Harada[9], K. Date[10], Y. Chihara[11], I. Hasegawa[12], N. Tamiya[13], T. Kijima[3], K. Takayama[1];

[1]Kyoto Prefectural University of Medicine, Kyoto, Japan, [2]Osaka International Cancer Institute, Osaka, Japan, [3]Hyogo Medical University, Nishinomiya, Japan, [4]Fujita Health University School of Medicine, Toyoake, Japan, [5]Fukuoka University Hospital, Nanakuma, Japan, [6]Japanese Red Cross Kyoto Daiichi Hospital, Kyoto, Japan, [7]Japanese Red Cross Kyoto Daini Hospital, Kyoto, Japan, [8]Saiseikai Suita Hospital, Suita, Japan, [9]Fukuchiyama City Hospital, Fukuchiyama, Japan, [10]Kyoto Chubu Medical Center, Nantan, Japan, [11]Uji-Tokushukai Medical Center, Uji, Japan, [12]Saiseikai Shigaken Hospital, Rittou, Japan, [13]Rakuwakai Otowa Hospital, Kyoto, Japan

Background and Aim: The proportion of elderly patients diagnosed with advanced stage lung cancer has been increasing owing to the aging of the population. Thus, formulating a treatment strategy for elderly non-small cell lung cancer (NSCLC) patients is essential. For NSCLC with programmed cell death ligand-1 (PD-L1) tumor proportion score (TPS) ≧ 50%, both immune checkpoint inhibitor monotherapy (ICI mono) and combination therapy of ICI and chemotherapy (ICI/Chemo) have been established as standard treatment options. However, evidence based on the clinical trials specifically for elderly patients is limited, and it is not clear whether ICI mono or ICI/Chemo should be used in elderly NSCLC patients with PD-L1 TPS ≧ 50%. This study aimed to clarify which clinical population will benefit from ICI/Chemo in elderly NSCLC patients with PD-L1 TPS ≧ 50%.

Method: We retrospectively analyzed 199 NSCLC patients aged ≧ 70 years of Eastern Cooperative Oncology Group performance status (ECOG PS) 0-1 with PD-L1 TPS ≧ 50% who were treated with ICI mono or ICI/Chemo. We analyzed the association between treatment outcome and baseline patient characteristics in each group. Comparing the treatment outcome, propensity score matching was used to reduce bias.

Results: Of the 199 patients, 131 received ICI mono, and 68 received ICI/Chemo. The median overall survival (OS; 25.0 vs. 42.2 months, P = 0.116) and median progression-free survival (PFS; 10.9 vs. 11.8 months, P = 0.231) did not significantly differ between the ICI mono and ICI/Chemo groups. Multivariate analysis revealed the factors independently associated with OS: smoking history in the ICI mono group (smoking history/non-smoking history, hazard ratio [HR] 0.36, 95% confidence interval [CI] 0.16-0.78, P = 0.048), and ECOG PS (ECOG PS 1/PS 0, HR 3.84, 95% CI 1.44-10.20, P = 0.007) and histology type in the ICI/Chemo group (Non-squamous cell carcinoma/squamous cell carcinoma, HR 0.17, 95% CI 0.06-0.44, P < 0.001). For patients with ECOG PS 0 (OS: 26.1 months vs. not reached, P = 0.0031, PFS: 6.5 vs. 21.7 months, P = 0.0436) or non-squamous cell carcinoma (OS: 23.8 months vs. not reached, P = 0.0038, PFS: 10.9 vs. 17.3 months, P = 0.0383) in the ICI/Chemo group, PFS and OS were significantly longer than in the ICI mono group.

Discussion and Conclusion: In elderly NSCLC patients with high PD-L1 expression, this study suggested that ECOG PS and histological type may be predictive clinical factor when choosing ICI mono or ICI/Chemo treatment.

#3730 Impact of proton pump inhibitor on ICI with or without chemotherapy for NSCLC with high PD-L1 TPS.

R. Sawada[1], H. Kawachi[1], T. Yamada[1], M. Tamiya[2], Y. Negi[3], Y. Goto[4], A. Nakao[5], S. Shiotsu[6], T. Takeda[7], A. Okada[8], T. Harada[9], K. Date[10], Y. Chihara[11], I. Hasegawa[12], T. Kijima[3], K. Takayama[1];

[1]Kyoto Prefectural University of Medicine, Kyoto, Japan, [2]Osaka International Cancer Institute, Osaka, Japan, [3]School of Medicine, Hyogo Medical University, Nishinomiya, Hyogo, Japan, [4]Fujita Health University School of Medicine, Toyoake, Aichi, Japan, [5]Fukuoka University Hospital, Nanakuma, Fukuoka, Japan, [6]Japanese Red Cross Kyoto Daiichi Hospital, Kyoto, Japan, [7]Japanese Red Cross Kyoto Daini Hospital, Kyoto, Japan, [8]Saiseikai Suita Hospital, Suita, Osaka, Japan, [9]Fukuchiyama City Hospital, Fukuchiyama, Kyoto, Japan, [10]Kyoto Chubu Medical Center, Nantan, Kyoto, Japan, [11]Uji-Tokushukai Medical Center, Uji, Kyoto, Japan, [12]Saiseikai Shigaken Hospital, Rittou, Shiga, Japan

Background and Aim: Immune checkpoint inhibitors (ICIs) have been widely used for the initial treatment of non-small cell lung cancer (NSCLC). Although both ICI monotherapy and the combination of ICI plus chemotherapy (chemo-ICI) are promising therapeutic options for patients with a programmed cell death ligand-1 tumor proportion score of 50% or higher (high PD-L1), the patient's clinical background and biomarkers differentiating the two options are still not well-defined. In our prior research, we found that a history of proton pump inhibitor (PPI) use independently have negative impact with significantly shorter overall survival (OS) and progression-free survival (PFS) in NSCLC patients harboring high PD-L1 with pembrolizumab monotherapy, but not with chemo-ICI. However, this OS data remain immature. Therefore, in our current study, we extended the follow-up period and conduct additional analysis including OS data to confirm this trend.
Method: Advanced NSCLC patients with high PD-L1 who had received pembrolizumab or chemo-ICI as the first-line treatment between March 2017 and December 2020 at 13 hospitals in Japan were analyzed. Survival outcomes were estimated using the Kaplan- Meier method and were compared using the log-rank test.
Results: A total of 425 patients with NSCLC were included in the study, with 271 patients (median [range] age, 72 [43-90] years; 215 [79%] men) receiving pembrolizumab monotherapy as their first-line treatment and 154 patients (median [range] age, 69 [36-86] years; 121 [79%] men) receiving chemo-ICI as their first-line treatment. The median follow-up duration was 22.8 months. Among patients with a history of PPI use, both median PFS (19.3 months vs. 6.8 months; HR, 0.53; 95% CI, 0.35-0.78; P = .003) and the median OS(not reached vs. 20.4 months; HR, 0.53; 95% CI, 0.34-0.85; P = .04) were significantly longer in the chemo-ICI group compared to the pembrolizumab monotherapy group. For patients without a history of PPI use, both median PFS (11.4 months vs. 10.8 months; HR, 0.99; 95% CI, 0.76-1.3; P = .36) and the median overall survival (42.2 months vs. 29.9 months, HR, 0.84; 95% CI, 0.62-1.16; P = .33) showed no significant differences between the groups.
Discussion and Conclusion: This retrospective study showed that a concomitant treatment with PPI is poor prognostic factor in patients harboring high PD-L1 and treated with ICI monotherapy compared with chemo-ICI in Japanese cohort and this tendency is durable in long-term follow-up. These results indicate that when deciding on an ICI treatment, with or without chemotherapy, it is essential to take into account a concomitant treatment with PPI.

#3731 Spliceosome: A gatekeeper for necroptosis.

X. Jiang, X. Ma, S. Balachandran, I. Canadas;
Fox Chase Cancer Center, Philadelphia, PA

Small cell lung cancer (SCLC) is the most aggressive type of lung cancer with a 5-year overall survival of approximately 5%. SCLC has high prevalence of somatic mutations, yet express low to zero neoantigen. Despite promising advances in immunotherapy, highly metastatic SCLC remains a devastating disease and only a small fraction of SCLC patients respond to immunotherapy. These poor survival and lack of therapy options stresses the unmet need to identify novel and effective targeted therapies for metastatic SCLC. Here, we demonstrate that targeting the splicing core component, SF3B1, in SCLC, is a molecular trigger for tumor killing and viral mimicry.SF3B1 inhibition through the small molecule Pladienolide B (PlaB) induces the accumulation of immunogenic double-stranded RNAs (dsRNAs), including right-handed dsRNA conformation (A-RNA), provoking a tumor-intrinsic innate immune response and tumor cell death in SCLC preclinical models. Strikingly, we discovered that PlaB treatment also induces the formation of Z-form nucleic acids (Z-NAs), which are unique, left-handed nucleic acids and necroptosis-activating ligands for the host sensor ZBP1.These endogenous A-RNAs and Z-NAs initiate tumor-intrinsic antiviral interferon (IFN) signaling in SCLC cells leading to tumor-intrinsic immunogenicity and apoptosis. Notably, we also found that Z-NAs derived from spliceosome inhibition trigger the activation of ZBP1, inducing RIPK3-mediated MLKL activation and eventual necroptosis, a highly immunogenic cell-death pathway, in ‘necroptosis competent’ cells, including mouse embryonic fibroblasts (MEFs). This opens unexplored strategies for spliceosome inhibitors to activate anti-tumor immune pathways not only in tumor cells themselves, but also in cells of the Tumor Microenvironment (TME), which too can break tolerance and enhance anti-tumor T cell responses which is crucial to enhance cancer immunotherapy responses. These findings demonstrate a unique and novel spliceosome-targeted mechanism to remodel the immunosuppressive TME of SCLCs. Also, our study suggests that SF3B1 inhibitors and potentially other spliceosome inhibitors might be used not only to selectively kill tumor cells, but also as compounds to generate Z-NAs in tumor cells and cells of the TME and trigger on-demand necroptosis without need for an active virus infection.

#3732 Peripheral pharmacodynamic activity of epcoritamab as monotherapy and in combination with rituximab + lenalidomide in patients with follicular lymphoma.

H. Si[1], J. Zhang[1], M. Wielgos-Bonvallet[1], L. Falchi[2], K. Linton[3], W. Jurczak[4], D. Belada[5], I. Altıntaş[6], M. Sacchi[1], E. Favaro[7], A. Rana[1], D. Hoehn[1], D. Soong[1], C. W. Chiu[1], M. Jure-Kunkel[1];

[1]Genmab, Plainsboro, NJ, [2]Memorial Sloan Kettering Cancer Center, New York, NY, [3]The Christie NHS Foundation Trust and Manchester Cancer Research Centre, Manchester, United Kingdom, [4]MSC National Research Institute of Oncology, Krakow, Poland, [5]University Hospital and Faculty of Medicine, Hradec Kralove, Czech Republic, [6]Genmab, Utrecht, Netherlands, [7]Genmab, Copenhagen, Denmark

Introduction: Epcoritamab (DuoBody®-CD3xCD20) is a subcutaneous IgG1 bispecific antibody that simultaneously binds to CD3 on T cells and CD20 on malignant B cells, inducing activation and cytotoxic activity of T cells to mediate killing of target lymphoma cells. Epcoritamab is approved in the US for the treatment of adults with relapsed/refractory (R/R) diffuse and high-grade large B-cell lymphoma after ≥2 lines of systemic therapy (also approved in Europe, the UK, Japan, and Canada). Here we present the pharmacodynamic effects of epcoritamab as monotherapy (EPCORE NHL-1: NCT03625037) or in combination with rituximab + lenalidomide (R^2) (EPCORE NHL-2: NCT04663347) in peripheral blood of patients with follicular lymphoma (FL), a heterogeneous disease for which many patients have an unmet medical need for efficacious, well-tolerated, off-the-shelf therapies.

Methods: In EPCORE NHL-1 expansion phase, adults with R/R FL received epcoritamab monotherapy; in EPCORE NHL-2, adults with R/R (arm 2) or newly diagnosed (ND) (arm 6) FL received epcoritamab combined with R^2. B-cell markers and T-cell proliferation and activation markers in whole blood were assessed using validated flow cytometry assays. Cytokines in plasma were measured using a validated multiplex immunoassay.

Results: Epcoritamab as monotherapy and in combination with R^2 induced rapid depletion of circulating peripheral B cells ($CD19^{\pm}$) in patients with detectable peripheral B cells at baseline. Additionally, within the first 2 cycles, epcoritamab monotherapy induced a transient elevation of peripheral $CD8^{\pm}$ and $CD4^{\pm}$ T cells expressing proliferation ($Ki67^{\pm}$%) and activation ($HLA\text{-}DR^{\pm}$% and $PD\text{-}1^{\pm}$%) markers. R/R and ND patient groups treated with epcoritamab + R^2 showed a trend for greater induction of proliferating and activated peripheral T cells. Likewise, elevation in T-cell absolute counts was observed from cycle 2 onward, with a trend of higher levels with epcoritamab + R^2 vs epcoritamab monotherapy. In addition, a moderate but transient elevation of circulating cytokines including IFNγ, IL-6, and IL-10 during cycle 1 was observed with epcoritamab monotherapy and epcoritamab + R^2. Importantly, IL-6 and IL-10 returned to approximate baseline levels prior to the subsequent dose. Compared with epcoritamab monotherapy, patients treated with epcoritamab + R^2 showed a trend for lower median levels of IL-6 peaks 24 hours after the first full dose.

Conclusion: The pharmacodynamic activity of epcoritamab combined with R^2 in R/R and ND FL was consistent with epcoritamab's mechanism of action as monotherapy. Epcoritamab + R^2 showed a favorable pharmacodynamic profile with a trend toward increased T-cell activation and T-cell elevation, and lower IL-6 levels. These data support the ongoing phase 3 trial of epcoritamab + R^2 compared with R^2 alone in patients with R/R FL (EPCORE FL-1: NCT05409066).

#3733 Gut microbiota-dependent bile acidtaurodeoxycholic acid, TDCAfacilitates anti-tumor immune responses by modulating cytotoxic CD8 T cell immunity.

W. Li, H. Wang, L. Coughlin, N. Poulides, P. Valle, J. Lichterman, X. Zhan, C. Liao, S. Palmer, X. Li, A. Koh;
UT Southwestern Medical Center, Dallas, TX

Gut microbiota are critical for effective immune checkpoint blockade therapy (ICT) for cancer. However, the underlying mechanisms by which gut microbiota and/or microbiota-derived metabolites augment antitumor response are largely unknown. Here, we utilized a preclinical melanoma (B16-F10) model and treated groups of mice (Jackson, C57BL/6J, female, 6-8 wks, n=14-26 per group) with seven distinct antibiotic treatments to induce unique gut microbiomes and metabolomes. Mice were then treated with ICT (anti-PD-1 and anti-CTLA-4), resulting in markedly heterogeneous tumor phenotypes (tumor volume and weight) as dictated by the specific antibiotic treatment. Using machine learning (e.g. random forest classifier), we identified metabolite candidates most strongly associated with ICT response (i.e. tumor volume and weight).One metabolite candidate, the bile acid taurodeoxycholic acid, TDCA, had previously been identified by my group as associated with anti-PD-1/anti-CTLA-4 response in human melanoma patients (PMID 28923537). Administration of TDCA alone is sufficient to overcome antibiotic-induced ICT hyporesponsiveness in mice. Utilizing both *in vitro*/*ex vivo* immune cell assays and *in vivo* preclinical models, we have validated that TDCA treatment directly boosted the antitumor cytotoxic CD8+ T cell responses (i.e. IFN-gamma production, anti-tumor cytotoxicity, tumor growth, etc.) without affecting innate immune responses. Bulk RNAseq of CD8 T cell analysis indicated that TDCA modulate CD8 T cell function through IFN pathway. Together, our findings suggest that the gut microbial metabolite TDCA could promote immunotherapy efficacy through regulation of CD8+ T cell immunity and has the potential to be utilized as a novel therapeutic agent to enhance ICT efficacy.

#3734 Tumoral and systemic immune modulation with neoadjuvant (NeoAd) intratumoral (IT) TAVO-EP (plasmid IL-12 electro gene transfer) and nivolumab (NIVO) in patients (pts) with operable locoregionally advanced melanoma.

A. A. Tarhini[1], Z. Eroglu[1], J. S. Zager[1], R. J. Gonzalez[1], A. A. Sarnaik[1], C. Cruse[1], D. B. De Aquino[1], E. Abraham[1], D. M. Acevedo[1], A. Richards[1], M. J. Schell[1], D. Kalos[1], P.-L. Chen[1], J. L. Messina[1], D. A. Canton[2], V. K. Sondak[1];

[1]H. Lee Moffitt Cancer Center, Tampa, FL, [2]OncoSec, San Diego, CA

Introduction: IT TAVO-EP (tavokinogene telseplasmid delivered by electroporation) results in localized expression of IL12 in the tumor microenvironment (TME). This study (NCT04526730) evaluated NeoAd TAVO-EP and NIVO. All patients provided a written informed consent (Advarra IRB Pro00041794). Biomarkers of tumoral and systemic immune responses were conducted and correlated with clinical outcomes.

Methods: NeoAd phase comprised up to 3 x4-week cycles of IT TAVO-EP and iv NIVO followed by surgery. Endpoints included pathologic complete response (pCR), near pCR, major response (pMR; pCR + near pCR) and nonresponse (pNR). Biospecimens were collected at screening, C1D8, C2D1 (~30 days from treatment start), pre-surgery (~90 days). Slides cut from FFPE tissue were analyzed by chromogenic immunohistochemistry (IHC) for $CD8^{\pm}$ tumor infiltrating lymphocytes (TIL) and PD-L1 (22C3 CDx assay). RNA extracted from FFPE tissue was subjected to NanoString's IO360 transcriptomic analysis, including Tumor Inflammation Signature (TIS). PBMCs were stained and analyzed via flow cytometry on an LSR Fortessa X-20. Serum samples were analyzed for cytokine levels using Luminex® MAGPIX® platform (15-plex).

Results: 16 pts were treated; 1 with PR declined surgery, 1 with early distant PD did not have surgery, 14 had surgery: 2 pNR, 3 near pCR, 9 pCR; pMR rate 12/15 (80%). In tumor, at baseline, 9/11 pts tested had <20% $CD8^{\pm}$ TIL, 7/11 <10% PD-L1 tumor proportion score (TPS) and 6/10 TIS of ≤0, predicting non-response to anti-PD-1. In 5 pts with evaluable matched tissue at baseline and C2D1: 5/5 had increased peritumoral CD8+ T cells, 4/5 increased CD8+ TIL, 2/5 increased PD-L1, 4/5 increased TIS at C2D1 compared to baseline. Tumoral transcriptome profile revealed significant upregulation of genes involved in innate and adaptive immune responses (IFN-gamma, APM, granzymes, CD8, PD-L1, JAK1, chemokines, others) at C2D1. In blood, proliferating Ki-$67^{\pm}$/$PD\text{-}1^{\pm}$/$CD8^{\pm}$ T cells expanded at C2D1 while total $PD1^{\pm}$/$CD8^{\pm}$ cells decreased. Decrease of $PD1^{\pm}CD8^{\pm}$ cells and other subtypes in blood at C2D1 coincided with TME infiltration by $CD8^{\pm}$ cells. Serum effector cytokines including IL12, IFN-gamma and IL2, showed no biologically meaningful changes following treatment or differences between responders and non-responders.

Conclusions: At baseline, most patients exhibited low CD8+ TIL, PD-L1 and TIS, with enhanced immune activation following treatment in the TME and blood including increased immune-related gene expression, CD8+ TIL, peritumoral CD8+ T cells and TIS. Four of 5 pts with negative predictive baseline biomarkers $[CD8^{\pm}TIL/PD\text{-}L1/TIS]^{low}$ experienced pCRs supporting activity of IL12/anti-PD1 based regimens in this setting.

#3735 Combinatorial targeting of tumor-microenvironment together with antigen vaccination using innovative nano-immuno-gel for enhanced cancer-immunotherapy.

A. K. Sunilkumar[1], M. Salvi[2], S. N. Mohammed[1], Z. T. Zakkariya[1], A. G. Cadena[2], S. Chappan[1], S. P. Radhakrishnan[1], M. Manohar[1], P. Keechilat[3], S. Nair[1], P. Romero[2], C. Jandus[2], **M. Koyakutty**[1];

[1]Amrita Vishwavidyapeetham University, Kochi, India, [2]Ludwig Institute for Cancer Research, Lausanne, Switzerland, [3]Amrita Institute of Medical Sciences (AIMS), Kochi, India

Successful cancer-immunotherapy need to address three critical factors: a) Relieving the immuno-suppressive tumor microenvironment (TME) b) expanding antigen specific, functionally avid effector T cells, c) triggering systemic immunity with a balanced innate-adaptive response for continued effector cell-feeder supply-chain and memory generation. Combinatorial engagement of such multi-elemental components demands smart, engineered immunotherapy systems compared to conventional vaccines. Here, we report an injectable Nano-Immuno-Gel (NIG) that can neutralize immunosuppressive components (e.g., myeloid derived suppressor cells (MDSCs), M2 macrophages (Mϕ) in TME, together with generating strong effector T cells by nano-vaccination, and sustained release of cytokines to enhance systemic immunity against tumor. In a proof-of-concept study, we show that sustained-release of myeloid-suppressive drug from NIG depot efficiently inhibited MDSCs and M2 Mϕ, not only in TME, but also in the circulation and in peripheral systems, thus creating a conducive, hot TME infiltrated with CD8 effector cells. Follow-up antigen vaccination with novel nano-adjuvant enhanced DC-T cell engagement and sustained IL15 release from NIG provided systemic NK/T cell activation, rendering significant control of the tumor growth. Our data demonstrate the potential of rationally engineered multi-functional nano-immuno-gels (NIG) to combine sequential neutralization of the suppressive TME, antigen vaccination, and concurrent systemic immune activation for highly effective combinatorial cancer immunotherapy.

#3736 Bridging the gaps: A cross-species approach to PD-1 and OX40 combination immunotherapy.

M. Sandey[1], D. Ruiz[1], J. Marable[1], D. Bedi[2], P. Agarwal[1];
[1]Auburn University, Auburn, AL, [2]Tuskegee University, Tuskegee, AL

Monoclonal antibodies (mAbs) targeting immune checkpoints, such as PD-1, PD-L1, and CTLA4, have provided unprecedented clinical benefits to human cancer patients. Novel strategies such as combination therapy with OX40 or 4-1BB agonists are currently under investigation in various pre-clinical studies to enhance the therapeutic benefits of immune checkpoint inhibitors. While syngeneic mouse tumor xenograft models offer valuable insights in pre-clinical testing, they fall short in capturing the nuanced heterogeneity within and between tumors and the dynamic tumor-immune interface. In contrast, canine patients with spontaneous neoplasms possess a closely analogous and intact immune system. These canine patients, who receive sophisticated and advanced medical therapy like their human counterparts, can serve as a vital intermediate pre-clinical model system between rodent studies and human clinical trials, potentially reducing clinical trial failures. In this study, we have developed a novel bispecific fusion protein, denoted BsOXPD, that combines OX40 agonism and PD-1 blockade into a single therapeutic. Our bispecific fusion protein employs an anti-PD-1 nanobody (Nb) to bind and block the PD1 pathway and the extracellular domain (ECD) of the OX40 ligand to stimulate the OX40 receptor. We have developed murinized, caninized, and humanized versions of this protein. All versions of the bispecific fusion protein retain their biochemical and functional properties following the murinization, caninization, and humanization processes. Importantly, all versions effectively disrupt the PD-1/PD-L1 axis in murine, canine, and human systems while concurrently acting as potent OX40 agonists. To further improve the humanized version of the BsOXPD, we partially humanized the anti-PD1 Nb by introducing amino acid substitutions in various framework regions. The humanized anti-PD1 Nb still completely inhibited the binding of human PD-L1 to the PD-1 receptor. The caninized version of BsOXPD exhibits no toxicities or immune-related adverse events (irAEs) following intravenous injection at doses of 1 mg/kg or 3 mg/kg body weight in healthy beagle dogs. In summary, we have designed a cross-species Nb-based fusion protein for PD1 blockade and OX40 agonism. Our next goal is to evaluate the therapeutic efficacy of caninized BsOXPD in pet dogs with oral melanoma in neoadjuvant settings. Therefore, our cross-species approach will offer comprehensive insights into the safety, pharmacokinetic (PK) profile, and clinical benefits associated with the concurrent application of PD1 blockade and OX40 agonism.

#3737 Molecular and early clinical characterization of the anti-CD73 antibody S095024 (Sym024).

A. Spreafico[1], J. R. Ahnert[2], D. Sommerhalder[3], M. Almena-Carrasco[4], N. Harouki Crochemore[4], **X. Ianopulos**[5], J. S. Jakobsen[6], E. Armbruster[7], A. Delmas[4], A. des Georges[7], C. Frohlich[6], J. Geronimi[4], M. M. Grandal[6], R. W. Hansen[6], J. Lantto[6], J. Legrand[4], F. Levasseur[4], M. Riva[6], C. Rodrigues[4], V. Seif[4], V. Askoxylakis[5], N. Lakhani[8];

[1]Princess Margaret Canada, Toronto, ON, Canada, [2]MD Anderson Cancer Center, Houston, TX, [3]Texas Oncology-San Antonio Babcock Next Oncology, San Antonio, TX, [4]Servier, Gif-sur-Yvette, France, [5]Servier, Boston, MA, [6]Servier, Ballerup, Denmark, [7]The City University of New York (CUNY), New York, NY, [8]START Midwest, Grand Rapids, MI

Background: Adenosine signaling is a central immunosuppressive mechanism affecting a broad set of immune cell types. Adenosine is generated from extracellular ATP by a group of ectonucleotidases including CD39 and CD73. Suppressing the adenosine pathway via CD73 blockade may enhance the potential of checkpoint inhibitor therapies.S095024 (Sym024) is a fully human, effector-function attenuated antibody that binds to human and cynomolgus CD73 with sub-nM affinity.

Methods: Preclinically, the stoichiometry and conformational structure of the binding interaction between CD73 and S095024 was assessed by SEC-MALS and cryo-EM and the ability of S095024 to inhibit CD73 activity was done *in vitro* covering 3-, 6- and 24-hour incubation periods. The clinical safety, tolerability, pharmacokinetics, and pharmacodynamics of S095024 alone or in combination with Sym021, an anti-PD1 antibody, was investigated in a first-in-human study (NCT04672434) in patients with selected types of advanced solid tumors. Following assessment of single agent S095024 (100 to 1500 mg IV Q2W) in part I, the safety and tolerability of S095024 (300 to 1500 mg IV Q2W) was assessed in combination with Sym021 (200 mg IV Q2W) in part II. A part IIa was added: patients received 3000 mg IV Q2W of S095024 in Cycle 1, followed by 3000 mg S095024 + 200 mg Sym021 from Cycle 2 onwards.

Results: Structural data indicate that S095024 binds to CD73 in a unique configuration by bridging the two monomers of the molecule, interacting in a 1:1 stoichiometry and effectively preventing the conformational state cycling required for catalysis. Functional data using a 20x cell line panel harboring a broad range of CD73 expression levels demonstrates that this interaction modus results in deep enzymatic inhibition. As of 12 Oct 2023, 43 patients have been treated with, S095024 in the FIH study. S095024, as a single agent (N=18) and in combination with PD-1 blockade (N=25) was well tolerated across all dose levels. The most frequent treatment emergent adverse events (≥15% patients) were fatigue, nausea, diarrhea, dyspnea, and vomiting. A dose proportional increase in drug exposure, both in monotherapy and combination, was observed starting at 900 mg. Target engagement assessed both peripherally (free soluble CD73) and intra-tumorally (enzymatic activity), showed a sustained decrease in free soluble CD73 in blood at dose levels ≥1500 mg and dose-dependent CD73 modulation, with >80% inhibition reached at ≥1500 mg in tumor biopsies.

Conclusions: These findings reveal the potential of S095024 (Sym024) to prevent adenosine-mediated tumor evasion and support further clinical investigation.

#3739 Different combination regimens for OX40 agonists and PD-1 inhibitors exert different antitumor effects in OX40 humanized mice.

Y. Li, Y. Zhang, X. Qiu, D. Feng, R. Sun, **D. X. He**;
Shanghai Model Organisms Center, Inc., Shanghai, China

OX40, also known as CD134 or TNFRSF4, is a member of the tumor necrosis factor receptor (TNFR) superfamily which mainly expressed on the surface of activated T cells including Treg cells. Engagement of OX40 with its ligand, TNFSF4, leads to effector T cell expansion and cytokine release, inhibits activation-induced cell death (AICD) and promotes the survival of antigen-specific memory T cells. In contrast to the massive hit of immune checkpoint inhibitors like PD-1 and PD-L1, the benefit of agonistic antibodies in clinical trials has not been completely demonstrated to date. On one hand, higher doses could leads to T cell exhaustion or AICD, paradoxically, with no efficacy improvement. Another hand, the limited understanding of the biology of immune checkpoints underlying “accelerator and brake” should account for the slow clinical progress of OX40-targeted biologics. It seems that the dosing sequence or timing of anti-OX40 and anti-PD-1 is an important consideration in combination therapies. Given this, we firstly evaluated the antitumor effects of two different anti-human OX40 agonists in syngeneic MC38 and Pan02 tumor models, respectively, in hOX40 knockin mice. We observed tumor regressions upon treatment of OX40 agonistic Ab1 in a dose-dependence way in the homozygous hOX40 knockin mice engrafted with MC38 tumors. The anti-hOX40 Ab1 at high-dose (10 mg/kg) led to ~60% TGI, but no response at very low dose (0.1 mg/kg). Furthermore, the homozygous hOX40 knockin mice inoculated with Pan02 pancreatic tumors were treated with a novel strong anti-hOX40 agonist (Ab2) and surrogate anti-mPD-1. Notably, Anit-hOX40 (Ab2) alone at low dose (1 mg/kg, Q3D*9 doses) exerted strong anti-tumor potency (TGI=59.3%, p< 0.005) and no statistical significant antitumor difference was observed between high-dose group (at 5mg/kg) and low-dose group (at 1 mpk) as monotherapy, though anti-hOX40 (Ab2) at 5mg/kg showed the best therapeutic response (TGI=72%, p=0.0002) among all treatment groups. In contrast, the second therapeutic response was observed in the combo group treated with first dosing of 5mg/kg anti-hOX40 (Ab2) combining delayed dosing of 10mg/kg anti-mPD-1 (TGI=64%, p< 0.005) and the concurrent dosing group of Ab2 (5 mg/kg, Q3D×9 doses) plus anti-mPD-1 (2 mg/kg, Q3D×9 doses) (TGI=62.3%, p= 0.001). In conclusion, different human-specific OX40 agonists displayed different anti-tumor activity as monotherapy, and different dose led to different antitumor potency for the same agonist. In terms of different combination regimens, although no advanced benefit was observed for the combination of anti-mPD-1/anti-OX40 (Ab2) in comparison to strong anti-OX40 agonist (Ab2) alone, it demonstrated that the dosing timing and sequence of either anti-PD-1 or anti-hOX40 did has impact on the therapeutic outcome.

#3740 Tusamitamab ravtansine induces immunogenic cell death and synergizes with anti-PD-1 or anti-PD-L1 antibody combination in solid tumor.

C. Nicolazzi, A.-M. Lefebvre, N. Moindrot, C. Larois, M. Classe, **S. Sidhu**;
Sanofi, Vitry-Sur-Seine, France

Tusamitamab ravtansine (SAR408701) is an antibody-drug conjugate (ADC) targeted to carcino-embryonic antigen-related cell adhesion molecule 5 (CEACAM5) and delivering DM4, a maytansinoid cytotoxic. CEACAM5 is highly expressed in several tumor types, including non-squamous non-small cell lung cancer (NSQ NSCLC). It is currently being evaluated in patients with advanced CEACAM5-positive NSQ NSCLC, in a phase II study in combination with pembrolizumab, and a phase III trial as single agent in comparison with docetaxel. Preclinical investigations were performed to determine whether SAR408701 could be beneficially combined with immune checkpoint inhibitors. We, first, demonstrated that the tusamitamab ravtansine payload, DM4, is able to induce robust immunogenic cell death (ICD) using an in vivo vaccination assay. In this assay, immunocompetent mice were “vaccinated” by DM4-treated CT26 cells and then later rechallenged with CT26 tumor cells. Tumor rejection was observed in more than 50% of “vaccinated” mice. The ICD was characterized by the expression or release of danger-associated molecular patterns (DAMPs), and we observed DAMP modulation such as calreticulin (CRT) exposure at the cell surface of dying tumor cells, and the release of the High-Mobility Group Box 1 (HMGB1) in the extracellular space by CT26 cells in response to DM4 treatment. We also showed that DM4-treated CT26 tumor cells implanted into mice or SAR408701 treatment of MC38 tumor-bearing mice induced an elevation of plasmatic level of murine IL-6 and INFγ, revealing potential antitumor immunity modulation by the ADC and its payload. Immunohistochemistry analysis of MC38 tumors also revealed that tusamitamab ravtansine treatment induced a dose-dependent increase of CD8 T-cell infiltration in tumors correlating to dose-dependent efficacy. Finally, tusamitamab ravtansine was combined with immune checkpoint inhibitors (ICIs) in immunocompetent mice bearing MC38 tumor model. In this model, the combination of tusamitamab ravtansine with anti-PD-1 or anti-PD-L1 antibody led to complete response and, even, tumor-free survivors at 120 days post tumor implantation while single agents were inactive or transiently active. In summary, these preclinical data show that tusamitamab ravtansine could be beneficially combined with immune checkpoint and strongly support their evaluation in clinical development.

#3741 Helper/killer hybrid epitope long peptide (H/K-HELP) cancer vaccine augments Th1-dependent CTL induction at tumor-draining lymph node to eradicate solid tumor: its application to develop an innovative combination cancer immunotherapy(iCCI).

T. Iwasaki[1], Y. Yazaki[1], T. Masuko[2], T. Nishimura[3];

[1]Precision Clinic Tokyo, Tokyo, Japan, [2]School of Pharmacy, Kindai University, Osaka, Japan, [3]Cancer Medical Research Center, Fujita Health University, Aichi, Japan

We have initially demonstrated the pivotal role of IFN-γ-producing tumor-antigen-specific Th1 cells for the complete eradication of established tumor mass by CTL. The accumulated evidence has clearly demonstrated that induction of Th1-dependent full activation of CTL at tumor-draining lymph nodes (TDLN) are crucial for inducing complete rejection of solid tumor by CTL. To induce Th1 immunity efficiently at TDLN in tumor-bearing host, we developed an artificially synthesized helper/killer-hybrid epitope long peptide (H/K-HELP), which conjugated killer and helper epitope peptides of cancer antigen by a glycine-linker. In mouse model, OVA-H/K-HELP was selectively presented in vivo by professional DC in vaccinated TDLN and sustained antigen presentation capability of DC to stimulate both CTL and Th1 cells. Thus, in contrast to short peptide, vaccination of OVA-expressing EG7-bearing mice with OVA-H/K-HELP caused a complete eradication of EG7 tumor mass. To apply these basic findings to clinical treatment of cancer patients, we then developed Survivin-H/K-HELP. Treatment of a patient with a triple-negative breast cancer patient with Survivin-H/K-HELP induced a complete response in a triple-negative breast cancer patient concomitantly with the induction of Th1-dependent cellular and humoral immune responses. In this clinical study, the patients showed Th1-dependent C'-fixing IgG antibody production and exhibited IFN-γ-producing Th1 cellular responses. Finally, we also applied H/K-HELP-pulsing DC-vaccine to develop an innovative combination cancer immunotherapy (iCCI). The iCCI consisting of radiation, low dose of immune check point inhibitors (ICIs:Nibolumab, Ipilimumab) and H/K-HELP-pulsed DC, all of which have been shown to initially modulate antitumor immunity at TDLN. Here, we described a successful outcome of a case of the stage IVA inoperable advanced hypopharyngeal squamous cell cancer patient with lymph node-metastasis. The iCCI treatment of the patient caused a complete disappearance of all cancers and the patient has been cancer free for over 15 months so far. Although the destruction mechanism of cancer is not determined, we image this iCCI might improve patient's antitumor immune capability in immune microenvironment around tumor (IMAT) including TDLN and TME. Our developed iCCI will become a promising strategy to overcome inoperable advanced cancers in future.

CLINICAL RESEARCH: Diagnostic Biomarkers 2
Poster Session

#3745 Metabolomic profiling of lipid and metabolite in cirrhosis patients with and without hepatocellular carcinoma.
H. Powell, E. Ruiz, S. L. Grimm, O. Najjar, L. Olivares, M. Scheurer, H. B. El Serag, C. Coarfa, S. Kaochar;
Baylor College of Medicine, Houston, TX

Early detection of hepatocellular carcinoma (HCC) is crucial for improving patient outcomes, as curative treatments are most effective at the early stages of the disease. The lack of robust biomarkers, particularly a non-invasive diagnostic tool, precludes significant improvement of clinical outcomes for HCC patients. Serum metabolites are one of the best non-invasive means for determining patient prognosis. Established biomarkers for HCC including alpha-fetoprotein (AFP), have shown suboptimal performance in early disease stages. This study aimed to develop a combined metabolite and lipid panel to differentiate early-stage HCC from cirrhosis. Unbiased metabolomic and lipidomic analyses of serum samples were performed for 28 and 30 patients with early HCC and cirrhosis, respectively. We developed an unbiased high-resolution liquid chromatography mass spectrometry (LC-MS) based metabolic profiling platform and evaluated differences in the serum global metabolome and lipidome. This method enabled the detection of over 1200 metabolites and up to 800 lipid molecules in this select cohort. We identified 124 metabolites and 246 lipids that were upregulated and 208 metabolites and 73 lipids that were downregulated in HCC compared to cirrhosis. Using multiomic integrative analysis, we identified the overlap between differentially expressed metabolites and lipid and previously published transcriptomic signatures and illustrate that the overlapping signature associates with clinical disease progression. Lastly, we leveraged machine learning models to identify a minimal panel of lipids and metabolites that accurately distinguish between cirrhosis patients with HCC and without HCC. The best performing classifier was derived using Support Vector Machines, achieving a median AUC of 0.98 over 100 cross-validation iterations, and we showed that we need as little as 12 metabolite and lipids for effective discrimination between cirrhosis and early HCC.

#3746 Identification of cancer specific extracellular vesical biomarkers to aid in diagnosis of cancer.

T. A. Hembrough[1], Z. Opheim[1], C. Bandoski[1], I. Isaac[2], M. Mehnert[2], A. Ezrin[1],
[1]Nexosome Oncology, Durham, NC, [2]Biognosys, Schlieren, Switzerland

The limitations of serial tumor biopsies are well known, thus liquid biopsies which allow for repeated plasma-based biomarker analysis are urgently needed. Extracellular vesicles (EVs) represent an extremely stable and emerging proteomic substrate which allows for deep enrichment of biologically relevant signals from plasma, and broad analysis of tumor associated and host response proteins. To identify novel biomarkers, we performed proteomics analysis on EVs purified using size exclusion chromatography and a proprietary buffer system which increases EV and corona protein recovery. Initial DIA mass spectrometry (MS) analysis was performed on EVs from 125 patients (25 each from CRC, breast, NSCLC, ovarian, and normal patients). A subset of 25 normal and 25 ovarian was subjected to a second deeper analysis on a much more powerful DIA platform. Initial analysis identified 204 unique proteins differentially expressed in ovarian cancer patients (>2-fold change; $p<0.05$). Repeat analysis of the ovarian vs normal cohorts on the Biognosys TrueDiscovery™ platform identified 645 differentially expressed, a significant increase in depth of analysis. These cancer exosome associated proteins represent a broad range of host response signals. Taking ~20 of the top proteins, we extended our analysis using ELISAs to determine if the results by MS were reproducible in a simpler format. The ELISA analysis recapitulated the MS results. This confirms that the TrueDiscovery™ platform can easily be translated into a simple, quick and distributable ELISA platform. Extending these results, a blinded cohort of ovarian and normal EVs was analyzed using a predefined cutoff for a host immune response biomarker. This blinded analysis demonstrated sensitivity of 1.0 and specificity of 0.9, exceptionally high values for a single analyte assay, underscoring the potential value of analyzing the host/immune response proteins in the context of the EV microenvironmentKey biomarkers from cancer patient EVs suggests it is possible to track host immunosuppressive environment via antigen presenting cell and check point antagonist biomarkers. In both cases, highly significant differences are seen comparing EVs from normal patient plasma versus cancer patient plasma. Interestingly, when these biomarkers are evaluated in pre-EV enriched plasma, no significant differences are seen. This underscores the unique nature of the EV microenvironment, and suggests that host immune response and tumor microenvironment may be recapitulated in the EV/host response proteome using our unique methods. These data confirm that the EV microenvironment represents a unique oncological ecosystem with highly specific and sensitive disease biomarkers which are not dysregulated in complete plasma. This novel approach to assessing cancer proteomics has great promise for real time, longitudinal analysis of cancer patient tumor/host immune biology.

#3747 Bronchial washing fluid sequencing is useful in the diagnosis of lung cancer with necrotic tumor.

J. Lim[1], H.-T. Shin[1], S. Park[2], W. Ryu[1], L. Kim[1], K.-H. Lee[1], S. Ko[2], S. Lee[3], J. Kim[1], J.-S. Ryu[1];

[1]Inha University College of Medicine, Incheon, Korea, Republic of, [2]Yonsei University Wonju College of Medicine, Wonju, Korea, Republic of, [3]DNA Link, Inc., Seoul, Korea, Republic of

Lung cancers identified with low-dose CT are typically early stage without endobronchial lesions, and most require a pathological diagnosis using invasive procedures. We conducted a study analyzing bronchial washing (BW) fluid using targeted panel sequencing to evaluate its diagnostic performance. And we aimed to elucidate the characteristics of patients group in which this method could be effectively applied. We prospectively enrolled patients with an incidental lung lesion suspected of early-stage lung cancer on chest CT and no visible endobronchial lesion on bronchoscopy from June 2017 to March 2018 at two independent hospitals. Lung cancer was histologically diagnosed using a diagnostic work-up including surgical lung biopsy, percutaneous needle biopsy, endobronchial ultrasound, and other biopsies. BW was performed on each patient in the subsegmental bronchus where the lung lesion was suspected to be located. Among shared genes between the panels for each cohort, we selected 8 genes that are frequently mutated known oncogenes/tumor suppressor genes in lung cancer not to consider passenger mutations for diagnosis. In addition, several filtering criteria were considered to differentiate cancer. Since criterion d considered definitive somatic mutations [known hotspot mutations or loss of function mutations with variant allele fraction (VAF) ≥ 2%] with criterion c (≥ 2 COSMIC11 variants with VAF ≥ 1%), the sensitivity was increased without loss of precision and the sensitivity of sequencing was higher than BW cytology. In total, 164 subjects (114 with lung cancer and 50 with benign) were enrolled. Of lung cancer patients, necrosis was observed on chest CT in 44 (38.6%) patients and malignant cells were identified upon BW cytological examination in 33 (28.9%) patients. Of total, 33 (20.1%) patients had complications related to invasive diagnostic test. By the panel with the criterion d, 42 patients (25.6%) were classified as cancer. The panel showed 100% of specificity, 100% of positive predictive value for diagnosing cancer whereas it had relatively low sensitivity. Twenty patients who were classified as cancer by sequencing despite of negative cytology. In the group with necrosis, the proportion of patients with positive for sequencing only was significantly higher than that of patients with positive for cytology only. In addition, the sensitivity of BW sequencing reached 75% in patients with necrotic tumors. The prevalence of necrotic tumors was significantly higher in SQC than in ADC. The significant proportion (66.7%) of primary tumors with positive for sequencing only and located in outer area had necrosis. This study demonstrated that BW sequencing could be applied for diagnosis in patients with necrotic lung lesion suspected of early-stage lung cancer in chest CT. It would be possible to reduce the frequency of unnecessary invasive procedures and subsequent complications.

#3748 Evaluation of immune cells from patient-derived tumor tissue and peritoneal washing cytology in correlation with immunohistochemical markers in endometrial cancer.

C. Shin, S. Lee, H. Chung, J. Kim, E. Ha, J. Seo, S. Shin;
School of Medicine, Keimyung University, Daegu, Korea, Republic of

Background This study aims to evaluate the characteristics and clinical correlations of tumor-infiltrating lymphocytes (TILs) in endometrial cancer, derived from fresh tumor tissue and peritoneal washing cytology. Furthermore, it seeks to explore the correlation between TILs and immunohistochemical markers in endometrial cancer.

Methods In this study, we investigated the nature of TILs extracted from endometrial tissue and peritoneal washing cytology, along with their correlation with immunohistochemical markers. Samples collected from endometrial cancer patients during surgery, with informed consent, were analyzed for immune cell composition using flow cytometry. We examined the association between pathological findings, a range of immunohistochemical markers (including LVSI, PD-L1, ER, P53, HER2, MLH1, MSH2, MSH6, PMS2, MSI), and the status of tumor-infiltrating immune cells (such as CD3-CD19+ B Cells, CD3-CD16+CD56+ NK Cells, CD4+CD25+ regulatory T cells (Treg), and CD3+CD8+ cytotoxic T cells).

Results Our analysis encompassed 25 endometrial cancer-derived samples. Notable observations include an increase in CD3-CD19+ B cells in the LVSI-positive group and a decrease in the ER-positive group ($p<0.05$, respectively). CD3-CD16+CD56+ NK Cells decreased in the ER-positive group, while CD3+CD8+ cytotoxic T cells were decreased in the HER2-positive group ($p<0.001$, $p<0.05$, respectively). Other immunohistochemical markers showed no significant differences.

Conclusion The study suggests that tumor-infiltrating immune cells from patient-derived tissue and peritoneal washing cytology may reflect the molecular and clinical characteristics of endometrial cancer. However, further research with an expanded sample size and correlation with oncologic outcomes is warranted to validate these findings.

#3749 The evaluation of expression level of Cxcl12 gene in peripheral blood samples of breast cancer patients.

A. Adamnejad Ghafour, S. Tuncer;
Istanbul University, Istanbul, Turkey

Breast cancer, like many other cancer types, is linked to the activation and overexpression of CXCR4. The overexpression of CXCR4 is associated with factors such as tumor growth, angiogenesis, increased metastasis, and therapeutic resistance. Similarly, CXCL12, a specific ligand for CXCR4, plays a significant role in tumorigenesis processes, including survival, migration, and microenvironmental interactions. The CXCL12/CXCR4 signaling pathway has been found to impact the development and progression of breast cancer, regulating proliferation, motility, and metastasis. Hence, molecules within the CXCL12/CXCR4 signaling pathway hold promise for determining breast cancer prognosis, treatment monitoring, and serving as therapeutic agents. The study, conducted at the Istanbul University Institute of Oncology, obtained ethical approval from the Istanbul Faculty of Medicine Ethics Committee. Genetic materials from 300 breast cancer patients and 150 control subjects underwent standard testing, matched based on crucial parameters. Real-time PCR with the MIC qPCR Cycler was statistically analyzed using GraphPad Prism ($p < 0.05$). Descriptive statistics were presented for categorical and quantitative variables, while the Kolmogorov-Smirnov test assessed the normal distribution of quantitative variables. Statistical comparisons between groups were performed using the Mann-Whitney U test and the Kruskal-Wallis test, was used for calculations. Notably, among the three genes—LASP1, CXCL12, and CXCR4—LASP1 exhibited the highest mean expression level at 11.64 with a considerable standard deviation of 11.80. In contrast, CXCL12 had a much lower mean expression level at 2.96 and a tighter distribution, and CXCR4 displayed the lowest mean expression level at 0.37 with a standard deviation of 0.74. The analysis of diagnostic groups indicated no significant differences in mean LASP1 and CXCL12 levels, but a significant variance in mean CXCR4 levels ($p<0.001$). Specifically, CXCR4 expression in group Breast and ovarian cancer was notably lower compared to Breast cancer, Bilateral Breast cancer, and Breast and Other cancer, while group Breast cancer exhibited significantly lower CXCR4 expression compared to groups Bilateral Breast cancer and Breast and Other cancer. However, there was no significant difference in CXCR4 expression between groups of Bilateral Breast cancer and Breast and Other cancer. These findings reveal distinct expression patterns of CXCR4 across diagnostic groups, suggesting potential implications for diagnostic categorization and underlying molecular pathways in breast cancer. Understanding these expression disparities could be crucial in deciphering the molecular intricacies influencing disease progression and treatment responses.

#3750 Dual isolation and profiling of circulating tumor cells and circulating tumor DNA from a single liquid sample using the Genesis Cell Isolation System and Droplet Digital PCR.

Y.-T. Kang[1], A. Bodunrin[2], E. Pusod[1], K. Simonyi[3], A. Corner[4], D. Coe[3], M. Racey[5], E. J. Dreskin[3];
[1]Bio-Rad Laboratories, Ann Arbor, MI, [2]Bio-Rad Laboratories, Pleasanton, CA, [3]Bio-Rad Laboratories, Hercules, CA, [4]Bio-Rad Laboratories, Watford, United Kingdom, [5]Bio-Rad Laboratories, Boulder, CO

Introduction: Recent advances in technology support the use of liquid biopsy as a noninvasive method for cancer monitoring and diagnosis. Circulating tumor cells (CTCs) and circulating tumor DNA (ctDNA) are both regarded as key liquid biopsy biomarkers, offering significant disease-related molecular insights. Despite their potential, dual isolation and profiling have been challenged in a clinical setting by the lack of established platforms and optimized protocols that support this approach. The Genesis System with Celselect Slides™ captures CTCs based on size and deformability, then the enriched cells can be recovered for subsequent downstream analysis. Concurrently, Droplet Digital PCR (ddPCR™) can be utilized to interrogate cell-free DNA (cfDNA) to determine the presence of a range of DNA aberrations present in ctDNA. This study, using a model lung CTC-ctDNA sample, illustrates the feasibility of this dual-biomarker approach to detect cancer-associated nucleic acid mutations simultaneously with CTC enumeration, using commercially available kits and instruments.
Methods: To model lung cancer samples, blood samples were prepared by spiking in two model circulating markers, cultured cancer cells (model CTCs, human lung cancer cell line A549) and fragmented genomic DNA containing *EGFR* mutations (model ctDNA, multiplexed 23 ctDNA [~145 bp band > 95%]), into whole blood from a healthy donor prior to enrichment/extraction. Plasma isolation from the whole blood model samples was performed using either two-step centrifugation or Ficoll-Paque PLUS solution for plasma/buffy coat separation. The extracted plasma layer was used for ctDNA separation, while the remaining cell layer was used for CTC isolation on the Genesis System with a modified protocol.
Results: The Genesis System isolated 78-79% of spiked cancer cells in whole blood at a concentration of 40 cells/ml. Despite additional plasma separation steps and liquid handling, the system isolated CTCs spiked in with minimal cell loss (<6%). With an optimized ctDNA extraction, more than 70% of spiked ctDNA in blood samples in the size range of 120-220 bp was extracted. Using the Bio-Rad QX200 ddPCR System and ddPCR *EGFR T790M* Mutation Detection Assay, blood samples with the model ctDNA spiked in showed positive droplets (17 copies) for *EGFR T790M* while control blood samples without model ctDNA spiked in showed no positive droplets.
Discussion and Conclusions: This work illustrates an optimized protocol for the dual isolation and profiling of CTCs and ctDNA from a single blood sample by using an automated CTC isolation platform and high-sensitivity ddPCR based ctDNA mutation detection. This protocol enables comprehensive liquid biopsy studies using a single blood sample from cancer patients with readily available instruments and kits, which can be applied to many other cancers.

#3751 Diagnostic assessment of Filamin A (FLNA) as a serum biomarker for identification of benign prostatic hyperplasia vs aggressive prostate cancer in a prospective Mexican cohort.

Prostate cancer (PCa) exhibits a significant health risk to aging men, in which effective diagnosis of high gleason (Gleason >7) cancers is of critical need. Currently, the main screening tool utilized for detection of prostate cancer is prostate specific antigen (PSA), however, PSA exhibits limited utility in men with benign prostatic hyperplasia (BPH) due to inherent elevated PSA as the result of an enlarged prostate, resulting in increasing unnecessary biopsies. In Mexico, there is currently a higher incidence of aggressive PCa due to the risk within the overall population as well as the need for increased screening tools. Since, there is a critical unmet need to evaluate novel PCa diagnostic test that could serve as a reflex test within the screening paradigm, we evaluated the recently developed test, pSTATEdx, which measures the cleaved portion of Filamin A (FLNA) via IP-MRM mass spectrometry in conjunction with the patients age, to determine the overall risk of aggressive prostate cancer. In the current study, we analyzed a prospective cohort from Mexico City and Guadalajara evaluating 34 BPH and 44 PCa in men exhibiting symptoms with PSA levels between 4-10 ng/mL, who were all referred for 12 core prostate biopsies due to suspicion of prostate cancer. Additionally, we assessed 41 non-diseased men as controls who had PSA below 1.5 ng/mL, who were not assessed further. Comparison of non-diseased controls with BPH/PCa men exhibited an AUC of 0.99, PPV 0.96, NPV 0.89, OR 118, and P value 2 e-20, thus demonstrating that pSTATEdx had significant utility in assessing prostate health independent of PSA. In comparison with previously published data, FLNA mean levels were 24 ng/mL in previously published American study cohort and 55 ng/mL in the Mexican BPH/PCa cohort with a P value of <0.001. Assessment of patient populations revealed that there was superior diagnostic performance of FLNA for patients between PSA 4-7, which represents an increased unmet need for biopsy decision support. Analysis of BPH compared to all PCa exhibited a sensitivity of 0.94 and specificity of 0.53, PPV 0.64, NPV of 0.91, and OR of 16.4. Diagnostic analysis of BPH compared to high gleason PCa exhibited a sensitivity of 1, specificity of 0.21, PPV 0.38, NPV of 1, and OR of inf in this pilot study. This assessment revealed promising insight that aggressive PCa was not missed using pSTATEdx. pSTATEdx demonstrated diagnostic utility in prevention of unnecessary biopsies in the Mexican population as a reflex test to those patients with PSA levels between 4-7 as well as demonstrated that aggressive prostate cancers were not missed with the risk score. Additional studies are planned in the future to expand the utility of pSTATEdx in Latin America.

#3753 Co-expression proteomic analysis of antibody drug conjugate receptor and payload biomarkers in breast cancer.

N. Ghafourian[1], **S. P. Thyparambil**[1], R. Mortensen[1], J. Chou[1], R. Heaton[1], X. B. Ling[2];
[1]mProbe, Rockville, MD, [2]Stanford University, Palo Alto, CA

The use of antibody drug conjugates (ADC) targeting HER2, and Trop 2 has made a great difference in the treatment of breast cancer. Such agents consist of an antibody targeting the receptor which is conjugated to a payload chemotherapy agent. Chemotherapy involves the use of anti-tubulin agents (e.g. docetaxel), topoisomerase inhibitors etc. We examined 507 breast cancer samples using targeted proteomics to quantitate biomarkers for ADC targets such as HER2, HER3, EGFR and Trop2 in our clinical proteomics (CLIA) laboratory. We also measured biomarkers that are associated with response and biomarkers that are associated with resistance to chemotherapeutic agents. Resistance markers include TUBB3 (taxanes), and response markers include TOPO1 (irinotecan, topotecan). Methods: Formalin fixed, paraffin embedded (FFPE) tissues blocks of breast cancer were sectioned, marked for tumor, laser capture microdissected, digested and analyzed by LC-selected reaction monitoring mass spectrometry. Seventy-two proteins were quantitated. Discussion:In our previous work, we have determined that >740 amol/µg HER2 corresponds to IHC 3+/2+ and FISH +. Based on the HER2 quantitation for each sample, the samples were segregated into three groups. Negative (Group A, <150 amol/µg), High expressors (Group C, >740 amol/µg), and Detected (Group B, 151-739 amol/µg). Groups A, B, and C were 39%, 46%, and 43% of the cases respectively. In Group A (HER2 negative), HER3 was detected in 14% of cases with a 3x range (181-602 amol/µg). EGFR was detected in 53% of samples with 139x range (108-14986 amol/µg). Trop2 was detected in 59% of cases ranging from 256 to 11900 amol/µg. Topo1 was detected in 86% of cases with a 12x range (402-4870 amol/µg) and TUBB3 was detected in 63% of cases at levels ranging from 755 to 11750 amol/µg. In Group B (HER2 detected), HER3 was detected in 38% with a 3x range (178-565 amol/µg). EGFR was detected in 34% at levels ranging from 104-7040 amol/µg. Trop2 was detected in 63% ranging from 157 to 12808 amol/µg. Topo1 was detected in 94% with a 12x range (413-5100 amol/µg). and TUBB3 was detected in 51% of cases at levels ranging from 757 to 9311 amol/µg.In Group 3 (HER2 highly expressed), HER3 was detected in 43% with a 5x range (189- 890 amol/µg). EGFR was detected in 30% at levels ranging from 101 to 565 amol/µg. Trop2 was detected in 68% ranging from 310 to14650 amol/µg. Topo1 was detected in 95% with a 6x range (487- 2885 amol/µg), and TUBB3 was detected in 64% of samples at levels ranging from 829 to 2300 amol/µg. Conclusion:The capacity to multiplex 72 protein biomarkers from 2-3 FFPE sections will help in design of ADCs bispecific antibodies and/or bispecific ADCs.

#3754 High staining reproducibility and scoring precision demonstrated in endometrial cancer stained with PD-L1 IHC 22C3 pharmDx used in conjunction with combined positive score.

J. Hand, A. Morones, D. Moquin, K. Martyniuk, M. Kalpakoff, S. Tabuena-Frolli, J. Milo, S. Hund;
Dako North America - Agilent Technologies, Carpinteria, CA

Background: PD-L1 IHC 22C3 pharmDx (SK006) is a qualitative immunohistochemical (IHC) assay using anti-PD-L1 clone 22C3 to detect PD-L1 in formalin-fixed, paraffin-embedded (FFPE) human endometrial cancer (ENDO) tissues. PD-L1 expression is determined using the Combined Positive Score (CPS) algorithm, which is the number of PD-L1 staining cells (tumor cells, lymphocytes, macrophages) divided by the total number of viable tumor cells, multiplied by 100. Validation testing evaluated the sensitivity and analytical performance of SK006 PD-L1 expression in FFPE ENDO specimens based on two PD-L1 expression cutoffs for all applicable studies: CPS ≥ 1 and CPS ≥ 10. Analytical performance studies included precision (combined precision, intra-run and intra-inter observer) and robustness (time, temperature, pH and re-use) testing.
Methods: FFPE ENDO specimens were stained with SK006 and scored using CPS. Negative percent agreement (NPA), positive percent agreement (PPA), and overall agreement (OA) with two-sided 95% bootstrap confidence intervals (CIs) were used for data analysis, based on PD-L1 binary status (positive/negative) at the evaluated cutoffs. Acceptance Criteria (AC): the lower bound of the two-sided 95% CI computed on percent agreement (NPA, PPA, and OA) must meet or exceed 85%. Sensitivity determined if SK006 could detect a range of CPS expression levels in ENDO specimens. Combined precision measured inter-instrument, -operator, and -day variation nested within the same study. Intra-run measured repeatability within the same run and Inter/Intra-Observer measured scoring reproducibility by 3 pathologists over 3 non-consecutive days. Robustness evaluated the staining performance of SK006 under varying Target Retrieval Solution (TRS) laboratory conditions: time (18-22min), temperature (95-99°C), pH (5.9-6.3) and re-use (up to 3 uses).
Results: The sensitivity data showed that SK006 could detect a range of CPS expression levels in ENDO specimens. Analyses for each analytical validation study, subject to AC, showed NPA, PPA, OA point estimates (PE) of ≥ 95.5% and CI lower bounds (CILB) of ≥ 87.1%.
Conclusion: PD-L1 IHC 22C3 pharmDx (SK006) used in conjunction with CPS provides high staining reproducibility and scoring precision for ENDO specimens at the CPS ≥ 1 and CPS ≥ 10 cutoffs, under standard day-to-day laboratory testing and scoring conditions.

#3755 Impact of antigen retrieval and other parameters on detection of FGFR2b in various solid tumors on a BenchMark ULTRA automated staining platform: Development of a new IHC assay for FGFR2b.

A. S. Watson, C. Le, A. M. Wertheimer, S. Escobedo, L. So, B. Bagevalu Siddegowda, J. D. Palting, S. Marion, **S. P. Stratton**, B. Aggeler;
Roche Tissue Diagnostics, Tucson, AZ

Background: Fibroblast growth factor receptor 2b (FGFR2b) is part of the FGFR transmembrane tyrosine kinase receptor family. This protein has gained more attention in recent years as a tumor progression biomarker in numerous solid tumors. The detection of FGFR2b by immunohistochemistry (IHC) has been used recently in immunotherapy clinical trials with multiple tumor types. During IHC assay development on formalin-fixed paraffin embedded tissue, a thorough study of antigen retrieval through cell conditioning or enzyme incubation, primary antibody incubation, and detection parameters is critical to evaluate staining performance.
Design: A study of an investigational anti-FGFR2b (FPR2-D) assay developed on a BenchMark ULTRA automated staining platform explored the effect of antigen retrieval and detection parameters on staining performance. VENTANA System Software was used to modify steps in the IHC staining protocol resulting in 42 permutations. Ten different solid tumors were stained with these modifications to the assay and subsequently evaluated for FGFR2b expression.
Result:s The results demonstrate that the staining clarity, intensity, and dynamic range within tissue cases of FGFR2b staining can vary widely between different solid tumor types. While most permutations of the initial assay parameters had minimal impact on the staining performance and readability by a pathologist, the order of the enzyme treatment and the cell conditioning steps (in addition to increased incubation time of primary antibody) had a significant impact when comparing across different solid tumors. Detection of FGFR2b seemed to have a greater susceptibility by tumor type to the antigen retrieval process than has traditionally been observed in other biomarkers.
Conclusion: The overall results of this investigation show the importance of an extensive parameter screening approach when evaluating new antibody targets and indication combinations in IHC to ensure optimal staining performance. This is critical to downstream testing and the potential use of new assays in the context of in vitro diagnostics.

#3757 The development of MAGMAS as a potential therapeutic target in temozolomide-resistant glioma.

J. D. Tran[1], J. J. Lepe[2], M. C. Kenney[2], B. C. Das[3], D. A. Bota[2];
[1]California State University, San Bernardino, CA, [2]University of California, Irvine, CA, [3]Long Island University, Brookville, NY

Glioblastoma (GBM) is one of the most aggressive types of brain cancer and remains a significant challenge for drug development in oncology today. Temozolomide (TMZ) is the standard of care for GBM, and resistance to this drug is modulated partly by the DNA repair enzyme O6-methylguanine-DNA methyltransferase (MGMT). Clinical studies demonstrated that low MGMT expression in GBM enhances sensitivity to TMZ and prolongs survival for patients. However, recent clinical studies indicate MGMT is a discordant biomarker since the predictive value of MGMT methylation is relatively low and there is a lack of modalities to inhibit MGMT expression. Furthermore, glioma stem cells (GSC) are another contributing factor for resistance due to tumor heterogeneity, self-renewal capacity and activation of DNA repair responses to overcome the effect of radiation and TMZ treatment. These resistance mechanisms contribute to tumor recurrence and present major impediments for the development of effective treatments.

MAGMAS, 13.8 kDa mitochondria protein, is a translocase of the inner mitochondrial membrane and regulates oxidative phosphorylation. Specifically, MAGMAS regulates the ATP stimulatory activity of DNAJC19 on mtHSP70 that drives the movement of peptides through the TIM23 complex into the mitochondrial matrix. Recent evidence suggests that MAGMAS can regulate oxidative phosphorylation via interactions with the respiratory complexes present in the inner mitochondrial membrane. Previously, our lab has shown MAGMAS overexpression in malignant glioma tissues of patients and murine intracranial xenografts. Additionally, pharmacological inhibition of MAGMAS with the small molecule BT9 promoted cytotoxicity and impaired respiratory functions in malignant glioma cells demonstrating that MAGMAS is a promising potential target for GBM patients. However, further studies are needed to investigate the role of MAGMAS across the spectrum from initial tumorigenesis to disease progression and to further determine how MAGMAS is implicated during the development of treatment resistance.

This study is designed to investigate the role of MAGMAS in GSCs and their contribution to TMZ resistance. We observed temozolomide-resistant (TR) U251-TR and D54 MG-TR GBM cell lines expressed significantly higher levels of MAGMAS and several stem cell markers than their drug-sensitive (S) parental cell lines. Therefore, we hypothesized that silencing MAGMAS re-sensitizes TR GBM cell lines to TMZ. We found that MAGMAS knockdown in D54-MG and U251 S/TR cells in the presence of escalating TMZ concentrations, caused enhanced sensitivity to TMZ. Consistent with these results, inhibition of MAGMAS with the novel BT9 inhibitor enhances the TMZ sensitivity in the TMZ-resistant cell lines. Additional studies of patient-derived cell lines are being utilized further to validate MAGMAS as it is an attractive target in TMZ-resistant GBM patients.

#3758 Evaluation of breast cancer-derived extracellular vesicles as diagnostic indicator for HER2 status.

Sol Moon, Min Woo Kim, Young Kim, Suji Lee, Hyojung Lee, Joon Ye Kim, Seung Il Kim, Jee Ye Kim

Department of Surgery, Yonsei University College of Medicine, Seoul, Korea, Republic of

HER2-low is a new distinct type of breast cancer that is characterized by low levels of the HER2 protein. As treatment paradigms for HER2-low breast cancer are rapidly evolving with the approval of antibody-drug conjugates, identification of HER2-low breast cancer with more sensitive and reproducible HER2 assays is needed. We aimed to investigate the utility of liquid biopsy in isolating tumor-derived extracellular vesicles (TDEs) for diagnosis of HER2 status. We adopted an affinity-based approach to isolate TDEs and performed CNV analysis of the ERBB2/neu genes using the tumor DNA present in TDEs (etDNA). HER2 status of etDNA had been determined by droplet digital PCR using HER2/EIF2C ratio, a highly accurate method to quantify DNA copy number. In our study, we utilized a variety of breast cancer cell lines categorized as HER2-low (MDA-MB-231, MCF7, ZR-75-1) and HER2-high (MDA-MB-453, BT-474, SK-BR-3) to confirm HER2 expression in extracellular vesicles (EVs) by flow cytometry. This analysis successfully demonstrated that EVs effectively reflect the HER2 status of the tumor cells, evidenced by a strong Pearson correlation coefficient ($r=0.987$, $p<0.001$). Further clinical validation was conducted with plasma samples from 22 breast cancer patients. In the clinical study, we observed a significant correlation between the CNV of tumor DNA present in TDEs and the HER2 status of primary tumors ($p<0.01$). Additionally, the Receiver Operating Characteristic (ROC) analysis yielded an impressive area under the curve (AUC) value of 0.838 ($p<0.01$), demonstrating a high level of accuracy in differentiating between high and low HER2 groups, with a sensitivity of 55.6% and a specificity of 100%. In summary, we show potential diagnostic tools for real-time, less invasive determination of HER2 status in primary tumors, providing continuous monitoring methods for HER2 status. Although further validation in larger cohorts and prospective studies is needed, our study indicates that TDE analysis could contribute to the assays for identification of the HER2 status in breast cancer patients.

#3759 First clinical evidence of the tissue nanomechanical signature as a novel diagnostic and prognostic tool in patients with non-small-cell lung cancer.

J. Alcaraz[1], H. Sanz-Fraile[1], **E. Marin**[2], P. Gausa Busquets[3], K. Neal[1], M. Arshakyan[1], M. Rico[1], M. Boada[3], D. Sanchez[3], R. Oropesa Nunez[4], G. Srivastava[4], A. Jizawi[4], S. Nizzero[4], T. Appenzeller[4], M. Gachechiladze[4], M. Loparic[4], M. Plodinec[4], N. Reguart[3],
[1]University Of Barcelona, Barcelona, Spain, [2]August Pi i Sunyer Biomedical Research Institute (IDIBAPS), Barcelona, Spain, [3]Hospital Clinic Barcelona, Barcelona, Spain, [4]ARTIDIS AG, Basel, Switzerland

Introduction: Complex structural remodelling of cells and extracellular matrix during cancer initiation and progression elicit substantial biomechanical alterations, which can be measured by Atomic Force Microscopy (AFM) at the nanoscale level. Clinical and translational evidence indicates that tissue nanomechanical signature (NS) can be a useful tool for rapid cancer diagnosis, and assessment of cancer aggressiveness. We demonstrated that the AFM-based Automated and Reliable Tissue Diagnostics (ARTIDIS) platform represents a valid method for rapid diagnosis, prognosis, and treatment response assessment in patients with breast cancer. Here we aimed to use this platform to examine tumour biopsies from non-small cell lung cancer (NSCLC) patients for the first time.
Methods: This is an ongoing, single center study at the Hospital Clinic of Barcelona and University of Barcelona (UHB) Spain, aiming to enroll 75 patients by January 2024 in the first phase, followed by 200 patients in the expansion phase. To date, 54 matching tumor and non-tumor fresh tissue biopsies were taken by experienced pathologists from fresh surgical resection specimens from 27 patients with previously diagnosed NSCLC. Tissue biopsies were measured with the ARTIDIS device in a blinded manner, without knowing the malignancy status of the biopsy. Routine clinico-pathologic parameters have been collected. The multiparametric nanomechanical signature has been analyzed in an automated manner using the proprietary AI-based ARTIDISNET software platform together with available clinico-pathologic parameters.
Results: In total, the NSCLC tissue samples included 16 squamous cell carcinoma (SCC), 6 Adenocarcinoma (ADC), 1 large cell carcinoma (LCC) and 4 other histological subtypes. Non-tumor tissues exhibited significantly varied composition, including normal lung parenchyma, bronchial tissues, fibrosis and inflammatory changes. Among the 27 patients, 5 patients developed distant progression within 12 months after ARTIDIS measurements. Results analysis showed that the ARTIDIS NS can reliably differentiate malignant NSCLC lesions from non-tumor lung tissue, with a sensitivity of 0.84, specificity of 0.81, positive predictive value (PPV) of 0.79, negative predictive value (NPV) of 0.86 and accuracy of 0.82. In addition, the ARTIDIS NS can differentiate patients with and without distant progression with a sensitivity of 0.62, specificity of 0.81, PPV of 0.42, NPV of 0.90 and accuracy of 0.77.
Conclusions: Here we demonstrated first clinical evidence of the ARTIDIS tissue NS as a novel diagnostic and prognostic tool in patients with NSCLC. This study aims to establish the diagnostic, prognostic, and predictive NS in patients NSCLC. In addition to local expansion at the UHB, study results will be further validated in ARTIDIS clinical program at MD Anderson Cancer Centre, USA.

#3760 The importance of optimizing DNA extraction conditions for formalin fixed paraffin embedded tissues.

M. G. Butler, B. Forson, M. Cowen, J. Ramprakash, D. Ruminski Lowe, **Y. Konigshofer**;
LGC Clinical Diagnostics, Inc., Gaithersburg, MD

The pre-analytic extraction of Formalin Fixed Paraffin Embedded Tissues (FFPETs) appears to have a profound effect on the ability to obtain meaningful data from the DNA therein. FFPETs represent important materials in Pathology that are used to diagnose and analyze cancer. As part of preparing FFPETs, the formalin fixation step preserves the structure of tissues through covalent modifications but can also damage nucleic acids through that same process. Over the last decade, the emergence of Molecular Pathology, which benefits from gentler fixation compared to Histopathology and especially Immunohistopathology, has led to changes in how FFPETs are prepared. However, the remnant FFPETs from over a decade ago may be far from representative of what is now prepared for Molecular Pathology by many laboratories. Here we discuss our optimization of FFPET extraction for gently fixed samples. When we prepared our Seraseq FFPE Homologous Recombination Deficiency (HRD) reference standards using fixation conditions that are recommended for Molecular Pathology and extracted the resulting FFPETs using generic conditions, our initial coverage data from Whole Genome Shotgun (WGS) sequencing was difficult to analyze for changes in copy number across the genome. A major contributor to nonuniform coverage was identified as the formalin reversal step, where deparaffinized proteinase K-digested tissue is heated in water to near boiling to attempt to detach formaldehyde from nucleic acids through hydrolysis. Given the gentler fixation conditions, this step was found to be mostly unnecessary, and omitting it improved the resulting data substantially. A reason for this appears to be that the gentler fixation conditions that are now in use may not protect the DNA from the effects of near-boiling water, where the lack of salt lowers the melting temperature of double stranded DNA fragments and causes them to denature unless they have a higher GC content. Different kits used for the extraction of nucleic acids from FFPETs may benefit from different optimizations to obtain improved sequencing data from today's Molecular pathology samples, and reference standards that represent such samples provide a useful tool for such optimizations.

#3761 A modified SELEX enables the efficient identification of DNA aptamers with potential for specific cancer targeting.

Yang Lin[1], Cho-Yi Chen[2], Zhi-Qian Lin[3], Bing-Hong Chen[3], Yi-Chen Sun[1], Kai-Feng Hung[3]

[1]Department of Opthalmology, Taipei Tzu-Chi Hospital, the Buddhist Tzu-Chi Medical Fiundation, New Taipei City, Taiwan, [2]National Yang Ming Chiao Tung University-Yangming Campus, Taipei, Taiwan, [3]Department of Medical Research, Taipei Veterans General Hospital, Taipei, Taiwan

Background: Aptamers have sparked significant interest in cell recognition due to their superior binding specificity and biocompatibility. Cell recognition can be mediated by targeting the major histocompatibility complex (MHC) that presents short peptides derived from intracellular antigens. Although numerous antibodies have demonstrated a specific affinity for the peptide-MHC complex, the number of aptamers that exhibit comparable characteristics is limited. However, the success rate of aptamer identification is low. This is possibly due to the presence of complementary sequences or sequences rich in quinine and cytosine that are less accessible for primers. Here, we use ovalbumin model antigen to explore whether aptamers with specificity for binding to a defined peptide-MHC complex can be identified. We developed DNA aptamers with modified SELEX by employing systemic consecutive selections with minimal PCR amplification. Furthermore, the other tumour antigen, claudin-6, was also used as a target to determine whether our modification for SELEX can be used with any selection technology.

Methods: To determine whether our modified SELEX has potential for selecting aptamer capable of cancer-specific targeting, we used ovalbumin presented by H-2Kb (to represent the specific antigen presented by MHC) and claudin-6 (a cancer-associated adhesion molecule) as a target for the selection of aptamers. This modified SELEX consisted of consecutive positive and negative selections with minimal PCR amplification. Meanwhile, the selection of candidate aptamers is based on their appearance in multiple rounds rather than enrichment, and is facilitated by several computational tools. The specificity and affinity of the candidate aptamer are validated by flow cytometry, immunohistochemistry, and immunofluorescence analysis with cells with or without these molecules.

Results: After high-throughput sequencing, a total of 211 candidate aptamers were selected for further analysis. The quadruplex forming G-rich sequences (QGRS) mapper, mFold modeling, and NUPACK web servers were used to predict the potential of G-quadruplex formation, resulting in only four potential aptamers. Using MTCQ1-OVA cells with FITC-conjugated aptamers, two aptamers showed selective binding to MTCQ1-OVA cells and had no binding specificity to MTCQ1-WT cells. The binding specificity was further validated by immunohistochemistry in tumour derived from mice inoculated with MTCQ1-WT or MTCQ1-OVA cells. In the pull-down assay, the binding affinity of these two candidate aptamers was 136.2 nM and 155.1 nM affinity.

Conclusions: This preliminary study demonstrated that our modification for SELEX is effective in the selection of aptamers with promising potential for specific cancer targeting. The identification of aptamers may facilitate further application in diverse biomedical fields.

#3762 11,000-plex aptamer based proteomics of bladder cancer urine for the discovery of novel disease biomarkers.

C. Mohan[1], K. Vanarsa[1], J. Castillo[1], L. Wang[2], Y. Lotan[3];
[1]University of Houston, Houston, TX, [2]Central South University, Changsha, China, [3]University of Texas Southwestern Medical Center, Dallas, TX

In search of more accurate, non-invasive biomarkers of bladder cancer (BC), a comprehensive aptamer-based screen of urine proteins was conducted using urine samples from a BC cohort, followed by systems biology analyses. Following an initial 1317-plex screen, an extended 11,000 plex aptamer-based proteomic screen is in progress. Based on the initial screen, 30 urine proteins were next ELISA validated in an independent cohort of 68 subjects, and the results are shown in Table 1. Of 21 urine proteins that discriminated BC from urology clinic controls (UC), urine D-dimer displayed the highest ROC AUC value (0.96) and sensitivity (95%) (Table 1). Furthermore, 9 urine proteins significantly discriminated more advanced BC (T1-T4) from earlier stages (Ta-Tis), with IL-8 and MMP-12 being the best performers. Urine MMP12 exhibited the highest specificity of 80% at fixed sensitivity for identifying advanced BC. Systems biology analysis implicated molecular functions related to extracellular matrix, collagen, integrin, heparin and transmembrane tyrosine kinase signaling in BC susceptibility, with HNF4A and NFKB1 emerging as key molecular regulators. STEM analysis of the dysregulated pathways implicated a functional role for the immune system, complement and interleukins in BC disease progression. Urine C2, D-dimer, and Elastase were additionally ELISA validated in a second BC cohort of Chinese ethnicity. Thus, comprehensive proteomics and independent ELISA validation have uncovered novel urine biomarkers for initial BC diagnosis and subsequent disease progression, that warrant further head to head comparison with current diagnostic tests.

#3763 Comparative spatial analyses of the tumor immune landscape in different mouse models of glioblastoma.

D. Klymyshyn[1], N. Jhaveri[1], A. Pratapa[1], N. Nikulina[1], T. H. Tam[1], N. Nelson[2], R. Dolcetti[3], D. Moi[3], R. Mazzieri[3], T. Mantamadiotis[4];
[1]Akoya Biosciences, Menlo Park, CA, [2]Abcam, Cambridge, United Kingdom, [3]Peter MacCallum Cancer Centre, Melbourne, Australia, [4]Department of Microbiology & Immunology, The University of Melbourne, Parkville, Australia

Background: Despite advances in treatment, glioblastoma (GBM) remains one of the most difficult types of cancer to treat, and the prognosis is poor. The current median survival time for patients with GBM is about 12-15 months, and the five-year survival rate is less than 10%. There is an unmet need for better GBM treatment options, leveraged from relevant experimental models. To develop new therapies, preclinical animal models are important for analyzing the biology of GBM and evaluating the efficacy of novel therapeutic strategies. While a variety of experimental models are used to study GBM, most preclinical investigations involve mice. In this study we utilize a spatial phenotyping application that permits comprehensive characterization and comparison of key proteins in the brain tumor immune microenvironment (TiME), and detailed comparison the TiME between different immune-competent GBM mouse models.
Methods: The Phenocycler-Fusion is a fast spatial biology solution that affords ultrahigh-plex single-cell spatial readouts. We used this solution for the whole slide imaging of mouse FFPE tissues and deep immune phenotyping of >40 proteins, comprising immune cell lineages, activation states and checkpoints, as well as biomarkers for tumor, vascular and neural landscapes of various GBM mouse models.
Results: Via single cell spatial phenotyping, we isolated spatial signatures within the mouse GBM tissue immune microenvironment. We focused on multiple immune biomarkers, including microglia/myeloid cells that were identified via the combinatorial expression of the key markers CD68, Iba-1, F4/80, Tmem119 and CD11b. The macrophages and their biomarker expression profiles exhibited significant inter- and intra-tumoral heterogeneity within different mouse GBM models, indicative of the heterogeneous and complex biology of GBM.
Conclusions: Our work encompasses the development of a custom antibody panel, an imaging workflow, as well as a novel bioinformatic analysis method. Deployment of this workflow on different mouse GBM models allowed us to study cell populations, according to biomarker profiles and spatial distribution. This study provides a deeper characterization of the diverse mouse GBM models to determine the optimal model that most accurately recapitulates the complex TiME of human GBM, including key features such as invasive tumor margins, high vascularity, blood-brain barrier, etc. We anticipate that this approach has enormous potential for a broad range of applications for which biomolecules' spatial information is important and will deepen our understanding of the GBM TiME.

#3764 Spatially resolved immune landscape revealed sex-biased T-cell infiltration in glioblastoma.

Y. Hao[1], G. Reid[1], A. Baker[1], K. L. Fink[2], G. J. Snipes[2], B. E. Mickey[2], A. E. Sloan[3], J. S. Barnholtz-Sloan[4], M. Berens[1];
[1]Translational Genomics Research Institute, Phoenix, AZ, [2]Baylor University Medical Center, Dallas, TX, [3]Piedmont Healthcare System, Atlanta, GA, [4]National Cancer Institute, Bethesda, MD

Glioblastoma (GBM) multiforme is the most aggressive type of brain cancer. These lethal brain tumors are characterized by the inter- and intra-tumor molecular heterogeneity and demonstrated cell plasticity. A male:female distribution of 1.6:1; survival outcome from treatment (debulking, radiation, and temozolomide) benefits females nearly twice that for males. Through spatial transcriptomics, we interrogated the immune landscape of GBM, seeking to tease out whether distinct biological and therapeutic niches in GBM were evident, and to understand how the tumor microenvironments contributed to the heterogeneity of GBM. We designed a set of RNA hybridization probes specifically for portraying the cell identities and cell functional states within GBM tumor. The probe set was used to profile six human GBM samples from male and female cohorts on the Vizgen MERSCOPE platform. An integrated analysis of 505,614 cells from the six samples yielded a rich and varied spatial cell atlas of glioblastoma. Our preliminary findings depict distinct spatial niches of different tumor cell subpopulations that are associated with local environmental factors such as hypoxia. We identified a small cluster of cells that are in neuronal-like state, which could potentially drive invasion. We found spatial proximity of CD4+ cells and cells that express HIF1A, suggesting the dynamic interactions between tumor cells, regulatory T cells and tumor microenvironment. We also observed significant difference in the degree of CD8+ T-cell infiltration in female samples versus male samples. The average CD4+/CD8+ T-cell ratio in males is twice as high as that of females, suggesting intrinsic sex-based differences in immune response to tumor. Expansion of these studies in additional specimens will further illuminate microenvironmental influences on glioma progression and may instruct specific interventions leading to more effective and predictable immune-oncology of this disease.

#3765 Single cell spatial proteomics analysis and computational evaluation pipeline.

Behnaz Bozorgui[1], Zeynep Dereli[1], Guillaume Thibault[2], John N. Weinstein[1], Anil Korkut[1]

[1]UT MD Anderson Cancer Center, Houston, TX, [2]OHSU, Portland, OR

Resolving tissue and proteomic heterogeneity is critical to decoding the structure and function of tumor-immune microenvironment (TIME). Such understanding requires profiling of tumor and immune cell proteomic features with spatial resolution at the single-cell level. Although such spatially resolved methods and data sets are becoming increasingly available, analytical and computational methods that can extract the highly complex features and interactions within TIME are lacking. To address that problem, we have developed a computational pipeline we call the Spatial Proteomics Analysis and Computational Evaluation Pipeline (SPACE). The SPACE pipeline is composed of many analysis modules for processing and mining highly multiplexed imaging-based data types to explore TIME composition, organization, and heterogeneity. The pipeline generates and interprets biomarker expression and positional information from multiplexed images using algorithms for image indexing, image registration, quality control, segmentation, identification and removal of non-specific signals, data normalization, automatic identification of missing data, and adjustment for left-over signals. The accurate intensity measurements at single cell level are then used to calculate the proposed spatial features that represent cellular interactions in TIME. A hierarchical decision tree of cell markers is used to annotate types and identities for individual cells. The SPACE enables statistical and differential analyses of complex spatial features as well as cell types/identities with respect to clinical annotations and genomic alterations. The visualization of spatial and imaging data is made possible through an open-source OMERO image repository and spatial maps that integrate diverse markers in a single representation. Here, we demonstrate the applications of our pipeline in diverse gastrointestinal tumor types (e.g., small bowel adenocarcinoma) and validate the importance of integrating tissue heterogeneity at spatial and single-cell level. The framework is applicable to nearly all highly multiplexed imaging data platforms, including but not limited to, CycIF, CODEX, and imaging mass cytometry.

#3766 Utilizing whole-transcriptome digital spatial profiling for glioblastoma clinical biomarker discovery.

A. Luo, K. Casella, S. Sharma, E. Baraban, C.-H. Lucas, E. Shenderov;
Johns Hopkins University School of Medicine, Baltimore, MD

Objective: *IDH*-wildtype glioblastoma (GBM) is the most aggressive brain tumor in adults. Notable for substantial inter- and intra-tumoral heterogeneity, GBM is highly resistant to standard-of-care treatment. Emerging spatial omics technologies, such as GeoMx Digital Spatial Profiling (DSP), offer novel approaches to interrogate the molecular features of regionally defined cellular ecosystems in cancer. Here, we leverage DSP to study whole-transcriptome gene expression signatures in a spatially defined manner across five *IDH*-wildtype GBMs. Methods: Formalin-fixed paraffin-embedded tumors were assessed histologically and three spatially distinct areas from each tumor were used to construct a custom “spatial” tissue microarray. From each set of three areas, we identified nine spatially distinct regions of interest (ROIs) for bulk transcriptomic analysis according to two histopathological features: distribution (cellular tumor core or tumor periphery) and vascular proximity (near or far). We evaluated normalized target expression data statistically using linear mixed modeling (LMM) with Benjamini-Hochberg correction. Results: 44 profiled ROIs and 8531 transcriptomic targets were analyzed following quality control trimming. 3D principal component analysis and unsupervised hierarchical clustering analysis showed clustering according to tumor specimen as well as distribution (core versus periphery), thereby substantiating the presence of inter- and intra-tumoral transcriptional heterogeneity. LMM-based differential gene expression analysis identified distinct molecular signatures when comparing core and periphery. Specifically, we observed elevated log2-transformed expression of migration and proliferation markers including *LAMC1* (p=0.00297) and *FABP7* (p=0.00434) in core ROIs and neurodevelopmental markers including *NTRK2* (p=0.00734) and *DAAM2* (p=0.00263) in periphery ROIs. Additionally, reactome analysis demonstrated considerable enrichment for the aberrant programmed cell death pathway (R-HSA-9645723, coverage=71.84%) in core ROIs and the MHC class II antigen presentation pathway (R-HSA-2132295, coverage=69.11%) in periphery ROIs. Interestingly, differential gene expression analysis did not reveal any biologically significant targets when subsetting for vascular proximity within cellular tumor core ROIs. However, reactome analysis of this regional subset demonstrated upregulation of various cellular proliferation pathways (G2/M transition, APC/C activity, DNA synthesis, etc.) within vessel-near ROIs when compared with vessel-far ROIs. Conclusions: We preliminarily characterize the molecular heterogeneity of GBM using a spatially guided approach. Ongoing analyses are focused on dataset validation, mixed cell deconvolution, further regional genotyping, and potential biomarkers.

#3767 A novel method to minimize HIER-induced alterations on H&E staining in an integrated mIF-H&E workflow.

K. Hwang, G. Vezeau, E. Olejnik, D. Wood, R. Cardenes, L. Duro, G. Chatterjee, J. H. Lee;
Ultivue, Inc., Cambridge, MA

Background: Hematoxylin and eosin staining (H&E) is widely used as an anatomical assay for clinical diagnosis. Researchers and clinicians also rely on molecular *in situ* techniques, such as multiplexed immunofluorescence (mIF), to gain deeper insights on cellular phenotypes and tissue microenvironment. As a result, there has been significant interest in combining anatomical stains with molecular imaging techniques, most commonly by using a terminal H&E stain after mIF staining. This allows a combination of the two assays but has been observed to show alterations in the H&E staining pattern. In this work we identify heat-induced epitope retrieval (HIER) as the root cause of alterations of the terminal H&E stain after mIF. We further demonstrate a new workflow combining an initial H&E stain with subsequent InSituPlex assay, to avoid these alterations and thus enable co-registration of highly sensitive multiplexed immunofluorescence with an unaltered H&E stain.

Methods: FFPE tissue slides were stained using a standard HIER protocol or a full mIF assay, followed by a standard H&E stain. Slides were imaged using a Zeiss Axioscan.Z1 scanner. Additional H&E-stained slides were prepared, and the H&E stain removed using a destaining protocol before carrying out InSituPlex® mIF staining for multiple markers. Fluorescence and brightfield images of the same slide were overlaid using UltiStacker® to assess qualitative differences between pre- and post-mIF H&E, and UltiAnalyzer.AI® was used to quantify cell densities and signal intensities between mIF image pre- and post-H&E.

Results: Alterations in H&E staining were observed between slides directly stained with H&E and slides stained with a terminal H&E after HIER alone or a full mIF assay. Calculated cell counts and tissue area were consistent throughout, but some tissue microstructures could be difficult to resolve after either HIER or full mIF. Our destaining protocol was successful in removing hematoxylin and eosin from directly-stained H&E slides and allowing subsequent mIF staining. For most biomarkers, qualitative and quantitative differences in InSituPlex mIF staining were minimal. Brightfield and fluorescent images were co-registered with sub-micron accuracy using UltiStacker, enabling molecularly defined cellular phenotyping within a traditional H&E image.

Conclusions: While the mIF to H&E workflow is widely used and is capable of allowing combined anatomical and cellular phenotyping, alterations in the H&E stain exist due to the use of HIER in most mIF protocols. An alternative method is possible in which H&E-stained slides are destained and then restained for mIF or other spatial assays, providing the same valuable combination of assay information but without the HIER-induced alterations in H&E staining pattern.

#3768 Optimization of digital pathology through laser capture microdissection with a 405 nm laser.

Thomas Philipson[1], Marissa Howard[1], Kevin Johnson[2], Amanda Still[1], Furkat Yunusov[1], Emanuel Petricoin[1], Virginia Espina[1], Noel Gonzalez[2], Alan Carpino[2], Lance Liotta[1]

[1]George Mason University, Fairfax, VA,[2]Targeted Bioscience, Jupiter, FL

Tumor cellular heterogeneity is a complex problem in cancer molecular diagnostics and personalized therapy. The tumor is a product of the different types and interactions of host and immune cells. Investigators have created a variety of methods to procure separate subpopulations of the tumor microenvironment for individual analysis. One of the most successful methods of this is laser capture microdissection (LCM). This method captures specific subpopulations of cells under direct microscopic visualization. This LCM technology has successfully been used for over 20 years, revealing a variety of insights into cancer pathogenesis and mechanisms of therapeutic response employed in numerous clinical trials. Nevertheless, there are two drawbacks to the current systems. For UV cutting (365 nm), the tissue is significantly damaged by the UV light energy. Infrared (808 nm) laser systems do not damage the tissue however, this method has low power and poor resolution. Our first hypothesis to be tested is that a new class of near UV 405 nm laser will have small capture areas approaching single cells while simultaneously preventing cellular damage. The second weakness of LCM is the requirement for an open-faced tissue section without a coverslip. Moreover, when visualizing the tissue of interest, the identification of regions of interest is obscured due to the refractive index mismatch between the laser microdissection cap and the tissue surface. We hypothesize that using a volatile organic compound with a refractive index similar to glass would elucidate the tissue region of interest to allow proper visualization. We successfully developed and tested a near 405 nm wavelength LCM system that utilizes a “liquid” coverslip to visualize the sample of interest with higher clarity, resolution, and contrast for immunohistochemistry, immuno-fluorescence, blood smear slides, and conventional hematoxylin-eosin tissue staining. Overall, these critical improvements LCM technology now allow for single-cell tissue capture, system automation, tissue visualization, and opens the door for artificial intelligence-assisted spatial profiling.

#3769 Spatial biology *in situ* hybridization and multiplexed immunohistochemistry detection compatibility using a modified protocol.

