Conclusion: This is the first study to suggest the potent anti-cancer activity of BAL0891 in bladder cancer. BAL0891 effectively worked on bladder cancer by two tracks which not only induced G2/M arrest but also increased in polyploidy. Furthermore, BAL0891 in combination with CDK4/6 inhibitor promoted anti-cancer effects. Lastly, this study suggests the use of TTK and PLK1 as the predictive biomarker for BAL0891. These data support further investigation of BAL0891 for the treatment of bladder cancer patients.

#5727 ISM9682A, a novel and potent KIF18A inhibitor, shows robust antitumor effects against chromosomally unstable cancers.

J. Zhang[1], F. Gao[1], W. Zhu[1], C. Xu[1], X. Ding[1], J. Shang[1], J. Qiao[1], S. Chen[1], X. Cai[1], X. Ding[1], S. Bavadekar[1], **S. Rao**[2], M. Zhang[1], F. Ren[1], A. Zhavoronkov[1]; [1]Insilico Medicine, Pu Dong Xin Qu, China, [2]Insilico Medicine, New York, NY

KIF18A belongs to the kinesin-8 subfamily and is a plus-end-directed motor, which regulates kinetochore microtubules dynamics to control mitotic chromosome alignment and spindle tension. Studies have shown that genetic depletion or pharmacological inhibition of KIF18A is a promising therapeutic approach for cancers, exhibiting high chromosomal instability (CIN-high), without having a significant impact on the normal division of euploid cells. Here, we report the discovery and preclinical evaluation of ISM9682A, a novel KIF18A inhibitor with excellent potency and high selectivity. ISM9682A is a potent KIF18A inhibitor with a single-digit nanomolar IC_{50} value and exhibits high selectivity over other kinesin family members. In addition, ISM9682A demonstrated excellent monotherapy anti-proliferative activity, with single-digit nanomolar IC_{50} values, in high-grade serous ovarian carcinoma (HGSOC) as well as in triple-negative breast cancer (TNBC) aneuploid cell lines with p53 mutation. Notably, ISM9682A exhibited a prolonged drug-target residence time indicated by both enzymatic and cellular assays. Consistent with the *in vitro* findings, ISM9682A displayed significant anti-tumor efficacy with a robust pharmacodynamic response (pH3, mitotic marker; γH2AX, DNA damage marker) in OVCAR3 and HCC1806 CDX models in a dose-dependent manner. In addition to its robust biological potency and high selectivity, ISM9682A exhibits favorable drug-like properties, including desirable *in vitro* ADMET characteristics and excellent *in vivo* exposure, clearance, as well as good oral bioavailability across multiple preclinical species. Collectively, these findings highlight the potential of ISM9682A as a novel and highly potent KIF18A inhibitor for the treatment of CIN-high cancers.

#5728 YB1 is a novel therapeutic for the treatment of triple negative breast cancer tumors.

W. Wang[1], L. Khalki[1], N. Zai[1], J. Szpendyk[2], A. Alkrekshi[2], B. Su[3], K. Sossey-Alaoui[1];
[1]Case Western Reserve University School of Medicine, Cleveland, OH, [2]MetroHealth System, Cleveland, OH, [3]Cleveland State University, Cleveland, OH

Metastatic breast cancer (BC) is the 2nd leading cause of death in women in the US, annually accounting for more than 43,000 deaths and 281,000 new cases of invasive BC. Amongst genetically distinct BC subtypes, those classified as being “triple-negative” (TNBC) are especially devastating due to their highly metastatic behavior, their propensity to recur rapidly, and their low response to standard-of-care therapies. In fact, the acquisition of chemoresistant phenotypes represents the main cause of disease recurrence, metastasis, and death in TNBC patients. Currently, the molecular mechanisms that regulate TNBC progression and metastasis remain unknown, as does the way these metastatic tumors acquire resistance to standard-of-care therapies. We recently established YB1 as a novel driver of these deadly TNBC activities, doing so by stimulating the cancer stem cell phenotype, and by disrupting normal cell cycle progression, therefore promoting therapy resistance and metastasis of TNBC tumors. YB1 is a multifunctional protein that acts as a transcription factor of cancer stem cell genes Nanog, Oct and Sox. Moreover, aberrant activation of YB1 contributes to the metastatic progression of several cancers, including TNBC. Our investigations revealed a major role of YB1 in the regulation of several hallmarks of cancer that drive TNBC tumors progression and metastasis, both in vitro and in preclinical mouse models of TNBC tumors. In extending these discoveries, we now show that aberrant YB1 expression activates oncogenic signaling leading to the dysregulation of cell cycle progression through the regulation of the Cyclin D/CDK4/6 complex signaling and the RB pathway. We also report the identification of a novel small molecule inhibitor, SU056, that specifically targets YB1 and inhibits its oncogenic activity in TNBC cell lines. We further show that the SU056-mediated inhibition of YB1, either as monotherapy or in combination with the CDK4/6 inhibitors, has a significant impact on inhibiting TNBC tumor progression and metastasis. In fact, the SU056-CDK4/6 inhibitors combination showed a synergistic effect when compared to monotherapy, at the same time reducing the toxicity associated with CDK4/6 inhibitors. Mechanistically, our studies revealed that genetic or pharmacologic targeting of YB1 inhibits TNBC tumor progression and metastasis through the regulation cyclin D-CDK4/6-RB pathway and blockade of cell cycle progression. Together, our data support the notion that targeting YB1 represents a potential therapeutic option for the treatment of TNBC, which could be enhanced when combined with standard of care treatment modalities.

#5729 ADCK1 inhibition alters cell proliferation and cell cycle progression in liver cancer cells.

N. A. Jacquet, Y. Zhao;
LSU Health Sciences Center - Shreveport, Shreveport, LA

In 2020, there were over 830,000 reported liver cancer deaths. Incidence rates of liver cancer have tripled, and death rates have doubled since the 1980s; giving this disease one of the highest mortality rates when compared to its incidence rate. Hepatocellular carcinoma (HCC) is derived from hepatocytes and is the main type of liver cancer in adults, accounting for 75-85% of all primary liver cancers. Current treatment options for HCC like radiation therapy and chemotherapy are imperfect and cause significant side effects. Tumorigenesis is dependent on an organism's cellular metabolism. Metabolic reprogramming is a promising area of focus for cancer therapeutics. Cancer cells thrive in nutrient-deficient environments by hijacking and reprogramming the cells existing cellular metabolism. Metabolic reprogramming is driven by genetic alterations and environmental cues. AarF Domain Containing Kinase 1 (ADCK1) is a protein-coding gene that acts as a mitochondrial protein with putative kinase activity. The role of ADCK1 has not been well studied, particularly in liver cancer. Our group has sought to study how ADCK1 impacts the metabolism and cellular environment of HCC cells to help establish a more effective drug target. Bioinformatics performed by our lab report that ADCK1 was highly expressed in HCC tumor cells. The expression levels of ADCK1 were also correlated with a decrease in patient survival. ADCK1 knockout clones were generated; these knockout cells showed decreased proliferation and altered cell cycle progression. Proteomics analysis demonstrated that loss of ADCK1 was also seen to alter the expression of proteins involved in several cellular processes related to the cell cycle and cellular metabolism. How ADCK1 regulates these processes will be studied in the future.

#5730 Targeting the cell cycle with AZD8421, a potent and highly selective CDK2 inhibitor.

C. R. Denz[1], M. Grondine[1], J. Fan[1], J.-R. Hsu[1], A. Jackson[2], J. Robinson[2], G. Guo[1], W. Li[1], Y. Wang[1], M. San Martin[1], L. Prickett[1], J. Johannes[1], A. Ghosh[1], D. Sudhan[1], C. Vasalou[1], R. Richards[1], K. Beaumont[1], M. Peters[1], L. Drew[1], S. Fawell[1], **F. W. Goldberg**[1];

[1]AstraZeneca Pharmaceuticals LP, Waltham, MA, [2]AstraZeneca Pharmaceuticals LP, Cambridge, United Kingdom

Cyclin-dependent Kinase 2 (CDK2) is a Ser/Thr kinase activated via interaction with its cyclin partners CCNE and CCNA, driving G1/S progression of the cell cycle. CDK2 inhibition has the potential to address multiple resistance mechanisms to CDK4/6 inhibitors in breast cancer. In addition, CCNE1 is frequently amplified and over-expressed in cancers including ovarian, uterine, breast, gastric and others, with pre-clinical data linking CDK2 inhibition sensitivity to high CCNE1. The CDK2 inhibitor field has historically suffered from high attrition in Phase I due to off-target toxicity. AZD8421 is a uniquely selective CDK2 inhibitor, that offers potential to show improved therapeutic index and combinability. As well as achieving CDK family selectivity in cells versus key off-targets (CDK1, CDK4/6, CDK9), AZD8421 had no significant kinase inhibition outside the CDK family. Only 7 distinct targets showed greater than 50% inhibition in a panel of 403 kinases when screened with 1µM of AZD8421. In nanoBRET assays measuring cellular target engagement, AZD8421 had an IC50 against CDK2 of 9nM with selectivity over CDK1, CDK4 and CDK6. In vitro cellular assays demonstrated that AZD8421 inhibits endogenous phospho-substrate at 58nM with >327-fold selectivity over CDK9 phospho-substrate pSer2 of RNAPII (>19.2 µM). In a CCNE1 amplified cell line, AZD8421 potently inhibited cell proliferation (69nM, OVCAR3), correlated with inhibition of pRB, arrest in G1/S phase of the cell cycle and induction of senescence, compared to a CCNE1 non-amplified cell line (SKOV3) with IC50 of 2.05 µM. In vitro combination assays in CDK4/6 inhibitor resistant breast cancer cell lines showed combination benefit with AZD8421 plus approved CDK4/6 inhibitors. In vivo, AZD8421 potently suppressed phosphorylation of Rb, and demonstrated robust monotherapy and CDK4/6i combination activity in breast and ovarian in vivo models. In vivo PD marker suppression and efficacy was demonstrated in CDK4/6 inhibitor resistant breast PDXs in combination with palbociclib (CDK4/6i). AZD8421 showed robust monotherapy activity in a CCNE1 amplified ovarian model OVCAR3 with regressions seen with monotherapy and in combination with palbociclib. Monotherapy activity and combination benefit in vivo with standard of care agents was also observed in ovarian PDX models with elevated levels of CCNE1. AZD8421 is a potent and highly selective CDK2 inhibitor, with double digit nM potency in cells, as well as suitable physical and pharmacokinetic properties for progression into the clinic.

CHEMISTRY: Drug Delivery
Poster Session

#5733 Development of a topoisomerase 1 inhibitor platform technology for efficacious and well tolerated ADCs.
R. Lyski, L. Bou, J. Sigurjonsson, D. Meyer, C. Neace, D. Ortiz, K. Snead, K. Smith, S. Jin, N. Stevens, J. Cochran, K. Alizadeh, N. Yeddula, E. McKinney, A. Peterson, L. Dotloe, J. Simmons, C. Carosino, K. Emmerton, N. Everds, S. Jeffrey, P. Senter;
Seagen Inc., Bothell, WA

Topoisomerase 1 (TOP1) inhibitors are a class of cytotoxic small molecules that have demonstrated effectiveness as therapeutic agents in cancer. However, the broad clinical application has been hindered by poor pharmacokinetic profiles and off-target toxicities. Antibody-drug conjugates (ADCs) enable the targeted delivery of cytotoxic payloads by specifically targeting cell-surface antigens expressed on cancers reducing systemic exposure and toxicity. TOP1-ADCs have received FDA approval for HER2- (trastuzumab-deruxtecan) and Trop2- (sacituzumab-govitecan) expressing solid tumors, demonstrating the promise for this drug class to improve the lives of patients. We have developed a novel drug-linker using a potent TOP1 inhibitor with desirable ADME properties, and a hydrophilic glycoside linker as a platform technology enabling ADCs with favorable physicochemical and biological properties. The TOP1 inhibitor payload was optimized for potency, with reduced P-glycoprotein efflux and enhanced permeability. The hydrophilicity of the linker facilitates the development of highly loaded ADCs (8 drugs/mAb) with high plasma stability, low aggregation, and pharmacokinetics similar to parental antibody. The resultant ADCs are potent and immunologically specific with activity in multidrug-resistant tumor models and bystander activity in heterogenous antigen models. Human cancer cell derived xenograft models demonstrated potent and specific ADC anti-tumor activity with several targets and indications. Improved activity was observed compared to corresponding govitecan- and deruxtecan-based ADCs. ADCs prepared from this drug-linker technology were well tolerated in rats after repeat administration of 60 mg/kg every 4 days for 4 doses. The excellent anti-tumor activity in several models and favorable safety profile demonstrates this platform TOP1 drug-linker technology has the potential for development as ADCs against many cancer targets.

#5734 Polymeric delivery with dual drug payloads for hepatocellular carcinoma (HCC) therapy.

L. Dai[1], G. Zhang[2], F. Dagher[1], A. Li[1], A. Gholizadeh[1], C. Li[2], D.-. Chow[1];

[1]University of Houston, Houston, TX, [2]University of Texas MD Anderson Cancer Center, Houston, TX

Background: The long-term survival of hepatocellular carcinoma (HCC) patients is hampered by high recurrence and drug resistance. Targeting sonic hedgehog (SHH) pathways can overcome drug resistance in HCC. In this study, we co-loaded SHH inhibitor, cyclopamine (CPA) and paclitaxel (PTX) in a novel polymeric nanomicellar drug delivery system (M-CPA/PTX), to overcome the drug resistance in HCC tumor models.

Method: The combinational effect *in vitro* was studied by treating HCC with CPA and PTX. The combinational index was calculated using CalcuSyn Biosoft software to determine the additive or synergistic effect of the combination. Three formulations (F0, F5, and F16) were selected for further testing based on formulation optimization using central composition design (CCD). The storage stability of M-CPA/PTXs at room temperature and 4 °C was evaluated by measuring the changes in micelle size, PDI, and encapsulation efficiency (EE) over pre-determined periods. In the pharmacokinetics (PK) study, nude mice were IP-injected with 5 mg/kg of PTX equivalent F0 and F16. Additionally, the toxicity of F0 was investigated using healthy Sprague Dawley rats, in which rats were intravenously injected with a single F0 dose of 1, 2, and 4 mg/kg/drug of M-CPA/PTX.

Results: Combinational effect study suggested that CPA and PTX, demonstrated synergistic effect in Hep3B and HepG2 cells compared to the mono-treatment, thus overcoming resistance. F0, F5, and F16 exhibited particle sizes of 75.27 ± 1.06, 54.63 ± 0.85, and 70.63 ± 3.39 nm, respectively. The release kinetics of both drugs from these micelles displayed significantly slow-release profiles from the micelles, with less than 10% cumulative release within 24 hours in plasma. The stability study indicated that both drugs' micelle size and EE were not appreciably changed over 6 weeks at room temperature and 4 °C. Notably, the biodistribution studies showed that F16 achieved significantly greater accumulations of CPA in the liver, kidney, and spleen compared to F0 ($P < 0.05$). Additionally, the maximal tolerable dose of F0 in rats was 4 mg/kg/drug for the M-CPA/PTX combination, which did not result in treatment-related mortality.

Conclusion: The combination of CPA and PTX offered promising synergistic effects on HCC treatment. F0, F5, and F16 were developed and characterized with the desired physicochemical properties and demonstrated controlled release characteristics for both payloads, suggesting their potential for sustained drug delivery in HCC therapy. Enhanced liver accumulation of F16 suggested favorable biodistribution for the site of action. Lastly, the safe toxicity profile supports the first choice of F0 among other lead candidates for further pre-clinical efficacy studies.

#5735 Efficient and safe delivery of doxorubicin by DNA fragments: A full preclinical study.

M. Park[1], Y. Kim[1], H. Cho[1], S. Mohammad[2], Y. Choi[2], H. Lee[1], S. Lee[1], E. Cedrone[3], B. Neun[3], M. Dobrovolskaia[3], D. Fruman[2], J. Kim[1], Y. Kwon[2]; [1]Pharma Research.Co., Ltd., Seongnam-si, Korea, Republic of, [2]University of California, Irvine, Irvine, CA, [3]National Cancer Institute, Frederick, MD

The clinical uses of anthracyclines (e.g., doxorubicin) are hampered especially by dose-dependent cardiac toxicity, resulting in a narrow therapeutic window. Doxorubicin formulations have marginally improved its therapeutic efficacy while suffering from difficult and costly manufacturing, poor characterization and quality control, limited scalability in production, and disappointingly low drug loading. This study employs DNA fragments extracted from the salmon sperm cells, which is known for high biocompatibility in various biomedical application, to self-assemble via intercalation by doxorubicin. DNA/DOX nanocomplexes are easy in manufacturing, high scalability, straightforward characterization and quantification, and efficiency in drug loading. Doxorubicin and DNA fragments were dissolved in water and mixed at the optimized 1:6 weight ratio, followed by stirring and incubation for 30 min. DNA/DOX nanocomplexes were characterized for doxorubicin loading and release, size, surface charge, and morphology by UV/fluorescence spectroscopy, stable isotope tracer ultrafiltration assay (SITUA), dynamic light scattering particle analysis, and transmission electron microscopy. The anticancer efficacy of the DNA/DOX nanocomplexes were tested in vitro and in vivo using syngeneic and PDX tumor models. Along with PD/PK studies, DNA/DOX nanocomplexes were also evaluated for their systemic and cardiac toxicity. Characterization and quantification studies revealed DNA/DOX nanocomplexes to be relatively monodisperse with a size of 40 nm in diameter, efficient for drug encapsulation (~100%) and drug loading (14.3%, w/w), and stable for storage while readily releasing doxorubicin in a cell. The self-assembled nanocomplexes were formed when doxorubicin inter- and intra-molecularly chelated DNA fragments. DNA/DOX nanocomplexes were more efficient in killing cancer cells in vitro than both doxorubicin and the liposomal doxorubicin Doxil. PD/PK studies demonstrated that DNA/DOX nanocomplexes circulated longer with less accumulation in the heart than doxorubicin, which altogether lower toxicity. A repeated administration of the DNA/DOX nanocomplexes to Sprague-Dawley rats exhibited a substantially lower cardiotoxicity score than that of doxorubicin. The improved anti-tumor efficacy of the DNA/DOX nanocomplexes were finally confirmed using a syngeneic lymphoma mouse model and PDX mouse models of triple-negative breast and ovarian cancers. Complexing doxorubicin with DNA fragments addresses the current technological challenges in achieving an efficient and safe therapy for a broad range of cancers. DNA/DOX nanocomplexes are amenable to rigorous chemistry, manufacturing, and controls (CMC) evaluation with proven anti-cancer efficacy and improved safety profiles. Clinical trials on DNA/DOX nanocomplexes for cancer chemotherapy are warranted to fully validate their clinical utilities.

#5736 Sonochemical preparation of SP94 peptide-decorated pH-responsive biodegradable biopolyester nanoparticles for targeted therapy in hepatocellular carcinoma.

M. Wu[1], Q. Wang[1], Z. Gong[1], Z. Liu[1], H. Zheng[1], X. Chen[1], **C. Zhong**[2];
[1]Zhejiang University of Science and Technology, Hangzhou, China, [2]Westlake University, Hangzhou, China

Stimulation in response to nanoparticles responding to endogenous stimuli in the tumor microenvironment has been extensively studied for the release of chemotherapeutic drug. Therefore, we aimed to develop a biocompatible delivery of taxol (TAX) delivery vector system for the treatment of hepatocellular carcinoma (HCC). A basic backbone, TAX loaded poly (3-hydroxybutyrate-co-3-hydroxyvalerate) PHBV nanoparticle (PHBV-TAX-NPs), were designed and prepared via sonochemical method. The pH-responsive shell of PHBV-TAX-NPs was formed by oxidative self-polymerization of dopamine (PDA) in an alkaline environment. The HCC-targeted peptide SP94 binds to PDA-coated nanoparticles (NPs) through the Michael reaction. Moreover, the nanoparticle surface-grafted SP94 peptide serve as a specific ligand for targeting HCC. The chemical structures and properties of these nanoparticles were characterized by transmission electron microscope, dynamic light scattering-autosizer, differential scanning calorimetry, fourier transform infrared spectroscopy, X-ray photoelectron spectroscopy and thermogravimetry. As expected, excellent targeting of these SP94-PDA-PHBV-TAX-NPs was demonstrated by cellular uptake and cytotoxicity experiments in HCC cells. Compared with that of free TAX, the SP94-PDA-PHBV-TAX-NPs showed more superior antitumor efficacy in the xenograft mouse model. Notably, the SP94-PDA-PHBV-TAX-NPs were except for their potent anticancer activity, it was less toxic *in vitro* and *in vivo* compared to TAX in mice. These studies suggest the potential beneficial use of SP94-PDA-PHBV-TAX-NPs in future HCC-targeted therapy with drug-loaded nanocarriers.

#5737 Enhancing cancer treatment Via a nanostructured chemoimmunotherapy gel facilitating interleukin-2 delivery and immunogenic cell death induction.

H. Mu[1], Y.-N. Ta[1], J. M. Tham[2], F.-F. Hsu[3], Y.-C. Lin[1], H.-C. Huang[1], Y.-C. Sung[1], C.-I. Huang[1], C.-L. Wu[1], C.-H. Chang[1], S. Yang[1], T.-Y. Lee[1], J. Wang[1], D. Duda[4], Y. Boucher[4], J.-H. Huang[1], W. Ang[2], Y. Chen[1];

[1]National Tsing Hua University, Hsinchu City, Taiwan, [2]National University of Singapore, Singapore, Singapore, [3]Academia Sinica, Taipei, Taiwan, [4]Massachusetts General Hospital and Harvard Medical School, Boston, MA

Background: The landscape of immunotherapy, employing recombinant cytokines like interleukin-2 (IL-2), confronts challenges marked by its short half-life, systemic toxicity, and constrained tumor accumulation. These hurdles are particularly evident in the context of the immunosuppressive milieu characterizing pancreatic ductal adenocarcinoma (PDAC). Chemo-immuno-therapeutic synergies, notably those provoking immunogenic cell death (ICD), have demonstrated superior efficacy. This investigation delves into Pt-NHC as a type II ICD inducer to surmount immunosuppression and amplify antitumor immunity within a highly tumor-accumulated liposomal drug delivery system. Additionally, the co-administration of the angiotensin receptor blocker, losartan, mitigates desmoplasia in PDAC, further augmenting the efficacy of immunotherapy.

Methods: To address the constraints of IL-2, a lipid-coated nanogel, IL2-Pt@Nanogel, was innovated, amalgamating silk fibroin-loaded IL-2 with Pt-NHC. The nanogel aimed to enhance IL-2 pharmacokinetics and optimize tumor targeting. Concurrently, losartan was employed to alleviate desmoplasia within the tumor microenvironment.

Result: The chemoimmunotherapy nanogel, when coupled with losartan, showcased therapeutic potential in murine models of desmoplastic PDAC. Pt-NHC induced ER-localized reactive oxygen species (ROS) and DAMP release, reshaping the immunosuppressive microenvironment by repolarizing M2-type macrophages to M1 and diminishing the regulatory T-cell population. Co-delivery of IL-2 and Pt-NHC in the nanogel enhanced T-cell infiltration and activation, curbing tumor progression in primary and liver metastasized PDAC models. Importantly, the addition of losartan reduced collagen accumulation within tumors, resulting in heightened infiltration of effector T cells and more pronounced suppression of tumor growth in PDAC and metastasized liver.

Conclusion: This study introduces an innovative nanogel delivery system (IL2-Pt@Nanogel) for chemoimmunotherapy, effectively addressing the challenges associated with IL-2 therapy. Leveraging the enhanced permeability and retention (EPR) effect, the nanogel improves IL-2 stability and tumor delivery. Pt-NHC incorporation induces ICD, reshaping the tumor microenvironment, and in synergy with losartan, elicits robust anticancer immunity. This strategy holds promise for clinical translation as a secure and efficient treatment for immunosuppressive and desmoplastic cancers, such as PDAC, presenting a distinctive therapeutic avenue.

#5738 Repurposing disulfiram for cancer: A drug delivery and population-based approach.

D. Heroux, A. W. Y. Leung, R. Gilabert-Oriol, M. B. Bally;
BC Cancer Research Institute, Vancouver, BC, Canada

Purpose: Disulfiram was approved by the FDA for treatment of alcohol abuse in 1951, although for over 40 years there has been evidence supporting disulfiram's use as an anti-cancer drug. Upon administration, disulfiram is hydrolyzed to form two molecules of DDC, which upon binding Cu forms $Cu(DDC)_2$, the proposed active form against cancer. It was our goal to formulate the water-insoluble $Cu(DDC)_2$ in liposomes to facilitate its repurposing for breast and colon cancers. In addition, we also initiated an ongoing population-based study assessing the protective and treatment effects of disulfiram with cancer.
Methods: $Cu(DDC)_2$ liposomes were generated by the thin-film hydration method followed by extrusion, using DSPC and cholesterol (55:45 molar ratio). DDC and $CuSO_4$ were added to the liposomes forming $Cu(DDC)_2$, which was transported inside the liposomes. Anti-tumor activity was evaluated in tumor-bearing mice with or without competent immune systems, and immune system activation was assessed via a cancer vaccination model and the expression of markers of immunogenic cell death (ICD). A study was also initiated for cancer cases and controls in British Columbia (BC Cancer) with at least one prescription of disulfiram from 1996-2022 (PharmaNET), patients treated with immune-modulating therapies (BC Cancer), and outcome of death (Vital Statistics).
Results: Liposomes encapsulating $Cu(DDC)_2$ had a size of 100 nm and polydispersity of 0.1, and caused a 40% reduction in tumor burden in a MDA-MB-231 xenograft model. In a syngeneic tumor model of breast cancer the response with immune-competent mice was greater than mice lacking immune function, and a cancer vaccination model and the presence of ATP, HMBG1 and surface-exposed calreticulin indicated the presence of ICD.
Conclusions: $Cu(DDC)_2$ was formulated in liposomes facilitating its parenteral administration, and its anti-cancer activity was found to be due in part to activation of the adaptive immune system through ICD. A case-control study is currently being employed to examine the clinical potential of disulfiram, as a protectant and as an adjuvant with immune-activating therapies such as checkpoint inhibitors and anthracyclines to potentially improve efficacy through induction of ICD.

#5740 Peptide-functionalized dendrimers for enhanced binding to immune checkpoint proteins.

P. A. Rawding[1], F. Coppola[2], D. Kim[1], M. Poellmann[1], D. Wheeler[1], P. Kral[2], S. Hong[1];
[1]University of Wisconsin-Madison, Madison, WI, [2]University of Illinois at Chicago, Chicago, IL

The human immune system has complex and dynamic mechanisms to distinguish and eliminate malignant cells and defend the body against cancer. Various therapeutic approaches to stimulate the immune system have thus been investigated, demonstrating strong anti-tumor immune responses capable of controlling metastasis and preventing recurrence. Nevertheless, existing cancer immunotherapies suffer from several limitations, including inconsistent benefits across cancer types and patients. In recent years, the utilization of peptides for immunotherapy has attracted a great deal of interest due to their ability to mimic protein functionalities while maintaining a high degree of modularity and synthetic reproducibility in their molecular design. However, the clinical translation of otherwise promising peptide-based immunotherapeutics has been hindered due to their significantly weaker binding to target proteins and short half-life in plasma circulation in comparison to their monoclonal antibody counterparts. Nevertheless, these issues can potentially be addressed by conjugation to nanoparticles, which enhances cell binding/uptake and prolongs circulation. To this end, our group has extensively investigated the use of poly(amidoamine) (PAMAM) dendrimers to improve the therapeutic utility of peptides. These dendrimers can facilitate the simultaneous binding of conjugated peptides to multiple cell receptors, resulting in a significantly enhanced binding interaction through the multivalent binding effect. Here, we report an efficient de novo nanoparticle design strategy that combines organic synthesis, phage display, and molecular dynamics to identify a novel immuno-oncology therapeutic modality. We first employed phage display to identify several highly selective sequences that bind to the mouse ortholog of TIGIT—an inhibitory receptor expressed on lymphocytes that has been identified as a potential therapeutic target to enhance anti-tumor immune responses. Subsequent computational modeling (NAMD with CHARMM force field) revealed several conserved regions of interaction that we hypothesize drive favorable binding interactions and enhance the binding affinity of the peptide inhibitors. We next incorporated experimental kinetic measurements of the identified sequences with adaptive evolution computational modeling to identify optimized mutant analogs for dendrimer conjugation. It was found that the TIGIT targeting DPCs (dendrimer-peptide conjugates) demonstrated increased binding avidity *in vitro* and anti-tumor efficacy *in vivo*, most notably when administered in combination with PD-L1 targeting DPCs to a syngeneic mouse model bearing mouse oral carcinoma (MOC1) tumors. Overall, this work demonstrates the potential of rational peptide design and our multi-functional DPC platform for the development of both effective and novel immuno-oncology therapeutics.

#5741 siteDAR, complete antibody drug conjugate, ADC characterization.

W. L. Martin, M. Senseney, B. Kusuma, J. Dugal-Tessier, **N. Jain**;
NJ Bio, Inc., Princeton, NJ

Antibody drug conjugate characterization currently extends to the global determination of the drug -to- antibody ratio (DAR). However, there can be confounding batch variability in pharmacological outcome from ADCs of the same drug, antibody, and DAR. Previously, DAR was obtained by quantifying the extent of modification of the intact antibody or its protein subunits. The coupling chemistry is used to infer which type of amino acids were modified but generally no specific sites of modification are identified and if identification is obtained, it is not quantitative. Borrowing the rigorously reproducible proteolytic digestion methods from multi-atribute mapping (MAM) used in monoclonal antibody manufacture, and compiling a comprehensive quantitative assignment of every abundant peptide in the ADC digest we can both calculate a DAR from the ion volume ratios and a quantitative map of the specific modified sites. This method, termed “siteDAR”, is applied here to both commercial Kadcyla® (ado-trastuzumab emtansine) and in-house preparations of ado-trastuzumab emtansine. We show that preparations of Kadcyla® with the same DAR can have significantly different quantitative maps of modification sites. We use siteDAR analysis in our ADC design cycle to characterize an ADC, and have developed an ADC synthesis method that was quantitatively verified, and had increased biosimilarity with commercially available Kadcyla®. siteDAR for commercial Kadcyla siteDAR for initial in-house Kadcyla Initial biosimilarity

#5742 Therapeutic efficacy of CA102N in pancreatic cancer.

L. Lin, S. Tu, **E. Tchaparian**;
Holy Stone Healthcare, Taipei, Taiwan

Pancreatic ductal adenocarcinoma (PDAC) is a challenging cancer to treat due to its aggressive nature and late-stage diagnosis. Considering the lack of effective therapies, there is an urgent need to develop new and effective therapeutics to improve the prognosis of patients. CA102N is a carrier-mediated novel anticancer product where hyaluronic acid is conjugated to Nimesulide-NH2. CA102N is currently under development for the treatment of solid tumors, including colorectal cancer. CA102N was safe and well tolerated in the first-in-human trial in patients with locally advanced or metastatic solid tumors. In the present study, the *in vitro* anticancer activity of CA102N was investigated in K-ras mutant PANC-1 pancreatic cancer cells. The antitumor efficacy was also tested *in vivo* in the PANC-1 mice model. Results demonstrated that CA102N inhibits cell growth, cell migration, angiogenesis, and cell proliferation in both K-ras mutant PANC-1 pancreatic cancer cells or tumors. Administration of CA102N in PANC-1 xenografts resulted in a dose-dependent and statistically significant decrease in tumor growth at 9.8 mg/kg and 14.7 mg/kg Nim equivalents, respectively, compared to the vehicle control group. A significant decrease (80%) in liver metastasis was also noted in the PANC-1 orthotopic mice model at 19.6 mg/kg Nim equivalents dose level. Mechanistically, CA102N was found to suppress the PI3k/Akt/mTOR and Raf/MEK/ERK signaling pathways, in addition to reducing the expressions of the N6-methyladenosine (m6A) reader and writer proteins, OCT3/4 transcription factor and RAS levels *in vivo*. CA102N also modified the tumor stroma and improved drug permeability *in vivo.* Based on this compelling data, CA102N shows promise as a potential treatment for pancreatic cancer. Combination therapies and regimens are currently being explored in *in vivo* models as a strategy for clinical development.

#5743 Liposome platform enables X-ray induced photodynamic therapy treatment against human triple negative breast cancer cells.

B. Yang[1], R. Sang[1], Y. Li[1], E. Goldys[1], **W. Deng**[2];
[1]University of New South Wales, Kensington, Australia, [2]University of Technology Sydney, Sydney, Australia

In this study, we employed X-ray induced photodynamic therapy (X-PDT) for the treatment on triple negative breast cancer (TNBC) cells. To do this, we rationally developed a liposome delivery system co-loaded with protoporphyrin IX (PPIX) and perfluorooctyl bromide (PFOB). Low-dose X-ray at 2Gy was employed to activate PPIX for reactive oxygen species (ROS) generation, and the co-loading of PFOB provided additional oxygen to augment ROS production. The highly toxic ROS triggered TNBC cell death. *In vitro* X-PDT effects including intracellular ROS generation, cytotoxicity, cell viability and apoptosis/necrosis assay in TNBC cells were studied. Our results indicate that the nanocarriers effectively induced X-PDT effect with very low dose radiation, which makes it possible to damage cancer cells. Our strategy may offer a paradigm-shifting treatment alternative for TNBC patients who need neoadjuvant radiotherapy but wish to avoid long term detrimental effect on functional outcome by undergoing X-PDT using only a fraction of the conventional radiotherapy.

#5745 Electrosprayed minocycline and temozolomide-loaded PLGA microparticles for the treatment of glioblastoma.

A. Rodriguez, J. Quintanilla, J. Amieva, M. A. Arriaga, S. Nievera, I. Davila, K. S. Martirosyan, S. Chew;
The University of Texas Rio Grande Valley, Brownsville, TX

Glioblastoma multiforme (GBM), the most common and aggressive form of malignant brain tumor, leads to poor prognoses with high rates of reoccurrence and low survival rates, therefore, it is vital to explore alternative treatments for GBM. Minocycline, a commonly used antibiotic and tetracycline derivative, has proven anti-angiogenic effects and the ability to inhibit tumor growth, making it an effective GBM treatment. Temozolomide is an alkylating antineoplastic agent and the current first-choice chemotherapy agent for GBM. Poly(lactic-co-glycolic acid) (PLGA) is widely used as a biomaterial for drug delivery due to its inert properties, great biocompatibility and versatility and has been approved by the FDA. Therefore, the objective of this project is to fabricate electrosprayed minocycline- and temozolomide-loaded PLGA microparticles with optimal morphology, drug loading, loading efficiency, and drug release kinetics for the treatment of GBM. The microparticles were fabricated by electrospraying vertically with a 2ml/hr flow rate, 14kV voltage, 20 cm distance for minocycline and a 10ml/hr flow rate, 10kV voltage, 10 cm distance for temozolomide with both collected on a copper/glass plate. The parameters that were investigated were the chamber humidity, duration of spraying, and the addition of polyethylene glycol (PEG), a hydrophilic polymer. To determine the microparticles' morphology, bright-field microscopy and scanning electron microscopy (SEM) were used. The absorbance measurements at 350 and 327 nm were used to determine drug loading, loading efficiency, and release kinetics for minocycline and temozolomide, respectively. Microparticles with low chamber humidity and duration of spraying were more spherical, less aggregated and easier to collect for both drugs. The addition of PEG to minocycline-loaded microparticles led to higher drug loading and loading efficiency (4.02% ± 0.34, 64.30% ± 5.47 vs. 3.23% ± 0.29, 49.40% ± 4.49) as the PEG helps the solubilization of minocycline. Using acetonitrile instead of dichloromethane as the solvent, increased drug loading and loading efficiency (4.72% ± 0.76, 70.77 ± 11.43 vs. 2.37% ± 0.27, 35.62% ± 4.09) for temozolomide-loaded microparticles as more temozolomide can be solubilized in acetonitrile. Drug release kinetics demonstrated a burst release of minocycline in the first hour (65.46%). To decrease the burst release, the microparticles can be incorporated into a scaffold or depot. Overall, electrospraying is a promising method to fabricate drug loaded PLGA microparticles with high drug loading, loading efficiency, and right morphology and we determined optimal parameters to successfully fabricate electrosprayed drug loaded PLGA microparticles in the micron size range with high drug loading and loading efficiency compared to the often-used emulsion solvent extraction/evaporation for microparticle fabrication.

#5746 Tris(4-methoxyphenyl) methanol conjugates of triptorelin as cell-penetrating anti-cancer prodrugs.

Ryan Beni, William Boadi, Jawzah Alnakhli, Samiyah Alhamed

Tennessee State University, Nashville, TN

Triptorelin® (TRP) is an anti-cancer drug used for the treatment of a wide range of hormone-responsive cancers, including prostate cancer. The increase in testosterone levels, known as the flare effect, is a major side effect of cancer chemotherapy when TRP is used in a combination regimen. Reports indicate that enhancing the cellular uptake and retention of TRP can improve its biological activity. In this study, TRP conjugates of tris(4-methoxyphenyl) methanol derivatives (TPMs) with optimized hydrophobicity were synthesized by reacting 2-substituted methoxybenzenes with 1,3,5-trioxane, followed by conjugation with TRP and sebacic acid to produce TRP-TPMs derivatives. The hydrophobicity of TRP was optimized by using the appropriate hydrophobic linker attached to the respective TPM to improve cellular uptake. The aim of the current studies was to evaluate the respective antiproliferative effects of the newly synthesized TRP-TPMs, physical mixtures of TPMs and TRP using different cell lines. Our hypothesis was that exposure of cells to TRP-TPMs derivatives can enhance the antiproliferative activities in cells in comparison to respective the physical mixtures and TRP. Antiproliferative studies in human acute lymphoblastic leukemia (CCRF-CEM), human ovarian adenocarcinoma (SK-OV-3), and mouse preadipocytes (3T3-L1) were carried out following exposure to the respective compounds. Our findings indicate that TRP-TPMs conjugates, at a concentration of 50 µM, significantly inhibited cell proliferation in CCRF-CEM, SK-OV-3, and 3T3-L1 cells by 21-37%, 24-73%, and 37-56%, respectively, following 72-hour incubation in comparison to the respective physical mixtures and TRP. Conjugation of TRP with the respective derivative of TPMs enhanced antiproliferative activities in all the cells (with no significant differences in cytotoxicity) compared to the physical mixtures of TPMs and TRP. The findings in the current studies suggest that TRP-TPMs can be used as potential prodrugs, to enhance the cells biological activity, and cellular uptake of TRP.

#5747 Microwave responsive thermosensitive lipid nanoparticles for spatiotemporal delivery of chemotherapeutics.

C. B. Aparicio-Lopez;
Kansas State University, Manhattan, KS

Pancreatic cancer is a highly lethal malignancy with an urge for the exploration of novel treatments. One promising approach is microwaved-induced hyperthermia, which has shown great antitumor and synergistic effects when combined with other therapies. The application of microwaves produces heat by dielectric hysteresis which depends on the dielectric properties of molecules. Ionic liquids (ILs) are compounds composed of ions with <100 °C melting point and have strong dielectric properties. In short, *we propose* the creation of microwave-sensitive nanoparticles using IL, enabling precise hyperthermia induction with low-powered microwaves in localized areas. To achieve this, we stabilize a core composed of 1-butyl-methylimidazolium bromide or 1-butyl-3-methylimidazolium hexafluorophosphate using Span 80, Tween 20, and Triton-X as surfactants, along with phosphatidylcholine lipids as “cosurfactants”. Employing a double emulsion procedure for fabrication, nanoparticles are characterized using dynamic light scattering, Fourier-transform infrared spectroscopy, and transmission electron microscopy. Furthermore, we assess microwave sensitivity by comparing thermal changes between liposomes loaded with 120 mM and 250 mM NaCl solutions. Subsequently, we evaluate biocompatibility and heat effects by incubating IL nanoparticles with BXPC3 and KPC cells, monitoring cell viability through MTT assays. We aim to confine the ILs within the nanoparticle core rather than incorporating them into the membrane. We anticipate increased microwave sensitivity, translating to reduced off-target effects and enhanced precision in hyperthermia treatment. This research holds promise for improving the therapeutic outcomes of pancreatic cancer treatment.

#5748 Inhibition of tumor growth using exosomes loaded with KRAS siRNA and surface-modified with tumor-targeted proapoptotic peptide.

L. Kang, S. Jeon, S. M. P. Vadevoo, S.-H. Kim, B. Lee;
Kyungpook National Univ. School of Med, Daegu, Korea, Republic of

Exosomes are extracellular vesicles naturally secreted by cells and serve as carriers of RNAs and proteins for cell-to-cell communications. KRAS is frequently mutated and plays a vital role in many tumors. Receptor expressed in lymphoid tissue (RELT), also known as tumor necrosis factor receptor superfamily 19-like, is upregulated in certain tumors such as lung and pancreatic tumors and is a potential tumor target. To selectively deliver cytotoxic agents to tumor, we loaded mesenchymal stem cell (MSC)-derived exosomes with a siRNA against KRAS and surface-modified them with the RELTpep-KLA peptide comprising a RELT-binding peptide (CRQTKN, named RELTpep) and proapoptotic peptide (KLAKLAKKLAKLAK, named KLA). Exosomes were isolated from cell culture medium using ultracentrifugation and transfected with the KRAS siRNA using a lipid-based reagent and then surfaced-modified with the RELTpep-KLA using a phospholipid-based membrane anchor. Compared with control peptide-KLA, RELTpep-KLA-targeted MSC-exosomes were more efficiently internalized into A549 lung tumor and Panc-1 pancreatic tumor cells expressing RELT on their surface and exhibited cytotoxicity to these tumor cells. RELTpep-KLA-targeted and KRAS siRNA-loaded MSC-exosomes reduced the phosphorylation of Erk and exhibited an enhanced cytotoxicity in A549 and Panc-1 tumor cells. Moreover, when intravenously injected, they inhibited tumor growth in Balb/c nude mice bearing subcutaneous Panc-1 human tumor xenografts more efficiently than those loaded with control siRNA or modified with control peptide-KLA. These results demonstrate that RELTpep-KLA-targeted MSC-exosomes carrying KRAS siRNA hold a potential for exosome-based targeted therapy against cancer.

#5750 Development of prostate specific membrane antigen-targeted liposomal zinc for the treatment of prostate cancer.

S. K. Mondal[1], A. L. Klibanov[2], A. Moore[1];
[1]Michigan State University, East lansing, MI, [2]University of Virginia, Charlottesville, VA

Introduction: Treatment choices for early-stage prostate cancer include mostly watchful waiting, radical prostatectomy, or radiation therapy, whereas for advanced cases hormone therapy followed by chemo/radiotherapy are the preferred options, despite their notable side effects. There is a need for more effective therapy with lower side effects, especially for advanced scenarios. Unlike normal epithelial prostate cells, cancerous ones show reduced zinc (Zn) levels due to ZIP1 zinc transporter downregulation. Zn deficiency allows m-aconitase to remain active, making prostate cancer cells energy efficient and grow. High levels of Zn are needed to inhibit m-aconitase, the enzyme responsible for the first reaction in the Krebs cycle. This study aims to induce energy starvation and cell death of prostate cancer cells by inhibiting m-aconitase using the prostate-specific membrane antigen (PSMA)-targeting liposomal zinc.
Methods: Liposomes were prepared by standard reverse phase evaporation method with DSPC, Cholesterol and DSPE-mPEG(2000) lipids. Zinc chloride was used to load Zn^{+2} into liposome following passive loading method. PSMA-expressing (PC3-PIP) and PSMA-null (PC3-LUC) human prostate cancer cells were used for in vitro studies. In the cell uptake study, cells were incubated with DiI-dye labeled liposomes for 2 hours before analyzing them by microscopy and flow cytometry. For the uptake inhibition study, cells were pre-incubated with PSMA-specific peptide for 2 hours before incubation with liposomes. Cytotoxicity studies were performed with PSMA-targeting Zn-loaded liposomes in PC3-PIP cells.
Results: We conjugated the PSMA-specific peptide and control peptide (ASP3) with DSPE-PEG(3400)-NHS, and used them at various amounts (1 to 4 mol% of total lipid) to prepare Zn-loaded PSMA-targeting liposomes (TL) and control liposomes (CL), respectively. The average hydrodynamic diameter of all the liposomes was 120 to 130 nm, and zeta potential ranged from -16 to -12 mV. The encapsulation efficiency and loading capacity of Zn^{+2} were 0.6% and 8.5%, respectively. Cellular uptake studies showed a higher accumulation of PSMA-targeting liposome (TL) compared to non-targeting liposome (CL) in PSMA-expressing PC3 cells, whereas both liposomes showed low uptake in PSMA non-expressing cell. Furthermore, pre-treatment of PSMA-expressing cells with PSMA-specific peptide reduced the uptake of TL, indicating that the uptake of TL liposome is PSMA dependent. Finally, cytotoxicity studies showed that Zn-loaded TL, induces cell death in the PSMA-expressing cells. Overall, we developed PSMA-targeting Zn-containing liposomes that selectively target and kill PSMA-expressing prostate cancer cells. Future work includes testing the effect of Zn-loaded TL on m-aconitase activity and testing of in vivo efficacy of the formulation in prostate cancer models.

#5751 Ultrasound responsive injectable hydrogels for on-demand drug delivery.

L. Xiang, G. Sener, A. Yildirim;
OHSU Knight Cancer Institute, Portland, OR

In this work, we developed ultrasound-responsive and injectable hydrogels for local and on-demand release of chemotherapeutics to solid tumors. Injectable hydrogels were prepared by using a zwitterionic monomer, sulfobetaine methacrylate (SBMA), without using any crosslinker. Gelation was performed at -20 ^{o}C using APS/TEMED as initiator, allowing the formation of strong electrostatic interactions between poly(SBMA) chains to physically crosslink the hydrogels. Monomer and initiator concentrations were carefully optimized to achieve injectable hydrogels with mechanical and thermal stability. To render ultrasound responsivity to the hydrogels, we loaded the hydrogels with hydrophobically (dodecyl) modified mesoporous silica nanoparticles (hMSNs) with sizes around 50 nm. When insonated with low-intensity focused ultrasound (LIUS), the hMSNs incept acoustic cavitation (i.e., growth and collapse of microsized bubbles), which in turn generates mechanical effects in the hydrogels such as shock waves or water jets. We found that loading the hydrogels with hMSN did not affect their injectability, and they remained mechanically stable at 37 °C for more than a week. hMSN-loaded hydrogels demonstrated strong ultrasound responsivity even at low particle concentrations (0.1 mg/mL) and ultrasound powers (25 W, 0.02% duty cycle). Finally, we loaded the hydrogels with a chemotherapy drug, doxorubicin (DOX, 0.2 mg/mL). DOX-loaded hydrogels demonstrated minimal release without LIUS treatment (<20% in a day). Application of LIUS (150 W, 1% duty cycle) for 5 min resulted in almost complete mechanical disintegration of the hydrogels, resulting in a burst DOX release. We also showed that the amount of released DOX could be controlled by tuning the LUIS power and its duration. In summary, we developed injectable hydrogels with strong ultrasound responsivity. These hydrogels hold great promise for local and on-demand drug delivery to solid tumors, which is currently under investigation in our laboratory.

#5752 Enhanced cancer therapy strategies utilizing gelatin-lipidoid hybrid nanoparticles for RNA delivery.

A. Gangula, D. Suresh, A. Suresh Babu, Z. Li, A. Upendran, R. Kannan;
University of Missouri - Columbia, Columbia, MO

Nanoparticle delivery platforms have provided impetus for the emergence of novel RNA-based cancer therapeutics due to their ability to circumvent the physiological and cellular barriers in the delivery. The clinical success of these strategies hinges primarily on the safety and efficacy of the delivery vehicle. Here, we have developed a gelatin-lipidoid hybrid nanoparticle (GLNP) that utilizes gelatin's biocompatibility, biodegradability, and lipidoids' high transfection efficiency. With GLNP, we have demonstrated the efficacy of delivering siRNA and silencing AXL, a receptor tyrosine kinase commonly associated with cancer progression, metastasis, and drug resistance. siRNA is attached to the surface of GLNP through covalent conjugation with gelatin, while the lipidoid on the system's interior electrostatically complexes with the siRNA. siRNAs are well protected by the GLNP when exposed to serum for at least 48 hours. The GLNP's bivalency significantly enhanced the downregulation of target genes *in vitro* and *in vivo*. Furthermore, the bivalent GLNP can simultaneously target and downregulate two oncogenes. Apart from siRNA, GLNP was also able to encapsulate and deliver mRNA, thereby suggesting the potential to simultaneously deliver RNA therapeutics to effect knockdown and expression of target proteins and maximize therapeutic effect. The length of the carbon chain of the lipidoid can be manipulated to influence the physico-chemical properties of the GLNP and its efficiency in encapsulating and delivering RNA drugs. Importantly, gelatin was found to effectively shield the cationic lipidoid and negate its toxicity. Toxicity studies indicate that high doses of GLNPs (up to 48 mg/kg BW) are well-tolerated with no significant changes in body weight, hematology, or serum chemistry. The co-administration of GLNP-siAXL and TKI in PDX models has shown notable control of tumor growth. It is important to note that immune checkpoint blockade (ICB) therapy has shown significant survival benefits in NSCLC patients. However, the therapeutic effect is limited to only 20% of patients due to several resistance mechanisms, such as increased expression of oncogenic proteins. Therefore, our future study will explore GLNP's ability to sensitize NSCLC tumors to immune therapy.

#5753 Milk-derived extracellular nanovesicles: A novel delivery strategy for transcriptome targeting therapies in cholangiocarcinoma.

Jack W. Sample[1], Mincheng Yu[2], Hendrien Kuipers[3], Danielle M. Carlson[2], Nathan W. Werneberg[2], Jennifer L. Tomlinson[1], Gregory J. Gores[2], Rory L. Smoot[4]

[1]Department of Surgery, Mayo Clinic, Rochester, MN,[2]Division of Gastroenterology and Hepatology, Mayo Clinic, Rochester, MN,[3]Department of Biochemistry and Molecular Biology, Mayo Clinic, Rochester, MN,[4]Department of Hepatobiliary and Pancreas Surgery, Mayo Clinic, Rochester, MN

Introduction: Cholangiocarcinoma (CCA) is an aggressive and heterogenous biliary malignancy. Previous therapeutic shortcomings have encouraged the investigation of new strategies, such as targeted therapeutics. YAP/TAZ, transcriptional coactivators of the hippo pathway, have been implicated in the tumorigenesis of CCA along with the Src familiar kinase, LCK. Milk-derived nanovesicles (MNVs) have emerged as a promising biologic delivery apparatus for hepatobiliary malignancy due to their predilection for hepatic uptake. We sought to investigate the utility of aptamer guided MNVs loaded with short interfering RNA (siRNA) targeting YAP, TAZ, and LCK.

Methods: MNVs were prepared and loaded with species-specific siRNA prior to decoration with an epithelial cellular adhesion molecule (EpCAM) targeting aptamer. In vitro studies were performed using murine and human CCA cell lines, SB1 and HuCCT-1, respectively. In vivo studies were carried out using C57BL/6 mice following Institutional Animal Care and Use Committee protocols.

Results: We previously validated EpCAM as an effective aptamer demonstrated by increased levels of expression in CCA cell lines using immunoblot, RT-PCR and immunofluorescence. Additionally, in vivo experiments demonstrated excellent biodistribution and affinity for tumor-selective uptake. To evaluate knockdown efficacy, CCA cell lines were incubated with EpCAM aptamer guided MNVs individually targeting YAP, TAZ, and LCK which resulted in downregulation of these targets on immunoblot and RT-PCR. MNVs were then loaded with equal concentrations of siRNA targeting YAP, TAZ, and LCK in combination which resulted in similar degrees of gene downregulation compared with single transcriptome targeting MNVs. Due to the role of YAP/TAZ activation in CCA systemic therapy resistance, we investigated the effect of MNVs loaded with either single target or combinatory target siRNA alongside and in combination with gemcitabine and cisplatin (GemCis). Incubation with both combinatory siRNA and GemCis significantly intensified cell death on Pi/Hoechst staining compared with single target knockdown alone. Similar findings were found using separate assays of cell viability, including ATP luminescent quantitation and caspase 3/7 activity. These data suggest MNV transcriptome targeting may induce a state of cell stress which allows for amplification of chemotherapy treatment effect.

Conclusion: Aptamer guided, nanovesicle mediated transcriptome targeting is a promising therapeutic strategy in preclinical CCA models that may potentiate chemotherapy response. Our future direction involves further investigating the role of CCA target downregulation and its effect on the tumor immune microenvironment utilizing aptamer guided nanovesicle delivery and inducible knockdown cell lines.

#5754 Targeting miR-92b with peptide-modified liposomes for glioblastoma treatment.

Annelis Odette Sanchez-Alvarez[1], Fatima Valiyeva[1], Pablo E. Vivas-Mejia[2]

[1]Cell Biology, University of Puerto Rico Comprehensive Cancer Center, San Juan, PR, [2]Biochemistry, University of Puerto Rico, Medical Sciences Campus, San Juan, PR

Focusing on enhancing drug delivery to the brain, we aim to optimize a nanocarrier system with a specific focus on glioblastoma (GBM). This involves the utilization of spherical nucleic acids (SNAs) enclosed in peptide-modified liposomes, a configuration previously proven to effectively penetrate the blood-brain barrier (BBB) in a GBM mouse model. Our objective is to enhance the nanocarrier's treatment load by optimizing the attachment of oligonucleotide-modified gold nanoparticles (OMI) to the SNAs. MicroRNAs (miRNAs) play crucial roles in GBM pathogenesis, with miR-92b identified as overexpressed in various cancers, including GBM. Previous research from our lab implicated miR-92b in targeting proteins (FBXW7 & SKP2) in the ubiquitination pathway. RNA sequencing confirmed the significance of these pathways. RNA sequencing of miR-92b inhibition in the U87 GBM cell line revealed impacts on cell cycle, apoptosis, DNA repair, and multiple cancer-related pathways. We successfully modified the gold nanoparticle size from 15 nm to 5 nm, increasing the surface area and improving OMI attachment efficiency from less than 5% to 50%. This alteration significantly enhances drug loading in the nanocarrier, providing a promising platform for clinical applications. Characterization of the optimized peptide-modified liposomes reassured the retention and potential improvement of original features related to nanoparticle size and internalization in cell cultures. Future in vivo experiments, utilizing a GBM mouse model, will assess the therapeutic effect of inhibiting miR-92b using peptide-modified liposomes as a drug delivery system. Our multifaceted approach, involving nanocarrier optimization and miR-92b inhibition, holds promise for developing an effective treatment strategy against GBM. The presented results highlight the potential translational impact of our research in addressing the challenges associated with GBM therapy.

#5755 Development of paclitaxel-loaded nanoparticles with high charge density.

Katherine Y. Bang, Preshita P. Desai

Department of Biotechnology and Pharmaceutical Sciences, Western University of Health Sciences, Pomona, CA

Paclitaxel (PTX) is a potent anticancer agent with desirable efficacy against pancreatic cancer when used in conjunction with gemcitabine. The current formulation of nab-paclitaxel shows an improved safety profile compared to the conventional PTX, but the highly potent nature of paclitaxel still poses a problem as it leads to severe side effects, such as neutropenia and neuropathy, calling for the development of carriers with better targeting ability. Tumor treating fields (TTFields) is a new noninvasive treatment modality which disrupts the mitosis of a cell with alternating electric fields with low and intermediate frequency (100 - 500 kHz). Highly polar or charged macromolecules are impacted by the presence of TTFields as they lose random motions essential for mitosis. In previous work on the formulation of self-assembling cationic-anionic nanoparticles (S-CAP NPs), gemcitabine was successfully loaded into the nanoparticles with optimal particle size, stability, and release profile responsive to TTFields. In this study, S-CAP NPs were developed with biocompatible polymers, DEAE-dextran (Ddex) and bovine serum albumin (BSA), via a relatively green method to load paclitaxel with minimal use of organic solvents. Based on the previous study and the proof of concept, it can be hypothesized that the S-CAP NPs can successfully carry PTX and release it in the presence of TTFields. Various parameters, such as temperature, rpm, and concentration, were tested to optimize the size, PDI, zeta potential, and stability of the particles. The HPLC method was developed for PTX and used to analyze drug loading. Numerous compositions of BSA and Ddex were tested, and the ratio of 10:1 (BSA:Ddex) developed the best parameters of the S-CAP NPs. At 50 °C, the zeta potential of the particle was -3.55 ± 0.23 mV for the NPs, but the particles agglomerated over time as BSA precipitates were formed. At -15°C, the particle size was 302.9 ± 2.0 nm (PDI = 0.307 ± 0.038). Varying concentrations of BSA and Ddex showed the formation of S-CAP NPs at lower concentration. The optimal particle was formed at room temperature (RT) with BSA 0.1% and Ddex 0.01% with a size of 264.6 ± 19.7 nm (PDI = 0.079 ± 0.028) and a zeta potential of -14.67 ± 0.07 mV. The particles showed desirable stability for 48 hours. The HPLC analysis (Agilent, Phenomenex C18, 150 x 4.6 mm, 5 micron) was tested for validity and robustness (r^2 = 0.9996). Currently, the drug loading was achieved at 1.9% and the optimization studies are ongoing. *In vitro* cell viability assay (MTS) with and without TTFields is under exploration. With the successful formulation of PTX-loaded S-CAP NPs, co-loading PTX and gemcitabine can be explored to reduce the treatment burden of the patients.

#5756 Silver graphene quantum dots as drug delivery platforms for anti-cancer application.

R. A. Villanueva[1], T. Cole[2], N. Medina[3], D. Morell[3], B. Weiner[3];
[1]University of Puerto Rico - Rio Piedras, San Juan, Puerto Rico, [2]University of Tulsa, Oklahoma, OK, [3]University of Puerto Rico - Rio Piedras, San Juan, PR

Prostate cancer (PCa) stands as the most frequently diagnosed cancer and the third leading cause of cancer-related deaths among men in the United States (2019). Various cancer treatments, including Rehabilitation therapy, Immunotherapy, Hormone therapy, Stem Cell Therapy, and Chemotherapy, are available. However, chemotherapy has notable limitations due to its tendency to harm healthy cells, resulting in side effects such as nausea, vomiting, alopecia, diarrhea, anemia, bleeding, and sterility. In response to these challenges, we developed nanoparticle (NP) drug delivery platforms for cancer treatment. These platforms utilize silver graphene quantum dots nanocomposites (AgGQD), known for their ability to enhance drug therapies. Silver nanoparticles (AgNPs) exhibit toxicity towards both normal and cancer cells by impacting mitochondrial function, reactive oxygen species (ROS) production, lactate dehydrogenase (LDH) release, cell cycle dysregulation, induction of apoptotic genes like Bax, micronucleus formation, chromosome aberration, and DNA damage. Additionally, AgNPs demonstrate antiangiogenic and antiproliferative properties by inhibiting PI3K phosphorylation of Akt, disrupting the signaling pathway, ultimately halting angiogenesis, depriving cells of oxygen, and causing tumor cell death. To mitigate the toxicity of AgNPs in healthy cells and enhance their performance as drug delivery platforms, graphene quantum dots (GQDs) were introduced in this study. Moreover, GQDs may contribute to improving the solubility of drugs with low water solubility. The NPs were synthesized using graphene quantum dots as reducing agents. The study involved identifying the IC50 value, conducting validation tests on AgGQD and AgGQD doped, and comparing their toxicity on cells. Confocal microscopy was employed to identify the intracellular location of the drug.

#5757 Graphene quantum dots-covered AuAg alloy nanoparticles as drug delivery platforms for anticancer applications.

A. D. Veloz Bonilla, B. Weiner, G. Morell, N. Medina-Berrios;
University of Puerto Rico, San Juan, Puerto Rico

Cancer continues to be a global health challenge, with millions suffering from its various forms. Prostate cancer, in particular, emerges as a significant health risk for men. Originating in the prostate gland—a small organ nestled in the male pelvis—this type of cancer the second most common cause of cancer-related deaths among men in the U.S. Despite numerous medical breakthroughs over the years, finding an effective treatment for prostate cancer remains a challenge. Our research is venturing into a new frontier in the fight against prostate cancer, focusing on an innovative method, it explores the potential of nanoparticles for targeted drug delivery. This targeted approach promises to not only intensify the therapeutic effect, but also minimize adverse side effects on healthy cells, ensuring a more balanced and effective treatment regimen. A key in this study is the drug Andrographolide (ADG), which has been previously recognized for its robust anti-cancer properties. However, one of its limitations is its hydrophobicity, which makes it challenging to administer due to solubility concerns. To navigate this challenge, we are pioneering the synthesis of AuAg (gold and silver) graphene quantum dots (GQDs) alloy nanoparticles. AuAg particles, in have been the subject of numerous studies due to their profound impact on cellular processes. By integrating a protective layer of GQDs, we aim to boost the nanoparticles' stability, all while preventing any potential release of harmful metallic ions. The primary objective of this advanced approach is to augment the solubility of andrographolide, paving the way for its targeted and efficient delivery to PC-3 cells. An integral part of our research involves determining the IC50 value, which is pivotal in indicating the concentration at which the drug can inhibit the growth of 50% of prostate cancer cells. Once the IC50 value for the AuAgGQDs is firmly established, our focus will shift to evaluating its effects on the morphology of Red Blood Cells (RBCs). By encapsulating andrographolide within the designed nanoparticles, such as AuAgGQDs and their derivatives, we aim to observe changes in morphology. If there is a change in morphology, it indicates successful drug encapsulation. Through this research, we are not just seeking a viable treatment method, but also aiming to expand the horizons of drug delivery systems. The insights gained from this study could very well revolutionize our understanding of therapeutic potential and underscore the importance of nanoparticles in the realm of biomedical applications.

#5758 Gold nanoparticles with graphene quantum dots as drug delivery platforms for anticancer applications.

F. M. Rosa Suarez[1], G. Morell[2], B. Weiner[1], N. Medina[2], W. Pantoja[1];
[1]Universidad de Puerto Recinto de Rio Piedras, San Juan, Puerto Rico, [2]Universidad de Puerto Rico Recinto de Rio Piedras, San Juan, Puerto Rico

Cancer is a global health challenge that has a profound impact on the lives of people worldwide, either directly affecting individuals or their loved ones. Among the various types of cancer, prostate cancer stands out as one of the most prevalent in men. Prostate cancer is primarily identified by symptoms related to urinary health. Conventional medical approaches often rely on drug-based treatments to address this form of cancer. However, like many treatments, drug therapy comes with its own set of challenges. In our research project, we propose an alternative approach for managing prostate cancer. Our innovative idea centers around utilizing nanoparticles as a means of drug delivery. Specifically, we are investigating the use of Taxol, also known as Paclitaxel, as the drug of interest. Taxol possesses a significant challenge due to its hydrophobic nature, which hinders its circulation within the bloodstream. Its solubility is extremely low, at 0.00025 mg per milliliter. To overcome this limitation, we have undertaken the synthesis and integration of AuNPs (gold nanoparticles) with GQDs (graphene quantum dots). This combination enhances the drug's hydrophilic properties, making it more effective in transportation. Our research has led us to conduct experiments on prostate cancer cells (specifically the PC3 cell line). We aim to compare the IC50 value, which represents the drug concentration required to kill 50% of the cancer cells, when using the drug alone versus when using the drug in conjunction with the nanoparticles. Taxol's IC50 value is determined to be 5.73nM. In addition to assessing the impact on cancer cells, we have also examined how the nanoparticles interact with blood, and how this interaction influences the morphology of red blood cells. Furthermore, we have characterized the system using various analytical techniques, including FTIR, NMR, Fluorescence, and UV-Vis spectroscopy. To pinpoint the accumulation sites of the drug and delivery agents, we have employed confocal microscopy on the cancer cells. Our ultimate objective is to equip the drug with the necessary components to facilitate its entry into prostate cancer cells effectively.

#5759 Design of Au-graphene quantum dot nanocomposite as a potential drug delivery system to solubilize Tetrandrine.

M. Perez Salva[1], N. Medina-Berrios[2], B. Weiner[1], G. Morell Marrero[1];
[1]University of Puerto Rico - Rio Piedras, San Juan, Puerto Rico, [2]University of Puerto Rico - Rio Piedras, San Juan, PR

Prostate cancer, along with various other types of cancer, has been a prominent focus in medical and clinical discussions for many years due to its high fatality rates and significant health risks. To enhance oncological healthcare, various methods and technologies, such as drug delivery systems (DDS), have been extensively studied. Developing an effective DDS offers distinct advantages compared to other approaches to anticancer drug treatment. Some anticancer drug molecules possess unfavorable properties that directly impact metabolism and solubility, issues that DDS aims to address. Recent progress in nanomaterial synthesis has introduced innovative and efficient drug systems, providing a new perspective on cancer treatments. Gold nanoparticles, particularly in conjunction with semiconductor graphene quantum dots (GQDs), play a role in creating a unified carrier system applicable to multiple therapeutic methods. The choice of graphene quantum dots is based on their widespread applications and diverse benefits, ranging from compatible size and core-shell chemistry richness to substantial progress in achieving signal homogeneity by reducing the distance between molecules and substrate. The selected model for the DDS is the hydrophobic alkaloid Tetrandrine. Despite its use in treating conditions such as hypertension, and arthritis, and exhibiting anti-cancer activities, Tetrandrine is highly insoluble as an anti-cancer drug, with a solubility of 24.1 µmol/L [15 µg/mL] in water and only 5mM in ethanol and DMSO. This research aims to enhance the solubility of hydrophobic Tetrandrine by incorporating it into gold graphene quantum dot nanocomposites, serving as a potential drug delivery system for combating prostate cancer. The synthesis of nanocomposites (Au-GQD, Au-NGQD, Au-SGQD) and Tetrandrine-loaded products (AuGQD-T, AuNGQD-T, AuSGQD-T) will be examined. Additionally, the properties of Tetrandrine loaded onto the nanoparticles will be scrutinized and characterized using NMR spectroscopy, UV-Vis, and fluorescence spectrum analyses.

#5760 Intra-tissue quantitative analysis using LC/MS will determine the mechanisms of interstitial pneumonia induced by antibody-drug conjugates.

S. Koganemaru[1], H. Fuchigami[2], C. Morizono[1], H. Shinohara[1], Y. Kuboki[1], K. Furuuchi[3], T. Uenaka[3], T. Doi[1], M. Yasunaga[2];
[1]National Cancer Center Hospital East, Kashiwa, Japan, [2]National Cancer Center, Kashiwa, Japan, [3]Eisai Inc., Exton, PA

Background: Antibody-drug conjugates (ADCs) are a new class of therapeutics that combine a monoclonal antibody with a cytotoxic agent (known as their payloads) via a synthetic linker. While ADCs are one of game changer and are the fastest growing classes with novel clinical benefits recently, interstitial pneumonia (ILD) is a clinical problem as a fatal adverse event. However, the mechanism of ADC-induced ILD is under investigation. Purpose: We clarify ADC-ILD mechanism by analyzing released payload distribution in the lung using a novel Trophoblast cell surface antigen 2 (TROP2)-targeting ADC.
Material and Methods: TROP2-eribulin is a novel TROP2-targeting ADC composed of the TROP2 antibody and cytotoxic payload eribulin conjugated by a cleavable linker. Four human cancer cell lines (A549, HeLa, NCI-H2110 and SKOV3) and one human- leukemia monocytic cell line (THP-1) were used in this study. Cell surface TROP2 antigen expression was evaluated by flow cytometry. We investigated the concentration and distribution of the TROP2-eribulin and the payload released from the TROP2-eribulin in tumor and lung tissue, using TROP2 low and high expression human cancer xenograft model that were treated with various doses of TROP2-eribulin. The concentration of erbulin was analyzed by liquid chromatograph mass spectrometry, and tissue distribution of ADCs was assessed by immunofluorescence (IF) assay.
Results: In vitro analysis showed that the concentration of intracellularly released eribulin was significantly higher in NCI-H2110 with high TROP2 expression compared to A549 with low TROP2 expression ($P < 0.05$). In vivo analysis, the concentration of released eribulin in tumor tissue was approximately 10-fold higher in the NIC-H2110 xenograft model than the A549 xenograft model, while analysis of lung tissue showed that TROP2-eribulin was distributed in lung tissue in a dose-dependent manner of TROP2-eribulin regardless of TROP2 expression, with significantly more eribulin released in the high-dose group of TROP2-eribulin than in the other dose groups ($P < 0.05$). IF assay showed that TROP2-eribuilin localized to alveolar macrophages. In the analysis using THP-1 cell, which mimic macrophage function, the concentration of eribulin released from TROP2-eribuilin was significantly reduced by the use of an Fc receptor inhibitor ($P < 0.05$).
Conclusions: Nonspecific uptake of ADC by alveolar macrophages via Fcγ receptors releases cytotoxic payload into lung tissue, regardless of tumor antigen expression levels. This understanding can help elucidate the pathogenesis of ADC-induced ILD.

#5761 A nanoplatform based on an *in situ* tumor vaccine and activation of STING and TLR7/8 pathways for enhanced NSCLC immunotherapy.

H. Zhou[1], H. Hou[2], B. Xu[3], Y. Huang[2], H. Qiu[4], **Z. Jiang**[5];

[1]Guangdong Provincial People's Hospital Guangdong Academy of Medical, Guangzhou, China, [2]South China University of Technology, Guangzhou, China, [3]School of Biomedical Sciences and Engineering, South China University of Technology, Guangzhou International Campus, Guangzhou, China, [4]Guangzhou University of Chinese Medicine, Guangzhou, China, [5]University of California, Berkeley, Berkeley, CA

Background: Immunotherapy has emerged as a promising treatment for tumors following surgical, radiotherapy, and chemotherapy interventions. Therapeutic tumor vaccines are considered highly effective in eliminating tumors and preventing their recurrence and metastasis due to their ability to induce or enhance T cell-mediated immune responses. However, the therapeutic efficacy of these vaccines is impeded by the heterogeneity present both between and within tumors. In contrast, in situ tumor vaccines, prepared from autologous antigens in tumor patients, present another promising strategy for generating comprehensive immune responses.

Methods: In this study, we designed a multifunctional nanopolymer, the transformable nanoassembly PEG-Ce6@PAEMA/R848. This assembly includes the photosensitizer polyethylene glycol-chlorin-e6 (PEG-Ce6), the tumor pH-sensitive polymer poly(2-azepane ethyl methacrylate) (PAEMA), and the immune adjuvant Resiquimod (R-848). The objective is to confirm the activation of bone marrow-derived dendritic cells (DCs) at the cellular level. Subsequently, we investigated the maturation of DCs in lymph nodes and tumor sites in vivo.

Results: In the particle characterization process, successful synthesis of nanoparticles was achieved, along with the verification of their acid-responsive function and toxic effects. Furthermore, in vitro experiments demonstrated the activation of bone marrow-derived dendritic cells (DCs) (Figure 1).To further investigate the in vivo vaccine effects, C57BL/6 mice were euthanized, and lymph nodes were extracted to examine the accumulation of FITC-PAEMA. It can be observed that, due to the reduction in size of the particles in the tumor acidic environment, the immune adjuvant can easily enter the lymph nodes. Activation of the STING pathway in dendritic cells within the lymph nodes was detected through qPCR. The maturation of dendritic cells (DCs) in the lymph nodes was determined using flow cytometry (Figure 2).

Conclusions: In this study, we developed a straightforward yet potent strategy focused on in situ tumor targeting. This approach effectively inhibits tumor growth while inducing immunogenic cell death and eliciting a systemic anti-tumor immune response against cancer cells. Additionally, we intend to validate the therapeutic efficacy of this strategy on metastatic and distal tumors in subsequent investigations.

#5762 Engineering cell membrane nanoparticlesenhance immunotherapy and radiodynamic therapy for lung adenocarcinoma by promoting cGAS-STING and ferroptosis.

Haiyu Zhou[1], Hongrui Qiu[1], Shiying Li[2], Bin Xu[3], Shengbo Liu[1], Huili Wang[1], Hengliang Hou[4], **Zhengyang Jiang**[5]

[1]Department of Thoracic Surgery, Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou, China,[2]Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou, China,[3]School of Biomedical Sciences and Engineering, South China University of Technology, Guangzhou International Campus, Guangzhou, China,[4]School of Medicine, South China University of Technology, Guangzhou, China,[5]University of California, Berkeley, Berkeley, CA

Background: Immunotherapy is a promising approach for lung cancer, but its effectiveness is limited by tumor heterogeneity. Nanoparticle-based targeted drug delivery systems offer advantages such as targeted drug-loading capacity, and hypotoxicity, showing great potential in improving therapeutic efficacy. This study introduces a targeted drug delivery strategy based on immune-activating nanoparticles that achieves precise drugs delivery in tumor areas. Consequently, this approach remodels the microenvironment and induces tumor cytotoxicity.

Method: In this study, we first constructed a targeted nanoparticle delivery system FP@CC. The vehicle utilized lung adenocarcinoma cell membranes as the outer shell and encapsulated iron-platinum nanoparticles and STING agonist Vadimezan. Then, TREM2 antibodies were conjugated on the outer layer. The structure of FP@CC-aT2 was characterized by HADDF-STEM and its safety was evaluated by hemolysis test. In vitro, its ability to induce death was verified by AM/PI staining, and to induce ferroptosis was detected by C11 assay. Furthermore, we evaluated its antitumor effects in subcutaneous tumor models. The composition of immune cells within the tumor microenvironment was analyzed using flow cytometry.

Results: We initially performed HADDF-STEM analysis on the nanoparticle precursor FP/Vad@CC, revealing its uniform sphericity. For security, no significant hemolysis was observed at different concentrations of FP/Vad@CC. Then, the structures of FP/Vad@CC-aT2 and FP/Vad@CC are relatively stable (Fig 1).The number of dead cells significantly increased after deal with FP@CC, and the effect was significantly enhanced when combined with X-ray. Moreover, C11, utilizing to assess the changes in intracellular reactive oxygen species (ROS), found that FP@CC led to a significant increase in ROS, comparable to induction by H2O2. Both could be effectively prevented by ferroptosis inhibitor(Fig 2).In vivo, FP/Vad@CC-aT2 was applied to a subcutaneous tumor model in C57. It exhibited excellent therapeutic efficacy and biocompatibility. Flow cytometry revealed that FP/Vad@CC-aT2 had the anticipated impact on macrophages within the tumor: a significant reduction in CD11high/CD206high cells and opposite in the ratio of M1/M2-like macrophages (Fig 3).

Conclusion: This study developed a targeted drug delivery strategy, FP/Vad@CC-aT2, to improve the tumor microenvironment (TME). We conducted preliminary experiments in vitro and in vivo to validate its physicochemical properties and tumor inhibitory effects, including the induction of ferroptosis. We assessed its safety in mouse and obtained initial evidence of FP/Vad@CC-aT2's ability to remodel the subtypes of macrophage.Moving forward, we will validate its therapeutic and impact on the TME after surgical procedures.

#5766 Fungal genomes in drug discovery: Application of CETSA to study the mechanism of action of brefeldin A.

T. Friman[1], B. M. Fontaine[2], A. Chernobrovkin[1], D. Martinez Molina[1], V. Brehmer[1], S. Lundgren[1], P. M. Castaldi[2], G. L. Verdine[2];
[1]Pelago Bioscience, Stockholm, Sweden, [2]LifeMine Therapeutics, Cambridge, MA

Fungal genomes encode a vast collection of chemical diversity that has evolved over millions of years to engage specific targets and modulate diverse biological processes. These Genetically Encoded small Molecules (GEMs) constitute a largely untapped source of potential therapeutics. Although fungal GEMs such as cyclosporine, lovastatin, and penicillin have revolutionized modern medicine, these GEMs were discovered serendipitously through bioactivity-guided fractionation of fungal extracts. LifeMine is redefining GEM discovery through the deployment of proprietary genomic search algorithms that enable GEM target prediction a priori. Our strategy facilitates focused search-and-retrieval campaigns to rationally discover molecules selected by Nature to modulate the desired target protein. These GEM drug leads often exhibit unique structural and mechanistic features, necessitating comprehensive deconvolution of the human target profile and mechanism of action during the development process from GEM to clinical candidate. As a proof-of-concept study, we leveraged CETSA Explore to study the biological mechanism of the fungal polyketide lactone Brefeldin A (BFA) in human THP-1 cells. This GEM, originally isolated from the filamentous fungus Penicillium brefeldianis, inhibits protein trafficking between the endoplasmic reticulum and the Golgi complex, eliciting antiviral, antifungal, and anticancer activity. Our CETSA profiling study confirmed the Golgi-associated guanine nucleotide exchange factor GBF1 as the primary target of BFA, validating the established mechanism of this GEM as an inhibitor of GBF1-mediated activation of the small GTPase ARF1. These results demonstrate the utility of integrating the LifeMine GEM discovery engine with downstream proteomic profiling technologies to facilitate the mechanistic characterization of fungal GEMs en route to novel therapeutics.

#5767 DNA binding mechanism of prostate cancer target ONECUT2.

A. Chatterjee, B. Gallent, M. Katiki, C. Qian, M. Harter, M. Freeman, R. Murali;
Cedars-Sinai Medical Center, Los Angeles, CA

Transcription factors (TF) are essential determinants of gene regulation and their aberrant expression frequently drive cancers. The binding of TFs to cognate DNA is central to their role in gene regulation. An understanding of their DNA binding mechanism is, therefore, of fundamental and therapeutic relevance. Generally, TFs bind DNA through defined DNA binding domains. The CUT and homeodomain are two such evolutionarily conserved elements found paired in multiple transcription factor families including ONECUT (OC), POU, CUX and SATB. However, the mechanism of cross-talk between the CUT and homeodomain to coordinatedly bind DNA remains unknown. Here, we report an integrative DNA binding analyses of the transcription factor OC2, a promising target for treatment of aggressive prostate cancer. We demonstrate that the homeodomain of OC2 thermodynamically stabilizes the DNA binding through allosteric modulation of CUT. The binding energetics is further dependent on base interactions by evolutionarily conserved amino acids in both CUT and homeodomain. In addition, we have discovered a unique arginine pair in the homeodomain, conserved within the ONECUT family, but not across POU and SATB families. We show that one arginine of this pair binds distinctly to DNA in respective complexes formed by OC2 and OC1. Notably, the above base-interactions are crucial for OC2-driven disease progression in a prostate cancer cell-line model. Taken together, our studies show that base-interactions by the evolutionarily conserved residues determine the basic DNA binding functionality through establishing favorable thermodynamics, while interactions by the arginine motif impart family-specific attributes. These findings also establish the homeodomain as a key regulator of DNA binding by OC2 and provide a mechanism for cooperative DNA binding by the CUT-homeodomain module in general. Importantly, these insights reveal vulnerabilities for therapeutic targeting of OC2.

#5768 Proximity labeling with molecular signal sensing of oncogenic *PIK3CA*.

Rong Li, Donghee Lee, Md Abdullah, Jong Hyuk Kim

Department of Small Animal Clinical Sciences, University of Florida, Gainesville, FL

PIK3CA mutations are major oncogenic drivers for oncogenesis. Mutant *PIK3CA* continuously activates the PI3K pathway, transmitting oncogenic signals within the transformed cells. Despite decades of efforts focused on targeting oncogenic *PIK3CA* for cancer therapy, the precise molecular and functional machinery remains incomplete due to the molecular complexity of the PI3K pathway. Mapping of proximity proteins in the oncogenic PI3K pathway and identifying mutant signals will signify a deep understanding of oncogenesis and a broad range of therapeutic applications. In this study, we hypothesize that *PIK3CA* mutant cancer cells establish a unique molecular program networking with distinct proteins, which differs from that of cancer cells with wild-type (WT) *PIK3CA*. To test this hypothesis, we have developed a novel bioengineering approach to decode protein-protein interactions of oncogenic *PIK3CA* and identify key molecular partners, potentially providing therapeutic vulnerabilities in cancer cells. First, we applied the proximity labeling technique, based on the fusion of a promiscuous protein ligase to a targeting protein of interest (POI), featuring proximity-dependent biotinylation of interacting and neighboring proteins. The promiscuous biotin ligases, BioID and BioID2, were utilized to integrate WT *PIK3CA* or gain-of-function hotspot mutations in at E545K or H1047R residues. To optimize the labeling protocol and biotinylation conditions, the BioID and BioID2 plasmids were fused with each POI, incorporating multiple combinations of protein tags, including myc, HA, and red fluorescence protein. Lamin A was used as the positive control, and a total of 15 plasmids were constructed in pcDNA3.1 mammalian expression vector. The sizes of the plasmids and the gene sequences were validated by PCR amplification and Sanger sequencing. Next, we employed a programmable nuclease, the prokaryotic Argonaute (pAgo), assisted by fluorescence resonance energy transfer technology, to detect oncogenic signals derived from mutant *PIK3CA* in cell-free conditions. To test our methods, we engineered two cancer cell lines (DHSA-1426 and COSB) derived from naturally occurring hemangiosarcoma in dogs, to induce *PIK3CA* H1047R mutations using CRISPR/Cas9. Our technical approach enables temporal and spatial molecular sensing of oncogenic *PIK3CA* and its functional interactome in living cancer cells by integrating high-resolution molecular mapping with a pAgo-based detection system. Our ongoing work involves the standardization and optimization of proximity labeling for oncogenic *PIK3CA* across ontogenetically distinct cancer cells. Furthermore, we will determine the sensitivity and specificity of the integrated approach to achieve proximity labeling with programmable detection of molecular signals from oncogenic *PIK3CA*.

#5769 Target identification of T-cell activating immunomodulatory tetrahydrothiazepines: DGKα and DGKζ inhibitors.

T. Luebbers[1], A. Britschgi[1], V. Costa[1], T. Friess[2], J.-C. Hau[1], G. Heidkamp[2], H. Kuehne[1], L. J. Martin[1], F. Roudnicky[1], M. Tzouros[1], A. Vandemeulebroucke[1]; [1]F. Hoffmann-La Roche Ltd., Basel, Switzerland, [2]Roche Diagnostics GmbH, Penzberg, Germany

We became interested in bicyclic tetrahydrothiazepine derivatives described in a Patent (WO 2016/139181) having immunomodulatory activities on CD3-activated T cells (CD4+ & CD8+) and NK cell increasing the secretion of several cytokines such as, e.g., IL-2, IFN-γ and/or TNF-α whereas corresponding unstimulated immune cells do not respond. Surprisingly - in contrast to what has been described in the patent - the N-H of the Amides 1 and 2 described in the patent was not required for potency and the oxadiazoles 1 and 2 were significantly more potent in T-cell proliferation and IL-2 release. Compound 1 was *in vivo* active in a single dose PD study in mice after CD3 activation and in a MC38 xenograft mice model showing single agent activity. Amide 1 and Amide 2 were identified in a phenotypic screen and the mode of action was unknown. Because of the promising pharmacological profile and *in vivo* activity, we were interested in the target. Here we describe how we identified the potential targets DGKα and DGKζ.

#5770 Inhibition of KRAS G12D mutant with small molecules.

D.-H. Lee, J. Lee;
Gangneung-Wonju National University, Gangneung, Korea, Republic of

Background: RAS mutations are occurring at a high rate in colorectal cancer, lung cancer, and pancreatic cancer. RAS is family of small GTPase proteins with important roles in cell growth, differentiation, proliferation, and survival. There are three types of RAS genes: HRAS, KRAS, and NRAS. The The RAS gene is the most commonly found oncogene in human cancer. KRAS exhibits a highest mutation rate compared to those of HRAS and NRAS in various cancer types.
Methods: Colorectal cell line LIM1215, SW48 and NSCLC cell line NCI-H1975, NCI-H838 were used for MTT assays. Apoptosis assay was performed using the annexin V-FITC apoptosis detection kit (BioBud, Cat. LS-02-100). Colony forming assay was performed with 6-well culture plates by seeding 500 cells/well. The expression levels of proteins involved in Q2a-induced signaling pathway were determined by Western blot. In vivo study was performed with tumor xenografts. HT-29 cells were implanted into the right flank of 5-week-old BALB/c nude mice. Tumor size was determined by measuring the diameter (width, length) of the tumor every two days with a digital caliper. All group mice sacrificed at day 19.
Results: Patients with cancer involving KRAS mutations are resistant to therapeutics that target epidermal growth factor receptor and show poor outcomes. In addition, effective treatments that target G12D in KRAS have not been developed. Thus, therapeutic agents targeting the G12D mutation in KRAS are needed. In this study, we identified the Q2a compound, a quinazoline-based derivative that specifically acts on the KRAS G12D mutation. This compound induced cell apoptosis by reducing phosphorylation of AKT in the PI3K pathway downstream of KRAS. Q2a compound specifically inhibited the growth of KRAS G12D mutant cells. In addition, cells with the KRAS G12D mutation were more sensitive to Q2a compound compared to the sensitivity of wild-type cells and those with other KRAS mutations, resulting in apoptosis. Treatment with the Q2a compound also decreased C-RAF phosphorylation in the MAPK pathway, which is downstream of KRAS. In KRAS G12D-mutated colorectal cancer xenografts, Q2a compound inhibited tumor production without significant liver toxicity.
Conclusion: Q2a compounds show potential as therapeutic agents that target KRAS G12D mutations in colorectal and pancreatic cancers.

#5771 Utilizing a photoreactive chloroalkane capture tag for target deconvolution.

T. Uyeda[1], R. Hurst[2], S. Levin[2], M. Rosenblatt[2], K. Zimmermann[2], R. F. Ohana[2];
[1]Promega Corporation, San Luis Obispo, CA, [2]Promega Corporation, Madison, WI

Identifying the physiologically relevant targets of bioactive compounds is often the rate limiting step toward understanding their mechanism of action. To this end, we developed a streamlined chemical proteomic strategy that utilizes a novel photoreactive cleavable chloroalkane tag, which can be attached to bioactive compounds to isolate their respective cellular targets for identification by mass spectrometry. The tag does not significantly affect compounds potency and membrane permeability, allowing for binding interactions to be established within intact cells under appropriate physiological conditions. UV-induced covalent photo-crosslinking “freezes” the cellular interactions and prevents their dissociation upon cell lysis. Effective enrichment of the cellular targets is achieved through their selective covalent capture onto HaloTag coated particles and subsequent selective release by tag cleavage. Putative targets identified by mass spectrometry can be readily verified using resonance energy transfer. By exchanging the chloroalkane tag for a fluorophore, direct binding to the targets can be revealed through proximity of the fluorophore to a small NanoLuc luciferase genetically fused to the putative target. This approach was used to identify physiologically relevant targets for bioactive compounds including those with low affinity and/or low abundance as well as insoluble targets with multiple trans membrane domains.

#5772 Structural insights and rational design, optimization of highly potent and selective novel GRK5/6 inhibitors for cancer therapy.

Yueyi Chen, Amol D. Sonawane, Rajesh Manda, Ranjith K. Gadi, Arun K. Ghosh, John J. G. Tesmer

Purdue University, West Lafayette, IN

G protein-coupled receptor kinases (GRKs) regulate cell signaling by triggering receptor desensitization via phosphorylation on G protein-coupled receptors (GPCRs). There are seven human GRKs (GRK1−GRK7) where GRK5 and GRK6 are structurally similar. GRK5 is ubiquitous and required for cancer progression in various cancer types. Knock-down of GRK5 has been shown to suppress prostate cancer and non-small-cell lung cancer growth. GRK6 is highly abundant in immune cells and is overexpressed in multiple myeloma (MM). Knocking down GRK6 has been shown to cause apoptosis of MM cells. Therefore, targeting GRK5 or 6 is a potential chemotherapeutic strategy. Currently, we are developing a series of inhibitors for GRK5/6 based on a lead compound derived from sunitinib and utilizing Cys474 residue unique in GRK5/6 to enhance selectivity by covalent capture. We tested a series of novel inhibitor warheads to improve potency and selectivity without potentially toxic functional groups. So far, we have identified several inhibitors with low nanomolar IC_{50} for GRK5 and more than 100,000-fold selectivity over GRK2, another closely related member expressed in the heart. I have developed a pipeline of X-ray crystallography of GRK5 available for soaking various ligands and have solved several structures of novel inhibitor-bound GRK5. The structure elucidated the binding mode of this new class of GRK5 inhibitors, where the core interacts with the adenine site, a fluorophenyl group stabilizes the P loop and density suggests in some cases covalent bond forming between the reversible covalent warhead and Cys474. Our ongoing studies focus on further compound optimizations based on SAR. Overall, the discovery of the inhibitors can significantly facilitate understanding and treatment and cancers.

#5773 Multi-omics profiling of chemotactic characteristics of brain microglia and astrocytoma.

Chih-Yi Chen[1], **Yu-Ching Huang**[1], Wen-Hsiu Su[1], Yi-Ting Liu[1], Chi-Sheng Chen[1], Chia-Yang Li[2], Kun-Che Chang[3], Chia-Yen Dai[4], Shu-Chi Wang[5]

[1]Kaohsiung Medical University, Kaohsiung, Taiwan,[2]Department of Biological Science and Technology / Department of Medicine, Graduate Institute of Medicine, College of Medicine, Kaohsiung Medical University / National Pingtung University of Science and Technology, Kaohsiung, Taiwan,[3]Department of Ophthalmology, Louis J. Fox Center for Vision Restoration, University of Pittsburgh School of Medicine, Pittsburgh, PA,[4]Hepatobiliary Division, Department of Internal Medicine, Kaohsiung Medical University Hospital / College of Medicine and Center of Excellence for Metabolic Associated Fatty Liver Disease, National Sun Yat-sen University, Kaohsiung, Taiwan,[5]Medical Laboratory Science and Biotechnology, Graduate Institute of Medicine, College of Medicine, Kaohsiung Medical University, Kaohsiung, Taiwan

Brain cancer is a deadly disease with low survival rates for over 70 % of patients. Therefore, there is a critical need to develop better treatment methods and strategies to improve patient outcomes. In this study, we explored the tumor microenvironment and discovered unique characteristics of microglia to interact with astrocytoma cells and promote proliferation and migration of collisions. The conditioned medium from the collisions expressed cell chemoattraction and anti-inflammatory responses. To further understand the interactions between microglia and astrocytoma cells, we used flow sorting and protein analysis found that the protein alterations were related to biogenesis in the astrocytoma cells and metabolic processes in the microglia. Both types of cells were involved in binding and activity in cell-cell interactions. Using STRING to demonstrate the protein cross-interaction between the cells. Furthermore, PHB and RDX interact with oncogenic proteins, which were significantly expressed in patients with Glioblastoma Multiforme (GBM) and low-grade glioma (LGG) according to GEPIA. To study the role of RDX in chemoattraction, the inhibitor-NSC668394 suppressed collision formation and migration in BV2 cells in vitro by down-regulating F-actin. Additionally, it suppressed macrophage infiltration in infiltrating islands in vivo of intracranial tumor-bearing mice. These findings provide evidence for the role of resident cells in mediating tumor development and invasiveness and suggest that potential interacting molecules may be a strategy for controlling tumor growth by regulating the infiltration of tumor-associated microglia in the brain tumor microenvironment.

#5774 Are 19del and L858R really not the same disease entities?.

Y. Heo[1], J. Kim[2], Y. Sung[3], **S. Kim**[2], C. Jung[3], J.-O. Kim[2], J.-y. Shin[2], G. Lee[4], S. Chun[4], S. Bu[5], Y. Lee[6], J. Kang[2];

[1]Research Center for Bioconvergence Analysis, Korea Basic Science Institute (KBSI), Chungcheongbuk-do,, Seoul, Korea, Republic of, [2]Seoul St. Mary's Hospital, Seoul, Korea, Republic of, [3]Department of Hospital Pathology, College of Medicine, The Catholic University of Korea,, Seoul, Korea, Republic of, [4]Division of Oncology, Department of Internal Medicine, College of Medicine, The Catholic University of Korea,, Seoul, Korea, Republic of, [5]Division of Cardiology, Department of Internal Medicine, Uijeongbu St. Mary's Hospital, College of Medicine, The Catholic University of Korea,, Seoul, Korea, Republic of, [6]Research Center for Bioconvergence Analysis, Korea Basic Science Institute (KBSI), Chungcheongbuk-do, Korea,, Seoul, Korea, Republic of

IntroductionThe similarities and differences between the two subtypes of common epidermal growth factor receptor (EGFR) mutations have been recognized by clinicians, but actual treatment strategies remain unchanged. The L858R mutation can be explained by the pharmacological conformational plasticity of the receptor protein and other co-occurring mutations, which may be subtypes of EGFR mutations or non-EGFR mutations, and differences in downstream signaling pathways. As long as we know that molecular differences lead to biological differences, it is a challenge for all of us that our treatment strategies must changeWe investigated the RWD, conformational structure and RNA expression profile about two types of common mutations in the mEGFR+ NSCLC patients.MethodWe collected the medical information for stage I-IIIA mEGFR+ NSCLC patients and explored the conformational structure by crystalized radiologic technique. And we performed RNA expression assay using multiplex IF and High-through-output Profiling. ResultOverall, the static structures of wild type (WT), L858R, and 19del (ΔL747-E749) EGFR did not show any significant differences. However, the difference in the static structure between WT-19del and L858R-19del was subtly greater than that of WT-L858R. In addition, further analyses demonstrated no significant structural differences in the phosphorylation sites. However, it should be noted that proteins do not exist as static structures in vivo, and they have a dynamic, flexible structure that changes over time, i.e., plasticity of proteins. Therefore, we investigated the X-ray B-factor value, which is an indicator of flexibility, dynamics, and plasticity of proteins. As expected, the loop or disordered regions mainly shows higher B-factor values, which indicates an active structure, highly changeable and dynamic. Together, the three types of the EGFR protein manifest wholly similar B-factor values, while several local regions present appreciably distinct B-factors. Physical properties such as the dynamic structure may affect intermolecular recognition of EGFR proteins and their function Recent biochemical and biophysical evidence suggests that oncogenic mutations have an impact on the conformational dynamics of enzymesConclusionIn conclusion, our results suggest that Patients with 19del and L858R mutations demonstrated a different clinical course.
It is necessary to consider the dynamic structural characteristics and functional differences of EGFR membrane proteins.

#5775 Structure and dynamics of the major *PDGFR*-β oncogene promoter G-quadruplex and insights into its cellular regulation.

Y. Han, J. Dickerhoff, D. Yang;
Purdue University, West Lafayette, IN

Overexpression of the receptor tyrosine kinase PDGFR-β promotes cancer growth and metastasis. PDGFR-β is a validated cancer target but PDGFR-β kinase inhibitors suffer from lack of selectivity and side effects. G-quadruplexes are an exciting class of non-B DNA secondary structures with functional importance. The G-quadruplex formed in the *PDGFR-β* promoter is a transcription repressor and targetable by small molecules. Therefore, the *PDGFR-β* promoter G-quadruplex is an attractive molecular target for anticancer drugs. Structural information of the *PDGFR-β* promoter G-quadruplex is crucial for understanding its cellular function and rational drug design. Herein, we used nuclear magnetic resonance (NMR) spectroscopy and biophysical methods to determine the structure and dynamics of the major G-quadruplex formed in the human *PDGFR-β* promoter. Unlike canonical G-quadruplexes formed by four runs of three continuous guanines (G), the major *PDGFR-β* G-quadruplex adopts a novel broken-strand structure where a two-G segment is continued by a non-adjacent guanine. The broken-strand G-quadruplex has a vacancy-G-tetrad (vG4) which is filled-in intramolecularly by a distal guanine. Interestingly, we discovered that the major *PDGFR-β* G-quadruplex is a novel mixture of two equilibrating broken-strand G-quadruplexes. Both structures adopt overall parallel-stranded folding with all 1-nt chain-reversal loops. However, a different 3'-filled-in guanine is delivered by a lateral loop, which forms structurally similar hairpin with a unique capping G-G base-pair. The formation of the equilibrating broken-strand G-quadruplexes and unique capping structures are both specific to the *PDGFR-β* promoter sequence. Intriguingly, the observed dynamic equilibrium between the two co-existing structures with different intramolecular fill-in guanines indicates a novel vG4 intermediate, which could be filled-in by cellular guanine metabolites such as cGMP. Therefore, our study provides critical insights into how the dynamics of the major *PDGFR-β* G-quadruplex lead to vG4 formation and potential regulation of gene transcription by cellular guanine metabolites. The determined molecular structures of the novel broken-strand G-quadruplexes provide a structural basis for rational design of small molecules to specifically target the major *PDGFR-β* promoter G-quadruplex for cancer therapeutics.

#5776 Target identification, selectivity profiling and binding site mapping of small molecule and peptide drugs by LiP-MS.

F. Sabino[1], M. Soste[1], D. Kamber[1], M. Ritorto[2], K. Hoeflich[2], M. Hale[2], B. Quade[2], X. Huang[2], N. Beaton[3], R. Bruderer[1], **Y. Feng**[1], L. Reiter[1];
[1]Biognosys AG, Schlieren, Switzerland, [2]Nested Therapeutics, Inc., Cambridge, MA, [3]Biognosys Inc., Newton, MA

Target identification in the cellular context is a critical step for both target-based and phenotypic drug discovery. Limited proteolysis coupled with mass spectrometry (LiP-MS) has emerged as a powerful technique for target deconvolution of small molecules or peptides in cell lysate without compound modification or genetic manipulation of cell lines [1,2,3,4]. Utilizing a non-specific protease under well-controlled conditions, LiP-MS exploits drug-induced structural alteration or steric hindrance on protein targets and utilizes quantitative mass spectrometry to probe over 250'000 peptides covering more than 9000 proteins in the proteome. To aid target ID, this workflow incorporates a 7-concentration dose response experiment and a machine-learning framework [1] to compute a LiP-score to rank identified target proteins, as well as predict potential binding site. In this study, we present target deconvolution results on four small molecule compounds and one peptide compound with very distinct pharmacological profile: 1) staurosporine, a broad-specific kinase inhibitor; 2) roniciclib, a failed clinical-stage pan-CDK inhibitor; 3) selumetinib, an allosteric, non-ATP-competitive MEK 1 and 2 inhibitor; 4) NST-628, a newly developed non-degradating molecular glue inhibiting the RAS/MAPK pathway; and 5) Acetyl-calpastatin, a 24 amino-acid polypeptide inhibitor of calpain 1 and 2. Target ID experiment with staurosporine and roniciclib yielded > 150 and 68 kinase targets were identified respectively. For the pan-kinase inhibitor roniciclib, both cell-cycle CDKs (CDK1/cyclin B, CDK2/cyclin E, CDK4 cyclin D) and transcriptional CDK9 were among the targets. For Selumetinib, LiP-score ranking identified MEK1 and MEK2 as the top two targets, and only kinases among a total of 23 targets. Furthermore, mapping the LiP-peptides from this experiment onto MEK1 showed that they are in close proximity to the selumetinib allosteric binding site on co-crystal structure. Last but not least, we assessed the target landscape of NST-628, a novel non-degrading molecular glue and identified MEK1 and MEK2 clearly as the primary targets. This finding is in line with orthogonal data obtained from X-ray crystallography [5]. Collectively, this data demonstrates that LiP-MS can be deployed to effectively identify protein drug targets and predict binding sites in complex cellular millieu independent of the compound's mechanism of action and without compound modification or labeling. These capabilities make LiP-MS a powerful addition to the target deconvolution toolbox.

#5777 Rewiring EWS/FLI1 with transcriptional chemical inducers of proximity (TCIPs).

M. J. Bond[1], R. P. Golden[2], R. C. Sarott[2], G. DiGiovanni[1], B. A. Karim[2], B. Howard[1], K. Ross[1], N. S. Gray[2], K. Stegmaier[1];
[1]Dana-Farber Cancer Institute, Boston, MA, [2]Stanford University, Stanford, CA

The purpose of this study was to determine if EWS/FLI1 (E/F), the oncogenic fusion protein that drives Ewing Sarcoma (ES), can be rewired to enhance expression of BCL6-controlled genes using Transcriptional Chemical Inducers of Proximity (TCIPs), a novel bivalent small molecule platform.
TCIP molecules recruit a transcriptional regulator, such as BRD4, to the transcriptional repressor BCL6. Upon binding, a ternary complex is formed on chromatin at BCL6-bound loci, causing transcriptional upregulation of BCL6 target genes. Since E/F does not have a *bona fide* ligand, we have used an exogenously expressed N terminal $FKBP^{F36V}$-EWS/FLI1 (N-FK-E/F) fusion system to study how modulation of E/F by TCIPs impacts the transcriptome of ES cells. To eliminate background signal from endogenous E/F, we used CRISPR/Cas9 to knockout (KO) endogenous E/F. Our exogenously expressed N-FK-E/F has mutated PAM motifs and is resistant to KO. In our proof-of-concept study we used TCIP1 consisting of *ortho*-AP1867 (oAP), a synthetic ligand for $FKBP^{F36V}$, linked to the BCL6 inhibitor BI3812 (BI) to rewire N-FK-E/F. We have also tested a negative control TCIP (TCIP NEG) that links oAP to a BI derivative that abolishes BCL6 binding. TCIP NEG has similar physiochemical properties to our active TCIP1; however, it cannot bind BCL6, serving as a negative control for ternary complex formation.
TCIP1 rapidly and dose-dependently increases the RNA and protein expression of several BCL6 target genes, like p21, in multiple ES models that stably express N-FK-E/F. TCIP NEG does not increase the expression of BCL6 target genes in ES cells. TCIP1 induces ternary complex formation in ES cell lysates, and ternary complex formation is necessary for activity in ES cells. TCIP1 is specific and does not increase BCL6 target gene levels to the same extent in ES cells expressing a FKBP-GFP construct or in parental ES cells lacking N-FK-E/F. RNA sequencing of EWS502 N-FK-E/F expressing cells shows that TCIP1 treatment induces a larger increase in expression of BCL6 target gene RNA than BCL6 inhibition. Moreover, CUT&RUN experiments in EWS502 N-FK-E/F expressing cells suggest TCIP1 leads to an accumulation of N-FK-E/F at the promoters of BCL6 target genes. Motif analysis showed that TCIP1 increases the likelihood of N-FK-E/F binding to BCL6 consensus sequences as wells as increases the likelihood of BCL6 binding to E/F recognition sequences. In future studies we will conduct RNA sequencing, CUT&RUN, and other ‘omics’ approaches (e.g. DisP-seq) to compare TCIP1 to TCIP NEG in multiple cell lines at multiple concentrations and time points.
Our data suggests that N-FK-E/F can be rewired to induce the expression of BCL6 target genes in ES. Since ES is driven solely by E/F, TCIPs may be promising next generation therapeutics. Our study provides a proof-of-concept that will be the foundation for the development of future TCIP molecules that recruit endogenous E/F once suitable ligands are developed.

#5778 Determining the structure and function relationship of the oxysterol-binding protein (OSBP) to guide drug development.

R. Bayimenye[1], J. L. Berrios-Rivera[1], S. Nimmo[1], C. R. Bourne[2], A. W. G. Burgett[1];

[1]University of Oklahoma Health Sciences Center, Oklahoma City, OK, [2]University of Oklahoma, Norman, OK

The human Oxysterol Binding Protein Structure and function relationship remains elusive, yet the anti-cancer and antiviral molecules library targeting OSBP and OSBP-Related proteins (ORPs) continues to grow. OSBP is a ubiquitously expressed protein in most eukaryotes, functioning as a master lipid sensor and cholesterol regulator in cells. OSBP and its closely related protein ORP4 are also reported to be essential in several human diseases, including viral infection and cancer cell proliferation. Our lab has shown that the natural product OSW-1 has potential anti-viral and anti-cancer activity through targeting OSBP and ORP4, as confirmed with protein-ligand interactions that showed binding with high affinity. Moreover, several anti-cancer molecules targeting the ORPs provoke different protein conformation changes and, therefore, lead to varying OSBP functions. However, the structure of full-length OSBP is still unknown, which leaves a gap in knowledge regarding the compounds' mechanism of action or how OSBP could be established as a molecular anti-cancer target. Our goal is to determine the structure and function relationship of OSBP with emphasis on the effect of small molecule ligands on cellular OSBP levels and function. In pursuit of this research goal, we aim to determine the in vitro activity of OSW-1 analogs (OA) isolated in our lab, as well as determine their interaction with OSBP and ORP4 proteins in multiple cancer cell lines. We mainly seek to determine the structure and ligand interaction with the OSBP-ligand binding domain (LBD) and full-length OSBP to shed light on the conformation changes that occur upon ligand binding. Preliminary data indicate that the tested OA compounds are active in multiple cancer cell lines with reduced OSBP levels effect, suggesting a similar mechanism of action to OSW-1. A transient expression of full-length OSBP and LBD showed that the truncated OSBP (LBD) was mostly found in the pellet, which could imply low solubility, while the full-length OSBP showed sufficient solubility. Our efforts are currently focused on purifying full-length OSBP. We are also working towards purifying full-length OSBP with a cleavage site that allows cutting out the LBD, thus solving the insolubility issue. Once obtained, the full-length OSBP and the ligand binding domain will be used for both binding and structure determination studies.

#5779 Enhancing selectivity and overcoming tissue-specific toxicity in drug discovery: A novel BET inhibitor with targeted delivery for prostate cancer treatment.

C. Tang[1], R. Traquete[1], E. Henderson[2], J. Conde[1], S. Picaud[3], P. Filippakopoulos[2], G. Bernardes[4];
[1]Instituto de Medicina Molecular, Lisbon, Portugal, [2]Ludwic Cancer Institute, Oxford, United Kingdom, [3]Nuffield Department of Medicine, Oxford, United Kingdom, [4]Yusuf Hamied Department of Chemistry, Cambridge, United Kingdom

Improving selectivity and circumventing tissue-specific toxicity remain significant challenges in the realm of contemporary drug discovery. Despite the advanced development of highly selective inhibitors, their systemic distribution often stimulates off-tissue unwanted side-toxicity. To address this, we engineered a highly selective inhibitor that specifically targets and releases a small molecule drug payload to a desired cell type.
As a proof of concept, we apply this method to epigenetic inhibitors of BET proteins, which are crucial regulators of gene transcription implicated in the progression and survival of cancer. We engineered a novel BET-selective chemotype conjugated to a Prostate-Cancer specific targeting component in order to overcome the off-tissue effects of state-of-the-art BET inhibitors.
To achieve delivery of the compound, we modified the benzodiazepine (BzD) scaffold of the well-established BET inhibitor I-BET762, conjugating the tertiary amine with a self-immolating motif, allowing for intracellular compound release upon an enzymatic trigger. This new chemotype, RT53, maintains the biochemical properties of I-BET762, showing potent and selective binding to BET bromodomains in a range of established biophysical assays.
In cells, RT53 phenocopied I-BET762 on cancer cell lines, including prostate cancer. We validated the established strong anti-proliferative effect following BET inhibition using clonogenic assays, flow cytometry, and monitored the suppression of MYC expression. Moreover, we established the transcriptional rationale for loss of cellular fitness using RNA sequencing, discovering strong down-regulation of solute carriers, depriving cells of nutrient flux and disrupting normal processes.
Furthermore, RT53 exhibits antitumor activity *in vivo*, in localized models of prostate cancer established in male athymic nude mice. The targeted delivery of RT53 demonstrated superior efficacy *in vivo* ameliorating on-target, off-tissue toxicity, as low-dose treatment led to almost complete elimination of grafted tumor sites, significant extension of survival, and no signs of toxicity on non-targeted tissues.
Taken together, our data establish a novel class of BET-specific inhibitors offering a handle for selective delivery *in vivo*, enhancing the therapeutic index while avoiding on-target off-tissue toxicity.

#5780 Simultaneous targeting existing proteins and nascent proteins for synergistic anticancer activity.

B. X. Li[1], J. Wang[1], B. Chao[1], J. Piesner[1], F. Kelly[2], S. Kaech Petrie[1], **X. Xiao**[1];
[1]OHSU Knight Cancer Institute, Portland, OR, [2]Oregon health & Science University, Portland, OR

Protein synthesis and subsequent delivery to the target locations in cells are essential for their proper functions. Newly synthesized proteins and existing protein have differential properties that can potentially be exploited for targeting to maximize therapeutic potentials. Methods to label and distinguish newly synthesized proteins from existing ones are critical to assess their differential properties, but such methods are lacking. We describe the first chemical genetics-based approach for selective labeling of existing and newly synthesized proteins that we termed as $_{CG}$-SLENP. Using HaloTag in-frame fusion with lamin A (LA), we demonstrate that the two pools of proteins can be selectively labeled using $_{CG}$-SLENP in living cells (https://doi.org/10.1101/2023.11.02.565346). We further employ our recently developed selective small molecule ligand LBL1 for LA to probe the potential differences between newly synthesized and existing LA. Our results show that LBL1 can differentially modulate these two pools of LA. We further extend our $_{CG}$-SLENP strategy to evaluate the differences of the two pools for BRD4 (bromodomain containing 4). These observed differences motivated us to investigate the synergistic anticancer properties of BRD4 degraders and inhibitors in triple negative breast cancer. Our results show that simultaneous targeting newly synthesized proteins and existing proteins display strong synergistic anticancer activities.

#5781 Development of RNA-Seq library preparation method for highly degraded FFPE RNA and ultra-low RNA input.

E. Star[1], N. Karim[1], B. DeGroen[1], M. Salgado[1], D. Wang[1], J. Li[1], K. Ilic[1], S. Beaudoin[2], C. Vakulskas[2], B. Min[1], P. Chen[1];
[1]Integrated DNA Technologies, Inc., Redwood City, CA, [2]Integrated DNA Technologies, Inc., Coralville, IA

RNA sequencing (RNA-Seq) has been widely used for investigating genetic variations, splicing, and gene expression in cancer research. However, RNA-Seq library preparation from archived formalin fixed paraffin embedded (FFPE) samples tends to fail due to both limited quantity and high degradation. We aimed to overcome the sample quality and quantity limitations by leveraging both in-house cDNA synthesis modules and the unique, single-stranded ligation strategy of the IDT xGen cfDNA & FFPE DNA Library Prep chemistry and workflow. This approach delivers high library conversion of input molecules and maximizes high quality data from sequencing. To represent the types of challenging cancer samples that may be lost during traditional RNA-Seq analyses, we collected thirty-seven low quality RNA FFPE samples (RIN <3) from lung, breast, colorectal, thyroid tumors and more. In addition, twenty-one frozen tissue RNA samples and Nine RNA reference materials were used as controls. Regardless of sample origin, 25 ng of total RNA were taken for RNA-Seq library preparation. In-house cDNA synthesis modules were used for the 1st and 2nd strand cDNA synthesis followed by Illumina library generation using IDT's xGen™ cfDNA & FFPE DNA Library Prep Kit. All sample types generated sufficient high-quality libraries (>1 ug) for hybridization capture enrichment. The RNA-seq libraries were captured using IDT's custom designed panel with 56 known fusion targets. We detected all expected fusion targets from the tested samples. No correlation was observed between sample quality and the number of genes detected between the different types of samples including the low quality FFPE. To test the lower limits of the workflow, a degraded FFPE sample and a Universal Human Reference RNA (UHR) were used to construct libraries with inputs from 1ng to 10pg. High quality libraries were successfully constructed with as low as 10pg of UHR and 50pg of the FFPE RNA sample. We demonstrated the flexibility of our current cfDNA & FFPE DNA Library Prep whose high conversion rate could be used for constructing libraries from low quality and degraded FFPE RNA in conjunction with our in-house cDNA synthesis modules. Libraries were successfully constructed from ultralow RNA input which could be leveraged for cfRNA applications. The high RT efficiency enables processing FFPE samples with very low-quality scores and provides users with an effective solution for their degraded RNA samples challenges.

#5782 Probing monomer - dimer and conformational transitions of PLK1 using catalytic and polo-box domain inhibitors.

M. Sanhaji[1], M. Raab[1], G. Merhej[2], C. Nageswara Rao[2], I. Babic[3], E. Nurmemmedov[3], K. Strebhardt[1], M. Wyatt[2], **C. McInnes**[2];
[1]Goethe University, Frankfurt, Germany, [2]University of South Carolina, College of Pharmacy, Columbia, SC, [3]Nerd Bio, San Diego, CA

Polo Like Kinase 1 (PLK1), a sought-after target for drug discovery, is an essential mitotic kinase consisting of a catalytic domain (KD) and a polobox domain (PBD), the latter of which plays roles in substrate recognition, subcellular localization and further acting as an autoinhibitory regulatory domain. PLK1 can exist either in an inhibited closed conformation or an open active state allowing interaction with and phosphorylation of substrates. PLK1 has also been shown to be regulated by interchange between monomeric and dimeric forms through binding to the Bora protein and by activation loop phosphorylation. We have described PBD-binding molecules termed abbapolins that inhibit cellular phosphorylation of a PLK1 substrate and induce loss of intracellular PLK1. In addition, due to their engagement of the cryptic pocket (ligand induced) of the PBD, we proposed that abbapolins would interfere with formation of PLK1 dimers. Here we provide evidence further supporting the ability of abbapolins to block PLK1 cellular dimerization and that this is related to their mechanism of anti-proliferative activity. In a separate study, using a cellular thermal shift assay, KD inhibitors were shown to decrease soluble PLK1, indicating that catalytic-site binding results in less stable PLK1 suggestive of an open conformation. We have extended these observations using a sensitive readout of cellular target engagement employing a Microtag overexpressed PLK1. In this format, we observe heat-induced destabilization of PLK1 upon nanomolar engagement by two lead KD inhibitors, BI2536 and onvansertib, currently being clinically evaluated. Furthermore, cyclapolin 9, a low molecular weight kinase inhibitor that, unlike the other two KD inhibitors does not protrude from the active site, did not induce significant destabilization. We have also carried out experiments using a fluorescently labeled version of BI2536 to probe the conformational effects of PBD binding upon the KD. These data solidify the observations that relief of autoinhibited PLK1 is induced by certain KD binders and highlight the conformational perturbations from KD versus PBD binding. These observations have implications for the development of ATP-competitive PLK1 inhibitors because catalytic inhibitors may conversely promote PLK1 non-catalytic functions, which may explain their lack of clinical efficacy to date. Furthermore, the demonstration that the abbapolins are mechanistically unique in terms of blocking the dimerization of PLK through the PBD provides impetus for their development as next generation PLK1 inhibitors.

#5783 Receptor tyrosine kinase Tyro3 interaction with ligands and inhibitors.

K. N. Hardeman, C. Starbird;
University of North Carolina, Chapel Hill, NC

TAM receptors (Tyro3, Axl, Mer) are a sub-family of receptor tyrosine kinases that regulate cell survival and homeostasis primarily through their role in clearance of apoptotic cells. While several receptor tyrosine kinases (RTKs) are targeted in various types of cancer therapies, interest in Tyro3 as a potential target in breast cancers has only recently grown. Determining the structure of Tyro3 with and without tyrosine kinase inhibitors (TKIs) bound will provide important missing information to aid in the design of treatments that can be combined with existing cancer treatments, as dual treatment is often necessary. I have designed constructs that will be used for crystallization of the Tyro3 kinase domains. I mapped the full portion of the kinase (called "Small"), an extended kinase ("Big"), and a smaller catalytic domain ("Cat"). The kinases were made through a molecular cloning method (Gibson Assembly), sequence verified, and expressed in insect cells for large scale purification. Ni-NTA and gel filtration will be used, followed by crystallization and soaking with inhibitors.

#5784 Structure-based drug design against caPCNA for selective cancer chemotherapy development.

J. Jossart, P. Haratipour, L. Gu, C. M. Li, R. Lingeman, Y. Liu, R. J. Hickey, L. H. Malkas, J. J. P. Perry;
Beckman Research Institute of The City of Hope, Duarte, CA

Proliferating cell nuclear antigen (PCNA) is critical to DNA replication and repair processes, and it is also a proliferation biomarker in a variety of human tumors. A unique cancer-associated isoform of the protein, caPCNA, has been previously identified, allowing for rational-based drug discovery studies to develop leads with the potential for selective therapeutic targeting of cancer cells. Several strategies have been employed to develop agents targeting caPCNA, including peptide and small molecule-based inhibitors, but the success in developing therapeutically tractable compounds has been limited so far. Here, we present the crystal structures and corresponding biochemical characterizations of our novel small molecule-based caPCNA inhibitors, which bind into the PIP-box binding pocket of PCNA. One of our lead compounds is now an investigational new drug that we observed selectively kills cancer cells, and it appears to induce replication stress, apoptosis and increase cancer cell sensitivity to genotoxic agents, while these effects are not observed in non-malignant cell controls. This caPCNA inhibitor is orally administrable, metabolic stable and it suppresses tumor growth as a monotherapy or as a combination treatment, and it has entered clinical trials in the United States. PCNA plays a critical role in temporarily dislodging RNA polymerase II from transcription replication conflict sites, to enable the replication fork to proceed. Thus, structure-based drug discovery approaches to target transcription replication conflict resolution machinery, such as PCNA protein, may open a novel therapeutic avenue for exploiting this cancer-selective vulnerability.

#5785 Shedding light on PARP1-E2F1 interaction by Cryo-EM.

P. Iglesias[1], E. Casajus-Pelegay[2], M. Moreno-Morcillo[2], L. Gonzalez-Rendo[1], L. Porres-Ventin[1], V. Arce[1], R. Fernandez-Leiro[2], **J. Costoya**[1];
[1]Universidade de Santiago de Compostela, Santiago de Compostela, Spain, [2]Spanish National Cancer Research Centre (CNIO), Madrid, Spain

Cell division is orchestrated by a complex network of interactions between proteins involved in numerous signaling pathways that control cell proliferation. One of these main players is the E2F family of transcription factors. The role of these key players is to regulate the expression of several genes important in cell proliferation, particularly those involved in progression through G1 and into the S-phase of the cell cycle. In fact, cell cycle deregulation is a hallmark of cancer, and multiple studies have highlighted the critical role of E2F hyperactivation in tumor progression, angiogenesis, and metastasis. However, targeting a master regulator of cell growth will also have a pernicious effect on non-cancerous cells, thus limiting its applications. In order to overwhelm these restrictions, we propose a therapeutic approach in which E2F transcriptional activity is specifically reduced in cells with hyperactivation of the pathway, such as cancer cells.We and others have shown that poly (ADP-ribose) polymerase 1 (PARP1) is a transcriptional co-activator of E2F1 and, owing to this, loss of PARP results in cell cycle re-regulation and reduction of tumor growth. Interestingly, this effect of PARP1 does not depend on its enzymatic activity, thus opening a completely new strategic approach. Furthermore, considering that most oncogenic processes are associated with cell cycle deregulation, disruption of PARP1-E2F1 interaction could provide a new therapeutic target with a wide spectrum of indications in cancer. Currently, we lack comprehensive structural details regarding the PARP-1/E2F1 protein-protein interaction. To address this, we used cryo-EM to investigate both the standalone structure of PARP1 (full length) and its interaction with E2F1. This approach yielded high-resolution structural insights into the PARP1-E2F1 complex, enabling precise identification of the protein-protein interaction interface (PPI). Through this exploration of structural and molecular determinants governing this interaction, we aim to develop innovative strategies for designing drugs targeted at disrupting this complex. This work was supported by Agencia Estatal de Investigación (AEI/10.13039/501100011033), Xunta de Galicia (GPC GI-1862, ED431B 2020/26; ED431G 2019/02) and European Regional Development Fund-ERDF.

#5786 Epstein-Barr virus nuclear antigen 1 (EBNA1)-targeting probes stimulate interferon-β production by nasopharyngeal carcinoma (NPC) cells to enhance the natural killer cell-mediated cytotoxicity against NPC.

L. Chen[1], X. H. Liu[1], H. T. Yuen[1], **W. C. Cho**[2], K.-L. Wong[3], H. L. Lung[1];
[1]Hong Kong Baptist University, Hong Kong SAR, China, [2]Queen Elizabeth Hospital, Hong Kong SAR, China, [3]The Hong Kong Polytechnic University, Hong Kong SAR, China

Introduction: The prevailing histologic subtype of nasopharyngeal carcinoma (NPC) in the endemic regions is non-keratinizing carcinoma which shows almost consistent association with latent infection by Epstein-Barr virus (EBV). Previously our group developed a series of Epstein-Barr virus nuclear antigen 1 (EBNA1)-targeting probes, which can disrupt the EBV latency maintained by EBNA1, and such lytic induction could alert the immune cells.
Methods: Natural killer (NK) cells of the innate immunity play a significant role in controlling EBV infection. In this study, we investigated whether our EBNA1 probes (ZRL5P4 & L2P4) could activate NK cells to eliminate NPC.
Results: Studies of clinical specimens indicated that tumor infiltration of the cytotoxic NK cell subset is a favorable prognostic marker for NPC patients. Furthermore, the cytotoxicity of circulating NK cells derived from NPC patients is equally well the cells from healthy individuals. If those patients' NK cells can be attracted to infiltrate into the tumors, the tumor burden should be relieved. Indeed, the NPC xenograft with the ZRL5P4 treatment showed heavy mouse NK cell infiltration and tumor size reduction. The essential role of those mouse NK cells was demonstrated. Next, we showed that ZRL5P4 could induce the production of a soluble factor by NPC cells to stimulate the NK cell cytotoxicity. Such NK cell activity was verified in a metastasis NPC model. Mechanistically, the EBNA1 probe treatment could induce the expression of EBV early lytic gene Rta and EBNA1 itself. Both Rta and EBNA1 are known transcription factors to drive the expression of LMP1, the NF-κB signaling was then activated, which turned on the production of the well-known NK cell activation cytokine IFN-β.
Conclusion: Taken together, our results demonstrated that our EBNA1 probes can mobilize NK cells to the tumor sites and activate their anti-tumor activity via the EBV reactivation and stimulation of IFN-β production.

#5787 Structure-function mapping of DHODH shows deviations in protein structure.

Ruchika Pokhriyal[1], Laura Evans[1], Hyuk-Soo Seo[1], Jillian K. O'Neil[1], Betty Rouaisnel[1], Atanas Kamburov[2], Judith Guenther[2], Stefan Gradl[2], Haribabu Arthanari[1], Sven Christian[2], Xiaoping Yang[3], Sirano Dhe-Paganon[1], Julie-Aurore Losman[1]

[1]Dana-Farber Cancer Institute, Boston, MA,[2]Bayer AG, Berlin, Germany,[3]Broad Institute of Harvard and MIT, Cambridge, MA

Dihydroorotate dehydrogenase (DHODH) is a CoQ-dependent enzyme that converts dihydroorotate to orotate in the *de novo* pyrimidine biosynthesis pathway. Multiple structures of DHODH in complex with various small molecule inhibitors have been solved that indicate that DHODH inhibitors bind in the CoQ binding tunnel of DHODH and act as competitive inhibitors of CoQ. We performed saturating mutagenesis screens to identify mutations in DHODH that confer resistance to brequinar and BAY2402234, two highly potent DHODH inhibitors. As expected, many of the resistance mutations localized to the drug/CoQ-binding tunnel of the enzyme. Among the top-scoring drug-binding-domain mutants in both the brequinar and BAY2402234 screens were substitutions A58H and A58T. *In silico* analysis predicted that A58H should impair DHODH binding to both brequinar and BAY2402234. However, A58T was predicted to only impair binding of DHODH to brequinar. We expressed the mutants in a DHODH inhibitor sensitive cell line and confirmed that they both confer resistance to brequinar and BAY2402234, and we then assessed the ability of the mutants to bind drug by cellular thermal shift assay (CETSA). We found that, as predicted, DHODH A58H did not bind brequinar or BAY2402234. However, to our surprise, we detected binding of both brequinar and BAY2402234 to DHODH A58T. We generated recombinant DHODH A58T and confirmed that the purified protein was enzymatically active and strongly drug-resistant by DCIP assay and then assessed binding of the mutant protein to brequinar and BAY2402234 by thermal shift assay (TSA). Consistent with our CETSA results, recombinant DHODH A58T bound both brequinar and BAY2402234 *in vitro*. These results suggested that DHODH A58T can simultaneously bind drug and CoQ. However, previously reported DHODH structures indicated that the drug/CoQ binding tunnel is quite narrow and rigid. To determine whether the structure of catalytically-active DHODH is more flexible than inhibitor-bound catalytically-inactive DHODH, we co-crystallized wild-type DHODH with decylubiquinone (DCU), a CoQ analog that can act as a DHODH co-substrate *in vitro*. We found that the structure of DCU-bound DHODH differs from previously published DHODH structures in two important ways: (1) there appears to be a second point of ingress into the active site of DHODH next to the CoQ tunnel that may be able to accommodate a highly non-polar molecule such as CoQ/DCU and (2) the ‘flap’ covering the DHO/orotate ingress/egress region of DHODH, which is ‘closed’ in inhibitor-bound DHODH, is ‘open’ in DCU-bound DHODH. We are currently working to solve the crystal structure of DHODH A58T bound to inhibitor and DCU to ask if DCU can access the active site of DHODH through an alternative hydrophobic tunnel and if DHODH A58T remains in the ‘open’ configuration when bound to drug.

#5788 Targeting p97-NPL4 pathway by copper chelators.

M. Mistrik, Z. Skrott, M. Loffelmann;
Palacky University in Olomouc, Olomouc, Czech Republic

Copper chelators forming stable complexes, such as the bis(diethyldithiocarbamate)-copper complex (CuET), derived from Antabuse (disulfiram, DSF), have shown pronounced anticancer activity. CuET induces aggregation of NPL4, a crucial cofactor of the p97 segregase in the ubiquitin-proteasome system, leading to proteotoxic stress and subsequent cancer cell death. Our study investigates whether NPL4 inhibition is unique to CuET or extends to other dithiocarbamate-copper complexes and distinct copper chelators. Utilizing a cellular NPL4 aggregation screening assay, we examined various chelators for their ability to induce NPL4 aggregation. Our findings reveal that this capacity is relatively common among structurally diverse DTCs-copper complexes and other unrelated copper chelators. Compounds that caused NPL4 aggregation also triggered NPL4-p97 complex immobilization, polyubiquitinated protein accumulation, and unfolded protein and heat shock responses. These responses correlated strongly with cancer cell cytotoxicity, particularly potent at nanomolar concentrations, underscoring NPL4 as a critical target. Our results demonstrate the broad potential of copper chelators in targeting NPL4, inducing lethal proteotoxic stress in cancer cells, and offering significant implications for drug development.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Cancer Treatment: New Technologies
Poster Session

#5792 Rapid and efficient generation of panels of T cell engaging (TCE) multispecific antibodies via complementary technologies.

Cory Ahonen, Nathan Sharkey, Melissa Durkin, Andrew Avery, Michael Battles, Beth Sharkey, Kyle Barlow, Arvind Sivasubramanian, Caitlin Stein, Bradley Lunde, **Kevin Schutz**, Bianka Prinz, Rob Pejchal, Paul Widboom, Eric Krauland

Adimab LLC, Lebanon, NH

A goal of immunotherapy is to induce an anti-tumor response that is potent and specific. However, there is increasing understanding that currently approved monospecific checkpoint inhibitors are not effective for all patients and/or indications. Thus, investigators are increasingly pursuing multispecific antibody treatments in an attempt to enhance clinical outcomes. These treatments may either take the form of mixtures (administered simultaneously or in series) of multiple monospecific antibodies, or as single entity, multispecific antibodies ('multispecifics'). In the case of multispecifics, the large number of possible topologies and complexity of manufacture necessitate the development and application of a robust set of complementary technologies. We have developed an exemplary set of such technologies. Herein, we demonstrate the ability to direct desired antibody chain pairing (HC-HC and HC-LC), isolate and engineer single-domain antibodies, as well as generate large (≥100) panels of multispecific antibodies with diverse topologies from a limited number of input molecules. These technologies can be leveraged in combination with our affinity and developability-optimized TCE αCD3 and αCD28 antibody panels to achieve desired potency without the need for additional discovery or engineering.

#5793 Functional DKK1 antibodies binding to cysteine-rich domain 1 or 2 of hDKK1 demonstrate antagonistic activities on tumor suppression or TCF/LEF signaling.

L. Wang, Z. Han, M. Yang, A. G. Lujan Hernandez, V. Prabhu, C. F. Hu, T. Htoy, M. Villalta, T. Z. Yuan, H. Giang, A. Sato;
Twist Bioscience, South San Francisco, CA

Wnt signaling plays an important role in embryonic development and tumorigenesis. These biological effects are exerted by activation of the β-catenin/TCF transcription complex and consequent regulation of a set of downstream genes. DKK1 has been shown to be a potent inhibitor of Wnt signaling via competing Wnt binding to LRP5/6. DKK1 is tumorigenic in multiple cancer types and also immunosuppressive via MDSCs and NK cells. Emerging evidence indicates that DKK1 has been involved in T cell differentiation and induction of cancer evasion of immune surveillance by accumulating MDSCs. Consequently, DKK1 has become a promising target for cancer immunotherapy, and the mechanisms of DKK1 affecting cancers and immune cells have received great attention. With Twist's precision DNA writing technologies, we have created phage display libraries with diversity greater than 1×10^{10}, and utilized machine learning model for optimal discovery. In this study, we discovered anti-DKK1 antibodies bind to different cysteine-rich domain (CRD) of hDKK1 by epitope binning and mapping, and block the binding of DKK1 to the receptor. Binding of the antibodies to different CRDs of hDKK1 lead to different activation effect. The *in vitro* functional assays showed that the interaction of Wnt to its receptor was restored in the presence of anti-DKK1 antibodies binding to DKK1 CRD2, resulting in TCF/LEF signaling upregulation. Moreover, anti-DKK1 antibodies binding to DKK1 CRD1 induced immune cell activation and led to tumor cell cytotoxicity. *In vivo* study indicated anti-DKK1 antibody lead is potent in tumor regression. Our anti-DKK1 lead shows promising efficacy in cancer immunotherapy without influencing Wnt canonical pathway.

#5794 DX2206, a humanized monoclonal antibody that targets IL1RAP, exhibits potent inhibition of IL-1 pathways and activities against tumors *in vitro* and *in vivo*.

Q. Liu, Y. Ru, Y. Jiang, H. Li, W. Li, L. Yang, **Q. Shi**;
Singlomics (Beijing DanXu) Biopharmaceuticals Co., Ltd., Beijing, China

Background: The Interleukin-1 Receptor Accessory Protein (IL1RAP) is found on cancer cells, stromal cells, and infiltrating immune cells within the tumor microenvironment (TME) of various cancers. It plays an important role in tumor development at various stages by activating IL-1 superfamily pathway, thus become an interesting target in cancer treatment.
Methods: We investigated the correlation between IL1RAP and tumor prognosis through the analysis of the public dataset. An antibody discovery campaign was performed and DX2206 was identified as the top clone against IL1RAP. Epitope of DX2206 was determined by examining the binding of DX2206 with different IL1RAP structural domains and in silico analysis. The activities of DX2206 against IL-1, IL-33, and IL-36 were examined using multiple assays with HEK293-Luc reporter cells, primary HUVEC cells, and A431 human skin squamous carcinoma cells. In vivo efficacy was evaluated in a CDX model.
Results: Based on public data, IL1RAP is overexpressed in various types of cancer patients compared to healthy individuals, and high expression of IL1RAP is associated with poor prognosis in multiple cancer types. Furthermore, high expression of the members of the IL-1 superfamily, such as IL1RAP, IL-1, and IL-36, are negatively correlated with pan-Cancer OS. Our epitope analysis indicated that DX2206 binds to a unique epitope within IL1RAP domain 2. In vitro assays demonstrated that DX2206 inhibited the activities of all three pathways, IL-1, IL-33, and IL-36, with sub-nanomolar IC50s. Simultaneously, it induced a potent ADCC effect in the tumor killing assay. Finally, in a CDX model, DX2206 significantly inhibited tumor growth in vivo.
Conclusions: We discovered a potent antagonist antibody, DX2206, that binds to a unique epitope of IL1RAP, inhibits all three pathways of signaling, and demonstrates in vitro and in vivo activities against tumors. Considering these characteristics, DX2206 emerges as an outstanding preclinical candidate for cancer therapy. IND enabling study was ongoing to expedite the candidate into clinic.

#5795 Potent and selective degradation of KAT2A and KAT2B induces profound cell state changes and inhibits growth of AML, SCLC and NEPC model systems.

K. S. Straley[1], J. Neef[1], I. Antony-Debre[2], M. Bhatta[1], S. Sharma[1], S. Sinicropi-Yao[1], J. DeBartolo[1], A. McRiner[1], B. Chan[1], H. Wilson[1], C. S. Lee[1], Z. Boudhraa[3], M. El Ezzy[3], U. Sharif[4], M. Bittinger[1], L. Antipov[1], T. G. Graeber[5], S. de Botton[2], K. E. Yen[1], D. S. Millan[1];
[1]Auron Therapeutics, Newton, MA, [2]Gustave Roussy Cancer Center, Villejuif, France, [3]Paraza Pharma, Inc., Laval, QC, Canada, [4]Sygnature Discovery, Alderley Park, United Kingdom, [5]UCLA, Los Angeles, CA

Phenotypic plasticity, or the ability of cancer cells to switch between cell states, has recently been recognized as a key hallmark of cancer. Cancer cells can hijack normal developmental pathways, preventing terminal differentiation or causing de-differentiation or transdifferentiation to a more proliferative, plastic cell state similar to those found in early development. Using our proprietary AI/ML platform AURIGIN, we created a high-resolution atlas to define the drivers of normal cell states during human development. After mapping primary human tumors to the atlas, we identified the histone acetyltransferase KAT2A as a key driver of tumor cell plasticity in a subset of acute myeloid leukemias (AML), small cell lung cancer (SCLC) and neuroendocrine prostate cancer (NEPC). Targeting KAT2A was genetically validated in MOLM-13 (AML) cells, where knockdown resulted in significant cell growth inhibition and induction of cell state changes consistent with a more mature differentiation phenotype. Similarly, an early tool heterobifunctional degrader of KAT2A and KAT2B (AUR101) resulted in potent growth inhibition and granulocytic differentiation in MOLM-13 cells and in 5/12 primary AML patient samples grown ex vivo. Treatment of NCI-H1048 SCLC cells with AUR101 potently degraded KAT2A/B, induced a significant shift from a dedifferentiated cell state to a more differentiated epithelial cell state and potently inhibited cell growth both in vitro and in vivo.

The strong biological validation of KAT2A/B in SCLC and AML tumors, led us to develop AUR1545, a novel sub-nanomolar degrader of KAT2A and KAT2B. AUR1545, with its improved drug like properties, was tested across representative models of AML, SCLC and NEPC. In vitro, treatment with AUR1545 inhibited proliferation and promoted profound cell state changes in MOLM-13 (AML) cells. In NCI-H1048 (SCLC), LASPC-01 (NEPC) cell lines as well as a primary NEPC organoid model, AUR1545 demonstrated potent antiproliferative effects. In vivo, AUR1545 significantly inhibited tumor growth in an NCI-H1048 xenograft model. Taken together, these data genetically and pharmacologically validate KAT2A and KAT2B as key drivers of cell state plasticity in SCLC, NEPC and AML tumors and point to their utility as novel targets in these aggressive, metastatic and drug resistant cancers.

#5796 A HER3 antibody that uniquely blocks the HER3 heterodimerization interface effectively inhibits tumor growth in pre-clinical models with potentially oncogenic HER3 mutations.

W. Toy[1], D. Thakkar[1], R. Magallanes[1], S. Wu[2], M. Poi[2], A. Mas[1], K. Paszkiewicz[1], P. Ingram[1], J. Boyd-Kirkup[1];
[1]Hummingbird Bioscience, Singapore, Singapore, [2]Caris Life Sciences, Phoenix, AZ

HER3 activation, via NRG1 ligand-dependent and -independent heterodimerization with HER2 or EGFR, has been associated with tumor progression and acquired resistance to therapies in multiple indications. HER3 mutations, detected in around 3% of cancer cases, may drive oncogenic signaling, leading to rapid tumor growth. Currently, there are no approved targeted therapies for HER3 mutations. Through analysis of real-world data and structural modelling of HER3 heterodimers, we identified four common HER3 mutations located within or close to the dimerization interface of HER3, suggesting a potential impact on HER3 heterodimerization. Immunoprecipitation assays confirmed that all four mutations increased the heterodimerization of HER3 with both HER2 and EGFR. Further, conversion of an endogenous HER3 mutation to wild type via CRISPR editing significantly reduced the growth of KYSE-150, a HER3 mutant cell line. HMBD-001 is a clinical-stage anti-HER3 antibody rationally developed to uniquely block the HER3 dimerization interface to potently inhibit HER3 heterodimerization. Through structural analysis and FACS binding on HER3 mutation cell lines, we confirmed that the binding epitope of HMBD-001 does not overlap with the selected HER3 mutations and therefore may be a good therapeutic option for patients with HER3 mutations. In vitro, HMBD-001 suppressed HER3 mutation-driven PI3K/AKT signaling, as demonstrated by the reduction of phosphorylated HER3 and AKT levels. In multiple cell- and patient-derived xenograft models with HER3 mutations HMBD-001 response achieved >80% tumor growth inhibition. Based on this encouraging preclinical data, a Phase Ib clinical trial (NCT05919537) has been initiated, evaluating HMBD-001 in patients with aberrant HER3 signaling, including HER3 mutations.

#5797 Next generation antibody drug conjugates: Multi-payload conjugates targeting multiple mechanisms of cell killing.

R. L. Kendall[1], M. Lobba[1], S. Johri[1], C. Symister[1], D. Trinter[1], M. Nguyen[1], D. Gutierrez[1], S. Brady[1], A. Lau[1], M. B. Francis[2];
[1]Catena Biosciences, Inc., Berkeley, CA, [2]University of California, Berkeley, Berkeley, CA

Introduction: ADCs have had tremendous impact on patient outcomes in breast cancer and are now second line therapy for stage IV HER2 positive metastatic breast cancer. However, many patients fail to respond or relapse after treatment with ADC therapies due to tumor heterogeneity and resistance to ADC payloads. We are developing next generation ADCs that deliver targeted combination chemotherapies with a single molecule.
Method: CatenaBio has developed a novel system capable of attaching distinct payloads at different sites to the same antibody, enabling the production of highly stable single-molecule targeted combination therapies, Multi-Payload-Conjugates (MPCs), with a well-defined drug-antibody ratio (DAR).
Results: We screened combinations of different payloads targeting several different mechanisms of cell division attached to trastuzumab at different DARs to optimize tumor cell killing. These targeted combination ADCs demonstrated robust killing in both HER2 high and low tumor cell lines. Additionally, these novel MPCs show potent inhibition of tumor growth in a HER2+ xenograft model of cancer.
Conclusion: Antibody Drug Conjugates have revolutionized the treatment of high HER2 positive breast cancer. More recently advances have been made in the design of ADCs to expand indications to include HER2 low as well as HER2 negative patients. Multi-payload Conjugates® offer the next step in ADC design and allow for the combination of multiple mechanisms of action in a single MPC that are highly effective across multiple breast cancer cell lines and HER2 expression levels. These molecules offer the potential to circumvent tumor resistance pathways and deliver deeper and more durable responses.

#5798 Preclinical safety assessment for specificity of biotherapeutics using the membrane proteome array.

K. S. Raghavan, J. T. Sullivan, C. Navia, R. H. Fong, B. J. Doranz;
Integral Molecular, Philadelphia, PA

Rigorous specificity analysis is critical for the development of antibody-based therapies, as even minimal off-target binding can lead to toxicity and clinical failures. Long believed to be exquisitely specific, recent preclinical data and our own work indicate that monoclonal antibodies (MAbs) frequently (~25%) display cross-reactivity. In many cases, off-target interactions occur with unrelated proteins that cannot be predicted by protein sequence homology. Cross-reactivity can lead to serious or even life-threatening consequences especially when MAbs are configured as bispecifics, antibody-drug conjugates (ADC) or CAR-T cell therapies, and IND applications for biotherapeutics require cross-reactivity assessment to prevent adverse events. Tissue cross-reactivity (TCR) studies have traditionally been used to screen for off-target binding, however, with poor predictive value for in vivo safety and toxicity. We developed the Membrane Proteome Array (MPA) platform to de-risk MAb-based therapeutics by testing for specificity across 6,000 human membrane proteins expressed in unfixed cells. The MPA assesses binding interactions by high-throughput flow cytometry allowing for high sensitivity detection and rapid analysis. All targets identified on the MPA screen are validated by secondary titration analysis. In contrast to TCR studies, proteins in the MPA exist in their native conformations and are not altered by fixation. Recently, we used the MPA to select a lead antibody candidate targeting the oncotherapeutic target Claudin 6 (CLDN6). Through MPA screening, we successfully identified a lead candidate devoid of cross-reactivity against other CLDN family members or any other membrane protein across the human genome. The MPA has also been used to rapidly evaluate the specificity of novel CAR-T cell therapies for cancer and autoimmunity. The MPA has been used for lead selection and data from the MPA has been accepted by the FDA as a part of IND applications for antibody-based therapies. The MPA is currently under consideration for being developed as an FDA-qualified Drug Development Tool.

#5800 Ultrasound-mediated nano-drug delivery system to enhance cancer treatment efficacy: An *in vitro* study.

Farshad Moradi Kashkooli, **Anshuman Jakhmola**, Tyler K. Hornsby, Graham A. Ferrier, Jahangir (Jahan) Tavakkoli, Michael C. Kolios

Toronto Metropolitan University, Toronto, ON, Canada

Conventional non-targeted nano-sized drug delivery systems face limitations such as restricted drug penetration depth and treatment efficacy in solid tumors. External stimulus such as ultrasound waves can trigger targeted, on-demand drug release from the nanocarriers. We demonstrate a first-of-its-kind use of low-intensity pulsed ultrasound (LIPUS) to induce Doxorubicin release from the surface of gold nanoparticle drug carriers. Our 1-MHz LIPUS beam is capable of penetrating tissue to sufficient depths with the required power/intensity for drug release applications with a nominal intensity of around 3 W/cm^2 in the region of interest (ROI). This level of intensity is necessary to elevate the tissue temperature to the mild hyperthermia range of 41 to 45 °C. Our *in vitro* experiments demonstrate a remarkable 22% enhancement in drug release with the addition of LIPUS. Measurements of drug release kinetics, with and without LIPUS, suggest that LIPUS shifts the drug release mechanisms from static (Fickian) to dynamic (non-Fickian) release *in vitro*. Thus, revealing the intricate interactions between ultrasound and drug release from gold nanoparticle drug carriers. To assess the efficacy of the delivery system, we developed an *in vitro* cell culture model with a customized ultrasound exposure setup. The LIPUS device was situated at the bottom base of a water tank, directing ultrasound beam upward toward a region of interest where the MDA-MB-231 breast cancer cells were located 35 mm away from the LIPUS element. We found that the LIPUS device operating at an acoustic power of around 4 W increased cell killing efficacy by approximately 15% ± 2% when compared to conventional nano-drug delivery, highlighting a significant improvement attributed to ultrasound-induced mechanical effects. At the cellular level, these results underscore the potential advantages of ultrasound-mediated nano-drug delivery over conventional chemotherapy and non-targeted nano-drug delivery.

#5801 Targeted delivery of Exatecan to tumors via a novel cell-penetrating, anti-DNA antibody.

Zaira Ianniello[1], Elias Quijano[2], Denise Hegan[1], Venu Bommireddy[3], Dale Ludwig[3], Peter M. Glazer[1]

[1]Therapeutic Radiology, Yale University School of Medicine, New Haven, CT,[2]Genetics, Yale University School of Medicine, New Haven, CT,[3]Gennao Bio, Pennington, NJ

The formulation of novel chemotherapeutics capable of precisely targeting and damaging tumor cells, while preserving the integrity of healthy tissues, represents a principal challenge and is recognized as one of the biggest achievements in cancer treatment in the last few decades. Antibody-drug conjugates (ADCs) hold significant potential as an effective cancer treatment, by targeting and delivering cytotoxic drugs exclusively to tumor cells that express distinct antigens associated with malignancy. Due to the necessity for specific surface antigens, therapies with ADCs are limited to specific tumor subtypes. In this study, we show the potential of a lupus-derived, cell-penetrating, anti-DNA antibody for delivering of cytotoxic payload to tumors *in vivo*. We utilized a fully humanized variant, named as V66, which was chemically linked to the Topoisomerase I inhibitor, Exatecan. The primary mechanism involved in V66 cellular penetration is mediated by the Equilibrative Nucleoside Transporter ENT2. The latter shows elevated expression in a substantial subset of cancer types in comparison to healthy tissues, broadening the range of applications for ADCs in tumor therapy. Using labeled V66, we demonstrated specific tumor delivery *in vivo*, with minimal impact on healthy tissues. *In vitro* experiments validated the nuclear localization of V66-Exatecan, where it triggers the activation of the DNA damage repair pathway (DDR). As a consequence of the profound DNA damage, exposure to V66-Exatecan leads to cell death, exhibiting low nanomolar EC_{50} values across a diverse range of cell lines. Furthermore, V66-Exatecan treatment presents synthetic lethality with BRCA2 deficiency, evidenced by a substantial increase in sensitivity. *In vivo* efficacy studies conducted in BRCA2 deficient tumors revealed a remarkable effectiveness of V66-Exatecan, leading to almost complete tumor regression and substantial improvement in the probability of survival. In addition to the lack of significant weight changes observed throughout the treatment, further toxicological studies conducted in serum and tissues demonstrated the absence of short- and long-term toxicity, with optimal liver and kidney function and the absence of damage to other tissues. Likewise, bone marrow cellularity remained unaffected. Collectively, these studies indicate that V66-Exatecan achieves targeted treatment of tumor cells, where it induces DNA damage leading to cell death. The *in vivo* application of V66-Exatecan leads to tumor regression without triggering general toxicity that is otherwise associated with Topoisomerase I inhibitors. This work provides the basis to advance a novel nuclear-penetrating ADC for delivering cytotoxic payloads.

#5802 An orally available small molecule JMBI-001 elicits MYC-synthetic lethality and anti-tumor immunity by disabling MKLP2-mediated cellular processes.

T. Zhang[1], Q. Shi[1], J. Kalashova[1], X. Liu[2], X. Zhou[2], C. Yang[1], Y. Long[1], H. Li[1], J. Li[1], G. Lv[1], D. Yu[1], X. Jiang[2], S. Zhang[2], J. Zhang[2], H. Liu[1], **D. Yang**[2]; [1]Chengdu Anticancer Bioscience, Chengdu, China, [2]J. Michael Bishop Institute of Cancer Research, Chengdu, China

The MYC oncogene, a pivotal regulator of various cellular processes, is deregulated in approximately 70 % of human malignancies. Mitotic Kinesin-like Protein 2 (MKLP2) plays a versatile role in both interphase and mitosis and has emerged as a significant prognostic indicator and therapeutic target in cancer. The undruggability of MYC and the scarcity of MKLP2 inhibitors, however, have impeded clinical translation. Our development of JMBI-001, a potent and orally bioavailable small-molecule compound, overcomes these barriers. JMBI-001 elicits loss of function phenotypes in MKLP2 and a synthetic lethal interaction with MYC overexpression. Extensive kinome and safety profiling have revealed no significant off-target effects, and the compound is well-tolerated in long-term animal studies. In preclinical models, JMBI-001 has demonstrated an average tumor growth inhibition rate of 75 % across more than 20 MYC-overexpressing tumor models, including those in the stomach, lung, colon, liver, breast, kidney, skin, and hematopoietic system. Its anti-tumor activity positively correlates with high MYC abundance, aligning with the selective eradication of cells with abundant MYC both *in vitro* and *in vivo*. Notably, JMBI-001 also robustly stimulates systemic anti-tumor immunity, enhancing NK and $CD3^{\pm}$ T cell infiltration in tumors of syngeneic cancer models. Moreover, additive or synergistic effects have been observed when combined with anti-PD1 therapy even in tumors refractory to the immune checkpoint blockade (ICB) therapy. The dual therapeutic actions of JMBI-001 stem from its disruption of MKLP2 functionalities, leading to anomalies, such as Golgi fragmentation in interphase and multipolarity in pro-metaphase. These disruptions lead to two key outcomes: apoptosis and immunogenic cell death, marked by secreted ATP, released high mobility group protein B1 (HMGB1), and surface-exposed calreticulin. These abnormalities, primed and amplified by deregulated MYC, are not observed in non-transformed cells, suggesting their potential as pharmacodynamic markers for monitoring JMBI-001's activity *in vivo*. In conclusion, JMBI-001 represents a novel class of anticancer agents that simultaneously triggers MYC synthetic lethality and anticancer immunity by targeting MKLP2-mediated cellular processes. Its unique mechanisms of action, exceptional bioavailability, potency at low nanomolar concentrations, wide-spectrum efficacy, and favorable safety profile establish JMBI-001 as a promising clinical study-ready drug candidate for treating MYC-driven cancers.

#5803 Tumor treating fields alter PDGFR-β localization in immortalized human pericytes in an *in vitro* model of the blood-brain barrier.

E. Salvador, T. Koeppl, A. F. Kessler, M. Burek, R.-I. Ernestus, M. Lohr, **C. Hagemann**;
University Hospital Wurzburg, Wuerzburg, Germany

Background: Tumor Treating Fields (TTFields) are alternating electric fields of intermediate frequency (100-500 kHz) and low intensity (1-3 V/cm). TTFields at 200 kHz, together with adjuvant chemotherapy, increased progression-free and overall survival of newly diagnosed Isocitrate dehydrogenase (IDH) wildtype and IDH mutant glioblastoma (GBM, WHO CNS 2016) patients in a randomized controlled trial and were therefore approved for the treatment of these patients. We recently demonstrated that TTFields at lower frequencies transiently increase the permeability of blood-brain barrier (BBB) models of murine and human origin by delocalizing junctional proteins such as claudin-5, ZO-1, and occludin in endothelial cells. The interaction between pericytes and endothelial cells contributes to the rigorous integrity of the BBB and is driven by endothelial cells releasing the platelet-derived growth factor β-subunit (PDGF-β), which binds to the receptor PDGFR-β on the surface of pericytes. Here, we investigated the effects of TTFields on pericytes in a human cell-based *in vitro* BBB model in order to gain a better understanding of the effects of TTFields on BBB integrity.
Methods: We prepared an in vitro BBB model composed of human brain microvascular endothelial cells and human pericytes. The model was subjected to TTFields at 100-300 kHz for 24 to 72 h. Afterwards, pericytes were incubated with Alexa Fluor 488-labeled anti-PDGFR-β antibody in order to visualize PDGFR-β localization and cell morphology under the microscope. To make sure that no cell loss occurred due to TTFields treatment, the nuclei of pericytes were counted.
Results: TTFields treatment altered the distribution of PDGFR-β staining after treatment, with fewer, less distinct and more punctate PDGFR-β foci. These changes were most prominent after 72 h of TTFields treatment at 300 kHz. We also observed larger nuclei in the pericytes after treatment but no significant loss of cells could be observed as per the nuclei count.
Conclusion: Together with the previously observed delocalization of tight junctional proteins in endothelial cells, the altered distribution of PDGFR-β pericytes could reveal new mechanistic insights into the effects of TTFields on BBB integrity.

#5804 Preclinical evaluation of LCB84, a novel next-generation TROP2 directed ADC utilizing a cancer selective linker and an MMAE payload.

S. Slocum, H. Kim, C.-W. Chung, C. Park;
LegoChem Biosciences, Inc, Daejeon, Korea, Republic of

LCB84 is an antibody-drug conjugate (ADC) that consists of an antibody targeting human trophoblast cell-surface antigen-2 (TROP2) linked to monomethyl auristatin E (MMAE) via a beta-glucuronidase cleavable linker with a drug-to-antibody ratio (DAR) of 4. LCB84 demonstrates tumor selective killing by multiple mechanisms, increasing both safety and efficacy in parallel. Firstly, the over-expression of TROP2 in many solid tumors allows for targeted delivery of MMAE by LCB84 to Trop2-positive tumor tissues. Secondly, the overexpression of beta-glucuronidase in the lysosome of most tumors facilitates the selective release of active payload within tumor cells compared to normal healthy tissues. Thirdly, the intrinsic selectivity of tubulin inhibitor payloads, such as MMAE, for proliferating cells provides additional protection for non-proliferating normal cells. MMAE is also cell-permeable in its free drug form and can lead to increased efficacy of LCB84 via a bystander effect, enabling activity in heterogenous tumors. LCB84 demonstrates superior efficacy in mouse tumor xenograft studies when compared to benchmark TROP2-targeting ADCs, including sacituzumab govitecan and datopotamab deruxtecan. LCB84 also shows an improved safety profile compared to these clinical benchmarks, as well as compared to traditional MMAE-bearing ADCs, in both *in vitro* and *in vivo* toxicity assessments. Additionally, LCB84 shows a stable preclinical pharmacokinetic profile with minimal loss of payload over time. The utilization of an ADC for target-mediated delivery, in combination with a stable beta-glucuronide trigger for selective payload release in tumors, allows for a superior preclinical therapeutic index which is expected to translate to a best-in-class ADC in the clinic.

#5805 A novel platform of diversified payloads to drive ADC innovation.

P. Orsini, M. Salsa, S. Rizzi, U. Cucchi, D. Faiardi, A. Burocchi, A. Ciavolella, R. Lupi, F. Gasparri, **B. Valsasina**;
Nerviano Medical Sciences, Nerviano, Italy

First generation of antibody drug conjugates (ADCs) for anticancer therapy has been described more than two decades ago with gemtuzumab-ozogamicin receiving the first approval in 2000. Over the last 4 years, 8 new ADCs got FDA approval essentially due to the innovation on the linker improving the disposition in patients and the manufacturability together with the technical advantages in the engineering of biologics and the introduction of new cytotoxic payloads such as deruxtecan. In the future, next generation ADCs will be developed exploring payloads beyond the currently used cytotoxins to improve safety, efficacy and durability of responses and therefore the short- and long-term therapeutic benefit to patients. Nerviano Medical Sciences (NMS) generated a portfolio of novel and diversified payload linkers leveraging on its proprietary chemical collection that includes cytotoxic and targeted payloads. A rigorous screening funnel has been applied considering diversification in terms of MoAs, pharmacokinetic properties, mechanism of resistance and combinability with other therapies to identify the optimal match with specific tumor types and targets, generating a new class of ADCs with improved selectivity and efficacy for hard-to-treat cancers even in chemoresistant settings. NMS ADC platform incorporates 1) our patent protected payload linker NMS-P945, a duocarmycin like DNA minor groove binder and alkylating agent inducing DNA damage, acting in chemoresistant cells with bystander effect and immunogenic cell death properties and generating ADCs highly efficacious in mouse xenograft models and safe when administered in NHP, 2) novel anthracyclines (PNU-682 derivatives) with an improved stability and safety profile and 3) targeted molecules with different mechanism of action including payloads active in synthetic lethality contexts. Payload linkers with different functionalization generated from each payload have been evaluated for chemical stability, sensitivity to lysosomal protease cleavage, and conjugability to monoclonal antibodies. The ADCs, generated with proof-of-concept antibodies (e.g. Trastuzumab), were characterized in terms of Drug to Antibody Ratio (DAR), aggregation level, plasma stability, antigen binding and differential antiproliferative activity in target positive vs target negative tumor cells. The best products resulting from the screening funnel have been subjected to a multidimensional analysis taking into consideration payload properties, tumor features and antigen expression in selected populations with the aim of identifying tumor types particularly sensitive to the payload. Our multidimensional approach coupling new payload linker with innovative MoA to careful selection of patients will allow to reach unprecedented efficacy and safety profile.

#5806 Discovery of a long half-life AURKA inhibitor to treat MYC-amplified solid tumors as a monotherapy and in combination with everolimus.

Y.-H. Chi, C.-P. Chang, T.-K. Yeh, C.-T. Chen, W.-P. Wang, Y.-T. Chen, C.-H. Tsai, Y.-F. Chen, Y.-Y. Ke, J.-Y. Wang, C.-P. Chen, T.-C. Hsieh, M.-H. Wu, C.-L. Huang, Y.-P. Chen, H. Zhuang;
National Health Research Insts., Miaoli County, Taiwan

Aurora kinase inhibitors such as alisertib can destabilize MYC-family oncoproteins and have demonstrated compelling anti-tumor efficacy. In this study, we report 6K465, a novel pyrimidine-based Aurora A (AURKA) inhibitor that reduces levels of c-MYC and N-MYC oncoproteins more potently than alisertib. In an analysis of the antiproliferative effect of 6K465, the sensitivities of small cell lung cancer (SCLC) and breast cancer (BC) cell lines to 6K465 were strongly associated with the protein levels of c-MYC and/or N-MYC. We also report DBPR728, an acyl-based prodrug of 6K465 bearing fewer hydrogen-bond donors that exhibited 10-fold improved oral bioavailability. DBPR728 induced durable tumor regression of c-MYC- and/or N-MYC- overexpressing xenografts including SCLC, triple-negative breast cancer (TNBC), hepatocellular carcinoma and medulloblastoma using a 5-on-2-off or once-a-week dosing regimen on a 21-day cycle. A single oral dose of DBPR728 at 300 mg/kg induced c-MYC reduction and cell apoptosis in the tumor xenografts for more than 7 days. The inhibitory effect of DBPR728 at a reduced dosing frequency was attributed to its uniquely high tumor/plasma ratio (3.6-fold within 7 days) and the long tumor half-life of active moiety 6K465. Furthermore, DBPR728 was found to synergize with the mTOR inhibitor everolimus to suppress c-MYC- or N-MYC- driven SCLC. Collectively, these results suggest DBPR728 has the potential to treat cancers overexpressing c-MYC- and/or N-MYC.

#5807 Bicycle Toxin Conjugates®for the treatment of solid tumors.

S. J. Walsh[1], J. Lahdenranta[2], P. Huxley[1], G. Mudd[1], G. Bennett[1], A. Brown[1], K. van Rietschoten[1], L. Chen[1], H. Scott[1], G. Ivanova-Berndt[1], K. Dzionek[1], M. Rigby[1], O. Burenkova[2], P. Jeffrey[1], P. Beswick[1], M. Skynner[1], N. Keen[2],

[1]Bicycle Therapeutics, Cambridge, United Kingdom, [2]Bicycle Therapeutics, Cambridge, MA

Bicycle Therapeutics is developing a unique class of chemically synthesized medicines. Based on its proprietary bicycle peptide (*Bicycle*®) phage display platform, Bicycles are a unique class of highly constrained peptides, which have demonstrated utility in the targeted delivery of different classes of payloads (for example cytotoxic agents, radioisotopes, immune modulators) into tumors. Bicycles are currently being explored in the clinic as Bicycle Toxin Conjugates® (BTCs) for targeted delivery of cytotoxic payloads into tumors. BTCs consist of a bicyclic peptide that is conjugated to a cytotoxic payload via a cleavable linker, which allows payload release in the tumor microenvironment or within the tumor cell. BTCs were developed to address the shortcomings of antibody drug conjugates (ADCs) in several ways. First, the small size of BTCs (~4 kDa) compared to large biologic entities such as monoclonal antibody (mAb)-based conjugates (~150 kDa) allows rapid distribution to tissues and extensive tumor penetration, which enables rapid delivery of payload into the tumor. Second, the peptidic nature of BTCs results in relatively short, yet tunable, duration of systemic exposure and liver-sparing renal elimination. These properties limit the body's exposure to payload and should therefore minimize damage to normal tissue. In this body of work, we used in vitro cytotoxicity and cell uptake assays and mouse and rat cell line derived xenograft models for 1) cytotoxicity and anti-tumor activity evaluation, and 2) Bicycle and toxin uptake and biodistribution evaluation. Here, we show that BTCs targeting a number of different tumor antigens can deliver toxins to tumor tissue producing durable responses in a range of preclinical in vivo models, spanning several solid tumor indications.

#5808 Designing arrays for delivering tumor treating fields (TTFields) to the mouse head.

S. Zbidat, R. Blatt, M. Sellevoll, M. Gabay, I. Schlachet, S. Cahal, S. Davidi, **I. Tzchori**, A. Haber, M. Giladi, Y. Palti;
Novocure Ltd, Haifa, Israel

Introduction: Tumor Treating Fields (TTFields) therapy is an approved treatment for glioblastoma (GBM), the most abundant malignant brain tumor. TTFields therapy is delivered to patients suffering from GBM continuously by two array pairs placed on their scalp. Since arrays for TTFields application to the mouse head are lacking, and as most GBM animal models are based on mice, in vivo studies of GBM treatment with TTFields are limited. The development of such arrays is challenging due to the small dimensions and specific geometries of the mouse head, but is needed to allow continued preclinical studies to broaden the understanding of the effects of TTFields on GBM.

Methods: We tested various array layouts to identify one that will be suited to the specific geometries of the mouse head. For animal well-being, the selected array was required to minimally restrict head movement. Additionally, we investigated adhesive tapes to allow on one hand good adherence of the arrays to the skin, and on the other hand easy array removal. To examine the feasibility of treating mice with these arrays, they were applied to mice for 11 days, while recording the electric currents and the actual treatment time (from which the percent usage could be calculated). To validate that the selected array layout delivers meaningful field intensity to the desired region, we performed field measurements using a floating scope.

Results: To tackle the limitation of the small head size, we developed an array layout in which only two arrays were situated on the head, while the opposing arrays were located on the mouse torso. Additionally, the arrays on the head were divided into two smaller disks. We also identified a thin and transparent adhesive tape (facilitating correct arrays positioning), that offered good tackiness and allowed easy removal without leaving residual adhesive on the skin. The arrays met the minimum treatment requirements: current ≥50 mA, usage ≥75%, field intensity ≥1 V/cm RMS. At the posterior side of the mouse head, at a location more directly underneath the arrays, field intensity was higher than at the anterior position.

Conclusion: TTFields could be delivered at sufficient intensities to mice heads by utilizing specifically engineered arrays. Our newly developed arrays are flexible and strongly adhering to enable efficient electric field delivery. By allowing TTFields delivery to mice heads, we will facilitate further advancing this research field.

#5810 The impact of scaffold, linker, homogeneity and payload selection on the efficacy and tolerability of anti-tubulin ADCs.

S. D. Collins, N. Keirstead, M. Damelin, D. Toader, K. Ishida, N. N. Kumar, K. L. Lancaster, K. C. Catcott, A. Yau, M. Bala, T. B. Lowinger; Mersana Therapeutics, Inc., Cambridge, MA

Antibody-drug conjugates (ADCs) achieve targeted drug delivery to a tumor and have demonstrated clinical success in many tumor types. The properties of an ADC, including its activity and safety profile, can be highly influenced by its characteristics and individual components, commonly viewed as the antibody, payload, linker, and drug-to-antibody ratio (DAR). However, multiple other characteristics can also significantly influence an ADC's overall drug-like properties, including DAR homogeneity, method of bioconjugation, hydrophilicity, and charge balance. Due to the multiparametric nature of ADC platform optimization, there are few examples in preclinical research, and even fewer in the clinical realm, where comparisons across platforms have been investigated for the same target, both preclinically and clinically, to elucidate how deliberate modifications in molecular design can improve drug-like properties and clinical outcomes. To that end, here we describe the improvements observed in preclinical characteristics, as well as their translational relevance to corresponding clinical characteristics. Two anti-NaPi2b ADCs were produced using two different platforms, XMT-1536 (Dolaflexin platform) and XMT-1592 (Dolasynthen platform), conjugated to the same antibody and employing the same payload. The Dolasynthen platform was deliberately designed, taking into account preclinical and clinical learnings from earlier ADC platforms, to improve both safety and efficacy. In addition, comparisons to clinically approved anti-tubulin ADC platforms are made to provide further context.

#5811 Ultralong CDR3 engineered interleukin-15 antibody fusion for T and NK cell expansion.

R. Huang, D. McGregor, V. Smider;
Applied Biomedical Science Institute, San Diego, CA

Interleukin (IL)-15 is a promising immunotherapeutic cytokine for cancer treatment because it can stimulate the proliferation and cytotoxicity of CD8+ T lymphocytes and nature killer (NK) cells, similar to the action of IL-2, which has been used to treat metastatic melanoma and renal cancer. IL-15 may have improved pharmacologic properties over IL-2 because it doesn't cause vascular leak syndrome or stimulate regulatory T cells. However, IL-15 is difficult to express as a stable soluble protein and has a short half-life *in vitro* and *in vivo*. To solve the problem, we designed an IL-15 ultralong CDR3 humanized bovine antibody fusion. Bovine ultralong CDR3 antibodies have a unique "stalk and knob" structure in which two antiparallel β-strands support a disulfide bonded knob protruding out of the antibody surface and forms a mini antigen binding domain. By replacing the knob domain with IL-15, we have created a chimeric CDR3-IL-15 IgG which functions as IL-15 *in vitro* and *in vivo* but can be easily produced in mammalian cells with increased stability. Thus, the CDR3 can stabilize IL-15 in the absence of its high affinity receptor α (Rα) chain. Furthermore, as IL-15 utilizes Rα for increased *trans* signaling to the receptor β and γ subunits, one variant candidate (CDR3-IL-15_Rα) was produced by co-expressing Rα sushi domain with the chimeric IgG. Both constructs have been demonstrated to be highly active in stimulating proliferation of NK cells and CD8+ T cells *in vitro* as well as in stimulating proliferation of NK cells and CD8+ T cells in rats and non-human primates (NHP). Although the CDR3-IL-15_Rα exhibited higher *in vitro* signaling activity than CDR3-IL-15, both were equally potent in stimulating the proliferation of NK cells and CD4+ and CD8+ T cells in NHP without any immunogenicity detected. Moreover, *in vivo* studies in NHP indicated that CDR3-IL-15 acted faster than CDR3-IL-15_Rα in stimulating the proliferation of these lymphocytes. CDR3-IL-15 is the first thermodynamically stabilized variant of IL-15 produced in the absence of its Rα chain, is highly active *in vivo*, and has multiple potential cancer applications as an T and NK cell stimulating agent.

#5812 Development of $\alpha_V\beta_5^+$ exosomes for liver-targeted therapy.

P. Acosta Montano, E. Olvera Felix, V. Castro Flores, P. Juarez, P. G. Fournier;
Centro de Investigacion Cientifica y de Educacion Superior de Ensenada, Ensenada, Mexico

Liver metastases are common in pancreatic and colorectal cancer. Their development is promoted by tumor-secreted exosomes that, thanks to the presence of the integrin $\alpha_V\beta_5$ on their membrane, home to the liver where they increase TGF-ß production by Kupffer cells, liver-resident macrophages, initiating the formation of the pre-metastatic niche. Considering that anti-TGF-β therapies have not been efficient in clinical trials or cause side-effects, our aim is to develop a liver-targeted anti-TGF-ß treatment using functionalized $\alpha_V\beta_5^+$ exosomes. We selected 293T cells as a human, non-cancerous cell line to obtain exosomes. 293T have an endogenous expression of $\alpha_V\beta_5$, and exosomes were isolated using differential centrifugation of conditioned media. The vesicles obtained had a diameter of 20 to 120nm according to dynamic light scattering and electron microscopy, as expected for exosomes, and Western blot confirmed the presence of the exosome marker CD81. When fluorescently labeled exosomes (SP-DiIC$_{18}$) were inoculated in the tail vein of Balb/C mice, they were detected in the liver 24 hours later. To increase the homing of 293T cell exosomes to the liver, we decided to overexpress $\alpha_V\beta_5$. 293T cells were co-transfected with plasmids coding the α_V and β_5 subunits. After antibiotic and clonal selections, we obtained 293T cells stably overexpressing $\alpha_V\beta_5$ (8.9x vs. parental), and isolated exosomes contained the exogenous integrin. *In vitro*, the internalization of $\alpha_V\beta_5^+$ exosomes was increased in RAW264.7 macrophages compared to exosomes from parental 293T cells. In mice, we confirmed that the overexpression of $\alpha_V\beta_5$ increases the homing of the exosomes to the liver (4.9x vs. parental) and that $\alpha_V\beta_5^+$ exosomes preferentially home to the liver when compared to lungs, kidneys, and brain. To functionalize the exosomes, we chose to express, in 293T cells, anti-TGF-ß factors that could be directly loaded into their exosomes before their isolation. First, we transduced 293T cells to express the mRNA of a soluble form of betaglycan (sBG) that can neutralize TGF-ß. sBG mRNA was detected in 293T cells, their exosomes, and in RAW264.7 cells treated with these exosomes. Low levels of sBG protein could be detected in the conditioned media of treated RAW264.7, but it did not prevent SMAD2/3 phosphorylation in HepG2 hepatocarcinoma cells, which could be due to the low levels of sBG mRNA in the exosomes. Since larger RNAs have been reported to be less transferred into exosomes, we used 2 shRNA to knock down *Tgfb1*. Although both shTgfb1 could efficiently knock down *Tgfb1* in transduced cells, the exosomes of 293T cells expressing these shTgfb1 did not decrease *Tgfb1* levels in treated RAW264.7 cells. Overall, although the functionalization of exosomes to target TGF-ß remains to be achieved, our results show that $\alpha_V\beta_5^+$ exosomes are nanocarriers that could be used for liver-targeted therapies.

#5813 AI-driven identification and validation of novel synthetic lethal gene pairs through deep mining of cancer dependency data.

D. S. Miller, O. Vipond, A. Brennan, A. Hercot;
Evariste Ltd, London, United Kingdom

The targeting of synthetic lethal (SL) gene pairs is emerging as a new paradigm in precision oncology, with the potential to deliver treatments with higher efficacy and fewer side-effects. However, existing approaches have focused on a few well-validated pairs, and there is a clear need to expand the toolbox of potential SL targets. We have performed deep mining of cancer dependency data using a suite of machine learning tools and AI algorithms underpinned by robust statistical analysis to identify the next generation of SL gene pairs.

To ensure robust, high confidence validation of multiple SL pairs simultaneously, we have used three cell lines and orthogonal assay formats. This has led to the confirmation of new druggable SL genes suitable for clinical development. We have identified the cancer subtypes with the strongest evidence of SL vulnerabilities and quantified patient populations who would most benefit from novel therapeutic agents. For one gene pair, we have generated novel best-in-class inhibitors of the target of interest, with exceptional selectivity over the SL partner, and used these chemical tools to validate the SL relationship in 2D and 3D models.

#5814 EPriL macrocycles as a platform for the rapid generation of effective kinase degrader antibody conjugates (DACs).

J. C. M. Uitdehaag, J. de Man, M. Muller, F. van Cauter, S. van Gemert, M. Hoffmann, Y. G. T. van Mil, W. R. Mulder, M. B. W. Prinsen, J. Sterrenburg, D. Vu, J. de Wit, E. Ensing, R. C. Buijsman;
Crossfire Oncology B.V., Oss, Netherlands

The therapeutic success of antibody drug conjugates (ADCs) drives a continuous search for novel payloads that can increase therapeutic window and thereby widen the applications for ADCs. Recently, heterobifunctional degraders have gained great interest as payloads, and degrader antibody conjugates (DACs) are seen as a novel therapeutic modality. Heterobifunctional degraders consist of a small molecule ligand that binds a target (protein of interest or POI), a spacer and an E3 ligase ligand, which can catalyze target degradation. Owing to their catalytic activity, degraders can have better potency than the equivalent inhibitors, making them suitable as ADC payload [1]. Degrader payloads can target a wider variety of mechanisms than classic payloads, which use the same antitumor strategies as chemotherapy, such as tubulin binding or topoisomerase inhibition.

Since many FDA-approved targeted therapies are based on the inhibition of protein kinases, we investigated degraders of these kinases as DAC payloads. Kinase DACs could bring enhanced targeting and therefore better therapeutic window to a field where classic ADC payloads have often shown substantial toxicities. As many heterobifunctional degraders show poor cell membrane penetration, their inhibitory potential could be increased as part of a DAC, where endocytic uptake is followed by intracellular release of the degrader payload.

To identify kinase degrader payloads, we present a workflow based on a platform called Energetically Privileged Ligands (EPriLs). EPriLs are macrocycle scaffolds that bind non-covalently in the kinase ATP pocket. Their unique binding mode avoids contacts with amino acid positions where resistance to kinase inhibitors frequently occurs. EPriL macrocycles can be decorated appropriately to rationally design specific inhibitors for many therapeutically relevant kinases, and provide synthetic handles to couple them to VHL or CRBN ligands to generate effective kinase degraders.

Here we describe how EPriL kinase degraders can be developed into effective DACs, using consecutive libraries of EPriL ligands, spacers, E3 ligase ligands and linkers. First, suitable degraders are identified, based on rapid and deep target degradation and potent antiproliferative activity on target cell lines. Degraders are then transformed into maleimide-linked degraders using convenient attachment of enzymatically cleavable linkers. In a medium throughput fashion, these maleimides are coupled to antibodies to generate DACs, which are tested for stability and biological potency. Applying this workflow to various well-validated kinase targets in oncology resulted in a promising kinase targeting DAC with favorable ADME properties, clear potentiation compared to the parent degrader, and increased selectivity for tumor cell lines.

#5815 Next-generation RNAi therapeutics: siRNA-loaded exosomes targeting KRAS G12C in non-small cell lung cancer (NSCLC).

H. Kim[1], Y. Choi[1], K. Kim[1], Y. Byun[1], T. Kim[1], J. Kim[1], S. An[1], D. Bae[1], M. Choi[1], J. Chung[1], K. Kwon[2];
[1]Exollence Biotechnology Co. Ltd, Seoul, Korea, Republic of, [2]Ewha Womans University School of Medicine and Ewha Medical Research Institute, Seoul, Korea, Republic of

Background: NSCLC represents the predominant subtype of lung cancer, boasting an overall 5-year survival rate of 26%, a figure that fluctuates based on the disease stage. Within NSCLC, certain cancer gene mutations, notably KRAS G12C, are currently classified as 'undruggable targets,' creating hurdles in achieving effective treatment. The development of innovative anticancer drugs aimed at these challenging targets is expected to present a viable solution to these difficulties.
Methods: Exosomes have garnered attention as an inventive drug delivery system for in vivo gene delivery through systemic injection. We used a new post-loading approach by actively loading KRAS G12C siRNA into exosomes using the shock waves (SWEET: shock wave exosome engineering technology) in this study. The effect of *in vitro* and *in vivo* were tested in NCI-H358 (KRAS G12C mt NSCLC) cells and its xenograft mouse model. The tumor size and weight were measured twice a week.
Results: We developed an exosome-based therapeutic using siRNA to effectively inhibit KRAS G12C, targeting NSCLC. The SWEET platform's post-loading method showed a high efficiency in loading KRAS G12C siRNA into exosomes. The KRAS G12C siRNA-loaded exosomes effectively silenced oncogenic KRAS G12C expression in cancer cells; they inhibited tumor growth when administered intravenously in a NSCLC xenograft mouse model. Remarkably, the anticancer effect of KRAS G12C-loaded exosome was similar to that of Sotorasib, a KRAS G12C mutation targeting anti-cancer drug.
Conclusion: Our study showed KRAS G12C siRNA loaded exosomes were effectively delivered to NSCLC tumor tissue via intravenous (IV) administration. And its anti-cancer effects were very similar to sotorasib, showing potential as a treatment for KRAS G12C mutation-expressing cancer. The effective delivery of siRNA to tumor tissues through exosomes highlights the potential of this technology as a promising approach for developing new RNAi therapeutics for cancer.

#5816 An effective delivery platform for nucleic acid therapeutics: Enhanced cancer cell internalization and endosomal escape.

S. Li[1], O. Tietz[2], A. H. El-Sagheer[3], T. Brown[1], K. A. Vallis[1];

[1]University of Oxford, Oxford, United Kingdom, [2]Macquarie University, Sydney, Australia, [3]University of Southampton, Southampton, United Kingdom

Nucleic acid therapeutics (NATs), such as siRNA and mRNA, show great potential as cancer medicines. However, translation of these compounds has been held back by their limited bioavailability in target tissues. The aim of this study was to test the use of a novel cell-penetrating peptide (CPP)-based delivery platform to enhance uptake of NAT into cancer cells. This platform consists of a highly efficient CPP that combines the advantages of multimerization and cyclization of the archetypal CPP, TAT peptide[1], plus a photochemical (PC) strategy to promote endosomal release of NAT into the cytoplasm[2]. Negatively charged NATs form complexes with cationic CPPs through charge:charge interaction. NATs (siRNA or mRNA) were incubated with CPP at different molar ratios and assessed in gel retardation assays. Efficiency of internalization of Cy3-NAT:CPP complexes was evaluated using live cell confocal imaging with quantification of intracellular fluorescence. The mechanism of cellular uptake of NAT:CPP was investigated using inhibitors of endocytosis (chlorpromazine, NaN3, amiloride and methyl-β-cyclodextrin). To trigger NAT release from intracellular vesicles, 420 nm/50 mA LED light irradiation was applied following pre-treatment of cells with a photosensitizer, fimaprofin. CPP-PC mediated internalization and endosomal release was used for delivery of glyceraldehyde 3-phosphate dehydrogenase (GAPDH) siRNA. GAPDH enzymatic activity assays (Sigma, USA) were conducted to confirm inhibition of GAPDH in HeLa, HEK293T and MDA-MB-231 cells. Transfection efficiency of mRNA encoding enhanced green fluorescence protein (eGFP) was evaluated by flow cytometry in HeLa cells. NAT:CPP complexes were found to be maximally efficient at a 10:1 molar ratio. Analysis of live cell confocal images indicated that GAPDH Cy3-siRNA:CPP complexes were more efficiently internalized compared to Cy3-siRNA + monomeric TAT or Cy3-siRNA + lipofectamine (****$p<0.0001$, one-way ANOVA). The combined CPP-PC platform delivers NAT via a clathrin-mediated endocytosis pathway. CPP-PC delivery of GAPDH siRNA caused marked GAPDH enzyme activity downregulation in HeLa (91%), MDA-MB-231 (51%) and HEK293T (44%) cells. These results were similar to the level of downregulation achieved with lipofectamine + GAPDH siRNA. Flow cytometric analysis revealed that 52.4% of HeLa cells expressed eGFP at 1 h following delivery of mRNA-eGFP by CPP-PC. Functional siRNA and mRNA were efficiently delivered into the cytoplasm of cancer cells through combined use of a multimeric/cyclized CPP plus photochemical-mediated endosomal release. This approach holds promise for clinical application, particularly in the treatment of intraluminal tumors. 1. Tietz, O. *et al.* Nat Chem. *14:* 284-93, 2022. 2. Selbo, P. K. *et al.* J Control Release. 148, 2-12, 2010.

#5817 pH responsive delivery of gemcitabine/pirarubicin co-loaded biodegradable polymeric nanoparticles for synergistic anti-cancer therapy.

P. Gupta[1], S. M. Kharbanda[2], H. Singh[1];

[1]Indian Institute of Technology Delhi (IIT Delhi), New Delhi, India, [2]Dana Farber Cancer Institute, Boston, MA

Gemcitabine, a nucleoside antimetabolite, is a widely known chemotherapeutic agent being used as a first line treatment alone or in combination with other chemo drugs for different types of cancer. However, due to its extremely short half-life in the body caused by enzymatic degradation and poor pharmacokinetics, the I.V. dosage of administration is quite high i.e., >1000 mg/m^2 for metastatic breast cancer treatment. Moreover, gemcitabine in combination with anthracyclines imparts synergy but free anthracyclines are reported to be associated with long term cardiac toxicity. Nanoparticle-based drug delivery systems have provided a befitted solution for improving the poor pharmacokinetic properties and systemic toxicity caused by the chemo drugs because of their ability to improve bioavailability of the drugs at the desired site as well as overcoming multi-drug resistance (MDR).In the present work, PLA-based biodegradable block copolymeric nanoparticles have been employed to co-load Gemcitabine and Pirarubicin for improved anti-cancer activity. Gemcitabine and Pirarubicin have been chemically conjugated to the amphiphilic block copolymer mPEG PLA via a pH responsive Schiff's Base linkage using a linker molecule Levulinic acid. The prepared PIRA/GEM co-loaded nanoparticles exhibited an optimum size, zeta potential and polydispersity index i.e., 187 ± 3.5 nm, -10 ± 2.0 and < 0.1 PDI respectively. Further, in the drug release experiments, these Nps displayed sustained and higher drug release in lysosomal pH (pH 5.0) than in the physiological buffer environment (pH 7.4) attributed to the pH sensitive bonding. The co-loaded Nps were prepared in multiple ratios (Pira: Gem - 1:1, 1:3, and 3:1) and investigated for *in-vitro* cellular inhibition studies in comparison to singly loaded drug Nps and corresponding free drug formulations in various breast cancer cell lines. Additionally, apoptotic studies revealed significant enhancement in synergistic activity in the case of PIRA/GEM co-loaded Nps in comparison to conventional free drug formulations. In conclusion, this nano-formulation demonstrated excellent anti-cancer activity against breast cancer cells therefore it may be used as a potential candidate for therapeutic use.

#5818 Differentiation of human papillomavirus-positive head and neck squamous cell carcinoma cells.

S. Gendreizig[1], L. Martinez-Ruiz[2], J. Florido[2], A. Lopez-Rodriguez[2], H. Pabla[1], F. Brasch[1], G. Escames[2], T. Busche[1], H. Sudhoff[1], L. U. Scholtz[1], I. Todt[1], F. Oppel[1];

[1]University Hospital OWL of Bielefeld University, Bielefeld, Germany, [2]University of Granada, Granada, Spain

Head and neck squamous cell carcinoma (HNSCC) represents a highly malignant disease and death rates remain at approximately 50% for decades. Thus, new tumor-targeting treatment strategies are desperately needed. In a previous study, we dissected human papillomavirus (HPV)-negative HNSCC cell differentiation via cornification and detected an epigenetically determined loss of cell malignancy. Analyzing the mechanisms underlying the differentiation of HNSCC cells may identify targets for anti-tumor therapy. Using patient-derived tumor cells, we created an HNSCC differentiation model in HPV+ tumor cells. Similar to HPV- cells, we observed a loss of malignant characteristics in HPV+ cell cultures in differentiating cell culture conditions including irregular enlarged cell morphology, cell cycle arrest with downregulation of Ki67, and reduced cell viability. Even though cornification was detected in HPV+ tumor cell cultures and HPV+ FFPE tumor tissue sections, cornification was not induced during HPV+ cell differentiation. Instead, RNA-seq and subsequent Gene Ontology analysis showed myocyte-like differentiation with upregulation of markers of myofibril assembly including TPM1, TAGLN, and ACTA1. Immunofluorescence staining of differentiated and undifferentiated primary HPV+ HNSCC cells confirmed an upregulation of these markers and the formation of parallel actin fibers, reminiscent of myoblast-lineage cells. Moreover, multi-marker immunofluorescence analysis of HPV+ tumor tissue sections revealed areas of cells co-expressing the identified markers of myofibril assembly, HPV surrogate marker p16, and stress-associated basal keratinocyte marker KRT17, indicating that the observed myocyte-like differentiation observed in vitro also occurred in human tissue. Normal tissue displayed a co-expression of TPM1, TAGLN, and ACTA1 in differentiating keratinocytes between the basal cell layer and the fully differentiated corneocytes. This shows that the expression of myocyte-lineage markers is reflected in differentiating non-malignant mucosal tissue. Our study suggests that the targeted differentiation of tumor cells might be therapeutically valuable in HPV+ HNSCCs as well.

#5819 An anti-TROP2-CPT113 ADC, exhibits potent targeted antitumor activity and favorable pharmacokinetic properties.

Huihui Guo, Xiangfei Kong, Yong Du, Zhicang Ye, Yongxiang Chen, Zhixiang Guo, Lingli Zhang, Lu Bai, Junxiang Jia, Yunxia Zheng, Wei Zheng, Jun Zheng, Wenjun Li, Yuanyuan Huang, Zhongliang Fan, Mengmeng Liu, Binbin Chen, Meng Dai, Juan Wang, Miaomiao Chen, Qingliang Yang, **Robert Y. Zhao**

Hangzhou DAC Biotechnology Co., Ltd., Hangzhou City, China

Trophoblast cell surface antigen 2 (TROP2) is highly expressed in a number of epithelial cancer types and is considered to be a poor prognostic marker. We have developed an anti-TROP2 antibody-drug conjugate, DXC1002, that contains a potent inhibitor of DNA topoisomerase I payload (CPT113) attached to the antibody mainly in the Fab region via a unique hydrophilic CrossConju™ linker. The anti-tumor activities of DXC1002 were studied in various human cancer cell lines and xenograft mouse models and pharmacokinetic profile of DXC1002 were evaluated in cynomolgus monkeys and rats. DXC1002 demonstrated potent anti-tumor activity in TROP2 tumor cells of various expression levels in vitro, and at low dose of 1 mg/kg for one injection, in both high and moderate Trop2 expression xenograft models. In plasma stability studies, wherein DXC1002 was incubated in the plasma of five different species for 168 hours (7 days) at 37 oC, over 90% ADC was intact, exhibiting good stability of the CrossConju™ linker. Pharmacokinetic studies of DXC1002 in monkeys (TROP2 cross-species) and rats (non-TROP2 cross-species) showed half-lives of about 61.27 and 236.77 hours, respectively. Systemic clearance in monkey and rat was 0.41-0.67 and 0.279-0.309 mL/h/kg, respectively. The longer half-lives and slower clearance observed in rats the results offered a more direct assessment of the linker stability as target-mediated clearance played no role in rats. In summary, with the conjugation of a DNA topoisomerase I inhibitor payload to Trop2 antibody via the CrossConju™ linker, DXC1002 demonstrates remarkable anti-tumor properties and pharmacokinetic profile, with a potential to be further validated in clinical applications.

#5820 An antibody drug conjugate platform based on novel camptothecin payloads with branch hydrophilic linkers and site-specific conjugation.

Yuanyuan Huang, Hangbo Ye, Qingliang Yang, Lingli Zhang, Huihui Guo, Xiaolei Liu, Wenjun Li, Lu Bai, Junxiang Jia, Juan Wang, Xiangfei Kong, Jun Zheng, Yifang Xu, Gengxiang Zhao, Linyao Zhao, Xiang Cai, Ziyu Zhao, Hui Xia, Xia Zhou, You Zhou, **Robert Y. Zhao**

Hangzhou DAC Biotechnology Co., Ltd., Hangzhou City, China

Antibody-drug conjugates (ADCs) have recently gained momentum as a therapeutic modality for the cell-specific delivery of small molecules beyond their originally-intended purpose of treating cancer. However, the selection of combinations of an optimum target, antibody, payload, linker as well conjugation, to achieve maximal therapeutic efficacy without excessive toxicity, still presents a significant challenge. Topoisomerase I (Topo I) inhibitors such as camptothecin (CPT) analogs represent the much success in ADC payload applications as two CPT analog-ADCs, trastuzumab deruxtecan (DS-8201a—Enhertu®) with Dxd payload and sacituzumab govitecan (Trodelvy™) with SN38 payload have been approved and over 20 CPT analog-ADCs are in the clinical trials now. Topo I inhibitors trigger cell apoptosis through their specific binding at the DNA-topoisomerase interface, leading to the inhibition of DNA supercoiling and entanglement, resulting in DNA damage and cell death. This class of payloads in ADCs has demonstrated more wider therapeutic windows in clinical trials than regular antitubulin payloads, such as maytansine and MMAE, based ADCs. Here, we detail the discovery of CPT analogs, as payloads with a branch hydrophilic linker and site-specific conjugation for ADCs designed to have a widened therapeutic window compared with Dxd-GGFG linked ADCs. The CPT analogs based on the core structure of SN-38, wherein the hydrogen of C-11 was replaced with fluorine, and the hydroxyl group of C-10 was optionally replaced with an amino or a ether group. Many of the novel CPT analogs were at single to tens of pM of IC_{50} potency in vitro against several tested tumor cell lines, and some were more potent than Exatecan in the comparison tests. The ADCs constructed with branch hydrophilic linkers and the CrossConju™ technology of chemically site-specific conjugation at Fab region of an antibody through C-10 position of the CPT payloads either with amide bond, either bond or carbamide bonds, or through C-20 position of the CPT payloads with carbamide or carbonate bonds, exhibited much better antitumor efficacy in vivo CDX tumor models, while having higher or similar MTDs in mice toxicity study in comparison with the ADC constructed with GGFG-Dxd, demonstrated wider therapeutic widows than that conjugated with GGFG-Dxd. Moreover, some of the constructed ADCs can overcomes *in vitro*- and *in vivo*-acquired resistance of commercial therapeutic drugs. Herein, we showcase our platform approach in CPT-ADC designs and constructions and can be thereby broadly applicable to construction of various CPT-ADCs for targeted treatment of cancers.

#5821 DXC008, a novel STEAP1 antibody-tubulysin analog conjugate with a function linker, demonstrates a potential to broaden therapeutic opportunities for prostate tumors.

Q. Yang, Y. Huang, J. Jia, H. Guo, L. Zhang, Y. Zhou, Z. Ye, H. Ye, Y. Xu, W. Li, Z. Zhao, L. Zhao, L. Bai, J. Zheng, **R. Y. Zhao**;
Hangzhou DAC Biotechnology Co., Ltd., Hangzhou, China

Six-transmembrane epithelial antigen of the prostate 1 (STEAP1), is a cell surface protein frequently expressed in prostate cancer, with limited expression in non-prostate tissues. A Steap1 antibody called Vandortuzumab conjugated with MMAE (DSTP3086S) was in the clinical phase I trial for treating STEAP1-expressing metastatic castration-resistant prostate cancer and showed acceptable safety at 2.4 mg/kg once every 3 weeks. However, many patients are nonresponsive to DSTP3086S due to low target expression levels and common treatment-related AEs which were caused by MMAE payloads. DXC008 was generated through screening the therapeutical index in vitro of conjugates of an anti-Steap1 antibody with varieties of payloads of tubulysin B analogs through function peptide spacer linkers. The generated DXC008 exhibited not only good affinity for Steap1 but also moderate affinity for Prostate-specific membrane antigen (PSMA) which is as well specifically overexpressed in most prostate cancer with limited expression in normal tissue. DXC008 demonstrated couple tens to a hundred of picomolar concentration (pM) of potency against several prostate tumor cells and over 60% internalization rate within 90 min in vitro. And in vivo it showed very good durable antitumor response as low dose as 1 mg/kg one injection in both high and moderate of both Steap1 and PSMA expression xenograft models. Pharmacokinetic profiles of DXC008 were favorable and the safety of Maximal Tolerable Dose (MTD) was over 120 mg/kg in single injection in mice. DXC008 has been forward to NHP toxicity study and it has potential to be a good STEAP1/PSMA-targeting ADC with a wide therapeutic window for prostate cancers.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Drug Resistance 3: Regulation of Gene Expression
Poster Session

#5825 Non-genetic determinants driving the evolutional trajectories of drug-tolerant-persisters in KRAS Non-small cell lung cancer.

C. Li[1], C. J. Graser[2], Q. Qin[1], A. Nimbalkar[1], U. Syed[1], B. Karakyriakou[1], S. Clark[1], A. Y. Saiki[3], P. E. Hughes[3], C. Ott[1], L. Pinello[1], F. Michor[2], A. Hata[1];
[1]Harvard Medical School/Massachusetts General Hospital, Boston, MA, [2]Dana-Farber Cancer Institute, Boston, MA, [3]Amgen Inc., Thousand Oaks, CA

Rare cell populations manage to evade the effects of cancer therapies, ultimately leading to drug resistance and subsequent cancer relapse. These resilient populations, often referred to as "persisters," exhibit distinct molecular characteristics when compared to the broader tumor population. In the current standard of clinical care for non-small cell lung cancer (NSCLC), patients typically undergo a series of standard treatments, such as surgery followed by chemotherapy/immunotherapy, and then targeted therapy, based on the disease stages. This continues until drug resistance emerges, with little attention given to the state of these persister cells in response to these treatments. In the case of drug resistance in KRAS-mutated NSCLC, ongoing clinical investigations are exploring the combined efficacy of KRAS G12Ci inhibitors with drugs that target mitogen-activated protein kinase (MAPK) feedback reactivation, immunotherapy, and chemotherapy. Despite the myriad of combination therapies, persister populations invariably emerge. The manner in which these persisters evolve to withstand therapies remains elusive. We employed a DNA barcode lineage tracing analysis coupled with mathematical modeling to decode persister evolution to therapies targeting different pathways, e.g., KRAS+ SHP2, KRAS+CDK4/6, and KRAS+MCL-1. Our model reveals that rapidly emerging persister populations are predetermined and do not exhibit clear genetic alterations. In some cells, common persisters exist in response to different therapies. Single-cell ATAC-RNA sequencing showed that these persisters are enriched in chromatin-binding of transcription factors that regulate classic non-homologous end-joining (cNHEJ) DNA repair (ZNF384), interferon response (IRF1), and stem-like characteristics (FOXP1), along with the activation of an IFN-γ transcriptional signature. These findings underscore the connection between specific DNA repair processes, chromosomal instability, and resistance to KRAS G12Ci. In other cells, however, distinct persister populations exist to different therapies, leading to the hypothesis that these diverse persister populations can be targeted orthogonally or sequentially to achieve tumor regression. In summary, our study unveils the heterogeneity in persister evolution trajectories in KRAS NSCLC. Our platform identifies targetable persister populations in NSCLC models and offers a proof-of-concept for non-standard strategies to combat drug resistance based on persister cell states.

#5826 Comprehensive analysis with single-cell RNA sequence and spatial transcriptomics unravels distinctive expression profile of apoptotic-related genes in EGFR-mutated lung cancer.

M. Izumi, M. Fujii, V. Ho, I. S. Kobayashi, S. S. Kobayashi;
Beth Israel Deaconess Medical Center, Boston, MA

Despite an initial marked response to targeted therapy with tyrosine kinase inhibitors (TKIs) in EGFR-mutated lung cancer, the duration of response is limited due to the inevitable development of acquired resistance. Anti- and pro-apoptotic genes play an important role in the survival of tumor cells. Currently, variations in these gene expression levels are not well characterized due to the complex interplay between the inducement of expression changes by EGFR-TKIs and the presence of inter- and intra-tumor heterogeneity. Here, a comprehensive analysis of apoptosis-related genes, including BCL-2 family members and the IAP family members, was conducted via single-cell RNA sequence (scRNA-seq) and spatial transcriptomics. scRNA-seq captured changes in apoptosis-related gene expression after EGFR-TKI treatment using different EGFR-mutated lung cancer cell lines. Notably, *BCL2L1* expression increased, whereas *MCL1* expression decreased after EGFR-TKI treatment. Other anti- and pro-apoptotic genes did not display consistent trends in the cell lines used. Additionally, scRNA-seq was carried out on samples collected from patients with EGFR-mutated lung cancer after the development of resistance to EGFR-TKIs in order to validate the results obtained from cell line data and to compare gene expression levels between tumor and non-tumor cells. *BCL2L1* exhibited high expression specifically in tumor cells; in contrast, *MCL1* expression was lower in tumor cells compared to non-tumor cells. Moreover, *BAD* and *XIAP* were highly expressed in a tumor-specific manner. To further corroborate the scRNA-seq findings and delineate the spatial heterogeneity in tumors, spatial transcriptomics was performed using EGFR-driven lung cancer transgenic mouse specimens in three conditions: prior to treatment, during therapeutic response after short-term treatment, and following acquired resistance to EGFR-TKIs. Spatial transcriptomics data demonstrated that an increased *BCL2L1* expression was observed in tumor tissues and that *MCL1* expression was significantly higher in tissue adjacent to tumors than in tumors. Finally, we demonstrated that genetic ablation of *BCL2L1* and pharmacological inhibition of *BCL2L1* overcame or delayed resistance to EGFR-TKIs *in vitro* and *in vivo*. Overall, *BCL2L1* is particularly important for tumor cell survival during the emergence of drug tolerance and the development of acquired resistance to EGFR-TKIs.

#5827 Identification of potential novel drivers and biomarkers of CDK4/6 inhibitor resistance in metastatic breast cancer.

L. F. Ott, M. Alawi, M. Stoupiec, E. Laakmann, M. Kriegs, V. Muller, K. Pantel, S. Riethdorf;
University Medical Center Hamburg-Eppendorf, Hamburg, Germany

Background: Inhibitors of the cyclin-dependent kinases 4 and 6 (CDK4/6i) have become part of the standard of care for patients with hormone receptor-positive metastatic breast cancer. Despite their initial benefit for most patients, the development of resistance to this treatment is almost inevitable. However, there is a lack of predictive or clinical markers that can be utilized to monitor resistance development, and their definition remains an unmet challenge.
Methods: We aimed to identify novel drivers and potential biomarkers of CDK4/6i resistance by creating and characterizing two ribociclib-resistant breast cancer cell lines. Ribociclib-resistant derivatives of MCF7 cells and the CTC (circulating tumor cell)-derived cell line CTC-ITB-01 were created by long-term exposure to the inhibitor for a minimum of 6 months and potential novel resistance drivers were identified by transcriptome analysis using RNA-sequencing. In addition to mRNAs encoding proteins that may contribute to resistance, we also investigated microRNAs as they are poorly characterized in the context of CDK4/6i resistance. Additionally, changes in the kinome activity were assessed by using PamGene technology.
Results: The RNA-sequencing analysis identified ≥ 2000 genes with differential expression in both resistant cell lines compared to their respective parental counterparts. Over Representation Analysis revealed that a high number of these genes encode proteins associated with the cell cycle, proliferation, epithelial-to-mesenchymal transition, various signaling pathways like Wnt, and the complement system. Evaluation of kinase activity using functional kinome profiling in the resistant versus parental CTC-ITB-01 cell line showed increased activity of the CDK and MAPK kinase subgroups, indicating a multifactorial resistance mechanism. Furthermore, the analysis of deregulated ncRNAs demonstrated increased expression of miR-146a-5p in both resistant cell lines and interestingly, a significant decrease of miR-205-5p levels in the resistant CTC-ITB-01 cell line. MiR-205-5p is described as a negative regulator of EMT and progression in breast cancer but has not been linked to CDK4/6i resistance yet. This result was validated by qPCR and miRNA *in situ*-hybridization.
Conclusion: Through our comprehensive transcriptome analysis of two ribociclib-resistant cell lines, we were able to identify several novel potential resistance drivers. Their utility as predictive or monitoring biomarkers
requires further investigation. Furthermore, discovering new resistance mechanisms could also help find new therapeutic strategies after CDK4/6i resistance development.
Acknowledgment: This project received funding from the Deutsche Krebshilfe DETECT high project (Nr.: 70114705) and the Horizon 2020 program RNADiagon (Nr.: 824036).

#5828 The genomic architecture of ibrutinib resistance in CLL: Oligoclonal progression with variable anatomical distribution.

C. Underbayev, J. Chen, H. M. Harris, L. T. Vaughn, A. Itsara, A. Wiestner;
National Heart, Lung & Blood Institute, Hematology Branch, National Institutes of Health, Bethesda, MD

Progressive disease (PD) in patients with chronic lymphocytic leukemia (CLL) on ibrutinib often presents with acquired mutations in *BTK* and/or *PLCG2*. Reported variant allele frequencies (VAF) are often low, leading some to question the role of these mutations. Further, several co-existing mutations are often identified. Here we investigated the clonal composition of PD on single cell level, across time, and different anatomic compartments. 84 CLL patients (52 treatment-naïve; 32 relapsed/refractory) with either a *TP53* aberration or age ≥65 years received single-agent ibrutinib 420 mg once daily until PD or limiting side effects on a phase 2 study (NCT01500733). The median progression-free survival was 86.6 months. 39 (46.4%) patients progressed, 31 with CLL (PD-CLL), and 8 with Richter's transformation. Median time to PD-CLL was 57.2 months. In PD-CLL patients, peripheral blood (PB) was sent for genotyping of known hotspot mutations in *BTK*/*PLCG2* (Neogenomics). We then designed digital droplet PCR probes to test for *BTK* C481S/R/Y and *PLCG2* R665W/L845/S707F mutations in samples collected at baseline, during response to ibrutinib and at PD in 29 patients. 26 (89.7%) patients had detectable *BTK/PLCG2* mutations (VAF range 0.04 - 0.96). 12 (41%) patients carried multiple *BTK/PLCG2* mutations. In 11 evaluable cases single-cell DNA sequencing (Mission Bio) showed individual mutations present in separate cells consistent with branching evolution. Having confirmed oligoclonality, we calculated the cumulative cell fraction (cCF) of *BTK/PLCG2* mutations in the 29 PD-CLL patients. 16 (55%) patients had cCF >0.5 (range 0.59-0.96), 10 patients (35%) had cCF < 0.5 (range 0.04-0.43) and 3 patients (10%) had no detectable mutations. *BTK/PLCG2* mutations were detected in samples collected at median 21.6 months (range 0 - 75) prior to PD. In 11 cases, we tested lymph node (LN) biopsies at PD. In 6 cases with cCF <0.5 in PB, 4 corresponding LN samples had higher cCF (0.01/0.92; 0/0.85; 0.06/0.69; 0.46/0.99 for PB/LN, respectively). In 5 cases, PB contained 2-6 distinct subclones with cCF >0.5, in 3 cases the corresponding LN harbored fewer subclones than PB (6/3; 3/2; 3/0 for PB/LN, respectively). To characterize the genomic background of PD-CLL, we performed whole-exome sequencing of longitudinal samples from 26 patients. In addition to *BTK/PLCG2*, the most frequently mutated genes were *TP53*, *SF3B1*, *NOTCH1*, and *POT1*. Furthermore, copy number variations (CNA), such as del17p, del13q, del14q, del3p, and del8p, were common. In summary, in our cohort *BTK*/*PLCG2* mutations were identified in 89.7% of PD-CLL patients. These mutations arise in oligoclonal populations with variable distribution across anatomical sites. In rare patients without *BTK/PLCG2* mutations, the co-evolution of putative driver mutations and multiple CNAs generated genomic complexity reminiscent of lymphoma transformation.

#5829 Elucidating the significance of amphiregulin and its implications for EGFR inhibition strategies in LKB1-mutant NSCLC.

X. K. Solone[1], X. Zhou[1], M. Yu[1], J. W. Li[2], F. Rimay[1], F. Kaye[1], L. Wu[1];
[1]University of Florida College of Medicine, Gainesville, FL, [2]Brown University, Providen, RI

LKB1-mutant non-small cell lung cancer (NSCLC) is aggressive and treatment-refractory, underscoring the need for new therapeutic strategies. Our comparative study involving mouse lung tumors driven by oncogenic $Kras^{G12D}$ and LKB1 loss as well as tumors driven solely by $Kras^{G12D}$, revealed that LKB1 loss upregulated amphiregulin (Areg), a pro-growth EGFR ligand. Therefore, this study investigates how the inactivation of LKB1 enhances AREG expression, the significance of elevated AREG in sustaining lung cancer growth, and the responses of AREG-high lung cancer to EGFR inhibitors. We first evaluated the potential clinical significance of AREG using The Cancer Genome Atlas (TCGA) lung adenocarcinoma dataset and the Cancer Cell Line Encyclopedia (CCLE) database. We observed that LKB1-null tumors with high AREG levels were associated with shorter patient survival and exhibited transcriptional signatures similar to EGFR-mutant tumors. High AREG expression also correlated positively in NSCLC cell lines with LKB1 mutations and Western blot analysis confirmed that elevated AREG levels in lung cancer cells were associated with constitutive EGFR signaling. We next explored the impact of LKB1 loss on AREG expression in lung cancer. Our prior RNA-seq and ChIP-seq investigations demonstrated CRTC2 and CREB enrichment on the AREG promoter in LKB1-null lung cancer cells. Upon LKB1 reintroduction, the enrichment diminished, indicating that CRTC-CREB transcriptionally induces AREG in LKB1-null lung cancer. To corroborate, reintroducing LKB1 or expressing a dominant-negative construct (dnCRTC), disrupting CREB/CRTC interaction, decreased AREG levels, as confirmed by RT-qPCR in LKB1-null lung cancer cells. This supports that AREG is a direct target of CRTC-CREB activation induced by LKB1 loss. To assess the impact of elevated AREG in LKB1-mutant lung cancer growth, we used RNA interference and antibodies to inhibit AREG. Both interventions decreased cell growth and colony formation, underscoring AREG is critical for LKB1-mutant lung cancer growth. Moreover, we investigated the potential correlation between AREG and the response to the EGFR tyrosine-kinase inhibitor Erlotinib in NSCLC cell lines, utilizing AREG expression data from CCLE and Erlotinib response data from the Genomics of Drug Sensitivity in Cancer (CDSC) databases. Stratifying NSCLC cell lines into sensitive, intermediate, and resistant categories revealed a potential positive association between AREG expression and Erlotinib sensitivity. Notably, LKB1-null lung cell lines with high AREG expression demonstrated heightened sensitivity compared to those with low AREG expression. Our study revealed that LKB1 loss increases AREG, triggering aberrant EGFR signaling critical for lung cancer growth, and AREG expression might impact the Erlotinib response in LKB1-inactive cells.

#5830 A first-of-its-kind model that reconstitutes targeted drug-induced cellular transdifferentiation.

P. Gopal, M. Abazeed;
Northwestern Univ. Feinberg School of Medicine, Chicago, IL

Introduction: Lung tumors treated with targeted therapies ultimately relapse due to intra-genic resistance mutations, bypass pathway activation, or cellular lineage changes. Newer precision therapies have higher selectivity and potency against both resistant and activating gene mutations, resulting in a significant increase in incidence of cellular transdifferentiation. The most common form of transdifferentiation is the change from lung adenocarcinomas (LUADs) to small cell lung cancer (t-SCLC) upon drug treatment which remains very poorly understood.

Methods: We have combined patient derived xenografts (PDX) and *ex vivo* lines with multi-omic characterization, high-content image-based morphometry and fluorescence tracking, and single-cell barcode tracing to better understand the process of lung tumor transdifferentiation.

Results: We have developed a first-of-its-kind t-SCLC model that reconstitutes *ex vivo* LUAD to SCLC transdifferentiation. Genomic and transcriptomic analyses of our NSCLC PDX collection identified tumors with mutation in *TP53* and *RB1*, two genes that are altered in virtually all *de novo* SCLCs. PDX sample CBX336 was identified as having mutations in both *TP53* and *RB1*, in addition to expressing the $KRAS^{G12C}$ oncogene. Upon treatment with Sotorasib, CBX336 tumors initially demonstrated slow tumor growth, followed by a dramatic increase in the growth after prolonged drug exposure. Our experimental and computational data suggest a highly coordinated procession toward transdifferentiation with the parallel upregulation of the neuroendocrine transcription factor *NEUROD1* across numerous epithelial cellular clones.

Conclusions: Our new experimental system allows characterization at the single-cell level. Ongoing work includes the integration of new resources to study lineage reprogramming, and advancing new therapeutic strategies.

#5831 The TLE1 transcriptional and epigenetic machinery contributes to EGFR targeted therapy resistance in human lung adenocarcinoma.

Hector Ramos Biliran[1], Xin Yao[1], **Nasir Roberts**[1], Prince Iheukwumere[1], Renwei Chen[2], Ma. Carmela Dela Cruz[3]

[1]Biology, Xavier University of Louisiana, New Orleans, LA,[2]Marine Science Institute, University of California, Santa Barbara, Santa Barbara, CA,[3]Molecular Medicine, MD-PHD program, University of the Philippines Manila, Manila, Philippines

In human lung adenocarcinoma that carry Epidermal Growth Factor Receptor (EGFR) sensitizing mutations, targeting the EGFR pathway with the use of EGFR tyrosine kinase inhibitors (EGFR-TKIs) has emerged as a promising therapeutic strategy providing initial clinical benefit to many patients. Unfortunately, resistance to EGFR-TKIs eventually develops leading to disease progression. In addition to genetic mutations, transcriptional and epigenetic mediated changes in gene expression remain an important mechanism contributing to EGFR-TKI resistance. Here, we report a novel function of the transcriptional corepressor Transducin-Like Enhancer of Split-1 (TLE1) in mediating EGFR-TKI resistance in EGFR mutant LUAD cells through its survival promoting gene transcriptional program. In EGFR mutant, EGFR TKI sensitive LUAD cells, sole activation of the TLE1 nuclear function attenuates EGFR TKI sensitivity with concomittant reduction of EGFR-TKI-mediated apoptosis. Conversely, downregulation of endogenous TLE1 expression via siRNAs/shRNAs and deletion of TLE1 gene via CRISPR-Cas9 in EGFR-mutant, EGFR-TKI resistant cells partially restore EGFR-TKI sensitivity via induction of EGFR-TKI apoptosis. Mechanistically, the anti-apoptosis promoting gene transcriptional program of TLE1 is dependent on its functional interaction with the transcriptional repressor HES-1, a downstream Notch target which has been associated with relapse in LUAD patients following EGFR-TKI treatment. Collectively, these studies indicate the TLE1 corepressor as a determinant of resistance to EGFR targeted therapy and raise the possibility that inhibiting TLE1 nuclear function may serve as an adjuct therapy to circumvent EGFR-TKI resistance.

#5833 Genomic mechanisms of RET inhibitor resistance in RET-fusion positive NSCLC.

X. Liu[1], M. Nilsson[1], T. Takehara[1], J. He[1], X. Huo[2], A. Kumar[2], J. Heymach[1], R. Kittler[2];
[1]UT MD Anderson Cancer Center, Houston, TX, [2]UT Southwestern Medical Center, Dallas, TX

RET fusions are a driver oncogene detected in 1-2% of non-small cell lung cancer (NSCLC) cases. Currently, two selective RET inhibitors (RETi), selpercatinib and pralsetinib have received FDA approval for *RET* fusion-positive NSCLC. However, *RET* fusions are highly heterogeneous and the impact of specific fusion partners and breakpoints on RETi sensitivity is not well understood. Moreover, most patients eventually develop resistance to RETi, and secondary *RET* mutations are thought to be a key mechanism of acquired resistance. Thus, we aimed to identify *RET*-dependent mechanism of RETi resistance in effort to improve treatment options and clinical outcomes. We engineered a panel of Ba/F3 cells expressing various RET fusion partners and breakpoints observed in clinical cases of NSCLC and evaluated their drug sensitivity profile against a panel of RETi including selpercatinib, pralsetinib, TPX-0046, lovatinib, zeteletinib and ponatinib. We determined that individual RET fusions impart distinct sensitivities to RETi. For example, cells expressing KIF-RET (K22, R12) were sensitive to selpercatinib and pralsetinib but less sensitive to ponatinib, whereas cells expressing KIF-RET (K15, R12) were highly sensitive to selpercatinib, pralsetinib, and ponatinib. Moreover, using *RET*-fusion positive NSCLCs, we observed that the RETi sensitivity profile of human cell lines was similar to that observed using Ba/F3 models. To identify potential resistance mutations, we utilized the LentiMutate approach. In KIF5B-RET (K15, R12) expressing cells, we identified G810S as being associated with resistance to both selpercatinib and pralsetinib, a finding consistent with previous reports and clinical observations. In addition, we identified Y806H/N, V804M/E, and M918T as being associtated with selpercatinib-resistance and L730I/V, E732K, and Y806H/N as being associated with pralsetinib-resistance. We next constructed Ba/F3 cells expressing KIF5B-RET in combination with each secondary mutation and evaluated RETi sensitivity. G810S and Y806N conferred resistance to selpercatinib and pralsetinib, as well as to RET-targeting multi-kinase inhibitors. V804M/E mutations conferred resistance to selpercatinib but not pralsetinib, whereas L730I/V and E732K mutations conferred resistance to pralsetinib but not selpercatinib, demonstrating RETi-specific resistance mutations. Cells expressing G810S secondary mutations were resistant to selpercatinib and pralsetinib, but sensitive to zeteletinib. Collectively, we show that individual *RET* fusion variants have distinct drug sensitivity profiles and that secondary resistance mutations are non-overlapping between RETi. The comprehensive characterization of *RET*-dependent mechanisms of resistance to RETi may provide therapeutic guidance for treating *RET*-fusion driven NSCLC and provide structural insights that can guide the development of new therapeutic regimens.

#5834 The GR-LEDGF/p75 transcriptional network promotes therapy cross-resistance in prostate cancer cells.

P. T. Ochoa[1], E. S. Sanchez-Hernandez[2], K. Cheng[1], I. Kremsky[1], C. Wang[1], C. A. Casiano[1];
[1]Loma Linda University, Loma Linda, CA, [2]Sanford Burnham Prebys Medical Discovery Institute, San Diego, CA

Prostate cancer (PCa) is the second leading cause of cancer mortality for men in the U.S. Patients who develop advanced PCa ultimately acquire therapy resistance and succumb to the disease. An emerging challenge in the treatment of advanced PCa is the development of therapy cross-resistance, in which molecular pathways promoting resistance to a particular drug or treatment also promote resistance to subsequent treatments. Although the mechanisms driving PCa therapy cross-resistance are not clearly understood, recent studies from our group and others implicate the glucocorticoid receptor (GR), a transcription factor, in resistance to both androgen receptor signaling inhibitors such enzalutamide (ENZ), and taxane drugs such as docetaxel (DTX). Our studies also showed that GR upregulates and interacts with the lens epithelium derived growth factor of 75 kD (LEDGF/p75) in a large panel of PCa cell lines. LEDGF/p75 is a stress transcription co-activator and oncoprotein that promotes cancer cell resistance to DTX and DNA-damaging drugs. GR and LEDGF/p75 are part of a large transcriptional network that include other oncogenic transcription factors linked to cancer chemoresistance such as β-catenin, Menin, MLL, JPO2, and c-Myc. We hypothesized that this transcriptional network plays a role in PCa therapy cross-resistance and could be a promising therapeutic target. We observed by Western blotting (WB) that both GR and LEDGF/p75 proteins are upregulated in ENZ-resistant and DTX-resistant PCa cell lines, and that GR silencing in both contexts abrogated LEDGF/p75 expression. MTT viability assays showed that ENZ-resistant PCa cells also exhibited cross-resistance to DTX. Bioinformatics studies, using publicly available RNA-seq datasets, identified overlapping differentially expressed genes (DEGs) between ENZ-resistant and DTX-resistant PCa cells. Individual silencing of GR and LEDGF/p75 in two DTX-resistant PCa cell lines followed by RNA-seq analysis also identified an overlap between DEGs regulated by GR and LEDGF/p75 with DEGs associated with both ENZ and DTX resistance in PCa. GSEA analysis of DEGs targeted by both GR and LEDGF/p75 in DTX-resistant PCa cells revealed enriched pathways associated with stress responses, androgen responses, and regulation of cell death and cell cycle. Further, we initiated studies to evaluate the efficacy of small molecule inhibitors targeting multiple components of the GR-LEDGF/p75 transcriptional network in sensitizing therapy-resistant PCa cells to DTX and ENZ. In conclusion, our results implicate the GR-LEDGF/p75 axis in promoting resistance to both ENZ and DTX in PCa cells. Further mining of RNA-seq data will identify potential molecular targets associated with PCa therapy cross-resistance, leading to the design of novel therapeutic strategies to attenuate this resistance.

#5835 Genome-Wide CRISPR gene knockout screens combined with selpercatinib identifies potent combination therapies for RET driven medullary thyroid carcinoma.

A. Rahmy[1], A. Fallatah[2], D. Milewski[2], M. Tian[2], Y. Song[2], Y. Kim[2], H.-C. Chou[2], X. Wen[2], C. Wang[2], J. Wei[2], R. Hawley[3], J. Glod[2], J. Khan[2];
[1]Case Western Reserve University School of Medicine, Cleveland, OH, [2]National Institute of Health, Bethesda, MD, [3]The George Washington University School of Medicine and Health Sciences, Washington, DC

Background: Medullary thyroid carcinoma (MTC) is a rare neuroendocrine tumor driven primarily by activating mutations in the RET proto-oncogene. It accounts for approximately 13% of thyroid cancer-related deaths. Total thyroidectomy is the main treatment option for MTC patients; however, its efficacy is limited due to the high prevalence of metastatic disease at diagnosis. Vandetanib, cabozantinib, and selpercatinib are RET signaling inhibitors (RETi), that have been approved for treating advanced MTC. Despite their effectiveness, many patients relapse or have refractory disease due to eventual resistance to these RETis.
Methods: In our study, we employed genome-wide clustered regularly interspaced short palindromic repeats (CRISPR) gene knockout (KO) in MTC cell lines treated with selpercatinib or vehicle to investigate the genetic mechanisms of resistance or sensitivity to RETi. Our overarching goal was to identify potential synergistic or additive drug combinations that may prevent or treat resistant disease.
Results: Our research identified key genes and pathways confirming the sensitivity or resistance of MTC cells to RETi. Notably, apoptotic genes along with RAS and mTOR signaling pathways were found to play a significant role in resistance development. Knocking out negative regulators of these pathways (such as NF1 and TSC2) conferred growth advantages to cells treated with RETi. Alternatively, knocking out BCL2, an antiapoptotic protein, led to increased lethality. These findings suggested that targeting RAS, mTOR, or antiapoptotic pathways in conjunction with RETi may be synergistic or have additive activity. To validate the CRISPR screening, we selectively knocked down NF1 in MTC cells and found it led to a nearly two-fold increase in IC50 for selpercatinib. Furthermore, in-vitro and in-vivo testing confirmed significant synergistic activity when using the combination of trametinib, an MEK inhibitor (MEKi; downstream of the RAS pathway), with selpercatinib.
Conclusions and Future Directions: We have identified a potent synergistic combination of MEKi with RETi as a novel synergistic drug combination to treat MTC, which may also prevent resistance to RETi. These results will be translated to patients through clinical trials conduced at the NCI.

#5836 CRISPR/Cas9 screening identifies genes affecting the sensitivity to the copanlisib/venetoclax combination in lymphoma cells.

S. Napoli[1], A. J. Arribas[1], E. Cannas[1], F. Fuzio[1], L. Cascione[1], A. Rinaldi[1], E. Zucca[2], A. Alimonti[1], A. Stathis[2], **F. Bertoni**[1];
[1]IOR - Institute of Oncology Research, Bellinzona, Switzerland, [2]Oncology Institute of Southern Switzerland, Bellinzona, Switzerland

Background: Copanlisib, a PI3K inhibitor with a higher selectivity on PI3Kα and PI3Kδ, is currently being evaluated as a single agent and in combination for lymphoma and solid tumor patients. We and others reported the synergism achieved by adding the BCL2 inhibitor venetoclax, and the combination is in its early clinical assessment (NCT04939272, NCT04572763, NCT03886649). To explore genes affecting the response to the combination, we performed a genome-wide CRISPR Cas9 screen in a marginal zone B cell lymphoma (MZL) cell line under drug exposure.
Methods: We generated, via lentiviral infection, a stable Cas9-expressing VL51 line, which was then infected (MOI 0.3) with the genome-wide Brunello guide RNA library, interrogating 19114 genes. After puromycin selection, 40M cells underwent DNA extraction (T0), 40M were exposed to DMSO (control arm), 40M to copanlisib (0.5nM) + venetoclax (25nM) (experimental arm) for 2 weeks. DNA at T0 and extracted at 2 weeks underwent Illumina sequencing according to the Broad Institute Genetic Perturbation Platform protocol. MAGeCK-MLE was used to model sgRNA read counts and assess the sgRNAs statistical enrichment ($P<0.05$ FDR< 0.15), GSEA for genesets enrichments.
Results: In the DMSO-treated cells, 160 genes had a positive β value (i.e., the sgRNAs knocking down the genes were positively enriched after 2 weeks), while 1152 had a negative β value (i.e., the sgRNAs knocking down the genes were negatively enriched after two weeks), for a total of 1152 differential enriched targets. In the cells exposed to the drug combination, 207 genes had positive and 1324 negative β, for a total of 1531 differentially enriched targets. Genes defined as essential, according to DepMap, represented 768/1152 (67%) and 843/1531 (55%) in control and experimental arms, respectively. The experimental arm did not massively differ from the control arm as shown by 815 genes (615, 74%, defined as essential by DepMap) overlapping between the 2 conditions and by highly significant enrichments at GSEA. A few genes were relevant only in VL51 exposed to copanlisib/venetoclax and not to DMSO. Selected hits were individually validated. Knocking down VKORC1L1, XCL1, RFK, MAP2K6, POC1A, and WTN5A improved the activity of the combination. WTN5A was also validated using recombinant protein (10 ng/mL), which reduced the effect of copanlisib/venetoclax. SPARCL1, MAPK4, ID2, and MSTN silencing reduced the activity of the combination. MSTN, coding for myostatin, was also validated by adding the recombinant protein (10 ng/mL), which increased the drugs anti-tumor activity.
Conclusions: A genome-wide genetic screening identified genes modulating the lymphoma cells response to the copanlisib/venetoclax combination, providing novel therapeutic targets or biomarkers.

#5837 Aryl hydrocarbon receptor is critical for enzalutamide-resistant prostate cancer growth.

C.-H. Chen, B. Wu;
Washington State Univ. College of Pharmacy, Spokane, WA

Therapy resistance is a ubiquitous and major challenge for curing cancer including prostate cancer. As the most prevalent non-skin cancer for men, prostate cancer is responsible for more than 30,000 deaths annually in the U.S. Despite a favorable prognosis at early stages, prostate cancer progressively develop into an incurable castration-resistant stage (CRPC) where prostate cancer grows in a low-androgen environment. Enzalutamide (ENZ) is the first drug approved by FDA for treating CRPC by inhibiting the residual androgen signaling. While ENZ significantly improves overall survival and quality of life, resistance inevitably develops and greatly limits its benefit. To understand ENZ resistance and identify novel therapeutic targets with the hope of overcoming resistance, we performed RNA-seq to analyze mRNA expression profiles from three ENZ-resistant human CRPC cell lines (C4-2B^{ENZR}, CWR-R1^{ENZR} and VCaP^{ENZR}) and identified the aryl hydrocarbon receptor (AHR) among the 114 commonly upregulated genes. AHR is a ligand-dependent transcription factor that has been shown to drive disease progression in multiple types of cancer. Stable shRNA-mediated knockdown of AHR substantially decreased growth of ENZ-resistant CRPC cells. Our pilot study also showed that AHR knockdown resulted in fewer and smaller CWR-R1^{ENZR} tumors in a xenograft mouse model. To elucidate the underlying mechanism of AHR-mediated cancer growth, gene set enrichment analysis (GSEA) revealed a declining trend of enrichment of the 114 commonly ENZ-upregulated genes among differentially altered genes upon AHR knockdown in ENZ-resistant cells, suggesting that AHR may act as a master regulator of ENZ resistance. Moreover, we found that the Hallmark androgen response gene set is downregulated in AHR-silenced ENZ-resistant cells, implying a role of AHR in sustaining androgen response for ENZ-resistance. Consistently, we performed AHR ChIP-seq and confirmed that AHR bound to promoter regions of several androgen-regulated genes in CWR-R1^{ENZR} cells. In addition, three peroxisome-related Hallmark gene sets are also negatively enriched in AHR-knockdown cells, which provides a rationale for further exploring a potential AHR-dependent connection of peroxisomal function to ferroptosis as a newly emerging mechanism of action for ENZ. In summary, our study suggests that AHR plays a critical role in maintaining ENZ-resistant CRPC growth with the likely involvement of modulating androgen signaling and ferroptosis susceptibility.

#5838 Un-methylation of NUDT21 promotes the development of enzalutamide resistance in prostate cancer by regulation of 3'UTR usage switch.

S.-C. Lin, S.-C. Lin;
National Cheng Kung University, Tainan, Taiwan

Enzalutamide, a second-generation anti-androgen drug, is a new treatment option for castration resistant prostate cancer (CRPC) patient. However, almost all CRPC patients develop drug resistance for enzalutamide after six to twelve months of treatment. According to our current findings, 3'UTR usage switches of RNA transcripts were observed in the prostate cancer specimen after acquiring enzalutamide resistance and nudix hydrolase 21 (NUDT21), an alternative polyadenylation (APA) regulator, was overexpressed in the enzalutamide resistant (EnzaR) cells, suggesting its potential role involved in regulation of 3'UTR usage switch. However, the underlying mechanism of how NUDT21 regulates 3'UTR usage switch during the development of enzalutamide resistance is still unclear. Interestingly, a potential mono-methylation (MME) is identified in NUDT21 protein by us, and it has never been examined before. Thus, we hypothesize that MME of NUDT21 may regulate the specificity of 3'UTR usage switch and involve in the development of EnzaR. To test the idea, a monoclonal antibody recognized NUDT21 MME was generated by us. Moreover, protein arginine methyltransferase 7 (PRMT7) was identified to be responsible for adding MME to NUDT21. In addition, androgen treatment increased both expression levels of NUDT21 MME and PRMT7 while decreased the expression level of NUDT21 total form in LNCaP cells via androgen receptor (AR) dependent manner. Next, co-treatment of enzalutamide and PRMT7 inhibitor leaded to increase of un-MME form of NUDT21 and it greatly enhanced the enzalutamide resistance in LNCaP cells. Importantly, binding profile of NUDT21 total form indeed had 3'UTR usage switch from distal to proximal APA site in COUP-TFII transcript after acquiring enzalutamide resistance, while its MME form attenuated this phenomenon. In addition, expression levels of NUDT21 MME and its total form were shown to conversely express in prostate cancer specimens. Finally, un-MME form of NUDT21 promoted the cancer growth in vitro and in vivo while its MME form did not. Taken together, our results suggest that down-regulation of PRMT7 by enzalutamide may lead to decrease of NUDT21 MME level and contribute to develop enzalutamide resistance by causing the 3'UTR usage switch of NUDT21 downstream transcript.

#5839 Identification of low-dose ligand dependent drug-resistance in ALK/ROS1 positive NSCLC via CRISPR library screening.

N. Kondo[1], T. Utsumi[1], K. Uchibori[1], Y. Miyazaki[2], R. Katayama[1];

[1]Japanese Foundation for Cancer Research, Tokyo, Japan, [2]Tokyo Medical and Dental University, Tokyo, Japan

Tyrosine kinase inhibitor (TKI) therapy has displayed significant effectiveness in treating patients with anaplastic lymphoma kinase (ALK) and ROS proto-oncogene 1 (ROS1)-positive non-small cell lung cancer (NSCLC). Nonetheless, the emergence of acquired resistance in most patients presents a major challenge. Drug-tolerant persister (DTP) cells have recently gained attention as potential sources of resistance, highlighting the need for a deeper understanding of drug resistance mechanisms. To address this issue, a comprehensive genome-wide CRISPR-Cas9 knockout screening was conducted using an ALK-positive NSCLC cell line derived from pleural effusion in a patient who had not been exposed to ALK-TKI treatment. Following a 9-day ALK-TKI treatment, sequencing analysis was performed to identify sgRNAs in DTP cells. Notably, this analysis detected the involvement of tumor suppressor genes, including NF2, BAX, and ERRFI1.NF2 depletion was found to induce a substantial resistance to ALK-TKIs, and a combination therapy involving mTOR inhibitors showed promise in partially overcoming this resistance. Moreover, knockout of ERRFI1 or BAX led to an increase in DTP cells, drawing particular attention to ERRFI1, also known as MIG6, which is known for negatively regulating EGFR signaling. One intriguing discovery was that the loss of MIG6 induced resistance to ALK-TKIs when exposed to a relatively low dose of EGF, comparable to concentrations in plasma of healthy adults. This resistance was attributed to the upregulation of the MAPK and PI3K/Akt/mTOR pathways. Similar to ALK-rearranged NSCLC, ROS1 fusion-positive NSCLC cell lines also showed resistance by MIG6 knockout. Interestingly, some cell lines with reduced MIG6 expression tended to develop resistance with low-dose EGF, even without prior treatment, and overexpression of MIG6 restored sensitivity to TKIs. We further explored the potential of combination therapy, combining ALK-TKIs with anti-EGFR antibodies, and this approach effectively addressed acquired resistance in both in vivo and in vitro models. Furthermore, an analysis of clinical samples revealed that individuals resistant to ALK-TKIs displayed decreased mRNA MIG6 levels in comparison to their sensitive counterparts. Investigating the mechanisms behind MIG6 expression, we confirmed that ALK-TKI therapy suppressed MIG6 expression levels, while factors such as corticosteroid usage or exposure to hypoxia induced the upregulation of MIG6, potentially influencing the formation of DTP cells. In conclusion, this research has unveiled a novel factor contributing to resistance in ALK and ROS1-TKI therapies by activating the EGFR pathway through exposure to low-dose ligands, shedding light on potential therapeutic strategies to combat acquired resistance.

#5840 Identifying drug tolerant persister to neoadjuvant osimertinib in resectable non-small cell lung cancer harbouring EGFR mutations (NORA) via single-cell RNA sequencing.

J. Lee[1], S.-J. Choi[1], Y. Park[1], K.-H. Park[1], S. Yong[1], H. Shim[2], B. Park[1], C. Lee[1], M. Hong[1], B. Cho[1], S. Lim[1];

[1]Yonsei University College of Medicine, Seoul City, Korea, Republic of, [2]Yonsei University, Seoul City, Korea, Republic of

Introduction: Adjuvant osimertinib is the standard of care for resected, stage IB-IIIA non-small cell lung cancer (NSCLC) harboring activating epidermal growth factor receptor (*EGFR)* mutation. Yet, the role of neoadjuvant osimertinib is not clear. In the NORA trial (NCT04816838), we aimed to identify the drug tolerant persister (DTP) after neoadjuvant osimertinib for surgically resectable, *EGFR*-mutated stage IA-IIIA NSCLC.

Methods: Patients harboring EGFR Exon 19 deletion or L858R at clinical stage IA-IIIA were given 80 mg of neoadjuvant osimertinib daily for two 28-day cycles followed by surgical resection and adjuvant osimertinib for 3 years. The key exploratory endpoint was to characterize the DTP via single-cell RNA sequencing (scRNA-seq) with pre and post-osimertinib samples.

Results: We performed scRNA-seq on twenty-five patients enrolled at Yonsei Cancer Center from June 2021 to March 2022. Patients with stage IA (n=8, 32%), IB (n=7, 28%), IIA (n=4, 16%), IIB (n=4, 16%), and IIIA (n=2, 8%) were included. For *EGFR* mutation, exon 19 del and L858R accounted for 10 (40%) patients and 15 (60%) patients, respectively. The ORR (all partial response) was 44% (n=11), major pathologic response (MPR) rate was 24% (n=6), and pathologic complete response rate was 0%. ScRNA-seq revealed a total of 252,339 cells (60 clusters) annotated as epithelial cells (10 clusters), fibroblasts (7 clusters), immune cells (17 clusters), myeloid (15 clusters), endothelial cells (11 clusters) that showed distinct enrichment in post-osimertinib samples, non-MPR, and L858R subset. We found that a distint epithelial subset, namely EP8-AGER, identified as alveolar type 1 (AT1) cells was enriched in the non-MPR subset showing activation of *Wnt*, *Hippo*, and *YAP/TAZ* pathway. Pseudotemporal ordering of this cluster showed activation of signaling pathway for *COL4A2/COL4A3* related to structural consistuent of extracellular matrix, and *RTKN2* associated with NF-κB. In the fibroblast subset, the proportion of FB6-CD74 associated with chemokine activity and NF-κB was higher in the non-MPR and L858R group. In the myeloid subset, CD8-C1-GZMK identified as $CD8^{\pm}$ T cells with activation/effector and cytotoxic signatures was also enriched in the post-osimertinib samples. Among macrophages, 3 clusters (annotated as SELENOP+, SPP1+, PLXDC2+) showed enrichment of cholesterol metabolism with activation of apolipoprotein E that promotes conversion of proinflammatory macrophages into anti-inflammatory phenotypes. Lastly, the proportion of EC9-LYZ, annotated as scavenging endothelial cells was higher in the non-MPR and L858R group.