S. T. Clarke, M. Voeun, L. Montoya, C. Vonnegut, B. Mandavilli;
Thermo Fisher Scientific, Eugene, OR

In the field of spatial-omics imaging, combining mRNA *in situ* hybridization (ISH) detection with multiplexed protein immunohistochemistry detection (IHC) is desirable. We present a simplified workflow in FFPE tissue sections where ISH is detected using branched ssDNA signal amplification visible by brightfield imaging combined with multiplexed IHC using directly labeled antibodies detected by fluorescence. In multiple studies mRNA expression of PCNA (Proliferating Cell Nuclear Antigen) shows moderate to high nuclear positivity observed in most cancer cells, with gliomas and lymphomas being the few negative exceptions. In contrast, expression of PCNA in adult non-cancerous tissue has low to no expression, with tonsil and bone marrow being the exceptions. We first show the relationship between proliferation as measured by EdU detection, PCNA antibody and PCNA mRNA expression in the embryonic mouse model where PCNA expression is prevalent in developing tissue. Then we demonstrate a simplified working protocol for combining ISH and IHC in FFPE human cancer tissue sections for the co-detection of PCNA mRNA together with IHC using a panel of six protein markers relevant to the tumor microenvironment. For IHC, we directly labeled validated unconjugated antibodies with fluorophores using amine-reactive chemistry and select the degree of labeling (DOL) and titer for optimal signal/background most useful for multiplexing on FFPE tissue. We found important protocol steps to consider for compatibility between IHC and ISH detection method. Loss of IHC protein epitope due to ISH protocol use of proteases and loss of ISH signal due to presence of RNase commonly present in IHC antibody relevant reagents can prevent combining IHC with ISH. Stabilizing IHC through refixation prior to ISH workflow is also required. Modifying the protocols to avoid these incompatible treatments and using directly labeled antibodies provides useful strategies for multiplexing IHC with ISH.

#3770 Comparative analysis of single cell expression and digital spatial profiling in FFPE tumor tissues.

A. Moore, A. O'Hara, P. Vishwanath, L. Turner, H. Latif, C. Mozdzierz, G. Zhou;
GENEWIZ from Azenta Life Sciences, South Plainfield, NJ

Formalin Fixed Paraffin Embedded (FFPE) tissues are a staple in clinical diagnostics associated with solid tumor. Next Generation Sequencing (NGS) approaches characterize genomes, epigenomes, transcriptomes, and proteomes from a single sample source. FFPE blocks from several different tumor tissue types were serially sliced into FFPE slides. Individual slides were then utilized to explore the genome, epigenome, single cell RNA-Seq (scRNA-Seq), and Digital Spatial Profiling (DSP). Here we present a comparative analysis of two transcriptomic modalities within one FFPE tissue sample: fixed-cell scRNA-Seq of the transcriptome and digital spatial profiling of the whole transcriptome. Independent analysis of scRNA-Seq and DSP identified common trends as well as distinct differences within the same sample. Comparative analysis within sample between modalities identified statistically significant differences, driven by local tumor microenvironment, but also highlighted commonalities between methods. Cross sample comparisons showed striking differences, as indicated by tumor type. These studies highlight the strengths of each assay individually, as well as the power of a dual-assay approach for comprehensive analysis of the tumor and its microenvironment. Conclusions from this standalone analysis were further aggregated into downstream multiomics analyses, including proteomics analysis, illustrating the expanding landscape of information that can be extracted from FFPE derived tissue and the potential for novel discovery and diagnostic power integrating these complex data types holds.

#3771 3D correlated multi-scale cellular and molecular architecture of solid tumors.

S.-Y. Lee[1], Y.-C. Wu[1], J. Zheng[1], E. Khalil[1], S. Wang[2], A. Lippert[3], J. Plank[3];
[1]University of Illinois at Chicago, Chicago, IL, [2]University of Chicago, Chicago, IL, [3]Southern Methodist University, Dallas, TX

A solid tumor presents heterogeneous 3D structures at tissue, cell, and molecule levels. To develop advanced cancer diagnostics and therapies, it is important to understand in-depth cellular and molecular architecture of a tumor at multiple scales. Here we introduce novel optical microscopy methodologies for in-depth 3D spatial analysis of tumor tissues: 1) LED photobleaching-mediated 3D multiplex immunofluorescence (IF) microscopy, 2) Correlated 3D multi-resolution optical microscopy, and 3) 3D tissue region-based cell type-selective multi-omics. We built a high-power LED light irradiator with a broad emission spectrum (490-700 nm) that bleaches a broad wavelength of fluorescence signals simultaneously throughout an optically cleared, 400 µm-thick tumor tissue. Cyclic workflow involving IF staining, optical tissue clearing, 3D confocal microscopy, and LED photobleaching enables visualization of multiple cell types in the same whole 400 µm-thick tumor tissue after computational 3D image registration. The constructed multiplex image offers comprehensive 3D cellular landscape of a tumor. We also developed a method for tracking regions of interest (ROIs) in the middle of a large tumor tissue using a UV-activated visible dye in light sheet microscopy. Light sheet microscopy allows imaging an optically cleared large-sized tumor tissue at a low spatial, tissue resolution. To mark the ROI positions on a tumor, the dye is infused into agarose gel surrounding the tumor tissue and be activated and present purple-colored lines where are exposed to UV light sheets in light sheet microscopy. The tumor tissue was physically sectioned at the marked ROI positions using a vibratome after reversing tissue clearing process. Sequential IF staining and high-resolution confocal microscopy permit for visualizing detailed cellular compositions of the ROIs in the tumor. The tissue and cellular-resolution 3D images from light sheet and confocal microscopy are correlatively integrated to display ‘Google Earth’-like multi-scale view of a tumor tissue. To further analyze the ROIs of a tumor at molecular level, we have developed optical microscope-mediated fluorescence lithography methods that allow fluorescently labeling of a selected cell type in ROIs of an optically cleared 3D tumor tissue. After wash free from clearing solution and dissociation of the tumor into cells, fluorescence-marked, intact cells from the ROIs are collected through flow cell sorting. Proteins and mRNAs are extracted from the collected cells and sent to LC-MS/MS analysis and RNA sequencing. The spatial multi-omics method provides in-depth molecular information of selected cells in the ROIs of a tumor. We believe all these 3D microscopy methods will provide powerful spatial analysis tools for better understanding cellular and molecular architecture of solid tumors.

#3772 Tissue-niche-based and cell-type-selective in-depth proteomics.

Y.-C. Wu[1], E. Abi Khalil[1], S. Weng[2], S. Lee[1];
[1]University of Illinois at Chicago, Chicago, IL, [2]University of Chicago, Chicago, IL

Introduction: The development, physiology function, and pathogenesis of the tissues are intricately orchestrated by the spatial organization of diverse cell populations. Proteins are the fundamental components within individual cells that control every function. Therefore, by integrating both information on cellular location and molecular profiling, spatial proteomics has emerged as an indispensable field for understanding mechanisms governing tissue homeostasis, disease progression, and therapeutic responses. Here, I introduce a spatial proteomics method designed to target selective cell phenotypes within definite tissue niches for in-depth spatial biology analysis.
Method: In this approach, we developed a sequential pipeline highlighted with immunofluorescence staining, microscopic photobleaching, fluorescence cell sorting, and liquid chromatography-mass spectrometry (LC-MS) analysis. The process begins with staining 400-µm-thick tissue macrosections with fluorescence-conjugated antibodies to visualize specific cell types of interest. We employed two different fluorescence-conjugated antibodies of the same clone (e.g., Alexa488-anti-CD11c and Alexa647-anti-CD11c antibodies) for the staining on every targeted cell (e.g., CD11c+ immune cells). We then introduced “photobleaching barcodes” using a confocal microscope to photobleach/exhaust either one of the fluorescence signals stained on cells by exposing it to the matched laser. This allows us to create differentiable fluorescence barcodes that label cells at distinct regions, incorporating cell spatial information into our fluorescence detection. After tissue dissociation, barcoded cells were sorted into different groups which were also classified by their original locations in the macrosection. Finally, protein extraction and LC-MS analysis were conducted on the collected cells to enable comprehensive spatial proteomic analysis.
Results: The initial application in investigating dendritic cell (DC) subsets in mouse spleen during lipopolysaccharide (LPS)-induced inflammation reveals significant proteome differences among three splenic DC subsets, categorized by their locations in or outside spleen T-cell zones as well as control DCs. Our result aligns with previously published proteome data in splenic DCs, underscoring the feasibility and reliability of our technology. Currently, we are in the process of evaluating breast cancer cell heterogeneity in human biopsy specimens using our approach to profile the tumor-immune microenvironment.
Conclusion: Spatial proteomic findings from both applications are poised to discover potential drug targets that benefit treatment efficacy for inflammatory diseases and breast cancer. This technology features deep protein profiling for cell-type-specific spatial proteomics and is designed for broad applications across diverse tissue specimens in various diseases.

#3773 Bladder cancer risk stratification with the Oncuria 10 plex bead-based urinalysis assay using three different Luminex xMAP instrumentation platforms.

S. Tanaka[1], T. Sakatani[1], K. Murakami[1], R. T. Waldron[1], W. Morales[1], W. Hogrefe[2], C. J. Rosser[2], H. Furuya[1];
[1]Cedars-Sinai Medical Center, Los Angeles, CA, [2]Nonagen Bioscience Corp, Los Angeles, CA

Introduction and Objectives: Oncuria® is a bead-based multiplex fluorescence immunoassay that coordinately measures 10 protein biomarkers in urine samples. The current study compared assay performance and output when urine samples were evaluated with the Oncuria assay using three different fluorescence-analyzing instruments commonly used in diagnostic laboratories worldwide.
Methods: We compared the performance of the clinically validated Oncuria bladder cancer (BC) multiplex immunoassay when data output was generated on three different analyzer systems. Voided urine samples from 36 subjects (18 with BC and 18 Controls) were reacted with Oncuria test reagents in three 96 well microtiter plates, and consecutively evaluated on the LED/image based MagPix, and laser/flow based Luminex 200 and FlexMap 3D (all xMAP instruments from Luminex Corp., Austin, TX). The BC assay uses magnetic bead based fluorescence technology (xMAP, Multi-analyte profiling; Luminex) to simultaneously quantify 10 protein analytes in urine specimens [i.e., angiogenin (ANG), apolipoprotein E (ApoE), carbonic anhydrase IX (CA9), CXCL8/interleukin-8 (IL-8), matrix metalloproteinase-9 (MMP-9), matrix metalloproteinase-10 (MMP-10), serpin A1/alpha-1 anti-trypsin (A1AT), serpin E1/plasminogen activator inhibitor-1 (PAI-1), CD138/syndecan-1 (SDC1), and vascular endothelial growth factor-A (VEGF-A)].
Results: All three platforms categorized all 10 analytes in identical samples at nearly identical concentrations, with variance across systems typically <5%. While the most contemporary instrument, the FlexMap 3D, output higher raw fluorescence values than the two comparator systems, standard curve slopes and analyte concentrations determined in urine samples were concordant across all three units. Forty-four percent of BC samples registered ≥1 analyte above the highest standard concentration, i.e., A1AT (n=7/18), IL-8 (n=5), and/or ANG (n=2). In Controls, A1AT was higher in one sample.
Conclusions: In conclusion, the Oncuria BC assay performed similarly well across three different flow analysis platforms for all 10 analytes simultaneously evaluated in urine samples. This agreement across instruments indicates that the test is amenable to standardized performance in laboratories using existing xMAP, without requiring costly outlays for new equipment.

#3774 Evaluation of FibraChek™ for non-invasive detection of hepatic fibrosis and hepatocellular carcinoma.

S. Tanaka[1], G. Xie[2], H. Furuya[1], W. Jia[3], C. J. Rosser[4];
[1]Cedars-Sinai Medical Center, Los Angeles, CA, [2]Human Metabolomics Institute Inc, Shenzhen, China, [3]Hong Kong Baptist University, Kowloon, Hong Kong, [4]Nonagen Bioscience Corp, Los Angeles, CA

Introduction and Objectives: The incidence of hepatocellular carcinoma (HCC) has almost tripled since the early 1980s in the United States where it is the fastest rising cause of cancer-related deaths. Advanced liver fibrosis and cirrhosis are ones of major risk factors for HCC. The recent evidence demonstrates that successfully treating the cause of early to moderate hepatic fibrosis may reverse most. For this reason, detecting hepatic fibrosis in an early stage is crucial. Liver biopsy is currently the gold standard for the assessment of hepatic fibrosis in clinical practice. Thus, there is an urgent clinical need for the development of non-invasive blood-based tests because of its ease of obtaining biological material. Previously, we developed FibraChek™, non-invasive blood-based tests. In this study, we tested the performance of FibraChek™ on detecting hepatic fibrosis and HCC in the US.
Methods: The performance of FibraChek™ was evaluated in a single-institutional cohort of 14 prospectively collected subjects presenting for chronic liver disease (NAFLD/NASH) patients with hepatic fibrosis, 19 prospectively collected subjects diagnosed with HCC, and 12 prospectively collected controls from the US. The algorithm uses weighted value of the 5 biomarkers: AST, ALT, Platelet, Taurocholic Acid (TCA) & Tyrosine plus age to derive a risk score. The ability of the test to identify patients harboring hepatic fibrosis or HCC was assessed. Hepatic fibrosis status was confirmed by tissue biopsy or definitive surgery. Diagnostic performance was assessed using AUC.
Results: FibraChek™ provided an AUC of 0.923 with an overall sensitivity of 93.9%, specificity of 81.8%, NPV 91.2% and PPV 81.8%. Interestingly, risk scores in HCC cohort indicated higher than those in patients with hepatic fibrosis. Thus, FibraChek™ may be also able to use for HCC detection.
Conclusions: Serum levels of a biomarker panel enabled the accurate discrimination of hepatic fibrosis and controls. The FibraChek™ test can achieve the easy, efficient, and accurate detection of hepatic fibrosis and HCC in a non-invasive patient setting.

CLINICAL RESEARCH: Metastasis Biomarkers
Poster Session

#3778 Comprehensive analysis of single disseminated cancer cells identifies a stem-like phenotype with strong prognostic impact.

T. Mederer[1], D. Spitzl[1], F. Elsner[1], B. Polzer[2], M. Ried[3], R. Neu[3], T. Robold[3], H.-S. Hofmann[3], C. A. Klein[1];
[1]University of Regensburg, Regensburg, Germany, [2]Fraunhofer-Institute for Toxicology and Experimental Medicine, Regensburg, Germany, [3]University Hospital of Regensburg, Regensburg, Germany

Introduction: Recent studies on disseminated cancer cells (DCCs) in Non-Small-Cell Lung Cancer (NSCLC) patients demonstrated their clinical relevance even in early tumor stages. However, their molecular and phylogenetic link to the primary tumor is currently unclear. Certain genetic alterations, such as TP53 or KRAS mutations, have been proposed to be clonal events and drivers of dissemination and metastasis. In this study, we analyzed the genome and transcriptome of single DCCs to identify the characteristics of early DCCs and their translational clinical value.
Materials and methods: From 2011 to 2019 we prospectively collected and analyzed bone marrow aspirates and lymph node samples from 296 newly diagnosed NSCLC patients undergoing tumor resection with curative intention. Presence of DCC was examined by i) immunocytology (IC) for Cytokeratin (clone A45-B/B3, bone marrow, BM-DCCs) or EpCAM (clone BerEp4, lymph node, LN-DCCs) and ii) immunofluorescent (IF) staining for EpCAM in a live cell suspension (clone HEA-125) from BM or LN. Single cells were isolated using micromanipulation and subjected to Whole Genome Amplification or combined Whole Genome/Transcriptome Amplification for IC and IF, respectively. Sanger sequencing for known hotspot mutations in TP53 and KRAS was performed on single DCCs. Gene expression profiles of DCCs were analyzed by single cell RNA sequencing and the results were compared with clinical data with a mean follow-up of 2.93 years (range 0.03-7.22).
Results: LN-DCCs were found in 44.8% and 59.6% by IC and IF, respectively. CK_{IC}^{pos} BM-DCCs were found in 45.2%, while $EpCAM_{IF}^{pos}$ BM-DCCs were present in 52.8%. LN-DCCs correlated with
reduced tumor-specific survival (TSS, p=0.009) and progression-free survival (PFS, p=0.025). $EpCAM_{IF}^{pos}$, but not CK_{IC}^{pos} BM-DCCs correlated with reduced TSS (p=0.003) and PFS (p=0.083). Genetic analysis of single DCCs revealed that TP53 or KRAS mutations could be found in 3.6% and 2.8% of analyzed BM-DCCs and 5.0% and 29.3% of LN-DCCs for IF and IC, respectively. Single cell RNA-seq showed distinct transcriptomic profiles for LN- and BM-DCCs, and identified a DCC phenotype with high stemness score in the bone marrow. Further analysis of potential transcriptome-based biomarkers identified a novel candidate marker for activated $EpCAM^{pos}$ BM-DCCs that strongly correlates with PFS and TSS (p<0.001).
Conclusions: DCCs in early-stage NSCLC have high prognostic value and predict reduced PFS and TSS. While genetic alterations in the TP53 and KRAS gene were not detected in the majority of analyzed DCCs, transcriptomic phenotypes provided relevant information and identified a subset of activated DCCs that correlate strongly with relapse and poor outcome.

#3779 Genomic and clinical characterization of metastatic patterns using real-word data from a large cohort of colorectal cancer patients.

P. Manca, A. V. Kris, H. Walch, C. Fong, J. Jee, K. Pichotta, N. Schultz, W. K. Chatila, R. Yaeger, F. Sanchez-Vega;
Memorial Sloan Kettering Cancer Center, New York, NY

Background: Colorectal cancers (CRCs) can exhibit disparate metastatic patterns that affect outcomes. We investigated associations between genomic features and organ-specific metastatic tropism and we compared the frequency of actionable alterations detected in patients undergoing longitudinal clinical sequencing.
Methods: We analyzed data for 6574 tumors from 6153 CRC patients, including 4510 primary and 2064 metastatic specimens. All patients had microsatellite stable (MSS) disease and were treated at Memorial Sloan Kettering. Paired primary and metastatic samples were available for 203 patients. Tumors were sequenced with MSK-IMPACT, a targeted DNA sequencing assay that identifies genomic alterations in 341-505 genes. Clinical annotations included sex, stage at diagnosis (Dx), and primary tumor location. History of metastatic disease was automatically retrieved from radiology reports using validated natural language processing methods; time to specific-site metastasis was modeled with Cox regression. False discovery rate (FDR) was used to correct for multiple hypothesis testing. The OncoKB knowledge base was used to identify clinically actionable alterations.
Results: Liver (n=1068, 51.7%) , peritoneal (n=269, 13.0%) and lung metastases (n=263, 12.7%) accounted for the majority of non-primary sequenced specimens. The frequency of actionable alterations (OncoKB Level≥3A) did not vary between unmatched metastatic and primary samples (12.3% vs 11.4%, p=0.302). In primary tumor samples from patients with localized disease at the time of diagnosis, TGFB pathway alterations were associated with increased risk of metastasis to the brain (HR=2.41, p=0.028), bone (HR=2.10, p<0.001), peritoneum (HR=1.82, p=0.001) and liver (HR=1.42, p=0.049). Alterations in the RAS pathway were associated with increased risk of lung (HR=1.47, p=0.009), peritoneum (HR=1.54, p=0.021) and liver (HR=1.44, p=0.026) metastases. By contrast, WNT pathway alterations were associated with a lower risk of developing lung (HR=0.69, p=0.033) and peritoneal metastasis (HR=0.68, p=0.081). Among patients with paired primary and metastatic samples, no significant difference was observed between the frequency of clinically actionable alterations in primary vs. metastatic specimens (16.7% vs. 18.2%, p=0.794). Presence of metastases-private or primary-private alterations did not correlate with site-specific metastasis risk.
Conclusions: The risk of developing metastatic disease and organ-specific dissemination might be linked to genomic abnormalities detectable at the localized stage. No significant difference in the frequency of actionable alterations was observed between primary and metastatic CRC samples.

#3780 From diagnostic labs to rapid near-patient testing: Bridging across RT-qPCR platforms of a clinicopathological and gene expression model for cutaneous melanoma patients.

L. Pozza[1], S. Zumrutcu[1], L. Bosman[1], A. van der Spek[1], M. Moreau[2], D. Tempel[1], J. Dwarkasing[1], **D. Bellomo**[1];
[1]SkylineDx, Rotterdam, Netherlands, [2]Biocartis, Mechelen, Belgium

Background: Gene expression signatures are becoming increasingly common in clinical settings, for diagnosis, risk stratification, and treatment response prediction. However, deployment in clinical practice often entails a molecular platform different from the one used for development. Transporting molecular signatures across platforms ("bridging") cannot be achieved directly, due to differences in scales and distributions in gene expression and requires bespoke methods. Here, we focused on the bridging of a clinicopathological and gene expression model (CP-GEP) across two reverse transcription-quantitative polymerase chain reaction (RT-qPCR) platforms: a single-plex SYBR Green qPCR, and a multiplex TaqMan probe-based qPCR (Idylla TM platform). CP-GEP is a regression model, combining eight genes (plus two housekeeping genes) and two clinicopathologic variables (age and Breslow thickness), able to stratify patients with melanoma into two groups based on their risk of sentinel lymph node metastasis.
Methods: For the bridging, we selected 150 samples of primary melanoma patients who underwent a sentinel lymph node biopsy from a cohort of stage I-III melanoma patients. We measured the expression of the eight genes on both qPCR platforms and quantified them as ΔCt. Within a bootstrapping scheme (500 repeats), for each gene, we learned a mapping ("bridging function") between ΔCt spaces, using all eight genes as regressors. Exploiting the linearity of per-gene bridging functions, we reparametrized the CP-GEP model so that we could directly use it in the target platform. We assessed the performance of the bridging, in terms of Percent Agreement (PA), defined as the percentage of the concordant binary outputs between the original and the bridged models; both in the bootstrapped samples and in 15 samples from an independent cohort.
Results: In the bootstrapped samples, we obtained a PA of 100%, in the intervals for which we had pre-defined acceptance criteria, based on the distance from the cut point; and we had a mean PA of 89.2% [95% CI, 85.23%, 94.6%] when we considered all samples. In the external validation, we achieved a PA of 100%; all performance metrics were identical. The continuous scores of the original and bridged models were in excellent agreement, with an R^2 equal to 0.95 both in the bridging and external validation cohorts.
Conclusions: We showed that a model, combining gene expression and clinicopathologic variables, originally developed on a single-plex SYBR Green RT-qPCR, often used in diagnostic labs, could be robustly reparametrized to be compatible with a multiplex TaqMan probe-based qPCR (Idylla TM platform), more suitable for point-of-care-diagnostics. The ability to transfer models across different molecular platforms can greatly accelerate the translation of fundamental research to clinical practice.

#3781 Tracking triple negative breast cancer (TNBC) evolution in the molecular residual disease (MRD) setting in the c-TRAK TN clinical trial.

M. Coakley[1], R. J. Cutts[1], P. Sritharan[2], S. Hrebien[1], C. Swift[1], K. Dunne[1], L. Kilburn[2], K. Goddard[2], G. Villacampa[2], P. Rojas[3], W. Emmett[3], C. Pipinikas[3], P. Hall[4], C. Harper-Wynne[5], T. Hickish[6], I. Macpherson[7], A. Okines[8], A. Wardley[9], D. Wheatley[10], S. Waters[11], J. M. Bliss[2], I. Garcia-Murillas[1], N. C. Turner[12]; [1]The Institute of Cancer Research, London, United Kingdom, [2]The Institute of Cancer Research, Sutton, United Kingdom, [3]Neogenomics/Inivata, Cambridge, United Kingdom, [4]University of Edinburgh,, Edinburgh, United Kingdom, [5]Maidstone and Tunbridge Wells NHS Trust, Maidstone, United Kingdom, [6]University Hospitals Dorset NHS Foundation Trust, Bournemouth, United Kingdom, [7]The Beatson West of Scotland Cancer Centre, Glasgow, United Kingdom, [8]Breast Unit, The Royal Marsden Hospital, London, United Kingdom, [9]Outreach Research & Innovation Group Ltd, Manchester, United Kingdom, [10]Royal Cornwall Hospitals NHS Trust, Truro, United Kingdom, [11]Velindre University NHS Trust, Cardiff, United Kingdom, [12]The Institute of Cancer Research & The Royal Marsden Hospital, London, United Kingdom

Background: Circulating tumor DNA (ctDNA) to track early tumor clones and to identify the point of origin of clones in relapsed disease, could provide novel insights into the impact of heterogeneity on the development of MRD and relapse in TNBC.

Methods: c-TRAK TN recruited 161 patients (pts) with early TNBC into prospective ctDNA surveillance after curative therapy. Two distinct early tissue samples were provided, and a subset provided a relapse biopsy. Tissue was whole exome sequenced (WES) and relapse plasma DNA underwent error-corrected WES. Clonal evolution analysis was performed for pts who developed MRD with a minimum of 2 samples with WES (n=44), and non-relapse pts with samples before and after neoadjuvant chemotherapy (NAC) (n=16). Clonal structures were inferred with Pyclone; the founding clone as the cluster with highest cellular prevalence (CP). Clones were validated and tracked using the RaDaR ctDNA assay, supplemented with a median of 9 (range 6-45) variants specific to each clone. Cluster hierarchy and phylogenetic tree structure was derived using ClonEvol.

Results: A median of 3 (range 1-5) clones per pt validated. Non-validated clones (12.9%) and pts with only 1 clone validated were removed, resulting in 56 pts for analysis. To assess the impact of spatial heterogeneity, contemporaneous paired early tissue was available from 17 pts who developed MRD. Primary tumor subclones were detected in the MRD or relapse in 88.9% (8/9) pts with a subclone detected in all regions, versus 37.5% (3/8) pts with a subclone unique to 1 region ($p = 0.049$). To assess the impact of NAC, paired tissue before and after NAC, was available in 32 pts. Distinct sub-clonal evolutionary patterns were identified. Subclones increased in CP or were first detected after NAC in 75% (24/32) pts. Subclones present prior to NAC were reduced or lost in 62% (20/32) pts. Sub-clonal persistence was observed in 46.8% (15/32) pts. Subclones first detected following NAC were detected in the MRD in 60% (6/10) pts. Following NAC, subclones reduced or lost re-emerged in the MRD in 30% (3/10) pts, versus subclones that persisted which were detected in the MRD in 100% (9/9) pts ($p=0.003$). In 21 pts, relapse samples were available. Relapse-unique subclones were identified in 57% (12/21) pts, with 2 new subclones in 1 pt. Relapse-unique subclones were not detected in MRD in 41.6% (5/12) pts, and were detected in the MRD in 66.7% (8/12) of pts.

Conclusion: Polyclonal metastasis is a common mode of metastasis in TNBC, with frequent detection of primary tumor subclones in the metastasis. NAC provides an evolutionary bottleneck, with subclones detected post NAC being the most likely to persist into the MRD and subsequent relapse. Relapsed cancer frequently had subclones not detected in the primary cancer, with approximately half of these potentially late arising, and half detectable in MRD suggesting early establishment of diversity.

#3782 IASLC grading system predict distant metastases for resected lung adenocarcinoma.

Y. Wang[1], M. R. Smith[1], Y. Liu[1], M. E. Green[2], O. A. Hassan[3], A. M. Balmaceda[4], T. Sexton[4], W. Li[4], F. Xing[1];
[1]Wake Forest University School of Medicine, Winston-Salem, NC, [2]Eastern Connecticut Pathology Consultants, Manchester, CT, [3]Atrium Health Cabarrus Medical Center, Concord, NC, [4]Atrium Health Wake Forest Baptist Medical Center, Winston-Salem, NC

The International Association for the Study of Lung Cancer (IASLC) proposed a new histological grading system for invasive lung adenocarcinoma (LUAD). However, whether this new grading system is able to predict distant metastases in LUAD patients has not been evaluated. This study investigated the feasibility of using this grading system to predict the occurrence of brain and bone metastases in patients with resectable LUAD which identifies patients who have a high probability of developing distant metastases after surgery. We collected clinical information and pathological reports of 179 early stage LUAD patients who underwent resection during 2008 to 2015 from Wake Forest Comprehensive Cancer Center. All patients were followed up for 5 years and both bone and brain metastasis-free survival were calculated. Tumor grading of all samples was evaluated by both IASLC grading and predominant pattern-based grading systems. The ability of predicting distant metastases using IASLC grading and tumor stage were examined by receiver operating characteristic curves (ROC). 28 out of 179 patients developed distant metastases in five years with a median overall survival of 60 months for metastasis-free patients and 38.9 for patients with distant metastasis. Compared to predominant pattern-based grading system, IASLC grading system showed a stronger correlation with distant metastasis incidence. Complex gland pattern is enriched in patients who developed bone and brain metastases compared to metastasis-free patients. IASLC grading system also showed a superior prediction power of distant metastasis compared to tumor stage with area under curve (AUC) of 0.69 for brain metastasis and 0.71 for bone metastasis. IASLC grading system is capable of predicting the incidence of distant metastasis among early-stage invasive LUAD patients.

#3783 Oral squamous carcinoma, LN metastasis.

H. Kawai, H. S. Eain, T. Ohara, M. W. Oo, Y. So, H. Nagatsuka;
Okayama Univ. Graduate School of Med., Dentistry & Pharm. Sci., Okayama, Japan

Due to genetically unstable nature of cancer cells, they give rise to genetically different variant subclones inside a single tumor. To enable the development of more efficacious therapies, it is crucial to understand cancer heterogeneity and subclone characteristics. Oral squamous cell carcinoma (OSCC) has high heterogeneity and plasticity. C-X3-C motif ligand 1 (CX3CL1) is the chemokine with anti- and pro-tumor functions. Our study reported CX3CL1 functions on cancer subclones with different phenotypes, both in vivo and in vitro. We found that Mouse OSCC (MOC) 1 and MOC2 cells responded in similar manners to CX3CL1 in vitro. However, in vivo, CX3CL1 increases cellular differentiation in indolent cancer (MOC1) while increasing metastasis in aggressive cancer (MOC2). These phenomena are influenced by different phenotypic tumor microenvironments created by indolent and aggressive cancer. From there, we established that when aggressive cancer cells gain CX3CL1 expression, they stimulate protumor immune system, promoting cancer metastasis via lymphatic vessels. A similar phenomenon was observed in metastatic OSCC patient samples, where CX3CL1 expression became intense in metastasis regions, consistent with aggressive subclone (MOC2) character; we correctly predicted patient outcomes by using CX3CL1 as prognostic indicator for long-term follow-up in metastatic OSCC patients. In conclusion, CX3CL1 is the key factor for stimulating aggressive cancer subclones to create new lymphatic networks for lymph node metastasis.

#3784 Methylated DNA markers for detection of peritoneal metastasis in pancreatic cancer.

K. Maheshwari, C. K. Berger, W. R. Taylor, D. W. Mahoney, K. N. Burger, A. M. Delgado, K. A. Doering, H. M. Streich, P. H. Foote, S. P. Cleary, T. E. Grotz, M. L. Kendrick, R. L. Smoot, P. P. Starlinger, C. A. Thiels, M. J. Truty, S. G. Warner, J. B. Kisiel, S. Majumder;
Mayo Clinic, Rochester, MN

Introduction: Laparoscopy with peritoneal lavage enhances staging accuracy in patients with pancreatic ductal adenocarcinoma (PDAC). Occult intra-abdominal metastases are identified by staging laparoscopy in approximately 20% of patients with radiologically localized PDAC. Peritoneal fluid cytology has limited sensitivity in detecting occult intra-abdominal metastasis. Methylated DNA markers (MDMs) can accurately detect PDAC from tumor tissue, blood, and pancreatic secretions. This study aims to assess the feasibility of assaying MDMs in peritoneal lavage fluid obtained at the time of staging laparoscopy for patients with PDAC.

Methods: Peritoneal lavage fluid (25-60 mL) obtained from patients with PDAC at the time of staging laparoscopy was centrifuged for 10 minutes at 1200×g. The pellet was resuspended and aliquoted into 200µL tubes and frozen at -80°C. DNA extracted from one aliquot was assayed for mutant *KRAS (G12A and G13D)* and then bisulfite converted to measure 13 MDMs (*GRIN2D, CD1D, ZNF781, FER1L4, RYR2, CLEC11A, AK055957, LRRC4, MAX.CHR5.4295, HOXA1, PRKCB, SHISA9, NTRK3)* and a normalizing reference gene (*B3GALT6*) using quantitative methylation specific PCR. The association of *KRAS* and the average signal from the 13 MDMs (MDMscore) with intra-abdominal metastasis (Y/N) was assessed with the area under the receiver operator characteristic curve (AUC).

Results: Among 48 PDAC patients, staging laparoscopy revealed intra-abdominal metastasis in 15 (31%). Of the 15 intra-abdominal metastases, 6 were found to have biopsy-confirmed intra-abdominal metastasis and positive peritoneal cytology, 4 were positive on peritoneal cytology alone, and 5 had biopsy-confirmed intra-abdominal metastasis alone. The sensitivity of the MDMscore for intra-abdominal metastasis was 87% (CI: 60-98%) at 90% (CI: 76-98%) specificity whereas the sensitivity for *KRAS* was 40% (CI: 16-68%) at 85% (CI: 68-95) specificity. The AUC for the MDMscore was 0.98 (CI: 0.94-1.00) compared to 0.62 (CI: 0.48-0.77) for that of *KRAS* ($p<0.0001$).

Conclusion: MDMs assayed from peritoneal lavage fluid collected during staging laparoscopy is a novel tool for accurate molecular staging of PDAC. These early results warrant further study in a larger cohort to assess impact on peritoneal staging and its clinical utility in the neoadjuvant treatment paradigm of PDAC.

#3785 Clinical and genomic characterization of melanoma brain metastases.

M. Padilla Mazzeo, H. S. Walch, R. Kumar, J. Eichholz, C. Cooper, N. Nandakumar, J. Shen, I. Khatri, L. Del Balzo, A. Skakodub, E. Miao, D. W. Kelly, K. Kwok Hei Yu, J. Wilcox, B. S. Imber, Y. Yu, Y. Yamada, H. Vasudevan, A. Ilica, N. Schultz, L. R. G. Pike;
Memorial Sloan Kettering Cancer Center, New York City, NY

Introduction: Melanoma has a high propensity for brain metastasis (BM). Although advancements in brain-penetrant treatments have resulted in improved central nervous system (CNS) disease control, BMs remain a significant cause of morbidity and mortality. The molecular features of melanoma BM are poorly defined, and there is an unmet need to identify biomarkers associated with CNS-specific outcomes.
Methods: We retrospectively identified 109 patients with melanoma BM who underwent craniotomy at Memorial Sloan Kettering Cancer Center (MSK) between 01/2014 and 04/2023. BM specimens were sequenced using MSK-IMPACT, an FDA-approved next-generation sequencing assay covering 341-505 genes with 700X coverage. Clinical characteristics and CNS-specific outcomes were available from 107 patients; CNS-specific radiographic endpoints were verified through direct inspection of contrast-enhanced MRI imaging by a board-certified neuroradiologist. Clinical data included baseline characteristics, prior systemic or radiotherapy (RT), and CNS-directed follow up including recording local progression of disease (POD), regional POD, and development of leptomeningeal disease (LMD).
Results: Majority (68%,73/107) patients were male with a median age at the time of primary diagnosis of 56 (range 3-88). Forty-eight patients (45%) had advanced disease (stages III and IV) at the time of initial diagnosis. At the time of BM development, half of the patients had 2-5 intracranial tumors present (50%) with a median diameter of largest BM of 33.4mm (range .9mm-64mm). The median KPS was 80 at the time of BM diagnosis, and 79% had neurologic symptoms prior to resection. 81 patients (76%) were treatment naïve at the time of resection and 56 patients (53%) developed CNS recurrence with the majority of those having local POD (29%,16/56) followed closely by regional POD of 1 lesion (25%,14/56). The most frequent genomic alterations in the cohort were *TERT* (87%), *CDKN2A* (50%), *BRAF* (43%), *NRAS* (28%), and *PTEN* (25%). The median fraction genome altered was 0.3047 and the median tumor mutational burden was 13.2 muts/Mb. We compared the genomic profiles of BM tumors of patients that had no progression, local POD, regional POD, and LMD. Compared to patients with no progression, patients with local POD were more likely to have *RB1* alterations (18.1% vs 2.1%, p = 0.04, q = 0.83) and patients with LMD were less likely to have *TERT* alterations (62.5% vs 93.8%, p = 0.03, q = 0.75).
Conclusions: Our analysis between genomic markers and clinical outcomes in melanoma BM reveals genomic features which may improve prediction and treatment strategies.

#3786 Genomic and transcriptomic characterization of peritoneal, lung and liver metastases of colorectal carcinoma reveals site-specific differences.

N. Crnovrsanin[1], S. Lakbir[2], R. d. Wit[2], S. L. C. Ketelaars[1], N. F. M. Kok[1], P. Snaebjornsson[1], G. A. Meijer[1], S. Abeln[2], R. J. A. Fijneman[1];
[1]Netherlands Cancer Institute, Amsterdam, Netherlands, [2]Vrije Universiteit, Amsterdam, Netherlands

Background: Metastasis in colorectal cancer (CRC) is a critical factor in patient outcomes, with 20% of patients affected at the time of diagnosis and up to 50% developing metachronous metastatic disease later on. Despite the growing importance of metastatic sites as independent predictors of overall survival (OS) and the ongoing development of new treatments, there has been limited effort to personalize systemic treatment based on specific metastatic locations. Aim: This study aims to compare the genomic landscape of different metastatic sites in CRC to detect novel diagnostic and therapeutic targets.
Methods: DNA whole-genome-sequencing and RNA gene expression data from metastatic CRC samples were retrieved from the Hartwig Medical Foundation (HMF). Single nucleotide variants (SNVs), somatic copy number aberrations (SCNAs) and structural variants (SVs) were reported by HMF with their pipelines. In addition, focal amplifications and deletions were identified using GISTIC2 (v6.15.30). We included 464 microsatellite stable samples derived from liver metastases (n=369), peritoneal metastases (n=58) and lung metastases (n=37). We compared DNA mutation frequencies between tumors from different metastatic sites (two-sided Mann-Whitney tests) and performed differential gene expression and pathway enrichment analysis.
Results: Liver metastases had the highest number of focal SCNAs per sample (median 33 vs 17 in peritoneum ($p < 0.001$); vs 18 in lung ($p < 0.001$)). Furthermore, we observed 39 site-specific SCNAs in liver, 9 in peritoneal and 15 in lung metastases. Of these, the most significant focal SCNAs were an amplification within 20q13.12 (79%) and deletion within 1p35.3 (64%) in peritoneal metastases and a deletion within 18q21.1 (84%) in lung metastases. Furthermore, peritoneal metastases displayed less genomic instability, featuring lower ploidy (median 2.65 vs 2.94 in liver ($p=0.025$); vs 3.15 in lung ($p=0.025$)) and lower aneuploidy scores (median 19 vs 26 in liver ($p=0.016$); vs 30 in lung ($p=0.016$)) while having no significant differences in tumor mutational burden or individual SNVs. Analysis of SVs revealed that peritoneal metastases exhibited fewer deletions (≥10kb; 1.3x fold change increase in liver and lung) and fewer duplications (≥1kb; 1.4x fold change increase in liver). Differential gene expression analysis uncovered higher expression of gene sets involved in the apical junction and the TGF-beta-signaling pathway in peritoneal metastases.
Conclusion: Specific focal SCNA and differences in genomic instability exhibit an association with preferential organotropism in CRC metastasis and could offer potential targets for the development of new diagnostic and therapeutic approaches.

#3787 Important role of GPX1 and NF-kb signaling pathway in human gastric cancer including cell proliferation and invasion.

B. Jang, J. Jung, Jr., S. Koh, Sr., K. Lee, Sr.;
Yeungnam University Medical Center, Daegu, Korea, Republic of

Background: Glutathione peroxidases(GPXs) are member of an antioxidant enzyme family. Their role is to eliminate the reactive oxygen species(ROS). Many available studies confirm that over expression of GPXs can promote cancer cell proliferation and invasion. Among the 8 GPXs, Glutathione peroxidase-1 (GPX1) is the most plentiful. Overexpression of GPX1 has been noted to promote invasion, migration, cisplatin resistance and proliferation in breast, colorectal and lung cancer. NF-kB is a ubiquitous nuclear transcription factor in the human body. that key role in cell proliferation, apoptosis and tumor progression. In reliable studies, inhibition of NF-kB expression has been shown to reduce the malignancy of Esophageal squamous cell carcinoma. Accordingly, the purpose of this study is to identify the GPX1 and NF-kB signaling pathway and their correlation with cancer cell proliferation and invasion in vitro using gastric cancer cell.
Methods: In our study, we used cell culture, Northern blotting, cDNA microarray analysis, western blotting, RT-PCR, Zymography, 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide(MTT) assay, GPX1 knock-down with short hairpin RNS(shRNA), Standard two-chamber invasion assay, Chromatin immunoprecipitation assay.
Results: First, we confirmed that the expression level of GPX1 was up-regulated by HGF(hepatocyte growth factor) in gastric cancer cells. The cells were treated with NF-kB inhibitor, Pyrrolidine dithiocarbamate(PDTC), and analyzed by Western blotting to identify the associated pathway of HGF-induced GPX1 with NF-kB. The HGF-induced GPX1 protein level was down regulated by PDTC. The role of GPX1 associated with NF-kB was determined by knock down GPX1 expression using GPX1-sh RNA. The GPX1-sh RNA treated cells showedvdown regulation of NF-kB and urokinase Plasminogen activator(uPA) also. To fine the upper regulator of GPX1 signaling pathway, we treated AKT inhibitor(LY294002) ant then analyzed by Western blotting to identify associated pathway of HGF-induced GPX1 with AKT. When AKT pathway was inhibited, GPX1 and NF-kB were down-regulated in gastric cancer cell. HGF-mediated cell proliferation and invasion *in vitro* was decreased in GPX1 knock down cell. We identified the putative binding site of GPX1 promotor containing NF-kB binding site and confirmed the function by CHIP assay.
Conclusions: This study aimed to investigate relationship between GPX1 and NF-kB in gastric cancer cells. Results showed that HGF induced GPX1 expression through the NF-kB and AKT pathway and GPX1 may play a significant role in cell proliferation and invasion in gastric cancer. Therefore, GPX1 can be a potential therapeutic target of gastric cancer for the treatment.

#3788 EpCAM+ DCCs isolated from the bone marrow of breast cancer patients display high stemness and potency scores.

E. Raya[1], H. Koerkel-Qu[1], L. Rudhart[1], L.-M. Kohler[1], A. Damboeck[1], C. Irlbeck[2], C. Botteron[2], M. Werner-Klein[1], S. Seitz[3], C. Klein[1];
[1]University of Regensburg, Regensburg, Germany, [2]Fraunhofer-Institut fur Toxikologie und Experimentelle Medizin ITEM, Regensburg, Germany, [3]University Hospital Regensburg St. Josef, Regensburg, Germany

Metastatic dissemination of cancer cells from primary to distant sites often occurs early and it has been shown that their detection is linked to poor outcomes. Eradication of disseminated cancer cells (DCC) has therefore become the primary goal of adjuvant therapies. Since the phenotype of DCC is largely unknown, we set out to search, isolate, and molecularly characterize these candidate metastasis founder cells from bone marrow of breast cancer patients, years before manifestation of metastasis.

We screened more than 200 bone marrow samples of breast cancer patients with no evident metastasis (UICC stage M0) for EpCAM-positive cells. EpCAM positive cells in the bone marrow of healthy donors were used as a negative control. In addition, we isolated DCC from breast cancer patients with manifest metastasis (UICC stage M1). We then performed single cell RNA sequencing after whole transcriptome amplification of the collected DCC and the healthy donor (HD) control cells. To confirm the malignant origin of picked DCCs, we projected the transcriptome data into the bone marrow atlas, inferred copy number alterations, and searched for mutations shared with the matched primary tumor. EpCAM-positive cells from control patients mostly comprised plasma cells. In contrast, DCCs derived from M0-stage breast cancer patient formed a unique, non-overlapping cluster in the bone marrow atlas. UMAP-clustering placed M1-stage DCC clearly separate from M0 stage DCC. Among the collected M0-stage DCCs, we identified at least three separate subclusters. Strikingly, M0-stage DCC displayed much higher stemness and potency scores than M1-stage DCCs, reminiscent of embryonic cells. DCCs, identified by EpCAM, display very high transcriptional stemness scores when isolated before metastatic manifestation. Upon expansion and proliferation, stemness scores are reduced indicating epithelial re-differentiation. The embryonic phenotype of M0-stage DCCs may reflect an early adaptive mechanism that enables DCC to survive in an ectopic environment and may impact on the metastatic potential of the DCC.

#3789 Discovery of liquid biopsy-based novel protein biomarkers for early detection of breast cancer metastasis.

C. Jinno[1], S. Tanaka[1], T. Fujii[2], H. Furuya[1];

[1]Cedars-Sinai Medical Center, Los Angeles, CA, [2]National Cancer Institute, Bethesda, MD

Introduction and Objectives: Despite recent advances in screening and therapeutic technology, breast cancer is still the first leading cause of cancer death among females. When detected early (i.e., SEER Stage Localized), the 5-yr survival rate is 99%. The 5-yr survival rate is still 86% when cancer cells have spread beyond the breast, but this spread is limited to nearby lymph nodes (SEER Stage Regional). However, when the disease is noted to be SEER Stage Distant or metastasis, the 5-yr survival rate is significantly reduced to 31%. The evidence suggests that breast cancer is manageable if distant metastasis could be prevented. Thus, the prevailing idea is that early detection of breast cancer metastasis in surveillance will likely be the best modality to address advanced breast cancer's dismal outcomes. Thus, liquid biopsy may be suitable for "early detection" of pre- and/or micro-metastasis because of its ease of obtaining biological material. In this pilot study, we explored the potential biomarkers for the early detection of breast cancer metastasis using publicly available datasets.
Methods: We obtained 2 publicly available datasets from GEO (GSE102484 and GSE234114) containing primary tumor samples taken from subjects with and without metastatic disease. Both datasets were generated by mRNA microarray (Affymetrix Human Genome U133 Plus 2.0 Array). With these datasets, we performed the differentially expressed gene (DEG) analysis using GEO2R based on GEOquery and *limma* (Linear Models for Microarray Analysis) with a threshold criterion of Log 2 fold change >0 and p-value <0.05 as the cut-off point. The significantly upregulated genes were further screened using VerSeDa (Vertebrate Secretome Database) to select secreted proteins.
Results: In the GSE102484 (N = 683, 582 non-metastasis and 101 metastasis), DEG identified 1798 upregulated and 1472 downregulated genes. Venn diagram analysis between the upregulated genes and VerSeDa identified 337 upregulated genes coding secreted proteins. In the GSE234114 (N = 120, 60 non-metastasis and 60 metastasis), DEG identified 2873 upregulated and 931 downregulated genes. Venn diagram analysis between the upregulated genes and VerSeDa identified 563 upregulated genes coding secreted proteins. By integrating the genes from GSE102484 and GSE234114, 82 commonly upregulated genes that code secreted proteins were identified.
Conclusions: In this study, we identified 82 candidate mRNA biomarkers that are upregulated in breast tumor with metastasis. The panel of biomarkers will be validated in blood-based liquid biopsy samples in the next study.

#3790 HtrA3 promotes malignant progression of colorectal cancer via PI3K-AKT-FOXO1 signaling pathway.

J. Zheng, X. Huang, X.-e. Peng, **Y. Wu**;
Fujian Medical University, Fu Zhou, China

High-temperature requirement protease A3 (HtrA3) is known to contribute to the progression of various carcinomas through tissue-specific actions, yet its precise role in colorectal cancer (CRC) remains unclear. Our study revealed that HtrA3 is significantly upregulated in CRC at both mRNA and protein levels. TCGA database analysis showed that higher HtrA3 expression in colon adenocarcinoma is linked to poorer patient survival. Moreover, increased HtrA3 expression in HCT116 cells boosted their proliferation, migration, and invasion, while decreasing HtrA3 in SW480 cells had the reverse effect. In HCT116 cells with high HtrA3 levels, there was an increase in p-PI3K, p-AKT, and p-FOXO1, which reduced upon treatment with the PI3K inhibitor LY294002. Conversely, in SW480 cells with lowered HtrA3, these molecular levels decreased and rose again after treatment with the PI3K activator 740Y-P. HtrA3 also promoted cell proliferation, migration, and invasion in the presence of LY294002 and 740Y-P. In vivo experiments demonstrated that HtrA3 overexpression accelerated xenograft tumor growth. This study confirms that HtrA3's overexpression in CRC cells promotes their proliferation, migration, and invasion by activating the PI3K-AKT-FOXO1 signaling pathway. Therefore, HtrA3 could be a significant factor in the advancement of CRC and may serve as a potential prognostic marker for guiding targeted CRC therapies.

#3791 A prognostic signature based on inherited genetic polymorphisms for patients with uveal melanoma.

T. Verrier[1], A. Le Ven[1], A. Houy[1], A. Garcia[1], P. Gaelle[1], N. Cassoux[1], M. Rodrigues[1], J. Noirel[2], M.-H. Stern[1];
[1]Institut Curie, Paris, France, [2]Conservatoire National des Arts et Metiers, Paris, France

Introduction: Uveal melanoma (UM) is the most frequent eye malignancy in adults. Two UM subtypes exist, defined by Gene Expression Profiling or by genomic status: GEP class 1/disomy 3 [D3] and GEP class 2/monosomy 3 [M3] defining low-risk or high-risk of developing metastasis, respectively. However, these prognostic signatures require tumor samples, which may be difficult to obtain. We previously identified by a genome-wide association study (GWAS) frequent single nucleotide polymorphisms (SNP) in *IRF4* and *HERC2* associated with risk for D3 or M3 UM, respectively (1). Here, we aim to design a prognostic signature for the D3 and M3 UM subtypes based on these constitutive polymorphisms, available from blood samples.
Experimental Procedures: We used the GWAS cohort of 1476 UM patients genotyped on GSA or Omni5. Risk SNPs coupled with clinical variables were used on a cohort of 497 UM patients (191 D3, 306 M3) in a statistical machine learning process to define a predictive signature of UM subtype. A cohort of 852 UM patients was used for validation.
Results: We retained two SNPs, rs12203592 (in *IRF4*) and rs12913832 (in *HERC2*), tumor diameter and thickness, age at diagnosis and gender. We validated the predictive model in the validation cohort. The predicted high-risk group showed a decrease in time to relapse (TR) (HR: 3.72 [2.57 - 5.41], logrank p-value = 1.35E-15), overall survival (OS) (HR: 3.85 [2.58 - 5.73], logrank p-value = 1.24E-14) and progression-free-survival (PFS) (HR: 3.61 [2.32 - 5.61], logrank p-value = 6.55E-11), compared with the predicted low-risk group.
Conclusion: Common germline polymorphisms contribute to the prediction of metastatic risk in patients with localized uveal melanoma. This information could be especially useful when access to the tumor is problematic.

#3793 Mutational and gene expression profiles of the primary tumor and matched brain metastasis of epithelial ovarian cancer reveal differences in LAMC3 and MYC target genes.

Rita Trozzi[1], Camilla Nero[1], Marianna Buttarelli[1], Marcello Salvi[2], Luciano Giaco[1], Angelo Minucci[1], Claudia Marchetti[1], Carolina Sassu[1], Federica Persiani[1], Lorenzo De Marco[1], Simona Duranti[1], Camarda Floriana[1], Valentina Iacobelli[1], Ilenia Marino[1], Luca Mastrantoni[1], Flavia Giacomini[1], Alessia Piermattei[1], Mariagrazia Valentini[1], Tina Pasciuto[1], De Bonis Maria[1], Giuseppina Raspaglio[1], Diana Giannarelli[1], Anna Fagotti[1], Davide Cacchiarelli[2], Giovanni Scambia[1]

[1]Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome, Italy,[2]Telethon Institute of Genetics and Medicine (TIGEM), Armenise/Harvard Laboratory of Integrative Genomics, Pozzuoli, Italy

Introduction: Brain metastases (BM) from Epithelial ovarian cancer (EOC) are a rare and late-stage disease manifestation, very poorly biologically characterized. We performed a multi-omics characterisation of primary EOC samples (PT) and the matched BM, to assess differences in mutational and gene expression profiles.

Material and Methods: We retrospectively collected data from EOC patients treated at Fondazione Policlinico Gemelli IRCCS who underwent surgical removal of BM between 2011 and 2022. We collected the formalin-fixed, paraffin-embedded (FFPE) tissue of the PT and the matched BM. An evaluation of single nucleotide variants (SNVs), insertions/deletions (indels) and copy number variations (CNVs) in 523 genes as well as known and unknown fusions and splicing variants in 55 genes was performed (Illumina TruSight Oncology 500 high throughput). Moreover, a bulk RNAseq analysis was conducted utilizing the NEGEDIA Digital mRNA-seq clinical-grade sequencing service. We acknowledged as differentially expressed genes if they exhibited a $-1 \leq \log2(\text{Fold Change}) \geq 1$ and $pAdj \leq 0.05$. To ensure specificity in identifying differential gene expressions pertinent to our tumoral tissues, genes associated with brain-related functionalities were systematically excluded from downstream analyses and identified through meticulous screening via the Human Protein Atlas. Clonal evolution was evaluated with two distinct algorithms: Pyclone VI and Sciclone.

Results: Matched PT/BM FFPE samples were collected from 10 different patients. We identified 21 SNVs: most of them were shared between the PT and the matched BM and TP53, CCND1, IRS2, and FGFR4 mutations emerged as the most frequently detected (shared in 70%, 50%, 50%, and 40% of the cases, respectively). Among 56 CNV detected, most of them were exclusive of the BM samples. Specifically, MYC family genes (MYC, MYCL, MYCN) were the most frequently amplified. At the clonal analysis, each patient showed at least two clusters. The majority of clusters turned out to be consistent among PT and BM demonstrating monoclonal evolution. Gene set variation analysis discovered 50 different gene sets between the PT and the BM ($p < 0.05$). Among them, the E2F targets, G2M checkpoint, MYC targets V1 and MYC targets v2 hallmarks showed higher expression in the BM. We identified 110 significant differentially expressed genes between PT and BM samples, including 27 upregulated and 83 downregulated genes. The gene LAMC3 emerged as notably upregulated in metastatic contexts.

Conclusion: This is the largest cohort present in the Literature of EOC PT and matched BM characterized with a multi-omics analysis. The intersection of LAMC3 and MYC target genes within the MET signalling network, a pathway recognized for bolstering cell motility, introduces a compelling avenue for future research.

#3794 Clinical impact of high-quality liquid biopsy for peritoneal lavage cytology in resectable pancreatic cancer.

M. Tanemura[1], K. Furukawa[2], T. Asaoka[2], D. Marukawa[1], H. Yasuoka[2], Y. Urata[3], D. Yamada[4], S. Kobayashi[4], H. Eguchi[4];
[1]Rinku General Medical Center, Izumisano, Osaka, Japan, [2]Osaka Police Hospital, Osaka, Japan, [3]Oncolys BioPharma Inc., Tokyo, Japan, [4]Osaka University Graduate School of Medicine, Suita, Osaka, Japan

Despite the general trends towards increased cancer survival, pancreatic ductal adenocarcinoma (PDAC) still has a dismal prognosis. Peritoneal recurrence is a major recurrence pattern after pancreatectomy. Peritoneal lavage cytology (CY) is employed widely in the diagnosis and staging of PDAC to rule out patients with occult peritoneal metastasis. However, the importance of CY status both as a sign of irresectability and as a prognostic factor for PDAC remains controversial. The purposes of this study were to determine whether CY+ status precludes radical resection and to propose novel liquid biopsy using peritoneal lavage fluid to detect viable peritoneal tumor cells (v-PTCs). We conducted this study to evaluate use of a new genetically modified telomerase-specific replication-selective adenovirus, expressing GFP (TelomeScan F35) in rapid detection of v-PTC dissemination (Telo-CY). We assessed the clinical utility of high-quality testing of Telo-CY in PDAC patients in comparison with the findings of conventional CY (Conv-CY). This study was approved by the IRB in our Hospital. Patients with resectable cytologically or histologically proven PDAC were enrolled. 100 ml of saline as peritoneal lavage fluid was harvested just after a laparotomy. Half of the fluid was examined by conv-CY, based on Papanicolaou staining and MOC-31 immunostaining, and the remaining half was analyzed to detect v-PTCs by Telo-CY. To distinguish between leucocyte and cells with epithelial origin, cells were stained with anti-CD45 mAb. To further distinguish cells with primary tumor origin, cells were labeled with anti-CEA, anti-CA19-9 and Ep-CAM mAbs. GFP(+) and CD45(-), and either CEA-, CA19-9- or Ep-CAM-(+) cells were counted as v-PTCs. Patients were followed to evaluate its clinical significance. Among 53 patients aged 53-87 years (30 males, 23 females), 5 were conv-CY(+), other 12 were Telo-CY(+). All 53 patients underwent surgical resection (PD/DP/TP=32/14/7). 2 patients were double-CY-(+) [conv-CY(+) and Telo-CY(+)], and peritoneal recurrence occurred at 7-9 months after surgery, despite adjuvant chemotherapy. 3 were conv-CY(+) alone, but Telo-CY(-), and no peritoneal recurrences were observed (0%). Conversely, 10 were Telo-CY(+) alone, but conv-CY(-), and 6 out of 10 patients were relapsed with peritoneal dissemination (60%). Remaining 38 patients were double-CY-negative (conv-CY- and Telo-CY-, conv-CY±), peritoneal recurrence was observed in 3 patients (8.3%). Although CY-positive status predicts poor prognosis and a higher risk of peritoneal dissemination after resection, it is not sufficient to preclude pancreatectomy by conv-CY alone. Combined CY examination with conv-CY and Telo-CY may open the window of opportunity for leading true results, accurately predicting peritoneal recurrence in PDAC patients. The CY status should be confirmed by staging laparoscopy prior to resection.

#3795 Possible role of miR-375-3p in cervical lymph node metastasis of oral squamous cell carcinoma.

M. Saika, K.-i. Nakashiro, N. Tokuzen, H. Shirai, D. Uchida;
Ehime University Graduate School of Medicine, Toon, Ehime, Japan

Latent cervical lymph node metastasis (LNM) is the most important prognostic factor in early oral squamous cell carcinoma (OSCC). However, no clinically useful predictors of LNM in early OSCC are available. In this study, we focused on the microRNAs (miRNAs) involved in the expression of numerous genes and explored those associated with latent cervical LNM in OSCC. Microarray analysis of miRNA expression showed that the expression levels of miR-375-3p were significantly reduced in primary OSCC tissues with latent cervical LNM. Subsequently, we quantified the expression of miR-375-3p by RT-qPCR and digital PCR. Similar to the results of miRNA microarray analysis, miR-375-3p was significantly downregulated in primary OSCC tissues with latent cervical LNM. The results of digital PCR showed a more significant difference than those of RT-qPCR. When the reference value for predicting latent cervical LNM was set to less than 57.85 copies based on the receiver operating characteristic curve, the sensitivity, specificity, accuracy, and area under the curve were 80%, 100%, 90%, and 0.942, respectively. Next, we examined the effects of miR-375-3p mimics on the growth and migration of four human OSCC cell lines (SAS-L1, HSC2, HSC3, and Ca9-22) that do not express miR-375-3p. When an miR-375-3p mimic was introduced into these cells, cell proliferation and migration were significantly suppressed. Total RNA was extracted from these cells reverse-transfected with miR-375-3p mimic for 48 hours. Microarray analysis and Ingenuity Pathway Analysis (IPA) miRNA target filter showed that miR-375-3p overexpression reduced the expression of 266 genes, of which 37 genes had the target sequences of miR-375-3p in their 3'-untranslated region. Among these target genes, CEPT1 and TIMM8A knockdown significantly inhibited the migration of all human OSCC cells, similar to miR-375-3p mimics. Furthermore, IPA core analysis revealed a decrease in expression of genes involved in the activation of PI3K-AKT pathways by miR-375-3p overexpression. These results indicated that downregulating miR-375-3p expression could promote cervical LNM by enhancing cell proliferation and migration in OSCC. We also found that CEPT1 and TIMM8A as novel target genes of miR-375-3p regulated the migration of human OSCC cells. The expression levels of miR-375-3p in primary OSCC tissues appear to be a useful biomarker for predicting latent cervical LNM.

#3796 Investigating unbiased whole transcriptome high-resolution spatial interactions within tumor masses.

M. M. Lee, J. Wilhelmy, T. Ong, W. Wang, B. Yeung, **C. Chang**, C. Fan;
Curio Bioscience, Inc., Palo Alto, CA

Tumor masses contain a diverse array of cell types, including both normal and tumor cells from different lineages, endothelial cells, and immune cells. Interactions among these cellular constituents and their spatial arrangements play a pivotal role in tumor development, progression, and metastasis. While single-cell analysis has provided valuable insights regarding the dissociated cellular composition of tumors, it falls short in elucidating the complex interplay of cell-cell interactions and spatial relationships that may drive tumor cellular behavior and gene expression.

We used the Curio Seeker Spatial Mapping Kits to uncover those spatial relationships in human tumor samples. The method captured whole transcriptomes and preserved the spatial locations of tumor cells, infiltrating immune cells, and normal cells by self segregating gene expression signatures and unbiased clustering. Amongst other findings by using Curio Seeker, we identified areas of immune cell infiltrates that were devoid of tumor cells, signifying zones of potential anti-tumor response.

The high spatial resolution, continuous gene expression maps from the Curio Seeker Spatial Mapping Kits reveal spatial interactions between different cellular populations that enable researchers to better understand how the interplay between tumor cell types and their cellular neighborhoods affect gene expression and tumor cell behavior.

#3797 Unveiling the spatial dynamics of the tumor microenvironment: Integrated RNA and protein profiling on the same slide through automated spatial multiomics analysis.

P. Juricic[1], **A. Manoukian**[1], A. Comberlato[1], P. Bordignon[1], A. Failletaz[1], A. Dikshit[2], E. Doolittle[2], R. Delvillar[2], S. Zhou[2], C.-w. Chang[2], L.-c. Wang[2], S. Brajkovic[1], M. Srinivasan[2], D. Dupouy[1];
[1]Lunaphore, Lausanne, Switzerland, [2]Advanced Cell Diagnostics, Newark, NJ

Spatial biology techniques have revolutionized our approach towards the study of the tumor microenvironment (TME) and its complex cellular interplay. On the one hand, multiplex immunofluorescence (mIF) methods have enabled a precise profiling of immune cells and other key cellular players of the TME while uncovering their spatial distribution and interactions. On the other hand, in situ hybridization (ISH) technologies have shown to provide complementary information to protein profiling such as the mapping of cytokine- and chemokine-expressing cells, essential for comprehending signaling networks and immune activation statuses.

Here, we made use of a novel multiomics approach that combines these two biological inputs by integrating RNAscope™ and sequential immunofluorescence (seqIF™) protocols to achieve same-slide co-detection of RNA and protein targets. The combined workflow is automated on COMET™, an advanced tissue staining and imaging platform. Through precise control over temperature and reagent distribution, the instrument ensures maximum efficiency and reproducibility of the assays. The integrated multiomics protocol allows for up to three RNAscope™ detection cycles combined with twelve seqIF™ cycles, for a final 12-plex RNA + 24-plex protein panel.

We first showed the capacity of COMET™ platform to fully automate the RNAscope™ protocol and demonstrated its sensitivity and specificity with the analysis of positive and negative control genes on HeLa cell pellets, highlighting the flexibility of sample selection. To illustrate the potential multiomics in unravelling the complexity of the TME, we designed a panel of 12-RNA-targeting probes for key biomarkers of tumor-infiltrating lymphocytes and their activation status, including multiple secreted molecules (e.g., cytokines and proteases). This was combined with a 24-antibody panel for the detection of protein biomarkers, selected to enable the single-cell profiling of different players within the TME. We applied this panel to characterize different human FFPE tumor tissues and showed that the co-detection of RNA and protein biomarkers on the same slide allows a better characterization of key cellular components involved in tumor progression and immune response.

Our results highlight the potential of spatial multiomics technologies in enhancing the efficiency of investigations of immune cell behavior and generally the understanding of cellular interplay in the TME. Their full automation on a platform like COMET™ will accelerate analysis and increase robustness by minimizing user intervention, and ultimately helping in the development of prognostic and predictive biomarkers, in the refinement of cancer diagnoses, and in the selection of new personalized therapies.

#3798 Advancements in multiplexed spatial phenotyping.

L. Montoya, S. Clarke, A. Harvey, J. Serafin, M. Voeun;
Leticia Montoya (Individual), Eugene, OR

Spatial omics is an expanding research area focused on integrating spatial knowledge of tissue with transcriptomics (RNA) and proteomics (protein). Understanding the complexity of the biological structure(s) is an important biological process in cancer immunotherapy research which requires accurate target classification. Translational profiling of 4+ targets on a single sample at one time can be difficult in many ways, such as, panel design, staining protocols, and data analysis. Furthermore, to design a reliable multi-target biomarker panel, there are many parts to overcome, such as protein abundance and localization, fluorophore compatibility, varying tissue types, and data characterization, to name a few. To address the needs of high target multiplex ability, labeling methods have advanced in cyclic detection enabling iterative labeling and detection using automated fluidics, however these approaches suffer from low simultaneous target throughput. Thermo Fisher Scientific can now provide a streamline process for tissue labelling; a process that enables sufficient labelling of high multiplexed panels completed within a couple of hours. We show successful detection of a wide range of various protein markers across numerous tissue organs used in various biological research applications with our uniform technique of labelling.

#3799 Spatial biomarker prediction in papillary renal cell carcinoma using artificial intelligence-based immunofluorescent inference.

J. Brewer[1], J. Vento[2], S. Haake[2], **A. Reddy**[1];
[1]Vindhya Data Science, Morrisville, NC, [2]Vanderbilt University Medical Center, Nashville, TN

Papillary renal cell carcinoma (pRCC) accounts for ~15-20% of the global burden for kidney cancers but still lacks effective mechanisms to predict patient responses to therapeutic intervention. Existing therapies targeting kidney cancers (anti-angiogenesis and immunotherapy) intimately involve the tumor microenvironment in their mechanism of action. However, the role of the physical organization of the tumor in determining therapeutic efficacy remains unknown. Previous efforts have utilized transcriptional profiling to stratify patients into treatment categories but here we propose to leverage artificial neural networks ("AI") to infer the expression of marker genes for particular cell types of interest based on ubiquitously expressed immunofluorescence channels, unstained brightfield images, and hematoxylin and eosin (H&E) stained images. We have developed AI models that are capable of the prediction of a range of relevant cell types based on the expression profile of DAPI, type IV collagen, and integrin beta-1, including endothelial cells, T cells, macrophages and other cell types. This work applies an AI model class known as generative adversarial networks (GANs) to produce photo-realistic simulated immunofluorescence images based on the input channels. This approach may allow us to accurately predict complex multiplex immunofluorescence (mIF) images from simpler, more routine histological methods, greatly reducing the cost burden required to profile histopathology images for cell types of interest. Our previous work identified a number of interesting cell-cell association clusters correlated with patient prognosis and this extension of that previous work aims to allow for the prediction of these interactions while obviating the need to perform the original, costly multiplex immunofluorescence assay or even a more reduced immunofluorescence staining panel which may still be out of reach for many clinical pathology labs and the interpretation of which may be challenging. By simplifying and increasing the availability of predictive AI models for digital pathology, we hope to further develop and apply predictive biomarkers for patient prognosis and treatment response in papillary renal cell carcinoma.

#3800 Next generation of spatial biology: High-throughput multiplexed Imaging Mass Cytometry™ with whole slide modes.

Q. Raza, **T. D. Pfister**, J. Chwee, L. Lim, D. Howell, N. Parsotam, D. King, C. Loh;
Standard BioTools Inc, Markham, ON, Canada

Gaining spatial insights into the cellular composition of tumor tissue has tremendous potential to inform clinical and translational researchers about mechanisms behind spatial predictors of immunotherapy success, disease etiology and progression. Imaging Mass Cytometry™ (IMC™) is a high-plex spatial biology imaging technique that enables deep characterization of the diversity and complexity of the tumor microenvironment (TME). IMC supports detailed assessment of cell phenotype and function using 40-plus metal-tagged antibodies simultaneously on a single slide without issues associated with fluorescence-based spectral overlap, tissue autofluorescence or implementation of multiple washing and acquisition cycles.

Currently, IMC enables user-defined regions of interest (ROI) in tissues to evaluate cellular and structural composition. To enhance the IMC user experience, we developed two new whole slide imaging (WSI) modes which enable streamlined workflows using ultrafast preview mode (PM) and high-throughput tissue mode (TM). PM samples the entire tissue at predefined spacing to rapidly capture a low-resolution image of all expressed markers in the antibody panel. PM generates an image in minutes to enable informed ROI placements while leaving the stained tissue intact for higher-resolution imaging. PM and TM are designed so acquisitions can easily occur on the same slide without additional processing steps. TM rapidly acquires images of the whole tissue at lower resolution (7 µm pixel size) at a quality that can be used for quantitative analysis of the tissue spatial biology. Specifically designed for high-throughput applications, TM in combination with a newly available 40-slide loader for the Hyperion XTi™ Imaging System permits automated and continuous imaging of more than 40 large tissue samples (400 mm^2 per tissue) per week.

We showcase the application of WSI modes using the newly developed Maxpar® Human Immuno-Oncology IMC Panel Kit. The 31-marker panel was combined with catalog antibodies to create a 40-plus-marker panel that expands the ability to conduct comprehensive high-plex tumor and immune cell profiling. Tumor tissue microarrays (TMA) and whole tumor tissue sections were stained with the expanded panel. Single-cell analysis of selected ROIs, on whole tumor sections and TMAs, guided by PM data successfully provided quantitative analyses of spatial biology at single-cell resolution. In parallel, TM on whole tumor sections followed by pixel-based analysis provided a spatially resolved quantitative assessment of specific tumor and immune components of the TME.

This work demonstrates the expanded capabilities of IMC and establishes it as a reliable high-plex spatial biology imaging platform with high-throughput imaging capabilities ideally suited for translational and clinical applications.

For Research Use Only. Not for use in diagnostic procedures.

#3801 Spatially resolved laser-activated cell sorting (SLACS) for high throughput spatial cell sorting in tumor research.

S. Lee, A. C. Lee;
Meteor Biotech Co., Ltd., Seoul, Korea, Republic of

Understanding of tumor heterogeneity and the microenvironment is a cornerstone in advancing cancer research and therapy. The Spatially resolved Laser-Activated Cell Sorter (SLACS) represents a novel approach in cancer research, allowing for high-throughput, precise cell isolation while preserving spatial information, which is crucial for studying tumor heterogeneity and the tumor microenvironment. The SLACS instrument utilizes laser-activated technology for selective isolation of cells from heterogeneous tissue samples, optimized for accuracy, speed, and minimal cell damage. This instrument has demonstrated effective isolation of specific cell types from complex tissue matrices, maintaining cell integrity and spatial information. Its high-throughput capacity significantly reduces sample processing time. This groundbreaking tool offers detailed exploration of tumor heterogeneity and the tumor microenvironment, providing valuable insights into cancer biology and potential therapeutic targets.

#3802 Integrating multiplex-staining and multiplex-DIA: Profiling the tumor microenvironment spatial proteome for precision cancer research.

X. Zheng, A. Mund, M. Mann;
University of Copenhagen, Copenhagen, Denmark

Our innovative dual-dimensional multiplexing approach ushers in a new era of spatial proteomic exploration. Multiplex-staining deepens understanding of tumor-stroma interactions. Our robust dimethyl labeling-based multiplex-DIA workflow enhances throughput and proteome depth in the Deep Visual Proteomics (DVP) technology. Now, our audacious integration of multiplex-staining with multiplex-DIA holds the promise of pushing the boundaries of spatial proteome profiling. This innovation combines the power of mass spectrometry (MS) with clinical viability in 1) requiring just one FFPE section for spatial proteome analysis at the resolution of individual cell types; 2) ingeniously transmuting MS revelations into a clinically feasible staining strategy. A force in personalized oncology, our innovation unravels the intricate dynamics of the cancer ecosystem while ensuring direct clinical relevance.

We conducted multiplex immunofluorescent staining on human cancers using the MACSima platform, followed by cellular phenotyping and automated single-cell laser microdissection. Subsequently, we loaded dimethyl-labelled 3-plex tryptic peptides onto Evotips and performed LC-MS analysis using the Evosep One coupled to timsTOF SCP.

Pre- and post-22-plex staining proteome analysis confirmed no significant protein loss, validating microdissection compatibility and excellent recovery. The key findings include: 1) profiling of 21 distinct cell types/subtypes in human tonsil cancer tissues, resulting in the identification of 4941 protein groups from a cellular volume of 110,859 μm^3, equivalent to approximately 55 cells; 2) observation of a loss of CD45RA/RO expression in tumor-infiltrating cytotoxic T cells, contributing to a reduction in MET and PDGF signaling activity within tumor cells; 3) the presence of abundant cytotoxic T cells, B cells, and plasma cells, coupled with a reduction in tumor cell proliferation, indicative of a hot tumor microenvironment. Proteome analysis revealed enhanced immune cell mobility and interactions with tumor cells. Moreover, our workflow facilitated the identification of potential diagnostic markers for mycosis fungoides, a marker-lacking skin lymphoma, where we achieved the identification of 2964 significant proteins out of a total of 6009. In addition, a rare lymphoma case study not only guided ABVD chemotherapy and suggested IL4 inhibition to address chemoresistance but also identified CDK, MCM, and PSMA/B/C/D/E inhibitors as promising candidates for targeted therapy. The integration of multiplex-staining and multiplex-DIA represents a significant stride in advancing personalized diagnostics and therapeutic strategies.

#3803 Spatial architecture of tumor and immune cell lineages in syngeneic mouse tumor tissues.

A. BOSE[1], L. Arvidson[2], E. Alonzo[2], M. J. Smith[1], K. O. White[1], R. A. Heil-Chapdelaine[1], G. Spang[2], M. Norton[2], S. Jensen[2], V. Agrawal[1];
[1]Leica Microsystems, Waltham, MA, [2]Cell Signaling Technology, Danvers, MA

Immune checkpoint blockade (ICB) therapies have demonstrated great clinical benefit in a variety of malignancies, but there are many patients that do not respond. Despite many preclinical and clinical studies, the mechanism of ICB is not completely understood. Development of novel therapies targeting other immunosuppressive mechanisms or combining ICB with conventional chemo or radio therapies have the potential to increase the number of patients that achieve durable responses. However, the optimal therapy or combination of therapies for a patient is likely influenced by which immunosuppressive mechanisms exist within the tumor microenvironment (TME) and the phenotype and function of tumor-infiltrating immune cells. To delineate the mechanisms of immunosuppression we selected FFPE tissue sections from three syngeneic murine cancer models and performed tumor-immune profiling to spatially understand the contributions of both immune cells and cancer cells. Mouse reactive antibodies targeting specific cellular populations will help identify the location of immune cells within the tumor site and can be used for proof-of-concept studies. This approach can lead to novel insights to synergize anti-tumor activity of ICB therapies and will help to identify differences between responders and non-responders. The Cell DIVE Multiplex Imaging Solution allows probing and imaging of dozens of biomarkers on a whole single tissue section with an iterative staining and dye inactivation workflow. At its core, Cell DIVE is a precise and adaptable open multiplexing solution that enables flexibility in antibody selection of biomarker panels used in a multiplexed imaging study. Cell Signaling Technology (CST®) has a broad portfolio of IHC-validated antibodies to detect key proteins in the TME, enabling immune cell detection and phenotyping in tissue. CST offers off the shelf (OTS), ready-to-ship antibody conjugates that have been verified to work on Cell DIVE and offers custom conjugation of IHC-validated antibodies to fluorophores and other detection reagents. CST employs a rigorous approach to IHC validation, followed by verification on the Cell DIVE platform to ensure successful detection of proteins. Here, we demonstrate multiplexed Cell DIVE imaging using a novel panel of dozens of CST biomarker antibodies across multiple mouse syngeneic tumor types. In summary, multiplexed whole slide imaging using validated antibodies and Aivia AI-based image processing software enables spatially resolved tissue analysis of the tumor microenvironment, including new insights into spatial biology.

#3804 Multiparameter cell-cycle measurement enables a better assessment of cancer aggressiveness than Ki67 LI alone.

Jan H. Mueller[1], Julia Ebner[1], Zhihao Huang[1], Maximilian Lennartz[1], Claudia Hube-Magg[1], Frank Jacobsen[1], Stefan Steurer[1], Christian Bernreuther[1], Till S. Clauditz[1], Andreas H. Marx[2], Till Krech[1], Eike Burandt[1], Guido Sauter[1], Ronald Simon[1], Sarah Minner[1], **Elena Bady**[1]

[1]University Medical Center Hamburg-Eppendorf, Hamburg, Germany,[2]Klinikum Fuerth, Fuerth, Germany

Background: Ki67 is expressed in the G1, S, G2 and M phase of the cell cycle. Immunohistochemical determination of the Ki67 labeling index (LI) is a clinically well-established tool for assessing the proliferative activity of tumors and critical clinical decisions are based on this parameter. Other cell cycle associated proteins have been evaluated for clinical utility much less intensively. This for example includes minichromosome maintenance-3 (MCM3) which is expressed earlier in the cell cycle than Ki67.

Design: To evaluate the difference and potential synergy between of Ki67 and MCM3 based proliferation indices, both proteins were analyzed by multiplex fluorescent immunohistochemistry in more than 1,580 colorectal carcinomas that were available in a tissue microarray format and results were compared with clinico-pathological parameters (pT, pN, grade, MSI, p53 status). A deep learning-based framework comprising a deep-learning based algorithm for automated cell and marker detection was used for image analysis.

Results: In our 1,583 evaluable colorectal cancers, the average Ki67 LI was 69% and the average MCM3-LI was 67%. There was a significant overlap between Ki67 and MCM3 staining: Of all panCK positive tumor cells, 56% were positive for both Ki67 and MCM3, 11% were only positive for Ki67, 8% showed positivity only for MCM3, and 25% were negative for both markers. According to the expression of Ki67 and MCM3, the following compartments of proliferating cells were defined: early ($MCM3^{+}/Ki67^{-}$), intermediate ($MCM3^{+}/Ki67^{+}$), and late phase of the cell cycle ($MCM3^{-}/Ki67^{+}$) as well as full proliferation ($MCM3^{+}$ or $Ki67^{+}$). Comparison with clinico-pathological parameters revealed the best p-values for the MCM3 LI in the comparison with pT ($p=2.7e^{-8}$), nodal metastasis (p=0.0002), and p53 alterations ($p=6e^{-11}$) while the “full proliferation” LI was most tightly linked to microsatellite instability ($p=1e^{-10}$). The Ki67 LI was best correlated to the grade (p=0.01).

Conclusion: The combined analysis of MCM3 and Ki67 enables the distinction of cells in early, intermediate, and late phase of the cell cycle. At least in colorectal cancer - a highly proliferative neoplasm - MCM3 quantification alone or in combination with Ki67 often resulted in stronger relationships with clinicopathological parameters than the Ki67 LI alone. These results suggest that a more subtle analysis of cell cycle proteins might enable a better evaluation of cancer aggressiveness than Ki67 measurement alone.

#3805 Intestinal microbiome with chemotherapy response and RAS mutation in patients with advanced or metastatic colorectal cancer: a pilot, exploratory study.

Jwa Hoon Kim[1], Boyeon Kim[2], Soohyeon Lee[1]

[1]Medical oncology, Korea University College of Medicine, Korea University Anam Hospital, Seoul, Korea, Republic of,[2]Cancer research institute, Korea University, Seoul, Korea, Republic of

Intestinal microbiomes interact with the tumor microenvironment, participating in inflammation and immune regulation, and are associated with the response to anticancer therapy. However, there has been limited research exploring the relationship between changes in the microbiome and treatment response in patients with metastatic colorectal cancer (mCRC) during chemotherapy and radiation therapy.This study included all 15 patients with mCRC treated with first-line systemic therapy between October 2021 and February 2023. We conducted 16S rRNA sequencing on baseline stool samples and investigated the association of intestinal microbiome with chemotherapy response and RAS mutation. The QIIME2 and R packages were used for analysis. As a results, Median age was 61 years (range, 35-73), and there were 8 patients with RAS-mutated mCRC. All patients were treated with first-line systemic therapy; FOLFOX (5-fluorouracil and oxaliplatin)-based (n=13) and FOLFIRI (5-fluorouracil and irinotecan)-based chemotherapy (n=2). Of them, 2 patients received short-course radiotherapy (ScRTx) to primary tumor before systemic chemotherapy, where pre- and post-ScRTx stool samples were collected. Among 15 patients, 9 patients (60%) achieved responses. Non-responders tend to exhibit higher alpha diversity (Chao1, Observed ASV) compared to responders. Firmicutes, Lactobacillus, Faecalibacterium, and the [Luminococcus]_gauvreauii_group were more prevalent in responders, whereas Bacteroidota, Prevotella, DTU089, Alistipes, Christensenellaceae_R-7_group, and Porphyromonas in non-responders. Despite no statistical significance, alpha diversity decreased in post-ScRTx compared to pre-ScRTx samples. Akkermansia, Prevotella, and Peptostreptococcus were more prevalent in the post-ScRTx compared to pre-ScRTx samples. Regarding the association of intestinal microbiome with RAS mutation, Bray curtis and weighted unifrac analyses revealed significant differences in beta diversity; higher incidence of Faecalibacterium, Lactobacillus, Prevotella, Anaerofilum, and UCG-005 in the RAS-wild type mCRC, while Bacteroides, Collinsella, Holdemanella, and Anaerostipes in RAS-mutated mCRC.This pilot study suggests the prognostic value of gut microbiomes and its association with RAS mutation in patients with mCRC treated with first line systemic therapy. A microbial functional study with immune cytokine change is planned to confirm these findings in future.

#3806 Impact of tumor-infiltrating lymphocytes, tertiary lymphoid structures, and neutrophil-to-lymphocyte ratio on the prognosis of patients with lung metastases from uterine leiomyosarcoma.

F. Mukohara[1], N. Matsuda[1], H. Yamamoto[2], T. Habu[1], D. Mizuno[1], R. Yoshichika[1], A. Matsuoka[1], T. Higashihara[1], N. Hayashi[1], M. Yoshikawa[1], M. Ohki[1], K. Shien[2], K. Suzawa[2], K. Takahashi[3], S. Toyooka[1];

[1]Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan, [2]Okayama University Hospital, Okayama, Japan, [3]Kameda Medical Center, Kamogawa, Chiba, Japan

In the tumor microenvironment, tumor-infiltrating lymphocytes (TILs) and tertiary lymphoid structures (TLSs) are known to play a major role in terms of antitumor immunity. It has been reported that the presence of TILs and TLSs is related to the prognosis of various cancers. In addition, neutrophil-to-lymphocyte ratio (NLR) has also been associated with the prognosis in them. We investigated the significance of TILs, TLSs and NLR as a prognosis indicator for lung metastases from uterine leiomyosarcoma. We retrospectively recruited 102 patients undergoing metastasetomy for lung metastases from uterine leiomyosarcoma at Okayama University Hospital from January 2006 to December 2019. TILs were evaluated by immunohistochemical staining of surgically resected specimens of lung metastases using anti-CD3/CD8/CD103/Foxp3 antibodies. TLSs were also evaluated using anti-CD20 antibodies. We counted the number of CD3/CD8/CD103/Foxp3-positive cells and classified TILs into high and low groups. We measured the density of CD20-positive cells and classified TLSs into high- and low-density groups. NLR was calculated from the blood examination immediately before the most recent pulmonary metastasectomy. We determined the cut-off value for NLR using a time-dependent receiver operating characteristic (ROC) curve analysis and classified the patients into NLR-high and NLR-low groups according to the cut-off value. In terms of TILs, both CD3 and CD8 were correlated with the prognosis. The overall survival (OS) was significantly better in patients with CD3-high group ($p = 0.018$), CD8-high group ($p = 0.017$), TLSs-high group ($p = 0.041$) and NLR-low group ($p = 0.018$), respectively. The status of CD103 and Foxp3 did not affect the prognosis. We assessed the impact of the combination of CD8-positive TILs or TLSs and NLR on the prognosis. Regarding CD8-positive TILs and NLR, the OS of CD8-high/NLR-low group was significantly better than that of CD8-low/NLR-high group ($p = 0.0078$). In terms of TLSs and NLR, the OS of TLSs-high/NLR low group was significantly better than that of TLSs-low/NLR-high group ($p = 0.010$). In conclusion, CD3-positive TILs, CD8-positive TILs, TLSs, and NLR are correlated with the prognosis, respectively. The combination of CD8-positive TILs or TLSs and NLR may be indicators to predict the prognosis of the patients with lung metastases from uterine leiomyosarcoma.

#3807 CXCL9:SPP1 macrophage polarity as a prognostic biomarker for localized colorectal cancer after surgical resection.

Y. Bang, J. Choi, H. Kim, K. Park, D. Pyo, Y. Cho, W.-Y. Park;
Samsung Medical Center, Seoul, Korea, Republic of

Background: There is an unmet need for additive predictive biomarkers for the recurrence of stage II/III colorectal cancer (CRC) after surgery. As recent studies showing the potential prognostic role of macrophage polarity defined by CXCL9 and SPP1, instead of conventional M1 and M2, we tried to evaluate the prognostic role of this biomarker in real-world practice setting, delineating biologic mechanisms.
Method: The RNA sequencing data of 273 tumors derived from patietns with stage II/III colorectal cancer who underwent surgical resection in 5 Korean cancer-centers were available for analysis. We initially divided two subgroups based on the ratio of expression level of CXCL9 per SPP1 expressions (CS ratio) and evaluated prognostic outcomes and compared immune cell proportions by deconvolutional method between subgroups.
Result: The CS ratio was higher in consensus molecular subtype (CMS)2 or CMS3 than others, and no significant differences were observed according to sidedness, stage, microsatellite instability status and medical centers. Total 69 (25.3%) patients were classified as low level of CS ratio group, and there were no significant differences in baseline characteristics, including age, sex, CMS, sidedness, stage, microsatellite instability status and medical centers. With a median follow-up of 58.2 months, the low CS ratio group showed poor 5-year recurrence-free survival (50.6 vs. 71.1%, HR=2.27, P = 0.002) and 5-year overall survival (69.7% vs. 85.9%, HR=1.75, P = 0.033). These trends were consistent across the subgroups. In the multivariate analyses including the potential prognostic factors (P < 0.1 in the univariate analyses), low CS ratio was significantly associated with poorer for RFS (adjusted HR = 1.96, P = 0.011) and OS (adjusted HR = 1.81, P = 0.002). These trends were consistent in the TCGA dataset (5 years OS: 69.7% vs. 85.9%, HR=1.98, P = 0.011). The low CS ratio group showed upregulated WNT signaling, and extracellular matrix organization pathway. Immune cell deconvolutional method exhibited the low CS ratio group showed more proportion of neutrophils, monocytes, whereas CD8+T cells, activated memory CD4+T cells were decreased, compared to high CS ratio group.
Conclusions: These results suggest that CS ratio could be an applicable prognostic biomarker in locally advanced colorectal cancer after surgical resection. Based on this classification, more advanced treatment strategy may be required for low CS ratio group to improve surgical outcomes.

CLINICAL RESEARCH: Outcome Investigation with Real World Data
Poster Session

#3811 Impact of antiviral treatment status on risk of extrahepatic cancers in patients with chronic hepatitis C.

M. Tao[1], J. Li[1], T. Wu[1], S. C. Gordon[1], L. B. Rupp[1], S. Trudeau[1], S. D. Holmberg[2], A. C. Moorman[2], P. R. Spradling[2], E. H. Teshale[2], M. A. Schmidt[3], Y. G. Daida[4], M. Lu[1];

[1]Henry Ford Health System, Detroit, MI, [2]Centers for Disease Control and Prevention, Atlanta, GA, [3]Kaiser Permanente-Northwest, Portland, OR, [4]Kaiser Permanente-Hawaii, Honolulu, HI

Background: Eradiation of hepatitis C virus (HCV) infection has been shown to reduce risk of liver cancer among HCV patients; however, there has been spare data on the effect of antiviral treatment on the risk of extrahepatic cancers. Using data from the Chronic Hepatitis Cohort Study (CHeCS), we investigated whether antiviral therapy impacts the risk of extrahepatic cancers among patients with HCV.
Methods: 17,485 HCV patients were included in the study, and they were followed until incidence of cancer including lung cancer, non-Hodgkin lymphoma (NHL), breast cancer or prostate cancer, death, or last follow-up. An extended landmark modeling approach was considered, which included time-varying covariates and propensity score justification for treatment selection bias and used generalized estimating equations (GEE) with a link function as multinominal distribution for a discrete time-to-event data. Death was considered a competing risk.
Results: Compared to untreated patients, patients with HCV treatment had significantly lower risk of lung cancer for direct-acting antiviral (DAA) treatment (hazard ratio (HR) = 0.47, 95% CI, 0.30-0.72) and for interferon-based treatment (IFN) (HR = 0.33, 95% CI, 0.20-0.50). The risk of NHL was only reduced among patients receiving DAA treatment. There were no significant associations between HCV treatment and risks of breast and prostate cancer.
Conclusion: Both DAA and IFN antiviral treatment independently reduce the risk of lung cancer, while the protective association with NHL was limited among HCV patients with DAA treatment. Our findings support the importance of timely initiation antiviral therapy in chronic HCV-infected patients.

#3812 Treatment guideline concordance for patients with metastatic hormone-sensitive prostate cancer (mHSPC) in the United States in IRONMAN, the International Registry for Men with Advanced Prostate Cancer.

H. D. McManus[1], L. Howard[1], K.-A. Crowell[1], T. Hyslop[2], J. Vinson[3], D. E. Rathkopf[4], P. Kantoff[5], L. A. Mucci[6], D. George[1], K. Stopsack[6];
[1]Duke Cancer Institute, Duke University School of Medicine, Durham, NC, [2]Thomas Jefferson University, Philadelphia, PA, [3]Prostate Cancer Clinical Trials Consortium, LLC, New York, NY, [4]Memorial Sloan Kettering Cancer Center, New York, NY, [5]Convergent Therapeutics, Newton Center, MA, [6]Harvard T.H. Chan School of Public Health, Boston, MA

Background: Treatment intensification strategies with an androgen receptor pathway inhibitor (ARPI) and/or docetaxel chemotherapy in addition to androgen deprivation therapy (ADT) are guideline recommended treatment options for patients with metastatic hormone-sensitive prostate cancer (mHSPC). Prevalence of guideline concordant care for mHSPC patients in the US and its changes over time are not well characterized.
Methods: The International Registry for Men with Advanced Prostate Cancer (IRONMAN) is a prospective cohort study of patients with newly diagnosed mHSPC and castration-resistant prostate cancer (CRPC). Therapies are captured by site personnel and by directly capturing data from treating physicians via physician questionnaires (PQ). We included all US patients with mHSPC enrolled from 2018 to January 1, 2023 with a completed PQ at enrollment. We examined patient characteristics, first-line treatments for mHSPC, and guideline concordance of first-line treatments. Guideline concordance was defined as a treatment regimen listed in the first National Comprehensive Cancer Network guidelines version for the year prior to treatment. Patients enrolled in clinical trials were excluded from analysis of treatment guideline concordance.
Results: Among the 636 US participants with mHSPC, physicians completed PQs for 458 participants (72%). Participants had a median age of 68 years (interquartile range 62 - 75). Three hundred eight (78%) were White, 72 (18%) were Black, 13 (3%) were other races/ethnicities: 65 did not report race. First-line treatment for mHSPC based on the PQ was most commonly ADT + ARPI (59%) followed by ADT + docetaxel (17%), ADT monotherapy (14%), ADT + first-generation antiandrogen (3%), ADT + ARPI + docetaxel (3%), and other treatments (5%). Overall, 384 (86%) participants received first-line treatment that was guideline concordant at the time of treatment. Treatment guideline concordance was highest in 2018 (99%) when ADT monotherapy was considered as guideline concordant but then decreased to 80% in 2019 and remained largely stable from 2019 to 2022 (85%). Overall, rates of guideline concordance were similar when stratified by race (88% for White patients vs 85% for Black patients), age (90% for patients <65 years old vs 85% for patients ≥65 years old), and treatment at a Comprehensive Cancer Center (CCC) (87% at CCC vs 86% at non-CCC).
Conclusion: Among patients with mHSPC treated in the US at 38 cancer centers, proportions of guideline concordant first-line treatment were high and remained stable over time, despite changes in approved therapies. Future efforts to understand reasons for treatment decisions will be important to better understand the relatively uncommon situations in which guidelines and actually received treatments differ for patients with mHSPC.

#3813 Relationship between race/ethnicity and oncologic outcomes in patients with biochemical recurrence after primary treatment for prostate cancer.

N. Khan[1], V. Quintero[1], C. Beck[2], M. Dimova-Dobreva[3], B. Patel[1];

[1]Bayer Healthcare Pharmaceuticals, Whippany, NJ, [2]Bayer AG, Wuppertal, Germany, [3]Bayer Consumer Care AG, Basel, Switzerland

Background: Prostate cancer (PC) is the most common form of cancer in men and accounts for ~35% and 24% of all new cancer diagnoses in Black and Hispanic men, respectively. Incidence rates of PC are higher and cancer is diagnosed at a younger age in Black compared to White men. The most frequently utilized primary treatment options are radical prostatectomy (with or without adjuvant radiotherapy) or radiotherapy. Despite the success of primary treatments for localized PC, many patients (pts) will eventually develop biochemical recurrence (BCR), defined as rising prostate-specific antigen (PSA) levels. Pts with BCR are at a higher risk of developing distant metastases and ultimately dying from PC. This targeted literature review aimed to assess the real-world (RW) relationship between race/ethnicity and BCR, and further identify any differences in oncologic outcomes (risk of metastases, PC-specific mortality, and overall survival).

Methods: A targeted literature search was performed using Embase, PubMed, and the past 2 years of American Society of Clinical Oncology conference proceedings. Selected studies were limited to English-language articles focusing on BCR and race or ethnicity among US populations, published between 1/2010 and 7/2023.

Results: Ten studies were selected after title and abstract review. Most studies had a White pt majority (83%-92%). Six studies reported no differences in BCR or oncologic outcomes when pts were stratified by race/ethnicity. Four studies reported a higher BCR risk for Black pts with low-risk PC after radical prostatectomy, but not for pts with high-risk PC. PSA and PSA doubling time (PSADT) were found to be strong predictors of oncologic outcomes.

Conclusions: The FDA draft guidance on diversity plans recommends that clinical trials enroll an adequate number of participants from underrepresented racial and ethnic populations. This requires an understanding of the diversity of the population that will eventually use the treatment and of which race/ethnicity differences in outcomes should be expected and investigated. Based on this targeted review among pts with localized PC, most RW studies had a White pt majority, and the race distribution in these studies aligned with published census and epidemiology data. In addition, findings suggest that race/ethnicity differences were not pronounced among high-risk PC pts in the US when given equal access to care or treatment, and that oncologic outcomes and BCR risk were similar across Black, White, and Hispanic pt populations. Conversely, PSA and PSADT may be stronger prognostic markers for BCR and oncologic outcomes. Future clinical trials are needed to support these RW findings and should aim to actively enroll racial/ethnic minorities to identify potential differences in efficacy and safety, and to help advance the evidence base for pt PC management.

#3814 Molecular background conditioning by temozolomide in neuroendocrine tumors.

E. Trevisani[1], A. Reni[1], I. Torresan[1], A. Rossi[1], M. Borghesani[1], S. Nicolini[1], C. Luchini[2], L. Landoni[3], D. Melisi[1], A. Scarpa[2], M. Milella[1], **A. Mafficini**[2], S. Cingarlini[1];

[1]University and Hospital Trust of Verona, Verona, Italy, [2]ARC-Net Centre for Applied Research on Cancer and University and Hospital Trust of Verona, Verona, Italy, [3]Pancreas Institute of University and Hospital Trust of Verona, Verona, Italy

Temozolomide (TMZ)-based regimens represent a valid therapeutic option in well-differentiated neuroendocrine tumors (NETs G2 and G3). As an alkylating agent, it increases DNA alteration by altering guanine residues, which either triggers cell death or results in novel missense mutations especially in *MGMT* deficient cells. Here, we describe an exploratory case series of TMZ-treated NETs cases that underwent NGS analysis at the University Hospital of Verona. Methods. We included 32 patients (16 G2 and 16 G3). NGS was performed before TMZ treatment for 22 cases (54%), after for 19 (46%) and in both for 4 cases (13%). We performed NGS on tissue samples for 73% of assays and *via* liquid biopsy for the remaining 27%. For tissue NGS, in 77% of samples we used an in-house panel encompassing 174 genes and in 23% commercial test interrogating at least 500 genes. Only ACMG/AMP class IV-V molecular alterations were considered for further analysis. Main Results From 2021 we performed NGS analysis on 32 NETs (G2 and G3) treated with TMZ-based regimes. Most cases (28 pf 32, 84.4%) were pancreatic NETs. Mean Ki-67 at baseline was 24.5% (range 3-60). The mean number treatments prior to TMZ were 1.4 and 0.5 between CAPTEM and subsequent NGS. The top five altered genes at baseline were *MEN1* (32%), *TP53* (14%), *DAXX* (14%), *PTEN* (9%) and *SMAD4* (9%). None of the patients showed a high TMB (>15Mut/Mb) at baseline, while 26% of post-TMZ samples displayed that feature. Mean TMB at baseline and after treatment was 6.51 (range 1-10.6) and 22.9 mut/Mb (range 1-216) respectively. Alterations in DDR systems genes, including *ATM, ATR, CHEK2, BRCA1, BRCA2, MLH1, MLH2, PMS2 MLH6* and *MUTYH,* were found in 8 patients (47%) after TMZ exposure; only one DDR-specific alteration (*MUTYH*) was found at baseline. DDR defects were enriched in patients exposed to higher numbers of treatments. The increase in mean TMB and enrichment in mutations in the DDR system is also confirmed when analysing the 6 cases having both pre- and post-TMZ treatment samples. Among other pathways, cell cycle deregulating genes (*CDKN1A, CDKN2B, CDKN1B, CDK12, CDK6, RB1*) were altered in 2 (11%) and 5 (29%) pre- and post-TMZ NGS samples respectively, the mTOR pathway (*MTOR, NF1, PIK3CA, AKT, TSC1, TSC2, PTEN*) in 2 (11%) and 8 (47%), and the MAPK pathway (*KRAS* and *BRAF*) in 1 (5%) and 2 (12%). Conclusions. The wide and effective use of temozolomide in neuroendocrine tumors, together with the potential therapeutic implications of DDR defects make this topic of great interest. The DDR pathway was one of the most affected by alterations in post-TMZ samples, although the genotoxic agent caused a general increase in the rate of somatic mutation. The status of DDR systems, either germinal or somatic, may represent an important selection and/or stratification parameter for future immunotherapy clinical studies also in neuroendocrine tumours provided that the analysis is carried out in a systematic, comprehensive and longitudinal way.

#3815 Clinical efficacy and safety of HER2 targeted therapy in patients with metastatic colorectal cancer: A systematic review and meta-analysis.

O. E. Villarreal, L. Xiao, J. Allam, A. Sorokin, Y. Yuan, S. Kopetz, K. P. S. Raghav;
The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Therapies targeting HER2 have shown clear benefit in patients with breast or gastric cancer,; and their use in metastatic colorectal cancer (mCRC) has been increasingly explored in recent years. HER2 overexpressed or amplified (HER2-positive) mCRC is seen in 2-8% of all mCRC cases and is enriched in RAS wild-type (WT) tumors, representing a patient population that may benefit from anti-HER2 therapies. Although, several single-arm and some non-comparative randomized clinical trials have now tested the use of diverse dual anti-HER2 therapies in mCRC, no summative analysis have been performed. We conducted a systematic review and meta-analysis to evaluate the overall clinical benefit (efficacy and safety) of dual-HER2 inhibition in patients with RAS-WT HER2-positive mCRC.

Methods: A systematic review of available literature was performed for clinical trials involving patients with mCRC treated with HER2 targeting therapy. Two independent reviewers selected studies and extracted data from PubMed and abstracts published at major international oncology meetings during the past 5 years. Case reports and other studies not meeting inclusion criteria were excluded, therefore a total of 13 studies were used for analysis. Patients with RAS-mutant tumors within each trial were excluded due to known limited benefit of dual HER2 inhibition in this subset. Inverse variance method with random-effects model was used for meta-analysis to determine the overall effect of the therapy on overall response rate (ORR), disease control rate (DCR), progression free survival (PFS) and treatment-related adverse events (TRAE).

Results: Systematic review identified 9 study cohorts which were utilized in the meta-analysis, encompassing a total of 279 patients with mCRC who received Trastuzumab (T) in combination with either Pertuzumab (P), Tucatinib (Tu), Pyrotinib (Py), or Lapatinib (L). Collectively, dual HER2 inhibition showed an ORR of 35.1% (95% CI: 29.4-41.0%), a DCR of 68.3% (95% CI: 62.5-73.9%), and a PFS of 5.2 months (95% CI: 4.4-6.0 months). Pooled TRAE of grade ≥ 3 across studies was 29.9% (95% CI: 18.8-42.4%) but displayed high inter-study heterogeneity ($p<0.0001$, $I^2 = 79\%$), mainly driven by one trial (Pyro-HER2; TRAE = 75.0%, 95% CI: 50.9-91.3%).

Conclusions: Overall, this comprehensive meta-analysis confirms that dual HER2 targeting therapies yield meaningful clinical efficacy, with favorable safety profiles, and improve outcomes in patients with RAS-WT HER2-positive mCRC.

#3817 Real-world clinical outcomes in patients with advanced ROS1+non-small cell lung cancer in the US.

R. Villacorta[1], S. Ray[1], Y. Yuan[1], S. Vijapur[2], S. Kim[2], H. Sun[2], S. Myers[2], V. Lam[3];
[1]Bristol Myers Squibb, Lawrenceville, NJ, [2]Genesis Research Group, Hoboken, NJ, [3]Johns Hopkins University, Baltimore, MD

Introduction: ROS1 rearrangements define a rare molecular subtype of non-small cell lung cancer (NSCLC), occurring in 1-2% of patients (pts) with advanced NSCLC (aNSCLC). Crizotinib and entrectinib received US approval for ROS1+ aNSCLC in March 2016 and August 2019, respectively. Few studies have addressed temporal trends in first-line (1L) utilization since these drugs' approval. This study describes treatment patterns and clinical outcomes in pts with ROS1+ aNSCLC in the US.

Methods: This retrospective study used the nationwide Flatiron Health (FH) electronic health record-derived de-identified database and included adult pts with ROS1+ aNSCLC who received 1L (index) therapy between March 2015 and December 2022. Pts were followed until March 31, 2023, and had ≥ 3 months of follow-up post-index date. Treatment-related (sequence, time to treatment discontinuation [TTD], time to next treatment [TTNT]) and clinical (real-world progression-free survival [rwPFS], overall survival [OS]) outcomes of 1L therapy were assessed using descriptive statistics and Kaplan-Meier methods.

Results: In the FH database, 87,784 pts had aNSCLC, and 242 were ROS1+. The median age was 65 years; most were female (64%), White (67%), non-squamous (91%) and had a history of smoking (52%), with most pts having ECOG performance status 0 (31%) or 1 (35%). 19% had brain metastases prior to or up to 30 days post-index. Median follow-up time was 14.2 months. In 1L treatment, only 59% received ROS1-sensitive TKI monotherapy (i.e. crizotinib, entrectinib, ceritinib), with 97 (40%) and 40 (17%) treated with crizotinib and entrectinib monotherapy, respectively. Median TTD and TTNT for 1L was 6.4 (95% CI: 5.0, 7.6) and 7.6 (95% CI: 6.5, 9.4) months, respectively. Among 1L crizotinib pts, 51% had 2L treatments and 57% of those initiated another ROS1-sensitive TKI (16% entrectinib). Among 1L entrectinib pts, 43% had 2L therapy; of these, 82% initiated another ROS1-sensitive TKI. Median rwPFS was 7.5 (95% CI: 6.2, 9.3) months (1L crizotinib, 8.6 [95% CI: 5.3, 13.0] months; 1L entrectinib, 8.0 [95% CI: 5.3, 13.6] months). Median OS was 29.0 (95% CI: 19.4, 35.9) months (1L crizotinib, 31 [95% CI: 19.4, not estimable [NE]] months; 1L entrectinib, NE). Patients initiated ROS1-sensitive TKIs (crizotinib, entrectinib or ceritinib) in 1L across each year of the study (2015: 67%, 2016: 58%, 2017: 51%, 2018: 47%, 2019: 63%, 2020: 81%, 2021: 52%, 2022: 68%). Overall, 5% received checkpoint-inhibitor (CPI) only, 17% chemotherapy alone, and 7% a chemotherapy/CPI combination.

Conclusion: Compared to relevant clinical trials, ROS1+ aNSCLC pts in this real-world study were older, had greater smoking exposure, and worse overall survival. Only 59% of pts initiated 1L ROS1-sensitive TKI monotherapy. These results highlight potential disparities in the diagnosis and treatment of ROS1+ NSCLC and opportunities for improving clinical outcomes.

#3818 Sociodemographic, access to care and survival outcomes for patients with mantle cell lymphoma: A national cancer database analysis with focus on Hispanics.

E. Toro Velez[1], C. Velez-Mejia[1], D. Rosas[2], Q. Liu[1], J. Michalek[1], A. Diaz Duque[3];

[1]UT Health Science Center at San Antonio, San Antonio, TX, [2]Memorial Healthcare System, Pembroke Pines, FL, [3]Mays Cancer Center, San Antonio, TX

Background: Mantle cell lymphoma (MCL), represents 3% of new cases of non-Hodgkin's lymphomas.(PMID 29348844) MCL affects mainly males; factors like ethnicity, age at presentation can have prognostic implications. Currently, it isn't clear if Hispanics (HI) have a survival difference compared to Non-Hispanics (NH).(PMID 31029647, PMID 25315847). This National Cancer Database (NCDB) analysis aims to clarify how sociodemographic factors affect presentation and survival in HI vs NH patients with MCL.

Methods: Data were analyzed on MCL patients in the United States reported to the NCDB 2004-2019. Demographic and treatment characteristics were compared between ethnic groups. Kaplan-Meier and Cox regression analyses were used to compare overall survival (OS). Multivariate analysis and propensity score matching was performed.

Results: Of 32515 of MCL patients, 1729 were HI, and 29309 NH. Male gender and identification as white predominated for both. HI were diagnosed at a younger median age of 65 years (y) vs 68 y for NH, p<0.001. Most patients were diagnosed between years 2016-2019. Stage IV predominated for HI and NH, p<0.001. As to Charlson-Deyo Score ≥2, HI had 6% vs NH 8%. Government sponsored was the most prevalent primary payer, HI (54%) and NH (60%). HI had a higher percentage of unknown/uninsured, 13% vs 4% for NH, p<0.001. In relation to census median income (2008-2012), the most prevalent bracket for HI and for NH was >$63,000, 29% and 37% respectively. When analyzing median income of less than $38,000, HI were 22% vs 13% for NH, p<0.001. For median distance in miles (mi) between the patient's residence and the hospital that reported the case (Great circle distance), HI lived at a median of 8.2mi, vs NH at median of 11.3mi. Most patients were treated at Academic/Research programs, 50% for HI and 39% for NH, p<0.001. On survival analysis, the survival probability at 2, 5 and 10 for HI was 74%, 57%, 44%, vs for NH was 72%, 54%, 36%, respectively. The median survival (MS) was 7.0 years for HI, vs 5.8 years for NH, with a statically significant difference in OS favoring HI, p=0.00015. On multivariate analysis, not insured status was independently associated with worse OS (HR 1.29, CI 1.08-1.55, p=0,01). The propensity matched analysis showed significant MS difference between HI vs NH (5.8 y vs. 5.6 y).

Conclusion: In this analysis, MCL is a malignancy that presents at advanced stages, affecting mainly the elderly white males. HI compared to NH have a statically significant benefit in OS, which might be driven by a younger population with less comorbidities. Despite HI having limited access to insurance and lower income; sociodemographic differences don't seem to be barriers for HI to access care at academic centers. Newer studies should focus on understanding what genetic and intrinsic disease factors cause HI to have an earlier presentation and a survival advantage over NH.

#3819 Real-world long-term survival outcomes of first-line immunotherapy-based regimens in advanced non-small cell lung cancer.

D. Waterhouse[1], S. Ray[2], K. A. Betts[3], S. Gao[3], Y. Yuan[2], M. Sundar[3], S. Rui[3], D. Stenehjem[4];

[1]Oncology Hematology Care (OHC)/ An affiliate of the US Oncology/SCRI Network, Cincinnati, OH, [2]Bristol-Myers Squibb, Lawrenceville, NJ, [3]Analysis Group, Los Angeles, CA, [4]Department of Pharmacy Practice and Pharmaceutical Sciences, University of Minnesota, Minneapolis, MN

Background: The real-world survival outcomes of first-line (1L) immunotherapy (IO)-based regimens for the treatment of advanced non-small cell lung cancer (aNSCLC) were assessed utilizing the Flatiron Health database from January 2011 to June 2023.

Methods: Adult patients (pts) with aNSCLC receiving 1L IO monotherapy or single-agent IO + chemotherapy on or after January 1, 2016, were identified. Pts were excluded if they had *EGFR/ALK* mutations or unknown histological type. Overall survival (OS) and real-world progression-free survival (rwPFS) of 1L IO monotherapy and IO + chemotherapy were described using Kaplan-Meier analyses.

Results: A total of 14,320 pts were included (5,166 pts receiving IO monotherapy; 9,154 pts receiving IO + chemotherapy). Among pts receiving IO monotherapy, the 1-, 2-, 3-, and 4-year OS rates were 52.3%, 36.5%, 27.4%, and 21.9%, respectively. The corresponding rwPFS rates were 29.2%, 17.5%, 12.7%, and 9.2%. Among pts receiving IO + chemotherapy, the 1-, 2-, 3-, and 4-year OS rates were 50.7%, 32.6%, 23.9%, and 19.2%. The corresponding rwPFS rates were 27.0%, 15.1%, 10.3%, and 7.8%. Table 1 presents the 4-year OS and rwPFS rates stratified by histological type, tumor programmed death ligand 1 (PD-L1) expression level, and Eastern Cooperative Oncology Group (ECOG) performance status. Patients with lower PD-L1 expression level (<1%), worse ECOG performance status (≥2), and squamous cell carcinoma had worse survival outcomes, regardless of the type of 1L treatment received.

Conclusions: The real-world survival rates for patients with aNSCLC who were treated with 1L IO-based regimens were lower than those observed in pivotal trials, which indicates an unmet need for the management of newly-diagnosed aNSCLC. However, on average approximately 1 in 11 pts receiving IO monotherapy and 1 in 13 pts receiving IO + chemotherapy remained progression-free at the four year landmark and achieved an extended period of survival.

Table: 4-year OS and rwPFS rates

	1L IO monotherapy			**1L IO + chemotherapy**		
	PD-L1 <1%	**PD-L1 ≥1-49%**	**PD-L1 ≥50%**	**PD-L1 <1%**	**PD-L1 ≥1-49%**	**PD-L1 ≥50%**
OS by histological type (sample size; 4-year rate, %)						
Squamous	122; 12.7	329; 14.0	814; 15.1	585; 11.7	647; 15.1	295; 23.3

#3820 Impact of primary site in early-stage follicular lymphoma on patient outcomes: Analysis of a large national database.

O. Davis[1], R. Kasht[2], A. Cohoon[3], S. Day[4], S. Ibrahimi[4], A. Asch[4], T. Al-Juhaishi[4];
[1]University of Oklahoma College of Medicine, Oklahoma City, OK, [2]OU Health, Oklahoma City, OK, [3]University of Oklahoma College of Public Health, Oklahoma City, OK, [4]OU Health - Stephenson Cancer Center, Oklahoma City, OK

Introduction: Follicular lymphoma (FL) is the most common indolent Non-Hodgkin lymphoma and is associated with better outcomes compared to other types of lymphoma. Despite this, cure is usually elusive and most patients experience multiple relapses within their lifetime. Previous studies have identified risk factors associated with worse outcomes, but little is known about the role of primary disease site in FL. We sought to investigate the outcomes of patients with extranodal early-stage FL compared to nodal disease using a large national cancer database.
Methods: The Surveillance, Epidemiology, and End Results (SEER) public database was used to identify and extract data for patients with FL. Early-stage disease was defined as stage I or II by the Ann Arbor staging system. Most patients in the database were diagnosed after 2000 so this was used as the diagnosis year cutoff and also to reflect the impact of recent management strategies on outcomes. Patients were divided into two groups based on their primary disease site. These two groups were nodal (includes spleen) and extranodal. Treatment effect (surgery, radiation, or chemotherapy) was analyzed when available. Survival was estimated using the Kaplan-Meier method and compared using log-rank tests. Cox proportional hazards models were used for adjusted survival analyses.
Results: A total of 13,400 patients with FL of all histologic grades diagnosed between 2000 and 2015 were identified in the SEER database. The median age at diagnosis was 65 years (2-100). A majority of patients were Caucasian (81%), had stage I disease (62%), and belonged to the nodal FL group (79%). Median overall survival (OS) for patients with nodal FL was 181 months [95% CI (175-187)]. Median OS for extranodal FL was 189 months [95% CI (179-195)]. Extranodal FL was associated with better OS compared to the nodal group [HR=0.89, 95% CI (0.84-0.96); p-value =0.00012] even after adjusting for age and race [HR=0.84 , 95% CI (0.79-0.90); p-value <0.0001].
Conclusions: In this analysis of a large national cancer database, early-stage FL presenting as extranodal disease can be seen in about 20% of patients and is associated with slightly better outcomes.

#3821 Real world outcomes among patients with newly diagnosed acute myeloid leukemia.

E. D. Pulte[1], L. L. Fernandes[2], J. Wynne[1], E. Hansen[2], A. J. Belli[2], A. Barcellos[2], C. M. Zettler[2], R. Bystrom[1], J. Vallejo[1], W. Gu[1], C. Lerro[1], K. Norsworthy[1], A. DeClaro[1], M. R. Theoret[1], D. Rivera[1], C.-K. Wang[2];

[1]Food & Drug Administration, Silver Spring, MD, [2]COTA Healthcare, New York, NY

Introduction: Treatment options for patients with acute myeloid leukemia (AML) have expanded in recent years. Although new treatments have demonstrated efficacy in clinical trials, less is known about their effect on outcomes in routine clinical practice. We examined outcomes for patients with newly-diagnosed AML (ND-AML) using real world data (RWD).

Methods: This retrospective observational study was conducted using the COTA real-world (rw) database, a de-identified source of longitudinal electronic health record data pertaining to the diagnosis, management, and outcomes of patients with cancer. Adult patients with ND-AML, diagnosed January 1, 2013 to March 20, 2023 were included. First-line treatment regimens were grouped into therapeutic categories and outcomes were summarized. The index date was defined as date of initiation of first-line therapy.

Results: Among 2516 patients with ND-AML included (Table), the most common regimens used were intensive chemotherapy with cytarabine (IC w/ara-C), hypomethylating agents with venetoclax (HMA+ven), and HMA alone. Complete response rate was highest in patients treated with IC w/ara-C or investigational regimen(s). Median overall survival (OS) was 16 mo overall, with highest median OS seen in patients treated with IC w/ara-C and investigational regimen(s). Median OS for patients treated with HMA+ven was 13.5 mo. Thirty-day mortality was lowest in patients treated with IC w/ara-C, CPX-351 (liposomal daunorubicin + cytarabine), and HMA+ven.

Conclusions: Results suggest that IC w/ara-C remains the standard of care for most patients with ND-AML and this regimen has a higher CR rate and median OS. Variation of patient demographics and clinical characteristics across treatment groups did not permit cross-treatment comparisons, though future analyses evaluating these subgroups may provide further insight into effectiveness and safety of AML regimens in routine care for populations underrepresented in clinical trials.

		rwCR rate	Median rwOS	30-day mortality
	N	% (95% CI)	Months (95% CI)	% (95% CI)
Overall	2516	45.3 (43.2, 47.3)	16.0 (14.9, 17.3)	5.9 (5.0, 6.8)
IC w/ara-C	1171	60.6 (57.8, 63.4)	36.4 (31.0, 46.0)	1.6 (0.9, 2.3)
HMA+ ven	300	33.7 (28.3, 39.3)	13.5 (11.4, 15.5)	3 (1.1, 4.9)
Decitabine	242	12.8 (8.9, 17.7)	8.4 (6.7, 9.9)	10.4 (6.5, 14.2)
Azacitidine	206	7.8 (4.5, 12.3)	7.2 (5.3, 9.6)	10.7 (6.4, 14.8)
Investigational	206	61.6 (54.6, 68.3)	21.3 (15.2, 27.8)	3.4 (0.9, 5.9)
Lower dose cytarabine	62	12.9 (5.7, 23.9)	8.7 (5.4, 16.1)	14.9 (5.4, 23.4)
CPX-351 based	61	55.7 (42.4, 68.5)	9.3 (7.3, 15.1)	0.0
No treatment	188	NA	1.9 (1.5, 2.8)	30 (22.7, 36.6)

#3822 Oncotype DX testing and differences in use of chemotherapy by age in an integrated system.

A. Aller[1], L. Lyon[2], L. Habel[2], A. Shirazi[1], R. Liu[1];

[1]Kaiser Permanente - Northern California, San Francisco, CA, [2]Kaiser Permanente - Northern California, Oakland, CA

Introduction: Oncotype DX (ODX) identifies breast cancer patients who are less likely to benefit from chemotherapy. We investigated patient factors associated with clinical application of ODX testing and chemotherapy use.

Methods: We identified a cohort of adult breast cancer patients with stage I-IIA, estrogen receptor positive, human epidermal growth factor receptor 2 negative, lymph node negative disease diagnosed within Kaiser Permanente Northern California between 2015 - 2021 eligible for ODX testing. Chi-square tests were used for bivariate analysis of categorical variables. Multivariable logistic regression was used to identify independent predictors of chemotherapy use in female patients with high risk ODX scores (>25).

Results: 8017 patients were eligible for ODX testing; of which 5,136 received testing (64%) and 576 patients (7%) had high risk ODX. ODX testing increased over the years (45% of eligible patients in 2015; 79% of eligible patients in 2021). Testing was frequent in larger lesions (74%), poorly differentiated tumors (73%), and younger patients (83% in patients <40 years at diagnosis; 12% in patients > 80 years). Chemotherapy was frequently administered in younger patient, and for larger, poorly differentiated tumors. For patients who possessed a high risk ODX score, chemotherapy administration differed by age. In comparison with the 90% of high risk patients <45 years who received chemotherapy, 58% of patients 60+ years at diagnosis with high risk ODX received chemotherapy. Comorbidity index and chemotherapy administration was not statistically significant (Table 1).

Conclusion: Oncologists frequently use ODX testing to guide chemotherapy management. Despite high risk ODX scores, older patients received less chemotherapy compared to their younger counterparts. Further investigation is needed to determine how age impacts clinician decision making and clinical outcomes following ODX testing.

Table 1. Multivariable Logistic Regression Analysis of Factors Associated with Chemotherapy

Women > 60 years with high risk oncotype DX scores (N=467)	Adjusted Odds Ratio (95% Confidence Interval)	P-values (Calculated using the Wald $\chi 2$ Statistic)
Age at Cancer Diagnosis (Reference: 60 - 69 years old)		
70-79	0.62 (0.40-0.96)	0.03
>79	0.11 (0.02-0.55)	0.01
Charlson Comorbidity Index (Reference = 0)		
1	0.76 (0.48-1.22)	0.26
2	0.62 (0.30-1.29)	0.20
3	0.65 (0.26-1.60)	0.35
4	0.54 (0.20-1.44)	0.22
5+	0.37 (0.10-1.35)	0.13

#3823 Clinical outcomes of uveal melanoma patients in the emergency department.

A. A. Beneke[1], **K. Taneja**[2], L. Ladehoff[3], K. Root[1], E. Toloza[4];
[1]University of Florida, Gainesville, FL, [2]Stony Brook University, Stony Brook, NY, [3]University of South Florida, Tampa, FL, [4]Moffit Cancer Center, Tampa, FL

Purpose: Uveal melanoma is a rare ocular malignancy that has not been well characterized at a large scale. Specifically, uveal melanoma diagnosis and outcomes in the emergency department (ED) has not been characterized.
Methods: The Nationwide Emergency Department Sample was queried from the last quarter of 2015 to 2019 to identify patients with a primary diagnosis of uveal melanoma. Multivariable logistic regression, with patient- and hospital-level characteristics as covariates, was used to identify factors associated with increased risk of inpatient admission.
Results: From the last quarter of 2015 to 2019, there were 1,274 ED encounters with a primary diagnosis of uveal melanoma. Most patients were less than 11 years old (43.4%), male (51.1%), or a Medicaid beneficiary (37.8%), and most belonged to a family in the lowest income quartile (32.0%). The median age of these patients was 35 years (IQR: 2-64). Most patients presented to hospitals in the South (53.9%), with a Trauma Level I designation (51.4%), and most to a metropolitan teaching hospital (89.1%). The most common ED outcomes were same-day discharge (61.6%) and admission to the inpatient setting (31.2%). Patients presenting to Trauma Level I hospitals were most likely to be admitted (odds ratio [OR]=2.21; p=0.031). The factors that were most significantly associated with decreased odds of inpatient admission were: patients who were not charged for services (often due to charity) (OR=0.13; p=0.040), Medicaid beneficiaries (OR=0.27; p=0.031), and private insurance beneficiaries (OR=0.34; p=0.047). Among the admitted patients, patients can be discharged to home with self-care (76.2%) or with home-health care (14.9%) or can be transferred to an intermediate-care facility (8.1%). The mean hospital length of stay was 5.7±0.6 days. In-hospital mortality rate for admitted patients was very low (0.8%).
Conclusion: Uveal melanoma patient outcomes are closely related to insurance status, indicating socioeconomic factors as a modulator of patient outcomes.

#3824 Efficacy of trastuzumab in combination with capecitabine and cisplatin vs 5-FU and cisplatin therapy for Korean patients with HER2-positive advanced gastric cancer Health Insurance Review and Assessment service (HIRA) data retrospective analysis.

h. Lee, J.-H. Kim, S. Kang, T. Park, Y. Choi;
Ajou University School of Medicine, Suwon, Korea, Republic of

The combinations of oral fluoropyrimidines and cisplatin such as capecitabine and cisplatin (XP) or 5-FU and cisplatin (FP) are regarded as a standard therapy against HER-2 positive advanced gastric cancer (AGC). Trastuzumab-XP(HXP) and trastuzumab-FP(HFP) is the most common regimen against AGC in Korea. The aim of the present study is to evaluate the effectiveness of trastuzumab-XP vs trastuzumab-FP.

Patients with HER2-positive AGC were assigned to the trastuzumabXP or trastuzumabFP group. We then retrospectively compared the efficacy and safety between both groups. As a first-line chemotherapy, trastuzumab in combination with XP or FP was administered to 2,399 patients: 1,913 with HXP and 486 with HFP. In the HXP group vs HFP group, median progression-free survival (mPFS), and median overall survival (mOS) were 8.02 vs 6.08 months (p <0.0001) and 13.27 vs 9.89 months (p <0.0001). In HFP group, mPFS and mOS were 10.15 vs 5.36 months (p <0.0001) and 15.15 vs 8.90 months (p <0.0001) in comparison HFP-H maintenance to HFP group. In HXP group, mPFS and mOS were 10.64 vs 13.44 vs 5.03 months (p <0.0001) and 20.14 vs 22.18 vs 9.10 months (p <0.0001) in comparison HXP-H maintenance, HXP-HX maintenance, and HXP group.

Trastuzumab in combination with XP and HX maintenance is a potential first-line therapeutic option for patients with HER2-positive AGC.

#3826 Predictive and prognostic factors in NUT carcinoma: A systematic review and individual patient data meta-analysis.

S. K. Abdulwali[1], A. M. El-Sibai[1], S. S. Ali[1], A. M. Alaklabi[1], H. M. Abdalla[1], A. N. Sabbah[1], A. Shafqat[1], N. A. Fawzy[1], B. N. Sabbah[1], A. Badran[2], **T. Z. Arabi**[1]; [1]Alfaisal University, Riyadh, Saudi Arabia, [2]King Faisal Specialist Hospital and Research Centre, Riyadh, Saudi Arabia

Background: NUT carcinoma (NC) is a rare cancer affecting midline structures and involving the lung, bones, and lymph nodes. Data on NC are limited mostly to case reports and case series.
Methods: PubMed, Web of Science, and Scopus were systematically searched for original articles describing confirmed NC patients. A quantitative individual patient data meta-analysis (IPD-MA) analyzing overall survival and risk factors for progression was performed for all NC patients with a clear age at diagnosis. Relevant patient characteristics and clinical parameters were compared in a multivariate Cox regression model.
Findings: Out of 4,701 studies screened, 175 studies met the inclusion criteria for the systematic review. 117 (66.9%) were case reports. 284 patients were included in the IPD-MA. 139 (48.9%) patients were male, 145 (51.1%) underwent surgery, 156 (54.9%) received radiotherapy, and 173 (60.9%) developed metastasis. The mean age at diagnosis was 35.82±18.33 and the median OS was 9 months. 77 (27.1%) patients received platinum-based agents, 39 (13.7%) received taxanes, and 15 (5.3%) received BET inhibitors as part of their first-line regiment. Age at diagnosis, gender, and the aforementioned drugs did not significantly influence OS. Presence of metastasis was an independent predictor of poor survival, while radiotherapy and surgery were significantly associated with better survival (table 1).
Interpretation: NC is associated with poor survival. Surgery and radiotherapy appear to be more effective treatment strategies, while medical modalities may not play a major role in the treatment of NC.

Predictors of overall survival in NUT carcinoma patients.

Parameter	Hazard ratio	95% confidence interval	P-value
Age at diagnosis	0.99	0.99-1	0.35
BET inhibitors	0.61	0.28-1.15	0.16
Platinum-based agents	0.73	0.47-1.13	0.16
Taxanes	1.29	0.78-2.1	0.31
Surgery	0.41	0.29-0.58	<0.0001
Female gender	1.12	0.83-1.51	0.45
Metastasis	1.76	1.26-2.49	0.0011
Radiotherapy	0.48	0.36-0.67	<0.0001

#3827 Optimizing the treatment schedule of radiotherapy combined with VEGFR-TKIs and PD-(L) 1 inhibitors in metastatic colorectal cancer.

Z. Lin, M. Zhai, T. Zhang;
Cancer Center, Union Hospital Tongji Medical College Huazhong University of Science and Technology, Wuhan, China

Background: The oral vascular endothelial growth factor receptor (VEGFR) inhibitor fruquintinib, an innovative Chinese drug, has recently been approved by the U.S. Food and Drug Administration (FDA) for third-line treatment of metastatic colorectal cancer (mCRC) in adults. This study aims to investigate the efficacy and safety of radiotherapy (RT) combined with VEGFR-TKIs (such as fruquintinib) and PD-(L) 1 inhibitors in mCRC, and explore optimal sequence of RT with the systemic regimen.

Methods: This retrospective study enrolled eligible patients with MSS/pMMR mCRC who had received RT in combination with anti-angiogenic drugs (Fruquintinib or Regorafenib) and immunotherapy (IT) between April 2018 and September 2023. Data on treatment response, progression-free survival (PFS), overall survival (OS), and adverse events were collected.

Results: A total of 42 pts were analyzed. For Fru + IT + RT (n = 33) and Reg + IT + RT (n = 9), ORR were 21.2% (7/33) and 11.1% (1/9); DCR were 81.8% (27/33) and 88.9% (8/9), respectively. Median PFS were 6.4 mo and 5.0 mo (P=0.856) while median OS were 17.2 mo and 7.2 mo (P=0.578), respectively. In-depth analysis of Fru + IT + RT treated population, the PFS and OS of 3rd-line treatment were superior to later (≥ 4th) -line treatment (median: 6.7 vs 4.2 mo, P=0.02) and (median: 17.5 vs 8.9 mo, P=0.27), seemingly. Additionally, RT before initiation of Fru + IT demonstrated superior PFS compared to simultaneous/sequential RT with Fru + IT (median 7.1 vs 6.1 vs. 3.2 mo, p<0.001). Simultaneously, pts with interval time ≤1 month, received numerically benefit compared to interval time >1 month between RT and FRU+IT (mPFS: 6.2 vs. 3.8 mo, P=0.16; mOS: not reached vs. 7.65 mo, P=0.08). Further subgroup analysis revealed that men, age ≤56 years, ECOG PS score of 1, primary focal resection, recurrent metastatic disease, liver/pulmonary metastases, and metastatic involvement of organs ≥2, were more favorably treated with Fru for prolonged OS. Intriguingly, the 3rd-line treatment of Fru exhibited a tendency to prolong OS compared to Reg. Cox multivariate regression analysis suggested that the cycle of Fru/Reg combined with PD-1 inhibitor treatment was a common independent influencing factor for PFS and OS. Safety was consistent with previous reports, and the incidence of AE appeared to be lower in Fru + IT + RT than in Reg + IT + RT.

Conclusion: In pts receiving RT of localized lesions, the addition of Fru combined with PD-1 inhibitor could prolong the pts' OS more than Reg plus PD-1 inhibitor. And radiotherapy sequential Fru + IT (interval time ≤1 mo) treatment is expected to be the optimal strategy for MSS/pMMR mCRC.

#3829 Identifying the genetic basis for resistance to aromatase inhibitors (AIs) in metastatic breast cancer (mBC) patients.

N. Singh, S. Agrawal;
ConcertAI, Bengaluru, India

Background: AIs, such as letrozole, anastrozole, and exemestane, are used to treat hormonal receptor positive (HR^{+}) breast cancer (BC) patients. Many patients either respond poorly or relapse on AIs. A comprehensive view of the underlying genomic landscape of such patients may aid in a better understanding of the resistance mechanisms and the development of new targeted therapies. This study leveraged a real-world clinico-genomic dataset of BC patients to identify key biomarkers and the corresponding high frequency mutations in this relapse/refractory patient population.

Methods: This retrospective study used ConcertAI's Genome360^{TM} BC dataset (N=3223). A cohort of HR^{+}/$HER2^{-}$ mBC patients who were either refractory to or relapsed on AIs (N=863) were included. To identify key resistance genes/pathways, only genomic data (from NGS tests) from a biopsy performed after tumor progression on AIs was considered. Prevalence analysis was done only based on known pathogenic/likely pathogenic variants. Pathway analysis of identified biomarkers with the mechanism of action of AIs was performed to identify and validate key resistance pathways. Further, signatures of unique protein alteration were identified within the biomarkers of interest.

Results: The median age of patients at the time of diagnosis was 54 years. Adenocarcinoma and Lobular/Ductal carcinoma were the two most prevalent histologies. 51% of patients in this cohort were treated with AIs in the first line. Table 1 lists the 20 most frequently altered genes observed in this cohort. Genes with a potential role in AI resistance based on pathway analysis are indicated. The most common mutations in selected biomarkers are also provided. These biomarkers were observed at a much lower frequency in patients who responded well to AIs.

Conclusion: This study provides insights into the genetic basis of resistance to AIs in mBC patients, opening up possibilities for development of new treatments to overcome resistance.

Table1: Top 20 biomarkers and their variants found in AI relapse/refractory mBC Patients.

Biomarker	**Prevalence (%)**	**Potential Role in AI Resistance**	**Key Variants**
ESR1	37.81	Yes	D538G, Y537, Y537N, E380Q, Y537C

#3830 Comparison of individual patient data from real-world experience with the ADAURA study for resected stage IB-IIIA EGFR-mutated non-small cell lung cancer.

H. Jung, J. Lee, B. Park, S. Park, J.-M. Sun, S.-H. Lee, J. Ahn, M.-J. Ahn;
Samsung Medical Center, seoul, Korea, Republic of

Introduction: In recent data of ADAURA study, adjuvant osimertinib demonstrated clinically significant improvement in overall survival in completely resected stage IB-IIIA with epidermal growth factor receptor (EGFR)-mutated NSCLC. Among 205 patients who experienced recurrence in the placebo arm, 89.8% of patients received subsequential treatment and 79.0% of patients in the placebo arm received EGFR-TKI after recurrence.
Methods: This study included patients with completely resected EGFR-mutated NSCLC who confirmed to pathologic stage II-IIIA between November 2015 and February 2019 at Samsung Medical Center (SMC data). They did not receive adjuvant EGFR-TKI. To compare overall survival between the SMC data and the ADAURA study, the individual patient data (IPD) approach was applied. We assessed the overall survival of individual patient data from real-world experience in comparison to the ADAURA study.
Results: A total of 547 patients were included in this study, with 51.0% at stage IB, 23.8% at stage II, and 25.2% at stage IIIA. The median follow-up duration was 71.4 months (range 1-92). At the time of data lock, 241 patients experienced recurrence in the SMC data. Among them, 230 patients (95.4%) received subsequent treatment, and 214 patients (88.8%) received EGFR-TKI after recurrence. In the stage IB and II, there was no difference of overall survival between the SMC data (reference) and the osimertinib arm of the ADAURA study (HR=0.83, 95% CI, 0.36-1.90, p=0.66 in stage IB; HR=1.08, 95% CI, 0.58-2.03, p=0.81 in stage II). However, in the stage IIIA, the 5-year survival rate was 68% in the SMC data and 85% in the osimertinib arm of the ADAURA study (HR=0.42, 95% CI, 0.24-0.73, p<0.01). In the stage IB-IIIA, the 5-year survival rate was 85% in the SMC data (reference), 78% (HR=1.68, 95% CI, 1.25-2.25, p<0.01) in the placebo arm of the ADAURA study, and 88% (HR=0.81, 95% CI, 0.56-1.16, p=0.24) in the osimertinib arm of the ADAURA study. In the stage II-IIIA, the 5-year survival rate was 77% in the SMC data (reference), 73% (HR=1.29, 95% CI, 0.92-1.82, p=0.14) in the placebo arm of the ADAURA study, and 85% (HR=0.62, 95% CI, 0.41-0.93, p= 0.02) in the osimertinib arm of the ADAURA study.
Conclusions: In this study, the majority of patients received EGFR-TKIs after recurrence. The 5-year overall survival in the real-world data demonstrated superiority over the placebo arm of the ADAURA study. In stage IB and II disease, there was no significant difference between the SMC data and the osimertinib arm of the ADAURA study. Consequently, patients with pathologic stage IIIA are considered strong candidates for adjuvant osimertinib.

#3831 Clinicopathologic determinants of survival in double/triple hit lymphoma: Analysis of a pooled database.

P. A. Haddad[1], S. Gupta[2], A. Gupta[3], C. Graham[2];
[1]LSUHSC-S Feist-Weiller Cancer Ctr./Overton Brooks VAMC, Shreveport, LA, [2]LSUHSC-S Feist-Weiller Cancer Ctr., Shreveport, LA, [3]Overton Brooks VAMC, Shreveport, LA

Background B-cell lymphoma with MYC, BCL2, and/or BCL6 rearrangements are classified as double/triple- hit lymphoma (DTHL). They usually, but not always, tend to be high-grade aggressive B-cell lymphoma with worse prognosis. Despite this classification, DTHL remains a heterogeneous group with varied molecular profiles, biological behavior, and prognosis. Therefore, we conducted this pooled database analysis to identify the prognostic factors, clinicopathological characteristics, and therapeutic strategies influencing survival in this rare disease.
Methods To study the demographic characteristics, molecular and immunohistochemical signatures, therapeutic interventions, survival, and prognostic factors, we compiled a pooled database of 161 cases that fit the diagnostic criteria for DTHL. Kaplan-Meier survival curves were constructed. Cox proportional hazards model and Log-rank tests were used to assess the influence of demographic and clinicopathologic factors on overall survival (OS) and disease-free survival (DFS).
Results A compiled a dataset of 161 patients with confirmed DTHL. The median age was 62 with F:M of 1.08. The median duration of symptoms before diagnosis was 2 months. DTHL involved the lymph nodes (41%), bone marrow (31%), bone (14%), CNS (5%), skin (4%), liver (3%), and spleen (2%). Constitutional symptoms were reported in 20%. The cohort consisted of primary (50%), secondary/transformed (16%), and follicular DTHL. The median OS and DFS of the cohort were 69 and 27 months, respectively. Bone marrow and extra-lymphatic organ involvement were associated with worse DFS and non-significant numerically worse OS. LDH>500 (p=0.006), PAX5-negative (p=0.01), CD79a-negative (p=0.02), and Ki67>80% (p<0.0001) were associated with worse OS. Similarly, CD5+, CD10+, and MUM1+ had worse OS, but did not reach statistical significance. Follicular DTHL was associated with the best median OS and DFS followed by primary then secondary/transformed in decreasing order. Advanced stage and high IPI were also associated with worse non-significant numerical OS. Age and sex did not impact OS. Compared to no treatment, chemotherapy and stem cell transplant had incrementally superior median OS (3 vs. 55 vs. NR months, p=0.008). Frontline intensive chemotherapy yielded similar DFS and OS to CHOP-like regimens. Patients who attained CR as their best response also had a superior median OS (p<0.0001).
Conclusion This study presents clinicopathologic data from a cohort of patients with primary, secondary, and follicular DTHL. It identifies the type of DTHL, IHC profile, LDH levels, type of therapy, and quality of response to treatment as critical determinants of OS.

#3832 Fluid-overload associated large B-cell lymphoma and determinants of outcomes: Analysis of a pooled database.

P. A. Haddad[1], S. Gupta[2], C. Graham[2];
[1]LSUHSC-S Feist-Weiller Cancer Ctr./Overton Brooks VAMC, Shreveport, LA, [2]LSUHSC-S Feist-Weiller Cancer Ctr., Shreveport, LA

Background: Fluid overload-associated large B-cell lymphoma (FOLBCL) is a new WHO lymphoma entity previously known as PEL-like lymphoma or HHV8-unrelated PEL-like lymphoma. It is a rare lymphoma that arises within fluid-filled body cavities without a solid component. FOLBCL occurs in the absence of immunodeficiency and is commonly associated with conditions associated with fluid overload. It expresses mature B-cell phenotype and occasional EBV infection markers. We conducted this study to delineate key clinicopathological characteristics, prognostic indicators, and treatment modalities that affect outcomes in this rare and newly defined lymphoma subtype.
Materials & Methods: To study the demographic characteristics, molecular and immunohistochemical signatures, therapeutic interventions, survival, and prognostic factors, we compiled a pooled database of 115 cases that fit the diagnostic criteria for FOLBCL. Kaplan-Meier survival curves were constructed. Cox proportional hazards model and Log-rank tests were used to assess the influence of demographic and clinicopathologic factors on overall survival (OS).
Results: A total of 115 patients with confirmed FOLBCL were identified. The median age was 74, with a peak incidence between 72 and 82 years. There was a male preponderance with M:F of 2. The pleural, pericardial, and peritoneal cavities were involved in 75%, 34, and 27%. The median duration of symptoms before diagnosis was 1 month. Patients presented with constitutional symptoms and hepatosplenomegaly in 13% and 1%, respectively—no patients presented with lymph node and bone marrow involvement. The median OS of the whole group was 16 months. Patients younger than 70 had better median OS than 70 and older (24 vs. 10 months, p=0.008). The presence of any malignant peritoneal effusion was associated with worse OS when compared to effusion limited to the thoracic cavity (7 vs. 24 months, p=0.005). LDH>500 was also associated with worse OS (p=0.02). Sex, the presence of fluid overload-causing conditions, and serum IL2R levels did not seem to impact OS. MYC re-arrangement had numerically worse OS when present but did not reach statistical significance. Chemotherapy demonstrated superior OS compared to no treatment (24 vs. 7 months, p=0.009). Patients who attained CR as their best response had a superior median OS (p<0.0001).
Conclusion: This study presents updated clinicopathologic data from a pooled cohort of patients with FOLBCL. It identifies the age, the primary location of cavitary disease, LDH, active therapy, and quality of response to treatment as key determinants of OS.

#3833 Primary cutaneous diffuse large B-cell lymphoma-leg type and clinicopathologic determinants of survival: Analysis of a pooled database.

P. A. Haddad[1], M. Amankwah[2];
[1]LSUHSC-S Feist-Weiller Cancer Ctr./Overton Brooks VAMC, Shreveport, LA, [2]LSUHSC-S Feist-Weiller Cancer Ctr., Shreveport, LA

Background: Primary Cutaneous Diffuse Large B-cell Lymphoma-Leg Type (PCDLBCL-LT) is a rare but non-indolent subtype of B-cell lymphoma. While most PCDLBCL-LT starts over the lower extremities, some cases may present at other cutaneous sites. The determinants of survival outcomes in this disease are not very well defined. Therefore, we conducted this pooled database analysis to identify the prognostic factors, clinicopathological characteristics, and therapeutic strategies that influence survival in this disease.
Methods: To study the demographic characteristics, molecular and immunohistochemical signatures, therapeutic interventions, survival, and prognostic factors, we compiled a pooled database of 122 cases that fit the diagnostic criteria for PCDLBCL-LT. Kaplan-Meier survival curves were constructed. Cox proportional hazards model and Log-rank tests were used to assess the influence of demographic and clinicopathologic factors on overall survival (OS) and disease-free survival (DFS).
Results: A total of 122 patients with confirmed PCDLBCL-LT were identified. The median age was 76. There was a male preponderance with M:F of 2.4. Seventy-three percent involved the extremities. The median duration of symptoms before diagnosis was 3.5 months. Involvement of lymph nodes, bone marrow, bone, and CNS occurred in 11%, 3%, 4%, and 3%, respectively. Constitutional symptoms were reported in 5%. The median OS and DFS of the whole group were 39 and 32 months, respectively. Patients younger than 70 had better median DFS (NR vs. 24 months, p=0.02) with a non-significant better median OS. Lymphadenopathy (45 vs. 18 months, p=0.006) and stage T3 compared to T1/T2 (16 vs 41 months, p=0.006) were associated with worse OS. Sex, constitutional symptoms, IHC phenotype, extra-lymphatic/extra-cutaneous organ involvement, and histologic cutaneous patterns did not impact OS. Compared to no treatment, chemotherapy, XRT+/-surgery, and stem cell transplant had numerically better OS without reaching statistical significance (5 vs. 39 vs. 41 vs. NR months, p=0.15). Patients who attained CR as their best response also had a superior median OS compared to responses less than CR and none (61 vs. 23 vs. 11 months, p<0.0001).
Conclusion: This study presents updated clinicopathologic data from a large, pooled cohort of patients with PCDLBCL-LT. It identifies age, lymph node involvement, T stage, type of therapy, and quality of response to treatment as critical determinants of OS.

#3834 Plasmablastic lymphoma provisional prognostic score.

P. A. Haddad[1], J. Lerner[2];
[1]LSUHSC-S Feist-Weiller Cancer Ctr./Overton Brooks VAMC, Shreveport, LA, [2]LSUHSC-S Feist-Weiller Cancer Ctr., Shreveport, LA

Background Plasmablastic Lymphoma (PBL) is a rare and aggressive subtype of non-Hodgkin's lymphoma. It tends to be associated with immunosuppressive clinical contexts, such as HIV infection and immunosuppressive therapies for autoimmune disorders and organ transplants. However, due to the rarity of the disease, which needs to be better understood, varied treatment approaches have been implemented, and no optimal data or guidelines for managing PBL are available. Therefore, we conducted this study to develop a provisional PBL prognostic score (PBLPS) for this rare disease.
Methods We used our constructed PBL database, which contains retrospective data on 300 cases. Such data included demographics such as sex, age, and race. It also included disease presentation symptoms, duration of symptoms before diagnosis, site(s) of the disease, blood counts, coexisting comorbidities, disease immunohistochemical and molecular phenotype, types of treatment, and survival outcomes. Of the 300 cases, 291 had complete survival and outcomes data, the sample chosen for this study. Cox proportional-hazards model and Log-rank tests were used to assess the influence of clinicopathologic factors on overall survival (OS). We included factors that statistically impacted OS and scored them by the impact of their hazard ratios.
Results The median OS of the cohort was 25 months. The following dichotomous variables were identified as impactful prognostic factors in this cohort: LDH>500 (p=0.04), CD4<100 (p=0.006), bone marrow (BM) involvement (p<0.0001), EBER-negative (p=0.01), HHV8+ (p=0.02), and involvement of liver (p=0.003), lungs/pleura (p<0.0001), and upper GI tract (p=0.001). A prognostic model was devised using these variables to identify different levels of risk. Involvement of BM and involvement of any of the worse prognosis organs (liver, lung/pleura, and/or upper GI tract) were each assigned a score of 2 when present. CD4<100, EBER-negative, and LDH>500 were assigned 1 point each as they had the lowest hazard ratios of all the other variables. In this exploratory cohort, we assigned low risk a score of 0, intermediate risk a score of 1-2, and high risk a score of 3-7. This prognostic score system led to our cohort's most optimal risk discriminatory model, where low, intermediate, and high risk had a median OS of NR, 15, and 4 months, respectively (p<0.0001).
Conclusion This PBLPS is a promising new tool for risk-stratifying patients with PBL. However, it still requires prospective validation.

#3835 Clinicopathologic determinants of survival in malignant histiocytic neoplasms: Analysis of a pooled database.

P. A. Haddad[1], D. Keerty[2];

[1]LSUHSC-S Feist-Weiller Cancer Ctr./Overton Brooks VAMC, Shreveport, LA, [2]LSUHSC-S Feist-Weiller Cancer Ctr., Shreveport, LA

Background: Malignant histiocytosis, also known as the M-group per the Histiocyte Society classification, represents a rare, aggressive malignant group of histiocytic neoplasms. It includes histiocytic neoplasms that occur de novo (pMHN) and those that develop in association with other malignant diseases (aMHN). However, little is known about factors that impact MHN clinical outcomes. We conducted this pooled database analysis to delineate key clinicopathological characteristics, prognostic indicators, and treatment modalities that affect survival in these rare diseases.

Methods: To study the demographic characteristics, molecular and immunohistochemical signatures, therapeutic interventions, survival, and prognostic factors, we compiled a pooled database of 281 cases of MHN. Kaplan-Meier survival curves were constructed. Cox proportional hazards model and Log-rank tests were used to assess the influence of demographic and clinicopathologic factors on overall survival (OS).

Results: A total of 281 patients with confirmed MHN were identified, with 77% pMHN and 23% aMHN. The median age was 45, with bimodal peaks between 0-13 and 52-65. There was a male preponderance with M:F of 1.6. Primary sites of involvement were liver (15%), CNS and spleen (13% each), thoracic, GI, and soft tissues (12% each), bones (11%), skin (10%), H&N (8%), and breast, heart, gonads, pancreas, and kidney (1% each). Lymphadenopathy and bone marrow (BM) were involved in 28% and 18%, respectively. Constitutional symptoms occurred in 12% and hemophagocytic syndrome (HPS) in 6%. The median OS of the whole group was 12 months. BM involvement had a worse median OS (5 vs. 60 months, p=0.0002). Stage 1 disease had better median OS than higher stages (p=0.0008). Furthermore, unifocal had better median OS than multifocal/multicentric disease (60 vs. 7 months, p=0.0001). The presence of inflammatory background positively impacted OS (p=0.01). The occurrence of HPS adversely affected OS (p<0.0001). Compared to no treatment, localized therapies such as surgery (S) and/or radiation therapy (RT) and systemic combination chemotherapy (CT) were statistically superior, with a median OS of 3, 24, and 16 months, respectively (p=0.009). Among systemic therapies, SCT and BRAF/MEK inhibitors were superior to conventional chemotherapy (p=0.02). Having CNS or splenic-lymphatic primary involvement tended to have a numerical but non-significant worse median OS than soft tissue or visceral disease. While female sex, size<10cm, and pMHN seemed to have numerically better OS, they did not reach statistical significance. There was no difference in median OS for age.

Conclusion: This study presents updated clinicopathologic data from a pooled cohort of patients with MHN. It identifies BM involvement, stage, extent of the disease, the inflammatory background status, occurrence of HPS, and treatment approach as critical determinants of OS.

#3836 Mast cell leukemia provisional prognostic score.

P. A. Haddad[1], S. Chennapragada[2];

[1]LSUHSC-S Feist-Weiller Cancer Ctr./Overton Brooks VAMC, Shreveport, LA, [2]LSUHSC-S Feist-Weiller Cancer Ctr., Shreveport, LA

Background Mast cell leukemia (MstCL) is a rare but aggressive variant of systemic mastocytosis (SM), defined by the presence of >20% atypical mast cells in the bone marrow. It is further classified into leukemic and aleukemic variants based on the presence or absence of >10% atypical mast cells in the peripheral blood, respectively. There is a wide variation in treatment regimens used to treat MstCL. Despite this, prognosis remains poor. While MstCL often follows an aggressive course, its outcomes vary considerably. We conducted this study to develop a provisional MstCL prognostic score (MCLPS) for this rare disease.
Methods We used our constructed MstCL database, which contains retrospective data on 144 cases. Such data included demographics such as sex, age, and race. It also included disease presentation symptoms, duration of symptoms before diagnosis, site(s) of the disease, blood counts, coexisting comorbidities, disease immunohistochemical and molecular phenotype, types of treatment, and survival outcomes. Of the 144 cases, only 104 had complete survival and outcomes data, the sample chosen for this study. Cox proportional-hazards model and Log-rank tests were used to assess the influence of clinicopathologic factors on overall survival (OS). We included factors that statistically impacted OS and scored them by the impact of their hazard ratios.
Results The median OS of the cohort was 9 months. The following dichotomous variables were identified as impactful prognostic factors in this cohort: Age<55 (6 vs. 15 months), Hgb<10g/dl (3 vs. 29 months), Plt<100K (3 vs. 23 months), leukemic phase (7 vs. 18 months), and complex cytogenetics (2.3 vs. 23 months). A prognostic model was devised using these variables to identify different levels of risk. Each variable was assigned a score of 1 when present for a maximum possible score of 5. In this exploratory cohort, low risk was assigned a score of 0, intermediate risk a score of 1-2, and high risk a score of 3-5. This prognostic score system led to our cohort's most optimal risk discriminatory model, where low, intermediate, and high risk had a median OS of 29, 8, and 2.4 months, respectively (p=0.0006).
Conclusion This MCLPS is a promising new tool for risk-stratifying patients with MstCL. However, it still requires prospective validation.

CLINICAL RESEARCH: Tumor Immune Response 2
Poster Session

#3840 Can serum exosomal content predict response to immunotherapy in hepatocellular carcinoma?.

Niramol Savaraj[1], Pablo Puente[2], Ying-Ying Li[1], Chunjing Wu[1], Jonathan D. Nguyen[1], Medhi Wangpaichitr[1], Peter J. Hosein[3], Lynn G. Feun[3]

[1]Univ. of Miami/VA Medical Ctr., Miami, FL,[2]University of Illinoid, Chicago, IL,[3]Medicine, Univ. of Miami, Miami, FL

While atezolizumab and bevacizumab combination has received FDA approval for the treatment of unresectable hepatocellular carcinoma (HCC), and recently durvalumab + tremelimumab also showed activity over sorafenib, there is no biomarker which can guild which patients can benefit from these regimens. The traditional PD-L1 positivity in the tumor by immunohistochemical staining which can predict possible response to immune checkpoint inhibitor in other solid tumors, such as melanoma and NSCLC, does not appear to apply to HCC. Thus, we attempt to explore whether exosomal content can be useful to predict response. HCC tumors exist in a complex microenvironment and serum exosomes can be generated from either tumor cells, macrophages, or other immune cells. Exosome act as new mediators for cell-cell communication transporting molecules such as lipids, proteins, and RNAs in vivo. Exosomal PD1 and PD-L1 have been implicated for possible biomarkers for immune checkpoint sensitivity. We isolated exosome from serum of unresectable HCC patients who underwent treatment with atezolizumab and bevacizumab. Blood sample was obtained prior to treatment, and then on cycle 3 and at the time of disease progression. Exosomes were isolated using the kit from System BioScience. Twenty patients were entered into the study. Five patients were not treated (received SBRT or other regional treatment), one was lost to follow up and one had atezolizumab only. In terms of antitumor response, eight patients had stable disease, three patients had partial response and two patients had progressive disease. Serum exosomal content data was available in 16 patients. Both PD1 and PDL1 are lowest in the three patients who had response followed by the group who had stable disease. In the two patients who had progressive disease, both exosomal PD-L1 and PD1 appeared to be the highest and did not change during treatment. Unlike in melanoma patients we have studied, other proteins in the antiapoptotic family such as Bcl-2 do not show any differences. While the number of patients are small and accrual is still ongoing, it appears that exosomal PD-L1/PD1 may have clinical value in predicting response to atezolizumab + bevacizumab therapy. Supported by Sylvester Comprehensive Cancer Center grant.

#3841 Tumor-derived microRNA125a induces CART cell apoptosis and failure in B cell malignancies.

O. Sirpilla, R. Sakemura, I. Can, T. N. Huynh, J. H. GIrsch, C. Manriquez Roman, C. M. Stewart, K. Yun, E. J. Ogbodo, L. Mai, O. Gutierrez Ruiz, M. Rodriguez, B. Kimball, H. Xia, J. C. Villasboas, S. Ansell, N. Bennani, P. B. Johnston, J. Paludo, J. Castro, M. Kharfandabaja, S. Parikh, N. Kay, Y. Lin, E. Siegler, S. Kenderian;
Mayo Clinic, Rochester, MN

Despite the remarkable efficacy of chimeric antigen receptor T -cell therapy (CART) for the treatment of B-cell malignancies, durable remission remains limited often due to tumor relapse. We have previously demonstrated that tumor-derived extracellular vesicles (EVs) induced CART cell failure in preclinical models. To characterize the impact of tumor EV induced CART cell dysfunction, we assessed microRNA (miRNA) profiles contained within tumor EVs from two independent patient cohorts and studied how they contributed to CART dysfunction. Our first cohort included patients with chronic lymphocytic leukemia (n=50). We previously showed that CLL patient derived EVs induce a state of CART cell dysfunction. To understand this dysfunction, we interrogated the miRNA cargo significantly enriched in CLL EVs and how their coculture impacts CART signaling by RNAseq. Here, we found a significant enrichment in miR-125a within CLL EVs as compared to healthy donor controls (*p=.0001*). CART cocultured with CLL EVs showed alterations in T cell activation pathways, where miR-125a targets TNFAIP3 and NFkB pathways were activated. These findings implicate miR-125a from CLL EVs in CART dysfunction. Next, we aimed to validate the impact of miRNA on CART cell outcomes in the clinic. We interrogated miRNA profiles from patients with diffuse large B cell lymphoma (DLBCL) treated with CART cell therapy (CART19-28ζ, axicabtagene ciloleucel). EV miRNA cargo was compared between responders (complete remission at 6 months, n=10) and non-responders (no response 1 month post CART19, n=10) to identify differentially enriched miRNAs across groups. miR-125a was again significantly upregulated in EVs of non-responders as compared to responders to CART19 treatment (*fold change=3.28, padj=.018*). To study the direct effect of miR-125a on CART cell functions, we generated and studied the effector functions of CART19-28z following transfection with miR-125a or negative miR control. CART19 cells transfected with miR-125a showed a dose dependent decrease in killing of lymphoma cells as compared to miR-control (*p=.0001*). miR-125a also significantly increased the rate of apoptosis in CART19 cells (*fold change=1.95, p=.024*) and decreased the level of CART proliferation (*fold change=.71, p=.013*) as compared to controls. Notably, miR-125a did not impact tumor cell growth, further verifying a direct CART effect. In summary, our studies demonstrate the impact of tumor derived miRNAs on CART cell outcomes. They identify that miR-125a is 1) associated with CLL EV induced CART dysfunction, 2) significantly elevated in non-responders to CART therapy in the clinic, and 3) able to decrease CART19 efficacy through reduced CART killing/proliferation and increased apoptosis. These results highlight a novel mechanism of CART19 failure induced through miRNA cargo delivery by tumor-derived EVs and the role of miR-125a in inducing CART19 dysfunction.

#3842 Neuroendocrine differentiation and treatment of human SCLC: NRF2 has a role..

S. Hamad[1], H. Joshi[2], Y. Li[3], H. Toma[2], N. Bendjilali[4], S. Jefferys[5], D. Corcoran[5], W. Elbezanti[2], B. Major[6], W. Bernard[7], F. Spitz[1];
[1]Cooper Medical School of Rowan University (CMSRU), Camden, NJ, [2]Cooper University Hospital, Camden, NJ, [3]Cooper University Health Care, Camden, NJ, [4]Rowan University, Glassboro, NJ, [5]University of North Carolina, Chapel Hill, NC, [6]Washington University School of Medicine in St. Louis, St. Louis, MO, [7]University of North Carolina, Chapel Hill, NJ

SCLC is a lethal form of lung cancer and highly metastatic disease with limited therapeutic options. Four main neuro and non-neuroendocrine SCLC molecular subtypes have been identified which further complicate the efforts of finding targeted therapies. NRF2 is a transcription factor that is known to protect cells from oxidative damage by regulating more than 500 cytoprotective genes. NRF2 is frequently mutated in non-small cell lung cancer (NSCLC), however, whether alterations occur in small cell lung cancer (SCLC) is not clear due to limited sequencing data. Recently, our group has discovered a previously unrecognized role of NRF2 signaling pathway in the development of SCLC using a novel genetically engineered mouse model (GEMM). In this study, we have investigated the role of NRF2 in the progression and regression of human SCLC. Human SCLC cell lines were generated with $NRF2^{E79Q/+}$ mutation (one of the most common mutations found in human tumors) to allow the constitutive activation of NRF2 in these cells. Results from hSCLC cell lines showed that NRF2 activation in NRF2-negative SCLCs can significantly inhibit their growth. Further, human SCLC gene expression data showed reduced levels of a NRF2 signature as hSCLC neuroendocrine SCLC transforms to non-neuroendocrine subtypes. As an anti-inflammatory pathway, NRF2 is known to inhibit immune cell gene signature. Our in vivo and invitro studies showed that NRF2 inhibits immune cell infiltration in SCLC; and increases PDL1 protein expression. Currently, we are investigating the effect of NRF2 activation in hSCLC growth, neuroendocrine differentiation and immune gene activation in vitro and in vivo. We are also using immune checkpoint inhibitors to determine the best therapeutic options for each SCLC subtype.

#3843 Role of CD4/CD8 double positive T cells in modulating response to anti-PD-1 treatment in renal cell carcinoma.

S. Sankaran, K. Jaganathan, B. Das, S. V, C. Bhowal, M. M, D. M, M. Nath, R. M, O. M, R. Malhotra, G. K, M. Malhotra, N. Pal Basak;
Farcast Biosciences, Bangalore, India

Presence of CD4+CD8+ Double Positive T (DPT) cells in the tumor microenvironment has been correlated with good prognosis[1]. Renal cell carcinoma (RCC) is reported to have relatively much higher DPT cell sub-populations as compared to other cancer types[1,2]. DPT cells in RCC were reported to express high programmed cell death protein-1(PD-1) and therefore is considered a potential target for checkpoint based immunotherapy[2]. However, the clinical relevance of these DPT cells in determining response to anti-PD-1 has not yet been studied. Using the near native Farcast™ TruTumor RCC histoculture platform, we attempted to elucidate the role of DPT in anti-PD1 response modulation. Fresh surgically resected RCC samples (n=18) along with matched blood were collected from consented patients. Explants were generated and distributed into arms. These arms were treated in culture with nivolumab (anti-PD1:132µg/ml) for 72 hours. The response was evaluated using histopathology and flow cytometry read-outs. DPT cells were gated and expressed as percentage of CD3 using flowcytometry. We observed a significantly higher proportion of DPT cells in RCC (Mean±SEM: 8.2±2.8) compared to head and neck squamous cell carcinoma (Mean±SEM: 1.2±0.4) and ovarian cancer (Mean±SEM: 0.7±0.1). DPT cell population was found to be well preserved on the TruTumor RCC platform post-culture. We stratified samples as high and low DPT cell sub cohorts based on 5% cut-off. Out of 18, 6 samples (33%) showed high DPT cells (with a range of 7-41%). Eighty-three percent (5 out of 6) of high DPT samples elicited a tumor cytotoxicity on treatment with Nivolumab treatment as compared to only 50% (6 out of 12) in low DPT samples. A significant decrease ($p<0.05$) in DPT cells was observed in the high DPT sub cohort upon Nivolumab treatment, with a concomitant increase in activated (Granzyme B+) DPT and cytotoxic T cells (CD8+) sub-populations was observed upon nivolumab treatment. However, total CD8+ proportions remained unchanged. In addition, an increase in effector (CD4+ FoxP3-) and decrease in Treg (CD4+FoxP3+) population was also observed. Only one out of six high DPT samples exhibited no cytotoxicity in response to nivolumab treatment. Interestingly in this non-responder sample there was a 3.1-fold increase in M2-like (CD68+CD206+) macrophages, as compared to a M1-like macrophage polarization observed in the remaining high DPT samples. In summary, our data suggests that presence of high percentage of DPT cells could favour better response to anti-PD1 therapy in RCC patients. The Farcast™ TruTumor platform thus provides powerful insights into the role of various immune cell sub-populations in modulating response to treatment with immune-oncology therapies.

#3844 Clinical implications of mixed response on prognosis of non-small cell lung cancer (NSCLC) patients treated with Immunotherapy.

S. Lee[1], T. Um[2], J. Lee[1], P. Kim[3], M. Yadav[2], M. J. A. Chuchuca[2], L.-Y. Chung[2], Y. Chae[2];

[1]Kyungpook National University, Daegu, Korea, Republic of, [2]Feinberg School Of Medicine, Northwestern University, Chicago, IL, [3]The University of Texas at Austin, Austin, TX

Background: Current methods for assessing the response of lung cancer patients to therapy (e.g. RECIST criteria) lack consideration for mixed response (MR) where some lesions increase while others decrease simultaneously. MR poses a challenge in deciding the continuation of therapy. Understanding the clinical implications of MR on patient prognosis within radiographic response categories is crucial for establishing effective treatment strategies for NSCLC.
Methods: This study analyzed 177 NSCLC patients with ≥2 lesions receiving first-line systemic treatment with immunotherapy. Clinical response was evaluated by RECIST v1.1 and immune-related RECIST (irRECIST). MR was defined as the simultaneous presence of ≥1 lesion increase and ≥1 lesion decrease during therapy. Two different definitions of MR were utilized. Definition-A (MR-A): the simultaneous presence of one or more lesions increasing ≥5mm and one or more lesions decreasing ≥5mm during therapy (Δ [baseline - first follow-up] ≥ 5 mm); and Definition-B (MR-B): the simultaneous presence of one or more lesions increasing >1mm and one or more lesions decreasing >1mm during therapy (any Δ [baseline - first follow-up]). Subgroup analysis was conducted using 94 patients with only intrathoracic lesions.
Results: Among the 177 patients, tumor responses based on RECIST were 3 CR (1.7%),42 PR (23.7%), 87 SD (49.2%), and 45 PD (25.4%). Based on irRECIST, responses were 3 CR (1.7%), 46 PR (26.0%), 89 SD (50.3%), and 39 PD (22.0%). MR-A and MR-B occurred in 19.8% (n=35) and 45.2% (n=80) of cases, respectively. In the irRECIST PD group, MR-A demonstrated significantly different median progression-free survival (mPFS) and median overall survival (mOS) compared to non-MR-A ($p<0.020$, $p<0.005$, respectively). The mPFS for MR-A group was 1.4 months (range 0.5-52.9) and non-MR-A group was 5.5 months (range 0.2-97.2) with the hazard ratio being 2.91 (95% CI 1.13-7.51). The mOS for MR-A and non-MR-A groups were 4.8 months (range 0.7-61.5) and 11.8 months (range 0.2-97.2), respectively, hazard ratio 4.87 (95% CI 1.43-16.56). No other significant results were found for other RECIST and irRECIST categories. Subgroup analysis of only intrathoracic lesion patients revealed no statistically significant results.
Conclusion: Contrary to our hypothesis, MR did not modify prognosis within the RECIST or irRECIST category. MR-A or MR-B in the RECIST or irRECIST PD group did not show a better prognosis, indicating the complexity of mixed responses in NSCLC patients treated with immunotherapy. Further research with larger cohorts are warranted.

#3846 The obesity paradox in immune checkpoint blockade: A pan-tumor analysis.

S. L. Alden[1], S. Charmsaz[2], M. Brancati[2], H. L. Li[1], A. Warner[1], K. Munjal[2], K. Howe[2], S. Mitchell[2], E. Griffin[2], M. Nakazawa[2], H.-L. Tsai[1], L. Danilova[1], C. Thoburn[1], J. Background: Chronic systemic inflammation mediated by pro-inflammatory cytokines serves as a major mechanism by which obesity contributes to cancer development. Paradoxically, elevated body mass (BMI) has been associated with improved outcomes after treatment with immune checkpoint inhibitors (ICIs) in many tumor types. The interplay between cytokine response and obesity after ICIs is poorly understood. To characterize underlying mechanisms, we investigated cytokine profiles in relation to obesity and clinical outcomes in patients treated with ICIs.

Methods: From June 2021 to October 2022, we enrolled and collected blood samples from patients with advanced or metastatic solid tumors who received ICIs as standard of care at Johns Hopkins. We calculated BMI using height and weight at treatment initiation, with BMI ≥30 obese and BMI <30 non-obese. Underweight patients (BMI <18.5) were excluded. The Bioplex 200 platform (Biorad, Hercules CA) was used to determine the plasma concentration of 37 cytokines at baseline and on-treatment, with the median cytokine value used to differentiate between high and low concentration.

Results: Among 94 patients, 29 (31%) were obese and 65 (69%) were non-obese, with a significant difference in sex (Fisher's exact test, p = 0.02), but no observed difference in age, race, cancer type, autoimmune disease, or presence of immune-related adverse events (irAE) based on BMI category; all the following hazard ratios (HR) are therefore adjusted for sex. Obese patients had improved progression free survival (PFS) (HR 0.41 [95% CI: 0.21-0.80], p=0.01) and overall survival (OS) (HR 0.16 [95% CI: 0.04-0.69], p=0.01). Eighty-six patients had cytokine data at baseline (range: eight days prior to day of initiation). Baseline IL-15 was significantly lower in obese patients (1.71 vs. 2.08, p=0.04), however, there was no difference in PFS (HR 1.49 [95% CI: 0.87-2.56], p=0.15) or OS (HR 1.22 [95% CI: 0.51-2.97], p=0.65) comparing low vs. high baseline IL-15. Eighty-two patients had cytokine data on-treatment (range: 21-349 days after initiation), with significantly lower levels of IL-6 (2.49 vs. 3.45, p=0.04), IL-8 (2.01 vs. 2.92, p=0.01), and IL-15 (1.70 vs. 1.81, p=0.01) in obese vs. non-obese patients, respectively. Low on-treatment IL-8 was associated with improved PFS (HR 0.52 [95% CI: 0.29-0.92], p=0.02) and OS (HR 0.17 [95% CI: 0.05-0.58], p<0.01), and low on-treatment IL-6 was associated with improved OS (0.25 [95% CI: 0.08-0.76], p=0.01).

Conclusions: In a diverse, pan-tumor ICI cohort, we observed a positive relationship between obesity and clinical outcomes with ICIs, with no correlation between obesity and irAEs. We also observed lower on-treatment levels of IL-6 and IL-8 in patients with obesity and that low on-treatment levels of IL-6 and IL-8 correlated with improved survival, suggesting that IL-6 and IL-8 may serve as mediating factors for improved outcomes in obese patients treated with ICIs.

#3847 Dual targeting of EGFL6 and VEGF-A to overcome immune suppression in ovarian cancer.

S. Umamaheswaran[1], L. S. Mangala[1], R. Joseph[1], N. B. Jennings[1], M. S. Kim[1], Y. Wen[1], E. Bayraktar[1], N. Zhang[2], Z. An[2], A. K. Sood[1];
[1]University of Texas MD Anderson Cancer Center, Houston, TX, [2]University of Texas Health Science Center at Houston, Houston, TX

Background: Ovarian carcinomas are known to have a high degree of immune suppression, which may be related, in part, to high levels of vascular endothelial growth factor-A (VEGF-A). Bevacizumab (anti-VEGF antibody) has been shown to increase infiltration of T-cells in the tumor microenvironment (TME). We have also identified EGFL6 as an important angiogenic protein. Here, we examined the biological effects of blocking EGFL6 and VEGF-A in ovarian cancer models.
Methods: We studied the *in vitro* (endothelial tube formation and migration assays) and *in vivo* (ID8$^{KO\text{-}Trp53;Brca2}$ and SKOV3-ip1 models) biological effects of EGFL6 and VEGF-A blockade. Tumor-infiltrating immune cells were studied by flow cytometry and immunohistochemistry staining.
Results: Blocking EGFL6 and VEGF-A simultaneously with monoclonal antibodies in RF24 endothelial cells decreased tube formation and migration significantly, in comparison to VEGF-A blockade alone ($p<0.001$). EGFL6 monotherapy in ID8$^{KO\text{-}Trp53;Brca2}$ tumor bearing syngeneic mice decreased tumor burden (~2.5 fold, $p<0.0001$) and increased the infiltration of IFNγ^{+} (~2.75 fold, $p<0.0001$) and GzmB^{+} (~1.75 fold, $p<0.01$) CD8^{+} T-cells and IFNγ^{+} (~2 fold, $p<0.0001$) and GzmB^{+} (~2 fold, $p<0.01$) CD4^{+} T-cells while decreasing PD-L1^{+} cells (~1.8 fold, $p=0.01$). Dual blockade of EGFL6 and VEGF-A in SKOV3-ip1 tumor bearing nude mice significantly decreased tumor burden (~3.72 fold, $p<0.01$) and angiogenesis (~2.36 fold, $p<0.05$) compared to controls and single-agent blockade. Similar blockade in ID8$^{KO\text{-}Trp53;Brca2}$ tumor bearing mice significantly decreased tumor burden (~4.2 fold, $p=0.0004$), improved CD8^{+} (~3.32 fold, $p=0.0004$) and CD4^{+} (~2.81 fold, $p<0.0001$) T-cell infiltration, NK cell infiltration (~2.3 fold, $p=0.0005$) and decreased myeloid-derived suppressor cells (MDSCs) (~1.92 fold,
$p=0.0278$) compared to EGFL6 and VEGF-A blockade alone.
Conclusions: Our results demonstrate that simultaneously targeting the angiogenesis drivers EGFL6 and VEGF-A in ovarian cancer significantly decreased tumor burden *in vivo* and increased the infiltration of T lymphocytes compared to single-agent blockade.
AACR Category: Tumor Microenvironment and Immune Oncology
Key words: ovarian cancer, immune suppression, angiogenesis, VEGF-A, EGFL6

#3848 Comprehensive protein analysis to identify the proteins responsible for sarcopenia and their impact on antitumor immunotherapy in non-small cell lung cancer.

T. Masuda[1], S. Watanabe[1], T. Wakabayashi[1], S. Tanaka[1], K. Shono[1], R. Suzuki[2], T. Sekiya[1], N. Yanagimura[1], M. Arita[1], A. Ohtsubo[1], T. Tanaka[1], K. Nozaki[1], Y. Saida[1], S. Hokari[1], R. Kondo[1], K. Shima[1], Y. Kimura[1], N. Aoki[1], Y. Ohshima[1], T. Koya[1], K. Sakai[3], K. Nishio[3], M. Yamazaki[1], H. Ishikawa[1], T. Kikuchi[1];
[1]Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan, [2]Sado General Hospital, Sado, Japan, [3]Kindai University Faculty of Medicine, Osaka, Japan

Background: Previous retrospective studies have shown that sarcopenia (Sar) is associated with poor outcome in cancer patients (pts) receiving immune checkpoint inhibitors (ICIs). We conducted a prospective study to determine whether Sar-related proteins induce Sar and reduce the efficacy of ICI.
Method: Non-small cell lung cancer (NSCLC) pts receiving ICI as first-line treatment at Niigata University Medical and Dental Hospital were eligible. Sar was diagnosed with physical performance and skeletal muscle mass. Comprehensive protein analysis of pre-treatment blood samples was performed to identify factors that correlate with muscle loss and ICI effects.
Result: 41 patients were enrolled from October 2019 through August 2022. PFS for Sar was 4.6 months, 6.7 months for Pre-Sar, and 16.7 months for Non-Sar (P=0.0028). OS for Sar was not reached, 15.7 months for Pre-Sar, and not reached for Non-Sar (P=0.0014). Leptin, IL-1β, IL-12, and Pentraxin 3 were significantly correlated with loss of muscle mass. In contrast, leptin, insulin, IGF-1, GDF-8, Activin A, IL-2Ra, IL-8, MMP-3, osteopontin, and Pentraxin-3 were significantly associated with poor OS. Pentraxin 3 and leptin were associated with both the effectiveness of immunotherapy and sarcopenia. A multivariate analysis that considered factors commonly associated with the effectiveness of immunotherapy, including age, PD-L1 expression rate, and neutrophil-lymphocyte ratio, Pentraxin 3 was determined to be an independent prognostic factor.
Conclusion: This study indicated that Sar-related proteins and inflammatory cytokines are involved in the development of Sar and ICI efficacy.

#3849 Frontline ibrutinib-based therapy enhances CART cell functions in patients with CLL: Analysis of the phase 3 randomized clinical trial ECOG-ACRIN E1912.

T. N. Huynh[1], V. Wang[2], T. Shanafelt[3], E. L. Siegler[1], C. M. Stewart[1], K. Yun[1], L. K. Mai[1], O. Sirpilla[1], J. H. Girsch[1], C. Manriquez-Roman[1], J. M. Feigin[1], M. Rodriguez[1], B. L. Kimball[1], H. Xia[1], R. L. Sakemura[1], I. Can[1], O. L. Gutierrez-Ruiz[1], E. J. Ogbodo[1], E. E. Tapper[1], L. A. J. Fonkoua[1], M. T. Hefazi[1], M. W. Ruff[1], S. Parikh[1], N. E. Kay[1], S. J. Kenderian[1];

[1]Mayo Clinic, Rochester, MN, [2]Dana-Farber Cancer Institute, Rochester, MN, [3]Stanford University School of Medicine, Stanford, CA

Introduction: Despite the remarkable activity of CD19-directed chimeric antigen receptor T cell therapy (CART19), durable remissions remain low, especially in chronic lymphocytic leukemia (CLL). Ibrutinib is an oral irreversible inhibitor of Bruton's tyrosine kinase and is a first line therapy for CLL. Preclinical and early clinical data indicate that ibrutinib plus CART19 may be synergistic through inhibition of IL2-inducible T cell kinase. To systematically study the effects of prior ibrutinib treatment on subsequent CART functions, we utilized blood samples from the pivotal clinical trial E1912 (NCT02048813). E1912 was a phase 3 randomized trial comparing treatment with ibrutinib/rituximab (IR) to fludarabine/cyclophosphamide/rituximab (FCR) in previously untreated patients with CLL, which led to the FDA approval of ibrutinib as a first-line therapy in CLL.

Methods: We evaluated the ex vivo expansion and effector functions of T cells and CART19 generated from patients (n=12) with CLL progression following treatment with IR or FCR. We generated CART19 from longitudinal samples obtained at baseline (pretreatment), 6 months post-treatment, 12 months post-treatment, and disease progression. Isolated T cells were lentivirally transduced to express CD28- or 41BB-costimulated CAR19. To assess antigen specific killing and proliferation, untransduced T cells or CART19 were co-cultured at a 1:1 ratio with the CD19+ cell line, JeKo-1, as a surrogate for CLL cells.

Results: Ex vivo T cell expansion increased from an average of 1.5-fold at baseline to 6.7-fold at 6 months, 11.6-fold at 12 months, and 16.9-fold at progression, following ibrutinib-based therapy ($p = 0.02$, 0.04, and 0.04, respectively). Improved T cell expansion was independent of disease burden ($p = 0.89$, 0.73, and 0.54 for expansion vs B cell count at 6 months, 12 months, and progression). T cell expansion significantly worsened following treatment with FCR-based therapy compared to ibrutinib-based therapy (0.6- vs 11.6-fold at 12 months and 0.9- vs 16.9-fold at progression; $p = 0.031$ and 0.039, respectively). Starting at 6 months post-IR, CART19 demonstrated improved antitumor activity and antigen-specific proliferation against JeKo-1. There was no significant difference in the expansion of 41BB- vs CD28-costimulated CART19 following ibrutinib treatment. However, 41BB-CART19 showed enhanced antigen-specific proliferation upon stimulation with JeKo-1 ($p = 0.008$, 0.02, and 0.02 at 6 months, 12 months, and progression).

Conclusion: Our results indicate significant improvement in T cell expansion and CART19 cell functions in patients with CLL following frontline ibrutinib-based therapy, and worsening T cell functions after FCR treatment. Improvement in T cell functions is independent of malignant B cell eradication and is more significant in 41BB-costimulated CART19.

#3850 Modeling individual variability in CD19 CAR-T therapy: An *in vivo* study with PBMC-humanized mice.

W. Lee, D. Rose, J. G. Keck, J. Yang;
The Jackson Laboratory-West, Sacramento, CA

Chimeric antigen receptor T-cell (CAR-T) therapy targeting CD19 has emerged as a transformative treatment for hematological malignancies. Despite its efficacy, significant inter-patient variability in response and associated toxicities pose challenges for its broader application. Understanding these variations is critical to optimize therapy and predict outcomes. This study aims to capture the individual variability observed in CD19 CAR-T cell therapy responses using PBMC-humanized mouse model, with a focus on efficacy, expansion, and cytokine induction profiles. Three human PBMCs (Donors A, B, C) used throughout the studies were pre-screened for in vivo cytokine induction and humanization levels. Autologous CD19 CAR-Ts with a CD28 costimulatory domain and CD3z chain were generated with varying transduction rates: 92%, 52%, and 95% for Donors A, B, and C, respectively. In the first experiment, irradiated female NSG™-MHC I/II double knock-out (DKO) mice were reconstituted with human PBMCs. Six days post humanization, the mice were treated with equal total number of autologous CAR-Ts. All three CAR-Ts showed efficacy, eradicating CD19 cells in peripheral blood. We observed a moderate but significant body weight loss only in mice treated with Donor B autologous CAR-Ts. Notably, CAR-T expansion varied across three donors and did not correspond with the purity (% transduction) of CAR-Ts. Donor B CAR-Ts with the lowest purity showed the highest CAR-T expansion. Donor B PBMCs resulted in the highest humanization level of CD19+ cells and we hypothesize that more CD19 targets led to higher CAR-T expansion. By measuring 33 cytokines from sera collected 2 days post treatment, we explored if human cytokine induction corresponded to the CAR-T expansion. Contrary to initial expectations, cytokines typically associated with robust CAR-T expansion, such as IL-2, IL-6, IL-10, IFNγ, and TNFα, did not peak in the Donor B cohort. To see if individual variability in efficacy and CAR-T cell expansion shows similar variation with increased targets of CD19 CAR-Ts, we engrafted DKO mice with B cell lymphoma (Raji-luc). Seven days after tumor engraftment, we humanized mice with Donor A, B, or C PBMCs and subsequently treated mice with autologous CAR-Ts. Donor A showed the fastest clearance of Raji-luc measured by IVIS bioluminescence imaging. In parallel with the previous experiment, we observed that Donor B CAR-Ts showed the highest expansion level among the three CAR-Ts. The study illustrates how a PBMC-humanized mouse model can reflect the variability in patient responses to CD19 CAR-T therapy. This model serves as a valuable tool for further investigation into the complex dynamics of CAR-T efficacy and toxicity, potentially guiding more tailored approaches in treatment design.

#3851 Beta-lapachone promotes tumor associated neutrophils (TANs) polarized towards anti-tumor (N1) phenotype.

X. Huang[1], S. Tumbath[1], L. Jiang[1], Y.-X. Fu[2];

[1]Indiana University School of Medicine, Indianapolis, IN, [2]University of Texas SouthwesternMedical Center, Dallas, TX

NAD(P)H:quinone oxidoreductase1 (NQO1) is overexpressed in most solid cancers, emerging as a promising target for tumor selective killing. β-lapachone (β-lap), an NQO1bioactivatable drug, exhibits significant antitumor effects on NQO1^{+} human solid cancer cell lines. It also induces immunogenic cell death in the tumor microenvironment (TME)and synergizes with anti-PD-L1 immunotherapy. However, the interaction between β-lap-mediated anti-tumor immune response and neutrophils, a novel antigen presenting cells(APCs), remains unknown. This study found β-lap treatment increased intracellular ROS formation and DNA damage to kill NQO1^{+} murine tumor cell lines and dicoumarol spared the lethality. Furthermore, flow cytometric analysis of immune cells in TME of subcutaneous tumor models indicated that there is a significant infiltration of neutrophils(CD11b^{+} Gr1^{high} cells) or Tumor Associated Neutrophils (TANs) following β-lap treatment. Depletion of neutrophils by co-addition of anti-Ly6G antibody abolished β-lap-induced anti-tumor efficacy in immune competent mice. Neutrophil mediated tumor cell killing determined *ex vivo* using bone marrow derived neutrophils and it was observed that in the presence of β-lap induced antigen, neutrophils were killing murine tumor cells. Moreover, exposure of these neutrophils to β-lap induced antigen medium induce antitumor N1-like properties, include increase in certain surface markers such as CD95(Fas) and CD54 (ICAM-1) as well as increase in intracellular cytokine IFN-β and decrease in TGF-β revealed by flow cytometric analysis. Corroborating to this, there is a significant increase of CD95 and IFN-β and a decrease in TGF-β were observed with TANs infiltrated into β-lap treated TME compared to vehicle treated tumors. Additionally, TLR/MyD88signaling deficiency decreased β-lap induced neutrophil tumor infiltration. BlockingHMGB1, depleting neutrophils, or TLR4/MyD88 deficiency lessened the antigen-specific T cell response. This study highlights that β-lap kills NQO1^{+} murine tumor cells through ROS production and DNA damage, and neutrophils play a pivotal role in its antitumor effects.

#3852 Comprehensive genomic profiling of recurrent or metastatic head and neck cancer presenting with combined positive score 90 or more.

Y. Saito, K. Hidenori, K. Kobayashi, O. Fukuoka, K. Yamamura, A. Shinozaki-Ushiku, K. Oda, K. Kondo;
University of Tokyo, Tokyo, Japan

Background. Biomarkers that predict response to immune checkpoint inhibitor (ICI) in recurrent metastatic squamous cell carcinoma of the head and neck (RMHNSCC) are not well known. Previously, we have found that Combined positive score (CPS) ≥90 and albumin >3.5 respond well to ICI treatment in patients with RMHNSCC treated with ICI irrespective of addition of chemotherapy. In the present study, we investigated whether RMHNSCC with CPS ≥90 has a characteristic genomic mutational profile.

Methods. CPS measurements were performed on a single tumor specimen at the time of diagnosis of RMHNSCC, as approved by Japanese health insurance. Tumor specimens were obtained from the primary tumor as much as possible, and sections that best reflected anti-tumor immunity were decided by a pathologist. We retrospectively reviewed the results obtained from comprehensive genomic profiling (CGP) testing of RMHNSCC cases with CPS ≥90 who were treated by ICI experienced at our institution.

Results. There were 117 eligible RMHNSCC cases. The number of primary lesions were oral cavity in 28 cases (23.9%), nasopharynx in 10 cases (8.5%), oropharynx in 21 cases (17.9%), hypopharynx in 33 cases (28.2%), and others in 18 cases (15.4%). Of 117 patients, 28 patients (23.9%) had a CPS ≥90. Of the 28 cases, the number of primary lesions were oral cavity in 12 cases (42.9%), nasopharynx in 4 cases (14.3%), oropharynx in 0 cases (0%), hypopharynx in 8 cases (28.6%), and others in 3 cases (10.7%). When ICI was administered, CPS ≥90 had a statistically significantly better prognosis than CPS <90 for OS and PFS. Of the 28 cases with CPS ≥90, CGP test was performed in 6 cases. The primary lesions in the 6 cases consisted of 3 oral cavity, 2 nasopharynx, 1 hypopharynx, and 1 maxillary sinus. All three oral primary cases had co-mutations in the *TERT* promoter and *HRAS*. Two of the nasopharyngeal primary cases had mutations in JAK3 and STAT, respectively. One of the hypopharyngeal primary cases had mutations in FGFR3.

Conclusion. RMHNSCC with CPS ≥90 had unique mutations that could account the enhanced PD-L1 expression, such as *TERT/HRAS* co-mutation, JAK-STAT pathway mutation, and *FGFR* pathway mutation. The above findings may be useful for predicting the efficacy of ICI for RMHNSCC.

#3853 T cell ferroptosis attenuates antitumor immune responses in sickle cell disease.