Conclusion: Neoadjuvant osimertinib resulted in the cellular reprogramming in the tumor microenvironment, notably AT1 epithelial cell which may lead to a loop between cancer cells and fibroblasts for the generation of DTP cells.

#5841 A genome wide CRISPR-Cas9 screen identifies mediators of resistance to dual PI3K/mTOR inhibition in glioblastoma multiforme.

A. V. Ferrotta[1], A. Izawa-Ishiguro[1], M. Grogan[2], I. K. Mellinghoff[2];

[1]Weill Cornell Graduate School of Medical Sciences, New York, NY, [2]Memorial Sloan Kettering Cancer Center, New York, NY

Glioblastoma multiforme (GBM) is a highly aggressive primary brain tumor with a devastating 5-year survival rate of 6.8%. The current standard of care, consisting of surgery, radiation, and temozolomide (TMZ), has remained unchanged for over the past 15 years despite its limited efficacy and the serious therapy-related adverse events associated to this regimen. Although some frequent genetic alterations have been identified in GBM, no targeted therapies have shown efficacy in these patients to date. Among these, the phosphoinositide 3-kinase (PI3K) pathway is a signaling network that regulates cell growth, proliferation, migration, and invasion. Extensive molecular characterization of GBM has identified alterations in the components of the PI3K pathway in 80% of primary GBMs, including amplification of receptor tyrosine kinases (RTKs), activating mutations in the PI3K catalytic subunit (PIK3CA), loss-of-function mutations in the PI3K regulatory subunit (PIK3R1), and loss of the major tumor suppressor of the pathway, phosphatase and tensin homologue (PTEN). Despite the universal upregulation of PI3K pathway signaling associated with these genetic alterations, clinical trials investigating PI3K inhibitors in GBM have failed due to insufficient antitumor activity and dose-limiting toxicities. To elucidate mechanisms of resistance to PI3K inhibition in GBM, we used a genome-wide functional CRISPR-Cas9 knockout screen to identify genes that mediate resistance to the dual PI3K/mTOR inhibitor XL765 in PTEN-null SF295 GBM cells. We identified reactivation of the PI3K pathway and inhibition of autophagy as potential resistance mechanisms to dual PI3K/mTOR inhibition. Using orthogonal approaches, we will functionally validate our candidate hits through mechanistic studies, with patient-derived models, and with *in vivo* orthotopic xenografts. Our findings will elucidate novel mechanisms of resistance to PI3K/mTOR inhibition in GBM and will streamline rational drug combinations aimed to overcome resistance, thus eventually maximizing therapeutic responses to PI3K inhibitors in GBM.

#5842 An epigenetic program that links oncogenic signaling to mitochondrial biogenesis supports leukemic cell survival in chronic lymphocytic leukemia.

O. M. Depies, S. Sinha, S. Parikh, N. Kay, **Z. Wang**;
Mayo Clinic, Rochester, MN

Therapeutic inhibition of BCR signaling using Bruton tyrosine kinase inhibitors (BTKis) has remarkable efficacy in the treatment of chronic lymphocytic leukemia (CLL). However, the efficacy of BTKis is limited by the development of drug resistance, which can be mediated through mutations in genes encoding proteins of BCR signaling pathways. Approaches targeting the BCR mutant proteins have been limited by the large heterogeneity of these mutations. In addition, BCR signaling mutations are only detected in up to two-thirds of the CLL patients who progressed with BTKi treatment, suggesting mechanisms beyond genetic mutations. We previously showed that the BCR signaling pathway impacts the chromatin landscapes of CLL B cells (Wang et al., Blood Cancer J. 2022), suggesting that epigenetic mechanisms are exploited by CLL B cells to support their survival. To gain insights into the epigenetic regulation of BTKi treatment in CLL B cells, we analyzed the genome-wide chromatin accessibility (ATAC-seq) and histone modification (H3K4me1, H3K4me3, H3K27ac, H3K27me3) profiles (CUT&Tag) of leukemic cells from 4 CLL patients on BTKi ibrutinib treatment in a sequential fashion (i.e., baseline, on ibrutinib treatment, and at relapse). We also performed the same analysis in a CLL cohort at two stages of ibrutinib treatment (baseline and while on treatment, n=20). Our studies showed that suppressing BCR signaling by BTKi leads to the downregulation of genes associated with mitochondrial translation, a key process of mitochondrial biogenesis. We also found decreased chromatin accessibility and H3K27ac deposition at the promoters of these MT genes. Interestingly, in patients who experienced disease progression on ibrutinib, there was a restoration of MT gene expression, chromatin accessibility, and H3K27ac levels at the MT gene promoters similar to baseline samples, suggesting an epigenetic-regulated MT both in BTKi treatment naïve and relapsed CLL patients. Importantly, MT inhibition led to a decreased survival of primary CLL B cells. These findings point toward an epigenetic mechanism utilized by BCR signaling to promote MT and leukemic cell survival. We then observed that the transcription factor NRF1 is enriched at the MT promoter in CLL B cells. CRISPR-mediated depletion of NRF1 led to reduced mitochondrial translation and cell survival in BCR signaling active malignant B cell lines and primary CLL B cells. These results suggest that NRF1 controls an epigenetic program linking BCR signaling to control MT, which in turn supports BCR signaling-dependent CLL B cell survival. Our findings demonstrated that BCR signaling utilizes epigenetic mechanisms that regulate mitochondrial metabolism to enhance cell survival in both treatment naïve and BTKi-relapsed CLL. These findings may provide new therapeutic directions for untreated and BTKi-relapsed CLL patients.

#5843 Exploring the implications of LPAR-1 expression in TKI-resistant NSCLC.

V. Srinivasan, Z. Li, R. Kannan, A. Upendran;
University of Missouri - Columbia, Columbia, MO

Introduction: Non-small cell lung cancer (NSCLC) is the most common type of lung cancer in the United States with a 5-year survival rate hovering between 20-30%. Mutations in EGFR can initially cause the tumors to respond to tyrosine kinase inhibitors (TKI). Osimertinib, a third generation TKI, is the preferred first or second line of treatment and despite being effective, recent reports indicate that patients develop resistance within 10-18 months of treatment. TKI resistance limits therapeutic options for patients and therefore, alternative strategies are being explored. In this context, Lysophosphatidic acid receptors (LPARs), a family of G-protein coupled receptors consisting of LPARs 1-6 expressed differentially in prostate, breast, ovarian, pancreatic, and brain cancers are being explored as potential targets for drug resistant cancers. Specifically, LPAR-1 has been shown to play a role in tumor cell clonogenicity, migration, and response to therapy in EGFR mutant NSCLC cells. Pharmacological inhibition or CRIPSR based deletion of LPAR-1 in EGFR mutant NSCLC cell lines HCC827 and NCI-H3255, increased TKI sensitivity by reducing clonogenic potential. Further, detailed pathway analysis in TKI sensitive and resistant EGFR mutant cell lines suggests that LPAR-1 expression influences drug sensitivity. Surprisingly, the role of LPAR-1 in TKI sensitivity is not well understood. In the present study, we have performed detailed investigation on the implications of LPAR-1 expression in the development of Osimertinib resistance.

Methods: Osimertinib resistant EGFR mutant cell lines (OR) were generated using dose-escalation method and drug-tolerant persisters (DTPs) were generated using a short-term high exposure method. Gene and protein expressions were examined using qPCR and western blotting. Subcutaneous tumor cell derived xenografts were generated for *in vivo* studies.

Results: LPAR-1 is downregulated in Osimertinib resistant NSCLC cells. Further, we also observe that LPAR-1 levels are lower in DTP cells, confirming a progressive loss of LPAR-1 with Osimertinib treatment. *In vivo* studies in cell derived xenografts correlated with the *in vitro* studies.

Conclusion: Our studies indicate LPAR-1 downregulation correlates to Osimertinib resistance in EGFR mutant NSCLC cell lines. LPAR-1 downregulation has a key role in development of Osimertinib resistance. Future studies will focus on delineating LPAR-1 signaling pathways related to TKI resistance and investigating the effect of LPAR-1 overexpression using CRISPR technology.

#5844 Landscapes of acquired EGFR and VEGF resistance alterations in colorectal cancer: findings from the PARADIGM biomarker study.

Introduction: Resistance mechanisms to anti-epidermal growth factor receptor (EGFR) treatment, such as panitumumab (PAN), in patients (pts) with metastatic colorectal cancer (mCRC) depend on the diversity of acquired gene alterations and clonal variation. To explore resistance mechanisms and emerging genomic alterations during PAN treatment, we analyzed the circulating cell-free DNA (cfDNA) samples from the PARADIGM trial (NCT02394795), which demonstrated survival benefits of PAN over bevacizumab (BEV), an anti-vascular endothelial growth factor (VEGF) antibody, in combination with first-line chemotherapy in pts with *RAS* wild-type (WT) mCRC.

Methods: cfDNA from blood samples were obtained pre- and post-treatment and analyzed for gene alterations using the custom PlasmaSELECT-R 91 PGDx panel (NCT02394834). We analyzed the landscapes of acquired alterations and their association with functional pathways in mCRC according to The Cancer Genome Atlas signaling classification.

Result: Among the enrolled 802 pts, 390 discontinued treatment due to progressive disease, of which 276 (70.8%) had evaluable pre- and post-treatment cfDNA samples (PAN, n=126; BEV, n=150). Though the proportion of pts with acquired alterations in any of 30 *RTK-RAS*-related genes was similar in PAN vs BEV (44.4% vs 42.7%), known *EGFR* resistance-related genes were observed more frequently in PAN compared with BEV: *KRAS* (19.1 vs 2.7%), *NRAS* (9.5 vs 2.7%), *BRAF* (11.1 vs 0.7%), *MAP2K1* (5.6 vs 0.7%), and *EGFR* (5.6 vs 3.3%). These acquired mutations clustered at hotspots within those genes in the PAN group, unlike in the BEV group. Furthermore, the co-occurrence rates of acquired alterations among the *RTK-RAS* pathway of the individual cases were higher in PAN (25.4%) vs BEV (9.3%), suggesting an increased subclonal complexity in PAN. There were few acquired alterations predominantly observed in BEV, and their biological significance remains unclear.

Conclusion: These results suggest that PAN treatment, compared with BEV, more commonly induces multiple resistant subclones in specific pathways under selective treatment pressure. Our findings provide valuable insight for further investigations into the mechanisms of acquired and resistance associated with PAN and BEV.

#5845 Cytarabine resistance leads to a unique mutational signature.

D. Cao[1], M. Yin[1], Z. Zhang[1], T. Baslan[2], J. Zhu[1], R. Bertoli[1], P. Meltzer[1], P. Aplan[1];
[1]National Cancer Institute, Bethesda, MD, [2]Memorial Sloan Kettering Cancer Center, New York, NY

The prognosis of recurrent T-cell acute lymphoblastic leukemia (T-ALL) is poor, mainly due to chemotherapy resistance. The mechanism(s) leading to chemoresistance at relapse are incompletely understood. We previously characterized a mouse strain that is hypomorphic for the DNA replication factor Mcm2. $Mcm2^{hypo}$ mice develop T-ALL due to acquired DNA copy number variations (CNV) involving tumor suppressor or oncogenes. We hypothesize that treatment of $Mcm2^{hypo}$ cells with specific chemotherapy agents may reveal CNV that lead to chemoresistance. We treated two $Mcm2^{hypo}$ T-ALL cell lines (designated 2883 and 2869) and an Mcm2 WT T-ALL cell line (designated 7298) with cytarabine (ARAC), an active agent often incorporated in T-ALL treatment regimens. After one year of treatment with gradually increasing ARAC concentrations, we obtained ARAC resistant cell lines (designated with the suffix CR) that tolerate drug concentrations up to 10,000X that of parental cell lines. These samples were characterized by sparse WGS (for CNV assessment), RNA-Seq and WES. Both the 2883CR and 2869CR cell lines had bi-allelic mutations involving Dck, which is the rate-limiting enzyme in the cytidine salvage pathway, and is thought to be required for metabolism of ARAC. In both cases, one allele was deleted while the second allele had a splice site/region mutation leading to partial intron retention and resultant frameshift. The 7298CR cell line had homozygous deletion of Dck. Western blotting showed absence of WT Dck protein in all three cell lines. Further analysis of WES data revealed thousands of acquired single nucleotide variants (SNV) in both Dck mutant $Mcm2^{hypo}$ cell lines. These mutations occurred in a specific trinucleotide context (C>T in a GCG context, T>C in a GTC context, T>G mutations in GTC and GTT context, and C>G in a GCC context) generating a mutational signature that is not present in the COSMIC database. In addition, the parental 2883 and 2869 cell lines showed fewer mutations (ie, hundreds vs thousands) in a similar context (C>T in a GCG context, T>C in a GTC context, T>G mutations in GTC and GTT context, but not the C>G in GCC context). A GEMINI (Genotoxic Mutational Signature Identified After Clonal Expansion In Vitro) assay of untreated 2883CR and 2869CR cells demonstrated that ongoing ARAC exposure was not required for the mutational signature. We hypothesize that the basic signature (C>T in a GCG context, T>C in a GTC context, T>G mutations in GTC and GTT context) can be produced by Mcm2 deficiency, and this signature is amplified and modified (to include a C>G in GCC context) by Dck inactivation. In summary, we identified three mechanisms responsible for Dck inactivation associated with ARAC resistance: copy number loss, splice site mutations, and splice region mutations. Moreover, Dck inactivation leads to a specific mutation signature. These findings add to emerging data that exposure to specific chemotherapy agents can lead to specific mutational signatures.

#5846 Inhibiting elements of the proteasome recovery pathway sensitizes glioblastoma to proteasome inhibitors.

A. Anand, M. Shaikh, C. Chokshi, B. Brakel, W. Maich, S. Grewal, C. Venugopal, S. Singh;
McMaster University, Hamilton, ON, Canada

Bacground: Glioblastoma (GBM) is the most common primary brain tumor, accounting for 15% of all central nervous system related tumors. Despite the aggressive standard of care treatment including chemotherapy, radiotherapy, and maximally safe surgical resection, patient outcomes are abysmal: with 95% of patients relapsing and a median overall survival of 15 months. Thus, this necessitates the rapid query for personalized therapeutics and agents that can potentiate the clinical effects of currently approved treatments. One such pathway that demonstrates aberrant functioning in cancer and is a targetable mechanism is the ubiquitin-proteosome pathway (UPP). Studies have shown that UPP related proteolysis remains constitutively active in cancer cells leading to the rapid degradation of proteins that regulate tumor suppressor genes and oncogenes. Despite robust preclinical evaluations for the usage of proteosome inhibitors against GBM, most tested proteosome inhibitors failed in phase II and III trials, indicating resistance.
Methods: We conducted an unbiased genome wide CRISPR-Cas9 screen in human HAP1 cells treated with the proteosome inhibitor, Bortezomib (BTZ), to identify genes that may lead to a BTZ-resistant phenotype. We identified several genes that when perturbed, sensitized cells to BTZ including N-glycanase-1 (NGLY-1), Nuclear factor Erythroid 2-Like-1 (NFE2L1), and DNA damage inducible 1 homolog 2 (DDI2). Herein we sought to evaluate the effects of perturbing components of the proteosome rescue pathway in our Singh lab patient derived GBM cell lines by utilizing CRISPR/Cas9 knockout technology *in vitro* and *in vivo*.
Results: The generation of NGLY-1, DDI2, and NFE2L1 KO cell lines demonstrated functional sensitivity to the proteosome inhibitor Marizomib (MZB) as observed through a significant reduction of the IC50 in the KO cell lines compared to a control. Functional evaluation also revealed a reduction in proliferation capacity as well as sphere formation in these genetically modified GBM lines. Ongoing *in vivo* work will aim to evaluate the mitigation of this resistant pathway in our NSG mouse models orthotopically transplanted with these patient derived KO cell lines. In an ongoing collaborative effort, we are working to identify and functionally assess a novel small molecule NGLY-1 inhibitor to evaluate preclinical sensitivity to MZB in our *in vitro* and *in vivo* models.

#5847 Characterizing mechanisms of BRAF/MEK inhibitor resistance in BRAF V600 mutant colorectal cancer vs. melanoma.

J. Maxwell, E. Rousselle, L. An, A. Rose;
McGill University, Montreal, QC, Canada

Background: BRAF V600 mutations comprise ~80% of all oncogenic BRAF mutations in metastatic colorectal cancer (mCRC). While most cancers with BRAF V600 mutations can be effectively treated with combined BRAF and MEK inhibition, BRAF V600 mutant mCRC acquire resistance through EGFR-mediated signaling. The profound difference in response rates to BRAF/MEK inhibitors in BRAF V600 mutant mCRC (12%) vs. melanoma (63-68%) is not sufficiently explained by increased EGFR signaling in CRC. Therefore, we sought to characterize the differences that exist between BRAF V600 mutant CRC and melanomas that could explain the differential sensitivity to BRAF/MEK inhibition and identify more effective treatments for BRAF V600 mutant CRC.
Methods: We assessed cell survival by clonogenic assay in the presence of small molecule inhibitors. In parallel, we mined TCGA RNAseq data to calculate the MAPK Pathway Activity Score (MPAS). RTK expression was assessed in TCGA data from patients with BRAF V600 mutant CRC vs. melanoma. We developed cells with acquired resistance to BRAF+MEK inhibitors (Encorafenib+Binimetinib; E+B) by culturing cells in increasing concentrations of drug over several months. RNA-sequencing and analysis was performed on parental and resistant cells treated with vehicle control or BRAF+MEK inhibitors.
Results: When comparing the efficacy of BRAF+MEK inhibitors across BRAF V600 mutant cells, we found that BRAF V600 mutant CRC cell lines (n=2) were less sensitive than melanoma cell lines (n=2). MPAS scores were significantly lower in BRAF V600 mutant CRC (n=46) vs. melanoma (n=188) tumors. We interrogated protein array data from the DepMap and identified increased activation of several RTKs (EGFR, HER2, HER3) in BRAF V600 CRC (n=8) vs. melanoma (n=39) cell lines. Similarly, we established resistant HT29 (BRAF V600 CRC) cells and observed sustained MAPK pathway activity despite a lack of difference in EGFR activity in the presence of BRAF+MEK inhibitor treatment. Both HT29 parental and resistant cells showed re-establishment of MAPK signaling after 72 hours. Resistant SkMel28 (BRAF V600 melanoma) cells showed increased pERK levels compared to resistant HT29 cells. RNAseq revealed increased expression of multiple RTKs (PDGFRB, ERBB2, ERBB3) and ligands/growth factors for multiple RTKs (FGF3, PDGFA, HB-EGF) in resistant HT29 cells. Shp2 is a protein tyrosine phosphatase that regulates signaling of multiple RTKs to activate the MAPK pathway. Accordingly, we assessed the efficacy of an inhibitor of Shp2 (TNO155) overcoming MAPKi resistance in BRAF V600 CRC cells. We confirmed that E+B+TNO155 more effectively inhibited cell growth and MAPK pathway activity in BRAF V600 CRC cell lines (n=2) *in vitro*.
Conclusion: Together, these data identify key, actionable drivers of MAPK inhibitor resistance in CRC and highlight Shp2 as a potential therapeutic target for BRAF V600 CRC.

#5848 Unraveling c-MET targeting resistance mechanisms in gastric cancer via single-cell transcriptome analysis; Novel therapeutic target discovery of ERO1A and VEGFA.

H. Kim[1], J. Kim[1], S.-J. Myung[1], C. Park[2], S. Kim[1];

[1]Asan Medical Center (AMC), Seoul, Korea, Republic of, [2]National Cancer Center, Goyang, Korea, Republic of

Background: Gastric cancer (GC) is the fifth most prevalent malignant tumor worldwide, and the fourth most common cause of mortality. c-MET has been reported to be associated with poor prognosis in GC. Over the decades, treatment approaches targeting HGF/c-MET have been developed including small molecule tyrosine kinase inhibitors, anti-c-MET and anti-HGF monoclonal antibodies. Unfortunately, the results of previous study support the development of acquired resistance to HGF/c-Met inhibitors. They suggest a possible resistance mechanism involving poor MET-status detection, crosstalk between c-MET and compensatory signaling pathways, the occurrence of acquired a new mutation, however, knowledge regarding the mechanism of c-MET inhibitor is limited.2.
Purpose: We identify new markers and mechanisms that induce drug resistance when c-MET-targeted inhibitors are treated in c-MET-amplified GC cell lines in 3D culture, and discover new therapeutic targets for GC via single cell-RNA sequencing analysis.3.
Material and Methods: Single cell-RNA sequencing is performed on c-MET amplified GC cell line in the 2D and 3D culture methods according to the presence or absence of c-MET inhibitor treatment. Through DEG and clustering analysis, the candidate genes estimated to impart resistance are selected and verified by qPCR. Through over-expression, induction of resistance for c-MET inhibitor treatment with target gene is evaluated in c-MET amplified GC cell line. c-MET inhibitor selected gene is constructed as a xenograft model to reveal the mechanism of drug resistance. Retrospective analysis confirms the relationship between target gene expression level and the resistance for c-MET inhibitor or other TKI treated patients with GC. 4.
Results: Treatment of c-MET-amplified GC cell lines with c-MET inhibitors under the conditions of 2D and 3D cultures confirmed that resistance was induced only in the 3D. We performed a high-precision single cell RNA-Seq analysis of 18056 single cells in total from c-MET amplified GC cell line MKN-45 in 2D/3D culture control as well as corresponding samples with volitinib treatment investigate their gene expression signatures. Fifteen selected candidate genes presumed to induce drug resistance were screened and validated by qPCR, with a total of six genes consistent with the sequencing results. After over-expression of six genes to the c-MET amplified gastric cancer cell line, c-MET inhibitors were treated and cell viability was performed to check for resistance to cell viability. Finally, ERO1A and VEGFA were over-expressed to confirm the resistant for the c-MET inhibitor treatment in vitro and in vivo.5.
Discussion: We plan to build a xenograft mouse model with candidate genes such as ERO1a and VEGFA to prove whether the candidate gene overcomes drug resistance when they are on or off.

#5849 Integrated multi-omics of hydroxychloroquine evolved cancer cells reveal survival requires transcriptional upregulation of glycolysis, exocytosis, and chromosome fidelity, but not autophagy.

M. Clark, S. G. Vaena, J. R. Delaney;
The Medical University of South Carolina (MUSC), Charleston, SC

Repurposed drugs are undergoing a renaissance in the era of genomics, particularly in oncology. Over 2,300 FDA-approved and natural product small molecules now exist, but challenges remain in identifying which cancer patients may best benefit from such drugs. To best position repurposed drugs, mechanisms of action and resistance to the drug in a cancer cell setting must be determined. Hydroxychloroquine (HCQ) and chloroquine are repurposed drugs reported to disrupt autophagy, a molecular recycling pathway which is essential for tumor cell survival, chemotherapeutic resistance, and stem cell phenotypes. However, oncology trials with chloroquine have no biomarker or other genetic test to categorize patients who may best respond to HCQ therapy. It is unclear how tumors mechanistically evolve resistance to HCQ. We pursued a multi-omic strategy in OVCAR3 ovarian cancer and CCL218 colorectal cancer cells. Two genome-scale screens were performed. In the forward genetic screen, cell populations were passaged in 93-independent cultures for 15 drug pulse-chases with HCQ or vehicle control. Evolved cells were collected and processed for bulk RNA-seq, exome-seq, and single cell RNA-seq (scRNA-seq). In the reverse genetic screen, a pooled Brunello CRISPR-Cas9 library of 19,114 genes targeted by multiple sgRNAs was used in cells over three pulse-chases of HCQ or vehicle control treatments. HCQ evolved cells displayed remarkably few mutational differences, but substantial transcriptional differences. Bulk transcriptomes revealed multiple broad-spectrum pathways associated with resistance to HCQ, including upregulation of glycolysis, exocytosis, and chromosome condensation/segregation, as well as downregulation of translation and apoptosis. Analysis of scRNA-seq data indicated cell clusters were differentially reliant on cytoskeletal regulation, DNA repair, and metabolism. The genome-scale Cas9 screen identified remarkably few autophagy genes. However, an integrated analysis of Cas9 hits with RNA-seq upregulated genes confirmed glycolytic genes KDM3A, ENO2, and PDK3 were essential for HCQ resistance. Additional integrated hits were NEK2, involved in exocytosis, and chromosome condensation/segregation genes CDK1 and CENPA. Transcriptional plasticity was the primary mechanism by which cells evolved resistance to HCQ. Contrary to the widely presumed autophagy-related mode of cell death, the multi-omic analysis instead prioritized glycolytic metabolism, exocytosis, and chromosome condensation/segregation as most involved in cancer cell survival with HCQ. Integrated multi-omic analysis defined high-value biomarkers of HCQ sensitivity and resistance. Our analysis may serve as a model for how to better define the effects and positioning of repurposed drugs in oncology.

#5850 Multiomics analysis unravels tumor metabolic reprogramming and potential resistance mechanism(s) to curative therapy in TNBC.

Z. Ren[1], K. Kurmi[2], R. Morris[1], S. Joshi[2], E. Zaniewski[1], J. Kreuzer[1], G. Elena Gioia[1], V. I. Bossuyt[1], B. N. Dontchos[1], G. X. Wang[1], S.-H. S. Chou[1], L. M. Spring[1], W. Haas[1], M. C. Haigis[2], L. W. Ellisen[1];

[1]Massachusetts General Hospital/Harvard Medical School, Boston, MA, [2]Harvard Medical School, Boston, MA

Drug resistance is the leading cause of treatment failure to completely eliminate viable tumor cells in ~40% of patients with triple negative breast cancer (TNBC). Making a major impact on the treatment and prognosis for TNBC patients requires a better understanding of drug resistance mechanism(s). Combining clinical data with high-throughput metabolomic and proteomic analyses, we probed the molecular basis for chemotherapy resistance in treatment-naive TNBC primary tumors, reflected by pathological complete response (pCR) and non-pCR after neoadjuvant chemotherapy (NAC). Metabolic profiling uncovered that glycolysis and oxidative phosphorylation (OXPHOS) co-exist in TNBC primary tumors compared to benign lesions regardless of pCR status, indicating metabolic reprogramming. However, non-pCR tumors were more enriched in OXPHOS and less in glycolysis relative to pCR tumors, pointing to the potential importance of OXPHOS in drug resistance. Moreover, parallel proteomic profiling of these same TNBC tumors supported the results from metabolic profiling, showing that OXPHOS was indeed highly enriched at the protein level, and may be regulated by SIRT5-mediated sirtuin signaling. In alignment with these findings, non-pCR tumors were abundantly enriched in immune-inhibitory metabolites that may be due to the products of SIRT5-mediated mitochondrial metabolism. Thus, these findings led me to hypothesize that SIRT5 may play an important role in chemoresistance through regulation of mitochondrial metabolism and ROS detoxification. Together, the metabolite resulted from SIRT5-mediated mitochondrial metabolism led to the suppression of immune cell infiltration in non-pCR tumors. Understanding SIRT5-mediated chemoresistance mechanism may uncover a metabolic and therapeutic vulnerability to resistant TNBCs.

#5851 Dysregulated RNA splicing promotes AML quiescence and chemoresistance.

E. Wang[1], C. Han[1], A. Calderon[1], A. Lawal[1], N. Hariramani[1], E. Crosse[2], R. Bradley[2];

[1]The Jackson Laboratory for Genomic Medicine, Farmington, CT, [2]Fred Hutchinson Cancer Research Center, Seattle, WA

Chemotherapy is the first-line treatment for patients with acute myeloid leukemia (AML). Although most achieve initial remission, an estimated 50% of patients will relapse with poor clinical outcome. The paucity of genetic lesions in AML patients that relapse from chemotherapy implicate non-genetic alterations that mediate chemoresistance. In this study, we conducted a longitudinal analysis of alternative splicing changes in a cohort of 19 AML patients at diagnosis and relapse post-chemotherapy treatment. We found that the long isoform of the transcription factor-encoding gene *RUNX1* (also known as RUNX1C) is upregulated in AML relapse cohorts and conferred chemotherapy resistance. Mechanistically, we show that B cell translocation gene 2 (*BTG2*) is an RUNX1C isoform-specific transcriptional target that promote transition into a quiescent and treatment-resistant state. Direct targeting of *RUNX1C* mRNA augments chemotherapy response in AML patient-derived xenograft (PDX) models *in vivo*. These findings uncover an isoform-specific functionality that influences chemotherapy responsiveness and offers a therapeutic strategy to sensitize leukemic cells to conventional chemotherapy treatments.

#5852 Tumor gene expression patterns affecting response to BCl-2 inhibitor venetoclax in acute myeloid leukemia.

J. Raygoza Garay[1], S. Yun[2], A. Osman[3], R. Ramlal[4], D. Feith[5], M. Churchman[6], P. Dhakal[1];

[1]University of Iowa Holden Comprehensive Cancer Center, Iowa City, IA, [2]H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL, [3]Huntsman Cancer Institute, Salt Lake City, UT, [4]University of Kentucky, Lexington, KY, [5]University of Virginia, Charlotesville, VA, [6]Aster Insights, Tampa, FL

Background: Venetoclax (VEN), a B-cell lymphoma-2 (BCL-2) inhibitor, is an important drug in acute myeloid leukemia (AML) treatment regimens. However, resistance to VEN-based therapy is a common challenge in AML management. Some factors contributing to resistance include dysregulation of BCL-2 family proteins, mutations in the TP53 gene, activating kinase mutations, and oxidative phosphorylation activity. Despite these insights, other mechanisms of resistance remain elusive. We aim to analyze tumor gene expression patterns associated with treatment response in patients who received VEN-based therapy.

Methods: Molecular and clinical data of the patients were obtained as part of the Oncology Research Information Exchange Network (ORIEN) Avatar dataset. RNA-Seq data from diagnostic Bone Marrow were processed to remove batch effects, and differential expression analysis was performed using DESeq2, while correcting for age at sample collection and sex of patients.

Results: We included 16 individuals treated with VEN-based therapy. Median age at the time of specimen collection was 65 years (interquartile range, 58-69), 9 (56%) male, 11 (69%) had active disease despite treatment with VEN. VEN-based therapy was used as 1st line, 2nd line, 3rd line, 4th line or more in 3, 4, 4, 2, and 3 patients, respectively. We found a total of 332 genes differentially expressed (fdr<0.05 and abs(log2FoldChange)>2.0) among patients having no evidence of active disease and those with no active disease at the time of last contact. Among those genes, we found HOXA7 and PRAME of particular interest. HOXA7 has been previously implicated in Bromodomain and Extraterminal Domain Inhibitors (BETi) inhibitor resistance in AML. This makes HOXA7 a potentially universal mechanism of chemotherapy resistance in AML. PRAME has been associated with leukemia cell survival, and its knockdown has been shown to induce apoptosis in K562 cells, which is only expressed in AML cells but not in normal hematopoietic cells. Pathway analysis found that the top two enriched pathways for the differentially expressed genes were *MET activates PTK2 signaling* (R-HSA-8874081) and *Metabolism of Angiotensinogen to Angiotensins*(R-HSA-2022377).

Conclusions: This study highlights some molecular mechanisms that give rise to AML resistance to VEN. Our results indicate that HOXA7 may potentially be a universal mechanism of chemotherapy resistance not limited to VEN-based therapy. Similarly, pathways enriched in resistant cells could be targeted to prevent or treat resistance to VEN-based therapy. These and other findings may help us identify resistance mechanisms in all AML cases vs those specific to VEN-based therapy, allowing the development of treatment strategies based on treatment mechanism. Also, analysis of these mechanisms can aid therapeutic decision-making and the development of effective treatment strategies to improve outcomes in AML.

#5853 Regulatory network inference of lung adenocarcinoma drug-tolerant persister cells.

L. Chabrier[1], C. Leonce[2], R. Schneider[2], C. Degletagne[2], P. Saintigny[2], A. Crombach[1], **S. Ortiz-Cuaran**[2];
[1]Inria Antenne Lyon La Doua. Universite de Lyon, INSA-Lyon, LIRIS, UMR 5205., Villeurbanne, France, [2]Univ Lyon, Claude Bernard Lyon 1 University, INSERM 1052, CNRS 5286, Centre Leon Berard, Cancer Research Center of Lyon, Lyon, France

Despite the effectiveness of the latest generation of cancer drugs, partial tumor response and subsequent disease relapse is commonly observed in patients. Recent evidence suggests that treatment resistance emerges from drug-tolerant persister cells (DTPC) that survive through non-genetic tumor cell adaptation. Although DTPC are mostly slow-cycling, a rare subset can re-enter the cell cycle under constitutive presence of treatment. Understanding how DTPC dynamically remodel their molecular portraits at the single-cell level may provide high-resolution insights into the molecular circuits associated with adaptive survival to therapy.Here, we use single-cell RNA sequencing (scRNA-seq) to identify potential mechanisms that promote survival of DTPC and decipher their underlying gene regulatory networks (GRNs), in a model of EGFR-mutant lung adenocarcinoma treated with osimertinib (EGFR inhibitor).
Gene expression analysis revealed fewer cell states in DTP compared to treatment-naïve cells (TN). We confirmed the acquisition of DTPC hallmarks (e.g., high epithelial-mesenchymal transition, slow-cycling phenotype, deficient DNA repair). We also identified subpopulations of cells that display intermediate transcriptional states: a pre-existing DTP-like state in a bulk of TN cells, and DTPC with enriched cell cycle signatures, evoking a phenotype of cycling DTPC. To characterize the GRN that govern TN cells, DTPC and the intermediate cell states, we applied the network inference tool PYSCENIC, which associates transcription factors (TFs) to their candidate target genes (TGs) on the basis of the scRNA-seq data and enrichment of TF binding motifs in the genomic regions around TGs. The resulting (GRN) consisted of 5 TF modules clustered on the basis of correlated TF activity.This analysis revealed that, compared to TN cells, DTPC and the intermediate cell states display a marked decreased expression of TFs and TGs involved in mRNA splicing, and more specifically in the initiation of spliceosome assembly through E-complex and A-complex formation. Interestingly, the splicing-related TFs all appear to have affinity for binding to a GCCxC consensus motif or close variant in genes (i.e., SNRPB and SNRPE) that code for key effectors of these initiation complexes. This pilot study highlights that scRNA-seq analyses coupled with inference of regulatory networks might enable the identification of molecular mechanisms that potentially trigger cell state transitions during drug-tolerance. The role of altered mRNA splicing in persistence to EGFR-targeted therapies will be explored experimentally in patient-derived cell lines and 3D organoid cultures.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Mechanisms of Drug Resistance 3
Poster Session

#5857 Trastuzumab deruxtecan resistance can be mediated by payload resistance or secondary extracellular ERBB2 mutations but sensitivity to HER2 tyrosine kinase inhibitors is maintained.

M. B. Nilsson[1], X. Le[1], J. He[1], X. Yu[1], X. Huo[2], A. Kumar[2], A. Poteete[1], Q. Huang[1], R. Kittler[2], J. Heymach[1];
[1]UT MD Anderson Cancer Center, Houston, TX, [2]UT Southwestern Medical Center, Dallas, TX

Among NSCLC patients, the most common HER2 mutation is the exon 20 insertion mutation, Y772dupYVMA, which accounts for over 40% of all HER2 mutations in lung cancer. Trastuzumab deruxtecan (T-DXd), a HER2 antibody-drug conjugate (ADC), received FDA approval for the treatment of HER2 mutant NSCLC yielding a confirmed objective response of 52% and a median duration of response of greater than 9 months. Unfortunately, patients that initially respond to T-DXd will eventually acquire resistance, and the mechanisms of resistance as well as effective targeting strategies to overcome resistance are not yet elucidated. We generated Ba/F3 cells expressing the HER2 YVMA insertion mutation with acquired resistance to T-DXd by culturing cells in T-DXd until resistance occurred. T-DXd resistant cells retained expression of HER2, but were resistant to the payload, deruxtecan, as well as other topoisomerase inhibitors. T-DXd resistant cells exhibited loss of topoisomerase I, a previously reported mechanism of topoisomerase inhibitor resistance. In parallel, we generated a PDX model of acquired T-DXd resistance and observed sustained expression of HER2 but loss of TOP1 in resistant tumors. T-DXd resistant cell lines were sensitive to payloads with alternate mechanisms of action including maytansine and likewise retained sensitivity to the HER2 ADC trastuzumab emtansine (T-DM1) which utilizes DM1 as a payload. Given that T-DXd resistant cells retained HER2 expression, we assessed whether they were sensitive to HER2 tyrosine kinase inhibitors (TKI). T-DXd resistant cells remained highly sensitive to HER2 TKIs including poziotinib, afatinib, BI-4142, and BI-1622. To investigate whether genomic alterations of HER2 could facilitate HER2 ADC resistance, we utilized the LentiMutate approach which employs an error-prone HIV-1 reverse transcriptase to produce a high frequency of mutations to identify resistance-associated mutations in cells treated with a HER2 ADC. Sequencing analysis revealed that resistant cells had an enrichment in point mutations within HER2 domain IV (D582N, F595C/S, E580K, C623Y), which includes the binding site of trastuzumab. To validate the impact of these mutations on HER2 ADC resistance, we generated cells expressing a HER2 exon 20 insertion in combination with the observed domain IV mutations. D582N and F695C/S co-mutations conferred resistance to T-DXd and T-DM1 but not to HER2 TKIs. These data demonstrate that resistance to T-DXd can be mediated by loss of sensitivity to the ADC payload in which case ADCs bearing payloads with alternate mechanisms of action as well as HER2 TKIs retain anti-tumor cell activity. Moreover, resistance to trastuzumab-based ADCs can also be mediated by secondary mutations within domain IV of HER2. However, these resistance mutations do not diminish HER2 TKI activity.

#5858 Systematic identification of pathways associated with antibody drug conjugate sensitivity in breast cancer.

B. Wu[1], S. Sun[1], N. Thimmiah[1], A. Nagayama[1], J. T. Coates[1], T. Liu[1], W. Thant[1], E. Bitman[1], D. Li[1], J. Doench[2], A. Bardia[1], L. W. Ellisen[3]; [1]Harvard Medical School/Massachusetts General Hospital, Boston, MA, [2]Broad Institute of MIT and Harvard, Cambridge, MA, [3]Harvard Medical School/Massachusetts General Hospital, Ludwig Center at Harvard, Boston, MA

Antibody drug conjugates (ADCs) are revolutionizing precision therapeutics in oncology. Sacituzumab Govitecan (SG), combining a Topoisomerase I (TOP1) inhibitor payload (SN38) and the tumor-selective antigen TROP2-targeting antibody hRS7, has demonstrated efficacy in challenging cancers including triple negative breast cancer (TNBC). Despite its promising clinical efficacy, the intricacies of sensitivity and resistance mechanisms to SG remain elusive.
To systematically interrogate ADC sensitivity mechanisms, we employed genome-wide CRISPR-Cas9 knockout screening to discover novel regulators influencing SG sensitivity in human TNBC cells. Interactome analysis of top SG sensitizing hits showed clustered pathways of interest, including DNA repair/replication, mTORC1/metabolism, ubiquitin/proteolysis and endosome trafficking/sorting. A top druggable hit sensitizing to SG was PARP1, encoding the poly (ADP-ribose) polymerase 1 that is a key enzyme required for single-strand break repair pathways and for DNA replication fork stability. Furthermore, the synergistic lethality between SG and PARP1 was confirmed in experiments combining SG with PARP inhibitor treatment of TNBC cell lines. To selectively identify SG/ADC-specific genes and pathways, we performed a secondary round of CRISPR knockout and activation screens using a custom library comprising top hits discovered in the primary screen, treating cells in parallel with either SG or cytotoxic payload SN38 alone. Pathway analysis of genes selectively modulating sensitivity to SG but not SN38 revealed novel mediators involved in TROP2 turnover and recycling. We then performed validation and mechanistic studies to elucidate how specific genetic permutations regulate antibody delivery and sensitivity to SG.
In summary, employing a systematic CRISPR screening method, we uncovered numerous novel pathways associated with both resistance and sensitization, playing a role in ADC delivery and target protein turnover. Our current focus involves prioritizing druggable genes and pathways, laying the foundation for proof-of-concept studies that will combine ADCs with specific targeted therapeutics, aiming to enhance tumor-killing efficacy.

#5859 PLK1 predicts aggressive behavior in CRC patients and its inhibition reverse chemoresistance in CRC cells.

D. Padmaja, M. Al-Rasheed, P. Poyil, A. K. Siraj, S. K. Parvathareddy, W. Haqawi, F. Al-Dayel, K. S. Al-Kuraya;
King Faisal Specialist Hospital & Research Centre, Riyadh, Saudi Arabia

Polo-like kinase 1 (PLK1) is a serine/threonine-protein kinase, that is involved in multiple stages of cell cycle progression in mammals. Dysregulation of PLK1 has been found in a variety of human cancers and was associated with poor prognoses in various cancers. However, its role in the pathogenesis of CRC from Middle Eastern ethnicity has not yet been explored. Therefore, we examined the expression of PLK1 protein in a large cohort of over 1000 Middle Eastern CRC cases by immunohistochemistry. Correlation with clinico-pathological parameters were performed. PLK1 overexpression was noted in 60.3% (693/1149) CRC cases and was significantly associated with larger tumor size (T3/T4 tumors), lymphnode metastasis, Stage III tumors, MSI-H status and p-ERK1/2 over-expression. Interestingly, on multivariate logistic regression analysis, we found that PLK1 was an independent predictor of lymphnode metastasis. However, no association was noted between PLK1 expression and clinical outcomes (DFS, RFS, OS, CSS). Our in vitro experimentation revealed that CRC cells expressing high levels of PLK1 exhibited resistance to 5-Fu treatment, whereas cells with low PLK1 expression demonstrated sensitivity to the treatment. To explore the role of PLK1 on chemoresistance, we inhibited PLK1 using specific inhibitor, volasertib and we showed that volasertib effectively reversed 5-Fu resistance in these cells. Furthermore, knockdown of PLK1 reduced the progression of epithelial-to-mesenchymal transition (EMT) and the stem cell-like properties in 5-Fu resistant cells, showing the role of PLK1 on inducing EMT and stemness in CRC. Interestingly, the forced expression of PLK1 triggered the activation of the CRAF-MEK-ERK-ZEB1 signaling cascade, whereas its inhibition led to the suppression of this cascade. In addition, we showed that silencing of ERK1/2 reversed the chemoresistance, EMT and stemness of PLK1 expressing CRC cell lines. Our findings underscore the significant role of PLK1 in conferring chemoresistance, and targeting PLK1 could represent a viable therapeutic approach for the treatment of patients with an aggressive subtype of CRC.

#5860 Understanding the biological role of MMP16 in cisplatin resistance in ovarian cancer.

J. Bonilla-Liriano[1], M. Rivera-Serrano[2], V. Reyes-Burgos[3], J. Rolon-Perez[3], F. Valiyeva[4], P. Vivas-Mejia[3];
[1]Interamerican University of Puerto Rico-Fajardo Campus, Fajardo, PR, [2]University of Puerto Rico-Rio Piedras Campus, Rio Piedras, PR, [3]University of Puerto Rico Medical Sciences Campus, San Juan, PR, [4]University of Puerto Rico Comprehensive Cancer Center, San Juan, PR

High-Grade Serous Ovarian Cancer (HGSOC) is the most common and lethal of Ovarian Cancer (OC) types, which accounts for eighty percent of deaths. Treatment for OC includes surgery and platinum-based therapy. However, around 70% of women with HGSOC become resistant to chemotherapy. Therefore, new therapeutic agents with higher specificity and efficacy are needed for women with advanced and drug-resistant OC. Matrix metalloproteases (MMPs) are a group of enzymes involved in the degradation of the extracellular matrix (ECM). Deregulation of MMPs contributes to tumor growth and metastasis in several cancer types. Preliminary studies of our research team found that MMP16 is higher in cisplatin-resistant as compared with cisplatin-sensitive OC cells. The aim of this project is to understand the role of MMP16 in the cisplatin resistance of OC cells. We hypothesize that MMP16 increased expression may contribute to cancer progression and drug-resistance. We performed experiments in A2780/A2780CP20 and OVCAR3/OVCAR3CIS human OC cells. To assess the MMP16 protein levels we used western blot analysis. To measure the mRNA levels, we used qRT-PCR. Kaplan-Meier survival curves were generated by interrogation of the KM Plotter patient database. The MMP16 protein and qRT-PCR experiments confirmed that protein and mRNA levels are more abundant in cisplatin-resistant as compared with cisplatin-sensitive cells. Interrogation of the KM plotter database showed that OC patients with higher MMP16 mRNA levels live less as compared with OC patients with lower MMP16 levels. Ongoing experiments are testing the biological effect of small interference RNA (siRNA) targeting MMP16 in cisplatin-resistant OC cells.

#5861 CDK4/6 therapy-induced senescence as a resistance mechanism-MiDAS touch.

Y. Gokmen-Polar, Y. Gu, L. Ruan, S. S. Badve;
Emory University School of Medicine, Atlanta, GA

Background: Cyclin-dependent kinase inhibitors (CDK4/6i) have revolutionized the therapy for estrogen receptor positive (ER+) breast cancer. Despite the response to CDK4/6i, resistance and recurrence are still a clinical reality, resulting in death due to breast cancer. G1 cell cycle arrest has been considered as the main mechanism of action of CDK4/6i in luminal breast cancer. However, the response to therapy does not correlate with the expression of CDK4/6 or key cell cycle proteins. It is also unclear whether CDK4/6i-induced senescence enhances the therapeutic response or mediates development of resistance.
Experimental Procedures: We have developed drug-tolerant persisters resistant to CDK4/6 inhibitors (CDK4/6i-DTPs) in a panel of estrogen receptor positive (ER+) cells to explore the molecular mechanisms associated with resistance. Using different cell phenotype assays (i.e., cell viability/cell cycle, senescence/senescence reversibility and wound healing) as well as senescence-associated secretory phenotype (SASP) human cytokine array of 105 markers, we characterized the phenotype and secretome of these CDK4/6i DTPs.
Summary: CDK4/6i-DTPs induced by abemaciclib, palbociclib and ribociclib (all from Selleckchem) demonstrated resistance to these drugs and dramatically slowed growth. The percentage of senescent cells reached 30-89% of the total population for all cell lines in all three drugs, whereas control parental cells exhibited around 10%. CDK4/6i DTPs also exhibited significant cell migration, and increased lysosomal phenotype compared to their parental sensitive cells. Further analysis with human cytokine array revealed that protein levels of growth differentiation factor 15 (GDF-15) are elevated in both cell lysates and conditioned-media of CDK4/6i DTPs, whereas Serpin E1 (Plasminogen Activator Inhibitor, Type I, PAI-1) was unique to secreted CDK4/6i DTPs. Interestingly, we did not observe changes in pro-inflammatory senescence-associated secretory phenotype (SASP) markers such as interleukins. Apart from being a SASP protein, GDF-15 is a mitochondrial cytokine (mitokine), suggesting a role in mitochondrial dysfunction-associated senescence (MiDAS). HMGB1, and LMNB1 are also down-regulated in CDK4/6-DTPs supporting the MiDAS phenotype. CDK4/6i-induced MiDAS appears to be transient, as CDK4/6i-DTPs reverted to the parental phenotype in drug-free culture media 20 days after the removal of CDK4/6i's. This included growth characteristics and sensitivity to CDK4/6i. This reversion of phenotype was observed in all five cell line models tested with all three drugs.
Conclusions: CDK4/6-induces a mitochondrial dysfunction-associated senescence (MiDAS). This appears to be transient in nature as withdrawal of the drug results reacquisition of parental cell phenotype and drug-sensitivity. Targeting MiDAS pathway might be critical to improve efficacy of CDK4/6 inhibitors.

#5862 Retrotransposable elements mediate the drug-tolerant persistence in claudin-low breast cancer chemo-treatment.

Z. Zhang[1], Y. Wang[2], X. Luo[1], X. Zhan[1], J. Ding[2], **T. P. Wu[1]**;
[1]Baylor College of Medicine, Houston, TX, [2]McGill University, Montreal, QC, Canada

The emergence of acquired drug resistance through treatment remains a critical threat to efficient cancer therapies, which most often lead to relapse and metastasis. The development of resistance is an evolutionary adaptation process that heavily depends on tumor heterogeneity (underpinned by cellular plasticity). Therefore, a longitudinal deconvolution of treatment adaptation is critical to uncover the driving-force mechanisms underpinning resistance adaptation. In the clinic, chemotherapy remains the mainstream treatment for TNBC, and one of the primary chemo-agents is doxorubicin. Although the initial responsive rate of doxorubicin-based chemotherapies is up to 70%, it is well recognized that TNBC cells usually generate an adaptive response and result in acquired drug-resistance and multi-drug resistant phenotypes. Although numerous mechanisms of chemo-resistance evolution have been proposed, most of these studies focused on the initial and terminal states, from which we could not deconvolute the adaptation routes and might miss the transient fate-switching events. We hypothesize that the claudin-low TNBC chemo-resistant cells may derive from the early-stage reversible chemo-tolerant persistent state, and early-stage state-switching mediated by epigenetic landscape reprogramming might determine the adaptation through treatment. We developed an in vitro “pulsing-treatment” model to test the hypothesis, which could mimic the clinical treatment and provide therapeutically relevant insights into the acute drug-induced stress response and regrowth. Unexpectedly, we found that the human endogenous retrovirus-like elements (HERVs) show an aberrant bursting in the adaptation. To further interrogate the adaptation, we did the longitudinal single-cell multi-omics sequencing. With a novel bioinformatic workflow, we integrated the HERV’s expression information with protein-coding genes profiling and chromatin accessibility. The preliminary result indicated that a subpopulation of HERV-high cells might transiently mediate the persistence of cancer cells at the early stage of the treatment, which coupled with whole transcriptomic and chromatin landscape reprogramming, and molecular subtype switching. In this study, we employed a new strategy to investigate the longitudinal adaptation route through treatment and uncover a non-canonical element, which shed new light on drug resistance research and novel target screening.

#5863 Double-negative prostate cancer emerges through a mixed basal, club, and hillock cell identity driven by KLF5.

S. Pitzen, Y. Qiu, S. Munro, S. Dehm;
University of Minnesota, Minneapolis, MN

The purpose of this study was to characterize the phenotypes and drivers of therapy-induced lineage plasticity during the development of castration resistant prostate cancer (CRPC). While the majority of localized prostate cancer can be cured with surgery or radiation, metastatic disease is lethal. Therapies targeting the androgen receptor (AR) are initially effective, but eventually men will develop CRPC. About 70-75% of CRPC displays restored AR signaling (ARPC), while the remaining 25-30% display lineage plasticity evidenced by the emergence of AR-negative subtypes including those that display neuroendocrine (NE) markers, or double negative CRPC (DNPC) lacking both AR and NE markers. AR independent manifestations of CRPC represent a clinical challenge because no effective therapies are available and therapeutic targets are largely unknown. We analyzed publicly available bulk and single-cell RNA-seq datasets derived from clinical CRPC specimens to characterize the cellular identity of AR-negative tumors. Using a database of all known transcriptional regulators, we identified potential drivers of these phenotypes. We performed siRNA-mediated knockdown experiments in a model of DNPC to explore the extent to which the candidate regulators maintain AR-negative cell identity and sustain growth of DNPC prostate cancer cells. We identified a subset of CRPC tumors that co-express gene sets defining basal, club, and hillock cells in the benign prostate. This data supports the existence of epithelial cell lineage plasticity manifesting within CRPC tumors, as well as individual CRPC tumor cells, wherein AR-positive tumor cells transform to a phenotype encompassing basal, club, and hillock cell identities. We nominated the stem cell transcription factor KLF5 as a regulator of basal, club, and hillock cell identities in CRPC. In cell line models of DNPC, knock down of KLF5 inhibited cell growth and reduced the expression of genes defining basal, club, and hillock cell identities. This work links a prevalent and poorly-defined subtype of AR-negative CRPC to AR-negative epithelial cell types in benign prostate tissue. Inhibition of KLF5 and its downstream effectors could represent a therapeutic strategy to prevent or delay lineage plasticity and thereby extend patient response to AR-targeted therapies.

#5864 YAP1 defines a highly plastic, persister cell population in small cell lung cancer (SCLC) following relapse.

C. Stewart[1], S. M. Groves[2], R. Wang[1], K. Ramkumar[1], Y. Xi[1], L. Diao[1], A. G. Serrano[1], A. Tanimoto[1], A. M. Victorian[1], S. Bhattacharyya[1], A. J. Halliday[1], N. Kalhor[1], L. M. S. Soto[1], P. F. S. Da Rocha[3], N. Vokes[1], L. G. Karacosta[1], J. Wang[1], J. V. Heymach[1], V. Quaranta[4], B. Glisson[1], L. A. Byers[1], C. M. Gay[1]; [1]UT MD Anderson Cancer Center, Houston, TX, [2]University of Virginia, Charlottesville, VA, [3]Hospital del Mar, Barcelona, Spain, [4]Vanderbilt University, Nashville, TN

SCLC is an aggressive, neuroendocrine malignancy notable for rapid, albeit transient, responses to therapy. We have previously shown that transcriptional heterogeneity among treatment-naïve SCLC tumors underlies four distinct transcriptional subtypes, each with distinct clinical vulnerabilities. Though previously hypothesized to delineate a distinct subtype, expression of YAP1 is largely absent from treatment-naïve SCLC. Less clearly defined is the transcriptional landscape of relapsed SCLC, the evolution of which may underlie SCLC's capacity for insurmountable resistance. To better define the biology of relapsed SCLC, we performed mass cytometry analysis of patient circulating tumor cells (CTCs), immunohistochemistry for ASCL1, NEUROD1, POU2F3, MYC and YAP1, and single-cell (sc)RNAseq of core needle biopsies from SCLC patients and preclinical models following resistance to standard-of-care therapies. In contrast to treatment-naïve SCLC, YAP1 mRNA and protein are detectable in patient CTC populations and tumors from relapsed patients and PDXs, albeit at levels lower than subtype-defining transcription factors (e.g. ASCL1, NEUROD1, or POU2F3). Notably, however, scRNAseq reveals these *YAP1* expressing cells to be mutually exclusive with *ASCL1* and *NEUROD1*, though not necessarily *POU2F3. YAP1*-expressing cells possess unique mesenchymal, inflamed features and exhibit high levels of transcriptional plasticity. Consistent with the upregulation of YAP1 following chemotherapy, *YAP1*-positive cell populations express senescence associated secretory phenotype genes and cancer stem cell genes, suggesting that these populations represent drug tolerant persister cells that may serve as a source for renewal of classical neuroendocrine populations within the tumor. Targeting these resistant populations may be critical to re-establish response in relapsed SCLC, and these analyses identified high expression of several surface proteins that are currently under investigation as targets for antibody-drug conjugates in SCLC clinical trials, including B7H3, TROP2 and HER2 antibody drug conjugates. These data suggest that the acquisition of YAP1 expression delineates a particularly recalcitrant tumor cell population observed almost exclusively in relapsed SCLC that is capable of driving tumor persistence and treatment resistance. Clinically, these data underscore the importance of constraining transcriptional plasticity in the frontline management of SCLC, but also of developing therapies aimed specifically at emergent populations capable of driving resistance, as with the YAP1-high cells identified here. The emergence of YAP1 following resistance in SCLC and the observation of YAP1 as a common feature of other high-grade neuroendocrine carcinomas exclusive of SCLC, likely explains the initial mischaracterization of YAP1 as a subtype-defining feature of SCLC.

#5865 Characterization and resistance mechanisms of PNP inhibitor forodesin-resistant cell lines..

N. Hosono[1], K. Oiwa[2], T. Tasaki[3], R. Nishi[1], L. Scott[4], O. A. O'Connor[4], T. Yamauchi[1];

[1]University of Fukui, Eiheiji, Japan, [2]Osu Hospital, Nagoya, Japan, [3]Japanese Red Cross Fukui Hospital, Fukui, Japan, [4]Columbia University, New York, NY

Background: The enzyme purine nucleoside phosphorylase (PNP) is involved in the purine salvage pathway and is present at high levels in lymphoid tissues. Children born with PNP deficiency are known to have significantly reduced T-cell counts but relatively normal B-cell immunity, suggesting PNP as one of the most promising therapeutic targets for T-cell malignancies. Forodesine (For, BCX-1777), a novel PNP inhibitor, was approved in Japan for the treatment of relapsed/refractory PTCL. To understand the cytotoxic effect of For and its mechanism of action, we established a For-resistant (For-R) leukemia cell line and explored the mechanism of resistance.

Methods: We established two For-R T-lymphoblastic leukemia cell lines (CCRF-CEM and MOLT4) through repeated escalating exposure to For and 2'-deoxyguanosined(dGuo). Gene expression analysis was performed to identify the mechanisms of resistance.

Results: For-R cells showed very high resistance compared to parental cells (IC_{50} value, CEM/CEM-R 4.2nM/>5x10^{5}nM, MOLT4/MOLT4-R 8nM/>5x10^{5}nM). When cross-resistance was examined in these For-R cells showed mild resistance to cytarabine. The expression of hENT1, a nucleoside transporter, was examined and found to be upregulated in both CEM-R and MOLT4-R cells, while the expression level of deoxycytidine kinase (dCK) was unchanged in both cells. Next, high performance liquid chromatography was used to assess the intracellular dGTP in each parental and its For-R cells. In the parental cells, intracellular dGTP levels increased promptly 4-6 hours after fosteredin administration, whereas in resistant cells, intracellular dGTP levels were higher than before fosteredin administration, and there was little change in dGTP levels after administration.

Conclusion: The established For-R cell line acquired a high resistance to For and showed high intracellular dGTP levels. Imbalance in intracellular GTP levels may be involved in the induction of cell death by For.

IC50 value of each cell lines

#5866 TESC mediates resistance to lenvatinib in hepatocellular carcinoma by regulating cell autophagy.

H. Zhuang, T. Zhang, J. Chen;
The Affiliated Cancer Hospital of Zhengzhou University and Henan Cancer Hospital, Zhengzhou, China

Objective: To investigate the mechanism by which TESC (Tescalcin) induces lenvatinib resistance in hepatocellular carcinoma (HCC) through autophagy mediation.
Methods:1) Utilized established liver cancer organoids from over 70 patients for lenvatinib drug sensitivity screening and transcriptome sequencing to identify lenvatinib-resistant genes. 2) Constructed stable TESC overexpression and downregulation liver cancer cell lines. Employed CCK8 assays to plot IC50 drug sensitivity curves, elucidating changes in lenvatinib sensitivity in liver cancer cells after TESC overexpression or downregulation. 3) Used TESC-stable cells to establish subcutaneous tumor models and intrahepatic tumor models in nude mice. After tumor formation, administered lenvatinib orally to observe whether TESC affects liver cancer sensitivity to lenvatinib in vivo. 4) Conducted Western blot (WB) analysis to assess the expression of autophagy-related molecules (LC3B II/I, P62, and Beclin1 proteins) in TESC downregulated or overexpressed stable cell lines and their control cell lines. Utilized the LC3-GFP-mRFP fluorescence dual-labeling lentivirus system and laser confocal microscopy to examine autophagic flux. 5)Treated TESC downregulated cells with the autophagy inhibitor 3-MA. Conducted WB to assess the expression levels of autophagy-related proteins and plotted drug sensitivity curves using IC50 experiments to evaluate the impact of 3-MA on reversing liver cancer cell sensitivity to lenvatinib.
Results: Compared to the control group, HCC cells overexpressing TESC showed an increased IC50 value and reduced sensitivity to lenvatinib, while TESC downregulation resulted in a decreased IC50 value and decreased sensitivity to lenvatinib. Subcutaneous tumor experiments in nude mice indicated that, compared to the control group, tumors with reduced TESC expression were more sensitive to lenvatinib. Additionally, in HCC cells overexpressing TESC, protein expression levels of LC3B II/I and Beclin1 significantly decreased, while P62 expression increased. Conversely, TESC downregulation significantly increased protein expression levels of LC3B II/I and Beclin1, while P62 expression decreased. Furthermore, results from the LC3-GFP-mRFP autophagy dual-labeling lentivirus system showed a significant reduction in fluorescence spots in the TESC overexpression group compared to the control group, indicating weakened autophagic flux. Treatment of TESC downregulated liver cancer cells with 3-MA resulted in an increased IC50 value compared to the control group.
Conclusion: TESC expression levels are associated with the sensitivity of liver cancer cells to lenvatinib, possibly by inhibiting autophagy and affecting the sensitivity of liver cancer cells to lenvatinib.

#5867 Early activation of HGF-cMET serves as a bypass pathway to ALK and RET tyrosine kinase inhibitors in non-small cell lung cancer.

T. Patil, T. Hinz, S. Pine, H. Saabawy, P. Bunn, E. L. Schenk, R. Camidge, L. Heasley;
University of Colorado Anschutz Medical Campus, Aurora, CO

Introduction: Alterations of the HGF-cMET axis, often through *MET* gene amplification, can act as resistance mechanism to tyrosine kinase inhibitors (TKIs) in patients with ALK and RET rearranged non-small cell lung cancer (NSCLC). The efficacy of targeting the cMET pathway through use of MET tyrosine kinase inhibitors continues to evolve. An unresolved question is whether the HGF-cMET pathway is activated early in cancer cells after ALK and RET TKI exposure. Here, we evaluate novel pre-clinical models to better characterize the onset of MET pathway-mediated resistance using murine cell lines and orthotopic murine models.

Methods: Murine *Eml4-Alk* (EA1 and EA3) and *Trim24-Ret* (TR.1) cell lines were cultured with increasing doses of alectinib (EA1 and EA3) or pralestinib or selpercatinib (TR.1) until resistance was acquired. A cell line was established from an orthotopic TR.1 tumor that progressed on selpercatinib (TR.1-1092). Passage control cells and the TKI-resistant cultures were submitted to clonogenic growth assays in targeting TKI or crizotinib (MET TKI). Control and TKI-resistant cell lines were submitted to HGF ELISA, MET immunoblotting and RNAseq. Orthotopic TR.1 tumors were established in C57BL/6 mice and after ~2 weeks, daily treatment with selpercatinib was performed for 21 days with weekly mCT to monitor tumor size. At 21 days when the tumors were beginning to progress, half the mice were treated with selpercatinib and crizotinib (a MET TKI) while the other half continued on selpercatinib alone.

Results: HGF levels (pg/µg) were significantly higher in alectinib-resistant EA1 cells vs. EA3 cells and was associated with retained sensitivity to crizotinib in alectinib-resistant EA1, but not EA3 cells. MET mRNA (but not gene copy number) and HGF mRNA/ protein levels in pralsetinib and selpercatinib resistant TR.1 lines were significantly higher than controls and accompanied by acquired sensitivity to crizotinib. In C57BL/6 mice bearing orthotopic TR.1 tumors, the progression on selpercatinib occurring after 2-3 weeks of treatment was reversed in a durable manner by co-treatment with crizotinib.

Conclusions: The HGF-cMET axis is activated early in response to ALK and RET TKI exposure through transcriptional mechanisms without evidence of *MET* gene amplification. These findings unveil a potential therapeutic window to disrupt the MET bypass pathway in ALK and RET rearranged NSCLC prior to overt clinical progression.

#5868 Upregulation of HER3 and MET in non-small cell lung cancer cells resistant to EGFR tyrosine kinase inhibitor.

M. Larsen, H. Lyu, C. Tan, Y. Wu, B. Liu;
LSU Health Sciences Center New Orleans, New Orleans, LA

Introduction: Prior research demonstrates the importance of studying epidermal growth factor receptor (EGFR) activating mutations for better understanding the biology of non-small cell lung cancer (NSCLC), which comprises the majority (~80%) of lung cancers. EGFR-targeted tyrosine kinase inhibitors (TKIs) have been used in the clinic to treat NSCLC with EGFR activating mutations. First and second-generation EGFR-TKIs are effective in NSCLC patients with the most common EGFR mutations (exon 19 deletion (Del19) and exon 21-point mutation (L858R)). A third generation EGFR-TKI, osimertinib (AZD9291), has been developed to target the T790M resistance mutation, but patients are starting to show resistance to this line of therapy as well. Our study aims to elucidate the underlying mechanism(s) of EGFR-TKI resistance in NSCLC cells.
Methods: NSCLC cell lines, including PC-9 and HCC827, which have the Del19 EGFR activating mutation, were utilized for experiments. From the parental cell lines, several cell lines resistant to the EGFR-TKIs were previously established. Cell proliferation (MTS) assays were used to confirm the resistance phenotype of the established cell lines. Western blot assays and RT-qPCR were utilized to determine changes in the expression level of several membrane receptors and their downstream effectors.
Results: Our preliminary analysis showed that both human epidermal growth factor 3 (HER3) and mesenchymal-epithelial transition factor (MET) were upregulated in the EGFR-TKI-resistant cell lines as compared to their parental counterparts. Further studies revealed an increased level of phosphorylated STAT3 (p-STAT3) and ERK1/2 (p-ERK1/2) in the resistant cell lines when compared to the parental cell lines, suggesting the possible involvement of HER3 and/or MET in the activation of downstream signaling pathways. Upregulation of HER3 and MET was found at both the protein and mRNA level.
Conclusion: Based on our initial findings, membrane receptors, including HER3 and MET, could be working together to continue activating downstream signaling pathways to evade the effects of osimertinib, resulting in resistance. Additional work is underway to define the role of HER3 and MET in the NSCLC cells resistant to EGFR-TKIs.

#5869 Investigation of molecular alterations associated with double resistance to BRAF and MEK inhibition in melanoma.

A. J. Isaak[1], G. R. Clements[1], L. Huang[1], Y. Qin[1], Q. Zho[2], G. Merlino[1], Y. Yu[1];
[1]National Institutes of Health, Bethesda, MD, [2]Southern Medical University, Guangzhou, China

More than 50% of melanomas harbor activating BRAF kinase mutations, with BRAFV600E representing more than 90% of BRAF mutations. Inhibition of mutant BRAF by BRAF inhibitors (BRAFi) in patients with advanced melanoma yields a remarkable initial clinical response. Limited duration response and disease recurrence of inhibitors occurs due to acquired drug resistance. Recently identified mechanisms of MAPK hyperactivation in acquired resistance to BRAFi have encouraged clinicians to employ a combination of BRAF and MAPK inhibitors to block the MAPK signaling pathway more effectively. However, most patients treated with this combination therapy still relapse due to de novo drug resistance. Therefore, innovative strategies are still necessary to improve the precision and durability of anti-melanoma therapies. To investigate the mechanism of both BRAFi and MEKi resistance (double resistance, DR) in mutant BRAF melanomas, we have developed models from four human melanoma cell lines to explore the hypothesis that molecular alterations are related to double resistance to BRAFi and MEKi in melanoma. We have found that BRAFi-MEKi double-resistant models exhibit distinct differences in morphology and growth kinetics. Specifically, BRAFi-MEKi double-resistant human melanomas express a higher level of FGFb and PAI-1 expression. We confirmed that overexpression of FGFb and PAI-1 in parental cells could increase the ability to resist BRAF and MEK inhibition. Additionally, we discovered that decreased expression of FGFb and PAI-1, via knock-down, inhibition, or CRISPR in double resistant cells, can restore cell sensitivity to treatments of BRAFi and MEKi. To further elucidate the role of FGFb and PAI-1 on resistant melanoma, we have extended our scope to *in vivo* mouse xenograft models. Our findings uncovered the mechanism of how melanoma cells can escape BRAFi and MEKi attacks and offer a rational strategy to guide future clinical treatments.

#5870 ecDNA-based amplification of multi-drug resistance genes leads to acquired resistance to taxane-based chemotherapy.

Kristen Holmes, Dean Perusse, Cory DuPai, Homa Hemmati, Julie Weiss, Claire Kuelbs, John Bibay, Joan Chen, Debbie Liao, Christian Hassig, Shailaja Kasibhatla

Boundless Bio, Inc., San Diego, CA

Focal amplification on extrachromosomal DNA (ecDNA) drives high gene copy number and intercellular genomic heterogeneity, which can fuel tumor adaptation and drug resistance. Targeted therapies have largely failed in patients with oncogene amplification, and patients whose tumors harbor ecDNA-based gene amplification have particularly worse survival compared to patients whose cancers harbor other genetic drivers. Due to the lack of approved therapies for patients with oncogene amplified cancers, many patients receive chemotherapy; however, resistance often develops through mechanisms such as ATP-binding cassette (ABC) transporter overexpression, rendering cross-resistance to other forms of chemotherapy. We examined whether ecDNA amplification in tumor cell lines drives ABC transporter overexpression to mediate resistance to paclitaxel, a commonly prescribed taxane chemotherapy for cancer patients.

We selected non-amplified (DLD1 and SW48) and amplified cell lines, including COLO320DM and COLO320HSR (*MYC* amplified on ecDNA or chromosomal loci, respectively); SNU16 and H716, (*FGFR2* and *MYC* amplified ecDNA); and H2170 (*ERBB2* and *MYC* amplified on ecDNA). All cell lines developed paclitaxel resistance, with the majority (5/7) gaining focal amplification of *ABCB1*, which encodes P-glycoprotein (P-gp), a common multi-drug resistance transporter. Four models--COLO320DM, COLO320HSR, SNU16, and H2170—developed *ABCB1* amplification on ecDNA; one non-amplified cell line (DLD1) acquired focal *ABCB1* amplification via a breakage-fusion-bridge (BFB) mechanism, a distinct form of amplification from ecDNA. ecDNA-based *ABCB1* amplifications exhibited hallmarks of ecDNA, including intercellular copy number heterogeneity and paclitaxel dose-dependent rapid evolution of *ABCB1* copy number.

We next assessed whether drug resistance was reversible in *ABCB1* amplified cell lines following removal of paclitaxel. Reversal of resistance was observed in COLO320DM and COLO320HSR via loss of *ABCB1* ecDNA within 4-6 weeks. However, in SNU16 and H2170 resistant cells, *ABCB1* amplification was retained up to 12 weeks of drug removal, with apparent integration into *MYC* ecDNA, demonstrating that ecDNA-enabled plasticity can result in both short- and long-term paclitaxel resistance.

Although targeted therapies have revolutionized treatment approaches for patients with actionable oncodriver alterations, most cancer patients do not have actionable drivers and most patients still receive chemotherapy at some point in their course of treatment. We demonstrated that ecDNA-based resistance to paclitaxel is common in cancer cell lines and may also drive resistance to chemotherapy in patients. Thus, ecDNA-directed therapies (ecDTx) may be an important treatment option for chemo-resistant patients, who currently do not have many effective therapeutic options.

#5871 Unveiling mechanisms of CDK4/6 inhibitor resistance in ER+ breast cancer models with acquired resistance.

B. Li, G. Liu, T. Ni, W. Shi, Q. Gu;
WuXi AppTec, Suzhou, China

Introduction: Cyclin-dependent kinase 4 and 6 (CDK4/6) inhibitors, including palbociclib, ribociclib, and abemaciclib, have revolutionized the treatment of estrogen receptor-positive (ER+) breast cancer. However, the development of resistance to these inhibitors poses a formidable challenge in the clinical management of ER+ breast cancer. This study aims to explore the common resistance mechanisms in three CDK4/6 inhibitor-resistant models induced by chronic exposure to these agents.
Methods: We developed models of resistance to palbociclib, ribociclib, and abemaciclib by repeatedly exposing murine xenografts to these CDK4/6 inhibitors. Resistance was confirmed through cell viability assays and in vivo tumorigenesis studies. The tumors were sequenced using NGS analyses, and genes of interest were validated through Western blotting and qPCR.
Results: In all resistant models, we identified a common resistant mechanism via NGS analyses, which was characterized by the overexpression of the FAT1, CCNE1, and AR genes. The upregulation of these genes at mRNA and protein levels was confirmed by qPCR analyses and western blotting, respectively. Our data indicate that upregulation of FAT1, CCNE1, and AR genes may play a critical role in mediating resistance to CDK4/6 inhibitors, namely palbociclib, ribociclib, and abemaciclib.
Conclusion: Our investigation uncovered a shared mechanism, characterized by the overexpression of FAT1, CCNE1, and AR genes, that underlay CDK4/6 inhibitors-induced drug resistance in ER+ breast cancer. These findings shed light on the shared pathways that drive CDK4/6 inhibitor resistance and provide insights into potential therapeutic targets for overcoming this resistance in breast cancer patients. Understanding these mechanisms is crucial for the development of more effective treatment strategies for CDK4/6 inhibitor-resistant cancers.

#5872 CDK1-SOX9 axis contributes to chemotherapy resistance in gastric cancer.

M. M. Al-Mathkour, S. Zhu, M. Genoula, W. El-Rifai;
University of Miami Miller School of Medicine, Miami, FL

Gastric carcinoma (GC) is the third most prevalent cause of cancer-related mortality worldwide, presenting a formidable challenge with the rise of resistance to chemotherapeutic agents, leading to treatment failures. Cyclin-dependent kinase 1 (CDK1) has garnered attention due to its substantial overexpression in various tumors, including GC, and its association with poor overall survival and relapse-free survival. This study aimed to understand the molecular and functional mechanisms underlying the CDK1-SOX9 axis in GC chemotherapy resistance. Through a comprehensive analysis of data from The Cancer Genome Atlas (TCGA) and our own integrated gene expression study, we found a positive correlation between CDK1 and SOX9 in both human and mouse GC tissues ($p<0.001$). Additionally, conserved alterations in miRNAs have been identified in the context of gastric carcinogenesis, evident in our local cohort and the TCGA dataset. Our in-depth investigation of premiR-145 has shed light on the existence of several CpG nucleotides. Notably, treatment with a DNMT inhibitor (5-Aza) has triggered the upregulation of miR-145 expression. Furthermore, the ectopic expression of CDK1 has been associated with increased DNMT1 phosphorylation and enhanced enzymatic activity. Conversely, silencing CDK1 reversed this effect, and the inhibition of DNMT1 reduced SOX9 protein expression. Using cisplatin-resistant cell lines revealed a significant increase in CDK1 and SOX9 expression where silencing CDK1 and SOX9 sensitized these cells to chemotherapy. This study provides valuable insights into the intricate mechanisms governing the CDK1-SOX9 axis in GC chemotherapy resistance, providing potential avenues for therapeutic interventions in this challenging malignancy.

#5873 ERα coordinates with squalene synthase to confer statin resistance in lung cancer.

Y.-F. Yang;
Kaohsiung Veterans General Hospital, Kaohsiung, Taiwan

Statins are widely used to treat hypercholesterolemia by inhibiting hydroxymethylglutaryl coenzyme A reductase (HMGCR). Accumulating evidence suggests that statins also have protective effects against cancer recurrence. However, the role of statins in preventing lung cancer and biomarkers for predicting statin treatment response remains lacking. This study analyzes molecular features that dictate statin sensitivity in lung cancer by correlating large-scale statin sensitivity data and basal gene expression in a collection of 125 lung cancer patients. We identified a gene signature associated with lovastatin sensitivity and showed that gene expression in mesenchymal molecular features, the cholesterol biosynthesis pathway, and estrogen receptor alpha (ERα) signaling were key determinants of lovastatin sensitivity in lung cancer cells. To this end, we further discovered that overexpression of a committed step enzyme in cholesterol biosynthesis farnesyl-diphosphate farnesyltransferase 1 (FDFT1), also known as squalene synthase (SQS), is capable of activating ERα and is associated with increased statin tolerance. In clinical specimens, overexpression of SQS positively correlated with nuclear expression of ERα in lung cancer patients, and the combination of SQS and ERα is a powerful prognostic predictor for lung cancer.
Activation of the SQS-ERα signaling axis and epithelial-to-mesenchymal transition (EMT) status represents two important features in determining statin sensitivity in lung cancer.

Keywords: Statin, cholesterol biosynthesis, squalene synthase, estrogen receptor α, Epithelial-mesenchymal transition

#5874 Phenotypic plasticity of TKI resistance reprograms cytoskeleton organization through cadherin-catenin and integrin pathways.

Chun Ma[1], Chia-Mei Young[2], Jerry Chieh-Yu Chen[3], Mong-Lien Wang[4]

[1]National Taiwan University College of Medicine, Taipei City, Taiwan,[2]Institute of Pharmacology, College of Medicine, National Yang Ming Chiao Tung University, Taipei City, Taiwan,[3]Taiwan International Graduate Program in Molecular Medicine, National Yang Ming Chiao Tung University and Academia Sinica, Taipei City, Taiwan,[4]Department of Medical Research, Taipei Veterans General Hospital, Taipei City, Taiwan

The acquired resistance to EGFR tyrosine kinase inhibitors (TKIs) restricts its clinical utility. Clinically, acquired resistance has been highly associated with epithelial-mesenchymal transition (EMT) traits. In this study, we characterized shared phenotypic plasticity features of TKI-resistant cells and aimed to find its key driver in three different cell lines harboring mutant EGFR. In vitro resistance cell lines were generated by dose-escalation exposure to osimertinib, a 3rd generation TKI, for more than 2 months. We employed canonical markers (E-cadherin, vimentin, pan-cytokeratin, and N-cadherin) along with additional markers (EpCAM and fibronectin) to define the EMT status of resistant cells. Moreover, cytoskeleton architecture (F-actin and Vimentin) was utilized to clarify the types of cell motility. Transcriptomics analysis illustrated enriched pathways at focal adhesion and adherens junction. Loss of adherens junction-related catenin (α-E-catenin, β-catenin, γ-catenin, p120 catenin) and aberrant activation of focal adhesion-related protein (p-FAK Y397 and Y576/57, p-Src Y416) confirmed the transcriptomics analysis of reduced contact inhibition and cell polarity. The resulting migration mode of resistant cells highly resembles ameboid movement. Mechanistically, we identified that YTHDF3, a metastasis-promoting regulator of mRNA methylation, destabilizes the mRNA of E-cadherin. Depletion of YTHDF3 in resistant cells reversed the cadherin-catenin pathway and distribution of vimentin and f-actin. In conclusion, resistant cells display ameboid-like movement resulting from loss of contact inhibition and aberrant activation of focal adhesion. Mechanistically, we identified that YTHDF3, a metastasis-promoting regulator of mRNA methylation, destabilizes the mRNA of E-cadherin. Depletion of YTHDF3 in resistant cells reversed the cadherin-catenin pathway and distribution of vimentin and f-actin. YTHDF3 serves as an RNA epitranscriptomic regulator that destabilizes CDH1 mRNA, thereby disrupting adherens junction formation and reducing integrin-mediated focal adhesion stabilization.

#5875 Upregulation of the RNA binding protein HuR by cancer-secreted exosome to mediate multidrug resistance.

K. K. To;
Chinese University of Hong Kong (CUHK), Hong Kong, Hong Kong

Background and Aim: Multidrug resistance (MDR) is an unresolved obstacle to cancer chemotherapy. It is usually caused by overexpression of drug efflux transporters including ABCG2. Exosomes are extracellular lipid vesicles released from all cells upon the fusion of multivesicular bodies with plasma membrane. Tumor-derived exosomes have been shown to mediate cell-to-cell transfer of oncogenic materials to promote drug resistance. Human antigen R (HuR) is an extensively studied RNA binding protein that regulates the stability, translation, and nucleus-to-cytoplasm shuttling of mRNAs. Numerous HuR-targeting mRNAs play crucial roles in tumorigenesis, invasion and metastasis. We have previously reported the induction of ABCG2 and MDR phenotype by HuR overexpression in colon cancer. HuR overexpression is linked with high-grade malignancy and poor prognosis in cancer patients. This study investigated the enrichment of HuR inducing microRNAs (miRNAs) in exosomes secreted from MDR colon cancer and its intracellular transfer to drive MDR.
Method: Cancer exosome-mediated transfer of miRNAs from ABCG2-overexpressing resistant colon cancer cells S1M1-80 to a few sensitive colon cell lines was evaluated. Exosomes were isolated from S1M1-80 conditioned medium by differential centrifugation method. The uptake of fluorescence-labeled exosome from donor MDR cancer cells by recipient sensitive cells was visualized by fluorescence microscopy. MiRNA microarray was conducted to identify differentially expressed miRNAs in drug sensitive cells after incubation with S1M1-80-secreted exosomes. Western blot and qPCR analysis were conducted to measure HuR and ABCG2 expression.
Result: Exosomes were isolated from resistant S1M1-80 cells, whose purity was confirmed by the presence of exosomal markers (Tsg101 and Alix) but absence of cellular marker (GRP78) by Western blot analysis. These exosomes reduced the apoptotic effect of SN-38 or 5-fluorouracil in sensitive colon cancer cell lines (HCT116, S1, and SW480) by inducing both HuR and ABCG2. A common upregulated miRNA (miR-155-5p) was identified by miRNA microarray in the sensitive cell lines after incubation with S1M1-80-derived exosomes. MiR-155-5p was found to induce HuR expression by promoting its translation. MiR-155-5p inhibitor was shown to reverse the upregulation of HuR in HCT116 cells after exosome incubation, which subsequently suppressed ABCG2 expression and the MDR phenotype. Furthermore, inhibition of exosome uptake by dynasore was found to prevent the induction of HuR/ABCG2, and re-sensitize the exosome-treated sensitive cells to SN38.
Conclusion: MDR cells-derived exosomes may spread the drug resistance phenotype by transferring a miR-155-5p/HuR/ABCG2 regulatory machinery to sensitive cells. Inhibition of this exosomal transfer of regulatory materials may prevent the spread of MDR and sensitize cancer cells to chemotherapy.

#5876 ALDH3A1 as a predictive marker for gemcitabine treatment in pancreatic cancer.

J. kim, J. Keum, C. Park, S. Bang;
Yonsei University College of Medicine, Seoul, Korea, Republic of

Background: Pancreatic cancer is one of the incurable cancer. The currently preferred chemotherapy regimens, including gemcitabine, do not extend patient survival by more than a year, and studies on drug resistance mechanisms or biomarkers for the drug sensitivity are very limited. Aldehyde dehydrogenase (ALDH) is a family of enzymes that play an essential role in cell survival and protection. In cancer cells, it is thought that overexpression of the ALDHs confers a survival advantage to the cells, which is associated with a poor prognosis. In this study, we analyzed the drug sensitivity between ALDH3A1 expression and gemcitabine in PDAC cells.

Method: In this study, we investigated the relationship between ALDH3A1 expression and gemcitabine sensitivity using 8 pancreatic cancer cell line. We observed changes in the pattern of ALDH3A1 expression in established gemcitabine resistance pancreatic cancer cell line. Following this, we functionally inhibited ALDH3A1 to determine its impact on gemcitabine sensitivity using shRNA method. To elucidate the molecular mechanisms related with ALDH3A1, we performed multi-omics analysis such as transcriptomics and proteomics.

Results: As a results, there was a negative correlation between ALDH3A1 expression (Protein & mRNA) and gemcitabine resistance 8 pancreatic cancer cell lines. However, in established gemcitabine resistance BxPC3 cells compared to control cells, gemcitabine resistance increased more than 1000 fold while the protein expression was decreased. In these results correlated with inhibition of ALDH3A1 expression using shALDH3A1 experiments both change ALDH3A1 expression and gemcitabine resistance. In biological phenotype experiments, cell proliferation and migration increased in the ALDH3A1 inhibition groups. When using combination treatment of gemcitabine and CB29, a known ALDH3A1 inhibitor, drug resistance increased by more than 2,000 fold in the combination treatment groups. In RNAseq analysis, Adherens junction, Ras signaling, Axon guidance, and JAK-STAT signaling pathway related genes were up regulated in shALDH3A1 treatment group compared control.

Conclusion: In this study, we demonstrated the negative correlation between ALDH3A1 and gemcitabine resistant in pancreatic cancer cell lines and suggesting that it may serves as a predictive marker for gemcitabine treatment in pancreatic cancer patients.

#5877 Disulfiram and its metal complexes reversed hypoxia induced stemness and synergized with first line drugs in primary patient derived pancreatic ductal adenocarcinoma cells.

Benjamin J. Small[1], Ogechi Nkeonye[1], Vinodh Kannappan[2], Shalini Kumarasamy[1], Kate Butcher[2], Karim Azar[1], Gowtham Rajendran[1], Yoshitha Lakshmanan Lakshmanan[1], Mark Morris[1], Christopher Heeschen[3], Yaohe Wang[4], Weiguang Wang[1]

[1]University of Wolverhampton, Wolverhampton, United Kingdom,[2]Disulfican Ltd, Wolverhampton, United Kingdom,[3]School of Medicine, Center for Single-Cell Omics, Shanghai Jiao Tong University, China,[4]Centre for Biomarkers and Biotherapeutics, Barts Cancer Institute, Queen Mary University, London, United Kingdom

Pancreatic ductal adenocarcinoma (PDAC) has a dismal 5-year survival rate (12%) and is predicted to become the second leading cause of cancer related deaths by 2030. The main treatment option for advanced PDAC, gemcitabine (GEM) and nab-paclitaxel (PAC) chemotherapy, has limited efficacy due to adverse toxicities and chemoresistance. Extensive desmoplasia in the PDAC microenvironment induces hypoxia that drives epithelial to mesenchymal transition (EMT) and promotes cancer stem cells (CSCs) leading to metastasis and acquired resistance. Drugs that target CSCs and EMT to overcome chemoresistance could improve patient outcome. Disulfiram (DSF), an FDA approved anti alcoholism drug, has excellent anticancer activity on chelation with Cu^{2+}/ Zn^{2+} ions to form the anticancer metabolites, Copper or Zinc Diethyldithiocarbamate (CuDDC or ZnDDC). The anticancer application of the current oral version of DSF is prevented by its short plasma half-life (< 4 minutes) and separate administration of oral Cu/Zn supplement leading to bioavailability issues. A stable, long circulating, injectable formulation of DSF, CuDDC or ZnDDC may overcome these pharmacokinetic issues. In this study albumin was used to develop soluble, stable and homogenous CuDDC and ZnDDC nanoparticles (Alb-CuDDC, Alb-ZnDDC) and their efficacy was compared with free DSF-Cu in a panel of normoxic, hypoxic and spheroid cultures of patient PDAC cells derived from primary, circulating and metastatic sites. Hypoxia and spheroid cultures of PDAC cells were highly resistant to GEM and PAC and had increased expression of CSC markers such as ALDH, CD133, ABCG2 and CA9. Alb-CuDDC and Alb-ZnDDC were cytotoxic to all PDAC cells (IC_{50s} ~300 nM and ~7000 nM, respectively) in normoxia and hypoxia and synergized with GEM and PAC. While DSF-Cu and Alb-CuDDC significantly reduced the expression of CSC markers and inhibited sphere reformation and migration of PDAC cells, Alb-ZnDDC was less effective in inhibiting these features. Therefore, the ability of PDAC cells to acquire resistance to Alb-ZnDDC was investigated. After long term exposure (> 4 months) to increasing doses of each drug (DSF-Cu, Alb-CuDDC and Alb-ZnDDC), PANC1 and BXPC3 PDAC cells acquired resistance only to Alb-ZnDDC. $PANC1_{ZR6}$ and $BXPC3_{ZR5}$ resistant cells showed increased expression of CSC markers and significant cross-resistance to PAC and GEM suggesting multidrug resistance. Importantly, no cross-resistance to Alb-CuDDC or DSF-Cu was observed, suggesting alternative mechanisms for Alb-ZnDDC. RNA sequencing is underway to identify potential mechanisms involved. To conclude, albumin formulation improved the solubility and stability of DSF-metal complexes. Alb-CuDDC targets CSCs and overcomes resistance in PDAC, similar to free DSF-Cu. Alb-ZnDDC may have alternative mechanisms which are yet to be elucidated.

#5878 ZNF397 loss triggers TET2-driven epigenetic rewiring, lineage plasticity, and AR-targeted therapy resistance.

P. Mu, Y. Xu, S. Deng;
UT Southwestern Medical Center, Dallas, TX

Cancer cells exhibit phenotypical plasticity and epigenetic reprogramming, which allows them to evade lineage-dependent targeted treatments by adopting lineage plasticity. The underlying mechanisms by which cancer cells exploit the epigenetic regulatory machinery to acquire lineage plasticity and therapy resistance remain poorly understood. We identified Zinc Finger Protein 397 (ZNF397) as a *bona fide* co-activator of the androgen receptor (AR), essential for the transcriptional program governing AR-driven luminal lineage. ZNF397 deficiency facilitates the transition of cancer cell from an AR-driven luminal lineage to a Ten-Eleven Translocation 2 (TET2)-driven lineage plastic state, ultimately promoting resistance to therapies inhibiting AR signaling. Intriguingly, our findings indicate that TET2 inhibitor can eliminate the AR targeted therapies resistance in ZNF397-deficient tumors. These insights uncover a novel mechanism through which prostate and breast cancers acquire lineage plasticity via epigenetic rewiring and offer promising implications for clinical interventions designed to overcome therapy resistance dictated by lineage plasticity.

#5879 Role of the inner mitochondrial membrane protein (Mic60) in MAPKi-resistant melanoma.

J. C. Ghosh, S. Del Aguila, H. Li, J. Villanueva, D. C. Altieri;
The Wistar Institute, Philadelphia, PA

Introduction: Metastatic melanoma is one of the most aggressive cancers, despite recent improvements in therapy. The rising melanoma incidence and mortality, along with its high propensity for metastasis highlights the urgency to find more effective therapeutic targets. The efficacy of targeted MAPK signaling pathway inhibitors (MAPKi) in metastatic melanoma therapy is limited by the development of resistance mechanisms that result in disease relapse. This situation necessitates alternative treatments for melanoma patients who develop resistance to targeted therapy. We have recently found out that there exists a group of human tumors that express lower levels of Mic60, a mitochondrial structural protein also known as mitofilin or inner membrane mitochondrial protein (IMMT). In a model of prostate cancer, we showed that Mic60-low tumors have lower mitochondrial fitness, but increased cell motility, invasion, and propensity to metastasize. However, a potential differential expression of Mic60 in melanoma has not been investigated and whether reduced mitochondrial fitness in Mic60-low tumors can expose new therapeutic vulnerabilities in combination with targeted therapies has not been determined.
Experimental Procedures: We analyzed melanoma-specific TMA for differential expression of Mic60 in tumor vs. adjacent normal tissue by IHC. Differential mRNA expression levels were examined by single-cell RNA-Seq and quantified by bioinformatics analysis. Differential therapeutic vulnerabilities of Mic60-low melanoma cell lines to mitochondrial-targeted small molecule Hsp90 inhibitor, Gamitrinib, were assessed for cell death induction and mitochondrial dysfunction.
Results: We identified subsets of melanoma patients with constitutively reduced or outright undetectable expression of Mic60, in vivo. By single-cell RNA-Seq, Mic60-low melanomas were characterized by reduced oxidative phosphorylation and decreased ATP production, slower cell cycle progression but paradoxically increased cell motility and invasion. Loss of Mic60 exposed new, actionable therapeutic vulnerabilities, and the combination of Gamitrinib plus MAPKi potently induced mitochondrial cell death in MAPKi-resistant melanoma cell lines.
Conclusion: Mic60 is heterogeneously expressed and often reduced in melanoma. Although this is associated with increased cell invasion and metastatic propensity, the combination of Gamitrinib plus MAPKi restored mitochondrial cell death in therapy-resistant, Mic60-low melanoma cells.

#5880 Induction of the p-glycoprotein with atorvastatin using colorectal cancer cells.

C. L. Farrell[1], A. Messersmith[2], W. Lei[3], B. Dyer[1];
[1]Clemson University, Clinton, SC, [2]Presbyterian College, Clinton, SC, [3]Manchester University, Fort Wayne, IN

Chemotherapy resistance is responsible for a majority of the cancer-associated mortalities. Efflux of the P-glycoprotein (P-gp) transporter is one of the many causes for chemotherapy resistance. The increased activity of the P-gp on the surface of the tumor cells leads to the removal chemotherapy drugs and allows a cancer to survive. The purpose of this study was to evaluate how atorvastatin impacts the P-gp expression in colorectal cancer cells. The colorectal cells, CACO2 cell line, were separated into drug treatment groups. The experimental groups were treated with the statin drug, atorvastatin, at different concentrations and doxorubicin as the positive control, for 3-4 months. Atorvastatin was selected for the study since it is a P-gp substrate and a potential inducer. Exon-spanning primers for the *ABCB1* gene were used to monitor changes in mRNA expression of the P-gp. Once overexpression of the *ABCB1* gene was achieved, the cells were tested for protein expression through western blots and flow cytometry. The P-pg-induced cells, which consisted of the atorvastatin-treated and doxorubicin-treated cells, and the untreated cells were then tested for chemotherapy-resistance using the PrestoBlue proliferation assay. The atorvastatin treatments were repeated for reproducibility by using two other colorectal cancer cell lines. The P-pg-induced cells, which consisted of the atorvastatin-treated and doxorubicin-treated cells, and the untreated cells were also studied for stability by removing the treatments of the atorvastatin for three months and monitoring for changes in expression of the *ABCB1* gene with rt-qPCR. Drug pathways of the treated cells were also studied for expression changes using RNA Sequencing (RNA-Seq). For the results, the overexpression of the *ABCB1* gene occurred in the 4th month of the study of the bi-weekly atorvastatin and doxorubicin treatments using the CACO2 cells. Protein assays were able to confirm the P-gp overexpression in the atorvastatin-treated and doxorubicin-treated cells. The chemotherapy-resistant assay revealed that the atorvastatin-treated cells were just as drug resistant to the chemotherapy as the doxorubicin-treated cells. Through the reproducibility experiment, the overexpression of the ABCB1 gene was observed in two other cell lines after long-term treatment of the drug therapy. Removal of the atorvastatin for three months revealed that the P-gp overexpression was not reversible. The RNA-Seq analysis identified other possible drug resistant markers in the atorvastatin pathway. This study implicates that late-stage cancer patients, who are treated for hypercholesterolemia, may be at higher risk for developing chemotherapy-resistant tumor cells. With the identification of chemotherapy-resistant tumors in chemotherapy-naïve cancer patients, doctors will be able to provide more precise approaches to treating patients through effective drug therapies.

#5881 Upregulation of TET2 expression by DNA methyltransferase (DNMT) inhibitors is associated with resistance in DNMT1 knockout colorectal cancer cells.

A. B. A. Laranjeira, D. Nguyen, L. C. Pelosof, J. H. Doroshow, **S. X. Yang**;
National Cancer Institute, Rockville, MD

Ten-eleven-translocation 2 (TET2) is a member of the TET family proteins (TET1-3) that convert 5-methylcytosine to 5-hydroxymethylcytosine (5-hmC) in DNA and causes site-specific DNA demethylation. The effects of DNMT1 on TET2 phenotype following DNMT inhibitor treatment is unclear in human cancer. In colorectal cancer HCT116 cells with *DNMT1* gene intact (*DNMT1*$^{+/+}$) and deletion (DNMT1$^{-/-}$) status, we found that TET2 expression was robustly increased in *DNMT1*$^{-/-}$ cells after treatment with 0.5 μM and 5 μM decitabine for 72 h, 96 h, and 120 h. The augmentation in TET2 expression was accompanied by a dose-dependent re-expression of p16^{ink4A} in *DNMT1*$^{-/-}$ cells. Particularly, TET2 upregulation was associated with resistance to DNMT inhibitors, showing a lack of induction of DNA damage, cell-cycle arrest and apoptosis after drug exposure in *DNMT1*$^{-/-}$ compared to *DNMT1*$^{+/+}$ cells. The treatment with 4'-thio-5-aza-2'-deoxycytidine (aza-T-dCyd) only up-regulated TET2 and re-expressed p16^{ink4A} at the lower dose of 0.5 μM, which was consistent with our previous findings that high dose of aza-T-dCyd at 5 μM predominantly eliminates the cancer cells with severe DNA damage by undergoing apoptosis and cell death (Scientific Reports, 13:5964, 2023). Moreover, both decitabine and aza-T-dCyd had minimal effects on TET2 upregulation and p16^{ink4A} re-expression in cells with intact *DNMT1* gene. The data suggest that the absence of *DNMT1* gene made the cells prone to TET2 upregulation upon DNMT inhibitor challenges. Future study is needed to investigate the interactive relationship between DNMT1 and TET2 as well as demethylation, and its impact on cancer treatment with DNMT inhibitors.

#5882 Targeting vulnerabilities of drug-tolerant persister cells in gastric cancer.

E. Puliga[1], L. Negro[2], M. Olivero[3], C. Orru[2], F. Maina[4], D. Conticelli[2], S. Corso[2], S. Giordano[2];
[1]Candiolo Cancer Institute - IRCCS-FPO, Candiolo, Italy, [2]University of Turin; Candiolo Cancer Institute - IRCCS-FPO, Turin, Italy, [3]University of Turin, Turin, Italy, [4]Candiolo Cancer Institute- IRCCS-FPO, Candiolo, Italy

Cytotoxic drugs often fail to eradicate cancers due to the presence of treatment-persistent tumor cells that represent a reservoir for relapse. These “residual” cancer cells escape from chemotherapy- induced death by entering a reversible slow proliferation state, known as drug tolerant persister (DTP) state. Although improvement of treatment options achieved a survival benefit, Gastric Cancer (GC) is still endowed with poor prognosis. Surgery and neo/adjuvant chemotherapy remain the keystone of treatment. However, most patients with advanced cancer relapse even after complete surgical resection, suggesting a critical role for DTP cells. We obtained GC DTP cells from primary cells upon first- and second-line chemotherapy regimens (FLOT and FOLFIRI). Cells were treated with doses corresponding to the drug maximal plasmatic concentration. At the end of the treatment, cells were left without drugs (washout). During this window of time, when cells had regrown, they were re-challenged with chemotherapy and resulted still sensitive to the treatments, thus fulfilling the criteria for bona fide DTP cells. GC DTPs showed increased expression of markers associated with gastric stem cells (i.e. LGR5), downregulation of proliferative markers (i.e. Ki67) and decreased levels of PS6, evaluated as a readout of mTOR activation. Interestingly, DTPs resulted positive to X-gal-based β-galactosidase staining, suggesting a chemotherapy-induced senescence-like status. RNA-seq analysis and gene expression arrays allowed the identification of genes specifically down/upregulated in DTP cells. Using the intuitive enrichment analysis web-based tool Enrichr, we discovered that 54/173 of the downregulated genes characterizing the persister state were targets of a single miRNA. By quantitative real-time PCR, we validated the expression of this miR in all the models of FOLFIRI- and FLOT-obtained persister cells and we found it strongly upregulated (up to 8-fold), highlighting its possible contribute in the establishment of the persister state. Since among the target genes of this miR there are genes involved in the Homolougus Recombination (HR) system, we performed TaqMan™ Array assay for Human DNA repair gene expression on FOLFIRI-obtained DTPs. We identified a significant downregulation of genes strictly correlated to the HR machinery, suggesting that the FOLFIRI-induced persister cells can temporarily enter in a “BRCAness” status that may be used for a synthetic lethality approach using PARP inhibitors. Targeting the drug tolerant persister state is an essential approach to diminish cancer cells when they are potentially in their most vulnerable state.

#5883 Role of major facilitative folate transporters SLC19A1 and SLC46A1 in cyclic dinucleotide transport and STING signaling.

H. McQuithey[1], M. Brzezinski[1], C. O'Connor[1], L. Matherly[2], **Z. Hou**[2];
[1]Wayne State University, Detroit, MI, [2]Barbara Ann Karmanos Cancer Institute, Detroit, MI

Activation of stimulator of interferon genes (STING) activates the transcription factor pIRF3, promoting gene transcription encoding type I interferons including IFNβ that stimulate broader immune responses. Targeting the STING pathway for cancer is especially compelling given its importance to the malignant phenotype. Cyclic dinucleotides (CDNs) function as STING agonists. Inspired by preclinical studies, two phase I clinical trials with CDNs including ADU-S100 were initiated but concluded early due to lack of anti-tumor efficacy. The reduced folate carrier (RFC; SLC19A1) has been identified as one of the primary means to transport CDNs through the cell membrane, although a study suggested that CDN and folate binding to RFC was as least partly distinct. While depletion of the proton-coupled folate transporter (PCFT; SLC46A1) in THP-1 cells had nominal effects on CDN stimulation, overexpressing PCFT increased STING signaling. Limited clinical responses may reflect the impact of physiologic variables governing RFC and PCFT not previously considered. Understanding the mechanisms of CDN uptake by RFC and PCFT under physiologic conditions may elucidate the role of CDNs on STING signaling. To study the impact of RFC levels on CDN transport and STING signaling, we used an engineered R1-11/Tet-on-RFC HeLa cell model induced with doxycycline. In R1-11/Tet-on-RFC cells, ADU-S100 showed a low affinity for binding to RFC, as measured by direct competition for transport with [^{3}H]methotrexate. RFC dose-dependence of ADU-S100 uptake and STING activation was confirmed by monitoring IFN-β (qPCR) and pIRF3 (Westerns). Maximum induction of pIRF3/IFNβ was seen in THP-1 and R1-11/Tet-on-RFC cells by ADU-S100 treatment at pH 7.2 (RFC pH optimum) in the presence of 25 nM leucovorin. Induction of pIRF3/IFNβ by ADU-S100 in THP-1 and R1-11/Tet-on-RFC cells were partially abolished by treatment with 200 μM of leucovorin or 10 μM of PT523 (RFC-specific inhibitor), suggesting the transport of folates and CDNs may share common albeit distinct mechanisms. ADU-S100 treatment showed no pIRF3 or IFN-β production in an engineered R1-11/Tet-on-PCFT HeLa model expressing high levels of PCFT, suggesting no direct transport by PCFT, even under optimal pH conditions. Interestingly, pIRF3/IFN-β induction was enhanced in R1-11/Tet-on-RFC/PCFT cells expressing constitutive PCFT in addition to RFC, compared to R1-11/Tet-on-RFC cells that express comparable RFC without PCFT. This may reflect previously unrecognized functional interactions between RFC and PCFT. In conclusion, RFC mediates ADU-S100 uptake and STING activation under physiologic conditions and this process is enhanced by concomitant expression of PCFT. Additional characterization of key molecular and biochemical determinants of CDN-based cancer therapeutics may lead to improved approaches for CDN therapy based on enhanced cellular uptake.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: New Targets
Poster Session

#5887 Identifying new immunotherapy targets using machine learning and ex vivo validation.

M. Augustine[1], N. Rocha Nene[1], K. Thakkar[1], D. Qian[1], E. Fitzsimons[1], B. S. Simpson[1], C. Watkins[2], C. Swanton[3], K. Litchfield[1];
[1]University College London (UCL), London, United Kingdom, [2]Royal Holloway University of London, London, United Kingdom, [3]The Francis Crick Institute, London, United Kingdom

Overview: Immunotherapy has revolutionized cancer treatment. However, existing immune checkpoint inhibitors (CPI) yield low response rates in most cancers, highlighting the need for new therapeutic options. Traditional immune-oncology (IO) target discovery relies on preclinical models, which struggle to recapitulate human tumor complexity, limiting translation potential. Attention is thus directed at harnessing multimodal patient molecular data with modern machine learning (ML) techniques to identify new IO targets which may have higher clinical viability.
Approach: We posed IO target discovery as a binary classification task, training ML systems on known candidate drug targets that have progressed to stage I or higher clinical trials. We constructed a rich knowledge graph database to support model development. Graph nodes (n=11,919) comprised genes with edges linking genes involved in n=99,275 protein-protein interactions (PPIs; PMID: 28936969). Genes were labelled with n=6,387 gene-disease associations alongside bulk exome and transcriptome (RNAseq) features from n=1,317 CPI-treated patients (PMID: 33508232). We considered the role of different immune subsets by incorporating cell type-specific PPIs from single cell RNAseq atlases of n=350 samples (PMID: 31786210). To capture how antigen processing affects immunotherapy response, we also examined the immunopeptidome of n=60 patients (PMID: 30556813). Causal data on immune responses to genetic perturbation stemmed from n=7 publicly available CRISPR tumor-T cell co-cultures and n=15,442 SNP-phenotype links. Lastly, we used interpretability analysis to understand drivers of model predictions and elucidate critical genes that influence multiple IO target pathways.
Results: Firstly, we developed an ensemble ML approach which achieved test ROC-AUC>0.75. Next, we used a graph-based ML framework which yielded superior performance (test ROC-AUC>0.90). Orthogonal validation confirmed these models can discriminate known targets by trial phase ($p<0.001$), predict patient response in new CPI trials ($p<0.05$), and identify genes that rank highly in unseen genome-wide CRISPR screens. Targets from both methods have entered experimental validation in patient-derived explants and organoid-immune co-cultures. Already, we have identified 2 novel targets predicted to relate to macrophage activity. Early data suggest that perturbing them leads to macrophage repolarization. Further validation experiments are ongoing.
Conclusions: We will reveal candidate targets, showing that our method is effective at uncovering new IO targets and can identify critical nodes in biological networks that might be attractive hits. In addition, deciphering data types that drive model predictions provides a broader immunobiological understanding of anti-tumor immune responses. Thus, our results endorse using ML and multimodal data for novel IO target discovery.

#5888 Novel immune-therapeutic target for lung cancer uncovered by SpliceIO™, an innovative platform that identifies disease-specific alternative splicing.

M. A. Manzanares, K. Anderson, H. Zumrut, S. Gera, N. Habib, N. Williams, S. Stanton, T. Floyd, S. Shah, D. Trahan, M. Akerman, G. Arun; Envisagenics Inc., Long Island City, NY

Alternative splicing (AS) plays a critical role in generating tumor-specific neoantigens targetable through an arsenal of immunotherapeutic modalities. Previous studies have demonstrated tumor-promoting activity of deregulated AS isoforms and mutated splicing factors, both of which increase the yield of neoantigen-encoding AS isoforms. Therefore, the identification of AS isoforms has the potential to produce novel therapeutic targets, especially in lung tumors where splicing deregulation is frequent. Envisagenics has developed SpliceIO, a proprietary software platform for AS-derived neoantigen discovery. SpliceIO uses RNA-seq data to uncover extracellular neoantigens encoded by transmembrane proteins. This predictive ensemble maximizes the value of RNA-seq data to predict fundamental aspects of neoantigen activity, such as protein localization, epitope accessibility, and cancer pathway relevance. Here, we summarize the discovery and validation of novel AS-derived neoantigens identified using SpliceIO in non-small cell lung cancer (NSCLC). Our novel SpliceIO-identified neoantigens in NSCLC were validated following our well-established experimental pipeline. We have confirmed RNA expression of the neoantigen-expressing transcripts in lung cancer cell lines and patient samples using a combination of RT-PCR as well as RNA-ISH. Further, we have validated the membrane-bound extracellular localization of neoantigen-containing isoforms at the protein level using Western blotting, GFP and c-Myc tagged isoform generation, eukaryotic cells transfection, and microscopy. Our top target showed high tumor specificity, heterogeneous distribution in tumor samples, high prevalence, confirmed novel extracellular N-terminal domain, and strong biological relevance in lung cancer. This demonstrates the potential of utilizing RNA splicing for identifying many more membrane associated proteins for tumor specific immunotherapeutic targeting. The combination of computational and experimental approaches to neoantigen identification using SpliceIO allows for novel target discovery amenable for targeted immunotherapeutic development for lung cancer treatment and other indications driven by deregulated AS.

#5889 An immunoproteasome activator that expands the MHC-class I immunopeptidome, unmasks neoantigens and enhances antimyeloma T-cell activity.

P. S. Rana, J. J. Ignatz-Hoover, J. J. Driscoll;
UH Cleveland Medical Center, Cleveland, OH

A hallmark of cancer is the ability to evade immunosurveillance mechanisms and thwart the efficacy of immunotherapeutic agents. The proteasome functions as an essential component of immunosurveillance by generating peptides from intracellular proteins that are then presented to T-cells. Antigens generated by the proteasome promote the infiltration of immune cells into tumors and improve tumor regression in response to immunotherapy. Cancer cells can evade elimination by the immune system by deregulating the antigen presentation machinery to downregulate the expression of proteins recognized by immune cells as antigens, creating an immunosuppressive microenvironment. In contrast to constitutive proteasomes, immunoproteasomes are a highly specialized proteasome variant that are highly expressed in antigen-presenting cells. Immunoproteasomes contain distinct catalytic subunits with active site substrate specificities distinct from constitutive proteasomes. Immunoproteasome degrade intracellular proteins to generate antigenic peptides that are the presented by MHC-class I (MHC-I) molecules on tumor cells for recognition by cytotoxic T-cells. We hypothesized that immunoproteasome activation could concomitantly increase the relative abundance and diversity of MHC-I antigens presented on multiple myeloma (MM) cells. High-throughput screening identified a novel small molecule (Compound A) that selectively increased immunoproteasome catalytic activity. Global proteomic integral stability assays determined that Compound A binds the proteasome structural subunit PSMA1 and that treatment with Compound A increased association of the proteasome activator PA28α/β (PSME1/2) activator with immunoproteasomes. The effect of Compound A on immunoproteasomes was abolished after the ablation of *PSMA1*, *PSME1*, or *PSME2* or by the treatment of cells with suicide inhibitors that target immunoproteasome-specific catalytic sites. Treatment of MM cells with Compound A doubled the total number of MHC-I-bound peptides and increased the level of specific MHC-bound peptides up to 200-fold. Interestingly, a number of tumor-associated antigens and neoantigens were dramatically unmasked following treatment of MM cells with the immunoproteasome activator. Importantly, the treatment of patient $CD138^{+}$ cells with Compound A promoted the antimyeloma activity of allogenic and autologous patient-derived $CD8^{+}$ T-cells. Taken together, our results demonstrate the paradigm-shifting translational impact of immunoproteasome activators to expand the myeloma immunopeptidome and have revealed novel, actionable antigenic targets to personalize T-cell-directed immunotherapy.

#5890 ZNF451 and doxorubicin resistance.

A. Rees, A. Blackman, D. Evans, J. Delaney;
The Medical University of South Carolina (MUSC), Charleston, SC

Precision medicine most often utilizes mutations in patient selection, however targetable mutations are exceedingly rare in high-grade serous ovarian cancer (OV). Aneuploidy and chromosome instability are major contributors to such genomic changes in OV. Genes are pervasively disrupted by copy-number alterations: 39% of all genes in the median solid tumor of all cancer types, and 67% in OV. A common second-line OV chemotherapeutic is peggylated-liposomal doxorubicin, a topoisomerase-II poison. To address which genes in OV contribute to doxorubicin sensitivity and resistance, we performed a CRISPR-Cas9 screen on 19,114 human genes in the presence or absence of doxorubicin. Positive control genes involved in drug-efflux and DNA repair were significant hits. The gene with both the highest significance and greatest magnitude of doxorubicin sensitization upon knockout was the E3 SUMO2/3 ligase ZNF451. ZNF451 exhibits a copy-number loss in 14% of patients and corresponds to ZNF451 protein reduction. ZNF451 is an attractive target for future combination therapies with doxorubicin to induce conditional lethality. ZNF451 may be valuable to study as a prognostic biomarker for topoisomerase-II inhibitor chemotherapy.

#5891 An image-based phenotypic screen identified CBP/p300 as new cancer drug resistance target and enabled the development of the clinical candidate TT125-802.

D. Gruber, C.-H. Fabritius, T. Bohnacker, M. Schwill, S. Laudato, R. Herrador, K. Westritschnig, T. Pattupara, S. Fluckiger-Mangual;
TOLREMO therapeutics AG, Basel, Switzerland

Resistance to targeted therapies is a major challenge in oncology. Genetic mechanisms of resistance such as gatekeeper mutations in the primary drug target can be readily identified. However, drug targets responsible for non-genetic resistance mechanisms such as transcriptional reprogramming remain elusive. Here we describe an innovative phenotypic screening approach that led to the development of the clinical candidate TT125-802 and identification of its target CBP/p300 which we discovered as a novel regulator of transcriptional resistance to a range of targeted therapies. Targeted cancer therapies have been reported to induce profound transcriptional reprogramming leading to drug resistance. For instance, inhibition of oncogenic MAPK signaling using a BRAF/MEK inhibitor combination in BRAF-V600E mutated melanoma, triggers expression of the pluripotency transcription factor SOX2 along with broader expression of associated stemness and EMT genes. We used this system as a model to screen for small molecules that prevent transcriptional escape mechanisms to targeted cancer therapies. For this, we developed an automated high-throughput immunofluorescence staining and analysis method of SOX2 as a surrogate marker for resistance-conferring transcriptional reprogramming. A hit-like high diversity library of 16'000 small molecules was screened using an image-based multi-parameter readout with an integrated counter-screen for general cell toxicity. A battery of downstream assessments including patentability, synthetic tractability, physico-chemical properties, and dose-dependent modulation of transcriptional resistance signatures was used to select the chemical scaffold TT125 for further hit to lead optimization. Hit to lead optimization was initially target agnostic. To de-orphan the scaffold, a chemical probe of TT125 was developed in house and used in a chemoproteomics assay. The transcriptional co-activators CBP/p300 were identified as the target of TT125. Biochemical assays revealed that the TT125 scaffold binds specifically to the bromodomain of CBP/p300 but not the histone acetyl transferase domain. Moreover, TT125 was confirmed to bind highly selectively to the bromodomain of CBP/p300 but not other bromodomain-containing proteins such as BRD2 or BRD4. Structure-based drug design along with in vivo PD models using transcriptional short-term readouts were used for lead optimization that resulted in the development of the potent and highly selective clinical candidate TT125-802. Validating our phenotypic approach to drug discovery and development, TT125-802 is currently being evaluated in a phase I oncology trial. The modular setup of our phenotypic screening system has the potential to power the discovery of additional novel modulators of transcriptional drug resistance.

#5892 SCUBE3 promotes therapy resistance in triple negative breast cancer.

D. Singh[1], D. Medina[1], B. Onyeagucha[2], R. Mojidra[3], P. Subbarayallu[1], A. Taylor[3], D. Lyu[4], S. Timilsina[1], P. P. Venkata[1], S. S. Nirzhor[1], S. M. Abdulsahib[1], T. Do[1], Y. Chen[1], R. Vadlamudi[3], M. K. Rao[1];

[1]UT Health San Antonio Greehey Children's Cancer Res. Inst., San Antonio, TX, [2]Mississippi university of women, Columbus, MS, [3]UT Health Science Center at San Antonio, San Antonio, TX, [4]UT Health San Antonio Barshop institute, San Antonio, TX

Introduction: The development of novel targeted therapies is urgently required for improving the outcome of triple negative breast cancer (TNBC) patients. Chemotherapy is the common treatment option for TNBC. However, resistance and tumor relapse remain the major obstacles hindering the effectiveness of chemotherapeutic agents in cancer patients. Therefore, identifying genes/factors that sensitize breast cancer cells to chemotherapeutic agents could improve treatment outcome in patients. Here we report Signal peptide CUB domain EGF-like 3 (SCUBE3) genes as a novel therapeutic adjuvant that can improve the efficacy of doxorubicin, a chemotherapeutic agent commonly used in treating breast cancer patients.

Methods: Unbiased high-throughput loss of function genomic screen was performed on breast cancer cells in the presence or absence of doxorubicin. Breast cancer cells lines (MDA-MB-231 and MDA-MB-468) were purchased from the American Type Culture Collection and cultured in standard medium. Breast cancer cells were transfected either with SCUBE3 overexpression plasmid or shRNA specific to SCUBE3. These overexpression/knockdown breast cancer cells were analyzed for cell viability, migration, invasion, colony formation, cell cycle, apoptosis assays, western blotting, and in vivo tumor xenograft study.

Results: Our finding demonstrated that SCUBE3 promotes breast cancer cell progression as knockdown of SCUBE3 inhibited the ability of breast cancer cells to form colony, migrate, and invade, while overexpression of SCUBE3 promoted tumor growth in preclinical mouse models. Our results revealed that SCUBE3 mediates its protumor effects by regulating genes involved in growth and survival in the MAPK pathway, DNA damage surveillance pathway including RAD51 and FOXM1, and apoptotic pathway including Mcl-1. We demonstrated that SCUBE3 promotes tumor growth and progression by interacting with and activating several oncoproteins.

Conclusions: Overall, our data suggests that SCUBE3 can be a potent therapeutic target for treating TNBC patients.

#5893 Crosstalk between sensory innervation and pancreatic ductal adenocarcinoma.

K. Wang, B. Ni, X. Wang, J. Hao;
Tianjin Medical Univ. Cancer Inst. & Hospital, Tianjin, China

In recent years, a growing body of research has illuminated the integral role of the nervous system in the initiation and progression of cancer, giving rise to the establishment of an emergent field known as cancer neuroscience. Pancreatic ductal adenocarcinoma (PDAC), constituting 90% of pancreatic cancers, manifests as a highly malignant solid tumor characterized by insidious onset, strong invasiveness, and a notable propensity for recurrence or metastasis. Consequently, the 5-year survival rate for PDAC remained dismally low at approximately 10% in 2021. Notably, PDAC is distinguished by perineural invasion (PNI), a phenomenon linked to postoperative recurrence and metastasis. A thorough exploration of the interplay between peripheral innervation and PDAC holds promise for identifying novel targets and therapies to enhance outcomes in PDAC. This study unveils a correlation between PDAC patients exhibiting high calcitonin gene-related peptide-positive (CGRP+) sensory innervation in the tumor microenvironment (TME) and diminished overall survival (OS) and disease-free survival (DFS) compared to those with lower CGRP+ nociceptive innervation. Concurrently, heightened CGRP+ sensory innervation corresponds to increased cancer pain, as assessed by Visual Analog Scale (VAS) scores. Further analysis reveals a negative association between CGRP+ nociceptive nerves and lymphatic metastasis, as well as tumor size in PDAC patients. In a murine PDAC model, the genetic or chemical ablation of CGRP+ sensory neurons significantly impedes disease progression. Additionally, sensory neuron ablation attenuates cancer-induced vesical pain and enhances the locomotor function of mice, suggesting an improvement in overall quality of life. Mechanically, within the TME of PDAC, the secretion of neuropeptides substance P (SP) and CGRP from sensory neurons is elevated, with CGRP exhibiting a more pronounced increase. Furthermore, the expression of the CGRP receptor—receptor activity modifying protein 1 (RAMP1)—surpasses that of the SP receptor in the TME. Subsequent blockade of the CGRP pathway using the RAMP1 antagonist Rimegepant significantly suppresses PDAC progression and alleviates cancer pain, accompanied by improved locomotor function. In summary, sensory innervation actively participates in the progression of PDAC through the secretion of CGRP. Consequently, the inhibition of the CGRP pathway emerges as a potential therapeutic strategy for both PDAC and cancer-induced pain.

#5894 Novel splicing-derived neoantigen in triple negative breast cancer uncovered by SpliceIO™ a robust platform for the discovery and validation of disease-specific immunotherapies.

N. Williams, M. A. Manzanares, K. Anderson, H. Zunrut, S. Gera, N. Habib, S. Stanton, T. Floyd, S. Shah, D. Trahan, M. Akerman, G. Arun; Envisagenics Inc., Long Island City, NY

Splicing dysregulation is a major hallmark of cancer, affecting tumor progression, metastasis, and therapy resistance. Aberrant alternative splicing (AS) plays a critical role in generating tumor-specific neoantigens targetable through an arsenal of immunotherapeutic modalities. Such neoantigens cannot be discovered using conventional DNA-based tools; they require specialized software for AS analysis using RNA-seq data. SpliceIO is Envisagenics' AI platform for AS-derived neoantigen discovery. SpliceIO uses a "predictive ensemble" approach to uncover neoantigens that are both stably expressed and located on the extracellular membrane of cancer cells. Using SpliceIO, we have analyzed more than 10,000 RNA-seq samples from 5 patient cohorts covering 5 breast cancer subtypes as well as 2,647 normal RNA-seq samples from GTEx. Our analysis has identified tumor-specific neoantigens present in AS transmembrane proteins specific for Triple Negative Breast Cancer. SpliceIO target candidates were validated experimentally using our well-established pipeline in which isoform specific transcripts are tested in cancer cell lines by PCR and primary tumor tissues by qPCR to confirm RNA expression. Tumor heterogeneity and prevalence is confirmed by RNA in-situ hybridization in Tissue Microarrays. Extracellular localization of the novel epitope is confirmed by clone generation with GFP and c-Myc tagging followed by microscopy, Western blotting, and proteomic analysis. Our top validated target presents high TNBC tumor specificity and heterogeneous distribution, and contains a novel extracellular N-terminal domain. These results strongly support the role of aberrant AS as a major source of tumor-specific neoantigens. Our combined computational and experimental approach promotes novel target discovery, enabling the development of novel immunotherapeutic for TNBC patients who are in critical need of better treatment options.

#5895 N17350 kills cancer cells, spares immune cells, and regresses CDX tumors from chemotherapy naive and experienced patients.

C. Cui[1], R. Gujar[1], C. Lee[1], M. Fumagalli[1], N. Martinez[1], H. Liu[1], N. Grigaitis[1], S. Feau[1], A. Bahador[2], A. P. Algazi[3], L. Becker[1];
[1]Onchilles Pharma, Inc., San Diego, CA, [2]South Coast Gynecologic Oncology, Inc, San Diego, CA, [3]University of California San Francisco, San Francisco, CA

Background. While multiple studies have demonstrated improved clinical outcomes in patients receiving concurrent chemotherapy and immunotherapy, clinical synergy may be limited by the destructive effects of DNA-damaging chemotherapy on non-cancer cells, including key constituents of anti-tumor immunity (e.g. mature T cells). Furthermore, when first-line chemotherapy fails, subsequent lines of chemotherapy produce lower response rates. Thus, new approaches that eradicate cancer cells while preserving immune cells may be required to more efficiently induce anti-tumor immunity as monotherapy or in combination with immunotherapy. Neutrophil elastase (ELANE), a neutrophil-derived serine protease, kills a wide range of cancer cells without harming immune cells through a unique mechanism involving histone H1 and the death domain of CD95. Here, we compared N17350, an optimized biologic leveraging the ELANE pathway, and chemotherapies for their ability to kill cancer cells and preserve immune cells from primary tumors of ovarian cancer (OvCa) patients and evaluated efficacy in OvCa patient cell-derived xenografts (CDXs) and a 4T1 model of metastatic breast cancer.

Methods. For in vitro studies, cancer cells and CD45+ immune cells were isolated from primary tumors of chemotherapy naïve and experienced OvCa patients. Cells were treated with N17350, oxaliplatin, or doxorubicin 24h post-isolation, and viability was quantified by calcein-AM. For in vivo studies, primary OvCa cells were injected into nude mice to create CDX models. Mice were treated with 2 doses of N17350 (400µg/100mm3, intratumoral) or carboplatin (100mg/kg, intraperitoneal), and effects on tumor growth were quantified. In 4T1 model, N17350 was compared to oxaliplatin, alone or in combination with anti-CTLA4, and effects on tumor growth and immune profile were assessed.

Results. N17350 killed primary cancer cells from all OvCa patients tested but was well tolerated by CD45+ tumor immune cells from the same patients. In contrast, doxorubicin and oxaliplatin showed similar toxicity to both cell types. N17350 killed cancer cells from chemotherapy naïve and experienced patients with equal efficacy, while doxorubicin and oxaliplatin showed less efficacy in patients previously treated with chemotherapy. N17350 rapidly regressed tumors in all OvCa CDX models and exhibited markedly improved efficacy over carboplatin. In the 4T1 model, N17350 outperformed oxaliplatin in terms of regressing tumors, elevating tumor immune cells, and combining with anti-CTLA4.

Conclusions. Our data demonstrate that N17350 kills OvCa tumors in vitro and in vivo while sparing CD45+ immune cells in both chemotherapy naïve and experienced patients. Together with previous data showing that N17350 induces immunogenic tumor cell death, these findings suggest that N17350 could improve clinical outcomes compared to chemoimmunotherapy.

#5896 Platform approach to develop antibodies specifically recognizing cancer-associated glycoforms.

P. Kehler, J. Gellert, L. Kalfhues, S. Marinoff, M. Weis, A. Franz, N. Kast, S. Gurka, M. Morche, E. Hartung, T. Lischke, S. Mayer-Hain, A. Danielczyk; Glycotope GmbH, Berlin, Germany

Introduction: Recent advances in antibody engineering have created a portfolio of highly potent therapeutic approaches like antibody-drug conjugates (ADCs), radioimmunoconjugates (RITs), chimeric antigen receptors (CARs) or bi-specifics. Due to the increased potency, these drugs are more than ever dependent on very clean targets to prevent side effects. We aim to address this major problem through our approach to develop antibodies with improved tumor specificity and reduced on-target/off-tumor binding utilizing the aberrant O-glycosylation on tumor cells. Altered glycosylation of proteins and lipids is one of the most drastic changes in cancer, giving rise to truncated or highly fucosylated and highly sialylated glycans which are almost absent on normal cells. Thus, developing antibodies against protein/carbohydrate combined epitopes (GlycoTargets) comprising these tumor-specific glycans enables highly potent therapies with reduced off-tumor toxicity.

Experimental procedures: A workflow and corresponding database was established to evaluate the O-glycosylation of proteins. The first and most basic criterion is the presence of suitable O-glycosylated peptide stretches in the extracellular domain of a protein based on predictions. For proteins fulfilling this criterion cancer-relevant expression is analyzed in a second step. This is done either using publicly available data or experimentally (immunohistochemistry or protein expression data). During the final major step, the theoretical existence of suitable O-glycosylation is confirmed by our own experimental data. This includes analysis of cellularly expressed proteins by anti-glycan antibodies and mass spectrometric studies.

Results summary: Case studies will be presented that highlight our workflow to identify suitable GlycoTargets based on publicly available data analysis and experimental confirmation. Additionally, the subsequent development of antibodies against the identified GlycoTargets will be shown.

Conclusion: A standardized process was developed for the data collection and prioritization of potential GlycoTargets. The obtained information is subsequently used for targeted discovery of antibodies that bind to protein/carbohydrate combined glycoepitopes (GlycoTargets) offering increased tumor-specificity compared to simple protein targets.

#5897 Understanding and targeting fatty acid CoA ligase ACSL4 in human prostate cancer.

J. Wu[1], M.-E. Wang[1], M. Chen[1], P. Jeong[2], J. Hong[2], L. Wan[3];

[1]Duke University School of Medicine, Durham, NC, [2]Duke University, Durham, NC, [3]Moffitt Cancer Center, Tampa, FL

Prostate cancer (PCa) is the most common non-cutaneous malignancy among men. Although localized prostate cancer is curable, recurrence of metastatic castration-resistant prostate cancer (mCRPC) is almost inevitable and is the major cause of death in human PCa. Recent findings from our lab and others demonstrate that RB1 loss drives lineage plasticity, metastasis, and lethality of prostate tumors initiated by PTEN loss. A downstream target upregulated by RB1 loss is acyl CoA synthetase long chain family member 4 (ACSL4), a fatty acid ligase with an essential role in utilization of long chain fatty acids. ACSL4 has been reported to be upregulated in cancers of various histological origins, including prostate cancer, and its high expression is correlated with aggressiveness of cancer. We hypothesize that ACSL4 is a critical downstream effector of RB1 loss-driven prostate tumorigenesis and pharmacological inhibition of ACSL4 could represent a novel therapeutic approach to the treatment of lethal RB1 deficient or ACSL4 overexpressing prostate cancer. Here we aim to develop novel ACSL4 inhibitors for preclinical studies. Through a structure based virtual screening that targeted ATP binding domains of ACSL4, we successfully identified 15 potential ACSL4 inhibitors. To validate the result, we performed an in vitro screening using various parental and isogenic human PCa cell lines, and found that 4 out of 15 compounds effectively inhibited PCa cell proliferation in a dose-response manner and their inhibitory effects positively correlated with cellular levels of ACSL4. Next, we will perform isotope-labeling enzyme activity assays to determine the specificity of the 4 candidate drugs, and PDPK analyses followed by characterizing their in vivo efficacies in preclinical studies, with a final goal to develop a well-validated ACSL4 inhibitor. Successful completion of this work will provide great insights into contributions of ACSL4 to prostate tumorigenesis as well as preclinical data of ACSL4 inhibitors to treat lethal prostate cancer.

#5898 Inhibition of the LONP1 ATPase domain induces mitochondrial proteotoxic stress and is cytotoxic to acute myeloid leukemia cells.

M. Tcheng, M. Gronda, R. Hurren, L. Zhang, C. Sarathy, Y. Yan, A. Arruda, M. D. Minden, A. D. Schimmer;
Princess Margaret Cancer Centre, Toronto, ON, Canada

Compared to normal hematopoietic cells, AML cells exhibit a heightened reliance on mitochondrial metabolism for survival and proliferation. To support this unique phenotype, AML cells increase import of nuclear-encoded mitochondrial proteins which must be properly folded by mitochondrial chaperones, proteases, and heat shock proteins. Failure to properly fold these precursors leads to protein aggregation, mitochondrial dysfunction, and cell death. To evaluate the reliance of AML cells on maintaining mitochondrial proteostasis, we assessed gene dependency datasets (eg: depmap.org) and identified the mitochondrial protease LONP1, as the top essential gene. LONP1 is a matrix-localized nuclear-encoded AAA+ protease. Proteins are unfolded by its ATPase domain and degraded by its serine-catalyzed proteolytic domain. Compared to hematopoietic cells, LONP1 mRNA was overexpressed in AML across three publicly available datasets. By immunoblotting, LONP1 protein was increased in 16/30 primary AML samples compared to bulk (n=8) and CD34+ blood cells (n=3). LONP1 genetic depletion reduced the growth and viability of OCI-AML2, OCI-M2, NB4, and TEX leukemia cells as well as primary AML cells. LONP1 depletion increased aggregated mitochondrial proteins and reactive oxygen species (ROS) production while reducing mitochondrial respiration and membrane potential. To determine the domain of LONP1 that was necessary for mitochondrial protein solubility, mitochondrial function, and AML survival, we over-expressed wild type, ATPase dead (E591A), or proteolytically dead (S855A) LONP1 cDNA in OCI-AML2 cells and knocked down endogenous LONP1 with shRNA targeting the 3'UTR of the endogenous gene. Wild type or proteolytically dead (S855A) but not the ATPase mutant (E591A) rescued mitochondrial protein solubility, mitochondrial respiration, ROS generation, membrane potential, and cell viability. Thus, the ATPase domain but not the proteolytic activity of LONP1 is necessary for mitochondrial proteostasis. Bardoxolone methyl (CDDO-Me) is a synthetic triterpenoid that allosterically inhibits the LONP1 ATPase site. CDDO-Me killed OCI-AML2 and NB4 cells with IC50 values of 178.5±29.7 and 156.5±39.7 nM, respectively. CDDO-Me (200 nM) killed 3 out of 4 primary AML samples with high LONP1 expression but none of the 10 primary AML samples with low LONP1. Likewise, CDDO-Me induced mitochondrial protein aggregation in AML cell lines and primary AML patient samples with high LONP1 expression but not AML cells or primary AML patient samples with low LONP1. In summary, LONP1 is over-expressed in a subset of AML cells and primary samples where it maintains mitochondrial protein solubility. Selective inhibition of the LONP1 ATPase domain leads to mitochondrial protein aggregation and AML cell death, representing a novel therapeutic strategy for AML.

#5899 Evaluation of Up284 as a selective proteasome inhibitor for prostate cancer therapy.

B. Karanam[1], R. Anchoori[2], Y. Chang[2];
[1]Tuskegee University, Tuskegee, AL, [2]Up Therapeutics, Frederick, MD

Recent research into prostate cancer treatment has unveiled a promising contender known as Up284. In laboratory experiments, this compound has exhibited a remarkable preference for targeting prostate cancer cells as opposed to normal cells. Specifically, in vitro cell viability assays using MTT have shown that prostate cancer cells display high sensitivity to Up284 at low nanomolar IC50 values, while primary human prostate epithelial cells and mouse keratinocytes exhibit minimal sensitivity. This establishes a notable therapeutic window between cancerous and non-cancerous cells, with Up284 significantly inhibiting colony formation in PC3 cells. Additional functional assays have confirmed Up284's potential, including the 4UbFL Reporter Gene assay, which has revealed robust, dose-dependent proteasome inhibition. This effect is supported by the accumulation of polyubiquitinated proteins in various prostate cancer cell lines following Up284 treatment, suggesting a distinct mechanism of toxicity compared to bortezomib. Furthermore, Up284 has been found to induce apoptosis in PC3 cells, surpassing the efficacy of bortezomib. Competitive binding assays have shown that Up284 exhibits a stronger binding affinity to the proteasomal receptor RPN13 than the prototype inhibitor RA190B. This is further supported by a Cellular Thermo Stabilization Assay (CETSA), which indicates that Up284 stabilizes RPN13 in cells.

A preliminary in vivo study utilizing the bone metastatic prostate cancer genetically engineered mouse model(BMPC GEMM) model for metastatic prostate adenocarcinoma has demonstrated that Up284 leads to significant tumor regression and increased levels of poly-ubiquitinated proteins in residual tumor tissues. Moreover, when Up284 is conjugated with an E3 ligase ligand, it successfully degrades RPN13, resulting in the death of PC3 cells. Up284 has also shown favorable pharmacokinetics/pharmacodynamics (PK/PD) profiles and safety in animal models. It is well-tolerated in mice and holds promise for oral administration, demonstrating a proteasome-dependent reporter protein stabilization effect superior to ixazomib. Importantly, Up284 has induced tumor regression and improved survival rates in various cancer models, including ovarian and breast cancers.

In conclusion, Up284 emerges as a lead candidate for targeted prostate cancer therapy due to its high specificity, substantial therapeutic index, and potent anti-cancer activity both in vitro and in vivo. Further development and clinical investigation of Up284 are warranted to fully explore its therapeutic potential.

#5900 INCB161734: A novel, potent, and orally bioavailable KRAS G12D selective inhibitor demonstrates antitumor activity in *KRAS G12D* mutant tumors.

M. R. Farren, V. Roman, A. Gallion, A. Allali-Hassani, A. Sokolsky, W. Kong, A. Smith, H. Wang, G. Correa, M. Deller, L. B. Epling, J. Procak, G. Zhang, K. Pecko, K. Kennedy, J. Boer, K. Kurzeja-Lipinski, M. Covington, K.-J. Chen, R. Wallower, J. Rocha, R. Pan, A. Perry, B. Yuska, X. Wang, R. Macarron, S. Kim; Incyte Research Institute, Wilmington, DE

KRAS G12D (G12D) is one of the most frequent oncogenic driver mutations, and is especially common in pancreatic (PDAC) and colorectal (CRC) cancers. Patients with *G12D*-mutated disease experience poor treatment outcomes, representing a significant unmet medical need. *G12D* mutation results in constitutively active signaling, including hyperactivation of the ERK and PI3K pathways, which drive cell proliferation and survival. Here we describe INCB161734, a novel, potent, selective, and orally bioavailable small molecule G12D inhibitor that demonstrates *in vivo* efficacy in *G12D*-bearing tumor models.

INCB161734 binds to both the GDP and GTP forms of the G12D mutant at the switch II pocket with picomolar affinity (K_D), and exhibits >80-fold selectivity over wildtype (WT) KRAS. INCB161734 potently inhibits SOS1-dependent GDP/GTP exchange activity in cell-free assays (IC_{50} <3 nM), and exhibits >40-fold selectivity for G12D versus WT KRAS. Additionally, INCB161734 demonstrates high selectivity for G12D over WT in various cellular assays using *G12D* mutant versus WT cancer derived cell lines. INCB161734 potently inhibits ERK phosphorylation (a correlate for KRAS activity), with a mean IC_{50} of 14.3 nM (range: 1.9-45.2 nM) across 7 human and 3 mouse *G12D* cell lines; mean 21.5% inhibition was observed at 1 µM (maximum tested concentration) across 14 WT cell lines. Likewise, INCB161734 inhibits proliferation of *G12D* mutant cell lines, with a mean IC_{50} of 154 nM (range: 8.3-318 nM) across the same 7 human *G12D* cell lines; <30% inhibition (mean 13%) was observed at 1 µM across the same 14 WT cell lines. Treatment with INCB161734 induces caspase 3/7 cleavage in a PDAC cell line (*G12D* HPAC), with EC_{50} <100 nM; caspase 3/7 cleavage in a WT cell line (NCI-H838) was not induced at doses as high as 5 µM. In addition, INCB161734 induced cell cycle arrest (S-phase inhibition) in the *G12D* HPAC cell line, with IC_{50} 12.8 nM; S-phase inhibition in the WT NCI-H838 cell line only occurred at much higher doses (IC_{50} >3.3 µM).

INCB161734 demonstrates excellent oral bioavailability with good absorption, low clearance, and low metabolic turnover. Orally dosed INCB161734 clearly shows target engagement, generating continuous near-maximal KRAS inhibition in *G12D* HPAC mouse xenograft tumors for almost the entire dosing interval. INCB161734 is efficacious against multiple types of *G12D*-mutated tumors and xenografts, resulting in significant tumor growth inhibition, growth arrest and/or regression in multiple PDAC (HPAC, Panc0403, and 2838c3) and CRC (CT26, GP2D, and LS513) mouse tumor models.

These preclinical results demonstrate that INCB161734 is a potent, selective, and orally bioavailable KRAS G12D inhibitor, strongly efficacious against *KRAS G12D* mutant tumors. The potential benefit of INCB161734 for patients with *KRAS G12D* mutant disease is under investigation in ongoing clinical trials.

#5901 A targetable secreted protein drives pancreatic cancer metastatic colonization and HIF1a nuclear retention.

N. Yamaguchi[1], G. Wu[2], E. Ravetch[2], M. Takahashi[2], A. G. Khan[3], A. Hayashi[4], W. Mei[2], D. Hsu[2], E. d. Stanchina[5], I. C. Lorenz[6], C. Iacobuzio-Donahue[5], S. F. Tavazoie[2];

[1]National Cancer Institute, Bethesda, MD, [2]The Rockefeller University, New York, NY, [3]Tri Institutional Therapeutics Discovery Institute, New York, NY, [4]Memorial Sloan Keterring Cancer Center, New York, NY, [5]Memorial Sloan Kettering Cancer Center, New York, NY, [6]Tri-Institutional Therapeutics Discovery Institute, New York, NY

Pancreatic ductal adenocarcinoma (PDAC) is an increasingly diagnosed cancer that kills 90% of afflicted patients. Thus, effective systemic therapy to PDAC remains a significant unmet medical need. **NPTX1 is over-expressed in *in vivo*selected highly metastatic pancreatic cancer cells and promotes liver metastasis:** *Ex vivo* mRNAseq of highly metastatic human and murine PDAC liver metastatic tumors identified neuronal pentraxin 1 (NPTX1) as a cancer secreted protein that becomes over-expressed during PDAC metastatic progression. CRISPRi-based silencing of NPTX1 reduced liver metastatic tumor burden by 15-fold in the highly metastatic clones. **NPTX1 is over-expressed in PDAC liver metastases and predicts survival of PDAC patients:** To assess NPTX1 protein expression *in situ*, two independent board-certified pathologists developed an immunohistochemical (IHC) scoring system and blindly scored NPTX1 expression in a large cohort of 125 primary and 47 liver metastatic PDAC tumors obtained through the rapid-autopsy program at MSKCC. Liver metastatic samples exhibited significantly higher IHC scores than primary PDAC samples (>2-fold increase). **NPTX1 upregulation promotes cell growth under hypoxia:** NPTX1 depletion suppressed growth of PDAC cells under hypoxia but not normoxia. Extracellular supplementation of recombinant NPTX1 was sufficient to rescue cell growth of NPTX1 depleted cells supporting the critical role of secreted NPTX1 in promoting cell growth under hypoxia. **AMIGO2 is a cell surface NPTX1 receptor and mediates HIF1a nuclear retention via specific HIF1a residues:** We next sought to identify the cell surface receptor for NPTX1. We reasoned that a receptor for NPTX1 may become upregulated as a feedback response to depletion of its ligand. mRNA sequencing of *ex vivo* NPTX1-depleted tumors identified AMIGO2. AMIGO2 promoted nuclear retention of HIF1a and conversely, its depletion drove the degradation of HIF1a. HIF1a/hypoxia reporter assay revealed that AMIGO2 depletion led to 300-fold reduction of HIF1a activity. Overexpression of a phosphomimetic construct at HIF1a serine 641 and 643, not a full length HIF1a ORF rescued AMIGO2 mediated HIF1a reporter signal reduction. **Therapeutic targeting of NPTX1-AMIGO2 axis in primary and metastatic PDAC:** Through phage display and mouse immunization campaigns, we identified 6 human IgG1 and 1 murine IgG1 antibodies that exhibited high affinity binding to human NPTX1. We identified anti- NPTX1 murine IgG1 antibody 31B01(31B01) as a lead antibody that substantially and significantly suppressed liver metastatic colonization by >80% outperforming gemcitabine. We also tested the impact of 31B01 on the pancreas orthotopic tumor growth. 31B01 suppressed orthotopic patient derived organoid (PDO) growth (>70% reduction), caused a regression response and dramatically extended the overall survival of treated mice harboring PDAC PDO.

#5902 Targeting MAPK-driven tumors via inhibition of MAP2K4.

M. Wade, E. Tamanini, M. Unbekandt, N. Wallis, J. Lyons, J. Munck, A. Woodhead, P. Schopf, J. Stow, C. East, M. Clark, J. St. Denis, P. Pathuri; Astex Pharmaceuticals, Inc., Cambridge, United Kingdom

MAPK pathway activation is a feature of multiple tumor types. Drugging KRAS and BRAF, the two main oncogenic drivers in the MAPK pathway, has proven successful in the clinic. Inhibition of the downstream effectors, MEK and ERK, can also induce tumor regression. Despite this, many tumors are intrinsically resistant to MAPK pathway inhibitors, or acquire resistance under selective pressure to drug treatment. This creates a need for combination treatments to improve clinical responses. A synthetic lethal (SL) interaction between inhibition of the MAPK pathway and blockade of JNK-JUN signaling has recently been described[1]. Specifically, data from yeast genetics and CRISPR knockout experiments in human cells have identified MAP2K4 as a potential therapeutic target that could be combined with MAPK inhibitors. To date, however, no potent MAP2K4 inhibitors with in vitro and cellular selectivity against key anti-targets have been reported. Here, we describe the development of potent covalent inhibitors of MAP2K4 kinase activity. Biochemical and cell-based assays show that the compound(s) are selective for MAP2K4 versus anti-targets including MAP2K7 and ERK kinases. The combination of MAP2K4 and MEK/ERK inhibitors was effective in cell lines driven by MAPK signaling. These data provide the rationale for further development of MAP2K4 inhibitors to advance our understanding of this novel drug combination.

References: 1. Xue Z, Vis DJ, Bruna A, Sustic T, van Wageningen S, Batra AS, et al. MAP3K1 and MAP2K4 mutations are associated with sensitivity to MEK inhibitors in multiple cancer models. Cell Res. 2018; 28:719-29.

#5903 MASTL small-molecule inhibition to target mitosis for cancer therapy.

Chad M. Toledo, Koleen J. Eisele, Dong Hyun Kim, Xinmeng Mu, Sonja Brun, Carl Davis, Eric C. Greenwald, Fion Hui, Meilan He, Yanling Yang, Ana Flores-Bojorquez, Yuxin Li, Penney L. Khamphavong, Joseph H. Lee, Jian Li, Dana J. Ramms, Greg Jones, Marin Auth, Cory L. Painter, Andrew Nager, Jon Oyer, Sergei L. Timofeevski, William E. Pierceall, Anwar Murtaza, Jonathan R. Heyen, Rebecca Gallego, Casey Quinlan, Indrawan McAlpine, Todd L. VanArsdale

Pfizer, San Diego, CA

Cell cycle/tumor repressors can be pharmacologically activated to repress uncontrollable proliferation of cancer cells. However, targeting cell cycle regulators of G2/M and mitotic checkpoints to achieve maximum therapeutic benefit remains a challenge due to a limited therapeutic index. Here, we identified highly potent and selective oral bioavailable clinical candidate inhibitors to the first-in-class oncology target Microtubule Associated Serine/Threonine Kinase-Like (MASTL) aimed at expanding therapeutic control of the cell cycle for cancer therapy. Breath of efficacy screening in multiple tumor indications in vitro followed by computational analyses identified the regulatory subunit PPP2R2A as a potential patient selection biomarker that strongly correlates to MASTL inhibitor response irrespective of cancer genetic alterations. Functional genetics studies confirmed that sensitivity to MASTL inhibition is defined by PPP2R2A expression. To identify genetic mediators of MASTL inhibitor resistance, a whole genome CRISPR knockout screen with the MASTL inhibitor was performed and further established that the MASTL inhibitor response is dependent on PPP2R2A containing PP2A complexes. Mechanistic studies (proteomics, resistance, functional genetics, and time-lapse microscopy) demonstrated that MASTL inhibition disrupts mitosis by activating the tumor suppressor PP2A, leading to a switch from CDK1 activity to CDK1 inactivity, mitotic defects, and cancer cell death. MASTL inhibition treatment in tumor models *in vivo* and in patient-derived organoid models results in potent tumor growth inhibition. Our results demonstrate that the first identified highly selective MASTL clinical candidate inhibitors represent a potential new cancer therapeutic strategy to target mitosis and mitotic exit by activating the tumor repressor PP2A to counter CDK1 activity.
All procedures performed on animals were in accordance with regulations and established guidelines and were reviewed and approved by an Institutional Animal Care and Use Committee or through an ethical review process.

#5904 Targeting NaV1.7 channels in pancreatic cancer: Implications for EF2K and P-Src/P-Fak/integrin β1 signaling pathways.

M. A. Erdogan[1], A. Caner[2];
[1]Izmir Katip Celebi University, Faculty of Medicine, Izmir, Turkey, [2]Ege University, Izmir, Turkey

Pancreatic cancer (PaCa) ranks as the fourth leading cause of cancer-related deaths in the United States and is among the top five worldwide. Its hallmark characteristics include early invasion, metastasis, resistance to chemotherapy and radiotherapy, and aggressive tumor progression. Evaluating new generation treatments with significant potential in this ongoing battle against cancer is crucial. Voltage-gated sodium channels (VGSC), long detected in various metastatic cell lines and tissue samples beyond breast, lung, and prostate cancer, are of particular interest. This study aimed to explore the therapeutic effects of inhibiting NaV1.7 and its neonatal variant, nNaV1.7, in pancreatic cancer cells. The study utilized human normal keratinocyte cell line HaCaT and pancreatic cancer cell lines PANC-1 and MiaPaCa-2. It investigated the roles and effects of adult and neonatal isoforms of the NaV1.7 channel in pancreatic cancer proliferation, invasion, and metastasis. The findings revealed significantly higher adult and neonatal NaV1.7 mRNA expressions in PANC-1 and MiaPaCa-2 cell lines compared to HaCaT cells. Specific siRNAs effectively downregulated channel mRNA and protein expressions. Notably, NaV1.7 siRNA treatments significantly inhibited cell proliferation and colony-forming capacity in PANC-1 and MiaPaCa-2 cells, without cytotoxic effects on HaCaT cells. Combining gemcitabine with specific NaV1.7 siRNAs enhanced drug efficacy in the PANC-1 cell line. Furthermore, NaV1.7 siRNAs significantly reduced cell invasion, migration, and wound healing in both cell lines. These siRNAs also induced apoptosis and G1 arrest in the cell cycle. They inhibited protein expressions involved in key signaling pathways, including P-Src/P-Fak/Integrin β1, EF2K, P-Akt, P-mTOR, PARP, Caspase-3/9, Cyclin D1/E1. This study is pioneering, as literature lacks research on the expression and function of NaV1.7 and nNaV1.7 in pancreatic cancer cells or tissue samples. In conclusion, NaV1.7 channel isoforms play a significant role in the development, progression, and metastasis of pancreatic cancer and present as a potential therapeutic target in PaCa.

#5905 Propentofylline enhances GBM sensitivity to temozolomide via targeting TROY signaling.

R. Eghlimi[1], D. Nascari[1], A. Beniwal[1], D. Alton[1], D. Grief[2], J. Loftus[2], M. Haluska[3], D. Coleman[3], N. Tran[2];
[1]Mayo Clinic Alix School of Medicine, Scottsdale, AZ, [2]Mayo Clinic Department of Cancer Biology, Scottsdale, AZ, [3]Oleolive, Shreveport, LA

Glioblastoma (GBM) is a high grade glioma that accounts for the majority of primary malignant brain tumors. The standard of care for GBM consists of maximal surgical resection, concurrent radiation and temozolomide (TMZ), and adjuvant TMZ. However, this has only led to a modest increase in median patient survival. TROY (TNFRSF19) is an orphan member of the TNF receptor superfamily that is differentially upregulated in GBM with low expression in normal brain tissue. Previously, we have reported that TROY is overexpressed in GBM and signals to mediate cell invasion and therapeutic resistance. Propentofylline (PPF) is a well-studied synthetic methylxanthine derivative that has strong BBB penetrance. We have shown that PPF decreases TROY expression in gliomas, inhibits invasion, and sensitizes GBM to TMZ in vitro. Here we examined the efficacy of PPF in combination with TMZ using in vivo studies of intracranial models of GBM patient-derived xenograft (PDX) models in murine. We tested 3 models of GBM PDX cells with various TROY expression levels (GBM8-high TROY; GBM43-moderate TROY; GBM22-low/no TROY). Our intracranial PDX experiments showed that PPF treatment alone did not increase survival in all PDX cells. The combination of PPF and TMZ treatment did provide a survival benefit ($p < 0.039$) relative to TMZ alone (only in GBM8-high TROY and GBM43-moderate TROY) that was partially lost when treatment was discontinued. However, continuous PPF administration following a concomitant PPF and TMZ treatment course led to extended survival ($p < 0.0015$) compared to TMZ alone resulting in increased DNA damage (γH2AX) and apoptotic markers (Cleaved Caspase-3). Immunohistochemical analyses showed that TROY expression was decreased in tumors treated with PPF. In addition, PPF-treated tumors showed a differential myeloid population with well circumscribed tumors as compared to control-treated or TMZ-treated tumors. Thus, our data demonstrates that PPF may provide a pharmacological approach to targeting TROY concomitant with standard-of-care to increase patient survival.

#5906 A new combinatorial therapy that synergistically targets the NuRD complex and proteostasis to eradicate quiescent ovarian cancer cells.

Qi Jiang[1], Michelle Ertel[2], Santiago Panesso- Gomez[1], Sara Sannino[3], April Sagan[4], Alexander J. Cole[1], Stacy C. McGonigal[1], Betsy Ann Varghese[5], Wayne Stallaert[5], Jeffrey L. Brodsky[3], Hatice U. Osmanbeyoglu[4], Ronald J. Buckanovich[6]

[1]Department of Internal Medicine, Magee-Womens Research Inst. & Foundation, Pittsburgh, PA,[2]UPMC Magee Women's Hospital, Pittsburgh, PA,[3]Department of Biological Sciences, University of Pittsburgh, Pittsburgh, PA,[4]Department of Biomedical Informatics, University of Pittsburgh, Pittsburgh, PA,[5]Department of Computational and Systems Biology, UPMC Hillman Cancer Center, University of Pittsburgh, Pittsburgh, PA,[6]Department of Internal Medicine, Division of Gynecologic Oncology, Department of Obstetrics and Gyne, Magee-Womens Research Inst. & Foundation, UPMC Hillman Cancer Center, Pittsburgh, PA

Despite advances in immune and targeted therapies, chemotherapy remains the primary treatment for ovarian cancer (OvCa) patients. Unfortunately, most OvCa patients develop chemotherapy-resistant disease that is inevitably fatal. Quiescence is an important yet poorly understood mechanism underlying chemotherapy resistance. Therefore, we aimed to characterize quiescent ovarian cancer (qOvCa) cells to identify novel therapeutic targets to improve OvCa patient outcomes. Primary patient-derived qOvCa cells and proliferating cells were isolated using a single-cell microfluidics culture device and collected for single-cell RNA-seq. scRNA-seq of qOvCa cells identified (i) downregulation of MBD3 and CHD4, which are components of the Nucleosome Remodeling and Deacetylase (NuRD) complex, and (ii) upregulation of proteasome-associated genes. Knockdown of either MBD3 or CHD4 by shRNA, or NuRD complex pharmacologic inhibition with the HDAC inhibitors such as Vorinostat resulted in significant cell growth arrest without cell death. Standard and Fucci reporter-based cell cycle analysis further confirmed that inhibition of the NuRD complex with Vorinostat induced 94.47% cells in the G0 phase ($p<0.0001$), suggesting a dense quiescent state. Through cell cycle phase maps produced by iterative immunofluorescence of 30 core cell cycle regulators and manifold learning, we found Vorinostat-treated OvCa cells demonstrated a completely different cell cycle structure from control cells, with most of the cells in an extreme G0 phase. Bulk RNA-seq of Vorinostat-treated cells in three OvCa cell lines validated the downregulation of pathways relating to cell cycle, cell division, and DNA replication (LFC<-1, $p<0.05$), which is consistent with stem cells. Upregulation of several pathways involved in proteostasis were also noted. We therefore performed a targeted drug screen for combinatorial therapy approaches to eradicate qOvCa. We found that Vorinostat combined with the proteasome inhibitor Carfilzomib demonstrated the most profound synergistic cell death (Loewe index synergy score 23-73). Increased proteasome activity was also found in both primary and Vorinostat-induced qOvCa, suggesting the essential role of the proteasome in qOvCa. Tumor xenograft studies confirmed that Vorinostat alone can delay tumor growth ($p<0.05$) and combinatorial therapy of Vorinostat and Carfilzomib is more efficacious ($p=0.0049$). Taken together, NuRD complex inhibition induces quiescence. Combination therapy with Vorinostat to induce quiescence combined with proteasome inhibitors resulted in the profound death of therapy-resistant quiescent cells. Our work suggests this is a novel therapeutic approach to eradicate chemoresistant qOvCa cells and increase cure rates.

#5907 Pre-clinical evaluation of a novel antibody drug conjugate (ADC) LM-317 targeting NaPi2b.

W. Huang, Z. Liu, Y. Li, H. Pan, X. Qin, D. Fei, **R. Li**;
LaNova Medicines Limited, Shanghai, China

Introduction: NaPi2b is a multi-transmembrane type II sodium-dependent phosphate transporters that regulates phosphate homeostasis in normal physiological condition [1]. It is highly expressed in ovarian cancer (OC), non-small-cell lung cancer (NSCLC), and papillary thyroid cancer, with limited expression in normal tissue, making it a promising target for antibody-drug conjugates (ADCs) [2,3]. LM-317 is a novel NaPi2b targeted humanized monoclonal antibody LM-117 conjugated to the next-generation topoisomerase I inhibitor LDX2 via a cleavable linker, with antibody-drug ratio of 8. Here, we present the preclinical *in vivo and in vitro* results of LM-317.

Results: LM-317 is highly specific cross-reactive with rhesus monkeys, cynomolgus monkeys, mouse, and rat NaPi2b. Concentration-dependent cell binding and internalization effects of LM-317 were observed in human NaPi2b-expressing cells, and OC and NSCLC cells expressing NaPi2b, with EC-50 of 0.92 - 9.7 nM and 1.51 - 4.76 nM, respectively. The cytotoxicity effect of LM-317 in NaPi2b -positive tumor cells was superior to LM-117-DXD, with IC-50 of 0.002 - 0.52nM. The *in vivo* studies showed that 1 mg/kg of LM-317 almost completely eradicated tumors in the OVCAR-3 xenograft mice model of OC, and similar antitumor activity was observed in the NCI-H175-xenograft mice model of NSCLC at the dose of 3 mg/kg. Single dose of 6 mg/kg of LM-317 showed sustained tumor eradication in the NSCLC xenograft -mouse model. LM-317 also exhibited potent tumor regression in the PDX model of OC and NSCLC. The tumor growth inhibition (TGI) value was 80%-100% in OC and NSCLC PDX models with different expression degree of NaPi2b after treatment with LM-317. The antitumor activity of LM-317 in cell line- and PDX models of OC and NSLCL was comparable to those of LM-117-DXD.

Conclusion: The novel ADC LM-317 targeting NaPi2b showed robust antitumor activity *in vitro*, and in the OC and NSCLC cell line derived models and PDX models. LM-317 could potentially provide therapeutic benefit to treat NaPi2b-positive tumors including OC and NSCLC in the future.

#5908 Angiosarcoma growth inhibition by targeting Doppel, a specific endothelial marker, with an antibody drug conjugate.

B. Kim[1], H. Lee[1], Y. Byun[1], Y. Ko[2], S. Kim[3];

[1]Seoul National University College of Pharmacy, Seoul, Korea, Republic of, [2]Pharosgen, Seoul, Korea, Republic of, [3]Asan Medical Center, University of Ulsan, Seoul, Korea, Republic of

Rare cancers are defined as cancers with an annual incidence rate lower than 15/100,000 by the National Cancer Institute. Despite what the terminology may suggest, rare cancers collectively are neither very rare, accounting for about a quarter of all cancers, nor less deadly than other forms of cancer. In fact, the comparative lack of research and case studies of rare cancers compared to other forms of cancer provides both an obstacle and a unique opportunity when it comes to drug development. While finding adequate animal models and cell lines to study the disease may be more difficult, the development of innovative treatment options for rare cancers is often incentivized by the Orphan Drug Act, accelerating approval from the FDA and acting as a gateway to approval for other indications. One such rare cancer is angiosarcoma, a rare cancer that originates from the endothelium. Angiosarcoma represents about 1% of total sarcomas and can develop anywhere in the body but occurs mainly in the breast, liver, or skin of the head and neck area. Angiosarcoma is characterized by a high metastasis rate of 16% to 44%, which results in a dismal prognosis, with overall survival ranging from 6 to 16 months. Considering the high reoccurrence rate and high metastatic potential of angiosarcoma, chemotherapeutic options seem to be the obvious choice. However, mainstream chemotherapies have failed to have long-term therapeutic effects. Another approach is the use of anti-angiogenic therapy, which proved effective but was unable to lead to a complete response. Herein, we describe a novel endothelial cell-targeting therapy option for the treatment of angiosarcoma. Previously, we have discovered Doppel, a 23 kDa GPI-anchored protein that is expressed specifically in the endothelium of tumor-associated blood vessels, except for the testis. Considering the fact that angiosarcoma is a rapidly growing tumor of endothelial origin, we hypothesized that Doppel might be a viable target for both the detection and treatment of angiosarcoma. We subsequently developed an antibody-drug conjugate to Doppel by conjugating a human antibody to MMAE using a unique linker, KGDEVD. When tested on xenografts of the angiosarcoma cell lines KU-CAS3 and KU-CAS5, the tumors responded extremely well to anti-Doppel ADC treatment. Most surprisingly, even tumors exceeding 1 cm^3 went into complete remission after 6 doses of the ADC. Thus, we delved deeper into the mechanism of action behind the ADC. ADC internalization was demonstrated using confocal microscopy. Apoptosis assays show that the ADC is capable of inducing apoptosis and caspase 3 expression in angiosarcoma cells, a crucial step in the activation of the KGDEVD linker. In-vitro toxicity assays of the ADC against KU-CAS3 show an IC50 value of 7.94 nM, much lower compared to normal endothelial cell lines.

#5909 Sulindac exhibits anti-proliferative effects in pre-clinical models of ovarian cancer.

N. Sinha, S. Chen, J. Haag, X. Shen, B. Deng, Z. Zhao, C. Zhou, V. Bae-Jump;
UNC Chapel Hill, Chapel Hill, NC

Objectives: Given the intricate relationship between inflammation and ovarian cancer (OC) development and progression, anti-inflammatory drugs may have potential in the prevention and treatment of OC. Sulindac exhibits potent anti-inflammatory effects through inhibition of COX1/COX2 pathways and promising anti-tumor activity in pre-clinical models of colorectal and endometrial cancer. Thus, we investigated the efficacy of sulindac as an anti-tumorigenic agent in OC pre-clinical cell and mouse models.

Methods: The human OC cell lines, MES and OVCAR5, and the K18-gT121$^{+/-}$;p53$^{fl/fl}$;Brca1$^{fl/fl}$ (KpB) mouse model of high-grade serous OC were used. Cellular proliferation was assessed by MTT and colony count assays. Apoptosis was assessed using cleaved caspase 3, 8, and 9 assays. To measure cellular stress, production of reactive oxygen species was measured by DCFH-DA assay, and the JC1 assay was used to assess changes in mitochondrial membrane potential. Cellular adhesion was evaluated by laminin assay, and cellular migration was determined by wound healing assay. Western immunoblotting was used to assess the effects of sulindac on downstream targets related to cellular stress, apoptosis, cellular invasion potential, cell cycle control, and inflammation. The KpB mice were treated with sulindac (7.5 mg/kg, oral gavage, daily) or placebo for four weeks.

Results: Sulindac inhibited cellular proliferation in a dose-dependent manner in the MES and OVCAR5 cells, with IC50s of 75.3 and 75.69 μM, respectively. Sulindac (100 μM) reduced colony formation by 81% in the MES cells and by 49% in the OVCAR5 cells ($p<0.01$). Treatment of MES and OVCAR5 cells with sulindac increased ROS production and decreased mitochondrial membrane potential, in a dose-dependent manner ($p<0.01$). Sulindac induced activity of cleaved caspase 3, 8, and 9, in MES and OVCAR5 cells ($p<0.01$). In addition, sulindac (100 μM) effectively decreased cellular adhesion by 31% in MES cells and by 23% in OVCAR5 cells ($p<0.01$). These results were confirmed by Western immunoblotting demonstrating that sulindac downregulated the anti-apoptotic proteins Bcl-xl and Mcl-1 and upregulated the pro-apoptotic proteins Bax and cellular stress proteins Bip, ATF-4, and PDI, in both cell lines. Sulindac downregulated expression of several epithelial-mesenchymal transition proteins in both cell lines, including beta-catenin, snail, and slug. Sulindac also downregulated expression of cell cycle proteins CDK4, CDK5, and Cyclin D1 and inflammatory protein COX-2 in both cell lines. After 4 wks of treatment, sulindac significantly inhibited tumor growth by 71% (1.89 g vs 0.54 g, $p<0.01$) in KpB mice.

Conclusions: Our results find that sulindac exhibited anti-tumorigenic effects in OC cell lines and the KpB OC mouse model. Given these promising pre-clinical results, further studies on the repurposing of sulindac for the prevention and treatment of OC is warranted.

#5910 Developing a novel humanized anti-FABP4 antibody for breast cancer treatment.

J. Hao, M. Yorek, J. Yu, A. Avellino, B. Li;
University of Iowa, Iowa City, IA

Circulating levels of adipocyte fatty acid binding protein (A-FABP, also known as FABP4) are linked with metabolic dysregulation. Our previous study demonstrated that high serum levels of FABP4 increased the risk of breast cancer, indicating that circulating FABP4 could be a potential therapeutic target for this disease. In this study, we generated mouse monoclonal antibodies (mAb) against FABP4 by immunizing C57BL/6 mice with recombinant human FABP4. After screening over 1300 hybridoma clones, we identified an FABP4 neutralizing mAb, named 12G2, which inhibited breast cancer growth in various mouse models. To facilitate clinical application, we engineered chimeric and humanized variants of the 12G2 mAb. Notably, the humanized variant, 12G2-variant 9 (12G2-vt9), effectively inhibited mammary tumor growth and progression by reducing the activity of FABP4/ALDH1 in different breast cancer mouse models. Our findings suggest that 12G2-Vt9 is a promising neutralizing mAb targeting FABP4-mediated cancer stemness through ALDH1 signaling, offering potential as a targeted therapeutic antibody for the clinical treatment of breast cancer.

#5911 *In vivo* efficacy of a novel peptide-conjugated drug in patient-derived xenograft models of breast cancer.

M. J. Elliott[1], M. Mcguire[1], J. Silvester[1], C. Tobin[1], S. El Ghamrasni[1], F. Lui[2], A. Zhai[2], O. Yoluk[2], A. Broom[2], T. Stone[2], G. Butterfoss[2], S. Popa[2], T. Lu[2], C. Ing[2], D. White[2], D. W. Cescon[1];

[1]UHN Princess Margaret Cancer Centre, Toronto, ON, Canada, [2]ProteinQure, Toronto, ON, Canada

Introduction: Antibody and peptide-conjugated drugs are rapidly entering the clinic for the treatment of patients with early and advanced breast cancer. These drugs are designed to achieve more targeted delivery of cytotoxic agents to tumor cells with robust clinical activity. ARB-1-6, a sortilin (*SORT1*) targeted peptide conjugated to the cytotoxic agent MMAE, has demonstrated pre-clinical activity and tolerability in cell line xenografts of breast cancer. To further characterize its spectrum of antitumor activity and biomarker correlates we evaluated ARB-1-6 in a collection of clinically and genomically annotated breast cancer patient-derived xenografts (PDX).

Methods: Breast cancer PDX models were generated and propagated under IRB approved protocols [14-8358]. ARB-1-6 was dosed in tumor-bearing SCID mice by tail vein injection at 3 mg/kg weekly x 4 doses. Tumor volume was measured twice weekly until day 35 or until models reached humane endpoints, after which tumors were collected. Animals were weighed regularly and assessed for treatment-related toxicity.

Results: 7 models (5 TN and 2 HR) have completed efficacy assessment to date. 3/7 models were derived from treatment naïve patients while 4/7 were derived from pre-treated patients (Table 1). Complete response (mRECIST) was seen in 5/7 (71.4%) models with stable disease occurring in 2/7 (28.6%). ARB-1-6 was well tolerated with no weight loss observed. Complete tumor regression was seen in a PDX derived from a patient with clinical resistance to a TROP2 antibody drug conjugate (ADC). Antitumor activity was observed in models with low *SORT1* RNA expression; SORT1 IHC and other correlatives studies are underway.

Conclusion: ARB-1-6 demonstrates substantial preclinical activity in PDX models at doses that are well tolerated in mice. Treatment of additional models is ongoing. Full results and correlative analyses including relationships between antitumor activity and target protein expression will be presented.

PDX Model Characteristics and Patient Treatment

PDX	Subtype	Pt. Treatment
1	TN	AC-T
2	TN	FEC-D, Gem+Carbo
3	TN	AC-T
4	TN	No
5	TN	No
6	HR	No
7	HR	TC, ET, Cape, Gem+Cis, TROP2-ADC

#5912 Rational design of a small-molecule inhibitor targeting the allosteric site of sos1 in oncogenic k-ras pancreatic cancer.

X. Duan, C. Evelyn, J. Biesiada, J. Johnson, W. Seibel, J. Meller, Y. Zheng;
Cincinnati Children's Hospital Medical Center, Cincinnati, OH

Oncogenic Kras signaling is a key therapeutic target in human cancers. Ras activation is catalyzed by guanine nucleotide exchange factors (GEFs), of which SOS1 is a major player that transduces receptor tyrosine kinase signaling to Ras. In addition to recently devised oncogenic Kras targeting small molecule inhibitors, disrupting the catalytic interaction between Ras and SOS1 has emerged as an attractive therapeutic strategy in working synergistically with Kras inhibitors and overcoming resistance. Previous studies have demonstrated an active “feed forward” loop of active Kras binding to the allosteric site of SOS1 that further stimulates SOS1 catalytic activation of wild type H/N/Kras, which is required for oncogenic Kras driven tumorigenesis. Here we have developed a rational approach that combines virtual screening with experimental screening to identify small molecule inhibitors that target the allosteric site of SOS1 to suppress oncogenic Kras mediated SOS1-regulated wild-type Ras activities. Unlike SOS1 catalytic site inhibitors which can have significant toxicity due to their ability to inhibit normal Ras signaling function, the lead SOS1 allosteric inhibitors developed in our laboratory binds to the allosteric site of SOS1 and blocks active Ras interaction with SOS1: we found these inhibitors can competitively suppresses SOS1-Ras interaction at the SOS1 allosteric site and dose-dependently inhibits the feed-forward SOS1 GEF activity. Mutagenesis and structure-activity relationship studies mapped the site of action to the SOS1 allosteric site, and preliminarily defined the chemical moieties in the inhibitor essential for the activity. The inhibitor showed dose-dependent and selective efficacy in inhibiting WT Ras activity, downstream signaling activities, and associated cell proliferation in KRAS mutation cells but not KRAS wild-type cells. Compared to the SOS1 catalytic inhibitor, BI3406, our inhibitors showed better selectivity for KRAS mutant pancreatic cancer cells vs. WT KRAS cells. These studies establish a proof of principle for the rational design of small molecule inhibitors targeting an oncogenic Kras specific allosteric site of SOS1 and provide a novel therapeutic concept to target KRAS-driven tumors more effectively.

#5913 TEAD1/4 inhibitors exhibit deeper biological impact and broader activity compared to TEAD1-only inhibitors in both monotherapy and combination without additional kidney toxicity.

F. Muller, S. Kunnimalaiyaan, P. Mangrolia, J. Olson;
Sporos Bioventures, LLC, Houston, TX

The TEAD transcription factors in association with the YAP/TAZ co-activators drive the expression of pro-proliferative and pro-oncogenic genes that underlies the transformed phenotype of many carcinomas. In addition, YAP-TEAD transcriptional activity is emerging as a major resistance mechanism for diverse precision oncology drugs, with the most extensive data for resistance to drugs targeting the MAPK pathway. There is a strong interest in generating inhibitors of YAP/TEAD transcriptional activity with TEAD palmitic acid site inhibitors having demonstrated encouraging pre-clinical activity and now clinical activity with confirmed objective responses with the TEAD1/2/3 inhibitor VT3989. However, the TEAD1-preferential inhibitor IK930 did not yield any objective responses but also showed a more favorable safety profile especially with respect to proteinuria. These contrasting clinical read-outs provide a good lead-in to a critical design challenge/question of TEAD palmitic acid site inhibitors: the optimization of inhibitory profile against the respective four TEAD paralogs (TEAD1-4). In depth bioinformatic analyses led Sporos investigators to conclude that while TEAD1 inhibition was a minimum requirement for anti-neoplastic activity, inhibition of other paralogs would be necessary for maximizing biological impact and a TEAD1/4 inhibitor would provide the best balance of anti-neoplastic activity and toxicity. Activity against TEAD2 was identified as counter-productive associated with a context-specific paradoxical stimulation of cell proliferation and tumor growth while activity against TEAD3 was flagged as a major driver of podocyte effacement and kidney toxicity. Here, we provide novel corroborating data supporting this selection of inhibitory profile. We provide an update on the pre-clinical efficacy and toxicology of SPR1, Sporos's TEAD1/4 preferential inhibitor which favorably contrasts with other TEAD inhibitors such as the TEAD1/3/4 inhibitor VT3989 and the TEAD1 inhibitor VT103 and IK930 in both the monotherapy and combination setting. We show that 1) SPR1 displays broader and deeper cell-based activity and extends the utility of TEAD inhibitors outside of mesothelioma and NF2 mutants 2) SPR1 shows stronger activity than TEAD1-only inhibitors in combination with MAPK and EGFR inhibitors in vitro and in vivo 3) SPR1 does not cause proteinuria in mice; dogs or rats even above therapeutic doses 4) SPR1 does not show the context-specific stimulation of tumor growth in Lung PDX previously observed with VT3989 and other inhibitors that include TEAD2 in their profile. Taken together - the data suggests SPR1 is positioned to become a best-in-class TEAD palmitic acid site inhibitor with broad utility in both monotherapy and combination setting.

#5914 Non-muscle myosin IIA as a promising therapeutic target in breast cancer.

Wasim Feroz, Rosalin Mishra, Mary Kate Kilroy, Joan T. Garrett

Pharmaceutical Sciences, University of Cincinnati, Cincinnati, OH

We aimed to determine the role of non-muscle myosin IIA (NMIIA) in breast cancer using various cancer cell lines including estrogen receptor (ER)+, HER2+ and triple negative breast cancers (TNBC). Myosin heavy chain 9 (*MYH9*) gene encodes for the heavy chain of the hexameric protein NMIIA. We have recently identified that NMIIA serves as a binding partner for HER3 following the inhibition of the HER family member compared to the vehicle control treatment, as observed in HER3 immunoprecipitates. We checked the basal protein and mRNA levels of NMIIA in different breast cancer cell lines and found higher levels of NMIIA in both HER2+ and TNBC cell lines compared to ER+ cell lines. These data correlate with clinical data of primary breast cancer patients with high *MYH9* being less likely in ER+ breast cancer patients and more likely in the PAM50 subtypes basal and HER2 enriched breast cancer patients. By employing a pool of four siRNA targeting *MYH9*, our data indicated a reduction in proliferation of HER2+ and TNBC cell lines when compared to the control siRNA. We have previously found that loss of *MYH9* sensitizes to the HER family inhibitor neratinib treatment as assessed by cell proliferation, colony formation on matrigel, cell migration and invasion. We aimed to determine if pharmacological inhibition of the NMIIA pathway would sensitize to neratinib. RhoA-associated kinase (ROCK) serves as a master regulator of NMIIA activity as it directly phosphorylates the regulatory light chain (RLC) of NMIIA. Pharmacological inhibition of ROCK-NMIIA pathway using the ROCK inhibitor GSK269962A alone or in combination with neratinib reduced the cell proliferation in HER2+ cell lines BT474 and MDA-MB-453 as indicated by MTT and cell proliferation assay. It is well known that HER2-targeted therapies cause the upregulation of HER3. Given our identification of NMIIA as one of the interacting partners of HER3, our focus will be on investigating the NMIIA-HER3 signaling axis to elucidate its contribution to an adaptive response to HER2 inhibition and potential treatment resistance. Furthermore, we will explore strategies to target NMIIA in breast cancer.

#5915 ADT-1004: A promising pan-RAS inhibitor for targeting KRAS mutations in pancreatic ductal adenocarcinoma.

D. Bandi[1], P. Ganji[1], S. Sarvesh[1], Y. Maxuitenko[2], J. Foote[1], A. Keeton[2], X. Chen[2], D. Buchsbaum[1], G. Piazza[2], B. El-Rayes[1];
[1]University of Alabama at Birmingham, Birmingham, AL, [2]Auburn University, Auburn, AL

Background/Objective: Pancreatic ductal adenocarcinoma (PDAC) is a highly challenging cancer with a dismal 5-year survival rate of under 12%. More than 90% of PDAC cases involve mutations in the GTPase KRAS. Unfortunately, existing drugs targeting the RAS family, like sotorasib, exclusively address the KRAS-G12C mutation, mainly found in NSCLC. In PDAC, most patients are diagnosed at advanced stages with unresectable tumors that exhibit various genetic mutations. Approximately 70% of these cases have KRAS-G12D mutations, often co-occurring with KRAS-G12V, KRAS-G12C, and KRAS-G12R mutations. This highlights the urgent need for innovative treatments that effectively address the complex mutation landscape in PDAC and avoid resistance mechanisms associated with mutant-specific or pan-KRAS inhibitors.

Methods: KPC-Luc (1×10^5) and 2838C3-Luc (1.5×10^5) PDAC cells carrying the KRAS-G12D mutation were injected into the pancreas of C57BL/6J mice. After one week, the mice were randomly divided into treatment groups (n = 7 per group) and received oral ADT-1004 at a dose of 40mg/kg body weight five times a week for four weeks. Tumor burden was assessed by bioluminescence signals using the IVIS Xenogen imaging system for patient-derived xenografts from PDAC patients with the KRAS-G12V mutation who were subcutaneously implanted in NSG mice. A week later, mice were randomized (n=7 per group) and treated orally with 40mg/kg of ADT-1004 five times a week for six weeks. Body weight and tumor size were measured twice weekly.

Results: ADT-1004, a prodrug of ADT-007 that exhibits potent inhibitory effects on the proliferation of both human and murine RAS mutant PDAC cell lines with single-digit nM IC_{50} values, compared with μM IC_{50} in PDAC cells with WT RAS, was well tolerated in mice at a dose up to 175 mg/kg bid orally with sustained plasma levels of ADT-007 that exceeded IC_{50} values by 50-fold and even higher concentrations in pancreatic tumors. When administered orally at 40mg/kg body weight, ADT-1004 resulted in substantial growth inhibition of the KRAS-G12D and KRAS-G12V tumors, leading to profound tumor regression without any accompanying loss in body weight. ADT-1004 also displayed a significant inhibitory effect on ERK phosphorylation. Notably, this inhibition is effective regardless of the specific RAS mutational codon or isozyme, as it specifically targets activated RAS and disrupts downstream KRAS signaling pathways.

Conclusion: These results highlight the promise of ADT-1004 as a potential breakthrough for treating PDAC. This novel pan-RAS inhibitor demonstrates potent inhibition of PDAC growth, irrespective of the specific KRAS mutation. Furthermore, it shows an excellent safety profile, with profound tumor regression and no impact on body weight in animal models. These findings open new possibilities for addressing the complex genetic landscape of PDAC.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Novel Antitumor Agents 4
Poster Session

#5920 Inhibition of TBL1 and β-catenin interaction sensitizes acute lymphoblastic leukemia to chemotherapy.

S. Hurwitz[1], R. Friedmann[1], T. Fourfouris[1], K. Lee[1], Z. Wan[1], C. Parekh[1], F. Navid[1], D. Bhojwani[1], K. Holloway[2], Y.-M. Kim[1];
[1]Children's Hospital Los Angeles, Los Angeles, CA, [2]Iterion Therapeutic, Houston, TX

BACKGROUND: Relapse of T-cell acute lymphoblastic leukemia (T-ALL) and B-cell acute lymphoblastic leukemia (B-ALL) post-chemotherapy or post-immunotherapy remains a therapeutic problem warranting novel therapeutic approaches. Aberrant Wnt pathway activation is a common feature in ALL as Wnt activation through β-catenin is involved in self- renewal of drug resistant leukemia cells. A therapeutical approach to target Wnt signaling in T-ALL and B-ALL remains elusive. Here, we focus on the effect of transducin β-like protein 1 (TBL1) inhibitor tegavivint in combination with chemotherapy in T-ALL and B-ALL. We hypothesize that interrupting the binding of TBL1 to β-catenin abrogates leukemia cell survival and test if tegavivint sensitizes these cells to chemotherapeutic agents such as VDL (Vincristine, Dexamethasone, L-asparaginase) as part of preclinical evaluation of tegavivint in T- and B-cell ALL.
METHODS: Four T-ALL cell lines one patient-derived T-ALL case, B-ALL cell lines and eight patient-derived B-ALL cases were used in vitro. We performed cytotoxicity studies using Annexin V/7AAD stainings and flow cytometry or Trypanblue counts to exclude dead cells, western blots, and co-immunoprecipitation assays to investigate effects of TBL-1 inhibition using tegavivint on β-catenin-mediated signaling. Tegavivint was injected intraperitoneally along with chemotherapeutic drugs.
RESULTS: β-catenin and TBL1 were uniformly expressed in all T-ALL and B-ALL cells as determined by western blotting, albeit at different levels. Tegavivint decreases β-catenin protein expression as seen through western blot as well as decreases the binding of TBL1 to β-catenin as seen through co-immunoprecipitation (co-IP) in both the T-ALL and B-ALL samples. We also determined that tegavivint as a monotherapy induced apoptosis in both cell lines and patient samples at as little of a dose of 5nM after 24 hours of incubation using Annexin-V/DAPI staining by flow cytometry. We observed that tegavivint can sensitize all cases to chemotherapy (V: Vincristine, D: Dexamethasone, L:L-Asparaginase or Peg-Asparaginase) within 24 hours of incubation. Lastly, in vivo evaluation of tegavivint showed that tegavivint alone and in combination with VD chemotherapy significantly extends survival of NSG mice engrafted with patient-derived T-ALL and B-ALL compared to control treated mice.
CONCLUSION: Our preliminary data shows that T-ALL and B-ALL are sensitive to TBL1-β-catenin inhibition using tegavivint as a monotherapy. Tegavivint can also sensitize T-ALL and B-ALL to chemotherapy (VDL). As our data supports our hypothesis that TBL-1-β-catenin inhibition is a new target in ALL therapy, further studies are in progress to preclinically evaluate this approach for clinical care.

#5921 PH027-1, a potent and selective small-molecule WRN inhibitor that targets MSI-H tumors.

F. Gao[1], B. Liu[1], L. Jing[2], J. Wang[1], Y. Wu[2], J. Wan[1], P. Zhang[1], Y. Gao[1], Z. Li[3], Y. Guo[1];
[1]Puhe Biopharma, Beijing, China, [2]Gongkang Bio, Suzhou, China, [3]Shiyu Children Foundation, Beijing, China

Background: High microsatellite instability (MSI-H) is highly prevalent across many cancer types including endometrium, gastric, ovary and colorectal cancer. It is well known that there is a clear synthetic lethality (SL) interaction between MSI-H and Werner syndrome protein (WRN) inhibition. WRN is a member of RecQ helicase family and involved in the maintenance of genome integrity. Different from other RecQ family members, WRN has two activity centers responsible for helicase and exonuclease activity, respectively. Further studies confirmed that an inhibition on helicase activity, but not exonuclease activity, is responsible for SL interaction with MSI-H. Also, Recent clinical observations supported that though loss-of-function of WRN could cause an early-aged disease Werner syndrome, selective loss of helicase but not exonuclease leads to only mild to moderate symptoms, suggesting a selective inhibitor of helicase activity has the potential to induce the SL interaction with MSI-H and keep patients safe.
Methods: Biochemical assays and cell-based assays were performed to evaluate *in vitro* activity and selectivity of PH027-1. The *in vivo* anti-tumor efficacy was tested in two cell-derived xenograft (CDX) mouse models with tumors harboring MSI-H. The *in vivo* pharmacokinetics (PK) properties were evaluated in mice, rats and dogs, and other *in vitro* and *in vivo* PK and safety properties were assessed with corresponding assay methods.
Results: Biochemical assays showed that PH027-1 potently inhibited helicase activity of WRN (IC50, 0.8 nM), but had no effect on other RecQ family members even at the highest tested concentration of 10 μM (IC50, all≥10 μM for BLM, RecQ4 and RecQ5). At the same time, PH027-1 did not affect the exonuclease activity of WRN at all tested concentrations. In cell-based assays, PH027-1 potently inhibited cell viability of MSI-H cancer cells SW48 and HCT116 at tens of nM, but had no effect on MSS cells (HT29 cancer cells and CD34+ hematopoietic stem cells) even at 10 μM. The tests were further expanded to 18 cancer cell lines covering uterus, gastric, ovary and colorectal cancer. Nine of twelve MSI-H cell lines were very sensitive to WRN inhibition, and all six MSS cell lines were totally resistant to the treatment. PH027-1 possessed excellent PK profiles as shown by *in vivo* PK studies, with absolute bioavailability of 58%~102% in mice, rats and dogs. In two CDX models (SW48 and HCT116), oral administration of PH027-1 dose-dependently inhibited tumor growth, and a nearly complete inhibition was observed at a dose of 20 mg/kg QD. Tumor regression was clearly shown at higher doses. All other *in vitro* and *in vivo* PK and safety tests showed favorable results and supported for preclinical development of PH027-1.
Conclusion: As a highly selective and potent inhibitor on helicase activity of WRN, PH027-1 has the potential to become a novel and safe approach for treatment of MSI-H tumors.

#5922 Characterization of the biological effects of a quadruplex-interacting molecule in dedifferentiated liposarcoma cells.

Eisa Naghshineh[1], Beatrice Tosoni[2], Lorenzo Di Pietro[1], Sandro Pasquali[1], Nadia Zaffaroni[1], Stephen Neidle[3], Sara N. Richter[2], Marco Folini[1]

[1]Department of Experimental Oncology, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy, [2]Department of Molecular Medicine, University of Padova, Padova, Italy, [3]UCL School of Pharmacy, University College London, London, United Kingdom

G-rich nucleic acid sequences can assume, under physiologic conditions, non-B secondary structures called G-quadruplexes (G4). The human genome contains thousands of putative quadruplex forming sequences (PQS), of which telomeres are the most extensively studied. PQS are frequently found in the promoters of oncogenes and transcription factors rather than in tumor suppressor or housekeeping genes, indicating an evolutionary selection of these elements based on gene function and suggesting a pivotal role of G4 in the regulation of gene expression. These observations have provided the rationale to explore G4 targeting as a therapeutic approach in cancer. Several small molecules have been indeed designed and characterized as G4-ligands (G4-L), most of them showing a "multiple-target" binding modality. Dedifferentiated liposarcoma (DDLPS) is a non-lipogenic disease characterized by aggressive local growth and multifocal local recurrences and the ability to elicit distant metastases. At the molecular level, DDLPS is marked by the amplification of the 12q13-q15 chromosomal region, leading to the abnormal expression of the *MDM2* oncogene. The gene has emerged as an actionable therapeutic target and, recently, PQS within its promoter have been reported to fold into G4 structures. In addition, in our previous study, we observed that pathways related to telomere maintenance are remarkably up-modulated in DDLPS. These findings open a new avenue to explore the therapeutic potential of G4-L in this malignancy. In the present study, the biological activity of a tetra-substituted naphthalene diimide (NDI) G4-L derivative (SOP1812/QN-302) has been characterized in two patient-derived DDLPS cell lines. In particular, the exposure of DDLPS cells to increasing concentrations of SOP1812 resulted in a marked cytotoxic activity *in vitro*, with IC50 values within the sub-micromolar range (~0.3 μM). Moreover, DDLPS cells treated with equitoxic amounts of the compound were characterized by an 80-90% inhibition of telomerase activity and a remarkable perturbation in the MDM2-p53 feedback loop, leading to a pronounced accumulation of basal and phosphorylated (S15/S46/S392) p53 protein. These effects were paralleled by a 3-4 time increase in the number of γ-H2AX foci, the appearance of the cleaved form of PARP-1 and a pronounced inhibition of cell growth over time. Altogether, our findings indicate that targeting G4 structures by quadruplex-interacting molecules may represent a potential novel and effective therapeutic strategy in DDLPS.

#5923 Innovative cyclic peptide disrupts IL-17RB/MLK4 Interaction for targeted pancreatic cancer therapy.

Y.-C. Lo, Y. Ko, C. Huang, J. Lee, D. Wu, Y. Wu, H. Yu, **C.-M. Hu**;
Academia Sinica - Genomics Research Center, Taipei, Taiwan

Interleukin-17B (IL-17B) and its receptor IL-17RB drive oncogenic signaling in pancreatic cancer by interacting with mixed-lineage kinase 4 (MLK4) and phosphorylating IL-17RB's tyrosine-447 site. Our study highlights a therapeutic peptide (amino acids 403-416 of IL-17RB) that disrupts MLK4 binding. Improving its efficacy, we transformed the linear peptide into a disulfide-bonded cyclic form, exhibiting enhanced uptake and stability. The modified cyclic peptide outperformed the linear counterpart, effectively inhibiting the growth and metastasis of PDAC tumor cells in vitro and in a mouse model. Molecularly, we identified the critical role of cysteine (C) residue C408 in IL-17RB, mediating interaction with arginine (R)216 in MLK4's kinase domain. This interaction is pivotal for the cyclic peptide's efficacy. Additionally, lysine (K) residue K410 in IL-17RB maintains the cyclic peptide's structural integrity. These findings provide a comprehensive molecular understanding of IL-17RB and MLK4 interaction, offering innovative strategies for designing therapeutic molecules against pancreatic cancer.

#5924 RNAi mediated inhibition of beta-catenin demonstrates anti-tumor efficacy and immune microenvironment modulation in preclinical hepatocellular carcinoma models.

T. Dadali[1], S. Miller[1], G. Saawant[1], S. Abbott[1], M. Yu[1], S. Morskaya[1], B. Lehrich[2], S. Monga[2], G. Lau[1], M. Maier[1], W. Broom[1];
[1]Alnylam Pharmaceuticals, Inc., Cambridge, MA, [2]University of Pittsburgh, Pittsburgh, PA

Hepatocellular carcinoma (HCC) is the fifth most common solid tumor worldwide, and the third most common cause of cancer-related deaths. For the 40% to 50% of HCC patients who are candidates for systemic therapies, the landscape has evolved significantly in the last 10 years, with most recently, immunotherapies such as combination of atezolizumab and bevacizumab emerging as the current first-line systemic therapy for patients with intermediate or advanced disease. However, there are no predictive biomarkers for patients with HCC to enable selection of those most likely to benefit from these therapies and this remains a disease with high unmet medical need. Activation of the WNT pathway via mutational events or indirect pathway activation is implicated in many cancers including up to 50% of HCC patient tumors. High expression of beta-catenin, encoded by the CTNNB1 gene, has been shown to correlate with decreased survival and more rapid disease progression in HCC patients. In addition, WNT/beta-catenin pathway activation has been shown to result in immune exclusion and resistance to immunotherapy in HCC. ALN-BCAT comprises a chemically modified siRNA encapsulated in a lipid nanoparticle formulation which generates robust and highly specific reductions of *CTNNB1* mRNA, downstream biomarkers and tumor cell proliferation in *in vitro* model systems. Anti-tumor activity has been demonstrated in multiple *in vivo* orthotopic HCC mouse models, in both early and late treatment settings as measured by liver to body weight ratio. Reductions in tumor burden were orthogonally confirmed by histology analysis and shown to be associated with changes in CTNNB1-related biomarkers. Finally, ALN-BCAT treatment results in changes in the tumor microenvironment in a mouse syngeneic HCC model, with increases in CD4+ and CD8+ T cells and reductions in M2 macrophages, consistent with a shift to a more immune stimulatory anti-tumor microenvironment. Here, we demonstrate that ALN-BCAT provides a novel approach to the inhibition of the WNT pathway as a therapeutic approach for treatment of HCC patients and WNT pathway activated tumors.

#5925 Safety, efficacy, pharmacokinetics, and pharmacodynamics of a second generation Irofulven analog CAP-0121 in preclinical cancer models.

R. T. Suhandynata[1], T. K. Nguyen[1], V. R. Kotamraju[2], J. D. Momper[1], M. J. Kelner[1];
[1]UC San Diego, La Jolla, CA, [2]Califia Pharma, San Diego, CA

Background: Irofulven is a semisynthetic sesquiterpene anticancer agent initially investigated for its unique mechanism of action and potential to overcome resistance observed in other chemotherapeutics. This study investigates the pharmacokinetics and pharmacodynamics of a second generation irofulven analog, CAP-121 (Califia Pharma), and its efficacy and safety in preclinical cancer models relative to irofulven.
Methods: 24-hour comprehensive PK was performed at two different intravenous (IV) doses in canines for irofulven (0.2 mg/kg and 1 mg/kg; MTD) and CAP-121 (1 mg/kg and 3 mg/kg). Plasma concentrations were measured by ultra-high performance liquid chromatography multiple reaction monitoring mass spectrometry. PK parameters were determined for both compounds using noncompartmental methods (Phoenix WinNonlin, version 8.4). PK parameters included area under the concentration vs time curve (AUC), maximum observed concentration (C_{max}), clearance (CL), volume of distribution (Vd), and elimination half-life ($t_{1/2}$). Canine platelet and neutrophil counts were measured across 28 days to ascertain the maximum tolerated dose (MTD); platelet count reversibility was also assessed. Mice xenograft models implanted with a drug resistant human ovarian cancer (A2870), or a drug-resistant human metastatic lung cancer (MV522), were dosed with irofulven (9 mg/kg; MTD) and CAP-121 (15, 20, and 25 mg/kg) and resulting tumor mass, % change in body weight, and platelet counts were compared relative to vehicle only.
Results: Systemic exposure, CL, Vd, and $t_{1/2}$ were similar between irofulven and CAP-121 at a 1 mg/kg IV dose. For irofulven, exposure increased approximately proportionally at doses of 0.2 mg/kg and 1 mg/kg. For CAP-121, exposure increased less than proportionally at doses of 1 mg/kg and 3 mg/kg. MTD of CAP-121 was found to be 3-fold higher in canines compared to irofulven as 3-fold more CAP-121 was required to match the platelet reduction with irofulven; platelet nadir was rapidly reversible for CAP-121. Canine nadir platelets were 3-fold higher for CAP-121 vs irofulven at the same dose (1 mg/kg). CAP-121 was superior to irofulven ($p < 0.02$) with regards to final tumor weights in mice xenograft models, even though MTD was not reached for CAP-121; a change in body weight and platelet loss was not observed for CAP-121 at up 25 mg/kg in mice.
Conclusion: The canine PK/PD study of CAP-121 demonstrates that CAP-121 has favorable PK parameters. With regards to *in vivo* anticancer cytotoxic activity, the two drug-resistant xenograft models confirm the superiority of CAP-121 over irofulven. Together, these findings indicate a wider therapeutic window in humans is expected for CAP-121 compared to irofulven, emphasizing the potential anticancer utility of CAP-121 for solid cancers without prolonged thrombocytopenia. Further investigation in clinical trials is warranted

#5926 YB-1 inhibition as an effective approach for the treatment of osteosarcoma.

K. Stefan[1], A. Dheeraj[1], D. Tailor[1], L. E. Davis[2], S. V. Malhotra[1];
[1]Knight Cancer Institute, Oregon Health & Science University, Portland, OR, [2]School of Medicine, Oregon Health & Science University, Portland, OR

Background: Osteosarcoma (OS) is a bone cancer primarily affecting adolescents and young adults, with about 20% of patients having detectable metastatic disease at the time of diagnosis. Despite a large number of clinical trial efforts, metastatic sarcoma remains a lethal disease, and there have been no meaningful advances in therapy or improvements in patient outcomes for decades. Y-box binding protein 1 (YB-1) is a multifunctional cold-shock protein that translationally activates diverse stress response factors with pro-metastatic activities in many cancer types. Importantly, YB-1 is strongly associated with poor outcomes in sarcoma patients and is a major metastatic driver in high-risk sarcomas.
Methods: We recently described a novel compound, CET056, that inhibits cancer progression via YB-1 inhibition. We hypothesized that CET056 had the potential to suppress the progression of OS and could provide a new treatment for this disease. We screened osteosarcoma human and mouse cell lines for YB-1 protein expression. OS cells were functionally characterized for responses to CET056 *in vitro* and *in vivo*.
Results: YB-1 expression was seen in nearly all cell lines tested. CET056 treatment of OS cells resulted in reduced cell viability and YB-1 protein expression in a dose- and time- dependent manner, as well as reduced formation of colonies and spheroids. *In vivo* efficacy studies, which employed a syngeneic subcutaneous tumor model, revealed that CET056 effectively inhibited tumor progression and enhanced overall survival in contrast to vehicle treated control mice.
Conclusion: These results support our hypothesis and illustrate that YB-1 inhibition by CET056 is a promising candidate for further development as a therapy for OS.

#5927 ACBP/DBI inhibition suppresses NASH-induced hepatocarcinogenesis.

S. Li[1], O. Motino[2], F. Lambertucci[2], M. C. Maiuri[2], I. Martins[2], G. Kroemer[2];

[1]Faculte de Medecine, Universite de Paris Saclay, Kremlin Bicetre, Centre de Recherche des Cordeliers UMRS1138, Inserm, Universite Paris Cite, Sorbonne Universite, Paris, France, [2]Centre de Recherche des Cordeliers UMRS1138, Inserm, Universite Paris Cite, Sorbonne Universite, Paris, France

Background: Non-alcoholic fatty liver disease (NAFLD) or its severe form non-alcoholic steatohepatitis (NASH) is becoming an ever more prevalent risk factor of hepatocellular carcinoma (HCC). Currently, there are no approved drugs for the treatment of NASH. Extracellular ACBP/DBI (Acyl coenzyme A binding protein, also called diazepam-binding inhibitor) acts as an autophagy checkpoint and neutralization of ACBP/DBI prevents NASH. Therefore, we investigated the functional roles, mechanisms, and clinical relevance of ACBP/DBI in HCC.

Methods: ACBP/DBI was blocked by four strategies: an inducible Acbp/Dbi knockout ($Acbp^{-/-}$, control: $Acbp^{+/+}$), a constitutive $Gabrg2^{F77I}$ mutation that prevents binding of ACBP/DBI to the receptor (control: WT), induction of ACBP/DBI-specific autoantibodies (induced by KLH-DBI, control: KLH), and monoclonal anti-DBI antibody (control: isotype). Three different types of HCC mouse models, including toxins/diet-based NASH-induced models (western diet plus CCl_4), hydrodynamic transfection of oncogenes (Myc+Ctnnb1), and orthotopic transplantation (Hep55.1C) were used in combination with the aforementioned ACBP/DBI inhibition strategies to determine the association of ACBP/DBI and HCC.

Results: ACBP/DBI inhibition attenuates tumorigenesis in mice with NASH, blunts oncogene induced HCC, and reduces the growth of orthotopically transplanted cancers. Mechanistically, ACBP/DBI inhibition retards cell cycle, suppresses cell proliferation, and favors ferroptosis, as determined by RNA-seq data and mass spectrometric metabolomics. CCK-8 proliferation, colony formation, and cell cycle assays performed on Huh-7, HepG2 and Hep55.1C cells demonstrated that ACBP/DBI knockdown reduced cell proliferation and induced G0/G1 arrest. IHC detection of Ki67 and PCNA in liver sections revealed antiproliferative effects of ACBP/DBI inhibition. qRT-PCR demonstrated the ACBP/DBI inhibition-induced upregulation of cell cycle inhibitor genes and downregulation of genes invoded in G0/G1 phase in liver tissues. qRT-PCR and immunoblot confirmed the upregulation of pro-ferroptotic and the downregulation of anti-ferroptotic genes and proteins in liver tissues upon ACBP/DBI inhibition. Primary HCC cell lines from $Acbp^{+/+}$ and $Acbp^{-/-}$ mice further confirmed the pro-ferroptotic effects of ACBP/DBI inhibition obtained in liver tissues. $Acbp^{-/-}$ cell lines were more sensitivity to RSL3-induced ferroptosis.

Conclusion: ACBP/DBI inhibition constitutes a potential strategy for treating NASH and NASH-induced HCC.

#5928 Structure-activity relationships for the pan-quadruplex experimental drug QN-302 and two analogs probed with comparative transcriptome profiling and molecular modeling.

Ahmed A. Ahmed[1], Shozeb Haider[1], Tariq Arshad[2], **Stephen Neidle**[1]

[1]School of Pharmacy, University College London (UCL), London, United Kingdom,[2]Qualigen Therapeutics Inc, Carlsbad, CA

The tetrasubstituted naphthalene diimide compound QN-302 binds to G-quadruplex DNA structures. It inhibits the transcription of cancer-related genes in pancreatic ductal adenocarcinoma (PDAC) cells, shows high potency in PDAC cells in vitro and in PDAC animal models. It is currently in Phase 1 clinical evaluation as an anticancer drug for advanced, metastatic solid tumors. A study of structure-activity relationships of QN-302 and two related analogs (CM03 and SOP1247) is reported here. These have been probed using comparisons of transcriptional profiles from whole-genome RNA-seq analyses, together with qualitative molecular modelling. Compounds CM03 and SOP1247 differ by the presence of a methoxy substituent in the former: these two have closely similar transcriptional profiles, whereas that of QN-302, although showing effects in the same cancer-related pathways, highlights the down regulation of distinct genes, for example in the hedgehog pathway. The distinct pattern of genes affected by QN-302 is hypothesized to contribute to its superior potency compared to CM03 and SOP1247. Its superior ability to stabilize quadruplex structures has been attributed to its benzyl-pyrrolidine substituent fitting into and filling most of the space in a quadruplex groove compared to the hydrogen atom in CM03 or the methoxy group in SOP1247.

#5929 HuR-targeted therapy promotes the adaptive immune response in medulloblastoma through the cGAS-Sting pathway.

M. Mehta, R. Raguraman, A. Munshi, R. Ramesh;
University of Oklahoma Health Sciences Center, Oklahoma City, OK

HuR is an RNA binding protein overexpressed in multiple human cancers and is involved in tumorigenesis, invasion, and metastasis. Genetic and pharmacologic inhibition of HuR demonstrated antitumor activity establishing HuR as a molecular target for cancer therapy. However, little is known about HuR's role in medulloblastoma (MB). In the present study, we investigated the effect of CMLD2, a small molecule inhibitor of HuR, on MB cell growth and on the adaptive immune response by assessing the cyclic GMP-AMP synthase (cGAS) - stimulator of interferon genes (STING) pathway. The cytoplasmic double-stranded DNA (dsDNA) sensing cGAS-STING signaling pathway plays pivotal role in host defense against cancers. Activation of the cGAS-STING signaling cascade induces the expression of pro-inflammatory cytokines and type I interferons promoting anti-tumor immunity. Human MB Daoy cells were treated with DMSO (control) or CMLD2 (20uM and 30uM). At 48 and 72 h after treatment, cells were collected and cell viability was determined using Trypan blue assay. A time and dose-dependent cytotoxicity was observed with 22.5% and 32.5% reduction in cell number with 20uM treatment ($p<0.01$) and 38.3% and 50.2% reduction with 30uM treatment ($p<0.001$) at 48 h and 72 h respectively compared to DMSO-treated control. Western blot analysis showed CMLD2 treatment inhibited HuR and markedly increased the expression of cGAS-STING pathway proteins (p-STING ^{Ser366}, p-TBK1 ^{Ser172}, p-IRF3^{Ser396} and pNF-KB^{Ser536}) at the two drug concentrations tested albeit greater increase in cGAS-STING protein expression was observed with 20uM treatment. Analysis for chemokines (CXCL10 and CCL5) and cytokine (IL-6) associated with the cGAS-STING pathway in cell culture supernatant collected from 20uM CMLD2 treatment showed significant increase in CXCL10 (1.96 ± 0.12 and 2.12 ± 0.06 fold increase at 48 h and 72 h; $p<0.01$) and CCL5 (1.21 ± 0.09 and 1.86 ± 0.05 fold increase at 48 h and 72 h; p=ns at 48 h; $p<0.01$ at 72 h) over DMSO-treated control. IL-6 expression significantly increased at 72h (1.98± 0.24 fold, $p<0.001$) but not at 48h after 20uM CMLD2 treatment compared to DMSO treated control. Our study results demonstrate CMLD2 mediated HuR targeting induces MB cell cytotoxicity and concurrently activates the cGAS-STING pathway. Testing of CMLD2 treatment in additional MB cell models and studying the impact of the cGAS-STING activation on immune cells (T cells, NK cells and macrophages) will aid in developing novel HuR-targeted treatment strategies in MB. Funding: The study was supported in part by a grant received from the National Cancer Institute of the National Institutes of Health (R01 CA 282735-01) and funds from the Jim and Christy Everest Endowed Chair in Cancer Developmental Therapeutics.

#5930 Measuring apoptotic effects of EP4A1 and EP4A2 on Kuramochi with a high-throughput multiplex image cytometric method.

J. McDonald[1], L. L. Chan[1], J. Reader[2], S. Mojica[1], M. Pierce[1];
[1]Revvity Health Sciences, Inc., Lawrence, MA, [2]University of Maryland, Princess Anne, MD

Ovarian cancer accounts for approximately 6% of all cancer death in women and has one of the highest mortality rates out of all gynecologic malignancies in the United States. Ovarian cancer can exhibit innate or acquired chemoresistance behavior, thus it is critical to identify novel therapeutic drug candidates. One of important characteristics of identifying potential chemotherapy drug candidate is the ability to induce apoptosis or programmed cell death in the target cancer cells. In order to measure apoptosis, various biomarkers are commonly employed such as Caspase 3, 7, 8 or 9, as well as Annexin V, which are all part of the cascade in apoptotic intrinsic pathway. However, typical fluorescent staining for image cytometry is not multiplexed that required multiple steps in order to determine the different type of apoptotic populations. In this work, we demonstrate a multiplexing apoptosis detection method to investigate the apoptotic effects of EP4A1, EP4A2, Paclitaxel, and Carboplatin on Kuramochi ovarian cancer cells. We employed the use of a high-throughput plate-based image cytometer (Celigo, Revvity Health Sciences Inc.) to image and analyze drug-treated Kuramochi cells stained with Annexin V-APC, Caspase 3/7 (488), and propidium iodide (PI) to assess the early- and late-stage apoptosis, as well as necrosis. We expected to see an increase in dual staining with the addition of EP4A to paclitaxel and carboplatin; however, the more interesting data was observed by separating single positive cell populations (Caspase, Annexin or PI only) from dual positive cell populations (Annexin + PI, Caspase + PI, Annexin +PI). The results show that treatment with EP4A lead to a time dependent increase in Caspase 3 cleavage but only in the single positive cell population. This trend was also observed in Annexin V single positive cell populations which is an indication of early apoptosis. The additive effect observed with the addition of EP4A was not seen in the dual positive cell populations. The high throughput nature of the image cytometry also allowed us to easily and quickly determine the optimal treatment conditions for this experiment. We were able to record multiple time points and not only capture proliferation, but also simultaneously collect data on caspase cleavage, Annexin-V staining and PI staining on multiple concentrations of compounds in monotherapy, dual therapy, and triple therapy combinations. Typically, it may be difficult to test multiple conditions in duplicate and triplicate using flow cytometry, while Celigo Image Cytometry may be used to obtain more robust data, and simultaneously acquire data of proliferation and multiplex staining with Annexin-V, PI and Caspase 3/7.

#5931 Investigating the therapeutic potential of STK17A inhibition in GBM.

J. R. Castro;
University of Miami Miller School of Medicine, Miami, FL

For decades, the survival rate for glioblastoma (GBM) has remained nearly stagnant, and currently the 5-year survival rate is only 5%. There is an unmet medical need for therapeutic development, as GBM is the most common primary brain tumor, yet only four FDA approved drugs have been developed for GBM over the last century. GBM is notoriously heterogeneous, and this has posed a challenge for researchers seeking to find therapeutic targets. However, by taking advantage of RNA sequencing, a potential biomarker and target for GBM has been identified: the kinase STK17A (Serine/Threonine Kinase 17A), also known as DRAK1. We confirmed that STK17A is overexpressed in brain cancers by analyzing public databases and single-cell RNA sequencing data from GBM patients, and further associated it with poor patient outcome. Little is known about STK17A, but it has been found to be involved with cell proliferation, tumorigenesis, and tumor metastasis. The role of STK17A in GBM pathophysiology and its therapeutic potential as a drug target remains a critical knowledge gap.In order to better understand STK17A's role in GBM pathophysiology, we first knocked down STK17A in GBM cell lines and determined that STK17A had functional roles in proliferation and morphology. Similar conclusions were drawn after knocking down STK17A *in vivo* in GBM xenograft mouse models. These findings supported STK17A as a viable therapeutic target. We then designed and optimized novel brain-penetrant STK17A inhibitors with IC50 values of <20nM in enzyme assays and <1μM in cell-based targeting engagement and proliferative assays. The designed and prepared novel STK17A inhibitors were further evaluated through kinase enzymatic assays and biological assays as well as *in vitro* proliferation and toxicity assays. We further characterized the inhibitors by showing Drug Metabolism and Pharmacokinetics (DMPK) properties *in vivo* in mouse models at 10 mg/kg via oral administration. We then used these potent, selective, and highly brain penetrant STK17A inhibitors to investigate the anti-tumor effects of STK17A inhibition in GBM *in vivo* and demonstrate the efficacy of our novel STK17A inhibitors.In conclusion, this work seeks to contribute to the field of targeted therapies for GBM by optimizing and examining the first iterations of novel brain penetrant STK17A inhibitors, initiating studies for the treatment of GBM *in vitro* and *in vivo*, and providing proof of efficacy for further studies in GBM patients. Ultimately, the results from our findings will lead to novel strategies for targeted drug development and more robust therapeutic options for GBM patients.

#5932 Immunomodulatory and anticancer effects of cyclical gemcitabine/nab-paclitaxel with continuous dosing of tinodasertib (AUM001) in preclinical KPC model.

W. Leong[1], S. Lee[2], J. Lim[1], S. Chen[2], F. Regis[2], R. Vidergar[1], S. K. Biswas[1], **B. Chowbay**[2];
[1]A*STAR - Singapore Immunology Network (SIgN), Singapore, Singapore, [2]National Cancer Centre Singapore, Singapore, Singapore

Background: PDAC has a poor 5-year survival outcome, and its aggressiveness limits the treatment efficacy. This is often driven by dysregulated mRNA translation of pro-tumorigenic genes that contribute to the proliferative and metastatic nature of PDAC. Synergizing chemotherapy with inhibition of oncogenic mRNA translation via MNK-coupled phosphorylation of eIF4E could potentially be viable. To support this hypothesis, we combined AUM001, a MNK inhibitor, with gemcitabine (GEM)-nab-paclitaxel (nPTX) with the aim of modulating tumor growth kinetics and maintaining it in a stable state.
Methods: PDAC KPC cells were subcutaneously inoculated into BL6 mice and randomized to five treatment groups. Chemotherapy involved administering GEM-nPTX intraperitoneally on days 1, 4, and 8. AUM001 was given orally daily for 8 days for both mono- and combination therapies and was further administered for an additional 3 weeks in continuous dosing group. IHC staining for Ki67, MVD, and stromal markers was conducted on FFPE sections as well as Western blot analysis of tumor tissues. Apoptosis was assessed using Annexin V. Immune profiling were evaluated by flow cytometric assay and GeoMx spatial transcriptomics analysis.
Results: The administration of GEM-nPTX and AUM001 (GPA) or GEM-nPTX alone (GP) led to an average 38% reduction in net tumor growth with no observed toxicity. Notably, continuous dosing of AUM001 (GPAc) following the cessation of chemotherapy exhibited a 45% decrease in net tumor growth (P=0.056) when compared to GPA. EIF4E phosphorylation and Myc expression were markedly inhibited in GPAc with lower recovery rate for MVD as compared to the GPA group at EOO ($P < 0.05$). A higher fraction of apoptotic cells was detected in the GPAc group at EOO than GPA group in reference to GP group (P=NS). GPA also resulted in a lower frequency of NK cells which was partially lifted in GPAc during observation phase. Macrophages which are known to have a pro-tumor role initially increased in frequency upon addition of AUM during chemotherapy, but subsequently decreased during observation. These modulations in infiltrating immune cells correlated with the differential expression of several immune related genes in the tumor associated CD45+ immune cells, revealed by the GeoMx analysis.
Conclusions: This study showed that sustained administration of AUM001 alongside cyclical GEM-nPTX is well-tolerated with good anti-tumor outcomes. Additionally, the maintenance of AUM001 may enhance the decrease in pro-oncogenic protein expression and remodel the tumor immune microenvironment. In conclusion, continuous dosing of AUM001 following the cessation of chemotherapy could stabilize the tumor state, potentiating its application in clinical settings as maintenance therapy for PDAC.

#5933 Identifying MC4R-targeted small molecule to investigate MC4R impact on cachexia progression.

J. Stokes, D. Taylor, M. Foss, B. Grau, S. Malhotra;
Oregon Health & Science University, Portland, OR

Background: The melanocortin system participates in energy homeostasis and appetiteregulation. This metabolic system is primarily located in the central nervous system,specifically in the hypothalamus and brainstem region. Within the melanocortin system,there are five established melanocortin receptors (MCR). MCRs are g-protein-coupledreceptors (GPCRs) and when these receptors are activated, they can increase neuronexcitation, regulate neurotransmitter release, regulate synaptic input, and alterconnection and strength. When Melanocortin-4 Receptor (MC4R) plays a critical role inthe progression of multiple metabolic diseases including cachexia. Cachexia is definedas the reduction of fat and lean mass, which is caused not just by lack of appetite, but byinflammatory impact. Cachexia is a symptom seen in numerous chronic diseases fromcancer to mitochondrial dysfunction to autoimmune inflictions. This makes MC4R apotentially strong therapeutic target.
Method: *In-silico* and high-throughput methods were used to identify small moleculesthat target and inhibit MC4R. For high-throughput screen, Hek293 cells withconstitutively active MC4R tagged with a nanoluciferase were used to identify molecules,specifically with inhibitory qualities. cAMP accumulation and β-arrestin recruitmentassay were used to determine the impact on MC4R functionality.
Results: 4738 small molecules were screened using high-throughput methods. Using a60% cutoff, 21 small molecules were identified as potential MC4R inhibitors. 17 arecurrently under investigation to confirm high-throughput results and identify functionalimpact. Several of these molecules have shown promising potential *in vitro* and will likelymove forward into *in vivo* studies.
Conclusion: This study identifies prospective small molecule inhibitors that targetMC4R and may be used as a probe to explore MC4R biology.

#5934 Ferroptosis induction therapy for castration resistant prostate cancer.

M. Awolowo, P. E. Dike, V. Odero-Marah;
Morgan State University, Baltimore, MD

Prostate cancer (PCa) is the most common non-skin cancer in men, and second leading cause of death. The fundamental treatment for treating PCa is androgen deprivation therapy which is an effective form of treatment initially. Nevertheless, the disease reoccurs in most men; this is referred to as castration-resistant PCa (CRPC), for which the standard treatment is enzalutamide. However, some develop resistance to this enzalutamide anti-androgen agent. Ferroptosis is an iron-dependent lipid peroxidation form of regulated cell death being investigated as a novel potential therapy for PCa using ferroptosis inducers such as RSL3; they have shown promise in selectively triggering cell death in cancer cells while sparing healthy tissues. We hypothesize that RSL3- induced ferroptosis will overcome enzalutamide resistance in PCa cells. To test this, we utilized C4-2B MDVR cells which represents a cell model for aggressive PCa that metastasized to the bone and is resistant to both castration therapy and the enzalutamide drug treatment. C42B-MDVR cells were treated with increasing concentrations of RSL3 followed by analysis of cell viability with MTS assay. A dose dependent reduction in cell viability was observed which was reversed by ferroptosis inhibitor, ferrostatin-1. Western blot analysis revealed a decreased expression of the antioxidant enzyme glutathione peroxidase 4 (GPX4) with ferroptosis induction indicating a mechanism of the RSL3-induced cell death. The limitations to our research are that the research was performed *in vitro* and have not been tested on mouse models to visualize the effects of the treatments in animals. In conclusion, ferroptosis inducer RSL3 decreases GPX4 expression and decreases proliferation of PCa cells while ferrostatin-1 reverses the effects of the RSL3 treatment. Thus, ferroptosis inducers present a potential novel therapeutic approach for CRPC patients who have developed resistance to conventional androgen therapies. #5935 Non-allosteric inhibition of enolase 1 sensitizes triple-negative breast cancer for checkpoint inhibitors.

D. Tailor[1], F. J. Garcia-Marques[2], A. Bermudez[2], W. Li[1], A. Dheeraj[1], S. J. Pitteri[2], S. V. Malhotra[1];

[1]Knight Cancer Institute, Oregon Health & Science University, Portland, OR, [2]Stanford University School of Medicine, Palo Alto, CA

Background: Triple-negative breast cancer (TNBC) is an aggressive type of breast cancer that commonly returns and spreads. Currently, very few options are available for TNBC treatment. Cancer cells exploit glycolytic machinery for the Warburg effect and aerobic glycolysis. Enolase 1 (ENO1) is the glycolytic enzyme expressed in most tissues, and many cancer cells have higher expression. Apart from the glycolytic role in the cytosol, ENO1 also plays different roles in cancer cells, including as a surface receptor.

Method: non-allosteric chemical inhibition was developed and tested *in vitro* for its efficacy and target validation. Subsequently, *in vivo* examinations were conducted on emerging small molecules in syngeneic and patient-derived murine models of breast cancer to unveil their anti-tumor efficacy.

Results: Our non-allosteric small molecule inhibitor, SU212, binds to ENO1 and restricts its movement within cells. SU212 treatment leads to the accumulation of ENO1 in the nucleus where it restrains the activity of c-Myc. The treatment causes the production of truncated ENO1 called myc promoter-binding protein 1 (MBP-1), which limits the activity of c-Myc. Stand-alone treatment of SU212 restrains the tumor progression and metastasis in orthotopic syngeneic and PDX mouse models. Combining SU212 and Anti-PD1 significantly inhibits tumor growth and metastasis in mouse models. C-Myc is linked to protein transcription that aids immune resistance and tumor evasion of immune surveillance. Suppression of c-Myc activity *via* SU212 treatment sensitizes the TNBC tumors for anti-PD1 therapy.

Conclusions: This study provides compelling preclinical data for further development of SU0212 as an immune therapy sensitizer for the treatment of TNBC.

#5936 A novel class of orally bioavailable small molecules induces potent and sustained tumor growth inhibition and T cell infiltration in various solid tumor mouse models.

B. Gapp[1], G. Zischinsky[2], M. Urban[1], N. Birnbacher[1], A. Schwarzbock[1], S. Grunaug[1], T. Gastaldi[1], A. Stutz[3], P. Nussbaumer[2], S. Stranner[1], J. Buchberger[1], A. Birbach[1], D. Schogl[1], M. Kuttke[1], A. Dohnal[1], R. Gugenberger[1];

[1]invIOs GmbH, Vienna, Austria, [2]Lead Discovery Center GmbH, Dortmund, Germany, [3]Pharma R&D Consulting Stuetz GmbH, Altmunster, Austria

The introduction of targeted immunomodulating agents has transformed cancer treatment over the last decade by demonstrating unprecedented efficacy in patients who respond. However, limited clinical response rates as well as adverse events underline the need to identify additional novel modalities in cancer immunotherapy. Here we report on the discovery of a novel class of low molecular weight compounds for oral application that selectively enhance tumor-reactive T cell cytotoxicity. Hit-to-lead development of compound hit series A was performed based on medicinal chemistry to investigate structure-activity-relations. A-306, a representative of the A compound class, induced increased T cell proliferation, elevated levels of the activation markers CD25 and CD69 as well as enhanced secretion of IFN-γ, IL-2 and TNF-α upon anti-CD3/CD28 stimulation. A-306 treatment without T cell receptor ligation had no effect on T cell activation, suggesting selective activation potential only in the context of antigen encounter. Furthermore, A-306 strengthened T-cell mediated killing of M21 melanoma cells and enhanced T cell function in response to viral antigens by showing a Th1 signature. Medicinal chemistry efforts resulted in front runner compounds A-481 and A-687 that show a similar profile and potencies down to nanomolar level. In a murine B16-SIY melanoma and EO771 breast cancer model oral single-agent administration with front runner compounds was well tolerated, showed good bioavailability in lymphoid organs and plasma and resulted in significant tumor growth inhibition beyond the end of treatment (D21). T cells from tumor draining lymph nodes of long-term surviving mice in both cancer models showed a distinct activation pattern indicative of anti-tumor immunity. Furthermore, oral application of A-481 in combination with intra peritoneal administration of anti-PD1 antibodies eradicated B16-SIY melanoma cells in a synergistic manner. Taken together, we report on the identification of a novel class of small molecules possessing high potential for selective anti-tumor activation of the immune system upon oral administration. Front runner compounds A-481 and A-687, which significantly inhibit tumor growth in a B16-SIY melanoma and EO771 breast cancer mouse model, lead to prolonged survival beyond the end of treatment and display a good safety profile. The final candidate compound will undergo testing in toxicity studies and enter a first-in-human trial in selected solid tumors in 2025.

#5937 KS20226, a first-in-class IRP2 inhibitor, preferentially induces reprogramming of iron metabolism and suppresses tumor growth in colorectal cancer.

J. Hwang[1], A. Park[2], C. Kim[1], C. Kim[1], J. Kwak[2], B. Kim[2], H. Shin[2], M. Ku[1], J. Yang[1], A. Baek[3], J. Choi[4], H. Lim[3], K. No[3], X. Zhao[1], U. Choi[1], T. Kim[1], K.-S. Jeong[5], H. Lee[2], S. Shin[1];

[1]Yonsei University College of Medicine, Seoul, Korea, Republic of, [2]Korea Research Institute of Chemical Technology, Daejeon, Korea, Republic of, [3]Yonsei University, Incheon, Korea, Republic of, [4]Dongduk Women's University, Seoul, Korea, Republic of, [5]Yonsei University, Seoul, Korea, Republic of

Background: Iron homeostasis plays a role in redox activity, mitochondrial function, and cell cycle regulation. Specifically, the dysregulation of iron metabolism is implicated in malignant transformation and cancer progression. Iron regulatory protein 2 (IRP2) is crucial for maintaining balance within iron levels and primarily controls genes associated with iron utilization. Our discovery of KS20226, a first-in-class IRP2 inhibitor, reveals remarkable potential as an effective anti-cancer drug candidate. We have elucidated the mechanisms underlying the therapeutic effects of KS20226, thereby highlighting the feasibility of targeting IRP2 in colorectal cancer (CRC).

Methods: The proliferation inhibitory activity of KS20226 was assessed the CCK-8 and 3D Spheroid models. To investigate mitochondrial function, we conducted measurement of oxidative phosphorylation (OCR) and glycoPER. Furthermore, gene expression analysis was performed through RNA sequencing (RNA-seq) using the Illumina HiSeq 2500 system platform (Macrogen Inc.). Differential expressed gene (DEG) analysis was carried out using the R package DESeq2, and pathway enrichment analysis was analyzed using GSEA (v_4.2.3.). For the observation of autophagic morphology, we utilized transmission electron microscopy (TEM), immunofluorescence staining targeting the autophagy marker LC3B, and immunoblotting.

Results: KS20226 exhibited a remarkable growth inhibitory effect in 10 different CRC cell lines, with GI_{50} values ranging from 1 to 10 μM. KS20226 suppressed IRP2 expression and the corresponding occupancy of the iron-responsive elements of ferritin H and transferrin receptor 1, resulting in iron deprivation, and efficiently controlled CRC growth. Pharmacologic inhibition of IRP2 induced reprogramming of mitochondrial respiration, reducing reliance on oxidative phosphorylation. The observed mitochondrial dysfunction induced by KS20226 was correlated with pathway analysis, revealing a decrease in the gene-set for HALLMARK_OXIDATIVE_PHOSPHORYLATION (NES = -1.38, p-value = 0.008) and an increase in the gene-set for POSITIVE_REGULATION_OF_AUTOPHAGY (NES=1.43, p-value=0.016). Immunoblotting demonstrated that KS20226 activated the phosphorylation of AMPK, ULK, and Beclin1 cascade, leading to the autophagic cell death of the CRC cells.

Conclusions: The reliance of cancer cells on iron metabolism to drive proliferation has led to the development of therapeutic strategies targeting the inhibition of IRP2. KS20226, a first-in-class IPR2 inhibitor, exhibits distinct therapeutic properties, such as perturbation of mitochondrial iron metabolism and induction of autophagic cell death. Our findings represent important progress toward exploiting IRP2-mediated abnormal iron metabolism in cancer, an unexplored area of research with substantial unmet needs.

#5938 Development of HH044, an orally bioavailable nNOS inhibitor, for the treatment of cutaneous melanoma.

A. Patel[1], S. Tong[1], R. B. Silverman[2], S. Yang[1];
[1]Chapman University, Irvine, CA, [2]Northwestern University, Evanston, IL

Background: Human cutaneous melanoma is one of the few cancers in which the incidence rate continues to increase, and despite recent advances in immune and targeted therapies, the 5-year survival rate of metastatic disease remains low. Neuronal nitric oxide synthase (nNOS) has been identified to contribute to melanoma development, stimulating disease progression, and facilitating escape of melanoma cells from the immune response. We developed a novel small molecule, HH044, which specifically inhibits nNOS activity and reduced nitric oxide production in melanoma cells. We aim to conduct a proof-of-concept study using our nNOS inhibitor administered orally for anti-melanoma treatment.

Methods: Human melanoma cell lines (A375, Sk-Mel-28, wm3211) were employed to analyze the anti-cancer activities of HH044 *in vitro*. An immune-competent syngeneic melanoma mouse model was used to determine the anti-tumor activity of HH044 when administered orally (50 mg/kg/day) or intraperitoneally (10 mg/kg/day) for 21 days. A pharmacokinetic study of drug levels in serum and tumor samples was conducted after a single dose given intraperitoneally or orally using LC-MS/MS analysis at different time points.

Results: HH044 has high selectivity of nNOS over iNOS (340-fold) and eNOS (540-fold). The IC_{50} of HH044 in melanoma cell lines was 5.27 ± 3.3 μM, while iNOS inhibitor 1200W did not exhibit any cytotoxicity up to 100 μM concentration. Of note, nNOS blockade by HH044 did not result in reactivation of iNOS, and expression levels of iNOS were not changed after HH044 treatment. I*n vivo* studies demonstrated that HH044 treatment given intraperitoneally exhibited potent anti-tumor activity and reduced tumor weight to 45% of control. When administered orally, HH044 at 50 mg/kg significantly reduced tumor growth to 61% of control and extended mice median survival from 32 days to 53 days. Pharmacokinetic analysis showed that oral administration achieved sufficient drug levels in xenograft tumors, which were well above the K_i value (0.005 μM) despite a wide range of bioavailability. The drug level peaked at 2 hours after a single dose (2.27 ± 0.666 μM in the tumor and 23.68 ± 17.43 μM in the serum). Intraperitoneal injection achieved much higher levels in serum and tumor samples, which also declined slower compared to oral gavage administration. By 24 hours, the drug levels in serum and xenograft tumors remained at 1.55 ± 0.12 μM and 1.77 ± 0.24 μM concentration, respectively. No significant systemic toxicities were observed with HH044 treatments either given via *i.p.* injection or orally. Further *in vivo* studies combining nNOS inhibitors with immune checkpoint blockade are currently underway.

Conclusions: HH044, as the first-in-class nNOS inhibitor, exhibits potent anti-melanoma activity by oral administration. Developing selective nNOS inhibitors has shown to be a novel therapeutic strategy to improve melanoma treatment.

#5939 Enhancing nab-paclitaxel chemotherapy response in gastric cancer preclinical models through Inhibition of the HGF/c-Met pathway with merestinib.

Q. Kaurich, J. Huang, S. Hassan, U. Holzen, **N. Awasthi**;
Indiana University School of Medicine, South Bend, IN

Background: Current treatments for primary metastatic or recurrent gastric adenocarcinoma (GAC) primarily involve combination chemotherapy, but the median survival time remains under a year. Nab-paclitaxel has displayed significant antitumor activity in preclinical GAC studies. GAC often exhibits overexpression of various growth factors and their receptors, which play a critical role in its pathophysiology. Aberrant activation of the HGF/c-Met pathway has been reported in up to 50% of GAC patients. We investigated the therapeutic potential of merestinib, a novel inhibitor targeting c-Met, along with Axl and DDR1/2 pathways, in combination with nab-paclitaxel in GAC preclinical models.
Methods: Animal survival studies were conducted using peritoneal dissemination xenografts in NOD/SCID mice implanted with MKN-45 cells. Tumor growth was assessed in subcutaneous xenografts using MKN-45 and SNU-1 cells in NOD/SCID mice. IHC analyses were performed to evaluate tumor cell proliferation and microvessel density. *In vitro* cell proliferation and protein expression were assessed using the WST-1 assay and Western blot analysis, respectively.
Results: Animal survival significantly improved with nab-paclitaxel (118%) and merestinib (41%) individually. The combination of merestinib with nab-paclitaxel (153%) resulted in further increased animal survival. In MKN-45 xenografts with high c-Met expression, a substantial reduction in tumor growth was observed with nab-paclitaxel and merestinib, showing a synergistic response. The net change in tumor size in the control, nab-paclitaxel, merestinib, and combination groups was 503 mm^3, 115 mm^3, 91 mm^3, and -9.7 mm^3 (tumor regression). In low c-Met expressing SNU-1 xenografts, the effect of merestinib and nab-paclitaxel was less pronounced compared to MKN-45 xenografts. The net change in tumor size in the control, nab-paclitaxel, merestinib, and combination groups was 219 mm^3, 105 mm^3, 131 mm^3, and 57 mm^3. Tumor cell proliferation and microvessel density corroborated the tumor growth study results. Nab-paclitaxel and merestinib reduced *in vitro* cell proliferation, with an additive effect in combination. The reduction in cell proliferation by nab-paclitaxel (10 nM), merestinib (100 nM), and their combination was 87%, 82%, and 94% in MKN-45, 59%, 50%, and 82% in SNU-1, and 53%, 19%, and 66% in gastric fibroblasts. In MKN-45 cells, merestinib increased the expression of pro-apoptotic proteins and decreased the expression of phospho-c-Met, phospho-EGFR, phospho-IGF-1R, phospho-ERK, and phospho-AKT.
Conclusion: Merestinib has strong antitumor activity in GAC, especially when administered with nab-paclitaxel, demonstrating a synergistic effect. These results provide compelling evidence for the potential clinical relevance of this combination therapy in improving the survival of GAC patients.

#5940 JAB-30355: A highly potent, orally bioavailable p53-Y220C reactivator.

Q. Zheng, P. Wang, C. Liang, Y. Li, X. Sun, A. Li, W. Zhang, W. Long, Y. Wang;
Jacobio Pharmaceuticals Co., Ltd, BeiJing, China

Background: As a key tumor suppressor, p53 precisely regulates cellular events such as cell cycle arrest, apoptosis, senescence, and DNA repair under physiological conditions. In 50-60% of human cancers, *TP53* gene is mutated. The *TP53* Y220C is a hotspot loss-of-function mutation occurring in around 1% of solid tumors. Application of p53-Y220C reactivator for restoration of p53 function represents a promising treatment strategy for patients with this mutation.
Methods: The Induced Allosteric Drug Discovery Platform (IADDP), which integrates medicinal chemistry, biochemical and biophysical studies, and computational techniques, was applied for the development of JAB-30355. The proportion of p53-Y220C with wild-type protein-like structure after JAB-30355 treatment was determined by immunoprecipitation. Thermal shift assay was applied to assess the thermal stability of JAB-30355-reactivated p53-Y220C protein. DNA binding assay was developed to evaluate the *in vitro* DNA binding activity. p53-luciferase reporter system was developed to evaluate the cellular transcriptional activity. qPCR and Western blotting were performed to evaluate the transcriptional and translational levels of p53 downstream targets, respectively. CellTiter-Glo assay was performed to evaluate the inhibitory activity of JAB-30355 on the viability of tumor cell lines harboring wild-type or Y220C mutated *TP53*. *In vivo* PK-PD study was conducted to evaluate the relationship between JAB-30355 concentration and expression of p53 target genes. Multiple CDX and PDX mouse models harboring *TP53* Y220C were used to evaluate the antitumor activity of JAB-30355.
Results: Immunoprecipitation assay and thermal shift assay results demonstrated that JAB-30355 efficiently restored the wild-type p53-like structure and enhanced protein stability of p53-Y220C in a dose-dependent manner. In addition, JAB-30355 significantly enhanced the DNA binding activity of p53-Y220C and subsequently increased the expression of p53 target genes, such as *CDKN1A*, *MDM2* and *PUMA*. JAB-30355 inhibited cell viability of multiple *TP53* Y220C-mutated cancer cell lines with IC_{50}s ranging from 0.2 to 0.7 μM, and exhibited good selectivity against *TP53* wild-type cells. Overall, the *in vitro* data demonstrated that JAB-30355 is a potent and selective p53-Y220C reactivator. *In vivo* PK-PD study showed good correlation between JAB-30355 exposure and activation of p53 target genes. Furthermore, JAB-30355 exhibited dose-dependent anti-tumor activity, inducing tumor stasis or regression in multiple CDX and PDX models of ovarian cancer, pancreatic cancer, gastric cancer, and small cell lung cancer, with overall good tolerability.
Conclusions: JAB-30355 is a highly potent, selective, and orally bioavailable p53-Y220C reactivator that will be tested in clinical space soon.