Z. Zhao[1], B. Hu[2], Y. Deng[1], M. Soeung[1], G. Genovese[1], W. Li[2], P. Msaouel[1], L. Yang[1], C. Lin[1];
[1]UT MD Anderson Cancer Center, Houston, TX, [2]University of Texas Health Science Center, Houston, TX

Background: Sickle cell disease (SCD) is the most common inherited blood disorder and arises from homozygosity for the HbS mutation (GAG>GTG: βGlu6Val) leading to the production of abnormal hemoglobin that cause sickle shaped red blood cells (RBCs). Individuals with SCD are at higher risk than the general population for developing hematologic malignancies or solid tumors such as renal medullary carcinoma (RMC). Although relatively rare, RMC is one of the most aggressive kidney cancers and is the third most common kidney cancer among children and young adults who harbor sickle hemoglobinopathies such as SCD or sickle cell trait (SCT) which occurs due to heterozygosity for the HbS mutation. Molecular profiling studies have shown that most cases involve biallelic inactivation of the *SMARCB1* gene, either through simultaneous hemizygous loss and translocation or by homozygous loss. The loss of *SMARCB1* and subsequent dysregulation of chromatin remodeling are key factors contributing to the development and progression of renal medullary carcinoma. Despite manifesting an inflamed tumor immune microenvironment, RMC consistently demonstrates resistance to conventional immune checkpoint inhibitors (ICI). Ameliorating the efficacy of immunotherapy of RMC is vital for research and potential therapeutic interventions by targeting $CD8^+$ T cells.

Methods: CyTOF was performed by using the spleen of WT mice and SCD mouse model. mRNA was isolated from $CD8^+$ T cells of Peripheral Blood Mononuclear Cell (PBMC) collected from healthy donors and SCD patients followed by bulk RNA sequencing. Hi-C was conducted using $CD8^+$ T cells isolated from PBMC of healthy donors and SCD patients. We employed DNA FISH (Fluorescence in Situ Hybridization) to examine alterations in gene architecture within $CD8^+$ T cells under varying conditions.

Results: RMC tumors exhibit accelerated tumor growth and reduced numbers of tumor resident $CD8^+$ T cells in SCD mice model compared with WT control. $CD8^+$ T cells in the SCD associated tumor microenvironment (TME) are subjected to ferroptosis by downregulation of *SLC7A11*; however, *SMARCB1* loss promotes the resistance of RMC tumor cells to ferroptosis. Genomic architecture of $CD8^+$ T cells is altered under SCD conditions, potentially contributing to immune dysfunction.

Conclusions: Our research has identified significant alterations in the 3D genome architecture of $CD8^+$ T cells in individuals with SCD. These alterations lead to transcriptional inhibition of *SLC7A11*, resulting in $CD8^+$ T cell ferroptosis and a hindered anti-tumor immune response in RMC. These findings elucidate the mechanistic relationship of SCD with ICI resistance in cancers such as RMC and provide novel avenues for therapeutically sensitizing tumors to immunotherapies in individuals with SCD.

Keywords: Sickle Cell Disease, Renal Medullary Carcinoma, SMARCB1, Ferroptosis, Genomic Architecture Alteration, Hi-C, SLC7A11

#3854 Revealing mismatch repair deficiency in Egyptian colorectal cancer patients using next generation sequencing a predictive biomarker for immunotherapy efficacy.

A. S. Youssef[1], M. Ragab[1], H. A. Ateya[1], M. Elberry[1], N. Fathy[1], A. Elleithy[2], A. Zekri[1], **O. S. Ahmed**[1], A. Nassar[1];
[1]National Cancer Institute, Cairo, Egypt, [2]Must University, Cairo, Egypt

Background: The mismatch repair (MMR) deficiency is a potential predictive biomarker for immunotherapy efficacy, particularly in colorectal cancer (CRC), where alterations in various DNA polymerases and MMR genes are prevalent. The accumulation of these genetic aberrations may cause a subsequent neoantigen formation. study aimed to identify the mutational profile of DNA polymerases and MMR genes in Egyptian CRC patients', providing insights into colorectal carcinogenesis and potential implications for immunotherapy.
Material and Methods: Thirty-nine blood samples from Egyptian patients with CRC and twenty-four blood samples from healthy controls were collected. The libraries were prepared by Qiaseq UMI-based targeted panel and sequenced via an Ion proton sequencer. The detected genetic variants with an average coverage of 500x were annotated against Cosmic, dbSNP, and ClinVar databases using Ingenuity Variant analysis (IVA).
Results: Our results revealed that the POLD1andPOLE genes (DNA polymerases) in the CRC patients, when compared with healthy controls, harbored 10 and 13 pathogenic variants (PVs), respectively. These PVs cause a loss of their functionality. The most frequently detected PVs and likely to be novel in the POLD1gene werec.44delC(31%)andc.3008delG(31%), while c.3510delA(18%)andc.2793delT(15%) were detected in the POLE gene. As per MMR genes, our study showed that the MLH1, MLH3, MSH2, MSH3, MSH6, PMS1,and PMS2 harbored 8, 13, 23, 19, 22, 23, and 7 PVs, respectively. The highly frequent PV in the MLH1wasc.469delT (26%), while the novel most frequently detected PV in the MLH3 wasc.1467delA (23%). Moreover, the PVs found highly frequent are c.2647delA (36%) in MSH2,c.1148delA (41%)in the MSH3, and c.2079delA (44%) in the MSH6. RegardingPMS1/2, the most frequently detected PV and likely to be novel was c.1647delA (44%) in PMS1, while c.869delT (13%) was the most prevalent PV in PMS2.
Conclusion: Our results revealed the MMR mechanism deficiency in Egyptian CRC patients offering crucial insights into colorectal carcinogenesis and neoantigen formation. These insights are pivotal for developing ethnic-based personalized immunotherapy strategies in Egyptian CRC patients, shedding light on their role in CRC. Interestingly, we have identified novel variants in the DNA repair enzymes. However, further investigations and validations are required to corroborate these findings and explore their clinical significance in the personalized medicine.

#3855 Kinetics of neoantigen-specific T cells in post-transplant relapse.

B. Neupane, J.-E. Lee, K. Ventura, K. Parr, K. Quann, **S. Ito**;
University of Pittsburgh School of Medicine, Pittsburgh, PA

Introduction: Graft-versus-leukemia effect (GVL) underpins the curative mechanism of allogeneic stem cell transplantation (alloSCT) for acute leukemias. Donor-derived T cells can recognize various antigens, including human leukocyte antigen (HLA), minor-histocompatibility antigens (miHA), over-expressed antigens, or neoantigens derived from somatic mutations of leukemia. However, the role of neoantigens has not been fully investigated in GVL. Here, we aimed to predict neoantigens and identify neoantigen-reactive T cells using samples after alloSCT. Materials: Leukemia blasts were purified from relapsed samples. Recipient saliva or T cells from pre-transplant peripheral blood (PB) were used as a recipient germline control, while donor monocyte or CD34 cells were used as donor controls. DNA/RNA isolated from these specimens were analyzed for whole exome sequencing (WES) paired with RNAseq. Somatic mutations were called using blasts and recipient germline controls by mutect and mpileup and annotation with SnpEff. Somatic mutations with variant allele frequency >20% were screened for neoantigen prediction bound to recipient HLA (IC50 < 500nM) by pVAC-seq. We also genotyped 73 SNPs associated with publicly known miHAs. Serial PB were stained for HLA-A*02:01 tetramers loaded with neoantigens or CMVpp65. T cells were stimulated with neoantigens for 10 days and tested for cytokine production in responses to target or control peptides. Results: We screened neoantigens in 8 patients relapsing after alloSCT (7 acute myeloid leukemia and 1 acute lymphoblastic leukemia) and their donors (4 matched siblings, 1 matched unrelated, 3 haploidentical). In 7 subjects, WES/RNAseq showed an average of 273 somatic mutations per patient (range 108- 609). In one subject, targeted next-generation sequencing was used to detect 2 somatic mutations. Among these mutations, seven out of eight subjects (87.5%) had potential neoantigen candidates, with a median number of 9 antigens per subject. In contrast, only 2 subjects (25%) had potential miHA. UPN8, a responder to donor lymphocyte infusion (DLI), showed dominant CMVpp65-specific T cells at the time of relapse and emergence of TP53- (neoantigen) or HA-2- (miHA) specific T cells after relapse. HA-2-specific T cells upregulated PD-1 expression at the time of graft-versus-host disease (GVHD), indicating activation of these miHA-specific T cells during GVHD. In two subjects (UPN3 and UPN8) who achieved long-term remission after DLI, CD8 T cells specific to neoantigens were detectable by IFN-γ/CD107a production in reaction to mutant peptides (*SDE2*.pK123X or *TP53*.pR248W) from post-relapse samples. Discussion: Our study showed the feasibility of in-silico neoantigens prediction and neoantigen-specific T-cell detection from a subject who developed relapse after alloSCT. Further investigation is needed to test if neoepitope burden and miHA disparity could correlate with transplant outcomes.

#3856 Nodal metastasis as an immune indicator in cancer (ca) therapy.

B. Fugere, J. Chen, T. C. Fugere, F. Mazahreh, N. Thalambadu, A. Safar;
University of Arkansas for Medical Sciences, Little Rock, AR

Introduction: Nodal Metastasis as an Immune Indicator in Cancer (Ca) Therapy Staging (sg) is widely used to identify appropriate treatment options & implement therapy. Tumor-Node-Metastasis (TNM) is the most utilized sg system. In it, nodal involvement is viewed simply as an adverse metric without biologic connotation, and gross metastasis (M1) eclipses other variables and denotes the least favorable sg. Ca's ability to thrive within the lymph node itself was intriguing to us in the immune-oncology (IO) era. Failure to overcome an immunogenic ca (e.g., dysfunctional apoptosis) leads to T-cell exhaustion (TCE) typified by PD-1 expression. Immune Checkpoint Inhibitors (ICI) address TCE by intercepting the PD-1:PDL-1 synapse. We reasoned that immune actions are distinct in tumor beds vs nodes & hypothesized that immunogenic N(+), implies ca's ability to defend itself (e.g., PDL-1 expression); N(0), reflects immune susceptibility and effective clearance outside the tumor bed. In the latter scenario, TCE is nonexistent; ICIs are less beneficial. Tumor beds (T, M) are sanctuaries exempt from immune action due to factors such as hypoxia, acidity, and poor tumor vasculature which lead to poor T-cell trafficking, to name a few. M1 develop from circulating ca stem cells, an immune-exempt entity.

Methods: We examined the interaction between ICIs & nodal involvement dichotomizing surveillance, epidemiology and end results SEER cases into N(0) or N(+) within M1 melanoma & lung cancer. 2005, 2015-17 denote pre-, and post ICI, respectively to provide mature survival data.

Results: Table 1 depicts the 4- or 5-year overall survival in the specified subsets.

	Expectations		SEER results: % Overall Survival at 5-y (melanoma) or 4-y (Lung ca)			
				Pre-ICI	Post ICI	Metric
Melanoma		Mechanism		2005	2015	Increment in 5yr OS
	N(0) favorable prognosis	Immunogenic tumor	N(0): 302 cases	20	29	8 (20 -12)
	N+ Predicts benefit to ICI	T-cell exhaustion in N(+) only	N(+): 210 cases	12	37	N(+): +25 > N(0): +9
				2005	2017	Increment in 4yr OS
Lung Cancer	N(0) similar to N(+)	Less immunogenic tumor	N(0) 9,583 cases	18	18	4 (18 -14)
	N+ Predicts benefit to ICI	T-cell exhaustion in N(+) only	N(+): 17,887 cases	14	20	+6

Conclusions: ICI benefit is more prominent in N(+) ca, where TCE is likely. N(0) ca represents immune-prone ca with less TCE & need to be viewed as a biologically distinct subset. Agents influencing T-cell access (angiogenic)/functionality should be considered in these cases. Finally, we suggest that PDL-1 testing should specify testing sites as nodal vs tumor bed expression.

#3857 Tumor-extrinsic BIRC3 promote sensitivity to checkpoint inhibition immunotherapy in breast cancer.

D. Yang, **J. Sun**, G. Ren, H. Li;
The First Affiliated Hospital of Chongqing Medical University, Chongqing, China

Baculoviral IAP repeat containing 3 (BIRC3) protein play a critical role in breast cancer. Blocking BIRC3 cause apoptosis in tumor cells, but its correlation with tumor immunity remains elusive. TCGA databases were employed to examine the expression of BIRC3 in breast cancer. The correlation between BIRC3 expression and T cell infiltration and function was employed in breast cancer tissues (n=92) by immunohistochemistry. Birinapant, a selective BIRC3 inhibitor, was then used to investigate the effect of BIRC3 blockade on tumor immune microenvironment (TIME) landscape of breast cancer syngeneic mouse models by flow cytometry. Survival analysis suggested that the low expression of BIRC3 was associated with poor overall survival (OS). Additionally, we uncovered the close association between BIRC3 expression and the profiles of immune cells in breast cancer microenvironment based on the TCGA dataset. Interestingly, we found that BIRC3 expression was positively correlated with cytotoxic T lymphocyte infiltration and T-cell effector function by immunohistochemistry. The in vivo experiments suggested that blocking BIRC3 might convert ‘hot’ tumor into ‘cold’ tumor, which was characterized by a decreased of $CD8^+$ T cell infiltration and inhibition of $CD8^+$T cell function. Furthermore, we observed that BIRC3 blocking combined with immune checkpoint blockade therapy (ICT) greatly restrains immunotherapy efficacy of breast cancer model. Our study revealed a positively association between BIRC3 and anti-tumor immune landscape in breast cancer. Notably, we established a validated prognosis model based on BIRC3 and BIRC3 associated immunomodulators in breast cancer.

#3858 Peripheral CD38+ effector memory (EM) T cells are dynamic biomarkers of response to neoadjuvant immune checkpoint blockade (NeoICB) in patients (pts) with resectable dedifferentiated liposarcoma (DDLPS) and undifferentiated pleomorphic sarcoma (UPS).

E. F. Nassif, H. Lu, M. Stanford, K. Millerchip, D. Romero, J. Malke, B. Matejka, J. E. Gershenwald, S. Kumari, D. H. Mak, A. J. Lin, J. K. Burks, W.-L. Wang, A. J. Lazar, N. Somaiah, C. Haymaker, C. L. Roland, **E. Z. Keung**;
UT MD Anderson Cancer Center, Houston, TX

Introduction: NeoICB is a promising approach for pts with DDLPS and UPS. However, biomarkers to identify which pts benefit from this treatment and understanding the mechanisms of response and resistance to ICB remains a challenge. **Methods:** We conducted a randomized phase 2 trial of neoICB (anti-PD1 +/- CTLA4) in pts with resectable DDLPS (n=17) and UPS (n=10). Pts with UPS received concurrent neoICB and radiation. The primary endpoint of the trial was pathological response; 3 DDLPS and 9 UPS pts were responders (R) and 14 DDLPS and 1 UPS pts were non-responders (NR). Peripheral blood mononuclear cells (PBMCs) were collected at baseline, prior to cycle 2 of neoICB (C2D1), and at the time of surgery (SURG). We performed mass cytometry (CyTOF) to identify immune cells associated with response and their dynamic changes with neoICB. We designed a custom 41-parameter panel using CD45 live cell barcoding with 31 markers for immune profiling, of which 23 were selected to detect key cell lineage and 8 to detect signaling markers. Batch correction and high dimensional data analyses were performed using CyCombine and CyTOF workflow R packages. Longitudinal comparisons between immune cell populations were conducted using Mann-Whitney U Test. **Results:** Of 79 available PBMC samples from 27 pts, 63 passed quality control after thawing (≥30% viability) and data clean-up (at least 10,000 events). Data was down-sampled to 5000 events for analysis. Of 19 immune cell types identified, monocytes were the most common followed by CD4+ and CD8+ T cells. There was an early increase in CD38+ effector/effector memory (EM) T cells at C2D1 in pts with DDLPS (CD8+ $p=0.005$, CD4+ $p<0.001$) and a similar increase observed in pts with UPS (CD8+ C2D1 p=NS, SURG $p=0.034$; CD4+ C2D1 $p=0.024$, SURG $p=0.06$) and these cells had higher Ki67 expression than CD38- T cells ($p<0.005$). At baseline, R pts with DDLPS had higher fractions of CD38+ EM CD8+ T cells than NR pts ($p=0.044$). Analysis in the UPS cohort was limited by the low number of NR pts. Higher expression of TIGIT was observed on CD38+ EM CD8+ T cells compared to CD38- counterparts at all time points. **Conclusion:** Peripheral CD38+ EM CD8+ T cells are associated with response to neoICB in pts with DDLPS. Longitudinal peripheral immune profiling reveals an increase in CD38+ EM CD8+ and CD4+ T cells with neoICB in pts with DDLPS and UPS. These cells are proliferative and express higher levels of TIGIT, which could be a future target for therapeutic exploration. Importantly, changes in the peripheral immune populations may precede changes in the tumor microenvironment (TME) as preliminary analyses of the TME did not identify early (C2D1) changes. TME imaging mass cytometry analyses are currently underway to associate peripheral and intratumor changes in immune populations.

#3859 HSP90 blockade activates antitumor immunity by suppressing tumor glycolytic flux in head and neck squamous cell carcinoma.

F. Chen, C. Tang, F. Yang, A. Ekpenyong, R. Qin, N. F. Saba, **Y. Teng**;
Emory University, Atlanta, GA

Accumulating evidence suggests that failure of antitumor immunity may be due to dysregulation of energy metabolism. Head and neck squamous cell carcinoma (HNSCC) exhibits increased activity of two key enzymes, pyruvate kinase M2 (PKM2) and platelet phosphofructokinase (PFKP), which are central to the glycolytic pathway responsible for the conversion of glucose to ATP energy. HSP90 is a molecular chaperone that plays a critical role in the folding, stabilization, and regulation of a wide range of client proteins involved in various cellular processes, including metabolism. However, whether HSP90 signaling contributes to tumor metabolism rewiring and antitumor immune response remains unknown. Using ganetespib as a drug model for HSP90 inhibition and combining results from clinical trials and animal treatment, our study demonstrated that HSP90 inhibition causes an obstruction of glycolytic flux in HNSCC cells by simultaneously suppressing both PKM2 and PFKP at the transcriptional and post-translational levels. In addition, ganetespib enhances T cell-driven antitumor immune responses by promoting CD8+ T cell infiltration into the tumor. Mechanistically, ganetespib downregulates IL8 signaling by inhibiting PKM2 and PFKP-mediated glycolysis in HNSCC cells, which in turn contributes to ganetespib-mediated T cell tumor infiltration. These findings provide a novel molecular basis for the use of effective HSP90 inhibitors to improve the outcome of HNSCC patients.

#3860 Characterizing peripheral immune correlates of tumor response in breast cancer patients immunized with the P10s-PADRE vaccine.

F. Jousheghany[1], J. P. Lee[1], B. Nounamo[1], V. Raj[2], J. L. Faulkner[1], E. Siegel[1], I. Makhoul[3], T. Kieber-Emmons[1], **B. Monzavi-Karbassi[1]**;
[1]University of Arkansas for Medical Sciences, Little Rock, AR, [2]University of Arkansas at Pine Bluff, Pine Bluff, AR, [3]Central Arkansas Radiation Therapy Institute, Inc, Little Rock, AR

Introduction: We demonstrated that vaccination of HR+/HER2− breast cancer subjects with P10s-PADRE cancer vaccine in combination with standard-of-care chemotherapy led to generation of antibodies (Ab), activation of Natural Killer (NK) and T cells, increases in IFNγ and TNFα, and increases in TILs and stromal CD3+ T cells. The current study was conducted to assess the vaccine's efficacy, particularly focusing on tumor shrinkage and pathologic Complete Response (pCR). Additionally, it aims to explore the association of specific peripheral-blood immune responses, such as antibody levels and NK and T-cell activation, with pCR and objective reduction in primary tumor size.
Methods: Blood samples collected at baseline and after treatment of at least 25 subjects were used in characterization of immune responses. Serum and plasma samples were used in ELISA, cytokine, and glycan-array assays to measure anti-peptide and anti-glycan antibodies and blood-cytokine levels. Peripheral blood mononuclear cells (PBMCs) were interrogated by RNA-seq, flow cytometry, and ELISpot assays.
Results: We observed that high levels of anti-peptide and anti-GD2 antibody responses correlated with pCR. Ab response was positively correlated with differential expression of CD56, GZMA, IFNγ, NKp46, and CD8b, among which GZMA and NKp46 showed a statistically significant association. Vaccine-induced functional cellular immune responses (measured by differential expression of IFNγ, GZMA, CD8, CD69, NKp46, CD56, and PRF1) correlated with reduction of primary tumor size. We also observed substantial differences among immune responders vs non-responders in immune gene expression and in cytokine production in post-immune PBMCs after specific and polyclonal stimulation.
Conclusions: The data suggest that immunization of HR+/HER2− breast cancer patients with P10s-PADRE in combination with chemotherapy leads to both humoral and cellular immune responses. While induction of a robust antibody response is a good marker for potential clinical efficacy, vaccine-associated increases of the ratio of CD8+ cells and the expression of CD69, CD8b, GZMA, IFNγ, NKp46, and PRF1 seem to serve as additional efficacy indicators. Future studies are underway to validate these findings and establish reliable prognostic biomarkers.

#3861 Associations of intragenic rearrangement burden with immune cell infiltration and response to immune checkpoint blockade in cancer.

H. Zhang, S. Lee, R. Muthakana, B. Lu, D. Boone, D. Lee, **X. Wang**;
University of Pittsburgh School of Medicine, Pittsburgh, PA

While immune checkpoint blockade (ICB) induces durable cancer remission, only a small subset of patients can receive benefits, whereas a substantial portion of patients encounter severe immune-related adverse events. Further, about 4-29% of patients experience dramatic acceleration of disease progression after ICB treatment. Predictive biomarkers of ICB responses are in high demand to ensure patient benefits and avoid tragic clinical outcomes. In addition to PD-L1 tests, several genetic biomarkers are associated with ICB effectiveness, such as tumor mutation burden (TMB), somatic copy number aberrations, indels, and microsatellite instability. However, none of these neoantigen markers are sufficient to discriminate ICB responders in diverse cancer entities of distinct genetic profiles. In particular, TMB fails to predict in the cancer types with low simple mutation rates, such as triple-negative breast cancer (TNBC), ovarian cancer, and esophageal cancers. In TNBC, high TMB only accounts for 5-10% of patients, whereas a much larger proportion of tumors are inflamed (26-50%), which suggests a possible uncharacterized major source of neoantigens. Similarly, TMB is not predictive of ICB response in ovarian cancers according to the IMagyn050 trial. In esophageal cancer, TMB is not associated with T cell infiltration and does not predict ICB response. Our analyses of Pan-cancer whole genomes revealed that intragenic rearrangement (IGR) burden is a pivotal contributor to immune infiltration in breast, ovarian, esophageal, and endometrial cancers, which correlates with increased Macrophage M1 and CD8+ T cell signatures. IGRs result in exon duplications or deletions through rearrangements of a genomic distance of tens of kilobases. Multivariate regression against spatially counted tumor infiltrated lymphocytes in breast, endometrial, and ovarian cancers suggest that IGR burden is a more influential covariate than other genetic aberrations in these cancers. In the MEDI4736 trial evaluating durvalumab in esophageal adenocarcinoma, IGR burden correlates with patient benefits. In the IMVigor210 trial evaluating atezolizumab in urothelial carcinoma, IGR burden increases with platinum exposure and predicts patient benefits for TMB-low, platinum-exposed tumors. Altogether, we demonstrate that IGR burden contributes to T-cell inflammation and predicts ICB benefits in TMB-low, IGR-dominant tumors, or in platinum-exposed tumors. IGRs as a cryptic class of structural variants have been heretofore overlooked in cancer genomics studies. The association of IGRs with ICB response has not been previously reported in cancer in general. The development of IGR burden-based predictive marker could increase effectiveness of ICB therapy, reduce severe side-effects and unnecessary costs.

#3862 Identification, profiling and clonotypic tracking of tumor-reactive T cells derived from bronchoalveolar lavage in lung cancer patients.

H. Ryu, W. Sun, M. A. Wurscher, V. S. Nair, **E. W. Newell**;
Fred Hutchinson Cancer Center, Seattle, WA

Immunotherapeutic strategies for disinhibiting T cell responses have revolutionized lung cancer treatment. However, the identification of tumor-reactive T cells and the acquisition of adequate tissue for molecular and immune profiling remains a challenge that hinders our ability to adequately characterize the mechanisms of immunotherapy response versus resistance. To address this gap, we are investigating the use of bronchoalveolar lavage (BAL) as an alternative to blood or tumor biopsy samples to identify tumor reactive T cells.

We collected cells from a prospective bronchoscopic biorepository of patients undergoing lung cancer evaluation that were subjected to bilateral BAL, phlebotomy, and tissue sampling. We then employed flow cytometry and single-cell multi-omic analyses to identify, characterize and clonotypically track tumor-reactive T cells obtained from BAL, blood and tumor samples from lung cancer patients. Analysis of BAL samples revealed a significant enrichment of terminally exhausted $CD8^{+}CD39^{+}CD103^{+}$ T cells in BAL from tumor-bearing lungs compared to non-tumor bearing lung BAL and blood PBMCs in 14 patients. We then used single-cell sequencing-based multi-omics to deeply profile bilateral BAL cells, blood PBMCs and tumor tissues from 5 of these patients.

By tracking T cell receptor (TCR) sequences across patient-matched samples, we found BAL derived T cell clonotypes that expressed markers of terminal exhaustion, such as CD39 and CXCL13 in the tumor, which strongly implicates them as being tumor reactive and relatively abundant in BAL. Further validation through functional assays is being used to confirm the tumor reactivity of these clones.

These data demonstrate the feasibility of capturing tumor-specific T cells during bronchoscopy, providing promising opportunities for patient outcome characterization and exploration of novel therapies. This relatively non-invasive and practical test during routine bronchoscopy offers a cost-effective and safe alternative to identifying tumor-reactive T cells from surgical specimens or biopsies.

#3863 Flow cytometry using stabilized whole blood to assess innate and adaptive immune cells (Monocytes, NK, T, and B cells) in immunotherapies.

J. Benko, S. Splitt, **A. Bisconte**, L. Lozza, R. Owen, D. Phippard;
Precision for Medicine, Frederick, MD

Flow cytometry assays using fresh whole blood which are interrogating either an extremely rare cell subset or a depleting immunotherapy, may require samples to be processed from global clinical sites over a wide geographical area, which can pose a major challenge for clinical operations. Precision for Medicine (PfM) has addressed these operational challenges using commercial stabilizers which are added to the blood allowing samples to be frozen at -80°C and subsequently batch processed for sample testing. We have performed a fit for purpose assay qualification of a multiparameter flow cytometry panel allowing the immunophenotypic analysis of monocyte, T cell, B cell and NK immune populations using Cytodelics™ fixed/stabilized healthy donor whole blood. Additionally, the assay was verified in whole blood samples from multiple solid tumor disease states including melanoma, colorectal cancer, head & neck, non-small cell lung cancer to demonstrate clinical application. In these oncology samples, we were able to assess both immune cell frequencies and their activation status in both fresh whole blood as well as fixed whole blood over a short-term sample stability study, where the samples had been stored at -80°C for several months. This data provides a representative example of the use of commercial stabilizing fixatives for clinical studies to extend the stability window of whole blood for subsequent assessment by flow cytometry. Fixed whole blood can be stored at -80°C, shipped on dry ice allowing multiple timepoints in a cohort to be assessed together, thus minimizing assay variability as compared to fresh whole blood analysis, and mitigating the impact of shipping delays and temperature excursions on the samples. With sufficient time for assay development there are several commercial stabilizers that can be tested to determine if the markers in the flow assay are compatible with these reagents, providing a valuable option to assess the impact of immunotherapies on the immune cells of interest and reducing operational challenges in global studies.

#3864 Role of NK/TAM cross-talk on T-CD8+ recruitment and efficacy of chemoimmunotherapy and MEKi combination in "cold" tumors.

L. Nuttin[1], C. Latour[1], S. Revy[1], R. Aucagne[2], G. Lalle[1], F. Ghiringhelli[3], **E. Limagne**[3];
[1]Center Georges-Francois Leclerc, Dijon, France, [2]University Hospital Francois Mitterrand, Dijon, France, [3]Center Georges-Francois Leclerc - INSERM U1231 - Universite Bourgogne, Dijon, France

In patients with non-small cell lung cancer (NSCLC), double platinum-based chemotherapy (cisplatin or carboplatin and pemetrexed) combined with the anti-PD-1 antibody has shown significant clinical benefit and has become the standard of care. In the context of so-called "cold" tumors, the immunogenic capacities of chemotherapies increase danger signals (type I IFNs, CXCL9/10) and favor both infiltration of NK/T-CD8+ cells and response to anti-PD-1. Despite the therapeutic progress represented by this new combination, some patients have limited benefit from chemo-immunotherapy, suggesting that in these patients, the immunogenic capacities of chemotherapy are limited. Recently, we were able to show that KRAS oncogene signaling restricts the ability of the cisplatin/pemetrexed doublet to induce the chemokine CXCL10, lymphocyte recruitment and sensitize to PD-L1 blockade. Thus, the addition of a MEK inhibitor (MEKi) to the chemo-immunotherapy combination restores an immunogenic signal through CXCL10, enabling T-CD8+ to infiltrate the tumor more extensively, making it more sensitive to immunotherapy. Here, we unravel the essential role of NK cells in the immunological and antitumoral effect of chemo-immunotherapy plus MEKi combination in the LLC1 preclinical lung cancer model. We showed that chemo/MEKi combination favors NK cell recruitment and activation in tumor bed through both CXCL10 and NKG2D-ligand (Rae1, Mult1). Then, IFNγ-producing NK cells trigger tumor associated macrophage switch from M2 toward M1 phenotype and amplify T-CD8+ cells recruitment through CXCL9 production by macrophages. Thus, NK cell depletion, CXCR3, CXCL9 or NKG2D-neutralization restrained chemo/MEKi therapeutic efficacy. However, IFNγ also triggers NKG2A-ligand expression (Qa-1b, HLA-E in human) which restrained NK cell activation and CD8+ T cell recruitment. Thus reducing the NKG2A pathway, by using Qa-1b-/- LLC1 cells, enhances chemo-immunotherapy/MEKi anti-tumor efficacy. Similar results were obtained in preclinical “cold” CT26 colon cancer model treated by chemo-immunotherapy. Our results underline a new role for NK cell activation to trigger TAM2/TAM1 switch, CXCL9 expression and amplify CD8 T cell recruitment in “cold” tumor. In a context of resistance to chemo-immunotherapy, MEKi or ICI targeting NK cells could be an interesting way to amplify the anti-tumor immune response by modulating both TAMs biology and the recruitment of CD8+ T cells.

#3866 Azvudine : An emerging immunomodulator in the treatment of cancer and viral infections.

P. Li, L. Jia, Z. Wang, J. Du;
Genuine Biotech, Henan, China

Azvudine (FNC) is a nucleoside analog that has secured approval from the CDE in China for the treatment of both AIDS and COVID-19. In these contexts, it has showed remarkable efficacy and safety when taken orally. Typically, nucleoside analog drugs function by integrating into DNA and impeding DNA synthesis, evident in drugs like 5-FU, Capecitabine, Ara-C, and Gemcitabine. Furthermore, FNC has been reported to exhibit robust anti-tumor properties, curbing cell proliferation, initiating G1 and S phase arrests, and advancing apoptosis across various human cancer cell lines. Grounded in this mode of action, we have ascertained that the anti-tumor effects of FNC intricately align with the expression of deoxycytidine kinase (dCK) both in vitro and *in vivo*. Remarkably, our studies delved into the effects and underlying mechanisms of FNC in enhancing the tumor microenvironment within solid tumors. Our findings, stemming from cell-based assays and *in vivo* animal experiments, elucidate the following: 1. FNC can trigger immunogenic cell death (ICD) in tumor cells. This is evidenced by the surface presentation and liberation of damage-associated molecular patterns (DAMPs) such as Calreticulin, HSP70, HSP90, Annexin A1, and HMGB1, which in turn stimulate both innate and adaptive immune responses. 2. FNC substantially reduces the population of monocytic-myeloid derived suppressor cells (M-MDSC) and Polymorphonuclear-myeloid derived suppressor cells (PMN-MDSC) in the tumor microenvironment. Concurrently, it boosts the infiltration and proliferation of CD8+T, CD4+T and NK cells. This instigates the transformation of the tumor microenvironment from a 'cold' state to a 'hot' one, enhancing the synergistic effects of PD-1 when used in tandem with FNC. This mechanism was substantiated through a high proportion of MDSCs observed in H22 and CT-26 syngeneic models, and contrastingly, a low proportion in MC38 and LL/2 in vivo syngeneic models. Notably, every animal subjected to combined FNC and PD-1 treatment in the H22 and CT-26 *in vivo* models witnessed complete tumor regression. Given these revelations, there's a compelling argument that FNC monotherapy possesses immense potential as an anti-tumor agent. The potent anticancer effects of FNC *in vitro* and *in vivo* warrants further investigation of its anticancer potential as immunomodulator.

#3867 Identification of novel biomarkers of immune toxicity from CAR T-cell therapy using ultrasensitive NULISA™ proteome technology.

Riley Kirkpatrick[1], Joanne Beer[2], Manishkumar S. Patel[1], Akansha Jalota[1], Agrima Mian[3], Ishara S. Ariyapala[2], Qinyu Hao[2], Wei Feng[2], Xiao-Jun Ma[2], Yuling Luo[2], Brian T. Hill[3], **Neetu Gupta**[1]

[1]Inflammation and Immunity, Cleveland Clinic, Cleveland, OH,[2]Alamar Biosciences, Fremont, CA,[3]Hematology and Medical Oncology, Cleveland Clinic, Cleveland, OH

Introduction: The efficacy of anti-CD19 chimeric antigen receptor (CAR) T-cell therapy in patients with relapsed/refractory large B-cell lymphoma (LBCL) is limited by acute toxic events, most notably cytokine release syndrome (CRS) and immune effector cell-associated neurotoxicity syndrome (ICANS). Identification of biomarkers of toxicities can allow for selection of high-risk patients and elucidate targetable mechanisms for mitigation. Previous biomarker studies have been constrained by relatively narrow panels of potential mediators and limited time points. Here, we employed NULISA, a novel ultrasensitive assay capable of simultaneously quantifying 204 inflammatory proteins from a single sample, to identify temporal proteome associations with acute toxicities in anti-CD19 CAR T-cell treated patients.

Methods: Baseline and post-treatment peripheral blood samples from 80 patients with LBCL who underwent anti-CD19 CAR-T cell therapy were collected within specific time intervals. Plasma samples (n=480) were analyzed with NULISA. CRS and ICANS were graded according to ASTCT consensus criteria. Patients were grouped according to their maximum CRS and ICANS scores. Differential protein abundance across the toxicity groups was assessed using linear mixed effects models fit for each protein, including a time by toxicity group interaction. Proteins showing significant associations were subjected to pathway enrichment and network analysis.

Results: Severe CRS and ICANS patient groups showed proteome upregulation beginning on day 1-2 and peaking at day 6-9, followed by extensive downregulation on day 11-16. The strongest upregulated pathway associations of severe CRS and ICANS were inflammatory response, IL-17 signaling, non-genomic action of vitamin D3, regulation of leukocyte proliferation, and cellular extravasation. Downregulated pathways included anti-microbial humoral response and TNFs binding to receptors. In addition to the previously identified inflammatory proteins IL-6, IFNγ, sIL-2Rα, CXCL8, CCL2, our analysis revealed significant association of several novel immune regulators and mediators. These included upregulated Th2 cytokines, IL-17A, IL-22, GZMB, CTLA4, IFNA1;IFNA13, and downregulated S100A12, IL-12B, CCL22, BDNF and TNFSFs, revealing exquisite temporal orchestration of lymphoid and myeloid activities during CRS and ICANS development.

Conclusions: This study represents the most comprehensive characterization of immune response to CAR T-cell therapy to date. Using the novel NULISA technology, we identified new proteins and functional pathways associated with CAR T-cell-induced toxicity, implicating them as potential biomarkers. These previously unidentified factors also provide a platform to further investigate the causative immune mechanisms of acute toxicities in CAR-T cell therapy.

BIOINFORMATICS / COMPUTATIONAL BIOLOGY / SYSTEMS BIOLOGY / CONVERGENT SCIENCE: Multi-omic Analysis and Translational Research Minisymposium

#3872 Multi-ancestral origins of colorectal lesionsMulti-ancestral origins of colorectal lesions.

R. O. Schenck, A. Khan, A. Horning, E. D. Esplin, D. Van Egeren, HTAN-FAP Consortium, W. Greenleaf, J. M. Ford, M. P. Snyder, C. Curtis;
Stanford University, Palo Alto, CA

The widely accepted paradigm that cancer initiation is a monoclonal event has not been definitively resolved. In sporadic cancers this is due to the requirement for longitudinal sampling to study this occult process, which occurs over years to decades. Individuals with familial adenomatous polyposis (FAP) possess a germline APC mutation, leading to hundreds of colonic polyps in adolescence and a 100% lifetime risk of colorectal cancer. Resected colons from FAP patients contain normal mucosa, benign and dysplastic polyps that embed the natural history of colorectal tumorigenesis at different points of malignant progression. Through genome sequencing of 127 independent polyps or mucosa samples from six FAP patients, we characterized the genomic landscape, relative timing of somatic alterations, and clonal dynamics in normal, dysplastic, and invasive colon tissue. Comparison with multi-region sequencing data from FAP patients and sporadic colorectal adenomas and carcinomas indicates similar molecular profiles, with canonical cancer driver genes present across benign and dysplastic premalignant lesions and shared mutational orders. Pairwise sample comparisons and phylogenetic reconstructions revealed extensive heterogeneity and subclonal sharing within a patient's benign and dysplastic lesions, irrespective of location in the colon. These data imply that polyps were initiated from multiple cells from distinct lineages whose most recent common ancestor arose during development. We corroborate these findings using a mechanistic mathematical model, which infers polyclonality in 100% of benign and 83% of dysplastic samples. Based on these findings, we propose a conceptual model of the multi-ancestral origin of intestinal malignancies.

#3873 Understanding spatial organization of cellular plasticity in pancreatic ductal adenocarcinoma.

I. Zamora[1], M. Parikh[1], B. K. Patel[2], L. Bi[1], D. Haviv[3], J. Cao[4], C. Shiau[2], M. Hemberg[5], W. L. Hwang[2], N. Hacohen[2], D. T. Ting[2], A. Mehta[2];
[1]Broad Institute of MIT and Harvard, Cambridge, MA, [2]Massachusetts General Hospital, Boston, MA, [3]Memorial Sloan Kettering Cancer Center, New York, NY, [4]Beth Israel Deaconess Medical Center, Boston, MA, [5]Brigham and Women's Hospital, Boston, MA

Pancreatic ductal adenocarcinoma (PDAC) is notorious for poor survival rates, underscoring the urgency of understanding factors that drive tumor progression. A key player in this process is epithelial-mesenchymal transition (EMT), known for its role in enhancing cancer cell adaptability, resistance to treatment, and metastasis. Our study focuses on EMT within PDAC, using single-cell spatial transcriptomics to explore how the tumor microenvironment influences changes in cellular states. We introduce a novel method involving Gaussian mixture models (GMM) to categorize EMT stages in single-cell data and utilize deep learning for label transfer of these tumor cell states, including intermediate cell states, onto spatial transcriptomic data with limited gene panels and sparse count profiles. We find strong spatial autocorrelation of classical cells and a dispersion of basal cells alongside other cells at intermediate stages of the EMT spectrum. By leveraging the spatial proximity of clonally related cells, we confirm that cells transition along the EMT spectrum in a gradient and infer transition rates. We next leverage density gradients of tumor cells in different states to identify distinct neighborhoods with varying EMT subtype composition. We observe significant variations in cell density among different EMT states. A focus on cancer-associated fibroblasts (CAFs) and macrophages reveals differences in these cells across density contours. We also examine differential ligand-receptor interactions across cell state gradients to better understand the cellular interactions that drive EMT transitions and alter the tumor environment. By leveraging spatial transcriptomics, this research aims to provide new biological insights into PDAC intratumoral heterogeneity, potentially leading to the identification of novel therapeutic targets to disrupt treatment resistance.

#3874 Adaptive heterogeneity enables the survival of residual malignant PDAC cells in response to RAS-GTP inhibition.

L. Tomassoni, U. N. Wasko, A. C. Garcia, T. C. Dalton, P. Laise, S. A. Sastra, C. F. Palermo, A. Califano, K. P. Olive;
Columbia University Irving Medical Center, New York, NY

More than 90% of human pancreatic ductal adenocarcinoma (PDAC) cases are driven by activating mutations in KRAS. RMC-7977 is a potent inhibitor of GTP-bound RAS proteins (RAS(ON)), including both wild type and mutant variants of KRAS, NRAS, and HRAS. The related investigational agent, RMC-6236, is a first-in-class, potent, orally bioavailable, RAS^{MULTI}(ON) inhibitor currently in Phase 1/1b clinical trials (NCT05379985). We performed preclinical studies in a range of models of PDAC, including the highly chemoresistant $K\text{-}ras^{LSL.G12D/+}$, $p53^{LSL.R172H/+}$, $Pdx1Cre^{tg/+}$ (KPC) genetically engineered mouse. RMC-7977 exhibited broad anti-tumor activity at tolerable doses, provoking radiographic responses in KPC pancreatic tumors and extending overall survival by 3-fold, the largest response observed yet in this model. RMC-7977 dosing produced a metronomic effect on RAS signaling in tumor and normal tissues, with full pathway inhibition at 4 hours post treatment that was restored by 24 hours. This pattern yielded tumor-selective effects on apoptosis and proliferation, consistent with RAS oncogene addition in PDAC. To understand the dynamic response of malignant cells following RAS-GTP inhibition, we did single cell RNA sequencing on KPC pancreatic tumors treated with RMC-7977 or vehicle at multiple timepoints. Using the ARACNe and VIPER algorithms [Maroling., et al. 2006; Alvarez., et al. 2016], we performed regulatory network analysis on the expression profiles of >210,000 cells to calculate the activities of >5000 transcriptional regulatory proteins per cell. Additionally, we assessed the impact of treatment on malignant cell subtypes as previously identified by our team based on their sets of hyperactivated developmental transcription factors [Laise., et al. 2022].

As expected, RAS pathway transcription factors, such as FOS and JUN, were repressed relative to controls in malignant cells by 4 hours after treatment with RMC-7977. However, at 24 hours, responses varied by cellular subtype: well-differentiated Gastrointestinal Lineage State (GLS) cells had restored MAPK activity, while poorly differentiated Morphogenic State (MOS) cells were still inactivated. Strikingly, we found that after one week of treatment (in actively regressing tumors, representing a state of residual disease), nearly all malignant cells had assumed the GLS state. Acquisition of resistance after weeks or months of treatment was associated with a restored diversity of malignant cell states, suggesting that the GLS state serves as a regulatory “safe harbor” in which residual malignant cells can undergo evolution and adaptation. Mechanistically, we found that RAS pathway signaling directly activates transcriptional regulators that drive the MOS state, elucidating an early adaptive response to RAS-GTP inhibition that enables residual cells to survive treatment prior to development of acquired resistance.

#3875 Glioblastoma mutational profiles drive cancer cell signaling and immune evasion.

M. Pourmaleki[1], B. D. Greenstein[1], C. J. Jones[1], S. Nandakumar[1], D. A. Navarrete[1], S. Mehta[1], C. Campos[1], T. J. Hollmann[2], N. D. Socci[1], T. Bale[1], S. P. Shah[1], I. K. Mellinghoff[1];

[1]Memorial Sloan Kettering Cancer Center, New York, NY, [2]Bristol Myers Squibb, Princeton, NJ

Glioblastoma multiforme (GBM) is the most common malignant brain tumor in adults with a median survival below two years. Characterization of GBM through gene expression profiling and DNA sequencing has identified disease subgroups and commonly altered genes and pathways, including alterations in the genes encoding neurofibromin-1 (*NF1*) and the epidermal growth factor receptor (*EGFR*). *NF1* and *EGFR* are involved in receptor tyrosine kinase (RTK), RAS/MEK/ERK, and PI3K signaling, and together, are genetically altered in over 60% of adult GBMs. Interestingly, *NF1* and *EGFR* alterations in GBM are almost always mutually exclusive. Here, we designed a multimodal approach integrating spatial proteomics, transcriptomics, and genomics to measure cell composition, immune cell function, cancer cell signaling, cellular spatial organization, gene expression, transcriptional subtypes, and genome alterations in 80 *NF1* and *EGFR* altered human GBMs with extensively curated treatment and survival data. We quantified the spatial expression of 42 proteins in over 31 million single cells measuring RTK/RAS/PI3K and Rb signaling and features of the TME, including 23 cell types covering tumor cells, immune cells, and brain resident cells. In addition to tumor genotype labels, we classified each GBM tumor by its transcriptional subtype (i.e., mesenchymal, classical, or proneural). We identified genotype-phenotype associations in GBM including hyperactive RAS signaling cellular niches, a macrophage-rich TME, and an epithelial-mesenchymal signature in *NF1* altered tumors and hyperactive RTK signaling and an immune desert TME in *EGFR* amplified tumors. Furthermore, we observed spatial heterogeneity in cancer cell signaling patterns suggestive of the presence of different tumor cell clones within different regions of each GBM tumor. Together, we identify several genotype-associated features of GBMs, reinforcing the value of integrating spatial multi-omic data for generation of genotype-driven therapeutic hypotheses, with implications for GBM genotype-based therapeutic stratification.

#3876 A spatial transcriptomic study of a triple-negative breast cancer (TNBC) patient-derived xenograft (PDX) model of residual disease refractory to conventional chemotherapy.

B. Strope, K. Pendleton, W. Bowie, G. Echeverria, **Q. Zhu**;
Baylor College of Medicine, Houston, TX

Combating chemotherapy resistance in TNBC is critical to improving quality of care and reducing fatality. To understand chemoresistance, it has been proposed that the spatial interactions between cell types in the tumor microenvironment (TME) could offer insights into the differential response to therapy and metastatic potential. Thus, this study utilizes spatially resolved transcriptomics (SRT) to profile the spatial interactions in TNBC TME. With the goal of understanding chemoresistance and providing a proof-of-concept for new technology, we launched a longitudinal SRT study of a TNBC PDX of residual disease before, during, and after adriamycin and cyclophosphamide (AC) treatment (Tx). SRT by 10X Visium was performed on Veh, AC-residual tumor (21 d post-Tx), and AC-regrown tumor (50 d post-Tx when tumors regrew). This study is divided into two parts. 1. Due to the lack of specialized tools for processing xenograft reads from SRT, we developed the Xenomake pipeline, which combines xenograft sorting and spatial barcode demultiplexing to assign reads into the host and graft organisms per spatial spot. It permits clustering the spots into stroma-rich (mouse), and epithelial-rich (human) regions. We show that it can find differential cytokines in the stroma (S) and epithelium (E), and finding SS, EE, and SE interactions. 2. Although using PDX necessitates immune-compromised mice, several types of stromal populations are present and analyzable. Thus, using Xenomake, we inferred the localization of stromal cell types in Visium spots including cancer associated fibroblasts (CAF), macrophages (MP), endothelial (ENDO), monocytes, and perivascular cells. We compared the spatial localization profiles (SLP) of stromal cell types across samples. With human reads, we computed the spatial pathway activity map (SPAM) for HALLMARK pathways. We correlated SPAM with stroma cell type SLP to survey stroma-epithelial interactions. Stroma cells are distributed in the tumor periphery in vehicle and AC50, while in AC21 there is a notable increase in stroma abundance and stroma infiltration within tumor mass. SLP of MP (Cd68+ and Csf1r+) is correlated with ENDO (Pecam1+), and CAF (Acta2+ and Pdgfrb+). Additionally, all 3 cell types are correlated with Vim and Cd44 expression. Although all samples show enrichment of MP, ENDO, and CAF, they interact differently with pathway activities of adjacent epithelial cells. In vehicle and AC50, the 3 cell types are colocalized with OXPHOS, MYC targets, E2F pathway, while in AC21, a switch to colocalization with EMT is observed. Further, hypoxia response and glycolysis display anti-correlation with stroma cell types, meaning that these pathway activities are further away from stroma and occupy distinct territories. The results suggest stroma-tumor metabolic crosstalk and ways of targeting residual disease.

#3877 Multi-modal analysis of paracrine signaling in group 3/4 medulloblastoma.

B. Yu, J. Jung, A. Diaz;
University of California, San Francisco (UCSF), San Francisco, CA

Medulloblastoma (MB) is the most common primary brain malignancy in kids, with the group 3 and 4 subtypes (G3/4) being the most aggressive. Recent single-cell genomics studies have identified the G3/4 MB cell of origin and point to disrupted stem-cell differentiation as a key factor in MB pathogenesis. However, surprisingly little is known about the contribution of tumor-supportive paracrine signaling to the ontogeny of this disease. The spatial organization of MB cellular hierarchies is not completely understood. We profiled N=24 G3/4 MBs from UCSF patients via single-nucleus RNA sequencing (snRNA-seq). Of these cases, N=10 were profiled via single-cell assay for transposase-accessible chromatin by sequencing (scATAC-seq). To capture the spatial context, we profiled an additional 20 samples via spatial transcriptomics using the Visium and Xenium platforms. We found that the standard Xenium brain capture set was inadequate, and we developed a highly specific capture set for G3/4 MBs. In particular, our panel resolves cell-type differences in the stage of MB lineage commitment, from rhombic-lip progenitors to more differentiated unipolar brush-like cells. Altogether, over 110,000 nuclear-sequencing libraries and over 1,898,000 spatially-resolved single-cell libraries were generated. We inferred cell-cell communication signals from our snRNA-seq data by identifying co-expressed receptors and their cognate ligands. We then performed an integrated analysis of our snRNA-seq and scATAC-seq data to infer the cis-regulatory enhancers of those signaling genes, as well as the transcription factors that bind them. We employed our spatial transcriptomics data to confirm paracrine signaling networks inferred from nuclear-sequencing data. We found that distinct MB cell types corresponding to different stages of differentiation occupied specific spatial domains. The results of our ongoing analysis of this spatially-resolved single-cell atlas will be presented. This study paves the way for innovative therapeutic strategies targeting paracrine signaling in G3/4 MB.

#3878 Therapy-associated remodeling of pancreatic cancer revealed by single-cell spatial transcriptomics and optimal transport analysis.

J. CAO[1], C. Shiau[2], D. Gong[2], M. T. Gregory[3], X. Yin[2], J.-W. Cho[1], P. L. Wang[2], J. Su[2], J. W. Reeves[3], J. A. Guo[2], N. A. Lester[2], J. Bae[2], R. Zhao[2], M. Hemberg[1], W. L. Hwang[2];

[1]Gene Lay Institute of Immunology and Inflammation, Brigham and Women's Hospital and Harvard Medical School, Boston, MA, [2]Center for Systems Biology, Department of Radiation Oncology, and Center for Cancer Research, Harvard Medical School and Massachusetts General Hospital, Boston, MA, [3]NanoString Technologies, Seattle, WA

The aggressive nature of pancreatic ductal adenocarcinoma (PDAC) is driven by cell-intrinsic features and cell-extrinsic interactions between tumor cells and the desmoplastic stroma, which is infiltrated with heterogeneous populations of cancer-associated-fibroblasts (CAFs) and immune cells. These features are able to drive emergent properties such as chemoresistance through diverse and not yet fully elucidated mechanisms. Through single-nucleus RNA-seq and whole-transcriptome digital spatial profiling of PDAC patient tumors, we previously reported marked heterogeneity in the malignant cells and CAF composition of PDAC. In this project, we performed high-plex single-cell spatial molecular imaging (990-plex SMI, Nanostring) to dissect the therapy-remodeled multicellular neighborhoods and malignant-stroma cell interactions in primary resected human pancreatic cancer with (n = 6) or without (n = 7) neoadjuvant chemotherapy and radiotherapy. SMI of the PDAC samples yielded ~753,000 high-confidence single cells and captured the heterogeneity of malignant cells and CAFs. We identified three malignant subtypes: classical (CLS), basal-like (BSL), and the recently characterized neural-like progenitor (NRP) malignant subtype that exhibits stem-like and neurodevelopmental features. To leverage the single-cell spatial resolution of SMI to further dissect treatment-associated changes in cell-cell interactions, we developed Spatially Constrained Optimal Transport Interaction Analysis (SCOTIA), an optimal transport model with a cost function that includes both spatial distance and ligand-receptor gene expression. Our results uncovered a marked enrichment in ligand-receptor interactions between CAFs and malignant cells in response to treatment. In combination with several complementary methods, including examination of downstream target gene expression and *ex vivo* 3D co-culture of CAF and PDAC cells, we found that IL-6 family signaling was the most consistently enriched interaction between CAFs and malignant cells after treatment. This led us to hypothesize that IL-6 signaling between CAFs and malignant cells may induce chemoresistance in cancer cells. To test this hypothesis, we treated three human cancer cell lines (AsPC1, Panc1, Panc0203) with 5FU with or without IL-6 and discovered that IL-6 induced chemoresistance for two of the lines (Panc1, Panc0203). Taken together, we have integrated novel experimental and computational approaches to enable high-resolution, spatially-guided discovery of treatment-associated remodeling in the pancreatic cancer microenvironment. Further studies will be conducted to dissect additional mechanisms by which candidate cell-cell interactions promote disease progression and/or resistance to cytotoxic therapy, with the ultimate goal of guiding novel therapeutic development.

CHEMISTRY: Identification, Optimization, and Characterization of Protein Degraders and Inhibitors Minisymposium

#3879 Development of potent, highly selective and efficacious SMARCA2 degraders.

L. Yang, W. Tu, L. Huang, L. Leng, W. Jiang, M. Wang, B. Wen, D. Sun, J. Stuckey, S. Wang;
University of Michigan, Ann Arbor, MI

In human lung, melanoma and other types of human cancers, the mammalian SWItch/Sucrose Non-Fermentable (SWI/SNF) helicase SMARCA4 is frequently mutated, which leads to inactivation of its functions. SMARCA2, a close homologous protein of SMARCA4, is an attractive synthetic lethality target for human cancers with SMARCA4 deficiency. Herein, we report the discovery and biological evaluation of potent, highly selective and efficacious SMARCA2 PROTAC degraders exemplified by UM-SMD-3236. UM-SMD-3236 has a DC_{50} value of <1 nM in inducing degradation of SMARCA2 in cells and demonstrates >400-fold selectivity over SMARCA4 protein. Of significance, while UM-SMD-3236 achieves a D_{max} of >95% against SMARCA2, it shows a D_{max} of 50% against SMARCA4 in cells. *In vivo*, a single intravenous dose of UM-SMD-3236 attains 85-93% of SMARCA2 depletion in tumor tissues for 7 days, while showing no reduction of the SMARCA4 protein. Weekly intravenous administration of UM-SMD-3236 is highly effective in inhibition of tumor growth in SMARCA4 deficient xenograft models of human cancer. Importantly, UM-SMD-3236 shows no signs of toxicity in mice at highly efficacious doses. UM-SMD-3236 represents a highly promising SMARCA2 degrader for extensive evaluation as a potential new therapy for the treatment of SMARCA4-deficient human cancers.

#3880 LYTAC targeting galectin-1 to enhance radioimmunotherapy of cancers in the upper aerodigestive tract.

Yuyan Jiang[1], Green Ahn[2], Mobeen Rahman[3], Hongbin Cao[1], Carolyn Bertozzi[2], Qunh Le[1]

[1]Radiation Oncology, Stanford University School of Medicine, Stanford, CA,[2]Chemistry, Stanford University, Stanford, CA,[3]Pathology, Stanford University School of Medicine, Stanford, CA

Non-small cell lung cancer (NSCLC) and head and neck cancer (HNC), ranking respectively as a leading cause of cancer-related death and the sixth most common cancer worldwide. Despite treatment advancements, there's a pressing need for more effective strategies to improve survival and quality of life for NSCLC and HNC patients. Carolyn Bertozzi group recently reported in Nature the groundbreaking protein degraders named lysosome-targeted chimeras (LYTACs), which have bispecific binding affinity that drives cell-surface endocytic receptors to drag membrane or extracellular oncogenic proteins to lysosomes for degradation. They have successfully targeted critical oncoproteins such as epidermal growth factor receptor (EGFR) and more. However, current degradation demonstration was limited to in vitro cancer cells, LYTACs' impact on immune cell modulation and their therapeutic potentials in preclinical animal models remain unknown and require extensive evaluation before venturing to clinical trials.Our group and others have identified galectin-1 (Gal-1) as a multifaceted immunosuppressive biomarker overexpressed in NSCLC and HNC. By interacting with glycosylated receptors (e.g. CD45) on immune cells, it results in apoptosis of cytotoxic T cells, expansion of regulatory T cells, and intratumoral recruitment of myeloid-derived suppressor cells. Despite promising as an immune checkpoint target, effective anti-Gal-1 therapies are currently absent in clinical trials.Through histopathological analyses, we have confirmed substantial LYTAC receptor (cation-independent mannose-6-phosphate receptor, CI-M6PR) expression in ~200 HNC and ~400 NSCLC patient samples. Collaborating with Bertozzi group, we have developed the first Gal-1 targeting LYTAC named G-M6Pn which triggers significant target protein degradation in various human HNC and NSCLC cell lines. Such efficient Gal-1 degradation leads to significant immunosuppression reversal by stimulating CD8+ T cell and natural killer (NK) cell activation while dampening regulatory T cell (Treg) activity in both cell experiments and humanized mouse tumor models, resulting in excellent tumor/metastases control and survival improvement on both NSCLC and HNC models. When synergized with stereotactic ablative radiotherapy, the antitumor immune responses are further amplified and G-M6Pn also mediates ‘abscopal effect’ inhibiting non-irradiated tumors. This study thus contributes to expediting clinical translation of LYTACs as novel immune checkpoint degraders to improve personalized radio-immunotherapy of cancer.

#3881 Discovery of highly potent, selective and efficacious STAT3 PROTAC degraders capable of achieving long-lasting tumor regression.

H. Zhou, D. Wu, L. Bai, R. K. Acharyya, H. Metwally, D. McEachern, B. Wen, D. Sun, S. Wang;
University of Michigan, Ann Arbor, MI

STAT3 (signal transducer and activator of transcription 3) is a transcription factor and a promising therapeutic targets for cancer and other human diseases. We have previously reported the discovery of SD-36 and SD-91 as potent, selective and highly efficacious STAT3 degraders. In the present study, we report the discovery and extensive evaluation of new, highly potent, selective and efficacious new STAT3 degraders. In direct comparison, these compounds are >50-times more potent than SD-36 in inducing STAT3 degradation in cells and demonstrates >500-fold degradation selectivity over other STAT members. Proteomic analysis showed that our best lead compound (UM-STAT3-1218) only reduces the levels of STAT3 protein in cells over other >6,700 proteins. (UM-STAT3-1218) achieves low nanomolar IC_{50} values in leukemia and lymphoma cancer cell lines with activated STAT3. A single intravenous dose of (UM-STAT3-1218) at 3 mg/kg reduces the STAT3 protein for >4 days in xenograft tumor and native tissues, without reducing another other STAT members. Impressively, a single dose of (UM-STAT3-1218) at 3 mg/kg achieves complete and long-lasting tumor regression in multiple xenograft tumor models without any signs of toxicity. Taken together, (UM-STAT3-1218) is a highly promising STAT3 degrader for the treatment of the treatment of human cancers and other human diseases in which STAT3 plays a key role.

#3882 Targeted degradation of undruggable proteins using a novel heterobifunctional proteomimetic platform.

M. Wang[1], M. Truica[2], B. Gattis[1], X. Zhang[1], S. Abdulkadir[2], N. Gianneschi[1];
[1]Northwestern University, Evanston, IL, [2]Northwestern University, Chicago, IL

Of the ~20,000 unique proteins in the human genome, only a subset can be modulated via traditional pharmacological approaches. “Undruggable” targets currently include proteins with pivotal roles in cancer pathogenesis. Our work aims to introduce a new paradigm for engaging these clinically relevant proteins using a modular platform we term the HYbrid DegRAding Copolymers (HYDRACs). HYDRACs multiplex targeting warheads with degradation inducers and have long circulation times plus high cell uptake. Preliminary studies on MYC and RAS, targets of immense pharmaceutical interest, highlight the potential of this platform to revolutionize drug design.

Methods: HYDRACs containing MYC- or RAS- targeting peptides randomly copolymerized with degrons were synthesized using ROMP. Fluorescent and biotin-tags were incorporated for use in uptake and pull-down assays. Viability following treatment with MYC-HYDRACs was performed in multiple cell lines with both cellular (MYC-independent lines) and polymer composition controls. Target engagement was assessed via immunoprecipitation and circular dichroism with protein degradation monitored by WB. Unbiased whole proteome analysis and RNAseq were done to confirm observed effects were selectively on-target. *In vivo* efficacy and biodistribution was assessed in tumor-bearing mice.

Results: HYDRACs show high levels of cell uptake and antiproliferative effects at sub-micromolar concentrations in a formulation- and target-dependent manner. Cells treated with MYC-HYDRACs displayed reduced MYC protein levels, which were rescued by proteasome or neddylation inhibition. Swapping out the degron for various validated E3 ligase recruiters maintained MYC degradation, highlighting the “plug-and-play” nature of this approach. On-target activity was confirmed via RNAseq. Biophysical analysis showed strong HYDRAC-protein interactions, orthogonally supported by the presence of target protein following pull-down of biotin-terminated HYDRACs. Target protein degradation only occurred following treatment with an intact HYDRAC compound. Mice bearing MYC-CaP tumors showed delayed tumor growth following treatment with MYC-HYDRACs, with compound accumulation in the tumor for up to 72 h following a single injection. Generalizability was demonstrated against RAS, with RAS-HYDRACs capable of degrading KRAS across multiple different alleles, acting as a pan-KRAS degrader.

Conclusions: We present a novel platform technology that addresses the challenges inherent to peptide delivery approaches. HYDRACs have the potential to dramatically alter the drug discovery landscape, allowing for the development of cancer-relevant target modulators for which there are no current viable therapies. We envision the HYDRAC platform as a generalizable approach to designing degraders of proteins of interest, greatly expanding the therapeutic armamentarium for TPD.

#3883 Cryo-EM-guided enhancement of target selectivity of a novel p97 inhibitor for treating multiple myeloma and acute myeloid leukemia.

J. Crawford[1], R. Munuganti[1], C. Leung[1], K. Singh[1], E. Gates[1], X. Zhu[1], M. Bally[2], N. Dos Santos[2], M. Sharifiaghdam[2], Z. Nosrati[2], P. Axerio-Cilies[3], A. Berezuk[3], S. Cholak[3], S. Subramaniam[4];

[1]Gandeeva Therapeutics, Burnaby, BC, Canada, [2]BC Cancer Research Centre, Vancouver, BC, Canada, [3]University of British Columbia, Vancouver, BC, Canada, [4]University of British Columbia; Gandeeva Therapeutics, Vancouver, BC, Canada

The AAA ATPase p97, also known as valosin-containing protein (VCP), serves to regulate protein homeostasis by facilitating the translocation of ubiquitinated proteins from membranes or chromatin to the proteasome for degradation. Certain cancers, including multiple myeloma (MM) and acute myeloid leukemia (AML) are known for the intracellular overexpression of proteins, and are thus susceptible to the inhibition of p97 and resulting proteotoxic stress. A known p97 inhibitor, CB-5083 entered human phase 1 clinical trials in 2015, but trials were terminated due to side effects that were later traced to strong interaction of the compound with the phosphodiesterase PDE6. To address this problem, we devised a subtractive approach that leveraged high resolution structures of CB-5083 bound to PDE6 and p97. Using this information, we designed a p97 inhibitor that no longer displayed significant off-target binding but retained strong on-target binding. The optimization process started when we identified the 7-azaindole core from an *in silico* screen as a suitable hit pharmacophore and confirmed the binding mode of several variants of this scaffold in p97 by cryo-EM. Through a structure-guided medicinal chemistry program, we identified GND-135, a potent, on-target binder through the synthesis of less than 100 compounds. The design was supported with about 50 cryo-EM structures throughout the optimization process. Compared to CB-5083, our compound GND-135 displays greatly reduced PDE6 activity (< 1% inhibition at 10 µM versus 89% inhibition for CB-5083) and more potent p97 ATPase inhibition (3 nM IC_{50} versus 12 nM for CB-5083). We also evaluated the pharmacokinetic profile of GND-135 in mice; the half-life and clearance of 6.6 h and 15.9 mL/min/kg respectively were deemed suitable for daily administration. Based on the initial profiling, we carried out an efficacy study in a cell derived xenograft mouse model of AML using a U937 cell line with subcutaneous implantation. In this model, where GND-135 was administered IP (40 mg/kg QD) and CB-5083 was administered orally (40 mg/kg QD) the compounds showed statistically comparable efficacy, which was differentiated from untreated control. Thus, GND-135 is a novel p97 inhibitor lead compound with on-target selectivity powered by cryo-EM driven rational drug design.

#3884 Artificial intelligence (AI)-enabled discovery of GLX1546, a novel and potent inhibitor of ULK1/2 kinases and autophagy.

G. Cui[1], X. Sun[2], W. Zhu[1], Q. Wang[1], J. Li[1], Z. Pan[2], **C. Li**[1];
[1]Galixir, Beijing, China, [2]Galixir, Shanghai, China

Background: Autophagy is an evolutionarily conserved process, critical for the recycling of damaged or excess cellular components, which promotes cell survival and growth under stress conditions. Cancer cells, especially those with RAS mutations, can activate the ULK1/2 (UNC-51-like kinase 1/2)-initiated autophagy pathway for survival and diminish RAS pathway inhibitors' efficacy. The combination of RAS pathway and ULK1/2 kinase inhibitors may provide synergistic or additive effects for RAS mutated solid tumors. We have identified a structurally small molecule, GLX1546, which shows strong inhibition against ULK1/2, as well as autophagy induced by RAS pathway inhibitors in cells.
Methods: Multiple dual-target activity predictive models were constructed and trained using extensive protein-ligand interaction data. These models, in conjunction with in-house built physicochemical property predictive models, were integrated into an AI-driven computational pipeline to perform the *in silico* screening on both ULK1/2 inhibitory activities and drug-like properties. ULK1/2 *in vitro* activities were assessed by enzymatic assays and cellular assays based on the phosphorylation of ULK substrate. The *in vivo* anti-tumor efficacy of GLX1546 was evaluated in A549 CDX mouse model both as monotherapy and in combination with trametinib.
Results: An AI-driven high-throughput virtual screening strategy using deep learning models was implemented for the discovery of novel and potent ULK1/2 small-molecule inhibitors. GLX1546 was developed as a potent ULK1/2 inhibitor with IC_{50} values of 1.13 nM for ULK1 and 4.75 nM for ULK2. Moreover, to address trametinib-induced activation of ULK1/2 in KRAS and BRAF mutated solid tumors, GLX1546 provided IC_{50} values of 54 nM in A549, 21 nM in HCT 116, 67 nM in MIA PaCa-2, and 76 nM in A375 cells against both basal and trametinib-induced pATG13. Furthermore, GLX1546 exhibited good exposure, sound safety, and high oral bioavailability (~100%) in mice. The combination of trametinib (PO, QD) with GLX1546 (PO, BID) in 21-day cycles also led to inhibition of ATG13 phosphorylation and greater tumor growth inhibition than trametinib alone in A549 CDX mouse model.
Conclusions: These results indicate that GLX1546 can inhibit ULK-mediated autophagy induced by trametinib. The combination of GLX1546 with RAS pathway inhibitors may offer a novel cancer therapy for RAS mutated cancers, highlighting AI as an effective tool for drug discovery.
Keywords: AI-driven drug discovery, autophagy, small-molecule inhibitors, ULK

#3885 A ubiquitin-specific proximity labeling method to study drug-induced ubiquitylation.

H.-T. Huang[1], R. J. Lumpkin[2], R. W. Tsai[1], K. A. Donovan[2], S. Su[1], X. Zhao[1], J. Chen[1], E. S. Fischer[2], W. R. Sellers[1];
[1]Broad Institute, Cambridge, MA, [2]Dana Farber Cancer Institute, Boston, MA

Targeted protein degradation is a promising therapeutic paradigm that offers new ways to disrupt protein functions. Currently, most studies that characterize the pharmacological effects of protein degraders utilize target-specific assays and global proteomics. However, information on the direct molecular consequence of protein degraders, i.e., induced protein ubiquitylation, is often lacking. Here we report the development of E-STUB (E3-substrate tagging by ubiquitin biotinylation), a ubiquitin-specific proximity labeling method that identifies ubiquitylated substrates in proximity to an E3 ligase of interest. We demonstrated that E-STUB can accurately identify the ubiquitylated targets induced by protein degraders in both CRBN and VHL systems—two of the most utilized E3 ligases by heterobifunctional degraders—and is likely generalizable to other E3 ligases. While we observed a high level of consistency between ubiquitylation and degradation for the induced substrates, E-STUB also detected ubiquitylation of non-degraded targets, providing novel and complementary insights to global proteomics. We also envision that E-STUB could be specifically used for the development of chemical inducers of proximity that catalyze non-degradative ubiquitylation events. In summary, we expect that the E-STUB approach can be widely useful for studying the principles of chemically induced ubiquitylation and the advancement of targeted protein degradation.

CLINICAL RESEARCH: Application of Real-World Evidence to Cancer Care
Minisymposium

#3886 Analysis of clonal heterogeneity within paired primary and metastatic tumor samples of patients with solid tumors and implications for neoantigen-based personalized cancer vaccines.

A. Obermayer[1], T. Shaw[1], D. Chang[1], J. Davis[1], J. K. Teer[1], X. Yu[1], X. Wang[1], D. Hedges[2], A. Tan[3], R. Rounbehler[2], A. Naqash[4], M. Gatti-Mays[1], A. Ratan[5], M. McCarter[6], H. Colman[7], I. Puzanov[8], S. Arnold[9], M. Churchman[2], P. Hwu[1], W. Dalton[2], G. Weiner[10], J. Conejo-Garcia[11], P. C. Rodriguez[1], B. Salhia[12], A. A. Tarhini[1];

[1]H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL, [2]Aster Insights, Tampa, FL, [3]Huntsman Cancer Institute, University of Utah,, Salt Lake City, UT, [4]Stephenson Cancer Center Oklahoma University, Okalahoma City, OK, [5]University of Virginia, Charlottesville, VA, [6]University of Colorado School of Medicine, Aurora, CO, [7]Huntsman Cancer Institute, University of Utah, Salt Lake City, UT, [8]Roswell Park Comprehensive Cancer Center, Buffalo, NY, [9]Markey Cancer Center, Lexington, KY, [10]University of Iowa, Iowa City, IA, [11]Duke University, Durham, NC, [12]USC Norris Comprehensive Cancer Center, Los Angeles, CA

Background: Neoantigen-based personalized cancer vaccines carry significant promise in treating solid malignancies. However, there are uncertainties regarding the choice between the primary or the metastatic tumor for neoantigen prediction in individual patients. Here, we conducted a thorough examination of somatic variations in 676 patients who had paired primary and metastatic solid tumors.

Methods: Patients were enrolled in the Total Cancer Care protocol (NCT03977402) to which patients provided an IRB-approved written informed consent within the Oncology Research Information Exchange Network (ORIEN). Whole-exome sequencing of 756 primary and metastatic tumor pairs was performed (N = 676 patients). These included Genitourinary (n=83), Gynecological (n=97), Gastrointestinal (n=213), Thoracic (n=33), Cutaneous (n=24), Breast (n=108), Endometrial (n=49), Sarcoma (n=35), Head-and-Neck (n=106) and others (n=8). The data was analyzed through the ORIEN AVATAR Molecular Analysis Pipeline for somatic mutation variant detection and variant annotation. In this analysis, we focused on somatic events that result in an in-frame alteration (such as missense, in-frame deletion and in-frame insertion) and out-of-frame protein-altering mutations (such as frameshifts, de novo start, out-of-frame, and nonstop gain). Clonal population structure was determined based on pyclone-vi.

Results: For in-frame events, bladder cancer, melanoma, and gynecological cancers shared close to 75% of the mutations between paired primary and metastatic cases. In contrast, sarcoma and thyroid cancer had a low overlap (~ 25%) of variants. For out-of-frame events, these events tend to have a lower proportion of shared somatic variants between primary and metastasis than in-frame variants. Oncogenic drivers (e.g., BRAF V600E, KRAS G12A, and TP53 loss-of-function) were highly likely to be present in both paired primary and metastatic tumors. Next, we performed additional analysis on evolutionary selection of protein-coding variants via dN/dS calculation. We found no significant global shift in dN/dS ratio between paired primary and metastatic tumors across malignancies. However, we found increased selection of protein-coding variants in brain and liver metastatic sites, which correlated with increased homologous recombination deficiency within these sites.

Conclusions: Our analysis demonstrates genetic variations that exist when comparing paired primary and metastatic tumors that appear to vary by histology. Variants are potentially undergoing negative selection supported by the preferential loss of out-of-frame events in metastatic tumors and positive selection in specific metastatic sites. Overall, understanding the clonal structure will be key to neoantigen prediction for effective neoantigen-based vaccines.

#3887 The origins and clinical impact of extrachromosomal DNA across 39 cancers.

C. Bailey[1], O. Pich[1], K. Thol[2], J. Luebeck[3], G. Stavrou[2], T. B. K. Watkins[1], N. E. Weiser[4], W.-T. Lu[1], J. Kittel[2], R. Bentham[2], N. Sharma[2], R. Salgado[5], D. Moore[6], M. Litovchenko[2], K. L. Hung[7], A. J. Cornish[8], B. Dameracharla[3], S. Nik-Zainal[9], V. Bafna[3], H. Chang[7], N. McGranahan[2], N. Kanu[2], Genomics England Consortium, P. S. Mischel[7], M. Jamal-Hanjani[2], C. Swanton[1];

[1]Francis Crick Institute, London, United Kingdom, [2]University College London, London, United Kingdom, [3]University of California at San Diego, La Jolla, CA, [4]Stanford University School of Medicine, Stanford, CA, [5]ZAS Hospitals, Antwerp, Belgium, [6]University College London Hospitals, London, United Kingdom, [7]Stanford University, Stanford, CA, [8]The Institute of Cancer Research, London, United Kingdom, [9]University of Cambridge, Cambridge, United Kingdom

Extrachromosomal DNA (ecDNA) is emerging as a major contributor to cancer drug resistance and poor outcome in many cancer types. To understand the underlying genetic and mutational processes associated with ecDNA formation and presence, we conducted an analysis of whole-genome sequencing data from 14,778 cancer patients representing 39 tumor types from the Genomics England cohort. Our findings revealed focal amplifications driven by ecDNA in 17.1% of tumor samples, exhibiting varying frequencies across tissues. Notably, liposarcomas (55.4%) and HER2+ breast cancers (46.4%) displayed higher rates compared to lower rates found in pancreatic adenocarcinomas (2%). In addition to oncogenic amplifications such as HER2 derived from ecDNA during cancer evolution, ecDNAs that did not contain oncogenes were enriched for immunomodulatory genes (e.g., CXCL6, LRRC32, and HLA-G). Immunomodulatory ecDNAs exhibited reduced T cell infiltration.

In the context of intrinsic and environmental mutational processes, deamination clock-like, tobacco smoking, and APOBEC cytidine deaminase signatures positively correlated with ecDNA presence. Conversely, mismatch repair deficiency (MMRd) and POLD1/POLE deficiency signatures exhibited a negative correlation. Mutational processes associated with tobacco exposure, UV light, and spontaneous deamination primarily occurred before ecDNA formation, while signatures of homologous recombination repair deficiency tended to manifest post-ecDNA formation.Notably, ecDNA was enriched at metastatic sites and significantly associated with shorter overall survival in multivariable analysis (HR 1.31, 95% CI 1.17-1.47), underscoring its clinical relevance. This study enhances our understanding of the mutational processes and tissue contexts that shape the ecDNA landscape in human cancer and highlights its implications for clinical outcomes.

#3888 *TOP1* mutations mediate cross resistance to ADCs in metastatic breast cancer.

R. O. Abelman[1], H. Barnes[1], A. J. Medford[1], A. Putur[1], B. Wu[1], C. Weipert[2], G. Fell[3], L. M. Spring[1], S. A. Wander[1], B. Moy[1], A. Varkaris[1], D. Juric[1], L. Ellisen[1], R. Corcoran[1], A. Bardia[1];

[1]Harvard Medical School/Massachusetts General Hospital, Boston, MA, [2]Guardant Health, Boston, MA, [3]Harvard Medical School/Dana Farber Cancer Institute, Boston, MA

Background: Antibody-drug conjugates (ADCs) have improved survival for patients with metastatic breast cancer (MBC). In patients with HER2 negative MBC, two ADCs have FDA approval: sacituzumab govitecan (SG) and trastuzumab deruxtecan (T-DXd), both with topoisomerase-I (topo-I) inhibitor payloads. Given the many other ADCs in development, there is great interest in using ADC after ADC to maximize treatment benefit for patients. However, there is limited understanding regarding resistance mechanisms to ADCs and impact on ADC sequencing. We conducted a translational study to address this, and here we report the incidence of *TOP1* mutations and clinical impact on ADC sequencing.

Methods: All patients with MBC treated with ADCs at a large academic medical institution (Massachusetts General Hospital) who had comprehensive plasma-based genotyping (500 gene GuardantOMNI panel) were included. Since both SG and T-DXd have topo-I inhibitor-based payloads, we particularly focused on *TOP1* mutations, variant allele frequency (VAF), and germline/somatic characterization. Incidence of *TOP1* mutations in the ADC cohort was compared to The Cancer Genome Atlas (TCGA). Clinical “cross-resistance” was defined as progressive disease (PD) as best response to second ADC (ADC2) or treatment time on ADC2 of less than 60 days.

Results: Based on comprehensive plasma-based genotyping we identified 4 distinct *TOP1* mutations: S57C, R364H, W401C, G359E, at a frequency of 6.0% (4/67) at the time of disease progression on ADC compared to a frequency of 0.5% described in primary breast cancer in TCGA. Two of the amino acids found to be mutated are known to form direct interactions with the DNA backbone (G359) or the topoisomerase inhibitor itself (R364). For clinical resistance, one patient was briefly on ADC2 but stopped after 1 dose for toxicity; among the other 3 patients, two had cross-resistance to ADC after ADC, with both ADCs containing topo-I inhibitor payloads. Median duration on first ADC was 455 days compared to a median of 52 days for ADC2. Finally, one patient treated sequentially with 3 ADCs (all with topo-I inhibitor payloads) was found to have rising TOP1 VAF with progressive ADC treatments.

Conclusion: This is the first report describing emergence of *TOP1* mutations under selective pressure from ADCs and the impact on mediating cross-resistance to ADC after ADC with topo-I inhibitor payloads. Novel ADCs with alternative payloads may potentially be more effective when used sequentially after an ADC with a topo-I inhibitor. Further biomarker research is needed to optimize ADC sequencing for patients with *TOP1* mutant MBC.

#3889 Genomic landscape of gynecologic cancers with poor prognosis in Japan, an analysis of the national database of comprehensive genomic profiling tests.

Q. Xi[1], H. Kage[1], M. Ogawa[1], A. Matsunaga[2], A. Nishijima[1], K. Sone[1], K. Kawana[2], K. Oda[1];
[1]The University of Tokyo, Tokyo, Japan, [2]Nihon University School of Medicine, Tokyo, Japan

Objective: Comprehensive genomic profiling (CGP) tests were approved in Japan in June 2019 under universal health insurance coverage for cancer patients who have finished (or almost finished) standardized treatment. All the data are collected to the "Center for Cancer Genomics and Advanced Therapeutics (C-CAT)" under written informed consent. Up to date, over 60,000 CGP data have been deposited with a 99.7% consent rate. This study aims to analyze mutational landscape of gynecologic cancers, especially with poor prognosis, by using this database.
Methods: We analyzed CGP datasets from 3,006 gynecologic cancer patients using FoundationOne® CDx (F1CDx), the most commonly tested in Japan. This study was ethically approved by our institutional ethics committee (#2021341G) and the Information Utilization Review Board of C-CAT (#CDU2022-026N).
Results: Endometrial cancers (n=561) showed high rates of tumor mutational burden-high (TMB-H) (13.9%) and MSI-high (MSI-H) (10.8%), especially in endometrioid carcinomas. *POLE* exonuclease mutations were less frequent (1.4%) compared to TCGA data (7%), while *TP53* mutations were more common (54.4% vs. 29% in TCGA), suggesting the impact of prognosis of the molecular subtypes. Other frequently mutated genes included *PIK3CA* (41%), *PTEN* (35%), *ARID1A* (31%) and *KRAS* (26%). In 839 cervical cancers, TMB-H prevalence was 14.2%, with low MSI-H at 1.5%. TMB-H was significantly higher in squamous cell carcinomas (20.6%) than adenocarcinomas (8.3%). Frequent mutations included *PIK3CA* (32%), *STK11* (20%), *TP53* (20%), *KRAS* (14%), and *CDKN2A* (11%). *TP53* mutations were significantly higher than TCGA data (<5%), particularly in mucinous carcinomas (60%), indicating a prevalence of HPV-independent tumors with poorer prognosis. Actionable mutations were generally more frequent in adenocarcinomas than in squamous cell carcinomas, including *KRAS* (32.2%), *TP53* (29.4%), *CDKN2A* (18.3%), and *ERBB2* (16.7%). In 1,606 ovarian cancers, the ratio of TMB-H was 5.0%, and MSI-H was 1.2%. TMB-H rates varied between 3.3-6.5% across histological types, while the ratio of MSI-H was significantly lower in serous carcinomas (0.3%) than non-serous carcinomas. Pathogenic mutations in the *POLE* exonuclease domain were rare in cervical (0.0%) and ovarian (0.2%) cancers.
Conclusion: The C-CAT database offers insights into the mutational landscape of various cancers and histological subtypes, especially those with poor prognosis, highlighting the unmet needs for drug development in these gynecologic cancers.

#3890 Comprehensive molecular and immunological characterization of early-onset esophagogastric cancer.

L. W. Wu[1], S. K. Deshmukh[2], S. Wu[2], J. Xiu[2], A. Farrell[2], V. Lam[3], E. Lou[4], S. Goel[5], C. Nabhan[2], R. H. Moy[1];
[1]Columbia University Irving Medical Center, New York, NY, [2]Caris Life Sciences, Phoenix, AZ, [3]Johns Hopkins Sidney Kimmel Comprehensive Cancer Center, Baltimore, MD, [4]University of Minnesota, Minneapolis, MN, [5]Rutgers Cancer Institute of New Jersey, New Brunswick, NJ

Background: The incidence of early-onset esophagogastric cancer (EOEGC), defined as age of diagnosis <50, has increased in recent decades. Compared to average-onset esophagogastric cancer (AOEGC), EOEGC are more likely to be genomically stable, have diffuse histology, and present with more advanced disease. Here, we utilized a large real-world data cohort to characterize EOEGC with molecular and immune signatures.
Methods: 5,175 esophagogastric cancer (EGC) samples (<50 yrs, n=530; ≥50 yrs, n=4645) were tested by next generation sequencing (NGS) (592, NextSeq; WES, NovaSeq) and whole transcriptome sequencing (WTS) (NovaSeq) (Caris Life Sciences, Phoenix, AZ). EGC patients with age <50 and ≥50 were classified as EOEGC and AOEGC, respectively. Deficient mismatch repair (dMMR)/microsatellite-instability (MSI) was tested by IHC and NGS. Tumor mutational burden (TMB) totaled somatic mutations per tumor (high>10 mt/MB). Pathway enrichment determined by Gene Set Enrichment Analysis (Broad Institute, Cambridge, MA). Immune cell fractions were calculated by deconvolution of WTS: Quantiseq. Statistical significance was determined using chi-square and Mann-Whitney U test with p-values adjusted for multiple comparisons (q < 0.05).
Results: EOEGC had higher frequency of *CDH1* (18.9% vs 6.5%) but lower frequency of *TP53* (65.9% vs 74.4%) mutations compared to AOEGC (all q<0.05). EOEGC had higher frequency of *CCNE1* (6.8% vs 4.4%), *MYC* (6.1% vs 4.1%) and *FGFR2* (3.45% vs 1.87%) copy number alterations and *ARHGAP26* (5.67% vs 2.2%) fusion. EOEGC had lower frequency of TMB high (3.8 vs 10.1%) and dMMR/MSI-H (1.3% vs 5.7%) (all p<0.05). EOEGC had pathway enrichment of epithelial mesenchymal transition (EMT) (NES: 1.8, FDR: 0.0) and angiogenesis (NES: 1.3, FDR: 0.24). EOEGC had lower median MAPK pathway activity score (MPAS) (-0.16 vs 0.13, p<0.05). Analysis of inferred immune cell infiltrates showed that EOEGC had increased infiltration of B cells (4.7% vs 3.9%) and M2 macrophages (3.6% vs 3%) but decreased infiltration of M1 macrophages (3.7% vs 4%) (all q<0.05). EOEGC had increased T cell inflamed signature (31.3% vs 26.1%, p<0.05) and increased expression of *HAVCR2* (*TIM3*) but decreased expression of *FOXP3* and *CD274* (PD-L1) (FC: 0.84-1.09, all p<0.05). There was no difference in *LAG3*, *CTLA4*, and *IDO1* gene expression.
Conclusion: EOEGC has several unique molecular and tumor immune microenvironment features. In this real world cohort, EOEGC has increased frequency of *CDH1* mutations, *ARHGAP26* fusions, enrichment of EMT and angiogenesis pathways, decreased MAPK pathway activity, decreased frequency of TMB high and dMMR/MSI-H, and a unique immune cell infiltrate with decreased M1 macrophages and increased M2 macrophages. These unique differential characteristics present therapeutic opportunities but also demonstrate the limitations of currently approved therapies in this subset of patients.

#3891 Early real-world experience with repeat multi-cancer early detection (MCED) testing.

R. Abrams[1], R. Shaknovich[2], J. Lipton[3], M. McMillin[4], A. Schneider[5], M. Margolis[2], X. Hou[2], Y. Oh[2], V. Le[2], E. Hubbell[2], R. Jiang[2], J. M. Venstrom[2], **O. K. Gordon**[6];

[1]Colorado Preventive Medicine, Denver, CO, [2]GRAIL, LLC, Menlo Park, CA, [3]Signature Healthcare, Charlotte, NC, [4]University of Illinois College of Medicine at Peoria, Peoria, IL, [5]MD2, Austin, TX, [6]Colorado Preventive Medicine, Los Angeles, CA

Background: An MCED test (Galleri®, GRAIL, LLC, Menlo Park, CA) has been in clinical use since April 2021. We previously reported the results of screening the first ~53,000 individuals in the US with this test from real-world (RW) practice. Here, we report the RW experience with repeated MCED testing in ~5800 individuals.

Methods: This MCED test analyzes targeted methylation in cell-free DNA and uses machine learning to detect a Cancer Signal (CS) and determine its Cancer Signal Origin (CSO). We analyzed results returned through August 2023 for those with a “No Cancer Signal Detected” (NCSD) result in Year 1 and an additional consecutive test. We excluded tests from clinical studies and sites that limited data sharing. Systematic collection of outcomes was attempted for all cases with a “CS detected” (CSD) result and continues via a quality assurance (QA) program.

Results: In this RW cohort, a second test was ordered in 5794 individuals (58% male, average age=61.3 y, range: 24.0-89.0 and 42% female, average age=60.5 y, range: 23.0-89.0). Median interval between blood draws was 12.9 months, and 81% (4693/5794) were tested 10-18 months after the initial test. Among the 5794, 26 received a CSD result in the second test, of which 20 were within 10-18 months, corresponding to a CSD rate (CSDR) of 0.45% (95% CI 0.31%-0.66%; 26/5794). The CSDR was slightly higher in males (0.50% [0.32%-0.81%; 17/3367]) vs females (0.37% [0.2-0.7%; 9/2427]) and was lower than the Year 1 CSDR of 0.95% (95% CI 0.87-1.0; 510/53,744). The top CSOs reported during second tests were: Lymphoid, Head & Neck, Bladder and Urothelial, Colon & Rectum, Anus. Among the 26 CSD cases, the QA program confirmed 12 clinical outcomes (8 with a cancer diagnosis, 4 with no cancer diagnosis), and 14 cases are still under investigation or without outcomes at this time. Among 8 cases with a confirmed cancer diagnosis, accuracy of the 1st CSO prediction was 100%, and diagnoses reflected invasive cancers across multiple cancer types including anus, colon, head & neck, urothelial tract, ovary, and lymphomas. Staging information was available in 5 cases, including 4 stage I cancers (4/5, 80%; anus, head & neck, lymphoma, bladder) and one stage IV cancer (ovary).

Conclusions: A subset of individuals who returned for MCED testing had cancers detected, including cancers without recommended screening, underscoring the potential value of annual screening with this MCED test. There may be systematic differences in this limited population of individuals who returned for repeat screening, reducing the signal detection rate through potential early adopter bias. Clinical data return was incomplete, and confirmed 8 cancers, including 4 stage I cancers. All cancers were found at the predicted CSO, demonstrating the clinical utility of this unique test feature that directs diagnostic work up.

#3892 Systematic generation of a clinicogenomic harmonized oncologic real-world dataset (MSK-CHORD).

Christopher J. Fong, Karl Pichotta, Thinh Tran, Michele Waters, Tom Fu, Mono Pirun, Mirella Altoe, Brooke Mastrogiacomo, Anisha Luthra, Mehnaj Ahmed, Arfath Pasha, Armaan Kohli, Raymond Lim, Tom Pollard, Darin Moore, Benjamin Gross, Avery Wang, Calla Chennault, Ritika Kundra, Ramyasree Madupuri, Ino de Bruijn, Aaron Lisman, Walid K. Chatila, Subhiksha Nandakumar, Anika Begum, Doori Rose, Kenneth L. Kehl, Deborah Schrag, Michael Berger, Jian Carrot-Zhang, Pedram Razavi, Bob Li, Peter Stetson, Nikolaus Schultz, Justin Jee

Memorial Sloan Kettering Cancer Center, New York, NY

Clinical data storage in unstructured notes and siloed datasets present a major challenge for large-scale cancer informatics. Whether natural language processing (NLP) combined with multimodal integration across datasets can produce a mineable resource and improve discovery of relationships between tumor genomics and clinical phenotypes is unknown.

We hypothesized that NLP could automatically annotate a pan-cancer corpus of 82,464 patients with tumor genomic sequencing. To develop algorithms to annotate free-text reports, we leveraged the AACR Project GENIE Biopharma Collaborative (BPC), a structured curation of EMR from five cancer types (non-small cell lung (NSCLC), breast, colorectal, prostate, and pancreatic cancer), to train and validate several Transformer and rule based-based NLP models. After automating the generation of NLP annotations alongside medication, demographic, tumor registry, survival, and tumor genomic sequencing data, we tested whether clinicogenomic relationships not apparent in the smaller BPC cohort might be discoverable in the larger cohort.

In 5-fold cross-validation, NLP Transformers accurately annotated the presence of cancer (AUC=0.99), cancer progression (AUC=0.97), and sites of disease (AUC=0.99) from radiology reports, and presence of prior outside treatment (AUC=0.98) and hormone receptor (HR) and HER2 receptor status (AUC=0.98, 0.98) from clinician notes. In addition, rule-based models, trained on non-BPC data and validated on the whole BPC cohort, annotated smoking status from clinician notes (ACC=0.95), and Gleason score (ACC=1.0), PD-L1 status (ACC=0.98), and mismatch repair deficiency (ACC=0.98) from histopathology reports. NLP annotations were merged with genomic and other structured clinical data to create a Clinicogenomic, Harmonized Oncologic Real-world Dataset (MSK-CHORD). Finally, we tested if associations not apparent in the BPC might be discoverable in MSK-CHORD. We found positive associations between Gleason score and gene-level alterations in prostate cancer including TP53, PTEN and BRCA2 ($q<0.1$), none of which were adequately powered for detection in the BPC. We found PD-L1 status was associated with better survival following immunotherapy treatment in NSCLC, but only in the larger MSK-CHORD was this association statistically significant. In breast cancer, NF1 mutations were associated with prior therapy in both cohorts, but this association was only significant in MSK-CHORD.

The infrastructure generating MSK-CHORD uses a combination of on-premise and cloud computing resources and open-source development operation applications to automate processes. Once annotations are created, data is imported into a local instance of cBioPortal, where researchers can visualize data and perform analyses. The system generating MSK-CHORD demonstrates how large-scale data delivery and integration can fuel cancer research.

CLINICAL RESEARCH: Early Detection and Progression Biomarkers
Minisymposium

#3893 A multimodal spatial-omics atlas of lung precancer and progression to adenocarcinoma.