#5941 Small molecule NSC59984 synergizes with PARP inhibitors in BRCA1 wild type ovarian cancer.

S. Zhang, L. Zhou, L. Zhang, M. Pinho-Schwermann, B. Carneiro, J. Sedivy, W. S. El-Deiry;
Brown University, Providence, RI

PARP inhibitors (PARPi) targeting poly (ADP-ribose) polymerase are the first clinically approved drugs designed to apply synthetic lethality in BRCA1 mutant/deficient cancer. However, the treatment can cause reversion of BRCA mutation which results in drug resistance. To explore new strategies to improve antitumor efficacy of PARPi, we applied PARPi in combination with a small molecule NSC59984 for cancer therapy. NSC59984 is a small molecular targeting mutant p53 degradation and activating p73 via ROS-ERK2-MDM2 pathway. The treatments with radiation or hydrogen peroxide showed that NSC59984 enhanced DNA comet tails and gamma-H2AX, correlated to reduction of rad51 foci in cancer cells. These results suggest that NSC59984 impairs DNA damage repair via abrogation of homologous recombination (HR). We further applied the combinational treatment of NSC59984 and PARPi in BRCA1 wild-type ovarian cancer cells and found that NSC59984 synergized with PARPi to reduce cell viability, inhibit colony formation, and increase cell death. The combination treatment enhanced DNA damage and correlated with reduction of BRCA1 at the protein level. These results, taken together, suggest that the induction of BRCAness causes a synthetical lethality with PARPi in BRCA1 wild-type cancer cells. Cell cycle profiling showed that the cells were arrested at the G2/M phase in response to combinational treatment. At the G2 phase arrest, the high doses of the combinational drugs led to cell death via mitotic catastrophe, and the intermediate doses induced cellular senescence defined by senescence phenotypic hallmarks including senescence-associated beta-gal staining and a secretome consistent with senescence-associated secretory phenotype (SASP). Therapy-induced senescence (TIS) in cancer cells is considered as one of the mechanisms of tumor recurrence and drug resistance. To reduce the risk of TIS in treatment, we applied senolytic treatment to target senescent cells in the combinational treatment. The senolytic drug ABT263 treatment eliminated the senescent cancer cells from the combinational treatment. ABT263, NSC59984 + PARPi combinational treatment further reduced cell viability. Our study provides a rationale for small molecular compounds targeting HR deficiency in combination with PARPi to treat BRCA1wild-type ovarian cancer cells, and additional senolytic treatment may be required to limit resistance by removal of the TIS.

#5942 Discovery of WRN inhibitors as targeted therapy in the treatment of microsatellite unstable (MSI-H) tumors.

W. Schonemann, A. Ludwig-Słomczyńska, &. Dudek, M. Krol, M. Farinone, U. Kulesza, W. Jasnosz, I. Mac, K. Zuchowicz, K. Wierzbicka, A. Buchcic-Szychowska, A. Gondela, A. Zagorska, O. Matuszewska, M. Sowińska, M. Nowogrodzki, M. Girardi, S. Paluch, S. Sukhomlinova, A. Chłopek, I. Levenets, K. Kozłowska-Tomczyk, K. Łagosz-Ćwik, M. Stoszko, S. Woroszyło, M. Mikulski, J. Jabłońska, M. Wiśniewska, K. Palus-Chramiec, P. Podkalicka-Gołda, A. Janiga, S. Sudoł-Tałaj, M. Sieprawska-Lupa, M. Miodek, J. Faber, R. Starczak, B. Winnik, A. Świrska, A. Kowal-Chwast, D. Gogola, S. Novak Ratajczak, A. Dudek, N. Gaud, G. Satała, A. Stachowicz, M. Swarbrick, K. Brzozka, **M. I. Zawadzka**;
Ryvu Therapeutics, Krakow, Poland

The synthetic lethality resulting from the inhibition of the WRN helicase protein has been observed in tumors characterized by high levels of microsatellite instability (MSI-H). This instability stems from a deficiency in the DNA mismatch repair (MMR) mechanisms, leading to the accumulation of DNA damage. This phenomenon is notably prevalent in 10-30% of colorectal, gastric, endometrial, and ovarian cancers. Specifically, the inhibition of WRN helicase activity induces DNA damage leading to cell cycle arrest and apoptosis exclusively in MSI-H cell lines. This selectivity underscores the therapeutic potential of WRN inhibitors, as they demonstrate efficacy against MSI-H cells while remaining non-toxic to microsatellite stable (MSS) cell lines. Ryvu is developing a chemical series of potent, selective WRN helicase inhibitors. Structure-based optimization facilitated the rapid expansion and delivery of a compound library with novel intellectual property (IP), demonstrating target engagement in cells and selective potency over other RecQ family members. The correlation between the cellular effect and selectivity upon treatment with these ligands was confirmed in the clonogenic assay, specifically in responder, microsatellite instable cell lines only, thereby leaving a substantial safety margin (>100x) relative to non-responder, microsatellite stable lines. Target engagement has been confirmed by dose dependent DNA damage pathway activation concomitant with WRN degradation in in vitro assays. The pharmacokinetic properties of these compounds are favorable for progressing to in vivo studies. The correlation between compound exposure and on-target effect was confirmed in PK/PD and efficacy studies in xenograft MSI-H cancer models. These data provide pharmacological proof-of-concept for the synthetic lethal effect of our inhibitors and support WRN inhibition as a new oncological therapy.

#5943 Development of a *SMART* theranostic agent for precision pancreatic cancer therapeutics.

E. A. Motea, J. J. Smith, O. Ketiku;
Indiana University School of Medicine, Indianapolis, IN

Pancreatic cancer is predicted to emerge as the second leading cause of cancer-related deaths in the United States by 2030. Pancreatic ductal adenocarcinoma (PDAC) - the most common form of pancreatic cancer - is often diagnosed as metastatic disease and has demonstrated the least improvement in overall survival over the last three decades with incidence rising by 0.5% to 1.0% per year due in part to lack of effective and tumor-selective treatment strategies. One approach to reduce host toxicity is the development of novel molecules and innovative therapeutic approaches that are nontoxic to normal cells but can be activated only under tumor-specific conditions for lethality, which we coined as SMART (Selective Method of Activation for Response in Tumors) therapeutic agents. We utilized explicit properties and biomarkers present in PDAC tumors but not in normal tissues to develop a SMART DNA-damaging anti-cancer agent with both therapeutic and diagnostic (theranostic) activities. We evaluated the tumoricidal effect of our SMART agent using long-term survival assays in PDAC cell lines and 3D co-culture spheroids, as well as in tumor xenograft model studies in mice. We also tested the ability of our SMART agent to treat, detect/diagnose (via click chemistry), and identify critical resistance mechanisms (via proteomics) as a single agent or as a chemosensitizer with predictive tumor biomarkers for tumor-selective therapeutic response. We found that our SMART small molecule induces tumor-selective lethal effects as a monotherapy or in combination with DNA repair inhibitors or small molecules known to generate hydrogen peroxide (H_2O_2) in a tumor-selective manner for activation. Using "click" chemistry, we detected and quantified the incorporation of our SMART small molecule as a DNA-damaging agent via flow cytometry that correlated with therapeutic response, which is a feature that could facilitate the stratification, treatment monitoring, and management of patients with pancreatic cancers. We also found that our SMART agent is less toxic and more effective as a monotherapy than cisplatin in PDAC cell line-derived xenograft studies in mice. Overall, our novel SMART theranostic agent could provide a significant advancement as they are preferentially activated under tumor-specific conditions to induce tumor-selective therapeutic response. Furthermore, the diagnostic component our SMART agent could provide oncologists with essential information to make rapid clinical decisions on treatment strategies. Our SMART agent is also remarkably versatile as it can be utilized as a chemosensitizer or as a chemical probe to identify targetable vulnerabilities to potentiate its therapeutic effects at lower doses.

#5944 Discovery of BH-30236: A novel macrocyclic CLK inhibitor targeting alternative splicing in cancers.

J. Cui, P. Jiang, W. Deng, D. Zhai, N. Ling, D. Li, Z. Wang, Y. Hu, L. Darjania, J. Whitten, E. Rogers, E. Rui;
BlossomHill Therapeutics, Inc., San Diego, CA

Aberrant alternative splicing is a newly recognized hallmark of cancer, that has been shown to play a critical role in tumorigenesis, cancer progression, and therapeutic resistance *via* multiple mechanisms, including increased proliferation, decreased apoptosis, promoted migration, enhanced metastatic potential, and induced evasion of immune surveillance. Serine and arginine-rich splicing factors (SRSFs) are RNA-binding proteins (RBPs) that regulate constitutive and alternative splicing. SRSFs are often mutated or overexpressed in cancers, resulting in widespread alterations in splicing patterns. The Cdc2-like kinase (CLK) family and dual-specificity tyrosine-regulated kinase (DYRK) phosphorylate SRSFs, influencing the assembly of spliceosome machinery, exon recognition, and splicing. Therefore, targeting CLK/DYRK kinases can modulate cancer specific splicing isoforms, opening avenues for new therapeutic interventions. BH-30236 was designed as a novel orally bioavailable, ATP-competitive, macrocyclic inhibitor of CLK with IC_{50}s of 0.134, 0.165, and 0.446 nM against CLK1, CLK2, and CLK4, respectively in enzymatic kinase assays. At clinically relevant concentrations, BH-30236 also inhibited DYRK1A/1B/2, proviral insertion site of moloney murine leukemia virus kinase 3 (PIM3), and FMS-like tyrosine kinase 3 (FLT3) with IC_{50}s of 0.111, 0.148, 0.562, 0.115 and 0.248 nM, respectively. In cancer cells, BH-30236 impaired the phosphorylation of SRSFs, Tau and 4EBP1, the direct downstream substrates of CLK, DYRK, and PIM kinases with IC_{50}s of 40-60 nM, ~50 nM, and ~80 nM, respectively. Furthermore, BH-30236 potently inhibited the FLT3 phosphorylation with an IC_{50} of 0.16 nM. Overall, BH-30236 regulated alternative splicing by primarily inducing skipped exons in favor of anti-tumor isoforms, leading to cancer cell death and growth suppression in a broad panel of cancer cell lines and *in vivo* efficacy studies. For example, BH-30236 potently inhibited cell proliferation with an IC_{50} of 0.62 nM in *FLT3-ITD* positive MV-4-11 cells and achieved complete tumor regression in the MV-4-11 cell-derived xenograft tumor model, even after dose cessation for 4 weeks. In MV-4-11 cells, BH-30236 increased pro-apoptosis splicing variant BCLxS, downregulated RNA expression of BCL2, MCL1, and AML stem cell markers CD33 and CD123. In addition, BH-30236 has demonstrated good human ADME and preclinical safety profiles. Collectively, the preclinical study results strongly support the clinical applications of the novel multikinase CLK inhibitor BH-30236 in hematological malignancies and solid tumors, as a single agent or in combination with other therapies.

#5945 Exploring the antiproliferative potential of KHS101 on triple negative breast cancer cell lines.

R. Gurung[1], A. W. Yirsaw[1], M. G. Khodary[1], T. Samuel[1], M. Sandey[2], C. C. Yates[3], D. Bedi[1];
[1]Tuskegee University, Tuskegee, AL, [2]Auburn University, Auburn, AL, [3]Johns Hopkins University, Baltimore, MD

Breast cancer is the second leading cause of cancer deaths in the world. Among its subtypes, triple-negative breast cancer (TNBC) is highly aggressive, particularly affecting African American (AA) women, with limited treatment choices. HSP60 protein promotes tumorigenesis and is being studied as a possible biomarker to treat cancers such as TNBC. The small molecule KHS101 specifically binds and inhibits the mitochondrial chaperone HSP60. In this study, we hypothesized that KHS101 would inhibit the proliferation of TNBC cells and therefore may have a therapeutic potential.We studied the antiproliferative effects of KHS101 on TNBC cell lines (MDA-MB-231, MDA-MB-468, HCC1806) through MTT cell proliferation and colony forming assays at varying doses and time points (24, 48, 72, and 96 hours). We performed cell cycle analysis to understand the cell cycle response and apoptotic events in treated or control cells. Additionally, the gene expression and frequently altered pathways resulting from KHS101 treatment were analyzed by RNA sequencing of cells treated with vehicle (DMSO) or with various concentrations of KHS101(1, 2.5, 5, and 7.5 uM) for 72 hours. We analyzed the data using GraphPad Prism and Microsoft Excel, with statistical significance set at $p \leq 0.05$.

TNBC cell lines exhibited significant dose-response and antiproliferative effects with increased KHS101 doses and treatment durations. Notably, AA breast cancer cells (MDA-MB-468) displayed heightened cytotoxicity and reduced proliferation compared to Caucasian American (CA) breast cancer cells (MDA-MB-231 and HCC1806). Cell cycle analysis revealed G2/M phase arrest, consistent with RNA sequencing data showing downregulation of the activation of ATM/ATR response in KHS101-treated cell lines compared to the controls. Gene set enrichment analysis indicated downregulation of the cell cycle control genes in MDA-MB-231 cells after 72 hours of KHS101 treatment (7.5 μM). Reactome pathway analysis in KHS101-treated MDA-MB-231 cells showed upregulation of IFN-gamma signaling and degradation of extracellular matrix. Similarly, Kegg pathway analysis showed upregulation in cell adhesion molecules, cytokine-cytokine receptor interaction, antigen processing and presentation, and Natural Killer cell-mediated cytotoxicity in KHS101-treated cancer cells compared to the controls. KHS101 demonstrates varying cytotoxic effects on TNBC cells, with potential implications for antitumor immune responses. Our findings highlight the distinct susceptibility of AA breast cancer cells and suggest KHS101 as a promising avenue for further research in understanding its mechanism of action and validating therapeutic potential in TNBC.

#5946 ZM-412, a potent and selective KIF18A inhibitor with robust efficacy as monotherapy in CIN-positive tumors and in combination with MMAE-conjugated ADC in CIN-negative tumors.

Feng Zhou[1], Lei Zhou[2], Ruina Wang[2], Liting Xue[1], Xiaokang Qin[2], Zhengtao Li[1], Jian Yu[2], Renhong Tang[1]

[1]State Key Laboratory of Neurology and Oncology Drug Development, Simcere Zaiming Pharmaceutical Co, Ltd., Shanghai, China, [2]Simcere Zaiming Pharmaceutical Co, Ltd., Shanghai, China

Chromosomal instability (CIN), a hallmark of human cancer, is defined as the perpetual missegregation of whole chromosomes during mitosis. KIF18A has emerged as a potential therapeutic target of synthetic lethality to induce CIN tumor cell death because it is more required for the proliferation of CIN tumor cells than normal diploidy cells. Here, we identified a potent and selective KIF18A inhibitor ZM-412. *In vitro*, ZM-412 inhibited the kinesin motor enzymatic activity with an IC_{50} less than 30 nM, and arrested OVCAR3 cells in the G2/M phase with an EC_{50} around 2.0 nM. ZM-412 also selectively inhibited the proliferation of a panel of CIN-positive tumor cell lines with IC_{50} values less than 50 nM, whereas it didn't affect the proliferation of CIN-negative cells such as PBMC and near-diploidy HCT116 as indicated by IC_{50} values over than 5 μM. A CIN-positive $HCT116^{CIN}$ model was established by cytochalasin D induction. Compared to parent HCT116 cells, it was sensitive to ZM-412 treatment, suggesting the high selectivity of ZM-412 to CIN tumors as monotherapy. Both KIF18A inhibitors and monomethyl auristatin E (MMAE) regulate microtubule dynamics, which provides a potential combination strategy. ZM-412 showed a significantly synergic effect with free MMAE or MMAE-conjugated ADC on the inhibition of proliferation in multiple kinds of cancer cell lines, including CIN-positive/negative tumor cell lines. *In vivo*, ZM-412 potently inhibited tumor growth in a dose-dependent manner in OVCAR3 and HT29 xenograft models. Moreover, ZM-412 showed a remarkable synergic effect on tumor growth inhibition with MMAE-conjugated LIV-1 ADC in OVCAR3 xenograft model. In conclusion, we discovered ZM-412 as a novel potent and selective KIF18A inhibitor, which has potential for the treatment of CIN cancers as monotherapy and for combination therapies for extended cancer types with MMAE-ADC.

#5947 Discovery of ACE-47228211, a highly potent and selective SOS1 inhibitor.

J. Wang, W. Li, S. Kumar, W. Pan, Z. Wen, T. Yin, G. Zhao, **K.-L. Yu**;
Acerand Therapeutics US, Carmel, IN

Dysregulation of receptor tyrosine kinase (RTKs) and KRAS signaling is the most frequent causes of cancer development and progression. SOS1 is one of the major guanine nucleotide exchange factors (GEFs) that facilitates the conversion of the inactive GDP-bound KRAS “off” state to the activated GTP-bound KRAS “on” state. SOS1 is therefore required for dysregulated RTKs, and wildtype and mutant KRAS proteins to drive cancer cells. In addition, SOS1 plays a crucial role in modulating the reactivation of the RAS/MAPK signaling upon the treatment of RAS/MEK/ERK inhibitors. Thus, blocking SOS1 and KRAS protein-protein interactions could be an effective strategy for targeting KRAS-MAPK driven cancers. Here, we report the discovery of a highly potent and orally bioavailable small molecule SOS1 inhibitor, ACE-47228211. This molecule has a unique novel scaffold. It exhibits an IC_{50} of 8.5 nM in the SOS1-KrasG12D (GDP) exchange assay and 5.0 nM in cellular ERK phosphorylation assay in H1957 cells. ACE-47228211 at 3 mg/kg (BID) demonstrated significant tumor growth inhibition in MiaPaca-2 KRAS G12C tumor model than MRTX0920 at 50 mg/kg (BID). When combined with Sotorasib (5 mg/kg QD), a Kras G12C inhibitor, ACE-47228211 at 3 mg/kg exhibited synergistic effect similar to MRTX0920 at 50 mg/kg. Further, ACE-47228211 demonstrated synergistic effects with EGFR and FGFR2 inhibitors in RTK mutant tumor models. ACE-47228211 has excellent ADME and physical properties with low risks of hERG, CYP inhibition and drug-drug interactions. The evaluation of ACE-47228211 in a safety panel of 87 targets and a kinase panel of >500 targets shows that this molecule has favorable selectivity and safety profiles. The molecule is currently in IND enabling stage of development.

#5948 FMC-376 a dual inhibitor of ON and OFF states of KRAS^{G12C} is broadly active in PDX models of resistance.

Y. Wang[1], R. M. Neve[2], J. Staunton[2], **K. R. Webster**[1];
[1]Frontier Medicines, Boston, MA, [2]Frontier Medicines, South San Francisco, CA

KRAS^{G12C} is a frequent activating mutation occurring in NSCLC, CRC, PDAC and other tumors that shifts KRAS into the active, GTP-bound (ON) state. KRAS was long considered undruggable until the recent discovery of single acting inhibitors, including those that bind the GDP-bound, inactive (OFF), state of KRAS^{G12C}. The most clinically advanced of these first-generation molecules have demonstrated clinical response rates of 37-43% and 6 to 7-month progression-free survival in lung cancer patients. While an important advance, a majority of cancers do not respond, and acquired resistance is common. FMC-376 is a next-generation dual inhibitor of both the ON and OFF states of KRAS^{G12C} with the potential to overcome resistance and deliver best-in-class durability of response. FMC-376 was discovered through the application of the Frontier^{TM} platform, which integrates chemoproteomics, machine-learning, and covalent fragment-based drug discovery. FMC-376 is a highly selective, irreversible inhibitor of KRAS^{G12C} that covalently binds to the mutant cysteine in KRAS^{G12C} and directly blocks the ON and OFF states of the mutant KRAS protein leading to a complete, durable blockade of downstream signaling. This further translates into more durable tumor regressions *in vivo* in comparison to OFF state inhibitors like sotorasib. Clinical resistance to first-generation inhibitors that can only bind the OFF state of KRAS^{G12C} has been associated with multiple mechanisms that drive upregulation of ON state KRAS^{G12C}. These known drivers of resistance include activating co-mutation/amplification/fusions of receptor tyrosine kinases, amplification of KRAS^{G12C} and non-mutational mechanisms that lead to paradoxical activation of KRAS^{G12C} due to release of negative feedback control upon KRAS inhibition, often referred to as adaptive resistance. In addition, multiple mutations that may act independently of KRAS are also associated with resistance. These include mutation of KEAP1, CDKN2A, SMARCA4, PI3K, PTEN, MTOR, HRAS, NRAS, RAF, and MAPK. *In vivo* profiling of FMC-376 against a panel KRAS^{G12C} mutant patient derived xenograft (PDX) models of NSCLC, CRC and PDAC, has demonstrated that dual inhibition of both ON and OFF KRAS^{G12C} leads to complete suppression and regression of tumors carrying a broad spectrum of known genomic and non-genomic (adaptive) drivers of clinical resistance to OFF state KRAS^{G12C} inhibitors. FMC-376 a clinical stage dual inhibitor of ON and OFF state KRAS^{G12C} has the potential to overcome limitations of single acting and OFF state KRAS^{G12C} inhibitors.

#5949 The clinical dual KRAS^{G12C} inhibitor FMC-376 has demonstrated potential as both a monotherapy and in combination for the treatment of patients with KRAS^{G12C} mutation positive NSCLC.

Y. Wang[1], A. Roberts[2], P. Calses[2], R. M. Neve[2], J. Staunton[2], **K. R. Webster[1]**;
[1]Frontier Medicines, Boston, MA, [2]Frontier Medicines, South San Francisco, CA

KRAS, a membrane-associated guanosine triphosphatase (GTPase), is the most frequently mutated oncogene in cancer with activating mutations occurring in approximately 25% of NSCLC. Of these, KRAS^{G12C} occurs in approximately 14% of adenocarcinomas and in 0.5 to 4% of squamous NSCLCs. This mutation impairs GTPase activity and GTP-hydrolysis leading to an increase in the active, GTP-bound (ON), state. KRAS was long considered undruggable until the recent discovery of inhibitors that bind the GDP-bound, inactive (OFF) state of KRAS^{G12C}. The most clinically advanced of these first-generation molecules have demonstrated clinical response rates of 37-43% and 6 to 7-month progression-free survival in patients with KRAS^{G12C} positive NSCLC. While significant, a majority of cancers do not respond, and acquired resistance is common. FMC-376 is a next-generation dual inhibitor of both the ON and OFF states of KRAS^{G12C}with the potential to deliver improved outcomes as both a monotherapy and in combination, for patients with KRAS^{G12C} positive NSCLC. FMC-376 was discovered through the Frontier^{TM} platform, which integrates chemoproteomics, machine-learning, and covalent fragment-based drug discovery. The potential for FMC-376 in the treatment of patients with KRAS^{G12C} mutant NSCLC has been assessed in a broad panel of NSCLC PDX models representing settings of sotorasib/adagrasib resistance, in a model of NSCLC CNS-metastasis and in combination with an immune checkpoint inhibitor. The dual ON + OFF state mechanism of action of FMC-376 is highly active across a panel of NSCLC CDX and PDX models, including those that carry co-mutations that are associated with both primary and acquired resistance to the OFF-state inhibitors adagrasib and sotorasib in NSCLC. These drivers of resistance include activating mutations of receptor tyrosine kinases (e.g. EGFR, MET, etc.), co-mutations including KEAP1 and adaptive resistance due to release of negative feedback control. Evaluation of FMC-376 in models where EGFR signaling is induced by EGF demonstrated rapid and durable target engagement in contrast to both sotorasib and adagrasib which show decreased effectiveness after EGF stimulation. As a result, FMC-376 is highly effective in NSCLC PDX models that have EGFR and MET upregulation. In addition, 27-42% of patients with KRAS^{G12C} positive NSCLC present with CNS metastasis. FMC-376 is highly active in an intracranial NSCLC model of CNS-metastasis, resulting in tumor regression. Furthermore, FMC-376 has demonstrated activity in combination with an anti-PD-1 mAb in a KRAS^{G12C} mutant mouse syngeneic tumor model. Together, these data demonstrate the potential of FMC-376, a next-generation clinical stage dual inhibitor of ON and OFF state KRAS^{G12C}, for the treatment of patients with KRAS^{G12C} mutant NSCLC as well as other KRAS^{G12C} positive tumors.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Novel Biologic Therapies and Therapeutic Targets
Poster Session

#5953 DUSP6 is a novel target in neuroendocrine tumors.

Majid Momeny[1], Vahid Khalaj[1], Solmaz AghaAmiri[1], Po Hien Ear[2], Servando Hernandez Vargas[1], Sukhen Ghosh[1], Ali Azhdarinia[1]

[1]The Univeristy of Texas Health Science Center Houston, Houston, TX,[2]Department of Surgery, University of Iowa, Iowa city, IA

Background: Neuroendocrine tumors (NETs) are rare malignancies derived from enterochromaffin cells of the diffuse neuroendocrine system and most frequently observed in the gastrointestinal tract and bronchopulmonary system. Surgery is the major treatment for localized NETs. In high-grade NETs, treatment opportunities include chemotherapeutic drugs such as temozolomide (TEM), and capecitabine and small-molecule targeted therapies such as everolimus or sunitinib. Despite promising initial responses, most patients develop therapy resistance by unknown mechanisms. Therefore, there is a pressing need to apprehend the mechanisms of resistance to improve the therapeutic efficacy of the current treatments. Phosphatases are emerging and novel targets in human malignancies and their modulation yields significant anti-tumor activities. Dual specificity phosphatase 6 (DUSP6) is a MAPK phosphatase and mainly binds to and dephosphorylates extracellular signal-regulated kinase (ERK)1/2. DUSP6 expression is increased in several malignancies, correlating with distant metastases and a worse clinical outcome. Moreover, DUSP6 mediates resistance to certain chemotherapeutics and small molecular tyrosine kinase inhibitors and its blockade increases therapeutic sensitivity. The current study aimed to investigate the contribution of DUSP6 to therapy resistance in the NET models.
Material and Methods: Using Western blot analysis, the expression of DUSP6 was measured in 8 clinical samples of small bowel neuroendocrine tumors, the NET cell lines BON-1, H69, IMR-32, QGP and H524 and two PDX models, 1452 (rectal neuroendocrine) and 913 (pancreatic neuroendocrine). The effects of DUSP6 depletion on cell viability were explored using a pharmacological inhibitor, BCI, and its siRNA-mediated knockdown. Moreover, BCI-mediated apoptotic cell death was measured by an annexin V/PI staining assay.
Results: DUSP6 expression was positive in 5 out of 8 clinical samples, 4 NET cell lines and both the PDX models. BCI treatment induced an apoptotic response in the NET models and synergistically increased sensitivity to TMZ and cisplatin in 1452 cells., RNAi-mediated depletion of *DUSP6* also increased sensitivity to sunitinib and triggered TMZ-induced apoptotic cell death in 1452 cells, which was associated with changes in (O^6-Methylguanine-DNA-methyltransferase) MGMT expression. These findings suggest that DUSP6 is an important therapeutic target in neuroendocrine tumors and its blockade is a promising therapeutic approach to enhance the therapeutic index of current treatments.

#5954 Big data-driven discovery of novel oncogenic fusion genes for anticancer therapy.

D. Kim[1], J. Park[2], J.-A. Kim[3], J.-H. Kim[4], T. Park[1], J. Park[1];

[1]Seoul National University, Pyeongchang, Korea, Republic of, [2]Hyundai Pharm Co., Gyeonggi-do, Korea, Republic of, [3]Korea Research Institute of Bioscience and Biotechnology, Daejeon, Korea, Republic of, [4]Korea Research Institute of Bioscience and Biotechnology, Deojeon, Korea, Republic of

The integration of big data analytics with cancer research is catalyzing a transformative approach in cancer treatment, primarily focusing on the discovery of novel and efficacious anticancer targets. Our study presents an advanced algorithm, specifically crafted to exploit the extensive data available in the field of oncology. We started with the genomic and clinical information of 8,864 patients with 33 different cancers (TCGA). Then we implemented the following algorithm to discover anti-cancer targets by analyzing the clinical significance (cBioPortal), drug development status (Cortellis), and oncogenicity (DepMap) of candidate genes: Candidate genes = {gene | gene ∈ Genes, [Frequency(gene) > 50, Drug(gene) ∈ {'biological testing', 'preclinical stage'}, Association(gene) ≥ 0.4, Publication(gene) ≤ 200] ∨ [Publication(gene) ≥ 200 ∧ Boolean(gene)]}. We employed this algorithm to analyze fusion genes, which represent promising anti-cancer targets known for their potential to elicit substantial clinical responses, but there is a high demand for new ones. We identified four druggable therapeutic targets out of a total of 15,291 fusion genes through the algorithm: frame-shifted FGFR3-TACC3, in-framed DLK1-RPS11, frame-shifted CHP1-RAD51B, and in-framed TBC1D22A-SMYD3. We conducted in vitro validation studies of these fusion genes in NIH3T3 cell lines, and it confirmed that all of the fusion genes not only produce mRNA and protein levels but also induce oncogenic effects on cellular behavior. In the case of FGFR3-TACC3, the introduced fusion gene induced mRNA ($p < 0.05$) and protein expression ($p < 0.05$) even when frame-shifted. In addition, the proliferation rate of transformed cells increased more than 4-fold on day 10 ($p < 0.0001$) and colony formation increased more than 5-fold on day 21 ($p < 0.01$) compared to wild-type cells. These results demonstrate the tumorigenicity of the fusion genes. Taken together, this study emphasizes the crucial role of big data in propelling oncology research forward. The algorithm we developed can offer a new pathway for creating innovative cancer treatment, marking a significant advancement in the realm of personalized cancer therapy.

#5955 *In vivo* precision therapy for glioblastoma using a nanodrug targeting microRNA-10b.

Bryan Doyun Kim[1], Elizabeth Kenyon[2], Ming Chen[2], Sujan Mondal[2], Ana deCarvalho[3], Anna Moore[2]

[1]Biomedical Engineering, Michigan State University, East Lansing, MI,[2]Radiology, Michigan State University, East Lansing, MI,[3]Henry Ford Health, Detroit, MI

Glioblastoma multiforme (GBM) is the most common and aggressive primary brain malignancy, which accounts for about half of all brain tumors. Notably, GBM has been shown to express high levels of microRNA-10b (miR-10b) compared to normal brain tissue, which expresses virtually no miR-10b. Importantly, the mounting body of evidence suggests that suppressing miR-10b in glioblastoma cells disrupts various pathways involved in tumor formation, ultimately leading to the suppression of tumor growth and an increase in apoptosis. We have recently reported that our experimental nanodrug targeting miR-10b (MN-anti-miR10b) effectively suppresses miR-10b expression, inhibits tumor cell migration and invasion, and decreases GBM cell viability *in vitro*. MN-anti-miR10b consists of an iron oxide core with cross-linked dextran, which acts as the delivery vehicle, and is further conjugated with Cy5.5 fluorophores and therapeutic anti-miR-10b locked-nucleic acid antagomirs. The iron oxide core provides MR imaging contrast while Cy5.5 enables optical imaging modalities *in vivo*. In this study, U251, human GBM cells, were orthotopically implanted in nude, athymic mice and injected via tail vein with PBS, scrambled antagomir vehicle control (MN-Scr), or MN-anti-miR10b (10 and 20 mg Fe/kg), beginning on day 7 post-implantation. Mice were injected with respective treatments once a week for 6 weeks before assessing changes in survival and expression of miR-10b. In one trial, we assessed the differences in survival between treatment groups after completion of the injection regimen and found that MN-anti-miR10b can increase survival compared to control groups. In another trial, mice were euthanized one week after the last injection and GBM tissues were assessed for miR-10b expression by qRT-PCR. RNA samples extracted from this trial have been submitted for RNA sequencing and differential gene expression analysis will be performed. Here, we demonstrated *in vivo* that MN-anti-miR10b can efficiently decrease miR-10b expression (57%) and increase median survival (MN-anti-miR10b: 54.5 days vs MN-Scr: 44 days vs PBS: 44 days) compared to PBS and MN-Scr treatment groups. These studies suggest the use of MN-anti-miR10b can be effective in the treatment of GBM *in vivo*.

#5956 *FLT3* alterations and inhibition in triple negative B-cell adult acute lymphoblastic leukemia patients.

Ordine Mauriziano, Torino, Italy

Backgroud: The prognosis of B cell ALL patients (pts) relapsing after Hematopoietic Transplant is poor and new drugs are needed. In acute myeloid leukemia, FLT3-inhibitors (FLT3i) are showing promising results in *FLT3*-mutated (mut) cases. Their potential use in *FLT3*-mut B-ALL has been poorly investigated.
Aim: To assess if *FLT3* could be a valid targetable marker in B-ALL.
Methods: We sequenced with a capture based large RNA-seq panel (1385genes) 183 adult B-ALL [n=52 Pos for Ph or t(4;11) or t(1;19) and n=131 Triple-Negative (TN) pts that are negative for Ph (n=43), t(4;11) and t(1;19) translocations] and 15 donors. To confirm *FLT3* muts, 13 available samples were further sequenced with Extended Myeloid Solution (98 genes; SOPHiA) where *FLT3* gene is fully covered. *In vitro* studies using 5 FLT3i [Gilteritinib (Gil), Midostaurin, Crenolanib, Sorafenib and Quizartibin] and Venetoclax (Ven) were conducted on pt primary cells and on TN and other B-ALL cell lines (MUTZ5, MHH-CALL4 Ph-like; NALM6;RS4;11, 697, REH) and 2 AML cell lines (OCI-AML3 FLT3;MV-4-11 FLT3-ITD).
Results: We found 15 *FLT3* mut in 14/131 TN B-ALL and in 1/43 Ph+ cases: 43.8% were TKD mut, 3 ITD mut, 3 splicing site mut,1 N-terminal, 1 juxta-membrane domain and 1 Ig-like site (Fig. 1A). After pathogenicity interpretation we excluded 3 variants and one mutation was not confirmed at DNA level. Overall 7.6% of TN were mut (Ph+ 2.3%). 81.8% of *FLT3*mut pts potentially druggable with FLT3i, mainly TKD (63.3%). Targeted NGS revealed the co-occurrence with other mutations (range 2-15), and in particular with *CSMD1* (n=4), *KDM6A, KMT2D* and *CREBBP* (n=3) alterations. Moreover, 11/13 samples carried copy number alteration (mean 12), mostly amplifications. *CDKN2A & IKZF1* were the most frequently altered genes (n=5;4 CN-loss). *FLT3* expression was increased in 11/15 cases compared to donors and wt pts. As reported, the expression was higher in *ZNF384* or *MLLr* B-ALL subtypes.To evaluate the effect of FLT3is in ALL, we treated *ex vivo* primary leukemic cells of 6 adult ALL patients (*FLT3*-mut n=4; *FLT3*-wt n=2) with increasing concentrations of 5 FLT3i for 24, 48 and 72h. We observed a trend towards greater response of *FLT3*-mut ALL cells compared to wt ones. The average IC50 values in response to the five FLT3i was 1.6 uM and 24.5 uM after 72h of treatment in *FLT3*-mut and *FLT3*-wt B-ALL, respectively (Fig. 1B). We than evaluated the sensitivity to the 5 Inhs in all cell lines. Interestingly MHH-CALL4 wt were more sensitive to Gil compared to OCI AML3 wt, and showed the same effect compare to MV-4-11 AML mut (F.1C). Given the effect of Gil in single agent, we combined it with Ven in wt B-ALL cells at increasing concentrations. Interestingly We noticed a strong additive effect with the higher Gil concentration and all Ven doses(F.1D).
Conclusions: *FLT3* alterations identify a novel subgroup of TN B-ALL with therapeutic potential also in combination regimens. Ricerca Corrente Italian MoH L3P1946.

#5957 Development of a selective, oral ATP-competitive CDK9 inhibitor, BLX-3030, for treatment of pancreatic cancer.

Y. Barrera-Millan[1], Z. Li[2], H. Vankayalapati[2], D. J. Bearss[2], D. D. Von Hoff[1], H. Han[1];
[1]TGen (The Translational Genomics Research Institute), Phoenix, AZ, [2]Biolexis Therapeutics, American Fork, UT

Introduction Transcription regulators, such as cyclin-dependent kinase 9 (CDK9), have been implicated in the super-enhancer driven transcriptional control of oncogenes in multiple cancers including pancreatic cancer. CDK9 has been shown to be employed by cancer cells for the constant production of short-lived oncoproteins such as c-Myc to maintain their survival. Due to its critical role in regulating transcription in cancer cells, CDK9 has emerged as a potential therapeutic target. Here, we report the antitumor activity of a selective, oral ATP-competitive CDK9 inhibitor, BLX-3030, in preclinical models for pancreatic cancer.

Experimental Procedures Fragment-based MolecuLern driven AI workflow methods were used to design a series of ATP-competitive CDK9 specific kinase inhibitors. BLX-3030 was selected as one of the most potent leads with an IC_{50} of 1.1 nM in a cell-free CDK9 kinase assay. A Sulforhodamine B (SRB) assay was used to evaluate the cell growth inhibitory activity of BLX-3030 in a panel of 10 pancreatic ductal adenocarcinoma (PDAC) and 2 pancreatic neuroendocrine tumor (pNET) cell lines. Western blotting was used to determine the effects of BLX-3030 treatment on c-Myc expression in cancer cells. The combination effects between BLX-3030 and standard of care regimen, gemcitabine (GEM) and nab-paclitaxel (NP), was assessed using the SRB assay. Finally, the *in vivo* antitumor activity of BLX-3030 alone or in combination with GEM and NP was evaluated in a mouse cell line xenograft model for pancreatic cancer.

Results BLX-3030 exhibited potent cell growth inhibitory activity in the panel of pancreatic cancer cell lines with IC_{50} values ranging from 133.5 nM to 508.1 nM. The potency of BLX-3030 in the cell lines appears to correlate with the expression level of c-Myc in the cell lines. BLX-3030 showed similar activities in PDAC and pNET cell lines with mean IC_{50} values of 244.5 nM and 194.6 nM, respectively. However, treatment with BLX-3030 for 48 hours did not seem to significantly reduce c-Myc expression in PSN-1 PDAC cells. When combined with GEM and NP, BLX-3030 demonstrated mostly additive effects in PSN-1 cells. Preliminary data from the *in vivo* study show that BLX-3030 improves the antitumor activity of GEM and NP.

Conclusion In summary, BLX-3030 potently inhibited the growth of both PDAC and pNET cells *in vitro*. The growth inhibitory activity of BLX-3030 in PDAC cell lines correlates with their c-Myc expression levels. BLX-3030 showed an additive effect when combined with standard of care drugs (GEM and NP) in PDAC cell lines. Overall, the novel CDK9 inhibitor, BLX-3030, demonstrated potent activity in pancreatic cancer cell line models and presents a promising preclinical lead for pancreatic cancer. (This work was supported in part by Biolexis Therapeutics and the Seena Magowitz Foundation).

#5958 Exploring AKR1C3 as a therapeutic target to overcome erlotinib resistance in lung adenocarcinoma.

W. C. Cho, K. P. Li, C. F. Wong, K. Y. Fung, J. C. H. Chow, K. M. Cheung, J. C. H. Chan, E. Y. T. Lau;
Queen Elizabeth Hospital, Hong Kong SAR, China

Introduction: Erlotinib has demonstrated promising efficacy in lung adenocarcinoma (LUAD) patients with epidermal growth factor receptor mutation. However, the development of resistance to erlotinib poses a significant challenge in achieving long-lasting treatment responses. Aldo-keto reductase family 1 member C3 (AKR1C3) is associated with tumor progression, drug resistance, and unfavorable prognosis. This study aims to assess the potential of AKR1C3 as a therapeutic target for overcoming erlotinib resistance in LUAD.

Methods: AKR1C3 expression was assessed in paired tumor tissues from 100 LUAD patients using reverse transcription quantitative polymerase chain reaction. Both in vitro and in vivo experiments were categorized into four treatment groups: a saline control (CTR), erlotinib (ER), an AKR1C3 inhibitor 3-(4-trifluoromethyl)phenylamino)benzoic acid (BA), and the combination of erlotinib with the AKR1C3 inhibitor (COM). An erlotinib-resistant cell line was established from the LUAD cell line HCC4006. The MTS assay was used to evaluate cell proliferation and viability. The combined effect of erlotinib and the AKR1C3 inhibitor was assessed using Synergyfinder and CompuSyn calculation software. Both cell line-derived xenograft (CDX) and patient-derived xenograft (PDX) models of erlotinib resistance to LUAD were established in NSG mice. The mice received daily oral gavage administration of the drugs for 31 days, while tumor volume was monitored biweekly.

Results: AKR1C3 expression was significantly upregulated by more than three-fold in LUAD tumor samples compared to normal counterparts ($p < 0.0001$). After 24 hours of treatment in erlotinib-resistant cells, the ER and BA groups exhibited inhibition rates of 7% and 9%, respectively, while the COM group demonstrated a substantially higher inhibition rate of 45%. Synergyfinder and CompuSyn analysis revealed a synergy score of 12 and a combination index of 0.5 for the COM group, indicating a robust synergistic effect between the two drugs. In the CDX model, the COM group exhibited a tumor volume reduction of 25% in erlotinib-resistant cells and 64% in parental cells compared to the CTR group. In the PDX model, the COM group displayed a significant reduction of 50.4% in tumor volume compared to the CTR group. There was no significant difference in the weight of body and internal organs among the four treatment groups in both xenograft models.

Conclusions: AKR1C3 overexpression was observed in the tumor tissues of LUAD patients. The combination of erlotinib and AKR1C3 inhibitor showed promising efficacy in overcoming erlotinib resistance in both *in vitro* and *in vivo* experiments. These findings highlight AKR1C3 as a potential therapeutic target for managing erlotinib resistance in LUAD patients. Targeting AKR1C3 represents a novel approach to overcome resistance and enhance treatment outcomes in LUAD patients undergoing erlotinib therapy.

#5959 Targeting TRIM11 is a potential therapeutic strategy for malignant gliomas.

K. Di[1], B. C. Das[2], D. A. Abrams[3], D. A. Bota[1];

[1]University of California, Irvine, Irvine, CA, [2]Arnold & Marie Schwartz College of Pharmacy & Health Sciences, Long Island University, Brooklyn, NY, [3]Mercy Medical Center, Cedar Rapids, IA

Background: TRIM11 (tripartite motif-containing protein 11) belongs to the TRIM/RBCC (the RING B-box coiled-coil) family of E3 ubiquitin ligases. Emerging evidence has demonstrated that TRIM11 is a novel target against cancer and neurodegenerative diseases as it plays vital role in cellular proliferation, differentiation, tumor progression, and apoptosis. Our previous work demonstrated that TRIM11 is over-expressed in high-grade gliomas and promotes proliferation, invasion, migration and tumor growth, suggesting that TRIM11 may be used as a target for malignant glioma treatment. The tumor suppressor p53 plays critical roles in tumor prevention, and deregulated p53 pathway has been found in a majority of glioblastomas (GBMs). Recent studies have shown that TRIM proteins are involved in the regulation of p53, and TRIM proteins are also regulated by p53.

Methods: To evaluate the effect of TRIM11 on GBM progression *in vivo*, we intracranially implanted GBM cells over-expressing TRIM11 in immunocompromised mice, and the animal survival was monitored. We have synthesized a series of TRIM11 inhibitors and evaluated their anti-GBM potential *in vitro*. Furthermore, we tested the crosstalk between TRIM11 and p53 by knocking down TP53 through RNA interference.

Results: Our *in vivo* data showed that the control group mice (GL261 parent line) survived longer than the mice bearing TRIM11 over-expressing GL261 tumors ($p<0.05$), suggesting TRIM11 enhances tumor progression *in vivo*. *In vitro* data showed that the oncogenic effect of TRIM11 may be related to its influence on the apoptosis pathway since a robust induction of poly (ADP-ribose) polymerase (PARP) was observed in TRIM11 over-expressing GBM cells. When treated with Temozolomide (TMZ), TRIM11 over-expressing cells were more resistant and showed a higher survival rate compared to parental cells. We screened a small library of TRIM11 inhibitors (~ 25 compounds), and identified several compounds which significantly inhibited the growth of both established and primary GBM cells in a dose-dependent manner, implicating that TRIM11 inhibitors may serve as novel agents for GBM treatment. We found that inactivation of p53 by siRNA increased the expression of TRIM11 and modulated the sensitivities of GBM cells to chemotherapy drugs.

Conclusion: Despite remarkable advances in the prognosis and multidisciplinary treatment strategies, GBM is still the most lethal primary brain tumor, and there is a pressing need for newer anti-GBM agents with novel targets and mode of action. Our preclinical studies demonstrate a significant anti-tumor effect of TRIM11 inhibitors on malignant glioma cells. Our finding that TRIM11 may be modulated by p53 adds a new layer of regulation to this complicated signaling pathway. A better understanding of the crosstalk between p53 and TRIM11 will benefit the clinical application of targeting p53 and TRIM11 signaling pathways for therapeutical indications in GBM.

#5960 Targeting CDK8: A translatable therapeutic approach for fusion-positive aRMS.

S. Zhang[1], C. Malone[1], B. Guedes[2], K. Engel[1], M. Just[2], K. Ross[1], A. Fahs[2], G. Digiovanni[1], D. Granum[2], R. Bentley[2], L. Barbar[2], C. Cerda-Smith[2], E. mendes[2], O. Erdogan[2], A. Kovach[2], K. Oristian[2], S. Zimmerman[2], J. F. Shern[3], K. Wood[2], C. Counter[2], C. M. Linardic[2], K. Stegmaier[1];
[1]DFCI/Harvard Medical School, Boston, MA, [2]Duke University School of Medicine, Durham, NC, [3]National Institute of Health, Bethesda, MD

Alveolar rhabdomyosarcoma (aRMS), characterized by poor overall survival and limited advancements in therapy over the past four decades, poses a great challenge in childhood cancer treatment. More than 60% of high-risk aRMS is driven by the oncofusion protein PAX3-FOXO1. The direct targeting of transcription factor fusions, however, is quite difficult. Given that PAX3-FOXO1 is reported to drive disease by controlling transcriptional programs to maintain an undifferentiated myoblastic state, an alternative approach would be to target the transcriptional machinery recruited by the fusion. To identify potential novel targets in aRMS, we utilized the Broad Institute's Cancer Dependency Map dataset, a collection of genome-wide CRISPR-Cas9 screens performed in over 1000 cancer cell line models. We focused on druggable dependencies that are selective to fusion-positive aRMS and intersected this data with PAX3-FOXO1-associated transcriptional complexes. Among these candidates, we identified CDK8 as a top selective dependency. Importantly, other components of the CDK8 kinase module in the mediator complex, such as CCNC, also scored as a strong selective dependency in fusion-positive aRMS. CDK8 expression is notably elevated in aRMS tumors compared to other pediatric tumors, and aRMS cell lines exhibit significantly higher CDK8 protein levels than non-transformed primary skeletal muscle cells.

We next validated these in silico results through the application of shRNA knockdown, CRISPR knockout, and the use of CDK8 kinase inhibitory small molecules, including BI-1347, SEL-120-34A, and JH-XII-178, which demonstrated on-target activity as assessed by STAT1^{Ser727} phosphorylation. Both genetic loss of CDK8 function and kinase inhibition impaired aRMS cell line growth *in vitro*. *In vivo* studies demonstrated a significant inhibition of xenograft tumor growth with both doxycycline inducible CDK8-directed shRNAs and with pharmacologic inhibition of CDK8 with SEL120-34A treatment. To understand the mechanisms by which CDK8 inhibition impairs aRMS growth, we evaluated the transcriptional consequences of CDK8 inhibition by RNA-sequencing in aRMS, as well as the chromatin accessibility by ATAC-sequencing. We discovered that loss of CDK8 led to gain of chromatin accessibility and the upregulation of hallmark genes involved in myogenesis, such as *MYH3*, *MYOG*, *MEF2C*, and *MYBPH*, as well as alteration of PAX3-FOXO1 gene expression programs. We next validated this differentiation phenotype both *in vitro* through detection of increased myogenin staining by immunofluorescence and *in vivo* by visualization of myofibrils in the xenograft tumors and increased myoglobin quantified by qRT-PCR after CDK8 inhibition.

In conclusion, this work identifies CDK8 as a novel and readily translatable therapeutic target in fusion-positive aRMS laying a robust foundation for further mechanistic and preclinical studies.

#5961 NRF2-responsive kinases in esophageal squamous cell carcinoma.

B. Subramaniyan[1], Z. Xiong[2], C. Paiboonrungruang[2], Y. Li[1], M. Ben Major[3], X. Chen[1];
[1]Cooper University Health Care, Camden, NJ, [2]Coriell Institute for Medical Research, Camden, NJ, [3]Washington University in St. Louis, St. Louis, MO

Esophageal squamous cell carcinoma (ESCC) ranks as the 7th most frequently diagnosed cancer and the 6th leading cause of cancer-related death worldwide. NRF2 is identified as a therapeutic target for human ESCC, with a mutation rate of approximately 10-22%. Hyperactive NRF2 promotes proliferation, metastasis, and resistance to radiation and chemotherapy in ESCC. Although some evidence suggest NRF2 regulates kinases which contribute to these phenotypes, it remains unclear which kinases are responsive to hyperactive NRF2. Using NRF2 ChIP-seq analysis, we have enrichment of 42 kinases including *Akt2* and *Pkm* and 31 phosphatases including *Pten* and *Dusp16* enriched in the *Keap1*$^{-/-}$ mouse esophagus in comparison with the wild-type esophagus. We further confirmed the binding of NRF2 to the promoter regions of mouse *Akt2* and *Pten*. mRNA expression profiling revealed enrichement of the PI3K/AKT, RAS, ERK, and GSK3 pathways in the *Keap1*$^{-/-}$ esophagus as compared to the *Nrf2*$^{-/-}$;*Keap1*$^{-/-}$ esophagus. Immunohistochemical staining showed that pAKT, p-mTOR, pS6, PKM2 were overexpressed in the *Keap1*$^{-/-}$ esophagus, as well as in the adult NRF2-hyperactive esophagus (*Sox2CreER;LSL-Nrf2*$^{E79Q/+}$). Using PhosphoExplorer array and PamChip array to analyze *NRF2*^{W24C}-KYSE70 cells (in comparison with *NRF2*^{null}-KYSE70 cells) and *Sox2CreER;LSL-Nrf2*$^{E79Q/+}$ mouse esophageal epithelium in comparison with wild-type mouse tissue, we further identified multiple kinases including PI3K as potential NRF2-responsive kinases. These findings suggest a potential role for kinases such as PI3K in NRF2-driven ESCC, and support the idea of targeting both NRF2 and NRF2-responsive kinases as a therapeutic strategy for ESCC.

#5962 Novel xCT-targeted biologics significantly suppress metastasis, improve survival, and sensitize primary tumors to chemotherapy in TNBC xenograft models.

H. Gong[1], J. Li[1], C. Becker[1], L. Timmerman[2], S. Sikandar[3], **Y. Huang**[1];
[1]Xomics Biopharma, Inc., Redwood City, CA, [2]University of California, San Francisco, CA, [3]University of California, Santa Cruz, CA

Background: Triple negative breast cancer (TNBC) is a highly heterogeneous subset of breast cancer, which has the worst prognosis and lacks specifically targeted therapeutic options. The TNBC subtype termed M/MSL is enriched with cells of high mesenchymal state and increased stemness, and is particularly resistant to current therapies[1,2]. But this cancer cell phenotype is susceptible to ferroptosis, hence targeting these aggressive tumors with ferroptosis inducers such as xCT inhibitors (xCTi) is an attractive alternative. The cystine/glutamate exchanger xCT/*SLC7A11* plays a key role in maintaining redox homeostasis in cancer cells. xCT is expressed on subsets of most solid tumors, including stem/progenitor and metastatic tumor cells. xCT inhibition yields a variety of anti-proliferative phenotypes including death by ferroptosis[3]. xCT knockout mice exhibit normal development and lifespan. Altogether, targeting xCT outside of CNS may potentially have widespread clinical utility in cancer treatment.
Results: We present preclinical data demonstrating development of novel, first-in-class xCT-targeted biotherapeutics (AX68c, AX76c) using studies in TNBC cell lines *in vitro* and in xenograft. We find that these agents have highly favorable pharmacokinetics, with FcRn-dependent serum half-lives greatly exceeding those of known small molecule xCTi. *In vitro*, AX68c or AX76c reduces glutathione levels in TNBC cells in accord with inhibition of xCT function. Analysis of anti-proliferative effects in a panel of TNBC cell lines revealed particular potency against those of M/MSL phenotype (IC50s 0.3-1uM). We further tested the susceptibility of the mesenchymal phenotype to AX68c and found that EMT induction in epithelial cancer cells significantly increased sensitivity in a ferroptosis-dependent manner. In wildtype and immunodeficient mice, AX68c is well tolerated at steady-state serum concentrations that are 15-300 fold of its *in vitro* IC50s in tested TNBC cells. In orthotopic MDA-MB-231 xenografts, AX68c treatment significantly reduced tumor metastasis and sensitized primary tumors to cisplatin and paclitaxel. Bulk RNAseq and GSEA analysis on primary tumors revealed treatment associated alterations in key cancer signaling pathways such as TGFβ, INFγ and TNFα/NFκB. In MDA-MB-436 orthotopic xenografts, AX68c alone led to significantly improved survival primarily through abrogating metastasis. Combining AX68c and cisplatin further prolonged survival through concurrent suppression of metastasis and primary tumor growth.
Conclusions: We conclude that our anti-xCT biologics may provide novel targeted therapies for M/MSL-subtype TNBC and metastatic tumors with a large mesenchymal component.

#5963 VGLL1-derived peptides demonstrated anticancer effect by inhibiting VGLL1-TEAD4 interaction.

S. Ock[1], C. Lee[1], W. Jung[1], I. Whang[2], K.-S. Kim[1], J. Han[1], S. Yim[1], B.-K. Kim[3], H.-S. Lee[1], K.-Y. Chang[1], **M. Won**[3];
[1]OneCureGEN Co., Ltd, Daejeon, Korea, Republic of, [2]Ewha Womans University, Seoul, Korea, Republic of, [3]Korea Research Institute of Bioscience & Biotechnology (KRIBB), Daejeon, Korea, Republic of

YAP/TAZ, cofactors of TEA domain-containing transcription factor TEADs (TEAD1-4), play a key role in the HIPPO pathway, which is involved in various function including embryonic development, organ size, cell proliferation, tissue regeneration, and the development and progression of several cancers. YAP/TAZ is therefore considered as master regulators of various cancers. However, we are interested in VGLL1, a cofactor of TEAD4, because it is mainly involved in the proliferation and metastasis of various cancers, including gastric, breast, pancreatic, and ovarian cancers. In gastric cancer, VGLL1 expression is regulated by the PI3K/AKT/β-catenin pathway. VGLL1 is then phosphorylated at S84 by TGF-β/ribosomal S6 kinase 2 (RSK2) and interacts with TEAD4 to express target genes such as MMP9, cyclin D1, IGFBP3, IGFBP5 and ITGαV. which are involved in cancer malignancy. We designed S84-containing VGLL1-derived peptides (VGLL1S84 peptides, SCVP), which consist of 7 to 15 amino acids linked to CPP, a cell-penetration peptide. We evaluated SCVP to inhibit the VGLL1-TEAD4 interaction and their therapeutic potential as anticancer agents. SCVP suppressed the growth of gastric and breast cancer cells expressing high levels of VGLL1, EGFR, and/or HER2. In the RNA-seq analysis of NUGC3 to elucidate the molecular mechanisms of SCVP induced cell death, SCVP-treated cells showed gene expression changes in metabolic pathway, RAS signaling, PI3K-AKT signaling, Wnt signaling, TNF signaling, and mTOR signaling. However, RNA-seq analysis of breast cancer cells treated with SCVP showed changes in the expression of genes involved in cell cycle, DNA replication, DNA repair, and apoptosis. Then, we performed CRISPR/Cas9 screening using SCVP and sgRNA library to explore companion biomarkers and genetic interactors of VGLL1 for targeted cancer therapy. As a result, we identified several candidate genes, including ZNF292 and PLK1, as synthetic lethal genes of VGLL1. As expected, HCC70 cells with ZNF292 mutation showed increased sensitivity to SCVP. We also found that SCVP in combination and the PLK inhibitor volasertib resulted in a synergistic effect on the growth inhibition of breast cancer cells. In conclusion, we demonstrated VGLL1 as a novel target for anticancer drug development, and elucidated the molecular mechanism and therapeutic potential of the SCVP in gastric and breast cancers.

#5964 Design and anticancer biological evaluation of novel 7-aza-8,9-methylenedioxyindenoisoquinoline derivatives that inhibit MYC and topoisomerase I.

Y. Han[1], **L. Chen**[1], A. Buric[1], V. Chintareddy[2], P. Chand[2], R. Riggs[3], M. Cushman[1], D. Yang[1];
[1]Purdue University, West Lafayette, IN, [2]Therachem Research Medilab LLC, Chelsea, AL, [3]Gibson Oncology LLC, Miami, FL

MYC is one of the most validated driver oncogenes and is overexpressed in most human cancers. However, the MYC protein is considered “undruggable” due to its disordered structure and difficulties associated with targeting transcription factors. The *MYC* gene promoter forms G- quadruplex, a four-stranded non-canonical DNA secondary structure. The *MYC* G-quadruplex functions as a transcription silencer and further inhibits *MYC* expression upon drug binding, representing an exciting approach for MYC-targeting cancer therapy. Indenoisoquinolines are topoisomerase I inhibitors with better physicochemical and biological properties than the clinical camptothecin drugs. We previously revealed a novel mechanism of action for active anticancer indenoisoquinolines by dual inhibition of MYC and topoisomerase I, where potent MYC inhibition was achieved through targeting its promoter G-quadruplex. Herein, we report the design, cellular activity, and in vivo efficacy of novel anticancer 7-aza-8,9-methylenedioxyindenoisoquinoline derivatives based on optimized substituents and π-π stacking interactions. Using biophysical, biochemical, and cellular assays, we demonstrated that the new indenoisoquinoline derivatives greatly stabilized the *MYC* promoter G-quadruplex, significantly lowered MYC protein and mRNA levels in cancer cells, and inhibited topoisomerase I activity. A *MYC* G-quadruplex mediated mechanism of action was evident by differential activities in Raji vs CA-46 cells. The importance of MYC targeting was corroborated by potent cytotoxicity against a panel of MYC-dependent cancer cell lines as well as the NCI-60 panel of human cancer cell lines. The top three candidates were evaluated for pharmacokinetics and in vivo anticancer properties. Excellent metabolic stability, bioavailability, and tumor accumulation were observed in xenograft mouse models. Potent and significant tumor growth inhibition was demonstrated in the aggressive RD-ES Ewing Sarcoma xenograft mouse model while the drugs were well-tolerated. In addition, favorable brain penetration and pharmacokinetics were established, which encourage future evaluations in difficult-to-treat brain tumors. In conclusion, we designed and developed 7-aza-8,9-methylenedioxyindenoisoquinoline derivatives that are dual inhibitors of MYC and topoisomerase I. Our drug candidates demonstrated excellent pharmacokinetics and in vivo anticancer activities with promising indications in MYC-dependent cancers.

#5965 First-in-class chemical induced proximity system achieves dose-dependent control of *TP53* activation in gastric cancer.

R. M. Kemper, T. J. Nelson, N. A. Hathaway, D. J. Crona;
UNC Eshelman School of Pharmacy, Chapel Hill, NC

Background: Gastric cancer (GC) remains a common and deadly disease, and inactivating *TP53* mutations occur in up to 68% of GC tumors. p53 is a master regulator of multiple cellular pathways, such as the cell cycle, apoptosis, and senescence. Previously, we demonstrated the ability to activate endogenous target gene expression using a novel chemical induced proximity system comprised of deactivated Cas9 (dCas9) and "chemical epigenetic modifiers" or "CEMs" (PMID: 31712774). In this study, we applied our dCas9-CEM system for the first time in oncology to activate *TP53* gene expression and selectively kill targeted cells in a preclinical model of GC.

Methods: AGS cells were derived from a gastric adenocarcinoma, and harbor wild-type *TP53*. They were transduced with our dCas9 system and either sgRNAs targeting *TP53 or a* non-targeting (NT) sgRNA. After 48 h CEM87 incubation (1-25 nM), expression of *TP53* and downstream targets (*CDKN1A and BBC3)* were evaluated by RT-qPCR. After 48 h CEM87 incubation (0.1-25 nM), colony-forming potential was assessed by crystal violet staining after 10 days. After 24 h incubation (5-25 nM), cells were fixed and stained with propidium iodide (PI), and DNA content was assessed by flow cytometry to determine cell cycle fractions. After 48 h incubation (50-200 nM), cells were fixed and stained with Annexin V and PI, and apoptosis was assessed by flow cytometry. Last, cells were treated with nine ascending concentrations (10 pM-100 μM) for 48 h, and cell viability was measured using CellTiter-Glo™. IC_{50} values were calculated using four-parameter non-linear regression.

Results: AGS-*TP53* cells show significantly increased expression of *TP53* and downstream target genes *CDKN1A* and *BBC3* versus AGS-NT cells after 10 nM CEM87 (105%, 99%, and 43% increase, *P*=0.004, 0.002, and 0.03, respectively; n=3). Colony formation was significantly reduced in AGS-*TP53* versus AGS-NT cells after 10 nM CEM87 (60.2% reduction, *P*=0.003; n=3). Treatment with 10 nM CEM87 also led to a G2/M stall after significantly reducing cells in both G1 (47.4% vs 38.9%, *P*<0.0001; n=3) and S-phase (25.1% vs 20.3%%, *P*<0.0001; n=3) in AGS-*TP53* versus AGS-NT cells. Treatment with 200 nM CEM87 significantly increased early apoptosis in AGS-*TP53* versus AGS-NT cells (28.7% vs 6.6%, respectively, *P*<0.0001; n=3). Last, CEM87 was 50 times more potent in AGS-*TP53* cells than AGS-NT cells (IC_{50}: 3 vs 146 nM; n=8).

Conclusions: These data highlight how our innovative system upregulates *TP53* expression and impacts downstream phenotypic effects of *TP53* activation in a preclinical model of GC.

#5966 PRT2527, a novel highly selective cyclin-dependent kinase 9 (CDK9) inhibitor, has potent antitumor activity in combination with BTK and BCL2 inhibition in various lymphoid malignancies.

N. Fultang, A. M. Schwab, S. McAneny-Droz, D. Heiser, P. Scherle, N. Bhagwat;
Prelude Therapeutics, Wilmington, DE

CDK9 is a master regulator of transcription that modulates transcription elongation via phosphorylation of RNA polymerase II. Short-term inhibition of CDK9 depletes short-lived transcripts and labile proteins such as MCL1, BFL1 and MYC to promote cancer cell death. We previously described PRT2527, a novel, potent, highly selective CDK9 inhibitor with anti-leukemic activity in various preclinical models. PRT2527 is currently under evaluation in a Phase I clinical trial in patients with relapsed/refractory hematologic malignancies (NCT05159518). Here we demonstrate PRT2527 potently inhibits cancer cell growth and induces cell death in various models of Diffuse Large B Cell Lymphoma (DLBCL), Mantle Cell Lymphoma (MCL) and Chronic Lymphocytic Leukemia (CLL), through depletion of MCL1, BFL1 and MYC. Specifically, we show that brief treatment with PRT2527 (6h) potently induces apoptosis and inhibits proliferation in DLBCL, MCL and CLL cell lines. We also show that the addition of BTK inhibitors (BTKi) or BCL2 inhibitors (BCL2i) potentiates the apoptosis response induced by PRT2527 *in vitro* and leads to more robust and durable responses including complete tumor regressions in DLBCL CDX and PDX models *in vivo*. In all studies, the combination of PRT2527 with BTKi or BCL2i is well tolerated. Mechanistically, we show that BTK inhibition upregulates BMF, an endogenous inhibitor of BCL2 and BCL-xL, driving cells towards MCL1 and BFL1 dependency in TMD-8 cells. Concurrent depletion of MCL1 and BFL1 with PRT2527 leads to complete inhibition of Bcl-2- family mediated survival signaling, potently inducing cell death. In similar fashion, Venetoclax-driven BCL2 inhibition also potentiates the anti-tumor activity of PRT2527. Consistent with these findings *in vitro*, we observe reduced BFL1 and MCL1 as well as increased BMF in tumors of mice treated with BTKi and PRT2527 suggesting complete Bcl-2 family inhibition. We also demonstrate potent induction of apoptosis in peripheral blood mononuclear cells isolated from patients with both treatment-naïve and relapse/refractory CLL following brief treatment with PRT2527 (6h). Co-treatment with BTKi or BCL2i further enhances the apoptotic effect of PRT2527, similarly suggesting combinatorial benefit. Additionally, we characterize the activity of PRT2527 in models of BTKi relapsed/refractory MCL where increased CDK9 dependency has previously been described. In an Ibrutinib-resistant Mino CDX model, we observe increased tumor growth inhibition following treatment with PRT2527 compared to tumors derived from parental Mino cells, suggesting PRT2527 is efficacious in BTKi-resistant MCL. Altogether these data provide a rationale for evaluating PRT2527 in combination with BTK and BCL2 inhibitors for the treatment of patients with relapsed/refractory lymphoid malignancies.

#5967 Blockade of Wnt5A/ROR1 signaling as cancer stem cell targeting therapy for metastatic prostate cancer.

C. A. Jamieson[1], J. Murtadha[1], C. S. Oh[1], M. T. Muldong[1], N. Etemadfard[1], E. Koutouan[1], Y. E. Yoon[2], S. Lee[1], O. S. Kwon[3], J. J. Oh[4], M. S. Kim[5], K. Willert[1], N. A. Cacalano[6], C. H. Jamieson[1], T. Gaasterland[1], R. R. Mckay[1], C. J. Kane[1], A. A. Kulidjian[7], C. E. Prussak[1];
[1]UC San Diego, La Jolla, CA, [2]Hanyang University College of Medicine, Seoul, Gyeonggi-do, Korea, Republic of, [3]Hallym University College of Medicine, Seoul, Youngdeungpo-gu, Korea, Republic of, [4]Seoul National University Bundang Hospital, Bundang-gu, Seongnam-si, Gyeonggi, Korea, Republic of, [5]Seoul Medical Center, Jungnang-gu, Seoul, Korea, Republic of, [6]UC Los Angeles, Los Angeles, CA, [7]Scripps Health MD Anderson, La Jolla, CA

BACKGROUND-- Wnt5A and its non-canonical Wnt receptor, ROR1, have emerged as a promising new signaling pathway target for lethal, metastatic prostate cancer. Wnt5A has emerged as a significant marker of poor prognosis in circulating tumor cells (CTCs) of metastatic castration resistant prostate cancer (mCRPC) patients. ROR1 is expressed in lethal types of mCRPC, especially neuroendocrine prostate cancer (NEPC). A therapeutic ROR1 antibody, Zilovertamab, has been clinically tested in chronic lymphocytic leukemia (CLL) and metastatic breast cancer and shown to be safe. We sought to investigate Zilovertamab-based therapies for metastatic prostate cancer in pre-clinical model systems.
HYPOTHESIS -- Wnt5A/ROR1 signaling may mediate a cancer stem cell program which makes cells resistant to therapies which target the cell cycle and proliferation. Blocking ROR1 may reveal vulnerabilities which sensitize cancer cells to chemotherapies like docetaxel.
METHODS-- ROR1 expression was determined using RNASeq, qRT-PCR, FACS, IHC and Western blotting. ROR1 signaling was blocked using the anti-ROR1 therapeutic antibody, Zilovertamab, or CRISPRCas9 ROR1 knock out. Cell growth was measured using an Incucyte real time imaging system. Stem cell activity was assessed in 3D organoids. Cell cycle analysis was performed in live cells in 2D cultures and 3D organoids using the *Fucci2BL* bicistronic Fluorescent, Ubiquitination-based Cell Cycle Indicator reporter system. PDX PCSD13 tumor growth was measured via calipers and IVIS. RNASeq was performed on tumors.
RESULTS-- We showed that ROR1 was expressed at high levels in mCRPC cell lines: PC3, DU145, and in the bone metastatic prostate cancer PDX: PCSD13. CRISPR/Cas9 Knock out of ROR1 in PC3 and DU145 cells showed increased sensitivity to docetaxel inhibition of proliferation in vitro in 2D real time Incucyte proliferation assays and in 3D organoids. Organoid formation was significantly reduced in ROR1 KO cells. Cells expressing the FUCCI live cell cycle tracker showed docetaxel led to G2 arrest and ROR1 signaling inhibition increased efficacy of docetaxel induced cell cycle arrest. Treatment of PCSD13 PDX in vivo with Zilovertamab plus docetaxel synergistically increased tumor growth inhibition in vivo and modulated cancer stem cell and cell cycle expression profiles.
CONCLUSIONS-- Cancer stem cells represent the fundamental precursors from which all diverse tumor subpopulations evolve. Thus, therapeutic targeting of these tumor initiating stem/progenitor cells may prevent the evolutionary diversification of a tumor and overcome a critical clinical barrier to cancer treatment. We showed synergistic response in our PDX and PCs cell line models to Zilovertamab plus docetaxel. We are now conducting a phase 1b clinical trial with zilovertamab plus docetaxel in patients with metastatic CRPC (CirmD, NCT05156905, PI R Mckay).

#5968 CDC7 is a targetable regulator of advanced prostate cancer.

A. B. Hartono[1], S. Paparaju[1], C. Lee[1], S. Liu[1], B. R. Alabi[2], E.-C. Hsu[2], J. D. Brooks[2], E. Corey[3], T. Stoyanova[1];

[1]UCLA - University of California Los Angeles, Los Angeles, CA, [2]Stanford University, Palo Alto, CA, [3]University of Washington, Seattle, WA

Prostate cancer is estimated to contribute to over 34,000 deaths in men residing in the United States, with the majority fatality due to metastatic disease. CDC7 is a kinase that regulates DNA replication and is an emerging cancer biomarker for poor prognosis in carcinomas such as Wilms tumor and hepatocellular carcinomas. In this study, we demonstrated that high level of CDC7 is associated with metastatic prostate cancer when compared to benign prostate tissues or localized prostate cancer. Furthermore, we found that CDC7 expression is highest in prostate cancer patient-derived xenografts (PDX) models of adenocarcinomas with neuroendocrine features. *In vitro*, we showed that inhibition of CDC7 with TAK-931, a CDC7 specific inhibitor, reduced the ability of aggressive prostate cancer cells to proliferate, migrate, and invade. Similarly, knock-down of CDC7 in prostate cancer cell lines inhibited cell growth in a colony formation assay. TAK-931 treated prostate cancer cell lines also showed an abnormal cell cycle profile, indicating that inhibiting CDC7 in aggressive prostate cancer could contribute to replication stress and promote apoptosis. Overall, this study demonstrates that CDC7 is a targetable protein that regulates advanced and aggressive prostate cancer growth.

#5969 VRK1 can be a therapeutic target in small cell neuroendocrine carcinoma of the uterine cervix.

Mariya Kobayashi[1], Satoshi Nakagawa[1], Mizuki Kanda[1], Yuji Kamei[1], Masuda Tatsuo[2], Mamoru Kakuda[1], Kosuke Hiramatsu[1], Toshihiro Kimura[1], Yutaka Ueda[1], Takayuki Enomoto[1], Masahiro Inoue[3], Tadashi Kimura[1]

[1]Department of Obstetrics and Gynecology, Osaka University, Suita, Japan,[2]StemRIM Institute of Regeneration-Inducing Medicine, Osaka University, Suita, Japan,[3]Department of Clinical Bio-Resource Research and Development, Graduate School of Medicine, Kyoto University, Kyoto, Japan

Objective: Small cell neuroendocrine carcinoma of the uterine cervix (SCNEC) is extremely rare but highly aggressive and its prognosis is usually poor. Vaccinia-related kinase (VRK)1 is a serine/threonine protein kinase that is involved in cell proliferation by regulating cell-cycle progression and inducing cell-cycle arrest in response to stress signals. VRK2 belongs to the same family as VRK1, and they are paralogs. VRK1 has been reported as a potential therapeutic target in nervous system tumors with low VRK2 expression. Previously, we identified high expression of VRK1 in SCNEC through proteomic analysis of isolated organoids. The objective of the present study is to investigate the effect of VRK1 on the proliferation of SCNEC and its potential as a therapeutic target.

Methods: The mRNA and protein expression of VRK1 and VRK2 in ten organoids and two cell lines derived from SCNEC were examined and compared with cervical cancer of other histological subtypes by RNA microarray and western blot analysis. The effect of VRK1 on tumor growth in vitro and in vivo (xenograft model) were evaluated by shRNA-mediated knockdown of VRK1 (shVRK1). RNA-seq was performed from the xenograft tumors. The effects of shVRK1 on cell proliferation were evaluated under various levels of oxidative stress induced by H_2O_2.

Results: VRK1 expression was higher in organoids and cell lines derived from SCNEC than those derived from squamous cell carcinoma and adenocarcinoma, while VRK2 expression was lower in SCNEC. Tumor growth was suppressed significantly by shVRK1 in vivo (mean weight: cell line 1: 0.62 vs 0.06g, $p<0.05$, 2: 1.79 vs 0.58g, $p<0.01$). Gene ontology analysis of RNA-seq data suggested that VRK1 is related to cellular responses to stress. Proliferation was slightly suppressed by shVRK1 under normal conditions; however, it was significantly enhanced under oxidative stress (Cell line 1: in shVRK1, -14.0% without oxidative stress vs -54.9% under H_2O_2 750μM, $p<0.01$, Cell line 2: similar to Cell line 1).

Conclusion: SCNEC exhibited high VRK1 and low VRK2 expression, and the tumor suppressive effect of shVRK1 was more significant in vivo than in vitro. VRK1 may play a role in the tumor microenvironment, including oxidative stress, and is a potential therapeutic target for SCNEC.

#5970 Carbamazepine mediated *SMARCA4* inhibition as a therapeutic target for *KRAS*-mutated CRC.

Aaron Shaykevich[1], Danbee Chae[1], Isaac Silverman[1], Jeremy Bassali[1], Netanel Louloueian[1], Alexander Siegman[1], Gargi Bandyopadhyaya[1], Sanjay Goel[2], Radhashree Maitra[1]

[1]Biology, Yeshiva University, New York, NY, [2]Oncology, Rutgers Cancer Institute of New Jersey, New Brunswik, NJ

Introduction: Carbamazepine (CBZ) is an autophagy inducer along with its other therapeutic properties. *KRAS*-mutated CRC has a worse prognosis and limited treatment options when compared to *KRAS* wild-type CRC. In this study, we followed the effects of CBZ treatment in the mutant and wild-type CRC cells. We herein report that CBZ exhibits mutant selectivity in efficacy and significantly modulates *SMARCA4* levels, a protein heavily implicated in both tumor suppression and proliferation, presenting a promising method for *KRAS*-mutated CRC treatment.

Methodology: 2 cell lines, HCT116 (*KRAS* mutant) and Hke3 (*KRAS* wild-type), were used in this study. These cells were treated with Carbamazepine (CBZ) for either 6 or 24 hours. Subsequently, RNA and protein extractions were performed to assess the expression levels of *SMARCA4* through quantitative polymerase chain reaction (qPCR) and Western blot analysis, respectively. Furthermore, the TCGA COAD-READ patient dataset was accessed using Xena. The data is used to assess the correlation of *KRAS* and *SMARCA4* wt-tumor vs. mutant-tumor. The dataset was also used to visualize the effect of high *SMARCA4* mRNA on the different patient cohorts.

Results: Basal levels of *SMARCA4* are higher in CRC patients than control ($p = 1.81e-16$). Patients with a *KRAS* mutation has higher levels than *KRAS*-wt ($p = 0.000005$). *KRAS* mutated cells treated with CBZ expressed less BRG1 (*SMARCA4* protein) at 24 hours (Fold Change = 0.68, $p= 0.041$). *KRAS* wildtype cells treated with CBZ expressed more BRG1 at 6 hours (Fold Change = 1.23, $p= 0.006$). The fold change of BRG1 in *KRAS*-mutant was significantly lower than in *KRAS*-wildtype at both 6 and 24 hours ($p= 0.013$ and $p= 0.002$). *KRAS* mutated cells treated with CBZ expressed less *SMARCA4* mRNA at 24 hours (Fold Change = 0.69, $p= 0.008$). *KRAS* wildtype cells treated with CBZ expressed more *SMARCA4* at 6 hours (Fold Change = 1.62, $p= 0.006$) and 24 hours (Fold Change = 1.31, $p= 0.06$). The fold change of *SMARCA4* in *KRAS*-mutant was significantly lower than in *KRAS*-wildtype at both 6 and 24 hours ($p= 0.0032$ and $p= 0.00009$). BRG1 expression affected overall survival for the first 1500 days - only in patients with a *KRAS*-mutant ($p= 0.015$).

Conclusion: This study sheds light on the potential therapeutic role of CBZ in colorectal cancer, particularly in the context of *KRAS*-mutated CRC. Our findings indicate that CBZ treatment has distinct effects on *SMARCA4* expression in CRC depending on *KRAS* mutation status. In *KRAS*-mutated cells, CBZ reduced *SMARCA4* protein and mRNA levels. Conversely, in *KRAS* wild-type cells, CBZ resulted in an increase in *SMARCA4* expression. Furthermore, our analysis of patient datasets reaffirmed the association between elevated *SMARCA4* and *KRAS*, since high *SMARCA4* expression led to worse overall survival rates, specifically in *KRAS*-mutant CRC patients. These findings emphasize the need for further exploration of CBZ as a potential treatment strategy for CRC.

#5971 F3 targeted near-infrared photoimmunotherapy: The ideal therapeutic approach for numerous malignancies.

S. Takao, A. Furusawa, H. Fukushima, S. Okuyama, M. Kano, H. Yamamoto, P. L. Choyke, H. Kobayashi;
National Cancer Institute, Bethesda, MD

Introduction: F3 is a cell surface protein that plays a role in blood clotting, but recent research has revealed its implication in cancer proliferation, metastasis, angiogenesis, and immune escape. TCGA cohort analysis has shown that elevated F3 is a common feature of many cancers, and generally correlates with poor patient survival. Therefore, the potential of F3 as a therapeutic target in cancer is worth exploring. Tisotsumab-vedotin, an antibody-drug conjugate (ADC) that targets F3, was approved by the FDA for cervical cancer and is undergoing clinical trials in some solid cancers. However, ADCs may give rise to concerns about drag resistance following cellular internalization. Herein, we developed and tested an F3 targeted near-infrared photoimmunotherapy (NIR-PIT) to overcome some of these resistance mechanisms.
Methods: We created a conjugate of tisotumab as an F3 antibody and IR700. The efficacy of F3-targeted NIR-PIT was investigated using multiple cancer cell lines (A431; epidermoid carcinoma, HPAF-II; pancreatic adenocarcinoma, HSC-2; oral carcinoma, HT-1376luc; bladder carcinoma, MDAMB231; breast adenocarcinoma, and SKOV-3; ovarian serous cystadenocarcinoma) in vitro. In vivo, the efficacy of F3-targeted NIR-PIT was evaluated in HPAF-II tumor using xenograft mouse models. In addition, the pathological change after NIR-PIT was also evaluated in A431, HPAF-II, HSC-2, HT-1376luc, MDAMB231, and SKOV-3 tumors.
Results: These cell lines showed F3 expression in vitro and in vivo. Additionally, F3 expression was specific to cancer cells in HPAF-II tumor model. In vitro, F3-targeted NIR-PIT damaged the multiple cell lines in an NIR light dose-dependent manner. In vivo, F3-targeted NIR-PIT suppressed tumor growth and improved survival rates compared to the untreated group. Pathologically, A431, HPAF-II, HSC-2, HT1376-luc, MDAMB231 and SKOV-3 tumors after NIR-PIT contain large numbers of necrotic cells that are shown typically less dark nuclei and eosinophilic cytoplasm with some vacuolar degeneration than untreated tumors.
Conclusions: F3-targeted NIR-PIT holds the efficacy against multiple cancers expressing F3, regardless of the specific cancer type. Therefore, this modality exhibits significant promise as a potential NIR-PIT option.

#5972 Therapeutic modulation of rock overcomes metabolic adaption to oxphos inhibition and suppresses tumor growth.

N. Blazanin, X. Liang, I. Mahmud, E. Kim, L. Tan, N. Esmaeili Anvar, W. Chan, M. Ha, R. Minelli, M. Peoples, P. Lorenzi, T. Hart, Y. Lissanu, N. Blazanin; UT MD Anderson Cancer Ctr., Houston, TX

Lung cancer is the top cause of cancer mortality. Despite recent advances, the majority of patients with lung cancer still lack effective therapeutic options, underscoring the dire need for additional treatment approaches. Genomic studies have identified frequent mutations in subunits of the SWI/SNF chromatin remodeling complex including *SMARCA4* and *ARID1A* in non-small cell lung cancer with a frequency of up to 33% in advanced stage disease, making it the most frequently mutated complex in lung cancer. Previous work in our lab, as well as others, have identified a metabolic vulnerability in targeting oxidative phosphorylation (OXPHOS) in SMARCA4-mutant lung cancer. However, OXPHOS inhibitors are still not approved to treat cancer due to modest efficacy and adverse effects. This strongly suggests that novel, efficacious and tolerated agents that synergize with OXPHOS inhibition are urgently needed. To this end, we undertook a functional genomics screen by utilizing a focused CRISPR-Cas9 library targeting genes with available FDA approved therapeutics in genetically defined lung cancer cell lines. Importantly, we utilized low doses of the OXPHOS inhibitor IACS-10759 that are known to be well tolerated in patients. Among our top validated hits was ROCK1/2 kinases and we demonstrate that Belumasudil, a clinically approved ROCK inhibitor with a robust safety and tolerability profile, displays a synergistic combination with IACS-10759. Furthermore, low doses of IACS-10759 synergized with ROCK inhibition in vivo eliciting marked tumor growth inhibition. Mechanistically, we showed that the combination of Belumasudil and IACS-10759 induced a profound energetic stress. This was primarily due to ROCK inhibition-mediated suppression of the normally observed adaptive increase in glycolysis upon OXPHOS inhibition. Steady-state metabolomics and C^{13}-glucose isotope tracing confirmed downregulation of multiple glycolytic metabolites and reduced glycolytic flux by the combination of ROCK inhibition and IACS-10759 and was associated with severe reduction in glucose uptake. In summary, our study identified a key role of ROCK kinases in metabolic adaptation of cancer cells and provides a strong rationale for pursuing ROCK inhibitors as novel combination agents with OXPHOS inhibition and lay the foundation for future clinical investigation in genetically defined subtypes of lung cancer.

#5973 Targeting prolyl 4-hydroxylase subunit alpha 1 with a small molecule inhibitor, diethyl-pythiDC, reduces pancreatic ductal adenocarcinoma growth and metastasis.

F. Afaq[1], M. Khushman[2], P. Bajpai[1], S. Al Diffalha[1], D. Otali[1], S. Varambally[1], U. Manne[1];

[1]University of Alabama at Birmingham, Birmingham, AL, [2]Washington University in St. Louis, St. Louis, MO

Background: Pancreatic ductal adenocarcinoma (PDAC) is a lethal disease that has a 5-yearrelative survival rate of less than 9%. It is the fourth leading cause of cancer-associated mortality,and is projected to become the second leading cause of cancer-related deaths by 2030. Since most(~80%) PDACs are diagnosed at late stages (metastasized), there is an urgent need to identifymolecular determinants that regulate PDAC progression and serve as candidates for therapeutictargeting. Prolyl 4-hydroxylase subunit alpha 1 (P4HA1) is the major isoform overexpressed inmost cancers, including PDAC. In PDAC, high expression of P4HA1 is associated with tumorprogression and poor clinical outcomes. Thus, we investigated if targeting P4HA1 in PDAC witha small molecule inhibitor; diethyl-pythiDC, had an inhibitory effect on cell proliferation, tumorprogression/growth, and metastasis.
Methods: To demonstrate the therapeutic efficacy of diethyl-pythiDC, we performed MTT, colonyformation, wound healing, Transwell, and western blot assays in various PDAC cell lines. Tumorgrowth and metastasis was evaluated with xenografts in NOD/SCID/IL2γ receptor-null (NSG)mice. Additionally, expression of P4HA1 in human PDAC and in adjacent normal pancreatictissues was assessed.
Results: In human PDACs, there was elevated expression of P4HA1 protein relative to adjacentnormal pancreatic tissues. Treatment of various PDAC cells (S2VP10, MIA PaCa2, BxPC-3, andPANC-1) with diethyl-pythiDC reduced cell proliferation and colony formation, and inducedG2/M cell cycle arrest. Diethyl-pythiDC reduced migration and invasion of PDAC cells bymodulating epithelial-mesenchymal transition (EMT) markers (N-cadherin, E-cadherin, andvimentin). In addition, diethyl-pythiDC reduced the expression of argonaute-2 (AGO2), acomponent of microRNA biogenesis implicated in tumorigenesis, and its downstream target,matrix metalloproteinase (MMP1). In preclinical animal models of PDAC, diethyl-pythiDCreduced tumor growth and metastasis. Furthermore, in xenograft tumors, diethyl-pythiDCtreatment reduced the expression of AGO2, MMP1, and the proliferative marker, PCNA, andmodulated proteins of the EMT.
Conclusions: Treatment with diethyl-pythiDC reduces PDAC progression by decreasing cellproliferation, arresting cells in the G2/M phase, downregulating AGO2/MMP1 expression, andmodulating the EMT. These findings suggest that targeting P4HA1 by diethyl-pythiDC could be aviable strategy to improve treatment for PDACs, particularly those expressing high levels ofP4HA1. They also provide a basis to conduct clinical trials to assess the utility of targeting P4HA1by diethyl-pythiDC.

#5974 Targeting VEGFR on tumor cells and activated vasculature through delivery of granzyme B.

K. A. Mohamedali, L. H. Cheung, A. Alvarez-Cienfuegos, W. N. Hittelman, M. G. Rosenblum;
UT MD Anderson Cancer Center, Houston, TX

Anti-VEGF therapy is a key therapeutic in several cancer treatment regimens. However, none of the current therapeutics are directly cytotoxic against tumor cells. $VEGF_{121}$ is the smallest isoform in the VEGF-A family of cytokines that binds to VEGF receptors R-1 and R-2. Both receptors are over-expressed on several tumor cells and the endothelium of tumor vasculature but not normal vasculature. We hypothesized that delivery of a cytotoxic payload through VEGFR-2 into tumor cells and tumor neovasculature would significantly enhance cancer therapy. Granzyme B is a key effector in immune-mediated cell killing through both caspase-dependent and -independent mechanisms. We previously reported the development of a fusion protein composed of granzyme B (GrB) and $VEGF_{121}$ (GrB/$VEGF_{121}$). Here, we report on GrB-Fc-$VEGF_{121}$, a fusion protein incorporating a human IgG heavy chain Fc fragment for dimerization to increase the molecular weight and improve *in vivo* circulation and targeting potential. We expressed and purified GrB-Fc-$VEGF_{121}$ from HEK-293E cells under serum-free conditions with a final yield of approximately 40 mg/L. The enzymatic activity of GrB in GrB-Fc-$VEGF_{121}$ was comparable to that of commercially available human GrB. We characterized this construct against both human and mouse VEGFR+ cell lines as this ligand cross-reacts to both species. GrB-Fc-$VEGF_{121}$ showed *in vitro* cytotoxicity in the nanomolar range against tumor and endothelial cell lines expressing high levels of VEGFR-1 or VEGFR-2, while receptor-negative cells demonstrated IC_{50} levels in the high micromolar range. GrB-Fc-$VEGF_{121}$ internalized into VEGFR-2+ tumor and endothelial cells within 2 hours of treatment while untargeted GrB did not internalize, suggesting internalization was receptor-mediated. Treatment of VEGFR2+ cells at the respective IC_{50} dose resulted in >50% cell death via apoptosis and/or necrosis within 48 h. *Ex vivo* serum stability studies indicated a gradual protein loss of GrB-Fc-$VEGF_{121}$ with an overall stability of about 50% over 96 hours. No toxicity was observed in mice treated with a total dose of 475 mg/kg (IP, QOD x 5), indicating that the maximum tolerated dose of GrB-Fc-$VEGF_{121}$ exceeds this dose level. *In vivo* efficacy studies in an OVCAR8 tumor xenograft model (20 mg/kg GrB-Fc-$VEGF_{121}$ x 5) resulted in significant growth inhibition of established tumors compared to vehicle controls. The number of CD31+ blood vessels and Ki-67+ proliferating tumor cells decreased significantly in treated tumors compared to controls. Pharmacokinetic studies are underway and will be reported. Thus, GrB-Fc-$VEGF_{121}$ significantly reduces tumor growth *in vivo* with no observed toxicity against normal tissues. This tumor- and vascular-targeting agent appears to have significant potential as a new class of targeted therapeutic agents with a unique mechanism of action. Research conducted, in part, by the Clayton Foundation for Research.

#5975 Characterization and pharmacokinetics of ligand traps targeting the human epidermal growth factor receptor (HER) family.

D. C. Maneval[1], C. Yang[2], C. Trevisiol[2], H. Shepard[2], P. Jin[2];

[1]Independent Consultant, Del Mar, CA, [2]Enosi Therapeutics, Eugene, OR

Antibodies targeting HER receptors have led to successful therapeutics for multiple human malignancies. Targeting the family of HER ligands provides an alternative strategy to inhibit signaling and subsequent proliferation of cancer cells. We have engineered ligand traps that bind the growth factors activating the HER family and have characterized a series of molecules (EN2000-Fc) using Surface Plasmon Resonance (SPR). Five distinct molecules were further evaluated for improved in vivo pharmacokinetics in mice that express human neonatal Fc receptor (FcRn). Mutations in the IgG Fc known to extend the *in-vivo* half-life of monoclonal antibodies were incorporated into the parental EN2000-Fc to generate 3 more distinct pan HER ligand traps. In addition, an EN2000-Fc variant with a full-length hinge was engineered, which is 5-amino-acid longer N-terminally than the parental molecule. These five molecules were synthesized (> 300 mg of each), purified (>98%), and characterized for *in vitro* and *in vivo* testing. Two variants were compared by evaluating the ligand binding affinity to 11 HER ligands using SPR. Both molecules showed comparable affinity against all ligands tested, confirming reproducibility of the pan HER ligand trap engineering technology. Among the ligands, HB-EGF had the highest affinity. High binding affinities to EGF, NRG1, NRG2, betacellulin and TGFα were also measured. The serum pharmacokinetics of the different ligand traps were compared in 6- to 8-week-old female C57BL/6 mice engineered to express human FcRn. Ligand traps were administered by single tail vein injection, and serum samples collected over a 28-day interval were analyzed by ELISA. Ligand traps with engineered Fc-mutations had 3- to 4-fold greater systemic exposure (area-under-the-curve) compared to ligand traps with the parental sequence, demonstrating improved *in vivo* characteristics of selected engineered fusion proteins. These results provide useful information for product candidate selection and for further preclinical development of a ligand trap targeting HER family receptors.

#5976 R9: A novel NuRD complex inhibitor for targeted therapy in triple negative breast cancer (TNBC).

k. zhang[1], S. Jacob[1], M. Dozmorov[1], I. Babic[2], E. Nurmemmedov[2], A. C. Faber[1];

[1]Virginia Commonwealth University - VCU, Richmond, VA, [2]Nerd bio, San Diego, CA

Triple Negative Breast Cancer (TNBC) is a highly aggressive breast cancer subtype, disproportionately affecting young and African American populations. TNBC constitutes up to 15% of breast cancers that lack effective targeted therapy. The Nucleosome Remodeling and Deacetylase (NuRD) complex, a pivotal chromatin remodeling entity, plays a crucial role in cancer development and progression. Specifically, the NuRD complex associates with SALL4 in cancer cells, contributing to the silencing of tumor-suppressor genes like PTEN. In this study, we discover R9, a novel small-molecule nucleotide analog, a first-in-class NuRD inhibitor. Utilizing computational and cellular methods, R9 demonstrated selective engagement with RBBP4, a key NuRD complex subunit. Cellular target engagement technology has been utilized to verify direct interaction of R9 with NuRD complex as well as to guide medicinal chemistry efforts. Mass spectrometry thermal proteome profiling (TPP) affirmed RBBP4 as the primary target of R9 with minimal off-target effects. In vitro studies reveal R9 displaying robust toxicity in TNBC cells, while sparing normal tissue derived cells. Encouragingly, R9 effectively impeded TNBC tumors growth in mice without inducing toxicity. Mechanistically, we demonstrate R9 induces DNA damage in sensitive TNBC cells, and the sensitivity correlates to DNA damage-vulnerable cancer cells, indicating DNA damage is a major effector of NuRD complex inhibition in TNBCs. We further demonstrate that R9 induces DNA damage through a c-MYC dependent manner. Ongoing studies aim to elucidate key transcription factors involved in NuRD complex inhibition and the role of MYC and DNA damage in response to NuRD complex inhibition. This research positions R9 as a promising candidate for targeted therapy in TNBC, offering potential insights into the intricate molecular pathways involved in TNBC tumor progression.

#5977 A first-in-human, open-label, multi-center phase 1 study of TST003, a GREM 1 inhibitor, in subjects with locally advanced or metastatic solid tumors.

Ismael Rodriguez Rivera[1], Lin Shen[2], Shivaani Kummar[3], Minal Barve[4], Caroline Germa[5], Chuan Qi[6], Lei chen[6], Jenny Milata[5], Jenny Yao[5], Li Shen[6], Xuelian Zhu[6]

[1]NEXT Oncology, San Antonio, TX,[2]Beijing Cancer Hospital, Beijing, China,[3]Division of Hematology and Medical Oncology, Oregon Health & Science University, Portland, OR,[4]Mary Crowley Cancer Research Centers, Dallas, TX,[5]Transcenta Therapeutics Inc., Princeton, NJ,[6]Suzhou Transcenta Therapeutics Co., Ltd, Shanghai, China

Background: Gremlin-1 (GREM1), a member of the TGF-β superfamily, plays a key role in EMT, and cancer cell proliferation by binding to BMPs. GREM1 is widely expressed in various human cancers and TME stromal cells. Overexpression of GREM1 is correlated with poor prognosis. TST003 is a novel humanized IgG1 monoclonal antibody targeting GREM1 with high affinity and selectivity, and it blocks GREM1 binding to BMP2/4 resulting in enhanced BMP signaling. This study will investigate TST003's safety, tolerability, and preliminary anti-tumor activity in patients with advanced solid tumors.
Objectives: The primary objectives are to evaluate the safety and tolerability and determine the maximum tolerated dose and/or optimal biologic dose(s) of TST003. Secondary objectives include pharmacokinetic, pharmacodynamic and preliminary anti-tumor activity of TST003. A comprehensive biomarker plan will be implemented to analyze GREM1 expression, BMP signaling pathway, and tumor microenvironment with tumor tissues (including tumor cells, CAFs, T_{eff}, T_{reg}, MDSCs and TAMs), as well as circulating tumor DNA to explore the correlation among drug exposure, pharmacodynamic markers and clinical outcomes.
Method: This is a first in human Phase 1 study in locally advanced or metastatic solid tumor subjects having tumor progression during or after prior therapies and have no standard therapy that could confer clinical benefit. It comprises of the Part 1 Dose Escalation and the Part 2 Pharmacodynamic Cohorts. Part 1 will evaluate sequential dose levels of 1, 3, 10, 20 and 30 mg/kg TST003 iv., every three weeks as a single agent. The traditional "3+3" design were used for dose escalation of the first two cohorts (1 and 3 mg/kg), and Bayesian Optimal Interval (BOIN) Design with prespecified cohort size of 3 is used in the following cohorts. Part 2 will include 2 pharmacodynamic cohorts to evaluate the pharmacokinetic (PK) profile, pharmacodynamic (PD) markers, preliminary tumor response, as well as safety of TST003 as monotherapy in locally advanced or metastatic colorectal adenocarcinoma (CRC) subjects. The 2 doses used in the pharmacodynamic cohorts will be chosen from Part 1 and are expected to be within the pharmacologically active range based on nonclinical PK/PD modeling and available clinical PK/PD data from the ongoing study. Baseline GREM1 expression will be analyzed by immunohistochemistry. In each pharmacodynamic cohort, around 13-18 subjects will be enrolled to ensure at least 7 GREM1 positive subjects. Eligible subjects will receive TST003 until unacceptable toxicity or disease progression by RECIST v1.1. The enrollment is ongoing in clinical centers in the US and China. No significant safety signals were reported in the first few patients treated with TST003.
Clinical Trial Information: NCT05731271.
Study Sponsor: Suzhou Transcenta Therapeutics Co., Ltd.

#5978 Therapeutic targeting of MELK using a drug repurposing approach to combat TNBC cells.

A. Arora, S. Sarkar, S. S. Ghosh;
Indian Institute of Technology Guwahati, Guwahati, India

Background: Triple-negative breast cancer (TNBC) is the most aggressive subtype of breast cancer linked to high chemo-resistant metastatic cases and limited therapeutic options due to the absence of conventional bioreceptors. Therefore, to treat TNBC, it is imperative to identify promising druggable biological targets.
Experimental Procedures: An integrated bioinformatic analysis of microarray datasets was performed to identify significantly differentially expressed genes (DEGs) in TNBC. For selecting a potent therapeutic target, the function and significance of the upregulated DEGs in TNBC was investigated by an *in silico* study employing the UALCAN portal, String database, KM plotter, and Enrichr tools. This analysis included gene expression validation, insights into protein-protein interactions, survival analysis, and pathway mapping of the genes. To obtain potent drugs binding to the selected target MELK (maternal embryonic leucine zipper kinase), a drug repurposing approach was employed starting with virtual screening followed by molecular dynamic simulation (MDS) using GROMACS. Further, the anti-cancer activity of the top two drugs was validated by live-dead imaging, gene expression analyses, MTT-based cell viability and ROS detection assays.
Results: Based on a stringent criterion for significant DEG identification ($log_2|FC|>1$ & adjust P-value < 0.05), 25 overlapping upregulated genes were obtained from three selected datasets. Further, *in silico* analysis revealed that MELK is significantly upregulated across the four stages and subtypes of breast cancer, including TNBC. Higher MELK expression and its oncogenic interactions correlated with poor overall survival of TNBC patients. Evidence suggests that the existing inhibitor for MELK (OTSSP167) has shown poor specificity. Therefore, to block its activity, a library of 1293 FDA-approved drugs was screened against the kinase domain of MELK. MDS study and analysis using parameters like RMSD, RMSF and pair distance revealed that the top 10 drugs were strongly stabilized by H-bonds in the binding pocket of MELK, with minimal deviation and reduced fluctuations of MELK upon drug binding. Binding free energy calculation of drug-MELK interaction using the MM-PBSA method revealed that nine drugs possessed higher binding energy than the inhibitor. The top two drugs obtained from the study (originally kinase and reductase inhibitors respectively) were further validated for their *in vitro* anti-cancer efficacy in MDA-MB-231 and MDA-MB-468 cells. Treatment with these drugs exhibited (a) a dose-dependent decrease in proliferation, (b) significant cell death, (c) a marked increase in the cellular ROS levels, and (d) a decrease in the expression of MELK and its downstream targets in TNBC cell lines.
Conclusion: The present study opens the avenue for using repurposed drugs as potential therapeutic molecules against MELK activity to combat TNBC progression.

#5979 Recombinant N-acetylgalactosamine-4-sulfatase (arylsulfatase B; ARSB) inhibits lung metastases in murine B16F10 syngeneic tumor model.

J. K. Tobacman[1], S. Bhattacharyya[2], I. O-Sullivan[1];
[1]University of Illinois at Chicago and Jesse Brown VAMC, Chicago, IL, [2]Jesse Brown VAMC, Chicago, IL

Activity of the enzyme N-acetylgalactosamine-4-sulfatase (Arylsulfatase B: ARSB), which removes the 4-sulfate group at the non-reducing end of chondroitin 4-sulfate (C4S) and dermatan sulfate, is reduced in several malignant cell lines and human tissues, including melanomas, mammary, prostate, and colon. Following tail vein injection of B16F10 melanoma cells in 12-week-old female C57BL/6J mice (n=11) and subsequent treatment by tail vein injection of bioactive, recombinant human ARSB (0.2 mg/kg), on days 2 and 7, development of metastatic lung lesions was markedly reduced. The average number of lesions declined from mean value of 114 (range: 10-278; n=5) to mean value of 2.5 (range: 0-9; n=6). These findings are consistent with our previous report of significant increase in survival and decrease in size of B16F10 subcutaneous melanomas in C57BL/6J mice treated with exogenous ARSB. The underlying mechanisms leading to inhibition of melanoma proliferation have profound impact on vital signaling pathways and transcriptional events. These pathways involve more or less binding with C4S when ARSB activity is modified. Notably, galectin-3 binding with C4S increases following exogenous ARSB, leading to decline in free nuclear galectin-3. This leads to reduced expression of the melanoma biomarker chondroitin sulfate proteoglycan CSPG)-4; also known as melanoma-associated chondroitin sulfate proteoglycan (MCSP). Expression of Programmed Death-Ligand 1 (PD-L1) is also reduced, declining from 1.34 ± 0.23 ng/mg protein (n=5) to 0.50 ± 0.05 ng/mg protein (n=6) following ARSB treatment. Inverse to the effect on galectin-3, SHP2, the ubiquitous non-receptor tyrosine phosphatase (PTPN11), binds less to C4S following treatment with exogenous ARSB. The resulting activation of SHP2 impacts on MAPK signaling, reducing phospho-ERK1/2 and phospho(T180/Y182)-p38-MAPK. These effects contribute to decline in matrix metalloproteinases MMP2 and MMP9 and thereby restrain invasiveness and metastasis. Following treatment with exogenous ARSB, the serum MMP2 declined from 267 ± 38 (ng/ml; n=5) to 121 ± 16 ng/ml (n=6), consistent with the observed decline in melanoma lesions. The impact of ARSB on signaling pathways and transcriptional events demonstrates how modification of a critical sulfation and the resulting impact on binding with C4S influences vital cell processes and can suppress tumor development. Recombinant human ARSB is an approved agent for the treatment of Mucopolysaccharidosis VI and is used safely and effectively for this congenital deficiency of ARSB. Exogenous ARSB may become an effective treatment for acquired deficiency of ARSB in melanoma.

#5980 Cancer therapeutic and prevention strategy targeting mutated mitochondria DNA.

H. Nagase;
Shin Nippon Biomedical Laboratories, Tokyo, Japan

As the energy factory for the cell, the mitochondrion, through its role of ATP production by oxidative phosphorylation, can be regarded as the guardian of well regulated cellular metabolism; the integrity of mitochondrial functions, however, is particularly vulnerable in cancer due to the lack of superstructures such as histone and lamina folds to protect the mitochondrial genome from unintended exposure, which consequently elevates risks of mutation. In cancer, mechanisms responsible for enforcing quality control surveillance for identifying and eliminating defective mitochondria are often poorly regulated, and certain uneliminated mitochondrial DNA (mtDNA) mutations and polymorphisms can be advantageous for the proliferation, progression, and metastasis of tumor cells and disseminated into microenvironment cells through extracellular vesicle and tunnel nano tube. Such pathogenic mtDNA aberrations are likely to increase and frequently be homoplasmic in metastatic cancer cells and, intriguingly, in normal cells in the tumor microenvironments as well. Distinct characteristics of these abnormalities in mtDNA may provide a new path for cancer therapy. We recently tested this hypothesis with a few PIP-TPP conjugates targeting mtDNA mutations to induce mutants reduction in heteoplasmic cells or apoptosis in homoplasmic or near homoplasmic cells in vivo model without major adverse effects. This finding reaffirms the feasibility of such a PIP-TPP-based mtDNA-targeting approach for anticancer therapy as well as perhaps cancer risk prevention. However, the absence of known mtDNA mutation hotspots limits the clinical application of somatic mutation-targeted PIP-TPPs. Thus, we designed CCCh-1005-TPP to selectively target a frequent ATP6 gene variant and often oncogenically homoplasmic in the associated with hypertrophic cardiomyopathy, colon, breast and ovarian cancer risk and found its anticancer effect in mouse xenograft models. Here we study preclinical trial of CCCh-1005-TPP, a promising novel anti-cancer agent for clearing abnormal mtDNA by reactivating mitochondrial quality control surveillance of mitophagy. Given those mechanistic insights may provide a promising therapeutic or maybe preventive approach of the pathogenic mtDNA removal in homoplasmic or heteroplasmic cells. Additional caveat is that this strategy may also use not only for cancer but also many other mitochondria related diseases, such as neurodegenerative, diabetic, renal, muscle and hearing loss diseases as well as aging.

#5981 Treatment of cholangiocarcinoma using humanized monoclonal antibodies targeting claudin-1.

Z. Nehme[1], M. Muller[1], E. Crouchet[1], F. Juehling[1], J. Moehlin[1], R. Desert[1], J. Brochon[1], F. Del Zompo[1], N. Roehlen[1], C. Thumann[1], P. Pessaux[1], E. Felli[1], A. Venkatasamy[2], P. Marchand[3], M. Onea[4], R. Iacone[5], M. Meyer[5], A. Toso[5], N. Bardeesy[6], L. Goyal[7], V. Ranvir[8], M. Fernandez-Vaquero[8], M. Heikenwalder[8], T. Ostyn[9], T. Roskams[9], P. Laquerriere[3], C. Schuster[1], L. Mailly[1], T. Baumert[1];

[1]University of Strasbourg, Inserm, Institut de Recherche sur les Maladies Virales et Hepatiques UMR_S1110, Strasbourg, France, [2]IHU Strasbourg, Institute of Image-Guided Surgery, Strasbourg, France, [3]CNRS, Institut Pluridisciplinaire Hubert Curien UMR 7178, Strasbourg, France, [4]Department of Pathology, Strasbourg University Hospital, Strasbourg, France, [5]Alentis Therapeutics, Allschwil, Switzerland, [6]Center for Cancer Research, Massachusetts General Hospital, Department of Medicine, Harvard Medical School, Boston, MA, [7]Division of Oncology, Stanford School of Medicine, Palo Alto, CA, [8]Division of Chronic Inflammation and Cancer, German Cancer Research Center, Heidelberg, Germany, [9]Department of Imaging and Pathology, University of Leuven, Leuven, Belgium

Introduction: Cholangiocarcinoma (CCA) is a highly aggressive adenocarcinoma of the hepatobiliary system showing an alarming rise in incidence and mortality with unsatisfactory treatment options. Claudin-1 (CLDN1) is a transmembrane protein expressed in tight junctions, but exposed at the cell surface on cancer epithelial cells. Using highly specific monoclonal antibodies (mAbs) targeting the extracellular loop 1 of exposed CLDN1 with an excellent safety profile (Roehlen, Saviano et al. Science Transl Med 2022), we aimed to investigate the role of CLDN1 as therapeutic target for CCA.

Methods: Integrative CCA patient CLDN1 expression analyses, spatial transcriptomics and mouse models were used to evaluate the role of CLDN1 as an oncogenic driver for CCA. Proof-of-concept studies were performed in cell line-derived xenograft (CDX) and patient-derived xenograft (PDX) mouse as well as patient CCA organoid models using humanized CLDN1 mAbs.

Results: Integrative expression analyses of CLDN1 in CCA patient tissues revealed robust CLDN1 upregulation across several cohorts and patients with well-characterized driver mutations. scRNASeq and spatial transcriptomics of patient CCA showed that CLDN1 expression in cancer cells is associated with stemness, oncogenic signaling and EMT. Gain-of-function studies using an orthotopic HDTVi and syngeneic mouse model revealed a decrease in survival and an enhanced tumor growth, unraveling a functional role of CLDN1 as an oncogenic driver in CCA. Targeting exposed CLDN1 using highly CLDN1-specific mAb demonstrated a robust anti-tumoral effect across intra- and extra-hepatic CCA mouse models, with a significant inhibition of metastatic disease including models with medium or low CLDN1 expression. Functional studies in patient-derived CCA organoids demonstrated that CLDN1 mAb decreased cellular viability and altered cancer cell plasticity and fate. Mechanistically, CLDN1 mAb treatment suppressed gene expression of pathways mediating proliferation, stemness and EMT by inhibition of Notch1, SRC-FAK, and Hippo-YAP signaling.

Conclusion: These results demonstrate that CLDN1 is a CCA driver and therapeutic target. The proof-of-concept studies in patient-derived models pave the way for the clinical development of CLDN1 mAbs to improve the outcomes of patients with advanced CCA.

#5982 Cannabinoid derived product is a potential novel therapeutic for papillary thyroid carcinoma.

C. Taico[1], I. Musa[1], F. Ardalani[1], A. Maskey[1], N. Yang[2], J. Breslin[3], R. Tiwari[1], J. Geliebter[1], X. Li[1];
[1]New York Medical College, Valhalla, NY, [2]General Nutraceutical Technology LLC, Elmsford, NY, [3]Breslin Research Institute, Taos, NM

Papillary thyroid carcinoma (PTC) is the most common thyroid cancer that usually affects women ages 20-50, presenting as an asymptomatic neck mass. Total or partial thyroidectomy shows an excellent prognosis; however, investigation into non-invasive therapeutics with minimal adverse effects is ongoing. In addition to driver mutations such as BRAF, RAS, and RET-PTC, p53 mutations have also been identified. The loss of function of p53 is linked to cancer progression from PTC to poorly differentiated thyroid cancer and possibly anaplastic thyroid cancer. The disruption of the Wnt cell pathway is documented to be related to malignant cell transformation in thyroid cancer, leading to remarkable upregulation of c-myc, resulting in enhancement of tumor growth and drug resistance. Previous studies revealed that upregulation of BCL-2 occurs at later stages of tumorigenesis and is involved in chemotherapy resistance in some forms of cancer. In PTC, the downregulation of BCL-2 is linked to its favorable prognosis. Cannabinoid Derived Products (CDPs) have shown effectiveness in inhibiting different types of cancer, with research dating back to the 1970s. Ongoing in-vitro and in-vivo studies show that CDPs can effectively modulate tumor growth. However, the apoptotic properties of CDPs are largely dependent on the cancer type and drug dose/concentration. Our investigation focuses on CDPs and its potential anti-cancer effects by modulation of gene expression. We investigated its effects on gene expression of p53, c-Myc, and BCL-2 in K1 cell line which consists of PTC cells obtained from metastasis of well-differentiated PTC. K1 PTC cells (1×10^6 cells/mL) were cultured with CDPs and incubated at 37°C under 5% CO_2 for 24 and 48 hours. Cells were harvested, and cell viability was determined via trypan blue exclusion assay. Using qRT-PCR, we determined the effects of CDPs on the expression of TP53, c-Myc, and BCL-2. Results show that the CDPs decreased the viability ($p < 0.001$) of K1 PTC cells in a dose and time-dependent manner. Within 24 hours, the cannabinoid-containing product increased the gene expression of TP53 ($p < 0.01$) and decreased the gene expression of BCL-2 ($p < 0.01$) and c-Myc ($p < 0.05$) in K1 PTC cells. The results suggest that CDPs interact as a potential regulator in cancer with the upregulation of p53 and downregulation of BCL-2 and c-Myc. Further in-vitro and in-vivo studies are needed to understand the mechanism and therapeutic potential of cannabinoid-containing products in papillary thyroid cancer.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Novel Therapeutics and Preclinical Models
Poster Session

#5986 Significance of LIF/LIFR axis in the progression of inflammatory breast cancer.

Bianca Romo[1], Zenaida Fuentes[1], Lois Randolph[1], Bindu Santhamma[2], Hareesh Nair[2], Christoforos Thomas[3], Ratna Vadlamudi[1], Suryavathi Viswanadhapalli[1]

[1]The University of Texas Health Science Center At San Antonio, San Antonio, TX,[2]Evestra Inc., Schertz, TX,[3]Houston Methodist, Houston, TX

Background: Inflammatory breast cancer (IBC) is a rare form of locally progressed breast cancer. Even though it is uncommon, IBC accounts for 7% of breast cancer deaths. There is a critical need for novel therapeutic targets to develop new therapeutics. IBC is more common in young women. Altered levels of growth factors, and cytokine signaling are suspected to play a role in the progression of IBC. *Leukemia* inhibitory factor (*LIF*) is the most pleiotropic member of the *interleukin*-6 family of *cytokines*. LIF and its receptor LIFR have been linked to the progression of many cancers including triple negative breast cancer. We recently developed a first-in-class inhibitor targeting LIFR named EC359. However, the role of the LIF/LIFR axis in IBC progression remains unknown. In this study, we examined the significance of LIFR and the effectiveness of LIFR inhibitor EC359 in treating IBC.
Methods: The effect of LIFR inhibitor EC359 on cell survival, colony formation, and apoptosis was evaluated using three well-established IBC model cells (SUM149, SUM190PT, and KPL4). Mechanistic studies were conducted using Western blotting, CRISPR KO, reporter assays, and RT-qPCR. KPL4 cell-based xenografts were used to test the efficacy of EC359 *in vivo*.
Results: Our results using Western blotting confirmed increased expression of LIF and LIFR in IBC cells compared to normal and $ER^{\pm}$ breast cancer cells. Treatment with EC359 significantly decreased IBC cell viability, long term colony formation ability with an IC_{50} of ~10-20 nM. Similarly, knock out of LIFR significantly reduced the progression of IBC model cells in cell viability and colony formation assays. Further EC359 treatment promoted apoptosis of IBC cells. Mechanistic studies confirmed that EC359 treatment substantially reduced LIF/LIFR downstream signaling including STAT3, AKT, and mTOR signaling. We also tested the utility of EC359 in treating IBC in vivo using KPL4 xenografts. EC359 (5mg/kg/day) is highly efficacious in reducing IBC xenograft tumor growth *in vivo*. IHC analyses of tumors confirmed decreased cell proliferation as measured by Ki67 staining.
Conclusion: Collectively, these studies demonstrated the therapeutic benefit of using EC359 to target the LIF/LIFR axis and opened the door for the development of new treatment approaches.

#5987 Targeting the spliceosome in high-risk B-cell acute lymphoblastic leukemia.

Y. Murakami, H. Konishi, C. Tepper, J. McPherson, N. Satake;
University of California Davis, Sacramento, CA

The outcome for children with high-risk B-cell acute lymphoblastic leukemia (B-ALL) is poor. Disease relapse is speculated to be due to leukemia cells escaping treatment. Our group discovered a unique cell subpopulation in B-ALL that has the capacity to initiate leukemia and is resistant to treatment. Transcriptome studies of this cell population highlight a unique RNA regulation process, specifically RNA splicing. In B-ALL, dysregulated splicing is reported to be associated with drug resistance and disease relapse. SF3B1 is a core component of the spliceosome and an essential protein in the RNA splicing process. SF3B1 inhibition is therapeutic in many cancers. In our current studies, we investigated the therapeutic potential of pladienolide B (Plad-B), an SF3B1 inhibitor, in B-ALL. SF3B1 protein expression was significantly higher in cell lines (Reh and JM1) and 28 primary B-ALL samples (14 each for standard-risk and high-risk), regardless of the risk group, than in normal B-cells (NBs) and hematopoietic stem cells (HSCs). Plad-B showed significant dose-dependent cytotoxicity in the cell lines with IC50 of 1.2nM and 0.6nM, respectively, and three harvested high-risk patient-derived xenograft (PDX) samples with almost the same IC50 as the cell lines. Plad-B did not show cytotoxicity in NBs and HSCs at the same tested concentrations. *In vivo* efficacy of Plad-B was tested using an Reh xenograft mouse model and a high-risk PDX model. Plad-B, as a single drug treatment, significantly prolonged survival in both models ($p<0.01$). G2/M cell cycle arrest and apoptosis induction were observed at 24 hours after Plad-B treatment in Reh and JM1. Splicing events were examined by RNA-seq in the treated cells at different time points (15 min, 30 min, and 60 min). Plad B demonstrated rapid splicing inhibition as early as 15 min post-treatment and, at 60 min, splicing was inhibited in 1,669 genes, including apoptosis-associated genes. 2,625 differential splicing events were observed in these genes with ~96% from intron retention and exon skipping. Furthermore, 202 genes showed significant changes in their expression over this time frame. Most of the genes were rapidly downregulated in the treatment group compared to the control, and some were slowly downregulated. There were also some genes which were upregulated, either rapidly or slowly, compared to the control. We demonstrated that Plad-B induced short pro-apoptotic spliced isoforms, instead of anti-apoptotic forms, in *BCL2L1* and *MCL-1*, as early as 60 min after treatment. In conclusion, these data demonstrated the therapeutic potential of SF3B1 inhibition in high-risk B-ALL. Plad-B rapidly inhibited splicing in many genes and downregulated the anti-apoptotic forms of apoptosis-associated genes, leading to cell apoptosis. In future studies, we will identify the downstream targets of Plad-B and further investigate the mechanism of rapid apoptosis induction by SF3B1 inhibition.

#5988 The role of the deubiquitinase USP7 and the E3/E4 ubiquitin ligase complex ITCH/UBE4B in the regulation of cell death in neuroblastoma.

C. Le Clorennec, C. SAMPAIO, P. E. ZAGE;
UCSD Moores Cancer Center, La Jolla, CA

Dysregulation of the Ubiquitin Proteasome System has been linked to many human diseases, including cancer. Expression of UBE4B ubiquitin ligase is associated with neuroblastoma patient outcomes and its functional roles in neuroblastoma pathogenesis are not known. We have recently identified a ubiquitin complex ITCH /UBE4B which mediates ubiquitination of Ku70 and c-FLIPL proteins for proteasomal degradation allowing HDAC inhibitor-mediated caspase-8 dependent apoptosis. We also confirmed that the deubiquitinase USP7, critical player in tumor suppression and DNA repair, can be a potential therapeutic target for neuroblastoma. Highly selective USP7 inhibitors have demonstrated significant antitumor activity in preclinical models of adult cancer, and we reported that these inhibitors alone can be more effective against neuroblastoma tumor growth. Our hypothesis is that USP7 inhibition will be more effective against neuroblastoma tumors through destabilization of ITCH/UBE4B complex protein targets allowing a stronger induction of cell death in response to treatment for the children. To evaluate efficacy of USP7 inhibitors in combination with HDAC inhibitors or chemotherapy against neuroblastoma tumor growth, neuroblastoma cell lines depleted for UBE4B or USP7 were treated with increasing concentrations of USP7 inhibitors alone or in combination with chemotherapy or with HDAC inhibitors. Cell proliferation was measured using continuous live cell imaging and apoptosis by caspase cleavage and PARP cleavage detection by western blot. We have evaluated also, whether ubiquitination/deubiquitination and degradation rates of p53, Ku70 and c-FLIPL proteins could modulate induction of apoptosis and necroptosis. USP7 inhibition resulted in decreases in cell viability in p53 wild-type neuroblastoma cell lines. USP7 inhibition induced apoptosis and necroptosis by increasing phosphorylation of MLKL, RIPK3 and RIPK1. In UBE4B or USP7 depleted cells, a huge induction of necroptosis and a small rate of apoptosis were observed. We also identified USP7 as a deubiquitinase of Ku70, stabilizing Ku70 at the basal level, leading to stabilization of Ku70/c-FLIPL/Bax complex. USP7 inhibition destabilizes ku70 and c-FLIPL for protein degradation leading to induction of apoptosis as well as necroptosis. UBE4B depletion in neuroblastoma inhibits HDAC inhibitors mediated caspase-8 mediated apoptosis but enhances necroptosis, due to the inhibition of Ku70 and c-FLIPL proteins degradation leading to the blockade of caspase-8 activation and the activation of the necroptosome. Our data suggests that USP7 and ITCH/UBE4B can control the switch between apoptosis and necroptosis in response to USP7 and HDAC inhibitors. USP7 inhibition and ITCH/UBE4B activation by HDAC inhibitors could be a promising therapeutic strategy for children with high-risk and relapsed neuroblastoma.

#5990 Microtubule-associated serine/threonine kinase-likeinhibitor, AD1208, as a novel cancer therapeutics.

S. CHOI, J. Ahn, K. Baek, Y. Choi, M. Im, J. Kim, J. Kim, J. Khoo, S. Lee, W. Yao, Y.-W. Park;
Avelos Therapeutics, Inc., Seoul, Korea, Republic of

Microtubule-associated serine/threonine kinase-like is an essential regulator of mitosis and emerged as a novel oncogenic kinase. It is upregulated in several cancer types, correlating with chromosome instability and poor patient survival. Here, we are reporting a MASTL inhibitor, AD1208, as a new cancer therapeutics.AD1208 inhibits kinase activity of MASTL with IC50 value of 7nM in competitive manner against ATP and induces apoptosis of colorectal cancer cells with IC50 of 150nM. Selectivity index is higher than 100 folds when the cytotoxicity was measured in normal colon cells. Synthetic lethality with BRCA was observed in knock out studies. Cell panel analysis, consist of 300 cell lines, indicated that the AD1208 is effective in cancers originated from stomach, colon, leukemia, lymphoma, and soft tissue. *In vivo* efficacy was confirmed in mouse xenograft model in dose dependent manner and synergistic effect with PARP inhibitor was observed. Kinase Assay Panel screening revealed that AD1208 is highly selective against 468 kinases. Inhibition of MASTL resulted in decreasing phosphorylated ENSA, inactivating CDK1 and arresting cell cycle progression at G2/M phase. Clinical adverse drug reactions of AD1208 were predicted by *in vitro* Safety Functional Panel screening to exhibit no meaningful safety-related issues. Currently, AD1208 is being conducted in IND enabling GLP-Tox studies, including genotoxicity, mutagenicity, safety pharmacology as well as *in vivo* safety studies. Taken together, AD1208 is identified as a novel and selective MASTL inhibitor exhibiting significant therapeutic potential to be a development candidate.

#5991 Improved venetoclax therapy by a novel conjugate with artemisinin by NOXA-mediated reduction of Mcl-1 and cyclin D1 protein in myeloid leukemia cells.

J. Zhang[1], Z. Zhang[1], S. Waxman[2], L. Zhao[1], Y. Jing[1];

[1]Shenyang Pharmaceutical University, Shenyang, China, [2]Icahn School of Medicine at Mount Sinai, New York, NY

Evasion of apoptosis is crucial for the growth, survival and chemoresistance of myeloid leukemia. The Bcl-2 selective inhibitor venetoclax is the only apoptosis inducer approved for clinical use. Venetoclax in combination with hypomethylating agents or low-dose cytarabine has now become the standard care for elderly AML patients. However, a sizeable fraction of patients are either refractory to venetoclax combination therapy or ultimately relapse. High or induced expression of Mcl-1 and Bcl-xL mediates venetoclax resistance. Previously we reported that artemisinin enhances venetoclax apoptosis induction by degrading Mcl-1 through NOXA induction. We designed a novel conjugate A1 of venetoclax with dihydroartemisinin. A1 shows dual functions of inhibiting Bcl-2 and inducing NOXA. A1 treatment releases Bim from both Bcl-2 and Mcl-1, further degrades Mcl-1 protein, and presents ten-fold stronger apoptotic induction ability in venetoclax insensitive cells. Acquired increase of Mcl-1 protein was observed in venetoclax resistant MOLM-13/VEN cells, which are sensitive to A1-induced apoptosis. In Bcl-xL expressing venetoclax refractory leukemia cells A1 obtains a new mechanism of inhibiting cell cycling by downregulating cyclin D1 through a new NOXA/cyclin D1 cascade, mediated through the endoperoxide moiety of artemisinin and intracellular iron, independent of Bcl-2 inhibition. We reveal a new compound A1 overcoming venetoclax resistance by NOXA-mediated degradation of Mcl-1 and cyclin D1 protein.

#5992 Expression of oncogenic ASSP2k in acute myeloid leukemia directly contributes to resistance to therapy and aggressiveness of the disease.

Alessia Ruiba, Marcus Schittenhelm, Anna Lena Ahrens, Vanessa Aellig, Kerstin Kampa-Schittenhelm

Klinik fur medizinische Onkologie und Hamatologie, Kantonsspital St. Gallen, St. Gallen, Switzerland

Background ASPP2 is a critical p53 activator initiating apoptotic cascades in the presence of cell stress. ASPP2k is a novel, dominant-negative, oncogenic splicing isoform of the tumor suppressor ASPP2, discovered in the context of a mutational screening of AML/ALL patient biopsies (expressed in >40% of the samples) (Schittenhelm MM et atl, EBioMed 2019). ASPP2k results from an aberrant exon 17 skipping: a premature STOP codon at the new exon16-exon18 junction site leads to the translation of a truncated protein. Indeed, ASPP2k lacks the ASPP2 C-terminus, containing the important p53 binding sites. Thus, ASPP2k impairs p53-dependent apoptosis activation, resulting in accelerated proliferation and attenuated chemotherapy-induced apoptosis in cancer cells.
Results ASPP2k silencing (KD) and overexpression (KI) functional consequences were evaluated in vitro and in vivo. ASPP2k was silenced in MOLM-14 cells and primary AML blasts. We found proliferation to be attenuated in ASPP2k KD cells compared to EV cells in both models ($p<0.0001$). Silencing of ASPP2k rendered cells more susceptible towards standard chemotherapy compared to controls (+30% Daunorubicin 10 nM, +20% Venetoclax 15 nM, $p<0.01$, Annexin/PI). Both cell models were subsequently injected intravenously into NSG mice: ASPP2k KD lead to a less aggressive disease development, resulting in a longer lifespan (30 and 42 days for EV and KD, respectively). Significant splenomegaly was noted for all control mice, while spleens from mice injected with ASPP2k KD cells were on average half in size and weight, arguing for a less aggressive biology of KD leukemia cells. Vice versa, ASPP2k up-regulation resulted in opposite results. IL-3 dependent Ba/F3 cells are a standard model to evaluate the oncogenic capacities of potential tumor drivers. Upon ASPP2k KI, Ba/F3 cells lost their IL-3 dependency. In line, overexpression of ASPP2k resulted in accelerated proliferation (+9.32 and +127.75 fold-change at 96h for EV and KI cells respectively, compared to 24h). When injected into NSG mice, ASPP2k KI Luc+ cells spread rapidly and invaded spleen, liver and brain, while no disease dissemination was noticeable control mice. Data from regular blood counts confirmed this notion. Animals injected with ASPP2k KI cells showed a rapid disease progression, while EV mice showed no signs of the illness. Further an increase of +122.5% in spleen weight was assessed in mice injected with ASPP2k KI cells compared to control animals at termination day, further underlining oncogenic potential of ASPP2k.
Conclusions In summary, we here show that ASPP2k directly contributes to resistance towards therapy in AML as well as aggressiveness of disease in vivo in all the investigated models, arguing for an oncogenic potential of the variant. Future studies evaluating ASPP2k as a prognostic/predictive model and potential target for therapy are warranted.

#5993 Temporal dynamics of ferroptosis vulnerability in a resistant cancer cell state.

L. Loftus, K. Pienta, S. Amend;
Johns Hopkins University School of Medicine, Baltimore, MD

Once cancer has metastasized it remains incurable as a result of evolved resistance to nearly all systemic therapies. Our group has demonstrated that an endocycling cancer cell state is an underappreciated mechanism of therapeutic resistance in many cancer settings. Cells in this state uncouple DNA replication from cell division to obtain abnormally high genomic content and cell size (over 40x volume). Resulting polyploidy and cellular hypertrophy provide survival advantages such as elevated genomic content, higher oxidative buffer capacity, increased autophagy, and heightened resistance to chemotherapy. Endocycling cancer cells are induced by multiple different classes of chemotherapy and present in vivo at increased frequencies both in metastatic sites and following chemotherapy. We hypothesize elimination of this overlooked resistant cancer cell state is critical for sustained anticancer therapies. Cancer cells, including those in the endocycling cancer cell state, leverage canonical cell cycle and cell death programs to evade apoptosis from external stressors including all classes of chemotherapy. Engaging cell cycle-independent death pathways is an alternative therapeutic strategy that circumvents cancer's trademark manipulation of the cell cycle[1]. Ferroptosis is a cell cycle agnostic form of cell death that occurs due to dysregulation of cellular iron and subsequent lipid peroxidation. While ferroptosis is emerging as a vulnerability in resistant cancers, efficacy of ferroptosis induction is highly heterogeneous depending on tissue type, cellular metabolism, and many other factors. We characterized oxidative damage, labile iron, lipid content, and signaling pathways in cells pre- and post-chemotherapy to assess vulnerability to ferroptosis. By inhibiting GPX4, the sole lipophilic antioxidant enzyme, we show induction of ferroptotic cell death across multiple cell lines and chemotherapies with cells in the endocycling state being more susceptible. Importantly, targeting cells in the endocycling cancer cell state (as opposed to untreated cell lines), also affords a more uniform elimination by ferroptosis. Ferroptosis also has a capacity to be immunogenic that may direct anti-cancer immune licensing in addition to direct cytotoxicity. These studies will directly contribute to development of ferroptosis engaging therapeutic strategies for resistant cancer cell states, particularly concerning the timing of intervention.

[1]Loftus, L.V.; Amend, S.R.; Pienta, K.J. Interplay between Cell Death and Cell Proliferation Reveals New Strategies for Cancer Therapy. *Int. J. Mol. Sci.* **2022**, *23*, 4723. https://doi.org/10.3390/ijms23094723

#5994 Neutrophils internalized through LC3-associated phagocytosis trigger tumor ferroptotic cell death in glioblastoma.

T. Y. Lu, P. P. Yee, S. Y. Chih, D. G. Aregawi, M. J. Glantz, B. E. Zacharia, H.-G. Wang, W. Li;
Penn State Health Milton S. Hershey Med. Ctr., Hershey, PA

Necrosis is commonly found in various solid tumors and predicts worse outcome. Chronic ischemia can initiate tumor necrosis, however, how the damaged tissue further expands is unclear. Previous studies found that neutrophils associate with necrosis and could contribute the necrosis development in glioblastoma (GBM) through transferring myeloperoxidase-containing granules into tumor cells and inducing tumor cell ferroptosis. How the neutrophilic granule transfer occurs is unknown. Here, through an unbiased small molecule screen, we found that statins can inhibit the neutrophil-induced tumor cell death through blocking the neutrophilic content transfer into tumor cells. Surprisingly, we found that neutrophils are engulfed by tumor cells before they are fragmented and release the MPO-containing contents in tumor cells. This process is through LC3-associated phagocytosis (LAP) and can be blocked by inhibiting the Vps34-UVRAG-containing PI3K complex. Inhibition of MPO or depletion of Vps34 in an orthotopic xenograft GBM mouse model showed that necrosis formation is reduced, and the tumor-bearing mice can survive longer. Therefore, this study revealed that the neutrophilic granule transfer is through LAP-mediated neutrophil internalization, which then trigger tumor ferroptotic cell death in glioblastoma. Blocking this process may improve prognosis of GBM.

#5995 How FDA-approved drug, Aprepitant, induces immunogenic death of cancer cells.

X. Dai, J. Zhu, S. Perry, Q. Jiang, D. J. Shapiro;
University of Illinois at Urbana-Champaign, Champaign, IL

Aprepitant is a long-standing FDA approved anti-nausea drug, recently re-purposed as an early-stage anticancer agent; how aprepitant kills cancer cells was not well studied. We find that aprepitant kills human and mouse cancer cells by hyperactivating the stress response pathway, the anticipatory unfolded protein response (a-UPR), thereby inducing immune cell activating necrotic cell death. Aprepitant is a small molecule neurokinin-1 receptor (NK-1R) antagonist widely used to prevent nausea and vomiting in cancer patients undergoing chemotherapy. Recently aprepitant has shown promise in mouse xenograft studies of colon, lung and pancreatic cancer and melanoma. Since aprepitant was thought to trigger release of calcium stored in the lumen of the endoplasmic reticulum, the step that we showed triggers hyperactivation of the a-UPR by ErSO family anticancer agents, we explored the role of the a-UPR in aprepitant action. Aprepitatnt robustly activates the PERK arm of the UPR increasing p-PERK and peIF2α, inhibiting protein synthesis. Notably, aprepitant treatment results in ATP depletion and activation of AMPK. Aprepitant induced rapid cell death was not blocked by apoptosis inhibitors or necroptosis inhibitors. In both standard 2-dimensional cell culture and 3-dimensional organoid culture aprepitant-treated breast cancer cells displayed typical features of necrotic cell death, including cell swelling, membrane rupture, and cytoplasmic vacuolization. Cell death by necrosis and membrane rupture leads to release of immune cell activating cell contents termed damage-associated molecular patterns (DAMPs). Aprepitant treatment induces release of the classic DAMPs, HMGB1 and ATP and medium from aprepitant-treated breast cancer cells enhances migration of differentiated human THP-1 macrophage. Thus aprepitant and other necrosis inducing therapies elicit immunogenic cell death (ICD) and may have the potential to enhance adjuvant immunotherapy. Genome-wide CRISPR screens with negative selection against aprepitant and other studies are being used to explore the pathways of aprepitant induced cell death and evaluate its therapeutic efficacy. Since FDA-approved aprepitant has been widely used for many years, identifying its pathway of action will both accelerate its clinical transition as an anticancer agent and help identify patients whose genetic profiles make them most likely to benefit from aprepitant therapy.

#5996 Genome-wide CRISPR screening reveals a central role for ferroptotic cell death in the anti-tumor response to mTOR inhibitors in HNSCC.

K. Koshizuka[1], X. Wu[1], K. Sato[1], P. T. T. Vo[1], G. M. Murawska[1], T. Ishikawa[1], Z. Wang[2], A. A. Molinolo[1], E. A. Dennis[1], P. Mali[1], J. Gutkind[1];
[1]University of California, San Diego, La Jolla, CA, [2]Zhejiang University School of Medicine, Zhejiang, China

Head and neck squamous cell carcinoma (HNSCC) is the sixth most common cancer globally, resulting in more than 300,000 deaths each year worldwide. Treatment options for HNSCC patients include surgery, radiation, chemotherapy and molecularly targeted therapies, and although immunotherapies have recently revolutionized the treatment landscape, <20% of HNSCC patients respond to immune check point blockade (ICB) therapies. The survival rate of HNSCC patients has changed only modestly over the past decades, and therefore HNSCC is a significant global health problem with high mortality and morbidity. Genomic alterations converging in the persistent activation of the PI3K/mTOR pathway (>80% cases) represent one of the most frequently altered signaling circuitries in HNSCC. This overreliance on PI3K/mTOR signaling for tumor growth may expose a cancer vulnerability that can be exploited therapeutically, as revealed in recent clinical trials using mTOR inhibitors (mTORi) in HNSCC in the adjuvant and neoadjuvant setting. Here, we took advantage of a whole-genome CRISPR screening approach to identify mechanisms of sensitivity and resistance to mTORi, aimed at increasing their clinical activity. We found that the activation of autophagy, a biological process that plays a paradoxical pro-survival or antitumoral role in a cancer specific fashion, is strictly required for mTORi cell growth inhibition in HNSCC. In depth analysis of our CRISPR screening also revealed multiple hits suggestive of a novel role for iron metabolism and ferroptosis downstream from mTORi. Ferroptosis is iron-dependent regulated cell death process caused by the peroxidation of polyunsaturated fatty acids. Indeed, we found that mTORi induces ferroptosis in HNSCC cells, and that inhibition of ferroptosis reduces the effect of mTORi. Evidence will be presented supporting a novel mechanism linking mTORi-triggered autophagy and the activation of ferroptotic death programs, as well as new synergistic combinations with mTORi by repurposing approved drugs that disable cellular ferroptotic defense mechanisms. Our studies uncovered how mTORi act in HNSCC, thereby revealing new multimodal precision therapies for HNSCC and many human malignancies displaying overactive PI3K/mTOR signaling.

#5998 Pharmacological inhibition of the LIF-LIFR autocrine loop reveals vulnerability of ovarian cancer to ferroptosis.

B. Ebrahimi[1], S. Viswanadhapalli[1], U. P. Pratap[1], R. Gopalam[1], X. Yang[1], P. P. Venkata[1], V. Drel[1], B. Santhamma[2], S. Konda[2], X. Li[1], A. L. Rodriguez Sanchez[1], H. Yan[1], G. R. Sareddy[1], Z. Xu[1], B. B. Singh[1], P. T. Valente[1], Y. Chen[1], Z. Lai[1], M. Rao[1], E. R. Kost[1], T. Curiel[3], R. R. Tekmal[1], H. B. Nair[2], R. K. Vadlamudi[1];

[1]University of Texas Health San Antonio, San Antonio, TX, [2]Evestra Inc, San Antonio, TX, [3]Dartmouth College, Hanover, NH

Introduction: Of all gynecologic cancers, epithelial ovarian cancer (OCa) stands out with the highest mortality rates. Despite all efforts, 90% of individuals who receive standard surgical and cytotoxic therapy experience disease recurrence. The potential involvement of leukemia inhibitory factor (LIF) and its receptor (LIFR) in the progression of OCa is still obscure. In this study, we examined the mechanisms by which disruption of LIF/LIFR autocrine loops contributes to the cell death of ovarian cancer cells.

Methods: The expression profiles of LIF and LIFR were obtained using 24 distinct OCa model cells, comprising both primary and established cell lines. The effects of EC359 on OCa cells were evaluated using reporter assays, colony formation, cell death, and cell viability. Flow cytometry was utilized to analyze lipid peroxidation. The Agilent Seahorse XF Pro Analyzer was used to calculate the extracellular acidification rate (ECAR) and oxygen consumption rate (OCR). Furthermore, flow cytometry was used for the preparation and analysis of lymphocytes. Mechanistic investigations were performed with RT-qPCR and RNA-seq analysis. The efficacy of the LIFR inhibitor EC359 as a targeted therapy was investigated using cell-based xenografts, syngeneic xenografts, patient-derived organoids (PDO), and patient-derived xenograft (PDX) models.

Results: Analysis of cancer databases revealed that elevated expression of LIF or LIFR was associated with poor progression-free survival of OCa patients and a predictor of poor response to chemotherapy. Using 24 different primary and established OCa cell lines that represent four subtypes of epithelial OCa, we demonstrated that LIF/LIFR autocrine signaling is active in OCa. Moreover, treatment with EC359, a novel LIFR inhibitor, significantly reduced OCa cell viability and cell survival with an IC_{50} ranging from 5 to 50 nM. Furthermore, EC359 diminished the stemness of OCa cells. Mechanistic studies using RNA-seq and rescue experiments unveiled that EC359 primarily induced ferroptosis by suppressing the glutathione antioxidant defense system. Using multiple in vitro, ex vivo, and in vivo models including organoids, cell-based xenografts, patient-derived explants, and xenograft tumors, we demonstrated that EC359 dramatically reduced the growth and progression of OCa. Additionally, EC359 therapy considerably improved tumor immunogenicity by robust $CD45^{+}$ leukocyte tumor infiltration and polarizing tumor-associated macrophages (TAMs) toward M1 phenotype while showing no impact on normal T-, B-, and other immune cells.

Conclusions: Collectively, our findings indicate that the LIF/LIFR autocrine loop plays an essential role in OCa progression and that EC359 could be a promising therapeutic agent for OCa.

#5999 Bitter taste receptors trigger pyroptosis and apoptosis through NLRP3 activation in oral cancer cells in response to a dysbiotic bacterial molecule: A possible role as pattern recognition receptors.

S. Yu, H. Lee, J. Shin, N.-Y. Song;
Yonsei University, Seoul, Korea, Republic of

Oral squamous cell carcinoma (OSCC) is the most common type of head and neck cancers. It has been reported that the composition of the oral microbiome was shifted in OSCC patients compared to healthy subjects. In particular, *Pseudomonas aeruginosa* is one of the most abundant oral microbes in OSCC patients. Bitter taste receptors (taste 2 receptors, TAS2Rs), known as G protein-coupled receptors (GPCRs), can recognize *P. aeruginosa*-derived quorum sensing molecules, such as N-(3-oxododecanoyl)-L-homoserine lactone (oxo-C12). Therefore, we explored the role of TAS2Rs in oral dysbiosis and cancers. Herein, we observed that TAS2Rs, such as TAS2R4, TAS2R14, and TAS2R38, mediated both pyroptosis and apoptosis, two distinct types of programmed cell death, in human OSCC HSC3 cells exposed to oxo-C12. Unexpectedly, TAS2Rs provoked pyroptosis and apoptosis in a GPCR-independent manner. Instead, TAS2Rs seemed to recruit NLRP3 inflammasome and subsequently activate caspase-8 in response to oxo-C12, implying the TAS2Rs-NLRP3-caspase-8 axis. Notably, the immunofluorescence staining showed considerable expression of TAS2Rs and NLRP3 in oxo-C12-treated HSC3 cells as well as human OSCC tissues, further supporting the presence of the alternative activation pathway of TAS2Rs. Moreover, siRNA knockdown of *MyD88* diminished oxo-C12-induced NLRP3 activation, caspase-8 cleavage and cell death marker expression, which implies that MyD88 is involved in activation of the TAS2Rs-NLRP3-caspase-8 axis. This also suggests that TAS2Rs might function as potential pattern recognition receptors, similar to toll-like receptors responsible for recognition of pathogen and their molecules. Based on The Cancer Genome Atlas analysis, downregulation of TAS2Rs was correlated with poor prognosis in OSCC patients. Taken together, TAS2Rs might trigger the host defense mechanism against microbial dysbiosis-induced cancer development. Thus, TAS2Rs could be promising chemotherapeutic targets for OSCC treatment, particularly via disconnecting interkingdom molecular links between microbial alterations and carcinogenesis.

#6000 A novel pathway controlling anticancer drug induced immunogenic cell death.

J. Zhu[1], S. Ghosh[1], D. Duraki[1], M. Boudreau[1], M. Jabeen[1], C. Mao[1], B. H. Park[2], G. Cheng[3], E. R. Nelson[1], P. J. Hergenrother[1], D. J. Shapiro[1];
[1]University of Illinois at Urbana-Champaign, Urbana, IL, [2]Vanderbilt Ingram Cancer Center, Nashville, TN, [3]Carle Illinois College of Medicine, Urbana, IL

Acting through estrogen receptor alpha (ERα), in orthotopic mouse xenograft models and a PDX, our non-competitive anticancer drug ErSO induces complete or near complete regression of primary and metastatic therapy-resistant ERα-positive breast, ovarian and endometrial tumors. ErSO is also highly effective in ovarian cancer PDOs from patient ascites. Unlike most anticancer agents which inhibit cancer cell proliferation or induce apoptosis, ErSO induces immune-cell-activating necrosis through sustained hyperactivation of the anticipatory unfolded protein response (a-UPR) pathway resulting in ATP depletion and cell swelling followed by membrane rupture. The medium from cancer cells killed by ErSO not only robustly activates mouse and human macrophages, but also dramatically increases monocyte migration. ErSO therefore has the potential to help extend the reach of immunotherapy to many solid tumors that do not express neoantigens. However, unlike apoptosis which has an established signaling pathway, how ErSO induces necrosis was unknown. From a genome-wide CRISPR-Cas9 screen in MCF-7 cells with negative selection against ErSO, we identified FGD3, a guanine exchange factor (GEF) of Rho GTPase Cdc42 as the top target. Consistent with the screen, through subsequent knockout and overexpression of FGD3 in human breast cancer cells, we found that the knockout cells have significant resistance to ErSO while the overexpressing cells exhibit increased sensitivity to killing by ErSO in both 2D cell culture and a 3D organoid model. Our data indicates that this protein is not an upstream regulator of the ErSO-induced necrosis pathway. Instead, it is a regulator of the last stage of necrosis - cell membrane rupture. Thus, we identified an actin reorganization signaling pathway with multiple components that plays a pivotal role in whether the breast cancer cell responds to a-UPR activation and swelling by membrane rupture and necrotic cell death or reorganizes its actin enabling the cancer cell to survive. RNA-seq and other studies indicate that by regulating actin reorganization, this axis is important in ErSO-persister breast cancer cells exhibiting long-term survival in ErSO. This work enables identification of breast cancer patients whose elevated levels of components of this signaling pathway make them most likely to benefit from this novel therapy. Notably, FGD3 knockout cells also show considerable resistance to necrosis or necroptosis induced by other anticancer drugs. Here, we describe a therapy that induces immunogenic cell death in ERα-positive breast, ovarian and endometrial cancer cells. We also show that, as cancer cells respond to agents that induce immunogenic cell death through membrane rupture, an actin regulating pathway plays a critical role in life-death decisions.

#6001 Repurposing dihydroergotamine mesylate as a potential MCL-1 inhibitor and its antitumor effect in pancreatic cancer cells.

P. Mittal[1], J. H. Lo[1], S. Soni[1], F. Battaglin[1], S. R. Gupta[2], L. Torres-Gonzalez[1], Y. Yang[1], S. Algaze[1], P. Jayachandran[1], K. Ashouri[1], A. Wong[1], W. Zhang[1], J. Yu[1], L. Zhang[1], J. Millstein[1], I. K. Singh[2], H. J. Lenz[1];

[1]USC - University of Southern California, Los Angeles, CA, [2]Deshbandhu College, University of Delhi, New Delhi, India

Background: Myeloid cell leukemia 1 (MCL-1) is an anti-apoptotic member of the BCL-2 protein family which is involved in intrinsic (mitochondrial) pathway of apoptosis and is deregulated in several cancers. Current MCL-1 specific inhibitors have limitations in terms of efficiency, tolerability, and off-target effects and challenges associated with shallow binding groove of MCL-1. In this study, dihydroergotamine mesylate (DHE), an approved anti-migraine drug, was found as a potential ligand of the MCL-1 BH3-binding pocket and was further evaluated for its potential MCL-1 inhibition and effect on pancreatic cancer cells.

Methods: PubChem Database was used for library preparation and virtual screening (OpenBabel and AutoDock Vina). The 55 crystal structures available for MCL-1 in Protein Data Bank (PDB) were clustered using principal component analysis with Bio3D R-package to select representative PDBs for further screening. Consensus voting and *k-means* clustering was used to shortlist compounds for Molecular dynamics (MD) simulations. MD simulations (100 nanoseconds) by GROMACS were employed to measure stability of ligands in MCL-1 binding pocket. DHE efficacy on cell proliferation was evaluated with MTS and clonogenic assays and on apoptosis using the FITC/Annexin V flow cytometry assay in MiaPaCa-2 and PANC-1 pancreatic cancer cell lines. Effect of DHE treatment on *MCL-1* gene and protein expression was analyzed using qRT-PCR and western blotting, respectively.

Results: Computational screening identified DHE (PubChem ID: 12308974) as a top hit exhibiting consistent interactions within the MCL-1 BH3-binding pocket. Notably, DHE displayed stable RMSD and formed four hydrogen bonds throughout MD simulations. *In vitro* results showed that DHE significantly reduced viability of MiaPaCa-2 and PANC-1 pancreatic cancer cells with IC50 values of 31 μM and 47 μM, respectively. DHE significantly (P<0.001) suppressed colony formation by pancreatic cancer cells in a dose-dependent (10μM, 20μM, and 40μM) manner. The percentage of Annexin V-positive and Propidium iodide-negative fraction in MiaPaCa-2 cells treated with DHE also increased in a dose-dependent manner. DHE did not have significant effect on *MCL-1* mRNA expression. However, western blotting demonstrated MCL-1 protein levels were significantly reduced in both pancreatic cancer cell lines upon DHE treatment.

Conclusion: Our findings showed DHE suppresses the pancreatic cancer cells viability and proliferation, and significantly increased early apoptotic cells. DHE treatment had no effect on *MCL-1* at the transcription level but significantly reduced the protein, suggesting posttranslational modifications, and thus future mechanism of action studies is required. The present study reports that the anti-migraine drug DHE might be a novel therapeutic agent for pancreatic cancer and needs to be explored further.

#6002 Increased ferroptosis sensitivity and epithelial to mesenchymal transition of breast cancer cells overcoming chemotherapeutic mediated apoptotic caspase activation.

R. Hausman[1], W. Brown[2], P. McDonald[2], S. Awrey[2], G. Sun[3], D. Montell[4], S. Dedhar[1];
[1]University of British Columbia, Vancouver, BC, Canada, [2]BC Cancer Research Institute, Vancouver, BC, Canada, [3]Cheeloo College of Medicine, Shandong University, Jinan, China, [4]University of California Santa Barbara, Santa Barbara, CA

The survival of cancer cells post chemotherapeutic treatment can lead to the presence of recurrent tumors and continues to be a barrier to effective cancer treatment. The majority of chemotherapeutics kill cells through the induction of executioner caspases and subsequent apoptotic death, and resistance to apoptosis can lead to the presence of anastatic cancer cells. Executioner caspase release was previously thought to be the point of no return from apoptotic cell death, however, it has been shown that removal of the reagent causing caspase release can lead to recovery of cells from apoptotic signaling, a phenomenon which has been termed ``Anastasis``. This presents a need for a better understanding of the underlying mechanisms behind cancer cell survival and the mechanisms that lead to cell recovery and recurrent tumors. We have hypothesized that when treated with chemotherapeutics, some cells will evade cell death even when executioner caspases have been activated. By identifying surviving anastatic cells and the pathways involved in their evasion of cell death, we hope to propose novel therapeutic strategies to prevent their survival. The novel CasExpress system, developed by the Denise Montell lab group, was used to identify and isolate a population of cells surviving caspase-3 activation as a result of chemotherapeutic treatment in Triple Negative Breast Cancer (TNBC) cell lines. The CasExpress system permanently labels these cells with GFP post caspase-3 activation. Analysis of this population of SUM159 anastatic cells, identified by their GFP expression, demonstrates that these cells have an increased resistance to further chemotherapeutic treatment, a decrease in levels of active caspase-3, an up-regulation of Cancer Stem Cell marker CD44, and a more mesenchymal phenotype. Furthermore, these “anastatic cells” express decreased levels of GPX-4, an enzyme that mitigates ferroptosis via lipid peroxide reduction, and are more sensitive to GPX-4 and xCT inhibitor mediated ferroptosis cell death.To investigate the link between Epithelial to Mesenchymal Transition (EMT) and ferroptosis mediated cell death, we used TGF-b to stimulate EMT in NMe mouse epithelial cells. We found that TGF-b induced EMT is associated with increased sensitivity to ferroptosis mediated by GPX-4 inhibition. Furthermore, the TGF-b induced EMT cells have a marked decrease in the expression of GPX4, similar to what was observed in the TNBC anastatic cells. These results indicate a potential link between EMT and an increased sensitivity to ferroptosis, and provide novel strategies for identifying and targeting chemotherapeutic resistant tumor cells.

#6003 The TNF-α-induced protein 3-interacting protein1 (TNIP1) suppresses HGF mediated NF-kB pathway activation and growth in gastric cancer cells.

J. Jung, s. koh, k. lee;
Yeungnam Univ., Daegu, Korea, Republic of

Background: TNF-α-induced protein 3-interacting protein 1 (TNIP1), an integral component in the regulation of immune responses and cellular pathways, is gaining increased attention in the scientific community. Its ability to interact with A20, a crucial ubiquitin-editing enzyme, forms a significant part of the body's mechanism to control inflammation and prevent unregulated immune responses, which are pivotal in the pathogenesis of autoimmune diseases. TNIP1's role extends beyond autoimmunity; it is also implicated in the regulation of cancer cell proliferation and survival, making it a potential target in cancer therapy. However, TNIP1 has not yet been elucidated on the tumorigenesis, proliferation, and invasion of human gastric cancer, and needs to be researched and discovered. In this study, the HGF-mediated association of TNIP1, nuclear factor kappa-B (NF-κB), and matrix metalloproteinase 9 (MMP9) and cancer cell proliferation and invasion were investigated in two types of human gastric cancer cell lines.
Methods: In this study, cell culture, cDNA microarray analysis, western blotting, Real-Time Polymerase chain reaction, Zymography, 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assay, TNIP1 knock-down with short hairpin RNA (shRNA), apoptosis, reagents and antibodies, standard two chamber invasion assay.
Results: In our study on gastric cancer cells, we found that hepatocyte growth factor (HGF) stimulation altered TNIP1 expression at both mRNA and protein levels, indicating a dynamic interaction between HGF and TNIP1. The use of LY294002, a PI3K/AKT pathway inhibitor, revealed TNIP1's involvement in the NF-kB pathway, showing changes in NFkB and TNIP1 expression post-HGF stimulation. TNIP1-shRNA expressing cells exhibited altered expression of p53, BCL-2, NFkB, and MMP9, markers crucial for tumor progression and metastasis. Notably, TNIP1 knockdown led to increased cell proliferation and enhanced invasion capabilities in gastric cancer cells. Furthermore, TNIP1 knockdown cells showed a significant decrease in apoptosis rates upon HGF treatment, as confirmed by propidium iodide staining and FACS analysis.
Conclusions: In conclusion, our results demonstrate that TNIP1 is closely associated with the NF-kB pathway and plays a critical role in modulating tumor invasion and apoptosis in gastric cancer cells. These findings suggest that TNIP1 could be a potential therapeutic target for the treatment of gastric cancer, providing new insights into the mechanisms of tumor progression and the development of targeted therapies.

#6004 HOXC8 epigenetically controls caspse-1 expression and pyroptosis in lung cancer cells.

L. Sun[1], R. Padia[1], O. Calbay[1], C. Chi[1], M. Akter[1], L. Jin[2], S. Huang[1];
[1]University of Florida, Gainesville, FL, [2]UT Health San Antonio, San Antonio, TX

Homeobox C8 (HOXC8) is a transcription factor preferentially overexpressed in a large percentage of lung adenocarcinoma (LUAD). To investigate the function of HOXC8 in LUAD, we showed that knockdown of HOXC8 led to massive LUAD cell death in a mechanism of pyroptosis because both YVAD, a caspase-1 (CASP1) inhibitor, and disulfiram, which prevents gasdemin D (GSDMD) pore formation, blocked cell death caused by HOXC8 depletion. Intriguingly, ASC and NLRP3, components of canonic inflammasome, were not involved in pyroptosis occurring in HOXC8-depleted cells. Instead, we found that silencing HOXC8 led to a marked increase in CASP1 abundance. As forced expression of CASP1 is sufficient to induce CASP1 activation and pyroptosis, we reason that HOXC8 deters pyroptosis by suppressing the level of CASP1. Moreover, we revealed that knockdown of HOXC8 augmented CASP1 transcription involving in HDAC1/2. In fact, HOXC8 and HDAC1 were in the same immunocomplex and the presence of HOXC8 is required for the recruitment of HDAC1 to CASP1 promoter. Since HOXC8 also binds CASP1 promoter, we conclude that HOXC8 negatively regulates CASP1 expression by drafting HDAC1/2 to CASP1. This study suggests that HOXC8 participates LUAD development by controlling CASP1 expression and pyroptosis.

#6005 Generation of new oncology cell models through long-term acclimation under hypoxic and hyperbaric culture conditions.

Y. Xing[1], A. Czachorowski[1], J. Lim[2], S. Wise[1];
[1]Labcorp, Ann Arbor, MI, [2]Xcell Biosciences, San Francisco, CA

Traditional cancer cell lines used as surrogate models *in vitro* and *in vivo* have made significant contributions to cancer research and drug discovery. While cell culture and animal studies are critical steps in determining the efficacy, pharmacodynamics, and mechanism of action of novel anti-cancer drugs, it is well-known that cells grown in 2D culture systems have modified growth characteristics and different responses to chemotherapeutic drugs compared to tumors *in vivo* as a result of differing structural and environmental conditions that fail to replicate *in vivo* tumor microenvironments. AVATAR bioreactors (Xcell Biosciences, San Francisco, CA) were invented to address these limitations by providing discrete control over oxygen and hyperbaric pressure levels to better mimic the *in vivo* environment and allow cultured cells to be grown in conditions which mimic the human body. To better serve preclinical research needs, we generated new tumor cell models by long-term acclimating (LTA) existing cancer cells in the AVATAR incubator system using 1% O_2 and 2 PSI conditions similar to the conditions expected in the tumor microenvironment (TME). Six different cancer cell lines of diverse origins including pancreas (MIA PaCa-2), breast (BT-474), colon (HCT116), prostate (LNCaP, PC-3) and melanoma (A-375) were adapted for 2-3 months with phenotypic changes recorded. Key marker changes were commonly observed in LTA cells compared to parental lines. For example, in HCT116 colorectal cancer cells, TME culture conditions induced a higher expression level of E-cadherin in both protein and mRNA levels (2.2-fold change), indicating a mesenchymal-epithelial transition of the cell after adaptation. This coincides with the observation that LTA adapted HCT116 cell bodies had a more angular cell morphology as compared to parental cells grown under conventional normoxic culture conditions. In-depth gene-expression analysis using a Nanostring tumor signaling pathway panel identified several common and tissue-specific gene and pathway changes. These included VEGFA, EGF receptor signaling pathway (EGFR, E-Cadherin, GRB7, c-Fos), TGF pathway (IGFBP3, TGFB1, TGFB2, SMAD7), and extracellular matrix signaling (LAMB3, ITGA5, ITGB3, ITGB8, PDGFA, CCND2). Current studies are focusing on drug response testing in 2D and 3D cultures based on above-mentioned gene and signaling pathway changes. Cell proliferation and migration capacity of xenograft LTA cells will be evaluated for the purposes of creating novel murine models for drug screening applications.

#6006 Modeling antibody drug conjugate sensitivity using urothelial carcinoma patient-derived models.

X. Tang[1], Z. Chen[1], J. Thomas[1], K. Nagar[1], J. Christin[2], N. Rustgi[2], S. Gao[1], E. de Stanchina[1], J. Coleman[1], M. Shen[2], H. Al-Ahmadie[1], G. Iyer[1], K. Kim[1], D. Solit[1];

[1]Memorial Sloan Kettering Cancer Center, New York, NY, [2]Columbia University, New York, NY

Introduction: Enfortumab Vedotin (EV), an antibody-drug conjugate (ADC) targeting Nectin-4, has emerged as a new standard-of-care for patients with metastatic urothelial cancer (UC). Promising results have also been observed in bladder cancer (BLCA) patients with ADCs targeting HER2. To identify predictive biomarkers of ADC sensitivity, we characterized a large and expanding biobank of patient-derived organoid (PDO) and xenograft (PDX) models for Nectin-4 and HER2 expression, and Nectin-4 and HER2-targeted ADC sensitivity.

Methods: We generated 19 PDOs and 34 PDXs that reflect the genomic and biologic heterogeneity of human UC. A subset of these models was further characterized using a multiplatform approach, including bulk and single-cell DNA and RNA sequencing and immunoblot for Nectin-4 and HER2 expression. We leveraged these models to study the biologic determinants of sensitivity to EV and the HER2-targeted ADC trastuzumab deruxtecan (T-DXd). PDX models were treated with EV (5 mg/kg IV on day 1, 3, 6) or T-DXd (10 mg/kg IV on day 1, 21, 42) or vehicle only as control. We also studied sensitivity to T-DXd and EV, as well as to their cytotoxic payloads (exatecan and vedotin) *in vitro* using paired PDO models.

Results: We observed high degree of variability of HER2 and Nectin-4 expression across UC PDOs and PDXs. In PDO models, sensitivity to EV correlated strongly with Nectin-4 expression, whereas HER2 expression was not strongly correlated with sensitivity to T-DXd. We also noted a poor correlation between Nectin-4 expression in PDOs and PDXs derived from the same patient. A subset of models, for example, SMBO-104 (*ERBB2* wildtype with low HER2 expression), exhibited significantly greater sensitivity to EV than to T-DXd. Conversely, T-DXd was significantly more active than EV in SMBO-170, a model with *ERBB2* amplification (~40 copies) and HER2 3+ expression. Sensitivity to exatecan, an analogue of the T-DXd payload deruxtecan, as measured by inhibition of cell proliferation and induction of apoptosis, was more predictive of T-DXd sensitivity than HER2 expression level.

Conclusion: In this study, we generated and biologically characterized UC patient-derived models with the goal of identifying predictive biomarkers of sensitivity to Nectin-4 and HER2-targeted ADCs. We observed significant heterogeneity of HER2 and Nectin-4 expression across models. Models were identified in which T-DXd was superior to EV, and vice versa. Sensitivity to the T-DXd cytotoxic payload was more predictive of PDX response than HER2 expression levels, with significant tumor regression observed with T-DXd in BLCA models with low HER2 expression. Our data suggest that clinical trials of HER2-targeted ADCs such as T-DXd should not be restricted to patients with HER2 overexpression and that novel biomarkers will be needed to identify those UC patients most likely to benefit from FDA-approved and investigational ADCs.

#6010 BRCA2 reversion alleles confer PARPi resistance via homology-directed repair, not fork protection.

R. Jensen, G. Moore, S. Lahiri;
Yale University School of Medicine, New Haven, CT

BRCA2 reversion alleles have been identified in relapsed, treatment resistant cancer patients. The reversions restore the open reading frame of the BRCA2 protein often resulting in significant sequence deletions with unknown functional consequences. No reports to date have introduced patient reversion mutations into a BRCA2 null cell model to analyze which BRCA2 functions are re-established and whether all or a subset of activities are required for PARPi resistance. Our study utilized BRCA2 reversion alleles identified through sequencing of circulating tumor DNA (ctDNA) from PARPi resistant ovarian cancer patients. We rigorously evaluated whether altered BRCA2 reversion proteins restore homology-directed repair (HDR), fork protection, or gap suppression to determine the specific activities required for PARPi resistance. We found that reverted BRCA2 proteins are functional for HDR by assessing survival response to PARPi, analyzing RAD51 foci at DSBs, DR-GFP reporter assays, RAD51 binding, and CRISPR/Cas9 gene targeting assays. Surprisingly, using the DNA fibercombing approach to assess replication fork dynamics, we identify two separation-of-function mutants, T1974 and C1654_M1890, which are deficient in fork protection, yet confer PARPi resistance. The mutations are located within the BRC 5-8 domain of BRCA2 proposed to play an important role in RAD51 nucleoprotein filament stability. Biochemical analyses of the purified proteins using single molecule FRET (smFRET) indicate reduced filament stability potentially explaining the deficit in fork protection. In conclusion, these separation-of-function BRCA2 mutations provide new mechanistic insight into the underlying biology of BRCA2 and reveal the specific functions needed to overcome PARPi-mediated cell death.

#6011 Pharmacological inhibition of PMS2 increases tumor mutational burden, induces microsatellite instability and elicits immune mediated rejection *in vivo*.

Tumors carrying defects in DNA mismatch repair (MMR-d) display high tumor mutational burden (TMB) and increased tumor neoantigen levels. MMR-d leads to accumulation of single nucleotide variants (SNVs) and insertions or deletions (indels) amongst repetitive DNA sequences generating microsatellite instability (MSI). Cancers that harbor >40% microsatellite variations are described as MSI-high (MSI-H). These tumors display unique clinical features including better prognosis, increased immune infiltration and remarkable response to immune checkpoint blockade (ICB) therapy. Colorectal cancer (CRC) patients with MMR-d often respond to therapies based on immune checkpoint blockade, whilst those with mismatch repair proficient (MMR-p) tumors do not. Therefore, identifying strategies to enhance the efficacy of immunotherapeutic treatments and transform this prevalent subgroup of CRCs from immunologically cold to hot remains an urgent and an unmet clinical need. We discovered NP1867 a first-in-class, potent, selective, covalent small molecule inhibitor of the DNA Mismatch Repair protein PMS2. We show by biochemical, biophysical, and protein-ligand X-ray crystallographic methods that NP1867 binds irreversibly to the ATP binding site of the *N*-terminal ATPase domain of PMS2. NP1867 displays potent binding to PMS2 in a NanoBRET cellular target engagement assay and inhibits MMR activity in mechanistic and functional cell-based assays of MMR-dependent DNA repair. Continuous treatment of murine CRC cell line CT26 (MMR-p) with NP1867 increases TMB, specifically enriches gained mutations with typical MMR-d related COSMIC mutational signatures, and elicits MSI-H status in a time-dependent manner, demonstrating for the first time that inhibition of PMS2 with a small molecule phenocopies the inactivation of MMR observed in patients. Remarkably, inoculation of immune-competent mice with CT26 cells pre-treated with NP1867 elicits tumor regressions in anti-PD1-treated animals, recapitulating the unique clinical features of MMR-d/MSI-H tumors. Conversely, no response is observed in immune-competent animals inoculated with control-treated cells. The extent of *in vivo* response correlates with the duration of *in vitro* NP1867 treatment and with the MSI-H status of treated CT26 cells. In conclusion, small molecule NP1867 functionally inhibits DNA MMR by targeting PMS2, enriches gained mutations with MMR-d COSMIC signatures, elicits MSI-H status, and enhances immune surveillance in preclinical models. These findings pave the way for the development of orally bioavailable compounds suitable for long-term dosing in animal models.

#6013 VIO-01, a pan-DDR DNA decoy mediating DNA repair abrogation and unleashing the anti-tumor immune response.

V. Zakharova, C. Doizelet, N. Babault, M.-C. Lienafa, F. Mazed, M. Debiais, P. Vilela, E. Perroud, W. Jdey;
Valerio Therapeutics, Paris, France

Background: Targeting specific DNA Damage Response (DDR) proteins has been worldwide studied and developed, with the example of PARP inhibitors being the only approved treatments in this field. Here, we describe the antineoplastic and immunomodulatory effects of VIO-01, a first-in-class DNA decoy-cholesterol conjugate, that operates as a pan repair proteins decoy, resulting in constitutive exhaustion of the DNA damage response.
Methods: VIO-01-induced DDR proteins trapping and cell cytotoxicity were examined in both homologous recombination proficient (HRP) and deficient (HRD) cancer cells. DNA repair efficacy was monitored by analyzing repair protein recruitment to damage sites. RNAseq analysis in HRP/HRD ovarian cancer cells was employed to uncover the molecular mechanisms underlying VIO-01 effects. Effects on the innate and adaptive immune responses were assessed by following T-cell mediated anti-tumor cytotoxicity. VIO-01 antitumor efficacy and biodistribution were also assessed. Additionally, the interest of cholesterol as a vector for VIO-01 was analyzed compared to other ligands like the folate receptor ligand.
Results: VIO-01 bounds to several DDR proteins, such as PARP1, KU70/80, MRN complex and MSH2/MSH3 with high affinity, resulting in an abrogation of single- and double-strand break repair. In line with this, and through global transcriptome analysis, VIO-01 treatment resulted in notable downregulation of Base Excision Repair, NHEJ and Nucleotide Excision Repair pathways in both HRP/HRD cell lines. Additionally, VIO-01 elicited the activation of the immune system and inflammatory responses in ovarian cancer cells. Conjointly, VIO-01 treatment induced a significant differentiation of monocytes into non-classical monocytes, leading to a shaping of the tumor microenvironment via CD8+ T cell recruitment in early stage of activation. The activity of VIO-01 was specific to tumor cells, while sparing healthy and immune cells, at odds with PARP inhibitors. In line with *in vitro* results, VIO-01 mediated antitumor efficacy *in vivo* coupled to tumor-targeting T-cell responses. These interesting effects were driven by a favorable ADME/PK profile, showing a long-lasting VIO-01 residence time VIO-01 into tumors (at least 3 days post treatment), coupled to a clear hijacking from the liver and a rapid blood clearance, ensuring a minimal toxicity. Moreover, regulatory toxicology studies demonstrated a favorable safety profile of VIO-01 in non-human primate with the major findings being a transient increase in complement factors induced by the binding of VIO-01 to factor H, which was not observed in human serum, predicting favorable safety profile in humans.
Conclusions: Our results provide a preclinical rationale for using VIO-01 to trigger DNA damage exhaustion and an antitumor immune response, paving the way for rapid clinical application in patients bearing HRD or HRP tumors.

#6014 PLK1-dependent phosphorylation of PRMT5 promotes DNA damage response in prostate cancer.

J. Peng[1], **Y. Zhang**[1], J. Wang[1], Q. Li[2], D. He[1], X. Wang[1], X. Rao[1], M. Wu[1], P. Mo[1], L. Wang[1], S. Wu[1], R. Wang[1], J. Liu[1], M. Nouri[1], I. Tadahide[1], X. Liu[1]; [1]University of Kentucky, Lexington, KY, [2]Emory University, Atlanta, GA

Prostate cancer stands out as the most frequently diagnosed cancer in men and is projected to be the second leading cause of cancer-related deaths among men in the US. Consequently, there is an urgent need for studies focusing on innovative therapeutic approaches. DNA Damage Response (DDR) is critical for cell survival, as it promotes genomic stability and reduces the risk of inheriting damage. DDR also promotes cancer cells' survival, making it a therapeutic target in cancer. PRMT5, an enzyme in the methyltransferase family, is frequently activated and overexpressed in various cancers, including prostate cancer. Furthermore, research has revealed that PRMT5 has been implicated in DDR in prostate cancer, and the regulation of PRMT5-dependent DDR is influenced by its phosphorylation. Polo-like kinase 1 (PLK1) is a serine/threonine kinase also reportedly involved in DDR in prostate cancer. Our preliminary study found that PRMT5 is positively correlated with PLK1 in prostate cancer based on the TCGA database. Nonetheless, the mechanism through which PRMT5 is regulated needs to be clarified. Here, we found that PLK1 phosphorylates PRMT5 at the S470 site, and this specific phosphorylation is required for maintaining the enzymatic activity of PRMT5. Moreover, Plk1-associated phosphorylation of PRMT5 subsequently promotes DNA damage repair, indicated by the decreasing level of γH2AX after DNA double-strand breaks (DSB). Our RNA-seq analyses of prostate cancer cells with wild-type or mutant S470 sites indicate that Plk1-associated phosphorylation on the S470 site exerts an influence on DNA replication and DDR pathways. These findings shed light on a novel perspective regarding the roles of PLK1-mediated PRMT5 phosphorylation in DDR, offering potential therapeutic strategies in prostate cancer.

#6015 Effect of antineoplastic drugs on cell-to-cell communication in the progression of colorectal cancer.

T. Lugo, A. Nguyen;
Texas Tech University, Amarilo, TX

Background: In the past few years, there has been notable progress in colorectal cancer research, resulting in novel development and delivery of drugs specifically designed for individual patient requirements. However, one of the major roadblocks in designing and treating colorectal cancer is the drug resistance found in advanced stages. Thus, there is a profound need to establish new methods to overcome this barrier. Previous work illustrated that cell-to-cell communications are dysfunctional for multitude of reasons in colorectal cancer cells. Restoration of cell-to-cell communication is a mean to deliver antineoplastic drugs via bystanding effect. Prior research has demonstrated that restoring gap junctions of cell-to-cell communication in breast cancer cells enhances the efficacy of cisplatin, a drug previously deemed resistant. Hence, this study seeks to assess the potency and efficacy of antineoplastic agents known to show resistance in colorectal cancer, with the intention to investigate how gap junctions can increase the efficacy of antineoplastic agents via restoration of cell-to-cell communication.
Method: We assessed cell viability utilizing the RealTime Glo MT Cell Viability assay (Promega, Inc.). Four specific colorectal cancer cell lines, Caco2, HT-29, SW620, and SW480, were used. Four antineoplastic agents, doxorubicin, cediranib, nilotinib, and erlotinib, were selected for the study and subsequently in the combination study of gap junction enhancer. The lethal dose at 50% (LD50) was calculated for each antineoplastic agent in each cell line.
Results: The results show significant variation of LD50. HT-29 cells dosed with doxorubicin showed LD50 of 8.9 µM, 1.6 µM, and 0.5 µM at 24 hours, 36 hours, and 48 hours of exposure, respectively. HT-29 cells dosed with erlotinib showed LD50 of 15.8 µM and 8.9 µM at 48 hours and 60 hours of exposure, respectively. SW620 dosed with doxorubicin showed LD50 is 0.5 µM at 36 hours of exposure. SW620 dosed with erlotinib showed LD50 of 15.8 µM and 0.5 µM at 48 hours and 60 hours of exposure, respectively. Caco2 cells dosed with cediranib showed LD50 of 2.8 µM and 1.6 µM at 36 hours and 48 hours of exposure, respectively.
Conclusion: The findings from this study revealed varying LD50 values for these cell lines when treated with the four distinct drugs. This enabled us to determine a foundational effect of these drugs on these cell lines, which had not been previously identified. Discovering this foundational effect will allow us to investigate the synergy effect when combined with gap junction enhancer by setting a baseline effect using these results.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Radiation, Theranostics, Radiotheranostics, Normal Tissue, and Cellular Stress
Poster Session

#6019 Biodistribution, molecular imaging and efficacy evaluation of a novel GPC3-targeted radiopharmaceutical therapy for hepatocellular carcinoma.

F. Lin[1], R. Clift[1], S. Horton[1], M. Guest[1], A. Noncovich[1], A. Bhat[1], S. Ballal[2], C. Bal[2], K. Shah[1], A. Karmann[1], **G. Li**[1];
[1]RayzeBio, San Diego, CA, [2]All India Institute of Medical Sciences, New Delhi, India

Introduction: Glypican-3 (GPC3) is a membrane-anchored oncofetal protein with minimal expression in normal tissues. Significant upregulation of GPC3 protein has been observed in the majority of hepatocellular carcinomas (HCC), and is associated with poor prognosis. The differential expression of GPC3 between tumor and normal tissues provides an opportunity for targeted radiopharmaceutical therapy (RPT) to treat HCC, a leading cause for cancer-related deaths worldwide.
Methods: The novel RPT agent RYZ-GPC3 comprises a small macrocyclic peptide binder with high affinity to GPC3 linked with a tetraxetan moiety capable of chelating a variety of radioisotopes. The affinity of peptide binders to GPC3 was determined by surface plasma resonance (SPR) and radioligand binding assays. Cellular internalization was radiometrically measured at multiple time points. Non-human primate (NHP) PET imaging was performed with ^{64}Cu. In vivo biodistribution, monotherapy and combination treatments with ^{177}Lu or ^{225}Ac were performed in HCC xenografts. Human imaging was conducted in HCC patients with ^{68}Ga PET/CT.
Results: The novel agent is a highly potent (K_D=0.7 nM) and selective peptide binder to GPC3 of human, mouse, canine and NHP origins, and is compatible with multiple radiometal isotopes. In vivo biodistribution study of [^{177}Lu]Lu-RYZ-GPC3 in HCC xenografts showed sustained tumor uptake of 16.6, 16.4, and 8.8 %ID/g at 24, 48, and 96 hours with fast renal clearance, resulting in favorable tumor/kidney ratios of 3.6, 10.2, and 13.0, respectively. Minimal or no uptake was observed in other normal tissues. PET imaging in NHP confirmed absence of on-target uptake by liver or other organs, and fast renal clearance. As monotherapy, durable (>60 days) tumor regression (TGI>100%) was achieved with ^{177}Lu (111 MBq)- and ^{225}Ac (0.111 MBq)-labeled RYZ-GPC3. At 10x lower injected activity, ^{177}Lu- and ^{225}Ac-labeled RYZ-GPC3 significantly improved anti-tumor effect of lenvatinib in multiple HCC models. Furthermore, PET/CT imaging in a 70-year-old patient with histologically proven HCC demonstrated distinct and avid [^{68}Ga]Ga-RYZ-GPC3 tumor uptake.
Conclusion: Preclinical data and preliminary human imaging demonstrate the potential of the novel binder as a theranostic agent for the treatment of patients with GPC3+ HCC.

#6020 GPC3-targeted radiopharmaceutical therapy for neuroendocrine prostate cancer.

R. Clift, F. Lin, K. Salvador, M. Guest, D. Kim, G. Han, **G. Li**;
RayzeBio, San Diego, CA

Introduction: Glypican-3 (GPC3) is a membrane-anchored oncofetal protein with minimal expression in normal tissues. Besides hepatocellular carcinoma, upregulation of GPC3 protein has been observed in a significant subset of treatment-emergent neuroendocrine prostate cancer (NEPC), which accounts for to 30% of prostate cancer cases refractory to anti-androgen and other therapies. The differential expression of GPC3 between NEPC cells and normal tissues provides a theranostic opportunity for targeted radiopharmaceutical therapy (RPT).

Methods: The novel RPT agent RYZ-GPC3 comprises a small macrocyclic peptide binder with high affinity to GPC3 linked with a tetraxetan moiety capable of chelating a variety of radioisotopes. The expression of GPC3 in NEPC cells was assessed by flow cytometry and immunohistochemistry (IHC). The affinity of peptide binders to GPC3 was determined by surface plasma resonance (SPR) and radioligand binding assays. In vivo biodistribution of [^{177}Lu]Lu-RYZ-GPC3 and anti-tumor therapy with [^{177}Lu]Lu-RYZ-GPC3 or [^{225}Ac]Ac-RYZ-GPC3 were performed in NEPC xenografts.

Results: The novel agent is a highly potent and selective peptide binder to GPC3 of human, mouse and NHP origins, and is compatible with multiple radiometal isotopes. In vivo biodistribution study of [^{177}Lu]Lu-RYZ-GPC3 in GPC3-positive NEPC xenografts showed sustained tumor uptake of 10.8, 12.6, 5.1, and 2.2 %ID/g at 2, 24, 72 and 168 hours post dose, respectively, with fast renal clearance. Minimal or no uptake was observed in other normal tissues. A single injection of [^{225}Ac]Ac-RYZ-GPC3 (11.1 kBq) resulted in significant tumor growth inhibition (TGI 109%) with durable regression and prolonged survival. All treatments were well tolerated.

Conclusion: Preclinical in vitro and in vivo data demonstrated the potential of the novel binder as a theranostic agent for the treatment of patients with GPC3+ NEPC.

#6021 Lutetium-177 (^{177}Lu) radiolabeled engineered antibody fragment against human prostate stem cell antigen (hPSCA) demonstrates targeting and antitumor effects in a syngeneic mouse model of pancreatic ductal adenocarcinoma (PDAC).

B. Chen, M. Farshbaf, F. B. Salazar, S. N. Ahmed, S. Jaiswal, J. Chean, A. Sherman, T. Hong, P. J. Yazaki, T. Olafsen, K. A. Zettlitz, A. M. Wu;
City of Hope, Duarte, CA

Introduction: hPSCA is a cell surface protein overexpressed in PDAC but minimally expressed in normal tissues, making it a promising therapeutic marker for targeted radiopharmaceutical therapy (TRT). Anti-hPSCA A2 scFv-Fc2DM antibody (A2DM) was engineered with a double mutation in the FcRn binding site for rapid blood clearance to the liver, reducing bone marrow and kidney radiotoxicity. The potential of using ^{177}Lu radiolabeled A2DM antibody for targeted anti-hPSCA imaging and TRT was investigated in a syngeneic mouse model of PDAC.

Methods: hPSCA knock-in mice were engrafted subcutaneously with KPC cells overexpressing hPSCA (KPC-hPSCA). ImmunoPET with zirconium-89 (^{89}Zr) radiolabeled with A2DM was conducted to confirm *in vivo* targeting. For imaging, A2DM and an isotype control (anti-CD20) antibody were radiolabeled with ^{89}Zr. Mice (n = 5; tumor sizes: 150 mm^3 - 180 mm^3) were i.v. injected with ^{89}Zr-A2DM or ^{89}Zr-isotype control (administered activity: 1.5 MBq/10 µg) or co-injected with excess cold antibody. ImmunoPET was acquired at 21 h post-injection. *Ex vivo* biodistribution was conducted and %ID/g was calculated based on decay-corrected standards. For therapy, KPC-hPSCA tumor bearing mice (n = 8 - 9, average tumor sizes: 20.1 ± 5.1 mm^3) was i.v. injected with ^{177}Lu-A2DM (administered activity: 17.8 MBq/10 µg or 9.25 MBq/10 µg) or saline. Tumor sizes and body weights measured every 2-3 days.

Results: ^{89}Zr immunoPET and biodistribution of A2DM demonstrated significantly higher tumor uptake (15.6 ± 0.6 %ID/g) than theisotype control (10.7 ± 1.0 %ID/g, p= 0.0001) or blocked control with 70-fold excess cold antibody (8.6 ± 1.3 %ID/g, p< 0.0001), suggesting A2DM binds to hPSCA-positive tumors in an antigen-specific manner. Therapy studies show tumor growth inhibition in a dose-dependent manner when treated with 17.8 MBq of ^{177}Lu-A2DM (tumor size at day 25: 178 ± 119 mm^3) or 9.25 MBq of ^{177}Lu-A2DM (tumor size at day 25: 309 ± 182 mm^3) (tumor size at day 25: 740 ± 317 mm^3, p= 0.006, 0.04 respectively, compared to saline). Median survival was significantly improved in mice treated with high dose of 17.8 MBq ^{177}Lu-A2DM compared to saline-treated group (48 vs. 25 days, p= 0.002). Median survival of mice treated with low dose 9.25 MBq of ^{177}Lu-A2DM showed a trend towards improved survival but results were not significant (48 vs. 34 days, p= 0.25). Minimal weight loss observed in the ^{177}Lu-A2DM and saline groups, suggesting the ^{177}Lu therapy was well tolerated.

Conclusions: ^{89}Zr immunoPET studies confirmed specific targeting of A2DM to KPC-hPSCA tumors *in vivo*. ^{177}Lu-A2DM therapeutic studies demonstrated significant tumor growth delay in a dose-dependent manner. Future studies will explore dose fractionation strategies, with the aim to enhance tumor growth control for PDAC.

#6022 Investigating the mechanisms behind salivary gland tissue sparing in response to ultra-high dose-rate FLASH proton radiotherapy.

G. S. Morcos, P. Chowdhury, M. M. Kim, K. Shoniyozov, J. Metz, L. Dong, C. Koumenis;
University of Pennsylvania, Philadelphia, NY

Background: Radiotherapy (RT) is a primary treatment for cancers of the head and neck. However, although highly efficacious in eliminating tumors, incidental damage to underlying tissue remains a major limitation of RT. In the case of head and neck cancer, damage to the otherwise healthy salivary glands is often unavoidable even at low dosages, leaving patients with lifelong xerostomia and other comorbidities. FLASH Proton RT (F-PRT) is a form of ultra-high dose RT and has been reported to spare healthy tissues while retaining its tumor-controlling efficacy. The first system to deliver dosimetrically identical FLASH Proton RT (F-PRT; 60- 110 Gy/sec) or Standard Proton RT (S-PRT; 0.5-1 Gy/sec) using double-scattered protons was designed by our group.
Aim: In this study, we aimed to investigate the effect of F-PRT on radiation-induced salivary gland dysfunction and the potential mechanism of this sparing effect by analyzing the effects of FLASH on two distinct salivary gland cell types: acinar and ductal cells.
Methods: The head and neck area of C57BL/6 mice were irradiated with a single dose of 16 Gy of F-PRT (128Gy/s) or S-PRT (0.95 Gy/s). Radiation-induced xerostomia was studied by measuring the saliva flow rate of mice at 5, 10, 14, and 28 days post-PRT. Expression of AQP5, SOX9, and Keratin- 18, 19 was studied at 2, 5, 10, 14, and 28 days post irradiation by both immunofluorescence and protein immunoblotting.
Results: Following irradiation with a single dose of 16 Gy, saliva flow was reduced by both treatments. However, the F-PRT-treated mice showed a significant improvement in salivary flow at 14 and 28 days post-irradiation, compared to those treated with S-PRT. Expression of AQP5 was significantly downregulated at 2, 5, 10 and 14 days post irradiation with S-PRT while F-PRT-treated mice showed a significant restoration of the AQP5 expression during the same time points. Expression of SOX9 showed no significant differences between S-PRT and F-PRT treated mice at earlier time points (2, 14 days), however, there was a significant difference in expression of SOX9 between the irradiated and unirradiated group. The difference in expression of SOX9 was visible from day 28 post-irradiation, where the F-PRT treated group showed increased expression compared to S-PRT.
Conclusion: Our findings demonstrate that F-PRT reduces radiation-induced hyposalivation and reinstates the expression of AQP5 in the acinar cells of the submandibular gland of mice. Furthermore, it demonstrates that on day 28 post-irradiation, F-PRT-treated mice displayed more SOX9-expressing progenitor cells in the submandibular salivary glands compared to S-PRT.
Acknowledgements: This work was supported by a Sponsored Research Agreement from IBA to Drs. C. Koumenis and L. Dong.

#6023 ^{225}Ac-FL-020 is a novel PSMA-targeting radionuclide drug conjugate (RDC) with superior in vivo anti-tumor activity.

F. Liu[1], J. Zhang[1], J. Yang[1], K. T. Thrane[2], M. W. Hallund[2], R. V. Gronlund[2], N. C. L. Wong[1];
[1]Full-Life Technologies Limited, Shanghai, China, [2]Minerva Imaging ApS, Olstykke, Denmark

Despite significant developments over the last few decades, metastatic castration-resistant prostate cancer (mCRPC) remains incurable. Prostate specific membrane antigen (PSMA), a prostate cancer-specific membrane marker which directly correlates with androgen independence, metastasis, and disease progression, has been well-established as a radioligand target for the diagnosis and treatment of mCRPC. Lutetium-177 (^{177}Lu)-PSMA-617 (PLUVICTO^{TM}) was approved in 2022 for the treatment of progressive PSMA-positive mCRPC. However, only 30% of patients showed a radiological response in the registrational trial. Meanwhile, recent clinical experience has shown very limited efficacy in low PSMA expressing patients. These data collectively request for further improvement in the clinical benefit of PSMA-targeted radiotherapy. Actinium-225 (^{225}Ac), an alpha emitter, is significantly more potent on cancer cell killing and has a shorter range in tissue penetration when compared to the beta emitter ^{177}Lu. Such a profile supports the development of ^{225}Ac based radiotherapies. Using our proprietary Clear-X^{TM} technology platform, we developed ^{225}Ac-FL-020, a novel ^{225}Ac-based PSMA radioligand therapy candidate which has demonstrated prominent pre-clinical properties. We have assessed the binding affinity against PSMA of the non-labeled vector FL-020 *in vitro*. The *in vivo* biodistribution profile of FL-020 was characterized by SPECT/CT imaging and biodistribution using Indium-111 (^{111}In)-FL-020 in PSMA high LNCaP tumor-bearing nude mice. In addition, anti-tumor activities of ^{225}Ac-FL-020 were evaluated in the LNCaP xenograft model and directly compared to ^{225}Ac-PSMA-617. FL-020 was found bound to LNCaP cells with an IC_{50} value of 51.55 nM. Meanwhile, the off-target screening showed that less than 50% inhibition of binding or activity was observed by FL-020 at 10 μM against 85 targets including receptors, ion channels, enzymes, and transporters, indicating the high selectivity of FL-020. Moreover, ^{111}In-FL-020 displayed a very promising *in vivo* distribution profile with high and sustained tumor uptake and fast systemic clearance. Furthermore, ^{225}Ac-FL-020 exhibited superior anti-tumor activity compared to ^{225}Ac-PSMA-617 at the same dose level (10 KBq/mouse) in the LNCaP xenograft model with a favorable safety profile as indicated by body weight and hematological parameters. A mechanistic study was also conducted in ^{225}Ac-FL-020-treated LNCaP tumor samples where DNA double-strand breaks and tumor cell apoptosis were observed, confirming the MOA of alpha emitters. Taken together, these results collectively demonstrate that ^{225}Ac-FL-020 is a potent and selective PSMA-targeting radioligand therapy candidate with superior anti-tumor activity and a favorable safety profile warranting further clinical development.

#6024 A novel carbonic anhydrase IX targeting radiopeptide, ^{64}Cu-PD-32766 and ^{177}Lu-PD-32766, exhibit promising theranostic potential in ccRCC tumors.

Yoshihide Mizukoshi[1], Shota Tsuchida[1], Hiroko Inaba[1], Tatsuro Kotake[1], Takanori Aoki[1], Kai Orihara[2], Yuichi Funase[2], Naoki Kanazawa[2], Hikaru Shimizu[1], Kaita Sawano[2], Kentaro Suzuki[2], Hayato Yanagida[1], Takeru Ehara[1], Hidetomo Kitamura[1], Satoshi Matsushima[2], Masato Murakami[1]

[1]PeptiDream Inc., Kawasaki, Japan,[2]PDRadiopharma Inc., Sammu, Japan

Introduction: Carbonic Anhydrase IX (CA9) is a zinc metalloenzyme that regulates the pH for cell growth. CA9 is considered an attractive target and is upregulated in a variety of cancers, especially, in 95% of clear cell renal cell carcinoma (ccRCC) where there remains a large clinical unmet need despite the availability of several newly approved medicines. PeptiDream has identified PD-32766, a novel macrocyclic peptide, targeting CA9 and can be labeled with radionuclides such as copper (^{64}Cu) and lutetium (^{177}Lu), which enables tumor-specific PET bioimaging and radiotherapy. Here we report the theranostic translational feasibility of PD-32766 for ccRCC.

Materials and Methods: PD-32766 was discovered using Peptide Discovery Platform System (PDPS), a proprietary screening system of PeptiDream. Binding affinity of PD-32766, ^{63}Cu-PD-32766 and ^{175}Lu-PD-32766 to CA9 was measured by SPR. For *in vivo* evaluation, we used a xenograft model in which VMRC-RCW (ccRCC cell line with similar CA9 expression level to clinical samples) was subcutaneously transplanted into nude mice. To assess biodistribution, ^{64}Cu-PD-32766 or ^{177}Lu-PD-32766 was dosed to VMRC-RCW xenograft mice, and the percentage of injected dose in tumors and major organs was quantified by cut and count method. To evaluate whether PET imaging can detect tumors, ^{64}Cu-PD-32766 was dosed to VMRC-RCW xenograft mice and after dosing, PET scanning was performed. For therapeutic experiments, ^{177}Lu-PD-32766 was dosed to VMRC-RCW xenograft mice and tumor volume was measured for 45 days after dosing.

Results: SPR analysis revealed that PD-32766, ^{63}Cu-PD-32766 and ^{175}Lu-PD-32766 exhibits an affinity of less than 0.2 nM for CA9. In *in vivo* biodistribution experiment, ^{64}Cu-PD-32766 and ^{177}Lu-PD-32766 showed specific and strong accumulation in tumors 4 hours after dosing (88 and 107% ID/g, for ^{64}Cu-PD-32766 and ^{177}Lu-PD-32766, respectively) and were highly retained in the tumors at 48 hours after dosing (37 and 51% ID/g, for ^{64}Cu-PD-32766 and ^{177}Lu-PD-32766, respectively). Maximal intensity in other normal tissues were 23 and 9 %ID/g (tumor/kidney=3.8 and 11.9 for ^{64}Cu-PD-32766 and ^{177}Lu-PD-32766, respectively at 4 hrs.). PET bioimaging of ^{64}Cu-PD-32766 clearly detected only tumors, consistent with the biodistribution data. In therapeutic experiments, ^{177}Lu-PD-32766 (30 MBq/mouse single or QW x3) was well tolerated and strikingly improved mouse survival compared with control animals for 45 days after transplantation, which suggests a robust tumor growth inhibition of ^{177}Lu-PD-32766 dosing. Taken together, PD-32766 showed specific tumor accumulation and strong therapeutic effect in a clinically relevant xenograft model of ccRCC.

Conclusion: PD-32766 has preferable properties for imaging and therapy with radionuclides and a great potential for theranostic use in ccRCC.

#6025 Discovery of novel macrocyclic peptide radioligands for tumor therapy by mRNA display.

A. Jaekel[1], K. Sherry[2], P. Desai[1], D. Fox III[2], T. Guo-Qing[2], M. Sturzbecher-Hoehne[1], D. Mewis[1], K. Noridomi[2], L. Rayman[1], P. Ye[2];
[1]Ariceum Therapeutics GmbH, Berlin, Germany, [2]UCB, Cambridge, MA

Radioligand therapeutics (RLT) aim to selectively deliver radioisotopes to cancer tissues to eradicate tumor cells while limiting the damage to surrounding tissues. They are composed of a tumor-targeting ligand and a radioactive payload. The therapeutic potential of RLT strongly depends on their biostability and residence time in tumor and healthy tissue after injection. Macrocyclic peptides are effective tumor-targeting ligands because their size and molecular characteristics confer optimal pharmacologic properties that can be fine-tuned during the development process. mRNA display is a powerful platform for macrocyclic peptide drug discovery that identifies high affinity peptide ligands through *in vitro* selection. Here, we describe the selection and initial characterization of macrocyclic peptides discovered by mRNA display that bind to the extracellular domain of a tumor target. Enrichment of the library for peptides that bound to the recombinant target protein was observed after four rounds of selection with no further enrichment in round five. The library of round 5 was sequenced by Illumina sequencing and the top 1,000 sequences (highest counts) were used to perform cluster analysis. We tested the top sequences of 43 different clusters in *in vitro* translation binding assays to validate the selection output and identify sequences for hit confirmation. Most of the sequences tested showed clear binding to the target protein and only a few peptides showed binding to a closely related protein from the same protein family. No non-specific binding of the discovered peptides to an irrelevant protein was observed showing the high specificity of the generated library. From this confirmatory selection data, we chose a subset of peptides for chemical synthesis. Binding affinity measurements were determined by surface plasmon resonance (SPR) and cellular binding of selected candidates to target-positive and -negative tumor cells was analyzed by flow cytometry. From this hit confirmation data, *in vitro* internalization and *in vitro* anti-tumor efficacy of radiolabeled peptide candidates for RLT are assessed. Our data highlights the potential of mRNA display platforms for fast and efficient discovery of highly specific macrocyclic peptides with optimal binding properties suitable for RLT.

#6026 A novel lutetium-177 radioligand therapy targeting FAP has potent antitumor activity in xenograft cancer model.

S. Lindeman, J. Higgins;
Immunome, Bothell, WA

Fibroblast Activation Protein (FAP) is an attractive target for cancer therapy due to its overexpression in most solid tumors, predominantly localized on cancer associated fibroblasts. Unfortunately, trials with first generation FAP-targeted radioligand therapies (RLTs) have produced only modest clinical responses, indicating the need for improvements. We developed a library of over 40 fully synthetic, novel FAP-targeted RLTs comprising a FAP inhibitor with a stable linker to an albumin binding domain and a DOTA-lutetium-177 payload. Screening this library for binding, biodistribution and pharmacology properties identified a ^{177}Lu-FAP RLT lead molecule. The novel ^{177}Lu-FAP RLT demonstrates high selectivity and binds to FAP with a sub-nanomolar binding affinity. Biodistribution of the ^{177}Lu-FAP RLT was evaluated in mice bearing U87MG tumors, demonstrating delivery and retention of a high tumor absorbed dose. In vivo efficacy of the ^{177}Lu-FAP RLT at 150 µCi or 500 µCi was evaluated in mice bearing U87MG tumors. The ^{177}Lu-FAP RLT elicits potent and dose-dependent antitumor activity with >80% reduction in tumor volume of 8/10 mice following a single 500 µCi dose. The treatment was well-tolerated, with no significant weight loss or deaths. The outstanding antitumor activity and high selectivity for FAP support further evaluation of this investigational RLT in patients with solid tumors.

#6027 ^{89}Zr-matuzumab and ^{225}Ac-matuzumab as a theranostic for epidermal growth factor receptor-positive KRAS wild-type colorectal and breast cancer xenografts.

F. Tikum, H. Fonge, F. Njotu, H. Babeker, J. K. Pougoue, N. Henning, A. Doroudi;
University of Saskatchewan, Saskatoon, SK, Canada

Background: About 80% of colorectal cancer (CRC) and 50 % of Triple-Negative breast cancer (TNBC) patients overexpress epidermal growth factor receptor (EGFR). Mutations in the KRAS oncogene (present in 40% of mCRC) lead to constitutive over-activation of EGFR and drive *de novo* resistance to anti-EGFR drugs. Here, we propose to target KRAS-mutant/BRAF mutant EGFR positive mCRC and TNBC using ^{225}Ac-labeled matuzumab, a humanized anti-EGFR monoclonal antibody.

Methods: *p*- -SCN-macropa was used to conjugate matuzumab for radiolabeling with ^{225}Ac and SCN-deferoxamine was used to conjugate matuzumab for labelling with ^{89}Zr. The radioimmunoconjugates were characterized by flow cytometry, HPLC and iTLC. *in vitro* cytotoxicity was evaluated in EGFR-positive mCRC, TNBC cell lines and 3D spheroids with different levels of EGFR density. Tumor growth was monitored using digital caliper. Mice were treated with either 10 MBq of ^{89}Zr-matuzumab for imaging or three doses of 13 KBq/dose administered of ^{225}Ac-matuzumab 10 days apart. *In vivo* study endpoint was tumor volume greater than or equal to 1500 mm^3.

Results: Flow cytometry showed about 95% binding to the cells in all EGFR-positive colorectal cell lines (DLD-1, SW620, SNU-C2B, HT-29) and breast cancer cell lines (MDA-MB-468, MDA-MB-231). *in vitro* studies showed enhanced cytotoxicity of ^{225}Ac-matuzumab compared with matuzumab. IC_{50} in the MDA-MB-468 cell line for ^{225}Ac-matuzumab (1.86 ± nM) was 35 times more effective than matuzumab (65.25± 7 nM). Similar trends were observed in the other KRAS-mutant mCRC cell lines and breast cancer cell lines. In 3D spheroid models, the IC_{50} of ^{225}Ac-matuzumab (3.0 ± 2 nM) in MDA-MB-468, was 20.79 times more effective than matuzumab (62.3 ± 1.38 nM). Similar trends were observed for all the other spheroid models as well. High uptake of ^{89}Zr-matuzumab was observed in both mCRC and TNBC xenografts. ^{225}Ac-matuzumab slowed tumor growth rate in MDA-MB-468 and MDA-MB-231 tumors models compared with control antibody or non-treated controls for 30 days. This study is still ongoing and will last for 2 more months.

Conclusion: ^{225}Ac-matuzumab shows very promising outcomes in KRAS-mutant mCRC models and breast cancer models and warrants further investigation.

#6028 Preferential tumor-to-normal tissue biodistribution and single-dose efficacy with ABD147, a DLL3-targeted engineered antibody-based radiotherapeutic, in preclinical small cell lung cancer models.

I. Kulic, **E. S. Melese**, E. Cummins, A. Mandel, R. Viswas, M. Abrams, A. Judge;
Abdera Therapeutics Inc., Vancouver, BC, Canada

Targeted radiotherapies represent an emerging treatment modality for aggressive cancers with limited treatment options, such as small cell lung cancer (SCLC). ABD147 is a Delta Ligand 3 (DLL3)-targeted antibody conjugate designed to carry and deliver cytotoxic radioactive isotopes to DLL3-expressing tumor cells. DLL3 is commonly expressed on the cell surface of neuroendocrine cancer cells, including SCLC, but has limited and predominantly intracellular expression in non-malignant tissues. The ABD147 antibody specifically binds human DLL3 with high affinity and is internalized by DLL3-expressing cancer cells. To minimize radiation exposure to normal tissue, ABD147 has been engineered to clear quickly from the blood compartment. Using indium-111 to determine ABD147 pharmacokinetics and biodistribution in mice, we demonstrate rapid blood and normal tissue clearance of ^{111}In-ABD147, as designed, following a single intravenous dose administration. However, ^{111}In-ABD147 retains high tumor accumulation (activity concentration of up to 30% ID/g) in xenograft mouse models of SCLC despite low DLL3 surface antigen expression on tumor cells (≤ 3000 copies). ^{111}In-ABD147 shows a favorable tumor-to-normal tissue distribution with predominant liver clearance. Following ABD147 therapeutic radioisotope delivery of actinium-225 or lutetium-177 (^{225}Ac-ABD147, ^{177}Lu-ABD147), we demonstrate single-dose tumor regression and dose-dependent sustained anti-tumor efficacy, corresponding to an extension of survival out to 84 days in multiple SCLC xenograft models. In summary, ABD147 can preferentially deliver radionuclides to DLL3-expressing tumor tissue while substantially reducing the systemic radioactive exposure typical of conventional IgG radioconjugates. Following promising results in preclinical models, including potent anti-tumor activity, ^{225}Ac-ABD147 is now progressing into clinical development.

#6029 ^{225}Ac/^{89}Zr labeled anti nectin 4 radioimmunoconjugates as theranostics against nectin 4 positive triple negative breast cancer.

H. Babeker, F. Njotu, J. Ketchmen, F. Tikum, A. Doroudi, E. Nwangele, M. Uppalapati, H. Fonge;
University of Saskatchewan, Saskatoon, SK, Canada

Nectin4 (N4) is a biomarker that is overexpressed in ~62% of triple negative breast cancer (TNBC) and its lack of expression in normal tissues makes it an ideal target for the therapy and PET imaging of TNBC. Methods: We developed a fully human antibody against nectin 4 (anti N4) using phage display. Anti N4 was radiolabeled with ^{89}Zr & ^{225}Ac, respectively, for imaging & radiotherapy using TNBC xenograft & syngeneic mouse models. TNBC murine 4T1 cells were transduced with human N4 and N4 expression was confirmed by FACS. Biodistribution & PET imaging of ^{89}Zr anti N4 radioimmunoconjugate (RIC) was studied in mice bearing N4 positive xenografts. Dosimetry of ^{225}Ac anti N4 was studied in healthy mice & the therapeutic efficacy was evaluated for 90 days in mice bearing MDA MB 468 xenograft & transduced 4T1 syngeneic models. Mice were treated with 2 doses of 350 nCi administered at 10 days apart. Tumor growth was monitored by a digital caliper. Results: The pharmacokinetic profile of ^{89}Zr-anti-N4 RIC showed biphasic distribution with a moderate elimination of 63 h. PET imaging & biodistribution of ^{89}Zr anti N4 in mice bearing MDA MB 468 xenograft showed high tumor uptake of 13.2 ± 1.12 %IA/g at 120 h. ^{225}Ac anti N4 was effectively internalized in MDA MB 468 and was cytotoxic to the cells with IC50 of 1.2 kBq/mL. Treatment with ^{225}Ac anti N4 led to complete tumor remission in all mice bearing MDA MB 468 xenografts and 4T1 syngeneic model by day 20 and 28, respectively. Conclusions: ^{89}Zr anti N4 was an effective PET imaging probe with specific uptake in tumor. ^{225}Ac anti N4 was effective as a therapeutic agent resulting in complete remission of tumors in both mouse xenograft & syngeneic models. These results are promising for the development of anti-N4 RICs as theranostics for TNBC.

#6030 Optimizing the therapeutic index of targeted α-particle radioimmuotherapy (TART) of HER2-positive breast cancer tumors in NRG mice with ^{225}Ac-labeled trastuzumab.

M. Kondo, Z. Cai, C. Chan, R. M. Reilly;
University of Toronto, Toronto, ON, Canada

Introduction: Our aim was to optimize the therapeutic index of TART of HER2-positive BC in NRG mice by studying the effectiveness and normal tissue toxicity of trastuzumab IgG, F(ab')$_2$ or Fab modified with DOTA for complexing the α-particle emitter, ^{225}Ac.

Methods: The toxicity of [^{225}Ac]Ac-DOTA-trastuzumab IgG, F(ab')$_2$ and Fab were assessed in NRG mice (n=5) injected i.v. with 2 and 4 kBq (total 80 μg) separated by 8 d. Body weight was monitored and complete blood cell (CBC) counts and alanine aminotransferase (ALT) and creatinine (CRE) were measured at 14 d post-injection (p.i.). TART was performed in NRG mice (n=7) with s.c. HER2-positive 164/8-1B/H2N.luc+ xenografts injected i.v. with 2 and 4 kBq (total 80 μg) separated by 8 d of [^{225}Ac]Ac-DOTA-trastuzumab IgG, F(ab')$_2$ or Fab. Control mice received irrelevant [^{225}Ac]Ac-DOTA-IgG, trastuzumab or saline. The tumor growth index (TGI=tumor volume/initial tumor volume) was measured and Kaplan-Meier median survival estimated. Tumor and normal tissue uptake (%ID/g) of [^{225}Ac]Ac-DOTA-trastuzumab IgG, F(ab')$_2$ and Fab (4 kBq) in tumor-bearing NRG mice were measured up to 14 d p.i..

Results: [^{225}Ac]Ac-DOTA-trastuzumab F(ab')$_2$ and Fab caused no decrease in CBC, while [^{225}Ac]Ac-DOTA-trastuzumab IgG decreased white blood cells by 4.5-fold, platelets by 7.5-fold, red blood cells by 1.2-fold and hematocrit by 1.2-fold compared to saline-treated mice. [^{225}Ac]Ac-trastuzumab F(ab')$_2$ or Fab caused no increase in ALT or CRE. Body weight was not decreased in all groups of mice. [^{225}Ac]Ac-DOTA-trastuzumab IgG, F(ab')$_2$ or Fab inhibited tumor growth (TGI at 15 d = 2.5, 1.8, and 1.9, respectively) vs. saline or trastuzumab (TGI= 6.3 and 5.2; P=0.0047 and 0.0028). Median survival was increased to 46 d for mice treated with [^{225}Ac]Ac-DOTA-trastuzumab F(ab')$_2$ vs. 29 d for Fab (P=0.008), 22 d for IgG (P=0.0005) and 15 d for saline (P=0.0005). Median survival for mice treated with [^{225}Ac]Ac-DOTA-IgG was 20 d and for trastuzumab was 22 d. Tumor uptake of [^{225}Ac]Ac-DOTA-trastuzumab IgG and F(ab')$_2$ at 48 h p.i. were 10.6 ± 0.6 and 8.7 ± 0.8, respectively, while uptake of [^{225}Ac]Ac-DOTA-trastuzumab Fab at 18 h p.i. was 3.1 ± 0.5 %ID/g. Elimination from the blood was slowest for [^{225}Ac]Ac-DOTA-trastuzumab IgG followed by F(ab')$_2$ then Fab. Spleen and liver uptake were greatest for [^{225}Ac]Ac-DOTA-trastuzumab IgG but much lower for F(ab')$_2$ and Fab. Kidney uptake was highest for [^{225}Ac]Ac-DOTA-trastuzumab Fab.

Conclusion: [^{225}Ac]Ac-DOTA-trastuzumab F(ab')$_2$ provided the highest therapeutic index, inhibiting tumor growth and improving survival while minimizing toxicity. TART with [^{225}Ac]Ac-DOTA-trastuzumab F(ab')$_2$ is a promising new treatment for HER2-positive BC that could be more effective than trastuzumab.

#6031 Fasting associated microbiota contributes to small intestinal radioprotection by modulating the epigenome.

P. Barrodia, E. Arslan, S. Jeter-Jones, R. R. Jeng, K. Rai, H. Piwnica-Worms;
UT MD Anderson Cancer Center, Houston, TX

Normal tissue toxicity often restricts the administration of effective radiation doses for optimal tumor cell elimination. We identified a novel host-protective effect conferred by short-term fasting when treating mice with high dose radiation. We showed that fasting mice for 24h induces epigenetic and transcriptional changes in small intestinal epithelial cells (siECs) and confers protection to small intestinal stem cells from high dose radiation. Here we report that fasting induces changes in the gut microbiome favoring bacteria producing metabolites, specifically short-chain fatty acids, that induce epigenetic changes in siECs. 16S rRNA sequencing of feces isolated from the small intestines of fed and fasted mice revealed a marked enrichment of *Akkermansia muciniphila* (*AKK*) in fasted relative to fed mice. Specific depletion of *AKK* through antibiotic treatment impaired the ability of fasting to provide organismal radioprotection whereas both organismal and OLFM4+ stem cell protection was restored in fasted animals upon reintroduction of *AKK*. *AKK* produces short chain fatty acids (SCFAs) including propionate which is able to induce histone modifications and our metabolomic analysis of feces isolated from the ileums of mice demonstrated a significant increase in propionic acid levels in fasted mice compared to fed mice. Importantly, we showed that *AKK* conditioned medium as well as its metabolite (propionate) are able to induce histone acetylation in Lgr5+ stem cell enriched epithelial spheroids cultured in vitro. We are currently employing high-dimensional analysis techniques, including single cell analysis, Cut&Tag and RNAseq to determine how the epigenetic and transcriptional changes induced by fasting provide organismal and SI radioprotection.

#6032 A novel “add-on” nanobody with an albumin-binding moiety based on the intelligent ligase-dependent conjugation (iLDC) technology: An innovative and versatile approach for next-generation radionuclide drug conjugates (RDCs) with enhanced pharmacokinetics and druggability.

C. Liu, K. Li, J. Li, J. Wang, X. Gao, Z. Mu, L. Shi, P. H. Song, G. Qin;
GeneQuantum Healthcare (Suzhou) Co., Ltd., Suzhou, China

Background: Radionuclide Drug Conjugates (RDCs) have become an attractive strategy in cancer treatment, but still faces significant drawbacks due to poor tumor penetration and undesirable pharmacokinetics of the targeting vehicles. Nanobodies, the smallest natural antigen-binding fragments, have been developed as targeting vehicles for RDCs owing to their outstanding tumor penetration, high affinity, high stability and low immunogenicity. However, the limitation of radiolabeling methods, the short blood circulation half-life and tumor retention time of nanobody hamper their application in targeted radionuclide therapy. To address those problems, this study explores a ^{177}Lu labeled anti-PSMA nanobody site-specifically conjugated with an albumin binding moiety, which improves PK profiles and radiotherapeutic efficacy by increasing circulation half-life and tumor uptake.

Results: A molecule with an albumin-binding moiety and a DOTA chelator fused in one molecular entity, utilizing a highly hydrophilic and stable branch linker, was efficiently and site-specifically conjugated to an anti-PSMA nanobody in a one-step manner based on GQ’s iLDC technology, which allows for more flexibilities in ^{177}Lu-labeling. The albumin-binding RDC maintained comparable antigen binding affinity and internalization compared to the parental nanobody, exhibiting medium affinity to albumin. Biodistribution and SPECT imaging studies performed in PSMA positive tumor-bearing mice showed enhanced blood circulation half-life of the albumin-binding RDC and, thereby, prolonged the time window for binding to PSMA, which resulted in a significantly higher accumulation and retention over time in PSMA positive tumor with higher tumor-to-blood and tumor-to-liver ratios compared to ^{177}Lu-PSMA-617. Remarkably, the albumin-binding RDC demonstrated superior antitumor efficacy with significant regression of tumor growth and no apparent toxicity or body weight loss was observed in all treated mice.

Conclusion: The introduction of an albumin-binding moiety enhanced blood circulation of the novel RDC developed by GQ’s iLDC, resulting in unprecedentedly high tumor uptake and retention over time, which conferred superior anti-tumor therapeutic efficacy. The applied strategy provides one promising novel paradigm for future RDC discovery and development which requires nanobody or other antibody fragments as targeting moiety, hence significantly expanding promise beyond current format.

#6033 Preclinical evaluation of an actinium-225 labeled PSMA-targeting small molecule (^{225}Ac-PSMA-Trillium (BAY 3563254)) for the treatment of metastatic castration resistant prostate cancer (mCRPC).

S. Zitzmann-Kolbe[1], A. Papple[2], T. Poethko[3], I. Moen[2], C. Schatz[1], S. Hillier[4], J. W. Babich[4], A. Cuthbertson[2], U. B. Hagemann[1];
[1]Bayer AG, Berlin, Germany, [2]Bayer AS, Oslo, Norway, [3]Bayer AG, Wuppertal, Germany, [4]Ratio Therapeutics, Inc., Boston, MA

PSMA is a clinically validated target for the treatment of mCRPC. Since the linear energy transfer and degree of induced DNA damage of alpha particles far exceeds that of beta particles, several investigational PSMA-targeted small molecules labeled with the alpha-emitter actinium-225 (^{225}Ac) have shown encouraging clinical signs of efficacy. However, xerostomia is often found as a dose-limiting side effect, presumably due to low levels of PSMA expression and efficient uptake of small molecules in salivary glands. To reduce these unwanted side effects a PSMA-targeted radioligand comprising a triad of important features was investigated. It consists of a high-affinity PSMA binder for specific tumor-targeting; a customized albumin-binding moiety designed to prolong plasma residence time and increase the therapeutic index by improving tumor uptake while reducing salivary gland uptake; and a chelator for efficient complexation of ^{225}Ac. From a series of compounds containing the same high-affinity PSMA-targeting moiety, but different chain lengths and albumin-binding domains, compound RPS-072 containing a PEG-3 and PEG-8 chain and an iodobenzyl moiety as albumin-binder was selected for further evaluation (J Nucl Med 2019; 60:656-663). This compound was the basis for the PSMA-Trillium with a DOTA chelator for imaging applications in humans (NCT05773703) or a macropa chelator for ^{225}Ac labeling resulting in ^{225}Ac-PSMA-Trillium. *In vitro* preclinical characterization of ^{225}Ac-PSMA-Trillium was performed to test affinities for PSMA and albumin. In a SPR assay, K_d was measured as 4.88×10^{11} M, K_{on} as 1.4×10^{7} 1/Ms and K_{off} as 6.6×10^{-4} 1/Ms. ^{225}Ac-PSMA-Trillium demonstrated good stability up to 48 h and induced potent in vitro cytotoxicity in the LNCaP subclone C4-2 (0.114 kBq/ml). *In vivo* biodistribution of ^{225}Ac-PSMA-Trillium showed consistent with the albumin binding property a relatively slow pharmacokinetics profile with 5 % ID/g still in the blood after 24 h and tumor accumulation peaking at ~ 20 % ID/g after 5-7 days. Tumor penetration was investigated using autoradiography which demonstrated fast, homogeneous, and even distribution across the tumor within 15 mins after injection. This property was also reflected by strong therapeutic efficacy in several PrCa models. In the LNCaP model a tumor growth inhibition was observed at a single dose dependent efficacy at 150 kBq/kg and 300 kBq/kg and increased the time to reach 400 mm^3 by 35 days for the 300 kBq/kg group. In the androgen independent PDX KuCaP-1 model, a single dose of 250 kBq/kg ^{225}Ac-PSMA-Trillium induced strong tumor growth inhibition over the course of 35 days. A first-in-human trial with ^{225}Ac-PSMA-Trillium is anticipated to start in the first half of 2024.

#6034 PSMA targeted alpha radiopharmaceutical [^{211}At]PSAt-3 inhibits tumor growth in a preclinical model of prostate cancer.

Lars Hvass[1], Marius Muller[2], Anne Clausen[1], Matthias Herth[2], Andreas Kjaer[1]

[1]Department of Biomedical Sciences, University of Copenhagen, Copenhagen, Denmark,[2]Department of Drug Design and Pharmacology, University of Copenhagen, Copenhagen, Denmark

Introduction: Prostate cancer continues to be a highly prevalent cancer diagnosis among men and a leading cause of cancer related deaths worldwide. With the introduction[^{177}Lu]Lu-PSMA-617, targeted radionuclide therapy has proven successful in increasing survival time for patients with metastasized castration resistant prostate cancer. However, despite encouraging results, such patients tend to develop progressive disease, and thus, enhanced efficacy is warranted. To this end, the use of radiopharmaceuticals harnessing alpha-emitters is a promising venue due to the potent energy deposition and short range of alpha particles in tissue. Here, we employ the PSMA targeting vector, [^{211}At]PSAt-3, for targeted alpha radionuclide therapy in a preclinical prostate cancer model.

Methods: [^{211}At]PSAt-3, a structural derivative of PSMA-617, in which the L-2-naphtylalanine was replaced by L-3-[^{211}At]astato-phenylalanine, was obtained by electrophilic [^{211}At]astatodesilylation. Evaluation of [^{211}At]PSAt-3 was conducted in male inbred nude mice of Balb/c background xenografted subcutaneously with human prostate cancer cells (LNCaP). Prior biodistribution studies were carried out with approximately 100 kBq intravenous injections, and subsequent biodistribution 2, 6 and 24h post injection (P.I.). For establishment of therapeutic effect, a single intravenous dose of [^{211}At]PSAt-3 was administered. To asses hematological toxicity, blood cell composition was assessed weekly.

Results: Favorable tumor uptake of 15.2±6 %ID/g was observed 2h after injection of [^{211}At]PSAt-3 in LNCaP xenografted nude mice, with subsequent 9±5.1% ID/g and 6.4±2.4% ID/g 6 and 24h P.I., respectively. [^{211}At]PSAt-3 cleared mainly by the kidneys, in which uptake was 72, 38 and 6% ID/g at 2, 6 and 24h P.I., respectively. Thyroid/throat uptake remained low at ~0.1% ID for all timepoints investigated, indicating a low degree of de-astatination. Initial efficacy studies using a single intravenous dose of 0.5 MBq (~20 MBq/kg) demonstrated significant growth delay and tumor volume reduction compared with control mice (saline). Blood platelet count was reduced after administration of [^{211}At]PSAt-3 and subsequently recovered. No signs of severe toxicity, and no significant weight loss between control and treated mice was observed, suggesting that the treatment is well tolerated.

Conclusion: 0.5 MBq [^{211}At]PSAt-3 was well tolerated in mice and demonstrated tumor volume reduction and significant delay of tumor growth. These findings suggest [^{211}At]PSAt-3 as a promising candidate for clinical translation.

#6035 Fluoride effects on thermal properties of irradiated dentin and enamel.

R. J. Kulchar[1], Y. Kakiuchi[1], V. Sanchez-Gamarra[1], J. Deng[2], F. Mante[1];
[1]University of Pennsylvania School of Dental Medicine, Philadelphia, PA, [2]University of Pennsylvania School of Nursing, Philadelphia, PA

Aim: Radiation therapy to treat oral cancer introduces various harms, including decreased hardness of dentin and enamel. Fluoride treatments, including silver diamine fluoride (SDF), have been used as a tool to combat these harms, but its influences on the thermal properties of dentin and enamel prior to and after radiation therapy are not well understood. Thus, this study analyzed how SDF influences the thermal stability of dentin and enamel that has been exposed to radiation therapy intended for head and neck cancer patients.
Methods: Forty human posterior teeth were collected, cleaned of debris and soft tissue, and then mounted into acrylic resin molds. The teeth were divided into two equal groups, with one group being the control (no treatment) and the other group receiving SDF treatment. Using an X-Rad 320ix biological irradiator, all teeth were subjected to two grays of radiation therapy every day for six weeks. Afterwards, the dentin and enamel were pulverized a SPEX freezer mill. Samples were heated in a NETZSCH Thermal Analysis instrument, and the amount of carbon dioxide and water released was determined. All teeth were heated to 1429 °C from room temperature.
Results: The SDF-treated dentin released the most carbon dioxide (49,611.82 ppm/mg), followed by irradiated dentin (47,672.76 ppm/mg) and untreated dentin (45,249.66 ppm/mg). In contrast, the SDF-treated enamel released less carbon dioxide (7,367.62 ppm/mg) than the control enamel (8,172.01 ppm/mg). The pattern of release of water was different from that of carbon dioxide. The control dentin group released the most water (45.56 ppt/mg), followed by the SDF-treated (39.72 ppt/mg) and irradiated dentin (23.51 ppt/mg). Similarly, the control enamel also released the highest amount of water (0.83 ppt/mg), as well as the highest amount of carbon dioxide. The SDF-treated enamel released around 65% of the water compared to the control enamel group (0.54 ppt/mg). Furthermore, the irradiated dentin had the largest heat reversal temperatures for carbon dioxide (85.19 °C) and water (86.57 °C).
Conclusions: The impacts of SDF treatment and radiation vary between dentin and enamel. Comparatively, dentin has a higher content of combustible material than enamel. Radiation treatment reduces the water content of both enamel and dentin, which may make teeth more susceptible to fracture. Therefore, regular dental check-ups and frequent fluoride treatment to increase the strength of the teeth are recommended for patients undergoing radiation therapy.

#6036 Flash proton radiotherapy mitigates radiation-induced salivary gland dysfunction and oral mucositis in mice.

P. Chowdhury, A. Velalopoulou, I. Verginadis, G. Morcos, M. Kim, J. Metz, L. Dong, A. Lin, C. Koumenis;
University of Pennsylvania, Philadelphia, PA

Background- Recent studies have reported that ultra-high dose rate "FLASH" Proton radiation therapy (F-PRT) decreases normal tissue toxicity while maintaining tumor-controlling efficacy compared to Standard Proton RT (S-PRT), that are used for patient treatments. However, although highly efficacious in eliminating tumors, damage to the otherwise healthy salivary glands and oral mucosa is often unavoidable in patients with head and neck cancer, leaving patients with lifelong xerostomia and other comorbidities.
Aim- In this study, we aimed to investigate the effect of F-PRT on radiation-induced oral mucositis and salivary gland dysfunction and in controlling orthotopic tumor growth.
Methods- The head and neck area of C57Bl/6 mice was irradiated with a single dose of 16 Gy or a fractionated dose of 8 Gy x 3 of F-PRT (128Gy/s) or S-PRT (0.95 Gy/s). Oral mucositis was analyzed by histopathological examination. Radiation-induced xerostomia was studied by measuring the saliva flow rate of mice. To examine the ability of F-PRT to control orthotopic head and neck tumors, tongue tumors were generated in mice and then irradiated with F-PRT/S-PRT.
Results- Following irradiation with a single dose or a fractionated dose, saliva flow was reduced by both treatments. However, the F-PRT-treated mice showed a significant improvement in salivary flow at 14 days ($p<0.05$) and 28 days ($p<0.005$) post irradiation. Expression of AQP5 was found to be significantly down-regulated at 2, 5, 10, and 14 days post irradiation with S-PRT. However, mice irradiated with F-PRT showed a significant restoration of the AQP5 expression post-RT. Oral mucositis started to appear on day 14, which showed more severity on day 28 post-irradiation with S-PRT. Histopathological analysis showed the presence of lingual gland atrophy only in the tongue of mice treated with S-PRT 28 and 60 days post-irradiation. F-PRT ameliorates radiation-induced jawbone loss compared to S-PRT as observed in mice irradiated either with a single dose or in a fractionated regime. The surviving fraction of F-PRT-treated mice with orthotopic tongue tumors was significantly ameliorated compared to S-PRT-treated mice.
Conclusion- This study demonstrates that F-PRT minimizes radiation-induced normal tissue toxicity after irradiation in mice's head and neck region. Moreover, the ability of F-PRT to control orthotopic head and neck tumors further determines the efficacy of this modality for clinical applications.

#6037 Copper-67 as a next-generation radioconjugate warhead for cancer therapy.

M. Harris[1], K. Gehlsen[1], L. McInnes[1], J. Lewis[2];

[1]Clarity Pharmaceuticals, Sydney, Australia, [2]Memorial Sloan Kettering Cancer Center, New York City, NY

Background and Purpose: Antibody drug conjugates (ADCs) have shown promise as cancer treatments. However, the efficacy of ADCs has been limited in solid tumors and can come with significant toxicities. Radioconjugates utilize various radionuclides that are chelated and can be conjugated to small molecules, peptides and antibodies. We propose Targeted Copper Theranostics (TCTs) which use copper-64 to image tumors and beta-emitting copper-67 to irradiate and kill cancer cells using various molecular targets of oncological relevance. We have evaluated the efficacy of copper-67 based therapy in three formats; peptides, antibodies, and pre-targeting of antibody conjugates in relevant tumor mouse models. Benefits of copper-67 [half-life, 61.8 h; 100% β^- energy in the range of 0.18-0.56 MeV] include high purity, high specific activity, manufacturing in a centralized distribution model at high yields on electron accelerators, and half-life suitable to various targeting formats. Copper-64 and copper-67 provide multiple logistical benefits relative to other radionuclides including Ga-68, F-18 and Lu-177.

Methods: We evaluated three tumor-targeting moieties conjugated to a sarcophagine bifunctional chelator (SAR), including: a peptide dimer targeting prostate specific membrane antigen (SAR-bisPSMA); an antibody 5B1, targeting the PDAC-specific biomarker carbohydrate antigen-19-9 (CA19-9); and a Tz-TCO IDEEA huA33 antibody/sarcophagine tetrazine conjugate targeting transmembrane glycoprotein A33. Various doses were administered of [^{67}Cu]Cu-SAR-bisPSMA in LNCAP xenografts; [^{67}Cu]Cu-SAR-5B1 (~10 µg) in FC1245 Ft2Ab PDAC tumor-bearing C57BL/6 mice; and [^{67}Cu]Cu-MeCOSAR-Tz in athymic nude mice bearing A33 antigen-expressing SW1222 human colorectal carcinoma xenografts 72 hours after administration of huA33-TCO.

Results: Administration of either 7.5, 15 or 30 MBq of [^{67}Cu]Cu-SAR-bisPSMA increased overall survival relative to the control group. Similarly, after administration of 4, 11, 18 MBq of [^{67}Cu]Cu-5B1, treated groups enhanced overall survival to 32 days compared to control (14 days). Pre-targeting using ~18.5, 37.0 or 55.5 MBq or fractionated dosing of two 27.8 MBq doses of [^{67}Cu]Cu-MeCOSAR-Tz showed efficient tumor growth reduction with enhanced overall survival for treated mice pre-administered huA33-TCO, from 68 days to >200 days (dose dependent) compared to control (21 days).

Conclusion: We report the inhibition of tumor growth with minimal radiotoxicity and each format demonstrated significantly improved overall survival compared to controls. Collectively our results demonstrated that TCTs using the sarcophagine chelator with copper-67 are effective radioconjugates across multiple formats with an acceptable safety profile. Copper-67-based TCTs are being translated in multiple theranostic clinical trials in the USA and Australia.

#6038 Copper-67 based targeted radiotherapy primes immunologically cold PDAC for immunotherapy.

Y. Rao[1], T. Viray[1], K. Gehlsen[2], **M. Harris**[2], L. McInnes[2], O. Majekodunmi[1], J. Lewis[1];
[1]Memorial Sloan Kettering Cancer Center, New York City, NY, [2]Clarity Pharmaceuticals, Sydney, Australia

Background and Purpose: Immune checkpoint therapy (ICT) has revolutionized cancer treatment however efficacy remains dismal for some cancers, including pancreatic cancers. Strategies to enhance immune responses include combining ICT with other existing cancer therapies. Targeted radiotherapy (TRT) uses a radiolabeled cancer-targeting vector, allowing for systematic delivery of specific radiation to all tumor sites while minimizing radiation exposure to healthy tissues. We propose Targeted Copper Theranostics (TCTs) as a TRT, utilizing copper-67 to irradiate and prime immunologically “cold” pancreatic adenocarcinoma (PDAC) and evaluate the efficacy of copper-67-based TRT-ICT combination therapy.
Methods: We evaluated two tumor-targeting vectors conjugated to a sarcophagine macrobicyclic chelator (SAR), an antibody—5B1, targeting the PDAC-specific biomarker carbohydrate antigen-19-9 (CA19-9), and a peptide RGD, targeting the αvβ3 integrin receptor, which is highly expressed in some PDAC tumors. We administrated ~1.1 MBq of [64Cu]Cu-SAR-bisRGD (~0.1 μg) or [64Cu]Cu-SAR-5B1 (~10 μg) to FC1245 Ft2Ab PDAC (a murine PDAC cell line expressing CA19-9) tumor-bearing C57BL/6 mice and performed biodistribution studies at 1 and 4 h for [64Cu]Cu-SAR-bisRGD-injected mice and at 24 and 48 h for [64Cu]Cu-5B1-injected mice. [67Cu]Cu-SAR-bisRGD- and [67Cu]Cu-SAR-5B1-based dose escalation studies and the combination of a copper-67-based TRT and ICT were performed to evaluate therapeutic efficacy of copper-67-based TRT and potential synergistic effects of combination therapy.
Results: Tumor uptake of [64Cu]Cu-SAR-bisRGD is ~5 %ID/g at 4h-post injection, and tumor uptake of [64Cu]Cu-SAR-5B1 is ~55 %ID/g 24h-post injection. In dose escalation studies, administration of ~11, 22, and 37 MBq of [67Cu]Cu-SAR-bisRGD (~1 μg) or administration of ~4, 11, 18 MBq of [67Cu]Cu-5B1(~150 μg) improved overall survival to 25 or 32 days respectively, compared to the control cohort (14 days). Based on weekly whole-blood analyses, no significant radiotoxicity was observed in mice receiving various doses of TRTs. The combination of 11 MBq of either [67Cu]Cu-SAR-bisRGD or [67Cu]Cu-SAR-5B1 in combination with either antiPD-L1/PD1 or antiCTLA4, improved overall survival by ~7 days compared to ICT-treated control groups.
Conclusion: Biodistribution studies demonstrated relatively high tumor specific uptake for [64Cu]Cu-SAR-bisRGD and [64Cu]Cu-SAR-5B1. Dose escalation study results suggest copper-67-based TRT could effectively inhibit tumor growth with minimal radiotoxicity. The combination of TRT with ICTs improved overall survival compared to single-ICT-treated control groups. Collectively, our results strongly support the hypothesis that TRT with [67Cu]Cu-SAR-bisRGD or [67Cu]Cu-SAR-5B1 could prime immunologically “cold” pancreatic adenocarcinoma (PDAC) to be responsive to ICTs.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Targeted Protein Degraders
Poster Session

#6042 CBP-8008: A first-in-class targeted pan-Bet protein degradation therapy using bi-specific XDC (Bi-XDC) technology for TNBC and mCRPC.

T. Wang, Z. Zhang, G. Wang, F. Pan, **R. Huang**;
Coherent biopharma (Suzhou) Co., Ltd., Suzhou, China

Bi-XDC is a breakthrough cellular targeting technology using multi-targeting ligands to effectively deliver the payload to and into specific cells. Several anticancer Bi-ligand drug conjugates including CBP-1008, CBP-1018, and CBP-1019 have been brought into various clinical stages in China and US. Targeted protein degradation molecules can degrade previously “undruggable” target proteins through their catalytic mechanism of action. The field target protein degradation has evolved since 2001, and more than 20 PROTACs are under clinical trials at different stages.