Understanding the earliest changes during lung adenocarcinoma (LUAD) development can set the stage for discovery of fertile targets for disease interception, thereby mitigating the dire public health burden of LUAD. We previously identified bulk-level molecular and immunological changes that are enriched in normal-appearing tissue (NAT) in the local niche of human LUAD, as well as those that commence in adenomatous premalignant lesions (aPMLs, LUAD precursors) and that are further enriched in LUADs. Yet, in-depth understanding of the identities, states, and properties of specific cell subsets in NAT and precancer that trigger LUAD remain largely elusive due to inherent roadblocks to sampling and characterizing aPMLs that are at the center of this trajectory. Here, we aimed to map molecular profiles, states, and interactions of cell subsets that underlie initiation in lesion-adjacent NAT, and to determine how features of these cells evolve along the aPML-LUAD spectrum. We analyzed an expanding cohort of archived matching NATs, aPMLs and LUADs, including challenging small samples, from up to 17 patients. Samples were analyzed using combined high-resolution, multi-modal Visium spatial transcriptomics (ST, n=17) and proteomics (n=12), as well as single-cell RNA-sequencing of fixed cells (scFFPE-seq) from consecutive sections of the same tissues from 15 patients. We also studied a subset of samples by high-plex spatial proteomics (COMET) or subcellular spatial gene expression analysis (Xenium). In total, we sequenced more than half a million single cells comprising diverse epithelial, immune, and stromal subsets, which were concordant with lineage clusters identified by ST analysis of the same samples. Loss of alveolar differentiation was a hallmark of tumor cell-enriched areas in aPMLs and LUADs, with a more pronounced effect in the LUADs. Alveolar intermediate cells (AICs), which we have previously shown to be involved in LUAD initiation, were found in lesion-adjacent NAT, and their signature was enriched in matching aPMLs and further in LUADs. In line with these findings, trajectory analysis showed that AICs are derived from normal alveolar type 2 cells and likely progress towards tumor cells. Spatial neighborhood analysis pointed towards strong crosstalk between AICs and macrophages. We also noted heterogeneity in immune infiltration including patterns indicative of progressive features along the NAT-aPML-LUAD continuum. For example, B cell lineages were not only increased in abundance in LUADs relative to aPMLs, but they also mobilized into relatively more mature tertiary lymphoid aggregates/structures. While T regulatory cells aggregated close to LUADs, they were rather scattered in matching aPMLs. Our multimodal and spatial atlas of NAT, nearby aPML and LUAD elucidates the earliest cellular events underlying transition of NAT to LUAD and that could inform of targets for interception of this trajectory.

#3894 The temporal influence of the tumor microenvironment in response to checkpoint blockade.

N. F. Greenwald[1], I. Nederlof[2], H. Horlings[2], M. Kok[2], C. Curtis[1], M. Angelo[1];
[1]Stanford University School of Medicine, Palo Alto, CA, [2]Netherlands Cancer Institute, Amsterdam, Netherlands

Immune checkpoint inhibition (ICI) has produced a paradigm shift in treatment across a range of cancer subtypes. However, our understanding of why only certain patients respond, as well as our ability to predict this response, is still quite limited. This is exacerbated by the complexity of the tumor microenvironment (TME), which contains cancer cells, immune cells, and stromal cells. These differing cell types can have context-dependent roles in either promoting or inhibiting anti-tumor immune responses, making it challenging to identify features which reliably correlate with patient outcome. In addition, the roles of these diverse cell types are often influenced by their location within the TME, meaning that assays without spatial information cannot fully resolve this complexity. To address these gaps, we mapped the spatial distribution and phenotype of 21 cell populations across 117 patients with metastatic triple negative breast cancer that received nivolumab (anti-PD1) through the TONIC clinical trial (NCT02499367). We collected metastatic samples prior to and during treatment to understand how anti-PD1 reshaped the TME. We also collected archival material from the original primary tumor for each patient. We generated multiplexed imaging data from these samples, identified the location and phenotype of each cell, and then quantified the spatial distribution, diversity, and functional marker status of all cell populations in the TME. We detected numerous features indicative of a productive immune response that correlated positively with clinical benefit, whereas features indicative of a suppressive microenvironment correlated negatively with clinical benefit. We observed significant temporal effects, where many pre-treatment predictive features were not predictive on-treatment; similarly, many on-treatment predictive features had no predictive power prior to treatment. Intriguingly, we found features in the original primary tumors which predicted subsequent (metastatic) response to immunotherapy. We observed substantial differences in predictive accuracy of multivariate models based on timepoint, with on-treatment samples exhibiting the best performance and primary tumor samples exhibiting the worst. Of note, we observed substantially worse predictive performance when using bulk DNA sequencing data to predict outcome from the same patients, highlighting the importance of spatial information. Taken together, we show that the features associated with a productive anti-tumor immune response are temporally structured, and differ based on what phase of response is profiled. Furthermore, using the primary tumor to assess whether metastatic TNBC patients are good candidates for ICI may miss important predictive signals. These findings shed new light on the determinants of ICI outcome, and may shape the design of subsequent trials to better understand the temporal aspects of ICI.

#3895 Prognostic significance of blood-based multi-cancer detection in cell-free DNA: 4-year outcomes analysis.

C. Swanton[1], M. Margolis[2], E. Hubbell[2], K. N. Kurtzman[2], S. Shih[2], O. Venn[2], M. Seiden[3];

[1]Cancer Evolution and Genome Instability Laboratory, The Francis Crick Institute, London, United Kingdom, [2]GRAIL, LLC, Menlo Park, CA, [3]Gladius Therapeutics, Inc, Philadelphia, PA

Background: The third substudy of the case-control Circulating Cell-free Genome Atlas (CCGA; NCT02889978) study reported an observed 99.5% specificity and 89% cancer signal origin prediction accuracy in true positives using a refined version of a blood-based multi-cancer early detection (MCED) test. A shared cancer signal has been detected across >50 cancer types. Most cancer types do not have recommended screening and are diagnosed once symptoms present. Previous analysis of participant outcomes evaluated the prognostic significance of cancer signal detection by an earlier version of the MCED test with 3-year longitudinal follow-up data. We present a longer follow-up time with an updated statistical model to robustly account for variation in cancer type and stage (ie, a cancer spectrum) when estimating survival hazards.

Methods: The MCED test utilizes targeted methylation sequencing of plasma cell-free DNA (cfDNA) and machine learning classifiers to estimate a cancer signal from tumor-derived cfDNA. We compared observed overall survival of participants with known cancer who had 4-year longitudinal follow-up data to expected survival from Surveillance, Epidemiology, and End Results (SEER) data matched for age, sex, cancer type, and stage to account for changes in the cancer spectrum between “Cancer Signal Detected” (CSD) and “No Cancer Signal Detected” (NCSD) groups using a refined MCED test version. Hazard ratios (HR) and Kaplan-Meier curves were calculated for these groups. A one sample test was used to estimate the HR and confidence interval against a reference survival distribution. A methylation-based estimate of ctDNA abundance was used to quantify the cfDNA tumor methylated fraction (TMeF).

Results: Follow-up data were available for 2471/2513 (98%) evaluable participants with known cancer (median 46.9 mos [IQR: 22.7 - 56.0]). Among 782 (31%) participants with known cancer that died during follow-up, the MCED test detected a cancer signal in 668 (85%). Accounting for the effect of cancer type and stage, the NCSD group had better survival than the CSD group (HR 0.585 [CI: 0.474-0.712]). Both the NCSD group and the CSD group had better survival than expected SEER-based survival ($p<0.05$, HR 0.432 [0.356-0.521] and $p<0.05$, HR 0.737 [0.684-0.791], respectively). TMeF increased with clinical stage ($p<0.05$) and was lower for NCSD cancers relative to CSD cancers for all stages ($p<0.05$).

Conclusions: In the third substudy of CCGA, extended follow-up confirmed the prognostic value of CSD compared to NCSD by the refined MCED test for participants with cancer.

#3896 Time to diagnosis analysis using miRNA-based ovarian cancer prediction models.

J. Webber[1], L. Wollborn[1], S. Mishra[1], S. Alimena[1], B. Testino[1], A. Vitonis[1], D. Cramer[1], D. Chowdhury[2], K. Elias[1];
[1]Brigham and Women's Hospital, Boston, MA, [2]Harvard Medical School, Boston, MA

Background: The recent literature proposes several diagnostic Machine Learning (ML) models for ovarian cancer based on miRNA expression profiling. These ML models are trained and validated on subjects whose miRNA sample was drawn proximate to cancer diagnosis (e.g., within one month). Whether these models remain useful remote from the time of diagnosis, when early detection or prevention would be most relevant, is unclear. Therefore, we examine the effect of time between blood draw and cancer diagnosis on miRNA-based ML model accuracy and the relevance of a cancer probability score, P_C, for estimating long-term cancer risk.

Methods: The study is based on the miRNA expression profiles of 2983 total subjects, which is comprised of 1829 subjects collected as part of the Biobank at Mass General Brigham (MGB), 110 samples from the Pelvic Mass Protocol at Brigham and Women's Hospital (Cramer), and 1044 samples which were obtained from the Prostate, Lung, Colorectal, and Ovarian (PLCO) cancer screening trial. miRNA expression was measured using a pre-specified panel of 179 miRNAs optimized for serum detection using the Fireplex® circulating miRNA assay. We trained ML models using 1865 controls and 74 ovarian cancer subjects (1829 Biobank + 55 Cramer + 55 PLCO). The training cancer samples were drawn between 1 day and 14 years from diagnosis, most within 30 days. The models were then validated on 769 control and 275 ovarian cancer subjects (989 PLCO + 55 Cramer) whose time to cancer diagnosis ranges between 1 and 1814 days (up to 5 years) after blood draw. Performance was reported as Area Under the receiver operator characteristic Curve (AUC).

Results: Among the validation set cases, we observe a decreasing trend in predicted cancer probability (P_C) with increasing log time ($R = -0.34$, $p < 0.0001$), and we see a similar trend in AUC score with time. On samples drawn within 21 days of cancer diagnosis, the ML model offers an AUC = 0.88, which decreases to AUC = 0.72 on samples drawn between 21 days and one year from diagnosis, and later plateaus at AUC ~ 0.72 up to five years from diagnosis.

Out of 2928 total subjects considered in the study, 286 had multiple blood draws taken over a 5-year time period. Using this data, we analyze the change in P_C over time per subject. The results show that P_C, for the average case subject, increased by 7% per year ($p = 0.02$). In contrast, when we applied the same analysis to control subjects, P_C increased by only 1% per year on average ($p = 0.62$). Thus, monitoring changes in P_C at regular intervals could be an informative cancer diagnostic.

In terms of relative risk, subjects with $P_C < 0.5$ had a relative 5-year cancer risk of 0.74, whereas subjects with $P_C > 0.5$ had relative risk 7.4 (i.e., an order of magnitude higher).

Conclusion: The results indicate that miRNA-based ML models can be used to identify individuals at increased long-term risk of ovarian cancer and provide a tool for profiling at regular intervals to allow earlier diagnosis of disease.

#3897 Isolation and molecular characterization of exosomes from glioblastoma patients using a microfluidic device after ultrasound-based opening of the blood-brain barrier.

Abha Kumari[1], Mark Youngblood[2], Andrew Gould[2], Yoon-Tae Kang[1], Li Chen[2], Karl Habashy[2], Chris Amidei[2], Rachel Ward[2], Cristal Gomez[2], Guillaume Bouchoux[2], Michael Canney[2], Roger Stupp[2], Adam M. Sonabend[2], Sunitha Nagrath[1]

[1]University of Michigan, Ann Arbor, MI,[2]Northwestern University, Chicago, IL

Glioblastoma (GBM) is a highly aggressive tumor of the brain. Current techniques of detection like magnetic resonance imaging and tissue biopsy are inaccurate or highly invasive, requiring alternatives like liquid biopsy. Exosomes are nanosized vesicles that contain cargo, reflective of their cellular origin and have been used for early diagnosis of cancer. However, in GBM, the blood-brain barrier (BBB) leads to a paucity of pathological information in blood. This study investigates the effect of opening the BBB on circulating exosomes and their potential for early detection of GBM using a microfluidic platform (^{Glio}ExoChip). In 20 patients enrolled in a clinical trial NCT03744026, a pulsed ultrasound emitter- Sonocloud-9 was implanted into their brains to open the BBB. We show that ^{Glio}ExoChip isolates GBM-specific exosomes with a high capture efficiency using phosphatidylserine and Annexin-V chemistry. Further, the amount of circulating EVs increases twofold after opening the BBB. Finally, the correlation between tumor growth rate and the exosome concentrations is evaluated longitudinally.

Methods: ^{Glio}ExoChip is a microfluidic platform with a polydimethylsiloxane top and a glass bottom, functionalized with neutravidin-biotinylated annexin-V. Experiments are performed with GBM cell-line derived exosomes, followed by patient plasma. Isolated exosomes are characterized using Nanoparticle tracking analysis (NTA), scanning electron microscopy, Bicinchoninic acid (BCA) assay and western blot. Statistical analyses are performed using Student's t-test and Pearson correlation.

Results: The microfluidic device ^{Glio}ExoChip has a high capture efficiency of exosomes derived from GBM cell lines, *i.e.,* 93.03±3.31% and 96.77±0.72% for GBM6 and U87, respectively. NTA and BCA showed that 15 times more exosomes were captured from patient plasma when compared with healthy. Further, western blot proved the presence of a glial protein and Flotillin-1 in exosomes isolated from patients. Exosome concentrations varied with different time points after sonication and had an average twofold increase from the BBB opening. In our longitudinal study with 8 patients, an association between the volumetric enhancement of the tumor and exosome concentrations after sonication shows that the average Pearson correlation among short progression-free survival (PFS) patients was 0.73 (avg. p=0.39), while no correlation was seen among long PFS patients (avg. r value=0.10; avg. p-value=0.54).

Conclusions: A microfluidic approach was used to investigate the role of circulating exosomes using phosphatidylserine-annexin V chemistry in GBM. BBB opening via sonication leads to an increase in the average GBM-specific exosome concentrations in plasma. Thus, exosomes are promising biomarkers for early detection in GBM.

#3898 SJPedPanel: A pan-cancer gene panel for childhood malignancies.

P. Kolekar, V. Balagopal, L. Dong, Y. Liu, S. Foy, Q. Tran, H. Mulder, A. Huskey, E. Plyler, Z. Liang, J. Ma, J. Nakitandwe, J. Gu, J. Maciaszek, D. Payne-Turner, S. Mallampati, L. Wang, J. Easton, J. Klco, X. Ma;
St. Jude Children's Research Hospital, Memphis, TN

Background: Extensive efforts in the past decade have revolutionized our understanding of the genetic underpinnings of childhood malignancies and identified numerous driver alterations that can provide potential targets for novel therapy and are excellent biomarkers for disease monitoring. For these purposes, a whole genome or exome sequencing approach can be resource prohibitive. Numerous gene panels are developed for adult cancers to address these challenges. Due to the dramatic differences in driver gene landscapes between pediatric and adult cancers, a gene panel for childhood cancers is needed.
Results: Here, we have developed a gene panel dedicated to childhood cancers. This panel (2.8 Mbp) covers 5275 coding exons of 357 driver genes, 297 introns frequently involved in rearrangements that generate fusion oncoproteins, commonly deleted regions, such as CDKN2A and PAX5 (for B-/T-ALL) and SMARCB1 (for ATRT), and 7,590 polymorphism sites to detect copy number alterations for interrogating tumors with aneuploidy, such as hyperdiploid and hypodiploid B-ALL or 17q gain neuroblastoma. We used driver alterations reported from an established real-time clinical genomics cohort (n=253) to investigate the effectiveness of this gene panel. Among the 485 pathogenic variants reported, our panel covered 417 variants (86%). For 90 rearrangements responsible for oncogenic fusions, our panel covered 74 events (82%). We re-sequenced 113 previously characterized clinical specimens at an average depth of 2,500X using SJPedPanel and recovered 355 (90%) of the 396 reported pathogenic variants. Among the 30 unique genes of the 41 missed alterations, 29 genes are mutated in pediatric cancers with a low frequency (<0.21%) and hence not covered in the panel. We then investigated the power of this panel in detecting mutations from specimens with low tumor content (as low as 0.1%) using cell line-based dilution experiments and discovered that this gene panel enabled us to detect ~80% variants with allele fraction of 0.2%, while the detection rate decreases to ~50% when the allele fraction is 0.1%. We finally demonstrate its utility in disease monitoring on clinical specimens collected from AML patients in morphologic remission.
Conclusion: Overall, our gene panel enables the detection of clinically relevant genetic alterations including rearrangements responsible for subtype-defining fusions for childhood cancers by targeted sequencing of ~0.15% of human genome. Our panel will significantly enhance the analysis of specimens with low tumor burdens for cancer monitoring and early detection.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Drug Discovery 1: New Targets and Approaches Minisymposium

#3900 A high-throughput platform identifies novel drug combinations towards acute myeloid leukemia therapy.

A. R. Soltis[1], B. Zhelyazkova[1], P. Drane[1], E. Eleftheriadis[1], A. Ventresco[1], D. A. Weitz[2], A. Lee[1], A. J. Iafrate[3];
[1]Hunter Biodiscovery, Inc., Boston, MA, [2]Harvard University, Cambridge, MA, [3]Massachusetts General Hospital, Boston, MA

Molecularly targeted therapies have reshaped oncology in recent decades, though not all patients are eligible for such treatments and resistance mechanisms limit clinical benefit. In response, combination therapies, which can induce potent synthetic lethalities, bypass drug resistance, and expand treatment options, are increasingly being developed. A major hurdle limiting novel combination therapy discovery is the sheer combinatorics associated with broadly testing two or more agents. Thus, there is a practical need for methodologies that prioritize test compounds and technologies for rapid and efficient screening. Towards these ends, we have developed a novel combination drug screening workflow that integrates machine learning-based drug synergy predictions with a high throughput droplet microfluidics-based screening platform. Our physical system, or FlowMatrix, consists of 9,216 nano wells arrayed in a 96 x 96 grid in which cells are incubated and drug compounds delivered via emulsified droplets along both its rows and columns to facilitate combination screening. Following multi-day incubation, live cells are imaged with fluorescence microscopy and drug combination synergies are calculated from cellular viabilities. In our current setup, which includes four dose drug treatments with replicates and controls, we capture complete data (control, single agent, and 4x4 drug-drug combination viability measurements) for up to 100 unique drug combinations within the 9,216 dual droplet loaded wells of one FlowMatrix. Our to-date screening efforts have focused on acute myeloid leukemia (AML) specifically, where we have profiled 12,700 AML cell line-drug combinations in our system. This encompasses >3,700 unique drug combinations profiled in 7 distinct AML cell lines with 183 total matrix runs. Among the strongest hits observed in our screens and confirmed with validation studies (~65% confirmation rate) are combinations currently being tested in clinical trials for other cancers and established therapies paired with non-cancer indicated drugs. In particular, we are interrogating combinations involving CDK12 inhibitors, which affect the transcription of DNA repair proteins, splicing, and cancer cell progression, including unexpected partner drugs that potentiate the effects of CDK12 blockade in AML cell lines. We have uncovered additional unexpected synergistic combinations with KIT inhibitors in *RUNX1-RUNX1T1* altered AML lines, ATR inhibitors (including an established combination with Gemcitabine), and the BCL-2 inhibitor Venetoclax, including known partnerships with chemotherapies (e.g. Decitabine and Daunorubicin) and other targeted inhibitors. Deeper studies are underway to further validate and characterize these candidates towards expanding treatment options for AML. Ultimately, our platform may radically enhance drug combination screening potential.

#3901 Therapeutic targeting of LGR5-positive cancer stem cells.

M. Mulero, C. Rice, S. A. Jahdav, W. Pi, A. Lin, M. Nguyen, O. Tai, **S. B. Howell**;
UCSD Moores Cancer Center, La Jolla, CA

Introduction: Destruction of cancer stem cells (CSC) is a major therapeutic goal. LGR5 marks active stem cells in many types of solid cancers. It has been very difficult to isolate good antibodies to native LGR5 and attempts to develop ADCs targeting LGR5 have not advanced. We took the alternative approach of using a natural LGR5 ligand to target monomethylauristatin (MMAE) to LGR5-expressing CSC. An Fc domain was fused to the LGR binding domains of RSPO1 and the sortase reaction was used to conjugate a Gly_3-val/cit-PAB-MMAE linker at the C-terminal end to create FcF2-MMAE. We previously reported its efficacy in ovarian models here document its activity in other aggressive cancer models.

Methods: FcF2-MMAE was produced by transient transfection in HEK293E cells and purified by a sequential Ni-NTA and ion exchange chromatography. OVCAR8 ovarian cancer cells were molecularly engineered to stably express an empty vector (OVCAR8/EV) or LGR5 (OVCAR8/LGR5.6) at a 10-fold higher level. The sortase A enzyme was produced *in E. coli*. Flow cytometry was used to quantify cell surface LGR5 in live cells using an anti-LGR5 antibody.

Results: DEPMAP tools were used to identify cell types with high levels of WNT signaling that drives expression of LGR5. FCM confirmed LGR5 expression in colon LoVo, gastric AGS and neuroblastoma SKNAS cells. All three lines were very sensitive to FcF2-MMAE; GI_{50} values in 2D cultures were: LoVo 4.5, AGS 0.7 and SKNAS 8.6 nM. IC_{50} values for stem cell-derived spheroids grown from these lines were: 11.0, 3.0 and 1.70 nM, respectively. The MTD of FcF2-MMAE was found to be >1.5 nmol/g in mice. The plasma half-life was 29.7 h. A q7dx4 IP dose schedule was found to be more effective than a q4dx4 IP schedule. FcF2-MMAE inhibited *in vivo* SC growth in all 3 models at a dose of 1 nmol/g q7dx4, producing cures in a fraction of AGS tumors and delaying SKNAS growth >2-fold in the absence adverse events. In addition to MMAE, we showed that FcF2-His could be conjugated to the either deruxtecan or PNU159682; FcF2-His loaded with either one of these cytotoxins had low nM or sub nM cytotoxicity and retained the same high selectivity of FcF2-MMAE when tested in isogenic OVCAR8/EV and OVCAR8/LGR5 cells.

Conclusions: FcF2-MMAE has activity in xenograft models of very aggressive tumors driven by high levels of WNT signaling (LoVo, AGS, and SKNAS) and LGR5 expression. Efficacy was obtained at doses well below its MTD indicating a wide therapeutic window. The FcF2 core accommodates multiple types of warheads without loss of targeting selectivity. The ability to switch out one cytotoxin for another provides versatility in targeting different diseases. FcF2-MMAE has advantages over ASCs. Its small size relative to antibodies favors better tumor penetration. The binding domains of RSPO1 also target stem cells expressing LGR4 and LGR6 as well as LGR5, something that cannot be achieved with an ADC. These features support the further development of FcF2-MMAE as a stem cell-targeted therapeutic.

#3902 The Nanoprimer: A significant opportunity to boost the efficacy of cancer therapies.

J. Devalliere, L. Poul, M. Bergere, F. Mpambani, A. Darmon, O. Jibault, M. Germain;
Curadigm, Paris, France

Nanomedicines are among the most promising novel delivery systems and are highly promising as therapeutic agents in oncology. However, their use is still limited by nanoparticle hepatic clearance which is responsible for low delivery to the target site. Moreover, the unintended liver distribution could cause harmful side effects. Curadigm's innovative Nanoprimer technology aims to shift the balance of therapeutics bioavailability and toxicity. The platform is designed to decrease nanomedicines' liver trapping and increase their systemic bioavailability for optimal accumulation in target tissues. This technology can redefine the benefit/risk ratio of therapeutics, improving their clinical outcomes and treatment value. The Nanoprimer is an engineered, biocompatible liposome that transiently and specifically occupies the cells of the mononuclear phagocytic system responsible for sub-optimal therapeutics bioavailability. The Nanoprimer is administered just before the therapeutic, temporarily reducing drug clearance and elimination. Proofs-of-concept were realized by combining the Nanoprimer with different therapeutic agents such as irinotecan-loaded liposomes and nucleic acid-loaded lipid nanoparticles (LNP). One example is a study conducted in collaboration with the Langer Lab at MIT that shows that the Nanoprimer increases mRNA- and siRNA-based therapeutics efficiency by 32% and 49% respectively. Efficacy studies in a triple-negative breast cancer mouse model reveal that the Nanoprimer increases by 2-fold the anti-tumor efficacy of siRNA LNP therapy. Data demonstrate the safety of the Nanoprimer, along with its ability to maximize the inhibition of primary tumor growth and pulmonary metastasis by systemic siRNA LNP treatment. In a collaborative study with the NCL*, the Nanoprimer was shown to stimulate the immune response in a systemic vaccine model using ovalbumin-coated gold nanoparticles (GNP-OVA). Administration of the Nanoprimer before immunization of mice by intravenous injection of GNP-OVA, results in a dramatic increase in anti-OVA antibody levels with IgGs detected as early as 7 days. Furthermore, IgG and IgM antibodies remain elevated at day 28 showing a robust and sustainable immune response. Nanoprimer ability to enhance immune response shows its great potential in immunotherapy, especially for cancer vaccines. Altogether, these data demonstrate that the ubiquitous nature of the Nanoprimer mode of action allows its application to a broad spectrum of therapeutics, from nucleic acid-loaded LNP to immunotherapy. Efficacy studies conducted in mouse models highlight the potential for the Nanoprimer to empower nanotechnology for oncology treatments. *We acknowledge NCL, Frederick National Laboratory for Cancer Research sponsored by the NCI for the help with conducting these experiments.

#3903 Discovery of ULBP6 as a novel immuno-oncology target using pleiotropic signals from 23andMe's genetic and health survey database.

S. Tilk[1], P. Fontanillas[1], W.-J. Chung[2], C. Hom[1], S. Shi[1], A. Diep[1], **K. Gerrick**[1], M. Poggio[1], P. Sood[1];
[1]23andme, Inc., South San Francisco, CA, [2]Loxo@Lilly, Stamford, CT

23andMe has assembled one of the largest platforms for human genetics research that combines genotypes from 14 million individuals, 80% of which are consented to participate in research, with billions of phenotypic data points collected from health survey data. Using these large scale genetic and phenotypic datasets, we have developed a unique target discovery platform that has identified hundreds of pleiotropic genetic variants with opposing directionality of effects in cancer and immune diseases. These immune-oncology (I/O) genetic associations point to already clinically validated immune checkpoint receptors (e.g., CTLA4) and those currently in clinical trials (e.g., CD200R1). This suggests that these I/O genetic associations could be linked to genes that are broadly utilized by tumor cells to evade the immune system and could be used to identify novel therapeutic targets involved in regulating anti-tumor immune response. Here, we utilized expression quantitative trait loci (eQTLs) and annotation of coding single nucleotide polymorphisms (SNPs) to link one of these signals to a causal gene, and identified ULBP6, a stress-induced ligand for the activating immunoreceptor NKG2D found on NK and T cells. ULBP6 is known to be shed from the cell surface of tumor cells to block its interaction with NKG2D to evade immune surveillance. Expression profiling of ULBP ligands in various tumor types using MSD, IHC, bulk and single-cell RNA-seq revealed tumor-intrinsic up-regulation of ULBP6 in squamous cancer subtypes. Collectively, these data suggest that ULBP6 is a promising therapeutic target, and that can potentially enhance anti-tumor immunity.

#3904 Multiplexed flow cytometry based immunophenotyping paired with functional *ex vivo* (MFLEX) drug profiling informs potential efficacy of therapeutic agents in acute myeloid leukemia.

R. Shah, H. Wander, M. Hsueh, M. Floren, W. Liu, P. Cheung, C. Andersen, M. White, N. Kingston, P. M. Gutierrez, L. Drew, G. Fabbri, E. Bibikova, D. Auclair; AstraZeneca US, South San Francisco, CA

Introduction: Acute Myeloid Leukemia (AML) is a heterogenous hematological malignancy with a complex clonal architecture that requires in-depth immunophenotyping for disease characterization. Conventional AML e*x vivo* models for preclinical drug screening lack functional readouts that provide single cell level data to identify drug activity in defined AML subsets with unique immune signatures. Here, we present a novel platform that links Multiparameter Flow cytometry with high-throughput *EX vivo* drug screening (MFLEX) in AML patient-derived cell models to simultaneously detect phenotypic changes and predict cell-subset specific drug responses in AML.

Method: We developed a 21-color high-dimensional immune profiling panel that captures AML heterogeneity by delineating primitive and mature AML blasts along with normal hematopoietic lineages. The panel also includes markers for functional measurement of apoptosis, proliferation, differentiation, and expression of BCL2 family proteins in lymphoid and myeloid cell subsets. *Ex vivo* culture conditions were optimized using physiologically relevant stroma-free cytokine-rich media that supports primary AML cells with minimal phenotypic shift, allowing for high throughput functional drug sensitivity testing. Timepoints and dosing conditions for AML standard of care (SoC) agents were optimized to support combination screens. Multi-parameter datasets were analysed for functional differences and visualized using dimension reduction methods.

Results: We tested MFLEX on clinically annotated AML samples to understand sensitivity profiles to venetoclax and combination partners: 5-azacytidine, cytarabine, fludarabine and gilteritinib. We identified distinct drug sensitivity profiles for venetoclax in AML patients with varying leukemic differentiation states where M0/M1 subtypes were more sensitive to therapy than M4/M5. We also observed cell lineage specific sensitivities, with myeloid blast being more sensitive to venetoclax compared to autologous CD4+ and CD8+ T-cells and this observed difference was correlated with higher expression of BCL2. Our platform demonstrated that patients who previously failed venetoclax therapy could benefit from a combination with 5-azacytidine or fludarabine and this was patient-specific. We further evaluated MFLEX's predictive value for patient clinical response by systematically comparing venetoclax sensitivity in patient-derived xenograft models *in vivo* vs *ex vivo* and found a high correlation between drug responses.

Conclusion: We have established a unique, immune drug screening platform, MFLEX, that has high translational value and can be implemented in clinical trials to identify drug response patterns, novel combinations, and potential biomarkers of response for patient stratification in AML.

#3905 Targeting RNA demethylase ALKBH5 blocks growth and improves therapy response in osteosarcoma.

D. Medina, S. Timilsina, P. Subbarayalu, P. P. Venkata, D. Singh, T. Do, S. Zhou, Y. K. Gupta, D. Zhou, M. K. Rao;
UT Health Science Center at San Antonio, San Antonio, TX

Background: Osteosarcoma (OS) arises primarily in children and adolescents, with a second peak in incidence in those over the age of 50. Unfortunately, outcomes of patients with metastatic or relapsed osteosarcoma have remained abysmal. Moreover, patients who survive have a highly compromised quality of life due to debilitating side effects associated with chemotherapy drugs. Virtually no new drug has been approved for treating OS in the last three decades. Recently our group showed that ALKBH5 is critical for promoting OS growth and metastasis and may thus serve as a unique driver of OS. We therefore hypothesized that epigenetic changes, specifically mRNA demethylation mediated by the RNA demethylase ALKBH5, play a pivotal role in OS growth and metastasis, and hence approaches aimed at inhibiting ALKBH5 activity could prove clinical utility for patients with OS.
Methods: shRNA and CRISPR-Cas9-based knockout were used to study the effect of depleting ALKBH5 in osteosarcoma and the effect it has on growth and metastasis. Fluorescence-based high-throughput screening (HTS) assay was used to identify targets of ALKBH5. FDA-approved and LOPAC compound libraries were used. SPR analysis was used to determine the Mefloquine-ALKBH5 interaction. *In vitro* and *In vivo* intratibial orthotopic models were used to test the efficacy of Mefloquine for blocking OS growth. Experiments are currently underway to test the effect of combining Mefloquine and doxorubicin in inhibiting OS growth and metastasis.
Results: We showed that upregulation of the ALKBH5 attenuates histone H2A monoubiquitination to result in the induction of key pro-tumorigenic genes and consequently unchecked cell cycle progression, incessant DNA replication, and upregulation of DSB repair. Unbiased high throughput screening using a LOPAC library identified mefloquine as a potential ALKBH5 inhibitor. SPR analysis showed the interaction of Mefloquine with ALKBH5 catalytic domain. M^6A dot blot confirmed that mefloquine inhibits the catalytic activity of ALKBH5. Cell-based assays showed reduced short-term and long-term growth with the treatment of mefloquine. *In vivo* models showed a reduction in tumor volume upon mefloquine oral treatment.
Conclusion: Our results establish RNA demethylase ALKBH5 as a novel driver of OS. This project has a direct translational relevance as an FDA-approved drug can be repurposed for treating OS patients as a monotherapy or in combination with doxorubicin and be formally tested in the clinic without much delay.

#3906 *Ex vivo* breast tumors for understanding the patient specific tumor microenvironment remodeling and drug responses.

E. Martin[1], M. Benz[2], K. Hebert[2], E. Byrne[3], F. Lau[1];
[1]Keliomics, Portland, OR, [2]Tulane University, New Orleans, LA, [3]Louisiana State University, Baton Rouge, LA

Breast cancer is a heterogeneous disease driven by cell-intrinsic and cell-extrinsic signaling cues. Many of these cues derive from the tumor microenvironment (TME), which is composed of adipocytes, vasculature, stem cells, immune cells, and the extracellular matrix (ECM). Through these diverse components, the TME modulates cellular proliferation, survival, and ultimately response to therapy. Despite this high-level understanding of tumor-TME crosstalk, no existing pre-clinical models accurately capture the TME *in vitro*. We overcame that hurdle by developing a method to maintain healthy human breast tissue (HBT) alive *ex vivo* for at least 8 weeks. By culturing breast cancer cells in that HBT, we created ex vivo breast tumors (EVBTs) that retained patient-specific features relevant to breast cancer including menopause status, obesity status, and response to therapy. Using these EVBTs, we demonstrate breast cancer subtype-specific alterations in lipid accumulation, ECM remodeling, and cytokine profiles. RNA sequencing showed that breast cancer cell line signatures were retained in the EVBTs system at 1 week and 2 weeks *in vitro*. We demonstrated donor-specific transcriptional changes to the core matrisome gene set. Finally, we demonstrate that our EVBTs retained patient-specific heterogeneity in response to standard of care endocrine therapy and neoadjuvant chemotherapies. Our novel tumor model allows for 1) real-time examination of breast cancer interactions with HBT and the TME and 2) the isolation of breast cancer-specific factors vs. patient-specific factors in the development and progression of breast cancer.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Novel Molecular Targets and Biomarkers Minisymposium

#3907 Novel public and tumor-wide neoantigens arising from clonal aberrant splicing events drive tumor-specific T-cell responses across diverse cancer types.

Darwin Kwok[1], Nicholas O. Stevers[1], Takahide Nejo[1], Lee H. Chen[1], Inaki Etxeberria[2], Jangham Jung[1], Kaori Okada[1], Maggie Colton Cove[1], Senthilnath Lakshmanachetty[1], Marco Gallus[1], Abhilash Barpanda[1], Chibo Hong[1], Gary KL Chan[1], Samuel H. [1]UCSF - University of California San Francisco, San Francisco, CA,[2]Memorial Sloan Kettering Cancer Center, New York City, NY

BACKGROUND: Immunotherapy in gliomas is limited by intratumor heterogeneity (ITH) and low mutational burden. We developed a novel comprehensive *in silico* pipeline for detecting tumor-specific splicing events (neojunctions), and across multiple cancer types, we successfully identified a new class of tumor-wide, public, alternatively spliced neoantigens (ASNs) that elicit CD8+ T-cell-mediated immune responses.

METHODS: Our pipeline identified recurring public neojunctions expressed in TCGA RNA-seq (positive sample rate (PSR) > 10%) and not in GTEx normal tissue RNA-seq data (PSR < 1%) across ten cancer types. To characterize tumor-wide neojunctions, we utilized available multi-site RNA sequencing across diverse cancer types. With gliomas, our in-house dataset comprised of 56 patients with approximately 10 maximally-distanced intratumoral biopsy sites per patient (*n*=535). Tumor-wide public neojunction expression was subsequently validated in RNA-sequencing and mass spectrometry (MS) data from patient-derived cell lines (*n*=68) and samples (*n*=447). Two independent algorithms then predicted peptide processing likelihood and HLA-binding affinity of ASN candidates. TCRs identified by *in vitro* sensitization (IVS) of donor-derived CD8+ T-cells followed by 10x VDJ scRNA-seq, were transduced into CD8+ T-cells and co-cultured with tumor cells to evaluate TCR functionality and cytotoxicity.

RESULTS: Pan-cancer analysis identified large subsets of neojunctions that were interpatiently and intratumorally conserved. Our glioma-specific analysis identified 789 public neojunctions, and 8 ASNs were validated in transcriptomic and proteomic glioma data and predicted to be presented by HLA-A*02:01 with high confidence. IVS and subsequent 10x VDJ scRNA-seq on expanded PBMC-derived CD8+ populations cultured against ASN-pulsed dendritic cells identified TCR clonotypes reactive against neojunctions in *RPL22* (*n*=7) and *GNAS* (*n*=1), the latter being highly intratumorally-conserved (detected in > 90% of spatially-mapped biopsies in 17/56 patients (26.78%)). TCR-transduced T-cells demonstrated recognition and immunogenic activation against endogenously processed and presented neoantigens in both pan-cancer cell lines and transfected COS7 cells and cytotoxicity against glioma cell lines. Pan-cancer analysis revealed the detection of both neojunctions in various tumor types beyond gliomas, with the GNAS neojunction notably found tumor-wide in mesothelioma, prostate cancer, and liver hepatocellular carcinoma spatial data.

CONCLUSION: Our unique integrative pipeline identified a novel class public tumor-wide splice-derived neoantigen candidates and ASN-specific TCRs, offering a promising off-the-shelf immunotherapy approach for diverse cancer types and tackling the critical challenge of ITH in immunotherapy resistance.

#3908 DHX9 inhibition as a novel therapeutic for cancer with loss-of-function mutations in DNA damage repair genes BRCA1 and BRCA2.

J. B. Castro, M. H. Daniels, S. Nayak, M. Laidlaw, D. Brennan, B. T. Johnston, J. Wu, A. Raman, C. Lu, S. J. Blakemore, S. J. Silver, P. Boriack-Sjodin, K. W. Duncan, J. A. Sager, R. A. Copeland;
Accent Therapeutics, Lexington, MA

DHX9 is a DEAH-box RNA helicase which can unwind regions of double-stranded DNA and RNA but has a greater propensity for secondary structures such as DNA/RNA hybrids (R-loops), circular RNA and DNA/RNA G-quadruplexes. Given the delicate balance of R-loop formation and resolution in maintaining efficient transcription and replication, the ability of DHX9 to unwind R-loops is important in helping to maintain genomic stability. In addition, DHX9 can interact and regulate a large variety of proteins, including key proteins in DNA damage repair pathways such as BRCA1, ATR, Ku86, and WRN. Previously we demonstrated that DHX9 inhibition was efficacious in microsatellite high (MSI-H) CRC xenograft tumor models. Efficacy attributed to DHX9 loss in MSI-H correlates with defective DNA repair pathways such as mismatch repair (MMR). Here we report results of preclinical studies in ovarian and breast cancer models that indicate patients with Loss-of-Function (LOF) mutations in the DNA damage repair genes BRCA1 and/or BRCA2, may also benefit from DHX9 inhibitor treatment. DHX9 small molecule inhibitor ATX968 was tested for anti-proliferative activity in a large cell panel of 300 cell lines, and bioinformatic analyses was performed to identify molecular variants that co-associate with sensitivity or resistance cell proliferation outcomes. Notably, selective dependency on DHX9 was observed in both ovarian and breast cancer cell lines that exhibit BRCA LOF, as defined by somatic mutations including single-nucleotide variants and/or copy number loss in BRCA1 and/or BRCA2. DHX9 inhibition leads to increased RNA/DNA secondary structures such as R-loops and G-quadruplexes, resulting in subsequent DNA damage and increased replication stress. Cell lines that exhibit BRCA LOF appear unable to resolve this replication stress and show S-G2 phase cell cycle arrest prior to onset of apoptosis. Furthermore, a potent and selective DHX9 inhibitor tool compound was dosed orally *in vivo* to assess DHX9 dependency within multiple human xenografts representing triple negative breast cancer and high-grade serous ovarian cancer with BRCA LOF. In all models, the tool DHX9 inhibitor was dosed orally at 100 mg/kg BID and it was well tolerated for a period of up to 28 days. Robust and significant tumor growth inhibition and regression was observed in multiple BRCA LOF models with minimal tumor growth inhibition observed in BRCA1 and BRCA2 wild type xenograft models. These results extend the opportunity for DHX9 inhibition to provide therapeutic benefit for patients with solid tumors beyond what was previously reported for MSI-H CRC. Together, this preclinical data package validates DHX9 as a tractable new target with potential utility as a novel treatment for patients with defective DNA repair, such as MMR and BRCA1 and/or BRCA2 LOF, across multiple tumor types including colorectal, breast and ovarian cancer.

#3909 PARG inhibitor sensitivity is correlated with accumulation of single strand DNA gaps in preclinical models of ovarian cancer.

R. Ravindranathan, O. Somuncu, Y. Jiao, A. da Costa, B. Lamarre, D. Martignetti, G. Zambrano, S. Mukkavalli, J. Liu, B. Kochupurakkal, J.-B. Lazaro, K. Parmar, G. Shapiro, A. D'Andrea;
Dana Farber Cancer Institute, Boston, MA

Poly (ADP-ribose) glycohydrolase (PARG) is a dePARylating enzyme which promotes DNA repair in conjunction with PARP1 by removal of poly (ADP-ribose) (PAR). Loss or inhibition of PARG results in replication stress and sensitizes cancer cells to DNA damaging agents, suggesting it is a potential therapeutic target for cancer therapy. Indeed, PARG inhibitors are now undergoing clinical development for patients having tumors with homologous recombination deficiency (HRD), such as ovarian and breast cancer patients with *BRCA1/2*-mutation. In this study, we investigated PARG inhibitor (PARGi)-PDD00017273 activity in preclinical models of ovarian cancer cell lines and primary patient-derived organoids. PARGi exhibited sensitivity in a subset of ovarian cancer cell lines that was distinct from PARP inhibitor sensitivity. Initially, we evaluated a PARGi-sensitive cell line, RMUGS. By gradually increasing the concentration of PARGi, we generated drug resistant cells. PARGi treatment resulted in increased S phase specific PAR, DNA-PARylation, DNA damage, and replication stress in the sensitive cells but not in cells with *de novo* or acquired resistance. In the sensitive cells, PARGi exposure also increased accumulation of PAR at the replication fork resulting from unligated Okazaki fragment processing. More importantly, PARGi treatment or PARG loss caused accumulation of single strand DNA (ssDNA) gaps in sensitive cells, as detected by the DNA fiber assays combined with S1 nuclease treatment. Regardless of the *BRCA*-status, the induction of ssDNA gaps in ovarian cancer cells correlated with PARGi sensitivity. Consistent with an increase in ssDNA gaps, PARGi exposure increased p-RPA, a ssDNA surrogate, at the replication fork in sensitive cells. p-RPA sites also colocalized with PAR suggesting that accumulation of PAR occurs at the ssDNA sites, perhaps, leading to the ssDNA gaps. Collectively, these results suggested that toxic accumulation of PAR at the replication fork leads to accumulation of ssDNA gaps due to Okazaki fragment processing defects and ovarian cancer cell killing after PARG inhibition. We further assessed PARG inhibition in patient-derived organoids (PDOs) and patient-derived xenograft (PDX)-derived organoids (PDXOs) as model systems of ovarian cancer. PARGi exhibited monotherapy activity in specific HR-deficient PDOs and PDXOs with *BRCA1* or *RAD51C* mutation and in a HR-proficient PDXO model. Importantly, PARGi exposure resulted in accumulation of ssDNA gaps in organoids of ovarian cancer and this phenotype directly correlated with drug sensitivity. PDOs can therefore be a useful model system for testing PARGi sensitivity. The detection of ssDNA gaps in PDOs may provide a functional biomarker to predict the response to PARG inhibitors in clinical trials.

#3910 The Atlas of Blood Cancer Genomes: A resource for therapeutic and biomarker development.

J. Shingleton[1], R. Pillai[2], S. Ondrejka[3], G. Bhagat[4], A. Chadburn[5], M. McKinney[1], J. Koff[6], D. Soliman[7], M. Czader[8], A. Louissaint[9], S. Li[10], C. Ong[11], A. Behdad[12], A. Developing a novel cancer therapy is an expensive, time-consuming, high-risk endeavor that involves identifying a molecular target as well as target indications. This process could be accelerated by a comprehensive interrogation of driver variants and gene expression profiles across cancer types. The Atlas of Blood Cancer Genomes (ABCG) project was initiated to elucidate the molecular basis of all leukemias and lymphomas, building on advances in genomic technologies, our capabilities for data analysis, and economies of scale.

The ABCG project includes collaborators from 25 institutions worldwide who contributed samples from 10,512 patients comprising every type of blood cancer in the World Health Organization classifications. All cases were de-identified and their associated pathology and clinical information entered into a purpose-built web-based system. All cases underwent pathology and clinical data review by experienced hematopathologists and oncologists. Samples were subjected to whole exome DNA and RNA sequencing.

We examined three classes of therapeutic targets with selected examples of application: 1. Surface markers: Surface markers are targets of many approved and experimental therapies in blood cancers (CAR-T cells, monoclonal and bispecific antibodies). We found that CD22, which has been evaluated as a target in diffuse large B-cell lymphoma (DLBCL), is also highly expressed in follicular lymphoma, adult ALL, mantle cell lymphoma, and high-grade B cell lymphoma, all areas of clinical need. We can evaluate the expression of virtually any marker or combination of markers across all blood cancers while noting areas of greatest clinical need within and across diseases, providing the basis to reclassify diseases by therapeutic target. 2. Genetic targets: Our work assesses the entire spectrum of genetic alterations including mutations and fusions. We found targetable alterations including BCR-ABL1 fusions, EZH2 Y641, IDH2 R140Q and BRAF V600E mutations in multiple cancers, albeit at low frequency, pointing to potential new indications for existing drugs in subsets of rare diseases. 3. Complex targets (immune or expression signatures or combinations of gene variants): Past work defined DLBCL immune and other signatures associated with response to avadomide, a novel cereblon inhibitor. We found that these signatures are also highly expressed in large subsets of peripheral T-cell lymphomas and acute myeloid leukemia, both areas of major unmet clinical need. Thus, we can interrogate immune and other signatures across the spectrum of cancers to uncover potential biomarkers of response.

The ABCG project will enable the comprehensive study of genomic and clinicopathological features of all blood cancers. We anticipate that our data, approaches and results will provide a lasting resource for molecular classification and therapeutic development in all leukemias and lymphomas.

#3911 A FGFR-p53 developmental signaling axis drives progression of salivary cancer.

Lee Moffitt Cancer Center, Tampa, FL,[10]Department of Otolaryngology/Head and Neck Surgery, University of North Carolina at Chapel Hill, Chapel Hill, NC,[11]Department of Cell and Tissue Biology; Program in Craniofacial Biology, University of California San Francisco, San Francisco, CA,[12]Department of Cell Biology and Physiology; McAllister Heart Institute, UNC School of Medicine, University of North Carolina at Chapel Hill, Chapel Hill, NC,[13]Department of Tumor Microenvironment & Metastasis; Head and Neck Oncology Program, H. Lee Moffitt Cancer Center, Tampa, FL

Mucoepidermoid carcinoma (MEC) is the most frequently occurring salivary gland (SG) malignancy. Treatments for high grade (HG) MEC are lacking due to a limited understanding of its diverse histological and clinical features. Consequently, patients with non-resectable HG MEC are often treated with adjuvant radiotherapy and suffer from increased rates of recurrence and metastasis with poor 5-year survival rates (30-50%) as compared to low grade (LG) MEC (76-95%). We previously demonstrated a role for IGF-1 signaling, an important mediator for SG development and branching morphogenesis, in MEC pathogenesis (Musicant et al, 2021). Here, we analyzed transcriptome profiles shared between fetal and adult normal parotid (PAR) tissues with MEC tumors to investigate programs involved in MEC progression. Using this information, we developed the first genetically engineered mouse model (GEMM) of advanced HG MEC via targeted oncogene expression in SG ductal cells. MEC samples from 21 PAR tumors (8 LG/13 HG), 8 age-matched normal, and 3 fetal PAR glands aged between 22-24 weeks of gestation (Saitou et al, 2020) were retrospectively collected from UCSF or UNC Surgical Pathology. RNAseq was performed on FFPE samples using Illumina HiSeq. Differential gene expression, gene set enrichment analyses (GSEA), and alternative splicing analyses were compared between fetal/normal/MEC according to tumor grade and CRTC1 (CREB-regulated transcription coactivator 1)/MAML2 (Mastermind-like 2) (C1/M2) status. Based on these analyses, we developed a GEMM combining C1/M2 expression with TP53 loss. GEMM tumors were subjected to RNAseq and reviewed by two independent pathologists for diagnostic confirmation of HG MEC.GSEA revealed significant overlap between MEC tumors and fetal SG for genes governing proliferation and developmental pathways associated with branching morphogenesis. Interestingly, upregulation of the negatively regulated p53 target FOXM1 along with a mutant-p53 gene signature (Troester et al, 2006) revealed that p53 dysregulation in HG tumors phenocopies that seen in fetal SG. Cre-inducible expression of C1/M2 alone was insufficient to induce MEC-like lesions when targeted to distinct salivary cell types (ductal Krt14-CreER, acinar Mist1-CreER, serous demilune Dcpp1-CreER). However, p53 alteration ($Tp53^{KO}$) with ductal C1/M2 expression drove MEC formation with histological and molecular features of human HG-MEC. Notably, transcriptome profiles implicate an FGFR-p53 developmental signaling axis in MEC progression. Our autochthonous GEMM recapitulates advanced HG-MEC *in vivo* providing the field with a powerful platform for identifying pathways for developing targeted therapies. Taken together, the integrated bioinformatics and mouse modeling of this study provide a critical step toward elucidating salivary MEC progression and suggest a role for FGFR targeted therapies in the treatment of non-resectable HG MEC.

#3912 ATM and PARP combined inhibition demonstrate synergistic antitumor efficacy in osteosarcoma models.

S. N. Kocinsky[1], J. J. Morsby[1], W. C. Wright[1], M. Wierdl[1], C. S. Wechsler[2], G. Alexe[2], P. Geeleher[1], K. Stegmaier[2], L. M. Guenther[1];
[1]St. Jude Children's Research Hospital, Memphis, TN, [2]Dana-Farber Cancer Institute, Boston, MA

Signatures of BRCAness are found in many osteosarcoma (OS) tumors, driving an interest in PARP inhibition (PARPi) for OS treatment. Although PARPi have shown limited efficacy as OS monotherapy, rational combination strategies have not yet been explored for this disease. We performed a genome-scale loss-of-function CRISPR-Cas9 screen in two OS cell lines in the presence and absence of olaparib, a small molecule PARPi. *ATM* knockout (KO) scored highly as a potent synergizer of PARPi across both cell lines. Here we report this screen finding as well as *in vitro* validation of PARPi and ATM inhibition (ATMi) synergy in OS models.

OS cell lines SAOS2 and CAL72 were infected with the Avana genome-scale lentiviral CRISPR library, targeting 20,000 genes with 4 uniquely barcoded guides (sgRNAs) per gene. After infection and antibiotic selection, cells were grown in an IC_{40} dose of olaparib or matched control for 18 days. Following DNA sequencing of barcodes and rigorous quality control, sgRNA dropout hits were calculated against the control arm. *ATM* KO sensitizing to PARPi was first validated utilizing a CRISPR-based genetic approach. *ATM* KO in CAL72 and SAOS2 was performed via lentiviral infection. After KO confirmation by western immunoblotting (WB), *ATM* KO and control KO cells were treated with PARPi in a dose range of 19.5 nM-10 µM. ATP-based and Incucyte assays were used to quantify differential cell viability. Secondly, the combination of a small molecule ATMi and a PARPi was studied in a panel of OS cell lines. Synergistic cytotoxicity was quantified using the Zero Interaction Potency (ZIP) model. DNA damage levels after PARPi and ATMi (by chemical inhibition and genetic KO) were assessed by WB for γH_2AX, a marker of DNA double-stranded breaks (DSBs).

In our genome-scale CRISPR screens, ATM arose as a top druggable hit across both lines. Reassuringly, *PARP1* KO scored as a top resistance mediator to PARPi, confirming biologic relevance of the screen and supporting the known PARP-trapping mechanism of these drugs in OS. At low-throughput, *ATM* KO lines trended toward increased sensitivity to PARPi in short-term viability assays. Combined chemical inhibition yielded highly synergistic ZIP scores across OS cell lines; synergy was achieved with both drugs in the low nanomolar range. γH_2AX levels were substantially increased in the setting of combined PARPi and ATMi (via chemical inhibition or genetic KO) as compared to inactivation of either PARP or ATM alone, indicating increased presence of DNA DSBs.

In conclusion, these data demonstrate synergy of ATM and PARP inhibition, providing promise for their potential combined use in the treatment of OS. Accumulation of DNA DSBs in response to PARP and ATM inactivation suggests a shared role in DNA damage repair as the molecular basis of synergism. Ongoing studies are investigating anti-tumor potential in *in vivo* OS models and exploring the mechanistic impact of the combination in OS tumors.

#3913 Molecular mechanism of action and targets of glucocorticoids in lymphoma therapy.

J. Choi[1], M. Ceribelli[1], J. D. Phelan[1], B. Haupl[2], D. Huang[1], G. W. Wright[1], T. Hsiao[1], V. Morris[1], F. Ciccarese[3], B. Wang[1], S. Corcoran[1], S. Scheich[1], X. Yu[1], W. Xu[1], Y. Yang[1], H. Zhao[1], J. Zhou[1], G. Zhang[1], J. Muppidi[1], G. G. Inghirami[4], T. Oellerich[2], C. J. Thomas[1], W. H. Wilson[1], L. M. Staudt[1];

[1]National Institutes of Health, Bethesda, MD, [2]Goethe University, Frankfurt, Germany, [3]Veneto Institute of Oncology IOV-IRCCS, Padova, Italy, [4]Weill Cornell Medicine, New York, NY

Prednisone is an anti-inflammatory glucocorticoid (GC) that is cytotoxic for normal and malignant B cells and, on this basis, has long been included in combination chemotherapies to treat aggressive B-cell lymphomas. However, the mechanisms by which GCs kill malignant lymphoma cells still largely remains elusive due to the pleiotropic consequences of GC binding to the glucocorticoid receptor (GR; *NR3C1*), a ligand-induced transcription factor. This prompted us to search for critical direct targets of GC action with the hypothesis that GCs may inhibit key survival pathways in lymphomas. To determine effector genes that increase glucocorticoid toxicity, we performed genome-wide CRISPR-Cas9 screens in the presence and absence of prednisolone. Screens in cell line models of Burkitt lymphoma (BL) and diffuse large B cell lymphoma (DLBCL) revealed strong synergy between GC treatment and inactivation of genes encoding components of the B cell receptor (BCR) signaling pathway (≥2 SD). To identify direct transcriptional GR targets and binding sites genome-wide, we performed the cleavage under targets and release using nuclease (CUT&RUN) assay and integrated this dataset with RNA-seq upon GC treatment. The pairwise comparison analysis ($p<0.05$) for GR-bound genes across BL and DLBCL cell lines revealed a significant enrichment of negative regulators of BCR/PI3K signaling and BCR-related tumor suppressors (*LAPTM5, KLHL14, ARID5B, DDIT4, DAPP1, INPP5D*, and *CSK*). Interestingly, expression of CSK, an inhibitor of all Src-family kinases (SFKs), was repressed while that of other BCR negative regulators were directly activated by binding of GR. Combinatorial deletion of activated genes counteracted the toxicity of GC up to 83.9%. In contrast, depletion of CSK paradoxically increased the cytotoxic effects of GC in BCR-dependent aggressive lymphoma with decreased proximal BCR signaling. To gain further insights on CSK function in aggressive lymphomas, we performed phospho-proteome and ubiquitinome profiling by treating lymphoma models with a small molecule inhibitor of CSK kinase activity (CSKi). The CSKi treatment initially increased constitutive BCR signaling, as expected, but then triggered exuberant ubiquitination of the LYN, HCK and BLK, leading to their proteasomal degradation. Consequently, the CSKi blocked BCR-dependent NF-κB activation in ABC DLBCL models and BCR-dependent PI3 kinase activation in models of GCB DLBCL and BL. In summary, inhibition of oncogenic BCR signaling is a major mode of action for GCs. Furthermore, small molecule inhibition of CSK kinase activity potentiated the effect of GCs on oncogenic BCR signaling and strongly synergized with GCs in killing ABC and GCB DLBCL models in vitro and preventing the growth of ABC and GCB DLBCL and patient-derived xenografts, warranting the development of clinical-grade CSK inhibitors for the treatment of these aggressive cancers.

IMMUNOLOGY: Immune Targets and Therapies
Minisymposium

#3914 IGSF8 is a novel innate immune checkpoint and cancer immunotherapy target.

X. Liu[1], Y. Li[2], X. Wu[2], H. Liu[2], H. Liu[2], C. Sheng[1], Q. Ding[2], Y. Tang[2], C. Liu[2], B. Xie[2], X. Xiao[2], Q. Yu[2], R. Zheng[2], X. Hu[1], T. Xiao[2];
[1]Gv20 Therapeutics LLC, Cambridge, MA, [2]Shanghai Xunbaihui Biotechnology Co., Ltd, Shanghai, China

Background: Loss of MHC-I antigen presentation is often associated with T-cell excluded tumors, and represents a common mechanism of both primary and acquired resistance to immune checkpoint blockade (ICB) treatment. MHC-I normally acts as a marker of “self” and cells that lack MHC-I are recognized and killed by innate immunity. In this study, we investigated the mechanism of innate immune evasion in tumors with MHC-I antigen presentation defects.
Methods: Integrating functional genomics, big data, and artificial intelligence, we discovered that IGSF8 expressed on cancer cells is an evolutionarily conserved innate immune checkpoint. IGSF8 is normally expressed in neuronal tissues and is not essential *in vitro* or *in vivo*. However, knockout of IGSF8 in B16-F10 melanoma cell line decreased tumor growth *in vivo*. For clinical relevance of IGSF8 in tumor immunity, we analyzed genomics, transcriptomics, and clinical data from The Cancer Genome Atlas (TCGA). We developed an antibody (GV20-0251) against IGSF8 and tested its function to induce immune cell killing of cancer cells *in vitro* and inhibit tumor growth *in vivo*.
Results: IGSF8 has receptors on both natural killer (NK) cells and dendritic cells (DC) to strongly suppress NK cytotoxicity and antigen presentation. In the TCGA tumor profiles, IGSF8 has highest mRNA expression in melanoma and is significantly overexpressed in many cancer types. IGSF8 also shows frequent copy number amplifications. In addition, IGSF8 expression is associated with low antigen presentation, low immune infiltration, and worse overall survival in patients with low MHC class I expression. Immunohistochemistry staining of various cancers showed that IGSF8 expression was primarily observed in malignant cells with low MHC-I. We developed a cross-species reactive antibody against IGSF8 (GV20-0251) which blocks IGSF8 interaction with NK and DC. Flow cytometry of the tumor infiltrating CD45+ cells revealed that IGSF8 inhibition significantly increased NK and dendritic cell infiltration. GV20-0251 enhances NK killing of cancer cells *in vitro* and increases antigen presentation, NK-mediated cytotoxicity, and T cell signaling *in vivo*. In multiple syngeneic tumor models (B16-F10, CT26, LLC, 4T1 and EMT6), anti-IGSF8 shows single-agent efficacy and is synergistic with anti-PD1 in controlling tumor growth.
Conclusions: IGSF8 is a novel innate immune checkpoint and cancer immunotherapy target. A phase 1 study is ongoing to explore the IGSF8 inhibitor GV20-0251 in patients with advanced or metastatic solid tumors (NCT05669430).

#3915 BMS-986442 (AGEN1777), a novel TIGIT/CD96 bispecific antibody, demonstrates superior monotherapy and combination activity versus conventional anti-TIGIT antibodies in preclinical models.

R. Ward[1], N. Ramsay[1], S. Campbell[1], H. Patel[1], M. Bushell[1], B. M. Morin[1], B. Wensley[1], D. A. Savitsky[1], P. Garcia-Broncano[1], B. Joshi[1], E. Briend[1], O. Ignatovich[1], Z. Jawad[1], N.-P. Rudqvist[1], N. Wilson[2], **D. Chand**[1];

[1]Agenus Inc, Lexington, MA, [2]Bristol Myers Squibb, Redwood City, CA

TIGIT immune checkpoint blockade can enhance anti-tumor immunity, however conventional anti-TIGIT antibodies have shown suboptimal activity in the clinic. Here, we present the first preclinical disclosure of BMS-986442 (AGEN1777), a novel and fully human Fc-enhanced bispecific antibody against TIGIT and CD96 co-receptor, that demonstrates superior pharmacological activity compared to conventional TIGIT monospecific antibodies (mAbs).

Gene expression of TIGIT, CD96, and the co-stimulatory counter-receptor CD226 in tumor samples from patients with cancer was identified using bulk and single cell RNA-sequencing. To target this interaction, Fc-engineered knob-in-hole bispecific antibodies against TIGIT and CD96 were developed and affinity optimized to achieve potent and complete blockade of TIGIT and CD96 ligand interactions. BMS-986442 and corresponding monospecific anti-TIGIT and anti-CD96 monoclonal antibodies were evaluated with or without anti-PD-1 in a variety of human T and NK cell stimulation assays. Mouse surrogate TIGIT/CD96 bispecific antibodies were developed and evaluated as monotherapy or together with anti-PD-1 in colorectal CT26 and breast orthotopic 4T1 tumor bearing mice.

In CT26 and 4T1 tumor-bearing mouse models, the Fc-enhanced TIGIT/CD96 bispecific antibody demonstrated superior tumor control compared to either anti-TIGIT, anti-CD96, or the combination of anti-TIGIT and anti-CD96 mAbs. Tumor control was dependent on co-engaging activating Fcγ receptors, as an Fc-silent bispecific antibody lacked anti-tumor activity. In the tumor microenvironment, efficacy was associated with increased frequency of CD226+ effector and TCF-1+ GrzB- memory precursor CD8 T cells, increased frequency and activation of cytotoxic NK cells, and increased activation of professional APCs, including B cells, MHC Class II monocytes, and dendritic cells as determined by expression of CD40, CD83, and CD86. In primary human *in vitro* assays, BMS-986442 potently enhanced T cell responsiveness and activation compared with conventional anti-TIGIT mAbs alone and in combination with anti-PD-1 (nivolumab). Lastly, BMS-986442 promoted superior NK cell activation in tumor co-culture assays.

In conclusion, BMS-986442 demonstrated a differentiated FcγR-dependent mechanism-of-action to enhance innate and adaptive immune responses compared with anti-TIGIT or anti-CD96 mAbs. BMS-986442 is currently advancing in phase I clinical studies in patients with advanced solid cancers (NCT05543629).

#3916 TNG260, a small molecule CoREST inhibitor, sensitizes STK11-mutant NSCLC to anti-PD1 immunotherapy.

A. Patel[1], S. Sahu[1], K. Geng[1], S. Punekar[1], J. Stephens[1], J. Deng[1], T. Chen[1], L. Ahronian[2], M. Zhang[2], J. Andersen[2], B. Haines[2], K.-K. Wong[1];
[1]NYU Langone Health, New York, NY, [2]Tango Therapeutics, Cambridge, MA

Loss of function (LOF) of the serine-threonine kinase STK11/LKB1, which has been reported in ~15% of non-small cell lung cancer (NSCLC), drives resistance to immune checkpoint therapies such as PD1. *In vivo* CRISPR screens in tumor-bearing immune competent mice identified the Corepressor of Repressor Element 1 Silencing Transcription (CoREST) complex as a synthetic lethal immune evasion target for *STK11*- mutant tumors. Here, we demonstrate that TNG260, a small molecule drug specifically targeting the CoREST complex, can sensitize STK11 mutant lung cancers to anti-PD1 immunotherapy. Combination treatment with TNG260 and anti-PD1 arrested *KRAS*/*STK11* mutant NSCLC tumor growth with no major toxicity observed, as confirmed in both allograft and genetically engineered mouse models (GEMMs) of STK11 mutant NSCLC. Further transcriptional analysis via bulk RNA-seq revealed that treatment of KRAS/STK11 mutant lung tumors with TNG260 promotes genes related to inflammatory responses and suppresses genes related to cell cycle and mitotic checkpoint(s). This phenotype was not observed in STK11 wildtype *KRAS*/*P53* mutant lung tumors. Furthermore, combinational treatment of TNG260 with PD1 antibody showed increased macrophages, neutrophils and dendritic cells signatures *in vivo*. Our data suggests that epigenetic reprogramming via TNG260 sensitizes STK11 mutant NSCLC tumors to anti- PD1 treatment via targeting of the CoREST complex. This work identifies new vulnerabilities in STK11 LOF cancers that can be exploited therapeutically. TNG260 is currently being investigated in combination with pembrolizumab for the treatment of STK11-mutant cancer (NCT05887492), including NSCLC.

#3917 A CXCR4 partial agonist TFF2-MSA improves anti-PD-1 immunotherapy in advanced gastric cancer by selectively targeting PMN-MDSC.

Jin Qian[1], Chenkai Ma[2], Quin T. Waterbury[1], Christine S. Moon[1], Xiaofei Zhi[1], Feijing Wu[1], Ruhong Tu[1], Biyun Zheng[1], Hiroki Kobayashi[1], Leah B. Zamechek[1], Ryan H. Moy[1], Arnold Han[1], Bruce Daugherty[3], Seth Lederman[3], Timothy C. Wang[1]

[1]Irving Cancer Research Center, Columbia University Irving Medical Center, New York, NY,[2]Integrated Diagnostic, Human Health, Health and Biosecurity, CSIRO, Westmead, Australia,[3]Tonix Pharmaceuticals, Inc., Chatham, NJ

Introduction: Advanced gastric cancer poses a challenge for PD-1 immunotherapy due in part to the prevalence of polymorphonuclear myeloid-derived suppressor cells (PMN-MDSCs). PMN-MDSCs are mostly immature granulocytes but coexist with mature neutrophils, complicating their precise targeting. While PMN-MDSCs highly express CXCR4, recent clinical trials suggest that CXCR4 antagonists may provide limited additive efficacy to PD-1 blockade. This study explored the efficacy of a secreted CXCR4 partial agonist, trefoil factor family 2 (TFF2), in the context of anti-PD-1 refractory gastric cancer.

Methods: We fused mouse TFF2 with murine serum albumin to generate a novel TFF2-MSA peptide with extended half-life, and evaluated its therapeutic effects with or without anti-PD-1 antibody. As histidine decarboxylase (HDC) is expressed in immature neutrophils, we used the HDC-GFP transgene to track PMN-MDSC *in vivo*. The HDC-GFP mice received subcutaneous or orthotopic implantation of murine syngeneic gastric cancer cells and subsequent treatments. Additionally, human blood was assessed for both serum TFF2 and immune profiles.

Results: The combination of TFF2-MSA plus anti-PD-1 antibody displayed remarkable synergy, boosting intratumoral cytotoxic CD8 T cells by 50-fold, leading to tumor regression or eradication, 80% reduction of distant metastasis and 2-fold extension of mouse survival. The immunosuppressive HDC-GFP^{+} PMN-MDSCs expressed the highest level of CXCR4 among immune cells, and TFF2-MSA treatment systematically reduced HDC-GFP^{+} PMN-MDSCs in the tumor, blood, spleen and their myeloid progenitors in the bone marrow. In contrast, CXCR4 antagonist AMD3100 in combination with anti-PD-1 failed to restrict tumor growth or PMN-MDSCs. Further single-cell RNA-seq and functional assays revealed that combination of TFF2-MSA plus anti-PD-1 induced a skewing of remaining tumor HDC-GFP^{+}PMN-MDSC compositions from highly immature CD300ld^{+} subsets to less immature subsets expressing interferon-stimulated genes, accompanied by reduced immunosuppression and increased antigen presentation functions. Rather than local reprogramming, this compositional shift stemmed from an IRF1-driven interferon response in splenic HDC-GFP^{+} PMN-MDSCs. In human, PMN-MDSCs marked by LOX1 significantly expanded in the blood of gastric cancer patients compared to healthy donors. Human LOX1^{+} PMN-MDSCs showed an inverse correlation with T cell number, activation, proliferation and the serum TFF2 level.

Conclusions: TFF2-MSA synergizes with PD-1 blockade by selectively targeting CXCR4^{high} PMN-MDSCs. This study provides a rational for a novel combination therapy of the CXCR4 partial agonist, TFF2-MSA, rather than CXCR4 antagonists, plus PD-1 blockade for treatment of advanced gastric cancer.

#3918 Targeting MARCO in combination with anti-CTLA4 leads to enhanced melanoma regression and immune cell infiltration via macrophage reprogramming.

H. Takahashi, P. Perez-Villarroel, R. Falahat, J. J. Mule;
Moffitt Cancer Center, Tampa, FL

Tumor-associated macrophages (TAM) are known to suppress responses to conventional therapeutics and the presence of TAM is generally related to poor prognosis in various cancers. Therefore, depletion of TAM has been one of the main strategies to break the ceiling of efficacy in cancer treatment. However, to date, TAM depletion strategies have not been successful in clinical trials[1]. Here, we introduce an approach to target TAM by employing Macrophage Receptor with Collagenous Structure (MARCO), a class A scavenger receptor, as a novel immune checkpoint. Previously, we showed MARCO to be the most upregulated mRNA in murine and human dendritic cells following their uptake of dead tumor cells (TP-DC)[2]. We also showed ex vivo treatment of TP-DC with anti-MARCO mAb (ED31) led to enhanced anti-tumor responses in vivo[3,4]. The aim of this current study was to explore whether targeting MARCO using ED31 could improve the efficacy of an immune checkpoint inhibitor in murine models of melanoma. In C57BL/6 mice with B16F10 tumors, adding ED31 to anti-CTLA4 mAb (αCTLA4) resulted in enhanced tumor regression and longer survival ($p=0.001$, $p<0.05$ vs αCTLA4 monotherapy; $p<0.05$, $p<0.01$ vs ED31 monotherapy, respectively). To explore the immune mechanism of ED31 with αCTLA4, we focused on the tumor microenvironment (TME) by flow cytometry. TME immune-profiling consistently revealed that one time treatment with this combination resulted in a rapid increase in the number of tumor infiltrating lymphocytes (TIL) including $CD8^{\pm}$T (2.8-fold) and $CD4^{\pm}$T cells (2.9-fold), NK cells (2.5-fold), activated $CD11c^{\pm}$DC (2.2-fold) and $F4/80^{\pm}$Mφ (2.5-fold), compared to αCTLA4 monotherapy (all with $p<0.0001$; vs αCTLA4 monotherapy, vs ED31 monotherapy, vs control, respectively). As measured by chemokine production using murine bone marrow-derived, in vitro M-CSF induced Mφ phenotypes (M1: polarized by IFNγ and LPS, M2: polarized by IL4, TAM-like Mφ: polarized by a supernatant from B16F10 cell line culture), ED31 exposure switched the pattern of chemokine productions from M2 and TAM-like Mφ into an M1 pattern. In vivo depletion of each immune cell type had a diminishing effect on the treatment efficacy ($p<0.001$ for CD8 depletion, $p=0.01$ for CD4-depletion, $p<0.01$ for NK1.1 depletion). However, Mφ depletion had a more profound impact by completely abrogating the anti-tumor efficacy and the associated survival benefit, in addition to completely reversing the increase in TIL infiltration and canceling the increase of M1 chemokines in vivo (all with $p<0.05$ vs Mφ depletion). These preclinical data support the proof-of-concept that a combination strategy of targeting MARCO along with αCTLA4 can lead to enhanced anti-tumor responses through utilizing TAMs rather than their depletion.

#3920 BND-35, a novel anti-ILT3 antibody for remodulation of the tumor microenvironment.

T. Peretz, Y. Pizem, L. Iancovici, E. Peled, M. Hakim, S. Hashmueli, I. Mandel, Y. Sapir, T. Ben Moshe;
Biond Biologics, Misgav Industrial Park, Israel

Background: ILT3 (LILRB4) is expressed in various suppressive myeloid cells including tumor associated macrophages (TAM), myeloid derived suppressor cells (MDSCs) and tolerogenic dendritic cells (DCtol). The binding of ILT3 to its ligands induces an immunosuppressive phenotype in myeloid cells, mediates the inhibition of T cells activity and generates an immunosuppressive tumor microenvironment (TME) which supports tumor growth. The inhibition of ILT3 can restore the anti-tumor activity of myeloid cells and T cells, and thus remodulate the TME from immunosuppressive to pro-inflammatory. Here we describe preclinical characterization of BND-35, a humanized IgG4, ILT3 antagonist antibody developed for the treatment of solid tumors.
Methods: BND-35 binding to ILT3 was evaluated by flow cytometry, ELISA and surface plasmon resonance. We investigated the ability of BND-35 to block ILT3 interactions with APOE and fibronectin, to enhance the pro inflammatory activity of various myeloid cells and reverse ILT3-mediated immune suppression of T cells by different suppressive myeloid cells using ELISA and in vitro and ex vivo cell-based assays. The anti-tumor activity of BND-35 was also evaluated in vivo in hILT3 transgenic mouse tumor models as well as in tumoroid systems generated from cancer patients.
Results: BND-35 binds ILT3, but not other ILT-family receptors, with low nanomolar affinity and blocks its interaction with APOE and fibronectin in a concentration-dependent manner. ILT3 blockade with BND-35 restored the pro-inflammatory activity of FcR-stimulated DCs and THP1 cells inhibited by fibronectin. BND-35 was also shown to restore an M1 phenotype in cancer patients' derived monocytes differentiated in the presence of autologous tumor cells. In addition, BND-35 restored T cell activity (both, CD4 and CD8 T cells) inhibited by either DCtol, MDSCs or M2 cells as a single agent and in combination with anti PD-1. BND-35 enhanced immune activity in a unique system of patient-derived tumoroids as evidenced by the secretion of pro-inflammatory cytokines. In vivo, blocking ILT3 activity with BND-35 resulted in decreased tumor growth and induced a pro-inflammatory phenotype in tumor resident T cells and myeloid cells populations as a single agent and in combination with anti PD-1.
Conclusions: BND-35 is an anti-ILT3 antagonist antibody that was shown to induce potent pro inflammatory activity of myeloid cells and enhance T cells activity inhibited by ILT3 expressing myeloid suppressive cells in multiple in vitro, ex vivo and in vivo models. By doing so, BND-35 can lead to TME remodelling from immunosuppressive to proinflammatory. Safety, tolerability, and anti-tumor activity of BND-35 will be explored in a first-in-human clinical trial in cancer patients with solid tumors.

IMMUNOLOGY: Understanding and Targeting Pathogenic Inflammation in Solid Tumors Minisymposium

#3921 The aged tumor microenvironment limits CD8^{+} T cell control of cancer.

A. Chen[1], S. Jaiswal[1], D. Martinez[1], C. Yerinde[1], K. Ji[1], V. Miranda[1], M. E. Fung[2], S. A. Weiss[2], M. Zschummel[1], K. Taguchi[1], C. S. Garris[1], T. R. Mempel[1], D. R. Sen[1];

[1]MGH/Harvard Medical School, Boston, MA, [2]Harvard Medical School, Boston, MA

Aging is associated with progressive loss of immune function, which parallels the rise in cancer incidence. The etiology and impact of age-related CD8^{+} T cell dysfunction in cancer remain poorly understood. Here, we demonstrate that increased tumor growth in aged hosts is associated with reduced CD8^{+} T cell infiltration and function. The transfer of young antigen-specific CD8^{+} T cells fails to restore tumor control in aged hosts due to the rapid induction of CD8^{+} T cell dysfunction. The aged tumor microenvironment drives a novel age-associated dysfunctional state (T_{ADys}) that is functionally, transcriptionally, and epigenetically distinct from canonical CD8^{+} T cell exhaustion. Overall, this study focuses on understanding the cell-intrinsic and -extrinsic effects on CD8^{+} T cell immunity in aging and explores a proper strategy to improve CD8^{+} T cell control of cancer.

#3922 Quaking modulates anti-tumor immunity by regulating antigen processing and presentation in dendritic cells.

Y. Li, J. Hu, C. Yee;
UT MD Anderson Cancer Center, Houston, TX

Dendritic cells are essential players in anti-tumor immunity. One of their critical roles is to process and present tumor associated antigens to T cells, thereby inducing antigen-specific T cell response. However, cellular factors and molecular pathways regulating antigen processing and presentation by DCs are not fully understood.Here, we revealed a potential regulatory role of a transcriptional co-activator, Quaking (QKI), and its binding partner, PPARδ in antigen processing and presentation by DCs. Consistent with our previous studies in neural stem cells and microglia, we found QKI and PPARδ enhance phagocytosis in DCs by upregulating genes involved in the formation of phagosome and endosomes. QKI- or PPARδ-deficient DCs showed reduced $CD8^+$ T cell priming capacity *in vitro. In vivo* tumor models suggested DC-specific knocking out of QKI or PPARδ promoted the tumor growth. Furthermore, ablation of QKI or PPARδ in DCs limited the effectiveness of immune checkpoint blockade in multiple tumor models.Together, these revealed a transcriptional regulation of antigen processing and presentation by DCs through QKI and PPARδ. Our data also suggested that perturbing this important function of DC would subvert their anti-tumor activity, highlighting the pivotal role of DCs in an effective anti-tumor immune response.

#3923 Targeting immunosuppressive TREM2^{+}tumor associated macrophages in prostate cancer.

A. J. Lee, K. Adusei, M. Praharaj, F. Shen, X. Wang, K. Bhatia, T. Nirschl, J. C. Zarif;
Johns Hopkins University School of Medicine, Baltimore, MD

With over 250,000 new cases annually, prostate cancer (PCa) is amongst the most diagnosed cancers in the United States. Despite a near-perfect 5-year survival rate in patients with localized disease with androgen deprivation therapy (ADT), about 10-20% of patients on ADT eventually develop castration-resistant prostate cancer (CRPC). Immunotherapies are typically ineffective in treating these treatment-resistant patients due to the abundance of immunosuppressive tumor-associated macrophages (TAMs) and lack of infiltrating lymphocytes. We propose to target these immunosuppressive macrophages through the triggering receptor expressed on myeloid cells 2 (TREM2), which has been identified as a major mediator of suppressive macrophage function but has not been studied in the context of PCa and CRPC. For this study, we analyzed publicly available RNA-seq datasets to query for TREM2 expression amongst patients with a range of prostate cancer disease states and cell types, measured tumor growth kinetics in two subcutaneous models of prostate cancer, and compared tumor immune infiltrates by flow cytometry. Our analysis of the TCGA prostate adenocarcinoma (PRAD) and the Stand Up to Cancer/Prostate Cancer Foundation (SU2C/PCF) datasets implicate *TREM2* expression with prostate cancer progression, by Gleason score and progression-free status, and with worse overall survival of patients with metastatic CRPC (mCRPC). Manual curation and analysis of 10 single-cell RNA-seq datasets with a total of 84 patients, encompassing primary PCa, CRPC, and mCRPC indicate that *TREM2* is highly and specifically expressed on TAMs in prostate cancer, with macrophages from patient-matched tumor samples expressing higher *TREM2* compared to normal adjacent tissue. B6CaP tumors, with a luminal cytokeratin profile, high AR expression, and high Myc expression, show slower tumor growth in *Trem2*$^{-/-}$ mice compared to tumors in *Trem2*^{wt} mice. On the other hand, RM1 tumors show no difference in growth kinetics on *Trem2*$^{-/-}$ mice. A major difference between the B6CaP and RM1 tumor microenvironments is the level of macrophage infiltration, where only 2-5% of immune cells in RM1 tumors are macrophages, compared to the 40-50% in B6CaP tumors. RM1 cells co-implanted with *Trem2*$^{-/-}$ macrophages show slower tumor growth, compared to tumor cells co-implanted with *Trem2*^{wt} macrophages, confirming the role of *Trem2*-expressing macrophages in mediating tumor growth. Consistent with previous reports of suppressive Trem2 signaling, we also observed higher levels of inflammatory cytokine production in *ex vivo* stimulated *Trem2*$^{-/-}$ TAMs. By targeting TREM2 in prostate cancer, we find that TAMs are less suppressive, more inflammatory, and permit cytotoxic lymphocyte infiltration to enhance anti-tumor responses by synergizing with chemo and immune checkpoint therapy.

#3924 Dual COX-2/sEH inhibition enhances immunotherapy and chemotherapy to induce bladder cancer regression.

K. L. Vazquez[1], E. Rothenberger[2], W. Wang[3], S. Hwang[4], D. R. Bielenberg[5], B. D. Hammock[4], D. Panigrahy[1];
[1]Beth Israel Deaconess Medical Center/Harvard Medical School, Boston, MA, [2]Harvard University, Boston, MA, [3]Purdue University, West Lafayette, IN, [4]University of California, Davis, Davis, CA, [5]Boston's Children Hospital, Boston, MA

Unresolved inflammation plays a critical role in bladder cancer initiation and progression. Chemotherapy (e.g. gemcitabine and cisplatin), the standard of care for advanced bladder cancer, disrupts inflammation resolution and is only partially effective in preventing tumor recurrence after treatment. Immunotherapy has emerged as a potential treatment option for bladder cancer patients, however it is ineffective in 80% of patients and can induce a pro-inflammatory cytokine storm. Therefore, there is a critical unmet medical need to improve chemotherapy and immunotherapy in bladder cancer. To address this, we have developed dual COX-2/sEH inhibitors (e.g. PTUPB). This lead compound is representative of a newly patented class of “dual acting” molecules that target two important enzymes in the arachidonic acid cascade with nanomolar binding affinity: cyclooxygenase-2 (COX-2) and soluble epoxide hydrolase (sEH). Oral dosing of PTUPB is well-tolerated in animal models. Since chemotherapy and immunotherapy both induce tumor-promoting inflammation via an eicosanoid/cytokine storm, we hypothesized that dual COX-2/sEH inhibition would enhance immunotherapy in experimental bladder cancer via anti-inflammatory mechanisms. When syngeneic (MB49) bladder tumors reached ~200 mm3 in immunocompetent mice, treatment was initiated with PTUPB, anti-CTLA-4, anti-PD1, gemcitabine & cisplatin, or various combinations thereof. Here we demonstrate that chemotherapy and/or immunotherapy stimulated sEH and COX-2 expression in tumor tissue which was counter-regulated by PTUPB. While monotherapy treatment with PTUPB, gemcitabine & cisplatin, anti-PD1 or anti-CTLA-4 suppressed tumor growth compared to control, the tumors escaped single treatments by the end of the study. Remarkably, dual COX-2/sEH inhibition in combination with chemotherapy (gemcitabine and cisplatin) and/or immune checkpoint blockade (anti-CTLA-4 or anti-PD1) induced sustained tumor regression via synergistic anti-tumor activities. Chemotherapy and/or immunotherapy induced the expression of ER stress response genes (e.g. BiP and CHOP) and angiogenic factors (e.g. EGF and VEGF-C) in bladder cancer tissue, which were repressed by PTUPB. PTUPB also prevented chemotherapy-induced toxicity and prolonged survival in an orthotopic MB49 tumor model. Taken together, our results demonstrate dual COX-2/sEH inhibition as a novel therapeutic approach to enhance immunotherapy in bladder cancer without overt toxicity.

#3925 Cancer-associated fibroblast-derived Dickkopf-1 impairs anti-tumor immunity in breast cancer by suppressing NK cell-mediated cytotoxicity.

S. Lee, B. Ricci, R. Faccio;
Washington University School of Medicine in St. Louis, St. Louis, MO

Despite early diagnosis, 10-20% of breast cancer patients experience metastatic disease within 5-10 years. While it is established that breast cancer cells have the capacity to evade immune responses, the mechanisms driving this evasion remain elusive. Therefore, finding ways to enhance anti-tumor immunity is crucial to improve patient outcomes. Dickkopf-1 (DKK1) is a Wnt inhibitor whose levels correlate with poor prognosis and decreased immune infiltration in various cancers. In this study, we used mice orthotopically injected with the PyMT, EO771, and 4T1 breast cancer lines. In all models, we found elevated DKK1 serum levels, and its neutralization with an αDKK1 Ab resulted in a significant reduction in primary tumor growth but also in metastatic dissemination. To identify the source of DKK1, we examined its expression in the tumor. DKK1 was detected in stromal cells with a fibroblast-like morphology but not in cancer cells or immune infiltrates. Co-staining confirmed colocalization between DKK1 and the CAF marker αSMA. To address the role of CAF-derived DKK1, we specifically deleted DKK1 in CAFs by generating FSP1CreDkk1fl/fl and αSMACreERT2Dkk1fl/fl mice. Both models showed a significant reduction in primary tumor growth while maintaining comparable serum DKK1 levels, indicating locally produced DKK1 supports tumor growth. To understand how DKK1 promotes tumor progression, we conducted bulk RNAseq of tumor cells isolated from IgG or αDKK1 treated mice. While no changes related to cell viability or cell cycle were observed, immune response-related genes were upregulated in αDKK1-treated cells. In support of this, αDKK1 did not reduce tumor growth in NSG immune-compromised mice. To pinpoint the immune cell targeted by DKK1, we depleted T, NK cells, or macrophages in WT tumor-bearing mice treated with αDKK1. Remarkably, only NK cell depletion negated αDKK1 anti-tumor effects. In vitro assays further demonstrated that rDKK1 or the presence of CAFs reduced NK cell cytotoxicity against tumor cells while αDKK1 restored it. To assess whether DKK1 levels correlated with tumor progression and immune suppression in breast cancer patients, we analyzed DKK1 serum levels and circulating NK cells at the diagnosis of metastatic bone disease and 15-18 months after standard care. DKK1 levels were significantly elevated in patients with progressive bone disease compared to those with stable disease. Importantly, NK cells from the progressive disease cohort had reduced perforin and granzyme B expression at the follow-up visit compared to baseline, indicating reduced cytotoxicity. Furthermore, rDKK1 reduced perforin in NK cells from healthy donors. In sum, our data show DKK1 is an important regulator of breast cancer progression, and we report for the first time DKK1 directly impairs NK cell cytotoxicity, creating an immune suppressive environment resistant to treatment.

#3926 ARF6-dependent endocytic trafficking of the interferon-gamma receptor drives adaptive immune resistance and response to immune checkpoint blockade.

Y. Wee[1], J. Wang[1], E. C. Wilson[1], C. P. Rich[1], A. Rogers[1], Z. Tong[2], E. DeGroot[3], Y. Gopal[3], M. Davies[3], H. A. Ekiz[1], J. K. Tay[1], C. Stubben[1], K. M. Boucher[1], J. M. Oviedo[2], K. C. Fairfax[2], M. A. Williams[1], S. L. Holmen[1], R. K. Wolff[1], **A. H. Grossmann**[1];

Interferon-gamma (IFNγ)-driven adaptive immune resistance (AIR) in cancer begins at the plasma membrane where cytokine signaling is initiated. Cytotoxic CD8+ T cells secrete IFNγ, eliciting tumor-intrinsic IFNγ signaling and expression of immunosuppressive genes, which are critical for effective therapeutic response to anti-PD-1 and anti-CTLA-4 immune checkpoint blockade (ICB). Although the IFNγ receptor (IFNγR) is expressed in all cell types, its surface density can determine a cell's responsiveness to ligand. Mechanistic control over this process remains a mystery. Herein we report that the endocytic trafficking protein ADP-Ribosylation Factor 6 (ARF6) is critical for IFNγ-driven AIR during primary tumor progression and in the setting of ICB therapy. The IFNγR1 subunit of the receptor is constitutively internalized in a ligand-independent manner. ARF6 is necessary for endocytic recycling of IFNγR1 and determines the steady-state surface density of the receptor. Loss of ARF6 results in lysosomal degradation of the receptor and controls IFNγR1 protein levels in melanoma, non-small cell lung cancer, colorectal cancer, and triple-negative breast cancer. IFNγ activates ARF6 in parallel with JAK1-STAT1 signaling, suggesting a positive feedback loop that allows tumor cells to dynamically respond to immune attack. Silencing ARF6 reduces tumor intrinsic IFNγ signaling and downstream expression of immunosuppressive genes. In murine melanoma, loss of ARF6 causes resistance to systemic ICB therapy. Likewise, low expression of ARF6 in patient tumors correlates with inferior outcomes with ICB. Our data provide new mechanistic insights into tumor immune escape, defined by ARF6-dependent adaptive immunity, and support that ARF6-dependent endomembrane trafficking of the IFNγ receptor shapes clinical outcomes of ICB therapy.

#3927 Metabolic inhibition of BATF2 dampens type-I interferon-mediated immune sensing of cancer.

W. Gong[1], H. Taner[1], Y. Wu[2], Z. Li[1], W. Cheng[1], C. Donnelly[3], F. Nor[1], Y. He[1], Z. Fitzsimonds[1], J. Li[1], H. Wen[4], S. Chinn[1], Y. Xie[2], J. Moon[1], Y. L. Lei[1]; [1]University of Michigan School of Dentistry, Ann Arbor, MI, [2]Michigan State University, East Lansing, MI, [3]Duke University Medical Center, Durham, NC, [4]Ohio State University, Columbus, OH

Background: The type-I interferon (IFN-I) system appeared before adaptive immunity during evolution as the primary defense system for metazoans. Initiating cancers frequently disable this first line of defense before establishing T-cell exhaustion programs. However, the molecules linking IFN-I, danger signals, and unique metabolic conditions in the tumor microenvironment (TME) remain to be discovered.

Methods: We performed centered log-ratio transformation on the cluster composition data using the R-package ALDEx2 to compare the clusters in single-cell data sets. IFN-I signatures were quantified using qPCR and ELISA. ChIP was performed to examine the H3K27me3 epigenetic marker on the promoters of BATF2 and IFN-I genes in bone marrow-derived macrophage (BMDM). For the cigarette smoke carcinogen-induced head and neck squamous cell carcinoma (HNSCC) model, experimental mice were fed with water containing 50 μg/mL of 4-NQO for 16 weeks and then switched to regular feeding water. We started monitoring 10 weeks post-treatment for the number, location, and diameter of the lesions. TME analysis was performed using single-cell RNA-Seq and multispectral imaging.

Results: We analyzed three large independent cohorts of patients and found that BATF2 strongly correlated with the immunogenicity of HNSCC, with a stronger correlation coefficient than *STING*. We generated *Batf2*$^{-/-}$ BMDM and found that *Batf2* deficiency rendered cells insensitive to STING agonists. However, the dsRNA-induced IFN-I activation was not affected by *Batf2* deletion. BATF2 interacted with STING, promoting its phosphorylation and oligomerization. Glutamine is enriched in the TME. We found that glutamine inhibited the BATF2-STING pathway by increasing a repressive epigenetic marker, H3K27me3, on the promoters of *BATF2* and *IFNB1*. The expression of BATF2 in cancer cells resulted in IFN-I- and γδ T-cell-dependent tumor rejection. Single-cell immune profiling showed that Batf2-expressing tumors contained significantly expanded Cxcl10^{+} myeloid cells and γδ T-cells. Utilizing the 4-NQO-induced HNSCC model, we found that BATF2 limited suppressive myeloid cells and expanded effector cells in the TME, serving as a potent tumor suppressor.

Conclusion: BATF2 is a glutamine-responsive tumor suppressor that limits tumor initiation by engaging the STING-γδ T-cell pathway.

MOLECULAR/CELLULAR BIOLOGY AND GENETICS: Advances in Cancer Genomics: Carcinogenesis, Tumor Evolution, and Heterogeneity Minisymposium

#3928 Genomic landscape and estimation of immune infiltration of soft tissue sarcoma histology subtypes from the ORIEN network.