To increase the efficacy vs. tolerability window, we combine Bi-XDC technology and the catalytic approach of targeted protein degradation, to form C-PROTAC, by taking advantage of our privileged Bi-XDC technology and PROTAC’s degradation property. Further medicinal chemistry optimization, spacer optimization, and evaluation of many linker payloads led to the identification of our preclinical candidate CBP-8008, a highly potent pan-Bet protein degrader conjugated to bi-ligand via a cleavable linker.

A small panel of cell lines was screened to identify which tumors were sensitive to the pan-Bet protein degradation. All the tested breast cancer and prostate cell lines were the most sensitive to the payload. CBP-8008 had a high affinity to the Prostate Specific Membrane Antigen (PSMA) and the folate receptor alpha (FRα). Much more CBP-8008 were binding the 293T-FP which overexpress both FR-α and PSMA than the cell lines which only express one target (293T-F or 293T-P) or negative cell line (293T). CBP-8008 can quickly enter cells through endocytosis after treatment for 15 min, and degradation of BRD2, BRD3, and BRD4 was observed in MDA-MB-231 after 6 h, which was similar to its payload. The compound was very stable in mouse and human plasma in vitro, and limited free payload was detected which potentially avoids hematotoxicity in clinical. In the tumor-beaning mice DMPK study, fewer free payload was detected in 6 hours while much more free payload was detected in the tumor than in the blood and the time was extended to 72 hours after a single dose treatment. We evaluated CBP-8008 in TNBC and mCRPC xenograft model and robust efficacy was observed as lower as 3 MPK, significantly better than BMS-986158, a potent Bet inhibitor in clinical.

In conclusion: CBP-8008 is currently in preclinical development as a potential first-in-class pan-Bet protein degradation therapy using Bi-XDC technology for TNBC and mCRPC

#6043 Discovery and characterization of a p300-selective degrader with potent anti-tumor activity in CBP mutant cancers.

M. R. Russell, C. L. Lowenstein, X. Zhang, J. Roach, J. Song, R. Nagilla, N. Kendsersky, S. Joshi, P. Orth, M. Tudor, Q. Deng, C. Aguilar-Bonavides, E. Behshad, S. Banjade, Z. Sui, C. Strickland, L. Jolivette, H. P. Mohammad;
SK Life Science Labs, King of Prussia, PA

Although precision medicine strategies for the treatment of human cancers are clinically successful, they have also revealed that only a small fraction of cancers carry actionable alterations in oncogenic drivers. To expand the druggable genome while maintaining an emphasis on genetically targeted therapies, recent efforts have focused on exploiting synthetic lethal relationships. Paralogous protein pairs are particularly compelling targets in this context due to the clear mechanistic basis for the synthetic lethality. As such, functional genomics screens as well as work from Ogiwara et al. have shown compelling rationale for targeting the histone acetylase transferase p300 in the context of CBP-deficient cancer types. We discovered potent heterobifunctional degraders with demonstrated selectivity for p300 over CBP. Our compound exhibits degradation of p300 within 2 hours (DC_{50} < 10nM, D_{max} > 90%) with minimal impact on CBP through 48 h (DC_{50} >1uM, D_{max} = 30%). Utilizing CRISPR-generated isogenic cell lines depleted for either CBP or p300, we observed significant growth inhibition in CBP knockout (KO) cells (gIC_{50} = 17nM) with minimal impact on growth of p300 KO (gIC_{50} = >10uM) or parental wild-type cells (gIC_{50} > 10uM). This translated to downstream pharmacology, where we observed a rapid and potent inhibition of global H3K27 acetylation in the CBP deficient context but a significantly attenuated response in p300 deleted or parental cells. We subsequently employed computational methods to identify and characterize CBP alterations, defining a putative loss-of-function (LoF) phenotype and confirming this sensitivity pharmacologically in cancer cell types harboring these endogenous mutations. Results mirrored what we observed with CBP depletion in these endogenous CBP LoF cell lines, with potent growth inhibition seen in multiple cell lines including LK-2 (gIC_{50} = 8nM), H1703 (gIC_{50} = 9nM), and TE-8 cells (gIC_{50} = 23nM). To confirm the *in vitro* results in an *in vivo* setting, we evaluated the response in mice harboring H1703 xenografts. Once daily oral administration of our compound led to almost complete degradation of p300 within H1703 xenograft tumors, resulting in a pronounced inhibition of tumor growth. Lastly, we profiled p300 degradation in human bone marrow derived myeloid progenitor colony-forming assays where we observed a significant reduction in toxicity (IC_{50} = 3.9uM) compared to a dual CBP/p300 inhibitor (IC_{50} = 121nM) or degrader (IC_{50} = 16nM), supporting the hypothesis that a p300-specific mechanism will offer an improved therapeutic index while maintaining anti-tumor efficacy in a biomarker population Taken together, our results suggest that a p300-selective degrader has the potential to serve as an effective therapeutic modality in CBP-mutated cancers.

#6044 EPriL: A platform for the rapid identification of degraders of inhibitor-resistant kinases.

M. Muller, J. de Man, J. C. M. Uitdehaag, F. van Cauter, S. van Gemert, M. Hoffmann, Y. G. T. van Mil, W. R. Mulder, M. B. W. Prinsen, J. Sterrenburg, D. Vu, J. de Wit, E. Ensing, R. C. Buijsman;
Crossfire Oncology B.V., Oss, Netherlands

Heterobifunctional kinase degraders (HKDs) are an important new class of therapeutic modalities, of which the first have recently entered clinical trials. HKDs are small molecules that comprise a kinase-of-interest binding moiety and an E3 ligase binding moiety connected via a spacer. HKDs are excellently suited to target kinases that have a scaffolding function, or that are resistant against conventional inhibitors. A HKD brings a kinase and an E3 ligase in proximity forming a ternary complex leading to ubiquitin-dependent catalytic degradation of the kinase of interest. This ternary complex formation is unique for each kinase which can make HKDs highly specific.

To discover novel HKDs, we have developed a platform called Energetically Privileged Ligands (EPriLs), which is based on a macrocycle scaffold that binds non-covalently in the kinase ATP pocket with near-covalent affinity, and allows binding to kinases that have acquired known inhibitor resistance mutations. The macrocyclic structure allows attachment of E3 ligase ligands with multiple exit vectors. With the EPriL platform, we have developed novel HKDs for various clinically relevant kinase targets, including Bruton's Tyrosine Kinase (BTK).

BTK inhibitor drugs are used as first line treatment for chronic lymphocytic leukemia (CLL), Waldenström macroglobulinemia (WM) and as second line treatment for mantle cell lymphoma (MCL). Despite their great success in the clinic, many patients on BTK inhibitors relapse eventually, mostly because of the emergence of resistance mutations in the BTK protein. These include BTK^{C481S}, which abrogates binding of covalent drugs, and BTK^{T474I}, BTK^{L528W} and BTK^{V416L} which preclude binding of non-covalent inhibitors like pirtobrutinib. HKDs can combat resistance by degrading such BTK variants, and by removing the scaffold function of BTK. BTK degraders such as NX-5948 and NX-2127 are currently in clinical Phase 1.

To show the applicability of the EPriL platform for the discovery of novel BTK degraders, we screened a library of more than 100 EPriL HKDs for biochemical binding to BTK, and tested their propensity to induce degradation of HiBiT-tagged BTK^{WT}, BTK^{C481S} and BTK^{T474I} in HEK293 cell lines. The degrading activity of hits was verified through western blot on the BTK-dependent DLBCL cell line TMD8. The best degraders - based on potency and efficacy - were tested in cell proliferation assays on a panel of TMD8 BTK mutant cell lines. In these lines, endogenous BTK was mutated by CRISPR to BTK^{C481S}, BTK^{T474I}, BTK^{L528W} or BTK^{V416L}. Several BTK degraders had potent (< 20 nM IC_{50}) antiproliferative activity on most TMD8 lines, including difficult-to-target variants such as BTK^{V416L} and BTK^{L528W}.

The unique binding mode of the EPriL scaffold thus translates to broad activity on resistance variants, while its selectivity ensures minimal degradation of off-target tyrosine kinases as observed for other degraders.

#6045 Development and characterization of ATC-324: An AUTOTAC-based androgen receptor degrader for prostate cancer treatment.

T. Pham[1], T. Bae[2], K. Sung[2], A. Najy[1], A. Zamiri[1], H. Jang[1], S. Mun[2], S. Kim[1], D. Shi[3], S. Kregel[4], E. Heath[1], M. Cher[1], Y. Kwon[2], H.-R. Kim[1];
[1]Wayne State University School of Medicine, Detroit, MI, [2]Seoul National University, Seoul, Korea, Republic of, [3]Wayne State University College of Pharmacy and Health Sciences, Detroit, MI, [4]Loyola University, Chicago, IL

Prostate cancer (PCa) progression is largely driven by the androgen receptor (AR), making it a prime target for therapy. However, therapy resistance often arises due to AR mutations and splice variants, such as AR-v7. AUTOTAC (AUTOphagy-TArgeting Chimera) is a novel protein degradation platform that utilizes the autophagy-lysosomal pathway to selectively degrade disease-causing proteins. In this study, we characterize ATC-324, an AUTOTAC-based AR degrader designed for the treatment of PCa. ATC-324 comprises enzalutamide linked to YT 6-2, a small molecule activator of the autophagy receptor p62/SQSTM1. ATC-324 induces the formation of the AR/p62 complex while activating autophagic flux, leading to the autophagy-lysosomal degradation of AR. To characterize ATC-324, we employed various AR-dependent, AR-null, and enzalutamide-resistant PCa cell lines. Given that bone metastasis is a major clinical complication of castrate-resistant PCa associated with greater morbidity and mortality, we utilized the bone-in-culture array (BICA) assay, an *ex vivo* bones culture model, to investigate the impact of ATC-324 on PCa cell survival and growth in the bone microenvironment. We demonstrated that ATC-324 effectively degrades wild-type, mutant, and splice variants of AR. In addition, ATC-324 induces AR-dependent apoptosis and cytotoxicity. Importantly, ATC-324 maintains its potency in enzalutamide-resistant PCa cells. Utilizing the BICA assay, we showed that ATC-324 exhibits cytotoxicity against 22Rv1 bone micrometastases at even lower concentrations than in 2D cell culture. In conclusion, our study demonstrates the successful development and characterization of ATC-324 as a potent and selective degrader of various forms of AR. Furthermore, its effectiveness against enzalutamide-resistant cells indicates its capability to overcome therapy resistance. The observed cytotoxicity against bone micrometastases suggests a therapeutic potential for combating bone metastasis, a major complication of castration-resistant PCa. Our study underscores the potential of the AUTOTAC platform to selectively degrade disease-causing proteins

#6046 CFT8634, a BRD9 BiDAC™ degrader, is active in a subset of multiple myeloma cell line models and synergistic when combined with pomalidomide or dexamethasone.

L. L. Poling, D. Cocozziello, M. He, E. Hurh, R. Lobbardi, K. L. Jackson, S. L. Fisher, R. M. Pollock;
C4 Therapeutics, Inc., Watertown, MA

Recent literature has shown that loss-of-function of BRD9, a component of the noncanonical SWI/SNF (ncSWI/SNF) complex, mediated by RNA interference or by BRD9 degrader compounds can inhibit multiple myeloma (MM) cell lines and primary MM cell proliferation *in vitro*, as well as inhibit mouse MM xenograft tumor growth *in vivo*. Additionally, *in vitro* synergy was observed when a BRD9 degrader was combined with either dexamethasone or pomalidomide. CFT8634 is a potent and selective oral BiDAC™ degrader of BRD9 that entered a clinical trial for the treatment of SMARCB1-perturbed cancers, including synovial sarcoma and SMARCB1-null tumors. Pharmacokinetic and pharmacodynamic data from this trial demonstrated dose-proportional human plasma exposure and robust BRD9 degradation in patients.

Here we show that CFT8634 has anti-proliferative activity in a subset of MM cell lines that translates into tumor growth inhibition in MM xenograft models at clinically relevant CFT8634 exposures. We observe that cell lines less sensitive to pomalidomide tend to be significantly more sensitive to CFT8634 treatment. As pomalidomide is a SoC treatment in MM, we interrogated the ability to combine CFT8634 and pomalidomide. CFT8634 demonstrates synergy with pomalidomide in MM cell lines where CFT8634 is anti-proliferative as a single agent. We further show that clinically relevant exposures of CFT8634 demonstrate synergy with pomalidomide *in vivo* in the NCI-H929 mouse xenograft model. This model is relatively unresponsive to pomalidomide alone, suggesting that CFT8634 can render otherwise recalcitrant MM tumors sensitive to the effects of pomalidomide in combination. Pharmacokinetic and pharmacodynamic analyses show that in combination, CFT8634 and pomalidomide do not interfere with the ability to degrade each other's targets (BRD9 and IKZF1/3, respectively) despite both utilizing the E3 ligase cereblon.

As the corticosteroid dexamethasone is another SoC treatment given in combination with pomalidomide, we explored the ability to combine dexamethasone with CFT8634. CFT8634 demonstrates synergy with dexamethasone in the RPMI-8226 *in vivo* xenograft model. This combination leads to tumor regressions at clinically relevant doses and outperforms the current combination of pomalidomide with dexamethasone.

In conclusion, we demonstrate *in vitro* and *in vivo* activity in an expanded set of MM models using the clinical oral BRD9 degrader CFT8634 as a single agent and show *in vivo* synergy between CFT8634 and SoC agents pomalidomide and dexamethasone at clinically relevant doses.

#6047 Discovery and characterization of PVTX-321, an estrogen receptor heterobifunctional degrader .

C. G. Havens, G. Xu, C. Lowenstein, D. Samanta, B. Vidal, E. Behshad, R. Nagilla, M. Russell, P. Orth, W. Wu, L. Jolivette, S. Priestley, H. Mohammad, Z. Sui; SK Life Science Labs, King of Prussia, PA

The estrogen receptor α (ERα) is a clinically validated target for the treatment of estrogen receptor-positive and human epidermal growth factor receptor 2-negative (ER+/HER2-) breast cancer. However, resistance to early line endocrine treatments due to mutations of the ESR1 gene encoding ERα is associated with poor prognosis and remains an area of unmet clinical need. ERα degradation using heterobifunctional degraders has emerged as a promising approach to tackle endocrine resistance through proteasome mediated degradation of the receptor. Here, we present the preclinical results for the development candidate, PVTX-321, an ERα heterobifunctional degrader. PVTX-321 is a rapid and potent ER heterobifunctional degrader as well as a full ERα antagonist. Both properties translate into potent antiproliferative activity across multiple ER+ breast cancer cell lines bearing either wild-type or clinically relevant ERα mutations (E380Q, Y537S and D538G). PVTX-321 demonstrates favorable oral bioavailability across different species and effectively induces dose-dependent degradation of ERα *in vivo*. Moreover, PVTX-321 achieves tumor regression as an oral agent at 10 mg/kg in MCF-7 mouse xenograft model. Furthermore, PVTX-321 possesses excellent *in vitro* and *in vivo* safety profiles and warrants further development for the treatment of ER+/HER2- breast cancer.

#6048 Targeting AR positive prostate cancer cells by the novel P300/CBP oral available PROTAC degrader.

j. luo, A. Prolia, Y. Qiao, j. tian, R. Mannan, S. Mahapatra, z. chen, R. Seri, S. Wang, A. Chinnaiyan;
University of Michigan, Ann ARBOR, MI

Background The Androgen Receptor (AR) serves as the core lineage-specific transcription factor for prostatic epithelial cells. Targeting AR is currently the most promising therapeutic strategy. However, the inevitable development of acquired resistance to anti-androgen treatments underscores the urgent need to devise new therapeutic strategies. Recent studies have revealed that in prostate cancer cells, AR is hijacked by oncogenic transcription factors, such as FOXA1 and HOXB13, which promiscuously bind to distinct enhancer sites, driving the progression of prostate cancer. This process leads to the formation of a substantially rewired AR cancer specific enhanceosome, requiring a variety of coregulators to exhibit oncogenic driver characteristics, which can be potential therapeutic targets for prostate cancer. Histone acetyltransferases (HATs) P300 and CBP are paralogs which play dominant roles in orchestrating high-order chromatin structures and transcription factor complexes by acetylating histone proteins at multiple residuals. Although accumulating evidence suggests that P300/CBP function as AR coregulator and targeting P300/CBP can markedly suppress AR-positive prostate cancer cell growth, including growth of castration-resistant prostate cancer (CRPC), most of the P300/CBP inhibitors have performed poorly in clinical trials.
Methods We developed a novel P300/CBP dual oral available PROTAC degrader, namely CBPD-409. The on-target effects of CBPD-409 were assessed by quantitative proteomics (TMT-mass spectrometry) in prostate cancer cell lines. The RNA-seq analysis was conducted to investigate CBPD-409 effects on global transcriptome in prostate cancer cells. The cytotoxicity of CBPD-409 in multiple prostate cancer cell lines was examined by cell-titer-glo and incucyte assays.
Conclusion In multiple cell lines, CBPD-409 exhibits remarked potency to degrade both P300 and CBP proteins in time and does dependent manner, without evident off-target effects. By employing CBPD-409, we demonstrate that degrading P300/CBP preferentially suppress AR+ prostate cancer cell growth. The global transcriptomic profiling in CBPD-409 treated prostate cancer cells revealed that loss of P300/CBP results in remarkedly downregulation of AR, Myc, FOXA1 and ERG signaling. Assessment of CBPD-409 cytotoxicity in a panel prostate cancer cell lines suggests that AR positive prostate cancer cells display highest sensitivity to CBPD-409.

#6049 Cell-based PROTAC screening for cancer drug discovery.

Y. Wan, H. Ma, J. Wu;
Reaction Biology, Malvern, PA

Proteolysis-Targeting Chimeras (PROTACs) have emerged as a promising strategy for selectively degrading specific target proteins, thereby offering a novel approach to precision cancer therapy. Among the most notable oncogenes, KRAS with the G12C mutation is responsible for 45%-50% of KRAS mutations in non-small cell lung carcinomas. Additionally, BRD4, a well-studied member of the Bromo- and Extra-Terminal (BET) protein family, is implicated in various hematological and solid tumors. The implementation of cell-based screening for PROTACs targeting either KRAS(G12C) or BRD4 represents a highly valuable platform for advancing cancer drug discovery. We utilized the NanoBRET™ Ternary Complex Assay, NanoBiT™ Assay, and Western Blot assay to evaluate the efficacy of PROTACs. The NanoBRET™ Ternary Complex Assay revealed that KRAS G12C degrader-1 and LC-2 effectively degrade KRAS(G12C), while dBET6 and MZ-1 demonstrated the ability to degrade BRD4. Notably, the NanoBiT™ assay showed that LC-2 dose-dependently degrades KRAS(G12C) in HEK293 cells co-transfected with KRAS(G12C)-LgBiT and KRAS(G12C)-SmBiT. Moreover, BET6 exhibited a dose-dependent degradation of endogenous BRD4 in HepG2 cells, and LC-2 demonstrated the degradation of endogenous KRAS(G12C) in MiaPaCa2 cells. In summary, the development of a robust cell-based assay platform for high-throughput screening of PROTACs marks a substantial advancement in cancer drug discovery. This approach not only enables the identification of promising PROTACs but also holds the potential for more effective and targeted interventions in the ongoing battle against cancer.

#6050 Targeting KRAS G12D mutant tumors with the PROTAC degrader RP03707.

X. Ji[1], H. Li[1], G. Wu[1], Q. Zhang[1], X. He[1], Y. Wu[1], B. Zong[1], X. Xu[1], C. Liang[1], B. Wang[1], Y. Zhang[1], Q. Hu[1], J. Zhou[2], W. Guo[1], B. Bai[1], L. Wang[1], J. Ai[1], L. Zhang[1], H. Zhou[1], S. Sun[1], Y. Wang[1], Y. Wang[1], Q. Fan[1], D. Chen[1], **T. Zhou**[1], J. Lu[1];

[1]Risen Pharmaceuticals Private Ltd., Shanghai, China, [2]University of California San Diego, San Diego, CA

RAS oncogene mutations are prevalent in approximately 19% of cancer patients, with the most frequent alteration occurring in codon 12 of the KRAS gene, resulting in a variety of G12X oncoproteins. Recent advances in drug discovery have yielded several KRAS G12C inhibitors currently in clinical use, benefiting a subset of patients. However, addressing the high-prevalence G12D mutation remains a substantial unmet medical need. Targeted protein degradation using PROTAC molecules offers a promising approach for treating KRAS G12D-associated tumors, potentially providing superior efficacy and mitigating the development of resistance, a challenge frequently observed with KRAS G12C inhibitors in clinical settings. In the present study, we report a PROTAC compound RP03707 that efficiently induces the degradation of the KRAS G12D mutant protein and inhibits tumor growth. Treatment of AsPc-1 cells with RP03707 results in significant degradation of the KRAS G12D protein, with a DC50 value in the sub-nanomolar range. Within 24 hours, the compound eliminates over 90% of G12D proteins and effectively suppresses downstream cellular MAPK signaling. Additional *in vitro* experiments demonstrate that RP03707 inhibits cell proliferation in multiple KRAS G12D mutant cell lines, surpassing the anti-tumor efficacy of enzyme inhibitors. In a mouse GP2d xenograft tumor model, a single intravenous administration of RP03707 at 10 mpk results in excellent compound penetration and retention in tumor tissues, followed by 90% reduction of G12D protein levels for 7 days. Profound inhibition of tumor growth is observed not only in mouse GP2d xenograft but also in other mouse KRAS G12D tumor models, even when the compound is administered in low and infrequent doses. Moreover, RP03707 exhibits high selectivity for degrading the KRAS G12D protein and possesses favorable drug-like properties. RP03707, therefore, meets the criteria for advancing into drug development and represents a valuable therapeutic option for treating KRAS G12D-associated tumors.

#6051 Discovery of oral SMARCA2 degraders for the treatment of SMARCA4 mutant tumors.

J. C. Clemente, L. Harikrishnan, S. Knight, D. Samanta, Z. Li, R. Nagilla, N. Kendsersky, S. Joshi, P. Orth, M. Tudor, Q. Deng, C. Aguilar-Bonavides, E. Behshad, Z. Sui, C. Strickland, L. Jolivette, H. P. Mohammad;
SK life science labs, King of Prussia, PA

The paralog enzymes SMARCA2 and SMARCA4 are mutually exclusive members within the SWI/SNF chromatin remodeling complex. This complex plays a crucial role in governing gene expression by altering the chromatin and rendering it accessible to transcription machinery. The process of chromatin remodeling by the SWI/SNF complex is dependent on ATP hydrolysis. Within the complex, either SMARCA2 or SMARCA4 serves as the sole component capable of catalyzing ATP hydrolysis and are thereby essential to the activity of the complex. SMARCA4 has been found to be mutated in various cancer types, including non-small cell lung carcinoma, colon adenocarcinoma, bladder, and endometrial cancer. In cancer cells where SMARCA4 is deleted, the functionality of the SWI/SNF complex and cell survival is dependent on the presence of SMARCA2, thereby resulting in synthetic lethality if SMARCA2 is depleted. Utilizing in vitro and in vivo model systems we have discovered potent, selective, and orally bioavailable heterobifunctional degraders targeting SMARCA2. Our lead molecules exhibit potent and selective degradation of SMARCA2 (DC_{50} < 10 nM) with no impact on SMARCA4 (DC_{50} > 1000 nM). Furthermore, a striking selective activity in proliferation assays was observed with SMARCA4 deleted cells exhibiting gIC50 ranging from 1 -10 nM and SMARCA4 WT cells > 1000 nM. Oral administration in mice harboring human cancer cell line xenografts revealed dose-dependent and selective *in vivo* degradation of SMARCA2. Degradation of SMARCA2 led to significant anti-tumor activity in SMARCA4 mutant NSCLC xenograft models. Together, these data demonstrate a foundation for the development of a best-in-class degrader for the treatment of SMARCA4 deleted cancers.

#6052 Systematic identification of novel targeted protein degradation mechanisms using SITESEEKER® technology.

C. Dillon;
PhoreMost Limited, Pampisford, United Kingdom

The rise of Targeted Protein Degradation (TPD) is rapidly changing perceptions about therapeutic target druggability and is rewriting many preconceived notions on drug design. However, the majority of monovalent molecular glue and heterobifunctional degraders in clinical and preclinical development rely predominantly on the recruitment of a single E3 ligase, Cereblon. Arising resistance, toxicities and restricted Protein-of-Interest scope may limit clinical potential, highlighting the need to uncover novel TPD mechanisms. To expand the potential of this modality, we have developed SITESEEKER®, a screening technology operating at substantially greater magnitude of complexity than extant target discovery platforms. SITESEEKER® utilizes computationally-derived encoded mini-protein fragments with huge shape diversity to systematically identify novel degrader mechanisms and define functionally-active binding sites on targets. SITSEEKER® allows for the discovery of targets that may be missed through traditional gene editing or knockdown approaches and can additionally provide valuable mechanistic insights that help to inform, unlock and truncate the path from target ID to drug discovery. We describe the identification of a cache of degrader motifs which showcase the breadth of proteome space yet to be explored within TPD. Moreover, we identify peptide motifs capable of driving degradation in a selective manner with potential to be translated into tissue- or cancer-selective degraders. The functional dependencies of prioritized degraders have been mapped to their cognate E3 ligase using combinatorial screening, giving rise to a number of E3 ligases with potential to be hijacked for TPD. PhoreMost is progressing a pipeline of monovalent and heterobifunctional oncology degrader programs arising from its platform. We demonstrate the effective hijacking of selected E3 ligases, identified by SITESEEKER®, through the discovery of high affinity small molecule binders and subsequent discovery of efficient heterobifunctional degraders against selected Proteins-of-Interest.

#6053 Mechanism of action of tumor-selective, chaperone-mediated protein degraders (CHAMPs).

X. Yang[1], Y. Dai[1], Q. Ding[1], F. Du[1], J. Li[1], C. Liu[1], C. Lv[1], L. Ma[1], T. L. Prince[2], Y. Sun[1], M. Wang[1], R. Wang[1], Y. Wang[1], Z. Wang[1], M. Wu[1], M. Xu[1], Z. Yang[1], L. Ye[1], W. Yin[1], C. Ying[1], H. Zhou[1], G. Wang[1], W. Ying[1], K. P. Foley[2];

[1]Ranok Therapeutics, Hangzhou, China, [2]Ranok Therapeutics, Waltham, MA

HSP90 mediates the folding of many important cancer-associated proteins, but it can also direct its substrates towards degradation via the ubiquitin-proteasome system. Furthermore, in tumor tissues, HSP90 complexes are in an activated state relative to normal tissues, and small molecule HSP90 inhibitors display unique tumor-selective pharmacokinetics. To take advantage of these attributes, we have developed a novel targeted protein degradation technology, termed Chaperone-Mediated Protein Degradation (CHAMP), and present here an in-depth characterization of the CHAMP mechanism of action. Initially, from a chemical library of greater than 1000 linkered HSP90 binders, hetero-bifunctional CHAMPs were synthesized in which target protein binders and HSP90 binders were covalently coupled together by short linkers. The resulting compounds were screened for target protein degradation and cancer cell cytotoxicity to identify promising leads for further optimization. We found that CHAMPs can degrade a wide variety of target proteins. This included proteins that are known to be regulated by HSP90, such as transcription factor BRD4 or ERK5 kinase. However, proteins that are normally independent of HSP90 function can also be degraded, including mutated KRAS and SHP2 phosphatase. In vitro, CHAMP treatment of cells resulted in formation of a ternary complex between the target protein, CHAMP compound and HSP90. Moreover, an X-ray crystal structure was solved for a mKRAS-CHAMP-HSP90 ternary complex. CHAMP-mediated degradation required both the target- and HSP90-binding moieties to be covalently coupled and involved ubiquitination of the target protein. Multiple ubiquitin E3 ligases were present in ternary complexes, and depending on the target protein, NEDD8 inhibition or CRISPR knockouts of individual E3 ligases could suppress proteasome-dependent target degradation. In vivo, irrespective of target, CHAMPs displayed prolonged exposure in tumors relative to plasma and normal tissues, resulting in prolonged target degradation in tumors and strong tumor growth inhibition at well-tolerated doses. CHAMP technology can be applied to a diversity of cancer-associated targets and has potential advantages relative to other protein degradation approaches, including an improved safety margin due to preferential accumulation in tumor tissues.

#6054 UPPGRADER: a bioinformatics-based novel E3 ligase discovery platform.

K. Ha[1], W. Song[2], W. Choi[1], G. Lee[1], S. Ryu[1], J. Lee[1], **H. Lee**[2];
[1]UPPTHERA, Incheon, Korea, Republic of, [2]Kyunghee University, Seoul, Korea, Republic of

In Target Protein Degradation (TPD) field, conventional E3 ligases utilized in the clinic are limited to CRBN and VHL, which opens the need for exploration of novel E3 ligases for the advancement of TPD. To address this, we have developed a proprietary platform, UPPGRADER, for systematic discovery of novel E3 ligases based on -omics data including single cell RNA sequencing (scRNA-seq) and whole genome sequencing (WGS), in conjunction with proteomics data and bioinformatics tools.UPPGRADER enables systematic analyses on alterations occurred in all genomic areas including E3 ligase genes and potential target genes. For example, analyzing Pan-Cancer Analysis of Whole Genomes (PCAWG) data identified amino acid changes into Cysteine or Lysine, which can be targeted by covalent binders with cancer specificity. Through such analysis, we discovered several novel E3 ligases, including but not limited to FBXW7, with the categorization of the findings based on specific cancer types.At the single cell expression level, UPPGRADER provides the capability to assess gene expression levels of E3 ligases and target proteins by proprietary measurements based on gene detection rate. This system also allows assessment of E3 ligase-Target gene co-expression per single cell. In colorectal cancer, UPPGRADER has shown that the co-expression of E3 ligase FBXW7 and well-known colorectal cancer target (KRAS) increases from 1% (4 out of 334) in normal epithelial cells to 17% (2,967 out of 17,458) in cancerous epithelial cells, highlighting a significant change in their simultaneous expression patterns during cancer progression.UPPGRADER also identified E3 ligase X which showed high co-expression level with KRAS gene alongside universal expression properties and high cancer cell dependencies. For E3 ligase X, we developed novel small molecule binders (nM binding affinity) with bioavailability > 20% in animal pharmacokinetics. Bifunctional degraders utilizing these binders displayed BRD4 degradation in more than 20 cell lines with double to triple digit nM DC50 and DC90 values. Other targets (AURKA, CRBN and others) were potently degraded with anticipated mechanism of action (assessed by E3 ligase KO cell line and proteasomal inhibitors).To conclude, UPPGRADER is a comprehensive bioinformatics tool for discovering novel E3 ligases with biological validations. Through recent explosion of scRNA-seq and WGS datasets in different diseases and mechanism-based identification of additional molecular targets, UPPGRADER is poised to advance the field of TPD.

#6055 COOTO-Me (10e) acts as a molecular glue to target NCOR/HDAC3 degradation.

P. Gong[1], M. Huang[1], X. Li[1], H. Wang[1], S. Waxman[2], L. Zhao[1], Y. Jing[1];

[1]Shenyang Pharmaceutical University, Shenyang, China, [2]Icahn School of Medicine at Mount Sinai, New York, NY

Histone deacetylase 3 (HDAC3) is overexpressed in cancer cells and functions as transcription repression complex with nuclear receptor corepressor (NCOR) to inhibit gene transcription. The pan-HDAC inhibitors have been approved for T-cell lymphoma with evident side effects. The selective HDAC3 inhibitors needs to be developed. Proteolysis-targeting chimera (PROTAC) approach is taken to design HDAC3 degraders with unsolved bioavailability obstacle. We screened small molecules with HDAC3 degradation ability and found two small molecules derived from glycyrrhetinic acid, methyl 2-cyano-3-oxo-18β-olean-1,9(11), 12-trien-30-oate (COOTO, 10e) and methyl 2-cyano-3,12-dioxo-18β-olean-1,9(11)-dien-30-oate (CDODO-Me, 10d), selectively decreased HDAC3 protein with increased acetylation of Histone 3. We explored the mechanism of HDAC3 degradation and found that 10e interrupted the interaction of HDAC3 with NCOR and induced degradation of both HDAC3 and NCOR protein. Biotin labeled 10e shows binding to both HDAC3 and NCOR directly as well as to E3 ligases SIAH2 and ITCH. Mass spectrometry analysis profiling reveals covalent interactions of 10e with multiple cysteine sites of SIAH2 in the binding regions for NCOR and HDAC3. Silencing SIAH2 blocks degradation of HDAC3. *N*-Acetylcysteine and GSH block the binding of 10e to HDAC3, NCOR and SIAH2. In addition, 10e decreased the levels of c-FLIP protein and increased the levels of NOXA protein leading to apoptosis induction. These data suggest that 10e functions as a molecular glue to attract SIAH2 to HDAC3 and NCOR to cause degradation through covalent binding.

#6056 Identification of first-in-class, orally bioavailable SOS1 bifunctional degraders for the treatment of KRAS- and RTK-driven cancers.

K. Begovich, A. Schoolmeesters, N. Rajapakse, E. Martinez, Q. Liu, A. Shakya, A. Okano, V. Mali, S. Huang, A. Chourasia, L. Fung;
BioTheryX, Inc., San Diego, CA

Monotherapies which target nodes within the RTK-RAS-MAPK pathway often display early potency in the clinic, but their preliminary response is limited as tumors begin to regrow due to adaptive and acquired resistance mechanisms. Disrupting proteins that mitigate either type of resistance mechanism in combination with oncogene-targeted agents could help extend and enhance the clinical potential of these drugs. Son of Sevenless 1 (SOS1), a RAS guanine nucleotide exchange factor, is a highly attractable protein to target given its role in transducing inputs from upstream receptor tyrosine kinases (RTKs) to downstream RAS proteins to regulate signaling pathways involved in cell proliferation and survival. Additionally, SOS1 is subject to MAPK-mediated negative feedback inhibition and drugs targeting upstream and downstream nodes relieves SOS1 from this inhibition resulting in pathway reactivation. To address this need, we have developed orally bioavailable SOS1 bifunctional degraders for cancers driven by KRAS and RTKs. Our top two lead molecules demonstrate CRBN- and proteasomal-mediated SOS1 degradation with DC_{50}s < 10nM and maximum degradation > 90%. Consistent with this notion, SOS1 degradation inhibited downstream signaling marker phopshoERK with IC_{50}s < 5nM and were 26- or 53-fold more potent when compared to the clinical SOS1 inhibitor. Notably, the SOS1 degraders exhibited weaker SOS1 binding compared to other SOS1 inhibitors highlighting that the potency is heavily driven by the catalytic nature of degradation rather than occupancy-driven events. Both SOS1 degraders displayed CRBN- and SOS1-dependent antiproliferative activity in KRAS- and EGFR- mutant, solid tumor cell lines as well as in BCR-ABL driven, CML cells with IC_{50} values ranging from 0.5-10nM. Consistent with our *in vitro* data, oral administration of our SOS1 degraders in mice harboring H358 (KRAS G12C) and H441 (KRAS G12V) xenografts resulted in SOS1 degradation, phosphoERK reduction and significant tumor growth inhibition. While SOS1 degrader monotherapy demonstrated *in vitro* and *in vivo* potency, combination of mutant or allele specific EGFR and KRAS inhibitors and ABL inhibitors with our proof-of-concept degraders prevented pathway reactivation associated with these inhibitors and lead to a more durable response. These combinations also yielded synergistic effects in *in vitro* proliferation assays as well as enhanced tumor growth inhibition in KRAS-mutant xenograft models. Together, our SOS1 degraders alone and in combination with other targeted agents demonstrated anti-tumor activity in a variety of KRAS- and RTK-driven cancer cell lines and xenograft models. These results support the potential of orally bioavailable SOS1 degraders to help mitigate pathway reactivation for enhanced efficacy and prolonged response duration.

#6057 Evaluation of a highly potent and selective STAT3 degrader as a new class of immunotherapy.

L. Bai, H. Zhou, J. Zhou, D. Wu, R. Acharyya, H. Metwally, D. McEachern, B. Wen, D. Sun, W. Zou, S. Wang;
University of Michigan, Ann Arbor, MI

STAT3 (signal transducer and activator of transcription 3) is a transcription factor and a promising therapeutic target for cancer and other human diseases. In addition to its role in regulation of tumor cells, STAT3 also plays a key role in regulation of immunity and is a promising therapeutic target for the development of new immuno-oncology drugs. Our laboratory has previously reported the development of potent and highly selective STAT3 degraders, including SD-36 and SD-91. Extensive optimization of SD-36 and SD-91 yielded new, highly potent, selective and efficacious STAT3 degraders. In direct comparison, our most potent, new STAT3 degrader (compound 1) is >50-times more potent than SD-36 in inducing STAT3 degradation in cells and demonstrates >500-fold degradation selectivity over other STAT members. A single intravenous administration of compound 1 in mice is highly effective in inducing complete depletion of STAT3 protein in tissues for 48-96 h without reducing the levels of other STAT proteins. Compound 1 is very effective in inhibition of tumor growth not only in tumor models responsive to immune checkpoint blockade (ICB) but also in tumor models resistant to ICB. Furthermore, combination of compound 1 with PD-1/PD-L1 antibodies greatly enhances the antitumor activity as compared to SD-1218 or ICB. Of significance, compound 1 is well tolerated in mice without any signs of toxicity in mice at highly efficacious doses. Our mechanistic studies show that STAT3 depletion has a major effect in modulation of the immune cells in mice. Collectively, our data suggest that selective STAT3 degradation hold great promise for new cancer immunotherapy.

#6059 Discovery of ETS-007, a first-in-class degrader targeting N-terminal domain of androgen receptor derived from AR liquid-liquid phase separation inhibitor.

Y. Li, M. Fei, Y. Miao, L. Feng, X. Fan, J. Li, Y. Chen, M. Xu, W. Cui, Q. Zheng, **J. Zhu**;
ETERN Therapeutics Co., Ltd., WuXi, China

Patients with advanced prostate cancer inevitably acquire resistance to anti-androgen therapies, and progress to lethal castration-resistant prostate cancer (CRPC). The resistance mechanisms involve AR gene amplification and overexpression, constitutively active ligand-independent splice variants such as AR-V7, and the mutations in the AR ligand-binding domain (LBD). Our previous study has shown that the AR N-terminal domain (NTD) is responsible for AR liquid-liquid phase separation (LLPS) capability, which is essential for AR/AR-V7 transcriptional activity. We conducted a compound library screening using an AR LLPS phenotypic assay and identified ET0516 as a hit to specifically inhibit AR LLPS and its downstream gene expression, indicating that inhibition of AR. LLPS through targeting its NTD is a feasible approach to overcome the resistance to current anti-androgens therapy. Here we report the identification of a novel AR degrader, ETS-007 which is originated and evolved from internal LLPS phenotypic screening, that effectively degrades both AR and AR-V7 proteins with DC_{50} of single-digit nM by inducing a protein-protein interaction between AR NTD and an E3 ligase complex. ETS-007 induced AR and AR-V7 polyubiquitination, followed by degradation which could be blocked by the protease inhibitor MG132. ETS-007 significantly inhibited cell proliferation in AR and/or AR-V7 positive cell lines, e.g. LNCaP and 22RV1, and downregulated the androgen responsive genes such as PSA and TMPRSS2. Compared with enzalutamide and ARV-110, ETS-007 could block transcriptional activities of AR-V7, and AR mutants in luciferase report assay. Oral administration of ETS-007 in an enzalutamide-resistant 22RV1 xenograft model led to intratumoral AR-V7 degradation and concomitant decrease in PSA protein levels, resulting in a remarkable tumor regression. Taken together, our findings provide preclinical evidence that ETS-007 as a potent AR-NTD degrader derived from our LLPS platform can effectively block the transcriptional activities of both AR and AR-V7 for the treatment of metastatic CRPC.

#6060 Discovery of potent SHP2 protein degraders with strong anti-tumor activities in KRAS mutant cancers.

S. Kim[1], J. Lee[2], J. Song[1], G.-T. Park[1], J. Jung[1], J. Na[1], D. Lee[1], S. Lee[2], J. Park[2], J. Kim[2], O. Bae[2], J. Han[2], J. Kang[2], M. Moon[1], Y. Shin[1], J. Ryu[2], S. Lee[2], S.-K. Park[1];

[1]SK Biopharmaceuticals Co., Ltd., Seongnam-si, Korea, Republic of, [2]Ubix Therapeutics, Seoul, Korea, Republic of

Background: SHP2 plays a pivotal role in modulating the RTK/RAS/MAPK signaling pathway, which is frequently dysregulated in various cancers. Multiple allosteric SHP2 inhibitors have been under active development for the treatment of RTK/RAS/MAPK-dependent cancers, while certain limitations have come to light, such as their inability to target the active form of SHP2 and narrow therapeutic index necessitating intermittent dosing to mitigate toxicity. To overcome these challenges, we have discovered SHP2 protein degraders as next generation SHP2 targeting agents. Here, we present compelling profiles of our SHP2 degraders.

Methods: We employed a variety of cancer cell lines harboring mutations in RTK, KRAS, or SHP2 for assessing *in vitro* activity of SHP2 degraders. For *in vivo* assessment of pharmacological profile, we utilized an NCI-H358 KRAS G12C mutant NSCLC xenograft. SHP2 protein levels in cell lysates and tumors were analyzed to assess SHP2 degradation efficiency. Simultaneously, ERK phosphorylation and DUSP6 mRNA levels were analyzed to evaluate downstream effects. Immunoprecipitation assays were used to assess the impact on SHP2's scaffolding roles.

Results: A series of SHP2 degraders have been identified, demonstrating highly efficient SHP2 degradation activity with DC_{50} values in subnanomolar ranges. Robust inhibition of ERK phosphorylation, followed by remarkable anti-cancer effects in multiple KRAS mutant cancer cell lines were observed. Interestingly, *in vitro* cell growth inhibition by SHP2 degraders are 10 times more potent than SHP2 inhibitors currently under clinical development. Further characterization reveals several advantages of SHP2 degraders compared to SHP2 inhibitors. First, we observed a more efficient disruption of SHP2 scaffolding function, such as the formation of the SHP2-GRB2-GAB1 complex. Second, we detected effective degradation of activating mutants of SHP2, such as E76K and T507K, which are typically not targeted by SHP2 inhibitors. Experiments using a KRAS mutant CDX model demonstrate compelling *in vivo* profiles. A single administration of lead compounds resulted in D_{max} values exceeding 95% in tumors, accompanied by the significant reduction of downstream signaling markers, such as p-ERK and DUSP6 mRNA. Notably, the reduced levels of SHP2 and downstream markers persist for several days. This suggests that utilizing intermittent dosing could be a viable approach with SHP2 degraders. Once-weekly intravenous administration achieved strong tumor growth inhibition without causing significant body weight loss.

Conclusion: We have successfully discovered novel SHP2 degraders exhibiting remarkable activities. We demonstrate that SHP2 degraders have potential to overcome the limitations associated with allosteric SHP2 inhibitors and provide a promising therapeutic option for RTK/RAS/MAPK-dependent cancer patients.

#6061 Development of target cell-penetrating scFv conjugate degrader for the selective inhibition of mutant, resistant KRAS cancer.

G. Yoon[1], B. Jo[1], D. Lee[1], J. Yang[2], M.-H. Park[2], S. Seok[2], J. Lee[2], C. Chung[2], Y. Park[1];

[1]Seoul National University, Seoul, Korea, Republic of, [2]Nano Intelligent Biomedical Engineering Corporation (NIBEC), Seoul, Korea, Republic of

The activation of mutations in the RAS gene, which is frequently observed in human cancers, induces downstream critical effectors, contributing to tumorigenesis. While attempts to directly target the GTP-bound, activated RAS have shown some success in certain cancer treatments, resistance remains a challenge. Our objective is to develop a cell-penetrating single-chain fragment variable (scFv) degrader that targets mutant KRAS for degradation. The scFv, binding specifically to antigens, can mitigate the side effects of non-specific binding seen with chemical drugs. However, due to the limited cell-penetrating capability of scFv, a delivery carrier is often necessary. In this study, a cancer targeting, and cell-penetrating synthetic peptide (CPP) was developed as a drug delivery carrier and added to the sequence of scFv. To this conjugate, a von Hippel-Lindau (VHL) expressing sequence was added to enable the scFv binding to mutant KRAS, enabling its proteasomal degradation. These conjugates were engineered as a plasmid DNA to be expressed as a protein conjugate in CHO cells. The purity of the scFv-VHL-CPP degrader was confirmed by SDS PAGE. In SPR results, the degrader not only exhibited high binding ability to mutant KRAS but also influenced the proliferation of KRAS mutant cells in cell viability tests. Mutant GTP-bound KRAS was reduced by the KRAS degrader in KRAS mutant cancer cells. The in vivo study further confirmed the degradation of the KRAS, as reflected by the significantly reduced tumor growth. In conclusion, a degrader protein binding to mutant KRAS that consists of cell penetrating peptide, scFv, and VHL is expected to become a new protein anticancer drug especially effective against mutant, resistant KRAS-mediated cancer cells. Especially, the design of the target cell penetrating peptide-scFv-VHL would be served as a platform for the target protein degrader development.

#6062 Potent and orally bioavailable BCL6 protein degraders demonstrate efficacy in pre-clinical models of diffuse large B-cell lymphoma (DLBCL).

J. Xu[1], Y. Li[1], **J. Wang**[1], P. Tang[2], Y. Liao[2], C. Zhang[2], P. Yan[2];
[1]Haisco Pharmaceutical Group Co., Ltd., Shanghai, China, [2]Haisco Pharmaceutical Group Co., Ltd., Chengdu, China

The B-cell lymphoma 6 (BCL6) transcription repressor protein is a protooncogene especially in diffuse large B-cell lymphoma (DLBCL), conferring survival, protection, and maintenance of lymphoma cells. BCL6 expression in normal B cells contributes to initiation and maintenance of the germinal centers (GC). Somatic mutations of the BCL6 gene including chromosome translocations have been shown to result in the deregulation of BCL6 expression and contributes to a subgroup of poor prognostic double- and triple-hit lymphomas. To solve this unmet clinical need, we have developed highly specific, potent, and orally bioavailable BCL6 protein degrader HSK43608 that demonstrates potent in vitro and in vivo efficacy in multiple pre-clinical DLBCL models. HSK43608 achieves >90% BCL6 degradation at 10 nM and DC_{50} of <1 nM in the OCI-Ly1 model following 24 hr treatment. Time-course studies showed >90% BCL6 degradation within 1 hr which could be maintained at 24 hrs. Importantly, medicinal chemistry efforts have resulted in the successful development of new-generation IMIDs to improve the oral bioavailability of BCL6 degrader for in vivo treatment. As expected, concentration of HSK43608 in tumor tissue was much higher than that in plasma in the DLBCL xenograft models. This tumor tissue enrichment of HSK43608 achieved >95% BCL6 degradation 48 hr after last dosing and convincing tumor growth inhibition. It is worth noting that BCL6 knockout mice suffer from myocarditis with eosinophils infiltration in heart muscle. The tissue distribution study demonstrated less HSK43608 in heart than in plasma, partially explained why there was no sign of myocarditis with eosinophils infiltration in the heart of the HSK43608 treated mice. Taking advantage of the new IMIDs structure, HSK43608 barely induce the degradation of the first generation IMIDs targets including GSPT1, SALL4, CK1α, Aiolos and Ikaros, indicating its safety. In summary, these results indicate HSK43608 as a potent and orally bioavailable BCL6 degrader and support further development.

#6064 Discovery of potent and selective EP300 degraders with anti-cancer activity.

M. Zimmerman, A. Adam, H. Ahmad, B. Adams, K. Adhikari, W. Austin, B. Bullock, J. Di Bernardo, T. Dixon, D. Daniels, C. Dominici, G. Elliot, B. Ethell, A. Gervais, M. Hossain, D. Huang, D. Lahr, M. Lin, D. Mayhew, K. Mizeracka, S. Negretti, T. Nguyen, O. Prifti, D. Sappal, S. Schiller, B. Sherbanee, D. Terry, N. Ucisik, E. Wittenborn, Q. Zhou, L. La Bonte;
Foghorn Therapeutics, Cambridge, MA

E1A binding protein (EP300) and CREB binding protein (CBP) are paralog histone acetyltransferases involved in many cellular processes via their activity as transcriptional co-activators. Dysregulation of one or both proteins has been implicated in various cancers, and functional genomic screens have demonstrated a bidirectional synthetic lethal relationship between the two genes in tumor cells. Due to the high homology between EP300 and CBP, identifying chemical matter that selectively targets EP300 or CBP has proven challenging. Here, we describe a potent, highly selective heterobifunctional degrader of EP300 with biological activity in CBP-deficient and EP300-dependent tumor cells. Targeted degradation of EP300 protein resulted in a stronger suppression of cell growth and survival than targeting the bromodomain or HAT activity of EP300/CBP with small molecule inhibitors. Anti-proliferative effects have been demonstrated in multiple cancer types, including malignant lymphomas and castration-resistant prostate tumors, highlighting the essential role of EP300 in mediating oncogenic transcription required for tumor cell growth and survival. Degradation of EP300 *in vivo* attenuated androgen-driven transcription and inhibited tumor growth in VCAP (AR+) prostate tumor xenografts. Importantly, no evidence of overt toxicity or thrombocytopenia was observed at therapeutically efficacious doses. These findings indicate that selective targeting of EP300 with targeted protein degradation is a safe and effective treatment strategy for advanced tumors.

#6065 Identification and characterization of paralogue selective CBP degraders for potential use in cancer therapy.

S. Thiyagarajan, C. Abbineni, K. Chaitanya T, A. Apte, I. Khan Iqbal, N. Kumar R, A. A B, A. Kumar, G. A R, A. B Kamath, D. Dattatray Mane, G. Raj A, R. Reghu, S. Mohapatra, S. Marappan, S. T Gore, S. Mukherjee, G. Daginakatte, K. Nellore, S. Chelur, M. Ramachandra, **S. Samajdar**;
Aurigene Oncology Limited, Bangalore, India

CBP and p300 are closely related epigenetic modulators that participate in chromatin remodeling and transcription and play an oncogenic role in a variety of cancers. Studies have indicated that the selective targeting of CBP is a highly attractive therapeutic strategy for cancers with p300 mutations because of synthetic lethality, those that are dependent on Wnt/β-catenin signaling and ERα and HER2-positive breast cancers. Prevalence of high mutation frequency of p300 in several cancers including skin cancers (27%), small cell lung cancers (8%), lymphoma (8-13%) and bladder cancer (9%) further highlight an opportunity for selective inactivation of CBP in cancer therapy. However, it has not been possible to identify selective inhibitors of p300 or CBP because of the conserved sequence and structure of functional domains such as HAT domain or bromodomain. We sought to achieve selective CBP targeting by utilizing the degrader approach, which in the recent time has proven to be useful in achieving paralog selectivity due to differentiated ternary complex formation. Additionally, the degrader approach offers several inherent advantages including stronger phenotype due to greater potency, sustained action due to catalytic mode of action, overcoming resistance and greater selectivity. Utilizing a combination of structure-guided modelling and iterative medicinal chemistry strategies, we identified first-in-class selective degraders targeting CBP with varying linker lengths and compositions. Our lead compounds exhibit remarkable bias in degrading CBP in cell lines harboring loss-of-function mutations in p300, while sparing wild-type cells. Selective CBP degraders disrupted β-catenin transactivation function in a dose-dependent manner and demonstrated good oral bioavailability and PK profile in preclinical species. Further optimization of potency, selectivity, ADME properties while evaluating *in vivo* efficacy in appropriate models and tolerability in higher species is ongoing towards identifying a development candidate.

#6066 An inhibitor of deubiquitinating enzyme UCHL5/USP14, VLX1570, enhances the cytotoxic effects of temsirolimus by suppressing PCNA in uuman renal cell carcinoma.

K.-L. Kuo[1], P.-M. Chow[2], C.-H. Hsu[2], S.-M. Liao[3], Y.-L. Chiu[4], J.-R. Dong[2], T.-Y. Ke[1], K.-H. Huang[1];
[1]National Taiwan University College of Medicine and Hospital, Taipei, Taiwan, [2]National Taiwan University Hospital, Taipei, Taiwan, [3]National Taiwan University College of Medicine, Taipei, Taiwan, [4]Far Eastern Memorial Hospital, New Taipei City, Taiwan

Renal cell carcinoma (RCC) is a common type of kidney cancer. The overall 5-year survival rate is 74%, but it drops to only 8% for Stage 4 cancers. Several treatments are available for metastatic RCC, including tyrosine kinase inhibitors, mTOR inhibitors, and immune checkpoint inhibitors. However, these treatments have limited success. VLX1570 is an inhibitor of deubiquitylating enzymes UCHL5/USP14 that is currently in Phase I clinical trials. It has shown promise in various cancer models, but its effects on RCC have not been reported. This study investigated the impact of UCHL5/USP14 expression on tumor progression and patient survival in a clinical cohort. The results showed that VLX1570 induced apoptosis and cell cycle arrest in RCC cells, leading to reduced cell viability. Additionally, VLX1570 synergized with temsirolimus in vitro, likely by inhibiting PCNA. Moreover, the combination treatment suppressed tumor growth in vivo more effectively than either VLX1570 or temsirolimus alone. These findings suggest that UCHL5/USP14 plays a role in RCC progression and prognosis, making it a promising therapeutic target for overcoming drug resistance in this cancer.

#6067 Identification of selective CBP degraders with robust preclinical PK, PD, efficacy and safety across solid tumor indications.

D. Sappal, A. Adam, H. Ahmad, B. Adams, K. Adhikari, W. Austin, B. Bullock, J. Di Bernardo, T. Dixon, D. Daniels, C. Dominici, G. Elliot, B. Ethell, A. Gervais, M. Hossain, D. Huang, D. Lahr, M. Lin, D. Mayhew, K. Mizeracka, S. Negretti, T. Nguyen, O. Prifti, S. Schiller, B. Sherbanee, D. Terry, N. Ucisik, E. Wittenborn, Q. Zhou, M. Zimmerman, L. La Bonte;
Foghorn Therapeutics, Cambridge, MA

CREB binding protein (CBP) and E1A binding protein (EP300) are paralog histone acetyltransferases involved in many cellular processes via their activity as transcription factor co-activators. Dysregulation of one or both proteins has been implicated in various cancer types, and functional genomic screens have revealed a bidirectional synthetic lethal relationship between these two paralogs in tumor cells. Due to the high homology between CBP and EP300, identifying selective chemical matter that selectively disrupts the activity of CBP has proven challenging. Small molecule inhibitors targeting the HAT or bromodomain of CBP/EP300 have been developed, however these agents exhibit hematopoietic toxicity resulting from dual inhibition, which limits their therapeutic window. Herein, we describe the PK, PD, and efficacy of selective, potent CBP degraders across various EP300-mutant cancer xenograft models. Our results show deep and sustained CBP degradation, leading to significant tumor growth inhibition in solid tumors. This anti-tumor activity was not associated with significant body weight loss or hematopoietic toxicity. Our CBP-selective protein degraders have the potential to be a first-in-class therapeutic option for patients with tumors harboring EP300 mutations.

#6068 Discovery of BTX-9341, a bifunctional degrader of CDK4 and CDK6 for HR+/HER2- breast cancer.

H. Majeski, A. Okano, K. Chahal, A. Pasis, C. Carlson, A. Shakya, Q. Liu, S. Huang, A. Hoskote Chourasia, L. Fung;
BioTheryX, Inc., San Diego, CA

CDK4/6 inhibitors (CDK4/6i) such as palbociclib, abemaciclib and ribociclib are used to treat HR+/HER2- breast cancer, but patients can develop resistance via many mechanisms, several of which converge on the upregulation of the cyclin D-CDK4/6 signaling node. This has been shown to limit the effectiveness of CDK4/6i in ER+ breast cancer with up to 20% patients exhibiting innate resistance and up to 70% patients developing acquired resistance after 3 years on therapy (Scheidemann, 2021). To address acquired resistance, we sought a degrader approach. We utilized our PRODEGY platform of Cereblon (CRBN) binders to synthesize CRBN mediated CDK4/6 bifunctional degraders and identified BTX-9341 as a development candidate. Breast cancer cell lines treated with BTX-9341 showed up to 85% degradation of CDK4 and CDK6 with DC_{50}s <1nM. CDK4/6 phosphorylates the protein RB which releases the transcription factor E2F, inducing the expression of genes which promote cell cycle progression. We examined RB phosphorylation by in-cell western, E2F target gene expression by qPCR and cell cycle progression by propidium iodide staining followed by flow cytometry. BTX-9341 was potent in all downstream assays, with phospho-RB IC_{50}s <30nM, E2F target gene downregulation and G0/G1 cell cycle arrest at concentrations as low as 10nM. These downstream effects were sustained throughout 72 hours with BTX-9341 treatment but recovered more rapidly with Palbociclib treatment. We used a 2D colony formation assay (CFA) to assess inhibition of proliferation by cell cycle arrest. BTX-9341 potently inhibited cell proliferation with CFA IC_{50}s of 20-50nM while CDK4/6i had CFA IC_{50}s of 50-1000nM. This increased activity was due to CRBN mediated target degradation, as demonstrated by a shift in CFA IC_{50} values in a CRBN knockout cell line towards the values seen with the inhibitors. In palbociclib-resistant HR+/HER2- cell line models BTX-9341 maintained a low CFA IC_{50} (<150nM) while CDK4/6i displayed micromolar CFA IC_{50}s. BTX-9341 displays excellent pharmacokinetic properties which allowed for oral dosing in xenograft studies. In several breast cancer xenograft models, BTX-9341 showed dose-dependent tumor growth inhibition, tumor regression at higher dose levels, and was effective with multiple alternate dosing regimens. These results show that BTX-9341 displays excellent single agent activity *in vitro* and *in vivo* and that this activity is maintained in CDK4/6i resistant models. This indicates that a degrader approach to targeting this pathway may be more effective than current therapies, and that using this modality in a post CDK4/6i setting may be more effective than switching CDK4/6 inhibitors.

#6069 Discovery and preclinical development of orally bioavailable potent BTK degrader, and its early clinical development for the treatment of relapsed and refractory B-cell malignancies.

S. Lee, S.-M. Yoo, Y. Lim, H. Kim, J. Ryu, J. Lim;
Ubix Therapeutics Co., Ltd., Seoul, Korea, Republic of

Background : Bruton tyrosine kinase (BTK) is an important signaling hub that activates the B-cell receptor (BCR) signaling cascade, which is critical for growth and survival of B-cell lymphoma or leukemia. BTK inhibitors have shown anti-tumor activity in patients with B-NHL. However, nearly half of the patients on current BTK inhibitors discontinue the treatment due to adverse effects and/or mutation-induced drug resistance. A degrader is a heterobifunctional chemical compound aimed at eliminating disease-causing proteins, rather than simply inhibiting proteins' enzymatic function, through the ubiquitin-proteasome system (UPS)-mediated protein degradation. This approach offers a unique solution for addressing relapse or refractory disease by removing overexpressed and mutated proteins, unlike traditional inhibitors. We thus designed UBX-382, a degrader targeting BTK.

Results : UBX-382 showed superior degradation activity for both wild-type (WT) and mutant BTK proteins in a single-digit nanomolar range of half-maximal degradation concentration when compared to the competing degrader programs in diffuse large B-cell lymphoma cell line. UBX-382 effectively addressed 7 out of 8 previously reported resistant BTK mutants in *in vitro* experiments and outperformed ibrutinib, ARQ-531, and MT-802 in inhibiting tumor growth in murine xenograft models harboring WT or C481S mutant BTK-expressing TMD-8 cells. Remarkably, oral dosing of UBX-382 for <2 weeks led to complete tumor regression in 3 and 10 mg/kg groups in murine xenograft models. Following this, further optimization was carried out for potency and PK profile. We nominated the candidate for IND filing and are planning a phase 1 clinical trial. For the first-in-human, open-label, multicenter, phase 1 study, patients in part 1 (dose escalation with BOIN design) had R/R B-cell malignancies and had received at least 2 prior therapies. The candidate will be administered orally at 5 mg once daily followed by 2 days, for a 7-day schedule over 28-day cycles. Part 2 (dose expansion) consisted of disease-specific cohorts, including CLL/SLL, DLBCL, MCL, FL, MZL, and WM. The primary endpoints were safety and tolerability, along with the definition of the maximum tolerated dose. Secondary endpoints included pharmacokinetics/pharmacodynamics and preliminary efficacy.

Conclusions : We have discovered potent BTK degrader exhibiting excellent anti-tumor activity in vitro and in vivo. In pre-clinical safety studies, the candidate of UBX demonstrated an acceptable safety profile. The candidate of UBX is currently preparing phase 1 clinical trials for hematological malignancies.

#6070 Identification of a molecular glue degrader that engages a cancer-specific E3 ligase.

Y. Liu, M. Larsen, B. Lin, I. A. Cardenal, J. R. Kennerdell, T. Finkel, **B. B. Chen**;
University of Pittsburgh School of Medicine, Pittsburgh, PA

To date, most successful molecular glues have leveraged ubiquitously expressed E3 ligases, most notably Cereblon in the case of the thalidomide derivatives. However, a number of specific E3 ligases are highly over-expressed in certain tumors. Compounds that engage such tumor-specific E3 ligases might provide a unique opportunity to develop molecular glues with higher therapeutic indexes. One such tumor-specific E3 ligase is FBXO5, a member of the F-box family of E3 ligases. Expression analysis suggests this E3 ligase is highly expressed in a wide array of tumor tissues when compared to the corresponding normal tissue, and that within a given tumor type, higher FBXO5 expression correlates with advanced tumor stage and worse disease-free survival. Here, we describe a small molecule (MW~400 Daltons) that uses FBXO5 to function as a molecular glue degrader. This compound, CL-200, exerts cytotoxicity in the nanomolar range across a number of diverse tumor types. The cytotoxicity of CL-200 is abrogated when FBXO5 is knockdown using siRNA. We have further determined that CL-200 induces the FBXO5-dependent proteasomal degradation of at least two critical neosubstrates. One identified neosubstrate is the p150 isoform of ADAR1, an enzyme that catalyzes the posttranscriptional conversion of adenosine to inosine in double-stranded RNA (dsRNA). Evidence suggests that ADAR1p150 is the isoform that confers oncogenic and immune modulating effects in many tumors. Another neosubstrate targeted by CL-200 is c-myc, a critical transcription factor linked to a wide array of tumors. Of note, both p150 ADAR1 or c-myc have been viewed as difficult-to-drug if not undruggable targets. As such, these data suggests that CL-200 functions as a novel molecular glue degrader that engages the cancer-specific E3 ligase FBXO5 to degrade both p150 ADAR1 and c-myc. Structural alteration of CL-200 suggest that chemical modifications can be made that retain the engagement with FBXO5 while altering the neosubstrate profile. Together, these results demonstrate the possibility of leveraging cancer-specific E3 ligases to develop novel molecular glues.

#6071 Identification of a molecular glue degrader targeting the full-length AR and AR-V7 splice variant.

Y. Liu, M. B. Larsen, B. Lin, I. A. Cardenal, J. Kennerdell, T. Finkel, **B. B. Chen**;
University of Pittsburgh School of Medicine, Pittsburgh, PA

Prostate cancer is the most common cancer in males and the fifth leading cause of cancer mortality worldwide. A variety of therapeutic approaches exist including steroid synthesis inhibitors and next-generation ligand binding domain (LBD) antagonists [e.g., enzalutamide (Enza)]. However, these approaches are only effective against tumors bearing the full-length androgen receptor (AR-FL). In the course of their disease, many patients acquire androgen receptor splice variant 7 (AR-V7), a mutant form of the receptor which lacks the LBD and is constitutively activated. To date, no effective therapy has been demonstrated for patients with metastatic prostate cancer bearing the AR-V7 signature. We have recently developed a high throughput platform that allows for the identification of ligands that can bind to a wide variety of protein targets. Using this approach, we screened a diverse chemical library of 100,000 small molecules to identify compounds that are bound to AR-V7. One such molecule, AR-600, directly bound to AR-V7 and moreover, induced proteasomal-mediated targeted protein degradation of both AR-V7 and AR-FL. In prostate cancer cell lines expressing AR-FL, AR-600 induced a gene expression profile similar to cells treated with Enza including a marked reduction in KLK3 (PSA) expression. Moreover, AR-600 inhibited the growth of 22RV1 cells (IC50=23 nM), a cell line that predominantly expresses AR-V7, as well as C4-2 cells that express predominantly full-length AR (IC50=51 nM). In contrast, the compound did not affect the growth of a wide variety of non-tumorigenic cells, non-prostate tumor cell lines or PC3 cells, a prostate cell line that exhibits AR-independent cell growth (IC50>100uM). Preliminary exploration of the mechanism of action of AR-600 (M.W. ~300 Daltons) demonstrates the compound works as a molecular glue. These results thereby identify a small molecule glue degrader that can specifically induce the targeted protein degradation of the AR-V7 splice variant. Given the strong association of this isoform with treatment resistance, this approach would appear to provide an attractive strategy for patients with metastatic castration resistant prostate cancer.

PREVENTION / EARLY DETECTION / INTERCEPTION: Biomarker-Based Screening
Poster Session

#6075 Most cancer deaths are unaddressed by current screening paradigms.

E. T. Chang[1], A. Kansal[1], **E. A. Hubbell**[1], G. A. Colditz[2], A. W. Kurian[3], C. A. Clarke[1];
[1]GRAIL, LLC, Menlo Park, CA, [2]Washington University School of Medicine, St. Louis, MO, [3]Stanford University, Stanford, CA

Cancer is the leading cause of death at ages ≤80 in the US. To understand the burden of cancer death potentially addressable by new or improved screening approaches, we estimated the proportion of US cancer deaths without recommended guideline-based screening, especially after accounting for lung cancer screening eligibility and adherence. Using 2018-2019 mortality data from the National Center for Health Statistics and published estimates of the proportion of screening-eligible lung cancer patients, we estimated that 31.4% of nearly 600,000 annual cancer deaths were from colorectal, female breast, cervical, and smoking-eligible lung cancers (Table). Further accounting for adherence to lung cancer screening guidelines reduced the estimated proportion of screened cancer deaths to 17.4%; thus, 82.6% of cancer deaths may not be addressed by current guideline-based screening. Among the cancers not covered by guideline-based screening are uncommon cancer types, which (as defined by the National Cancer Institute) comprised 30.4% of cancer deaths. According to incidence-based mortality data from Surveillance, Epidemiology, and End Results registries, 24.7% of all cancer deaths were from stage 4 cancer types without guideline-based screening. These estimates, based on population data without patient-level information on mode of diagnosis, almost certainly underestimate the percentage of cancer deaths missed by currently available screening efforts. The large proportion of cancer deaths unaddressed by guideline-based screening represents a vast opportunity for new cancer screening technologies that are safe, effective, accessible, and affordable to enable earlier detection and successful treatment of the full spectrum of cancer types that contribute to the overall cancer burden.

Table. Deaths from cancer by primary type in 2018-2019, US National Center for Health Statistics, with eligibility for and adherence to guideline-based low-dose computed tomography screening for lung cancer

	All cancer types	Lung	Colon/rectum	Breast (female)	Uterine cervix	**Total screened**	**% of all**
All cancer deaths	1,198,854	281,681	104,059	84,745	8,290	478,775	**39.9%**
Eligible for screening based on smoking (63.7% of lung)*		179,431	104,059	84,745	8,290	376,525	**31.4%**
Adherent to smoking-guideline-based screening (6.6% of lung)†		11,842	104,059	84,745	8,290	208,936	**17.4%**
*Modeled estimate of proportion of lung cancer patients eligible for screening (Landy et al. 2023). †Lung cancer screening receipt from 2019 American College of Radiology Lung Cancer Screening Registry (Fedewa et al. 2022).							

#6076 Mathematical oncology in the context of early breast cancer detection.

J. Mason, S. N. Shishido, G. Courcoubetis, D. Tessone, E. Liljegren, A. Naghdloo, J. Hicks, J. J. Nieva, P. Kuhn;
USC - University of Southern California, Los Angeles, CA

Breast cancer (BC) is the most common cancer in women globally, with approximately 94% of patients initially diagnosed with early-stage disease. However, despite the initial lack of detectable metastases and administration of subsequent treatments, 40% of these patients will develop recurrence over their lifetime. The standard screening method for BC is mammography, with a tissue biopsy to confirm diagnosis. However, only ~60% of all cases are currently diagnosed via this pathway, primarily due to the limited (86.9%) sensitivity. To demonstrate the feasibility of a liquid biopsy (LBx) test for early BC detection and assessment, we employed the third-generation, High Definition Single Cell Assay (HDSCA3.0) to detect and characterize rare cells (e.g., circulating tumor cells [CTCs]) and acellular structures (e.g., oncosomes) in patient peripheral blood samples using immunofluorescent (IF) imaging. We have previously investigated this signal in a cohort of early-stage BC patients (n = 74), late-stage BC patients (n = 26), and age- and gender-matched controls (n = 30) and observed statistically significant differences in levels of total rare cells, CTCs, and oncosomes via a manual approach. For this study, we employed a hybrid methodology, that utilizes both automatic and manual techniques, to investigate the reproducibility of the signal in an expanded validation set. Within this modified approach, we employ an outlier detection algorithm to accelerate the rare event identification and curation process (minimizing the manual portion), a separate machine learning model to classify the events based on their IF expressions, and a suite of applications to enumerate and quantify the result. After implementation, we quantified the results of the fully manual and hybrid approaches to determine the signal loss associated with scale up. Utilizing the hybrid approach, we observed similar results as with the fully manual and were able to stratify the three cohorts with high accuracy. Namely, there was an increase in the total rare cell and CTC populations in late-stage BC patients, and an increase in the oncosome population for the early-stage BC patients. To note, these patients included a subset with invasive lobular carcinoma (ILC; n = 19), which manifests in ~5-15% of BC cases and is considered “mammogram silent” due to the biological development of the disease. Additionally, employing the hybrid approach allowed for analyzing patient samples in less time while minimizing overall signal loss. In summary, we have been able to detect reproducible patterns in the enumeration of rare cells and oncosomes with high accuracy. When utilized at the patient-level, these analytes can power prediction models that are capable of stratifying disease from non-disease. The results presented here demonstrate the utility of a LBx test as a companion to screening mammography in the detection of early-stage BC across various histologies.

#6077 Chimeric RNAs are abundantly expressed in precancerous breast tissue of sporadic breast cancer patients.

A. Bhardwaj[1], S. Thevasagayampillai[2], S. Rankothgedera[2], P. Verma[1], M. B. Castillo[2], A. C. Koh[1], C. Albarracin[1], P. H. Gunaratne[2], I. Bedrosian[1];
[1]UT MD Anderson Cancer Center, Houston, TX, [2]University of Houston, Houston, TX

Background: Immuno-prevention efforts in breast cancer (BC) have been hampered by the lack of known neoantigenic targets that can be used for a cancer prevention vaccine. RNA fusions represent attractive candidates as these are more immunogenic than insertion / deletion mutations and are substantial source of neoantigens. The objective of this study was to characterize chimeric RNAs in precancerous breast tissue. **Methodology:** Novel RNA fusions were identified by mining the sequence reads from RNA sequencing of 25 Her2 positive, 25 hormone receptor positive (HR) and 25 triple negative (TN) breast tumors and paired histologically normal tissues by Qiagen's CLC pipeline. Breast samples from women undergoing breast reduction surgery were used as controls to exclude normal tissue associated chimeric mRNAs from analysis. Neoantigen prediction was performed by MHCnuggets. Chimeric mRNAs were validated by PCR. Ribosomal profiling was performed to assess if fusion transcripts are engaged with ribosomes. **Results:** A median of 36 novel RNA fusions (range 7-877) were identified in the tumor samples. In line with high genomic instability of TNBC subtype of BC, about 1/3 of the TN tumors expressed greater than 300 RNA fusions. In order to identify RNA fusions that are relevant for BC prevention, we investigated the presence of RNA fusions in the paired histologically normal samples as compared to the index tumor. We restricted these analyses to top 20 fusion transcripts that were present across the set of 75 tumor samples and also detected in 1 or more of the TCGA samples. Interestingly, we found that more than 1/3 of the histologically normal samples express at least 1 of the top 20 RNA fusions. When compared to the corresponding tumor, we found up to 50% of the paired normal tissue expressed RNA fusions identified in the tumor, supporting a role for these chimeric mRNA as an early molecular change during breast tumorigenesis. To validate the robustness of the prediction pipeline, PCR validation was performed for the chimeric mRNA with highest prevalence, NSFP1- LRRC37A2 which confirmed the presence of the transcript in 72% (13/18) of the predicted positive patient samples. MHCnuggets pipeline predicted 15 neopeptides from intergenically spliced chimeric NSFP1 [Exon 1-13] - LRRC37A2 [Exon 2-14], ¼ of which we validated to be immunogenic by ELISA. In order to confirm that the translation of the chimeric NSFP1- LRRC37A2 transcript, we investigated their enrichment in polysome enriched fraction obtained from a BC cell line confirmed to express the fusion transcript by PCR. Enrichment of transcripts in the polysomal fraction confirmed that these transcripts are likely to be translated. **Conclusions:** RNA fusions are frequently present in at risk breast tissue and are the source of substantial number of neoantigens. These RNA fusion- derived neoantigens may provide novel opportunities for developing vaccines for BC prevention.

#6078 Circulating tumor cell-based early detection of breast cancer.

J. M. Drake[1], K. J. Kamalanathan[2], C. Galeano-Garces[2], N. Bristow[2], N. Heller[2], M. Ahmadi[2], O. Hedeen[2], A. Hesch[2], G. Schaap[2], J. Hapke[2], J. Miller[2], I. Babris[2], T. Le[2], T. Clacko[2], J. Hong[1], B. Konety[3], J. Parthasarathy[2];

[1]University of Minnesota, Minneapolis, MN, [2]Astrin Biosciences, Inc., Saint Paul, MN, [3]Allina Health, Minneapolis, MN

Although mammograms have been a useful tool since the first half of the 20th century and have an acceptable sensitivity (87%) in the general population, that drops to <50% in women with dense breasts making it an ineffective screening tool in this population. Cell free DNA (cfDNA) has proven to be an inadequate alternative in this population, and while MRI is acceptable, it is expensive. Astrin Biosciences has developed a blood-based assay that detects circulating tumor cells (CTCs) at a high sensitivity to serve as an alternative screening method to mammography in breast cancer early detection, specifically in women with high-density breasts.

Astrin's technology integrates holographic imaging, machine learning, and microfluidics to identify CTCs in the blood stream. Omics analysis can then be performed on the collected cells to further differentiate patients with cancer from matched healthy controls. Astrin has initiated a small cohort study to investigate the sensitivity and specificity of CTC detection in women with early-stage breast cancer. Astrin's small cohort study, including patients with ductal carcinoma in situ, stage 1, and stage 2 breast cancer patients, demonstrated > 85% sensitivity and specificity. A large cohort study is being conducted to validate these preliminary results.

The small cohort study demonstrates the ability of Astrin Bioscience's platform to detect cancer cells at an early stage, particularly in breast cancer. This technology will drastically increase the effectiveness of breast cancer screening modalities available to patients. Additionally, since it is a blood-based assay, it can be performed at shorter intervals in high-risk populations than mammograms which require a full patient appointment.

#6079 Comparison of FIT and cell-free DNA analyses for detection of individuals with colorectal cancer in population based screening.

P. H. Wisse[1], C. Rubio-Alarcon[1], S. J. Schraa[2], A. C. Mosquera[1], M. Sausen[3], R. J. A. Fijneman[1], G. R. Vink[2], M. de Wit[1], J. Phallen[4], V. E. Velculescu[4], B. Carvalho[1], G. A. Meijer[1];

[1]Netherlands Cancer Institute, Amsterdam, Netherlands, [2]University Medical Center Utrecht, Utrecht, Netherlands, [3]Personal Genome Diagnostics, Baltimore, MD, [4]Johns Hopkins University School of Medicine, Baltimore, MD

Background The fecal immunochemical test (FIT) is widely used in population based colorectal cancer (CRC) screening programs. Recently, circulating cell-free DNA (cfDNA) analyses have emerged as a new avenue for early cancer detection. The performance of cfDNA methods in comparison with FIT is currently unknown. The present study compared pre-operative cfDNA analyses to FIT for detection of patients with CRC who participated in a population-based screening program. **Methods** In the Dutch national CRC screening program, individuals aged 55-75 years are biennially invited to perform a single FIT. The database of the Dutch CRC screening program was queried to identify individuals with FIT data who also participated in two cfDNA studies, PLCRC-MEDOCC and PLCRC-PROVENC3 (AACR abstract C. Rubio Alarcón). Sensitivities with 95% confidence intervals (CI) for detecting individuals with CRC were determined for FIT, tumor-informed cfDNA analyses, as well as both tests combined. For FIT, sensitivities were determined at 20 µg and 47 µg hemoglobin (Hb)/g feces positivity cut-offs as these represent the most commonly used international and Dutch cut-offs, respectively. Liquid biopsy analyses were performed using next generation sequencing of cfDNA. Tumor-specific alterations were identified through parallel next generation sequence analysis of resected tumor tissues. **Results** The query identified 120 individuals with stage I (n=3, 2.5%), stage II (n= 57, 47.5%) and stage III (n=60, 50.0%) CRC who had participated in the Dutch CRC screening program and either PLCRC-MEDOCC or PLCRC-PROVENC3. All FIT samples were collected at a median time of 38 days before diagnosis (IQR 27-112 days). FIT sensitivity for detection of individuals with CRC was 83.3% (100/120 CRCs, 95% CI 75.4-89.5%) at a 20 µg Hb/g feces cut-off and 80.0% (96/120, 95% CI 71.7-86.7%) at a 47 µg Hb/g feces cut-off. Tumor-informed cfDNA analyses detected 75.8% (91/120, 95% CI 67.2-83.2%) of individuals with CRC in this population. The combination of cfDNA analyses and and FIT (20 µg Hb/g feces cut-off) identified almost all individuals with CRCs (119/120, sensitivity 99.2%, 95% CI 97.0-100%). The individual who was missed had a cancer that was a T3N0 microsatellite stable moderately differentiated adenocarcinoma in the ascending colon. **Discussion** While both FIT and cfDNA analyses identified most CRC cases (75-83%) in this series, both tests also demonstrated a substantial level of complementarity, indicating that in principle combining FIT with cell-free DNA testing would allow to increase sensitivity of CRC screening. Since the cell-free DNA tests used here are tumor-informed, which in real life screening practice is not feasible, it remains to be determined to what extent this result can be reached using non-tumor-informed approaches.

#6081 DNA integrity and preanalytical handling of endocervical samples for use in liquid biopsy-based diagnostics and monitoring of gynecological cancer.

J. M. Lauesgaard, T. Carlsson, A. Linder, S. Schumacher, K. Sundfeldt;
University of Gothenburg, Gothenburg, Sweden

Background: Liquid biopsies from the gynecological tract can be useful for analysis of cell free DNA (cfDNA) (1, 2, 3). Sampling procedure and optimal preanalytical handling are poorly investigated. In this study, we aimed to evaluate how the profile and integrity of DNA, sampled from the female genital tract, were affected by preanalytical handling.

Methods: Biobanked/archival (stored at -80℃ after 48h at room temperature (RT)) and freshly obtained clinical samples were analyzed together with standardized *in vitro* samples. Archival and *in vitro* samples were preserved in methanol-based solution, imitating clinical handling of endocervical samples which are initially stored at RT for 48h before further handling. The fragmentation profile of archival and *in vitro* samples was analyzed. Time series of *in vitro* samples at RT and 4℃, with extraction at 6-hour intervals from 0 to 96h, were performed. The fresh clinical samples were collected from the endocervix in methanol-based solution and from the vagina in a solution designed to preserve DNA and placed at 4℃ resp RT. Extraction was performed within 4h and at 48h.

Results: Accumulation of short DNA fragments were observed in the archival samples and in the in *vitro* samples, indicating that fragmentation was initiated prior to 48h. Time series showed that the quantity of short DNA fragments gradually increased with time at both RT and 4℃ but at a slower rate in 4℃. At RT the percentage of fragments between 100-350bp increased 12-fold (0.39% vs 4.75%, p=0.002). The freshly obtained endocervical samples showed a similar significant increase in short fragments in samples stored at RT compared with samples stored at 4℃ (p= 0.02 for 100-230bp; p= 0.007 for 230-350bp; p= 0.03 for 100-2500bp) at 4h-48h.

Conclusion: Pre-analytical handling of endocervical samples can be optimized. Lowering temperature from RT to 4℃ immediately haltered DNA fragmentation.

#6082 Rapid on-site nucleic acid detection using CRISPR and digital signal processing for portable and integrated cervical cancer screening in low resource settings.

C. Lee, H. Kim, H. Lee, T. Randall, A. Ly, H. Lee, **C. M. Castro**;
Massachusetts General Hospital, Boston, MA

Addressing the global disparity in cancer care necessitates the development of rapid and affordable nucleic acid (NA) testing technologies. This need is particularly critical for cervical cancer. Molecular detection of human papillomavirus (HPV) has emerged as a highly accurate screening method, surpassing traditional Pap smears. However, implementing this transition in low- and middle-income countries has been challenging due to the high costs and centralized facilities required for current NA tests. Here, we present CreDiT (CRISPR Enhanced Digital Testing), an advanced diagnostic system for rapid, on-site NA detection. CreDiT integrates two major technical breakthroughs: i) a one-pot CRISPR strategy that simultaneously amplifies both target NAs and analytical signals, and ii) a robust fluorescent detection method based on digital communication (encoding/decoding) technology. These innovations enhance CreDiT's practical utility, offering a rapid assay (<35 minutes) that integrates NA extraction and detection in a single streamlined workflow. Furthermore, CreDiT's straightforward probe design enables easy incorporation of new NA targets, while its compact device provides robust signal detection. We adapted CreDiT for point-of-care HPV screening by designing probes for high-risk HPV genes (HPV16, HPV18, HPV45, HPV31, HPV33, HPV58) and oncoprotein mRNAs (*E6*, *E7*, $p16^{INK4a}$) and developing a portable CreDiT device capable of processing 12 samples. CreDiT demonstrated sensitive detection of cell-derived HPV DNA targets down to single copies and accurately identified HPV types in every clinical cervical brushing specimen (n = 121) we tested. This technology has the potential to facilitate prompt and reliable triaging of high-risk HPV, overcoming pathology bottlenecks and circumventing geographical and socioeconomic barriers to effective cervical cancer screening in resource-limited regions. This work has spearheaded recent screening research efforts in Uganda and Ghana.

#6083 Inter-observer agreement in ultrasound-detected steatotic liver in the Chile Biliary Longitudinal Study (BiLS).

Maria Spencer Sandino[1], Vanessa Van De Wyngard[1], David Wynne[2], Maya Balakrishnan[3], Noldy Mardones[4], Ruth Pfeiffer[5], Allan Hildesheim[5], Catterina Ferreccio[1], Jill Koshiol[5]

[1]Public Health, Pontificia Universidad Catolica de Chile, Santiago, Chile,[2]Interventional Radiology, Baylor College of Medicine, Houston, TX,[3]Gastroenterology, Baylor College of Medicine, Houston, TX,[4]Hospital Dr. Hernan Henriquez Aravena, Temuco, Chile,[5]Infections and Immunoepidemiology Branch, Nacional Cancer Institute, Rockville, MD

Background: Metabolic-associated steatotic liver disease (MASLD) is a prevalent chronic liver condition with an increased risk of cancer-related mortality. In Latin America, MASLD prevalence is estimated at 40%, with Chile reporting rates of 47.5% in 2019. Early detection is crucial for MASLD control and management. Liver biopsy, the gold standard for diagnosis, is invasive and costly. Ultrasound (US) is a preferred alternative, yet its precision varies depending on the observer interpretation.

Methods: We conducted a cross-sectional analysis of a subset of baseline US images from the Chile Biliary Longitudinal Study (Chile BiLS), a cohort of women aged 50-74 with gallstones in Chile. Of the 4,032 participants recruited from Cautín Province in the Araucanía region, a random sample of 10% of the images were selected for review by a radiologist from Baylor College of Medicine (Observer 1) and compared to the original readings generated at the baseline exam by a team of Chile BiLS ultrasound technicians. To assess reproducibility, 33 blinded duplicate images from the 10% sample were reanalyzed by Observer 1 and an additional Chile BiLS technician who was not part of the original baseline team (Observer 2). Inter- and intra-observer agreement was assessed using weighted kappa values. Images were categorized as none, mild, moderate/severe.

Results: Of the 409 images reviewed, agreement between Observer 1 and original readings across all categories of steatosis was poor (kappa: 0.09; CI 95% 0.06;0.11, p <0.001). The 33 duplicates compared to the original readings showed slight agreement for Observer 1 (kappa: 0.11 CI 95% 0.02;0.20, p <0.05) and fair for Observer 2 (kappa: 0.28 (CI 95% 0.07 - 0.49, p <0.001). The intra-observer agreement for Observer 1 was moderate, with a kappa of 0.41 (CI 95% 0.09 - 0.74, p <0.05), and for Observer 2, it was substantial with a weighted kappa of 0.69 (CI 95% 0.5 - 0.9, p <0.001).

Conclusion: The study highlights the variability in US interpretation of hepatic steatosis, emphasizing the importance of standardized training and methodology. US's sensitivity and specificity is operator dependence, which impacts the diagnostic interpretation. Our findings underscore the significance of inter and intra-observer comparisons for optimal diagnosis, especially when US is the primary diagnostic tool in MASLD assessment. Finally, our results emphasize the importance of group training. Observer 2, who underwent the same training as the original Chile BiLS ultrasound technicians and was consistently exposed to this technique as a diagnostic method, exhibited more consistent results. This reinforces the importance of collective training initiatives to enhance the reliability and accuracy of US in MASLD diagnosis.

#6084 Identification of plasma proteins for early detection of cancer, including lung, in the Atherosclerosis Risk in Communities (ARIC) study.

M. Ru[1], C. Douville[1], K. R. Butler[2], C. E. Joshu[1], J. Lu[1], A. Prizment[3], J. Coresh[1], E. A. Platz[1];

[1]Johns Hopkins University, Baltimore, MD, [2]University of Mississippi Medical Center, Jackson, MS, [3]University of Minnesota, Minneapolis, MN

Background: Plasma proteins, directly secreted from tumor cells or a result of the body's response to a tumor, may have utility for early detection. We aimed to identify plasma protein combinations that predict prediagnostic cancers in a prospective study.

Methods: We sampled from 8,186 ARIC study participants without a cancer diagnosis at blood draw and with 4,877 log2-transformed proteins measured by SomaScan. We selected as cases those diagnosed within 5 years after blood draw and were registry/medical record confirmed. We selected as controls those who never had a cancer history by 2015 and did not die of cancer. Participants with possible liver, kidney, or inflammatory conditions were excluded (eGFR-cr<30, top 1% of plasma AST, ALT, CRP). Highly correlated proteins (r>±0.75), abundant or known markers (albumin, CRP, PSA), and proteins with wide log2-transformed distributions (SD>1 and >10% outliers-1.5 IQR away from 25th or 75th percentile) among controls were excluded. Recursive feature elimination (RFE) with random forest (RF) was used to select the top 10 informative proteins based on accuracy. Non-protein features included demographic, lifestyle (e.g., smoking), and medical factors. We next divided participants into train and test sets in 7:3 ratio stratified by case status. RF including top 10 proteins from the RFE and non-protein features trained in the train set were used to predict near-term cancer status in the test set and to calculate prediction performance. Random Over-Sampling Examples were used to balance between rare cases (<3%) and controls in the dataset.

Results: We included 210 cases (98 diagnosed within 2 years) and 7,042 controls with 3,476 proteins. 58% were female, 24% were Black, and median age was 57 years (IQR: 52-62). The most common cancer was lung (27%). In the test set, sensitivity and specificity of the model for total cases diagnosed within 2 years were 0.19 and 0.91. Results for cases diagnosed within 3 (0.24, 0.88) and 5 (0.29, 0.87) years were similar. Using the top 10 informative proteins for total cancer, sensitivity was 0.68 and specificity was 0.56 for lung cancers diagnosed within 2 years; for lung cancers diagnosed within 3 (0.55, 0.77) or 5 (0.53, 0.79) years, sensitivity decreased but specificity increased. Using the top 10 informative proteins specific for lung cancer, which did not overlap with the top 10 for total cancer, sensitivity and specificity were 0.69 and 0.67 for lung cancers diagnosed within 2 years.

Conclusions: In this study, in which blood draw preceded diagnosis, top informative proteins did not provide sufficient sensitivity for all-cancer near-term prediction. For lung cancer, further optimization may improve the sensitivity and specificity to achieve the range required for population implementation for screening. Validation with more cases, and on other proteomic platforms are needed. Funding NHLBI, NCI, NPCR

#6085 Leveraging targeted epigenetic and genetic detection for cost-effective cancer classification.

R. Crawford[1], B. Krajacich[2], E. Lleshi[1], A. Negrea[1], L. Andreasen[1], J. Fullgrabe[1], J. Monahan[1], D. Morley[1], F. Puddu[1], D. McDade Walker[1], S. Kruglyak[3], P. Creed[1];

[1]biomodal, Cambridge, United Kingdom, [2]Element Biosciences, San Diego, CA, [3]Element Biosciences, San Diego, United Kingdom

The combinatorial power of genetics and epigenetics is vital to understanding biology in healthy and cancerous states. Utilizing a recent novel approach, we enable the simultaneous identification of modified cytosine and the canonical bases A, C, T & G in an enzymatic single-workflow solution. Generating this information across the whole genome provides a much-improved understanding of genetic and epigenetic changes, but can require a large amount of sequencing, particularly when exploring at depth. Enrichment protocols such as target enrichment enable deep interrogation of target areas whilst maintaining cost effectiveness.

Target enrichment panels enable the selective isolation of sequences of interest through target hybridization. Using commercially available panels combined with the novel enzymatic single-workflow solution we show uniform performance across a range of input amounts with reduced sequencing requirements. Samples used were cell free DNA (cfDNA) from patient samples with either Stage I or IV Colorectal Cancer and reportedly healthy controls and were targeted using pan-cancer and methylome panels. Widespread differences such as hypermethylation are clearly observed in late-stage cancer vs early-stage or healthy controls demonstrating utility of the approach for applications such as liquid biopsy.

Refining genetic and epigenetic investigations to a narrower region of interest can improve detection of low prevalence disease associated biomarkers at significant sequencing depth and lower sequencing costs.

#6087 Cytomics-on-chip and AI-driven predictive analysis platform for early detection of epithelial cancers.

K. Srinivasan Rajsri[1], M. P. McRae[1], N. J. Christodoulides[1], K. Algashaamy[2], M. T. Garcia-Buitrago[3], F. Chen[4], F.-M. Deng[4], J. S. Smith[5], J. T. McDevitt[1]; [1]NYU, New York, NY, [2]Jupiter Medical Center, Jupiter, FL, [3]University of Miami, Miller School of Medicine, Miami, FL, [4]NYU Langone Health, New York, NY, [5]University of North Carolina, Gillings School of Global Public Health, Chapel Hill, NC

Cancer is the 2nd leading cause of death (over 605,000 people) in the US, at an expense of over $200B, with 1 in 3 people projected to have cancer during their lifetime per CDC. Despite the significant impact of early detection and screening on prognosis, only some cancers are diagnosed at an early stage. Carcinomas, comprising >80% of cancer incidence, allow ease in cytology sample access chairside, due to the lesions' epithelial presentation. This presents a unique opportunity for early detection and screening in epithelial cancers. In low-resource healthcare settings, from clinical examination to the long, tedious and expensive diagnostic journey for cancers & pre-cancerous lesions, can lead to missed, delayed or over diagnosis scenarios. This affects treatment initiation and potentially outcome. To facilitate early intervention, there is compelling need to develop accurate and effective minimally invasive screening platforms. Recent advances in the -omics disciplines, microfluidics and AI tools are starting to reveal promising signatures of early disease detection, with potential to drastically improve screening and diagnostic systems. We are developing a novel application of the cytomics-on-chip platform, for enabling chairside, quantitative screening of suspicious epithelial lesions. The biosensor module involves 1. a single use, cytomics platform employing a cartridge with cellular array and high specificity biomarker reagents, that allows single cell molecular imaging to be completed in a portable analyzer. 2. a microfluidics module that allows cytomorphometric measurements to be completed. 3. The results generated are utilized to train machine learning algorithms to detect cyto-signatures and provide an intuitive result that may be utilized by health care practitioners in clinical-decision making. The first cell-based point-of-care oncology tool has recently been validated with high accuracy (99.3%), sensitivity and specificity, in a multi-site prospective clinical study. Here we demonstrate a pilot study towards development of a smart single cell cytomics-on-chip platform for prompt cytomorphometric and biomarker characterization towards diagnosis of urothelial, anal and cervical cancers, and dysplasia lesions, utilizing brush/pap and fresh urine samples. This has potential for continuous quantitative indexing, for disease categorization. As cancers become more pervasive, improved early detection/screening methods that are accurate, cost effective, easy to implement during routine clinical practice, and providing minimal discomfort to the patient, are urgently needed, improving confidence in clinicians' decisions.

#6088 Predicting the risk of any-type cancer in asymptomatic adults using noninvasive glycosaminoglycan profiling.

F. Gatto;
Karolinska Institutet, Stockholm, Sweden

Background: Early detection of cancers through screening can reduce mortality. However, screening excludes individuals not considered at an increased risk of developing cancer, as determined by age, sex, or tobacco use. No molecular biomarker is routinely used to predict risk. Here, we investigated urine glycosaminoglycan profiles (GAGomes) as noninvasive biomarkers for any-cancer risk prediction.
Methods: In this population-based case-control study, we included adults aged over 18 years from the Lifelines Cohort Study, Netherlands who were presumed healthy at baseline. All cases who self-reported any-type cancer or died by the 5-year study visit were confirmed in the Dutch Cancer Registry and matched 1:3 to randomly selected controls (1:1 for the interim analysis). We first developed a logistic regression reference model, including age, sex, and clinical variables to predict any-type cancer. Next, we added urine GAGomes (as a single aggregate score) to the model and assessed model improvement using the likelihood ratio test. We categorized the output of the saturated model (clinical variables plus urine GAGome score) into four groups based on bespoke specificity cut-offs: low-, moderate-, intermediate-, and high-risk. We estimated odds-ratios (ORs) for their association with any-type cancer compared to the moderate-risk group, as well as their sensitivity across subsets. Using the so-estimated OR in the high-risk group, we calculated the minimum pre-test 5-year absolute risk needed to reclassify an adult into a post-test 5-year absolute risk >3.00%.
Results: In the interim analysis, we included 2054 adults (median age = 51 years, 57% females). Of them, 924 were diagnosed with any-type cancer over a 6 year-follow-up period (median time to diagnosis = 1.4 years). Urine GAGomes were found to be independent risk factors when added to the reference model, explaining 27% of the variance (Nagelkerke R^2 = 0.26 vs. 0.21, $p < 0.0001$). The ORs in the low-, intermediate-, and high-risk groups were 0.05 (95% CI: 0.02-0.13 p < 0.0001), 5.31 (95% CI: 3.84-7.48, p < 0.0001) and 27.6 (95% CI: 14.3 - 51.6, p < 0.0001), respectively. The high-risk group detected +80% more cancers than the reference model at the same specificity (99.29%), particularly *in situ* and stage I (+204% and +64%) and among those aged 50-69 (+247%). Adults with a pre-test 5-year absolute risk > 0.25% returning a high-risk group would be reclassified to a post-test 5-year absolute risk > 3.00% for any-type cancer.
Conclusion: Implementing urine GAGomes as a strategy for risk-stratified targeted screening could identify adults with increased risk of any-type cancer who are currently excluded from screening.

#6090 Integration of innate and adaptive immune signatures for early detection of cancer.

E. Fitzsimons[1], A. Coulton[1], H. Fu[1], M. Augustine[1], R. Lee[2], J. Reading[1], K. Litchfield[1];

[1]University College of London (Incorporated in England and Wales), London, United Kingdom, [2]The Royal Marsden NHS Foundation Trust, London, United Kingdom

Up to 50% of cancer patients are diagnosed at a late stage with tumors that are often unresectable, leading to intensive treatments and a preventable loss of life. Whilst multiple assays have been developed to tackle the issue of disease mortality, these approaches have serious limitations. For example, circulating tumor DNA (ctDNA) preferentially detects hard-to-treat tumors and micrometastatic disease, with limited sensitivity and specificity for early-stage malignancy, underscoring an urgent need for novel early detection strategies.

Substantial evidence exists to demonstrate that signals related to innate (e.g. pro-inflammatory cytokines) and adaptive (e.g. antibodies and T cell receptors [TCRs]) immune engagement arise early in the development of cancer. The immune system therefore offers potential as an exquisitely sensitive and highly specific intrinsic early detection system for cancer. Here we propose the development of a pan-cancer novel early detection assay, using peripheral blood to measure three key cancer-specific components of the anti-tumor immune response: i) T cell receptor (TCR) sequences, ii) antibody signatures, iii) cytokine markers.

Our preliminary data demonstrates that an age and smoking-matched cohort of lung cancer patients can be distinguished from healthy donors using TCR sequencing data processed through a published machine learning approach ($p<0.01$). In support of this, a pilot study on a custom peptide microarray comprised of lung cancer associated antigens and recurrent neoantigens demonstrated that lung cancer patient samples show significantly higher antibody intensities than healthy donors. Thirdly, using data from a prospective cohort study, we have demonstrated that inflammatory markers can be leveraged to predict future cancer diagnosis, and identified key protein markers for future work. These data provide proof-of-principle for the use of these analytes as a tool for early detection.

We are actively curating a unique cohort of samples for this work from a prospective study, Nodule Immunophenotyping Biomarker for Lung Cancer Early Diagnosis (NIMBLE) (NCT05432739), which recruits patients with indeterminate lung nodules that may represent early cancers (>280 patients to date). This malignancy has high mortality rates and a significant need for early detection strategies. Through this, we aim to understand the early immunobiological response to cancer and leverage this information to design a novel multi-parametric immunopredictor assay for early detection of cancer.

#6091 Multi-cancer early cancer detection and cancer-type identification with high sensitivity non-invasive using urine: Pancreatic lung cancer early detection.

E. Di Luccio[1], T. Hirotsu[2];

[1]HIROTSU BIO SCIENCE INC., Fujisawa city, Japan, [2]HIROTSU BIO SCIENCE INC., Tokyo, Japan

N-NOSE, a breakthrough cancer detection test from HIROTSU BIO SCIENCE, utilizes the unique chemotactic behavior of the nematode *C. elegans*. This nematode is drawn to the urine of individuals with 15 different types of cancers (including stomach, colon-rectum, lung, breast, pancreas, liver, prostate, uterus, esophagus, gallbladder, bile duct, kidney, urinary bladder, ovary, oropharynx) while avoiding urine from healthy persons, making N-NOSE a comprehensive primary screening tool. It has a high accuracy rate, with 87.5% sensitivity and 90.2% specificity for early-stage cancers. Being non-invasive and reasonably priced, N-NOSE has been a significant success in Japan since its 2020 launch, with over 500,000 screenings.This presentation delves into the technology aspect of N-NOSE in Japan, comparing its clinical research and key findings with competitors to underscore its effectiveness in early cancer detection. Furthermore, N-NOSE now advances to not only detect cancer but also identify its type in a noninvasive way, using urine and with high PPV.With pancreatic cancer being particularly lethal, we outline “N-NOSE plus pancreas,” the world’s first pancreatic cancer detection test at an early stage. This involves genetically modifying *C. elegans* to react specifically to early-stage pancreatic cancer urine samples, a development centered on the newly identified cr-4 GPCR in AWC neurons. Next, we profile our newest liver-cancer-specific test, “N-NOSE plus liver,” which offers early liver cancer detection with high sensitivity and specificity using urine.Finally, we highlight how N-NOSE bridges the gap in cancer screening and type identification, offering a complete, non-invasive solution.

#6092 Three-dimensional multi-omic analysis of early invasion of human pancreatic ductal adenocarcinoma from IPMN.

S. Datta, S. M. Shin, J. Kanacharoen, M. J. Pfluger, K. Hirose, A. Forjaz, S. Graham, P.-H. Wu, R. H. Hruban, D. Wirtz, W. J. Ho, A. L. Kiemen, L. D. Wood; Johns Hopkins University School of Medicine, Baltimore, MD

Background: Pancreatic ductal adenocarcinoma (PDAC) is a deadly cancer, with only 11% of patients surviving beyond 5 years. Intraductal papillary mucinous neoplasm (IPMN), a precancerous lesion and the most common type of neoplastic pancreatic cyst, presents a critical opportunity for cancer interception, but the drivers of malignant progression in IPMN are still largely unknown. Although the immunosuppressive microenvironment of PDAC has been well characterized, the timing of the development of these immune alterations in IPMNs is not well studied and could provide a rational foundation for cancer immuno-prevention. Moreover, the inception of invasive PDAC and its spread into the microenvironment from IPMN is complex, multifactorial, and, due to its unique anatomy, challenging to analyze with traditional 2-dimensional visualization. We sought to capture the precise point of transition from IPMN to invasive carcinoma utilizing CODA, a supervised deep learning tool for three-dimensional (3D) reconstruction of serially sectioned human tissue, in order to quantitatively assess the molecular and cellular alterations associated with malignant progression.

Method: Formalin-fixed paraffin-embedded (FFPE) tissue blocks with PDAC arising from IPMN were serially sectioned, every third slide was stained with H&E, and digitized at 20x magnification. Following pathologist-guided annotations on a subset of H&E slides, CODA generated 3D models of each tissue block, including automated annotation of 9 pancreatic tissue components. Using these annotations, we identified the transition from IPMN to invasive carcinoma in each sample and selected regions for multi-omic profiling based on quantitative features of the cellular microenvironment. Multi-omic profiling of IPMN, transition zone, and PDAC included laser capture microdissection followed by whole exome sequencing to identify somatic DNA alterations, as well as spatial transcriptomics to identify alterations in gene expression in neoplastic cells and spatial proteomics to identify cellular alterations in the surrounding microenvironment.

Results: CODA generated accurate annotation on all the H&E slides from each case and robustly identified regions of interest for multi-omic profiling. Spatial proteomic profiling using imaging mass cytometry revealed a decrease in T cell density as IPMNs transition into PDAC. Sub-clustering of the T cell compartment identified decreases in multiple T cell subsets, including activated cytotoxic T cells and helper T cells, in the transition zone compared to IPMN.

Conclusion: In this study, we integrated multi-omic profiling with CODA-generated high-resolution 3D tissue maps to identify molecular and cellular drivers of malignant progression in human PDAC.

#6093 Evaluation of preanalytical and physiological variables affecting cfDNA-based multi-cancer early detection test.

H. Bao, X. Chen, X. Wu, W. Tang, M. Wu, S. Tang, X. Wu, Y. Shao;
Nanjing Geneseeq Technology Inc., Nanjing, China

Background: The multi-cancer early detection (MCED) tests utilizing blood-based circulating cell-free DNA (cfDNA) have gained significant attention in the market as a promising approach for early cancer detection. However, potential effects of preanalytical and physiological variables, including extraction methods, preservation techniques, and physiological factors such as diet, on the accuracy and reliability of MCED results remains poorly investigated. In this study, we aimed to evaluate the impact of physiological variables during blood collection and preanalytical procedures on the outcomes of a MCED test.
Methods: A total of 105 plasma samples from 19 healthy donors was collected and analyzed using a MCED test (MERCURY) which leverages the low-coverage whole-genome sequencing and a set of genome-wide features based on cfDNA fragmentomics. Samples were controlled for preanalytical procedures, including transportation condition and preservation time or physiological conditions (before/after meal or exercise) at blood collection.
Results: Repeat blood collection (N=4) from the 5 healthy participants consistently yielded negative results for cancer (PPA: 100.0%; 95% CI [56.6%,100.0%]). Among the 5 healthy participants, plasma samples frozen within 1 year (7 days, 3 months, 9 months) showed the same agreement with the reference condition as non-frozen samples (PPA: 100.0%; 95% CI [56.6%,100.0%]), except for one sample frozen for 1 year, which showed a higher risk score and became a positive signal (PPA:80.0%; 95% CI [37.6%,96.4%]). Transportation conditions within 2 hours, 24 hours, 48 hours, and 96 hours at room temperature or 4℃ did not affect the test outcomes, as all samples remained in agreement with the reference condition as of 2 hours at 4℃ (PPA:100.0%; 95% CI [61.0%,100.0%]). Physiological conditions, including pre- and post-meal as well as pre- and post-exercise states, did not exert any influence on the test results, as all samples exhibited agreement with the reference condition (PPA:100.0%; 95% CI [43.9%,100.0%]).
Conclusions: The results of this study suggest that variables such as time of blood collection and plasma freezing time may not significantly affect the accuracy of the MCED test in healthy participants. Transportation conditions and physiological conditions evaluated in this study did not have a notable influence on the test outcomes. Nevertheless, it is advised that the freezing duration of plasma samples should not exceed one year.

#6094 Detection of MRD assessment with the Personalis NeXT Personal assay using MATRIX plasma-in-plasma contrived samples.

P. Labrousse[1], H. Russell[1], S. Hamid[2], G. Bartha[3], J. Lyle[3], D. Norton[3], J. Northcott[3], **S. M. Boyle**[3], R. Chen[3], D. Stetson[1], J. Hadfield[2];
[1]AstraZeneca, Waltham, MA, [2]AstraZeneca, Cambridge, United Kingdom, [3]Personalis, Inc., Fremont, CA

Detection of circulating tumor DNA (ctDNA) has been shown to correlate with clinical outcome of oncology patients. Molecular residual disease (MRD) profiling by ctDNA is being rapidly deployed. Current tumor-informed MRD tests assess a relatively small number of personalized variants, placing limits on their detection sensitivity and ultimately leading to false-negative results due to insufficient assay limit of detection (LOD). Here we report a performance evaluation of the Personalis NeXT Personal tumor-informed MRD assay, using a novel design for contrived samples that are highly commutable to clinical samples, enabling robust assessment of these emerging MRD assays.

Novel samples were built from commercially acquired matched tumor and plasma samples, across different indications. The cancer patient plasma was diluted into a background of healthy donor plasma to create the 72 plasma-in-plasma samples in each study (total of 144). Personalis performed WGS on the matched solid tumor and normal samples from each patient. ~1800 somatic variants were selected for each patient. A personalized panel was designed and used to enrich for the selected targets in the individual plasma samples. An aggregated signal across MRD targets was evaluated to determine the presence of ctDNA in each plasma sample.

MATRIX 1 panels averaged 1863 variants (range: 1818 to 1888) selected for MRD tracking. With 152 clinically relevant variants and additional assay components, an average of 2206 variants were assessed per patient. MATRIX 2 panels averaged 1836 variants (range: 1819 to 1867) selected for MRD tracking. In the MATRIX 1 study, tumor signal was detected in all analyzed samples, including 9 samples at 0.002% tumor plasma dilution, with an assay sensitivity of 100%. The MATRIX 2 study showed tumor signal detected in 14 of 16 samples at 0.001% tumor plasma dilution. The 2 false negatives were reported at the 0.001% tumor plasma dilution. Thus, the assay sensitivity was 87.5% at the lowest dilution (0.001%) and 96.8% overall.

The MATRIX plasma-in-plasma approach is a robust option for assessing the analytical sensitivity of MRD assays to low levels of ctDNA. This approach addresses all parts of an MRD assay for both the plasma and tumor/normal tissues, utilizing real clinical samples while allowing direct interrogation of sensitivity. The Personalis NeXT Personal assay shows ultra-high sensitivity with reproducible data down to the 1-3 PPM range.

#6095 Lung cancer risk assessment with the INTEGRAL protein panel: Preliminary results from development and validation in the Lung Cancer Cohort Consortium.

H. Zahed[1], K. Alcala[1], D. C. Muller[2], R. Hung[3], M. Johansson[1], **H. A. Robbins**[1], The Lung Cancer Cohort Consortium;
[1]International Agency for Research on Cancer, Lyon, France, [2]Imperial College London, London, United Kingdom, [3]Lunenfeld-Tanenbaum Research Institute, Sinai Health, Toronto, ON, Canada

Background: In the NCI-funded Integrative Analysis of Lung Cancer Etiology and Risk (INTEGRAL) program, the Lung Cancer Cohort Consortium (LC3) recently identified 36 proteins associated with lung cancer risk in pre-diagnostic blood samples after evaluating 1,161 proteins in 731 case-control pairs (Nature Communications, 2023). Based on these data, we designed the INTEGRAL panel, which measures absolute concentrations of 21 proteins, to optimize lung cancer risk assessment for screening beyond prediction models (e.g. PLCOm2012) or categorical screening criteria (e.g. USPSTF-2021).
Methods: To evaluate the performance of the INTEGRAL panel, we assayed blood from participants selected as a representative case-cohort sample from 14 LC3 cohorts, divided into development and validation sets (Annals of Epidemiology, 2023). Here, we present preliminary results from the 7 cohorts in the development set, including 807 lung cancer cases diagnosed within 3 years of blood draw and 1,144 sub-cohort representatives, who were weighted to represent all current and former smokers in their corresponding cohorts. We first fit a flexible parametric survival model in 4 cohorts (n=478 cases) including a subset of proteins and age, smoking duration, and smoking intensity. The model was subsequently evaluated in the remaining 3 cohorts (n=329 cases) and benchmarked against the PLCOm2012 risk score and USPSTF2021 screening criteria.
Results: The preliminary model includes 4 proteins (CEACAM5, MMP12, SCF, LPL). Compared with the PLCOm2012 score, the model improved discrimination of future lung cancer for cases occurring over 3 years (AUC=0.81 vs. 0.76, p<0.0001) and over 1 year (AUC=0.86 vs. 0.78, p<0.0001). At the USPSTF-2021 specificity of 76%, the protein model increased sensitivity by an absolute difference of 14% over 3 years and 25% over 1 year compared to USPSTF-2021, and by 9% over 3 years and 17% over 1 year compared to the PLCOm2012 model. When screening the same number of participants as PLCOm2012, the protein model identified more future cases (223 vs 193), and the cases identified only by the protein model were predicted to gain more life-years from 3 LDCT screens compared with the PLCOm2012-identified cases (4.2 vs. 3.6 life-years).
Conclusions: Preliminary results suggest that the INTEGRAL protein panel can improve risk discrimination beyond questionnaire-based risk prediction models, as well as identify future cases who have more life-years to gain from screening. Final validation is planned for completion in early 2024, by analysis of fully independent data from 7 additional LC3 cohorts (n=560 cases and 1,126 sub-cohort representatives).

#6096 Targeting premalignant lung cancer to intercept progression to invasive disease.

M. Martin, Y. He, B. Bhinder, L. Yoffe, S. L. Zhong, A. Singh, O. Elemento, S. Jiang, N. Altorki, **V. Mittal**;
Weill Cornell Medicine, New York, NY

Increased implementation of low dose CT-guided screens in the clinic has led to the identification of premalignant lung nodules (ground glass opacity, GGO) which progress to invasive adenocarcinoma[1,2]. Using integrated genomic analysis of a cohort of >300 patients with premalignant lesions, we constructed the first high-resolution landscape of composition, lineage/functional states, developmental trajectories, and multicellular crosstalk networks, which revealed potential targets for therapeutic intervention. We uncovered that early lesions exhibit marked immune-suppressive phenotypes characterized by increased T lymphocyte exhaustion to cytotoxic scores, decrease in NKT cells, elevated Tregs, increased myeloid suppressor activity, accumulation of immunosuppressive myeloid cells activation of unfolded protein response (UPR) sensor IRE1α that activates the multitasking transcription factor XBP1 known to drive malignant progression. Targeting IRE1α endoribouclease with a small molecule drug limited disease progression with marked immunomodulation in our newly developed Kras and EGFR driven mouse models, which mirror progression of human precursor lesions to invasive disease. As an immunoprevention approach, we have generated LNP-mRNA vaccines targeting top two shared neoantigens in premalignant lesions, which have shown marked immunogenicity and efficacy in early disease. Our work provides the molecular foundation for precision oncology strategies to intercept transition of preinvasive to invasive adenocarcinoma. 1. Altorki, N.K.*, et al. Nat Rev Cancer*, 2019. *2*. #6097 The role of B-cell receptor repertoire in lung squamous premalignant lesions.

D. J. Chiu, C. Merenstein, M. Lenburg, S. Mazzilli, J. Beane;
Boston Univ. School of Medicine, Boston, MA

Objective: B cells and plasma cells (PCs) play a vital role in the pathogenesis of lung cancer and provide prognostic predictive value. However, the role of B cells in the bronchial premalignant lesions (PMLs), the precursor of lung squamous cell carcinoma, is poorly understood. Prior work has shown that progression of proliferative subtype, a PML molecular subtype enriched with bronchial dysplasia, to a higher histology grade is associated with downregulation of antigen processing and presentation. In this study, we seek to understand the role of B cells, PCs, and the B-cell receptor (BCR) repertoire in progression of the bronchial PML.

Methods: We performed bulk targeted BCR sequencing on 69 endobronchial biopsies obtained from 29 subjects at high-risk for developing lung cancer. The Immcantation pipeline were applied to obtain the V(D)J germline segment assignment using the human reference from IMGT, clonal cluster assignment, and mutational load quantification for each BCR sequences by pooling all the BCR sequences from the same subjects. The clones with frequency less than 10^{-4} were filtered out. We then performed the repertoire analysis, such as clonality diversity, isotype switching frequency, and somatic hypermutation rate (SHM) rate at sample levels and investigated the association with transcriptional signature derived from bulk RNA-seq and the clinical progression of PMLs.

Results: The B cell and PC transcriptional signatures and B cell chemoattractants gene expression are associated with progression in proliferative subtype PMLs. The number of BCR clones, the class switch from IgG3 to IgG1, and the mutational rates of total and CDR3 regions were positively correlated with the B cells and PCs transcriptional signatures. Among the 31 PMLs of proliferative subtype, regressive lesions showed higher proportions of IgG heavy chain usage, higher SHM rate in CDR3 and total BCR regions, and higher frequency of class switch from IgD/M to IgG and from IgG3 to IgG1. Biopsies within the same patient had a higher proportion of shared BCR clones when they were sampled at the same timepoint than when they were sampled from the same anatomic location at different timepoints. The preserved clones of BCRs at the same anatomic location over different times had higher clonality, more class switch from IgD/M to IgG or IgA and from IgG3 to IgG1, and increased SHM rates than the non-preserved clones.

Conclusions: These results suggest B and plasma cells exert anti-tumor effects that prevent bronchial PMLs from progressing to higher grade lesions by switching to IgG1 BCRs and increasing SHM rates.

#6098 Spatial single-cell immune microenvironment analysis reveals the transition from innate to adaptive immune response during early lung adenocarcinoma carcinogenesis.

B. Zhu[1], P. Chen[1], M. Aminu[1], J. Fujimoto[1], L. Hong[1], A. L. Moreira[2], J.-R. Li[3], Y. Tian[1], L. M. Solis Soto[1], P. Edwin Roger[1], O. Shi[1], H. Chen[1], F. R. Rojas[1], E. Vilar[1], A. Maitra[1], K. Chen[1], N. Navin[1], C. L. Haymacker[1], V. Velcheti[4], D. H. Sterman[4], P. Andrew Futreal[1], D. L. Gibbons[1], I. I. Wistuba[1], J. V. Heymach[1], C. Cheng[3], H. I. Pass[2], J. Wu[1], J. Zhang[1];

Introduction: Lung cancer remains the leading cause of cancer death worldwide. Although prevention holds the promise to reduce lung cancer mortality, the results from randomized trials have been disappointing, likely due to our rudimentary knowledge of early lung cancer carcinogenesis. Cancer initiation and progression involve complex processes dependent on the dynamic interplay of individual cells within the tumor microenvironment (TME). Our understanding of the multicellular composition, interaction, spatial distribution, and functional dynamics during the early evolution from precancer to invasive LUAD is limited.

Methods: We performed spatial single cell immune microenvironment analysis of 10 normal, 40 AAH, 22 AIS, 18 MIA, and 34 IAC by Imaging Mass Cytometry (IMC) and analyzed high-dimensional images of 1,618 regions-of-interest (ROIs) using a 34-plex marker. Using machine learning approaches, we classified 4,828,879 cells into 14 major cell types, which were subjected to further analysis for multicellular composition, interaction, spatial distribution, and functional dynamics in LUAD precursors of different stages.

Results: From AAH to AIS, MIA, and IAC, we observed a gradual escalation in the density (number of cells/mm2) of all immune subsets. Proportionally, adaptive immune cells exhibited a progressive increase, whereas innate immune cells demonstrated a concurrent decrease with the neoplastic progression from normal lung to AAH, AIS, MIA, and ADC. Notably, macrophages emerged as the predominant immune cells within the immune microenvironment of these LUAD precursors. Upon closer examination of subtypes, protumor M2 macrophages showed a gradual increase from AAH to AIS, MIA, and IAC, whereas anti-tumor M1 macrophages increased from normal to AIH, AIS and subsequently decreased in AIS, MIA, and IAC stages. These alterations resulted in a progressive increase in M2/M1 ratios from AAH to IAC stages. Furthermore, M2 macrophages exhibited higher heterotypic interactions with epithelial cells than M1 across LUAD precursors of different stages, especially in the later stages. Co-expression analysis revealed 5 modules that distinguishes each histological stage. Tim-3 module was significantly enriched in AAH lesions, while NK cell-related features were enriched at AIS stage, B cell-related features enriched at MIA stage and Ki-67-related adaptive immune features enriched in IAC stage.

Conclusion: The spatial single cell immune microenvironment analysis revealed a transition from innate to adaptive immunity during initiation and early progression of LUAD progression and innate immunity may play critical roles during early LUAD development. Therefore, reprograming innate immunity such as repolarization of M2/M1 may provide avenues to intercept LUAD precursors to prevent invasive LUAD.

#6099 Identification of intrinsic precursors of Barrett's and gastric intestinal metaplasia.

Wa Xian[1], Frank McKeon[1], Yusuke Yamamoto[2], Melika Khorrami[1], Melina Khorrami[1], zaal Mory[1], Jeremy Siegelman[1], Amber Su[1], Raul Caballero Montes[1], Ashley Hoffman[1], Jaffer Ajani[1], Christopher Crum[3], William Bachovchin[4], Shan Wang[1], Matthew Vincent[1], Crystal Nguyen[1]

[1]University of Houston, Houston, TX,[2]National Cancer Institute, Tokyo, Japan,[3]Harvard University, Boston, MA,[4]Tufts University, Boston, MA

The origin of Barrett's esophagus (BE) and gastric intestinal metaplasia (GIM), obligate precursors of esophageal adenocarcinoma (EAC) and intestinal gastric cancer (iGC), has intrigued investigators for decades and would likely guide preemptive strategies. From endoscopic biopsies of clinically confirmed BE and GIM, we have cloned stem cells committed to intestinal metaplasia in vitro. Remarkably, the gene expression profiles of BE and GIM stem cells are highly related down to broad arrays of transcription factors compared with stem cells of the normal gastric mucosa. Using cell surface markers in common between BE and GIM stem cells, we have identified clusters of cells at the squamocolumnar junction and the distal stomach in mice and have used Fluorescence-activated cell sorting (FACS) to clone these cells from both sites. These murine clones can be differentiated in air-liquid interface cultures, and both are committed to intestinal metaplasia marked by goblet cells and Alcian blue staining. To ask whether similar cells exist in humans, we generated stem cell libraries from endoscopic biopsies taken from the gastroesophageal junction (GEJ) and the antrum-body junction (ABJ) in patients without BE or GIM. FACS sorting of these stem cell libraries using the same cell surface markers common to BE and GIM stem cells and the murine precursors, we have identified stem cells from the GEJ and ABJ that show similar gene expression profiles and share a commitment to intestinal metaplasia upon in vitro differentiation. Using identical transformation protocols involving retrovirally transduced protooncogenes, we find that these transformed intrinsic cells give rise to tumors with expression profiles similar to EAC and iGC in TCGA datasets, whereas transformed gastric mucosal stem cells yield tumors marked by signet ring cells typical of diffuse gastric cancer. Lastly, we find that drugs we have developed that target the stem cells of BE and GIM also eliminate the putative precursor cells of BE and GIM, suggesting the potential of therapeutics that might eliminate the emergence of intestinal metaplasia and the cancers derived from them.

#6101 PLASMUT: An R Package for estimating the probability of tumor-specific mutations in cell-free DNA.

A. S. Arun[1], J. E. Medina[2], S. Cristiano[2], D. C. Bruhm[2], R. J. A. Fijneman[3], G. A. Meijer[3], A. Leal[2], V. E. Velculescu[2], R. B. Scharpf[2];
[1]Yale University School of Medicine, New Haven, CT, [2]Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins University School of Medicine, Baltimore, MD, [3]Department of Pathology, Netherlands Cancer Institute, Amsterdam, Netherlands

Noninvasive approaches for detection of tumor-specific mutations in cell-free DNA (cfDNA) have the potential to track a patient's response to treatment, enabling effective and timely decisions on therapy. However, mutations in cfDNA arising from clonal hematopoeisis (CH) are common and tumor biopsies for definitive identification of the origin of these mutations are not always available. Sequencing of matched cells from buffy coat and the absence of mutations in these cells has been used to rule-out white blood cell (WBC) mutations, but uneven sequencing depths between matched cfDNA and buffy coat and the fraction of mutant alleles are generally ignored by rule-based tests. A probabilistic approach that quantifies the evidence of tumor-derived mutations in cfDNA is needed.
We developed a Bayesian framework to estimate the probability that a mutation identified in cfDNA is tumor specific. Our approach requires the number of reads with a mutant allele in plasma (y_p) and WBCs (y_w) and the corresponding number of total distinct reads at these locations. The posterior odds that a mutation is tumor-derived (S) versus CH or germline (H) is given by the ratio of the probabilities of observing the distinct reads given each model times the prior odds. Estimation of the Bayes factor is obtained by integrating over the unobserved mutant allele fractions in plasma and WBCs using Monte Carlo importance sampling. We applied this approach to 52 patients with initially unresectable colorectal cancer (CRC) liver metastases in the CAIRO5 clinical trial (NCT02162563), using ultra-deep targeted sequencing of cfDNA from plasma and matched WBCs.
Among the CAIRO5 patients analyzed, we identified 95 mutations with moderate evidence of tumor-derived cfDNA mutations (Bayes factor > 10) and 19 mutations that were CH-derived (Bayes factor < 0.1). For a subset of 47 cfDNA mutations with no corresponding mutation identified by WBC sequencing, the evidence of tumor origin was highly variable (Bayes factor range: 0.03 to 5.6). While the standard rule-based approach identifies all of these mutations as tumor-derived, none of these mutations reach a moderate evidence cutpoint (all Bayes factors < 6). As a false positive would lead to identification of cfDNA mutations that do not track tumor burden, requiring even higher levels of evidence (Bayes factor > 99) for the selection of cfDNA mutations could be warranted, and still identifies one or more cfDNA mutations in 43 of the patients. This approach is implemented in the R package PLASMUT available from Bioconductor (doi:10.18129/B9.bioc.plasmut).
We developed an approach that quantifies the evidence between two competing models for the origin of mutations in cfDNA. A cutpoint for determination of the probability of tumor-derived cfDNA mutations can be tailored to the disease application, balancing the potential benefits of noninvasive testing with the harms of false positives and negatives.

#6102 Clinicopathological and genetics features of endometrial cancer in Algerian women: The first nation-wide study.

F. Cherbal[1], C. Mehemmai[1], M. Saidi[1], Y. Santoudji[1], D.-E. Seddik[1], A.-L. Boumehdi[1], F. Gouaref[2], K. Bentabak[2], H. Mahfouf[3], M. Oukkal[4]; [1]Molecular Genetics Team, LBCM, Faculty of Biological Sci., USTHB, Algiers, Algeria, [2]Oncological Surgery and LiverTransplantation services, EHS Pierre and Marie Curie, Univ. of Algiers 1, Algiers, Algeria, [3]Mohamed El Kolli Publ. Hosp., Academic Med. Oncology Services,Rouiba, Sch. of Med., Univ. of Algiers1, Algiers, Algeria, [4]Clinic of Med. Oncology Amine Zirout, Univ. Hosp. of Beni-Messous, Sch. of Med., Univ. of Algiers-1, Algiers, Algeria

Background: Endometrial cancer represents the fourth common cancer in women in Algeria and the fifth cause of cancer mortality. In the present study, we aimed to determine, clinical, tumor and genetics characteristics associated with endometrial cancer in Algerian women. In addition, we screened for germline pathogenic variants in MMR genes in endometrial cancer patients with strong family history of Lynch syndrome (LS).

Materials and Methods: Our study population included 273 patients diagnosed with endometrial cancer between 2010 and 2021. Data were collected from three public hospitals that covered 29 provinces among 48 in Algeria. Patient and tumor information included: age at diagnosis, menopausal status, histological type, histological grade, TNM stage, FIGO stage, tumor markers CA125, ACE, CA19-9, family history with cancer and age at menarche . *MLH1* (exons 1, 9, 10, 13, 16), *MSH2* (exons 5, 6, 7, 12), *MSH6* (exons 4 and 8) and *PMS 2*(exons 6 and 10) were screened by PCR-Sanger direct sequencing in 14 LS families .

Results: The mean age at diagnosis was 58.88 years. The mean age at menarche was 13.5 years. The proportion of endometrial cancer patients with premenopausal status was 21.62%. The commonest histological type was endometrioid adenocarcinoma (66.79%) followed by clear cell carcinoma (8.10%), carcinosarcomas (3.86%), serous carcinoma (3.47%) and mucinous carcinoma (2.7%). We found that the proportion of tumors with histological grade I (34.74%), grade II (27.41%) and grade IV (21.40%) was commonest in 83.55% of the patients. Our results showed that 73.74% of the patients were diagnosed at stage I (50.19%), stage II (12.74%) and stage III (10.81%), respectively. For the FIGO staging, our results showed that 74.12% of the patients were diagnosed at stage I (52.89%), stage III (10.81%) and stage I (10.42%), respectively. 16.21%, 3.08%, 6.94% of the patients were positive for CA125, ACE and CA19-9, respectively. We noticed that 56 patients (20.43%) had a positive family history with HBOC syndrome (17), Lynch syndrome (26) and Cowden syndrome (13), respectively. We identified two distinct germline pathogenic variants in *MLH1* gene in two LS families. We detected the new germline pathogenic variant *MLH1* c.53_63delinsT in young patient diagnosed with endometrial cancer and colorectal cancer (CRC) at age 43y and 44 y, respectively. The rare pathogenic germline variant *MLH1* c.1546C>T has been detected in young woman diagnosed with CRC at age 41y and endometrial and ovarian cancers at age 52y, respectively.

Conclusions : In this first study, we reported some clinical, biological, tumor and genetics features of endometrial cancer in Algerian women. Interestingly, we noticed that the median age of diagnosis was younger that the average age in Europe and America. Genetic counseling and testing is recommended for endometrial cancer patients diagnosed before age 50 with a family history of Lynch syndrome.

#6103 The association of genetic polymorphisms in DNA repair genes XRCC1 and 3 with cervical cancer risk among Bangladeshi females.

M. Rahman[1], L. Das[1], S. Rahman[1], A. Hossain[2], R. Sultana[3];

[1]Khulna University, Bangladesh, Khulna, Bangladesh, [2]Dhaka International University, Bangladesh, Dhaka, Bangladesh, [3]Decent Spacialized Dental Care, Khulna, Bangladesh

Introduction and Objective: Worldwide, cervical cancer ranks the second most common cancer in women. Sequence variations in DNA repair genes X-ray repair cross complementing (XRCC) 1 and 3 genes can lead to can result cellular function aberration leading to cancers. Single nucleotide polymorphisms (SNPs) in XRCC1 (Arg399Gln) and XRCC3 (Thr241Met) genes have been shown to cause individual variation in their DNA repair capacity. The aim of this study was to investigate the association of XRCC1 Arg399Gln and XRCC3 Thr241Met SNPs with susceptibility to cervical cancer among Bangladeshi populations.
Methods: In the current case-control study 124 cervical cancer patients and 148 age matched healthy controls were recruited. Genomic DNAs were isolated from peripheral blood collected from the participants and genotyped for candidate SNPs using polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP) method.
Results: For XRCC1, heterozygous Arg/Gln and combined heterozygous plus variant homozygous Gln/Gln genotypes showed 1.78-fold (95% CI 1.0037 to 2.8771, p=0.0484) and 1.8627-fold (95% CI 1.1470 to 3.0250, p = 0.0119) increased risk of cervical cancer, respectively, when compared with normal homozygous Arg/Arg genotype. The variant Gln allele was positively associated with cervical cancer by 1.68-fold increase (95% CI 1.1732 to 2.3980, p = 0.0046). Similarly, for XRCC3, Thr/Met heterozygous and combined Thr/Met + Met/Met genotypes were found to be associated with 1.6993-fold (95% CI 1.0398 to 3.0166, p=0.0354) and 1.8312-fold (95% CI 1.0890 to 3.0791, p = 0.0225) higher risk, respectively, when compared with normal homozygous Thr/Thr genotypes. The variant Met allele showed significant association with 1.71-fold increased risk.
Conclusion: XRCC1 (Arg399Gln) and XRCC3 (Thr241Met) SNPs may be positively associated with increased cervical cancer risk in Bangladeshi females.

#6104 EDRN Lung Team Project #2 validation of molecular biomarkers for the early detection of lung cancer in the setting of indeterminate pulmonary nodules.

J. C. Willey[1], E. L. Grogan[2], S. A. Deppen[2], J. G. Herman[3], M. N. Kammer[2], M. B. Schabath[4], L. Sorbara[5], H. I. Pass[6], J.-C. J. Tsay[7], Z. Feng[8], A. Spira[9], E. L. Crawford[1], J. Dahlgren[10], S. M. Dubinett[11], K. R. Rieger-Christ[12], M. E. Lenburg[9].

[1]University of Toledo, Toledo, OH, [2]Vanderbilt University Medical Center, Nashville, TN, [3]University of Toledo, Pittsburg, PA, [4]Moffitt Cancer Center, Tampa, FL, [5]National Cancer Institute, Bethesda, MD, [6]NYU Langone Health, New York, NY, [7]New York University School of Medicine, New York, NY, [8]Fred Hutchinson Cancer Center, Seattle, WA, [9]Boston University, Boston, MA, [10]Fred Hutchinson Cancer Center, Toledo, OH, [11]University of California Los Angeles, Los Angeles, CA, [12]Lahey Hospital and Medical Center, Burlington, MA

Background: The goal of the Early Detection Research Network (EDRN) Lung Team Project #2 (LTP-2) is to establish a cohort (n= 300) of high-risk people with indeterminate pulmonary nodules (6mm-30mm) to clinically validate the diagnostic accuracy of existing molecular and imaging biomarkers discovered and analytically validated through the EDRN program. These biomarkers comprise signals measured in serum (glycan or cytokine), plasma (protein, miRNA, RNA, or methylated circulating tumor DNA), airway epithelial cells (RNA or DNA), nasal brush cells (RNA or DNA), and/or chest CT images.

Methods: Eligible participants had an indeterminate nodule discovered incidentally or through low-dose CT screening within 14 months prior to enrollment and were aged 45-90 years, with 20 pack-years or more cigarette smoking history, free of lung cancer, and willing to provide blood, nasal brushing, and optionally bronchoscopic brush biopsy specimens. Baseline medical and demographic data were collected from each subject. Baseline and years 1 and 2 follow-up CT images were obtained. Each specimen at each respective site was labeled with a 2-D barcode provided by the DMCC and specimen information was entered into the Validation Study Information Management System (VSIMS) developed by the EDRN Data Management and Coordinating Center (DMCC). Aliquots of blinded specimens from selected cases and controls will be dispensed to each EDRN site for biomarker analysis. Analysis plan: Primary endpoint: The positive diagnostic likelihood ratio (DLR+) will be used to measure biomarker performance within values of DLR+ >= 2 or DLR- <= 0.5, a range considered clinically useful for any patients with indeterminate lung nodules. The sample size calculation targeted >80% power to test the null hypotheses that a) a positive biomarker does not alter risk across a range of specificities, and b) a negative biomarker does not alter risk across a range of sensitivities. The EDRN Data Management and Coordinating Center (DMCC) will unblind and complete analysis and report results. Exploratory endpoint: The diagnostic accuracy of combined biomarkers will be calculated using a logistic regression model with flexible functional forms.

Results and Discussion: More than 300 subjects were enrolled into the LTP2 cohort including a sufficient number of cases and controls (cohort size n>300) to reach power according to calculated estimates. Chest CT images were collected and are in the process of transfer to a central database. Plasma specimens have been distributed to test sites. RNA and DNA extraction from NBC and AEC is in process and based on results thus far the specimen quality and quantity is more than sufficient from the number of subjects needed to reach power for the primary endpoint and to conduct the planned exploratory analyses.

POPULATION SCIENCES: Cancer Disparities 3: Using Molecular Epidemiological Approaches to Decipher Cancer Disparities
Poster Session

#6107 Survival differences by socioeconomic status in Merkel cell carcinoma: A retrospective analysis using the National Cancer Database.
R. C. Chang, E. K. Brunsgaard, D. Reid;
Rush University Medical Center, Chicago, IL

Introduction: Merkel cell carcinoma (MCC) is a rare and aggressive skin cancer whose incidence and survival outcomes demonstrate disparities based on patients' socioeconomic status (SES). This study aims to evaluate the impact of SES on MCC diagnosis age, comorbidity burden, treatment modalities, and survival outcomes using the National Cancer Database.
Methods: We conducted a retrospective analysis of 9742 patients diagnosed with MCC from 2016 to 2020 in the United States. To assess how socioeconomic status influences outcomes, a composite score was created by adding income and education quartile assignments (1, 2, 3, 4), to create new composite SES quartiles of 2-3, 4-5, 6-7, and 8. Patients were stratified into quartiles based on their SES (lowest Q1 to highest Q4). Binomial test was performed for categorical variables and ANOVA was performed for continuous. Survival differences were examined with Cox proportional hazards models and Kaplan-Meier curves.
Results: Patients with lower SES presented with MCC at younger ages, with the average age of patients in the lowest SES Q1 being 73.8 years (95% CI 73.15-74.35) and the highest SES Q4 being 75.0 years (95% CI 74.48-75.46). Patients in SES Q1 also had higher Charson-Deyo scores, indicating more comorbidities than patients in SES Q4 (8.41% vs 5.8%, $p < 0.001$). They were also more likely to have advanced stage 4 MCC (9.67% vs 7.79%, $p < 0.01$) compared to patients in SES Q4. When treated with surgery, patients in SES Q1 were more likely to be treated with local tumor excision (14.39% vs 10.83%, $p < 0.001$) whereas patients in SES Q4 were more likely treated with Mohs surgery (5.02% vs 3.56%, $p < 0.01$). Survival probabilities for patients SES Q1 were worse at 1 year (82.99% vs 85.81%, $p<0.001$), 3 years (61.18% vs 68.49%, $p < 0.001$) and 5 years (45.99% vs 55.09%, $p < 0.001$) compared to patients in SES Q4.
Conclusion: This study highlights disparities in age at diagnosis, comorbidities, treatment, and survival outcomes in MCC patients based on SES. Patients in lower SES quartiles are diagnosed younger, bear higher comorbidity burdens, and have worse rates of survival.

#6108 Investigation of breast tumor biology and microenvironment in women of African descent using a single cell multiomic approach.

A. R. Harris[1], H. Liu[2], B. Jenkins-Lord[3], T. H. Dorsey[2], F. Makokha[4], S. Sayed[5], G. Gierach[1], S. Ambs[2];
[1]National Cancer Institute, Rockville, MD, [2]National Cancer Institute, Bethesda, MD, [3]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, [4]Mount Kenya University, Thika, Kenya, [5]Aga Khan University Medical Center, Nairobi, Kenya

Women of African descent are at an increased risk of developing and dying from aggressive subtypes of breast cancer. A connection between aggressive disease and Western Sub-Saharan African ancestry has been postulated, but it remains largely unknown to what extent breast cancer in Africa is reminiscent of breast cancer in U.S. African American (AA) women who experience disproportionately high mortality rates. We performed ATAC- and RNA-sequencing on 9 human triple-negative breast cancer cell lines of U.S. origin and discovered that African ancestry influences the chromatin landscape, leading to disparate transcription factor (TF) activity and downstream gene expression patterns indicative of an aggressive tumor biology. Here, we describe an ambitious study that employs single-nucleus (sn) ATAC- and RNA-sequencing (snMultiome) of frozen breast tumors to characterize chromatin accessibility and gene expression patterns with single-cell resolution in AA (n=33), Kenyan (n=25), and European American (EA, n=24) women in relation to genetic ancestry, risk factor exposures, clinical characteristics, and 5-year survival. To achieve this, we successfully isolated intact, high-quality single nuclei from archival frozen breast tumor tissue through an optimized combination of enzymatic digestion and automated tissue homogenization. We performed snMultiome sequencing of 82 tumors using the 10x Genomics platform. Following filtering, normalization (SCT for snRNA; LSI for snATAC), peak calling (MACS2), and integration (Harmony), our dataset includes a total of 296,557 nuclei. Cancerous (163,419 nuclei) and non-cancerous (133,138 nuclei) cells were distinguished based on DNA copy number (CopyKat). Within the microenvironment, 11 major immune, epithelial, and stromal cell types were successfully annotated, exhibiting distinct patterns by population group (e.g. AA tumors showed markedly increased abundance of myeloid and T-cells, while Kenyan tumors showed increased abundance of pericytes and fibroblasts). A large number of enriched TFs within each cell type varied significantly by population group, suggesting distinct chromatin accessibility patterns related to genetic ancestry. Within cancerous cells, striking intra- and inter-tumoral heterogeneity was observed by genetic ancestry even within molecular subtype groups. Current efforts focus on in-depth molecular characterization of ancestry- and risk factor-related differences in the tumor epithelium and microenvironment and distinct signatures present in lethal disease. This project holds the potential to yield crucial insights into how ancestry or other factors may influence the etiology of different breast cancer subtypes, as well as produce clinically actionable biomarkers and therapeutic targets to enhance precision medicine within patient populations at high risk for aggressive disease.

#6109 Determinants of generalized self-efficacy and genetic knowledge among Hispanic/Latino colorectal cancer patients participating in ENLACE: A Cancer Moonshot Study.

J. Sanchez Mendez[1], J. O. Culver[1], C. N. Ricker[1], N. Gutierrez[1], S. Algaze[1], J. D. Carpten[2], H.-J. Lenz[1], M. C. Stern[1];
[1]USC - University of Southern California, Los Angeles, CA, [2]City of Hope, Duarte, CA

Background: Colorectal cancer (CRC) is the third most common cancer, and second cause of cancer death in the United States (US). Among US Hispanic/Latino/a/x (H/L) individuals, CRC represents the second and the third most common cancer and the most common cause of cancer death for men and women, respectively. Despite this, the tumor landscape, and key determinants of outcomes in CRC H/L patients are understudied.
Methods: To address this need, we launched the ENLACE study, to engage H/L CRC patients in germline and somatic sequencing and identify the optimal approaches for patient participation. Through the Center for Patient Engagement in Cancer Characterization Studies (COPECC) patients were recruited from two healthcare facilities: a safety-net hospital (Los Angeles General Medical Center, LA Gen) and the USC Norris Comprehensive Cancer Center (Norris) a university medical center. Surveys to assess demographics, acculturation, Latino values, health literacy, discrimination, health system distrust, numeracy, and generalized self-efficacy (GSE) were evaluated upon recruitment, and after return-of-results (ROR) for somatic and germline testing.
Results: After the first year of the project, a total of 100 H/L CRC patients >18 years of age were included in the ENLACE study, 89 participants completed baseline surveys (49 female, median age 53 (IQR = 16) and 21 completed questionnaires after ROR. A majority self-identified as White (61%), Mexico born (51%), catholic (74%), only spoke Spanish at home (35%) and married (49%). Higher levels of GSE were reported in patients with higher scores for numeracy ($p = 0.005$) and in males when compared to females ($p = 0.016$). This association was driven by participants from Norris (n=33) as reported by stratified analyses. In contrast, among participants from LA Gen (n=66) we observed an association with higher median values for the Mexican American acculturation scale and mainstream values and a marginally significant increase in the GSE ($p = 0.072$ & 0.083, respectively). Additionally, LA Gen participants with a greater than the median score for GSE had a marginally significant higher mean score in the KnowGene scale ($p = 0.056$) with a reduction in the number of times the “Don’t Know” option was selected ($p = 0.045$). No statistically significant difference in the generalized self-efficacy score and KnowGene scale were reported after reception of results ($p = 0.2386$ & 0.1337, respectively)
Conclusion: We report differences in GSE and cancer genetic knowledge amongst CRC H/L patients in the ENLACE study that may inform understanding of disparities and social determinants in the populations treated at two different healthcare facilities.

#6110 Computational exploration of genomic differences in Black patients treated with chemoradiation for head and neck squamous cell carcinoma (HNSCC).

C. C. Lattimore, C. J. Washington, D. Braithwaite, S. D. Karanth, K. M. Fredenburg;
University of Florida, Gainesville, FL

Background: Black patients treated with chemoradiation for head and neck squamous cell carcinoma (HNSCC) experience significantly worse survival outcomes than White patients treated with the same modality. Our group aims to explore potential sociodemographic and biological factors undermining this differing response to therapy. Here, we present our computational findings of genomic differences in Black compared with White HNSCC patients receiving chemoradiation.

Methods: We obtained gene expression, phenotype, and clinical datasets for the Cancer Genome Atlas (TCGA) HNSCC cohort from the UCSC Xena web browser. Of the 528 HNSCC patients, 131 (Black=13, White=118) of those receiving chemoradiation had gene expression, phenotype, and clinical data available. Our analysis included anatomic sites involving the oral cavity, hypopharynx, and larynx, and excluded the oropharynx. We performed differential gene expression analysis in Black compared with White (reference population) patients via edgeR in R studio (-log2FC < -1 or log2FC >1; p value < 0.05; FDR < 0.05). The Database for Annotation, Visualization, and Integrated Discovery (DAVID) webtool was used to identify significantly enriched molecular processes and pathways.

Results: 462 genes were found to be significantly differentially expressed between Black and White HNSCC patients receiving chemoradiation. Of these genes, 198 were found to be higher in Black patients, and the most significant included *JPH3, PCSK1N, DCUN1D5, CRYGS*, and *CCL7* ($p < 0.005$, FDR < 0.005). 264 were found to be lower in Black patients, with the most significant being *KBTBD12*, *CMYA5*, *NEFH*, *LDB3*, *PYGM* ($p < 0.005$, FDR < 0.005). Genes found to be higher in Black patients showed enrichment for processes such as EGFR tyrosine kinase inhibitor resistance ($p < 0.005$), drug metabolism ($p < 0.005$), and chemical carcinogenesis ($p < 0.005$). Genes found to be lower in Black patients showed enrichment for muscle-related processes such as myogenesis ($p < 0.005$), actin-binding ($p < 0.005$), muscle protein ($p < 0.005$), and hypertrophic cardiomyopathy ($p < 0.005$).

Conclusion: In conclusion, using TCGA, we identified differentially expressed genes between Black and White HNSCC patients receiving chemoradiation. Moreover, these findings suggest that biological processes may differ in Black compared with White patients receiving chemoradiation, and this may dictate differing response to therapy. Additional studies will involve further computational analysis using other datasets for validation.

#6111 Real world incidence of ALK alterations in Hispanic NSCLC patients in Los Angeles.

R. C. Hsu, D. Poei, J. S. Thomas, J. J. Nieva;
USC - University of Southern California, Los Angeles, CA

Introduction: Race and ethnicity affect the distribution of molecular alterations seen in populations of lung cancer patients. ALK fusions occur in 4-5% of non-small cell lung cancer (NSCLC) patients overall. We characterized ALK alteration presence in NSCLC Hispanics treated at a large academic institution in Los Angeles. Methods: 607 NSCLC patients treated at Los Angeles General Medical Center (LAGMC) (n=174) and Norris Comprehensive Cancer Center (NCCC) (n=433) who received comprehensive genomic profiling (CGP) were evaluated from July 2017 to June 2023. Fisher's exact test was done to compare differences in prevalence between Hispanics and non-Hispanics. Multivariate logistic regression was performed to evaluate the role of Hispanic ethnicity controlling for site of treatment, age at initial diagnosis, sex, and smoking history. Results: Hispanics represented 23% (n=141) and 7.2% of patients (n=44) had ALK alterations (Table 1). Hispanics (12.76%, n = 18/141) were more likely to have ALK alterations than Non-Hispanics (5.58%, n = 26/466) (p=0.0083). In 18 Hispanic ALK patients, the median age was 53 years, 50% female (n=9), and 61.11% never smokers (n=11) versus a median age of 62.1 years, 46.80% female (n=66), and 53.19% never smokers (n=75) in all Hispanics (n=141). 94.44% of ALK Hispanics (n=17) were diagnosed as Stage IV versus 72.34% (n=102) in all Hispanics. Brain metastasis was seen in 61.11% (n=11) of Hispanic ALK patients versus 33.33% (n=47) in all Hispanics. Multivariate logistic regression showed Hispanic ethnicity HR 2.338 (95% CI 1.105-4.907) and age at diagnosis HR 0.9275 (95% CI 0.9025-0.9519) were significant variables in ALK alteration incidence. Conclusions: Hispanics represented 23% of the NSCLC population tested for CGP but 41% of the ALK altered patients. This highlights the need to study Hispanic ethnicity in the biology of ALK alterations, ensure Hispanics have equal access to CGP, and greater Hispanic representation in ALK inhibitor clinical trials.

Clinical Characteristics of NSCLC patients at LAGMC and NCCC receiving CGP

	Hispanic	**Asian**	**Non-Hispanic Black**	**Non-Hispanic White**	**Other/Unknown**	**Total**
Number of ALK alterations (%)	18 (12.76%)	9 (4.41%)	0 (0.00%)	15 (8.24%)	2 (4.44%)	44 (7.2%)

#6112 Uncovering clinicopathological factors contributing to racial inequities in pancreatic cancer in Hampton Roads, Virginia.

F. W. Chaudhry, Z. L. Kolkey, A. E. Hannah, R. A. Hoefer, A. Tang;
Eastern Virginia Medical School, Norfolk, VA

Introduction: Pancreatic Ductal Adenocarcinoma (PDAC) is the 3rd leading cause of cancer-related deaths, with 12% surviving 5 years post-diagnosis. The delayed symptom onset, lack of effective screening, and advanced presentation render most patients ineligible for surgery. For inoperable PDAC, treatment offers only palliative support, resulting in a 1-year median survival, in contrast to 3 years for operable cases. Black patients face a 30-70% higher PDAC mortality rate than other racial groups in the United States. In Hampton Roads, Virginia, from 2015-2019, the black PDAC population had a mortality rate of 17.3%, notably surpassing the 10.8% rate among white PDAC patients. Consequently, this project aims to address the disparate disease burden of PDAC in the black Hampton Roads community.

Methods: Chart review of 427 inoperable PDAC patients from the Sentara Cancer Network and Virginia Oncology Associates was conducted. Age at diagnosis, treatment date, treatment type, and death date of the black and white inoperable cohorts were extracted. Average length of disease, age of onset, and time from diagnosis to treatment were calculated. KM survival analysis compared the cohorts' survival rates.

Results: From 2008 to 2016, the white cohort had shorter survival rates than the black cohort. The black population averaged a disease length of 249 days, while the white population faced 190 days. The average age at diagnosis was 67 in the black cohort and 70 in the white cohort. 42.1% of white PDAC patients did not receive treatment, while 29.9% of black PDAC patients went untreated.

Discussion: While the black population faces higher mortality, the white PDAC inoperable cohort had shorter disease duration and lower survival. A higher number of white patients also did not receive therapy, likely due to their older age, leading to added comorbidities and advanced stages of disease. Elder patients often decline treatment due to its limited impact on lifespan and quality of life. Further, the longer survival found in black patients may paradoxically contribute to a high mortality rate in Black patients. 21% of the black cohort survived over a year, prompting questions about their classification as inoperable and their access to the only curative treatment. This discovery motivates examination of the decisions behind labeling these patients as inoperable. The ongoing investigation into factors, such as stage at diagnosis and standard of care adherence, strives to continue to uncover the reasons for the high mortality rate in the Black PDAC Hampton Roads population.

#6113 Racial disparity in HER2-positive breast cancer: A single cancer center registry review.

A. Hodges[1], C. Rosenbaum[2], C. Santana[3], P. A. Niravath[3], H. Mai[3], D. Jain[3], J. C. Chang[3], J. Xu[2], **K. Sun**[3];
[1]Houston Methodist Research Institute, Houston, TX, [2]Houston Methodist Center for Health Data Science & Analytics, Houston, TX, [3]Houston Methodist Neal Cancer Center, Houston, TX

Background: Racial disparity outcomes in HER2-positive breast cancer have been previously described but the literature is limited. We examined data from our cancer center registry to investigate racial disparity in HER2-positive breast cancer.
Method: We retrospectively queried patients diagnosed with HER2-positive breast cancer from Houston Methodist Cancer Center registry from 2016 to 2022. Patients' demographics, cancer staging, treatment and outcomes including recurrence and survival were recorded and analyzed. We used the distressed communities index (DCI), a composite metric of multiple socioeconomic factors based on the patient's zip code at diagnosis, as a surrogate of socioeconomic status. Multivariable logistic regression and Cox proportional hazards analysis were used. A p value <0.05 is considered statistically significant.
Results: From 2016 to 2022, 992 patients were retrieved. 58.4% (579/992) patients were White, 17.3% (172/992) black, 16.2% (161/992) Hispanic and 8.1% (80/992) Asian. Although Black and Hispanic patients lived in more distressed communities, Black and Asian patients were diagnosed with more advanced disease. There were no statistically significant differences in neoadjuvant treatment received and pathologic complete response (pCR) rate among racial groups (table 1). Patients with higher stages are more likely to receive neoadjuvant treatment (OR: 5.49 [CI: 3.61-8.49] and 5.59 [CI: 3.15-10.2] for Stage 2 and 3 respectively). ER-HER2+ subtype was the only predictor of achieving pCR (OR: 0.47, CI: 0.29-0.79). Younger age, receiving neoadjuvant treatment and earlier stages were associated with improved all-cause mortality. There were no differences in receiving neoadjuvant treatment between racial groups, DCI; race and DCI are not associated with pCR or all-cause mortality.
Conclusion: Our retrospective study from a single institution revealed no significant racial disparities in the treatment and outcome of HER2-positive breast cancers.

Table 1 Characteristics of HER2-positive breast cancer in different racial groups

Variables	**Asian**, N = 80	**Black**, N = 172	**Spanish**, N = 161	**White**, N = 579	**p-value**
Age (at diagnosis), mean (SD)	54 (13)	54 (12)	53 (13)	57 (13)	<0.001

#6114 Trends in hematological cancer subtype mortality by educational attainment and sex in the United States, 2000-2020.

E. C. Marlow, F. Islami, A. Jemal;
American Cancer Society, Atlanta, GA

Objective: To examine mortality trends for hematological cancer subtypes (leukemia, Hodgkin's lymphoma, non-Hodgkin's lymphoma, and myeloma) by educational attainment and sex in the United States.
Methods: Using data on 1,082,234 U.S. deaths from 2000-2020, age-standardized death rates were calculated by sex and educational attainment (high school/GED or less, some college, and 4 years of college or more). Annual percentage change (APC) and 95% confidence intervals (CI) for mortality rates were generated using Joinpoint regression.
Results: For all hematological cancer subtypes, mortality rates were largest among males and those with the least education for all study years. In general, decreasing trends were observed in recent years for non-Hodgkin's lymphoma, myeloma, and leukemia mortality rates. Non-Hodgkin's lymphoma mortality rates, for example, decreased among males and females in 2009-2020 (APC: -2.0%; 95%CI: -2.4%, -1.5% and APC: -2.8%; 95%CI -3.2%, -2.3%). As another example, non-Hodgkin's lymphoma mortality rates among most educated males decreased in 2000-2012 (APC: -1.8%; 95%CI: -2.2%, -1.3%) followed by a steeper decline in 2012-2020 (APC: -3.7%; 95%CI: -4.4%, -2.9%); a similar pattern was observed among most educated females (APC: -1.6%; 95%CI: -2.2%, -1.0% in 2000-2011 and APC: -4.1%; 95%CI: -4.9%, -3.4% in 2011-2020). Trends in Hodgkin's lymphoma death rates however differed by educational attainment. For example, mortality rates among least educated males increased in 2000-2009 (APC: 1.7%; 95%CI: 0.8%, 2.5%) and remained unchanged in 2009-2020 (APC: -0.3%; 95%CI: -0.9%, 0.3%). Rates among least educated females also increased in 2000-2020 (APC: 0.4%; 95%CI: 0.1%, 0.7%). In contrast, mortality rates declined for most educated males from 2010-2020 (APC: -1.9%; 95%CI: -2.6%, -1.2%) and most educated females from 2011-2020 (APC: -3.5%; 95%CI: -4.8%, -2.2%).
Conclusion: Hematological cancer mortality rates were highest among males and those with least education. In general, mortality rates have declined in recent years for non-Hodgkin's lymphoma, myeloma, and leukemia for males and females among all educational attainment groups, while Hodgkin's lymphoma has shown a slight increasing trend among least educated males and females.

#6115 Genetic ancestry specific meQTLs control immune function regulation in a breast cancer cohort of African and European patients.

K. Founta[1], N. Chambwe[2];
[1]Zucker School of Med. at Hofstra/Northwell, Hempstead, NY, [2]The Feinstein Institutes for Medical Research, Manhasset, NY

Black women with significant African ancestry experience a disproportionately higher incidence of the most aggressive and invasive breast cancer subtypes, along with worse clinical outcomes across all demographic groups within the United States. These health disparities arise from complex interactions between genetic, sociocultural, and environmental factors. Epigenetic mechanisms, such as DNA methylation (DNAm), which regulate gene expression have been proposed as a means to capture the molecular impact of adverse environments on tumor biology. While DNAm levels can be influenced by environmental stimuli, they are also regulated by individual genotypes at methylation quantitative trait loci (meQTLs), posing a challenge to modeling the impact of the environment on cancer molecular characteristics. We hypothesized that ancestry differential DNAm in breast cancer is a result of differential genotype frequencies of SNPs due to ancestry at meQTL loci that can result in phenotypic differences between breast cancer patients of African and European ancestry through differential gene expression regulation. To investigate this hypothesis, we leveraged multi-omic data from The Cancer Genome Atlas (TCGA) breast cancer cohort to perform integrative analysis in patients of European and African ancestry (n=578). 804 CpGs were significantly differentially methylated between European and African ancestry breast cancer patients. meQTL analysis at these sites identified 37 cis-meQTLs and 748 trans-meQTLs, regulating methylation at CpG sites enriched in CpG Islands, enhancers, and other open chromatin regions. 54% of the cis- and 69% of the trans-meQTLs show evidence of differential genotype frequencies by ancestry. Association analysis between methylation and local gene expression revealed that 683 of the 804 ancestry differentially methylated sites regulate the expression of 5,774 genes. We found a statistically significant enrichment for genes involved in immune-related functions such as MHC class II protein complex assembly and the regulation of leukocyte cell-cell adhesion. Intriguingly, 10.5% of these genes encode transcription factors (TFs), and out of these ~23% are linked to African-ancestry specific open chromatin regions in breast cancer cell lines derived from African-ancestry donors. Our findings show that ancestry specific DNAm differences display strong genetic associations via ancestry associated meQTLs, affecting fundamental immunological processes in breast cancer. Our findings suggest that the effects of ancestry-specific genetic regulation may be more profound than previously appreciated, while pointing to the potential for confounding due to genetic ancestry when using DNA methylation as a molecular readout of environmental exposures.

#6116 Rs2363956, a coding variant of ANKLE1, drives triple-negative breast cancer disparity by altering DNA damage response.

Y. Guerra[1], R. Martini[1], O. Elemento[1], M. B. Davis[2];

[1]Weill Cornell Medicine, New York, NY, [2]Morehouse School of Medicine, Atlanta, GA

African American women have a 42% higher breast cancer mortality rate than European American women and are over twice as likely to develop triple-negative breast cancer (TNBC). We have previously demonstrated that this higher incidence of TNBC is tied to ancestry-related biological determinants of TNBC tumor biology, including possible novel genetic drivers that may result in reduced treatment efficacy.

Within the TCGA BRCA cohort, we have previously found that high ANKLE1 gene expression significantly improves survival in European Americans but not in African Americans. This difference may be attributed to the presence of a polymorphic variant of ANKLE1, rs2363956. The minor G allele of rs2363956 leads to a structural alteration in ANKLE1, potentially changing its functionality. Interestingly, among our International Center for the Study of Breast Cancer Subtypes (ICSBCS) patient cohort, we observed that 41-53% of European Americans with TNBC were homozygous for the G allele as compared to only ~14% of African American patients. These observations suggest that the presence of the rs2363956 polymorphic variant may drive differences between European American and African American patients.

ANKLE1 is a conserved gene among eukaryotic organisms and has been reported as an endonuclease implicated in DNA damage repair. Among our patient cohort (n=62) we have observed that patients homozygous for the G allele (n=13) are enriched for COSMIC mutational signatures 2 and 13 ($P \leq .05$ and $P \leq .001$, respectively), that denote overactivity of APOBEC deaminases, as compared to patients homozygous for the T allele (n=19). Therefore, the increased mutational burden present in those patients caused by APOBEC overactivity may sensitize those cancer cells to chemotherapeutics or other therapies.

Alternatively, the patients homozygous for the T allele may have an increased capacity for DNA damage repair that does not involve APOBEC activity. Using the MDA-MB-231 cell line, which is homozygous for the T allele, we performed an ANKLE1 knockdown with siRNA in order to examine the impact of ANKLE1 loss on DNA damage repair. Upon treatment with 25 µM, 10 µM, and 5 µM of Cisplatin we observe increased γ-H2AX and cell shrinkage in the ANKLE1 knockdowns as compared to cells treated with control siRNA, denoting increased DNA damage and apoptosis. Additionally, after knocking down ANKLE1 we observed decreased proliferation.

Based on these observations, ANKLE1 is critical for DNA damage response in TNBC cells and may be implicated in the genomic stability of TNBC. The polymorphic variants observed may impact this function and in part explain why European American patients have improved survival, as compared to African American patients.

#6117 Characterizing cancer patterns in Okinawan vs. mainland Japanese Americans: The Multiethnic Cohort.

S. A. Streicher[1], S.-Y. Park[1], C. W. K. Chiang[2], X. Sheng[2], D. Bogumil[2], D. V. Conti[2], C. A. Haiman[2], L. R. Wilkens[1], L. Le Marchand[1];
[1]University of Hawai'i Cancer Center, Honolulu, HI, [2]University of Southern California, Los Angeles, CA

Differences in chronic disease rates have been documented in Japan between Okinawa and mainland Japan. Limited data exist on whether these differences are also present in Okinawans and mainland Japanese who have migrated to the US. We used genotyped genome-wide association study data from the Multiethnic Cohort Study (MEC) to identify Japanese Americans of Okinawan or mainland ancestral similarity, and to investigate these two groups for differences in baseline chronic disease risk factors and for incidence of the four most common cancers during follow-up after blood draw. Cancer cases were identified via linkage to state cancer registries. Principal component analysis followed by uniform manifold approximation and projection (UMAP) was run using 15,678 single nucleotide polymorphisms among the 24,484 MEC Japanese Americans with blood samples. The Okinawan cluster was confirmed by labeling male MEC participants with Okinawan surnames on UMAP plots. Hazard ratios (HR), 95% confidence intervals (CI), and two-sided p-values were reported for Cox proportional hazards models, comparing cancer incidence between Okinawan and mainland Japanese individuals. The Okinawan cluster included 3,649 individuals (15% of the MEC Japanese Americans) and the mainland Japanese cluster included 19,611 individuals (80% of the MEC Japanese Americans). Small clusters of part-Okinawan and/or part-mainland Japanese (5% of the MEC Japanese Americans) were not included in the analysis. Ninety-six percent of Okinawan Americans and 94% of mainland Japanese Americans in MEC were born in the US. Okinawans were more likely to have a higher body mass index and daily alcohol intake, and less likely to be a current or former smoker, compared to mainland Japanese (all p-values<0.05). Post-menopausal Okinawan women were significantly more likely to be diagnosed with breast cancer (age-adjusted HR=1.39, 95% CI=1.10-1.75) compared to post-menopausal mainland Japanese women. This association was not modified by adjusting for additional known breast cancer risk factors (HR=1.36, 95% CI=1.07-1.73). Okinawans were also less likely to be diagnosed with lung cancer (HR=0.75, 95% CI=0.58-0.98); however, this association was no longer significant when adjusting for known risk factors, including smoking history (HR=0.82, 95% CI=0.62-1.07). There were no significant differences in risk of colorectal or prostate cancer between Okinawan and mainland Japanese individuals. Our results in this US-based sample are consistent with recent trends of higher breast cancer and lower lung cancer age-adjusted incidence rates reported from Japan for the Okinawan prefecture compared to mainland prefectures. Investigating reasons for the observed breast cancer risk difference may identify new risk factors for this disease in the Okinawan and other populations.

#6118 Sex-related disparity in immune checkpoint inhibitor benefit for patients with esophageal squamous cell carcinoma: A systematic review and meta-analysis.

C. Zhang, P. Wu, J. Liu, D. Li, N. Sun, J. He;
National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China

Sex-related dimorphism in cancer incidence and immune response is widely recognized, yet the impact of an individual's sex on the effectiveness of Immune Checkpoint Inhibitors (ICIs) for patients with advanced esophageal squamous cell carcinoma (ESCC) remains poorly understood. In this study, we conducted a comprehensive meta-analysis to evaluate the heterogeneity of ICIs in patients with advanced ESCC. We collected studies from PubMed, MEDLINE, Embase, and Scopus, spanning from the inception of the databases to September 30, 2023. These studies focused on phase III randomized trials comparing first-line ICIs (PD-1/PD-L1) plus chemotherapy with chemotherapy alone for advanced or metastatic ESCC. Additionally, we reviewed abstracts and presentations from AACR, ASCO, ESMO, and WCLC. Inclusion criteria mandated the reporting of overall survival (OS) data stratified by sex and nonselective baseline PD-L1 expression. The study adhered to Preferred Reporting Items for Systematic Reviews and Meta-analyses (PRISMA) guidelines. The analysis included 6 randomized clinical trials comprising 3603 ESCC patients, of whom 3090 (85.8%) were male and 513 (14.2%) were female. A significant OS benefit was observed for ICIs plus chemotherapy in all patients (HR, 0.68; 95% CI, 0.62-0.74; P < 0.001). Similarly, ICIs plus chemotherapy correlated with a significantly prolonged OS in males (HR, 0.67; 95% CI, 0.61-0.74, P < 0.001). However, there was no significant OS benefit observed in females with ICIs plus chemotherapy (HR, 0.79; 95% CI, 0.58-1.09; P = 0.148). Females had a tendency toward less benefit than males (pooled HR, 1.18; 95% CI, 0.89-1.57; P = 0.245). Our findings suggest that there is no statistically significant association between patient sex and the efficacy of ICIs for ESCC patients. Importantly, we report, for the first time, a lack of survival benefit with the ICI plus chemotherapy regimen in the first-line setting compared to chemotherapy alone in female ESCC patients.

#6119 Association of genetic African ancestry and triple-negative breast cancer risk: Findings from the African-ancestry breast cancer genetics consortium.

G. Jia[1], L. Liu[1], J. R. Palmer[2], C. A. Haiman[3], W. Zheng[1];

[1]Division of Epidemiology, Department of Medicine, Vanderbilt Epidemiology Center, Vanderbilt-Ingram Cancer Center, Vanderbilt University Medical Center, Nashville, TN, [2]Slone Epidemiology Center at Boston University, Boston, MA, [3]Department of Preventive Medicine, Keck School of Medicine, University of Southern California, Los Angeles, CA

Triple-negative breast cancer (TNBC) is an aggressive breast cancer subtype that lacks target treatments. It has been reported that African-American women have a higher incidence of TNBC and are diagnosed at an earlier age than women of European ancestry. This disparity may be attributed to both genetic and non-genetic risk factors that are associated with the African ancestry. In this study, we investigated whether genotype-derived African ancestry might be related to an elevated risk of TNBC, with adjustments for several known genetic and non-genetic risk factors. Included in the study are self-reported Black breast cancer patients diagnosed with TNBC (n =2,292) or estrogen receptor (ER)-positive cancer (n =7,863) and 9,324 controls included in the African-ancestry Breast Cancer Genetics (AABCG) Consortium. We estimated the global ancestry by Admixture and the local ancestry by FLARE, using reference of the European- and African-ancestry samples from the 1000 Genome Project. Odds ratios (OR) and 95% confidence interval (CI) per ten percent increase of the global African ancestry proportion were estimated using logistic regressions comparing TNBC with controls (case-control analyses) or with ER-positive cases (case-case analyses), adjusted for age. Similar analyses were conducted for the local African ancestry proportion at each of the 12 genomic regions that were identified in AABCG in relation to TNBC risk. Results for each participating study were meta-analyzed using fixed or random effect models. We further adjusted for non-genetic risk factors including body mass index (BMI), number of live births, breastfeeding, and menopausal status. A polygenic risk score (PRS) was constructed using 13 independent risk variants at the 12 TNBC risk loci. The PRS was additionally adjusted to investigate whether these risk variants mediated the association of African ancestry with TNBC risk. No significant association was observed between TNBC risk and global African ancestry proportion (OR: 1.03, 95% CI: 0.98-1.08) in case-control comparisons. Compared with ER-positive cases, however, TNBC cases had a higher global African ancestry, resulted in an OR of 1.09 (95% CI: 1.04, 1.13, P =5.35×10^{-5}). A similar association was observed with additional adjustment for non-genetic risk factors, with an OR of 1.08 (95% CI: 1.03, 1.12, P =0.003). Similar patterns were also found for local ancestry proportion at six of the 12 TNBC risk loci (P <0.05). Further adjustment for the PRS attenuated the association between global ancestry and a TNBC diagnosis in case-case comparisons (OR: 1.05, 95% CI: 1.01, 1.10, P =0.013). Our study suggests that women with a higher African ancestry are more likely to be diagnosed with a TNBC than ER-positive breast cancer and genetic factors identified to date partially explain this association.

#6120 Genomic profiling of *KRAS* and *EGFR*-altered non-squamous non-small cell lung cancer reveal ancestry-specific co-alterations with therapeutic implications.

S. D. Sisoudiya[1], A. A. Houle[2], T. M. Fernando[2], T. R. Wilson[2], J. L. Schutzman[2], J. K. Lee[1], A. B. Schrock[1], E. S. Sokol[1], S. Sivakumar[1], Z. Shi[2], G. Pathria[2]; [1]Foundation Medicine, Inc., Cambridge, MA, [2]Genentech, Inc., South San Francisco, CA

Background: Racial and ethnic disparities are highly prevalent in cancer care and impact treatment outcomes, with an underrepresentation of minority populations in clinical studies. The impact of genetic ancestry on the genomic landscape of tumors remains understudied. To address this, we sought to comprehensively characterize the ancestry-based genomic co-alteration landscape and immunotherapy-related biomarkers in *KRAS* and *EGFR*-altered tumors, two major driver populations in non-squamous non-small cell lung cancer (non-Sq NSCLC).

Methods: Our study consisted of 68,197 adult patients with non-Sq NSCLC who underwent comprehensive genomic profiling using FoundationOne® or FoundationOne®CDx during routine clinical care in the United States. Genetic ancestry was inferred using a SNP-based approach. Tumor mutational burden (TMB) was calculated across 0.8-1.2 megabases. PD-L1 expression was determined by immunohistochemistry using the Dako 22C3 PD-L1 antibody.

Results: Overall, 81% of the patients were of European (EUR; n= 55,430), 10% of African (AFR; n=7,062), 5% of East Asian (EAS; n=3,297), 3% of Admixed American (AMR; n=2,011) and less than 1% of South Asian ancestry (SAS; n=497). *KRAS* was the most frequently altered oncogene in EUR (39%) and AFR (33%), whereas *EGFR* was most frequently altered in EAS (53%), SAS (36%), and AMR (30%) ancestry groups. While *STK11* and *KEAP1* alterations co-occurred with *KRAS* across all ancestry groups, they were significantly (FDR p <= 0.05) less frequent in EAS (16%) and AMR (15%) compared to EUR (28%). Additional ancestry-specific co-alteration patterns in *KRAS*-altered tumors included co-occurrence with *GNAS* alterations in AMR (Odds ratio, OR: 3.5, $p < 10^{-5}$), co-occurrence with *ARID1A* alterations in SAS (OR: 4.7, p = 0.02), and mutual exclusivity with *NF1* alterations in EUR (OR: 0.4, $p < 10^{-5}$) and AFR (OR: 0.4, $p < 10^{-5}$). In contrast, *EGFR*-altered tumors had a more conserved co-alteration landscape across all ancestry groups. Despite the known mutual exclusivity of *KRAS* and *EGFR* alterations, 13% of patients of EAS ancestry (compared to 2-4% of other ancestry groups) with *KRAS* alterations had co-occurring *EGFR* alterations; notably, a majority of these patients had an amplification in *KRAS* and/or *EGFR*, potentially representing treatment resistance mechanisms. Among immunotherapy-associated biomarkers, PD-L1 expression was similar across ancestries. Of note, patients of AFR ancestry with *KRAS* or *EGFR* alterations had higher TMB and the SAS ancestry group had the lowest TMB.

Conclusion: Our study provides a comprehensive landscape of ancestry-specific patterns in *KRAS* and *EGFR*-altered non-Sq NSCLC. These findings can help better understand cancer disparities, aid in the development of new therapeutic strategies and inform more inclusive clinical trials and treatment decisions.

#6121 Racial differences in the intratumoral immune cell infiltrate in luminal breast cancer.

N. Hippalgaonkar[1], G. Chlipala[1], D. Huo[2], G. Rauscher[1], N. Adler[1], J. Kitajewski[1], K. Hoskins[1];
[1]University of Illinois at Chicago, Chicago, IL, [2]University of Chicago, Chicago, IL

Background: Black women have a higher rate of breast cancer mortality compared with their non-Hispanic White (NHW) counterparts, with an 80% higher likelihood of breast cancer death from axillary node-negative, ER-positive (a.k.a. luminal) tumors (Hoskins et al, JAMA Oncol 2021). Black women are 30% more likely to have ER-positive tumors with a high-risk gene expression profile, indicating a role for tumor biology in this disparity (Hoskins et al, JAMA Oncol 2023). The underlying biological mechanisms responsible are unknown. The aim of this study was to investigate the immune cell infiltrate in ER-positive breast tumors as a potential driver of disproportionately aggressive luminal tumor biology among Black women.

Methods: Gene expression data from ER-positive tumors diagnosed in women identified as Black or NHW in The Cancer Genome Atlas (TCGA) were deconvoluted with the CIBERSORT tool to estimate the relative intratumoral proportion of 22 immune cell types within each tumor. Differential analysis of imputed immune cell fractions comparing race was conducted with the Mann-Whitney test. P-values were adjusted for multiple comparisons with the false discovery rate (FDR) method. Linear regression of previously reported ancestry estimates for breast cancer patients in TCGA (Huo, et al, JAMA Oncol 2017) was used to test for association between African ancestry and proportion of regulatory T cells (Tregs) in tumors from Black women.

Results: CIBERSORT analysis of tumors found a significantly increased proportion of Tregs in tumors from Black (n=86) than NHW (n=534) patients, with $\log_2$ fold-change= 0.74 (FDR-corrected p-value= 0.01). Plasma cells, T follicular helper cells and M_0 macrophages were increased in tumors from Black women with uncorrected p-values < 0.05, but racial differences in these cell types were not significant after FDR correction (p >0.1). Ancestry analysis among Black women indicated that African ancestry was not associated with the intratumoral proportion of Tregs (1 SD change in proportion African ancestry was associated with 0.06 standard deviation increase in Tregs, p > 0.3). Confirmation of findings with a racially diverse breast tumor TMA from an independent cohort is ongoing and results will be presented.

Conclusions: Increased pro-tumorigenic Treg infiltrate in ER-positive breast tumors from Black women may contribute to a disproportionately aggressive tumor phenotype and racial survival disparity. The findings could have therapeutic implications and suggest that immune checkpoint inhibitors may have increased activity against luminal breast cancer in Black patients. Although this study did not show a statistically significant effect for genetic admixture within African Americans, larger studies are needed to distinguish the contribution of ancestry vs. social context, environmental, and behavioral factors as the driver of this racial difference in tumor biology.

#6122 Disparities in biomarker testing practices in patients with metastatic non-small cell lung cancer (NSCLC) in the United States (US).

M. J. Dennis[1], D. Abrahami[2], M. Vieira[2], D. Benjumea[3], M. Boyd[3], A. Shao[3], K. Duncan[2], J. Kelton[2], **S. P. Patel**[4];
[1]Dana-Farber Cancer Institute, Boston, MA, [2]Pfizer, Inc., New York, NY, [3]Genesis Research Group, Hoboken, NJ, [4]University of California - San Diego, San Diego, CA

Background: Molecular testing is recommended in National Comprehensive Cancer Network guidelines for nonsquamous mNSCLC patients. While testing rates have been increasing, data from other tumor types suggest possible disparities in access to and use of biomarker testing. This study investigated real-world biomarker testing characteristics stratified by demographics for the EGFR, ALK, ROS-1, BRAF, MET, RET, and PD-L1 biomarkers in US patients diagnosed with mNSCLC.
Methods: This study of adults ≥18 years old with stage IV mNSCLC used the nationwide Flatiron Health electronic health record (EHR)-derived de-identified database (01/2011-04/2023). Biomarker testing rate (i.e., proportion of patients with mNSCLC with at least one biomarker test) was quantified. Unadjusted biomarker testing rates were assessed in groups of patients stratified by demographic and clinical characteristics, including age group, sex, race, insurance type, Eastern Cooperative Oncology Group (ECOG) performance status (PS), smoking status, histology, and US region.
Results: In 42,037 patients with mNSCLC, 34,510 (82.1%) received at least one test. The rates for each test were: ALK: 71.6%, BRAF: 48.8%, EGFR: 74.9%, MET: 41.4%, PD-L1: 49.3%, RET: 42.3%, and ROS1: 54.2%. Yearly testing rates increased, with the most recent year suggesting that anywhere from 78.7% of patients to 88.7% of patients received a test for at least one biomarker, with PD-L1 and EGFR being the least and most frequently tested, respectively. Rates of testing varied by age group, with 87.2% of younger patients (ages 18 to <50) receiving a test compared to 80.8% of older patients (ages ≥80). Asian patients had the highest testing rate (91.5%) whereas Black and Hispanic/Latino patients had the lowest (80.8% and 80.6% respectively). 82.2% of White patients, the largest racial demographic in this dataset, received at least one test. Commercial health plans had a slightly higher testing rate compared to Medicare or Medicaid (87.1%, 81.6% and 81.2%, respectively). Rates decreased as ECOG PS increased; in patients with ECOG PS=0, 89.6% received a biomarker test, whereas in patients with ECOG PS=3 and ECOG PS=4, 81.1% and 76.3% received a test, respectively. Smoking status (current or former) was associated with less testing (80.7%) compared to patients with no history of smoking (91.1%), and patients with non-squamous histology were more frequently tested (88.0%) compared to squamous histology (61.2%). The differences by sex and region were marginal.
Conclusion: This study provides contemporary data on real-world biomarker testing and disparities in mNSCLC in the US. Results suggest that more work can be done to evaluate and address disparity gaps in specific subsets, including Black and Hispanic patients and those with a current or former history of smoking.

#6123 Validating cancer modulated allostatic load as a composite biomarker for mortality in patients with cancer.

Christopher J. Fong[1], Kaicheng U[2], Cheryl Phua[1], Xuechun Bai[1], Michele Waters[1], Tom Fu[1], Kanika Arora[1], Tomin Perea-Chamblee[1], Devika Jutagir[1], Michael Berger[1], Nikolaus Schultz[1], Adam Schoenfeld[1], Francesca Gany[1], Justin Jee[1], Jian Carrot-Zhang[1]

[1]Memorial Sloan Kettering Cancer Center, New York, NY, [2]Cornell University, Ithica, NY

Allostatic load (AL) is the cumulative burden of chronic stress and life events typically measured by lab and vital values routinely collected during standard care. AL has been associated with adverse socioenvironmental stressors and increased mortality rates including risk of cancer death. Despite modifications of AL as a result of progressing cancer and anti-cancer treatments, AL may serve as a valuable biomarker for cancer outcomes, and highlight similar disparities across sociodemographic groups agnostic of a history of cancer diagnosis. Recent investigations have shown associations of AL with overall mortality rates in patients with non-small cell lung cancer (NSCLC) and breast cancer, as well as various social determinants of health. The impact of AL on different malignancies, particularly in the context of genetic variations identified through genomic profiling, is yet to be thoroughly investigated.

We identified a pan-cancer cohort of 29,433 patients sequenced with the MSK-IMPACT targeted panel sequencing assay, and collected clinical, genomic, and lab data. We first studied the association of AL with patient and tumor characteristics such as tumor type, stage, cancer genomics, comorbidities, social deprivation defined by the Yost index, and genetic ancestry. We derived AL using 10 standard biomarkers across cardiovascular, metabolic, renal, and immune systems, and created a composite AL summary score with a range between 0 and 10. Composite AL summary score into quartiles for comparisons. We found that AL was increased with higher cancer stage, older age, smoking, multiple comorbidities, African ancestry, and Yost index. Multivariate logistic regression analysis showed that AL was correlated with mutations e in KRAS and anti-correlated with EGFR mutations (FDR<0.02).

Next, we investigated AL as a biomarker for mortality in patients with cancer and compared its prognostic value to other biomarkers. Using a Cox proportional hazard model we found that AL was significantly associated with shorter overall survival, controlling for stage and socioeconomic variables (HR=1.7, 2.2, 2.7 in AL Quartiles 2-4 respectively). Finally, we decomposed AL into its individual markers to quantify the most important features driving outcomes. Using a Random Survival Forest model with a focus on NSCLC patients, we found that albumin and alkaline phosphatase were the strongest features of shorter survival in our AL composite model.

Our findings suggest that elevated AL is associated with a poorer prognosis across multiple cancer types, a trend observable across different stages of cancer. The association between AL and clinically actionable mutations highlights the importance of understanding the relationship between somatic alterations and social/environmental factors. The study underscores the utility of AL as a powerful prognostic tool that can be routinely collected in a clinical setting.

#6124 A comprehensive pan-cancer study nominating NF-κB-mediated TNFA signaling-induced hypoxia as a risk factor in Hispanic cancer progression.

T. Samanta, J. Park, B. Kaipparettu;
Baylor College of Medicine, Houston, TX

The Hispanic (HA) population is the second largest racial/ethnic group in the United States after non-Hispanic White (NHW). Though the HA population usually has a lower reported incidence of cancers compared to NHW, there are racial disparities exist in the mortality rate of some of the cancers. Factors related to the Social Determinants of Health (SDOH), such as higher poverty rates, less education, and reduced access to health care, are known to increase the risk of diagnosing advanced-stage cancer in HA compared to the NHW population. The contribution of such SDOH in the HA cancer population has been studied in the past years. However, the contribution of biological and genetic mechanisms to HA cancer disparity has not been well understood. Thus, in this study, we performed a comprehensive analysis of different databanks to understand the common genetic and biological factors that contribute to the pan-cancer disparity in the HA population. To identify HA and NHW populations, we used self-reported racial/ethnic information. Analysis of the "*All of Us*" database suggested a high prevalence of infection-related cancers such as Liver, Stomach, and Cervix Uteri in the HA population compared to the NHW population. SEER database also showed an increased percentage of diagnoses with infection-related cancers and poor survival of the HA population with these cancers compared to the NHW. We then analyzed the TCGA transcriptome data from primary tumors from HA and NHW patients. We only selected cancers with data from at least ten patients in each group. TCGA data confirmed that the tumors from HA cancer patients primarily express high inflammatory and immune-responsive signatures. Specifically, we found a high enrichment of NF-κB induced TNFA signaling in HA tumors. We also observed a significant correlation between TNFA and Hypoxia signature in many HA cancers. Since hypoxia is known to be associated with resistance to radiation and chemotherapy, targeting the increased hypoxia signature in HA tumors may be critical for sensitizing HA patients to cancer therapy. Overall, our pan-cancer analyses suggest an increased prevalence of many infection-related cancers in the HA population. HA tumors are enriched with TNFA, NF-κB, and hypoxic signatures. Specific targeting of these signatures may be critical in managing the HA patients who currently suffer from racial disparity in cancer incidence and survival.

#6125 Differential expression of chemokine genes by race and Breast Cancer Consensus Subtypes in hormone receptor positive breast cancer.

A. M. Fielder, M. Ratnam, G. Dyson, K. Purrington;
Wayne State University School of Medicine, Detroit, MI

Hormone receptor positive (HR+) breast cancer is a heterogeneous subtype and African American women (AAW) are twice as likely to have HR+ tumors with lower levels of HR staining (1-10%) compared to European American women (EAW). These tumors are associated with substantially worse survival compared to strongly HR+ tumors. We further hypothesized that HR+ tumors from AAW would be more likely to have molecular features typically associated with HR-negative breast cancer and poor prognosis. To test this, we used the Breast Cancer Consensus Subtyping (BCCS) method and evaluated expression of chemokine receptors known to be differentially expressed by race, PAM50 subtypes, and survival. We downloaded The Cancer Genome Atlas (TCGA) expression data for 394 female EA and AA HR+/HER2- breast cancer patients using the cBio Cancer Genomics Portal. Breast Cancer Consensus Subtypes (BCCS) were determined using the R program BCCSclassifier. BCCS classification results in five subtypes: ER-negative non-basal-like (BCS1), ER-negative basal-like (BCS2), ER+ highly proliferative with poor prognosis (BCS3), ER+ stromal infiltration with good prognosis (BCS4), and ER+ hormone response genes highly expressed with good prognosis (BCS5). High and low expression of chemokines (*ACKR1*, *ACKR4*, *CCR3*, *CCR6*, *CCRL2*, *CXCR1*, *CXCR2*, *CXCR4*, *CXCR6*, *CX3CR1*) was dichotomized based on median expression of each gene within our study cohort. Distribution of BCCS by race was assessed with multinomial logistic regression. Associations between chemokine gene expression, BCC subtype and race were evaluated using logistic regression. An alpha value of 0.05 was set to determine statistical significance. From the TCGA cohort, AAW were more likely to have the BCS2 ER-negative basal-like phenotype (OR=7.17, p<0.001) as well as the poor prognosis highly proliferative ER+ BCS3 phenotype (OR=2.83, p=0.036) versus the high hormone expression BCS5 subtype. In multivariable models evaluating both race and BCCS subtype, AAW were 6.17 times more likely to have lower than median expression of *CX3CR1* (p<0.001) and *CXCR2* (OR=2.23, p=0.0096) compared to EAW. Notably, all chemokine receptors consistently showed significantly lower expression in BCS1-4 subtypes compared to BCS5. For *CCRL2*, the effect estimates for BCS4 vs. BCS5 significantly differed by race (p=0.039). In AAW, BCS4 was associated with higher than median expression (OR=1.99, p=0.49), although not statistically significant. In EAW, BCS4 was associated with lower than median expression (0.23, p<0.001). Our findings show that AAW with HR+ breast cancer have tumors with more inherently aggressive molecular subtypes associated with poor prognosis compared to EAW. These results also further support the premise that HR+/HER2- tumors are highly heterogeneous and strongly suggest that chemokine gene expression is associated with breast cancer subtype.

#6126 Understanding disparities in lung cancer using single cell RNA sequencing data transformed by the Gerchberg Saxton algorithm.

S. Ay[1], L. Liu[1], E. Forbes[1], U. Topaloglu[2], W. Zhang[1];

[1]Wake Forest University School of Medicine, Winston Salem, NC, [2]National Cancer Institue, Rockville, MD

Purpose An overarching goal of this study is to reduce disparities in lung cancer research commonly manifested by racial and/or gender under-representations. By employing the Gerchberg-Saxton (GS) algorithm, we aim to diminish data noise/bias in single-cell RNA sequencing (scRNA-seq) gene expression data, thereby enabling more equitable research outcomes. An immediate goal is to remove extensive data bias associated with scRNA-seq data thus enhancing downstream Machine Learning analyses.

Background: We have successfully applied the GS algorithm for fairer mortality rate predictions across different racial groups [1]. In this study, we seek to apply the GS algorithm to the scRNA-seq data that interrogate the cellular landscapes of lung cancer and the tumor microenvironment.

Methodology: The application of the GS algorithm to single cell RNA data involved a series of steps. Initially, all data frames were transposed, switching columns and rows to represent gene expressions and single cells, respectively. The algorithm was then meticulously applied to each column, allowing for the uniform distribution of certain specific gene expression information across all single cells within the data frame. This column-wise application was crucial to maintain the integrity of individual cell characteristics while ensuring a fair structural distribution of gene expression data. The process aimed to balance the representation of genes across all cells, addressing inherent biases and noises in the original data structure.

Data: The study utilizes a previously unpublished scRNA-seq dataset comprising 14 lung cancer patients from Wake Forest Baptist Comprehensive Cancer Center, including 6 African American and 8 Caucasian patients.

Results: One out of 14 preliminary clustering results are presented in Figure 2 using ScanPy [2]. The initial findings are based on a restricted set of cell marker genes, which will be further developed with additional markers in subsequent analyses. With the application of the Gerchberg-Saxton algorithm, the Shannon Entropy [3] analysis revealed a more uniform randomness across gene expressions (Figure 1), and the unsupervised clustering indicated a clearer separation of cell types, significantly enhancing the ability for downstream analyses. The data transformation will be applied to the whole dataset for comparative analyses of cellular landscapes between lung cancer from different races and genders, to be reported at the AACR 2024 Annual Meeting.

Conclusions: Our preliminary studies showed that the Gerchberg-Saxton algorithm is effectiveness in normalizing data distribution for scRNA-seq data, which has led to enhanced resolution of cell type differentiations in clustering analysis. With this refined methodology, we are better poised to better address lung cancer health disparities revealed by single cell sequencing analysis.

#6127 Characterization of germline and somatic homologous recombination deficiency features in high-grade serous ovarian cancer among Black individuals.

K. Lawson-Michod[1], M. E. Barnard[2], N. Davidson[3], L. J. Collin[1], C. Johnson[4], L. A. Salas[5], C. Greene[3], J. R. Marks[6], L. Peres[7], J. M. Schildkraut[8], J. A. Doherty[1];

[1]University of Utah Huntsman Cancer Institute, Salt Lake City, UT, [2]Boston University Chobanian & Avedisian School of Medicine, Boston, MA, [3]University of Colorado Anschutz Medical Campus, Denver, CO, [4]Rollins School of Public Health, Emory University, Atlanta, GA, [5]Geisel School of Medicine at Dartmouth, Dartmouth Cancer Center, Hanover, NH, [6]Duke University School of Medicine, Durham, NC, [7]Moffitt Cancer Center, Tampa, FL, [8]Rollins School of Public Health Emory University, Atlanta, GA

Background: Approximately 50% of high-grade serous ovarian carcinomas (HGSOC) are homologous recombination deficient (HRD). HRD is associated with increased T-cell infiltration and improved survival. This study aimed to describe the distribution of HRD features and cytotoxic T-cell infiltration by gene expression subtype among Black HGSOC cases.

Methods: We included Black HGSOC cases from the African American Cancer Epidemiology Study and the North Carolina Ovarian Cancer Study. We used RNASeq data to assign gene expression subtypes (n=160), and whole exome sequencing data from matched blood and tumor formalin-fixed paraffin-embedded specimens (n=206) to characterize HRD features. We defined HRD features as (1) germline variants and somatic mutations in HRD genes, and (2) HRD-associated signatures (SBS3 and ID6) that we obtained from de novo mutational signature analysis for single-base pair substitution, insertion, and deletion. We estimated the proportion of intratumoral cytotoxic T cells using multiplex immunofluorescence (n=125).

Results: The subtype distribution in our study was 39% immunoreactive, 29% mesenchymal 27% proliferative, and 4% differentiated. Germline variants and somatic mutations in any HRD gene were observed in 27% and 23% of cases, respectively, and at least one of these was observed in 42% of cases. Pathogenic germline variants and somatic mutations were observed in 7% and 3% of cases, respectively. The prevalence of germline or somatic variants by gene was 16% for *BRCA1*, 14% for *BRCA2*, 11% for *ATM*, 5% for *RAD51*, and 2% each for *BRIP1*, *PALB2*, and *BARD1*. We observed a COSMIC HRD signature in 43% of cases, with 25% SBS3 only, 5% ID6 only, and 13% with both signatures. The prevalence of any HRD gene variant or signature was higher in immunoreactive cases (52% and 59%, respectively) than in mesenchymal (28% and 43%) or proliferative (44% and 28%) cases. Germline HRD variants were more common in the proliferative subtype (44%) compared with immunoreactive (25%) and mesenchymal (17%). In contrast, somatic HRD mutations were more common in the immunoreactive subtype (33%), compared with proliferative (16%) and mesenchymal (15%). This was due to a higher occurrence of *BRCA1* somatic mutations in the immunoreactive subtype (25%) compared with proliferative (9%) and mesenchymal (8%). A higher proportion of cytotoxic T-cells (≥1% vs <1%) was also observed in the immunoreactive subtype (44%) compared with mesenchymal (31%) and proliferative (11%).

Conclusion: We observed differences in the distribution of HRD features and cytotoxic T-cells by gene expression subtype. In particular, in the immunoreactive subtype, the most common gene expression subtype in Black HGSOC cases, we observed a higher occurrence of any HRD feature, somatic *BRCA1* mutations, and cytotoxic T cell infiltration than in any of the other gene expression subtypes.

#6128 Association between neighborhood disinvestment and all-cause survival moderated by epigenetic age among women with breast cancer.

J. J. Plascak[1], K. Archer[2], A. A. M. Llanos[3], S. J. Mooney[4], C. Y. Xing[5], A. G. Rundle[3], H. Zarbl[6], B. Qin[7], N. Zeinomar[7], M. Schootman[8], S. Yao[9], C. Ambrosone[9], K. Pawlish[10], K. Demissie[11], E. V. Bandera[7], C.-C. Hong[9];

[1]The Ohio State University College of Medicine, Columbus, OH, [2]The Ohio State University College of Public Health, Columbus, OH, [3]Columbia University Mailman School of Public Health, New York, NY, [4]University of Washington School of Public Health, Seattle, WA, [5]San Francisco Department of Public Health, San Francisco, CA, [6]Rutgers University School of Public Health, Piscataway, NJ, [7]Rutgers Cancer Institute of New Jersey, New Brunswick, NJ, [8]University of Arkansas for Medical Sciences College of Medicine, Fayetteville, AR, [9]Roswell Park Comprehensive Cancer Center, Buffalo, NY, [10]New Jersey Department of Health, Trenton, NJ, [11]SUNY Downstate Health Sciences University School of Public Health, Brooklyn, NY

Background: DNA methylation is hypothesized to mediate relationships between chronic social disadvantage and cancer outcomes. We investigated whether epigenetic age acceleration mediates the association between modifiable neighborhood disinvestment and survival within a cohort of women with breast cancer.
Methods: Individual-level data were from the Women's Circle of Health Follow-up Study, a breast cancer cohort comprising women self-identifying as African American or Black, diagnosed 2013-2019 in New Jersey residents. Demographic, socioeconomic, health behavior, and dietary characteristics were self-reported. Peripheral blood samples from 312 participants collected 18-24 months after diagnosis were profiled for DNA methylation using Illumina's MethylationEPIC array. After pre-processing, pace of biological aging was estimated using DunedinPACE. Neighborhood disinvestment was assessed using a previously validated virtual audit of 6 disinvestment indicators - garbage, graffiti, dumpsters, poor building conditions, poor yard conditions, abandoned buildings - in 14,671 Google Streetview streetscapes. Accelerated failure time models of all-cause mortality as functions of neighborhood disinvestment and pace of biologic aging were fit to estimate survival time ratios (TR), adjusted for stage at diagnosis and neighborhood socioeconomic composition using causal mediation analyses. End of follow-up was August 13, 2023.
Results: There were 46 all-cause deaths through follow-up (median=6.9 years), and 5-year overall survival probability was 0.90 (95% CI: 0.86, 0.93). Minimum, median, and maximum pace of biologic aging was 0.87, 1.26, and 1.72 indicating accelerated aging (> 1.0) among most participants. There was no evidence for mediation of the neighborhood disinvestment - survival effect by pace of biologic aging (indirect effect p-value=0.33). There was evidence of an interaction between pace of biologic aging and neighborhood disinvestment in the adjusted model: survival time decreased 37% (95% CI: 4% - 59%, p=0.03) per 1 standard deviation (SD) increase in neighborhood disinvestment at pace of biologic aging values 1 SD below the average (< 1.13). There was no evidence of such association at pace of biologic aging values 1 SD above the average (p=0.86).
Conclusion: Greater neighborhood disinvestment may be associated with shorter survival following a breast cancer diagnosis among those with slower than average epigenetic age acceleration, due to the cumulative nature of neighborhood disinvestment as a chronic indicator of social disadvantage.

#6129 Emerging disparities in the clinical actionability landscape for patients with inferred African ancestry.

K. Arora, S. P. Suehnholz, H. Zhang, R. Kundra, S. Nandakumar, M. Nissan, A. Brannon, C. Bandlamudi, M. Ladanyi, A. Drilon, D. B. Solit, N. Schultz, M. F. Berger, D. Chakravarty;
Memorial Sloan Kettering Cancer Center, New York, NY

The past decade has seen a surge in the approval and availability of precision oncology therapies targeting distinct genomic alterations. We sought to determine whether these advances have benefitted patients with cancer from various ancestral backgrounds equally over time. We therefore annotated all genomic alterations identified in a pan-cancer cohort of 55,970 solid tumor samples sequenced with the MSK-IMPACT clinical assay using incremental versions of the precision oncology knowledge base OncoKB and computed the fraction of samples with OncoKB Level 1 alterations (biomarkers included in the FDA drug label) per year based on the annual cumulative FDA-approved targeted therapies. In 2010, 4.4% of patients with inferred African ancestry (AFR), and 2.4% of patients with inferred non-Ashkenazi Jewish European ancestry (EUR) had Level 1 alterations, largely explained by differences in cancer type prevalence between these groups. However, by mid-2023, AFR had a significantly lower percent of Level 1 alterations (25.3%) compared to EUR (31.2%), and this difference remained significant after adjusting for cancer type and disease status (q-value = 2.6e-08).

Next, we compared AFR versus EUR percentages of Level 1 alterations over time in breast and colorectal (CRC) patient samples, two cancers in which racial disparities of cancer incidence and outcomes are well-documented. We observed that prior to 2019, the fraction of breast cancer patient samples with a Level 1 alteration was similar among AFR (13%) and EUR (12.2%), primarily due to comparable rates of *ERBB2* amplifications (12.4% in AFR, 11.7% in EUR). However, following the breast cancer-specific FDA approvals of alpelisib+fulvestrant for *PIK3CA*-mutant disease in 2019 and elacestrant for *ESR1*-mutant disease in 2023, a significant shift in Level 1 actionability was observed between EUR (45%) and AFR (34%) attributed in part to the paucity of *PIK3CA* (26.3% vs. 36.2% in EUR) and *ESR1* (4.1% vs. 7.5% in EUR) oncogenic alterations in AFR.

We further observed AFR with CRC to have lower prevalence of MSI-H (5.8% vs.10.7% in EUR), TMB (12.5% vs. 18.8% in EUR) and *BRAF* V600E (5.1% vs. 9% in EUR). Correspondingly, in 2023, 16.4% of AFR with CRC have Level 1 alterations compared to 25.4% of EUR. Moreover, while AFR have higher rates of *KRAS* mutations (57.2% vs. 42.6% in EUR), they have a lower prevalence of the standard care biomarker KRAS G12C (3.4% vs. 7% of *KRAS*-mutant CRC in EUR) further exacerbating the disparities in CRC clinical actionability.

Taken together, here we demonstrate that a significant disparity exists in the clinical actionability landscape of AFR with cancer compared to EUR, largely due to differences in relative mutational frequencies of Level 1 genomic alterations.

#6130 Association of vitamin D-related genetic variants and prostate cancer risk in Black men.

T. M. Layne[1], J. H. Rothstein[1], X. Song[1], W. Sieh[2], R. J. Klein[1];
[1]Icahn School of Medicine at Mount Sinai, New York, NY, [2]MD Anderson Cancer Center, Houston, TX

Background: What we know of the relationship between vitamin D status and prostate cancer has largely been characterized among men of European ancestry, hereafter referred to as “White”. Research among White men indicate positive associations between circulating vitamin D status, as measured by concentrations of 25-hydroxyvitamin D (25(OH)D), with prostate cancer risk, and that genetic scores based on genome-wide associated single nucleotide polymorphisms (SNPs) reflecting high vs. low 25(OHD) is positively associated with aggressive disease. Limited research exists elucidating this relationship among men of African ancestry, hereafter referred to as “Black”. This is despite the fact that Black populations experience chronically lower circulating 25(OH)D, and ancestry-specific differences in genetic variants in some vitamin D-related genes. Given the paucity of research in this area, we examined the role of genetic variants in six commonly studied genes in the vitamin D pathway involved in synthesis (*CYP27A1* and *CYP27B1)*, transport (*GC)*, activity (*VDR* and *RXR*), and metabolism (*CYP24A1*) in relation to prostate cancer among Black men.
Methods: We assessed a total of 78 candidate SNPs in six vitamin D pathway genes that were either previously associated with circulating 25(OHD) and/or associated with prostate cancer risk in studies of White men. We compared vitamin D gene SNP associations with prostate cancer in Black and White men using summary statistics from a large GWAS of over 10,000 prostate cancer cases and 10,000 controls among Black men and over 85,000 cases and 91,000 controls among White men. A statistical significance threshold of 0.00064 (0.05/78 candidate SNPs) was used to adjust for multiple comparisons.
Results: None of the examined SNPs were significantly associated with prostate cancer risk among Black men after adjustment for multiple comparisons. However, four SNPs were nominally significant in Black men, including two in *RXR* [rs41400444 OR=1.09, 95% CI: 1.01-1.17, *P* = 0.024 and rs10881574 OR = 0.93, 0.867-0.999, *P* = 0.04556] and two in *VDR* [rs2853563 OR = 1.07, 1.012-1.13, *P* = 0.0173 and rs1156882 OR = 1.06, 1.00-1.12, *P* = 0.0495]. The latter SNP rs1156882 was also positively associated with prostate cancer risk in White men (OR = 1.035, 1.02-1.06, *P* = 0.00024), along with VDR SNP rs4516035 (OR = 1.027, 1.012-1.042, *P* = 0.00055), both after correction for multiple comparisons.
Conclusions: We observed non-significant, though suggestive, associations between genetic variants in vitamin D pathway genes previously associated with prostate cancer or vitamin D levels in White populations and prostate cancer risk in Black men. Future research exploring the potential role of vitamin D pathway genes and prostate cancer in Black men -- a population at high risk both for low circulating vitamin D and prostate cancer - will need to identify vitamin D-related genetic variants specific to carcinogenesis in Black men.

#6131 Increasing self efficacy, self confidence, and genetic knowledge via the Community Genetic Navigation Engagement Specialist Train-the-Trainer program.

Janet Rodriguez[1], Joel Sanchez Mendez[2], Yaneth L. Rodriguez[2], Lourdes Baezconde-Garbanati[2], Charite Ricker[3], Rosa Barahona[2], Bianca Rosales[2], Daisy Hernandez[3], Natalia Gutierrez[3], Julie Culver[3], Mariana Stern[1]

[1]USC Norris Comprehensive Cancer Center, Los Angeles, CA,[2]Department of Population and Public Health Sciences, Keck School of Medicine of USC, University of Southern California, Los Angeles, CA,[3]Department of Medicine, Division of Medical Oncology, USC Norris Comprehensive Cancer Center, Los Angeles, CA

Background: Colorectal cancer (CRC) is the second and third leading cause of cancer deaths in US Hispanic/Latino (H/L) men and women, respectively. The Community Genetic Navigation Specialists (CoGENES) train-the-trainer program created a workforce of community health workers (CHWs) to educate H/L individuals about genetic testing, counseling, and research.

Methods: The CoGENES three-week program, consisted of six in-person sessions, with a curriculum in both Spanish/English developed and delivered by experts, in Spanish, using presentations and hands-on activities. Acculturation, Latino values, self-efficacy, genetics and tumor testing knowledge, and self-confidence were assessed via pre- and post-training. Differences in scores were analyzed via Wilcoxon matched-pairs signed-rank tests with exact p-values.

Results: Median age of the 12 participants was 50 (IQR = 12), 9 were female, 92% were Mexican-born, half completed 1-2 years of college, and 67% were very hispanic oriented. Self-efficacy increased after training, with pre- training median-score = 38.5 (IQR = 3) and post-training score = 39.5 (IQR =2.5) ($p = 0.0547$). Certainty about understanding tumor testing increased after training ($p = 0.0039$). The median number of correct answers on the 16-item genetic knowledge scale increased from 6.5 to 9.5 and the median number of “don’t know” responses decreased from 5 to 0 after training. Finally, self-confidence to train future CoGENES was significantly higher ($p = 0.0098$) at post-test.

Conclusion: The CoGENES culturally tailored program led to improved self-efficacy, increased genetic knowledge, and self-confidence in a cohort of Hispanic community health educators. Findings will be shared within COPECC, and other NCI funded programs.

#6132 Exploring genomic complexity in lung cancer at the Tijuana/California border: A real-world perspective through liquid biopsy comprehensive genomic profiling.

Jorge Alberto Guadarrama-Orozco[1], Jennifer Ramirez-Puente[2], Elizabeth Dominguez-Gonzalez[3]

[1]Hospital General Tijuana, Tijuana, Mexico,[2]ISSSTE Tijuana, Tijuana, Mexico,[3]Universidad Autonoma de Baja California, Tijuana, Mexico

Objective: This study explores the application of liquid biopsy with next-generation sequencing (NGS) in profiling the genomic landscape of lung cancer patients from the Tijuana/California Border region. Specifically, we employ blood-based comprehensive genomic profiling (CGP) to assess the complexity of the genomic profile in these patients.

Materials and Methods: From April 2019 to November 2023, 37 lung cancer patients from Tijuana underwent profiling using the FoundationOne®Liquid CDx (F1LCDx®) assay, focusing on circulating tumor DNA (ctDNA). The assay, which spans 324 cancer-related genes and genomic signatures, provides insights into tumor fraction (TF) and blood-based tumor mutational burden (bTMB). Variants were classified based on the ESMO Scale of Clinical Actionability for molecular Targets (ESCAT).

Results: A notable 88.6% of patients exhibited at least one detectable alteration in plasma. The most frequently mutated genes were TP53 (51.3%), EGFR (16.2%), DNMT3A (13.5%), and KRAS (10.8%). Tumor mutational burden (TMB) was assessable in 9 out of 37 patients, with values ranging from 0 to 10 mut/Mb. According to ESCAT classification, 63.1% of samples revealed potentially actionable alterations (Tier I-II), while an additional 24.1% harbored alterations for which approved drugs are available in other cancer types (Tier III).

Conclusion: Liquid biopsy NGS emerges as a viable and valuable strategy for guiding personalized therapy. Given restricted accessibility to new drugs or clinical trials in Mexico, the use of blood-based CGP may enhance the identification of druggable alterations, thereby increasing the likelihood of accessing targeted drugs or enrolling in clinical trials.

#6133 Genetic profiling landscape among gynecological and breast cancer patients in the borde city of Tijuana, Mexico: A comprehensive study.

Jorge Alberto Guadarrama-Orozco[1], Paula Leal-Anaya[2], Eva Guerrero-Santillan[3]

[1]Medical Oncology, Hospital General Tijuana, Tijuana, Mexico,[2]Medical Genetics, Hospital General Tijuana, Tijuana, Mexico,[3]Prevencion y Control del Cancer de la Jurisdiccion de Servicios de Salud No. 2, Tijuana, Mexico

Background: Individuals in Tijuana have been identified as having multicultural and racial diversity. In Baja, California, Mexico, the prevalence and composition of cancer-predisposing germline variants in gynecologic cancers in Tijuana patients have not been evaluated.
Aim and Methods: We aimed to evaluate the prevalence of pathogenic variants (PV) using a panel of 84 cancer-predisposing genes in breast, endometrial, and ovarian cancer from the General Hospital of Tijuana during the period of October 2021-October 2023, who were contacted and invited to participate in the evaluation. Pre- and post-test genetic counseling was given, and a questionnaire on personal, gyneco-obstetric, demographic, and lifestyle variables was conducted. Peripheral blood samples were obtained from all patients, and Next-generation sequencing (NGS) was performed on the Illumina commercial platform (Illumina, SD, USA). Variants were classified according to the American College of Medical Genetics and Genomics (ACMG). Data was collected and descriptive statistics was applied to describe the characteristics of the population.
Results: A total of 51 patients were included in our cohort; 98.0% (50/51) were females and 2% (1/51) were males. Among study participants (mean age ±standard deviation: 46.1 ± 10.9), 49% reported a personal history of cancer (25/51). Diagnosis of breast cancer was present in 80.3% of the patients (41/51), 9% (5/51) with ovarian cancer, and 3.9% (2/51) with endometrial cancer. Twenty-five percent of participants (13/51) harbor a PV or likely pathogenic (LP) variant distributed among four cancer-risk genes (BRCA1, BRCA2, ATM, and TP53). The distribution by gene in the patients with a PV was: BRCA1 in 61% (8/13), BRCA2 in 23% (3/13), TP53 in 8% (1/13), and ATM in 8% (1/13). Whereas 39.2% (20/51) had variants of uncertain clinical significance in genes with ambiguous or non-well-established risk association for cancer (BARD1, AXIN2, GPC3, NF2, CEBPA, MSH3, ALK, DIS3L2, CDC73, BAP1, RAD51D, NF1, MSH2, BLM, NBN, BRCA2, BARD1, RUNX1, RECQL4, EGFR, PALB2, CASR, and POLD1), and 35.2% (18/51) had negative results for both; PV and VUS.
Conclusion: Our findings show a diverse pathogenic variant composition among the recruited individuals of the gynecological cancer population in Tijuana, Mexico, consistent with being a high-risk population for genetic diseases, which warrants further investigation to adequately assess the burden of hereditary cancer and implement appropriate preventative programs. Disparities in access to testing have a significant impact on affected populations, due in part to underrepresentation in surveys of regional cancer etiology and in genomic variant databases.

#6134 The Latino Colorectal Cancer Consortium: A resource for colorectal cancer disparities research.

N. C. Lorona[1], M. Matejcic[2], D. Sobieski[3], N. T. Nguyen[1], H. J. Hoehn[4], D. B. Diaz[5], K. Shankar[3], E. Jean-Baptiste[4], D. Coppola[6], C. Fulmer[7], O. Saglam[6], K. Jiang[6], T. Lee Moffitt Cancer Center & Research Institute, Tampa, FL, [7]Department of Pathology, Robert J. Tomsich Pathology and Laboratory Medicine Institute, Cleveland Clinic Foundation, Cleveland, OH, [8]Puerto Rico Biobank, Ponce Health Sciences University, Ponce, PR, [9]Department of Molecular Oncology, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL, [10]Department of Gastrointestinal Oncology, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL, [11]Department of Preventive Medicine, Keck School of Medicine, University of Southern California/Norris Comprehensive Cancer Center, Los Angeles, CA, [12]Department of Biostatistics and Bioinformatics, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL

Purpose: The Latino Colorectal Cancer Consortium (LC3) was established to fill a gap in representation of the diverse Hispanic/Latino/a/x community in cancer genomic research and to enhance understanding of determinants of disparities in the burden of colorectal cancer (CRC).

Methods: The LC3 joins together three established studies with deeply-annotated clinical, epidemiologic, and biologic data available for a heterogenous group of Hispanic/Latino/a/x men and women diagnosed with primary colorectal adenocarcinoma: the Hispanic Colorectal Cancer Study (California), the Total Cancer Care Protocol at Moffitt Cancer Center (Florida), and the Puerto Rico Biobank (southern Puerto Rico). Each contributing study collected data on demographics, medical history, family history, and lifestyle factors. Vital status, cause of death, treatment, and clinical characteristics were obtained through medical chart abstraction and/or linkage to cancer registries. Blood, saliva, or normal colonic tissues were used to extract and genotype germline DNA for a subset of participants. Tumor tissues (snap frozen or formalin-fixed paraffin-embedded) were evaluated by pathologists for diagnosis, tissue content, tumor cellularity, necrosis, immune infiltration, and additional histopathologic characteristics.

Results: The LC3 has assembled 2,041 participants across the three studies to date, with recruitment ongoing. Median age at diagnosis is 57 (range: 19-93), 54% of participants are male, and 63% are colon cancer cases (vs. rectal cancer). Participants were diagnosed between 1999 and 2022. The target is to generate comprehensive multi-omic data on 600 LC3 participants. To date, 243 have genome-wide germline genotyping, 323 have paired tumor/normal whole exome sequencing, and 257 have T cell receptor immunosequencing (immunoSEQ, Adaptive Biotechnologies). Further, 206 cases are represented on a set of tissue microarray blocks (target N=281). Bulk RNA-seq data are to be generated on 250 tumors.

Conclusions: The LC3 fills an important gap in research infrastructure for the scientific community. Key strengths of this unique consortium are its ability to capture a diversity of Latino CRC patients with respect to nativity and cultural heritage and to represent the spectrum of stages from early to metastatic. Ultimately, research from the LC3 will inform development of equitable precision medicine approaches and predictive models to improve the health of the rapidly-growing, heterogeneous Hispanic/Latino/a population.

#6135 Racial and ethnic differences in site of *de novo* metastases in patients with colorectal cancer: A SEER analysis.

N. C. Lorona[1], M. C. Stern[2], S. L. Schmit[3], J. C. Figueiredo[1];

[1]Samuel Oschin Comprehensive Cancer Institute, Cedars Sinai Medical Center, Los Angeles, CA, [2]University of Southern California/Norris Comprehensive Cancer Center, Los Angeles, CA, [3]Cleveland Clinic, Cleveland, OH

Purpose: Disparities in colorectal cancer (CRC) mortality may be driven by differences in access to care, tumor biology, and propensity to spread to distant sites. We examine differences in patterns of de novo metastases by race/ethnicity and age.

Methods: We identified 248,732 CRC patients listed in the Surveillance, Epidemiology, and End Results (SEER) database diagnosed with a first primary invasive CRC from 2010-2020, aged 20+ years at diagnosis, with complete data on SEER summary stage, and not diagnosed only by autopsy/death certificate. Outcomes included de novo metastatic site (no metastasis, liver, lung, brain, bone) and pattern (no metastasis, liver only, lung only, liver and lung, other). We used logistic regression to calculate odds ratios (OR) and 95% confidence intervals (95% CI) for the associations between 1) demographic and tumor characteristics (site, side, T stage, N stage) and site of de novo metastases , and 2) race/ethnicity and site of de novo metastases stratified by age (20-49, 50-74, 75+). We used multinomial logistic regression to assess the association between demographic and tumor characteristics and pattern of metastasis. Models adjusted for age, race/ethnicity, sex, site (colon, rectum), side (left, right), T stage, and N stage.

Results: 62,844 stage IV CRC cases were diagnosed from 2010-2020, and liver was the most common metastatic site (72%). Relative to age 50-74, age 20-49 at diagnosis was more strongly associated with de novo liver metastases (OR: 1.07; 95% CI: 1.02-1.11) and less with lung (OR: 0.86; 95% CI: 0.80-0.92) or brain (OR: 0.69; 95% CI: 0.52-0.93) metastases. Relative to Non-Hispanic White (NHW) patients, Non-Hispanic American Indian/Alaskan Native (AI/AN) patients had a higher risk of lung metastases (OR: 1.33; 95% CI: 1.07-1.65), Non-Hispanic Asian/Pacific Islander (API) patients had lower risks of liver (OR: 0.87; 95% CI: 0.83-0.92) and brain (OR: 0.67; 95% CI: 0.48-0.95) metastases, and Non-Hispanic Black (NHB) patients had higher risks of liver (OR: 1.35; 95% CI: 1.29-1.41), lung (OR: 1.36; 95% CI: 1.27-1.45), and bone (OR: 1.23; 95% CI: 1.08-1.41) metastases. In age-stratified analyses, the risks for NHB patients persisted across groups, while lower risks for API patients were not observed in the 20-49 group. API patients aged 20-49 had a higher risk of de novo lung (OR: 1.31; 95% CI: 1.06-1.61) and bone (OR: 1.63; 95% CI: 1.13-2.37) metastases, and the increased risk of lung metastases for AI/AN patients was larger in magnitude (OR: 2.26; 95% CI: 1.39-3.68). Age 20-49 was more strongly associated with a liver-only pattern (OR: 1.14; 95% CI: 1.09-1.19) and with less common distant sites (OR: 1.33; 95% CI: 1.25-1.41).

Conclusions: Racial/ethnic differences in de novo metastatic CRC patterns exist overall and across age groups. These findings are consistent with disparities in risk of stage IV CRC and can inform surveillance priorities in CRC survivors.

#6139 Genetic modifiers of KRAS-mutant colorectal cancer.

N. P. Tjader[1], J. Ramroop[2], T. Gandhi[1], P. T. Campbell[3], A. T. Chan[4], S. Gallinger[5], G. G. Giles[6], M. J. Gunter[7], T. A. Harrison[8], M. Hoffmeister[9], P. A. Newcomb[8], S. Ogino[10], A. I. Phipps[8], C. Qu[8], R. E. Schoen[11], A. Pellatt[12], M. O. Woods[13], B. Van Guelpen[14], P. Stevens[1], H. Hampel[15], U. Peters[8], J. P. McElroy[1], A. E. Toland[1];

[1]The Ohio State University, Columbus, OH, [2]The City College of the City, University of New York, New York, NY, [3]Albert Einstein College of Medicine, Bronx, NY, [4]Harvard Medical School, Boston, MA, [5]University of Toronto, Toronto, ON, Canada, [6]Cancer Council Victoria, East Melbourne, Australia, [7]Imperial College London, London, United Kingdom, [8]Fred Hutchinson Cancer Center, Seattle, WA, [9]German Cancer Research Center (DKFZ), Heidelberg, Germany, [10]Harvard T.H. Chan School of Public Health, Boston, MA, [11]University of Pittsburgh, Pittsburgh, PA, [12]MD Anderson Cancer Center, Houston, TX, [13]Memorial University of Newfoundland, St. John's, NL, Canada, [14]Umea University, Umea, Sweden, [15]City of Hope National Medical Center, Duarte, CA

Somatic driver mutations in *KRAS* are found in ~40% of colorectal cancers (CRCs) and are associated with worse outcomes. In the US, individuals of African ancestry with CRC are more likely to have tumors with *KRAS* mutations than individuals of European ancestry, even after considering differences in socioeconomic status and other risk factors. Germline variants can influence somatic mutation events and may provide a selective advantage such that a mutated cell is more likely to progress to a cancer. Germline variants have been found to associate with somatic mutations in a variety of tumors. Based on ancestry differences in *KRAS* tumor mutation frequency, we hypothesized that germline variants altering molecular pathways that support *KRAS* tumorigenesis will associate with *KRAS*-mutant status. To test this, we performed a two-step association study using *KRAS* mutation status as our phenotype in individuals with microsatellite stable CRC. First, we conducted a discovery analysis using genome-wide germline genotypes and somatic mutation data from 6,386 non-Hispanic White CRC patients from the Cancer Genome Atlas and the GECCO consortium, considering sex and tumor location as covariates. To select variants for additional study, we used *in-silico* tools, such as expression quantitative trait loci (eQTL), to predict how associated variants may alter gene expression and chromatin. After reviewing relevant genomic features, excluding SNVs with minor allele frequency <10% and pruning SNVs in linkage disequilibrium (r^2>0.75), we identified candidate loci for a multi-ancestry independent validation analysis. In the discovery analysis, no variants met genome-wide significance thresholds (*p*-value <$5x10^{-8}$), though 3 SNVs associated with *KRAS* mutation status with *p*-values <$1x10^{-6}$ and 50 with *p*-values <$1x10^{-5}$. Of these 50 SNVs, 21 met criteria for validation. We chose 80 additional SNVs (*p*-value <$1x10^{-4}$) with predicted functional effect, for a total of 101 SNVs for analyses. In our preliminary validation analysis of 1,487 individuals grouped by self-reported race, no variants had a significant association in all populations. The rs726800 variant showed nominal association with *KRAS* mutation status (*p*-value=0.028) in self-reported non-Hispanic White individuals. This variant is within potential cis-regulatory distance of *HS3ST3A1* and *COX10-DT*, both of which have been reported as cancer biomarkers. Nominal associations were identified in self-reported Black (n=7 SNVs) and Hispanic or Latino (n=3 SNVs) individuals, though both groups had limited sample sizes. Additional validation samples are being analyzed, as well as analysis with adjustment for genetic ancestry. Future functional studies of top candidate variants will add mechanistic insight. In summary, we identified germline SNVs that associate with *KRAS* somatic mutations in CRC and may inform the cellular context that supports development of colorectal tumors with *KRAS* mutations.

#6140 Gene-environment interactions for lifetime water arsenic exposure and bladder cancer risk in the New England Bladder Cancer study.

H. Pomares-Millan[1], S. Koutros[2], N. Rothman[2], D. Baris[2], M. Schwenn[3], A. Johnson[4], D. T. Silverman[2], M. R. Karagas[1], M. N. Passarelli[1];
[1]Dartmouth Geisel School of Medicine, Hanover, NH, [2]National Cancer Institute, Bethesda, MD, [3]Formerly Maine Cancer Registry, Augusta, ME, [4]Formerly Vermont Department of Health, Burlington, VT

Environmental arsenic and genetic susceptibility have both been shown to increase bladder cancer risk, yet little is known about their respective interaction. We conducted a gene-environment interaction (GxE) study to characterize lifetime arsenic exposure from drinking water, inherited susceptibility, and bladder cancer risk in the New England Bladder Cancer Study. Exposures were estimated from arsenic measured in water samples collected at home and workplace. We evaluated common single-nucleotide polymorphisms (SNPs) i) from the latest bladder cancer genome-wide association study (n= 28), ii) from candidate gene studies of arsenic or bladder cancer (n= 16 SNPs), and iii) SNPs from a large genome-wide association study of arsenic metabolism (n = 4 SNPs) as potential effect modifiers of the arsenic-bladder cancer relationship. We coded SNPs as the absence or presence of a risk/effect allele for bladder cancer or arsenic metabolism in 2,019 adults (928 bladder cancer cases and 1,091 controls) and arsenic exposures as tertiles. Odds ratios (OR) with 95% confidence intervals (CI) adjusted for age, sex, smoking status, high-risk occupation, and principal components of genetic ancestry were estimated using logistic regression models. P-values for multiplicative interaction were calculated. Out of 48 SNPs, we found evidence of interaction for 7 SNPs at the statistical significance level of $P<0.05$. Most SNPs involved in GxE interactions are mapped to genomic regions known or suspected to function in arsenic metabolism. For the association between cumulative lifetime water arsenic (mg) and bladder cancer, the strongest evidence of an interaction was with rs1046428 (near *GSTZ1* on 14q23); among those with one or two copies of the T risk allele, OR_{T2vsT1}: 1.52, CI: 1.11 - 2.07; $OR_{T3\ vsT1}$: 1.44, CI: 1.05 - 1.98, $P_{interaction}$ = 0.01; among those with no risk allele copy, OR_{T2vsT1}: 0.91, CI: 0.62 - 1.35; $OR_{T3\ vsT1}$: 0.97, CI: 0.65 - 1.44. For average daily water arsenic (µg/day), we found evidence of interaction among those with risk allele for rs1801133 (A/A, A/G; *MTHFR* on 1p36) $OR_{T2\ vsT1}$: 1.70, CI: 1.18 - 2.44; $OR_{T3\ vsT1}$: 1.53, CI: 1.06 - 2.23, $P_{interaction}$ = 0.02, in those with no copies of risk allele OR_{T2vsT1}: 0.85, CI: 0.61 - 1.17; $OR_{T3\ vsT1}$: 1.11, CI: 0.79 - 1.54; and rs1801131 (G/G; G/T; *MTHFR*) $OR_{T2\ vsT1}$: 1.59, CI: 1.14 - 2.22; $OR_{T3\ vsT1}$: 1.63, CI: 1.16 - 2.29, $P_{interaction}$ = 0.01, whereas in those with no risk allele OR_{T2vsT1}: 0.84, CI: 0.59 - 1.19; $OR_{T3\ vsT1}$: 1, CI: 0.69 - 1.44. For 40-year lagged cumulative lifetime water arsenic (mg) and average daily water arsenic (µg/day), we found suggestive interactions with rs2234636 (*SLC39A2* on 14q11), and rs1495741 (*NAT2* on 8p22). Our study provides evidence of interactions between lifetime arsenic exposure and genetic variants that function in xenobiotic metabolism on bladder cancer occurrence.

#6141 Genetic risk, health-associated lifestyle, and risk of early-onset total cancer and breast cancer: A prospective cohort study.

[1]Harvard T.H. Chan School of Public Health, Boston, MA, [2]University of Washington, Seattle, WA, [3]National Cancer Institute, Rockville, MD

Background Early-onset cancer (diagnosed under 50 years of age) is generally more aggressive. Its rising incidence is a global concern. The associations between genetic risk, lifestyle, and the risk of early-onset cancer may inform preventive strategies.

Methods We studied the association between genetic risk, lifestyle and early-onset cancers among 66308 white British participants enrolled in the UK Biobank before age 50. Genetic risk was assessed using sex-specific composite total cancer polygenic risk scores (PRSs). We calculated composite PRSs as weighted sums of previously-developed cancer site-specific PRSs using weights obtained from lasso regression. We considered a breast cancer-specific PRS for analyses on breast cancer among women. A health-associated lifestyle score (HLS) was calculated based on baseline smoking, BMI (men only), physical activity, alcohol intake, and diet. Cox models were used to estimate hazard ratios (HRs) and 95% confidence intervals (CIs) of early-onset total cancer and breast cancer across genetic risk and HLS groups in women and men.

Results A total of 1247 incident invasive early-onset cancer cases (820 in women, 427 in men) were documented, including 386 cases of early-onset breast cancer. In multivariable-adjusted analyses with 2-year latency, higher genetic risk (highest vs. lowest tertile of PRS) was associated with significantly increased risks of early-onset total cancer in women (composite PRS HR=1.85; 95% CI, 1.50-2.29), early onset total cancer in men (composite PRS HR=1.94; 95% CI, 1.45-2.59), and early-onset breast cancer in women (breast-cancer PRS HR=3.06; 95% CI, 2.20-4.25). The HRs (95% CI) of early-onset total cancer in women and men, and early-onset breast cancer in women associated with adopting an unfavorable lifestyle (highest vs. lowest tertile of HLS) were 1.49 (0.99, 2.25), 1.14 (0.67, 1.95), and 1.78 (0.97, 3.24), respectively, in the total study population; 1.85 (1.02, 3.36), 3.27 (0.78, 13.72), and 1.67 (0.71, 3.90), respectively, in those with high genetic risk; 1.25 (0.60, 2.57), 1.11 (0.42, 2.89), and 1.66 (0.54, 5.11), respectively, in those with intermediate genetic risk; and 1.15 (0.44, 2.98), 1.16 (0.39, 3.40), and 2.10 (0.57, 7.75), respectively, in those with low genetic risk. Compared to individuals with both low genetic risk and a favorable lifestyle, those with high genetic risk and an unfavorable lifestyle had substantially increased risks of early-onset total cancer in women (3.07; 1.64-5.78) and men (2.18; 0.78-6.11), and significantly higher early-onset breast cancer risk in women (4.11; 1.56-10.85).

Conclusion Genetic and lifestyle factors were independently associated with risks of early-onset total cancer and breast cancer. Compared to those with low genetic risk, individuals with a high genetic risk may benefit more from adopting a healthy lifestyle in preventing early-onset cancer.

#6142 Interactions of processed meat and red meat intake with pathway-based polygenic risk scores for colorectal cancer: A novel approach for PRSs construction.

J. Sanchez Mendez[1], M. C. Stern[1], Y. Fu[1], J. Morrison[1], J. P. Lewinger[1], E. Kawaguchi[1], B. Queme[1], H. Mi[1], F. Qu[2], U. Peters[2], L. Hsu[2], S. B. Gruber[3], L. Li[4], M. Cotterchio[5], L. Le Marchand[6], A. J. Pellat[7], E. A. Platz[8], W. J. Gauderman[1];

[1]USC - University of Southern California, Los Angeles, CA, [2]Fred Hutchinson Cancer Research Center, Seattle, WA, [3]CIty of Hope National Medical Center, Duarte, CA, [4]Univesity of Virginia, Charlottesville, VA, [5]Cancer Care Ontario, Ontario, ON, Canada, [6]University of Hawaii Cancer Center, Honolulu, HI, [7]University of Utah, Salt Lake City, UT, [8]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD

Introduction: Colorectal cancer (CRC) is the third most common cancer, and second cause of cancer death worldwide. Established CRC risk factors (E) include high red meat and processed meat intake. Genome-wide association studies (GWAS) have reported over 200 genetic variants associated with CRC risk. We used functional annotation data to identify subsets of GWAS variants within known pathways and constructed corresponding pathway Polygenic Risk Scores (pPRS). We evaluated pPRS by E interactions to determine whether genes within specific pathways interacted with meat intake to impact CRC risk.
Methods: A pooled sample of 54,531 CRC controls and 48,260 cases of European ancestry from 27 studies were analyzed. Study-specific quartiles for red and processed meat intake were generated through in-person interviews and structured self-administered questionnaires. Variants were imported to AnnoQ for annotation (n=203) and analyzed for overrepresentation in PANTHER-reported pathways with Fisher's exact test. Standard approaches were used to compute polygenic risk score weights relating the 203 variants to CRC. The subset of weights corresponding to each of five pathways were then used to compute the corresponding pPRS. Covariate-adjusted logistic regression models evaluated pPRSxE interactions with red meat and processed meat intake.
Results: A total of 34 unique variants were overrepresented in five pathways: Apoptosis signaling, Alzheimer disease-presenilin, Wnt-signaling, Gonadotropin-releasing hormone receptor, and TGF-beta signaling. We found a statistically significant interaction between TGF-beta-pPRS and red meat intake ($p = 0.0012$). Stratified analyses reported a dose-response trend in the red meat and CRC risk association, with decreasing estimates of red meat and CRC risk association, comparing first to fourth quartiles of meat intake, with increasing quartiles of TGF-beta-pPRS: 13% (Q1), 12% (Q2), 7% (Q3), and 6% (Q4). This association remained significant after adjustment for all other variants ($p = 0.0013$), and all other pPRS with variants that did not overlap with the TGF-beta-pPRS ($p = 0.0012$). Independent GxE interaction models for individual variants that were included in the TGF-beta pathway showed significant interactions with red meat for rs2337113 (intron *SMAD7* gene, Chr18), and rs2208603 (intergenic region *BMP5*, Chr6) ($p = 0.013$ & 0.0108, respectively). We did not find significant pPRS x red meat interactions for the other four pathways or with any pPRS x processed meat.
Conclusion: This pathway-based interaction analysis revealed a statistical interaction between SNPs in the TGF-beta pathway and red meat consumption that impacts CRC risk. These findings shed light into the possible mechanistic link between CRC risk and red meat consumption.

#6143 Association of polygenic risk score and prostate tumor biomarkers with lethal prostate cancer.

A. Wang[1], A. Plym[2], K. H. Stopsack[1], L. A. Mucci[1], K. L. Penney[1];
[1]Harvard T.H. Chan School of Public Health, Boston, MA, [2]Karolinska Institutet, Stockholm, Sweden

Prostate cancer (PCa) is a highly heritable cancer. While polygenic risk scores (PRS) stratify overall PCa risk among cancer-free men, they have not been reported to predict lethal outcomes in PCa patients. We aimed to examine to what extent PRS modifies associations between tumor biomarkers with cancer prognosis after diagnosis.

We included men with primary, non-metastatic PCa in the Health Professionals Follow-up Study (HPFS) and Physicians' Health Study (PHS). The PRS was constructed with 451 risk variants identified from prior PCa GWAS, measured on DNA from blood or buccal, standardized by adjusting for mean and standard deviation (SD) based on men without PCa with array-based genotyping data in HPFS/PHS. Prostate tumor biomarkers of molecular subtypes (*TMPRSS2:ERG* fusion, PTEN loss, and *TP53* missense mutations from validated immunohistochemistry assays), insulin/lipid signaling pathways (FASN, IR, and IGF1-R), and cellular proliferation and tumor microenvironment (Ki-67, apoptosis rates, and angiogenesis) were measured on tumor tissue from radical prostatectomy or TURMP. Sample sizes varied by tumor biomarkers, ranging from 214 for angiogenesis markers to 598 for ERG protein expression. We first used either logistic or negative binomial regression to evaluate the association between the PRS and the protein expression (levels) of each individual biomarker, and then evaluated the addition of multiplicative interaction terms between PRS and biomarkers to logistic regression models for lethal PCa, defined as metastases or death from PCa. Lastly, we evaluated the predictive performance for lethal PCa by area under the curve (AUC). All models adjusted for age at diagnosis and Gleason score.

Among all patients included in the analysis, the median age at diagnosis was 66 (interquartile range: 62-70) years, with 20% having a Gleason score≥8 and 10% having lethal PCa. PRS showed no association with lethal PCa (OR per SD increase PRS=0.95, 95%CI 0.85-1.06) or most tumor biomarkers, except for the apoptosis index (per SD in PRS corresponding to 0.22 units increase, 95%CI 0.02-0.42). Statistically significant interactions were found between PRS and p53 overexpression (p interaction = $1.6x10^{-5}$), PTEN loss ($p=3.7x10^{-3}$), FASN (p=0.03), and Ki-67 ($p=1.6x10^{-3}$), suggesting that compared to men with a PRS higher than the median, *TP53* missense mutation, PTEN loss, higher FASN intensity, and higher Ki-67 indices were more strongly associated with lethal PCa in patients with lower PRS. Incorporating PRS with tumor biomarkers into predictive models enhanced the AUC beyond a model with tumor biomarker and age. The largest improvements were observed when combining the PRS with Ki-67 and apoptosis, showing absolute increases of 5% and 7% respectively.