A. C. Soupir[1], O. E. Ospina[1], D. Hedges[2], J. K. Teer[1], M. D. Radmacher[2], D. M. McKean[2], N. Seligson[3], M. McCarter[4], B. Wilkey[5], G. Riedlinger[6], J. Groundland[7], B. J. Miller[8], B. Schneider[9], R. Patel[10], A. Rafeh-Naqash[11], S. Edge[12], B. Salhia[13], C. Moskaluk[14], M. Johns[15], M. L. Churchman[2], O. Hampton[2], D. Liebner[16], B. L. Fridley[1], A. S. Brohl[1];

[1]H. Lee Moffitt Cancer Center, Tampa, FL, [2]Aster Insights, Hudson, FL, [3]University of Florida, Gainesville, FL, [4]Univerity of Colorado Denver, Denver, CO, [5]University of Colorado Anschutz, Denver, CO, [6]Rutgers Cancer Institute of New Jersey, New Brunswick, NJ, [7]Huntsman Cancer Institute, Salt Lake City, UT, [8]Holden Comprehensive Cancer Center, Iowa City, IA, [9]IU Health Simon Cancer Center, Indianapolis, IN, [10]UK Markey Cancer Center, Lexington, KY, [11]University of Oklahoma Health Sciences Center, Oklahoma City, OK, [12]Roswell Park Comprehensive Cancer Center, Buffalo, NY, [13]University of Southern California, Los Angeles, CA, [14]University of Virginia, Charlottesville, VA, [15]Emory, Atlanta, GA, [16]Ohio State University, Columbus, OH

Sarcomas encompass a group of malignant diseases arising from mesenchymal origins. Given their rarity and diversity, a fundamental understanding of the genomic underpinnings for many sarcoma subtypes is still lacking. Studies are often limited to one or several of the more common subtypes or a narrow evaluation of a broader sampling. We therefore report on one of the largest comprehensive omics evaluation in sarcomas to date, including whole exome sequencing (WES; n = 1170) and RNA-sequencing (n = 983) of tissues from 29 different sarcoma histologic subtypes collected at 13 institutions in the US as part of the Oncology Research Information Exchange Network (ORIEN). We identified recurrent somatic mutations previously identified in sarcomas (e.g. *TP53*, *KIT*) as well as other cancer types (e.g. *BRCA1*). The burden of putatively pathogenic driver point mutations was higher in metastatic samples (median = 3) as compared to primary tumor samples (median = 2; $p < 0.001$). We observed frequent copy number alterations including whole genome doubling more commonly in metastatic compared to primary tumors (23.4% vs. 16.9%; $p = 0.0.25$). Inspection of gene expression dimensionality reduction (UMAP) showed separation of gastrointestinal stromal tumors (GISTs), leiomyosarcomas, myxoid liposarcomas, and well/de-differentiated liposarcomas from the other histologies. Differential expression analysis for these four histologies with gene set enrichment analysis highlights the diversity of disease-specific pathways and need for sarcoma subtype-specific translational focus. Estimation of immune cell abundances based on RNA-seq followed by hierarchical clustering identified five immune subtypes. The subtypes ranged from low (clusters A, B) to high (clusters D, E) immune infiltration with higher abundance of T, B, Natural Killer (NK), and myeloid cells (FDR < 0.01). Intermediate immune group C was predominantly composed by GISTs and marked by an enrichment for NK cells (FDR < 0.01) compared to all groups except the immune “hot” group E; however, this immune group exhibited modest infiltration by other immune cell types. Notably, we observed significant differences in the overall survival of patients with sarcomas in immune enriched (C, D, E) compared to immune depleted clusters (A, B; $p = 0.002$). In summary, we report the genomic and expressional landscape of over 1000 sarcomas, representing one of the largest comprehensive profiling efforts in this disease. We identify the mutational and copy number variation landscape and observe differences between primary and metastatic samples. We highlight expression pathways that are enriched in histologic subtypes that cluster most distinctly from others, providing a subtype-specific roadmap for further translational efforts. Finally, we define immune enriched or depleted sarcoma subgroupings that carry a prognostic impact.

#3929 Comparative genomics of breast cancer in indigenous African and western populations first results from the E-Predict study.

Breast cancer (BC) stands as the foremost female malignancy globally and is the most prevalent cancer in numerous developing countries, particularly in sub-Saharan Africa (SSA). Over the past decade, significant strides in comprehending the pathobiology of the disease and tumour dynamics have greatly enhanced treatment options, particularly in industrialized nations. Regrettably, SSA countries have witnessed only marginal, if any, improvements, with mortality rates surpassing incidence rates. Unfavourable outcome, early onset and high-grade tumours are predominant in SSA. Despite these challenging clinical phenotypes, there is currently a limited understanding of the primary molecular drivers, primarily due to a dearth of reliable data. Furthermore, there is a paucity of research conducted in, and pertinent to, the challenges of the disease in low-income countries (LICs), despite a rising incidence and higher mortality-to-incidence ratios. We thus established an international translational cancer research consortium in five distinct African countries. This initiative has contributed to the creation of a high-quality repository of biomaterials. Additionally, we have conducted whole exome sequencing on the initial 100 cases of breast cancer, comparing the molecular architecture of these tumors with data from The Cancer Genome Atlas (TCGA). We examining and compared the clinical disease phenotypes between indigenous African women and Western patients. A higher proportion of grade III tumors was observed in African patients aged between 30 to 59 years as compared to other patients within the same age group. In comparative molecular analyses, we found a significantly elevated tumor mutational burden in African patients (median of >15/MB) in contrast to other populations within the TCGA (median ~ 0.7/MB). Gene sets featuring co-occurring mutations, predicted to be associated with survival using the TCGA dataset, showed high mutation rates in the African cohort. Notably, co-occurring mutations between *PIK3CA* and genes linked to genomic instability, such as *BIRC6* (HR: 11.7, p = 2.7e-05), *KMT2C* (HR: 4.7, p = 4.01e-04), *NEB* (HR: 3.84, p = 0.48), and *PCLO* (HR: 4.9, p = 0.016), among others, strongly correlated with poor overall survival and were highly mutated within the African cohort. Interestingly, within the TCGA, patients with early breast cancer onset exhibit twice as many mutations in *KMT2C*, a gene known for its association with DNA damage repair, genomic instability, and showed an improved response to immune checkpoint inhibition. These initial findings suggest that breast cancer genomics in indigenous African populations may exhibit substantial differences, potentially warranting consideration for distinct therapeutic modalities for these patients.

#3930 The therapeutic implications of consensus genomic subtypes of gastric adenocarcinoma.

Yun Seong Jeong[1], Young-Gyu Eun[2], Sung Hwan Lee[3], Sang-Hee Kang[4], Sun Young Yim[5], Eui Hyun Kim[6], Joo Kyung Noh[2], Bo Hwa Sohn[1], Ju-Seog Lee[1]

[1]UT MD Anderson Cancer Center, Houston, TX, [2]Kyung Hee University, Seoul, Korea, Republic of, [3]CHA Bundang Medical Center, Seongnam, Korea, Republic of, [4]Korea University Guro Hospital, Seoul, Korea, Republic of, [5]Korea University College of Medicine, Seoul, Korea, Republic of, [6]Yonsei University College of Medicine, Seoul, Korea, Republic of

Background: Gastric adenocarcinoma (GAC) is heterogeneous lethal disease in genomic and clinical level. Although the clinical relevance of genomic and molecular subtypes of GAC has been demonstrated, differences in classification methods have made it difficult to use these findings in clinical applications. We aim to examine a consensus of genomic subtypes and correlate them with clinical outcomes.

Method: We collected genomic data from 2527 GAC tumors and divided the data into discovery (n = 1427) and validation sets (n = 1100). A cluster of clusters approach (COCA) was used to find consensus subtypes of gastric tumors. We constructed the GAC predictor of the integrated consensus subtype with 120 genes (GPICS120) and applied it to the validation data set in order to validate the clinical significance of the new subtypes. By analyzing genomic and proteomic data we evaluated each subtype's potential response rate to standard and experimental treatments such radiation therapy, targeted therapy, and immunotherapy and further validated their functional significance in cell line models.

Results: We identified 6 clinically and molecularly distinct genomic consensus subtypes (CGSs) by integrating 8 previously established genomic subtypes. CGS1 is characterized by worst prognosis, remarkably high stem cell characteristics, high IGF1 expression, and low genomic alterations. CGS2 showed canonical epithelial gene expression patterns. CGS3 and CGS4 are characterized by high copy number alterations and low immune activity. CGS5 has highest mutation burden and moderately elevated immune activity that is characteristics of MSI-high tumors. The majority of CGS6 tumors have extremely high methylation, high immune activity, and are EBV-positive. The most intriguing finding is that CGS1 is the most responsive to immunotherapy whereas CGS3 is significantly associated with benefit of chemoradiation therapy due to high basal level of ferroptosis. Furthermore, we showed that ferroptosis inducer statin sensitized radiation-resistant GAC cells to ionizing radiation, suggesting that statin can be used to enhance the efficacy of chemoradiation in GAC and it would warrant further investigation in preclinical models.

Conclusion: Consensus subtype is robust classification system and can serve as the basis for future clinical trials as well as pre-clinical research into targeted subtype-based therapies.

#3931 Breast cancer genomic architecture contributes to immune escape across metastasis.

Lise Mangiante, Kathleen Houlahan, Cristina Sotomayor Vivas, Alvina Adimoelja, Seongyeol Park, Aziz Khan, Sophie Pribus, Zhicheng Ma, Jennifer Caswell-Jin, Christina Curtis

Stanford University School of Medicine, Stanford, CA

Clinically, breast tumors are stratified based on the expression of three receptors - estrogen receptor (ER), progesterone receptor (PR) and human epidermal growth factor receptor-2 (HER2). Breast cancer is a highly heterogeneous disease, and a more detailed understanding of its genomic drivers, mechanisms of immune evasion, and evolution may inform more effective and personalized treatment. Previously, we established a genome-driven breast cancer classification scheme that defines 11 integrative subgroups (ICs) of disease with distinct copy number aberrations (CNAs), transcriptional profiles, and clinical outcomes. Specifically, we identify four subgroups of ER+ disease (IC1, IC2, IC6, IC9) with a persistent risk of lethal distant relapse up to two decades after diagnosis, each with focal copy number drivers and two distinct subgroups of triple-negative disease (Curtis et al. Nature 2012; Rueda et al. Nature 2019). These findings nominate new therapeutic strategies, however, it is not known how mutational processes and genomic architecture differ across the ICs to sculpt the development and evolution of disease, nor how their microenvironments differ. To interrogate the genomic and immune landscape of breast cancer throughout the disease continuum, we established a meta-cohort of 2,873 breast tumors spanning pre-invasive (ductal carcinoma in situ), primary invasive, and metastatic breast cancer, including 1,865 with whole-genome sequencing, 1,738 with whole-transcriptome sequencing, and 730 with both modalities. We developed a fully containerized bioinformatic workflow to interrogate copy number alterations, complex classes of structural variation, and neoantigens. Analysis of this large clinically curated compendium identifies highly concordant mutational signatures and higher order genomic features in high-risk ER+ (IC1,2,6,9) and HER2+ (IC5) tumors, including distinct patterns of structural variation. In contrast, triple-negative tumors (predominantly IC10) were characterized by global genomic instability and tandem duplications, whilst a third group is largely genomically stable. These distinct genomic architectures were associated with specific tumor microenvironments. As expected, triple-negative tumors were immune-enriched. In contrast high-risk ER+ and HER2+ tumors demonstrated immune-depleted profiles, as compared to typical risk ER+ tumors. These microenvironment classifications were maintained from primary tumors to metastatic lesions, except triple-negative tumors that exhibited increased immune depletion during metastasis. Taken together, our data demonstrate that complex structural alterations established early in breast cancer contribute to immune evasion, and persist throughout the life history of the tumor through metastasis.

#3932 Multi-omics characterization of molecular features and global-local genomic ancestry analysis of colorectal cancer in Hispanic-Latinos.

E. I. Velazquez Villarreal[1], S. Rajpara[1], Y. Jin[2], M. Postel[1], B. Waldrup[1], F. Wu[1], D. Loza[1], H.-J. Lenz[3], D. W. Craig[2], J. D. Carpten[2];
[1]Keck School of Medicine of USC, Los Angeles, CA, [2]Beckman Research Institute of the City of Hope, Los Angeles, CA, [3]Norris Comprehensive Cancer Center KSOM, Los Angeles, CA

Introduction: Clinical factors and molecular characteristics play pivotal roles in shaping therapeutic strategies and prognoses in colorectal cancer (CRC), the second leading cause of cancer-related mortality in the United States. Despite an overall decline in mortality, the Hispanic/Latino (H/L) population in the Los Angeles area exhibits mortality rates up to 20% higher than their Caucasian American counterparts, often with diagnoses at a younger age and advanced disease stages. Few studies have utilized substantial H/L sample sizes and integrated comprehensive clinical and multi-omics data to conduct integrative translational analysis of reported genomic alterations and their implications for colorectal tumorigenesis.
Methods: We collected clinical, DNA, and RNA sequencing data from 36 primary CRC Tumor/Normal (T/N) samples and 82 primary CRC T/N samples within the H/L population in the Los Angeles area through the Participant Engagement and Cancer Genome Sequencing (PE-CGS) Network and the Oncology Research Information Exchange Network (ORIEN), respectively. Additionally, we retrieved two CRC samples with spatial transcriptomic (ST) data from the 10xGenomics database. This data underwent Whole Exome and RNA sequencing analysis. Furthermore, we conducted global and local genomic ancestry analyses to establish correlations between self-ancestral identification and the five main superpopulations. ST data was analyzed using recently released bioinformatics tools. Clinical and genomic data were integrated.
Results: In these studies, distinct age-of-onset, Amerindian (AMR), and survival patterns were observed, with significant mutations identified in key genes, including APC, TP53, KRAS, and PIK3CA. Cancer heterogeneity was evident, influenced by mutation type, microsatellite instability, subsite, and ethnicity. Ancestry analysis indicated genetic diversity, with a predominant AMR heritage and cases showcasing substantial European genetic proportions alongside AMR ancestry. Additionally, RNA sequencing has been conducted, with ongoing transcriptomic analysis in both studies, and the results are set for presentation at the annual meeting. The ST analysis generated initial maps, delineating diverse cellular populations and revealing the samples' distinct immunological and inflammatory signals.
Conclusion: Our study has delved into the molecular profiling of CRC tumors among H/L patients, contributing essential insights into the DNA and RNA level characterization of CRC tumors and the multifaceted clinical and genomic heterogeneity within our aimed population. It also provides crucial insights into CRC tumor heterogeneity and the tumor microenvironment. These findings serve as the cornerstone for forthcoming sample analyses within our PE-CGS project to potentially lead to the development of personalized treatments.

#3933 Comprehensive molecular characterization of mitochondrial mutational landscape across the evolution of lung adenocarcinoma.

A. Singh[1], S. Dasgupta[2], A. L. Koppayi[3], L. Rooper[4], V. Mishra[1], D. Sidransky[5], N. Agrawal[1], K. Suresh[5], E. Izumchenko[1];
[1]University of Chicago, Chicago, IL, [2]University of South Alabama, Alabama, AL, [3]Northwestern University, Chicago, IL, [4]John Hopkins University, Baltimore, MD, [5]Johns Hopkins University School of Medicine, Baltimore, MD

The human mitochondrial genome is prone to genetic alterations, which lead to somatic mutations, changes in mtDNA copy number and altered expression of respiratory chain subunits. This is in part due to the fact that mtDNA has a limited ability to repair itself when it is damaged. Although a buildup of somatic mutations in mtDNA has been associated with increased cancer risk, the role of mtDNA alterations in malignant transformation of lung adenocarcinoma has not been addressed. Therefore, a clear understanding of changes in mtDNA along the pathway of lung tumorigenesis is critical for identifying molecular biomarkers related to carcinogenesis and tumor progression. Like all solid tumors, lung adenocarcinoma is thought to be initiated and to progress through a series of genetic alterations, including changes in mtDNA. Lungs resected for primary adenocarcinomas often harbor minute discrete foci of cytologically atypical pneumocyte proliferations designated as atypical adenomatous hyperplasia (AAH). Evidence suggests that AAH represents an initial step in the progression to adenocarcinoma in situ (AIS), minimally invasive adenocarcinoma (MIA) and ultimately fully invasive adenocarcinoma (ADA). In this study we used a unique cohort of 52 patients with matched specimens (n=133) representing different steps of disease progression (AAH, AIS, and MIA) coupled with novel ultra-deep mitochondrial sequencing (mtDNA-Seq) method to assess the mtDNA mutational landscape throughout the continuum of lung adenocarcinoma development. Utilizing a custom bioinformatics workflow, somatic mutations were detected in a subset of the premalignant non-invasive lesions, with overall higher mutational load observed in MIA and ACA specimens. Additionally, large degree of inter-patient heterogeneity were observed for mtDNA copy numbers in conjunction with the clonal histological evolution of pulmonary neoplasia. Moreover, an appreciable number of coding and non-coding mutations from regulatory regions of the mtDNA were detectable in the precursor AAH lesions and the continuum of LUAD progression. Majority of shared mutations showed heteroplasmic transition with increase in fractional abundance in ADA, compared to the AHH lesions, thereby indicating spatial clonal expansion as they progressed histologically. Here we report the first comprehensive characterization of mitochondrial mutational landscape in dynamic evolution of lung adenocarcinoma, and provide insight into the heterogeneity of clonal events associated with the progression from noninvasive to malignant disease.

#3934 Smoking's influence on divergent paths to lung cancer.

E. J. Evans, Jr.[1], F. Marongiu[2], E. Lim[3], O. Pich[3], Y. Zhuang[1], D. Gao[1], W. Hill[3], C. Murphy[3], R. Turner[3], M. Ghosh[1], Y. Miller[1], M. Jamal-Hanjani[4], C. Swanton[3], J. DeGregori[1];

[1]University of Colorado Anschutz Medical Campus, Aurora, CO, [2]Unversity of Cagliari, Cagliari, Italy, [3]The Francis Crick Institute, London, United Kingdom, [4]University College London, London, United Kingdom

Lung cancer is the leading cause of cancer mortality in the world. Many studies have highlighted how mutagens from cigarette smoke promote specific mutations such as G12 mutations in *KRAS*, contributing to clonal evolution that leads to lung cancer. Despite the indisputable correlation between smoking and lung cancer, people who have never smoked account for the 7th leading cause of cancer mortality. Given the differences in predominant exposures, we hypothesize that the clonal evolution between people with and without smoking histories are markedly different. Therefore, we analyzed lung samples from people with different cigarette smoking exposure to elucidate smoking's effect on the somatic mutational landscape in the progression to lung cancer. To observe somatic mutations subjected to different exposures of smoking, we used a rare-mutation detection technique called DuplexSeq to analyze somatic variants from 200+ lung samples. We acquired DNA from cells from bronchoscopy brushings and lung punches of histologically normal tissue from people with and without lung cancer and who currently, formerly, or never smoked cigarettes. Through collaborations, we characterized mutations using bioinformatic pipelines, various databases, and statistical methods. In samples from people who smoke, we observe an enhancement of mutations with higher variant allele frequencies and pervasive positive selection acting on mutations in many cancer-associated genes. From our bronchoscopy brushings, *NOTCH1* mutations show the most definitive increase of protein-altering variants, while *NF1* and *KRAS* show a predominance of driver mutation in lung punches. Unexpectedly, people without lung cancer who never smoked had a notable presence of pathogenic mutations in *PTEN* and *PIK3CA*. Furthermore, multiple punches from the same individual highlight how expansions of mutations have stronger similarity within an individual than across individuals regardless of smoking status. This association points to the importance of the inherent lung microenvironment in influencing the mutational landscapes in lung cancer progression. Altogether, these results show how smoking increases the oncogenicity of observable mutations in the lung but does not preclude the presence of oncogenic clones, emphasizing the value of precision diagnoses and prevention. Ongoing research will be centered around functional assays to determine the impact of observed mutations on tissue function and longitudinal studies using mutational landscapes as a proxy for lung cancer risk.

MOLECULAR/CELLULAR BIOLOGY AND GENETICS: Novel Mechanisms of Oncogenesis and New Therapeutic Targets Minisymposium

#3935 Involvement of nanoscale physical communication in obesity-associated breast cancer severity.

T. Saha, B. B. Srinivasan, S. Sengupta;
Harvard Medical School, Brigham and Women's Hoapital, Cambridge, MA

Obesity is a risk factor for several cancers, including breast cancer, and contributes up to 20% of cancer-related deaths. Growing evidence from both clinical and preclinical studies indicates that increased obesity is associated with increases in cancer incidence, progression, metastasis, and therapeutic resistance. According to the Centers for Disease Control and Prevention (CDC), more than 70% and 40% of American adults can be classified as overweight and obese, respectively. However, treatment strategies for dealing with cancer in obese patients have not advanced apart from lifestyle interventions. However, several signaling mechanisms have been proposed related to the inflammatory and metabolic impact of obese adipocytes in promoting cancer progression. However, a lack of mechanistic understanding led to no specific treatment strategies have been proposed which can specifically downregulate the key regulator by which obese adipocytes promote cancer progression. Thus, translational research initiatives are immediately needed to provide mechanistic justifications for these striking statistics in order to better serve this growing segment of the population.

Here, we have shown the role of nanoscale physical communication between breast cancer cells and adipose tissue in promoting cancer progression. Using high-resolution optical and electron microscopy, we have found that breast cancer cells form nanoscale tubular communications with obese adipocytes. Moreover, the cancer cells hijack mitochondria from obese adipocytes. However, coculturing cancer cells and obese adipocytes in the Boyden chamber, allowing exosomal and paracrine communication but blocking direct physical communication, revealed negligible mitochondria transfer. This observation indicates an active transfer of mitochondria via nanotube. A significantly higher rate of mitochondria transfer from obese adipocytes to cancer cells has been observed than non-differentiated pre-adipocytes. The transfer of mitochondria results in an increase in the metabolism of the cancer cells. The mechanistic investigation of the nanotube formation revealed actin's presence as the major component in the nanotube. The exocyst-GTPase protein complex has a prime contribution in actin remodeling and nanotube formation. Inhibition of exocyst-GTPase using a pharmacological inhibitor results in a significant reduction in nanotube-mediated mitochondria transfer.

Conclusion: Our goal is to (i) investigate the direct physical connection between adipocytes and cancer cells and the effect on cancer progression and (ii) eliminate mortality related to obesity-associated breast cancer severity by introducing a new therapeutic strategy. Here, we have shown how cancer cells communicate with obese adipocytes and receive additional metabolic power for proliferation. The *in vivo* investigation of the same is under progress.

#3936 Altered endosomal pH regulation: molecular mechanisms of oncogenesis and therapeutic dependencies.

H. Dopeso[1], Y. Zhu[1], L. Gusain[1], T. Basili[1], D. Brown[1], F. Derakhshan[1], E. da Silva[1], R. Koche[1], P.-J. Hamard[1], X. Guo[2], E. Toska[3], E. DeStanchina[1], H. Zhang[1], J. Reis-Filho[1], B. Weigelt[1], F. Pareja[1];

[1]Memorial Sloan Kettering Cancer Center, New York, NY, [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, [3]Johns Hopkins University, Baltimore, MD

ATP6AP1 and *ATP6AP2,* which we previously identified to be recurrently altered in granular cell tumors (GCTs), encode for accessory proteins of the vacuolar (V)-ATPase, which controls endosomal acidification. The mechanistic basis of how *ATP6AP1/AP2* loss of function (LOF) leads to oncogenesis remains to be elucidated. Here, we sought to unravel the molecular mechanisms downstream of *ATP6AP1/AP2* inactivation resulting in oncogenesis and identify associated therapeutic dependencies. Using CRISPR/Cas9 technologies, we generated *ATP6AP1*-knock out (KO), *ATP6AP2*-KO and non-target (NT) control immortalized Schwann cells, the likeliest cell of origin of GCTs. Compared to NT controls, *ATP6AP1/AP2*-KOs displayed increased cellular proliferation, migration, and anchorage independent growth. *ATP6AP1/AP2*-KOs, but not NT controls, demonstrated *in vivo* tumorigenesis upon subcutaneous implantation in NSG mice. In addition, *ATP6AP1/AP2*-KOs, compared to NT controls, displayed abnormal bulk endocytic function, evidenced by reduced endocytic cargo delivery to lysosomes in a DQ-Red BSA assay, and increased LC3BII/LC3BI ratio and expression of the autophagy marker GABARAP, indicating altered autophagic flux. ATAC-seq analysis of our cell modes revealed changes in chromatin accessibility upon *ATP6AP1/AP2* inactivation, affecting transcription factors (TFs) associated to the Wnt pathway, including LEF/TCF (canonical Wnt) and NFAT (non-canonical Wnt), and TFs associated to autophagy pathways, among others. RNA-sequencing analysis revealed expression changes in key Wnt pathway components upon *ATP6AP1/AP2* LOF, such as biphasic modulators (*DKK1*, *DKK2* and *SFRP1*), secreted ligands (*WNT2*, *WNT9a* and *WNT7B*), transcriptional regulators (*TLE1*, *TLE2*, *TLE3* and *TLE4*) and receptors (*LGR5*, *FZD7* and *FZD1*). Consistent with these findings, *ATP6AP1/AP2*-KOs displayed upregulation of downstream canonical (MYC, Cyclin D1) and non-canonical (NFATC1, CALM1) Wnt targets at the mRNA and protein levels, and increased sensitivity to pharmacologic inhibition of the Wnt pathway, with significantly lower IC50s to IWR-1, compared to NT controls. Lastly, *ATP6AP1/AP2*-KOs displayed increased sensitivity to pharmacologic inhibition or induction of autophagy and/or endocytic processes, with lower IC50s to Chloroquine, N-Ethylmaleimide, Torin-1 and Bafilomycin-A1 compared to NT controls. Taken together, we demonstrate that *ATP6AP1*/*AP2* inactivation leads to the acquisition of oncogenic properties *in vitro* and in *vivo*, altered endocytosis and autophagy. Furthermore, our findings suggest that *ATP6AP1/AP2* LOF results in chromatin accessibility changes leading to activation of an oncogenic transcriptional program with increased signaling via the Wnt pathway. Notably, inactivation of these genes results in unique and previously unknown vulnerabilities, offering potential avenues for therapeutic exploration.

#3937 Investigating the role of fibulin 3 in pancreatic tumorigenesis.

H. Song[1], J. Hsu[1], X. Lin[1], S. Ogawa[2], V. Pantazopoulou[2], K. Peck[2], C. Bottomley[2], S. Okhovat[2], M. Stamp[2], K. Curtis[2], J. D. Esko[1], D. D. Engle[2];
[1]University of California, San Diego, La Jolla, CA, [2]Salk Institute for Biological Studies, La Jolla, CA

Pancreatic ductal adenocarcinoma (PDA) is a highly lethal malignancy with a five-year survival rate of less than 11%, making it one of the deadliest cancers. Notably, 95% of PDA cases exhibit *KRAS* mutations, contributing to highly dysregulated cell signaling networks. Despite extensive research into the interplay of various oncogenic pathways in pancreatic tumorigenesis, targeted therapies against these signaling networks have displayed modest efficacy, with most patients rapidly developing therapeutic resistance. Recent studies highlight the significance of the carbohydrate antigen 19-9 (CA19-9) as a functional biomarker linked to disease progression and resistance. However, understanding the detailed functions of CA19-9-modified proteins in PDA has been limited due to the lack of adequate models for synthesizing CA19-9. To address this challenge, we have developed unique mouse and 3D organoid culture models capable of producing CA19-9. CA19-9 elevation in mice with *KRAS*-mutations results in an aggressive PDA phenotype through increased tumor proliferation and microenvironment (TME) remodeling. Furthermore, our research has identified Fibulin 3 (FBLN3), an extracellular matrix glycoprotein, as a secreted, CA19-9-modified protein that stimulates tumorigenesis. In this study, we found that FBLN3 not only facilitates tumor proliferation but also drives epithelial-mesenchymal transition (EMT) and promotes STAT3 pathways activation in the CA19-9^{pos}, *KRAS*-mutant PDA organoids. Additionally, in both CA19-9^{pos}, *KRAS*-mutant PDA mouse models and human PDA, FBLN3 is expressed by cancer-associated fibroblasts (CAFs), suggesting its role in TME remodeling. These findings have significant implications for providing novel insights into PDA biology and paracrine signaling mechanisms, identifying FBLN3 as a potential therapeutic target for the improved treatment of this devastating disease.

#3938 A novel mouse model reveals potential therapeutic strategies for RIT1-driven lung adenocarcinomas.

A. Mozzarelli[1], A. Cuevas-Navarro[2], A. Urisman[3], P. Castel[1],
[1]NYU Grossman School of Medicine, New York, NY, [2]Memorial Sloan Kettering Cancer Center, New York, NY, [3]University of California San Francisco, San Francisco, CA

Gain-of-function oncogenic mutations in *RIT1* have been identified in lung adenocarcinoma and are mutually exclusive with other reported driver mutations, highlighting the role of RIT1 as a cancer driver. RIT1 is a poorly-studied non-classical RAS GTPase and, to date, there are no reported genetically-engineered mouse models of RIT1-driven lung adenocarcinoma. Here, we have generated a conditional knock-in allele within the endogenous mouse *Rit1* locus, introducing the most frequent mutation observed in lung adenocarcinomas ($RIT1^{M90I}$). Upon intranasal administration of adenovirus encoding the Cre recombinase to induce somatic recombination in the mouse lungs, we observed the formation of discrete adenomas. Although $Rit1^{M90I}$ mutation can promote lung tumor initiation in mice, we found that this phenotype is less penetrant than the common $Kras^{G12D}$ mutation. Immunohistochemistry analysis of $Rit1^{M90I}$ and $Kras^{G12D}$ tumors showed expression of typical histological markers associated with lung adenocarcinoma (i.e., TTF1 and SPC), as well as increased levels of Ki67 and pERK expression. Next, to develop potential pharmacological strategies for RIT1-driven lung tumors, we first explored drugs that inhibit the RAS/MAPK pathway and are either FDA-approved or under clinical development. *In vitro* experiments with cell lines carrying the $RIT1^{M90I}$ mutation demonstrated high sensitivity to SHP2, MEK, RAF, and RAS inhibitors. *In vivo*, SHP2 and RAS, but not MEK, inhibitors slowed down tumor progression in both cell line and patient-derived xenografts. Our results indicate that, although RAS signaling might be needed for RIT1-dependent growth, these tumors are not sensitive to MAPK inhibition as a monotherapy and, hence, other pathways could contribute to tumor growth. Therefore, we decided to explore whether targeting RIT1 directly, could be a more beneficial strategy for these tumors. In order to inhibit oncogenic RIT1 directly, we have undertaken two complementary approaches. First, because RIT1 mutations were shown to impair its proteolysis, we explored whether restoring RIT1 proteasomal degradation could be a promising strategy. Recently, the development of Proteolysis Targeting Chimeras (PROTAC) has demonstrated that targeted degradation can be used as a pharmacological approach for the treatment of cancer. Therefore, we have tested successfully several proof-of-concept PROTAC approaches that caused degradation of oncogenic RIT1 in different cellular models. Second, we used a chemical biology approach to assess whether covalent inhibitors directed against the closely-related GTPase KRAS could cross-react and bind to oncogenic RIT1. We have identified a molecule that binds RIT1 and we are currently characterizing it in our preclinical models. Overall, our work provides comprehensive insights into the oncogenic role of RIT1 in lung cancer emphasizing its potential as a therapeutic target.

#3939 Ror2, a novel key regulator driving cell fate decisions throughout pancreatic tumor progression.

S. Benitz[1], A. Steep[2], M. Nasser[1], J. Preall[3], U. Mahajan[4], I. Loveless[1], H. McQuithey[1], E. Davis[1], H.-J. Wen[1], D. Long[1], T. Metzler[5], S. Zwernik[1], D. Salas-Escabillas[1], L. Huang[1], N. Steele[1], I. Regel[4], F. Bednar[6], H. Crawford[1];

[1]Henry Ford Health System, Detroit, MI, [2]Center of Translational Data Science, Chicago, IL, [3]Cold Spring Harbor Laboratory, Cold Spring Harbor, NY, [4]Ludwig Maximilian University of Munich, Munich, Germany, [5]Technical University of Munich, Munich, Germany, [6]University of Michigan, Ann Arbor, MI

Introduction: Reprogramming of pancreas cell fate drives development of pancreatic ductal adenocarcinoma (PDAC). Acinar cells, the most probable origin of pancreatic cancer, undergo a rapid cell identity switch towards a duct-like phenotype upon $Kras^{G12D}$ expression and when combined with pancreatitis or the loss of acinar differentiation factors. Metaplastic and dysplastic duct-like cells are heterogeneous with a proportion acquiring features reminiscent of gastric lineages. While some gastric signatures are maintained in the classical PDAC subtype, they are eroded in the more aggressive, basal-like PDAC. Since subtype identity has a major impact on prognosis and therapeutic targetability, druggable targets that regulate cellular reprogramming in pancreatic cancer can be exploited to increase sensitivity to therapy.

Methods: To elucidate mechanisms responsible for early reprogramming, pancreatic tissue of mice with conditional $Kras^{G12D}$ expression and loss of Pdx1 was analyzed by single-nucleus ATAC-seq. Expression of identified target genes was studied in precancerous lesions and PDAC by using multiplex RNAscope and IHC staining. Computational analyses of publicly available sequencing data were used to establish correlation to PDAC subtype identity. Genes were functionally studied in PDAC cell lines.

Results: By performing snATAC-seq and RNA-seq of early transformed pancreatic tissue, we discovered that acinar cells with the combined expression of $Kras^{G12D}$ and loss of Pdx1 activate expression of a gastric metaplastic gene signature accompanied by elevated levels of the receptor kinase Ror2. Ror2 is also highly expressed in distinct subpopulations of metaplastic and dysplastic cells, associated with a gastric neck cell phenotype and enhanced proliferative capacity. In contrast, $Ror2^{Low}$ lesions are characterized by a gastric pit cell-like and a senescent phenotype. Genetic ablation of Ror2 resulted in a shift in lesion identity, enriching those with a pit cell and senescent identity. In PDAC, we found that Ror2 anti-correlates with a similar gastric pit cell phenotype that is maintained in the classical subtype PDAC but is strongly associated with the more aggressive basal-like subtype. Overexpression of ROR2 in human PDAC cell lines with a classical differentiation induced loss of the classical gene signature as well as epithelial-to-mesenchymal transition. Moreover, ROR2 enforces a strong dependency on AKT signaling, causing increased vulnerability of ROR2-expressing cells to AKT inhibition, but increased resistance to the KRAS inhibitor MRTX1133.

Conclusions: We discovered Ror2 as a critical determinant of precancerous lesion as well as PDAC subtype identity. Its role in driving an aggressive PDAC phenotype that is inherently resistant to Kras inhibition suggests that inhibiting this receptor tyrosine kinase will enhance sensitivity to the new generation of targeted therapies.

#3940 Nuclear translocation of HER3 promotes breast cancer progression and dissemination recruiting immune cells via CXCL1 and CXCL8.

T. Cheytan, R. Wurth, N. Hahnen, E. Donato, C. Klein, R. Weber, D. Colombo, J. Krijgsveld, M. Sprick, A. Trumpp;
German Cancer Research Center, Heidelberg, Germany

Breast cancer is a highly complex multifactorial disease, which can be driven by the aberrant regulation of different signaling pathways including receptor tyrosine kinase (RTK) signaling. Notably, while RTKs have been classically described as transmembrane receptors, they can also translocate to the nucleus, even though the functional importance of this process remains largely unexplored for most RTKs. Here, we report a novel role for the nuclear form of the RTK human epidermal growth factor receptor 3 (HER3) in driving primary breast cancer growth and metastasis. Firstly, using different patient-derived organoids (PDOs) established from metastatic breast cancer patients, we demonstrated the robust translocation of the activated phosphorylated HER3 receptor (pHER3) from the plasma membrane to the nucleus in response to its ligand Neuregulin 1 (NRG1). Interestingly, the nuclear translocation was observed not only in the HER2-positive breast cancer subtype but also in luminal and triple-negative breast cancer-derived cells. In order to decipher the functional role of nuclear HER3 (nHER3), we identified and mutated its nuclear localization signal, resulting in decreased nuclear translocation of the receptor while its membrane form remained intact. This reduction in nHER3 remarkably impeded primary tumor growth and metastatic spread in different patient-derived xenograft (PDX) models. Conversely, selective overexpression of HER3 in the nucleus led to increased primary tumor growth and metastatic burden in vivo. In order to decipher the mechanism of action of nHER3, we performed co-immunoprecipitation followed by global mass spectrometric analysis to identify the protein binding partners of the receptor in the nucleus. Specifically, nHER3 was found to interact with different transcription factors such as the AP-2 family of transcription factors and with major chromatin remodeling complexes like the nucleosome remodeling and deacetylase (NuRD) complex, implicating its role in transcriptional regulation. Furthermore, gene expression analysis of PDOs expressing the wild-type or the mutated form of HER3 revealed the modulation of several key growth regulators such as early growth response 3 (EGR3) by nHER3. The nHER3-EGR3 axis further controlled downstream effectors like the immune chemoattractants CXCL1 and CXCL8. Accordingly, PDX from breast cancer cells overexpressing nHER3 showed significantly increased immune infiltration, suggesting a possible role of nHER3 in regulating the tumor microenvironment. Altogether, we report here a novel non-canonical role of the nuclear form of HER3 receptor in driving breast tumorigenesis, with key implications for our understanding and targeting of RTK signaling in breast cancer.

#3941 Wild-type KRAS dosage in mutant KRAS lung cancer: Implications for tumorigenesis and therapeutic response.

T. Ivanisevic[1], G. Vande Velde[2], P. Zhao[1], W. Magits[1], R. N. Sewduth[1], A. A. Sablina[1];
[1]VIB-KU Leuven Center for Cancer Biology, Leuven, Belgium, [2]Nuclear Medicine and Molecular Imaging, Leuven, Belgium

Lung adenocarcinomas (LUAD) are frequently driven by activating mutations in the Kirsten rat sarcoma viral oncogene homolog (KRAS). Previous studies have suggested that wild-type (wt)-RAS signaling may modulate cancer progression and drug resistance in these tumors. However, the interplay between oncogenic KRAS and wt-RAS-like GTPases in lung cancer biology and treatment remains debated. Here, we investigated the impact of increased wt-KRAS dosage in LUAD harboring mutant KRAS on lung cancer phenotypes and response to anti-KRAS therapies. Increased wt-KRAS dosage occurs in LUAD due to the loss of LZTR1, a proteostatic regulator of RAS-like GTPases. *LZTR1* mutations, deletions, or downregulation co-occur with oncogenic KRAS mutations in more than 40% of LUAD patients. Using a global protein stability screen, we identified LZTR1 as the main regulator of the stability of wt-KRAS, but not of the oncogenic KRAS mutants. Proteomic analysis of LUAD cells confirmed that LZTR1 loss leads to elevated expression of wt-KRAS, but not of KRAS-G12D, indicating that *LZTR1* loss affects wt-RAS rather than mutant KRAS signaling. *LZTR1* loss in LUAD patients is associated with poor prognosis and hypoxic expression signatures. In a mouse model of *Kras*-mutated LUAD, *Lztr1* haploinsufficiency promoted tumor initiation and progression. Moreover, *Lztr1* loss results in hypoxic tumors with inflamed, tortuous, insufficiently perfused, and leaky vessels. Integrative proteomic and phosphoproteomic analysis revealed increased RAL/TBK1 pathway activity in *LZTR1*-depleted lung cancer cells and *Lztr1*-deleted tumors. This leads to enhanced secretion of proangiogenic and proinflammatory factors, such as VEGF and TNFα, by *LZTR1*-deficient cells and an increased number of neutrophils in *Lztr1*-deleted tumors. TNF-activated neutrophils present at vascular branching points can modulate vascular remodeling by influencing the formation and function of blood vessels. Pharmacological inhibition of RAL/TBK1 signaling with amlexanox, an anti-NF-κB/TBK1 drug, reduces TNFα secretion, decreases the number of neutrophils, and normalizes the tumor-associated vasculature. We demonstrated that increased wt-KRAS dosage, but not other small GTPases, mimicked the effects of LZTR1 loss on RAL/TBK1 signaling and VEGF secretion, suggesting that LZTR1 loss alters the heterogeneity of KRAS-mutated lung cancer by modulating wt-KRAS levels. Furthermore, MRTX1133 a selective inhibitor of KRAS-G12D, showed limited effect in the *Kras-G12D*, *Lztr1*-loss LUAD model, whereas the combination of MRTX1133 and amlexanox suppress tumor growth, likely due to the restoration of the tumor vasculature by RAL/TBK1 inhibition. Our study reveals novel insights into the role of wt-KRAS dosage in mutant KRAS lung cancer and identifies potential therapeutic strategies to target patients with dysregulated KRAS proteostasis due to LZTR1 loss.

POPULATION SCIENCES: Cancer Disparities Research
Minisymposium

#3942 Mailed at-home self-sampling for HPV testing increases screening participation among under-screened patients in a U.S. safety net health system: Results of the PRESTIS trial.

Jane R. Montealegre[1], Elizabeth Y. Chiao[2], Matthew L. Anderson[3], Susan G. Hilsenbeck[4], Shaun Bulsara[4], Susan L. Parker[1], Maria Daheri[5], **Trisha L. Amboree**[1], Kathleen M. Schmeler[6], Maria L. Jibaja-Weiss[7], Mohammad Zare[8], Ashish A. Deshmukh[9], Michael E. Scheurer[10]

[1]Behavioral Science, UT MD Anderson Cancer Center, Houston, TX,[2]Epidemiology, UT MD Anderson Cancer Center, Houston, TX,[3]Obstetrics and Gynecology, University of South Florida Morsani School of Medicine, Tampa, FL,[4]Medicine, Baylor College of Medicine, Houston, TX,[5]Harris Health System, Houston, TX,[6]Gynecologic Oncology, UT MD Anderson Cancer Center, Houston, TX,[7]School of Health Professions, Baylor College of Medicine, Houston, TX,[8]Family and Community Medicine, University of Texas Health Science Center-Houston, Houston, TX,[9]Medical University of South Carolina, Charleston, SC,[10]Pediatrics, Baylor College of Medicine, Houston, TX

Background: In global settings, self-sampling for human papillomavirus (HPV) testing is associated with a pooled 2-fold increase in cervical cancer screening participation over usual care among underscreened persons. The Prospective Evaluation of Self-Testing to Increase Screening (PRESTIS) Trial is the first pragmatic randomized controlled trial (RCT) in the U.S. to evaluate the effectiveness of mailed at-home self-sampling for HPV testing in a safety net health system setting. Safety net systems provide care to medically underserved individuals at elevated cervical cancer risk. We hypothesized that patients who were mailed a self-sampling kit would have greater screening participation compared with those receiving usual care; and that patient navigation, a patient-centered intervention to address barriers to care, would further increase participation.
Methods: PRESTIS is a three-arm pragmatic RCT of n=2,270 patients in a U.S. safety net health system who are under-screened for cervical cancer (i.e., no Pap in 3.5 years or Pap/HPV co-test in 5.5 years). Eligible participants were identified through the electronic health record (EHR) and randomized to arms: 1) telephone recall to provider-performed screening (usual care); 2) telephone recall + mailed self-sampling kit for HPV testing; or 3) telephone recall + mailed self-sampling kit + telephone-based patient navigation. Self-sampled swabs were tested for high-risk (HR)-HPV. HR-HPV+ patients were navigated to clinical follow-up. The primary outcome, incidence of screening participation, was ascertained by EHR review at 6 months post-randomization and defined as return of a completed kit or attendance for provider-performed screening.
Results: Participants were enrolled 02/2020-08/2023. Primary outcomes have been ascertained for n=2,115 participants. Participants were predominantly Hispanic/Latina (68.6%); 53.4% indicated Spanish as primary language; and 60.3% were uninsured. Mean age was 47.9 years (SD: 10.4 years); median time since last screening test was 9.5 years (range: 1.6-21.7 years). In intent-to-treat analyses, screening participation was 15.3% (95% CI 13.0% - 17.9%) in Arm 1; 44.0% (40.4% - 47.6%) in Arm 2; and 51.4% (47.7% - 55.0%) in Arm 3. Relative incidence of screening in Arms 2 and 3 versus Arm 1 was 2.90 (2.42 - 3.47) and 3.36 (2.82 - 4.01), respectively. Relative incidence of screening in Arm 3 versus Arm 2 was 1.16 (1.04 - 1.29).
Conclusion: Compared with usual care, mailed at-home self-sampling increased screening participation among an under-screened population by almost three-fold when used alone and over 3.3-fold when combined with telephone-based patient navigation. After FDA approval, self-sampling for HR-HPV testing has the potential to dramatically increase participation in cervical cancer screening in underserved populations.

#3943 Refined race and ethnicity categories for an EHR-based cohort to study disparities in liver cancer risk.

M. C. DeRouen[1], C. A. Thompson[2], A. J. Canchola[1], A. Cortella[1], P. Inamdar[1], J. Chu[1], S. Nie[3], M. Vu[4], M. Somsouk[1], M. M. Tana[1], A. D. Rubinsky[1], I. Cheng[1], M.-O. Klm[1], M. Segal[1], C. Ho[5], Y. G. Daida[3], S.-Y. Liang[4], H. B. El-Serag[6], S. L. Gomez[1], S. Shriff-Marco[1];

[1]UCSF - University of California San Francisco, San Francisco, CA, [2]UNC - University of North Caroline Chapel Hill, Chapel Hill, NC, [3]The Center for Integrated Healthcare Research-Kaiser Permanente Hawai'i, Honolulu, HI, [4]Palo Alto Medical Foundation Research Institute, Palo Alto, CA, [5]California Pacific Medical Center, Sutter Health, San Francisco, CA, [6]Baylor College of Medicine, Houston, TX

Purpose: To develop a schema for harmonized, detailed characterization of race and ethnicity data for an electronic health record (EHR)-based cohort linked to cancer registry data to assess disparities in hepatocellular carcinoma (HCC) risk.

Methods: We assembled an cohort of adults with 1+ encounter in 2000-2017 by pooling EHR data from three healthcare systems (Kaiser Permanente Hawai'i, Sutter Health, San Francisco Health Network). EHR data to define sociodemographic and clinical factors were linked to population-based state cancer registries for data on incident HCC (ICD-03 site/histology C22.0/8170-8175) through 2017. We extracted, harmonized and developed schemas to characterize multiple response race and ethnicity data across systems. We used Cox proportional hazards regression to examine disparities in HCC risk across racial and ethnic groups, comparing observations across categorization schema.

Results: The cohort included 4,248,553 adults; 2,916 had incident HCC. A race and ethnicity schema that prioritized small populations and disaggregation of heterogenous groups defined 16 categories and was used to analyze pooled data from Kaiser Permanente Hawai'i and Sutter Health. With this schema, we observed variation in HCC risk across ethnic groups that are typically aggregated into larger ethno-racial categories (e.g., Asian American). Compared to non-Hispanic (NH) White males, Vietnamese American males had greater risk of HCC (hazard ratio (HR): 7.42; 95% CI: 4.25, 12.96) as did American Indian/Alaska Native, Black, Chinese American, Hispanic, Native Hawaiian, and Pacific Islander males; Asian Indian, Filipino, Japanese, and Korean American males did not. Among females, every group except American Indian/Alaska Native, Asian Indian American, and Pacific Islander females had greater risk of HCC than the NH White group. Due to less granular data from San Francisco Health Network during our study period, we developed a second, grouped schema aggregating categories from the detailed schema; it resulted in seven race and ethnicity categories and was used to analyze pooled data from all three healthcare systems. Compared to the categorization of race and ethnicity used by the US Census, which also has seven categories, we observed different patterns in HCC risk disparities for the smallest groups (i.e., American Indian/Alaska Native and Native Hawaiian).

Conclusions: Analysis of a large EHR-based cohort linked to cancer registry data using a race and ethnicity characterization schema that prioritizes small populations yields valuable knowledge on disparities in HCC risk. Thus, to advance research on health disparities using EHR data, researchers must critically assess racial and ethnic categories typically available from healthcare system data repositories. We offer recommendations to operationalize EHR data on race and ethnicity to facilitate its meaningful use in research.

#3944 Addressing stomach cancer disparities by assessing *Helicobacter pylori* infections among American Indian adults from the Navajo Nation.

D. Pete[1], N. R. Salama[1], J. W. Lampe[1], M. C. Wu[1], A. I. Phipps[2];
[1]Fred Hutchinson Cancer Center, Seattle, WA, [2]University of Washington, Seattle, WA

Background. The Navajo Nation, the largest tribe in the United States (US), is experiencing a high burden of stomach cancer, possibly due to a high prevalence of *Helicobacter pylori (Hp)* infection. *Hp* is a major risk factor for stomach cancer and *Hp* strains that carry the *cagA*-gene are linked to greater gastrointestinal disease severity. Yet little research has investigated the prevalence and correlates of *Hp* and *cagA* infection in Navajo people. We assessed the prevalence and correlates of *Hp* infection and *cagA*-gene carriage in adult tribal members residing in the Navajo Nation.
Methods and Material. We conducted a community-based cross-sectional study in the Navajo Nation in 2021 during the COVID-19 pandemic. Participants were recruited using online and offline platforms, including social media, a study website, newspaper advertisements, flyers, word of mouth, and community outreach. Stool samples collected from participants were analyzed with droplet digital PCR for *Hp* 16S and *cagA* virulence genes. Demographic characteristics, health, and dietary factors were collected from self-administered health and food questionnaires sent via mail.
Results. Of 99 participants, half (49.5%) were 18-44 years old and 73.7% were female. About sixty percent (57.7%, 95% CI: 47.6-67.3) of participants were infected with *Hp*, twice the US population prevalence (27%). Among *Hp*-infected participants, 76.7% (95% CI: 64.0-86.6) were *cagA*-gene positive, four times the *cagA* gene prevalence in White people (19%). Controlling for age and sex, monthly use of Navajo herbal medicines was positively associated with *Hp* infection (OR=3.73, 95% CI: 1.05-17.87). No significant associations with *Hp* and *cagA*-gene were observed with other risk factors such as older age, males, lower education, and high sodium intake.
Conclusion. A substantial proportion of Navajo adults in our study had *Hp* and *cagA*-positive infections. Given studies showing the antibacterial activity of Indigenous herbal medicines, monthly use of Navajo herbal medicines was an unexpected risk factor for *Hp* infection. This observation may be due to reverse causality, where participants with gastrointestinal conditions used Navajo herbal medicines for gastrointestinal symptom relief, particularly when participants had limited access to healthcare services due to the COVID-19 pandemic. Possible environmental transmission of *Hp* in the preparation of herbal medicines (i.e., water source, utensils) could be another source of exposure. Given the high burden of *Hp* and *cagA*-positive infections, culturally tailored health education strategies and interventions addressing these infections present an opportunity for research and cancer prevention among Navajo adults.

#3945 The development of a culturally adapted tobacco prevention curriculum for LGBTQ+ youth across California: Formative research.

M. Fine[1], Z. Surani[1], L. J. Finster[1], J. T. Greene[2], C. L. N. Kajiwara[2], R. Zaldivar[3], **B. Halpern-Felsher**[2], R. W. Haile[1];
[1]Cedars-Sinai Medical Center, Los Angeles, CA, [2]Stanford University School of Medicine, Palo Alto, CA, [3]The Wall Las Memorias, Los Angeles, CA

Purpose: LGBTQ+ youth exhibit some of the highest rates of tobacco use and tobacco-related morbidity and mortality, making access to cancer prevention at an early age particularly critical. The purpose of this study is to develop an LGBTQ+ culturally tailored tobacco prevention curriculum within the Stanford Tobacco Prevention Toolkit, to help prevent LGBTQ+ students from starting or escalating the use of any tobacco product.
Methods: A community-based participatory research (CBPR) was established between the Cedars-Sinai Cancer Research Center for Health Equity, facilitated by Community Outreach and Engagement, in collaboration with The Wall Las Memorias and the Stanford REACH Lab to conduct basic formative focus groups in the LGBTQ+ community. Seventy-six participants were recruited, and 9 focus groups were conducted (33 participants among LGBTQ+ youth; 19 community advocates and educators; and 24 parents/caregivers/guardians). A thematic analysis was conducted to identify lesson topics and subject matter content to be included in the curriculum and the best strategies to deliver the lesson to LGBTQ+ youth.
Results: Several themes emerged from the focus groups, including an overall theme noting a desire for more safe spaces and peer support to discuss tobacco, vaping, and marijuana use among LGBTQ+ youth. LGBTQ+ youth noted tobacco, vaping, and marijuana were very accessible through friends and social groups in the school setting. They also expressed that tobacco, vaping, and marijuana use were associated with pressures to fit in, an increasing ‘normalization’ of marijuana use, and social media channels that glorify vaping and tobacco use. LGBTQ+ youth also expressed that they do not see tobacco prevention messaging relevant to themselves or their peers nor through their preferred information channels. Parents, educators, and community advocates expressed that they would like to be offered opportunities for education and direct involvement in LGBTQ+ research. With this information, the REACH Lab is developing the LGBTQ+ curriculum.
Conclusions This CBPR approach builds upon the existing validated set of curricula contained in the Stanford Tobacco Prevention Toolkit, which is theory-driven and has reached over 3 million middle and high school students. Once completed, the LGBTQ+ Focused Tobacco Prevention Curriculum will be added to the Tobacco Prevention Toolkit and will be the first informed/validated tobacco prevention program for LGBTQ+ youth.

#3946 Weaving equity into the fabric of health: A deep dive into race, social determinants of health and facility type in pancreatic adenocarcinoma care.

C. Wu, Z. Song, R. Akhund, C. McLeod, L. Wood, H. Chen, J. Rose, S. Bhatia, A. Gillis;
University Of Alabama At Birmingham, Birmingham, AL

Introduction: Pancreatic adenocarcinoma (PDAC) remains one of the deadliest malignancies, with significant differences in survival rates observed among various racial and ethnic groups. Despite advancements in care, ongoing racial disparities stress the need to uncover underlying causes. This study seeks to evaluate the interplay of race, social determinants of health, and treatment facility on overall survival (OS) of PDAC patients.
Methods: In this retrospective cohort study, we identified PDAC patients from January 1, 2004, to December 31, 2019, using National Cancer Database (NCDB) data. Patients not receiving treatment (surgery, chemotherapy, or radiation) or who were missing race were excluded. We performed a multivariable cox proportional hazards regression to explore the race and all-cause mortality relationship, stratified by facility type and income status. Patients were divided into income quartiles (SES) with the lowest SES represented by median zip code level income ≤$40,227, while highest SES indicated income levels ≥$63,333. Treating facility type included community or academic hospital. A two-sided P-value <0.05 was considered significant.
Results: The total cohort included 210,520 patients. The average age of the cohort was 66.4 (SD:10.7) years and most patients were white (80%, N=168,467), male (52.2%, N=109,844), treated at academic facility type (65.5%, N=136,623), and the highest SES was the largest (38.4%, N=71,205). In unadjusted analysis, Black patients had lower OS than Whites (HR: 1.05 (95% CI: 1.04-1.07, p<0.001)). As SES increases there was a corresponding decrease in hazards (p<0.001). In the multivariable subgroup analysis, survival were not significant for Black and White patients in highest SES at academic facilities (p=0.8). Of note, highest SES Black patients in community hospitals had worse survival than highest SES White patients (HR: 1.08 (95% CI:1.01-1.16, p=0.03)). However, lowest SES Blacks treated at academic facilities had superior survival compared to lowest SES Whites (HR: 0.93 (95% CI: 0.89-0.96, p<0.001)).
Conclusion: Survival differences among Black individuals were linked to SES and facility type. Highest SES was not protective for Black patients treated at community hospitals compared to their White counterparts, indicating additional factors driving outcomes. These findings highlight the intricate influence of race, SES, and perhaps biology on survival outcomes. Addressing these complexities through targeted research and intervention is crucial for reducing health disparities and fostering a more equitable healthcare landscape.

#3947 Non-BRCA variants in hereditary breast and ovarian cancer patients in the Northern Mexico population.

C. H. Burciaga-Flores, Sr.[1], D. C. Perez-Ibave[1], M. L. Garza-Rodriguez[1], O. Vidal-Gutierrez[1], C. M. Villarreal-Garza[2], D. Aguilar y Mendez[2];
[1]Universidad Autonoma de Nuevo Leon, Monterrey, Mexico, [2]Hospital Zambrano Helion Tec Salud, Monterrey, Mexico

Background: Hereditary cancer syndromes explain 5-10% of all cancer cases. Germline pathogenic variants in BRCA1 and BRCA2 genes (BRCA) are present in 2-3% of all breast cancer (BC), and 15% of all ovarian cancer (OC) cases. BRCA1 and BRCA2 pathogenic variants (PV) represent 25-28% of BC and 40% of OC patients with a positive familial history. BRCAs are the most studied genes for the prevalence, family history, preventive surgeries, and target treatment options in both BC and OC. There are other genes, important in the diagnosis, pathogenesis, and treatment options of the patients: TP53, PALB2, CHEK2, among others. This study aims to identify the prevalence of non- BRCA genes related to the development of hereditary breast and ovarian cancer syndrome in patients of Northeast Mexico.
Methods: This is a multicenter study that recruited patients from two reference oncology centers in Nuevo Leon, Mexico: the CECIL (The CUCC Early Cancer Detection Clinic) Hereditary Cancer Registry and Hereditary Cancer Program from Tec Salud. From March of 2016 to March of 2023, a total of 872 patients meeting NCCN criteria were evaluated by Medical Geneticists from both centers and were tested with NGS multigene cancer panels.
Results: A total of 665 (76.26%) patients with a clinical diagnosis of HBOC (Hereditary Breast Hereditary Cancer Syndrome) were included. We found 310 (46.6%) patients had at least one variant, 180 (58%) with at least one pathogenic variant, and 130 (41%) with a VUS (a variant of uncertain significance). BRCA1 was found in 79 (43.8%) and BRCA2 in 32 (17.7%) of all PV. Non-BRCA PV were found in 69 (38.3%) patients: 4 ATM, 2 BLM, 3 BRIP1, 22 CHEK2, 4 CDKN2A, 5 MUTYH, 10 PALB2, 4 RAD51C, 2 SDHA, 2 TP53, 2 WRN, CDH1, CDK4, DICER, MSH3, NBN, PTEN, RAD50, USH2A one of each. Is remarkable that 19 of the 22 patients with CHEK2 and 5 of the 10 patients with PALB2 had the recurrent PV c.707T>C and c.2167_2168del, respectively.
Conclusions: Non-BRCA PV in Northern Mexico corresponds to one-third of the BC and OC cases, including HRD (homologous recombination deficiency) genes. HDR patient carriers are potential targets of iPARP therapies. This project reinforces the fact that multigene panels should be employed to ensure a complete diagnosis in hereditary cancer patients.

#3948 HPV45 and HPV52 prevalence, within-type variants, and precancer/cancer risks differ by race/ethnicity.

Aimee J. Koestler[1], Chase W. Nelson[1], Meredith Yeager[2], Zigui Chen[3], Laurie Burdett[2], Sambit K. Mishra[2], Michael Dean[2], Elizabeth Suh-Burgmann[4], Thomas Lorey[5], Phillip E. Castle[1], Mark Schiffman[1], Lisa Mirabello[1]

[1]Division of Cancer Epidemiology and Genetics, National Cancer Institute, National Institutes of Health, Rockville, MD, [2]Cancer Genomics Research Laboratory, Leidos Biomedical Research, Inc., Frederick, MD, [3]Department of Microbiology, The Chinese University of Hong Kong, Hong Kong, China, [4]Division of Research, Kaiser Permanente Northern California, Oakland, CA, [5]Regional Laboratory and Women's Health Research Institute, Division of Research, Kaiser Permanente Northern California, Oakland, CA

Introduction: Persistent infection with a high-risk HPV (HR-HPV) type causes cervical cancer and many other cancers in both men and women. Our published data have shown that the distribution of specific HPV16/35 sublineages and genetic variants differ around the world and confer greater risk of cervical precancer/cancer in the populations where the virus is thought to have originated and coevolved. More studies are needed to evaluate the relationship between race/ethnicity, HR-HPV genetic variation, and precancer/cancer risk.

Objective: To evaluate HPV45 and HPV52 genetic variation, and how it relates to a woman's race/ethnicity and cervical precancer/cancer risk, using HPV whole-genome sequencing of 774 HPV45+ and 719 HPV52+ women in the NCI-Kaiser Permanente Northern California (KPNC) HPV Persistence and Progression cohort; and compared to HPV16/35.

Methods: We viral genome sequenced 557 HPV45+ and 345 HPV52+ controls (women with benign infections [≤CIN1]), and 94 HPV45+ and 227 HPV52+ precancer/cancer cases (CIN3+). We evaluated HPV45 and HPV52 prevalence for each type by a woman's self-reported race/ethnicity, and compared them to HPV16 and HPV35 using existing comparable NCI-KPNC data. To assess associations between HPV45 and HPV52 genetic variation (viral sublineages and SNPs) and infection outcome, we used Fisher's Exact Tests and logistic regression to estimate the OR and 95% CI.

Results: For HPV45, we determined that sublineages have varying histology-specific precancer/cancer risk (ORs ranged from 2-14), and that the sublineage distribution significantly varied by race/ethnicity ($p < 0.001$). By race, the HPV45 A2 sublineage was most prevalent in Asian/PI women and was associated with the highest risk of CIN3+ in these women compared to other races/ethnicities (OR=5.7, 95% CI=1.5-29.4), while the B2 sublineage was associated with increased risk of CIN3+ in Black women only (OR=6.1, 95% CI=1.2-33.6). The prevalence of each HR-HPV type (HPV16/35/45/52) significantly varied by race/ethnicity ($p < 0.001$). For each type, White was the most reported race/ethnicity; however, Black women were a greater proportion of the HPV35+ cases compared to other types (15% vs 8-10%), and Asian/PIs were a greater proportion of HPV52+ cases (26% vs 10-13%). HPV52 genome analyses are still underway; we will present the complete study results (i.e., sublineage risk by race) at AACR.

Conclusions: We conducted the largest studies of HPV45 and HPV52 genome variation to date. We demonstrate that specific HPV45 sublineages vary by race and are associated with an increased risk of precancer/cancer for specific races/ethnicities, and that HPV52 infection has a greater prevalence in Asian/PI women compared to other racial groups. Our data suggest that certain HR-HPV types and specific sublineages of these types are more common in specific racial/ethnic groups and potentially linked to differing risks by race.

Minisymposium

#3949 SMARCAL1 is a novel synthetic lethal target in ALT+ osteosarcoma and neuroblastoma.

M. Wierdl[1], J. L. Catlett II[2], N. Ocasio-Martinez[2], J. D. Johnson, Jr.[1], A. Herman[3], N. V. Dharia[2], G. Alexe[2], E. A. Sweet-Cordero[4], E. Bernstein[5], K. Stegmaier[2], **L. M. Guenther**[1];

[1]St. Jude Children's Research Hospital, Memphis, TN, [2]Dana-Farber Cancer Institute, Boston, MA, [3]Broad Institute of MIT and Harvard, Cambridge, MA, [4]UCSF School of Medicine, San Francisco, CA, [5]Icahn School of Medicine at Mount Sinai, New York, NY

Osteosarcoma (OS) is an aggressive pediatric solid tumor that is difficult to treat with established therapies. We performed CRISPR/Cas9 screening in 13 OS cell lines as part of the Dependency Map project. Mining this data to identify genes whose knockout (KO) leads to selective anti-viability in OS, we observed the helicase *SMARCAL1* as a selective dependency in OS ($p<0.0001$; effect size = -0.275). Given the genomic instability of OS and SMARCAL1's related, established role in replication stress, we first validated our screens by CRISPR KO in OS lines in vitro. This demonstrated selective antiviability of *SMARCAL1* KO in dependent OS lines. To orthogonally validate *SMARCAL1* dependency, we deployed a dTAG system, utilizing a hetero-bifunctional small molecule targeting the tagged protein for degradation by an E3 ubiquitin ligase. We observed antiviability of dependent lines after SMARCAL1 degradation. In parallel, in order to ascertain importance of this gene in vivo, we performed a barcoded CRISPR pooled screen against pre-selected OS dependencies in an OS cell line xenograft in NSG mice. After sequencing of tumor gDNA, we identified *SMARCAL1* as a top hit, suggesting relevance *in vivo*.We next investigated biomarkers of *SMARCAL1* dependency. A role for SMARCAL1 has been described in alternative lengthening of telomeres (ALT). We asked whether ALT+ OS cell lines are enriched for *SMARCAL1* dependency. We found a correlation between ALT+ OS and *SMARCAL1* dependence in our CRISPR screens. We then asked if this extends to other ALT+ tumors. Neuroblastoma (NB), the most common extracranial pediatric solid tumor, is enriched for ALT. When we looked specifically at NB models, we observed that *SMARCAL1* was the most enriched dependency in ALT+ NB compared with other NB lines ($p<0.0001$; effect size = -0.785). We then performed *SMARCAL1* KO in 2 ALT+ ATRX-altered NB lines and one ALT+ ATRX-WT NB line. We found that *SMARCAL1* KO led to antiviability in the ATRX-altered ALT+ cell lines, while the ALT+ ATRX-WT cell line was unaffected. This suggests that dependency on *SMARCAL1* is specific to ATRX alteration, rather than ALT alone.In order to confirm synthetic lethality between ATRX and SMARCAL1, we next utilized a human OS line not included in the DepMap screen, which has biallelic inactivation of *SMARCAL1*. We infected this line with our SMARCAL1 dTAG, leading to constitutive overexpression of SMARCAL1, and then performed ATRX KO. We observed that SMARCAL1 overexpression rescued the antiviability effect of ATRX KO. This could be reversed by degradation of exogenous SMARCAL1, suggesting that ATRX and SMARCAL1 can compensate for one another. Taken together, these findings demonstrate that *SMARCAL1* is a selective dependency engendered by the loss of WT ATRX in OS and NB and that SMARCAL1 is playing a critical role in mediating ALT. Studies are ongoing to determine the mechanism of SMARCAL1's activity and potential for targeting this enzyme for therapeutic benefit.

#3950 Dedifferentiation unveils origin of Ewing sarcoma.

U. Kapoor[1], C. Hafemeister[1], L. Shaw[2], K. Muelbacher[1], J. Moldaschl[3], D. Egger[4], S. Toegel[2], C. Kasper[3], M. Farlik[2], F. Halbritter[1], H. Kovar[1];
[1]St. Anna Children's Cancer Research Institute, Vienna, Austria, [2]Medical University of Vienna, Vienna, Austria, [3]University of Natural Resources and Life Sciences (BOKU), Vienna, Austria, [4]Leibniz University Hannover, Hannover, Germany

Ewing sarcoma (ES) is an aggressive pediatric bone tumor in adolescents primarily driven by the expression of the fusion oncogene EWS::FLI1. Although the etiology of ES remains controversial, human mesenchymal stem cells (hMSCs) are considered to be the likely cell of origin. This is not only due to their ability to tolerate ectopic EWS::FLI1 expression, but also because the transcriptome of EWS::FLI1 expressing hMSCs is highly similar to that of primary Ewing tumors. However, to date a cellular differentiation-based model of ES does not exist. With the intent to understand ES histogenesis, this study aims to establish the first comprehensive single-cell differentiation atlas (both transcriptome and epigenome) of juvenile bone marrow-derived hMSCs with and without EWS::FLI1 expression. We sought to study the consequences of inducing the EWS::FLI1 oncogene expression at various time points of hMSC differentiation into adipo-, chondro-, osteo- and neuro-genic lineages. Our workflow utilizes physiology-mimicking conditions including serum-free differentiation, hypoxia, and growth/differentiation as spheroids. We pooled bone marrow-derived hMSCs isolated from eleven healthy juvenile donors, engineered them to conditionally express EWS::FLI1, and carried out multi-lineage differentiation for 10 days where EWS::FLI1 was induced daily for 24h or 72h. This temporally resolved atlas of 105 samples representing normal and perturbed differentiation allowed us to map ES patient tumor data to multiple lineages and time-points across stages of lineage commitment. Single-cell RNA-seq analysis of ~271,000 transcriptomes revealed an apparent and dynamic dedifferentiation in the presence of EWS::FLI1 across all four lineages. Preliminary analysis of genes detected in the EWS::FLI1 high cluster uncovers a specific lineage preference and time window that shares the transcriptomic signature with tumor cells, indicating the potential cell/stage of tumor-origin. Our results provide new insight into the enigmatic cell of origin of Ewing sarcoma, laying the foundation for the development of much-needed pre-clinical models for tailoring therapies. This study is supported by a generous grant (#20) of the Alex’s Lemonade Stand Foundation (ALSF) Crazy8 Program.

#3951 Timing the development of chemoresistance in relapsed pediatric cancer.

S. Blay[1], M. Layeghifard[1], S. Davidson[1], D. Chen[1], A. Schwertschkow[1], V. Ramaswamy[1], M. Taylor[1], E. Papaemmanuil[2], A. Villani[1], D. Malkin[1], L. Alexandrov[3], M. Cowley[4], A. Shlien[1];

[1]SickKids, Toronto, ON, Canada, [2]Memorial Sloan Kettering Cancer Center, New York City, NY, [3]University of California, San Diego, CA, [4]Children's Cancer Institute, New South Wales, Australia

Survivors of pediatric cancer face lifelong battles with severe morbidities, which includes a significant risk of recurrence. Pre-existing genetic variation within primary tumors may offer certain cell populations an evolutionary advantage, increasing the likelihood that some will be resistant to treatment. But the inherent complexity of the tumor means finding these markers of resistance has yet to be fully explored across childhood cancer. To address this, we developed a pipeline that combines clonal evolution reconstruction with mutational signature extraction at the subclonal level to elucidate changes in mutational processes. Using this pipeline to analyze 1,743 pediatric tumor genomes we found a common pattern of parallel evolution in most pediatric cancers, irrespective of their tissue of origin. Further, we detected therapy-associated mutational signatures linked to specific treatments such as temozolomide, platinum, fluorouracil, and thiopurine in post-treatment tumor subpopulations. Of 235 samples with known treatment exposure, 37.9% displayed one or more treatment-associated signatures. In the context of the phylogenetic tree, we identified specific subpopulations with therapy signatures. In multi-sample cases, resistant subpopulations had ancestors present in primary tumors at the time of diagnosis, suggesting certain subpopulations possessed the ability to withstand chemotherapy-induced pressures from an early stage and then expanded following treatment. Finally, we observed differences in the timing of mutational signatures between antimetabolite and alkylating agent treatments, reflecting the mechanisms of these drugs. Antimetabolite agents showed subclonal mutational signatures occurring in later branches, likely due to dependence on cell cycling. In contrast, alkylating agents displayed signatures in both early and late subpopulations, as they are unaffected by cell cycle state. Thus, investigating mutational signatures at the subclonal level unveils new insights into the clonal dynamics of pediatric cancers and the development of chemoresistance. This research offers valuable insights for identifying pediatric cancer patients at greater risk of recurrence, enabling the development of more effective treatment plans to enhance their quality of life and overall survival rates.

#3952 Multiomic single-cell tumor evolution models of minimal residual disease in pediatric B-cell acute lymphoblastic leukemia.

S. M. Foltz[1], A. Loren[2], C. Chen[1], R. Mehta[2], E. Li[3], J. Xu[2], F. Alikarami[1], K. M. Bernt[1], K. Tan[1];
[1]Children's Hospital of Philadelphia, Philadelphia, PA, [2]University of Pennsylvania, Philadelphia, PA, [3]Stanford University School of Medicine, Palo Alto, CA

Detection of minimal residual disease (MRD) after initial diagnosis (IDX) and therapy is a strong prognostic marker for relapse in pediatric B-cell acute lymphoblastic leukemia (B-ALL). Previous studies have explored clonal genetic and gene expression changes between initial diagnosis and relapse. However, studying tumor cells present at MRD is challenging due to their low abundance. Examining the genomic profiles of leukemia cells that resist induction chemotherapy and understanding their evolutionary relationship to cells present at diagnosis may lead to a better understanding of the cells that eventually seed relapse. We analyzed somatic point mutations, indels, and copy number variants from 41 pediatric B-ALL patients with high-risk B-ALL. We specifically focused on patients from the following four common high-risk subtypes: KMT2A-rearranged, Ph+, Ph-like, and iAMP21, who had detectable disease at the end of induction. Leukemic burden at end-induction (day 29) ranged from 0.03% to 66.00%. Data were generated in partnership with the National Cancer Institute's Human Tumor Atlas Network and the Children's Oncology Group.

Our data set of 41 patients includes 39 with paired initial diagnostic and end-induction samples that we used to create tumor evolution models based on single cells across disease stages. We produced single-cell multiome gene expression (scRNA) and chromatin accessibility (scATAC) profiles (10x Genomics) with a median of 7428 leukemic blast cells at IDX (range: 2490-14219) and 1907 at MRD (range: 240-10167) after filtering. We called somatic mutations from scRNA and scATAC using SComatic and Monopogen, and we detected copy number changes using Numbat and EpiAneufinder. We also designed a targeted DNA sequencing panel including 335 variants based on B-ALL literature and database searches to produce scDNA (Mission Bio) for 24 patients (16 IDX-MRD pairs) with a median of 2346 cells profiled at IDX (range: 340-8849) and 1828 at MRD (range: 596-5133). We built tumor phylogenies based on somatic SNVs and CNVs with COMPASS. Using multiple tools and complementary single-cell omics data types to detect somatic changes improved our confidence in the events used for tumor evolution tree construction.

Our approach allowed us to define recurrent genomic events and patterns across pediatric B-ALL subtypes and to describe the clonal evolution of cells measured at initial diagnostic and end-induction disease stages. We were also able to link cell-specific mutation events to their transcriptional and epigenomic signatures, including mapping mutation events along the B-cell development trajectory and within differentially expressed gene pathways. Some cases showed dramatic shifts in subclonal structure between IDX and MRD that may be related to therapy-induced clonal selection, such as a loss of *NRAS* hotspot mutation.

#3953 BET inhibitor increases DNA damage, modulates Wnt signaling, and suppresses osteosarcoma growth in naïve and metastatic disease models.

N. Riyahi[1], P. H. Pandya[1], B. J. Bailey[2], E. A. Dobrota[2], C. Young[2], H. E. Shannon[2], F. Barghi[1], R. Malko[1], K. Bijangi-Vishehsaraei[1], M. A. Trowbridge[3], K. Coy[3], F. M. Kennedy[3], A. L. Sinn[3], S. Angus[1], M. J. Ferguson[1], M. Saadatzadeh[1], K. E. Pollok[1],
[1]Indiana University School of Medicine, Indianapolis, IN, [2]Herman B Wells Center for Pediatric Research, Indianapolis, IN, [3]Preclinical Modeling and Therapeutics Core, Indiana University Melvin and Bren Simon Comprehensive Cancer Center, Indianapolis, IN

Osteosarcoma (OS) is an aggressive bone cancer in pediatric adolescent and young adult patients. Survival rate for metastatic and relapsed OS patients remains dismal at <30%. Additionally, no effective standardized salvage therapy currently exists for these patients, in part, due to genomic complexities arising from moderate levels of replication stress (RS). Bromodomain and extra-terminal domain protein inhibitors (BETi) are an underexplored option to target RS for BETi creates an imbalance between transcription-replication kinetics resulting exacerbation of oncogenic RS and cell death. BET proteins are epigenetic readers that play a role in regulating gene expression networks as well as DNA replication and repair. We tested the hypothesis that BET inhibition leads to decreased OS cell growth and potentiates the efficacy of salvage therapy via gene dysregulation and increased DNA damage and RS. Combination index and Bliss independence analyses of bivalent BET inhibitor (BETi) AZD5153 or PROTAC ARV825 in combination with salvage agents demonstrated additive-to-synergistic cell growth inhibition in OS lines. Increased apoptotic-mediated cell death was observed following AZD5153+topotecan. In addition, γ-H2AX levels and comet assays demonstrated that BETi+topotecan induces its effect, in part through increased RS *in-vitro*. AZD5153 monotherapy significantly suppressed OS tumor growth in patient-derived xenografts (PDXs) derived from both naïve (PDX96) and metastatic (TT2) OS compared to vehicle ($p<0.05$). Moreover, AZD5153 reduced lung metastatic lesions and increased survival in the 143B OS lung colonization model. *In-vivo* mechanisms of drug-induced tumor response were evaluated. Anti-tumor effect correlated with increased γ-H2AX following AZD5153 exposure in PDX96, indicative of increased RS. RNA-seq analysis and protein validation from vehicle versus BETi-treated PDX96 highlighted dysregulation of several key genes involved in DNA damage response including elevated TXNIP, a tumor suppressor which can induce DNA damage and apoptosis. Downregulation of TCF7, a downstream effector of the Wnt pathway, was also observed following BETi. Global kinome profiling and validation experiments revealed increased activity and expression of EphA2 and EphA4 receptors both implicated in development of drug resistance. Furthermore, in BETi-treated PDX96 tumors, Wnt/β-catenin pathway activation emerged as tumors rebounded once BETi treatment was stopped. TT2 PDX was resistant to commonly used salvage agents ifosfamide and irinotecan; however, combination BETi+ topotecan increased the probability of survival compared to each agent alone ($p<0.05$) and was well tolerated. These data collectively suggest that BET inhibition alone or in combination with low-dose salvage therapy holds promise as novel treatment strategies in aggressive OS.

#3954 Increased mosaic chromosomal alterations among survivors of childhood acute myeloid leukemia.

X. Zhang[1], N. Qin[2], Q. Dong[1], C. Chen[1], J. Easton[1], H. Mulder[1], X. Chen[1], K. Shelton[1], C. Im[3], Y. Yasui[1], G. Armstrong[1], K. K. Ness[1], M. M. Hudson[1], P. Auer[4], J. Zhang[1], Z. Wang[1];

[1]St. Jude Children's Research Hospital, Memphis, TN, [2]Nanjing Medical University, Nanjing, China, [3]University of Minnesota, Twin City, MN, [4]Medical College of Wisconsin, Milwaukee, WI

Background: We previously characterized point mutations of clonal hematopoiesis (CH) including single nucleotide variants or small insertion/deletions residing in a set of cancer-related genes (e.g., *DNMT3A* and *TET2*), and found that CH point mutations occurred at a much higher prevalence in childhood cancer survivors (CCS) than in age-sex-race matched community controls. However, mosaic chromosomal alterations (mCAs), another form of CH with megabase-scale structural alterations (copy gain, copy loss and copy-neutral loss of heterozygosity), have not been examined.
Methods: Detection of mCAs was performed on whole-genome sequencing (WGS, 30X) data from 5-year CCS with the Mosaic Chromosomal Alterations (MoChA) caller which utilizes phased genotypes, coverage, and B allele frequency (BAF) at heterozygous sites (HETS). We implemented the pipeline established by the TOPMed consortium to detect low mutant cell fractions (CF >1%). Variant filtration criteria: minor allele frequency <1%, the read depth of either allele <5, and only one variant retained in each 1Kb window. Called mCA filtration criteria: <100 HETS; lod score <5; relative coverage >2.9 or BAF deviation >0.16 and relative coverage >2.5. Autosomal mCAs (CF ≥1%, HETS >100 and length >1Mb) retained. Multivariable Cox models evaluated the association between mCAs and specific late-effects including all-cause mortality, obesity, myocardial infarction (MI) or cardiomyopathy (CMP); multivariable logistic models evaluated the association between mCAs and childhood cancer diagnoses. All models were adjusted for age, sex and therapeutic exposures.
Results: In our evaluation of 4,330 CCS (median age at blood draw: 26.8 years) and 433 controls (33.6 years) with WGS data from the St. Jude Lifetime Cohort, the prevalence of mCAs was slightly higher among CCS than community controls (4.83% vs. 4.16%). Among CCS, mCAs were associated with therapeutic exposures (alkylating agents: odds ratio [OR]=1.48, 95% CI=1.09-2.00; antimetabolites: 1.53, 1.02-2.31; corticosteroids: 0.60, 0.40-0.91). In contrast to recent mCA studies in the general population, we observed no co-occurrence with CH point mutations, and no associations with late-effects including all-cause mortality, obesity, MI or CMP. Interestingly, mCAs were significantly associated with the primary diagnosis of acute myeloid leukemia (AML, OR=2.86, 95% CI=1.63-5.01). Furthermore, this finding was replicated in 2898 5-year survivors from the Childhood Cancer Survivor Study (OR=3.77, 95% CI=1.94-7.33).
Conclusion: mCAs were not associated with age-related morbidities and mortality among CCS. However, we identified a striking association between mCAs and previous diagnoses of AML independent of treatment exposures. If validated among AML patients at the time of diagnosis, mCAs, which reflect the underlying genome instability, may serve as a diagnostic biomarker for AML.

#3955 A proteogenomic study of high-grade glioma among adolescents and young adults.

To unravel the molecular mechanisms underlying high-grade glioma (HGG) in adolescent and young adult (AYA) patients, we conducted a comprehensive proteogenomic analysis for 34 AYA (age 15-40) and 59 pediatric (age 0-15) HGG cases. Our approach involved whole genome sequencing, methylation profiling, RNA sequencing, and a suite of mass spectrometry-based proteomic experiments, including global proteomic, phosphoproteomic, and glycoproteomic profiling. The proteomics study successfully identified and quantified approximately 11,000 proteins, 33,000 phosphosites, and 3000 glycopeptides with a 50% missing filtering threshold. To identify the unique characteristics of AYA HGG in contrast to both pediatric and adult HGG, we further integrated a proteogenomic dataset of 99 adult GBM tumors previously published by CPTAC and collaborators (PMID: 33577785).

Our study unveiled a collection of mutations, copy number variations, epigenetic modifications and gene fusions that exhibited different frequencies across tumors from pediatric, AYA, and adult patients. Moreover, the influence of these genetic variations on RNA/protein activities also varied across different age groups. Clustering analysis using age-dependent molecular profiles revealed striking differences in RNA/protein/phosphosite activities between patients aged 15-26 and 26-40. Additionally, significantly better overall survival (OS) was observed in the 26-40 age group compared to all other age groups, highlighting distinct biological characteristics within the AYA category that differentiate adolescents from young adults.By leveraging proteogenomic datasets from normal brain tissues (PMID: 30518843), we identified genes, proteins, and pathways with differential age-dependent molecular profiles between tumor and normal brain tissues. Notably, this analysis highlighted significant alterations in proteins from the oxidative phosphorylation, tricarboxylic acid (TCA) cycle, and myelin sheath pathways in tumors compared to normal tissues, some of which were found to be sex-specific.To search for prognostic markers, we introduced a novel approach called Trans-Population Survival Analysis through Interpolation of Age-Dependent Tumor Molecular Profiles. Applying this method on the kinase activity scores derived from the phosphoproteomic data, we identified 150 kinases whose activities were significantly associated with OS among AYA patients. Additionally, employing a causal network analysis tool, we pinpointed six kinases causally linked to OS, suggesting their potential as treatment targets. This study not only characterizes the molecular landscape of AYA HGG but also explores the disease trajectory across the lifespan. Our findings shed light on the intricate interplay of various factors influencing glioma etiology and patient outcomes, paving the way for a deeper understanding of HGG in the AYA population.

IMMUNOLOGY: Adaptive Immunity in Tumors
Poster Session

#3959 Unraveling the anti-tumor partnership of CD169$^{\pm}$ macrophages and CD8$^{\pm}$ T cells in a preclinical breast cancer model.
N. Couturier, M. Boutet, K. Nishitani, W. Guo, G. Lauvau;
Albert Einstein College of Medicine, Bronx, NY

In this study, we describe both the individual and the cooperative mechanisms by which CD169$^{\pm}$ macrophages (MP) and CD8$^{\pm}$ T cells support an anti-tumor immune response against breast cancer tumors. Breast cancer is the second leading cause of death in women of all ages each year, thus a deeper understanding of the molecular determinants that promote tumor development and suppress the anti-tumor immune response is still greatly needed. Here we use high dimensional flow cytometry, functional assays, and new mouse models to investigate the MP - T cell anti-tumor partnership. With our collaborators, we developed a preclinical mouse model of breast cancer by genetically engineering mammary stem cells to harbor three cancer driver mutations that are frequently associated in human patients: functional loss of the tumor suppressor genes p53 and mixed-lineage leukemia protein 3, and constitutive activation of the PI3 kinase. To characterize the immune cells in this tumor model, we developed a powerful 30-color high dimensional spectral flow cytometry panel to track and phenotype most known immune cell subsets. We found that CD169$^{\pm}$ MP rapidly infiltrated and outnumbered all other populations during tumor growth, suggesting that they play an important role in shaping the tumor microenvironment. Surprisingly, although current literature describes breast cancer MP to be highly immunosuppressive, our phenotypic analysis showed only low expression of the pro-tumor MP markers TREM2 and CD206, but extremely high expression of the anti-tumor markers FOLR2 and CD64. To further investigate if these MP promoted or prevented tumor growth, we selectively depleted CD169$^{\pm}$ MP in tumor-bearing mice and observed significantly accelerated tumor growth compared to the non-depleted control group, suggesting that these MP promoted anti-tumor responses. MP depletion also affected tumor-infiltrating CD8$^{\pm}$ T cells, which produced lower effector functions (e.g., secretion of IFNγ, CCL3, TNF), indicating that MP may also boost anti-tumor CD8$^{\pm}$ T cell responses. To further test if CD8$^{\pm}$ T cells control tumor growth, we depleted either CD8$^{\pm}$ or CD4$^{\pm}$ T cells in tumor-bearing mice and observed that only CD8$^{\pm}$ but not CD4$^{\pm}$ T cell depletion accelerated tumor growth compared to the control group. MP have been documented to provide type I IFN signals to CD8$^{\pm}$ T cells via the triggering of the STING pathway. To explore this mechanism in our model, we created a CD169^{cre}STING$^{flox/KO}$ mouse in which MP lack functional STING. Tumors in these mice grew much faster compared to those in the control group, consistent with the hypothesis that STING sensing occurs in tumor MP and promotes anti-tumor effector CD8$^{\pm}$ T cell responses. Overall, our data provide evidence for an unexpected anti-tumor role for CD169$^{\pm}$ MP in breast tumors, presumably through enhancing anti-tumor effector CD8$^{\pm}$ T cell responses.

#3960 Establishment of humanized mouse models engrafted with luciferase-expressing acute myeloid leukemia cell lines.

E. Bayon, A. Mersni, A. Wetzel, J. Ville, **K. Ho Wang Yin**;
Transcure Bioservices, Archamps, France

Introduction: Because acute myeloid leukemia (AML) is a very aggressive and quickly developing cancer, for which actual treatments are either inefficient, poorly tolerated, or leading to resistance, there is a strong need for an effective platform to evaluate novel therapies. Our aim is to provide a relevant humanized mouse model as a precious tool to evaluate innovated treatments to cure AML.
Methods: Mice were humanized with CD34+ hematopoietic stem cells to reconstitute a complete human immune system. Three AML cell lines, namely OCI-AML2, OCI-AML3 and MOLM-14, all expressing mCherry and luciferase, were intravenously engrafted at different doses in non-humanized and CD34-humanized mice. Tumor proliferation was monitored by bioluminescence imaging (BLI) thanks to luciferase expression on tumor cells. Their expression of mCherry was also exploited to determine the presence of tumor cells in blood and tissues using flow cytometry.
Results: All AML cell lines engrafted in mice, but we observed different growth kinetics and homogeneity depending on the humanization of mice and the dose injected. Indeed, tumor grew more slowly and heterogeneously in humanized mice, which underlines the role of human immune cells reconstituted in mice. This was improved by increasing the number of tumor cells injected. Tumor cells were found in femurs, spleen, kidneys, ovary, lungs, and uterus depending on the cell line. Mice survival was also highly affected by the tumor cell line engrafted. We observed that MOLM14 was the most aggressive model, while OCI-AML3 reached a steady state and were tolerated by mice over a long period.
Conclusion: We established 3 different AML cell lines in a model of humanized mice which nicely recapitulates the growth of tumor cells in target organs. These 3 models behave differently in terms of growth kinetic, tolerability by mice, and organs infiltrated, which gives plenty of opportunities to evaluate novel therapies designed to cure AML.

#3961 Impact of CD8 resident memory T cells on antitumor immunity and response to cancer immunotherapy.

S. Corgnac, Jr., I. DAMEI, Jr., **F. Mami-Chouaib, Sr.**;
Gustave Roussy, Villejuif, France

$CD8^{\pm}$ resident memory T (T_{RM}) cells expressing the CD103 integrin accumulate in human lung tumors and are associated with a favorable prognosis. We have previously demonstrated that a high density of $CD103^{\pm}CD8^{\pm}$ T cells in human lung tumors is a biomarker of response to immune checkpoint blockade (ICB) immunotherapy. However, a large fraction of human tumors is only weakly infiltrated by $CD8^{\pm}$ T_{RM} cells, and the reason of this T_{RM} desert is not explained. Therefore, defining the molecular signals that give rise and maintain T_{RM} cells within the tumor microenvironment (TME) and the mechanisms that potentiate antitumor T_{RM} functions are important challenges. Data obtained in pre-clinical mouse colorectal cancer and melanoma models demonstrate that knocking-out CD103 impairs antitumor T-cell immunity and response to ICB and therapeutic peptide vaccine. Moreover, immunization of melanoma-bearing mice with the cancer vaccine results in a dramatic decrease in the percentage of $CD103^{\pm}$ T_{RM} cells among $CD8^{\pm}$ tumor-infiltrating T lymphocytes (TIL). Algorithm analyses applied to spectral cytometry data of TIL support the conclusion that upon activation with the peptide vaccine a T_{RM} subset gives rise to tumor-specific effector T cells. The mechanisms associated with the decrease in CD103 expression on $CD8^{\pm}$ T cells and lead to a T_{RM} differentiation shift will be presented as well as the key role of TGF-b in $CD8^{\pm}CD103^{\pm}$ T_{RM} formation and persistence in the TME. Our data demonstrate that tumor $CD8^{\pm}CD103^{\pm}$ T_{RM} are capable of mounting a potent antitumor immunity and suggest that a fine balance between diverse signals in the tumor ecosystem is required to induce their differentiation and thereby optimize response to cancer immunotherapy.

#3962 A CCR6$^{\pm}$Th1-like CD4$^{\pm}$T-cell cluster involved in HEV formation predicted lung cancer patients requiring anti-CTLA-4 therapy.

H. Kagamu, S. Yamasaki, A. Mouri, O. Yamaguchi, A. Shiono, F. Nishihara, Y. Miura, K. Hashimoto, H. Imai, K. Kaira, K. Koabayashi, K. Horimoto;
Saitama Medical University International Medical Center, Hidaka city, Japan

Background: CD4$^{\pm}$ T cells are known to help in cytotoxic T-cell priming, clonal proliferation, migratory and infiltrative capacity, and target cell killing function by licensing dendritic cells. Although CXCR3$^{\pm}$ CCR6^{-} classical Th1 CD4$^{\pm}$ T cells are thought to be essential for acute cellular immunity, such as antiviral responses, the details of Th1-type CD4$^{\pm}$ T cells required for anti-tumor immunity as a long-term chronic T cell immune responses over years remain unclear. We reported the Th7R, a CCR6 expressing Th1-like CD4$^{\pm}$ T cell cluster predicted anti-PD-1 antibody therapy efficacy and postoperative recurrence-free survival.
Objective: In this study, we focus on two Th1-like CD4$^{\pm}$ T cell clusters, Th1 and Th7R, to determine their functions and roles in long-lasting anti-tumor immune phenomena.
Methods: We studied patients with advanced stage lung cancer treated with immune checkpoint inhibitors (Pembrolizumab monotherapy n=63, Ipilimumab + Nivolumab n=148) and stage I-II lung cancer patients undergoing surgery (n=54). Mass cytometry, single cell RNA sequencing, and immunohistochemical staining were performed using peripheral blood, tumor-infiltrating lymphocytes and lymph node T cells. These studies were approved by the IRB of Saitama Medical University International Medical Center, and all patients gave written consent.
Results: Unlike classical Th1, which highly expresses *PRF1*, *GZMB*, *GNLY*, and *NKG7*, Th7R expressed *LTβ*, *CXCR6*, *CTLA-4*, *CD28*, and *CXCL13*. Analysis of HEV index (MECA79$^{\pm}$ /CD31$^{\pm}$ vessels) by MECA79 and CD31 staining of tumor tissues showed that Th7R in peripheral blood correlated with tumor tissue HEV index, suggesting that LTβ and CXCL13 expressed by Th7R are involved in HEV formation.Th1 mainly expressed PD-1 and did not express CTLA-4, whereas Th7R expressed both PD-1 and CTLA-4. When pre-treatment peripheral Th7R quartile was used to analyze OS after Ipilimumab + Nivolumab treatment, both the top 25% and intermediate 50% patients showed favorable prognosis, but the lower 25% had significantly poor OS. In contrast, only the top 25% Th7R patients but not the intermediate 50% and lower 25% patients who were treated with Pembrolizumab had favorable OS. Thus, it is likely that the Th7R intermediate 50% patients required anti-CTLA-4 therapy to achieve antitumor immune responses. These results may be useful for stratification of patients requiring anti-CTLA-4 antibody therapy as well as for predicting the therapeutic response of Ipilimumab + Nivolumab.
Conclusion: Th7R exhibits LTβ and CXCL13 expression, which is absent in classical Th1, and may help maintain sustained T-cell immunity through HEV/TLS formation. Th7R may be a biomarker to select the patients who benefit from anti-CTLA-4 treatment.