In conclusion, PRS integration with tumor biomarkers at diagnosis potentially improves the prediction of lethal PCa, thereby informing more targeted management strategies.

#6144 A polymorphic *TERT* tandem repeat creating an expandable intronic G4 quadruplex is associated with *TERT* expression, relative leukocyte telomere length and cancer risk.

[1]National Cancer Institute, Rockville, MD, [2]National Institute on Aging, Bethesda, MD, [3]National Cancer Institute, Bethesda, MD

A multi-cancer GWAS region at human chromosome 5p15 encodes telomerase reverse transcriptase (TERT). One of the GWAS signals is rs10069690-T, which creates an alternative intron 4 splicing site, co-producing full-length (FL) and truncated *INS1b* transcript for dominant-negative telomerase-nonfunctional TERT. A variable number tandem repeat (VNTR6-1, 38 bp repeat unit) within intron 6 remains uncharacterized in relation to GWAS signals and cancer risk. We hypothesized that VNTR6-1 might contribute to GWAS signals represented by rs10069690.

We scored VNTR6-1 and rs10069690 in short-read WGS data (n=3,202) from the 1000 Genomes Project with a machine learning model using the GLMnet engine, and in phased long-read assemblies (n=544). We defined two VNTR6-1 groups: Short (24-27 copies) and Long (40.5-66.5 copies); the VNTR6-1-Long group was preferentially linked with rs10069690-T compared to C allele (p=2.53E-13). We show that haplotypes of rs56345976 and rs33961405 alleles can predict VNTR6-1 groups. We imputed VNTR6-1 in UK Biobank controls (n=351,634), PLCO cancer cases and controls (n=100,445), and African Burkitt lymphoma cases (aBL, n=79).

Functional studies in aBL tumors revealed a suggestive association between reduced total *TERT* expression, rs10096690-T (p=0.035) and VNTR6-1-Long (p=0.053). VNTR6-1 forms a G4 quadruplex structure sensitive to G4 stabilizing ligands, altering the ratio between *FL-TERT* and a dominant-negative *TERT-β* isoform in isogenic cell lines with/without VNTR6-1. In GTEx and TCGA, several metrics related to cell proliferation and telomerase activity correlated positively with *FL-TERT* expression and negatively with *TERT-β* expression.

We created a composite marker with 0, 1 or 2 copies of the *FL-TERT*-associated haplotype (VNTR6-1-Short/rs10069690-C) to capture the effects of these variants that negatively affect *TERT* expression and telomerase activity. The number of copies of the VNTR6-1/rs10069690 haplotype was associated with relative leukocyte telomere length in UK Biobank controlling for sex and age (β=0.049, p=8.75E-78). This marker was also associated with a reduced risk of bladder and prostate cancer but an increased risk of breast, endometrial, ovarian, thyroid cancer, and glioma in PLCO.

Our findings reveal that germline variants VNTR6-1-Long/rs10069690-T underlie the multi-cancer GWAS signal and jointly decrease *TERT* expression and telomerase activity, potentially reducing the risk of some cancers by limiting cell growth. However, decreased telomerase activity could deregulate stem cell-driven tissue regeneration and genome integrity, increasing the risk of other cancers. Our findings unveil novel mechanisms of cancer susceptibility and propose therapeutic avenues for targeting *TERT* isoform ratios to modulate telomerase activity and its cellular effects.

#6145 A trans-ethnic meta-analysis identified additional novel genomic loci associated with cervical cancer.

A. B. Kamiza, J.-T. Brandenburg, M. Ramsay, C. Mathew;
University of the Witwatersrand, Johannesburg, South Africa

Introduction: Cervical cancer is the second most common cause of cancer-related deaths among women worldwide. Genome-wide association studies (GWAS) have identified genetic variants associated with cervical cancer. However, these discoveries have been limited by the small sample sizes of the individual cohorts. To identify additional novel loci associated with cervical cancer, we performed a trans-ethnic meta-analysis.
Methods: GWAS summary data for trans-ethic meta-analysis were identified in women of European ancestry from the UK Biobank, East Asian ancestry from Biobank Japan, and African ancestries from the pan-UK Biobank and Johannesburg cancer study. Meta-analyses were performed using fixed effect inverse variance weighted method implemented in GWAMA. To localize putative genomic loci associated with cervical cancer, we performed fine mapping using the Bayesian approach by calculating the marginal posterior probability of causality for each single nucleotide polymorphisms (SNPs) and 99% credible set size.
Results: Our meta-analysis identified four additional novel genomic loci associated with cervical cancer. These loci include: rs147778467 (odds ratio [OR] = 1.12, 95% confidence interval [CI] = 1.08-1.16, P-value = 3.12×10^{-08}) in *RGS21*, rs53150478 (OR =1.03, 95%CI = 1.01-1.05, P-value = 4.48×10^{-08}) in *MAN1C1*, rs113842373 (OR = 0.68, 95%CI = 0.56-0.81, P-value = 2.31×10^{-09}) in *LINCO1850* and rs75372437 (OR = 0.80, 95%CI = 0.72-0.88, P-value = 3.32×10^{-08}) in *RNU6-356P*. These loci are implicated in carcinogenic pathways. Moreover, our Bayesian fine mapping identified five loci with a marginal posterior probability of causality > 1 and reduced the 99% credible set sizes.
Conclusion: We identified additional novel loci associated with cervical cancer and our fine mapping identified loci with a high posterior probability of being causal.

#6146 Characterizing underlying molecular mechanisms of prostate cancer risk variants identified from multi-ethnic GWAS.

Z. Wu, A. Vu, E. S. Nelson-Moore, H. Cao, S. K. Rhie;
USC - University of Southern California, Los Angeles, CA

Prostate cancer (PCa) is a complex disease with the second leading cause of cancer death in US males. Multi-ethnic genome-wide association studies (GWAS) identified a thousand genetic variants associated with PCa risk in different races. However, the majority of risk variants are located in non-coding regions, making it challenging to understand their contribution to PCa risk. Non-coding regions include functional regulatory elements (REs) such as promoters and enhancers, whose activity can be evaluated by histone modification H3K4me3 and H3K27ac, respectively. In this study, we integrated PCa risk variants with hundreds of H3K4me3 and H3K27ac ChIP-seq data from normal and cancer prostate cell lines and tissues, finding 122 variants in promoters and 301 variants in enhancers. Enhancers are distal to promoters, and they form loops to regulate gene expression, mediated by transcription factors (TFs). Enhancer activities are tightly associated with cell fate. Genetic variants can affect the activity of enhancers by changing the binding preference of TFs and such changes can affect chromatin interactions and dysregulate gene expression. We hypothesize that allele changes of enhancer variants contribute to PCa risk differently among individuals from different ancestries, leading to the development of heterogeneous PCa molecular subgroups, characterized by genetic alterations including TMPRSS2-ERG fusion. By integrating H3K27ac ChIP-seq data from prostate cell lines derived from European (EUR) and African (AFR) ancestries, we found 185 risk variants in enhancers in EUR cell lines and 69 risk variants in enhancers in AFR cell lines. Next, we integrated patient tissue-derived H3K27ac ChIP-seq data and performed chromatin quantitative trait loci (cQTL) and allelic imbalance (AI) analyses to determine risk variants associated with enhancer activity. Among the 185 risk enhancer variants in EUR and 69 in AFR cell lines, we found 130 and 46 with significant association, respectively. To determine TFs that change binding upon allele change of enhancer risk variants, we integrated hundreds of TF ChIP-seq data from prostate cell lines and tissues. Among the 185 risk enhancer variants in EUR and 69 in AFR cell lines, we found 142 and 44 variants bound by TFs, respectively. When we further performed cQTL and AI analyses for FOXA1, HOXB13, and AR, we found 87 and 29 variants significantly associated with TF binding affinity, respectively. Moreover, we found that these associations differ between TMPRSS2-ERG fusion positive and negative tumors. To identify the target genes of enhancer risk variants, we are currently integrating chromatin interaction data including Hi-C and Micro-C. Overall, this study provides valuable insights into the underlying molecular mechanisms of risk variants in various populations and individuals which lead to the development of heterogeneous PCa subgroups.

#6147 Genome-wide association study identifies new genetic susceptibility loci for multiple primary cancers.

S. He[1], J. Perry[2], S. Li[1], B. D. Mitchell[3], Y. Zhang[2], S. Chen[2], L. Beane-Freeman[1], K. H. Barry[3], S. I. Berndt[1];

[1]National Cancer Institute, Shady Grove, MD, [2]University of Maryland Baltimore, Baltimore, MD, [3]University of Maryland School of Medicine, Baltimore, MD

Objectives: Genetic susceptibility is thought to contribute to the development of multiple primary cancers (MPC), often called secondary cancers. Although rare variants contribute to risk, these only account for a small fraction of MPC cases. The contribution of common variants to risk is unknown.

Methods: To identify common genetic variants associated with the risk of MPC, we conducted a trans-ancestry meta-analysis of genome-wide association studies (GWAS), including 7,360 MPC cases and 138,684 controls from the Prostate, Lung, Colorectal and Ovarian (PLCO) Cancer Screening Trial and UK Biobank (UKBB). Association analyses were performed separately by genetic ancestry, genotype platform, and study, adjusting for age, sex, and principal components, and the results were meta-analyzed together using a fixed effects model. Genome-wide SNP heritability was estimated using GCTA. Pathway and functional enrichment analyses were conducted to gain insights into potential biological mechanisms underlying discovered loci.

Results: We identified one novel locus at chromosome 3q26.2 (LRRC34, rs7621631) that was associated with MPC risk ($P=1.16x10^{-8}$). Variants in this region have been previously associated with telomere length, suggesting a possible underlying mechanism. In sex-stratified analyses, we identified an additional locus at chromosome 12q24.33 (intergenic, rs10466868) associated with MPC in men ($P= 7.76x10^{-8}$), but not women. Although the risk associated with these two discovered loci was small, the genome-wide SNP heritability was estimated to be 12%, suggesting that there are likely more common variants to be discovered for MPC risk.

Conclusions: Our study demonstrates that common genetic variation contributes to the risk of multiple primary cancers and suggests additional loci are likely to be identified with larger studies.

#6148 Multiple new Ewing sarcoma susceptibility loci expand knowledge of germline genetic etiology and nominate mechanisms of risk.

A. K. Hubbard[1], W. Zhou[1], C. Boyce[2], J. Khan[3], M. M. Hudson[4], K. K. Ness[4], Z. Wang[5], K. A. Janeway[6], P. J. Lupo[7], L. M. Morton[1], S. J. Chanock[1], T. G. P. Grunewald[8], O. Delattre[9], M. J. Machiela[1], Ewing Sarcoma Germline Genetics Group;

[1]National Cancer Institute, Rockville, MD, [2]Westat, Rockville, MD, [3]National Cancer Institute, Bethesda, MD, [4]St. Jude's Children's Hospital, Memphis, TN, [5]St. Jude's Children's Research Hospital, Memphis, TN, [6]Dana-Farber, Boston, MA, [7]Baylor College of Medicine, Houston, TX, [8]German Cancer Research Center, Heidelberg, Germany, [9]Institut Curie Research Center, Paris, France

Ewing sarcoma (EwS) is a rare and aggressive pediatric cancer with peak incidence in the second decade of life. EwS occurs primarily in children of European ancestry suggesting a genetic component to susceptibility. Prior investigations identified six susceptibility loci associated with EwS, with evidence for additional signals not reaching the commonly accepted threshold for genome-wide significance (i.e., $p<5\times10^{-8}$). At least two of these loci demonstrate evidence of tagging variation in length of nearby GGAA microsatellites, which alter binding of the pathognomonic *EWSR1::FLI1* fusion resulting in downstream dysregulation of target genes promoting sarcomagenesis. To identify additional susceptibility loci, we performed the largest genome-wide association study (GWAS) to date consisting of 1,640 EwS cases and 8,457 cancer-free individuals of European ancestry from 8 studies and matched by principal components. Genotype imputation was carried out by study/array using TOPMed data as the reference and each set was analyzed using PLINK 1.9 adjusting for significant principal components. Variants were included in each study if minor allele count was greater than five in each set of cases. Individual study results were combined using fixed effects meta-analysis in Metasoft with variants demonstrating evidence for heterogeneity excluded.For previously reported EwS loci (i.e., 1p36.22, 6p25.1, 10q21.3, 15q15.1, 20p11.22 and 20p11.23), odds ratios (OR) remained high for GWAS (OR=1.5-2.4) and the $-\log_{10}$ p-values grew by several orders of magnitude, providing strong evidence for replication in the additional 907 EwS cases and 7,111 cancer-free controls. Our analysis identified five novel loci reaching genome-wide significance ($P\text{-value}_{meta}< 5\times10^{-8}$) at 5q32, 7q32.3, 8q24.2, 13q32.3, and 17q23.2. Risk allele frequency of newly identified loci ranged from 0.001 to 0.75with estimated ORs ranging from 1.31-4.30. eQTL analyses nominated nearby biologically plausible candidate genes for future functional investigation including *LARS1*, a gene implicated in osteosarcoma and skeletal muscle dysgenesis, at the 5q32 locus and *COX5BP6*, a gene implicated in age at menarche and testosterone levels, at 13q32.3.Our results add to evidence supporting a strong inherited genetic component to EwS risk and particularly a genetic architecture harboring a substantial number of common variants with moderate effect. Ongoing work is focusing on enrichment analyses of GGAA microsatellite repeat sequences in identified risk loci to search for evidence for germline-somatic interactions with *EWSR1::FLI1*.

#6149 Polygenic risk score and lung adenocarcinoma risk among never-smokers by *EGFR* mutation status.

Hu[1], W. Zheng[10], Y. Kim[11], X.-O. Shu[10], Q. Cai[10], P.-C. Yang[12], D. Lin[13], K. Chen[14], Y.-L. Wu[15], H. Shen[16], T. Kohno[4], S. J. Chanock[1], N. Rothman[1], Q. Lan[1];

[1]National Cancer Institute, Rockville, MD, [2]National Health Research Institutes, Zhunan, Taiwan, [3]Aichi Cancer Center Research Institute, Nagoya, Japan, [4]National Cancer Research Institute, Tokyo, Japan, [5]National University of Singapore and National University Health System, Singapre, Singapore, [6]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, [7]National Heart Lung and Blood Institute, Bethesda, MD, [8]School of Public Health, Nanjing Medical University, Nanjin, China, [9]Albert Einstein College of Medicine, Bronx, NY, [10]Vanderbilt University, Nashville, TN, [11]Seoul National University College of Medicine, Seul, Korea, Republic of, [12]National Taiwan University Hospital, Taipei, Taiwan, [13]Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China, [14]Tianjin Medical University Cancer Institute and Hospital, Tianjin, China, [15]Guangdong Academy of Medical Sciences, Guangzhou, China, [16]Nanjing Medical University, Nanjing, China

Background: Lung cancer is the leading cause of cancer mortality worldwide, and incidence rates for the disease in never-smokers is among the highest in East Asian (EAS) women. Epidermal growth factor receptor (EGFR) is a transmembrane protein that regulates cellular proliferation and apoptosis, and mutations in the EGFR gene have been found to be a defining hallmark of lung adenocarcinoma (LUAD). We investigated if overall genetic susceptibility to LUAD, defined as a polygenic risk score (PRS), is differentially associated with LUAD by EGFR mutation status.

Methods: The study consists of 998 female never-smoking histologically confirmed LUAD cases with data on EGFR mutation status and 4,544 female never-smoking controls from the Female Lung Cancer Consortium in Asia. Germline DNA samples were genotyped using the 370K, 610Q, or 660W microarrays. Genomic DNA extracted from fresh, frozen or formalin-fixed paraffin-embedded tumor tissue samples of LUAD cases were genotyped for EGFR mutations on exons 19 and 21. We defined cases with EGFR mutation on either exon as EGFR+ (n=518) and cases without such EGFR mutation as EGFR- (n=480). Weights from 942,592 single nucleotide variants derived from a previously conducted genome-wide association study were used in a Bayesian-based approach, LDpred2, to derive a PRS for all participants. We estimated the odds ratios (OR) and 95% confidence intervals (CI) for the association between continuous PRS, PRS quartiles and tumor EGFR mutation status using logistic regression models in a case-case analysis, as well as using a multinomial logistic regression treating controls as the reference. All models were adjusted for age, study and the top 10 principal components.

Results: In case-case comparisons, compared to EGFR- LUAD, we found a positive association between continuous PRS and risk of EGFR+ LUAD (OR=1.17, 95% CI: 1.02, 1.34), as well as a dose-response relationship between quartiles of the PRS and EGFR+ LUAD (p-trend=0.003). We further found that the association between the fourth quartile of the PRS with EGFR+ LUAD (OR=8.63, 95% CI: 5.67, 13.14) was significantly higher than the association between the fourth quartile of the PRS with EGFR- LUAD (OR=3.50, 95% CI: 2.44, 5.00) compared to controls (p-heterogeneity=0.004).

Conclusions: We found that the PRS developed for LUAD in EAS individuals was more strongly associated with EGFR+ LUAD compared to EGFR- LUAD, suggesting that germline genetic susceptibility may be differentially associated with LUAD in never-smoking female EAS patients depending on the cancer's mutation status. Given that patients with LUAD respond differently to treatments that are used as targeted therapy depending on their EGFR mutation status, our findings may have important public health and clinical implications, which may guide risk stratification, screening, and treatment.

#6150 *MMP14* and *MKLN1* as colorectal cancer susceptibility genes and a drug repurposing candidate from genome-wide association study in South Korea.

D. Yun[1], J.-H. Yang[2], S.-S. Kweon[2], J.-a. Sim[3], M. Kim[4], J. Park[4], S. Jeong[4], A. Shin[4], N. Song[1];
[1]Chungbuk National University, Cheongju, Korea, Republic of, [2]Chonnam National University, Hwasun, Korea, Republic of, [3]Hallym University, Chuncheon, Korea, Republic of, [4]Seoul National University, Seoul, Korea, Republic of

Background: One of the major topics about colorectal cancer (CRC) is to find susceptible genes. Furthermore, functional interpretation of post-GWAS analysis gains attention and various approaches to find drug-repurposing candidates are used in cancer research. Our study aims to identify susceptible genes for CRC and provide drug-repurposing candidates.
Methods: CRC patients in Seoul National University Hospital with prospective follow-up were recruited. From blood-derived DNA, genome-wide SNPs were genotyped using the Korea Biobank Array and 409,063 SNPs were extracted. SNP-based logistic regression model was fit for the event of CRC estimating beta values. Furthermore, post-GWAS analysis was conducted using regulatory function, multiple annotation and gene expression database. Drug-repurposing candidate was identified through the pre-trained deep neural network with susceptible genes.
Results: We used 500 participants of CRC cases and 1,500 participants of healthy controls. For GWAS, statistically significant associations were mapped to *MKLN1*, *MMP14*, *PTPN14* and *MKL2* genes. For post-GWAS analysis, strong associations were found for *MKLN1* (rs75170436, 7q32.3, Beta=-0.90, *P*-value=5.90×10^{-13}) and *MMP14* (rs3751489, 14q11.2, Beta=-1.91, *P*-value=2.31×10^{-12}). From the drug-repurposing analysis, PPARδ/β agonist (GW0742; Binding score=3.79(*MKLN1*), 12.06(*MMP14*)) was identified for both genes with the highest score.
Conclusions: We revealed *MKLN1* and *MMP14* genes as susceptible genes associated with CRC development. Additionally, we identified PPARδ/β agonist (GW0742) as a drug-repurposing candidate for the treatment of CRC. These findings can promote the understanding of CRC development and provide a novel therapeutic candidate for CRC patients in the future.

#6151 Relationship between polygenic risk score, lifestyle factors, and colorectal cancer risk.

W.-Y. Huang, E. Loftfield, R. Landy, D. Wang, H. A. Katki, J. Shi, L. Wang, M. J. Machiela, N. D. Freedman, S. I. Berndt;
NCI Div. of Cancer Epidemiology & Genetics, Bethesda, MD

Although heritable factors are estimated to explain up to 35% of colorectal cancers (CRC), most are diagnosed in people without a family history of CRC suggesting that inherited genetic variants, environmental factors, or a combination of both, contribute to CRC risk. We explored the relationship between a polygenic risk score (PRS) for CRC risk and lifestyle risk factors to understand whether individuals with higher genetic risk, who do not develop CRC, engage in healthier lifestyle behaviors, or conversely, whether those with lower genetic risk, who do develop CRC, engage in riskier behaviors in the Prostate, Lung, Colorectal, and Ovarian (PLCO) Cancer Screening Trial.

Using summary statistics obtained from a large independent GWAS meta-analysis of CRC by the GECCO consortium, we developed a genome-wide PRS for CRC using SBayesR and applied it to participants of European ancestry genotyped in the PLCO Trial (n=74,396). For all subjects, we computed an environmental (E) score based on 19 lifestyle risk factors for CRC, a WCRF/AICR score that measured adherence to the 2018 Cancer Prevention recommendations, and a 2015 healthy eating index (HEI) with higher values indicating healthier lifestyle profiles. We used t-tests to evaluate differences in lifestyle scores between CRC-free participants in the highest quartile of PRS and incident CRC cases in the lowest quartile of PRS. To examine the correlations between the PRS and lifestyle scores, we performed multivariable linear regression models regressing PRS on each lifestyle score. We used multivariable Cox hazards regression models to compute hazard ratios and 95% confidence intervals for CRC risk; multiplicative interactions between PRS and lifestyle scores were evaluated using the Wald test for the interaction terms.

During the 15 years follow-up period, a total of 1,052 CRC cases were diagnosed. Individuals in the highest quartile of PRS who remained cancer-free were more likely to engage in healthier behaviors than those in the lowest quartile of PRS who were diagnosed with incident CRC (E-score: -0.01 vs. -0.18, WCRF/AICR score: -0.05 vs. -0.32, HEI score: 0.06 vs. -0.13); however, differences were not statistically significant (*P* value: 0.1 to 0.4). PRS and lifestyle scores were significantly (all *P* <0.0001), albeit weakly (β: -0.02 to -0.03), associated among participants who remained CRC-free but not among CRC cases (*P*: 0.1 to 0.3). PRS-lifestyle score interactions were not statistically significant (*P*: 0.2 to 0.4).

Although the differences and multiplicative interaction models were not statistically significant, we found that individuals with a higher PRS who remained CRC-free were slightly more likely to engage in healthier behaviors than those at a lower genetic score who developed CRC. Additional studies with larger sample size are warranted to further explore the interplay between genetic risk and lifestyle factors related to CRC risk.

#6152 Genetic associations with hematologic malignancies: An evaluation of CLL polygenic risk score and MBL status in the Mayo Clinic Biobank Cohort.

R. Mwangi[1], D. P. Robinson[1], S. J. Achenbach[1], G. Kleinstern[2], A. D. Norman[1], K. G. Rabe[1], J. E. Olson[1], N. E. Kay[1], R. Griffin[1], N. J. Boddicker[1], E. Braggio[3], S. A. Parikh[1], C. A. Hanson[1], C. M. Vachon[1], J. R. Cerhan[1], T. D. Shanafelt[4], S. L. Slager[1];

[1]Mayo Clinic, Rochester, MN, [2]University of Haifa, Haifa, Israel, [3]Mayo Clinic, Phoenix, AZ, [4]Stanford University, Stanford, CA

Chronic Lymphocytic Leukemia (CLL) exhibits a substantial familial risk that extends beyond CLL to other B-cell lymphomas (including follicular lymphoma and diffuse large B-cell lymphoma). Monoclonal B-cell Lymphocytosis (MBL), a precursor to CLL, is also associated with a significant risk for hematologic malignancies overall and for lymphoid malignancies, specifically. Moreover, previous research has shown an association between the CLL polygenic risk score (CLL-PRS) and common lymphoma subtypes. This study aims to further evaluate CLL-PRS associations with hematological cancer overall and by lineage while also considering MBL status a strong risk factor for lymphoid malignancies.

Utilizing the Mayo Clinic Biobank, we selected individuals aged 40 years or older, residing in proximal counties, who had no prior hematologic malignancies, and with available biospecimens. MBL screening was done using 8-color flow cytometry, and MBL with CLL (CD5+/CD20dim) or atypical CLL (CD5+/CD20+) immunophenotype were included. CLL-PRS was calculated from 41 known susceptibility variants, with weights being the log of the odds ratios from the largest CLL genome-wide association study. Incident hematologic malignancies were ascertained through ICD codes and confirmed via medical record review. Hazard ratios (HR) and 95% confidence intervals (CIs) for associations with hematologic malignancies were estimated through Cox regression.

Of 7,332 participants, 1,150 (16%) screened positive for MBL; median age was 67 years (range 40-101), and 37% male. Median follow-up was 2.9 years (range 0-13), and 56 hematologic cancers were identified. After adjusting for age and sex, the CLL-PRS was associated with increased risk of developing hematologic (HR=1.49, 95%CI=1.12-1.98, P=0.006) which was all attributable to lymphoid cancers (HR=1.79, 95%CI=1.26-2.56, P=0.001). When adjusting for baseline MBL status in the models, the CLL-PRS associations remained significant but were attenuated for hematological (HR=1.33, 95%CI=0.99-1.79, P=0.058) and lymphoid (HR=1.56, 95%CI=1.07-2.26, P=0.020) malignancies, while MBL status was also significantly associated with risk of hematologic (HR=2.76, 95%CI=1.55-4.91, P=0.001) and lymphoid (HR=3.61, 95%CI=1.78-3.32, P<0.001) malignancies.

In this prospective cohort study of individuals screened for MBL, CLL-PRS was associated with an elevated risk of hematologic malignancies overall and within the lymphoid lineage, underscoring a shared genetic etiology across many B-cell lymphomas. However, the associations between CLL-PRS and hematologic malignancies were attenuated when accounting for MBL status or when analyzing among MBL-positive individuals, highlighting the role of MBL status in these associations. Further research with expanded cohorts is needed to unravel these complex genetic and clinical interactions.

#6153 Proteome-wide association study and functional validation identify novel protein markers for pancreatic ductal adenocarcinoma.

J. Zhu[1], K. Wu[2], S. Liu[1], A. Masca[1], H. Zhong[1], T. Yang[3], D. H. Ghoneim[1], P. Surendran[4], T. Liu[5], Q. Yao[6], T. Liu[7], S. Fahle[4], A. Butterworth[4], M. A. Alam[8], J. V. Vadgama[2], Y. Deng[1], H.-W. Deng[9], C. Wu[10], Y. Wu[2], **L. Wu**[1];

[1]University of Hawaii at Manoa, Honolulu, HI, [2]Charles R Drew University of Medicine and Science, Los Angeles, CA, [3]University of Michigan School of Public Health, Ann Arbor, MI, [4]University of Cambridge, Cambridge, United Kingdom, [5]Johns Hopkins University, Baltimore, MD, [6]Baylor College of Medicine, Houston, TX, [7]Pacific Northwest National Laboratory, Richland, WA, [8]Tulane University, New Orleans, LA, [9]Tulane University, New Orlean, LA, [10]The University of Texas MD Anderson Cancer Center, Houston, TX

Pancreatic ductal adenocarcinoma (PDAC) remains a lethal malignancy, largely due to the paucity of reliable biomarkers for early detection and therapeutic targeting. Existing blood protein biomarkers for PDAC often suffer from replicability issues, arising from inherent limitations such as unmeasured confounding factors in conventional epidemiologic study designs. To circumvent these limitations, we use genetic instruments to identify proteins with genetically predicted levels to be associated with PDAC risk. Leveraging genome and plasma proteome data from the INTERVAL study, we established and validated models to predict protein levels using genetic variants. By examining 8,275 PDAC cases and 6,723 controls, we identified 40 associated proteins, of which 16 are novel. Functionally validating these candidates by focusing on two selected novel protein-encoding genes, *GOLM1* and *B4GALT1*, we demonstrated their pivotal roles in driving PDAC cell proliferation, migration, and invasion. Furthermore, we also identified potential drug repurposing opportunities for treating PDAC. Our dual approach enhances our understanding of PDAC etiology and potentially opens new avenues for therapeutic interventions.

#6154 Targeted CRISPRi screen identifies functional variants and novel target genes at multiple renal cell carcinoma (RCC) susceptibility loci.

Timothy Winter[1], Timothy Myers[1], Leandro Colli[2], Lea Jessop[1], Jiyeon Choi[1], Mitchell J. Machiela[1], Mark P. Purdue[1], Kevin Brown[1], Stephen Chanock[1]

[1]National Cancer Institute Center for Cancer Research, Rockville, MD, [2]Universidade de Sao Paulo (USP), Faculdade de Medicina de Ribeirao Preto (FMRP), Sao Paulo, Brazil

Genome-wide association studies (GWAS) have identified 13 renal cell carcinoma (RCC) risk regions, as well as 7 regions with nominal significance, but detailed investigation of how these regions function is required to reveal the underlying biological bases of disease susceptibility. While detailed study of four loci have implicated critical pathways in RCC, causal genes and pathways for most loci remain unidentified. To identify such causative variants and target genes, we evaluated a set of variants based on Massively Parallel Reporter Assays (MPRA), eQTL analysis, capture Hi-C, and an arrayed CRISPR inhibition (CRISPRi) screen. The MPRA identified 196 variants across 19 regions with significant allele-specific effects, indicating cis-regulatory activity. Of these, 39 variants across 10 RCC loci displayed chromatin loops allowing physical interaction with the promoter of 24 nearby putative gene targets, as well as a significant cis-eQTL with the same gene. To confirm the presence of a cis-regulatory relationship between these 39 candidate variants and 24 putative target genes, we performed an arrayed CRISPRi screen in ACHN (RCC) and HEK293T (embryonic renal) cells covering each of the 10 nominated regions. Cells were stably transduced with inactive Cas9 fused to the ZIM3 transcriptional repressor domain and cis-regulatory relationships were assessed by TaqMan qPCR for the target genes. The screen identified multiple novel relevant target genes of RCC predisposition variants, including *UCK2* at 1q24, *ABL2 and TDRD5* at 1q25, *GTDC1* at 2q22, *GPR37* at 7q31, *AGBL3* and *CALD1* at 7q33, and *MAP2K1* at 15q22. At some regions, evidence indicates cis-regulatory relationships occur between a target gene and all variants predicted to be 'causative' at the region (e.g., *UCK2* at 1q24 and *ABL2* at 1q25). For other regions, cis-regulatory relationships occur between a gene and only one variant tested (e.g., *GPR37* at 7q31 and *TDRD5* at 1q25).Previously, target genes of only four RCC susceptibility regions had been identified and published. This study identifies eight novel target genes across six additional RCC susceptibility regions, representing a significant advance in understanding of the underlying biology of RCC susceptibility variants. Furthermore, ongoing screening using the orthologous method, CRISPR activation (CRISPRa), and integration of both normoxic and hypoxic conditions continues to provide further insight into the underlying biology at these regions.

#6155 Germline variants in cancer susceptibility genes and subsequent neoplasm risks after childhood cancer: A pooled analysis of two large-scale cohorts.

S. A. Zamani[1], D. M. Karyadi[1], S. W. Hartley[1], J. N. Sampson[2], T. Gibson[1], P. Kraft[1], S. J. Chanock[1], L. M. Morton[1];
[1]National Cancer Institute, Rockville, MD, [2]Food and Drug Administration, Silver Spring, MD

Background: Increasing evidence suggests germline genetic susceptibility influences the risk of developing subsequent neoplasms (SNs)—a major cause of morbidity and mortality—among childhood cancer survivors, but studies have been hampered by sample size and limited gene sets. We pooled two large-scale cohorts of childhood cancer survivors to characterize overall and specific SN risks among individuals carrying germline variants in 88 known cancer susceptibility genes with an autosomal dominant inheritance pattern.
Methods: Using whole-genome or whole-exome sequencing data from the Childhood Cancer Survivor Study and St. Jude Lifetime Cohort (median [interquartile range] follow-up, 29.7 [13.8] years), we identified rare, potentially protein-damaging germline variants with SnpEff/ClinVar. Conditional logistic regression evaluated overall SN and SN-specific risk, with up to 100 SN-free controls matched to cases by age, sex, primary childhood cancer type, SN type, radiation dose, chemotherapy, study, and follow-up time.
Results: Among 11840 individuals (50.6% female) who survived childhood cancer, 2162 (18.3%) developed at least one SN. The risk of developing any SN was elevated among 288 survivors carrying rare, potentially protein-damaging germline variants in an autosomal dominant cancer susceptibility gene (cases=13.3%; controls=9.6%; odds ratio [OR], 1.48; 95% confidence interval [CI], 1.30-1.70; P=5.12x10^{-5}). A similar proportion of carriers was observed among those who developed common SNs such as basal cell carcinoma (N=107/882, 12.1%), meningioma (N=52/373, 13.9%), breast cancer (N=49/353, 13.9%), and thyroid cancer (N=32/243, 13.2%). Higher frequencies of carriers were observed in less common SNs, specifically sarcoma (N=24/151, 15.9%), colorectal cancer (N=15/72, 20.8%), and glioma (N=16/64, 25.0%). The observed associations were generally consistent regardless of treatment type for first primary childhood cancer. Gene-specific analyses revealed that the risk of developing any SN was most pronounced among individuals carrying variants in *TP53* (cases=0.6%; controls=0.04%; OR, 9.93; 95% CI, 4.62-21.34; P=0.001) and *FANCM* (cases=0.9%; controls=0.5%; OR, 2.45; 95% CI, 1.48-4.03; P=0.018).
Conclusion: In large-scale cohorts of childhood cancer survivors with long-term follow-up, individuals carrying potentially protein-damaging germline variants in known autosomal dominant cancer susceptibility genes have substantially increased SN risk, emphasizing the importance of genetic testing and consideration of genetic risk in follow-up guidelines. However, these individuals account for a small fraction of all SN cases, warranting future research on underlying risk factors in this population.

#6156 Deciphering the genomic landscape of Chilean cancer: Unveiling driver pathway divergence, and novel germline and actionable somatic variants.

E. Gonzalez[1], J. Toro[2], A. Blanco[1], C. Tapia[2], S. Rivas[1], J. Erices[2], F. Osorio[2], G. Sepulveda-Hermosilla[3], M. Freire[3], V. Garate[3], J. Caceres-Molina[3], I. Gallegos[2], O. Barajas[2], M. Ahumada[2], E. Bustamante[2], J. Gonzalez[2], C. Ibanez[4], A. Corvalan[4], G. Owen[4], M. Garrido[5], R. Armisen[1], **K. Marcelain**[2]; [1]Universidad del Desarrollo, Santiago, Chile, [2]Universidad de Chile, Santiago, Chile, [3]CORFO Center of Excellence in Precision Medicine, Pfizer Chile, Santiago, Chile, [4]Pontificia Universidad Catolica de Chile, Santiago, Chile, [5]Universidad Mayor, Santiago, Chile

Advances in understanding the genetic landscape of cancer have paved the way for more precise molecular profiling and the development of more efficacious therapeutic options. However, underrepresentation in clinical research endeavors has left the Latin American population uncharacterized, which may prevent them from reaping the benefits of these advancements. This study sought to identify the genetic drivers and actionable mutations in solid tumors from Chilean patients, enhancing our understanding of the mutational landscape in a population with a genetically diverse background shaped by admixture.Methods: 468 biopsy tissues from gastric (171), gallbladder (91), breast (72), Ovarian (69), and colorectal (65) Chilean cancer patients were collected in several pathology services and biobank at Universidad de Chile. Target-sequencing was performed using Oncomine Comprehensive Assay v.1 and v.3; and TumorSec cancer panel. Data from TCGA, MSK-IMPACT, and ACCR GENIE cohorts was accessed through cBioportal and used for comparison with non-Hispanic populations. Variants were annotated with CGI, CancerVar, OncoKB, and ClinVar tools.Results: Overall, tumors have mutations mainly in TP53 (42.4%), PIK3CA (12.5%), KRAS (9.6%), PTEN (4.7%), BRCA1/2 (9%). Driver mutations were present in TP53 (42%), PIK3CA (16%), KRAS (10%), ERBB2 (7%), PTEN (7%), BRCA1/2 (8%), ATM (7%), among others. Accionable mutations were found primarily in PIK3CA (17%), KRAS (10%), ERBB2 (9%), and NTRK1/2/3 (4.8%). Besides already-known mutations, many “novel” mutations were also found in all tumor types. About 5-15% of novel variants were predicted drivers, including variants in CDH1, NOTCH1, BRCA1/2, MTOR, TSC2, and MSH2 genes. Significantly, key driver mutations identified in non-Hispanic patients from international cohorts are also prevalent in admixed Chilean patients. However, variations at the driver pathway level were also observed. Notably, the PI3K and MTOR pathways were more frequently affected in Chilean CRC and GBC, respectively. Furthermore, mutations in specific genes, such as TP53 in GBC, were associated with Amerindian genetic ancestry.The observed differences could be attributed to the abundance of newly identified driver-predicted variants, though the possibility of the admixed genetic background influencing the oncogenic process in various tissue types cannot be excluded.

#6157 Population-specific 5-hydroxymethylcytosine signatures in circulating cell-free DNA and overall survival among Blacks and Whites with multiple myeloma.

B. Wang[1], Z. Zhang[2], B. Derman[1], K. Kowitwanich[1], J. Cheung[1], A. Jakubowiak[1], C. He[1], W. Zhang[2], B. Chiu[1];
[1]University of Chicago, Chicago, IL, [2]Northwestern University Feinberg School of Medicine, Chicago, IL

Background: Epigenetic modifications play important roles in the prognosis of multiple myeloma (MM). To date, DNA methylation (i.e., 5-methylcytosine) is the most extensively studied cytosine modification. Emerging evidence suggests that 5-hydroxymethylcytosine (5hmC), a product of 5mC through demethylation, in circulating cell-free DNA (cfDNA) is associated with the overall survival (OS) of MM. We also showed that African Americans (AAs) and European Americans (EAs) with MM have distinct genome-wide 5hmC profiles. However, no study has evaluated whether the association between 5hmC profiles and OS in MM differs between EAs and AAs.
Methods: A total of 586 newly diagnosed patients with MM at the University of Chicago Medical Center were prospectively enrolled between 2010-2019. The current study profiled genome-wide 5hmC in plasma-derived cfDNA for 303 patients using the 5hmC-Seal and next-generation sequencing. Data cutoff was February 28, 2022. Vital status was ascertained using the National Death Index. OS was defined as the time from diagnosis until death from any cause. The 5hmC-Seal data were mapped to the human genome reference (hg19) and annotated to gene bodies. In each population, patients were randomly divided into a training set (EAs, n=147; AAs, n=64) and a testing set (EAs, n=64; AAs, n=28). After selecting the top 10% candidate genes associated with OS in age-adjusted univariate Cox proportional hazards model, we applied multivariable Cox models with elastic net regularization for feature selection through leave-one-out cross-validation. The optimal "*alpha*" and "*lambda*" were evaluated to maximize model performance measured by the Harrell's Concordance Index. The differential 5hmC enrichment levels of selected genes were used to compute a weighted prognostic score (wp-score). The associations between the wp-scores and OS were evaluated in the testing sets, adjusting for established prognostic factors (e.g., age, stage).
Results: Of the 303 MM patients, 94 (30.92%) were AA and 210 (69.08%) were EA. The median follow-up was 108 months. Our preliminary analyses identified 26 and 10 5hmC marker genes associated with OS in EAs and AAs, respectively. Importantly, none of these genes overlap between the two groups. We used these genes to compute wp-scores in EAs and AAs. In the training sets, patients with a higher wp-score had worse OS. The same trend was observed in the testing sets: hazard ratios (HR) in EAs: 1.31, 95% CI: (0.83, 2.06) and HR in AA: 11.94, 95% CI: (1.88, 75.68) after controlling for established prognostic factors.
Conclusions: Our findings suggest that different epigenetic modifications in cfDNA might be associated with OS between EAs and AAs with MM and the 5hmC marker gene-based wp-scores are independent prognostic factors for MM.

#6158 Tumor genomic heterogeneity in non-small cell lung cancer (NSCLC) patients from Latin America.

Javiera Garrido[1], Evelin Gonzalez[1], Gonzalo Sepulveda-Hermosilla[1], Matias Freire[2], Alejandro Blanco[1], Solange Rivas[1], Katherine Marcelain[3], Gareth I. Owen[4], Carolina Ibañez[4], Alejandro Corvalan[4], Marcelo Garrido[5], Rodrigo Assar[2], Rodrigo Lizana[2], Javier Caceres-Molina[2], Diego Ampuero[2], Liliana Ramos[2], Paola Perez[6], Osvaldo Aren[7], Sara Chernilo[8], Cristina Fernandez[8], Maria Loreto Spencer[9], Jacqueline Flores[10], Giuliano Bernal[11], Monica Ahumada[3], German Rasse[12], Carolina Sanchez[13], Maria Galli de Amorim[14], Gabriela Branco[14], Diana Noronha Nunes[14], Emmanuel Dias-Neto[14], Helano C. Freitas[14], NIRVANA team, Ricardo Armisen[1]

[1]Centro Genetica y Genomica, Instituto de Ciencias e Innovacion en Medicina, Facultad de Medicina, Universidad del Desarrollo, Santiago, Chile,[2]Center of Excellence in Precision Medicine, Pfizer, CORFO, Santiago, Chile,[3]Departamento de Oncologia Basico Clinica, Facultad de Medicina, Universidad de Chile, Santiago, Chile,[4]Advanced Center for Chronic Diseases and Department of Hematology and Oncology, Pontificia Universidad Catolica de Chile, Santiago, Chile,[5]Centro de Oncologia de Precision, Universidad Mayor, Santiago, Chile,[6]National Institute of Health, National Institute of Dental and Craniofacial Research, Bethesda, MD,[7]Centro de Investigacion Clinica Bradford Hill, Santiago, Chile,[8]Instituto Nacional del Torax, Santiago, Chile,[9]Department of Pathology, Hospital Clinico Regional de Concepcion Dr. Guillermo Grant Benavente, Concepcion, Chile,[10]Departamento de Salud Publica, Facultad de Medicina, Universidad Catolica del Norte, Coquimbo, Chile,[11]Departamento de Ciencias Biomedicas, Facultad de Medicina, Universidad Catolica del Norte, Coquimbo, Chile,[12]Hospital de Puerto Montt, Puerto Montt, Chile,[13]Centro de Genomica y Bioinformatica, Universidad Mayor, Santiago, Chile,[14]Laboratory of Medical Genomics, A. C. Camargo Cancer Center, Sao Paulo, Brazil

Motivation: Life prospects of non-small cell lung cancer (NSCLC) patients have greatly improved over the last decades with the adoption of tumor genomic profiling. A better understanding of the mutational landscape has allowed for a more precise molecular characterization and the development of more effective treatment alternatives. However, tumors present a widespread heterogeneity, and many challenges remain to fully comprehend the influencing factors. Of particular importance is the Latin America population which i) is commonly underrepresented in clinical trials and large-scale epidemiological studies, ii) presents higher incidence and mortality rates in comparison to the developed world, and iii) is constituted by a genetically admixed population. Our research attempts to close this gap by investigating the interplay between sociodemographic, clinical, and lifestyle factors, and the effect these exert on the mutational profiles of Latin-American NSCLC patients.

Methodology: The study population is derived from the NIRVANA study, a cross-sectional multicenter observational study aiming to characterize and validate molecular diagnostic technologies for NSCLC patients in Chile, Brazil, and Peru. Between July 2015 to October 2018, 5030 NSCLC patients were recruited from 37 centers, meeting inclusion criteria of age ≥18, histologically or cytological proven NSCLC diagnostic, and naïve treatment. Exclusion criteria included prior chemotherapy treatment and refusal to give informed consent. Primary or metastatic NSCLC samples were collected during standard of care biopsy and processed for the DNA and RNA isolation. Next Generation Sequencing (NSG) genomics profiles were obtained using the Oncomine Focus Assay (OFA). Covariates of interest, including sociodemographic, clinical, and lifestyle factors, were assessed at enrollment. QC-approved genomic profiles were obtained for 1864 participants.

Results and Conclusions: The prevalence of mutations and fusions in the eight most relevant NSCLC genes (*EGFR*, *KRAS*, *ALK*, *MET*, *RET*, *BRAF*, *ROS1* and *ERBB2*) varies based on sociodemographic, clinical and lifestyle characteristics. Clear distinctions emerged in the prevalence of *EGFR*, *KRAS* and *ERBB2* mutations among the three countries (*EGFR*: 20.9%, 17.6%, 35.3%; *KRAS*: 21.8%, 15.6%, 10.3%; *ERBB2*: 2.8%, 3.3%, 4.4% for Brazil, Chile, and Peru, respectively). Furthermore, distinct association patterns were identified between the prevalence of genetic alterations and the studied factors, with attributes such as sex, tobacco use and ethnicity mostly influencing the occurrence of *EGFR*, *ALK* and *ROS1* alterations. These findings provide novel insights into NSCLC studies among Latin-American patients, potentially serving as guidelines for more tailored strategies in the overall management of this underrepresented population.

#6159 Single cell analysis of circulating peripheral blood mononuclear cells in African American men with prostate cancer and their association with lethal disease.

M. U. Ahmed, T. Dorsey, S. Ambs;
National Cancer Institute, Bethesda, MD

Prostate cancer is a leading cause of cancer-related deaths among men in the United States and affects African American (AA) men more so than other men. We and others previously described a distinct tumor immunobiology in AA prostate cancer patients. Furthermore, we discovered a serum proteome-defined suppression of tumor immunity signature that is prevalent among these patients and associated with lethal prostate cancer. In the current study, we sought to investigate the composition of circulating peripheral blood mononuclear cells (PBMCs) in AA and European American (EA) prostate cancer patients and their association with patient group and lethal prostate cancer. We obtained high-quality RNA-sequencing data for 277336 single cells representing circulating PBMCs from 59 AA and EA men. In the analysis, being an AA patients associated with an increased abundance of exhausted T cells, higher numbers of plasma B cells and CD16+ monocytes. Gene signatures indicative of T cell exhaustion and Treg activity were generally elevated in AA PBMCs while T cell effector function features were decreased. Within the overall cell population, interferon gene signatures were robustly elevated in AA than EA patients. This gene signature pattern that we observed in AA patients also associated with lethal prostate cancer, namely the T cell exhaustion, Treg activity and elevated interferon signaling gene signatures, may contribute to immune dysfunction and immune injury; pointing to potential clinical implications. Lastly, the interferon-induced transmembrane protein (IFITM3), interferon alpha inducible protein (IFI6), cysteine rich protein-1 (CRIP1), and the RAC family small GTPase2 (RAC2) were notably upregulated in AA patient-derived immune cells. In summary, we show that circulating immune cell populations and the associated gene signatures differ between men of African and European descent. Those elevated in AA patients correlated with lethal prostate cancer.

#6160 Mutational signatures and their associations with social determinants of health.

P. Swaminathan, M. Deaton, C. Hattum, B. Solomon, W. Spanos, D. Starks, R. Elsey, C. Williams, T. Meissner;
Avera Cancer Institute, Sioux Falls, SD

Introduction: Mutational signatures, or unique patterns of genetic mutations due to exogenous and endogenous mutational processes, are being continuously identified through the analysis of cancer patients' genomes. While cancer research has developed and mortality rates have declined, disparities in cancer outcomes have widened. Social determinants of health (SDOH), such as access to health care, education, and economic stability are essential to addressing health equity. While much research is ongoing regarding the identification and etiology of mutational signatures, little work has been published regarding the associations of these signatures with SDOH. Therefore, this study proposes an exploration into the relationships between the presence of mutational signatures and SDOH within an adult pan-cancer patient population.

Methods: Variant calls from whole exome sequencing for each patient was used to infer the presence of 58 single base substitution (SBS) mutational signatures. Descriptive statistics were calculated for 455 unique patients. Previously documented associations between primary diagnosis site and distinct signatures were used to validate the predicted signatures in the patient population. Signature profiles were then linked to 208 patient health records with complete SDOH. Logistic regression predicting the presence of each signature was modeled for these patients. Full models for each signature included age, gender, Rural-Urban Commuting Area (RUCA) code, tobacco and alcohol usage, education, income, housing condition, and access to healthcare. Stepwise selection was used to determine significant variables.

Results: The most common signatures in the complete population (n = 455) were SBS1 (clock-like; 98%) and SBS39 (95%), followed by SBS5 (clock-like; 38%) and SBS22 (aristolochic acid exposure; 36%). However, SBS24 (aflatoxin exposure; p = .019) and SBS7a (UV exposure; p = .002) were significantly more common in lung and skin cancer patients respectively. Each patient had 4.1 signatures on average, with a range of 2-7. The average number of signatures per patient varied significantly by primary diagnosis (ANOVA p = .014). Patients with a vulva/vagina (4.8) or bladder/urinary tract (4.9) diagnosis had the highest number of signatures while those with a liver (3.3) or kidney (3.6) diagnosis had the lowest. Logistic regression models for the population with SDOH (n = 208) showed poor housing condition was associated with SBS4 (tobacco smoking; p = 0.091). Any issue in accessing healthcare was associated with SBS13 (AID/APOBEC; p = 0.114) and SBS21 (MMR; p = 0.076). Greater rurality was associated with SBS16 (p = .144) and SBS21 (p = .107). The relationship was inverse for SBS1 (p = .121).

Conclusion: Multiple significant relationships between different SDOH and mutational signatures was revealed, pointing the need to extend this research to larger patient populations with diverse SDOH.

#6161 Investigating the relationships between race and socioeconomic status on the biology of ER+ breast cancer.

J. T. DeWitt, E. Oropeza, S. Haricharan;
Sanford Burnham Prebys Med. Discovery Inst., San Diego, CA

Black women in the US have worse health care options, poorer educational opportunities, and decreased income quality which collectively contribute to an overall lower socioeconomic status (SES) compared to white women. Furthermore, although the incidence of estrogen receptor positive (ER+) breast cancer is similar for Black and white women in the US, Black patients have significantly worse outcomes. The field has traditionally focused on systemic factors such as SES to explain outcome disparities. Consequently, differences in the molecular biology between tumors from Black and White women remains a gap in knowledge in the field. Recent studies have found that Black cancer patients have a unique gene expression profile that may modulate treatment response. However, how SES contributes to these differences in molecular biology and whether these differences in SES alter treatment response remain unknown. One challenge to addressing these questions is that existing datasets significantly underrepresent Black women and are not sufficiently annotated to understand the complex interplay between molecular biology and SES. Here, we present analysis of RNA expression datasets from 60 ER+ patient tumors (38 Black, 22 White), with corresponding SES and patient outcome annotations which suggest that the ECM and TIME of ER+ breast cancer are influenced by race and factors of SES including BMI and community poverty burden. We further provide evidence that these alterations in the TME may also associate with worse patient outcomes.

#6165 Early detection of pancreatic cancer by hyperpolarized magnetic resonance.

P. L. Smith, J. S. Enriquez, R. Howell, O. L. Roux, S. Pudakalakatti, P. Dutta, F. Mcallister, P. Bhattacharya;
UT MD Anderson Cancer Center, Houston, TX

Introduction: Pancreatic cancer is difficult to diagnose due to its asymptomatic presentation at early stages. Therefore, there is an unmet need for non-invasive imaging markers that can help identify the aggressive pancreatic lesions at an early time point. One of the most promising imaging biomarkers is the conversion of hyperpolarized (HP) pyruvate to lactate[1-3]. With HP metabolic imaging, the conversion will be monitored among different premalignant models at different timepoints as well as tested against pancreatitis, a known confounder of pancreatic cancer in the clinic.

Methods: HP [1-^{13}C]pyruvate Magnetic Resonance Spectroscopy (MRS) was employed to study the metabolic processes in tamoxifen inducible genetically engineered mouse models (P48CreERT2;LSL-K*ras*^{G12D}(iKC)) with pre-invasive pancreatic intraepithelial neoplasia (PanIN) precursor lesions, invasive pancreatic cancer model (P48CreERT2;LSL-K*ras*^{G12D}; LSL-*p53*^{R172H} (iKPC)) and control animals (P48CreERT2 (iC)) at 7T Bruker MRI scanner. These mice were imaged before tamoxifen induction at 10-, 20-, and 30-weeks post induction. For the pancreatitis model, iC and iKC mice they were treated with caerulein for three weeks, 7 weeks after tamoxifen induction. The pancreatitis mice were imaged 24 hours after the last caerulein injection.

Results/Discussion: HP lactate-to-pyruvate ratio is increased in the cancer models compared to the control model. In the iKPC mouse model, at the 20-week post induction imaging there was a significant increase of the lactate-to-pyruvate ratio compared to the 10-weektime point after induction. The 20-week iKPC time point ratio compared to the iKC and control mouse models was significantly higher, indicating the aggressive nature of the disease. Even in the iKC model there is a slight increase
of the lactate-to-pyruvate ratio at 20-weeks post induction compared to both previous time points, pre-induction and 10-week. No change in the lactate-to-pyruvate ratio was not observed with the pancreatitis phenotype. In the future, we plan on imaging at earlier timepoints or at smaller intervals in the iKPC model, to observe the exact moment the metabolism switches to lactate.

Conclusion: Our data demonstrates that the metabolic flux to lactate is only increasing in the premalignant models of pancreatic cancer but not in the pancreatitis model, suggesting that the differentiation between early pancreatic cancer and pancreatitis can be achieved by hyperpolarized metabolic imaging. We are currently in the process of translating this in a clinical trial at MD Anderson Cancer Center.

#6166 A whole-organ *ex vivo* optical imaging technique for non-destructive, more precise identification of serous tubal intraepithelial carcinoma (STIC) in fallopian tubes.

N. M. Bardhan[1], V. Rastogi[1], R. L. Stone[2], A. M. Belcher[1];

[1]Massachusetts Institute of Technology (MIT), Cambridge, MA, [2]Johns Hopkins University School of Medicine, Baltimore, MD

Objective

With the recent discovery of the fallopian tube (FT) origin of the most common and lethal type of ovarian cancer, high grade serous cancer (HGSC), engineering solutions to overcome the limitations of standard histopathology to more reliably identify incipient HGSCs and their serous tubal intraepithelial carcinoma (STIC) precursors are much needed. This investigation tests the potential of whole-organ *ex vivo* optical imaging of freshly excised FTs to label and sample abnormal tubal epithelium prior to formalin fixation and paraffin embedding for standard histopathology.

Methods

This investigation prototyped “OVASEEK”, a whole-organ, near-infrared optical imaging platform for identification of STICs. This prospective biospecimen protocol with annotated clinical data was approved by the IRB. Following salpingectomy at the time of hysterectomy for benign indications, FTs from study participants are longitudinally bivalved. Half of the FT is retained for routine evaluation using the Sectioning and Extensively Examining the Fimbriated end (SEE-FIM) protocol by Johns Hopkins gynecologic pathologists (Gyn Path), while the other half is sent overnight in organ transplant media to MIT for imaging on OVASEEK. Hyperspectral “label free” first pass imaging is performed using a series of band-pass filters. Second pass fluorescence imaging is then performed using nanoparticles tagged with anti-LAMC1 antibodies targeting laminin γ1, a known STIC surface marker. Abnormal signal(s) on OVASEEK imaging of the FT epithelium are tattooed with black ink, the tissue is formalin fixed and returned to Gyn Path for serial sectioning. Research findings are reported in an addendum to the formal pathology report in the electronic medical record and discussed with the patient by the gynecologic oncologist co-investigator.

Results

OVASEEK enabled non-destructive imaging over a wide field-of-view ~ 12×12 cm, with features of interest in the 1,050-1,550 nm range. In this pilot study, OVASEEK identified histopathologic abnormalities missed by standard SEE-FIM in 20% of FTs (n=2 out of 10). In each case, OVASEEK found microscopic (~200 µm) foci of salpingitis, a lymphoplasmacytic infiltrate consistent with inflammation. Performance of serial sectioning and histopathologic examination of the tattooed epithelium yielded this diagnosis.

Conclusion

Work is ongoing to improve the resolution, speed and sensitivity of OVASEEK for STIC detection. Identification of µm-sized foci of inflammation using OVASEEK is proof-of-principle that whole-organ *ex vivo* imaging of freshly excised FTs may be an innovation that improves the diagnostic performance of routine histopathology. Accurate and reproducible diagnosis of STIC and concurrent microscopic HGSC is imperative to the understanding of the early pathogenesis of HGSC in clinically actionable ways.

#6167 Spatial transcriptomic analysis identifies pancreatic cancer cell surface markers for imaging and therapy.

J. Wang, A. J. Kare, M. K. Schneider, J. Seo, A. Iagaru, G. W. Charville, W. G. Park, K. W. Ferrara;
Stanford University, Palo Alto, CA

Pancreatic cysts and precancer lesions have been reported in up to 50% of adults; however, few of the precancer lesions develop into aggressive pancreatic ductal adenocarcinoma (PDAC). Strategies for the differentiation of precancers and PDAC are needed. Recently proposed molecular imaging targets to accomplish this goal include integrin $\alpha_v\beta_6$ and fibroblast activation protein (FAP). To discover and quantitatively evaluate potential imaging and therapeutic targets, we performed Visium spatial transcriptomic (ST) sequencing on human surgical sections of normal tissue adjacent to precancers, intraductal papillary mucinous neoplasms and PDAC. All human tissues were collected in accordance with the Stanford Institutional Review Board. The resulting data were correlated with immunohistochemistry (IHC) and combined with analysis with publicly available spatial and single cell PDAC datasets to create a quantitative PDAC cancer surfaceome score. Pseudotime and receiver operating characteristic (ROC) analyses were also performed. We found that clusters with high cancer surfacesome scores were spatially correlated with a cellular morphology consistent with cancer. In the cancer cluster, the expression of surface markers *CLDN4*, *GPRC5A*, *TSPAN8*, and *CEACAM5* was enhanced more than 13-fold compared with the normal pancreas, while *FAP* and *ITGB6* were differentially expressed by less than 4-fold. Within cancer clusters, the fraction of spots overexpressing *CLDN4*, *S100P*, *ITGB6*, *MUC5AC*, *TFF1*, *CEACAM5*, and *FAP* was 88%, 87%, 78%, 66%, 59%, 47%, and 38%, respectively. The Pearson's correlation across space and expression intensity between *CLDN4*, *S100P*, *GPRC5A*, *TSPAN8*, *MUC1* and *TFF1* was greater than 0.6 for all combinations. The correlation of mRNA encoding *ITGB6* and *FAP* with cancer surfaceome markers was smaller, e.g. 0.37 and 0.01 versus *S100P*, respectively. The area under the curve (AUC) for the differentiation of PDAC from normal or precancerous tissue for *CLDN4*, *S100P*, *MUC5AC*, *TFF1*, *CEACAM5*, and *TSPAN8* was 0.9, 0.5, 0.3, 0.5, 0.8, and 0.4, respectively. From pseudotime trajectory analysis, we found that *MUC5AC* and *TFF1* increased at a precancerous pseudotime whereas *CLDN4* increased in time and space in spots corresponding to a PDAC-specific surfaceome score. This work demonstrates the feasibility of using spatial transcriptomics and IHC in human pancreatic cancer samples to discover and compare the expression of cell surface markers that can be employed in imaging and therapeutic protocols.

#6168 Sex-distinct patterns of molecular pathways associated with brain tumor edema.

P. R. Jackson[1], L. Curtin[1], S. Ranjbar[1], K. W. Singleton[1], M. M. Mrugala[1], R. S. Zimmerman[1], B. R. Bendok[1], P. Canoll[2], K. R. Swanson[1];
[1]Mayo Clinic, Phoenix, AZ, [2]Columbia University Irving Medical Center, New York, NY

Magnetic resonance imaging (MRI) is a centerpiece of clinical management of brain tumor patients, yet the biology underlying even commonly interpreted imaging changes is unclear. The purpose of this project was to understand what biology is associated with brain tumor edema abundance and if that association was sex distinct. We have developed a two-compartment model of MRI signal intensity to quantitatively estimate relative edema abundance from T2-weighted MRIs. Multiparametric MRIs were preprocessed with bias field correction and intensity normalization. The images were co-registered and segmented for abnormal regions and normal tissue. The segmentations and preprocessed images were utilized in the edema mathematical model to estimate the fraction of extracellular space (Fecs) and fraction of intracellular space (Fics). Through an ongoing image-localized biopsy collection protocol, we analyzed 179 samples (Female: 75; Male: 104) from 55 patients (Female: 21; Male: 34) for bulk RNA-Seq. Samples were characterized by their edema Fecs scores and underwent differential expression, gene set enrichment analysis using MSigDB hallmarks and cellular deconvolution using CIBERSORTx. Through differential expression and gene set enrichment analyses of these spatial biopsies, we have identified sex-distinct gene expression and pathways corresponding to regions of high vs low edema. Within highly edematous regions, male samples were amplified for respiratory pathways, while female samples were suppressed. Connecting changes on MRIs with molecular markers from image-localized biopsies provides an opportunity to identify the biological drivers of brain tumor associated imageable edema. Specifically, elucidating the sex-distinct patterns connecting changes on MRI with cellular populations and molecular pathways could be used to better interpret imaging of patients and interpreting treatment response.

#6169 High throughput *in-situ* spatial sequencing of proteins and RNA in FFPE tissue.

Michael Lawson, Yuji Ishitsuka, Andrew Pawlowski, Zhenmin Hong, Jake Koh, Kenneth Gouin, Nathan Ing, Richard Que, Yeoan Youn, Sara Ding, Tony Facchini, Ryan Costello, Katelyn Nelson, Jamie Stover, Howon Lee, Sarthak Duggal, Taylor Plaziak, Kaitlin Cameron, Mimi Abdu, Daan Witters, Martin Fabani, Eli Glezer

Singular Genomics, San Diego, CA

We have developed an high throughput high resolution in situ multi-omic platform to enable studies in the rapidly evolving landscape of oncology and immunology research.

Despite the potential of existing tools, the speed and throughput of current methodologies pose significant limitations. Here, we introduce a novel spatial sequencing platform employing a rapid 4-color SBS chemistry with sub-micron resolution imaging and an ultra-high throughput capacity. The platform simultaneously profiles RNA transcripts and proteins within formalin-fixed paraffin-embedded (FFPE) tissues. With up to 40 cm^2 of tissue area imaging within a 24-hour timeframe, the platform can power extensive, multi-omic studies in cancer research.

To evaluate the performance of the platform, we prepared 5 um serial sections from healthy and tumor kidney FFPE block and used a novel tool to precisely position multiple tissue sections on a slide. Following probe binding and amplification, we used SBS readout to profile 105 transcripts and 6 proteins (via DNA-conjugated antibodies). Images were analyzed using a custom pipeline for feature detection and decoding, and cell segmentation using Cellpose. Results showed strong correlation to single-cell transcription profiles and cell type signatures defined by scRNA-Seq. Additionally, we see good agreement between single cell transcript and protein profiles. Existing spatial biology platforms are known to struggle with degraded and challenging clinical sample types (e.g. decalcified bone marrow), due to RNA fragmentation. We successfully profiled immune cells in FFPE-embedded bone marrow biopsies, measuring 143 transcript targets and 8 proteins. We believe this represents a significant step forward for in-situ analysis of bone marrow samples, and could be valuable for studying the pathology and response to treatment in blood cancers such as AML and CML.

In-situ sequencing of antibody genes and T-cell receptors provides a deeper view of cellular immune response. As a step towards this goal, we demonstrated in-situ sequencing of antibody heavy and light chains within a B cell line, resulting in accurate readout of 28 bases within the CDR3 regions.

In conclusion, we present an SBS-based approach for in-situ detection of targeted gene transcripts and proteins at an unprecedented throughput, and its application to the analysis of human kidney and bone marrow FFPE tissue samples. The capability to deeply profile tissues at high throughput could enable larger translational studies, and assembly of 3D maps of gene and protein expression at sub-cellular resolution.

#6170 Risk stratification of smoldering multiple myeloma using fourier transform infrared spectroscopy of serum.

D. Dingli[1], D. Khonkhammy[2], C. Gunnarson[2], G. Schlauderaff[2], D. Q. Pham[2], A. Khammanivong[2];
[1]Mayo Clinic, Rochester, MN, [2]Oncodea Corporation, St Paul, MN

Background: Smoldering multiple myeloma (SMM) is a state where patients have more than 10% clonal plasma cells or a serum monoclonal protein > 3g/dl but no evidence of end organ damage. Patients with SMM are at risk of developing active multiple myeloma (defined by the CRAB criteria). The best stratification system with respect to the risk of progression to active myeloma is the 20/2/20 (20% plasma cells, M protein >2.0 g/dl, and involved to uninvolved immunoglobulin free light chain ratio >20). The presence of ≥2 criteria predicts a 50 - 60% risk of progression within 2 years. Thus, many patients considered 'high-risk' may *not* progress in this time frame, and patients with ≤1 risk factor *can* progress to active myeloma. Therefore, improved risk stratification methods are needed to correctly identify patients at high risk of progression. We hypothesized that Fourier Transform InfraRed (FTIR) spectroscopic analysis of serum combined with artificial intelligence (AI) can correctly risk stratify patients with SMM.

Methods: We identified 192 SMM patients: 96 who progressed and 96 who did not progress within 2 years of diagnosis. We used stored sera from the time of diagnosis to perform FTIR to determine differences in the spectra of patients who did/did not progress and train an AI algorithm. A randomized 10-fold cross-validation analysis was performed using 172 samples (86 from each group) for training and the remaining 20 for testing to assess the model across 10 independent iterations. Subsequently, we blindly tested the trained model against an independent set of serum samples (N=24) from patients who progressed ≤3 years of diagnosis. Receiver operator characteristic (ROC) analysis was used to assess the FTIR AI algorithm output compared to the clinical outcome data.

Results: From the 96 patients who *progressed*, 48 had complete data for the 20/2/20 risk stratification. 11 patients (23%) had ≤1 of the criteria and so would have been considered at low likelihood to progress. Of the 96 who did *not progress* within 2 years, 49 had complete data for risk stratification. Of these, 27 (55.1%) met the high-risk criteria of the 20/2/20 classification and would have been predicted to progress within 2 years. FTIR/AI model correctly identified the patients at risk of progression (95% accuracy) with AUC of 0.96. Similarly, it was able to classify patients who did not progress within 2 years of diagnosis (94% accuracy) with an AUC of 0.96. FTIR/AI correctly predicted the patients at risk of progression within 2 years (90%) and 3 years (87.5%) in the blinded validation group with an AUC of 0.89 and 0.82, respectively.

Conclusion: Analysis of serum in patients with newly diagnosed SMM with FTIR is able to correctly identify those at risk of progression within 2 or 3 years of diagnosis with an accuracy of ~90% in a blinded external validation study. FTIR may, therefore, be used to assess SMM patient risk before committing to potentially toxic therapy.

#6171 Evolution of the spatial myeloid-lymphoid engagement in glioblastoma under temozolomide treatment.

S. P. Castillo, A. Jahedi, P. Gupta, J. T. Huse, K. Kannan, Y. Yuan, K. P. L. Bhat;
The University of Texas MD Anderson Cancer Center, Houston, TX

The current standard of care for glioblastoma (GBM), encompassing surgery, chemotherapy, and radiation, fails to extend patient survival beyond ~12-15 months. Even advanced immunotherapies, such as checkpoint blockade and chimeric antigen receptor-armored T-cell therapies, are ineffective in GBM due to tissue-specific niche-dependent escape strategies employed by glioma cells. Immune effectiveness, a finely regulated spatial and context-dependent process, underpins such a dismal state of the present therapeutic options. Herein, we applied CO-Detection by indEXing (CODEX), a state-of-the-art multiplex imaging platform, to elucidate the immune cell networks of the tumor microenvironment. By harnessing computational tools on multiplexed regions of interest across whole-slide images, we characterize the immune repertoire of GBMs by studying intratumor heterogeneity across space-histological territories- and time, matching pre- and post-treatment tissue sections of GBMs from seven patients under treatment (Stupp protocol). We aimed to assess changes in the interactions between the two main compartments of the immune system, myeloid and lymphoid, pre- and post-treatment using spatial statistics. We designed a computational workflow for the georeferencing, classification, and phenotyping individual cells of CODEX images across 105 regions of interest, representative of a mosaic of histologically defined cellular tumor (CT) or infiltrating tumor. We defined six major immune phenotypes and evaluated their spatial association with $Cd45^{-}Nestin^{\pm}Olig2^{\pm}$ glioma cells. We modeled the GBM ecosystem and the cells' spatial coexistence as spatial point processes that allowed the projection of coexistence networks. After stringent quality control, we detected and phenotyped 2.3M cells. Despite interpatient heterogeneity, some patients maintained an even immune composition, while others showed an enrichment in microglia, particularly in CT. Spatial network analyses revealed an increased coexistence between myeloid and lymphoid cells after treatments despite T cells being canonically considered moderately abundant. Quantitatively, the immune meta-network displayed higher edge density and lower modularity post-treatment compared with pre-treatment, reflecting increased lymphoid-myeloid engagement. In summary, we detected an increased spatial myeloid-lymphoid engagement in GBM undergoing chemo-radiation treatments. Spatiotemporal rearrangement of tumor-immune interactions indicates mechanisms implicated in disease recurrence and resistance to standard treatment, opening the frontiers for developing new targeted immunotherapies.

#6172 Accurate PD-L1 IHC assessment in urothelial carcinoma by an AI algorithm robust across multiple sites, antibody clones, and scanners.

N. Abele[1], D. Calvopina[2], D. Mulder[2], P. Frey[2], E. Karakok[3], F. G. Salman[3], M. Oktay[3], M. Eckstein[1], S. Springenberg[2], A. Hartmann[1], T. Lang[2];

[1]Institute of Pathology, University Hospital Erlangen, Friedrich-Alexander-Universitat Erlangen-Nurnberg, Comprehensive Cancer Center Erlangen-EMN (CCC ER-EMN), Erlangen, Germany, [2]Mindpeak GmbH, Hamburg, Germany, [3]Memorial Hospitals Group, Istanbul, Turkey

Background: Immunotherapy against PD-L1 is used for treatment of several indications of Urothelial Carcinoma (UC). Recent results indicate that it is likely to become part of the standard first-line treatment regimen for advanced UC in the near future. Accurate readout of Immunohistochemical (IHC) PD-L1 expression is therefore essential to inform UC treatment decisions. However, manual PD-L1-scoring is prone to high inter- and intra-observer variability. Artificial intelligence (AI) may help to improve standardization, accuracy and efficiency of PD-L1 IHC scoring. Yet, previous AI-based approaches struggled to show consistency across images that are diverse with regards to the source institutions, antibody clones, and scanning hardware used. Methods: We developed an AI software for PD-L1 tumor proportion scoring (TPS/TC) on whole-slide images (WSIs) of UC without human supervision. PD-L1 analysis by the software is fully-automated, does not require any adaptation steps, and is concordant with current clinical guidelines. The performance of the software was evaluated on two cohorts of PD-L1 stained UC samples against ground-truth (GT) TPS/TC scores given by human pathologists in clinical routine. The first cohort (n = 53) consisted of samples stained with the 22C3 antibody clone (Agilent) derived from four institutions and three scanner models. It contained both tissue microarray samples and scans of UC resectates. A second validation cohort consisted of n = 83 WSIs stained with the SP263 clone (Ventana), collected from two institutions. Results: For the threshold of TPS≥1% (cut-off established for adjuvant therapy with Nivolumab), agreement rates of AI scores with human GT scores were 92.5% for cohort 1 (22C3) and 96.4% for cohort 2 (SP263). Sensitivity/specificity values were 92.3%/92.9% for cohort 1 and 100%/93.6% for cohort 2. Across both cohorts (n = 136) the agreement rate between AI and human was 94.9%. Conclusions: Across 136 UC samples stained with two PD-L1 antibody clones, and derived from a total of four institutions and three scanner models, the fully automatic AI system showed excellent agreement with human pathologist scores. These results on challenging validation data show the potential of AI applications to standardize and optimize PD-L1 scoring and demonstrate consistency and safety of suitable AI-based systems for application in clinical routine.

#6173 The development and evaluation of a convolutional neural network for melanoma detection in whole slide images.

E. L. Clarke[1], D. Magee[1], J. Newton-Bishop[1], W. Merchant[2], M. Hall[1], R. Insall[3], N. Maher[4], R. Scolyer[4], G. Farnworth[1], A. Ali[1], S. O'Shea[5], D. Treanor[1]; [1]University of Leeds, Leeds, United Kingdom, [2]Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom, [3]University College London, London, United Kingdom, [4]Melanoma Institute Australia, Sydney, Australia, [5]South Infirmary Victoria University Hospital, Cork, Ireland

The current melanoma staging system is predictive of 74% of the variance in survival, with prognostic biomarkers subject to high levels of inter-observer variation. The application of convolutional neural networks (CNNs) to whole slide images (WSIs), may reveal new insights into tumor morphology and therefore patient prognosis.

Melanoma morphology appears to be of greater significance than in other solid tumors, with Breslow thickness remaining the strongest prognostic indicator. Other biomarkers based on tumor morphology have been generated and although some have been found to be prognostically superior to Breslow thickness, none have been integrated into clinical workflows. This may in part be explained by their demands on pathologist time. Therefore, this work outlines the development and evaluation of a CNN for invasive cutaneous melanoma detection in WSIs, which may be used for prognostic biomarker generation.

1,157 WSIs containing cutaneous melanoma from five datasets (three from the University of Leeds, one from the Melanoma Institute Australia, as well as The Cancer Genome Atlas) have been used in the initial development and evaluation of the CNN. A custom-designed 2-class tumor segmentation network with a fully convolutional architecture was trained using annotations. The CNN was evaluated using various methodologies, including comparison at per-pixel and per-tumor levels as compared to manual annotation, as well as variation across 3 scanning platforms (Leica Aperio AT2 (Milton Keynes, UK), Roche Ventana DP600 (Arizona, US) and Hamamatsu NanoZoomer S360 (Hamamatsu City, Japan).

The CNN detected and located invasive melanoma tissue of no specific type with an average per-pixel sensitivity and specificity of 97.6% and 99.9% respectively across the 5 test sets. There were no statistical differences between tumor dimensions generated by the CNN as compared to manual annotation. Similarly, there were no statistically significant differences between CNN generated tumor dimensions across three scanning platforms.

We have developed and performed initial evaluation of a CNN which appears to accurately detect invasive cutaneous melanoma of no specific type in WSIs for objective evaluation of tumor morphology. Future work should interrogate these data further for its propensity to predict survival outcomes.

#6175 Deep learning-based survival prediction for hepatocellular carcinoma using whole slide images.

S. Lee[1], H.-J. Jang[2];

[1]Seoul St. Mary's Hospital, The Catholic University of Korea, Seoul, Korea, Republic of, [2]College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic of

There is an increasing need for classifiers to effectively stratify prognosis in patients with hepatocellular carcinoma (HCC). Deriving interpretable prognostic features using deep-learning (DL)-based prognostic models from pathology images remains a challenge. In this study, we developed a computational approach based on DL to predict the overall survival (OS) of HCC patients from formalin-fixed paraffin-embedded histopathology whole slide images. A DL model for classifying good and poor prognosis was developed on a total of 460 patients with 2 independent cohorts from Seoul St. Mary's Hospital. The primary outcome was OS. The training set (SSM1, n = 292) included HCC patients that had undergone surgical resection. The classifier was then independently tested on the second HCC dataset (SSM2, n = 168). The area under the curve (AUC) for the receiver operating characteristic (ROC) curves was 0.850 and 0.781 for SSM1 and SSM2 datasets, respectively. In addition, we have tried to establish DL model for prediction of OS based on clinicopathological features, including Edmondson-Steiner grade, pT stage, vascular invasion, Ki-67 index, and cytokeratin 19 immunohistochemical expression. Random forest model was applied to classify the good and poor prognosis groups and The AUROCs for the random forest was 0.705 for the SSM1 dataset, which are inferior to that of DL prediction. These findings suggest that the DL techniques can be applied to refine the prognostic prediction of HCC patients.

#6176 Identifying poor prognosis stage I lung adenocarcinoma patients through novel morphological biomarker based on computational pathology.

F. J. Song[1], A. Andoni[1], M. Kordahi[2], S. Batelli[1], A. Meier[1], M. Schick[1], E. Mahieu[1], G. Schmidt[1], C. E. Myers[3], M. Abadier[4], A. Dasgupta[3], C. Abbosh[5], D. Hodgson[5], M. Orain[2], F. C. Lamaze[2], Y. Bosse[2], P. Joubert[2];

[1]AstraZeneca, Munich, Germany, [2]Institut universitaire de cardiologie et de pneumologie de Quebec - Universite Laval, Quebec City, QC, Canada, [3]AstraZeneca, Gaithersburg, MD, [4]AstraZeneca, Waltham, MA, [5]AstraZeneca, Cambridge, United Kingdom

Current practice for evaluating prognosis of resectable lung adenocarcinoma (LUAD) patients relies on the Tumor, Node, Metastasis staging system. Despite low relapse risk, post-recurrence survival in a stage I population is poor with a median post relapse survival of around 25 months. There is a need for a biomarker that can enrich for stage I patients with relapse risk to identify a population likely to benefit from adjuvant therapy. In this study, we aim to identify a predictive biomarker of relapse in early-stage lung cancer following surgical resection using AI-based computational pathology.

The retrospective patient cohort analyzed in this study consisted of a total of 166 patients that underwent surgical resection for a clinical stage I LUAD. Out of these, 54 patients experienced disease recurrence within 5 years, and 112 patients had a confirmed disease-free period of at least 5 years post-surgery. For each patient, at least one digitized slide (average = 2.46) stained with haematoxylin and eosin (H&E) was available for analysis. The project was accepted by the IUCPQ ethics committee (2022-3751, 22138).

Manual annotations delineating the tumor core (TC) were drawn by pathologists. We then applied several proprietary image analysis models capable of distinguishing epithelium, stroma, and necrosis within the tumor tissue as well as detecting tumor infiltrating lymphocytes (TILs) and cell nuclei. In this project, we additionally introduce a novel approach rooted in mathematical graph theory to encoding topological aspects of the tissue morphology. A cell-graph constructed from the positions of cell nuclei was used to calculate cell-level graph-theoretic measures which were then aggregated to the slide-level by computing the median. In total, 23 data readouts were obtained of which 14 were based on the standard image analysis pipeline alone, and a further 9 originated from our newly developed graph-based approach.

We identified promising biomarkers using the Wilcoxon rank-sum test and the area under the ROC curve (AUROC); robustness of this evaluation was investigating using resampling methods, using 100 bootstrap samples and 100 repeats of 3-fold cross-validation, respectively. This allowed us to evaluate the prognostic value of the biomarkers with respect to 5-year relapse or death.

We were able to identify the best prognostic biomarker for relapse to be the median weighted clustering coefficient (CC) across all cells in the TC area, which is derived from the graph-based analyses. The median CC was able to achieve a whole-cohort AUROC of 0.695 (average cross-validated AUROC = 0.675, 95% interval 61.7%-70.4%) as well as a relapse vs relapse-free Wilcoxon test p-value of 4.65x10-5 (bootstrapped average = 0.0002). In addition, we were also able to demonstrate that the biomarker shows some relation to the architecture patterns.

#6177 Machine learning enables prediction of ADC targets from whole slide H&E images.

Z. R. McCaw, A. Shcherbina, Y. Shah, insitro Research Team, P. Tagari, D. Koller, C. Probert;
Insitro, South San Francisco, CA

Background: The efficacy of antibody-drug conjugates (ADCs) depends on the expression and specificity of the target antigen by tumor cells. Although H&E-stained slides are routinely collected during cancer care, specialized IHC staining is typically required to ascertain antigen expression. Such stains are not always available or readily deployed. The need to perform separate IHC tests for each candidate ADC may burden clinical labs and can hinder access to care in resource-limited settings. Here we develop an ensemble of machine learning models to accurately predict the expression of 166 distinct ADC targets directly from H&E images.

Methods: For each ADC-targeted gene, patients with copy-number amplifications (CNAs) were identified from somatic whole exome sequencing. Genes differentially expressed in patients with CNAs were identified from bulk transcriptomics. For each gene, an expression signature was developed based on the expression levels of differentially upregulated genes. Next, whole-slide, H&E-stained histopathology images were embedded into a lower-dimensional representation via a transformer model trained with self-supervised learning. Neural networks were developed to predict a patient's probability of having a CNA in an ADC-targeted gene, as indicated by an expression signature exceeding the p90. All evaluation metrics were ascertained by 5-fold cross-validation, with training and evaluation on independent patients.

Results: For each of the 166 ADC-targeted genes, a median of 154 patients were found to harbor a CNA, and the expression signature included a median of 180 genes. In all cases, patients with CNAs had significantly higher expression signatures than those without. For predicting likely CNA status directly from H&E histopathology images, the mean AUROC was 0.888 (95% CI, 0.876-0.900) and the mean AUPRC was 0.571 (95% CI, 0.531-0.611). Among the 166 ADC-targeted genes, the AUROC exceeded 0.95 for 31.3%, 0.8 for 80.7%, and 0.725 for 100%. The best-predicted ADC target was SLC7A5 (AUROC: 0.995 [95% CI, 0.994-0.998]; AUPRC: 0.967 [95% CI, 0.963-0.976]).

Conclusion: We have developed models that accurately predict the likely expression of ADC targets based solely on H&E images. The ability to accurately discern the presence of ADC antigens from H&E images has numerous potential applications, including cohort refinement, computer-aided diagnosis, and personalized treatment planning.

#6178 Automating tumor purity assessment: Advanced AI-driven segmentation and classification of nuclei in H&E stained slides.

N. R. Wagner, K. Kikuchi, K. Fukuda, N. Spasic, S. Littlechild, S. Todorovic, D. Stojnev, M. Jovanovic, C. Weston;
Reveal Biosciences Inc., San Diego, CA

Background
Tumor purity, the proportion of cancerous cells within a tumor mass, is a pivotal factor in oncological research and clinical practice and plays a significant role in the molecular testing workflow, particularly when selecting samples for genomic analysis. Accurate assessment of tumor purity is crucial for understanding tumor behavior, guiding treatment decisions, and predicting patient outcomes. Traditional methods of analyzing hematoxylin and eosin (H&E) stained slides for tumor purity are predominantly pathologist manual readouts. This process is both time-consuming and prone to inter- and intra-observer variability, leading to inconsistencies in diagnosis and treatment planning. Here, we introduce an automated AI-based product designed to streamline tumor purity analysis. The RevealAI-HE digital assay leverages state-of-the-art AI algorithms to automate the segmentation and classification of nuclei in H&E slides, enhancing the accuracy, consistency, and speed of tumor purity assessment. RevealAI-HE aims to assist pathologists in decision-making, support oncology research, streamline molecular testing workflows, and improve personalized care.
Methods
H&E stained solid tumor slides were imaged using 3D-Histech Pannoramic 1000 and 250 scanners. From this dataset, 104 regions of interest (ROIs) were manually selected to cover a wide range of H&E stain intensities in 14 different indications. A nuclear segmentation model based on StarDist-H&E was deployed on these ROIs, and a pathology expert manually assigned one of three classifications to each nuclei: tumor, immune, and stroma. The resulting ground-truth dataset of over 26,000 classified nuclei was used for training a classifier model based on a ResNet architecture. For model evaluation, the nuclei dataset was randomly split into training (80%) and testing (20%) the model, and the training data was batched and randomized for each training epoch to ensure robustness and generalizability. The nuclear segmentation, nucleus classifier, and tumor purity statistics models were integrated into an end-to-end digital assay (RevealAI-HE) using Reveal Biosciences' proprietary digital assay development pipeline. RevealAI-HE is integrated into Reveal Biosciences' flagship whole slide image management system, ImageDx.
Results
The RevealAI-HE digital assay's nucleus classification model achieved a high accuracy across all 14 indications. Compared to manual methods, the AI system significantly reduced the time required for tumor purity analysis. Furthermore, the AI model exhibited excellent consistency in its analyses, addressing the issue of variability seen in manual assessments. These results indicate that our AI product, in many aspects, surpasses the current gold standard of tumor purity analysis (pathologist readout), offering a more efficient, accurate, and reproducible approach.

#6179 Machine learning (ML)-spatial quantification of the tumor microenvironment (TME) identifies differences associated with response to bintrafusp alfa (BA) *vs* pembrolizumab (PEM) treatment in the Phase 3 INTR@PID Lung 037 study.

J. Abel[1], A. Machl[2], A. Gerhold-Ay[3], L. Yu[1], D. Sanghavi[1], B. Trotter[1], N. Patel[1], Y. Gerardin[1], R. Srinivasan[4], S. Brutus[5], T. Mrowiec[3]; [1]PathAI, Boston, MA, [2]EMD Serono, Billerica, MA, [3]The Healthcare Business of Merck KGaA, Darmstadt, Germany, [4]Calico Life Sciences, South San Francisco, CA, [5]Mass General Brigham Ventures, Cambridge, MA

Background: ML digital pathology models can accurately quantify predictive biomarkers like PD-L1.[1] We combined tissue conserving ML assessment of the TME in hematoxylin and eosin (H&E)-stained whole slide images (WSI) with RNAseq for high-dimensional TME quantification for biomarker discovery. The orthogonal methods were applied to a retrospective analysis of a Phase 3 trial directly comparing BA, a first-in-class bifunctional fusion protein composed of the extracellular domain of TGF-βRII (a TGF-β “trap”) fused to a human IgG1 monoclonal antibody blocking PD-L1, and the anti-PD-1 PEM.

Methods: Non-small cell lung cancer ML models previously trained to exhaustively quantify cell types and tissue regions in H&E-stained tissue were refined and deployed on 273 WSI from the INTR@PID Lung 037 study/NCT03631706. Human interpretable features (HIFs) describing the complex spatial organization of the TME were extracted from model predictions. HIFs were selected for analysis using K-means consensus clustering and describe the frequency of lymphocytes in cancer epithelium (cTILs); macrophages, fibroblasts, and granulocytes in stroma; and the abundance of cancer cells relative to all other cells in tumor. Bulk RNAseq was performed for 186 samples yielding 177 WSI-RNAseq pairs. Spearman correlation between HIFs and gene expression or signature was computed. Top gene associations were analyzed via gene-set enrichment analysis. HIFs were used for immunophenotyping (immune excluded, inflamed, and desert) via prespecified cutoffs on tumor-infiltrating lymphocyte abundance, and for biomarker discovery via Cox modeling of PFS and OS.

Results: Gene expression and signatures were associated with HIFs quantifying immune spatial abundance in TME (e.g., cTILs vs. immune checkpoint signature[2]). Improved PFS and OS were associated with an immune-inflamed phenotype for PEM (PFS, HR=0.36, p=0.007, 95% CI 0.17-0.75; OS, HR=0.37, p=0.065, 95% CI 0.13-1.06). In interaction with BA, stromal macrophages were associated with improved survival (PFS, HR=0.72, p=0.062, 95% CI 0.53-1.02; OS, HR=0.62, p=0.058, 95% CI 0.38-1.02) and an increased likelihood of treatment response (odds ratio=1.61, p=0.015). PFS and OS were nearly identical between arms in immune-excluded cases (PEM vs. BA PFS, HR=0.93, p=0.73, 95% CI 0.63-1.39; OS, HR=1.09, p=0.77, 95% CI 0.62-1.92.

Conclusion: Together HIFs and immunophenotyping enabled response prediction to BA and PEM. PEM response was greater for immune-inflamed tumors, while BA response was associated with macrophage infiltration of stroma. ML-based spatial analysis of the TME shows promise for immunotherapy biomarker discovery and validation. [1]V Baxi, et al. *Modern Pathology*. 2022; 35(1):23-32. [2]S Mariathasan, et al. *Nature*. 2018; 554(7693):544-548.

#6180 Tumor microenvironment phenotypes predict recurrence in African Americans diagnosed with colorectal cancer: A comparative study of manual grading with digital pathology.

D. Wu[1], R. Xia[1], M. Alawad[1], L. Lee[2], T. Gonda[1], W. Cao[1], S. Hacking[1];

[1]NYU Grossman School of Medicine, New York, NY, [2]NYU Long Island School of Medicine, New York, NY

African Americans face a higher rate of colorectal cancer (CRC) incidence and mortality compared to other ethnicities. Identifying key prognostic factors is essential for better outcomes in this group. This study focused on the prognostic value of stromal grading in the tumor microenvironment (TME) of African American CRC patients, using both manual grading and digital pathology. A retrospective analysis of CRC cases in African Americans was conducted. Two cohorts were established: a control cohort (patients without recurrence) and a recurrence cohort (patients with recurrence). Stromal grading was performed manually, categorizing tumors into Grade 1 (low risk), Grade 2 (moderate risk), and Grade 3 (high risk), and we also quantified the TME percentages by digital pathology: myxoid, collagen, immune and tumor. In the control cohort (N=40), stromal grading identified 30 Grade 1, 7 Grade 2, and 3 Grade 3 cases. Conversely, the recurrence cohort (N=17) demonstrated a starkly different distribution, with 1 Grade 1, 3 Grade 2, and 13 Grade 3 cases. The Chi-square statistic was notably significant ($p<0.0001$), indicating a strong association between higher stromal grades and the likelihood of recurrence. By unpaired t-test, high myxoid stroma ($p<0.0001$), low collagen ($p<0.0001$), and low tumor ($p=0.0002$) by digital pathology were associated with recurrence. TME phenotypes are a significant prognostic and recurrence indicator in African American patients with CRC. The marked difference in stromal grades and digital pathology features between the control and recurrence cohorts suggests that higher stromal grades, along with higher myxoid, lower collagen and lower tumor percentages are associated with an increased risk of recurrence. These findings underscore the need for tailored therapeutic strategies and more vigilant surveillance in African American patients exhibiting high-risk TME phenotypes. The efficacy of manual and digital pathology evaluation of the TME also warrants further exploration to enhance prognostic accuracy and treatment personalization.

#6181 Digital pathology workflow: Building a bridge for translational biomarker development in humanized mice.

M. Hakkarainen[1], T. Bragge[1], J. Rytkonen[1], E. Oswald[2], **J. B. Schueler**[2];
[1]Charles River Laboratories, Inc., Kuopio, Finland, [2]Charles River Laboratories, Inc., Freiburg, Germany

The introduction of immune checkpoint inhibitors (ICIs) directed against programmed death protein 1 (PD-1), as well as cytotoxic T lymphocyte antigen 4 (CTLA-4), has revolutionized the treatment of non-small cell lung cancer (NSCLC) in the last decade. These therapies have shown significant success in a subset of NSCLC patients, leading to durable response and improved overall survival. However, clear predictive biomarkers for response are still yet to be defined. Tumor-infiltrating lymphocytes (TILs) as one important part of the tumor microenvironment (TME) have proven to be predictive biomarkers in other tumor types such as melanoma, whereas not fully understood in NSCLC. The assessment of TILs typically involves techniques such as flow cytometry (FC) or immunohistochemistry (IHC). While the former has the advantage of being quantitative and relatively easy to standardize it lacks translational value as most clinical samples will be examined using IHC. The current study aims to compare both methods at terminal end point and for treatment outcome, using a panel of 14 NSCLC PDX models, implanted in humanized NSG mice and treated with anti-CTLA4, anti-PD1 and the combination thereof. Based on FC analyses of the untreated tumor tissue the PDX models were stratified into seven hot (>5% TILs) and seven cold (<5% TILs) tumors. The IHC samples were analyzed by digital pathology for TIL infiltration by making use of automated segmentation of the three main tissue classes: tumor, stroma and necrosis. Small number of IHC slides were manually annotated to form a training set, which were then used to train a deep learning model using Visiopharm, a commercial AI platform for image analysis. By quantification of TILs in a spatial context of the tumor tissue, across all models, tumor was the most prominent tissue class. The tissue class distribution as well as the TIL rate (FC or IHC measure) is a model immanent feature. Under treatment, the ratio was stable in case of the cold tumors. In the hot tumors the stroma compartment increased while tumor tissue decreased. Treatment sensitive models displayed an increase of TILs confirmed by FC and IHC. The latter revealed that the TILs specifically increased in the tumor tissue whereas decreased or was stable in the stroma. This observation was significantly more pronounced in cold tumors compared to hot tumors (Oneway ANOVA, $p < 0.001$). Furthermore, a positive correlation between FC and IHC results on CD45 positive cells in the tumors ($p< 0.002$) could be confirmed. In this study, we proofed the feasibility of software-based image analysis as translational relevant read-out in preclinical animal experiments. The possibility to reproducibly quantify tissue classes, immune cell markers and including spatial information paves the way towards discovery of novel features predicting response in translational immuno-oncology research.

#6182 Artificial intelligence (AI)-powered quantification of glypican-3 (GPC3) expression facilitates patient selection for GPC3-targeted therapy in solid tumors.

E. Meng[1], R. Meng[2], Y. Tong[3], Y. Li[3], H. Wang[2], P. Fiorentini[4], E. Attieh[5], Q. Tang[2], A. Kefsi[4], S. Masciari[2], G. Abbadessa[2], C. Combeau[5], L. Tang[1], B. Pasquier[5], **R. Wang**[2];

[1]Sanofi, Jiangsu, China, [2]Sanofi, Newton, MA, [3]WuXi AppTec Co., Ltd., Shanghai, China, [4]Sanofi, Vitry-sur-Seine, France, [5]Sanofi, Chilly-Mazarin, France

Introduction: GPC3 is a glycosyl-phosphatidylinositol-anchored cell surface glycoprotein that functions to control cell growth and differentiation in early development. Membrane GPC3 is highly expressed in hepatocellular carcinoma (HCC) and moderately in squamous non-small cell lung cancer (SQ-NSCLC) with limited expression in normal tissues which makes it an attractive target for immune cell engagers. This study aims to develop an AI-powered algorithm to evaluate GPC3 expression and compare it with manual immunohistochemistry (IHC) scoring in HCC, adeno-NSCLC and SQ-NSCLC.

Methods: 147 NSCLC (94 SQ-NSCLC and 53 adeno-NSCLC) and 113 HCC FFPE tumor blocks were obtained from commercial sources. GPC3 protein level was quantified by a qualified IHC assay for tumor cell membrane and cytoplasm individually. PD-L1 expression is reported as tumor cell proportion score (TPS), combined positive score (CPS) and immune cell proportion score (IPS/IC) TPS, regardless of staining pattern and intensity. FFPE slides were stained for GPC3+ (GC33, Ventana), PD-L1+ (22C3, Dako) cells and then scanned at 20x using the Aperio Versa8 scanner. Machine learning (ML) models were developed using the digitized whole slide images to identify GPC3+ tumor area. Data-driven cutoffs were applied to model-generated human-interpretable features of GPC3+ percentage of tumor area to classify samples as positive and negative. As an orthogonal approach to the GPC3+ percentage cutoff method, tissue and cell annotations were used to train a convolutional neural network (CNN) to classify GPC3 positivity.

Results: The epidemiology profiling results revealed that GPC3 protein is highly expressed in HCC (57.5% cases with > 1% positive cells), followed by SQ-NSCLC (52.1%) and adeno-NSCLC (5.7%). GPC3 expression was only detected in tumor cells with two staining patterns observed: membrane + cytoplasm and cytoplasm-only. There was no significant correlation between GPC3 and PD-L1 expression across tumor types, although a trend of lower level of PD-L1 was observed in the samples with GPC3 ≥50%. ML model quantification of GPC3+ and GPC3- showed high concordance with the consensus score of 2 independent pathologists on a test set of held-out samples not used in training. This concordance was comparable to that of individual annotators to consensus. Instead, GPC3 positivity results using both cutoff and CNN methods showed moderate concordance with 2-way pathologist consensus.

Conclusions: Here we profiled GPC3 expression across tumor types and showed high level of expression in HCC followed by SQ-NSCLC. We have established an AI-powered digital pathology platform that can provide a standardized, scalable, and reproducible method of characterizing GPC3 positivity to support further patient selection in clinical study.

#6183 Exploring the role of microenvironment context on diagnostic accuracy in tissue microarray core selection.

A. Woicik[1], Z. R. McCaw[1], B. Dulken[2], insitro Research Team, C. Probert[1];
[1]Insitro, South San Francisco, CA, [2]Stanford School of Medicine, Stanford, CA

Background: Tissue Microarrays (TMAs) stand to significantly improve the efficiency of multiplex spatial studies by including core samples taken from many tumor blocks in a single slide. However, as TMAs become increasingly prevalent, the implication of core selection within the tumor microenvironment (TME) on downstream discoveries is not well understood. This raises the question of which TME contexts are most predictive for scientific analyses.
Methods: We segment whole tissue section (WTS) slides with a U-Net trained on pathologist annotations of tumor, DCIS, LCIS, normal, stromal, immune, and necrotic microenvironment contexts in 100 TCGA BRCA slides. We focus on 5-way PAM50 subtype prediction in breast cancer. We produce image embeddings for each core using a vision transformer pre-trained on histopathology images and use an attention-based aggregation model to predict PAM50 subtype. To evaluate the impact of core TME contexts in a held-out test set, we sample 0.6mm radius circular sections from 281 WTS images from 54 patients to produce one dataset of “majority non-cancerous” cores that the TME annotation model predicts as majority normal breast epithelial or necrotic tissue and one “majority cancerous” TMA dataset for the remaining cores.
Results: We find that core microenvironment context directly influences diagnostic accuracy. Maximizing tumor content improves diagnostic accuracy on the PAM50 task, with the majority cancerous TMAs obtaining an AUROC of 0.80 (95% confidence interval 0.75-0.85), relative to 0.72 (95% CI 0.66-0.78) for majority non-cancerous TMAs and 0.82 (95% CI 0.80-0.84) for WTS images.
Notably, our context-aware TMA sampling achieves accuracy within 2% of the WTS images, while poorly selected TMA cores underperform the WTS baseline by 10% on average. While TCGA is curated to contain patients with a very high tumor burden, and consequently random TMA selection performs well on this cohort (AUROC 0.77; 95% CI 0.74-0.79), our study indicates that tissue context is an important consideration when selecting cores from real donor tissue blocks.
Our results demonstrate that TMA core sampling protocols should be informed by TME context to maximize analysis accuracy, and that intelligent core sampling can largely close the gap to WTS image accuracies on clinically-relevant tasks like PAM50 subtype prediction. These findings highlight the need for thoughtful TMA dataset construction and usage, especially as core selection becomes increasingly automated. We argue both for more targeted core selection from donor tissue blocks and for filtering of existing datasets. To avoid performance degradation, pipelines should identify and exclude these less task-relevant TMEs, where simulation serves as an efficient and task-specific approximation of TME context relevance.

#6184 A novel approach to Barrett's esophagus risk stratification: Whole-slide image analysis for aneuploidy detection.

C. Ercan[1], X. Pan[1], T. G. Paulson[2], M. D. Stachler[3], C. C. Maley[4], Y. Yuan[1];

[1]The University of Texas MD Anderson Cancer Center, Houston, TX, [2]Fred Hutchinson Cancer, Seattle, WA, [3]University of California San Francisco, San Francisco, CA, [4]Arizona State University, Tempe, AZ

Background

Barrett's esophagus (BE) is the only known precursor of esophageal adenocarcinoma (EAC) and there is a need for biomarkers in BE for risk stratification for cancer progression. Aneuploidy has been suggested as a factor in the development, initiation or progression of EAC in patients with BE, and it has been found predictive for EAC progression (Hadjinicolaou, et al. 2020, Sikkema, et al. 2009). However, current assays for detecting aneuploidy require valuable tissue, hence validation studies are limited. We hypothesise that routine histology images can be used to detect ploidy status. We aim to develop a sensitive, accurate, and easy-to-use deep learning tool for this purpose.

Methods

We used a weakly supervised deep learning-based approach called clustering-constrained-attention multiple-instance learning (CLAM) (Lu et al., 2021) to detect aneuploidy on hematoxylin and eosin-stained whole slide images of endoscopical biopsies from BE, for which the ploidy status had been determined by flow cytometry. To benchmark the model's performance, we also trained a traditional fully supervised algorithm, ResNet50 (He et al., 2016), with the same dataset. The models were trained on 388 slides (51 aneuploid) from the Seattle Barrett's Esophagus Annotated Resource (BEAR) and then applied to an independent test cohort of BEAR patients, consisting of 279 slides (36 aneuploid).

Results

The multi-attention-branch CLAM model achieved AUC of 0.82 and 76.4% balanced accuracy for aneuploidy on the internal test subset (10% of the cohort). On the independent test dataset, the model achieved AUC of 0.85 and 79.3% balanced accuracy, while performance of the fully supervised model was AUC of 0.65 and 33.1 balanced accuracy. In a challenging subset for image-based diagnosis, including 253 samples (29 aneuploid) without dysplasia or atypical mitosis (a major feature of aneuploidy samples) the model achieved a 67.6% accuracy and an AUC of 0.83. Both the flow results (p=2.84e-7) and the model's predictions (p=2.18e-3) revealed a correlation between progression to EAC and ploidy status.

Conclusion

We developed a deep learning model for predicting aneuploidy in BE biopsies. The weakly-supervised approach can perform much better compared to the traditional fully-supervised model. Aneuploidy is correlated with cancer progression and stands as a promising candidate for the prediction of cancer progression in BE patients. Although atypical mitosis is the primary histological indicator of aneuploidy, our model can still make aneuploid predictions in the absence of atypical mitosis, as it doesn't rely solely on a single parameter. Our model is efficient, capable of processing hundreds of samples resource-effectively, and thus an ideal adjunct to standard histologic evaluation. This classifier may facilitate molecular-based improvements in identifying individuals at high risk of progression.

#6185 Generative AI for virtual HE-staining of whole slide images of unstained breast cancer tissue.

L. Latonen[1], U. Khan[2], S. Koivukoski[1], J. Hartman[3], **P. Ruusuvuori**[2];
[1]University of Eastern Finland, Kuopio, Finland, [2]University of Turku, Turku, Finland, [3]Karolinska Institutet, Stockholm, Sweden

Introduction Hematoxylin and eosin (HE) is the standard stain used in histology to make tissue visible to the human eye by highlighting certain cellular and tissue structures, and it is a technique that is widely used in the diagnosis of cancer and other pathologies. Chemical staining, however, is irreversible, making the tissue unusable for subsequent measurements, such as spatial transcriptomics. Here we utilize generative AI method based on pix2pix image-to-image translation to generate virtual HE-staining for whole slide images (WSIs) acquired of unstained tissue with brightfield microscopy and perform a thorough histological evaluation for the feasibility in breast cancer diagnostics.

Materials and Methods We optimized sample preparation and imaging setup for virtual staining purposes, and developed a custom generative adversarial network architecture for learning the virtual staining from paires samples of unstained and H&E stained tissue. Here, we focus on the utility of virtual staining in breast cancer diagnostics, using a set of breast cancer samples for acquiring whole slide images from unstained tissue before H&E staining and from reference H&E stained tissue after chemical staining. Hold-out set of sample pairs are left for validation, allowing us to evaluate the virtual staining performance for a vast array of tissue components and to examine the potential shortcomings in staining reproduction. We use a comprehensive set of quantitative metrics both on pixel and object level to evaluate virtual staining quality. In addition, we perform thorough visual evaluation of histological feasibility by histology experts to examine the computational staining.

Results We demonstrate that by careful optimization of both sample preparation and imaging workflow, as well as the computational methods, generative adversarial networks can be used for virtual staining of whole slide images of breast cancer tissue acquired from unstained tissue using regular bright field microscopy. We analyzed the virtual staining performance quantitatively and visually, and highlight the potential of the method through successful cases and demonstrate the applicability in breast cancer diagnostics, as well as discuss the challenges and shortcomings of virtual staining for clinical samples.

Conclusions We demonstrate the potential of virtual HE staining for clinical histopathology of breast cancer tissue. Notably, our virtual staining based on generative AI shows promise towards more sustainable and streamlined sample processing and staining process in digital pathology.

#6186 Histopathology-derived molecular portrait of serous ovarian cancer.

Yajas Shah, Zachary R. McCaw, Anna Shcherbina, Christopher Probert

insitro, South San Francisco, CA

Background: The progression of ovarian cancer (OV) is often evaluated through clinical staging and molecular profiling of genomic alterations and subtypes, with the molecular profiling of tumors playing a crucial role in cancer management by informing therapeutic decisions. However, collecting molecular data is expensive, time-consuming, and can be sensitive to sample handling protocols. These factors prevent routine implementation at many care centers, thereby limiting benefit to patients. This work examines the viability of an image-centric method for inferring molecular endophenotypes and predicting overall survival in OV, leveraging commonly gathered histopathology scans.

Methods: Embedding representations of digitized Hematoxylin and Eosin slides were produced using a self-supervised histology model. First, we assessed the ability of the embeddings to predict overall survival using Cox proportional hazards models by calculating the concordance index. Next, these embeddings served as input features to machine learning models trained to predict genomic patterns within tumors, including molecular subtypes, driver gene alterations, and mutational processes, leading to a more comprehensive analysis of the prognostic potential of our approach.

Results: Histopathological embeddings were found to be more predictive of patient survival than traditional factors such as age, histological grade, and clinical stage. Embedding risk combined with clinicopathological risk had a higher predictive value than clinicopathological risk alone (0.578 vs 0.569, p = 0.025). Moreover, embedding risk alone was more predictive of survival (0.577 vs 0.569, p = 0.038). Risk scores derived from embeddings and all clinicopathological features were uncorrelated (R = 0.03), indicating that embeddings provide unique prognostic information. Motivated by these findings, we investigated the reasons behind the enhanced accuracy in survival prediction. We found that models trained on embeddings predicted previously defined molecular subtypes (TCGA, 2011), achieving area under the receiver operating characteristic curve (AUROC) scores as follows: Differentiated (0.86), Immunoreactive (0.85), Mesenchymal (0.9), and Proliferative (0.89). Similarly, our models identified crucial oncogenic events, including the loss of TP53 and CDKN2A, and instances of whole genome duplication (AUROCs of 0.85, 0.99 and 0.8).

Conclusions: Taken together, this work showcases the potential utility of standard of care digitized histopathology scans for imputing genomic patterns and predicting overall survival in OV. Our results suggest that imputation could provide a fast and scalable solution for deploying patient screening biomarkers, thereby playing a pivotal role in shaping the future of precision medicine.

#6187 Multimodal characterization of tertiary lymphoid structures identified via deep learning on digitized H&E images in NSCLC.

N. Beig, E. Liu, G. Schau, A. Amitai, B. Nabet, R. Jesudason, E. Fuentes, H. Koeppen, S. Kaya, N. S. Patil, M. K. Srivastava, R. Johnston, C. Kozlowski, J. Giltnane, D. Ruderman;
Genentech, Inc., South San Francisco, CA

Background: Tertiary lymphoid structures (TLS) have recently shown association with improved outcomes for patients treated with immunotherapy across several cancer types. But pathologist-led identification of TLS on routine hematoxylin and eosin (H&E) stained images is time-consuming & lacks standardization. We developed a deep learning (DL) approach to identify TLS on digitized H&E whole slide images (WSI) of non-small cell lung cancer (NSCLC). We also elucidate underlying identified TLS biology by investigating corresponding transcriptomic profiles & multiplex immunofluorescence (mIF) images.
Methods: DL model was trained using mature TLS (mTLS) annotated by 5 board-certified pathologists following standardized definitions across WSI of NSCLC, breast & bladder cancers. Model was validated using blinded, exhaustive annotations on 60 WSI by the same pathologists in consensus. To identify underlying biology associated with model-identified TLS presence, phase 3 clinical trial of advanced NSCLC with H&E and corresponding bulk RNA-Seq was analyzed using differentially expressed genes(DEG). Cellular phenotypes of model-identified TLS were elucidated in procured NSCLC WSI labeled with mIF panel & then H&E stained.
Results: DL model achieved a validation F1-score of 0.56 (precision=0.52). DEG analyses resulted in significant association of TLS related gene signatures with model-identified TLS presence ($q<0.05$). Immuno-histopathological evaluation of model-identified mTLS revealed concordance with central clusters of CD20+ B cells surrounded by a mix of CD20+ B & CD3+ T cells.
Conclusions: We developed a DL model to detect TLS in H&E WSI & demonstrated their concordance in transcriptomics and mIF. With further validation, DL identified TLS could potentially serve as an imaging-based biomarker in clinical outcome datasets.

#6188 Pathomics of prostate cancer incorporating histology and mass spectrometry imaging.

J. M. Luna[1], H. Nakhoul[1], C. Weimholt[1], E. H. Kim[1], S.-K. Song[1], P. M. Angel[2], R. R. Drake[2], J. E. Ippolito[1];

[1]Washington University School of Medicine in St. Louis, St. Louis, MO, [2]Medical University of South Carolina, Charleston, SC

Background: Recent evidence shows that interactions between tumor cells, immune cells, and extracellular matrix (ECM) proteins in the stroma play an important role in prostate cancer (PCa) progression. However, to date these factors are not accounted for in clinical evaluation of PCa patients. Our team has developed methods based on matrix-assisted laser desorption/ionization (MALDI) imaging to identify sets of ECM glycan and collagen molecules associated with PCa. In this study, we leverage computational imaging methods and pathomic textural features to assess the potential of MALDI imaging to guide the identification of regions in PCa hematoxylin and eosin stain (H&E) images as tumor or non-tumor.

Methods: We used a cohort of PCa patients (n=10), who have undergone radical prostatectomy, with grade groups GG3−GG5, and with available H&E and N-glycan MALDI images. We used five MALDI images per patient representing the distribution of N-glycan species at 1419, 2539, 2686, 1663, and 1809 m/z. For each MALDI image, an N-glycan mask was generated and co-registered with the corresponding H&E image via computational imaging methods (i.e., Otsu thresholding, largest connected components labeling, sequential affine and B-spline registration using mutual information). To quantify the overlap of each mask with tumor regions, we calculated Dice scores between the masks and the pathology annotation in H&E. To assess differences in imaging patterns of regions indicated by the different masks, we extracted a set of pathomic textural features (n=70) from the H&E image within each mask using PyRadiomics, and we performed Wilcoxon signed rank tests across all pathomic textural features for all paired combinations of the five masks.

Results: The mean Dice scores between the pathology tumor annotation and the N-glycan masks from 1419 (0.56 [0.44–0.65]) and 2539 m/z (0.64 [0.59–0.82]) was significantly higher ($p<0.008$) than the Dice score of 1663 (0.24 [0.17–0.36]), 1809 (0.31 [0.13–0.45]), and 2686 m/z (0.32 [0.19–0.37]). This suggests a large overlap between 1419 and 2539 m/z and tumor, and large overlap between 1663 and 1809 m/z and non-tumor regions. Consistent with these results, our pathomic textural analysis showed that 50 out of 70 features were significantly different ($p<0.05$) between the masks derived from 1419 and 1663 m/z, 52 between 1419 and 1809 m/z, 62 between 2539 and 1663 m/z, and 57 between 2539 and 1809 m/z ($p<0.05$). Moreover, there were only 23 significantly different features between 1419 and 2539 m/z ($p<0.05$), and 0 features between 1663 and 1809 m/z. Further evaluation is needed for 2686 m/z for which a mean of 54 [45–64] significantly different features ($p<0.05$) from all other masks were found.

Conclusions: We provide preliminary evidence that MALDI imaging can elucidate tissue properties and guide pathomic textural analysis in H&E images, with potential applications in treatment guidance and prognostication of PCa.

#6189 Deep-learning model trained on multiplex immunofluorescence-stained tissue samples predicts the survival of patients with non-small cell lung cancer better than PD-L1 TPS alone.

K. V. Hoebel, J. R. Lindsay, J. V. M. Alessi, J. L. Weirather, I. D. Dryg, J. Altreuter, M. M. Awad, S. J. Rodig, W. E. Lotter;
Dana-Farber Cancer Institute, Boston, MA

In non-small cell lung cancer (NSCLC), the composition and structure of the tumor immune microenvironment (TME) critically impact patient outcomes, necessitating improved computational approaches to characterize the TME beyond traditional metrics like the PD-L1 tumor proportion score (TPS). Here, we developed an interpretable deep-learning model that robustly predicts patient overall survival (OS) and identifies unique PD-L1 enriched neighborhoods linked to patient prognosis.

We utilized a dataset of 507 NSCLC patient biopsy samples prospectively acquired as part of the DFCI ImmunoPROFILE project. Each sample was stained for Cytokeratin as tumor marker, PD-L1, PD-1, CD8, and FOXP3 using a targeted multiplex immunofluorescence assay. Inner tumor regions of interest were automatically processed for spatially resolved identification and quantification of marker expression at the single-cell level.

The dataset was divided into 380 patients for model development and 127 for testing. The deep-learning model, a graph neural network (GNN), was trained to predict OS based on local cell neighborhoods using a weakly supervised training paradigm. The GNN models neighborhoods as a graph, with cells and their corresponding marker expression representing nodes and edges connecting adjacent cells, for an average of 42 cells per neighborhood. Survival predictions were obtained by averaging predictions over all neighborhoods from one sample.

The GNN model demonstrated robust performance with a concordance index (c-index) of 0.79 on the test data, surpassing traditional metrics such as TPS and immune marker density-based models (c-index: 0.50 and 0.74, respectively).

Beyond assessing performance, we investigated the features learned by the GNN using k-means clustering in the model's feature space. We identified three clusters that were notably enriched in PD-L1 positive tumor cells. The first cluster shows an especially "high TPS" phenotype, where the GNN predicted such neighborhoods to be generally poor for survival. The other two clusters were additionally enriched with PD-L1 positive immune cells (ICs) and associated with favorable survival predictions. Notably, one cluster was also enriched with other types of ICs ("PD-L1 IC mixed"), which the GNN predicted as especially favorable for survival compared to exclusive enrichment of PD-L1 ICs ("PD-L1 IC dominant"). A score summarizing these three PD-L1 expression patterns was significantly associated with OS (p-value: 0.01; HR: 0.72, 95% CI: 0.16-1.27), validating the features learned by the GNN.

In sum, we developed a highly interpretable deep-learning model leveraging cellular neighborhood graphs, which effectively identifies expression patterns correlating with NSCLC prognosis, offering promise for developing personalized treatment strategies.

#6190 Patterns of EGFR and HER3 co-expression in solid tumors.

M. Wood, C. Morrison, J. S. Khalili, Y. Zhu;
SystImmune Inc., Redmond, WA

EGFR and HER3 are members of the ERBB receptor family and transmit growth and survival signals to cancer cells upon ligand binding. While both receptors are well established targets for cancer therapy, greater understanding of the relationship of their expression patterns in human cancer is needed to establish the scope of therapeutic potential. To evaluate the co-expression pattern of EGFR and HER3, cancer FFPE tissue microarrays from several cancer types were evaluated by immunofluorescence imaging and digital pathology, including cell-by-cell marker intensity and spatial analyses within the tumor and stromal compartments. Tissue cores were assigned H-scores, and individual cells were binned into 0, 1+, 2+, 3+ scoring based on established digital pathology methods using QuPath software. Spatial cytometry was used to further evaluate single-cell expression intensity. Analysis was conducted widely on multiple normal human tissues as well as cases of NSCLC adenocarcinoma n=86, NSCLC squamous cell carcinoma n=84, SCLC n=43, TNBC n=45, Biliary tract cancers n=80, Nasopharyngeal carcinomas n=60. Overall, the results of this analysis show the intermediate to high prevalence of EGFR and HER3 co-expression within each indication, as well as the frequency of EGFR and HER3 expressing cells. Furthermore, EGFR and HER3 heterodimers were confirmed by proximity ligation assay in certain index cases. Notably, of several observations, we observe NSCLC cases show a profound absence of EGFR- HER3+ tumor cells. Additionally, we observe that co-expression of EGFR and HER3 in normal human tissues is rare and of low signal intensity.

#6191 Simultaneous prediction of tumor microenvironment biomarkers from pathology slides using multi-task deep regression.

Omar S. M. El Nahhas, Marta Ligero, Jakob N. Kather

EKFZ for Digital Health, UK Carl Gustav Carus der TU Dresden, Dresden, Germany

Understanding the Tumor Microenvironment (TME) is crucial for tailoring personalized cancer treatments and improving patient outcomes. Using deep learning, we can predict properties of the TME from standard Hematoxylin and Eosin (H&E) stained slides, including specific gene expression signatures. While past models were limited to single signature predictions, we explore the potential of multi-task deep learning to identify multiple biomarkers at once, allowing more complex relationships and interactions to be modeled simultaneously. Our study focuses on the prediction of expression patterns of tumor, stromal, and immune cells in breast cancer (BC).

We developed a multi-task transformer-based deep regression model, trained in a weakly-supervised setting, to predict biomarkers in the TME from routine H&E-stained pathology slides of a BC cohort (n=876). The performance was evaluated using Pearson's correlation coefficient (r) and spatial heatmaps generated via gradient-weighted class activation mapping.

Our model achieved a significant correlation coefficient above 0.40 ($p<0.0001$) for all predicted TME biomarkers in the holdout test set (n=176). This includes the biomarkers lymphocyte infiltrating signature score ($r=0.46$, $p<0.0001$), tumor infiltrating lymphocyte regional fraction ($r=0.48$, $p<0.0001$), leukocyte fraction ($r=0.43$, $p<0.0001$), stromal fraction ($r=0.42$, $p<0.0001$), and tumor cell proliferation ($r=0.47$, $p<0.0001$). Notably, the model's heatmaps highlighted the pertinent cells and histological characteristics for its predictions.

These data show that our deep learning model accurately predicts multiple TME biomarkers concurrently from routine pathology slides. This approach offers a promising avenue for cost-effective and efficient biomarker quantification in the TME, with potential applicability across various cancer types.

#6193 Exploring interplay between tumor intrinsic features and immune cell phenotypes in multi-tumor tissue microarrays by a single step 15-plex fluorescence immunohistochemistry and imaging on the Orion platform.

R. Van Krieken, J. O. Bender, S. Kekchidou, M. Burgin, K. Ruma, N. Dakappagari, J. Bordeaux;
Navigate BioPharma, Carlsbad, CA

Purpose: Deeper understanding of the intricacies between tumor microenvironments and immune cell infiltrates is critical for creation of next generation therapies. However, current immunohistochemistry protocols in clinical practice are restricted to one to six markers (cell types) and rely on multiple rounds of antigen retrieval and sequential staining over two days. This current workflow has high risk for tissue and signal loss. Hence, we explored utility of a single step staining workflow using 15 distinct antibodies conjugated novel flours (Argo Dye System) of formalin fixed paraffin embedded (FFPE) tumor microarrays and imaged on the Orion microscope (Rarecyte). Fidelity of the staining was assessed by comparing data from the Orion platform to internally developed clinical grade assays. The implementation of higher plex imaging will enable greater insight into immune surveillance, mechanisms of resistance and patient stratification while minimizing patient tissue required for analysis.

Study Design: We utilized a custom panel developed by RareCyte (Hoescht, CD3e, CD4, CD8a, CD20, CD68, CD163, FOXP3, Ki67, Pan-CK, PD1, PDL1, CD45, Granzyme B, LAG3) to evaluate expression of immune markers on a pan-tumor and melanoma TMA including Hodgkin's lymphoma, ovarian cancer, esophageal carcinoma, hepatic cell carcinoma, head and neck cancer. Serial sections were stained with 6-plex clinical grade assays, and correlation scores were determined between the 15-plex Orion and 6-plex assays utilizing TSA-based amplification.

Results: In this study, the performance of Orion platform was assessed by quantitative and qualitative measures. Linear regression between the 6-plex clinical grade assays and 15-plex Orion workflow were calculated for a panel of biomarkers including CD3, CD4, CD8, CD68, CD163, CK, FOXP3, GZMB, Ki67, and PD1. Our results demonstrated that the Orion performed similarly to clinical grade assays both in terms of proportion of cells and fluorescence intensity (R^2 ~ 0.7-0.98, Slope ~ 0.7-1.1).

Conclusion: Our results suggest that the Orion platform offers a reliable and efficient solution for comprehensive biomarker analysis. Our results demonstrate that this platform can successfully capture the expression of 15 biomarkers on a single FFPE slide which offers workflow advantages over traditional TSA-based fIHC multiplexing that is limited to detection of 6 biomarkers on a single slide. The ability to analyze a wider range of biomarkers through a single platform has the potential to enhance the efficiency of biomarker analysis, leading to improved diagnostic and therapeutic outcomes in clinical practice.

#6198 *TP53* mutational clusters stratify the Li-Fraumeni syndrome spectrum.

N. W. Fischer[1], B. Laverty[2], R. Kafri[3], K. N. Maxwell[4], E. R. Woodward[5], C. Kratz[6], D. Malkin[1];
[1]The Hospital for Sick Children, Toronto, ON, Canada, [2]The University of Toronto, Toronto, ON, Canada, [3]University of Toronto, Toronto, ON, Canada, [4]University of Pennsylvania, Pennsylvania, PA, [5]University of Manchester, Manchester, United Kingdom, [6]Hannover Medical School, Hannover, Germany

Li-Fraumeni syndrome (LFS) is a highly penetrant cancer predisposition disorder caused by germline variants in the *TP53* tumor suppressor gene. LFS has recently been redefined as a 'spectrum' disorder to reflect the highly variable cancer types with largely unpredictable ages-of-onset and disease severity. The broad functional gradient associated with different *TP53* variants is thought to contribute to LFS heterogeneity, although it is still poorly understood and there is an unmet clinical need for risk stratification strategies to improve variant interpretation and patient care. Here, we performed an unsupervised cluster analysis leveraging p53 mutagenesis datasets (Kato et al., 2003 & Giacomelli et al., 2018) that revealed five *TP53* mutational clusters with unique mutation patterns, structural features, and functional consequences. Stratifying germline carriers based on the five clusters exposed important clinical characteristics to consider for patient management, such as ages-of-onset, tumor type development, and survival outcomes. In particular, we discovered an osteosarcoma-prone subgroup comprised of monomeric mutant p53 carriers with aggressive cancer phenotypes. We also identified a cluster of *TP53* variants found more often in non-cancer and healthy older populations, and carriers of these variants that developed cancer had less "LFS-like" phenotypes including an older age-of-onset and a significantly higher frequency of colorectal cancers. Remarkably, our *TP53* variant clustering strategy could also stratify breast cancer survival among germline carriers. This work provides a new framework to delineate the LFS spectrum toward the development of machine learning-based approaches for personalized cancer surveillance plans.

#6199 Defining and capturing progression in glioma by harnessing NLP in unstructured electronic health records.

S. Chappidi[1], H. Lee[2], **S. Jagasia**[3], C. Syal[4], G. Zaki[3], D. Junkin[4], N. Golightly[4], P. Chitwood[4], K. Camphausen[3], A. Krauze[3];
[1]National Cancer Institute / University of Cambridge, Bethesda, MD / Cambridge, United Kingdom, [2]National Cancer Institute / Johns Hopkins University, Bethesda / Baltimore, MD, [3]National Cancer Institute, Bethesda, MD, [4]NIH Integrated Data Analysis Platform, National Institutes of Health, Bethesda, MD

Gliomas exhibit nearly uniform recurrence and poor prognosis. Management of high-grade tumors is surgery followed by chemoirradiation (CRT). Radiographic progression is assessed using contrast-enhanced MRI with reporting captured in Electronic Health Records (EHR). The ability to harness large scale EHR data is limited by the Response Assessment in Neuro-Oncology (RANO) tumor progression criteria, which defines progression as an aggregate of clinical and/or radiographic parameters requiring clinician judgement. As a result, glioma progression is not captured systematically in large data sets, limiting Progression Free Survival (PFS) as an outcome endpoint in data analysis. We developed an AI-based method using natural language processing to capture PFS parameters for analysis of MRI radiology reports. 1088 available brain MRI radiology reports for 81 patients with a pathologically confirmed diagnosis of glioblastoma (GBM) were aggregated in the NIH Integrated Data Analysis Platform. MRI reports were systematically analyzed and PFS manually captured using RANO criteria as ground truth. Common report terms indicating progression were compiled and included in task prompts applied to Large Language Model (LLM) Extraction Tools. The words *progression* (n=1047) and *stable* (n=1133) did not necessarily indicate either overall progression or stability in a report. Yet, in the 24 (30%) patients who progressed within 3 months of CRT, *recurrence* and *mass effect* occurred in 3.7% and 53% of reports, respectively, which was comparable to the term frequencies of 5.8% and 54% in patients with stable disease. Thus, *mass effect* and *recurrence* could not necessarily be used alone as terms to signal overall progression. The analysis identified other commonly employed radiology report terms relevant to determining tumor progression including *enhancement* (n=2445), *perfusion* (n=2085), *enhancing* (n=1785), *resection* (n=1576), and *increased* (n=1331), which allowed for experimentation with more detailed LLM extraction task prompts. Our method flagged radiographic progression prior to clinician-coded progression in 43 (53%) patients. Future directions include handling further clinical context such as surgical features, radiation therapy dates, progress notes, and the coadministration of agents such as bevacizumab and steroids. These results indicate the feasibility of LLMs to identify tumor progression dates using EHR text with potential transferability to large glioma data sets pending further optimization and validation.

#6200 Single-cell analyses unravel novel immune and tumor cell characteristics linked to the response to neoadjuvant immune checkpoint blockade in patients with gastric cancer.

E. Dai[1], J.-J. Qin[2], C. Hu[2], Z. Xu[2], G. Han[1], Y. Chu[1], R. Wang[1], M. Dang[1], Y. Liu[1], G. Pei[1], J. Jiang[1], F. Peng[1], Y. Zhang[1], A. L. Faustino[1], J. A. Ajani[1], L. Wang[1], X. Cheng[2];

[1]The University of Texas MD Anderson Cancer Center, Houston, TX, [2]The Cancer Hospital of the University of Chinese Academy of Sciences, Hangzhou, China

Background: Gastric cancer remains the leading cause of cancer-related deaths worldwide, ranking fifth for incidence and fourth for mortality. Combining neoadjuvant therapy with immune checkpoint inhibitors has demonstrated improved outcomes for patients with gastric cancer. However, responses exhibit heterogeneity, and the understanding of the mediators influencing therapy response is limited.

Methods: In this study, we collected 80 blood and tumor samples from 22 gastric cancer patients treated with XELOX/SOX alone or its combination with Nivolumab (anti-PD-1). Paired single-cell RNA-, TCR-, and BCR-sequencing were performed on pre- and post-treatment samples to investigate the dynamics of immune and tumor cells during the development of response/resistance to therapy.

Results: Our findings revealed that elevated levels of baseline CD4 and $CD8^{+}$ tissue-resident memory T (T_{RM}) cells, in activated and stressed states, are associated with a superior response to combined therapy, and treatment further amplifies this cell population in responsive patients. Tracking T cell receptor clones across pre-/post-treated blood and tumor samples disclosed that the expanded clonotypes of T_{RM} cells are exclusively detected in tumors, and considerable preexisting clones contribute to the expansion of these T cell populations following treatment. The simultaneous presence of T_{RM}, B, and dendritic cells in pre-treated tumors predicted a favorable response, and they concertedly expanded in tumors responsive to anti-PD-1 therapy.

Conclusions: Our findings highlight the significance of T_{RM} cells in effective responses to anti-PD-1 therapies and indicate that their cellular communication with B and dendritic cells play a pivotal role in shaping the antitumor immunity elicited by combination therapy. Together, this study illuminates vital immune cell subsets during immune checkpoint blockade treatment, provides biological insights into the mechanism of successful combination therapy, and unravels potential targets for improving treatment efficacy in gastric cancer.

#6201 Early-onset CRC, vitamin A deficiency, and stem cell origin of cancer.

B. M. Boman, V. O. Hunsu, C. O. B. Facey;
Helen F. Graham Cancer Center & Research Institute, Newark, DE

The recent surge in early-onset CRC (EOCRC) has been attributed to a Westernized lifestyle, but the underlying molecular mechanism is largely unknown. In our cancer genetics clinic, we provide care for 10-20 young (<50 age) CRC patients per year. But, only a fraction (~15%) of these young CRC patients are found to have CRC-predisposing germline mutations which doesn't provide a hereditary factor that can explain EOCRC. Other genetic studies have found that the spectrum of somatic alterations was largely comparable between EOCRC and adult-onset CRC, particularly common are mutations occurring in *APC* and other members of the WNT pathway. Since a genetic etiology has not turned-up, we are exploring possible lifestyle factors. We hypothesize that vitamin A (retinol) deficiency is a likely etiologic factor because vitamin A is an essential nutrient that is not made by the human body. Thus, young individuals might be prone to any cancer-initiating effects of a vitamin A deficient diet. Indeed, many population-based studies (including ones on well-nourished populations) have reported a high prevalence of vitamin A deficiency in pre-school-aged children. Since *APC* mutation commonly occurs in early-onset CRCs, we conjecture that vitamin A (retinol) metabolism and *APC* mutation-induced activation of WNT signaling may be co-factors in promoting EOCRC. Accordingly, we have been investigating whether there is a functional connection between WNT and vitamin A/retinoic acid (RA) signaling, and if *APC* mutation generates an imbalance in a WNT:RA-linked mechanism that contributes to CRC development by impeding retinoid-induced colonic stem cell (SC) differentiation. We previously reported that RA signaling mainly occurs in aldehyde dehydrogenase-positive (ALDH+) SCs and that *APC* mutation leads to overpopulation of ALDH+ SCs and incomplete differentiation during CRC development. Thus, our findings suggest that *APC* mutation attenuates RA signaling in ALDH+ SCs, which might explain how vitamin A deficiency contributes to EOCRC development.

#6202 Integrating public single-cell transcriptomics and patient profiles to guide clinical development.

J. Russella-Pollard, J. Whitener, J. Byck, M. Manne, H. Alostaz, M. Elia, K. Krukowski, G. Wong, F. Adrian, L. Schweizer, R. H. I. Andtbacka, **C. Hatzis**; HiFiBiO Therapeutics, Cambridge, MA

Background: Single-cell technologies provide invaluable insights into disease biology and drug development by revealing complex interactions among different cell types within patients. However, harnessing the potential of publicly available single-cell data remains challenging due to the lack of integrated data across diverse single cell platforms.

Methods: To maximize the potential of single cell insights, we have created an AI/ML powered curation and data integration process within our Drug Intelligence Science (DIS®) platform. This automated process integrates single cell transcriptomic data from publicly available sources with our in-house generated datasets from ex vivo translational efforts and clinical programs. Relevant public datasets are identified and retrieved using an automated Python-based GEO dataset crawler tool, and standardized metadata are curated. A reference atlas of 31 immune and 4 non-immune cell types is generated from the database and is used to consistently label cells across datasets. Additionally, cell-level gene expression integration and normalization across datasets is achieved using generative modeling techniques. To facilitate multiuser visualization and interrogation of the curated and integrated datasets, we have developed Cellect, a customized version of CellxGene Gateway.

Results: The current single-cell database comprises 15 million cells analyzed in >5,000 samples collected from >2,500 patients across 160 curated unique human studies, spanning oncology (56%), autoimmune disease (AID, 21%), and viral infection (15%), with the remaining being from reference healthy tissues (8%). We focused dataset curation on indications of interest for our internal clinical development efforts. Uniquely, data from approximately 300 patients who received standard of care (SOC) treatment including immune checkpoint inhibitor (IO) therapy were integrated to delineate mechanisms of drug response and resistance. The post-SOC resource was used to identify (1) treatment settings where these mechanisms are enriched and (2) markers co-expressed with targets of interest (e.g., PD1, CTLA4, OX40, TNFR2, etc.) in specific cell populations to inform combination strategies.

Conclusions: We have presented an AI/ML guided approach to address the key challenge of integrating single-cell data across platforms and demonstrated that relevant disease biology is retained upon integration. We outline a path for deploying this solution at scale for bench and computational scientists to guide target as well as indication selection, as was done for our ongoing clinical programs, including our first-in-class TNFR2 agonist (HFB200301, NCT05238883) and second-generation OX40 agonist (HFB301001, NCT05229601).

#6203 An altered profile of ribosomal proteins and ERK-eIF4E translational control in an inflammatory breast cancer model of acquired resistance and reversal is associated with pathological complete response in patients.

G. R. Devi[1], P. PAI[1], M. W. Foster[1], D. S. Sannareddy[1], S. Lee[1], S. V. Laere[2];
[1]Duke University School of Medicine, Durham, NC, [2]University of Antwerp, Antwerp, Belgium

Background: Drug resistance is a major challenge in inflammatory breast cancer (IBC), a hyperproliferative subtype characterized by the presence of diffuse tumor cell clusters that show high level of heterogeneity. As the degree of tumor heterogeneity during cancer progression can cause evolution of cell states that can either compete or co-operate resulting in therapeutic failure, the study objective was to identify drug resistance networks that can serve as biomarkers or therapeutic targets.
Methods: Integrated transcriptomic and proteomic profiling approach was conducted in a progression model of acquired drug resistance and its reversal comprised of a treatment-naïve patient-derived SUM149 cell line, along with two isogenic derivatives and representing drug-resistant (rSUM149) and resistance-reversal states (rrSUM149). Global gene expression analysis in IBC patients (n=87) recorded responses to neoadjuvant chemotherapy. Based on the data, targeted multikinase inhibitors were evaluated in viability and signaling assays.
Results: We identified specific ribosomal proteins associated with resistance acquisition, which correlated with high levels of pERK, CDK1, XIAP, and SOD2. Conversely, the resistance reversal in rrSUM149 showed almost complete normalization to the profile of SUM149. However, VIPER analysis revealed proteins related to ribosomal processes (AGO2, Exportin 1, RPL5) that did not revert in rrSUM149, suggesting this pathway may have pleiotropic effects in governing drug resistance. Notably, genes linked to ribosomal processes were significantly enriched ($P<0.001$) among the overexpressed genes in IBC patients (n=87) who exhibited pCR to neoadjuvant chemotherapy. This is crucial as IBC tumors, including rSUM149, exhibit MAPK hyperactivation including in the presence of EGFR tyrosine kinase inhibitors. Treatment with Merestinib, a multikinase inhibitor, suppressed pERK, peIF4E, downstream targets like CDK1, and ribosomal protein IMP3 underscoring the impact on protein synthesis signaling crucial for countering translational dependence in cancer cells. Additionally, Merestinib synergized with EGFR-TKI (lapatinib) in increasing cell death in all three states.
Conclusion: Overall, our study describes adaptive changes in response to both therapeutic stress and therapy break that have the potential to serve as biomarkers or extended for pharmacological interrogation toward precision medicine for this rare, understudied cancer. Furthermore, the ability of Merestinib, in clinical trials, to target translational dependence is attractive as cancer cells often appropriate these signaling pathways to gain tolerance to various stress stimuli. Support: NIH-R01CA264529; DoD Breast Cancer Breakthrough level 2 Award W81XWH2010153

#6204 Differential gut microbiome alpha diversity in endometrial and ovarian carcinoma patients.

C. T. Finnicum[1], T. Meissner[2], C. Davis[1], S. Viet[1], J. L. Petersen[1], M. Deaton[2], B. Solomon[2], W. Spanos[2], D. Starks[2], R. Elsey[2], E. A. Ehli[1], C. Williams[2]; [1]Avera Genetics, Sioux Falls, SD, [2]Avera Cancer Institute, Sioux Falls, SD

Background: Emerging research underscores the gut microbiome's critical role in cancer development, progression, and response to treatment. As a part of the “ASAP” study, which focuses on the implementation of comprehensive molecular profiling and deep clinical annotation of electronic health records in participants diagnosed with or at risk of developing cancer, we have established a microbiome-associated biobank and corresponding clinical dataset to systematically explore the dynamics of the gut microbiome as patients progress through cancer treatment. We describe a pilot project where we explore the baseline microbiome samples collected from ASAP participants, particularly from those with endometrial and ovarian carcinomas.

Methods: Stool samples from patients were collected at the time of enrollment in the ASAP study and sampling is repeated every three months to align with the additional biosampling procedures. Microbial DNA was extracted from the baseline stool samples and subjected to sequencing of the V4 region of the 16S rRNA gene. After generating species level operational taxonomic units (OTUs), alpha diversity measures were generated in the form of the inverse Simpson index. In order to determine whether there was a difference in alpha diversity between individuals with ovarian (N = 37) and endometrial (N = 35) carcinomas, we employed a t-test with 100,000 permutations to derive an empirical p-value.

Results: We present sequencing results from the initial n=297 samples. Our comparison of the alpha diversity between ASAP study participants with ovarian and endometrial carcinomas showed a significant difference between the two groups, with the ovarian cancer patients having a lower alpha diversity (empirical p-value = 0.03915). Due to the uniform sampling, biobanking, and analytical procedures, our study allows the ability to explore microbiome features amongst various cancer diagnoses while minimizing laboratory and analytical differences that plague microbiome reproducibility.

Conclusions: We observed a significant difference in alpha diversity between patients with endometrial and ovarian carcinomas. Although the current results are preliminary, the wealth of information available in the ASAP protocol will allow us to continue exploring the association of the gut microbiome with cancer and the associated treatment.

#6205 Identify drugs for metastatic castration-resistance prostate cancer (mCRPC) patients with high glycolytic activity through *in silico* approach.

M.-C. Su, A. Lee, R. Huang;
University of Minnesota, Minneapolis, MN

Prostate cancer (PC) remains a prominent cause of cancer-related mortality among men in the United States. A significant factor contributing to the mortality of PC patients is the development of resistance to second-generation antiandrogen therapies, particularly androgen receptor-signaling inhibitors (ARSI), which is pronounced in patients with late-stage PC, metastatic castration-resistance prostate cancer (mCRPC). Therefore, there is an urgent need for novel therapeutics beyond AR signaling inhibition for patients with mCRPC. One of the key drivers of resistance to ARSI and a critical feature of CRPC is cancer metabolism reprogramming to elevated glycolysis. However, the current research on finding drugs to impede high-glycolytic tumor growth is hurdled by a resistance raised from metabolic plasticity. The aim of this research is to quickly repurpose existing drugs for inhibiting high-glycolytic mCRPC growth while proactively circumstancing resistance from metabolic plasticity through computational approaches. To do this, we imputed a large number of drug responses in patients with mCRPC using a computational algorithm (OncoPredict), identified drugs that were projected to show higher sensitivity in high-glycolytic tumors, and performed in vitro validation. Furthermore, to maximize drug efficacy, we identified biomarkers for drug candidates. By implementing this computational pipeline, we identified a number of drugs with various mechanisms of action that show higher efficacy in mCRPC with high glycolysis. Furthermore, we successfully validated the efficacy of these nominated drug candidates including an anti-parasitic agent, an HSP90 inhibitor, and a CDK inhibitor. These drug candidates exhibited superior tumor growth inhibition in *in vitro* models of high glycolysis-induced advanced PC. In conclusion, this study introduces an innovative *in silico* approach to unveil the existing drugs' unknown potential for the treatment of patients with mCRPC. Our findings hold promise for development of effective therapeutics for combating this challenging disease.

#6206 Molecular stratification of AML: Integrative genomic and immune profiling points to high risk subgroup and targetable molecular drivers.

K. Karagoz, L. Brady, B. Higgs, H. Si;
Genmab, Plainsboro, NJ

Background: Acute Myeloid Leukemia (AML) is a complex hematological malignancy characterized by clinical diversity. The ability to accurately subtype patients can inform prognosis and guide therapeutic approaches. With the integration of multi-omics data, it is possible to elucidate the molecular mechanisms underpinning unique AML subtypes, with intent to identify potential drug targeting pathways in a precision medicine strategy.
Method: RNAseq datasets from Beat-AML (discovery, N=462), TCGA-AML (validation, N=173), and Leucegene (validation, N=452) were analyzed through non-negative matrix factorization to delineate distinct transcriptomic-driven molecular subtypes within AML. A curated set of the top 1,000 most variable genes was utilized to minimize analytical noise. GSVA was used for pathway analyses across Hallmark, KEGG, Reactome, and the immune microenvironment was characterized via xCell. Recurring DNA variants were examined in each subtype. Clinical outcomes of each subtype were analyzed using the Kaplan-Meier method and assessed by a log-rank test. These insights were subsequently validated in two independent cohorts - TCGA AML and Leucegene. The most influential components of immunological effector mechanisms, which characterize poor prognostic subpopulation, were assessed using bootstrap forest partitioning as a feature selection technique.
Results: Our Beat-AML analysis identified 5 distinct clusters. Cluster 3 consisted of 20% of AML cases (n=86), and displayed a worse overall survival with a HR (95% CI) of 1.41 (1.03, 1.92, P=0.03). This cluster was characterized by three co-mutations: FLT3, NPM1, and DNMT3A. Pathway analysis highlighted biological processes key to antibody therapy intervention, specifically complement pathways, NK cell cytotoxicity, and FCGR-mediated phagocytosis as enriched within this subpopulation. Concurrently, oncogenic (PI3K/AKT/MTOR, TGFB, NOTCH) and metabolic pathways (fatty acid and oxidative phosphorylation) were activated. Immune profiling indicated increased levels of M2 macrophages. Using bootstrap forest partitioning, C2 and ITGAM were identified as key genes defining cluster 3. These observations were confirmed in TCGA AML and Leucegene cohorts.
Conclusion: Our comprehensive analysis identified a distinct high-risk AML subgroup characterized by unique genomic, transcriptomic, and immunological patterns. The combined presence of NPM1/FLT3-ITD and DNMT3A mutations in cluster 3—each previously attributed with varied prognostic outcomes—warrants in-depth biological investigation. With these consistent AML subgroup results identified across three independent cohorts (total of 1,087 patients), we highlight the complexities within the molecular landscape of AML and emphasize the need for tailored therapeutic approaches - a transformative shift in AML treatment.

#6207 Exploring colorectal cancer with ARIA: Biomedical insights.

N. Nikolic[1], S. Kleinstein[2], J. Radenkovic[1], M. Kovacevic[1];
[1]Velsera, Belgrade, Serbia, [2]Velsera, Charlestown, MA

Gaining the promised benefits from the population-scale datasets, both clinical and genomic, is often hindered by the inability to easily access, explore and manipulate such complex data - a difficulty that ARIA was designed to overcome.
In the field of biomedicine, organizations harness extensive datasets, gaining profound insights into patients and participants, thereby unleashing possibilities for accelerating research, especially in the realms of drug development and precision medicine. To facilitate navigation through the intricate landscape of biomedical data, Velsera has innovated ARIA to catalyse efficient and insightful analysis, with a keen emphasis on user-friendliness to ensure accessibility across a diverse professional audience. To demonstrate the practical application of ARIA, we explore genomic and clinical datasets to identify key differences in colorectal cancer progression. CRC, the third most common cancer globally, has unique characteristics in origination and progression from benign to pathogenic. Here we investigate differences between patients with polyps that do and do not progress to CRC, including key environmental factors such as smoking history, inactive lifestyle and obesity in conjunction with their known clinical and genetic risk factors. This exploration into the abilities of ARIA demonstrate the ability to analyse complex datasets combining both clinical and genomics data at a large scale.
For the purpose of this demonstration, a Synthea Dataset, encompassing synthetic clinical and genomic data for 122,011 patients across various age groups, was utilized. This dataset was generated by Velsera specifically for testing ARIA functionalities.
In conclusion, ARIA empowers efficient analysis of complex biomedical datasets, providing a comprehensive understanding of disease mechanisms and facilitating valuable insights.

#6208 Characterization of molecular evolution in myelodysplastic neoplasms.

Ivan Civettini[1], Valentina Crippa[1], Federica Malighetti[1], Matteo Villa[1], Andrea Aroldi[2], Fabrizio Cavalca[2], Alex Graudenzi[3], Lorenza Maria Borin[2], Luca Mologni[1], Rocco Piazza[1], Carlo Gambacorti-Passerini[1], Daniele Ramazzotti[1]

[1]Medicine and Surgery, University of Milano-Bicocca, Milan, Italy,[2]Hematology, Fondazione IRCCS San Gerardo dei Tintori, Monza, Italy,[3]Department of Informatics, University of Milano-Bicocca, Milan, Italy

Myelodysplastic neoplasms (MDS) are hematopoietic stem cell disorders. The IPSS-Mol model, a scoring system that combines molecular and clinical features to stratify MDS patients, can identify individuals at high-risk of developing Acute Myeloid Leukemia (AML), enabling the targeted application of disease-modifying therapies. However, the molecular evolutionary patterns in MDS and their impact on Overall Survival (OS) and Leukemia-Free Survival (LFS) remain unexplored. Shifting from conventional static mutational analyses used by IPSS-Mol to a dynamic evolutionary approach, we employed the ASCETIC framework to analyze data from the IPSS-Mol Database (3,323 patients, 152 genes) and understand the dynamics of MDS progression. According to ASCETIC, genes related to DNA methylation displayed low ranks, indicating their tendency to manifest early in the progression of the disease. In contrast, genes associated with cellular signaling typically appeared in the later stages of tumor progression, while genes involved in RNA splicing exhibited intermediate ranks.Regarding molecular evolution in MDS, ASCETIC identified five clusters, each characterized by distinct evolutionary signatures and significantly different OS and LFS rates ($p < 0.001$). The median OS for the C1, C2, C3, C4, and C5 clusters were 79.3, 64.1, 28.9, 16.2, and 14.8 months, respectively. Subsequently, we compared ASCETIC's clusters with the different risk groups defined by the IPSS-Mol score. Among the 1158 patients initially classified as V-Low/M-Low risk by IPSS-Mol, ASCETIC identified 55 patients placed in C4 and C5. These patients exhibited lower OS ($p = 0.005$) and LFS ($p = 0.02$). Conversely, among the 905 IPSS-Mol M-High/V-High risk patients, ASCETIC identified 468 patients (51.7%) classified as low risk (C1-C2-C3), who were associated with longer median OS and LFS ($p < 0.001$). The differences between conventional mutational analyses and our evolutionary approach primarily, but not exclusively, arise from the evaluation of TP53 mutations and ASXL1. In the IPSS-Mol model, a higher risk is conferred if multi-hit TP53 alterations occur or in the presence of ASXL1 mutations.Conversely, ASCETIC assesses the impact of mutations differently. It considers not only the Variant Allele Frequencies of individual- and/or co-mutations but also the evolutionary trajectories that lead to TP53 and/or ASXL1. This approach results in different risk weights assigned to each evolutionary trajectory.Lastly, we identified patients with NPM1 mutations, classified as MDS patients in the original dataset but now categorized as AML according to 2022-WHO. Within this high-risk context, ASCETIC differentiated between patients with shorter and longer Overall Survival (OS) ($p < 0.001$).Our study reveals the influence of evolution on MDS prognosis, offering insights into the integration of the ASCETIC framework with the IPSS-Mol. Validation on external cohort is ongoing.

#6209 From data disparity to data harmony: A comprehensive pan-cancer omics data collection.

L. Meunier, G. Appe, A. Behdenna, V. Bernu, H. Brull Corretger, P. Dhillon, E. Fox, J. Haziza, C. Lescure, C. Marijon, C. Petit, S. Weill, A. Nordor;
Epigene Labs, Paris, France

In cancer research, the exponential growth of omics datasets offers a significant opportunity for scientific advancement. However, challenges such as the lack of uniform standards, in both clinical and omic data, hinder the effective utilization of these datasets, thus impeding our understanding of cancer biology and the development of innovative therapeutic approaches.Addressing these challenges, we have created a novel collection of pan-cancer omics datasets with extensive clinical data harmonization and consistent omic data normalization.Here, we focused on patient-derived gene expression microarray datasets from the Gene Expression Omnibus database. To navigate the complexities presented by the diverse clinical descriptions inherent in these datasets, we leveraged our proprietary ontology, machine learning models, and domain expert quality control processes to homogenize the clinical data elements.Datasets were then selected based on sample composition, molecular data compatibility, and clinical data availability, then passed through a uniform preprocessing and normalization pipeline to maximize data quality. Finally, gene names were aligned on a single annotation reference, and potential batch effects were adjusted before expression data were merged together.We obtained a total of 32,825 transcriptomic sample profiles from 470 datasets, covering 13,435 genes and 45 clinical data elements, across 30 cancer types. Healthy tissue was favored over adjacent tissue, to minimize the risk of introducing biases related to cancer patient background genomic profiles into downstream analyses. We compared our collection with The Cancer Genome Atlas (TCGA), the most commonly used RNA-seq transcriptomic dataset in cancer research. It covers 30 out of the 33 TCGA cancer types, with on average 4.2 times more samples per cancer type ([0.3; 45.5], median 3.4). Despite the two data collections being based on distinct technologies, we observed a Pearson correlation of 0.69 over the 11,753 genes in common, and a 100% overlap of the differentially expressed genes between genders. This consistency highlights cross-technology reliability and complementarity.We have built and continuously enriched a comprehensive dataset collection enabling the secondary analysis of high-quality omic data. This initial work - focused on microarray datasets - allows us to streamline design, exploration and validation of various omics data-driven studies in cancer research.Our ongoing efforts involve not only the continued integration of microarray datasets but also the integration of pan-cancer RNA-seq and single-cell data. This initiative is set to expand further, encompassing a broader range of omics datasets in the future.

#6210 The cancer omics and drug experimental response dataset (CODERData): A harmonized benchmark dataset for machine learning models of drug response prediction.

J. Jacobson[1], S. Schwartz[2], M. Weil[3], N. Kumar[2], S. Gosline[1];

[1]Pacific Northwest National Laboratory, Seattle, WA, [2]Pacific Northwest National Laboratory, Richland, WA, [3]Frederick National Laboratory for Cancer Research, Frederick, MD

Background: Determining a patient's response to a specific therapy is a vital step in developing personalized cancer treatment. Personalized treatment relies on two key technological advancements: algorithms tailored to each patient's molecular profiles, and comprehensive datasets detailing the effects of patient diversity on drug response. Despite recent advancements in machine learning-based models, each new algorithm requires curation of numerous datasets, which poses a significant burden to researchers who need to evaluate and compare various algorithms. Currently, datasets include extensive genomics, transcriptomics, proteomics and metabolomics measurements along with drug response data (i.e., cell viability) for each cell line, collected through the Cancer Cell Line Encyclopedia (CCLE) and other initiatives. Additional omics data is available for tumor organoids and patient samples generated by consortia such as Human Cancer Model Initiative (HCMI) and the Clinical Proteomic Tumor Analysis Consortium (CPTAC). However, to date there has been little public effort to annotate and harmonize these data across repositories.

Methods: To address this need, we developed the Python package *coderdata* that collates the most up-to-date cancer omics and drug response data. We curated four public cancer datasets, establishing reproducible pipelines that standardize data retrieval, formatting, and integration so the datasets can be built on a cluster if needed. The datasets undergo bi-monthly synchronization with FigShare, ensuring the data is up to date and available. Scientists can use *coderdata* to retrieve and format data on the command line interface as well as within Python scripts.

Results: *Coderdata* is a straightforward Python package that will enable the development and benchmarking of diverse machine learning applications in cancer research. At its core, it represents reproducible data harmonization that enables heterogeneous datasets to be analyzed in bulk. This Python package downloads and standardizes data from multiple consortia-related resources including HCMI, CPTAC, CCLE, and BeatAML, together representing 4931 multi-omics samples from across 250+ cancer types. These datasets include cancer data metrics such as copy number, mutation, transcriptomics, proteomics, miRNA, methylation, and drug response data.

Conclusions: The applications of machine learning in cancer biology are hampered by the distributed nature of existing datasets. As such, the collection and standardization of data by *coderdata* substantially reduces the time investment required for data curation in cancer research. Direct access to benchmark multi-omics and drug response datasets enables scientists to focus on algorithm development for tumor drug response prediction, potentially accelerating the discovery of therapeutic strategies.

#6211 Clinical and prognostic assessment of the lncRNA ZFAS1-related gene signature in colorectal cancer.

P. Ahluwalia, T. Leeman, A. Mondal, A. Vashisht, H. Singh, N. Omar, K. Jones, R. Kolhe;
Augusta University, Augusta, GA

Colorectal cancer (CRC) is one of the leading causes of cancer death with a rapidly rising incidence rate in younger adults. It is projected to be the leading cause of death in adults under 50 years old by 2030. Although progress over the last couple of decades has improved the clinical management of patients affected by CRC, there is a lack of accurate biomarkers to stratify CRC patients. Among several other biomolecules, lncRNAs (long non-coding RNAs) are non-coding transcripts under 200 nucleotides that can regulate gene expression. Furthermore, lncRNAs are important players in oncogenesis and cancer progression and have the potential to be used as reliable biomarkers. Through this study, we explored the clinical relevance of lncRNAs in colorectal cancer. To analyze the distribution of lncRNAs, we utilized de-identified FFPE (formalin-fixed paraffin-embedded) blocks from Augusta University (n = 88). FFPE blocks were sectioned to extract tissue segments and were subsequently stained using H&E (hematoxylin and eosin dyes) to identify the tumor and adjacent normal regions. The quantification of the gene expression was performed using a medium-throughput NanoString platform. Further analyses were performed using clinicopathological features of the institutional cohort and an independent Cancer Genome Atlas (TCGA) dataset. TCGA contains genomic data along with clinical and molecular characterization of over 11,000 samples of various lineages. In the institutional cohort, *ZFAS1* showed higher gene expression in the low survival group for stage II and III colorectal cancer patients, while no significant difference was observed in stage I and IV patients. *ZFAS1* expression did not significantly correlate with other clinicopathological parameters, including race, alcohol consumption, tobacco consumption, age, grade, and family history of cancer. In an orthogonal TCGA analysis, higher *ZFAS1* expression was associated with genomic perturbations, including significantly altered tumor mutational burden (TMB), aneuploidy, fractional genome alteration, and microsatellite instability. Further, a 21-gene signature was developed for prognostication using gene co-expression network analysis. The gene signature was significantly associated with overall and disease-free survival in the TCGA-CRC cohort. Immune deconvolution analysis of the RNA sequencing data revealed that higher expression of the 21-gene signature was associated with increased infiltration of regulatory T cells while being inversely correlated with the overall level of T cells. In conclusion, our study identified the clinicopathological role of *ZFAS1* lncRNA and its interaction genes with prognostic significance in colorectal cancer. Further investigation into the therapeutic relevance of the *ZFAS1*-related gene signature may prove invaluable in improving the clinical outcomes of colorectal cancer patients.

#6212 A differential ligand-receptor network inference method to identify alterations in communication between myeloid cells and CD8 T cells in response to PancVAX neo-epitope peptide vaccine, anti-CTLA-4 and anti-PD-1 antibodies in a murine model of pancreatic ductal adenocarcinoma.

J. T. Mitchell, A. Deshpande, A. L. Huff, C. Cherry, S. Nagaraj, K. Krishnan, D. Lvovs, J. H. Elisseeff, E. M. Jaffee, N. Zaidi, E. J. Fertig;
Johns Hopkins University School of Medicine, Baltimore, MD

Pancreatic Ductal Adenocarcinoma (PDAC) is a deadly cancer with a low tumor mutational burden that leads to the generation of few neo-epitopes derived from mutated genes that can be recognized by cytotoxic T cells. The immunosuppressive microenvironment of PDAC comprises suppressive cell populations that include myeloid cells, cancer associated fibroblast subpopulations, and regulatory T cells that reduce T cell infiltration and cytotoxic function. We have developed a murine personalized cancer vaccine to enhance cytotoxic T cell function against PDAC, PancVAX (Kinkead et al, *JCI Insight* 2018). Survival benefit with PancVAX was dependent on the addition of immune checkpoint inhibitor (ICI) therapy to increase the number of cytotoxic CD8 T cells infiltrating tumors and maintain their cytotoxic function (Huff et al, *JCI Insight* 2023). Yet, the impact of cell-cell communication on effector T cell function arising from the immunosuppressive microenvironment of PDAC remains unknown. We previously developed a ligand-receptor inference method called Domino that infers inter- and intra-cellular signaling networks in single-cell RNA-seq data (Cherry et al, *Nat Biomed Eng* 2021). However, this technique is limited to data from single conditions. Understanding how this combination immunotherapy alters cellular signaling networks requires new computational tools that identify changes in regulatory networks between treatment conditions. We developed capabilities for assessment of differential signaling with Domino founded on a basis of differential signal receipt. Active receptors are identified by receptor expression in recipient cells that is correlated with downstream transcription factors in the intracellular signaling cascade. Identification of causative ligands for receptor activation is assessed by a probability of interaction for ligand-receptor interactions between cell types. This probability metric considers mean expression of ligand and receptor genes as well as the number of sender cells for comparison across treatment groups. Comparing communication networks in PancVAX alone to PancVAX with ICI, PancVAX with ICI enhances cell-cell adhesion and interferon gamma signaling in cytotoxic CD8 T cells towards exhausted CD8 T cells. Macrophages in PancVAX with ICI enhance expression of immune checkpoint ligands towards CD8 T cells, despite the presence of blocking ICI antibodies. Intracellular signaling downstream of PD-1 in exhausted T cells shows diminished numbers of transcription factors linked to PD-1 signaling. This software informs prioritization of inhibitory signals for modulation in future immunotherapy regimens and can be applied generally to other tumor subtypes and treatment contexts.

#6213 *De*termination of permissive and restraining *c*ancer-*a*ssociated *f*ibroblast (DeCAF) subtypes.

Xianlu Laura Peng[1], Elena Kharitonova[2], Joseph Kearney[3], Yi Xu[1], Priscilla Chan[4], Changfei Luan[4], Brian Belt[5], Roheena Panni[6], Arthi Hariharan[4], Ian McCabe[1], Ashley Morrison[4], Ashley Cliff[4], David C. Linehan[5], Alina Iuga[7], Naim U. Rashid[2], Jen Jen Yeh[3]

[1]Department of Pharmacology, The University of North Carolina at Chapel Hill, Chapel Hill, NC,[2]Department of Biostatistics, The University of North Carolina at Chapel Hill, Chapel Hill, NC,[3]Department of Surgery, The University of North Carolina at Chapel Hill, Chapel Hill, NC,[4]Lineberger Comprehensive Cancer Center, The University of North Carolina at Chapel Hill, Chapel Hill, NC,[5]The Center for Tumor Immunology Research, University of Rochester Medical Center, Rochester, NY,[6]Department of Surgery, Washington University at St. Louis Hill, St. Louis, MO,[7]Department of Pathology and Laboratory Medicine, The University of North Carolina at Chapel Hill, Chapel Hill, NC

Cancer-associated fibroblasts (CAFs) in pancreatic adenocarcinoma (PDAC) are known to play a significant role in regulating tumor progression, invasion, and metastasis. Multiple studies using experimental strategies, as well as single-cell RNA-sequencing (scRNAseq) technology, have shown the existence of subpopulations of PDAC CAFs, with divergent physical and biological characteristics. However, how these CAF subpopulations translate to clinical practice remains unclear. Using a combination of sc- and bulk RNAseq data, we present two CAF subtypes with permissive (permCAF) and restraining (restCAF) characteristics in patients, and developed a clinically usable single-sample classifier (DeCAF) using using 11 independent datasets with high reproducibility (AUC = 0.961). We found that the permCAF patients tend to be associated with a “myxoid” histological features, while restCAF samples were more “collagenized” ($p = 0.018$). Patients with permCAF tumors had a median overall survival (OS) of 18.5 m compared to 30.2 m for restCAF tumors, with a stratified HR = 1.66 ($p < 0.001$) for patients with permCAF tumors. Basal-like tumors were found to be associated permCAF subtype ($p < 0.001$). DeCAF and PurIST (basal-like/classical) subtypes were independently associated with OS ($p < 0.001$). Analysis of a phase Ib trial FOLFIRINOX in combination with a CCR2 inhibitor (PF-04136309; NCT01413022) , we found that in patients with classical tumors, increasing permCAF probability was associated with response ($r = -0.688$, $p<0.001$). Tumors with permCAF subtype are enriched in neutrophils using CIBERSORT and may explain the positive response to CCR2 inhibition. More intriguingly, we found similar associations with OS in kidney renal clear cell carcinoma (KIRC, $p = 0.001$) and mesothelioma (MESO, $p = 0.019$). DeCAF subtypes are associated with histological subtype in MESO ($p = 0.021$) and grade in KIRC ($p = 0.056$). Taken together, DeCAF subtypes explain the role of CAF subtypes in patients, provide a foundation for the translation of preclinical studies, and facilitate the design of future therapeutic approaches and clinical trials.

#6214 OncodynamiX as an artificial intelligence (AI) based platform for precision medicine.

D. Sivanandhan[1], P. R. Bhargav[2], S. M. Vasista[2], S. Narayanbhatla[2], S. Kamath[2], O. Sailaja[2], D. Chakraborty[2], S. Babu[1];
[1]TheraIndx Lifesciences, Bangalore, India, [2]OncoDynamiX Lifesciences, Bangalore, India

Introduction: In spite of the recent advances in cancer research, cancer incidence and mortality rate still remain high. Although genomic based approaches are used more extensively for identifying the right treatment approach, only a few patients benefit from this because a) only a limited number of mutations have been classified as driver mutations that are of 'significance' and b) in case of multiple mutations, the approach to identify right drug or drug combinations is not well understood. In this regard, there is a need for approaches that use artificial intelligence where exhaustive omics data is effectively processed, mined and utilized to device personalized therapy. Therefore, we used OncodynamiX an AI driven Cancer Biology platform to identify the right drug(s) for patients that had limited or no treatment options. We present here 2 case studies, one patient with stage 4 uterine serous adenocarcinoma and another one with endometrial adenocarcinoma.

Methods: OncodynamiX platform has over 15 million data points, including mutation, CNA, mRNA and protein data for 1500 cell lines as well as potency, efficacy, target, phenotype and network information on more than 250 drugs. Based NGS data from the patients, OncodynamiX platform identified direct or indirect targetable alterations and then picked drugs or compounds shown to be active in the altered pathways. Based on this, a drug-gene alteration matrix was created which formed the basis for identification of appropriate drug(s).

Results: The first patient with uterine serous adenocarcinoma had the following mutations: PIK3CA (Gain of function, GoF), TP53 (Loss of Function, LoF), PPP2R1A (LoF), APC (Conservation of function); Copy number amplification or high expression was reported for the following genes: BRD4, MYC, NOTCH3, CCNE1 and MUC16. Based on the drug-gene alteration matrix and all available drug data, WEE1 inhibitor was suggested to be the best therapy option for this patient. Accordingly, the patient was treated with WEE1 inhibitor in a then ongoing clinical trial. The second patient with endometrial adenocarcinoma had FBXW7, BRCA1, and PIK3R1 LoF, PIK3CA GoF and TP53 switch of function mutations, amplifications in CCNE1, FGFR1, NSD3, ZNF217 and ZNF70033 and loss of PTEN and FAS. For this patient, Pazopanib and Evrolimus combination was recommended and the patient was treated accordingly. Both patients responded well for the treatment as measured by RECIST response and continued with the treatment for over a year.

Conclusion: The studies presented above highlight the promise of this AI-based approach in personalized medicine. In multiple cases we have used OncodynamiX approach where clear clinical benefit was demonstrated. To further validate this approach, we are initiating a clinical trial with 250 patients. Such approaches should be adopted more widely for significant improvement in life expectancy as well as in quality of life of patients.

#6215 Systematic identification and clinical implications of glycogenes in cancer research: An integrative omics approach.

Y.-H. Chen, Y.-S. Jou;
Academia Sinica - Institute of Biomedical Sciences (IBMS), Taipei, Taiwan

Glycosylation and its products are crucial in clinical routines but are overshadowed by a framework embedding genomic participants in cancer development. The glycosylation scheme varies between research groups, presenting clinical concerns that demand understanding in cancer research beyond the glycome. Our work aims (a) to enhance the canonical framework by identifying potential glycosylation-associated genes (glycogenes) and (b) to advance translational cancer study, offering a unified perspective on integrative omics and explainable machine learning with glycogene integration.

The expansion of the glycosylation framework involved initial text mining from curated databases like OMIM, InterPro, and Reactome. Dysregulation of identified genes was affirmed across 29 TCGA solid cancers, encompassing over 7,000 patients with primary tumors. And healthy tissue data from GTEx facilitated tumor-normal comparisons. Subsequently, integrative omic analysis, involving transcriptome and methylome, was applied to confirm the stratification feasibility of glycogenes and to revealed cancer clusters within the UMAP space. After cluster discovery, profiling from survival analysis and drug response prediction highlighted clinical differences between clusters. Employing a survival forest model and explainable artificial intelligence (XAI), personalized assessments, including a 5-year survival predictor and risk factors for individuals, were developed.

Our study verified over 3,000 glycogenes, expanding the conventional configuration of glycosylation and constituting 10-30% of differentially expressed genes between tumors and healthy tissues. Whether transcriptome or methylome alone, glycogenes demonstrated stratification ability. Advanced omic integration further discovered 16 cancer clusters out of 29 TCGA cancers, associated with anatomical source, morphology, and genomic similarity. Utilizing drug resources from GDSC, this specialized geneset exhibited drug predicting ability, displaying a distinct drug response profile among the 16 clusters. To finalize the clinical potential, a survival forest for 5-year survival model construction concluded forecasters with a time-dependent AUC (0.77 to 0.92 on average) for each cancer cluster. With XAI implementation, survival risk factors were developed and assessed for each individual locally.

Here we identified over 3,000 glycogenes, elaborating the classic glycosylation structure and emphasizing genomic importance in cancer research. Glycogenes demonstrated translational potential, supported by diverse survival distributions and drug responses across cancer clusters discovered by the integrative omic approach. The integration of XAI provided a tailored perspective for implementing glycogenes in clinical cancer research.

#6216 Single cell DNA sequencing of BRAF treatment resistant anaplastic thyroid cancer.

A. Thennavan, M. Tarabichi, P. Wu, M. Martin, R. Dadu, M. Cabanillas, N. Busaidy, Y. C. Henderson, M. Zafereo, M. D. Williams, S. Lai, N. Navin, J. R. Wang; UT MD Anderson Cancer Center, Houston, TX

Anaplastic thyroid cancer (ATC) is one of the most lethal cancers. Although dramatic responses to *BRAFV600E*-mutated ATC are seen with BRAF/MEK inhibition, treatment resistance inevitably develops, limiting survival. In this study we sequentially profiled *BRAFV600E*-mutated ATC at diagnosis, after BRAF/MEK targeted therapy and at the time of disease recurrence using both bulk and single-cell DNA/RNA sequencing. We profiled (~400-800 single cells) for each patient - Patient 1 (n = 704 cells); Patient 2 (n = 817 cells) and Patient 3 (n = 407 cells). At diagnosis, we show that tumor cell populations were characterized by a predominance of arm-level aneuploidies. Across all patients, there is a sharp decline in tumor cells post BRAF-targeted treatment. Interestingly, we observe at least 2 distinct tumor subclones present in the pre-treatment tumor and subsequently there was an expansion event that occurred in each patient after BRAF treatment. This was associated with acquiring unique copy number aberrations (CNA)events and the dominance of these subclones in the recurrent disease. For Patient 2, we also performed single-cell RNA sequencing and show that the recurrent tumor cells have high proliferation and stem-cell like cell states even though they had higher differentiation scores. Importantly, correlating the scDNAseq identified CNA with the inferred CNA from scRNAseq, we show proof of concept that copy number aberrations can be directly correlated with gene expression changes and gene dosage effects. Collectively our data reveal an early polyclonal dissemination model of clones in BRAF-mutated ATCs and suggests that treatment resistance to BRAF inhibition develops as a results of incomplete elimination of viable tumor cell reservoirs in ATC.

#6217 Differential genome-wide gene regulatory networks for lung cancer.

M. Zhang[1], Z. Jiang[2], D. Zhang[1];

[1]University of California, Irvine, Irvine, CA, [2]Purdue University, West Lafayette, IN

Background: Lung cancer remains the leading cause of cancer death worldwide due to the fact that most cases are diagnosed at distant stages, and treatment is less effective. During the past two decades, much effort has been devoted to understanding tumor biology and developing targeted therapeutics, which have significantly improved patient survival. With the increasingly available multi-omics data from healthy controls and lung cancer patients, we constructed gene regulatory networks for the two main subtypes of non-small-cell lung cancer (NSCLC), the most common type of lung cancer. In addition, differential networks were constructed by integrative analysis of data from lung cancer tissue and tissues from healthy lungs.

Methods: Transcriptomics and genomic data were obtained from the patients with lung adenocarcinoma (LUAD) and lung squamous cell carcinoma (LUSC) tissue available in The Cancer Genome Atlas (TCGA) project, and both types of omics data of normal lung tissue were downloaded from The Genotype-Tissue Expression (GTEx) consortium. The networks for each subtype and the differential networks were constructed by utilizing our newly developed machine learning tools, two-stage penalized least square (2SPLS) approach, and analysis of variance of directed networks (NetANOVA), respectively.

Results: For the top three identified subnetworks of LUAD, we identified some well-known genes associated with lung cancer, such as EGFR, IRF1, KRAS, ERBB2, PIK3CA, MYC, at bootstrap frequency >90%. Based on the top three subnetworks with a bootstrap frequency of 100%, results from the Ingenuity Pathway Analysis (IPA) indicated several significant pathways, primary immunodeficiency signaling and communication between innate and adaptive immune cells. GO enrichment analysis showed statistically significant biological processes, including immune response, extracellular matrix organization, and significant KEGG pathways such as Hematopoietic cell lineage. The differential networks between LUAD, LUSC, and healthy lungs showed the same regulations across all three groups, such as the regulation between EEF2 and RACK1, the perturbations between LUAD and healthy (two-way regulations between HIGD2A and ARL10), and LUSC and healthy (GRB14 regulates EIF3E) respectively. In addition, we identified the differences between LUAD and LUSC, such as bi-directional regulations between CLTB and ARL10.

Conclusion: Although all groups share most regulations, we identified differential gene regulations between healthy lung tissue and lung cancer tissue and between LUAD and LUSC of NSCLC. Using multi-omics data generated from lung tissues, coupled with advanced machine learning methods, the causal relationships between genome-wide genes from the analysis will help us understand the molecular mechanism of lung cancer and facilitate the development of personalized treatment strategies.

#6218 Haplotype-resolved analysis of cancer genomes and epigenomes using Oxford Nanopore sequencing.

P. Reschenederr[1], P. James[1], S. McKenzie[2], A. Talenti[1], S. Aganezov[2], D. Turner[1], S. Juul[2];
[1]Oxford Nanopore Technologies plc, Oxford, United Kingdom, [2]Oxford Nanopore Technologies Inc, New York, NY

Cancer is a complex and dynamic disease driven by somatic genomic and epigenomic alterations that accumulate over time. These changes give rise to heterogeneous collections of cells or clones, each with distinct (epi)genomic profiles within a single tumour. Accurate characterisation of these changes is crucial for understanding the mechanisms driving the disease, identifying potential therapeutic targets, and personalising treatment strategies. Due to the technological constraints of short-read and array-based approaches, cancer research has historically had a strong focus on detecting small genomic changes like SNPs and small indels (SNVs) as well as the broad characterisation of large-scale copy number changes (CNVs), mostly ignoring other important variant classes and epigenetic modifications. Here we demonstrate how Oxford Nanopore native long-read sequencing enables the direct detection of not only SNVs, but also break point-resolved simple and complex structural variants (SVs and CNVs), haplotype phasing of all variant types, and identification of DNA modifications like 5-methylcytosine (5mC) and 5-hydroxy-methylcytosine (5hmC) from a single tumour-normal dataset. We illustrate how our end-to-end somatic workflow streamlines analysis for the different variant classes and benchmark somatic SNV and SV calling performance using well characterised cancer cell lines and in-silico benchmarking datasets at different sequencing depths. Finally, we use real-world tumour-normal pairs to showcase a comprehensive sample to answer tumour-normal analysis using Nanopore sequencing. This includes the characterisation of complex patterns of somatic SVs in the different cancer samples, the identification of unique 5mC methylation patterns, exploring characteristic differences in 5hmC levels between tumour and normal samples as well as showing how Nanopore long reads enable haplotype and clone specific CNV calling as well as phasing of genetic and epigenetic variation.

#6219 Type V collagen promotes lung adenocarcinoma metastasis by regulating tumor mechanical stress and the implication for prognosis and therapeutic strategies.

G. Zhu, Y. Wang, Y. Wang, C. Chen, Y. Li, H. Liu, **J. Chen**;
Tianjin Medical University, Tianjin, China

Introduction: The mechanical environment of the human body influences physiological and pathological processes, and understanding these biomechanical aspects holds promise for medical research. Tumor microenvironment changes, including extracellular matrix (ECM) alterations, result the changing of mechanical characteristics of the tissue, play a crucial role in cancer progression and metastasis, including lung adenocarcinoma (LUAD), one of a major histology type of lung cancer. This study focuses on elucidating how mechanical characteristics, especially those related to the ECM, influence LUAD and the signaling pathways involved.
Methods: Cell culture, transfection, Western blot, immunofluorescence, immunohistochemistry, Transwell assay, scratch wound-healing assay were used to investigate the behavior changes of LUAD cells under different treatment. Bioinformatics analyses, and machine learning-based integrative approaches were employed to build the SVM_Score, which was built with relevant base membrane (BM) genes. Patient-derived tumor organoids, myofibroblasts, and co-culture systems were established. Sorafenib, which can inhibited collagen and fibronectin synthesis, was used to explore the proliferation and migration changing of lung cancer cells co-cultured with myofibroblasts.
Results: Mechanical stress, simulated by matrix application, enhanced LUAD cell migration and invasion, correlating with ECM alterations and EMT pathway activation. SVM_Score predicted LUAD patient prognosis and EMT propensity across multiple datasets, revealing its robust prognostic capabilities. Lower SVM_Scores were associated with worse survival outcomes, increased cancer-related pathways, higher Tumor Mutation Burden and altered immune microenvironment characteristics. SVM_Score was also linked to myofibroblast-secreted COL5A1, a key marker for mechanical stress. Patient tissues with low SVM_Scores exhibited higher COL5A1 expression, enhanced EMT propensity, and increased internal mechanical stress. Sorafenib, by inhibiting COL5A1 secretion, attenuated the pro-tumor effects of myofibroblasts, inhibiting proliferation and migration of LUAD cells, and rendering LUAD cells more sensitive to chemotherapy.
Conclusion: This comprehensive study unveils the intricate relationship between mechanical stress, ECM alterations, and LUAD progression. SVM_Score emerges as a potent prognostic tool, reflects tumor mechanical characteristics. Sorafenib intervention targeting COL5A1 secretion provides a potential therapeutic strategy to mitigate LUAD aggressiveness. These findings contribute to a deeper understanding of the biomechanical aspects of LUAD, offering insights for future research and clinical applications.

#6220 TRIP13 augments pancreatic cancer progression- An integrated systems biology study.

S. Dhasmana[1], A. Dhasmana[1], S. Rios[1], I. A. E. Perez[1], S. Khan[1], F. Afaq[2], U. Manne[2], M. M. Yallapu[1], S. C. Chauhan[1];
[1]University of Texas Rio Grande Valley, McAllen, TX, [2]University of Alabama at Birmingham, Birmingham, AL

Background- Pancreatic cancer (PanCa) is one of the most aggressive forms of cancer and its incidence rate is continuously increasing every year. It is expected that by 2030, PanCa will become the 2nd leading cause of cancer related deaths in the United States due to the lack of understanding of the complexity of disease, early diagnostic methods, and extremely poor survival. Despite great advancements in biomedical research, there are very limited modalities available for the early detection of PanCa and its treatment. Thus, understanding of disease biology and identification of newer diagnostic and therapeutic modalities are high priority research in the field. Our group has identified Thyroid Receptor Interacting Protein -13 (TRIP13) as an oncogenic protein which contributes to early events of PanCa.

Methodology- High dimensional omics and structural elucidation of TRIP13 was conducted using publicly available databases like Consurf, Phosphosite, GTEx and GEPIA2. Molecular biology techniques were applied to cross validate all our bioinformatics data. qPCR, immunoblotting and IHC analysis was performed in progressive PDAC cell lines and human tissues to decipher the expression level of TRIP13 in various pathological staging including functional enrichment analysis using Linkdomics.

Results- The structural elucidation analysis revealed that most of the functionally exposed residues, phosphorylation and ubiquitylation sites situated at AAA domain of TRIP13. As compared to normal, TRIP13 is significantly over expressed in pancreatic tumor samples. Pathological staging 2 and 1 (early stages) showed relatively higher expression of TRIP13 as compared advanced stage. Of the total 7 isoforms of TRIP13, only one isoform (TRIP13-001) has shown the over expression in pancreatic tumor samples and shown association with poor survival. In correlation studies, TRIP13 has shown positive association with other pancreatic cancer biomarkers (CEACAM5, S100A4, MUC1, MSLN, CA125). The functional enrichment analyses suggest that TRIP13 is involved in important patho-physiological pathways like DNA repair, viral carcinogenesis, cellular senescence, and cell cycle. Our wet lab experiments also support our computational biology observation.

Conclusion- This integrated computational biology study suggests a potential role of TRIP13 in pancreatic cancer progression *via* modulation of important oncological pathways. Wet lab experimentations also validated the involvement of TRIP13 in pancreatic cancer progression. TRIP13 expression may be associated with patient prognosis. Thus, its inhibitory small molecules can be useful for boosting pancreatic cancer therapies in clinical settings.

Key words- TRIP13, Pancreatic cancer, Early events of cancer, Integrative Biology, Transcriptomics, Computational biology

#6221 First-in-human study of acoustic cluster therapy consisting of PS101 combined with chemotherapy and insonation in patients with liver metastases of colorectal cancer origin.

U. Banerji[1], W. Yau[2], M. T. O'Leary[1], N. Bush[3], S. Gurung[2], A. Snapir[4], J. C. Bamber[1], N. Tunariu[1];

[1]The Institute of Cancer Research and The Royal Marsden Hospital NHS Foundation Trust, London, United Kingdom, [2]The Royal Marsden Hospital NHS Foundation Trust, London, United Kingdom, [3]The Institute of Cancer Research, Sutton, United Kingdom, [4]EXACT Therapeutics AS, Oslo, Norway

Background: Suboptimal delivery of anti-cancer agents to cancer tissue compromises the effectiveness of therapeutics. PS101 consists of microclusters of perfluorobutane microbubbles and perfluoromethylcyclopentane (PFMCP) microdroplets. Acoustic cluster therapy (ACT) consists of PS101 administered intravenously and insonated over a tumour with diagnostic ultrasound (2 MHz or above), which fuses the components of PS101 to form larger ACT bubbles that are temporarily trapped in capillaries, followed by low frequency (0.5 MHz) insonation, which induces oscillation of the ACT bubbles, stretching capillaries. Given concurrently with chemotherapy, this enhances delivery of chemotherapy to target tissues.

Methods: We describe a first-in-human phase1 study to evaluate the safety and tolerability, pharmacokinetics, and preliminary anti-cancer activity of ACT treatment and the chemotherapy regimens FOLFOX or FOLFIRI in patients with liver metastases of colorectal origin (NCT04021277). The dose escalation cohorts evaluated safety of 20 µL/kg and 40 µL/kg dose levels of PS101 combined with chemotherapy. The primary assessment of anti-tumor activity consisted of within-patient comparison of radiographic responses between ACT-treated lesions (insonated) and control lesions (non-insonated).

Results: We had previously treated mice bearing SW620 xenografts treated with a control arm of Irinotecan at 60 mg/kg IP or Irinotecan plus PS101 at 2ml/kg and insonation in the experimental arm and showed a difference in survival in the experimental arm 34 days Vs 54 days p <0.01 (1). In the first in human clinical trial 8 patients were enrolled into the dose escalation part of the study, of which 2 subjects were not evaluable for dose escalation decision. There were no CTCAE grade 3, or above AEs or SAEs related to PS101 or the ultrasound. 4/8 patients discontinued treatment due to AEs - all related to chemotherapy. Median plasma concentration of PFMPC 5 minutes after the injection was 117 ng/ml (n=3, range 82 to 158) in the 20 µl/kg cohort and 233 ng/ml (n=4, range 217 to 275) in the 40 µl/kg cohort. 5 out of 6 patients had greater shrinkage of the insonated lesion compared with control lesions. The median percentage difference in maximum diameter of lesions between baseline and week 8 assessments, for insonated and non-insonated lesions, was -16% (range 25 to -42) and -3% (range 12 to -19), respectively. The dose expansion part of the study is ongoing, randomizing patients receiving FOLFIRI chemotherapy up to 10 patients each between 20 µl/kg and 40 µl/kg dose levels.

Conclusions: Following preclinical activity in xenograft models, the ongoing first in human study of ACT in patients with colorectal cancer has shown clinical translation of differential activity in insonated metastasis. Reference:

#6222 Exposing the heterogeneity of the lipidome in the TME of cutaneous melanoma following treatment with NUC-7738 in combination with anti-PD-1 therapy.

A. L. Dickson[1], G. M. Zickuhr[1], I. Um[1], Y. Zhang[1], R. Plummer[2], S. P. Blagden[3], S. N. Symeonides[4], N. Cook[5], T. Evans[6], M. Elshani[1], D. J. Harrison[1]; [1]University of St. Andrews, St. Andrews, United Kingdom, [2]Freeman Hospital, Newcastle Upon Tyne, United Kingdom, [3]Churchill Hospital, Oxford, United Kingdom, [4]Western General Hospital, Edinburgh, United Kingdom, [5]University of Manchester, Manchester, United Kingdom, [6]The University of Glasgow, Glasgow, United Kingdom

Background. Malignant melanoma exhibits distinct lipid profiles compared to normal tissue and changes in the lipidome influence multiple aspects of tumor biology. Lipidomic alterations within the tumor microenvironment (TME) may influence the efficacy of anti-PD-1 therapy. In combination with anti-PD-1 agent pembrolizumab, NUC-7738 (3'-deoxyadenosine [3'-dA] which is phosphorylated and protected with a phosphoramidate moiety attached at the 5'-position) has shown promising activity in anti-PD-1 refractory melanoma (Phase 2; NCT03829254). NUC-7738 generates sustained intracellular levels of 3'-dATP, which profoundly alters RNA regulatory processes in tumor cells, resulting in impaired cellular responses and changes in expression of proteins related to lipid biosynthesis. To interrogate components of the TME before and after NUC-7738 + pembrolizumab treatment, we developed a novel workflow incorporating Mass Spectrometry Imaging (MSI) to co-register lipidomic changes with molecular markers. Machine learning accelerated the interpretation of complex data obtained from paired patient biopsies.

Methods. Snap frozen paired biopsies from patients with advanced cutaneous melanoma treated with NUC-7738 ±pembrolizumab were analyzed by desorption electrospray ionization (DESI)-MSI. Specific metabolic (e.g., ASAH1) and immune (e.g., CD8, CD20) markers were investigated by multiplex immunofluorescence (mIF) post DESI-MSI. Target selection was guided by bulk RNA-seq data. Raw MSI data was visualized using Waters HDI® software. Data extracted from selected regions of interest was exported into MetaboAnalyst 5.0 for statistical analysis. LIPID MAPS® Structure Database was used to assign lipid species. mIF/mIHC images were analyzed by HALO® AI.

Results. Single 10 µm tissue sections allowed co-registered DESI-MSI and mIF, suitable for further informatic and AI-enabled image analysis. This facilitated direct comparison of lipids, cells, and protein expression in the TME, before and after treatment with NUC-7738, a compound known to cause profound changes in poly(A) tail regulation. MSI data analyses of the TME uncovered intra-tumoral heterogeneity of the lipidome and demonstrated changes following treatment.

Conclusion. This platform provides a powerful investigative tool to simultaneously explore the myriad of factors in the TME that contribute to tumorigenesis and therapeutic response. Further analyses of the role of the lipidome in the TME and intra-tumoral heterogeneity will be explored in paired biopsies from patients with PD-1 inhibitor refractory melanoma.

#6223 Personalized MRI-informed forecasting of prostate cancer progression during active surveillance.

G. Lorenzo Gomez[1], C. Wu[2], J. P. Yung[2], J. F. Ward[2], H. Gomez[3], A. Reali[4], T. E. Yankeelov[5], A. M. Venkatesan[2], T. J. R. Hughes[5];
[1]Fundacion Instituto de Investigacion Sanitaria de Santiago de Compostela, Santiago de Compostela, Spain, [2]The University of Texas MD Anderson Cancer Center, Houston, TX, [3]Purdue University, West Lafayette, IN, [4]University of Pavia, Pavia, Italy, [5]The University of Texas at Austin, Austin, TX

Low and intermediate-risk prostate cancer (PCa) patients are eligible for active surveillance (AS), whereby treatment is delayed until progression to higher-risk disease is detected via longitudinal multiparametric magnetic resonance imaging (mpMRI) scans, biopsies, and prostate specific antigen (PSA) tests. However, AS relies on a population-based observational paradigm in which standard testing frequencies may not match the patient's tumor dynamics, resulting in a delayed diagnosis of progressive disease. To address these issues, we propose to advance AS towards a patient-specific predictive paradigm by leveraging computational tumor forecasts obtained with a biomechanistic model informed by mpMRI and clinical data collected during standard AS.

Here, we present a retrospective study with n = 16 PCa cases. All patients had three mpMRI scans obtained over 2.6 to 5.6 years during AS. Our biomechanistic model describes PCa growth in terms of the dynamics of tumor cell density as a combination of tumor cell mobility and net proliferation. The model is defined on the patient's prostate geometry, which is segmented on T2-weighted MRI data. Tumor cell density estimates are derived from apparent diffusion coefficient (ADC) maps obtained from diffusion-weighted MRI data. To facilitate modeling, the longitudinal imaging datasets are non-rigidly co-registered for each patient. We initialize the model with the tumor cell density map obtained from the ADC map of the first scan. The model is parameterized by minimizing the model-data mismatch in tumor cell density at the second scan date, and then we perform a tumor forecast up to the third scan date. Finally, we build a logistic classifier from a panel of model-based biomarkers calculated from the personalized model forecasts (e.g., tumor volume, total proliferation activity) at the times of histopathological assessment (i.e., biopsy, surgery) to classify tumors as low risk (Gleason score 3+3, n = 16) or intermediate-high risk (Gleason score ≥ 3+4, n = 15).

We obtained a concordance correlation coefficient (CCC) for tumor volume of 0.89 at both model calibration and forecasting horizon. The spatial fit of tumor cell density yielded a median Dice score and CCC of 0.80 and 0.59 at the second mpMRI date, and of 0.76 and 0.60 at the third mpMRI date, respectively. The logistic classifier of PCa risk yielded an area under the ROC curve of 0.90 and operates at optimal sensitivity, specificity, and accuracy of 86.7%, 93.8%, and 90.3%, respectively. The time trajectories of PCa risk obtained from the temporal predictions of the model-based biomarkers enabled identification of PCa progression by more than 1 year. Thus, while further development and validation over larger cohorts are required, these results suggest that our forecasting technology is a promising tool to predict PCa progression in AS and, hence, optimally guide monitoring and treatment decisions during AS.

#6224 Drop-like deformation of nuclei in cancer patient tissue.

C. R. Dubell[1], T.-C. Wang[1], I. Singh[1], D. G. Rosen[2], S. Chakraborty[3], T. P. Lele[1];
[1]Texas A&M University, College Station, TX, [2]Michael E. Debackey Veterans Affairs Medical Center, Houston, TX, [3]University at Buffalo, Buffalo, NY

In this study, we investigated nuclear deformations in cancer tissues and their clinical relevance to diagnostics.
Introduction: Cancers are graded by pathologists examining biopsy slides stained with hematoxylin and eosin for factors including nuclear atypia, which can include features like lobules, invaginations, large nuclear size, and prominent nucleoli. While the importance of nuclear atypia has been known for centuries, its cause remains unclear. Nuclear shaping has been studied extensively in vitro, leading to the liquid drop model of nuclear shaping, which states that nuclear shape changes can occur due to excess area in the form of wrinkles or folds in the lamina. When the lamina becomes fully taut, the nucleus reaches a limiting steady shape. Wrinkles allow the nuclear shape to mirror the cell shape such as in invading cancer cells. The applicability of this model to nuclei in cancer tissues from human patients is untested. Here, tissues were stained for nuclear lamina proteins to test for the presence of excess area in the lamina. Diagnostic relevance of the drop model was assessed by quantitative Fourier analysis of high-resolution images of lamin-stained nuclei.
Methods: Deidentified patient tissues from breast, colon, head and neck, and skin were immunostained for lamin B1 and imaged at high resolution (60X, 1.5 NA). Nuclei were then roughly segmented by the deep learning program Cellpose, followed by segmentation with a custom approach that sensitively detects micron-scale variations in the laminar contour. An Elliptical Fourier Analysis was performed to quantify nuclear irregularity by describing nuclear shape with a series of elliptical harmonics. More irregular nuclei are described by larger Fourier coefficients at higher frequencies.
Results: Folds and wrinkles in the nuclear lamina were observed in healthy tissue from all four tissue types studied, indicating the presence of excess area in the lamina. The presence of irregular nuclear shape including wrinkling/folds in the lamina was quantified with the Elliptical Fourier Coefficient (EFC) ratio. Posterior probability analysis related EFC ratio to tumor grade to assess the clinical value of the excess area found in the nuclear lamina. This revealed cancer-type dependent trends between EFC ratio and tumor grade.
Conclusions: Observations of wrinkling/folds in the nuclear lamina in healthy and cancerous tissue are consistent with the liquid drop model of nuclear deformation. Quantification of nuclear lamina wrinkling with the EFC ratio, along with other nuclear shape parameters, can be a powerful approach for computer-based, explainable, clinical grading. Our findings reveal a fundamental principle of nuclear deformation in cancer tissues and suggest a new approach for improving the accuracy in cancer grading.

#6225 Tumor evolution through selection by ECM stiffness.

T.-C. Wang[1], S. Sawhney[1], D. Morgan[2], R. Rashmi[3], M. R. Estecio[4], A. Brock[2], I. Singh[3], R. L. Bennett[5], C. F. Baer[5], J. D. Licht[5], T. P. Lele[1]; [1]Texas A&M University, College Station, TX, [2]The University of Texas at Austin, Austin, TX, [3]Texas A&M University, Bryan, TX, [4]University of Texas MD Cancer Center, Houston, TX, [5]University of Florida, Gainesville, FL

In this study, we used experimental evolution to investigate the extent to which the mechanical stiffness of the tumor extracellular matrix (ECM) exerts selection pressure on a genetically diverse population of breast cancer cells. Polyacrylamide hydrogels were fabricated and conjugated with collagen type I to create the ECM with different stiffness. MDA-MB-231 cells were continuously cultured on the hydrogels of the same corresponding stiffness. Growth rate was determined at certain time points by harvesting and counting the cells. Abundance of clonal MDA-MB-231 cells labeled with heritable DNA barcodes underwent the same selection was identified with sequencing of DNA barcode tags. Cellular phenotypes were characterized through immunofluorescence staining and confocal microscopy. 3D migration of the cancer cells was examined using Boyden chamber assay. Cellular contractility was measured through traction force microscopy. Whole genome transcriptome sequencing (RNA-seq), assay for transposase-accessible chromatin with sequencing, and reduced representation bisulfite sequencing were performed for transcriptomic and epigenetic analysis. Sustained culture of MDA-MB-231 breast cancer cells overall three months on soft ECM resulted in an increased proliferation rate and beta1 integrin-dependent spreading area of the cells. Such changes did not occur in clonal cells with low genetic variation and did not occur in ancestral cells on stiff substrates. Barcode analysis revealed two distinct surviving populations post-genetic selection, with one demonstrating robust proliferation on both soft and stiff ECM, and the other exhibiting preferential adaptation to the soft matrix. The soft-selected populations exhibited nuclear localization of the transcriptional regulator yes-associated protein and less wrinkled nuclei compared with ancestral populations when both populations were grown on soft ECM. Aggressive migration was observed in the soft-selected populations, indicating a more malignant selected phenotype. The soft-selected cells showed increased RhoA activity and contractile tension on a soft substrate compared to the ancestral cells. RNA-seq analysis revealed systematic differences between ancestral, stiff-selected, and soft-selected populations corresponding to enriched biological processes related to cell adhesion and ECM organization. Significant differences in DNA methylation and chromatin accessibility were observed in soft selected populations which were correlated with changes in RNA expression. ECM stiffness exerts selection pressure on genetically variable cancer cell populations, selecting specific genetic variants in a cell population optimally adapted for that stiffness. Selected variants on soft ECM tend to be highly migratory, proliferative and generate high traction even on soft ECM. Our results highlight the importance of ECM stiffness-driven evolution in cancer development.

#6226 Identifying nested spatial units as a conserved organizing principle of the spatial tumor microenvironment.

V. Behera, H. Giba, B. A. Doran, J. P. Kline, A. S. Raman;
University of Chicago, Chicago, IL

Heterogeneity of therapeutic response amongst cancer patients has a profound impact on cancer-related mortality. It has been widely hypothesized that diversity in clinical outcomes is driven by variability in tumor biology at scales ranging from inter-patient to inter-cellular. Indeed, the advent of technologies describing the tumor microenvironment (TME) at cellular resolution has demonstrated that TME organization is heterogeneous with respect to intra-tumor spatial location, body tumor location (primary vs metastatic), patient, and tumor type. However, the organizing principles that govern TME heterogeneity remain unclear. Without such organizing principles, it remains an arduous task to link descriptions of tumor biology heterogeneity to clinical outcomes in a mechanistically explainable manner. Through the application of network statistical inference models to spatial transcriptomic data, we have identified that nested spatial units (NSUs) are a core organizing principle of the TME. We find that NSUs are widely conserved across 96 patient biopsies of 14 distinct tumor types and 3 body locations (primary, abdominal metastases, brain metastases). Moreover, NSUs represent a transferrable organizing blueprint that allows for the spatial location of individual spots (5-50 cells) in a tumor biopsy to be predicted by the NSUs of a secondary, unrelated biopsy (Pearson correlation of spot-spot distance: 0.04 - 0.71, median 0.25). By using NSUs as the organizing unit of comparison, we identify variation in gene expression, biological pathways, and multicellular structures occurring across tumors in a distance-dependent manner. In summary, NSUs provide a foundation for the comparative analysis of tumor spatial biology and a path by which spatial biology can be mechanistically linked to patient outcomes.

#6227 A systems biology approach for identifying targetable vulnerabilities in Ewing sarcoma.

F. S. Dela Cruz[1], P. S. Mundi[2], A. Siddiquee[1], K. Guillan[1], D. You[1], G. Ibanez Sanchez[1], A. Ndengu[1], A. Califano[3], A. L. Kung[1],
[1]Memorial Sloan Kettering Cancer Center, New York, NY, [2]Columbia University Irving Medical Center:, New York, NY, [3]Columbia University Irving Medical Center, New York, NY

Background: Targeting fusion oncoproteins like the canonical EWS/ETS fusions in Ewing sarcoma remain an elusive challenge. To circumvent these challenges, we have utilized transcriptome-based systems biology approaches that identify targetable Master Regulator proteins (MRs) critical to maintaining the cancer cell state. OncoTarget analysis generates a rank order list of targetable MRs while OncoTreat analysis uses cognate cell lines matched to patient tumors to identify drugs that invert the MR signature. We used OncoTarget and OncoTreat analyses to identify existing drugs which could be repurposed to target MRs active in Ewing sarcoma.
Methods: A gene regulatory interactome was developed from 122 pediatric sarcoma samples to enable identification of MR targets using OncoTarget. To enable OncoTreat analysis, 2 cognate cell lines were subjected to high-throughput drug perturbational screens. Cells were treated with sub-lethal concentrations of 335 compounds (FDA approved or investigational drugs). Ex vivo drug screens using PDX-derived cells were performed as a complementary assay to validate predictions. In vivo validation was performed in Ewing sarcoma PDXs.
Results: The MR architecture of 3 Ewing sarcoma PDX models was evaluated using OncoTarget. OncoTreat analysis identified 43 drugs predicted to be active in at least 1 Ewing sarcoma PDX while OncoTarget analysis identified 20 MR targets predicted in at least 1 Ewing sarcoma PDX. DOT1L and AURKB were predicted targets across multiple Ewing sarcoma PDXs. Ex vivo screening of dissociated cells from 2 Ewing sarcoma PDXs was performed to select the most potent agents for in vivo validation. Three OncoTreat (clarithromycin, tivozanib and obataclax) and two OncoTarget (DOT1L targeted with EPZ-5676 and AURKB targeted with baracertib) predicted drugs were evaluated in a STAG2 mutant Ewing sarcoma PDX and all demonstrated significant abrogation of tumor growth including complete regression in baracertib-treated animals ($p<0.01$).
Conclusion: These systems biology approaches can identify non-oncogene encoded vulnerabilities in Ewing sarcoma and hold the potential for expanding the number of therapeutic options for tumors driven by untargetable oncoproteins.

#6231 Multi-omic characterisation of clear cell renal carcinoma reveals endogenous and exogenous processes related to its aetiology.

R. Cortez Cardoso Penha II[1], A. Sexton Oates[1], S. Senkin[1], H. Park[1], N. Alcala[1], M. Foll[1], K. Smith-Byrne[2], P. Brennan[1], J. Mckay[1];
[1]International Agency for Research on Cancer, Lyon, France, [2]Oxford University, Oxford, United Kingdom

Endogenous and exogenous exposures are associated with distinctive molecular marks in somatic tissues, including human tumours. Integrative multi-omic approaches could help improving the resolution to detect the molecular marks associated with disease aetiology. Here, we leveraged the overlapping molecular information of clear cell renal cell carcinomas (ccRCC) tumours from Mutographs cohort by integrating DNA methylation, transcriptome, and whole-genome sequencing-based somatic mutation data to explore and gain new insights into exposures linked to ccRCC aetiology. Our novel framework identified important sources of biological variance across ccRCC tumours that were summarized as molecular components. We inferred these molecular ccRCC components into independent datasets to further explore their relationship with molecular and epidemiological features of ccRCC, normal adjacent kidney tissues, and other cancer types. Our results revealed a major ccRCC molecular component correlating with cellular mitotic age-related features, particularly the mitotic epigenetic clock (age-adjusted epiTOC2), clock-like DNA mutational signatures (SBS1/ID1), and telomere attrition. This molecular component was overrepresented in ccRCC tumours in comparison with normal paired kidney tissues, associating with *PBRM1* and *SETD2* somatic cancer driver mutations, genome stability, tumor stage, grade and ccRCC patient survival, independently to chronological age. Pan-cancer analysis supported the mitotic-age effect, represented by this molecular component, in other cancer types. Another ccRCC component was associated with tobacco usage, the presence of tobacco related DNA mutational and methylation signatures, increased total mutation burden, and sex. This component was also related to the epigenetic regulation of xenobiotic metabolism-related genes (e.g., *GSTP1*), further suggesting a relationship with genotoxic compounds. We further identified molecular components related to the ccRCC tumour microenvironment and cell proliferation, including one component related to *BAP1* cancer driver mutations, pro-inflammatory immune cells, and ccRCC patient survival. In conclusion, our study reports a novel framework to molecular characterize ccRCC tumours using an integrative multi-omic approach, providing additional insights into the molecular footprints of endogenous and exogenous exposures in ccRCC tumours, including molecular components with prognostic value for patients.

#6233 Characterizing variants of uncertain significance in the tumor suppressor gene known as phosphatase and tensin homolog (PTEN).

Ajay P. Singh, Jasmine Wen, David Nguyen, Vedanta Khan, Kiran Dhami, Kaitlynn Meier-Ross, Benjamin Martin, Jesse T. Chao

Medical Biophysics, University of Toronto, Toronto, ON, Canada

PTEN is an important tumor suppressor that plays an essential role in regulating cell proliferation. Loss of PTEN function is implicated in approximately 50% of metastatic cancers. Individuals with pathogenic *PTEN* variants are at significantly elevated risk of developing hereditary cancer syndromes such as PTEN hamartoma tumor syndrome. While genetic testing for *PTEN* is valuable for identifying individuals at risk, 47% of 3065 publicly reported *PTEN* variants are not conclusively classified; they either have conflicting interpretations of pathogenicity or are labeled as “Variants of Uncertain Significance (VUS)” and are not clinically actionable. The lack of a clear interpretation for these *PTEN* variants hinders the targeted care and surveillance of patients and places a strain on the healthcare system. To overcome this issue, our aim is to develop a clinically relevant tool for assessing the pathogenic effects of *PTEN* variants.We hypothesize that loss of function (LoF) PTEN variants will lead to changes in cellular phenotypic profiles that can be measured through single-cell phenotypic profiling. Thus, our goal is to investigate the functional status of exogenously expressed *PTEN* variants in *PTEN*-/- HEK 293 cells. We developed a multiplexed high content imaging assay to characterize PTEN and its key signaling partners such as phospho-Akt. Additionally, we developed a deep learning based single-cell phenotypic profiling pipeline named Paracell that uses subcellular segmentation to extract 540 phenotypic features. Cells that exhibit abnormal phenotypic profiles are indicative of loss of PTEN function. Preliminary results from testing 73 missense variants of *PTEN* showed that functional and LoF PTEN variants form distinctive clusters in a two-dimensional UMAP plot based on Paracell outputs, suggesting that our approach can identify potentially pathogenic variants of PTEN.Through characterizing novel VUS, we can elucidate structural domains involved in PTEN’s tumor suppressing activity. The result of these classifications will enable more optimized detection, diagnosis, and surveillance strategies for *PTEN*-related cancers. Ultimately, we aim to contribute to improving the genetic testing of PTEN and the development of targeted therapies.

#6234 Single-cell analysis of state-transition from health to leukemia and the leukemic cell heterogeneities in inv(16) acute myeloid leukemia (AML).

Y.-H. Fu, L. Zhang, Y.-C. Chen, D. E. Frankhouser, L. Uechi, D. O'Meally, S. Branciamore, G. Marcucci, R. Rockne, Y.-H. Kuo;
City of Hope National Medical Center, Duarte, CA

AML is an aggressive hematological malignancy with heterogeneous genetic abnormalities. Using a conditional knock-in mouse model (*Cbfb*$^{56M/+}$*/Mx1-Cre*) to mimic the somatic acquisition of fusion gene *CBFB-MYH11* (CM), created in the recurrent chromosome translocation inv(16)(p13q22) of AML, we previously reported that the blood transcriptome undergoes state-transition from health to leukemia. In this study, we analyze the transcriptomic alterations and leukemic cell heterogeneities in a leukemia state-space using single-cell RNA sequencing (scRNA-seq). CM expression was induced in *Cbfb*$^{56M/+}$*/Mx1-Cre* mice by poly (I:C) injection, and scRNA-seq analysis was performed on peripheral blood mononuclear cells (PBMC) and bone marrow (BM) cells from leukemic mice and age-matched wild-type (WT) controls. More than 105,000 cells were subjected to the following dimensionality reduction and cell type annotation. By performing principal component analysis (PCA), we observed a Y-shape cell distribution with emergence of a divergent branch occupied by leukemic cells which can be mapped to a leukemic state. The principal components 1 and 2 (PC1 and PC2) clearly distinguish the leukemic cells from normal cell types such as myeloid cells and lymphocytes. By accessing the eigenvalue of genes for PC1 and PC2, we quantified the crucial genes and pathways related to leukemia progression at a single-cell level. We characterized cKit+ leukemic cell clusters by transcriptome-based correlation and gene expression pattern and found that they resembled stem cells and megakaryocytic-erythroid progenitors (MEP) with dysregulated pathways, including upregulated "inflammatory response" and downregulated pathways related to Myc targets, oxidative phosphorylation, mitochondrial protein translation, and ribosomal biogenesis/assembly. Examining the 31 clusters (C0-C30) seen in cKit+ BM cells, we identified 9 leukemic clusters exhibiting distinct features, including high heme-metabolism (C0, C1, and C2), high proliferation (C1, C8), S phase (C4, C10), low oxidative phosphorylation (C2, C5, C17), high Cd9 (C10), high Egfl7 (C7, C8). In conclusion, our study unveils state-transition from health to leukemia at single-cell resolution, and uncovers diverse biological heterogeneities associated with the inv(16) AML state. Further refinement of transcriptome state-transition and single-cell analysis will provide an analytical framework for modeling the dynamic changes during disease evolution at the single-cell level.

#6235 Clinical and phenotypic consequences of HLA mediated antigen presentation deficiency in pancreatic adenocarcinoma at bulk and single-cell resolution.

M. J. Geuenich[1], B. Gruenwald[2], G. O'Kane[2], C. Yu[1], T. Ju[1], A. Zhang[3], O. Hamza[3], G. Jang[3], F. Notta[3], S. Gallinger[3], K. R. Campbell[1];
[1]Lunenfeld-Tanenbaum Research Institute, Toronto, ON, Canada, [2]Princess Margaret Cancer Centre, Toronto, ON, Canada, [3]Ontario Institute of Cancer Research, Toronto, ON, Canada

Introduction:
Pancreatic ductal adenocarcinoma (PDAC) is a highly lethal neoplasm of the pancreas characterized by a low survival rate and limited treatment options. Despite the success of immunotherapy in various cancer types, its efficacy in PDAC remains low. The underlying reasons for this discrepancy are not fully understood, despite PDAC exhibiting a moderate mutation burden. One possible determinant could be the loss of heterozygosity (LOH) at the human leukocyte antigen (HLA) loci, resulting in compromised antigen presentation. In this work, we aim to identify and validate HLA LOH events in two independent cohorts to gain insights into both their prevalence and clinical and phenotypic impact on PDAC.
Methods:
We applied LOHHLA, a specialized pipeline to identify HLA LOH events from paired whole genome sequencing to two independent cohorts comprising over 650 patients. We contextualized these results with the paired transcriptome-wide gene expression data and immunohistochemistry stains. In addition, we developed a machine learning classifier to predict HLA LOH from transcriptomic data. We transfer this classifier to single cell RNA sequencing data to identify the impact of (subclonal) HLA LOH on the tumor microenvironment.
Results:
HLA LOH events occur in approximately 30% of PDAC patients, with about 50% of these deletions being focal deletions. We find evidence that focal but not non-focal LOH is a driver of immune escape. Overall, we find that HLA LOH events are early genetic alterations and observe a significant association between HLA LOH and the Basal PDAC expression subtype. In addition, we find that HLA expression is the most important determinant of lymphocyte infiltration followed by an intact HLA locus. Moreover, our transcriptomic classifier allowed us to accurately identify HLA LOH events from RNA sequencing data, which we successfully validated in an independent cohort. Finally, we applied this classifier to single cell sequencing data and identified phenotypic differences in multiple compartments of the tumor microenvironment between samples with intact HLA and HLA LOH.
Conclusions:
In conclusion, our study provides the most in depth characterization of the consequences of altered antigen presentation in PDAC to date. We have demonstrated that HLA LOH occurs in a substantial proportion of patients. Overall, these findings contribute to a better understanding of the immune landscape in PDAC and may have implications for the development of immunotherapeutic strategies tailored to this challenging cancer type.

#6236 Systems biology modeling identifies SMARCD3 as a master regulator facilitating everolimus resistance in ER+ breast cancer.

E. F. Medina, P. A. Cosgrove, E. Farmaki, V. K. Grolmusz, F. Chi, J. I. Griffiths, A. H. Bild, A. Nath;
Beckman Research Institute of The City of Hope, Duarte, CA

Breast cancer is the most common malignancy in women and estrogen receptor positive (ER+) breast cancers represent nearly 75% of all breast tumors. Everolimus, an mTORC1 inhibitor, in combination with exemestane has been approved for patients with metastatic ER+ breast cancer. However, many patients eventually develop resistance to everolimus and leads to poor survival outcomes. Characterizing everolimus-resistant cells can reveal targetable molecular phenotypes that can eventually lead to new therapeutic targets. In this study, we elucidate systems-level phenotypic distinctions between everolimus sensitive and refractory cells. We generated several isogenic ER+ breast cancer cell lines resistant or sensitive to everolimus. We then leveraged transcriptomic profiles from sensitive and resistant cells before or after everolimus treatment to decipher the underlying mechanisms essential to the resistant state. Using linear mixed effect models, we identified several meta-phenotypes that were distinct between sensitive and resistant cell states. These included growth-factor signaling, cell cycle, metabolism, stemness, and apoptosis meta-phenotypes. Our analyses also identified strong activation of growth-factor receptors including IGF1R/INSR and ESR1 in the resistant cells, which were maintained despite everolimus treatment. Next, we adopted a transcriptional regulatory network reconstruction framework to identify the master regulators responsible for the activation of resistance meta-phenotypes. We identified SMARCD3 as the key master regulator controlling expression of genes across diverse resistance meta-phenotypes, including growth-factor signaling. Further, using transcriptomic profiles from a neoadjuvant trial of 23 post-menopausal ER+ breast cancers treated with everolimus, we found that SMARCD3 expression was elevated in resistant tumors. To confirm the role of SMARCD3 in everolimus resistance, we repressed transcription of the SMARCD3 gene using CRISPR interference to re-sensitize resistant cells to everolimus treatment. In conclusion, we used context-specific cell transcriptomic profiles and integrative systems-biology approaches to elucidate mechanisms of resistance in response to everolimus treatment in ER+ breast cancer. Our findings suggest SMARCD3 upregulation promotes resistance to everolimus treatment and may serve as a novel therapeutic target in ER+ breast cancer.

#6237 Large-scale imputation models for multi-ancestry proteome-wide association analysis.

C. Wu[1], Z. Zhang[1], X. Yang[2], B. Zhao[3];

[1]UT MD Anderson Cancer Center, Houston, TX, [2]Purdue University, West Lafayette, IN, [3]University of Pennsylvania, Philadelphia, PA

Proteome-wide association studies (PWAS) decode the intricate proteomic landscape of biological mechanisms for complex diseases. Traditional PWAS model training relies heavily on individual-level reference proteomes, thereby restricting its capacity to harness the emerging summary-level protein quantitative trait loci (pQTL) data in the public domain. Here we introduced a novel framework to train PWAS models directly from pQTL summary statistics. By leveraging extensive pQTL data from the UK Biobank, deCODE, and ARIC studies, we applied our approach to train large-scale European PWAS models (total n = 88,838 subjects). Furthermore, we developed PWAS models tailored for Asian and African ancestries by integrating multi-ancestry summary and individual-level data resources (total n = 914 for Asian and 3,042 for African ancestries). We validated the performance of our PWAS models through a systematic multi-ancestry analysis of over 700 phenotypes across five major genetic data resources. Specifically, we identified several novel and well-known genes for various cancers; we highlighted eight genes associated with six cancer traits across all three PWAS model cohorts, including CTSF, RSPO3, CRTAM, LAYN, CHRDL2, DPEP1, NFASC, and NAAA. Our results bridge the gap between genomics and proteomics for drug discovery, highlighting novel protein-phenotype links and their transferability across diverse ancestries. The developed PWAS models and data resources are freely available at www.gcbhub.org.

#6238 Integrated multi-omic/modal profiling enables improved characterization of oncogenic processes, with impact to clinical actionability in the GenMineTOP tested population.

B. Losic[1], K. Tatsuno[2], V. R. Singan[1], H. Ueda[2], A. Ushiku[3], V. Jayakumar[4], E. Hattori[4], T. Ichijo[4], T. Sasa[4], M. Akahori[4], S. Hayashi[4], E. Hsiao[1], S. Feupe[1], D. Vo[1], T. Geier[1], S. Tsutsumi[2], T. Ushiku[3], K. Watanabe[3], K. Oda[3], H. Kage[3], J. Radecki-Crandall[1], D. T. Cheng[1], H. Aburatani[2];
[1]Realm IDx, Aliso Viejo, CA, [2]Research Center for Advanced Science and Technology, The University of Tokyo, Tokyo, Japan, [3]The University of Tokyo Hospital, Tokyo, Japan, [4]Konica Minolta, Tokyo, Japan

Introduction: It is becoming increasingly apparent that tumor gene expression and spatial H&E profiling can be used to improve the accuracy of DNA-only tumor profiling for clinically relevant use-cases. Future development and deployment of integrative (multi-omic (DNA+RNA) and/or multi-modality (omics + imaging)) tests for treatment and clinical trial profiling hinges on the demonstration of clear robustness and performance gains of prognostic and predictive integrative predictors in a clinical setting. In this work we present several analyses quantifying the utility of integrative testing. We show that a multi-omic test combining tumor expression signatures with DNA profiles substantially improves tumor-of-origin prediction for cancers of unknown primary and also significantly improves MSI detection and resolution. We also show that a simple multi-modality model combining spatial features of tumor infiltrating lymphocytes of tumors with tumor expression is prognostic for MSI-positive patients.

Methods: *Multi-omic*Tumor-of-origin: 163 patient sample expression profiles were profiled using the GenMineTOP test. GenMineTOP is a tumor-normal, joint DNA+RNA capture PMDA-approved test in current clinical service in Japan. The samples were clustered using DNA-only, RNA-only, and joint DNA+RNA profiling signatures. MSI prediction: 940 samples from the TCGA COAD, UCEC, and READ cohorts with matched MMR IHC MSI-calling, DNA-NGS-based MSI calling, and RNA-seq data were utilized to train, test and validate an expression-based pan-cancer MSI caller. Additional orthogonal validation was carried out using GenMineTOP multi-omic profiles. *Multi-modality* Spatial context of TIL and tumor-expression: 158 MSI+ samples from the TCGA-UCEC cohort with matched fresh-frozen H&E 20X images and RNA-seq data were utilized to mine spatial features of tumor-infiltrating lymphocytes and derive gene expression signatures, respectively. A Cox-proportional hazard model for patient survival using gene expression and spatial TIL features was constructed while regressing out tumor stage, gender, age, and ethnicity.

Results & Conclusions: Our multi-omic results quantify the benefit of combining DNA and RNA profiles from GenMineTOP to classify tumor-of-origin from unknown primaries reduces classification error by approximately 50%. Additionally, our expression-based MSI status prediction model not only significantly improves NGS DNA (MSI-sensor) based MSI prediction (log-ratio test, pval < 1e-7) but also strongly suggests that nonlinear differential expression drives the improvement in MSI prediction. Our multi-modality results demonstrate that mining the spatial context of endogenous tumor immune response has nontrivial prognostic utility ($p < .05$).

#6239 Human computer interface guided approach to accelerate anticancer drug discovery: Application to human estrogen receptor interactome.

R. V. Rajnarayanan, A. Alsabagh;
NYITCOM at Arkansas State, Jonesboro, AR

Structure-based drug discovery of target specific drugs greatly rely on the existence of high resolution X-ray crystal structure of the target proteins. Flexible and dynamic regions including hinges and loops which constitute major protein-protein interaction sites as well as allosteric sites are often beyond the scope of current tools and techniques available for protein folding and modeling. Human ability in recognizing patterns and to solve complex puzzles are far superior to any existing computer program at folding these atypical regions of proteins. We have utilized an unconventional combination of using dynamic three-dimensional protein models as physical human computer interface (HCI) devices and integrated proteomics data to predict flexible and dynamic protein-protein interfaces and allosteric pockets of key regulatory proteins to accelerate compound discovery. To this end, we have successfully utilized 1) Flexible HCI devices to generate an ensemble of dynamic three dimensional structures which includes a subset of biologically active conformations among others (thereby exploring the viable chemical space) and 2) Structure refinement and efficient filtering of biologically active conformations can be accomplished by integrating protein-protein interface and fold proteomics data. Here we present AI ready, HCI guided exploration of human estrogen receptor interactome and early in vitro confirmatory analyses. AI approachs to predict 3D protein structures from amino acid sequences like AlphaFold are often on par with experimentally generated structures and AI-guided structure prediction or docking approaches have been reported to significantly reduce computer time utilization. Streamlining of HCIguided tools to enable access to dynamic druggable pockets in protein targets will accelerate drug discovery.

#6240 Mutation impact on mRNA versus protein expression across human cancers.

Y. Liu, A. Elmas, **K.-l. Huang**;
Icahn School of Medicine at Mount Sinai, New York, NY

Cancer mutations are often assumed to alter proteins, thus promoting tumorigenesis. However, how mutations affect protein expression has rarely been systematically investigated. We conduct a comprehensive analysis of mutation impacts on mRNA- and protein-level expressions of 953 cancer cases with paired genomics and global proteomic profiling across six cancer types. Protein-level impacts are validated for 47.2% of the somatic expression quantitative trait loci (seQTLs), including mutations from likely “long-tail” driver genes. Devising a statistical pipeline for identifying somatic protein-specific QTLs (spsQTLs), we reveal several gene mutations, including *NF1* and *MAP2K4* truncations and *TP53* missenses showing disproportional influence on protein abundance not readily explained by transcriptomics. Cross-validating with data from massively parallel assays of variant effects (MAVE), *TP53* missenses associated with high tumor TP53 proteins were experimentally confirmed as functional. Our study demonstrates the importance of considering protein-level expression to validate mutation impacts and identify functional genes and mutations.

#6241 A large scale proteogenomic atlas for precision oncology research.

N. Simchi, O. Givton, D. Daitchman, E. Seger, K. Pevzner;
Protai, TEL AVIV, Israel

Recent advances in the field of mass spectrometry proteomics have led to growth in proteomics research resulting in a massive and rapid increase in the volume of high-quality publicly available proteomics datasets. This growth creates an underutilized resource with potential for new discoveries. Effectively utilizing this vast resource of preclinical and clinical samples is a major challenge.

We utilize the growing availability of proteomics and post-translational modifications (PTMs) data for drug and biomarker discovery. This innovative computational approach enables the integration of preclinical and clinical data, both public and proprietary, with a specific emphasis on extracting valuable biological insights that are only observable at the protein level or through PTMs.

We developed a platform that combines multi-omic data curated from the public domain, together with internally generated high quality proteomic and phosphoproteomic data. The platform incorporates diverse clinical annotations, tumor and normal samples, drug sensitivity, patient outcomes and relevant bioinformatic knowledge bases.

The platform can be leveraged to generate insights addressing diverse clinical needs. For example, we demonstrate how our platform can be utilized to estimate the clinical prevalence of a certain protein or protein signature, in order to identify novel response biomarkers with the highest likelihood of success by confirming its presence and variance in clinical datasets. In addition, these insights enable novel understanding of response and resistance mechanisms, thus establishing a framework that expedites the generation of hypotheses for subsequent investigation and experimental validation.

#6242 A workflow execution system in a data fabric for integrative cancer analyses.

A. Venkat, P. Ribeyre, J. Qureshi, S. S. Narumanchi, J. M. Maxwell, B. Winslow, S. V. d. Garcia, C. Meyer, T. Garcia, P. Vassilatos, C. Malson, **Z. Zhang**, R. Grossman;
University of Chicago, Chicago, IL

Cancer researchers are increasingly conducting multi-omic research and performing integrative analyses on combinations of genomic, proteomic, transcriptomic, imaging, single cell and other data modalities. However, it is quite challenging for a researcher to effectively access, aggregate and analyze data and metadata from different data sources in a scalable and reproducible manner, as the individual datasets may be disconnected from each other, and have separate authentication and authorization requirements. We developed a workflow execution system in a data fabric called the Biomedical Research Hub (BRH) to overcome these challenges for academic researchers. The BRH is powered by the Gen3 technology, an open-source Kubernetes based software stack that allows cancer researchers to create their own data fabric and interoperate with data from multiple data sources. The workflow execution system utilizes nextflow and allows researchers to run containerized applications in the cloud in a secure and isolated environment. Data from multiple resources can be combined for analysis using convenient pay models including NIH STRIDES. We plan to demonstrate the application of our system on a scientific use case involving Clonal Hematopoiesis of Indeterminate potential (CHIP), a phenomenon that has been associated with aging, cancer, cardiovascular diseases, infection and all-cause mortality. We run containerized CHIP workflows on the cloud, utilizing two datasets accessible through BRH: i) The Genomic Data Commons, the world's largest source of harmonized cancer data and ii) BioDataCatalyst, an NHLBI ecosystem that drives discovery and innovation for heart, lung, blood and sleep disorders. Our system is ideally suited for machine learning on large aggregated cancer datasets and federated learning tasks.

#6243 Rapid autopsy reveals the interplay of tumor heterogeneity at genomic, transcriptomic, and spatial dimensions.

N. Yao[1], R. Vanguri[2], J. Patel[1], J. Lihm[1], A. Fisher[3], I. Jarchum[3], S. Umeda[1], H. Li[1], S. Ely[3], T. Hollmann[3], C. Iacobuzio-Donahue[1], B. Greenbaum[1];
[1]Memorial Sloan Kettering Cancer Center, New York, NY, [2]Children's Hospital of Philadelphia, Philadelphia, PA, [3]Bristol Myers Squibb, New York, NY

Incomplete understanding of tumor heterogeneity across primary and metastatic sites often lead to ineffective cancer treatments. To comprehensively interrogate tumor heterogeneity at genomic, transcriptomic, and spatial levels, we established a novel rapid autopsy protocol to obtain multiregional tri-omic data consisted of whole exome sequencing, mRNA-sequencing, and multiplexed immunohistochemistry on primary and metastatic tumors and associated microenvironments (TMEs). We applied this protocol to six patients with various primary tumor types: non-small cell lung cancer (NSCLC), small cell lung cancer (SCLC), urothelial cancer, and one mixed case with both NSCLC and SCLC. A total of 50 tumor samples with paired tri-omic data were obtained across 16 different primary and metastatic organs to interrogate heterogeneities underlying tumor evolution and treatment resistance mechanisms.

We constructed mutation-based phylogeny trees to reveal structural differences in tumor evolution trajectories across patients and infer heterogeneous tumor antigen landscape. We uncovered highly entropic phylogenetic structures having unique variants gained at each metastasis as well as low entropic structures with high sharing across sites. The mixed case had a clonal sweep structure with two metastases developed prior to the rest of the metastasis. In this case, older clones were shown to have strong association with APOBEC mutation signatures, enhanced subclonal mutation burden and loss of human leukocyte antigen heterozygosity as mechanisms of immune evasion.

Integrating transcriptome and spatial profiles, we revealed that tumor intrinsic expressions and extrinsic immune infiltration levels covary with tissue types rather than with mutation-based phylogenetic clusters. Across patients, samples that had high similarities in mutational landscape varied in their pro-tumor expression programs and the cellular composition of TMEs. In particular, lung samples across patients had the highest effector T cell population and major histocompatibility complex (MHC) class I, II presentations compared to other tissue types. Contrasting small cell carcinoma (SCC) and adenocarcinoma (Adeno) samples from lung tissues further revealed that SCC had more immunosuppressive TMEs with downregulation of MHC class II. Liver metastasis samples were further characterized to have the most aggressive phenotypes enriched in genomic instability measured by aneuploidy compared to other metastatic sites.

In sum, we present a novel technology and computational framework that enables a three-dimensional profiling of tumor heterogeneity. This work suggests that single-site biopsies are insufficient to capture tumor heterogeneity and calls for multi-modal integrations to design treatments that can overcome tumor-specific resistance mechanisms.

#6244 MultiTME: A Bayesian method for integration and analysis of multimodal, multi-patient spatial profiling data.

Haoran Zhang[1], Jeff Quinn[2], Liron Yoffe[3], Vivek Mittal[3], Wesley Tansey[2]

[1]Department of Computer Science, The University of Texas At Austin, Austin, TX,[2]Computational Oncology, Memorial Sloan Kettering Cancer Center, New York, NY,[3]Weill Cornell Medicine, New York, NY

The role of the tumor microenvironment (TME) in cancer evolution and progression is complex and multi-faceted. Multiple cellular phenotypes and patterns of cell-cell communication have been implicated as drivers of drug resistance and metastasis. The spatial architecture of the TME is emerging as particularly important in characterizing the trajectory of tumor growth and response to therapy. Accordingly, there has been a rapid rise in technologies to spatially profile the TME. Each technology focuses on a different modality (e.g. transcriptomics, proteomics, metabolomics) and operates at a different granularity, from coarse-grained tissue spots aggregating dozens of cells to fine-grained subcellular resolution. There is currently no computational method capable of drawing unified inferences across modalities. We introduce MultiTME, a single, holistic generative model for jointly modeling multimodal data across multiple samples in a cohort. MultiTME addresses these challenges through a two-dimensional integration of both samples and multimodal data. MultiTME incorporates a cohort of tissue samples, enabling the joint modeling of different samples within a single analytical framework. This integration allows for a comprehensive analysis of the spatial distribution of cell types across multiple samples, enhancing the understanding of TME variability and the identification of robust biomarkers. MultiTME also integrates multimodal data with varying resolutions, such as Spatial Transcriptomics (ST), single-cell RNA sequencing (scRNA-seq), and Imaging Mass Cytometry (IMC), and provides a multi-layered understanding of the TME. This integration enables the modeling of TME at a finer scale and the discovery of cell types and subtypes that are not distinguishable using single-modal approaches. It also provides concurrent expression profiles across different modalities, leading to the identification of novel biomarkers. We demonstrate MultiTME's efficiency and scalability with a dataset of coupled ST, scRNA-seq, and IMC from a cohort of 8 lung cancer patients. MultiTME's capability to handle both intra-cohort and inter-modality variability offers a panoramic view of TME and helps identify biomarkers and therapeutic targets for cancer screening and treatment. MultiTME is open source.

#6245 Missed opportunity at the subcellular level: Enhancing the utility of cellular imaging modality in spatial transcriptomic profiling of tumor tissues.

X. Song, X. Yu, C. M. Moran-Segura, G. D. Grass, R. Li, **X. Wang**;
Moffitt Cancer Center, Tampa, FL

Mini-bulk or single-spot spatial transcriptomic technologies, such as GeoMX Digital Spatial Profiler (DSP), have revolutionized our ability to probe spatial heterogeneity and examine transcripts at a subcellular level. In cancer research, this level of granularity is crucial for uncovering the distinct gene expression signatures within specific compartments or structures of interest such as tumor, immune, stroma, and tertiary lymphoid structures. However, in most GeoMX DSP studies, the spatial information obtained from multiplex immunofluorescence imaging has been primarily used for identifying the regions of interest (ROI), rather than as an integral part of the downstream transcriptomic data interpretation. To fix this missed opportunity, we developed a machine learning based analytical framework to fully leverage the rich spatial context provided by the in situ imaging modality. The framework has two main functionalities. (1) ROI cropping and cell segmentation: our framework enables the automated cropping of ROI images, followed by a cell segmentation process utilizing a multi-color-optimized deep learning model pre-trained based on the TissueNet. (2) Cell typing and integrative spatial analysis: the pipeline extracts cell-level morphological features (e.g. cell size and circularity), and AI-driven characteristics. These features are subsequently employed for cell typing and the quantification of cell mixture. The framework is equipped to perform a series of advanced spatial analyses, such as spatial metrics calculation and consensus clustering analysis with the matched gene expression data. To validate the framework, we conducted GeoMX DSP analyses on samples obtained from bladder cancer and upper tract urothelial carcinoma, encompassing 56 ROIs annotated by pathologists. Our results demonstrated high accuracy, with the calculated tumor-immune proportions aligning precisely with the original annotations. We further compared the cell deconvolution results of our framework with those obtained using SpatialDecon. Consistency was noted across both methods, with a high correlation reaching 0.90. However, we observed that SpatialDecon tends to underestimate tumor purity in tumor core regions, with discrepancies as large as 0.30, and overestimating tumor purity in stromal regions. Additionally, analysis of ROIs in tumor margins revealed that SpatialDecon consistently overestimates the overall proportions of immune cells. In conclusion, our results underscore the importance of integrating in situ imaging with subcellular-level spatial transcriptomics for a more accurate and reliable analysis of tumor tissues. Our approach provides critical insights into the tumor microenvironment and cellular interactions, with significant implications for both research and clinical applications in oncology.

#6246 De novo mutation discovery in a mouse model and a human patient sample of non-Hodgkin's lymphoma.

D. K. Sullivan[1], E. Albinali[2], M. Boffelli[3], L. Pachter[3];
[1]David Geffen School of Medicine, University of California, Los Angeles, Los Angeles, CA, [2]Gretchen Whitney High School, Cerritos, CA, [3]California Institute of Technology, Pasadena, CA

Cancer encompasses many different diseases, all typically involving an accumulation of genetic alterations. However, despite the genomic complexity of this group of diseases, cancer genomic studies typically rely on sequence alignment to a "reference genome" prior to analysis. Such approaches can provide gene expression quantification of known, annotated genes. However, they miss the detection of fusion genes, novel transcripts, virus insertions, and other genetic insults that may be present in cancer beyond an altered gene expression profile. Here, we develop a workflow for de novo identification and quantification of "outside of reference genome" genetic aberrations. This workflow leverages klue, a method we developed that is based on the compact de Bruijn graph, which can extract sequences uniquely found in a "tumor" sample but not in a "normal" control sample from genomic sequencing data. We first applied this method to an RNA-seq experiment from the EμSRα-tTA/TetO-MYC mouse model, which is a MYC-driven autochthonous transgenic mouse model of T-cell acute lymphoblastic lymphoma (T-ALL). We extracted k-mer contigs present in the mouse tumor samples but are present neither in the spleens of wild-type mice of the same genetic background nor in the standard mouse reference genome assembly. We then mapped RNA-seq reads from the T-ALL mouse tumor samples to these contigs. The contigs with the highest number of mapped reads (i.e. the highest counts) were run through BLAST to determine their identities. The mapped contigs with the highest counts were the tTA transgenic element sequence and the human MYC transgene. This result showcases this workflow's success in isolating and quantifying "reference-absent" tumor-unique sequences. Next, we applied klue to whole genome sequencing (WGS), whole exome sequencing (WES), and RNA-seq data from a patient with B-cell follicular lymphoma (with matched normal specimen) from the Texas Cancer Research Biobank, as this data is unrestricted open access. Tumor-unique contigs in sequencing reads were extracted and analyzed with BLAST and BLAT. In one case, a nonsynonymous point mutation in the SPI1 (also known as PU.1) oncogene was found. The sequencing reads from the tumor sample showed both the "normal variant" of SPI1 as well as the mutant SPI1:H268P, suggesting a heterozygous mutation. Altogether, these results suggest that the idea of first identifying tumor-unique sequences then doing post hoc analysis of those sequences is a viable approach for de novo mutation discovery in cancer genomics.

#6247 Comprehensive characterization of cancers with epithelial mesenchymal transition phenotype through long-read sequencing.

Y. Tanaka, H. Mano;
National Cancer Center Japan, Tokyo, Japan

Introduction: Pancreatic ductal adenocarcinoma (PDAC) and linitis-plastica type gastric cancer (STAD) are the most representative refractory cancers even in the era of molecularly targeted therapy and immunotherapy. Extensive characterization of these tumors, especially regarding the genomic and epigenomic characteristics of pure cancer cells, has been hampered by the high stromal content in the primary tumor samples. Here we took advantage of cancer cells purified from malignant ascites and established corresponding cell lines to overcome the limitations associated with the analysis and to discover their vulnerabilities.