#3963 Indoleamine 2,3-dioxygenase 1 (IDO1) regulates immune evasion in lymphoma.

J. Park[1], S.-J. Yoo[1], Q. Hu[2], C. M. Fielder[2], H. Yoon[2], J. Hong[3], B.-S. Kim[4], Y. Koh[3], T. Kim[2], S.-S. Yoon[3], C. Yan[2];
[1]Seoul National University, Seoul, Korea, Republic of, [2]Vanderbilt University Medical Center, Nashville, TN, [3]Seoul National University Hospital, Seoul, Korea, Republic of, [4]Eunpyeong St. Mary Hospital, Seoul, Korea, Republic of

Recently, anti-programmed death (anti-PD) therapy has been at the forefront of cancer therapy. However, the clinical efficacy of anti-PD therapy in DLBCL remains obscure. The marginal response to anti-PD therapy in DLBCL indicates that different mechanisms of immune evasion other than the PD-1/PD-L1 pathway may be present. To investigate the mechanisms of resistance to anti-PD therapy in DLBCL, we assessed gene expression in patients with DLBCL in public database. Accordingly, we found indoleamine 2,3-dioxygenase 1 (IDO1), a key enzyme responsible for tryptophan catabolism, is highly expressed in DLBCL. IDO1 expression is upregulated by IFN-gamma produced by T cells in tumor microenvironments (TMEs) of various cancer types. Upregulated IDO1 leads to the production of kynurenine, which creates an immunosuppressive TMEs. However, it remains unknown whether IDO1 induces immune evasion in DLBCL and if so, which subsets of IDO1 expressing cells are responsible for immune evasion in DLBCL. To address these questions, we first determined the intrinsic role of IDO1 in lymphoma cells. We knocked down IDO1 expression (IDO1 KD) in a human DLBCL RC-K8 cell line using short hairpin RNA. We observed decreased cell proliferation in IDO KD lymphoma cells compared with control cells. We also found increased susceptibility to apoptosis in IDO1 KD RC-K8 cells compared with IDO1 WT control, when these were co-cultured with THP-1-derived macrophages or activated Jurkat T lymphocytes. These data suggest that lymphoma IDO1 has an intrinsic role of lymphoma progression and makes lymphoma sensitive to cytotoxic immune cells. To validate the anti-tumor effect of IDO1 deficiency in immune cells, we assessed EL4 lymphoma growth and immune TME of lymphoma in syngeneic wild type (WT) and *Ido1* knock-out (KO) mice. The growth of EL4 lymphoma tumor was significantly suppressed in *Ido1* KO mice compared to WT mice (*Ido1* KO: 621.9mm^3 vs WT: 1228mm^3, N=22, P<0.001). Immune TME assessment revealed a decreased frequency of regulatory T cells, yet, the increased proportions of B cells, MHC II+ antigen-presenting cells, monocytes, and NK cells in *Ido1* KO tumors compared with WT control. In summary, IDO1 is highly expressed in DLBCL. IDO1 up-regulation may drive lymphoma progression both intrinsically and extrinsically (immune evasion). This data suggests that IDO1 overexpression may be one of the mechanisms of resistance to anti-PD therapy. We will extend our studies to determine a combination effect of IDO1 inhibitors with immune checkpoint inhibitors including anti-PD therapy in DLBCL.

#3964 A cancer survival program against activated T cell attack.

M. X. Wang, B. E. Mauch, A. F. Williams, T. Barazande-Pour, F. Araujo Hoffmann, S. H. Harris, C. P. Lathrop, C. E. Turkal, M. H. Paw, D. A. G. Gervasio, T. Tran, T. Guo, G. A. Daniels, S. J. Park, M. J. Hangauer;
University of California San Diego - UCSD, La Jolla, CA

The immune-cancer interactions downstream of immune checkpoint inhibition present the next targetable interface of cancer immunity. Despite evidence for cytotoxic T lymphocyte (CTL) infiltration and cytolytic activity within immunotherapy-responsive tumors, partial responses and acquired resistance are common, indicating additional barriers for complete tumor elimination. We report a survival program engaged within residual cancer cells exposed to weeks of activated CTLs. Contrary to immune-evasion mechanisms, we observe a residual antigenic cancer cell subpopulation which activates CTLs, survives within IFNγ-high environments, and withstands CTL-induced apoptosis. This cancer survival program, termed immune-induced persistence, is reversibly-driven (non-genetic) and prevents the complete CTL-mediated elimination of cancer cell populations by supporting the survival of quiescent cancer 'persister' cells against activated CTL attack. Persister cells display sublethal caspase activity and caspase-dependent DNA damage, consistent with CTL-induced genomic instability, and depend on the inhibitors of apoptosis proteins for survival. Notably, immune-induced persistence presents a markedly distinct survival program than drug-induced persistence, including distinctive apoptotic profiles, stress response pathways, and vulnerabilities. Thus, cancer cell populations can transiently adopt non-redundant survival programs in response to various cytotoxic environments. Features of immune-induced persistence are observed within CTL-treated human cancer cell lines, immune-treated human tumor slice cultures, and intratumor transcriptional heterogeneity programs. Under continued CTL exposure, persistent cancer populations give rise to genetically distinct cancer clones, including stably resistant immune escape variants, modeling acquired resistance to cancer immunotherapies. We propose sublethal interactions between effector immune cells and cancer persister cells as a critical and targetable variable at the interface between activated immunity and cancer.

#3965 A cytolytic effector CD8+ T cell response is associated with remission in adult T-cell leukemia/lymphoma.

E. Guillen[1], E. Liu[1], Y. Wang[1], A. Shastri[1], A. Sica[1], A. Verma[1], X. Zhang[1], J. Ramos[2], H. Ye[1], G. Lauvau[1];
[1]Albert Einstein College of Medicine, Bronx, NY, [2]University of Miami, Miller School of Medicine, Miami, FL

Introduction: Adult T-cell leukemia/lymphoma (ATLL) is a rare blood cancer that develops in 3-5% of human T-lymphotropic virus-1 (HTLV1) carriers when the combination of viral oncoproteins and somatic mutations lead to malignant transformation of HTLV1 infected CD4+ T cells. ATLL has the worst overall survival among peripheral T cell lymphomas and remains a fatal disease despite efforts to improve outcomes over the last 35 years. First-line combination chemotherapy rarely achieves a durable response and two immune-modulating treatments (α-CCR4 and α-PD-1 monoclonal antibodies) failed in clinical trials. These findings highlight an urgent need to improve our understanding of the functional state of host immunity in ATLL patients. A host immune response against HTLV1 is pivotal in preventing ATLL development. Malignant ATLL cells can escape immune surveillance by preventing antigen presentation and engaging immune checkpoints. The prospect of an ATLL clone inducing systemic suppression was suggested in the literature but has not been directly examined. Furthermore, HTLV1-specific CD8+ cytotoxic T lymphocytes (CTLs) play an important role during viral latency, yet it remains unknown if they play a clinically relevant role during ATLL treatment.

Methodology: In this work, we hypothesized that malignant ATLL cells will exhibit a suppressive immune phenotype and that effective therapeutic interventions will augment anti-ATLL CTLs to promote durable remission. We implemented an immune profiling approach to analyze PBMC samples from ATLL patients. Specifically, we developed a powerful 30-marker spectral flow panel to discriminate malignant ATLL cells from non-transformed lymphocytes (T, B, and NK cells) and monitor the expression of key transcription factors and markers associated with proliferation, cytolysis, and exhaustion. We analyzed diagnostic samples from the Montefiore-Einstein ATLL Biobank and samples collected during a phase 2 clinical trial aimed to assess the efficacy of a promising Belinostat/Zidovudine/Interferon-α combination therapy against ATLL (NCT02737046).

Results: Our findings reveal that malignant ATLL cells exhibit an immune phenotype associated with robust immunosuppression and yet distinct from other suppressive immune cells (i.e., regulatory T cells). Additionally, we discovered that ATLL patient samples contained a unique population of phenotypically exhausted CD8+ T cells, the proportion of which was drastically reduced in patients under remission. Remarkably, a decrease in this exhausted subset correlated with the expansion of highly cytolytic CD8+ CTLs.

Conclusion: Altogether, our findings suggest that ATLL cells may drive CD8+ CTLs into exhaustion to achieve immune evasion and that a robust anti-ATLL CTL response actively contributes to a remission state.

#3966 NK receptors enable TCR-mediated CTL recognition and killing of cancer cells expressing non-mutated tumor-associated antigens.

B. Dong[1], N. Obermajer[2], T. Tsuji[1], J. Matsuzaki[1], C. Bonura[1], H. Withers[1], M. Long[1], C. Chavel[1], S. H. Olejniczak[1], H. Minderman[1], R. P. Edwards[2], W. J. Storkus[2], P. Romero[3], P. Kalinski[1];

[1]Roswell Park Comprehensive Cancer Center, Buffalo, NY, [2]University of Pittsburgh School of Medicine, Pittsburgh, PA, [3]University of Lausanne and Ludwig Institute for Cancer Research, Lausanne, Switzerland

Background: Responsiveness or ignorance of antigens presented to naïve T cells by dendritic cells (DC) involves the CD28-driven “signal 2”, but it is unclear how activated CTLs respond to the same non-mutated tumor-associated antigens (TAAs) presented by cancer versus healthy cells to avoid autoimmunity. Since $CD8^{\pm}$ T cells express activating NK receptors (NKRs) and NKR ligands are commonly expressed by cancer cells but not healthy tissues, we evaluated the crosstalk between NKRs and TCR during recognition of cancer cells by DC-primed TAA-specific CTLs.

Methods: Associations between DNAM-1, NKG2D, CTL markers, and patients’ survival was analyzed using TCGA. *In vitro* sensitization was used to induce human TAA-specific CTLs by TAA-loaded DCs. The roles of DNAM-1 and NKG2D in CTL recognition and killing were tested using IFN-γ ELISpot, conjugate formation, degranulation, and cytotoxicity assays. The mechanisms and molecular effects of NKR-mediated costimulation were analyzed using IsoPlexis, calcium flux, western blot, and RNA sequencing. Double-transduction of T cells with TCR and NKR constructs or pre-treatment of cancer cells by chemotherapy was used to manipulate the levels of NKRs on T cells or their ligands on cancer cells.

Results: TCGA analysis revealed that DNAM-1 and NKG2D are strongly associated with intratumoral $CD8^{\pm}$ T cells rather than NK cells, being critical for the long-term survival of melanoma patients. Human DC-primed CTLs significantly upregulated DNAM-1 and NKG2D compared to naïve $CD8^{\pm}$ T cells, but retained strict dependence on TCR in cancer cell recognition. Unexpectedly, blockade of DNAM-1 and NKG2D prevented the TCR-mediated CTL recognition and killing of cancer cells expressing low-TAA levels, but were redundant in the recognition of high-TAA-expressing cancer cells. DNAM-1, and to a lesser extent NKG2D, lowered TCR activation threshold and enhanced proximal TCR signaling and CTL polyfunctionality. NKR overexpression in TCR-transgenic T cells or chemotherapy-driven elevation of NKR ligands on cancer cells allowed effective recognition and killing of weakly immunogenic cancer cells.

Conclusions: Reduced TCR activation threshold in the presence of NKR costimulation enables CTL activation by low levels of cognate MHC I-peptide complexes on cancer cells. Our data helps explain the ability of non-mutated “self” antigens to mediate tumor rejection in the absence of autoimmunity, and provides new tools to enhance the effectiveness of cancer therapies.

#3967 ISM9182A, a novel HPK1 inhibitor, exhibits immune modulatory activity and robust monotherapy anti-tumor effects in preclinical studies.

C. X. Chen[1], C. Pu[1], J. Peng[1], X. Ding[1], H. Lu[1], X. Ding[1], M. Zhang[1], S. Bavadekar[2], **S. Rao**[2], F. Ren[1], A. Zhavoronkov[2];
[1]Insilico Medicine, Shanghai, China, [2]Insilico Medicine, New York, NY

The hematopoietic progenitor kinase 1 (HPK1 or MAP4K1) is a member of the Ste20 serine/threonine kinase super family that negatively regulates immune cells, including T cells, B cells and dendritic cells (DCs). Thus HPK1 is an attractive immuno-oncology target in many tumor types. Here, we report ISM9182A as a novel, potent, and selective inhibitor of HPK1.ISM9182A demonstrated nanomolar enzymatic potency against HPK1 with >100-fold selectivity against other MAP4K family kinases. ISM9182A inhibited the phosphorylation of SLP-76 at Ser376 dose-dependently with an IC50 of 30nM in human peripheral blood mononuclear cells. Moreover, ISM9182A enhanced IL-2 and IFNγ secretion upon CD3/CD28 co-stimulation in a dose-dependent manner without affecting T cell proliferation. Treatment of human pan T cells with ISM9182A also significantly reversed PGE2-mediated immunosuppression of human pan T cell activation and further boosted IL-2 and IFNγ secretion compared to CD3/CD28 co-stimulation. In monocyte-derived DCs stimulated with TNF-α/IL-1β/PGE-2, ISM9182A significantly upregulated CD80, CD86, and CD83 expression, demonstrating its potency to promote DC maturation. ISM9182A showed no obvious toxicity towards human T cell, B cells, and monocytes without CD3/CD28 co-stimulation. *In vivo* PK data revealed favorable ADME properties and good oral bioavailability of ISM9182A across different species. In a CT-26 murine syngeneic mouse model, oral administration of ISM9182A exhibited potent antitumor effects with p-SLP76 inhibition in both murine spleen and tumor, without body weight loss. In summary, ISM9182A is a potent and selective HPK1 inhibitor and a promising immuno-oncology agent.

#3968 Class I HLA-independent lysis of cancer cells by tumor-infiltrating CD8 T cells.

H. Xie, A. Jiang, J. Perera, A. Dey, N. Smith, M. Sade-Feldman, R. T. Manguso, N. Hacohen, R. W. Jenkins;
Massachusetts General Hospital, Harvard Medical School, Boston, MA

T cell-based therapies have transformed cancer treatment, although intrinsic or acquired resistance develops in nearly half of the patients. Tumor-infiltrating CD8+ T lymphocytes (TILs) are key determinants of anti-tumor immunity by secretion of cytotoxic granules, such as granzymes and perforin, and effector cytokines, such as TNFa and IFNg. A deep understanding of how CD8+ TILs eliminate cancer cells will help identify resistance mechanisms and develop new therapeutic strategies. Here, we demonstrate that TILs eliminated matched melanoma cells in a time and dose-dependent manner but in a class I HLA-independent fashion. Specifically, blocking class I HLA-TCR interaction either by the deletion of B2M (resulting in loss of class I HLA surface expression) or TCR genes did not alter the activity of these TILs. We further confirmed that TIL-mediated killing is contact-dependent. After excluding the potential roles of CD1d and MR1-restrictive T cells, gamma delta T cells, and NKG2D in TIL-mediated killing, a whole-genome CRISPR/Cas9 screen was performed in cancer cells. We identified that genes involved in JAK-STAT and cell-extrinsic apoptosis pathways are necessary for TIL-mediated killing. Together, these findings demonstrate that expanded CD8 TILs from melanoma patients are capable of eliminating melanoma cells via a novel, class I MHC-independent mechanism by coactivation of both JAK-STAT and cell-extrinsic apoptosis pathways.

#3969 Alzheimer's disease-associated amyloid precursor protein improves anti-tumor immunity by inhibiting ceramide-mediated lethal mitophagy and restoring mitochondrial fumarate metabolism in aging T-cells.

M. Kassir, H. G. Lee, N. Oleinik, W. Wofford, C. Walton, F. Atilgan, P. Chakraborty, K. Calisir, O. Sahin, S. Mehrotra, B. Ogretmen;
The Medical University of South Carolina (MUSC), Charleston, SC

The association between Alzheimer's disease (AD) and lower cancer incidence has been observed in several epidemiological studies without much mechanistic insight. We aimed to understand this cancer resistance mechanism linked to AD and exploit it for broader cancer therapies. A hallmark of AD is the accumulation of amyloid precursor protein (APP) in neuronal mitochondria, inhibiting mitophagy, abrogating the clearance of dysfunctional mitochondria, and contributing to AD pathology. In addition to neurons, mitophagy plays an important role in T-cells, where excessive ceramide-dependent mitophagy in aging T-cells inhibits their energy metabolism and limits their anti-tumor functions. Thus, attenuation of ceramide-dependent mitophagy plays a favorable role in enhancing aging T-cell anti-tumor function. Given that APP is also processed in T-cells, we hypothesized that APP accumulates aberrantly in aging Alzheimer's T-cells, inhibiting mitophagy and enhancing T-cell anti-tumor activity. Employing techniques of lipidomics, metabolomics, imaging, molecular biology, and genetic models, we show that AD T-cells from a mouse model and human patients are protected against aging-associated ceramide-dependent mitophagy, which enhanced their secretion of inflammatory anti-tumor cytokines. The excessive localization of APP to the T-cell mitochondria, where it inhibits the accumulation of ceramide synthase 6 (CerS6) and C14/C16-ceramides, attenuated the levels of mitophagy and protected the Alzheimer's T-cells from metabolic defects observed in aging, namely protecting against the exhaustion of fumarate pools. Both in vitro and in vivo re-supplementation of fumarate to aging WT mouse T-cells effectively rescued their viability, cytokine production, and tumor killing capacity both *in vitro* and in adoptive T-cell transfers to mice with melanoma, functionally mimicking the AD phenotype. The fumarate supplementation also led to a decrease in ceramide-dependent mitophagy in the WT aging T-cells, indicating an interplay between ceramide-dependent mitophagy and fumarate metabolism which contributes to the protection of the anti-tumor function in aging AD T-cells. Moreover, we show that Alzheimer's mice that express APP in the brain and T-cells, but not AD mice that express APP only in the brain, are protected against the growth of both carcinogen-induced and allografted tumors. Finally, transfer of mitochondria from AD T-cells to aging WT T-cells improved their metabolic fitness and anti-cancer functions. In summary, we show that AD-associated APP improves anti-tumor immunity of aging T-cells by inhibiting ceramide-mediated lethal mitophagy and restoring mitochondrial fumarate metabolism. These data provide a novel mechanism to explain reduced cancer incidences in AD patients.

#3970 Impairment of tumor reactive CD8 T cells in liver cancer.

R. S. Trehan[1], M. Soliman[1], X. Wang[2], P. Huang[1], N. Kedei[1], X. Zhu[1], M. Seifert[1], M.-R. Benmebarek[1], A. Nur[1], F. Korangy[1], C. Ma[1], T. F. Greten[1]; [1]National Cancer Institute, Bethesda, MD, [2]Albert Einstein College of Medicine, Bronx, NY

Tumor reactive (TR) CD8 T cells in the liver have been studied in the setting of both immunotherapy and cellular therapy with the predominant dogma that these cells have equivalent functionality in the liver as compared to other organ sites. Herein, we detail that TR+ CD8 T cells are functionally impaired in the liver immune microenvironment in mice with liver tumors.TR+ CD8 T cells were studied in BALB/c and C57BL/6 mice injected intrahepatic, intravenous, and subcutaneously with either a colon (CT26) or a melanoma (B16F10) cancer cell line to create intrahepatic, pulmonary and subcutaneous tumors, respectively. Additionally, an αCD8 antibody with IgG control was used to conduct functional studies. Samples were analyzed using flow cytometry and liver weights were measured. A high frequency of TR+ CD8 T cells were found in the liver in mice with intrahepatic tumors. Despite ~70% of CD8 T cells being tumor reactive in intrahepatic tumors, liver tumor growth kinetics were faster than subcutaneous tumors. Higher proportion of the TR+ CD8 T cells were found to be exhausted in the liver tumor by flow cytometry. Functional depletion of the CD8 T cells caused a fivefold higher tumor growth in the subcutaneous model but in contrast had no effect on intrahepatic tumors. In conclusion, despite the high frequency of “killer” tumor reactive T cells in the liver, the growth kinetics of the liver tumors, flow cytometry as well as functional studies demonstrate the impairment of TR+ CD8 T cells in the liver. We aim to dissect the mechanisms mediating intrahepatic TR CD8+ T cell exhaustion in primary liver tumors as well as metastatic models. Additionally, we aim to determine significant costimulatory molecules specific to intrahepatic exhaustion which could lead to better therapeutic models.

#3971 Progesterone impacts regulatory T cell activity to promote immunosuppression in the mammary gland.

E. I. Chowanec, L. R. Werner, C. R. Hagan;
University of Kansas Medical Center, Kansas City, KS

Estrogen and progesterone signaling together drive hormone-receptor positive breast cancer growth and progression. However, there have been limited studies on the independent role that progesterone and its receptor, the progesterone receptor (PR), play in the development of breast cancer. Studies in the Hagan lab have shown that progesterone signaling promotes mammary tumor growth and changes the immune landscape of the mammary gland towards immunosuppression. Regulatory T-cells (Tregs) are immune cells known to promote immunosuppression in the tumor microenvironment. The data from our lab shows that among hormone receptor positive breast cancers, higher levels of PR expression correlates to higher levels of Tregs in the tumor microenvironment. To determine if progesterone signaling increases the number of Tregs in the tumor-bearing mammary gland, we used a syngeneic orthotopic murine tumor model, E0771 cells, engineered to express mouse PR or control empty vector. Mice were treated with progesterone or placebo for 7 days before implantation of the modified E0771 cells. The results of this study show that progesterone promoted tumor growth, and flow cytometry analysis at tumor endpoint showed that PR-positive tumors treated with progesterone harbored more Tregs than mice treated with placebo. Additionally, initial studies using flow cytometry and RNA-seq indicate increased Treg activity following progesterone treatment in PR+ tumor-bearing mice. As progesterone treatment promoted tumor growth and Treg recruitment in progesterone receptor-positive tumors, these data imply that progesterone treatment may promote the release of secreted factors impacting the immune cells in the mammary microenvironment. To determine if progesterone treatment results in cytokine or chemokine changes that may affect Treg recruitment, cytokine arrays and enzyme-linked immunosorbent assays (ELISAs) were performed using cell culture supernatant from murine mammary tumor cells expressing progesterone receptor (E0771-PR) treated with progesterone (0-72 hours). E0771-PR cells treated with progesterone showed higher levels of cytokines and chemokines that have been linked to Treg recruitment and differentiation, such as MCSF. Our findings demonstrate that progesterone signaling promotes an immune suppressed microenvironment in the mammary gland through an increase in Tregs. This evidence provides rationale to investigate the use of anti-progestins as a mechanism to overcome the immune-cold tumor microenvironment seen in progesterone receptor positive breast tumors.

#3972 Personalized immune-organoid co-culture system for modeling the anti-tumor immune response in breast cancer patients.

C.-H. Hong[1], W.-J. Ryu[1], S. Park[2], T. Kim[1], Y. Hwang[1], H. Han[1], S. Jo[2], T. Kweon[2], G. Kim[1], M. Kim[1], H. Park[1], J. Sohn[1];

[1]Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, Korea, Republic of, [2]Yonsei University College of Medicine, Seoul, Korea, Republic of

Recent studies have reported the effectiveness of immune checkpoint blockade (ICB) therapy in breast cancer patients. However, only a subset of patients benefits from ICB therapy due to various immunosuppressive mechanisms. The development of personalized predictive models for the anti-tumor immune response is essential to broaden the indication of ICB therapy. Here, we suggest a novel model platform using a co-culture system with patient tumor-derived organoids and matched immune cells to predict the immune response of individual patients. We successfully established fifty-nine cases of patient-derived breast cancer organoids with matched peripheral blood mononuclear cells (PBMCs) (subtype: Luminal A, 18.6%; Luminal B, 28.8%; Triple-negative breast cancer, 35.6%; HER2-positive, 17.0%). Three rapidly proliferating organoids (one Luminal B and two TNBC organoids) were selected to develop an immune-organoid co-culture (IOC) system. To mimic the anti-tumor immune response, cytotoxic immune cells were expanded from PBMCs by modified cytokine-induced killer (CIK) cell expansion protocol utilizing IL-2/IL-15. The CIK cells were co-cultured with patient-derived tumor organoids for killing assay to enable the prediction of ICB responsiveness *in vitro*. The CIK cells were expanded in the IOC system by stimulation of PBMC with IL-2/IL-15 in the presence of matched tumor organoids for 11 to 14 days. The CIK cells exhibited tumor organoid-specific killing (measured by Caspase-3, 15.22% ± 8.58, mean ± SEM) on organoid co-culture and showed induction of CD107a and CD137 expression in CD8+ T cells and NK cells with the PD-1 blocking antibody. The CIK-mediated tumor organoid deaths and immune cell activation were reduced by HLA class I blocking antibody (W6/32) treatment, confirming HLA-TCR mediated immune response and killing of tumor organoids in the IOC system (-14.85% in organoid-specific lysis and -7.46% in CD107a expression). In the live cell imaging of the IOC system, the interaction between T cells and tumor organoid cells and subsequent induction of Caspase 3 was noted. Our IOC system could directly measure the immunogenic tumor organoid killing by immune cells on ICB treatment in individual breast cancer patients. Moreover, the analysis of immune receptor profiles may reveal immune modulating mechanisms in each patient. We expect the IOC system to serve as a useful platform for personalized immunotherapy and exploration of combinatory therapy to enhance the anti-tumor efficacy of ICB in breast cancer patients.

#3973 Cancer B cell blueprint reveals dysfunctional extra-follicular dominance with therapeutic opportunity.

J. Ma[1], Y. Wu[1], L. Ma[2], X. Yang[1], T. Zhang[1], G. Guo[2], J. Fan[1], X. Zhang[3], Q. Gao[1];

[1]Zhongshan Hospital Fudan University, Shanghai, China, [2]Zhejiang University, ZheJiang, China, [3]Shanghai Institute of Immunity and Infection, Shanghai, China

B cells are essential components of humoral immunity but harbor multifaceted functions across cancers. To decode tumor-infiltrating B cells, we generated the B cell blueprint encompassing single-cell transcriptome, BCR repertoire, and chromatin accessibility data across 20 cancer types (483 samples, 266 patients). Strikingly, B cells harbored extraordinary heterogeneity and composed of 15 subsets, which were grouped into two independent developmental paths (extra-follicular [EF] versus germinal-center [GC]) exhibiting organ preference. Of note, colon adenocarcinoma and hepatocellular carcinoma are the two representative types of cancer enriched for GC and EF pathways, respectively. We affirm that EF-dominant cancers correlate with dysregulated immune responses and worse clinical outcomes. We then identify the dynamic metabolic-epigenetic-signaling networks in fine-tuning tumor-infiltrating B cell differentiation and managing the balance between the EF and GC pathways. Atypical memory (AtM) B cells, the primary progenitors of EF-derived ASCs, exhibit an exhausted and bystander phenotype and develop independently of the GC pathway. We find that the AtM B cells reside in the center of immature TLSs and spatially relocate to the periphery during TLS maturation. Finally, we mechanistically link these findings to specific transcription factors and epigenomic regulations. We demonstrate that the glutamine-derived metabolite α-ketoglutarate (αKG) could increase the expression of AtM B cell associated transcription factors Tbet and BATF and promote their differentiation, accompanied by the activation of mammalian target of rapamycin complex 1 (mTORC1) signaling. Consequently, AtM B cells acquire an immunoregulatory function that dampens anti-tumor T cell responses and fosters an immunosuppressive microenvironment.

#3974 Macronutrient composition dictates MASH-associated HCC immunosurveillance through microbiota alteration and metabolic adaptation.

N. T. Ryujin[1], J. Huang[1], A. Nguyen[1], J. Edwards[1], Y. Cheng[2], J. Wen[1], A. Damania[1], N. Ajami[1], S. Rosario[3], M. Long[3], L. Alexandrov[2], **S. Shalapour**[1];
[1]UT MD Anderson Cancer Center, Houston, TX, [2]University of California San Diego, La Jolla, CA, [3]Rosewell Park Comprehensive Cancer Center, Buffalo, NY

Hepatocellular carcinoma (HCC) is the most common form of liver cancer, with an estimated incidence of over one million cases by 2025. The advances in vaccines against HBV and HCV have led to a decrease in the number of virus-related cases; however, the obesity epidemic has contributed to a drastic increase in metabolic dysfunction-associated steatohepatitis (MASH) related HCC cases (e.g., obesity and type 2 diabetes induced HCC). Considering this trend, we aim to understand how lifestyle choices, like food composition, in combination with alcohol consumption at a “social drinking level” impacts host metabolism, and subsequently the development of MASH-induced HCC. We hypothesize that the impact of dietary composition on dysbiosis and immune cells, particularly adaptive immune cell metabolic status, will drive the phenotype. We have developed a MASH-induced HCC murine model, with long-term dietary intervention including seven different customized diets: normal chow (NC), ketogenic, solid high fat diet (sHFD), or isocaloric liquid Lieber DeCarli Diets (LDC): high fat/low carb (HF), high fat/low carb with ethanol (HF-EtOH), low fat/high carb (LF), and low fat/high carb with ethanol (LF-EtOH). Mice began special diet in late adolescences and disease progression was monitored over the course of a year, where mice developed HCC. Our model allowed for a comprehensive understanding of MASH-induced HCC where disease initiation could be studied beyond known contributors like obesity or body mass index (BMI). The animal model was analyzed comprehensively with high-parameter flow cytometry (FC), 16S sequencing, bulk RNA-seq, scRNA/ATAC-seq, and WGS. Long-term diet intervention led to macronutrient specific microbiota dysregulation, alterations in systemic metabolism and suppression of adaptive immune response, consequently impacting the progression of HCC. Customized dietary interventions showed a specific phenotype regarding HCC development and progression with distinct mutational genotype and particular response to immunotherapy. T and B cell subpopulation deficiency had a significant impact on MASH-induced HCC development in a macronutrient composition dependent manner. In summary, each dietary intervention showed a distinct pattern and effect on dysbiosis, systemic metabolic reprograming, cellular transcriptomic and epigenetic alteration, and particularly immune cell effector function. Additionally, some compositions supported the immuno-escape mechanism of malignant cells through regulation of their MHC machinery. Collectively, these accumulated data construct an atlas for understanding the underlying molecular mechanisms contributing to lifestyle-induced HCC providing the knowledge needed to advance effective strategies for treatment and prevention.

#3975 A therapeutic screening platform for assessing antigen-specific T cell-mediated tumor killing *in vitro*.

E. Klaver, H. Leonard, E. Lieverse, O. Brand, O. Reelfs, C. Kirkham, L. Schewitz-Bowers, **L. Brackenbury**;
Charles River Laboratories, Bristol, United Kingdom

Many cancers remain resistant to conventional therapies, consequently there has been an exponential rise in the number of therapeutics harnessing the power of the immune system in an oncology setting, with several remarkable examples of success. High frequencies of infiltrating tumor-specific T cells have been linked to improved patient outcomes, which highlights the importance of uncovering how therapeutics can enhance their function. To explore this functionality in a preclinical setting it is critical to have physiologically relevant models. Here, we demonstrate that common issues, such as low precursor frequencies and restricted HLA-types can be overcome via access to HLA-typed samples and use of expansion platforms which attain high numbers of antigen-specific T cells. Furthermore, we show how these systems enable vaccine immunogenicity screening and assessment of therapeutic efficacy. Healthy blood donations were screened for HLA type and antigen-specific T cells were expanded by either co-culture with peptide-pulsed dendritic cells or polyclonal stimulation following multimer enrichment and FACS sorting. Following expansion, the large number of antigen-specific T cells generated enabled the T cells to be assessed via phenotyping, cytokine secretion, or functional killing assays in a 2D or 3D tumor setting. Tumor targets with either 1) endogenous antigen expression, 2) antigen introduced via lentiviral overexpression or 3) peptide loading of MHC class I were utilized. Validated readouts for measuring antigen-specific killing included flow cytometry and time-lapse imaging (IncuCyte), alongside quantification of antigen-specific IFNγ responses by ELISpot. These pre-clinical platforms represent a suite of physiologically relevant T cell assays which can be used to perform candidate selection in tumor associated antigen/neoantigen vaccine drug development programs, pharmacological inhibition of checkpoint pathways, or co-stimulatory agonist discovery. In combinatorial approaches with radio- or chemotherapy, the development of novel immunotherapies offers hope to many patients with treatment-resistant cancers.

#3976 Single-cell TCRα/β and TCRγ/δ immune receptor profiling and immunophenotyping using a 96-well plate sorted-cell approach.

A. Chenchik, T. Liu, M. Makhanov, D. Hu, L. Kobzik, K. Ghias, P. Diehl;
Cellecta, Inc., Mountain View, CA

Single-cell immune receptor profiling is a revolutionary approach that allows investigators to combine clonotype repertoire identification with paired-chain information and the phenotype of cells (e.g., cell subtype). Single-cell immune receptor profiling can be performed using a medium-throughput approach (1,000-5,000 cells) using microwell arrays or droplet microfluidics technologies. However, these assays are more complicated to run and require expensive reagents and limited sequencing throughput when compared to bulk immune receptor profiling methods.

Here, we describe a low-throughput, single-cell immune profiling strategy using sorted cells in 96-well plates. The plate is pre-aliquoted with either T-cell receptor (TCR) α/β or TCR γ/δ primers along with 30 crucial T-cell markers. We perform multiplex RT-PCR amplification and sequencing of the CDR3 regions. The resulting data provides the abundant clonotype counts along with the chain pairing information for these α/β and γ/δ chains, together with the T-cell subtype information using gene-expression profiles. By analyzing the TCR gene rearrangement at the single-cell level, researchers can better understand T cell development, proliferation, and clonality, which are crucial for studying diseases such as cancer, immunodeficiency, and autoimmunity. Furthermore, single-cell TCR sequencing when combined with RNA sequencing datasets, facilitates the identification of γδ T cells. This method provides a standardized tool for identifying potential γδ T cell-based cancer immunotherapies. The technology's cost-effectiveness and ability to analyze clonotypes and immunophenotypes of cells in a single assay make it a valuable tool for unraveling the immune dynamics in various diseases.

#3977 Neoadjuvant chemotherapy and radiation shape the local and regional adaptive antitumor immune response in lung squamous cell carcinomas..

R. Krupar[1], J. Nieder[2], J. Braegelmann[3], M. Haarmann[3], T. Goldmann[4], S. Ruane[1], T. Milbich[1], C. Boehm[1], L. Ruff[1], J. Ribbat-Idel[1], C. Watermann[2], S. Perner[5], C. Kuempers[2];

[1]Aignostics GmbH, Berlin, Germany, [2]University Hospital Schleswig-Holstein, Campus Luebeck, Luebeck, Germany, [3]Faculty of Medicine and University Hospital Cologne, Cologne, Germany, [4]Research Center Borstel, Leibniz Lung Center, Borstel, Germany, [5]Institute of Haematopathology, Hamburg, Germany

Chemotherapy (CT) and radiotherapy (RT) are known for their stimulating as well as inhibiting effects on the anti-tumor immune response. This study aimed to understand how CT and RT change the local immune microenvironment of the tumor and the regional immune response in draining lymph nodes. Evaluations were performed on lung squamous cell carcinomas (LUSC) with a special focus on tertiary lymphoid structures (TLS) and lymph follicles.

A cohort of 21 untreated LUSC (naiveLUSC) and 21 matched neoadjuvantly treated LUSC (neoLUSC) was compiled. Digitized H&E whole slide images of the tumor and of two representative probes of a proximal and distal lymph node were assessed. A pathologist blinded to the groups assigned tumors to one of three immunophenotypes (inflamed, excluded, desert) by visual analysis. Tertiary lymphoid structures (TLS) in the tumor area and lymph follicles in the regional lymph nodes were counted and characterized according to their maturation status (with/without germinal center). RNAseq analyses were performed for a subset of tumors.

NeoLUSC tended to more frequently have a desert immune phenotype (6/21 versus 1/21, p=0.0931). The mean number of TLS was significantly reduced in neoLUSC compared to naiveLUSC (4 versus 9, p=0.0179). Additionally, neoLUSC had a significantly lower likelihood for the presence of mature TLS with germinal centers (3/21 versus 9/21, p=0.0327). While the mean number of lymph follicles in regional lymph nodes was comparable between neoLUSC and naiveLUSC, neoLUSC had a significantly reduced number of mature lymph follicles (20% versus 41% of lymph follicles, p=0.0376) in distant lymph nodes and showed a similar, but less pronounced trend in proximal lymph nodes. In general, the amount of TLS correlated with the amount of lymph follicles in naiveLUSC patients (p=0.0154), but not in neoLUSC patients. Across the complete cohort, long-term survivors (>2 years) tended to have higher numbers of lymph follicles in lymph nodes than short term survivors (1.6 versus 1.1 lymph follicles/mm2, p=0.0805). RNAseq analysis revealed a significant upregulation of inflammatory gene sets and downregulation of cell cycle associated gene sets in neoLUSC as compared to naiveLUSC.

This study demonstrates that CT and RT are potent, but multimodal influencers of the local tumor immune microenvironment as well as the regional immune response of the draining lymph nodes. While gene expression results underline the inflammation promoting effect of CT and RT, histological evaluations suggest that CT and RT negatively affect the adaptive anti-tumor immune response by reducing the development and maturation of TLS and lymph follicles in the lymph nodes. Next steps include an artificial intelligence based cell characterization and spatial evaluation of the tumor immune microenvironment to further unveil functional changes induced by CT and RT.

#3978 B-cell activating factor (BAFF) enhances antitumor immunity.

K. Aziz, K. Munjal, K. Howe, M. Yarchoan;
Johns Hopkins University School of Medicine, Baltimore, MD

Immunotherapies that modulate T cell function have been firmly established in cancer immunotherapy, whereas the potential for B cells in the antitumor immune response is not as well understood. B cell-activating factor (BAFF) is a cytokine belonging to the TNF ligand family that activates B cells and is linked to autoimmunity. Our preliminary research has identified BAFF as a target for enhancing antitumor immunity through enhancing presentation of tumor neoantigens and inducing tertiary lymphoid structures which can orchestrate tumor-specific T cell immune responses and correlate with improved clinical response. Since broad activation of B cell response could be detrimental and possibly induce autoimmune side effects, identification of specific B cell receptors that coordinate anti-tumor immunity is prudent. BAFF has three known receptors (BAFF-R, TACI and BCMA), and the effects of these specific BAFF ligand-receptor interactions on antitumor immunity are not known. Here we first generated BAFF-overexpressing cell lines using genomic editing [KPC-BAFF (pancreas), B16F10-BAFF (melanoma), and PancO2-BAFF (pancreas)] and examined their tumor growth in syngeneic immunocompetent host. Secondly, we investigated the effects of BAFF-overexpression on tumor response when individual receptors are knocked out using BAFF-R-KO, TACI-KO and BCMA-KO mice. Our results show significantly hindered tumor growth when the BAFF expressing stable cell lines are introduced to immunocompetent host, compared to parental cell lines. Tumor response experiments in receptor knockout mice is currently in progress. Successful identification of the BAFF receptor candidate that drives anti-tumor response is an exciting prospect for clinical translation. Development of agonists for the specific receptor may allow selective modulation of this particular B cell function in context of cancer therapy without perturbation of broad systemic humoral immunity.

#3979 PD-1 signals regulate NKG7 that is required for CD8+ T cells to sustain cytotoxicity and durable antitumor memory responses.

Zhiming Mao[1], Joanina Gicobi[1], Jacob Hirdler[2], Xin Liu[2], Michelle Hsu[1], Emilia Dellacecca[1], Wenjing Zhang[3], Fabrice Lucien-Matteoni[1], Haidong Dong[1]

[1]Immunology, Mayo Clinic College of Medicine and Science, Rochester, MN,[2]Urology, Mayo Clinic College of Medicine and Science, Rochester, MN,[3]Virology and Gene Therapy, Mayo Clinic College of Medicine and Science, Rochester, MN

Cytotoxic CD8+ T cells play a key role in response to anti-PD-1/PD-L1 immune checkpoint inhibitors (ICI) therapy. However, the exact effector molecules that are regulated by PD-1 signals in cytotoxic CD8+ T cells have not been completely defined. Lack of this knowledge is a crucial problem in addressing how to overcome the low clinical response rate to ICI therapy. When exploring why certain patients not responding to ICI therapy, we found non-responders did not have an elevated NKG7 expression in CD8+ T cells as responders to ICI therapy. The difference in NKG7 expression in CD8+ T cells between non-responders and responders to anti-PD-1 therapy prompted us to investigate the potential role of PD-1 signaling in regulating NKG7 expression. To that end, we generated a CD8+ T cell-specific *Pdcd1* conditional knockout mice (CD8 E8ICre-*Pdcd1*$^{fl/fl}$, also known as CD8-PD-1 cKO) where *Pdcd1* is deleted after thymic selection of single positive CD8+ T cells. We observed a delayed tumor growth and prolonged survival in CD8-PD-1 cKO mice compared to control mice after B16-OVA melanoma tumor challenge. On Day 12, when the CD8-PD-1 cKO mice demonstrated their ability to control tumor growth, we conducted single cell RNA sequencing on isolated tumor infiltrating CD8+ T cells, revealing a significant increase of *Nkg7* expression in effector CD8+ T cells in the *Pdcd1* deficient CD8+ T cells compared to the control wild type T cells. *Pdcd1*-deficient effector CD8+ T cells also had increased expression of genes linked to NFAT/Calcineurin signaling pathway including *Nfatc1*, *S100a4*, *Tbet* and *Tox,* suggesting *Nkg7* could be regulated by *Pdcd1* via the NFAT pathway. To determine the impact of increased NKG7 expression in CD8+ T cells, we used OVA protein as a surrogate tumor antigen in vaccination. We found a complete B16-OVA tumor rejection in CD8-PD-1 cKO mice compared to control mice when tumor cells were injected on day 7 after vaccination with OVA protein and poly (I:C) (as an adjuvant), but only a partial rejection on day 21. The CD8-PD-1 cKO mice that were tumor-free for 30-40 days rejected 2nd tumor challenge with B16-OVA tumors. This long-term protection is tumor antigen (OVA) specific because these mice did not reject B16F10 tumor cells that do not express OVA antigen. We also found effector memory CD8+ T cells with high cytotoxicity increased in the spleen of CD8-PD-1 cKO mice after OVA antigen immunization compared to control. In conclusion, we found NKG7 is one of the effector molecules in *cytotoxic* CD8+ T cells, which can be regulated by PD-1 signals through NFAT signaling. Targeting the PD-1-NFAT pathway may be a new option to overcome low responses of T cells to ICI therapy in treatment of refractory cancer.

#3980 Investigating the role of host obesity in promoting immunotherapy resistance.

H. N. Ogbonna, Z. Roberts, H. Kvarnberg, F. Dempsey, P. N. Song, A. G. Sorace, L. Norian;
University of Alabama at Birmingham, Birmingham, AL

Obesity is linked to an increased risk of various cancers, including renal cell carcinoma (RCC). Many RCC patients have obesity at diagnosis and treatment initiation, and our lab has found that this significantly impairs immunotherapy outcomes. Both preclinical and clinical reports, from our lab and others, have demonstrated that obesity reduces the efficacy of CD8+ T cell-dependent immunotherapy by increasing pro-tumorigenic IL-1β. Combining anti-PD-1 based therapy with anti-IL-1β triggers the recruitment of CD8+ T cells and improves the efficacy of anti-PD-1 based immunotherapy. However, the mechanistic links between obesity and increased IL-1β production remains unknown. Our objective is to identify mechanisms promoting IL-1 β-driven immunosuppression within renal tumors of obese mice. In our *in vivo* studies, we utilized a BALB/c mouse model of diet-induced obesity (DIO) and lean controls in combination with the Renca-Luc RCC cell line. Using flow cytometry and western blot, we respectively assessed leukocyte populations producing IL-1β and tumor energetics. Flow cytometry revealed that intra-tumoral IL-1β is produced primarily by tumor associated macrophages (TAMS). Immunoblotting demonstrated that increased IL-1β production is linked to altered mitochondrial function and ATP production. These early findings support the hypothesis that obesity driven IL-1β expression is mediated by tumor-associated macrophages and that mitochondrial dysfunction drives immune suppression. Understanding these molecular and immune-related mechanisms may pave the way for novel strategies to reduce immunosuppression in obese RCC patients, thus improving immunotherapeutic efficacy and overall clinical outcomes.

#3981 Immune targeting progesterone receptor in hormone receptor positive breast cancer.

A. E. Wilson[1], J. Wei[1], G. Lei[1], X.-Y. Yang[1], C.-X. Liu[1], M. Gajda[1], T. Wang[1], C. Hagan[2], Z. C. Hartman[1];
[1]Duke University School of Medicine, Durham, NC, [2]University of Kansas Medical Center, Kansas City, KS

Background: Hormone receptor positive (HR^+) breast cancer (BC) is a subtype of BC that is characterized by expression of estrogen receptor (ER) and progesterone receptor (PR). A cornerstone treatment for this subtype of BC is endocrine inhibition therapy (EIT), in which estrogen and ER are suppressed using antagonists to suppress tumor growth. However, patients eventually obtain resistance to EIT. Metastatic HR^+BC is the deadliest form of BC, with no cure. Current therapies currently only utilize the ER-axis, with no PR-targeted therapies. Little is known about the role of PR in these BCs, but we have found evidence for an immunosuppressive role for PR in HR^+BC. Yet, it is unclear how PR mediates immunosuppression and if this axis can be therapeutically targeted. We hypothesized that PR confers local immunosuppression through the stimulation of immunosuppressive transcriptional activity and that we can immunologically target this axis using a PR vaccine.

Experimental methods: To assess the immune impact of PR, we expressed the isoforms of PR (A, B and A+B) in mouse mammary cancer cells and assessed their capacity to elicit PR signaling. We assessed the impact of PR expression on T cell activity in targeting PR^+ mammary tumors that express GFP, along with using GFP-specific JEDI $CD8^+$ T cells. We explored the ability of PR to protect against GFP xenoantigen immune responses by engrafting PR^+ mammary cells into immune competent and deficient mice. Lastly, we engineered 1st generation adenoviral vectors encoding mouse and human PR and utilized two antiprogestins (Mifepristone and Onapristone) in vivo. Using our vectors, we vaccinated BALB/c in the footpad and assessed PR-specific immunity using IFNγ ELISPOT.

Results: Using PR signaling reporters, we found canonical PR signaling activity in the absence of progesterone (P4) by PR-A and in the presence of P4 by PR-B, but the most profound activation of PR signaling was seen through combined expression of PR-A and B. While expression of these genes did not confer striking cytotoxic T cell resistance in vitro, combination of PR-A+PR-B in 67NR cells permitted successful tumor engraftment in immune competent mice, despite xenoantigen expression. GFP expression did not alter tumor growth in immunodeficient mice, suggesting a key role in modulating local anti-tumor immunity. The use of either Mifepristone or Onapristone significantly suppressed tumor engraftment in immune competent mice in vivo. We found that an Ad-PR vaccine could elicit T cell responses against human PR-specific epitopes, a potential step towards immune targeting these BCs.

Conclusions: We found that murine PR-A and PR-B can confer robust P4 signaling that is linked to an immunosuppressive phenotype in vivo. We developed a PR vaccine that elicited PR-specific T cell responses in vivo. We are currently examining the mechanisms that underlie PR-mediated immunosuppression and exploring the potential of PR vaccines in HR^+BC.

#3982 Evaluating the effects of obesity on immune responses in renal tumors.

F. Dempsey, L. Norian;
University of Alabama at Birmingham, Birmingham, AL

Understanding the effects of obesity on cancer progression and treatment is a critically important area of research. Obesity is reaching epidemic proportions in our country and is known to increase the risk for many cancers, including renal cell carcinoma, which is among the ten most common cancers in both men and women. Our lab has shown that obesity leads to worse outcomes in advanced renal cancer patients treated with immunotherapy as compared to lean patients, but the cause for this difference is unknown. To investigate this further, we utilized a murine model with diet-induced obese mice and lean mice that were challenged with orthotopic renal tumors. The tumors grew out over three weeks and were harvested for flow cytometry staining. We stained for markers associated with immune function to better characterize what might be causing patients with obesity to be less responsive to immunotherapy. Our preliminary findings show that DIO mice had a greater tumor burden than lean controls over time. We also found that there compositional differences in multiple subsets of T cells in DIO versus lean mice. In the future, we will expand our murine studies to evaluate the phenotype and function of both tumor cells and immune cells. Additionally, we will continue these studies in human samples to further examine associations between obesity and immunotherapy outcomes.

#3983 Antigen-presenting cancer-associated fibroblasts provide an alternate mechanism for CD4 T cell activation in murine pancreatic ductal adenocarcinoma.

S. Maru, L. Andaloori, K. Howe, K. Munjal, J. Leatherman, E. J. Pearce, E. M. Jaffee;
Johns Hopkins University, Baltimore, MD

Despite the advent of immune checkpoint inhibitors (ICI) that have markedly changed the treatment landscape for select tumors, pancreatic ductal adenocarcinoma (PDAC) remains unresponsive to such an approach. Features of the PDAC tumor microenvironment that contribute to treatment resistance, including the influence of cancer-associated fibroblasts (CAF) on immune and tumor cells, remain poorly understood. Antigen-presenting CAFs (apCAFs) express MHC-II and activate CD4 T cells in genetically engineered PDAC mouse models, but are rarely found in human PDAC. In a human PDAC atlas consisting of six published single-cell RNA-sequencing datasets, we identified 370 apCAFs out of 8736 total CAFs, the majority of which were from one dataset. Understanding apCAF regulation can reveal how to promote their differentiation and enhance T cell activating capacity in PDAC.
Methods: Two KPC clones that differ in sensitivity to ICIs, sKPC (sensitive) and rKPC (resistant), derived from the autochthonous KPC murine model of PDAC, were implanted orthotopically into the pancreas or subcutaneously into the flank of syngeneic C57BL/6 mice. Tumors were harvested at 14-28 days post implantation for quantification of T cells, dendritic cells, and CAFs. To evaluate function, apCAFs were sorted and $CD11c^{\pm}$ and $CD4^{\pm}$ T cells were isolated from tumors. Naïve $CD4^{\pm}$ T cells were also isolated from OT-II mice. apCAFs and $CD11c^{\pm}$ cells were pulsed with OVA and co-cultured with OT-II $CD4^{\pm}$ T cells, or co-cultured with sKPC tumor infiltrating $CD4^{\pm}$ T cells in the presence of endogenous peptides.
Results: Total CAFs are equivalent between tumors, but apCAFs are significantly more abundant in sKPC tumors. Furthermore, the apCAF to dendritic cell ratio within these tumors ranged from 5:1 to 50:1. $CD11c^{\pm}$ dendritic cells sorted from sKPC tumors and pulsed with OVA peptide robustly activate naïve OT-II $CD4^{\pm}$ T cells, as expected from professional APCs; sorted apCAFs also activate naïve OT-II $CD4^{\pm}$ T cells, although to a lesser degree. When apCAFs or $CD11c^{\pm}$ dendritic cells are cultured with tumor-infiltrating $CD4^{\pm}$ T cells, however, they upregulate CD4 activation markers to a similar extent.
Conclusions: apCAFs are more abundant in tumors derived from ICI-sensitive KPC clones and greatly outnumber dendritic cells. Functionally, apCAFs from sKPC tumors stimulate tumor-derived CD4 T cells to the same degree as $CD11c^{\pm}$ dendritic cells, implicating a role in activation of the immune response in ICI-sensitive tumors. Although a small proportion of the tumor microenvironment, the apCAF subset may be enhanced in number and function by CAF-targeted modulators to affect the antitumor response; transcriptomics analyses are currently underway to identify regulators of apCAFs. Such a strategy could provide a solution to the currently unmet need for new and more effective treatments for PDAC patients.

#3984 Full-length TCR and BCR repertoire analysis, integrated with mRNA and surface proteins characterization, in a tumor mouse model.

A. Rezvan[1], X. Shi[1], M. Sen[1], S. Widmann[2], **A. Tyznik**[2];
[1]BD Biosciences, San Jose, CA, [2]BD Biosciences, San Diego, CA

Full-length TCR and BCR analysis with single-cell multiomic assays provides an understanding of immune responses, offering insights into the complete receptor structure and functionality that is crucial for accurately assessing the diversity and specificity of immune repertoires. Studying mouse immune cell heterogeneity can be achieved by simultaneous mRNA and surface protein profiling. However, when coupled with full-length TCR and BCR analysis, this integrated approach provides a more comprehensive understanding of immune responses and cellular function in healthy and diseased conditions. In this study, we used the MC38 colon carcinoma model to study T and B cell heterogeneity and clonotype diversity. We stained single-cell suspensions prepared from bone marrow, thymus, spleen and tumor tissues with 20 AbSeq (CITE-Seq) antibody oligos and sample-multiplexing tags. We then loaded 50,000 isolated T and B cells into two lanes of an 8-lane microwell cartridge for single-cell capture by a single-cell analysis system. To aid in the simultaneous analysis of clonality and gene expression, we carried out library preparation using a full-length TCR/BCR multiomic assay and a mouse immune response panel. The combination of mRNA and protein expression confirmed the elevated expression of exhaustion and activation markers in tumor-infiltrating lymphocytes (TILs). We identified high-frequency clonotypes within TILs and tracked their frequency across other tissues. Tumor-burdened mice splenic T cells showed shared TCR combinations with TILs, which were absent in healthy tissue. The results show the ability to successfully profile T and B cell receptors using a full-length TCR/BCR multiomic assay in a mouse tumor model and the use of transcriptome, protein and TCR/BCR clonal information to investigate immune cell characteristics across multiple samples.

#3985 Immune-competent “NoGlow” transgenic mice overcome restrictive tolerance to multiple xenoantigens and simultaneously permit identification, tracking, and temporal gene expression in tumor cells.

T. N. Trotter, A. Wilson, J. McBane, C. Dagotto, X. Yang, J. Wei, G. Lei, H. Thrash, H. K. Lyerly, Z. Hartman;
Duke University, Durham, NC

The ability to temporally regulate gene expression and track labeled cells make animal models powerful biomedical tools. However, sudden exposure to xenobiotic genes (e.g. GFP, luciferase (luc), or rtTA3) triggers inadvertent immune responses that can significantly suppress foreign gene expression or result in complete rejection of transplanted cells. Although germline expression of foreign genes somewhat addresses these challenges, native fluorescence and bioluminescence abrogates their utility as cellular reporters and spatiotemporally restricted expression can lead to suboptimal xenoantigen tolerance. Even in endogenous cancer models, we find that the means of tissue-directed expression of the same foreign gene yield significant differences in overall tolerance. Thus, the degree of tolerance to foreign genes strongly impacts the utility of different genetic modification and can strongly influence experimental outcomes and interpretations. To overcome these unwanted immune responses and enable reliable cell tracking/gene regulation, we developed a novel mouse model that selectively expresses antigen-intact but non-functional forms of GFP, luc, and rtTA3. These "NoGlow" mice possess no detectable background fluorescence or luminescence and mount limited adaptive immune responses against transgenic xenoantigens even after vaccination. Furthermore, we demonstrate that NoGlow mice allow tracking and tetracycline inducible gene regulation of triple-transgenic cells expressing GFP/luc/rtTA3, in contrast to transgene-negative immune competent mice which completely eliminate these cells. Notably, this model enables de novo metastasis from orthotopically implanted, triple-transgenic tumor cells, despite high xenoantigen expression. Finally, we observed model and sex-based differences in immune tolerance to the encoded xenoantigens after activation by different tissue-specific CREs, illustrating the obstacles of tolerizing animals to foreign genes and validating the utility of NoGlow mice to dissect the mechanisms of central and peripheral tolerance. Altogether, the NoGlow model provides a critical resource for in vivo studies across multiple disciplines, including oncology, developmental biology, infectious disease, autoimmunity, and transplantation.

#3986 Exploring nonsense-mediated decay inhibition as a novel approach to improve immunogenicity in small cell lung cancer.

L. A. Torres Fernandez[1], V. Bohm[2], L. Maas[1], A. Schollhorn[3], J. Kaufmann[4], J. D'Rozario[1], L. Kaiser[1], N. Gehring[2], M. Peifer[4], C. Gouttefangeas[3], R. K. Thomas[1], J. George[1];

[1]Department of Translational Genomics, Medical Faculty, University of Cologne, Cologne, Germany, [2]Institute of Genetics, department of RNA biology, University of Cologne, Cologne, Germany, [3]Institute for Immunology, University of Tubingen, Tubingen, Germany, [4]Center for Molecular Medicine Cologne (CMMC), University of Cologne, Cologne, Germany

Cancer immunotherapy has revolutionized the field of oncology and is one of the most promising treatments for lung cancer. Small cell lung cancer (SCLC) is highly aggressive and patients often relapse due to chemotherapy resistance. In the recent years, chemotherapy has been combined with immune checkpoint inhibition (ICI) for SCLC treatment, leading to improved responses in some patients, but also leaving a high number of non-responders to address. Paradoxically, SCLC has one of the highest tumor mutational burden, including remarkably abundant frameshifts (FS) which could create highly immunogenic neoantigens (NeoAg). However, FS-harbouring transcripts are often degraded via Nonsense-Mediated Decay (NMD). We therefore aimed to inhibit the NMD pathway to increase the immunogenicity of SCLC.

Our lab has so far profiled the mutational landscape of more than 400 SCLC patients and generated over 100 patient-derived xenotransplant models. We analyzed genome and transcriptome sequencing data of multiple tumors to interrogate the NMD target repertoire in SCLC. We determined tumor-specific mutations and predicted NeoAg based on the HLA-I-binding ability of mutant peptides. Upon NMD inhibiton, we validated the expression and presentation of NeoAg via transcriptomics, proteomics and HLA-I-immunopeptidomics. NMD-sensitive mutated transcripts included a wide range of somatic alterations beyond FS-mutations, suggesting an overall increase of potential tumor-specific NeoAg. We furthermore evaluated immunogenicity after NMD perturbation employing *in vitro* co-cultures as well as immunocompetent *in vivo* mouse models. Inhibition of NMD in tumor cells resulted in an HLA-I-dependent enhancement of T cell-mediated tumor killing *in vitro*, and *in vivo* experiments showed reduced tumor growth accompanied by increased immune infiltration upon controlled induction of NMD inhibition.

Altogether, NMD inhibition in SCLC led to an upregulation of NeoAg expression in tumor cells accompanied by enhanced T cell responses *in vitro* and *in vivo*. Our strategy provides a novel approach for the treatment of low immunogenic tumors which could be combined with ICI to enhance the efficacy of immunotherapy.

#3987 PD-L1 antigen stability using PD-L1 IHC pharmDx on human cancer tissues.

M. Kalpakoff, E. Olander, K. Jones, S. Hund, T. Evans, J. Barreto, D. Moquin, G. Toland, S. Tabuena-Frolli, K. Kersch, K. Kulangara, J. Musser; Agilent Technologies, Inc., Carpinteria, CA

Diagnostic evaluation and selection of potential pembrolizumab-responsive patients is achieved by determining the programmed cell death ligand-1 (PD-L1) expression using the companion diagnostic PD-L1 IHC 22C3 pharmDx assay, for several indications. PD-L1 expression is evaluated by immunohistochemistry (IHC) and is currently the most widely used selective biomarker for response to pembrolizumab anti-PD-1 therapy. Antigen stability on cut tissue sections, also referred to as cut section stability (CSS), and its impact on IHC results is of interest when determining PD-L1 positive or negative status for clinical trials and diagnostic purposes. Since the stability of cut sections from formalin-fixed paraffin-embedded (FFPE) tissue relies on retention of PD-L1 antigenicity following tissue sectioning, the aim of these studies was to measure CSS across multiple tumor indications using combined positive score (CPS). The impact of aged cut sections was evaluated for PD-L1 expression based on pathologist CPS scores of blinded and randomized stained sections. To assess CSS, fresh unstained 4µm cut tissue sections were stored in the dark at 2-8 °C. Staining was performed according to the instructions for use at predefined timepoints. Studies included neoplastic specimens from biliary tract adenocarcinoma (BTAC), cervical cancer (CC), colorectal (CRC) and gastric (GC) carcinoma, esophageal cancer (EC), head and neck squamous cell carcinoma (HNSCC), nasopharyngeal (NPC), ovarian (OC), renal cell (RCC), and triple negative breast (TNBC) carcinoma. Data for each indication and timepoint were used to evaluate average drift in CPS scores over time, starting with scores from a set of respective slides stained at timepoint zero, prior to aging of unstained cut slides. CSS for each specimen within each indication was based on the intersection point of the two-sided 95% confidence interval for the regression line on CPS drift with allowable drift limits. Overall CSS for each indication was defined based on the specimen that exhibited the shortest shelf-life. Linear regression analysis was performed to evaluate average CPS drift over time and define the CSS per indication. This analysis identified the following CSS (in days) for each tumor type when stored at 2-8 °C: 105 (CC), 113 (OC), 115 (BTAC), 135 (EC), 163 (GC), 180 (RCC), 197 (HNSCC), 231 (TNBC), 240 (NPC), and 300 (CRC). The minimal shelf life for unstained cut sections stored at 2-8 °C across the 10 indications in these studies was 105 days, indicating a possible minimum threshold for indications tested when sectioned specimens are stored at 2-8 °C. These data provide high confidence in determining PD-L1 expression on properly stored aged cut sections. Commercial claims may be shorter based on region, as specified in the local instructions for use.

#3988 Deep spatial immunophenotyping of lymphoid aggregates in pancreatic cancer using multi-omic integration of ultra high-plex proteomics and transcriptomics.

D. Gong[1], J. Cao[2], P. Wang[3], N. Jhaveri[4], Y. Hou[4], B. B. Cheikh[5], H. Ji[5], M. Gregory[6], J. Reeves[6], M. Patrick[6], C. Shiau[3], J. Su[3], J. A. Guo[1], J. M. Beechem[6], M. Hemberg[2], W. L. Hwang[3], R. Park[7],

[1]Massachusetts Institute of Technology (MIT), Cambridge, MA, [2]Brigham and Women's Hospital, Boston, MA, [3]Massachusetts General Hospital, Boston, MA, [4]Akoya Biosciences, Menlo Park, CA, [5]Massachusetts Institute of Technology (MIT), Menlo Park, CA, [6]NanoString Technologies, Seattle, WA, [7]MD Anderson Cancer Center, Houston, TX

The most well-described mechanism of immune evasion in PDAC is exclusion of immune cells by a desmoplastic stroma, but such immune exclusion is not uniform. Through single-nucleus RNA-seq and whole-transcriptome digital spatial profiling of patient tumors, we previously reported marked heterogeneity in the immune composition of PDAC. Here, we developed a novel multi-omics workflow integrating single cell spatial proteomics (96-plex, Akoya Phenocycler®-Fusion) and transcriptomics (990-plex, Nanostring CosMx) in primary patient PDAC tumors to systematically study spatial relationships and functional states of malignant, stromal, and immune cells. Consecutive sections from four independent tumors enabled whole slide proteomic assessment of >3.5M cells, and transcriptomic assessment of >200K cells. Strikingly, we observed an abundance of immune cell aggregates in all tissue sections, up to 57 within a 1 cm2 tumor section. Aggregates were diverse in composition with representation of myeloid cells, CD8+ T cells, and stromal cells, including fibroblasts and nerves. B/T lymphoid aggregates were well vascularized with co-localized CD31+CD34+ endothelial cells and appeared at various phases of maturation towards putative tertiary lymphoid structures (TLSs) containing CD38+ B cells, CD4+ T cells, and CD21+ follicular DCs. These tissues were enriched for interferon stimulated genes in T cells and type 1 interferon response signatures in malignant cells and cancer associated fibroblasts (CAFs) forming inflammatory multicellular hubs that have been associated with improved response to immune checkpoint blockade. Surprisingly, B cells, in addition to macrophages and CD8+ T cells, were major producers of interferon gamma (B cells: 13.7%, macrophages: 36.6%, CD8+ T cells: 12.1% of IFNG+ cells). Finally, to gain insight into the necessary factors for TLS formation in PDAC, we quantified the expression of chemokines and adhesion molecules associated with TLS initiation. Activated dendritic cells expressed CCL19 and CCL21, endothelial cells expressed CCL21, and in concert with inflammatory CAFs (iCAFs), CXCL12. Malignant cells expressed CXCL13 and CCL20 and displayed high levels of cell adhesion molecules ICAM1, VCAM1, and ICAM2. Together, our data suggests that the functions of lymphoid tissue organizer cells can be substituted by endothelial cells, dendritic cells, iCAFs, and, surprisingly, malignant cells. Our spatial immunophenotyping study of pancreatic cancer thus highlights the marked immune heterogeneity of the disease and suggests a central role for malignant and stromal cells in mediating diverse mechanisms of immune evasion and engagement. Functional studies will be conducted to investigate these mechanisms of tumor-immune crosstalk and identify novel immunotherapeutic vulnerabilities for this deadly disease.

IMMUNOLOGY: Adoptive Cell Therapies 3: CAR-T Cells
Poster Session

#3992 Tandem CAR-T cells against mesothelin and MUC16^{ecto}to overcome tumor-antigen heterogenicity.

D. Salas-Benito, F. Birocchi, A. Armstrong, A. A. Bouffard, T. Kienka, F. Korell, M. B. Leick, T. Berger, M. V. Maus;
Mass General Cancer Center, Charlestown Navy Yard, MA

Introduction: Antigen heterogeneity is a challenge for CAR-T cell therapy in solid tumors due to antigen escape when targeting a single antigen. In ovarian cancer (OC), mesothelin (meso) and Mucin16 (MUC16) are two of the most overexpressed antigens. Moreover, CA125, which is part of MUC16, is lost in some OC patients, but the ectodomain remains on the cell surface. Targeting both antigens (Meso and MUC16^{ecto}) with a tandem-CAR configuration could overcome antigen heterogeneity to improve CAR-T cell efficacy in OC.

Material and Methods: We designed a library of different CARs with tandem Meso and MUC16^{ecto} scFv combinations with varying G4S linker lengths, fused to a CD8 hinge/transmembrane domain and 41BBz intracellular domain. A series of constructs was then tested in an NFAT-GFP reporter system in Jurkat cells to determine which configuration induced maximal T cell activation and antigen-binding capacity via flow cytometry. We identified the top 2 activators and binders, produced primary human tandem CAR-T (TanCAR) cells by LV transduction, and tested their cytotoxicity *in vitro*against dual antigen-expressing or single antigen-expressing tumor cells using luciferase killing assays and Incucyte. We measured the cytokine production with a Luminex® Multiplex Assay and used a z-Movi® Cell Avidity Analyzer to test the tandem scFv avidity towards the antigens. Also, we examined TanCAR activity against a mixed tumor model in NSG mice. Their *in vitro* and *in vivo* activity were compared to CAR T cells targeting either single antigen (SS1-anti-Meso or 4H11-anti-MUC16^{ecto}).

Results: We found that TanCAR1 and TanCAR3 as the configurations with the best activation and binding capacity in response to cognate antigen. TanCAR1 and TanCAR3 had superior *in vitro* cytotoxic capacities compared to SS1 or 4H11 in tumor models expressing both antigens and in mixed cultures of tumor cells expressing one, both, or neither target antigen. From this mixed culture, we analyzed the remaining tumor cell populations by flow cytometry and observed an overgrowth of the population not targeted by CAR. In response to tumor cells, tandem CARs also produced INFg, IL6, IL-18, IL-13, and GM-CSF regardless of whether one or two antigens were expressed. For further experiments, we pursued TanCAR1 due to its slightly better functionality compared to TanCAR3. TanCAR1 had the same avidity for cells expressing the single antigens as SS1 or 4H11 CARs, but an intermediate avidity for the double Ag-expressing cell line compared to the single CARs. Finally, we tested TanCAR1-T cells in an *in vivo* mixed tumor model, showing that they better controlled and reduced tumor growth compared to either SS1 or 4H11.

Conclusion: Targeting Meso and MUC16^{ecto} through a tandem CAR design allows for a better anti-tumor response compared to CAR T cells targeting a single antigen. This approach may combat antigen heterogeneity by preventing antigen escape.

#3993 A tunable safety switch for solid tumor CAR T-cell therapy.

K. Misawa, M. Taleb, S. Banerjee, W.-R. Vista, N. K. Chintala, P. S. Adusumilli;
Memorial Sloan Kettering Cancer Center, New York, NY

On-target off-tumor toxicity, cytokine release syndrome (CRS), and immune effector cell-associated neurotoxicity syndrome (ICANS) are severe immune-related adverse events (irAEs) that are frequently associated with Chimeric Antigen Receptor (CAR) T-cell therapy. Current efforts to manage such therapy-related toxicities involve incorporation of an inducible suicide agent within CAR constructs, such as iCaspase-9 or herpes simplex virus type 1 thymidine kinase that can be selectively activated to produce toxic effects within CAR T cells and attenuate their activity. However, while activation of these agents helps to mitigate or overcome such unwarranted toxicities, the therapeutic benefit of CAR T cells anti-tumor activity is also compromised. Therefore, to continue maintenance of CAR T cells' therapeutic function while minimizing irAEs, an ideal safety switch should 1) rapidly inhibit the activation and proliferation of CAR T cells exposed to the target antigen, 2) reversibly inhibit activity without inducing CAR T cell elimination and 3) be clinically translatable for safe application in patients. Our laboratory investigated one such safety switch to inhibit CAR T-cell activity while maintaining their therapeutic function. We showed that incorporating a mutant variant of c-KIT D816V (KITv) in the intracellular domain of mesothelin-targeting second-generation CAR T cells (M28z-KITv) improved efficacy in solid tumors with low antigen, or an immunosuppressive environment. Herein, we evaluate the use of Dasatinib, a clinically available multitarget (BCR, SRC, c-KIT) tyrosine kinase inhibitor (TKI), as a tunable safety switch to reversibly inhibit M28z-KITv CAR T-cell functional activity. In cohorts of mice established with lung adenocarcinoma, daily administration of Dasatinib starting on day 1 or day 3 after CAR T-cell administration stabilized tumor growth, which otherwise continued to regress in untreated mice, indicating inhibition of CAR T-cell functional activity. Upon discontinuation of Dasatinib, tumors regressed, indicating reversal of CAR T-cell functional activity. In an experiment conducted to investigate functional persistence of CAR T cells upon long-term exposure to Dasatinib (1 month), we noted uninhibited activity of CAR T cells to rechallenged tumors. Dasatinib, thus may act as a tunable safety switch to regulate M28z-KITv CAR T-cell activity without compromising its therapeutic function.

#3994 N glycosylation inhibition hinders immunosuppressive tumor microenvironment cells improving CAR T cell efficacy.

C. Sirini, B. Greco, C. Balestrieri, B. Camisa, L. Falcone, R. El Khoury, O. Botrugno, G. Giovannoni, G. Tonon, E. Brunetto, M. Cangi, F. Pedica, A. Bergamini, F. Ciceri, C. Bonini, M. Casucci;
IRCCS San Raffaele Scientific Institute, Milano, Italy

Adoptive transfer of CAR T cells demonstrated impressive results against B-cell malignancies, but still limited efficacy against solid tumors. In this context, multiple challenges need to be overcome, including poor tumor recognition and strong immunosuppression within the tumor microenvironment (TME). Our Unit has recently reported that pharmacological inhibition of N-glycan synthesis in cancer cells increases CAR T cell efficacy by improving tumor recognition and preventing T cell exhaustion. In this project, we investigated the role of N-glycosylation blockade on TME cells in the context of colorectal cancer (CRC) and pancreatic adenocarcinoma (PDAC)-derived liver metastases, exploiting CEA-specific CAR T cell therapy. To understand the effect of N-glycosylation blockade on TME cells (both M2-like macrophages, M2-M and Hepatic stellate cells, HepSCs), we analyzed the phenotypic and transcriptional profile and we performed in vitro functional assays, such as tripartite co-cultures, suppressive assays and released-cytokines analysis. *In vitro* studies revealed that N-glycosylation inhibition abolishes the ability of both TME cells to restrain T cell proliferation and increases the elimination of cancer cell lines and patient-derived tumor organoids (PDOs from CRC-liver metastases). Interestingly, these effects were associated with profound phenotypic and transcriptional changes in M2-M and HepSCs. In particular, the treatment was able to inhibit M2-polarization in terms of surface markers expression, IL-10 secretion and gene expression profile, and was shown to hinder the activation of HepSCs. Moreover, to evaluate the effect of N-glycosylation inhibition on TME cells *in vivo*, we exploited immunodeficient mice reconstituted with a human immune system (huSGM3), engrafted intra-liver with tumor cells and treated with CEA CAR T cells. Interestingly, in this *in vivo* model, the presence of human immune cells supports CAR T cell responses and helps recreate an immune TME more representative of the human disease. Importantly, using these mice we observed that N-glycosylation inhibition improves CEA CAR T cells fitness, enhancing their antitumor activity in terms of survival. This effect is associated with a modulation of human immune TME populations and in particular with the downregulation of immunosuppressive genes in tumor-infiltrating human immune cells (from scRNAseq and Nanostring analysis). Overall, these data suggest that blocking N-glycosylation can help overcome multiple barriers that currently limit CAR T cell efficacy in solid tumors, acting not only on tumor cells, but also on immunosuppressive tumor microenvironment cells.

#3995 A novel chimeric Fas signal redirect receptor enhances the durability of anti-tumor activity and serial killing potential of CAR T cells.

C. Ecker, **E. Peralta**, H.-Y. Chu, L. Loter, M. Tsuda, E. Avramis, M. Denholtz, A. Witty, T. Lee, B. Valamehr;
Fate Therapeutics, San Diego, CA

Chimeric antigen receptor (CAR) T-cell therapies have demonstrated remarkable success in hematological malignancies but only modest efficacy in solid tumors. Apoptosis induced by Fas receptor signaling can be a substantial barrier to CAR T-cell antitumor activity, as many solid tumors express high levels of Fas ligand (FasL). Here we describe a novel synthetic construct where the ectodomain of Fas receptor is fused to the signaling endodomain of a stimulatory receptor, creating a Fas signal redirect receptor (Fas-SRR). This unique design not only prevents Fas-dependent cell death, but also augments the long-term killing potential of induced pluripotent stem cell (iPSC)-derived CAR-T (CAR-iT) cells. Fas-SRR constructs with unique T-cell activation signaling endodomains were designed and compared to two control arms: a dominant negative receptor (Fas-DNR), which blocks Fas signal but does not promote activation; and a Fas-41BB fusion receptor, where the 41BB endodomain is fused to FasR ectodomain to direct activation upon FasL:Fas engagement. Fas-SRR designs were validated in Jurkat reporter cells treated with Fas agonist to measure signal redirection via Fas-SRR. To conduct a head-to-head comparison, CAR-iT cells were engineered to express a CAR under the regulation of the TRAC locus and to express either a Fas-DNR, a Fas-41BB, or FAS-SRR constructs at high purity (>90% transgene expression). No major differences were seen in maturation phenotype (>95% TRAC-CAR expression) of these cells, indicating compatibility of the FAS-SRR constructs with CAR-iT cell generation. Functional testing of the Fas-SRR$^{\pm}$ CAR-iT cells was performed in a long-term restimulation assay where effector cells were repeatedly exposed to target cells over multiple rounds of co-culture. Complete loss of target cell lysis was observed by round six in the co-cultures with FAS-DNR cells, where loss of CAR-iT cell persistence led to accumulation of target cells. After eight rounds of co-culture, the Fas-41BB cells and the majority of Fas-SSR cell constructs also began to exhibit minimal activity toward target cells. However, the top Fas-SRR cell constructs continued to show durable antitumor activity (>97% cytolysis) through the end of the 9-round rechallenge assay. Of note, GSEA analysis identified significant upregulation of NFkB and RELA target genes in cells having the top FAS-SRR construct versus the less durable designs. These results reinforce the advantage of attenuating Fas-FasL interactions to prevent apoptosis and, more importantly, demonstrate the unique therapeutic value in redirecting Fas signaling to improve T-cell potency over an extended duration. Additional studies are underway to further investigate the implications of Fas signal redirection in CAR T and CAR-iT cells and to further understand the module of genes involved in supporting serial stimulation performance.

#3996 Secreted cytokine-αPDL1 fusion proteins improve solid tumor chimeric antigen receptor (CAR) T-cell therapy.

L. Christian[1], J. P. Murad[1], L. Lopez[1], A. Park[1], J. Yang[2], E. Lee[3], C. Trac[1], S. Forman[1], S. J. Priceman[1];

[1]Beckman Research Institute of The City of Hope, Duarte, CA, [2]Ohio State University, Columbus, OH, [3]Georgia Institute of Technology, Atlanta, CA

Background: Success of Chimeric Antigen Receptor (CAR) T cells therapy for solid tumors are limited by the suppressive solid tumor microenvironment (TME), T cell exhaustion, lack of persistence, and poor trafficking to tumors. Strategies to improve this include therapeutic combinations, such as checkpoint inhibition (CPI) or cytokine support. However, CPI therapy has largely failed because of refractory and resistant tumors and cytokine administration can lead to lethal toxicities. To this end, we propose that enabling CAR T cells to secrete bi-functional fusion proteins consisting of cytokine modifiers (ie: IL12, IL15, or TGFβ-trap) combined with checkpoint inhibition (αPDL1 scFv) can provide tumor PDL1 sequestered cytokine activity and local tumor-immune modulation to boost solid tumor CAR T cell efficacy, enhance CPI impacts, and safely improve durable outcomes. **Methods:** Mouse T cells dual transduced to express surface CAR targeting prostate or ovarian solid tumors in addition to secretable cytokine fused to an αPDL1 scFv were generated. *In vitro*, the PDL1 blockade capacity and tumor-surface cytokine presentation of supernatants from dual transduced CAR T cells was assessed on PDL1 induced tumor cells. Further, secreted fusion protein transduced CAR T cells were assessed for function, phenotype, and cytokine release in a repetitive tumor rechallenge assay. *In vivo*, mouse CAR T cells dual transduced with fusion proteins and appropriate controls were assessed for anti-tumor efficacy, survival kinetics, and toxicity in immunocompetent solid tumor mouse models of prostate cancer and intraperitoneal disseminated ovarian cancer. **Results:** CAR T cells were shown to be successfully dual transduced, and secreted αPDL1-cytokine fusion proteins exhibiting functional PDL1 binding characteristics *in vitro*. CAR T cells engineered with αPDL1-IL12 fusion protein had greater anti-tumor activity and CAR specific expansion compared to other tested fusion proteins in *in vitro* co-culture assays. In a syngeneic prostate tumor model, mice receiving CAR T cells with αPDL1-IL12 fusion T cells out competed other cytokine fusion combinations. In a syngeneic ovarian tumor model we safely achieved 100% curative response rate with CAR secreting αPDL1-IL12 fusion in contrast to CAR with αPDL1^{mut}IL12 control along with tumor regional PDL1 blockade on myeloid subsets within the TME. **Conclusions:** Our findings suggest that CAR T cells engineered to secrete αPD-L1-IL12 fusion protein show improved tumor control, less systemic toxicity, and enhanced expansion which promotes eradication of disease in two independent *in vivo* tumor models with two unique solid tumor CAR targets. We believe this strategy has the potential to improve solid tumor CAR T-cell efficacy and enhance durable innate immune responses.

#3997 PARP inhibitors plus anlotinib as bridging therapy for TGFβ-insensitive CAR-T cell therapy targeting MSLN and CD19 in advanced ovarian cancer.

Huayi Li[1], Minghua Xiang[1], Jiahao Liu[1], Wei Mu[2], Li Zhu[2], Xuejiao Zhao[1], Gordon B. Mills[3], Qinglei Gao[1], **Yong Fang**[1]

[1]Department of Gynecological Oncology, Cancer Biology Research Center, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China,[2]Department of Hematology, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China,[3]Department of Cell, Development and Cancer Biology, Oregon Health and Sciences University; Knight Cancer Institute, Portland, OR

Background: The efficacy of chimeric antigen receptor (CAR) T cell therapy remains modest for the treatment of solid tumors due to restricted T cell infiltration and immunosuppressive tumor microenvironment (TME). Leveraging the window of opportunity between leukapheresis and infusion using bridging therapy might improve TME and potentiate CAR-T cell therapy. Here, we assessed the potential of poly (ADP-ribose) polymerase (PARP) inhibitors plus anlotinib as bridging therapy for CAR-T cells with resistance to TGFβ and capability of rapid expansion by bait-and-switch strategy of dual-targeting mesothelin (MSLN) and CD19 in preclinical models of advanced ovarian cancer.

Methods: Immunocompetent mice bearing ID8 tumors were treated with niraparib (21 days) plus anlotinib (14 days) and euthanized at different timepoints (0, 7, or 14 days since discontinuation) to quantify tumor-infiltrating T cells and profile T cell functions. CAR-T cells transfected with dominant-negative TGFβRII dual-targeting MSLN and CD19 were produced by IASO Biotherapeutics. NSG mice bearing MSLN-positive cell- or patient-derived xenografts (CDX or PDX) of ovarian cancer received CAR-T cells alone or after bridging therapy (niraparib plus anlotinib followed by a wash-out period of 7 days). Tumor volume was balanced before CAR-T cell infusion. Replication-deficient NALM6 cells pre-treated with mitomycin C were injected to provide CD19 antigen. A PET scan that visualized granzyme B release was used to track CAR-T cells and assess immune-mediated tumor killing.

Results: Niraparib combined with anlotinib increased tumor-infiltrating T cells without impairing T cell functionality. The effects of promoting T cell infiltration remained significant at 14 days after discontinuation, which might associate with lasting activation of cGAS-STING pathway and secretion of downstream chemokines (CXCL10 and CCL5), and normalized tumor vasculature featured by better perfusion and reduced leakage. The engineered CAR-T cells could resist TGFβ and displayed improved proliferation, cytotoxicity, cytokine release, and in vivo antitumor activities upon CD19 stimulation. Importantly, bridging therapy significantly increased CAR-T cell infiltration, curbed tumor growth, and prolonged survival in mice bearing SKOV3 CDX, HRD-negative PDX, and another multidrug-resistant PDX. PET imaging showed that bridging therapy increased tumor-infiltrating CAR-T cells and boosted tumor-killing capability.

Conclusions: PARP inhibitors plus anlotinib as bridging therapy facilitated CAR-T cell infiltration and enhanced antitumor activities in multiple preclinical models of advanced ovarian cancer, and an early phase I trial (NCT05141253) is ongoing to evaluate PARP inhibitors plus anlotinib as bridging therapy for CAR-T cell therapy in patients with refractory MSLN-positive ovarian cancer.

#3998 Preclinical efficacy of a synthetic Notch-based combinatorial immunotherapy against colorectal cancer with HER2 amplification.

M. Cortese[1], E. Torchiaro[1], A. D'Andrea[2], C. Petti[1], F. Invrea[1], L. Franco[1], C. Donini[2], V. Leuci[2], S. M. Leto[1], V. Vurchio[1], F. Cottino[1], C. Isella[2], S. Arena[2], F. Vigna[2], A. Bertotti[2], L. Trusolino[2], D. Sangiolo[2], E. Medico[2];

[1]Candiolo Cancer Institute - IRCCS, Candiolo, Italy, [2]University of Turin, Turin, Italy

HER2 amplification occurs in about 5% of colorectal cancers (CRC) and is only partially associated with clinical response to combined HER2/EGFR targeted treatment. An alternative approach, based on Adoptive Cell Therapy (ACT) using T cells engineered with anti-HER2 Chimeric Antigen Receptor (CAR), proved toxic due to "on-target off-tumor" activity. Therefore, we developed a combinatorial ACT strategy to safely target HER2 amplification in CRC using a synNotch-based artificial regulatory network. A synthetic Notch receptor was employed in which the extracellular domain is an anti-HER2 scFv and the intracellular domain contains the GAL4VP64 artificial transcription factor. Engagement of the HER2-synNotch by overexpressed HER2 on the surface of target cells induces GAL4VP64 cleavage and translocation to the nucleus, where it drives expression of a CAR under a GAL4-responsive promoter. In this way, only cells co-expressing both HER2 and the CAR target are killed. Carcinoembryonic antigen (CEA) was selected as a colon-specific CAR target: CEA expression is indeed restricted to the digestive tract and is increased in CRC. The natural killer cell line NK-92 was chosen as effector to be engineered. NK-92 cells transduced with HER2-synNotch and inducible CEA-CAR lentiviral vectors were subsequently sorted in the OFF and ON state to select those with the higher CAR induction after synNotch engagement. Subsequently, cloning of sorted cells led to identification of an optimally responsive clone (clone 5F), in terms of specificity and amplitude of CAR induction. The 5F clone demonstrated significant activity *in vitro* and *in vivo* specifically against HER2amp CRC models, with no effects on cells with physiological HER2 levels. *In vitro*, the 5F clone displayed selective cytotoxicity against HER2amp/CEA+ CRC cells, with minimal killing activity against HER2amp/CEA- cells, or HER2norm/CEA+ cells. Additional assays on 3D organoids highlighted better recruitment and infiltration by the 5F clone respect to NK-92 WT cells, only in HER2amp models. *In vivo*, NK-92.5F significantly impaired tumor growth in two different HER2amp CRC models, with no effect on HER2norm CRC cells. To further improve survival, tumor penetration and *in vivo* efficacy of the NK-92.5F clone, a more complex system was built, in which HER2 synNotch engagement drives expression of both the CEA-CAR and IL2. 5F-IL2 cells displayed further increased cytotoxicity *in vitro*. *In vivo*, 5F-IL2 cells drastically increased survival of mice carrying HER2amp CRC xenografts with respect to the parental 5F clone. The observed selective therapeutic efficacy both *in vitro* and *in vivo* of this innovative HER2 synNotch/CEA-CAR system, and its future evolutions, opens perspectives for possible clinical applications in cases of HER2amp CRC resistant or partially responsive to HER2/EGFR blockade.

#3999 Augmentation of antitumor effects by CAR-T cells secreting anti-PD-1 single-chain antibody fused with IL-21.

Y. Li[1], J. Zhao[1], X. Cheng[2], H. Li[2], R. Tian[1], Q. He[1], S. Wang[1];

[1]Institute of Biophysics, Chinese Academy of Sciences, Beijing, China, [2]CD(Suzhou)Biopharma Co.,Ltd., Suzhou, China

Background: Chimeric antigen receptor (CAR) T cell therapy has shown remarkable responses in hematologic malignancies. However, many patients suffer from limited response and tumor relapse due to lack of persisting CAR-T cells and immune escape. Delivery of immunomodulatory cytokines is one of the strategies to improve immune function; however, the systemic effect of cytokines can be detrimental.

Methods: To prevent the toxic effects of cytokines, we proposed the concept of targeting cytokines to tumor-specific T cells in vivo. To this end, we developed CAR-T cells secreting a fusion protein (PD-1Ab21) composed of anti-PD-1 single chain antibody and IL-21, which target IL-21 to CAR-T cells to promote their proliferation and differentiation into memory cells while blocking the PD-1 signal of CAR-T cells. The secretion and functions of PD-1Ab21 were identified. The proliferation and differentiation of CAR-T cells secreting PD-1Ab21 (PD-1Ab21-CAR-T) were compared in vitro with that of the conventional CAR-T cells. The therapeutic effects of CAR-T cells secreting PD-1Ab21 were studied in immunodeficient mice engrafted with human Burkitt lymphoma Daudi, multiple myeloma cell U266 and Her2/neu+ breast cancer cell BT474.

Results: The results showed that the culture supernatant of PD-1Ab21-CAR-T cells, like anti-PD-1 antibody, blocked the binding of PD-1 to PD-L1 and stimulated STAT3 phosphorylation in human T lymphocytic leukemia cell Hut78 with the same activity as IL-21. In the conventional culture milieu with high dose of IL-2, the proliferation of the PD-1Ab21-CAR-T cells was not different from that of conventional CAR-T cells. While cultured with low dose of IL-2 that could not support the proliferation of conventional CAR-T cells, the PD-1Ab21-CAR-T cells still showed significant proliferation. A major fraction of the PD-1Ab21-CAR-T products was shown to co-express CCR7, CD62L and CD45RA, and express high level of TCF-1, indicating a memory stem-like phenotype. While the most of conventional CAR-T cells showed effector phenotype defined as CD45RA+CCR7-. Furthermore, adoptive transfer of PD-1Ab21-CAR-T cells exhibited significantly improved CAR-T cell expansion and resulted in superior tumor eradication in the xenograft models of human B-cell malignancy, multiple myeloma and Her2/neu+ breast cancer. The enhanced cellular function by secreting PD-1Ab21 was mediated through an autocrine and/or paracrine manners.

Conclusion: We developed an enhanced CAR-T cells. Our data provide preclinical evidence to support the translation of this design for an improved CAR-T cell-mediated anti-tumor response.

#4001 Monocyte transcriptome profiles associated with clinical response in patients with B-cell non-Hodgkin's lymphoma receiving CD19-directed CAR-T therapy.

A. de Menezes Silva Corraes, P. Wang, R. Bansal, H. Zhang, Z. Shao, K. Regan, E. Moreno Cortes, A. Khurana, N. Bennani, Y. Wang, P. Hampel, J. Paludo, P. Johnston, H. Murthy, M. Iqbal, S. Ansell, J. Munoz, A. Rosenthal, M. Kharfan-Dabaja, J. Castro, S. Kenderian, H. Dong, Y. Li, Y. Lin;
Mayo Clinic, Rochester, MN

Background Although CAR T-cell therapy has achieved remarkable response in patients (pts) with B-cell non-Hodgkin's lymphoma (NHL), 20-30% of pts still have primary refractory disease (PD1), and another 30-40% relapse (PD2). We and others have shown that monocytes can modulate T-cell functions and impact clinical response to chemoimmunotherapy in NHL. Given that monocytes nadir and recovery kinetics differ from lymphocytes post lymphodepletion chemotherapy, we hypothesize that monocyte phenotype at peak CAR-T expansion and in the early month post CAR-T can modulate immune responses.
Methods scRNAseq were performed on peripheral blood mononuclear cells of NHL pts prior to lymphodepletion chemotherapy (pre), at peak CAR-T expansion (peak), and one month following CAR-T (M1). Seurat v4.3.0 was used for unsupervised hierarchical clustering analysis. Lugano criteria was used to determine clinical responses which were categorized as CR (complete remission), PD1, or PD2.
Results We analyzed 129,981 monocytes from 77 samples of 32 pts (16 CR, 4 PD1, 12 PD2) and 5 healthy controls. Unsupervised hierarchical clustering analysis identified 13 monocyte clusters: 4 classical monocyte (CM) clusters with transcriptome profiles for enriched signaling in IL-6, TGFβ, EMT, and p53; 2 intermediate monocyte (IM) clusters enriched for IL-1 or CD38 signaling; 2 non-classical monocytes (NM), one with increased CD36 expression; 3 monocytic MDSC clusters with enrichment of TGFβ, SIRPα, and HIF1α signaling; and 2 lymphoma-associated monocytes, expressing CD163 or CD169. At Pre and Peak, the distribution of the monocyte clusters was similar in pts with CR, PD2, or PD1, with only a slight decrease in the percent of NM in the PD2 group at Pre and slight increase of CD36 NM in PD1 at Peak. Compared to Pre, all pts had increased percent of CD36 NM and IL-1 IM at Peak. Interestingly, while the distribution of monocyte clusters was similar at Pre and Peak across clinical responses, GSEA showed that monocytes in CR pts, compared to PD1 and PD2, had gene expression enrichment of MYC target V2 pathway at Pre and TGFβ pathway at Peak. At M1, pts in PD1 had increased percent of p53 and TGFβ CM and decreased percent of NM. In contrast, pts with CR had decreased percent of IL-6 CM, p53 CM, TGFβ CM, IL-1 IM and increased percent of NM. Notably, as pts with CR and PD2 may appear similar clinically at M1, pts with PD2, compared to CR, have increased IL-6 CM, IL-1 IM, and decreased NM. In addition, GSEA showed that PD2 pts had increased IFNα response. Our results demonstrate that monocyte phenotype differences at Pre and Peak could be associated with CAR-T clinical response, and that persistent inflammatory monocyte signaling at M1 in pts with clinical response is associated with relapse. These data suggest a role for development of monocyte biomarkers to predict response and therapeutic targeting.

#4002 Investigating CAR-T cell efficacy and activation in the disseminated NALM6-luc human B-cell acute lymphoblastic leukemia model.