Methods: We developed cell lines from malignant ascitic fluid samples obtained from 60 patients with PDAC and 59 patients with linitis-plastica type STAD. We performed comprehensive multi-omic analyses of these cell lines using long-read whole-genome sequencing (WGS) for complex somatic genomic alterations and for methylation aberration. We also conducted long-read RNA sequencing (iso-seq) for full-length isoform exploration, and chromatin immunoprecipitation coupled with sequencing (ChIP-seq) for enhancer analysis. Complementary short-read whole-genome sequencing and RNA sequencing were also performed.

Results: Comprehensive transcriptome analyses identified a cluster with high epithelial-mesenchymal transition (EMT) characteristics, consisting of the majority of the PDAC cell lines and a half of the STAD cell lines. ChIP-seq analysis against H3K27ac revealed the distinct transcriptional circuit that generated EMT cluster-specific super-enhancers governed by SMAD3, independent of cancer type. Most of the transcriptional activity was controlled by the gene methylation. We also identified the differential expression levels of the splicing factors between the EMT-activated and the non-activated groups. Comprehensive isoform analysis by iso-seq revealed that the isoform usage was completely different between the EMT group and the other, especially in genes of the actomyosin pathway which confer characteristic features of the EMT cluster in the cell morphology and cell motility. Using the CHM13 reference genome, long-read WGS analyses revealed the recurrent structural alterations specific to the EMT group such as those involving *CDKN2A*. We also identified PDAC-specific structural alterations.

Conclusion: We identified the distinct molecular characteristics of the EMT-activated group in PDAC and linitis-plastica type STAD which may confer the therapeutic resistance. Our findings provide an interesting insight for the further innovation of the treatment strategy for these intractable cancers.

#6248 Multilayered molecular interactions underlying glioblastoma pathogenesis through multi-omics analysis.

T. Nakashima[1], Y. Funakoshi[1], R. Yamamoto[1], Y. Sugihara[1], S. Nambu[2], Y. Arakawa[3], S. Tanaka[2], J. Ishida[4], R. Saito[5], R. Hanaya[6], K. Yoshimoto[7], Y. Narita[1], H. Suzuki[1];

[1]National Cancer Center Japan, Tokyo, Japan, [2]The University of Tokyo, Tokyo, Japan, [3]Kyoto University Graduate School of Medicine, Kyoto, Japan, [4]Okayama University Graduate School of Medicine, Okayama, Japan, [5]Nagoya University Graduate School of Medicine, Aichi, Japan, [6]Graduate School of Medical and Dental Sciences, Kagoshima University, Kagoshima, Japan, [7]Graduate School of Medical Science, Kyushu University, Fukuoka, Japan

Glioblastoma, IDH-wild type (GBM) is the most common malignant and treatment-refractory brain tumor with a dismal prognosis. Despite the identification of various driver genes in previous large-scale genomic analyses, there has been limited progress in the development of novel treatments. Acquiring an extensive understanding of the molecular mechanisms underlying GBM pathogenesis is crucial to improve prognostic outcomes. We analyzed 289 whole-genome sequencing data (WGS) including 159 unpublished deep WGS (≥ ×120 coverage) along with RNA-seq, DNA methylation array, and assay for transposase-accessible chromatin with sequencing (ATAC-seq) to uncover the molecular mechanisms regulating development and progression of GBM. Our deep WGS enables us to delineate a fine view of clonal architecture, where mutational signature varies between clonal and subclonal mutations, suggesting that different mutational processes contribute to GBM pathogenesis depending on its developmental stage. The differentiation status of tumor cells detected by transcriptional deconvolution analysis is associated with multi-layer profiles including genomic alterations, expression subtypes, DNA methylation, and open chromatin status. Tumors predominantly comprised of differentiated cells display genetic and epigenetic profiles that align with the classical subtype, whereas tumors predominantly composed of stem-like cells exhibit profiles consistent with the proneural subtype. ATAC-seq unveils genome-wide chromatin accessibility features associated with gene expression subtypes. Motif enrichment analysis of differentially accessible sites among the subtypes identified specific transcription factors. The proneural subtype is enriched for the SOX10 binding motif, which is associated with regulating cell states, and exhibits higher expression of SOX10 compared to other subtypes. Conversely, the mesenchymal and classical subtypes are enriched for the CREB1 binding motif, which promotes cell proliferation and angiogenesis through TGFβ2 upregulation, wherein TGFβ2 expression is significantly elevated. These findings support a model in which the difference in chromatin structure also regulates the progression of GBM.Our analysis reveals the multi-layer molecular interactions underlying the progression of GBM enhancing our understanding of the pathogenesis.

#6249 Single-cell RNA sequencing investigation of multi-stage NASH-related HCC mouse model.

T. Suoangbaji, V. X. Zhang, D. W. Ho, I. O. Ng;
The University of Hong Kong, Pokfulam, Hong Kong

Hepatocellular carcinoma (HCC) is one of the most frequent malignancies and a leading cause of cancer-related death worldwide. Its incidence is also one of the most rapidly increasing in the West. Most (>80%) of HCCs are diagnosed at advanced stage and therefore not operable. Even after surgical resection, the long-term prognosis of HCC remains unsatisfactory due to high recurrence rates. It is also an extremely difficult-to-treat cancer. Most HCC patients have a background of chronic liver disease, including chronic viral infection, excessive alcohol consumption or non-alcoholic fatty liver disease NAFLD)/steatohepatitis (NASH). In June 2023, new nomenclature of NAFLD and NASH have been internationally announced as metabolic dysfunction-associated steatotic liver disease (MASLD) and metabolic dysfunction-associated steatohepatitis, respectively. Due to the enforcement of neonatal HBV vaccination program and the availability of effective antiviral treatments on HBV and HCV, the global incidence of viral hepatitis-related HCC has been declining, whereas NAFLD/NASH-related incidence of HCC has been increasing. We established NASH-related HCC mouse model using Western diet (WD) plus carbon tetrachloride (CCl_4) method. This model demonstrated steatosis, fibrosis, obesity and HCC with high incidence. It has also been reported to accurately portrait the key pathological features of the patients. Next, we collected liver tissue samples at different timepoints (normal; Week 12: NAFLD/NASH; Week 18: fibrosis/cirrhosis; Week 32: HCC) and analyzed them using single-cell RNA sequencing (scRNA-seq). Single-cell sequencing offers an unprecedented platform to perform systematic and in-depth investigation of the admixed tumor microenvironment (TME) in HCC tumor. We have taken advantage of the unique multi-dimensional capacity of scRNA-seq to delineate multifaceted landscapes and cell-cell communication in multi-stage NASH-related HCC mouse model. After removing the low-quality cells, our multi-stage dataset consisted of >130,000 cells. Using typical cell type markers, we identified major cell types, namely T cells, B cells, myeloid cells, liver sinusoidal endothelial cells, hepatic stellate cells, hepatocytes and HCC tumor cells. We observed a change in the cell type composition during disease progression. Throughout our study, we closely examined the communication level between different cell types to identify any irregularities or disturbances that could lead to NASH-related HCC. Our findings concluded that hepatic stellate cells, despite existing in low proportion at all stages, exhibited the strongest level of interaction with other cell types. Moreover, our data also established the comprehensive multi-stage cellular landscape of NASH-relative HCC.

#6250 The RNA editing landscape of lung cancer in never smokers.

J. Sang, W. Zhao, T. Zhang, M. Landi;
National Cancer Institute, Rockville, MD

Adenosine-to-Inosine (A-to-I) editing represents a crucial RNA modification mechanism, holding the potential to drive carcinogenesis. This sophisticated post-transcriptional process is catalyzed by a series of ADAR (adenosine deaminase acting on RNA) family members, which can profoundly reshape the cellular epitranscriptomic landscape. While previous explorations have illuminated the important role of A-to-I editing in lung cancer tumorigenesis and prognosis, most studies have focused on lung cancer from smokers. To investigate the contribution on RNA-editing in lung cancers in never smokers (LCINS) , we embarked on a rigorous dissection of A-to-I RNA editing events in 603 LCINS. Harnessing transcriptome and whole-genome sequencing technologies, we identified 15,880 A-to-I sites, of which 75% were positively linked to the enzymatic activity of *ADAR1*. 92.80% of detected editing sites were located at Alu repetitive regions, with the remainder in non_Alu repeat (4.1%) and non-repeat regions (3.1%). The global RNA editing levels, measured as Alu Editing Index (AEI), were found to be significantly associated with *ADAR1* expression, Tumor Mutational Burden, and Neoantigens Burden. A subtle correlation between global RNA editing levels and tumor stage was also noted. Delving into cancer-associated editing events, we identified 5,539 differentially edited sites in tumors compared with normal tissues, which were located at 823 genes, including several key tumor suppressors and oncogenes, like *MDM2*, *BRAF*, *TP53*, *BRCA2*, *ATM*, and *VHL*. Subsequent pathway analysis identified TGF-beta, Notch Signaling, and DNA Damage Response as the key pathways for cancer progression. Using the characterized A-to-I editing profiles, we built a prognostic risk stratification model, with high risk scores significantly linked to poor survival outcomes, even after adjusting for other clinical factors. Our study provides a comprehensive A-to-I editing landscape of lung cancer in never smokers, highlighting the potential roles of RNA modifications in the pathogenesis of this lethal disease.

#6251 Validation and implementation of whole-transcriptome sequencing assay into cancer care: An experience from a cancer center.

Jillian A. Moran[1], Edward G. Hughes[2], Donald C. Green[2], Shrey Sukhadia[2], Gregory J. Tsongalis[2], Samantha F. Allen[2], Laura Tafe[2], Brianna Houde[2], Nevena B. Ognjenovic[3], Jennifer N. Barbuto[2], Ivy Riano[4], Parth Shah[5]

[1]Geisel School of Medicine at Dartmouth College, Hanover, NH,[2]Department of Pathology and Laboratory Medicine, Dartmouth-Hitchcock Medical Center, Lebanon, NH,[3]Department of Molecular and Systems Biology, Geisel School of Medicine, Hanover, NH,[4]Hematology/Oncology, Dartmouth Cancer Center, Lebanon, NH,[5]Dartmouth Cancer Center, Lebanon, NH

Introduction Transcriptome sequencing is a well-established diagnostic tool to characterize and quantify gene expression profiles and to detect fusion transcripts. The utilization of whole-transcriptome sequencing (WTS), in clinical workflows can tremendously help improve diagnosis, risk stratification, and therapy selection. However, there are multiple challenges to widespread clinical implementation of WTS including nucleic acid input, defining appropriate quality control (QC) criteria, tumor specific baseline controls and depth of sequencing. Here, we present a validation study to deploy routine whole transcriptome sequencing with automated analysis in a mid-size academic center. **Methods** Nucleic acid material was obtained through clinical residual samples in the Center for Genomics and Advanced Technology. RNA samples were extracted using the Purigen Ionic® FFPE to Pure RNA Kit. RNA input sample quantities ranged from 34-100ng. WTS libraries were prepared using the Illumina® RNA Prep with Enrichment (L) Tagmentation kit with the Illumina Exome Panel for FFPE tumor samples. The validation was performed on a set of patient samples with known clinically reported variants from the Illumina TruSight® Tumor 170 assay. A total of 84 true positives with reportable fusions, 5 splicing events, 16 negative samples, and 15 limit of detection (LOD) samples were used. Libraries were prepared in a three-plex format. Sequencing was performed on the Novaseq-6000 system using S2 and S4 flow cells with a target read count of 100 million. All data was processed through the AUGMET informatics platform for demultiplexing, quality control, fusion detection, transcript quantification and determination of alternatively spliced transcript. **Results** The WTS validation assay demonstrated 98% (n=49/50) sensitivity, with only one false negative, and 100% (n=68/68) specificity. A final review of our data was determined to develop stable QC standards for RNA sequenced libraries to be > 60M reads and > 130bp read length. When analyzing (LOD) for WTS, interestingly, read length was inversely proportional to input and as a result detection of the clinically relevant fusion. Based on our LOD experiments, a minimum input threshold of 20ng of RNA was determined to maintain the sensitivity and specificity. An LOD study for tumor purity was not performed due to the known lack of correlation between tumor purity and fusion transcript quantity. **Discussion** WTS can detect all clinically reported fusions and splicing events with comparable sensitivity to panel assays. Moreover, simultaneously available transcript quantification and variant calling provide the ability to implement several disease classifiers. This work lays the foundation for integration with our clinically available tumor exome sequencing assay to allow joint exome transcriptome analysis in a single informatics platform.

#6252 Driver indel discovery and allelic imbalance in >9,000 tumor RNA-Seq samples from the Cancer Genome Atlas (TCGA).

K. Hagiwara, A. Thrasher, J. Zhang;
St. Jude Children's Research Hospital, Memphis, TN

High-throughput DNA sequencing technologies have enabled unbiased screening of genomic alterations such as single nucleotide variants (SNVs) and small insertions/deletions (indels). However, variant analysis using transcriptomic sequencing (RNA-seq) data has not become standard due to challenges in distinguishing true variants, in particular indels, from artifacts that can arise from RNA-seq mapping and library preparation. We have previously developed a tool, RNAIndel, which classifies indels as somatic, germline, or artifacts using a machine learning-based model. Here, we present enhanced somatic indel discovery by incorporating tumor RNA-Seq data with conventional paired tumor-normal DNA-Seq by re-analyzing the Cancer Genome Atlas (TCGA) data using RNAIndel. Our analytic process involves running RNAIndel on 9,101 TCGA tumor RNA-Seq samples across 33 cancer types hosted on Cancer Genomics Cloud by Seven Bridges Genomics (https://www.cancergenomicscloud.org) and comparing the result with the reference somatic indel set generated from paired tumor/normal whole-exome sequencing (WES) data using an ensemble caller developed by NCI Genomic Data Commons (GDC). The comparison validates the RNAIndel variants by matching to the corresponding WES dataset. We also use the GDC indel set to test their expression in RNA-Seq. Indel alignments across sequencing platforms were compared by indelPost, an algorithm that we developed, to perform indel realignment to overcome the differences in mapping algorithms (BWA vs. STAR) and read lengths (100-bp vs. 50-bp) in WES versus RNA-Seq data.The joint DNA/RNA indel analysis provides important insights into the expression profile of indels in known cancer driver genes versus non-drivers. First, indels in driver genes are more likely expressed than those in non-drivers (79% vs. 50%, $p < 2.2 \times 10^{-16}$). Second, mutant allele expression is frequently upregulated for truncating indels in tumor-suppressor genes (TSG) as allelic imbalance was detected in 6% of such variants in TSGs vs. 2% non-drivers. This may indicate a potential second hit leading to loss of the wild-type allele of in the TSGs. Third, allelic imbalance for in-frame indels was also frequent for oncogenes (20%) compared with the non-drivers (7%). The high expression likelihood of driver genes and the enriched indel allele expression for TSGs and oncogenes both support the use of RNA-Seq to enhance driver indel discovery. Indeed, our analysis reveals ~10% additional driver indels by RNA-Seq analysis which are absent from the GDC reference indel set. These indels affect prominent driver genes, most frequently *CDKN2A*, *TP53* and *ARID1A*. Our experience argues for incorporating de novo indel analysis in RNA-Seq as a standard approach for future cancer genomic analysis.

#6253 Single-cell RNA sequencing reveals metastatic site-specific biomarkers for predicting response to CDK4/6 inhibition in advanced HR+/HER2- breast cancer.

L. Luo[1], P. Yang[2], S. Mastoraki[1], Y. Wang[1], N. M. Kettner[1], A. Singareeka Raghavendra[1], D. Tripathy[1], S. Damodaran[1], K. K. Hunt[1], Z. Li[1], K. Keyomarsi[1]; [1]UT MD Anderson Cancer Center, Houston, TX, [2]Rice University, Houston, TX

Background: Cyclin-dependent kinase 4/6 inhibitors (CDK4/6i), in combination with endocrine therapy, are established as standard treatment for advanced HR+/HER2- breast cancer (BC). However, response heterogeneity is observed, with approximately one-third of patients exhibiting intrinsic resistance. This study investigates the mechanisms of variable responses to CDK4/6i through single-cell RNA sequencing of metastatic site biopsies, revealing distinct biomarkers for predicting CDK4/6i response.

Methods: Single-cell RNA sequencing analyzed metastatic tumors from advanced HR+/HER2- BC patients pre-CDK4/6i treatment at baseline (BL) and/or at disease progression. BL samples were from CDK4/6i responders (n = 8, median progression-free survival [mPFS] = 17 months), while progressors were categorized as early-progressors (EP, n = 3, mPFS = 3 months) and late-progressors (LP, n = 8, mPFS = 10 months). Metastatic sites included liver (10), pleural effusions (6), ascites (2), and bone (1). InferCNV distinguished tumor cells, and functional analysis utilized the Molecular Signatures Database.

Results: Both EP and LP tumor cells exhibited reduced estrogen response and increased IFN-γ pathways compared to BL tumors. LP tumors displayed enhanced Myc targets, EMT, TNF-α, and inflammatory pathways compared to EP tumors, revealing differential mechanisms of early versus late progression. Predictive signatures, including *TFF3* and *MGP*, were significantly upregulated in BL tumor cells across different metastatic sites. Metastasis-specific markers included *APOA* and *SERPINA1* (liver), and *AGR2* (pleural effusion). BL and LP responders showed increased tumor infiltrating CD8+ T cell and NK cells compared to EP non-responders. Notably, despite a high CD8+ T frequency in responder tumors, functional analysis revealed a significant upregulation of genes associated with stress/apoptosis and exhaustion in proliferative CD4+ and CD8+ T cells from BL compared to LP tumors, including *HSP90* and *HSPA8*, associated with poor response to immune checkpoint inhibitors. These findings suggest potential benefits of immunotherapy for CDK4/6i late progressors. Longitudinal biopsies further revealed dynamic NK cell expansion and enhanced cytotoxic T cell activity alongside the downregulation of stress/apoptosis gene expression at progression compared to BL tumors.

Conclusion: This study underscores the significance of metastatic site-specific biomarkers in predicting outcomes to CDK4/6i. Tumor-infiltration lymphocytes may also serve as baseline predictors, while stress/apoptosis gene signatures suggest checkpoint inhibitor usage in CDK4/6i late progressors. These potentially actionable findings emphasize the need to optimize therapeutic approaches based on microenvironment-specific changes following disease progression.

#6254 Casein kinase II (CK2) expression in pediatric solid tumors.

A. Beeravally Nagulapally, C. Behura, D. Gandra, G. Sholler;
Penn State Health Milton S. Hershey Med. Ctr., Hershey, PA

Despite recent advances, high-risk neuroblastoma (NB) and sarcomas account for 15% and 5% of all pediatric cancer deaths, respectively. Many patients attain remission, but approximately half of patients relapse. Genomic alterations such as MYCN amplification and ALK mutations have been shown to be important in prognosis and treatment. Despite improvements, approximately 20% of patients have refractory or recurrent disease after therapy, underscoring the need for further genomic understanding and new approaches to treatment.CK2 is a serine/threonine kinase that regulates numerous cellular processes such as cell growth, proliferation, and survival. Overexpression of CK2 is associated with a poor prognosis in several adult solid tumors, making it a potential target of interest in pediatric solid tumors. This study aims to investigate CK2 expression among patients with NB, Ewing sarcoma (EWS), and rhabdomyosarcoma (RMS) and its correlation with patient survival. MethodsPatients were enrolled in NMTRC008/009: “Feasibility Trial Using Molecular Guided Therapy for Patients with Relapsed/ Refractory Childhood Cancer” and BCC-001. WES and RNA-Seq were performed at the Translational Genomics Research Institute and Sema4 or Caris respectively. RNA expression levels were compared to a normal whole-body reference and a pediatric cancer reference. Differential expression data were interpreted in the context of systems biology.ResultsTumor WES was performed on 297 patients (212 NB, 50 EWS, 35 RMS) and RNA-Seq on 284 patients (210 NB, 39 EWS, 35 RMS). The most common mutations or copy number alterations were seen in MYCN, ATRX, ALK, CDKN2A, and chr17q+ in NB; EWSR1-FLI1 fusion in EWS; PAX3-FOXO1 fusion in RMS. RNA expression analysis was performed to understand MYCN-driver status by covariance and interactions and to identify subsets of patients with high/low expression of CK2 in different tumors. CK2 bimodal expression is seen across various cancers and normal tissues, implying distinct sub-groups exist in the data. In NB, overexpression of the CK2 gene with statistical significance was found in MYCN-amplified and chr17q+ tumors. A positive and negative correlation of the CK2 gene is seen with several target genes like MYCN, TRIM71, LIN28B, and HMGA2, JAK2, AR, STAT3, EGFR, LEF1, and NFKB2, respectively. In EWS and RMS, subgroups are identified with high and low expression of the CK2 gene.ConclusionGenomic sequencing of pediatric solid tumors showed a low mutation burden. RNA analysis resulted in the identification of potential novel therapeutic targets involving CK2 pathways. High expression of CK2 correlates with MYCN status. Further analysis of patient molecular subgroups is ongoing.

#6255 Personalized medicine for DCIS.

A. Hazra;
Brigham and Women's Hospital, Harvard Medical School, Boston, MA

Background: In 2023, 55,720 women will be diagnosed with non-invasive ductal carcinoma in situ (DCIS) in the United States. We evaluated RNA sequencing (RNA-Seq), clinical and social factors that drive subsequent breast events in a DCIS study population enriched for Black women (30%).
Methods: RNA was extracted from macrosections of archival formalin-fixed paraffin-embedded (FFPE) DCIS tissue from Resource Archival Human Breast Tissue (RAHBT) from the St. Louis Breast Tissue Registry at Washington University School of Medicine and the Dana Farber Cancer Institute patient cohorts. Tissues were prepared by microsection of 5 uM whole section from unstained slides (Fisher). RNA was extracted using Qiagen RNeasy FFPE Kits from macrosectioned DCIS specimens. Purified total RNA was evaluated for quality and quantity using the Agilent Fragment Analyzer RNA assay. Bulk RNA sequencing was piloted in DCIS case-control samples using the SMART-seq and Hybrid Capture platforms at the DFCI Molecular Biology Core Facilities. Raw reads were aligned to the GRCh38/hg38 reference genome using STAR. Preliminary quality control analysis of a curated gene list showed higher quality data using the Hybrid Capture technology. Libraries for Hybrid Capture were pooled in 8plex reactions and hybridized to Twist Exome 2.0 probes for target enrichment. The final library pools were sequenced on an Illumina NovaSeq. Cases were defined as women diagnosed with DCIS in 1999 or later with subsequent invasive breast cancer, local DCIS recurrence, or lobular CIS recurrence. Controls were defined as women diagnosed with DCIS in 1999 or later without subsequent breast events during a similar follow-up time. The R package DESeq2 was used for data analysis.
Results: The mean age at DCIS diagnosis was 56.3 (Std Dev 10.23). The mean follow-up time was 147.8 months. Hybrid Capture RNA-Seq files are stored and analyzed from the Harvard Medical School O2 Cluster using R programming (version 4.2.2, DEGreport). Quality control analyses demonstrated that the majority of the samples sequenced by Hybrid Capture had over 20 million total reads. Principal Component Analyses (PCA) and hierarchical clustering analyses of 19,821 protein-coding genes were conducted on the 143 DCIS samples sequenced using Hybrid Capture. PC1 was race (9%). A significant association was observed for follow-up time (PC3, 4.03%).
First, we explored the association of the candidate gene ERBB2. The mean transcript abundance for ERBB2 was 11784.37 (case-control p-value=0.08). Preliminary analysis of selected genes of interest did not show statistically significant differences between cases and controls after FDR p-value adjustment. Differential gene expression analyses are ongoing.
Conclusion: This study demonstrates the feasibility of generating high-quality RNA-seq data from diverse, archival DCIS samples.

#6256 Prevalence of BRCA1 and BRCA2 proteins in breast cancer in a nigerian population and their relationship with different breast cancer morphological variants.

S. Raphael, A. Oluwasesan;
University of Abuja, Abuja, Nigeria

Background: Breast cancer is the commonest site specific cancer in women and a leading cause of cancer death among women in Nigeria and globally. The trend in Nigeria and Africa is that breast cancers are seen in younger age groups, are of higher grades and follow an aggressive course. It has been suggested that this may largely be due to mutation in BRCA genes with the attendant alteration in function of its proteins. This study aimed at determining the prevalence of BRCA1 and BRCA2 proteins in breast cancers seen in our environment as well as to see any association between these proteins and different morphological variants.

Materials and Methods: A descriptive study using tissue blocks of all histologically diagnosed breast cancer in our department between 2013 and 2017. Fresh sections were recut for histological grading and immunohistochemistry. Proteintech BRCA1 and BRCA2 polyclonal antibodies and detection kit were used.

Results: One hundred and thirty (130) cases met the inclusion criteria for this study. The mean (SD) age of the patients was 44.8 (10.3) years with ages ranging from 26 to 79 years. There were more cases of breast cancer (73.1%) seen before 50 years. Two (2) Male Breast Cancer (MBC) cases were seen, giving the female to male ratio of 64:1. The commonest morphological variant encountered was Invasive Carcinoma, No Special Type at 84.6% of cases. This was followed by invasive medullary (7.8%). The least common variant was papillary cancer at 0.8%. The tumors seen were mostly grade 3 (71.2%), followed by grade 2 at 22.7% and the least was grade 1 at 6.1%. Positivity for BRCA1 and BRCA2 proteins was seen in 27.7% and 30.0% of cases respectively. One of the MBC showed reactivity for BRCA1 protein. No significant relationship was seen between BRCA 1/2 proteins expression and age or breast cancer histotypes.

Conclusion: BRCA 1 and 2 proteins are an important risk factor for breast cancers seen in this environment. However, there is no association with age distribution and morphological variants of the breast cancer in our population.

#6257 Genome wide, high-throughput, high-resolution structural variation detection at low variant allele fraction for oncology samples.

A. R. Hastie, P. Lynch;
Bionano, San Diego, CA

Structural variation detection remains an elusive undertaking. For decades, G-banded karyotyping has remained the standard practice for nearly all hematological malignancy samples. Cancers are diseases of the genome and structural variants (SVs) are a hallmark of nearly all cancers, are often drivers of oncogenicity, and can sometimes be targeted for treatment, as highlighted by the discovery of the Philadelphia chromosome and later the development of targeted kinase inhibitors. One of the most important limitations of karyotyping, its requirement for cells to divide in culture, has prevented its application for most solid tumors and therefore, there is considerably less understanding of the impact of SVs in solid tumors. Optical genome mapping is a technique that is revolutionizing cytogenomics and unlocking the understanding of SVs in the genome at a level never seen before. It not only can detect nearly all variants that a karyotype can, but it can provide 10,000x higher resolution and does not require cell culture. Because of this, it is being adopted for oncology studies across hematological malignancies and solid tumors. This study demonstrates the performance of a new high throughput Stratys instrument for generation of optical genome map data at extraordinarily high coverage depth. With this instrument, 12 samples can be loaded at once, each loaded onto its own cartridge and the instrument can collect 400x genome coverage for each of these samples in 24 hours. The instrument has random access to the cartridges so that completed samples can be swapped out to facilitate optimal instrument run efficiency. To date, this system has been demonstrated to run 60 samples in a week, each at 400x coverage. Data from the instrument can be processed by Bionano Access™ and VIA™ software to call SVs, copy number variants (CNVs), regions of loss of heterozygosity (LOH), on a genome wide basis, and to classify those variants automatically according to guidelines such as the National Comprehensive Cancer Network (NCCN), World Health Organization (WHO), and National Health Services (NHS, United Kingdom). This new high throughput system with advanced bioinformatic data analysis has the potential to further transform structural variation analysis in cancer research.

#6258 Inference of gene expression using fragmentation patterns from targeted high-depth sequencing of cell-free DNA.

Emily Leff, **Alexander Tseng**, Victoria Cheung, Ehsan Tabari, Kimberly Walter, Alex Lovejoy, Cheng-Ho J. Lin

Freenome, South San Francisco, CA

Cell-free DNA (cfDNA) circulating in blood plasma arises primarily from cellular chromatin fragmentation and release due to cell death. Studies have demonstrated that the assessment of fragmentomic features of cfDNA enables gene expression inference and tissue-of-origin classification with potential applications for noninvasive cancer detection. However, due to low depth of coverage of sites of interest, current whole genome sequencing (WGS) methods have not been able to infer expression of individual genes or limited gene sets. Therefore, we developed a targeted sequencing approach that enables individual gene expression inference from cfDNA fragmentation patterns based on transcriptional start-site gene activation probability (TSS-GAP).

To assess the sensitivity of this method for cfDNA-inferred gene expression profiling, we applied TSS-GAP to blends of micrococcal nuclease (MNase)-digested DNA from a cancer cell line (LS180) and sorted peripheral blood mononuclear cells (PBMC), with LS180 DNA at varying concentrations (0.1-10%). This enabled the determination of the limit of detection (LoD), relative to healthy donor background levels, on the basis of the genes' activation probabilities (TSS-GAP scores).

We found 936 genes with high inferred expression in the LS180 cancer cell line and low inferred expression in non-cancer samples (i.e. CD4, CD14, and plasma cfDNA from 4 healthy donors) and used those for healthy donor background and LoD assessment. Using these gene-level background values as cutoffs, blends were assessed to determine the lowest blend level at which expression of the gene was able to be differentiated from background. Out of the 936 genes, 326 (34.8%) were detectable at a blend level of 0.1%, 59 (6.3%) at 0.3%, 31 (3.3%) at 1%, 19 (2.0%) at 3%, and 39 (4.2%) at 10%. In total, 416 genes could be detected by TSS-GAP at levels 1% of or lower above background, highlighting the potential of our method for detecting expression of certain genes even from a small fraction of cells contributing cfDNA to liquid biopsy samples. Further expansion of this work could consider the utility of such a method for circulating tumor DNA (ctDNA) detection, cfDNA tissue-of-origin classification, and deconvolution of cell types contributing to cfDNA found in blood.

#6262 Optimal cut-off age for AJCC staging system in Middle Eastern patients with differentiated thyroid cancer.
S. K. Parvathareddy, A. K. Siraj, P. Annaiyappanaidu, S. O. Ahmed, N. Siraj, Z. Qadri, S. Azam, K. S. Al-Kuraya;
King Faisal Specialist Hospital & Research Centre, Riyadh, Saudi Arabia

Background: Differentiated Thyroid Cancer (DTC) has an indolent nature and generally has favorable prognosis. AJCC TNM classification is the most adopted system to evaluate the biological behavior of DTC. Age cut-off of 55 years has been included in the eighth edition of TNM staging system since it led to better prediction of disease specific survival (DSS) of patients with DTC. However, optimal age cut-off in DTC patients from Middle Eastern ethnicity has not been fully explored. We evaluated the optimal age cut-off for the TNM staging system to predict DSS in Middle Eastern patients with DTC.
Methods: We retrospectively analyzed a large cohort of 1721 adult DTC patients who underwent surgery between 1990 to 2018. The optimal age cut-off value was determined using several age cut-offs (between 20 and 85 years) to assess DSS. Harrel's C-Index, Akaike information criterion (AIC) and Bayesian Information Criterion (BIC) were used to assess the statistical model performance of the TNM staging system (eighth edition), with different age cut-offs for prediction of DSS. The proportion of variation explained (PVE) was also calculated to compare predictability of DSS in patients with DTC.
Results: The median age of patients at diagnosis was 39.9 years (IQR 31.0 - 51.7 years) and 75.5% (1299/1721) were female. Median follow up was 9.3 years and 10 years DSS was 97.1%. For DTC overall, an age cut-off of 50 years had the best statistical model performance. On receiver operating characteristic curve analysis, the optimal age cut-off for prediction of DSS was 50.5 years (area under the curve = 0.872, $p < 0.0001$).
Conclusion: In this large cohort of Middle Eastern DTC patients, an age cut-off of 50 years was more appropriate for TNM staging to achieve better predictability for DSS. Therefore, implementation of different age cut-off for DTC in Middle Eastern patients could improve the predictive value for TNM staging system, and allow for better therapeutic and surveillance approach for these patients.

#6264 Role of Nuclear ErbB3 localization in regulating ligand-dependent ErbB2-ErbB3 heterodimer activation and downstream targets in prostate cancer.

M. K. Jathal, M. M. Mudryj, P. M. Ghosh;
UC Davis, Sacramento, CA

Objective: Prostate cancer (PCa)-specific nuclear expression of ErbB3, a receptor tyrosine kinase of the epidermal growth factor receptor (EGFR) family, has long been recognized. While an 80kDa nuclear variant of ErbB3 has been identified, full-length 185 kDa ErbB3 also translocates to the nucleus in PCa in a bone microenvironment and androgen status-dependent manner. Here, we studied potential mechanisms by which nuclear ErbB3 may regulate PCa progression.
Methods: ErbB3 localization was investigated *in vitro* (human prostate cancer cell lines, LNCaP, C4-2, 22Rv1) using amiloride or heregulin-1β (ErbB3-specific ligand). ErbB3 expression and subcellular localization were analyzed using immunofluorescent microscopy and subcellular fractionation followed by immunoblot. Physiological readouts included viability, migration and reporter gene assays.
Results: Here we show that ErbB3 can occupy a nuclear/perinuclear location in prostate cancer cells. The hormone sensitive PCa line LNCaP expressed higher levels of nuclear ErbB3 compared to castration resistant lines C4-2 and 22Rv1. The diuretic amiloride was previously shown to inhibit ErbB3 internalization by macropinocytosis thus we investigated whether it could also modulate ErbB3 nuclear localization in PCa cells. In LNCaP cells, amiloride dose dependently prevented ErbB3 nuclear transport, whereas in C4-2 and 22Rv1, no such effect was observed. Further analysis revealed that amiloride promoted ErbB3 expression in the membrane, where ErbB3 underwent ligand-dependent phosphorylation, formed ErbB2/ErbB3 dimers, and in turn phosphorylated the downstream targets AKT and ERK1/2 (p42/p44MAPK). On the other hand, EGFR phosphorylation and dimerization were unaffected by amiloride. Our results suggest that ErbB3 is stored in the nuclear region in an inactive form, whereas upon stress induction, including androgen deprivation, ErbB3 is translocated to the plasma membrane, where it is activated by ligand binding, and causes downstream signaling.
Conclusion: We previously showed that the EGFR/ErbB2 dual inhibitor lapatinib failed to affect PCa - we now show that this may be due to modulation of nuclear and cytoplasmic ErbB3 expression. Amiloride prevented translocation (and thus expression of) ErbB3 to the nucleus and retained this RTK in the membrane, resulting in the formation of active ErbB2/ErbB3 dimers. Lapatinib was then able to inhibit and inactivate its specific target, ErbB2, thereby inducing significant apoptosis. The above indicates a novel role for nuclear ErbB3 in PCa that can be regulated by the combination of amiloride and lapatinib.

#6265 FLCN variants and their role in parathyroid cancer and atypical parathyroid tumors.

C. Burke, J. Bellizzi, J. Costa-Guda, A. Arnold;
UConn Health, Farmington, CT

Parathyroid carcinoma (PC) is rare, poses challenges in definitive diagnosis and treatment, and carries a high rate of recurrence and mortality. Atypical parathyroid tumors (APT) have histopathologic features of malignancy but lack unequivocal evidence of invasion and are of uncertain malignant potential. Analysis of genetic alterations that may play a role in PC development, particularly those that might serve as markers of malignant potential, is important for further understanding this disease. *FLCN* is a gene found on chromosome 17 that encodes folliculin, a ubiquitously expressed protein with roles in multiple cellular processes such as apoptosis and cell signaling. Inactivating *FLCN* mutations cause Birt-Hogg-Dubé syndrome (BHD), an autosomal dominant condition characterized by benign fibrofolliculomas, pulmonary cysts and spontaneous pneumothorax, and increased risk of renal cancer. Benign parathyroid tumors had previously been reported in a few BHD patients and recently one study has reported a link between *FLCN* mutations and parathyroid carcinoma. Germline frameshift mutations in *FLCN*, accompanied by somatic loss of the normal allele, were reported in two unrelated PC patients, both with clinical features suggestive of BHD, but no established diagnosis of BHD. An identical somatic frameshift *FLCN* mutation was reported in one PC and one APT. Interestingly, the authors noted low coverage of *FLCN* on whole exome sequencing, resulting in the failure to detect variants identified by Sanger sequencing, thus raising the possibility that prior studies may have missed *FLCN* variants. To better understand the frequency of germline or somatic *FLCN* mutations in PC and APT, we performed Sanger sequence analysis of the entire coding region of the *FLCN* gene on available tumor DNA from 11 PCs and 15 APTs. We identified no inactivating *FLCN* mutations in any of the PC or APT samples examined. A germline missense variant, resulting in a p.Gly325Val change, predicted to be benign/tolerated by *in silico* analyses, was seen in one PC and a synonymous variant (c.1233G>A) was seen in one APT. The absence of pathogenic mutations in our series parathyroid carcinoma and atypical parathyroid tumors suggests that *FLCN* mutations are rare in these parathyroid tumors. Nevertheless, germline *FLCN* testing and/or additional screening for BHD-related lesions in parathyroid carcinoma patients merits further consideration and study.

#6266 Neurotensin receptor 1 regulates dimerization of HER2-HER4 and proliferation of non-small cell lung cancer cells.

T. W. Moody[1], I. Ramos-Alvarez[2], R. T. Jensen[2];

[1]National Cancer Institute, Rockville, MD, [2]NIDDK, Bethesda, MD

The neurotensin receptor 1 (NTSR1) is a 418 amino acid type A G protein-coupled receptor which causes phosphatidylinositol turnover and proliferation of non-small cell lung cancer (NSCLC) cells (Moody et al., Peptides 2021; 137: 710480). Adding the agonist NTS to NSCLC cells increases transactivation of the receptor tyrosine kinases (RTK) EGFR, HER2 and HER3 (Moody et al., Biology 2023 12: 957). The RTK tyrosine phosphorylation and growth caused by NTS is impaired by SR48692, a small molecule NTSR1 antagonist. The effects of NTS were investigated on HER4 using NSCLC cells. By Western blot, cell lines NCI-H522 and H661 had high levels of NTSR1, HER 4 and neuregulin 1 (NRG1), a ligand for HER4 but not NTSR2, HER3 or NRG2. By RT-PCT, high levels of HER4 and its isoforms JM-a, CYT1 and CYT2 were present in NCI-H522 and H661 cells. Adding NTS (0.1 μM) or NRG1 (0.01 μg/ml) to NCI-H522 or H661 cells increased P-Tyr^{1284}-HER4 and P-ERK 3-fold. Using immunoprecipitation techniques, adding NTS to NSCLC cells increased formation of HER4-HER2 heterodimers which leads to cancer proliferation (Lucas et al., Pharmacol Rev 2022; 74:18). The increase in PY1284-HER4 caused by NTS was impaired by SR48692, HER4 siRNA, NRG1 siRNA or ibrutinib (TKI). The NTSR1 regulation of HER4 transactivation is impaired by GM6001 (MMP inhibitor]), PP2 (Src inhibitor) or N-acetylcysteine (antioxidant). The clonal growth of NSCLC cells is increased by NTS or NRG1 but decreased by SR48692 or ibrutinib. The results indicate that NTS increases the formation of HER2/HER4 heterodimers leading to the proliferation of NSCLC cells.

#6267 Evaluating estrogen receptor signaling modifications at bone marrow related stiffnesses in metastatic breast cancer.

L. A. Northcutt, M. Rafat, J. Rhoades;
Vanderbilt University, Nashville, TN

Bone metastasis is highly prevalent in breast cancer (BC) patients with metastatic disease and can increase the risk of hypercalcemia and pathological fractures. Several studies have evaluated the mechanisms of metastasized BC cells' involvement in bone destruction, but how the bone marrow (BM) microenvironment contributes to this process remains ambiguous. Recent studies have shown that as BC cells experience increased stiffnesses outside of the primary microenvironment, there is higher expression of epithelial-to-mesenchymal transition (EMT) markers, increased expression of osteolytic proteins, and decreased drug responses. However, these changes have not been evaluated at stiffnesses relative to the BM. Estrogen receptor (ER) status also plays a pivotal role in BC patient survival. Clinical studies have indicated that the majority of ER+ patients with metastatic disease have more incidences of bone metastases compared to ER- patients. There is some evidence that suggests that the physical properties can also affect estrogen receptor signaling at the primary site, however, there is minimal work to establish how the physical factors of the BM can affect ER sensitivity after metastasis. We hypothesize that higher stiffness ranges of the BM can alter the estrogen receptor sensitivity of metastasized tumor cells and increase osteolysis. To analyze this question, we seeded ER+ BC cell lines (MCF7s and T47Ds) on CytoSoft® Rigidity Plates that mimicked the stiffness of the BM (0.5 - 32 kPa). After 2 days in culture, we probed the expression of downstream estrogen signaling factors, GREB1, PGR, and TIFF1, to evaluate estrogen activity using western blot. Our results show an increase in downstream estrogen signaling at higher stiffnesses (32 kPa) compared to lower stiffnesses (0.5 kPa) at the protein level but not at the transcriptional level. In the future, we will analyze factors associated with osteolysis (*ITGB3*, *TGFB-RII*, and *PTHLH*). Additionally, we plan to conduct RNA sequencing to analyze any larger transcriptional changes at different stiffnesses. Overall, this work gives insight into how estrogen signaling changes in the BM compared to the primary site. It will also give us insight into potential therapeutic targets for ER+ BC after metastasis to the bone.

#6268 A study of orphan nuclear receptor SHP (NR0B2) in prostate cancer progression.

H. Lam, F. Chan;
The Chinese University of Hong Kong, NA, Hong Kong

Prostate cancer (PCa) is a significant male cancer in many countries accounting for around 14% of new cancer cases globally in 2020 and ranked as 3rd common cancer in males in Hong Kong. The major risk factors include old age, high-fat diet, and genetics. Compared to other cancers, PCa is unique as its initial and advanced growth is androgen dependent. As tumor progresses, it accumulates numerous genetic alterations. Main therapeutic options include surgery, radiotherapy and or active surveillance. Upon treatment failure or when metastasis develops, androgen-deprivation therapy (ADT) with the use of potent androgen receptor (AR) antagonists and androgen biosynthesis inhibitors (e.g. Enzalutamide and abiraterone acetate) aiming to suppress AR signaling axis are the standard treatment options. However, the effect of these treatments is short-lived, in which nearly all patients will inevitably relapse to a hormone-independent and metastatic stage known as metastatic castration-resistant prostate cancer (mCRPC) within few years and further drive progression to a more lethal subtype, described as treatment-induced neuroendocrine prostate cancer (NEPC). The treatment options are limited and therefore resulted in high mortality, representing an emerging clinical problem. Recent studies have illustrated that NEPC progression follows a lineage plasticity model with a phenotypic transition to AR loss and neuroendocrine transdifferentiation. Our preliminary study has identified a nuclear receptor NR0B2 (SHP, small heterodimer partner SHP), which is a unique ligand-independent orphan nuclear receptor without a DNA-binding domain, that displays a significant up-regulation in clinical NEPC and prostate cancer cells with NEPC phenotype. Mechanistic studies revealed that SHP could directly interact with AR utilizing its NR Box1 motif while inducing repression on the AR transactivation via its another NR Box2 motif. Based on this, we conducted *in vitro* growth studies and revealed that NR0B2 overexpression could promote growth differentially in AR-negative PCa cells. However, AR-positive PCa cells were insensitive to AR blockade, providing supporting evidence that NR0B2 may be involved in repressing AR activity in prostate cancer cells. Multiple key NEPC and oncogenic TGFβ signaling markers showed significant upregulation in gene expression. Based on this, we hypothesize that upregulation of NR0B2 could play an important role in driving the advanced progression of CRPC via its direct interference of AR signaling axis and through other AR-independent signaling pathways, including activation of TGFβ signaling. (Study supported by a CUHK Direct Grant for Research 2022-2023, Project No. 2022.081)

#6269 Assessment of new generation endocrine therapies for the treatment of breast to bone metastasis.

E. K. Zboril, J. E. Altman, N. S. Hairr, R. K. Myrick, A. L. Olex, M. G. Dozmorov, J. Harrell;
Virginia Commonwealth University - VCU, Richmond, VA

Estrogen receptor (ER) signaling is the main driver of tumorigenesis in ER+ breast cancers by inducing proliferation and survival through genomic and non-genomic means, therefore inhibition of ER signaling has been a mainstay of treatment for decades. Roughly 30 percent of patients will develop treatment-refractory recurrence or metastasis within their lifetime, which may include metastasis to the bone, lung, liver, and brain. Although advances in treatment approaches have prolonged average progression free survival, metastatic breast cancer remains incurable. A new endocrine therapy, Elacestrant, has been approved by the FDA for the treatment of ER+, ESR1-mutant advanced or metastatic breast cancer. The mechanism of action of Elacestrant involves both degradation of ER and modulation of ER signaling through non-degradative means. The central hypothesis of this study was that Elacestrant may prolong progression free survival in animal models of breast to bone metastasis, because modulation of ER in the bone would decrease the incidence of osteoporosis which is induced by other endocrine therapies. However, we discovered that prolonged Elacestrant treatment induces destruction of the trabecular bone structure and increased adipocyte mass within the bone, consistent with an osteoporotic phenotype. Ongoing studies will seek to determine if other endocrine therapies will provide better protection to the bone architecture while reducing metastatic burden in animal models. Additionally, we will evaluate organotropic efficacy of new endocrine therapies on multi-organ metastasis to determine if utility is contingent upon the metastatic site.

#6270 Anti-metastatic effects of estrogen receptor β in inflammatory breast cancer.

H. Nagandla[1], S. Tastsoglou[2], K. Cuong Cap[1], A. Phillips[1], W. Qian[1], J. Zhou[1], J. Chang[1], S. Krishnamurthy[3], N. Ueno[4], A. Hatzigeorgiou[2], C. Thomas[1]; [1]Houston Methodist Research Institute, Houston, TX, [2]University of Thessaly, Lamia, Greece, [3]University of Texas, Houston, TX, [4]University of Hawaii, Honolulu, HI

Inflammatory breast cancer (IBC) is a rare but highly aggressive form of breast cancer with a 5-year survival rate of less than 50%. Although 20-30% of women with IBC have distant metastasis at the time of diagnosis, the biology underlying the aggressive behavior of the disease is poorly understood and molecular markers that distinguish IBC from non-IBC have not yet been identified. In response to the urgent need of discovering new targeted therapies in IBC, we have studied the second estrogen receptor (ERβ) since prior work from our lab correlated higher tumor expression of ERβ in samples from IBC patients with longer metastasis free survival. We showed that ERβ exerted anti-metastatic activity in IBC by inhibiting actin-based cell migration through the suppression of RhoC GTPase signaling. However, since estrogen receptors elicit their effects by inducing global cellular alterations, we have now adopted an integrated genomic approach to fully understand the anti-metastatic effects of ERβ in IBC and delineate the underlying transcriptional regulatory circuits. We found ERβ binding sites in IBC cells and combined this information with gene expression data to identify downstream direct target genes and associated pathways. Our findings suggest the regulation of tumor micro-environment and metabolism as the primary targets of ERβ and we are currently working to pinpoint the crucial regulatory components in these functions. Our findings thus offer an opportunity to better understand the mechanism of ERβ action in aggressive breast cancer, serving as a critical step in validating its tumor repressive role.

#6271 Novel insights into androgen receptor-variant 7 subnuclear localization and function in castration resistant prostate cancer.

M. K. Naidoo, P. Giannakakou;
Weill Cornell Medicine, New York, NY

Prostate cancer (PC) stands as the most frequently diagnosed and second leading cause of cancer death among American men. PC mortality is predominantly attributed to castration-resistant prostate cancer (CRPC), often emerging within 2-3 years following the initiation of androgen deprivation therapy. This resistance primarily arises from sustained androgen receptor (AR) signaling, ultimately resulting in a compromised response to AR-directed therapies. AR splice variant expression is a key contributor to the persistent AR signaling in CRPC. AR-variant 7 (AR-V7) is the most clinically prevalent variant, expressed in about 75% of patients with CRPC and confers resistance to standard of care (SoC) treatments. AR-V7 differs from the full-length AR (AR-fl) because it lacks the ligand binding and hinge domains, rendering it resistant to SoC treatments. Currently, there are no selective inhibitors for AR-V7. Therefore, we sought to identify unique biological features of AR-V7, distinct from AR-fl, to exploit therapeutic options for targeting AR-V7. Previous studies have demonstrated high sequence homology, largely overlapping cistromes, and gene transactivation profiles between AR-V7 and AR-FL. Our published mechanistic studies revealed that AR-V7 utilizes a unique nuclear import pathway, not shared by AR-fl, allowing for constitutive import and activation of target genes in the nucleus. Herein, we report an additional novel subnuclear phenotype of AR-V7 in LNCAP95 and 22RV1 cells modeling CRPC. Staining with AR-V7- and AR-fl- specific antibodies revealed that unlike AR-fl, AR-V7 exhibited prominent nucleolar localization. To validate AR-V7 nucleolar localization, CRPC cells stained with fibrillarin (nucleolar marker), and subsequent fluorescence intensity analysis revealed that AR-V7 was predominantly localized in fibrillarin positive nucleoli, whereas AR-fl protein was solely localized in the nucleoplasm. This suggests a novel functional role of AR-V7 in the nucleus. To further confirm AR-V7 nucleolar localization, Actinomycin D (ActD) was used as a tool compound to disrupt nucleolar integrity. Treatment with ActD for 4 hours in CRPC cells significantly reduced the area of fibrillarin positive nucleoli and prompted AR-V7 re-distribution out of the nucleoli and into the nucleoplasm. Ongoing efforts to further investigate AR-V7 nucleolar function in CRPC cells include mutating the predicted nucleolar localization signal located in AR-V7 and identifying nucleolar-interacting proteins through proximity-labeling assays. In conclusion, we unveiled a novel nuclear compartmentalization of AR-V7 within the nucleolus, the primary hub for ribosomal biogenesis. These observations suggest that AR-V7 could regulate the high levels of protein synthesis occurring in CRPC cells, creating a window of a potential therapeutic opportunity for selective inhibition.

#6272 Loss of SIRT6 diverts TGF-β signaling to promote liver cancer.

K. Ohshiro[1], X. Xiang[2], X. Yang[2], K. Bhowmick[2], M. I. Hassan[3], T. Mohammad[3], **L. Mishra**[2];
[1]Feinstein Institutes for Medical Research, New York, NY, [2]Feinstein Institutes for Medical Research & Cold Spring Harbor Laboratory, New York, NY, [3]Jamia Millia Islamia, New Delhi, India

Background: In the US, ~35% of individuals on the waitlist for a liver transplant who had hepatocellular cancer (HCC) also had metabolic dysfunction-associated steatohepatitis (MASH). Yet, key signaling mechanisms controlling cellular transformation in this obesity-driven HCC remain only partially understood. SIRT6 is NAD^+-dependent protein deacetylases that limits the activity of the lipogenic transcription factors SREBP1/2. Reduced SIRT6 is associated with human fatty liver and cancer. However, SIRT6 also limits liver fibrosis by inhibiting TGF-β signaling through the deacetylation of SMAD2 and SMAD3. We found that Smad3 driven TGF-β signaling is modulated by βII-Spectrin (encoded by *SPTBN1*), and that a hot mutation in HCC- D1089Y encompasses the SPTBN1-SMAD3 binding site (*Gastro 2018; 154:195-210*). In stressed hepatocytes, βII-Spectrin promotes lipogenesis through interactions between caspase-cleaved forms of both SREBP1 and βII-Spectrin *(Sci Transl Med 2021;13:624)*. Liver-specific knockout of βII-Spectrin (LSKO) blocks fatty liver and HCC. Here we explored the extent of βII-spectrin-D1089Y regulation of SIRT6 expression through SMAD3, and the combined roles of SIRT6 and SPTBN1 in human HCC.
Methods: We generated a SPTBN1-D1089Y mutant mouse and examined SIRT6 in the SPTBN1-D1089Y mutant mouse liver tissues and MEFs. TGF-β/Smad3 pathway activity was analyzed in SPTBN1-D1089Y mutant MEFs via western blot and RNA-seq. SIRT6 expression was examined in mouse MAFLD/MASH (GSE156059). Structure-based molecular docking simulations using three-dimensional structural coordinates of human SIRT6 (ID: Q8N6T7) and β2SP (ID: Q01082) from the AlphaFold database, followed by interactions between SIRT6 and SPTBN1.
Results: SIRT6 levels are decreased in SPTBN1-D1089Y mutant liver cancer cell line and mouse liver tissues. TGF-β/SMAD3 pathway activity was altered in SPTBN1-D1089Y mutant MEF cells with decreased phospho-SMAD3 levels. The structural model predicted specific interactions between human SPTBN1 and SIRT6. Overexpression of Flag-SIRT6 reduced βII-Spectrin acetylation in HepG2 cells. TGF-β induced SMAD3, βII-Spectrin coimmunoprecipitation with SIRT6. SIRT6 knockdown increases nSREBP1, SCD1 (encoded by a nSREBP1 target gene), and βII-Spectrin in HepG2 cells. SIRT6 RNA expression is significantly decreased in liver macrophages from mice with NAFLD/NASH.
Conclusions: Our data indicated a SMAD dependent as well as a SMAD3 independent role of SPTBN1 in regulating SIRT6. βII-spectrin-D1089Y together with SIRT6 deficiency may increase the susceptibility to MASH/HCC via regulating the crosstalk between macrophage and hepatocytes or regulating MASH and HCC.

#6273 GGCT expression is a useful marker for the diagnosis of follicular thyroid carcinoma.

T. Mitsuhashi[1], S. Ogasawara[1], M. Nakayama[1], R. Kondo[1], J. Akiba[1], K. Murotani[2], T. Ono[1], F. Sato[1], H. Umeno[1], H. Yano[1];
[1]Kurume Univ. School of Medicine, Kurume, Japan, [2]Kurume Univ., Kurume, Japan

Background: Follicular thyroid carcinoma (FTC) and follicular adenoma (FA) have similar histological findings. FTC is distinct from FA based on the presence of capsular or vascular invasion in the tissues, but it is difficult to confirm the diagnosis in some cases. In this study, we aimed to establish useful molecular maker for differential diagnosis between FTC and FA.
Methods: This study included FTC (n = 32), FA (n = 64), and follicular tumors of uncertain malignant potential (FT-UMP, n = 5). Invasive front tissue and tumor center tissue from 3 cases of FTC were collected using a laser microdissection system; RNA was extracted, followed by microarray analysis to examine molecules that were commonly highly expressed in the invasive front. Subsequently, immunohistochemical staining of gamma-glutamyl cyclotransferase (GGCT) was performed. For assessment of GGCT expression, the intensity of the nuclear staining was stratified using a four-tiered scale (0 to 3) and percentage of positive cells (0-100%) in the hotspot. Multiplying intensity score and percent of positive cells, an expression score ranging from 0 to 300 was calculated. The Ki-67 labeling index was examined in 20 cases of FTC, 25 cases of FA, and 4 cases of FT-UMP from the same cohort. We counted at least 2,000 tumor cells in the hot spot for the assessment of Ki-67 labeling index.
Results: Microarray analysis revealed GGCT exhibited high expression levels at the invasive front of FTC. In immunohistochemical assessment, GGCT expression scores were significantly higher in FTC than in FA (118.5 ± 51.4 vs. 57.3 ± 34.7, $p < 0.0001$). The median Ki-67 labeling index were 3.9% (range 0.2 - 16.1) for FTC and 2.4% (range 0.3 - 7.0) for FA. FTC showed a higher Ki-67 index than FA (Wilcoxon rank sum test, $p = 0.0444$). With GGCT expression score, applying a cutoff value of 101.1, the distinction between FTC and FA resulted in a sensitivity of 68.8% and a specificity of 87.5% (AUC: 0.832). With Ki-67 labeling index, applying a cutoff value of 4.0%, the distinction between FTC and FA resulted in a sensitivity of 50.0% and a specificity of 80.0% (AUC: 0.677). The GGCT expression score was positively related with the Ki-67 labeling index in the FTC cases. (Spearman's $\rho = 0.5293$, $p = 0.0164$). There were no significant associations between GGCT expression scores and clinicopathological parameters, including age, gender, tumor diameter, pT stage, pN stage, pattern of capsular invasion, number of foci of vascular invasion, and the presence of distant metastasis.
Conclusions: GGCT is a potential marker for differentiating FTC from FA. The GGCT expression of FTC may contribute to estimating the invasive activity and proliferative activity.

#6274 Integrated multi-omics revealed the involvement of MYC and mTOR pathways in radiation resistance of adrenocortical cancer.

B. Ramamoorthy[1], P. Mishra[1], M. Boufraqech[1], N. Michael[1], M. Cam[1], R. Finney[1], T. Meyer[2], R. Holewinski[2], T. Andresson[2], M. Wong[1], S. Shema[1], D. Tillo[1], N. Nilubol[1];

[1]National Cancer Institute, Bethesda, MD, [2]Leidos Biomedical Research, Inc., Frederick, MD

The morbidity and mortality of patients with adrenocortical cancer (ACC) are commonly due to locoregional postoperative recurrence and progressive systemic metastasis. Surgical resection remains the only curative treatment option, but even with complete resection, locoregional recurrence rates remain high. Adjuvant radiation therapy (RT) has been shown to reduce recurrence rates and may improve overall survival in selected patients. However, half of the patients receiving postoperative RT still develop locoregional recurrence, clearly demonstrating the heterogeneous nature of ACC. Minimal investigation into the mechanisms underlying radiation response and resistance in ACC has been performed, but elucidating this information is critical to improving outcomes. To address this knowledge gap, NCI-H295R cells were treated with fractionated radiation at 1 Gray (Gy) per day for 5 consecutive days for two consecutive weeks, cumulating in a total radiation dose of 10 Gy. Treated and control ACC cells were harvested on days 7 and 14 for bulk RNA-sequencing (RNA-Seq) and total proteomics by liquid chromatography and tandem mass spectrometry. Significantly differentially expressed genes (DEGs) and proteomes (adj. p. value <0.05) that overlapped between day 7 and day 14 were selected for further analysis and comparison with publicly available gene expression data sets in ACC (The Cancer Genome Atlas (TCGA); Gene Expression Omnibus: GSE12368, GSE33371, GSE75415, GSE90713).

There were 3993 DEGs and 423 proteomes identified, respectively. Of these, there were 139 overlapping DEGs with respective proteomes found, 72 of which were differentially expressed in the 4 GEO data sets comparing normal adrenal cortex to ACC. RNA-Seq pathway analysis demonstrated enrichment of E2F targets, G2M checkpoint, mTORC1 signaling, and MYC targets v1, while total proteomics pathway analysis revealed enrichment of cell cycle, transcriptional regulation, cellular stress and injury, alterations of RNA metabolism, and metabolism proteomes. Given that *MYC* and *mTOR* are both involved in transcriptional regulation and cell cycle regulation, and mTORC1 in particular is associated with cellular metabolism, the RNA-Seq and proteomics pathway analyses show general consistency with each other.

TCGA gene expression analysis showed that overexpression of *MYC* or *mTOR* was correlated with shorter overall survival (OS) and disease-free survival (DFS) in the entire ACC cohort ($p<0.05$). Together, the combination of *in vitro* pathway analysis and TCGA analysis suggests a potential involvement of the MYC and mTOR pathways in radiation resistance in ACC. Further *in vitro* and *in vivo* studies are warranted to identify specific molecular compounds that target MYC and mTOR pathways and improve radiation response in ACC.

#6275 Exposure to neighborhood violence rewires glucocorticoid receptor binding and drives proliferation and invasiveness in lung tumor samples.

H. Heath[1], J. Yoo[1], V. Sharma[1], H. McGee[1], A. Soliman[1], A. Mohamed[2], A. K. Matthews[3], R. Winn[4], Z. Madak-Erdogan[1], S. Kim[5];
[1]University of Illinois at Urbana-Champaign, Champaign, IL, [2]University of Illinois at Chicago, Chicago, IL, [3]Columbia University, New York, NY, [4]Virginia Commonwealth University, Richmond, VA, [5]University of Illinois at Chicago, Champaign, IL

Background: Despite smoking less, Black men experience higher incidence of lung cancer compared to white men. This health disparity is even more prevalent in Black men from Chicago, suggesting local neighborhood factors impacting tumorigenesis. Preliminary data indicate that, compared to white men, Black men are more likely to reside in neighborhoods with high levels of violence and have elevated levels of hair cortisol.
Objective: To understand the link between lung tumorigenesis and exposure to neighborhood violence, our objective is to investigate the chromatin recruitment of the receptor for cortisol, called the glucocorticoid receptor (GR), and to correlate this recruitment with target gene expression levels.
Methods: Utilizing CUT & RUN, we identified the gene binding sites of GR using 15 lung tumor and corresponding healthy tissue samples from lung cancer patients living in Chicago. GR recruitment to chromatin was correlated with the neighborhood homicide rate obtained using patients' zip codes. Spatial transcriptome profiles for these 15 lung tumor samples were obtained from the Space Ranger pipeline and gene expression hot spots of GR target genes were visualized using Loupe Browser (10x Genomics).
Results: GR recruitment to regulatory regions of chromatin increases with greater zip code level violence rates. In patients from high violence neighborhoods, tumor samples had higher magnitude of binding compared to normal neighboring tissue. In tumor samples from patients living in high violence compared to low violence neighborhoods, GR binding is seen in genes that are associated with increased tumor aggressiveness. Hot-spot analysis of these genes found strong co-expression of genes associated with proliferation and invasion in samples from high violence but not low violence neighborhoods.
Conclusion: Exposure to neighborhood violence may impact tumor biology via increased GR recruitment to genes associated with proliferation and invasion.

#6276 In vitro neuroendocrine differentiation of BPH-1 cells under beta-adrenergic stimulation.

N. Pigat, L. N. Garrido, C. Lefevre, M. Baures, V. Goffin, A.-S. Armand, **T. Capiod**;
Institut Necker-Enfants Malades (INEM), Paris, France

Recent studies have shown that adrenergic fibers from the sympathetic nervous system (SNS), acting through stromal β2-adrenergic receptors, play an important role in the initial phases of cancer development by promoting tumor cell survival. Recent epidemiological data suggest that β-blocker intake is associated with improved survival of prostate cancer patients. Hypertension and high blood pressure have been suggested to increase prostate cancer development suggesting that the use of β-blockers in these patients could also reduce prostate cancer risk. β-adrenoceptors signal through the cAMP/PKA pathway that is known to promote neuroendocrine differentiation (NED) in LNCaP prostate cancer cell line. While neuroendocrine (NE) cells expressing synaptophysin (SYN) represent a minor cell population in the epithelial compartment of normal prostate glands, the population of NE-like cells, exhibiting NE phenotypes and expressing NE markers, is increased in, and correlates with, cancer progression, androgen-independent state and poor prognosis. Expression of the routine tissue biomarker of *prostate cancer* AMACR in NE-like cells discriminates them from NE cells. Our aim was to investigate whether NED could also be associated with benign prostatic hyperplasia (BPH) as recent studies showed that an increase in neuroendocrine cell density occurred before development of BPH in hypertensive rats. Our results showed that a 10-day treatment with 100µM IBMX (blocking cAMP degradation) and 10µM forskolin (FSK, adenylate cyclase activator) to trigger sustained activation of the cAMP/PKA pathway led to an increase in SYN and AMACR expression in BPH-1 cells (qPCR and WB). Similar results were observed by combining the effect of the β-adrenoceptor agonist isoproterenol (1µM) and FSK. The same treatments reduced BPH-1 cell proliferation rates by 40% and 60%, respectively, as expected for NED. Effects on AMACR and SYN expression and cell proliferation were fully reversed by the β-blocker carvedilol (5µM). This data suggests that β-adrenoceptors could be linked to the development of NE-like cells in BPH, a non-lethal disease affecting the transition zone (TZ). As 20% of the prostate cancer occur in this TZ, this observation may need further investigation.

#6277 Tall cell variant papillary thyroid carcinoma from Middle Eastern patients have worse outcome than classical papillary thyroid carcinoma using propensity score matching.

K. S. Al-Kuraya, S. K. Parvathareddy, A. K. Siraj, S. O. Ahmed, N. Siraj, M. Manakhan, H. Aldossari;
King Faisal Specialist Hospital & Research Centre, Riyadh, Saudi Arabia

The tall cell variant of Papillary Thyroid Carcinoma (TCV-PTC) is the most common aggressive variant of PTC. The impact of TCV-PTC on patients' prognosis still remains controversial. Moreover, the clinico-pathological and prognostic effect of TCV-PTC from Middle Eastern ethnicity remains unexplored. We aimed to study TCV-PTC in comparison to classical PTC in Middle Eastern patients and their impact on prognosis. We performed a retrospective cohort study of tall cell variant (TCV-PTC) and classic variant of papillary thyroid carcinoma (CV-PTC) after post-surgical radioactive iodine therapy. We used the propensity score matching (1:3 matching ratio) to account for differences between recipients of TCV-PTC vs CV-PTC. Univariate and multivariate analysis were performed to assess the independent factors for persistent/recurrent disease. Kaplan-Meier curve analyses were used to compare disease-free survival (DFS). In total, 174 (16.3%) patients with TCV-PTC and 891 (83.7%) patients with CV-PTC were included. After propensity score matching, 174 pairs of patients were selected (TCV-PTC, n = 174; CV-PTC, n = 522). In the matched analysis, higher proportions of TCV-PTC experienced persistent/recurrent disease compared with CV-PTC (25.7% vs 31.4%; p = 0.0119). In multivariate analyses of clinical and tumor characteristics, histological type of TCV-PTC (odds ratio, 2.09; 95% confidence interval, 1.28-3.40; p = 0.0031) was associated with increased risk of persistent/recurrent disease. The five-year DFS rates for the TCV-PTC and CV-PTC groups were 48.5% and 73.1%, respectively. The Kaplan- Meier analysis indicated that the TCV-PTC group (p < 0.0001) had shorter DFS. In conclusion, when other clinico-pathological factors were similar, this propensity score matched analysis showed that histological subtype TCV-PTC is by itself an independent predictive marker of persistent/recurrent disease in Middle Eastern patients. Therefore, individualized therapeutic approaches might be needed for this aggressive PTC subtype.

#6278 Effect of tumor size and BRAF mutational status in Middle Eastern differentiated thyroid cancer.

R. Bu, A. K. Siraj, S. K. Parvathareddy, K. Iqbal, S. Azam, Z. Qadri, M. Al-Rasheed, W. Haqawi, A. D. Benito, K. S. Al-Kuraya;
King Faisal Specialist Hospital & Research Centre, Riyadh, Saudi Arabia

Background: Risk stratified treatment strategies have become a focus in the treatment of Differentiated Thyroid Cancer (DTC). Tumor size at diagnosis has been widely used as a major mortality risk factor in risk stratification of DTC, but whether this is generally applicable, particularly in patient with different *BRAF* genetic backgrounds, is unclear. The current study was designed to analyze whether tumor size at diagnosis is a major prognostic factor in Middle Eastern DTC.
Methods: We conducted a comparative study of the relationship between tumor size at diagnosis and event free survival with respect to *BRAF* status in 1709 consecutive patients treated surgically for Middle Eastern DTC. Patients were divided into four groups according to the size of tumor (≤4 cm vs. >4 cm) and BRAF mutation status: Group 1 (≤4 cm without BRAF mutation, n = 587), Group 2 (≤4 cm with BRAF mutation, n = 765), Group 3 (>4 cm without BRAF mutation, n = 198) and Group 4 (>4 cm with BRAF mutation, n = 159). Predictors of event-free survival (EFS) were compared using the Log-rank test and Cox proportional hazards models.
Results: Following multivariate analysis, patients with tumors >4cm did worse than patients with tumors <4cm with respect to EFS (Group 3 vs Group1 HRadjusted=1.38, 95% CI=1.02-1.86, p = 0.0359; Group 4 vs Group 2 HRadjusted=1.61, 95% CI=1.20-2.16, p = 0.0017). However, patients did not differ according to EFS, regardless of the presence of *BRAF* mutation within each size category (Group 2 vs Group 1 HRadjusted=0.98 CI=.78-1.23, p=0.8415 ; Group 4 vs Group 3 HRadjusted=1.17, 95% CI=0.84-1.62, p=0.3523]
Conclusion: Tumor size is an independent predictor of EFS in Middle Eastern DTC patients, regardless of *BRAF* mutational status.

#6279 Estrogen signaling in low-grade serous ovarian carcinoma.

Y. T. Tsang, C. O. Ng, D. Gershenson, **K.-K. Wong**;
UT MD Anderson Cancer Center, Houston, TX

High level of estrogen in the blood of women has been linked to the progression and possibly development of ovarian cancer. Almost all low-grade serous ovarian cancer (LGSOC) expresses estrogen receptor alpha (ERα protein encoded by the gene *ESR1*) and develops during reproductive age of women. However, recent studies suggested that a higher expression of ERα correlates with better survival. In a phase II clinical trial, hormonal therapies have been shown to be associated with a clinical benefit rate of 61% for recurrent ER-positive LGSOC patients. The study also indicated that women with recurrent LGSOC who received hormonal therapies had a significantly longer progression-free survival but not overall survival. Endocrine therapies have proven to be effective in treating breast cancer. Unfortunately, in ovarian cancer clinical trials (GOG0281 and PARAGON), these treatments have not achieved comparable results, with an objective response rate of only approximately 14%. To understand the ESR1 regulation in LGSOC, we have performed RNAseq and ChIPseq analyses of LGSOC tumor tissues. We also forced over-expression of ESR1 in LGSOC cell lines. Using RNAseq data, we aligned the sequencing reads to all the known ESR1 transcript variants. We found that ESR1 transcript variant 1, 2, 3 and X11 were the major transcripts expressed. Variants 1, 2 and 3 encode the regular 66 kDa ESR1 protein, while the X11 variant encodes a 52 kDa ESR1 protein. Both 66 kDa and 52 kDa ESR1 proteins were also detected in LGSOC tumor tissues by western blots. To further explore the function of ESR1 66kDa in LGSOC, we over-expressed ESR1 variant 1 in two LGSOC cell lines (HOC-7 and HCC5075) by transfecting with an expression plasmid. Total proteins were extracted from the mock control and transfected cells for functional proteomic analysis by reverse phase protein arrays (RPPA). From the RPPA data, overexpressing ESR1 in LGSOC cell lines suppressed DNA repair pathways but activated cell cycle and mitosis pathways. To further delineate the ESR1 DNA binding sites in LGSOC, we performed ChIPseq analysis of these tumor samples as well as two ovarian cancer cell lines that express ESR1 protein. Our results demonstrated that ESR1 regulated “cistromes” in ER positive ovarian carcinoma is very different from that in ER positive breast cancer as much less ESR1 binding sites were found in LGSOC. There are ESR1 binding sites common to both types of cancers, but we found quite a few unique ESR1 binding sites. We are trying to integrate the ChIPseq and RNAseq data and hopefully identify, for the first time, an ovarian cancer specific ERα cistrome. ER expression may not always correlate with activation of ESR1 signaling pathways, which may be one of the reasons underlying endocrine therapy resistance in ovarian cancer. The results of an integrated analyses will also give us insight on the management of ER positive LGSOC by identifying new genetic targets that may be used in combination with endocrine therapy.

#6280 Vitamin D enhances luminal differentiation of prostate organoids more than androgens.

O. F. Cerna, Jr., L. Nonn, M. Schlicht, K. Krieger;
University of Illinois at Chicago, Chicago, IL

Background: Prostate Cancer (PCa) is a prevalent disease affecting over two million men worldwide. Vitamin D is a fat-soluble hormone that is well-known for its role in the maintenance of strong bones and has anti-cancer effects in prostate cancer. Vitamin D is synthesized in the skin in response to sun exposure and may be supplemented with diet. However, since melanin hinders this synthesis many African Americans are deficient in vitamin D. Vitamin D circulates as 25-hydroxyvitamin D3 (25D) and 25-dihydroxyvitamin D3 (1,25D). Hydroxylation of 25D by the kidney or within tissues forms the active hormone 1,25D. 1,25D binds the vitamin D receptor (VDR), a steroid transcription factor. Androgens are the main regulatory hormones involved in prostate growth and differentiation. Epithelial differentiation is the process in which progenitor or stem cells become specialized cells, such as basal or luminal. In the prostate, luminal epithelial cells are the most differentiated and are the origin of PCa. We used mouse prostate organoids to replicate the differentiation process in vitro and to help identify the role of 1,25D on epithelial differentiation in the presence and absence of other androgens.
Methods: Primary mouse prostate cells were isolated from dorsal lateral lobes and grown as organoids. Over two weeks, we treated these organoids with concentrations of 1,25D and androgen (dihydrotestosterone, DHT). The four treatment groups were control, 1,25D only, DHT only and 1,25D+DHT. Organoids were imaged and analyzed for number, size and phenotype. Phenotypes were identified as luminal, acinar, or solid.
Results: Luminal phenotypes were more prevalent in 1,25D conditions compared to control or DHT alone. The number, size and percent of luminal organoids was highest in 1,25D + DHT compared to all other groups. Ongoing studies include examination of prostate organoids from mice with a vitamin D-deficient diet and staining of the organoids for differentiation markers.
Conclusions/Significance: We observed that 1,25D enhanced luminal epithelial differentiation in mouse prostate organoids. These findings suggest that chronic vitamin D deficiency may increase risk of aggressive prostate cancer, due to decreased epithelial differentiation. This has implications for the disparity of aggressive PCa observed in African American men who have lower vitamin D levels compared to their white counterparts.

#6281 Context dependent role of glucocorticoids in breast cancer..

W. Effah, S. Ponnusamy, S. Asemota, Y. Khosrosereski, R. Narayanan;
University of Tennessee Health Science Center, Memphis, TN

Glucocorticoids bind to the transcription factor glucocorticoid receptor (GR) and regulate genes in response to cellular metabolism, inflammation, and stress. Although GR has been extensively evaluated in inflammation and metabolic diseases, its role as a therapeutic target in cancer has not been thoroughly studied. Results from studies with another member of the steroid receptor family, androgen receptor (AR), demonstrated that the AR is an oncogene in estrogen receptor (ER)-negative breast cancer, but a tumor suppressor in ER-positive breast cancer. We expected a comparable mechanism with GR in different breast cancer subtypes. In this study, we evaluated the role of GR in various breast cancer subtypes and discerned the mechanism of action. Six breast cancer cell lines and seven patient-derived xenografts (PDXs) were characterized by Western blot for their expression of GR, ER and AR. Proliferation assays were performed in cell lines with a dose-response of a synthetic glucocorticoid, dexamethasone. Subsequently, we performed xenograft studies in cell line xenografts (CDXs) and PDXs. GR was ubiquitously expressed in various cell lines and PDX models. Dexamethasone reduced cell proliferation in ER-positive models, while it increased the proliferation in ER-negative cell lines, suggesting that the GR might have a mechanism of action that is similar to AR. GR antagonist, mifepristone, reversed the effects of dexamethasone. CDX studies in an ER-positive cell line, MCF7 suggested that dexamethasone (10 mpk) inhibited the tumor growth significantly that was better than the standard of care fulvestrant. This result was confirmed in an ER positive PDX model HCI013. Study by Obradović et al, indicates that glucocorticoids have an oncogenic role and furthermore promote breast cancer metastasis in TNBC model thereby validating the subtype and context dependent role of the glucocorticoid receptor. We are currently exploring the mechanism of GR's context-dependent tumor suppressor and oncogenic role in distinct breast cancer subtypes.

#6282 Novel androgen related gene network in prostate cancer cell model.

Alex L. McDonald, Spencer Snow, Shuk-mei Ho, Yuet-kin Leung

Pharmacology and Toxicology, University of Arkansas for Medical Sciences, Little Rock, AR

Prostate cancer stands as the foremost cause of cancer-related deaths among men in the United States, with the primary treatment being androgen receptor (AR) antagonists relying on current androgen signaling knowledge. Most of this knowledge is derived from next-generation sequencing experiments, but the oversight of splice variants and highly similar sequences in multiple loci can hinder a comprehensive understanding. In an effort to unveil the complete androgen receptor transcriptional program, we employed a novel sequencing analysis protocol. Using a R1881-LNCaP model, we identified 212 upregulated and 92 downregulated genes, of which a notable one-third (68 upregulated and 39 downregulated) had not been previously associated with androgen. Among these novel transcripts, 5.6% lacked splice variants, while 16.3% exhibited one or more splice variants, including 3.8% from seven unique gene families. Recognized androgen-regulated genes, such as ORM1, STEAP4, NPPC, ORM2, and KLK3, were validated as upregulated, while GRB10, FN1, PPFIA2, and PLA2G2A were confirmed as downregulated in this in-vitro model. Utilizing chromatin immunoprecipitation-sequencing (ChIP-seq) data, we found that 13% of the genes contained at least one androgen response element within 5 kb upstream or downstream. Further validation through real-time PCR confirmed the expression levels of 90% of the selected genes (18). Ingenuity Pathway Analysis revealed two major regulators (ESRRA and ARFGEF2) in causal networks likely interacting with the novel genes. Intriguingly, 57.1% of ESRRA-involved genes contained at least one ESRRA binding site in a ChIP-seq dataset. Although ESRRA is known to activate androgen biosynthesis in castration-resistant prostate cancer, its interaction with AR and co-regulation of androgen signaling remain unknown. Ongoing studies involve the characterization of these networks in prostate cancer cell lines, examining anchorage-independent capacity, invasion, migration, proliferation, and progression. Data collection and comparison will ascertain whether the signaling is driven by mutated AR, and the role of ARv7 will be elucidated through gene lockdown experiments.

#6283 Tumor repressive effects of estrogen receptor β mRNA-based therapy in aggressive breast cancers.

K. Cap, A. Phillips, K. A. Court Pinto, K. D. Zambo, W. Qian, J. Zhou, J. Chang, B. Godin, **C. Thomas**;
Houston Methodist Research Institute, Houston, TX

Inflammatory breast cancer (IBC) and triple-negative breast cancer (TNBC) are the most aggressive forms of breast cancer due to their high propensity to develop distant metastases and the lack of specific effective targeted therapies. The failure of previous research to produce viable therapeutic targets combined with the absence of estrogen receptor α (ERα) in TNBC and the majority of IBC led us to explore the second ER (ERβ) as a molecule with targeting potential. We previously reported the anti-metastatic effects of ERβ in both TNBC and IBC. Considering the anti-tumor activity together with the decreased expression of ERβ in IBC and TNBC tumors, we employed an mRNA-based approach to induce tumor-specific upregulation of the receptor and restore its anti-metastatic activity. Our findings show that complexes of ERβ mRNA with lipid nanoparticles (LNPs) enable *in vitro* translation of a functional protein with strong anti-invasive activity. More importantly, direct administration of ERβ mRNA-LNPs in orthotopically grown IBC and TNBC tumors results in high tumor levels of the receptor and an evident inhibition of metastasis demonstrating for the first time the ability of ERβ mRNA to prevent progression of the disease. Our study may have important clinical implications by establishing ERβ mRNA as a novel and specific therapy intervention that either alone or in combination with existing treatments can substantially repress metastasis, eliminate associated mortality and benefit patients with aggressive breast cancer.

#6284 Multimoics reveal aberrant pathways and regulation of castration resistant and metastatic prostate cancer.

A. M. Horning, C.-N. Hung, B. Liebermann, C.-W. Chou, C.-K. Lin, Y. V. Wang, V. X. Jin, M. A. Liss, C.-M. Wang, C.-L. Lin, M. Chen, T. H. Huang, **C.-L. Chen**; UT Health Science Center at San Antonio, San Antonio, TX

Prostate cancer is a highly heterogeneous disease and in the end, 30% of patients will experience metastatic and fatal castration resistant prostate cancer (mCRPC). In spite of the vigorous efforts to search the causes of metastatic CRPC (mCRPC), the mechanisms are still largely unresolved. To understand the progression of mCRPC, we utilized scRNA-seq to profile global expression patterns in LNCaP, LNCaP-Abl and PC3 representing castration sensitive and resistant states. ScRNA-seq revealed 335 and 2393 differentially expressed (DE) genes in early and advanced castration resistant states enriched in 43 and 163 aberrant pathways. These included focal adhesion, adherens junction, leukocyte transendothelial migration, ECM-receptor interaction, regulation of actins, gap junction, TGFb, WNT, Hippo, Ephrin and other pathways. Upregulation of these pathways predicted worst disease free/overall survival of The Cancer Genomes Atlas (TCGA) PC cohort using Kaplan-Meir estimation. Further scRNA-seq also indicated most of the pathways were also enriched in *ex vivo* circulating tumor cells derived from biochemical recurrent or mCRPC patients. Small molecule perturbation verified function of 9 pathways involved in cell proliferation, migration, invasion, and organoid formation of mCRPC cell lines and CTCs. We then delved into how these genes are regulated by the global chromatin landscape through Assay for Transposase-Accessible Chromatin and high throughput DNA-seq (ATAC-seq). In castration sensitive LNCaP, active chromatins are associated with genes but most of them are located in distal intergenic regions. Conversely, the majority (51.9-57.6%) of open chromatins in castration resistant PC cells are situated in promoters that lie within 1kb of transcription start sites. KEGG pathway enrichment analysis uncovered Hippo, Wnt, tight junction, adherens junction, circadian and other pathways that corroborate the scRNA-seq findings. GRO-seq data indicated that nascent transcription supports gene body transcription in castration resistant cells but leads to massive pausing in castration sensitive cells.

#6285 Defining androgen receptor function and the effects of PARP inhibition in BRCA1/2-deficient vs. proficient prostate cancer.

N. A. Traphagen, E. Wheeler, R. Li, X. Qiu, M. Brown;
Dana-Farber Cancer Institute, Boston, MA

Mutation or loss of the tumor suppressor genes *BRCA1* and *BRCA2* promotes the development of aggressive prostate cancer with poor outcomes and a high risk of metastatic relapse. Approximately 15% of metastatic prostate tumors are BRCA1/2-deficient. These tumors are frequently resistant to standard-of-care treatments that block androgen receptor (AR) function, although the mechanisms underlying this effect remain unclear. PARP inhibitors are synthetically lethal with BRCA1/2-deficiency and are commonly used as a late-line treatment in metastatic prostate cancer; however, both preclinical and clinical data have provided conflicting results on whether PARP inhibitors can be effective in BRCA1/2-proficient prostate tumors. BRCA1, BRCA2, PARP-1, and PARP-2 all have proposed roles in regulating transcription and the chromatin landscape. We therefore hypothesized that loss of BRCA1, BRCA2, and/or inhibition of PARP modulates AR function through changes in global chromatin structure and transcriptional pathways. We used patient-derived xenograft models and next-generation sequencing techniques to profile AR function in BRCA1/2-deficient vs. proficient prostate tumors. We found that loss of BRCA1 and BRCA2 is associated with chromatin accessibility changes, and differentially accessible regions correlate with DNA binding motifs for AR and AR cofactors. ChIP-seq for AR in these tumors demonstrated that BRCA1/2-deficiency is associated with an altered AR cistrome and a global decrease in AR genomic binding. Corresponding RNA-seq data confirmed a downregulated androgen response in BRCA1/2-deficient tumors. In cell line models, inhibition of PARP1 and PARP1/2 inhibited AR-driven transcription. Combining PARP inhibition with either androgen deprivation or the AR antagonist enzalutamide dampened the growth-inhibitory effects of PARP inhibitor treatment. Together, these results indicate that BRCA1/2-deficiency and PARP inhibition modulate AR function in prostate cancer.

#6286 Metabolic abnormalities are early predictors of liver metastasis in patients with ER+ breast tumors.

A. N. Mogol[1], M. Goel[1], A. Lam[1], D. Dutta[2], B. Barnick[2], M. Grosse Perdekamp[2], Z. Madak Erdogan[1];
[1]University of Illinois at Urbana-Champaign, Urbana, IL, [2]Carle Cancer Institute, Urbana, IL

Approximately 70% of human breast cancers express estrogen receptor alpha (ERα), providing a potential for targeted endocrine therapy for patients. Unfortunately, 30-40% of ER+ patients still experience recurrence and metastasis, with a 5-year relative overall survival rate of just 24% for patients with metastatic disease. In our preliminary analysis of the data from a large cohort of ER+ MBC patients, liver metastases were associated with reduced overall survival compared to other sites, while on the standard of care estrogen receptor antagonist, Fulvestrant (Fulv). This supports data from previous clinical trials showing that patients with liver metastases are less responsive to estrogen receptor alpha (ERα) targeting endocrine therapies compared to patients with bone or lung metastases. However, the factors underlying site-specific responses of MBC to ER antagonists are unknown.

In this study, we investigated the concept that response of liver metastatic tumors is impacted by systemic glucose metabolism and the presence of liver metastatic tumors in turn will affect glucose homeostasis in the body. In our preliminary studies, metastatic liver tumors upregulated expression of enzymes that increased glycogen deposition in tumor cells in response to Fulv. Further analysis showed that a ketogenic diet restored Fulv response of metastatic liver tumors. Based on these results, we investigated if there was a relationship between metastatic site and response to endocrine therapy and if the metabolic status related to glucose homeostasis impacts metastatic disease response. We also searched if glucose homeostasis abnormalities can be indicators of liver metastasis.

We obtained electronic health records from 192 patients with stage IV estrogen receptor positive breast cancer and analyzed glucose metabolism and liver panel markers including ALT, AST and ALP. Our results showed that more than 85% of patients with liver metastases have another accompanying metastasis and these patients are at a higher risk of diabetes diagnosis compared to other metastatic site patients. A higher % of patients with liver metastasis were deceased. We also observed increased levels of ALT, AST and ALP with liver metastasis and our preliminary analysis indicates that these blood biomarkers along with metabolic disease status (diabetes, hypertension, lipidemia) are good predictors of liver metastasis. Detecting early changes in markers of glucose metabolism may provide an easy diagnostic tool for early detection of liver metastases as well as assessment of treatment response. This may lead to accurate adjustment of treatment choices with improved outcome of patients with liver metastases from breast cancer.

CLINICAL RESEARCH: Addressing Physical and Psychological Effects of Cancer Survivorship
Poster Session

#6290 Effects of a circuit, interval-based exercise program on vascular function among cancer survivors.
C. N. Christopher, D.-W. Kang, P. Gonzalo-Encabo, R. L. Wilson, A. J. Normann, M. K. Norris, C. M. Dieli-Conwright;
Dana-Farber Cancer Institute, Boston, MA

Background: Cancer survivors are at an increased risk of cardiovascular comorbidity, including atherosclerosis, hypertension, and heart failure, due to negative impacts of cancer treatments on vascular function. Exercise is recommended in recent cardio-oncology rehabilitation guidelines and has been shown to improve vascular function in clinical populations; however, its effects on vascular function are understudied in clinical oncology settings.
Purpose: This pilot study examined whether a circuit, interval-based exercise intervention can improve vascular function, assessed by brachial artery flow-mediated dilation (baFMD) and carotid intima media thickness (cIMT) in breast, prostate, and colorectal cancer survivors.
Methods: Overweight or obese (BMI>25.0 kg/m^2), sedentary breast, prostate or colorectal cancer survivors were randomized to exercise (n=60) or usual care (n=30). Survivors in the 4-month exercise intervention trained three times/week, in a circuit, interval-based supervised moderate-vigorous aerobic (65-85% of VO_2max) and resistance (65-85% of 1-repetition maximum) program. cIMT and baFMD were measured at baseline and post-intervention via an ultrasound. Paired t-tests and repeated-measures analysis of variance were run to assess within- and between-group differences.
Results: The study sample included breast (n=38), prostate (n=24), colorectal (n=28) cancer survivors who were 63.2 ± 10.8 years old, completed chemotherapy and/or radiation (75%) and were obese (87%). Post-intervention, baFMD significantly increased in the exercise group compared to the control group (between-group mean difference: 6.3%; 95% CI: [1.9 to 9.3], p=0.001). There was also a significant reduction in cIMT in the exercise group compared to the control group (between-group mean difference: -0.039mm, 95% CI: [-0.080 to -0.009], p=0.002).
Conclusions: Our findings in this pilot study support that a circuit, interval-based aerobic and resistance exercise intervention may improve vascular function in breast, prostate, and colorectal cancer survivors. Future studies are recommended to understand how exercise interventions can be utilized clinically to improve cardiovascular disease risk and co-morbidity among cancer survivors.

#6291 Changes in physical activity and ischemic stroke risk after cancer diagnosis: A nationwide cohort study.

D. Shin[1], W. Jung[2], I. Cho[1], J. Jung[3], M. Cho[4], H. Koo[5], B.-L. Cho[6], J. Park[6], H. Kwon[6], K. Han[7], Y.-M. M. Park[8];
[1]Samsung Medical Center, Seoul, Korea, Republic of, [2]Kangdong Sacred Hospital, Seoul, Korea, Republic of, [3]The Catholic University of Korea, Seoul, Korea, Republic of, [4]Kangbuk Samsung Hospital, Seoul, Korea, Republic of, [5]Seoul National University Bundang Hospital, Seongnam, Korea, Republic of, [6]Seoul National University Hospital, Seoul, Korea, Republic of, [7]Soongsil University, Seoul, Korea, Republic of, [8]University of Arkansas for Medical Sciences, Little Rock, AR

Background: Physical inactivity is prevalent after cancer treatment, which may pose a greater risk of ischemic stroke in cancer survivors.
Objective: To investigate the association between physical activity change from pre- to post-diagnosis and ischemic stroke risk among cancer survivors.
Methods: Cancer survivors without prior history of cardiovascular disease were identified. Pre- and Post-adherence to physical activity was determined within two years from cancer diagnosis. The primary outcome was incident ischemic stroke. Using the Fine-Gray model, sub-distribution hazard ratios (sHRs) and 95% confidence intervals (CIs) for ischemic stroke risk were calculated, considering death as a competing risk.
Results: Among 269,943 cancer survivors (mean [SD] age 56.3 [12.1] years, 45.7% male), 10.1% remained active, 11.4% became inactive, and 16.6% became active post-diagnosis. During 1,109,566.68 person-years[YMP1] , remaining active both pre- and post-diagnosis was associated with 15% decreased risk of ischemic stroke (sHR 0.85, 95% CI 0.75-0.96), compared to those who remained inactive. Cancer survivors who became active, and inactive post-diagnosis showed a 16%, and 11% lower risk of ischemic stroke (sHR 0.84, 95% CI 0.75-0.93; sHR 0.89, 95% CI 0.79-0.99) than those who remained inactive.
Conclusions: Our findings suggest that staying physically active is associated with a reduced risk of ischemic stroke among cancer survivors. Notably, these advantages are not limited to individuals who were physically active before their diagnosis, and it is not too late to start post-diagnosis. Preventive strategies against ischemic stroke in cancer survivors should emphasize the incorporation of regular physical activity at any stage of their cancer journey.

#6293 Influence of prescription opioids and recreational cannabis use on efficacy outcomes and adverse events related to immune checkpoint inhibitors.

H. Mahadevia, B. Eidenschink, A.-L. Cheng, A. Desai, S. Harry, L. Kujtan;
University of Missouri - Kansas City School of Medicine, Kansas City, MO

Introduction: Opioids and cannabis possess immunomodulatory properties. However, the effect of opioid receptor activity on immune function is complicated, facilitated by several mechanisms and can lead to enhancement or inhibition. Similarly, the relation between cannabinoid ligands of diverse types and endocannabinoid receptors on various immune cells is complex. We hereby delineate the effect of prescription opioids and recreational cannabis use on immune-related adverse events (IRAEs) during immune checkpoint inhibitor (ICI) therapy in various cancers, as well as efficacy outcomes in advanced non-small cell lung cancer (aNSCLC).

Methods: This is a retrospective cohort study of adult patients with advanced cancers who received ICI with or without chemotherapy for at least two months at an urban safety net hospital from January 2016 to June 2022. All patients, as well as a subset of patients with aNSCLC, were divided into two arms based on whether they were prescribed opioids during ICI therapy or not (OP vs. NO). Similarly, they were grouped based on whether they reported recreational cannabis use during ICI therapy (since initiation of therapy) or not (CA vs. NC). Incidence of IRAEs, median overall survival (mOS) and median progression-free survival (mPFS) calculated per RECIST 1.1 were the outcome variables. Multivariate logistic regression and alternative log-rank test were utilized for analysis with adjustments for demographics, insurance status, BMI, ECOG, PD-L1, TMB, smoking and concurrent chemotherapy.

Results: 230 patients received ICI-based therapy; 47% were female, 34% were African American and 6.5% were Hispanic. There was no significant difference in the incidence of IRAEs between OP (n=144) and NO (n=86; p=0.225). However, CA (n=44) had higher IRAEs than NC (n=186) with an odds ratio estimate of 2.023 (X^2=4.18, CI 1.03-3.97, p=0.04). Among 110 patients with aNSCLC, 46% were female. Patients with aNSCLC in the OP arm (n=69) had no significant difference in mOS (HR=1.34, CI 0.8-2.25, p=0.26) or mPFS (HR=1.21, CI 0.69-2.1, p=0.51) compared to patients in the NO arm (n=51). Similarly, the two arms CA (n=21) and NC (n=89) had no difference in mOS (HR:0.96, CI 0.5-1.83, p=0.89) or mPFS (HR:1.18, CI 0.61-2.29, p=0.63) for aNSCLC.

Conclusion: Recreational cannabis use during ICI therapy increased the incidence of IRAEs. Prescription opioids and recreational cannabis use did not significantly affect survival outcomes for ICI in aNSCLC. Prescription opioid use also did not significantly influence the occurrence of IRAEs. This study suggests that recreational cannabis may need to be used with caution in this patient population due to its influence on IRAEs. On the other hand, opioids appear to be a safe option for pain management in these patients. Larger studies are warranted to shed more insight into the effect of these substances on ICI therapy.

#6294 Subclinical atherosclerosis in newly diagnosed colorectal cancer patients.

Julia A. Levy[1], Maimoona Nadri[1], Elham Kazemian[1], Katelyn M. Atkins[2], Jordan O. Gasho[2], Katrina D. Silos[2], Cody Ramin[3], Andriana P. Nikolova[4], Erin M. Siegel[5], Biljana Gigic[6], Adetunji T. Toriola[7], Jennifer Ose[8], Christopher I. Li[9], David Shibata[10], Cornelia M. Ulrich[8], Jane C. Figueiredo[1]

[1]Department of Medicine, Samuel Oschin Comprehensive Cancer Institute, Cedars-Sinai Medical Center, Los Angeles, CA,[2]Department of Radiation Oncology, Samuel Oschin Comprehensive Cancer Institute, Cedars-Sinai Medical Center, Los Angeles, CA,[3]Department of Biomedical Sciences, Samuel Oschin Comprehensive Cancer Institute, Cedars-Sinai Medical Center, Los Angeles, CA,[4]Department of Cardiology, Cedars-Sinai Medical Center, Los Angeles, CA,[5]Department of Cancer Epidemiology, Moffitt Cancer Center, Tampa, FL,[6]Department of General, Visceral and Transplantation Surgery, Heidelberg University Hospital, Heidelberg, Germany,[7]Division of Public Health Sciences, Department of Surgery, Washington University School of Medicine, St. Louis, MO,[8]Department of Population Health Sciences, Huntsman Cancer Institute, University of Utah, Salt Lake City, UT,[9]Division of Public Health Sciences, Fred Hutchinson Cancer Research Cente, Seattle, WA,[10]Department of Surgery, Washington University, St. Louis, MO

Introduction: Recent advances in early detection and treatment have improved survival rates for patients with colorectal cancer (CRC), and emerging data suggests patients may be at elevated risk of cardiovascular disease (CVD). However, there are no standard recommendations for assessing CVD risk in patients with CRC. Coronary artery calcium (CAC) is a measure of the quantity of coronary artery calcification using noninvasive scanning and has been shown to be predictive of CVD risk. This prospective cohort study utilizes CAC to evaluate the occurrence of subclinical atherosclerosis at the time of CRC diagnosis and the risk of major adverse cardiovascular events (MACE). **Methods:** The ColoCare Study is a prospective cohort study across six U.S. and European sites. Data from one of the ColoCare consortium sites in Los Angeles, California was analyzed. Adults with newly diagnosed stage I- IV colorectal cancer and available non-contrast CT scans were included. Electronic medical records were reviewed for assessment of baseline cardiovascular risk factors and adverse events. Subclinical atherosclerosis was defined as the presence of CAC (CAC>0). CAC was manually measured from routine oncologic diagnostic CT and PET-CT scans at the time of cancer diagnosis using the Agatston method. MACE was defined as hospitalization due to heart failure, cardiomyopathy, ischemic heart disease, or ischemic stroke after the diagnosis of CRC cancer. Multivariable-adjusted Cox regression was used to evaluate the association between CAC at diagnosis and the risk of MACE. **Results:** Among 109 individuals with CAC measured at the time of CRC diagnosis, 41 (37.6%) had subclinical atherosclerosis (CAC=1-399 [n=29], CAC>400 [n=12]). Individuals with CAC>0 were older (67.0 vs. 51.9 years, p<0.01), more likely to be former or current smokers (48.0 vs. 29.0 years, p=0.04), and to have hypertension (61% vs. 23%, p<0.01) compared to those without CAC (CAC=0). Among individuals with CAC (n=41), 51.2% had scores >100, and 29.2% had scores >400, indicating moderate and severe atherosclerosis respectively. Among patients with moderate or greater CAC burden (>100; statin therapy indicated), 28.6% were not on statin therapy. CAC>0 was associated with an increased incidence of MACE (13% vs. 53%, p<0.01). **Discussion:** Subclinical atherosclerosis was observed in nearly 40% of patients with CRC at diagnosis and MACE occurred in 38.2% of patients. Most patients were under-optimized for CVD risk, with nearly 30% of statin-eligible patients with at least moderate CAC burden not prescribed statin therapy. These findings highlight an opportunity for improved CVD risk mitigation in patients with CRC, including guidelines-based CVD risk factor modification.

#6295 Role of MAPK11 in the protective mechanisms against toxicity of tyrosine kinase inhibitors.

Anna Pavlovna Hnatiuk, David Staudt, Mark Mercola

Cardiovascular Institute, Stanford University, Stanford, CA

Introduction and purpose of the study: Targeted therapies with Tyrosine Kinase Inhibitors (TKIs) have drastically improved the survival of cancer patients. However, long term exposure to TKIs has been associated with severe adverse events such as heart failure, impairing patient survival and life quality, and limiting treatment options. Cardioprotective effect of MAPK11 has been described against cardiac ischemic disease. In addition, MAPK11 has also been reported as an important mediator in cancer development and progression. Therefore the aim of this study is to evaluate the potential therapeutic and dual anti-cancer and cardio-protective effect of MAPK11 inhibition during TKI treatment.

Experimental procedures: For this study we used the TKI ponatinib as a paradigm of cardiac toxicity. Ponatinib has been used as a gold standard therapy for the drug resistant type of Chronic Myeloid Leukemia (CML) due to T315I-ABL1 mutation, and has been associated with high risk of cardiac toxicity. We performed *in vitro* functional assays to evaluate the cardiotoxicity and cardiac protection using human iPSC-cardiomyocytes (hiPSC-CMs), and anti-cancer effect in T315I mutated KCL-22 CML cells. The cardiotoxicity was evaluated by impairment of cardiomyocytes contractile function during TKI (ponatinib) treatment, the cardiac-protection was evaluated by restoration of contractile function post-inhibition of MAPK11 with RNA silencing (siRNA) technique. The anti-cancer effect was evaluated using a cell viability and proliferation assay during inhibition of MAPK11 by siRNA and ABL1 inhibition as a positive control.

Summary of unpublished data: Pretreatment with siRNA MAPK11 inhibition significantly improved the contractile function of the cardiomyocytes during treatment with ponatinib when compared to those that did not receive MAPK11 inhibition. Moreover, when compared to the positive control of siRNA ABL1 inhibition, the MAPK11 inhibition showed similar anti-cancer effect in the T315I mutated KCL-22 CML cells proliferation and survival assay.

Conclusions: Our study suggests that the inhibition of MAPK11 is a potential druggable therapeutic target with dual action of anti-cancer effect for the mutant form of CML, as well as a substantial protective effect against the cardiac toxicity associated with the TKI ponatinib that could bring insights in the development of safer oncological drugs.

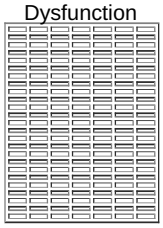
#6296 Biomarkers associated with atherosclerosis-related cardiovascular dysfunction in cancer survivors treated with anthracyclines.

K. W. Reding[1], A. Vasbinder[1], N. O'Connell[2], B. Demissei[3], W. Szewczyk[1], R. Cheng[1], A. Ladd[4], A. Lucas[4], J. Meyer[1], S. Bowen[1], F. Salloum[4], R. D'Agostino, Jr.[2], G. Lesser[2], K. Weaver[2], B. Ky[3], W. Tang[5], W. Hundley[4];

[1]University of Washington, Seattle, WA, [2]Wake Forest University, WInston-Salem, NC, [3]University of Pennsylvania, Philadelphia, PA, [4]Virginia Commonwealth University, Richmond, VA, [5]Cleveland Clinic, Cleveland, OH

Introduction: Cancer survival has increased in part due to treatment advances. However, anthracycline chemotherapy increases cardiovascular (CV) morbidity risk, including atherosclerotic CV disease (ASCVD). Among those receiving anthracyclines, it is yet unclear who is at greatest risk of ASCVD, a major cause of CV mortality. Elucidating pathophysiologic processes involved in the development ASCVD could shed light on strategies to identify those at risk.
Methods: Analyses were performed on 279 lymphoma and breast cancer survivors enrolled in the PREVENT study [clinical trial WF-98213) through Wake Forest NCI Community Oncology Research Base (NCORP) and Alliance (A221501)]. CV dysfunction was measured via cardiac MRI (cMRI) at baseline (pre-treatment) and 6-months post-diagnosis to ascertain aortic distensibility and wall thickness in the descending aorta. Biomarkers were measured at baseline and 6-months and were log-transformed to base 2. Multiple linear regression was used to determine associations between biomarker and outcome at 6 months, adjusted for baseline biomarker and cMRI outcome, age, race, sex, body mass index, and smoking history.
Results: The mean age (SD) of cancer survivors 49 (12) years; 92% were women. The mean aortic distensibility and mean wall thickness at baseline was 0.002 (0.0014) and 2.99 (0.41), respectively. Table 1 shows the associations between biomarkers and aortic distensibility and wall thickness of the descending aorta. After adjustment for confounders, Arginine, CRP, MPO, and ornithine were associated with 6-month aortic distensibility, and the HDL and SDMA were associated with aortic wall thickness.
Conclusions: The findings of this study suggest that biomarkers in oxidative stress and inflammatory pathways may be involved in pathophysiology of ASCVD among cancer survivors receiving anthracyclines. These results require further study in larger cohorts to better define mechanistic pathways involved.

Association of Biomarkers with Atherosclerosis-Related Cardiovascular Dysfunction



#6297 “They should get a cardiologist to be a part of the team when you first go”: A qualitative analysis of racial differences in the cancer care experience amongst breast cancer patients receiving cardiotoxic therapy.

A. Turner[1], A. Vijil[1], S. Gomez-Trillos[2], V. Williams[1], P. Omeaku[3], S. Hong[4], A. L. Sutton[1];
[1]Virginia Commonwealth University, Richmond, VA, [2]Lombardi Comprehensive Cancer Center, Washington D.C., DC, [3]Virginia Commonwealth University School of Population Health, Richmond, VA, [4]Massey Comprehensive Cancer Center, Richmond, VA

Background: Black breast cancer survivors are up to three times more likely to develop cancer therapy-related cardiac dysfunction (CTRCD) when compared to White survivors. Reasons behind this disparity are not fully understood, and studies examining these disparities have been limited. One contributor may be variations in communications about CTRCD risk and risk prevention strategies between providers and patients by race and ethnicity. This study assessed racial differences in Black versus White breast cancer patients with provider communication regarding cardiotoxic treatments.
Methods: Study participants were recruited from a comprehensive cancer center. Eligibility included identifying as a Black/African American or White woman, a diagnosis of stage I-III breast cancer, and receipt of anthracyclines and/or trastuzumab. Semi-structured interviews were conducted with survivors. Interviews were audio-recorded, transcribed, and were reconciled using Dedoose.
Results: Interviews were conducted with 16 survivors (8 Black, 8 White) with a median age at diagnosis of 53 years. Prior to starting treatment, 100% of white survivors reported that a provider discussed CTRCD risk, however only 75% black survivors reported CTRCD discussion. Although all women received information on prevention strategies including exercise and nutrition, there were differences in timing of information delivered. Black women desired to have information at the beginning of treatment, but no White women mentioned a desire to receive information earlier. A greater proportion of White women reported engaging in prevention strategies such as exercising and eating healthy during treatment. In terms of knowledge gained, 75% of White Women reported being satisfied with the information given regarding cardiotoxic risk and prevention whereas only 45% of Black women reported being satisfied.As 65% of Black women (vs. White) reported being less than satisfied with the information given, Black women were also more likely to recommend access to additional resources. For example, one Black woman suggested that “they [care team] should get a cardiologist to be a part of the team when they first go.
Conclusion & Implications: Fewer Black women reported being satisfied with their medical visits regarding CTRCD risk and prevention strategies. Racial differences in assessments of these experiences highlight opportunities to develop culturally-tailored communication interventions to reduce racial disparities in CTRCD; however, future research is needed to assess interpersonal aspects of care during the receipt of cardiotoxic treatment.

#6298 The value of routine trastuzumab-related cardiac toxicity monitoring in gastrointestinal cancers.

S. R. Kosydar, M. Castrichini, M. Zhu, H. Xie;
Mayo Clinic, Rochester, MN

Background: It is a common practice to monitor trastuzumab-related cardiac toxicity (TRCT) using left ventricular ejection fraction (LVEF) in patients who receive trastuzumab-containing therapy for human epidermal growth factor receptor 2 (HER2)-positive cancers. However, this monitoring approach does not appear cost effective in patients with HER2-positive gastrointestinal (GI) cancers given poor overall survival (OS). Here, we aim to examine the incidence of clinically significant TRCT in this target population.

Methods: This is a retrospective cohort study of patients with advanced HER2-positive GI cancers who received trastuzumab-containing therapies (trastuzumab +/- pertuzumab, chemotherapy +/- immunotherapy + trastuzumab, trastuzumab deruxtecan) between 2011 and 2023. HER2 status was determined by immunohistochemistry, fluorescent in situ hybridization, and/or next generation sequencing. LVEF was estimated by serial transthoracic echocardiograms (TTE). Continuous variables were summarized as median and interquartile range (IQR). Paired Wilcoxon signed rank test was used to compare serial LVEF. OS was estimated using Kaplan-Meier method.

Results: A total of 243 patients were included in this study with a median age of 64 (IQR: 55-70) years. 139 (57%) patients had esophageal or GEJ adenocarcinoma; 45 (19%) patients had gastric cancer; 37 (15%) patients had colorectal cancer; and the rest had other GI cancers. Median follow-up time was 18.6 (IQR: 9.2-36) months. Median OS from cancer diagnosis and the first dose of trastuzumab-containing therapy were 24.1 (95%CI: 20.2-30.2) and 11.7 (95%CI: 10.4-15.6) months, respectively. Patients received a median of 13 cycles of trastuzumab-containing therapy for a median duration of 4.1 (IQR: 1.4-10.1) months. The median number of TTE each patient had throughout therapy was 2 (IQR: 1-4). Median baseline LVEF was 61% (IQR: 56-65%) which was significantly higher ($p<0.001$) than the median lowest LVEF of 58% (IQR: 53-62%) during therapy, but not different ($p=0.14$) from the most recent median LVEF of 60% (IQR: 56-64%) after discontinuation of trastuzumab. Among 176 patients with serial LVEF data, 16 (9%) had > 10% LVEF drop; 7 (44%) of these 16 patients had LVEF recovery. None of the cardiovascular risk factors prior to trastuzumab treatment including hypertension, diabetes, hyperlipidemia, peripheral arterial disease, coronary artery disease, and stroke were significantly associated with the development of TRCT.

Conclusion: The incidence of clinically significant LVEF drop appears low in patients with advanced GI cancers as post-treatment LVEF recovery to baseline was observed at the population level. The value of using TTE to monitor TRCT in these patients with short OS should be further assessed in the perspective of cost effectiveness.

#6299 Psychometric evaluation of the FACIT-SP 12 in a primary brain tumor patient population.

E. Vera, B. Ozer, A. Acquaye-Mallory, V. Pillai, A. Choi, E. Grajkowska, T. Kunst, H. Miller, K. Reinhart, T. S. Armstrong, M. Stockdill;
National Cancer Institute, Bethesda, MD

Spirituality is a social determinant of health associated with psychosocial adjustment to serious illnesses including cancer but is not often assessed in clinical care. Here we perform psychometric evaluation of a tool developed to report spiritual well-being in chronic illness in a cohort of 248 patients with primary brain tumors (PBT) enrolled in a natural history study (NCT02851706, PI: T. Armstrong). Participants completed the Functional Assessment of Chronic Illness Therapy-Spiritual Well-Being 12 (FACIT-SP 12) as part of yearly clinical outcome assessments. Total score, Meaning/Peace and Faith scores were calculated. Internal consistency (Cronbach's alpha) and construct validity (principal components analysis with varimax rotation) evaluated psychometric properties of the FACIT-SP 12; one-way ANOVAs, one-sample t-test and Wilcoxon signed rank tests evaluated group differences (sig. $p<0.05$) on patient report of spirituality/beliefs including belief in god(s)/higher power, being religious, and prayer and in comparison to scores of previously reported studies. Participants were majority male (57%), white (79%) with high grade tumor (59%) and a median age of 48 (range: 20-82). Seven different religions were reported (majority Christianity [55%]) but also spiritual non-religious (9%), no beliefs (13%), and 6% preferring not to answer. The principal components analysis confirmed the original 2 factor solution (Meaning/Peace and Faith) and explained 66.8% of the variance (KMO =0.87, 43% of residuals < 0.05), with one item not loading cleanly on either factor ("I know that whatever happens with my illness, things will be okay"). Cronbach's alphas were 0.90, 0.90, and 0.89, for the total, Meaning/Peace, and Faith scales, respectively. For all three spiritual/belief questions, patients who responded "yes" had higher total and faith scores than those who responded "no"; but not in the Meaning/Peace score when reporting religion ($p=0.108$). This cohort reported lower total scores (mean=32.5), Meaning/Peace scores (mean=23.4, median=24.0) and Faith scores (mean=9.2, median=10.0) compared to the initial validation in other solid tumors and HIV/AIDs (means=38.5, 25.2, 13.6, respectively) and to a smaller, less diverse PBT sample (medians: Meaning/Peace=25.8, Faith=14.0). The FACIT-SP 12 demonstrated internal consistency and construct validity, with lower scores in comparison to populations in prior studies. More diverse belief systems than previously reported may contribute to differences among studies. Future analysis should explore the increased percentage of "prefer not to answer" respondents compared to earlier reports, associations with clinical and self-reported outcomes including symptoms and quality of life, evaluation of illness-related factors that contribute to poor spiritual well-being, and a longitudinal look at spiritual well-being.

#6300 Associations of biological aging with perceived stress in patients with head and neck cancer: A longitudinal study.

Y. Lin, T. Spikes, D. Bruner, S. Paul, A. Miller, K. Conneely, N. Saba, C. Xiao;
Emory University, Atlanta, GA

Introduction: Biological aging leads to an increased risk of morbidity and mortality in patients with head and neck cancer (HNC) undergoing intensity-modulated radiotherapy (IMRT). This progression can be exacerbated by the burden of stress arising from HNC and IMRT. While stress has been linked to inflammation, the associations of biological aging measures including inflammatory markers and epigenetic age acceleration (EAA) with stress over cancer treatment remain underexplored. The purpose of this study was to examine the associations between biological aging and stress in patients with HNC receiving IMRT across four time points (i.e., pre- (T1), end of (T2), 3 months (T3), and 12 months (T4) post-IMRT).

Methods: We conducted a prospective longitudinal study. Stress was assessed using the Perceived Stress Scale (PSS) across four time points along with the assessment of biological aging markers: peripheral inflammatory markers (i.e., interleukin [IL-6], IL-1β, IL-10, IL-1ra, C-reactive protein [CRP], soluble tumor necrosis factor receptor 2 [sTNFR2], and TNF-α) and EAA. EAA was calculated using DNAmPhenoAge, adjusted for chronological age. Liner mixed effects models were used to examine the associations between biological aging measures and stress across time.

Results: A total of 176 patients with HNC were enrolled in the study with a mean age of 59.9±10.0 years, 72.7% male, and 77.3% non-Hispanic White. Stress scores increased from T1 to T2 (p<0.001), decreased significantly at T3 (p<0.001) which were lower than the baseline scores (T1), and then gradually decreased at T4 (p=0.029). Significant associations of CRP, IL- 1ra, and TNFR-2 with stress were identified across time (all p values <0.05), controlling for covariates (i.e., age, human papillomavirus status, chemotherapy, and surgery): elevated inflammatory markers were associated with higher levels of stress. In a separate model, higher stress scores were also associated with increased EAA controlling for the same covariates (p=0.015): an increment of 10 units in stress scores was associated with an age acceleration of 7.2 months across time.

Conclusions: Findings from our study suggest that biological aging measures (inflammatory markers and EAA) are associated with stress across time in patients with HNC receiving IMRT. Clinicians and researchers may use the findings to develop personalized psychosocial interventions that reduce stress so as to deaccelerate biological aging for patients with HNC during their treatment and survivorship.

#6301 Mapping survivor-specific supportive care resources: A digital landscape analysis of NCI-designated cancer centers.

A. Taylor, K. Sterba, E. Graboyes;
The Medical University of South Carolina (MUSC), Charleston, SC

Background: Optimal care for cancer survivors requires a comprehensive array of supportive care services to address the multitude of physical, psychological, social, financial, and health promotion needs of this population. To understand options to address their unique needs, survivors and their caregivers may seek information from online sources. Although National Cancer Institute-Designated Cancer Centers (NCIDCCs) serve as leaders in cancer treatment and care delivery, as well as credible sources for survivors to receive information on their recovery, no study has characterized the digital landscape of survivorship offerings on their website. This study aims to characterize the supportive care services offered to cancer survivors on NCIDCCs.
Methods: Of the 72 NCIDCCs, 65 provide clinical care. We reviewed the webpage of each to identify supportive care offerings. Services were categorized based on the four domains of the quality-of-life model: (1) physical well-being, (2) psychological well-being, (3) social well-being, and (4) spiritual well-being. Supportive care services were classified as survivor-specific if the online description included information that specifically catered to cancer survivors.
Results: Of the 65 clinical NCIDCC websites, 100% offer supportive care services and 54% offer supportive care services specific to survivors (**Table**). The most common supportive care service offered was nutrition (90.6%) and the least commonly offered was caregiver support (7.9%). Behavioral medicine was offered most frequently for survivors (28.3%) and caregiver support was offered the least (0%). Out of the four domains of the quality-of-life model, spiritual well-being services were offered the least at NCIDCCs.
Conclusion: More than half of the NCIDCC websites provided survivor-specific supportive care services.

Supportive care services on websites of NCI-Designated or Comprehensive Cancer Centers (N = 65)

#6303 Innovative strategies for managing chemotherapy-induced alopecia: Scalp cooling.

S. I. Gaumond[1], R. Abdin[2], R. O. McPhillips[1], L. M. Ferrari[1], S. Mufarrej[1], J. J. Jimenez[1];
[1]University of Miami Miller School of Medicine, Miami, FL, [2]Florida Atlantic University, Boca Raton, FL

Chemotherapy-Induced Alopecia (CIA) is a visibly distressing consequence of chemotherapy. Although it does not pose a life-threatening risk, CIA can significantly affect patient's self-esteem. Regarding the mechanism of action, stress induced by chemotherapy treatment can lead to the shedding of hair follicles, generating varying degrees of hair loss. In recent years, scalp cooling has emerged as a beneficial preventative agent for CIA due to its ability to induce vasoconstriction in the scalp and reduce follicular metabolic rate. To assess the efficacy of scalp cooling in preventing CIA, we conducted a review of randomized control trials published on PubMed in the last 10 years. Five studies met our inclusion criteria, in which three examined hair preservation and two evaluated treatment duration efficacy. All studies investigating hair preservation with scalp cooling reported highly significant results from the cooling device when compared to a placebo (56.3% vs. 0%, 39.3% vs. 0%, and 50.5% vs. 0%, respectively). Additionally, one of these studies also assessed hair regrowth, revealing higher rates in the scalp cooling group compared to the control at 6 weeks (89% vs. 12%) and at 12 weeks (100% vs. 59%). Both studies evaluating the effectiveness of scalp cooling based on treatment duration concluded that 20 minutes of cooling was as effective as 45 and 90 minutes in preventing CIA. Collectively, these findings add to the mounting evidence endorsing scalp cooling as a powerful management strategy in averting CIA.

#6304 Seizure self-report and monitoring: Agreement between patient and clinician report and implications for care in patients with IDH-mutant and IDH-wild type gliomas.

H. Miller[1], E. Grajkowska[1], A. Acquaye-Mallory[1], A. Choi[1], J. Reyes[1], M. R. Gilbert[1], E. K. Avila[2], T. S. Armstrong[1], E. Vera[1];
[1]National Cancer Institute, Bethesda, MD, [2]Memorial Sloan Kettering Cancer Center, New York, NY

Primary brain tumor (PBT) patients commonly experience seizures, which can be measured and monitored by a variety of tools. Here, we explore the concordance between 2 tools and their use in reporting seizures over time among PBT patients enrolled in a natural history study (NCT02851706, PI: T. Armstrong). Patients complete the M.D. Anderson Symptom Inventory - Brain Tumor (MDASI-BT), which measures symptom severity (including seizure) within the last 24 hours from 0-10; and, as part of the same visit, pairs of clinicians and patients complete the Seizure Control Composite Index (RANO-SCCI), which includes the questions 'Have you ever had a seizure' (RANO-SCCIQ1) and 'Have you had a seizure since your last clinic visit' (RANO-SCCIQ2). Responses to each measure are reported in aggregate and by IDH status. Participants included 89 patients with gliomas who were primarily white (84%) males (62%) with a median age of 48 years (range: 27-78) and KPS ≥ 90 (85%). Based on patient reports, 65% endorsed ever having a seizure (RANO-SCCIQ1), 17% had a recent seizure (RANO-SCCIQ2), and 12% had a seizure within the last 24 hours (MDASI-BT). For the RANO-SCCIQ1 data, patients and clinicians generally agreed except for 6 pairs (7%) where clinicians indicated a seizure but patients did not. Of the 59 who reported recent seizures (RANO-SCCIQ2), two pairs (3%) disagreed, with patients indicating a recent seizure but clinicians not endorsing a seizure had occurred. Good overall agreement (86%) was observed between the RANO-SCCIQ2 and MDASI-BT for both clinician and patient responses, with 3 and 2 paired disagreements respectively, in which seizures were indicated in the last 24 hours but not recorded as a recent seizure on the (RANO-SCCIQ2). Comparing clinician report of seizures in those with IDH-mutated (n=39) to IDH-wildtype (n=15) tumors, 85% (33/39) versus 47% (7/15) reported ever having a seizure and 7 of 33 (21%) with IDH-mutant and 1 of 7 (14%) with IDH-wild type (IDH-WT) tumors respectively reported a seizure since the last visit. Disparities in recognition of seizures between patient and clinician highlights a need for patient education to increase awareness of events and recognition of ongoing risk. Although those with IDH-mutated tumors are at higher risk of having seizures, nearly half of those with IDH-WT reported ever having seizures, underscoring the need for all patients to be educated on recognizing and assessing seizure symptoms.

#6305 Evaluating clinical and sociodemographic risk for symptom-related functional interference in the primary brain tumor population.

B. A. McIver, T. S. Davis, K. Reinhart, E. Vera, A. Choi, T. Kunst, M. Johnson, E. Grajkowska, H. Miller, T. S. Armstrong, M. L. Wright;
National Cancer Inst. - Bethesda Campus, Bethesda, MD

Purpose: Primary brain tumors have a high propensity for causing physical and activity-related disabilities due to the location within the brain and use of targeted treatments resulting in significant symptom burden. In other cancers, physical function impacts mood, quality of life, and even mortality. This exploratory study aims to identify factors associated with activity-related functional interference in a cross-sectional cohort of 584 primary brain tumor patients enrolled in a natural history study (NCT03251989, PI: T.S. Armstrong).

Methods: Sociodemographic (age, race, ethnicity, income, education, employment, body mass index [BMI]) and disease-related clinical data were collected at study entry. Activity-related interference (work, walking, and general activity) and health status were reported via the MD Anderson Symptom Inventory-Brain Tumor. Activity-related interference means ≥ 2 were categorized as moderate/severe. Logistic regression assessed univariate associations with moderate/severe interference, with sig. <0.05.

Results: This sample had a median age of 49 years (range 18-85), and was mostly male (57%), with a high-grade tumor (grade 3/4) (74%), glioblastoma (39%), on active treatment (21%) and prior tumor recurrence (49%). Risk factors for moderate/severe activity-related interference included: ≥ 2 surgeries (OR = 1.55, 95% CI [1.11, 2.18], $P = 0.011$), ≥ 2 radiation treatments (OR = 2.87, 95% CI [1.59, 5.17], $P < 0.001$), currently on active treatment (OR = 1.47, 95% CI [0.97, 2.22], $P = 0.066$), disease progression (OR = 1.87, 95% CI [1.24, 2.84], $P = 0.003$), prior recurrence (OR = 1.57, 95% CI [1.13, 2.19], $P = 0.007$), and poor KPS (OR = 3.61, 95% CI [2.55, 5.12], $P < 0.001$), but not tumor grade (OR = 1.05, 95% CI [0.72, 1.54], $P = 0.790$). Sociodemographic risk factors for moderate/severe activity-related interference included: less than a high school education (OR = 2.03, 95% CI [1.18, 3.51], $P = 0.011$), on disability (OR = 3.20, 95% CI [1.79, 5.71], $P < 0.001$), or unemployed (OR = 3.81, 95% CI [2.34, 6.19], $P < 0.001$), an annual income less than $49,999 (OR = 2.62, 95% CI [1.28, 5.35], $P = 0.008$), or childhood in a rural area (OR = 1.87, 95% CI [1.24, 2.84], $P = 0.003$), but not BMI, smoking status, or past physical activity in the 10 years prior to report.

Conclusion: As expected, activity-related interference is associated with disease and treatment associated clinical characteristics, with significant risk derived from sociodemographic factors such as education, childhood environment, employment, and household income. Future studies should further explore these associations longitudinally to identify individuals at the highest risk of activity-related interference due to their brain tumor as well as interventions designed for those who may be socioeconomically disadvantaged.

CLINICAL RESEARCH: Adoptive Cellular Therapy 2
Poster Session

#6311 From bench to bedside: GMP manufacturing and testing of an LGR5-targeting CAR-T against colorectal cancer.

V. Bandara[1], B. Gundsambuu[1], S. Napoli[1], J. Foeng[1], D. McPeake[1], T. Tylis[1], E. Thompson[2], S. Mills[3], A. Cowin[3], C. Bonder[2], T. Sadlon[1], S. McColl[4], S. Barry[1];

[1]University of Adelaide, North Adelaide, Australia, [2]University of South Australia, Adelaide, Australia, [3]University of South Australia, Mawson Lakes, Australia, [4]Carina Biotech, Mawson Lakes, Australia

Colorectal cancer is the third most diagnosed cancer worldwide, and is responsible for the second largest number of cancer related deaths, warranting the need for new treatments. The successful use of chimeric antigen receptor T (CAR-T) cells against B-cell malignancies has inspired the search for CAR-T cell therapies against solid tumours such as colorectal cancer. Cancer stem cells (CSC) are a small population of cells within a tumour with the capacity to self-renew, differentiate, and initiate new tumours. CSC are resistant to chemotherapy and radiotherapy and are enriched in residual disease. Targeting CSC is a strategy to reduce the tumours' ability to generate new cells. Leucine-rich G protein-coupled receptor 5 (LGR5) is a marker of CSC and LGR5^{+} cancer cells are implicated in tumour progression and metastasis in colorectal cancer. We designed and tested a chimeric antigen receptor (CAR) targeting the extracellular domain of LGR5. LGR5-targeting CAR-T cells showed significant antigen-specific cytotoxicity and IFNγ release against colorectal cancer (CRC) cell lines *in vitro,* and *in vivo* efficacy in a CRC xenograft mouse model. We confirmed the specificity and safety of the LGR5 targeting CAR-T cells by testing against normal human tissues. A GMP ready protocol for clinical scale manufacture of LGR5-targeting CAR-T cells have been developed using CD3+ T-cells from healthy donors. We have successfully tested this protocol using CRC patient-derived CD3+ T-cells and were able to generate clinically relevant cell numbers (80-fold expansion) with high CAR expression. Cells manufactured using this GMP protocol expressed markers of self-renewing naïve-like and central memory phenotype and showed very low percentage of cells that were triple-positive for PD1, TIM3 and LAG3. This protocol has been successfully tested and validated in a GMP manufacturing facility for the production of LGR5 targeting CAR-T cells, in preparation for an FDA approved first in man clinical trial against metastatic colorectal cancer, starting in 2023 (NCT05759728).

#6312 Orthogonal IL-2/IL-2Rβ signaling selectively enhances and sustains a synthetic effector state via a novel mechanism and outperforms constitutive armoring approaches.

Ethan Jung, Helena Silva, Marie Semana, Ivan Cheng, Somya Singh, Michele Bauer, Mohammed Ali, Henry Rosas, Ryan Burgess, George Zeng, Woei Chang, Navneet Ratti, Deepti Rokkam, Patrick J. Lupardus, Martin Oft, **Paul-Joseph Aspuria**

Synthekine, Menlo Park, CA

CAR T cell therapy has demonstrated remarkable clinical efficacy against blood malignancies. However, prominent barriers, including limited proliferation, CAR T cell persistence, and poor T cell effector function, hinder its potential, especially in solid tumors. Various engineering approaches attempt to address these issues by armoring CAR T cells with factors that enhance the function and maintenance of T cells in the anti-tumor response. We previously described a human orthogonal IL-2/IL-2R system consisting of a pegylated, IL-2 mutein (STK- 009) that does not significantly activate the wild type receptor and a mutated IL-2 Receptor Beta (oRβ) that does not significantly respond to its native ligand, wild type IL-2. This system provides a “private IL-2 signal” in engineered oRβ-expressing cells while avoiding signaling in bystander immune cells, reducing toxicities. We have demonstrated STK-009/oRβ’s ability to selectively expand oRβ-expressing CAR T cells (SYNCAR T cells) targeting heme (SYNCAR-001, CD19) and solid tumor (SYNCAR-002, GPC3) targets at will. Importantly, the system enhanced anti-tumor control driving deep and durable responses in both bulky lymphoma and hepatocellular carcinoma (HCC) tumor models. Additionally, in a non-human primate model, STK-009 did not potentiate wild type T or NK cells and exhibited no evidence of toxicity. Currently, the combination of STK-009 + SYNCAR-001 is undergoing Phase I clinical trials (NCT05665062).

Here, we conducted a direct comparison of several armoring approaches including the SYNCAR platform, the overexpression of c-Jun, an IL-15/IL-15Rα fusion, and IL-18 in human CAR T cells targeting GPC3. To assess their effects in overcoming CAR T cell dysfunction, cells were subjected to continuous antigen exposure *in vitro*. STK-009 treated SYNCAR-002 T cells displayed an enhanced proliferative capacity, sustained effector cytokine secretion, and an increased activation state when compared to other armoring technologies and PBS treatment. In a HCC tumor model, treatment with STK-009/SYNCAR-002 demonstrated superior tumor control with minimal toxicities. Interestingly, IL-18 overexpression also controlled tumors, but was accompanied by uncontrolled CAR T cell expansion and toxicity resembling severe GVHD.

scRNAseq analyses revealed STK-009-treated SYNCAR-002 T cells simultaneously activated effector genes and repressed an exhaustion gene signature. This analysis also identified a novel mechanism by which STK-009/oRβ signaling induces a superior synthetic effector state via transcriptional repression of the stress response/proteosome.

These findings support the advantages of an orthogonal platform that selectively drives and sustains potent T cell effector function without safety concerns associated with constitutively expressed armored approaches.

#6313 Enhancing CAR T cell-based immunotherapy outcomes in PDAC: Evaluating iC9.B7-H3 CAR T cells in adjuvant, neoadjuvant, and monotherapy settings.

S. Arya[1], S. Sanatkar[1], M. Ventin[1], G. Cattaneo[1], C. Martin[1], G. Lionetto[1], J. Jia[1], F. Chen[1], D. Ting[1], X. Wang[1], S. Ryeom[2], C. Ferrone[3], S. Ferrone[1];
[1]Massachusetts General Hospital, Boston, MA, [2]Columbia University Irving Medical Center, New York, NY, [3]Cedars-Sinai Medical Center, Los Angeles, CA

Background: Pancreatic ductal adenocarcinoma (PDAC) is among the most aggressive and lethal cancers worldwide. Despite negative margin resections and subsequent systemic therapy, PDAC often recurs. Additionally, most patients present with locally advanced and unresectable tumors at the time of diagnosis. Cancer-associated fibroblasts (CAFs) contribute to the highly desmoplastic tumor microenvironment (TME) and form a biophysical barrier, limiting immune cell infiltration. Moreover, CAF-secreted factors suppress the anti-tumor activity of T cells and shift cancer cells toward invasive proliferative and mesenchymal phenotypes. Therefore, targeting CAFs can enhance T-cell infiltration and improve the efficacy of T-cell based immunotherapeutic strategies. B7-H3 is an immune checkpoint molecule highly expressed on PDAC cells and CAFs. In this study, we investigate the use of Chimeric Antigen Receptor (CAR) T cells targeting B7-H3 to eliminate metastatic PDAC in a preclinical mouse model in three different settings: I. Adjuvant II. Neoadjuvant III. CAR T cell monotherapy. Our CART-B7-H3 construct includes an inducible caspase 9 (iC9) suicide gene, which allows for the controlled elimination of the CAR T cells in the event of overwhelming cytokine release syndrome.

Methods: To validate the therapeutic potential of iC9.B7-H3 CAR T cells *in vivo*, NSG mice were orthotopically engrafted with $1x10^5$ patient-derived PDAC6 cells and $9x10^5$ hCAF1 cells at a ratio of 1:9, reflecting a clinically relevant model. In the adjuvant group, mice underwent surgical resection of the primary tumor (distal pancreatectomy and splenectomy) after 25 days. On days 30 and 60, they received systemic iC9.B7-H3 CAR T cell treatment ($5x10^6$). In the neoadjuvant group, mice were systemically treated with iC9.B7-H3 CAR T cells on day 19 and underwent surgical resection of the primary tumor on day 25, following another systemic CAR T cell dose on day 60. In the CAR T monotherapy group, mice received systemic iC9.B7-H3 CAR T cells on days 19 and 60.

Results: *In vivo*, iC9.B7-H3 CAR T cells in the neoadjuvant group effectively eradicated both local and distant PDAC metastases for the length of the experiment (180 days) and significantly increased the survival ($P=0.0018$), indicating long-term efficacy in the treatment of PDAC metastases with no adverse side effects. In the adjuvant and CAR T monotherapy groups, iC9.B7-H3 CAR T cells effectively control tumor growth, eliminate metastases, and significantly increase survival ($P<0.0001$ and $P=0.0007$, respectively).

Conclusion: These data suggest that the neoadjuvant application of iC9.B7-H3 CAR T cells may demonstrate persistent efficacy in eradicating both local and distant PDAC metastases. iC9.B7-H3 CAR T cells adjuvantly and as monotherapy achieved significant tumor control.

#6314 Potent inhibition of tumor relapse after anti-HER2 affibody tagged with cotinine (switch) plus anti-cotinine switchable CAR T cell therapy by repeated re-injection of the switch.

K. Kim[1], S. Kim[1], E.-H. Lee[1], S.-Y. Lim[1], S. Kim[1], E.-Y. Kim[1], H.-J. Lee[1], S. Kim[1], M. Yoon[1], Y.-H. Lee[1], I.-S. Hwang[1], Y. Lee[1], J.-H. Kim[1], J.-S. Lee[1], **J. Chung**[2];

[1]AbClon, Inc., Seoul, Korea, Republic of, [2]Cancer Research Institute, Seoul National University College of Medicine, Seoul, Korea, Republic of

Chimeric antigen receptor (CAR) T cells targeting CD19 or the B cell maturation antigen (BCMA) have demonstrated impressive initial clinical responses. However, on follow-up assessment, a notable fraction of the patients with significant initial clinical response eventually experienced relapse. CAR T cell therapies targeting solid tumors have shown an even lower rate of clinical response as well as shorter remission periods. A prior study has shown that re-injection of the anti-HER2 CAR T cells was effective in a rhabdomyosarcoma relapse patient (Cancer Res 79, LB147 (2019)), but the repeated production of CAR T cells is costly, thus raising questions about its feasibility in practice. Previously, we developed a cotinine-based CAR T cell system (zCART) comprised of a tumor antigen-specific affibody conjugated with cotinine and an anti-cotinine scFv CAR, and demonstrated the anti-tumor activity of an anti-HER2 zCART treatment in both *in vitro* and *in vivo* settings. In this study, we tested the efficacy of anti-HER2 zCART treatment *in vivo* using an intraperitoneal (IP) tumor model with a single infusion of zCART cells. The anti-HER2 switch was injected daily for 7 days. When the HER2 positive tumor relapsed, the mice were re-treated with the same dose of anti-HER2 switch treatment for an additional 7 days. We observed that re-injection of only the anti-HER2 switch and not combined with zCART cells effectively and potently inhibited relapse of HER2 positive tumors. Furthermore, the efficacy of the anti-HER2 switch re-injection treatment was maintained in one additional relapse. In summary, the zCART system has potential to treat cancer relapse following CAR T cell therapy without the need for an additional production round of CAR T cells.

#6316 Exploring the resistant mechanism of CAR T cell therapy targeting CLDN18.2 by single-cell sequencing.

Mingyang Ma[1], Changsong Qi[1], Chang Liu[1], Lei Jiang[1], Min Tao[1], Dan Liu[1], Panpan Zhang[1], Zhi Peng[1], Xiaotian Zhang[1], Jifang Gong[1], Yang Chen[1], Chunhong Zheng[2], Mi Deng[2], Lin Shen[1]

[1]Peking University Cancer Hospital, Bei Jing, China,[2]Peking University International Cancer Institute, Bei Jing, China

Chimeric antigen receptor T cell (CAR T) therapy has achieved remarkable success in treating hematological malignancies but still faces overwhelming challenges for solid tumors. Our previous clinical trial (NCT03874897) has demonstrated promising results in patients with advanced CLDN18.2-positive gastric after receiving CT041 CAR T cell product. Though the disease control rate (DCR) reached 73% in 37 patients, it was unclear who would benefit from this therapy. Here in this study, we dynamically collected peripheral blood and ascites samples from 5 patients in this clinical trial before and at 3 and 7 days after the infusion of CT041, respectively. Utilizing single-cell sequencing analysis, we found that patients with a high proportion of naive-like T cells were more likely to benefit from CT041. Furthermore, we discovered that the high expression of CLDN18 in the ascites epithelial cells was correlated with a favorable prognosis, while ascites epithelial cells showing high MYC expression and the strong interaction between tumor cells and T cells were identified as adverse prognostic factors for CT041 treatment. These findings may provide theoretical evidence for subsequent screening of CAR T cell therapy benefitable population and improving the efficacy of CAR T cell therapy.

#6317 Developing a fully human heavy chain only Claudin-18.2-specific CAR-T cell therapy.

Jason Noon, Yao Lu, Itishree Kaushik, Oyku Ay, Adam Luk, Bradley Delaney, David DeMeritt, **Musheng Bao**

NONA BIOSCIENCES, Natick, MA

Camelid VHH/nanobodies have been widely applied as the antigen binding domain of CAR-T cell therapies due to a smaller size and simpler structure compared to the traditionally used single chain variable fragment (scFv). Additionally, camelid VHH/nanobodies provide greater flexibility for dual-targeting CAR-T cell therapies. However, camelid VHH/nanobodies require laborious and costly humanization and still have a significant risk of inducing anti-drug antibodies when administered to patients. Transgenic mice exclusively harboring the most stable human VH genes (HCAb Harbour Mice®) provide one of the best solutions to get fully human heavy chain only antibodies (HCAbs). To efficiently identify lead HCAb VHs for Claudin-18.2-targeting CAR-T cells, we developed an innovative direct CAR-function based HCAb library screening platform. From Claudin-18.2-immunized HCAb Harbour Mice®, we constructed a total VH library in a CAR lentiviral vector that we developed in-house. After producing the lentiviral particle library, we transduced a Jurkat-NFAT-GFP reporter cell line and stimulated with Claudin-18.2 overexpression cell line. Subsequently, GFP positive reporter cells, representing Claudin-18.2-specific CARs, were isolated through FACS sorting, expanded, and further stimulated with Claudin-18.2-positive NUGC-4 tumor cells. Then, Next Generation Sequencing and abundance ranking was performed on VHs recovered from sorted CAR-reporter cells. Lead VH candidates were cloned into the CAR-P2A-RFP lentiviral vector, and many of these VH clones exhibited superior Claudin-18.2-specific functionality compared to a clinically-validated reference scFv in both reporter and primary CAR-T cells. Many lead VH clones also exhibited excellent developability as soluble HCAbs. These data suggest that this innovative method of combining our fully human HCAb and CAR-based library screening platform will provide new avenues for CAR-T cell therapies.

#6318 Development of an anti-PD-L1 CAR T therapeutic treating advanced gastric cancer with enhanced efficacy and lower off-tumor activities.

M. Baek[1], J.-I. Yu[1], E.-J. Choi[1], Y. Lim[1], J. Yang[1], S.-R. Choi[1], Y. Choi[2], M. Kim[1], J. H. Rhee[1], J.-J. Lee[1];

[1]Vaxcell-Bio Therapeutics, Hwasun-eup, Jeollanamdo, Korea, Republic of, [2]Chonnam National University Medical School, Hwasun-eup, Jeollanamdo, Korea, Republic of

Purpose: Driven by a relentless unmet need with unsatisfied cancer therapy, we aimed to develop chimeric antigen receptor T-cell (CAR-T) therapy for targeting advanced gastric cancer (AGC) expressing PD-L1. We constructed a 2nd generation CAR lentiviral vector expressing a unique anti-PD-L1 scFv with moderate affinity (VaxCAR001) in order to compare scFvs derived from Avelumab or Atezolizumab. This project focused on the efficacy and safety of PD-L1 CAR-Ts, which are affected by their binding affinity and dissociation with the target protein, PD-L1 during the treatment period.

Methods and Results: The findings of this study revealed significant differences among PD-L1-targeting CAR-T cells with different affinities and dissociations. VaxCAR001 cells, showing intermediate affinity, demonstrated a higher CD8 ratio (up to 78% compared to 58% in Avelumab-derived and 45% in Atezolizumab-derived CAR-T), reduced expression of inhibitory markers including Tim-3, LAG-3, and TIGIT, (8%, 39% and 13% in VaxCAR001 vs 35%, 55% and 42 % in Avelumab, 19%, 51% and 34% in Atezolizumab scFv-derived CAR-T, respectively) and more sustained cytotoxicity. Notably, it maintained strong cytotoxicity even one month after production, while the Avelumab or Atezolizumab ScFv-derived CAR-T cells did not. In multicellular spheroid 3D co-culture with CAR T cells, VaxCAR001 exhibited superior infiltration into the core of spheroid and induced higher CAR-T-mediated killing for 3D tumor spheroids as indicated by LDH assay (68%, 800% increased than Avelumab or Atezolizumab scFv-derived CAR-T). Moreover, in an MSI-high AGC mouse model, treatment with VaxCAR001 cells resulted in a significant reduction in tumor size and prolonged survival until the end of the study period. On the other hand, treatment with the Avelumab or Atezolizumab scFv-derived CAR-T cells led to high mortality, with most mice succumbing within three weeks after CAR-T cell injection, suggesting an on-target off-tumor effect.

Conclusion: This study demonstrates that VaxCAR001 cells bearing intermediate affinity and high dissociation rate for target PD-L1 showed the superior killing of PD-L expressing tumor cells in vitro and in vivo and manifested better safety profiles, as compared to CAR-T cells bearing scFv derived from commercial anti-PD-L1 targeting monoclonal antibodies such as avelumab and atezolizumab. VaxCAR001 revealed extended cytotoxicity, enhanced infiltration into tumor spheroids, and greater tumor size reduction in *in vivo* models. Importantly, it also demonstrated superior safety profiles, as evidenced by reduced expression of inhibitory markers and fewer off-tumor adverse effects. These findings would accelerate the clinical stage developments as an effective and safer treatment strategy against AGC.

#6319 Characterization of AB-1015 logic-gated CAR induction (ON kinetics), receptor turnover (OFF kinetics), and logic gate sensitivity to ALPG/P and MSLN.

X. Tang, M. Chew, R. Sudhakar, H. Yun, D. Sakamoto, V. Sail, A. Fearon, J. Williams, J. Feng, S. Santoro;
Arsenal Biosciences, South San Francisco, CA

CAR T cell activity in solid tumors is limited, in part, by off-tumor toxicity. To address this obstacle, AB-1015 contains an “AND” logic gate, consisting of a priming receptor (PrimeR) and an inducible chimeric antigen receptor (CAR) that is upregulated by PrimeR activation. The AB-1015 logic gate targets ALPG/P and MSLN, which are coexpressed in ovarian tumors but not normal tissues. AB-1015 CAR induction within the tumor is expected to be a dynamic process influenced by multiple factors, including antigen density, target cell abundance, as well as tumor microenvironmental factors. To characterize CAR induction and receptor turnover, we developed an in vitro assay with plate-bound ALPG to induce CAR. CAR induction occurred quickly in response to ALPG priming, with most ICT cells expressing CAR within 24 hrs, and plateaued by 72 hrs. Once removed from ALPG, CAR expression returned to baseline within 96 hrs. Similar to conventional CAR T cells, the presence of the cytolytic target antigen (MSLN) was expected to increase the rate of CAR turnover on AB-1015. To assess this, we measured the CAR functional half-life of AB-1015 cells once removed from ALPG priming. The cytotoxic activity of AB-1015 cells rapidly decreased in the absence of ALPG, reaching baseline within 24 hrs. Of note, our in vitro assay did not result in 100% CAR induction from all PrimeR+ AB-1015 cells. To understand whether this reflected biology versus a limitation of our in vitro assay, we conducted a CAR induction, sorted the CAR- cells, then performed a second induction. ICT cells that did not express CAR after the first induction were shown to be able to induce CAR during the second induction assay, thereby demonstrating that all PrimeR+ ICT cells have the potential to induce CAR. To assess the sensitivity of AB-1015 for low density ALPG/P and MSLN, isogenic cell lines were engineered to express each antigen at variable levels. In co-culture, AB-1015 was able to prime and kill targets expressing ALPG and MSLN at or below the limit of detection using immunohistochemistry. In light of these observations, the specificity of AB-1015 was verified using a dual flank in vivo model where one tumor expressed both ALPG and MSLN, and the contralateral tumor expressed MSLN alone. While robust anti-tumor activity was observed against the ALPG+/MSLN+ tumor, no activity was detected against the MSLN+ tumor. In summary, AB-1015 CAR induction and receptor turnover kinetics is a dynamic process. A reductionist in vitro model system was developed, enabling analysis of CAR induction and receptor turnover. Importantly, we demonstrated that all PrimeR+ ICT cells have the potential to induce CAR. Finally, the in vivo specificity of AB-1015 for ALPG+/MSLN+ tumors was established using a dual flank specificity model. Together, these data support the continued development of AB-1015 in a phase I clinical trial (NCT05617755).

#6320 CAR-T cells targeting LGR5: An effective treatment for chemotherapy resistant ovarian cancer.

W. Wang[1], V. Bandara[2], N. A. Lokman[1], Z. K. Price[1], T. M. Noye[1], S. Napoli[2], B. Gundsambuu[2], M. K. Oehler[1], S. C. Barry[2], **C. Ricciardelli**[1];
[1]University of Adelaide, Adelaide, Australia, [2]University of Adelaide, North Adelaide, Australia

Ovarian cancer is the second leading cause of cancer-related mortality among gynaecological cancers in the Western world. CAR-T cell therapy is an adoptive immunotherapy used to treat some blood cancers. This study has investigated whether leucine-rich repeat-containing G protein-coupled receptor 5 (LGR5) is a suitable target for CAR-T cell therapy for ovarian cancer. We assessed the cytotoxic effects of LGR5-targeting CAR-T cells on a range of ovarian cancer cell lines and primary serous ovarian cancer cells derived from patient ascites (at diagnosis and following relapse with chemotherapy resistant disease) in monolayer culture, 3D spheroid assays and patient-derived explant assays. OVCAR3 and a chemoresistant patient-derived xenograft (PDX) models have been used to assess whether LGR5-targeting CAR-T cells can inhibit growth and metastasis *in vivo*. We found that LGR5 is highly expressed in high-grade serous ovarian carcinoma (HGSOC) cancer cell lines and LGR5 expression was increased in chemotherapy resistant primary ovarian cancer cells. We demonstrated that LGR5-targeting CAR-T cells were cytotoxic and significantly inhibited the survival of ovarian cancer cell lines and chemotherapy-resistant primary ovarian cancer cells with high LGR5 expression levels in both monolayer culture and 3D spheroids compared to un-transduced CD3+ T cells. In patient-derived explant assays, we observed increased apoptosis in HGSOC tissues expressing high LGR5 following treatment with LGR5-targeting CAR-T cells. *In vivo,* LGR5-targeting CAR-T cell treatment decreased the tumour burden in mice with OVCAR3 xenografts and a chemotherapy-resistant PDX model with high LGR5 expression, compared to CD3+ T cells. In summary, LGR5-targeting CAR-T cells have great potential to be developed as a novel immunotherapy for ovarian cancer.

#6321 Developing a lenalidomide-inducible safety switch for CAR T cell therapy.

D. Sarkar[1], W. Lin[1], J. Y. Kim[1], N. H. Knudsen[2], I. C. Lane[1], T. Kienka[1], M. C. Kann[1], A. A. Bouffard[1], A. Cheng[2], M. V. Maus[1], R. T. Manguso[2], M. Jan[1]; [1]Massachusetts General Hospital, Boston, MA, [2]Broad Institute of MIT and Harvard, Boston, MA

While CAR T cell therapy is a medical breakthrough against various hematological malignancies, yet treatment failures often occur at least in part due to excessive engineered T cell activity leading to severe toxicities. To combat this, strategies pairing CAR T cells with safety systems, for example, suicide switches engineered to induce cell death are being actively pursued. However, existing designs have limited performance characteristics and generally use unapproved small molecule controllers or non-human sequences. To overcome these issues, we have developed a novel suicide switch leveraging the well-tolerated, FDA-approved anti-cancer drug lenalidomide, as a controller of the stability of fusion proteins tagged with a “degron” sequence. Specifically, we engineered a stoichiometric pair of transgenes using the apoptotic DNase pair, caspase activating DNase (CAD) and its degron tagged inhibitor (ICAD-degron). We hypothesized that the overexpressed ICAD-degron could restrain CAD, until lenalidomide treatment degrades ICAD to unleash CAD for apoptosis. We found that our system was stably overexpressed and rapidly induced cell death even at sub-nanomolar concentrations of lenalidomide. A comparison of our design with the frontline safety switch, inducible Caspase 9 in primary human T cells revealed that the lenalidomide-induced suicide switch enabled more complete depletion of engineered cells. We tested the effects of our suicide switch on CAR T cell function and found comparable proliferation and tumor cell cytolysis with fast depletion upon lenalidomide addition. In vivo, lenalidomide suicide switch CAR T cells exhibited similar anti-tumor function as control CAR T cells and were rapidly depleted after drug treatment. In summary, utilizing all human sequences and a clinically approved drug controller, we developed a suicide switch that is well tolerated and can rapidly induce cell death even at sub-therapeutic concentrations of lenalidomide. More broadly, chemogenetic regulation of stoichiometric protein pairs is a generalizable strategy for post-translational control of highly active transgenic elements.

#6322 CCTx-001 CAR T-cells targeting the AML specific antigen IL-1RAP show robust pre-clinical anti-tumor efficacy.

E. De Dreuzy, S. Reda El Sayed, D. Genin, C. Primus, L. Bouquet, A. Collette, O. Favre-Bulle, E. Rutjens, J. Hasskarl, K. Pavletic, M. Deschamps, C. Ferrand, R. C. Sainson;
Advesya, Besancon, France

Despite significant advancements in acute myeloid leukemia (AML) treatment, patients with relapsed/refractory (r/r) AML have limited therapeutic options. Novel approaches are urgently needed. CAR T-cell therapy has shown remarkable success in hematological malignancies. However, its application in AML has been hampered by the absence of highly AML-specific antigens, making current CAR T-cell AML therapies under development poorly tolerated and effective. This pre-clinical study introduces a novel CAR T-cell therapy, CCTx-001, specifically designed to target IL-1RAP, a 78-kDa transmembrane glycoprotein. IL-1RAP, is highly expressed on AML cells but not on healthy hematopoietic stem and progenitor cells (CD34+ HSPC). Additionally, transcriptomic analyses reveal a correlation between high IL-1RAP expression and poor prognosis in AML patients. IL-1RAP's predominant presence on myeloid leukemia cells, coupled with their dependence to IL-1RAP-related pathways for their survival, presents a promising avenue for CAR T-cell therapy without the risk of treatment-induced antigen loss. CCTx-001, an autologous CAR T-cell therapy, was developed to target IL-1RAP on AML cells. It comprises CD8+ and CD4+ T-cells transduced with a highly specific anti-IL-1RAP Single-Chain Variable Fragment (scFv), an IgG1 hinge region, CD28, 4-1BB co-stimulatory domains, and a CD3ζ activation domain. In vitro experiments confirmed CCTx-001's efficacy in killing AML cell lines and primary AML cells of varying IL-1RAP expression levels, also demonstrating cytotoxicity and cytokine release that was dependent on the (E:T) ratio and target expression. Furthermore, in vivo studies using immunocompromised NCG mice confirmed CCTx-001's ability to target IL-1RAP and inhibit the growth of IL-1RAP-positive human AML tumor xenografts, leading to increased survival time. Biodistribution analyses confirmed the successful adoptive transfer, expansion and persistence of CCTx-001 CAR T-cells in vivo, only when injected into IL-1RAP-expressing tumor-bearing mice, which correlated with reduced levels of circulating AML cells. The promising preclinical data presented herein warrant the evaluation of CCTx-001 CAR T-cell therapy in clinical trials for r/r AML patients. CCTx-001 CAR T-cell therapy offers a potential breakthrough in addressing the unmet medical needs of AML patients with resistant or refractory disease.

#6323 Preclinical evaluation of CB-012, an allogeneic anti-CLL-1 CAR-T cell therapy, that exhibits specific and potent cytotoxicity in acute myeloid leukemia (AML) xenograft models.

B. Francica, E. Garner, S. Namburi, C. Colgan, T. Fowler, D. Mutha, A. Aviles, M. Stanaway, R. Guo, Z. An, E. Kelly, E. Degagne, G. Kwong, L. Edwards, E. Jakes, M. Shaw, B. Schilling, J. Huynh, R. Luu, M. Sidorov, R. Mousali, M. Otsmaa, P. Lauer, J. Skoble, S. Kanner;
Caribou Biosciences, Berkeley, CA

Background: CLL-1 is a compelling therapeutic target for AML as it is highly expressed on AML tumor cells and leukemic stem cells but is not expressed on hematopoietic stem cells. CB-012 was engineered with a next-generation Cas12a CRISPR hybrid RNA-DNA (chRDNA) genome-editing technology and leverages both checkpoint disruption and immune cloaking armoring strategies to potentially improve antitumor activity. The CB-012 anti-CLL-1 CAR was developed with a fully human scFv and the CD28 costimulatory domain and is currently in development for the treatment of relapsed or refractory AML (r/r AML). Here we describe preclinical studies that supported the CB-012 IND clearance by the FDA in October 2023.

Methods: Cas12a chRDNA guides were implemented to generate five genome edits in the manufacture of CB-012. A multiplex genome-editing strategy was designed to enhance the antitumor activity of CB-012 through prevention of GvHD, PD-1 checkpoint disruption, and suppression of allograft rejection. *In vitro* and *in vivo* studies evaluated the specificity of antigen binding, antigen-dependent activity, and toxicologic potential.

Results: CB-012 demonstrated potent antigen-dependent expansion and cytotoxic activity against CLL-1^{+} human AML cell lines and patient-derived cells in co-cultures. In AML xenograft models, a single dose of CB-012 CAR-T cells resulted in robust tumor control, leading to significant prolongation of survival. CB-012 co-culture with multiple CLL-1-negative cell types representing vital tissues demonstrated that the anti-CLL-1 scFv does not exhibit tissue cross-reactivity. In an unbiased cell surface protein microarray, the anti-CLL-1 scFv demonstrated highly specific interaction with human CLL-1, with no detectable non-specific interactions. CB-012 CAR-T cells exhibited limited tissue infiltration and expansion in treatment naïve, immunocompromised murine models.

Conclusion: CB-012, the first allogeneic anti-CLL-1 CAR-T cell therapy using both checkpoint disruption and immune cloaking armoring, demonstrated specific and potent CLL-1-targeted cytolytic activity *in vitro* and *in vivo*. Specificity of the anti-CLL-1 scFv was demonstrated in an unbiased protein-binding study and no adverse safety signals were observed from CB-012 in murine toxicology models. These preclinical studies supported the IND clearance of CB-012, which is being evaluated in the AMpLify trial, a Phase 1, first-in-human clinical trial for patients with r/r AML (NCT06128044).

#6324 Antagonism-enforced braking system to enhance CAR T cell therapeutic specificity.

T. Kondo[1], F. X. P. Bourassa[2], S. Achar[1], J. DuSold[1], P. Cespedes[3], M. Wahlsten[1], A. Kvalvaag[3], G. Gaud[4], P. Love[4], M. Dustin[3], G. Altan-Bonnet[1], P. Francois[2], N. Taylor[1];

[1]National Cancer Institute, Bethesda, MD, [2]McGill University, Montreal, MD, [3]University of Oxford, Oxford, United Kingdom, [4]Eunice Kennedy Shriver National Institute of Child Health and Human Development, Bethesda, MD

Chimeric Antigen Receptor (CAR) T cell immunotherapy represents a breakthrough in the treatment of hematological malignancies. However, the rarity of cell surface protein targets that are specific to cancerous but not vital healthy tissue has hindered its broad application to solid tumor treatment. While new logic-gated CAR designs have shown reduced toxicity against healthy tissues, the generalizability of such approaches across tumors remains unclear. Here, we harness a universal characteristic of endogenous T cell receptors (TCRs), their ability to discriminate between self and non-self ligands through inhibition of response against self (weak) antigens, to develop a broadly applicable method of enhancing immunotherapeutic precision. We hypothesized that this discriminatory mechanism, known as antagonism, would apply across receptors, allowing for a transfer of specificity from TCRs onto CARs. We therefore systematically mapped out the responses of CAR T cells to joint TCR and CAR stimulations. We first engineered murine T cells with an ovalbumin-specific TCR to express a CAR targeting murine CD19 and discovered that the expression of a strong TCR antigen on $CD19^{\pm}$ leukemia enhanced CAR T killing. Importantly though, the presence of a weak TCR antigen antagonized CAR T responses, assessed by *in vitro* multiplexed dynamic profiling as well as *in vivo* cytotoxicity. We developed a mathematical model based on cross-receptor inhibitory coupling that accurately predicted the extent of TCR/CAR antagonism across a wide range of immunological settings. This model was validated in a $CD19^{\pm}$ B16 mouse melanoma model showing that TCR/CAR antagonism decreased the infiltration of a tumor-reactive T cell cluster, while TCR/CAR agonism enhanced infiltration of this T cell cluster. We then applied our quantitative knowledge of TCR/CAR crosstalk to design an Antagonism-Enforced Braking System (AEBS) for CAR T cell therapy. This was assessed in a model system using a CAR targeting the tyrosine-protein kinase erbB-2 (HER2) together with a hedgehog acyltransferase (HHAT) peptide-specific TCR that binds strongly to mutated tumor neoantigen while retaining weak affinity for the wild-type self-antigen on healthy tissue. We established a humanized *in vivo* model of CAR T function and found that AEBS CAR T cells maintained high anti-tumor activity against a human lung adenocarcinoma (PC9) but notably, their anti-tissue cytotoxicity against human bronchial epithelial cells (BEAS-2B) was minimized. AEBS CAR T cells therefore sharpen the discriminatory power of synthetic anti-tumor lymphocytes. Our work highlights a novel mechanism by which TCRs can enforce CAR T cell specificity, with practical implications for the rational design of future anti-leukemia immunotherapies.

#6325 Lineage tracing defines responding CAR T cells in patients with B cell malignancies.

Frank[1], L. Muffly[1], G. K. Claire[1], S. Bharadwaj[1], S. Dahiya[1], K. A. Kong[1], M. M. Davis[1], S. K. Plevritis[1], E. Sotillo[1], B. Sahaf[1], D. B. Miklos[1], C. L. Mackall[1]; [1]Stanford University, Stanford, CA, [2]University of Miami, Miami, FL, [3]Rutgers University - New Brunswick, New Brunswick, NJ

Autologous T cells engineered to express a chimeric antigen receptor (CAR) have transformed the standard of care for patients with B cell malignancies, but >50% of patients progress following therapy. Here, we sought to understand key T cell intrinsic factors impacting efficacy: CAR T cell expansion, persistence, and homing to the tumor. Using an endogenous T cell receptor (TCR) sequence as a 'barcode', we followed individual T cell clonotypes at the single-cell level from pre-manufacture apheresis and infusion products to tumor-involved lymph nodes and blood at peak and late expansion in 22 adult patients with relapsed or refractory large B cell lymphoma (LBCL) or acute lymphoblastic leukemia (ALL) treated with axicabtagene ciloleucel, an FDA-approved CD19-CAR T cell therapy, or bispecific CD19/CD22-CAR T cells on an investigator-initiated trial (NCT03233854). The resulting CAR T cell atlas comprises matched transcriptome (scRNA-seq) and surface protein expression (CITE-seq) for 846,344 cells from 97 samples, with 251,175 unique TCR clonotypes identified, including 17,479 clonotypes that could be traced across ≥2 timepoints in $CAR^{\pm}$ cells, enabling lineage tracing at scale for the first time. We found that T cells present in apheresis that preferentially expand during manufacturing primarily comprise T central memory (T_{cm}) cells and are enriched for predicted specificity to common viruses, including influenza, but also include a subset of T regulatory (T_{reg}) cells. In infusion products, CAR T conventional (non-T_{reg}) cells with superior abilities to home to the tumor, expand, and persist post-infusion share features of activated T effector memory (T_{em}) phenotype enriched for expression of BATF3 and high TCF4 transcription factor activity. Baseline apheresis and infusion products were enriched for cells classified as T_{regs} in patients with poor response. This observation aligned with our recent work linking post-infusion CAR T_{regs} to progression following CD19-CAR T cell therapy. We therefore performed lineage tracing and methylation analysis of the T_{reg}-specific demethylated region (TSDR) in the *FOXP3* gene and found that post-infusion CAR T_{regs} are primarily derived from pre-existing T_{regs}. Of interest, flow cytometry analysis of baseline blood from a cohort of 53 patients treated with CD19-CAR for LBCL showed that T_{regs} are elevated in baseline blood relative to healthy donors. Removing T_{regs} from healthy donor T cells prior to manufacturing enhanced CAR T cell expansion and anti-tumor activity against JeKo-1 human lymphoma cell line, whereas adding 5% T_{regs} to mimic patient T cells rendered the resulting CAR T cells less active. These analyses pinpoint the identities of apheresis T cells and infusion CAR T cells with properties impacting efficacy, and also identify pre-existing T_{regs} as limiting efficacy of CAR T cell immunotherapies.

#6326 Targeting *PRDM1* to enhance CAR T cell efficacy against diffuse large B cell lymphoma (DLBCL).

S. Wang, L. Xie, X. Chen, A. Cooper, J. Chorazeczewski, J. Kline;
University of Chicago, Chicago, IL

CAR T cell therapy has shown remarkable success in treating patients with relapsed or refractory (r/r) DLBCL, but a majority (>60%) will experience disease progression. A key failure mechanism is the rapid terminal differentiation and exhaustion of CAR T cells, driven by persistent antigen exposure *in vitro* during manufacturing and *in vivo* in the DLBCL environment, which culminates in poor persistence and short-term effector functions. Recent studies have identified the transcriptional repressor PR/SET domain 1 (*PRDM1*) as a key regulator that drives differentiation of T cells toward these unwanted fates. Further, single cell transcriptomic profiling of r/r DLBCL biopsies has revealed *PRDM1* enrichment in a cluster of exhausted-like $CD8^{\pm}$ CAR T cells. These observations indicate that targeting *PRDM1* could prevent or delay terminal differentiation/exhaustion in CAR T cells, thereby enhancing their persistence for lasting anti-tumor activity. Using CRISPR/Cas9 targeting, we have demonstrated that *PRDM1*-deficient CAR T cells exhibit enhanced proliferative capacity, memory characteristics, and resilience against exhaustion upon repeated stimulation. Moreover, genetic ablation of *PRDM1* also promoted the *in vivo* expansion and persistence of CAR T cells, which led to significantly improved survival of lymphoma-bearing mice. Mechanistically, loss of *PRDM1* leads to de-repression of PPARGC1A (PGC1α), a master regulator of mitochondrial biogenesis and antioxidant activity. This confers elevated tolerance to oxidative damage in CAR T cells lacking *PRDM1*, which showed increased capacity to buffer oxidative stress induced by mitochondrial uncouplers and constant stimulation. These findings suggest that *PRDM1* loss may improve CAR T cell fitness through PGC1α upregulation and mitochondrial activation. From a translational perspective, we assessed the potential synergistic effects of PGC1α agonist, bezafibrate, with CAR T cells. Dual therapy with bezafibrate and CAR T cells mediated more robust expansion and anti-tumor immunity of CAR T cells without causing discernible adverse events. Importantly, bezafibrate alone had no direct tumoricidal effects, which indicates that bezafibrate suppressed tumor growth through modulating CAR T cell functions. Moving forward, we will uncover the previously uncharted role of *PRDM1* in orchestrating the mitochondrial and metabolic activity of CAR T cells. Building upon a correlation between *PRDM1* expression and CAR T cell dysfunction, we aim to pioneer the use of *PRDM1* and/or its target genes as novel biomarkers for predicting clinical responses of r/r DLBCL patients to CAR T cell therapy. Our endeavors will shed light on the long-standing conundrum of CAR T cell dysfunction and offer solutions that may be applicable for improving T cell-based therapy against cancer in general.

#6327 Impact of G-CSF on safety and efficacy of CAR T-cell therapy in non-Hodgkin lymphoma.

Lay She Ng[1], Claire I. Yee[2], Radhika Bansal[1], Mohamed A. Kharfan-Dabaja[3], Grzegorz S. Nowakowski[1], Allison C. Rosenthal[2], Javier Munoz[2], Januario Castro[2], Wern Lynn Ng[4], Hemant S. Murthy[3], Yi Lin[1], Matthew R. Buras[2], Madiha Iqbal[3], Yucai Wang[1], Talal Hilal[2]

[1]Mayo Clinic Minnesota, Rochester, MN,[2]Mayo Clinic Arizona, Phoenix, AZ,[3]Mayo Clinic Florida, Jacksonville, FL,[4]UPMC Harrisburg, Harrisburg, PA

Introduction: Chimeric antigen receptor T-cell (CAR-T) therapy is an established treatment modality for the management of refractory and/or relapsed non-Hodgkin lymphoma (NHL). Despite restrictions on granulocyte colony-stimulating factor (G-CSF) use in registration clinical trials due to potential worsening of cytokine release syndrome (CRS), G-CSF is often prescribed for neutrophil recovery post-CAR-T in clinical practice. We conducted a retrospective study to assess the association between G-CSF use and the safety and efficacy of CAR-T.

Methods: Following Institutional Review Board approval, we retrospectively analyzed NHL patients receiving commercial CD19-targeted CAR-T across Mayo Clinic sites (Arizona, Florida, and Minnesota) between October 2017 and May 2023. Demographics, labs, and post CAR-T events were collected. Electronic medical records were reviewed for G-CSF exposure within Day 1 - 100 post-CAR T. Differences by G-CSF status were examined using a Chi-square test and Kruskal Wallis tests. Hazard ratios (HR) and 95% confidence intervals (CI) for overall survival (OS) were calculated using Cox model.

Results: Among 270 CAR-T patients; 106 received G-CSF within 30 days and 164 did not. Median age was 56.9 with G-CSF and 58.3 without G-CSF. Most were male (75.2% G-CSF, 62.6% no G-CSF). Diffuse large B cell lymphoma was the predominant NHL subtype (67.0% G-CSF, 65.2% no G-CSF).

G-CSF within 30 days was not associated with reduced incidence of neutropenic fever (11.7% G-CSF vs 9.9% no G-CSF, p = 0.6593) or documented infection (22.1% vs 18.3%, p = 0.4439). G-CSF correlated with decreased profound neutropenia duration (ANC < 100 µL, 0 vs 2 days, p < 0.0001) and incidence within 30 days (31.7% vs 60.4%, p < 0.0001) as well as incidence of protracted profound neutropenia (> 7 days, 3.8% vs 22.8%, p < 0.0001). G-CSF was associated with a higher incidence of cytopenias between days 30 -100: severe neutropenia (ANC < 500/uL, 28.8% vs 15.2%, p = 0.0075), severe anemia (Hb < 8 g/dL, 21% vs 9.7%, p = 0.0114), and severe thrombocytopenia (Plt < 50 g/L, 35.2% vs 20.9%, p = 0.0099). Logistic regression analysis showed that none of the examined covariates, including prior autologous stem cell transplant, ECOG PS score, and receipt of bridging therapy, were associated with severe neutropenia likelihood.

G-CSF was associated with a higher CRS incidence (89.6% vs 79.9%, p = 0.0343), but grade 3 CRS or higher (4.7% vs 3.7%, p = 0.6675) was no different. No difference in complete response rates (66% vs 61.1%, p = 0.4707) or 2-year OS (p = 0.523) was observed between the 2 groups.

Conclusion: G-CSF within 30 days was associated with reduced duration and incidence of profound neutropenia without a significant impact on incidence of neutropenic fever or documented infections. There was a signal of association between G-CSF and increased incidence of low-grade CRS and delayed cytopenias (day 30-100) that warrants confirmation in larger studies.

#6328 Preclinical development of CAR T cells with antigen-inducible IL-18 enforcement to treat G_{D2}-positive solid cancers.

L. Fischer-Riepe[1], S. Kailayangiri[1], K. Zimmermann[2], R. Pfeifer[3], M. Aigner[4], B. Altvater[1], S. Kretschmann[4], S. Voelkl[4], J. Hartley[5], C. Dreger[5], K. Petry[3], A. Bosio[3], A. von Doellen[6], W. Hartmann[7], H. Lode[8], D. Goerlich[9], A. Mackensen[4], M. Jungblut[3], A. Schambach[2], H. Abken[5], **C. Rossig**[1];
[1]University Children's Hospital Munster, Muenster, Germany, [2]Institute of Experimental Hematology, Hannover Medical School, Hannover, Germany, [3]Miltenyi Biotec B.V. & Co. KG, Bergisch Gladbach, Germany, [4]Friedrich Alexander University Erlangen-Nuremberg (FAU) and Universitatsklinikum Erlangen, Erlangen, Germany, [5]Leibniz Institute for Immunotherapy (LIT) and University of Regensburg, Regensburg, Germany, [6]Institute of Transfusion Medicine and Cell Therapy, University Hospital Muenster, Muenster, Germany, [7]Gerhard-Domagk-Institute of Pathology, University of Muenster, Muenster, Germany, [8]University Medicine Greifswald, Greifswald, Germany, [9]Institute of Biostatistics and Clinical Research, University of Muenster, Muenster, Germany

Cytokine-engineering is a promising strategy to overcome limitations of CAR T cell therapy in solid tumors. We have developed a novel investigational medicinal product, consisting of CAR T cells directed against ganglioside GD2 along with CAR-inducible secretion of IL-18, to enforce their activation response and effector functions in the microenvironment of solid cancers. Our lentiviral all-in-one vector combines constitutive expression of a 14.G2a antibody-derived GD2-specific, 4-1BB-costimulated CAR with inducible nuclear factor of activated T cells (NFAT)-driven expression of the human IL-18 transgene. A control construct contains EGFP in the place of IL-18 (GD2EGFPCART). Lentiviral transduction of T cells from various individual donors with both preclinical and clinical batches of virus resulted in CAR surface expression in >40% of T cells. GD2IL18CART contained effector memory and central memory T cell phenotypes at similar frequencies as the control. CAR engagement by immobilized anti-idiotype antibody or by GD2-positive tumor cells selectively induced IL-18 release, with production of IL-18 strictly depending on GD2 antigen engagement. GD2IL18CART responded to interaction with GD2-positive tumor cells with superior IFN-γ, TNF-α and IL-2 cytokine release and superior target cytolysis compared to the control CAR T cells without inducible IL-18, whereas IL-6 was secreted at similar concentrations. In an NSG xenograft model of disseminated GD2-positive tumors, GD2IL18CART had superior *in vivo* anti-tumor activity than GD2EGFPCART, with eradication of GD2-positive tumor xenografts as detected by bioluminescence imaging while the control achieved only limited extension of progression-free survival. Finally, we established GMP-compliant manufacturing of GD2IL18CART that is feasible and efficient at clinical scale, using an automated protocol and device. Three validation runs confirmed robust expansion of CAR+ T cells to final cell numbers of $3.5x10^9$ CAR+ cells (median; range 3.4 to $3.7x10^9$), with consistent transduction efficiencies of >54% at the in-process control time-point and at harvest. GD2IL18CART from clinical-scale manufacturing runs responded to interaction with GD2 with strictly antigen-dependent secretion of both IL-18 and IFN-γ and efficiently lysed various GD2-positive tumor targets. In conclusion, we assembled all prerequisites for clinical evaluation of an IL-18 cytokine enhanced, GD2-specific CAR T cell product for the treatment of patients with a variety of solid tumors, recruited on the basis of GD2 immunofluorescence pre-screening (EU CT 2022-501725-21-00). Besides addressing the safety of GD2IL18CART therapy in pediatric and adult patients as the primary endpoint, the study will allow to gain substantial knowledge on the biological effects of IL-18 in the TME of the individual solid tumors.

#6329 Pooled *in vivo* screening of hundreds of T cell therapy designs using spatial multi-omics identifies novel designs with superior TME performance.

C. Kontur, G. Povysil, M. Sah, M. London, N. Chen, A. Dyatel, S. Pu, D. V. Phizicky, **X. Wang**;
Waypoint Bio, Inc., New York, NY

Background: Adoptive cell therapies such as CAR T have been curative for many liquid tumors, yet this success has struggled to translate to solid tumors due to the challenges posed by the solid tumor microenvironment (TME). Pooled CAR screens (e.g. CAR-POOLING) have recently emerged as a powerful approach for testing many designs for improving CAR T cell performance. However, these screens are typically restricted to univariate readouts (e.g. abundance) and cannot measure the cell-cell and cell-TME interactions that are critical for CAR T success in solid tumors. Here, we present a platform for performing pooled screens *in vivo* using spatial biology, facilitating simultaneous measurement of cell autonomous phenotypes, cell-cell interactions, and cell-environment interactions for hundreds of distinct cell therapy designs in a single mouse.

Methods: We developed a custom spatial biology workflow to determine the identity of specific CAR constructs, armorings, or combinations in specific individual cells from a microscope image ("design deconvolution"). We combined this design deconvolution with simultaneous multiplexed spatial biology phenotyping in the same cells & samples, followed by computer vision interpretation to quantify each design's performance across functional categories important for efficacy in solid tumors such as: tumor infiltration, tumor cell killing, proliferation, response to antigen heterogeneity & escape, exhaustion, persistence, and activity in immunosuppressive tumor microenvironments. In multiple mouse cancer models, we quantified the performance of hundreds of different cell therapy designs.

Results: Using our pooled screens, we identified designs with superior performance in solid tumors across one or more key functional categories (e.g. infiltration, activity in immunosuppressive TMEs, etc.). We also mapped the landscape of cell therapy design principles by comparing dozens of existing designs derived from the literature head-to-head in the same animal, and we compared these benchmarked designs to novel cell therapies designed to improve CAR T function. We used these data to identify common rules that govern the design-phenotype relationship for CAR Ts in solid tumors and to identify CAR T designs with desired properties in solid tumors.

Conclusions: Using a pooled *in vivo* screening platform, we discovered cell therapies that outperform existing designs across a variety of clinically-relevant metrics. Our spatial multi-omics measurements are critical for identifying designs that can effectively traffic to, infiltrate, and function in the solid tumor microenvironment. We are now using our pooled *in vivo* screens to identify highly efficacious designs in multiple solid tumor models.

#6330 A novel monoclonal antibody for the detection, enrichment and activation of cells expressing scFv-based chimeric antigen receptors.

A. Singh, S. L'Heureux, J. Fisher;
Cell Signaling Technology, Inc., Danvers, MA

Introduction: Chimeric Antigen Receptor (CAR)-T cell therapy is a highly innovative form of immunotherapy that has proven to be successful in the treatment of B cell malignancies and multiple myeloma. As this treatment modality continues to evolve toward the targeting of novel tumor antigens and engineering of CAR constructs that enhance cell persistence, there is a need for reagents that can be leveraged to selectively interrogate multiple aspects of CAR-T cell biology. Here, we report on a novel and highly versatile recombinant rabbit monoclonal antibody raised against the Gly4Ser peptide linker, which is commonly integrated into single-chain variable fragment (scFv)-based CARs. This antibody can be leveraged for flow cytometry-based CAR detection, bead-based CAR-T cell enrichment, and selective activation of CAR transduced cells.

Methods: The recombinant monoclonal antibody, E7O2V, was generated by immunizing rabbits with a synthetic peptide containing multiple repeats of the Gly4Ser core pentapeptide. E7O2V was directly conjugated to a panel of fluorophores and validated for specificity in a live cell flow cytometry assay using non-transduced and CAR-transduced primary human T cells. To assess its utility in cell enrichment using bead-based sorting, a biotinylated conjugate of E7O2V was used in combination with streptavidin releasable magnetic meads to immunoaffinity purify CAR transduced cells from a mixed population. Finally, a plate-bound antibody stimulation assay was leveraged to assess the ability of E7O2V to selectively activate CAR transduced cells.

Results: Live cell flow cytometric analysis of CAR-transduced primary human T cells revealed that E7O2V could detect surface expressed CARs, independent of scFv specificity. No specific staining was observed on non-transduced cells. Furthermore, flow cytometric analysis of bead-free, purified cells revealed that biotinylated E7O2V could enrich CAR transduced cells to a high degree of purity and viability. E7O2V was found to selectively activate CAR transduced cells, but not non-transduced cells, as demonstrated by upregulation of cell surface activation markers, including CD69 and CD25.

Conclusions: Exploiting the commonly used Gly4Ser linker of scFv-based CARs for antibody discovery, we identified a novel and highly versatile monoclonal antibody, E7O2V. This antibody binds to CARs of varying antigen specificity and can be leveraged in multiple assay formats to interrogate various attributes of CAR transduced cells, including CAR expression, CAR signaling, and transcriptome profiling enabled by bead-based enrichment.

#6331 A novel automated platform for rapid manufacturing of CAR T cells.

S. sa, E. Nguyen, J. Pan, **L. Yu**;
Applied Cells, Santa Clara, CA

Autologous cell therapy using genetically modified T cells to express chimeric antigen receptor (CAR) has yielded durable responses in cancers patients. However, currently only a small portion of patients are privileged to receive the treatment. High cost and long manufacturing time contribute to the key limitations prohibiting cell therapy broad adoption. Researchers discovered that reducing ex vivo culture improves anti-tumor activity of CAR T cells[1] and recently demonstrated the process of generating functional CAR T cells within 24 hours[2]. This rapid process provides great promise in cost reduction of CAR T therapy and opportunity to have cells manufactured in close-to-patient settings. CART cell manufacturing process involves: (1) collection of peripheral blood; (2) isolation of T cells; (3) performing transduction via viral vector; (4) washing CAR T cells to remove viral vector, and (5) harvesting CAR T cells in IV fluid. Conventional process uses magnetic separation and serial centrifugation technologies on multiple platforms with manual operations. Here we demonstrate the feasibility of rapid manufacturing CAR T cells on an automated platform with closed fluidics without centrifugation steps. The platform, MARS® Atlas, is built with innovative technologies in immune-magnetic cell isolation and acoustic cell washing and implemented as a modular system. In this feasibility test, T cells were isolated from peripheral blood from a healthy donoron MARS® magnetic module. eGFP expressing lentivirus were added to the enriched T cells. After short incubation, cells and virus were washed with fresh medium on the MARS® acoustic module and cells were incubated with virus overnight without activation. Infected cells were washed on the acoustic module to remove free virus. Product CAR T cells were harvested in saline solution and ready for QC analysis. Starting from 20mL of peripheral blood, magnetic T cell separation was done 2mL/min achieving 90% T cell purity, 90% recovery. In the first acoustic wash, medium exchange of the mixture of cells and virus took place at 0.9mL/min flow rate. As a result, 90% removal of contaminating molecule and 99.6% recovery of T cells were achieved. The second acoustic wash completed medium exchange of transfected cells at 0.9mL/min with 96.7% removal of virus and 90% CAR T cell recovery. As a result, 18 million GFP expressing T cells were produced.

In this study we have demonstrated the feasibility of rapidly manufacturing CAR-T cells on an automated platform MARS® Atlas. This result indicates the MARS® Atlas being a potential CAR T manufacturing platform to be used in close-to-patient settings to enable low-cost cell therapy.

#6332 Evaluating the relationship of affinity, functional avidity, and *in vivo* potency in KIR-CAR T cells.

J. Xu[1], S. Nunez-Cruz[2], J. M. Leferovich[2], G. Gulendran[2], C. Zhang[2], N. D. Yucel[1], M. C. Blair[1], W. S. Stanley[1], L. A. Johnson[1], D. L. Siegel[2], M. C. Milone[2]; [1]Verismo Therapeutics, Philadelphia, PA, [2]University of Pennsylvania, Philadelphia, PA

Chimeric antigen receptors (CARs) targeting CD19 demonstrate remarkable clinical outcomes in patients (pts) with B-cell malignancies. Importantly, all four FDA-approved CD3ζ-based CAR T cell therapies use the same FMC63-derived single-chain variable fragment (scFv) to target CD19+ tumors. Although response rates are high in diffuse large B cell lymphoma, only ~40% of pts achieve durable, long-term remissions. Improved CAR T cell therapies are therefore needed. We have previously shown that a novel killer immunoglobulin receptor (KIR)-based CAR expressed in T cells as a multichain receptor with DAP12 (KIR-CAR T) has enhanced anti-tumor activity in several preclinical solid tumor models suggesting that this platform may show better activity in lymphoma. Some recent studies report that lower-affinity CD19 binders compared to the benchmark FMC63-scFv yield equivalent or increased anti-tumor activity of CAR T in pts, raising the question of optimal affinity for a KIR-based CAR. In this study, we aimed to evaluate the relationship of affinity, functional avidity, and in vivo potency of CD19 binders in a KIR-based CAR T cell. Using a highly-diverse 40-billion member canine scFv phage display library, we generated 19 unique human CD19-specific binders that compete with FMC63 binder supporting a similar binding epitope. Different KIR-CAR T cells were generated, and relative affinities were compared via binding to a recombinant (rec) CD19 protein. We found that although CAR receptor expression was similarly expressed, the concentration of soluble rec CD19 protein required to saturate the surface CAR varied more than 2-log among the different scFv binders suggesting a range of affinities relative to FMC63. We selected several scFvs with lower, and equivalent CD19 binding MFI compared to the FMC63-scFv and found that all scFvs could mediate similarly robust in vitro potency. In vivo anti-tumor efficacy was next assessed using the NSG xenograft mouse model of B-cell leukemia NALM6 cells. Interestingly, despite their comparable in vitro functions, some binders with relatively similar binding MFI failed to control the tumors. In contrast, two binders with an ~30-fold apparent affinity relative to FMC63 exhibited robust anti-tumor activity comparable to the benchmark scFv. These preliminary data suggest that the in vivo functional activity of chimeric KIR-based immunoreceptors is insensitive to binder affinity over a wide range of affinities. The failure of some scFvs with comparable affinity and binding epitope suggest that other, yet to be characterized attributes of the binder may be critical for optimal function. Further characterization of these binders is being conducted to understand the relationship between affinity, functional avidity, antigen density, and in vivo potency. This study paves the way for developing an improved CD19-specific KIR-CAR T cell therapy for treating pts with B-cell malignancies.

#6333 A high-parameter mass cytometry panel for the functional characterization of CAR T cells.

D. Mahamed, G. Awong, T. Selvanatham;
Standard BioTools, Markham, ON, Canada

High-parameter flow cytometry provides a powerful tool for in-depth analysis of CAR T cell therapy, from characterizing CAR T cell populations to understanding their interactions within the tumor microenvironment. This information is crucial for advancing CAR T cell therapies and improving their effectiveness in treating cancer.

To address the need for deep immunoprofiling at all stages of CAR T cell therapy, we created a robust and comprehensive mass cytometry panel of antibodies against 44 cell surface and intracellular markers. This assay allows for comprehensive characterization of CAR T cell features including surface marker expression, activation state, cytokine production, and differentiation status. These data will provide researchers with a better understanding of the phenotype of the CAR T cells used in therapy and can guide optimization efforts to enhance expansion, persistence, and self-renewal. For example, newer-generation CAR T cells (T cells redirected for antigen-unrestricted cytokine-initiated killing, or TRUCKs) that are engineered to produce cytokines such as IL-2 to enhance their own survival can be evaluated *in vitro* to select CAR constructs with the most potent anti-tumor activity.

The lyophilized and validated 30-marker Maxpar® Direct™ Immune Profiling Assay™ enables comprehensive characterization of immune cell populations in both whole blood and PBMC. The 7-marker Maxpar Direct T Cell Expansion Panel 3 (OX40, TIGIT, CD69, PD-1, Tim-3, ICOS, and 4-1BB) and the Maxpar Direct Basic Activation Expansion Panel (CD107a, IL-2, TNFα, IFNγ, perforin, and granzyme B) are add-on modules that can further characterize CAR T cell exhaustion, degranulation, cytokine production, and cytotoxicity against target cells. We also compared CAR T detection options for sensitivity and specificity using a CD19 CAR-transduced cell line spiked into healthy donor PBMC. Indirect staining with Miltenyi Biotec biotinylated CD19 CAR Detection Reagent followed by anti-biotin- or streptavidin-conjugated metal tags was compared against a directly conjugated or biotinylated anti-G4S linker antibody. We included sample multiplexing using 6 metal-tagged CD45 antibodies to address the need to minimize batch effects, crucial to multi-site and longitudinal studies. Samples were acquired on a CyTOF® XT™ instrument, and preliminary data analysis was performed using Maxpar Pathsetter™ for automated enumeration of immune cells.

By combining the lyophilized single-tube Maxpar Immune Profiling Assay and Expansion Panels with specific detection of CAR T cells, this assay enables researchers to analyze multiple key parameters simultaneously at the single-cell level at all stages of CAR T therapy development.

For Research Use Only. Not for use in diagnostic procedures.

#6334 Metabolic reprogramming enhances expansion and potency of CAR T cells.

Y. Xing[1], S. Eaker[2], Y. Bronevetsky[2], C. Garcia[2], H. Lemar[2], E. Massi[2], A. Wong[2], S. Barnes[1], D. Germain[1], S. Wise[1], **J. Lim**[2];
[1]Labcorp Early Development Laboratories, Ann Arbor, MI, [2]Xcellbio, San Francisco, CA

Cell therapies, such as Chimeric Antigen Receptor (CAR) T cell therapy, have revolutionized the treatment of hematological malignancies, but their use in solid tumors remains a significant challenge for the field. This is due, in part, to immunosuppressive mechanisms in the tumor microenvironment (TME), which include reduced oxygen tension, high interstitial pressure, and an abundance of immunosuppressive proteins, resulting in mitochondrial dysfunction, exhaustion, and depletion of adoptively transferred cells. Metabolic manipulation of therapeutic cells could overcome these barriers to enable cell therapy success in solid tumors. To this end, we have employed AVATAR technology (Xcellbio, San Francisco, CA), an incubation system that enables precise control of oxygen tension and hyperbaric pressure on cells in culture to improve the manufacture of adoptive T cell therapies. Using a CD19 CAR T model system, we have shown that transduction and expansion of CAR T cells under reduced oxygen and hyperbaric pressure conditions yield greater percentages and total numbers of lentiviral-transduced cells. While cells transduced in a standard CO_2 incubator yielded 10-20% CD19 CAR+ cells, transduction in the AVATAR system with increased pressure yielded 15-40% CD19 CAR+ cells. Similarly, T cell cultures performed under pressurized AVATAR conditions generated ~2X more viable cells after 10 days. Furthermore, these metabolically reprogrammed cells exhibit enhanced potency, with improved anti-tumor cytotoxic activity in vitro. We have extended these studies to measure the ability of AVATAR-expanded CD19 CAR T cells to control the growth of CD19-expressing NALM6-Luc tumor cells in vivo compared to CAR T cells grown in a conventional CO_2 incubator. Mice (female NOD.Cg-*Prkdc*^{scid} *Il2rg*^{tm1Wjl}/SzJ, Jackson Laboratories, Bar Harbor, ME) dosed with the AVATAR-expanded cells exhibited good tumor control and increased persistence of CAR T cells in relevant organs, along with alterations in cell trafficking to the bone marrow and spleen. The transferred cells maintained a less differentiated phenotype, with central memory and effector memory populations, as measured by expression of the markers CD45RA and CD62L, dominating the T cell compartment. This work showcases the benefits of metabolic reprogramming to improve the yield and functional potency of CAR T cells, which has direct applications to reducing the cost and improving the efficacy of these lifesaving treatments. The AVATAR technology is currently being translated into a closed system bioreactor for use in GMP cell therapy manufacturing.

#6335 Armoring CAR-T therapy with PD-1 blockade: a powerful strategy for enhancing anti-tumor effects in pancreatic cancer.

Z. Zhang, J. Huang, Z. Zhao, X. Wang, C. He, S. Yang, Q. Gu;
WuXi AppTec, Shanghai, China

Chimeric antigen receptor-modified T cells (CAR-T) have been widely applied in the treatment of hematological malignancies and are currently under investigation for their potential effectiveness against solid tumors. Nevertheless, the effectiveness of CAR-T in treating solid tumors remains unsatisfactory due to a range of factors, including CAR-T cell infiltration and heterogeneity. The efficacy of CAR-T therapy is substantially influenced by the tumor microenvironment. This is particularly evident when PD-L1 is activated through CAR-T, leading to the inhibition of CAR-T cell activity via the PD-1 pathway. In this study, we engineered a CAR-T therapy that targets mesothelin and concurrently expresses a membrane-bound PD-1 receptor. This design blocks the PD-1 on CAR-T cells, effectively counteracting the suppression of CAR-T function mediated by PD-L1. We observed a substantial upregulation of PD-L1 on AsPC-1 tumor cells after 4 hours of IFN-γ stimulation in vitro. CAR-T cells engineered to co-express PD-1 antibody (aMSLN-28BBZ-mPD-1) exhibited similar short-term cytotoxicity and cytokine secretion profiles to those of the traditional third-generation CAR-T (aMSLN-28BBZ). Notably, aMSLN-28BBZ-mPD-1 displayed significantly improved long-term target cell killing. Furthermore, in an *in vivo* model of pancreatic cancer, aMSLN-28BBZ-mPD-1 demonstrated enhanced anti-tumor activity when compared to the traditional aMSLN-28BBZ, as supported by RNAscope analysis and immunofluorescence assays of tumor tissues. These analyses revealed a marked upregulation of PD-L1 expression and enhanced CAR-T cell infiltration in the aMSLN-28BBZ-mPD-1 treatment group. In summary, our study demonstrates that co-expression of a membrane-bound PD-1 antibody overcomes PD-L1 mediated CAR-T suppression, as observed in both *in vitro* and *in vivo*. This innovative strategy underscores its therapeutic potential and value in treating solid tumors. Keywords: CAR-T, PD-1, Tumor Microenvironment, Pancreatic Cancer

#6336 Unleashing CAR T cell activity against osteosarcoma using tumor specific RNA-based vaccination.

A. Barpujari, R. Liu, E. Ogando-Rivas, X. Ma, H. Taoa, H. Gomez, D. Mitchell, J. Huang, E. Sayour, P. Castillo;
University of Florida, Gainesville, FL

Background: Metastatic osteosarcoma (OSA) has a dismal prognosis despite novel targeted therapies, including CAR T cells. Unleashing CAR T cell therapy against poorly immunogenic cancers requires new technologies that activate the tumor microenvironment (TME), while inducing CAR T cell migration, proliferation, and persistence into tumor to sustain tumor-specific immunity. We have developed tumor RNA-loaded nanoparticle (CD70-encoding RNA-NP) vaccines to overcome CD70-specific CAR T cell limitations in OSA.

Methods: Using two murine solid tumor models (K7M2 osteosarcoma and B16F0 melanoma, in Balb/c and C57Bl/6 background) highly metastatic to lungs, we implant K7M2 and B16F0 intravenously (i.v.). We subsequently generated NPs complexed with RNA encoding for CD70 antigen and control vaccine (GFP RNA). RNA-NPs are administered intravenously beginning on day 5 post-tumor implantation and day 7, 14 & 21. Mouse CD70-specific CAR T cells are manufactured after activation of T cells with CD3 and CD28 antibodies for 2 days. CAR T cells are ready for use in downstream experiments 2 days after pMSGV8-mCAR transduction and cells were injected (i.v.) on day 6.

Results: In preliminary data, we show that intravenous administration of CD70-encoding RNA-NPs rapidly recruit CD70-directed CAR T cells into tumor stroma unlocking their activity in two immunocompetent aggressive lung metastatic tumor models. Interestingly, regression of CD70-expressing tumors associates with CAR T cell mobilization out of peripheral blood and into reticuloendothelial (RES) tissues (i.e., lung, and spleen), a phenomenon that correlates with upregulation of vaccine-induced type I interferon (IFN) and activation of CCR2 pathway. In addition to the CAR T-mediated antitumor killing, an antigen spreading phenomenon was observed. The long-term survival benefit (150 days) provided by this approach reached 70-80% in both models compared with 0-10% of control groups.

Conclusions: Based on these findings, we hypothesize that tumor trafficking and persistence of CD70 CAR T cells depend on coordinated cytokine/chemokine signaling that can be ignited through intravenous RNA-NP vaccination. RNA-NPs in combination with CAR T cells prolong long-term survival of mice bearing these aggressive tumor models which was not only mediated by CAR T cells but also by activation of endogenous adaptive immunity. Future studies include the evaluation of this approach in large animal models prior to translation into first-in-human clinical trials.

#6340 Novel conditionally active tetravalent B7-H3 x CD3 T-cell engagers targeting solid tumors.
A. Cugnetti, PhD, H. Liu, P. McNeeley, K. Woodard, C. Chang, G. Frey, W. J. Boyle, J. M. Short;
BioAtla, San Diego, CA

B7-H3, also known as CD276, is an immune-checkpoint molecule and a type 1 transmembrane protein that exerts a variety of biological functions. In cancer biology, the overexpression of B7-H3 is correlated with tumor cell invasion and metastasis, decreased T-cell infiltration and function, poor prognosis, and resistance to therapy. As B7-H3 is expressed in multiple solid tumors and plays an important role in modulating anti-tumor immune response as well as promoting cancer cell formation, it became an important target for the development of antibody-based immunotherapy. Many forms of bispecific antibodies targeting B7-H3 have shown antitumor response in preclinical studies. However, bispecific T-cell engagers (TCE) targeting B7H3 and CD3 have been correlated with cytokine release syndrome and hepatic adverse events, a common toxicity observed using TCEs which has limited the development of this immunotherapeutic in clinic. We leveraged BioAtla's Conditionally Active Biologic (CAB) platform (1) to develop a DualCAB T-cell engager targeting B7-H3 and CD3. This DualCAB-TCE molecule, BA3142, was engineered to bind with high affinity to both recombinant B7-H3 and CD3 receptor/antigens under conditions that mimic the acidic tumor microenvironment, but with low affinity in alkaline physiological conditions. *In vitro* and *in vivo* efficacy and toxicity data for the clone BA3142 will be presented. Our data demonstrated that BA3142 promotes cytotoxicity of B7-H3-expressing cancer cells *in vitro* and induces significant tumor regression *in vivo*. In Non-Human Primates BA3142 bispecific antibody was tolerated up to 25 mg/kg with minimal cytokine release and no clinical and histopathological signs of toxicities. The CAB technology offers the opportunity to expand the number of targets suitable for drug development in a new class of DualCAB TCEs with superior safety margin and potency in the clinic.

#6341 Targeting myeloid epithelial tyrosine kinase (MERTK) receptor in acute myeloid leukemia using a novel antibody-drug conjugate, RGX-019-MMAE.

A. Tyagi[1], M. Siddiqui[1], I. Kurth[2], S. Takeda[2], A. Eckstrom[1], J. Borgman[1], A. Maiti[1], V. Battula[1];
[1]UT MD Anderson Cancer Center, Houston, TX, [2]Inspirna, Inc., New York, NY

Background: Myeloid epithelial reproductive tyrosine kinase (MERTK), a transmembrane protein receptor from the TAM (Tyro3, Axl, Mertk) family, is overexpressed in cancer and associated with reduced apoptosis and chemoresistance, making it an attractive therapeutic target. RGX-019-MMAE, a novel humanized IgG1-MMAE antibody-drug conjugate (ADC) (Inspirna, Inc), selectively binds to MERTK with high affinity on tumor cells, resulting in internalization and degradation of the receptor. It then induces cytotoxicity through the release of the payload, MMAE (monomethyl auristatin E), which disrupts mitosis. We hypothesize that targeting MERTK via RGX-019-MMAE exerts an antileukemic effect.

Methods: First, to determine the clinical relevance of MERTK, using the Oregon Health and Science University (OHSU) acute myeloid leukemia (AML) dataset, we divided patients into low and high MERTK mRNA expression based on mean expression and compared their overall survival. To identify the AML subtypes with the highest MERTK expression, we analyzed samples from 810 AML patients at MD Anderson using reverse phase protein arrays (RPPA), as well as 8 AML cell lines and the peripheral blood of 9 AML patients using flow cytometry. Then, the cell lines with the highest MERTK expression were treated with varying doses of RGX-019-MMAE or isotype control for 120 hours and assessed for viability with CellTiter-Glo 2.0. Likewise, we administered RGX-019-MMAE to primary cells from AML patients and determined the anti-leukemic effect. Finally, we investigated the synergistic effect of RGX-019-MMAE with venetoclax, a BCL2 inhibitor, or cytarabine, a chemotherapy agent, *in vitro*.

Results: In the AML OHSU dataset, patients with high MERTK mRNA expression had significantly worse overall survival (p=0.02). RPPA revealed that patients with PTPN11 mutation, t (9;11), and monocytic AML subtypes had significantly higher MERTK protein expression. MERTK protein expression varied in AML cell lines and was highest in Kasumi-1 and OCI-AML3. Treatment of these two cell lines with RGX-019-MMAE resulted in significantly more killing of leukemic cells than the isotype control ADC in a dose-dependent manner (p<0.01). Similarly, in primary AML cells with high MERTK expression, RGX-019-MMAE treatment induced significant cell death compared to the control ADC. In addition, Kasumi-1 and OCI-AML3 cells treated with RGX-019-MMAE combined with venetoclax or cytarabine showed a synergistic cytotoxic effect in a dose-dependent manner.

Conclusion: High MERTK expression in monocytic AML suggested that MERTK is a promising therapeutic target in this subtype. RGX-019-MMAE significantly induced AML cell death and produced a synergistic anti-leukemic effect in combination with chemotherapeutic agents and targeted therapy *in vitro*, suggesting its potential for targeting patients with high-risk AML.

#6342 Anti-tumor in vivo efficacy of different classes of anti-CLEC-1 myeloid checkpoint antibodies in monotherapy and in combination with chemotherapeutic agents.

A. Morello[1], M. Derame[1], M. Drouin[1], E. Wilhelm[1], S. Neyton[1], I. Baccelli[1], C. Mary[1], V. Gauttier[1], I. Girault[1], K. Biteau[1], C. Batty[1], G. Teppaz[1], A. Desselle[1], M. Colonello[1], M. Malloci[1], E. Chiffoleau[2], N. poirier[1];

The c-type lectin receptor CLEC-1 is a pattern recognition receptor [1] expressed by endothelial and myeloid cells in mice, non-human primates, and humans. While genetic deletion of CLEC-1 in mice does not lead to any developmental defect, CLEC-1 deletion or CLEC-1 targeting promotes anti-tumor response by increasing cross-presentation of necrotic or damaged cells by cDC1 dendritic cells and by enhancing T-cell activation [2]. To date, the identification of CLEC-1 endogenous ligand(s) and their biological activity into myeloid or endothelial cells remained to be fully investigated. We aimed to further characterize ligands that are involved into CLEC-1 activation and develop monoclonal antagonist anti CLEC-1 antibody anti-tumor therapy that are able fully counteract inhibitory signaling induced into myeloid cells. Using LC/MS campaign, we confirmed CLEC-1 specific binding to the E3 ubiquitin ligase TRIM21and to the secreted histidine rich glycoprotein (HRG) as previously described [2] and also identify several novel intra-cellular and cell surface proteins that bind to CLEC-1 receptor in protein specific-manner. To block interaction of CLEC-1 ligands, we developed different class of antagonist monoclonal antibodies and evaluated their anti-tumor efficacy in humanized CLEC-1 KI orthotopic and ectopic tumor mouse models fully resistant or partially resistant to ICI therapy. While blocking of CLEC-1 binding to its secreted ligand HRG moderately increases anti-tumor responses, inhibition of CLEC-1 binding to its cytoplasmic and membrane ligands significantly impairs MC38 tumor growth (n=12, p=0.04). Importantly, high anti-tumor efficacy was observed in combination therapy with cyclophosphamide in MC38 mouse model. Additionally, antagonist anti-CLEC-1 antibodies significantly increase overall survival of Hepa1.6-bearing mice (n=32 for each treatment, $p<0.002$), as compared to corresponding isotype control treatment in 3 independent experiments. Altogether, our results further dissect the mechanism of action of the myeloid checkpoint CLEC-1 in its ability to impair anti-tumor immunity and support its use as a novel and highly promising anti-CLEC antagonist antibody for cancer immunotherapy.

#6343 AnTenGager™, a novel "2+1" T cell engager platform, enables conditional T cell activation with reduced risk of CRS.

Bing Hou[1], Hui Yuwen[2], Tengteng Li[2], Yijing Ren[2], Ao Sun[2], Zaoshun Hu[3], Jay Mei[1], Bo Shan[1]

[1]Antengene Corporation, Shaoxing, China,[2]Antengene Corporation, Shanghai, China,[3]Antengene Biologics, Hangzhou, China

Background: CD3+ T cell engaging bispecific antibodies (TCE) redirect T cells to attack targeted tumor cells by simultaneously binding TAA on cancer cells and CD3 complex on a T cell to form a TCR-independent immune synapse. Multiple TCEs have demonstrated promising therapeutic efficacy in the treatment of hematological malignancies. In contrast, suboptimal efficacy in the treatment of solid tumors and the risk of inducing cytokine release syndrome (CRS) continue to be major challenges. Several factors, such as format, affinity, and valency of the antibody, TAA copy number, and antigen size and epitope, can impact the therapeutic efficacy and safety of a TCE. In this study, we developed a novel "2+1" TCE platform, AnTenGager™, which enables conditional T cell binding and activation upon TAA-crosslinking, potent anti-tumor activity, and reduced risk of CRS.

Methods: Humanized CD3 antibodies were derived from mouse hybridoma, followed by affinity optimization utilizing Computer Aided Drug Design. The Fab-scFv-Fab format was used as the backbone structure of AnTenGagers. The anti-CD3 scFv sequences and the length of peptide linkers between VH/VL, scFv/CH1, and scFv/CH2 were screened and compared in different preclinical assays. LALA mutations (L234A, L235A) were introduced to abolish the Fc receptor binding capability. In a series of *in vitro* and/or *in vivo* models, the efficacy, safety and developability of AnTenGagers targeting multiple TAAs, such as Her2, GD2, CDH6, LILRB4, FLT3 and GPRC5D, were evaluated.

Results: A library of humanized parental CD3 antibodies with a broad spectrum of affinities were generated, some of which cross react with monkey CD3. AnTenGagers exhibited limited binding to CD3-positive cells before TAA-crosslinking, suggesting a reduced risk of CRS that is caused by systemic CD3+T cell activation. Four CD3 sequences with varying affinities were utilized to construct AnTenGagers with identical TAA-targeting arm. Compared to clinical benchmarks targeting the same TAA, all AnTenGagers demonstrated substantially lower binding capacity to CD3+ cells in the absence of TAA-crosslinking, while inducing increased cytotoxicity against target-positive tumor cells. In addition, they induced significantly less ex-vivo cytokine release by human PBMC than benchmarks. Notably, all AnTenGagers demonstrated enhanced in vivo efficacy compared to the benchmark, exhibiting complete response (CR) in PBMC humanized MM1S mouse CDX model while the serum concentration of proinflammatory cytokines was substantially lower in groups treated with AnTenGagers. AnTenGagers also demonstrated good developability with high expression yield, good thermostability and high stability under different stress conditions.

Conclusions: These results suggested that AnTenGager™ is a promising platform for developing the next generation of TCEs with enhanced efficacy and safety.

#6344 Engineering of ICAM-1 refractory antibodies for the development of therapeutic antibodies and antibody drug conjugates (ADCs) in ICAM-1 over-expressing cancers.

B. Kline, L. Grasso, N. Nicolaides;
Navrogen Inc., Cheyney, PA

Human cancers employ a number of mechanisms to evade host immune responses against novel antigens generated from aberrant over-expression, mutations and/or epigenetic alterations. Humoral immunity utilizes antibodies and immune-effector cells as well as molecular immune complexes involving the complement system to mediate the killing of dysregulated cancer cells. We refer to these anti-cancer mechanisms as Humoral Immuno-Oncology (HIO). HIO suppression is mediated by tumor-produced proteins called HIO factors. One such factor is CA125, which was previously shown to bind IgG-type antibodies and inhibit their immune-effector activities, including antibody dependent (ADCC) and complement dependent (CDC) cellular cytotoxicity. Using a combination of experimental screening and literature searches, a second protein produced by tumors and associated with a variety of cancer indications was discovered and found to be soluble ICAM-1 (sICAM-1). Through various functional studies we reported that sICAM-1 and membrane ICAM-1 (mICAM-1) are capable of binding IgG1-type antibodies that in turn inhibits their immune-effector activity. Through a combination of truncation and substitution mutagenesis, we identified a four amino acid motif within the CH3 domain of IgG1 essential for ICAM-1 binding, resulting in the inhibition of ADCC activity. While traditional glycine and alanine substitutions in this region abrogated ICAM-1 binding, these modifications caused tertiary structural changes in the Fc domain that resulted in loss of ADCC activity. Through a combinatorial amino acid substitution approach, we identified a four amino acid combination within the $_{407}$YSKL$_{410}$ to $_{407}$FARV$_{410}$ motif that resulted in antibodies refractory to sICAM-1 binding with robust ADCC activity. Additionally, isogenic wildtype and ICAM-1 knockdown target cell lines showed mICAM-1 inhibited target cell killing of a saporin antibody drug conjugate (ADC) and this was the direct result of mICAM-1 reducing antibody internalization, a requisite for maximal ADC target cell killing. The inhibitory activity of mICAM-1 could be overcome employing antibodies containing the $_{407}$FARV$_{410}$ substitution. These findings highlight yet another mechanism by which tumors can suppress the host's immune system for survival and offer new concepts for developing antibody-based therapies that can aid in the treatment of various cancer indications, especially those over-expressing ICAM-1. Moreover, the findings here offer diagnostic and therapeutic clinical design opportunities to improve upon existing approved immune-mediated therapies for which this factor is present.

#6345 In vitro characterization of a dual antagonistic anti-LILRB2/LILRB4 monoclonal antibody.

B. L. Daugherty[1], X. Ge[2], C. L. Hsieh[2], B. A. Zabel[2], S. Lederman[1];

[1]Tonix Pharmaceuticals, Inc, Chatham, NJ, [2]Curia Global, Inc, San Carlos, CA

Introduction: Myeloid-derived suppressor cells (MDSCs) in the tumor microenvironment are a potential therapeutic target in immune checkpoint cancer therapy, but MDSC-targeted therapies have yet been shown to improve survival. The leukocyte immunoglobulin (Ig)-like receptor B2 is a member of the leukocyte Ig-like receptor (LILR) family and is predominantly expressed on the surface of cells of the myelomonocytic lineage (monocytes, macrophages and dendritic cells). LILRB2 is a negative regulator of myeloid cells and is an immune checkpoint receptor. We chose to generate mAbs against LILRB2 as a potential immunotherapeutic for cancer.

Methods: PentaMice® strains (5 WT mouse strains comprising 9 MHC class II haplotypes to maximize Ab diversity) were immunized with human LILRB2. Lymphocytes were fused with a myeloma partner to generate lead monoclonal hybridomas. 24 purified anti-LILRB2 mAbs were generated and evaluated by arrayed surface plasma resonance (SPR, Carterra® LSA® instrument) to assign epitope bins. mAb humanization was performed in silico to maximize T20 “humanness” scores (algorithm developed by Curia). Humanized mAbs were transiently expressed using Curia’s TunaCHO™ platform and tested in in vitro MDSC assays. Autologous co-cultures of magnetic bead enriched-human blood-derived MDSC (HLA-DR-CD14+) model cells and T cells (CD3+) were stimulated with plate-bound anti-CD3/CD28 to induce T cell activation. Cytokine secretion was assessed 4 days later.

Results: A total of 384 hybridoma supernatants were selected from the primary screen. 245 were confirmed by ELISA and 178 stained HEK293 cells expressing LILRB2 cells by flow cytometry (FACS). 24 hybridomas were further selected, cloned and sequenced. Five epitope bins were identified via Carterra® LSA® instrument. Two clones were chosen for humanization, designated 6-I11A and 4-O19A and were recombinantly expressed with the human IgG4 isotype. FACS analysis on HEK293 cells expressing either huLILRB2 or huLILRB4 revealed that clone hu4-O19A-IgG4 was specific for huLILRB2. Surprisingly, clone hu6-I11A-IgG4 stained both huLILRB2 and huLILRB4. FACS analysis with hu4-O19A-IgG4 on human MDSCs exhibited an EC50 of 11.9 nM and a KD of 1.5 nM in binding to recombinant huLILRB2 antigen, while hu6-I11A-IgG4 had an EC50 of 3.2 nM and a KD of 0.6 nM. In co-cultures with human MDSCs and T cells, both hu6-I11A-IgG4 and hu4-O19A-IgG4 reversed cytokine suppression by the MDSCs by increasing GM-CSF, IL-10, TNFα, and IL-6, while suppressing IL-13, and had little effect on IL-17A, MIP-3α, IL-4, IL-2 and IFNγ compared to treatment with the isotype control, with hu6-I11A-IgG4 having a greater effect as an antagonist than hu4-O19A-IgG4.

Conclusions: We have identified a dual anti-LILRB2/LILRB4 antagonist. Targeting MDSCs with this antibody offers great promise for immunotherapy for cancer as well as its immense potential for synergy with PD-1 blockade.

#6346 IgG engineered to target PIGR-mediated transcytosis specifically targets intracellular oncoproteins and abrogated tumor growth.

C. Anadon Galindo, L. Lopez-Bailon, R. A. Chaurio, J. A. Mine, N. E. Plappert, J. R. Conejo-Garcia;
Duke University School of Medicine, Durham, NC

Despite their long half-life, therapeutic antibodies are considered ineffective against intracellular antigens due to their perceived inability to penetrate epithelial cells. Using recombinant antibodies targeting common mutations in oncogenes, we have demonstrated that dimeric IgA, but not the same antibody on an IgG backbone, penetrates human epithelial cancer cells through PIGR-dependent directional transcytosis, specifically neutralizing mutated oncodrivers and expelling antigens outside the cell, bound to secretory IgA. Accordingly, targeting of KRASG12D abrogated tumor cell proliferation in cell culture assays. In vivo, $KRAS^{G12D}$-specific dIgA1 limited the growth of RAS^{G12D}-mutated ovarian and lung carcinomas, including in syngeneic tumor-bearing immunocompetent mice. Moreover, dIgA targeting of $KRAS^{G12D}$ restricted tumor growth more effectively than small-molecule $KRAS^{G12D}$ inhibitors, supporting the potential of this approach for the treatment of human cancers. Since producing dimeric IgA is more challenging than producing monomeric IgG, and because the half-life of IgA is shorter (4-7 days) than IgG (21 days), we have developed a new approach combining $KRAS^{G12D}$ specific IgG with a peptide that could join PIGR and penetrates tumor cells through transcytosis, that showed the same effect than IgA controlling tumor growth. Our results provide a rationale for developing modified IgG cell-penetrating antibodies to effectively target common mutations in intracellular oncogenes that drive many aggressive and frequent human cancers. In addition, further experiments suggest that these antibodies could be effectively used to target tumors that have become resistant to existing KRAS inhibitors.

#6347 To develop a tumor selective INF-γ-Yervoy fusion antibody to increase the therapeutic effect and safety of current Yervoy therapy in cancer.

C.-H. Chuang;
Department of Medical Laboratory Science and Biotechnology, Kaohsiung Medical University, Kaohsiung, Taiwan

Introduction: Immune checkpoint inhibitor therapy is a highly promising strategy for clinical treatment of cancer. Among these inhibitors, yervoy stands out for its ability to induce cytotoxic T cell proliferation and activation by binding to CTLA-4. However, FDA has reported that yervoy would induce the over-activation of immune cells and cause the serious side effects. In additional, the therapeutic efficacy and application of Yervoy were still limited by the MHC expression of patient's tumor.
Strategy: Therefore, we have developed a protease specific pro INF-γ-Yervoy to increase the therapeutic effect and safety of current immune checkpoint blockade therapy in cancer. We used the MMP-2/9 protease substrate as a linker between INF-γ and Yervoy. Using the concept of spatial shielding, IFNγ and Yervoy can block their functions from each other. Once the INF-γ-Yervoy arrives to the tumoral region, the INF-γ-Yervoy will be removed from Hinge Yervoy by the over-expressed MMPs protease locally so that the Yervoy will recruit its binding ability in order to increase the drug selectivity and improve the side effects. The INF-γ also can increase the MHC I expression in tumor to overcome the MHC-limitation of Yervoy.
Result: On activation by MMP, IFNγ-yervoy not only restored yervoy's binding ability but also released biologically active IFNγ. This finding confirms the reliability of IFNγ-yervoy's functionality. In vivo studies demonstrated that IFNγ-yervoy enhances the therapeutic effect of yervoy against colorectal cancer by increasing CD8+ and CD4+ lymphocyte infiltration into the tumor area and inducing MHC-I expression in tumor cells. Mice treated with IFNγ-yervoy showed higher survival rates and body weight, as well as lower CD4+ and CD8+ lymphocyte activation rates in the blood and reduced organ damage.
Conclusion: These results provide strong evidence that tumor-selective IFNγ-yervoy can improve the effectiveness of yervoy while reducing its side effects. It is likely that future immunotherapies would rely on such antibodies to activate local cancer cells or immune cells, thereby increasing the therapeutic effectiveness of cancer treatments and ensuring their safety. Keyword: Immune checkpoint inhibitor therapy, IFNγ, yervoy, rectal cancer, CTLA4

#6348 Unveiling diverse trimeric forms of STEAP1 in human prostate cancer cells: Exploring STEAP1-STEAP2 interdependence for expression and plasma membrane localization.

C. Li[1], L. Liang[1], J. Park[1], O. Pryshchep[1], B. Staley[1], P. Li[1], B. Alba[1], X. Liu[1], F. Li[1], G. L. Moore[2], M. J. Bernett[2], U. Muchhal[2], J. Desjarlais[2], A. Coxon[3], J. M. Bailis[1];

[1]Amgen, South San Francisco, CA, [2]Xencor, Inc, Pasadena, CA, [3]Amgen, Thousand Oaks, CA

Six-Transmembrane Epithelial Antigen of the Prostate 1 (STEAP1) is an emerging therapeutic target that is a member of the STEAP1-4 family of metalloreductases. We recently reported the preclinical characterization of xaluritamig (AMG 509), a STEAP1 XmAb® 2+1 T-cell engager molecule that is being developed for the treatment of prostate cancer (Nolan-Stevaux et al, 2023). Xaluritamig is designed to preferentially target tumor cells that express high levels of STEAP1. However, prostate tumor cells also express high levels of STEAP2. Here, we characterize the interactions between STEAP1 and STEAP2 in prostate cancer cell lines and the impact to xaluritamig activity. Bulk mRNA as well as single-cell gene expression data (scRNAseq) reveal a strong correlation between STEAP1 and STEAP2 expression in human prostate cancer, suggesting that the STEAP proteins may form both homotrimers and heterotrimers in prostate tumors. To test this idea, we investigated the structural behavior of STEAP1/2 trimers in human prostate cancer cell lines that endogenously express STEAP1 and STEAP2. Using xaluritamig and the parental anti-STEAP1 antibody, we show that STEAP1 primarily forms heterotrimers with STEAP2 in prostate cancer cells but can also assemble as homotrimers in the absence of STEAP2. Both STEAP1/2 heterotrimers and STEAP1 homotrimers can be targeted by xaluritamig, leading to T cell-dependent cellular cytotoxicity. Similarly, we found that anti-STEAP2 antibodies detected STEAP2 homotrimers when STEAP1 expression was ablated in cells, and that both STEAP1/2 heterotrimers and STEAP2 homotrimers were targeted by a STEAP2-specific T-cell engager molecule. We also demonstrate that neither STEAP1 nor STEAP2 significantly influences the mRNA or protein expression of the other. Our data elucidates the versatility of STEAP family members in forming both homotrimers and heterotrimers on the plasma membrane of human prostate cancer cells and the potential for therapeutic targeting with STEAP1/2-directed therapies. Characterizing the capability of existing STEAP1 or STEAP2 targeting therapeutics to bind their respective targets, whether within a homotrimer or heterotrimer, is crucial for a comprehensive understanding of the therapeutic potential of these drugs. Further research will help delineate the mechanism underlying the formation of STEAP1/2 trimers in cancer cells and continue advancing our understanding of this intriguing biological relationship.

#6349 2MW4991, a novel ADCC-enhanced integrin αvβ8 blocker, exhibits high anti-tumor potency and was well tolerated in cynomolgus monkeys.

C. Guo, Z. Han, X. Cen, Sr., H. Wu, J. Zhang, X. Gui;
Mabwell (Shanghai) Bioscience Co., Ltd., Shanghai, China

Background: The three highly structurally related TGF-β isoforms (TGF-β1, TGF-β2, and TGF-β3) exert greatly different effects on cancer and immune cells under various physiological conditions. Efforts to target the TGF-β pathway have been hampered by systemic toxicity or limited efficacy due to challenges associated with the global inhibition of TGF-βs. Recently, TGF-β1 was proven to be a critical player in generating an immunosuppressive tumor microenvironment (TME). TGF-β1 is expressed as an inactive latent form (L-TGF-β1) and activated upon binding to integrins, and integrin αvβ8 is a key activator of TGF-β1 in TME. Here, an ADCC-enhanced αvβ8 blocking antibody, 2MW4991, was developed to specifically inhibit TGF-β1-mediated signaling for the treatment of αvβ8-expressing cancers.

Methods: Binding ability, specificity, and affinity of antibodies were measured by Flow cytometry and Biacore T200. A blocking assay was performed using U251MG cells and TGF-β signaling reporter cells. Jurkat/h FcγRIIIa reporter system was used to assess the ADCC activity of 2MW4991. Mouse syngeneic tumor models were used to characterize the *in vivo* anti-tumor efficacy. A repeat dose administration study was performed in cynomolgus monkeys to evaluate the pharmacokinetic and toxicity profiles of 2MW4991.

Results: ScRNA-seq analysis of kidney renal clear cell carcinoma (KIRC) and head and neck squamous cell carcinoma (HNSCC) clinical samples revealed that αvβ8 highly expresses in tumor and some myeloid-derived cells, suggesting the development of ADCC-enhanced αvβ8 blocking antibodies for the treatment of αvβ8-expressing cancers. 2MW4991 showed sub-nanomolar binding affinity and high specificity to αvβ8, with no cross-reactivity to other integrins. 2MW4991 could effectively block TGF-β1 release in a GARP/L-TGF-β1/αvβ8 reporter system. In an immune-excluded EMT6 syngeneic model, 2MW4991 promoted substantial tumor regression and reversed immune suppressive TME by significantly increasing tumor infiltration of CD8+ T and innate immune cells. As expected, TGF-β1 blockade significantly increased the sensitivity of anti-PD-1 therapy in a combination study. Furthermore, 2MW4991 displayed potent anti-tumor efficacy in the human αvβ8 knock-in syngeneic model mimicking αvβ8 expression in human cancers. In a repeat dose administration NHP study, 2MW4991 showed a good pharmacokinetic profile and was well tolerated at a high dose of 100 mg/kg, accompanied by significantly declined pharmacodynamic biomarker TGF-β1 in peripheral blood.

Conclusion: Integrin αvβ8 is a main activator of TGF-β1 in the TME and overexpressed in some cancer types. 2MW4991 demonstrated potent anti-tumor activity by unleashing the immune cells suppressed by TGF-β1 in TME and Fc-mediated immune functions. These compelling preclinical results support further evaluation of 2MW4991 in clinical trials.

#6350 2MW4691, a novel CCR8/CTLA-4 bispecific antibody, displays potent anti-tumor efficacy by specifically depeleting tumor-infiltrating Tregs and blocking CTLA-4 signaling on CD8+ T cells.

C. Guo, Jr.[1], X. Dai[1], X. Xiong[1], H. Liu[2], X. Cen, Sr.[1], H. Wu[1], J. Zhang[1], X. Gui[1];

[1]Mabwell (Shanghai) Bioscience Co., Ltd., Shanghai, China, [2]Institution: ShanghaiTech University, Shanghai, China

Background: Regulatory T cells (Tregs) are one of the representative immunosuppressive cells playing a critical role in tumor microenvironment by suppressing anti-tumor immune responses. A great many Treg-depleting therapeutics targeting CTLA-4, CCR8, and CD25 are currently being investigated in clinical trials, and the overwhelming majority of these studies showed systemic toxicity or limited efficacy. Novel modalities favoring tumor-infiltrating Tregs depletion are urgently needed. Here, a CCR8/CTLA-4 bispecific antibody 2MW4691 with inequivalent target arm affinities was developed to specifically deplete tumor-infiltrating Tregs and block CTLA-4 signaling on CD8+ T cells.

Methods: Single-cell RNA sequencing data collection and computational analysis were applied to investigate CCR8 and CTLA-4 gene expression profiles in tumor-infiltrating Tregs. 2MW4691 was generated by combining parental bivalent anti-CCR8 and anti-CTLA-4 antibodies with different target arm affinities. CCR8 and CTLA-4 single and double-positive cells were used to evaluate the binding and blocking abilities of 2MW4691. Human FcγRIIIa receptor system, NK cells, and hPBMCs were used to assess the ADCC activity of 2MW4691. hCCR8/hCTLA-4 double transgenic mouse syngeneic models were used to evaluate the anti-tumor efficacy of 2MW4691 *in vivo*. A repeat dose administration study was performed in cynomolgus monkeys to evaluate the pharmacokinetic and toxicity profiles of 2MW6471.

Results: Single-cell RNA sequencing analysis confirmed the co-expression of CCR8 and CTLA-4 in tumor-infiltrating Tregs of NSCLC patients. 2MW4691 was designed as a tetravalency symmetric structure with high binding affinity to CCR8 and low binding affinity to CTLA-4, which resulted in strong ADCC activity towards CCR8 single and CCR8/CTLA4 double-positive cells, but limited ADCC activity towards CTLA-4 single positive cells in cell-based assays. In the staphylococcal enterotoxin B stimulation assay, 2MW4691 promoted T-cell activation, suggesting that it maintained the ability to block CTLA-4-mediated downstream signaling from its parental anti-CTLA-4 antibody. *In vivo*, 2MW4691 exhibited potent anti-tumor efficacy in hCCR8 or hCTLA4 humanized mice bearing MC38 tumors. Further, the advantage in tumor inhibition of 2MW4691 compared with its parental antibodies was proved in the hCCR8/hCTLA-4 double knock-in mouse model. In the NHP study, 2MW4691 exhibited good pharmacokinetic and safety profiles with negligible impact on peripheral T cells.

Conclusion: 2MW4691 demonstrated superior anti-tumor efficacy compared with its parental antibodies in CDX models and favorable tolerability in NHPs. The encouraging preclinical results support further evaluation of 2MW4691 in clinical trials.

#6351 MUC1*-ADCs are effective against heterogeneous solid tumor cancers.

C. C. Bamdad, B. S. Smagghe, S. T. Moe, M. G. Carter, T. J. Grant, K. R. Yi, M. J. Nash, J. P. Marquez, N. K. Miller, J.-L. S. Nash, D. S. Miller, D. M. Walkley, A. K. Stewart;
Minerva Biotechnologies, Waltham, MA

Purpose: To develop a MUC1*-ADC for the treatment of over 75% of solid tumor cancers.
Methods: MUC1* (muk 1 star) is a growth factor receptor created after cleavage and release of the N-terminal portion of MUC1. The targeting antibody, huMNC2, has already demonstrated safety and cancer selectivity in a 1st-in-human CAR-T clinical trial for treatment of metastatic breast cancers. MNC2 is an IgG1 antibody that only recognizes the conformational epitope created when MUC1 is cleaved by specific tumor-associated enzymes. Confocal microscopy and pHlourin2 were employed to measure antibody internalization as a function of time. We conjugated MNC2 to MMAE, MMAF, Dxd and exatecan via several different linkers. MUC1*-ADCs with DARs ranging from 4-8 were tested in vitro and in vivo for efficacy against a panel of solid tumor cancers. Heterogenous MUC1* tumors were made by mixing different ratios of mCherry wild-type cancer cells with GFP MUC1* overexpressed cancer cells. Resulting H scores ranged from 10-280 (max 300).
Results: Cancer cells internalized the MUC1* MNC2 antibody within 2 hours. In vitro, MUC1*-ADC IC50s ranged from 1.3nM to 20.0nM, depending on the linker-payload and cancer subtype, wherein the majority had an IC50 of about 10nM. In general, efficacy in animals was seen across multiple cancer sub-types treated with multiple MUC1*-ADCs. Efficacy in animals xenografted with heterogeneous MUC1* tumors showed a dependence on antigen density. Greatest efficacy was observed for breast cancer xenografts with an H Score >10 treated with MNC2-Deruxtecan. However, only pancreatic tumors with higher H Scores were completely eliminated by MNC2-MMAE, MNC2-Deruxtecan and MNC2-exatecan. MNC2-ADC and MNC2-CAR share the same antibody. No off-tumor toxicity was observed in animals treated with MNC2-ADC, which mimicked lack of off-target toxicities for MNC2-CAR T cells in humans.
Conclusions: These data, combined with MNC2-CAR T data from our 1st-in-human trial for metastatic breast cancer, supports a conclusion that the MUC1* antibody MNC2 is safe and could have high therapeutic value as a MUC1*-ADC for multiple solid tumors with both high and low antigen density.

#6352 Preclinical discovery of ARX622: A site-specific, TLR7 agonist, HER2-targeted immune-stimulatory antibody drug conjugate for treatment of multiple solid tumor types.

D. Mills, J. Kim, E. Wood, K. Tatsukawa, N. Knudsen, J. Nelson, L. Skidmore, K. GC, H. Tran, M. Pal, H. Hashemi, Y. Buechler, S. Zhang, D. O'Connor; Ambrx, San Diego, CA

Traditional antibody-drug conjugates leverage the specificity of antibodies to deliver cytotoxic payloads to tumor microenvironments (TMEs), thereby reducing systemic toxicities associated with non-targeted chemotherapeutics. Analogously, a novel class of immune-stimulating antibody conjugates (ISACs) has recently emerged to selectively deliver synthetic immune agonists to the TME without systemic immune activation. The first generation of ISACs and the majority of approved and investigational ADCs contain payloads linked to native lysine or cysteine residues, which can lead to heterogenous drug-antibody ratios (DARs), reduced antibody stability, and labile conjugation, all of which limit therapeutic index. Here we describe the generation and preclinical characterization of ARX622, a site-specific TLR7-selective agonist ISAC targeting HER2. To avoid the instability issues of previous generation ADCs and ISACs, ARX622 has a homogenous and stable DAR via oxime bond-mediated payload conjugation to a synthetic amino acid, para-acetyl phenylalanine (pAF), which is recombinantly incorporated at defined heavy chain positions. Similar to cytotoxic ADCs built on this site-specific conjugation platform, ARX622 ISAC and total mAb pharmacokinetic (PK) profiles in non-human primates (NHPs) are indistinguishable, demonstrating in vivo stability and minimal payload deconjugation. Accordingly, ARX622 displays an extended PK profile in mice compared to a DAR-matched random cysteine ISAC containing the same antibody and payload. In the presence of HER2-expressing cells, ARX622 selectively induces proinflammatory cytokine production, type I and III IFN secretion, and APC maturation. In a syngeneic tumor model, ARX622 promotes complete tumor regressions, immunologic memory, and epitope spreading. In xenograft systems, single doses of ARX622 induce complete regression of large, established tumors (>1000mm3), and robustly inhibit tumor growth in mice that have progressed through prior treatment with HER2-targeted mAbs or ADCs. In HER2-low xenografts, ARX622 monotherapy inhibits tumor growth, and promotes complete regression of late-stage (800mm3) tumors when sequentially combined with a HER2-ADC. Based on PK data at efficacious doses in mice and tolerated exposures in NHP toxicity studies, ARX622 has an estimated therapeutic index of ~60x. Taken together, ARX622's mAb-like properties, high stability, broad immune mechanism induction, strong anti-tumor activity alone or in combination with ADCs, and wide therapeutic index make it a strong candidate for further development toward treating patients with a variety of HER2-expressing solid tumors.

#6353 AM105: A novel bispecific antibody with Anti 4-1BB affibodies and EGFR antibody.

D.-W. Kim, H.-J. Lee, S. Kim, M. Yoon, Y. Lee, I.-S. Hwang, Y. Lee, J.-H. Kim, J.-S. Lee;
AbClon, Inc., Seoul, Korea, Republic of

T cell engaging bispecific antibodies have emerged as promising treatments for hematologic malignancies. While most antibodies are CD3-based, offering therapeutic benefits, they are often associated with severe side effects and limited efficacy in solid tumors. To address these challenges, we present AM105, a groundbreaking anti 4-1BB affibodies based bispecific antibody designed to target EGFR. We carefully engineered AM105 with distinct binding affinities for EGFR (KD = 1.8 nM) and 4-1BB (KD = 60 nM), favoring EGFR binding. Affibody specificity was confirmed through a cross-reactivity test with proteins of TNF-receptor superfamily and 21 cell lines expressing 4-1BB or not. In cytotoxicity assays, AM105 exhibited superior tumor cell killing compared to cetuximab, particularly in EGFR-expressing cell lines. Notably, AM105 displayed remarkable efficacy in cell lines harboring RAS and/or BRAF mutations, traditionally unresponsive to EGFR-targeting treatments. In vivo experiments utilizing humanized 4-1BB mice demonstrated AM105's exceptional tumor cell elimination compared to cetuximab. The anti-tumor effects persisted even in the face of new tumor cell introductions, suggesting the induction of T cell memory function. Our findings collectively establish AM105 as a potent therapeutic agent with strong anti-tumor T cell activity. The unique 4-1BB based Affibodies (AffiMab format) of AM105 holds promise for addressing the limitations of current bispecific antibodies, positioning it as a potential breakthrough in cancer immunotherapy.

#6354 The HER2/4-1BB bispecific antibody, YH32367 (ABL105) demonstrates optimal efficacy and safety for HER2-expressing tumors and exhibits synergistic efficacy when combined with anti-PD-L1.

E. Lee[1], Y. Park[1], M. Choi[1], J. Shin[1], K. Kim[1], J. Park[1], J. Kim[1], K. Ahn[1], Y. Lee[2], K. Park[2], W. Son[2], D. Yeom[2], J. Eon[2], H. Lee[2], H. Jung[2], J. Won[2], S.-W. Oh[1], Y. Kim[1],

[1]Yuhan Co, Ltd., Seoul, Korea, Republic of, [2]ABL Bio Inc., Seongnam-Si, Korea, Republic of

Overexpression/amplification of the human epidermal growth factor receptor 2 (HER2) is associated with clinically aggressive subtypes in various cancers. Currently, new HER2-targeted therapy like trastuzumab deruxtecan have improved outcomes not only for HER2-positive tumors but also for HER2-low tumors. However, curing cancer patients who develop resistance to current HER2-targeted therapies or experience unwanted side effects remains a significant challenge. Therefore, there is a pressing need for more advanced treatments, and one promising approach involves combination with immunotherapy. 4-1BB (CD137) is a key costimulatory receptor expressed on activated T-cells and natural killer cells, making it a promising therapeutic target in cancer. This study presents the anti-tumor efficacy of the HER2/4-1BB bispecific antibody, YH32367 (ABL105), against both HER2-positive and HER2-low tumors. Additionally, the study suggests that YH32367 could be a viable treatment option for combination with anti-PD-1 antibody (Ab). YH32367 has been designed to overcome the challenges with HER2 resistance via tumor-directed 4-1BB agonism. YH32367 induced IFN-γ secretion and thereby eliciting tumor cell death in co-culture condition with hPBMC and HER2-expressing tumor cells. YH32367 showed superior efficacy in eradicating tumors and triggered long-term anti-tumor immunity in MC38/hHER2-bearing h4-1BB KI mouse models, compared to benchmark 4-1BB/HER2-bispecific molecule and anti-HER2 Ab. Even in HER2-low tumor, YH32367 was more effective than benchmark 4-1BB/HER2-bispecific molecule. Additionally, when YH32367 was administered in combination with anti-PD-1 Ab to h4-1BB KI mice bearing HER2-low tumors, a synergistic effect was observed, surpassing the effects of anti-PD-1 Ab alone or anti-HER2 Ab-drug conjugate. The potent anti-tumor efficacy of YH32367 was also verified in HER2 expressing tumor-bearing hPBMC humanized mice. In terms of toxicity, YH32367 demonstrates a favorable safety profile, which was confirmed through a 4-week GLP toxicity study using cynomolgus monkeys at doses of 10, 30, and 100 mg/kg. In summary, YH32367 has demonstrated significant anti-tumor effects, impacting tumor immunity in h4-1BB KI mice with HER2-low and HER2-positive tumors. Furthermore, its combination with anti-PD-1 Ab has shown synergistic efficacy, indicating that YH32367 may offer treatment options not only as a monotherapy but also in combination therapy for HER2 expressing tumors. The phase 1 dose escalation study is currently underway (NCT05523947), and a dose optimization study to determine the recommended phase 2 dose (RP2D) is scheduled for the second half of 2024.