P. Pandey, **D. Draper**, S. Barnes, Y. Xing, D. Germain, L. Kucharczyk, R. Stacey;
Labcorp Early Development, Ann Arbor, MI, MI

Introduction: Chimeric Antigen Receptor T (CAR-T) cell therapy has emerged as a promising approach for treating hematological malignancies, particularly B-cell acute lymphoblastic leukemia (B-ALL). This study aimed to delve into the activation dynamics and therapeutic efficacy of CD19 CAR-T cells in a disseminated NALM6-luc human B-ALL murine model.
Experimental design: NALM6-Luc-mCh-Puro cells were implanted intravenously in female NSG (NOD.Cg-Prkdcscid Il2rgtm1Wjl/SzJ) mice. Animals were treated with CD19 CAR-T cells alone and in combination with ibrutinib. The anti-tumor activity was assessed, and the persistence and activation of CAR-T cells in the blood were evaluated using flow cytometry. Additionally, ddPCR analysis was employed to quantify CAR copy numbers, providing insights into the T-cell persistence over time.
Results: Treatment with CD19 CAR-T cells exhibited notable anti-cancer activity and that activity was enhanced in combination with ibrutinib, in line with other reports. The increased time to progression was noted as 69.2% for the CAR-T group and 138.4% for the combination of CAR-T and ibrutinib compared to control. Flow cytometry analysis showed that CAR-T cells persisted in the blood throughout the study. The mean CAR-T absolute cell count for both CAR-T and CAR-T plus ibrutinib treated groups increased from 2 cell/µL blood on Day 0 to 11 and 51 cells/µL of blood, respectively, by Day 39. The progressive increase of PD-1+ and LAG-3+ percentage cells correlates positively with tumor burden, indicating a dynamic link between biomarker upregulation and the presence of tumor cells in mice. ddPCR analysis revealed an initial CAR copy decrease in all groups, followed by gradual increase in tumor-bearing mice treated with CD19 CAR-T cells, with a dramatic increase observed by Day 39. Results from CAR-T treated and CAR-T plus ibrutinib treated groups were comparable, showing mean copy numbers per ng of DNA increasing from less than 1 on day 4 to 17.9 and 23.3, respectively, on day 39. Importantly, no changes were noted in non-tumor implanted mice, emphasizing the tumor dependency for CAR-T cell expansion.
Conclusion: This study emphasizes the marked anti-cancer activity of CD19 CAR-T cells in the NALM6-Luc-mCh-Puro B-ALL murine model. Comprehensive analysis of CAR-T cell persistence and activation, including insights from ddPCR, provides a robust understanding of therapeutic response dynamics. The observed in vivo anti-cancer efficacy aligns with the persistence of CAR-T cells revealed by flow cytometry and the dynamic expansion captured through ddPCR analysis. Our results indicate ddPCR and flow cytometry as complementary and independent methods for assessing the systemic CAR-T cell persistence, contributing to optimizing therapy for B-cell acute lymphoblastic leukemia.

#4003 TBK1 inhibition enhances CAR-T cell efficacy against patient-derived organotypic tumor spheroids.

L. Maggs[1], Y. Sun[1], G. Cattaneo[1], M. Ventin[1], F. Chen[1], M. Q. Rasmussen[1], X. Wang[1], C. R. Ferrone[2], S. Ferrone[1], R. W. Jenkins[1];
[1]Massachusetts General Hospital, Boston, MA, [2]Cedars-Sinai, Los Angeles, CA

Novel therapeutic strategies are needed to improve the efficacy of chimeric antigen receptor (CAR)-T cells in the treatment of solid tumors. Here, we set out to evaluate novel therapeutic strategies to improve the efficacy of B7-H3 (*CD276*) directed (B7-H3.CAR-T) using 3D microfluidic cultures of patient-derived organotypic tumor spheroids (PDOTS). PDOTS are generated from fresh patient tumor tissue and contain tumor cells, autologous immune cells and stromal cells, therefore recapitulating key features of the tumor microenvironment (TME), enabling the study of tumor-immune dynamics. We confirmed activity of B7-H3.CAR-T in PDOTS, although a strong correlation between B7-H3 expression and CAR-T efficacy was not observed. Mechanistic studies subsequently demonstrated dynamic upregulation of co-inhibitory receptors on CAR-T cells following target cell encounter leading to CAR-T cell dysfunction and limiting CAR-T efficacy in B7-H3 expressing tumors. PD-1 blockade restored CAR-T activity in monotypic and organotypic tumor spheroids with improved tumor control and upregulation of effector cytokines. Given the emerging role of TANK-binding kinase 1 (TBK1) as an immune evasion gene, we examined the effect of TBK1 inhibition on CAR-T efficacy. Similar to PD-1 blockade, TBK1 inhibition restored CAR-T activity in monotypic and organotypic tumor spheroids, prevented CAR-T cell dysfunction, and enhanced T cell proliferation. Inhibition or deletion of TBK1 also enhanced sensitivity of cancer cells to immune-mediated killing. Taken together, our results demonstrate the feasibility and utility of *ex vivo* profiling of CAR-T cells using PDOTS, and suggest that targeting TBK1 is a novel strategy to enhance CAR-T efficacy by overcoming tumor-intrinsic and -extrinsic resistance mechanisms.

#4004 Fine-tuning affinity/avidity of anti-CAIX CAR T cells to mitigate on-target off-tumor toxicity in clear cell renal cell carcinoma.

S.-C. Yuan[1], Y. Wang[1], R. Abbas[1], P. Mathenge[1], C. Chien[1], C. D. Coherd[1], B. Bajoua[1], M. R. Chang[1], N. Murugan[1], G. M. Kastrunes[1], G. Wang[2], S.-M. Hoang[3], W. A. Marasco[1];

[1]Dana-Farber Cancer Institute, Boston, MA, [2]Yale University, New Haven, CT, [3]Lumicks, Waltham, MA

On-target off-tumor toxicity (OTOT) is one of the major hurdles preventing tumor-associated antigen (TAA) targeted therapy from effectively treating patients with solid tumors due to the shared presence of the same TAA on normal tissues. We have previously demonstrated high expression of carbonic anhydrase IX (CAIX) in ccRCC patient samples and low-density expression on healthy bile duct epithelium. In 2006, a clinical trial was stopped due to OTOT bile duct toxicity observed in patients infused with anti-CAIX CAR T cell therapy. To address the issue of OTOT in the bile duct, we performed affinity/avidity fine-tuning of the anti-CAIX CAR G36 to specifically target ccRCC tumor cells with high CAIX expression while sparing cholangiocytes with low CAIX expression. We generated a complementarity-determining region (CDR) single variant mutagenesis library of G36 and displayed the library on yeast for screening. Using flow cytometry, we were able to identify six populations based on antigen-binding affinity: high, med-high, med, med-low, low, and loss of binding. These libraries were sequenced via PacBio, a next generation sequencing (NGS) platform that excels in long-read sequencing, providing a powerful tool to detect single mutations in the scFv. The results were analyzed to identify enriched mutations compared to the wild-type G36, and inspected using *in silico* modeling and docking. Furthermore, enriched mutants from med-low and low populations were tested in CAR-T format for their cytotoxic capacity on tumor cells and bile duct cholangiocytes, as well as their avidity. We demonstrate that mutations in CDR2 and CDR3 of the heavy chain successfully mitigate OTOT toxicity on cholangiocytes with physiological levels of CAIX expression while maintaining tumor-killing capacity, shedding light on CDR mutagenesis as a useful tool to mitigate OTOT toxicity.

#4005 HER2 TKIs enhance the anti-tumor activity of HER2-targeting CAR-T and CAR-NK cells against NSCLC.

Y. Yang, M. B. Nilsson, A. Poteete, J. He, Q. Huang, J. V. Heymach;
UT MD Anderson Cancer Center, Houston, TX

Approximately 3% of non-small cell lung cancer (NSCLC) cases harbor *ERBB2*/HER2 mutations. Notably, the majority of actionable HER2 mutations in NSCLC are in-frame insertions in exon 20. Current HER2-targeting approaches, including antibody-drug conjugates (ADCs) such as trastuzumab deruxtecan, have shown promising response rates. To explore novel strategies for targeting HER2-positive NSCLC, we investigated chimeric antigen receptor (CAR)-based therapies to enhance the anti-tumor activity of immune effector cells. We engineered a series of HER2 CAR constructs utilizing scFvs derived from trastuzumab, pertuzumab, and FRP5, recognizing distinct domains of HER2. These scFvs were integrated into second-generation BB3z (with 4-1BB and CD3z intracellular domains) and third-generation 28BB3z (with CD28, 4-1BB, and CD3z intracellular domains) CAR backbones, which were subsequently transduced into activated T and natural killer (NK) cells to generate CAR-T and CAR-NK cells, respectively. High transduction efficiencies were achieved, with over 80% in CAR-T cells and over 50% in CAR-NK cells. We next evaluated their activity against a panel of NSCLC cell lines expressing varying levels of HER2 *in vitro* using firefly luciferase assays. All HER2 CAR-T cells demonstrated more than 90% killing against H2170 (HER2 high) and H322 (HER2 medium) at an effector:target (E:T) ratio of 10:1, whereas HER2 CAR-T cells yielded a killing effect of 35% against A549 (HER2 low) cells. HER2-targeting CAR-NK cells also displayed potent cytotoxicity against HER2-expressing NSCLC cells. Moreover, we observed that treatment of HER2 mutant and HER2 amplified NSCLC cells with low doses of HER2 tyrosine kinase inhibitors (TKIs) such as poziotinib enhanced the expression of HER2 on the cell surface. This upregulation resulted in enhanced activation of HER2 CAR-T and CAR-NK cells in coculture experiments as measured by CD107a expression on effector cells. Additionally, treatment with the HER2 TKI poziotinib potentiated the killing activity mediated by HER2 CAR-T and CAR-NK cells. Using a HER2 YVMA duplication patient-derived xenograft (PDX) NSCLC model, we observed that the *in vivo* combination of poziotinib with HER2 CAR-NK cells exhibited superior anti-tumor activity as compared to poziotinib treatment alone. In conclusion, HER2 CAR-T and CAR-NK cells effectively target HER2-mutant and HER2-positive NSCLC, and their combination with HER2 TKIs enhances vulnerability to HER2-targeting strategies.

#4006 IL12-secreting CAR-T cells eliminate the requirement for lymphodepletion and promote epitope spreading via local antigen presenting cells.

Aditya Mohan, Steven Shen, Kelly Hotchkiss, Sarah Quackenbush, John Sampson, Peter Fecci, Anoop Patel

Duke University Medical Center, Durham, NC

Introduction: EGFRvIII is a commonly studied tumor-specific antigen in glioblastoma (GBM) and poses an enticing target for immunotherapy. Its varied expression, however, complicates its effectiveness as a Chimeric Antigen Receptor (CAR) T cell target. Given the increasing prominence of Interleukin-12 (IL12) in treating solid tumors, its synergy with EGFRvIII specific CARs in treating preclinical models of GBM is explored.
Methods: To simulate tumor heterogeneity, mice were implanted with equal ratios of CT2A and CT2A EGFRvIII+ cells. We developed EGFRvIII-specific third-generation CAR T cells, both with and without IL12 using a MSGV retrovirus backbone and transduced them into murine T cells. Their antitumor effectiveness was gauged by evaluating survival rates, and their capability to enhance and modify the tumor environment was determined using single-cell sequencing.
Results: Standalone EGFRvIII CARs were unsuccessful in curing mice with heterogeneous tumors. However, 60% of mice treated with EGFRvIII CARs combined with IL12 were long term survivors. IL12 secreting CARs exhibited prolonged persistence in vivo, and there was no need for prior lymphodepletion before ALT introduction. Our studies reveal that EGFRvIII CARs secreting IL12 can eliminate EGFRvIII negative tumor cells by drawing on the inherent CD8 T cell compartment. Moreover, IL12 prominently impacted microglia among all Antigen Presenting Cells in the tumor environment, amplifying antigen presentation processes and broadening epitope exposure.
Conclusion: By leveraging IL12, EGFRvIII CARs can counteract antigen heterogeneity in tumors by recruiting endogenous CD8 T cells and polarizing microglia. These IL12-secreting CARs outlast their traditional counterparts without requiring lymphodepletion. Harnessing CAR-T cells that secrete IL12 represents a novel strategy for overcoming tumor heterogeneity and treating GBM in a clinical context.

#4007 AIC100 CAR-T cells targeting ICAM-1 are efficacious against solid tumors in xenograft mouse models of non-small cell lung cancer (NSCLC) and cervical cancer (CC).

A. Birt, S. Josiah, K. L. Joyce, S. Alla, M. P. Gallagher, J. Puc, H. Nguyen, E. Walsh Martin, S. Gupta;
AffyImmune Therapeutics Inc., Natick, MA

Purpose: Establish preclinical proof of concept efficacy with CAR T cells (AIC100) in xenograft models of solid tumors (NSCLC and CC) expressing high levels of surface ICAM-1.

Experimental: AIC100 is a third generation CAR T cell with micromolar affinity to ICAM-1, tuned lower than most CARs used to date in pre-/clinical studies. Affinity tuned AIC100 drug product is expected to selectively bind and kill tumor cells while safely sparing healthy cells. AIC100 also co-expresses somatostatin receptor 2 (SSTR2), which enables *in vivo* monitoring of AIC100 distribution and expansion by DOTATATE PET/CT imaging. To test preclinical efficacy of AIC100 in NSCLC and CC, four xenograft mouse models were generated using tumor cell lines known to have ICAM-1 expression (verified by flow cytometry) to test efficacy of AIC100. Reporter cell lines transfected with Luciferase were H226 NSCLC adenocarcinoma, H441 NSCLC squamous cell carcinoma, HeLa CC adenocarcinoma and SW756 CC squamous cell carcinoma. AIC100 efficacy was established by in vitro cytotoxicity prior to in vivo studies. NSG mice (n=10 per cell line) were inoculated via tail vein injection ($1.0x10^6$ cells) in cell growth media. Mice were imaged to ensure solid tumor formation which occurred in all mice within 3-5 days in the lung. At D0, mice were randomized into 2 groups (n=5 per group) of vehicle (PBS) and AIC100. At D1, mice were injected with AIC100 ($1.0x10^7$ live T cells) or vehicle. Mice were followed by weight and clinical observations 2x weekly and imaging by IVIS weekly. The study continued until vehicle group was euthanized due to tumor related co-morbidities at which time the study concluded.

Results: AIC100 showed clear treatment benefit in both models of NSCLC and CC. In CC HeLa model, in mice treated with AIC100, primary tumors were significantly reduced by D8 and eliminated in 5/5 mice by D22. In CC SW756 model, in mice treated with AIC100, tumor growth was reduced in size by D22. In NSCLC H441 model, in mice treated with AIC100, primary tumors were largely eliminated in 5/5 mice by D15. In NSCLC H226 model, in mice treated with AIC100, tumors were significantly reduced by D8 and largely eliminated by D57 (4/5 mice). A clear survival benefit was observed in AIC100 treated mice in NSCLC H226 xenograft model. These results show treatment benefit by AIC100 in 2 tumor models per indication and establish proof of concept for the potential development of AIC100 as a treatment for ICAM-1 expressing NSCLC and CC cancers.

Conclusions: AIC100 has significant treatment benefit in NSCLC and CC tumors with ICAM-1 expression in *in vivo* preclinical studies.

#4008 DASH CAR-T: accelerating CD276-targeted immunotherapy for pancreatic cancer.

Haiying Wang, Tian Deng, Hao Li, Yue Yao, Yuan Tian, Hongwei Wang, **Pengfei Jiang**

Shanghai Hrain Biotechnology Co., Ltd., Shanghai, China

B7 homolog 3 protein (B7-H3), recognized as CD276, is a pivotal immune checkpoint molecule extensively expressed in cancer cells, presenting a limited presence in normal tissues. Immunohistochemical analysis of 150 pancreatic cancer patients revealed positive CD276 staining in 66% of cases, with elevated expression correlating to diminished disease-free survival. Additional findings from an independent study on 59 patients highlighted significantly elevated CD276 levels, particularly in lymph node metastasis and advanced pathology. This study introduces an innovative Chimeric Antigen Receptor T (CAR-T) therapy targeting CD276, leveraging our DASH CAR-T manufacturing platform. Significantly, our approach reduces the ex vivo cell expansion time from 10 days to 1-2 days. T cells were enriched, activated, and transduced with a CD276 CAR-encoding retroviral vector, achieving the final product in 2-3 days. In preclinical models, our shorten-time CAR-T against CD276 exhibited superior expansion and heightened tumor-killing efficacy. Remarkably, DASH CAR-T demonstrated superior tumor control compared to conventional CAR-T, requiring only one-tenth of the dosage. This research advances our understanding of CD276 in pancreatic cancer and presents a transformative approach in CAR-T therapy manufacturing. The shortened production timeline and enhanced therapeutic outcomes underscore the potential clinical impact of our novel CAR-T strategy, offering a more efficient and potent treatment option for pancreatic cancer.

#4009 Discovery of inhibitory CAR target DSG1 for damping NECTIN4 on-target off-tumor toxicity in iPSC-derived CAR-T cell therapy.

Matthew S. Hall, Christopher M. Dower, Michael Miller, John Wheeler, Jill Carton, Ohad Manor, Hyam Levitsky

Century Therapeutics LLC, Philadelphia, PA

Century Therapeutics is developing NECTIN4 targeted induced Pluripotent Stem Cell (iPSC) derived Chimeric Antigen Receptor (CAR) T cell therapy. NECTIN4 targeted antibody drug conjugate enfortumab vedotin, while generally well tolerated, causes severe skin adverse events in some patients, thought to be driven by on-target off-tumor toxicity against NECTIN4 displaying skin keratinocytes. We include a safety switch in our first clinical-stage iPSC-derived CAR-NK cell therapy, CNTY-101, which provides an antibody target for elimination of the engineered cells should that be necessary. An additional method for reducing the incidence and severity of this type of adverse event is through the incorporation of an inhibitory CAR, also known as a NOT-gate, directed against antigen expressed on normal skin keratinocytes, but the optimal surface protein to target with such an inhibitory CAR for a NECTIN4 targeted therapy is unknown. Here, we identify DSG1 (Desmoglein-1) as a top inhibitory CAR target for NECTIN4 targeted CAR-T cell therapy by conducting a multi-omics analysis of public single-cell RNAseq, bulk RNAseq, and protein microarray immunohistochemistry datasets. We find that DSG1 is constitutively and uniformly displayed on the surface of skin keratinocytes in the layers of epidermis where they display NECTIN4, and DSG1 gene expression in normal skin is uniformly high across individuals. Conversely, DSG1 mRNA and protein are rarely expressed in NECTIN4 expressing cancer indications including bladder, breast, non-small cell lung, ovarian, and pancreatic. Further, autoimmune antibodies specific to DSG1 have been described, suggesting that DSG1 is targetable by a CAR in situ. Finally, DSG1 is not expressed by our iPSC-derived CAR-T cells. While NECTIN4 expression is greatest in skin keratinocytes, epithelial cells in other tissues express NECTIN4 at lower levels. In this study, we compare the expression levels of NECTIN4 to targets associated with tissue and cell-type specific on-target off-tumor toxicity in primary CAR-T cell clinical trials. Our findings support the strategy of DSG1-directed inhibitory CAR incorporation into NECTIN4 specific CAR-T cell therapeutic candidates.

#4010 Assessing impacts of tumor burden and CAR-T cell dosage on the toxicity and efficacy profile of CD19 CAR-T therapy in a PBMC-humanized mouse model.

W. Lee, D. Rose, J. G. Keck, J. Yang;
The Jackson Laboratory, Sacramento, CA

Chimeric antigen receptor T-cell (CAR-T) therapy is a significant advancement in treating hematological malignancies, yet it faces challenges due to its variable therapeutic responses and the risk of severe toxicities. This study delves into the effects of tumor burden and CAR-T cell doses on the toxicity profile of the therapy, employing a PBMC-humanized mouse model engrafted with luciferase-labeled Raji B cell lymphoma (Raji-luc). By exploring high vs. low tumor burden and high vs. low CAR-T dose scenarios, we aim to gain insights into the dynamic relationship between these factors and CAR-T-induced toxicity and efficacy. In the first experiment, we established PBMC humanized mouse models with a high tumor burden and a low tumor burden. 10 days (high burden) or 7 days (low burden) after the Raji-luc inoculation, mice were engrafted with 10M human PBMCs and dosed with CD19 autologous CAR-Ts. In mice with low tumor burden, CAR-T treatment demonstrated significant efficacy, as evidenced by IVIS imaging, while the high tumor burden model exhibited reduced efficacy. CAR-T treatment in Raji-bearing mice did not induce weight loss in either high or low burden models. CD19 CAR-T cells effectively reduced the target cell population in peripheral blood, with greater expansion observed in the higher tumor burden model. We also evaluated human cytokine levels post-CAR-T treatment, revealing higher cytokine induction in the high tumor burden model, peaking at 2 days post-treatment. Secondly, in a CAR-T dose-response study, we treated PBMC-humanized Raji-bearing mice with 10M, 15M, and 20M CAR-T cells. Higher CAR-T cell doses (15M and 20M) resulted in observable toxicity measured by body weight loss, while the 10M dose did not. All CAR-T doses effectively slowed tumor growth and induced significant CAR-T cell expansion. Selected human cytokines, such as IL-5 and RANTES, demonstrated a dose-response correlation with CAR-T treatment. Additionally, IL-6 and IL-10 were significantly correlated with tumor burden rather than CAR-T doses. The differential cytokine responses observed in our study provide valuable insights into the utility of the PBMC-humanized mouse model for investigating the biological responses associated with CD19 CAR-T therapy. Our findings underscore the utility of the PBMC-humanized mouse model in assessing variability in toxicity and cytokine responses to CAR-T therapy. This model offers valuable insights into the factors influencing CAR-T treatment outcomes and provides a platform for planning more precise treatment and enhancing the safety and efficacy of CAR-T therapy.

#4011 Locoregional GPC3 chimeric antigen receptor (CAR)-T cell therapy is associated with improved tumor control in hepatocellular carcinoma by enhancing CAR-T cell trafficking and functionality.

J. Wang, K. Tsang, J. Qiu, B. Feng;
The Chinese University of Hong Kong, Hong Kong, Hong Kong

Despite the rapid development of anti-cancer immunotherapy, the prognosis of hepatocellular carcinoma (HCC) patients is far from satisfactory. Glypican-3 (GPC3) CAR-T cell therapy has shown varied patient response. One of the potential reasons of low response rates may be due to the limited CAR-T cell infiltration. Therefore, locoregional GPC3 CAR-T therapy has been a promising option, with a hope of enhancing CAR-T cell tumor penetration. In this study, the therapeutic efficacy and underlying mechanisms of locoregional GPC3 CAR-T cell delivery were explored using HCC mouse xenografts. Orthotopic NOD-scid IL2Rg^{null} (NSG) HCC models were established by tumor fragment implantation into the liver. CAR-T cell injections were performed via the tail vein and portal vein to simulate systemic and locoregional administrations, respectively. Compared to the systemic treatment, locoregional therapy could better control the tumor growth, and was associated with improved liver function. In addition, the locoregional therapy group demonstrated a higher percentage of tumor-infiltrating CAR-T cells which showed an increased expression level of the cytotoxicity marker *GZMB* and a reduced level of the exhaustion marker *LAG3*. Moreover, significantly higher IFN-gamma level was found in the blood of the locoregional therapy group, indicating a better CAR-T cell functionality. In conclusion, we have demonstrated that locoregional administration of CAR-T cells is associated with increased CAR-T cell infiltration and better therapeutic efficacy. Additionally, CAR-T cells being injected locoregionally are correlated with enhanced functionality and reduced exhaustion phenotype. These findings highlight the potential of locoregional GPC3 CAR-T therapy as a promising treatment strategy for HCC patients.

#4012 SOT302: Dual expression of exogenous glutamine oxaloacetate transaminase (GOT2) and TP53-induced glycolysis and apoptosis regulator (TIGAR) enhance CAR T cell activity in preclinical solid tumor models.

Emily Kuiper, Samyabrata Bhaduri, Daniel Garafola, Kshitij Sharma, Jennifer Coccia, Kathleen Whiteman, **Amy Jensen-Smith**

SOTIO Biotech, Inc., Boston, MA

Background: Despite success in hematological malignancies, CAR T therapy has had limited efficacy against solid tumors. The suppressive tumor microenvironment limits CAR T activity through various mechanisms including competition for available nutrients and chronic stimulation resulting in reduced effector functions or T cell exhaustion. CAR T cells with enhanced metabolic fitness or more durable memory phenotype could potentially improve the clinical outcome in solid tumors. GOT2 plays an important role in mitochondrial function and maintenance of redox homeostasis. We have previously demonstrated enhancement of CAR T cells overexpressing GOT2. TIGAR is an enzyme known to promote antioxidative activites and reduce reactive oxygen species and has a role in protecting against apoptosis. Here we tested SOT302 CAR T cells expressing both GOT2 and TIGAR in preclinical solid tumor models.
Results: Expression of GOT2 and TIGAR transgenes were confirmed by qRT-PCR and western blot. Activity of GOT2 and TIGAR were confirmed by measuring aminotransferase activity (AST) and glutathione production, respectively. Compared to control CAR T cells, SOT302 is enriched for CD8+ Tscm cells and has a higher percentage functional, non-senescent (CD28+CD57-) cells. SOT302 has similar cytokine expression and cytotoxicity in standard co-culture assays compared to controls. SOT302 cells were chronically stimulated with plate-bound antigen every 3-4 days for 4 rounds. SOT302 had greater expansion of cells and were less exhausted and had better cytolytic capacity compared to controls. SOT302 cells were then evaluated in tumor xenograft mouse models. Consistent with our previous findings, CAR T cells expressing the single GOT2 transgene were more efficacious compared to CAR T cells alone. Expression of the single TIGAR transgene had no apparent benefit over CAR alone, however SOT302 cells expressing both GOT2 and TIGAR had superior anti-tumor activity compared to CAR alone and CAR+GOT2. No overt toxicity or significant body weight loss was observed. Ex vivo analyses to measure peripheral expansion, tumor infiltration and exhaustion were also performed. Preliminary findings indicate that SOT302 has better peripheral expansion compared to CAR alone and similar expansion compared to CAR+GOT2 controls. SOT302 cells had better tumor infiltration compared to both the CAR alone and CAR+GOT2 cells. Tumor infiltrating SOT302 cells also exhibited lower levels of exhaustion compared to CAR alone or CAR+GOT2 controls.
Summary: SOT302 cells express exogenous GOT2 and TIGAR transgenes and have superior anti-tumor activity in preclinical solid tumor models. These data suggest that SOT302 may be a promising candidate for patients with solid tumor cancers.

#4013 Increasing mitochondrial respiration by silencing MCJ/DnaJC15 enhances CD8 CAR-T cell therapy efficacy.

M.-H. Wu[1], E. L. Giddings[2], F. Valenca-Pereira[1], C. Pham-Danis[1], F. Cendali[1], M. C. Yarnell[1], A. J. Novak[1], J. Henao-Mejia[3], R. A. Flavell[4], A. D'Alessandro[1], M. E. Kohler[1], M. Rincon[1];

[1]University of Colorado Anschutz Medical Campus, Aurora, CO, [2]University of Vermont, Burlington, VT, [3]University of Pennsylvania, Philadelphia, PA, [4]Yale University, New Haven, CT

Chimeric antigen receptor (CAR)-T cell therapy is a promising treatment against leukemia and lymphoma. However, poor initial treatment response and post-therapy relapse have found to be common and remained to be resolved. Modulating T cell immunometabolism is considered a novel therapeutic approach to enhance CAR-T cell therapy. We have identified MCJ (*DnaJC15*) as an endogenous negative regulator of Complex I of the electron transport chain in mitochondria. MCJ is abundantly expressed in mouse CD8 cells relative to other immune cells. We propose that MCJ can be a therapeutic target to enhance mitochondrial respiration in CD8 CAR-T cells. We will show that loss of MCJ in mouse CD8 cells leads to superior anti-tumor response against melanoma. In addition, we will show that MCJ-deficient murine CD8 CAR-T cells have enhanced killing activity against leukemia both *in vitro* and *in vivo*. We have recently revealed that MCJ is also expressed in human CD8 cells and the levels of MCJ are heterogenous among human population. Similar to murine CD8 cells, MCJ knockdown in human CD8 cells enhances mitochondrial membrane potential and effector functions. We have designed a new CAR construct to silence MCJ in human CD8 CAR-T cells. MCJ-deficient human CD8 cells show superior cytotoxicity against leukemia with increased mitochondrial metabolism. Together, these data demonstrate that MCJ is a promising target to improve CAR-T cell therapy through modulating the T cell metabolism. We are currently investigating the effect of MCJ-deficient CD8 CAR-T cells against solid malignancy.

#4014 Humanized mouse model to assess PBMC donor derived autologous CD19 CAR Ts for efficacy against Raji tumors and related cytokine release.

S. Ramalingam, D. Cai, L. Shopland, J. G. Keck;
The Jackson Laboratory, Sacramento, CA

Immuno-oncology cell therapies engage the immune system to treat cancer. In recent years, adoptive T-cell therapy with CD19-specific chimeric antigen receptors (CARs) has shown promise for treatment of various malignancies, including acute lymphoblastic leukemia. However, CAR-T-cell therapies have been hampered by various adverse events, including cytokine release syndrome (CRS). To predict and minimize CRS effects from CAR-T therapies, a human immune preclinical murine model that combines efficacy and toxicity readouts is essential. Here, we describe the development of PBMC humanized mouse model based on the NSG-MHC I/II-DKO strain to study autologous CD19 CAR-T treatment related tumor growth inhibition and CRS *in vivo*. Three different PBMC donors were used to generate CAR-T (CD28-Cd3z) directed against a CD19 epitome. Our preliminary data demonstrate that CD19 CAR-T treatment stimulated dynamic and PBMC donor dependent cytokine release with IFN-g, IL-10, IL-4, IL-2, IL-6 and TNF. Our model showed elevation of shared proinflammatory cytokines (IFN-g, IL-10, IL-2 and TNF) observed in humans after CD19 CAR-T treatment. Currently, we are evaluating our PBMC based cytokine release model in CD19 CAR-T cells tumor control study. Our results to date indicate that PBMC-engrafted NSG-MHC I/II-DKO mouse models are vital platforms to screen adoptive T-cell therapy for potential CRS.

#4015 Improvement of CAR T cell potency against low-density targets like L1CAM and FGFR4 in rhabdomyosarcoma.

C. Piccand[1], A. Timpanaro[2], S. Anton-Joseph[1], M. Bernasconi[1], J. K. Rossler[3];

[1]University of Bern/Inselspital, Bern, Switzerland, [2]Seattle Children's Hospital, Seattle, WA, [3]Novartis, Basel, Switzerland

Rhabdomyosarcoma (RMS) is the most common pediatric soft tissue sarcoma. Overall survival rates are low for metastatic RMS, emphasizing the urgent need of improved therapies. Chimeric Antigen Receptor (CAR) Ts have shown remarkable results against hematological malignancies, but CAR T cell therapy remains challenging in solid tumors, mainly due to a lack of ideal tumor specific targets, and of the immunosuppressive tumor microenvironment (TME). To maximize antitumoral activity against RMS and to address optimal CAR T persistence *in vivo*, novel CAR constructs were investigated against upregulated RMS targets. By surfaceome profiling, we recently identified L1CAM as promising candidate for RMS CAR T cell therapy, and confirmed CD276 and FGFR4 expression. CD276- (CD276.CD28HD.28TM.28CSD.3z) and Dual-CAR Ts targeting both CD276 and FGFR4 (F8-FR4.CD28HD.28TM.28CSD.3z) showed tumor eradication in an orthotopic RMS model, whereas FGFR4-CAR Ts exhibited only a partial response *in vivo.* Moreover, CD276-CAR Ts showed a limited activity against RMS tumors expressing lower amounts of CD276, eradicating the tumor in 1/5 mice, underlying the need of improved CAR T cell potency against low-density target-expressing tumors. First, to improve FGFR4-CAR Ts activity, we optimized the recognition of FGFR4 epitope by modifying the CAR moiety “hinge”. We replaced the CD28-derived hinge with various hinges of different length: no hinge, IgG4 (12aa), IgG4CH3 (119aa), and IgG4CH2CH3 (229aa). Luciferase assays showed effective *in vitro* killing capacity of FGFR4-CAR Ts expressing an IgG4-derived hinge, with a tumor cell survival less than 10% at Effector to Target (E:T) ratio of 5:1. They also released the double amount of IFN-γ (50pg/ml) compared to the other constructs, when co-incubated with Rh4 cells. Next, to verify the potential of L1CAM as CAR T target for RMS, we generated a panel of L1CAM-CARs expressing either a long (IgG4CH2CH3, 229aa) or a short (CD28, 35aa) Hinge, and a CD28- or 41BB-derived costimulatory domain (CSD). L1CAM.IgG4CH2CH3Hinge.28TM.28CSD.3z CAR Ts outperformed the other constructs, killing ~60% of Rh30 at the E:T ratio of 1:1 and more than 90% at the E:T ratio of 5:1. They also exhibited a 3-fold higher IFN-γ release (120 pg/ml) compared to the other constructs. However, although our examination of patient-derived TMA revealed a strong immunoreactivity for L1CAM, more expressed in aggressive RMS subtypes, the selected L1CAM-CAR Ts against Rh30 cells, exhibiting ~10’000 L1CAM copies, showed limited activity in an *in vivo* pilot study. Based on these results and on the RMS TME investigation, which revealed consistent collagen (COL4A1, COL4A2 and COL18A1) deposition in RMS-derived mice tumor xenografts, we hypothesize that co-expressing a collagenase, able to partially degrade the dense extracellular matrix surrounding tumors, will lead to an improved CAR T cell infiltration and activity *in vivo*.

#4016 mRNA encoding a CAR specific stimulating protein (CSSP) mediates tumor metabolism regulated (TMR) CAR signaling for CAR-T expansion beyond the tumor microenvironment.

Frederic Vigant, Anirban Kundu, Michael Betts, Sid P. Kerkar, Gregory I. Frost

Exuma Biotech Corp., West Palm Beach, FL

Background: Unlike hematologic targets, TMR Chimeric Antigen Receptors with binding restricted to antigen in the tumor microenvironment lack CAR dependent stimulatory signals for proliferation outside the tumor. Increased exposure to CAR-T is associated with improved clinical outcomes and therefore tools to safely and selectively increase proliferation represent potential adjunctive CAR-T therapeutics. Therefore, we developed a surrogate CAR Specific Stimulating Protein (CSSP) approach encoded by synthetic mRNA for expression in antigen presenting cells to boost CAR-T proliferation *in vitro* and *in vivo*.
Methods: NFAT-Luc reporter lymphocytes were transduced with lentivectors encoding TMR CARs with or without epitopes reactive to CSSP's in the CAR. Subsequently, PBMCs were transfected with LNPs containing synthetic mRNAs for either GFP or candidate membrane bound CSSPs. Transfection efficiency was confirmed by microscopy and flow cytometry. The activity of CSSP's expressed in monocytes cultured with T cells expressing CAR variants with NFAT-luc reporter was measured by luciferase expression and compared to CD3 stimulation. Additionally, the kinetics of CAR stimulation with monocytes expressing CSSPs were determined by serial luciferase measurements. Finally, the proliferation of PBMCs transduced with a TMR-HER2 CAR co-cultured with CSSP treated purified monocytes were evaluated.
Results: Following exposure of PBMCs expressing CSSPs to TMR-CAR-expressing NFAT T cells, CAR specific luciferase signaling was readily detectable compared to non-specific CD3 stimulation, indicating that the CSSPs were capable of CAR specific stimulation through the CD3ζ chain of the CAR. Two of the CSSP variants demonstrated stimulation in a CAR specific fashion at levels similar to or greater than non-specific CD3 stimulation. In kinetic experiments, stimulation of NFAT could be detected over a period of 8 days, indicating persistence of the CSSP similar to GFP in antigen presenting cell controls. Finally, co-culture of CSSP mRNA expressed in purified monocytes were capable of TMR-HER2-CAR T cells stimulation, which do not proliferate when cultured with HER2 antigen expressing cells under physiologic conditions.
Conclusion: TMR-CAR-T cells can achieve proliferative capacity outside the tumor microenvironment using synthetic mRNA encoding CAR Specific Stimulatory Proteins. This novel mRNA approach may provide additional tools to promote the proliferation and/or persistence of solid tumor targeted CAR-T cells outside the tumor environment.

#4017 CAR T cell-mediated cytotoxicity and cytokine release in response to varying levels of antigen expression on target cells.

S. Barnes[1], D. Sullivan[1], D. Lazar[2], K. Haupt[3], D. Califano[1], S. Chvatal[1], D. Millard[1];
[1]Axion BioSystems, Atlanta, GA, [2]Axion BioSystems, Madison, WI, [3]Promega Corporation, Madison, WI

The development of immunotherapies relies on the use of in vitro potency assays, which are crucial for understanding the complex interactions between immune cells (effectors) and cancer cells (targets). Chimeric antigen receptor (CAR) T-cell therapy is an immunotherapeutic approach that exhibits promise; however, varying levels of antigen expression on the surface of tumor cells can influence the efficacy of CAR T cell-mediated killing. To fully understand the impact of target antigen density on CAR T cell activity, we utilized a matrix approach to assess both target cell death, using an impedance-based in vitro potency assay to quantify CAR T cell-mediated cytotoxicity, as well as cytokine release with homogeneous Lumit™ immunoassays. SKOV3 (high HER2 expression), A549 (low HER2 expression), or MDA-MB-231 (no HER2 expression) target cells were seeded into a 96-well microplate with embedded electrodes in the substrate that detect the attachment and proliferation of target cells. HER2 CAR T cells were added after 24 hours at effector-to-target (E:T) ratios of 1:5 or 1:1 and target cell cytolysis was recorded continuously by the Maestro Z for 72 hours. Cytolysis of the target cells was calculated by comparing the treated wells to no treatment control wells and full lysis wells (1% TritonX). At 72 hours post CAR T cell addition, complete killing was observed in SKOV3 cells at the 1:1 ratio, while A549 cells exhibited only 80% cytolysis. MDA-MB-231 cells showed 20% cytolysis, likely due to nonspecific killing by non-engineered T cells, as approximately only 78% of the CAR T cell population was CAR positive. Because the cytolysis assay was label-free, cytokine analysis was able to be multiplexed with the same plates. To assess release of pro-inflammatory cytokines, TNF-α and IFN-γ, we collected supernatant post-antigen exposure at 24, 48, and 72 h. At the 1:1 E:T ratio, CAR T cells co-cultured with target cells expressing low (A549) or high (SKOV3) levels of HER2 had the highest TNF-α production at 24 hours, with CAR T cells co-cultured with SKOV3 cells releasing 30.6% more TNF-α when compared to A549 cells. The highest levels of IFN-γ were detected in both A549 and SKOV3 groups at the 1:1 E:T ratio, with the highest levels observed from CAR T cells co-cultured with SKOV3 cells at 72 hours, releasing approximately 1459.6 +/- 357.3 pg/mL of IFN-γ, compared to 1093.8 +/- 387.5 pg/mL IFN-γ released by CAR T cells co-cultured with A549 cells. As expected, CAR T cells co-cultured with MDA-MB-231 cells did not release any detectable TNF-α or IFN-γ at either E:T ratios during the duration of the experiment. Future work will continue to explore multiplexed potency assays for the evaluation of CAR T cell therapies.

#4018 An innovative *in vivo* model for CAR-T cell therapy development: Tolerability and efficacy evaluation of CD19-targeting CAR-T cells on human lymphoma using the chicken CAM assay.

Yan Wang[1], Xavier Rousset[1], Chloe Prunier[1], Emilien Dosda[1], Alejandra Gutierrez-Guerrero[2], Pauline Abrial[2], Inna Menkova[2], **Jean Viallet**[1]

[1]Inovotion, La Tronche, France,[2]Allogenica, Villeurbanne, France

BACKGROUND Chimeric antigen receptor (CAR) T cell therapy is a revolutionary approach in cellular immunotherapy, where a patient's T cells are genetically engineered to recognize and attack cancer cells. In the last decade, several CAR-T cell therapies have been approved by the FDA. However, this encouraging outcome was obtained only with certain blood cancers, like B cell leukemias, lymphomas, etc. Many research / clinical trials are now underway worldwide to extend the CAR T-cell therapy benefits to a large spectrum of cancers, using rodents. This model presents several drawbacks, such as the immunodeficiency of humanized models, ethical constraints, time, and cost. An alternative, pertinent, 3Rs-compliant *in vivo* model for developing CAR-T therapy is urgently needed. Xenografts on the chicken embryo's ChorioAllantoic Membrane (CAM) have proven extremely valuable for *in vivo* cancerology studies. In this work, we evaluated *in vivo* the anti-tumor efficacy of CD19-targeting CAR-T cells on human lymphoma using Inovotion's CAM assay.

METHODS Human lymphoma Raji cells (ATCC) were grafted on the CAM on embryonic development day (EDD) 9. A 2nd generation of CD19-targeting CAR-T cells (CAR-T-(CD3/4-1BB)) developed by Allogenica (France) were co-injected at EDD9 at E/T (effector CAR-T cell *vs* target Raji cell) ratio 1:1. One group was injected with CAR-T (CD3/4-1BB) only once at EDD9 and a second group received a first injection of CAR-T (CD3/4-1BB) at EDD9 and a second injection at EDD13. Embryonic viability was checked daily. On EDD18. The efficacy of CAR-T therapy was evaluated basing on tumor weight, metastatic invasion in the lower CAM and CAR-T infiltration in tumors detected by qPCR. Activation of the chicken embryo immune system was detected as well.

RESULTS The treatment with CAR-T-(CD3/4-1BB) cells was well tolerated *in ovo*, no significant embryo mortality/abnormality was observed. CAR-T-(CD3/4-1BB) cells prevented tumor formation (tumor weight was 88.67% to 90.62% lower than control, $p < 0.001$); and prevented metastasis formation in the lower CAM (86.88% to 81.43% lower than control, $p < 0.001$).

CONCLUSION Different to *in vitro* models and immunodeficient murine models, chicken embryo possesses a progressively mature immune system. Our results show that CAR-T-(CD3/4-1BB) cells can prevent tumor formation and metastatic invasion when co-injected with tumor cells. Inovotion's CAM assay is a viable alternative *in vivo* model for developing CAR-T cell therapy on a large spectrum of cancers. It is fully 3Rs-compliant.

#4019 Development of mRNA chimeric antigen receptor T cells targeting MET in aggressive B-cell lymphomas.

P.-H. Chen[1], R. Raghunandan[2], M. Muschen[1], S. G. Katz[1];
[1]Yale School of Medicine, New Haven, CT, [2]Yale University, New Haven, CT

Multiple versions of CAR T cells targeting the cell surface protein CD19 are approved by the FDA to treat refractory B-cell malignancies. However, durable remissions range from 60% in B-cell leukemias to 40% in B-cell lymphomas. Major reasons for resistance to CD19-CAR treatment relate to heterogeneous or loss of CD19 expression. In addition, CD19-CAR leads to B-cell depletion which increases the risk for infection. These limiting factors necessitate research into alternative targets for CAR therapy against B-cell lymphomas.Using a large data set from clinical trials, we found that approximately 30-70% of diffuse large B-cell lymphomas (DLBCL) express MET. We hypothesize that these MET-positive B-cell lymphomas can potentially be targeted with chimeric antigen receptor (CAR) T-cells against MET receptor. We constructed a second-generation anti-MET-CAR by fusing the scFv fragment of an anti-MET monoclonal antibody with the human CD28 hinge/transmembrane/cytoplasmic domain and CD3ζ cytoplasmic domain. Stable MET-CAR Jurkat cells showed increased CD69 expression upon stimulation by MET-positive lymphoma cell lines such as Karpas-422 and OCI-LY3. Using primary human T cells, we further demonstrated that the mRNA MET-CAR T-cells mediated cytotoxicity against DLBCL cell lines. Of note, while CD19-CAR T-cells showed only low level of cytotoxicity against the CD19-/MET+ OCI-LY3 cell line, MET-CAR T cell was able to mediate substantial tumor cell lysis.In summary, the preliminary data demonstrate that MET-CAR is capable of mediating cytotoxicity against MET-positive DLBCL. Some cell lines such as OCI-LY3 are negative for CD19 but positive for MET expression, and MET-CAR is capable of mediating cell lysis while CD19-CAR is ineffective. These results suggest that some large B-cell lymphomas negative for CD19, either intrinsic or secondary to loss of CD19 as a result of resistance mechanism, may show MET expression and will likely benefit from MET-targeted immunotherapy.

#4020 Donor-dependent anti-tumoral efficacy of human CD19 CAR T cells in a leukemic xenograft mouse model.

P. Metzger[1], C. N. Castro[1], J. F. Hummel[1], M. Roman Azcona[2], D. Antony[2], C. Mussolino[2], D. Zurr[3], S. Adamsky[3], H. Weber[1];
[1]Reaction Biology Europe GmbH, Freiburg, Germany, [2]Medical Center - University of Freiburg, Freiburg, Germany, [3]Lepton Pharmaceuticals Ltd, Zichron Yakkov, Israel

The recent advances in cellular immunotherapies have revolutionized the treatment options for hematological malignancies. Among others, genetically engineered T cells to express chimeric antigen receptors targeting CD19 have shown clinical success in patients with B cell malignancies. However, depending on the study design only one to two thirds of the patients experience a complete response upon CD19 CAR T cells treatment. Antigen escape, immune suppressive microenvironment, CAR T cell dysfunction as well as lack of CAR T cell persistence have been discussed to be reasons for the lack of sustained therapy response. Well established models for the preclinical evaluation of cellular therapies are needed for the evaluation of next generation CAR T cells as well as novel combination therapies.

Here, we describe a xenograft animal model of human acute lymphoblastic leukemia (NALM-6 cells) with a suboptimal treatment response to human CD19 CAR T cells from three different donors. First, the activation status and memory phenotype of the CAR T cells from the different donors was characterized by flow cytometry and the anti-tumoral efficacy of the CD19 CAR T cells was evaluated in an in vitro co-culture killing assay using luciferase expressing NALM-6 cells. Next, CD19 CAR T cells from three donors were injected in NALM-6_luc tumor bearing animals. The tumor growth was monitored by bioluminescence imaging and the phenotype of the transferred CAR T cells was checked by flow cytometry.

The frequency of memory T cells differed between the donors whereas the T cells from all donors exhibited all low expression of activation markers. In vitro, all three donors showed high and comparable anti-tumoral killing efficacy independent of their memory status. In vivo, CD19 CAR T cells from all three donors delayed the tumor growth significantly although none of the animals had a complete remission. In line with the individual memory status of the CAR T cells prior to infusion, there were slight differences in the kinetics of the anti-tumoral response. The flow cytometric analysis revealed that the transferred CAR T cells were almost absent in the peripheral blood and spleen whereas for individual animals tumor cells and highly activated CAR T cells were detectable in the bone marrow of the animals.

In summary, the NALM-6_luc xenograft model is a value tool for evaluating next generation cellular therapies and novel combination strategies to overcome the current limitations of cellular therapies.

#4021 The development of CAR T cell therapeutics targeting tumor specific CD146.

E. Uzuner[1], H. Mole[1], C. W. Wong[1], M. L. Fernandez Carro[1], R. Leshem[1], K. Sefton[1], H. Tovey[2], A. Picken[2], M. Blot-Chabaud[3], A. F. L. Hurlstone[1];
[1]University of Manchester, Manchester, United Kingdom, [2]FUJIFILM Diosynth Biotechnologies, Billingham, United Kingdom, [3]Aix-Marseille University, Marseille, France

Chimeric antigen receptor (CAR) T cells represent a promising class of "living drugs" for cancer treatment. These primary T cells are genetically engineered to express a synthetic antigen receptor, incorporating various domains to enhance their effector functions. While CAR T cells have shown success against liquid cancers, their application to solid cancers is hindered by significant "on-target/off-tumor" toxicities due to the absence of specific target proteins. In this study, we aim to enhance the tumor specificity of CAR T cells by targeting a tumor-specific version of CD146. CD146 is a glycoprotein widely expressed in several solid tumors, particularly melanoma and ovarian cancer. However, it is also expressed on benign cells, such as endothelial cells, pericytes, and smooth muscle cells. Nevertheless, a CD146 isoform exists that is enriched in cancer cells.
We assessed CAR activity using flow cytometry to measure surface CD69 expression (an early activation marker) on CAR-expressing Jurkat cells co-cultured with various CD146-positive and CD146-negative human melanoma and ovarian cancer cell lines. The killing ability of primary CAR-T cells was evaluated by measuring the relative luciferase activity of target cells, and their effector functions were further analyzed by ELISA for the secretion of IFN-g and TNF-a.
Through multiple rounds of protein engineering, we have developed a CAR construct capable of reprogramming T cells to respond to a tumour-enriched CD146 isoform. Our CAR demonstrated antigen-dependent activation of Jurkat cells when co-cultured with CD146-positive human melanoma and ovarian cancer cell lines, comparable to a CAR targeting pan-CD146. Moreover, primary CAR T cells exhibited proportional killing activity and other effector functions.
We have successfully engineered a CAR with specificity for a tumour-enriched isoform of CD146. Our future work will involve rigorously evaluating the tumor selectivity of our CAR, as well as assessing the ability of primary CAR T cells expressing this CAR to control tumor growth in vivo.

IMMUNOLOGY: Combination Approaches
Poster Session

#4025 A phase II trial of neoadjuvant gemcitabine, cisplatin plus tislelizumab followed by concurrent chemoradiotherapy in locoregionally advanced nasopharyngeal carcinoma: Clinical efficacy, safety and the biomarker analysis.

X.-Y. Li, S.-Y. Xie, Q.-Y. Chen, H.-Q. Mai, L.-Q. Tang;
Sun Yat-sen University Cancer Center (SYSUCC), Guangzhou, China

Immune checkpoint inhibitors (ICIs) have been widely used in recurrent or metastatic nasopharyngeal carcinoma (NPC), but the addition of ICIs to chemoradiotherapy in locoregionally advanced (LA) NPC requires further investigation. We conducted a phase II, single-arm trial to evaluate the efficacy and safety of neoadjuvant gemcitabine, cisplatin (GP) plus tislelizumab followed by concurrent chemoradiotherapy (CCRT) in LA-NPC. All participants received 3 cycles of GP chemotherapy plus tislelizumab (200 mg) followed by 3 cycles of cisplatin-based CCRT. The primary endpoint was the clinical complete response rate (CR) after neoadjuvant chemoimmunotherapy (NAT). The secondary endpoints include pathological CR rate, progression-free survival (PFS), overall survival (OS), locoregional relapse-free survival (LRRFS), distant metastasis-free survival (DMFS), etc. Pretreatment blood samples and paired (pre-/post-NAT) tissue biopsies were collected to perform full-spectrum peripheral T-cell profiling, PD-L1 and tertiary lymphoid structures (TLS) staining. Among all 63 participants, the CR rate after NAT reached 41.3% (95% CI, 28.8%-53.8%), far exceeding our hypothesized CR rate of 22%. The objective response rate (ORR) and pCR rate after NAT were 88.9% (95% CI, 80.9% to 96.9%) and 74.6% (95% CI, 62.1% to 84.7%), respectively. As of July 15th, 2023, after the median follow-up of 25 months, the 2-year PFS and OS were 98.4% and 100%. The incidence of grade 3-4 immunotherapy-related adverse events was 1.6%. The compliance of CCRT was not compromised. Patients who achieved CR had significantly more circulating CD4+ and CD8+ effector memory T cells (Tem), regulatory T cells (Treg) and follicular helper T cells (Tfh). The peripheral abundance of LAG3+ Tem and Tfh were independently predictive of NAT response. The number and maturation of TLS significantly increased after NAT in the CR group, but not in the Non-CR group. GP chemotherapy plus tislelizumab followed by CCRT was highly therapeutic and safe in treating LA-NPC, further randomized phase III studies are awaited.

#4026 The combination of DLL4/VEGF-a blockade and immunomodulation can eliminate MHC class I negative tumors in mice.

Diana I. Albu, Rachael Duffy, Amy Daniel Ulumben, Jason Kong, Jessica Zolotarevsky, Melissa Brundin, Mei Su, Ruturaj Jadhav, Kris F. Sachsenmeier, Bing Gong, Thomas J. Schuetz, Alberto Visintin

Compass Therapeutics, Boston, MA

CTX-009 is a bispecific antibody targeting VEGF-A and DLL4 which is undergoing clinical investigation in patients with multiple tumor types, including biliary tract and colon cancers. In biliary tract cancers, checkpoint inhibitor therapy has been shown to improve outcomes when combined with chemotherapy. In an effort to increase the breadth and duration of response of CTX-009, we set out to investigate the combined anti-tumor efficacy of this bispecific antibody and immunotherapy in preclinical models. Here we report the evaluation of the combination of the mouse surrogates of CTX-009 and CTX-471, an agonistic anti-mouse CD137 antibody, or monoclonal antibodies that disrupt the PD-1/PD-L1 signaling axis. Coupling VEGF-A/DLL4 targeting with either CD137 agonism or PD-1/PD-L1 blockade markedly increased the anti-tumor efficacy of the individual treatments alone in multiple syngeneic mouse tumor models. Tumor growth inhibition was accompanied by pharmacodynamic evidence consistent with enhancement of anti-tumor immunity. Notably, the combination of CTX-009 and CTX-471 retained potent anti-tumor activity even in a tumor line (MC38) which was made MHC I deficient through the deletion of the beta 2 microglobulin gene. This system may model the clinically relevant unmet need characterized by tumor escape through the loss of antigen presentation machinery such as HLA LOH. Interestingly, the model cell lines CT26 and MC38 failed to thrive in the B2M-deficient setting and depletion of NK cells markedly increased their ability to grow. This implies that NK cells might be involved in controlling tumor growth in this setting, and that the combined action of CTX-471 and CTX-009 in the tumor stroma enhances NK cell activity. The findings presented here suggest that CTX-009 may provide enhanced clinical benefit when combined with immunomodulatory agents, such as agonistic anti-CD137 antibodies or PD-1/PD-L1 blockers in tumors where immune checkpoint inhibitors have failed.

#4027 From tumor progression to therapeutic control: Combinatorial targeting of immune vulnerabilities in TNBC.

A. Poissonnier[1], E. V. Egeland[2], W. Horton[1], S. Sivagnanam[1], O. Stapleton[3], R. Erbe[3], N. Kirchberger[1], K. Betre[1], A. Skaist[3], L. Danilova[3], A. Fields[1], P. Ordentlich[4], A. C. Adey[1], E. J. Fertig[3], L. M. Coussens[1];

[1]OHSU Knight Cancer Institute, Portland, OR, [2]2Dept. of Tumor Biology, Institute for Cancer Research,, Oslo, Norway, Norway, [3]Johns Hopkins Univ., Sidney Kimmel Comprehensive Cancer Center, Baltimore, MD, [4]Syndax Pharmaceuticals, Inc, Waltham, MA

Triple-negative breast cancer (TNBC) is an aggressive form of breast cancer, associated with limited treatment options and high mortality rates. Although immune checkpoint inhibitors (ICIs) show promise, early clinical results indicate benefits in only a specific subset of patients with TNBC. Preclinical evidence indicates that infiltrating macrophages contribute to breast tumor progression by restricting $CD8^{\pm}$ T cell infiltration, activation, and cytotoxicity within tumor microenvironments. Preliminary data has revealed that immune-competent mammary tumor-bearing MMTV-PyMT transgenic mice have slowed tumor progression following sequential combination of a microtubule poison (paclitaxel; PTX) to enhance tumor immunogenicity, plus a macrophage-depleting/reprogramming agent such as a colony-stimulating factor 1 receptor blocking antibody (αCSF1R), and undergo primary tumor regression in 60% of transgenic mice when an ICI targeting PD-1 is applied (3x therapy) by a $CD8^{\pm}$ T cell-dependent mechanism. Response to 3x therapy is associated with localized $CD8^{\pm}$ T effector and resident memory cell expansion, and increased antigen-specific clonal expansion at primary tumor sites. We hypothesized that epigenetic plasticity was limiting T cell memory and thus impeding long-term tumor control. Using a class 1 benzamide histone deacetylase (HDAC) inhibitor (e.g., entinostat) sequentially added to PTX/αCSF1R/αPD-1 therapy (4x) resulted in primary tumor stasis in 100% of mice, and significantly enhanced overall survival, in two transgenic mouse models of breast cancer (MMTV-PyMT and C3-(1)-TAg). Cohorts were analyzed at distinct time points for primary and metastatic tumor burden, in addition to immunophenotyping (flow cytometry), transcriptional (bulk and scRNA-Seq), epigenetic (sciATAC-Seq), and T cell receptor (TCR) changes correlating with 4x responses. Improved outcome and tumor stasis was associated with increased presence of long-lived central and stem-like memory $CD8^{\pm}$ T cell infiltration, intra-tumoral B memory cell, and $CD4^{\pm}$ T follicular helper cell infiltration. Tumor stasis was achieved by B and T cell-dependent mechanisms where B cell depletion led to decreased T cell cytotoxicity. Adoptive serum transfer (AST) from 4x-treated MMTV-PyMT mice into either 3x-treated or untreated MMTV-PyMT mice elicited tumor stasis and control. These preclinical studies indicate the complexity of myeloid, B cell and T cell interactions that are co-opted by tumors, and identify novel paths to therapeutic tumor control by targeting vulnerable immune communication programs.

#4028 Inhibition of IL25 IL17RA improves immune related adverse events of checkpoint inhibitors and reveals antitumor activity.

X. Hu, S. Bukhari, C. Tymm, K. Adam, S. Lerrer, B. Henick, R. Winchester, **A. Mor**;
Columbia University Irving Medical Center, New York, NY

Immune checkpoint inhibitors (ICI) have improved outcomes and extended patient survival in several tumor types. However, ICI often induces immune-related adverse events (irAEs) that warrant therapy cessation, thereby limiting the overall effectiveness of this class of therapeutic agents. Currently, available therapies used to treat irAEs might also blunt the antitumor activity of the ICI themselves. Therefore, there is an urgent need to identify treatments that have the potential to be administered alongside ICI to optimize their use. Using a translationally relevant murine model of anti-PD-1 and anti-CTLA-4 antibodies-induced irAEs, we compared the safety and efficacy of prednisolone, anti-IL-6, anti-TNFα, anti-IL-25 (IL-17E), and anti-IL-17RA (the receptor for IL-25) administration to prevent irAEs and to reduce tumor size. While all interventions were adequate to inhibit the onset of irAEs pneumonitis and hepatitis, treatment with anti-IL-25 or anti-IL-17RA antibodies also exerted significant additional antitumor activity. Mechanistically, IL-25/IL-17RA blockade reduced the number of organ-infiltrating lymphocytes. These findings suggest that IL-25/IL-17RA may serve as an additional target when treating ICI-responsive tumors, allowing for better tumor control while suppressing immune-related toxicities.

#4029 HPK1 inhibitor reinvigorates exhausted tumor-infiltrating CD8 T cells and synergizes with anti-PD-1 blockade in gynecologic malignancies.

J. Park[1], Y. Lee[1], S. Kim[1], **S. Lim**[2], A. Park[2], J. Kim[2], J. Lee[2], S. Kim[1], S.-H. Park[3], J.-Y. Lee[1];

[1]Yonsei University College of Medicine, Seoul, Korea, Republic of, [2]1ST Biotherapeutics, Inc., Yongin-si, Korea, Republic of, [3]Korea Advanced Institute of Science and Technology, Daejeon, Korea, Republic of

HPK1 (Hematopoietic Progenitor Kinase 1) is a negative intracellular immune checkpoint that interferes with the priming and activation of T cells. In recent years, several HPK1 inhibitors have been discovered as novel immune-oncology drugs with promising potential to improve anti-tumor immune responses. However, there has been no study showing the effects and potential application of HPK1 in gynecologic malignancies. Therefore, we investigated the expression and role of HPK1 in tumor-infiltrating CD8 T cells (CD8 TILs) and how the selective small molecule kinase inhibitor, FB849, affected the reinvigoration of exhausted CD8 TILs in gynecologic cancers. We isolated TILs from patients with newly diagnosed endometrial (*n*=53) and ovarian cancer (*n*=46). The immunological properties and HPK1 signaling pathway of CD8 TILs were explored using flow cytometry. TILs were *in vitro* stimulated with anti-CD3 in the presence of FB849 and/or anti-PD-1, and their proliferation was assessed. We observed that HPK1 marked severely exhausted PD-1$^{\pm}$CD8 TILs, and high HPK1 expressers had more exhausted PD-1$^{\pm}$CD8 TILs compared to low HPK1 expressers. In addition, FB849 could successfully restore the effector function of exhausted CD8 TILs. In particular, the reinvigorating capacity of FB849 was negatively correlated with phosphorylated SLP76$^{\pm}$PD-1$^{\pm}$CD8 TILs in endometrial cancer. In addition, FB849 further enhanced anti-PD-1-mediated reinvigoration of CD8 TILs in endometrial cancer. However, there was no synergistic effect of FB849 + anti-PD-1 in terms of proliferative capacity in ovarian cancer. Overall, the results of our present study provide a rationale for clinical trials investigating the anti-tumor efficacy of FB849 ± anti-PD-1 tailored to the respective properties of gynecologic malignancies.

#4031 P-selectin as an emerging target for the treatment of primary and secondary brain tumors.

E. Yeini[1], R. Frommer-Shapira[2], A. Talianski[2], P. Ofek[1], S. Pozzi[1], N. Albeck[1], D. Ben-Shushan[1], G. Tiram[1], S. Golan[1], R. Kleiner[1], R. Sheinin[1], S. Reich-Zeliger[3], R. Grossman[4], Z. Ram[1], H. Brem[5], T. Hyde[5], P. Magod[1], D. Friedmann-Morvinski[1], A. Madi[1], R. Satchi-Fainaro[1];

[1]Tel Aviv University, Tel Aviv, Israel, [2]Sheba Medical Center, Ramat Gan, Israel, [3]Weizmann Institute of Science, Rehovot, Israel, [4]Rambam Health Care Campus, Haifa, Israel, [5]John Hopkins Hospital, Baltimore, MD

Glioblastoma (GB) is an aggressive type of brain cancer with a high mortality rate. It is a highly angiogenic tumor exhibiting an extremely invasive nature. As such, its brain microenvironment plays a crucial role in its progression. Microglia are the brain resident immune cells that have been shown to facilitate GB cell invasion and immune suppression. The mechanism by which GB cells alter microglia behavior is yet to be fully understood. One proposed mechanism involves adhesion molecules such as the Selectins family of proteins which are expressed on the surface of endothelial and immune cells and are involved in immune modulation and cancer immunity. We have previously shown that one member of the Selectin family, P-Selectin (SELP), is expressed by GB cells. Here, we investigated the functional role of SELP in GB-microglia interactions. First, we found that microglia cells facilitate the expression and secretion of SELP by GB cells, and that GB cells facilitate the expression of P-Selectin ligand-1 (PSGL-1) by Glioma-associated microglia/macrophages (GAMs). We then showed that SELP mediates GAMs-enhanced GB invasion and proliferation in our unique 3D-bioprinted *ex vitro* models and has a role in GAMs activation state. These findings were validated *in vivo*, showing that inhibition or downregulation of SELP leads to reduced tumor growth, increased overall survival, and improved immune response. Single-cell RNA-seq analysis of the tumors revealed an increase in pro-inflammatory GAMs signature, reduction in cancer cell tumorigenesis potential, and improved T cell activation. Thus, combining SELP inhibition with other immune checkpoint inhibitors, such as anti-PD-1, may have a synergistic effect by harnessing both the innate and the adaptive immune systems against the tumor. Furthermore, we found SELP/PSGL-1 axis to be involved in the progression of brain metastasis originating from melanoma, and breast, and lung cancer. Thus, we have begun an investigator-initiated clinical trial, testing the efficacy of the anti-SELP antibody, Crizanlizumab, alone or in combination with anti-PD-1 antibody, Nivolumab, for GB and melanoma brain metastasis patients (NCT05909618). Crizanlizumab, approved by the FDA and EMA for sickle cell pain crisis (VOC, Vaso-Occlusive Crisis) of sickle-cell anemia patients, was proven to be safe for human use, and efficient in inhibiting SELP function. As such, it has the potential to reduce tumor burden and improve patient outcomes. This work can improve our understanding of GAMs function, which may pave the way for new and effective treatments for primary and secondary brain tumors.

#4032 ATRA induces an interferon response to reprogram the immunosuppressive tumor microenvironment and overcomes resistance to immune checkpoint inhibition in murine models of LKB1-deficient non-small cell lung cancer.

W. P. Crosson, R. Li, R. Salehi-Rad, R. J. Lim, J. Abascal, B. P. Kahangi, E. Perez Reyes, M. Oh, C. Dumitras, N. Edgar, R. Chew, R. Jocobo, A. Tfayli, Z. Jing, K. Krysan, L. Tran, S. M. Dubinett, B. Liu;
UCLA - University of California Los Angeles, Los Angeles, CA

Lung cancer remains the deadliest form of cancer, claiming 1.8 million lives worldwide in 2020. While treatment options have improved with the advent of immune checkpoint inhibitors (ICI), many patients do not respond to immunotherapy or develop resistance following initial response. A significant subset of non-small cell lung cancer (NSCLC) patients harbors somatic co-mutations in *Kirsten rat sarcoma virus (KRAS)* and *Liver kinase 1 [LKB1,* also known as *serine/threonine kinase 11 (STK11)]* genes, whose tumors are characterized by an immunosuppressive tumor microenvironment (TME) that are resistant to ICI. Our studies revealed that *all-trans* retinoic acid (ATRA), a metabolite derived from vitamin A, sensitized a murine model of NSCLC with increased tumor mutational burden (*Kras* ^{G12D} *P53*$^{-/-}$*Lkb1*$^{-/-}$; KPL-3M) to PD-1 blockade. The ATRA and anti-PD-1 combination therapy improved local and systemic T cell activation and generated systemic tumor-specific immunity. To understand ATRA-mediated anti-tumor effects, we performed single cell RNA sequencing (scRNA-seq) of KPL-3M murine tumors with or without 6 daily ATRA treatments. scRNA-seq analysis revealed a reduction of neutrophils as well as an enrichment in T cell and natural killer (NK) cell populations in the TME. Furthermore, scRNA-seq analysis revealed elevated expression of interferon (IFN) downstream genes in multiple immune subpopulations in the TME. Preliminary *ex vivo* studies indicated that ATRA increases NOX2 levels, intracellular reactive oxygen species (ROS), and IFN signaling in the neutrophils in KPL-3M tumors. Our findings suggest that ATRA may reshape the TME by activating IFN signaling in multiple cell subtypes to sensitize resistant tumors to ICI immunotherapy.

#4033 Leukocyte-based biomimetic nanoparticles for combined targeted and immunotherapy in osteosarcoma.

G. Romano[1], B. Ha[1], J. T. Yustein[2], F. Taraballi[3];
[1]Drexel University College of Medicine, Philadelphia, PA, [2]Emory University School of Medicine, Atlanta, GA, [3]Houston Methodist Hospital, Houston, TX

Osteosarcoma is the most diffuse bone cancer in the pediatric population, with most patients showing resistance to therapy. All patients are administered systemic high-dose cytotoxic chemotherapy regimens. Many targeted and immune therapy approaches are currently in clinical trials for treating osteosarcoma, but single treatments are not showing promise. While combined targeted and immunotherapy appears to be a possible avenue, developing solutions for patients who show intolerable toxicity or lack of synergy is critical. Nanoparticles (NPs) have successfully been used to prolong the half-life of drugs, favor extended release, reduce systemic toxicity, and reach beyond biological barriers. Biomimetic NPs represent an emerging class of NPs as a system to mimic naturally occurring processes. One class of biomimetic NPs is leukosomes, leukocyte-based biomimetic NPs that target inflamed tissues. Leukosomes are synthesized by integrating proteins isolated from the membranes of circulating leukocytes in the NPs' wall. Leukosomes' biomolecular profile helps them adhere to tumor-inflamed vasculature and promotes their self-tolerance and ability to evade immune clearance from the mononuclear phagocyte system (MPS). We have demonstrated the feasibility of a "one-two punch" approach for leukosome-mediated bone cancer treatment. Specifically, the first "punch" (a multi tyrosine kinase inhibitor, mTKI) induces an immunogenic response, which is subsequently targeted by leukosomes delivering a second class of compounds (immunomodulating nucleic acids, second "punch"). Indeed, even a single mTKI administration increases the amount of leukosomes localized to tumors, which is amplified by a second dosage in a dose-dependent manner. Importantly, leukosome infiltration was paralleled by an increase in immune infiltration, especially in Cd8+ T-cell abundance and macrophages. After several iterations and protocol adjustments, leukosome compositions and microfluidic parameters have been optimized to load either siRNA or mRNA. Current experiments are optimizing the "second punch" targeting immune checkpoint inhibitors (siRNAs vs. PD1/PDL-1). Interestingly, we showed the leukosomes produced using the membranes of human or mouse macrophages pre-treated with LPS show increased surface concentration of adhesion molecules (e.g., Siglec-1) that further enhance their localization at the inflamed site while decreasing filtration by the MPS. In addition to increased delivery to the tumor site, this strategy reduces the therapeutic strain because it is sequential ("one-two punch") and uses nucleic acids instead of antibodies to target immune checkpoints. Overall, our work describes a novel rationale-based sequential approach that can be *paradigm-shifting* in the field as it harnesses treatment-induced inflammation to boost intratumoral drug delivery.

#4034 Lag3 blockade enhances the anti-tumor effect of dual GITR agonism and PD-1 blockade in a preclinical melanoma model.

R. R. Maniyar[1], Y. Elhanati[2], L. Mangarin[1], Y. Marouf[1], A. Ahmed[1], B. Greenbaum[2], J. Wolchok[1], T. Merghoub[1];
[1]Weill Cornell Medicine, New York, NY, [2]Memorial Sloan Kettering, New York, NY

Immune checkpoint blockade (ICB) therapies, specifically anti PD-1 and anti CTLA-4, have resulted in tremendous success in the clinic. However, a substantial number of patients still relapse due to either inherent or acquired resistance to ICB therapies. In this scenario, activation of T cell co-stimulation pathways along with ICB emerges as a promising strategy to improve anti-tumor responses. Engagement of Glucocorticoid induced TNFR Related protein (GITR) costimulatory molecule, leads to enhanced activation of cytotoxic T cells while destabilizing suppressive T regulatory cells in the tumor microenvironment. Additionally, combining GITR agonism with PD-1 blockade improves the anti-tumor response in a murine model of advanced melanoma resistant to ICB, positioning GITR as an attractive immunotherapeutic target. In this study, we evaluated the therapeutic efficacy of combining blockade of the immune checkpoint LAG3 with GITR agonism for treating ICB-resistant advanced melanoma, using the B16 model. The combination of LAG3 blockade with GITR agonism was well tolerated, leading to better tumor control and improved survival. Our data revealed increased B cell infiltration and activation within tumors and draining lymph nodes (LNs) of treated mice. B cell depletion diminished the anti-tumor effect of the combination therapy, suggesting that B cells play an active role in controlling tumor growth. Spleens from treated mice exhibited increased lymphocytic hyperplasia, along with more and larger germinal centers. B cell receptor sequencing revealed an increased clonality and reduced entropy. Treating B cells with GITR agonism and LAG3 blockade *in vitro* led to increased activation and proliferation, suggesting a direct effect of these therapies on B cells. Furthermore, adding LAG3 blockade to the dual combination of GITR agonism and PD-1 blockade resulted in superior tumor control and increased B cell activity in the draining LNs. Collectively, our findings suggest that the humoral response significantly contributes to the anti-tumor responses elicited by ICB when combined with GITR agonism. This triple combination therapy (LAG3 blockade + PD1 blockade + GITR agonism) holds promise as a safe and potent therapeutic strategy to overcome ICB resistance. Further investigation into the mechanism of action by which GITR agonism leads to enhanced B cell responses when combined with ICB is warranted in order to design more effective therapies for cancer treatment.

#4035 Lipid-based nanoparticle combination immunotherapy with sitravatinib for the systemic treatment of high-risk neuroblastoma.

Miranda Diaz-Infante[1], Griffin Kane[1], Christina Lusi[1], Meghan Brassil[1], Kim Wigglesworth[2], Christian Alarcon[3], Jason Shohet[2], Prabhani Atukorale[1]

[1]Biomedical Engineering, University of Massachusetts Amherst, Amherst, MA,[2]UMass Chan Medical School, Worcester, MA,[3]Kansas City University, Kanas City, KS

We seek to develop a systemic, innate immunomodulatory nanoparticle therapy that combines synergistically with sitravatinib for the treatment of high-risk neuroblastoma, where metastasis is the largest hurdle for current treatment modalities. Here, we utilize a unique lipid-based nanoparticle (LNP) system comprised of co-encapsulated agonists of the Stimulator of Interferon Genes (STING) and Toll-like Receptor 4 (TLR4) pathways (immuno-NPs) that can be safely administered in the systemic blood circulation for delivery to the tumor microenvironment (TME) and uptake by perivascular innate antigen-presenting cells (APCs). STING/TLR4 agonists together promote the synergistic production of Type I interferon β (IFNβ), a key activator of anti-tumor immunity from the TME itself. Here, we also focus on sitravatinib, an investigational drug shown to inhibit receptor tyrosine kinases such as discoidin domain receptor 2 (DDR2), which can inhibit the sustained remodeling of collagen around primary tumors. The inhibition of such is vital to treatment as sustained collagen remodeling can facilitate the metastasis of cancer cells via epithelial-mesenchymal transition (EMT). We hypothesize that the downstream effects of sitravatinib treatment will augment tumor clearance and increase the therapeutic efficacy of immuno-NPs with respect to recruiting APCs. Our early pilot studies in humanized mice bearing orthotopic SH-5YSY tumors show that immuno-NPs are effective at tumor clearance. We found that mice inoculated subcutaneously with syngeneic 9464D-GD2 tumors showed decreased tumor growth when treated with our novel combination therapy in comparison to monotherapy controls. In both humanized and syngeneic tumor models, our ongoing mechanistic studies involve quantification of EMT in primary tumors, systemic nanoparticle deposition at metastatic sites, and the mechanistic impact of combination therapy on IFNβ-promoted elimination of metastasis. Here, we have proposed and tested an immunotherapy with great promise for treating neuroblastoma. However, the impact of nanoparticle-based immunotherapy reaches far beyond neuroblastoma: it has the potential to be a platform for the development of immunotherapies specific to other highly metastatic cancer types.

#4036 Integrating dendrimers and peptide-based biologics to co-target immune checkpoints and oncogenic pathways for HNSCC treatment.

D. Kim, P. Rawding, M. Iida, K. Kostecki, B. Mehall, D. Wheeler, S. Hong;
University of Wisconsin-Madison, Madison, WI

The utilization of peptides as cancer therapeutics has tremendous potential given their nature of mimicking protein functionalities while maintaining a high degree of modularity in their molecular design. However, their translation into the clinic remains a challenge due to their inferior binding kinetics, poor bioavailability, and short plasma half-life. To address these, we employed multivalent dendrimers that improve the binding and stability of the peptide-based biologis. We herein present a translatable, modular nanoparticle platform, utilizing generation 7 (G7) poly(amidoamine) (PAMAM) dendrimers conjugated with engineered peptides (dendrimer-peptide conjugates, DPCs). This approach capitalizes on the multivalent binding effect mediated by dendrimers. We found that DPCs functionalized with peptides targeting programmed death-ligand 1 (PD-L1, $DPC^{PD\text{-}L1}$), a crucial immune checkpoint protein in HNSCC, exhibit significantly lower K_D at 163 nM, which was three orders of magnitude stronger than free peptides. Furthermore, $DPC^{PD\text{-}L1}$ prolonged the serum half-life to 10.8 hours, approximately 14 times longer than that observed with PD-L1-binding peptide alone. The enhanced binding kinetics and plasma stability of $DPC^{PD\text{-}L1}$ were translated into the *in vivo* efficacy, as evidenced by a significant 40% reduction in tumor volume after four injections of $DPC^{PD\text{-}L1}$ at a dosage of 50 mg/kg in mice bearing oral carcinoma (MOC1) tumors. The transcriptomic analysis of $DPC^{PD\text{-}L1}$-treated tumor tissues revealed an increased population of CD4- and CD8-positive lymphocytes while decreasing the regulatory T cells and tumor cell proliferation, which is likely related to the observed efficacy. Expanding on this study, we have employed peptides designed to bind to the epidermal growth factor receptor (EGFR), a key player in the oncogenic pathways of HNSCC. These peptides were conjugated to G7 PAMAM dendrimer, forming DPC^{EGFR}. Similar to $DPC^{PD\text{-}L1}$, DPC^{EGFR} displayed improved binding affinity as proven by biophysical measurements and a series of *in vitro* assays. All these results highlight the versatility of our DPC platform, suggesting its potential applicability not only for targeting immune checkpoint proteins but also for intervening oncogenic pathways. With its simplicity, modularity, and versatility, this platform indicates the possibility of broadening its scope to incorporate multiple targeting and therapeutic factors, paving the way for its clinical translation, and providing new avenues in HNSCC treatment.

#4037 Optimizing the efficacy of anti-VEGF/cytotoxics/anti-PD-1 scheduling in a lung cancer mice model through B and T cells monitoring.

G. Sicard[1], D. Protzenko[1], S. Giacometti[1], R. Fanciullino[1], F. Barlesi[2], **J. Ciccolini**[1];
[1]Aix-Marseille University, Marseille, France, [2]Paris Saclay University, Paris, France

The exact modalities of combinatorial regimens associating Immune Checkpoint Inhibitors (ICI) with other treatments are yet to be defined. Understanding how and when cytotoxics best reshape tumor immunity could help optimizing the scheduling of ICI's. *In vivo* studies were performed on C57BL/6 mice grafted with LL/2lung cancer cells. A longitudinal immunomonitoring study on tumor, spleen and blood after multiple treatments including Cisplatin, Pemetrexed and anti-VEGF as single agents and in combination was performed for up to 21 days to determine the best time-window during which immune checkpoint inhibitors should be added. Finally, an efficacy study was conducted comparing the antiproliferative performance of various schedules of anti-VEGF, Pemetrexed-Cisplatin doublet, plus anti-PD-1 (i.e., immunomonitoring-guided scheduling, concurrent dosing or a random sequence). Immunomonitoring showed marked differences between treatments, organs and time-points. However, harnessing tumor immunity (i.e., promoting CD8 lymphocytes or increasing the CD8/Treg ratio) started on D7 and peaked on D14 with the anti-VEGF followed by cytotoxics combination. Therefore, a two-week delay between anti-VEGF/cytotoxic and anti-PD1 administration was considered the best sequence to test. Efficacy studies then confirmed that this sequence achieved higher anti-proliferative efficacy compared to other treatment modalities (i.e. -71% in tumor volume compared to control at the end of the study). Anti-VEGF and cytotoxic agents show time-dependent immunomodulatory effects, suggesting that sequencing is a critical feature when combining these agents with immune checkpoint inhibitors. Our efficacy study confirmed that sequencing treatments further enhances anti-proliferative effects in lung cancer models compared to concurrent dosing.

#4038 TU2218 (TGFβRI/VEGFR2 dual inhibitor) maximizes the benefit of cancer immunotherapies.

Jihyun Lee, Nam-Hoon Kim, Jeong Su Park, Jihyun Noh, Sowon Bae, Hun-Taek Kim

TiumBio Co., Ltd., Seongnam-si, Korea, Republic of

Approved anti-PD-1 antibodies play a pivotal role in driving innovative clinical outcomes through combination with cytotoxic agents, targeted therapies, or other immune checkpoint inhibitors in various cancers. Anti-PD-1 antibody-based combination therapies have led to a paradigm shift in cancer treatment from cytotoxic agents or targeted therapy to immunotherapy. Considering this change in the regimen, the clinical development of TU2218 aims to accelerate approval and clinical application by improving the efficacy and safety of clinically proven combination therapies. TU2218 is characterized by the following four mechanisms of action: 1) improvement of T lymphocyte activity, 2) suppression of Treg, 3) improvement of costimulatory signal defects, and 4) overcoming endothelial cell anergy. Based on the mechanisms of action, TU2218 is expected to show significant clinical effects when combined with immune checkpoint inhibitors by lowering the intensity of immune evasion and changing more favorably to immune checkpoint inhibitors. To test the feasibility of various combination options based on TU2218, in vivo efficacy studies were conducted in 4T1, MC38, and CT26 syngeneic tumor models. In the 4T1 of TNBC type, a level of tumor reduction was significant to $p<0.001$ on TU2218 and anti-PD-1 antibody combination group compared to vehicle, whereas anti-PD-1 antibody alone or anti-PD-1 antibody and paclitaxel combination group was not significant. Combination therapy with anti-CTLA4 antibody and anti-PD-1 antibody has been approved for some cancers but has therapeutic limitations due to safety issues such as immune-related toxicity and needs improvement. In the MC38, the effectiveness of a dose-sparing strategy of anti-CTLA4 antibody was evaluated by adding TU2218 to the anti-CTLA4 antibody and anti-PD-1 antibody combination regimen to improve safety concerns. In the anti-CTLA4 antibody sparing group, co-administration of TU2218 maintained the anti-tumor activity despite reducing 90% or 60% of the original anti-CTLA4 antibody dose. In effect, the difference in anti-tumor activity between the group with a reduced dose of anti-CTLA4 antibody and the group without was not statistically significant. In CT26, the efficacy of Lenvatinib and anti-PD-1 antibody combination therapy was compared with the combination of Lenvatinib, anti-PD-1 antibody, and TU2218. The efficacy of the Lenvatinib anti-PD-1 antibody, and TU2218 combination group was superior to that of TGI 99% and CR 67% than the Lenvatinib and anti-PD-1 antibody combination group of TGI 76% and CR 17%. Moreover, a statistical difference in anti-tumor activity between the two groups was significant at $p<0.001$. Collectively, the combination therapies using TU2218 not only improved efficacy but also showed high safety profiles without weight loss or any toxicity signs, supporting the feasibility of the combination strategy of TU2218.

#4039 Enhanced anti-cancer efficacy of the AhR Inhibitor DA-4505 in combination with anti-PD-1 treatment: Attenuation of lung metastasis and elimination of tumor.

D. Kim[1], S. Baek[2], S. Yang[2], Y. Kim[2], J. Hwang[2], S. Lee[1], S.-s. Kang[3], M. Kim[4], H. Han[4], K. Na[4], C. Lee[4], Y. Han[4], T. Han[5], H. Doh[5], J. Cho[5], D. Kim[5], D. Cha[5], J. Kim[4], Y. Byeon[4], Y. Kim[4], M. Yun[6], J. Lee[7], M. Hong[7], S. Lim[7], K.-H. Pyo[6], B. Cho[7];

[1]Brain Korea 21 PLUS Project for Medical Science, Yonsei University College of Medicine, Seoul, Korea, Republic of, [2]Yonsei University College of Medicine, Seoul, Korea, Republic of, [3]JEUK Institute for Cancer Research, JEUK Co., Ltd.,, Gumi, Korea, Republic of, [4]Severance Biomedical Science Institute, Yonsei University College of Medicine, Seoul, Korea, Republic of, [5]Dong-A ST Research Institute, Yongin, Korea, Republic of, [6]Yonsei New Il Han Institute for Integrative Lung Cancer Research, Yonsei University College of Medicine, Seoul, Korea, Republic of, [7]Division of Medical Oncology, Department of Internal Medicine and Yonsei Cancer Center, Severance Hospital, Yonsei University College of Medicine, Seoul, Korea, Republic of

Background: The Aryl hydrocarbon receptor (AhR) is one of the most predominant regulators of cancer metabolism. AhR plays a crucial role in inhibiting the activation of immune cells and promoting the growth of tumor cells. Here, we propose that a best-in-class AhR inhibitor, DA-4505, improves anti-tumor efficacy in combination with anti-PD-1.

Methods: To explore the anti-tumor effects, DA-4505 was administered at a daily dose of 10 mg/kg either alone or in combination with anti-PD-1 (10 mg/kg) in a syngeneic mouse model. Tumor volume, survival rates, and metastasis were measured, and immune profiles were evaluated using mIHC, flow cytometry, and scRNAseq.

Results: The synergistic anti-tumor effects of the DA-4505 and aPD-1 combination therapy were observed across four mouse tumor models (CT26, 4T1, LLC, TC1). The combination group demonstrated a significant improvement in anti-tumor efficacy compared to the monotherapy groups. Despite the moderate response of aPD-1 in the CT26 colon tumor model, the combination group displayed heightened anti-tumor effects through increase in CD8 T cell activity (P<0.05). In the LLC and TC1 lung cancer models, the combination therapy demonstrated improved anti-tumor effects and survival rates (P<0.001). Notably, the LLC model exhibited a significant increase in M1-type macrophages, while the TC1 model showed a significant augmentation in functional markers of $CD3^{\pm}$ T cells within the combination group (P<0.05). In both models, there was a significant reduction in the ratio of immunosuppressive M-MDSC and PMN-MDSC in the combination group. Immune depletion assays elucidated that DA-4505 mediated anti-tumor effects by increase in $CD8^{\pm}$ T cells, NK cells, and macrophages in the CT26 model. In contrast, the LLC model exhibited the contribution of macrophages and $CD4^{\pm}$ T cells to anti-tumor effects in the combination group (P<0.05). To assess the impact on metastasis inhibition, an orthotopic model of 4T1 mouse tumor was established, revealing a significantly increased anti-tumor effects and survival rate in the combination group, accompanied by a reduced lung metastasis ratio. H&E staining confirmed diminished migration of tumor tissue to adjacent areas. scRNAseq analysis of CT26 tumor samples indicated consistent changes at the gene expression level, reflecting a decrease in metastasis-related MMP and VEGF genes in the combination group and an increasing trend in cytotoxicity-related genes following DA-4505 treatment.

Conclusion: The AhR inhibitor, DA-4505, has demonstrated enhanced anti-tumor efficacy when administered in combination with anti-PD-1. Furthermore, it not only promoted tumor elimination but also demonstrated significant efficacy in inhibiting metastasis. This study highlights the potential of combining AhR inhibitors with immunotherapies for clinical treatment.

#4040 Hypoxia-induced HIF-1α/USP3 pathway promoting immune escape in lung squamous cell carcinoma.

Background: Immune escape poses a significant mechanism for tumor progress as well as enormous challenge for the treatment of lung squamous cell carcinoma (LUSC). The close association between hypoxic environments and tumor immune escape, with PD-L1 serving as a key marker, has garnered considerable attention. This study aims to delve into the molecular mechanisms underlying the regulation of PD-L1 deubiquitination by the hypoxia-induced HIF-1α/USP3 pathway, shedding light on the immune escape mechanisms in LUSC.
Methods: NSCLC cells were cultured under hypoxia condition and the expression of USP3, HIF-1α and PD-L1 were measured by Western blot. Chromatin Immunoprecipitation (ChIP) and Co-immunoprecipitation (CO-IP) were employed to elucidate the direct regulatory mechanisms of the HIF-1α/USP3 pathway in PD-L1 deubiquitination. In vitro T cell-mediated killing assays was used to investigate the functional roles of USP3 in antitumor immunity in NSCLC.
Results: We demonstrated that hypoxia score was increased in LUSC and negatively correlated with CD8+ T cell infiltration. Hypoxia as a major factor triggering LUSC cell immunosuppression and against T cell surveillance via stabilization of PD-L1. Mechanistically, USP3, induced by HIF-1α, is required for hypoxia-mediated PD-L1 stabilization in LUSC cells. USP3 inhibits the ubiquitination and degradation of PD-L1. The combination of USP3 inhibitors with PD-1/PD-L1 monoclonal antibodies significantly enhances the anti-LUSC effect, possibly through promoting the infiltration of CD8+ T and NK cells.
Conclusion: This research unveils a novel mechanism by which hypoxia, through the HIF-1α/USP3 pathway, regulates PD-L1 deubiquitination, thereby promoting immune escape in LUSC. Furthermore, our study provides a new strategy involving USP3 inhibitors in combination with PD-1/PD-L1 monoclonal antibodies, offering novel insights for molecular targeted therapy and reversal of drug resistance in LUSC.

#4041 Translational assessment of triple combination with Tislelizumab (anti-PD-1), LBL-007 (anti-LAG-3) and Surzebiclimab (anti-TIM-3) highlights its strong anti-tumor activity and clinical potential in solid tumors such as HNSCC.

Background: Therapeutics targeting PD-(L)1 have demonstrated impressive clinical activity in several type of cancers. However, only a small proportion of patients develop long-term response and resistance frequently occurs. LAG-3 and TIM-3 are inhibitory immune checkpoints frequently upregulated and co-expressed with PD-1 on tumor-infiltrating T cells, contributing to T cell dysfunction. Thus, we hypothesized that simultaneously targeting PD-1/LAG-3/TIM-3 would further restore T cell response and the triple combination of Tislelizumab (Tisle, anti-PD-1), LBL-007 (anti-LAG-3) and Surzebiclimab (Surze, anti-TIM-3) would provide greater clinical benefit.**Methods:** To evaluate the rationale and the anti-tumor activity of triple combination, LAG-3 and TIM-3 expression were analyzed in *in vitro* T cells, syngeneic mouse models and cancer patients with anti-PD-(L)1 therapy. The effects of dual blockade of PD-1/LAG-3, PD-1/TIM-3 and the triple blockade of PD-1/LAG-3/TIM-3 on T cell function were evaluated in *in vitro* activated PBMCs and the anti-tumor efficacy were evaluated in syngeneic mouse models. Relevant gene expression and immune signatures were ranked across 31 solid tumor types in TCGA.**Results:** Both LAG-3 and TIM-3 expression on T cells were upregulated by anti-PD-1 treatment in syngeneic mouse tumors, similar trend was observed in cancer patients with anti-PD-(L)1 therapy. Dual combination of Tisle/LBL-007 or Tisle/Surze enhanced IFNγ production in *in vitro* activated human T cells. The dual blockade of PD-1/LAG-3 or PD-1/TIM-3 significantly enhanced tumor growth inhibition compared with anti-PD-1 monotherapy in syngeneic mouse models. The triple combination of Tisle/LBL-007/Surze further enhanced IFNγ production in *in vitro* activated T cells. In a mouse MC38 colon carcinoma model, the triple blockade of PD-1/LAG-3/TIM-3 demonstrated enhanced anti-tumor activity compared with either dual combination, evidenced by trend of increased tumor growth inhibition and higher tumor-free incidence rate. Finally, the responsiveness of PD-1/LAG-3/TIM-3 triple combination was predicted using 5 signatures, including early effector T cell signature, inflamed signature, LAG-3, TIM-3 and PD-L1 expression. The *in silico* analyses indicated strong potential in clinical utility such as squamous cell carcinoma of the head and neck (HNSCC).**Conclusions:** The concurrent blockade of PD-1/LAG-3/TIM-3 represents a promising strategy to enhance T cell function and anti-tumor activity. The results demonstrated the therapeutic potential of the triple combination. A Ph2 study evaluating Tisle in combination with LBL-007 and/or Surze in first-line treatment of recurrent or metastatic HNSCC (NCT05909904) is recruiting.

#4042 Cbl inhibition increases the response of cytotoxic T cells to sub-optimal stimulation and drives enhanced anti-tumor responses alone or in combination with PD-1 blockade.

L. Yamashiro, S. Marubayashi, R. Rayaji, A. Battsooj, K. Mrouj, H. Singh, Y. Lee, A. Chen, L. Shen, A. Mailyan, K. Yu, M. Podunavac, J. Yu, D. Liu, C. Hardman, J. Yin, S. Gangam, K. Lawson, M. Leleti, M. Walters, D. DiRenzo;

INTRODUCTION: Herein, we describe a series of experiments to define the unique biology of dual Cbl-b/c-Cbl (Cbl) inhibition in amplifying T cell activation and anti-tumor responses. Through their E3 ubiquitin ligase activity, Cbl-b and c-Cbl have been shown to negatively regulate multiple signaling proteins downstream of the T cell receptor (TCR), suggesting that inhibition may yield enhanced anti-tumor T cell activity. Indeed, using a dual Cbl-b/c-Cbl small molecule inhibitor, we demonstrate that Cbl blockade enhances T cell activity under standard and sub-optimal stimulation conditions. Moreover, Cbl inhibition increases mouse syngeneic tumor control alone or in combination with α-PD-1, as described below.

METHODS: Human $CD8^+$ T cells were isolated from healthy human blood and activated using α-CD3 or α-CD3/CD28 stimulation. Mouse OT-I splenocytes were stimulated with SIINFEKL or lower affinity ovalbumin peptides and cytokine production was assessed. For tumor studies, mice were inoculated with syngeneic cancer cells and were treated with Cbl inhibitor (30 mg/kg, QD) +/- α-PD-1 (10 mg/kg, Q5D) starting at a tumor volume of 75 mm^3.