#6355 Urokinase plasminogen activator receptor-associated protein (uPARAP) is overexpressed in human glioblastomas and is a therapeutic target for antibody-drug conjugates (ADC).

I. Gregersen[1], C. R. Lokke[1], J. B. Lange[1], P. Barkholt[1], C. Come[1], T. Broberg[1], M. M. Petersen[1], C. M. Lynch[1], D. Mumberg[1], N. Behrendt[2], L. H. Engelholm[2]; [1]Adcendo ApS, Copenhagen, Denmark, [2]The Finsen Laboratory, Copenhagen, Denmark

Background: Glioblastoma Multiforme (GBM), primarily arising in the brain's frontal and temporal lobes, is a devastating malignancy originating from astrocytes. Despite treatment advancements, the prognosis remains bleak, with a median survival of 15-18 months and a 10% five-year survival rate.Our study explored a novel targeted approach to combat this challenge. uPARAP is an endocytic receptor expressed at low levels on selected mesenchymal cell types but highly overexpressed on the majority of Soft-Tissue- and Bone Sarcomas. It internalizes fragments of collagen and transfers them to the lysosome for degradation.
Methods & Results: First, we analyzed formalin-fixed paraffin-embedded (FFPE) tumors from GBM patients through immunohistochemistry (IHC) staining. Interestingly, a majority of the samples showed strong but varying uPARAP expression. In parallel, we detected and quantified uPARAP receptor expression in GBM cell lines by flow cytometry, underscoring its potential as a therapeutic target.Next, we generated an antibody-drug conjugate (ADC) linked to monomethyl auristatin E (MMAE), a potent antimitotic agent. Confocal microscopy showed rapid internalization of the ADC in several GBM cell lines *in vitro*. Cellular cytotoxicity was demonstrated in Incucyte and Alamar Blue *in vitro* assays. Finally, anti-tumor activity of the uPARAP-ADC was studied in a GBM patient-derived xenograft (PDX) model *in vivo*, where it resulted in significant tumor regression with a tumor growth inhibition (TGI) of 92 and 97% at 3 and 6 mg/kg, respectively.
Conclusions: Our findings show that uPARAP is overexpressed on GBM tumors and that a uPARAP-targeted ADC has anti-tumor activity in a PDX model of GBM. This research provides initial evidence that uPARAP-ADCs could become a novel treatment option for this highly aggressive disease.

#6356 Novel antibody targeting tumor NKG2D ligand MIC: Preclinical studies and clinical development plan for mCRPC.

J. D. Wu[1], J. Sosman[1], M. Kocherginsky[2], A. Serritella[1], M. Hussian[1], D. J. Vanderweele[1];
[1]Northwestern University - Evanston, Chicago, IL, [2]Northwestern University, Chicago, IL

In response to genomic insults and DNA double-strand breaks, the stressed epithelial cells express the MHC I-chain related molecule (MIC) on the surface as a byproduct of activating the ATM pathway. The MIC molecule itself has no known impact on tumor survival or growth. In the context of immune microenvironment, tumor cell surface MIC can activate NK cells and co-stimulate CD8 T cells by engaging in the activating receptor NKG2D to hinder the early tumorigenesis. However, in established malignancies, in particular metastatic diseases, tumor cells shed surface MIC to release the soluble form MIC (sMIC). It has been well demonstrated that, in contrary to cell surface MIC, sMIC is highly immune suppressive by disturbing NK cell homeostasis and repolarizing NK cells function, impairing antigen-specific CD8 T cell function by downmodulating NKG2D expression and CD3z expression, and facilitating immune suppression of MDSCs and TAMs in tumor microenvironment. We have demonstrated that MIC is prevalently expressed by prostate tumor cells and significantly upregulated in mCRPC tumors. We have shown significantly elevated levels of serum sMIC in prostate cancer patients with metastatic diseases. We have developed a novel class of clinical candidate monoclonal antibody huB10G5 that can target both sMIC and surface MIC to re-invigorate both NK and CD8 T cell function and inhibit MDSCs and TAMs in preclinical models. The huB10G5 has an acceptable safety profile and is currently completing CMC for IND enabling. We hypothesize that huB10G5 is a novel immune therapeutic reagent for mCRPC patients. To test our hypothesis, we first conducted serial studies of the clinical candidate huB10G5 in pre-clinical models of prostate cancers. We found that huB10G5 can effectively induce 100% long-term tumor complete regression (CR) as low as 1.0 mg/KG. These animals are fully protected from tumor re-challenge. The anti-tumor effect is mediated by the combined action of NK and CD8 T cells. With the support of our pre-clinical efficacy and safety data, we have planned to initiate Phase I clinical trial with huB10G5 for mCRPC patients in 2024.

#6358 Arming tumor-associated macrophages to inhibit cancer progression.

J. P. Reddy[1], Z. Yu[1], R. M. Shepard[1], T. Von Schalscha[1], S. J. McCormack[2], S. M. Weis[1], D. A. Cheresh[1], H. I. Wettersten[1];
[1]University of California San Diego - UCSD, La Jolla, CA, [2]Alpha Beta Therapeutics, Camden, DE

Integrin αvβ3 is a marker of cancer progression in a range of epithelial cancers. In the 1990s, a humanized anti-αvβ3 antibody (Etaracizumab) was developed to target αvβ3+ cancer cells via NK cell-mediated cytotoxicity. While it demonstrated safety and some efficacy in clinical trials, our recent study of the immune microenvironment in αvβ3+ human epithelial tumors revealed increased tumor-associated macrophages (TAMs) but minimal NK cell accumulation. Accordingly, we re-engineered Etaracizumab to favor TAM engagement over NK cells and compared the efficacy of this antibody (ABT101) to that of Etaracizumab in various αvβ3+ epithelial cancer models. While ABT101 and Etaracizumab exhibited identical affinity for αvβ3, ABT 101 showed superior anti-tumor activity in vivo. Notably, depleting NK cells in mice had no impact on ABT101's effectiveness, while macrophage depletion completely abolished its anti-tumor activity. Interestingly, tumors in mice treated with ABT101 displayed a significant increase in TAMs. Here we define an "antigen-effector cell matching" strategy that allows for maximal anti-tumor activity for various drug resistant epithelial cancers. ABT101 will enter clinical trials for patients with drug resistant lung cancer in the first quarter of 2024.

#6359 Development of PSMA x CD3 T-cell engagers using an integrated, functional approach.

V. de Puyraimond, M. Mai, A. Amash, N. Blamey, G. Conaghan, J. Fernandes Scortecci, A. Goodman, A. Lee, I. Yu, F. von Bank, K. Caldwell, L. Clifford, I. Knarston, K. Bullock, M. Cid, C.-L. Crichlow, L. Devorkin, F. Dickson, P. Farber, S. Hannie, C. Lai, V. Li, S. K. Masterman, I. Niemietz, P. Pouliot, P. Xiang, B. C. Barnhart, **R. Tonikian**;
AbCellera, Vancouver, BC, Canada

In this study, we used a functional approach to generate CD3 T-cell engager (TCE) molecules targeting prostate-specific membrane antigen (PSMA). We present data on the robust *in vitro* characterization of T-cell activity and selection of molecules for further assessment. TCE function is dictated by the interplay between multiple factors that form the immune synapse, including binding kinetics, binding geometry, and epitopes of the CD3- and tumor-binding arms. To diversify immune synapse parameters, we engineer hundreds of bispecific molecules from highly diverse parental antibodies, and employ a high-throughput process to select molecules with desired functional properties. We applied this approach to engineer CD3 TCEs targeting PSMA. PSMA is an attractive target for the treatment of castration-resistant prostate cancer due to its high expression in prostate cancer cells and low relative expression in other tissues. We discovered hundreds of diverse, fully human PSMA-binding antibodies using high-throughput single B-cell screening and selected human/cynomolgus cross-reactive binders with a broad range of affinities and epitopes. We paired these with human/cynomolgus cross-reactive CD3-binding antibodies from our TCE platform to generate 180 bispecific PSMA x CD3 TCEs. CD3-binding antibodies covered several orders of magnitude of affinity (nanomolar to micromolar) and included binders specific for different CD3 subunits. We used high-throughput T-cell dependent cellular cytotoxicity (TDCC) and cytokine release assays to identify molecules with desired functional profiles. Bispecifics selected for further assessment had functional profiles spanning a range of properties that have been observed in clinical molecules, including potent killing and low cytokine release. To profile T-cell properties that are associated with anti-tumor immune responses, we subjected selected molecules to a battery of additional *in vitro* functional assessments, including proliferation, cytokine and chemokine production, and TDCC using cynomolgus T cells. Results demonstrate that a functional approach that begins with highly diverse CD3- and tumor-binding antibodies can generate promising TCEs with minimal need for protein engineering and optimization.

#6360 A novel CAR-NK cell therapy to target lung adenocarcinoma cells.

S. Zolov, **S. Chuikov**, S. Katkam, D. Shield, V. G. Keshamouni;
University Of Michigan, Ann Arbor, MI

Cell Adhesion Molecule (CADM1) is a Bonafede tumor suppressor with 40% of NSCLC tumors lose CADM1 expression either by loss of heterozygosity or promoter hypermethylation. The tumor suppressive ability of CADM1 is attributed to its cell adhesion function. However, we previously demonstrated that CADM1 also mediates its tumor suppression through regulation of NK-mediated immunosurveillance. In tumors that do not lose CADM1, it is expressed on cell surface and up regulated during TGF-β-induced EMT making it a biomarker for potential therapeutic targeting. Here we report the design and development of T and NK specific CAR that would specifically target lung cancer cells in CADM1 dependent manner. Anti-CADM1 single chain variable fragment (CADM1-scFv) was fused to NK or T cell specific transmembrane and co-stimulatory domains. The resulting CAR constructs were cloned into a retroviral vector, from which viral stocks were generated to transduce human and mouse cells. Next, we introduced anti-CADM1-CAR-NK construct into NK92 cell line and tested it in a cytotoxicity assay using A549-GFP-ffluc cell line as a target. We observed a significant increase in the killing of target cells with anti-CADM1-CAR-NK cells compared with non-transduced NK92 cells. This effect was significantly reduced when A549- GFP-ffluc-CADM1 KO cells were used as target. Next, we generated anti-CADM1-CAR-T cells by transducing human $CD3^{\pm}$ T-cells purified from human PBMCs. Similar to anti -CADM1-CAR-NK, anti-CADM1-CAR-T cells showed increased T-cell specific cytotoxicity in a CADM1-dependent manner. Next, we evaluated the efficacy of anti-CADM1-CAR-T cells through adoptive transfer into NSG mice xenografted with human lung adenocarcinoma cells into mouse lungs. The administration of anti-CADM1-CAR-T cells markedly reduced tumor size and enhanced the survival rate of the mice. Importantly this effect was dependent on CADM1 expression, as mice xenografted with human CADM1 KO cells showed neither tumor size reduction nor increased survival. Finally, using IHC staining, we demonstrated that anti-CADM1-CAR-T cells directly target xenografted tumors in the mouse lungs. In conclusion, our findings indicate that CAR-NK and CAR-T cells targeting CADM1-expressing lung tumors have a significant therapeutic potential for the treatment of NSCLC.

#6361 KY-HC-mouse: A low-cost and rapid nanobody discovery platform.

G. Wu, F. Hao, F. He, H. Peng, Y. Gu, J. Ning;
Kyinno Biotechnology Co., Ltd, Beijing, China

Nanobodies, primarily derived from camelid animals, have gained prominence in antibody-drug development due to their small molecular weight and ease of modification. However, the high cost associated with camelid animals for nanobody discovery led us to develop a strain of heavy-chain mice known as KY-HC-mouse. This genetically modified mouse expresses IgG without the CH1 domain, resulting in the production of nanobodies in IgG format. Utilizing hybridoma techniques, we developed a variety of nanobodies against multiple targets, such as PSMA, CD38, PD-L1, CD28, and 4-1BB, from KY-HC-mouse. These nanobodies all demonstrate high affinity, with KD ranging from 0.01 nM to 10 nM. We also selected antagonist nanobodies that block the interaction of PD1 and PDL1, as well as agonist nanobodies that stimulate 4-1BB signaling in T cells. After humanization, most nanobodies have a half-life of more than five days in the blood of both mice and monkeys. Subjected to various treatments, such as high concentration, low pH, repeated freezing and thawing, and high temperature, most humanized nanobodies show neither aggregation nor degradation, suggesting good developability of these nanobodies. Finally, we have developed multiple bispecific antibodies (BsAbs) targeting both PDL1 and 4-1BB, PSMA and 4-1BB, or B7H3 and 4-1BB. These BsAbs exhibit good developability and efficacy. In conclusion, our KY-HC-mouse is a powerful nanobody discovery platform.

#6362 The bispecific antibody KA-3002, targeting PSMA and 4-1BB, specifically enhances T cell activity within prostate tumors.

G. Wu, J. Liang, H. Peng, F. Hao, T. Liu, J. Ning;
Kyinno Biotechnology Co., Ltd, Beijing, China

Cancer immunotherapy with 4-1BB agonists has faced limitations in further clinical development due to dose-limiting toxicity. PSMA, highly expressed in normal prostate tissue and prostate cancer, is a clinically validated target for prostate cancer treatment. In this study, we developed a bispecific antibody (BsAb), KA-3002, targeting PSMA and human 4-1BB, with the aim of restricting 4-1BB stimulation to the interior of tumors. KA-3002 was developed based on our nanobody antibody discovery platform. KA-3002, in IgG1 format, features mutations in the Fc domain to eliminate ADCC, ADCP, and CDC activity. It contains two identical nanobodies at the C-terminal against 4-1BB to stimulate 4-1BB signaling in T cells and binds to PSMA with two Fabs at the N-terminal. KA-3002 exhibits high avidity binding to prostate tumor cells expressing PSMA (EC50<1nM) and also binds to 4-1BB expressed on 293T cells and activated human T cells. In the presence of a low concentration of CD3 antibody to stimulate T cell activation, co-culture of tumor cells expressing PSMA with primary T cells isolated from human PBMC enhances T cell activation and proliferation. In PBMC humanized immunodeficient mouse tumor models, KA-3002 effectively suppresses the growth of 22Rv1 tumors, which highly express PSMA. The antibody also demonstrates a half-life of more than five days in the blood of Balb/c mice. Finally, we assessed the developability of this antibody with different treatments such as high concentration, low pH, repeated freezing and thawing, and high temperature. KA-3002 shows neither aggregation nor degradation. In conclusion, the BsAb KA-3002, developed with our nanobody antibody discovery platform, emerges as a promising pre-clinical candidate drug for the treatment of prostate cancer.

#6363 The biparatopic antibody KA-3005 against MET is suitable for developing antibody-drug conjugates (ADCs) to treat MET-expressing cancers.

G. Wu, J. Liang, H. Peng, F. Hao, T. Liu, J. Ning;
Kyinno Biotechnology Co., Ltd, Beijing, China

MET is overexpressed in a significant fraction of lung (25%-50%) and gastroesophageal cancers, making the targeting of MET with an antibody-drug conjugate (ADC) an attractive approach. Here, we developed a bispecific antibody (BsAb) named KA-3005, targeting two different epitopes within the extracellular domain of MET using our common light chain antibody discovery platform. KA-3005 has a regular antibody structure with an identical light chain, developed using knob-into-hole technology. This antibody exhibits significantly higher avidity to MET expressed on tumor cells, with an EC50 of less than 0.1nM compared to its parent antibodies. It also completely blocks the binding of HGF to MET and the MET downstream pathway at a concentration as low as 1nM. This biparatopic antibody demonstrates a faster internalization rate upon binding to the surface of tumor cells expressing MET than its parent antibodies. KA-3005 effectively suppressed the growth of HCC827-HGF tumors in a xenograft mouse model. Additionally, it has a half-life of more than five days in the blood of Balb/c mice. Finally, we assessed the developability of KA-3005 under different treatments such as high concentration, low pH, repeated freezing and thawing, and high temperature, and it showed neither aggregation nor degradation. In conclusion, this biparatopic antibody, KA-3005, developed with our common light chain antibody discovery platform, is stable and holds potential for the development of ADCs targeting MET.

#6364 The bispecific antibody KA-3006 against both EGFR and MET surpasses amivantamab in efficacy.

G. Wu, J. Liang, H. Peng, F. Hao, T. Liu, J. Ning;
Kyinno Biotechnology Co., Ltd, Beijing, China

A bispecific antibody (BsAb) like amivantamab, which targets both the epidermal growth factor receptor (EGFR) and mesenchymal-epithelial transition factor (MET) by blocking downstream pathways, has been proven to overcome resistance to targeted therapies, including EGFR inhibitors, in patients with various cancers. In this study, we developed a bispecific antibody, KA-3006, targeting both EGFR and MET using our common light chain antibody discovery platform. KA-3006 has a regular antibody structure with an identical light chain, developed through knob-into-hole technology. It exhibits high affinity for MET and relatively low affinity for EGFR. KA-3006 specifically blocks both the binding of EGF to EGFR and HGF to MET with higher efficiency than amivantamab, resulting in the blockade of downstream signaling from EGFR and MET. In comparison to amivantamab, KA-3006 demonstrates a faster internalization rate when binding to the surface of tumor cells expressing both EGFR and MET. KA-3006 showed superior antitumor activity over amivantamab in the HCC827-HGF in vivo model. Additionally, KA-3006 has a half-life of more than five days in the blood of Balb/c mice. Finally, we assessed the developability of this BsAb with different treatments such as high concentration, low pH, repeated freezing and thawing, and high temperature, and KA-3006 showed neither aggregation nor degradation. In conclusion, the BsAb KA-3006, developed with our common light chain antibody discovery platform, is a promising pre-clinical candidate drug for the treatment of various solid cancers with overactivated EGFR and MET signaling, and it holds potential for developing ADCs targeting both EGFR and MET.

#6365 The bispecific antibody KA-3008, targeting both EGFR and B7H3, increases internalization and minimizes on-target, off-tumor toxicity.

G. Wu, L. Ding, H. Peng, F. Hao, F. He, J. Ning;
Kyinno Biotechnology Co., Ltd, Beijing, China

EGFR and B7H3 are highly expressed in various solid tumors, as well as in different normal tissues. Targeting EGFR or B7H3 alone with inhibitory monoclonal antibodies or antibody-drug conjugates (ADCs) may result in on-target, off-tumor toxicity. In this study, we developed a bispecific antibody (BsAb) named KA-3008, targeting both EGFR and B7H3 using our common light chain antibody discovery platform. KA-3008, in IgG1 format, features a regular antibody structure with an identical light chain, developed through knob-into-hole technology. Compared to its parent antibodies, its affinities for both EGFR and B7H3 decrease by more than ten times. It binds to cell lines expressing EGFR or B7H3 alone with an EC50 of more than 10nM, while it binds to cell lines expressing both EGFR and B7H3 with an EC50 of less than 1nM. KA-3008 also blocks the binding of EGF to EGFR and increases internalization when binding to both EGFR and B7H3 compared to binding to EGFR or B7H3 alone. In human tumor mouse models, KA-3008 effectively suppresses the growth of NCI-H1568 tumors expressing both EGFR and B7H3, but does not affect the growth of MS751 tumors that only highly express EGFR with low expression of B7H3. Additionally, KA-3008 has a half-life of more than five days in the blood of Balb/c mice. Finally, we assessed the developability of this BsAb with different treatments such as high concentration, low pH, repeated freezing and thawing, and high temperature, and KA-3008 shows neither aggregation nor degradation. In conclusion, the BsAb KA-3008, developed with our common light chain antibody discovery platform, is stable and holds potential for the development of ADCs targeting both EGFR and B7H3.

#6366 The triple-specific antibody KA-3009 against EGFR, B7H3, and 4-1BB specifically enhances T cell activity within the tumor.

G. Wu, T. Liu, J. Liang, H. Peng, F. Hao, J. Ning;
Kyinno Biotechnology Co., Ltd, Beijing, China

Cancer immunotherapy with 4-1BB agonists faces limited further clinical development due to dose-limiting toxicity. Moreover, EGFR and B7H3 are highly expressed in various solid tumors, as well as in different normal tissues. In this study, we developed a trispecific antibody, KA-3009, targeting EGFR, B7-H3, and human 4-1BB, with the aim of restricting 4-1BB stimulation within tumors. KA-3009 was developed based on our common light chain bispecific antibody discovery platform and nanobody antibody discovery platform using knob-into-hole technology. It is in IgG1 format with mutations in the Fc domain to eliminate ADCC, ADCP, and CDC activity. Featuring two identical nanobodies at the C-terminal against 4-1BB, KA-3009 binds to EGFR and B7H3 respectively with two Fabs at the N-terminal, sharing an identical light chain. KA-3009 exhibits low avidity binding to tumor cells expressing only EGFR or B7H3, while binding to tumor cells co-overexpressing EGFR and B7H3 with increased avidity by more than ten times. Additionally, KA-3009 binds to 4-1BB expressed on 293T cells and activated human T cells. In the presence of a low concentration of CD3 antibody to stimulate T cell activation, co-culture of tumor cells co-expressing EGFR and B7H3 with primary T cells isolated from human PBMC enhances T cell activation and proliferation. In PBMC humanized immunodeficient mouse tumor models, KA-3009 effectively suppresses the growth of NCI-H1568 tumors expressing both EGFR and B7H3 but does not affect the growth of MS751 and NCI-H661 tumors, which only express EGFR or B7H3, respectively. Moreover, KA-3009 has a half-life of more than five days in the blood of Balb/c mice. Finally, we assessed the developability of this antibody with different treatments such as high concentration, low pH, repeated freezing and thawing, and high temperature, and KA-3009 shows neither aggregation nor degradation. In conclusion, the triple-specific antibody KA-3009, developed with our common light chain antibody discovery platform and nanobody antibody discovery platform, is a promising pre-clinical candidate drug for the treatment of different solid cancers that co-overexpress EGFR and B7H3.

#6370 Evaluating the risk of carcinomas among children with congenital anomalies: A population-based study of 21 million births.

J. M. Schraw[1], T. A. Desrosiers[2], T. M. Chambers[1], M. E. Scheurer[1], C. J. Shumate[3], W. N. Nembhard[4], M. M. Yazdy[5], E. Nestoridi[5], A. E. Janitz[6], J. Tanner[7], R. S. Kirby[7], J. L. Salemi[7], C. D. Huff[8], S. E. Plon[1], P. J. Lupo[1];
[1]Baylor College of Medicine, Houston, TX, [2]University of North Carolina at Chapel Hill, Chapel Hill, NC, [3]Texas Department of State Health Services, Austin, TX, [4]University of Arkansas for Medical Sciences, Little Rock, AR, [5]Massachusetts Department of Public Health, Boston, MA, [6]University of Oklahoma Health Sciences Center, Oklahoma City, OK, [7]University of South Florida, Tampa, FL, [8]University of Texas MD Anderson Cancer Center, Houston, TX

Background: Carcinomas in childhood are rare, limiting our understanding of their epidemiology. While congenital anomalies are one of the strongest risk factors for childhood cancer overall, their association with carcinomas is understudied. We evaluated the associations between chromosomal and non-chromosomal congenital anomalies and risk of carcinoma through age 18 years.
Methods: We leveraged the Genetic Overlap Between Anomalies and Cancer in Kids (GOBACK) Cohort, which includes linked data from population-based birth defects and cancer registries for 21 million births between 1990-2018 in nine U.S. states. We used Cox regression to estimate the hazard ratio (HR) and 95% confidence interval (CI) for the hazard of carcinomas among children with major congenital anomalies relative to children without these conditions, adjusting for sex, state of birth, and maternal age. We performed sensitivity analyses excluding cases diagnosed with carcinomas during the first 2 years of life to assess the potential impact of incidental discovery of anomalies during cancer diagnosis or treatment on our findings.
Results: Our study population numbered 21,829,628 children, including 635,632 with major anomalies and 879 with carcinomas (incidence rate: 4.2 per million person-years). Mean follow-up time was 9.6 years. The most common diagnoses were thyroid (N=600 cases) and hepatocellular carcinoma (HCC; N=68 cases). Prevalence of major anomalies was 4.0% in children with carcinomas and 2.9% in children without carcinomas. The hazard of carcinomas was increased for both children with chromosomal or genetic syndromes (HR 5.3, CI 2.6-10.6; N=8) and children with non-syndromic anomalies (HR 1.6, CI 1.2-2.4; N=31). When we evaluated carcinomas by type, we observed associations between 1) chromosomal or genetic syndromes and renal cell carcinoma (HR 57.8, CI 20.7-161.3; N<5), 2) non-syndromic congenital anomalies and HCC (HR 3.8, CI 1.6-8.8; N=6), and to a lesser degree, 3) non-syndromic congenital anomalies and thyroid carcinoma (HR 1.4, CI 0.9-2.2; N=17). Notably, sensitivity analyses suggested associations were not attributable to incidental discovery of anomalies during cancer diagnosis or treatment.
Discussion: In this comprehensive assessment of congenital anomalies and carcinomas in children, we report novel associations. The observed associations between congenital anomalies and carcinoma could be due to factors including: 1) common genetic pathways; 2) *in utero* exposures that lead to both conditions; or 3) postnatal exposures among children with congenital anomalies. Ultimately, our findings could yield new insights into the etiologies of carcinomas in childhood and inform clinical surveillance practices for children with congenital anomalies.

#6371 Prenatal exposure to medication and risk of childhood cancer - A systematic review and meta-analysis.

A. Lubtow, M. Marron, **R. Nagrani**, W. Ahrens, L. Brackmann;
Leibniz Institute for Prevention Research and Epidemiology - BIPS, Bremen, Germany

The use of medication during pregnancy carries a potential health risk for the unborn child. However, the majority of drugs examined in previous observational studies have shown inconsistent results with the risk of childhood cancer, and these findings have not been consolidated in drug-specific meta-analyses. To address this gap, a systematic search was conducted in the databases PubMed and Science Citation Index for studies on medication use during pregnancy and the risk of childhood cancer. Studies with exposure to diethylstilbestrol as a known teratogen were excluded. Meta-analyses with estimates for random effects models with 95% confidence intervals were conducted, if at least three studies on the same research question were available. The I^2 statistic was calculated to quantify between-study heterogeneity. Statistical significance of I^2 was analyzed with the Q statistic (*P* value for heterogeneity (*P*)). Study quality was summarized based on a self-developed scoring system with five items. The systematic literature search yielded 2,373 studies, of which 62 were included in the systematic review. We conducted a total of 37 analyses including exposure to 12 different types of medications during pregnancy and 13 different outcomes of childhood cancer. Pooled odds ratios (OR) showed an increased risk of acute leukemia (AL) and its subtype acute lymphoblastic leukemia (ALL) after prenatal exposure to antiemetics (AL: OR= 1.47 (95 % confidence interval 1.02; 2.14) I^2= 0.0 % *P*= 0.44; ALL: OR= 1.27 (1.01;1.59) I^2= 0.0 % *P*= 0.93) and any kind of antibiotics (AL: OR= 1.13 (1.01; 1.27) I^2= 0.0 % *P*= 0.53; ALL: OR= 1.12 (1.01; 1.24) I^2= 19.7 % *P*= 0.26). In addition, an increased risk of childhood cancer in general was observed when mothers took nitrosatable antibiotics (OR= 1.32 (1.14; 1.53) I^2= 0.0 % *P*= 0.97). Finally, the use of analgesics (OR= 1.40 (1.00; 1.95) I^2= 43.8 % *P*= 0.15) during pregnancy was associated with an increased risk of neuroblastoma in the offspring. All these analyses did not reveal any indications of heterogeneity between the analyzed studies. The remaining 31 analyses showed no association. Our results suggest that the use of nitrosatable antibiotics during pregnancy may be associated with an increased risk of childhood cancer. Maternal intake of antibiotics and antiemetics may increase the risk of AL and ALL in their children. An increased risk of childhood neuroblastoma could be associated with prenatal exposure to analgesics. However, the underlying disease of the mother, which is treated with the investigated medication, could be the actual reason for the development of childhood cancer in the offspring.

#6372 Germline pathogenic variants are enriched in pediatric central nervous system tumor patients and associate with somatic functional consequences.

R. J. Corbett[1], R. Kaufman[1], S. W. McQuaid[2], Z. Vaksman[1], S. Phul[1], M. A. Brown[1], J. L. Mason[1], H. Desai[3], R. Hausler[3], A. S. Naqvi[1], A. Chroni[1], Z. Geng[1], B. Zhang[1], C. Zhong[1], Y. Zhu[1], A. P. Heath[1], M. Li[1], Penn Medicine BioBank, P. B. Storm[1], A. C. Resnick[1], K. N. Maxwell[3], M. Bornhorst[4], K. A. Cole[1], A. J. Waanders[2], S. P. MacFarland[1], J. [1]Children's Hospital of Philadelphia, Philadelphia, PA, [2]Ann & Robert H. Lurie Children's Hospital of Chicago, Chicago, IL, [3]University of Pennsylvania, Philadelphia, PA, [4]Children's National Hospital, Washington, DC, DC

The genetic contribution of rare pathogenic germline variation to central nervous system (CNS) tumor formation in pediatric patients without a family history of cancer remains unclear. We sought to characterize the prevalence, spectrum, and clinical significance of pathogenic germline variation in cancer predisposition genes (CPGs) in 838 patients profiled in the Pediatric Brain Tumor Atlas (PBTA) by whole genome sequencing (n=821) or whole exome sequencing (n=17). Rare variants in 214 CPGs were annotated as pathogenic (P) or likely pathogenic (LP) consistent with American College of Medical Genetics criteria using AutoGVP, our open-source automated pathogenicity assessment tool. To assess enrichment of P/LP variants in the PBTA, we compared the frequency of CPG P/LP variants in cases to a tumor-free control cohort from Penn Medicine BioBank (PMBB; n=6,295). Somatic alterations, mutational signatures, and gene set enrichment analyses from matched tumor sequencing were integrated to characterize functional consequences associated with germline pathogenic variation. We observed 215 germline P/LP variants within 76 distinct CPGs in 189 (22.6%) PBTA patients. CPG P/LP variants were most prevalent among patients with a plexiform neurofibroma diagnosis (9/14, 64.3%), and least prevalent among patients with craniopharyngioma (3/39, 7.8%). We detected syndrome-associated P/LP variants in 45/58 (77.6%) patients with a clinically reported cancer predisposition syndrome and incidentally in another 37 patients. CPG P/LP variants were significantly enriched in the PBTA cohort relative to the PMBB control cohort (OR=2.0, p=1.0E-12, CI=1.6-2.4), and *NF1* harbored the most significant excess P/LP variant burden (OR=30.7, p=4.57E-13, CI=11.2-105.1). We observed a significant enrichment of mismatch repair (MMR) gene P/LP variants in patients with high-grade gliomas (HGG) and tumors from MMR P/LP carriers exhibited significantly higher MMR-deficiency mutational signature exposures relative to tumors from non-carrier HGG patients (SBS14: W=478, p=1.71E-05). Overall, 90/215 (41.9%) of identified germline P/LP variants co-occurred with at least one corresponding somatic alteration in matched tumors, including oncogenic SNV (n=5), copy number variation (n=28), loss of heterozygosity (n=54), differential gene expression (n=23), and proximal alternative splicing (n=19). In summary, rare germline P/LP variants are enriched in PBTA patients and are associated with somatic events in the same gene, resulting in gene- and pathway-specific functional consequences. Our work emphasizes a role for pathogenic germline variation in pediatric CNS tumor development and frequent under-identification of cancer predisposition syndromes, underscoring the importance of germline sequencing in personalized patient care strategies.

#6373 Effectiveness of tumor surveillance across pediatric cancer predisposition syndromes.

M. R. Perrino[1], A. Blake[1], C. E. Morin[2], L. Taylor[1], R. B. McGee[1], S. Lewis[1], S. Hines-Dowell[1], A. Pandey[1], P. Turner[1], M. Kubal[1], Y. Su[1], L. Tang[1], L. Howell[1], L. W. Harrison[1], Z. Abramson[1], A. Schechter[1], N. D. Sabin[1], K. E. Nichols[1];

[1]St. Jude Children's Research Hospital, Memphis, TN, [2]Cincinnati Children's Hospital Medical Center, Cincinnati, OH

Background: Pediatric oncology patients are increasingly recognized as having an underlying cancer predisposing syndrome (CPS). For individuals diagnosed with a CPS, surveillance is often recommended to detect new tumors at their earliest and most curable stages. Screening is heavily based on radiologic imaging, however data on the effectiveness and outcomes of surveillance are limited.

Methods: Patients with a clinical and/or molecular CPS diagnosis, including 274 children and young adults with 35 CPS at a single specialty pediatric oncology center, were monitored using standardized surveillance protocols over an average of 3 years (range 1 month - 12 years). Patients with hereditary retinoblastoma were excluded as surveillance was completed by a separate team. The cohort included 139 patients (50.7%) with a prior tumor history while 135 (49.3%) had no prior cancer. This study reviewed tumors diagnosed, method of detection, clinical course, and patient outcomes. Individual reports from 1,533 surveillance tests including diagnostic imaging, colonoscopy, and upper endoscopy, were assessed and classified for accuracy. Sensitivity, specificity, positive predictive value (PPV), and negative predictive values (NPV) were calculated for selected surveillance methods, and themes of common strengths or weaknesses of specific imaging modalities were identified.

Results: During the study period from January 1, 2009 - September 31, 2021**,** 35 asymptomatic tumors were detected in 27 patients through surveillance (9.9% of the cohort), while five symptomatic tumors were detected in five patients (1.8%) outside of surveillance. Ten tumors (28.6%) discovered through surveillance were identified on first surveillance imaging. Among these 35 new tumors, 19 (54.3%) were diagnosed in children with a previously treated cancer, six (17.1%) were diagnosed in patients still being treated for cancer, and 10 (28.6%) were diagnosed in those with no prior cancer history. Malignant solid and brain tumors identified through surveillance were more often localized (20 of 24; 83.3%) than similar tumors detected before CPS diagnosis (71 of 125; 56.8%, $p \leq 0.0001$). Of the 24 tumors identified through surveillance and surgically resected, 17 (70.8%) had completely negative margins. When analyzed across all CPS, the sensitivity (96.4%), specificity (99.6%), PPV (95.7%), and NPV (99.6%) of surveillance testing was high, with few false positive (n=6/1,533, 0.4%) or false negative (n=5/1,533, 0.3%) reports. No invasive interventions were performed due to false positive results.

Conclusion: Patients with CPS are at increased risk of primary and secondary tumor development with 10% of our cohort developing a tumor in a short time span. Surveillance effectively enabled early detection of new brain and solid tumors across a wide spectrum of CPS which allowed for complete surgical resection and successful treatment in most cases.

#6374 Socio-demographic predictors of recruitment in neuroblastoma therapeutic clinical trials.

D. Hunter-Schlichting, J. Sample, K. Knowles, D. Van Riper, L. Spector, E. Marcotte;
University of Minnesota, Minneapolis, MN

The generalizability of clinical trial outcomes hinges upon the equitable access and enrollment of diverse patient populations. Yet, disparities persist that may influence enrollment patterns. In neuroblastoma, the impact of ethnicity, socioeconomic status (SES), distance to care, and age at diagnosis on enrollment in therapeutic trials remains underexplored. We aimed to investigate these factors in neuroblastoma patients to identify potential disparities in clinical trial participation. We utilized the Childhood Cancer Research Network data, selecting neuroblastoma cases from 2008-2015, excluding those >21 years old or with incomplete data. We focused on factors influencing enrollment in therapeutic trials (ANBL0032, ANBL0421, ANBL0531, ANBL0532, ANBL0621, ANBL0931, ANBL1021, ANBL1221, ANBL1232). Key predictors examined were ethnicity, age at diagnosis, SES (via Yost Index), and distance to care from home to treatment hospital. We employed Poisson regression to calculate adjusted risk ratios (aRR) and 95% confidence intervals for trial participation. Analyzing 3,148 neuroblastoma cases from the CCRN registry, the ethnic composition was as follows: 68% were non-Hispanic White, 14% Hispanic, and 10% NH Black and SES distribution was even across quintiles. Age at diagnosis was a significant factor in trial enrollment: children >2 years were 94% more likely to enroll than those under 2 years ($p < 0.001$). Race, ethnicity, SES, and distance to care showed no significant effect on enrollment, all with non-significant p-values. In CCRN, neuroblastoma patient's age at diagnosis was a determinant in therapeutic trial enrollment, providing insight into design strategies to encourage trial participation. While common barriers like race, ethnicity, SES, and distance to care did not impact enrollment in our cohort, the significant role of age highlights an area where focused efforts can ensure that all age groups have equitable access to the potential benefits of therapeutic trials.

Category		**N**	**aRR (95% CI)**	**p-value**
Race and Ethnicity	Non-Hispanic (NH) White	2139	ref

#6375 Genetic testing station increases access to germline genetic testing.

C. Hamilton[1], M. Niell Swiller[1], F. Bhansali[2], A. Hoover[1], S. Bottomley[1], M. Lewis[1], B. Russell[1], J. A. Martinez[1], B. Karlan[1], N. Federman[1], V. Y. Chang[1]; [1]University of California, Los Angeles, Los Angeles, CA, [2]Kaiser Pernanente Northwest, Vancouver, WA

Despite evidence of clear benefit, genetic testing of pediatric oncology patients for germline variants remains rare due to a variety of factors, including insurance/financial barriers, limited knowledge about genetic testing, and competing interests for time and resources. Limited access to genetic testing, pre-test counseling and multidisciplinary care have been shown to disproportionately affect patients with limited resources. This represents a critical unmet need in pediatric oncology. Genetic testing station (GTS) is a pre-test counseling video tool that reviews what genetic testing is, why it might be indicated, and explains potential results. Similar video tools have been successfully used in other settings to increase rates of genetic testing, but there are no published reports on the effectiveness of a video education intervention to increase genetic testing in pediatric oncology patients. To test the effectiveness of GTS on genetic testing knowledge and feelings about genetic testing compared to in-person counseling, we use 5 previously validated tools pre- and post-intervention. The initial surveys measure genetic testing knowledge, decisional conflict, healthy literacy, evaluation of GTS and demographics. If participants complete genetic testing, we use the MICRA to assess the impact on their cancer risk assessment. Our GTS arm is recruited from UCLA Pediatric Sarcoma patients, and the in-person counseling arm is recruited from the UCLA Cancer Predisposition clinic. We have recruited 28 participants in the GTS arm and seven in the in-person counseling arm, of which 10 are patients over 18 years old, two are patients between 12-17 years old, and 23 are parents. In our GTS arm, there are 20 female and eight male participants. A majority identify as white or Latino. For the in-person counseling arm, there are four male and three female participants who identify as white, Middle Eastern, or Latino. A similar percentage score with high health literacy, 68% in the GTS arm and 71% for the in-person counseling arm. The majority of patients have no decisional conflict pre- or post-intervention for the GTS group, while the in-person counseling arm shows high initial decision conflict that is fully resolved with counseling. There is a statistically significant increase in genetic testing knowledge for five out of 10 questions comparing pre- and post-GTS. For GTS participants who have completed genetic testing and the MICRA, there is overall low distress and uncertainty, but higher scores for parents than adult or minor patients. In conclusion, there has been high interest in germline genetic testing in pediatric oncology patients with all families deciding to pursue genetic testing after viewing GTS. GTS is an effective tool in increasing genetic testing knowledge in participants. Therefore, GTS is a promising approach to increase access to genetic testing, while providing adequate pre-test counseling and no decisional conflict.

#6376 Establishment of the Consortium for Childhood Cancer Predisposition and the Childhood Cancer Predisposition Study.

A. Villani[1], G. M. Brodeur[2], L. R. Diller[3], C. Edgerton[4], J. Kamihara[3], W. Kohlmann[5], S. P. MacFarland[2], L. Maese[5], D. Malkin[1], K. E. Nichols[6], M. R. Perrino[6], S. E. Plon[7], S. Rednam[7], **C. C. Porter**[4];

[1]The Hospital for Sick Children, University of Toronto, Toronto, ON, Canada, [2]Children's Hospital of Philadelphia, University of Pennsylvania, Philadelphia, PA, [3]Dana-Farber/Boston Children's Cancer and Blood Disorders Center, Harvard Medical School, Boston, MA, [4]Children's Healthcare of Atlanta & Emory University, Atlanta, GA, [5]Huntsman Cancer Institute, University of Utah, Salt Lake City, UT, [6]St. Jude Children's Research Hospital, Memphis, TN, [7]Texas Children's Hospital, Baylor College of Medicine, Houston, TX

Background: Genetic predisposition contributes to a much higher proportion of cancer in children than previously appreciated. This creates a unique opportunity to develop improved methods to identify children at increased risk for cancer, enable early detection or prevention of tumors, and improve cure rates with decreased morbidity. However, several challenges have impeded successful research and systematic approaches to the care of children with cancer predisposition.

Methods: We established the Consortium for Childhood Cancer Predisposition (C^3P), currently comprised of seven large pediatric institutions in North America. The long-term goal of C^3P is to improve outcomes for children with genetic susceptibility to cancer through collaborative research and data sharing. To this end, we have developed the Childhood Cancer Predisposition Study (CCPS), a multicenter registry and biorepository, to achieve three main aims: 1) Establish and maintain the infrastructure for recruitment, participation, collection and sharing of clinical data and biological samples for children with cancer predisposition syndromes (CPS); 2) Define the spectrum of disease in children with CPS and explore the unique characteristics and management approaches of CPS-related tumors compared to their sporadic counterparts; and 3) Evaluate the clinical impact and effectiveness of standard and emerging tumor surveillance strategies.

Results: The CCPS opened to enrollment in May, 2021 and is currently recruiting at 3 member sites. To date, 276 primary subjects and 44 family members have been enrolled, 211 in the last year. In total, 37 different cancer predisposition diagnoses are represented among participants, including those that are more prevalent, e.g., Li-Fraumeni syndrome (n=42), DICER1 syndrome (n=27), and PTEN Hamartoma Syndrome (n=21), and those which are very rare, e.g., Rothmund-Thomson syndrome (n=2). There is excellent uptake on obtaining samples, with the CCPS Biorepository at Emory University receiving biospecimens from 261 subjects to date, including constitutional DNA (n=261), frozen peripheral blood mononuclear cells (n=32), and plasma samples for ctDNA analysis (n=26).

Conclusions: C^3P has established the infrastructure to facilitate comprehensive collaborative work to improve outcomes for children with cancer predisposition, which represent a wide variety of disorders. Future efforts will include the development of innovative strategies to promote recruitment beyond the primary C^3P sites and the support of additional clinical and biological studies of specific CPS.

#6377 UNC AYA Cancer Program: Reach and influence on cancer care delivery.

J. N. Stein[1], D. M. Ritzwoller[1], A. C. Wardell[1], E. R. Haines[2], B. Thom[1], L. Lux[1], A. B. Smitherman[1];

[1]University of North Carolina Chapel Hill, Chapel Hill, NC, [2]Wake Forest University School of Medicine, Wake Forest, NC

Category:

Cancer Disparities and Inequities Research

Purpose of the study

Adolescent and young adults (AYAs, aged 13-39) with cancer face barriers to care and stagnant outcomes. National groups have called for the development of AYA-specific programs, yet how these programs influence outcomes remains largely unexplored. With a dedicated AYA Cancer Program at the University of North Carolina (UNC) since 2015, we conducted a retrospective study to describe the AYA population and compare outcomes between those receiving program support and those who did not.

Methods

Linking electronic health records and NC Cancer Registry data, we defined a cohort of AYA patients who received cancer treatment at UNC from 2014-2022. We compared sociodemographic, clinical, utilization, and supportive care measures for those who received AYA Program contact and those who did not. Chi-square and two-group t-tests were used for comparison.

Results

Of 4044 AYAs receiving care at UNC, 670 engaged with our AYA Program (**Table 1**). Program-contacted patients were younger at diagnosis, more likely to be Black, have metastatic disease or hematologic malignancies, and more likely to receive systemic therapy. Program patients had increased clinical trial enrollment, more palliative care and fertility counseling.

Conclusions

Our findings suggest AYAs contacted by our program represent a distinct population with higher clinical and social needs. Despite higher rates of acute care events and no-shows, they were more likely to receive guideline-recommended care - clinical trial enrollment, fertility counseling, and palliative care. Future analyses will compare outcomes using adjusted modeling, and track trends over time. Results will inform next steps for the UNC AYA Cancer Program and other centers aiming to improve care delivery for AYAs.

Table 1. Notable results for AYAs with and without program contact

		AYA Program Contact (n=670)	No AYA Program Contact (n=3374)	P value
Age at diagnosis	Mean years	27	31	<0.01
Sex	Female	55%	61%	0.02
	Male	45%	39%	
Race	White	56%	61%	<0.01
	Black	26%	20%	
	Other	18%	16%	
Ethnicity	Hispanic	13%	12%	0.29
	Non-Hispanic	86%	84%	
Marital Status	Married/Partnered	34%	42%	<0.01
	Not Married	65%	51%	
Cancer Type	Solid	54%	87%	<0.01
	Hematologic	46%	13%	
Stage	Metastatic	52%	18%	<0.01
Treatment	Chemotherapy	85%	37%	<0.01
	Radiotherapy	6%	12%	
	Immunotherapy	18%	9%	
Clinical Trial Enrollment		45%	26%	<0.01
No-Shows	Mean	7	4	<0.01
Supportive Care	Palliative care visits	19%	3%	<0.01
	Advance Care Planning	14%	5%	
	Fertility visit	18%	2%	
	Hospice enrollment	3%	0.7%	
Complications	ED visit	68%	48%	<0.01
	Unplanned hospitalization	63%	29%	

#6378 Systems-level immunomonitoring in children with solid tumors.

Q. Chen[1], **B. Zhao**[1], Z. Tan[1], G. Hedberg[1], J. Wang[1], L. Gonzalez[1], C. Mugabo[1], A. Johnsson[1], L. Paez[1], L. Rodriguez[1], A. James[1], Y. Chen[1], J. Mikes[1], H. Barcenilla[1], C. Wang[2], M. M. Davis[2], L.-M. Carlson[1], N. Pal[1], N. Herold[1], K. Blomgren[1], D. Repsilber[3], T. Lakshmikanth[1], P. Kogner[1], L. Ljungblad[1], P. Brodin[1]; [1]Karolinska Institutet, Stockholm, Sweden, [2]Stanford University School of Medicine, Stanford, CA, [3]Orebro University, Orebro, Sweden

Background: Cancer is the leading cause of death from disease in children. Curing cancer requires cytostatic drugs and radiation, as well as systemic immune responses to clear malignant cells. Determinants of such responses in children of different ages and with different tumors are unknown. Novel immunotherapies can potentiate anti-tumor immune responses, but so far, very few children with solid tumors have benefitted and markers of productive anti-tumor immune responses in children are lacking.

Methods: 119 children at the Section for Pediatric Oncology, Astrid Lindgren Children's Hospital, Karolinska University Hospital in Stockholm, Sweden, diagnosed with solid tumors were recruited to Immune Systems Against Cancer in Children (ISAC) cohort from March 2018 to April 2021. Whole blood samples were collected for immune cell composition (Mass cytometry), plasma protein abundances (Olink assays), transcriptomics, and clonality analysis. Whole genome sequencing data from tumor tissue of children included in the ISAC cohort was obtained from the Swedish Childhood Tumor Biobank and was used for mutational load and signatures analysis.

Results: We find that the variation among systemic immune system states is determined predominantly by tumor type, and not age or sex as is the case among healthy children. We also show that specific groups of tumors elicit similar immune response states, which could inspire future updates to treatment protocols for such cancers. This illustrates the potential of this unbiased approach and inclusion of children with diverse solid tumors, whereby shared patterns can lead to novel hypotheses regarding underlying mechanisms among groups of patients, rarely considered together in more reductionist studies of individual tumor types. We also report that general, as well as specific, mutational profiles of neuroblastomas are associated with specific differences in immune responses and finally, we show that clonally expanded T cell responses are rarely observed at baseline in children but can be elicited by successful treatments and monitored as biosensors of therapeutic responses enabling precision oncology in the future. Such monitoring should be considered a complement to the already established precision medicine approaches based on tumor genetics.

Conclusions: Our findings suggest the importance of systemic immunity in coordinating and sustaining immune responses against tumors, but also that the developmental changes in human immune systems must be considered when developing and applying new immunotherapeutic interventions for children of different ages with various tumors. Our findings could also inspire the development of future strategies to trigger more productive immune responses against tumors in children.

#6379 Comparison of lipid profiles in children with solid tumors receiving chemotherapy and healthy children.

J. Bai[1], M. Houser[1], M. Martin[2], C. Powell[2], K. Maner-Smith[1], K. S. Sutton[1], T. Olson[1], D. W. Bruner[1];
[1]Emory University, Atlanta, GA, [2]Children's Healthcare of Atlanta, Atlanta, GA

Background: Lipid metabolism plays an important role in the regulation of synaptic function and plasticity.Cancer chemotherapy (chemo) can disturb the lipid profile, potentially linked with neuropsychological toxicities. This study aimed to compare the lipid profiles between children with cancer receiving chemo and healthy children.
Methods: A prospective, observational study was conducted in 21 children with solid tumors enrolled from Children's Healthcare of Atlanta (CHOA) and 16 controls. Children with solid tumors were consented precycle 2 chemo (T_1) and followed at the end of chemo (T_2). Controls completed one timepoint of data collection. At T_1 (n=21) and T_2 (n=13), fecal samples were collected for lipidomics analysis. Fecal lipids were processed using a high-resolution, untargeted lipidomics LC-MS approach. MetaboAnalyst and linear mixed models were used to analyze the data with false discovery rate correction (FDR 0.2).
Results: There were no significant differences in age, sex, race, and body mass index between the groups. In total 241 lipid features were identified with high confidence and analyzed. A comparison between children with solid tumors at T_2 (n=12) vs. controls (n=16) detected 8 differential lipids, which can be clustered into 4 classes, including 4 triglycerides (TG), 2 phosphatidylcholine (PC), 1 sphingomyelin (SM), and 1 lysophosphatidylcholine (LPC). Additionally, 24 differential lipids were detected for children with solid tumors from T_1 to T_2 (n=12), including 6 classes: 9 SM, 7 PC, 3 diacylglycerols (DG), 2 TG, 2 monoacylglycerols (MG), and 1 phosphatidylethanolamine (PE). Compared with controls, children with solid tumors at T_2 had higher levels of SM (e.g., SM(d36:1)) and lower levels of TG (e.g., TG(18:0/18:0/20:0)), LPC (e.g., LPC(20:4)), and PC (e.g., PC(33:4). Compared with children at T_1, those at T_2 had higher levels of SM (e.g., SM(d36:1)), PE (e.g., PE(16:0p/20:4), PC (e.g., PC(30:0), and PC(36:1)), and lower levels of TG (e.g., TG(18:0/18:0/20:0) and TG(18:0/16:0/18:0)), LPC (e.g., LPC(20:4)), DG (e.g., DG(18:0/16:0) and DG(18:0/18:0)), and MG (e.g., MG(18:0)).
Conclusion: Children with cancer chemo had alterations in fecal lipid profiles impacting the metabolism of PC, SM, TG, PE, MG, and DG. The increased PC and the dysregulation of LPC in comparison with controls suggest the decreased activity of phospholipase A2 (PLA2), primarily reported in inflammatory disease. Altered activity of lysophospholipid acyltransferase (LPCAT), diacylglyceride acyltransferase (DGAT), and phosphatidylethanolamine methyl transferase (PEMT) could also explain changes in PC and glycerolipids. Combined, these suggest dysregulation of the Kennedy or Lands pathways towards PC synthesis. Future work is needed to study whether the disturbed lipid metabolisms were associated with treatment toxicities and outcomes such as cognitive dysfunction based on literature.

#6380 Exploring immune checkpoint inhibitor-related adverse events in pediatric cancer patients: A pharmacovigilance analysis of VigiBase and the FDA adverse event reporting system (FAERS) database.

J. Shen[1], A. Lin[1], Q. Cheng[2], J. Zhang[1], P. Luo[1];

[1]Department of Oncology, Zhujiang Hospital, Southern Medical University, Guangzhou, China, [2]Xiangya Hospital, Central South University, Changsha, China

Background: With the widespread use of immune checkpoint inhibitors (ICIs) in the treatment of childhood cancers, their associated ICIs-related adverse events (irAEs) have become an important challenge. Our study was conducted to explore the pediatric high-risk ICIs-related AEs (pediatric irAEs) and explore the underlying mechanisms of pediatric irAEs.

Methods: We analyzed ICIs-related adverse reaction reports in VigiBase from 1967 to 2023 and the FDA Adverse Event Reporting System (FAERS) database from 2013 to 2022. Using three methods, the reporting odds ratio (ROR), the proportional reporting ratio (PRR), and the information component (IC), we conducted a disproportionality analysis between pediatric and adult cancer patients using ICIs to discover pediatric irAEs. Furthermore, we explored the impact of clinical factors on the occurrence of pediatric irAEs and their subsequent prognosis through univariate and multivariate logistic regression analyses. Finally, combining these data with pan-cancer transcriptome data from the Gene Expression Omnibus (GEO) database, we explored the potential biological mechanisms related to pediatric irAEs.

Results: We identified 4 categories of pediatric irAEs in the VigiBase and FAERS databases, including cytokine release syndrome ($ROR_{VigiBase}$ = 17.05; ROR_{FAERS} = 14.17), acute respiratory distress syndrome ($ROR_{VigiBase}$ = 10.26; ROR_{FAERS} = 12.39), seizure ($ROR_{VigiBase}$ = 7.18; ROR_{FAERS} = 10.63) and febrile neutropenia (FN) ($ROR_{VigiBase}$ = 3.01; ROR_{FAERS} = 4.84). The occurrence of pediatric irAEs may be related to mechanisms such as activation of immune cells, imbalance of inflammatory factors, activation of pathogen recognition, downregulation of inhibitory synapses, excitation/inhibition imbalance and central nervous system dysfunction.

Conclusion: This study systematically analyzed the high-risk irAEs that may occur after using ICIs in pediatric cancer patients. Next, we explored the possible biological mechanisms of these pediatric irAEs to provide certain theoretical guidance for the prevention and treatment of adverse reactions in pediatric cancer patients after treatment with ICIs.

#6381 Long-term kidney function after treatment for unilateral, non-metastatic, non-syndromic Wilms tumor. A report from the St. Jude Lifetime Cohort Study.

D. M. Green, M. Wang, M. J. Krasin, A. M. Davidoff, D. Srivastava, D. W. Jay, K. K. Ness, B. L. Shulkin, J. Q. Lanctot, K. C. Shelton, R. C. Brennan, M. J. Ehrhardt, S. Dixon, B. A. Kurt, L. L. Robison, M. M. Hudson, S. L. Spunt;
St. Jude Children's Research Hospital, Memphis, TN

Background: We previously reported that the estimated glomerular filtration rate (eGFR) was decreased among survivors of unilateral, non-metastatic, non-syndromic Wilms tumor (WT) treated with whole abdomen radiation therapy (WART) compared to controls, but not compared to unirradiated WT survivors (Pediatr Blood Cancer 2020;67:e28271). The impact of sex on estimates of kidney function among adult survivors of WT has not been well-documented.
Methods: We clinically evaluated male and female WT survivors with creatinine and cystatin C, calculated eGFR using the Chronic Kidney Disease - Epidemiology (CKD-EPI) equations with and without cystatin C and measured ^{99m}Tc diethylenetriamine pentaacetic acid (DTPA) plasma clearance. WT survivors consisted of 20 treated with unilateral nephrectomy (UN), non-nephrotoxic chemotherapy (NNC) and whole abdomen radiation therapy (WART) (mean - 20.2 Gray (Gy); standard deviation (SD) - 9.12 Gy), and 20 treated with UN, no radiation therapy, and NNC. Correlations between ^{99m}Tc DTPA clearance and eGFR were calculated.
Results: Among female WT survivors, none of the eGFR calculations was statistically significantly correlated with ^{99m}Tc DTPA clearance. Among male WT survivors, ^{99m}Tc DTPA clearance correlated well with eGFR calculations that included creatinine. Results are shown in the Table.
Conclusions: Among female survivors of unilateral, non-metastatic, non-syndromic WT who have undergone UN, eGFR is poorly correlated with ^{99m}Tc DTPA clearance. Evaluation of treatment-related changes in body composition may provide insight into these results.

Correlation between eGFR and 99mTc DTPA clearance

		Females		
eGFR(CKD-EPI)		^{99m}Tc DTPA clearance		
	No radiation therapy (n=13)		Whole abdomen radiation therapy(n=12)	
	Pearson correlation coefficient	p-value	Pearson correlation coefficient	p-value
Creatinine only	0.109	0.723	-0.295	0.352
Cystatin C only	0.311	0.301	0.094	0.782
Creatinine and cystatin C	0.348	0.244	-0.028	0.935
		Males		
	No radiation therapy (n=6)		Whole abdomen radiation therapy(n=6)	
	Pearson correlation coefficient	p-value	Pearson correlation coefficient	p-value
Creatinine only	0.827	0.043	0.859	0.028

Creatinine and cystatin C	0.878	0.021	0.866	0.026

#6382 Risk prediction of dyslipidemia in long-term survivors of childhood cancer: A report from the St. Jude Lifetime Cohort.

K. Petrykey[1], K. Li[1], L. Xie[1], A. Neupane[1], A. Delaney[1], C. Yu[1], S. Dixon[1], B. Ky[2], C. Im[3], I. B. Rhea[4], J. A. Towbin[1], J. N. Johnson[1], M. Bolier[5], V. G. Pluimakers[6], L. Broer[5], S. J. C. Neggers[5], M. M. van den Heuvel-Eibrink[6], R. M. Howell[7], K. K. Ness[1], M. M. Hudson[1], G. T. Armstrong[1], Y. Yasui[1], Y. Sapkota[1];

[1]St. Jude Children's Research Hospital, Memphis, TN, [2]University of Pennsylvania School of Medicine, Philadelphia, PA, [3]University of Minnesota, Minneapolis, MN, [4]University of Tennessee Health Science Center, Memphis, TN, [5]Erasmus Medical Center, Rotterdam, Netherlands, [6]Princess Maxima Center for Pediatric Oncology, Utrecht, Netherlands, [7]The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Dyslipidemia is a significant contributor to the increased risk of cardiovascular morbidity and premature mortality in long-term survivors of childhood cancer. Identifying individuals at risk at an early stage provides an opportunity for tailored prevention approaches.
Methods: Long-term childhood cancer survivors from the St. Jude Lifetime Cohort, (SJLIFE, n=2,559; median age 41 years, range 20-77 years) were directly assessed for dyslipidemia. Risk factors under consideration included demographic characteristics, cancer treatment exposures (cumulative doses of anthracyclines, platinum agents, glucocorticoids, and radiation therapy), comorbid conditions at the time of assessment (hypertension, diabetes mellitus, growth hormone deficiency, hypogonadism, hypothyroidism, cardiomyopathy, and chronic kidney disease), and externally validated multi-ancestry general-population polygenic risk scores (PRSs) for lipid values (total cholesterol, LDL-C, HDL-C, and triglycerides). Multivariable logistic regression predicted a 15-year risk of dyslipidemia (CTCAE grade ≥2 hypercholesterolemia and/or hypertriglyceridemia) including variables selected by the stepwise approach. Performance of the model was assessed by the area under the receiver operating characteristic curve (AUC).
Results: Dyslipidemia was clinically identified in 543 (25.1%) SJLIFE survivors. AUC of a clinical model with sex, race, age at prediction, and comorbid conditions (diabetes, growth hormone deficiency, hypogonadism, hypothyroidism, and hypertension) was 0.80 (95% CI, 0.78-0.82). Inclusion of cancer treatment exposures (cumulative doses of anthracyclines, cisplatin, carboplatin, glucocorticoids, abdominal and cranial radiation therapy) significantly increased AUC to 0.82 (95% CI, 0.80-0.84; $P=2.1\times10^{-4}$). Addition of two PRSs for LDL-C (one included only genome-wide significant variants adjusted for statins and another consisted of all genome-wide variants) and the PRS for triglycerides provided further significant improvement in AUC to 0.86 (95% CI, 0.84-0.88; $P=4.2\times10^{-12}$).
Conclusions: We developed a prediction model with good performance for identifying the risk of dyslipidemia in childhood cancer survivors. In addition to demographics and comorbidities, cancer treatments and inherited genetic factors contributed significantly to improving the risk prediction of dyslipidemia. Results may refine risk stratification for dyslipidemia in survivors and present opportunities for more precise and personalized preventive strategies to address cardiovascular health. Independent validation in survivors from the Childhood Cancer Survivor Study and the Dutch Childhood Cancer Survivor Study (DCCSS)-LATER is currently underway.

#6383 Targeting radiation-induced fibrosis: Exploring promising therapeutic avenues and innovative assessment methods.

P.-A. Bissey[1], L. Massignan[2], R. Mancini[2], W. Shi[1], J. Williams[1], M. Reed[2], K. W. Yip[1], F.-F. Liu[1];

[1]Research, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada, [2]Centre for Medicinal Chemistry and Drug Discovery, Krembil Research Institute, University Health Network, Toronto, ON, Canada

Introduction: Radiation therapy is a vital cancer treatment for nearly 50% of patients, yet it poses a significant challenge in the form of radiation-induced fibrosis (RF). RF affects about 60% of those undergoing radiation, leading to painful scarring from excessive collagen accumulation. In head and neck cancer patients, as an example, RF reduces tissue flexibility, causing limited neck mobility and impaired swallowing. Furthermore, approximately 30% of patients also face disease recurrence post-radiation, with RF increasing surgical complications. Our laboratory previously identified the role of reduced fatty acid oxidation in RF (Zhao *et al; Nat Metab*;1(1):147 2019), offering a promising avenue for future drug development. We described the potential therapeutic benefit of caffeic acid phenethyl ester (CAPE) in countering pro-fibrotic metabolic changes. Our current objective is to develop more effective lead compounds to mitigate RF.
Methods: Collagen expression, utilized as a surrogate marker for fibrosis, was quantified using ELISA, Western blot analysis, and RT-qPCR. Metabolic changes were assessed by examining the expression levels of PPARG and CD36. CAPE-like analogs were derived from an in-house collection, a commercially available library, and structure-activity relationship (SAR) analyses. *In vivo*, RF was induced in the hindlimbs of mice through exposure to 40 Gy, followed by weekly X-ray evaluations of hindlimb angles for 16 weeks. During X-ray assessments, both hindlimbs were subjected to a 5 g weight to enable measurement of the joint angle between the femur and tibia (wherein higher acute angles were a measure of worsening fibrosis). Skin samples from irradiated and unirradiated limbs were collected for the evaluation of collagen deposition, utilizing Picro Sirius staining followed by polarized microscopy.
Results: Amongst 200 newly synthesized analogs, approximately one-third successfully reduced collagen secretion in human primary dermal fibroblasts. The most promising compounds exhibited a half-maximum inhibition concentration (IC50) for collagen secretion from 1 to 5µM. They also decreased intracellular collagen production and gene expression, associated with upregulation of PPARG and CD36 transcripts. The joint angle measurements *in vivo* revealed three distinct phases in the development of dermal fibrosis: 1) inflammatory; 2) recovery; and 3) fibrotic phases.
Conclusions: We have successfully synthesized novel and potent analogs of CAPE which were able to reduce secretion of collagen. Furthermore, a novel method for the *in vivo* assessment of fibrosis was also developed. This innovative approach will facilitate the detailed assessments of future compounds capable of reducing collagen deposition *in vivo*, thereby providing an innovative avenue to mitigate one of the most pressing late normal tissue toxicities of radiation therapy.

#6384 DNA methylation based aging biomarkers mediate the association between patient-reported symptoms and all-cause late-mortality: A report from the St. Jude Lifetime Cohort.

Q. Li, Y. Pan, X. Zhang, N.-M. Plonski, C. Chen, Q. Dong, K. Shelton, J. Easton, H. Mulder, J. Zhang, G. Neale, E. Walker, D. Srivastava, G. T. Armstrong, K. Ness, I.-C. Huang, Z. Wang;
St. Jude Children's Research Hospital, Memphis, TN

Background: Long-term survivors of childhood cancer experience high rates of patient-reported symptoms and evidence for accelerated molecular aging. Both are established to increase the risk for late-mortality (>5 years from cancer diagnosis). We aim to investigate if accelerated molecular aging mediates the association between symptoms and all-cause late-mortality.
Methods: DNA methylation (DNAm)-based aging biomarkers were derived from the DNAm Age Calculator, including epigenetic age acceleration (EAA) using multiple clocks (e.g., GrimAge and PhenoAge) and other DNAm-predicted biomarkers (e.g., DNAmB2M: beta-2-microglobulin, DNAmTL: telomere length) adjusted for age and standardized. Survivors self-reported the presence of 10 symptom domains (cardiac, pulmonary, sensory, motor/movement, nausea, pain, fatigue, memory, anxiety, and depression) that were aggregated into a total symptom burden score. Multiple linear regression tested the association between each aging biomarker and symptom prevalence, adjusting for the age of symptom survey, sex, and cancer treatment exposures. Cox regression tested the association of each aging biomarker or symptom domain with mortality. Aging biomarkers mediation for the symptom-mortality association was assessed by using the Accelerated Failure Time model and the mediation R package. False discovery rate was controlled for multiple testing.
Results: Among 2,206 survivors (47% males) who had DNAm measured on (52%) or after the survey, the median duration from the symptom survey to DNA sampling were 0.48 years (IQR: 0.09-4.27 years). EAA_GrimAge was the aging biomarker most closely associated with total symptom burden (beta [95%CI] = 0.576 [0.455, 0.697] years, $P=2.89\times10^{-18}$) and eight of ten domain-specific symptoms except for motor/movement and memory. Seven aging biomarkers (e.g., DNAmB2M: 1.91 [1.48, 2.48], $P=1.87\times10^{-5}$; EAA_GrimAge: HR [95%CI] = 1.17 [1.09, 1.26], $P=3.1\times10^{-4}$) and five symptom domains (e.g., pulmonary: 2.54 [1.44, 4.49], P=0.004; cardiac: 2.25[1.28, 3.97], P=0.01; total symptom burden: 1.47 [1.18, 1.82], P=0.0019) were associated with mortality risk. EAA (e.g., EAA_GrimAge) mediated the association between symptoms (cardiac: % mediation =0.13 [0.044, 0.379], P=0.008; pulmonary: 0.186 [0.075, 0.486], P=0.008; and total symptoms: 0.206 [0.078, 0.503], P=0.012) and late mortality. In addition, the association between symptoms and mortality was mediated by DNAmB2M and DNAmTL (e.g., pulmonary: 0.152 [0.046, 0.378], P=0.008; 0.12 [0.031, 0.373], P=0.021).
Conclusions: EAA, DNAmB2M and DNAmTL mediated the association between the presence of specific symptom domains and late-mortality, suggesting that accelerated molecular aging may be an underlying biological pathway explaining the associations between symptom burden and mortality.

#6385 St. Jude Survivorship Portal: Sharing and analyzing large clinical and genomic datasets from pediatric cancer survivors.

G. Matt[1], E. Sioson[1], J. Wang[1], C. Lu[1], A. Zaldivar Peraza[1], K. Gangwani[1], R. Paul[1], C. Reilly[1], A. Ać[1], K. Shelton[1], Q. Liu[2], S. Sandor[1], C. McLeod[1], W. Qiu[2], J. Patel[1], F. Wang[1], C. Im[3], Z. Wang[1], C. L. Wilson[1], N. Bhakta[1], K. Ness[1], G. T. Armstrong[1], M. M. Hudson[1], L. L. Robison[1], J. Zhang[1], Y. Yasui[1], X. Zhou[1];

[1]St. Jude Children's Research Hospital, Memphis, TN, [2]University of Alberta, Edmonton, AB, Canada, [3]University of Minnesota Medical School, Minneapolis, MN

Survivors of childhood cancer are at risk for developing various adverse health conditions as adults that are attributable to the cancer and treatments they were exposed to as children. Cancer survivorship research relies on large-scale, longitudinal studies that generate a wide range of demographic, clinical, and genetic data on cancer survivors. Nevertheless, the absence of cancer survivorship data portals has made it challenging to broadly share cancer survivorship data. We have created the St. Jude Survivorship Portal (https://survivorship.stjude.cloud), the first data portal for sharing, analyzing, and visualizing childhood cancer survivorship data. The portal hosts data from two large cohorts of pediatric cancer survivors: the St. Jude Lifetime Cohort Study (SJLIFE) and the Childhood Cancer Survivor Study (CCSS). Over 1,600 clinical variables and over 400 million genetic variants from over 7,700 childhood cancer survivors are stored on the portal. The data can be explored using an interactive data dictionary and a genome browser specialized for population genetics analysis. Summary statistics of variables and genetic variants are computed on-the-fly and visualized through interactive and customizable charts. Survivor cohorts can be filtered or customized and may also be divided into groups for comparative analysis. Tools for performing cumulative incidence and regression analyses have been integrated into portal environment, allowing users to perform real-time statistical analyses on the stored survivorship data. Finally, users may also download individual-level clinical and genotype data from the portal using the controlled-access data download feature. Through various use-cases of survivorship research, we used the portal to explore the ototoxic effects of platinum-based chemotherapy, uncover a novel association between limb amputation, age, and long-term mental health, and identify a novel haplotype in *MAGI3* strongly associated with cardiomyopathy specifically in survivors of African ancestry. The St. Jude Survivorship Portal provides a comprehensive, powerful, and easy-to-use interface for sharing and analyzing childhood cancer survivorship data that will serve as a valuable research tool for the broader survivorship research community.

#6389 An exosome-based liquid biopsy powered by machine learning predicts progression-free and overall survival before commencing first-line EGFR inhibitors for metastatic colorectal cancer: *The EXONERATE Study*.

X. Caiming[1], A. Mannucci[1], R. Souvick[1], E. Francis[2], O. Helena[2], A.-O. Vicente[3], E. Pilar[4], F.-M. Carlos[5], S. Antonieta[6], G. Javier[7], R. Jose Ramon[8], M.-R. M. Marta[9], F.-P. Julen[10], M. Hermini[11], A. Jorge[12], F. Jaime[13], M. Joan[2], A. Goel[1];

[1]Beckman Research Institute of The City of Hope, Duarte, CA, [2]IDIBAPS, University of Barcelona, Barcelona, Spain, [3]Hospital Universitario Miguel Servet, Zaragoza, Spain, [4]Hospital Universitario Lozano Blesa, Zaragoza, Spain, [5]Fundacion Instituto Valenciano de Oncologia, Valencia, Spain, [6]Hospital Universitari Arnau de Vilanova, Lleida, Spain, [7]Hospital General Universitario of Elche, Elche, Spain, [8]Hospital Infanta Cristina, Badajoz, Spain, [9]Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, [10]Hospital Mutua de Terrasa, Barcelona, Spain, [11]Hospital Son Espases, Palma, Spain, [12]Hospital La Fe de Valencia, Valencia, Spain, [13]Hospital Universitario La Paz, CIBERONC, Madrid, Spain

Introduction: We developed a liquid biopsy assay based on **exo**somal and cell-free microR**N**A (exo- and cf-miRNA, respectively) for patients with chemotherapy-naïve, m**e**tastatic, unresectable, **RA**S and BRAF wild-type colorectal cancer (mCRC), to predict progression-free (PFS) and overall survival (OS) before the commencement of first-line **t**reatment with **E**GFR inhibitors (EXONERATE).
Methods: Patients with mCRC were consecutively enrolled in two open-label, nationwide clinical trials and received first-line cetuximab or panitumumab. Cf- and exo-miRNA expression was quantified using RT-qPCR in plasma samples obtained before exposure to EGFR inhibitors. The prespecified primary endpoint was 12-month PFS, hierarchically tested in left-sided mCRC, right-sided mCRC, and the entire cohort. As secondary endpoints, the EXONERATE status was correlated with PFS and OS hazard ratios (HR).
Results: After excluding those with RAS/BRAF mutations and unavailable samples, the complete analysis dataset comprised 120 patients (94 with left-sided and 26 with right-sided mCRC; 87 received cetuximab and 33 panitumumab). As expected, right-sided mCRC patients showed inferior PFS and OS outcomes (HR 1.80 [$CI_{95\%}$ = 1.13 - 2.80] and 1.80 [$CI_{95\%}$ = 1.00 - 3.27], respectively). Genome-wide small RNA sequencing on 20 patient samples identified 12 cf- and 14 exo-miRNA candidates, then narrowed to 8 and 9 based on best performance. We employed machine learning algorithms to develop two liquid biopsy assays, one based on cf- and the other on exo-miRNAs, predicting 12mPFS with AUC values of 0.84 and 0.81, respectively. These were then combined to establish the EXONERATE assay for left-sided mCRC (AUC = 0.89), successfully validated in right-sided mCRC patients (AUC= 0.84). Among left-sided mCRC patients, 35% were EXONERATE-high, exhibiting shorter median PFS (mPFS = 9.5 vs. 18.5 months, p<.001) and a higher mortality rate (HR 0.21 [$CI_{95\%}$ = 0.10 - 0.42]). In the right-sided mCRC cohort, the EXONERATE-high panel robustly identified patients with shorter mPFS (8.6 vs. 23.7 months, p=.0042) and predicted 12mPFS with high accuracy (sensitivity 100%, NPV 81%, PPV 100%). Although in univariate analysis both the EXONERATE panel and sidedness showed associations with PFS and OS, in multivariate analysis only the EXONERATE panel could fully account for the differences in PFS and OS (HR 0.22 and HR 0.19, respectively). Hence, we employed the EXONERATE panel agnostically of tumor sidedness and observed that EXONERATE-high patients demonstrated poorer survival outcomes in mPFS (8.9 vs. 19.6 months, HR 0.27 [$CI_{95\%}$ = 0.17 - 0.41]) and mOS (22.6 vs. >60 months, HR 0.18 [$CI_{95\%}$ = 0.09 - 0.37]).
Conclusion: The EXONERATE panel robustly predicted PFS and OS outcomes in both right- and left-sided mCRC patients before receiving either EGFR inhibitor.

#6390 Exploratory biomarker analysis of phase 3 ASTRUM-005 study: Serplulimab versus placebo plus chemotherapy for extensive-stage small cell lung cancer.

Y. Cheng[1], L. Han[2], L. Wu[3], J. Chen[4], H. Sun[5], G. Wen[6], Y. Ji[7], A. Zimina[8], J. Shi[9], Z. Pan[10], J. Shi[11], X. Wang[12], F. Yang[13], X. Yang[13], M. Chen[13], S. Zhong[13], Q. Wang[13], J. Li[13], J. Cheng[13], C. Ling[13], Y. Shan[13], J. Zhu[13], The ASTRUM-005 Study Group;

[1]Jilin Cancer Hospital, Changchun, China, [2]Xuzhou Central Hospital, Xuzhou, China, [3]Hunan Cancer Hospital/the Affiliated Cancer Hospital of Xiangya School of Medicine, Central South University, Changsha, China, [4]Tianjin Medical University General Hospital, Tianjin, China, [5]Jiamusi Cancer Hospital, Jiamusi, China, [6]The First Affiliated Hospital of Nanchang University, Nanchang, China, [7]The First Affiliated Hospital of Xinxiang Medical University, Xinxiang, China, [8]Budgetary Healthcare Institution of Omsk Region "Clinical Oncology Dispensary", Omsk, Russian Federation, [9]Linyi Cancer Hospital, Linyi, China, [10]The First Affiliated Hospital of Zhejiang University School of Medicine, Hangzhou, China, [11]Cangzhou People's Hospital, Cangzhou, China, [12]The First Affiliated Hospital of Guangdong Pharmaceutical University, Guangzhou, China, [13]Shanghai Henlius Biotech, Inc., Shanghai, China

Background First-line serplulimab plus chemotherapy (chemo) significantly improved OS compared with chemo alone for patients with extensive-stage small cell lung cancer (ES-SCLC) in the phase 3 ASTRUM-005 study. In this exploratory biomarker analysis, we retrospectively evaluated the association of proteome signature, genetic mutations, and hematological indices with efficacy.

Methods: Serum proteomics data were generated via Olink® Explore 3072 platform for 168 patients (training: 80; validation: 88). Genetic mutations were assessed by Med1CDx™ panel for 305 patients. Baseline neutrophil-to-lymphocyte ratio (NLR), platelet-to-lymphocyte ratio (PLR), and lactate dehydrogenase (LDH) levels were analyzed in all 585 patients. Clinical data cutoff date was June 13, 2022.

Results: From Olink data, we generated a 15-protein signature. Results in the validation cohort are shown in the table below. Patients with upper signature score derived higher PFS (7.89 vs 4.17 mo, HR 0.37) and OS (17.18 vs 9.74 mo, HR 0.27) benefit from adding serplulimab, than those with lower signature score (PFS: 4.40 vs 4.34 mo, HR 0.68; OS: 9.05 vs 9.22 mo, HR 0.76). Patients with mutations in RB1 or NOTCH pathway had better tumor responses to the treatment of serplulimab-chemo (ORR: 80% and 86%, respectively) when compared to patients without mutations in RB1 or NOTCH pathway (ORR: 58% and 68%). Patients with NLR ≤4.6, PLR ≤338.3, and LDH ≤ upper limit of normal tended to have longer PFS and OS in both treatment groups; NLR and LDH were further proven to be independent prognostic biomarkers in multivariate regression (P = 0.002 and P <0.001, respectively).

Conclusions: We found a 15-protein signature showing predictive power for serplulimab-chemo treatment; RB1 or NOTCH pathway mutations were enriched in serplulimab-chemo responders; baseline NLR and LDH were independent prognostic biomarkers for ES-SCLC. The above findings warrant further investigations.

	Serplulimab-chemo (n=48)	Placebo-chemo (n=40)	HR (95% CI)	P
Upper signature score, n	31	34		
Median PFS (95% CI), months	7.89 (1.27, 10.74)	4.17 (2.96, 4.34)	0.37 (0.21, 0.66)	<0.001
Median OS (95% CI), months	17.18 (11.01, NE)	9.74 (6.90, 12.65)	0.27 (0.15, 0.50)	<0.001
Lower signature score, n	17	6		
Median PFS (95% CI), months	4.40 (3.61, 5.75)	4.34 (2.66, NE)	0.68 (0.23, 2.02)	0.488
Median OS (95% CI), months	9.05 (6.67, 11.73)	9.22 (4.53, NE)	0.76 (0.29, 1.98)	0.570

#6391 Spatial proteomic profiling unveils pre-existing anti-tumor immunity as a hallmark of exceptional benefit from immunotherapy in NSCLC.

S. Hernandez[1], R. Bach[2], M. Giner[2], W. Lu[1], L. Kostousov[1], S. Barnes[1], K. Khan[1], L. Masfarre[2], X. Villanueva[2], I. Sanchez[2], N. Navarro[2], A. Taus[2], M. Galindo[2], M. Hardy[2], R. Del Rey-Vergara[3], A. Inanez[3], B. Sanchez-Espiridion[1], L. Moliner[4], S. Clave[2], B. Bellosillo[2], A. Rovira[3], J. Perera-Bel[3], I. Wistuba[1], E. Arriola[2], L. M. Solis[1], **P. Rocha**[2];

[1]MDAnderson Cancer Center, Houston, TX, [2]Hospital del Mar, Barcelona, Spain, [3]Hospital del Mar Research Institute, Barcelona, Spain, [4]Catalan Institute of Oncology, Barcelona, Spain

Background: Immunotherapy is firmly established as a treatment regimen in various solid tumors due to its exceptional benefits observed in a select group of patients. Despite widespread use of immune checkpoint blockade (ICB) across diverse solid tumors, including non-small cell lung cancer (NSCLC), the quest for a clinically informative biomarker for long-term benefit remains unmet. Here we investigate the potential utility of clinicopathological and spatial proteomic profiling of tumor specimens from NSCLC patients to identify predictive biomarkers of long-term benefit to ICB.

Methods: Forty-nine patients diagnosed with advanced NSCLC who received ICB at Hospital del Mar, Barcelona between 2017-2021 were included. Long-term responders (LTR, n=21) were defined as patients achieving a maintained radiologic response for more than 2 years, and short-term responders (STR, n=28) as patients presenting disease progression within the first six months of ICB initiation. Clinicopathological information, incidence of immune related adverse (irAES) and PD-L1 tumor proportion score assessed by IHC was available for all of them. DSP GeoMx was performed in subset of patients (LTR n=14 and STR n=14), to assess 49 immune biomarkers. Pancytokeratin (panCK; epithelial), CD3, CD20 and SYTO 13 (nuclear) were utilized as morphology biomarkers. Regions of interest were placed in tissue areas containing tumor and segmented in Tumor (PanCK+) and tumor microenvironment (TME) (PanCK-) that was used on downstream analysis. Digital counts were normalized using the protein expression of housekeeper proteins. Statistical analysis was performed using linear mixed models. A *P* value less than 0.05 was considered significant.

Results: Our analysis revealed specific characteristics of LTR patients compared with STR, namely LTR population was enriched for PD-L1 positive in tumors ($p=0.005$) and a higher incidence of immune-related adverse events (irAEs) ($p=0.001$). Within the Tumor compartment, LTR patients displayed significantly higher levels of IDO1, CD8, PD-L1, CD45, HLA-DR and STING, while STR patients exhibit higher levels of B7-H3, CD56 and OX40L ($p<0.05$ for all proteins). Comparison analysis of the TME compartment between LTR and STR revealed augmented levels of IDO1, CD8, CD45, CD11c, CD27 and CD3 in LTR patients, and lower levels of B7H3 and OX40L compared with STR patients ($p<0.05$ for all proteins).

Conclusions: Our comprehensive analysis of metastatic NSCLC patients treated with ICB has unveiled distinct clinicopathological and immunological features associated with long-term benefit of ICB, highlighting the presence of pre-existing antitumor immunity as a stronger predictor of long-term benefit. These findings offer insights into potential biomarkers and therapeutic strategies for enhancing ICB outcomes in metastatic NSCLC.

#6392 Activity of HER2-and TROP2- antibody drug conjugates (ADCs) in small cell lung cancer (SCLC) models with SLFN11 as a predictive biomarker.

B. Zhang, A. Ibrahim, C. Stewart, L. Diao, Q. Wang, L. Shen, Y. Xi, A. Serrano, L. M. Solis, W.-L. Wang, K. Ramkumar, R. J. Cardnell, R. Wang, A. Duarte, Jr., J. Wang, L. A. Byers, C. Gay;
UT MD Anderson Cancer Center, Houston, TX

Background: Small-cell lung cancer (SCLC) is a highly aggressive malignancy with its few treatment options devoid of biomarker selection, and a 5-year survival rate of less than 7%. Our group previously established four transcriptionally defined subtypes of SCLC, each with distinct cell surface targets (*Gay et al, Cancer Cell 2021).* Further, we identified SLFN11 (a putative DNA/RNA helicase) as a candidate biomarker of sensitivity to DNA-damaging agents, including topoisomerase inhibitors. Human epidermal growth factor receptor 2 (HER2/*ERBB2*) expression has been previously described in a subset of SCLCs and has been linked to poor prognosis. HER2 antibody-drug conjugates (ADCs) like trastuzumab deruxtecan (T-DXd) (where the payload is a topoisomerase I inhibitor) have received FDA approval for various solid tumors, highlighting their therapeutic potential. Similarly, TROP2 (*TACSTD2*) ADC sacituzumab govitecan has shown promising clinical efficacy in a SCLC (TROPiCS-03 basket trial). However, it is unclear what the predictive biomarkers are to these ADCs in SCLC.
Methods: Expression of *ERBB2 and TACSTD2* mRNA was analyzed using publicly available patient datasets. We also characterized surface expression of HER2 and TROP2 by flow cytometry in SCLC cell lines at baseline and after cisplatin/etoposide treatment. We then assessed the cytotoxicity of T-Dxd and sacituzumab govitecan in a panel of SCLC cell lines representative of each SCLC subtype, as well as SLFN11 status.
Results: Analyses of HER2/*ERBB2* and TROP2/*TACSTD2* in SCLC cell lines and patient datasets showed a range of *ERBB2* and *TACSTD2* expression with enrichment in the non-neuroendocrine subtypes (SCLC-P and SCLC- I subtypes). We further validated HER2 and TROP2 surface levels by flow cytometry in a subset of SCLC cell lines. Intriguingly, we observed that surface expression of both HER2 and TROP2 increase after frontline chemotherapy cisplatin/etoposide treatment. As expected, T-Dxd and sacituzumab govitecan exhibit cytotoxicity in a subset of SCLC cell lines. We found a strong correlation between the *in vitro* cytotoxicity (IC50) of sacituzumab govitecan with SLFN11 (rho= 0.74, p=0.015). Importantly, SLFN11 is bimodally distributed in SCLC and we found *ERBB2* and *TACSTD2* to be enriched in the SLFN11-high group of SCLC patients. We also found *ERBB2* and *TACSTD2* to be correlated with each other (rho = 0.53, p <0.001).
Conclusion: In this study, we demonstrate that HER2/*ERBB2* and TROP2/*TACSTD2* are enriched in a subset of SCLC. FDA-approved ADCs, T-DXd and sacituzumab govitecan each have preclinical activity in SCLC with SLFN11 as a predictive biomarker of payload cytotoxicity. We also found HER2 and TROP2 target levels increase after frontline chemotherapy (cisplatin/etoposide) in SCLC, which suggest their efficacy may be enhanced in relapsed SCLC where treatment options are extremely limited.

#6393 The predictive role of TNF-related genes in patients receiving immune checkpoint inhibitors.

O. E. Ababneh[1], S. Kato[2], D. Nishizaki[2], H. Miyashita[3], S. Lee[2], M. Nesline[4], S. Pabla[5], J. Conroy[5], P. DePietro[5], H. Ko[4], R. Kurzrock[6];
[1]Jordan University of Science & Technology, Irbid, Jordan, [2]University of California San Diego, San Diego, CA, [3]Dartmouth Cancer Center, Lebanon, NH, [4]Labcorp Oncology, Durham, NC, [5]OmniSeq Inc., Buffalo, NY, [6]Medical College of Wisconsin Cancer Center, Milwaukee, WI

Introduction: Not all patients respond to immune checkpoint inhibitors (ICI) even when they have favorable FDA-approved biomarkers. The tumor necrosis factor superfamily (TNFSF) and tumor necrosis factor receptor superfamily (TNFRSR) play critical roles in various biological processes, including inflammation, immune regulation, and cell death. In this study, we sought to investigate the predictive role of TNF-related genes in patients receiving ICI.
Methods: The RNA expression levels of 18 TNF-related genes were assessed in a pan-cancer cohort of 217 patients treated with immune checkpoint inhibitors (ICI) at the University of California San Diego (UCSD) Moores Cancer Center. Using a reference population of 735 tumors and 35 histologies, transcript abundance was adjusted to internal housekeeping gene profiles and rated (0-100th percentile). The patients were clustered into two groups based on the 18 TNF-related genes expression using Ward's hierarchical clustering. Associations between overall survival and previously demonstrated independent ICI predictive variables were assessed. Bonferroni correction for multiple comparisons was used and considered statistically significant when p-value ≤ 0.05.
Results: Four TNF-related genes (CD137, CD70, GITR, and TNFSF9) were associated with positive programmed death-ligand 1 (PD-L1) expression (PD-L1≥1% immunohistochemistry TPS), while TNFSF18 was associated with negative PD-L1 expression (corrected p-value<0.05). No gene was associated with microsatellite instability-high (MSI-H) or high tumor mutational burden (TMB-H) (TMB≥10 mutations/Mb) (corrected p-value>0.05). We clustered the patients based on their 18 TNF-related genes expression into two signature clusters, high (n=94) and low (n=123). Patients in the high expression signature cluster were more likely to have high PD-L1 compared to the low expression cluster (corrected p-value<0.05). The high expression signature cluster was associated with better survival compared with the low expression cluster (HR=1.49, 95%CI: 1.05-2.13 (p=0.026)). When adjusting for TMB, MSI, PD-L1, TP53 and KRAS status, the TNF high expression signature cluster was still associated with better overall survival (HR=1.71, 95%CI:1.11-2.66 (p=0.016)). Other than the TNF high expression signature cluster group, only the presence of KRAS mutation was a predictor of a longer survival (HR=2.09, 95%CI:1.28-3.42 (p=0.003)).
Conclusion: A high TNF-related gene expression profile may serve as an independent predictor for longer overall survival for patients treated with ICI.

#6394 Tissue nanomechanical signature predicts response to neoadjuvant chemotherapy in patients with breast cancer.

M. Gachechiladze[1], S. Nizzero[1], T. Appenzeller[1], L. Briner[2], R. Burian[1], S. Schadelin[2], S. Muenst-Soysal[2], T. Vlaijnic[2], E. Obermann[3], S. Dellas[2], S. Forte[4], Z. Marusić[5], A. Jizawi[1], P. Ndiaye[1], P. Oertle[1], G. Zaugg[1], M. Loparic[1], M. Plodinec[1];

[1]ARTIDIS AG, Basel, Switzerland, [2]University Hospital Basel, Basel, Switzerland, [3]Cantonal Hospital Luzern, Luzern, Switzerland, [4]Radiology Clinic Baden, Baden, Switzerland, [5]University Hospital Centre Zagreb, Zagreb, Croatia

Background: Neoadjuvant chemotherapy (NACT) is increasingly used in patients with breast cancer. However, predicting response to NACT remains a challenge in everyday clinical practice. Increasing (pre)- and clinical evidence demonstrate the importance of cancer biomechanics in mediating therapy response. We and others have previously demonstrated that complex biomechanical alterations in cancer tissues, can be measured by the Atomic Force Microscopy (AFM) at the nanoscale level. Incorporating AFM measurements of clinical biopsies within standard of care is thus a promising avenue to leverage tissue mechanics as prognostic and predictive biomarker for solid cancers.

Methods: Fresh clinical biopsy samples from 545 breast cancer patients were measured using the AFM-based Automated and Reliable Tissue Diagnostics (ARTIDIS) investigational device - ART-1. Measurements were performed on baseline biopsies within routine clinical workflow in the Breast Clinic, University Hospital Basel. This cohort comprises 30 patients who received NACT including: anthracycline and/or taxane based chemo (n=17), and anthracycline and/or taxane with platinum chemo (n=13). Study endpoints were radiological complete response (rCR) prior and pathological complete response (pCR) after surgery. Multiparametric nnanomechanical signature data has been analyzed in an automated manner using the proprietary ARTIDISNET software platform.

Results: From the 30 patients who received NACT, 12 patients presented with rCR, 17 patients presented with rPR, and 1 patient presented with rNR. pCR has been achieved only in 9 patients. In this study, he ARTIDIS nanomechanical signature of response to NACT in breast cancer showed 100% negative predictive value (NPV) and 89% positive predictive value (PPV), with 93% of accuracy for patients receiving chemotherapy, independent of molecular subtype or treatment regimen. Sensitivity was 100% and specificity was 85% (AUC=0.91).

Conclusion: ARTIDIS nanomechanical signature can be seamlessly integrated within clinical settings to predict response to standard of care NACT in patients with breast cancer in a prospective manner. These results are currently being validated in a global, multicentre prospective study in breast cancer (ANGEL, NCT06085833), enrolling in total 2706 patients, with the aim to support implementation of the ARTIDIS nanomechanical signature into routine clinical practice.

#6395 Metabolic dysregulation as a determinant of prognosis and response to sorafenib in liver cancer.

H. Park[1], S. Park[1], S.-H. Lee[2], Y. Jeong[1], B. Sohn[1], S. Yim[3], J.-S. Lee[1];

[1]UT MD Anderson Cancer Center, Houston, TX, [2]CHA Bundang Medical Center, Seoul, Korea, Republic of, [3]Korea University, Seoul, Korea, Republic of

Background & Aims: Elevated metabolic activity is a defining characteristic of liver cancer. Nevertheless, our understanding of the molecular underpinnings of high metabolic activity in liver cancer and its impact on clinical outcomes and treatment responses remains limited. We aimed to elucidate the metabolic features of liver cancer associated with clinical outcomes, particularly overall survival and responsiveness to sorafenib treatment.

Methods: Utilizing cross-species comparisons of genomic data, we integrated gene expression profiles from liver tissues in metabolically challenged mice and from patients with cirrhosis and liver cancer. To categorize patients, we developed a genomic predictor and applied it to gene expression data from a cirrhosis cohort (n=216) and large liver cancer cohorts (n=1390). Comprehensive statistical and informatics analyses were conducted to evaluate clinical significance, including overall survival and responses to standard treatments. Moreover, we integrated genomic data derived from patient-derived xenograft (PDX) models into our analytical framework.

Results: Our integrated data analysis unveiled three distinct metabolic subtypes of tissues: high, moderate, and low metabolic subtypes. In the cirrhosis cohort, the high metabolic subtype was significantly associated with early liver cancer development. Among liver cancer cohorts, the high metabolic subtype exhibited characteristics such as poor survival, heightened hepatic stem cell features, increased genomic instability, and elevated expression of AFP, KRT19, EPCAM, and SALL4. Notably, when liver cancer patients undergoing systemic sorafenib treatment were stratified using our genomic predictor, those with low and moderate metabolic activity derived significant benefits from sorafenib therapy. Conversely, the high metabolic subtype displayed substantial resistance to sorafenib, suggesting that metabolic activity may dictate the response of liver cancer cells to sorafenib treatment. Gene network analysis of the metabolic expression signature identified multiple signaling pathways that potentially contribute to sorafenib resistance in liver cancer cells. Our analysis predicted the activation of pathways such as the TGF-β pathway (TGFB1), consistent with previous findings of TGF-β pathway activation in highly metabolic cancer cells. Additionally, our analysis identified YAP1, HIF1A, and MAPK pathways as activated pathways in sorafenib-resistant liver cancer.

Conclusions: This study identifies clinically and metabolically distinct subtypes of liver cancer, biomarkers associated with these subtypes, and mechanisms underlying metabolic-mediated resistance of liver cancer cells to sorafenib. Furthermore, the metabolic subtypes observed in PDX models provide valuable tools for selecting appropriate preclinical models for future research endeavors.

#6396 Ex vivo 3D micro tumor testing to assess chemotherapy and immunotherapy responses for NSCLC patients.

E. Koedoot[1], T. J. P. Sijsenaar[1], L. J. Ceton[1], D. J. van der Meer[1], T. J. van Brakel[2], P. van Zwam[3], E. Geraedts[4], **W. Vader**[1], E. F. Smit[5], L. C. Steinbusch[5], C. M. J. Steendam[2];

[1]VitroScan B.V., Leiden, Netherlands, [2]Catharina Ziekenhuis, Eindhoven, Netherlands, [3]PAMM, Eindhoven, Netherlands, [4]Groene Hart Ziekenhuis, Gouda, Netherlands, [5]LUMC, Leiden, Netherlands

Background: Systemic treatment options for NSCLC patients consists of chemo-, targeted or immunotherapy. Although predictive biomarkers can guide treatment decisions, response prediction for chemo- and immunotherapy is still a challenge. Recent studies showed the potential of functional testing to assess patient sensitivity to drugs in various cancers, but NSCLC is lacking. This study reports the feasibility of ex vivo 3D micro lung tumor testing with native tumor microenvironment (TME) to enable treatment sensitivity profiling for all drug classes in parallel.

Methods: Fresh NSCLC tumor tissue was collected from pleural fluid stage IVa/b (N=24) or resected primary tumor for stage I-III disease (N=11). Tumor clusters were isolated and exposed to drugs, while preserving the TME. Thirteen therapies were included, including cisplatin, pembrolizumab, osimertinib, and positive control for immune sensitivity (SEA). Morphological features were extracted from high-throughput 3D imaging data. Chemo- and targeted therapy sensitivity was based on AUC comparison of fitted dose-response curves. Immunotherapy sensitivity was classified on percentage and statistical significance of tumor killing, immune cell proliferation and cytokine profiling.

Results: The overall assay success rate for solid samples was 64% (7/11), with 100% (4/4) success after protocol optimization. For pleural fluids, the overall success rate was 33% (8/24), caused by many samples arriving without tumor content (13/24, 54%). Excluding these samples, a technical success rate of 73% (8/11) was obtained. The assay was robust and reproducible (mean Z' = 0.38, CV = 16.1%). Results were delivered in two weeks and on average, eight treatments were tested in parallel per sample.

Patient-specific response profiles were observed for chemo-, targeted and immunotherapy. General immunotherapy sensitivity (SEA) was measured in 50% (6/12) of the tissues. Distinct responses were observed for the different immunotherapies: 33% (4/12), 17% (2/12) and 8% (1/12) of the patients responded to pembrolizumab, atezolizumab and/or ipilimumab, respectively. Strong response to osimertinib was observed in a patient with EGFR exon 19 mutation (AUC = 0.26) versus resistance in a WT patient (AUC=0.92).

Conclusion: Ex vivo 3D micro tumor testing using liquid and solid tissues is feasible for NSCLC patients with resected primary tumor or pleuritis carcinomatosa. Distinct patient sensitivity profiles for chemo-, targeted and immunotherapies were measured. A preliminary correlation of targeted therapy response with mutation status was found.

Discussion: The ex vivo 3D micro tumor testing platform is proven predictive for platinum-based therapy. The current study established the methods to accurately measure ex vivo NSCLC responses to all drug classes to correlate with clinical measures and further validate the platform for guiding treatment decisions.

#6397 Immune profiling for improving responsiveness to ipilimumab plus nivolumab checkpoint blockade treatment in patients with metastatic melanoma.

J. Baginska, **J. Chen**, G. Tarantino, A. Giobbie-Hurder, J. L. Weirather, M. Severgnini, M. Manos, K. Burke, J. D. Russell, M. Brainard, E. Gabriel, R. Brennick, M. Nazzaro, E. Hathaway, M. Holovatska, C. Manuszak, S. Ranashinge, D. Liu, F. Hodi;
Dana-Farber Cancer Institute, Boston, MA

Background:aCTLA-4 and aPD-1 combination therapy has significantly improved clinical outcomes in patients with metastatic melanoma, with 50%-60% of patients responding to treatment, but predictors of response and treatment induced immunological effects are poorly characterized. Identifying circulating immune populations as biomarkers could reveal crucial insights into the mechanisms driving treatment success.
Methods: Using unbiased single-cell profiling (with cytometry by Time-Of-Flight, CyTOF), we characterized the systemic immune compartments of over 250 peripheral blood mononuclear samples from 89 patients with advanced melanoma before and during combination therapy. We evaluated the association between circulating immune populations and clinical outcome using nonparametric Mann-Whitney tests, and investigated the prognostic values of these features using survival analysis. Additionally, we assessed treatment-induced immunological effects, providing insights into the dynamic changes within the immune system during therapy.
Results: We characterized circulating T cells, NK cells, B cells, and monocytes from peripheral blood. Following combination therapy, there was a shift from naïve and central memory T cells to effector populations in both CD4+ and CD8+ T cells compartments. There was also a broad activation observed in both adaptive and innate populations, characterized by an elevation of multiple co-stimulatory and co-inhibitory molecules. Lower CD8+ NK cell populations prior to combination therapy were predictive of durable clinical benefit (DCB). Pre-treatment measurements of Tregs were not predictive of outcome, but higher Tregs one month after starting therapy, as well as increases of Tregs from pre to post treatment, predicted better progression free survival (PFS) and overall survival (OS). Starting from early on treatment, higher “exhausted-like” CD8+ T cells, characterized by positive expression of at least two co-inhibitory markers, is associated with resistance.
Conclusions:aCTLA-4 and aPD-1 combination therapy led to a longitudinal shift from naïve and central memory to effector phenotypes in T cells, along with a broad activation in both adaptive and innate populations. Within innate immune compartment, favorable clinical outcome was associated with lower CD8+ NK cells, capable of regulating proliferation and activation of CD4+ T cells. Interestingly, one month after the start of the therapy, the increase in Tregs and a decrease in 'exhausted-like' CD8+ T populations are associated with a better response. Collectively, these analyses suggest potential treatment-specific correlates of efficacy and may enable biomarker-selected patient populations in future.

#6399 Real-world experience of an Asian pan-cancer combined DNA/RNA next generation sequencing (NGS) tissue biopsy assay.

J. Chan[1], J. Lee[1], Z. Wan[2], A. Lim[1], T. Ko[1], C.-Y. Ng[1], D. Poon[3], J. Samol[4], T. So[5], S. Choo[6], R. Kanesvaran[1], C.-V. Hui[7], J.-K. Au[8], A. Helali[9], T. Yip[2], V. Rajasegaran[1], S. Lim[10], R. Weng[10], P. Tan[11], B. Teh[1], M.-H. Tan[2], J. Poh[2];

[1]National Cancer Centre Singapore, Singapore, Singapore, [2]Lucence Diagnostics Pte Ltd, Singapore, Singapore, [3]Dr DYH Poon & Associates, Mt Elizabeth Novena Specialist Centre, Singapore, Singapore, [4]Department of Medical Oncology, Tan Tock Seng Hospital, Singapore, Singapore, [5]Hong Kong Integrative Oncology Centre, Hong Kong SAR, Hong Kong, [6]Curie Oncology, Singapore, Singapore, [7]Department of Oncology, Centro Hospitalar Conde de Sao Januario, MACAO SAR, Macao, [8]Hong Kong Precision Oncology Society, HONG KONG SAR, Hong Kong, [9]LKS Faculty of Medicine, The University of Hong Kong, HONG KONG SAR, Hong Kong, [10]Diagnostics Development Hub (DxD Hub), A National Platform Hosted by A*STAR, Singapore, Singapore, [11]Luma Medical Centre, Singapore, Singapore

Introduction: Comprehensive molecular profiling with combined DNA-RNA next-generation sequencing (NGS) on tumor tissue is now increasingly being used as standard-of-care for sequence therapy selection to improve cancer survival. Combined DNA-RNA NGS is also considered standard-of-care for central nervous system (CNS) tumor classification. Despite the genetic heterogeneity and diversity of cancers, most commercial combined DNA/RNA NGS assays are validated in Western populations, resulting in knowledge gaps in patient outcomes. We report here for the first time a range of actionable outcomes from a comprehensive DNA/RNA tissue NGS assay designed specifically to probe Asian-prevalent cancers and biomarkers in an international multicenter real-world study in Asia.

Methods: 1,002 formalin-fixed paraffin-embedded tissue samples from 995 Asian cancer patients across >70 centers in 7 countries and/or territories underwent real-world DNA/RNA NGS testing in a CAP-accredited CLIA-certified laboratory. Genomic alterations including SNVs, INDELS, gene fusions, CNVs, TMB, and MSI were analyzed using an Asian-centric pan-cancer hybrid-capture NGS panel that comprehensively profiles 572 cancer-related genes and 91 RNA fusion partners (UNITED). Biomarkers were considered actionable if the therapeutic indication in any solid tumor or hematological cancer was FDA-approved, guidelines-recommended, or supported by well-powered phase III clinical trials.

Results: 27 cancer types were represented in 1,002 tissue samples, with lung, breast, colorectal, and prostate cancers comprising 45.5% of clinical volume. 79.5% of samples harbored ≥1 actionable biomarker, with the most frequently altered genes being *TP53*, *KRAS*, *PIK3CA, EGFR,* and *NF1*. Overall, 42.6% of samples had ≥1 biomarker with an indication in the patient's cancer type, including 81.5% of lung, 59.0% of breast, 61.8% of colorectal, and 42.1% of prostate cancers. Across the pan-cancer cohort, 13.3% was TMB-high and 1.9% was MSI-high. 26.3% of samples were from cancer types outside the original assay design; the top 3 were pancreatic cancer (7.3%), sarcoma (3.3%), and CNS tumor (3.1%). Cancers of unknown primary (CUP) also constituted a significant proportion (3.8%). In CNS tumors, 38.7% harbored an actionable mutation in *IDH1*, *BRAF*, or *H3-3A*. In CUP, 78.8% harbored an actionable mutation; 50% of samples harbored biomarkers that additionally informed potential tumor origin, including mutations in *EGFR*, *MET*, *ALK*, *ROS1*, and *BRCA1*.

Conclusion: The use of an Asian-focused pan-cancer DNA/RNA NGS panel resulted in detection of actionable biomarkers in 79.5% of clinical cases. These findings support the utility of DNA/RNA NGS assays in informing standard-of-care therapeutic decisions in Asian cancer patients for maximizing cancer survival.

#6400 Tislelizumab combined with XELOX as a neoadjuvant therapy for locally advanced gastric and gastroesophageal junction adenocarcinomas: A prospective, phase II trial.

H. Zhou[1], T. Han[1], L. Tuo[1], Q. Yang[2], R. Gao[1], P. Yu[1], J. Wei[1], C. Zhu[3], J. Wang[3], P. Cheng[3], X. Kang[3], S. Pi[4], H. Liu[4], X. Pan[4], X. Li[1], G. Ji[1];
[1]Department of Gastrointestinal Surgery, Xijing Hospital of Digestive Diseases, Xijing Hospital, Fourth Military Medical University, Xi'an, Shaanxi, China, [2]State Key Laboratory of Cancer Biology, National Clinical Research Center for Digestive Diseases and Xijing Hospital of Digestive Diseases, The Fourth Military Medical University, Xi'an, China, [3]Department of Translational Medicine, Amoy Diagnostics Co., Ltd., Xiamen, China, [4]Medical Affairs Department of BeiGene (Beijing) Co., Ltd., Beijing, China

Background: Combing anti-PD-(L)1 antibody with chemotherapy in neoadjuvant therapy of gastric/gastroesophageal junction (G/GEJ) adenocarcinomas is a promising strategy, but clinical data are remain insufficient. Whether immunotherapy biomarkers in previous studies (TMB, MSI, PD-L1, etc.) have equivalent predictive value for G/GEJ remains to be verified. In this phase II clinical trial of tislelizumab in combination with chemotherapy, potential therapy-related biomarkers in tumor samples, and changes in the tumor microenvironment during treatment were analyzed, and a predictive model for efficacy was developed.
Methods: This was a prospective, single-center, single-arm, phase II trial. Patients with G/GEJ adenocarcinomas (stage cT3-4aN+M0) were treated with PD-1 inhibitor tislelizumab in combination with oxaliplatin plus capecitabine (XELOX) as neoadjuvant treatment for 2 or 3 cycles. The primary endpoint was the major pathological response (MPR). The secondary endpoints included pathological complete response (pCR) rate, R0 resection rate, and safety. Tumor samples underwent RNA-sequencing (Amoy Diagnostics Co Ltd, Xiamen, China), to identify potential biomarkers, and a predictive model was developed to explore factors influencing tumor response and survival.
Results: 28 patients were enrolled; mean age was 59.5 years (SD = 8.2), 19 (67.9%) patients were male; 14 (50.0%) patients with primary tumor location in the stomach, and 14 (50.0%) patients with primary tumor location in the GEJ. All patients were EB virus negative. Except one patient with PMS2 loss, 27 patients were pMMR. Nine (32.1%) patients achieved MPR after treatment, with four (14.3%) of them achieved pCR. The R0 resection rate was 96.4%, with 14 (50.0%) patients achieved objective response. No serious adverse events were reported. The most common grade 2 TRAEs during neoadjuvant treatment were anemia (5 of 28, 17.86%) and nausea (3 of 28, 10.71%). Analysis of differentially expressed genes revealed enrichment of the antigen processing and presentation pathway in the MPR group, while the TGF-β signaling pathway was enriched in the non-MPR group. Notably, the differential immune microenvironment analysis also uncovered significant differences in the TGF-β signature between the MPR and non-MPR groups. Additionally, a therapeutic response prediction model (HT score) was developed with an AUC of 0.98 (0.932-1) in the training set, and its performance was validated in publicly available datasets.
Conclusion: Tislelizumab combined with XELOX holds promise as a neoadjuvant therapy for resectable G/GEJ adenocarcinomas, especially for EBV- and pMMR population, offering a well-tolerated safety profile. Moreover, the HT score has the potential to predict treatment efficacy in this regimen.
Trial registration numbers: NCT05507658 and NCT05508399.

#6401 Predictive models for first-line immunotherapy based on spatial tumor immune microenvironment in patients with advanced non-small cell lung cancer (NSCLC).

C. Xiang[1], J. Zheng[2], S. Chen[2], Z. Shang[1], S. Yang[2], L. Guo[1], L. Jiao[3], Y. Wang[2], **Y. Han**[1];
[1]Shanghai Chest Hospital, Shanghai, China, [2]Virtue Diagnostics (Suzhou) Co., Ltd., Shanghai, China, [3]Panovue Biotechnology (Beijing) Co., Ltd, Beijing, China

Background: Anti-programmed cell death protein 1/programmed cell death ligand 1 (anti-PD1/PDL1) based immunotherapy is the standard first-line treatment for advanced NSCLC patients without targetable driver mutations, but PDL1 immunohistochemistry (IHC) shows limited predictive value as companion diagnostics. Recent studies have elucidated a strong relationship between immunotherapy efficacy and tumor immune microenvironment (TIME) using single-cell multi-omics technology. In this study, we aim to develop predictive models for both objective response rate (ORR) and progression-free survival (PFS) using TIME features with machine learning in advanced NSCLC patients treated with first-line immunotherapy.

Methods: A total of 210 patients with advanced NSCLC who received anti-PD-1/PDL-1 therapy at Shanghai Chest Hospital from Jan. 2020 to Jan. 2023 were included in this study. Among them, 110 cases who received pembrolizumab were randomly split into training set and validation set with a 2:1 ratio. The remaining patients were designated as independent validation cohort. Five multiplex immunohistochemistry (mIHC) panels were developed based on literature review and in-house dataset mining. mIHC tests were performed using baseline tumor samples. Immunotherapy efficacy was evaluated by ORR and PFS (RECIST v1.1). ORR and PFS models were developed using machine learning methods in training set with 5-fold cross-validation and further validated in validation set and independent validation cohort.

Results: After data cleaning, 68 cases in training set and 34 cases in validation set were further analyzed. In terms of single immune- or spatial- based biomarker, positive rate of PD1+ cells in stroma and spatial relationship of PD1+/PDL1+ cell pairs exhibited the highest correlation with ORR. In addition, positive rate of PDL1+ tumor cells and nearest distance between FOXP3+ cells and tumor cells were highly correlated with PFS. Our ORR model achieved an AUC of 0.82 in the training set and 0.82 in the validation set. When applying optimal cutoff in our PFS model to stratify patients into low- and high- risk groups, low-risk group showed prolonged PFS in both training set ($p < 0.0001$; HR: 0.25, 95% CI [0.13 - 0.51]) and validation set ($p = 0.00046$; HR: 0.22, 95% CI [0.09 - 0.55]). Moreover, our ORR model outperformed PDL1 IHC (AUC: 0.81 vs 0.60; DeLong's test $p = 0.005$) in these 102 patients. Independent validation of the models is still awaited.

Conclusion: Using machine learning methods, we developed and validated ORR and PFS predictive models for first-line immunotherapy in advanced NSCLC patients based on mIHC technology. Our models displayed superior diagnostic performance compared to PDL1 IHC results.

#6402 Treatment resistance and survival prediction using a machine learning gene expression signature in pancreatic adenocarcinoma.

J. Liu[1], X. Lin[1], C. D. Shriver[2], H. Hu[1];

[1]Chan Soon-Shiong Institute of Molecular Medicine at Windber, Windber, PA, [2]Uniformed Services University of the Health Sciences; Walter Reed National Military Medical Center, Bethesda, MD

Background: Pancreatic adenocarcinoma (PAAD) is highly aggressive and difficult to treat. The 5-year survival rate is only 12.5%. The Cancer Genome Atlas (TCGA) data has shown about 51% of PAAD patients didn't achieve complete response after first course of treatment (CRAFCT); this study is to use TCGA data to develop survival-treatment associated gene signature to screen the patients, and provide novel therapeutic strategies to customize patient treatment. **Methods:** RNAseq data of 177 PAAD patients and their clinical data were downloaded from TCGA data portal and processed. The dataset was randomly split into training and testing data. RNAseq data analysis and survival analyses were performed on the training data to identify the survival-treatment associated genes, and a survival-treatment gene signature was derived and independently tested on the test data using signature score by cutoff, logistic regression, and random forest. Furthermore, the signature was validated by an independent dataset of 96 cases. **Results:** Among the 177 patients, 137 patients had the information of CRAFCT, and 122 patients had specific treatment information. Among those 122 patients, 99% received chemotherapy, 36% received radiation therapy. About half of the PAAD patients (51%) didn't achieve CRAFCT. RNAseq data analysis identified 304 significantly expressed genes associated with the status of complete response Yes vs No, and survival analyses further selected 55 genes associated with both treatment and survival as a signature. This signature, using z-scaled scores and the cut-off of 0.3, was applied to the 99 patients of training data; the accuracy is 0.66, and the patients predicted to be Yes had a significantly better (p=0.005, HR=0.42) overall survival than those predicted No. To further test the signature, we applied it to the test data of 78 patients; the random forest model showed patients screened to be Yes had a significantly better (p=0.016, HR=0.43) overall survival than those screened No. The signature (using 40 of the 55 genes) was applied to an independent dataset of 96 cases to significantly screen the patients to be Yes vs No (resistance to treatment) with p=0.04 and HR=0.57, showing the 55-gene signature is valid and robust. **Conclusion:** A 55 survival-treatment associated gene signature was developed and validated robustly, and can potentially be applied as a novel strategy to screen patients for treatment response/resistance. These 55 genes could also be targeted to develop new drugs for those difficult to treat PAAD patients. **Disclaimer:** The contents of this publication are the sole responsibility of the author(s) and do not necessarily reflect the views, opinions or policies of USUHS, HJF, the DoD or the Departments of the Army, Navy or Air Force. #6403 Presence of Stroma AReactive Invasion Front Areas (SARIFA) - a potential novel histopathological tool for therapy response prediction in colorectal cancer.

N. G. Reitsam[1], K. Offermanns[2], B. Grosser[1], J. Zimmermann[1], C. Simons[2], J. N. Kather[3], P. A. van den Brandt[4], B. Markl[1], H. I. Grabsch[2],
[1]University of Augsburg, Augsburg, Germany, [2]University Medical Center+, Maastricht, Netherlands, [3]Technical University Dresden, Dresden, Germany, [4]Department of Epidemiology, Maastricht, Netherlands

Background: Although many approaches based either on molecular investigations or on deep-learning algorithms applied to tissue sections have been proposed to stratify colorectal cancers (CRC) patients, clinical implementation of these novel cost-and time-consuming techniques is lacking, and conventional tumor-node-metastasis (TNM) staging remains one of the key factors to determine patient's treatment. Hence, we developed a novel and solely Haematoxylin and Eosin (H&E) based histopathologic prognostic biomarker, called SARIFA (Stroma AReactive Invasion Front Areas, i.e., direct contact between tumor cells and fat cells).

Materials/Methods: Based on a previous study, in which we could show that gene-expression based computational drug response prediction (*oncoPredict*) indicates a SARIFA-dependent differential drug sensitivity, we investigated whether SARIFA-status can predict which CRC patients might benefit from adjuvant therapy. SARIFA-status was established for 1,727 CRC patients from the prospective Netherlands Cohort Study. Multivariate-adjusted Cox regression analysis was performed (median follow-up: 4.79 years, with 1,463 deaths being observed in the first 10 years of follow-up [933, 63.8%, were CRC-related]). Only stages II to IV were included for further analysis regarding differential treatment response (n = 1,384).

Results: In Multivariate-adjusted Cox regression analysis including patient age, sex, tumor location, pTNM stage, grade of differentiation, and mismatch repair status, SARIFA-positive CRC patients (n=496) benefitted significantly from adjuvant therapy ($HR_{CRC\text{-}specific}$ 0.59; 95% CI 0.44-0.78) compared to SARIFA-positive patients treated with surgery alone, which was not significant for SARIFA-negative CRC patients ($HR_{CRC\text{-}specific}$ 0.88; 95% CI 0.68-1.15). Regarding overall survival (OS), adjuvant therapy led to better OS outcomes regardless of SARIFA-status ($HR_{overall\ all\ patients}$ 0.74; 95% CI 0.62-0.87).

Conclusion: Our results suggest that SARIFA-positivity predicts a CRC-specific survival benefit from adjuvant therapy. As SARIFA-positivity is closely linked to an upregulation of lipid metabolism and an altered immune response, further studies are warranted to explore the potential benefit of not only conventional chemotherapy but also immunotherapy, targeted therapy as well novel drugs targeting lipid-metabolism. As SARIFA-status can be assessed fast and easily on for every cancer patient available H&E slides, SARIFA-status could serve as an ideal biomarker for a more detailed patient stratification in prospective clinical trials, and should be implemented into clinical routine if further validated.

#6404 GRB2 stabilizes RAD51 at reversed replication forks restricting genomic instability and associated innate immune response.

Z. Ahmed, Z. Ye, S. Xu, Y. Shi, X. Cheng, Y. Zhang, S. Roy, S. Namjoshi, M. A. Longo, T. Link, K. Schlacher, G. Peng, D. Yu, B. Wang, J. Tainer;
The University of Texas MD Anderson Cancer Center, Houston, TX

Growth factor receptor-bound protein 2 (GRB2) is a cytoplasmic adapter for tyrosine kinase signaling and a nuclear adaptor for homology-directed-DNA repair. Here we find nuclear GRB2 protects DNA at stalled replication forks from MRE11-mediated degradation in the BRCA2 replication fork protection axis. Mechanistically, GRB2 binds and inhibits RAD51 ATPase activity to stabilize RAD51 on stalled replication forks. In GRB2-depleted cells, PARP inhibitor (PARPi) treatment releases DNA fragments from stalled forks into the cytoplasm that activate the cGAS-STING pathway to trigger pro-inflammatory cytokine production. Moreover in a syngeneic mouse metastatic ovarian cancer model, GRB2 depletion in the context of PARPi treatment reduced tumor burden and enabled high survival consistent with immune suppression of cancer growth. Collective findings unveil GRB2 function and mechanism for fork protection in the BRCA2-RAD51-MRE11 axis and suggest GRB2 as a potential therapeutic target and an enabling predictive biomarker for patient selection for PARPi and immunotherapy combination.

#6405 Identification of molecular targets in bladder cancer variants using single-cell analysis.

H. Yang[1], H. Song[1], P. Allegakoen[1], K. Lu[1], E. Yip[1], K. Hui[1], K. Chang[1], C. Kasap[1], J. Gayle[2], B. Stohr[1], A. Wiita[1], C.-K. C. Ding[1], M. V. Meng[1], J. Chou[1], S. P. Porten[1], F. W. Huang[1];

[1]University of California San Francisco, San Francisco, CA, [2]University of California Santa Barbara, Santa Barbara, CA

Introduction and objectives: Variant subtypes in bladder cancer, also known as histologic variants, are clinically aggressive tumors associated with poor prognosis. The rarity of these tumors has made molecular characterization elusive using bulk transcriptional profiling. The aim of this study was to use single cell RNA sequencing to identify molecular features associated with variant subtypes that could be potential targets for therapy.

Methods: Fresh tissue from bladder cancer patients undergoing surgery at our institution was sequenced using a bead-based single-cell RNA sequencing platform (Seq-Well) to generate an atlas of 9 tumors containing variants (micropapillary, nested, squamous differentiation, pleomorphic giant-cell like, plasmacytoid, small cell) and 3 tumors with pure urothelial carcinoma (UC) histology. Pathologic diagnoses were independently confirmed. Analysis was performed using the Seurat package in R Studio. Immunostaining validation was performed on a separately banked cohort. Bulk RNA sequencing data and clinical data were extracted and analyzed from The Cancer Genome Atlas (TCGA) database. Chimeric Antigen Receptor (CAR) T cells targeting TM4SF1 were generated by lentiviral transduction of primary human T cells and tested against publicly available bladder cancer cell lines.

Results: Variant tumors were enriched in TM4SF1, a surface molecule that we demonstrate to be susceptible to CAR T therapy in vitro. Variants also share a cell state characterized by highly specific expression of *MUC16* (CA125), which is enriched in metastatic sites, harbors transcriptional hallmarks of epithelial-mesenchymal transition and luminal-basal plasticity, and is associated with poor survival and resistance to chemotherapy. Finally, we find evidence of transcriptional mimicry between variants and similar appearing non-urothelial cells (e.g. plasmacytoid:plasma cell), suggesting common pathways between distinct cell types that could be exploited.

Conclusion: We have identified several targetable molecular features within variant bladder cancer subtypes. These findings set a critical starting point for future therapeutic investigation.

#6406 Clinical and translational results of the academic ARIANES Phase 2 basket study: Longitudinal single-cell analysis of patient tumors identifies biological correlates of response to PARP inhibitors and anti-PD-L1 therapy.

J. Vibert[1], C. Henon[1], L. Tselikas[1], B. Bonnet[1], A. Pages[1], A. Bernard-Tessier[1], L. Colmet-Daage[1], R. Chabanon[1], N. Dorvault[1], C. Astier[1], A. Gazzah[1], A. Jeanson[1], A. Parpaleix[1], R. Flippot[1], N. Naoun[1], A. Patrikidou[1], P. Lavaud[1], G. Baciarello[1], E. Colomba[1], A. Fuerea[1], L. Albiges[1], C. Massard[1], S. Ponce[1], Y. Loriot[1], S. Champiat[1], C. Baldini[1], F. Bouquet[2], N. Droin[1], K. Fizazi[1], D. Vasseur[1], P. Martin-Romano[1], E. Rouleau[1], K. Ouali[1], S. Postel-Vinay[1];
[1]Gustave Roussy, Villejuif, France, [2]F. Hoffmann-La Roche Ltd, Basel, Switzerland

Background: Poly (ADP-ribose) polymerase inhibitors (PARPi) have immunomodulatory properties that may potentiate anti-PD-L1 therapy. To explore this, we developed the academic ARIANES phase 2 basket trial, which evaluated the PARPi rucaparib (R) and the anti-PD-L1 atezolizumab (A) in selected patients (pts). We performed single-cell RNA + T cell receptor sequencing (scRNA+TCR-seq) on 3 sequential tumor biopsies in a pts subset.
Methods: ARIANES comprised 4 molecularly-selected DNA damage response deficient (DDRd), 3 platinum-sensitive, and 2 unselected cohorts of pts with non-small cell lung (NSCLC), prostate (CRPC), and other non-breast non-ovarian cancers. R was administered for 3 weeks, followed by R+A. Primary endpoint was overall response rate (ORR) at 12 weeks per cohort. scRNA+TCR-seq was performed on fresh biopsies collected at baseline, on R, and on R + A in the same lesion, with concomitant plasma collection. We tracked the evolution over time of tumor and microenvironment cells, differentially expressed genes and signatures within each cell population, and TCR clonal dynamics.
Results: ARIANES enrolled 130 pts, including 27 DDRd CRPC and 3 DDRd NSCLC pts, on which we focus here. Best ORR by RECIST v1.1 was 22% (6/27) in CRPC pts, and mPFS: 7.9 months (95% CI 4 - 11.1) at data cut-off. ORR was 0% in NSCLC pts. We successfully profiled 3 sequential fresh biopsies in 2 *BRCA2*-mutant CRPC, 1 *ATM*-mutant, and 1 *RAD54L*-mutant NSCLC pts. Tumor, T and B lymphoid, myeloid, plasma, dendritic, NK, endothelial, and stromal cells were identified in all samples. Differential expression testing unveiled *PARP1* upregulation in tumor cells on R. One CRPC pt with prolonged partial response displayed activation of innate immune sensing pathways (including cGAS-STING and IFN signaling) in tumor and immune cells, as well as JAK/STAT and *CCL5*, all increasing gradually on R and R + A; scTCR-seq revealed the expansion of specific T cell clonotypes on R + A. One *ATM*-mutant NSCLC pt with 6-month stable disease displayed increased cGAS/STING, JAK/STAT and *CCL5* activation on R in NK cells only, and no TCR expansion. None of the above was observed in the 2 pts who progressed. Complete clinical and translational study results will be presented at the congress.
Conclusion: Sequential scRNA+TCR-seq enables the dynamic assessment of tumor and immune cells on therapy. Our data confirms the potential of R to activate innate immune pathways in pt tumors, and R + A to induce T cell activation and clonal expansion. To our knowledge, this is the first study providing a longitudinal single-cell resolution analysis of the clonal evolution of tumor and immune cells in pts on PARPi + anti-PD-L1. We identify potential biological correlates of therapy response, including the activation of innate immune pathways and TCR expansion.

#6407 Identification of novel chemotherapy-related CHIP variations in patients with high-grade serous ovarian cancer.

S. Corvigno, A. Asare, J. Yao, L. Zhao, N. Fleming, J. Celestino, R. A. Hajek, E. A. Arboleda Goette, R. T. Rogers, T. V. Nguyen, R. N. Montoya, K. H. Lu, A. A. Jazaeri, S. N. Westin, A. K. Sood, S. Lee;
UT MD Anderson Cancer Center, Houston, TX

Background: Hematopoietic lineage differentiation is subjected to genetic mutations that, due to fitness advantages, might give rise to clonally expanded populations. Clonal hematopoiesis of indeterminate potential (CHIP) is defined as the outgrowth of a single clone driven by acquired somatic mutations in hematopoietic stem cells (HSCs), in the absence of hematological abnormalities. Previous studies have shown the association of CH with aging and a higher risk of developing secondary hematologic malignancies in cancer patients treated with chemotherapy agents. It is therefore of great interest to study CH incidence prior to and post chemotherapy exposure and its association with the evolution of hematologic malignancies. We aimed to characterize CHIP variants of a highly selected group of patients with high-grade serous ovarian cancer (HGSC) who underwent neoadjuvant chemotherapy (NACT).
Methods: Comprehensive ultra-high-depth whole exome sequencing, employing unique molecular barcode technologies, was performed using plasma-derived cell-free DNA (cfDNA) and matched white blood cells (WBC) DNA and tumor DNA from pre-NACT (n=10) and post-NACT (n=10) samples of patients with HGSC. CHIP variants were defined as heterozygous variants found in both the WBC and cfDNA samples from the same patients with variant allele frequency less than 5% in the WBC and higher than 0.5% in cfDNA samples.
Results: Our analysis identified 93,088 variants, impacting 13,780 genes. Among them, 463 variants were already known and published, and 5,548 variants were common to the COSMIC genes signature. The number of CHIP variants significantly decreased after chemotherapy ($p = 0.004$). We then focused on CHIP variants enriched after chemotherapy and identified 77 that showed higher VAF in post-NACT cfDNA samples, which may be associated with the development of therapy-related acute myeloid leukemia/myelodysplastic syndrome (t-AML/MDS). Among them, interestingly, we found a missense mutation with protein change in *CDK12* (chr17_39492765_G_T). We noticed that 38% of the CHIP variants found in cfDNA samples, were also found in matched tumor samples. Among these, another *CDK12* missense mutation (chr17_39492768_A_T) showed higher VAF in post-NACT tumors.
Conclusions: Our innovative approach detected a higher number of CHIP variants than currently characterized. Analysis of cfDNA from HGSC patients consistently demonstrated a reduction in CHIP mutations post-NACT. The subset of variants with increased VAF post-NACT may be associated with therapy-related t-AML/MDS. The detection of cfDNA CHIP variants in matched tumors highlights the potential predictive role of CHIP in t-AML/MDS development, emphasizing its consideration in therapeutic protocols.

#6408 Early carcinoembryonic antigen (CEA) dynamics to predict the efficacy of fruquintinib (F) + best supportive care (BSC) in patients with metastatic colorectal cancer (mCRC) enrolled in FRESCO-2.

(TDCA), Lexington, MA,[14]HUTCHMED, Florham Park, NJ,[15]Vall d'Hebron Barcelona Hospital Campus, Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Spain

Background: The phase 3 FRESCO-2 trial (NCT04322539) demonstrated a significant survival benefit with fruquintinib (F) + BSC vs placebo (P) + BSC as third or later line of therapy for patients (pts) with mCRC. Based on the results of FRESCO-2, F was FDA-approved for adults with previously treated mCRC, irrespective of biomarker status. In mCRC, CEA levels and imaging are routinely used to monitor response to systemic therapy. We investigated early CEA changes during treatment in FRESCO-2 and possible relationships with efficacy.

Methods: Pts with abnormal baseline (BL) CEA were included based on local lab reference ranges. Serum CEA levels were measured at BL and Day 1 (D1) of each 28-day cycle (C) except C1. Changes in CEA levels were analyzed at C2D1 and C3D1. CEA response was defined as ≥50% decrease from BL, and CEA progression was defined as ≥100% increase from BL. Tumor evaluation was performed by CT or MRI scan every 2 cycles. Overall survival (OS) and progression-free survival (PFS) were evaluated by Kaplan-Meier method; hazard ratio (HR) was estimated via Cox proportional hazards model; p-value was generated from log rank test.

Results: Overall, 88.3% (407/461) vs 90.4% (208/230) of pts had abnormal BL CEA in F vs P arms; median BL CEA values were similar between treatment arms (Table). At C3D1, the proportion of pts who had a CEA response was significantly higher with F vs P (35.5% vs 3.8%, *P* <0.001) and the proportion who had CEA progression was significantly lower (5.7% vs 47.2%, *P* <0.001). Pts in the F arm with CEA response at C3D1 had improved OS and PFS vs pts without CEA response and pts with CEA progression (Table). These results were consistent for pts who had an early CEA response at C2D1 (Table).

Conclusion: CEA response at C2D1 and C3D1 could be considered an early predictor for improved OS and PFS. Pts with CEA response seem to benefit from F + BSC compared with pts without response or with CEA progression.

Table. CEA changes from baseline in pts in the F + BSC vs P + BSC arms, and OS and PFS based on CEA response in pts in the F + BSC arm

	CEA changes from baseline by treatment arm (ITT population)

#6409 A multiparametric flow cytometry assay to monitor regeneration of B-cells following anti B-cell therapy in cancer and autoimmune patients.

Amit Kumar Mehta, Ruby Tandon, Anil Pahuja, Jane Gao, Kevin Nguyen, Naveen Dakappagari, Zeni Alfonso

Navigate BioPharma, Carlsbad, CA

Purpose Functional dysregulation of B-cells leads to a variety of autoimmune disorders and blood cancers. Multiple B-cell depleting therapies (e.g., BTK inhibitors, antibodies or CAR-Ts) are currently in active clinical trial investigation. Following therapeutic elimination of pathogenic B-cells, it is critical to monitor the productive regeneration of fully functional B-cells as they mediate innate and adaptive immune responses. To this end, we developed a multiparametric flow cytometry assay for exquisite monitoring of early stages of B cell development, maturation, and antibody production to correlate it with treatment outcomes and determine if continuous depletion of B-cells is necessary to maintain clinical benefits for patients.

Study Design We designed a high throughput 12-parameter flow cytometry panel incorporating primary differentiation markers namely, CD45, CD3, CD38, CD10, CD27, CD19, CD20, IgD, Lambda & Kappa Light Chains required for identification of different developmental stages of B-cells in peripheral blood using an in vitro diagnostic grade flow cytometry system (BD FACSLyric). The optimized method underwent robust fit-for-purpose analytical validation per CLSI H62 guidelines with emphasis on establishing assay sensitivity, specificity, and reproducibility across experimental days, operators, and instruments.

Results We were able to reliably identify different stages of B-cell development, namely, Naïve (CD19+CD20+IgD+CD27-), Unswitched/Marginal (CD19+CD20+IgD+CD27+), Memory (CD19+CD20+IgD-CD27+), Transitional (CD19+CD20+IgD+CD27-CD10+), Antibody Secreting Cells (CD19+CD20-IgD-CD27+CD38^{hi}) as well as clonality (CD19+CD20+Lambda+ or Kappa+). The lower limit of quantitation was determined to be around 60 events, based upon analysis of 90 data points with good reproducibility (CV range: 0-11.7%) across experimental days, operators and instruments demonstrating sensitive detection and robust performance.

Conclusion In summary, we have developed and validated a 12-parameter flow cytometry assay focusing on monitoring the regeneration of different subsets of B-cells in various B-cell malignancies (Non-Hodgkin's Lymphoma, B CLL) and autoimmune disorders (Multiple Sclerosis, Rheumatoid Arthritis, Systemic Lupus Erythematosus). The high reproducibility/robustness of the assay demonstrates its suitability for use in clinical trials as a valuable tool for safety monitoring and disease evaluation enabling development of novel therapeutic agents.

#6410 An exosomal microRNA signature predicts the efficacy of ramucirumab plus paclitaxel in advanced gastric cancer: Findings from the prospective IVY trial.

K. Shoda[1], C. Xu[1], Y. Asahii[2], T. Nagasaka[3], D. Ichikawa[4], A. Goel[1];

[1]Beckman Research Institute of City of Hope, Monrovia, CA, [2]Biomedical Research Center of City of Hope, Monrovia, CA, [3]Kawasaki Medical School, Okayama, Japan, [4]University of Yamanashi, Yamanashi, Japan

Purpose: With rapid advances in the development of effective therapeutic regimens in patients with advanced gastric cancer, it is imperative to establish individualized treatment approaches that can help identify patient subsets that have the highest likelihood of response to a specific regimen. Although ramucirumab plus paclitaxel therapy is the standard second-line treatment for patients with advanced gastric cancer, biomarkers that can help predict therapeutic response are still lacking. This longitudinal study aimed to establish a liquid-biopsy assay that can predict response to ramucirumab plus paclitaxel therapy in patients with advanced gastric cancer.

Experimental Design: A prospective observational multicenter study (named the IVY study) enrolled 115 patients who received ramucirumab plus paclitaxel treatment. We collected serum specimens prior to the initiation of the treatment regimen. Patients were divided into responders and non-responders according to the response evaluation criteria in solid tumors (RECIST). We performed small RNA-sequencing (sRNA-Seq) in a subset of 28 patients with and without response to identify exosomal microRNA-based biomarkers that allowed risk stratification and response prediction in patients with advanced gastric cancer.

Results: The sRNA-Seq analysis and rigorous bioinformatic approaches using machine-learning algorithms allowed us to identify a panel of 10 exosomal microRNAs that robustly predicted resistance to ramucirumab plus paclitaxel treatment (AUC: 0.83). The panel of exosomal miRNAs was also shown to have a robust prognostic value for predicting survival outcomes in gastric cancer patients treated with ramucirumab plus paclitaxel, and Cox proportional hazards regression analysis showed that patients classified as high risk on the panel of exosomal miRNAs independent poor prognostic factor (OS: HR = 2.74, 95% CI = 1.56-4.81, P < 0.01, RFS: HR = 1.84, 95% CI = 1.16-2.92, P < 0.01). Following logistic regression and backward elimination, we trained a clinically feasible 5 exosomal miRNA signature by combining it with the Body Mass Index data, an independent clinical predictor (AUC: 0.84). We subsequently successfully validated the performance of this signature in the prospective clinical trial cohort (AUC: 0.87). Finally, we established a prognostic risk nomogram based on the circulating exosomal miRNA signature for a non-invasive and personalized pre-therapeutic selection approach.

Conclusions: We have developed a novel liquid biopsy-based assay that allows robust prediction of response to ramucirumab plus paclitaxel treatment in gastric cancer patients, and our assay provides a framework for a personalized medicine approach that can provide risk-based management and treatment for each patient prior to the initiation of therapy.

#6411 The gut microbiome is associated with recurrence free survival in patients with resected Stage III or Stage IV melanoma treated with immune checkpoint inhibitors.

M. Usyk[1], R. B. Hayes[1], R. Knight[2], A. Gonzalez[2], H. Li[1], I. Osman[1], J. S. Weber[1], J. Ahn[1];
[1]NYU Grossman School of Medicine, New York, NY, [2]University of California - San Diego, San Diego, CA

The gut microbiome (GMB) plays a crucial role in immune checkpoint blockade (ICB) therapy outcomes for metastatic melanoma patients, yet there remains a lack of consensus regarding the specific microbiota associated with clinical outcomes, particularly across different geographic regions. Furthermore, investigations into the relationship between GMB and melanoma outcomes in the adjuvant setting are notably absent. This highlights the pressing need for a comprehensive, large-scale study spanning diverse geographic locations within a well-controlled clinical trial environment. In this study, we conducted shotgun sequencing on pre-treatment stool samples collected from 674 melanoma patients participating in an international, randomized, double-blind, phase III adjuvant trial evaluating clinical outcomes following adjuvant nivolumab plus ipilimumab versus nivolumab. Our recruitment encompassed three continents and five geographically distinct regions. Given the significant influence of geographic region on GMB composition, we employed three analytical approaches: (a) region-specific analyses, (b) combined meta-analyses across regions, and (c) sub-set paired analyses involving subjects closely matched for overall GMB. Additionally, we assessed GMB stability by examining samples collected serially prior to therapy and at weeks 7 and 29 of ICB treatment. Through region-specific and meta-analyses, we identified ten pre-treatment gut bacterial markers, including Eubacterium, Ruminococcus, Clostridium, and Firmicutes, which exhibited associations with melanoma recurrence in the adjuvant setting. The predictive capacity of these microbial markers was directly proportion to GMB similarity (Spearman correlation = 0.86, $p<0.001$ for AUC vs. beta-diversity). Notably, for closely matched patients in terms of their GMB composition, the prediction of recurrence using the recurrence-associated markers, in conjunction with clinical characteristics, yielded an AUC of 0.917 (95% CI: 0.825-1.00). Furthermore, GMB remained largely stable across serial samples collected before and after treatment (PERMANOVA $R2 = 0.867$, $p\text{-val}<0.001$, at baseline, week 7, and week 29). This study underscores the remarkable stability of GMB during adjuvant ICB therapy for melanoma and identifies specific bacterial biomarkers that hold promise for predicting melanoma recurrence within the adjuvant treatment setting. The gut microbiome emerges as a potential source of microbial biomarkers for individualized prediction of melanoma recurrence in clinical practice.

#6412 Combination of liquid biopsy and PET/CT enhances prediction of pathological response to neoadjuvant immunochemotherapy in patients with esophageal squamous cell carcinoma.

Weixiong Yang[1], Zengli Fang[1], Xiaoyan Wang[2], Hui Luo[2], Shuishen Zhang[1], Bo Zeng[1], Zhenguo Liu[1], Chenxuan Wang[3], Qiuxiang Ou[3], Lingling Yang[3], **Haimeng Tang**[3], Sai-Ching J. Yeung[4], Chao Cheng[1]

[1]Department of Thoracic Surgery, The First Affiliated Hospital of Sun Yat-sen University, Guangzhou, China,[2]Department of Nuclear Medicine, The First Affiliated Hospital of Sun Yat-sen University, Guangzhou, China,[3]Nanjing Geneseeq Technology Inc, Nanjing, China,[4]Department of Emergency Medicine, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Neoadjuvant immunochemotherapy (NICT) demonstrated remarkable efficacy in esophageal squamous cell carcinoma (ESCC) patients. An accurate evaluation of treatment response is critical before surgery. Therefore, this study aimed to explore and evaluate the use of non-invasive and clinical assessments to predict pathological response to NICT prior to surgery in these patients.

Methods: A total of 71 ESCC patients who received NICT between March 2020 and February 2022 were recruited in this study. Clinicopathological characteristics and PET/CT assessment before and after NICT were evaluated. Peripheral blood mononuclear cells (PBMCs) were prospectively collected for genomic and T cell receptor (TCR) profiling using targeted next-generation sequencing and multiplex PCR, respectively. Univariate analysis was performed to identify features associated with pathological complete response (pCR) of primary tumor. Optimal predictive features were identified using the least absolute shrinkage and selection operator (LASSO) regression model. Subsequently, a prediction model was established using logistic regression, followed by receiver operating characteristic (ROC) analysis and internal validation.

Results: Univariate analyses revealed significant associations between pCR and post-NICT features, including ctDNA, PET/CT parameters, and TCR clonality and diversity. Optimal predictive features were identified as post-NICT SUVmax, ctDNA positivity, and TCR clonotype clonality, and their area under the ROC curve (AUC) was 0.784 (95%CI: 0.644-0.924), 0.739 (95%CI: 0.664-0.813), and 0.682 (95%CI: 0.535-0.829), respectively. The final prediction model integrating these three features achieved an AUC of 0.918 (95%CI: 0.849-0.986), an accuracy of 0.768 (95%CI: 0.661-0.875), a sensitivity of 1.000 (95%CI: 1.000-1.000), and a specificity of 0.705 (95%CI: 0.568-0.841), indicating excellent predictive performance.

Conclusion: The combination of post-therapy ctDNA status, TCR clonality, and PET/CT assessments showed robust predictive power for assessing pathological response to NICT in ESCC, suggesting the potential to inform clinical decision-making for these patients. Future large-scale studies are warranted to strengthen and verify the findings from our study.

#6413 Biomarkers of response and progression to Pembrolizumab and Vorinostat combination in late-stage squamous cell carcinoma patients of different locations included in the PEVOsq basket trial.

C. Le Tourneau[1], L. Mazzarella[2], B. Cabarrou[3], M. Francisco[4], C. Dupain[1], M. Halladjian[1], G. Frige[2], B. Duso[2], Y. Zhan[2], E. Guerini-Rocco[2], R. Noberini[2], T. Bonaldi[2], M. Tonini[5], G. Marret[1], C. Coutzac[6], E. Coquan[7], M. Saint-Ghislain[1], O. Le Saux[6], L. Chanas[1], F. Legrand[8], D. Filippini[1], E. Jeannot[1], S. Bernhart[9], G. Balogh[9], M. Jimenez[8], T. Filleron[3], N. Servant[4], M. Kamal[1];

[1]Institut Curie, Paris, France, [2]IEO - Istituto Europeo di Oncologia IRCCS, Milan, Italy, [3]Institut Claudius Regaud, IUCT-Oncopole, Toulouse, France, [4]INSERM U900, Paris, France, [5]Luxembourg Institute of Health, Luxembourg, Luxembourg, [6]Centre Leon Berard, Lyon, France, [7]Centre Francois Baclesse, Caen, France, [8]Unicancer, Paris, France, [9]Universitat Leipzig, Leipzig, Germany

Background: Epigenetic modulation plays a major role in escaping tumor immunosurveillance. PEVOsq (NCT04357873) was an open-label, non-randomized, multi-center, basket phase II trial evaluating the efficacy of pembrolizumab (P) and the vorinostat (V) HDAC inhibitor in 112 patients (pts) with recurrent and/or metastatic squamous cell carcinoma (SCC) of the cervix, head and neck, anus, vulva/vagina, penis, and lung. Results showed an objective response rate (ORR) of 25%, the highest being in anal (31%) and cervical (39%) (ASCO #397612). We report here early biomarkers of response and progression to P+V.

Patients and Methods: Pts had to undergo a tumor biopsy at baseline, and optional biopsies on-treatment (after cycle 2), and at progression for translational analyses. PD-L1 expression (n=102), tumor-infiltrating lymphocytes quantification (n=39), HPV typing (n=111), WES (n=83), RNAseq (n=82) and liquid chromatography-mass spectrometry (LC-MS) quantitative analysis of histone post-translational modifications (PTMs) (n=44) were performed on baseline samples.SNVs, CNVs, TMB, MSI status (by MSI sensor), aneuploidy score (AS), mutational signatures, immune signatures, and histone modifications were correlated with response and progression.

Results: Sixty-six pts were HPV+ (59%). Most frequently altered genes were *PIK3CA* (30%), *TP53* (30%), *KMT2D/C* (18 and 17%), and *FGF3/4* (17%). MSI was detected in 4 pts (5%), and TMB-high (>10mut/Mb) in 13 pts (16%). High AS (>10) was detected in 34 pts (40%), and was significantly associated with HPV- status (p=0.03). TMB high and MSI were associated with MMR mutational signatures (p<0.01). TMB high was also associated with APOBEC (p=0.02) and DNA polymerase (POL) signatures (p <0.01). Biomarkers associated with improved overall survival (OS) included HPV positivity (7.8 months versus 17.4 months, p<0.01), high TMB (not reached versus 10.3 months, p=0.01), and high PD-L1 CPS score (13.2 months versus 7.0 months, p=0.06).Deconvolution of immune cell infiltration showed an expected trend for increased CD8 and decreased neutrophil infiltration in non progressor pts.Interestingly, LC-MS histone PTMs profiling showed a significant decrease in H4K5K8K12K16-4ac (p=0.05) and increase in H3K27me2K36me1 in non progressor pts (p=0.03). At the transcriptomic level, although not statistically significant, we observed modulation in the expression of genes associated with H3K36me1 (KDM2A, SETD3, SMYD2), and H3K27me3 (KDM6A) regulation, as well as HDAC genes.

Conclusions: HPV+ status was associated with improved OS, together with a high TMB and PD-L1 expression. CD8, macrophages and neutrophil signatures at baseline were associated with response. Promising epigenetic biomarkers were identified using LC/MS and will be correlated to transcriptomic and genomic data.

#6414 Molecular differentiation between complete and incomplete responders to neoadjuvant therapy in rectal cancer.

F. Huang[1], M. McLeod[1], R. Irwin[1], M. Smithson[1], Z. Yue[2], M. Gao[1], K. Hardiman[1], Z. Chong[1];
[1]University of Alabama at Birmingham, Birmingham, AL, [2]Auburn University, Auburn, AL

Neoadjuvant chemoradiotherapy (nCRT) is the standard treatment for locally advanced rectal cancer, but only 20-40% of patients completely respond to this treatment. This study aims to identify the molecular features associated with a response to nCRT. We generated and collected genomic and transcriptomic data from 712 cancers prior to treatment from our own data and from publicly available data. A comprehensive integrated analysis was performed. We found that patients with a complete response have decreased risk of both local recurrence and future metastasis. We identified multiple molecular differences between complete and incomplete responders. Complete responders have a higher tumor mutation burden and more significant co-occurring mutations than the incomplete responders. In addition, mutations in DNA repair genes were enriched in complete responders and they also had lower expression of these genes indicating that defective DNA repair is associated with complete response to nCRT. Using logistic regression, we identified three significant predictors of complete response: tumor size, mutations within specific network genes, and the existence of three or more specific co-occurrent mutations. In incompletely responder tumors, abnormal cell-cell interaction and increased cancer associated fibroblasts were associated with recurrence. Additionally, gene expression analysis identified a subset of immune hot tumors with worse outcomes and upregulation of immune checkpoint proteins. Our study directly informs the clinical management of rectal cancer by elucidating the molecular differences between tumors with complete and incomplete responses to neoadjuvant chemoradiotherapy (nCRT), as well as the features of tumors prone to recurrence. We have pinpointed critical molecular markers and clinical indicators—such as tumor size, specific gene mutations, and particular mutation patterns—that are significant predictors of treatment response. These findings offer valuable biomarkers for personalizing treatment strategies. Additionally, the observed mutation enrichment in DNA repair genes among complete responders suggests new avenues for therapeutic innovation. By highlighting the distinct molecular and immune profiles of non-responder tumors at higher recurrence risk, our research supports the advancement of precision oncology approaches, enhancing prognosis and treatment customization in rectal cancer care, ultimately striving to bridge the gap between scientific discovery and clinical application.

#6415 Comparison the results from PD-L1 IHC and PD-L1 multiplex immunofluorescence for the prediction of anti-PD-1 immunotherapeutic response.

H. Sun[1], X. Liu[1], T. Jiao[2], Q. Guo[2], H. Du[2], S. Han[1], L. Zhu[1], Z. Zhang[1], Y. Kong[2], **N. Li**[1];

[1]Beijing PhenoVision Bio Co., ltd, Beijing, China, [2]Department of Renal Cancer and Melanoma, Peking University Cancer Hospital & Beijing Institute for Cancer Research, Beijing, China

PD-L1 immunohistochemistry (IHC) is a popular clinical test before anti PD-1/PD-L1 immunotherapy (IMT). Multiplex immunofluorescence (mIF) exhibits its advantage to evaluate more than one target on one FFPE section to provide the features of multiple target expression and co-expression signals. Here, based on our pathology controlled mIF detection system and AI based analysis data, we compared IHC PD-L1 TPS to mIF PD-L1 TPS, PD-L1 positive rate, and other target positive rates in one mIF panel, to evaluate their correlations. The correlations of IHC PD-L1 TPS, mIF PD-L1 TPS, mIF PD-L1 positive rate and other marker positive rate to anti PD-1 IMT response were further analyzed in this study. Thirty melanoma patient samples in this study have received PD-1 IMT. 13 cases exhibited partial response (PR) and 17 cases were progressive disease (PD). PFS of PR group and PD group was 27.3 and 4.8 months, respectively. Archived patient FFPE sections were examined utilizing mIF of PN 6-Plex Detection Kit (Beijing PhenoVision Bio Co., ltd) targeted CD68, CD3, CD20, S100, PD-L1 (CST, E1L3N) and PD-1. The staining images were scanned, tumor areas were labeled by pathologists and analyzed using PhenoVision mIF AI analysis system trained from Oncotopix Discovery system (Visopharm). Series sections were examined utilizing Dako PD-L1 IHC 22C3 pharmDx and TPS was scored by one clinical pathologist. mIF TPS was calculated after AI data analysis, using PD-L1/S100 co-positive cell number divided by S100 positive cell number. Data mining was performed using log-rank Mantel-Cox test, Cox regression analysis and binary logistic regression model in SPSS. In current study, the correlation between pathology scored TPS (pTPS) and mIF PD-L1 positive rate was observed (Pearson correlation coefficient (PCC)=0.447, $p<0.05$). The consistency rate between pTPS and mIF TPS was 70% with no statistical significance. Moreover, the correlation between pTPS and mIF PD1/CD3 copositive rate was detected (PCC=0.604, $p<0.01$). Interestingly, mIF PD-1/CD3 copositive rate predicted PR and PD groups (AUC=0.8, $p<0.01$). Not pTPS nor mIF PD-L1 rate showed predictions here. Current results indicate that pTPS exhibited correlation to mIF PD-L1 positive rate instead of mIF PD-L1 TPS. CD3/PD-1 copositive rate but not pTPS nor mIF PD-L1 positive rate, shows its potential to predict anti PD-1 IMT response through the pathology controlled mIF detection system and AI based analysis system.

#6416 Early stage endometrioid endometrial cancer recurrence risk stratification using a machine learning RNA-seq gene expression signature.

Rafi Pelossof[1], Talal Ahmed[1], Seung Won Hyun[1], Chithra Sangali[1], Ben Terdich[1], Calvin Chao[1], Michael Toboni[2], Casey Cosgrove[3], Elizabeth Kidd[4], Brook Howitt[5], **Timothy Taxter**[1]

[1]Tempus, Chicago, IL,[2]Obstetrics and Gynecology, University of Alabama Birmingham, Birmingham, AL,[3]Gynecologic Oncology, The Ohio State University, Columbus, OH,[4]Radiation Oncology, Stanford University, Palo Alto, CA,[5]Pathology, Stanford University , Palo Alto, CA

Endometrioid endometrial cancer (EEC) adjuvant therapy decisions rely on risk stratification using histology, grade, stage, and lymphovascular space invasion (LVSI). Recently, molecular classification systems originating from TCGA, evaluated in GOG-210 and PORTEC-3 defined four prognostic subtypes based on POLE, MSI-H/MMR-D, and p53 alterations. Although valuable, this molecular approach still has significant limitations such as applicability to the majority of EEC patients categorized as no-specific molecular profile (NSMP) and the potential need to resolve pathogenic and prognostic heterogeneity within MMR-D, and TP53 subtypes. These unmet needs were key motivators for Tempus to develop a molecular classifier predicting distant recurrence risk in early-stage EEC with a focus on high intermediate-risk (HIR) patients.

The RNA-seq-based gene expression profiler (GEP) was trained using a machine-learning pipeline with TCGA data which resulted in a 24 gene signature that classifies EEC patients as molecular risk (MR) high or low (MR-high, MR-low). The GEP MR test was then evaluated on a de-identified cohort of EEC patients (N=1037) from Tempus to test associations with known pathologic or molecular prognostic features. The GEP-MR risk predictor showed significant enrichment of MR high-risk in G3 versus G1/2 histology (p-value < 5e-8). A high correlation was found between the MR score and copy number alteration score (t-test p-value < 1e-5). Next, a clinical evaluation was performed in an early-stage EEC case-control cohort of patients with documented recurrence or no recurrence event at four years (N=109), from Stanford. In the entire cohort, the MR-high group had a significantly higher rate of distant recurrence in comparison to the MR-low group (HR=4.8, N=109). Next, we performed a subgroup analysis in the clinically important HIR patients. In this subgroup, the MR-high group had a significantly higher rate of distant recurrence in comparison to the MR-low group (HR=8.0, N=56). Lastly, given the significance of genomic biomarkers in the evolution of EEC FIGO staging, we stratified outcomes by the established TCGA subtypes as a reference standard and performed a subgroup analysis in patients classified as having no specific molecular profile (NSMP). Among patients who were NSMP, the MR-high group showed a significantly higher rate of distant recurrence in comparison to the MR-low group (HR=7.92, N=67).

These evaluation studies demonstrate the performance of the GEP MR test in early-stage EEC distant recurrence risk stratification, specifically HIR patients, necessitating further studies to validate the test for clinical use in informing adjuvant clinical management.

#6417 Urinary PKM2 in muscle invasive bladder cancer.

D. Matye, J. Leak, E. Abbott, B. Woolbright, J. Taylor III;
University of Kansas Medical Center, Kansas City, MO

Background & Aims: Biomarkers are commonly used for both detection of cancer and monitoring response to treatment. Although several biomarkers have demonstrated promise in patients with bladder cancer (BCa), only urine cytology is widely utilized. Increased availability of effective biomarkers may improve clinical decision making and reduce the need for more invasive imaging. The M2 isoform of pyruvate kinase (PKM2) is upregulated in a number of cancers, including BCa, and promotes metabolic changes, including a shift to aerobic glycolysis. The aim of this study was to determine whether urine PKM2 levels are useful for detection and monitoring response to cisplatin-based neoadjuvant chemotherapy in patients with muscle invasive BCa.
Methods: Urine samples from patients enrolled in the University of Kanas Medical Center Bladder Cancer Biorepository were analyzed for levels of PKM2. Patients were included if they had both T2 stage disease and had received cisplatin-based neoadjuvant chemotherapy and were compared to healthy controls. Patients were categorized based on their pathological response to treatment and recurrence of disease within two years of definitive surgery. Urinary PKM2 levels were measured and evaluated for their ability to predict response to treatment and two-year disease-free survival.
Results: Immunohistochemistry revealed high levels of PKM2 within muscle invasive tumors compared to adjacent tissue. Patients with BCa had 150-fold increase in levels of urinary PKM2 compared to controls. However, there were no differences in urine PKM2 levels in patients with complete pathological response compared to those with no response. Urine PKM2 showed limited predictive value for disease recurrence (area under receiver operating characteristic curve = 0.65).
Conclusion: Urine levels of PKM2 are significantly elevated in patients with muscle invasive BCa and may be useful for tumor detection. Urinary PKM2 is less effective at monitoring response to treatment and may instead represent a marker of urothelial susceptibility to tumor formation.

#6418 Single-cell double expression of MYC and BCL2 proteins by fluorescent multiplex IHC is mainly in lymphoma cells with significant prognostic impact in large B-cell lymphoma while suggesting high cutoffs for routine IHC.

Z. Y. Xu-Monette[1], Y. Li[2], Q. Au[3], H. Nunns[3], W. Shi[1], A. Tzankov[4], C. Visco[5], G. Bhagat[6], E. Hsi[7], X. X. Zhao[7], K. Dybkaer[8], A. Chiu[9], W. Tam[10], Y. Zu[11], F. B. [1]Duke University Medical Center, Durham, NC, [2]Baylor College of Medicine, Houston, TX, [3]NeoGenomics Laboratories, Aliso Viejo, CA, [4]University Hospital Basel, Basel, Switzerland, [5]University of Verona, Verona, Italy, [6]Columbia University Irving Medical Center and New York Presbyterian Hospital, New York, NY, [7]Wake Forest University, Winston-Salem, NC, [8]Aalborg University Hospital, Aalborg, Denmark, [9]Mayo Clinic, Rochester, MN, [10]Weill Medical College of Cornell University, New York, NY, [11]The Methodist Hospital, Houston, TX, [12]The University of Texas MD Anderson Cancer Center, Houston, TX, [13]Dana-Farber Cancer Institute, Boston, MA, [14]Asan Medical Center, Seoul, Korea, Republic of, [15]San Raffaele H. Scientific Institute, Milan, Italy, [16]Odense University Hospital, Odense, Denmark, [17]Gundersen Lutheran Health System, La Crosse, WI, [18]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [19]Hospital Universitario Marques de Valdecilla, Santander, Spain, [20]Northwestern University, Chicago, IL, [21]The First Affiliated Hospital of Zhengzhou University, Zhengzhou, China, [22]The First Affiliated Hospital of Xiamen University, Xiamen, China

Introduction: MYC+BCL2+ double expression (DE) is a biomarker for poor prognosis in diffuse large B-cell lymphoma (DLBCL), likely due to the cooperation between MYC and BCL2 oncoproteins in tumor cells. However, as generally MYC and BCL2 are separately assessed on two different slides by immunohistochemistry (IHC), MYC+ and BCL2+ results are from different cells. With the WHO-recommended cutoffs, ≥40% for MYC and ≥50% for BCL2 (sum < 100%), there is chance that the so-called DE comes from non-overlapping regions of the tumor (not single-cell DE). Moreover, tumor expression scores based on morphology assessment often vary among pathologists. In this study, we performed fluorescent multiplex IHC (fmIHC) using a MultiOmyx™ immunofluorescence platform (NeoGenomics Laboratories, Inc.) to determine single-cell MYC and BCL2 co-expression for prognostic analysis in DLBCL.
Patients and Methods: Co-expression of MYC, BCL2, and 11 immunophenotypic markers by fmIHC was digitally quantified for 547 patients with DLBCL. Percentage of cells with MYC/BCL2 double or single expression was calculated for various cell types. Prognostic analysis was performed for de novo DLBCL cases, including 108 patients treated CHOP chemotherapy, and 356 patients treated with rituximab (R)-CHOP.
Results: First, although MYC and BCL2 were expressed in multiple cell types, the vast majority (>90%) of MYC+BCL2+ DE cells were lymphoma cells. Frequencies of MYC and BCL2 co-expression were consistent with random distribution of independent MYC/BCL2 expression in positive cases. The activated B-cell-like subtype compared with the germinal center B-cell-like subtype had a significantly higher mean percentage of MYC+BCL2+ DE, but not single BCL2 or MYC expression, in PAX5+ cells. Second, in both the R-CHOP and CHOP cohorts, high percentages of DE in PAX5+ cells and in all DAPI+ cells were associated with significantly poorer survival of DLBCL patients. Very high percentage of single BCL2 expression in PAX5+ cells was also associated with poorer survival, however, only in a small number of patients in both cohorts. Only in the R-CHOP cohort, high single MYC expression in PAX5+ cells (in a significant proportion of the cohort) was associated with significantly poorer overall survival. In the R-CHOP cohort, eight cases had *MYC*/*BCL2* double hit by FISH, including 3 cases with MYC/IGH fusions (DE) and 5 cases with MYC/non-IGH rearrangements (only one DE). The exclusion of these double hit cases did not impact the significance of DE and single MYC+ expression.
Summary: True MYC+BCL2+ double protein expression at the single cell level is predominantly in lymphoma cells, and associated with significantly poor survival of DLBCL patients. Our results suggest high cutoffs for common MYC/BCL2 IHC to identify true double expressor lymphoma.

CLINICAL RESEARCH: Predictive Biomarkers 6
Poster Session

#6422 Comprehensive proteogenomic profiling and biomarker analyses in resected extrahepatic cholangiocarcinoma: A prespecified exploratory analysis of the phase 2 STAMP trial.

H. Jeong[1], J.-H. Oh[1], H.-S. Ahn[1], B.-Y. Ryoo[1], K.-p. Kim[1], J. Jeong[1], I. Park[1], S.-M. Hong[1], J. Shin[1], C. Park[1], Y. Cho[2], K. Kim[1], C. Sung[1], C. Yoo[1]; [1]Asan Medical Center (AMC), Seoul, Korea, Republic of, [2]AMC Sciences, Seoul, Korea, Republic of

Background: Biliary tract cancer constitutes a heterogeneous group of diseases with a limited understanding of its molecular characteristics and prognostic/predictive biomarkers. We performed prespecified exploratory analyses of the STAMP trial, a multicenter randomized phase 2 trial of adjuvant capecitabine (CAP) or gemcitabine plus cisplatin (GemCis) for patients with resected extrahepatic cholangiocarcinoma (EH-CCA) with regional lymph node metastasis.
Methods: Among 101 patients included in the intention-to-treat population of the STAMP trial, a total of 89 patients (45 in the GemCis group and 44 in the CAP group) were included in the current biomarker analysis after excluding 12 patients without available tissue and blood samples. Whole exome sequencing and proteomics were performed using surgical specimens.
Results: *TP53* (63%), *SMAD4* (20%), and *KRAS* (18%) mutations were the most frequent in the pooled population. Somatic mutations in homologous recombination deficient (HRD) genes were present in 20% of patients, while one patient (1%) had a germline *ATM* mutation. The prevalence of microsatellite instability was 1%. Somatic mutations in known targetable genes were observed in 54 patients (60.7%) and proteogenomic integrative analysis revealed significant HER2 pathway alteration with *HER2* amplification in 4 patients (7%). The characteristics of prognostic biomarkers varied by the adjuvant regimen used. In the adjuvant GemCis group, somatic mutations were associated with poor disease-free survival (DFS) and overall survival (OS), including *KRAS* (log-rank p=0.004 for DFS and p=0.003 for OS), *FBXW7* (p=0.021 for DFS and p=0.011 for OS), and *PIK3CA* (p<0.001 for DFS and p=0.042 for OS) mutations. In the adjuvant CAP group, copy number alterations (CNAs) such as 8q24.21 amplification (p=0.006 for DFS and p=0.707 for OS) and 3q26.1 amplification (p=0.020 for DFS and p=0.026 for OS) were associated with poor survival, while 11q13.3 amplification (p=0.017 for DFS and p=0.099 for OS) was associated with improved survival. Additionally, a higher HRD score showed a tendency toward better DFS and OS in the GemCis group, but not in the CAP group, although it did not reach statistical significance in both groups (p>0.05). Non-negative matrix clustering of proteomics data classified patients into 4 clusters. Among those, cluster 2, which showed alterations in the metabolism pathway, was associated with higher CNA level, higher tendency of HRD scores, and favorable survival with GemCis (p=0.039 for DFS and p=0.100 for OS) but not with CAP.
Conclusions: Comprehensive proteogenomic analyses enable the identification of prognostic biomarkers and may guide the selection of adjuvant chemotherapy in resected EH-CCA.

#6423 KRAS mutation detection by Sanger sequencing using the SeqStudio Flex capillary electrophoresis instrument.

A. Karger[1], A. Patel[1], K. Tseng[1], C. Ornelas[1], M. Napier[1], R. Beck[2], K. Collwell[2], S. Fahl[2], C. Bornarth[1];
[1]Thermo Fisher Scientific, Pleasanton, CA, [2]Discovery Life Sciences, Huntsville, AL

The detection of mutations in the KRAS gene highly associated with cancer is one of the most widely used Sanger sequencing capillary electrophoresis (CE) applications in molecular diagnostics. In addition to their traditional role in cancer diagnostic, KRAS mutations have recently gained additional relevance as pharmacogenomics (PGx) markers for a significant number of new oncology therapeutics. KRAS mutation detection assays are used as companion diagnostics (CDx) for these cancer treatments. Analysis by Sanger Sequencing of KRAS mutations is cost effective and lends itself for use in resource limited healthcare settings. While there are currently no commercial kits for targeted sequencing of the KRAS mutation hotspots available, the online Applied Biosystems Primer Designer™ Tool (thermofisher.com) allows standardization of the PCR primer design between labs and repeat orders of the KRAS assays by using these commercially available assay ID numbers. Here we demonstrate the use of Primer Designer KRAS mutation detections assays for mutation in codon 12, 13 and 61 totaling to 8 allele variants. The data was generated on the SeqStudio Flex CE instrument using reference standard DNA as well as DNA extracted from FFPE solid tumor samples. We show accuracy of variant call (OPA 100% (64/64)) and concordance (OPA 98.3% (59/60)) in a side-by-side comparison of the SeqStudio Flex with the legacy Model 3500 Genetic Analyzer instrument using a set of commercially available (Horizon Discovery) KRAS reference DNA samples. Primary solid tumor samples are processed to Fresh Frozen Paraffin Embedded samples (FFPE) for further disease marker evaluation. These samples are stable for long term at ambient temperatures and provide the opportunity to evaluate prospective biomarkers at large scale to understand their potential utility. Discovery Life Sciences has generated a large-scale biorepository of human biospecimen, including FFPE, plasma/sera, buffy coat, and PBMCs. Archival FFPE samples from oncology indications associated with KRAS mutations, such as non-small cell lung cancer and colorectal cancer, were analyzed and identified samples with KRAS mutations, demonstrating the potential diagnostic utility of these assays. Finally, cell-free (cf) DNA from double spun plasma from relevant indications was also successfully evaluated for KRAS mutations, highlighting the potential for these assays in liquid biopsy studies. The study demonstrates the robustness of the Primer Designer KRAS mutation detection sequencing assays using reference standard DNA as well as DNA derived from FFPE DNA and cfDNA from patient derived tumor samples. For Research Use Only. Not for use in diagnostic procedures.

#6424 A patient centric full spectrum flow cytometry assay for comprehensive phenotyping of CAR T cells in clinical trials.

K. Vaughan, S. Muthusamy, C. Zhao, A. Carbajal, C. Fu, N. Dakappagari, Z. Alfonso;
Navigate BioPharma, Carlsbad, CA

Purpose While there is a strong desire to fully understand next generation CAR-T product characteristics in clinical trials, limited amounts of blood specimens are available as the enrolled patients are very sick and lymphodepleted. To address this high unmet need, we developed a single tube 20-color full spectrum flow cytometry assay for an in-depth characterization of CAR-T cells that support fulfilment of five key clinical trial endpoints, namely, manufacturing success (fitness and memory state), pharmacokinetics, response or resistance (ICIs), efficacy (gross tumor burden) and safety (B cell regeneration) for use across a broad range of CAR-T therapies and clinical indications.

Study Design: The single tube 20-parameter full spectrum flow cytometry (FC) assay was designed to include CD45, HLA-DR, CD3, CD4, CD8, CD56 as backbone markers, CD45RA, CCR7, CD95, CD25 and CD127 antibodies allowed for the identification of all major subsets of CD4 and CD8 T cells. CXCR3, CD38, PD1, LAG3, and TIM3 were used for identification of activation/exhaustion phenotypes, while CD20 and HLA-DR were useful for identification of B cells and monocytes respectively. Additionally, we left two parameters (PE and AF647) open for customized CAR-T detection reagents or other customized markers. This assay was developed using Cytek® Northern Lights™ and frozen PBMCs.

Results This robust 20-color full spectrum FC assay allowed a thorough analysis of the major T cell populations cells. FMO (Fluorescence-Minus-One) control studies confirmed the specificity of the antibodies and of the panel in identifying Naïve, EMRA, CM, EM, Th17, T stem cell memory and regulatory T cells with minimum background on all parameters. This method showed to be highly reproducible and can be adapted for use with many CAR-T detection reagents.

Conclusion In summary, we developed a robust 20-parameter multiparameter full spectrum flow cytometry assay focused on different populations of T cells in a single tube. The inclusion of drop ins for prospective CAR-T cell detection reagents allows for easy integration of future advances in CAR-T cell research. This universal panel shows great potential for usage across CAR-T clinical trials, as it serves as a valuable tool understand product fitness, PK, biomarker monitoring and disease burden simultaneously.

#6425 Harnessing big data from pan-cancer concerning more than 1300 patients with immune checkpoint inhibitors identifies novel predictive biomarkers.

P. Wu, C. Zhang, A. Shen, X. Gu, N. Sun, J. He;
National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Beijing, China

Immune-checkpoint inhibitors (ICIs) have revolutionized cancer therapy, yet many patients face the challenges of either not benefiting or developing resistance to ICIs. Advances in genome sequencing allow the exploitation of high-dimension oncological data in the research and development of precision immuno-oncology. We conducted a comprehensive literature review involving cancer patients treated with ICIs [anti-programmed cell death protein 1 (PD-1)/programmed death-ligand 1 (PD-L1), anti-cytotoxic T-lymphocyte antigen 4 (CTLA-4), or their combination] and collected available transcriptomic data from pretreatment biopsies along with corresponding clinical outcomes. Biomarkers for ICI response were independently investigated within each study using the logistic regression method and combined with the odds ratio (OR) for meta-analysis. A total of 210 formalin-fixed paraffin-embedded pan-cancer samples with pretreatment biopsies from the National Cancer Center retrospective cohort were collected for validation. Reverse transcription-quantitative polymerase chain reaction (RT-qPCR) and immunohistochemistry (IHC) were employed to validate the stable and clinically applicable utility of the genomic biomarker identified in our analysis. Across 18 studies, we identified 1106 cancer patients who received immunotherapy with pre-treatment transcriptomic data, including melanoma, non-small cell lung cancer (NSCLC), renal cell carcinoma (RCC), stomach adenocarcinoma (STAD), glioblastoma (GBM), and bladder urothelial carcinoma (BLCA), of which 8421 genes were available in all datasets. Meta-analysis based on a common effect model revealed that 332 genes were positively correlated with a favorable response to ICIs, and 404 genes were negatively associated with the therapeutic outcome, with all pooled OR being statistically significant (P <0.05). We identified a novel biomarker, ZBED2 (Zinc Finger BED-Type Containing 2), which demonstrated superior predictive value over other biomarkers for ICI efficacy (pooled OR, 0.596; 95% CI, 0.450-0.788, P =0.002). Similarly, RT-qPCR (AUC: 0.821) and IHC (AUC: 0.789) results further validated the predictive utility for ICI response in the real-world cohort of 210 cancer patients with pretreatment samples receiving ICIs. Additionally, we observed that the expression of ZBED2 was favorably associated with the overall survival of patients receiving immunotherapy (HR: 0.72). In summary, our study provides a in-depth analysis of potentially predictable biomarkers for ICIs in cancer and highlights the potential of large-scale meta-analyses in identifying stable biomarkers. ZBED2 emerges as a novel predictive biomarker for ICIs and may guide the implementation of risk-related therapeutic strategies.

#6426 Identification of potential immune biomarkers for GSK-3 inhibitor elraglusib (9-ING-41) in patients with relapsed/refractory metastatic cancer.

T. Weiskittel[1], K. Huntington[2], L. Zhang[3], A. Koukol[4], B. A. Carneiro[5], H. Li[1], A. Ugolkov[4], W. El-Deiry[3], A. Mazar[4];

[1]Mayo Clinic, Rochester, MN, [2]Genesis Drug Discovery & Development (GD3), Hamilton Township, NJ, [3]The Warren Alpert Medical School of Brown University, Providence, RI, [4]Actuate Therapeutics, Inc., Fort Worth, TX, [5]Brown University, Providence, RI

Cytokines mediate strong immunomodulatory effects in cancer. Elraglusib (9-ING-41), an inhibitor of GSK-3, is a potent antitumor and immune-modulatory agent in phase 2 clinical trials for the treatment of various cancers. Here, we examined the immune environment of elraglusib-treated cancer patients by measuring peripheral blood protein levels to explore whether the expression level of cytokines/chemokines/soluble cell receptors/growth factors (CCSG) is correlated with clinical outcome. Using a customized Luminex platform, the expression of forty CCSG hypothesized to be linked to GSK-3 activity was assessed in pre-dose plasma samples obtained from 45 cancer patients with relapsed/refractory metastatic disease (NCT03678883; the 1801 trial). All patients in the 1801 trial were treated with elraglusib (dose range: 1-15 mg/kg) either as a single agent (Part 1; n=21) or in combination with chemotherapy (Part 2; n=24). Pre-dose peripheral blood protein levels were examined as binary predictors of clinical outcome using optimal cutoff points determined by maximally selected rank statistics. In the aggregate Part 1 and 2 populations (n=45), we identified 13 CCSG that significantly stratified the cohort by overall survival (OS). High pre-dose levels of CD95 and TNFRSF10C were associated with better OS. CD95 was a better prognostic of OS than TNFRSF10C (HR: 2.27, 95% CI: 1.10-4.67, p-value: 0.023). Low pre-dose levels of 11 CCSG were also significantly associated with favorable OS, with IL-8 being the most predictive (HR: 0.137, 95% CI: 0.0545-0.346, p-value: <0.0001). Part 1 and 2 predose samples were also analyzed separately, and many of the biomarkers identified in the aggregate analysis retained significance in the separated analysis. In Part 1, CXCL5, IFN-alpha, and IL-18 emerged as unique markers, and in Part 2, CCL22 was the single unique marker.The results of our exploratory study identified several putative biomarkers of elraglusib clinical benefit and demonstrated potential immunomodulatory mechanisms of elraglusib that will be used to inform the further clinical development of elraglusib for the treatment of metastatic cancer.

#6427 Phase II study of trametinib alone and in combination with uprosertib in patients with metastatic triple negative breast cancer previously treated with chemotherapy: OSU 13317.

V. Prasath[1], H. Boutrid[2], E. Mrozek[2], M. Lustberg[3], R. Weslowski[1], R. Layman[4], M. Abdel-Rasoul[1], C. Timmers[5], E. MacRae[6], G. T. Budd[7], L. Harris[8], C. Isaacs[9], R. Ismail-Khan[10], E. C. Dees[11], A. S. Poklepovic[12], H. X. Chen[8], M. Villalona-Calero[13], W. Carson[1], G. L. Johnson[11], D. G. Stover[1], B. Ramaswamy[1]; [1]The Ohio State University College of Medicine, Columbus, OH, [2]The Ohio State University Medical Center, Columbus, OH, [3]Yale School of Medicine, New Haven, CT, [4]MD Anderson Cancer Center, Houston, TX, [5]Incyte, Wilmington, DE, [6]Columbus Oncology Associates, Columbus, OH, [7]Cleveland Clinic Foundation, Cleveland, OH, [8]National Cancer Institute, Bethesda, MD, [9]Georgetown University Medical Center, Washington, DC, [10]Moffitt Cancer Center, Tampa, FL, [11]UNC School of Medicine, Chapel Hill, NC, [12]Virginia Commonwealth University, Richmond, VA, [13]City of Hope, Duarte, CA

Introduction: Triple negative breast cancers (TNBCs) are a poor prognosis subset of breast cancer and preclinical data implicate activation of the RAS/MEK/ERK pathway in TNBC chemotherapy resistance. Preclinical data demonstrate that blockade of both RAS/MEK/ERK and PI3K/AKT pathways synergizes to overcome resistance to single agent MEK inhibitors. The purpose of this study was to determine the response rate for the selective allosteric MEK1/MEK2 inhibitor trametinib alone and in combination with AKT inhibitor uprosertib in patients with metastatic TNBC previously treated with chemotherapy.

Patients and Methods: This was an open-label, two-part, phase II, single-arm, multicenter study through the ETCTN. Eligibility criteria included patients with metastatic TNBC with measurable disease who had received between 1-3 prior chemotherapy regimens. All patients underwent a mandatory pretreament biopsy and received trametinib alone (2mg) as Part I of the study. At progression, patients underwent a second biopsy and moved to Part II with trametinib (1.5mg) and uprosertib (50mg). Available biopsies were profiled quantitative targeted absolute proteomics (QTAP) for kinome assay and whole transcriptome profiling via microarray. Blood samples were collected at baseline, at cycle 2 day 1 (C2D1), and at progression for circulating tumor DNA (ctDNA) analysis via ultra-low pass whole genome sequencing.

Results: Between October 2013 and January 2017, 37 patients were enrolled at 8 centers and, subsequently, 19 of these patients entered Part II. Adverse event data has been previously presented. On trametinib alone (Part I), 2 patients had a partial response (PR) and 6 patients had stable disease (SD) as best response. Of the 19 evaluable patients on trametinib + uprosertib (Part II), 3 patients had a PR and 3 patients had SD. Integrated analysis of matched samples with QTAP kinome and transcriptome data QTAP kinome assay in demonstrated MEK1/2 inhibition at progression on trametinib alone in 4/4 patients with evaluable tissue confirming target engagement and one patient with biopsy after trametinib+uprosertib demonstrated AKT1 inhibition. ctDNA was evaluable in 34 patients at C1D1 with tumor fraction (TFx) range 0-75.9%. 6/23 patients had ctDNA ‘clearance’ (tumor fraction of 0%) at C2D1. Of these 6, 3 (50%) had PR as best response, compared with only PR in only 1/17 patients without ctDNA clearance at C2D1.

Conclusions: Trametinib alone and in combination with uprosertib demonstrates anti-tumor activity in a subset of TNBC patients with kinome evidence of target engagment. ctDNA clearance at C2D1 may be useful as an early biomarker to identify patients most likely to respond. Understanding biomarkers of response and resistance may guide future opportunities for MEK/AKT inhibition in TNBC.

#6428 Transcriptome analysis of tissues and peripheral blood revealed potential biomarkers for chemo/radio-immunotherapy in non-small cell lung cancer.

J. Hu[1], J. Zhang[1], P. Cheng[2], Y. Chen[2], C. Zhu[2], F. Yi[2], C. Xie[1];
[1]Department of radiation and medical oncology, Zhongnan Hospital of Wuhan University, Wuhan, China, [2]Amoy Diagnostics Co., Ltd., Xiamen, China

Background: Combination of anti-PD-(L)1 antibody with chemotherapy has shown promising efficacy in advanced/metastatic non-small cell lung cancer (NSCLC). Dynamics of peripheral blood mononuclear cells (PBMC) might have impact on repertore of immune cells further resulting different immune infiltration in tumor microenvironment. Thus, monitoring changes in PBMC during therapy or measuring tumor microenvironment provides the possibility to predict the efficacy of tumor immunotherapy.
Methods: Patients diagnosed with NSCLC (Stage III-IV)were enrolled in this study. Anti-PD-L1 and chemo/radio combination therapy was performed as adjuvant therapy. Tumor samples were obtained prior to adjuvant therapy PBMC samples were obtaind at multiple time points, including prior adjuvant therapy, 3 months after adjuvant therapy, and 3 months after adjuvant therapy. Tumor and PBMC mRNA sequencing were performed by Amoy Diagnostics Co Ltd. (Xiamen, China). Patients who achieved CR/PR/SD and PFS > 6 months were defined as well responders. Pathway enrichment and GSEA analyses were performed by clusterProfiler (version 4.0.5) on GO, KEGG, and from six different gene sets. Correlations between immune cellular signature ES scores and gene expression were estimated using Pearson correlation.
Results: 28 patients were enrolled; mean age was 60.38±7.86 years, 27 (96.4%) patients were male. 21 (75.0%) patients were identified as responder and 7 (25.0%) were non-responder. In the baseline tumor samples, immune infiltration was more extensive in responders compared to non-responders. Cytotoxic lymphocytes, activated $CD8^{\pm}$ T cell, and NK cells were significantly enriched in responders. High expression of CCL17 and down regulation of CTSG/PLK1/PRTN3, a signaling axis that inhibits histone H3 hydrolysis and promotes monocyte to macrophage differentiation, was significant in responders. Dynamic monitoring of PBMC before and after treatment showed significant upregulation of immune infiltration-related pathways in responders, including effector cells, NK cells and $CD8^{\pm}$ T cells. In the non-responder group, the up-regulated pathways after treatment were mainly enriched in tumor growth rate, EMT, and matrix remodeling. Multi-time point analysis showed that CEACAM5/ MKI67 level and tumor proliferation rate in non-responders were higher than those in responders at each time point after treatment.
Conclusion: Baseline tumor transcripton signatures and dynamic changes in PBMC could be applied to develop novel biomarkers for immune-related therapy. Patients with stronger immune infiltration signals in baseline tumor samples and PBMC after treatment had better immune response. The upregulation of proliferation-related signals in PBMC predicts poor immune response.

#6429 Critical role of elevated TMEM176B gene expression in humanized patient-derived xenografts mouse models of triple negative breast cancer.

Y. Her, J. Yun, W. Heo, J.-I. Kim, H.-B. Lee, W. Han, H.-G. Moon;
Seoul National University, Seoul, Korea, Republic of

Objective: In the cancer research, a highly promising in vivo platform for personalized treatment involves the adoption of an advanced approach—specifically, the grafting of patient-derived xenografts (PDX) onto humanized mouse models. These models capture distinctive aspects of interaction with the human immune system and the tumor microenvironment (TME). In this study, we have engineered humanized triple-negative breast cancer (TNBC) PDX models to observe alterations in differentially expressed genes, thereby enhancing our understanding of the intricacies of personalized treatment in this context.
Method: We utilized two TNBC PDX models established for the humanized models, where CD34+ hematopoietic stem cells were transplanted into immunodeficient mice. RNA sequencing was performed to identify altered gene expression in humanized PDX models compared to NSG PDXs. Additionally, we generated stable cell lines overexpressing TMEM176B in MDAMB231 and Hs578T cells, and we knocked down TMEM176B in 4T1 cells using recombinant techniques
Results: In the humanized model, the growth of PDX tumors did not show a significantly faster or markedly different rate compared to previous studies. However, upon conducting RNA sequencing in the PDX model, the expression of the TMEM176B gene was consistently downregulated. Consequently, we transfected and observed that the increased expression of TMEM176B in MDAMB231 and Hs578T cell lines resulted in enhanced cell proliferation in vitro. Transplanting MDAMB231 cells overexpressing TMEM176B into athymic nude mice resulted in accelerated tumor growth. The study further investigates the expression of TMEM176B in an immune-competent environment by knocking down the gene in 4T1 cells or transplanting the control group into a balb/c mouse model. Tumors with TMEM176B knockdown exhibited inhibited growth, increased CD3+ T cell infiltration, and significant inhibition when treated with anti-PD-L1 compared to the control group.
Conclusion: This research demonstrates the utility of PDX models, particularly humanized PDX models, in studying the complexities of cancer biology and the tumor microenvironment. The findings regarding TMEM176B and its role in tumorigenesis and immune responses in triple-negative breast cancer provide valuable insights for further research and potential therapeutic interventions.

#6430 Gene expression signature quantifies the cellular contribution of the tumor *vs.* the microenvironment in determining colorectal cancer prognosis and therapeutic outcome.

M. Yang[1], T. J. Yeatman[1], M. V. Nebozhyn[2], M. J. Schell[3], L. Pflieger[4], A. Loboda[2], W. J. Pledger[5], R. Soundararajan[1], M. Maurin[1], H. Wang[1], J. Rodriguez Silva[1], A. Alden[1];

[1]University of South Florida, Tampa, FL, [2]Merck, Sharp and Dohme, West Point, PA, [3]Moffitt Cancer Center & Research Institute, Tampa, FL, [4]Phenome Health, Seattle, WA, [5]Tampa General Hospital Cancer Institute, Tampa, FL

Accumulating evidence has suggested that cancer progression and therapeutic response may depend on not only tumor cells but also their tumor microenvironment (TME). However, their contributory roles are complex and not well understood. Here we report an analysis of 2373 human colorectal cancer (CRC) tumors representing all stages, leading to identification of a 20-gene signature capable of quantifying the cellular contribution of the tumor vs. the TME in determining colorectal cancer prognosis and therapeutic outcome. We classified these tumors into the consensus molecular subtypes (CMS1-4) with distinct, variable TME cellular features defined by CIBERSORT deconvolution analysis of bulk gene expression data. Surprisingly, all the 10 positive signature genes (portending worse survival) were strongly correlated with the TME-rich CMS1 and CMS4 tumors. By contrast, all the 10 negative signature genes (portending better survival) were highly related to the TME-poor CMS2 and CMS3 tumors. A single cell expression analysis from an independent database further revealed that strikingly, all the 10 positive genes were principally expressed by the immune/stromal TME whereas all the 10 negative genes were predominantly expressed in epithelial tumor cells. These data suggest that the TME has an equally important role as do tumor cells in determining CRC prognosis and support targeting the TME to improve survival. Moreover, distinct gene expression from tumor cells versus the TME also showed a differential impact on therapeutic outcome. Retrospective analyses on two independent clinical trial datasets show that the 20-gene signature score significantly predicted progression free survival in metastatic CRC patients treated with cetuximab, an FDA-approved EGFR inhibitor therapy. These data suggest a potential for the 20-gene signature as a predictive biomarker to identify “sensitive” versus “resistant” subpopulations of CRC patients to improve outcome of EGFR-targeted therapy.

#6431 First NGS-based companion diagnostic to aid in the selection of targeted therapy for anaplastic thyroid cancer patients with *BRAF V600E* mutations.

T. Clark, T. Nater, J. Maxfield, J. Peterson, K. Hotchkiss, C. Russo, A. Velasco Roth;
Thermo Fisher Scientific, Carlsbad, CA

Introduction: While anaplastic thyroid cancer (ATC) is rare, it is the most aggressive form of thyroid cancer. All ATCs are considered stage IV at diagnosis and response rates to standard systemic therapies are poor with dismal long-term outcomes. As such, molecular profiling of ATCs has increasingly been used to identify therapeutic targets that may inform individualized therapy. Current clinical guidelines recommend molecular profiling, especially *BRAF V600E* mutation assessment, be performed at the time of ATC diagnosis to inform decisions related to the use of targeted therapies. On September 29, 2023, the FDA granted companion diagnostic approval to the Oncomine™ Dx Target Test (ODxT Test) as an aid in the selection of patients with *BRAF V600E*-mutated ATC who may be eligible for treatment with dabrafenib in combination with trametinib. Here we report the assay performance data which supports the clinical benefit of the ODxT Test as an aid in the selection of targeted therapy for ATC patients with *BRAF V600E* mutations.

Methods: The ODxT Test is a targeted next-generation sequencing (NGS) *in vitro* diagnostic assay used to detect somatic changes in human DNA and RNA isolated from FFPE tissue samples. To validate the clinical benefit of the ODxT Test for the selection of ATC patients with *BRAF V600E* mutations, a retrospective clinical concordance study was performed on 35 patients enrolled in the ATC cohort of the ROAR trial, a phase II study of dabrafenib in combination with trametinib in subjects with rare cancers with *BRAF V600E* mutations. The study evaluated the overall percent agreement (OPA), positive percent agreement (PPA), and negative percent agreement (NPA) for the detection of *BRAF V600E* mutations between the ROAR trial central confirmatory assay, bioMerieux THxID™ BRAF test (THxID), and the ODxT Test. Due to the small number of *BRAF V600E*-mutated ATC patients enrolled in the ROAR trial, 167 commercially-obtained thyroid cancer specimens were also included in the concordance analysis.

Results: Of the 202 specimens included in the study with a valid ThxID result, 199 had sufficient material for testing with the ODxT Test and were included in the clinical concordance analysis. The point estimates of PPA, NPA and OPA were 99.0%, 100%, and 99.4%, respectively, when excluding ODxT Test invalid results and the lower bounds of the 95% Wilson Score confidence intervals for PPA, NPA, and OPA were 94.4%, 93.7%, and 96.4% respectively.

Conclusion: The ODxT Test was shown to be effective in identifying *BRAF V600E* mutations in ATC patients through a clinical concordance study using specimens from patients enrolled in the ROAR trial and commercially-sourced samples. The results support the expanded indication to the ODxT Test and marks the first FDA-approved NGS-based companion diagnostic for patients with *BRAF V600E*-mutated ATC.

#6432 Co-expression of HERV-R, CCND1, BRAF, FOXA1, TMPRSS2, ATF4 and low expression of BAZ1B and KMT2D is associated with early detection and poor prognosis of prostate cancer in African Black men from Nigeria.

F. Mohammed[1], K. Stawiski[2], H. S. Musa[3], S. K. Owolabi[1], S. Abubakar[4], S. O. Rotimi[5], A. K. Umar[6], Y. Iliyasu[7], A. Bello[1], F. T. Odedina[8], C. C. Yates[9], K. Petrie[3], F. W. Huang[10], S. Ibrahim[1];

[1]Ahmadu Bello University, Zaria, Nigeria, [2]Medical University of Lodz, Lodz, Poland, [3]University of Sunderland, Sunderland, United Kingdom, [4]Aminu Kano Teaching Hospital, Kano, Nigeria, [5]Covenant University, Ota, Nigeria, [6]Federal Medical Centre, Birnin Kebbi, Nigeria, [7]Ahmadu Bello University Teaching Hospital, Zaria, Nigeria, [8]Mayo Clinic, Jacksonville, FL, [9]Johns Hopkins School of Medicine, Baltimore, MD, [10]University of California, San Francisco, San Francisco, CA

Prostate cancer (CaP) is a heterogeneous disease characterized by features of non-aggressive, slow-growing disorders to fast-growing disease. Men of African ancestry have disproportionately higher incidence and mortality rates for CaP than men of European ancestry. While there is evidence for a higher genetic predisposition for incidence of CaP in men of African ancestry compared to men of European ancestry, there is paucity of molecular biology and transcriptomic studies on the role of Human endogenous retroviruses (HERVs) in relation to CaP-associated genes in CaP pathogenesis and prognosis. In this study, we performed bulk RNA sequencing (RNA-seq) on formalin-fixed paraffin-embeded (FFPE) CaP samples from Nigerian CaP patients to investigate the expression significance of HERV-R in relation to FOXA1, TMPRSS2, BAZ1B, KMT2D, ATF4 and BRAF genes. Based on this findings, we used immunohistochemistry (IHC), enzyme-linked immunosorbent assay (ELISA) and immunofluorescence (IF) to confirm the expression pattern of the HERV-R and FOXA1, TMPRSS2, BAZ1B, KMT2D, ATF4 and BRAF proteins on 45 FFPE CaP and blood plasma samples, and 5 CaP-free samples from patients in Zaria, Nigeria. Most of these patients were longitudinally followed from 2017 to date. The DESeq2 procedure was used for data processing, analysis, and differential expression analysis of the aforementioned genes. We found a significant expression of HERV-R in relation with FOXA1, TMPRSS2, BAZ1B, KMT2D, ATF4, CCND1 and BRAF in the CaP from rural Africans in Nigeria. HERV-R expression was found to be associated with increased PSA level, higher Gleason grade and poor prognosis of CaP. A CaP sample from an 80-year-old patient that was histologically diagnosed to have no malignancy seen despite high PSA level of >100 and poor disease outcomes shows a significant cytoplasmic expression of HERV-R, indicating that HERV-R may serve as an important biomarker for early detection. Unfortunately, we lost the 80-year-old patient to late detection before revisiting his case for proper histological diagnosis and management. In addition, some histologically diagnosed BPH samples that are apparently reported to be CaP-free show stromal cells expression of HERV-R and in some cases show expression of HERV-R in the prostatic glandular areas. In contrast, stromal cells of the CaP samples show no expression of HERV-R, but strong expression in the glandular areas. This may implicate a gradual transition from benign prostatic lesion to malignant prostatic disease. HERV-R expression in CaP may have a relationship with BRAF, CCND1, FOXA1, TMPRSS2 and ATF4 genes. These findings combined together, underscore the importance of the expanded concept of HERV-R expression and CaP associated genes in early detection of CaP and prognosis.

#6433 Anti-CD36 monoclonal antibody can sensitize the neoadjuvant chemotherapy response in PDAC by eliminating the senescent tertiary lymphatic structure.

J. Yan, T. Zhou, C. Yang, Y. Xie, J. Yu, J. Hao;
Pancreas Center, Tianjin Medical University Cancer Institute and Hospital, National Clinical Research Center for Cancer; Tianjin Key Laboratory of Digestive Cancer; Tianjin's Clinical Research Center for Cancer, Tianjin, China

Objective: Pancreatic ductal adenocarcinoma (PDAC) is deadly and aggressive. Neoadjuvant chemotherapy (NAC) may reduce tumor volume and alter the resectability of the tumor. The efficacy of neoadjuvant chemotherapy in patients is still limited. Tertiary lymphoid structures (TLSs) develop in peripheral non-lymphoid tissues and are essential for the immune response and correlate with chemotherapy in various tumor types. However, more research is needed to determine how TLSs affect neoadjuvant chemotherapy in PDAC. We aim to determine how neoadjuvant chemotherapy affects tumor-infiltrating lymphocytes (TLSs) in PDAC patients. We also want to find a biomarker to boost PDAC neoadjuvant chemotherapy response.
Methods: We retrospectively collected formalin-fixed paraffin embedded (FFPE) tissues from 115 PDAC patients without preoperative treatment and 72 patients pretreated with neoadjuvant chemotherapy. Multispectral images were processed using AI-powered image analysis software (Tissue Gnostics; Zeiss, Germany). The 10X Genomics platform was used to sequence single cells in tissue samples from five patients who received neoadjuvant chemotherapy (NAC) and five patients who had not received any treatment before analysis (pretreatment naïve, PN). TLS was separated using Laser Microdissection. The mouse model was created by orthotopically injecting tumor cells into the pancreas.
Results: Patients who received NAC have a senescent microenvironment. High-throughput single-cell sequencing showed that the senescent gene signature score was enriched in the NAC group, especially in immune cells. The percentage of $p16^{\pm}$ $CD20^{\pm}$ B cells and $P16^{\pm}$ $CD3^{\pm}$ T cells in TLSs also increased in the NAC group. Spatial transcriptomics analysis exhibited that CD36 is highly expressed in senescent TLSs, which suggested that CD36 may be a marker for senescent TLSs. Moreover, CD36+ TLSs induced the infiltration of MDSCs and regulatory T cells. CD36+ TLSs were an independent prognostic factor for poor overall survival (OS) (HR=0.67, p=0.002) and progression-free survival (PFS) (HR=0.71, p=0.003). A mice orthotopic xenograft model showed that an anti-CD36 monoclonal antibody eliminated senescent TLSs in pancreatic tissue. MDSCs and Tregs in the surrounding tissue also decreased. Additionally, in vivo KPC mice model showed that the combination of an anti-CD36 and chemotherapy reduced tumor volume and increased survival compared to chemotherapy alone.
Conclusion: NAC has the potential to induce the senescence of tumor-associated TLSs, a phenomenon that has been linked to unfavorable prognosis in PDAC. CD36 serves as a viable marker for senescent TLSs that can be targeted. The administration of an anti-CD36 monoclonal antibody can potentially enhance the efficacy of chemotherapy in PDAC by selectively eliminating CD36+ senescent TLSs in mouse models.

#6434 Microenvironment of adjacent non-neoplastic regions determines prognostic outcomes in locally advanced colorectal cancer after surgical resection: A multi-center & multi-omics study.

Y. Bang[1], J. Choi[1], K. Park[1], J. Lim[1], D. Pyo[1], Y. Cho[1], T.-Y. Kim[2], K. Park[2], S.-B. Ryoo[2], S.-B. Kang[3], C. Yu[4], K.-y. Lee[5], J. Lee[5], J.-Y. Lee[6], Y.-J. Kim[6], W.-Y. Park[1];

[1]Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of, [2]Seoul National University Hospital, Seoul National University College of Medicine, Seoul, Korea, Republic of, [3]Seoul National University College of Medicine, Seoul National University Bundang Hospital, Seongnam, Korea, Republic of, [4]Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic of, [5]Uijeongbu St. Mary's Hospital, College of Medicine, The Catholic University, Uijeongbu, Korea, Republic of, [6]College of Life Science and Biotechnology, Yonsei University, Seoul, Korea, Republic of

Background: There is an unmet need for additive predictive biomarkers for the recurrence of stage II/III colorectal cancer (CRC) after surgery. We hypothesized that the heterogeneities of tumors present a substantial impediment to finding agnostic biomarkers. To avoid this, we focused on the normal tissue from the margins of resected specimens.

Methods: We divide the groups using RNA sequencing derived from 273 tumors and 273 paired normal tissues from 5 Korean cancer centers. Groups were defined as follows: tumor-like microenvironment in normal mucosa (tNME): high level of tumor signature in normal mucosa; healthy normal microenvironment (hNME): low tumor signature in normal tissue. The impact of this classification was further evaluated in TCGA cohort. For the mechanistic explanation, we conducted 16s rRNA metagenomics and single-cell RNA sequencing from 47 patients and validated by spatial transcriptomics.

Results: There were no significant differences between subgroups in baseline characteristics, including age, sex, medical centers, sidedness, stage and the distance between tumor and paired normal tissue. With a median follow-up of 58.2 months, the tNME group showed poor 5-year recurrence-free survival (54.7 vs. 73.0%, HR=1.94, *P*=0.002) and 5-year overall survival (OS; 78.2 vs. 83.0%, HR=1.76, *P*=0.033). In addition, tNME showed a trend toward poorer 5-year OS (34.5% vs. 68.8%, HR=3.76, *P*=0.071) in TCGA. The pathway analysis exhibited tNME had decreased maintenance of membrane while increased expression of humoral reaction to bacteria. Only the tNME group showed similar microbiome diversity between tumor and normal tissues, consisting of more proportion of carcinogenic genera, including fusobacterium and bacteroides than hNME. scRNA-seq revealed a positive co-occurrence of Th17, *GZMK*^{high}CD8+T cells, and *IL1B*^{high} neutrophils in the tumor and normal tissues of tNME. A high proportion of *EMP1*^{high} epithelial cells, were observed in the tNME group, with upregulated epithelial-mesenchymal transition (EMT), bacterial-cellular-invasion and leukocyte signaling pathways. The cell-cell interaction analysis suggest Th17 cells promote *IL1B*^{high} neutrophil retention, increasing crosstalk with CD8+ T cells, and inducing the production of high levels of *GZMK*, which in turn decreases E-cadherin in the intestinal epithelium. A weak intestinal barrier may provoke more bacteria-infected cancer cells, promoting cancer cell progression via EMT and recruiting *IL1B*^{high} neutrophils and *GZMK*^{high}CD8+T cells, resulting in a vicious cycle.

Conclusions: The microenvironmental status of normal tissues offers a promising biomarker for stage II/III CRC. Microbiota dysbiosis-induced organized microniches with immune and epithelial cells was related to metachronous recurrence after surgical resection.

#6436 Tumor-educated platelets for therapy stratification of metastasized castration resistant prostate cancer (CRPC).

J. A. Nilsson, M. Lundholm, L.-A. Tjon-Kon-Fat, L. Kohn, C. Thellenberg-Karlsson, A. Josefsson, P. Wikstrom;
Umea University, Umea, Sweden

One in ten men diagnosed with prostate cancer will have metastases. At some point the metastases becomes castration therapy resistant, contributing leading to the high mortality of prostate cancer. Novel androgen directed treatments, like abiraterone and enzalutamide, have made substantial difference to therapy response, yet only within subgroups of CRPC patients. Correct therapy stratification may prolong the life of the patients, possibly turning a deadly disease into a more chronic disease. For this to happen we need predictive biomarkers that can be used to longitudinally follow the disease in order to identify vulnerabilities and to monitor acquired resistance, e.g. we need to develop personalized liquid biopsy platforms. Using the platelet enriched fraction of a blood sample we here show that we can use the platelets ability to sequester material during circulation to provide information derived from the tumor, a.k.a. tumor-educated platelets. This information could be used as a companion diagnostic to identify patients that will respond to therapy, and to longitudinally monitor tumor progression. In this study, a previously published three gene profile, plt3G profile, was validated in a larger cohort (n=97) and showed that combined analysis of the three genes transcripts (*KLK3, FOLH1, NPY*) could be used to identify long-term responders regarding progression-free survival after enzalutamide (n=47; PFS; LR p<0,001, HR 0,32, p<0,001) or abiraterone (n=50; PFS; LR p=0.007, HR 0,45, p=0,009) -treatment. Furthermore, progression and resistance development could be accurately longitudinal followed. The plt3G profile showed a significant overlap with circulating tumor DNA (ctDNA) biomarkers, but in addition also provided predictive information around treatment response. Tumor-educated platelets provide therapy-predictive biomarkers as well as biomarkers for longitudinal monitoring of disease progression and resistance development, which ultimately could provide information for therapy switching. Their easy accessibility makes tumor-educated platelets an attractive biosource to be used alone or in combination others, to enable a fluid biomarker platform with the aim to turn a lethal cancer disease into a more chronic disease.

#6438 Subcutaneous fat mass predicts progression-free survival in patients treated with antibody-drug-conjugates in early-phase clinical trials.

M. Delaye[1], L. Lawrance[2], Y. Belkouchi[2], F. Wirth[2], P. Decazes[3], A. Bone[4], K. Ouali[1], A. Hollebecque[1], C. Smolenschi[1], R. Bahleda[1], A. Gazzah[1], S. Champiat[1], F.-X. Danlos[1], C. Henon[1], K. Beshiri[1], M. Sakkal[1], A. Marabelle[1], J.-M. Michot[1], V. Ribrag[1], C. Parisi[1], C. Massard[1], V. Goldschmidt[1], P. Vera[3], S. Ponce-Aix[1], N. Lassau[5], S. Ammari[5], C. Baldini[1];

[1]Gustave Roussy, Villejuif, France, [2]Biomaps, UMR1281 INSERM, CEA, CNRS, University of Paris-Saclay, Villejuif, France, [3]Henri Becquerel Cancer Center, Rouen, France, [4]Guerbet Research, Villepinte, France, [5]Gustave Roussy Cancer Campus, Villejuif, France

Background: Antibody drug conjugates (ADCs) have revolutionized the treatment of many solid tumours and hematological diseases. Little is known about the influence of body composition on efficacy and safety of ADCs.

Methods: All patients treated with ADCs in early phase clinical trials between 03/2015 and 03/2023 at the Drug Development Department at Gustave Roussy were retrospectively included in the analysis. A deep learning software (Anthropometer3DNet) automatically measured anthropometric parameters in 3D on pretreatment scans, allowing multi-slice measurements of muscle body mass (MBM), fat body mass (FBM), subcutaneous fat mass (SFM) and visceral fat mass (VFM). Other clinical and biological parameters were also retrieved and evaluated. Primary endpoints were progression-free survival (PFS) and overall survival (OS). Survival analysis was performed using Cox regression models and Kaplan-Meier (KM) estimator. Cut-offs were determined using the maxstat method. Anthropometric parameters' effect on toxicity was also evaluated using a ROC analysis.

Results: A total of 136 patients were treated with ADCs. The most frequent tumor types were non-small cell lung cancer (56 patients, 41%) and colorectal cancer (31 patients, 23%). Median age, ECOG PS, albumin and number of previous lines of treatment were 60.8 years (30 to 85), 1, 42 g/L and 3 respectively. In the overall cohort, median PFS and OS were 2.8 and 8.6 months respectively, 90 (66%) patients had experienced toxicity, of which 46 were grade 3-4. The Royal Marsden Hospital (RMH) prognostic score of 2 or more was significantly associated with worse PFS (HR=2.13, p=0.007) and OS (HR=2.12, p=0.008). The number of treatment lines was significantly associated with worse OS (HR=1.21, p<0.001). For the anthropometric parameters, SFM (HR=0.89, p=0.013) and FBM (HR=0.89, p=0.02) were significantly associated to PFS. Higher SFM (cutoff: 3.3 kg/m2) and FBM (cutoff: 3.6 kg/m2) were significantly associated with longer PFS (mPFS=3.8 vs 2.3 months and 3.7 vs 1.9 respectively). Patients with higher SFM and FBM had numerically but non-significantly longer (mOS=8.5 vs 7.7 months and 8.6 vs 6.4 months respectively). All anthropometric parameters were significantly associated with all-grade toxicity in the univariate but not in the multivariate analysis. None of the parameters were associated with grade 3-4 toxicity.

Conclusions: In this large monocenter cohort, 3D measured high SFM and FBM were significantly associated with PFS. Automatic extraction of body composition parameters using AI may help in anticipating the benefits of ADCs in patients included in early-phase clinical trials.

#6439 Next-generation sequencing based detection of HER2 copy number predicts pathological response to neoadjuvant therapy in HER2 positive breast cancer.

H. Dai, D. Jiao, X. Guo, J. Qiao, L. Li, Z. Lu, X. Chen, C. Wang, M. Yan, Z. Liu;
The Affiliated Cancer Hospital of Zhengzhou University, Zheng Zhou, China

Purpose: Achieving pathologic complete response (pCR) following neoadjuvant chemotherapy is associated with better prognosis for HER2 positive breast cancer. However, clinical and biological heterogeneity of HER2 positive disease significantly affect prognosis and treatment response. Early prediction of treatment benefit could enable tailored anti-HER2 therapy. Next-generation sequencing (NGS) based genomic tests including copy number (CN) detection are widely used in breast cancer patients. We aim to evaluate the association of HER2 copy number detected by NGS with pCR rate of HER2 positive breast cancer after neoadjuvant chemotherapy.

Methods: HER2 positive breast cancer patients underwent neoajuvant chemotherapy in Henan Cancer Hospital From January 2022 to March 2023 were included in the study. Pretreatment tumour specimens were subjected to pan-cancer 1021-gene panel genomic sequencing. Copy number of HER2 was obtained from the panel. Copy number of >=4 was classified as HER2 amplified and HER2 copy number <4 was classified as HER2 non-amplified. All patients underwnt definitive surgery after receieveing neoadjuvant chemotherapy containing taxanes, trastuzumab and pertuzumab. pCR was defined as pathological stage ypT0/Tis ypN0.

Results: In total, 299 HER2 positive breast cancer patients were eligible for the analysis. 87 were classified as HER2 non-amplified (29.1%) by copy number and 212 patients were classified as amplified group (70.9%). The HER2 non-amplified group tends to have a higher proportion of hormone receptor positive (HR+) patients (71.3% vs. 50.5%, p=0.002). Other clinicopathological parameters were well distributed between the groups. 91.3% of patients in HER2 amplified group had strong positive HER2 expression (IHC 3+), while only 10.5% of patients in HER2 non-amplified group had HER2 expression of IHC 3+. Patients with HER2 IHC 3+ had a PCR rate of 75.8% and Patients with HER2 IHC 2+ had a pCR rate of 20.0% (20.0% vs. 75.8% p<0.001). Patients in the amplified group had a pCR rate of 76.9% and pCR rate of the non-amplified group was12.6% (12.6% vs. 76.9% p<0.001). In a multivariable logistic regression with HER2 copy number by NGS, HR status and HER2 IHC, the HER2 copy number predicted pCR rate independently of HER2 IHC and HR status.

Conclusions: NGS based detection of HER2 copy number could predict response to neoadjuvant therapy in HER2 positive patients. The discordance between IHC/FISH and NGS based detection of HER2 amplification may reflect HER2 heterogeneity. HER2 heterogeneity promotes resistance to anti-HER2 therapy. Noval antibody-drug conjugates (ADC) with bystander effect, such as Trastuzumab deruxtecan, have shown anti-tumor effect even in HER2 low expression tumors. Thus, prospective study is needed to optimize anti-HER2 therapy for patients with HER2 heterogeneity.

#6440 Novel N-myristoyltransferase immunohistochemistry-based predictive and prognostic tests for breast cancer.

A. Shrivastav[1], D. Reddick[1], A. Meher[1], S. Varma Shrivastav[2], S. Mittal[1], V. K. Gadi[3], L. Murphy[4];

[1]The University of Winnipeg, Winnipeg, MB, Canada, [2]Oncodrex Inc., Winnipeg, MB, Canada, [3]University of Illinois Cancer Center, Chicago, IL, [4]CancerCare Manitoba, Winnipeg, MB, Canada

Breast cancer (BC) is the most common cancer worldwide, surpassing lung cancer incidence for the first time in 2020, and is the most common cancer diagnosed in American women. Despite the relative success of endocrine therapies in treating hormone receptor-positive (HR+) BC, de novo and developed resistances to these therapies (endocrine resistance) are still significant concerns. Furthermore, triple-negative breast cancer has a poor prognosis and remains one of the most challenging cancers to treat. We have discovered that the expression and localization of N-myristoyltransferase 2 (NMT2) could be prognostic and predictive markers for metastatic BC. We determined the expression patterns of NMT2 by immunohistochemical (IHC) analyses on primary tumor samples from treatment naïve BC patients. This retrospective study was blinded, and the tumor tissues in duplicate were stained with NMT2 monoclonal/polyclonal antibodies on an autostainer (Leica Bond). Stained slides were scored, and an "H" score representing the intensity and percent positive cells was given to each sample. In a combined cohort of BC represented by ER+, Triple Positive, and Triple Negative (n= 598) cases, we determined the expression and localization of NMT2. The localization pattern of NMT2 turned out to be a significant prognostic and predictive molecular signature. The nuclear localization serves as both prognostic and predictive markers. In a cohort of 447 ER+ BC cases that included 18 triple positive cases, the majority of the cases showed negative staining for nuclear NMT2 (n=394) and positive nuclear staining with differential expression in 53 cases. Whereas, in a cohort of 151 TNBC cases, nuclear NMT2 staining was positive in most cases (n= 116) and negative in 20 cases (undetermined; n= 15). The most important finding was the dichotomy of the nuclear NMT2 staining in predicting treatment response and prognosis. Both high cytoplasmic H score (>180) and positive nuclear staining (>0) predicted significant association with worse clinical outcomes for OS (HR = 1.72, *P* = .0284, 95% CI 1.06 to 2.81 for cytoplasmic NMT2 and HR = 1.74, *P* = 0.0006, CI 1.27 to 2.39 for the nuclear NMT2). Nuclear NMT2 status alone predicted a significant association with worse clinical outcomes to RFS (HR = 1.56, *P* = 0.0027, CI 1.17 to 2.09). The data from our study indicate that NMT2 could be a potential marker for predicting the likelihood of recurrence of BC and become part of routine first-line prognostic and predictive tests.

#6441 Discovery of ARID1A loss as a patient biomarker for NXP800 - A developmental activator of the integrated stress response (ISR) and inhibitor of the HSF1 pathway in ovarian cancer.

Robert H. te Poele, Marissa Powers, Swee Sharp, Emmanuel de Billy, Maria Taskinen, Loredana Pellegrino, Sharon Gowan, Asadh Miah, Angela Hayes, Matthew Cheeseman, Keith Jones, Suzanne Eccles, Florence Raynaud, Paul Clarke, Paul Workman

Centre for Cancer Drug Discovery, The Institute of Cancer Research, Sutton, United Kingdom

Background. HSF1 helps cancer cells cope with multiple stresses caused by oncogene activation.
Methods. See details below.
Results. We discovered the bisamide NXP800 as an inhibitor of HSF1-mediated transcription through phenotypic screening and med chem optimization. Gene expression microarray analysis of human cancer cell lines and tumor xenografts treated with bisamide inhibitors indicated activation of the ATF4 axis of the ISR as a key mechanism of action. In SK-OV-3 ovarian cancer xenografts, NXP800 showed clear PK/PD relationships with increased expression of ATF4 transcriptional target genes alongside decreased expression of HSF1 transcriptional targets. NXP800 also caused tumor regressions in this model. Expanding in additional human ovarian cancer xenograft models, we observed efficacy in five and a complete lack of response in three others. The sensitive models all had homozygous deleterious mutations in the ARID1A gene, whereas the non-responding xenografts were all wild type (WT). ARID1A is a component of the SWI/SNF chromatin remodelling complex involved in repression and activation of target genes. Subsequent screening of the large Sanger human cancer cell line panel confirmed ARID1A as the most significant common disease-related alteration predicting sensitivity to NXP800 in ovarian cancer cell lines. This predictive relationship was confirmed in an ARID1A isogenic HCT-116 cell line pair; sensitivity was greater in the homozygous ARID1A mutant cells compared to WT, resulting in PARP cleavage in the mutant cells only. In vivo there was no effect in WT HCT-116 xenografts whereas growth inhibition was observed in the homozygous mutant cells, resulting in significantly smaller tumors. In addition, the induction of ATF4 target genes was stronger and more prolonged in the mutant cells. It is known that whereas short term ATF4 activation is adaptive, persistent activation can promote the induction of apoptosis. CHIP-seq analysis confirmed clear relationships between ARID1A status, ATF4 and HSF1 promoter occupancy, and the distribution of BRG1 and RNA pol II at target sites, although these were often gene-specific and complex. A relatively simple example is the regulation of the INHBE gene (expression of which is a PD biomarker). In untreated samples there is no binding of ATF4, BRG1 and RNA pol II at the INHBE promoter. NXP800 treatment results in the recruitment of BRG1, ATF4 and RNA pol II in ARID1A mutant TOV-21G cells but not in the RMGI WT cells, leading to increased expression in the mutant cells only.
Conclusions. We propose that ARID1A loss alters the binding and recruitment of ATF4 and HSF1 leading to the altered and prolonged expression of ATF4 target genes and increased sensitivity to NXP800. NXP800 is currently in phase Ib for the treatment of ARID1A mutant platinum resistant ovarian cancer (NCT05226507).

#6442 Evaluation of drug target engagement on pharmacodynamic biomarkers in human plucked scalp hair.

G. Tudor, F. Ponthan, A. Boanas, M. Brown, C. Booth;
Epistem Ltd., Manchester, United Kingdom

Plucked hair is a valuable surrogate tissue to monitor pharmacodynamic (PD) responses in a clinical trial. Hair collection is a minimally invasive, simple technique amenable to frequent sampling and hence patient compliance. We have developed a method to assess target expression changes following exposure of plucked hairs to chemotherapeutic agents and other potential therapeutics. Successful *ex vivo* responses provide proof of concept data prior to clinical studies. Since hairs are epithelial appendages, many signaling pathways active in other epithelial tissues, including cancers, are also present in hairs. Highly proliferative scalp hair can be utilized as a surrogate tissue to measure proliferation, phosphorylation and DNA damage responses after treatment. Furthermore, hairs are highly vascularized, suggesting administered Test Articles may be delivered efficiently to the hair in a similar manner to other highly vascularized tissues, including many tumor types. Human plucked scalp hair was placed in maintenance media in the presence of chemotherapeutic agents that have different mechanisms of action (e.g. Gemcitabine, Epirubicin, Erlotinib) for a range of timepoints. Hairs were fixed post-exposure and longitudinal sections were immunohistochemically labelled for markers relating to DNA damage/repair or signaling pathways directly relating to target engagement. Examples include p-Chk1, g-H2AX, p-ERK1/2, and p-AKT. Quantitative image analysis to measure the level of labelling was performed using an Aperio ScanScope®. The relative number of positively labelled cell nuclei or relative labelled tissue area (depending on the labelling pattern of the target), of the hair outer root sheath was analyzed, along with label intensity. In subsequent clinical trials, formaldehyde fixed hairs from patients were returned to the lab, sectioned, labelled and quantified. If antibody labelling is not possible or more detailed information on pathway modulation may be useful, drug treated plucked hairs can be subjected to Next Generation Sequencing (NGS) gene expression analysis. The expected changes in labelling were observed, reflecting known tumor responses. For example, Gemcitabine (linked to DNA polymerase inhibition) increased p-Chk1 labelling after 4 hours and strongly induced p53 by 24 hours. Epirubicin (anthracycline topoisomerase II inhibitor) increased g-H2AX labelling up to 24 hours. Erlotinib (EGFr pathway inhibitor) decreased levels of both p-ERK1/2 and p-AKT after only 10 minutes. We have demonstrated that plucked hair is a valuable PD biomarker tissue for various chemotherapy agents. Proof of concept studies performed *ex vivo* can inform the design of clinical studies by indicating optimum biomarkers and timepoints. Further, each hair is an independent unit thereby allowing replicate tissues (hairs) to be sampled, improving statistical confidence compared to single readout markers.

#6443 Enhanced detection of ctDNA molecular response for immunotherapy treated non-small cell lung cancer through analyses of cell-free and matched white blood cell DNA.

J. B. Jackson[1], P. Rocha[2], J. R. White[1], A. P. Georgiadis[1], E. L. Verner[1], A. Greer[1], R. B. Mora[3], L. M. Pinto[3], N. Navarro[3], A. Taus[3], B. B. Paricio[3], S. Clave[3], M. T. Sausen[1], E. Arriola[2],

[1]Personal Genome Diagnostics (PGDx)/Labcorp, Baltimore, MD, [2]Hospital del Mar Medical Research Institute, Barcelona, Spain, [3]Hospital del Mar, Barcelona, Spain

Introduction: Immune checkpoint inhibitors (ICIs) have greatly improved clinical outcomes for patients with non-small cell lung cancer (NSCLC), however, programmed death-ligand 1 (PD-L1) and tumor mutation burden (TMB) have failed to consistently predict therapeutic response and outcomes in this population. There remains a critical unmet need to identify patients who are likely to experience clinical benefit from treatment, particularly as additional treatment regimens become available. Longitudinal cell-free tumor DNA (ctDNA) assessments have recently been applied as a strategy to identify molecular response (mR) and better predict long term clinical response. Through this real-world analysis of NSCLC, we explore the technical and biological considerations associated with determination of ctDNA mR through matched cell-free and white blood cell (WBC) DNA analyses and apply this optimized approach to assess therapeutic response to ICIs.

Methods: Plasma from 50 patients with advanced or metastatic NSCLC who received ICIs from 2017-2019 at Hospital del Mar had detectable pre-treatment ctDNA and underwent analysis using the 521 gene PGDx elio plasma complete liquid biopsy assay. Patient blood was collected prior to the start of ICI therapy, early on-treatment (median 4 weeks; range 2.4-9 weeks) and longitudinally throughout clinical follow-up and disease progression. Matched WBCs were also analyzed for each patient to identify alterations arising from germline polymorphisms and clonal hematopoiesis (CH). mR was calculated as the percent change in mean variant allele frequency of the tumor-specific alterations assessed at the early on-treatment timepoint compared to the pre-treatment timepoint, and compared to radiographic response, progression-free, and overall survival (OS).

Results: Best overall response for patients within the cohort was 4% complete response, 26% partial response, 34% stable disease, and 36% progressive disease. The removal of germline or CH variants allowed for improved characterization of tumor-specific somatic alterations and associations with radiographic and survival-based endpoints. With the integrated ctDNA and matched WBC approach, we observed a mR rate of 34% (17/50) with a median OS of 36.8 months compared to 9.2 months for patients experiencing molecular progression at the early on-treatment timepoint (HR 5.6, 95% CI 2.4-12.7, p<0.001, log-rank test). Specifically, of all patients that survived ≤12 months after initiation of treatment, 84% (21/25) were categorized as experiencing molecular progression through early on-treatment ctDNA analyses.

Conclusions: This real-world study of ICI treated, advanced NSCLC highlights the opportunity afforded through integrated analyses of ctDNA and matched WBCs to accurately determine mR and the associations with radiographic response and OS.

#6444 Assessing cytotoxic T cell responses to immune checkpoint inhibitors in murine and human tumor samples using metabolic imaging.

J. Ouellette[1], J. Degnan[1], A. Kellner[1], E. Flietner[1], L. Doebert[1], Z. Swider[1], E. Wait[1], V. Pope[1], L. Hrycyniak[1], S. Caenepeel[1], K. Eliceiri[2], T. S. Ramasubramanian[1], **M. J. Korrer**[1];

[1]Elephas Bio, Madison, WI, [2]University of Wisconsin, Madison, WI

Background Immune checkpoint inhibitors (ICI) have revolutionized cancer treatment. Unfortunately, existing FDA approved biomarkers do not accurately predict which patients will respond. The Elephas Cybrid™ platform aims to improve ICI response prediction by imaging a patient's biopsy treated with ICI ex vivo. Multiphoton microscopy (MPM) is a powerful imaging technique to interrogate the biological changes in live tumor fragments (LTFs) following ICI treatment. MPM allows rapid visualization of biological processes in 3D living tissues in a non-destructive fashion allowing for longitudinal assessment of a sample. We and others have used label-free metabolic imaging to demonstrate that changes in T cell metabolism and activation status are correlated. Using MPM imaging we successfully demonstrated T cell activation and T cell mediated cytotoxicity in response to ICI in LTFs and tumor biopsies.

Methods Tumors were cut into LTFs, sorted, and cultured using the Cybrid platform. LTF structure and metabolic status were assessed using intrinsically fluorescent NAD(P)H and FAD. Anti-CD8 nanobodies and cleaved caspase 3/7 dye were used to characterize T cell cytotoxicity. Multi-channel fluorescence intensity and lifetime were obtained over 48 hours using MPM.

Results Murine CT26 LTFs generated with the Cybrid platform were treated with ICI and cytotoxicity was assessed in the intact LTFs by monitoring caspase 3/7 activity using MPM over 48 hours. We found that ICI treatment resulted in a significant increase in caspase 3/7 activity compared to control treated LTFs. By blocking the interaction of T cells with tumor cells through antibody blockade, we demonstrated that the cytotoxicity observed was T cell mediated. As additional confirmation, we measured changes in cytotoxicity in the ICI resistant LLC1 tumor model. As expected, we did not observe an increase in cytotoxicity in LLC1 LTFs treated with ICI. MPM allows for the tracking of labeled T cells and characterization of their metabolism as a means of assessing changes in their activation state. We used a CD8 nanobody to label T cells in CT26 LTFs and then characterized the shift in metabolism following ICI treatment. Finally, we applied the Cybrid platform to human biopsies treated with ICI and characterized the cytotoxicity and shifts in T cell metabolism in living tissue. These data show that the Cybrid platform can measure changes in T cell metabolism and T cell cytotoxicity in response to ICI in 3D living tissue.

Conclusions The methods presented herein will advance the field of cancer diagnostics by progressing from fixed tissue imaging and genetic characterization to the assessment of clinically relevant ICI-treated biopsies. Understanding the response of biopsies to immunotherapies will allow clinicians to make more informed treatment decisions and improve the lives of those with cancer.

#6445 Exploring the relationship between PSCA and PD-L1 by a comprehensive tumor immunohistochemical analysis.

Y. Guo[1], R. Gonzalez[1], J. Yom[1], B. Gilmore[1], T. Qu[1], X. Hu[2], A. Han[1], Z. Guo[1], E. Zewdu[1], X. Liu[1], W. Fu[1];

[1]Origene Technologies Inc, Rockville, MD, [2]OriGene Wuxi Biotechnology Co., Ltd, Wuxi, China

Prostate Stem Cell Antigen (PSCA) is a well-established diagnostic marker in various cancers and a promising target for immunotherapy. Programmed Death-Ligand 1 (PD-L1) plays a crucial role in cancer immune regulation and is known to influence patient response to checkpoint inhibitors. The objective of this study is to elucidate the relationship between PSCA and PD-L1 in diverse cancer types and to provide valuable insights for the development of an effective immunotherapy strategy.

To accomplish this, immunohistochemical (IHC) analysis was conducted on paraffin-embedded Cytosections obtained from 20 lung cancers, 20 prostate cancers, 32 bladder cancers, and 20 normal tissues for each respective cancer type. Antibodies generated by Origene were utilized to detect the expression of PSCA and PD-L1 on the cell surface. The IHC results of tumor tissue were standardized against corresponding normal samples, and the correlation between these two genes was statistically analyzed using analysis of variance (ANOVA). The findings reveal a significant positive correlation between the expression of PSCA and PD-L1 ($r=+0.78$, $P=0.016$), suggesting an underlying mechanism driving their co-expression in the studied cancers.

Understanding PSCA and PD-L1 coexpression in bladder, lung, and prostate cancers has great potential for informing tailored immunotherapies. Future research should explore functional consequences within the tumor microenvironment, advancing precision immunotherapy for improved outcomes in these challenging malignancies.

#6446 Genialis™ krasID: Biology-Driven Machine Learning to Personalize KRAS Inhibitor Therapeutics.

J. Wheeler, A. Lovse, K. Ziberna, M. Stajdohar, L. Ausec, J. Kokosar, D. Pointing, A. Pai, R. Rosengarten, M. Uhlik;
Genialis, Inc, Boston, MA

Breakthroughs in targeted KRAS therapeutics (KRASi) have the potential to transform the treatment landscape for several of the most common cancers including lung, colorectal, and pancreatic. Despite the recent approvals of KRASi and the anticipation of more to come, both the rate of patient response and the durability of these responses remain significant areas requiring improvement. Biomarkers that can predict response to KRASi and guide effective patient selection and drug combination strategies will be key to realizing the full potential of this emerging therapeutic field. While most biomarkers predominantly rely on a single analyte (e.g. KRAS mutation status), Genialis' biomarkers are constructed using high-dimensional and/or multimodal data that capture the underlying biological complexity unique to each individual patient. Genialis' ResponderID™ is a machine learning-based biomarker discovery framework that models fundamental aspects of cancer biology to predict the clinical benefit based on the patient's own biology. Here we report progress towards the development of a first-in-class, RNA-based biomarker, ResponderID™ KRAS, capable of stratifying KRAS G12C inhibitor response in lung cancer patients using RNA sequencing data. Trained on thousands of lung cancer samples, our biomarker models therapeutic response by unifying two core KRAS biologic axes, dependency and activation, to identify those patients most likely to respond. The performance characteristics of ResponderID™ KRAS thus far has been evaluated on a real world dataset of lung cancer patients treated with Sotorasib. ResponderID™ KRAS serves as an independent biomarker designed to inform clinical trial design, select for therapeutic efficacy, identify rational combination strategies, and expedite approvals across various therapeutic contexts.

#6447 Development of a fully automated immunoassay system of serum pembrolizumab to forecast therapeutic effectiveness.

N. Noda[1], T. Takahashi[1], S. Yagishita[2], M. Miura[1], Y. Takahashi[1], Y. Irino[1], M. Yanagida[1], A. Hamada[2];
[1]Sysmex Corporation, Kobe, Japan, [2]National Cancer Center Research Institute, Tokyo, Japan

Recently, immuno-oncology treatments utilizing immune checkpoint inhibitors including pembrolizumab have attracted attention. Such treatments demonstrate potential effectiveness against cancers resistant to existing drugs, while offering the benefit of reduced side effects. Nonetheless, there is a specific group of patients who do not experience adequate therapeutic benefits from pembrolizumab. Despite the issue, the development of a comprehensive evaluation system to forecast therapeutic effectiveness is still in development. A strategy to predict therapeutic effectiveness involves evaluating the trough level or the steady state plasma-concentration of a drug in the blood. Ohuchi, M. *et al.* (Lung Cancer, 2022) demonstrated that patients with lower trough levels have shorter overall survival and progression-free survival durations, according to LC-MS/MS measurement of pembrolizumab. Furthermore, Wang, N. *et al* (Lung Cancer, 2023) demonstrated that the optimization of the dosage interval, grounded on the steady state plasma-concentration (target concentration, 15 µg/mL) of pembrolizumab, extended the duration of progression-free survival. Despite the potential of LC-MS/MS measurements in predicting patient prognosis and the benefits of PK-guided therapy, their implementation in clinical settings is hindered by the complex and time-consuming pre-treatment process for samples. Consequently, there is a growing need for a practical and clinically feasible drug concentration measurement system. Aiming to construct a clinically applicable pembrolizumab measurement system, we have been dedicated to developing a fully automated immunoassay system using anti-pembrolizumab antibodies. We developed two measurement systems of pembrolizumab in serum using two different antibodies targeting pembrolizumab. Using less than 10 µl serum, these systems can quantify the concentration of pembrolizumab ranging from 0.125 to 500 µg/mL within an hour, thereby enabling PK-guided therapy in clinical settings. After developing the measurement systems, we performed a correlation analysis with the LC-MS/MS system, using 70 samples with varying pembrolizumab concentrations ranging from 1.80 to 85.0 µg/mL. The results demonstrated that our measurement systems have a good correlation with LC-MS/MS measurement. Furthermore, the two immunometric measurement systems demonstrated a significant correlation with each other, substantiating the accuracy of the newly developed measurement system in determining the levels of pembrolizumab in the serum. The fully automated immunoassay systems we developed can measure pembrolizumab in serum within an hour, potentially paving the way for personalized treatment based on the serum concentration of pembrolizumab in clinical practice.

#6448 Prevalence and spectrum of *PIK3CA* mutations in Indian breast cancer patients.

R. Katara, T. Bhardwaj, M. Rawat, D. K. Sharma, V. Kumar, S. Sharma, V. Dagar, P. Kumar, S. K. Mohanty;
CORE Diagnostics India, Gurgaon, India

Introduction: Breast carcinomas are the most commonly encountered cancers in women globally. Due to advancements in cancer research the death rate in breast cancer has reduced by 41% since 1989; however, the downward trend has recently slowed emphasizing on new breast carcinomas treatment discovery. Breast carcinomas are molecularly categorized by the expression of specific hormone receptors, as well as the overexpression of human epidermal growth factor receptor 2 (HER2). Approximately 80% of breast cancers have been termed HER2-negative, but researchers now recognize that 55% of all breast cancers may actually contain low levels of HER2, levels that are still targetable by HER2-directed therapies such as Trastuzumab Deruxtecan. The phosphoinositide 3-kinase (PI3K) pathway is the most frequently altered pathway in HR+/HER2- breast carcinomas and is associated with tumor development, disease progression, and endocrine resistance.

Methodology: The study entailed histological verification of breast cancer, and thence the extraction of DNA from formalin fixed, paraffin embedded (FFPE) tissue samples. A tumor content of 20% was the cut-off for performing the *PIK3CA* mutation analysis. The DNA was subjected to mutation analysis using a FDA-approved *PIK3CA* RGQ Real Time PCR based assay that has ability to detect 11 mutations in the *PIK3CA* gene encompasses exons 7, 9, and 20.

Results: A total of 696 breast cancer patient samples (with more than 20% neoplastic tissue content) were screened for *PIK3CA* mutations. Of these, 275 (39.5%) (Male: Female ratio = 1:26.5; Age range = 30-80 years) harbored a mutation of the *PIK3CA* gene. Females were commonly affected; however, the males were also found to have *PIK3CA* mutation. The most common affected age group is from 41 to50 years. The positivity rate exon wise were as follows: Exon 7 (1.45%), Exon 9 (39.27%), and Exon 20 (44.27%). There was presence of co-mutations amongst different exons, which comprised of 4%. HR+/HER2- (50%) followed by HR-/Her2- (3.27%) and HR+/HER2+ (1.82%). The HER2- cases (Score 1 and Score 2) by IHC were considered as low positive cases (14%).

Conclusion: This is one of the largest study to report frequency of *PIK3CA* mutations in the Indian population. *PIK3CA* mutations are commonly encountered in hormone receptor positive and HER2 Negative metastatic breast cancer and have shown promising clinical outcome leading to better prognosis. It provides insights into genotyping each breast cancer and exploits the usage of PI3K/AKT inhibitors together with other combination of drugs for effective target treatment strategies.

Keywords: Breast carcinomas, *PIK3CA*, HR/HER2, Targeted Therapeutic

#6449 KDM6A expression loss is a common feature in low grade non-invasive urothelial carcinomas of the urinary bladder.

F. Viehweger[1], N. Gorbokon[1], H. Plage[2], S. Hofbauer[2], K. Furlano[2], S. Weinberger[2], B. Ralla[2], A. Franz[2], A. Fendler[2], M. de Martino[2], F. Ro?ner[2], S. Schallenberg[2], S. Elezkurtaj[2], **M. Lennartz**[1], T. Mandelkow[1], E. Bady[1], A. H. Marx[3], H. Samtleben[3], M. Fisch[1], M. Rink[4], M. Slojewski[5], K. Kaczmarek[5], T. Ecke[6], S. Koch[6], N. Adamini[7], R. Simon[1], G. Sauter[1], J. Weischenfeldt[8], T. Klatte[2], T. Schlomm[2], D. Horst[2], H. Zecha[7], M. Kluth[1], S. Minner[1];
[1]University Medical Center Hamburg-Eppendorf, Hamburg, Germany, [2]Charite - Universitatsmedizin Berlin, Corporate Member of Freie Universitat Berlin, Humboldt-Universitat zu Berlin and Berlin Institute of Health, Berlin, Germany, [3]Academic Hospital Fuerth, Fuerth, Germany, [4]Marienhospital Hamburg, Hamburg, Germany, [5]Pomeranian Medical University, Szczecin, Poland, [6]Helios Hospital Bad Saarow, Bad Saarow, Germany, [7]Albertinen Hospital, Hamburg, Germany, [8]University of Copenhagen, Copenhagen, Denmark

KDM6A, also known as UTX (ubiquitously transcribed X chromosome tetratricopeptide repeat protein) is an epigenetic regulator which is frequently mutated in urothelial carcinoma. Because KDM6A loss causes a dependency on EZH2, a potential therapeutic target, KDM6A analysis may have therapeutic importance. Most data on KDM6A mutations are derived from next generation sequencing (NGS). However, because of the combination of a high rate of truncating KDM6A mutations, the localization of KDM6A on chromosome Xp11.3, and the male predominance in bladder cancer, many KDM6A mutations should result in a complete loss of KDM6A protein expression and become detectable by immunohistochemistry (IHC). To study the prevalence and the potential diagnostic and clinical role of KDM6A expression loss, more than 2,100 tumors were analyzed by IHC in a tissue microarray format. The cohort included 1,128 patients who underwent radical cystectomy for muscle-invasive disease (pT2-4). A complete KDM6A expression loss occurred in 36% of 350 pTa G2 low-grade, 23% of 152 pTa G2 high-grade, and 18.5% of 92 pTa G3 tumors (p=0.0002). As compared to pTa G3 tumors, the frequency of KDM6A expression loss did not differ significantly in pT2 (17.2%), pT3 (21.9%), and pT4 (18.2%) cancers. Within pT2-4 carcinomas, KDM6A staining was unrelated to pT, pN, grade, L-status, V-status, overall survival, recurrence-free survival, and cancer-specific survival (p≥0.18 each). A KDM6A loss was more common in male (22.2%) than in female patients (15.4%; p<0.0001), and within male patients, a KDM6A loss was more frequent in tumors with Y-chromosome loss (36.1%) than in cancers without a Y-chromosome loss (16.3%; p<0.0001). KDM6A expression loss was significantly associated with increased p63 expression (p<0.0001) and high uroplakin 1b staining (p=0.0013) but unrelated to CK20, GATA3, UpK1b, and p53 staining. In summary, our data demonstrate that truncating KDM6A mutations occur in a significant subset of urothelial carcinomas which is linked to low-grade non-invasive cancer, male gender and loss of the Y chromosome. The predominance of KDM6A loss in low grade tumors makes KDM6A IHC a promising new tool for identification of low grade dysplasia in biopsies and early bladder cancer detection in cytology.

#6450 High mobility group protein 2 (HMGA2) is highly expressed in a broad range of human cancers.

K. Moller, F. Lutz, F. Viehweger, M. Kluth, C. Hube-Magg, C. Bernreuther, G. Sauter, A. H. Marx, R. Simon, T. Krech, S. Steurer, C. Fraune, S. Minner, N. Gorbokon, **M. Lennartz**, E. Burandt, A. Menz;
University Medical Center Hamburg-Eppendorf, Hamburg, Germany

The high mobility group protein 2 (HMGA2) is an essential component of the enhanceosome. It can attach to AT-rich binding sites in the DNA minor groove, affect the conformation of the DNA, and thereby modify the transcription of numerous genes. HMGA2 is preferentially expressed during organogenesis. Aberrant expression of HMGA2 in adult tissues is commonly associated with tumor formation and cancer aggressiveness. Accordingly, HMGA2 represents a potential drug target. To better comprehend the role of HMGA2 expression in cancer, a tissue microarray containing 8,344 samples from 115 different tumor entities and 608 samples of 76 different normal tissue types was analyzed. In normal tissues, a strong nuclear HMGA2 staining was limited to few cell types from the amnion, placenta, seminal vesicle, endocervix, fallopian tube, and respiratory epithelium. HMGA2 expression was generally markedly higher in cancer than in corresponding normal tissues. HMGA2 staining was found in 2,695 (42.7%) of the 6,313 interpretable tumor samples, including 701 (11.1%) with weak, 769 (12.2%) with moderate, and 1,225 (19.4%) with strong positivity. A total of 93 of 115 tumor categories showed HMGA2 expression in at least one case, and 69 tumor categories included at least one case with strong HMGA2 staining. The frequency of HMGA2 positivity was particularly high in cancers of the ovary and the endometrium (52.6-92.6%), pancreatico-biliary cancers (48.1-75.5%), thyroidal neoplasms (53.4-95%), salivary gland neoplasms (66.7-98%), nonseminomatous testicular germ cell tumors (73.5-93.5%), colorectal adenocarcinoma (81.6%), papillary renal cell carcinoma (68.2%), and in squamous cell carcinomas (36-81.5%). Tumor entities with a particularly low expression of HMGA2 included prostatic adenocarcinomas (1.3-4%), non-invasive urothelial carcinomas (1.8-4.3%), hepatocellular carcinoma (3.2%), and non-Hodgkin’s lymphomas (0%) It is concluded, that HMGA2 is highly expressed in a very broad range of tumor entities. These findings emphasize a potential role of HMGA2 as a drug target and demonstrate utility for HMGA2 IHC for the distinction of neoplastic from non-neoplastic tissues in several organs.

CLINICAL RESEARCH: Profiling Cancer with Real-World Evidence
Poster Session

#6454 Genomic characterization of vulvar squamous cell carcinoma.

S. R. Selitsky[1], T. Thong[1], K. Roche[1], J. Guinney[1], P. Sethupathy[2], C. Igartua[1];
[1]Tempus Labs, Chicago, IL, [2]Cornell University, Ithaca, NY

Introduction: Understanding the molecular underpinnings of vulvar squamous cell carcinoma (vSCC) has strong potential for clinical impact, given the unmet need for this rare cancer. vSCCs have two main etiologies, including human papillomavirus (HPV) infection or skin conditions such as lichen sclerosis. Clinically, few treatment options with limited efficacy are available for recurrent vSCCs and large whole transcriptome disease subtyping studies are limited due to the rarity of this cancer type. Here, we present a whole transcriptome subtyping study of 244 vSCC clinical samples with DNA genomic profiling. Furthermore, we compared vSCCs to other SCC disease subtypes (pan-SCC), including lung, esophageal, skin, urothelial, anal, and head and neck (HN). Our goal was to gain novel insights into the molecular landscape of vSCCs to inform new routes of therapy.
Methods: Deidentified records of SCC patients were selected from the Tempus clinico-genomic database. The vSCC cohort was predominantly composed of, but not exclusively, naive or pre-treatment primary tissue. The pan-SCC cohort was limited to randomly sampled primary pre-treatment female samples with paired RNA and DNA sequencing. To perform vSCC subtyping, we used bulk RNA-seq and clustered the samples using FastPG-CC, an internally developed consensus-clustering extension of FastPG, a graph-based parallelized clustering tool. We next performed differential expression, pathway analysis, and cell type abundance estimation.
Results: Unbiased gene expression clustering analysis identified three vSCCs clusters; an HPV+ cluster (HPV+, 32% of vSCC samples), HPV- cluster (HPV-, 33%), and an intermediate cluster which contained both HPV+ and HPV- samples (Mix, 35%). The HPV- cluster was enriched for TP53 and TERT promoter mutations, EMT and tumor microenvironment gene expression-derived pathways, and was most similar to HPV- oral HN tumors. The HPV+ cluster was enriched with PIK3CA mutations, cell cycle gene expression and was most similar to other HPV+ SCC samples, including cervical, anal, and HN. The Mix cluster was enriched for neutrophils, fatty acid metabolism and was most similar to skin SCC.
Conclusions: We performed a multi-modal molecular subtyping analysis on a large cohort of vSCCs and identified three molecular subtypes, which enabled us to identify heterogeneity within vSCC, and observe that a subset of vSCCs share features with SCC tumor types for which there are emerging therapy options. Thus, this approach identifies a subset vSCCs that may be responsive to existing SCC therapeutics.

#6455 Investigating clinical trial eligibility criteria to improve MatchMiner trial matching.

H. Klein, T. Mazor, M. Galvin, J. Hansel, E. Mallaber, P. Trukhanov, J. Provencher, J. Lindsay, M. Hassett, E. Cerami;
Dana-Farber Cancer Institute, Boston, MA

As the number of precision medicine (PM) trials and the volume of patient genomic data have grown, it has become challenging for clinicians and trial staff to identify PM trial options for patients. At Dana-Farber Cancer Institute (DFCI), we have addressed this challenge by developing our own open source institutional trial matching software called MatchMiner. MatchMiner algorithmically matches patient genomic and clinical data with PM trial eligibility data. PM trial eligibility data is manually curated into a human- and computer-readable structured format called clinical trial markup language (CTML), for trial matching with DFCI's institutional genomic assay OncoPanel. MatchMiner has 2 main modes of clinical use: (1) patient-centric, where clinicians can search for trial matches for individual patients and (2) trial-centric, where trial staff can identify patients that match their trial's genomic eligibility. Thus far, more than 300 DFCI patients have enrolled onto trials facilitated by MatchMiner.

In its current implementation, MatchMiner uses limited clinical data (gender, age, and cancer type) to match patients to trials. Although this limited data gives clinicians a head start on assessing available trial options, incorporating more clinical data into MatchMiner would provide more precise trials options and reduce additional work to assess patient eligibility. Here, we investigated clinical trial eligibility criteria that were available for trials at DFCI with the goal of improving specificity of trial matching for MatchMiner. We attempted to answer 2 main research questions 1) what categories of clinical data comprise the eligibility criteria for precision medicine trials at DFCI and 2) which categories are most relevant for trial matching?

We first investigated the clinical eligibility criteria across several PM lung cancer trials. After extracting the inclusion and exclusion criteria from the protocol documents, we found criteria could be classified into 10 distinct categories. The most common categories making up almost half of the eligibility criteria were "Prior Therapy" and "Prior or Concurrent Non-Cancerous Disease". Within some categories, we found it appropriate to also make subcategories to make our analysis more informative such as "Prior Therapy, Surgery" or "Disease Status, CNS". We next broadened our search to non-lung trials to see if criteria was consistent across other cancer types. We found similar proportions of clinical criteria for the non-lung trials compared to the lung trials, but did find some additional subcategories. Overall, having similar categories of criteria across trials suggests that common clinical data could be used for many different PM trials. Currently, we are investigating which categories are most relevant for trial matching and the use of AI for structuring unstructured clinical data.

#6456 The utility of clinical sequencing in the diagnosis and treatment of soft tissue sarcomas; Real world data based on nation-wide database.

E. Nakada, T. Fujiwara, T. Kunisada, S. Takihira, D. Ennishi, H. Yamamoto, K. Ninomiya, S. Tomida, M. Futagawa, A. Hirasawa, S. Toyooka, T. Ozaki; Okayama University Hospital, Okayama City, Japan

Purpose: Soft tissue sarcomas (STS) are rare and heterogeneous tumors arising from mesenchymal connective tissue, accounting for approximately 1%-2% of all malignancies. Due to their rarity and heterogeneity, it is challenging for accurate diagnosis, prognosis, and treatment of sarcoma. Recently, next-generation sequencing (NGS)-based comprehensive cancer genome profiling (CGP) has increasingly become a routine practice for patients with solid cancers worldwide. To collect genomic information and clinical characteristics of patients who underwent CGP, the Center for Cancer Genomics and Advanced Therapeutics (C-CAT) has also been established since 2018 in Japan. Almost all the clinical and genomic data of patients who received CGP tests the had been collected in C-CAT. Here, we examined the utility of CGP test in the diagnosis and treatment of STS using this nation-wide database.

Patients and Methods: We retrospectively evaluated the records of patients with STS who received F1CDx between 2019 and 2022 and registered in C-CAT. This assay carries 324 genes and determines nucleotide substitutions, insertions/deletions, and copy number (CN) alterations of 309 genes, fusions of 36 genes, tumor mutation burden (TMB) and microsatellite instability (MSI). High TMB (TMB-H) was defined as a TMB value >10 muts/Mb. Ranges of the MSI score were assigned MSI-High (MSI-H) or microsatellite stable (MSS).

Results: From 2019 to 2022, 1387 patients with STS were registered in C-CAT. The histological types included leiomyosarcoma in 357 patients, dedifferentiated liposarcoma in 178 patients, and undifferentiated pleomorphic sarcoma in 82 patients, and the others. The most commonly altered genes included TP53, CDKN2A, Rb1, and CDKN2B. Among the 1387 cases, we observed 110 fusion events in 108 cases (7.7%), and 2 cases showed 2 types of fusion transcripts. Fifteen (2.8%) patients were re-classified based on the detection of highly histology-specific translocations. Among them, an initial diagnosis of sarcoma NOS was classified as Ewing Sarcoma (*EWSR1-FLI1* in 2 patients), *NTRK*-rearranged spindle cell neoplasm (NTRK fusion in 3 patients), *CIC*-rearranged sarcoma (*CIC-DUX4* in 3 patients), and sarcoma with *BCOR* genetic alterations (*BCOR-ZC3H7B* in 1 patient) as these gene fusions were identified. Druggable gene alterations was detected in 347 patients (25%) and 55 patients (4%) who received genotype-matched therapy. In 38 patients for whom the effect of treatment could be evaluated, complete response and partial response were achieved in 2 (5%) and 10 (26%) patients, respectively.

Discussion: In conclusion, the comprehensive genomic profiling test appears to be an important tool in the diagnosis and treatment of sarcomas.

#6457 The real-world data of comprehensive genomic profiling tests with tissue specimens from lung cancer patients in Japan.

K. Fujii, M. Morishita, M. Ueki, H. Ikushima, H. Isago, K. Watanabe, K. Oda, H. Kage;
The University of Tokyo Hospital, Tokyo, Japan

Introduction: Molecularly targeted therapy improves prognosis of lung cancer patients with specific genomic alterations, and thus it is important to identify actionable genomic alterations leading to appropriate therapy. In Japan, comprehensive genomic profiling (CGP) tests have been covered by insurance since June 2019. 99.7% of the CGP data under insurance coverage have been registered with the nationwide database: Center for Cancer Genomics and Advanced Therapeutics (C-CAT). C-CAT data include CGP test results and clinical information such as companion diagnostic results for *EGFR*, *ALK*, *ROS1*, and *BRAF* as well as therapeutic history. The aim of this study is to evaluate the usefulness of CGP tests for identifying actionable genomic alterations in real-world lung cancer patients.

Methods: Among the 3,240 lung cancer patients registered in the C-CAT database by September 2023, 2,076 non-small cell lung cancer cases were tested using tissue specimens and analyzed retrospectively. The analysis was based on the levels of evidence defined by C-CAT. Level A indicated approved drugs for the particular cancer type, while level C indicated approved drugs or presence of positive clinical trials regardless of cancer type. Level F indicated that the genomic alteration was an oncogenic marker.

Results: The cases were divided into two groups: 335 cases with known genomic alterations with positive results from companion diagnostic tests or use of specific inhibitors and 1,741 cases without. Genomic alterations with level A, A to C, and A to F were identified in 430 cases (24.7%), 1174 cases (67.4%), and 1718 cases (98.7%) with unknown genomic alterations, respectively. Genomic alterations with level A included rearrangement of *RET* (43 of 1741 cases, 2.5%), *ALK* (14 cases, 0.8%), *ROS1* (8 cases, 0.5%), and *NTRK1* (2 cases, 0.1%), and mutations of *EGFR* (124 cases, 7.1%), *MET* (38 cases, 2.2%), *ERBB2* (122 cases, 7.0%), *KRAS G12C* (66 cases, 3.8%), and *BRAF V600E* (15 cases, 0.9%). Genomic alterations with level C included mutations in *KRAS* (185 cases, 10.6%), *PIK3CA* (99 cases, 5.7%), *BRAF* (55 cases, 3.2%), and *PTEN* (32 cases, 1.8%) and amplifications in *ERBB2* (147 cases, 8.4%) and *MET* (68 cases, 3.9%). Among cases with known genomic alterations, *ALK* and *ROS1* fusion genes were not detected in 11 of 49 (22.4%) and 17 of 46 (37.0%), while *EGFR* and *BRAF* mutation was not detected in 11 of 218 (5.0%) and 3 of 4 cases (75.0%), respectively. The detection rate of fusion genes was lower than that of mutated genes (70.5% vs 93.7%, $p<0.001$).

Conclusion: In non-small cell lung cancer patients with unknown driver genes, driver oncogenes with corresponding approved therapy were found in a quarter of the patients. CGP tests offer the possibility of increasing the opportunities of receiving new therapies. CGP tests may have a lower detection rate for fusion genes compared with other mutations.

#6458 Clinical significance of cancer genome profiling tests for gastrointestinal cancer patients with liver metastasis.

T. Sakuma, M. Yashiro, Y. Fukui, K. Maruo, G. Tsujio, Y. Yamamoto, H. Kasashima, K. Maeda;
Osaka Metropolitan University, Osaka City, Japan

Introduction: Distant metastasis is one of critical prognostic factors for patients with gastrointestinal cancer. Especially, liver metastasis shows high effects on prognosis of patients with gastrointestinal cancer. In Japan, cancer genome profiling (CGP) testing have been available for patients who have no selective standard treatment options since 2019. Based on the genetic mutations by CGP test, therapeutic drugs with evidence have been discussed at expert panels. CGP data has been accumulated in around 60,000 cases. It is necessary to evaluate the clinical significance of CGP tests for gastrointestinal cancer patients with liver metastasis to receive high benefits of CGP testing through C-CAT. **Aims**: We aimed to analyze the clinical significance CGP tests for gastrointestinal cancer patients with liver metastasis. **Materials and methods**: A total of 3,738 patients of gastrointestinal cancer with liver metastases including 215 cases of esophageal cancer, 347 cases of gastric cancer, and 3,176 cases of colorectal cancer, was enrolled in this study. Three types of CGP tests, including NCC Oncopanel, FoundationOne CDx, and FoundationOne Liquid, were performed, and the CGP data was collected to Center for Cancer Genomics and Advanced Therapeutics in Japan (C-CAT) database. Adequate treatment for each patient was discussed at the expert panel meeting according to the results from the CGP tests. **Results**: A total of 2,882 cases (77.1%) in 3,176 cases have been revealed druggable. However, only 216 cases (13.3%) were medicated by anti-cancer treatments. In the 216 treated cases, disease control case, complete response (CR), partial response (PR), or stable disease (SD) was only 52 cases. In 52 cases, six cases (4 of SD cases and 2 of PR cases) was administered encorafenib-based chemotherapies based on *BRAF* gene mutation. Five genes, *ZNF217, SRC, ARFRP1, BARD1, FGF10*, were significantly more frequently expressed on liver metastasis cases, in compared to other metastasis cases in gastrointestinal cancer. **Conclusion**: Around 13% of gastrointestinal cancer patients with liver metastasis might have a druggable benefit by CGP testing. *BRAF* mutation might be promising target for patients with liver metastasis. *ZNF217, SRC, ARFRP1, BARD1, FGF10* might be associated with metastatic process to liver in gastrointestinal cancer.

#6459 Molecular profiling of advanced non-small cell lung cancer in response to first-line immune checkpoint inhibitors and/or chemotherapy using multimodal real-world data.

X. Fu, J. Kardos, P. Correa, M. Wang, L. Li, J. Egen, S. Iqbal;
Gilead Sciences, Foster City, CA

Background: Up to 85% of lung cancer patients have non-small cell lung cancer (NSCLC). Standard of care for NSCLC includes immune checkpoint inhibitors (ICI) and/or platinum-based chemotherapy (CT). However, therapy success is limited with up to 70% of patients not responding to ICI. Mechanisms of resistance across treatments are not fully understood. In this study, we explore real-world data to characterize molecular and genomic changes in advanced NSCLC treated with ICI, ICI+CT, or CT.

Methods: Stage III/IV NSCLC patients receiving first-line (1L) ICI, ICI+CT, or CT were identified from Tempus Labs, Inc.'s de-identified, multimodal real-world database. Patients' solid tissue biopsies taken pre- or post-1L underwent next generation sequencing with the Tempus xT assays (DNAseq of 648 genes at 500x coverage and whole transcriptome RNAseq). Patients' clinical and outcome data were abstracted from electronic health records. We analyzed changes in gene expression, pathway enrichment, estimated immune cell components, and somatic mutations in responders (complete/partial response) and non-responders (progression/stable disease) upon 1L treatment.

Results: 1L non-responders (70%, 51%, and 47%) were identified across cohorts (143 ICI, 764 ICI+CT, and 228 CT, respectively). 58% of pre-1L biopsies were taken from distal metastatic tissues. Distinct pathways altered post-1L include the downregulated E2F target pathway in CT cohort, and upregulated TNFα/NFκB signaling and the hypoxia and protein secretion pathways in ICI cohort. Significant (FDR < 0.05) augmented expression was observed for 90, 23, and 65 genes in non-responders vs. responders post ICI, ICI+CT, and CT, respectively. RNAseq deconvolution reveals decreased plasma and CD4+ activated T cell fraction in metastatic biopsies, whereas increased CD4+ activated T cell and monocyte fraction was seen after treatment only in ICI cohort. Genes with oncogenic driver mutations reported in NSCLC were detected including TP53 (68%), KRAS (30%), STK11 (13%), EGFR (11%), CDKN2A (10%), KEAP1 (9%), and NF1 (7%). Of the 250 mutated genes, 72 (29%) were commonly not detected post-1L, whereas 38, 3, and 8 unique genes with loss of detectable mutations were identified post-1L of ICI, ICI+CT, and CT, respectively. Since loss of detectable mutations is a sign of loss of subpopulations of cancer cells hosting such mutations that succumb to therapy, these genetic mutations could be used to select patients who can benefit from such therapy.

Conclusions: Distinct molecular characteristics including tumor immune components and genomic alterations are associated with 1L response in advanced NSCLC. Real-world data analyses provide opportunity to explore distinct mechanisms of therapy resistance and identify potential biomarkers of therapy response for further validation in clinical studies.

#6460 Incidence of pathogenic germline variants and presumed germline pathogenic variants in Japanese lung cancer patients using comprehensive genomic profiling tests.

M. Ueki, K. Watanabe, M. Morishita, K. Fujii, H. Ikushima, H. Isago, K. Oda, H. Kage;
The University of Tokyo Hospital, Tokyo, Japan

Introduction: Pathogenic germline variants (PGVs) and presumed germline pathogenic variants (PGPVs) are often detected with comprehensive genomic profiling (CGP) tests. Using the Center for Advanced Cancer Genomics and Therapeutics (C-CAT) database, we investigated the incidence of PGV and PGPV detected by CGP tests in Japanese lung cancer patients.
Methods: Among 3,240 lung cancer cases registered in C-CAT between June 2019 and August 2023, 321 were tumor/normal paired NCC Oncopanel (NOP), 773 were FoundationOne Liquid CDx (F1L), and 2,145 were tumor-only FoundationOne CDx (F1CDx). We analyzed cancer susceptibility genes in accordance with the national guideline. In F1L and F1CDx, PGPV was determined based on variant allele frequency (VAF) and medical history. Differences between groups in the detection of PGV and PGPV were tested using chi-squared test, and differences in age were tested using t-test.
Results: The incidence of PGV in NOP and PGPV in F1L and F1CDx were 4/321 (1.2%), 36/773 (4.7%), and 141/2145 (6.6%), respectively (NOP vs F1L vs F1CDx; p = 0.001 NOP vs F1L; p = 0.006, NOP vs F1CDx; p < 0.001, F1L vs F1CDx;p=0.190). The 4 PGVs detected by NOP were in the *ATM*, *BRCA2*, *MSH6*, and *TP53* genes. Notably, two out of four patients were in their 30s while the other two were in their 70s. In the F1L dataset, 36 patients (4.7%) had PGPV: 8 patients (1.0%) had *PALB2*, 6 patients (0.8%) had *BRCA2*, and 4 patients (0.5%) had *CHEK2* variants. In the F1CDx dataset, 141 had PGPV: 19 patients (0.9%) each had *BRCA1* or *BRCA2* variants and 18 patients (0.8%) had *PALB2* variant. There was no significant age difference between PGPV(-) and PGPV(+) patients (F1L:63.3 vs. 62.4 years; p = 0.938, F1CDx: 65.5 vs 65.0 years; p = 0.749). Most cases with PGV or PGPV were non-small cell lung cancer: 4/4 in NOP, 34/36 in F1L, and 110/141 in F1CDx.
Discussion: The incidence of PGV in lung cancer patients was at least 1% and found in both younger and older patients. A circulating tumor DNA panel and a tumor-only tissue panel detected PGPVs at a significantly higher rate than detection of true PGVs by tumor/normal paired tissue panel, suggesting the use of tumor/normal paired panels may mitigate the burden of both patients and clinicians with concerns from false positive PGPV. The majority of detected PGV/PGPV were in homologous recombination repair genes.

#6461 Prevalence and implications of potentially pathogenic germline variants among adult patients in the Philippines with solid malignancies who underwent tumor genomic profiling: A multi-institutional, cross-sectional study.

Paula Isabel Gimena Franco, Frances Victoria Que, Jose Jasper Andal, Daphne Ang

St. Luke's Medical Center, Quezon City, Philippines

Background: In high income countries, 2-10% of tumor genomic profiling reports reveal incidental pathogenic germline variants. A third of these patients would not qualify for genetic testing based on current guidelines. In South East Asia, despite increased use of outsourced genomic profiling platforms, there are no published studies exploring the prevalence of these potentially pathogenic germline variants (PPGV). Our study determined the prevalence of PPGVs among adult patients with solid malignancies who underwent liquid or tissue-based tumor genomic profiling in the Philippines.
Methods: Annotated reports of patients with solid cancers who underwent tumor genomic profiling using *FoundationOne* or *FoundationOne Heme*between January 2021 to July 2023 were reviewed (Ethical Board ID: SL-23143). PPGVs were identified according to recommendations from American Board of Medical Genetics and Genomics and expert review. PPGV criteria include having a variant allele frequency of >30% and were categorized as: 1) high penetrance gene (HP), founder variant (FV), or variant associated with clinical presentation (VA). Cross-checking the pathogenicity through *ClinVar* database was also done.
Results: Out of 446 patients, 13 PPGV variants were found in 50 (11.2%) patients at a median age of 60.5 years. Of these, 28 (54%) had high penetrance (*BRCA1, BRCA2, MSH2, MSH6, MLH1, RAD51C, RAD51D*), 24 (46%) patients had VA (*APC, SMAD4, CDH1, CDKN2A,PTEN*) and two patients with lung cancer had a founder variant (*EGFR p.Thr790Met*). PPGVs were primarily found in colorectal (42% of 50 patients with PPGVs), breast (16%), ovarian (6%) and lung (6%) cancer patients ($p<0.001$). HP genes were mostly found in females (71.4%, $p = 0.03$), driven by *BRCA1/2* variants (15 females and 2 males).
Conclusions: The presence of PPGVs warrants formal genetic counselling and germline testing. Given the similar prevalence of PPGVs in this study compared with data from other countries, and the diagnostic and therapeutic implications of detecting incidental PPGVs, we underscore the need for cancer genetics to be incorporated into standard oncologic care in the Philippines.

#6462 Somatic mutational profile in MUTYH- associated colorectal cancers (MUTYH-CRCs).

D. Kaldas[1], T. Biachi de Castria[2];

[1]University of South Florida, Tampa, FL, [2]Moffitt Cancer Center, Tampa, FL

Background: Biallelic inactivation of MUTYH leads to hereditary predisposition to colorectal polyposis and CRC. Herein we evaluated co-alterations in somatic next-generation sequencing (NGS) in patients with MUTYH-CRC, mainly KRAS G12C, high tumor mutational burden and microsatellite instability (MSI-H)/mismatch repair deficiency (dMMR).

Methods: Data was collected on patients with MUTYH-CRC in the period between 2015 and 2023 at Moffitt Cancer Center (Tampa, Florida, United States). All patients with MUTYH-CRC were included regardless disease stage. Different germline panels were used to detect MUTYH and Foundation One, Caris and Moffitt STAR (in house NGS) were used to detect somatic co-alterations.

Results: A total of 36 patients were identified with MUTYH- CRC, the median age at diagnosis was 44-year-old, 55% were men. All patients had a somatic NGS available, 18 patients (50%) had KRAS mutation, and specifically KRAS G12C was detected in 9 patients (24%), 6 patients (17%) had MSI-H/dMMR, 5 patients (14%) had BRAF mutation and 4 patients (11%) with BRCA2 mutation.

Conclusion: MUTYH-CRC is associated with a high incidence of targetable alterations including KRAS G12C and BRAF. Considering unique characteristics in MUTYH-CRC tumor microenvironment, including T cell infiltrate, trials combining KRAS G12C/ BRAF inhibitors and immune checkpoint inhibitors are warranted.

#6463 Highly frequent gene mutations and co-occurring genes analysis in colorectal cancer.

Q. Zha, F. Scarpa, M. Rengaraj, A. Juncker-Jensen;
NeoGenomics, Aliso Viejo, CA

Background: Colorectal cancer (CRC) is the second most leading cause of cancer-related deaths worldwide. Understanding the molecular alterations that drive CRC is critical for improving patient outcomes. Next-generation sequencing (NGS) has revolutionized CRC molecular profiling by simultaneous analysis of multiple genes with high accuracy and sensitivity. In this study, we analyzed a cohort of CRC formalin-fixed paraffin-embedded (FFPE) samples to identify highly frequent gene mutations and co-occurring genes in CRC.

Methods: FFPE samples from CRC patients tested from January 2020 to May 2023 were analyzed using NeoTYPE® Colorectal Tumor Profile. This profile analyzes 44 biomarkers through a combination of NGS focusing on a panel of 36 genes known to be frequently mutated in CRC, as well as 3 FISH and 3 IHC biomarkers. Gene mutation frequency, co-occurring mutation genes and clinical significance were explored and analyzed. In addition, immunotherapy markers, Microsatellite Instability (MSI) and Tumor Mutation Burden (TMB) were assessed.

Results: A total of 2,920 patients (1,577 men and 1,343 women) with CRC were included in this study. Average sequence coverage was 2386X with mean minor allelic frequency of 30%. A higher average number of variant allele frequency were observed in metastatic versus primary colorectal cancer ($P < .001$). We found that APC, TP53, KRAS, PIK3CA and ARID1A were the most frequently mutated genes. APC truncated mutation p. R1450* were the most common mutations. KRAS, PIK3CA and TP53 missense mutations are the prevalent consequence. Notably, a subset of patients exhibited high microsatellite instability (MSI-H) or TMB high, indicating potential eligibility for immune checkpoint inhibitor therapy. In addition, we found APC mutations co-occurring with TP53 or KRAS mutations ($p <.001$) in our cohort.

Conclusion: Our results provide insight into the genetic landscape of CRC and highlight the importance of understanding co-occurring mutations in this disease. Specifically, APC mutations frequently coincide with TP53 mutations, jointly contributing to the onset of CRC. TP53 often play a role in promoting genomic instability and evading mechanisms that regulate cell growth. The identification of highly frequent mutations and co-occurring genes may have important implications for the development of targeted therapies and personalized treatment approaches for CRC patients.

#6464 Real-world evidence (RWE) presented at AACR annual meetings: A 10-year trend analysis.

J. Zong[1], L. C. Bylsma[2], O. Lunacsek[1], X. Jiang[2], J. Fryzek[2];
[1]Bayer HealthCare Pharmaceuticals Inc., Whippany, NJ, [2]EpidStrategies, A Division of ToxStrategies, LLC, Rockville, MD

Introduction: RWE is increasingly used in the oncology community, particularly following the 2016 21st Century Cures Act. A recent analysis of RWE presented at ASCO reported a significant increase in relative frequency of RWE abstracts from 2011-2021[1]. We conducted a similar trend analysis of RWE presented at AACR and predictive factors associated with publication.
Methods: EMBASE was queried for abstracts presented at AACR 2013-2022, using terms related to study designs and methodologies that employ use of RWE. Details on study design, location, data source, patient number, cancer site, analytical approach, endpoints, and presentation type (oral vs. poster) were extracted and analyzed. Searches in Google Scholar identified published manuscripts associated with each abstract. The Cochran-Armitage trend test and Monte-Carlo estimation of the exact test were used to detect trends over time; p-values are provided for descriptive purposes. Relative risk ratios were calculated to determine statistically significant predictors of publication.
Results: Of 56,920 total abstracts presented at AACR from 2013-2022, 611 (1.1%) RWE abstracts were identified. The proportion of presented abstracts with RWE increased from 0.6% in 2013 to 2.0% in 2022 ($p<0.001$). Among the RWE abstracts, use of electronic medical record (2013: 0% vs. 2022: 9.3%; $p=0.002$) and genomics databases (i.e., GENIE) (2013: 0% vs. 2022: 8.3%; $p=0.006$) increased over time. While majority of RWE abstracts were presented as posters (95.9%), the proportion of oral presentations increased in the last decade (2013: 0.0% vs. 2022: 3.7%; $p=0.005$). Abstracts with sample sizes <500 decreased significantly over time ($p=0.002$); those with sample sizes 5,000-<50,000 increased significantly over time ($p=0.001$). The proportion of abstracts including multiple cancer sites (vs. single-site) increased from 5.1% in 2013 to 20.4% in 2022 ($p<0.001$). The most common cancer sites were lung, breast, and colorectal. Statistically significant factors associated with publishing an abstract into a manuscript included study sample size 500-<5,000 or ≥100,000, inferential statistics (vs. descriptive), propensity score matching, and effectiveness or disease burden endpoints.Conclusion: RWE studies presented at AACR increased in the recent decade, with more robust study designs, incorporation of novel clinico-genomic databases such as GENIE, and advanced analytical approaches. These findings suggest the value of RWE has been increasingly recognized by the oncology research community and that RWE is being used to provide critical insights and inform patient care. Given FDA's recent guidance on RWE to support regulatory decision-making, this trend will likely continue.
[1] Azad Fet al. Longitudinal trends of real-world evidence (RWE) reporting in oncology conferences: An 11-year ASCO Annual Meeting analysis.

#6465 A population-based analysis of brain metastasis burden and management in 8705 small cell lung cancer patients.

K. Gaebe[1], A. W. Erickson[1], S. Chen[2], A. Sahgal[3], B. H. Lok[4], K. K. W. Chan[3], S. Das[5];
[1]University of Toronto, Toronto, ON, Canada, [2]Queens University, Kingston, ON, Canada, [3]Sunnybrook Health Sciences Centre, Toronto, ON, Canada, [4]Princess Margaret Cancer Centre, Toronto, ON, Canada, [5]St. Michael's Hospital, Toronto, ON, Canada

Introduction: Patients with small cell lung cancer (SCLC) have historically been characterized by poor overall survival (OS) and high risk for brain metastases (BM), but large-scale real-world evidence on clinical presentation and treatment in this population is lacking.
Methods: The aim of this study was to describe the clinical characteristics and outcomes of patients with SCLC and BM in Ontario, Canada. This retrospective cohort study included all patients in Ontario, Canada, who were diagnosed with SCLC between April 2010 and March 2018. Data were analyzed between June 2022 and July 2023. Kaplan-Meier and multivariable Cox regression analyses were performed to compare overall survival (OS) between patient cohorts stratified by disease stage, BM diagnosis, or first-line intracranial treatment modality.
Results: 8705 patients were included. Median age at diagnosis was 68 years (range 18-103). Median OS of all patients was 7.46 months (95% confidence interval, CI, 7.23-7.69). 32% (n=2686) of patients developed BM (synchronous, 43.7%; asynchronous, 56.3%) and had median OS of 9.76 months (95% CI, 9.36-10.22). 102, 1654, and 880 patients received stereotactic radiosurgery (SRS), whole brain radiation therapy (WBRT), and no treatment, respectively, for their BM in the first-line setting or after prophylactic cranial irradiation (PCI). In propensity score-matched analyses, OS was equivocal between SRS- and WBRT-treated cohorts among patients who did not receive PCI (hazard ratio, HR, 1.18, 95% CI, 0.75-1.81) and those who received PCI prior to BM development (HR, 0.77, 95% CI, 0.53-1.13).
Conclusions: Survival for patients with SCLC remains poor, and many patients present with BMs. With careful selection, patients with SCLC may benefit from SRS treatment.

#6466 Multi-omics analysis of molecular characteristics and transformation mechanisms of stage I-III micropapillary lung adenocarcinoma.

K. Shao[1], S. Gao[1], F. Tan[1], A. Shao[2], X. Feng[1], Q. Xue[1], Y. Qu[1], B. Zheng[1], W. Zheng[1], H. Chen[3], Q. Ou[3], **H. Tang**[3];

[1]National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China, [2]Columbia University Irving Medical Center, Vagelos College of Physicians and Surgeons, New York, NY, [3]Nanjing Geneseeq Technology Inc., Nanjing, China

Background: The micropapillary pattern (MIP) is recognized as a high-grade histological subtype in lung adenocarcinoma (LUAD), with its presence often indicative of a poorer prognosis. Despite distinctive molecular characteristics of MIP, there is a research gap regarding the molecular mechanisms underlying micropapillary transformation and prognosis factors for micropapillary LUAD.

Methods: Surgically resected tumor samples from 101 patients with stage I-III LUAD and MIP components exceeding 30% were collected. The tumor samples were microdissected to separate MIP components from non-MIP components, and both fractions underwent RNA and DNA whole-exome sequencing (WES). The molecular profiles between MIP and non-MIP components, along with MIP-naïve LUAD tissues from an external cohort, were compared. Associations between molecular characteristics and recurrence-free survival were also assessed.

Results: The genomic landscapes of MIP and non-MIP components within tumor tissues featuring MIP patterns exhibited remarkable similarity. At the transcriptomic level, MIP components displayed elevated PRB4 expression (FDR < 0.001), an up-regulated cell cycle pathway (P = 0.004), and reduced natural killer cell-mediated cytotoxicity (P = 0.066). Nevertheless, in comparison to MIP-naïve LUAD tissues, the MIP components showed higher chromosomal instability (P < 0.001) and revealed eighteen enriched somatic alterations, encompassing EGFR mutations, EGFR amplifications, and CDKN2A/CDKN2B deletions, all linked to up-regulations in cell proliferation pathways and down-regulated immune pathways. In the context of MIP transformation, shared mutations were observed in 97.8% (91/93) of patients between MIP and non-MIP components within the same tissues, suggesting a common origin. The subclonal fractions were comparable between paired MIP and non-MIP components, while a significant co-occurrence of EGFR amplification, CDKN2A deletion, and CDKN2B deletion was identified in MIP components. A comprehensive analysis combining differential gene expression and Cox analysis, employing a both-direction stepwise Akaike Information Criteria selection, identified the high expressions of five genes (*GALNT4, MIAT, FOSL1, LAT2, SMN2*) as adverse factors associated with the recurrence of micropapillary LUAD.

Conclusions: We conducted an in-depth analysis of the molecular characteristics and transformation mechanisms of micropapillary lung adenocarcinoma, employing microdissection techniques to investigate at both genomic and transcriptomic levels within a substantial cohort, providing insights for the precision medicine of this aggressive cancer subtype.

#6467 Causal personalized treatment estimation framework using real-world electronic health record (EHR) data to inform cancer care decisions.

Sumana Srivatsa[1], David Walsh[1], Mayada Aljehani[2], Jason Weinreb[1], Nathan Becker[1], Benjamin H. Ellis[1], Renee George[1], Xingyao Chen[2], Naim Matasci[2], Reva Basho[2], **Mitchell E. Gross**[3], Christine L. Swisher[4]

[1]The Ronin Project Inc, San Mateo, CA, [2]Ellison Institute of Technology, Los Angeles, CA, [3]Ellison Institute of Technology & University of Southern California, Los Angeles, CA, [4]The Ronin Project Inc & Ellison Institute of Technology, San Mateo & Los Angeles, CA

Background: The average treatment effects (ATEs) from randomized controlled trials often do not generalize across populations, or they are not sufficiently personalized to capture the benefits and risks to individual patients. Real-world data aids in validating and extending trial results, but can introduce biases that invalidate the causal interpretation. Here, we propose a robust statistical framework, which uses real-world EHR data to evaluate the efficacy of cancer treatments at both population and individual levels. We demonstrate the ability of our framework to deliver personalized insights in metastatic prostate cancer treatments.

Methods: We assembled a retrospective cohort of metastatic prostate cancer patients from a large academic medical center. We gathered demographic, comorbidity, cancer treatment, and outcome data from the EHR or natural language processing of clinician narratives, and social determinants of health from Census data. We used doubly robust machine learning with bootstrap standard errors to compute the ATE and personalized treatment estimates (PTEs), comparing the impact of ADT (androgen depravation therapy) + chemotherapy (ACT) and ADT + combination anti-androgen therapy (ACAT) on percentage reduction in PSA levels in metastatic prostate cancer.

Results: The baseline characteristics of our cohort are summarized in Table 1a. Our approach found that ACAT reduces PSA levels significantly more than ACT, and captured the heterogeneity in treatment effects across individuals (Table 1b). Through simulation studies, we demonstrated that any reasonable bias from unobserved confounding or missing information was small compared to the estimated treatment effects and their standard errors.

Conclusion: We presented a doubly robust framework and demonstrated its utility in analyzing real-world data, enabling us to uncover the diversity in treatment responses among individuals with metastatic prostate cancer.

Results summary

a. Baseline demographic characteristics.		
	ADT + chemotherapy N = 302	**ADT + combination therapy N = 114**
Treatments	Any ADT + Docetaxel or Cabazitaxel	Any ADT + Abiraterone or apalutamide or Enzalutamide
Age		
Mean (SD)	69.3 (8.76)	66.7 (8.17)
Median [Min, Max]	69.0 [47.0, 94.0]	66.5 [46.0, 86.0]
Race		
Asian	8 (2.6%)	2 (1.8%)
Black or African American	48 (15.9%)	7 (6.1%)
White or Caucasian	224 (74.2%)	99 (86.8%)
Other	22 (7.3%)	6 (5.3%)
Max PSA treatment start (ng/mL)		
Mean (SD)	34.9 (98.5)	83.3 (448)
b. Treatment effects estimation		
ATE (95% CI)	32.0% [24.6%, 40.8%]	
PTEs: 25th and 75th percentiles	29.0%, 34.3%	

#6468 Nodular lymphocyte predominant hodgkin lymphoma: A national cancer database analysis with focus on hispanics.

E. Toro Velez[1], D. Rosas[2], C. Velez-Mejia[1], Q. Liu[1], J. Michalek[1], A. Diaz Duque[3];
[1]UT Health Science Center at San Antonio, San Antonio, TX, [2]Memorial Healthcare System, Pembroke Pines, FL, [3]Mays Cancer Center, San Antonio, TX

Background: Nodular lymphocyte-predominant Hodgkin lymphoma (NLPHL) is a rare and distinct subtype of Hodgkin Lymphoma.(PMID 26149294) 80% manifest at early stages, with a male and black race predilection.(PMID 26149195) Previous analysis have shown similar survival of Hispanics (HI) compared to Non-Hispanics (NH).(J Clin Oncol 10.1200/JCO.2023.41.16_suppl.e19512) This National Cancer Database (NCDB) analysis aims to clarify how sociodemographic factors affect presentation and survival in HI vs NH patients with NLPHL. **Methods:**Data were analyzed on NLPHL patients in the United States reported to the NCDB 2004-2019. Demographic and treatment characteristics were compared between ethnic groups. Kaplan-Meier and Cox regression analyses were used to compare overall survival (OS) between HI and NH populations. Multivariate analysis and propensity score matching was performed. **Results:**Of 5517 of NLPHL patients, 379 were HI, and 4904 NH. Male gender and white race predominated for both. HI were diagnosed at a younger median age of 44 years (y) vs 48 y for NH, p=0.001. Most patients were diagnosed between years 2016-2019. Stage I predominated for both, p<0.001. As to Charlson-Deyo score ≥2, both HI and NH had 4%. Private insurance as primary payer was the most prevalent type for HI (53%) and NH (65%). HI had a higher percentage of unknown/uninsured, 12% vs 6% for NH, p<0.001. In relation to census median income (2008-2012), the most prevalent bracket for HI (27%) was $48,000-$62,000, and for NH (35%) was >$63,000. Regarding median income of <$38,000, HI were 29% vs 16% for NH, p<0.001. For median distance in miles (mi) between the patient's residence and the hospital that reported the case (great circle distance), HI lived at a median of 6.3mi, vs NH at median of 9.5mi. Majority of HI (56%) were treated at Academic/Research programs; while most of NH (39%) were treated at Comprehensive Community Cancer programs, p<0.001. On survival analysis, the survival probability at 2, 5 and 10 y for HI was 96%, 92%, 86%, vs for NH was 96%, 92%, 84%, respectively. The median survival time wasn't reached for both HI and NH, and no statically significant difference was seen, p=0.57. On multivariate analysis, HI was not associated with worse OS (HR 0.76, CI 0.44-1.31, p=0,33). The propensity matched analysis confirmed not reached OS on both cohorts. **Conclusion:**NLPHL is a disease that affects young males, at early stages, for both HI and NH. Unlike previous studies, in this analysis white race predominates; which could be explained by the increase in reported cases over years. Despite HI having more uninsured population with lower median income quartiles, this wasn't a barrier to access care at academic/research programs. Although no difference in OS was seen among ethnicities, there is a tendency that might favor HI. More studies are needed to determine if specific demographic factors truly influence survival in NLPHL.

#6469 The association of mismatch repair gene alterations with elevated tumor mutational burden in microsatellite stable gastrointestinal cancers.

C. D. O'Donnell, M. Zhu, H. Xie;
Mayo Clinic, Rochester, MN

Background: Benefit from single-agent immune checkpoint inhibitor has been observed in 5-10% of the patients with microsatellite stable (MSS) gastrointestinal (GI) cancers. However, a reliable predictive marker to immune checkpoint inhibitor has not been discovered in this patient population. We sought to assess the incidence of mismatch repair (MMR) gene alterations and their association with tumor mutational burden (TMB) in MSS GI cancers.
Methods: This is a retrospective cohort study of patients with advanced GI cancer who had molecular profiling of the tumor using either Guardant360 blood-based or Tempus tissue next generation sequencing (NGS) platforms between 2020 and 2023. We assessed four MMR genes including *MLH1*, *MSH2*, *MSH6* and *PMS2* for alterations. Continuous variables were summarized as median and interquartile range (IQR) and compared using Mann-Whitney test. Categorical variables were summarized as counts and proportions and compared using Fisher's exact test.
Results: A total of 2920 patients with Guardant360 were included with a median age of 65 (IQR: 56-73) years. 870 (30%) patients had pancreas cancer; 846 (29%) patients had colorectal cancer; 688 (24%) patients had biliary tract cancers; and the rest had other GI cancers. Among patients evaluable for microsatellite instability (MSI) status, 58 patients (2%) had MSI-high GI cancers, 31 (53%) of whom had MMR gene alterations. 2445 (98%) patients had MSS GI cancers, 130 (5.3%) of whom had MMR gene alterations. Patients with MSS GI cancers bearing MMR gene alterations had a median age of 70 (IQR: 62-75) years, significantly older than those without MMR gene alterations ($p<0.001$). In addition, patients with MMR gene alterations had significantly higher median blood TMB of 11 (IQR: 7.4-16) mut/Mb compared to 7.7 (IQR: 4.8-11) mut/Mb in patients without MMR gene alterations. In MSS GI cancers, MMR gene alterations are more commonly associated with the presence of alterations in *APC* ($p=0.03$), *TP53* ($p=0.01$), *CTNNB1* ($p<0.001$) and *SMAD4* ($p=0.01$). 1453 patients with GI cancer and Tempus tissue NGS data were included as a validation cohort. They had comparable demographics with the Guardant360 cohort. 14 (1.6%) of 896 patients with MSS GI cancers had MMR gene alterations, significantly fewer ($p<0.001$) than those found in the Guardant360 cohort. Patients with MMR gene alterations and wild type POLE had significantly higher ($p=0.001$) median TMB of 9.8 (IQR: 4.8-14) mut/Mb compared to 4.7 (IQR: 3.2-6.3) mut/Mb in patients without MMR gene alterations.
Conclusions: MMR gene alterations can be identified by clinical NGS platforms in a small proportion of patients with MSS GI cancers. They are associated with elevated TMB, which may suggest a hypermutated profile serving as a basis for potential role of immune checkpoint inhibitor in MSS GI cancers.

#6470 Real-world analysis of insurance status and survival in patients with selected GI cancers.

R. AbuAyed[1], J. Schwanke[1], B. Patterson[1], M. White[1], S. Marmor[1], E. Jensen[1], C. Tignanelli[1], E. Lou[2], A. Prakash[2];
[1]University of Minnesota Medical School, Minneapolis, MN, [2]University of Minnesota, Minneapolis, MN

Background: Health insurance is a critical determinant of healthcare access and outcomes in gastrointestinal (GI) cancers. Epidemiological data have shown that insurance-associated healthcare outcomes vary by diagnosis, geographic location, and demographics. Thus, it is critical for cancer providers to understand local impacts of insurance status on patient outcomes. Here, we present real-world outcomes for pancreatic, hepatobiliary, and colorectal cancer (CRC) patients in 11 Midwest hospitals based on insurance status.
Methods: We identified patients diagnosed with colorectal, pancreatic, and hepatobiliary cancers within 11 Midwest hospitals from 2011-2021 with North American Association of Central Cancer Registries data. Health insurance was defined as private, Medicaid, Medicare, and uninsured. Effect of insurance status at diagnosis on overall survival (OS) in selected cancers combined and by cancer type were calculated using a Cox proportional hazard (CoxPH) model controlling for age, sex, race, stage, time to treatment initiation (TTI), and Charlson Comorbidity Index (CCI). We evaluated differences in TTI by insurance status using t-tests. We analyzed stage and treatment modality by insurance status using chi-square tests. Post-hoc analysis of TTI by OS used CoxPH.
Results: Relative to private insurance, Medicaid and Medicare insurance status significantly reduced OS for all selected GI cancers combined (HR 1.38, 95% CI 1.17 - 1.62 and HR 1.25, 95% CI 1.11 - 1.40, respectively; $p<0.001$) and for CRC (HR 1.49, 95% CI 1.12 - 1.98 and HR 1.28, 95% CI 1.06 - 1.54, respectively; $p<0.01$). Uninsured patients had significantly reduced OS only for pancreas cancer (HR 6.36, 95% CI 2.56 - 15.8; $p<0.001$). No significant associations between insurance status and OS were noted in Hepatobiliary cancer. TTI was significantly associated with insurance status ($p<0.001$) and mean TTI for Medicaid (35.8 days) and Medicare (27.9 days) patients was longer than mean TTI for privately insured patients (23.3 days; $p<0.01$). TTI for uninsured patients was not significantly different than for privately insured. Analysis of TTI and OS showed no increased hazard for patients with TTI of 36 days versus 23 days (HR 0.87, 95% CI 0.75 - 1.02; $p=0.085$). Treatment modality and stage did not differ as a function of insurance status in this dataset.
Discussion: Our results expand previous work by demonstrating a survival impact for GI cancer patients with Medicaid or Medicare insurance. This disparity persists despite controlling for known prognostic factors such as age, stage, CCI, and TTI. Notably, TTI varied by insurance suggesting it may account for a portion of this disparity but did not independently drive survival. Further work is required to identify and develop targeted interventions to address other drivers of reduced survival in those without private insurance.

#6471 Trends in chemotherapy utilization in acute myeloid leukemia (AML) in last 15 years.

P. Dhakal[1], B. Loeffler[1], A. Ravindra[1], A. Pyakuryal[2], V. R. Bhatt[3];

[1]University of Iowa, Iowa City, IA, [2]Pokhara University, Pokhara, Nepal, [3]University of Nebraska Medical Center, Omaha, NE

Introduction: Chemotherapy (Chemo) can relieve symptoms and improve quality of life and survival in AML, including in many older and frail adults. However, in a prior study from the US, almost a quarter of patients (pts) with new diagnoses of AML between years (yrs) 2003 and 2011 did not receive chemo (Bhatt et al., Blood Advances, 2018). Our study examined trends in chemo utilization in the last 15 yrs to test the hypothesis that chemo use has increased in more recent yrs. We also examined any disparities in chemo use.

Methods: We utilized the National Cancer Database to identify 78,864 pts diagnosed with AML between 2004 and 2019 and divided them into 2 cohorts based on date of diagnosis, 2004-2010 and 2011-2019. We used logistic regression to estimate effect of demographic and disease characteristics on odds of receiving chemo and evaluate differences in these effects between the constructed patient cohorts.

Results: Seventy-seven percent of total pts received chemo. Compared to 73% in 2004, 81% of pts received chemo in 2019. The receipt of chemo declined with increasing age with higher use of chemo in all groups in 2011-2019 compared to 2004-2010: >80 (yrs)= 40 vs 33%, 71-80 yrs= 72 vs 63%, 60-70 yrs= 87 vs 84%, 41-59 yrs= 93 vs 92%, and 18-40 yrs = 95 vs 94%.The receipt of chemo was lowest in white pts overall; in black pts, receipt of chemo increased in 2011-2019

compared to 2004-2010: black= 83 vs 76%, white= 78 vs 75%, and others 83 vs 83%. The receipt of chemo was lowest in therapy-related (t)-AML in 2011-2019 and 2004-2010: t-AML 64 vs 60%, acute promyelocytic leukemia= 88 vs 87%, core binding factor AML 93 vs 88% and other 77 vs 74%. In multivariable analysis, the odds of receiving chemo increased in 2011-2019 compared to 2004-2010 in all pts, particularly in older adults. Compared to white, black pts had similar odds of receiving chemo in 2004-2010, but odds were higher in 2011-2019 (Odds ratio, 1.2, 95% confidence interval, 1.1-1.3. Pts with t-AML were less likely to receive chemo compared to all other subtypes in 2004-2010 and 2011-2019. Female sex, lower income, public insurance, higher comorbidity score, and shorter distance to treatment facility were associated with a lower likelihood of receiving chemo; however, chemo utilization did not differ over the two time periods based on these variables.

Conclusion: To our knowledge, this is the largest scale analysis of chemo utilization in AML in real-world practice. Chemo receipt increased significantly over the yrs, particularly among older adults, black pts, core binding factor, and t-AML. These recent trends are encouraging and represent novel findings. Despite these results, healthcare disparity based on sex, socioeconomic, and healthcare system factors continues to persist. In addition to developing safer and more effective chemo regimens, other innovative strategies to tackle these disparities are crucial to improve outcomes.

#6472 Response to PARP inhibitors in patients with breast cancer metastatic to the central nervous system.

S. Lee[1], R. Bansal[2], M. E. Hughes[3], A. E. D. Van Swearingen[2], H. N. Moore[2], D. O. Kamson[1], S. Sahebjam[1], G. Kirkner[3], A. Gorfinkel[3], S. Sammons[3], N. U. Lin[3], C. Anders[2], C. A. Santa-Maria[1];

[1]Johns Hopkins University, Baltimore, MD, [2]Duke Cancer Institute, Durham, NC, [3]Dana-Farber Cancer Institute, Boston, MA

Background: Central nervous system (CNS) metastasis from breast cancer can be challenging to treat due to the limited blood brain barrier penetration of many systemic therapies. PARP inhibitors (PARPi) block single-strand DNA break repairs and have activity in cancers with homologous recombination repair deficiency; they are FDA approved for patients with metastatic HER2 negative breast cancer with germline BRCA1/2 mutations. While preclinical studies suggest that PARPi have CNS penetration, clinical data is limited. The goal of our study is to describe the clinical benefit of PARPi in patients with breast cancer CNS metastasis.

Methods: This retrospective case series was conducted at three academic cancer centers (Johns Hopkins, Dana-Farber, and Duke) and included patients with the following criteria: (1) age≥18 years with a breast cancer diagnosis (any subtype); (2) diagnosis of parenchymal brain metastasis or leptomeningeal disease (LMD); and (3) received PARPi (olaparib, talazoparib) for CNS metastasis. Clinical and pathologic information were analyzed with descriptive statistics (median, range) and Kruskal-Wallis rank sum tests. Survival analysis was performed using Kaplan-Meier curves with log-rank p-values.

Results: Although this analysis includes one center's experience, we will present a combined dataset (N = 45) at the main conference. 11 patients were identified at Johns Hopkins. 4 (36.4%) were Black and 6 (54.5%) were White; 6 (54.5%) had ER+HER2- disease and 5 (45.5%) had TNBC at time of brain metastasis; 5 (45.5%) had BRCA1 mutations, 5 (45.5%) had a BRCA2 mutations, and 1 patient (9%) had a BARD1 mutation; 7 (63.6%) had brain metastasis and 4 (36.4%) had LMD. Median lines of therapy prior to PARPi was 6 [1 - 11]; 8 patients (72.7%) had previous CNS radiation (5 SRS and 3 WBRT) and 3 (27.3%) had previous CNS surgery. On average, patients remained on PARPi for 5 months [0.5 - 66], and overall survival (OS) time from PARPi to death was 16 months [2 - 66]. Time on PARPi was 5 months [2 - 66] for patients with brain metastasis and 3 months [0.5 - 10] for those with LMD (p=0.22). Duration of PARPi and OS did not differ significantly between ER+HER2- and TNBC (p=0.74 and 0.69, respectively), BRCA 1 and 2 (p=0.78 and 0.72, respectively), or brain and LMD metastasis (p=0.22 and 0.91, respectively). Black patients had significantly shorter PARPi duration and survival than White patients (PARPi 2 vs. 8 months, p=0.028 and OS 4 vs 18 months, p=0.028). Prior CNS radiation was significantly associated with longer PARPi duration and survival (PARPi 5 vs 1 month, p=0.02 and OS 17 vs. 3 months, p=0.032). Prior CNS surgery was significantly associated with longer PARPi duration, but not overall survival (PARPi 18 vs 3 months, p=0.05 and OS 28 vs. 7 months, p=0.14).

Conclusions: PARPi are associated with significant clinical benefit in patients with breast cancer CNS metastasis. Larger data series will help confirm these observations.

#6473 Evaluation of bladder cancer patients' utilization of urologic telehealth services.

S. Goldenthal, T. Posid, V. Heh, D. Denis-Diaz, H. Asif, C. Arnold, H. Gold, **T.-H. Kim**, A. Ndumele, S. Amin, M. Lierz, V. Xu, T. Cronin, A. Khuhro, C. Lee;
The Ohio State University Wexner Medical Center, Columbus, OH

Introduction: Infection control practices and public policy in response to the COVID-19 pandemic shifted healthcare practices towards a telemedicine format. Even two years after peak onset of the pandemic, many clinics, including our own institution, maintain a working telehealth option for patient visits. Our objective was to evaluate patient utilization of telehealth visits versus in-person visits at our institution and whether this was impacted by clinical stage, rural/urban status, distance from a large urban academic center, payor status, or comorbidities.

Methods: Medical Record Numbers for all patients with bladder cancer were pulled via the Qlik platform from the period 7/1/2019-2/28/2022. Chart review was conducted to pull clinical data on patients including telehealth versus in person visits, demographic data, clinical stage, comorbidities (diabetes, smoking status, BMI), rural/urban status by zip code (>50,000, <50,000 individuals) and income levels by zip code (25K-49.9K, 50K-99.9K, <100K), payor status (Medicare, Managed care, Medicaid, other government, ODRC, or self-pay), patient distance, and gas savings/carbon footprint.

Results: 430 patients completed in person visits while 268 completed telehealth visits. There was no statistically significant difference for in person visits vs. telehealth visits regarding patients' race (p=0.541), ethnicity (p=0.394) age (p=0.862), urban/rural status (p=0.507), payor status (p=0.127), mean zip code income (p=0.175), and comorbidities (p=0.626 for diabetes, p = 0.706 for smoking, p = 0.459 for BMI), and clinical stage (p=0.07). There was a statistically significant difference in mean distance (14.85 miles versus 26.86 miles, p<0.01).

Conclusion: Patients' with bladder cancer receive care from their urologist via in person visits versus telehealth at similar rates irrespective of their urban/rural status, demographics, payor status, relevant comorbidities, or relative income. Patients are more likely to engage in care with their urologist via telehealth if they live farther from a large urban academic center, which produces an economical and environmental impact via gas/time savings and reduced carbon footprint.

#6474 Real-world assessment of turn-around time for actionable variant testing in NSCLC in the community setting.

B. D'Alessio, A. Stephen, C. Cochran, C. Hager, Z. Velasco, A. Weaver, L. Jackson, J. Riley, A. Tubbs, **G. A. Pestano**;
Biodesix, Inc., Boulder, CO

Introduction: Rapid turnaround times (TAT) is a key parameter when evaluating the performance of cell free (cf) nucleic acid testing in clinical oncology practice. The purpose of this study was to evaluate the impact of the real-world factors on TAT for actionable variants in NSCLC, detected using commercially available molecular diagnostic tests. These test services are run in a single, centralized laboratory site and utilized primarily by practices in the community across the United States.

Methods: In this study, de-identified reference data was reviewed for a ddPCR test that evaluates hotspot mutations including Single Nucleotide Variants (SNV), Insertions and Deletions (INDEL), and gene fusions. The NGS panel additionally tests for Copy Number Amplification (CNA) mutations. Specimen processing was initiated when the specimen was entered into the Laboratory Information System (LIS) and ended when the test result was ready for release. The turnaround time evaluation excluded holidays, and weekends unless the start or end-point occurred on a non-business day.

Results: In total, 35,441 specimen results were analyzed. Specimens were typically received in the laboratory within 24 hours of being shipped (88% in 24 hours). Tests by ddPCR included 30,490 (86%) results, while NGS testing accounted for 4,951 (14%) of results. The average analytic lab processing TAT for the ddPCR and NGS test ranged between 2 and 3 days (ddPCR median = 24.5 hours; NGS panel median = 69.7 hours). When no information was missing on the specimen test request form, the turn-around time for the ddPCR tests averaged 30.2 hours and NGS panel averaged 66.2 hours. The percentage of missing or inaccurate information was similar when test requests were initially received. The largest impact factor impacting initiation of specimen processing was information related annotation of the stage of cancer, followed by demographic information related to patient and specimen identifiers.

Conclusion: The focus on rapid turnaround times from specimen collection to results released is critical in oncology. Site and patient information, shipping methods, technologies and workflows used in the laboratory are all part of the test process and impact the release of potentially actionable results. Our study has highlighted that rapid turnaround of results is highly feasible for molecular tests being sent out from community practices across the US to a centralized reference laboratory. Specifically, actionable variant results related to NSCLC were successfully detected in the laboratory and were ready for delivery in 2 to 3 days. Automated methods for parsing the information necessary for test requests and delivery will continue to be important in maintaining rapid test result turnaround times.

#6475 Leveraging real-world pancreatic cancer datasets to drive drug discovery and patient health.

K. Abdilleh[1], **Z. Worman**[2], R. Beck[2], C. Fisher[2], D. Sain[2], J. DiGiovanna[2], L. Matrisian[1], S. Doss[1], B. Davis-Dusenbery[2];
[1]Pancreatic Action Network, Manhattan Beach, CA, [2]Velsera, Cambridge, MA

Pancreatic cancer is the third leading cause of cancer-related death in the United States. Current therapeutic options offer a dismal overall survival with the 5-year survival at just ~12%. Analysis of the clinical and molecular underpinnings of pancreatic cancer is critical to developing both early detection methodologies as well as novel therapeutic options. The aggressiveness and deadly nature of this disease warranted the development of a data repository and analysis system dedicated to pancreatic cancer data. The Pancreatic Cancer Action Network's (PanCAN) SPARK platform is a cloud-based data and analytics platform, powered by Velsera, that integrates real-world patient health data from PanCAN research initiatives and accelerates research by making pancreatic cancer data easier to access and use. Encompassing clinical, imaging, and genomics data from over 600 patients with pancreatic cancer within PanCAN's Know Your Tumor ® (KYT) precision medicine service, the SPARK platform connects with petabytes of publicly available cancer data via the Cancer Genomics Cloud (CGC), also powered by Velsera. The CGC is part of NCI's Cancer Research Data Commons (CRDC), a cloud-based data science infrastructure that connects data with analytics tools to allow researchers to share, integrate, analyze, visualize, and drive scientific discovery.

Here, we demonstrate the application of these datasets by providing a case study demonstrating how to combine and enrich data to accelerate pancreatic cancer research. Currently, the genomic and proteomic data available on CRDC amounts to 402 and 304 cases of pancreatic tumor samples, respectively. We will use the capabilities of the SPARK and CGC platforms, which provide ready-to-use tools for multi-omics analysis that require no coding knowledge. Using the KYT and CRDC open-access pancreatic cancer data, we aim to demonstrate how to perform integrated analysis of data from diverse scientific domains, and share with collaborators all in one space, streamlining and increasing the potential for new scientific discoveries.

Further expansion of the PanCAN and CGC datasets will undoubtedly provide a more comprehensive understanding of pancreatic cancer tumor biology. SPARK and CGC's cloud based computation infrastructure, along with numerous available cancer datasets and easy-to-use multi-omics data processing workflows and data analytic tools will be instrumental in this process.

#6476 Solving the real-world data challenge: A hybrid resourcing model to curate RWD at scale.

J. Rudolph[1], K. L. Kehl[2], M. Bernstein[3];

[1]Memorial Sloan Kettering Cancer Center, New York, NY, [2]Dana-Farber Cancer Institute, Boston, MA, [3]Vasta Global (an Omega Healthcare company), Boca Raton, FL

Introduction: As cancer treatments become more complex, the need for structured real-world data (RWD) to support clinical research is critical. However, researchers often lack resources to curate data in-house. Organizations are challenged with timely data curation at the quality and scale needed for real world applications.

Methods: As members of the AACR Project GENIE (Genomics Evidence Neoplasia Information Exchange) Biopharma Collaborative (BPC), Memorial Sloan Kettering Cancer Center (MSK) and Dana-Farber Cancer Institute (DFCI) partnered with Vasta Global, an Omega Healthcare company, to build a model for curating RWD at scale, allowing for cost-effective RWD curation while leveraging expert resources and best practices. The approach includes managing a hybrid onshore and offshore team with clear communication and recurring check-ins, cross-training curators on different EHRs to reallocate Vasta Global resources and maintain project pace, building program-specific clinical data curation training, establishing QA and delivery methods, standardizing data curation, assigning productivity standards, aligning data quality practices and benchmarks, and developing data visualizations and analytics to show progress and insights.

Results: In Phase 1 of the AACR GENIE BPC, data was curated from four sites: MSK, DFCI, Vanderbilt Ingram Cancer Center (VICC) in Nashville, and Princess Margaret Cancer Centre, University Health Network (UHN) in Toronto. During Phase 1, MSK and DFCI, with Vasta Global's assistance, delivered high-quality RWD for 6,475 patients (NSCLC = 1,591; CRC = 1,264; Bladder = 639; Breast = 957; Pancreas 989; and Prostate = 1,035). All data for these cohorts will be publicly available by Spring 2024 in the AACR Project GENIE cBioPortal. MSK and DFCI generated usable and fit-for-purpose RWD to help advance oncology clinical decision-making and data sharing.

Conclusion: Accelerating RWD curation will empower the oncology community to leverage data-driven insights and advance treatment opportunities for cancer patients. Working alongside lead sites, a partner like Vasta Global enables researchers to leverage extensive expertise in the BPC data model, allowing for consistency and scalability of the BPC program. In this hybrid model, research partners can curate RWD in a cost-effective way, while remaining focused on core research responsibilities.

#6477 Modulators of hospital length of stay after intracranial neoplasm excision.

J. Hsiung[1], K. Taneja[2], L. Ladehoff[3], K. Patel[4], E. Toloza[5];
[1]Highland Park High School, Highland Park, NJ, [2]Stony Brook University, Stony Brook, NY, [3]University of Florida, Gainesville, FL, [4]Cooper Medical School, Camden, NJ, [5]Moffitt Cancer Center, Tampa, FL

Purpose: Intracranial neoplasms are the leading cause of cancer death among men under 40 years old. A major part of the standard of care is excision of the tumor, but there is a lack of robust large-patient studies of outcomes for these patients.
Methods: The Nationwide Inpatient Sample was queried from 2018 to 2020 to identify patients with an intracranial neoplasm. Multivariable linear regression with patient- and hospital-level characteristics as covariates was used to identify factors associated with long hospital stays.
Results: From 2018 to 2020, there were 97,795 hospital encounters with a primary diagnosis of an intracranial neoplasm. Of these patients, 64.6% underwent a tumor excision procedure during their hospital visit. The average age of these patients undergoing excision was 57.80.2 years. Most patients were male (58.6%), white (79.1%), private insurance beneficiaries (46.3%), and of the highest income quartile (26.8%). These patients most commonly presented to hospitals in the West (34.9%), with a medium number of beds (36.4%), and presented to rural hospitals (41.7%). The most common locations of these neoplasms were the frontal (29.1%), temporal (21.3%), and parietal (12.1%) lobes. Neoplasms in more than one location in the brain occurred in 4.5% of patients. Multivariable linear regression identified the following factors as significantly associated with longer hospital stays: identifying as Black (beta=2.08; p<0.001), identifying as an Asian or Pacific Islander (beta=1.22; p=0.017), being a Medicaid beneficiary (beta=2.25; p<0.001), and being uninsured (beta=1.63; p<0.001). Having a neoplasm in the cerebral ventricle (beta=4.93; p<0.001), cerebellum (beta=2.81; p<0.001), or brain stem (beta=3.45; p<0.001), and having multiple neoplasms (beta=1.85; p=0.008) were also associated with longer hospital stays. Interestingly, having a parietal (beta=-0.54; p=0.011) or occipital (b=-0.99; p<0.001) lobe neoplasm was associated with shorter hospital stays.
Conclusion: Intracranial neoplasms are deadly condition and excision of tumor is a important life-saving treatment option. In this study, we demonstrated that location of neoplasm, race, and insurance status are significant modulators of the length of a hospital stay after surgery.

#6478 Intracranial neoplasms: Disparities in access to care.

J. Hsiung[1], K. Taneja[2], L. Ladehoff[3], K. Patel[4], E. Toloza[5];
[1]Highland Park High School, Highland Park, NJ, [2]Stony Brook University, Stony Brook, NY, [3]University of Florida, Gainesville, FL, [4]Cooper Medical School, Camden, NJ, [5]Moffitt Cancer Center, Tampa, FL

Purpose: Excision of intracranial neoplasms is a life-saving procedure. However, there is not much research that has demonstrated how demographic variables interact with a patient's access to healthcare for intracranial neoplasms.
Methods: The Nationwide Inpatient Sample was queried from 2018 to 2020 to identify patients with an intracranial neoplasm. Multivariable logistic regression with patient- and hospital-level characteristics as covariates was used to identify factors associated with receiving an intracranial tumor excision.
Results: From 2018 to 2020, there were 97,795 hospital encounters with a primary diagnosis of an intracranial neoplasm. Of these patients, 64.6% underwent a tumor excision procedure during their hospital visit. The average age of all patients with intracranial neoplasm was 58.90.2 years. Most intracranial neoplasm patients were male (59.0%), White (73.8%), Medicare beneficiaries (45.1%), and of the highest income quartile (26.4%). These patients commonly presented to hospitals in the West (35.0%), with a medium number of beds (36.4%), and to rural hospitals (39.1%). The most common locations of these neoplasms were the frontal (18.9%), temporal (12.0%), and parietal (7.5%) lobes. Neoplasms in more than one location in the brain occurred in 5.8% of patients. Multivariable logistic regression identified the following factors as significantly associated with a decreased odds ratio (OR) of receiving an excision surgery: identifying as Black (OR=0.63; p<0.001), Hispanic (OR=0.82; p=0.001), or Asian or Pacific Islander (OR=0.78; p=0.009) and being a Medicaid Beneficiary (OR=0.84; p=0.008). Presenting to a hospital in the South (OR=1.30; p<0.001) or in the West (OR=1.38; p<0.001) were associated with higher chances of having a surgical excision.
Conclusion: There are very substantial differences in access to care for brain cancer patients. Race and insurance status are related to a patient's chance of receiving tumor excision therapy.

#6479 Metastases in uveal melanoma patients: Trends and risk factors.

A. A. Beneke[1], **K. Taneja**[2], L. Ladehoff[3], K. Root[1], E. Toloza[4];

[1]University of Florida, Gainesville, FL, [2]Stony Brook University, Stony Brook, NY, [3]University of South Florida, Tampa, FL, [4]Moffitt Cancer Center, Tampa, FL

Purpose: Uveal melanoma has a high tendency to metastasize. Due to its rarity, there has not been large population studies that have demonstrated the effect of demographic variables on a patient's risk to have metastases.

Methods: The Nationwide Emergency Department Sample was queried from the last quarter of 2015 to 2019 to identify patients with a diagnosis of uveal melanoma. Multivariable logistic regression, with patient- and hospital-level characteristics as covariates, was used to identify factors associated with a higher chance of developing a metastasis and specific metastasis locations.

Results: From the last quarter of 2015 to 2019, there were 7,561 ED encounters with a diagnosis of uveal melanoma. Of these patients, 5.8% had at least one metastasis. Most patients with a metastasis were at least 65 years of age (47.1%), male (54.4%), a Medicare beneficiary (45.2%), and belonged to a family in the highest income quartile (29.7%). The median age of these patients was 61 years (IQR: 32-74). Most patients presented to hospitals in the South (40.7%), with a Trauma Level I designation (56.1%), and to a metropolitan teaching hospital (72.9%). The most common sites of metastasis were liver (17.0%), brain (5.3%), and bone (2.0%). Multivariable logistic regression identified the following factors to be associated with increased risk of developing a metastasis: private insurance (odds ratio [OR]=1.62; p=0.012), highest income quartile (OR=2.30; p<0.001), and 2nd highest income quartile (OR=1.78; p=0.002). The following factors were associated with higher odds of developing a liver metastasis specifically: no-charge/charity work (OR=15.8; p=0.012), highest income quartile (OR=1.99; p=0.003), and second highest income quartile (OR=1.66; p=0.035). Presenting to a Trauma Level I hospital was associated with decreased risk of developing a liver metastasis (OR=0.57; p=0.016). Belonging to the highest income quartile was associated with a higher chance of developing a brain metastasis (OR=2.13; p=0.023) or a bone metastasis (OR=2.74; p=0.045). Among patients with a metastasis, the in-hospital mortality rate was 8.3%.

Conclusion: Metastasis is an important complication to monitor in uveal melanoma patients. In this study, we have demonstrated that income and insurance status are factors that are associated with higher rates of metastases. Physicians should place special attention to these groups to ensure that metastases are minimized.

#6480 In-hospital mortality risk factors for uveal melanoma patients in the emergency department.

A. A. Beneke[1], **K. Taneja**[2], L. Ladehoff[3], K. Root[1], E. Toloza[4];
[1]University of Florida, Gainesville, FL, [2]Stony Brook University, Renaissance School of Medicine, Stony Brook, FL, [3]University of South Florida, Tampa, FL, [4]Moffitt Cancer Center, Tampa, FL

Purpose: A considerable amount of uveal melanoma patients present to the emergency department (ED) for a complication related to their primary tumor. However, there is not much research into the primary reasons for these patients to present to the ED and their outcomes.
Methods: The Nationwide Emergency Department Sample was queried from the last quarter of 2015 to 2019 to identify patients with a diagnosis of uveal melanoma. Multivariable logistic regression, with patient- and hospital-level characteristics as covariates, was used to identify factors associated with increased risk of in-hospital death.
Results: From the last quarter of 2015 to 2019, there were 7,561 ED encounters with a secondary diagnosis of uveal melanoma. Most patients were at least 65 years of age (43.5%), male (52.5%), and a Medicare beneficiary (44.2%), or belong to a family in the 3rd income quartile (25.6%). The median age of these patients was 61 years (IQR: 32-74). Most patients presented to hospitals in the South (40.8%), with a Trauma Level I designation (47.2%), and to a metropolitan teaching hospital (72.6%). The most common diagnosis for presentation to the ED were the following general clinical categories: blood disorders (7.1%), genitourinary tract disorders (5.1%), infections (6.0%), respiratory diseases (9.0%), nervous system disorders (4.8%), endocrine/nutrition disorders (4.3%), and vascular disorders (8.3%). The rate of metastatic uveal melanoma was 5.8%. The rate of in-hospital mortality was 3.6%. In a multivariable logistic regression identified the following clinical categories as factors associated with a higher risk of in-hospital death: infections (odds ratio [OR]=10.22; p<0.001), metastases (OR=10.22; p<0.001), genitourinary tract disorders (OR=7.05; p<0.001), respiratory diseases (OR=3.31; p=0.031), and vascular disorders (OR=3.14; p=0.044). Nervous system, blood, and endocrine/nutrition disorders were not associated with a higher rate of in-hospital mortality. The only demographic variable associated with a higher risk of in-hospital death was being part of the top income quartile (OR=3.10; p=0.14).
Conclusion: Physicians have to be mindful of different complications associated with uveal melanoma that can lead to presentation to the ED and possible in-hospital death. Specifically, physicians need to be mindful of infections, metastases, genitourinary tract disorders, respiratory diseases, and vascular disorders in these patients.

CLINICAL RESEARCH: Targeting Kinase and ERK Pathways
Poster Session

#6484 Overcoming resistance to EGFR-TKI in NSCLC by simultaneously inhibition of anti-apoptotic proteins.

Sandra Weller[1], Tobias Beigl[1], Frank Essmann[1], Annika Harsch[1], Hans-Georg Kopp[2], Tom Ekstrom[1]

[1]Robert Bosch Center for Tumor Diseases (RBCT), Stuttgart, Germany,[2]Robert Bosch Center for Tumor Diseases, Stuttgart, Germany; Robert Bosch Hospital, Stuttgart, Germany

Lung cancer is the second most common cancer worldwide with 1.8 million deaths in 2020 being the leading cause of cancer related death. With 86% of cases, non-small cell lung cancer (NSCLC) is the most prominent subtype. The survival rate improved over the past 20 years by application of targeted therapies. Driver mutations in protein kinases such as the epidermal growth factor receptor (EGFR) are frequent and have evolved as therapeutic targets in anti-cancer therapy. Inhibitors of receptor tyrosine kinase (RTKIs), prominently EGFR-TKIs, are effective in anti-cancer therapy but tumor evolution inevitably generates resistance. Thus, strategies for the treatment of patients with acquired resistance to RTKIs remains an urgent need. Resistance in solid tumors is overcome by a combination of bortezomib with the BH3-mimetic ABT-199 (Muenchow et al. 2020). Also, overcoming ALK-TKI resistance in NSCLC was described by Tanimoto et al. (2021) by proteasome inhibiton that mediates induction of NOXA. Furthermore, the novel described BCL-2 independent activity of ABT-199 to transactivate NOXA expression (Weller et al. 2022) represents a generally active principle by combining drugs with independent mechanism of action. We hypothesize, that combined treatment of EGFR-TKI Osimertinib (OSI) with BH3-mimetics enhances sensitivity to apoptosis induction. To explore this hypothesis, we investigated cell death induction by combined administration of OSI and BH3-mimetics or PIs in NSCLC differing in their mutational status. In addition, we analyzed the expression of BCL-2 family proteins and their relevance and regulation during RTKI-induced cell death by RNA sequencing and Western Blot. These analyses will be performed in cellular model systems of NSCLC with specific resistance mediating mutations of EGFR or activated parallel survival pathways. We found that BCL-2 inhibitors enhance efficacy of OSI in NSCLC, resulting in synergistic cell death induction. Additionally, the sensitivity to BCL-2 inhibitors tends to increase in OSI-resistant NSCLC. Western Blot analysis and RNA sequencing data of OSI-resistant NSCLC identified BCL-2 overexpression and an EMT signature as resistance-mediating mechanisms, which can be overcome by combination of OSI with BCL-2 inhibitors. Indeed, our data suggest that combination of OSI with BCL-2 inhibitors disrupts resistance to OSI in NSCLC. We propose that BCL-2 inhibitors sensitize OSI-resistant NSCLC to effectively induce cell death. Thus, studying the molecular mechanism of synergistic efficacy of RTKI/BCL-2 inhibitor combination therapies, should prompt future efforts in the clinical evaluation of combinatorial regimens. We hypothesize that a general therapeutic concept which relies on simultaneous blocking of driver mutations and survival-promoting BCL-2 proteins represents a generally active principle of a tumor-agnostic mechanism of action.

#6485 Profile guided low dose drug combination strategies and kinase activities with prognostic and therapeutic avenues in pancreatic ductal adenocarcinoma.

A. Valles Marti[1], G. Mantini[2], C. Waasdorp[2], R. de Goeij- de Haas[2], A. Henneman[2], S. Piersma[2], T. Pham[2], J. Knol[2], J. Verheij[3], F. Dijk[3], H. Halfwerk[3], E. Giovannetti[2], C. Jimenez[2], M. F. Bijlsma[2],

Introduction: Pancreatic ductal adenocarcinoma (PDAC) is a devastating disease, commonly characterized by multiple aberrant signaling. Phosphoproteomics provides a direct read-out of these complex signaling networks and the resultant clinically relevant phenotype, as well as a functional scaffold to identify new targets. In the absence of an oncogenic driver, low dose (LD) kinase inhibitor (KI) combinations against multiple (parallel) activated kinases might provide higher efficacy and reduce toxicity as compared to single drug treatment. Aims: 1) To identify targets and test combinations of multiple KIs at LDs for potential synergism in preclinical models. 2) To chart the phosphoproteome of 42 PDAC tumors to reveal signalling pathways that may be involved in PDAC progression.
Methods: By using a two step phosphopeptide enrichment with phosphotyrosine immunoprecipitation and immobilized metal affinity chromatography, followed by label free MS analysis, we analyzed phosphoproteome data of 7 immortalized and 2 primary PDAC cell lines, and of 42 PDAC tumors. We used integrative inferred kinase activity (INKA) scoring of the maxquant output to identify hyperactive kinases. For the cell line panel, five KIs were selected based on targeting coverage of the INKA profiles. LD were set as IC20s for 2,3,4 drug combinations. Cell growth inhibition was assessed by SRB assay. Median-effect analysis was used to assess synergy. Functional testing was performed in immortalized 2D, xenoderived 2D and 3D cultures. Effective low dose 3 drug combinations were further validated using patient-derived xenografts.
Results: High INKA scoring of multiple activities per cell line without clear outliers of single kinases underscores the need for combination therapies. Multiple LD combinations showed effective growth inhibition (70 to 92%) and synergism, mostly 3 drug combinations, which required targeting of several RTKs and downstream signaling. Different responses were further observed between epithelial and mesenchymal cell lines. These top performing combinations were further validated in PDAC organoids and *in vivo*. Clinical utility of these kinase targets was then confirmed in 42 tumor phosphoprofiles, which were characterized in different subtypes with distinct therapeutic options. Phosphoproteome signals and kinases activities with potential prognostic value and mutational associations were further described.
Conclusion: Our INKA pipeline, which can rank kinase activities in individual tumors, is optimally suited to specifically prioritize actionable kinases with targeting purposes. Tailored LD combination strategies exhibited promising efficacy in preclinical models and may ultimately improve treatment outcomes.
Next Steps: Multicellular patient-derived models will be used to further study and target the TME in PDAC tumors.

#6486 Correlation of *nab*-sirolimus tumor drug levels and improved tumor suppression in *KRAS G12C* non-small cell lung cancer xenografts treated with *nab*-sirolimus in combination with *KRAS* inhibitors.

S. Hou[1], J. Nieva[2], M. Zalath[1], N. Desai[1];

[1]Aadi Bioscience, Inc., Pacific Palisades, CA, [2]University of Southern California, Los Angeles, CA

Background: *KRAS* mutations are found in a variety of tumor types, including non-small cell lung cancer (NSCLC), where *KRAS G12C* mutation is present in ~12% of NSCLC patients. *KRAS G12C* inhibitors (KRAS G12Cis), sotorasib and adagrasib, are approved for the treatment of *KRAS G12C*-mutated, locally advanced or metastatic NSCLC. The mTOR pathway is often activated in patients with *KRAS* mutations and may contribute to resistance to KRAS G12Cis. *nab*-Sirolimus is a nanoparticle albumin-bound intravenously (IV) administered form of the mTOR inhibitor (mTORi) sirolimus and is approved for the treatment of patients with advanced malignant perivascular epithelioid cell tumors. This study assessed tumor and blood drug level correlation with antitumor activity of *nab*-sirolimus or everolimus alone or in combination with KRAS G12Cis.

Methods: Athymic mice bearing subcutaneous *KRAS G12C*- and *STK11*-mutated NSCLC xenografts (NCI-H2122) were treated with saline, mTORis *nab*-sirolimus (IV) or everolimus (oral) at clinically relevant and equal weekly dose of 15 mg/kg/wk, or KRAS G12Cis sotorasib (oral) or adagrasib (oral) at 30 mg/kg/day alone or in combination. Tumor volume changes from baseline were assessed; tumor and blood samples were harvested at the end of study (6 wks) for analysis of trough drug levels by LC-MS/MS, and tumor lysates were analyzed for downstream markers for mTOR inhibition by Western blot.

Results: In *nab*-sirolimus plus KRAS G12Ci treated groups, significantly slower tumor growth was observed compared with single agent treated groups and everolimus plus KRAS G12Ci treated groups. Compared with single-agent *nab*-sirolimus (170.1 ng/g), treatment with *nab*-sirolimus plus sotorasib resulted in reduced tumor *nab*-sirolimus drug levels (73.6 ng/g, P=0.0040); while similar tumor *nab*-sirolimus drug levels were observed for *nab*-sirolimus plus adagrasib (121.6 ng/g, P=ns). Corresponding to greater antitumor activity, significantly greater tumor trough mTORi drug levels were observed in *nab*-sirolimus plus either sotorasib or adagrasib treated groups compared with similar everolimus combinations (85-fold, P<0.0001; and 91-fold, P=0.0050, respectively). Correspondingly, stronger mTOR downstream target inhibition of pS6 were observed for *nab*-sirolimus plus KRAS G12Ci treated groups compared with everolimus plus KRAS G12Ci treated groups.

Conclusions: The addition of a KRAS G12Ci to *nab*-sirolimus significantly reduced tumor volume and increased tumor drug levels, suggesting enhanced tumor targeting compared with everolimus plus KRAS G12Cis and correlating to improved antitumor activity and mTOR target suppression. Clinical dose-finding studies are needed to determine potential drug-drug interactions between *nab*-sirolimus and KRASis.

#6487 The selective WEE1 inhibitor azenosertib shows synergistic anti-tumor activity with KRAS^{G12C} inhibitors in multiple KRAS^{G12C} models.

Nathan M. Jameson, Gabriel Kim, Catherine Lee, Blake Skrable, Alexandra Shea, Monah Abed, Olivier Harismendy, Jianhui Ma, Doris Kim, Mark R. Lackner

Zentalis Pharmaceuticals, San Diego, CA

KRAS^{G12C} is a potent oncogenic driver which results in downstream hyperactivation of MAPK signaling and unchecked oncogenic growth, while simultaneously increasing replication stress (RS) and accumulation of DNA damage. KRAS^{G12C}-specific inhibitors are approved and/or recommended in metastatic non-small cell lung cancer (NSCLC) and colorectal cancer (CRC), and while responses are robust, some patients are inherently resistant, and most responders acquire resistance. Resistance mechanisms include reactivation of MAPK signaling, and cancer cells which escape MAPKi are reported to have high levels of genomic instability. WEE1 is a kinase involved in cell cycle progression, allowing cells to repair damaged DNA before entering the next cell cycle phase. Consequently, inhibition of WEE1 leads to premature cell cycle entry and RS, thereby driving cancer cells through the cell cycle with unchecked accumulation of DNA damage, ultimately resulting in mitotic catastrophe and cell death. We hypothesized that high levels of genomic instability and RS in *KRAS^{G12C}* mutant and KRAS^{G12C} inhibitor-resistant tumors present a vulnerability to WEE1 inhibition and provide rationale for combining azenosertib, a novel, selective, and orally bioavailable WEE1 inhibitor, with KRAS^{G12C} inhibitors.

Here, we report azenosertib in combination with KRAS^{G12C} inhibitors as an effective therapeutic strategy for *KRAS^{G12C}* tumors. *In vitro* combination of azenosertib with multiple KRAS^{G12C} inhibitors demonstrated synergistic cell growth inhibition across a panel of *KRAS^{G12C}* cell lines in both 2D and 3D assays. *In vivo* treatment with azenosertib in KRAS^{G12C} inhibitor-sensitive cell line-derived xenograft (CDX) models of NSCLC (NCI-H358, NCI-H2122, NCI-H1792), CRC (SW837, SW1463), and pancreatic cancer (MIA PaCa-2) demonstrated significant monotherapy activity as well as synergistic tumor growth inhibition (TGI) when combined with KRAS^{G12C} inhibitors, including tumor regression in some models. Importantly, the KRAS^{G12C} inhibitor-resistant SW1573 NSCLC CDX model demonstrated synergistic TGI in the combo arm (84%) when compared against monotherapy azenosertib (31%) or adagrasib (58%). Similarly, treatment of a KRAS^{G12C} inhibitor-resistant patient-derived xenograft (PDX) model of CRC resulted in synergistic TGI in the combination arm (61%) relative to monotherapy azenosertib (17%) or adagrasib (2%). Finally, analysis of biomarkers from both *in vitro* and *in vivo* tumor samples demonstrated synergistic increases in protein markers of RS, DNA damage, and apoptosis with combination therapy.

Taken together, our results suggest that the combination of azenosertib with KRAS^{G12C} inhibitors enhances tumor growth inhibition over single agent therapy and may be an effective treatment option for patients with *KRAS^{G12C}* tumors.

#6489 Paradoxical activation of kinases occurs directly with ATP-competitive kinase inhibitors and is observable biochemically at physiologically relevant drug concentrations.

C. M. Loch, M. Eason, S. Liang, A. Goupil, A. Acinapura, J. Purcell, M. Domiguez;
Reaction Biology Corporation, Malvern, PA

We sought to screen all FDA approved, cancer-indicated, kinase targeting drugs using the gold standard radiometric biochemical activity assay (HotSpot) against the largest collection of kinases in the world (>100 drugs against 735 total kinases including 395 wild type and 340 mutants). One of these drugs, mitapivat, is an activator of Pyruvate Kinase. Here, we show mitapivat-driven biochemical inhibition of several, but not all, mutants of c-KIT. We also observed the equal and opposite phenomenon whereby many ATP-competitive kinase inhibitors demonstrate biochemical activation of certain kinases, several of which seem particularly susceptible to the effect. Previous work by other investigators (at Genentech and the Rosen lab, MSKCC) demonstrated that PLX4720 (precursor to Vemurafenib) paradoxically activated wild type BRAF, but not BRAF mutants, by driving dimerization of the kinase in drug concentrations insufficient to inhibit both members of the dimerized pair. Our data suggests this phenomenon may be more widespread than previously appreciated and fully observable in vitro. Such paradoxical activation could be driving both toxicities and inefficacy against cancers expressing some of these activatable kinases. This information could suggest novel opportunities for combination therapy and improve outcomes by contraindicating certain medication from use based on tumor expression profile.

#6490 Pt1a and sorafenib combination treatment exerts synergistic anti-hepatocellular carcinoma effect through RNA m^{6}A methylation modification.

Y. Huang[1], Y. Cui[1], I. B. Huang[2], Y. Wang[1], Y. Xuan[1], P. Wan[3], C. Lok[2], C. Che[3], S. Ma[4];

[1]School of Biomedical Sciences, Li Ka Shing Faculty of Medicine, The University of Hong Kong, Hong Kong SAR, China, [2]Laboratory for Synthetic Chemistry and Chemical Biology, Health@InnoHK, Hong Kong SAR, China, [3]State Key Laboratory of Synthetic Chemistry, Department of Chemistry, The University of Hong Kong, Hong Kong SAR, China, [4]State Key Laboratory of Liver Research, The University of Hong Kong, Hong Kong SAR, China

Hepatocellular carcinoma (HCC) is the most common type of liver cancer and has a poor prognosis. The survival benefits of sorafenib in patients with advanced HCC are modest owing to acquired resistance. Accumulating evidence has demonstrated that cancer stemness is an important cause of drug resistance and the root cause of tumor recurrence. [PtII(C^N^N)(NHC2Bu)]PF6 (Pt1a) is a newly developed platinum-based drug containing N-heterocyclic carbene with proven anticancer properties against a range of tumor types. However, its role in targeting cancer stemness and its ability to sensitize cancer cells to overcome molecular-targeted therapy drug resistance in HCC remains elusive. Herein, we demonstrate the synergistic inhibitory effect of sorafenib and Pt1a combination treatment on HCC through RNA m^{6}A methylation modification. In cultured HCC cells and patient-derived organoids, the drug combination synergistically reduced the cell viability and promoted cell apoptosis compared to single-drug treatment. Combination treatment also attenuated self-renewal, as evidenced by a marked decrease in tumor-initiating cancer cell frequency, as measured by limiting dilution spheroid formation assay. These findings were further validated in HCC patient-derived xenograft mouse models and a mouse HCC model induced by hydrodynamic tail vein delivery of NRAS+AKT coactivation plasmids. Notably, the combination treatment with sorafenib and Pt1a, but not a single treatment, led to a significant reduction in tumor burden. The combination treatment was also effective in decreasing tumor-initiating cell frequency, as measured by subjecting the harvested tumor cells for limiting dilution spheroid formation assay *ex vivo*. Mechanistically, integrative RNA-sequencing and thermal proteome profiling analyses both indicated the enrichment of m^{6}A-related pathways in combination drug treatment. An increased global m^{6}A level upon combination treatment was validated using m^{6}A dot blotting, confirming that the synergistic effect may be mediated by the elevated global m^{6}A level in HCC cells. Collectively, our study demonstrated that Pt1a and sorafenib combination treatment synergistically inhibited the viability and stemness of HCC cells by increasing global RNA m^{6}A level. These findings supported the potential of Pt1a as a therapeutic option for HCC and overcoming sorafenib drug resistance. Ongoing studies are focused on identifying m^{6}A regulators and downstream targets involved in combination treatment.

#6491 Epigenetic-based combinatorial therapy is synergistic in KRAS/LKB1 mutant non-small cell lung cancers.

M. Zucker, K. Devore, L. Chesney, G. Hirschfeld, A. Reyna, B. Linnane, J. Mascarenhas, M. Murray, A. Miller, P. Gonzales, S. Gately;
Translational Drug Development, LLC (TD2), Scottsdale, AZ

KRAS and LKB1 mutations (KL) in non-small cell lung cancer (NSCLC) patients often results in poor prognosis, a high tumor mutational burden, and resistance to conventional therapy. The metabolic changes with these mutations can create unique vulnerabilities to be targeted therapeutically. HDAC inhibition has been reported as a promising approach to overcome MEK inhibitor resistance in animal models of melanoma, pancreatic cancer, and KL mutant NSCLC. Inhibition of HDAC3 and HDAC6 have independently been shown to have therapeutic activity in KL NSCLC. We now report on the activity of two novel HDAC3/6 inhibitors in cell culture and mouse models of human KL (A549) compared to KRAS/TP53-mutant NSCLC (KP) (CALU-6) alone and individually combined with the MEK inhibitor trametinib. GB-1101 inhibits HDAC3 and HDAC6 and GB-3103 inhibits HDAC1,3,6,10. SynergyFinder multi-dose combination data analytics showed synergistic interactions for both GB-1101 or GB-3103 when combined with trametinib in KL mutant A549 cells with maximum synergy scores of δ = 9.24 and 4.21, using zero interaction potency (ZIP) for synergy scoring. GB-1101 or GB-3103 when combined with trametinib in KP mutant CALU-6 cells did not demonstrate synergistic interaction with synergy scores of δ = -1.58 and -0.53, respectively. Mice were inoculated subcutaneously with $5.0x10^6$ A549 or CALU-6 cells and treatment with GB-1101 (75 mg/kg qd, oral), GB-3103 (5.0 mg/kg qd, subcutaneous), trametinib (1.0 mg/kg qd, oral) and each drug in combination with trametinib was initiated when tumors reached an average of $120mm^3$. Single agent and combination treatments were well tolerated. GB-1101 exhibited tumor growth inhibition (TGI) of 33.0% in the A549 (KL) compared to 8.5% in CALU-6 (KP). In combination with trametinib, GB-1101 showed increased activity (TGI=92.7%) compared to trametinib alone (TGI=69.5%) in KL mutant A549. In KP mutant CALU-6 tumors, combination benefit was not observed; combination of GB-1101 and trametinib yielded a TGI=93% equivalent to trametinib alone (TGI=91%). GB-3103 resulted in a TGI of 66.7% in the KL mutant A549 and TGI= 55.9% in KP mutant CALU-6. In KL mutant A549, GB-3103 in combination with trametinib, showed increased inhibition (TGI=94.3%) compared to trametinib alone (TGI=69.5%). No combination benefit was seen for GB-3103 in KP mutant CALU-6 with the combination treatment TGI of 93.1% compared to trametinib alone TGI=90.7%. These results confirm and extend the finding that for KL mutant NSCLC, HDAC3/6 inhibitors show therapeutic benefit in combination with trametinib that is not observed in KP tumors. These data reveal a promising epigenetic-based combinatorial strategy for treating lung cancers harboring concurrent KRAS/LKB1 mutations, a path for clinical translation, and the potential to improve treatments for KRAS/LKB1 mutant NSCLC patients where there are currently no robust therapeutic strategies.

#6492 KRAS inhibitor-based combinations in pancreatic cancer identified through Optim.AI.

J. Lim[1], E. K. Chow[2], M. Rashid[1];

[1]KYAN Technologies Pte Ltd, KYAN Technologies Pte Ltd, Singapore, [2]National University of Singapore, Singapore, Singapore

PURPOSE: KRAS is the most frequently mutated oncogene in almost all cancers, including pancreatic ductal carcinoma (PDAC) and colorectal cancer. Increased development efforts targeting KRAS mutations have yielded recent FDA approvals of two KRAS G12C inhibitors. However, this is beneficial for only a small proportion of patients especially with indications like PDAC, where G12C mutations are rare (1%) while G12D mutations account for approximately 45%. Hence, there is a need to develop methods to target a broader range of KRAS mutations. Beyond direct gene mutation, activation of oncogenic KRAS and downstream or parallel signaling through other genomic alterations may benefit from KRAS-specific therapeutic strategies, especially combination therapy. In this study, Optim.AI™, a hybrid computational-experimental platform is harnessed to identify mutation-specific optimal therapies and to stratify efficacious drug combinations containing KRAS inhibitors in pancreatic cancer.

METHODS: Optim.AI™ utilizes small datasets to rationally converge upon optimal drug combinations within a defined drug search space. By mapping experimental data points to a second-order quadratic function, Optim.AI™ predicts cell killing efficacies for all possible combinations, independent of the background of the models utilized. In this study, pancreatic cancer cell lines, with varying KRAS mutations, were tested with an array of 155 different combinations consisting of 12 drugs at varying concentrations. The drugs include KRAS G12C inhibitors, Sotorasib and Adagrasib, KRAS inhibitors in development, and approved therapies used clinically for PDAC. Post-drug treatment viability was measured and used for Optim.AI™ analysis, to rank and compare the top therapies across the different cell lines.

RESULTS: Through Optim.AI™ analysis, we observed a range of sensitivities towards KRAS inhibition, even for both Sotorasib and Adagrasib. Compared against HT-29 cell line, harboring wild type KRAS, we have identified distinct combinations of KRAS inhibitors with standard of care drugs on cell lines with G12D, G12V and G12C KRAS mutants. Subsequent validation of the top and bottom ranked combinations for the respective cell lines correspond to the predicted Optim.AI™ results.

CONCLUSIONS: This study has demonstrated the differential sensitivities of the KRAS inhibitors across several pancreatic cancer cell lines, with different KRAS mutational profiles. Notably, we have identified KRAS inhibitor-based combinations that are distinctly different from wild type KRAS cell line. These preliminary findings could be used to drive precision medicine by identifying suitable biomarkers to potentially stratify pancreatic cancer patients and improve treatment outcomes. Future work includes evaluating the clinical significance of these combinations by validating them on patient-derived organoids.

#6493 CRISPR-directed prime editing sensitizes EGFR inhibitor by correcting oncogenic KRAS mutants In NSCLC.

Q. Fang, C. Yang, C. Huang, H. Wang, j. Yu, J. Hao;
Tianjin Medical Univ. Cancer Inst. & Hospital, Tianjin, China

EGFR inhibitor has been demonstrated with huge therapeutic potential in advanced non-small cell lung cancer (NSCLC), while the patients carrying KRAS mutation had poor response to EGFR inhibitor. KRAS mutation is the most frequent molecular alteration found in advanced NSCLC, which is associated with a poor prognosis without available targeted therapy. Previous research showed that CRISPR-directed prime editor could induce unconstrained correction for KRAS mutants (*KRAS*^{G12D}, *KRAS*^{G12C}, *KRAS*^{G12V}). Accordingly, it would be a promising strategy to combine PE-based genetic therapy with EGFR inhibitor for enhanced therapy in NSCLC. Here,we selected several PE variants with reported highly efficient reverse transcriptase, among which eEc48-based PE6a showed the highest editing efficiency toward KRAS mutation. The lentivirus-mediated PE6a editing inhibited cell proliferation and invasion *in vitro* and *in vivo*. After that, EGFR inhibitor combined with PE6a was employed in patient-derived organoid (PDO) model carrying diverse KRAS mutants. We found that PE6a editing significantly inhibited PDO proliferation compared to EGFR inhibitor alone and control. Correspondingly, the transcriptome sequencing also showed that the cell apoptosis, cell growth and cell motility signaling were inhibited upon PE6a editing. Our findings demonstrated that the PE-directed genetic therapy could sensitize EGFR inhibitor in NSCLC, providing an alternative choice for NSCLC patients carrying KRAS mutant.

#6495 Lenvatinib as a potential treatment option for invasive mucinous lung adenocarcinoma.

Tarik Demir, Carolyn Moloney, Liam Il-Young Chung, Young Kwang Chae

Feinberg School of Medicine, Northwestern University, Chicago, IL

Introduction: Invasive mucinous adenocarcinoma (IMA) accounts for approximately 4-20% of non-small-cell lung carcinoma (NSCLC). Genetic alterations and RNA sequencing analysis of IMAs reveal a unique mucinous signature similar to gastrointestinal mucinous tumors. Due to its rarity, focused clinical trials for IMA patients are often not feasible. These patients respond poorly to platinum-based conventional chemotherapy, or immunotherapy. Lenvatinib is a multitargeted-TKI with demonstrated activity in patients with RET fusion-positive lung adenocarcinoma, thyroid, hepatocellular and gastric carcinoma.
Methods: Here, we present two RET fusion-negative mucinous lung adenocarcinoma cases that received a multitargeted TKI lenvatinib with a clinical and survival benefit.
Results: Case #1: An 81-year-old female initially diagnosed with cT4N0M0 IMA (TTF1 and CDX2 focally positive) was started on neoadjuvant treatment for a 12cm tumor. She underwent right thoracotomy/right lower lobectomy/mediastinal lymph node dissection, and pathology confirmed ypT4N1M0 mucinous adenocarcinoma. Three months post-operatively, the patient had disease progression in the lungs. She had no targetable mutations. She had four subsequent lines of treatment including nivolumab/nab-paclitaxel as the fourth-line treatment. After six months of nivolumab/nab-paclitaxel, lenvatinib was added to the combination due to clear disease progression evident on imaging. After twelve cycles of nivolumab/nab-paclitaxel/lenvatinib combination treatment, patient achieved a partial response per RECIST 1.1 (-35.7% change from baseline to current). The patient reported less dyspnea and increased activity tolerance. Approximately nine months after the start of the treatment, patient showed progressive lung disease. The patient died after one more line treatment with 41 months of total overall survival. **Case#2:** A 56-year-old male initially diagnosed with stage IVA IMA (TTF1 negative). After four lines of treatments, patient was started on lenvatinib alone. The patient reported marked improvement in dyspnea and pain and increased activity tolerance with lenvatinib. Imaging confirmed treatment response after three months of treatment. The patient was subsequently enrolled in the double lung transplant (DLT) registry aimed for lung-limited malignancies (D.R.E.A.M.) registry study (NCT05671887), and he is alive with 25 months follow-up since DLT.
Conclusion: We report two cases of metastatic RET fusion-negative mucinous lung adenocarcinoma, in which treatment with the multitargeted TKI Lenvatinib led to significant clinical improvement. Biological rationale to explain the effect of lenvatinib in invasive mucinous lung adenocarcinoma needs to be explored.

#6496 Assessment of tyrosine kinase inhibitor bypass mechanisms in lung cancer using single cell multiomics, patient derived organoids and rationally designed drug screens.

L. Liu, A. Strange, S. Lee, B. Gao, D. Merrick, T. Patil, J. DeGregori, D. Camidge, S. R. Pine, **H. E. Sabaawy**;
University of Colorado Anschutz Medical Campus, Aurora, CO

Lung cancer (LC) is the leading cause of cancer-induced mortality, with 350 patients in the US dying from LC daily, the majority from non-small cell lung cancer (NSCLC). Molecular-targeted therapy such as tyrosine kinase inhibitors (TKI) are effective in first and subsequent lines of therapy against oncogenic drivers (KRAS, EGFR, or ALK fusions, others); however, nearly all treated patients progress eventually and run out of therapeutic options. Key reasons are the lack of predictive biomarkers and LC models that reflect the underlying heterogeneity and different phenotypic cell states among subclones within and between patients. Here, we developed a novel platform for refining the resolution of molecular interrogation to the single cell level, using single cell spatial multiomic (scSpMO), coupled with rational designed drug screens in patient-derived organoids (PDOs) from LC biopsies obtained upon progression. By deriving LC PDOs in epithelial and tumor microenvironment (TME) conditions to faithfully maintain the histological and genetic features of their respective LC tissues, we identified enrichment conditions for LC PDOs guided by tumor mutation variants and activated pathways. PDOs are maintained under the same treatment condition in the clinic (e.g., Lorlatinib) and drug testing is tailored to identify next lines of combined therapy. With six patients enrolled and others in ongoing studies, single cell PDOs (at >80% establishment rate) were used to determine key molecular bypass mechanism for resistance to TKI, including on-target variants, driver bypass, lineage plasticity and acquired resistance. Functional assays for acquired resistance such as PI3K/AKT signaling, Src kinase, BRAF fusion and MET hyperactivity allow the identification of potential novel combined lines of therapy for each patient through the compassionate care program and/or trial participation. Our platform when empowered with datasets of bulk, scRNA-seq and scSpMO signatures of primary human NSCLC, together with PDOs offer the ability to perform analysis of LC phenotypes such as lineage transformation in high-content assays, predict and/or act on resistance to therapy and provides a path for precision medicine-guided immediate impact on patient care.

#6497 Molecular characterization and drug sensitivity of a gastric FGFR2-TACC2 and a pancreatic KRAS p.G12C primary culture.

S. Garcia-Roman[1], E. Meshoulam Nikolaeva[2], J. Garcia Mosquera[2], M. Garzon Ibanez[1], R. Roman[1], S. Rodriguez[1], C. Rodriguez[1], C. Mayo de las Casas[1], R. Rosell[2], M. A. Molina-Vila[1], C. Aguado Esteban[1];

[1]Pangaea Oncology, Barcelona, Spain, [2]Instituto Oncologico Dr. Rosell, Barcelona, Spain

Introduction and Objectives: Gastric and pancreatic cancers lack effective therapies, leading to low survival rates particularly in the metastatic setting. Fibroblast growth factor receptor 2 (*FGFR2*) amplification and fusions with *TACC2* appear in 5.5% and 2.1% of gastric tumors, respectively. In pancreatic cancers, the *KRAS* p.G12C mutation is limited to 1-2% of cases. FDA has recently approved drugs targeting both alterations, pemigatinib and infigratinib for cholangiocarcinoma with *FGFR2* fusions; sotorasib and adagrasib for *KRAS* p.G12C mutant lung cancers. Here, we report the initiation of primary cultures that can be used as preclinical models for testing antitumor agents in gastric and pancreatic tumor cells.

Materials and Methods: Pleural effusions were collected from a gastric and a pancreatic cancer patient, both metastatic. Cells were isolated by centrifugation, cultured for 2-3 months in complete medium and genotyped using next generation sequencing (NGS) and RNA nCounter hybridization. Primary cultures were treated with specific drugs depending on their molecular alterations and clinical guidelines. Cell viability was determined by MTT.

Results: Tumor cells from the pleural effusion of the gastric cancer patient were grown in suspension. NGS and nCounter revealed a *FGFR2-TACC2* fusion, a *FGFR2* amplification (160 copies) and a *TP53* p.G245S mutation (100% variant allele fraction, VAF). The fusion and the amplification were confirmed by FISH. Cells were sensitive to erdafitinib, with IC_{50}=40 nM in MTT assays. Irinotecan, 5-fluorouracil and cisplatin were also tested; IC_{50} were below the described plasma C_{max} in the first two cases. The patient was treated with first-line fluoropyrimidine and oxaliplatin with partial response and a 5-month progression-free survival. Due to rapid deterioration, 2nd line treatment was not administered. The tumor cells from the pancreatic cancer patient were adherent, NGS revealed a *KRAS* amplification (9 copies) accompanied by a *KRAS* p.G12C mutation (81% VAF) and a *TP53* p.R175H mutation (99% VAF). MTT assays were performed to determine the cells' response to oxaliplatin, 5-fluorouracil, irinotecan, gemcitabine, nab-paclitaxel, adagrasib and sotorasib. IC_{50}s below plasma C_{max} were found in the last three cases. Remarkably, the IC_{50} for sotorasib was 100 nM and for adagrasib was 300 nM. The patient was treated with first-line gemcitabine and nab-paclitaxel with partial response but discontinued after three months due to hematological toxicity.

Conclusions: Primary cultures can be initiated from malignant pleural effusions and used for genetic characterization and drug sensitivity profiling. Primaries with specific alterations can be employed as preclinical models to test targeted therapies.

#6498 MEK inhibitor mirdametinib suppresses MAP kinase pathway activity and inhibits tumor growth in atypical teratoid/rhabdoid tumors.

Y. Deng, K. Malebranche, T. Findlay, A. Geethadevi, C. Eberhart, J. Rubens, E. Raabe;
Johns Hopkins University School of Medicine, Baltimore, MD

Atypical teratoid/rhabdoid tumors (AT/RT) are deadly infantile brain tumors currently lacking effective treatments. Our prior studies examining AT/RT primary tissues have shown an elevated expression of phospho-ERK, a downstream effector of MEK in the mitogen-activated protein (MAP) kinase pathway. The increased activity of this pathway potentially leads to more aggressive cancer growth, emergence of drug resistance, and poor treatment outcomes in AT/RT patients. Mirdametinib is a novel, highly specific MEK1/2 inhibitor that has been reported to have superior blood-brain-barrier penetration compared to other MEK inhibitors. It is currently in development as a monotherapy for low-grade glioma as well as NF1-related plexiform neurofibromas. We hypothesized that mirdametinib can inhibit AT/RT tumor growth and improve overall survival. We examined the in vitro effect of mirdametinib treatment on five AT/RT cell lines (CHLA04, CHLA05, CHLA06, CHLA266, and BT37). Mirdametinib decreased MAP kinase pathway activity in the tested cell lines (western blot, phospho-ERK). Cell lines treated with mirdametinib exhibited decreased viability at 72hr (Muse Cell Viability Assay, CHLA05 t-test $p=0.011$, CHLA06 t-test $p<0.001$, BT37 t-test $p<0.01$ compared to DMSO control) and lower rates of proliferation (western blot, phospho-RB; BrdU immunofluorescence staining, CHLA05 t-test $p=0.015$, CHLA06 t-test $p<0.0001$, BT37 t-test $p<0.0001$ compared to DMSO control). Furthermore, mirdametinib induced apoptosis in AT/RT cells (western blot, cPARP; Muse Annexin V Assay, CHLA04, CHLA05, CHLA06, and BT37, t-test $p<0.0001$, CHLA266, t-test $p<0.01$ compared to DMSO control; cleaved caspase-3 immunofluorescence staining, CHLA05, CHLA06, and BT37, t-test $p<0.0001$ compared to DMSO control). We then tested the efficacy of mirdametinib in vivo. We treated mice bearing orthotopic CHLA06 tumors with a daily oral delivery of the drug. Mirdametinib treatment significantly extended the survival of treated mice in this very aggressive model (17 to 24 days, log-rank test $p=0.038$ compared to vehicle control) and decreased the expression of phospho-ERK (western blot, phospho-ERK), demonstrating that mirdametinib engaged its target in vivo. Testing against additional AT/RT orthotopic xenografts is currently underway. Our studies suggest that pharmacologically inhibiting the MAP kinase pathway may be an effective strategy to target AT/RT. Mirdametinib can potentially be an effective treatment to help extend survival in this deadly disease.

#6499 The landscape of MET exon 14 skipping mutations in non-small cell lung cancer patients identified by next-generation sequencing.

C. Shi[1], G. Ning[2], Z. Qinglan[2];

[1]Jiangsu Province Hospital of Chinese Medicine, Affiliated Hospital of Nanjing University of Chinese Medicine, Nanjing, China, [2]3D Medicines Inc., Shanghai, China

Background: MET exon 14 skipping mutations (METex14) account for approximately 0.9%-4% in patients with non-small cell lung cancer (NSCLC). The primary detection methods are DNA and RNA-based next-generation sequencing (NGS). However, the effect of amplicon-based library construction (ALC) and capture-based library construction (CLC) on the detection characteristics of METex14 during the NGS process is not yet fully understood. Here we described the landscape of METex14 in NSCLC patients, as identified by NGS using two different library construction methods.

Methods: A total of 6811 samples with NSCLC were enrolled in this study, including 3839 samples performed by DNA-based NGS with CLC, 64 samples performed by RNA-based NGS with CLC and 2908 samples performed by the synchronous DNA-based and RNA-based NGS with ALC. Only the pathogenic mutations and likely pathogenic mutations in clinical significance were rolled into our analysis.

Results: The ranking of different methods, as determined by the positive rates for METex14, was RNA-based NGS with ALC (71/2908, 2.44%), RNA-based NGS with CLC (1/64, 1.56%), DNA-based NGS with CLC (54/3839, 1.41%) and DNA-based NGS with ALC (14/2908, 0.48%). Out of 2908 samples performed by the synchronous DNA-based and RNA-based NGS with ALC, 73 samples (2.51%) had METex14 detected at either the DNA or RNA level. METex14 were only detected at the RNA level in 59 patients, while they were only detected at the DNA level in 2 patients. This might be due to the limited probe design at DNA level and the Y1003 site which could not be detected at RNA level. As revealed by DNA-based NGS, the mutation forms causing METex14 include point mutations, indels, and large segment duplications. And the highest mutation rate is in the splice donor site (30.9%), the lowest is observed at position Y1003 (2.9%). Additionally, METex14 is more prevalent in patients over 60 years of age in Chinese NSCLC, with a statistically significant difference (P=0.0043).

Conclusion: RNA-based detection of MET 14 skipping yielded a higher detection rate compared to DNA-based NGS, regardless of ALC or CLC. Combining DNA and RNA analysis is more suitable for detecting MET exon 14 skipping and increases the positive rate.

#6500 Dependence of EGFR-mutant NSCLC on MET as demonstrated by vebreltinib, a novel and selective brain-penetrating MET kinase inhibitor.

X. Zhang[1], E. Liu[2], Y. Song[1], P. Yu[1], S. Redkar[1], G.-L. Yu[1];

[1]Apollomics, Inc., Foster City, CA, [2]Zhejiang Apollomics Biotech Co., Ltd., Hangzhou, China

Background: Although EGFR inhibitors (EGFRi), preferably osimertinib, have offered substantial benefit for the classical plus T790M EGFR-mutant NSCLC patients, drug resistance develops and poses a critical challenge for long-term survival. The resistance is rooted to either on-target secondary EGFR mutations or compensatory oncogenic pathways bypassing EGFRi intervention, one of which appears to be treatment-acquired *MET* amplification (*MET*amp). In this study we set out to understand the conditions when the tumor cells become dependent on MET.

Methods: NSCLC patient-derived tumor models (PDX) carrying classical and T790M EGFR driver mutations were selected based on EGFRi history and concurrent *MET* gene copy numbers or RNA expression levels: Type 1) resistant to osimertinib with *MET*amp; Type 2) partially resistant to osimertinib with *MET*amp; and Type 3) sensitive to osimertinib with low *MET* expression, no *MET*amp. These PDX xenograft mice were treated with vebreltinib (APL-101) at clinically relevant doses as single agent or in combination with osimertinib. The pharmacodynamic effects on EGFR and MET phosphor (P)- and total proteins were analyzed from tumor samples harvested during and at the end of treatments.

Results: Vebreltinib single agent inhibited tumor growth of the type-1 PDX. One such PDX was resistant to chemotherapies, BRAF inhibitor and EGFRi including osimertinib, was inhibited by vebreltinib with ED50 of 3 mg/kg (p.o/q.d.). Another such PDX tumor appeared to be eradicated by vebreltinib treatment at 10 mg/kg (p.o/q.d.) and the mice became tumor-free on Day 18 and remained so after dosing stop on day 21 with last observation at study end (Day 70). In comparison, reference METi savolitinib showed only partial tumor size reduction against the same PDX tumor, not as durable as vebreltinib, and did not eradicate tumor growth at the same dose as vebreltinib or in combo with Osimertinib. Re-grown tumor after savolitinib osimertinib combo dosing stop was inhibited completely by vebreltinib follow-on treatment. In the type-2 PDX, tumor growth was partially inhibited by vebreltinib but was completely inhibited by combo of vebreltinib and osimertinib. The anti-tumor activity of vebreltinib in type-1 and type-2 PDX was associated with pharmacodynamic inhibition of P-MET and P-EGFR and MET protein degradation. In the type-3 PDX, tumor growth appeared to be eradicated by osimertinib and not inhibited by vebreltinib. However, addition of vebreltinib suppressed tumor re-growth after osimertinib dosing stop.

Conclusion: EGFR-mutant NSCLC resistance to EGFRi may be dependent on MET pathway regardless of acquired *MET*amp, whereas *MET*amp may dictate the degree of MET dependence. Our data supports the hypothesis that adding vebreltinib to EGFRi overcome MET dependent resistance with durable effect or preventing MET dependent resistance to maximize therapeutic benefits.

#6501 Development and characterization of covalent inhibitors of the RAS-PIK3CA interaction.

J. Klebba, J. Tamiya, J. Wang, H. Miao, K. Lamb, A. Snead, A. Esparza-Oros, R. Lin, C. Yue, S. Grabow, S. Bernard, Y. Liu, B. Horning, M. Hoffman, M. Pariollaud, T. Wyrick, H. Parker, J. Sigler, M. Pastuszka, D. Weinstein, T. Kinsella, M. Patricelli;
Vividion Therapeutics, San Diego, CA

RAS proteins are membrane bound GTPases that when hyperactivated, act as oncogenes through activation of the MAPK & PI3K pathways. Each of these pathways has oncogenic potential, as exemplified by the high frequency of BRAF mutations in melanoma and PIK3CA and PTEN mutations in breast and gynecological cancers. Simultaneous activation of these pathways, as occurs in RAS driven cancers, generates aggressive cancers that present a significant clinical challenge. KRAS, the most commonly mutated RAS isoform, is also the most frequently mutated oncogene in cancer. While treatment options have improved for a subset of these patients due to the accelerated approval of KRAS-G12C inhibitors, the rapid development of resistance highlights the continued need for effective treatments. In RAS driven cell and animal models, dual inhibition of the MAPK &PI3K pathways has shown superior efficacy relative to targeting the individual pathways, however dose limiting toxicities in humans have prevented this combination strategy from finding clinical success. While physiological activation of the MAPK pathway is RAS dependent, the interaction between RAS and the catalytic subunit of PI3Kα, PIK3CA, serves as an amplifier but not a primary activator of this pathway. This interaction is particularly important in cancerous cells as it serves to amplify basal PI3K activity and support tumor progression. Conversely, in healthy cells, RAS independent activation of PI3K by upstream signaling factors is sufficient for maintaining physiological homeostasis. Unfortunately, traditional strategies of targeting the PI3K pathway have been unable to capitalize on this therapeutic opportunity as they do not discriminate between RAS dependent and RAS independent signaling. This leads to on-target dose-limiting toxicities, most commonly hyperglycemia and rash. We have discovered small molecules that disrupt the RAS:PIK3CA interaction through covalent ligation of C242, in the RAS binding domain, adjacent to the RAS binding interface. Using a Nanobit system to measure the RAS:PIK3CA interaction and signaling assays in “RAS active” cells, we have optimized molecules that disrupt the RAS:PIK3CA interaction and inhibit RAS mediated activation of PIK3CA. These molecules show robust inhibition of PIK3CA signaling, and tumor growth inhibition in cancer models, but unlike PIK3CA active site inhibitors, they do not impact glucose handling. Profound efficacy is seen when these RAS:PIK3CA inhibitors are used in combination with an agent targeting the MAPK pathway or with a therapy directly targeting mutant KRAS. Finally, we found that ligation of C242 on PIK3CA blocks HER2/3 driven activation of PI3Kα in a RAS independent manner. Overall, our data supports the clinical investigation of these molecules, particularly in combination with rationally chosen therapies where they may provide a tolerable and efficacious means of blocking the PI3K pathway.

#6503 D3S-001, a second-generation GDP-bound KRAS G12C inhibitor, overcomes nucleotide cycling and demonstrates robust preclinical and clinical activities.

J. Zhang[1], S. Lim[2], M. Yu[3], C. Chen[1], J. Wang[1], W. Wang[1], H. Rui[1], J. Lu[1], S. Lu[4], T. Mok[5], Z. Chen[1], B. Cho[2];

[1]D3 Bio (Wuxi) Co., Ltd., Shanghai, China, [2]Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, Korea, Republic of, [3]Yonsei University College of Medicine, Seoul, Korea, Republic of, [4]School of Medicine, Shanghai Jiaotong University, Shanghai, China, [5]Chinese University of Hong Kong, Hong Kong, Hong Kong, China

First-generation KRAS G12C inhibitors [G12Ci(s)], such as sotorasib and adagrasib, are limited by the depth and duration of clinical responses. One potential explanation for their modest clinical activity is the dynamic “cycling” of KRAS between its GDP- and GTP-bound states, raising controversy whether targeting the GDP-bound form can fully block this oncogenic driver. We herein report D3S-001, a second-generation GDP-bound G12Ci with faster target engagement (TE) kinetics, depletes cellular active KRAS G12C at sub-nanomolar concentrations, overcomes nucleotide cycling, and demonstrates durable anti-tumor activities preclinically and in a phase 1 clinical trial (NCT05410145).

Covalent efficiency and TE kinetics were measured by SPR, LC-MS and ELISA. Anti-tumor efficacy was assessed in cell line-derived xenograft (CDX) and patient-derived xenograft or organoid (PDX or PDO) models. Activity in brain metastatic tumors and tumors with acquired resistance to sotorasib was investigated.

Preclinically, D3S-001 exhibited exceptionally high covalent efficiency with a k_{inact}/K_I of 1.43×10^6 $M^{-1}s^{-1}$, the highest among all reported G12Ci(s) to date and a 20- to 70-fold improvement over adagrasib and sotorasib, respectively. In whole cells, D3S-001 depleted GTP-bound active KRAS G12C with an inactivation $t_{1/2}$ of 5.8 minutes, allowing >95% TE (5x $t_{1/2}$) in 30 minutes which is within the time required for epithelial growth factor (EGF) to induce KRAS GDP to GTP transition. By contrast, sotorasib and adagrasib required 3.7 and 2.8 hours, respectively, to reach 95% TE. In the presence of EGF, the ability of sotorasib and adagrasib to block KRAS was compromised by over 55%, whereas TE kinetics of D3S-001 was nearly unaffected, a unique feature differentiating D3S-001 from earlier GDP-bound G12Ci(s). The covalent efficiency of D3S-001 correlated with robust anti-tumor activity at sub-nanomolar concentrations and durable tumor regressions in CDX and PDX/PDO models of different cancer types. In a sotorasib-resistant PDX model, D3S-001 exhibited robust efficacy of tumor regression, while sotorasib and adagrasib showed no effect. Treatment with D3S-001 also resulted in sustained intracranial tumor remission in brain metastasis models.

In the first-in-human trial of D3S-001, durable RECIST responses in patients were observed across all dose cohorts from 50 mg to 900 mg QD. Durable intracranial activity was also observed. Response rate and duration are reported in a companion clinical trial abstract submitted to this AACR meeting.

In conclusion, D3S-001 is a second-generation GDP-bound KRAS G12Ci that overcomes GDP-to-GTP cycling. Its high covalent efficiency and rapid TE kinetics correlated with robust anti-tumor activity preclinically and translated into promising clinical activity with a high response rate and durable responses in a phase 1 trial.

#6504 Exploratory analysis using serial cell-free DNA in patients treated with amivantamab in non-small cell lung cancer with EGFR exon 20 insertion mutations.

Geun-Ho Park, Sehhoon Park, Hyen-Ae Jung, Jong-Mu Sun, Jin Seok Ahn, Myung-Ju Ahn, Se-Hoon Lee

Division of Hematology-Oncology, Department of Medicine, Sungkyunkwan University School of Medicine, Samsung Medical Center, Seoul, Korea, Republic of

Introduction: Epidermal growth factor receptor (EGFR) exon 20 insertion (ex20 ins) mutation showed limited clinical activity with conventional EGFR tyrosine kinase inhibitors (TKIs). Amivantamab is the first bispecific antibody to be approved for the treatment of metastatic non-small cell lung cancer (NSCLC) with EGFR ex20ins mutation. However, limited data is available in terms of predictive biomarkers and the resistance mechanism. In this study, we conducted an exploratory analysis to elucidate a genomic landscape using circulating tumor DNA (ctDNA) from plasma samples.

Patients and Methods: This study include result from 79 blood samples, which has been prospectively collected from 27 EGFR ex20ins mutated NSCLC patients (confirmed by either tissue or plasma-based test) who were treated with amivantamab. ctDNAs were obtained from plasma, which was serially collected at baseline, after 2 cycles of treatment, 2 cycles prior to the treatment discontinuation, and at the time point of disease progression. Guardant OMNI panel (Guardant Health, CA, USA) was used for the genomic profiling.

Results: The median follow-up duration was 5.8 months (range 2.7-12.7). The overall response rate was 40.7% (95% confidence interval [CI] 24.5-59.2, n=11), and median progression-free survival was 5.8 months (95% CI 3.9-15.9) with a median duration of response of 9.8 months (95% CI, 7.3-NA). Patients with EGFR ex20ins not detected from ctDNA at baseline (n=10) showed significantly longer PFS compared to patients with EGFR ex20ins identified at baseline plasma sample (n=17) (14.6 vs 3.9 months; hazard ratio [HR] 0.40, 95% CI 0.17-0.95, P<0.05).The most common concurrent somatic variations at baseline were *TP53* (62.9%), *TERT* (18.5%), *ATM* (18.5%). Longer median PFS was observed in patients without EGFR amplification (n=18) compared to patients with concurrent EGFR amplification (n=9) (11.1 vs. 2.5 months; HR 0.30, 95% CI 0.11-0.77, *P* <0.05).

The presence of plasma EGFR ex20ins at C2D15 predicted poor PFS (17.8 vs 2.7 months; HR 0.17, 95% CI 0.06-0.47, *P* <0.01), regardless of baseline its presence or absence. Based on the paired analysis using baseline and at the timepoint of disease progression, putative resistance mechanism to amivantamab was identified in 14 patients (60.8%), which were *PDGFRB* (28.5%), followed by *PTEN* (21.4%), *CHEK2* (21.4%).

Conclusions: This study provides a comprehensive longitudinal ctDNA analysis in patients with EGFR ex20ins mutant NSCLC who were treated with amivantamab. Our results suggested that the presence of ctDNA for EGFR ex20ins mutation and co-alteration with EGFR amplification at baseline might be related to the clinical outcomes of amivantamab.

#6505 Targeting *PINK1* reduces medulloblastoma progression in animal models.

R. N. Alsubaiee[1], A. Alghamdi[1], B. M. Alrfaei[2];
[1]King Saud University, Riyadh, Saudi Arabia, [2]King Abdullah Internation Medical Research Center, Riyadh, Saudi Arabia

Medulloblastoma is a brain cancer that mainly arises during infancy and childhood. Medulloblastoma is the most common pediatric malignant brain tumor worldwide. It comprises of approximately 20% of all childhood brain tumors and 63% of intracranial embryonic tumors. One of the major effects of proliferating cancer cells is altered mitochondrial metabolism, as well as aberrant metabolism. Medulloblastoma patients suffer severe complications due to intensive and long-term treatments. Thus, we aim to improve applications against medulloblastoma by targeting the *PINK1* gene. We hypothesize that *PINK1* inactivation slows down medulloblastoma progression. PINK1 is a mitochondrial serine/threonine protein kinase that protects cells by controlling mitochondria quality in response to cellular stress. PINK1 recruits parkin to target damaged mitochondria for degradation through autophagy. In this study, *PINK1* has been knocked-out using gene editing technology (CRISPR/Cas9) in two commercial medulloblastoma cell lines (DAOY, and D283 cell lines). We validated *PINK1* editing using RT-PCR and Western blot. Then, cell viability was studied in comparison to the control sample. The control sample contained scramble fragments with empty CRISPR/Cas9. We studied apoptosis and performed cell cycle analysis using flow cytometry. Next, orthotopic medulloblastoma mouse model was generated which showed differential survivals comparing the *PINK1* knockout group and control. The results showed a low expression of *PINK1* within the *PINK1* knockout group. In addition, the Western blot showed reductions in *PINK1* expression in the knockout group. The knockout group showed more apoptosis (cell death) 40% more than the control. The mouse model showed increased survival of the *PINK1* knockout group compared to the control with a p-value of 0.0288 (log-rank). Our analysis shows that survival differences approximately extend human life by one year. We conclude that inhibiting the *PINK1* gene in medulloblastoma decreases cell metabolic activities. *PINK1* Knockout in medulloblastoma enhances the apoptosis pathways. Engrafted medulloblastoma mouse model treated with *PINK1* inhibitor showed superior survival than the control. These results qualify PINK1 to be used as potential therapeutic target for medulloblastoma. The Future work needs additional preclinical studies to investigate the proper dose of *PINK1* inhibitor and measurement of toxicity index.

#6506 SOS1 inhibition in combination with HER2 inhibition in models of HER2-driven cancer.

R. L. Schenk[1], K. Kostyrko[1], J. Popow[1], C. Gewinner[2], A. Baum[1], C. Albrecht[1], M. Hinkel[1], R. Jacob[1], T. Madensky[1], R. Ruzicka[1], E. Strauss[1], H. Lyu[3], A. M. Lopez[3], N. Feng[3], C. P. Vellano[3], J. R. Marszalek[3], T. P. Heffernan[3], M. Pearson[1], M. H. Hofmann[1];

[1]Boehringer Ingelheim RCV GmbH & Co. KG, Vienna, Austria, [2]Boehringer Ingelheim Pharma GmbH & Co.KG, Biberach, Germany, [3]The University of Texas MD Anderson Cancer Center, Houston, TX

Cancers driven by amplifications or mutations of the gene *ERBB2* (coding for the receptor tyrosine kinase (RTK) HER2) have been the focus of HER2-targeting antibodies as well as small molecule inhibitors. Despite initial efficacy, resistance to these HER2-targeted therapies inevitably develops. One strategy to tackle this resistance is to identify rational combinations to address common pathways/factors that contribute to resistance. One such common mechanism of resistance is reactivation of the Mitogen-activated protein kinase (MAPK) pathway. SOS1 is a guanine nucleotide exchange factor (GEF) which regulates the MAPK pathway by catalyzing the exchange of RAS-GDP (inactive) to RAS-GTP (active). SOS1 is activated by multiple different RTKs - upon RTK-ligand binding, autophosphorylation of the RTK recruits the GRB2-SOS1 protein complex to the plasma membrane, enabling the complex to bind and activate RAS-GDP. Given SOS1's role downstream of RTKs and upstream of the MAPK pathway, we sought to investigate the potential of a SOS1 inhibitor (SOS1i) in combination with a HER2 inhibitor (HER2i) in preclinical models of cancer driven by HER2 mutation or gene amplification. Using in vitro and in vivo models we found evidence of added benefit of SOS1i in combination with HER2i, as well as enhanced inhibition of MAPK signaling, as seen by decrease in ERK activation and expression of MAPK effector genes such as DUSP6. Taken together, we propose that SOS1 inhibition combined with HER2 inhibition may be a rational strategy for deeper and more prolonged responses to HER2 inhibitor treatment by preventing resistance via the MAPK pathway.

#6507 Simulation driven identification of combinations for the WEE1 inhibitor Debio 0123 results in synergistic effect with cabozantinib validated *in vivo*.

B. Elek[1], A. V. Chessex[2], L. Piggott[2], O. Papp[1], I. Fekete[1], **D. Veres**[1];
[1]Turbine.AI, Budapest, Hungary, [2]Debiopharm International SA, Lausanne, Switzerland

Introduction: Debio 0123, a potential best-in-class, brain-penetrant, WEE1 inhibitor is being studied as monotherapy and in combination with standard of care therapies in patients with solid tumors in Phase I trials. The compound's mechanism of action enables a wide range of combination treatment options with the aim to increase therapeutic window, and improve treatment outcomes in cancer. WEE1 is a tyrosine kinase that is activated in response to DNA-damage acting at the G2/M and S-phase checkpoints, allowing DNA damage repair before entering mitosis. Inhibition of WEE1 increases cell sensitivity to DNA damaging agents leading to genomic instability and apoptosis. Debiopharm, in collaboration with Turbine set out to identify novel combination opportunities for Debio 0123.
Methods: Two approaches were used to identify synergistic combinations of Debio 0123. (1) an *in vitro* screening panel of 35 cancer cell lines and 70 compounds and (2) using Turbine's proprietary Simulated Cell™ solution. The *in silico* approach combines simulation with machine learning, modelling how thousands of signalling proteins interact thereby characterizing cellular level cancer behaviour and response or resistance to treatment. Millions of simulations can be carried out, identifying responder/resistant cell lines to single-or combined drug treatments, thus informing wet lab screening. Turbine built a comprehensive *in silico* model of WEE1 and associated mechanistic pathways based on scientific literature. Network-based *in silico* avatars of 116 cancer cell lines were established using public/proprietary genomic and transcriptomic data, and trained on *in vitro* dose-response to a representative set of reference compounds. High-resolution combination matrices of 59 compounds and Debio-0123 were tested *in silico*. Synergistic combinations were identified and taken forward to *in vitro* assays and *in vivo* studies.
Results: Sensitizing combinations, including DNA damaging agents as well as targeted therapies were identified using both the *in silico* and *in vitro* screens. Turbine predicted synergistic anti-tumour activity *in silico* between Debio 0123 and cabozantinib. Although previously tested using traditional screening methods, this combination had not been identified as a synergistic combination for Debio 0123. Further *in vitro* testing in multiple cell lines demonstrated synergy between these agents at all doses tested. *In vivo* testing in a CAKI-1 (renal cell carcinoma) model showed moderate monotherapy effects but significant synergy when Debio 0123 and cabozantinib were dosed in combination.
Conclusion: We demonstrated that an *in silico* computational approach to model cancer signalling pathways can complement conventional screening methodologies to identify novel, clinically actionable combination opportunities for Debio 0123.

#6509 GT0486, a novel mTORC1/2 dual inhibitor, exhibits synergistic antitumor efficacy in combination with BTK inhibitors.

X. Hou, H. Yan, X. Zhang, W. Qian, D. Chen, Z. Ren, Y. Tong;
Kintor Pharmaceutical Limited, Suzhou, China

Mammalian target of rapamycin (mTOR), a serine/threonine kinase, is the central signal molecule in regulating cell growth, metabolism, angiogenesis, and survival. The first generation of mTOR inhibitors specifically inhibit mTORC1 but are insensitive to mTORC2 and cannot eliminate the downstream signaling cascade in cancer. GT0486, a second-generation mTORC1/2 dual inhibitor, can selectively suppress mTOR kinase activity while has no inhibitory effect on other kinase receptors. We investigate the anti-tumor efficacy of GT0486 in a variety of tumor cells and xenograft animal models *in vitro* and *in vivo*. The combination effects of GT0486 and BTKi (BTK inhibitor) were also evaluated. Compared with other mTOR inhibitors (GDC-0349, AZD-2014, Rapamycin, GDC-0941, and CC-223), GT0486 exhibits the stronger inhibitory activity on human tumor cells, such as U87(glioma), PC-3(prostate cancer), MDA-MB-468(breast cancer) and Huh-7(liver cancer). In B-cell lymphoma, compared with the CC-223, GT0486 shows greater inhibitory potency against TMD8, DoHH2 and WSU-DLCL2, with IC50 values of 85nM, 96nM and 83nM, respectively. Moreover, in the U87 and the PC-3 xenograft animal models, GT0486 strongly reduced tumor growth in dose dependent manner. High synergistic effects were observed with GT0486 in combination with BTK inhibitors, including Acalabrutinib, Ibrutinib, Zanubrutinib and Orelabrutinib in the BTKi sensitive TMD8 cells. In BTKi resistant DoHH2 cells, GT0486 also enhanced the drug sensitivity of BTKi. The possible biomarkers on the synergistic mechanism were further studied. GT0486 improves the role of BTKi on cell cycle arrest in phase G1. At the same time, the phosphorylation levels of mTOR downstream effectors AKT, 4EBP1 and S6 were dose-dependently downregulated after GT0486 treatment, and a significant reduction were observed when combined with BTKi. These results demonstrate that GT0486 is a promising dual mTOR1/2 inhibitor, which is currently undergoing clinical phase I study in China for the treatment of solid tumors. Strong synergistic effects observed with GT0486 in combination with BTKi in this study might open a way for a novel treatment strategy in clinical trials.

#6510 BPI-511966,a potent and selective HPK1 inhibitor with robust single-agent efficacy for cancer immunotherapy.

Y. Zhang, X. Zhu, W. Wu, Z. Xia, Z. Zou, H. Han, C. Yang, H. Chen, T. Ma, X. Liu, J. Guo, H. Wu, **H. Lan**, L. Ding, J. Wang, Q. Zhou;
Betta Pharmaceuticals Co.,Ltd, Hangzhou, China

Although immune checkpoint inhibitors (ICIs) have become the standard treatment for many types of cancers, a large proportion of patients fail to respond to ICIs. Hematopoietic progenitor kinase 1 (HPK1) has been validated as a negative intracellular immune checkpoint that constrains T-cell activation. Genetic or pharmacological ablation of HPK1 induces a robust anti-cancer immune response *in vivo*, highlighting the potential of HPK1 as a next-generation target for cancer immunotherapy. Herein, we reported the discovery of BPI-511966, a highly potent ATP-competitive HPK1 inhibitor. The compound strongly inhibited HPK1 kinase with an IC_{50} of 2.3 nM at physiologically relevant ATP concentration (1 mM) and reduced phosphorylation of SLP-76, a substrate adaptor of HPK1, in Jurkat T cells *in vitro*, with an IC_{50} value of 11 nM. Development of an optimal HPK1 inhibitor requires not only high potency for target engagement but also high selectivity to spare other kinases that are essential for T cell activation. BPI-511966 showed >100-fold higher IC_{50} (364 nM) against MAP4K3/GLK, an HPK1 homology kinase promoting T-cell activation, and also demonstrated weak inhibition in a panel of other immune-related kinases. The remarkable potency and selectivity of BPI-511966 translate into robust T cell-enhancing efficacy *in vitro*. Treatment with BPI-511966 promoted both IL-2 and IFN-γ production by Jurkat T cell and human PBMC in a dose-dependent manner. The on-target action of BPI-511966 was validated in HPK1-KO Jurkat T cells, in which no significant impacts on SLP-76 phosphorylation and IL-2 secretion were observed. *In vivo*, single dose escalation of BPI-511966 in mice leads to dose-proportional increases in drug exposure, accompanied by inhibition of SLP-76 phosphorylation in peripheral $CD3^{\pm}$ T cells. Furthermore, repeated oral administration of BPI-511966 as a single agent significantly suppressed CT-26 tumor growth in immune-competent mice (92% TGI), correlating with increased infiltration of $CD45^{\pm}$ $CD8^{\pm}$ cells and enhanced cytokine production in tumor. Notably, the efficacy of BPI-511966 is abrogated in immune-compromised mice, suggesting its vital role in promoting anti-cancer immunity. In summary, this study presents a novel, highly potent, and selective HPK1 inhibitor BPI-511966. The robust single-agent activity of BPI-511966 makes it a promising small molecule I/O agent to address ICI resistance as monotherapy or in combination.

#6511 BPI-520105, a highly potent, CNS-penetrant 4th generation EGFR inhibitor overcoming major EGFR resistance mutations in NSCLC.

J. Guo, L. Liu, X. Liu, B. Fu, G. Bai, C. Qiu, W. Ren, X. Song, G. Du, X. Sun, Y. Zhang, W. Cai, P. Wang, H. Chen, X. Liu, Z. Zou, J. Zhao, X. Jv, H. Lan, L. Ding, J. Wang;

Betta Pharmaceuticals Co.,Ltd, Hangzhou, China

EGFR activating mutations are prevalent in 10-50% of NSCLC patients. The most common EGFR mutations, L858R (L) and Del19 (D), initially respond to first-, second-, or third-generation (1G, 2G and 3G) EGFR-TKIs. However, on-target resistance, primarily by T790M (T) and C797X(C), inevitably emerges post-treatment and leads to disease progression. Different treatment sequence give rise to different complex mutations. In patients resistant to the 3G TKI osimertinib, double mutations L858R/ C797X or Del19/C797X (LC or DC) were observed at a frequency of up to 12% after first-line osimertinib, and triple mutations L858R/T790M/C797S or Del19/T790M/C797S (LTC or DTC) were up to 20% after second-line osimertinib. There are no approved targeted therapy options for these complex resistant mutations. In this study, we developed BPI-520105, a 4th generation EGFR inhibitor capable of targeting all aforementioned major forms of EGFR activating and resistance mutations in NSCLC. It might be an optimal way to address this urgent medical need. *In vitro,* BPI-520105 potently inhibited the activity of a variety of EGFR kinases, as well as inhibited the proliferation and EGFR phosphorylation in cell lines bearing relative mutations, including single (D, L), double (DT, LT, and DC, LC) and triple (LTC, DTC) mutations. Meanwhile, BPI-520105 exhibited relative weakness towards wild type EGFR and IGF1R, demonstrating good selectivity in kinase and cell-based assays. Despite being a reversible EGFR inhibitor, BPI-520105 sustained the inhibition of pEGFR and pERK for up to 24 hours in the western blot assay. *In vivo*, oral administration of BPI-520105 displayed significant dose-dependent antitumor effect in multiple EGFR mutant xenograft models, including HCC827 (D), NCI-H1975 (LT), BaF3-EGFR-LC/DC, and BaF3-EGFR-LTC models. Remarkably, BPI-520105 significantly prolonged the lifespan of mice with brain orthotropic BaF3-EGFR-DTC-Luc2 allografts, demonstrating its activity towards brain metastasis. Additionally, BPI-520105 exhibited favorable ADME properties, with high oral exposure across various preclinical species. In summary, BPI-520105 is a highly potent, CNS-penetrant, wide type sparing, and orally bioavailable 4th generation EGFR inhibitor, holding promise for the treatment of NSCLC patients with resistance mutations post 3G progression or even at front line.

#6512 BPI-501836: A highly potent small molecule inhibitor targeting KRAS^{G12D} mutation.

X. Yang, Y. Lu, R. Xu, X. Kong, Y. Sun, X. Zhu, X. Liu, Z. Zou, H. Chen, Y. Liu, J. Sun, H. Han, C. Yang, J. Guo, H. Lan, Q. Zhou, L. Ding, H. Wu, **J. Wang**; Betta Pharmaceuticals Co.,Ltd, Beijing, China

As one of the most notorious un-druggable oncogenes, mutant KRAS impairs the transition of RAS from its active GTP-binding form to the inactive GDP-binding form, leading to sustained activation of downstream MAPK pathway and ultimately tumorigenesis. The recent approved KRAS^{G12C} inhibitors have demonstrated clinical benefits in KARS^{G12C} mutant patients. However, the other prevalent KRAS mutations, such as KRAS^{G12D}, remain a huge unmet medical challenge. There's no approved KRAS^{G12D} specific inhibitors yet. Here we present BPI-501836, a highly potent and selective small molecular inhibitor for KRAS^{G12D}. *In vitro,* BPI-501836 exhibited very high potency by disrupting the KRAS^{G12D} and cRAF interaction in a cell-free assay. In cell-based assays, BPI-501836 inhibited proliferation of KRAS^{G12D} mutant cell lines with sub-nanomolar IC_{50} values, without affecting wide type or non-G12D KRAS mutant cell lines. Moreover, it also attenuated ERK phosphorylation in KRAS^{G12D} mutant cells. *In vivo*, tumor regression was observed following the administration of 6 mg/kg (iv, QW) BPI-501836 in KRAS^{G12D} human pancreatic Panc04.03 xenograft mouse models, or in the KRAS^{G12D} human pancreatic PK-59 xenograft mouse models with an intraperitoneal injection of 20 mg/kg per week. Noteworthy was the prolonged half-life of BPI-501836 observed across various species, coupled with its high distribution in tumor tissues. Moreover, sustained suppression of ERK phosphorylation in tumor tissues persisted for up to 144 hours after the last dose of BPI-501836 in both xenograft mouse models. This extended pharmacodynamic effect supports the feasibility of a once-weekly dosing schedule in clinical applications. Safety assessments conducted through a 4-week repeated infusion (intravenous, twice weekly) of BPI-501836 in beagle dog demonstrated favorable safety profiles. In conclusion, BPI-501836 emerges as a highly potent and selective KRAS^{G12D} inhibitor, exhibiting promising pharmacokinetics, pharmacodynamics, and safety profiles in pre-clinicalstudies. BPI-501836 is currently in IND-enabling stage and holds potential for further development as a therapeutic agent.

#6513 Discovery and characterization of a KRAS$^{G12C/D/V}$ degrader with potent anti-tumor activity in KRAS^{mut}-driven preclinical models.

Z. Li, R. Xu, X. Yang, Z. Zou, X. Kong, H. Chen, Y. Sun, Y. Zhao, J. Guo, C. Yang, H. Han, X. Liu, H. Lan, L. Ding, Q. Zhou, H. Wu, **J. Wang**;
Betta Pharmaceuticals Co.,Ltd, Beijing, China

KRAS mutations are one of the most common oncogenic drivers for multiple cancers. KRAS^{G12X} mutations are identified in approximately 25% of lung cancer, 24% of colorectal (CRC), and 79% of pancreatic ductal adenocarcinoma (PDAC). Although the approval of Sotorasib in 2021 by the FDA partially addressed the needs of patients with KRAS^{G12C} mutant, other mutations, such as G12D and G12V, still lack effective target therapies. Here, we report RD0255359, a proteolysis targeting chimera (PROTAC) KRAS$^{G12C/D/V}$ degrader with highly potent cell viability and KRAS$^{G12C/D/V}$ degradation ability. *In vitro*, RD0255359 exhibited a remarkable KRAS degradation property in NCI-H358 (G12C), AGS (G12D), and SW620 (G12V) cell lines at concentrations below 10 nM. RD0255359 suppressed the proliferation of these cells with nanomolar IC_{50} without affecting the viability of KRAS^{WT} or KRAS-independent cell lines. Meanwhile, using protease inhibitor MG132 or corresponding ligand pretreatment and VHL^{KD}-AGS cell experiment confirmed that RD0255359-induced KRAS degradation was VHL and UPS dependent. *In vivo*, weekly IV injection of 1-10 mg/kg RD0255359 led to tumor growth suppression or tumor regression in PK-59 PDAC xenograft model. The *in vivo* PK/PD demonstrated that durable KRAS degradation could be achieved with once- weekly IV injection. Notably, after injection, the drug can distribute into tumor tissue rapidly and abundantly, and maintaining a high concentration till the next administration. Taken together, RD0255359 is a highly potent and selective KRAS$^{G12C/D/V}$ degrader with favorable PK properties. It exhibits a promising therapeutic index in preclinical studies.

CLINICAL RESEARCH: Tumor Microenvironment and Cancer Immunity
Poster Session

#6516 Single-cell protein activity inference reveals lymphocytic immune infiltration in diffuse intrinsic pontine glioma induced by focused ultrasound.

E. White[1], H.-J. Wei[2], E. Fernandez[2], H. Minns[2], J. Pavisic[2], R. Gartrell[2], C.-C. Wu[2], A. Califano[2], **A. Obradovic**[2];
[1]Columbia University, New York, NY, [2]Columbia University Irving Medical Center, New York, NY

Diffuse intrinsic pontine glioma (DIPG) is a highly aggressive pediatric brain tumor, located in the brainstem, and traditionally thought to be immune-excluded with no significant infiltration by cytotoxic T-cells, and therefore not amenable to immunotherapies. Focused ultrasound technology (FUS) for drug delivery is being investigated for DIPG in both preclinical and clinical trial settings. In this study, we sought to study the effects of FUS and radiation therapy (RT) on immune cell infiltration in DIPG tumors to assess their ability to alter the immune microenvironment and potentially enhance combination immunotherapies. Specifically, we generated single-cell RNAseq profiles for 27,780 cells from syngeneic orthotopic DIPG tumors (KPAP cell line containing H3K27M mutation, ATRX and P53 loss, and PDGFRA overexpression) after 14 days of tumor growth across the following treatment arms: vehicle control, FUS, and RT (n=2 each group). FUS was applied by 4-point sonication around the tumor with a pressure of 0.6 Mpa at days 8 and 11 post tumor implantation (PTI). RT was administered in fractions of 3 Gy daily from days 8 to 11 PTI (12Gy total). We leveraged a set of algorithms for network-based inference of regulatory protein activity to infer a set of context-matched gene regulatory networks from which protein activity can be inferred by expression of downstream targets. By this approach, we identified distinct clusters of immune cells segregating by cell type as inferred by singleR and activity of known lineage markers. Strikingly, we found that both RT and FUS significantly depleted a TGFb-expressing population of immune-suppressive macrophages as compared to vehicle controls. Importantly, FUS only additionally increased T-cell infiltration into the tumor micro-environment over three-fold as compared to vehicle controls, which was not observed in response to RT. Further protein validation is underway. This has significant implications for therapeutic combinations of FUS-mediated drug delivery with immune checkpoint inhibitors in DIPG, such that in addition to drug delivery, FUS-mediated immune modulatory effects may provide more proinflammatory response to enhance immunotherapy.

#6517 ALDOC as an indicator of HMGB1 blockade combined with checkpoint inhibitor based immunotherapy in GBM patients.

Y.-F. Yang[1], M.-H. Chan[2], C.-L. Chen[3], M. Hsiao[4], **Y.-C. Chang**[2];
[1]Kaohsiung Veterans General Hospital, Kaohsiung, Taiwan, [2]National Yang Ming Chiao Tung University, Taipei, Taiwan, [3]Taipei Medical University Hospital, Taipei, Taiwan, [4]Academia Sinica, Taipei, Taiwan

Aldolase is an enzyme that takes part in glycolysis by catalyzing a six-carbon intermediate to yield two three-carbon products, requiring ATP. The aldolase family comprises three members, namely ALDOA, ALDOB, and brain-specific ALDOC. Low-grade gliomas and glioblastoma (GBM) are characterized by shared genetic events, including chromosome 1p/19q codeletion, EGFR amplification, and ATRX loss of function, in which ALDOC plays a role. Additionally, ALDOC is responsive to IDH1 mutations. If patients display IDH1 mutations, it is expected that ALDOC performance will be relatively higher. This finding suggests a more favorable prognosis. The ALDOC promoter region's function is impeded by hypermethylation, which declines as glioma progresses. The regulatory mechanisms and implications remain unclear. We established a multi-omics profile and identified several crucial mechanisms activated upon the loss of ALDOC expression. Among these mechanisms, we found HMGB1 to have a key role in linking the immune response, tumor microenvironment, and epigenetic modifications. We compared the proteomic and secretomic platforms in an ALDOC overexpression/knockdown model, which showed abundant HMGB1 expression following ALDOC inhibition. Importantly, there is an inverse correlation between ALDOC expression and HMGB1 protein levels. Additionally, our findings reveal that upregulation of ALDOC promotes its translocation to the nucleus, thereby enhancing its binding affinity with HMGB1. This, in turn, enables extracellular release of HMGB1 in GBM, which triggers signaling via receptors for advanced glycation end-products (RAGE) and several cytokines. Moreover, HMGB1 remodels the immune microenvironment and upregulates multiple immune checkpoint molecules, including PD-L1, PD-L2, B7-H3, and MHCs. Not all GBM models exhibited significant effects when combined with immune checkpoint blockade using HMGB1 blockade. However, ALDOC knockout mice demonstrated poorer survival and treatment efficacy, suggesting that ALDOC may be crucial for a personalized immunotherapy strategy.

#6518 BPM 31510: Targeting the tumor microenvironment (TME) via mitochondrial-mediated ROS production.

S. Gesta[1], M. D. Nastke[1], S. Nagpal[2], L. Recht[2], M. A. Kiebish[1], N. R. Narain[1], V. R. Modur[1];

[1]BPGbio Inc., Framingham, MA, [2]Stanford University, Palo Alto, CA

The tumor microenvironment (TME) consists of an enriched population of immune cells and milieu of factors that modulate key cellular processes such as angiogenesis, metabolism, apoptosis, migration, and proliferation. Previous studies have suggested that BPM 31510 induces ROS through high intra-cellular levels of ubidecarenone in aggressive cancer phenotypes both *in vitro* and *in vivo* through induction of mitochondrial ROS. Furthermore, we have previously observed efficacy of BPM 31510 in a highly aggressive *in vivo* orthotopic rat C6 glioma model where BPM 31510 was administered in combination with radiotherapy. In a pancreatic xenograft mouse model, we previously reported that BPM 31510 impacted the immune cells in the TME by increasing absolute number of infiltrated CD8+ T-cells and decreasing absolute number of infiltrated CD4+ T-cells. Moreover, an *ex vivo* study of PBMC's from healthy volunteers suggests that BPM 31510 increases T-cell viability and function while also decreasing T-cell exhaustion. Currently, an ongoing first-line phase 2b study of BPM 31510 in glioblastoma in combination with radiotherapy and temozolomide will assess the clinical efficacy and potential for mechanistic synergy of multiple ROS-inducing mitochondrial mediated regimens on this aggressive cancer phenotype. BPM 31510 will be assessed in this study to provide further evidence for the impact of ROS on immunomodulation. Taken together, BPM 31510 increases mitochondrial ROS/OXPHOS in cancer cells while impacting TME-related immune cell modulation.

#6519 Dendritic cell vaccine cell numbers and survival in patients with primary glioblastoma.

R. O. Dillman, G. I. Nistor, K. Godding, R. Robles, H. S. Keirstead;
AIVITA Biomedical, Inc., Irvine, CA

Standard glioblastoma (GBM) treatment is associated with poor survival. A promising novel immunotherapy consists of autologous dendritic cells (DC) pulsed with autologous tumor antigens (ATA) from a lysate of irradiated self-renewing autologous cancer cells. An open-label, phase 2 trial was conducted in 57 patients with primary GBM. Here we report correlations between survival and DC-ATA doses. Two autologous intermediate products were manufactured for each patient: a tumor cell line established from resected GBM, and DC differentiated from cryopreserved peripheral blood monocytes (MC). Patients were enrolled prior to standard radiation therapy (RT) and temozolomide (TMZ) chemotherapy. DC-ATA were manufactured during RT/TMZ, divided into individual doses, then cryopreserved in liquid nitrogen. For each patient-specific vaccine batch, cell numbers were calculated using a hemocytometer; viability was determined before cryopreservation (cryo) using trypan blue and post-cryo using 7ADD per flow cytometry. After RT/TMZ, up to 8 doses were injected s.c. concurrent with TMZ over 6 months. Patients were grouped into tertiles based on DC-ATA cell numbers and survival. Prism 10.03 was used to generate survival curves and calculate correlation coefficients and log-rank and T-Test comparisons. As previously reported, cell line success rate was 71/73, sufficient MC numbers were collected by leukapheresis for 63/65; DC-ATA was successfully manufactured for 60/60; 57 patients were treated; median progression free survival (PFS) and overall survival (OS) were 10.4 and 16.0 months respectively. Correlations were strong between total and viable DC-ATA pre-cryo (0.97, $p<0.0001$) and post-cryo (0.95, $p<0.0001$), but weaker between DC-ATA pre- and post-cryo (0.30, $p=0.02$), and between viable DC-ATA pre- and post-cryo (0.37, $p=0.004$). When patients were grouped by OS tertiles, medians were 9.8, 18.1, and more than 36 months. There were no differences in the average millions (M) of DC-ATA pre-cryo (10.0, 9.7, 9.6), viable DC-ATA pre-cryo (8.5, 7.8, 7.9), DC-ATA post-cryo (9.0, 10.3, 10.8) or viable DC-ATA post-cryo (6.0, 7.3, 7.4). Similarly, when patients were grouped into tertiles by DC-ATA numbers, there were no differences in OS curves associated with DC-ATA pre-cryo, viable DC-ATA pre-cryo, DC-ATA post-cryo, or viable DC-ATA post-cryo. Pre-cryo viable DC-ATA numbers ranged from 0.27 to 27.0 M. An ineffective dose was not identified; pre-cryo viable DC-ATA doses of less than 2M were associated with OS of 10.4, 13.0, 13.3, and 36.4+ months. Also, there was no OS difference by number of MC used to manufacture DC or by number of DC manufactured. In conclusion, there was no evidence for a dose/response relationship between DC-ATA dose and OS for any of the parameters tested. This data supports that pre-cryo cell counts can be used to establish treatment doses. Pre-cryo viable cell counts of 2M DC-ATA per dose seem sufficient.

#6520 Clinical verification oftherelationship betweenserum lipid metabolism andtumor immune microenvironment inpostmenopausal hormone receptor-positive/HER2-negative breast cancer patients.

W. Goto, H. Matsuda, S. Henmi, M. Nishikawa, A. Kouchi, R. Kouhashi, A. Yabumoto, K. Takada, Y. Tauchi, K. Ogisawa, T. Morisaki, S. Kashiwagi; Osaka Metropolitan University, Abenoku, Osaka, Japan

Background: Recently, some basic research has reported that the tumor immune microenvironment (TIME) is related to the therapeutic efficacy and prognosis of breast cancer patients, and that the regulation of metabolism can affect TIME and enhance antitumor immunity. Suppression of aromatase expression from adipose tissue is the standard adjuvant endocrine therapy for postmenopausal hormone receptor (HR)-positive/human epidermal growth factor receptor 2 (HER2)-negative breast cancer, but few studies have examined the impact of controlling lipid metabolism on TIME and cancer prognosis.
Materials and Methods: Except for patients with ductal carcinoma in situ, 531 postmenopausal HR-positive/HER2-negative breast cancer patients treated with curative surgery between 2011 and 2017 were examined. Serum lipid levels and systemic immune-related markers were evaluated by blood samples, and tumor-infiltrating lymphocytes (TILs) in cancer tissue samples were investigated by immunohistochemistry. We also examined the relationship between lipid metabolism, TIME, and prognosis, respectively.
Results: Good serum lipid control group was significantly correlated with low neutrophil- to-lymphocyte ratio (NLR) ($p = 0.024$) and high TILs ($p = 0.039$). The median follow-up time for the assessment of prognosis was 5.5 years, and 67 patients had recurrence. Only patients treated with aromatase inhibitor as adjuvant endocrine therapy showed significantly better recurrence-free survival (RFS) in the good lipid control group ($p = 0.025$, log-rank). Also, multivariate analyses showed that good serum lipid control was an independent prognostic factor for recurrence (HRs = 4.722, 95%CI: 1.006-22.161, $p = 0.049$). Patients with high CD8/FOXP3 ratio (CFR) had significantly better RFS ($p=0.027$, log-rank) and tended to have good lipid control.
Conclusions: Good control of serum lipid metabolism may inhibit the acquisition of resistance to endocrine therapy by improving TIME and induce favorable outcome in postmenopausal HR-positive/HER2-negative breast cancer patients.

#6521 Macrophage-targeting immunotherapy enhances chemotherapy response in primary and metastatic triple-negative breast cancer models.

M. E. Fernandez, Y. Alshehry, L. Graham, J. E. Koblinski, H. D. Bear, D. H. Sweet, S. R. P. da Rocha;
Virginia Commonwealth University - VCU, Richmond, VA

Triple-negative breast cancer (TNBC) is a highly aggressive breast cancer subtype that lacks targeted treatment options. While immune checkpoint blockade leads to significant benefits in the treatment of TNBC when in combination with chemotherapy, recurrence, metastasis, and chemoresistance still remain major challenges. The purpose of this study was to assess the ability of a colony-stimulating factor 1 receptor inhibitor (CSF-1Ri) to shift the phenotype of the tumor microenvironment (TME) in murine models of TNBC, and the potential benefit of such in enhancing standard of care chemotherapy. We focused on targeting tumor-associated macrophages (TAMs) as they are the most abundant immune infiltrate in the TNBC TME and are associated with worsening overall survival (OS) and metastasis free survival (MFS). Targeting TAMs, specifically M2-like TAMs, has been shown to inhibit tumor progression and improve OS in the clinic. We selected pexidartinib (PLX) as the CSF-1Ri of choice, given its translational potential (FDA approved) and gemcitabine (GEM) as chemotherapy, given its ability to target myeloid derived suppressor cells and M2-like TAMs. For primary TNBC we employed 4T1 mammary carcinoma cells transfected with luciferase reporter gene in BALB/c mice as an immunocompetent model. Mice were injected with 100,000 cells in the 4^{th} mammary fat pad, and tumors established over the course of fifteen days. Mice were then exposed to daily administrations of PLX (8 mg/kg), and weekly administrations of GEM (60 mg/kg). Tumor volumes were recorded every other day. The TME was analyzed with flow cytometry (FC), immunohistochemistry (IHC), and multiplex immunofluorescence (mIF). For the metastatic model, mice were inoculated with 100,000 4T1-luc cells in the flank. On day six, mice were exposed to treatments as outlined above. Mice underwent survival surgery to remove the primary tumor on day thirteen and were then treated with adjuvant therapy. Metastasis and OS were tracked. FC analysis indicated only combination therapy (11.8% ± 2.1) significantly decreased total TAMs compared to vehicle (22% ± 2) in the primary tumor. Combination therapy also showed the greatest depletion of M2-like TAMs (2.2% ± 0.6), with a significant decrease compared to both vehicle (15.6% ± 0.4) and GEM (6.6% ± 0.9). This TME modulation was confirmed using IHC and mIF. After four cycles of treatment, combination therapy (232.9 mm^3 ± 130.8) had a significant effect on tumor burden compared to GEM alone (369.7 mm^3 ± 165.8), indicating a correlation between tumor phenotype and therapeutic benefit. Furthermore, combination therapy led to the greatest prolongation of MFS and OS in the resection model, indicating that combination therapy has efficacy in the neoadjuvant and adjuvant setting. In conclusion, targeting TAMs in TNBC primes the tumor for combination with chemotherapy in TNBC.

#6522 Epigenetic modulation decreases myeloid suppression to improve response to immune checkpoint inhibition in breast cancer.

A. G. Baugh[1], E. Gonzalez[1], J. Kreger[2], Y. Liu[2], B. Al-Zubeidy[1], L. Danilova[3], S. M. Shin[3], V. H. Narumi[1], S. Castanon[1], J. Jang[1], E. J. Fertig[3], A. Cimino-Mathews[3], E. M. Jaffee[3], V. Stearns[3], R. M. Connolly[4], W. Ho[3], A. MacLean[2], **E. T. Roussos Torres**[1];

[1]Keck School of Medicine, University of Southern California, Los Angeles, CA, [2]University of Southern California, Los Angeles, CA, [3]Johns Hopkins University, Baltimore, MD, [4]University College Cork, Cork, Ireland

Immune checkpoint inhibitors (ICIs) promote a durable anti-tumor immune response. Unfortunately, many patients with breast cancer are thought to be intrinsically resistant. One potential mechanism of resistance is a myeloid suppressed tumor microenvironment (TME). Targeting myeloid suppression is under investigation as a therapeutic strategy to sensitize tumors to ICI. In our trial, NCI-9844, we demonstrated that the combination of the epigenetic modulator, entinostat with ICIs—nivolumab (anti-PD-1) + ipilimumab (anti-CTLA-4), leads to a 25% objective response rate in patients with advanced breast cancer. Work in our preclinical models showed entinostat decreases suppressive function by myeloid derived suppressor cells (MDSCs). We hypothesized that entinostat decreases intra-tumoral MDSC suppression via the STAT3/AP-1 axis and drives cellular shifts within the TME to improve response to ICI. Here, we examined expression of upstream, downstream, and interacting factors within the STAT3 pathway in MDSCs treated with entinostat. Macro-dissected lung metastases from entinostat treated NeuN mice revealed differential gene expression of AP-1 subunits JunB and FOSL1 in MDSCs identified by single cell RNA sequencing (scRNAseq). Western blot of isolated intratumoral MDSCs from lung metastases revealed decreased STAT3 phosphorylation upon entinostat treatment. In an entinostat treated MDSC-like cell line, J774M, JunB phosphorylation and FOSL1 were both decreased. scRNAseq also revealed decreased gene expression of STAT3 upstream receptors IL4RA and IFNGR1 and increased expression of STAT3 negative regulator SOCS3. Chromatin immunoprecipitation sequencing is planned to further narrow the molecular mechanism of action. Cell-cell communication analysis of scRNAseq data was performed to evaluate the contribution of entinostat treated macrophages, dendritic cells (DCs), and natural killer (NK) cells on MDSC function. We observed increased frequency of DC populations (classic DC2s and Ccr7 DCs). Following combined treatment with entinostat + ICIs, we also found increased DC to T cell signaling strength for receptor-ligand pairs involved in T cell activation, including Tnfsf9__Tnfrsf9, Cd70_Cd27, H2-dmb2_Cd4, and Cd80_Cd28. Analysis of macrophage-T cell interactions revealed a synergistic decrease in signaling associated with immunosuppression after combined treatment, such as Cd80_Ctla4, Tnf_Tnfrsf1b, and Entpd1_Adora2a. Suppressive function of treated sub-populations of macrophages is planned to determine functional effect of findings. Finally, we are using imaging mass cytometry and bulk RNA sequencing to evaluate proposed mechanisms in patient specimens (NCI-9844). The goal of this work is to identify the molecular and cellular mechanisms driving myeloid suppression of the TME thereby identifying potential therapeutic targets.

#6523 TOX upregulation promotes a GPX4-dependent CD8$^{\pm}$ T cell ferroptosis in tumor microenvironments.

J. Li, Q. Zhu, X. Liu;
Sun Yat-sen University Cancer Center (SYSUCC), Guangzhou, China

Frequency and function of CD8$^{\pm}$ tumor-infiltrating T cells (TILs) decide on clinical outcome of cancer immunotherapy; and TOX function as a crucial regulator of TIL dysfunction. In the present study, we found that multiplex factors, such as tumor cell, viral antigens and hypoxia, in tumor microenvironments (TME) induced CD8$^{\pm}$ TIL ferroptosis by upregulating TOX. Single cell RNA-sequencing revealed that TOX modulated *Havcr2, Pdcd1, Hmox1, Gpx4,* and *Ctsb* transcription in human and murine CD8+ TILs. We further generated TOX conditional knockout in CD8+ T cell ($Tox^{flox/flox}Cd8^{Cre}$, CKO) mice and the tumor-bearing CKO mice exhibited increased anti-tumor immunity and survival time. TOX upregulation increased reactive oxygen species (ROS), lipid peroxidation, and ferrous iron, leading to a GPX4-dependent CD8$^{\pm}$ T cell ferroptosis. Genetic or antibody ablation of TOX, TIM-3, or HO-1 indicated that these molecules orchestrated CD8$^{\pm}$ TIL ferroptosis by inducing iron overload and lipid peroxidation. Targeting TOX, PD-1, TIM-3, or ferroptosis boosted the anti-tumor suppression of tumor-specific T cell-based adoptive cell therapy (ACT) in murine tumor model. TOX, TIM-3 and GPX4 were prognostic predictors in human cervical cancer. This finding identifies a novel mechanism of tumor-induced CD8$^{\pm}$ T cell ferroptosis underwent by TOX that provides new insights in improving TIL-based ACT immunotherapy.

Key words: TOX, CD8$^{\pm}$ T cells, ferroptosis, tumor microenvironments, cancer immunotherapy

#6524 Single-cell landscape of cancer-associated fibroblasts in immunotherapy resistance of hepatocellular carcinoma.

P. P. Wong, J. Cao, Z. Xiong, H. Wu, Q. Cao, B. Chen, K.-F. To, S. L. Chan, W. Kang, A. S. Cheng;
Chinese University of Hong Kong (CUHK), Hong Kong, Hong Kong

Introduction: The advent of immune checkpoint blockade (ICB) therapy has revolutionized the treatment approach for hepatocellular carcinoma (HCC). However, the response rate to ICB therapy remains low (below 20%). This limited response rate can be attributed to the considerable heterogeneity observed in HCC cells and the tumor microenvironment (TME). Recent research has highlighted the pivotal role of cancer-associated fibroblasts (CAFs) in orchestrating various components within the TME of HCC. Although the significance of lipid metabolism-associated CAFs in the efficacy of ICB therapy has been demonstrated in HCC murine models [1], the functions and contributions of other CAF subtypes remain largely unknown. Therefore, identifying CAF heterogeneity could advance our comprehension of HCC TME and potentially augment ICB efficacy.

Methods: We performed single-cell RNA sequencing on tumor biopsy specimens obtained from patients with advanced HBV-related HCC who had participated in a pembrolizumab (anti-PD1) phase II clinical trial (NCT03419481). Our objective was to examine the dynamic alterations in the HCC TME before and during anti-PD1 treatment (upon 2-cycle). We utilized the Seurat and Cellchat packages for bioinformatics analysis which enabled us to investigate the associations between changes in the proportions of CAF subtypes and the patients' clinical responses, as well as the potential cell-cell interactions involving CAF and other TME components.

Results: We identified four CAF subtypes within the TME: cycling, inflammatory, matrix, and vascular CAFs in our anti-PD1 HCC patient cohort. Among the anti-PD1 non-responders, there was a significant increase in the proportions of cycling CAFs (cCAFs) and matrix CAFs (matCAFs) compared to the responders. Notably, matCAFs exhibited a high enrichment of Gene Ontology (GO) Terms related to the extracellular matrix (ECM), whose higher proportion correlated with poor prognosis of patients. Moreover, a distinct collagen pathway signal was found between matCAFs and two immunosuppressive cell types, namely regulatory T cells and M2 macrophages in the non-responders.

Discussion and Conclusion: The presence of matCAFs within the HCC tumor may associate with the development of an immunosuppressive TME and unfavorable prognosis for patients. Targeting this specific CAF subtype holds promise as a potential strategy to overcome resistance to ICB therapy.

Acknowledgments: The CUHK Strategic Seed Funding for Collaborative Research Scheme and The Li Ka Shing Foundation.

#6525 Modulating the immune response in cholangiocarcinoma: Targeting sulfatase-2 for therapeutic intervention.

T. R. Brooks[1], N. Campbell[2], M. Keim[2], L. R. Roberts[2];

[1]Mayo Clinic Graduate School of Biomedical Sciences, Rochester, MN, [2]Mayo Clinic, Rochester, MN

Cholangiocarcinoma (CCA) is an aggressive epithelial malignancy of the bile ducts. Recent reports have suggested a rise in the incidence of CCA globally. Current treatments for CCA have limited effectiveness, with only 20-30% response rates in patients with advanced cancer. Thus, there is a growing need to investigate new therapeutic targets for CCA. The tumor microenvironment (TME) is a potential target for novel therapies. The TME plays an important role in progression and metastasis of cancer through facilitating immune escape. Recent studies have demonstrated potential roles for heparan sulfate proteoglycans (HSPGs) in tumorigenesis. Sulfatase 2 (SULF2) is a heparan sulfate editing sulfatase that removes the 6-O sulfate moiety within the heparan sulfate (HS) chains and alters the affinity of HS chains for growth factors and cytokines and their receptors, thus modulating HSPG function in cell signaling pathways. HSPG specific sulfatases have been recently identified as a potential therapeutic target in CCA. We aimed to assess the effects of anti-Sulfatase-2 antibody on immune cells in the tumor microenvironment of syngeneic CCA xenografts in C57BL6 mice. Mice bearing syngeneic CCA xenografts were treated with an anti-sulf2 antibody, and the tumors compared to untreated control xenografts. After treatment, the tumors were harvested and analyzed by Cytometry by time of flight (Cytof) to identify changes in the types and numbers of immune cells in the tumor xenografts. Treatment with anti-sulf2 antibody resulted in a decrease in immunosuppressive cells such as tumor associated macrophages (TAMs) and myeloid derived suppressor cells (MDSC) compared to the control. There was also an increase in anti-tumor cells such as T-cells and NK cells, suggesting that suppressing sulf-2 in the microenvironment can shift the TME toward an anti-tumorigenic rather than a pro-tumorigenic environment. In summary, our work demonstrates the potential to target Sulfatase 2 as a therapeutic mechanism for immunomodulation of the tumor microenvironment. Future experiments to determine the relationship between specific clinical phenotypes and the number, activities and types of immune cells seen in the TME, and experiments in other hepatobiliary cancers models, such as hepatocellular carcinoma and gallbladder cancer, will be conducted.

#6526 Spatial characterisation of the tumour immune microenvironment in ARID1A-deficient gastric cancer.

Norbert Sheng Cong Tay[1], Yan Fen Peng[1], Heike Grabsch[2], Anand D. Jeyasekharan[1]

[1]Cancer Science Institute of Singapore, Singapore, Singapore, [2]Pathology, Maastricht University Medical Center, Maastricht, Netherlands

AT-Rich Interacting Domain 1A (ARID1A) is an important component in SWI/SNF Complex, a chromatin remodeller and an established tumor suppressor gene that is mutated in a variety of cancer types. This includes endometrial (~45%), bladder (~20%), and gastric (~15%). ARID1A mutations usually lead to a loss of protein expression or function, which results in tumor progression. The loss of ARID1A has been linked to genomic instability, potentially making the tumor more immunogenic/ amenable to immune checkpoint inhibitor therapy. However, there is a discrepancy between clinical and mechanistic studies in determining the consequence of ARID1A-loss on the tumor immune microenvironment (TIME): clinical studies have shown that ARID1A mutation is a potential predictive biomarker for immunotherapy success, whereas another mechanistic study found that ARID1A-loss results in a cold TIME that is less amenable to immunotherapy. Considering this controversy, our overarching objective is to use multiple high-dimensional microscopy-based techniques to robustly and comprehensively characterize the TIME sculpted by ARID1A-loss. We study this in the context of gastric cancer, a disease which has heterogenous responses to PD-1 based immunotherapy and also shows frequent (10-25%) mutations in ARID1A. We looked at two retrospective cohorts with 250 patients each, one from UK (Leeds) and one from Japan (KCCH). To ascertain ARID1A-loss in these patients, we have set up an IHC-based assay comparing ARID1A expression between tumor and stroma regions. From this, we derive a ratio. In both studies, we were able to clearly stratify the cohort into ARID1A-loss and ARID1A-wildtype. Leeds had about 23 cases (10%) of ARID1A-loss, while KCCH had 39 cases (17.9%). Looking at the clinical parameters, we realized that ARID1A-loss does not stratify for survival nor staging of the tumor, which is also seen in ARID1A-mutation studies. Using multiplex immunohistochemistry (IHC), we saw differences in the immune cell population. ARID1A-loss patients seem to have a greater proportion of CD3+ cells in the Leeds (1423 vs 666 cells/mm^2, p = 0.0269) and KCCH cohorts (1457 vs 1268 cells/mm^2, p = 0.1745). Interestingly, CD68+ cells also show an increase in the ARID1A-loss population in the Leeds (802.1 cells/mm^2 vs 580.3 cells/mm^2, p = 0.0649) and KCCH cohorts (659 vs 623.2 cells/mm^2). However, CD20+ cells show no changes in abundance for either cohort (249.1 vs 193.2 cells/mm^2, p = 0.4985; and 361.6 vs 357.5 cells/mm^2, p = 0.9634) respectively. Overall, there seems to be an increase in the T-cell population in ARID1A-loss tumors and an increase in the macrophage population in stroma regions of ARID1A-loss tumors. The B-cell population remains unchanged. To complement our preliminary findings, we will leverage hyperplex and spatial transcriptome techniques to uncover the interactions between tumor cells and the TIME.

#6527 Fucosyltransferase 5 promotes immune evasion in ovarian cancer by suppressing double negative T cells.

S. Fung[1], S. To[1], A. Hassan[2], P. Ip[2], A. Wong[2];
[1]Laboratory for Synthetic Chemistry and Chemical Biology, Hong Kong, China, [2]The University of Hong Kong, Hong Kong, China

Emerging evidence suggests that aberrant glycosylation in cancer impact on various stages in the disease progression including immunomodulation, but the underlying mechanisms remain poorly understood. Our previous data demonstrated that fucosyltransferase 5 (FUT5), a glycosyltransferase responsible for the terminal step in synthesizing Lewis antigens, may contribute to peritoneal metastasis of ovarian cancer. In this study, using clinical samples of high grade serous ovarian cancer (HGSOC), the most common subtype, we found that high expression of FUT5 is associated with a worse outcome. By employing multiplex immunohistochemistry (IHC) to examine T cell subsets, we found a significant decrease in $CD3^{+}CD4^{-}CD8^{-}$ (double negative, DN) T cells in $FUT5^{high}$ (n=10) compared to $FUT5^{low}$ samples (n=10), while there is no difference in the abundance of $CD8^{+}$ cytotoxic T cells, $CD4^{+}$ helper T cells or $CD4^{+}Foxp3^{+}$ regulatory T cells. Tumor-infiltrating DN T cells has been shown to mediate potent anti-tumor response. In addition to their cytotoxic capabilities, DN T cells largely exhibit modulatory functions on other T cell subsets. To further investigate, we performed additional IHC staining and observed a significant increase in proliferating ($Ki67^{+}$) $CD8^{+}$ tissue resident memory cells, which are known to be important for cancer immunity. In addition, we observed a decrease in metastases in the FUT5 knockdown group, accompanied by an increase in DN T cells in ascites and omental metastatic tumors in humanised mice, as revealed by flow cytometry, confirming a direct immunomodulatory role of FUT5. Together, these findings reveal a novel role of FUT5 in promoting immune evasion by suppressing anti-tumor DN T cells, which could provide novel insights for immunotherapy in HGSOC, which has a low response rate to immune checkpoint inhibitors (This research is supported by RGC SRFS2223-7S05, HMRF 08192286 and LSCCB under the Health@InnoHK Program launched by ITC, HKSAR).

#6528 Integrin αvβ6 upregulation as a mechanism of T-cell evasion in head and neck squamous cell carcinoma.

W. J. MacDonald, P. R. Srinivasan, M. Pinho-Schwermann, S. Zhang, V. Tajiknia, C. Purcell, J. Strandberg, N. Stubbs, W. S. El-Deiry;
Legorreta Cancer Center at Brown University, Providence, RI

Head and neck squamous cell carcinoma (HNSCC) encompasses malignancies of the mucosal epithelium in the oral cavity, pharynx, and larynx. The lack of effective screening strategies and the typically late stage of detection are contributors to a considerable annual death toll of HNSCC. Additionally, the anatomical proximity of the malignancy to delicate structures of the head and neck leads to tremendous treatment-related morbidity. Therefore, there is great interest in developing life-saving therapies and strategies for treatment de-escalation. The immune checkpoint inhibitor pembrolizumab (αPD-1) has been approved for recurrent or metastatic HNSCC and as a frontline therapy for unresectable disease. However, only about a quarter of patients respond to αPD-1 therapy. The immunosuppressive effect of TGFβ has been widely described as relevant to the HNSCC tumor microenvironment. However, attempts to blockade TGFβ have failed mainly due to the widespread side effects of disrupting a highly promiscuous cytokine. Integrin αvβ6 is a major activator of the inert latent TGFβ into the active, immunosuppressive form. With its high relative specificity to HNSCC tissue, inhibition of αvβ6 could offer a safer approach for disrupting TGFβ to overcome resistance to immune checkpoint blockade. After screening αvβ6 expression levels of HNSCC cell lines via flow cytometry, cell lines FaDu and CAL27 were selected for further investigation due to high endogenous ITGB6 expression (FaDu 35.57% cells ITGB6+, CAL27 95.69% cells ITGB6+). The cell lines were transduced with a doxycycline-inducible short hairpin RNA (shRNA) knockdown of αvβ6 using a lentiviral system. Both knockdown and control shRNA cell lines were pretreated with 1 μg/mL of doxycycline for five days to induce the shRNA and subsequently co-cultured with TALL-104 T-cells. Quantitative fluorescence microscopy of the co-culture revealed that the knockdown of αvβ6 substantially increased T-cell killing over 24hrs (FaDu CTRL shRNA 6.72%±2.49 dead vs. FaDu ITGB6 shRNA 12.80%±3.16 dead, $p<0.001$). However, treatment of FaDu and CAL27 cell lines with active-TGFβ showed no change in PD-L1 expression via flow cytometric analysis. To determine whether the T cell evasive effect of αvβ6 is driven by other immune checkpoints on the cancer cells or by the direct effect that TGFβ has on immune cells, we show the generation of relevant mouse αvβ6 shRNA knockdown cells. These syngeneic in vivo studies will facilitate cytokine profiling to uncover the dynamics of tumor-immune cell interactions in response to αvβ6 inhibition.

#6529 Multi-lineage de-differentiation (MLDD) towards the TTF1-low phenotype is a major determinant of immune response within STK11-deficient non-small cell lung cancer.

R. Shivahare[1], N. J. Song[1], B. Nourmohammadi[1], J. Imam[1], O. Sanabria[1], J. M. Amann[1], Q. Ma[2], Z. Li[1], D. P. Carbone[1], J. Kaufman[1];
[1]The Ohio State University Comprehensive Cancer Center, Columbus, OH, [2]The Ohio State University College of Medicine, Columbus, OH

Background: The loss of serine/threonine kinase 11 (STK11) in non-small cell lung cancer (NSCLC) is associated with poor prognosis and resistance to immune checkpoint blockade (ICB) in 20-25% of cases. Experimental evidence from murine models suggests that STK11 loss contributes to lineage plasticity, while clinical observations indicate its impact on differentiation phenotypes in patients. However, the intricate interplay between differentiation states, the tumor microenvironment (TME), and clinical outcomes remains poorly elucidated. This study aims to comprehensively characterize these interactions to enhance our understanding of the complex dynamics underlying STK11-deficient NSCLC pathogenesis and therapeutic responses.
Methods: By leveraging large multi-omics datasets, we already demonstrated the low immune infiltration in TTF1-low and neuroendocrine MLDD subsets of LKB1-deficient tumors. In this study, we used GEMM-derived two KPL (Kras, TP53, and STK11 mutations) and one KPL-restored line to inject subcutaneously in F1 hybrid mice of B6 and Sv129 backgrounds. Tumor size was monitored at regular intervals, and upon reaching a sufficient size, tumors were harvested and partitioned for the characterization of immune cells (T-cells and NK cells) by flow cytometry and identification of the MLDD phenotypes through gene expression analysis using Nanostring technology.
Results: Mice injected with the STK11 WT line (2695L) exhibited smaller tumor volumes compared to those injected with STK11 mutant lines (2695X and 2381T4). Our comprehensive analysis, combining flow cytometry and Nanostring techniques, revealed that STK11 mutant lines displayed notably low infiltration of CD8+ T-cells, an elevated proportion of exhausted T-cells, and a manifestation of the TTF1-low immune phenotype characterized by high myeloid-derived suppressor cells (MDSCs) and increased KLRC1/KLRC2 expression. The presence of MDSCs in the STK11 mutant line correlated with pro-inflammatory cytokines but exhibited an inverse correlation with MHC-2 expression. MHC-2 expression was inversely correlated with CD8+ T-cell percentage and positively correlated with naïve T-cell percentage.
Conclusions: The data obtained from the study indicates that the MDSC phenotype seems to be important for immune evasion in STK11-loss tumors. Follow-up flow cytometry and gene expression experiments with combined T-cells and myeloid/PMN MDSC-related gene panels, along with further experiments involving cIAP1/PD1 inhibitors, are imperative to substantiate and expand upon our current findings.

#6530 TREM1 inhibition: A novel approach to suppress tumor growth and enhance immune checkpoint therapy.

A. Ajith, K. Moamouni, D. Horuzsko, A. Horuzsko;
Augusta University, Augusta, GA

In the context of cancer, inflammation is a multifaceted contributor to tumorigenesis. The Triggering Receptor Expressed on Myeloid Cells 1 (TREM1) is recognized for its role in amplifying inflammatory responses, yet its specific pro-tumorigenic mechanisms have remained elusive. This study employs Trem1-deficient mice and a novel inhibitor, VJDT, to explore the therapeutic potential of targeting TREM1 in cancer. Both genetic silencing and pharmacological inhibiton of Trem1 led to remarkable reductions in tumor growth in mouse models of melanoma (B16F10) and fibrosarcoma (MCA205). In-depth analysis using single-cell RNA sequencing unveiled that TREM1 deficiency resulted in a decrease in the frequency and suppressive capabilities of myeloid-derived suppressor cells (MDSCs) within the tumor microenvironment, concomitant with an increase in cytotoxic CD8+ T cells and enhanced T cell activation. Furthermore, TREM1 inhibition not only curtailed tumor growth but also potentiated the effectiveness of anti-PD-1 therapy, primarily by mitigating MDSC frequency and reversing T cell exhaustion. Notably, in melanoma xenografts from patient samples, pharmacological TREM1 inhibition via VJDT treatment significantly downregulated critical oncogenic pathways linked to cell proliferation, migration, and survival. This research underscores the pivotal role of TREM1, expressed both within cancer cells and the tumor microenvironment, in driving cancer progression. Consequently, targeting TREM1 for therapeutic intervention holds promise for reshaping the immunosuppressive tumor milieu and augmenting the success of immune checkpoint therapy.

#6531 Anti-tumor immune function of NR2F6, an orphan nuclear receptor, in stromal cells.

H. Kim[1], Y. Feng[1], M. Radaeva[2], E. Sergienko[1], A. Cherkasov[2], Z. A. Ronai[1];

[1]Sanford Burnham Prebys Med. Discovery Inst., La Jolla, CA, [2]Vancouver Prostate Centre, Vancouver, BC, Canada

Growing evidence points to the importance of the tumor microenvironment (TME) in tumor growth control, progression, and therapy response. Among those is the greater understanding of immune system components within the TME as mediators of tumor growth control. NR2F6 is an orphan nuclear receptor, which was shown to serve as an immune intrinsic checkpoint component and has been suggested to elicit tumor-intrinsic suppression of anti-tumor immunity. Correspondingly, genetic depletion of NR2F6 in CD8 T cells abrogates the immune-activating cytokines (e.g., IL-2, IFNg). In addition, genetic ablation of NR2F6 in melanoma cells activates CD8 T cell-mediated anti-tumor immunity partly by suppressing the expression of tumor-intrinsic immune repressors NACC1 and FKBP10. Notably, combined genetic ablation of tumor cells (NR2F6 KO melanoma) and stroma cells (NR2F6 KO mouse) resulted in a more pronounced inhibition of tumor growth compared with ablation of either tumor cells or TME. The latter provides the foundation for screening NR2F6 inhibitors, which are expected to have a strong systemic (tumor inhibition and immune cell activation) effect on tumor growth. Interestingly, single-cell transcriptomic data from human tumors identified high expression of NR2F6 in stroma cells, cancer-associated fibroblasts (CAFs), and tumor-associated endothelial cells (TAEs). Consistent with these, scRNAseq analysis of mouse melanoma revealed higher expression of NR2F6 in SMA+ immune suppressive myo-CAFs than in immune activating CAFs. Studies that directly reveal the role of stromal NR2F6 in anti-tumor immunity and tumor growth and the state of NR2F6 inhibitors will be discussed.

#6532 Blockade of CD24 sensitizes pancreatic cancer to Kras inhibitors.

Y. Wei[1], M. Liu[1], E.-Y. Yen[1], J. Yao[1], P. T. Nguyen[1], X. Wang[1], Z. Yang[1], A. Yousef[1], D. Pan[1], Y. Jin[1], M. S. Theady[1], J. Park[1], Y. Cai[1], M. Takeda[1], M. Vasquez[2], Y. Zhou[3], H. Zhao[2], A. Viale[1], H. Wang[1], D. Zhao[1], R. A. DePinho[1], W. Yao[1], H. Ying[1];

[1]UT MD Anderson Cancer Center, Houston, TX, [2]Houston Methodist Cancer Center, Houston, TX, [3]University of Texas Health Science Center at Houston, Houston, TX

Pancreatic ductal adenocarcinoma (PDAC) is predominantly driven by KRAS oncogene. KRAS, long considered an undruggable target, has been targeted by drugs including a $KRAS^{G12C}$ inhibitor (G12Ci), AMG 510, which is approved for the treatment of $KRAS^{G12C}$-mutant non-small cell lung cancer (NSCLC). AMG 510 also exhibited promising anticancer activity in human PDAC, with 21% response rate and over 70% patients experiencing certain level of tumor control. However, targeting KRAS oncogenes faces the major challenge of therapy resistance, which severely limited its survival benefit. While multiple studies have elucidated potential resistance mechanisms to G12Ci in lung cancer, the molecular mechanisms underlying resistance in PDAC remains elusive. Here, using $KRAS^{G12C}$-driven mouse PDAC model, we found that similar to the clinical observation, $KRAS^{G12C}$ tumors exhibit only partial response to AMG 510 treatment. CyTOF analysis indicates that such tumor persistence following G12Ci treatment occurs even in the presence of conversion from a ‘cold’ pro-tumor immune microenvironment to a ‘hot’ anti-tumor immune environment, as evidenced by the prominent increase in both cytotoxic T cells and M1-like macrophages. Interestingly, we discovered that the expression of CD24, which was recently identified as a new ‘do not eat me’ signal, is significantly upregulated on the surface of persist tumor cells after G12Ci treatment which suppresses the function of anti-tumor macrophages. Anti-CD24 blocking mAb enhanced macrophage-mediated phagocytosis in vitro and significantly sensitizes $KRAS^{G12C}$ tumors to AMG 510 treatment in vivo in a macrophage-dependent manner. Similar findings were observed in $KRAS^{G12D}$-driven PDAC model. Our findings identified a novel immune combination to improve the outcome of KRAS targeted therapy in PDAC.

#6533 Pivotal role of specific LYVE1^{+} tissue resident macrophages in PDAC progression & immunotherapy resistance.

H. Li, J. Yan;
University of Louisville, Louisville, KY

Pancreatic ductal adenocarcinoma (PDAC) is characterized by dense fibrotic stroma and abundant myeloid cell infiltration, which render it resistant to any therapeutic interventions, including immunocheckpoint blockade (ICB) therapy. Understanding the composition and function of myeloid cells within the PDAC microenvironment may help identify promising targets for PDAC immunotherapy. Tissue resident macrophages (TRMs) contribute to organogenesis and tissue regeneration and metabolism. In this study, we discovered a distinct population of pancreas TRMs that highly express lymphatic vessel hyaluronan receptor 1 (LYVE-1). Single cell RNAseq data reveal that LYVE-1+ TRM cluster in the pancreas expresses high levels of complement activation genes and transcription factors such as c-Maf and Stab1. RNAseq data also confirm that LYVE-1+ TRMs express enriched genes related to mannose binding, endocytosis, and glutathione metabolic process, while LYVE-1 negative macrophages express enriched genes related to antigen processing and presentation, T cell activation, and phagocytosis. Multiparameter flow cytometric analysis demonstrates that LYVE-1+ TRMs express M2-like markers, including increased CD163, CD206 and decreased MHC Class II molecule. During PDAC development and progression, LYVE-1+ TRMs expand and localize around the tumor border, promoting fibrotic stroma formation. Imaging mass cytometry (IMC) also reveals abundant infiltration of LYVE-1+CD14+CD68+ macrophages in human PDAC tumors and colocalized with collagen deposition. This subset of macrophages also highly express c-Maf. Through the use of Lys-Cre-c-Maf $^{f/f}$ mice, we demonstrate that depletion of c-Maf from myeloid cells significantly reduces LYVE-1+ TRMs and polarizes them to resemble an M1-like phenotype. In conclusion, our findings suggest that LYVE-1+ macrophages are a unique subset of myeloid cells within the pancreas and likely play a critical role in PDAC progression and immunotherapeutic resistance. Future work will focus on targeting LYVE1+ TRMs using various approaches, such as conditional knockout mice and small molecule inhibitors, to determine their therapeutic potential for PDAC treatment.

Presented by Dr. Hong Li

#6534 Overcoming B regulatory cell induced STING resistance by dual functional albumin nanomedicine to prolong survival of pancreatic cancer.

C. Li, S. Mao, H. Zhao, D. Mahamadou, Z. Liu, H. Wen, M. He, M. Wang, J. Tao, B. Wen, T. Hoang, B. Jacobovitz, F. Wen, W. Gao, D. Sun;
University of Michigan, Ann Arbor, MI

Pancreatic cancer is the most lethal form of cancer with a 5-year survival at 11% and lacks treatment options. Immunotherapy, specifically anti-PD-1/PD-L1 antibody, proves ineffective for pancreatic cancer patients due to the immunosuppressive tumor microenvironment (TME). STING agonist has emerged as the most effective immune modulator to regulate immunosuppressive TME to enhance the efficacy of immunotherapy across many different cancer types. However, two challenges hinder the use of STING agonist in pancreatic cancer: (A) STING agonist strongly stimulates induction of B regulatory cells (Bregs) in pancreatic tumor and lymph node, leading to an intrinsic resistance to STING agonist and a severe compromised efficacy. (B) Most STING agonists are used by local intra-tumor injection in clinical trials, which only shrinks the local tumors without inhibiting distal tumors or metastasis, whereas it is also not feasible for intra-tumor injection for pancreatic cancer in clinical trials. In response, we developed a first-in-class dual functional drug (SH-273) to overcome STING resistance by eliminating Bregs in both tumors and lymph nodes for long-term efficacy in pancreatic cancer. SH-273 has dual function to stimulates STING function (EC50 100 nM) and inhibits PI3Kγ (IC50 7 nM) that eliminate Bregs to overcome STING resistance. Interestingly, SH-273 achieved dual function with an opposite mechanism in regulating IRF3 phosphorylation in myeloid cells (increase) vs. in Bregs (decrease). In addition, we developed an albumin nanoparticle of SH-273 (Nano-273) for systemic delivery to enhance drug targeting to tumor and lymph node to activate systemic anticancer immunity. 3D imaging results indicated that albumin nano formulation greatly enhanced drug lymphoid draining and pancreatic tumor penetrating. Nano-273, combined with anti-PD-1, achieved long-term median survival of 200 days in LSL-KrasG12D; LSL-Trp53R172H/+; Pdx1cre/+ (KPC) mice (a substantial 67% increase from 120 days without treatment). The 80-day survival extension is significant as KPC mice mimic human pancreatic cancers with Kras/P53 mutations that are unresponsive to other available therapies. Single cell RNA-sequencing and flow cytometry revealed that Nano-273, combined with anti-PD-1, reduces Bregs by 5 to 7-fold while increasing other B cell subtypes by 4-fold in both pancreatic tumors and lymph nodes, compared to control group or group treated with STING agonist alone. These findings suggest that Nano-273 overcomes STING resistance by eliminating Bregs and induced systemic immunity to achieve long-term anti-tumor efficacy in pancreatic cancer.

#6535 Targeting estrogen receptor signaling in tumor associated myeloid cells to enhance anti-tumor immunity.

B. Chakraborty[1], M. Brown[1], P. Chakraborty[2], A. Goyal[3], C. Chang[1], D. McDonnell[1];
[1]Duke University, Durham, NC, [2]UNC Chapel Hill, Chapel Hill, NC, [3]U MASS Med School, Worcester, MA

Immune checkpoint inhibitors (ICB) have significantly improved outcomes across the spectrum of cancers, especially in patients with metastatic melanoma or non-small cell lung cancer (NSCLC). Despite encouraging efficacy in some patients, the development of primary and acquired resistance and severe toxicity associated with these treatment regimens, together with the overall low response rates, have limited their widespread use. Mining publicly available transcriptomic datasets, we have demonstrated that the response to ICB in patients with melanoma is influenced by the functionality of tumor associated macrophages (TAMs). Thus, it is of significance that we have demonstrated that 17-β estradiol (E2), working through myeloid cell intrinsic estrogen receptor alpha (ERα), promotes tumor growth in preclinical mouse models by polarizing tumor associated macrophages towards an immune-suppressive state in a manner that suppresses $CD8^{+}$T cell functionality and limits ICB efficacy independent of gender. Transcriptomic analysis of tumor infiltrating myeloid cells isolated from E2-treated syngeneic tumors revealed that the type I interferon (IFN) signaling pathway was suppressed and that this activity could be reversed by the addition of fulvestrant a Selective Estrogen Receptor Downregulator. The importance of type I IFN signaling in E2-regulated tumor growth was confirmed in syngeneic mouse tumor models (B16F10-melanoma and LLC1-NSCLC cells) by showing that inhibiting type I interferon receptor (IFNAR) activity using blocking antibodies reversed the protective effects of E2 deprivation (ovariectomy) on tumor growth. Further, using *in vitro* cultures of macrophages from mouse bone marrow or peripheral blood mononuclear cells from deidentified human donors, we demonstrated that E2-dependent inhibition of type I IFN signaling could be attributed to increased efferocytosis by myeloid cells. These findings were recapitulated *in vivo* using an IFN reporter mouse (*Mx1-egfp*) implanted with labelled tumor cells (mCherry-Spectrin labelled LLC1), where we demonstrated that E2 mediated-suppression of myeloid cell intrinsic interferon signaling within the tumor microenvironment is contingent upon their engulfment of apoptotic cancer cells. Mechanistically, this enhanced efferocytosis was attributed to increased expression of the fractalkine receptor (CX3CR1) in E2-treated myeloid cells- as either genetic or pharmacological depletion of CX3CR1 in mouse reversed E2-mediated tumor growth (B16F10 and LLC1), myeloid cell polarization (from immunosuppressive to proinflammatory), myeloid cell intrinsic type I IFN signaling and reinvigorated $CD8^{+}$T cell function. Taken together, our results highlight the potential clinical utility of targeting the E2/ER-CX3CR1 pathway as a means to enhance response to ICBs.

#6536 Enhanced membrane stability of mRNA nanoparticle derived TNFSF14 results in superior T-cell and NK cell stimulation.

A. Sallets[1], W. Liu[1], M. L. Leong[1], R. Prins[2], D. M. Da Silva[2], D. J. Fernandez[2], C. J. McKinlay[1], E. E. Lemmens[1], C. S. Rae[1], S. Adusumilli[1], R. Low[1], S. Bandi[1], G. Kannan[1], W. Kast[2], S. Deutsch[1], O. A. W. Haabeth[1];

[1]Nutcracker Therapeutics, Inc., Emeryville, CA, [2]University of Southern California, Los Angeles, CA

Resulting from intracellular translation of nanoparticle delivered mRNA, mRNA therapeutics offers an unparalleled opportunity to direct the expression of proteins to specific subcellular compartments. Many cytokines, especially the immunomodulatory Tumor Necrosis Factor (TNF) superfamily members, exist as both membrane and soluble proteins. Trimeric members of the TNF superfamily are known to be susceptible to protease cleavage resulting in their release from the membrane. Membrane and soluble versions of the immunomodulators may have different activity. Several studies have shown that membrane expressed TNFSF members more efficiently cross-link TNFSF receptors resulting in a stronger activation or inhibition signal. Moreover, the activity of membrane expressed proteins is confined to the cells that express the protein and the cells that interact with the protein expressing cell. Thus, directing the expression of immunostimulatory proteins to the membrane could be a transformative way to enhance the activity while mitigating the toxicity by limiting systemic exposure. In this study we utilized Nutcracker Therapeutics Inc. unique mRNA platform to develop a membrane stabilized version of tumor necrosis factor super family member 14, also known as LIGHT, with superior co-stimulatory activity and stability. LIGHT is an immunomodulatory cytokine that primarily acts on lymphocytes and innate immune cells through the cis or trans binding of HVEM or lymphotoxin beta receptor (LtbR). LIGHT has been implicated in multiple inflammatory diseases and is currently being evaluated in the development of immunotherapies against cancer. LIGHT stimulatory activity depends on the displacement of the inhibitory BTLA that is normally bound to HVEM and LtbR. Studies have shown that membrane bound LIGHT, but not soluble LIGHT, can effectively displace BTLA. In this study, we hypothesized that the advantageous activities of mRNA derived membrane expressed LIGHT could be further enhanced with an engineered LIGHT molecule that is less susceptible to membrane shedding. We made multiple variants of Engineered LIGHT where different regions of the putative protease sensitive sites were replaced with either a flexible or rigid linker. In short, we found that i) the soluble version of LIGHT can inhibit immune stimulatory capability of membrane expressed LIGHT; ii) membrane bound LIGHT enhances co-stimulation of antigen-specific T cells; iii) engineered LIGHT enhances membrane expression and increases stability; and iv) a design using a novel rigid linker to replace the putative protease sensitive region of LIGHT showed best overall activity. Here, we demonstrate the capability of our integrated platform to design and deliver an enhanced, membrane stabilized LIGHT molecule. This engineered transmembrane molecule represents a new class of drug uniquely enabled by nanoparticle delivered mRNA.

#6537 A novel CCR4 antagonist induces potent anti-tumor response through inhibition of Treg migration into the tumor microenvironment.

Rashmi Nair, Chandrasekhar Abbineni, Krishna Chaitanya Talluri, Amit A Dhudashiya, Aravind AB, Naveen Kumar R, Ramya R, D. Balasubramanyam, Pathur Obanna, Rabin Madhaiyan, DS Samiulla, Girish Daginakatte, Kishore Narayanan, Kavitha Nellore, Shekar Chelur, Susanta Samajdar, Murali Ramachandra

Aurigene Oncology Limited, Bangalore, India

Regulatory T cells (Tregs), an immunosuppressive subset of $CD4^{\pm}$ T cells, play a vital role in maintaining immune homeostasis by regulating response to self antigens and maintaining tolerance. On the contrary, Tregs infiltrating the tumor microenvironment (TME) impede effective anti-tumor immunity by inhibiting tumor-specific T cell responses and generating a suppressive TME, thus promoting tumor progression. Clinically, Tregs have been proven to play a significant role in resistance to immune checkpoint inhibitors (ICIs) leading to lower response rates. Hence, targeting Tregs would lead to activation of tumor-specific effector T cells and improved long-term anti-tumor immune responses with ICI treatment. CCR4, a chemokine receptor highly expressed on Tregs, spearhead the migration of Tregs and their accumulation in the TME, by responding to the chemokines CCL22 and CCL17 secreted by the inflamed cells in the tumor. CCR4 expression is associated with poor prognosis in various solid tumors. This warrants the therapeutic targeting of CCR4-expressing Tregs to enable effective and durable anti-tumor immune responses. We sought to discover and develop novel small molecule antagonists of CCR4 for use in cancer therapy. Multiple series of CCR4 antagonists were identified by iterative medicinal chemistry efforts and SAR based approach. These compounds were optimized towards attaining required potency, acceptable physicochemical properties, high selectivity and desirable pharmacokinetic profile to achieve anti-tumor activity. Aurigene's CCR4 antagonists exhibited potent inhibition of CCR4 activity in the reporter-based β-arrestin recruitment assay. This translated well into potent inhibition of CCL22-mediated chemotaxis of CCR4-expressing Tregs in an *in vitro* cell migration assay. Furthemore, the lead compounds showed desirable drug-like properties and excellent pharmacokinetic exposure in rodents. In an ongoing study in a syngeneic mice tumor model, one of the lead compounds is being evaluated for impact on Treg infiltration, CD8:Treg ratio in the tumor and efficacy. In summary, we have identified novel CCR4 antagonists with desirable drug-like properties that are being evaluated further to identify a clinical candidate.

#6538 Modulation of human macrophage differentiation, phenotype and function *in vitro* as a strategy to characterize novel tumor microenvironment modulators.

C. N. Castro, T. Sahner, C. Obodozie, P. Metzger, **H. Weber**;
Reaction Biology Europe GmbH, Freiburg, Germany

Macrophage infiltration of the tumor microenvironment is a key process that can determine the success or failure of anti-tumor therapies. Thus, many immunooncology therapies are being developed to modulate the macrophage differentiation program towards the anti-tumor M1 subset, while hindering the M2 subset associated with tumor progression. Monocyte-derived macrophages comprise a crucial in vitro cellular tool to evaluate the plasticity potential between the different polarization states. Several hurdles like their in vitro adherence, low cell number yield and the donor-to-donor variability pose technical challenges when using in vitro differentiated macrophages for compound screening and titration or functional assays.
At Reaction Biology we have established human macrophage assay pipelines to evaluate the novel macrophage polarization compounds in vitro. By isolating monocytes from frozen PBMC stocks it is possible to have access to the same donor or group of donors PBMC for repetitive analysis. We have developed a differentiation protocol that allows us to use different plate format from 6-well to 48 well plates, and thus increase and modulate the throughput according to the required readout.
The effect of therapeutic compounds can be analyzed by flow cytometry. Our data shows that human primary monocytes grown under M1 polarizing conditions express high levels of CD86 and CD80 in contrast to those cultivated under M2 polarizing conditions, with high expression of CD163, CD206, and CD209. Cell culture supernatant can be used to determine cytokine secretion. The functionality of the different macrophage subtypes can be further investigated using a pH-sensitive phagocytosis tracker, like pHRodo-Zymosan or pHRodo-Ecoli, which shows differential uptake according to differentiation profile. Moreover, treated macrophages can be used in coculture with T cells to investigate their capability to foster or inhibit an immune response.
Our data shows the value of monocyte-derived macrophage assays in the evaluation and efficacy assessment of TME modulators.

#6539 RNAi mediated silencing of *STAT3* in tumor-associated immune cells induces robust anti-tumor effects in immunotherapy resistant tumors.

S. Ganesh, M. Kim, J. Lee, X. Feng, H. Sivagurunatha Krishnan, R. Rijnbrand, A. Beaudry, J. A. Lockridge, V. Uttamsingh, J. Hanrahan;
Dicerna Pharmaceuticals, Inc., Lexington, MA

Malignant tumors are often associated with an immunosuppressive tumor microenvironment (TME), rendering most of them resistant to standard-of-care immune checkpoint inhibitors (CPIs). Signal transducer and activator of transcription 3 (STAT3), a ubiquitously expressed transcription factor, has well-defined immunosuppressive functions in several leukocyte populations within the TME. Since the STAT3 protein has been challenging to target using conventional pharmaceutical modalities, we investigated the feasibility of applying systemically delivered RNA interference (RNAi) agents to silence its mRNA directly in tumor-associated immune cells. In preclinical murine tumor models, chemically stabilized acetylated small-interfering RNAs (siRNAs) selectively silenced *Stat3* mRNA in multiple relevant cell types in TME and tumor-draining lymph nodes (TDLN), reduced STAT3 protein levels, and increased cytotoxic T-cell infiltration. In murine models of CPI-resistant tumors, RNAi-mediated *Stat3* silencing resulted in tumor growth inhibition, which was further enhanced and resulted in tumor regressions in combination with CPIs. Our findings suggest that targeting *STAT3* directly and reducing STAT3 protein in the suppressive immune cell populations in the TME and TDLN may overcome some of the current limitations of immunotherapy and be of therapeutic benefit especially for cancer patients who failed to respond to standard immunotherapy treatments alone. A human active STAT3 conjugate is currently in Phase 1 clinical trial for treatment of immunotherapy refractory cancer types (NCT06098651).

#6543 A map of osteosarcoma cell architecture reveals convergence of pediatric cancer mutations on protein assemblies.

M. Hu[1], L. V. Schaffer[1], E. L. Huttlin[2], G. Qian[1], A. Latham[3], A. Pal[3], L. Vaites[2], T. Le[4], Y. Qin[1], C. Churas[1], D. Pratt[1], R. Bachelder[1], P. Zage[1], I. Echeverria[3], A. Sali[3], J. Harper[2], S. P. Gygi[2], E. Lundberg[4], T. Ideker[1],

[1]University of California San Diego - UCSD, La Jolla, CA, [2]Harvard Medical School, Boston, MA, [3]University of California San Francisco - UCSF, San Francisco, CA, [4]Stanford University, Stanford, CA

Pediatric tumors are characterized by a low incidence of somatic mutations, which occur in different genomic patterns from adult cancers. For these reasons, interpreting the functional impact of mutations in pediatric cancer patients has remained difficult. One approach to interpreting rare coding mutations is to analyze the convergence of these mutations on larger structural and functional units, such as protein complexes, super assemblies, biomolecular condensates, and organelles. Towards this aim, we created a cancer cell map in the osteosarcoma cell line based on proteome-wide integration of protein interactions and immunofluorescent imaging in U-2 OS pediatric bone cancer cells. This multiscale integrated cell map of U-2 OS cell organizes 5,254 proteins into 270 protein assemblies. Using this multiscale cell map, we analyze 772 genomes from 18 cancer types reported in the DKFZ pan-pediatric cancer study to identify 25 protein assemblies in the map under mutational pressure. This analysis reveals mutated protein assemblies involved with chromatin maintenance and remodeling as well as cell integrity and mobility. For example, we identify a Collagen Biosynthesis and Remodeling Complex, as mutated in 9 cancer types and 15 patients in the dataset, indicating extracellular matrix remodeling is associated with pediatric cancer progression. We also identify a putative biological condensate, which we call the Nuclear Transcription Suppression Complex (NTSC). This protein assembly is found mutated in 20 patients across 10 cancer types, implicating intrinsically disordered proteins in development of pediatric cancer. Overall, this work illustrates how a global multiscale map of cell architecture enables a mechanistic understanding of clinical patient genomes.

#6544 Targeting resistance mechanisms to AR-targeted therapy in prostate cancer through inhibition of CREBBP/EP300.

B. V. Dougherty[1], B. C. Thomas[2], A. M. Walsh[1], V. Calvo[1], K. E. Ware[3], A. J. Armstrong[3], J. Renstrup[1], J. A. Somarelli[3], E. E. Schadt[1];
[1]Pathos, Chicago, IL, [2]Nova Southeastern University, Fort Lauderdale, FL, [3]Duke University, Duram, NC

Standard initial treatment for men with metastatic prostate cancer involves targeting the androgen receptor (AR) with androgen deprivation therapy or androgen-receptor signaling inhibitors. Resistance eventually develops, such as through AR-activating alterations, leaving few targeted options for patients. Here, we utilize data from 4,509 prostate cancer patients with longitudinal clinical and DNA/RNA sequencing data to elucidate mechanisms of resistance and identify potential therapeutic vulnerabilities in resistant disease. By constructing comprehensive regulatory networks, termed hybrid networks, built across different disease stages, combining features from WGCNA, causal mediation analysis, probabilistic causal network inference, and public knowledge graphs, we uncover subnetworks strongly associated with disease progression and resistance. These subnetworks reflect biological processes for cell cycle, E2F, DNA repair, MYC, and AR, comprehensively identifying broad transcriptional changes that drive disease progression and resistance.

Selected subnetwork scores, derived from RNA expression, were significantly associated with outcomes in both the hormone-sensitive and castration-resistant settings, demonstrating that the subnetworks capture early and late resistance. The hybrid networks identified the transcriptional co-activators CREBBP and EP300 as key modulators of these subnetworks, suggesting that targeting CREBBP/EP300 may be effective in treating both early and late-stage disease.

Prostate cancer cell lines were treated with FT-6876, a small molecule inhibitor of CREBBP/EP300, and growth inhibition was measured in both enzalutamide sensitive and resistant cell lines, covering a wide range of resistance mechanisms. The selected subnetworks were enriched for genes down-regulated following treatment with FT-6876, suggesting that targeting CREBBP/P300 addresses multiple resistance-related pathways. Differential changes in protein abundance and protein acetylation between enzalutamide sensitive and resistant cell lines identified changes in fatty acid metabolism as a common, downstream event in response to treatment with FT-6876, suggesting an additional mechanism for response to FT-6876.

Together, our integrated theoretical and experimental analyses support the hypothesis that targeting CREBBP/EP300 may provide therapeutic benefits to prostate cancer patients. Further, the subnetworks identified may serve as mechanistically-informed biomarkers for identifying patients who may benefit from inhibition of CREBBP/EP300.

#6545 Reversing lineage plasticity and drug resistance in lethal prostate cancer.

A. Vasciaveo, J. J. Li, D. Karagiannis, X. Chen, A. Califano, C. Lu, M. M. Shen;
Columbia University Irving Medical Center, New York, NY

Although major mechanisms of resistance to targeted therapies include mutation of the drug target, recent evidence suggests cell-adaptive mechanisms as alternative avenues for escaping treatment. In several cancers, tumor cells become plastic in response to target inhibition, changing their identity and molecular programs without acquiring further mutations. In the case of castration-resistant prostate cancer (CRPC) treated with standard-of-care, next-generation anti-androgens enzalutamide, tumor cells often switch lineage to survive drug pressure, acquiring neuroendocrine (NE) features and thereby transforming into neuroendocrine prostate cancer (CRPC-NE). Existing targeted therapies for CRPC and CRPC-NE provide limited benefit, representing an unmet clinical need. Hence, the elucidation of tumor plasticity and consequent heterogeneity that contribute to drug resistance is of paramount importance to identify novel therapeutic opportunities.

We have recently developed a network-based precision cancer medicine framework to characterize molecular and drug sensitivity profiles of ~100 Genetically-Engineered Mouse Models (GEMM)-derived tumors of prostate cancer (Vasciaveo, et al. 2023). This study revealed that tumors derived from GEMMs with the loss of function of both Pten and Trp53 (NPp53) align with CRPC patients and exhibit high heterogeneity in regulatory programs and histopathologic features, including NE differentiation. We then adopted the NPp53 model to generate several 3D organoid lines in order to study tumor plasticity and heterogeneity. To elucidate their tumors' regulatory programs, we reverse-engineered genome-wide regulatory networks using multimodal single-cell RNASeq and ATACSeq data to identify Master Regulator (MR) proteins implementing tumor cell identities and characterize their epigenetic landscape.

Our network-based regulatory analysis identified several distinct cell populations, including cells activating epithelial-to-mesenchymal (EMT) programs and NE differentiation, all resistant to enzalutamide treatment. Cross-species analysis aligned these cells to human CRPC and CRPC-NE tumors. In particular, our analyses have shed light into the roles of NSD2, a known MR of lethal prostate cancer, whose ablation restored sensitivity to enzalutamide.

In summary, we leveraged single-cell, multimodal data from CRPC and CRPC-NE 3D mouse organoids to elucidate regulatory programs of drug resistant, lethal prostate cancer and characterize its heterogeneity. Importantly, we also identified a mechanism that can be exploited for therapeutic intervention to restore tumor cells' sensitivity

#6546 Spatial immunology landscapes that correlate with survival in triple negative breast cancer.

A. Foroughi pour[1], J. Martinek[1], T.-C. Wu[1], S. Sivajothi[1], Z. Liu[1], J. Zhou[1], D. Rimm[2], P. Robson[1], K. Bates[2], K. Palucka[1], J. H. Chuang[1];
[1]The Jackson Laboratory for Genomic Medicine, Farmington, CT, [2]Yale University School of Medicine, New Haven, CT

Triple negative breast cancer (TNBC) is an aggressive subtype of breast cancer characterized by negative immunohistochemistry staining for estrogen receptor (ER), progesterone receptor (PR), and human epidermal growth factor receptor 2 (HER2). Treatment options for TNBCs are limited due to lack of tumor-specific targeted therapies, resulting in poor prognosis and patient survival. This is exacerbated by lack of prognostic markers of response. While current studies suggest tumor immune interactions are important, current immune activity quantifications, such as scores quantifying abundance of tumor-infiltrating lymphocytes (TILs), are not sufficient to define tumor immune status. We used imaging mass cytometry (IMC) to measure 33 markers on primary tumors of 100 patients undergone chemotherapy with long-term follow-up to explore the tumor immune microenvironment of TNBCs. Concordant with previous studies, a higher ratio of T-cells was associated with response to chemotherapy and longer overall survival (adjusted p-value<0.05). Moreover, using Kmeans clustering we identified 13 distinct cellular neighborhoods, reflective of the heterogenous nature of TNBCs. Among others, we identified a neighborhood, characterized by low CD14+ expression, low cytokeratin, high vimentin expression and high CD45RO, that contributes highest impact on correlation with overall survival (adjusted p-value<0.01). These results suggest an important role for memory T cells in the stroma. Thus, resolving spatial organization of the tissue is important to understanding patient response to therapy in TNBCs.

#6547 Dysregulated FGFR3 signaling alters immune landscape in bladder cancer and presents therapeutic possibilities.

D. R. Bergman[1], E. Trujillo[2], L. Li[3], A. T. Pearson[3], R. Sweis[3], T. L. Jackson[4];
[1]Johns Hopkins University, Baltimore, MD, [2]GemPharmatech, San Diego, CA, [3]University of Chicago, Chicago, IL, [4]University of Michigan, Ann Arbor, MI

Bladder cancer is an increasingly prevalent global disease that continues to cause morbidity and mortality despite recent advances in treatment. Immune checkpoint inhibitors (ICI) and FGFR-targeted therapeutics have had limited success in bladder cancer when used as monotherapy. Emerging data suggests that the combination of these two therapies could lead to improved clinical outcomes. The optimal strategy for combining these agents remains uncertain. Mathematical models, and more specifically agent-based models (ABMs), have shown recent successes in uncovering the multiscale dynamics that shape the trajectory of cancer. They have enabled the optimization of treatment methods and identification of novel therapeutic strategies. To assess the combined effects of anti-PD-1 antibodies and anti-FGFR3 small molecule inhibitors (SMI) on tumor growth and the immune response, we built an ABM that captures key facets of tumor heterogeneity and CD8+ T cell compartments, their spatial interactions, and their response to therapeutic pressures. With our model, we quantify how tumor antigenicity and FGFR3 activating mutations impact disease trajectory and response to anti-PD-1 antibodies and anti-FGFR3 SMI. We find that even a small population of weakly antigenic tumor cells bearing an FGFR3 mutation can render the tumor resistant to combination therapy. However, highly antigenic tumors can overcome therapeutic resistance mediated by FGFR3 mutation. The optimal therapy depends on the strength of the FGFR3 signaling pathway. Under certain conditions, ICI alone is optimal; in others, ICI followed by anti-FGFR3 therapy is best. These results point to the need to quantify FGFR3 signaling and the fitness advantage conferred on bladder cancer cells harboring this mutation. Employing this ABM modeling approach may enable rationally designed treatment plans to improve clinical outcomes.

#6548 Leveraging compact feature sets for TCGA-based molecular subtype classification on new samples.

K. Ellrott[1], C. K. Wong[2], C. Yau[3], M. A. A. Castro[4], J. Lee[1], B. Karlberg[1], J. K. Grewal[5], V. Lagani[6], B. Tercan[7], V. Friedl[2], T. Hinoue[8], V. Uzunangelov[2], L. Westlake[9], X. Robertson[5], T. A. Knijnenburg[7], C. C. Benz[13], J. M. Stuart[2], J. C. Zenklusen[10], A. D. Cherniack[9], P. W. Laird[8];
[1]OHSU, Portland, OR, [2]University of California Santa Cruz, Portland, OR, [3]University of California, San Francisco, San Fransico, CA, [4]Federal University of Parana, Curitiba, Brazil, [5]BC Cancer, Vancouver, BC, Canada, [6]JADBio Gnosis DA, Heraklion, Greece, [7]Institute for Systems Biology, Seattle, WA, [8]Van Andel Institute, Grand Rapids, MI, [9]Broad Institute, Cambridge, MA, [10]National Cancer Institute, Bethesda, MD, [11]The University of Texas MD Anderson Cancer Center, Houston, TX, [12]University of North Carolina at Chapel Hill, Chapel Hill, NC, [13]Buck Institute for Research on Aging, Novato, CA

The NCI's The Cancer Genome Atlas (TCGA) project profiled over 10,000 tumor samples over the course of 10 years. As different tissue-specific working groups reviewed all of the available data, these patient samples were separated into distinct molecular subtypes, and these clusters were reported in various marker papers. While these assignments provided invaluable information about the common patterns of molecular characteristics in different types of cancer there was no consistent methodology for assigning new samples to these defined molecular subtypes.The NCI's Tumor Molecular Pathology group was formulated to create machine learning-based models that could be applied to non-TCGA samples and determine their TCGA mapped subtypes. Five modeling systems, JADBio, SKGrid by the Oregon Health and Science University, CloudForest by the Institute of Systems Biology, AKLIMATE by University of California Santa Cruz and subSCOPE by BC Cancer's Genome Sciences Centre, were trained to recognize TCGA subtypes using multi-omic measurements from gene expression, DNA methylation, miRNA expression, copy number, and somatic mutation calls. While the TCGA samples were profiled using multi-omic technologies, single platform and/or compact feature set models also were assessed for their ability to assign these classifications. Each machine learning system created predictive models for 106 subtypes from 26 cancer types using as few features as possible, with a maximum of 100 features allowed for scored models. A set of 411,706 models was developed, composed of results of each of the learning methods across the various omic platforms. Top models, both multi-omic and single platform, were selected for each cancer type. On average, models were able to achieve an overall weighted F1 score of 0.895 with 42 features. While the top models for each cancer type had an overall weighted F1 mean performance of 0.936 with a mean of 29 features, in 20 of the 26 cancer types models using only gene expression provided the best performance. Analysis of features selected by the models showed some known onco-drivers were selected by many models, but many times different models would utilize features of different genes with similar levels of performance. Network-level analysis revealed that many genes of these selected features operated within the same pathways.Transferability of these models to external datasets was tested, taking TCGA breast cancer trained models and applying them to AURORA and METABRIC datasets. Interestingly, despite the data platform difference between TCGA (RNAseq) and METABRIC (microarray), model performance saw only minimal degradation of F1 values in transfer. This set of models and the training dataset will provide new opportunities for researchers and translational scientists to connect new tumors to the subtypes seen in the TCGA cohorts.

#6549 Mechanistic models of tumor and patient heterogeneity explain and predict clinical outcomes of large B-cell lymphoma (LBCL) treatment.

A. E. Pomeroy, A. C. Palmer;
University of North Carolina at Chapel Hill, Chapel Hill, NC

Introduction: Heterogeneity between patients and within tumors poses challenges to effective cancer treatment. Drug combinations can overcome heterogeneity by increasing the probability that a patient will have response to one or more drugs. This approach is successful in numerous disease settings, but technological advances have led to new approach to addressing heterogeneity: precision approaches to stratify patients into subpopulations with more uniform, stronger responses to specific drugs. These strategies can be implemented together to improve patient outcomes. We have developed computational mechanistic models of cancer treatment in the context of both sources of heterogeneity which explain and predict clinical outcomes of treatment of LBCL with combination therapy and CAR T-cell therapy.

Combination therapy: Our novel population tumor kinetics (pop-TK) model simulates clinical combination therapy outcomes by implementing multidrug dose response functions in heterogeneous populations of tumor cells, within heterogeneous cohorts of patients. Informed by the outcomes of novel drugs in phase 2 trials in relapsed/refractory (r/r) patients, the pop-TK model accurately predicted of outcomes of seven first-line phase 3 trials of novel combinations. Most notably, informed by treatment of r/r LBCL with polatuzumab-vedotin (pola), the pop-TK predicted the success of modifying the standard treatment regimen (RCHOP) with pola before the clinical trial results were published. The pola combination improves overall survival (OS) and PFS in Activated B-Cell (ABC) LBCL (hazard ratio (HR): OS 0.3, PFS 0.4), but reduces OS (HR: 1.6) and does not improve PFS (HR: 1.0) in Germinal Center B-Cell (GCB) LBCL. The subtype specific difference in PFS was also predictable based on subtype results of r/r trials (predicted HR: ABC 0.3, GCB 0.9).

CAR T-cell therapy: We used a population pharmacokinetic/pharmacodynamic (pop-PK/PD) model of CAR T-cell therapy to reproduce the PFS distribution and the distribution CAR T-cell abundance for CAR T therapy in r/r LBCL patients. The impact of tumor size on patient outcome in our model and in clinical studies led us to computationally explore the impact treating smaller tumors with CAR T-cell therapy on treatment outcomes. We found that using detectable circulating tumor DNA (ctDNA) as a biomarker for administering CAR T-cell therapy immediately after RCHOP increased the proportion of simulated patients without a second disease progression event by 30% (HR: 0.43 [0.34, 0.55]).

Conclusions: The pop-TK model supports LBCL subtype biomarker for pola performance, and the pop-PK/PD model demonstrates that detectable ctDNA is a potential biomarker for early CAR T-cell administration. These examples of model-driven precision trial design have the potential to improve outcomes using readily-available biomarkers and existing therapies.

Lurie Comprehensive Cancer Center of Northwestern University, Chicago, IL, [11]The University of Texas MD Anderson Cancer Center, Houston, TX, [12]University of Utah, Huntsman Cancer Institute, Salt Lake City, UT, [13]SWOG Statistics and Data Management Center, Seattle, WA; Fred Hutchinson Cancer Center, Seattle, WA, [14]The West Clinic, Wolf River, Germantown, TN

Background: The phase II randomized trial S1616 (NCT03033576) showed that patients with melanoma refractory to anti-PD-1-based therapy had improved progression free survival (HR=0.63, p=0.037) and objective response (28% vs 9%) to the combination of ipilimumab with nivolumab compared to ipilimumab. Here, we report molecular and spatial proteomic features of biopsies collected from patients on S1616, both prior to and during therapy.
Methods: Biopsies collected from patients from both arms at baseline (N=68 patients total) and early on-therapy (N=51; 43 with paired timepoints) were analyzed by whole exome sequencing (n=185 samples), RNA sequencing (n=105), histopathologic staining (n=149), and multiplexed ion beam imaging (n=45). Multiple biopsies were available for some patients. Mutations, gene expression, and tumor microenvironment were compared across timepoints and response to combination (N=18 responders [CR/PR], N=44 nonresponders [SD/PD]).
Results: Baseline biopsies from patients responsive to combination had increased expression of genes (n=482, FDR<0.05) associated with coagulation and complement, fatty acid metabolism, oxidative phosphorylation, hypoxia, and interferon gamma response gene sets (FDR<0.05), compared to nonresponsive biopsies. Baseline biopsies from responders also had low levels of effector CD8 T cells (PD1+, TIM-3+, GZMB+, Ki67+) colocalized with tumor cells and myeloid populations expressing higher levels of MHC Class II.
On-therapy biopsies from responders showed decreased detection of driver mutations by genomics, reduced gene expression of pathways enriched at baseline (oxidative phosphorylation, complement) by transcriptomics, and increased CD8 T cell to tumor cell ratios by histopathology, supporting observations of tumor regression. On-therapy biopsies from responders also had increased gene expression of genes related to inflammatory cytokine signaling. This correlated with increased proportions of effector CD8 T cells, compared to paired baseline or nonresponding biopsies, and increased organization of nonactivated CD8 T cells near mature endothelial structures (SMA+, CD31+ regions) adjacent to tumor.
Biopsies from nonresponders did not demonstrate these dynamics and instead contained exhausted CD8 T cells (PD1+, TIM-3+, granzyme B-, Ki67-) colocalized with FOXP3+, CD4+ Tregs and CD163+, PD-L1+ M2 macrophages, both at baseline and on-therapy.
Conclusion: In patients with melanoma refractory to anti-PD-1, addition of anti-CTLA-4 facilitates tumor-reactive CD8 T-cell infiltration and decreased suppressor cell dynamics, resulting in regression of some tumors with distinct transcriptome features. Conversely, biopsies from patients whose tumors progress on combination therapy lack expression of metabolic pathways and show CD8 T-cells restricted in proximity to M2 macrophages and Tregs.

#6551 Comprehensive genomic and transcriptomic analyses capture the effects of epigenetic therapy priming on immune checkpoint blockade response in non-small cell lung cancer.
